This section demonstrates how you can use PROC SURVEYREG to perform a regression analysis for sample survey data. For a complete description of the usage of PROC SURVEYREG, see the section “[Syntax: SURVEYREG Procedure](#)” on page 7942. The section “[Examples: SURVEYREG Procedure](#)” on page 7985 provides more detailed examples that illustrate the applications of PROC SURVEYREG.

Simple Random Sampling

Suppose that, in a junior high school, there are a total of 4,000 students in grades 7, 8, and 9. You want to know how household income and the number of children in a household affect students’ average weekly spending for ice cream.

In order to answer this question, you draw a sample by using simple random sampling from the student population in the junior high school. You randomly select 40 students and ask them their average weekly expenditure for ice cream, their household income, and the number of children in their household. The answers from the 40 students are saved as the following SAS data set IceCream:

```
data IceCream;
  input Grade Spending Income Kids @@;
  datalines;
7 7 39 2 7 7 38 1 8 12 47 1
9 10 47 4 7 1 34 4 7 10 43 2
7 3 44 4 8 20 60 3 8 19 57 4
7 2 35 2 7 2 36 1 9 15 51 1
8 16 53 1 7 6 37 4 7 6 41 2
7 6 39 2 9 15 50 4 8 17 57 3
```

```

8  14  46  2   9   8  41  2   9   8  41  1
9   7  47  3   7   3  39  3   7  12  50  2
7   4  43  4   9  14  46  3   8  18  58  4
9   9  44  3   7   2  37  1   7   1  37  2
7   4  44  2   7  11  42  2   9   8  41  2
8  10  42  2   8  13  46  1   7   2  40  3
9   6  45  1   9  11  45  4   7   2  36  1
7   9  46  1
;

```

In the data set `IceCream`, the variable `Grade` indicates a student's grade. The variable `Spending` contains the dollar amount of each student's average weekly spending for ice cream. The variable `Income` specifies the household income, in thousands of dollars. The variable `Kids` indicates how many children are in a student's family.

The following PROC SURVEYREG statements request a regression analysis:

```

title1 'Ice Cream Spending Analysis';
title2 'Simple Random Sample Design';
proc surveyreg data=IceCream total=4000;
  class Kids;
  model Spending = Income Kids / solution;
run;

```

The PROC SURVEYREG statement invokes the procedure. The `TOTAL=4000` option specifies the total in the population from which the sample is drawn. The `CLASS` statement requests that the procedure use the variable `Kids` as a classification variable in the analysis. The `MODEL` statement describes the linear model that you want to fit, with `Spending` as the dependent variable and `Income` and `Kids` as the independent variables. The `SOLUTION` option in the `MODEL` statement requests that the procedure output the regression coefficient estimates.

Figure 94.1 displays the summary of the data, the summary of the fit, and the levels of the classification variable `Kids`. The “Fit Statistics” table displays the denominator degrees of freedom, which are used in F tests and t tests in the regression analysis.

Figure 94.1 Summary of Data

Kids 4	0.000000	0.00000000	.	.

NOTE: The denominator degrees of freedom for the t tests is 39.
Matrix X'X is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

Stratified Sampling

Suppose that the previous student sample is actually drawn using a stratified sample design. The strata are grades in the junior high school: 7, 8, and 9. Within strata, simple random samples are selected. Table 94.1 provides the number of students in each grade.

Table 94.1 Students in Grades

Grade	Number of Students
7	1,824
8	1,025
9	1,151
Total	4,000

In order to analyze this sample by using PROC SURVEYREG, you need to input the stratification information by creating a SAS data set with the information in Table 94.1. The following SAS statements create such a data set called StudentTotals:

```
data StudentTotals;
    input Grade _TOTAL_;
    datalines;
7 1824
8 1025
9 1151
;
```

The variable Grade is the stratification variable, and the variable _TOTAL_ contains the total numbers of students in each stratum in the survey population. PROC SURVEYREG requires you to use the keyword _TOTAL_ as the name of the variable that contains the population total information.

In a stratified sample design, when the sampling rates in the strata are unequal, you need to use sampling weights to reflect this information. For this example, the appropriate sampling weights are the reciprocals of the probabilities of selection. You can use the following DATA step to create the sampling weights:

```
data IceCream;
    set IceCream;
    if Grade=7 then Prob=20/1824;
    if Grade=8 then Prob=9/1025;
    if Grade=9 then Prob=11/1151;
    Weight=1/Prob;
run;
```

If you use PROC SURVEYSELECT to select your sample, PROC SURVEYSELECT creates these sampling weights for you.

The following statements demonstrate how you can fit a linear model while incorporating the sample design information (stratification):

```

title1 'Ice Cream Spending Analysis';
title2 'Stratified Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
  strata Grade /list;
  class Kids;
  model Spending = Income Kids / solution;
  weight Weight;
run;

```

Comparing these statements to those in the section “[Simple Random Sampling](#)” on page 7935, you can see how the TOTAL=StudentTotals option replaces the previous TOTAL=4000 option.

The STRATA statement specifies the stratification variable Grade. The LIST option in the STRATA statement requests that the stratification information be included in the output. The WEIGHT statement specifies the weight variable.

[Figure 94.4](#) summarizes the data information, the sample design information, and the fit information. Note that, due to the stratification, the denominator degrees of freedom for F tests and t tests are 37, which is different from the analysis in [Figure 94.1](#).

Figure 94.4 Summary of the Regression

Ice Cream Spending Analysis	
Stratified Sample Design	
The SURVEYREG Procedure	
Regression Analysis for Dependent Variable Spending	
Data Summary	
Number of Observations	40
Sum of Weights	4000.0
Weighted Mean of Spending	9.14130
Weighted Sum of Spending	36565.2
Design Summary	
Number of Strata	3
Fit Statistics	
R-square	0.8219
Root MSE	2.4185
Denominator DF	37

For each stratum, [Figure 94.5](#) displays the value of identifying variables, the number of observations (sample size), the total population size, and the calculated sampling rate or fraction.

Figure 94.5 Stratification and Classification Information

Stratum Information				
Stratum Index	Grade	N Obs	Population Total	Sampling Rate
1	7	20	1824	1.10%
2	8	9	1025	0.88%
3	9	11	1151	0.96%

Class Level Information					
Class Variable	Levels	Values			
Kids	4	1	2	3	4

Figure 94.6 displays the tests for the significance of model effects under the stratified sample design. The Income effect is strongly significant, while the Kids effect is not significant at the 5% level.

Figure 94.6 Testing Effects

Tests of Model Effects			
Effect	Num DF	F Value	Pr > F
Model	4	124.85	<.0001
Intercept	1	150.95	<.0001
Income	1	326.89	<.0001
Kids	3	0.99	0.4081

NOTE: The denominator degrees of freedom for the F tests is 37.

The regression coefficient estimates for the stratified sample, along with their standard errors and associated *t* tests, are displayed in Figure 94.7.

Figure 94.7 Regression Coefficients

Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	-26.086882	2.44108058	-10.69	<.0001
Income	0.776699	0.04295904	18.08	<.0001
Kids 1	0.888631	1.07000634	0.83	0.4116
Kids 2	1.545726	1.20815863	1.28	0.2087
Kids 3	-0.526817	1.32748011	-0.40	0.6938
Kids 4	0.000000	0.00000000	.	.

NOTE: The denominator degrees of freedom for the t tests is 37.
 Matrix X'WX is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

You can request other statistics and tests by using PROC SURVEYREG. You can also analyze data from a more complex sample design. The remainder of this chapter provides more detailed information.

Output Data Sets

You can use the OUTPUT statement to create a new SAS data set that contains the estimated linear predictors and their standard error estimates, the residuals from the linear regression, and the confidence limits for the predictors. See the section “[OUTPUT Statement](#)” on page 7960 for more details.

You can use the Output Delivery System (ODS) to create SAS data sets that capture the outputs from PROC SURVEYREG. For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

For example, to save the “ParameterEstimates” table ([Figure 94.7](#)) in the previous section in an output data set, you use the ODS OUTPUT statement as follows:

```

title1 'Ice Cream Spending Analysis';
title2 'Stratified Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
  strata Grade /list;
  class Kids;
  model Spending = Income Kids / solution;
  weight Weight;
  ods output ParameterEstimates = MyParmEst;
run;

```

The statement

```
ods output ParameterEstimates = MyParmEst;
```

requests that the “ParameterEstimates” table that appears in [Figure 94.7](#) be placed into a SAS data set MyParmEst.

The PRINT procedure displays observations of the data set MyParmEst:

```
proc print data=MyParmEst;
run;
```

Figure 94.8 displays the observations in the data set MyParmEst. The section “ODS Table Names” on page 7983 gives the complete list of the tables produced by PROC SURVEYREG.

Figure 94.8 The Data Set MyParmEst

Ice Cream Spending Analysis Stratified Sample Design						
Obs	Parameter	Estimate	StdErr	DenDF	tValue	Probt

6	Kids 4	0.000000	0.00000000	37	.	.

Syntax: SURVEYREG Procedure

The following statements are available in the SURVEYREG procedure:

```
PROC SURVEYREG < options > ;
  BY variables ;
  CLASS variables ;
  CLUSTER variables ;
  CONTRAST 'label' effect values < ... effect values > < / options > ;
  DOMAIN variables < variable*variable variable*variable*variable ... > ;
  EFFECT name = effect-type (variables < / options > ) ;
  ESTIMATE < 'label' > estimate-specification < / options > ;
  LSMEANS < model-effects > < / options > ;
  LSMESTIMATE model-effect lsestimate-specification < / options > ;
  MODEL dependent = < effects > < / options > ;
  OUTPUT < keyword < =variable-name > ... keyword < =variable-name > > < / option > ;
  REPWEIGHTS variables < / options > ;
  SLICE model-effect < / options > ;
  STORE < OUT= > item-store-name < / LABEL='label' > ;
  STRATA variables < / options > ;
  TEST < model-effects > < / options > ;
  WEIGHT variable ;
```

The PROC SURVEYREG and MODEL statements are required. If your model contains classification effects, you must list the classification variables in a CLASS statement, and the CLASS statement must pre-

cede the MODEL statement. If you use a CONTRAST statement or an ESTIMATE statement, the MODEL statement must precede the CONTRAST or ESTIMATE statement.

The rest of this section provides detailed syntax information for each of the preceding statements, except the EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, SLICE, STORE, and TEST statements. These statements are also available in many other procedures. Summary descriptions of functionality and syntax for these statements are shown in this chapter, and full documentation about them is available in Chapter 19, “Shared Concepts and Topics.”

The CLASS, CLUSTER, CONTRAST, EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, REPWEIGHTS, SLICE, STRATA, TEST statements can appear multiple times. You should use only one of each of the following statements: MODEL, WEIGHT, STORE, and OUTPUT.

The syntax descriptions begin with the PROC SURVEYREG statement; the remaining statements are covered in alphabetical order.

PROC SURVEYREG Statement

PROC SURVEYREG <options> ;

The PROC SURVEYREG statement invokes the SURVEYREG procedure. It optionally names the input data sets and specifies the variance estimation method.

Table 94.2 summarizes the options available in the PROC SURVEYREG statement.

Table 94.2 PROC SURVEYREG Statement Options

Option	Description
ALPHA=	Sets the confidence level
DATA=	Specifies the SAS data set to be analyzed
MISSING	Treats missing values as a nonmissing
NOMCAR	Treats missing values as <i>not missing completely at random</i>
ORDER=	Specifies the sort order
RATE=	Specifies the sampling rate
TOTAL=	Specifies the total number of primary sampling units
TRUNCATE	Specifies class levels using no more than the first 16 characters of the formatted values
VARMETHOD=	Specifies the variance estimation method

You can specify the following options in the PROC SURVEYREG statement:

ALPHA= α

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces $100(1 - \alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

DATA=SAS-data-set

specifies the SAS data set to be analyzed by PROC SURVEYREG. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

MISSING

treats missing values as a valid (nonmissing) category for all categorical variables, which include [CLASS](#), [STRATA](#), [CLUSTER](#), and [DOMAIN](#) variables.

By default, if you do not specify the MISSING option, an observation is excluded from the analysis if it has a missing value. For more information, see the section “[Missing Values](#)” on page 7964.

NOMCAR

requests that the procedure treat missing values in the variance computation as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the NOMCAR option, PROC SURVEYREG computes variance estimates by analyzing the nonmissing values as a domain or subpopulation, where the entire population includes both nonmissing and missing domains. See the section “[Missing Values](#)” on page 7964 for more details.

By default, PROC SURVEYREG completely excludes an observation from analysis if that observation has a missing value, unless you specify the [MISSING](#) option. Note that the NOMCAR option has no effect on a classification variable when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The NOMCAR option applies only to Taylor series variance estimation. The replication methods, which you request with the [VARMETHOD=BRR](#) and [VARMETHOD=JACKKNIFE](#) options, do not use the NOMCAR option.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the classification variables (which are specified in the [CLASS](#) statement).

This option also determines the sort order for the levels of [DOMAIN](#) variables.

This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the

sort order is machine-dependent. For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

RATE=*value* | *SAS-data-set*

R=*value* | *SAS-data-set*

specifies the sampling rate as a nonnegative *value*, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the RATE= option for BRR or jackknife variance estimation, which you request with the [VARMETHOD=BRR](#) or [VARMETHOD=JACKKNIFE](#) option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7965 for more details.

The *value* in the RATE= option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYREG converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the [TOTAL=](#) or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

TOTAL=*value* | *SAS-data-set*

N=*value* | *SAS-data-set*

specifies the total number of primary sampling units in the study population as a positive *value*, or specifies an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the TOTAL= option for BRR or jackknife variance estimation, which you request with the [VARMETHOD=BRR](#) or [VARMETHOD=JACKKNIFE](#) option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7965 for more details.

If you do not specify the TOTAL= or [RATE=](#) option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

TRUNCATE

specifies that class levels should be determined using no more than the first 16 characters of the formatted values of the CLASS, STRATA, and CLUSTER variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases before SAS 9.

VARMETHOD=BRR <(method-options)>

VARMETHOD=JACKKNIFE | **JK** <(method-options)>

VARMETHOD=TAYLOR

specifies the variance estimation method. **VARMETHOD=TAYLOR** requests the Taylor series method, which is the default if you do not specify the **VARMETHOD=** option or the **REPWEIGHTS** statement. **VARMETHOD=BRR** requests variance estimation by balanced repeated replication (BRR), and **VARMETHOD=JACKKNIFE** requests variance estimation by the delete-1 jackknife method.

For **VARMETHOD=BRR** and **VARMETHOD=JACKKNIFE** you can specify *method-options* in parentheses. Table 94.3 summarizes the available *method-options*.

Table 94.3 Variance Estimation Options

VARMETHOD=	Variance Estimation Method	<i>Method-Options</i>
BRR	Balanced repeated replication	FAY <=value> HADAMARD=SAS-data-set OUTWEIGHTS=SAS-data-set PRINTH REPS=number
JACKKNIFE	Jackknife	OUTJKCOEFS=SAS-data-set OUTWEIGHTS=SAS-data-set
TAYLOR	Taylor series linearization	None

Method-options must be enclosed in parentheses following the method keyword. For example:

```
varmethod=BRR(reps=60 outweights=myReplicateWeights)
```

The following values are available for the **VARMETHOD=** option:

BRR <(method-options)>

requests **balanced repeated replication** (BRR) variance estimation. The BRR method requires a stratified sample design with two primary sampling units (PSUs) per stratum. See the section “**Balanced Repeated Replication (BRR) Method**” on page 7971 for more information.

You can specify the following *method-options* in parentheses following **VARMETHOD=BRR**:

FAY <=value>

requests **Fay’s method**, a modification of the BRR method, for variance estimation. See the section “**Fay’s BRR Method**” on page 7972 for more information.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

HADAMARD=SAS-data-set**H=SAS-data-set**

names a SAS data set that contains the [Hadamard matrix](#) for BRR replicate construction. If you do not provide a Hadamard matrix with the `HADAMARD= method-option`, PROC SURVEYREG generates an appropriate Hadamard matrix for replicate construction. See the sections “[Balanced Repeated Replication \(BRR\) Method](#)” on page 7971 and “[Hadamard Matrix](#)” on page 7973 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the `HADAMARD= method-option`.

In the `HADAMARD=` input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the `HADAMARD=` data set. All values in the data set must equal either 1 or -1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is, $\mathbf{A}'\mathbf{A} = R\mathbf{I}$, where \mathbf{A} is the Hadamard matrix of dimension R and \mathbf{I} is an identity matrix. PROC SURVEYREG does not check the validity of the Hadamard matrix that you provide.

The `HADAMARD=` input data set must contain at least H variables, where H denotes the number of first-stage strata in your design. If the data set contains more than H variables, the procedure uses only the first H variables. Similarly, the `HADAMARD=` input data set must contain at least H observations.

If you do not specify the `REPS= method-option`, then the number of replicates is taken to be the number of observations in the `HADAMARD=` input data set. If you specify the number of replicates—for example, `REPS=nreps`—then the first $nreps$ observations in the `HADAMARD=` data set are used to construct the replicates.

You can specify the `PRINTH` option to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

OUTWEIGHTS=SAS-data-set

names a SAS data set that contains replicate weights. See the section “[Balanced Repeated Replication \(BRR\) Method](#)” on page 7971 for information about replicate weights. See the section “[Replicate Weights Output Data Set](#)” on page 7978 for more details about the contents of the `OUTWEIGHTS=` data set.

The `OUTWEIGHTS= method-option` is not available when you provide replicate weights with the `REPWEIGHTS` statement.

PRINTH

displays the Hadamard matrix.

When you provide your own Hadamard matrix with the `HADAMARD= method-option`, only the rows and columns of the Hadamard matrix that

are used by the procedure are displayed. See the sections “[Balanced Repeated Replication \(BRR\) Method](#)” on page 7971 and “[Hadamard Matrix](#)” on page 7973 for details.

The `PRINTH method-option` is not available when you provide replicate weights with the `REPWEIGHTS` statement because the procedure does not use a Hadamard matrix in this case.

REPS=number

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the `HADAMARD= method-option`, the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section “[Balanced Repeated Replication \(BRR\) Method](#)” on page 7971 for more information. If a Hadamard matrix cannot be constructed for the `REPS=` value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the `REPS=` value that you specify.

If you provide a Hadamard matrix with the `HADAMARD= method-option`, the value of `REPS=` must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the `REPS= method-option`, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the `REPS=` or `HADAMARD= method-option` and do not include a `REPWEIGHTS` statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with the `REPWEIGHTS` statement, the procedure does not use the `REPS= method-option`. With a `REPWEIGHTS` statement, the number of replicates equals the number of `REPWEIGHTS` variables.

JACKKNIFE | JK <(method-options)>

requests variance estimation by the delete-1 jackknife method. See the section “[Jackknife Method](#)” on page 7972 for details. If you provide replicate weights with a `REPWEIGHTS` statement, `VARMETHOD=JACKKNIFE` is the default variance estimation method.

You can specify the following *method-options* in parentheses following `VARMETHOD=JACKKNIFE`:

OUTJKCOEFS=SAS-data-set

names a SAS data set that contains jackknife coefficients. See the section “[Jackknife Method](#)” on page 7972 for information about [jackknife coefficients](#). See the section “[Jackknife Coefficients Output Data Set](#)” on page 7978 for more details about the contents of the `OUTJKCOEFS=` data set.

OUTWEIGHTS=SAS-data-set

names a SAS data set that contains replicate weights. See the section “[Jackknife Method](#)” on page 7972 for information about replicate weights. See the section “[Replicate Weights Output Data Set](#)” on page 7978 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with the [REPWEIGHTS](#) statement.

TAYLOR

requests Taylor series variance estimation. This is the default method if you do not specify the VARMETHOD= option or a [REPWEIGHTS](#) statement. See the section “[Taylor Series \(Linearization\)](#)” on page 7970 for more information.

BY Statement

BY variables ;

You can specify a BY statement with PROC SURVEYREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SURVEYREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid domain (subpopulation) analysis, where the total number of units in the subpopulation is not known with certainty. You should use the DOMAIN statement to obtain domain analysis. For more information about subpopulation analysis for sample survey data, see Cochran (1977).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the PROC SURVEYREG statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC SURVEYREG statement.

You can use multiple CLASS statements to specify classification variables.

CLUSTER Statement

CLUSTER *variables* ;

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters (primary sampling units (PSUs)), in the CLUSTER statement. See the section “Primary Sampling Units (PSUs)” on page 7966 for more information.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

When determining levels of a CLUSTER variable, an observation with missing values for this CLUSTER variable is excluded, unless you specify the MISSING option. For more information, see the section “Missing Values” on page 7964.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses variables from all CLUSTER statements to create clusters.

Prior to SAS 9, clusters were determined by using no more than the first 16 characters of the formatted values. If you want to revert to this previous behavior, you can use the TRUNCATE option in the PROC SURVEYREG statement.

CONTRAST Statement

CONTRAST *'label' effect values* < / options > ;

CONTRAST *'label' effect values* < . . . *effect values* > < / options > ;

The CONTRAST statement provides custom hypothesis tests for linear combinations of the regression parameters $H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$, where \mathbf{L} is the vector or matrix you specify and $\boldsymbol{\beta}$ is the vector of regression parameters. Thus, to use this feature, you must be familiar with the details of the model parameterization used by PROC SURVEYREG. For information about the parameterization, see the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

Each term in the MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or a special notation by using variable names and operators. For more details about how to specify an effect, see the section “Specification of Effects” on page 3324 in Chapter 42, “The GLM Procedure.”

For each CONTRAST statement, PROC SURVEYREG computes Wald’s F test. The procedure displays this value with the degrees of freedom, and identifies it with the contrast label. The numerator degrees of freedom for Wald’s F test equal $\text{rank}(\mathbf{L})$. The denominator degrees of freedom equal the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of strata. Alternatively, you can use the **DF=** option in the MODEL statement to specify the denominator degrees of freedom.

You can specify any number of CONTRAST statements, but they must appear after the MODEL statement.

In the CONTRAST statement,

<i>label</i>	identifies the contrast in the output. A label is required for every contrast specified. Labels must be enclosed in single quotes.
<i>effect</i>	identifies an effect that appears in the MODEL statement. You can use the INTERCEPT keyword as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.
<i>values</i>	are constants that are elements of \mathbf{L} associated with the effect.

You can specify the following options in the CONTRAST statement after a slash (/):

E

displays the entire coefficient \mathbf{L} vector or matrix.

NOFILL

requests no filling in higher-order effects. When you specify only certain portions of \mathbf{L} , by default PROC SURVEYREG constructs the remaining elements from the context. (For more information, see the section “Specification of ESTIMATE Expressions” on page 3345 in Chapter 42, “The GLM Procedure.”)

When you specify the NOFILL option, PROC SURVEYREG does not construct the remaining portions and treats the vector or matrix \mathbf{L} as it is defined in the CONTRAST statement.

SINGULAR=value

tunes the estimability checking. If \mathbf{v} is a vector, define $\text{ABS}(\mathbf{v})$ to be the largest absolute value of the elements of \mathbf{v} . For a row vector \mathbf{l} of the matrix \mathbf{L} , define

$$c = \begin{cases} \text{ABS}(\mathbf{l}) & \text{if } \text{ABS}(\mathbf{l}) > 0 \\ 1 & \text{otherwise} \end{cases}$$

If $\text{ABS}(\mathbf{l} - \mathbf{lH})$ is greater than $c \cdot \text{value}$, then $\mathbf{l}\boldsymbol{\beta}$ is declared nonestimable. Here, \mathbf{H} is the matrix $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$. The *value* must be between 0 and 1; the default is 10^{-7} .

As stated previously, the CONTRAST statement enables you to perform hypothesis tests $H_0: \mathbf{L}\boldsymbol{\beta} = 0$.

If the \mathbf{L} matrix contains more than one contrast, then you can separate the rows of the \mathbf{L} matrix with commas.

For example, for the model

```
proc surveyreg;
  class A B;
  model Y=A B;
run;
```

with A at 5 levels and B at 2 levels, the parameter vector is

$$(\mu \ \alpha_1 \ \alpha_2 \ \alpha_3 \ \alpha_4 \ \alpha_5 \ \beta_1 \ \beta_2)$$

To test the hypothesis that the pooled A linear and A quadratic effect is zero, you can use the following \mathbf{L} matrix:

$$\mathbf{L} = \begin{bmatrix} 0 & -2 & -1 & 0 & 1 & 2 & 0 & 0 \\ 0 & 2 & -1 & -2 & -1 & 2 & 0 & 0 \end{bmatrix}$$

The corresponding CONTRAST statement is

```
contrast 'A Linear & Quadratic'
  a -2 -1 0 1 2,
  a 2 -1 -2 -1 2;
```

DOMAIN Statement

DOMAIN *variables* < *variable*variable variable*variable*variable ...* > ;

The DOMAIN statement requests analysis for domains (subpopulations) in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains might be unrelated to the sample design. Therefore, the sample sizes for the domains are random variables. Use a DOMAIN statement to incorporate this variability into the variance estimation.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently. See the section “[Domain Analysis](#)” on page 7976 for more details.

Use the DOMAIN statement on the entire data set to perform a domain analysis. Creating a new data set from a single domain and analyzing that with PROC SURVEYREG yields inappropriate estimates of variance.

A domain variable can be either character or numeric. The procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (*), then every possible combination of levels of these variables determines a domain. The procedure performs a descriptive analysis within each domain that is defined by the domain variables.

When determining levels of a DOMAIN variable, an observation with missing values for this DOMAIN variable is excluded, unless you specify the **MISSING** option. For more information, see the section “[Missing Values](#)” on page 7964.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

EFFECT Statement

EFFECT *name=effect-type (variables < / options>)* ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “[GLM Parameterization of Classification Variables and Effects](#)” on page 383 in Chapter 19, “[Shared Concepts and Topics](#).”

You can specify the following *effect-types*:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.
MULTIMEMBER MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 94.4 summarizes the *options* available in the EFFECT statement.

Table 94.4 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect

Table 94.4 continued

Option	Description
Lag Effects Options	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Multimember Effects Options	
NOEFFECT	Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
      < , ... <'label'> estimate-specification <(divisor=n)> >
      </ options> ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form $\mathbf{L}\boldsymbol{\beta}$. You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 94.5 summarizes the options available in the ESTIMATE statement.

Table 94.5 ESTIMATE Statement Options

Option	Description
Construction and Computation of Estimable Functions	
DIVISOR=	Specifies a list of values to divide the coefficients
NOFILL	Suppresses the automatic fill-in of coefficients for higher-order effects
SINGULAR=	Tunes the estimability checking difference
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple comparison adjustment of estimates
ALPHA= α	Determines the confidence level ($1 - \alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiplicity-corrected p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits
CORR	Displays the correlation matrix of estimates
COV	Displays the covariance matrix of estimates
E	Prints the L matrix
JOINT	Produces a joint F or chi-square test for the estimable functions
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the ESTIMATE statement, see the section “[ESTIMATE Statement](#)” on page 437 in Chapter 19, “[Shared Concepts and Topics](#).”

LSMEANS Statement

LSMEANS < *model-effects* > < / *options* > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted margins*—that is, they estimate the marginal means over a hypothetical balanced population.

Table 94.6 summarizes available options in the LSMEANS statement.

Table 94.6 LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies the covariate value in computing LS-means
BYLEVEL	Computes separate margins
DIFF	Requests differences of LS-means
OM=	Specifies the weighting scheme for LS-means computation as determined by the input data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level $(1 - \alpha)$
STEPDOWN	Adjusts multiple-comparison p -values further in a step-down fashion
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
LINEs	Produces a “Lines” display for pairwise LS-means differences
MEANS	Prints the LS-means
PLOTS=	Requests graphs of means and mean comparisons
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMEANS statement, see the section “[LSMEANS Statement](#)” on page 453 of Chapter 19, “[Shared Concepts and Topics](#).”

LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
              < , ... <'label'> values <divisor=n> >
              </options> ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 94.7 summarizes the options available in the LSMESTIMATE statement.

Table 94.7 LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
BYLEVEL	Computes separate margins
DIVISOR=	Specifies a list of values to divide the coefficients
OM=	Specifies the weighting scheme for LS-means computation as determined by a data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level ($1 - \alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiple-comparison p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
ELSM	Prints the K matrix
JOINT	Produces a joint F or chi-square test for the LS-means and LS-means differences
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMESTIMATE statement, see the section “[LSMESTIMATE Statement](#)” on page 470 in Chapter 19, “[Shared Concepts and Topics](#).”

MODEL Statement

MODEL *dependent* = < *effects* > < / *options* > ;

The MODEL statement specifies the dependent (response) variable and the independent (regressor) variables or effects. The dependent variable must be numeric. Each term in a MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or with special notation by using variable names and operators. For more information about how to specify an effect, see the section “[Specification of Effects](#)” on page 3324 in Chapter 42, “[The GLM Procedure](#).”

Only one MODEL statement is allowed for each PROC SURVEYREG statement. If you specify more than one MODEL statement, the procedure uses the first model and ignores the rest.

Table 94.8 summarizes the options available in the MODEL statement.

Table 94.8 MODEL Statement Options

Option	Description
ADJRSQ	Compute the adjusted multiple R-square
ANOVA	Produces the ANOVA table
CLPARM	Requests confidence limits
COVB	Displays the estimated covariance matrix
DEFF	Displays design effects
DF=	Specifies the denominator degrees of freedom
I	Displays the inverse or the generalized inverse of the $X'X$ matrix
NOINT	Omits the intercept
PARMLABEL	Displays the labels of the parameters
SINGULAR=	Tunes the estimability checking
SOLUTION	Displays parameter estimates
STB	Displays standardized parameter estimates
VADJUST=	Specifies whether to use degrees of freedom adjustment
X	Displays the $X'X$ matrix, or the $X'WX$ matrix

You can specify the following options in the MODEL statement after a slash (/):

ADJRSQ

requests the procedure compute the adjusted multiple R-square.

ANOVA

requests the ANOVA table be produced in the output. By default, the ANOVA table is not printed in the output.

CLPARM

requests confidence limits for the parameter estimates. The SURVEYREG procedure determines the confidence coefficient by using the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence bounds. The CLPARM option also requests confidence limits for all the estimable linear functions of regression parameters in the **ESTIMATE** statements.

Note that when there is a **CLASS** statement, you need to use the **SOLUTION** option with the CLPARM option to obtain the parameter estimates and their confidence limits.

COVB

displays the estimated covariance matrix of the estimated regression estimates.

DEFF

displays design effects for the regression coefficient estimates.

DF=value

specifies the denominator degrees of freedom for the F tests and the degrees of freedom for the t tests. For details about the default denominator degrees of freedom, see the section “[Denominator Degrees of Freedom](#)” on page 7974 for details.

I | INVERSE

displays the inverse or the generalized inverse of the $X'X$ matrix. When there is a **WEIGHT** variable, the procedure displays the inverse or the generalized inverse of the $X'WX$ matrix, where **W** is the diagonal matrix constructed from **WEIGHT** variable values.

NOINT

omits the intercept from the model.

PARMLABEL

displays the labels of the parameters in the “Estimated Regression Coefficients” table, if the effect contains a single continuous variable that has a label.

SINGULAR=value

tunes the estimability checking. If \mathbf{v} is a vector, define $\text{ABS}(\mathbf{v})$ to be the largest absolute value of the elements of \mathbf{v} . For a row vector \mathbf{l} of the matrix \mathbf{L} , define

$$c = \begin{cases} \text{ABS}(\mathbf{l}) & \text{if } \text{ABS}(\mathbf{l}) > 0 \\ 1 & \text{otherwise} \end{cases}$$

If $\text{ABS}(\mathbf{l} - \mathbf{H})$ is greater than $c * \text{value}$, then $\mathbf{l}\beta$ is declared nonestimable. Here, \mathbf{H} is the matrix $(X'X)^{-1}X'X$. The *value* must be between 0 and 1; the default is 10^{-4} .

SOLUTION

displays a solution to the normal equations, which are the parameter estimates. The **SOLUTION** option is useful only when you use a **CLASS** statement. If you do not specify a **CLASS** statement, PROC SURVEYREG displays parameter estimates by default. But if you specify a **CLASS** statement, PROC SURVEYREG does not display parameter estimates unless you also specify the **SOLUTION** option.

STB

produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor.

VADJUST=DF | NONE

specifies whether to use degrees of freedom adjustment $(n - 1)/(n - p)$ in the computation of the matrix **G** for the [variance estimation](#). If you do not specify the **VADJUST=** option, by default, PROC SURVEYREG uses the degrees-of-freedom adjustment that is equivalent to the **VARADJ=DF** option. If you do not want to use this variance adjustment, you can specify the **VADJUST=NONE** option.

X | XPX

displays the $X'X$ matrix, or the $X'WX$ matrix when there is a **WEIGHT** variable, where **W** is the diagonal matrix constructed from **WEIGHT** variable values. The **X** option also displays the crossproducts vector $X'y$ or $X'Wy$.

OUTPUT Statement

OUTPUT < **OUT=SAS-data-set** > < keyword < =variable-name > ... keyword < =variable-name > >
< /option > ;

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimated linear predictors and their standard error estimates, the residuals from the linear regression, and the confidence limits for the predictors.

You can specify the following options in the OUTPUT statement:

OUT=SAS-data-set

gives the name of the new output data set. By default, the procedure uses the DATA n convention to name the new data set.

keyword < =variable-name >

specifies the statistics to include in the output data set and names the new variables that contain the statistics. You can specify a keyword for each desired statistic (see the following list of keywords). Optionally, you can name a statistic by providing a variable name followed an equal sign to contain the statistic. For example,

```
output out=myOutDataSet p=myPredictor;
```

creates a SAS data set myOutDataSet that contains the predicted values in the variable myPredictor.

The keywords allowed and the statistics they represent are as follows:

LCLM L	lower bound of a $100(1 - \alpha)\%$ confidence interval for the expected value (mean) of the predicted value. The α level is equal to the value of the ALPHA= option in the OUTPUT statement or, if this option is not specified, to the ALPHA= option in the PROC SURVEYREG statement. If neither of these options is set, then $\alpha = 0.05$ by default, resulting in the lower bound for a 95% confidence interval. If no variable name is given for this keyword, the default variable name is _LCLM_.
PREDICTED PRED P	predicted values. If no variable name is given for this keyword, the default variable name is _PREDICTED_.
RESIDUAL R	residuals, calculated as ACTUAL – PREDICTED. If no variable name is given for this keyword, the default variable name is _RESIDUAL_.
STDP STD	standard error of the mean predicted value. If no variable name is given for this keyword, the default variable name is _STD_.
UCLM U	upper bound of a $100(1 - \alpha)\%$ confidence interval for the expected value (mean) of the predicted value. The α level is equal to the value of the ALPHA= option in the OUTPUT statement or, if this option is not specified, to the ALPHA= option in the PROC SURVEYREG statement. If neither of these options is set, then $\alpha = 0.05$ by default, resulting in the upper bound for a 95% confidence interval. If no variable name is given for this keyword, the default variable name is _UCLM_.

The following option is available in the OUTPUT statement and is specified after a slash (/):

ALPHA= α

specifies the level of significance α for $100(1 - \alpha)\%$ confidence intervals. By default, α is equal to the value of the **ALPHA=** option in the PROC SURVEYREG statement or 0.05 if that option is not specified. You can use values between 0 and 1.

REPWEIGHTS Statement

REPWEIGHTS *variables* *</ options>* ;

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option in the PROC SURVEYREG statement. If you do not provide replicate weights for these methods by using a REPWEIGHTS statement, then the procedure constructs replicate weights for the analysis. See the sections “Balanced Repeated Replication (BRR) Method” on page 7971 and “Jackknife Method” on page 7972 for information about replicate weights.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a **CLUSTER** or **STRATA** statement. If you use a REPWEIGHTS statement and do not specify the **VARMETHOD=** option in the PROC SURVEYREG statement, the procedure uses **VARMETHOD=JACKKNIFE** by default.

If you specify a REPWEIGHTS statement but do not include a **WEIGHT** statement, the procedure uses the average of replicate weights of each observation as the observation’s weight.

You can specify the following options in the REPWEIGHTS statement after a slash (/):

DF=*df*

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. By default, the degrees of freedom equals the number of REPWEIGHTS variables.

JKCOEFS=*value*

specifies a jackknife coefficient for **VARMETHOD=JACKKNIFE**. The coefficient *value* must be a nonnegative number. See the section “Jackknife Method” on page 7972 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the **JKCOEFS=values** or **JKCOEFS=SAS-data-set** option.

JKCOEFS=values

specifies jackknife coefficients for **VARMETHOD=JACKKNIFE**, where each coefficient corresponds to an individual replicate that is identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

See the section “Jackknife Method” on page 7972 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the **JKCOEFS=SAS-data-set** option. To specify a single jackknife coefficient for all replicates, use the **JKCOEFS=value** option.

JKCOEFS=SAS-data-set

names a SAS data set that contains the jackknife coefficients for **VARMETHOD=JACKKNIFE**. You provide the jackknife coefficients in the **JKCOEFS=** data set variable **JKCoefficient**. Each coefficient value must be a nonnegative number. The observations in the **JKCOEFS=** data set should correspond to the replicates that are identified by the **REPWEIGHTS** variables. Arrange the coefficients or observations in the **JKCOEFS=** data set in the same order in which you list the corresponding replicate weight variables in the **REPWEIGHTS** statement. The number of observations in the **JKCOEFS=** data set must not be less than the number of **REPWEIGHTS** variables.

See the section “[Jackknife Method](#)” on page 7972 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the **JKCOEFS=values** option. To specify a single jackknife coefficient for all replicates, use the **JKCOEFS=value** option.

SLICE Statement

SLICE *model-effect* < / *options* > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the **LSMEANS** statement, which are summarized in [Table 19.21](#). For details about the syntax of the SLICE statement, see the section “[SLICE Statement](#)” on page 498 in Chapter 19, “[Shared Concepts and Topics](#).”

STORE Statement

STORE < **OUT=** *item-store-name* < / **LABEL=** *'label'* > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “[STORE Statement](#)” on page 501 in Chapter 19, “[Shared Concepts and Topics](#).”

STRATA Statement

STRATA *variables* < / *options* > ;

The STRATA statement specifies variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7965 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the **REPWEIGHTS** statement, you do not need to specify a STRATA statement.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

When determining levels of a STRATA variable, an observation with missing values for this STRATA variable is excluded, unless you specify the **MISSING** option. For more information, see the section “**Missing Values**” on page 7964.

You can use multiple STRATA statements to specify stratum variables.

You can specify the following options in the STRATA statement after a slash (/):

LIST

displays a “Stratum Information” table, which includes values of the STRATA variables and the number of observations, number of clusters, population total, and sampling rate for each stratum. See the section “**Stratum Information**” on page 7980 for more details.

NOCOLLAPSE

prevents the procedure from collapsing (combining) strata that have only one sampling unit for the Taylor series variance estimation. By default, the procedure **collapses** strata that contain only one sampling unit for the Taylor series method. See the section “**Stratum Collapse**” on page 7968 for details.

TEST Statement

TEST < *model-effects* > < / *options* > ;

The TEST statement enables you to perform *F* tests for model effects that test Type I, Type II, or Type III hypotheses. See Chapter 15, “**The Four Types of Estimable Functions**,” for details about the construction of Type I, II, and III estimable functions.

Table 94.9 summarizes the options available in the TEST statement.

Table 94.9 TEST Statement Options

Option	Description
CHISQ	Requests chi-square tests
DDF=	Specifies denominator degrees of freedom for fixed effects
E	Requests Type I, Type II, and Type III coefficients
E1	Requests Type I coefficients
E2	Requests Type II coefficients
E3	Requests Type III coefficients
HTYPE=	Indicates the type of hypothesis test to perform
INTERCEPT	Adds a row that corresponds to the overall intercept

For details about the syntax of the TEST statement, see the section “[TEST Statement](#)” on page 502 in Chapter 19, “[Shared Concepts and Topics](#).”

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “[Missing Values](#)” on page 7964 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

If you do not specify a WEIGHT statement but provide replicate weights with a [REPWEIGHTS](#) statement, PROC SURVEYREG uses the average of replicate weights of each observation as the observation’s weight.

If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYREG assigns all observations a weight of one.

Details: SURVEYREG Procedure

Missing Values

If you have missing values in your survey data for any reason, such as nonresponse, this can compromise the quality of your survey results. If the respondents are different from the nonrespondents with regard to a survey effect or outcome, then survey estimates might be biased and cannot accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and/or you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYREG. For more information, see Cochran (1977); Kalton and Kaspyzyk (1986); Brick and Kalton (1996).

If an observation has a missing value or a nonpositive value for the [WEIGHT](#) variable, then that observation is excluded from the analysis.

An observation is also excluded from the analysis if it has a missing value for any design ([STRATA](#), [CLUSTER](#), or [DOMAIN](#)) variable, unless you specify the [MISSING](#) option in the PROC SURVEYREG statement. If you specify the [MISSING](#) option, the procedure treats missing values as a valid (nonmissing) category for all categorical variables.

By default, if an observation contains missing values for the dependent variable or for any variable used in the independent effects, the observation is excluded from the analysis. This treatment is based on the assumption that the missing values are missing completely at random (MCAR). However, this assumption sometimes is not true. For example, evidence from other surveys might suggest that observations with missing values are systematically different from observations without missing values. If you believe that missing values are not missing completely at random, then you can specify the [NOMCAR](#) option to include these

observations with missing values in the dependent variable and the independent variables in the variance estimation.

Whether or not you specify the **NOMCAR** option, the procedure always excludes observations with missing or invalid values for the **WEIGHT**, **STRATA**, **CLUSTER**, and **DOMAIN** variables, unless you specify the **MISSING** option.

When you specify the **NOMCAR** option, the procedure treats observations with and without missing values for variables in the regression model as two different domains, and it performs a domain analysis in the domain of nonmissing observations.

If you use a **REPWEIGHTS** statement, all **REPWEIGHTS** variables must contain nonmissing values.

Survey Design Information

Specification of Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the **RATE=** or **TOTAL=** option in the **PROC SURVEYREG** statement. (You cannot specify both of these options in the same **PROC SURVEYREG** statement.) The **RATE=** and **TOTAL=** options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for **BRR** or jackknife variance estimation.

If you do not specify the **RATE=** or **TOTAL=** option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the **RATE=** option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the **TOTAL=** option for a multistage design, you should input the total number of PSUs in the study population. See the section “**Primary Sampling Units (PSUs)**” on page 7966 for more details.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the **RATE=value** or **TOTAL=value** option. If your sample design is stratified with different sampling rates or population totals in different strata, use the **RATE=SAS-data-set** or **TOTAL=SAS-data-set** option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the **DATA=** option.

The secondary data set must contain all the stratification variables listed in the **STRATA** statement and all the variables in the **BY** statement. If there are formats associated with the **STRATA** variables and the **BY** variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the **TOTAL=SAS-data-set** option, the secondary data set must have a variable named **_TOTAL_** that contains the stratum population totals. Or if you specify the **RATE=SAS-data-set** option, the secondary data set must have a variable named **_RATE_** that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of **_TOTAL_** or **_RATE_** for that stratum and ignores the rest.

The *value* in the **RATE=** option or the values of **_RATE_** in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage

form as a number between 1 and 100, and PROC SURVEYREG converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the `TOTAL=value` option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

Primary Sampling Units (PSUs)

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs when the Taylor series variance method is used. See the section “[Variance Estimation](#)” on page 7969 for more information.

BRR or jackknife variance estimation methods draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. These subsamples are constructed by deleting PSUs from the full sample.

If you use a `REPWEIGHTS` statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a `CLUSTER` statement. Otherwise, you should specify a `CLUSTER` statement whenever your design includes clustering at the first stage of sampling. If you do not specify a `CLUSTER` statement, then PROC SURVEYREG treats each observation as a PSU.

Computational Details

Notation

For a stratified clustered sample design, observations are represented by an $n \times (p + 2)$ matrix

$$(\mathbf{w}, \mathbf{y}, \mathbf{X}) = (w_{hij}, y_{hij}, \mathbf{x}_{hij})$$

where

- \mathbf{w} denotes the sampling weight vector
- \mathbf{y} denotes the dependent variable
- \mathbf{X} denotes the $n \times p$ design matrix. (When an effect contains only classification variables, the columns of \mathbf{X} that correspond this effect contain only 0s and 1s; no reparameterization is made.)
- $h = 1, 2, \dots, H$ is the stratum index
- $i = 1, 2, \dots, n_h$ is the cluster index within stratum h
- $j = 1, 2, \dots, m_{hi}$ is the unit index within cluster i of stratum h
- p is the total number of parameters (including an intercept if the `INTERCEPT` effect is included in the `MODEL` statement)
- $n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$ is the total number of observations in the sample

Also, f_h denotes the sampling rate for stratum h . You can use the **TOTAL=** or **RATE=** option to input population totals or sampling rates. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7965 for details. If you input stratum totals, PROC SURVEYREG computes f_h as the ratio of the stratum sample size to the stratum total. If you input stratum sampling rates, PROC SURVEYREG uses these values directly for f_h . If you do not specify the **TOTAL=** or **RATE=** option, then the procedure assumes that the stratum sampling rates f_h are negligible, and a finite population correction is not used when computing variances.

Regression Coefficients

PROC SURVEYREG solves the normal equations $\mathbf{X}'\mathbf{W}\mathbf{X}\boldsymbol{\beta} = \mathbf{X}'\mathbf{W}\mathbf{y}$ by using a modified sweep routine that produces a generalized (g2) inverse $(\mathbf{X}'\mathbf{W}\mathbf{X})^-$ and a solution (Pringle and Rayner 1971)

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^- \mathbf{X}'\mathbf{W}\mathbf{y}$$

where \mathbf{W} is the diagonal matrix constructed from **WEIGHT** variable values.

For models with class variables, there are more design matrix columns than there are degrees of freedom (df) for the effect. Thus, there are linear dependencies among the columns. In this case, the parameters are not estimable; there is an infinite number of least squares solutions. PROC SURVEYREG uses a generalized (g2) inverse to obtain values for the estimates. The solution values are not displayed unless you specify the **SOLUTION** option in the **MODEL** statement. The solution has the characteristic that estimates are zero whenever the design column for that parameter is a linear combination of previous columns. (In strict terms, the solution values should not be called estimates.) With this full parameterization, hypothesis tests are constructed to test linear functions of the parameters that are estimable.

Design Effect

If you specify the **DEFF** option in the **MODEL** statement, PROC SURVEYREG calculates the design effects for the regression coefficients. The design effect of an estimate is the ratio of the actual variance to the variance computed under the assumption of simple random sampling:

$$\text{DEFF} = \frac{\text{variance under the sample design}}{\text{variance under simple random sampling}}$$

See Kish (1965, p. 258) for more details. PROC SURVEYREG computes the numerator as described in the section “[Variance Estimation](#)” on page 7969. And the denominator is computed under the assumption that the sample design is simple random sampling, with no stratification and no clustering.

To compute the variance under the assumption of simple random sampling, PROC SURVEYREG calculates the sampling rate as follows. If you specify both sampling weights and sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is calculated as

$$f_{\text{SRS}} = n / w_{..}$$

where n is the sample size and $w_{..}$ (the sum of the weights over all observations) estimates the population size. If the sum of the weights is less than the sample size, f_{SRS} is set to zero. If you specify sampling rates for the analysis but not sampling weights, then PROC SURVEYREG computes the sampling rate under simple random sampling as the average of the stratum sampling rates:

$$f_{\text{SRS}} = \frac{1}{H} \sum_{h=1}^H f_h$$

If you do not specify sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is assumed to be zero:

$$f_{\text{SRS}} = 0$$

Stratum Collapse

If there is only one sampling unit in a stratum, then PROC SURVEYREG cannot estimate the variance for this stratum for the Taylor series method. To estimate stratum variances, by default the procedure collapses, or combines, those strata that contain only one sampling unit. If you specify the **NOCOLLAPSE** option in the STRATA statement, PROC SURVEYREG does not collapse strata and uses a variance estimate of zero for any stratum that contains only one sampling unit.

Note that stratum collapse only applies to Taylor series variance estimation (the default method, also specified by **VARMETHOD=TAYLOR**). The procedure does not collapse strata for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option.

If you do not specify the **NOCOLLAPSE** option for the Taylor series method, PROC SURVEYREG collapses strata according to the following rules. If there are multiple strata that contain only one sampling unit each, then the procedure collapses, or combines, all these strata into a new pooled stratum. If there is only one stratum with a single sampling unit, then PROC SURVEYREG collapses that stratum with the preceding stratum, where strata are ordered by the **STRATA** variable values. If the stratum with one sampling unit is the first stratum, then the procedure combines it with the following stratum.

If you specify stratum sampling rates by using the **RATE=SAS-data-set** option, PROC SURVEYREG computes the sampling rate for the new pooled stratum as the weighted average of the sampling rates for the collapsed strata. See the section “Computational Details” on page 7966 for details. If the specified sampling rate equals 0 for any of the collapsed strata, then the pooled stratum is assigned a sampling rate of 0. If you specify stratum totals by using the **TOTAL=SAS-data-set** option, PROC SURVEYREG combines the totals for the collapsed strata to compute the sampling rate for the new pooled stratum.

Sampling Rate of the Pooled Stratum from Collapse

Assuming that PROC SURVEYREG collapses single-unit strata h_1, h_2, \dots, h_c into the pooled stratum, the procedure calculates the sampling rate for the pooled stratum as

$$f_{\text{Pooled Stratum}} = \begin{cases} 0 & \text{if any of } f_{h_l} = 0 \text{ where } l = 1, 2, \dots, c \\ \left(\sum_{l=1}^c n_{h_l} f_{h_l}^{-1} \right)^{-1} \sum_{l=1}^c n_{h_l} & \text{otherwise} \end{cases}$$

Analysis of Variance (ANOVA)

PROC SURVEYREG produces an analysis of variance table for the model specified in the **MODEL** statement. This table is identical to the one produced by the GLM procedure for the model. PROC SURVEYREG computes ANOVA table entries by using the sampling weights, but not the sample design information about stratification and clustering.

The degrees of freedom (df) displayed in the ANOVA table are the same as those in the ANOVA table produced by PROC GLM. The Total DF is the total degrees of freedom used to obtain the regression coefficient

estimates. The Total DF equals the total number of observations minus 1 if the model includes an intercept. If the model does not include an intercept, the Total DF equals the total number of observations. The Model DF equals the degrees of freedom for the effects in the MODEL statement, not including the intercept. The Error DF equals the Total DF minus the Model DF.

Multiple R-Square

PROC SURVEYREG computes a multiple R-square for the weighted regression as

$$R^2 = 1 - \frac{SS_{error}}{SS_{total}}$$

where SS_{error} is the error sum of squares in the ANOVA table

$$SS_{error} = \mathbf{r}'\mathbf{W}\mathbf{r}$$

and SS_{total} is the total sum of squares

$$SS_{total} = \begin{cases} \mathbf{y}'\mathbf{W}\mathbf{y} & \text{if no intercept} \\ \mathbf{y}'\mathbf{W}\mathbf{y} - \left(\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij} \right)^2 / w_{...} & \text{otherwise} \end{cases}$$

where $w_{...}$ is the sum of the sampling weights over all observations.

Adjusted R-Square

If you specify the **ADJRSQ** option in the MODEL statement, PROC SURVEYREG computes an multiple R-square adjusted as the weighted regression as

$$ADJRSQ = \begin{cases} 1 - \frac{n(1 - R^2)}{n - p} & \text{if no intercept} \\ 1 - \frac{(n - 1)(1 - R^2)}{n - p} & \text{otherwise} \end{cases}$$

where R^2 is the multiple R-square.

Root Mean Square Errors

PROC SURVEYREG computes the square root of mean square errors as

$$\sqrt{\text{MSE}} = \sqrt{n SS_{error} / (n - p) w_{...}}$$

where $w_{...}$ is the sum of the sampling weights over all observations.

Variance Estimation

PROC SURVEYREG uses the Taylor series method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs (Fuller 2009; Woodruff 1971; Fuller 1975;

Fuller et al. 1989; Särndal, Swensson, and Wretman 1992; Wolter 2007; Rust 1985; Dippo, Fay, and Morganstein 1984; Rao and Shao 1999; Rao, Wu, and Yue 1992; Rao and Shao 1996). You can use the **VARMETHOD=** option to specify a variance estimation method to use. By default, the Taylor series method is used. However, replication methods have recently gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis.

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The parameters of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. You can use the **REPWEIGHTS** statement to provide your own replicate weights for variance estimation.

The following sections provide details about how the variance-covariance matrix of the estimated regression coefficients is estimated for each variance estimation method.

Taylor Series (Linearization)

The Taylor series (linearization) method is the most commonly used method to estimate the covariance matrix of the regression coefficients for complex survey data. It is the default variance estimation method used by PROC SURVEYREG.

Use the notation described in the section “**Notation**” on page 7966 to denote the residuals from the linear regression as

$$\mathbf{r} = \mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}$$

with r_{hij} as its elements. Let the $p \times p$ matrix **G** be defined as

$$\mathbf{G} = \frac{n-1}{n-p} \sum_{h=1}^H \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})' (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})$$

where

$$\begin{aligned} \mathbf{e}_{hij} &= w_{hij} r_{hij} \mathbf{x}_{hij} \\ \mathbf{e}_{hi\cdot} &= \sum_{j=1}^{m_{hi}} \mathbf{e}_{hij} \\ \bar{\mathbf{e}}_{h\cdot\cdot} &= \frac{1}{n_h} \sum_{i=1}^{n_h} \mathbf{e}_{hi\cdot} \end{aligned}$$

The Taylor series estimate of the covariance matrix of $\hat{\boldsymbol{\beta}}$ is

$$\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \mathbf{G} (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}$$

The factor $(n-1)/(n-p)$ in the computation of the matrix \mathbf{G} reduces the small sample bias associated with using the estimated function to calculate deviations (Hidioglou, Fuller, and Hickman 1980). For simple random sampling, this factor contributes to the degrees of freedom correction applied to the residual mean square for ordinary least squares in which p parameters are estimated. By default, the procedure use this adjustment in the variance estimation. If you do not want to use this multiplier in variance estimation, you can specify the `VADJUST=NONE` option in the `MODEL` statement to suppress this factor.

Balanced Repeated Replication (BRR) Method

The balanced repeated replication (BRR) method requires that the full sample be drawn by using a stratified sample design with two primary sampling units (PSUs) per stratum. Let H be the total number of strata. The total number of replicates R is the smallest multiple of 4 that is greater than H . However, if you prefer a larger number of replicates, you can specify the `REPS=number` option. If a $number \times number$ Hadamard matrix cannot be constructed, the number of replicates is increased until a Hadamard matrix becomes available.

Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights for the remaining PSUs. The new weights are called replicate weights.

Replicates are constructed by using the first H columns of the $R \times R$ Hadamard matrix. The r th ($r = 1, 2, \dots, R$) replicate is drawn from the full sample according to the r th row of the Hadamard matrix as follows:

- If the (r, h) element of the Hadamard matrix is 1, then the first PSU of stratum h is included in the r th replicate and the second PSU of stratum h is excluded.
- If the (r, h) element of the Hadamard matrix is -1 , then the second PSU of stratum h is included in the r th replicate and the first PSU of stratum h is excluded.

Note that the “first” and “second” PSUs are determined by data order in the input data set. Thus, if you reorder the data set and perform the same analysis by using BRR method, you might get slightly different results, because the contents in each replicate sample might change.

The replicate weights of the remaining PSUs in each half-sample are then doubled to their original weights. For more details about the BRR method, see Wolter (2007) and Lohr (2010).

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the `VARMETHOD=BRR(PRINTH)` *method-option*. If you provide a Hadamard matrix by specifying the `VARMETHOD=BRR(HADAMARD=)` *method-option*, then the replicates are generated according to the provided Hadamard matrix.

You can use the `VARMETHOD=BRR(OUTWEIGHTS=)` *method-option* to save the replicate weights into a SAS data set.

Let $\hat{\beta}$ be the estimated regression coefficients from the full sample for β , and let $\hat{\beta}_r$ be the estimated regression coefficient from the r th replicate by using replicate weights. PROC SURVEYREG estimates the covariance matrix of $\hat{\beta}$ by

$$\widehat{\mathbf{V}}(\hat{\beta}) = \frac{1}{R} \sum_{r=1}^R (\hat{\beta}_r - \hat{\beta}) (\hat{\beta}_r - \hat{\beta})'$$

with H degrees of freedom, where H is the number of strata.

Fay's BRR Method

Fay's method is a modification of the **BRR** method, and it requires a stratified sample design with two primary sampling units (PSUs) per stratum. The total number of replicates R is the smallest multiple of 4 that is greater than the total number of strata H . However, if you prefer a larger number of replicates, you can specify the **REPS= method-option**.

For each replicate, Fay's method uses a Fay coefficient $0 \leq \epsilon < 1$ to impose a perturbation of the original weights in the full sample that is gentler than using only half-samples, as in the traditional BRR method. The Fay coefficient $0 \leq \epsilon < 1$ can be set by specifying the **FAY = ϵ method-option**. By default, $\epsilon = 0.5$ if the **FAY method-option** is specified without providing a value for ϵ (Judkins 1990; Rao and Shao 1999). When $\epsilon = 0$, Fay's method becomes the traditional **BRR** method. For more details, see Dipbo, Fay, and Morganstein (1984); Fay (1984, 1989); Judkins (1990).

Let H be the number of strata. Replicates are constructed by using the first H columns of the $R \times R$ **Hadamard matrix**, where R is the number of replicates, $R > H$. The r th ($r = 1, 2, \dots, R$) replicate is created from the full sample according to the r th row of the Hadamard matrix as follows:

- If the (r, h) element of the Hadamard matrix is 1, then the full sample weight of the first PSU in stratum h is multiplied by ϵ and the full sample weight of the second PSU is multiplied by $2 - \epsilon$ to obtain the r th replicate weights.
- If the (r, h) element of the Hadamard matrix is -1 , then the full sample weight of the first PSU in stratum h is multiplied by $2 - \epsilon$ and the full sample weight of the second PSU is multiplied by ϵ to obtain the r th replicate weights.

You can use the **VARMETHOD=BRR(OUTWEIGHTS=) method-option** to save the replicate weights into a SAS data set.

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the **VARMETHOD=BRR(PRINTH) method-option**. If you provide a Hadamard matrix by specifying the **VARMETHOD=BRR(HADAMARD=) method-option**, then the replicates are generated according to the provided Hadamard matrix.

Let $\hat{\beta}$ be the estimated regression coefficients from the full sample for β . Let $\hat{\beta}_r$ be the estimated regression coefficient obtained from the r th replicate by using replicate weights. PROC SURVEYREG estimates the covariance matrix of $\hat{\beta}$ by

$$\hat{V}(\hat{\beta}) = \frac{1}{R(1 - \epsilon)^2} \sum_{r=1}^R (\hat{\beta}_r - \hat{\beta}) (\hat{\beta}_r - \hat{\beta})'$$

with H degrees of freedom, where H is the number of strata.

Jackknife Method

The jackknife method of variance estimation deletes one PSU at a time from the full sample to create replicates. The total number of replicates R is the same as the total number of PSUs. In each replicate, the sample weights of the remaining PSUs are modified by the jackknife coefficient α_r . The modified weights are called replicate weights.

The jackknife coefficient and replicate weights are described as follows.

Without Stratification If there is no stratification in the sample design (no **STRATA** statement), the jackknife coefficients α_r are the same for all replicates:

$$\alpha_r = \frac{R-1}{R} \quad \text{where } r = 1, 2, \dots, R$$

Denote the original weight in the full sample for the j th member of the i th PSU as w_{ij} . If the i th PSU is included in the r th replicate ($r = 1, 2, \dots, R$), then the corresponding replicate weight for the j th member of the i th PSU is defined as

$$w_{ij}^{(r)} = w_{ij} / \alpha_r$$

With Stratification If the sample design involves stratification, each stratum must have at least two PSUs to use the jackknife method.

Let stratum \tilde{h}_r be the stratum from which a PSU is deleted for the r th replicate. Stratum \tilde{h}_r is called the *donor stratum*. Let $n_{\tilde{h}_r}$ be the total number of PSUs in the donor stratum \tilde{h}_r . The jackknife coefficients are defined as

$$\alpha_r = \frac{n_{\tilde{h}_r} - 1}{n_{\tilde{h}_r}} \quad \text{where } r = 1, 2, \dots, R$$

Denote the original weight in the full sample for the j th member of the i th PSU as w_{ij} . If the i th PSU is included in the r th replicate ($r = 1, 2, \dots, R$), then the corresponding replicate weight for the j th member of the i th PSU is defined as

$$w_{ij}^{(r)} = \begin{cases} w_{ij} & \text{if } i\text{th PSU is not in the donor stratum } \tilde{h}_r \\ w_{ij} / \alpha_r & \text{if } i\text{th PSU is in the donor stratum } \tilde{h}_r \end{cases}$$

You can use the **VARMETHOD=JACKKNIFE(OUTJKCOEFS=)** *method-option* to save the jackknife coefficients into a SAS data set and use the **VARMETHOD=JACKKNIFE(OUTWEIGHTS=)** *method-option* to save the replicate weights into a SAS data set.

If you provide your own replicate weights with a **REPWEIGHTS** statement, then you can also provide corresponding jackknife coefficients with the **JKCOEFS=** option.

Let $\hat{\beta}$ be the estimated regression coefficients from the full sample for β . Let $\hat{\beta}_r$ be the estimated regression coefficient obtained from the r th replicate by using replicate weights. PROC SURVEYREG estimates the covariance matrix of $\hat{\beta}$ by

$$\hat{V}(\hat{\beta}) = \sum_{r=1}^R \alpha_r (\hat{\beta}_r - \hat{\beta}) (\hat{\beta}_r - \hat{\beta})'$$

with $R-H$ degrees of freedom, where R is the number of replicates and H is the number of strata, or $R-1$ when there is no stratification.

Hadamard Matrix

A Hadamard matrix **H** is a square matrix whose elements are either 1 or -1 such that

$$\mathbf{H}\mathbf{H}' = k\mathbf{I}$$

where k is the dimension of \mathbf{H} and \mathbf{I} is the identity matrix of order k . The order k is necessarily 1, 2, or a positive integer that is a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension $k = 8$:

1	1	1	1	1	1	1	1
1	-1	1	-1	1	-1	1	-1
1	1	-1	-1	1	1	-1	-1
1	-1	-1	1	1	-1	-1	1
1	1	1	1	-1	-1	-1	-1
1	-1	1	-1	-1	1	-1	1
1	1	-1	-1	-1	-1	1	1
1	-1	-1	1	-1	1	1	-1

Degrees of Freedom

PROC SURVEYREG produces tests for the significance of model effects, regression parameters, estimable functions specified in the **ESTIMATE** statement, and contrasts specified in the **CONTRAST** statement. It computes all these tests taking into account the sample design. The degrees of freedom for these tests differ from the degrees of freedom for the ANOVA table, which does not consider the sample design.

Denominator Degrees of Freedom

The denominator *df* refers to the denominator degrees of freedom for F tests and to the degrees of freedom for t tests in the analysis.

For the **Taylor series** method, the denominator *df* equals the number of clusters minus the actual number of strata. If there are no clusters, the denominator *df* equals the number of observations minus the actual number of strata. The *actual number of strata* equals the following:

- one, if there is no **STRATA** statement
- the number of strata in the sample, if there is a **STRATA** statement but the procedure does not collapse any strata
- the number of strata in the sample after collapsing, if there is a **STRATA** statement and the procedure collapses strata that have only one sampling unit

Alternatively, you can specify your own denominator *df* by using the **DF=** option in the **MODEL** statement.

For the **BRR** method (including **Fay's method**) without a **REPWEIGHTS** statement, the denominator *df* equals the number of strata.

For the **jackknife** method without a **REPWEIGHTS** statement, the denominator *df* is equal to the number of replicates minus the *actual number of strata*.

When there is a **REPWEIGHTS** statement, the denominator *df* equals the number of **REPWEIGHTS** variables, unless you specify an alternative in the **DF= option** in a **REPWEIGHTS** statement.

Numerator Degrees of Freedom

The numerator *df* refers to the numerator degrees of freedom for the Wald *F* statistic associated with an effect or with a contrast. The procedure computes the Wald *F* statistic for an effect as a Type III test; that is, the test has the following properties:

- The hypothesis for an effect does not involve parameters of other effects except for containing effects (which it must involve to be estimable).
- The hypotheses to be tested are invariant to the ordering of effects in the model.

See the section “[Testing Effects](#)” on page 7975 for more information. The numerator *df* for the Wald *F* statistic for a contrast is the rank of the **L** matrix that defines the contrast.

Testing

Testing Effects

For each effect in the model, PROC SURVEYREG computes an **L** matrix such that every element of **Lβ** is estimable; the **L** matrix has the maximum possible rank that is associated with the effect. To test the effect, the procedure uses the Wald *F* statistic for the hypothesis $H_0: \mathbf{L}\boldsymbol{\beta} = 0$. The Wald *F* statistic equals

$$F_{\text{Wald}} = \frac{(\mathbf{L}\hat{\boldsymbol{\beta}})'(\mathbf{L}'\hat{\mathbf{V}}\mathbf{L})^{-1}(\mathbf{L}\hat{\boldsymbol{\beta}})}{\text{rank}(\mathbf{L}'\hat{\mathbf{V}}\mathbf{L})}$$

with numerator degrees of freedom equal to $\text{rank}(\mathbf{L}'\hat{\mathbf{V}}\mathbf{L})$.

In the [Taylor series](#) method, the denominator degrees of freedom is equal to the number of clusters minus the number of strata (unless you specify the denominator degrees of freedom with the **DF=** option in the **MODEL** statement). For details about denominator degrees of freedom in replication methods, see the section “[Denominator Degrees of Freedom](#)” on page 7974. It is possible that the **L** matrix cannot be constructed for an effect, in which case that effect is not testable. For more information about how the matrix **L** is constructed, see the discussion in Chapter 15, “[The Four Types of Estimable Functions](#).”

You can use the **TEST** statement to perform *F* tests that test Type I, Type II, or Type III hypotheses. For details about the syntax of the **TEST** statement, see the section “[TEST Statement](#)” on page 502 of Chapter 19, “[Shared Concepts and Topics](#).”

Contrasts

You can use the **CONTRAST** statement to perform custom hypothesis tests. If the hypothesis is testable in the univariate case, the Wald *F* statistic for $H_0: \mathbf{L}\boldsymbol{\beta} = 0$ is computed as

$$F_{\text{Wald}} = \frac{(\mathbf{L}_{\text{Full}}\hat{\boldsymbol{\beta}})'(\mathbf{L}_{\text{Full}}'\hat{\mathbf{V}}\mathbf{L}_{\text{Full}})^{-1}(\mathbf{L}_{\text{Full}}\hat{\boldsymbol{\beta}})}{\text{rank}(\mathbf{L})}$$

where \mathbf{L} is the contrast vector or matrix you specify, $\boldsymbol{\beta}$ is the vector of regression parameters, $\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}\mathbf{X}'\mathbf{W}\mathbf{Y}$, $\widehat{\mathbf{V}}$ is the estimated covariance matrix of $\hat{\boldsymbol{\beta}}$, $\text{rank}(\mathbf{L})$ is the rank of \mathbf{L} , and \mathbf{L}_{Full} is a matrix such that

- \mathbf{L}_{Full} has the same number of columns as \mathbf{L}
- \mathbf{L}_{Full} has full row rank
- the rank of \mathbf{L}_{Full} equals the rank of the \mathbf{L} matrix
- all rows of \mathbf{L}_{Full} are estimable functions
- the Wald F statistic computed using the \mathbf{L}_{Full} matrix is equivalent to the Wald F statistic computed by using the \mathbf{L} matrix with any row deleted that is a linear combination of previous rows

If \mathbf{L} is a full-rank matrix and all rows of \mathbf{L} are estimable functions, then \mathbf{L}_{Full} is the same as \mathbf{L} . It is possible that \mathbf{L}_{Full} matrix cannot be constructed for contrasts in a CONTRAST statement, in which case the contrasts are not testable.

Domain Analysis

A **DOMAIN** statement requests that the procedure perform regression analysis for each domain.

For a domain D , let I_D be the corresponding indicator variable:

$$I_D(h, i, j) = \begin{cases} 1 & \text{if observation } (h, i, j) \text{ belongs to domain } D \\ 0 & \text{otherwise} \end{cases}$$

Let

$$v_{hij} = w_{hij} I_D(h, i, j) = \begin{cases} w_{hij} & \text{if observation } (h, i, j) \text{ belongs to domain } D \\ 0 & \text{otherwise} \end{cases}$$

The regression in domain D uses v as the weight variable.

Computational Resources

Due to the complex nature of survey data analysis, the SURVEYREG procedure requires more memory than an analysis of the same regression model by the GLM procedure. For details about the amount of memory related to the modeling, see the section “[Computational Resources](#)” on page 3379 in Chapter 42, “[The GLM Procedure](#).”

The memory needed by the SURVEYREG procedure to handle the survey design is described as follows.

Let

- H be the total number of strata
- n_c be the total number of clusters in your sample across all H strata, if you specify a **CLUSTER** statement
- p be the total number of parameters in the model

The memory needed (in bytes) is

$$48H + 8pH + 4p(p + 1)H$$

For a cluster sample, the additional memory needed (in bytes) is

$$48H + 8pH + 4p(p + 1)H + 4p(p + 1)n_c + 16n_c$$

The SURVEYREG procedure also uses other small amounts of additional memory. However, when you have a large number of clusters or strata, or a large number of parameters in your model, the memory described previously dominates the total memory required by the procedure.

Output Data Sets

You can use the Output Delivery System (ODS) to create a SAS data set from any piece of PROC SURVEYREG output. See the section “[ODS Table Names](#)” on page 7983 for more information. For a more detailed description of using ODS, see Chapter 20, “[Using the Output Delivery System](#).”

PROC SURVEYREG also provides an **OUTPUT statement** to create a data set that contains estimated linear predictors and their standard error estimates, the residuals from the linear regression, and the confidence limits for the predictors.

If you use BRR or jackknife variance estimation, PROC SURVEYREG provides an output data set that stores the replicate weights and an output data set that stores the jackknife coefficients for jackknife variance estimation.

OUT= Data Set Created by the OUTPUT Statement

The **OUTPUT** statement produces an output data set that contains the following:

- all original data from the SAS data set input to PROC SURVEYREG
- the new variables corresponding to the diagnostic measures specified with statistics keywords in the OUTPUT statement (PREDICTED=, RESIDUAL=, and so on)

When any independent variable in the analysis (including all classification variables) is missing for an observation, then all new variables that correspond to diagnostic measures are missing for the observation in the output data set.

When a dependent variable in the analysis is missing for an observation, then the residual variable that corresponds to R is also missing in the output data set. However, the variables corresponding to LCLM, P, STDP, and UCLM are not missing.

Replicate Weights Output Data Set

If you specify the `OUTWEIGHTS= method-option` for `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`, PROC SURVEYREG stores the replicate weights in an output data set. The `OUTWEIGHTS=` output data set contains all observations from the `DATA=` input data set that are valid (used in the analysis). (A valid observation is an observation that has a positive value of the `WEIGHT` variable. Valid observations must also have nonmissing values of the `STRATA` and `CLUSTER` variables, unless you specify the `MISSING` option.)

The `OUTWEIGHTS=` data set contains the following variables:

- all variables in the `DATA=` input data set
- `RepWt_1`, `RepWt_2`, . . . , `RepWt_n`, which are the replicate weight variables

where n is the total number of replicates in the analysis. Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the `OUTWEIGHTS= method-option` to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYREG or in the other survey procedures. You can use the `REPWEIGHTS` statement to provide replicate weights for the procedure.

Jackknife Coefficients Output Data Set

If you specify the `OUTJKCOEFS= method-option` for `VARMETHOD=JACKKNIFE`, PROC SURVEYREG stores the [jackknife coefficients](#) in an output data set. The `OUTJKCOEFS=` output data set contains one observation for each replicate. The `OUTJKCOEFS=` data set contains the following variables:

- `Replicate`, which is the replicate number for the jackknife coefficient
- `JKCoefficient`, which is the jackknife coefficient
- `DonorStratum`, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a `STRATA` statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the `OUTJKCOEFS= method-option` to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYREG or in the other survey procedures. You can use the `JKCOEFS=` option in the `REPWEIGHTS` statement to provide jackknife coefficients for the procedure.

Displayed Output

The SURVEYREG procedure produces output that is described in the following sections.

Output that is generated by the `EFFECT`, `ESTIMATE`, `LSMEANS`, `LSMESTIMATE`, and `SLICE` statements is not listed below. For information about the output that is generated by these statements, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

Data Summary

By default, PROC SURVEYREG displays the following information in the “Data Summary” table:

- Number of Observations, which is the total number of observations used in the analysis, excluding observations with missing values
- Sum of Weights, if you specify a WEIGHT statement
- Mean of the dependent variable in the MODEL statement, or Weighted Mean if you specify a WEIGHT statement
- Sum of the dependent variable in the MODEL statement, or Weighted Sum if you specify a WEIGHT statement

Design Summary

When you specify a CLUSTER statement or a STRATA statement, the procedure displays a “Design Summary” table, which provides the following sample design information:

- Number of Strata, if you specify a STRATA statement
- Number of Strata Collapsed, if the procedure collapses strata
- Number of Clusters, if you specify a CLUSTER statement
- Overall Sampling Rate used to calculate the design effect, if you specify the DEFF option in the MODEL statement

Domain Summary

By default, PROC SURVEYREG displays the following information in the “Domain Summary” table:

- Number of Observations, which is the total number of observations used in the analysis
- total number of observations in the current domain
- total number of observations not in the current domain
- Sum of Weights for the observations in the current domain, if you specify a WEIGHT statement

Fit Statistics

By default, PROC SURVEYREG displays the following regression statistics in the “Fit Statistics” table:

- R-square for the regression
- Root MSE, which is the square root of the mean square error
- Denominator DF, which is the denominator degrees of freedom for the F tests and also the degrees of freedom for the t tests produced by the procedure

Variance Estimation

If the variance method is not Taylor series (see the section “[Variance Estimation](#)” on page 7969) or if the [NOMCAR](#) option is used, by default, PROC SURVEYREG displays the following variance estimation information in the “Variance Estimation” table:

- Method, which is the variance estimation method
- Number of Replicates, if you specify the [VARMETHOD=BRR](#) or [VARMETHOD=JACKKNIFE](#) option
- Hadamard Data Set name, if you specify the [VARMETHOD=BRR\(HADAMARD=\)](#) *method-option*
- Fay Coefficient, if you specify the [VARMETHOD=BRR\(FAY\)](#) *method-option*
- Replicate Weights input data set name, if you provide replicate weights with a [REPWEIGHTS](#) statement
- Missing Levels, which indicates whether missing levels of categorical variables are included by the [MISSING](#) option
- Missing Values, which indicates whether observations with missing values are included in the analysis by the [NOMCAR](#) option

Stratum Information

When you specify the [LIST](#) option in the [STRATA](#) statement, PROC SURVEYREG displays a “Stratum Information” table, which provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- [STRATA](#) variable(s), which lists the levels of [STRATA](#) variables for the stratum
- Population Total, if you specify the [TOTAL=](#) option
- Sampling Rate, if you specify the [TOTAL=](#) option or the [RATE=](#) option. If you specify the [TOTAL=](#) option, the sampling rate is based on the number of nonmissing observations in the stratum.
- N Obs, which is the number of observations
- number of Clusters, if you specify a [CLUSTER](#) statement
- Collapsed, which has the value ‘Yes’ if the stratum is collapsed with another stratum before analysis

If PROC SURVEYREG collapses strata, the “Stratum Information” table also displays stratum information for the new, collapsed stratum. The new stratum has a Stratum Index of 0 and is labeled ‘Pooled.’

Class Level Information

If you use a CLASS statement to name classification variables, PROC SURVEYREG displays a “Class Level Information” table. This table contains the following information for each classification variable:

- Class Variable, which lists each CLASS variable name
- Levels, which is the number of values or levels of the classification variable
- Values, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.

X'X Matrix

If you specify the XPX option in the MODEL statement, PROC SURVEYREG displays the $X'X$ matrix. When there is a WEIGHT variable, the procedure displays the $X'WX$ matrix. This option also displays the crossproducts vector $X'y$ or $X'Wy$, where y is the response vector (dependent variable).

Inverse Matrix of X'X

If you specify the INVERSE option in the MODEL statement, PROC SURVEYREG displays the inverse or the generalized inverse of the $X'X$ matrix. When there is a WEIGHT variable, the procedure displays the inverse or the generalized inverse of the $X'WX$ matrix.

ANOVA for Dependent Variable

If you specify the ANOVA option in the model statement, PROC SURVEYREG displays an analysis of variance table for the dependent variable. This table is identical to the ANOVA table displayed by the GLM procedure.

Tests of Model Effects

By default, PROC SURVEYREG displays a “Tests of Model Effects” table, which provides Wald’s F test for each effect in the model. The table contains the following information for each effect:

- Effect, which is the effect name
- Num DF, which is the numerator degrees of freedom for Wald’s F test
- F Value, which is Wald’s F statistic
- Pr > F, which is the significance probability corresponding to the F Value

A footnote displays the denominator degrees of freedom, which is the same for all effects.

Estimated Regression Coefficients

PROC SURVEYREG displays the “Estimated Regression Coefficients” table by default when there is no CLASS statement. Also, the procedure displays this table when you specify a **CLASS** statement and also specify the **SOLUTION** option in the MODEL statement. This table contains the following information for each regression parameter:

- Parameter, which identifies the effect or regressor variable
- Estimate, which is the estimate of the regression coefficient
- Standardized Estimate, which is the standardized regression coefficient
- Standard Error, which is the standard error of the estimate
- t Value, which is the t statistic for testing H_0 : Parameter = 0
- Pr > |t|, which is the two-sided significance probability corresponding to the t Value
- Pr > |t|, which is the two-sided significance probability corresponding to the t Value

Covariance of Estimated Regression Coefficients

When you specify the **COVB** option in the MODEL statement, PROC SURVEYREG displays the “Covariance of Estimated Regression Coefficients” matrix.

Coefficients of Contrast

When you specify the **E** option in a CONTRAST statement, PROC SURVEYREG displays a “Coefficients of Contrast” table for the contrast. You can use this table to check the coefficients you specified in the CONTRAST statement. Also, this table gives a note for a nonestimable contrast.

Analysis of Contrasts

If you specify a **CONTRAST** statement, PROC SURVEYREG produces an “Analysis of Contrasts” table, which displays Wald’s F test for the contrast. If you use more than one CONTRAST statement, the procedure displays all results in the same table. The “Analysis of Contrasts” table contains the following information for each contrast:

- Contrast, which is the label of the contrast
- Num DF, which is the numerator degrees of freedom for Wald’s F test
- F Value, which is Wald’s F statistic for testing H_0 : Contrast = 0
- Pr > F, which is the significance probability corresponding to the F Value

Hadamard Matrix

If you specify the **VARMETHOD=BRR(PRINTH)** *method-option* in the PROC SURVEYREG statement, the procedure displays the Hadamard matrix.

When you provide a Hadamard matrix with the **VARMETHOD=BRR(HADAMARD=)** *method-option* but the procedure does not use the entire matrix, the procedure displays only the rows and columns that are actually used to construct replicates.

ODS Table Names

PROC SURVEYREG assigns a name to each table it creates; these names are listed in [Table 94.10](#). You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

To improve the consistency among procedures, tables that are generated by the **ESTIMATE** statements are changed slightly in appearance and formatting compared to releases prior to SAS/STAT 9.22. However, the statistics in the “Estimates” table remain unchanged. The “Coef” table replaces the previous “EstimateCoef” table that displays the **L** matrix coefficients of an estimable function of the parameters.

The **EFFECT**, **ESTIMATE**, **LSMEANS**, **LSMESTIMATE**, and **SLICE** statements also create tables, which are not listed in [Table 94.10](#). For information about these tables, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

Table 94.10 ODS Tables Produced by PROC SURVEYREG

ODS Table Name	Description	Statement	Option
ANOVA	ANOVA for dependent variable	MODEL	ANOVA
ClassVarInfo	Class level information	CLASS	Default
ContrastCoef	Coefficients of contrast	CONTRAST	E
Contrasts	Analysis of contrasts	CONTRAST	Default
CovB	Covariance of estimated regression coefficients	MODEL	COVB
DataSummary	Data summary	PROC	Default
DesignSummary	Design summary	STRATA CLUSTER	Default
DomainSummary	Domain summary	DOMAIN	Default
Effects	Tests of model effects	MODEL	Default
FitStatistics	Fit statistics	MODEL	Default
HadamardMatrix	Hadamard matrix	PROC	PRINTH
InvXPX	Inverse matrix of $X'X$	MODEL	I
ParameterEstimates	Estimated regression coefficients	MODEL	SOLUTION
StrataInfo	Stratum information	STRATA	LIST
VarianceEstimation	Variance estimation	PROC	Default
XPX	$X'X$ matrix	MODEL	XPX

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set MyStrata, which contains the “StrataInfo” table, an output data set MyParmEst, which contains the “ParameterEstimates” table, and an output data set Cov, which contains the “CovB” table for the ice cream study discussed in the section “[Stratified Sampling](#)” on page 7938:

```

title1 'Ice Cream Spending Analysis';
title2 'Stratified Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
    strata Grade /list;
    class Kids;
    model Spending = Income Kids / solution covb;
    weight Weight;
    ods output StrataInfo = MyStrata
               ParameterEstimates = MyParmEst
               CovB = Cov;
run;

```

Note that the option CovB is specified in the MODEL statement in order to produce the covariance matrix table.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

When ODS Graphics is enabled, the [ESTIMATE](#), [LSMEANS](#), [LSMESTIMATE](#), and [SLICE](#) statements can produce plots that are associated with their analyses. For information about these plots, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

Examples: SURVEYREG Procedure

Example 94.1: Simple Random Sampling

This example investigates the relationship between the labor force participation rate (LFPR) of women in 1968 and 1972 in large cities in the United States. A simple random sample of 19 cities is drawn from a total of 200 cities. For each selected city, the LFPRs are recorded and saved in a SAS data set `Labor`. In the following DATA step, LFPR in 1972 is contained in the variable `LFPR1972`, and the LFPR in 1968 is identified by the variable `LFPR1968`:

```
data Labor;
  input City $ 1-16 LFPR1972 LFPR1968;
  datalines;
New York      .45      .42
Los Angeles   .50      .50
Chicago       .52      .52
Philadelphia  .45      .45
Detroit       .46      .43
San Francisco .55      .55
Boston        .60      .45
Pittsburgh    .49      .34
St. Louis     .35      .45
Connecticut   .55      .54
Washington D.C. .52      .42
Cincinnati   .53      .51
Baltimore     .57      .49
Newark        .53      .54
Minn/St. Paul .59      .50
Buffalo       .64      .58
Houston       .50      .49
Patterson     .57      .56
Dallas        .64      .63
;
```

Assume that the LFPRs in 1968 and 1972 have a linear relationship, as shown in the following model:

$$\text{LFPR1972} = \beta_0 + \beta_1 * \text{LFPR1968} + \text{error}$$

You can use PROC SURVEYREG to obtain the estimated regression coefficients and estimated standard errors of the regression coefficients. The following statements perform the regression analysis:

```
title 'Study of Labor Force Participation Rates of Women';
proc surveyreg data=Labor total=200;
  model LFPR1972 = LFPR1968;
run;
```

Here, the `TOTAL=200` option specifies the finite population total from which the simple random sample of 19 cities is drawn. You can specify the same information by using the sampling rate option `RATE=0.095` ($19/200=.095$).

Output 94.1.1 summarizes the data information and the fit information.

Output 94.1.1 Summary of Regression Using Simple Random Sampling

Study of Labor Force Participation Rates of Women	
The SURVEYREG Procedure	
Regression Analysis for Dependent Variable LFPR1972	
Data Summary	
Number of Observations	19
Mean of LFPR1972	0.52684
Sum of LFPR1972	10.01000
Fit Statistics	
R-square	0.3970
Root MSE	0.05657
Denominator DF	18

Output 94.1.2 presents the significance tests for the model effects and estimated regression coefficients. The F tests and t tests for the effects in the model are also presented in these tables.

Output 94.1.2 Regression Coefficient Estimates

Tests of Model Effects				
Effect	Num DF	F Value	Pr > F	
Model	1	13.84	0.0016	
Intercept	1	4.63	0.0452	
LFPR1968	1	13.84	0.0016	
NOTE: The denominator degrees of freedom for the F tests is 18.				
Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	0.20331056	0.09444296	2.15	0.0452
LFPR1968	0.65604048	0.17635810	3.72	0.0016
NOTE: The denominator degrees of freedom for the t tests is 18.				

From the regression performed by PROC SURVEYREG, you obtain a positive estimated slope for the linear relationship between the LFPR in 1968 and the LFPR in 1972. The regression coefficients are all significant at the 5% level. The effects Intercept and LFPR1968 are significant in the model at the 5% level. In this example, the F test for the overall model without intercept is the same as the effect LFPR1968.

Example 94.2: Cluster Sampling

This example illustrates the use of regression analysis in a simple random cluster sample design. The data are from Särndal, Swensson, and Wretman (1992, p. 652). A total of 284 Swedish municipalities are grouped into 50 clusters of neighboring municipalities. Five clusters with a total of 32 municipalities are randomly selected. The results from the regression analysis in which clusters are used in the sample design are compared to the results of a regression analysis that ignores the clusters. The linear relationship between the population in 1975 and in 1985 is investigated.

The 32 selected municipalities in the sample are saved in the data set `Municipalities`:

```
data Municipalities;
  input Municipality Cluster Population85 Population75;
  datalines;
205 37 5 5
206 37 11 11
207 37 13 13
208 37 8 8
209 37 17 19
6 2 16 15
7 2 70 62
8 2 66 54
9 2 12 12
10 2 60 50
94 17 7 7
95 17 16 16
96 17 13 11
97 17 12 11
98 17 70 67
99 17 20 20
100 17 31 28
101 17 49 48
276 50 6 7
277 50 9 10
278 50 24 26
279 50 10 9
280 50 67 64
281 50 39 35
282 50 29 27
283 50 10 9
284 50 27 31
52 10 7 6
53 10 9 8
54 10 28 27
55 10 12 11
56 10 107 108
;
```

The variable `Municipality` identifies the municipalities in the sample; the variable `Cluster` indicates the cluster to which a municipality belongs; and the variables `Population85` and `Population75` contain the municipality populations in 1985 and in 1975 (in thousands), respectively. A regression analysis is performed by PROC SURVEYREG with a `CLUSTER` statement:

```

title1 'Regression Analysis for Swedish Municipalities';
title2 'Cluster Sampling';
proc surveyreg data=Municipalities total=50;
  cluster Cluster;
  model Population85=Population75;
run;

```

The TOTAL=50 option specifies the total number of clusters in the sampling frame.

Output 94.2.1 displays the data and design summary. Since the sample design includes clusters, the procedure displays the total number of clusters in the sample in the “Design Summary” table.

Output 94.2.1 Regression Analysis for Cluster Sampling

Regression Analysis for Swedish Municipalities	
Cluster Sampling	
The SURVEYREG Procedure	
Regression Analysis for Dependent Variable Population85	
Data Summary	
Number of Observations	32
Mean of Population85	27.50000
Sum of Population85	880.00000
Design Summary	
Number of Clusters	5

Output 94.2.2 displays the fit statistics and regression coefficient estimates. In the “Estimated Regression Coefficients” table, the estimated slope for the linear relationship is 1.05, which is significant at the 5% level; but the intercept is not significant. This suggests that a regression line crossing the original can be established between populations in 1975 and in 1985.

Output 94.2.2 Regression Analysis for Cluster Sampling

Fit Statistics	
R-square	0.9860
Root MSE	3.0488
Denominator DF	4

Output 94.2.2 *continued*

Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	-0.0191292	0.89204053	-0.02	0.9839
Population75	1.0546253	0.05167565	20.41	<.0001
NOTE: The denominator degrees of freedom for the t tests is 4.				

The CLUSTER statement is necessary in PROC SURVEYREG in order to incorporate the sample design. If you do not specify a CLUSTER statement in the regression analysis, as in the following statements, the standard deviation of the regression coefficients are incorrectly estimated.

```

title1 'Regression Analysis for Swedish Municipalities';
title2 'Simple Random Sampling';
proc surveyreg data=Municipalities total=284;
  model Population85=Population75;
run;

```

The analysis ignores the clusters in the sample, assuming that the sample design is a simple random sampling. Therefore, the TOTAL= option specifies the total number of municipalities, which is 284.

Output 94.2.3 displays the regression results ignoring the clusters. Compared to the results in Output 94.2.2, the regression coefficient estimates are the same. However, without using clusters, the regression coefficients have a smaller variance estimate, as in Output 94.2.3. By using clusters in the analysis, the estimated regression coefficient for effect Population75 is 1.05, with the estimated standard error 0.05, as displayed in Output 94.2.2; without using the clusters, the estimate is 1.05, but with the estimated standard error 0.04, as displayed in Output 94.2.3. To estimate the variance of the regression coefficients correctly, you should include the clustering information in the regression analysis.

NOTE: The denominator degrees of freedom for the t tests is 31.				

Example 94.3: Regression Estimator for Simple Random Sample

By using auxiliary information, you can construct regression estimators to provide more accurate estimates of population characteristics. With ESTIMATE statements in PROC SURVEYREG, you can specify a regression estimator as a linear function of the regression parameters to estimate the population total. This example illustrates this application by using the data set *Municipalities* from [Example 94.2](#).

In this sample, a linear model between the Swedish populations in 1975 and in 1985 is established:

$$\text{Population85} = \alpha + \beta * \text{Population75} + \text{error}$$

Assuming that the total population in 1975 is known to be 8200 (in thousands), you can use the ESTIMATE statement to predict the 1985 total population by using the following statements:

```

title1 'Regression Analysis for Swedish Municipalities';
title2 'Estimate Total Population';
proc surveyreg data=Municipalities total=50;
  cluster Cluster;
  model Population85=Population75;
  estimate '1985 population' Intercept 284 Population75 8200;
run;

```

Since each observation in the sample is a municipality and there is a total of 284 municipalities in Sweden, the coefficient for Intercept (α) in the ESTIMATE statement is 284 and the coefficient for Population75 (β) is the total population in 1975 (8.2 million).

[Output 94.3.1](#) displays the regression results and the estimation of the total population. By using the linear model, you can predict the total population in 1985 to be 8.64 million, with a standard error of 0.26 million.

Output 94.3.1 Use the Regression Estimator to Estimate the Population Total

Regression Analysis for Swedish Municipalities Estimate Total Population

Regression Analysis for Dependent Variable Population85					
Estimate					
Label	Estimate	Standard Error	DF	t Value	Pr > t
1985 population	8642.49	258.56	4	33.43	<.0001

Example 94.4: Stratified Sampling

This example illustrates the use of the SURVEYREG procedure to perform a regression in a stratified sample design. Consider a population of 235 farms producing corn in Nebraska and Iowa. You are interested in the relationship between corn yield (CornYield) and total farm size (FarmArea).

Each state is divided into several regions, and each region is used as a stratum. Within each stratum, a simple random sample with replacement is drawn. A total of 19 farms is selected by using a stratified simple random sample. The sample size and population size within each stratum are displayed in [Table 94.11](#).

Table 94.11 Number of Farms in Each Stratum

Stratum	State	Region	Number of Farms	
			Population	Sample
1	Iowa	1	100	3
2		2	50	5
3		3	15	3
4	Nebraska	1	30	6
5		2	40	2
Total			235	19

Three models for the data are considered:

- Model I — Common intercept and slope:

$$\text{Corn Yield} = \alpha + \beta * \text{Farm Area}$$

- Model II — Common intercept, different slope:

$$\text{Corn Yield} = \begin{cases} \alpha + \beta_{\text{Iowa}} * \text{Farm Area} & \text{if the farm is in Iowa} \\ \alpha + \beta_{\text{Nebraska}} * \text{Farm Area} & \text{if the farm is in Nebraska} \end{cases}$$

- Model III — Different intercept and different slope:

$$\text{Corn Yield} = \begin{cases} \alpha_{\text{Iowa}} + \beta_{\text{Iowa}} * \text{Farm Area} & \text{if the farm is in Iowa} \\ \alpha_{\text{Nebraska}} + \beta_{\text{Nebraska}} * \text{Farm Area} & \text{if the farm is in Nebraska} \end{cases}$$

Data from the stratified sample are saved in the SAS data set `Farms`. In the data set `Farms`, the variable `Weight` represents the sampling weight. In the following DATA step, the sampling weights are the reciprocals of selection probabilities:

```
data Farms;
  input State $ Region FarmArea CornYield Weight;
  datalines;
Iowa      1 100   54 33.333
Iowa      1  83   25 33.333
Iowa      1  25   10 33.333
Iowa      2 120   83 10.000
Iowa      2  50   35 10.000
Iowa      2 110   65 10.000
Iowa      2  60   35 10.000
Iowa      2  45   20 10.000
Iowa      3  23    5  5.000
Iowa      3  10    8  5.000
Iowa      3 350 125  5.000
Nebraska  1 130   20  5.000
Nebraska  1 245   25  5.000
Nebraska  1 150   33  5.000
Nebraska  1 263   50  5.000
Nebraska  1 320   47  5.000
Nebraska  1 204   25  5.000
Nebraska  2  80   11 20.000
Nebraska  2  48    8 20.000
;
```

The information about population size in each stratum is saved in the SAS data set `StratumTotals`:

```
data StratumTotals;
  input State $ Region _TOTAL_;
  datalines;
Iowa      1 100
Iowa      2  50
Iowa      3  15
Nebraska  1  30
Nebraska  2  40
;
```

Using the sample data from the data set `Farms` and the control information data from the data set `StratumTotals`, you can fit Model I by using PROC SURVEYREG with the following statements:

```

title1 'Analysis of Farm Area and Corn Yield';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
  strata State Region / list;
  model CornYield = FarmArea / covB;
  weight Weight;
run;

```

Output 94.4.1 displays the data summary and stratification information fitting Model I. The sampling rates are automatically computed by the procedure based on the sample sizes and the population totals in strata.

Output 94.4.2 displays tests of model effects and the estimated regression coefficients.

Output 94.4.2 Estimated Regression Coefficients and the Estimated Covariance Matrix

Tests of Model Effects			
Effect	Num DF	F Value	Pr > F
Model	1	21.74	0.0004
Intercept	1	4.93	0.0433
FarmArea	1	21.74	0.0004

NOTE: The denominator degrees of freedom for the F tests is 14.

Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	11.8162978	5.31981027	2.22	0.0433
FarmArea	0.2126576	0.04560949	4.66	0.0004

NOTE: The denominator degrees of freedom for the t tests is 14.

Covariance of Estimated Regression Coefficients		
	Intercept	FarmArea
Intercept	28.300381277	-0.146471538
FarmArea	-0.146471538	0.0020802259

Alternatively, you can assume that the linear relationship between corn yield (CornYield) and farm area (FarmArea) is different among the states (Model II). In order to analyze the data by using this model, you create auxiliary variables FarmAreaNE and FarmAreaIA to represent farm area in different states:

$$\text{FarmAreaNE} = \begin{cases} 0 & \text{if the farm is in Iowa} \\ \text{FarmArea} & \text{if the farm is in Nebraska} \end{cases}$$

$$\text{FarmAreaIA} = \begin{cases} \text{FarmArea} & \text{if the farm is in Iowa} \\ 0 & \text{if the farm is in Nebraska} \end{cases}$$

The following statements create these variables in a new data set called FarmsByState and use PROC SURVEYREG to fit Model II:

```
data FarmsByState;
  set Farms;
  if State='Iowa' then do;
    FarmAreaIA=FarmArea;
    FarmAreaNE=0;
  end;
```

```

else do;
    FarmAreaIA=0;
    FarmAreaNE=FarmArea;
end;
run;

```

The following statements perform the regression by using the new data set `FarmsByState`. The analysis uses the auxiliary variables `FarmAreaIA` and `FarmAreaNE` as the regressors:

```

title1 'Analysis of Farm Area and Corn Yield';
title2 'Model II: Same Intercept, Different Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
    strata State Region;
    model CornYield = FarmAreaIA FarmAreaNE / covB;
    weight Weight;
run;

```

Output 94.4.3 displays the fit statistics and parameter estimates. The estimated slope parameters for each state are quite different from the estimated slope in Model I. The results from the regression show that Model II fits these data better than Model I.

Output 94.4.3 Regression Results from Fitting Model II

Analysis of Farm Area and Corn Yield				
Model II: Same Intercept, Different Slopes				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable CornYield				
Fit Statistics

Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	4.04234816	3.80934848	1.06	0.3066
FarmAreaIA	0.41696069	0.05971129	6.98	<.0001
FarmAreaNE	0.12851012	0.02495495	5.15	0.0001
NOTE: The denominator degrees of freedom for the t tests is 14.				
Covariance of Estimated Regression Coefficients				
	Intercept	FarmAreaIA	FarmAreaNE	
Intercept	14.511135861	-0.118001232	-0.079908772	
FarmAreaIA	-0.118001232	0.0035654381	0.0006501109	
FarmAreaNE	-0.079908772	0.0006501109	0.0006227496	

For Model III, different intercepts are used for the linear relationship in two states. The following statements illustrate the use of the NOINT option in the MODEL statement associated with the CLASS statement to fit Model III:

```

title1 'Analysis of Farm Area and Corn Yield';
title2 'Model III: Different Intercepts and Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
  strata State Region;
  class State;
  model CornYield = State FarmAreaIA FarmAreaNE / noint covB solution;
  weight Weight;
run;

```

The model statement includes the classification effect State as a regressor. Therefore, the parameter estimates for effect State present the intercepts in two states.

Output 94.4.4 displays the regression results for fitting Model III, including parameter estimates, and covariance matrix of the regression coefficients. The estimated covariance matrix shows a lack of correlation between the regression coefficients from different states. This suggests that Model III might be the best choice for building a model for farm area and corn yield in these two states.

However, some statistics remain the same under different regression models—for example, Weighted Mean of CornYield. These estimators do not rely on the particular model you use.

Example 94.5: Regression Estimator for Stratified Sample

This example uses the corn yield data set FARMS from [Example 94.4](#) to illustrate how to construct a regression estimator for a stratified sample design.

As in [Example 94.3](#), by incorporating auxiliary information into a regression estimator, the procedure can produce more accurate estimates of the population characteristics that are of interest. In this example, the sample design is a stratified sample design. The auxiliary information is the total farm areas in regions of each state, as displayed in [Table 94.12](#). You want to estimate the total corn yield by using this information under the three linear models given in [Example 94.4](#).

Table 94.12 Information for Each Stratum

Stratum	State	Region	Number of Farms		Total Farm Area
			Population	Sample	
1	Iowa	1	100	3	13,200
2		2	50	5	
3		3	15	3	
4	Nebraska	1	30	6	8,750
5		2	40	2	
Total			235	19	21,950

The regression estimator to estimate the total corn yield under Model I can be obtained by using PROC SURVEYREG with an ESTIMATE statement:

```

title1 'Estimate Corn Yield from Farm Size';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
  strata State Region / list;
  class State Region;
  model CornYield = FarmArea State*Region /solution;
  weight Weight;
  estimate 'Estimate of CornYield under Model I'
    INTERCEPT 235 FarmArea 21950
    State*Region 100 50 15 30 40 /e;
run;
```

To apply the constraint in each stratum that the weighted total number of farms equals to the total number of farms in the stratum, you can include the strata as an effect in the MODEL statement, effect State*Region. Thus, the CLASS statement must list the STRATA variables, State and Region, as classification variables. The following ESTIMATE statement specifies the regression estimator, which is a linear function of the regression parameters:

```
estimate 'Estimate of CornYield under Model I'
        INTERCEPT 235 FarmArea 21950
        State*Region 100 50 15 30 40 /e;
```

This linear function contains the total for each explanatory variable in the model. Because the sampling units are farms in this example, the coefficient for Intercept in the ESTIMATE statement is the total number of farms (235); the coefficient for FarmArea is the total farm area listed in [Table 94.12](#) (21950); and the coefficients for effect State*Region are the total number of farms in each strata (as displayed in [Table 94.12](#)).

[Output 94.5.1](#) displays the results of the ESTIMATE statement. The regression estimator for the total of CornYield in Iowa and Nebraska is 7464 under Model I, with a standard error of 927.

Output 94.5.1 Regression Estimator for the Total of CornYield under Model I

Estimate Corn Yield from Farm Size Model I: Same Intercept and Slope				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable CornYield				
Estimate				
Label	Estimate	Standard Error	DF	t Value
Estimate of CornYield under Model I	7463.52	926.84	14	8.05
Estimate				
Label	Pr > t			
Estimate of CornYield under Model I	<.0001			

Under Model II, a regression estimator for totals can be obtained by using the following statements:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model II: Same Intercept, Different Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
    strata State Region;
    class State Region;
    model CornYield = FarmAreaIA FarmAreaNE
                state*region /solution;
    weight Weight;
    estimate 'Total of CornYield under Model II'
            INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
            State*Region 100 50 15 30 40 /e;
run;
```

In this model, you also need to include strata as a fixed effect in the MODEL statement. Other regressors are the auxiliary variables FarmAreaIA and FarmAreaNE (defined in [Example 94.4](#)). In the following ESTIMATE statement, the coefficient for Intercept is still the total number of farms; and the coefficients for FarmAreaIA and FarmAreaNE are the total farm area in Iowa and Nebraska, respectively, as displayed in [Table 94.12](#). The total number of farms in each strata are the coefficients for the strata effect:

```
estimate 'Total of CornYield under Model II'
      INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
      State*Region 100 50 15 30 40 /e;
```

[Output 94.5.2](#) displays that the results of the regression estimator for the total of corn yield in two states under Model II is 7580 with a standard error of 859. The regression estimator under Model II has a slightly smaller standard error than under Model I.

Output 94.5.2 Regression Estimator for the Total of CornYield under Model II

Estimate Corn Yield from Farm Size					
Model II: Same Intercept, Different Slopes					
The SURVEYREG Procedure					
Regression Analysis for Dependent Variable CornYield					
Estimate					
Label	Estimate	Standard Error	DF	t Value	Pr > t
Total of CornYield under Model II	7580.49	859.18	14	8.82	<.0001

Finally, you can apply Model III to the data and estimate the total corn yield. Under Model III, you can also obtain the regression estimators for the total corn yield for each state. Three ESTIMATE statements are used in the following statements to create the three regression estimators:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model III: Different Intercepts and Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
  strata State Region;
  class State Region;
  model CornYield = state FarmAreaIA FarmAreaNE
    State*Region /noint solution;
  weight Weight;
  estimate 'Total CornYield in Iowa under Model III'
    State 165 0 FarmAreaIA 13200 FarmAreaNE 0
    State*region 100 50 15 0 0 /e;
  estimate 'Total CornYield in Nebraska under Model III'
    State 0 70 FarmAreaIA 0 FarmAreaNE 8750
    State*Region 0 0 0 30 40 /e;
  estimate 'Total CornYield in both states under Model III'
    State 165 70 FarmAreaIA 13200 FarmAreaNE 8750
    State*Region 100 50 15 30 40 /e;
run;
```

The fixed effect State is added to the MODEL statement to obtain different intercepts in different states, by using the NOINT option. Among the ESTIMATE statements, the coefficients for explanatory variables are different depending on which regression estimator is estimated. For example, in the ESTIMATE statement

```
estimate 'Total CornYield in Iowa under Model III'
      State 165 0 FarmAreaIA 13200 FarmAreaNE 0
      State*region 100 50 15 0 0 /e;
```

the coefficients for the effect State are 165 and 0, respectively. This indicates that the total number of farms in Iowa is 165 and the total number of farms in Nebraska is 0, because the estimation is the total corn yield in Iowa only. Similarly, the total numbers of farms in three regions in Iowa are used for the coefficients of the strata effect State*Region, as displayed in Table 94.12. Output 94.5.3 displays the results from the three regression estimators by using Model III. Since the estimations are independent in each state, the total corn yield from both states is equal to the sum of the estimated total of corn yield in Iowa and Nebraska, $6246 + 1334 = 7580$. This regression estimator is the same as the one under Model II. The variance of regression estimator of the total corn yield in both states is the sum of variances of regression estimators for total corn yield in each state. Therefore, it is not necessary to use Model III to obtain the regression estimator for the total corn yield unless you need to estimate the total corn yield for each individual state.

Output 94.5.3 Regression Estimator for the Total of CornYield under Model III

Estimate Corn Yield from Farm Size				
Model III: Different Intercepts and Slopes				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable CornYield

Total CornYield in Iowa under Model III	6246.11	851.27	14	7.34
Estimate				
Label	Pr > t			
Total CornYield in Iowa under Model III	<.0001			

Example 94.6: Stratum Collapse

In a stratified sample, it is possible that some strata might have only one sampling unit. When this happens, PROC SURVEYREG collapses the strata that contain a single sampling unit into a pooled stratum. For more detailed information about stratum collapse, see the section “Stratum Collapse” on page 7968.

Suppose that you have the following data:

```

data Sample;
    input Stratum X Y W;
    datalines;
10 0 0 5
10 1 1 5
11 1 1 10
11 1 2 10
12 3 3 16
33 4 4 45
14 6 7 50
12 3 4 16
;

```

The variable Stratum is again the stratification variable, the variable X is the independent variable, and the variable Y is the dependent variable. You want to regress Y on X. In the data set Sample, both Stratum=33 and Stratum=14 contain one observation. By default, PROC SURVEYREG collapses these strata into one pooled stratum in the regression analysis.

To input the finite population correction information, you create the SAS data set StratumTotals:

```

data StratumTotals;
    input Stratum _TOTAL_;
    datalines;
10 10
11 20
12 32
33 40
33 45
14 50
15 .
66 70
;

```

The variable Stratum is the stratification variable, and the variable _TOTAL_ contains the stratum totals. The data set StratumTotals contains more strata than the data set Sample. Also in the data set StratumTotals, more than one observation contains the stratum totals for Stratum=33:

```

33 40
33 45

```

PROC SURVEYREG allows this type of input. The procedure simply ignores strata that are not present in the data set Sample; for the multiple entries of a stratum, the procedure uses the first observation. In this example, Stratum=33 has the stratum total _TOTAL_=40.

The following SAS statements perform the regression analysis:

```

title1 'Stratified Sample with Single Sampling Unit in Strata';
title2 'With Stratum Collapse';
proc surveyreg data=Sample total=StratumTotals;
    strata Stratum/list;
    model Y=X;
    weight W;
run;

```

Output 94.6.1 shows that there are a total of five strata in the input data set and two strata are collapsed into a pooled stratum. The denominator degrees of freedom is 4, due to the collapse (see the section “[Denominator Degrees of Freedom](#)” on page 7974).

Output 94.6.1 Summary of Data and Regression

Stratified Sample with Single Sampling Unit in Strata With Stratum Collapse	
The SURVEYREG Procedure	
Regression Analysis for Dependent Variable Y	
Data Summary	
Number of Observations	8
Sum of Weights	157.00000
Weighted Mean of Y	4.31210
Weighted Sum of Y	677.00000
Design Summary	
Number of Strata	5
Number of Strata Collapsed	2
Fit Statistics	
R-square	0.9564
Root MSE	0.5111
Denominator DF	4

Output 94.6.2 displays the stratification information, including stratum collapse. Under the column Collapsed, the fourth stratum (Stratum=14) and the fifth (Stratum=33) are marked as ‘Yes,’ which indicates that these two strata are collapsed into the pooled stratum (Stratum Index=0). The sampling rate for the pooled stratum is 2% (see the section “[Sampling Rate of the Pooled Stratum from Collapse](#)” on page 7968).

Output 94.6.3 displays the parameter estimates and the tests of the significance of the model effects.

Output 94.6.2 Stratification Information

Stratum Information					
Stratum Index	Collapsed	Stratum	N Obs	Population Total	Sampling Rate
1		10	2	10	20.0%
2		11	2	20	10.0%
3		12	2	32	6.25%
4	Yes	14	1	50	2.00%
5	Yes	33	1	40	2.50%
0	Pooled		2	90	2.22%

NOTE: Strata with only one observation are collapsed into the stratum with Stratum Index "0".

Output 94.6.3 Parameter Estimates and Effect Tests

Tests of Model Effects			
Effect	Num DF	F Value	Pr > F
Model	1	173.01	0.0002
Intercept	1	0.00	0.9961
X	1	173.01	0.0002

NOTE: The denominator degrees of freedom for the F tests is 4.

Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	0.00179469	0.34306373	0.01	0.9961
X	1.12598708	0.08560466	13.15	0.0002

NOTE: The denominator degrees of freedom for the t tests is 4.

Alternatively, if you prefer not to collapse strata with a single sampling unit, you can specify the NOCOLLAPSE option in the STRATA statement:

```

title1 'Stratified Sample with Single Sampling Unit in Strata';
title2 'Without Stratum Collapse';
proc surveyreg data=Sample total=StratumTotals;
  strata Stratum/list nocollapse;
  model Y = X;
  weight W;
run;

```

Output 94.6.4 does not contain the stratum collapse information displayed in Output 94.6.1, and the denominator degrees of freedom are 3 instead of 4.

Output 94.6.4 Summary of Data and Regression

Stratified Sample with Single Sampling Unit in Strata Without Stratum Collapse	
The SURVEYREG Procedure	
Regression Analysis for Dependent Variable Y	
Data Summary	
Number of Observations	8
Sum of Weights	157.00000
Weighted Mean of Y	4.31210
Weighted Sum of Y	677.00000
Design Summary	
Number of Strata	5
Fit Statistics	
R-square	0.9564
Root MSE	0.5111
Denominator DF	3

In Output 94.6.5, although the fourth stratum and the fifth stratum contain only one observation, no stratum collapse occurs.

Output 94.6.5 Stratification Information

Stratum Information				
Stratum Index	Stratum	N Obs	Population Total	Sampling Rate
1	10	2	10	20.0%
2	11	2	20	10.0%
3	12	2	32	6.25%
4	14	1	50	2.00%
5	33	1	40	2.50%

As a result of not collapsing strata, the standard error estimates of the parameters, shown in Output 94.6.6, are different from those in Output 94.6.3, as are the tests of the significance of model effects.

Output 94.6.6 Parameter Estimates and Effect Tests

Tests of Model Effects			
Effect	Num DF	F Value	Pr > F
Model	1	347.27	0.0003
Intercept	1	0.00	0.9962
X	1	347.27	0.0003

NOTE: The denominator degrees of freedom for the F tests is 3.

Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	0.00179469	0.34302581	0.01	0.9962
X	1.12598708	0.06042241	18.64	0.0003

NOTE: The denominator degrees of freedom for the t tests is 3.

Example 94.7: Domain Analysis

Recall the example in the section “[Getting Started: SURVEYREG Procedure](#)” on page 7935, which analyzed a stratified simple random sample from a junior high school to examine how household income and the number of children in a household affect students’ average weekly spending for ice cream. You can use the same sample to analyze the average weekly spending among male and female students. Because student gender is unrelated to the design of the sample, this kind of analysis is called domain analysis (subgroup analysis).

This example shows how you can use PROC SURVEYREG to perform domain analysis. The data set follows:

```
data IceCreamDataDomain;
  input Grade Spending Income Gender$ @@;
  datalines;
7 7 39 M 7 7 38 F 8 12 47 F
9 10 47 M 7 1 34 M 7 10 43 M
7 3 44 M 8 20 60 F 8 19 57 M
7 2 35 M 7 2 36 F 9 15 51 F
8 16 53 F 7 6 37 F 7 6 41 M
7 6 39 M 9 15 50 M 8 17 57 F
8 14 46 M 9 8 41 M 9 8 41 F
9 7 47 F 7 3 39 F 7 12 50 M
7 4 43 M 9 14 46 F 8 18 58 M
9 9 44 F 7 2 37 F 7 1 37 M
7 4 44 M 7 11 42 M 9 8 41 M
8 10 42 M 8 13 46 F 7 2 40 F
9 6 45 F 9 11 45 M 7 2 36 F
7 9 46 F
;
```

```

data IceCreamDataDomain;
  set IceCreamDataDomain;
  if Grade=7 then Prob=20/1824;
  if Grade=8 then Prob=9/1025;
  if Grade=9 then Prob=11/1151;
  Weight=1/Prob;
run;

```

In the data set `IceCreamDataDomain`, the variable `Grade` indicates a student's grade, which is the stratification variable. The variable `Spending` contains the dollar amount of each student's average weekly spending for ice cream. The variable `Income` specifies the household income, in thousands of dollars. The variable `Gender` indicates a student's gender. The sampling weights are created by using the reciprocals of the probabilities of selection, as follows:

```

data StudentTotals;
  input Grade _TOTAL_;
  datalines;
7 1824
8 1025
9 1151
;

```

In the data set `StudentTotals`, the variable `Grade` is the stratification variable, and the variable `_TOTAL_` contains the total numbers of students in the strata in the survey population.

The following statements demonstrate how you can analyze the relationship between spending and income among male and female students:

```

title1 'Ice Cream Spending Analysis';
title2 'Domain Analysis by Gender';
proc surveyreg data=IceCreamDataDomain total=StudentTotals;
  strata Grade;
  model Spending = Income;
  domain Gender;
  weight Weight;
run;

```

Output 94.7.1 gives a summary of the domains.

Output 94.7.1 Domain Analysis Summary

Ice Cream Spending Analysis	
Domain Analysis by Gender	
The SURVEYREG Procedure	
Gender=F	
Domain Regression Analysis for Variable Spending	
Domain Summary	
Number of Observations	40
Number of Observations in Domain	19
Number of Observations Not in Domain	21
Sum of Weights in Domain	1926.9
Weighted Mean of Spending	9.37611
Weighted Sum of Spending	18066.5
Ice Cream Spending Analysis	
Domain Analysis by Gender	
The SURVEYREG Procedure	
Gender=M	
Domain Regression Analysis for Variable Spending	
Domain Summary	
Number of Observations	40
Number of Observations in Domain	21
Number of Observations Not in Domain	19
Sum of Weights in Domain	2073.1
Weighted Mean of Spending	8.92305
Weighted Sum of Spending	18498.7

Output 94.7.2 shows the parameter estimates for the model within each domain.

Output 94.7.2 Parameter Estimates within Domain

Ice Cream Spending Analysis				
Domain Analysis by Gender				
The SURVEYREG Procedure				
Gender=F				
Domain Regression Analysis for Variable Spending				
Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	-23.751681	2.30795437	-10.29	<.0001
Income	0.735366	0.04757001	15.46	<.0001
NOTE: The denominator degrees of freedom for the t tests is 37.				
Ice Cream Spending Analysis				
Domain Analysis by Gender				
The SURVEYREG Procedure				
Gender=M				
Domain Regression Analysis for Variable Spending				
Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	-23.213291	2.13361241	-10.88	<.0001
Income	0.729419	0.04589801	15.89	<.0001
NOTE: The denominator degrees of freedom for the t tests is 37.				

For this particular example, the effect Income is significant for both models built within subgroups of male and female students, and the models are quite similar. In many other cases, regression models vary from subgroup to subgroup.

Example 94.8: Compare Domain Statistics

This example is a continuation of [Example 94.7](#) in which domain analyses for male and female students were performed. Suppose that you are now interested in estimating the gender domain means of weekly ice cream spending (that is, the average spending for males and females, respectively). You can use the SURVEYMEANS procedure to produce these domain statistics by using the following statements:

```
proc surveymeans data=IceCreamDataDomain total=StudentTotals;
  strata Grade;
  var spending;
  domain Gender;
  weight Weight;
run;
```

[Output 94.8.1](#) shows the estimated spending among male and female students.

Output 94.8.1 Estimated Domain Means

The SURVEYMEANS Procedure				
Domain Analysis: Gender				
Gender	Variable	N	Mean	Std Error of Mean
F	Spending	19	9.376111	1.077927
M	Spending	21	8.923052	1.003423
Domain Analysis: Gender				
Gender	Variable	95% CL for Mean		
F	Spending	7.19202418	11.5601988	
M	Spending	6.88992385	10.9561807	

You can also use PROC SURVEYREG to estimate these domain means. The benefit of this alternative approach is that PROC SURVEYREG provides more tools for additional analysis, such as domain means comparisons in a LSMEANS statement.

Suppose that you want to test whether there is a significant difference for the ice cream spending between male and female students. You can use the following statements to perform the test:

```

title1 'Ice Cream Spending Analysis';
title2 'Compare Domain Statistics';
proc surveyreg data=IceCreamDataDomain total=StudentTotals;
  strata Grade;
  class Gender;
  model Spending = Gender / vadjust=none;
  lsmeans Gender / diff;
  weight Weight;
run;

```

The variable Gender is used as a model effect. The **VADJUST=NONE** option is used to produce variance estimates for domain means that are identical to those produced by PROC SURVEYMEANS. The **LSMEANS** statement requests that PROC SURVEYREG estimate the average spending in each gender group. The **DIFF** option requests that the procedure compute the difference among domain means.

Output 94.8.2 displays the estimated weekly spending on ice cream among male and female students, respectively, and their standard errors. Female students spend \$9.38 per week on average, and male students spend \$8.92 per week on average. These domain means, including their standard errors, are identical to those in Output 94.8.1 which are produced by PROC SURVEYMEANS.

Output 94.8.2 Domain Means between Gender

Ice Cream Spending Analysis					
Compare Domain Statistics					
The SURVEYREG Procedure					
Regression Analysis for Dependent Variable Spending					
Gender Least Squares Means					
Gender	Estimate	Standard Error	DF	t Value	Pr > t
F	9.3761	1.0779	37	8.70	<.0001
M	8.9231	1.0034	37	8.89	<.0001

Output 94.8.3 shows the estimated difference for weekly ice cream spending between the two gender groups. The female students spend \$0.45 more than male students on average, and the difference is not statistically significant based on the *t* test.

Output 94.8.3 Domain Means Comparison

Differences of Gender Least Squares Means						
Gender	_Gender	Estimate	Standard Error	DF	t Value	Pr > t
F	M	0.4531	1.7828	37	0.25	0.8008

If you want to investigate whether there is any significant difference in ice cream spending among grades, you can use the following similar statements to compare:

```

title1 'Ice Cream Spending Analysis';
title2 'Compare Domain Statistics';
ods graphics on;
proc surveyreg data=IceCreamDataDomain total=StudentTotals;
    strata Grade;
    class Grade;
    model Spending = Grade / vadjust=none;
    lsmeans Grade / diff plots=(diff meanplot(cl));
    weight Weight;
run;
ods graphics off;

```

The Grade is specified in the CLASS statement to be used as an effect in the MODEL statement. The DIFF option in the LSMEANS statement requests that the procedure compute the difference among the domain means for the effect Grade. The ODS GRAPHICS statement enables ODS to create graphics. The PLOTS=(DIFF MEANPLOT(CL)) option requests two graphics: the domain means plot “MeanPlot” and their pairwise difference plot “DiffPlot”. The CL suboption requests the “MeanPlot” to display confidence. For information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

Output 94.8.4 shows the estimated weekly spending on ice cream for students within each grade. Students in Grade 7 spend the least, only \$5.00 per week. Students in Grade 8 spend the most, \$15.44 per week. Students in Grade 9 spend a little less at \$10.09 per week.

Output 94.8.4 Domain Means among Grades

Ice Cream Spending Analysis Compare Domain Statistics					
The SURVEYREG Procedure					
Regression Analysis for Dependent Variable Spending					
Grade Least Squares Means					
Grade	Estimate	Standard Error	DF	t Value	Pr > t
7	5.0000	0.7636	37	6.55	<.0001
8	15.4444	1.1268	37	13.71	<.0001
9	10.0909	0.9719	37	10.38	<.0001

Output 94.8.5 plots the weekly spending results that are shown in Output 94.8.4.

Output 94.8.5 Plot of Means of Ice Cream Spending within Grades

Output 94.8.6 displays pairwise comparisons for weekly ice cream spending among grades. All the differences are significant based on t tests.

Output 94.8.6 Domain Means Comparison

Differences of Grade Least Squares Means						
Grade	_Grade	Estimate	Standard Error	DF	t Value	Pr > t
7	8	-10.4444	1.3611	37	-7.67	<.0001
7	9	-5.0909	1.2360	37	-4.12	0.0002
8	9	5.3535	1.4880	37	3.60	0.0009

Output 94.8.7 plots the comparisons that are shown in Output 94.8.6.

Output 94.8.7 Plot of Pairwise Comparisons of Spending among Grades

In Output 94.8.7, the spending for each grade is shown in the background grid on both axes. Comparisons for each pair of domain means are shown by colored bars at intersections of these grids. The length of each bar represents the width of the confidence intervals for the corresponding difference between domain means. The significance of these pairwise comparisons are indicated in the plot by whether these bars cross the 45-degree background dash-line across the plot. Since none of the three bars cross the dash-line, all pairwise comparisons are significant, as shown in Output 94.8.6.

Example 94.9: Variance Estimate Using the Jackknife Method

This example uses the stratified sample from the section “Getting Started: SURVEYREG Procedure” on page 7935 to illustrate how to estimate the variances with replication methods.

As shown in the section “Stratified Sampling” on page 7938, the sample is saved in the SAS data set IceCream. The variable Grade that indicates a student’s grade is the stratification variable. The variable Spending contains the dollar amount of each student’s average weekly spending for ice cream. The variable

Income specifies the household income, in thousands of dollars. The variable Kids indicates how many children are in a student's family. The variable Weight contains sampling weights.

In this example, we use the jackknife method to estimate the variance, saving the replicate weights generated by the procedure into a SAS data set:

```

title1 'Ice Cream Spending Analysis';
title2 'Use the Jackknife Method to Estimate the Variance';
proc surveyreg data=IceCream
    varmethod=JACKKNIFE(outweights=JKWeights);
    strata Grade;
    class Kids;
    model Spending = Income Kids / solution;
    weight Weight;
run;

```

The **VARMETHOD=JACKKNIFE** option requests the procedure to estimate the variance by using the jackknife method. The **OUTWEIGHTS=JKWeights** option provides a SAS data set named JKWeights that contains the replicate weights used in the computation.

Output 94.9.1 shows the summary of the data and the variance estimation method. There are a total of 40 replicates generated by the procedure.

Output 94.9.1 Variance Estimation Using the Jackknife Method

Ice Cream Spending Analysis	
Use the Jackknife Method to Estimate the Variance	
The SURVEYREG Procedure	
Regression Analysis for Dependent Variable Spending	
Data Summary	
Number of Observations	40
Sum of Weights	4000.0
Weighted Mean of Spending	9.14130
Weighted Sum of Spending	36565.2
Design Summary	
Number of Strata	3
Variance Estimation	
Method	Jackknife
Number of Replicates	40

Output 94.9.2 displays the parameter estimates and their standard errors, as well as the tests of model effects that use the jackknife method.

Output 94.9.2 Variance Estimation Using the Jackknife Method

Tests of Model Effects				
Effect	Num DF	F Value	Pr > F	
Model	4	110.48	<.0001	
Intercept	1	133.30	<.0001	
Income	1	289.16	<.0001	
Kids	3	0.90	0.4525	

NOTE: The denominator degrees of freedom for the F tests is 37.

Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	-26.086882	2.58771182	-10.08	<.0001
Income	0.776699	0.04567521	17.00	<.0001
Kids 1	0.888631	1.12799263	0.79	0.4358
Kids 2	1.545726	1.25598146	1.23	0.2262
Kids 3	-0.526817	1.42555453	-0.37	0.7138
Kids 4	0.000000	0.00000000	.	.

NOTE: The denominator degrees of freedom for the t tests is 37.
 Matrix X'WX is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

Output 94.9.3 prints the first 6 observation in the output data set JKWeights, which contains the replicate weights.

The data set JKWeights contains all the variable in the data set IceCream, in addition to the replicate weights variables named RepWt_1, RepWt_2, ..., RepWt_40.

For example, the first observation (student) from stratum Grade=7 is deleted to create the first replicate. Therefore, stratum Grade=7 is the donor stratum for the first replicate, and the corresponding replicate weights are saved in the variable RepWt_1.

Because the first observation is deleted in the first replicate, RepWt_1=0 for the first observation. For observations from strata other than the donor stratum Grade=7, their replicate weights remain the same as in the variable Weight, while the rest of the observations in stratum Grade=7 are multiplied by the reciprocal of the corresponding jackknife coefficient, 0.95 for the first replicate.

Output 94.9.3 The Jackknife Replicate Weights for the First 6 Observations

The Jackknife Weights for the First 6 Obs										
Obs	Grade	Spending	Income	Kids	Prob	Weight	RepWt_1	RepWt_2	RepWt_3	RepWt_4

Overview: SURVEYSELECT Procedure

The SURVEYSELECT procedure provides a variety of methods for selecting probability-based random samples. The procedure can select a simple random sample or can sample according to a complex multistage sample design that includes stratification, clustering, and unequal probabilities of selection. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population.

To select a sample with PROC SURVEYSELECT, you input a SAS data set that contains the sampling frame, which is the list of units from which the sample is to be selected. The sampling units can be individual observations or groups of observations (clusters). You also specify the selection method, the desired sample size or sampling rate, and other selection parameters. PROC SURVEYSELECT selects the sample and produces an output data set that contains the selected units, their selection probabilities, and their sampling weights. When you select a sample in multiple stages, you invoke the procedure separately for each stage of selection, inputting the frame and selection parameters for each current stage.

PROC SURVEYSELECT provides methods for both equal probability sampling and probability proportional to size (PPS) sampling. In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. In PPS sampling, a unit's selection probability is proportional to its size measure. For details about probability sampling methods, see Lohr (2010); Kish (1965, 1987); Kalton (1983); Cochran (1977).

PROC SURVEYSELECT provides the following equal probability sampling methods:

- simple random sampling (without replacement)
- unrestricted random sampling (with replacement)
- systematic random sampling
- sequential random sampling
- Bernoulli sampling

This procedure also provides Poisson sampling and the following probability proportional to size (PPS) sampling methods:

- PPS sampling without replacement
- PPS sampling with replacement
- PPS systematic sampling
- PPS algorithms for selecting two units per stratum
- sequential PPS sampling with minimum replacement

The procedure uses fast, efficient algorithms for these sample selection methods. Thus, it performs well even for large input data sets or sampling frames.

PROC SURVEYSELECT can perform stratified sampling by selecting samples independently within strata, which are nonoverlapping subgroups of the survey population. Stratification controls the distribution of the sample size in the strata. It is widely used in practice toward meeting a variety of survey objectives. For example, with stratification you can ensure adequate sample sizes for subgroups of interest, including small subgroups, or you can use stratification toward improving the precision of the overall estimates. When you use a systematic or sequential selection method, PROC SURVEYSELECT can also sort by control variables within strata for the additional control of implicit stratification.

For stratified sampling, PROC SURVEYSELECT provides survey design methods to allocate the total sample size among the strata. Available allocation methods include proportional, Neyman, and optimal allocation. Optimal allocation maximizes the estimation precision within the available resources, taking into account stratum sizes, costs, and variances.

PROC SURVEYSELECT provides replicated sampling, where the total sample is composed of a set of replicates, and each replicate is selected in the same way. You can use replicated sampling to study variable nonsampling errors, such as variability in the results obtained by different interviewers. You can also use replication to estimate standard errors for combined sample estimates and to perform a variety of other resampling and simulation tasks.

Getting Started: SURVEYSELECT Procedure

In this example, an Internet service provider conducts a customer satisfaction survey. The survey population consists of the company's current subscribers. The company plans to select a sample of customers from this population, interview the selected customers, and then make inferences about the entire survey population from the sample data.

The SAS data set `Customers` contains the sampling frame, which is the list of units in the survey population. The sample of customers will be selected from this sampling frame. The data set `Customers` is constructed from the company's customer database. It contains one observation for each customer, with a total of 13,471 observations.

The following PROC PRINT statements display the first 10 observations of the data set Customers and produce Figure 95.1:

```
title1 'Customer Satisfaction Survey';
title2 'First 10 Observations';
proc print data=Customers(obs=10);
run;
```

Figure 95.1 Customers Data Set (First 10 Observations)

Customer Satisfaction Survey First 10 Observations					
Obs	CustomerID	State	Type	Usage	
1	416-87-4322	AL	New	839	
2	288-13-9763	GA	Old	224	
3	339-00-8654	GA	Old	2451	
4	118-98-0542	GA	New	349	
5	421-67-0342	FL	New	562	
6	623-18-9201	SC	New	68	
7	324-55-0324	FL	Old	137	
8	832-90-2397	AL	Old	1563	
9	586-45-0178	GA	New	615	
10	801-24-5317	SC	New	728	

In the SAS data set Customers, the variable CustomerID uniquely identifies each customer. The variable State contains the state of the customer's address. The company has customers in four states: Georgia (GA), Alabama (AL), Florida (FL), and South Carolina (SC). The variable Type equals 'Old' if the customer has subscribed to the service for more than one year; otherwise, the variable Type equals 'New'. The variable Usage contains the customer's average monthly service usage, in minutes.

The following sections illustrate the use of PROC SURVEYSELECT for probability sampling with three different designs for the customer satisfaction survey. All three designs are one-stage, with customers as the sampling units. The first design is simple random sampling without stratification. In the second design, customers are stratified by state and type, and the sample is selected by simple random sampling within strata. In the third design, customers are sorted within strata by usage, and the sample is selected by systematic random sampling within strata.

Simple Random Sampling

The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set by using simple random sampling:

```
title1 'Customer Satisfaction Survey';
title2 'Simple Random Sampling';
proc surveyselect data=Customers method=srs n=100
                  out=SampleSRS;
run;
```

The PROC SURVEYSELECT statement invokes the procedure. The DATA= option names the SAS data set Customers as the input data set from which to select the sample. The METHOD=SRS option specifies simple random sampling as the sample selection method. In simple random sampling, each unit has an equal probability of selection, and sampling is without replacement. Without-replacement sampling means that a unit cannot be selected more than once. The N= option specifies a sample size of 100 customers. The OUT= option stores the sample in the SAS data set named SampleSRS.

Figure 95.2 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 100 customers is selected from the data set Customers by simple random sampling. With simple random sampling and no stratification in the sample design, the selection probability is the same for all units in the sample. In this sample, the selection probability for each customer equals 0.007423, which is the sample size (100) divided by the population size (13,471). The sampling weight equals 134.71 for each customer in the sample, where the weight is the inverse of the selection probability. If you specify the STATS option, PROC SURVEYSELECT includes the selection probabilities and sampling weights in the output data set. (This information is always included in the output data set for more complex designs.)

The random number seed is 39647. PROC SURVEYSELECT uses this number as the initial seed for random number generation. Because the SEED= option is not specified in the PROC SURVEYSELECT statement, the seed value is obtained by using the time of day from the computer's clock. You can specify SEED=39647 to reproduce this sample.

Figure 95.2 Sample Selection Summary

Customer Satisfaction Survey Simple Random Sampling	
The SURVEYSELECT Procedure	
Selection Method	Simple Random Sampling
Input Data Set	CUSTOMERS
Random Number Seed	39647
Sample Size	100
Selection Probability	0.007423
Sampling Weight	134.71
Output Data Set	SAMPLESRS

The sample of 100 customers is stored in the SAS data set SampleSRS. PROC SURVEYSELECT does not display this output data set. The following PROC PRINT statements display the first 20 observations of SampleSRS:

```
title1 'Customer Satisfaction Survey';
title2 'Sample of 100 Customers, Selected by SRS';
title3 '(First 20 Observations)';
proc print data=SampleSRS (obs=20);
run;
```

Figure 95.3 displays the first 20 observations of the output data set SampleSRS, which contains the sample of customers. This data set includes all the variables from the DATA= input data set Customers. If you do not want to include all variables, you can use the ID statement to specify which variables to copy from the input data set to the output (sample) data set.

20	207-64-7308	GA	New	193

Stratified Sampling

In this section, stratification is added to the sample design for the customer satisfaction survey. The sampling frame, which is the list of all customers, is stratified by State and Type. This divides the sampling frame into nonoverlapping subgroups formed from the values of the State and Type variables. Samples are then selected independently within the strata.

PROC SURVEYSELECT requires that the input data set be sorted by the STRATA variables. The following PROC SORT statements sort the Customers data set by the stratification variables State and Type:

```
proc sort data=Customers;
  by State Type;
run;
```

The following PROC FREQ statements display the crosstabulation of the Customers data set by State and Type:

```
title1 'Customer Satisfaction Survey';
title2 'Strata of Customers';
proc freq data=Customers;
  tables State*Type;
run;
```

Figure 95.4 presents the table of State by Type for the 13,471 customers. There are four states and two levels of Type, forming a total of eight strata.

Figure 95.4 Stratification of Customers by State and Type

Customer Satisfaction Survey				
Strata of Customers				
The FREQ Procedure				
Table of State by Type				
State	Type			
Frequency				
Percent				
Row Pct				
Col Pct	New	Old		Total
AL	1238	706		1944
	9.19	5.24		14.43
	63.68	36.32		
	14.43	14.43		
FL	2170	1370		3540
	16.11	10.17		26.28
	61.30	38.70		
	25.29	28.01		
GA	3488	1940		5428
	25.89	14.40		40.29
	64.26	35.74		
	40.65	39.66		
SC	1684	875		2559
	12.50	6.50		19.00
	65.81	34.19		
	19.63	17.89		
Total	8580	4891		13471
	63.69	36.31		100.00

The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set according to the stratified sample design:

```

title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers method=srs n=15
                  seed=1953 out=SampleStrata;
    strata State Type;
run;

```

The STRATA statement names the stratification variables State and Type. In the PROC SURVEYSELECT statement, the METHOD=SRS option specifies simple random sampling. The N= option specifies a sample size of 15 customers for each stratum. If you want to specify different sample sizes for different strata, you can use the N=SAS-*data-set* option to name a secondary data set that contains the stratum sample sizes. The SEED= option specifies 1953 as the initial seed for random number generation.

Figure 95.5 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 120 customers are selected.

Figure 95.5 Sample Selection Summary

Customer Satisfaction Survey Stratified Sampling	
The SURVEYSELECT Procedure	
Selection Method	Simple Random Sampling
Strata Variables	State Type
Input Data Set	CUSTOMERS
Random Number Seed	1953
Stratum Sample Size	15
Number of Strata	8
Total Sample Size	120
Output Data Set	SAMPLESTRATA

The following PROC PRINT statements display the first 30 observations of the output data set SampleStrata:

```

title1 'Customer Satisfaction Survey';
title2 'Sample Selected by Stratified Design';
title3 '(First 30 Observations)';
proc print data=SampleStrata(obs=30);
run;

```

Figure 95.6 displays the first 30 observations of the output data set SampleStrata, which contains the sample of 120 customers, 15 customers from each of the eight strata. The variable SelectionProb contains the selection probability for each customer in the sample. Because customers are selected with equal probability within strata in this design, the selection probability equals the stratum sample size (15) divided by the stratum population size. The selection probabilities differ from stratum to stratum because the stratum population sizes differ. The selection probability for each customer in the first stratum (State='AL' and Type='New') is 0.012116, and the selection probability for customers in the second stratum is 0.021246. The variable SamplingWeight contains the sampling weights, which are computed as inverse selection probabilities.

Stratified Sampling with Control Sorting

The next sample design for the customer satisfaction survey uses stratification by State and also control sorting by Type and Usage within State. After stratification and control sorting, customers are selected by systematic random sampling within strata. Selection by systematic sampling, together with control sorting before selection, spreads the sample uniformly over the range of type and usage values within each stratum (state). The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set according to this design:

```
title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling with Control Sorting';
proc surveyselect data=Customers method=sys rate=.02
                  seed=1234 out=SampleControl;
    strata State;
    control Type Usage;
run;
```

The STRATA statement names the stratification variable State. The CONTROL statement names the control variables Type and Usage. In the PROC SURVEYSELECT statement, the METHOD=SYS option requests systematic random sampling. The RATE= option specifies a sampling rate of 2% for each stratum. The SEED= option specifies the initial seed for random number generation.

Figure 95.7 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 271 customers is selected by using systematic random sampling within strata determined by State. The sampling frame Customers is sorted by control variables Type and Usage within strata. The type of sorting is serpentine, which is the default when SORT=NEST is not specified. See the section “[Sorting by CONTROL Variables](#)” on page 8057 for a description of serpentine sorting. The sorted data set replaces the input data set. (To leave the input data set unsorted and store the sorted input data in another data set, use the OUTSORT= option.) The output data set SampleControl contains the sample of customers.

Figure 95.7 Sample Selection Summary

Syntax: SURVEYSELECT Procedure

The following statements are available in the SURVEYSELECT procedure:

```
PROC SURVEYSELECT options ;
  CONTROL variables ;
  FREQ variable ;
  ID variables ;
  SAMPLINGUNIT | CLUSTER variables </ options > ;
  SIZE variable ;
  STRATA variables </ options > ;
```

The **PROC SURVEYSELECT** statement invokes the SURVEYSELECT procedure. Optionally, it identifies input and output data sets. It also specifies the selection method, the sample size, and other sample design parameters. The PROC SURVEYSELECT statement is required.

The **SIZE** statement identifies the variable that contains the size measures of the sampling units. This statement is required for any probability proportional to size (PPS) selection method unless you specify the **PPS** option in the **SAMPLINGUNIT** statement.

The remaining statements are optional. The **STRATA** statement identifies a variable or set of variables that stratify the input data set. When you specify a STRATA statement, PROC SURVEYSELECT selects samples independently from the strata that are formed by the STRATA variables. The STRATA statement also provides options to allocate the total sample size among the strata.

The **SAMPLINGUNIT** statement identifies a variable or set of variables that group the input data set observations into sampling units (clusters). Sampling units are nested within strata. When you specify a SAMPLINGUNIT statement, PROC SURVEYSELECT selects clusters instead of individual observations.

The **CONTROL** statement identifies variables for ordering units within strata. It can be used for systematic and sequential sampling methods. The **ID** statement identifies variables to copy from the input data set to the output data set of selected units.

The **FREQ** statement identifies a variable that contains the frequency of occurrence for each observation. The FREQ statement is available only for sample allocation when no sample is selected, which you can request by specifying the **ALLOC=** and **NOSAMPLE** options in the **STRATA** statement.

The rest of this section gives detailed syntax information for the CONTROL, FREQ, ID, SAMPLINGUNIT, SIZE, and STRATA statements in alphabetical order after the description of the PROC SURVEYSELECT statement.

PROC SURVEYSELECT Statement

```
PROC SURVEYSELECT options ;
```

The PROC SURVEYSELECT statement invokes the SURVEYSELECT procedure. Optionally, it identifies input and output data sets. If you do not name a **DATA=** input data set, the procedure selects the sample from the most recently created SAS data set. If you do not name an **OUT=** output data set to contain the sample of selected units, the procedure still creates an output data set and names it according to the **DATA_n** convention.

The PROC SURVEYSELECT statement also specifies the sample selection method, the sample size, and other sample design parameters.

If you do not specify a selection method, PROC SURVEYSELECT uses simple random sampling (**METHOD=SRS**) by default unless you specify a **SIZE** statement or the **PPS** option in the **SAMPLINGUNIT** statement. If you do specify a **SIZE** statement (or the **PPS** option), PROC SURVEYSELECT uses probability proportional to size selection without replacement (**METHOD=PPS**) by default. See the description of the **METHOD=** option for more information.

You must specify the sample size or sampling rate except when you request Poisson sampling (**METHOD=POISSON**), request a method that selects two units from each stratum (**METHOD=PPS_BREWER** or **METHOD=PPS_MURTHY**), or specify the **MARGIN=** option in the **STRATA** statement for sample allocation. You can use the **SAMPSIZE=*n*** option to specify the sample size, or you can use the **SAMPSIZE=SAS-data-set** option to name a secondary input data set that contains stratum sample sizes.

You can also provide stratum sampling rates, minimum size measures, maximum size measures, and certainty size measures in the secondary input data set. See the descriptions of the **SAMPSIZE=**, **SAMPRATE=**, **MINSIZE=**, **MAXSIZE=**, **CERTSIZE=**, and **CERTSIZE=P=** options for more information. You can name only one secondary input data set in each invocation of the procedure. See the section “**Secondary Input Data Set**” on page 8071 for details.

Table 95.1 summarizes the *options* available in the PROC SURVEYSELECT statement. Descriptions of the *options* follow in alphabetical order.

Table 95.1 PROC SURVEYSELECT Statement Options

Option	Description
Input and Output Data Sets	
DATA=	Names the input SAS data set
OUT=	Names the output SAS data set that contains the sample
OUTSORT=	Names an output SAS data set that stores the sorted input data set
Selection Method	
METHOD=	Specifies the sample selection method
Sample Size	
SAMPSIZE=	Specifies the sample size
SELECTALL	Selects all stratum units when the sample size exceeds the total
Sampling Rate	
SAMPRATE=	Specifies the sampling rate
NMIN=	Specifies the minimum stratum sample size
NMAX=	Specifies the maximum stratum sample size
Replicated Sampling	
REPS=	Specifies the number of sample replicates
Size Measures	
MINSIZE=	Specifies the minimum size measure
MAXSIZE=	Specifies the maximum size measure
CERTSIZE=	Specifies the certainty size measure
CERTSIZE=P=	Specifies the certainty proportion

Table 95.1 *continued*

Option	Description
Control Sorting	
SORT=	Specifies the type of sorting
Random Number Generation	
SEED=	Specifies the initial seed
RANUNI	Requests the RANUNI random number generator
Displayed Output	
NOPRINT	Suppresses the display of all output
OUT= Data Set Contents	
JTPROBS	Includes joint probabilities of selection
OUTALL	Includes all observations from the DATA= input data set
OUTHITS	Includes a distinct copy of each selected unit
OUTSEED	Includes the initial seed for each stratum
OUTSIZE	Includes additional design and sampling frame information
STATS	Includes selection probabilities and sampling weights

You can specify the following *options* in the PROC SURVEYSELECT statement:

CERTSIZE

requests certainty selection, where the certainty size values are provided in the secondary input data set. Use the CERTSIZE option when you have already named the secondary data set in another option, such as the [SAMPSIZE=SAS-data-set](#) option. See the section “[Secondary Input Data Set](#)” on page 8071 for details.

The CERTSIZE option is available for [METHOD=PPS](#) and [METHOD=PPS_SAMPFORD](#). The CERTSIZE option is not available with the [SAMPLINGUNIT](#) statement.

In certainty selection, PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the stratum certainty size values. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the [METHOD=](#) option.

You provide the stratum certainty size values in the secondary input data set variable `_CERTSIZE_`. Each certainty size value must be a positive number. The variable `Certain` in the OUT= data set identifies the certainty selections, which have selection probabilities equal to 1.

If you want to specify a single certainty size value for all strata, you can use the [CERTSIZE=certain](#) option.

CERTSIZE=certain

specifies the certainty size value, which must be a positive number. PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the value *certain*. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the [METHOD=](#) option.

The CERTSIZE= option is available for [METHOD=PPS](#) and [METHOD=PPS_SAMPFORD](#). The CERTSIZE= option is not available with the [SAMPLINGUNIT](#) statement.

The variable `Certain` in the OUT= data set identifies the certainty selections, which have selection probabilities equal to 1.

If you request a stratified sample design with the **STRATA** statement and specify the **CERTSIZE=certain** option, PROC SURVEYSELECT uses the value *certain* for all strata. If you do not want to use the same certainty size for all strata, use the **CERTSIZE=SAS-data-set** option to specify a certainty size value for each stratum.

CERTSIZE=SAS-data-set

names a SAS data set that contains certainty size values for the strata. PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the stratum certainty size values. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

The **CERTSIZE=** option is available for **METHOD=PPS** and **METHOD=PPS_SAMPFORD**. The **CERTSIZE=** option is not available with the **SAMPLINGUNIT** statement.

You provide the stratum certainty size values in the **CERTSIZE=** data set variable **_CERTSIZE_**. Each certainty size value must be a positive number. The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

The **CERTSIZE=** input data set should contain all the **STRATA** variables, with the same type and length as in the **DATA=** data set. The **STRATA** groups should appear in the same order in the **CERTSIZE=** data set as in the **DATA=** data set. The **CERTSIZE=** data set must include a variable named **_CERTSIZE_** that contains the certainty size value for each stratum. The **CERTSIZE=** data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single certainty size value for all strata, you can use the **CERTSIZE=certain** option.

CERTSIZE=P

requests certainty proportion selection, where the stratum certainty proportions are provided in the secondary input data set. Use the **CERTSIZE=P** option when you have already named the secondary data set in another option, such as the **SAMPSIZE=SAS-data-set** option. See the section “[Secondary Input Data Set](#)” on page 8071 for details.

The **CERTSIZE=P** option is available for **METHOD=PPS** and **METHOD=PPS_SAMPFORD**. The **CERTSIZE=P** option is not available with the **SAMPLINGUNIT** statement.

In certainty proportion selection, PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the stratum certainty proportion of the total stratum size. The procedure repeats this process with the remaining units until no more certainty units are selected. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

You provide the stratum certainty proportions in the secondary input data set variable **_CERTP_**. Each certainty proportion must be a positive number. You can specify a proportion value as a number between 0 and 1. Or you can specify a proportion value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

If you want to specify a single certainty proportion for all strata, you can use the **CERTSIZE=P=p** option.

CERTSIZE=P= p

specifies the certainty proportion. PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the proportion p of the total stratum size. The procedure repeats this process with the remaining units until no more certainty units are selected. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

The CERTSIZE=P= option is available for **METHOD=PPS** and **METHOD=PPS_SAMPFORD**. The CERTSIZE=P= option is not available with the **SAMPLINGUNIT** statement.

The value of the certainty proportion p must be a positive number. You can specify p as a number between 0 and 1. Or you can specify p in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

If you request a stratified sample design with the **STRATA** statement and specify the CERTSIZE=P= p option, PROC SURVEYSELECT uses the certainty proportion p for all strata. If you do not want to use the same certainty proportion for all strata, use the **CERTSIZE=P=SAS-data-set** option to specify a certainty proportion for each stratum.

CERTSIZE=P=SAS-data-set

names a SAS data set that contains certainty proportions for the strata. PROC SURVEYSELECT automatically selects all sampling units with size measures greater than or equal to the certainty proportion of the total stratum size. The procedure repeats this process with the remaining units until no more certainty units are selected. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

The CERTSIZE=P= option is available for **METHOD=PPS** and **METHOD=PPS_SAMPFORD**. The CERTSIZE=P= option is not available with the **SAMPLINGUNIT** statement.

You provide the stratum certainty proportions in the CERTSIZE=P= data set variable **_CERTP_**. Each certainty proportion must be a positive number. You can specify a proportion value as a number between 0 and 1. Or you can specify a proportion value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

The CERTSIZE=P= input data set should contain all the **STRATA** variables, with the same type and length as in the **DATA=** data set. The **STRATA** groups should appear in the same order in the CERTSIZE=P= data set as in the **DATA=** data set. The CERTSIZE=P= data set must include a variable named **_CERTP_** that contains the certainty proportion for each stratum. The CERTSIZE=P= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single certainty proportion for all strata, you can use the **CERTSIZE=P= p** option.

DATA=SAS-data-set

names the SAS data set from which PROC SURVEYSELECT selects the sample. If you omit the DATA= option, the procedure uses the most recently created SAS data set. In sampling terminology, the input data set is the *sampling frame* (the list of units from which the sample is selected).

By default, the procedure uses input data set observations as sampling units and selects a sample of these units. Alternatively, you can use the **SAMPLINGUNIT** statement to define sampling units as groups of observations (clusters).

JTPROBS

includes joint probabilities of selection in the OUT= output data set. This option is available for the following probability proportional to size selection methods: **METHOD=PPS**, **METHOD=PPS_SAMPFORD**, and **METHOD=PPS_WR**. By default, PROC SURVEYSELECT outputs joint selection probabilities for **METHOD=PPS_BREWER** and **METHOD=PPS_MURTHY**, which select two units per stratum.

For details about computation of joint selection probabilities for a particular sampling method, see the method description in the section “[Sample Selection Methods](#)” on page 8058. For more information about the contents of the output data set, see the section “[Sample Output Data Set](#)” on page 8072.

MAXSIZE

requests adjustment of size measures according to the stratum maximum size values provided in the secondary input data set. Use the MAXSIZE option when you have already named the secondary input data set in another option, such as the **SAMPSIZE=SAS-data-set** option. See the section “[Secondary Input Data Set](#)” on page 8071 for details.

The MAXSIZE option is available when you use size measures for any PPS selection method and also include a **STRATA** statement. You provide size measures by specifying the **SIZE** statement or the **PPS** option in the **SAMPLINGUNIT** statement.

You provide the stratum maximum size values in the secondary input data set variable `_MAXSIZE_`. Each maximum size value must be a positive number.

When a size measure exceeds the specified maximum value for its stratum, PROC SURVEYSELECT adjusts the size measure downward to equal the maximum size value. If your sampling units are individual observations, the variable `AdjustedSize` in the OUT= data set contains the adjusted size measures.

If you use a **SAMPLINGUNIT** statement to define sampling units (clusters), then the procedure applies the MAXSIZE adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the **PPS** option, or the sum of the observation size measures if you specify a **SIZE** statement. The output data set variable `UnitSize` contains the adjusted sampling unit size measures.

If you want to specify a single maximum size value for all strata, you can use the **MAXSIZE=max** option.

MAXSIZE=max

specifies the maximum size value. The value of *max* must be a positive number.

When a size measure exceeds the value *max*, PROC SURVEYSELECT adjusts the size measure downward to equal *max*. If your sampling units are individual observations, the variable `AdjustedSize` in the OUT= data set contains the adjusted size measures.

If you use a [SAMPLINGUNIT](#) statement to define sampling units (clusters), then the procedure applies the MAXSIZE adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the [PPS](#) option, or the sum of the observation size measures if you specify a [SIZE](#) statement. The output data set variable UnitSize contains the adjusted sampling unit size measures.

The MAXSIZE=*max* option is available when you use size measures for any PPS selection method. You provide size measures by specifying the [SIZE](#) statement or the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

If you request a stratified sample design with the [STRATA](#) statement and specify the MAXSIZE=*max* option, PROC SURVEYSELECT uses the maximum size *max* for all strata. If you do not want to use the same maximum size for all strata, use the [MAXSIZE=SAS-data-set](#) option to specify a maximum size value for each stratum.

MAXSIZE=SAS-data-set

names a SAS data set that contains maximum size values for the strata. You provide the stratum maximum size values in the MAXSIZE= data set variable `_MAXSIZE_`. Each maximum size value must be a positive number.

The MAXSIZE=*SAS-data-set* option is available when you use size measures for any PPS selection method and also include a [STRATA](#) statement. You provide size measures by specifying the [SIZE](#) statement or the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

When a size measure exceeds the maximum size value for its stratum, PROC SURVEYSELECT adjusts the size measure downward to equal the maximum size value. If your sampling units are individual observations, the variable AdjustedSize in the OUT= data set contains the adjusted size measures.

If you use a [SAMPLINGUNIT](#) statement to define sampling units (clusters), then the procedure applies the MAXSIZE adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the [PPS](#) option, or the sum of the observation size measures if you specify a [SIZE](#) statement. The output data set variable UnitSize contains the adjusted sampling unit size measures.

The MAXSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the MAXSIZE= data set as in the DATA= data set. The MAXSIZE= data set must include a variable named `_MAXSIZE_` that contains the maximum size value for each stratum. The MAXSIZE= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single maximum size value for all strata, you can use the [MAXSIZE=max](#) option.

METHOD=name

M=name

specifies the method for sample selection.

If you do not specify the METHOD= option, PROC SURVEYSELECT uses simple random sampling ([METHOD=SRS](#)) by default unless you specify a [SIZE](#) statement or the [PPS](#) option in the [SAMPLINGUNIT](#) statement. If you do specify a [SIZE](#) statement (or the [PPS](#) option), PROC SURVEYSELECT uses probability proportional to size selection without replacement ([METHOD=PPS](#)) by default.

The following values are available for the METHOD= option:

BERNOULLI

requests Bernoulli sampling, which consists of N independent selection trials, each with constant inclusion probability π , where N is the total number of sampling units in the stratum or data set. The sample size is not fixed but is a random variable. See the section “[Bernoulli Sampling](#)” on page 8061 for details.

When you specify METHOD=BERNOULLI, you must provide the sampling rate (inclusion probability π) by using the [SAMPRATE=](#) option. For stratified sampling (which you request with the [STRATA](#) statement), you can specify the same sampling rate for each stratum with the [SAMPRATE=r](#) option. Or you can specify different sampling rates for different strata by using the [SAMPRATE=\(values\)](#) or [SAMPRATE=SAS-data-set](#) option.

Because Bernoulli sampling is based on a specified inclusion probability instead of a fixed sample size, METHOD=BERNOULLI does not use the [SAMPSIZE=](#) option. Also, the [ALLOC=](#) option in the [STRATA](#) statement (which allocates the total sample size among strata) is not available with METHOD=BERNOULLI.

POISSON

requests Poisson sampling. A generalization of Bernoulli sampling, Poisson sampling consists of N independent selection trials with a separate inclusion probability specified for each unit, where N is the total number of sampling units in the stratum or data set. The sample size is not fixed but is a random variable. See the section “[Poisson Sampling](#)” on page 8062 for details.

You must provide inclusion probabilities for Poisson sampling in the [SIZE](#) variable. The probability values should be between 0 and 1. If a value of the SIZE variable is missing, nonpositive, or greater than 1, PROC SURVEYSELECT omits the observation from sample selection.

Because Poisson sampling is based on specified inclusion probabilities instead of a fixed sample size, METHOD=POISSON does not use the [SAMPSIZE=](#) option. Also, the [ALLOC=](#) option in the [STRATA](#) statement (which allocates the total sample size among strata) is not available with METHOD=POISSON.

The [SAMPLINGUNIT](#) statement is not available with METHOD=POISSON.

When METHOD=POISSON is specified with the [SAMPRATE=](#) option and without a [SIZE](#) statement, PROC SURVEYSELECT uses [METHOD=BERNOULLI](#).

PPS

requests selection with probability proportional to size and without replacement. See the section “[PPS Sampling without Replacement](#)” on page 8062 for details. If you specify METHOD=PPS, you must name a size measure variable in the [SIZE](#) statement or specify the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

PPS_BREWER | BREWER

requests selection according to Brewer’s method. Brewer’s method selects two units from each stratum with probability proportional to size and without replacement. See the section “[Brewer’s PPS Method](#)” on page 8066 for details. If you specify METHOD=PPS_BREWER, you must name a size measure variable in the [SIZE](#) statement or specify the [PPS](#) option in the [SAMPLINGUNIT](#) statement. You do not need to specify the sample size with the [SAMPSIZE=](#) option because Brewer’s method selects two units from each stratum.

PPS_MURTHY | MURTHY

requests selection according to Murthy's method. Murthy's method selects two units from each stratum with probability proportional to size and without replacement. See the section "[Murthy's PPS Method](#)" on page 8066 for details. If you specify METHOD=PPS_MURTHY, you must name a size measure variable in the [SIZE](#) statement or specify the [PPS](#) option in the [SAMPLINGUNIT](#) statement. You do not need to specify the sample size with the [SAMPSIZE=](#) option because Murthy's method selects two units from each stratum.

PPS_SAMPFORD | SAMPFORD

requests selection according to Sampford's method. Sampford's method selects units with probability proportional to size and without replacement. See the section "[Sampford's PPS Method](#)" on page 8067 for details. If you specify METHOD=PPS_SAMPFORD, you must name a size measure variable in the [SIZE](#) statement or specify the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

PPS_SEQ | CHROMY

requests sequential selection with probability proportional to size and with minimum replacement. This method is also known as Chromy's method. See the section "[PPS Sequential Sampling](#)" on page 8064 for details. If you specify METHOD=PPS_SEQ, you must name a size measure variable in the [SIZE](#) statement or specify the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

PPS_SYS

requests systematic selection with probability proportional to size. See the section "[PPS Systematic Sampling](#)" on page 8064 for details. If you specify METHOD=PPS_SYS, you must name a size measure variable in the [SIZE](#) statement or specify the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

PPS_WR

requests selection with probability proportional to size and with replacement. See the section "[PPS Sampling with Replacement](#)" on page 8064 for details. If you specify METHOD=PPS_WR, you must name a size measure variable in the [SIZE](#) statement or specify the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

SEQ

requests sequential selection according to Chromy's method. If you specify METHOD=SEQ and do not specify a [SIZE](#) statement (or the [PPS](#) option in the [SAMPLINGUNIT](#) statement), PROC SURVEYSELECT uses sequential zoned selection with equal probability and without replacement. See the section "[Sequential Random Sampling](#)" on page 8060 for details.

If you specify METHOD=SEQ and also specify a [SIZE](#) statement (or the [PPS](#) option in the [SAMPLINGUNIT](#) statement), PROC SURVEYSELECT uses METHOD=PPS_SEQ, which is sequential selection with probability proportional to size and with minimum replacement. See the section "[PPS Sequential Sampling](#)" on page 8064 for more information.

SRS

requests simple random sampling, which is selection with equal probability and without replacement. See the section "[Simple Random Sampling](#)" on page 8059 for details. METHOD=SRS is the default if you do not specify the METHOD= option and also do not specify a [SIZE](#) statement (or the [PPS](#) option in the [SAMPLINGUNIT](#) statement).

SYS

requests systematic random sampling. If you specify **METHOD=SYS** and do not specify a **SIZE** statement (or the **PPS** option in the **SAMPLINGUNIT** statement), PROC SURVEYSELECT uses systematic selection with equal probability. See the section “[Systematic Random Sampling](#)” on page 8060 for more information.

If you specify **METHOD=SYS** and also specify a **SIZE** statement (or the **PPS** option in the **SAMPLINGUNIT** statement), PROC SURVEYSELECT uses **METHOD=PPS_SYS**, which is systematic selection with probability proportional to size. See the section “[PPS Systematic Sampling](#)” on page 8064 for details.

URS

requests unrestricted random sampling, which is selection with equal probability and with replacement. See the section “[Unrestricted Random Sampling](#)” on page 8059 for details.

MINSIZE

requests adjustment of size measures according to the stratum minimum size values provided in the secondary input data set. Use the **MINSIZE** option when you have already named the secondary input data set in another option, such as the **SAMPSIZE=SAS-data-set** option. See the section “[Secondary Input Data Set](#)” on page 8071 for details.

The **MINSIZE** option is available when you use size measures for any PPS selection method and also include a **STRATA** statement. You provide size measures by specifying the **SIZE** statement or the **PPS** option in the **SAMPLINGUNIT** statement.

You provide the stratum minimum size values in the secondary input data set variable **_MINSIZE_**. Each minimum size value must be a positive number.

When a size measure is less than the specified minimum value for its stratum, PROC SURVEYSELECT adjusts the size measure upward to equal the minimum size value. If your sampling units are individual observations, the variable **AdjustedSize** in the **OUT=** data set contains the adjusted size measures.

If you use a **SAMPLINGUNIT** statement to define sampling units (clusters), then the procedure applies the **MINSIZE** adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the **PPS** option, or the sum of the observation size measures if you specify a **SIZE** statement. The output data set variable **UnitSize** contains the adjusted sampling unit size measures.

If you want to specify a single minimum size value for all strata, you can use the **MINSIZE=min** option.

MINSIZE=min

specifies the minimum size value. The value of *min* must be a positive number.

When a size measure is less than the value *min*, PROC SURVEYSELECT adjusts the size measure upward to equal *min*. If your sampling units are individual observations, the variable **AdjustedSize** in the **OUT=** data set contains the adjusted size measures.

If you use a **SAMPLINGUNIT** statement to define sampling units (clusters), then the procedure applies the **MINSIZE** adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the **PPS** option, or the sum of the observation size

measures if you specify a [SIZE](#) statement. The output data set variable `UnitSize` contains the adjusted sampling unit size measures.

The `MINSIZE=min` option is available when you use size measures for any PPS selection method. You provide size measures by specifying the [SIZE](#) statement or the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

If you request a stratified sample design with the [STRATA](#) statement and specify the `MINSIZE=min` option, PROC SURVEYSELECT uses the minimum size *min* for all strata. If you do not want to use the same minimum size for all strata, use the `MINSIZE=SAS-data-set` option to specify a minimum size value for each stratum.

MINSIZE=*SAS-data-set*

names a SAS data set that contains minimum size values for the strata. You provide the stratum minimum size values in the `MINSIZE=` data set variable `_MINSIZE_`. Each minimum size value must be a positive number.

The `MINSIZE=SAS-data-set` option is available when you use size measures for any PPS selection method and also include a [STRATA](#) statement. You provide size measures by specifying the [SIZE](#) statement or the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

When a size measure is less than the minimum size value for its stratum, PROC SURVEYSELECT adjusts the size measure upward to equal the minimum size measure. If your sampling units are individual observations, the variable `AdjustedSize` in the `OUT=` data set contains the adjusted size measures.

If you use a [SAMPLINGUNIT](#) statement to define sampling units (clusters), then the procedure applies the `MINSIZE` adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the [PPS](#) option, or the sum of the observation size measures if you specify a [SIZE](#) statement. The output data set variable `UnitSize` contains the adjusted sampling unit size measures.

The `MINSIZE=` input data set should contain all the [STRATA](#) variables, with the same type and length as in the `DATA=` data set. The [STRATA](#) groups should appear in the same order in the `MINSIZE=` data set as in the `DATA=` data set. The `MINSIZE=` data set must include a variable named `_MINSIZE_` that contains the minimum size measure for each stratum. The `MINSIZE=` data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single minimum size value for all strata, you can use the `MINSIZE=min` option.

NMAX=*n*

specifies the maximum stratum sample size *n* for the [SAMPRATE=](#) option. When you specify the [SAMPRATE=](#) option, PROC SURVEYSELECT calculates the stratum sample size by multiplying the total number of units in the stratum by the specified sampling rate. If this sample size is greater than the value `NMAX=n`, then PROC SURVEYSELECT selects only *n* units.

The maximum sample size *n* must be a positive integer. The `NMAX=` option is available only with the [SAMPRATE=](#) option, which can be used with equal probability selection methods ([METHOD=SRS](#), [METHOD=URS](#), [METHOD=SYS](#), and [METHOD=SEQ](#)). The `NMAX=` option is not available with [METHOD=BERNOULLI](#), where the [SAMPRATE=](#) option specifies the constant inclusion probability.

NMIN=*n*

specifies the minimum stratum sample size *n* for the **SAMPRATE=** option. When you specify the **SAMPRATE=** option, PROC SURVEYSELECT calculates the stratum sample size by multiplying the total number of units in the stratum by the specified sampling rate. If this sample size is less than the value **NMIN=*n***, then PROC SURVEYSELECT selects *n* units.

The minimum sample size *n* must be a positive integer. The **NMIN=** option is available only with the **SAMPRATE=** option, which can be used with equal probability selection methods (**METHOD=SRS**, **METHOD=URS**, **METHOD=SYS**, and **METHOD=SEQ**). The **NMIN=** option is not available with **METHOD=BERNOULLI**, where the **SAMPRATE=** option specifies the constant inclusion probability.

NOPRINT

suppresses the display of all output. You can use the **NOPRINT** option when you want only to create an output data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, “Using the Output Delivery System.”

OUT=SAS-data-set

names the output data set that contains the sample. If you omit the **OUT=** option, the data set is named **DATA n** , where *n* is the smallest integer that makes the name unique.

The output data set contains the units that are selected for the sample, in addition to design information and selection statistics, depending on the selection method and output options that you request. See descriptions of the options **JTPROBS**, **OUTALL**, **OUTHITS**, **OUTSEED**, **OUTSIZE**, and **STATS**, which specify information to include in the output data set. See the section “Sample Output Data Set” on page 8072 for details about the contents of the output data set.

By default, the output data set contains only those units that are selected for the sample. To include all observations from the input data set in the output data set, use the **OUTALL** option.

By default, the output data set includes one copy of each selected unit, even when a unit is selected more than once, which can occur when you use with-replacement or with-minimum-replacement selection methods. For with-replacement or with-minimum-replacement selection methods, the output data set includes a variable **NumberHits** that records the number of hits (selections) for each unit. To include a distinct copy of each selection in the output data set when the same unit is selected more than once, use the **OUTHITS** option.

If you specify the **NOSAMPLE** option in the **STRATA** statement, PROC SURVEYFREQ allocates the total sample size among the strata but does not select the sample. In this case, the **OUT=** data set contains the allocated sample sizes. See the section “Allocation Output Data Set” on page 8075 for details.

OUTALL

includes all observations from the **DATA=** input data set in the **OUT=** output data set. By default, the output data set includes only those units selected for the sample. When you specify the **OUTALL** option, the output data set includes all observations from the input data set and also contains a variable that indicates each observation’s selection status. The variable **Selected** equals 1 for an observation that is selected for the sample, and equals 0 for an observation that is not selected. For information about the contents of the output data set, see the section “Sample Output Data Set” on page 8072.

The **OUTALL** option is available for equal probability selection methods (**METHOD=SRS**, **METHOD=URS**, **METHOD=SYS**, **METHOD=SEQ**, and **METHOD=BERNOULLI**). The **OUTALL** option is also available for **METHOD=POISSON**.

OUTHITS

includes a distinct copy of each selected unit in the **OUT=** output data set when the same sampling unit is selected more than once. By default, the output data set contains a single copy of each unit selected, even when a unit is selected more than once, and the variable `NumberHits` records the number of hits (selections) for each unit. If you specify the **OUTHITS** option, the output data set contains m copies of a sampling unit for which `NumberHits` equals m . For example, with the **OUTHITS** option a unit that is selected three times is represented by three copies in the output data set.

A sampling unit can be selected more than once by with-replacement and with-minimum-replacement selection methods, which include **METHOD=URS**, **METHOD=PPS_WR**, **METHOD=PPS_SYS**, and **METHOD=PPS_SEQ**. The **OUTHITS** option is available for these selection methods.

See the section “[Sample Output Data Set](#)” on page 8072 for details about the contents of the output data set.

OUTSEED

includes the initial seed for each stratum in the **OUT=** output data set. The variable `InitialSeed` contains the stratum initial seeds. See the section “[Sample Output Data Set](#)” on page 8072 for details about the contents of the output data set.

To reproduce the same sample for any stratum in a subsequent execution of PROC SURVEYSELECT, you can specify the same stratum initial seed with the **SEED=SAS-data-set** option, along with the same sample selection parameters. See the section “[Random Number Generation](#)” on page 8058 for more information.

The “Sample Selection Summary” table displays the initial random number seed for the entire sample selection, which is the same as the initial seed for the first stratum when the design is stratified. To reproduce the entire sample, you can specify this same seed value in the **SEED=** option, along with the same sample selection parameters.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. In previous releases, PROC SURVEYSELECT used the RANUNI random number generator, which you can now request by specifying the **RANUNI** option. To reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1, specify the **RANUNI** option with the **SEED=** option (for the same input data set and sample selection parameters).

OUTSIZE

includes additional design and sampling frame information in the **OUT=** output data set.

If you use a **STRATA** statement, the **OUTSIZE** option provides stratum-level values in the output data set. Otherwise, the **OUTSIZE** option provides overall values.

The **OUTSIZE** option includes the sample size or sampling rate in the output data set, depending on whether you specify the **SAMPSIZE=** option or the **SAMPRATE=** option, respectively. For PPS selection methods, the **OUTSIZE** option includes the total size measure in the output data set. If you do not provide size measures, or if you specify a **SAMPLINGUNIT** statement, the **OUTSIZE** option includes the total number of sampling units.

If you request size measure adjustment or certainty selection, the **OUTSIZE** option includes the following information in the output data set: the minimum size measure if you specify the **MINSIZE=** option, the maximum size measure if you specify the **MAXSIZE=** option, the certainty size measure if you specify the **CERTSIZE=** option, and the certainty proportion if you specify the **CERTSIZE=P=** option.

For **METHOD=BERNOULLI**, the OUTSIZE option includes the following information in the output data set: total number of sampling units, selection probability (sampling rate), expected sample size, and actual sample size. See the section “[Bernoulli Sampling](#)” on page 8061 for descriptions of these statistics.

For more information about the contents of the output data set, see the section “[Sample Output Data Set](#)” on page 8072.

OUTSORT=SAS-data-set

names an output data set to store the sorted input data set. This option is available when you specify a **CONTROL** statement to sort the **DATA=** input data set for systematic or sequential selection methods (**METHOD=SYS**, **METHOD=PPS_SYS**, **METHOD=SEQ**, and **METHOD=PPS_SEQ**).

If you specify **CONTROL** variables but do not name an output data set with the **OUTSORT=** option, then the sorted data set replaces the input data set.

RANUNI

requests uniform random number generation by the method of Fishman and Moore (1982), which PROC SURVEYSELECT used in releases prior to SAS/STAT 12.1. This is the same random number generator that the RANUNI function provides.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. Developed by Matsumoto and Nishimura (1998), the Mersenne-Twister random number generator has a very long period and good statistical properties. This is the random number generator that the RAND function provides for the uniform distribution.

See the section “[Random Number Generation](#)” on page 8058 for details, and see *SAS Functions and CALL Routines: Reference* for information about the RANUNI and RAND functions.

You can specify the RANUNI option with the **SEED=** option to reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1. To reproduce a sample by using the RANUNI and **SEED=** options, you must also specify the same input data set and sample selection parameters.

REPS=nreps

specifies the number of sample replicates. The value of *nreps* must be a positive integer.

When you specify the **REPS=** option, PROC SURVEYSELECT selects *nreps* independent samples, each with the same sample size or sampling rate and the same sample design that you request. The variable Replicate in the **OUT=** data set contains the sample replicate number.

You can use replicated sampling to provide a simple method of variance estimation for any form of statistic, and also to evaluate variable nonsampling errors such as interviewer differences. For information about replicated sampling, see Lohr (2010); Wolter (2007); Kish (1965, 1987); Kalton (1983). You can also use the **REPS=** option to perform a variety of other resampling and simulation tasks. See Cassell (2007) for more information.

SAMPRATE=r

RATE=r

specifies the sampling rate, which is the proportion of units to select for the sample. The sampling rate *r* must be a positive number. You can specify *r* as a number between 0 and 1. Or you can specify

r in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The SAMPRATE= option is available only for equal probability selection methods ([METHOD=SRS](#), [METHOD=URS](#), [METHOD=SYS](#), [METHOD=SEQ](#), and [METHOD=BERNOULLI](#)). For systematic random sampling (METHOD=SYS), PROC SURVEYSELECT uses the inverse of the sampling rate r as the selection interval. See the section “[Systematic Random Sampling](#)” on page 8060 for details. For Bernoulli sampling (METHOD=BERNOULLI), PROC SURVEYSELECT uses the sampling rate r as the inclusion probability. See the section “[Bernoulli Sampling](#)” on page 8061 for details. For the other equal probability selection methods, PROC SURVEYSELECT converts the sampling rate r to the sample size before selection by multiplying the total number of units in the stratum or frame by the sampling rate and rounding up to the nearest integer.

If you request a stratified sample design with the [STRATA](#) statement and specify the SAMPRATE= r option, PROC SURVEYSELECT uses the sampling rate r for each stratum. If you do not want to use the same sampling rate for each stratum, use the [SAMPRATE=\(values\)](#) option or the [SAMPRATE=SAS-data-set](#) option to specify a sampling rate for each stratum.

SAMPRATE=(values)

RATE=(values)

specifies stratum sampling rates, where the stratum sampling rate is the proportion of units to select from the stratum. You can separate *values* with blanks or commas. The number of SAMPRATE= values must equal the number of strata in the input data set.

List the stratum sampling rate values in the order in which the strata appear in the input data set. When you use the SAMPRATE=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

Each stratum sampling rate value must be a nonnegative. You can specify a rate value as a number between 0 and 1. Or you can specify a rate value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

To select a sample from a stratum, the value of the stratum sampling rate must be positive. If you specify a stratum sampling rate of 0, then PROC SURVEYSELECT does not select a sample from the stratum. This has the effect of subsetting the input data set before sample selection; the stratum that you omit is not included in the sampling frame or represented in the sample.

The SAMPRATE= option is available only for equal probability selection methods ([METHOD=SRS](#), [METHOD=URS](#), [METHOD=SYS](#), [METHOD=SEQ](#), and [METHOD=BERNOULLI](#)). For systematic random sampling (METHOD=SYS), PROC SURVEYSELECT uses the inverse of the stratum sampling rate as the stratum selection interval. See the section “[Systematic Random Sampling](#)” on page 8060 for details. For Bernoulli sampling (METHOD=BERNOULLI), PROC SURVEYSELECT uses the stratum sampling rate as the inclusion probability for the stratum. See the section “[Bernoulli Sampling](#)” on page 8061 for details. For the other equal probability selection methods, PROC SURVEYSELECT converts the stratum sampling rate to the stratum sample size before selection by multiplying the total number of units in the stratum by the sampling rate and rounding up to the nearest integer.

SAMPRATE=SAS-data-set

RATE=SAS-data-set

names a SAS data set that contains stratum sampling rates, where the stratum sampling rate is the proportion of units to select from the stratum. The SAMPRATE= data set should include a variable `_RATE_` that contains the stratum sampling rates.

Each sampling rate value must be a nonnegative number. You can specify a rate value as a number between 0 and 1. Or you can specify a rate value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

To select a sample from a stratum, the value of the stratum sampling rate must be positive. If you specify a stratum sampling rate of 0, then PROC SURVEYSELECT does not select a sample from the stratum. This has the effect of subsetting the input data set before sample selection; the stratum that you omit is not included in the sampling frame or represented in the sample.

The SAMPRATE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPRATE= data set as in the DATA= data set.

The SAMPRATE= option is available only for equal probability selection methods ([METHOD=SRS](#), [METHOD=URS](#), [METHOD=SYS](#), [METHOD=SEQ](#), and [METHOD=BERNOULLI](#)). For systematic random sampling ([METHOD=SYS](#)), PROC SURVEYSELECT uses the inverse of the stratum sampling rate as the stratum selection interval. See the section “[Systematic Random Sampling](#)” on page 8060 for details. For Bernoulli sampling ([METHOD=BERNOULLI](#)), PROC SURVEYSELECT uses the stratum sampling rate as the inclusion probability for the stratum. See the section “[Bernoulli Sampling](#)” on page 8061 for details. For the other equal probability selection methods, PROC SURVEYSELECT converts the stratum sampling rate to the stratum sample size before selection by multiplying the total number of units in the stratum by the sampling rate and rounding up to the nearest integer.

SAMPsize=*n*

N=*n*

specifies the sample size, which is the number of units to select for the sample. The sample size *n* must be a positive integer. For selection methods that select without replacement, the sample size *n* must not exceed the number of units in the input data set.

If you do not specify a [SAMPLINGUNIT](#) statement, then your sampling units are observations, and PROC SURVEYSELECT selects *n* observations. If you use a SAMPLINGUNIT statement to define sampling units as groups of observations (clusters), then the procedure selects *n* clusters.

If you specify the SAMPsize=*n* option and request stratified selection with the [STRATA](#) statement, PROC SURVEYSELECT selects *n* units from each stratum unless you also specify the [ALLOC=](#) option in the [STRATA](#) statement to allocate the total sample size among the strata.

If you specify the [ALLOC=](#) option in the [STRATA](#) statement and the SAMPsize=*n* option, PROC SURVEYSELECT allocates the total sample size *n* among the strata according to the allocation method that you request. See the section “[Sample Size Allocation](#)” on page 8067 for details. If you specify the [MARGIN=](#) option with the [ALLOC=](#) option in the [STRATA](#) statement, PROC SURVEYSELECT determines the stratum sample sizes that provide the requested margin of error for the allocation. Therefore, you cannot use the SAMPsize= option with the [MARGIN=](#) option.

For methods that select without replacement, the sample size n must not exceed the number of units in any stratum. If you do not want to select the same number of units from each stratum, use the **SAMPsize=(values)** option or the **SAMPsize=SAS-data-set** option to specify a sample size for each stratum.

For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units available in the stratum. If you specify the **SELECTALL** option, PROC SURVEYSELECT selects all stratum units when the stratum sample size exceeds the number of units in the stratum.

SAMPsize=(values)

N=(values)

specifies stratum sample sizes, where the stratum sample size is the number of units to select from the stratum. You can separate *values* with blanks or commas. The number of SAMPsize= values must equal the number of strata in the input data set.

List the stratum sample size values in the order in which the strata appear in the input data set. When you use the SAMPsize=(values) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

Each stratum sample size value must be a nonnegative integer. To select a sample from a stratum, the value of the stratum sample size must be positive. If you specify a stratum sample size of 0, then PROC SURVEYSELECT does not select a sample from the stratum. This has the effect of subsetting the input data set before sample selection; the stratum that you omit is not included in the sampling frame or represented in the sample.

For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units available in the stratum. If you specify the **SELECTALL** option, PROC SURVEYSELECT selects all stratum units when the stratum sample size exceeds the number of units in the stratum.

SAMPsize=SAS-data-set

N=SAS-data-set

names a SAS data set that contains stratum sample sizes, where the stratum sample size is the number of units to select from the stratum. The SAMPsize= input data set should include a variable named `_NSIZE_` or `SampleSize` that contains the stratum sample sizes.

Each stratum sample size value must be a nonnegative integer. To select a sample from a stratum, the value of the stratum sample size must be positive. If you specify a stratum sample size of 0, then PROC SURVEYSELECT does not select a sample from the stratum. This has the effect of subsetting the input data set before sample selection; the stratum that you omit is not included in the sampling frame or represented in the sample.

The SAMPsize= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPsize= data set as in the DATA= data set. The SAMPsize= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units available in the stratum. If you specify the **SELECTALL** option, PROC SURVEYSELECT selects all stratum units when the stratum sample size exceeds the number of units in the stratum.

SEED

indicates that stratum-level initial seeds are included in the secondary input data set. Use the SEED option when you have already named the secondary input data set in another option, such as the [SAMPsize=SAS-data-set](#) option. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

You provide the stratum initial seeds in the secondary input data set variable named `_SEED_` or `InitialSeed`. The initial seeds must be positive integers.

See the description of the [SEED=SAS-data-set](#) option for more information about initial seeds for random number generation.

SEED=number

specifies the initial seed for random number generation. The SEED= value must be a positive integer. If you do not specify the SEED= option, or if the SEED= value is negative or 0, PROC SURVEYSELECT uses the time of day from the computer’s clock to obtain the initial seed. See the section “[Random Number Generation](#)” on page 8058 for more information.

If you request a stratified sample design with the [STRATA](#) statement, you can use the [SEED=SAS-data-set](#) option to specify an initial seed for each stratum. Otherwise, PROC SURVEYSELECT generates random numbers continuously across strata from the random number stream initialized by the SEED= value.

You can use the [OUTSEED](#) option to include the stratum initial seeds in the output data set.

Whether or not you specify the SEED= option, PROC SURVEYSELECT displays the value of the initial seed in the “Sample Selection Summary” table. If you need to reproduce the same sample in a subsequent execution of PROC SURVEYSELECT, you can specify this same seed value in the SEED= option, along with the same sample selection parameters, and PROC SURVEYSELECT will reproduce the sample.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. In previous releases, PROC SURVEYSELECT used the RANUNI random number generator, which you can now request by specifying the [RANUNI](#) option. To reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1, use the [RANUNI](#) option with the SEED= option (for the same input data set and sample selection parameters).

SEED=SAS-data-set

names a SAS data set that contains initial seeds for the strata. You provide the stratum seeds in the SEED= input data set variable `_SEED_` or `InitialSeed`.

The initial seed values must be positive integers. If the initial seed value for the first stratum is not a positive integer, PROC SURVEYSELECT uses the time of day from the computer’s clock to obtain the initial seed. If the initial seed value for a subsequent stratum is not a positive integer, PROC SURVEYSELECT continues to use the random number stream already initialized by the seed for the previous stratum. See the section “[Sample Selection Methods](#)” on page 8058 for more information.

The SEED= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SEED= data set as in the DATA= data set. The SEED= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

You can use the [OUTSEED](#) option to include the stratum initial seeds in the output data set.

Whether or not you specify the `SEED=` option, PROC SURVEYSELECT displays the value of the initial seed in the “Sample Selection Summary” table. If you need to reproduce the same sample in a subsequent execution of PROC SURVEYSELECT, you can specify this same seed value in the `SEED=` option, along with the same sample selection parameters, and PROC SURVEYSELECT will reproduce the sample.

If you specify initial seeds by strata with the `SEED=SAS-data-set` option, you can reproduce the same sample in a subsequent execution of PROC SURVEYSELECT by specifying these same stratum initial seeds, along with the same sample selection parameters. If you need to reproduce the same sample for only a subset of the strata, you can use the same initial seeds for those strata in the subset.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. In previous releases, PROC SURVEYSELECT used the RANUNI random number generator, which you can now request by specifying the `RANUNI` option. To reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1, use the `RANUNI` option with the `SEED=` option (for the same input data set and sample selection parameters).

SELECTALL

requests that PROC SURVEYSELECT select all stratum units when the stratum sample size exceeds the total number of units in the stratum. By default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum, unless you are using a with-replacement selection method.

The `SELECTALL` option is available for the following without-replacement selection methods: `METHOD=SRS`, `METHOD=SYS`, `METHOD=SEQ`, `METHOD=PPS`, and `METHOD=PPS_SAMPFORD`.

The `SELECTALL` option is not available for with-replacement selection methods, with-minimum-replacement methods, or those PPS methods that select two units per stratum.

SORT=NEST | SERP

specifies the type of sorting by `CONTROL` variables. The option `SORT=NEST` requests nested sorting, and `SORT=SERP` requests hierarchic serpentine sorting. The default is `SORT=SERP`. See the section “[Sorting by CONTROL Variables](#)” on page 8057 for descriptions of serpentine and nested sorting. Where there is only one `CONTROL` variable, the two types of sorting are equivalent.

The `SORT=` option is available when you specify a `CONTROL` statement for systematic or sequential selection methods (`METHOD=SYS`, `METHOD=PPS_SYS`, `METHOD=SEQ`, and `METHOD=PPS_SEQ`). When you specify a `CONTROL` statement, PROC SURVEYSELECT sorts the input data set by the `CONTROL` variables within strata before selecting the sample.

The `SORT=` option and the `CONTROL` statement are not available with a `SAMPLINGUNIT` statement. See the descriptions of the `CONTROL` and `SAMPLINGUNIT` statements for more information.

When you specify a `CONTROL` statement, you can also use the `OUTSORT=` option to name an output data set that contains the sorted input data set. Otherwise, if you do not specify the `OUTSORT=` option, the sorted data set replaces the input data set.

STATS

includes the selection probability and sampling weight in the `OUT=` output data set for equal probability selection methods when you do not specify a `STRATA` statement. By default, the output data set does not include these values for equal probability selection methods unless you specify a `STRATA` statement. The `STATS` option applies to the following selection methods: `METHOD=SRS`, `METHOD=URS`, `METHOD=SYS`, `METHOD=SEQ`, and `METHOD=BERNOULLI`.

In addition to the selection probability and sampling weight, the STATS option includes the following statistics in the output data set for **METHOD=BERNOULLI**: total number of sampling units, expected sample size, actual sample size, and adjusted sampling weight. See the section “[Bernoulli Sampling](#)” on page 8061 for more information.

For PPS selection methods, the output data set contains selection probabilities and sampling weights by default. The STATS option has no effect for PPS methods.

For more information about the contents of the output data set, see the section “[Sample Output Data Set](#)” on page 8072.

CONTROL Statement

CONTROL *variables* ;

The CONTROL statement names variables for sorting the input data set before sample selection. The CONTROL variables can be character or numeric. If you also specify a **STRATA** statement, PROC SURVEYSELECT sorts by CONTROL variables within strata.

Control sorting is available for systematic and sequential selection methods (**METHOD=SYS**, **METHOD=PPS_SYS**, **METHOD=SEQ**, and **METHOD=PPS_SEQ**). Ordering the sampling units before systematic or sequential selection can provide additional control over the distribution of the sample.

Control sorting is not available when you use a **SAMPLINGUNIT** statement, which defines groups of observations as units (clusters) for sample selection. See the description of the **SAMPLINGUNIT** statement for information about ordering clusters before systematic or sequential selection.

By default (or if you specify the **SORT=SERP** option in the **PROC SURVEYSELECT** statement), PROC SURVEYSELECT uses hierarchic serpentine sorting by the CONTROL variables. If you specify the **SORT=NEST** option, the procedure uses nested sorting. For more information about serpentine and nested sorting, see the section “[Sorting by CONTROL Variables](#)” on page 8057.

You can use the **OUTSORT=** option in the **PROC SURVEYSELECT** statement to name an output data set that contains the sorted input data set. If you do not specify the **OUTSORT=** option when you use the CONTROL statement, then the sorted data set replaces the input data set.

FREQ Statement

FREQ *variable* ;

The FREQ statement names a numeric variable that contains the frequency of occurrence of each observation. If you use a FREQ statement, PROC SURVEYSELECT assumes that an observation represents n observations, where n is the value of the FREQ variable for the observation. The FREQ statement is not available when you specify a **SAMPLINGUNIT** statement.

The FREQ statement is available only for sample allocation when no sample is selected, which you can request by specifying the **ALLOC=** and **NOSAMPLE** options in the **STRATA** statement. The **ALLOC=** option requests allocation of the total sample size among the strata, and the **NOSAMPLE** option requests that no sample be selected after allocation. When you specify the **NOSAMPLE** option, the procedure computes stratum sample sizes according to the allocation method that you request, but does not select the

sample. See the sections “[Allocation Options](#)” on page 8052 and “[Sample Size Allocation](#)” on page 8067 for details.

The sum of the FREQ variable values (frequencies) represents the total number of sampling units. The sum of the frequencies in a stratum represents the total number of sampling units in the stratum. When you use a FREQ statement, the sample size allocation is based on the expanded total and stratum frequencies.

Values of the FREQ variable must be nonmissing and nonnegative. If a value of the FREQ variable is 0, PROC SURVEYSELECT ignores the observation. If a value of the FREQ variable is not an integer, PROC SURVEYSELECT uses only the integer portion as the frequency of the observation.

ID Statement

ID *variables* ;

The ID statement names one or more variables from the **DATA=** input data set to include in the **OUT=** output data set of selected units. If there is no ID statement, PROC SURVEYSELECT includes all variables from the input data set in the output data set. The ID variables can be either character or numeric.

SAMPLINGUNIT | CLUSTER Statement

SAMPLINGUNIT | CLUSTER *variables* *</ options>* ;

The SAMPLINGUNIT statement names variables that identify the sampling units as groups of observations (clusters). The combinations of categories of SAMPLINGUNIT variables define the sampling units. If there is a **STRATA** statement, sampling units are nested within strata.

When you use a SAMPLINGUNIT statement to define units (clusters), PROC SURVEYSELECT selects a sample of these units by using the selection method and design parameters that you specify in the **PROC SURVEYSELECT** statement. If you do not use a SAMPLINGUNIT statement, then PROC SURVEYSELECT uses the input data set observations as sampling units by default.

The SAMPLINGUNIT variables are one or more variables in the **DATA=** input data set. These variables can be either character or numeric. The formatted values of the SAMPLINGUNIT variables determine the SAMPLINGUNIT variable levels. Thus, you can use formats to group values into levels. See the **FORMAT** procedure in the *Base SAS Procedures Guide* and the **FORMAT** statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

You can use a SAMPLINGUNIT statement with any equal probability selection method or PPS selection method. The SAMPLINGUNIT statement is not available for Poisson sampling (**METHOD=POISSON**).

If you specify the **PPS** option in the SAMPLINGUNIT statement and do not specify a **SIZE** statement, then the procedure computes sampling unit size as the number of observations in the sampling unit. If you specify a **SIZE** statement with a SAMPLINGUNIT statement, then the procedure computes sampling unit size by summing the size measures of all observations in the sampling unit.

By default, PROC SURVEYSELECT sorts the input data set by the SAMPLINGUNIT variables within strata before sample selection. This groups the observations into sampling units and orders the sampling units by the SAMPLINGUNIT variables. If you do not want the procedure to sort the input data set by the SAMPLINGUNIT variables, then specify the **PRESORTED** option in the SAMPLINGUNIT statement. By

using the PRESORTED option, you can provide the order of the sampling units for systematic and sequential selection methods. The **CONTROL** statement is not available with the SAMPLINGUNIT statement.

Note that the SAMPLINGUNIT statement defines groups of observations (clusters) to use as sampling units, and PROC SURVEYSELECT selects a sample of these units. When you use a SAMPLINGUNIT statement, PROC SURVEYSELECT does not select samples of observations from within the sampling units (clusters). To select independent samples within groups, use the **STRATA** statement.

You can specify the following *options* in the SAMPLINGUNIT statement after a slash (/):

PPS

computes a sampling unit's size measure as the number of observations in the sampling unit. The procedure then uses these size measures to select a sample according to the PPS selection method that you specify with the **METHOD=** option in the PROC SURVEYSELECT statement.

This option has no effect when you specify a **SIZE** statement. When you specify a **SIZE** statement, the procedure computes sampling unit size by summing the size measures of all observations that belong to the sampling unit.

PRESORTED

requests that PROC SURVEYSELECT not sort the input data set by the SAMPLINGUNIT variables within strata. By default, the procedure sorts the input data set by the SAMPLINGUNIT variables, which groups the observations into sampling units and orders the units by the SAMPLINGUNIT variables.

The PRESORTED option enables you to provide the order of the sampling units. For systematic and sequential selection methods, ordering provides additional control over the distribution of the sample and gives some benefits of proportionate stratification. Systematic and sequential methods include **METHOD=SYS**, **METHOD=PPS_SYS**, **METHOD=SEQ**, and **METHOD=PPS_SEQ**. See the descriptions of these methods in the section “[Sample Selection Methods](#)” on page 8058 for more information.

When you specify the PRESORTED option, the procedure treats the sampling unit groups as NOTSORTED. Like the BY statement option NOTSORTED, this does not mean that the data are unsorted by the SAMPLINGUNIT variables, but rather that the data are arranged in groups (according to values of the SAMPLINGUNIT variables) and that these groups are not necessarily in alphabetical or increasing numeric order. For more information about the BY statement NOTSORTED option, see *SAS Language Reference: Concepts*.

SIZE Statement

SIZE *variable* ;

The **SIZE** statement names one and only one variable that contains size measures that are used for PPS selection. The **SIZE** variable must be numeric.

If you specify a **SAMPLINGUNIT** statement with a **SIZE** statement, the procedure computes a sampling unit's size by summing the size measures of all observations that belong to the sampling unit. Alternatively, if you specify the **PPS** option in the SAMPLINGUNIT statement and do not use a **SIZE** statement, the procedure computes sampling unit size as the number of observations in the sampling unit.

When the value of a sampling unit's size measure is missing or nonpositive, that sampling unit is excluded from the sample selection. See the section “[Missing Values](#)” on page 8056 for more information.

You can adjust the size measure values by using the [MAXSIZE=](#) option, the [MINSIZE=](#) option, or both of these options in the [PROC SURVEYSELECT](#) statement.

All PPS selection methods require size measures, which you can provide by specifying a [SIZE](#) statement (or by specifying the [PPS](#) option in the [SAMPLINGUNIT](#) statement). PPS selection methods include the following: [METHOD=PPS](#), [METHOD=PPS_BREWER](#), [METHOD=PPS_MURTHY](#), [METHOD=PPS_SAMPFORD](#), [METHOD=PPS_SEQ](#), [METHOD=PPS_SYS](#), and [METHOD=PPS_WR](#). For details about how size measures are used in sample selection, see the descriptions of PPS selection methods in the section “[Sample Selection Methods](#)” on page 8058.

Note that a sampling unit's size measure, which you provide for PPS selection by specifying a [SIZE](#) statement, is not the same as the *sample size*. The sample size is the number of units to select for the sample; you specify the sample size with the [SAMPSIZE=](#) option in the [PROC SURVEYSELECT](#) statement.

For [METHOD=POISSON](#), the variable that is specified in the [SIZE](#) statement provides inclusion probabilities for Poisson sampling. See the section “[Poisson Sampling](#)” on page 8062 for details. When the value of the [SIZE](#) variable is missing, nonpositive, or greater than 1, the sampling unit is not included in the sample selection.

STRATA Statement

STRATA *variables* </ options> ;

The STRATA statement names variables that partition the input data set into nonoverlapping subgroups (strata). The combinations of levels of STRATA variables define the strata. [PROC SURVEYSELECT](#) then selects independent samples from these strata, according to the selection method and design parameters that you specify in the [PROC SURVEYSELECT](#) statement. For information about the use of stratification in sample design, see Lohr (2010); Kalton (1983); Kish (1965, 1987); Cochran (1977).

The STRATA variables are one or more variables in the [DATA=](#) input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the STRATA variables determine the STRATA variable levels. Thus, you can use formats to group values into levels. See the [FORMAT](#) procedure in the *Base SAS Procedures Guide* and the [FORMAT](#) statement and SAS formats in *SAS Formats and Informats: Reference*.

The STRATA variables function much like BY variables, and [PROC SURVEYSELECT](#) expects the input data set to be sorted in order of the STRATA variables.

If you specify a [CONTROL](#) statement, or if you specify [METHOD=PPS](#), the input data set must be sorted in ascending order by the STRATA variables. This means you cannot use the STRATA option [NOTSORTED](#) or [DESCENDING](#) when you specify a [CONTROL](#) statement or [METHOD=PPS](#).

If your input data set is not sorted by the STRATA variables in ascending order, use one of the following alternatives:

- Sort the data by using the [SORT](#) procedure with the STRATA variables in a [BY](#) statement.
- Specify the [NOTSORTED](#) or [DESCENDING](#) option in the STRATA statement (when you do not specify a [CONTROL](#) statement or [METHOD=PPS](#)). The [NOTSORTED](#) option does not mean that the

data are unsorted but rather that the data are arranged in groups (according to values of the STRATA variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the STRATA variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

Allocation Options

The STRATA options request allocation of the total sample size among the strata. You can use the **ALLOC=** option to specify the allocation method. Available allocation methods include proportional allocation (**ALLOC=PROP**), optimal allocation (**ALLOC=OPTIMAL**), and Neyman allocation (**ALLOC=NEYMAN**). See the section “[Sample Size Allocation](#)” on page 8067 for details about these methods.

Instead of requesting that PROC SURVEYSELECT compute the sample allocation, you can provide the allocation proportions by using the **ALLOC=(values)** option or the **ALLOC=SAS-data-set** option. Then PROC SURVEYSELECT allocates the total sample size among the strata according to the proportions that you provide. Allocation proportions are relative stratum sample sizes, n_h/n , where n_h is the stratum h sample size and n is the total sample size.

You can use the **SAMPSIZE=** option in the PROC SURVEYSELECT statement to specify the total sample size to be allocated among the strata. Alternatively, you can specify the desired margin of error in the **MARGIN=** option, and the procedure determines the stratum sample sizes that are required to achieve that margin. See the section “[Specifying the Margin of Error](#)” on page 8069 for details.

When you request sample allocation, by default PROC SURVEYSELECT computes the allocation of the total sample size among the strata and then selects the sample. If you specify the **NOSAMPLE** option, the procedure computes the allocation but does not select the sample. In this case the **OUT=** output data set contains the stratum sample sizes that are computed according to the specified allocation method. See the section “[Allocation Output Data Set](#)” on page 8075 for details.

You can use the **ALLOC=** option with any selection method except **METHOD=PPS_BREWER** and **METHOD=PPS_MURTHY**, which select two units from each stratum.

Table 95.2 summarizes the *options* available in the STRATA statement. Descriptions of the *options* follow in alphabetical order.

Table 95.2 STRATA Statement Options for Sample Allocation

Option	Description
ALLOC=name	Specifies the allocation method
ALLOC=(values)	Provides allocation proportions
ALLOCMIN=	Specifies the minimum sample size per stratum
ALPHA=	Specifies the confidence level
COST=	Provides stratum costs
MARGIN=	Specifies the margin of error
NOSAMPLE	Allocates but does not select the sample
STATS	Displays additional allocation statistics
VAR=	Provides stratum variances

You can specify the following *options* in the STRATA statement after a slash (/):

ALLOC=*name*

specifies the method for allocating the total sample size among the strata. The following values for *name* are available:

PROPORTIONAL | PROP

requests proportional allocation, which allocates the total sample size in proportion to the stratum sizes, where the stratum size is the number of sampling units in the stratum. See the section “[Proportional Allocation](#)” on page 8068 for details.

OPTIMAL | OPT

requests optimal allocation, which allocates the total sample size among the strata in proportion to stratum sizes, stratum variances, and stratum costs. See the section “[Optimal Allocation](#)” on page 8068 for more information. If you specify ALLOC=OPTIMAL, you must provide the stratum variances with the [VAR=\(values\)](#), [VAR=SAS-data-set](#), or [VAR](#) option. You must provide the stratum costs with the [COST=\(values\)](#), [COST=SAS-data-set](#), or [COST](#) option.

NEYMAN

requests Neyman allocation, which allocates the total sample size among the strata in proportion to the stratum sizes and variances. See the section “[Neyman Allocation](#)” on page 8069 for more information. If you specify ALLOC=NEYMAN, you must provide the stratum variances with the [VAR=\(values\)](#), [VAR=SAS-data-set](#), or [VAR](#) option.

ALLOC=(*values*)

lists stratum allocation proportions. You can separate *values* with blanks or commas.

Each allocation proportion specifies the percent of the total sample size to allocate to the corresponding stratum. The number of ALLOC= values must equal the number of strata in the input data set. The sum of the allocation proportions must equal 1.

Each allocation proportion must be a positive number. You can specify each value as a number between 0 and 1. Or you can specify a value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

List the allocation proportions in the order in which the strata appear in the input data set. If you use the ALLOC=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

ALLOC=SAS-data-set

names a SAS data set that contains stratum allocation proportions. You provide the stratum allocation proportions in the ALLOC= data set variable `_ALLOC_`.

Each allocation proportion specifies the percent of the total sample size to allocate to the corresponding stratum. The sum of the allocation proportions must equal 1.

Each allocation proportion must be a positive number. You can specify the value as a number between 0 and 1. Or you can specify the value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The ALLOC= data set should contain all the STRATA variables, with the same type and length as in the DATA= input data set. The STRATA groups should appear in the same order in the ALLOC= data set as in the DATA= data set. The ALLOC= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary data set in each invocation of the procedure.

ALLOCMIN=*n*

specifies the minimum sample size to allocate to a stratum. When you specify ALLOCMIN=*n*, PROC SURVEYSELECT allocates at least *n* sampling units to each stratum. If you do not specify the ALLOCMIN= option, PROC SURVEYSELECT allocates at least one sampling unit to each stratum by default.

The minimum stratum sample size *n* must be a positive integer. The ALLOCMIN value *n* times the number of strata should not exceed the total sample size to be allocated. For without-replacement selection methods, the ALLOCMIN value should not exceed the number of sampling units in any stratum.

ALPHA= α

specifies the level of the confidence interval for the [MARGIN=](#) determination of stratum sample sizes. See the section “[Specifying the Margin of Error](#)” on page 8069 for details.

The value of α must be between 0 and 1; the default is 0.05. A confidence level of α produces a $100(1 - \alpha)\%$ confidence interval. The default of ALPHA=0.05 produces a 95% confidence interval.

COST

indicates that stratum costs are included in the secondary input data set. Use the COST option when you have already named the secondary input data set in another option, such as the [VAR=SAS-data-set](#) option. You provide the stratum costs in the secondary input data set variable `_COST_`.

A stratum cost represents the per-unit cost (the survey cost of a single unit in the stratum). Each stratum cost must be a positive number. Cost values are required if you specify the [ALLOC=OPTIMAL](#) option.

COST=(*values*)

specifies stratum costs, which are required if you specify the [ALLOC=OPTIMAL](#) option. You can separate *values* with blanks or commas.

A stratum cost represents the per-unit cost (the survey cost of a single unit in the stratum). Each stratum cost must be a positive number.

The number of COST= values must equal the number of strata in the input data set. List the stratum costs in the order in which the strata appear in the input data set. If you use the COST=*values* option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

COST=SAS-data-set

names a SAS data set that contains the stratum costs. You provide the stratum costs in the COST= data set variable `_COST_`.

A stratum cost represents the per-unit cost (the survey cost of a single unit in the stratum). Each stratum cost must be a positive number. Stratum costs are required if you specify the [ALLOC=OPTIMAL](#) option.

The `COST=` data set should contain all the STRATA variables, with the same type and length as in the `DATA=` input data set. The STRATA groups should appear in the same order in the `COST=` data set as in the `DATA=` data set. The `COST=` data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

MARGIN=*value*

specifies the desired margin of error for estimating the overall mean from the stratified sample. When you specify the `MARGIN=` option, PROC SURVEYSELECT determines the stratum sample sizes required to achieve this margin for the allocation method or proportions that you specify in the `ALLOC=` option. See the section “[Specifying the Margin of Error](#)” on page 8069 for details.

The `MARGIN=` *value* must be a positive number. When you specify the `MARGIN=` option, you must also provide the stratum variances in the `VAR=(values)`, `VAR=SAS-data-set`, or `VAR` option.

You can use the `ALPHA=` option to set the level of the confidence interval that the `MARGIN=` computation uses. The default of `ALPHA=0.05` specifies a 95% confidence interval.

You can request the `MARGIN=` option for any allocation method (proportional, optimal, or Neyman) or for allocation proportions that you provide (`ALLOC=(values)` or `ALLOC=SAS-data-set`). When you use the `MARGIN=` option, you cannot specify a total sample size in the `SAMPsize=` option in the PROC SURVEYSELECT statement.

NOSAMPLE

requests that PROC SURVEYSELECT allocate the total sample size among the strata but not select the sample. When you specify the `NOSAMPLE` option, the `OUT=` output data set contains the stratum sample sizes that PROC SURVEYSELECT computes. See the section “[Allocation Output Data Set](#)” on page 8075 for details.

STATS

displays statistics for the sample allocation. If you specify the `MARGIN=` option, the `STATS` option displays the expected margin of error for the allocation. See the section “[Specifying the Margin of Error](#)” on page 8069 for details. If you request `ALLOC=OPTIMAL` or `ALLOC=NEYMAN` without the `MARGIN=` option, the `STATS` option displays the expected variance, which is computed from the stratum variances that you provide and the allocated stratum sample sizes. If you request `ALLOC=OPTIMAL`, the `STATS` option also displays the total stratum cost, which is computed from the stratum costs that you provide and the allocated stratum sample sizes.

VAR

indicates that stratum variances are included in the secondary input data set. Use the `VAR` option when you have already named the secondary input data set in another option, such as the `COST=SAS-data-set` option. You provide the stratum variances in the secondary input data set variable `_VAR_`.

Each stratum variance must be a positive number. Stratum variances are required if you specify the `ALLOC=OPTIMAL`, `ALLOC=NEYMAN`, or `MARGIN=` option.

VAR=(values)

lists stratum variances, which are required if you specify the `ALLOC=OPTIMAL`, `ALLOC=NEYMAN`, or `MARGIN=` option. You can separate *values* with blanks or commas.

Each stratum variance must be a positive number. The number of `VAR=` values must equal the number of strata in the input data set. List the stratum variances in the order in which the strata appear in the

input data set. If you use the VAR=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

VAR=SAS-data-set

names a SAS data set that contains the stratum variances. You provide the stratum variances in the VAR= data set variable `_VAR_`.

Each stratum variance must be a positive number. Stratum variances are required if you specify the `ALLOC=OPTIMAL`, `ALLOC=NEYMAN`, or `MARGIN=` option.

The VAR= data set should contain all the STRATA variables, with the same type and length as in the DATA= input data set. The STRATA groups should appear in the same order in the VAR= data set as in the DATA= data set. The VAR= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

Details: SURVEYSELECT Procedure

Missing Values

PROC SURVEYSELECT treats missing values of `STRATA` and `SAMPLINGUNIT` variables like any other STRATA or SAMPLINGUNIT variable value. The missing values form a separate, valid variable level.

When you use a `FREQ` statement for sample size allocation, all values of the frequency variable must be nonmissing. If there is a missing or nonpositive frequency, PROC SURVEYSELECT does not perform the allocation.

When you specify a `SIZE` variable, any sampling units that have missing or nonpositive size measures are excluded from the sample selection. The procedure provides a log note that reports the number of observations omitted due to missing or nonpositive size measures.

If you do not use a `SAMPLINGUNIT` statement with the `SIZE` statement, your sampling units are input data set observations, and observations that have missing or nonpositive size measures are excluded from the sample selection. If you do use a `SAMPLINGUNIT` statement with the `SIZE` statement, the procedure computes sampling unit size by summing the size measures of all observations in the unit. When summing the observation size measures, the procedure omits any observations that have missing or nonpositive size measures. If the size of an entire sampling unit is missing or nonpositive, the procedure excludes that unit from the sample selection. When a sampling unit is selected, the output data set includes all observations that belong to the selected unit, regardless of whether an observation’s size measure is missing.

If you provide stratum-level design or allocation information in a secondary input data set, the variable values should be nonmissing. For example, if a stratum value of `_NSIZE_` (or `SampleSize`) in the `SAMPSIZE=` secondary input data set is missing or negative, PROC SURVEYSELECT cannot select a sample from the stratum. The procedure gives an error message and skips the stratum. Similarly, if other secondary data

set variables have missing values for a stratum, a sample cannot be selected from the stratum. These variables include `_NRATE_`, `_MINSIZE_`, `_MAXSIZE_`, `_CERTSIZE_`, and `_CERTP_`. Additionally, if any of the sample allocation variables in the secondary input data set have missing or nonpositive values, PROC SURVEYSELECT cannot compute the sample allocation. Variables that provide information for allocation include `_ALLOC_`, `_VAR_`, and `_COST_`. See the section “[Secondary Input Data Set](#)” on page 8071 for details.

Sorting by CONTROL Variables

If you specify a [CONTROL](#) statement, PROC SURVEYSELECT sorts the input data set by the CONTROL variables before selecting the sample. If you also specify a [STRATA](#) statement, the procedure sorts by CONTROL variables within strata. Sorting by CONTROL variables is available for systematic and sequential selection methods, which include [METHOD=SYS](#), [METHOD=PPS_SYS](#), [METHOD=SEQ](#), and [METHOD=PPS_SEQ](#). Sorting provides additional control over the distribution of the sample and gives some benefits of proportionate stratification.

Control sorting is not available when you use a [SAMPLINGUNIT](#) statement, which defines groups of observations as units (clusters) for sample selection. See the description of the [SAMPLINGUNIT](#) statement for information about ordering clusters before systematic or sequential selection.

When you specify a CONTROL statement, the sorted data set replaces the input data set by default. Alternatively, you can use the [OUTSORT=](#) option to name an output data set that contains the sorted input data set.

PROC SURVEYSELECT provides two types of sorting: hierarchic serpentine sorting and nested sorting. By default (or if you specify the [SORT=SERP](#) option), the procedure uses serpentine sorting. If you specify the [SORT=NEST](#) option, then the procedure sorts by the CONTROL variables according to nested sorting. These two types of sorting are equivalent when there is only one CONTROL variable.

If you request nested sorting, PROC SURVEYSELECT sorts observations in the same order as PROC SORT does for an ascending sort by the CONTROL variables. See the chapter “The SORT Procedure” in the *Base SAS Procedures Guide* for more information. PROC SURVEYSELECT sorts within strata if you also specify a STRATA statement. The procedure first arranges the input observations in ascending order of the first CONTROL variable. Then within each level of the first control variable, the procedure arranges the observations in ascending order of the second CONTROL variable. This continues for all CONTROL variables that are specified.

In hierarchic serpentine sorting, PROC SURVEYSELECT sorts by the first CONTROL variable in ascending order. Then within the first level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in ascending order. Within the second level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in descending order. Sorting by the second CONTROL variable continues to alternate between ascending and descending sorting throughout all levels of the first CONTROL variable. If there is a third CONTROL variable, the procedure sorts by that variable within levels formed from the first two CONTROL variables, again alternating between ascending and descending sorting. This continues for all CONTROL variables that are specified. This sorting algorithm minimizes the change from one observation to the next with respect to the CONTROL variable values, thus making nearby observations more similar. For more information about serpentine sorting, see Chromy (1979) and Williams and Chromy (1980).

Random Number Generation

The probability sampling methods provided by PROC SURVEYSELECT use random numbers in their selection algorithms, as described in the following sections and in the references cited. PROC SURVEYSELECT uses a uniform random number function to generate streams of pseudo-random numbers from an initial starting point, or *seed*. You can use the **SEED=** option to specify the initial seed. If you do not specify the **SEED=** option, PROC SURVEYSELECT uses the time of day from the computer's clock to obtain the initial seed. See the description of the **SEED=** option for details about specifying initial seeds for strata, storing stratum seeds in the output data set, and reproducing samples.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. The Mersenne-Twister generator (Matsumoto and Nishimura 1998) has a very long period ($2^{19937} - 1$) and very good statistical properties. The algorithm is a twisted generalized feedback shift register. This is the same random number generator that the RAND function provides for the uniform distribution. See *SAS Functions and CALL Routines: Reference* for more information.

In previous releases, PROC SURVEYSELECT used the RANUNI random number generator, which you can now request by specifying the **RANUNI** option. This uniform random number generator is based on the method of Fishman and Moore (1982), which uses a prime modulus multiplicative generator with modulus 2^{31} and multiplier 397,204,094. This is the same uniform random number generator that the RANUNI function provides. For more information about the RANUNI function, see *SAS Functions and CALL Routines: Reference*.

To reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1, you can use the **RANUNI** option with the **SEED=** option (for the same input data set and selection parameters).

Sample Selection Methods

PROC SURVEYSELECT provides a variety of methods for selecting probability-based random samples. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population. For more information about probability sampling, see Lohr (2010); Kish (1965, 1987); Kalton (1983); Cochran (1977).

In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. PROC SURVEYSELECT provides the following methods that select units with equal probability: simple random sampling, unrestricted random sampling, systematic random sampling, sequential random sampling, and Bernoulli sampling. In simple random sampling, units are selected *without replacement*, which means that a unit cannot be selected more than once. Both systematic and sequential equal probability sampling are also without replacement. In unrestricted random sampling, units are selected *with replacement*, which means that a unit can be selected more than once. In without-replacement sampling, the *number of hits* refers to the number of times a unit is selected.

In probability proportional to size (PPS) sampling, a unit's selection probability is proportional to its size measure. PROC SURVEYSELECT provides the following methods that select units with probability proportional to size (PPS): PPS sampling without replacement, PPS sampling with replacement, PPS systematic sampling, PPS sequential sampling, Brewer's method, Murthy's method, and Sampford's method. PPS sampling is often used in cluster sampling, where you select clusters (or groups of sampling units) of varying

size in the first stage of selection. For example, clusters might be schools, hospitals, or geographical areas, and the final sampling units might be students, patients, or citizens. Cluster sampling can provide efficiencies in frame construction and other survey operations. For more information, see Lohr (2010); Kalton (1983); Kish (1965), in addition to the other references cited in the following sections.

The following sections give detailed descriptions of the sample selection methods available in PROC SURVEYSELECT. In these sections, n_h denotes the sample size (the number of units in the sample) for stratum h , and N_h denotes the population size (number of units in the population) for stratum h , for $h = 1, 2, \dots, H$. When the sample design is not stratified, n denotes the sample size, and N denotes the population size. For PPS sampling, M_{hi} represents the size measure for unit i in stratum h , M_h is the total of all size measures for the population of stratum h , and $Z_{hi} = M_{hi}/M_h$ is the relative size of unit i in stratum h .

Simple Random Sampling

The method of simple random sampling (**METHOD=SRS**) selects units with equal probability and without replacement. Each possible sample of n different units out of N has the same probability of being selected. The selection probability for each individual unit equals n/N . When you request stratified sampling with a **STRATA** statement, PROC SURVEYSELECT selects samples independently within strata. The selection probability for a unit in stratum h equals n_h/N_h for stratified simple random sampling.

By default, PROC SURVEYSELECT uses Floyd's ordered hash table algorithm for simple random sampling. This algorithm is fast, efficient, and appropriate for large data sets. See Bentley and Floyd (1987) and Bentley and Knuth (1986) for details.

If there is not enough memory available for Floyd's algorithm, PROC SURVEYSELECT switches to the sequential algorithm of Fan, Muller, and Rezucha (1962), which requires less memory but might require more time to select the sample. When PROC SURVEYSELECT uses the alternative sequential algorithm, it writes a note to the log. To request the sequential algorithm, even if enough memory is available for Floyd's algorithm, you can specify **METHOD=SRS2** in the PROC SURVEYSELECT statement.

Unrestricted Random Sampling

The method of unrestricted random sampling (**METHOD=URS**) selects units with equal probability and with replacement. Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of hits (selections) for each unit equals n/N when sampling without stratification. For stratified sampling, the expected number of hits for a unit in stratum h equals n_h/N_h . Note that the expected number of hits exceeds 1 when the sample size n is greater than the population size N .

For unrestricted random sampling, by default, the output data set contains a single copy of each unit selected, even when a unit is selected more than once, and the variable **NumberHits** records the number of hits (selections) for each unit. If you specify the **OUTHITS** option, the output data set contains m copies of a sampling unit for which **NumberHits** equals m . For example, with the **OUTHITS** option a unit that is selected three times is represented by three copies in the output data set. For information about the contents of the output data set, see the section “**Sample Output Data Set**” on page 8072.

Systematic Random Sampling

The method of systematic random sampling (**METHOD=SYS**) selects units at a fixed interval throughout the sampling frame or stratum after a random start. If you specify the sample size (or the stratum sample sizes) with the **SAMPSIZE=** option, PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals N/n , or N_h/n_h for stratified sampling. The selection probability for each unit equals n/N , or n_h/N_h for stratified sampling. If you specify the sampling rate (or the stratum sampling rates) with the **SAMPRATE=** option, PROC SURVEYSELECT uses the inverse of the rate as the interval for systematic selection. The selection probability for each unit equals the specified rate.

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the **CONTROL** statement to order the input data set by the CONTROL variables before sample selection. If you also use a **STRATA** statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies systematic selection to the observations in the order in which they appear in the input data set.

Sequential Random Sampling

If you specify the **METHOD=SEQ** option and do not include a **SIZE** statement, PROC SURVEYSELECT uses the equal probability version of Chromy's method for sequential random sampling. This method selects units sequentially with equal probability and without replacement. See Chromy (1979) and Williams and Chromy (1980) for details. See the section “PPS Sequential Sampling” on page 8064 for a description of Chromy's PPS selection method.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the **CONTROL** statement to sort the input data set by the CONTROL variables before sample selection. If you also use a **STRATA** statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. By default (or if you specify the **SORT=SERP** option), the procedure uses hierarchic serpentine ordering for sorting. If you specify the **SORT=NEST** option, the procedure uses nested sorting. See the section “Sorting by CONTROL Variables” on page 8057 for descriptions of serpentine and nested sorting. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies sequential selection to the observations in the order in which they appear in the input data set.

Following Chromy's method of sequential selection, PROC SURVEYSELECT randomly chooses a starting unit from the entire stratum (or frame, if the design is not stratified). With this unit as the first one, the procedure treats the stratum units as a closed loop. This is done so that all pairwise (joint) selection probabilities are positive and an unbiased variance estimator can be obtained. The procedure numbers units sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, PROC SURVEYSELECT accumulates the expected number of selections (hits), where the expected number of selections $E(S_{hi})$ equals n_h/N_h for all units i in stratum h . The procedure computes

$$I_{hi} = \text{Int}\left(\sum_{j=1}^i E(S_{hj})\right) = \text{Int}(in_h/N_h)$$

$$F_{hi} = \text{Frac}\left(\sum_{j=1}^i E(S_{hj})\right) = \text{Frac}(in_h/N_h)$$

where $\text{Int}(\cdot)$ denotes the integer part of the number, and $\text{Frac}(\cdot)$ denotes the fractional part.

Considering each unit sequentially, Chromy's method determines whether unit i is selected by comparing the total number of selections for the first $(i - 1)$ units,

$$T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj}$$

with the value of $I_{h(i-1)}$.

If $T_{h(i-1)} = I_{h(i-1)}$, Chromy's method determines whether or not unit i is selected as follows. If $F_{hi} = 0$ or $F_{h(i-1)} > F_{hi}$, then unit i is selected with certainty. Otherwise, unit i is selected with probability

$$(F_{hi} - F_{h(i-1)}) / (1 - F_{h(i-1)})$$

If $T_{h(i-1)} = (I_{h(i-1)} + 1)$, Chromy's method determines whether or not unit i is selected as follows. If $F_{hi} = 0$ or $F_{hi} > F_{h(i-1)}$, then the unit is not selected. Otherwise, unit i is selected with probability

$$F_{hi} / F_{h(i-1)}$$

Bernoulli Sampling

Bernoulli sampling, which you request by specifying the **METHOD=BERNOULLI** option, is an equal probability selection method for which the total sample size is not fixed. PROC SURVEYSELECT performs an independent random selection trial for each of the N sampling units in the input data set by using the constant inclusion probability (sampling rate) that you specify. You can specify a single value of the inclusion probability π to use for all N sampling units, or you can specify separate stratum-level values of π_h to use for the N_h units in each stratum.

You provide the inclusion probability (or probabilities) by specifying the **SAMPRATE=** option. For stratified sampling (which you request with the **STRATA** statement), you can specify the same sampling rate for each stratum by using the **SAMPRATE= r** option. Or you can specify different sampling rates for different strata by using the **SAMPRATE=(values)** or **SAMPRATE=SAS-data-set** option.

In Bernoulli sampling, the sample size n (number of units selected) is not fixed; it is a random variable that has a binomial distribution with parameters N and π . The possible values of n range from 0 to N . The expected value of the sample size is πN (or $\pi_h N_h$ for stratified sampling), and the variance of the sample size is $\pi(1 - \pi)N$.

For Bernoulli sampling, the selection probability is the inclusion probability that you specify by using the **SAMPRATE=** option. PROC SURVEYSELECT computes the sampling weight as the inverse of the selection probability, which is $1/\pi$. For Bernoulli sampling, the procedure also computes an adjusted sampling weight as the ratio of the total number of sampling units to the actual sample size, N/n (or N_h/n_h for stratified sampling). The joint selection probability for any two distinct units is π^2 . See Särndal, Swensson, and Wretman (1992) for more information.

You can specify the **STATS** option to include the following information in the **OUT=** output data set for **METHOD=BERNOULLI**: total number of sampling units, selection probability, expected sample size, actual sample size, sampling weight, and adjusted sampling weight.

Poisson Sampling

Poisson sampling, which you request by specifying the **METHOD=POISSON** option, is an unequal probability sampling method for which the total sample size is not fixed. A generalization of Bernoulli sampling, Poisson sampling also consists of independent random selection trials for the N sampling units in the input data set, but the sampling units can have different inclusion probabilities. You provide inclusion probabilities for Poisson sampling in the variable that you specify in the **SIZE** statement.

The expected value of the sample size for Poisson sampling is $\sum_i \pi_i$, where π_i is the inclusion probability for sampling unit i . The variance of the sample size is $\sum_i \pi_i(1 - \pi_i)$.

For Poisson sampling, the selection probability for unit i is the inclusion probability π_i that you specify by using the **SIZE** statement. PROC SURVEYSELECT computes the sampling weight for unit i as the inverse of the selection probability, which is $1/\pi_i$. The joint selection probability for any two distinct units i and j is $\pi_i \pi_j$ for Poisson sampling. See Särndal, Swensson, and Wretman (1992) for more information.

PPS Sampling without Replacement

If you specify the **METHOD=PPS** option, PROC SURVEYSELECT selects units with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals $n_h Z_{hi}$, where n_h is the sample size for stratum h , and Z_{hi} is the relative size of unit i in stratum h . The relative size equals $M_{hi}/M_{h\cdot}$, which is the ratio of the size measure for unit i in stratum h (M_{hi}) to the total of all size measures for stratum h ($M_{h\cdot}$).

Because selection probabilities cannot exceed 1, the relative size for each unit must not exceed $1/n_h$ for **METHOD=PPS**. This requirement can be expressed as $Z_{hi} \leq 1/n_h$, or equivalently, $M_{hi} \leq M_{h\cdot}/n_h$. If your size measures do not meet this requirement, you can adjust the size measures by using the **MAXSIZE=** or **MINSIZE=** option. Or you can request certainty selection for the larger units by using the **CERTSIZE=** or **CERTSIZE=P=** option. Alternatively, you can use a selection method that does not have this relative size restriction, such as PPS with minimum replacement (**METHOD=PPS_SEQ**).

PROC SURVEYSELECT uses the Hanurav-Vijayan algorithm for PPS selection without replacement. Hanurav (1967) introduced this algorithm for the selection of two units per stratum, and Vijayan (1968) generalized it for the selection of more than two units. The algorithm enables computation of joint selection probabilities and provides joint selection probability values that usually ensure nonnegativity and stability of the Sen-Yates-Grundy variance estimator. For details, see Fox (1989); Golmant (1990); Watts (1991).

Notation in the remainder of this section drops the stratum subscript h for simplicity, but selection is still done independently within strata if you specify a stratified design. For a stratified design, n now denotes the sample size for the current stratum, N denotes the stratum population size, and M_i denotes the size measure for unit i in the stratum. If the design is not stratified, this notation applies to the entire sampling frame.

According to the Hanurav-Vijayan algorithm, PROC SURVEYSELECT first orders units within the stratum in ascending order by size measure, so that $M_1 \leq M_2 \leq \dots \leq M_N$. Then the procedure selects the PPS sample of n observations as follows:

1. The procedure randomly chooses one of the integers $1, 2, \dots, n$ with probability $\theta_1, \theta_2, \dots, \theta_n$, where

$$\theta_i = n(Z_{N-n+i+1} - Z_{N-n+i})(T + iZ_{N-n+1})/T$$

where $Z_j = M_j/M$ and

$$T = \sum_{j=1}^{N-n} Z_j$$

By definition, $Z_{N+1} = 1/n$ to ensure that $\sum_{i=1}^n \theta_i = 1$.

2. If i is the integer selected in step 1, the procedure includes the last $(n - i)$ units of the stratum in the sample, where the units are ordered by size measure as described previously. The procedure then selects the remaining i units according to steps 3 through 6.
3. The procedure defines new normed size measures for the remaining $(N - n + i)$ stratum units that were not selected in steps 1 and 2:

$$Z_j^* = \begin{cases} Z_j / (T + iZ_{N-n+1}) & \text{for } j = 1, \dots, N - n + 1 \\ Z_{N-n+1} / (T + iZ_{N-n+1}) & \text{for } j = N - n + 2, \dots, N - n + i \end{cases}$$

4. The procedure selects the next unit from the first $(N - n + 1)$ stratum units with probability proportional to $a_j(1)$, where

$$\begin{aligned} a_1(1) &= iZ_1^* \\ a_j(1) &= iZ_j^* \prod_{k=1}^{j-1} (1 - (i-1)P_k) \quad \text{for } j = 2, \dots, N - n + 1 \end{aligned}$$

and

$$P_k = M_k / (M_{k+1} + M_{k+2} + \dots + M_{N-n+i})$$

5. If stratum unit j_1 is the unit selected in step 4, then the procedure selects the next unit from units $(j_1 + 1)$ through $(N - n + 2)$ with probability proportional to $a_j(2, j_1)$, where

$$\begin{aligned} a_{j_1+1}(2, j_1) &= (i-1)Z_{j_1+1}^* \\ a_j(2, j_1) &= (i-1)Z_j^* \prod_{k=j_1+1}^{j-1} (1 - (i-2)P_k) \quad \text{for } j = j_1 + 2, \dots, N - n + 2 \end{aligned}$$

6. The procedure repeats step 5 until all n sample units are selected.

If you specify the **JTPROBS** option, PROC SURVEYSELECT computes the joint selection probabilities for all pairs of selected units in each stratum. The joint selection probability for units i and j in the stratum equals

$$P_{(ij)} = \sum_{r=1}^n \theta_r K_{ij}^{(r)}$$

where

$$K_{ij} = \begin{cases} 1 & N - n + r < i \leq N - 1 \\ rZ_{N-n+1} / (T + rZ_{N-n+1}) & N - n < i \leq N - n + r, \quad j > N - n + r \\ rZ_i / (T + rZ_{N-n+1}) & 1 \leq i \leq N - n, \quad j > N - n + r \\ \pi_{ij}^{(r)} & j \leq N - n + r \end{cases}$$

$$\pi_{ij}^{(r)} = \frac{r(r-1)}{2} P_i Z_j \prod_{k=1}^{i-1} (1 - P_k)$$

$$P_k = M_k / (M_{k+1} + M_{k+2} + \dots + M_{N-n+r})$$

PPS Sampling with Replacement

If you specify the **METHOD=PPS_WR** option, PROC SURVEYSELECT selects units with probability proportional to size and with replacement. The procedure makes n_h independent random selections from the stratum of N_h units, selecting with probability $Z_{hi} = M_{hi}/M_{h\cdot}$. Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of hits (selections) for unit i in stratum h equals $n_h Z_{hi}$. If you specify the **JTPROBS** option, PROC SURVEYSELECT computes the joint expected number of hits for all pairs of selected units in each stratum. The joint expected number of hits for units i and j in stratum h equals

$$P_{h(ij)} = \begin{cases} n_h(n_h - 1)Z_{hi}Z_{hj} & \text{for } j \neq i \\ n_h(n_h - 1)Z_{hi}Z_{hi}/2 & \text{for } j = i \end{cases}$$

PPS Systematic Sampling

If you specify the **METHOD=PPS_SYS** option, PROC SURVEYSELECT selects units by systematic random sampling with probability proportional to size. Systematic sampling selects units at a fixed interval throughout the stratum or sampling frame after a random start. PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals $M_{h\cdot}/n_h$ for stratified sampling and M/n for sampling without stratification. Depending on the sample size and the values of the size measures, it might be possible for a unit to be selected more than once. The expected number of hits (selections) for unit i in stratum h equals $n_h M_{hi}/M_{h\cdot} = n_h Z_{hi}$. See Cochran (1977, pp. 265–266) and Madow (1949) for details.

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the **CONTROL** statement to order the input data set by the CONTROL variables before sample selection. If you also use a **STRATA** statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies systematic selection to the observations in the order in which they appear in the input data set.

PPS Sequential Sampling

If you specify the **METHOD=PPS_SEQ** option, PROC SURVEYSELECT uses Chromy's method of sequential random sampling. See Chromy (1979) and Williams and Chromy (1980) for details. Chromy's method selects units sequentially with probability proportional to size and with minimum replacement. Selection *with minimum replacement* means that the actual number of hits for a unit can equal the integer part of the expected number of hits for that unit, or the next largest integer. This can be compared to selection *without replacement*, where each unit can be selected only once, so the number of hits can equal 0 or 1. The other alternative is selection *with replacement*, where there is no restriction on the number of hits for each unit, so the number of hits can equal $0, 1, \dots, n_h$, where n_h is the stratum sample size.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the **CONTROL** statement to sort the input data set by the CONTROL variables before sample selection. If you also use a **STRATA** statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. By default (or if you specify the **SORT=SERP** option), the procedure uses hierarchic

serpentine ordering to sort the sampling frame by the CONTROL variables within strata. If you specify the **[SORT=NEST](#)** option, the procedure uses nested sorting. See the section “[Sorting by CONTROL Variables](#)” on page 8057 for descriptions of serpentine and nested sorting. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies sequential selection to the observations in the order in which they appear in the input data set.

According to Chromy’s method of sequential selection, PROC SURVEYSELECT first chooses a starting unit randomly from the entire stratum, with probability proportional to size. The procedure uses this unit as the first one and treats the stratum observations as a closed loop. This is done so that all pairwise (joint) expected number of hits are positive and an unbiased variance estimator can be obtained. The procedure numbers observations sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, Chromy’s method partitions the ordered stratum sampling frame into n_h zones of equal size. There is one selection from each zone and a total of n_h hits (selections), although fewer than n_h distinct units might be selected. Beginning with the random start, the procedure accumulates the expected number of hits and computes

$$E(S_{hi}) = n_h Z_{hi}$$

$$I_{hi} = \text{Int}\left(\sum_{j=1}^i E(S_{hj})\right)$$

$$F_{hi} = \text{Frac}\left(\sum_{j=1}^i E(S_{hj})\right)$$

where $E(S_{hi})$ represents the expected number of hits for unit i in stratum h , $\text{Int}(\cdot)$ denotes the integer part of the number, and $\text{Frac}(\cdot)$ denotes the fractional part.

Considering each unit sequentially, Chromy’s method determines the actual number of hits for unit i by comparing the total number of hits for the first $(i - 1)$ units,

$$T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj}$$

with the value of $I_{h(i-1)}$.

If $T_{h(i-1)} = I_{h(i-1)}$, Chromy’s method determines the total number of hits for the first i units as follows. If $F_{hi} = 0$ or $F_{h(i-1)} > F_{hi}$, then $T_{hi} = I_{hi}$. Otherwise, $T_{hi} = I_{hi} + 1$ with probability

$$(F_{hi} - F_{h(i-1)}) / (1 - F_{h(i-1)})$$

And the number of hits for unit i equals $T_{hi} - T_{h(i-1)}$.

If $T_{h(i-1)} = (I_{h(i-1)} + 1)$, Chromy’s method determines the total number of hits for the first i units as follows. If $F_{hi} = 0$, then $T_{hi} = I_{hi}$. If $F_{hi} > F_{h(i-1)}$, then $T_{hi} = I_{hi} + 1$. Otherwise, $T_{hi} = I_{hi} + 1$ with probability

$$F_{hi} / F_{h(i-1)}$$

Brewer's PPS Method

Brewer's method (**METHOD=PPS_BREWER**) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals $2M_{hi}/M_h = 2Z_{hi}$. (Because selection probabilities cannot exceed 1, the relative size for each unit, Z_{hi} , must not exceed $1/2$.)

Brewer's algorithm first selects a unit with probability

$$\frac{Z_{hi}(1 - Z_{hi})}{D_h(1 - 2Z_{hi})}$$

where

$$D_h = \sum_{i=1}^{N_h} \frac{Z_{hi}(1 - Z_{hi})}{1 - 2Z_{hi}}$$

Then a second unit is selected from the remaining units with probability

$$\frac{Z_{hj}}{1 - Z_{hi}}$$

where unit i is the first unit selected. The joint selection probability for units i and j in stratum h equals

$$P_{h(ij)} = \frac{2Z_{hi}Z_{hj}}{D_h} \left(\frac{1 - Z_{hi} - Z_{hj}}{(1 - 2Z_{hi})(1 - 2Z_{hj})} \right)$$

See Cochran (1977, pp. 261–263) and Brewer (1963) for details. Brewer's method yields the same selection probabilities and joint selection probabilities as Durbin's method. See Cochran (1977) and Durbin (1967) for details.

Murthy's PPS Method

Murthy's method (**METHOD=PPS_MURTHY**) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals

$$P_{hi} = Z_{hi}(1 + K_h - (Z_{hi}/(1 - Z_{hi})))$$

where $Z_{hi} = M_{hi}/M_h$ and

$$K_h = \sum_{j=1}^{N_h} (Z_{hj}/(1 - Z_{hj}))$$

Murthy's algorithm first selects a unit with probability Z_{hi} . Then a second unit is selected from the remaining units with probability $Z_{hj}/(1 - Z_{hi})$, where unit i is the first unit selected. The joint selection probability for units i and j in stratum h equals

$$P_{h(ij)} = Z_{hi}Z_{hj} \left(\frac{2 - Z_{hi} - Z_{hj}}{(1 - Z_{hi})(1 - Z_{hj})} \right)$$

See Cochran (1977, pp. 263–265) and Murthy (1957) for details.

Sampford's PPS Method

Sampford's method (`METHOD=PPS_SAMPFORD`) is an extension of Brewer's method that selects more than two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals $n_h M_{hi} / M_h = n_h Z_{hi}$. (Because selection probabilities cannot exceed 1, the relative size for each unit, Z_{hi} , must not exceed $1/n_h$.)

Sampford's method first selects a unit from stratum h with probability Z_{hi} . Then subsequent units are selected with probability proportional to

$$\lambda_{hi} = Z_{hi} / (1 - n_h Z_{hi})$$

and with replacement. If the same unit appears more than once in the sample of size n_h , then Sampford's algorithm rejects that sample and selects a new sample. The sample is accepted if it contains n_h distinct units.

If you specify the `JTPROBS` option, PROC SURVEYSELECT computes the joint selection probabilities for all pairs of selected units in each stratum. The joint selection probability for units i and j in stratum h equals

$$P_{h(ij)} = K_h \lambda_{hi} \lambda_{hj} \sum_{t=2}^{n_h} \left([t - n_h (Z_{hi} + Z_{hj})] L_{h,(n_h-t)}(\bar{i}\bar{j}) \right) / n_h^{t-2}$$

where

$$K_h = 1 / \sum_{t=1}^{n_h} (t L_{h,(n_h-t)} / n_h^t)$$

$$L_{h,m} = \sum_{S_h(m)} \lambda_{hi_1} \lambda_{hi_2} \cdots \lambda_{hi_m}$$

and $S_h(m)$ denotes all possible samples of size m , for $m = 1, 2, \dots, N_h$. The sum $L_{h,m}(\bar{i}\bar{j})$ is defined similarly to $L_{h,m}$ but sums over all possible samples of size m that do not include units i and j . See Cochran (1977, pp. 262–263) and Sampford (1967) for details.

Sample Size Allocation

If you specify the `ALLOC=` option in the `STRATA` statement, PROC SURVEYSELECT allocates the total sample size among the strata according to the method that you request. PROC SURVEYSELECT provides proportional allocation (`ALLOC=PROP`), optimal allocation (`ALLOC=OPTIMAL`), and Neyman allocation (`ALLOC=NEYMAN`). For more information about these allocation methods, see Lohr (2010); Kish (1965); Cochran (1977). You can also directly provide the allocation proportions by using the `ALLOC=(values)` option or the `ALLOC=SAS-data-set` option. Then PROC SURVEYSELECT allocates the sample size among the strata according to the proportions that you provide. Allocation proportions are the relative stratum sample sizes, n_h/n , where n_h is the sample size for stratum h and n is the total sample size.

You can use the `SAMPSIZE=n` option in the `PROC SURVEYSELECT` statement to specify the total sample size to allocate among the strata. Or you can specify the desired margin of error in the `MARGIN=` option in the `STRATA` statement, and PROC SURVEYSELECT computes the stratum sample sizes necessary to achieve that margin of error for the allocation method that you request. See the section “Specifying the Margin of Error” on page 8069 for details.

Proportional Allocation

When you specify the **ALLOC=PROP** option in the **STRATA** statement, PROC SURVEYSELECT allocates the total sample size among the strata in proportion to the stratum sizes, where the stratum size is the number of sampling units in the stratum. The allocation proportion of the total sample size for stratum h equals

$$f_h^* = N_h / N$$

where N_h is the number of sampling units in stratum h and N is the total number of sampling units for all strata. If you specify the total sample size n in the **SAMPsize=** option in the **PROC SURVEYSELECT** statement, the procedure computes the target sample size for stratum h as

$$n_h^* = f_h^* \times n$$

The target sample size values, n_h^* , might not be integers, but the stratum sample sizes are required to be integers. PROC SURVEYSELECT uses a rounding algorithm to convert the n_h^* to integer values n_h and maintain the requested total sample size n . The rounding algorithm includes the restriction that all values of n_h must be at least 1, so that at least one unit is selected from each stratum. If you specify a minimum stratum sample size n_{min} in the **ALLOCmin=** option in the **STRATA** statement, then all values of n_h are required to be at least n_{min} . For without-replacement selection methods, PROC SURVEYSELECT also requires that each stratum sample size must not exceed the total number of sampling units in the stratum, $n_h \leq N_h$. If a target stratum sample size exceeds the number of units in the stratum, PROC SURVEYSELECT allocates the maximum number of units, N_h , to the stratum, and then allocates the remaining total sample size proportionally among the remaining strata.

PROC SURVEYSELECT provides the target allocation proportions f_h^* in the output data set variable **AllocProportion**. The variable **ActualProportion** contains the actual proportions for the allocated sample sizes n_h . For stratum h , the actual proportion is computed as

$$f_h = n_h / n$$

where n_h is the allocated sample size for stratum h and n is the total sample size. The actual proportions f_h can differ from the target allocation proportions f_h^* due to rounding, the requirement that $n_h \geq 1$ (or $n_h \geq n_{min}$), and the requirement that $n_h \leq N_h$ for without-replacement selection methods.

Optimal Allocation

When you specify the **ALLOC=OPTIMAL** option in the **STRATA** statement, PROC SURVEYSELECT allocates the total sample size among the strata in proportion to stratum sizes, stratum costs, and stratum variances. You provide the stratum costs and variances by using the **COST=** and **VAR=** options, respectively.

Optimal allocation minimizes the overall variance for a specified cost, or equivalently minimizes the overall cost for a specified variance. For details, see Lohr (2010); Cochran (1977); Kish (1965). For optimal allocation, PROC SURVEYSELECT computes the proportion of the total sample size for stratum h as

$$f_h^* = \frac{N_h S_h}{\sqrt{C_h}} / \sum_{i=1}^H \frac{N_i S_i}{\sqrt{C_i}}$$

where N_h is the number of sampling units in stratum h , S_h is the standard deviation within stratum h , C_h is the unit cost within stratum h , and H is the total number of strata.

If you specify the total sample size n in the **SAMPsize=** option in the **PROC SURVEYSELECT** statement, the procedure computes the target sample size for stratum h as

$$n_h^* = f_h^* \times n$$

As described in the section “**Proportional Allocation**” on page 8068, the values of n_h^* are converted to integer sample sizes n_h by using a rounding algorithm that requires the sum of the stratum sample sizes to equal n . The final stratum sample sizes n_h are also required to be at least 1, or at least n_{min} if you specify a minimum stratum sample size in the **ALLOCmin=** option in the **STRATA** statement. For without-replacement selection methods, the final sample sizes cannot exceed the stratum sizes.

Neyman Allocation

When you specify the **ALLOC=NEYMAN** option in the **STRATA** statement, **PROC SURVEYSELECT** allocates the total sample size among the strata in proportion to stratum sizes and stratum variances. Neyman allocation is a special case of optimal allocation (described in the section “**Optimal Allocation**” on page 8068), where the costs per unit are the same for all strata. For Neyman allocation, the proportion of the total sample size for stratum h is computed as

$$f_h^* = N_h S_h / \sum_{i=1}^H N_i S_i$$

If you specify the total sample size n in the **SAMPsize=** option in the **PROC SURVEYSELECT** statement, the procedure computes the target sample size for stratum h as $n_h^* = f_h^* \times n$. The n_h^* are converted to integer sample sizes n_h by using a rounding algorithm that requires the sum of the stratum sizes to equal n . The final sample sizes n_h are required to be at least 1, or at least n_{min} if you specify a minimum sample size in the **ALLOCmin=** option in the **STRATA** statement. For without-replacement selection methods, the final sample sizes must not exceed the stratum sizes.

Specifying the Margin of Error

Instead of specifying the total sample size to allocate among the strata, you can specify the desired margin of error for estimating the overall mean from the stratified sample. Based on the requested allocation method and the stratum variances that you provide, **PROC SURVEYSELECT** computes the stratum sample sizes that are required to achieve this margin of error. You specify the margin of error in the **MARGIN=** option in the **STRATA** statement, and you provide stratum variances in the **VAR=** option. You can use the **MARGIN=** option with any allocation method (proportional, optimal, or Neyman) or with allocation proportions that you provide (**ALLOC=(values)** or **ALLOC=SAS-data-set**).

The margin of error e is the half-width of the $100(1 - \alpha)\%$ confidence interval for the overall mean based on the stratified sample,

$$e = z_{\alpha/2} \times \sqrt{\text{Var}(\bar{y}_{str})}$$

where $\text{Var}(\bar{y}_{str})$ is the variance of the estimate of the mean from the stratified sample and $z_{\alpha/2}$ is the $100(1 - \alpha/2)$ percentile of the standard normal distribution. You can specify the value of α in the **ALPHA=** option in the **STRATA** statement. By default, **PROC SURVEYSELECT** uses a 95% confidence interval (**ALPHA=0.05**).

For the specified margin of error e , PROC SURVEYSELECT computes the target stratum sample sizes n_h^* for without-replacement selection methods as

$$n_h^* = f_h^* \left(\sum_{i=1}^H N_i^2 S_i^2 / f_i^* \right) / \left((eN/z_{\alpha/2})^2 + \sum_{i=1}^H N_i S_i^2 \right)$$

where N_i is the number of sampling units in stratum i , S_i^2 is the variance within stratum i , N is the total number of sampling units for all strata, and H is the total number of strata.

The values of f_h^* are the stratum allocation proportions, which PROC SURVEYSELECT computes according to the allocation method that you request. See the sections “[Proportional Allocation](#)” on page 8068, “[Optimal Allocation](#)” on page 8068, and “[Neyman Allocation](#)” on page 8069 for details.

For with-replacement selection methods, PROC SURVEYSELECT computes the target stratum sample sizes as

$$n_h^* = f_h^* \left(\sum_{i=1}^H N_i^2 S_i^2 / f_i^* \right) / (eN/z_{\alpha/2})^2$$

See Lohr (2010, p. 91), Cochran (1977, Chapter 5), and Arkin (1984, Chapter 10) for more information.

The target sample size values n_h^* might not be integers, but the stratum sample sizes are required to be integers. PROC SURVEYSELECT rounds all fractional target sample sizes up to integer sample sizes. If you specify a minimum stratum sample size n_{min} in the `ALLOCMIN=` option in the `STRATA` statement, then all stratum sample sizes n_h are required to be at least n_{min} .

For without-replacement selection methods, a stratum sample size cannot exceed the number of units in the stratum. If a target stratum sample size does exceed the number of units in the stratum, the procedure sets $n_h = N_h$ for that stratum, removes the stratum from the variance computation (because it contributes nothing to the sampling error), revises the allocation proportions f_h^* for the remaining strata, and computes the stratum sample sizes again. If a stratum sample size equals the number of units in its stratum, the procedure also removes that stratum from the variance computation and revises the sample sizes for the remaining strata. See Cochran (1977, p. 104) and Arkin (1984, p. 176) for details.

When you specify the `STATS` option with the `MARGIN=` option in the `STRATA` statement, PROC SURVEYSELECT displays the expected margin of error for the sample allocation. The expected margin of error (for the overall mean based on the stratified sample) is computed from the stratum sizes (N_i), the stratum variances that you provide (S_i^2), and the allocated stratum sample sizes that the procedure computes (n_i). For without-replacement selection methods, the expected margin of error is

$$e = z_{\alpha/2} \times \frac{1}{N} \sqrt{\sum_{i=1}^H \frac{N_i^2 S_i^2}{n_i} \left(1 - \frac{n_i}{N}\right)}$$

For with-replacement selection methods, the expected margin of error is

$$e = z_{\alpha/2} \times \frac{1}{N} \sqrt{\sum_{i=1}^H \frac{N_i^2 S_i^2}{n_i}}$$

The expected margin of error should be less than or equal to the value specified in the `MARGIN=` option. Any difference between the expected margin and the specified value is due to rounding the target stratum sample sizes up to integer values and increasing stratum sample sizes to equal the required minimum value (`ALLOCMIN=`).

Secondary Input Data Set

The primary input data set for PROC SURVEYSELECT is the **DATA=** data set, which contains the list of units from which the sample is selected. You can use a secondary input data set to provide stratum-level design and selection information, such as sample sizes or rates, certainty size values, or stratum costs. This secondary input data set is sometimes called the **SAMPSIZE=** input data set. You can provide stratum sample sizes in the **_NSIZE_** (or SampleSize) variable in the **SAMPSIZE=** data set.

The secondary input data set must contain all the **STRATA** variables, with the same type and length as in the **DATA=** data set. The **STRATA** groups should appear in the same order in the secondary data set as in the **DATA=** data set. You can name only one secondary data set in each invocation of the procedure.

You must name the secondary input data set in the appropriate **PROC SURVEYSELECT** or **STRATA** option, and use the designated variable name to provide the stratum-level values. For example, if you want to provide stratum-level costs for sample allocation, you name the secondary data set in the **COST=SAS-data-set** option in the **STRATA** statement. The data set must include the stratum costs in a variable named **_COST_**. You can use the secondary input data set for more than one option if it is appropriate for your design. For example, the secondary data set can include both stratum costs and stratum variances, which are required for optimal allocation (**ALLOC=OPTIMAL**).

Instead of using a separate secondary input data set, you can include secondary information in the **DATA=** data set along with the sampling frame. When you include secondary information in the **DATA=** data set, name the **DATA=** data set in the appropriate options, and include the required variables in the **DATA=** data set.

Table 95.3 lists the available secondary data set variables, together with their descriptions and the corresponding options.

Table 95.3 PROC SURVEYSELECT Secondary Data Set Variables

Variable	Description	Statement	Option
ALLOC	Allocation proportion	STRATA	ALLOC=
CERTP	Certainty proportion	PROC	CERTSIZE=P=
CERTSIZE	Certainty size	PROC	CERTSIZE=
COST	Cost	STRATA	COST=
MAXSIZE	Maximum size	PROC	MAXSIZE=
MINSIZE	Minimum size	PROC	MINSIZE=
NSIZE	Sample size	PROC	SAMPSIZE=
RATE	Sampling rate	PROC	SAMPRATE=
SEED	Random number seed	PROC	SEED=
VAR	Variance	STRATA	VAR=

Sample Output Data Set

PROC SURVEYSELECT selects a sample and creates a SAS data set that contains the sample of selected units, unless you specify the **NOSAMPLE** option in the **STRATA** statement. If you specify the **NOSAMPLE** option, PROC SURVEYSELECT allocates the total sample size among the strata but does not select the sample. When you specify the **NOSAMPLE** option, the output data set contains the allocated sample sizes. See the section “Allocation Output Data Set” on page 8075 for details.

You can specify the name of the sample output data set in the **OUT=** option in the PROC SURVEYSELECT statement. If you omit the **OUT=** option, the data set is named **DATA n** , where n is the smallest integer that makes the name unique.

The output data set contains the units that are selected for the sample. These units are either observations or groups of observations (clusters) that you define by specifying the **SAMPLINGUNIT** statement. If you do not specify the **SAMPLINGUNIT** statement to define units (clusters), then PROC SURVEYSELECT uses observations as sampling units by default.

By default, the output data set contains only those units that are selected for the sample. But if you specify the **OUTALL** option, the output data set includes all observations from the input data set and also contains a variable that indicates each observation’s selection status. The variable **Selected** equals 1 for an observation selected for the sample, and equals 0 for an observation not selected. The **OUTALL** option is available for equal probability selection methods.

By default, the output data set contains a single copy of each selected unit, even if the unit is selected more than once, and the variable **NumberHits** records the number of hits (selections) for each unit. A unit can be selected more than once if you use a with-replacement or with-minimum-replacement selection method (**METHOD=URS**, **METHOD=PPS_WR**, **METHOD=PPS_SYS**, or **METHOD=PPS_SEQ**). If you specify the **OUTHITS** option, the output data set includes a distinct copy of each selected unit in the output data set. For example, with the **OUTHITS** option a unit that is selected three times is represented by three copies in the output data set.

The output data set also contains design information and selection statistics, depending on the selection method and output options you specify. The output data set can include the following variables:

- **Selected**, which indicates whether or not the observation is selected for the sample. This variable is included if you specify the **OUTALL** option. **Selected** equals 1 for an observation that is selected for the sample, or 0 for an observation that is not selected.
- **STRATA** variables, which you specify in the **STRATA** statement.
- **Replicate**, which is the sample replicate number. This variable is included when you request replicated sampling with the **REPS=** option.
- **SAMPLINGUNIT (CLUSTER)** variables, which you specify in the **SAMPLINGUNIT** statement.
- **ID** variables, which you name in the **ID** statement.
- **CONTROL** variables, which you specify in the **CONTROL** statement.

- Zone, which is the selection zone. This variable is included for `METHOD=PPS_SEQ`.
- SIZE variable, which you specify in the `SIZE` statement.
- AdjustedSize, which is the adjusted size measure. This variable is included if you request adjusted sizes with the `MINSIZE=` or `MAXSIZE=` option when your sampling units are observations.
- UnitSize, which is the sampling unit (or cluster) size measure. This variable is included if you specify the `SAMPLINGUNIT` statement.
- Certain, which indicates certainty selection. This variable is included if you specify the `CERTSIZE=` or `CERTSIZE=P=` option. Certain equals 1 for units that are included with certainty because their size measures exceed the certainty size value or the certainty proportion; otherwise, Certain equals 0.
- NumberHits, which is the number of hits (selections). This variable is included for selection methods that are with replacement or with minimum replacement (`METHOD=URS`, `METHOD=PPS_WR`, `METHOD=PPS_SYS`, and `METHOD=PPS_SEQ`).

The output data set includes the following variables if you request a PPS selection method or if you specify the `STATS` option in the `PROC SURVEYSELECT` statement for other methods:

- ExpectedHits, which is the expected number of hits (selections). This variable is included for selection methods that are with replacement or with minimum replacement, where the same unit can be selected more than once (`METHOD=URS`, `METHOD=PPS_WR`, `METHOD=PPS_SYS`, and `METHOD=PPS_SEQ`).
- SelectionProb, which is the probability of selection. This variable is included for selection methods that are without replacement.
- SamplingWeight, which is the sampling weight. This variable equals the inverse of ExpectedHits or SelectionProb.

If you specify the `STATS` or `OUTSIZE` option for `METHOD=BERNOULLI`, the output data set contains the following variables. If you specify a `STRATA` statement, the output data set includes stratum-level values of these variables; otherwise, the output data set includes overall values.

- Total, which is the total number of sampling units
- SelectionProb, which is the selection probability that you specify by using the `SAMPRATE=` option
- ExpectedN, which is the expected value of the sample size
- SampleSize, which is the actual sample size

If you specify the `STATS` option for `METHOD=BERNOULLI`, the output data set also contains the following variable:

- AdjSamplingWeight, which is the adjusted sampling weight

For **METHOD=PPS_BREWER** and **METHOD=PPS_MURTHY**, which select two units from each stratum with probability proportional to size, the output data set contains the following variable:

- **JtSelectionProb**, which is the joint probability of selection for the two units selected from the stratum.

If you specify the **JTPROBS** option to compute joint probabilities of selection for **METHOD=PPS** or **METHOD=PPS_SAMPFORD**, then the output data set contains the following variables:

- **Unit**, which is an identification variable that numbers the selected units sequentially within each stratum.
- **JtProb_1**, **JtProb_2**, **JtProb_3**, ..., where the variable **JtProb_1** contains the joint probability of selection for the current unit and unit 1. Similarly, **JtProb_2** contains the joint probability of selection for the current unit and unit 2, and so on.

If you specify the **JTPROBS** option for **METHOD=PPS_WR**, then the output data set contains the following variables:

- **Unit**, which is an identification variable that numbers the selected units sequentially within each stratum.
- **JtHits_1**, **JtHits_2**, **JtHits_3**, ..., where the variable **JtHits_1** contains the joint expected number of hits for the current unit and unit 1. Similarly, **JtHits_2** contains the joint expected number of hits for the current unit and unit 2, and so on.

If you specify the **OUTSIZE** option, the output data set contains the following variables. If you specify a **STRATA** statement, the output data set includes stratum-level values of these variables; otherwise, the output data set includes overall values.

- **MinimumSize**, which is the minimum size measure specified with the **MINSIZE=** option. This variable is included if you specify the **MINSIZE=** option.
- **MaximumSize**, which is the maximum size measure specified with the **MAXSIZE=** option. This variable is included if you specify the **MAXSIZE=** option.
- **CertaintySize**, which is the certainty size measure specified with the **CERTSIZE=** option. This variable is included if you specify the **CERTSIZE=** option.
- **CertaintyProp**, which is the certainty proportion specified with the **CERTSIZE=P=** option. This variable is included if you specify the **CERTSIZE=P=** option.
- **Total**, which is the total number of sampling units in the stratum. This variable is included if there is no **SIZE** statement, or if you specify a **SAMPLINGUNIT** statement.
- **TotalSize**, which is the total of size measures in the stratum. This variable is included if there is a **SIZE** statement, or if you specify the **PPS** option in the **SAMPLINGUNIT** statement.

- **TotalAdjSize**, which is the total of adjusted size measures in the stratum. This variable is included if you request adjusted sizes with the **MAXSIZE=** or **MINSIZE=** option.
- **SamplingRate**, which is the sampling rate. This variable is included if you specify the **SAMPRATE=** option.
- **SampleSize**, which is the sample size. This variable is included if you specify the **SAMPSIZE=** option, or if you specify **METHOD=PPS_BREWER** or **METHOD=PPS_MURTHY**, which selects two units from each stratum.

If you specify the **OUTSEED** option, the output data set contains the following variable:

- **InitialSeed**, which is the initial seed for the stratum.

If you specify the **ALLOC=** option in the **STRATA** statement, the output data set contains the following variables:

- **Total**, which is the total number of sampling units in the stratum.
- **Variance**, which is the stratum variance. This variable is included if you specify the **VAR**, **VAR=(values)**, or **VAR=SAS-data-set** option for the **ALLOC=OPTIMAL**, **ALLOC=NEYMAN**, or **MARGIN=** allocation option.
- **Cost**, which is the stratum cost. This variable is included if you specify the **COST**, **COST=(values)**, or **COST=SAS-data-set** option for **ALLOC=OPTIMAL**.
- **AllocProportion**, which is the target allocation proportion (the proportion of the total sample size to allocate to the stratum). PROC SURVEYSELECT computes this proportion by using the specified allocation method.
- **SampleSize**, which is the sample size allocated to the stratum.
- **ActualProportion**, which is the actual proportion allocated to the stratum. The value of **ActualProportion** equals the allocated stratum sample size divided by the total sample size. This value can differ from the target **AllocProportion** due to rounding and other restrictions. See the section “[Sample Size Allocation](#)” on page 8067 for details.

Allocation Output Data Set

When you specify the **NOSAMPLE** option in the **STRATA** statement, PROC SURVEYSELECT allocates the total sample size among the strata but does not select the sample. In this case, the **OUT=** data set contains the allocated sample sizes.

You can specify the name of the allocation output data set with the **OUT=** option in the PROC SURVEYSELECT statement. If you omit the **OUT=** option, the data set is named **DATA n** , where n is the smallest integer that makes the name unique.

The allocation output data set contains one observation for each stratum. The data set can include the following variables:

- STRATA variables, which you specify in the [STRATA](#) statement.
- Total, which is the total number of sampling units in the stratum.
- Variance, which is the stratum variance. This variable is included if you specify the [VAR](#), [VAR=\(values\)](#), or [VAR=SAS-data-set](#) option for the [ALLOC=OPTIMAL](#), [ALLOC=NEYMAN](#), or [MARGIN=](#) allocation option.
- Cost, which is the stratum cost. This variable is included if you specify the [COST](#), [COST=\(values\)](#), or [COST=SAS-data-set](#) option for [ALLOC=OPTIMAL](#).
- AllocProportion, which is the target allocation proportion (the proportion of the total sample size to allocate to the stratum). PROC SURVEYSELECT computes this proportion by using the specified allocation method.
- SampleSize, which is the sample size allocated to the stratum.
- ActualProportion, which is the actual proportion allocated to the stratum. The value of ActualProportion equals the allocated stratum sample size divided by the total sample size. This value can differ from the target AllocProportion due to rounding and other restrictions. See the section “[Sample Size Allocation](#)” on page 8067 for details.

Displayed Output

By default, PROC SURVEYSELECT displays two tables that summarize the sample selection: the “Sample Selection Method” table and the “Sample Selection Summary” table.

If you request sample allocation but no sample selection, PROC SURVEYSELECT displays two tables that summarize the allocation: the “Sample Allocation Method” table and the “Sample Allocation Summary” table.

You can suppress display of these tables by specifying the [NOPRINT](#) option.

PROC SURVEYSELECT creates an output data set that contains the units that are selected for the sample. Or if you request sample allocation but no sample selection, PROC SURVEYSELECT creates an output data set that contains the sample size allocation results. (See the sections “[Sample Output Data Set](#)” on page 8072 and “[Allocation Output Data Set](#)” on page 8075 for information about these output data sets.) The procedure does not display the output data set that it creates. Use PROC PRINT, PROC REPORT, or any other SAS reporting tool to display the output data set.

PROC SURVEYSELECT displays the following information in the “Sample Selection Method” table:

- Selection Method
- Sampling Unit Variables, if you specify a [SAMPLINGUNIT](#) statement
- Size Measure variable, if you specify a [SIZE](#) statement

- Size Measure: Number of Observations, if you specify the **PPS** option in the **SAMPLINGUNIT** statement and do not specify a **SIZE** statement
- Minimum Size Measure, if you specify the **MINSIZE=** option
- Maximum Size Measure, if you specify the **MAXSIZE=** option
- Certainty Size Measure, if you specify the **CERTSIZE=** option
- Certainty Proportion, if you specify the **CERTSIZE=P=** option
- Strata Variables, if you specify a **STRATA** statement
- Control Variables, if you specify a **CONTROL** statement
- Control Sorting (Serpentine or Nested), if you specify a **CONTROL** statement
- Allocation (Proportional, Neyman, Optimal, or Input), if you specify the **ALLOC=** option in the **STRATA** statement
- Margin of Error, if you specify the **MARGIN=** option in the **STRATA** statement
- Confidence Level, if you specify the **ALPHA=** option in the **STRATA** statement

PROC SURVEYSELECT displays the following information in the “Sample Selection Summary” table:

- Input Data Set name
- Sorted Data Set name, if you specify the **OUTSORT=** option
- Random Number Seed
- Sample Size or Stratum Sample Size, if you specify the **SAMPSIZE=*n*** option
- Sample Size Data Set, if you specify the **SAMPSIZE=SAS-data-set** option
- Sampling Rate or Stratum Sampling Rate, if you specify the **SAMPRATE=*r*** option for **METHOD=SRS**, **METHOD=URS**, **METHOD=SYS**, or **METHOD=SEQ**.
- Selection Probability or Stratum Selection Probability, if you specify the **SAMPRATE=*r*** option for **METHOD=BERNOULLI**
- Sampling Rate Data Set, if you specify the **SAMPRATE=SAS-data-set** option
- Minimum Sample Size or Stratum Minimum Sample Size, if you specify the **NMIN=** option with the **SAMPRATE=** option
- Maximum Sample Size or Stratum Maximum Sample Size, if you specify the **NMAX=** option with the **SAMPRATE=** option
- Allocation Input Data Set name, if you specify the **ALLOC=SAS-data-set** option in the **STRATA** statement
- Variance Input Data Set name, if you specify the **VAR=SAS-data-set** option in the **STRATA** statement

- Cost Input Data Set name, if you specify the `COST=SAS-data-set` option in the `STRATA` statement
- Selection Probability, if you specify `METHOD=SRS`, `METHOD=SYS`, or `METHOD=SEQ` and do not specify a `SIZE` statement or a `STRATA` statement
- Expected Number of Hits, if you specify `METHOD=URS` and do not specify a `STRATA` statement
- Total Number of Units, if you specify `METHOD=BERNOULLI` or `METHOD=POISSON` and do not specify a `STRATA` statement
- Expected Sample Size, if you specify `METHOD=BERNOULLI` or `METHOD=POISSON` and do not specify a `STRATA` statement
- Sample Size, if you specify `METHOD=BERNOULLI` or `METHOD=POISSON` and do not specify a `STRATA` statement
- Sampling Weight, if you specify an equal probability selection method (`METHOD=SRS`, `METHOD=URS`, `METHOD=SYS`, `METHOD=SEQ`, or `METHOD=BERNOULLI`) and do not specify a `STRATA` statement
- Adjusted Sampling Weight, if you specify `METHOD=BERNOULLI` and do not specify a `STRATA` statement
- Number of Strata, if you specify a `STRATA` statement
- Stratum Minimum Sample Size, if you specify the `ALLOCMIN=` option in the `STRATA` statement
- Number of Replicates, if you specify the `REPS=` option
- Total Sample Size, if you specify a `STRATA` statement or the `REPS=` option
- Expected Margin of Error, if you specify the `STATS` option with the `MARGIN=` option in the `STRATA` statement
- Expected Variance, if you specify the `STATS` option without the `MARGIN=` option in the `STRATA` statement for `ALLOC=OPTIMAL` or `ALLOC=NEYMAN`
- Total Stratum Costs, if you specify the `STATS` option with `ALLOC=OPTIMAL` in the `STRATA` statement
- Output Data Set name

If you specify the `NOSAMPLE` option in the `STRATA` statement, PROC SURVEYSELECT allocates the total sample among the strata but does not select the sample. When you specify the `NOSAMPLE` option, PROC SURVEYSELECT displays the “Sample Allocation Method” table and the “Sample Allocation Summary” table. The “Sample Allocation Method” table includes the following information:

- Allocation (Proportional, Neyman, Optimal, or Input)
- Margin of Error, if you specify the `MARGIN=` option in the `STRATA` statement
- Confidence Level, if you specify the `ALPHA=` option in the `STRATA` statement
- Sampling Unit Variables, if you specify a `SAMPLINGUNIT` statement

- Strata Variables
- Frequency Variable
- Selection Method, if you specify the **METHOD=** option

PROC SURVEYSELECT displays the following information in the “Sample Allocation Summary” table.

- Input Data Set name
- Allocation Input Data Set name, if you specify the **ALLOC=SAS-data-set** option in the **STRATA** statement
- Variance Input Data Set name, if you specify the **VAR=SAS-data-set** option in the **STRATA** statement
- Cost Input Data Set name, if you specify the **COST=SAS-data-set** option in the **STRATA** statement
- Number of Strata
- Stratum Minimum Sample Size, if you specify the **ALLOCMIN=** option in the **STRATA** statement
- Total Sample Size
- Expected Margin of Error, if you specify the **STATS** option with the **MARGIN=** option in the **STRATA** statement
- Expected Variance, if you specify the **STATS** option without the **MARGIN=** option in the **STRATA** statement for **ALLOC=OPTIMAL** or **ALLOC=NEYMAN**
- Total Stratum Costs, if you specify the **STATS** option with **ALLOC=OPTIMAL** in the **STRATA** statement
- Allocation Output Data Set name

ODS Table Names

PROC SURVEYSELECT assigns a name to each table that it creates. You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.” Table 95.4 lists the table names.

Table 95.4 ODS Tables Produced by PROC SURVEYSELECT

ODS Table Name	Description	Statement	Option
Method	Sample selection method	PROC	Default
Method	Sample allocation method	STRATA	NOSAMPLE
Summary	Sample selection summary	PROC	Default
Summary	Sample allocation summary	STRATA	NOSAMPLE

Examples: SURVEYSELECT Procedure

Example 95.1: Replicated Sampling

This example uses the Customers data set from the section “Getting Started: SURVEYSELECT Procedure” on page 8021. The data set Customers contains an Internet service provider’s current subscribers, and the service provider wants to select a sample from this population for a customer satisfaction survey.

This example illustrates replicated sampling, which selects multiple samples from the survey population according to the same design. You can use replicated sampling to provide a simple method of variance estimation, or to evaluate variable nonsampling errors such as interviewer differences. For information about replicated sampling, see Lohr (2010); Wolter (2007); Kish (1965, 1987); Kalton (1983).

This design includes four replicates, each with a sample size of 50 customers. The sampling frame is stratified by State and sorted by Type and Usage within strata. Customers are selected by sequential random sampling with equal probability within strata. The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set by using this design:

```
title1 'Customer Satisfaction Survey';
title2 'Replicated Sampling';
proc surveyselect data=Customers method=seq n=(8 12 20 10)
                  reps=4 seed=40070 ranuni out=SampleRep;
    strata State;
    control Type Usage;
run;
```

The STRATA statement names the stratification variable State. The CONTROL statement names the control variables Type and Usage.

In the PROC SURVEYSELECT statement, the METHOD=SEQ option requests sequential random sampling. The REPS= option specifies four replicates of this sample. The N=(8 12 20 10) option lists the stratum sample sizes for each replicate. The N= option lists the stratum sample sizes in the same order as the strata appear in the Customers data set, which has been sorted by State. The sample size of eight customers corresponds to the first stratum, State = ‘AL’. The sample size 12 corresponds to the next stratum, State = ‘FL’, and so on.

The SEED= option specifies 40070 as the initial seed for random number generation. The RANUNI option requests random number generation by the RANUNI generator, which PROC SURVEYSELECT used in releases prior to SAS/STAT 12.1. (Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default.) You can specify the RANUNI option with the SEED= option to reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1. To reproduce a sample by using the RANUNI and SEED= options, you must also specify the same input data set and sample selection parameters.

Output 95.1.1 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 200 customers is selected in four replicates. PROC SURVEYSELECT selects each replicate by using sequential random sampling within strata determined by State. The sampling frame Customers is sorted by the control variables Type and Usage within strata, according to hierarchic serpentine sorting. The output data set SampleRep contains the sample.

Output 95.1.1 Sample Selection Summary

Customer Satisfaction Survey	
Replicated Sampling	
The SURVEYSELECT Procedure	
Selection Method	Sequential Random Sampling With Equal Probability
Strata Variable	State
Control Variables	Type Usage
Control Sorting	Serpentine
Input Data Set	CUSTOMERS
Random Number Seed	40070
Number of Strata	4
Number of Replicates	4
Total Sample Size	200
Output Data Set	SAMPLEREP

The following PROC PRINT statements display the selected customers for the first stratum, State = 'AL', from the output data set SampleRep:

```

title1 'Customer Satisfaction Survey';
title2 'Sample Selected by Replicated Design';
title3 '(First Stratum)';
proc print data=SampleRep;
    where State = 'AL';
run;

```

Output 95.1.2 displays the 32 sample customers of the first stratum (State = 'AL') from the output data set SampleRep, which includes the entire sample of 200 customers. The variable SelectionProb contains the selection probability, and SamplingWeight contains the sampling weight. Because customers are selected with equal probability within strata in this design, all customers in the same stratum have the same selection probability. These selection probabilities and sampling weights apply to a single replicate, and the variable Replicate contains the sample replicate number.

Output 95.1.2 Customer Sample (First Stratum)

Customer Satisfaction Survey Sample Selected by Replicated Design (First Stratum)							
Obs	State	Replicate	CustomerID	Type	Usage	Selection Prob	Sampling Weight
1	AL	1	882-37-7496	New	572	.004115226	243

Example 95.2: PPS Selection of Two Units per Stratum

This example describes hospital selection for a survey by using PROC SURVEYSELECT. A state health agency plans to conduct a statewide survey of a variety of different hospital services. The agency plans to select a probability sample of individual discharge records within hospitals by using a two-stage sample design. First-stage units are hospitals, and second-stage units are patient discharges during the study period. Hospitals are stratified first according to geographic region and then by rural/urban type and size of hospital. Two hospitals are selected from each stratum with probability proportional to size.

The data set HospitalFrame contains all hospitals in the first geographical region of the state:

```
data HospitalFrame;
  input Hospital$ Type$ SizeMeasure @@;
  if (SizeMeasure < 20) then Size='Small ';
  else if (SizeMeasure < 50) then Size='Medium';
  else Size='Large ';
  datalines;
034 Rural  0.870   107 Rural  1.316
079 Rural  2.127   223 Rural  3.960
236 Rural  5.279   165 Rural  5.893
086 Rural  0.501   141 Rural 11.528
042 Urban  3.104   124 Urban  4.033
006 Urban  4.249   261 Urban  4.376
195 Urban  5.024   190 Urban 10.373
038 Urban 17.125   083 Urban 40.382
259 Urban 44.942   129 Urban 46.702
133 Urban 46.992   218 Urban 48.231
026 Urban 61.460   058 Urban 65.931
119 Urban 66.352
;
```

In the SAS data set HospitalFrame, the variable Hospital identifies the hospital. The variable Type equals 'Urban' if the hospital is located in an urban area, and 'Rural' otherwise. The variable SizeMeasure contains the hospital's size measure, which is constructed from past data on service utilization for the hospital together with the desired sampling rates for each service. This size measure reflects the amount of relevant survey information expected from the hospital. See Drummond et al. (1982) for details about this type of size measure. The variable Size equals 'Small', 'Medium', or 'Large', depending on the value of the hospital's size measure.

The following PROC PRINT statements display the data set Hospital Frame and produce [Output 95.2.1](#):

```
title1 'Hospital Utilization Survey';
title2 'Sampling Frame, Region 1';
proc print data=HospitalFrame;
run;
```

Output 95.2.1 Sampling Frame

Hospital Utilization Survey Sampling Frame, Region 1				
Obs	Hospital	Type	Size Measure	Size
1	034	Rural	0.870	Small
2	107	Rural	1.316	Small
3	079	Rural	2.127	Small
4	223	Rural	3.960	Small
5	236	Rural	5.279	Small
6	165	Rural	5.893	Small
7	086	Rural	0.501	Small
8	141	Rural	11.528	Small
9	042	Urban	3.104	Small
10	124	Urban	4.033	Small
11	006	Urban	4.249	Small
12	261	Urban	4.376	Small
13	195	Urban	5.024	Small
14	190	Urban	10.373	Small
15	038	Urban	17.125	Small
16	083	Urban	40.382	Medium
17	259	Urban	44.942	Medium
18	129	Urban	46.702	Medium
19	133	Urban	46.992	Medium
20	218	Urban	48.231	Medium
21	026	Urban	61.460	Large
22	058	Urban	65.931	Large
23	119	Urban	66.352	Large

The following PROC SURVEYSELECT statements select a probability sample of hospitals from the HospitalFrame data set by using a stratified design with PPS selection of two units from each stratum:

```

title1 'Hospital Utilization Survey';
title2 'Stratified PPS Sampling';
proc surveyselect data=HospitalFrame method=pps_brewer
                 seed=48702 out=SampleHospitals;
    size SizeMeasure;
    strata Type Size notsorted;
run;

```

The STRATA statement names the stratification variables Type and Size. The NOTSORTED option specifies that observations with the same STRATA variable values are grouped together but are not necessarily sorted in alphabetical or increasing numerical order. In the HospitalFrame data set, Size = 'Small' precedes Size = 'Medium'.

In the PROC SURVEYSELECT statement, the METHOD=PPS_BREWER option requests sample selection by Brewer's method, which selects two units per stratum with probability proportional to size. The SEED= option specifies 48702 as the initial seed for random number generation. The SIZE statement names SizeMeasure as the size measure variable. It is not necessary to specify the sample size with the N= option, because Brewer's method always selects two units from each stratum.

Output 95.2.2 displays the output from PROC SURVEYSELECT. A total of eight hospitals were selected from the four strata. The data set SampleHospitals contains the selected hospitals.

Output 95.2.2 Sample Selection Summary

Hospital Utilization Survey Stratified PPS Sampling	
The SURVEYSELECT Procedure	
Selection Method	Brewer's PPS Method
Size Measure	SizeMeasure
Strata Variables	Type Size
Input Data Set	HOSPITALFRAME
Random Number Seed	48702
Stratum Sample Size	2
Number of Strata	4
Total Sample Size	8
Output Data Set	SAMPLEHOSPITALS

The following PROC PRINT statements display the sample hospitals and produce Output 95.2.3:

```

title1 'Hospital Utilization Survey';
title2 'Sample Selected by Stratified PPS Design';
proc print data=SampleHospitals;
run;

```

Output 95.2.3 Sample Hospitals

Hospital Utilization Survey Sample Selected by Stratified PPS Design							
Obs	Type	Size	Hospital	Size Measure	Selection Prob	Sampling Weight	Jt Selection Prob

6	Urban	Medium	218	48.231	0.42448	2.35584	0.11211
7	Urban	Large	058	65.931	0.68060	1.46929	0.36555
8	Urban	Large	119	66.352	0.68495	1.45996	0.36555

The variable SelectionProb contains the selection probability for each hospital in the sample. The variable JtSelectionProb contains the joint probability of selection for the two sample hospitals in the same stratum. The variable SamplingWeight contains the sampling weight component for this first stage of the design. The final-stage weight components, which correspond to patient record selection within hospitals, can be multiplied by the hospital weight components to obtain the overall sampling weights.

Example 95.3: PPS (Dollar-Unit) Sampling

A small company wants to audit employee travel expenses in an effort to improve the expense reporting procedure and possibly reduce expenses. The company does not have resources to examine all expense reports and wants to use statistical sampling to objectively select expense reports for audit.

The data set `TravelExpense` contains the dollar amount of all employee travel expense transactions during the past month:

```
data TravelExpense;
  input ID$ Amount @@;
  if (Amount < 500) then Level='1_Low ';
  else if (Amount > 1500) then Level='3_High';
  else Level='2_Avg ';
  datalines;
110 237.18 002 567.89 234 118.50
743 74.38 411 1287.23 782 258.10
216 325.36 174 218.38 568 1670.80
302 134.71 285 2020.70 314 47.80
139 1183.45 775 330.54 425 780.10
506 895.80 239 620.10 011 420.18
672 979.66 142 810.25 738 670.85
192 314.58 243 87.50 263 1893.40
496 753.30 332 540.65 486 2580.35
614 230.56 654 185.60 308 688.43
784 505.14 017 205.48 162 650.42
289 1348.34 691 30.50 545 2214.80
517 940.35 382 217.85 024 142.90
478 806.90 107 560.72
;
```

In the SAS data set `TravelExpense`, the variable `ID` identifies the travel expense report. The variable `Amount` contains the dollar amount of the reported expense. The variable `Level` equals '1_Low', '2_Avg', or '3_High', depending on the value of `Amount`.

In the sample design for this audit, expense reports are stratified by `Level`. This ensures that each of these expense levels is included in the sample and also permits a disproportionate allocation of the sample, selecting proportionately more of the expense reports from the higher levels. Within strata, the sample of expense reports is selected with probability proportional to the amount of the expense, thus giving a greater chance of selection to larger expenses. In auditing terms, this is known as monetary-unit sampling. See Wilburn (1984) for details.

PROC SURVEYSELECT requires that the input data set be sorted by the STRATA variables. The following PROC SORT statements sort the `TravelExpense` data set by the stratification variable `Level`.

```
proc sort data=TravelExpense;
  by Level;
run;
```

Output 95.3.1 displays the sampling frame data set `TravelExpense`, which contains 41 observations.

Output 95.3.1 Sampling Frame

41	545	2214.80	3_High

The following PROC SURVEYSELECT statements select a probability sample of expense reports from the TravelExpense data set by using the stratified design with PPS selection within strata:

```

title1 'Travel Expense Audit';
title2 'Stratified PPS (Dollar-Unit) Sampling';
proc surveyselect data=TravelExpense method=pps n=(6 10 4)
                 seed=47279 out=AuditSample;
    size Amount;
    strata Level;
run;

```

The STRATA statement names the stratification variable Level. The SIZE statement specifies the size measure variable Amount. In the PROC SURVEYSELECT statement, the METHOD=PPS option requests sample selection with probability proportional to size and without replacement. The N=(6 10 4) option specifies the stratum sample sizes, listing the sample sizes in the same order as the strata appear in the TravelExpense data set. The sample size of 6 corresponds to the first stratum, Level = '1_Low'; the sample size of 10 corresponds to the second stratum, Level = '2_Avg'; and 4 corresponds to the last stratum, Level = '3_High'. The SEED= option specifies 47279 as the initial seed for random number generation.

Output 95.3.2 displays the output from PROC SURVEYSELECT. A total of 20 expense reports are selected for audit. The data set AuditSample contains the sample of travel expense reports.

Output 95.3.2 Sample Selection Summary

Example 95.4: Proportional Allocation

This example uses the Customers data set from the section “[Getting Started: SURVEYSELECT Procedure](#)” on page 8021. The data set Customers contains an Internet service provider’s current subscribers, and the service provider wants to select a sample from this population for a customer satisfaction survey. This example illustrates proportional allocation, which allocates the total sample size among the strata in proportion to the strata sizes.

The section “[Getting Started: SURVEYSELECT Procedure](#)” on page 8021 gives an example of stratified sampling, where the list of customers is stratified by State and Type. [Figure 95.4](#) displays the strata in a table of State by Type for the 13,471 customers. There are four states and two levels of Type, forming a total of eight strata. A sample of 15 customers was selected from each stratum by using the following PROC SURVEYSELECT statements:

```

title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers method=srs n=15
    seed=1953 out=SampleStrata;
    strata State Type;
run;

```

The STRATA statement names the stratification variables State and Type. In the PROC SURVEYSELECT statement, the N= option specifies a sample size of 15 customers for each stratum.

Instead of specifying the number of customers to select from each stratum, you can specify the total sample size and request allocation of the total sample size among the strata. The following PROC SURVEYSELECT statements request proportional allocation, which allocates the total sample size in proportion to the stratum sizes:

```
title1 'Customer Satisfaction Survey';
title2 'Proportional Allocation';
proc surveyselect data=Customers n=1000
                 out=SampleSizes;
    strata State Type / alloc=prop nosample;
run;
```

The STRATA statement names the stratification variables State and Type. In the STRATA statement, the ALLOC=PROP option requests proportional allocation. The NOSAMPLE option requests that no sample be selected after the procedure computes the sample size allocation. In the PROC SURVEYSELECT statement, the N= option specifies a total sample size of 1000 customers to be allocated among the strata.

[Output 95.4.1](#) displays the output from PROC SURVEYSELECT, which summarizes the sample allocation. The total sample size of 1000 is allocated among the eight strata by using proportional allocation. The allocated sample sizes are stored in the SAS data set SampleSizes.

Output 95.4.1 Proportional Allocation Summary

Customer Satisfaction Survey	
Proportional Allocation	
The SURVEYSELECT Procedure	
Allocation	Proportional
Strata Variables	State Type
Input Data Set	CUSTOMERS
Number of Strata	8
Total Sample Size	1000
Allocation Output Data Set	SAMPLESIZES

The following PROC PRINT statements display the allocation output data set SampleSizes, which is shown in [Output 95.4.2](#):

```
title1 'Customer Satisfaction Survey';
title2 'Proportional Allocation';
proc print data=SampleSizes;
run;
```

Output 95.4.2 Stratum Sample Sizes

Customer Satisfaction Survey Proportional Allocation						
Obs	State	Type	Total	Alloc Proportion	Sample Size	Actual Proportion
1	AL	New	1238	0.09190	92	0.092
2	AL	Old	706	0.05241	52	0.052
3	FL	New	2170	0.16109	161	0.161
4	FL	Old	1370	0.10170	102	0.102
5	GA	New	3488	0.25893	259	0.259
6	GA	Old	1940	0.14401	144	0.144
7	SC	New	1684	0.12501	125	0.125
8	SC	Old	875	0.06495	65	0.065

The output data set `SampleSizes` includes one observation for each of the eight strata, which are identified by the stratification variables `State` and `Type`. The variable `Total` contains the number of sampling units in the stratum, and the variable `AllocProportion` contains the proportion of the total sample size to allocate to the stratum. The variable `SampleSize` contains the allocated stratum sample size. For the first stratum (`State='AL'` and `Type='New'`), the total number of sampling units is 1238 customers, the allocation proportion is 0.09190, and the allocated sample size is 92 customers. The sum of the allocated sample sizes equals the requested total sample size of 1000 customers.

The output data set also includes the variable `ActualProportion`, which contains actual stratum proportions of the total sample size. The actual proportion for a stratum equals the stratum sample size divided by the total sample size. For the first stratum (`State='AL'` and `Type='New'`), the actual proportion is 0.092, while the allocation proportion is 0.09190. The target sample sizes computed from the allocation proportions are often not integers, and PROC SURVEYSELECT uses a rounding algorithm to obtain integer sample sizes and maintain the requested total sample size. Due to rounding and other restrictions, the actual proportions can differ from the target allocation proportions. See the section “[Sample Size Allocation](#)” on page 8067 for details.

If you want to use the allocated sample sizes in a later invocation of PROC SURVEYSELECT, you can name the allocation data set in the `N=SAS-data-set` option, as shown in the following PROC SURVEYSELECT statements:

```

title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers method=srs n=SampleSizes
    seed=1953 out=SampleStrata;
    strata State Type;
run;

```

Overview: TPSPLINE Procedure

The TPSPLINE procedure uses the penalized least squares method to fit a nonparametric regression model. It computes thin-plate smoothing splines to approximate smooth multivariate functions observed with noise. The TPSPLINE procedure allows great flexibility in the possible form of the regression surface. In particular, PROC TPSPLINE makes no assumptions of a parametric form for the model. The generalized cross validation (GCV) function can be used to select the amount of smoothing.

The TPSPLINE procedure complements the methods provided by the standard SAS regression procedures such as the GLM, REG, and NLIN procedures. These procedures can handle most situations in which you

specify the regression model and the model is known up to a fixed number of parameters. However, when you have no prior knowledge about the model, or when you know that the data cannot be represented by a model with a fixed number of parameters, you can use the TPSPLINE procedure to model the data.

The TPSPLINE procedure uses the penalized least squares method to fit the data with a flexible model in which the number of effective parameters can be as large as the number of unique design points. Hence, as the sample size increases, the model space also increases, enabling the thin-plate smoothing spline to fit more complicated situations.

The main features of the TPSPLINE procedure are as follows:

- provides penalized least squares estimates
- supports the use of multidimensional data
- supports multiple SCORE statements
- fits both semiparametric models and nonparametric models
- provides options for handling large data sets
- supports multiple dependent variables
- enables you to choose a particular model by specifying the model degrees of freedom or smoothing parameter
- produces graphs with ODS Graphics

Penalized Least Squares Estimation

Penalized least squares estimation provides a way to balance fitting the data closely and avoiding excessive roughness or rapid variation. A penalized least squares estimate is a surface that minimizes the penalized squared error over the class of all surfaces that satisfy sufficient regularity conditions.

Define \mathbf{x}_i as a d -dimensional covariate vector from an $n \times d$ matrix \mathbf{X} , \mathbf{z}_i as a p -dimensional covariate vector, and y_i as the observation associated with $(\mathbf{x}_i, \mathbf{z}_i)$. Assuming that the relation between \mathbf{z}_i and y_i is linear but the relation between \mathbf{x}_i and y_i is unknown, you can fit the data by using a semiparametric model as follows:

$$y_i = f(\mathbf{x}_i) + \mathbf{z}_i \boldsymbol{\beta} + \epsilon_i$$

where f is an unknown function that is assumed to be reasonably smooth, $\epsilon_i, i = 1, \dots, n$, are independent, zero-mean random errors, and $\boldsymbol{\beta}$ is a p -dimensional unknown parameter vector.

This model consists of two parts. The $\mathbf{z}_i \boldsymbol{\beta}$ is the parametric part of the model, and the \mathbf{z}_i are the regression variables. The $f(\mathbf{x}_i)$ is the nonparametric part of the model, and the \mathbf{x}_i are the smoothing variables. The ordinary least squares method estimates $f(\mathbf{x}_i)$ and $\boldsymbol{\beta}$ by minimizing the quantity:

$$\frac{1}{n} \sum_{i=1}^n (y_i - f(\mathbf{x}_i) - \mathbf{z}_i \boldsymbol{\beta})^2$$

However, the functional space of $f(\mathbf{x})$ is so large that you can always find a function f that interpolates the data points. In order to obtain an estimate that fits the data well and has some degree of smoothness, you can use the penalized least squares method.

The penalized least squares function is defined as

$$S_\lambda(f) = \frac{1}{n} \sum_{i=1}^n (y_i - f(\mathbf{x}_i) - \mathbf{z}_i \boldsymbol{\beta})^2 + \lambda J_2(f)$$

where $J_2(f)$ is the penalty on the roughness of f and is defined, in most cases, as the integral of the square of the second derivative of f .

The first term measures the goodness of fit and the second term measures the smoothness associated with f . The λ term is the smoothing parameter, which governs the tradeoff between smoothness and goodness of fit. When λ is large, it more heavily penalizes rougher fits. Conversely, a small value of λ puts more emphasis on the goodness of fit.

The estimate \hat{f}_λ is selected from a reproducing kernel Hilbert space, and it can be represented as a linear combination of a sequence of basis functions. Hence, the final estimates of f can be written as

$$\hat{f}_\lambda(\mathbf{x}_i) = \theta_0 + \sum_{j=1}^d \theta_j \mathbf{x}_{i,j} + \sum_{j=1}^p \delta_j B_j(\mathbf{x}_j)$$

where B_j is the basis function, which depends on where the data \mathbf{x}_i are located, and $\boldsymbol{\theta} = \{\theta_0, \dots, \theta_d\}$ and $\boldsymbol{\delta} = \{\delta_1, \dots, \delta_p\}$ are the coefficients that need to be estimated.

For a fixed λ , the coefficients $(\boldsymbol{\theta}, \boldsymbol{\delta}, \boldsymbol{\beta})$ can be estimated by solving an $n \times n$ system.

The smoothing parameter can be chosen by minimizing the generalized cross validation (GCV) function.

If you write

$$\hat{\mathbf{y}} = \mathbf{A}(\lambda) \mathbf{y}$$

then $\mathbf{A}(\lambda)$ is referred to as the *hat* or *smoothing* matrix, and the GCV function $\text{GCV}(\lambda)$ is defined as

$$\text{GCV}(\lambda) = \frac{(1/n) \|(\mathbf{I} - \mathbf{A}(\lambda)) \mathbf{y}\|^2}{[(1/n) \text{tr}(\mathbf{I} - \mathbf{A}(\lambda))]^2}$$

PROC TPSPLINE with Large Data Sets

The calculation of the penalized least squares estimate is computationally intensive. The amount of memory and CPU time needed for the analysis depends on the number of unique design points, which corresponds to the number of unknown parameters to be estimated.

You can specify the **D=** option in the MODEL statement to reduce the number of unknown parameters. The option groups design points by the specified range (see the **D=** option on page 8114).

PROC TPSPLINE selects one design point from the group and treats all observations in the group as replicates of that design point. Calculation of the thin-plate smoothing spline estimates is based on the reprocessed data. The way to choose the design point from a group depends on the order of the data. Hence, different orders of input data might result in different estimates.

By combining several design points into one, this option reduces the number of unique design points, thereby approximating the original data. The value you specify for the **D=** option determines the width of the range used to group the data.

Getting Started: TPSPLINE Procedure

The following example demonstrates how you can use the TPSPLINE procedure to fit a semiparametric model.

Suppose that *y* is a continuous variable and *x1* and *x2* are two explanatory variables of interest. To fit a bivariate thin-plate spline model, you can use a MODEL statement similar to that used in many regression procedures in the SAS System:

```
proc tpspline;  
  model y = (x1 x2);  
run;
```

The TPSPLINE procedure can fit semiparametric models; the parentheses in the preceding MODEL statement separate the smoothing variables from the regression variables. The following statements illustrate this syntax:

```
proc tpspline;  
  model y = z1 (x1 x2);  
run;
```

This model assumes a linear relation with *z1* and an unknown functional relation with *x1* and *x2*.

If you want to fit several responses by using the same explanatory variables, you can save computation time by using the multiple responses feature in the MODEL statement. For example, if *y1* and *y2* are two response variables, the following MODEL statement can be used to fit two models. Separate analyses are then performed for each response variable.

```
proc tpspline;
  model y1 y2 = (x1 x2);
run;
```

The following example illustrates the use of PROC TPSPLINE. The data are from Bates et al. (1987).

```

The data set Measure contains three variables x1, x2, and y. Suppose that you want to fit a surface by using the variables x1 and x2 to model the response y. The variables x1 and x2 are spaced evenly on a $[-1 \times 1] \times [-1 \times 1]$ square, and the response y is generated by adding a random error to a function $f(x_1, x_2)$. The raw data are plotted in three-dimensional scatter plot by using the G3D procedure. In order to visualize those replicates, half of the data are shifted a little bit by adding a small value (0.001) to x1 values, as in the following statements:

```
data Measure1;
  set Measure;
run;

proc sort data=Measure1;
  by x2 x1;
run;
```

```

data Measure1;
  set Measure1;
  if mod(_N_, 2) = 0 then x1=x1+0.001;
run;

proc g3d data=Measure1;
  scatter x2*x1=y /size=.5
          zmin=9 zmax=21
          zticknum=4;
  title "Raw Data";
run;

```

Figure 96.1 displays the raw data.

Figure 96.1 Plot of Data Set MEASURE

The following statements invoke the TPSPLINE procedure, to analyze the Measure data set as input. In the MODEL statement, the x1 and x2 variables are listed as smoothing variables. The LOGNLAMBDA= option specifies that PROC TPSPLINE examine a list of models with $\log_{10}(n\lambda)$ ranging from -4 to -2.5. The OUTPUT statement creates the data set estimate to contain the predicted values and the 95% upper and lower confidence limits from the best model selected by the GCV criterion.

```
ods graphics on;
proc tpspline data=Measure;
  model y=(x1 x2) /lognlambda=(-4 to -2.5 by 0.1);
  output out=estimate pred uclm lclm;
run;

proc print data=estimate;
run;
```

When ODS Graphics is enabled, PROC TPSPLINE produces several default plots. One of the default plots is the contour plot of the fitted surface, shown in Figure 96.2. The surface exhibits nonlinear patterns along the directions of both predictors.

Figure 96.2 Fitted Surface from PROC TPSPLINE

Figure 96.3 shows the “Criterion Plot” that provides a graphical display of the GCV selection process. Three sets of values are shown in the plot: the specified smoothing values and their GCV values, the examined smoothing values and their GCV values during the optimization process, and the best smoothing parameter and its GCV value. The final thin-plate smoothing spline estimate is based on $\log_{10}(n\lambda) = -3.4762$, which minimizes the GCV.

Figure 96.3 The GCV Criterion by $\log_{10}(n\lambda)$

Figure 96.4 shows that the data set Measure contains 50 observations with 25 unique design points. The final model contains no parametric regression terms and two smoothing variables. The order of the derivative in the penalty is 2 by default, and the dimension of polynomial space is 3. See the section “Computational Formulas” on page 8117 for definitions.

Figure 96.4 also lists the GCV values along with the supplied values of $\log_{10}(n\lambda)$. The value that minimizes the GCV function is -3.5 among the given list of $\log_{10}(n\lambda)$.

The residual sum of squares from the fitted model is 0.246110, and the model degrees of freedom are 24.593203. The standard deviation, defined as $\text{RSS}/(\text{tr}(\mathbf{I} - \mathbf{A}))$, is 0.098421. The predictions and 95% confidence limits are displayed in Figure 96.5.

50	1.0	1.0	15.9014	15.8761	15.7402	16.0120

You can also use the `TEMPLATE` and `SGRENDER` procedures to create a perspective plot for visualizing the fitted surface. Because the data in the data set `Measure` are very sparse, the fitted surface is not smooth. To produce a smoother surface, the following statements generate the data set `pred` in order to obtain a finer grid. The `LOGNLAMBDA0=` option requests that `PROC TPSPLINE` fit a model with a fixed $\log_{10}(n\lambda)$ value of -3.4762 . The `SCORE` statement evaluates the fitted surface at those new design points.

```
data pred;
  do x1=-1 to 1 by 0.1;
    do x2=-1 to 1 by 0.1;
      output;
    end;
  end;
run;

proc tpspline data=measure;
  model y=(x1 x2)/lognlambda0=-3.4762;
  score data=pred out=predy;
run;

proc template;
  define statgraph surface;
    dynamic _X _Y _Z _T;
    begingraph /designheight=360;
      entrytitle _T;
      layout overlay3d/rotate=120 cube=false xaxisopts=(label="x1")
        yaxisopts=(label="x2") zaxisopts=(label="P_y");
        surfaceplotparm x=_X y=_Y z=_Z;
      endlayout;
    endgraph;
  end;
run;

proc sgrender data=predy template=surface;
  dynamic _X='x1' _Y='x2' _Z='P_y'
    _T='Plot of Fitted Surface on a Fine Grid';
run;
```

The surface plot based on the finer grid is displayed in [Figure 96.6](#). The plot indicates that a parametric model with quadratic terms of x_1 and x_2 provides a reasonable fit to the data.

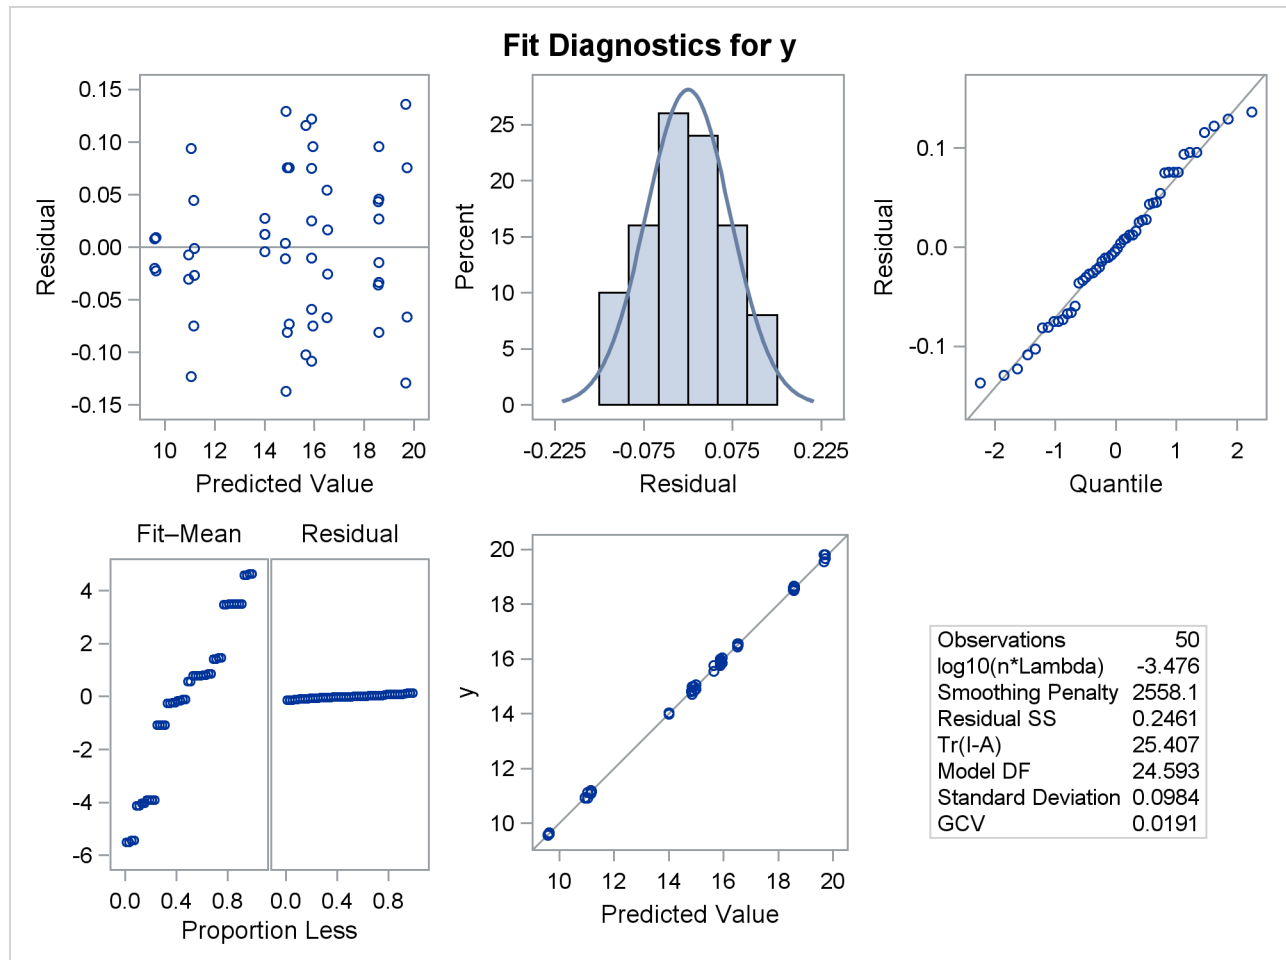

Figure 96.6 Plot of TPSPLINE Fit

[Figure 96.7](#) shows a panel of fit diagnostics for the selected model that indicate a reasonable fit:

- The predicted values closely approximate the observed values.
- The residuals are approximately normally distributed and do not show obvious systematic patterns.
- The [RFPLOT](#) shows that much variation in the response variable is addressed by the fit and only a little remains in the residuals.

Figure 96.7 Fit Diagnostics

Syntax: TPSPLINE Procedure

The following statements are available in the TPSPLINE procedure:

```

PROC TPSPLINE < options > ;
  MODEL dependents = < variables > (variables) < / options > ;
  SCORE DATA=SAS-data-set OUT=SAS-data-set < keyword ... keyword > ;
  OUTPUT < OUT=SAS-data-set > keyword ... keyword ;
  BY variables ;
  FREQ variable ;
  ID variables ;

```

The syntax in PROC TPSPLINE is similar to that of other regression procedures in the SAS System. The PROC TPSPLINE and MODEL statements are required. The SCORE statement can appear multiple times; all other statements appear no more than once.

The statements available for PROC TPSPLINE are described in alphabetical order after the description of the PROC TPSPLINE statement.

PROC TPSPLINE Statement

PROC TPSPLINE < options > ;

The PROC TPSPLINE statement invokes the TPSPLINE procedure. [Table 96.1](#) summarizes the options available in the TPSPLINE statement.

Table 96.1 PROC TPSPLINE Statement Options

Option	Description
DATA=	Specifies the SAS data set to be read
PLOTS	Controls the plots that are produced through ODS Graphics

You can specify the following options:

DATA=SAS-data-set

specifies the SAS data set to be read by PROC TPSPLINE. The default value is the most recently created data set.

PLOTS < (global-plot-options) > < = plot-request < (options) > >

PLOTS < (global-plot-options) > < = (plot-request < (options) > < ... plot-request < (options) > > >

controls the plots that are produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=residuals(smooth)
plots(unpack)=diagnostics
plots(only)=(fit residualHistogram)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc tpspline;
  model y = (x);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC TPSPLINE produces a default set of plots. The following table lists the plots that are produced.

Table 96.2 Graphs Produced

Plot	Conditional on:
ContourFitPanel	LAMBDA= or LOGNLAMBDA= option specified in the MODEL statement
ContourFit	Model with two predictors

Table 96.2 *continued*

Plot	Conditional On
CriterionPlot	Multiple values for the smoothing parameter
DiagnosticsPanel	Unconditional
ResidualBySmooth	LAMBDA= or LOGNLAMBDA= option specified in the MODEL statement
ResidualPanel	Unconditional
FitPanel	LAMBDA= or LOGNLAMBDA= option specified in the MODEL statement
FitPlot	Model with one predictor
ScorePlot	One or more SCORE statements and a model with one predictor

For models with multiple dependent variables, separate plots are produced for each dependent variable. For models in which multiple smoothing parameters are specified with the LAMBDA= or LOGNLAMBDA= option in the MODEL statement, the plots are produced for the selected model only.

Global Plot Options

The *global-plot-options* apply to all relevant plots generated by the TPSPLINE procedure, unless they are overridden by a *specific-plot-option*. The following *global-plot-options* are supported by the TPSPLINE procedure:

ONLY

suppresses the default plots. Only the plots specifically requested are produced.

UNPACK

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACK to get each plot individually. You can specify PLOTS(UNPACK) to unpack the default plots. You can also specify UNPACK as a suboption with the CONTOURFITPANEL, DIAGNOSTICS, FITPANEL, RESIDUALS and RESIDUALSBYSMOOTH options.

Plot Requests

You can specify the following specific *plot-requests* and controls for them:

ALL

produces all plots appropriate for the particular analysis. You can specify other options with ALL; for example, to request that all plots be produced and that only the residual plots be unpacked, specify PLOTS=(ALL RESIDUALS(UNPACK)).

CONTOURFIT <(OBS=*contour-options*)>

produces a contour plot of the fitted surface overlaid with a scatter plot of the data for models with two predictors. You can use the following *contour-options* to control how the observations are displayed:

GRADIENT

displays observations as circles colored by the observed response. The same color gradient is used to display the fitted surface and the observations. Observations where the predicted response is close to the observed response have similar colors—the greater the contrast between the color of an observation and the surface, the larger the residual is at that point. OBS=GRADIENT is the default if you do not specify any *contour-options*.

NONE

suppresses the observations.

OUTLINE

displays observations as circles with a border but with a completely transparent fill.

OUTLINEGRADIENT

is the same as `OBS=GRADIENT` except that a border is shown around each observation. This option is useful for identifying the location of observations where the residuals are small, because at these points the color of the observations and the color of the surface are indistinguishable.

CONTOURFITPANEL <(options)>

produces panels of contour plots overlaid with a scatter plot of the data for each smoothing parameter specified in the `LAMBDA=` or `LOGNLAMBDA=` option in the MODEL statement, for models with two predictors. If you do not specify the `LAMBDA=` or `LOGNLAMBDA=` option or if the model does not have two predictors, then this plot is not produced. Each panel contains at most six plots, and multiple panels are used when there are more than six smoothing parameters in the `LAMBDA=` or `LOGNLAMBDA=` option. The following *options* are available:

OBS=contour-options

specifies how the observations are displayed. See *contour-options* for the CONTOURFIT option for details.

UNPACK

suppresses paneling.

CRITERIONPLOT | CRITERION <(NOPATH)>

displays a scatter plot of the value of the GCV criterion versus the smoothing parameter value for all smoothing parameter values examined in the selection process. This plot is not produced when you specify one smoothing parameter with either the `LAMBDA0=` or `LOGNLAMBDA0=` option in the MODEL statement. When you supply a list of values for the smoothing parameter with the `LAMBDA=` or `LOGNLAMBDA=` option and PROC TPSPLINE obtains the optimal smoothing parameter by minimizing the GCV criterion, then the plot contains the supplied list of smoothing values and the optimal smoothing parameter in addition to the values examined during the optimization process. You can use the NOPATH suboption to disable the display of the optimization path in the plot in this case.

DIAGNOSTICSPANEL | DIAGNOSTICS <(UNPACK)>

produces a summary panel of fit diagnostics that consists of the following:

- residuals versus the predicted values
- a histogram of the residuals
- a normal quantile plot of the residuals
- a “Residual-Fit” (RF) plot that consists of side-by-side quantile plots of the centered fit and the residuals
- response values versus the predicted values

You can request the five plots in this panel as individual plots by specifying the UNPACK option. You can also request individual plots in the panel by name without having to unpack the panel. The fit diagnostics panel is produced by default whenever ODS Graphics is enabled.

FITPANEL <(options)>

produces panels of plots that show the fitted TPSPLINE curve overlaid on a scatter plot of the input data for each smoothing parameter specified in the **LAMBDA=** or **LOGNLAMBDA=** option in the MODEL statement. If you do not specify the **LAMBDA=** or **LOGNLAMBDA=** option or the model has more than one predictor, then this plot is not produced. Each panel contains at most six plots, and multiple panels are used when there are more than six smoothing parameters in the **LAMBDA=** or **LOGNLAMBDA=** option. The following *options* are available:

CLM

includes a confidence band at the significance level specified in the **ALPHA=** option in the MODEL statement in each plot in the panels.

UNPACK

suppresses paneling.

FITPLOT | FIT <(CLM)>

produces a scatter plot of the input data with the fitted TPSPLINE curve overlaid for models with a single predictor. If the CLM option is specified, then a confidence band at the significance level specified in the **ALPHA=** option in the MODEL statement is included in the plot.

NONE

suppresses all plots.

OBSERVEDBYPREDICTED

produces a scatter plot of the dependent variable values by the predicted values.

QQPLOT | QQ

produces a normal quantile plot of the residuals.

RESIDUALBYSMOOTH <(SMOOTH)>

produces, for each predictor, panels of plots that show the residuals of the TPSPLINE fit versus the predictor for each smoothing parameter specified in the **LAMBDA=** or **LOGNLAMBDA=** option in the MODEL statement. If you do not specify the **LAMBDA=** or **LOGNLAMBDA=** option, then this plot is not produced. Each panel contains at most six plots, and multiple panels are used when there are more than six smoothing parameters in the **LAMBDA=** or **LOGNLAMBDA=** option in the MODEL statement. The **SMOOTH** option displays a nonparametric fit line in each plot in the panel. The type of nonparametric fit and the options used are controlled by the underlying template for this plot. In the standard template that is provided, the nonparametric smooth is specified to be a loess fit that corresponds to the default options of PROC LOESS, except that the **PRESEARCH** suboption in the **SELECT** statement is always used. It is important to note that the loess fit that is shown in each of the residual plots is computed independently of the smoothing spline fit that is used to obtain the residuals.

RESIDUALBYPREDICTED

produces a scatter plot of the residuals by the predicted values.

RESIDUALHISTOGRAM

produces a histogram of the residuals.

RESIDUALPANEL | RESIDUALS <(options)>

produces panels of the residuals versus the predictors in the model. Each panel contains at most six plots, and multiple panels are used when there are more than six predictors in the model.

The following *options* are available:

SMOOTH

displays a nonparametric fit line in each plot in the panel. The type of nonparametric fit and the options used are controlled by the underlying template for this plot. In the standard template that is provided, the nonparametric smooth is specified to be a loess fit that corresponds to the default options of PROC LOESS, except that the PRESEARCH suboption in the SELECT statement is always used. It is important to note that the loess fit that is shown in each of the residual plots is computed independently of the smoothing spline fit that is used to obtain the residuals.

UNPACK

suppresses paneling.

RFPLOT | RF

produces a “Residual-Fit” (RF) plot that consists of side-by-side quantile plots of the centered fit and the residuals. This plot “shows how much variation in the data is explained by the fit and how much remains in the residuals” (Cleveland 1993).

SCOREPLOT | SCORE

produces a scatter plot of the scored values at the score points for each **SCORE** statement. **SCORE** plots are not produced for models with more than one predictor.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC TPSPLINE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the TPSPLINE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

If one variable in your input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC TPSPLINE treats the data as if each observation appears n times, where n is the value of the FREQ variable for the observation. If the value of the FREQ variable is less than one, the observation is not used in the analysis. Only the integer portion of the value is used.

ID Statement

ID *variables* ;

The ID statement is optional, and more than one ID statement can be used. If variables are specified in the ID statement, their values are displayed in tooltips to identify observations in the plots produced by PROC TPSPLINE.

MODEL Statement

MODEL *dependent-variables* = < *regression-variables* > (*smoothing-variables*) < / *options* > ;

The MODEL statement specifies the dependent variables, the independent regression variables, which are listed with no parentheses, and the independent smoothing variables, which are listed inside parentheses.

The regression variables are optional. At least one smoothing variable is required, and it must be listed after the regression variables. No variables can be listed in both the regression variable list and the smoothing variable list.

If you specify more than one dependent variable, PROC TPSPLINE calculates a thin-plate smoothing spline estimate for each dependent variable by using the regression variables and smoothing variables specified on the right side.

If you specify regression variables, PROC TPSPLINE fits a semiparametric model by using the regression variables as the linear part of the model.

Table 96.3 summarizes the options available in the MODEL statement.

Table 96.3 MODEL Statement Options

Option	Description
ALPHA=	Specifies the significance level
DF=	Specifies the degrees of freedom
DISTANCE=	Defines a range in which points are treated as replicates
LAMBDA0=	Specifies the smoothing parameter
LAMBDA=	Specifies a set of values for the λ parameter
LOGNLAMBDA0=	Specifies the smoothing parameter on the $\log_{10}(n\lambda)$ scale
LOGNLAMBDA=	Specifies a set of values for the λ parameter on the $\log_{10}(n\lambda)$ scale
M=	Specifies the order of the derivative
RANGE=	Specifies the range for smoothing values to be evaluated

You can specify the following options in the MODEL statement:

ALPHA=number

specifies the significance level α of the confidence limits on the final thin-plate smoothing spline estimate when you request confidence limits to be included in the output data set. Specify *number* as a value between 0 and 1. The default value is 0.05. See the section “[OUTPUT Statement](#)” on page 8116 for more information about the OUTPUT statement.

DF=df

specifies the degrees of freedom of the thin-plate smoothing spline estimate, defined as

$$df = \text{tr}(\mathbf{A}(\lambda))$$

where $\mathbf{A}(\lambda)$ is the *hat* matrix. Specify *df* as a value between zero and the number of unique design points n_q . Smaller *df* values cause more penalty on the roughness and thus smoother fits.

DISTANCE=number

D=number

defines a range such that if the L_∞ distance between two data points $(\mathbf{x}_i, \mathbf{z}_i)$ and $(\mathbf{x}_j, \mathbf{z}_j)$ satisfies

$$\|\mathbf{x}_i - \mathbf{x}_j\|_\infty \leq D/2$$

then these data points are treated as replicates, where \mathbf{x}_i are the smoothing variables and \mathbf{z}_i are the regression variables.

You can use the DISTANCE= option to reduce the number of unique design points by treating nearby data as replicates. This can be useful when you have a large data set. Larger DISTANCE= option values cause fewer n_q points. The default value is 0.

PROC TPSPLINE uses the DISTANCE= value to group points as follows: The data are first sorted by the smoothing variables in the order in which they appear in the MODEL statement. The first point in the sorted data becomes the first unique point. Subsequent points have their values set equal to that point until the first point where the maximum distance in one dimension is larger than $D/2$. This point becomes the next unique point, and so on. Because of this sequential processing, the set of unique points differs depending on the order of the smoothing variables in the MODEL statement.

For example, with a model that has two smoothing variables (x_1 , x_2), the data are first sorted by x_1 and x_2 (in that order), and then uniqueness is assessed sequentially. The first point in the sorted data $\mathbf{x}_1 = (x_{11}, x_{21})$ becomes the first unique point, $\mathbf{u}_1 = (u_{11}, u_{21})$. Subsequent points $\mathbf{x}_i = (x_{1i}, x_{2i})$ are set equal to \mathbf{u}_1 until the algorithm comes to a point with $\max(|x_{1i} - u_{11}|, |x_{2i} - u_{21}|) > D/2$. This point becomes the second unique point \mathbf{u}_2 , and data sorting proceeds from there.

LAMBDA0=number

specifies the smoothing parameter, λ_0 , to be used in the thin-plate smoothing spline estimate. By default, PROC TPSPLINE uses the λ parameter that minimizes the GCV function for the final fit. The LAMBDA0= value must be positive. Larger λ_0 values cause smoother fits.

LAMBDA=list-of-values

specifies a set of values for the λ parameter. PROC TPSPLINE returns a GCV value for each λ point that you specify. You can use the LAMBDA= option to study the GCV function curve for a set of values for λ . All values listed in the LAMBDA= option must be positive.

LOGNLAMBDA0=number

LOGNL0=number

specifies the smoothing parameter λ_0 on the $\log_{10}(n\lambda)$ scale. If you specify both the LOGNL0= and LAMBDA0= options, only the value provided by the LOGNL0= option is used. Larger $\log_{10}(n\lambda_0)$ values cause smoother fits. By default, PROC TPSPLINE uses the λ parameter that minimizes the GCV function for the estimate.

LOGNLAMBDA=list-of-values

LOGNL=list-of-values

specifies a set of values for the λ parameter on the $\log_{10}(n\lambda)$ scale. PROC TPSPLINE returns a GCV value for each λ point that you specify. You can use the LOGNLAMBDA= option to study the GCV function curve for a set of λ values. If you specify both the LOGNL= and LAMBDA= options, only the list of values provided by the LOGNL= option is used.

In some cases, the LOGNL= option might be preferred over the LAMBDA= option. Because the LAMBDA= value must be positive, a small change in that value can result in a major change in the GCV value. If you instead specify λ on the $\log_{10}(n\lambda)$ scale, the allowable range is enlarged to include negative values. Thus, the GCV function is less sensitive to changes in LOGNLAMBDA.

The DF= option, LAMBDA0= option, and LOGNLAMBDA0= option all specify exact smoothness of a nonparametric fit. If you want to fit a model with specified smoothness, the DF= option is preferable to the other two options because $(0, n_q)$, the range of df, is much smaller in length than $(0, \infty)$ of λ and $(-\infty, \infty)$ of $\log_{10}(n\lambda)$.

M=number

specifies the order of the derivative in the penalty term. The *number* must be a positive integer. The default value is $\max(2, \text{int}(d/2) + 1)$, where d is the number of smoothing variables.

RANGE=(lower, upper)

specifies that on the $\log_{10}(n\lambda)$ scale only smoothing values greater than or equal to *lower* and less than or equal to *upper* be evaluated to minimize the GCV function.

OUTPUT Statement

OUTPUT **OUT**=SAS-data-set < keyword ... keyword > ;

The OUTPUT statement creates a new SAS data set that contains diagnostic measures calculated after fitting the model.

All the variables in the original data set are included in the new data set, along with variables created by specifying *keywords* in the OUTPUT statement. These new variables contain the values of a variety of statistics and diagnostic measures that are calculated for each observation in the data set. If no *keyword* is present, the data set contains only the original data set and predicted values.

Details about the specifications in the OUTPUT statement are as follows.

OUT=SAS-data-set

specifies the name of the new data set to contain the diagnostic measures. This specification is required.

keyword

specifies the statistics to include in the output data set. The names of the new variables that contain the statistics are formed by using a prefix of one or more characters to identify the statistic, followed by an underscore (_), followed by the dependent variable name.

For example, suppose that you have two dependent variables—say, *y1* and *y2*—and you specify the keywords PRED, ADIAG, and UCLM. The output SAS data set will contain the following variables:

- P_y1 and P_y2
- ADIAG_y1 and ADIAG_y2
- UCLM_y1 and UCLM_y2

The keywords and the statistics they represent are as follows:

RESID R	residual values, calculated as fitted values subtracted from the observed response values: $y - \hat{y}$. The default prefix is R_.
PRED	predicted values. The default prefix is P_.
STD	standard error of the mean predicted value. The default prefix is STD_.
UCLM	upper limit of the Bayesian confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits. The default prefix is UCLM_.
LCLM	lower limit of the Bayesian confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits. The default prefix is LCLM_.
ADIAG	diagonal element of the hat matrix associated with the observation. The default prefix is ADIAG_.
COEF	coefficients arranged in the order of $(\theta_0, \theta_1, \dots, \theta_d, \delta_1, \dots, \delta_{n_q})$, where n_q is the number of unique data points. This option can be used only when there is only one dependent variable in the model. The default prefix is COEF_.

SCORE Statement

SCORE DATA=SAS-data-set OUT=SAS-data-set < keyword ... keyword > ;

The SCORE statement calculates predicted statistics for a new data set. If you have multiple data sets to predict, you can specify multiple SCORE statements. You must use a SCORE statement for each data set.

You can request diagnostic measures that are calculated for each observation in the SCORE data set. The new data set contains all the variables in the SCORE data set in addition to the requested variables. If no *keyword* is present, the data set contains only the predicted values.

The following keywords must be specified in the SCORE statement:

DATA=SAS-data-set

specifies the input SAS data set that contains the smoothing variables *x* and regression variables *z*. The predicted response (\hat{y}) value is computed for each (*x*, *z*) pair. The data set must include all independent variables specified in the MODEL statement.

OUT=SAS-data-set

specifies the name of the SAS data set to contain the predictions.

keyword

specifies the statistics to include in the output data set for the current SCORE statement. The names of the new variables that contain the statistics are formed by using a prefix of one or more characters to identify the statistic, followed by an underscore (_), followed by the dependent variable name. The keywords and the statistics they represent are as follows:

PRED	predicted values
STD	standard error of the mean predicted value
UCLM	upper limit of the Bayesian confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits.
LCLM	lower limit of the Bayesian confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits.

Details: TPSPLINE Procedure

Computational Formulas

The theoretical foundations for the thin-plate smoothing spline are described in Duchon (1976, 1977) and Meinguet (1979). Further results and applications are given in: Wahba and Wendelberger (1980); Hutchinson and Bischof (1983); Seaman and Hutchinson (1985).

Suppose that \mathcal{H}_m is a space of functions whose partial derivatives of total order *m* are in $L_2(E^d)$, where E^d is the domain of *x*.

Now, consider the data model

$$y_i = f(\mathbf{x}_i) + \epsilon_i, i = 1, \dots, n$$

where $f \in \mathcal{H}_m$.

Using the notation from the section “[Penalized Least Squares Estimation](#)” on page 8096, for a fixed λ , estimate f by minimizing the penalized least squares function

$$\frac{1}{n} \sum_{i=1}^n (y_i - f(\mathbf{x}_i) - \mathbf{z}_i \boldsymbol{\beta})^2 + \lambda J_m(f)$$

$\lambda J_m(f)$ is the penalty term to enforce smoothness on f . There are several ways to define $J_m(f)$. For the thin-plate smoothing spline, with $\mathbf{x} = (x_1, \dots, x_d)$ of dimension d , define $J_m(f)$ as

$$J_m(f) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \sum \frac{m!}{\alpha_1! \cdots \alpha_d!} \left(\frac{\partial^m f}{\partial x_1^{\alpha_1} \cdots \partial x_d^{\alpha_d}} \right)^2 dx_1 \cdots dx_d$$

where $\sum_i \alpha_i = m$. Under this definition, $J_m(f)$ gives zero penalty to some functions. The space that is spanned by the set of polynomials that contribute zero penalty is called the polynomial space. The dimension of the polynomial space M is a function of dimension d and order m of the smoothing penalty, $M = \binom{m+d-1}{d}$.

Given the condition that $2m > d$, the function that minimizes the penalized least squares criterion has the form

$$\hat{f}(\mathbf{x}) = \sum_{j=1}^M \theta_j \phi_j(\mathbf{x}) + \sum_{i=1}^n \delta_i \eta_{md}(\|\mathbf{x} - \mathbf{x}_i\|)$$

where $\boldsymbol{\theta}$ and $\boldsymbol{\delta}$ are vectors of coefficients to be estimated. The M functions ϕ_j are linearly independent polynomials that span the space of functions for which $J_m(f)$ is zero. The basis functions η_{md} are defined as

$$\eta_{md}(r) = \begin{cases} \frac{(-1)^{m+1+d/2}}{2^{2m-1} \pi^{d/2} (m-1)! (m-d/2)!} r^{2m-d} \log(r) & \text{if } d \text{ is even} \\ \frac{\Gamma(d/2-m)}{2^{2m} \pi^{d/2} (m-1)!} r^{2m-d} & \text{if } d \text{ is odd} \end{cases}$$

When $d = 2$ and $m = 2$, then $M = \binom{3}{2} = 3$, $\phi_1(\mathbf{x}) = 1$, $\phi_2(\mathbf{x}) = x_1$, and $\phi_3(\mathbf{x}) = x_2$. $J_m(f)$ is as follows:

$$J_2(f) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left(\left(\frac{\partial^2 f}{\partial x_1^2} \right)^2 + 2 \left(\frac{\partial^2 f}{\partial x_1 \partial x_2} \right)^2 + \left(\frac{\partial^2 f}{\partial x_2^2} \right)^2 \right) dx_1 dx_2$$

For the sake of simplicity, the formulas and equations that follow assume $m = 2$. See Wahba (1990) and Bates et al. (1987) for more details.

Duchon (1976) showed that f_λ can be represented as

$$f_\lambda(\mathbf{x}_i) = \theta_0 + \sum_{j=1}^d \theta_j \mathbf{x}_{ij} + \sum_{j=1}^n \delta_j E_2(\mathbf{x}_i - \mathbf{x}_j)$$

where $E_2(s) = \frac{1}{2^3\pi} \|s\|^2 \log(\|s\|)$ for $d = 2$. For derivations of $E_2(s)$ for other values of d , see Villalobos and Wahba (1987).

If you define \mathbf{K} with elements $K_{ij} = E_2(\mathbf{x}_i - \mathbf{x}_j)$ and \mathbf{T} with elements $T_{ij} = (X_{ij})$, the goal is to find vectors of coefficients $\boldsymbol{\beta}$, $\boldsymbol{\theta}$, and $\boldsymbol{\delta}$ that minimize

$$S_\lambda(\boldsymbol{\beta}, \boldsymbol{\theta}, \boldsymbol{\delta}) = \frac{1}{n} \|\mathbf{y} - \mathbf{T}\boldsymbol{\theta} - \mathbf{K}\boldsymbol{\delta} - \mathbf{Z}\boldsymbol{\beta}\|^2 + \lambda \boldsymbol{\delta}' \mathbf{K} \boldsymbol{\delta}$$

A unique solution is guaranteed if the matrix \mathbf{T} is of full rank and $\boldsymbol{\delta}' \mathbf{K} \boldsymbol{\delta} \geq 0$.

If $\boldsymbol{\alpha} = \begin{pmatrix} \boldsymbol{\theta} \\ \boldsymbol{\beta} \end{pmatrix}$ and $\mathbf{X} = (\mathbf{T} \ \mathbf{Z})$, the expression for S_λ becomes

$$\frac{1}{n} \|\mathbf{y} - \mathbf{X}\boldsymbol{\alpha} - \mathbf{K}\boldsymbol{\delta}\|^2 + \lambda \boldsymbol{\delta}' \mathbf{K} \boldsymbol{\delta}$$

The coefficients $\boldsymbol{\alpha}$ and $\boldsymbol{\delta}$ can be obtained by solving

$$\begin{aligned} (\mathbf{K} + n\lambda \mathbf{I}_n) \boldsymbol{\delta} + \mathbf{X}\boldsymbol{\alpha} &= \mathbf{y} \\ \mathbf{X}'\boldsymbol{\delta} &= \mathbf{0} \end{aligned}$$

To compute $\boldsymbol{\alpha}$ and $\boldsymbol{\delta}$, let the QR decomposition of \mathbf{X} be

$$\mathbf{X} = (\mathbf{Q}_1 \ \mathbf{Q}_2) \begin{pmatrix} \mathbf{R} \\ \mathbf{0} \end{pmatrix}$$

where $(\mathbf{Q}_1 \ \mathbf{Q}_2)$ is an orthogonal matrix and \mathbf{R} is an upper triangular, with $\mathbf{X}'\mathbf{Q}_2 = \mathbf{0}$ (Dongarra et al. 1979).

Since $\mathbf{X}'\boldsymbol{\delta} = \mathbf{0}$, $\boldsymbol{\delta}$ must be in the column space of \mathbf{Q}_2 . Therefore, $\boldsymbol{\delta}$ can be expressed as $\boldsymbol{\delta} = \mathbf{Q}_2\boldsymbol{\gamma}$ for a vector $\boldsymbol{\gamma}$. Substituting $\boldsymbol{\delta} = \mathbf{Q}_2\boldsymbol{\gamma}$ into the preceding equation and multiplying through by \mathbf{Q}_2' gives

$$\mathbf{Q}_2'(\mathbf{K} + n\lambda \mathbf{I})\mathbf{Q}_2\boldsymbol{\gamma} = \mathbf{Q}_2'\mathbf{y}$$

or

$$\boldsymbol{\delta} = \mathbf{Q}_2\boldsymbol{\gamma} = \mathbf{Q}_2[\mathbf{Q}_2'(\mathbf{K} + n\lambda \mathbf{I})\mathbf{Q}_2]^{-1}\mathbf{Q}_2'\mathbf{y}$$

The coefficient $\boldsymbol{\alpha}$ can be obtained by solving

$$\mathbf{R}\boldsymbol{\alpha} = \mathbf{Q}_1'[\mathbf{y} - (\mathbf{K} + n\lambda \mathbf{I})\boldsymbol{\delta}]$$

The influence matrix $\mathbf{A}(\lambda)$ is defined as

$$\hat{\mathbf{y}} = \mathbf{A}(\lambda)\mathbf{y}$$

and has the form

$$\mathbf{A}(\lambda) = \mathbf{I} - n\lambda \mathbf{Q}_2[\mathbf{Q}_2'(\mathbf{K} + n\lambda \mathbf{I})\mathbf{Q}_2]^{-1}\mathbf{Q}_2'$$

Similar to the regression case, if you consider the trace of $\mathbf{A}(\lambda)$ as the degrees of freedom for the model and the trace of $(\mathbf{I} - \mathbf{A}(\lambda))$ as the degrees of freedom for the error, the estimate σ^2 can be represented as

$$\hat{\sigma}^2 = \frac{\text{RSS}(\lambda)}{\text{tr}(\mathbf{I} - \mathbf{A}(\lambda))}$$

where $\text{RSS}(\lambda)$ is the residual sum of squares. Theoretical properties of these estimates have not yet been published. However, good numerical results in simulation studies have been described by several authors. For more information, see O'Sullivan and Wong (1987); Nychka (1986a, b, 1988); Hall and Titterton (1987).

Confidence Intervals

Viewing the spline model as a Bayesian model, Wahba (1983) proposed Bayesian confidence intervals for smoothing spline estimates as

$$\hat{f}_\lambda(\mathbf{x}_i) \pm z_{\alpha/2} \sqrt{\hat{\sigma}^2 a_{ii}(\lambda)}$$

where $a_{ii}(\lambda)$ is the i th diagonal element of the $\mathbf{A}(\lambda)$ matrix and $z_{\alpha/2}$ is the $1 - \alpha/2$ quantile of the standard normal distribution. The confidence intervals are interpreted as intervals “across the function” as opposed to pointwise intervals.

For SCORE data sets, the hat matrix $\mathbf{A}(\lambda)$ is not available. To compute the Bayesian confidence interval for a new point \mathbf{x}_{new} , let

$$\mathbf{S} = \mathbf{X}, \mathbf{M} = \mathbf{K} + n\lambda\mathbf{I}$$

and let $\boldsymbol{\xi}$ be an $n \times 1$ vector with i th entry

$$\eta_{md}(\|\mathbf{x}_{\text{new}} - \mathbf{x}_i\|)$$

When $d = 2$ and $m = 2$, ξ_i is computed with

$$E_2(\mathbf{x}_i - \mathbf{x}_{\text{new}}) = \frac{1}{2^3 \pi} \|\mathbf{x}_i - \mathbf{x}_{\text{new}}\|^2 \log(\|\mathbf{x}_i - \mathbf{x}_{\text{new}}\|)$$

$\boldsymbol{\phi}$ is a vector of evaluations of \mathbf{x}_{new} by the polynomials that span the functional space where $J_m(f)$ is zero. The details for \mathbf{X} , \mathbf{K} , and E_2 are discussed in the previous section. Wahba (1983) showed that the Bayesian posterior variance of \mathbf{x}_{new} satisfies

$$n\lambda \text{Var}(\mathbf{x}_{\text{new}}) = \boldsymbol{\phi}'(\mathbf{S}'\mathbf{M}^{-1}\mathbf{S})^{-1}\boldsymbol{\phi} - 2\boldsymbol{\phi}'\mathbf{d}_\xi - \boldsymbol{\xi}'\mathbf{c}_\xi$$

where

$$\begin{aligned} \mathbf{c}_\xi &= (\mathbf{M}^{-1} - \mathbf{M}^{-1}\mathbf{S}(\mathbf{S}'\mathbf{M}^{-1}\mathbf{S})^{-1}\mathbf{S}'\mathbf{M}^{-1})\boldsymbol{\xi} \\ \mathbf{d}_\xi &= (\mathbf{S}'\mathbf{M}^{-1}\mathbf{S})^{-1}\mathbf{S}'\mathbf{M}^{-1}\boldsymbol{\xi} \end{aligned}$$

Suppose that you fit a spline estimate that consists of a true function f and a random error term ϵ_i to experimental data. In repeated experiments, it is likely that about $100(1 - \alpha)\%$ of the confidence intervals cover the corresponding true values, although some values are covered every time and other values are not covered by the confidence intervals most of the time. This effect is more pronounced when the true surface or surface has small regions of particularly rapid change.

Smoothing Parameter

The quantity λ is called the smoothing parameter, which controls the balance between the goodness of fit and the smoothness of the final estimate.

A large λ heavily penalizes the m th derivative of the function, thus forcing $f^{(m)}$ close to 0. A small λ places less of a penalty on rapid change in $f^{(m)}(\mathbf{x})$, resulting in an estimate that tends to interpolate the data points.

The smoothing parameter greatly affects the analysis, and it should be selected with care. One method is to perform several analyses with different values for λ and compare the resulting final estimates.

A more objective way to select the smoothing parameter λ is to use the “leave-out-one” cross validation function, which is an approximation of the predicted mean squares error. A generalized version of the leave-out-one cross validation function is proposed by Wahba (1990) and is easy to calculate. This generalized cross validation (GCV) function is defined as

$$\text{GCV}(\lambda) = \frac{(1/n)\|(\mathbf{I} - \mathbf{A}(\lambda))\mathbf{y}\|^2}{[(1/n)\text{tr}(\mathbf{I} - \mathbf{A}(\lambda))]^2}$$

The justification for using the GCV function to select λ relies on asymptotic theory. Thus, you cannot expect good results for very small sample sizes or when there is not enough information in the data to separate the model from the error component. Simulation studies suggest that for independent and identically distributed Gaussian noise, you can obtain reliable estimates of λ for n greater than 25 or 30. Note that, even for large values of n (say, $n \geq 50$), in extreme Monte Carlo simulations there might be a small percentage of unwarranted extreme estimates in which $\hat{\lambda} = 0$ or $\hat{\lambda} = \infty$ (Wahba 1983). Generally, if σ^2 is known to within an order of magnitude, the occasional extreme case can be readily identified. As n gets larger, the effect becomes weaker.

The GCV function is fairly robust against nonhomogeneity of variances and non-Gaussian errors (Villalobos and Wahba 1987). Andrews (1988) has provided favorable theoretical results when variances are unequal. However, this selection method is likely to give unsatisfactory results when the errors are highly correlated.

The GCV value might be suspect when λ is extremely small because computed values might become indistinguishable from zero. In practice, calculations with $\lambda = 0$ or λ near 0 can cause numerical instabilities that result in an unsatisfactory solution. Simulation studies have shown that a λ with $\log_{10}(n\lambda) > -8$ is small enough that the final estimate based on this λ almost interpolates the data points. A GCV value based on a $\lambda \leq 10^{-8}$ might not be accurate.

ODS Table Names

PROC TPSPLINE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. [Table 96.4](#) lists these names. For more information about ODS, see Chapter 20, “[Using the Output Delivery System.](#)”

Table 96.4 ODS Tables Produced by PROC TPSPLINE

ODS Table Name	Description	Statement	Option
DataSummary	Data summary	PROC	Default
FitSummary	Fit parameters and fit summary	PROC	Default
FitStatistics	Model fit statistics	PROC	Default
GCVFunction	GCV table	MODEL	LOGNLAMBDA, LAMBDA

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set named FitStats which contains the FitStatistics table, an output data set named DataInfo which contains the DataSummary table, an output data set named ModelInfo which contains the FitSummary table, and an output data set named GCVFunc which contains the GCVFunction table.

```
proc tpspline data=Melanoma;
  model Incidences=Year /LOGNLAMBDA=(-4 to 0 by 0.2);
  ods output FitStatistics = FitStats
             DataSummary   = DataInfo
             FitSummary     = ModelInfo
             GCVFunction    = GCVFunc;
run;
```

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

You can reference every graph produced through ODS Graphics with a name. [Table 96.5](#) lists the names of the graphs, along with the relevant PLOTS= options.

Table 96.5 Graphs Produced by PROC TPSPLINE

ODS Graph Name	Plot Description	PLOTS Option
ContourFitPanel	Panel of thin-plate spline contour surfaces overlaid on scatter plots of data	CONTOURFITPANEL
ContourFit	Thin-plate spline contour surface overlaid on scatter plot of data	CONTOURFITPANEL
DiagnosticsPanel	Panel of fit diagnostics	DIAGNOSTICS

Examples: TPSPLINE Procedure

Example 96.1: Partial Spline Model Fit

This example analyzes the data set `Measure` that was introduced in the section “[Getting Started: TPSPLINE Procedure](#)” on page 8098. That analysis determined that the final estimated surface can be represented by a quadratic function for one or both of the independent variables. This example illustrates how you can use PROC TPSPLINE to fit a partial spline model. The data set `Measure` is fit by using the following model:

$$y = \beta_0 + \beta_1 x_1 + \beta x_1^2 + f(x_2)$$

The model has a parametric component (associated with the x_1 variable) and a nonparametric component (associated with the x_2 variable). The following statements fit a partial spline model:

```
data Measure;
  set Measure;
  x1sq = x1*x1;
run;

data pred;
  do x1=-1 to 1 by 0.1;
    do x2=-1 to 1 by 0.1;
      x1sq = x1*x1;
      output;
    end;
  end;
run;

proc tpspline data= measure;
  model y = x1 x1sq (x2);
  score data = pred out = predy;
run;
```

Output 96.1.1 displays the results from these statements.

Output 96.1.1 Output from PROC TPSPLINE

Raw Data	
The TPSPLINE Procedure	
Dependent Variable: y	
Summary of Input Data Set	
Number of Non-Missing Observations	50
Number of Missing Observations	0
Unique Smoothing Design Points	5
Summary of Final Model	
Number of Regression Variables	2
Number of Smoothing Variables	1
Order of Derivative in the Penalty	2
Dimension of Polynomial Space	4
Summary Statistics of Final Estimation	
log10(n*Lambda)	-2.2374
Smoothing Penalty	205.3461
Residual SS	8.5821
Tr(I-A)	43.1534
Model DF	6.8466
Standard Deviation	0.4460
GCV	0.2304

As displayed in [Output 96.1.1](#), there are five unique design points for the smoothing variable x_2 and two regression variables in the model (x_1, x_1^2) . The dimension of the polynomial space is the number of columns in $(\{1, x_1, x_1^2, x_2\}) = 4$. The standard deviation of the estimate is much larger than the one based on the model with both x_1 and x_2 as smoothing variables (0.445954 compared to 0.098421). One of the many possible explanations might be that the number of unique design points of the smoothing variable is too small to warrant an accurate estimate for $f(x_2)$.

The following statements produce a surface plot for the partial spline model by using the surface template that is defined in the section “[Getting Started: TPSPLINE Procedure](#)” on page 8098.

```
proc sgrender data=predy template=surface;  
  dynamic _X='x1' _Y='x2' _Z='P_y' _T='Plot of Fitted Surface on a Fine Grid';  
run;
```

The surface displayed in [Output 96.1.2](#) is similar to the one estimated by using the full nonparametric model (displayed in [Output 96.2](#) and [Output 96.6](#)).

Output 96.1.2 Plot of PROC TPSPLINE Fit from the Partial Spline Model

Example 96.2: Spline Model with Higher-Order Penalty

This example continues the analysis of the data set `Measure` to illustrate how you can use PROC TPSPLINE to fit a spline model with a higher-order penalty term. Spline models with high-order penalty terms move low-order polynomial terms into the polynomial space. Hence, there is no penalty for these terms, and they can vary without constraint.

As shown in the previous analyses, the final model for the data set `Measure` must include quadratic terms for both x_1 and x_2 . This example fits the following model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_1^2 + \beta_3 x_2 + \beta_4 x_2^2 + \beta_5 x_1 x_2 + f(x_1, x_2)$$

The model includes quadratic terms for both variables, although it differs from the usual linear model. The nonparametric term $f(x_1, x_2)$ explains the variation of the data that is unaccounted for by a simple quadratic surface.

To modify the order of the derivative in the penalty term, specify the `M=` option. The following statements specify the option `M=3` in order to include the quadratic terms in the polynomial space:

```
data Measure;
  set Measure;
  x1sq = x1*x1;
  x2sq = x2*x2;
  x1x2 = x1*x2;
run;

proc tpspline data= Measure;
  model y = (x1 x2) / m=3;
  score data = pred out = predy;
run;
```

Output 96.2.1 displays the results from these statements.

Output 96.2.1 Output from PROC TPSPLINE with M=3

Raw Data	
The TPSPLINE Procedure	
Dependent Variable: y	
Summary of Input Data Set	
Number of Non-Missing Observations	50
Number of Missing Observations	0
Unique Smoothing Design Points	25
Summary of Final Model	
Number of Regression Variables	0
Number of Smoothing Variables	2
Order of Derivative in the Penalty	3
Dimension of Polynomial Space	6
Summary Statistics of Final Estimation	
log10(n*Lambda)	-3.7831
Smoothing Penalty	2092.4495
Residual SS	0.2731
Tr(I-A)	29.1716
Model DF	20.8284
Standard Deviation	0.0968
GCV	0.0160

The model contains six terms in the polynomial space is the number of columns in $((\{1, x_1, x_1^2, x_1x_2, x_2, x_2^2\})) = 6$). Compare Output 96.2.1 with Output 96.1.1: the $\log_{10}(n\lambda)$ value and the smoothing penalty differ significantly. In general, these terms are not directly comparable for different models. The final estimate based on this model is close to the estimate based on the model by using the default, M=2.

In the following statements, the REG procedure fits a quadratic surface model to the data set Measure:

```
proc reg data= Measure;
  model y = x1 x1sq x2 x2sq x1x2;
run;
```

The results are displayed in [Output 96.2.2](#).

Output 96.2.2 Quadratic Surface Model: The REG Procedure

Raw Data					
The REG Procedure					
Model: MODEL1					
Dependent Variable: y					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F

x1x2	1	-0.04814	0.12748	-0.38	0.7076

The REG procedure produces slightly different results. To fit a similar model with PROC TPSPLINE, you can use a MODEL statement that specifies the degrees of freedom with the DF= option. You can also use a large value for the LOGNLAMBDA0= option to force a parametric model fit.

Because there is one degree of freedom for each of the terms intercept, x1, x2, x1sq, x2sq, and x1x2, the DF=6 option is used as follows:

```
proc tpspline data=measure;
  model y=(x1 x2) /m=3 df=6 lognlambda=(-4 to 1 by 0.5);
  score data = pred
    out = predy;
run;
```

The fit statistics are displayed in [Output 96.2.3](#).

Output 96.2.3 Output from PROC TPSPLINE Using M=3 and DF=6

Raw Data

Smoothing Penalty	0.0000
Residual SS	8.9384
Tr(I-A)	43.9997
Model DF	6.0003
Standard Deviation	0.4507
GCV	0.2309

Output 96.2.4 shows the GCV values for the list of supplied $\log_{10}(n\lambda)$ values in addition to the fitted model with fixed degrees of freedom 6. The fitted model has a larger GCV value than all other examined models.

Output 96.2.4 Criterion Plot

The final estimate is based on 6.000330 degrees of freedom because there are already 6 degrees of freedom in the polynomial space and the search range for λ is not large enough (in this case, setting DF=6 is equivalent to setting $\lambda = \infty$).

The standard deviation and RSS (Output 96.2.3) are close to the sum of squares for the error term and the root MSE from the linear regression model (Output 96.2.2), respectively.

For this model, the optimal $\log_{10}(n\lambda)$ is around -3.8 , which produces a standard deviation estimate of 0.096765 (see Output 96.2.1) and a GCV value of 0.016051, while the model that specifies DF=6 results in a $\log_{10}(n\lambda)$ larger than 1 and a GCV value larger than 0.23074. The nonparametric model, based on the GCV, should provide better prediction, but the linear regression model can be more easily interpreted.

Example 96.3: Multiple Minima of the GCV Function

The data in this example represent the deposition of sulfate (SO₄) at 179 sites in the 48 contiguous states of the United States in 1990. Each observation records the latitude and longitude of the site in addition to the SO₄ deposition at the site measured in grams per square meter (g/m^2).

You can use PROC TPSPLINE to fit a surface that reflects the general trend and that reveals underlying features of the data, which are shown in the following DATA step:

```
data so4;
    input latitude longitude so4 @@;
    datalines;
32.45833  87.24222  1.403  34.28778  85.96889  2.103
33.07139  109.86472  0.299  36.07167  112.15500  0.304
31.95056  112.80000  0.263  33.60500  92.09722  1.950
34.17944  93.09861  2.168  36.08389  92.58694  1.578

    ... more lines ...

43.87333  104.19222  0.306  44.91722  110.42028  0.210
45.07611  72.67556  2.646
;

data pred;
    do latitude = 25 to 47 by 1;
        do longitude = 68 to 124 by 1;
            output;
        end;
    end;
run;
```

The preceding statements create the SAS data set so4 and the data set pred in order to make predictions on a regular grid. The following statements fit a surface for SO₄ deposition:

```
ods graphics on;
proc tpspline data=so4 plots(only)=criterion;
    model so4 = (latitude longitude) /lognlambda=(-6 to 1 by 0.1);
    score data=pred out=prediction1;
run;
```

Partial output from these statements is displayed in [Output 96.3.1](#) and [Output 96.3.2](#).

Output 96.3.1 Partial Output from PROC TPSPLINE for Data Set SO₄

Model DF	38.7250
Standard Deviation	0.2979
GCV	0.1132

Output 96.3.3 displays the CriterionPlot of the GCV function versus $\log_{10}(n\lambda)$.

Output 96.3.3 GCV Function of SO₄ Data Set

The GCV function has two minima. PROC TPSPLINE locates the global minimum at 0.277005. The plot also displays a local minimum located around -2.56 . The TPSPLINE procedure might not always find the global minimum, although it did in this case. If there is a predetermined search range based on prior knowledge, you can use the **RANGE=** option to narrow the search range in order to find a desired smoothing value. For example, if you believe a better smoothing parameter should be within the $(-4, -2)$ range, you can obtain the model with $\log_{10}(n\lambda) = -2.56$ with the following statements.

```
proc tpspline data=so4;
  model so4 = (latitude longitude) / range=(-4,-2);
  score data=pred out=prediction2;
run;
```

Output 96.3.4 displays the output from PROC TPSPLINE with a specified search range from the smoothing parameter.

Output 96.3.4 Output from PROC TPSPLINE for Data Set SO₄ with $\log_{10}(n\lambda) = -2.56$

Raw Data	
The TPSPLINE Procedure	
Dependent Variable: so4	
Summary of Input Data Set	
Number of Non-Missing Observations	179
Number of Missing Observations	0
Unique Smoothing Design Points	179
Summary of Final Model	
Number of Regression Variables	0
Number of Smoothing Variables	2
Order of Derivative in the Penalty	2
Dimension of Polynomial Space	3
Summary Statistics of Final Estimation	
log10(n*Lambda)	-2.5600
Smoothing Penalty	177.2160
Residual SS	0.0438
Tr(I-A)	7.2083
Model DF	171.7917
Standard Deviation	0.0779
GCV	0.1508

The smoothing penalty in Output 96.3.4 is much larger than that displayed in Output 96.3.2. The estimate in Output 96.3.2 uses a large λ value; therefore, the surface is smoother than the estimate by using $\log_{10}(n\lambda) = -2.56$ (Output 96.3.4).

The estimate based on $\log_{10}(n\lambda) = -2.56$ has a larger value of degrees of freedom, and it has a much smaller standard deviation.

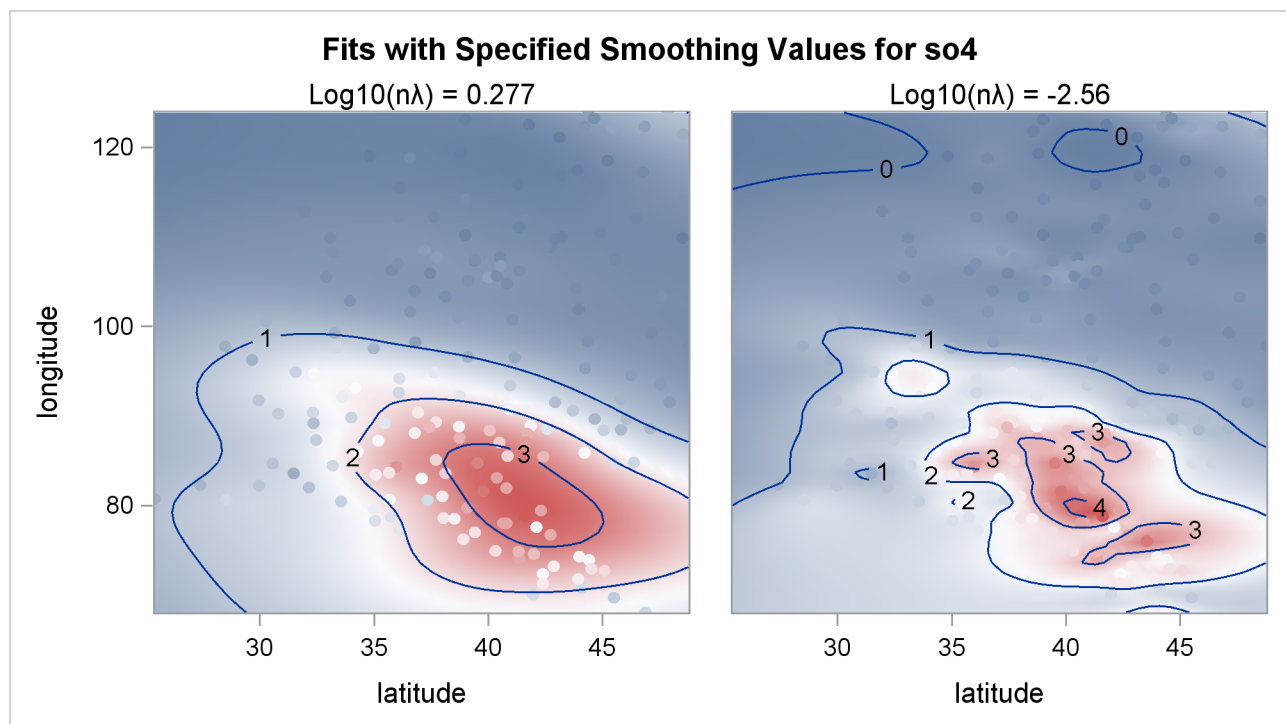

However, a smaller standard deviation in nonparametric regression does not necessarily mean that the estimate is good: a small λ value always produces an estimate closer to the data and, therefore, a smaller standard deviation.

When ODS Graphics is enabled, you can compare the two fits by supplying 0.277 and -2.56 to the **LOGN-LAMBDA=** option:

```
proc tpspline data=so4;
  model so4 = (latitude longitude) / lognlambda=(0.277 -2.56);
run;
```

Output 96.3.5 shows the contour surfaces of two models with the two minima. The fit that corresponds to the global minimum 0.277 shows a smoother fit that captures the general structure in the data set. The fit at the local minimum -2.56 is a rougher fit that captures local details. The response values are also displayed as circles with the same color gradient by the default **GRADIENT** contour-option. The contrast between the predicted and observed SO_4 deposition is greater for the smoother fit than for the other one, which means the smoother fit has larger absolute residual values.

Output 96.3.5 Panel of Contour Fit Plots by 0.277 and -2.56

The residuals for the two fits can be visualized in **RESIDUALBYSMOOTH** panels. **Output 96.3.6** is a panel of plots of residuals against smoothing variable Latitude. **Output 96.3.7** is a panel of plots of residuals against smoothing variable Longitude. Both panels show that the residuals from the model with the global minimum are larger in absolute values than the ones from the local minimum. This is expected, since the optimal model achieves the smallest GCV value by significantly increasing the smoothness of fit and sacrificing a little in the goodness of fit.

Output 96.3.6 Panel of Residuals by Latitude Plots**Output 96.3.7** Panel of Residuals by Longitude Plots

In summary, the fit with $\log_{10}(n\lambda) = 0.277$ represents the underlying surface, while the fit with the $\log_{10}(n\lambda) = -2.56$ overfits the data and captures the additional noise component.

Example 96.4: Large Data Set Application

This example illustrates how you can use the `D=` option to decrease the computation time needed by the TPSPLINE procedure. Although the `D=` option can be helpful in decreasing computation time for large data sets, it might produce unexpected results when used with small data sets.

The following statements generate the data set large:

```
data large;
  do x=-5 to 5 by 0.02;
    y=5*sin(3*x)+1*rannor(57391);
    output;
  end;
run;
```

The data set large contains 501 observations with one independent variable `x` and one dependent variable `y`. The following statements invoke PROC TPSPLINE to produce a thin-plate smoothing spline estimate and the associated 99% confidence interval. The output statistics are saved in the data set fit1.

```
proc tpspline data=large;
  model y =(x) /lognlambda=(-5 to -1 by 0.2) alpha=0.01;
  output out=fit1 pred lclm uclm;
run;
```

The results from this MODEL statement are displayed in [Output 96.4.1](#).

The difference between the two estimates is minimal. However, the CPU time for the second MODEL statement is only about 1/7 of the CPU time used in the first model fit.

The following statements produce a plot for comparison of the two estimates:

```
data fit2;
  set fit2;
  P1_y      = P_y;
  LCLM1_y   = LCLM_y;
  UCLM1_y   = UCLM_y;
  drop P_y LCLM_y UCLM_y;
run;

proc sort data=fit1;
  by x y;
run;

proc sort data=fit2;
  by x y;
run;

data comp;
  merge fit1 fit2;
  by x y;
  label p1_y    ="Yhat1" p_y="Yhat0"
        lclm_y ="Lower CL"
        uclm_y ="Upper CL";
run;

proc sgplot data=comp;
  title "Comparison of Two Estimates";
  title2 "with and without the D= Option";

  yaxis label="Predicted y Values";
  xaxis label="x";

  band x=x lower=lclm_y upper=uclm_y /name="range"
        legendlabel="99% CI of Predicted y without D=";
  series x=x y=P_y/ name="P_y" legendlabel="Predicted y without D="
        lineattrs=graphfit(thickness=1px pattern=shortdash);
  series x=x y=P1_y/ name="P1_y" legendlabel="Predicted y with D=";
```

```

lineattrs=graphfit(thickness=1px color=red);
discretelegend "range" "P_y" "Pl_y";
run;

```

The estimates from fit1 and fit2 are displayed in [Output 96.4.3](#) with the 99% confidence interval from the fit1 output data set.

Output 96.4.3 Comparison of Two PROC TPSPLINE Fits with and without the D= Option

Example 96.5: Computing a Bootstrap Confidence Interval

This example illustrates how you can construct a bootstrap confidence interval by using the multiple responses feature in PROC TPSPLINE.

Numerous epidemiological observations have indicated that exposure to solar radiation is an important factor in the etiology of melanoma. The following data present age-adjusted melanoma incidences for 37 years from the Connecticut Tumor Registry (Houghton, Flannery, and Viola 1980). The data are analyzed by Ramsay and Silverman (1997).

```

data melanoma;
  input  year incidences @@;
  datalines;
1936    0.9  1937    0.8  1938    0.8  1939    1.3
1940    1.4  1941    1.2  1942    1.7  1943    1.8
1944    1.6  1945    1.5  1946    1.5  1947    2.0
1948    2.5  1949    2.7  1950    2.9  1951    2.5
1952    3.1  1953    2.4  1954    2.2  1955    2.9
1956    2.5  1957    2.6  1958    3.2  1959    3.8
1960    4.2  1961    3.9  1962    3.7  1963    3.3
1964    3.7  1965    3.9  1966    4.1  1967    3.8
1968    4.7  1969    4.4  1970    4.8  1971    4.8
1972    4.8
;

```

The variable incidences records the number of melanoma cases per 100,000 people for the years 1936 to 1972. The following model fits the data and requests a 90% Bayesian confidence interval along with the estimate:

```

ods graphics on;
proc tpspline data=melanoma plots(only)=(criterionplot fitplot(clm));
  model incidences = (year) /alpha = 0.1;
  output out = result pred uclm lclm;
run;

```

The output is displayed in [Output 96.5.1](#)

Output 96.5.1 Output from PROC TPSPLINE for the MELANOMA Data

GCV	0.0888

The estimated curve is displayed with 90% confidence interval bands in [Output 96.5.2](#). The number of melanoma incidences exhibits a periodic pattern and increases over the years. The periodic pattern is related to sunspot activity and the accompanying fluctuations in solar radiation.

Output 96.5.2 PROC TPSPLINE Estimate and 90% Confidence Interval of Data Set MELANOMA

Wang and Wahba (1995) compare several bootstrap confidence intervals to Bayesian confidence intervals for smoothing splines. Both bootstrap and Bayesian confidence intervals are across-the-curve intervals, not pointwise intervals. They concluded that bootstrap confidence intervals work as well as Bayesian intervals concerning average coverage probability. Additionally, bootstrap confidence intervals appear to be better for small sample sizes. Based on their simulation, the “percentile- t interval” bootstrap interval performs better than the other types of bootstrap intervals.

Suppose that \hat{f}_λ and $\hat{\sigma}$ are the estimates of f and σ from the data. Assume that \hat{f}_λ is the “true” f , and generate the bootstrap sample as

$$y_i^* = \hat{f}_\lambda(\mathbf{x}_i) + \epsilon_i^*, \quad i = 1, \dots, n$$

where $\boldsymbol{\epsilon}^* = (\epsilon_1^*, \dots, \epsilon_n^*)' \sim N(0, \hat{\sigma}^2 \mathbf{I})$. Denote $f_\lambda^*(\mathbf{x}_i)$ as the random variable of the bootstrap estimate at \mathbf{x}_i . Repeat this process K times, so that at each point \mathbf{x}_i , you have K bootstrap estimates $\hat{f}_\lambda^*(\mathbf{x}_i)$ or K realizations of $f_\lambda^*(\mathbf{x}_i)$. For each fixed \mathbf{x}_i , consider the statistic D_i^* , which is similar to the Student’s t statistic,

$$D_i^* = \left(f_\lambda^*(\mathbf{x}_i) - \hat{f}_\lambda(\mathbf{x}_i) \right) / \hat{\sigma}_i^*$$

where $\hat{\sigma}_i^*$ is the estimate of $\hat{\sigma}$ based on the i th bootstrap sample.

Suppose $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$ are the lower and upper $\alpha/2$ points, respectively, of the empirical distribution of D_i^* . The $(1 - \alpha)100\%$ bootstrap confidence interval is defined as

$$\left(\hat{f}_\lambda(\mathbf{x}_i) - \chi_{1-\alpha/2} \hat{\sigma}, \quad \hat{f}_\lambda(\mathbf{x}_i) - \chi_{\alpha/2} \hat{\sigma} \right)$$

Bootstrap confidence intervals are easy to interpret and can be used with any distribution. However, because they require K model fits, their construction is computationally intensive.

The feature of multiple dependent variables in PROC TPSPLINE enables you to fit multiple models with the same independent variables. The procedure calculates the matrix decomposition part of the calculations only once, regardless of the number of dependent variables in the model. These calculations are responsible for most of the computing time used by the TPSPLINE procedure. This feature is particularly useful when you need to generate a bootstrap confidence interval.

To construct a bootstrap confidence interval, perform the following tasks:

- Fit the data by using PROC TPSPLINE and obtain estimates $\hat{f}_\lambda(\mathbf{x}_i)$ and $\hat{\sigma}$.
- Generate K bootstrap samples based on $\hat{f}_\lambda(\mathbf{x}_i)$ and $\hat{\sigma}$.
- Fit the K bootstrap samples with the TPSPLINE procedure to obtain estimates of $\hat{f}_\lambda^*(\mathbf{x}_i)$ and $\hat{\sigma}_i^*$.
- Compute D_i^* and the values $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$.

The following statements illustrate this process:

```
proc tpspline data=melanoma plots(only)=fitplot(clm);
  model incidences = (year) /alpha = 0.1;
  output out=result pred uclm lclm;
run;
```

The output from the initial PROC TPSPLINE analysis is displayed in [Output 96.5.3](#). The data set result contains the predicted values and confidence limits from the analysis.

Output 96.5.3 Output from PROC TPSPLINE for the MELANOMA Data

Comparison of Two Estimates with and without the D= Option	
The TPSPLINE Procedure Dependent Variable: incidences	
Summary of Input Data Set

Number of Smoothing Variables	1
Order of Derivative in the Penalty	2
Dimension of Polynomial Space	2
Summary Statistics of Final Estimation	
log10(n*Lambda)	-0.0607
Smoothing Penalty	0.5171
Residual SS	1.2243
Tr(I-A)	22.5852
Model DF	14.4148
Standard Deviation	0.2328
GCV	0.0888

The following statements illustrate how you can obtain a bootstrap confidence interval for the Melanoma data set. The following statements create the data set bootstrap. The observations are created with information from the preceding PROC TPSPLINE execution; as displayed in [Output 96.5.3](#), $\hat{\sigma} = 0.232823$. The values of $\hat{f}_{\hat{\lambda}}(\mathbf{x}_i)$ are stored in the data set result in the variable P_incidence.

```

data bootstrap;
  set result;
  array y{1070} y1-y1070;
  do i=1 to 1070;
    y{i} = p_incidences + 0.232823*rannor(123456789);
  end;
  keep y1-y1070 p_incidences year;
run;

ods listing close;
proc tpspline data=bootstrap plots=none;
  ods output FitStatistics=FitResult;
  id p_incidences;
  model y1-y1070 = (year);
  output out=result2;
run;
ods listing;

```

The DATA step generates 1,070 bootstrap samples based on the previous estimate from PROC TPSPLINE. For this data set, some of the bootstrap samples result in λ s (selected by the GCV function) that cause problematic behavior. Thus, an additional 70 bootstrap samples are generated.

The ODS listing destination is closed before PROC TPSPLINE is invoked. The PLOTS=NONE option suppresses all graphical output. The model fits all the $y_1 \dots y_{1070}$ variables as dependent variables, and the models are fit for all bootstrap samples simultaneously. The output data set result2 contains the variables year, $y_1 \dots y_{1070}$, $p_{y_1} \dots p_{y_{1070}}$, and $p_{incidences}$.

The ODS OUTPUT statement writes the FitStatistics table to the data set FitResult. The data set FitResult contains the two variables Parameter and Value. The FitResult data set is used in subsequent calculations for D_i^* .

In the data set FitResult, there are 63 estimates with a standard deviation of zero, suggesting that the estimates provide perfect fits of the data and are caused by $\hat{\lambda}$ s that are approximately equal to zero. For small sample sizes, there is a positive probability that the λ chosen by the GCV function will be zero (Wang and Wahba 1995).

In the following steps, these cases are removed from the bootstrap samples as “bad” samples: they represent failure of the GCV function.

The following SAS statements manipulate the data set FitResult, retaining the standard deviations for all bootstrap samples and merging FitResult with the data set result2, which contains the estimates for bootstrap samples. In the final data set boot, the D_i^* statistics are calculated.

```

data FitResult;
  set FitResult;
  if Parameter="Standard Deviation";
  keep Value;
run;

proc transpose data=FitResult out=sd prefix=sd;

data result2;
  if _N_ = 1 then set sd;
  set result2;
run;

```

```

data boot;
  set result2;
  array y{1070} p_y1-p_y1070;
  array sd{1070} sd1-sd1070;
  do i=1 to 1070;
    if sd{i} > 0 then do;
      d = (y{i} - P_incidences)/sd{i};
      obs = _N_;
      output;
    end;
  end;
  keep d obs P_incidences year;
run;

```

The following SAS statements retain the first 1,000 bootstrap samples and calculate the values $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$ with $\alpha = 0.1$.

```

proc sort data=boot;
  by obs;
run;

data boot;
  set boot;
  by obs;
  retain n;

  if first.obs then n=1;
  else n=n+1;
  if n > 1000 then delete;
run;

proc sort data=boot;
  by obs d;
run;

data chi1 chi2 ;
  set boot;
  if (_N_ = (obs-1)*1000+50) then output chi1;
  if (_N_ = (obs-1)*1000+950) then output chi2;
run;

proc sort data=result;
  by year;
run;

proc sort data=chi1;
  by year;
run;

proc sort data=chi2;
  by year;
run;

```

```

data result;
  merge result
    chi1(rename=(d=chi05))
    chi2(rename=(d=chi95));
  keep year incidences P_incidences lower upper
    LCLM_incidences UCLM_incidences;

  lower = -chi95*0.232823 + P_incidences;
  upper = -chi05*0.232823 + P_incidences;

  label lower="Lower 90% CL (Bootstrap)"
    upper="Upper 90% CL (Bootstrap)"
    lclm_incidences="Lower 90% CL (Bayesian)"
    uclm_incidences="Upper 90% CL (Bayesian)";
run;

```

The data set result contains the variables year and incidences, the PROC TPSPLINE estimate P_incidences, and the 90% Bayesian and 90% bootstrap confidence intervals.

The following statements produce [Output 96.5.4](#):

```

proc sgplot data=result;
  title "Age-adjusted Melanoma Incidence for 37 Years";

  xaxis label="year";
  yaxis label="Incidences";

  band x=year lower=lclm_incidences upper=uclm_incidences/name="bayesian"
    legendlabel="90% Bayesian CI of Predicted incidences"
    fillattrs=(color=red);
  band x=year lower=lower upper=upper/name="bootstrap"
    legendlabel="90% Bootstrap CI of Predicted incidences"
    transparency=0.05;
  scatter x=year y=incidences/name="obs" legendlabel="incidences";
  series x=year y=p_incidences/name="pred"
    legendlabel="predicted values of incidences"
    lineattrs=graphfit(thickness=1px);

  discretelegend "bayesian" "bootstrap" "obs" "pred";
run;

ods graphics off;

```

[Output 96.5.4](#) displays the plot of the variable incidences, the predicted values, and the Bayesian and bootstrap confidence intervals.

The plot shows that the bootstrap confidence interval is similar to the Bayesian confidence interval. However, the Bayesian confidence interval is symmetric around the estimates, while the bootstrap confidence interval is not.

Output 96.5.4 Comparison of Bayesian and Bootstrap Confidence Interval for Data Set MELANOMA

Overview: TRANSREG Procedure

The TRANSREG (transformation regression) procedure fits linear models, optionally with smooth, spline, Box-Cox, and other nonlinear transformations of the variables. You can use PROC TRANSREG to fit a curve through a scatter plot or fit multiple curves, one for each level of a classification variable. You can also constrain the functions to be parallel or monotone or have the same intercept. PROC TRANSREG can be used to code experimental designs and classification variables prior to their use in other analyses.

The TRANSREG procedure fits many types of linear models, including the following:

- ordinary regression and ANOVA
- metric and nonmetric conjoint analysis (Green and Wind 1975; de Leeuw, Young, and Takane 1976)
- linear models with Box-Cox (1964) transformations of the dependent variables
- regression with a smooth (Reinsch 1967), spline (de Boor 1978; van Rijckevorsel 1982), monotone spline (Winsberg and Ramsay 1980), or penalized B-spline (Eilers and Marx 1996) fit function
- metric and nonmetric vector and ideal point preference mapping (Carroll 1972)
- simple, multiple, and multivariate regression with variable transformations (Young, de Leeuw, and Takane 1976; Winsberg and Ramsay 1980; Breiman and Friedman 1985)
- redundancy analysis (Stewart and Love 1968) with variable transformations (Israels 1984)
- canonical correlation analysis with variable transformations (van der Burg and de Leeuw 1983)
- response surface regression (Meyers 1976; Khuri and Cornell 1987) with variable transformations

The data set can contain variables measured on nominal, ordinal, interval, and ratio scales (Siegel 1956). You can specify any mix of these variable types for the dependent and independent variables. PROC TRANSREG can do the following:

- transform nominal variables by scoring the categories to minimize squared error (Fisher 1938), or treat nominal variables as classification variables
- transform ordinal variables by monotonically scoring the ordered categories so that order is weakly preserved (adjacent categories can be merged) and squared error is minimized. Ties can be optimally untied or left tied (Kruskal 1964). Ordinal variables can also be transformed to ranks.
- transform interval and ratio scale of measurement variables linearly or nonlinearly with spline (de Boor 1978; van Rijckevorsel 1982), monotone spline (Winsberg and Ramsay 1980), penalized B-spline (Eilers and Marx 1996), smooth (Reinsch 1967), or Box-Cox (Box and Cox 1964) transformations. In addition, logarithmic, exponential, power, logit, and inverse trigonometric sine transformations are available.

Transformations produced by the PROC TRANSREG multiple regression algorithm, requesting spline transformations, are often similar to transformations produced by the ACE smooth regression method of Breiman and Friedman (1985). However, ACE does not explicitly optimize a loss function (de Leeuw 1986), while PROC TRANSREG explicitly minimizes a squared-error criterion.

PROC TRANSREG extends the ordinary general linear model by providing optimal variable transformations that are iteratively derived. PROC TRANSREG iterates until convergence, alternating two major steps: finding least squares estimates of the model parameters given the current scoring of the data, and finding least squares estimates of the scoring parameters given the current set of model parameters. This is called the method of alternating least squares (Young 1981).

For more background on alternating least squares optimal scaling methods and transformation regression methods, see Young, de Leeuw, and Takane (1976); Winsberg and Ramsay (1980); Young (1981); Gifi (1990); Schiffman, Reynolds, and Young (1981); van der Burg and de Leeuw (1983); Israels (1984); Breiman and Friedman (1985); Hastie and Tibshirani (1986). (These are just a few of the many relevant sources.)

Getting Started: TRANSREG Procedure

This section provides several examples that illustrate a few of the more basic features of PROC TRANSREG.

Fitting a Curve through a Scatter Plot

PROC TRANSREG can fit curves through data and detect nonlinear relationships among variables. This example uses a subset of the data from an experiment in which nitrogen oxide emissions from a single cylinder engine are measured for various combinations of fuel and equivalence ratio (Brinkman 1981). This gas data set is available from the Sashelp library. The following step creates a subset of the data for analysis:

```
title 'Gasoline and Emissions Data';

data gas;
    set sashelp.gas;
    if fuel in ('Ethanol', '82rongas', 'Gasohol');
run;
```

The next step fits a spline or curve through the data and displays the regression results. For information about splines and knots, see the sections “[Smoothing Splines](#)” on page 8263, “[Linear and Nonlinear Regression Functions](#)” on page 8250, “[Simultaneously Fitting Two Regression Functions](#)” on page 8254, and “[Using Splines and Knots](#)” on page 8233, as well as [Example 97.1](#). The following statements produce [Figure 97.1](#):

```
ods graphics on;

* Request a Spline Transformation of Equivalence Ratio;
proc transreg data=Gas solve ss2 plots=(transformation obp residuals);
  model identity(nox) = spline(EqRatio / nknots=4);
  where fuel in ('Ethanol', '82rongas', 'Gasohol');
run;
```

The **SOLVE** algorithm option, or *a-option*, requests a direct solution for both the transformation and the parameter estimates. For many models, PROC TRANSREG with the SOLVE *a-option* can produce exact results without iteration. The **SS2** (Type II sums of squares) *a-option* requests regression and ANOVA results. The **PLOTS=** option requests plots of the variable transformations, a plot of the observed values by the predicted values, and a plot of the residuals. The dependent variable NOx was specified with an **IDENTITY** transformation, which means that it will not be transformed, just as in ordinary regression. The independent variable EqRatio, in contrast, is transformed by using a cubic spline with four knots. The **NKNOTS=** option is known as a transformation option, or *t-option*. Graphical results are enabled when ODS Graphics is enabled. The results are shown in Figure 97.1 through Figure 97.5.

Figure 97.1 Iteration, ANOVA, and Regression Results

PROC TRANSREG increases the squared multiple correlation from the original value of 0.00917 to 0.82429. Iteration 0 shows the fit before the data are transformed, and iteration 1 shows the fit after the transformation, which was directly solved for in the initial iteration. The change values for iteration 0 show the change from the original EqRatio variable to the transformed EqRatio variable. For this model, no improvement on the initial solution is possible, so in iteration 1, all change values are zero. The ANOVA and regression results show that you are fitting a model with 7 model parameters, 4 knots plus a degree 3 or cubic spline. The overall model fit is identical to the test for the spline transformation, since there is only one term in the model besides the intercept, and the results are significant at the 0.0001 level. The transformations are shown next in Figure 97.2.

Figure 97.2 Transformations

The transformation plots show the identity transformation of NOx and the nonlinear spline transformation of EqRatio. These plots are requested with the `PLOTS=TRANSFORMATION` option. The plot on the left shows that NOx is unchanged, which is always the case with the `IDENTITY` transformation. In contrast, the spline transformation of EqRatio is nonlinear. It is this nonlinear transformation of EqRatio that accounts for the increase in fit that is shown in the iteration history table.

Figure 97.3 Residuals

The residuals plot in Figure 97.3 shows the residuals as a function of the transformed independent variable.

The “Spline Regression Fit” plot in Figure 97.4 displays the nonlinear regression function plotted through the original data, along with 95% confidence and prediction limits. This plot clearly shows that nitrous oxide emissions are largest in the middle range of equivalence ratio, 0.08 to 1.0, and are much lower for the extreme values of equivalence ratio, such as around 0.6 and 1.2.

Figure 97.4 Fitting a Curve through a Scatter Plot

This plot is produced by default when ODS Graphics is enabled and when there is an IDENTITY dependent variable and one non-CLASS independent variable. The plot consists of an ordinary scatter plot of NOx plotted as a function of EqRatio. It also contains the predicted values of NOx, which are a function of the spline transformation of EqRatio (or TEqRatio shown previously), and are plotted as a function of EqRatio. Similarly, it contains confidence limits based on NOx and TEqRatio.

The “Observed by Predicted” values plot in Figure 97.5 displays the dependent variable plotted as a function of the regression predicted values along with a linear regression line, which for this plot always has a slope of 1. This plot was requested with the OBP or OBSERVEDBYPREDICTED suboption in the PLOTS= option. The residual differences between the transformed data and the regression line show how well the nonlinearly transformed data fit a linear-regression model. The residuals look mostly random; however, they are larger for larger values of NOx, suggesting that maybe this is not the optimal model. You can also see this by examining the fit of the function through the original scatter plot in Figure 97.4. Near the

middle of the function, the residuals are much larger. You can refit the model, this time requesting separate functions for each type of fuel. You can request the original scatter plot, without any regression information and before the variables are transformed, by specifying the SCATTER suboption in the PLOTS= option.

Figure 97.5 Observed by Predicted

These next statements fit an additive model with separate functions for each of the different fuels. The statements produce [Figure 97.6](#) through [Figure 97.9](#).

```
* Separate Curves and Intercepts;
proc transreg data=Gas solve ss2 additive plots=(transformation obp);
  model identity(nox) = class(Fuel / zero=none) |
    spline(EqRatio / nknots=4 after);
run;
```

The **ADDITIVE** *a-option* requests an additive model, where the regression coefficients are absorbed into the transformations, and so the final regression coefficients are all one. The specification **CLASS**(Fuel / **ZERO=NONE**) recodes fuel into a set of three binary variables, one for each of the three fuels in this data set. The vertical bar between the **CLASS** and **SPLINE** specifications request both main effects and interactions. For this model, it requests both a separate intercept and a separate spline function for each fuel. The original

two variables, Fuel and EqRatio, are replaced by six variables—three binary intercept terms and three spline variables. The three spline variables are zero when their corresponding intercept binary variable is zero, and nonzero otherwise. The nonzero parts are optimally transformed by the analysis. The **AFTER** *t-option* specified with the SPLINE transformation specifies that the four knots should be selected independently for each of the three spline transformations, *after* EqRatio is crossed with the CLASS variable. Alternatively, and by default, the knots are chosen by examining EqRatio before it is crossed with the CLASS variable, and the same knots are used for all three transformations. The results are shown in Figure 97.6.

ZERO=SUM and ZERO=NONE coefficient tests are not exact when there are iterative transformations. Those tests are performed holding all transformations fixed, and so are generally liberal.						

The first iteration history table in Figure 97.6 shows that PROC TRANSREG increases the squared multiple correlation from the original value of 0.18543 to 0.95870. The remaining iteration histories pertain to PROC TRANSREG's process of comparing models to test hypotheses. The important thing to look for is convergence in all of the tables.

Figure 97.7 Transformations

The transformations, shown in Figure 97.7, show that for all three groups, the transformation of EqRatio is approximately quadratic.

Figure 97.8 Fitting Curves through a Scatter Plot

The fit plot, shown in [Figure 97.8](#), shows that there are in fact three distinct functions in the data. The increase in fit over the previous model comes from individually fitting each group instead of providing an aggregate fit.

Figure 97.9 Observed by Predicted

The residuals in the observed by predicted plot displayed in [Figure 97.9](#) are much better for this analysis.

You could fit a model that is “in between” the two models shown previously. This next model provides for separate intercepts for each group, but calls for a common function. There are still three functions, one per group, but their shapes are the same, and they are equidistant or parallel. This model is requested by omitting the vertical bar so that separate intercepts are requested, but not separate curves within each group. The following statements fit the separate intercepts model and create [Figure 97.10](#):

```
* Separate Intercepts;
proc transreg data=Gas solve ss2 additive;
  model identity(nox) = class(Fuel / zero=none)
                    spline(EqRatio / nknots=4);
run;
```

The ANOVA table and fit plot are shown in [Figure 97.10](#).

Figure 97.10 Separate Intercepts Only

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	9	196.7548	21.86165	100.61	<.0001
Error	100	21.7294	0.21729		
Corrected Total	109	218.4842			

Figure 97.10 *continued*

Now, squared multiple correlation is 0.9005, which is smaller than the model with the unconstrained separate curves, but larger than the model with only one curve. Because of the restrictions on the shapes, these curves do not track the data as well as the previous model. However, this model is more parsimonious with many fewer parameters.

There are other ways to fit curves through scatter plots in PROC TRANSREG. For example, you could use smoothing splines or penalized B-splines, as is illustrated next. The following statements fit separate curves through each group by using penalized B-splines and produce Figure 97.11:

```
* Separate Curves and Intercepts with Penalized B-Splines;
proc transreg data=Gas ss2 plots=transformation lprefix=0;
  model identity(nox) = class(Fuel / zero=none) * pbspline(EqRatio);
run;
```

This example asks for a separate penalized B-spline transformation, **PBSPLINE**, of equivalence ratio for each type of fuel. The **LPREFIX=0** *a-option* is specified in the PROC statement so that zero characters of the **CLASS** variable name (Fuel) are used in constructing the labels for the coded variables. The result is label components like “Ethanol” instead of the more redundant “Fuel Ethanol”. The results of this analysis are shown in Figure 97.11.

Figure 97.11 continued

Figure 97.11 continued

With penalized B-splines, the degrees of freedom are based on the trace of the transformation hat matrix and are typically not integers. The first panel of plots shows AICC as a function of lambda, the smoothing parameter. The smoothing parameter is automatically chosen, and since the smoothing parameters range from essentially 0 to almost 800, it is clear that some functions are smoother than others. The plots of the criterion (AICC in this example) as a function of lambda use a linear scale for the horizontal axis when the range of lambdas is small, as in the first and third plot, and a log scale when the range is large, as in the second plot. The transformation for equivalence ratio for Ethanol required more smoothing than for the other two fuels. All three have an overall quadratic shape, but for Ethanol, the function more closely follows the smaller variations in the data. You could get similar results with [SPLINE](#) by using more knots.

For other examples of curve fitting by using PROC TRANSREG, see the sections “[Smoothing Splines](#)” on page 8263, “[Linear and Nonlinear Regression Functions](#)” on page 8250, “[Simultaneously Fitting Two Regression Functions](#)” on page 8254, and “[Using Splines and Knots](#)” on page 8233, as well as [Example 97.3](#). These examples include cases where multiple curves are fit through scatter plots with multiple groups. Special cases include linear models with separate slopes and separate intercepts. Many constraints on the slopes, curves, and intercepts are possible.

Main-Effects ANOVA

This example shows how to use PROC TRANSREG to code and fit a main-effects ANOVA model. PROC TRANSREG has very extensive and versatile options for coding or creating so-called dummy variables. PROC TRANSREG is commonly used to code classification variables before they are used for analysis

in other procedures. See the sections “Using the DESIGN Output Option” on page 8331 and “Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO” on page 8335. In this example, the input data set contains the dependent variables *y*, factors *x1* and *x2*, and 12 observations. PROC TRANSREG can be useful for coding even before running procedures with a CLASS statement because of its detailed options that enable you to control how the coded variable names and labels are constructed. The following statements perform a main-effects ANOVA and display the results in Figure 97.12 and Figure 97.13:

```

title 'Introductory Main-Effects ANOVA Example';

data a;
  input y x1 $ x2 $;
  datalines;
8 a a
7 a a
4 a b
3 a b
5 b a
4 b a
2 b b
1 b b
8 c a
7 c a
5 c b
2 c b
;

* Fit a main-effects ANOVA model with 1, 0, -1 coding;
proc transreg ss2;
  model identity(y) = class(x1 x2 / effects);
  output coefficients replace;
run;

* Display TRANSREG output data set;
proc print label;
  format intercept -- x2a 5.2;
run;

```

The **SS2** *a-option* requests results based on Type II sums of squares. The simple ANOVA model is fit by designating *y* as an **IDENTITY** variable, which specifies no transformation. The independent variables are specified with a **CLASS** expansion, which replaces them with coded variables. There are $(3-1)+(2-1) = 3$ coded variables created by the CLASS specification, since the two CLASS variables have 3 and 2 different values or levels. In this case, the **EFFECTS** *t-option* is specified. This option requests an *effects coding* (displayed in Figure 97.13), which is also called a deviations from means or 0, 1, -1 coding. The **OUTPUT** statement requests an output data set with the data and coded variables. The **COEFFICIENTS** output option, or *o-option*, adds the parameter estimates and marginal means to the data set. The **REPLACE** *o-option* specifies that the transformed variables should replace the original variables in the output data set. The output data set variable names are the same as the original variable name. In an example like this, there are no nonlinear transformations; the transformed variables are the same as the original variables. The **REPLACE** *o-option* is used to eliminate unnecessary and redundant transformed variables from the output data set. The results of the PROC TRANSREG step are shown in Figure 97.12.

Figure 97.12 shows the ANOVA results, fit statistics, and regression tables. The output data set, with the coded design, parameter estimates and means, is shown in Figure 97.13. For more information about PROC TRANSREG for ANOVA and other codings, see the section “ANOVA Codings” on page 8270.

Figure 97.13 Output Data Set from PROC TRANSREG

Introductory Main-Effects ANOVA Example									
Obs	_TYPE_	_NAME_	y	Intercept	x1 a	x1 b	x2 a	x1	x2
1	SCORE	ROW1	8	1.00	1.00	0.00	1.00	a	a
2	SCORE	ROW2	7	1.00	1.00	0.00	1.00	a	a
3	SCORE	ROW3	4	1.00	1.00	0.00	-1.00	a	b
4	SCORE	ROW4	3	1.00	1.00	0.00	-1.00	a	b
5	SCORE	ROW5	5	1.00	0.00	1.00	1.00	b	a
6	SCORE	ROW6	4	1.00	0.00	1.00	1.00	b	a
7	SCORE	ROW7	2	1.00	0.00	1.00	-1.00	b	b
8	SCORE	ROW8	1	1.00	0.00	1.00	-1.00	b	b
9	SCORE	ROW9	8	1.00	-1.00	-1.00	1.00	c	a
10	SCORE	ROW10	7	1.00	-1.00	-1.00	1.00	c	a
11	SCORE	ROW11	5	1.00	-1.00	-1.00	-1.00	c	b
12	SCORE	ROW12	2	1.00	-1.00	-1.00	-1.00	c	b
13	M COEFFI	y	.	4.67	0.83	-1.67	1.83		
14	MEAN	y	.	.	5.50	3.00	6.50		

The output data set has three kinds of observations, identified by values of `_TYPE_` as follows:

- When `_TYPE_='SCORE'`, the observation contains the following information about the dependent and independent variables:
 - `y` is the original dependent variable.
 - `x1` and `x2` are the independent classification variables, and the `Intercept` through `x2 a` columns contain the main-effects design matrix that PROC TRANSREG creates. The variable names are `Intercept`, `x1a`, `x1b`, and `x2a`. Their labels are shown in the listing.
- When `_TYPE_='M COEFFI'`, the observation contains coefficients of the final linear model (parameter estimates).
- When `_TYPE_='MEAN'`, the observation contains the marginal means.

The observations with `_TYPE_='SCORE'` form the score or data partition of the output data set, and the observations with `_TYPE_='M COEFFI'` and `_TYPE_='MEAN'` form the output statistics partition of the output data set.

Syntax: TRANSREG Procedure

The following statements are available in the TRANSREG procedure:

```

PROC TRANSREG < DATA=SAS-data-set>
                < PLOTS=(plot-requests)>
                < OUTTEST=SAS-data-set> < a-options> < o-options> ;

MODEL < transform(dependents < / t-options>) >
        < transform(dependents < / t-options>)...=>
        transform(independents < / t-options>)
        < transform(independents < / t-options>)... > < / a-options> ;

OUTPUT < OUT=SAS-data-set> < o-options> ;

ID variables ;
FREQ variable ;
WEIGHT variable ;
BY variables ;

```

To use PROC TRANSREG, you need both the PROC TRANSREG and MODEL statements. To produce an OUT= output data set, the OUTPUT statement is required. PROC TRANSREG enables you to specify the same options in more than one statement. All of the MODEL statement *a-options* (algorithm options) and all of the OUTPUT statement *o-options* (output options) can also be specified in the PROC TRANSREG statement. You can abbreviate all *a-options*, *o-options*, and *t-options* (transformation options) to their first three letters. This is a special feature of PROC TRANSREG and is not generally true of other SAS/STAT procedures. See [Table 97.1](#) for a list of options available in the PROC TRANSREG statement.

The PROC TRANSREG statement starts the TRANSREG procedure. Optionally, this statement identifies an input and an OUTTEST= data set, specifies the algorithm and other computational details, requests displayed output, and controls the contents of the OUT= data set (which is created with the OUTPUT statement). The DATA= and OUTTEST= options can appear only in the PROC TRANSREG statement. All *a-options* and *o-options* are described in the sections on either the MODEL or OUTPUT statement, in which these options can also be specified.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC TRANSREG statement. The remaining statements are described in alphabetical order.

PROC TRANSREG Statement

```

PROC TRANSREG < DATA=SAS-data-set>
                < PLOTS=(plot-requests)>
                < OUTTEST=SAS-data-set> < a-options> < o-options> ;

```

The PROC TRANSREG statement invokes the TRANSREG procedure. Optionally, this statement identifies an input and an OUTTEST= data set, specifies the algorithm and other computational details, requests displayed output, and controls the contents of the OUT= data set (which is created with the OUTPUT statement). The DATA=, OUTTEST=, and PLOTS= options can appear only in the PROC TRANSREG statement. [Table 97.1](#) summarizes the options available in the PROC TRANSREG statement. The *a-options* are also available in the MODEL statement, and the *o-options* are also available in the OUTPUT statement.

Table 97.1 Options Available in the PROC TRANSREG Statement

Option	Description
Data Set Options (PROC Statement)	
DATA=	Specifies input SAS data set
OUTTEST=	Specifies output test statistics data set
ODS Graphics (PROC Statement)	
PLOTS=	Specifies ODS Graphics selection
Input Control (PROC or MODEL)	
REITERATE	Restarts the iterations
TYPE=	Specifies input observation type
Method and Iterations (PROC or MODEL)	
CCONVERGE=	Specifies minimum criterion change
CONVERGE=	Specifies minimum data change
MAXITER=	Specifies maximum number of iterations
METHOD=	Specifies iterative algorithm
NCAN=	Specifies number of canonical variables
NSR	Specifies no restrictions on smoothing models
SINGULAR=	Specifies singularity criterion
SOLVE	Attempts direct solution instead of iteration
Missing Data Handling (PROC or MODEL)	
INDIVIDUAL	Fits each model individually (METHOD=MORALS)
MONOTONE=	Includes monotone special missing values
NOMISS	Excludes observations with missing values
UNTIE=	Unties special missing values
Intercept and CLASS Variables (PROC or MODEL)	
CPREFIX=	Specifies CLASS coded variable name prefix
LPREFIX=	Specifies CLASS coded variable label prefix
NOINT	Specifies no intercept or centering
ORDER=	Specifies order of CLASS variable levels
REFERENCE=	Controls output of reference levels
SEPARATORS=	Controls CLASS coded variable label separators
Control Displayed Output (PROC or MODEL)	
ALPHA=	Specifies confidence limits alpha
CL	Displays parameter estimate confidence limits
DETAIL	Displays model specification details
HISTORY	Displays iteration histories
NOPRINT	Suppresses displayed output
PBOXCOXTABLE	Prints the Box-Cox log likelihood table
RSQUARE	Displays the R square
SHORT	Suppresses the iteration histories
SS2	Displays regression results
TEST	Displays ANOVA table
TSUFFIX=	Shortens transformed variable labels

Table 97.1 *continued*

Option	Description
UTILITIES	Displays conjoint part-worth utilities
Standardization (PROC or MODEL)	
ADDITIVE	Fits additive model
NOZEROCONSTANT	Does not zero constant variables
TSTANDARD=	Specifies transformation standardization
Predicted Values, Residuals, Scores (PROC or OUTPUT)	
CANONICAL	Outputs canonical scores
CLI	Outputs individual confidence limits
CLM	Outputs mean confidence limits
DESIGN=	Specifies design matrix coding
DREPLACE	Replaces dependent variables
IREPLACE	Replaces independent variables
LEVERAGE	Outputs leverage
NORESTOREMISSING	Does not restore missing values
NOSCORES	Suppresses output of scores
PREDICTED	Outputs predicted values
REDUNDANCY=	Outputs redundancy variables
REPLACE	Replaces all variables
RESIDUALS	Outputs residuals
Output Data Set Coefficients (PROC or OUTPUT)	
COEFFICIENTS	Outputs coefficients
COORDINATES=	Outputs ideal point coordinates
MEANS	Outputs marginal means
MREDUNDANCY	Outputs redundancy analysis coefficients
Output Data Set Variable Name Prefixes (PROC or OUTPUT)	
ADPREFIX=	Specifies dependent variable approximations
AIPREFIX=	Specifies independent variable approximations
CDPREFIX=	Specifies canonical dependent variables
CILPREFIX=	Specifies conservative individual lower CL
CIPREFIX=	Specifies canonical independent variables
CIUPREFIX=	Specifies conservative-individual-upper CL
CMLPREFIX=	Specifies conservative-mean-lower CL
CMUPREFIX=	Specifies conservative-mean-upper CL
DEPENDENT=	Specifies METHOD=MORALS untransformed dependent
LILPREFIX=	Specifies liberal-individual-lower CL
LIUPREFIX=	Specifies liberal-individual-upper CL
LMLPREFIX=	Specifies liberal-mean-lower CL
LMUPREFIX=	Specifies liberal-mean-upper CL
PPREFIX=	Specifies predicted values
RDPREFIX=	Specifies residuals
RPREFIX=	Specifies redundancy variables
TDPREFIX=	Specifies transformed dependents

Table 97.1 *continued*

Option	Description
TIPREFIX=	Specifies transformed independents
Macros Variables (PROC or OUTPUT)	
MACRO	Creates macro variables
Other Options (PROC or OUTPUT)	
APPROXIMATIONS	Outputs dependent and independent approximations
CCC	Outputs canonical correlation coefficients
CEC	Outputs canonical elliptical point coordinates
CPC	Outputs canonical point coordinates
CQC	Outputs canonical quadratic point coordinates
DAPPROXIMATIONS	Outputs approximations to transformed dependents
IAPPROXIMATIONS	Outputs approximations to transformed independents
MEC	Outputs elliptical point coordinates
MPC	Outputs point coordinates
MQC	Outputs quadratic point coordinates
MRC	Outputs multiple regression coefficients

DATA=SAS-data-set

specifies the SAS data set to be analyzed. If you do not specify the DATA= option, PROC TRANSREG uses the most recently created SAS data set. The data set must be an ordinary SAS data set; it cannot be a special TYPE= data set.

OUTTEST=SAS-data-set

specifies an output data set to contain hypothesis tests results. When you specify the OUTTEST= option, the data set contains ANOVA results. When you specify the SS2 *a-option*, regression tables are also output. When you specify the UTILITIES *o-option*, conjoint analysis part-worth utilities are also output. For more information about the OUTTEST= data set, see the section “OUTTEST= Output Data Set” on page 8313.

PLOTS <(global-plot-options)> <= plot-request <(options)>>**PLOTS <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>)>**

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=(residuals transformation)
plots(unpack)=boxcox
plots(unpack)=(transformation boxcox(p=0))
plots=(residuals(unpack) transformation(dep unp) boxcox(t rmse))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc transreg plots=all;
    model identity(y) = pbspline(x);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled, but you do not specify the PLOTS= option, then PROC TRANSREG produces a default set of plots. The fit, scatter, residual, and observed-by-predicted plots are available with [METHOD=MORALS](#) and also with [METHOD=UNIVARIATE](#) when there is only one dependent variable. When no method is specified and there is more than one dependent variable, and when regression plots are requested, the default method is set to [METHOD=MORALS](#). When there is more than one dependent variable, when [METHOD=](#) is not specified, or when [METHOD=MORALS](#) is specified and [PLOTS=ALL](#) is specified, the plots that are produced might be different from those you would see with [METHOD=UNIVARIATE](#) and [PLOTS=ALL](#). Certain plots appear by default when ODS Graphics is enabled and certain combinations of options are specified. The Box-Cox $F = t^2$ and log-likelihood plots appear when a [BOXCOX](#) dependent variable transformation is specified. The regression fit plot appears for models with a single dependent variable that is not transformed (for example, [IDENTITY\(y\)](#)), a single quantitative independent variable that might or might not be transformed, and at most one [CLASS](#) independent variable. Preference mapping plots appear when the [COORDINATES](#) *o-option* is used.

The global plot options include the following:

INTERPOLATE

INT

uses observations that are excluded from the analysis for interpolation in the fit and transformation plots. By default, observations with zero weight are excluded from all plots. These include observations with a zero, negative, or missing weight or frequency and observations excluded due to missing and invalid values. You can specify [PLOTS\(INTERPOLATE\)=\(plot-requests\)](#) to include some of these observations in the plots. You might want to use this option, for example, with sparse data sets to show smoother functions over the range of the data (see the section “[The PLOTS\(INTERPOLATE\) Option](#)” on page 8340). Observations with missing values in [CLASS](#) variables are excluded from the plots even when [PLOTS\(INTERPOLATE\)](#) is specified.

ONLY

ONL

suppresses the default plots. Only plots specifically requested are displayed.

UNPACKPANEL

UNPACK

UNP

suppresses paneling. By default, multiple plots can appear in some output panels. Specify [UNPACKPANEL](#) to get each plot in a separate panel. You can specify [PLOTS\(UNPACKPANEL\)](#) to unpack the default plots. You can also specify [UNPACKPANEL](#) as a suboption with [TRANSFORMATION](#), [RESIDUALS](#), [PBSPLINE](#), and [BOXCOX](#).

The plot requests include the following:

ALL

produces all appropriate plots. You can specify other options with ALL; for example, to request all plots and unpack only the residuals, specify PLOTS=(ALL RES(UNP)).

BOXCOX <(options)>

BOX <(options)>

requests a display of the results of the Box-Cox transformation. These results are displayed by default when there is a Box-Cox transformation. The BOXCOX plot request has the following options:

P=*n*

adds t or $F = t^2$ curves to the legend for the functions where $p(t) < n$, where t is the t statistic corresponding to the optimal lambda. You can specify P=0 to suppress the legend and P=1 to see all curves in the legend. The default value comes from the BOXCOX(variable / ALPHA=p) specification, which by default is 0.05.

RMSE

RMS

plots the root mean square error as a function of lambda.

T

plots t statistics rather than $F = t^2$ statistics.

UNPACKPANEL

UNPACK

UNP

plots the t or $F = t^2$ and log-likelihood plots in separate panels.

FIT <(options)>

requests a regression fit plot. This plot is produced by default whenever it is appropriate. It is produced when the dependent variable is specified with the IDENTITY *transform*, and when there is one quantitative independent variable (for example, IDENTITY for linear fit, SPLINE or one of the other transformations for a nonlinear fit, or PSPLINE) and at most one CLASS variable. When there is a CLASS variable, separate fits are produced within levels based on your model. You would specify the FIT plot request only to specify a FIT option or with the ONLY global plot option. The FIT plot request has the following options:

FORMULA

FOR

displays the fit function as an equation in regression fit plots. This option is valid when a fit plot is produced and either an IDENTITY *transform* or a PSPLINE *expansion* with degree less than ten and no knots is specified for a single independent variable. When this option is specified, you can output the formula to a data set by using the ods output **formula**=SAS-data-set statement. This is the formula, complete with Unicode specifications for polynomials, that is used in the fit plot template to make the formula.

NOCLM

suppresses the confidence limits in regression fit plots.

NOCLI

suppresses the individual prediction limits in regression fit plots.

NOOBS

suppresses the observations showing only the fit function and optionally the confidence and prediction limits.

NONE

suppresses all plots.

OBSERVEDBYPREDICTED**OBP****OBS**

plots the transformed dependent variable as a function of the regression predicted values.

PBSPLINE <(UNPACKPANEL)>**PBS <(UNPACK)>**

requests the penalized B-spline criterion plots. You would specify the PBSPLINE plot request only to specify a PBSPLINE option or with the ONLY global plot option. The PBSPLINE plot request has the following option:

UNPACKPANEL**UNPACK****UNP**

plots each criterion plot in a separate panel.

PREFMAP**PRE**

plots ideal point or vector preference mapping results when either two **IDENTITY** or two **POINT** independent variables are specified along with the **COORDINATES** option.

RESIDUALS <(options)>**RES <(options)>**

plots the residuals as a function of each of the transformed independent variables, except coded CLASS variables. The RESIDUALS plot request has the following options:

CLASS**CLA**

plots the residuals as a function of each of the transformed independent variables, including coded **CLASS** variables. Note that the ALL plot request, which you use to request all plots, specifies the RESIDUALS plot request without the CLASS option.

UNPACKPANEL**UNPACK****UNP**

plots the residuals in separate plots, not several per panel.

SMOOTH**SMO**

adds a LOESS smooth function to the residuals plots.

SCATTER**SCA**

plots the scatter plot of observed data, before the transformations, for models with a single quantitative dependent variable, a single quantitative independent variable, and at most one CLASS independent variable.

TRANSFORMATION <(options)>**TRA** <(options)>

plots the variable transformations. The TRANSFORMATION plot request has the following options:

DEPENDENTS**DEP**

plots only the dependent variable transformations.

INDEPENDENTS**IND**

plots only the independent variable transformations.

UNPACKPANEL**UNPACK****UNP**

plots the transformations in separate plots, not several per panel.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC TRANSREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the NOTSORTED or DESCENDING option in the BY statement for the TRANSREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC TRANSREG then treats the data set as if each observation appeared n times, where n is the value of the FREQ variable for the observation. Noninteger values of the FREQ variable are truncated to the largest integer less than the FREQ value. The observation is used in the analysis only if the value of the FREQ statement variable is greater than or equal to 1.

ID Statement

ID *variables* ;

The ID statement includes additional character or numeric variables in the **OUT=** data set. The variables must be contained in the input data set. The first variable is used to label points in PREFMAP plots. These variables are also used in some plots as tip variables.

MODEL Statement

```
MODEL < transform(dependents </ t-options>) >
      < transform(dependents </ t-options>)...=>
      transform(independents </ t-options>)
      < transform(independents </ t-options>)... > </ a-options> ;
```

The MODEL statement specifies the dependent and independent variables (*dependents* and *independents*, respectively) and specifies the transformation (*transform*) to apply to each variable. Only one MODEL statement can appear in PROC TRANSREG. The *t-options* are transformation options, and the *a-options* are algorithm options. The *t-options* provide details for the transformation; these depend on the *transform* chosen. The *t-options* are listed after a slash in the parentheses that enclose the variable list (either *dependents* or *independents*). The *a-options* control the algorithm used, details of iteration, details of how the intercept and coded variables are generated, and displayed output details. The *a-options* are listed after the entire model specification (the *dependents*, *independents*, transformations, and *t-options*) and after a slash. You can also specify the algorithm options in the PROC TRANSREG statement. When you specify the

DESIGN *o-option*, *dependents* and an equal sign are not required. The operators *, |, and @ from the GLM procedure are available for interactions with the **CLASS** expansion and the **IDENTITY** transformation. They are used as follows:

```

Class(a * b ...
      c | d ...
      e | f ... @ n)
Identity(a * b ...
         c | d ...
         e | f ... @ n)

```

In addition, transformations and spline expansions can be crossed with classification variables as follows:

```

transform(var) * class(group)
transform(var) | class(group)

```

See the section “[Types of Effects](#)” on page 3325 in Chapter 42, “[The GLM Procedure](#),” for a description of the @, *, and | operators and see the section “[Model Statement Usage](#)” on page 8220 for information about how to use these operators in PROC TRANSREG. Note that nesting is not implemented in PROC TRANSREG.

The next three sections discuss the transformations available (*transforms*) (see the section “[Families of Transformations](#)” on page 8183), the transformation options (*t-options*) (see the section “[Transformation Options \(t-options\)](#)” on page 8190), and the algorithm options (*a-options*) (see the section “[Algorithm Options \(a-options\)](#)” on page 8200).

Families of Transformations

In the MODEL statement, *transform* specifies a transformation in one of the following five families:

Variable expansions	preprocess the specified variables, replacing them with more variables.
Nonoptimal transformations	preprocess the specified variables, replacing each one with a single new nonoptimal, nonlinear transformation.
Nonlinear fit transformations	preprocess the specified variable, replacing it with a smooth transformation, fitting one or more nonlinear functions through a scatter plot.
Optimal transformations	replace the specified variables with new, iteratively derived optimal transformation variables that fit the specified model better than the original variable (except for contrived cases where the transformation fits the model exactly as well as the original variable).
Other transformations	are the IDENTITY and SSPLINE transformations. These do not fit into the preceding categories.

The transformations and expansions listed in [Table 97.2](#) are available in the MODEL statement.

Table 97.2 Transformation Families

Transformation	Description
Variable Expansions	
BSPLINE	B-spline basis
CLASS	set of coded variables
EPOINT	elliptical response surface
POINT	circular response surface & PREFMAP
PSPLINE	piecewise polynomial basis
QPOINT	quadratic response surface
Nonoptimal Transformations	
ARSIN	inverse trigonometric sine
EXP	exponential
LOG	logarithm
LOGIT	logit
POWER	raises variables to specified power
RANK	transforms to ranks
Nonlinear Fit Transformations	
BOXCOX	Box-Cox
PBSPLINE	penalized B-splines
SMOOTH	noniterative smoothing spline
Optimal Transformations	
LINEAR	linear
MONOTONE	monotonic, ties preserved
MSPLINE	monotonic B-spline
OPSCORE	optimal scoring
SPLINE	B-spline
UNTIE	monotonic, ties not preserved
Other Transformations	
IDENTITY	identity, no transformation
SSPLINE	iterative smoothing spline

You can use any transformation with either dependent or independent variables (except the **SMOOTH** and **PBSPLINE** transformations, which can be used only with independent variables, and **BOXCOX**, which can be used only with dependent variables). However, the variable expansions are usually more appropriate for independent variables.

The *transform* is followed by a variable (or list of variables) enclosed in parentheses. Here is an example:

```
model log(y) = class(x);
```

This example finds a **LOG** transformation of *y* and performs a **CLASS** expansion of *x*. Optionally, depending on the *transform*, the parentheses can also contain *t-options*, which follow the variables and a slash. Here is an example:

```
model identity(y) = spline(x1 x2 / nknots=3);
```

The preceding statement finds **SPLINE** transformations of *x1* and *x2*. The **NKNOTS=** *t-option* used with the **SPLINE** transformation specifies three knots. The **identity(y)** transformation specifies that *y* is not to be transformed.

The rest of this section provides syntax details for members of the five families of transformations listed at the beginning of this section. The *t-options* are discussed in the section “[Transformation Options \(t-options\)](#)” on page 8190.

Variable Expansions

PROC TRANSREG performs variable expansions before iteration begins. Variable expansions expand the original variables into a typically larger set of new variables. The original variables are those that are listed in parentheses after *transform*, and they are sometimes referred to by the name of the *transform*. For example, in `CLASS(x1 x2)`, `x1` and `x2` are sometimes referred to as CLASS expansion variables or simply CLASS variables, and the expanded variables are referred to as coded or sometimes “dummy” variables. Similarly, in `POINT(Dim1 Dim2)`, `Dim1` and `Dim2` are sometimes referred to as POINT variables.

The resulting variables are not transformed by the iterative algorithms after the initial preprocessing. Observations with missing values for these types of variables are excluded from the analysis.

The [POINT](#), [EPOINT](#), and [QPOINT](#) variable expansions are used in preference mapping analyses (also called PREFMAP, external unfolding, ideal point regression) (Carroll 1972) and for response surface regressions. These three expansions create circular, elliptical, and quadratic response or preference surfaces (see the section “[Point Models](#)” on page 8294 and [Example 97.6](#)). The [CLASS](#) variable expansion is used for main-effects ANOVA.

The following list provides syntax and details for the variable expansion *transforms*.

BSPLINE

BSP

expands each variable to a B-spline basis. You can specify the [DEGREE=](#), [KNOTS=](#), [NKNOTS=](#), and [EVENLY= t-options](#) with the BSPLINE expansion. When [DEGREE=*n*](#) (3 by default) with *k* knots (0 by default), $n + k + 1$ variables are created. In addition, the original variable appears in the [OUT=](#) data set before the [ID](#) variables. For example, `bspline(x)` expands `x` into `x_0 x_1 x_2 x_3` and outputs `x` as well. The `x_:` variables contain the B-spline basis vectors (which are the same basis vectors that the [SPLINE](#) and [MSPLINE](#) transformations use internally). The columns of the BSPLINE expansion sum to a column of ones, so an implicit intercept model is fit when the BSPLINE expansion is specified. If you specify the BSPLINE expansion for more than one variable, the model is less than full rank. Variables specified in a BSPLINE expansion must be numeric, and they are typically continuous. See the sections “[SPLINE and MSPLINE Transformations](#)” on page 8300 and “[SPLINE, BSPLINE, and PSPLINE Comparisons](#)” on page 8302 for more information about B-splines.

CLASS

CLA

expands the variables to a set of coded or “dummy” variables. PROC TRANSREG uses the values of the formatted variables to determine class membership. The specification `class(x1 x2)` fits a simple main-effects model, `class(x1 | x2)` fits a main-effects and interactions model, and `class(x1 | x2 | x3 | x4 @ 2 x1 * x2 * x3)` fits a model with all main effects, all two-way interactions, and one three-way interaction. Variables specified with the CLASS expansion can be either character or numeric; numeric variables should be discrete. See the section “[ANOVA Codings](#)” on page 8270 for more information about CLASS variables. See the section “[Model Statement Usage](#)” on page 8220 for information about how to use the operators `@`, `*`, and `|` in PROC TRANSREG.

EPOINT**EPO**

expands the variables for an elliptical response surface regression or for an elliptical ideal point regression. Specify the **COORDINATES** *o-option* to output PREFMAP ideal elliptical point model coordinates to the **OUT=** data set. Each axis of the ellipse (or ellipsoid) is oriented in the same direction as one of the variables. The EPOINT expansion creates a new variable for each original variable. The value of each new variable is the square of each observed value for the corresponding original variable. The regression analysis then uses both sets of variables (original and squared). Variables specified with the EPOINT expansion must be numeric, and they are typically continuous. See the section “**Point Models**” on page 8294 and **Example 97.6** for more information about point models.

POINT**POI**

expands the variables for a circular response surface regression or for a circular ideal point regression. Specify the **COORDINATES** *o-option* to output PREFMAP ideal point model coordinates to the **OUT=** data set. The POINT expansion creates a new variable having a value for each observation that is the sum of squares of all the POINT variables. This new variable is added to the set of variables and is used in the regression analysis. For more information about ideal point regression, see Carroll (1972). Variables specified with the POINT expansion must be numeric, and they are typically continuous. See the section “**Point Models**” on page 8294 and **Example 97.6** for more information about point models.

PSPLINE**PSP**

expands each variable to a piecewise polynomial basis. You can specify the **DEGREE=**, **KNOTS=**, **NKNOTS=**, and **EVENLY** *t-options* with PSPLINE. When **DEGREE=n** (3 by default) with *k* knots (0 by default), $n + k$ variables are created. In addition, the original variable appears in the **OUT=** data set before the **ID** variables. For example, **pspline(x / nknots=1)** expands *x* into *x*_1 *x*_2 *x*_3 *x*_4 and outputs *x* as well. Unlike BSPLINE, an intercept is not implicit in the columns of PSPLINE. Variables specified with the PSPLINE expansion must be numeric, and they are typically continuous. See the sections “**SPLINE, BSPLINE, and PSPLINE Comparisons**” on page 8302 and “**Using Splines and Knots**” on page 8233 for more information about splines. Also see Smith (1979) for a good introduction to piecewise polynomial splines.

QPOINT**QPO**

expands the variables for a quadratic response surface regression or for a quadratic ideal point regression. Specify the **COORDINATES** *o-option* to output PREFMAP quadratic ideal point model coordinates to the **OUT=** data set. For *m* QPOINT variables, $m(m + 1)/2$ new variables are created containing the squares and crossproducts of the original variables. The regression analysis uses both sets (original and crossed). Variables specified with the QPOINT expansion must be numeric, and they are typically continuous. See the section “**Point Models**” on page 8294 and **Example 97.6** for more information about point models.

Nonoptimal Transformations

The nonoptimal transformations, like the variable expansions, are computed before the iterative algorithm begins. Nonoptimal transformations create a single new transformed variable that replaces the original variable. The new variable is not transformed by the subsequent iterative algorithms (except for a possible linear transformation with missing value estimation). The following list provides syntax and details for nonoptimal variable transformations.

ARSIN

ARS

finds an inverse trigonometric sine transformation. Variables specified in the ARSIN *transform* must be numeric and in the interval $(-1.0 \leq x \leq 1.0)$, and they are typically continuous.

EXP

exponentiates variables (x is transformed to a^x). To specify the value of a , use the **PARAMETER=** *t-option*. By default, a is the mathematical constant $e = 2.718\dots$. Variables specified with the EXP *transform* must be numeric, and they are typically continuous.

LOG

transforms variables to logarithms (x is transformed to $\log_a(x)$). To specify the base of the logarithm, use the **PARAMETER=** *t-option*. The default is a natural logarithm with base $e = 2.718\dots$. Variables specified with the LOG *transform* must be numeric and positive, and they are typically continuous.

LOGIT

finds a logit transformation on the variables. The logit of x is $\log(x/(1 - x))$. Unlike other transformations, LOGIT does not have a three-letter abbreviation. Variables specified with the LOGIT *transform* must be numeric and in the interval $(0.0 < x < 1.0)$, and they are typically continuous.

POWER

POW

raises variables to a specified power (x is transformed to x^a). You must specify the power parameter a by specifying the **PARAMETER=** *t-option* following the variables. Here is an example:

```
power(variable / parameter=number)
```

You can use POWER for squaring variables (PARAMETER=2), reciprocal transformations (PARAMETER=-1), square roots (PARAMETER=0.5), and so on. Variables specified with the POWER *transform* must be numeric, and they are typically continuous.

RANK

RAN

transforms variables to ranks. Ranks are averaged within ties. The smallest input value is assigned the smallest rank. Variables specified in the RANK *transform* must be numeric.

Nonlinear Fit Transformations

Nonlinear fit transformations, like nonoptimal transformations, are computed before the iterative algorithm begins. Nonlinear fit transformations create a single new transformed variable that replaces the original variable and provides one or more smooth functions through a scatter plot. The new variable is not transformed by the subsequent iterative algorithms. The nonlinear fit transformations, unlike the nonoptimal

transformations, use information in the other variables in the model to find the transformations. The nonlinear fit transformations, unlike the optimal transformations, do not minimize a squared-error criterion. The following list provides syntax and details for nonoptimal variable transformations.

BOXCOX

BOX

finds a Box-Cox (1964) transformation of the specified variables. The BOXCOX transformation can be used only with dependent variables. The **ALPHA=**, **CLL=**, **CONVENIENT**, **GEOMETRICMEAN**, **LAMBDA=**, and **PARAMETER=** *t-options* can be used with the BOXCOX transformation. Variables specified in the BOXCOX *transform* must be numeric, and they are typically continuous. See the section “[Box-Cox Transformations](#)” on page 8222 and [Example 97.2](#) for more information about Box-Cox transformations.

PBSPLINE

PBS

is a noniterative penalized B-spline transformation (Eilers and Marx 1996). The PBSPLINE transformation can be used only with independent variables. By default with PBSPLINE, a cubic spline is fit with 100 evenly spaced knots, three evenly spaced exterior knots, and a difference matrix of order three (**DEGREE=3** **NKNOTS=100** **EVENLY=3** **PARAMETER=3**). Variables specified in the PBSPLINE *transform* must be numeric, and they are typically continuous. See the section “[Penalized B-Splines](#)” on page 8260 and [Example 97.3](#) for more information about penalized B-splines.

SMOOTH

SMO

is a noniterative smoothing spline transformation (Reinsch 1967). You can specify the smoothing parameter with either the **SM=** or the **PARAMETER=** *t-option*. The default smoothing parameter is **SM=0**. The SMOOTH transformation can be used only with independent variables. Variables specified with the SMOOTH *transform* must be numeric, and they are typically continuous. See the sections “[Smoothing Splines](#)” on page 8263 and “[Smoothing Splines Changes and Enhancements](#)” on page 8267 for more information about smoothing splines.

Optimal Transformations

Optimal transformations are iteratively derived. Missing values for these types of variables can be optimally estimated (see the section “[Missing Values](#)” on page 8289). The following list provides syntax and details for optimal transformations.

LINEAR

LIN

finds an optimal linear transformation of each variable. For variables with no missing values, the transformed variable is the same as the original variable. For variables with missing values, the transformed nonmissing values have a different scale and origin than the original values. Variables specified in the LINEAR *transform* must be numeric. See the section “[OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations](#)” on page 8298 for more information about optimal scaling.

MONOTONE**MON**

finds a monotonic transformation of each variable, with the restriction that ties are preserved. The Kruskal (1964) secondary least squares monotonic transformation is used. This transformation weakly preserves order and category membership (ties). Variables specified with the **MONOTONE** *transform* must be numeric, and they are typically discrete. See the section “[OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations](#)” on page 8298 for more information about optimal scaling.

MSPLINE**MSP**

finds a monotonically increasing B-spline transformation with monotonic coefficients (de Boor 1978; de Leeuw 1986) of each variable. You can specify the **DEGREE=**, **KNOTS=**, **NKNOTS=**, and **EVENLY=** *t-options* with **MSPLINE**. By default, PROC TRANSREG fits a quadratic spline with no knots. Variables specified with the **MSPLINE** *transform* must be numeric, and they are typically continuous. See the section “[SPLINE and MSPLINE Transformations](#)” on page 8300 for more information about monotone splines.

OPSCORE**OPS**

finds an optimal scoring of each variable. The OPScore transformation assigns scores to each class (level) of the variable. The Fisher (1938) optimal scoring method is used. Variables specified with the **OPSCORE** *transform* can be either character or numeric; numeric variables should be discrete. See the sections “[Character OPScore Variables](#)” on page 8293 and “[OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations](#)” on page 8298 for more information about optimal scaling.

SPLINE**SPL**

finds a B-spline transformation (de Boor 1978) of each variable. By default, PROC TRANSREG fits a cubic spline with no knots. You can specify the **DEGREE=**, **KNOTS=**, **NKNOTS=**, and **EVENLY=** *t-options* with **SPLINE**. Variables specified with the **SPLINE** *transform* must be numeric, and they are typically continuous. See the sections “[SPLINE and MSPLINE Transformations](#)” on page 8300, “[Specifying the Number of Knots](#)” on page 8301, and “[SPLINE, BSPLINE, and PSPLINE Comparisons](#)” on page 8302, and “[Using Splines and Knots](#)” on page 8233 for more information about splines.

UNTIE**UNT**

finds a monotonic transformation of each variable without the restriction that ties are preserved. PROC TRANSREG uses the Kruskal (1964) primary least squares monotonic transformation method. This transformation weakly preserves order but not category membership (it might untie some previously tied values). Variables specified with the **UNTIE** *transform* must be numeric, and they are typically discrete. See the section “[OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations](#)” on page 8298 for more information about optimal scaling.

Other Transformations

IDENTITY

IDE

specifies variables that are not changed by the iterations. Typically, the IDENTITY transformation is used with a simple variable list, such as `identity(x1-x5)`. However, you can also specify interaction terms. For example, `identity(x1 | x2)` creates x_1 , x_2 , and the product $x_1 \times x_2$; and `identity(x1 | x2 | x3)` creates x_1 , x_2 , $x_1 \times x_2$, x_3 , $x_1 \times x_3$, $x_2 \times x_3$, and $x_1 \times x_2 \times x_3$. See the section “Model Statement Usage” on page 8220 for information about how to use the operators @, *, and | in PROC TRANSREG. Variables specified in the IDENTITY *transform* must be numeric.

The IDENTITY transformation is used for variables when no transformation and no missing data estimation are desired. However, the REFLECT *t-option*, the ADDITIVE *a-option*, and the TSTANDARD=Z, and TSTANDARD=CENTER options can linearly transform all variables, including IDENTITY variables, after the iterations. Observations with missing values in IDENTITY variables are excluded from the analysis, and no optimal scores are computed for missing values in IDENTITY variables.

SSPLINE

SSP

finds an iterative smoothing spline transformation of each variable. The SSPLINE transformation does not generally minimize squared error. You can specify the smoothing parameter with either the SM= *t-option* or the PARAMETER= *t-option*. The default smoothing parameter is SM=0. Variables specified with the SSPLINE *transform* must be numeric, and they are typically continuous.

Transformation Options (t-options)

If you use a nonoptimal, nonlinear fit, optimal, or other transformation, you can use *t-options*, which specify additional details of the transformation. The *t-options* are specified within the parentheses that enclose variables and are listed after a slash. You can use *t-options* with both the dependent and the independent variables. Here is an example of using just one *t-option*:

```
proc transreg;
  model identity(y)=spline(x / nknots=3);
  output;
run;
```

The preceding statements find an optimal variable transformation (SPLINE) of the independent variable, and they use a *t-option* to specify the number of knots (NKNOTS=). The following is a more complex example:

```
proc transreg;
  model mspline(y / nknots=3)=class(x1 x2 / effects);
  output;
run;
```

These statements find a monotone spline transformation (MSPLINE with three knots) of the dependent variable and perform a CLASS expansion with effects coding of the independents.

Table 97.3 summarizes the *t-options* available in the MODEL statement.

Table 97.3 Transformation Options

Option	Description
Nonoptimal Transformation	
ORIGINAL	Uses original mean and variance
Parameter Specification	
PARAMETER=	Specifies miscellaneous parameters
SM=	Specifies smoothing parameter
Penalized B-Spline	
AIC	Uses Akaike's information criterion
AICC	Uses corrected AIC
CV	Uses cross validation criterion
GCV	Uses generalized cross validation criterion
LAMBDA=	Specifies smoothing parameter list or range
RANGE	Specifies a LAMBDA= range, not a list
SBC	Uses Schwarz's Bayesian criterion
Spline	
DEGREE=	Specifies the degree of the spline
EVENLY=	Spaces the knots evenly
EXKNOTS=	Specifies exterior knots
KNOTS=	Specifies the interior knots or break points
NKNOTS=	Creates n knots
CLASS Variable	
CPREFIX=	Specifies CLASS coded variable name prefix
DEVIATIONS	Specifies a deviations-from-means coding
EFFECTS	Specifies a deviations-from-means coding
LPREFIX=	Specifies CLASS coded variable label prefix
ORDER=	Specifies order of CLASS variable levels
ORTHOGONAL	Specifies an orthogonal-contrast coding
SEPARATORS=	Specifies CLASS coded variable label separators
STANDORTH	Specifies a standardized-orthogonal coding
ZERO=	Controls reference levels
Box-Cox	
ALPHA=	Specifies confidence interval alpha
CLL=	Specifies convenient lambda list
CONVENIENT	Uses a convenient lambda
GEOMETRICMEAN	Scales transformation using geometric mean
LAMBDA=	Specifies power parameter list

Table 97.3 continued

Option	Description
Other t-options	
AFTER	Specifies operations occur after the expansion
CENTER	Specifies center before the analysis begins
NAME=	Renames variables
REFLECT	Reflects the variable around the mean
TSTANDARD=	Specifies transformation standardization
Z	Standardizes before the analysis begins

The following sections discuss the *t-options* available for nonoptimal, nonlinear fit, optimal, and other transformations.

Nonoptimal Transformation t-options

ORIGINAL

ORI

matches the variable's final mean and variance to the mean and variance of the original variable. By default, the mean and variance are based on the transformed values. The ORIGINAL *t-option* is available for all of the nonoptimal transformations.

Parameter t-options

PARAMETER=number

PAR=number

specifies the transformation parameter. The PARAMETER= *t-option* is available for the **BOXCOX**, **EXP**, **LOG**, **POWER**, **SMOOTH**, **SSPLINE**, and **PBSPLINE** transformations. For **BOXCOX**, the parameter is the value to add to each value of the variable before a Box-Cox transformation. For **EXP**, the parameter is the value to be exponentiated; for **LOG**, the parameter is the base value; and for **POWER**, the parameter is the power. For **SMOOTH** and **SSPLINE**, the parameter is the raw smoothing parameter. (See the **SM=** option for an alternative way to specify the smoothing parameter.) The default for the PARAMETER= *t-option* for the **BOXCOX** transformation is 0 and for the **LOG** and **EXP** transformations is $e = 2.718 \dots$. The default parameter for **SMOOTH** and **SSPLINE** is computed from **SM=0**. For the **POWER** transformation, you must specify the PARAMETER= *t-option*; there is no default. For **PBSPLINE**, the parameter is the order of the difference matrix, which provides some control over the smoothness of the transformation. The default order parameter with **PBSPLINE** is the maximum of the **DEGREE=** *t-option*, and 1. With **PBSPLINE**, the default is **DEGREE=3** and **PARAMETER=3**, which works well for most problems.

SM=n

specifies a smoothing parameter in the range 0 to 100, just like PROC GLOT uses. For example, **SM=50** in PROC TRANSREG is equivalent to **I=SM50** in the SYMBOL statement with PROC GLOT. You can specify the **SM=** *t-option* only with the **SMOOTH** and **SSPLINE** transformations. The smoothness of the function increases as the value of the smoothing parameter increases. By default, **SM=0**.

Spline t-options

The following *t-options* are available with the **SPLINE**, **MSPLINE** and **PBSPLINE** transformations and with the **PSPLINE** and **BSPLINE** expansions.

DEGREE=*n*

DEG=*n*

specifies the degree of the spline transformation. The degree must be a nonnegative integer. The defaults are **DEGREE=3** for **SPLINE**, **PSPLINE**, and **BSPLINE** variables and **DEGREE=2** for **MSPLINE** variables.

The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

EVENLY<=*n*>

EVE<=*n*>

is used with the **NKNOTS=** *t-option* to space the knots evenly. The differences between adjacent knots are constant.

If you specify **NKNOTS=*k*** and **EVENLY**, *k* knots are created at

$$\text{minimum} + i((\text{maximum} - \text{minimum}) / (k + 1))$$

for $i = 1, \dots, k$. Here is an example:

```
spline(x / nknots=2 evenly)
```

When the variable *x* has a minimum of 4 and a maximum of 10, then the two interior knots are 6 and 8. Without the **EVENLY** *t-option*, the **NKNOTS=** *t-option* places knots at percentiles, so the knots are not evenly spaced. By default for the **BSPLINE** expansion and the **SPLINE** and **MSPLINE** transformations, the smaller exterior knots are all the same and all just a little smaller than the minimum. Similarly, by default, the larger exterior knots are all the same and all just a little larger than the maximum. However, if you specify **EVENLY=*n***, then the *n* exterior knots are evenly spaced as well. The number of exterior knots must be greater than or equal to the degree. You can specify values larger than the degree when you want to interpolate slightly beyond the range of your data. The exterior knots must be less than the minimum or greater than the maximum; hence the knots across all sets are not precisely equally spaced. For example, with data ranging from 0 to 10, and with **EVENLY=3** and **NKNOTS=4**, the first exterior knots are -4.000000000001 , -2.000000000001 , and -0.000000000001 , the interior knots are 2, 4, 6, and 8, and the second exterior knots are 10.000000000001 , 12.000000000001 , and 14.000000000001 .

With the **BSPLINE** and **PSPLINE** expansions and the **SPLINE** and **MSPLINE** transformations, evenly spaced knots are not the default. With the **PBSPLINE** transformation, evenly spaced interior and exterior knots are the default. If you want unevenly spaced knots with **PBSPLINE**, you must use the **KNOTS=** *t-option*.

EXKNOTS=number-list

EXK=number-list

specifies exterior knots for **SPLINE** and **MSPLINE** transformations and **BSPLINE** expansions. Usually, this *t-option* is not needed; PROC TRANSREG automatically picks suitable exterior knots. The only time you need to use this option is when you want to ensure that the exact same basis is used for

different splines, such as when you apply coefficients from one spline transformation to a variable in a different data set (see the section “[Scoring Spline Variables](#)” on page 8245).

Specify one or two values. If the minimum EXKNOTS= value is less than the minimum data value, it is used as the exterior knot. If the maximum EXKNOTS= value is greater than the maximum data value, it is used as the exterior knot. Otherwise these values are ignored. When EXKNOTS= is specified with the [CENTER](#) or [Z](#) *t-options*, the knots apply to the original variable, not to the centered or standardized variable.

The B-spline transformations and expansions use a knot list consisting of exterior knots (values just smaller than the minimum), the specified (interior) knots, and exterior knots (values just larger than the minimum). You can use the [DETAIL](#) *a-option* to see all of these knots. If you use different exterior knots, you get different but equivalent B-spline bases. You can specify exterior knots in either the [KNOTS=](#) or [EXKNOTS=](#) *t-options*; however, for the [BSPLINE](#) expansion, the [KNOTS=](#) *t-option* creates extra all-zero basis columns, whereas the [EXKNOTS=](#) *t-option* gives you the correct basis. See the [EVENLY=](#) *t-option* for an alternative way to specify exterior knots.

KNOTS=*number-list* | *n* TO *m* BY *p*

KNO=*number-list* | *n* TO *m* BY *p*

specifies the interior knots or break points. By default, there are no knots. The first time you specify a value in the knot list, it indicates a discontinuity in the *n*th (from [DEGREE=*n*](#)) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the (*n* – 1) derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the [KNOTS=](#) *t-option* with the [NKNOTS=](#) *t-option*. You should keep the number of knots small (see the section “[Specifying the Number of Knots](#)” on page 8301).

NKNOTS=*n*

NKN=*n*

creates *n* knots, the first at the 100/(*n* + 1) percentile, the second at the 200/(*n* + 1) percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if [NKNOTS=3](#), knots are placed at the 25th percentile, the median, and the 75th percentile. You can use the [EVENLY=](#) *t-option* along with [NKNOTS=](#) to get evenly spaced knots. By default, with the [BSPLINE](#) and [PSPLINE](#) expansions and the [SPLINE](#) and [MSPLINE](#) transformations, [NKNOTS=0](#). By default, with the [PBSPLINE](#) transformation, [NKNOTS=100](#).

The value specified for the [NKNOTS=](#) *t-option* must be ≥ 0 .

You cannot use the [NKNOTS=](#) *t-option* with the [KNOTS=](#) *t-option*.

You should keep the number of knots small (see the section “[Specifying the Number of Knots](#)” on page 8301).

Penalized B-Spline *t-options*

The following *t-options* are available with the [PBSPLINE](#) transformation.

AIC

specifies that the procedure should select the smoothing parameter, λ , that minimizes the (Akaike 1973) information criterion (AIC). By default, the (AICC) criterion is minimized.

AICC

specifies that the procedure should select the smoothing parameter, λ , that minimizes the corrected Akaike information criterion (Hurvich, Simonoff, and Tsai 1998). This is the default criterion unless the AIC, CV, GCV, or SBC *t-option* is specified.

CV

specifies that the procedure should select the smoothing parameter, λ , that minimizes the cross validation criterion (CV). By default, the (AICC) criterion is minimized.

GCV

specifies that the procedure should select the smoothing parameter, λ , that minimizes the generalized cross validation criterion (Craven and Wahba 1979). By default, the (AICC) criterion is minimized.

LAMBDA=number-list**LAM=number-list**

specifies a list of penalized B-spline smoothing parameters. By default, PROC TRANSREG considers lambdas in the range 0 to 1E6. Alternatively, you can specify the RANGE *t-option* with LAMBDA=, such as LAMBDA=1E3 1E5 RANGE, to only consider lambdas in a narrower range. Note that the algorithm might not actually evaluate the criterion at the minimum and maximum if it does not have to. In particular, it avoids evaluating the criterion at LAMBDA=0 (no smoothing) unless it is the only LAMBDA= value specified. You can also specify a list of lambdas, such as LAMBDA=1 TO 10, and the procedure selects the best lambda from the list. In all cases, the lambda that minimizes the specified criterion (or AICC by default) is chosen.

RANGE**RAN**

specifies that the LAMBDA= *t-option* specifies two lambdas that define a range of values, from which an optimal lambda is selected. By default, PROC TRANSREG considers lambdas in the range 0 to 1E6.

SBC

specifies that the procedure should select the smoothing parameter, λ , that minimizes Schwarz's Bayesian criterion (Schwarz 1978; Judge et al. 1980). By default, the (AICC) criterion is minimized.

Class Variable t-options**CPREFIX=n | number-list****CPR=n | number-list**

specifies the number of first characters of a CLASS expansion variable's name to use in constructing names for coded variables. When you specify CPREFIX= as an *a-option* or an *o-option*, it specifies the default for all CLASS variables. When you specify CPREFIX= as a *t-option*, it overrides the default only for selected variables. A different CPREFIX= value can be specified for each CLASS variable by specifying the CPREFIX=number-list *t-option*, like the ZERO=formatted-value *t-option*.

DEVIATIONS**DEV**

requests a deviations-from-means coding of **CLASS** variables. The coded design matrix has values of 0, 1, and –1 for reference levels. This coding is referred to as “deviations-from-means,” “effects,” “center-point,” or “full-rank” coding. For example, here is the coding for two-, three-, four-, and five-level factors:

	Number of Levels									
	Two	Three		Four			Five			
a	1	1	0	1	0	0	1	0	0	0
b	-1	0	1	0	1	0	0	1	0	0
c		-1	-1	0	0	1	0	0	1	0
d				-1	-1	-1	0	0	0	1
e							-1	-1	-1	-1

EFFECTS**EFF**

See the **DEVIATIONS** *t-option*.

LPREFIX=*n* | *number-list*

LPR=*n* | *number-list*

specifies the number of first characters of a **CLASS** expansion variable’s label (or name if no label is specified) to use in constructing labels for the coded variables. When you specify **LPREFIX**= as an *a-option* or an *o-option*, it specifies the default for all **CLASS** variables. When you specify **LPREFIX**= as a *t-option*, it overrides the default only for selected variables. A different **LPREFIX**= value can be specified for each **CLASS** variable by specifying the **LPREFIX**=*number-list t-option*, like the **ZERO**=*formatted-value t-option*.

ORDER=**DATA** | **FREQ** | **FORMATTED** | **INTERNAL**

ORD=**DAT** | **FRE** | **FOR** | **INT**

specifies the order in which the **CLASS** variable levels are to be reported. The default is **ORDER**=**INTERNAL**. For **ORDER**=**FORMATTED** and **ORDER**=**INTERNAL**, the sort order is machine dependent. When you specify **ORDER**= as an *a-option* or an *o-option*, it specifies the default ordering for all **CLASS** variables. When you specify **ORDER**= as a *t-option*, it overrides the default ordering only for selected variables. You can specify a different **ORDER**= value for each **CLASS** specification.

ORTHOGONAL**ORT**

requests an orthogonal-contrast coding of **CLASS** variables. For example, here is the orthogonal-contrast coding for two-, three-, four-, and five-level factors:

	Number of Levels									
	Two	Three		Four			Five			
a	1	1	-1	1	-1	-1	1	-1	-1	-1
b	-1	0	2	0	2	-1	0	2	-1	-1
c		-1	-1	0	0	3	0	0	3	-1
d				-1	-1	-1	0	0	0	4
e							-1	-1	-1	-1

The sum of the coded values within each column is zero, all columns within a factor are orthogonal, and the *i*th column represents a contrast between the *i*th level and the combination of all preceding

levels and the last level. The X matrix is orthogonal and $X'X$ is diagonal with this coding only if the experimental design is orthogonal.

SEPARATORS='string-1' < 'string-2' >

SEP='string-1' < 'string-2' >

specifies separators for creating **CLASS** expansion variable labels. By default, SEPARATORS=' ' * ' ("blank" and "blank asterisk blank"). When you specify SEPARATORS= as an *a-option* or an *o-option*, it specifies the default separators for all **CLASS** variables. When you specify SEPARATORS= as a *t-option*, it overrides the default only for selected variables. You can specify a different SEPARATORS= value for each **CLASS** specification.

STANDARDORTH

STA

ORTHEFFECT

requests a standardized-orthogonal coding of **CLASS** variables. For example, here is the standardized-orthogonal coding for two-, three-, four-, and five-level factors:

	Number of Levels									
	Two	Three		Four			Five			
a	1	1.22	-0.71	1.41	-0.82	-0.58	1.58	-0.91	-0.65	-0.50
b	-1	0.00	1.41	0.00	1.63	-0.58	0.00	1.83	-0.65	-0.50
c		-1.22	-0.71	0.00	0.00	1.73	0.00	0.00	1.94	-0.50
d				-1.41	-0.82	-0.58	0.00	0.00	0.00	2.00
e							-1.58	-0.91	-0.65	-0.50

The sum of the coded values within each column is zero, the sum of squares of the coded values within each column is equal to the number of levels, all columns within a factor are orthogonal, and the *i*th column represents a contrast between the *i*th level and the combination of all preceding levels and the last level. The X matrix is orthogonal and $X'X$ is diagonal ($X'X = nI$, the number of observations times an identity matrix) with this coding only if the experimental design is orthogonal.

ZERO=FIRST | LAST | NONE | SUM

ZER=FIR | LAS | NON | SUM

ZERO='formatted-value' < 'formatted-value' ... >

is used with **CLASS** variables. The default is ZERO=LAST.

The specification CLASS(variable / ZERO=FIRST) sets to missing the coded variable for the first of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO=LAST) sets to missing the coded variable for the last of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO='formatted-value') sets to missing the coded variable for the category with a formatted value that matches 'formatted-value', implying a zero coefficient for that category. With ZERO=formatted-value, the first formatted value applies to the first variable in the specification, the second formatted value applies to the next variable that was not previously mentioned, and so on. For example, `class(a a*b b b*c c / zero='x' 'y' 'z')` specifies that the reference level for a is 'x', for b is 'y', and for c is 'z'. With ZERO='formatted-value', the procedure first looks for exact matches between the formatted values and the specified value. If none are found, leading blanks are stripped from both and the values are compared again. If zero or two or more matches are found, warnings are issued.

The specifications ZERO=FIRST, ZERO=LAST, and ZERO=*'formatted-value'* are used for reference cell models. The Intercept parameter estimate is the marginal mean for the reference cell, and the other marginal means are obtained by adding the intercept to the coded variable coefficients.

The specification CLASS(variable / ZERO=NONE) sets to missing none of the coded variables. The columns of the expansion sum to a column of ones, so an implicit intercept model is fit. If you specify ZERO=NONE for more than one variable, the model is less than full rank. In the model `model identity(y) = class(x / zero=none)`, the coefficients are cell means.

The specification CLASS(variable / ZERO=SUM) sets to missing none of the coded variables, and the coefficients for the coded variables created from the variable sum to 0. This creates a less-than-full-rank model, but the coefficients are uniquely determined due to the sum-to-zero constraint.

In the presence of iterative transformations, hypothesis tests for ZERO=NONE and ZERO=SUM levels are not exact; they are liberal because a model with an explicit intercept is fit inside the iterations. There is no provision for adjusting the transformations while setting to 0 a parameter that is redundant given the explicit intercept and the other parameters.

Box-Cox t-options

The following *t-options* are available only with the **BOXCOX** transformation of the dependent variable (see the section “Box-Cox Transformations” on page 8222 and [Example 97.2](#)).

ALPHA=*p*

ALP=*p*

specifies the Box-Cox alpha for the confidence interval for the power parameter. By default, ALPHA=0.05.

CLL=*number-list*

specifies the Box-Cox convenient lambda list. When the confidence interval for the power parameter includes one of the values in this list, PROC TRANSREG reports it and can optionally use the convenient power parameter instead of the more optimal power parameter. The default is CLL=1.0 0.0 0.5 –1.0 –0.5 2.0 –2.0 3.0 –3.0. By default, a linear transformation is preferred over log, square root, inverse, inverse square root, quadratic, inverse quadratic, cubic, and inverse cubic. If you specify the **CONVENIENT** *t-option*, then PROC TRANSREG uses the first convenient power parameter in the list that is in the confidence interval. For example, if the optimal power parameter is 0.25 and 0.0 is in the confidence interval but not 1.0, then the convenient power parameter is 0.0.

CONVENIENT

CON

specifies that a power parameter from the **CLL=** *t-option* list is to be used for the final transformation instead of the **LAMBDA=** *t-option* value if a CLL= value is in the confidence interval. See the CLL= *t-option* for more information about its usage.

GEOMETRICMEAN

GEO

divides the Box-Cox transformation by $\bar{y}^{\lambda-1}$, where \bar{y} is the geometric mean of the variable to be transformed. This form of the Box-Cox transformation essentially converts the transformation back to original units, and hence it permits direct comparison of the residual sums of squares for models with different power parameters.

LAMBDA=*number-list*

LAM=*number-list*

specifies a list of Box-Cox power parameters. The default is LAMBDA=−3 TO 3 BY 0.25. PROC TRANSREG tries each power parameter in the list and picks the best one. However, when the **CONVENIENT** *t-option* is specified, PROC TRANSREG chooses a convenient value from the confidence interval instead of the optimal value. For example, if the optimal power parameter is 0.25 and 0.0 is in the confidence interval but not 1.0, then the convenient power parameter 0.0 (log transformation) is chosen instead of the more optimal parameter 0.25. See the **CLL=** *t-option* for more information about its usage.

Other t-options

AFTER

AFT

requests that certain operations occur after the expansion. This *t-option* affects the **NKNOTS=** *t-option* when the **SPLINE** or **MSPLINE** transformation is crossed with a **CLASS** specification. For example, if the original spline variable (1 2 3 4 5 6 7 8 9) is expanded into the three variables (1 2 3 0 0 0 0 0 0), (0 0 0 4 5 6 0 0 0), and (0 0 0 0 0 0 7 8 9), then, by default, **NKNOTS=1** would use the overall median of 5 as the knot for all three variables. When you specify the **AFTER** *t-option*, the knots for the three variables are 2, 5, and 8. Note that the structural zeros are ignored when the internal knot list is created, but they are not ignored for the exterior knots.

You can also specify the **AFTER** *t-option* with the **RANK**, **SMOOTH**, and **PBSPLINE** transformations. The following specifications compute ranks and smooth transformations within groups, after crossing, ignoring the structural zeros:

```
class(x / zero=none) | rank(z / after)
class(x / zero=none) | smooth(z / after)
```

CENTER

CEN

centers the variables before the analysis begins (in contrast to the **TSTANDARD=**CENTER option, which centers after the analysis ends). The **CENTER** *t-option* can be used instead of running PROC STANDARD before PROC TRANSREG (see the section “**Centering**” on page 8336). When the **KNOTS=** *t-option* is specified with **CENTER**, the knots apply to the original variable, not to the centered variable. PROC TRANSREG centers the knots.

NAME=(*variable-list*)

NAM=(*variable-list*)

renames variables as they are used in the MODEL statement. This *t-option* lets you use a variable more than once.

For example, if x is a character variable, then the following step stores both the original character variable x and a numeric variable xc that contains category numbers in the **OUT=** data set:

```
proc transreg data=a;
  model identity(y) = opscore(x / name=(xc));
  output;
  id x;
run;
```

With the **CLASS** and **IDENTITY** transformations, which can contain interaction effects, the first name applies to the first variable in the specification, the second name applies to the next variable that was not previously mentioned, and so on. For example, `identity(a a * b b b * c c / name=(g h i))` specifies that the new name for *a* is *g*, for *b* is *h*, and for *c* is *i*. The same assignment is used for the (not useful) specification `identity(a a b b c c / name=(g h i))`. For all *transforms* other than **CLASS** and **IDENTITY** (all those in which interactions are not supported), repeated variables are not handled specially. For example, `spline(a a b b c c / name=(a g b h c i))` creates six variables: a copy of *a* named *a*, another copy of *a* named *g*, a copy of *b* named *b*, another copy of *b* named *h*, a copy of *c* named *c*, and another copy of *c* named *i*.

REFLECT

REF

reflects the transformation

$$y = -(y - \bar{y}) + \bar{y}$$

after the iterations are completed and before the final standardization and results calculations. This *t-option* is particularly useful with the dependent variable in a conjoint analysis. When the dependent variable consists of ranks with the most preferred combination assigned 1.0, the REFLECT *t-option* reflects the transformation so that positive utilities mean high preference. (See [Example 97.4.](#))

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z

TST=CEN | NOM | ORI | Z

specifies the standardization of the transformed variables for the hypothesis tests and in the **OUT=** data set (see the section “[Centering](#)” on page 8336). By default, TSTANDARD=ORIGINAL. When you specify TSTANDARD= as an *a-option* or an *o-option*, it determines the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization only for selected variables. You can specify a different TSTANDARD= value for each transformation. For example, to perform a redundancy analysis with standardized dependent variables, specify the following:

```
model identity(y1-y4 / tstandard=z) = identity(x1-x10);
```

Z

centers and standardizes the variables to variance one before the analysis begins (in contrast to the **TSTANDARD=Z** option, which standardizes after the analysis ends). The *Z t-option* can be used instead of running PROC STANDARD before PROC TRANSREG (see the section “[Centering](#)” on page 8336). When the **KNOTS=** *t-option* is specified with *Z*, the knots apply to the original variable, not to the standardized variable. PROC TRANSREG standardizes the knots.

Algorithm Options (a-options)

This section discusses the options that can appear in the PROC TRANSREG or MODEL statement as *a-options*. They are listed after the entire model specification and after a slash. Here is an example:

```
proc transreg;
  model spline(y / nknots=3)=log(x1 x2 / parameter=2)
    / nomiss maxiter=50;
  output;
run;
```

In the preceding statements, **NOMISS** and **MAXITER=** are *a-options*. (**SPLINE** and **LOG** are *transforms*, and **NKNOTS=** and **PARAMETER=** are *t-options*.) The statements find a spline transformation with 3 knots on y and a base 2 logarithmic transformation on x1 and x2. The **NOMISS** *a-option* excludes all observations with missing values, and the **MAXITER=** *a-option* specifies the maximum number of iterations.

Table 97.4 summarizes the *a-options* available in the PROC TRANSREG or MODEL statement.

Table 97.4 Options Available in the PROC TRANSREG or MODEL Statement

Option	Description
Input Control	
REITERATE	Restarts iterations
TYPE=	Specifies input observation type
Method and Iterations	
CCONVERGE=	Specifies minimum criterion change
CONVERGE=	Specifies minimum data change
MAXITER=	Specifies maximum number of iterations
METHOD=	Specifies iterative algorithm
NCAN=	Specifies number of canonical variables
NSR	Specifies no restrictions on smoothing models
SINGULAR=	Specifies singularity criterion
SOLVE	Attempts direct solution instead of iteration
Missing Data Handling	
INDIVIDUAL	Fits each model individually (METHOD=MORALS)
MONOTONE=	Includes monotone special missing values
NOMISS	Excludes observations with missing values
UNTIE=	Unties special missing values
Intercept and CLASS Variables	
CPREFIX=	Specifies CLASS coded variable name prefix
LPREFIX=	Specifies CLASS coded variable label prefix
NOINT	Specifies no intercept or centering
ORDER=	Specifies order of CLASS variable levels
REFERENCE=	Controls output of reference levels
SEPARATORS=	Specifies CLASS coded variable label separators
Control Displayed Output	
ALPHA=	Specifies confidence limits alpha
CL	Displays parameter estimate confidence limits
DETAIL	Displays model specification details
HISTORY	Displays iteration histories
NOPRINT	Suppresses displayed output
PBOXCOXTABLE	Prints the Box-Cox log likelihood table

Table 97.4 continued

Option	Description
RSQUARE	Displays the R square
SHORT	Suppresses the iteration histories
SS2	Displays regression results
TEST	Displays ANOVA table
TSUFFIX=	Shortens transformed variable labels
UTILITIES	Displays conjoint part-worth utilities
Standardization	
ADDITIVE	Fits additive model
NOZEROCONSTANT	Does not zero constant variables
TSTANDARD=	Specifies transformation standardization

The following list provides details about these *a-options*. The *a-options* are available in the PROC TRANSREG or MODEL statement.

ADDITIVE**ADD**

creates an additive model by multiplying the values of each independent variable (after the **TSTANDARD=** standardization) by that variable's corresponding multiple regression coefficient. This process scales the independent variables so that the predicted-values variable for the final dependent variable is simply the sum of the final independent variables. An additive model is a univariate multiple regression model. As a result, the ADDITIVE *a-option* is not valid if **METHOD=CANALS**, or if **METHOD=REDUNDANCY** or **METHOD=UNIVARIATE** with more than one dependent variable.

ALPHA=number

ALP=number

specifies the level of significance for all of the confidence limits. By default, ALPHA=0.05.

CCONVERGE=n

CCO=n

specifies the minimum change in the criterion being optimized (squared multiple correlation for **METHOD=MORALS** and **METHOD=UNIVARIATE**, average squared multiple correlation for **METHOD=REDUNDANCY**, average squared canonical correlation for **METHOD=CANALS**) that is required to continue iterating. By default, CCONVERGE=0.0.

CL

requests confidence limits on the parameter estimates in the displayed output.

CONVERGE=n

CON=n

specifies the minimum average absolute change in standardized variable scores that is required to continue iterating. By default, CONVERGE=0.00001. Average change is computed over only those variables that can be transformed by the iterations; that is, all **LINEAR**, **OPSCORE**, **MONOTONE**, **UNTIE**, **SPLINE**, **MSPLINE**, and **SSPLINE** variables and nonoptimal transformation variables with missing values.

CPREFIX=*n***CPR=*n***

specifies the number of first characters of a **CLASS** expansion variable's name to use in constructing names for coded variables. Coded variable names are constructed from the first *n* characters of the **CLASS** expansion variable's name and the first $32 - n$ characters of the formatted **CLASS** expansion variable's value. For example, if the variable **ClassVariable** has values 1, 2, and 3, then, by default, the coded variables are named **ClassVariable1**, **ClassVariable2**, and **ClassVariable3**. However, with **CPREFIX=5**, the coded variables are named **Class1**, **Class2**, and **Class3**. When **CPREFIX=0**, coded variable names are created entirely from the **CLASS** expansion variable's formatted values. Valid values range from -1 to 31 , where -1 indicates the default calculation and 0 to 31 are the number of prefix characters to use. The default, -1 , sets *n* to $32 - \min(32, \max(2, fl))$, where *fl* is the format length. When you specify **CPREFIX=** as an *a-option* or an *o-option*, it specifies the default for all **CLASS** variables. When you specify **CPREFIX=** as a *t-option*, it overrides the default only for selected variables.

DETAIL**DET**

reports on details of the model specification. For example, it reports the knots and coefficients for splines, reference levels for **CLASS** variables, Box-Cox results, the smoothing parameter, and so on. The **DETAIL** option can take two optional suboptions, **NOCOEFFICIENTS** and **NOKNOTS** (or **NOC** and **NOK**). To suppress knots from the details listing, specify **DETAIL(NOKNOTS)**. To suppress coefficients from the details listing, specify **DETAIL(NOCOEFFICIENTS)**. To suppress both knots and coefficients from the details listing, specify **DETAIL(NOKNOTS NOCOEFFICIENTS)**.

SOLVE**SOL****DUMMY****DUM**

provides a canonical initialization. When there are no monotonicity constraints, when there is at most one canonical variable in each set, and when there is enough available memory, **PROC TRANSREG** (with the **SOLVE a-option**) can usually directly solve for the optimal solution in only one iteration. The initialization iteration is number 0, which is slower and uses more memory than other iterations. However, for some models, specifying the **SOLVE a-option** can greatly decrease the amount of time required to find the optimal transformations. During iteration 0, each variable is replaced by an expanded variable and the model is fit to the larger, expanded set of variables. For example, an **OPSCORE** variable is expanded into coded (or “dummy”) variables, as if **CLASS** were specified, and a **SPLINE** variable is expanded into a B-spline basis, as if **BSPLINE** were specified. Then for each expanded variable, the results of iteration zero are constructed by multiplying the expanded basis times the β subvector to get the optimal transformation. This *a-option* can be useful even in models where a direct solution is not possible, because it provides good initial transformations of all the variables.

HISTORY**HIS**

displays the iteration histories even when the **NOPRINT a-option** is specified.

INDIVIDUAL**IND**

fits each model for each dependent variable individually. This means, for example, that when INDIVIDUAL is specified, missing values in one dependent variable will not cause that observation to be deleted for the other models with the other dependent variables. In contrast, by default, missing values in any variable in any model can cause the observation to be deleted for all models. The INDIVIDUAL *a-option* can be specified only with **METHOD=MORALS**.

This *a-option* also affects the order of the output. By default, the number of observations table is printed once at the beginning of the output. With INDIVIDUAL, a number of observations table appears for each model.

LPREFIX=*n***LPR=*n***

specifies the number of first characters of a **CLASS** expansion variable's label (or name if no label is specified) to use in constructing labels for coded variables. Coded variable labels are constructed from the first *n* characters of the CLASS expansion variable's name and the first 127 – Argumentn characters of the formatted CLASS expansion variable's value. Valid values range from –1 to 127. Values of 0 to 127 specify the number of name or label characters to use. The default is –1, which specifies that PROC TRANSREG should pick a value depending on the length of the prefix and the formatted class value. When you specify LPREFIX= as an *a-option* or an *o-option*, it determines the default for all CLASS variables. When you specify LPREFIX= as a *t-option*, it overrides the default only for selected variables.

MAXITER=*n***MAX=*n***

specifies the maximum number of iterations (see the section “Controlling the Number of Iterations” on page 8290). By default, MAXITER=30. You can specify MAXITER=0 to save time when no transformations are requested.

METHOD=CANALS | MORALS | REDUNDANCY | UNIVARIATE**MET=CAN | MOR | RED | UNI**

specifies the iterative algorithm. By default, METHOD=UNIVARIATE, unless you specify options that cannot be handled by the UNIVARIATE algorithm. Specifically, the default is METHOD=MORALS for the following situations:

- if you specify **LINEAR**, **OPSCORE**, **MONOTONE**, **UNTIE**, **SPLINE**, **MSPLINE**, or **SSPLINE** transformations for the independent variables
- if you specify the **ADDITIVE** *a-option* with more than one dependent variable
- if you specify the **IAPPROXIMATIONS** *o-option*
- if you specify the **INDIVIDUAL** *a-option*
- if ODS Graphics is enabled, regression plots are produced, and there is more than one dependent variable

CANALS

specifies canonical correlation with alternating least squares. This jointly transforms all dependent and independent variables to maximize the average of the first *n* squared canonical correlations, where *n* is the value of the **NCAN=** *a-option*.

- MORALS** specifies multiple optimal regression with alternating least squares. This transforms each dependent variable, along with the set of independent variables, to maximize the squared multiple correlation.
- REDUNDANCY** jointly transforms all dependent and independent variables to maximize the average of the squared multiple correlations (see the section “[Redundancy Analysis](#)” on page 8295).
- UNIVARIATE** transforms each dependent variable to maximize the squared multiple correlation, while the independent variables are not transformed.

MONOTONE=*two-letters*

MON=*two-letters*

specifies the first and last special missing value in the list of those special missing values to be estimated with within-variable order and category constraints. By default, there are no order constraints on missing value estimates. The *two-letters* value must consist of two letters in alphabetical order. For example, MONOTONE=DF means that the estimate of .D must be less than or equal to the estimate of .E, which must be less than or equal to the estimate of .F; no order constraints are placed on estimates of ._, .A through .C, and .G through .Z. For details, see the section “[Missing Values](#)” on page 8289.

NCAN=*n*

NCA=*n*

specifies the number of canonical variables to use in the METHOD=CANALS algorithm. By default, NCAN=1. The value of the NCAN= *a-option* must be ≥ 1 .

When canonical coefficients and coordinates are included in the OUT= data set, the NCAN= *a-option* also controls the number of rows of the canonical coefficient matrices in the data set. If you specify an NCAN= value larger than the minimum of the number of dependent variables and the number of independent variables, PROC TRANSREG displays a warning and sets the NCAN= *a-option* to the maximum value.

NOINT

NOI

omits the intercept from the OUT= data set and suppresses centering of data. You cannot specify the NOINT *a-option* with iterative transformations since there is no provision for optimal scaling without an intercept. The NOINT *a-option* can be specified only when there is no implicit intercept and when all of the data in a BY group absolutely will not change during the iterations.

NOMISS

NOM

excludes all observations with missing values from the analysis, but does not exclude them from the OUT= data set. If you omit the NOMISS *a-option*, PROC TRANSREG simultaneously computes the optimal transformations of the nonmissing values and estimates the missing values that minimize squared error. For details, see the section “[Missing Values](#)” on page 8289.

Casewise deletion of observations with missing values occurs when the NOMISS *a-option* is specified, when there are missing values in expansions, when there are missing values in METHOD=UNIVARIATE independent variables, when there are weights less than or equal to 0, or when there are frequencies less than 1. Excluded observations are output with a blank value for the _TYPE_ variable, and they have a weight of 0. They do not contribute to the analysis but are scored and transformed as *supplementary* or *passive* observations.

See the section “[Passive Observations](#)” on page 8294 for more information about excluded observations.

NOPRINT

NOP

suppresses the display of all output unless you specify the [HISTORY](#) *a-option*. The NOPRINT *a-option* without the HISTORY *a-option* disables the Output Delivery System (ODS), including ODS Graphics, for the duration of the procedure run. The NOPRINT *a-option* with the HISTORY *a-option* disables all output except the iteration history, again including ODS Graphics, for the duration of the procedure run. For more information, see Chapter 20, “[Using the Output Delivery System](#).”

NOZEROCONSTANT

NOZERO

NOZ

specifies that constant variables are expected and should not be zeroed. By default, constant variables are zeroed. This option is useful when PROC TRANSREG is used to code experimental designs for discrete choice models (see the section “[Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO](#)” on page 8335). When these designs are very large, it might be more efficient to use the [DESIGN=*n*](#) *a-option*. It might be that attributes are constant within a block of *n* observations, so you need to specify the NOZEROCONSTANT *a-option* to get the correct results. You can specify this option in the PROC TRANSREG, MODEL, and OUTPUT statements.

NSR

specifies that no restrictions are placed on the use of [SMOOTH](#) and [SSPLINE](#) and the ordinary least squares is used to find the coefficients and predicted values. By default, only certain types of models can be specified with SMOOTH and ordinary least squares is not used to find the coefficients and predicted values. See the section “[Smoothing Splines Changes and Enhancements](#)” on page 8267 for more information about the NSR option and smooth transformations.

ORDER=DATA | FREQ | FORMATTED | INTERNAL

ORD=DAT | FRE | FOR | INT

specifies the order in which the [CLASS](#) variable levels are to be reported. The default is ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine dependent. When you specify ORDER= as an *a-option* or an *o-option*, it determines the default ordering for all CLASS variables. When you specify ORDER= as a *t-option*, it overrides the default ordering only for selected variables.

DATA	sorts by order of appearance in the input data set.
FORMATTED	sorts by formatted value.
FREQ	sorts by descending frequency count; levels with the most observations appear first.
INTERNAL	sorts by unformatted value.

PBOXCOXTABLE

PBO

prints the Box-Cox table with the log likelihood displayed as a function of lambda. The important information in this table is displayed in the Box-Cox plot, so when ODS Graphics is enabled and the plot is produced, the table is not produced by default. When ODS Graphics is not enabled or when the plot is not produced, the table is produced by default. Specify the PBOXCOTABLE option if you want to see the table in addition to the plot.

REFERENCE=NONE | MISSING | ZERO**REF=NON | MIS | ZER**

specifies how reference levels of **CLASS** variables are to be treated. The options are REFERENCE=NONE, the default, in which reference levels are suppressed; REFERENCE=MISSING, in which reference levels are displayed and output with missing values; and REFERENCE=ZERO, in which reference levels are displayed and output with zeros. You can specify the REFERENCE= option in the PROC TRANSREG, MODEL, or OUTPUT statement, and you can specify it independently for the **OUT=** data set and the displayed output. When you specify it in only one statement, it sets the option for both the displayed output and the **OUT=** data set.

REITERATE**REI**

enables PROC TRANSREG to use previous transformations as starting points. The REITERATE *a-option* affects only variables that are iteratively transformed (specified as **LINEAR**, **OPSCORE**, **MONOTONE**, **UNTIE**, **SPLINE**, **MSPLINE**, and **SSPLINE**). For iterative transformations, the REITERATE *a-option* requests a search in the input data set for a variable that consists of the value of the **TDPREFIX=** or **TIPREFIX=** *o-option* followed by the original variable name. If such a variable is found, it is used to provide the initial values for the first iteration. The final transformation is a member of the transformation family defined by the original variable, not the transformation family defined by the initialization variable. See the section “Using the REITERATE Algorithm Option” on page 8291 for more information about the REITERATE option.

RSQUARE**RSQ**

prints a table with only the model R square.

SEPARATORS='string-1' < 'string-2' >**SEP='string-1' < 'string-2' >**

specifies separators for creating **CLASS** expansion variable labels. By default, SEPARATORS=' ' * ' ("blank" and "blank asterisk blank"). The first value is used to separate variable names and values in interactions. The second value is used to separate interaction components. For example, the label for the coded variable for the A=1 and B=2 cell is, by default, 'A 1 * B 2'. If SEPARATORS='=' 'x' is specified, then the label is 'A=1xB=2'. When you specify SEPARATORS= as an *a-option* or an *o-option*, it determines the default separators for all **CLASS** variables. When you specify SEPARATORS= as a *t-option*, it overrides the default only for selected variables.

SHORT**SHO**

suppresses the iteration histories.

SINGULAR=*n***SIN=*n***

specifies the largest value within rounding error of zero. By default, SINGULAR=1E-12. PROC TRANSREG uses the value of the SINGULAR= *a-option* for checking $1 - R^2$ when constructing full-rank matrices of predictor variables, checking denominators before dividing, and so on. PROC TRANSREG computes the regression coefficients by sweeping with rational pivoting.

SS2

produces a regression table based on Type II sums of squares. Tests of the contribution of each transformation to the overall model are displayed and output to the OUTTEST= data set when you specify the OUTTEST= option. When you specify the SS2 *a-option*, the TEST *a-option* is automatically specified for you. See the section “[Hypothesis Tests](#)” on page 8303 for more information about the TEST and SS2 options. You can suppress the variable labels in the regression tables by specifying the NOLABEL option in the OPTIONS statement.

TEST**TES**

generates an ANOVA table. PROC TRANSREG tests the null hypothesis that the vector of scoring coefficients for all of the transformations is zero. See the section “[Hypothesis Tests](#)” on page 8303 for more information about the TEST option.

TSUFFIX=*n***TSU=*n***

specifies the number of characters in “Transformation” to append to variable labels for transformed variables. By default, all characters are used.

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z**TST=CEN | NOM | ORI | Z**

specifies the standardization of the transformed variables for the hypothesis tests and in the OUT= data set. By default, TSTANDARD=ORIGINAL. When you specify TSTANDARD= as an *a-option* or an *o-option*, it determines the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization only for selected variables.

CENTER centers the output variables to mean zero, but the variances are the same as the variances of the input variables.

NOMISS sets the means and variances of the transformed variables in the OUT= data set, computed over all output values that correspond to nonmissing values in the input data set, to the means and variances computed from the nonmissing observations of the original variables. The TSTANDARD=NOMISS specification is useful with missing data. When a variable is linearly transformed, the final variable contains the original nonmissing values and the missing value estimates. In other words, the nonmissing values are unchanged. If your data have no missing values, TSTANDARD=NOMISS and TSTANDARD=ORIGINAL produce the same results.

ORIGINAL sets the means and variances of the transformed variables to the means and variances of the original variables. This is the default.

Z standardizes the variables to mean zero, variance one.

The final standardization is affected by other options. If you also specify the **ADDITIVE** *a-option*, the **TSTANDARD=** option specifies an intermediate step in computing the final means and variances. The final independent variables, along with their means and standard deviations, are scaled by the regression coefficients, creating an additive model with all coefficients equal to one.

For nonoptimal variable transformations, the means and variances of the original variables are actually the means and variances of the nonlinearly transformed variables, unless you specify the **ORIGINAL** nonoptimal *t-option* in the MODEL statement. For example, if a variable *x* with no missing values is specified as **LOG**, then, by default, the final transformation of *x* is simply the log of *x*, not the log of *x* standardized to the mean of *x* and variance of *x*.

TYPE=*'text'|name*

TYP=*'text'|name*

specifies the valid value for the **_TYPE_** variable in the input data set. If PROC TRANSREG finds an input **_TYPE_** variable, it uses only observations with a **_TYPE_** value that matches the **TYPE=** value. This enables a PROC TRANSREG **OUT=** data set containing coefficients to be used as input to PROC TRANSREG without requiring a WHERE statement to exclude the coefficients. If a **_TYPE_** variable is not in the data set, all observations are used. The default is **TYPE='SCORE'**, so if you do not specify the **TYPE=** *a-option*, only observations with **_TYPE_='SCORE'** are used. Do not confuse this *a-option* with the data set **TYPE=** option. The **DATA=** data set must be an ordinary SAS data set.

PROC TRANSREG displays a note when it reads observations with blank values of **_TYPE_**, but it does not automatically exclude those observations. Data sets created by the TRANSREG and PRINQUAL procedures have blank **_TYPE_** values for those observations that were excluded from the analysis due to nonpositive weights, nonpositive frequencies, or missing data. When these observations are read again, they are excluded for the same reason that they were excluded from their original analysis, not because their **_TYPE_** value is blank.

UNTIE=*two-letters*

UNT=*two-letters*

specifies the first and last special missing values in the list of those special missing values that are to be estimated with within-variable order constraints but no category constraints. The *two-letters* value must consist of two letters in alphabetical order. By default, there are category constraints but no order constraints on special missing value estimates. For details, see the sections “[Missing Values](#)” on page 8289 and “[Optimal Scaling](#)” on page 8298.

UTILITIES

UTI

produces a table of the part-worth utilities from a conjoint analysis. Utilities, their standard errors, and the relative importance of each factor are displayed and output to the **OUTTEST=** data set when you specify the **OUTTEST=** option. When you specify the UTILITIES *a-option*, the **TEST** *a-option* is automatically specified for you. See [Example 97.4](#) and [Example 97.5](#) for more information about conjoint analysis.

OUTPUT Statement

OUTPUT **OUT**=SAS-data-set < o-options > ;

The OUTPUT statement creates a new SAS data set that contains coefficients, marginal means, and information about the original and transformed variables. The information about original and transformed variables composes the score partition of the data set; observations have `_TYPE_='SCORE'`. The coefficients and marginal means compose the coefficient partition of the data set; observations have `_TYPE_='M COEFFI'` or `_TYPE_='MEAN'`. Other values of `_TYPE_` are possible; for details, see “`_TYPE_` and `_NAME_` Variables” later in this chapter. For details about data set structure, see the section “Output Data Set” on page 8305. To specify the name of the output data set, use the **OUT=** option.

OUT=SAS-data-set

specifies the output data set for the data, transformed data, predicted values, residuals, scores, coefficients, and so on. When you use an OUTPUT statement but do not use the **OUT=** specification, PROC TRANSREG creates a data set and uses the `DATAn` convention. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

To control the contents of the data set and variable names, use one or more of the *o-options*. You can also specify these options in the PROC TRANSREG statement.

Output Options (o-options)

Table 97.5 summarizes the options available in the OUTPUT statement. These options include the **OUT=** option and all of the *o-options*. Many of the statistics created in the OUTPUT statement are exactly the same as statistics created by PROC REG. More details are given in the sections “Predicted and Residual Values” on page 6708, “Model Fit and Diagnostic Statistics” on page 6715 in Chapter 79, “The REG Procedure,” and Chapter 4, “Introduction to Regression Procedures.”

Table 97.5 Options Available in the OUTPUT Statement

Option	Description
Identify output data set	
OUT=	Outputs data set
Predicted Values, Residuals, Scores	
CANONICAL	Outputs canonical scores
CLI	Outputs individual confidence limits
CLM	Outputs mean confidence limits
DESIGN=	Specifies design matrix coding
DREPLACE	Replaces dependent variables
IREPLACE	Replaces independent variables
LEVERAGE	Outputs leverage
NORESTOREMISSING	Does not restore missing values
NOSCORES	Suppresses output of scores
PREDICTED	Outputs predicted values
REDUNDANCY=	Outputs redundancy variables
REPLACE	Replaces all variables
RESIDUALS	Outputs residuals

Table 97.5 *continued*

Option	Description
Output Data Set Coefficients	
COEFFICIENTS	Outputs coefficients
COORDINATES=	Outputs ideal point coordinates
MEANS	Outputs marginal means
MREDUNDANCY	Outputs redundancy analysis coefficients
Output Data Set Variable Name Prefixes	
ADPREFIX=	Specifies dependent variable approximations
AIPREFIX=	Specifies independent variable approximations
CDPREFIX=	Specifies canonical dependent variables
CILPREFIX=	Specifies conservative individual lower CL
CIPREFIX=	Specifies canonical independent variables
CIUPREFIX=	Specifies conservative-individual-upper CL
CMLPREFIX=	Specifies conservative-mean-lower CL
CMUPREFIX=	Specifies conservative-mean-upper CL
DEPENDENT=	Specifies METHOD=MORALS untransformed dependent
LILPREFIX=	Specifies liberal-individual-lower CL
LIUPREFIX=	Specifies liberal-individual-upper CL
LMLPREFIX=	Specifies liberal-mean-lower CL
LMUPREFIX=	Specifies liberal-mean-upper CL
RDPREFIX=	Specifies residuals
PPREFIX=	Specifies predicted values
RPREFIX=	Specifies redundancy variables
TDPREFIX=	Specifies transformed dependents
TIPREFIX=	Specifies transformed independents
Macros Variables	
MACRO	Creates macro variables
Other Options	
APPROXIMATIONS	Outputs dependent and independent approximations
CCC	Outputs canonical correlation coefficients
CEC	Outputs canonical elliptical point coordinates
CPC	Outputs canonical point coordinates
CQC	Outputs canonical quadratic point coordinates
DAPPROXIMATIONS	Outputs approximations to transformed dependents
IAPPROXIMATIONS	Outputs approximations to transformed independents
MEC	Outputs elliptical point coordinates
MPC	Outputs point coordinates
MQC	Outputs quadratic point coordinates
MRC	Outputs multiple regression coefficients

For the coefficients partition, the **COEFFICIENTS**, **COORDINATES**, and **MEANS** *o-options* provide the coefficients that are appropriate for your model. For more explicit control of the coefficient partition, use the options that control details and prefixes. The following list provides details about these options.

ADPREFIX=*name***ADP=***name*

specifies a prefix for naming the dependent variable predicted values. The default is ADPREFIX=P when you specify the **PREDICTED** *o-option*; otherwise, it is ADPREFIX=A. When you specify the ADPREFIX= *o-option*, the PREDICTED *o-option* is automatically specified for you. The ADPREFIX= *o-option* is the same as the PPREFIX= *o-option*.

AIPREFIX=*name***AIP=***name*

specifies a prefix for naming the independent variable approximations. The default is AIPREFIX=A. When you specify the AIPREFIX= *o-option*, the **IAPPROXIMATIONS** *o-option* is automatically specified for you.

APPROXIMATIONS**APPROX****APP**

is equivalent to specifying both the **DAPPROXIMATIONS** and the **IAPPROXIMATIONS** *o-options*. If you specify **METHOD=UNIVARIATE**, then the APPROXIMATIONS *o-option* specifies only the DAPPROXIMATIONS *o-option*.

CANONICAL**CAN**

outputs canonical variables to the **OUT=** data set. When you specify **METHOD=CANALS**, the CANONICAL *o-option* is automatically specified for you. The **CDPREFIX=** *o-option* specifies a prefix for naming the dependent canonical variables (default Cand), and the **CIPREFIX=** *o-option* specifies a prefix for naming the independent canonical variables (default Cani).

CCC

outputs canonical correlation coefficients to the **OUT=** data set.

CDPREFIX=*name***CDP=***name*

provides a prefix for naming the canonical dependent variables. The default is CDPREFIX=Cand. When you specify the CDPREFIX= *o-option*, the **CANONICAL** *o-option* is automatically specified for you.

CEC

outputs canonical elliptical point model coordinates to the **OUT=** data set.

CILPREFIX=*name***CIL=***name*

specifies a prefix for naming the conservative-individual-lower confidence limits. The default prefix is CIL. When you specify the CILPREFIX= *o-option*, the **CLI** *o-option* is automatically specified for you.

CIPREFIX=*name***CIP=***name*

provides a prefix for naming the canonical independent variables. The default is CIPREFIX=Cani. When you specify the CIPREFIX= *o-option*, the **CANONICAL** *o-option* is automatically specified for you.

CIUPREFIX=*name***CIU=***name*

specifies a prefix for naming the conservative-individual-upper confidence limits. The default prefix is CIU. When you specify the CIUPREFIX= *o-option*, the **CLI** *o-option* is automatically specified for you.

CLI

outputs individual confidence limits to the **OUT=** data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in the following *o-options*: **LILPREFIX=** (default LIL for liberal individual lower), **CILPREFIX=** (default CIL for conservative individual lower), **LIUPREFIX=** (default LIU for liberal individual upper), and **CIUPREFIX=** (default CIU for conservative individual upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

CLM

outputs mean confidence limits to the **OUT=** data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in the following *o-options*: **LMLPREFIX=** (default LML for liberal mean lower), **CMLPREFIX=** (default CML for conservative mean lower), **LMUPREFIX=** (default LMU for liberal mean upper), and **CMUPREFIX=** (default CMU for conservative mean upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

CMLPREFIX=*name***CML=***name*

specifies a prefix for naming the conservative-mean-lower confidence limits. The default prefix is CML. When you specify the CMLPREFIX= *o-option*, the **CLM** *o-option* is automatically specified for you.

CMUPREFIX=*name***CMU=***name*

specifies a prefix for naming the conservative-mean-upper confidence limits. The default prefix is CMU. When you specify the CMUPREFIX= *o-option*, the **CLM** *o-option* is automatically specified for you.

COEFFICIENTS**COE**

outputs either multiple regression coefficients or raw canonical coefficients to the **OUT=** data set. If you specify **METHOD=**CANALS (in the MODEL or PROC TRANSREG statement), then the **COEFFICIENTS** *o-option* outputs the first *n* canonical variables, where *n* is the value of the NCAN= *o-option* (specified in the MODEL or PROC TRANSREG statement). Otherwise, the **COEFFICIENTS** *o-option* includes multiple regression coefficients in the **OUT=** data set. In addition, when you specify the CLASS expansion for any independent variable, the **COEFFICIENTS** *o-option* also outputs marginal means.

COORDINATES=<n>**COO=<n>**

outputs either ideal point or vector model coordinates for preference mapping to the **OUT=** data set. When **METHOD=CANALS**, these coordinates are computed from canonical coefficients; otherwise, the coordinates are computed from multiple regression coefficients. For details, see the section “[Point Models](#)” on page 8294.

When ODS Graphics is enabled and vector model coordinates are requested, a plot is produced with points for each row and vectors for each column. If the vectors are plotted based on the actual computed coordinates, then often the vectors are short. A better graphical display is produced when the vectors are stretched. The absolute lengths of each vector can optionally be changed by specifying **COORDINATES=n**. Then the vector coordinates are all multiplied by *n*. Usually, *n* is a value such as 2, 2.5, or 3. The default is 2.5. Specify **COORDINATES=1** if you want to see the vectors without any stretching. The relative lengths of the different vectors are important and interpretable, and these are preserved by the stretching.

CPC

outputs canonical point model coordinates to the **OUT=** data set.

CQC

outputs canonical quadratic point model coordinates to the **OUT=** data set.

DAPPROXIMATIONS**DAP**

outputs the approximations of the transformed dependent variables to the **OUT=** data set. These are the target values for the optimal transformations. With **METHOD=UNIVARIATE** and **METHOD=MORALS**, the dependent variable approximations are the ordinary predicted values from the linear model. The names of the approximation variables are constructed from the **ADPREFIX= o-option** (default **A**) and the original dependent variable names. For ordinary predicted values, use the **PREDICTED o-option** instead of the **DAPPROXIMATIONS o-option**, since the **PREDICTED o-option** uses a more relevant prefix (“P” instead of “A”) and a more relevant variable label suffix (“Predicted Values” instead of “Approximations”).

DESIGN=<n>**DES=<n>**

specifies that your primary goal is design matrix coding, not analysis. Specifying the **DESIGN o-option** makes the procedure run faster. The **DESIGN o-option** sets the default method to **UNIVARIATE** and the default **MAXITER=** value to zero. It suppresses computing the regression coefficients, unless they are needed for some other option. Furthermore, when the **DESIGN o-option** is specified, the **MODEL** statement is not required to have an equal sign. When no **MODEL** statement equal sign is specified, all variables are considered independent variables, all options that require dependent variables are ignored, and the **IREPLACE o-option** is automatically specified for you.

You can use **DESIGN=n** for coding very large data sets, where *n* is the number of observations to code at one time. For example, to code a data set with a large number of observations, you can specify **DESIGN=100** or **DESIGN=1000** to process the data set in blocks of 100 or 1000 observations. If you specify the **DESIGN o-option** rather than **DESIGN=n**, PROC TRANSREG tries to process all observations at once, which might not work with very large data sets. Specify the **NOZEROCONSTANT a-option** with **DESIGN=n** to ensure that constant variables within blocks are not zeroed. See the sections “[Using the DESIGN Output Option](#)” on page 8331 and “[Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO](#)” on page 8335 for more information about the **DESIGN** option.

DEPENDENT=*name*

DEP=*name*

specifies the untransformed dependent variable for **OUT=** data sets with **METHOD=MORALS** when there is more than one dependent variable. The default is **DEPENDENT=_DEPEND_**.

DREPLACE

DRE

replaces the original dependent variables with the transformed dependent variables in the **OUT=** data set. The names of the transformed variables in the **OUT=** data set correspond to the names of the original dependent variables in the input data set. By default, both the original dependent variables and the transformed dependent variables (with names constructed from the **TDPREFIX=** (default T) *o-option* and the original dependent variable names) are included in the **OUT=** data set.

IAPPROXIMATIONS

IAP

outputs the approximations of the transformed independent variables to the **OUT=** data set. These are the target values for the optimal transformations. The names of the approximation variables are constructed from the **AIPREFIX=** *o-option* (default A) and the original independent variable names. When you specify the **AIPREFIX=** *o-option*, the **IAPPROXIMATIONS** *o-option* is automatically specified for you. The **IAPPROXIMATIONS** *o-option* is not valid when **METHOD=UNIVARIATE**.

IREPLACE

IRE

replaces the original independent variables with the transformed independent variables in the **OUT=** data set. The names of the transformed variables in the **OUT=** data set correspond to the names of the original independent variables in the input data set. By default, both the original independent variables and the transformed independent variables (with names constructed from the **TIPREFIX=** *o-option* (default T) and the original independent variable names) are included in the **OUT=** data set.

LEVERAGE<=*name***>**

LEV<=*name***>**

creates a variable with the specified name in the **OUT=** data set that contains leverages. Specifying the **LEVERAGE** *o-option* is equivalent to specifying **LEVERAGE=Leverage**.

LILPREFIX=*name*

LIL=*name*

specifies a prefix for naming the liberal-individual-lower confidence limits. The default prefix is LIL. When you specify the **LILPREFIX=** *o-option*, the **CLI** *o-option* is automatically specified for you.

LIUPREFIX=*name*

LIU=*name*

specifies a prefix for naming the liberal-individual-upper confidence limits. The default prefix is LIU. When you specify the **LIUPREFIX=** *o-option*, the **CLI** *o-option* is automatically specified for you.

LMLPREFIX=*name***LML=***name*

specifies a prefix for naming the liberal-mean-lower confidence limits. The default prefix is LML. When you specify the LMLPREFIX= *o-option*, the [CLM o-option](#) is automatically specified for you.

LMUPREFIX=*name***LMU=***name*

specifies a prefix for naming the liberal-mean-upper confidence limits. The default prefix is LMU. When you specify the LMUPREFIX= *o-option*, the [CLM o-option](#) is automatically specified for you.

MACRO(*keyword=name...*)**MAC**(*keyword=name...*)

creates macro variables. Most of the options available within the MACRO *o-option* are rarely needed. By default, PROC TRANSREG creates a macro variable named `_TrgInd` with a complete list of independent variables created by the procedure. When PROC TRANSREG is being used for design matrix creation prior to running a procedure without a CLASS statement, this macro provides a convenient way to use the results from PROC TRANSREG. For example, a PROC LOGISTIC step that uses a design matrix coded by PROC TRANSREG can use the following MODEL statement:

```
model y=&_trgind;
```

PROC TRANSREG, also by default, creates a macro variable named `_TrgIndN`, which contains the number of variables in the `_TrgInd` list. These macro variables can be used in an ARRAY statement as follows:

```
array indvars[&_trgindn] &_trgind;
```

See the sections “Using the DESIGN Output Option” on page 8331 and “Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO” on page 8335 for examples of using the default macro variables.

The available *keywords* are as follows.

- | | |
|------------------------|--|
| DN= <i>name</i> | specifies the name of a macro variable that contains the number of dependent variables. By default, a macro variable named <code>_TrgDepN</code> is created. This is the number of variables in the DL= list and the number of macro variables created by the DV= and DE= specifications. |
| IN= <i>name</i> | specifies the name of a macro variable that contains the number of independent variables. By default, a macro variable named <code>_TrgIndN</code> is created. This is the number of variables in the IL= list and the number of macro variables created by the IV= and IE= specifications. |
| DL= <i>name</i> | specifies the name of a macro variable that contains the list of the dependent variables. By default, a macro variable named <code>_TrgDep</code> is created. These are the variable names of the final transformed variables in the OUT= data set. For example, if there are three dependent variables, y1–y3, then <code>_TrgDep</code> contains, by default, Ty1 Ty2 Ty3 (or y1 y2 y3 if you specify the REPLACE <i>o-option</i>). |

- IL=name** specifies the name of a macro variable that contains the list of the independent variables. By default, a macro variable named `_Trglnd` is created. These are the variable names of the final transformed variables in the **OUT=** data set. For example, if there are three independent variables, `x1–x3`, then `_Trglnd` contains, by default, `Tx1 Tx2 Tx3` (or `x1 x2 x3` if you specify the **REPLACE o-option**).
- DV=prefix** specifies a prefix for creating a list of macro variables, each of which contains one dependent variable name. For example, if there are three dependent variables, `y1–y3`, and you specify **macro (dv=Dep)**, then three macro variables, `Dep1`, `Dep2`, and `Dep3`, are created, containing `Ty1`, `Ty2`, and `Ty3`, respectively (or `y1`, `y2`, and `y3` if you specify the **REPLACE o-option**). By default, no list is created.
- IV=prefix** specifies a prefix for creating a list of macro variables, each of which contains one independent variable name. For example, if there are three independent variables, `x1–x3`, and you specify **macro (iv=Ind)**, then three macro variables, `Ind1`, `Ind2`, and `Ind3`, are created, containing `Tx1`, `Tx2`, and `TX3`, respectively (or `x1`, `x2`, and `x3` if you specify the **REPLACE o-option**). By default, no list is created.
- DE=prefix** specifies a prefix for creating a list of macro variables, each of which contains one dependent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify **macro (de=d)**, then a macro variable `d1` is created for **identity(y)**. The `d1` macro variable is shown next, wrapped onto two lines:

```

4                                TY
IDENTITY                        Y

```

The first part is the number of parts (4), the second part is the transformed variable name, the third part is the transformation, and the last part is the input variable name. By default, no list is created.

- IE=prefix** specifies a prefix for creating a list of macro variables, each of which contains one independent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify **macro (ie=I)**, then three macro variables, `I1`, `I2`, and `I3`, are created for **class(x1 | x2)** when both `x1` and `x2` have values of 1 and 2. These macro variables are shown next, with extra white space removed:

```

5      Tx11      CLASS      x1      1
5      Tx21      CLASS      x2      1
8      Tx11x21   CLASS      x1      1      CLASS      x2      1

```

For **CLASS** variables, the formatted level appears after the variable name. The first two effects are the main effects, and the last is the interaction term. By default, no list is created.

MEANS**MEA**

outputs marginal means for **CLASS** variable expansions to the **OUT=** data set.

MEC

outputs multiple regression elliptical point model coordinates to the **OUT=** data set.

MPC

outputs multiple regression point model coordinates to the **OUT=** data set.

MQC

outputs multiple regression quadratic point model coordinates to the **OUT=** data set.

MRC

outputs multiple regression coefficients to the **OUT=** data set.

MREDUNDANCY**MRE**

outputs multiple redundancy analysis coefficients to the **OUT=** data set.

NORESTOREMISSING**NORESTORE****NOR**

specifies that missing values should not be restored when the **OUT=** data set is created. By default, the coded **CLASS** variable contains a row of missing values for observations in which the **CLASS** variable is missing. When you specify the **NORESTOREMISSING** *o-option*, these observations contain a row of zeros instead. This is useful when PROC TRANSREG is used to code experimental designs for discrete choice models and there is a constant alternative indicated by a missing value.

NOSCORES**NOS**

excludes original variables, transformed variables, predicted values, residuals, and scores from the **OUT=** data set. You can use the **NOSCORES** *o-option* with various other options to create an **OUT=** data set that contains only a coefficient partition (for example, a data set consisting entirely of coefficients and coordinates).

PREDICTED**PRE****P**

outputs predicted values, which for **METHOD=UNIVARIATE** and **METHOD=MORALS** are the ordinary predicted values from the linear model, to the **OUT=** data set. The names of the predicted values' variables are constructed from the **PPREFIX=** *o-option* (default **P**) and the original dependent variable names. When you specify the **PPREFIX=** *o-option*, the **PREDICTED** *o-option* is automatically specified for you.

PPREFIX=*name*

PDPREFIX=*name*

PDP=*name*

specifies a prefix for naming the dependent variable predicted values. The default is **PPREFIX=P** when you specify the **PREDICTED** *o-option*; otherwise, it is **PPREFIX=A**. When you specify the **PPREFIX=** *o-option*, the **PREDICTED** *o-option* is automatically specified for you. The **PPREFIX=** *o-option* is the same as the **ADPREFIX=** *o-option*.

RDPREFIX=*name*

RDP=*name*

specifies a prefix for naming the residual (dependent) variables to the **OUT=** data set. The default is RDPREFIX=R. When you specify the RDPREFIX= *o-option*, the **RESIDUALS** *o-option* is automatically specified for you.

REDUNDANCY<=STANDARDIZE | UNSTANDARDIZE>

RED<=STA | UNS>

outputs redundancy variables to the **OUT=** data set, either standardized or unstandardized. Specifying the REDUNDANCY *o-option* is the same as specifying REDUNDANCY=STANDARDIZE. The results of the REDUNDANCY *o-option* depends on the TSTANDARD= option. You must specify **TSTANDARD=Z** to get results based on standardized data. The TSTANDARD= option controls how the data that go into the redundancy analysis are scaled, and REDUNDANCY=STANDARDIZE|UNSTANDARDIZE controls how the redundancy variables are scaled. The REDUNDANCY *o-option* is automatically specified for you when you specify the **METHOD=REDUNDANCY** *a-option*. The **RPREFIX=** *o-option* specifies a prefix (default Red) for naming the redundancy variables.

REFERENCE=NONE | MISSING | ZERO

REF=NON | MIS | ZER

specifies how reference levels of **CLASS** variables are to be treated. The options are REFERENCE=NONE, the default, in which reference levels are suppressed; REFERENCE=MISSING, in which reference levels are displayed and output with missing values; and REFERENCE=ZERO, in which reference levels are displayed and output with zeros. You can specify the REFERENCE= option in the PROC TRANSREG, MODEL, or OUTPUT statement, and you can specify it independently for the **OUT=** data set and the displayed output. When you specify it in only one statement, it sets the option for both the displayed output and the **OUT=** data set.

REPLACE

REP

is equivalent to specifying both the **DREPLACE** and the **IREPLACE** *o-options*.

RESIDUALS

RES

R

outputs the differences between the transformed dependent variables and their predicted values. The names of the residual variables are constructed from the **RDPREFIX=** *o-option* (default R) and the original dependent variable names.

RPREFIX=*name*

RPR=*name*

provides a prefix for naming the redundancy variables. The default is RPREFIX=Red. When you specify the RPREFIX= *o-option*, the **REDUNDANCY** *o-option* is automatically specified for you.

TDPREFIX=*name*

TDP=*name*

specifies a prefix for naming the transformed dependent variables. By default, TDPREFIX=T. The TDPREFIX= *o-option* is ignored when you specify the **DREPLACE** *o-option*.

TIPREFIX=*name*

TIP=*name*

specifies a prefix for naming the transformed independent variables. By default, TIPREFIX=T. The TIPREFIX= *o-option* is ignored when you specify the [IREPLACE](#) *o-option*.

WEIGHT Statement

WEIGHT *variable* ;

When you use a WEIGHT statement, a weighted residual sum of squares is minimized. The WEIGHT statement has no effect on degrees of freedom or number of observations, but the weights affect most other calculations. The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than 0.

Details: TRANSREG Procedure

Model Statement Usage

```
MODEL < transform(dependents </ t-options>) >
      < transform(dependents </ t-options>)... = >
      transform(independents </ t-options>)
      < transform(independents </ t-options>)... > </ a-options> ;
```

Here are some examples of model statements:

- linear regression

```
model identity(y) = identity(x);
```

- a linear model with a nonlinear regression function

```
model identity(y) = spline(x / nknots=5);
```

- multiple regression

```
model identity(y) = identity(x1-x5);
```

- multiple regression with nonlinear transformations

```
model spline(y / nknots=3) = spline(x1-x5 / nknots=3);
```

- multiple regression with nonlinear but monotone transformations

```
model mspline(y / nknots=3) = mspline(x1-x5 / nknots=3);
```

- multivariate multiple regression

```
model identity(y1-y4) = identity(x1-x5);
```

- canonical correlation

```
model identity(y1-y4) = identity(x1-x5) / method=canals;
```

- redundancy analysis

```
model identity(y1-y4) = identity(x1-x5) / method=redundancy;
```

- preference mapping, vector model (Carroll 1972)

```
model identity(Attrib1-Attrib3) = identity(Dim1-Dim2);
```

- preference mapping, ideal point model (Carroll 1972)

```
model identity(Attrib1-Attrib3) = point(Dim1-Dim2);
```

- preference mapping, ideal point model, elliptical (Carroll 1972)

```
model identity(Attrib1-Attrib3) = epoint(Dim1-Dim2);
```

- preference mapping, ideal point model, quadratic (Carroll 1972)

```
model identity(Attrib1-Attrib3) = qpoint(Dim1-Dim2);
```

- metric conjoint analysis

```
model identity(Subj1-Subj50) = class(a b c d e f / zero=sum);
```

- nonmetric conjoint analysis

```
model monotone(Subj1-Subj50) = class(a b c d e f / zero=sum);
```

- main effects, two-way interaction

```
model identity(y) = class(a|b);
```

- less-than-full-rank model—main effects and two-way interaction are constrained to sum to zero

```
model identity(y) = class(a|b / zero=sum);
```

- main effects and all two-way interactions

```
model identity(y) = class(a|b|c@2);
```

- main effects and all two- and three-way interactions

```
model identity(y) = class(a|b|c);
```

- main effects and only the b*c two-way interaction

```
model identity(y) = class(a b c b*c);
```

- seven main effects, three two-way interactions

```
model identity(y) = class(a b c d e f g a*b a*c a*d);
```

- deviations-from-means (effects or (1, 0, −1)) coding, with an a reference level of '1' and a b reference level of '2'

```
model identity(y) = class(a|b / deviations zero='1' '2');
```

- cell-means coding (implicit intercept)

```
model identity(y) = class(a*b / zero=none);
```

- reference cell model

```
model identity(y) = class(a|b / zero='1' '1');
```

- reference line with change in line parameters

```
model identity(y) = class(a) | identity(x);
```

- reference curve with change in curve parameters

```
model identity(y) = class(a) | spline(x);
```

- separate curves and intercepts

```
model identity(y) = class(a / zero=none) | spline(x);
```

- quantitative effects with interaction

```
model identity(y) = identity(x1 | x2);
```

- separate quantitative effects with interaction within each cell

```
model identity(y) = class(a * b / zero=none) | identity(x1 | x2);
```

Box-Cox Transformations

Box-Cox (1964) transformations are used to find potentially nonlinear transformations of a dependent variable. The Box-Cox transformation has the form

$$\begin{array}{ll} (y^\lambda - 1)/\lambda & \lambda \neq 0 \\ \log(y) & \lambda = 0 \end{array}$$

This family of transformations of the positive dependent variable y is controlled by the parameter λ . Transformations linearly related to square root, inverse, quadratic, cubic, and so on are all special cases. The limit

as λ approaches 0 is the log transformation. More generally, Box-Cox transformations of the following form can be fit:

$$\begin{array}{ll} ((y + c)^\lambda - 1)/(\lambda g) & \lambda \neq 0 \\ \log(y + c)/g & \lambda = 0 \end{array}$$

By default, $c = 0$. The parameter c can be used to rescale y so that it is strictly positive. By default, $g = 1$. Alternatively, g can be $\bar{y}^{\lambda-1}$, where \bar{y} is the geometric mean of y .

The **BOXCOX** transformation in PROC TRANSREG can be used to perform a Box-Cox transformation of the dependent variable. You can specify a list of power parameters by using the **LAMBDA=** *t-option*. By default, **LAMBDA=** -3 TO 3 BY 0.25. The procedure chooses the optimal power parameter by using a maximum likelihood criterion (Draper and Smith 1981, pp. 225–226). You can specify the **PARAMETER=** *c* transformation option when you want to shift the values of y , usually to avoid negatives. To divide by $\bar{y}^{\lambda-1}$, specify the **GEOMETRICMEAN** *t-option*.

Here are three examples of using the **LAMBDA=** *t-option*:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);
model BoxCox(y) = identity(x1-x5);
```

Here is the first example:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
```

LAMBDA=0 specifies a Box-Cox transformation with a power parameter of 0. Since a single value of 0 was specified for **LAMBDA=**, there is no difference between the following models:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
model log(y) = identity(x1-x5);
```

Here is the second example:

```
model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);
```

LAMBDA= specifies a list of power parameters. PROC TRANSREG tries each power parameter in the list and picks the best transformation. A maximum likelihood approach (Draper and Smith 1981, pp. 225–226) is used. With Box-Cox transformations, PROC TRANSREG finds the transformation before the usual iterations begin. Note that this is quite different from PROC TRANSREG's usual approach of iteratively finding optimal transformations with ordinary and alternating least squares. It is analogous to **SMOOTH** and **PBSPLINE**, which also find transformations before the iterations begin based on a criterion other than least squares.

Here is the third example:

```
model BoxCox(y) = identity(x1-x5);
```

The default **LAMBDA=** list of -3 TO 3 BY 0.25 is used.

The procedure prints the optimal power parameter, a confidence interval on the power parameter (based on the **ALPHA=** *t-option*), a “convenient” power parameter (selected from the **CLL=** *t-option* list), and the log likelihood for each power parameter tried (see [Example 97.2](#)).

To illustrate how Box-Cox transformations work, data were generated from the model

$$y = e^{x+\epsilon}$$

where $\epsilon \sim N(0, 1)$. The transformed data can be fit with a linear model

$$\log(y) = x + \epsilon$$

The following statements produce [Figure 97.14](#) through [Figure 97.15](#):

```
title 'Basic Box-Cox Example';

data x;
  do x = 1 to 8 by 0.025;
    y = exp(x + normal(7));
    output;
  end;
run;

ods graphics on;

title2 'Default Options';

proc transreg data=x test;
  model BoxCox(y) = identity(x);
run;
```

Figure 97.14 Basic Box-Cox Example, Default Output

Figure 97.14 shows that PROC TRANSREG correctly selects the log transformation $\lambda = 0$, with a narrow confidence interval. The $F = t^2$ plot shows that F is at its largest in the vicinity of the optimal Box-Cox transformation.

The rest of the output, which contains the ANOVA results, is shown in Figure 97.15.

Figure 97.15 Basic Box-Cox Example, Default Output

Dependent Variable BoxCox(y)	
Number of Observations Read	281
Number of Observations Used	281

Figure 97.15 continued

The TRANSREG Procedure Hypothesis Tests for BoxCox(y)					
Univariate ANOVA Table Based on the Usual Degrees of Freedom					
Source	DF	Sum of Squares	Mean Square	F Value	Liberal p
Model	1	1145.884	1145.884	1053.66	>= <.0001
Error	279	303.421	1.088		
Corrected Total	280	1449.305			
The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.					
Root MSE		1.04285	R-Square	0.7906	
Dependent Mean		4.49653	Adj R-Sq	0.7899	
Coeff Var		23.19225	Lambda	0.0000	

This next example uses several options. The **LAMBDA=** *t-option* specifies power parameters sparsely from -2 to -0.5 and 0.5 to 2 just to get the general shape of the log-likelihood function in that region. Between -0.5 and 0.5 , more power parameters are tried. The **CONVENIENT** *t-option* is specified so that if a power parameter like $\lambda = 1$ or $\lambda = 0$ is found in the confidence interval, it is used instead of the optimal power parameter. **PARAMETER=2** is specified to add 2 to each y before performing the transformations. **ALPHA=0.00001** specifies a wide confidence interval.

These next statements perform the Box-Cox analysis and produce Figure 97.16 and Figure 97.17:

```

title2 'Several Options Demonstrated';

proc transreg data=x ss2 details
    plots=(transformation(dependent) scatter
           observedbypredicted);
    model BoxCox(y / lambda=-2 -1 -0.5 to 0.5 by 0.05 1 2
                 convenient parameter=2 alpha=0.00001) =
           identity(x);
run;

```

Figure 97.16 Basic Box-Cox Example, Several Options Demonstrated

The results in Figure 97.16 and Figure 97.17 show that the optimal power parameter is -0.1 , but 0 is in the confidence interval, and hence a log transformation is chosen. The actual Box-Cox transformation, the original scatter plot, and observed by predicted values plot are shown in Figure 97.17.

Coeff Var	20.99591	Lambda	0.0000

Univariate Regression Table Based on the Usual Degrees of Freedom

Variable	DF	Coefficient	Type II Sum of Squares	Mean Square	F Value	Liberal p
Intercept	1	0.42939328	8.746	8.746	9.32	>= 0.0025
Identity(x)	1	0.92997620	999.438	999.438	1064.82	>= <.0001

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

Figure 97.17 *continued*

Figure 97.17 continued

The next example shows how to find a Box-Cox transformation without an independent variable. This seeks to normalize the univariate histogram. This example generates 500 random observations from a lognormal distribution. In addition, a constant variable z is created that is all zero. This is because PROC TRANSREG requires some independent variable to be specified, even if it is constant. Two options are specified in the PROC TRANSREG statement. `MAXITER=0` is specified because the Box-Cox transformation is performed before any iterations are begun. No iterations are needed since no other work is required. The `NOZERO-CONSTANT` *a-option* (which can be abbreviated NOZ) is specified so that PROC TRANSREG does not print any warnings when it encounters the constant independent variable. The MODEL statement asks for a Box-Cox transformation of y and an IDENTITY transformation (which does nothing) of the constant variable z . Finally, PROC UNIVARIATE is run to show a histogram of the original variable y , and the Box-Cox transformation, T_y . The following statements fit the univariate Box-Cox model and produce Figure 97.18:

```

title 'Univariate Box-Cox';

data x;
  call streaminit(17);
  z = 0;
  do i = 1 to 500;
    y = rand('lognormal');
    output;
  end;
run;

proc transreg maxiter=0 nozeroconstant;
  model BoxCox(y) = identity(z);
  output;
run;

proc univariate noprint;
  histogram y ty;
run;

```

The PROC TRANSREG results in [Figure 97.18](#) show that zero is chosen for lambda, so a log transformation is chosen. The first histogram shows that the original data are skewed, but a log transformation makes the data appear much more nearly normal.

Figure 97.18 Box-Cox with No Independent Variable

Figure 97.18 *continued*

Using Splines and Knots

This section illustrates some properties of splines. *Splines* are curves, and they are usually required to be continuous and smooth. Splines are usually defined as piecewise polynomials of degree n with function values and first $n - 1$ derivatives that agree at the points where they join. The abscissa or X-axis values of the join points are called *knots*. The term “spline” is also used for polynomials (splines with no knots) and piecewise polynomials with more than one discontinuous derivative. Splines with no knots are generally smoother than splines with knots, which are generally smoother than splines with multiple discontinuous derivatives. Splines with few knots are generally smoother than splines with many knots; however, increasing the number of knots usually increases the fit of the spline function to the data. Knots give the curve freedom to bend to more closely follow the data. See Smith (1979) for an excellent introduction to splines.

In this section, an artificial data set is created with a variable y that is a discontinuous function of x . (See [Figure 97.20](#).) Notice that the function has four unconnected parts, each of which is a curve. Notice too that there is an overall quadratic trend—that is, ignoring the shapes of the individual curves, at first the y values tend to decrease as x increases, then y values tend to increase. While these artificial data are clearly not realistic, their distinct pattern helps illustrate how splines work. The following statements create the data set, fit a simple linear regression model, and produce [Figure 97.19](#) through [Figure 97.20](#):

```

title 'An Illustration of Splines and Knots';

* Create in y a discontinuous function of x.;

data a;
  x = -0.000001;
  do i = 0 to 199;
    if mod(i, 50) = 0 then do;
      c = ((x / 2) - 5)**2;
      if i = 150 then c = c + 5;
      y = c;
    end;
    x = x + 0.1;
    y = y - sin(x - c);
    output;
  end;
run;

ods graphics on;

title2 'A Linear Regression Fit';
proc transreg data=a plots=scatter rsquare;
  model identity(y) = identity(x);
run;

```

The R square for the linear regression is 0.1006. The linear fit results in Figure 97.19 show the predicted values of y given x . It can clearly be seen in Figure 97.19 that the linear regression model is not appropriate for these data.

Figure 97.19 A Linear Regression Fit

Figure 97.19 *continued*

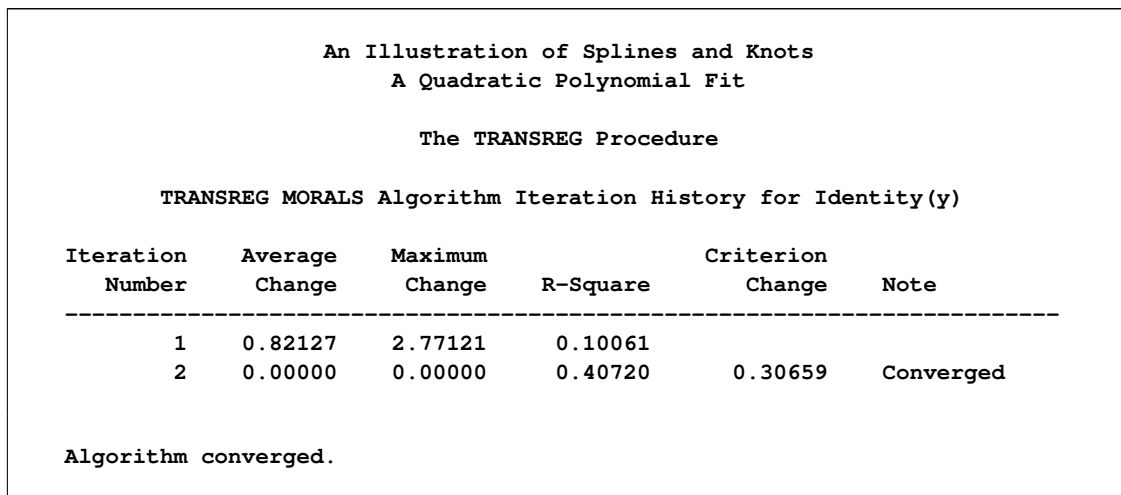

Figure 97.20 The Original Scatter Plot

The next PROC TRANSREG step finds a degree-two spline transformation with no knots, which is a quadratic polynomial. The spline is a weighted sum of a single constant, a single straight line, and a single quadratic curve. The following statements perform the quadratic analysis and produce [Figure 97.21](#):

```
title2 'A Quadratic Polynomial Fit';

proc transreg data=A;
  model identity(y)=spline(x / degree=2);
run;
```

The R square in [Figure 97.21](#) increases from 0.10061, which is the linear fit value from before, to 0.40720. The plot shows that the quadratic regression function does not fit any of the individual curves well, but it does follow the overall trend in the data. Since the overall trend is quadratic, if you were to fit a degree-three spline with no knots (not shown) would increase R square by only a small amount.

Figure 97.21 A Quadratic Polynomial Fit**Figure 97.21** continued

The next step uses the default degree of three, for a piecewise cubic polynomial, and requests knots at the known break points, $x=5$, 10, and 15. This requests a spline that is continuous, has continuous first and second derivatives, and has a third derivative that is discontinuous at 5, 10, and 15. The spline is a weighted sum of a single constant, a single straight line, a single quadratic curve, a cubic curve for the portion of x less than 5, a different cubic curve for the portion of x between 5 and 10, a different cubic curve for the portion of x between 10 and 15, and another cubic curve for the portion of x greater than 15. The following statements fit the spline model and produce [Figure 97.22](#):

```
title2 'A Cubic Spline Fit with Knots at X=5, 10, 15';

proc transreg data=a;
  model identity(y) = spline(x / knots=5 10 15);
run;
```

The new R square in [Figure 97.22](#) is 0.61730. The plot shows that the spline is less smooth than the quadratic polynomial and follows the data more closely than the quadratic polynomial.

The TRANSREG Procedure					
TRANSREG MORALS Algorithm Iteration History for Identity(y)					
Iteration Number	Average Change	Maximum Change	R-Square	Criterion Change	Note
1	0.85367	3.88449	0.10061		
2	0.00000	0.00000	0.61730	0.51670	Converged
Algorithm converged.					

Figure 97.22 continued

The same model could be fit with a DATA step and PROC REG, as follows:

```
data b;                /* A is the data set used by transreg */
  set a(keep=x y);
  x1=x;                /* x */
  x2=x**2;             /* x squared */
  x3=x**3;             /* x cubed */
  x4=(x> 5)*((x-5)**3); /* change in x**3 after 5 */
  x5=(x>10)*((x-10)**3); /* change in x**3 after 10 */
  x6=(x>15)*((x-15)**3); /* change in x**3 after 15 */
run;

proc reg;
  model y=x1-x6;
run; quit;
```

The output from these previous statements is not displayed. The assignment statements and comments show how you can construct terms that can be used to fit the same model.

In the next step, each knot is repeated three times, so the first, second, and third derivatives are discontinuous at $x=5$, 10, and 15, but the spline is continuous at the knots. The spline is a weighted sum of the following:

- a single constant
- a line for the portion of x less than 5
- a quadratic curve for the portion of x less than 5
- a cubic curve for the portion of x less than 5
- a different line for the portion of x between 5 and 10
- a different quadratic curve for the portion of x between 5 and 10
- a different cubic curve for the portion of x between 5 and 10
- a different line for the portion of x between 10 and 15
- a different quadratic curve for the portion of x between 10 and 15
- a different cubic curve for the portion of x between 10 and 15
- another line for the portion of x greater than 15
- another quadratic curve for the portion of x greater than 15
- another cubic curve for the portion of x greater than 15

The spline is continuous since there is not a separate constant or separate intercept in the formula for the spline for each knot. The following statements perform this analysis and produce [Figure 97.23](#):

```
title3 'First - Third Derivatives Discontinuous at X=5, 10, 15';

proc transreg data=a;
  model identity(y) = spline(x / knots=5 5 5 10 10 10 15 15 15);
run;
```

Now the R square in [Figure 97.23](#) is 0.95542, and the spline closely follows the data, except at the knots.

Figure 97.23 Spline with Discontinuous Derivatives

Algorithm converged.					

Figure 97.23 continued

The same model could be fit with a DATA step and PROC REG, as follows:

```
data b;
  set a(keep=x y);
  x1=x;                      /* x                      */
  x2=x**2;                   /* x squared              */
  x3=x**3;                   /* x cubed                */
  x4=(x>5) * (x-5);          /* change in x after 5   */
  x5=(x>10) * (x-10);        /* change in x after 10  */
  x6=(x>15) * (x-15);        /* change in x after 15  */
  x7=(x>5) * ((x-5)**2);     /* change in x**2 after 5 */
  x8=(x>10) * ((x-10)**2);   /* change in x**2 after 10 */
  x9=(x>15) * ((x-15)**2);   /* change in x**2 after 15 */
  x10=(x>5) * ((x-5)**3);    /* change in x**3 after 5 */
  x11=(x>10) * ((x-10)**3); /* change in x**3 after 10 */
  x12=(x>15) * ((x-15)**3); /* change in x**3 after 15 */
run;

proc reg;
  model y=x1-x12;
run; quit;
```

The output from these previous statements is not displayed. The assignment statements and comments show how you can construct terms that can be used to fit the same model.

Each knot is repeated four times in the next step. Now the spline function is discontinuous at the knots, and it can follow the data more closely. The following statements perform this analysis and produce [Figure 97.24](#):

```
title3 'Discontinuous Function and Derivatives';

proc transreg data=a;
  model identity(y) = spline(x / knots=5 5 5 5 10 10 10 10
                             15 15 15 15);
run;
```

Now the R square in [Figure 97.24](#) is 0.99254. In this step, each separate curve is approximated by a cubic polynomial (with no knots within the separate polynomials). (Note, however, that the separate functions are connected in the plot, because PROC TRANSREG cannot currently produce separate functions for a model like this. Usually, you would use a CLASS variable to get separate functions.)

Figure 97.24 Discontinuous Spline Fit

1	0.90271	3.29184	0.10061		
2	0.00000	0.00000	0.99254	0.89193	Converged
Algorithm converged.					

Figure 97.24 continued

To solve this problem with a DATA step and PROC REG, you would need to create all of the variables in the preceding DATA step (the B data set for the piecewise polynomial with discontinuous third derivatives), plus the following three variables:

```
x13=(x > 5); /* intercept change after 5 */
x14=(x > 10); /* intercept change after 10 */
x15=(x > 15); /* intercept change after 15 */
```

The next two examples use the `NKNOTS=` *t-option* to specify the number of knots but not their location. `NKNOTS=4` places knots at the quintiles, whereas `NKNOTS=9` places knots at the deciles. The spline and its first two derivatives are continuous. The following statements produce [Figure 97.25](#) and [Figure 97.26](#):

```
title3 'Four Knots';

proc transreg data=a;
  model identity(y) = spline(x / nknots=4);
run;

title3 'Nine Knots';

proc transreg data=a;
  model identity(y) = spline(x / nknots=9);
run;
```

The R-square values displayed in [Figure 97.25](#) and [Figure 97.26](#) are 0.74450 and 0.95256, respectively. Even though the knots are not optimally placed, the spline can closely follow the data with `NKNOTS=9`.

Figure 97.26 *continued*

Scoring Spline Variables

This section shows you how to find spline transformations of variables in one data set and apply the same transformations to variables in another data set. This is illustrated with artificial data. In these data sets, the variable y is approximately a linear function of nonlinear transformations of the variables x , w , and z . The model is fit using data set X , and those results are used to score data set Z . The following statements create the two data sets:

```

title 'An Illustration of Splines and Knots';
title2 'Scoring Spline Variables';

data x;
  do i = 1 to 5000;
    w = normal(7);
    x = normal(7);
    z = normal(7);
    y = w * w + log(5 + x) + sin(z) + normal(7);
    output;
  end;
run;

```

```

data z;
  do i = 1 to 5000;
    w = normal(1);
    x = normal(1);
    z = normal(1);
    y = w * w + log(5 + x) + sin(z) + normal(1);
    output;
  end;
run;

```

First, you run PROC TRANSREG to fit the transformation regression model asking for spline transformations of the three independent variables. You must use the `EXKNOTS=` *t-option*, because you need to use the same knots, both interior and exterior, with both data sets. By default, the exterior knots will be different if the minima and maxima are different in the two data sets, so you get the wrong results if you do not specify the `EXKNOTS=` *t-option* with values less than the minima and greater than the maxima of the six `x`, `y`, and `w` variables. If the ranges in all three pairs were different, you would need separate spline transformation for each variable with different knot and exterior knot specifications. The following statements fit the spline model:

```

proc transreg data=x solve details ss2;
  ods output splinecoef=c;
  model identity(y) = spline(w x z / knots=-1.5 to 1.5 by 0.5
                             exknots=-5 5);
  output out=d;
run;

```

The results of this step are not displayed. The nonprinting “SplineCoef” table is output to a SAS data set. This data set contains the coefficients that were used to get the spline transformations and can be used to transform variables in other data sets. These coefficients are also in the details table. However, in the “SplineCoef” table, they are in a form directly suitable for use with PROC SCORE.

The next step reads the second input data set, `Z`, and generates an output data set with the B-spline basis for each of the variables:

```

proc transreg data=z design;
  model bspl(w x z / knots=-1.5 to 1.5 by 0.5 exknots=-5 5);
  output out=b;
run;

```

Note that the same interior and exterior knots are used in both of the previous steps. The next three steps score the B-spline bases created in the previous step by using the coefficients generated in the first PROC TRANSREG step. PROC SCORE is run once for each `SPLINE` variable in the statements that follow:

```

proc score data=b score=c out=o1(rename=(spline=bw w=nw));
  var w;;
run;

proc score data=b score=c out=o2(rename=(spline=bx x=nx));
  var x;;
run;

proc score data=b score=c out=o3(rename=(spline=bz z=nz));
  var z;;
run;

```

The following steps merge the three transformations with the original data and plot the results:

```

data all;
  merge d(keep=w x z tw tx tz) o1(keep=nw bw)
        o2(keep=nx bx) o3(keep=nz bz);
run;

proc template;
  define statgraph twobytwo;
    begingraph;
      layout lattice / rows=2 columns=2;
      layout overlay;
        seriesplot y=tw x=w / connectorder=xaxis;
        seriesplot y=bw x=nw / connectorder=xaxis;
      endlayout;
      layout overlay;
        seriesplot y=tx x=x / connectorder=xaxis;
        seriesplot y=bx x=nx / connectorder=xaxis;
      endlayout;
      layout overlay;
        seriesplot y=tz x=z / connectorder=xaxis;
        seriesplot y=bz x=nz / connectorder=xaxis;
      endlayout;
    endlayout;
  endgraph;
end;
run;

proc sgrender data=all template=twobytwo;
run;

```

The plots in [Figure 97.27](#) show that the two transformations for each variable, original and scored, are the same function. The two functions in each plot are on top of each other and are indistinguishable. Furthermore, PROC TRANSREG found the functional forms that were used to generate the data: quadratic for w, log for x, and sine for z.

Figure 97.27 Scoring Spline Variables Example

The next statements show how to run PROC TRANSREG, output the interior and exterior knots to an output data set with ODS, extract the knots, and use them in a DATA step to re-create the B-spline basis that PROC TRANSREG makes. In practice, you would never need to use a DATA step to make the B-spline basis since PROC TRANSREG does it automatically. The following statements show how you could do it yourself:

```
data x;
  input x @@;
  datalines;
1 2 3 4 5 6 7 8 9 10
;

ods output details=d;
proc transreg details design;
  model bspline(x / nkn=3);
  output out=y;
run;
```

```

%let k = 0;
data d;
  set d;
  length d $ 20;
  retain d ' ';
  if description ne ' ' then d = description;
  if d = 'Degree' then call symput('d', compress(formattedvalue));
  if d = 'Number of Knots'
    then call symput('k', compress(formattedvalue));
  if index(d, 'Knots') and not index(d, 'Number');
  keep d numericvalue;
run;

%let nkn = %eval(&d * 2 + &k); /* total number of knots */
%let nb = %eval(&d + 1 + &k); /* number of cols in basis */

proc transpose data=d out=k(drop=_name_) prefix=Knot;
run;

proc print; format k: 20.16;
run;

data b(keep=x:);
  if _n_ = 1 then set k; /* read knots from transreg */
  array k[&nkn] knot1-knot&nkn; /* knots */
  array b[&nb] x_0 - x_%eval(&nb - 1); /* basis */
  array w[%eval(2 * &d)]; /* work */
  set x;
  do i = 1 to &nb; b[i] = 0; end;

  * find the index of first knot greater than current data value;
  do ki = 1 to &nkn while(k[ki] le x); end;
  kki = ki - &d - 1;

  * make the basis;
  b[1 + kki] = 1;
  do j = 1 to &d;
    w[&d + j] = k[ki + j - 1] - x;
    w[j] = x - k[ki - j];
    s = 0;
    do i = 1 to j;
      t = w[&d + i] + w[j + 1 - i];
      if t ne 0.0 then t = b[i + kki] / t;
      b[i + kki] = s + w[&d + i] * t;
      s = w[j + 1 - i] * t;
    end;
    b[j + 1 + kki] = s;
  end;
run;

proc compare data=y(keep=x:) compare=b
  criterion=1e-12 note nosummary;
  title3 "should be no differences";
run;

```

The output from these steps is not shown. There are several things to note about the DATA step. It produces the same basis as PROC TRANSREG only because it uses exactly the same interior and exterior knots. The exterior knots (0.999999999999 and 10.000000000001) are just slightly smaller than 1 (the minimum in x) and just slightly greater than 10 (the maximum in x). Both exterior knots appear in the list three times, because a cubic (degree 3) polynomial was requested. The complete knot list is: 0.999999999999 0.999999999999 0.999999999999 3 6 8 10.000000000001 10.000000000001 10.000000000001. The exterior knots do not have any particular interpretation, but they are needed by the algorithm to construct the proper basis. The construction method computes differences between each value and the nearby knots. The algorithm that makes the B-spline basis is not very obvious, particularly compared to the polynomial spline basis. However, the B-spline basis is much better behaved numerically than a polynomial-spline basis, so that is why it is used.

Linear and Nonlinear Regression Functions

This section shows how to use PROC TRANSREG in simple regression (one dependent variable and one independent variable) to find the optimal regression line, a nonlinear but monotone regression function, and a nonlinear and nonmonotone regression function. To find a linear regression function, specify the **IDENTITY** transformation of the independent variable. For a monotone curve, specify the **MSPLINE** transformation of the independent variable. To relax the monotonicity constraint, specify the **SPLINE** transformation. You can get more flexibility in spline functions by specifying knots. The more knots you specify, the more freedom the function has to follow minor variations in the data. This example uses artificial data. While these artificial data are clearly not realistic, their distinct pattern helps illustrate how splines work. The following statements generate the data and produce [Figure 97.28](#) through [Figure 97.31](#):

```

title 'Linear and Nonlinear Regression Functions';

* Generate an Artificial Nonlinear Scatter Plot;
data a;
  do i = 1 to 500;
    x = i / 2.5;
    y = -((x/50)-1.5)**2 + sin(x/8) + sqrt(x)/5 + 2*log(x) + cos(x);
    x = x / 21;
    if y > 2 then output;
  end;
run;

Figure 97.28 Linear Regression

Figure 97.29 A Monotone Regression Function**Figure 97.30** A Nonlinear Regression Function

Figure 97.31 A Less-Smooth Nonlinear Regression Function

The squared correlation is only 0.15 for the linear regression in [Figure 97.28](#). Clearly, a simple linear regression model is not appropriate for these data. By relaxing the constraints placed on the regression line, the proportion of variance accounted for increases from 0.15 (linear) to 0.61 (monotone in [Figure 97.29](#)) to 0.90 (nonlinear but smooth in [Figure 97.30](#)) to almost 1.0 with 100 knots (nonlinear and not very smooth in [Figure 97.28](#)). Relaxing the linearity constraint permits the regression function to bend and more closely follow the right portion of the scatter plot. Relaxing the monotonicity constraint permits the regression function to follow the periodic portion of the left side of the plot more closely. The nonlinear **MSPLINE** transformation is a quadratic spline with knots at the deciles. The first nonlinear nonmonotonic **SPLINE** transformation is a cubic spline with knots at the deciles.

Different knots and different degrees would produce slightly different results. The two nonlinear regression functions could be closely approximated by simpler piecewise linear regression functions. The monotone function could be approximated by a two-piece line with a single knot at the elbow. The first nonmonotone function could be approximated by a six-piece function with knots at the five elbows.

With this type of problem (one dependent variable with no missing values that is not transformed and one independent variable that is nonlinearly transformed), PROC TRANSREG always iterates exactly twice (although only one iteration is necessary). The first iteration reports the R square for the linear regression line and finds the optimal transformation of x . Since the data change in the first iteration, a second iteration is performed, which reports the R square for the final nonlinear regression function, and zero data change. The predicted values, which are a linear function of the optimal transformation of x , contain the Y coordinates for the nonlinear regression function. The variance of the predicted values divided by the variance of y is the R square for the fit of the nonlinear regression function. When x is monotonically transformed, the transformation of x is always monotonically increasing, but the predicted values increase if the correlation is positive and decrease for negative correlations.

Simultaneously Fitting Two Regression Functions

One application of ordinary multiple regression is fitting two or more regression lines through a single scatter plot. With PROC TRANSREG, this application can easily be generalized to fit separate or parallel curves. To illustrate, consider a data set with two groups and a group membership variable *g* that has the value 1 for one group and 2 for the other group. The data set also has a continuous independent variable *x* and a continuous dependent variable *y*. When *g* is crossed with *x*, the variables *g1x* and *g2x* both have a large partition of zeros. For this reason, the **KNOTS=** *t-option* is specified instead of the **NKNOTS=** *t-option*. (The latter would put a number of knots in the partition of zeros.) The following example generates an artificial data set with two curves. While these artificial data are clearly not realistic, their distinct pattern helps illustrate how fitting simultaneous regression functions works. The following statements generate data and show how PROC TRANSREG fits lines, curves, and monotone curves through a scatter plot:

```

title 'Separate Curves, Separate Intercepts';

data a;
  do x = -2 to 3 by 0.025;
    g = 1;
    y = 8*(x*x + 2*cos(x*6)) + 15*normal(7654321);
    output;
    g = 2;
    y = 4*(-x*x + 4*sin(x*4)) - 40 + 15*normal(7654321);
    output;
  end;
run;

ods graphics on;
ods select fitplot(persist);

title 'Parallel Lines, Separate Intercepts';

proc transreg data=a solve;
  model identity(y)=class(g) identity(x);
run;

title 'Parallel Monotone Curves, Separate Intercepts';

proc transreg data=a;
  model identity(y)=class(g) mspline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Parallel Curves, Separate Intercepts';

proc transreg data=a solve;
  model identity(y)=class(g) spline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Slopes, Same Intercept';

```

```

proc transreg data=a;
  model identity(y)=class(g / zero=none) * identity(x);
run;

title 'Separate Monotone Curves, Same Intercept';

proc transreg data=a;
  model identity(y) = class(g / zero=none) *
                      mspline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Curves, Same Intercept';

proc transreg data=a solve;
  model identity(y) = class(g / zero=none) *
                      spline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Slopes, Separate Intercepts';

proc transreg data=a;
  model identity(y) = class(g / zero=none) | identity(x);
run;

title 'Separate Monotone Curves, Separate Intercepts';

proc transreg data=a;
  model identity(y) = class(g / zero=none) |
                      mspline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Curves, Separate Intercepts';

proc transreg data=a solve;
  model identity(y) = class(g / zero=none) |
                      spline(x / knots=-1.5 to 2.5 by 0.5);
run;
ods select all;

```

The previous statements produce [Figure 97.32](#) through [Figure 97.40](#). Only the fit plots are generated and displayed.

Penalized B-Splines

You can use penalized B-splines (Eilers and Marx 1996) to fit a smooth curve through a scatter plot with an automatic selection of the smoothing parameter. See [Example 97.3](#) for an example. With penalized B-splines, you can find a transformation that minimizes any of the following criteria: [CV](#), [GCV](#), [AIC](#), [AICC](#), or [SBC](#). These criteria are all functions of λ . For many problems, all of these criteria produce nearly identical results. However, for some problems, the choice of criterion can have a large effect. When the default results are not satisfactory, try the other criteria. Information criteria such as AIC and AICC are defined in different ways in the statistical literature, and these differences can be seen in different SAS procedures. Typically, the definitions differ only by a positive (additive or multiplicative) constant, so they are equivalent, and each of the definitions of the same criterion produces the same selection of λ . The definitions that PROC TRANSREG uses match the definitions that PROC REG uses. The penalized B-spline matrices, statistics, and criteria are defined as follows:

n	number of observations
y	dependent variable
\mathbf{W}	diagonal matrix of observation weights
w_i	weight for the i th observation
\mathbf{B}	B-spline basis for the independent variable
λ	nonnegative smoothing parameter
\mathbf{D}	difference matrix, penalizes lack of smoothness
$\mathbf{H} = \mathbf{B}(\mathbf{B}'\mathbf{W}\mathbf{B} + \lambda\mathbf{D}'\mathbf{D})^{-1}\mathbf{B}'$	hat matrix

h_{ii}	i th diagonal element of \mathbf{H}
$\hat{\mathbf{y}} = \mathbf{H}\mathbf{y}$	penalized B-spline transformation of \mathbf{y}
$\text{SSE} = \sum_{i=1}^n w_i (y_i - \hat{y}_i)^2$	error sum of squares
$t = \sum_{i=1}^n w_i h_{ii}$	weighted trace of \mathbf{H}
$\sum_{i=1}^n w_i \left(\frac{y_i - \hat{y}_i}{1 - h_{ii}} \right)^2$	CV - cross validation criterion
$\sum_{i=1}^n w_i \left(\frac{y_i - \hat{y}_i}{n - t} \right)^2$	GCV - generalized cross validation criterion
$n \log(\text{SSE}/n) + 2t$	AIC - Akaike's information criterion
$1 + \log(\text{SSE}/n) + \frac{2(t+1)}{n-t-2}$	AICC - corrected AIC (default)
$n \log(\text{SSE}/n) + t \log(n)$	SBC - Schwarz's Bayesian criterion

For more information about constructing the B-spline basis, see “[SPLINE and MSPLINE Transformations](#)” on page 8300 and the section “[Using Splines and Knots](#)” on page 8233. The nonzero elements of \mathbf{D} , order 1 are (1 -1), order 2 are (1 -2 1), order 3 (the default) are (1 -3 3 -1), order 4 are (1 -4 6 -4 1), and so on. The nonzero elements for each order are made from the nonzero elements from the preceding order by subtraction: $\mathbf{d}'_{i+1} = (\mathbf{d}'_i \ 0) - (0 \ \mathbf{d}'_i)$. Within an order, the first nonzero element of row i is in column i —that is, each row of \mathbf{D} is made from the preceding row by shifting the nonzero elements to the right one position. For example, with $k = 4$ knots, order $o = 3$, and degree $d = 3$, \mathbf{D} is the $((d+1+k-o) \times (d+1+k))$ matrix:

$$\begin{bmatrix} 1 & -3 & 3 & -1 & 0 & 0 & 0 & 0 \\ 0 & 1 & -3 & 3 & -1 & 0 & 0 & 0 \\ 0 & 0 & 1 & -3 & 3 & -1 & 0 & 0 \\ 0 & 0 & 0 & 1 & -3 & 3 & -1 & 0 \\ 0 & 0 & 0 & 0 & 1 & -3 & 3 & -1 \end{bmatrix} \quad \text{where} \quad \begin{array}{r} \begin{array}{cccc} 1 & -1 & 0 & \\ 0 & 1 & -1 & \\ 1 & -2 & 1 & 0 \\ 0 & 1 & -2 & 1 \\ 1 & -3 & 3 & -1 \end{array} \end{array}$$

The weighted trace of the hat matrix, $t = \sum_{i=1}^n w_i h_{ii}$, provides an estimate of the number of parameters needed to find the transformation and is used in df calculations. Note, however, that in some cases, particularly with error-free or nearly error-free data, this value can be *much* larger than you might expect. You might be able to directly create a function by using [SPLINE](#) or [BSPLINE](#) with many fewer parameters that fits essentially just as well as the penalized B-spline function.

By default with [PBSPLINE](#), a cubic spline is fit with 100 evenly spaced knots, three evenly spaced exterior knots, and a difference matrix of order three. Options are specified as follows: [PBSPLINE](#)(x / [DEGREE=3](#) [NKNOTS=100](#) [EVENLY=3](#) [PARAMETER=3](#)). By default, PROC TRANSREG searches for an optimal

lambda in the range 0 to 1E6 by using parabolic interpolation and Brent's (Brent 1973; Press et al. 1989) method. Alternatively, you can specify a lambda range or a list of lambdas by using the **LAMBDA=** option. Be aware, however, **LAMBDA=0** and values near zero might cause numerical problems including floating point errors. Also be aware that larger lambdas might cause numerical problems—for example, the error sum of squares for the model, $\Sigma(y - \hat{y})^2$, might be greater than the total sum of squares, $\Sigma(y - \bar{y})^2$ —implying that the model with the transformation fits less well than simply predicting by using the mean. When this happens, you will see this message: ERROR: Degenerate transformation with PBSPLINE.

You can fit a single curve through a scatter plot ($y \times x$) as follows:

```
model identity(y) = pbspline(x);
```

Alternatively, you can fit multiple curves through a scatter plot, one for each level of Group, as follows:

```
model identity(y) = class(group / zero=none) * pbspline(x);
```

There are several options for how the smoothing parameter, λ , is chosen. Usually, you do not specify the smoothing parameter, λ , and you let PROC TRANSREG choose λ for you by minimizing one of the information or cross validation criteria. By default, PROC TRANSREG first considers ranges defined by $\lambda = 0$ and $\lambda = 1, 10, 100, 1000, 10,000, 100,000, 1,000,000$. If it finds a range that includes the minimum, it stops and does not consider larger λ values. Then it performs further searches in that range. For example, if the initial evaluations at $\lambda = 1$ and $\lambda = 10$ show that there is at least a local minimum in the range 0 to 10, then larger values are not considered. Note that the zero smoothing case, $\lambda = 0$, provides a boundary on the range even though the criterion is not evaluated at $\lambda = 0$. The criterion is not evaluated at $\lambda = 0$ unless **LAMBDA=0** is the only value specified. Also note that the default approach is not the same as specifying the options **LAMBDA=0 1E6 RANGE**. When a range of values is specified, along with the **RANGE t-option**, PROC TRANSREG does not try to find smaller ranges based on powers of 10.

PROC TRANSREG avoids evaluating the criterion for **LAMBDA=** values at or near zero unless you force it to consider them. This is because zero smoothing is rarely interesting and the results are numerically unstable. Values of λ at or near zero often result in predicted values that are far outside the range of the data, particularly with interpolation and x values that do not appear in the data set. Also, zero smoothing is prone to numerical problems including floating point errors. This is particularly true when there is a small number of observations, a large number of knots, a high degree, or a perfect or near perfect fit. If you force PROC TRANSREG to evaluate the criterion at or near $\lambda = 0$, you can easily get bad results.

Note that when some observations appear more than once, such as when you have the kind of data where you can use a **FREQ** statement, then you should consider directly specifying lambda based on a preliminary analysis, ignoring the frequencies. Alternatively, specify a range of λ values, such as **LAMBDA=0.1 1E6 RANGE**, that steers λ away from values near zero. With the default lambda list, a cross validation criterion does not perform well in choosing a smoothing parameter with replicated data. Leaving one observation out of the computations changes the frequency for that observation from one positive integer to the next smaller positive integer, so in some sense, the point corresponding to that observation is never really left out of any computations. The resulting fit will be undersmoothed unless you specify a larger λ .

Smoothing Splines

You can use PROC TRANSREG to plot and output to a SAS data set the same smoothing spline function that the GPLOT procedure creates. You request a smoothing spline transformation by specifying **SMOOTH** in the MODEL statement. The smoothing parameter can be specified with either the **SM=** or the **PARAMETER=** *o-option*. The results are saved in the independent variable transformation (for example, Tx, when the independent variable is x) and the predicted values variable (for example, Py, when the dependent variable is y).

You can display the smoothing spline by using PROC TRANSREG and ODS Graphics (as shown in [Figure 97.41](#)). The following statements produce [Figure 97.41](#):

```
title h=1.5 'Smoothing Splines';

ods graphics on;

data x;
  do x = 1 to 100 by 2;
    do rep = 1 to 3;
      y = log(x) + sin(x / 10) + normal(7);
      output;
    end;
  end;
run;

proc transreg;
  model identity(y) = smooth(x / sm=50);
  output p;
run;
```

Figure 97.41 Smoothing Spline Displayed with ODS Graphics

You can also use PROC GLOT to verify that the two procedures produce the same results. The PROC GLOT plot request `y * x = 1` displays the data as stars. The specification `y * x = 2` with `I=SM50` requests the smooth curve through the scatter plot. It is overlaid with `Py * x = 3`, which displays with large dots the smooth function created by PROC TRANSREG. The results of the following step are not displayed:

```
proc gplot;
  axis1 minor=none label=(angle=90 rotate=0);
  axis2 minor=none;
  symbol1 color=blue v=circle i=none; /* data */
  symbol2 color=blue v=none i=sm50; /* gplot's smooth */
  symbol3 color=red v=dot i=none; /* transreg's smooth */
  plot y*x=1 y*x=2 py*x=3 / overlay haxis=axis2 vaxis=axis1 frame;
run; quit;
```

You can plot multiple nonlinear functions, one for each of several groups as defined by the levels of a **CLASS** variable. When you cross a **SMOOTH** variable with a **CLASS** variable, specify **ZERO=NONE** with the **CLASS** expansion. The following statements create artificial data and produce Figure 97.42:

```
title2 'Two Groups';

data x;
  do x = 1 to 100;
    Group = 1;
    do rep = 1 to 3;
      y = log(x) + sin(x / 10) + normal(7);
```

```

        output;
    end;
    group = 2;
    do rep = 1 to 3;
        y = -log(x) + cos(x / 10) + normal(7);
        output;
    end;
end;
run;

proc transreg ss2 data=x;
    model identity(y) = class(group / zero=none) *
                      smooth(x / sm=50);

    output p;
run;

```

The ANOVA table in [Figure 97.42](#) shows the overall model fit. The degrees of freedom are based on the trace of the transformation hat matrix, and are typically not integers. The “Smooth Transformation” table reports the degrees of freedom for each term, which includes an intercept for each group; the regression coefficients, which are always 1 with smoothing splines; the 0 to 100 smoothing parameter (like the one PROC GPLOT uses); the actual computed smoothing parameter; and the name and label for each term.

Figure 97.42 continued

The **SMOOTH** transformation is valid only with independent variables. Typically, it is used only, as in the two preceding examples, in models with a single dependent variable, a single independent variable, and optionally, a single classification variable that is crossed with the independent variable. The various standardization options such as **TSTANDARD=**, **CENTER**, **Z**, and **REFLECT** are by default not permitted when the **SMOOTH** transformation is part of the model.

The **SMOOTH** transformation can also be used in other ways, but only when you specify the **NSR** *a-option*. (See the section “[Smoothing Splines Changes and Enhancements](#)” on page 8267.) When you specify the **NSR** *a-option*, and there are multiple independent variables designated as **SMOOTH**, **PROC TRANSREG**

tries to smooth the i th independent variable by using the i th dependent variable as a target. When there are more independent variables than dependent variables, the last dependent variable is reused as often as is necessary. For example, consider the following statements:

```
proc transreg nsr;
  model identity(y1-y3) = smooth(x1-x5);
run;
```

Smoothing is based on the pairs (y1, x1), (y2, x2), (y3, x3), (y3, x4), and (y3, x5).

The SMOOTH transformation is a noniterative transformation. The smoothing of each variable occurs before the iterations begin. In contrast, **SSPLINE** provides an iterative smoothing spline transformation. It does not generally minimize squared error; hence, divergence is possible with SSPLINE.

Smoothing Splines Changes and Enhancements

How the results of the transformation are processed in PROC TRANSREG has changed with SAS 9.2. In particular, some aspects of the syntax along the coefficients and predicted values have changed. The new behavior was required to make the smoothing splines work properly with ODS Graphics and to make SMOOTH work consistently with the new **PBSPLINE** (penalized B-spline; see the section “**Penalized B-Splines**” on page 8260) capabilities. However, you can use the new **NSR** *a-option*, if you want the old functionality. Here are two typical uses of the SMOOTH transformation:

```
proc transreg;
  model identity(y) = smooth(x / sm=50);
  output p;
run;

proc transreg;
  model identity(y) = class(group / zero=none) * smooth(x / sm=50);
  output p;
run;
```

For the first model, the variable x is smoothly transformed by using a smoothing parameter of **SM=50**, and the results are stored in the transformed variable Tx . The second model has two groups of observations corresponding to **group=1** and **Group=2**. Separate curves are fit through each group. The results for the first group are stored in the transformed variable $TGroup1x$, and the results for the second group are stored in the transformed variable $TGroup2x$. The predicted values are stored in Py . In the first case, $Py = Tx$, and in the second case, $Py = TGroup1x + TGroup2x$. These represent the two standard usages of the SMOOTH transformation, and you can use ODS Graphics to display fit plots with a single or multiple smooth functions. For the first model, which is the most typical usage, the syntax has not changed, nor has the transformed variable. For the second model, the syntax has slightly changed, but the transformed variables have not. The details of the syntax changes are discussed later in this section. The primary change involves what happens after the SMOOTH transformation is found. Now, by default, ordinary least squares (OLS) is no longer used to find the coefficients when there are smooth transformations, and in the iteration history table the OLS R square is no longer produced.

Here is some background for the change. The first three of the four models shown next have much in common:

```
model identity(y) = smooth(x / sm=50);
model identity(y) = rank(x);
model identity(y) = log(x);
model identity(y) = spline(x);
```

Before SAS 9.2, the **SMOOTH**, **RANK**, and **LOG** transformations all requested that PROC TRANSREG preprocess the data, nonlinearly transforming x before using OLS to fit a model to the preprocessed results. All of these first three transformations of x are nonoptimal in the sense that none of them is based in any way on the OLS regression model that follows the preprocessing of the data. In contrast, the fourth model requests a spline transformation. In this model, both the nonlinear transformation and the final regression model seek to minimize the same OLS criterion. Some PROC TRANSREG transformations, such as **SPLINE**, **MSPLINE**, **OPSCORE**, **MONOTONE**, and so on, seek to minimize squared error, whereas others, such as **SMOOTH**, **LOG**, **EXP**, and **RANK**, do not. For the latter, the data are simply preprocessed before analysis. There is a philosophical difference, however, between **SMOOTH** and the nonoptimal transformations. The **SMOOTH** and **PBSPLINE** transformations use the dependent variable and a model (but not OLS) to compute the transformation, whereas **LOG**, **EXP**, **RANK**, and the other nonoptimal transformations do not. A log transformation, for example, would be the same, regardless of context, whereas the **SMOOTH** and **PBSPLINE** transformations depend on the model.

The principal change to **SMOOTH** in PROC TRANSREG with SAS 9.2 involves making PROC TRANSREG aware of the underlying smoothing spline model. This makes **SMOOTH** and **PBSPLINE** perform similarly, and less like **LOG**, **EXP**, **RANK**, and the other nonoptimal transformations. Previously, if you specified **SMOOTH** and then examined the regression coefficients, you would probably get an intercept very close to but not exactly 0, and the remaining coefficients would be very close to but not exactly 1. This is because PROC TRANSREG was using OLS to find the coefficients. This has changed. Now, PROC TRANSREG recognizes that the **SMOOTH** transformation has an implicit intercept (see the section “**Implicit and Explicit Intercepts**” on page 8294); hence there is no separate intercept. Furthermore, now the other parameters are exactly 1, which are the correct parameters for the non-OLS smoothing spline model. Hence, the predicted values are now the sum of the transformed variables. When there is no **CLASS** variable, the predicted values exactly match the transformed variable. The **SMOOTH** transformation is no longer a form of preprocessing; it now changes the nature of the model from OLS to a true smoothing-spline model. If you still want the old behavior, preprocessing and then OLS, you can get the old default functionality by specifying the **NSR a-option**.

The new, default functionality assumes that you either want to fit a smooth function through the data or fit separate functions, one for each level of a **CLASS** variable. It also recognizes the smoothing-spline model as a model with an implicit intercept. For these reasons, the syntax for models with a **CLASS** variable has slightly changed, as is shown next:

```

proc transreg nsr; /* old */
  model identity(y) = class(group / zero=none) |
                    smooth(x / after sm=50);

  output p;
run;

proc transreg; /* new */
  model identity(y) = class(group / zero=none) *
                    smooth(x / sm=50);

  output p;
run;

```

Previously, the [AFTER](#) *t-option* was required when you wanted to fit separate and independent functions within each group. This *t-option* specifies that PROC TRANSREG should find the smoothing spline transformations *after* it crosses the independent variable with the CLASS variable. Previously, by default, PROC TRANSREG found an overall smooth transformation and then crossed it with the CLASS variable, which is probably not what you want. You can still specify the [AFTER](#) *t-option*, but now it is assumed with CLASS * SMOOTH. If you specify AFTER without the NSR *a-option*, PROC TRANSREG suppresses the note that AFTER is assumed. It does not affect the model. If you do not want AFTER to be in effect by default, you must specify the NSR *a-option*. Also previously, you typically needed to specify the vertical bar instead of the asterisk to cross the CLASS and SMOOTH variables. The difference is that the bar adds both crossed variables and separate group intercepts to the model, whereas the asterisk adds only the crossed variables to the model. Since the SMOOTH transformation is now recognized as providing an implicit intercept, you should use the asterisk and not the vertical bar.

The default behavior of the SMOOTH transformation needed to change for several reasons. SMOOTH was originally provided as nothing more than a way to get PROC GPLOT's smoothing splines into an output data set in the transformed variables. However, with new enhancements to PROC TRANSREG such as ODS Graphics and PBSPLINE, the old method for SMOOTH did not fit well. The old method produced predicted values that were not the correct values to plot in order to show the smoothing spline fit. Now, with this change, ODS Graphics can always plot the predicted values. PBSPLINE and SMOOTH are similar in spirit, and for both, OLS results are not truly appropriate. Before SAS 9.2, PROC TRANSREG fit linear models, linear models with nonlinearly preprocessed variables, and linear models with optimal nonlinear transformations that minimized squared error. Now it also has the ability to fit non-OLS models for scatter plot smoothing.

One aspect of the SMOOTH transformation has unconditionally changed with SAS 9.2. Previously, PROC TRANSREG did not evaluate the effective degrees of freedom by examining the trace of the transformation hat matrix. It simply used the number of categories in the *df* calculations, which for continuous variables is the number of observations. This made it impossible to get a sensible ANOVA test for the overall fit. With SAS 9.2, the degrees of freedom are always based on the trace. This *df* change also affects the [SSPLINE](#) transformation, which finds a smooth transformation by using the same algorithm as SMOOTH. The difference is that the SMOOTH transformation occurs once, as an analysis preprocessing step, whereas SSPLINE transformations occur iteratively and in the body of the alternating least squares algorithm.

Iteration History Changes and Enhancements

With SAS 9.2, PROC TRANSREG no longer always prints an iteration history table by default, and in some cases, the table it prints is not the same as it was previously. This change is due to the increasing use of PROC TRANSREG with transformations that are not based on alternating least squares. Here is some background for the change. PROC TRANSREG's processing can be divided into three steps. In the first step, the data are read and certain transformations, such as [SMOOTH](#), [PBSPLINE](#), [BOXCOX](#), [RANK](#), [LOG](#) and the other nonoptimal transformations, are performed. These transformations are not based on OLS. In the second step, the alternating least squares iterations are performed according to [METHOD=UNIVARIATE](#), [MORALS](#), [REDUNDANCY](#), or [CANALS](#). It is in the second step that the alternating least squares transformations ([SPLINE](#), [MSPLINE](#), [MONOTONE](#), [OPSCORE](#), [LINEAR](#), and [UNTIE](#)) are iteratively found. In the third step, the results are displayed. In some cases, the results are appropriately based on using the method of OLS applied to the optimally transformed variables. In other cases, such as with smoothing splines and penalized B-splines, OLS-based results are not appropriate. Furthermore, for many of these types of models, nothing changes in the iterations, so the computations needed to realize that nothing changes are not needed, nor is the iteration history table.

With SAS 9.2, the iteration history is not printed for models where it is known that nothing will change in the iterations. Suppose the [NOMISS](#) option is specified or there are no missing data. If [METHOD=UNIVARIATE](#), if there are no iterative transformations ([SPLINE](#), [MSPLINE](#), [MONOTONE](#), [OPSCORE](#), [LINEAR](#), and [UNTIE](#)), and if the [MAXITER=](#) option is not specified, then by default, an iteration history table is not produced. If you want to see an iteration history, there are many things you can do, such as specifying [MAXITER=](#), changing the method to [MORALS](#), or changing [IDENTITY](#) to [LINEAR](#).

With models with smoothing splines or penalized B-splines, the iteration history will not contain an R square. This is because the iterations are based on the method of alternating least squares, but the smoothing splines and penalized B-splines are not based on a least squares model. Hence, an ordinary R square in the iterations, based on a computed intercept, which is typically not exactly zero, and a computed slope, which is typically not exactly one, will not be exactly the same as the correct R square, which is based on an intercept and slope of zero and one. The final reported results include the correct R square in the fit statistics table after the ANOVA table. If you want to see only the correct R square from the results, without the iteration history, you can specify the new [RSQUARE](#) option.

ANOVA Codings

This section illustrates several different codings of classification variables and hence several different ways of fitting two-way ANOVA models to some data. Each example fits an ANOVA model, displays the ANOVA table and parameter estimates, and displays the coded design matrix. Note throughout that the ANOVA tables and R squares are identical for all of the models, showing that the codings are equivalent. For each model, the parameter estimates are stated as a function of the cell means. The formulas are appropriate for a design such as this one, which is balanced and orthogonal (every level and every pair of levels occurs equally often). They will not work with unequal frequencies. Since this data set has $3 \times 2 = 6$ cells, the full-rank codings all have six parameters. The following statements create the input data set, and display it in [Figure 97.43](#):

```

title 'Two-Way ANOVA Models';

data x;
  input a b @@;
  do i = 1 to 2; input y @@; output; end;
  drop i;

Class.a3b2	1	1.0000000	6.00	6.00	0.41	0.5461	a 3 * b 2

The sum of the regression table DF's, minus one for the intercept, will be greater than the model df when there are ZERO=SUM constraints.

The parameter estimates are

$$\begin{aligned}
 \hat{\mu} &= \bar{y} = 13.3333 \\
 \hat{\alpha}_1 &= (\bar{y}_{11} + \bar{y}_{12})/2 - \bar{y} = (15 + 14)/2 - 13.3333 = 1.1667 \\
 \hat{\alpha}_2 &= (\bar{y}_{21} + \bar{y}_{22})/2 - \bar{y} = (5 + 16)/2 - 13.3333 = -2.8333 \\
 \hat{\alpha}_3 &= (\bar{y}_{31} + \bar{y}_{32})/2 - \bar{y} = (11 + 19)/2 - 13.3333 = 1.6667 \\
 \hat{\beta}_1 &= (\bar{y}_{11} + \bar{y}_{21} + \bar{y}_{31})/3 - \bar{y} = (15 + 5 + 11)/3 - 13.3333 = -3 \\
 \hat{\beta}_2 &= (\bar{y}_{12} + \bar{y}_{22} + \bar{y}_{32})/3 - \bar{y} = (14 + 16 + 19)/3 - 13.3333 = 3 \\
 \hat{\gamma}_{11} &= \bar{y}_{11} - (\bar{y} + \hat{\alpha}_1 + \hat{\beta}_1) = 15 - (13.3333 + 1.1667 + -3) = 3.5 \\
 \hat{\gamma}_{12} &= \bar{y}_{12} - (\bar{y} + \hat{\alpha}_1 + \hat{\beta}_2) = 14 - (13.3333 + 1.1667 + 3) = -3.5 \\
 \hat{\gamma}_{21} &= \bar{y}_{21} - (\bar{y} + \hat{\alpha}_2 + \hat{\beta}_1) = 5 - (13.3333 + -2.8333 + -3) = -2.5 \\
 \hat{\gamma}_{22} &= \bar{y}_{22} - (\bar{y} + \hat{\alpha}_2 + \hat{\beta}_2) = 16 - (13.3333 + -2.8333 + 3) = 2.5 \\
 \hat{\gamma}_{31} &= \bar{y}_{31} - (\bar{y} + \hat{\alpha}_3 + \hat{\beta}_1) = 11 - (13.3333 + 1.6667 + -3) = -1 \\
 \hat{\gamma}_{32} &= \bar{y}_{32} - (\bar{y} + \hat{\alpha}_3 + \hat{\beta}_2) = 19 - (13.3333 + 1.6667 + 3) = 1
 \end{aligned}$$

The constraints are

$$\alpha_1 + \alpha_2 + \alpha_3 \equiv \beta_1 + \beta_2 \equiv 0$$

$$\gamma_{11} + \gamma_{12} \equiv \gamma_{21} + \gamma_{22} \equiv \gamma_{31} + \gamma_{32} \equiv \gamma_{11} + \gamma_{21} + \gamma_{31} \equiv \gamma_{12} + \gamma_{22} + \gamma_{32} \equiv 0$$

Only four of the five interaction constraints are needed. The fifth constraint is implied by the other four. (Given a 2×3 table with four marginal sum-to-zero constraints, you can freely fill in only two cells. The values in the other four cells are determined from the first two cells and the constraints.) A full-rank model has six estimable parameters. This less-than-full-rank model has one parameter for the intercept, two for

the first main effect (plus one more as determined by the first constraint), one for the second main effect (plus one more as determined by the second constraint), and two for the interactions (plus four more as determined by the next four constraints). Six of the twelve parameters are determined given the other six and the constraints. Notice that $\hat{\mu}$, $\hat{\alpha}_1$, $\hat{\alpha}_2$, $\hat{\beta}_1$, $\hat{\gamma}_{11}$, and $\hat{\gamma}_{21}$ match the corresponding estimates from the effects coding.

 &= ((15 - 14 - 11 + 19)/4) \times \sqrt{2/3} \times \sqrt{2/2} = 1.8371 \\
 \hat{\gamma}_{21} &= (((-\bar{y}_{11} + \bar{y}_{12} - \bar{y}_{31} + \bar{y}_{32})/2 + (\bar{y}_{21} - \bar{y}_{22}))/6) \times \sqrt{6/3} \times \sqrt{2/2} \\
 &= (((-15 + 14 - 11 + 19)/2 + (5 - 16))/6) \times \sqrt{6/3} \times \sqrt{2/2} = -1.7678
 \end{aligned}$$

The numerators in the square roots are sums of squares of the coded values for the unstandardized-orthogonal codings, and the denominators are the numbers of levels. These terms convert the estimates from the orthogonal contrast coding to the standardized-orthogonal coding. The term $\sqrt{2/2}$, which is 1 and could be dropped, is included in the preceding formulas to show the general pattern. Notice the regression tables for the orthogonal-contrast coding and the standardized-orthogonal coding. Some of the coefficients are different, but the rest of the table is the same since the coded variables for the two models differ only by a constant.

Missing Values

PROC TRANSREG can estimate missing values, with or without category or monotonicity constraints, so that the regression model fit is optimized. Several approaches to missing data handling are provided. All observations with missing values in **IDENTITY**, **CLASS**, **POINT**, **EPOINT**, **QPOINT**, **SMOOTH**, **PBSPLINE**, **PSPLINE**, and **BSPLINE** variables are excluded from the analysis. When **METHOD=UNIVARIATE** (specified in the PROC TRANSREG or MODEL statement), observations with missing values in any of the independent variables are excluded from the analysis. When you specify the **NOMISS** *a-option*, observations with missing values in the other analysis variables are excluded. Otherwise, missing data are estimated, and the variable means are the initial estimates.

You can specify the **LINEAR**, **OPSCORE**, **MONOTONE**, **UNTIE**, **SPLINE**, **MSPLINE**, **SSPLINE**, **LOG**, **LOGIT**, **POWER**, **ARSIN**, **BOXCOX**, **RANK**, and **EXP** transformations in any combination with nonmissing values, ordinary missing values, and special missing values, as long as the nonmissing values in each variable have positive variance. No category or order restrictions are placed on the estimates of ordinary missing values. You can force missing value estimates within a variable to be identical by using special missing values (see “DATA Step Processing” in *SAS Language Reference: Concepts*). You can specify up to 27 categories of missing values, in which within-category estimates must be the same, by coding the missing values with **._** and **.A** through **.Z**.

You can also specify an ordering of some missing value estimates. You can use the **MONOTONE=** *a-option* in the PROC TRANSREG or MODEL statement to indicate a range of special missing values (a subset of the list from **.A** to **.Z**) with estimates that must be weakly ordered within each variable in which they appear. For example, if **MONOTONE=AI**, the nine classes, **.A**, **.B**, ..., **.I**, are monotonically scored and optimally scaled just as **MONOTONE** transformation values are scored. In this case, category but not order restrictions are placed on the missing values **._** and **.J** through **.Z**. You can also use the **UNTIE=** *a-option* (in the PROC TRANSREG or MODEL statement) to indicate a range of special missing values with estimates that must be weakly ordered within each variable in which they appear but can be untied.

The missing value estimation facilities enable you to have partitioned or mixed-type variables. For example, a variable can be considered part nominal and part ordinal. Nominal classes of otherwise ordinal variables are coded with special missing values. This feature can be useful with survey research. The class “unfamiliar with the product” in the variable “Rate your preference for ‘Brand X’ on a 1 to 9 scale, or if you are unfamiliar with the product, check ‘unfamiliar with the product’” is an example. You can code “unfamiliar with the product” as a special missing value, such as **.A**. The 1s to 9s can be monotonically transformed, while no monotonic restrictions are placed on the quantification of the “unfamiliar with the product” class.

A variable specified for a **LINEAR** transformation, with special missing values and ordered categorical missing values, can be part interval, part ordinal, and part nominal. A variable specified for a **MONOTONE** transformation can have two independent ordinal parts. A variable specified for an **UNTIE** transformation can have an ordered categorical part and an ordered part without category restrictions. Many other mixes are possible.

Missing Values, UNTIE, and Hypothesis Tests

PROC TRANSREG can estimate missing data and monotonically transform variables while untying tied values. Estimates of ordinary missing values (**.**) are all permitted to be different. Analyses with **UNTIE** transformations, the **UNTIE=** *a-option*, and ordinary missing data estimation are all prone to degeneracy

problems. Consider the following example. A perfect fit is found by collapsing all observations except the one with two missing values into a single value in *y* and *x1*. The following statements produce [Figure 97.60](#):

```

Generally, the use of ordinary missing data estimation, the UNTIE transformation, and the UNTIE= *a-option* should be avoided, particularly with hypothesis tests. With these options, parameters are estimated based on only a single observation, and they can exert tremendous influence over the results. Each of these parameters has one model degree of freedom associated with it, so small or zero error degrees of freedom can also be a problem.

Controlling the Number of Iterations

Several *a-options* in the PROC TRANSREG or MODEL statement control the number of iterations performed. Iteration terminates when any one of the following conditions is satisfied:

- The number of iterations equals the value of the **MAXITER=** *a-option*.

- The average absolute change in variable scores from one iteration to the next is less than the value of the **CONVERGE=** *a-option*.
- The criterion change is less than the value of the **CCONVERGE=** *a-option*.

You can specify negative values for either convergence *a-option* if you want to define convergence only in terms of the other option. The criterion change can become negative when the data have converged, so it is numerically impossible, within machine precision, to increase the criterion. Usually, a negative criterion change is the result of very small amounts of rounding error, since the algorithms are (usually) convergent. However, there are cases where a negative criterion change is a sign of divergence, which is not necessarily an error. When you specify an **SSPLINE** transformation or the **REITERATE** or **SOLVE** *a-option*, divergence is perfectly normal.

When there are no monotonicity constraints and there is only one canonical variable in each set, PROC TRANSREG (with the **SOLVE** *a-option*) can usually find the optimal solution in only one iteration. (There are no monotonicity constraints when none of the following is specified: **MONOTONE**, **MSPLINE**, or **UNTIE** transformation or the **UNTIE=** or **MONOTONE=** *a-option*. There is only one canonical variable in each set when **METHOD=MORALS** or **METHOD=UNIVARIATE**, or when **METHOD=REDUNDANCY** with only one dependent variable, or when **METHOD=CANALS** and **NCAN=1**.)

The initialization iteration is number 0. When there are no monotonicity constraints and there is only one canonical variable in each set, the next iteration shows no change, and iteration stops. At least two iterations (0 and 1) are performed with the **SOLVE** *a-option* even if nothing changes in iteration 0. The **MONOTONE**, **MSPLINE**, and **UNTIE** variables are not transformed by the canonical initialization. Note that divergence with the **SOLVE** *a-option*, particularly in the second iteration, is not an error. The initialization iteration is slower and uses more memory than other iterations. However, for many models, specifying the **SOLVE** *a-option* can greatly decrease the amount of time required to find the optimal transformations.

You can increase the number of iterations to ensure convergence by increasing the value of the **MAXITER=** *a-option* and decreasing the value of the **CONVERGE=** *a-option*. Since the average absolute change in standardized variable scores seldom decreases below $1\text{E-}11$, you should not specify a value for the **CONVERGE=** *a-option* less than $1\text{E-}8$ or $1\text{E-}10$. Most of the data changes occur during the first few iterations, but the data can still change after 50 or even 100 iterations. You can try different combinations of values for the **CONVERGE=** and **MAXITER=** *a-options* to ensure convergence without extreme overiteration. If the data do not converge with the default specifications, try **CONVERGE=1E-8** and **MAXITER=50**, or **CONVERGE=1E-10** and **MAXITER=200**. Note that you can specify the **REITERATE** *a-option* to start iterating where the previous analysis stopped.

Using the REITERATE Algorithm Option

You can use the **REITERATE** *a-option* to perform additional iterations when PROC TRANSREG stops before the data have adequately converged. For example, suppose that you execute the following step:

```
proc transreg data=a;
  model mspline(y) = mspline(x1-x5);
  output out=b coefficients;
run;
```

If the transformations do not converge in the default 30 iterations, you can perform more iterations without repeating the first 30 iterations, as follows:

```
proc transreg data=b reiterate;
  model mspline(y) = mspline(x1-x5);
  output out=b coefficients;
run;
```

Note that a WHERE statement is not necessary to exclude the coefficient observations. They are automatically excluded because their `_TYPE_` value is not SCORE.

You can also use the REITERATE *a-option* to specify starting values other than the original values for the transformations. Providing alternate starting points might help avoid local optima. Here are two examples:

```
proc transreg data=a;
  model rank(y) = rank(x1-x5);
  output out=b;
run;

proc transreg data=b reiterate;
  /* Use ranks as the starting point. */
  model mspline(y) = mspline(x1-x5);
  output out=c coefficients;
run;

data b;
  set a;
  array tx[6] ty tx1-tx5;
  do j = 1 to 6;
    tx[j] = normal(7);
  end;
run;

proc transreg data=b reiterate;
  /* Use a random starting point. */
  model mspline(y) = mspline(x1-x5);
  output out=c coefficients;
run;
```

Note that divergence with the REITERATE *a-option*, particularly in the second iteration, is not an error since the initial transformation is not required to be a valid member of the transformation family. When you specify the REITERATE *a-option*, the iteration does not terminate when the criterion change is negative during the first 10 iterations.

Avoiding Constant Transformations

There are times when the optimal scaling produces a constant transformed variable. This can happen with the [MONOTONE](#), [UNTIE](#), and [MSPLINE](#) transformations when the target is negatively correlated with the original input variable. It can happen with all transformations when the target is uncorrelated with the original input variable. When this happens, the procedure modifies the target to avoid a constant transformation. This strategy avoids certain nonoptimal solutions.

If the transformation is monotonic and a constant transformed variable results, the procedure multiplies the target by -1 and tries the optimal scaling again. If the transformation is not monotonic or if the multiplication by -1 did not help, the procedure tries using a random target. If the transformation is still constant, the

previous nonconstant transformation is retained. When a constant transformation is avoided by any strategy, this message is displayed: “A constant transformation was avoided for *name*.”

With extreme collinearity, small amounts of rounding error might interact with the instability of the coefficients to produce target vectors that are not positively correlated with the original scaling. If a regression coefficient for a variable is zero, the formula for the target for that variable contains a zero divide. In a multiple regression model, after many iterations, one independent variable can be scaled the same way as the current scaling of the dependent variable, so the other independent variables have coefficients of zero. When the constant transformation warning appears, you should interpret your results with extreme caution, and recheck your model.

Constant Variables

Constant and almost constant variables are zeroed and ignored. When constant variables are expected and should not be zeroed, specify the **NOZEROCONSTANT** *a-option*.

Character OPSCORE Variables

Character **OPSCORE** variables are replaced by a numeric variable containing category numbers before the iterations, and the character values are discarded. Only the first eight characters are considered in determining category membership. If you want the original character variable in the output data set, give it a different name in the OPSCORE specification (OPSCORE(x / name=(x2)) and name the original variable in the **ID** statement (ID x;).

Convergence and Degeneracies

When you specify the **SSPLINE** transformation, divergence is normal. The rest of this section assumes that you did not specify **SSPLINE**. For all the methods available in PROC TRANSREG, the algorithms are convergent, in terms of both the criterion being optimized and the parameters being estimated. The value of the criterion being maximized (squared multiple correlation, average squared multiple correlation, or average squared canonical correlation) can, theoretically, never decrease from one iteration to the next. The values of the parameters being solved for (the scores and weights of the transformed variables) become stable after sufficient iteration.

In practice, the criterion being maximized can decrease with overiteration. When the statistic has very nearly reached its maximum, further iterations might report a decrease in the criterion in the last few decimal places. This is a normal result of very small amounts of rounding error. By default, iteration terminates when this occurs because, by default, **CCONVERGE**=0.0. Specifying **CCONVERGE**=-1, an impossible change, turns off this check for convergence.

Even though the algorithms are convergent, they might not converge to a global optimum. Also, under extreme circumstances, the solution might degenerate. Because two points always form a straight line, the algorithms sometimes try to reach this degenerate optimum. This sometimes occurs when one observation is an ordinal outlier (when one observation has the extreme rank on all variables). The algorithm can reach an optimal solution that ties all other categories producing two points. Similar results can occur when there

are many missing values. More generally, whenever there are very few constraints on the scoring of one or more points, degeneracies can be a problem. In a well-behaved analysis, the maximum data change, average data change, and criterion change all decrease at a rapid rate with each iteration. When the rate of change increases for several iterations, the solution might be degenerating.

Implicit and Explicit Intercepts

Depending on several options, the model intercept is nonzero, zero, or implicit, or there is no intercept. Ordinarily, the model contains an explicit nonzero intercept, and the Intercept variable in the **OUT=** data set contains ones. When **TSTANDARD=CENTER** or **TSTANDARD=Z** is specified, the model contains an explicit, zero intercept and the Intercept variable contains zeros. When **METHOD=CANALS**, the model is fit with centered variables and the Intercept variable is set to missing.

If you specify **CLASS** with **ZERO=NONE** or **BSPLINE** for one or more independent variables, and **TSTANDARD=NOMISS** or **TSTANDARD=ORIGINAL** (the default), an implicit intercept model is fit. The intercept is implicit in a set of the independent variables since there exists a set of independent variables the sum of which is a column of ones. All statistics are mean corrected. The implicit intercept is not an option; it is implied by the model. Specifying **SMOOTH** or **PBSPLINE** also implies an implicit intercept model.

With **METHOD=CANALS**, the Intercept variable contains the *canonical intercept* for canonical coefficients observations: $\hat{\beta}_0 = \bar{y}'\hat{\alpha} - \bar{x}'\hat{\beta}$ where $Y\hat{\alpha} \approx X\hat{\beta}$.

Passive Observations

Observations can be excluded from the analysis for several reasons; these include zero weight; zero frequency; missing values in variables designated **IDENTITY**, **CLASS**, **POINT**, **EPOINT**, **QPOINT**, **SMOOTH**, **PBSPLINE**, **PSPLINE**, or **BSPLINE**; and missing values with the **NOMISS a-option** specified. These observations are passive in that they do not contribute to determining transformations, R square, sums of squares, degrees of freedom, and so on. However, some information can be computed for them. For example, if no independent variable values are missing, predicted values and redundancy variable values can both be computed. Residuals can be computed for observations with a nonmissing dependent and nonmissing predicted value. Canonical variables for dependent variables can be computed when no dependent variables are missing; canonical variables for independent variables can be computed when no independent variables are missing, and so on. Passive observations in the **OUT=** data set have a blank value for **_TYPE_**.

Point Models

The expanded set of independent variables generated from the **POINT**, **EPOINT**, and **QPOINT** expansions can be used to perform ideal point regressions (Carroll 1972) and compute ideal point coordinates for plotting in a biplot (Gabriel 1981). The three types of ideal point coordinates can all be described as transformed coefficients. Assume that m independent variables are specified in one of the three point expansions. Let \mathbf{b}' be a $1 \times m$ row vector of coefficients for these variables and one of the dependent variables. Let \mathbf{R} be a matrix created from the coefficients of the extra variables. When coordinates are requested with the **MPC**, **MEC**, or **MQC o-option**, \mathbf{b}' and \mathbf{R} are created from multiple regression coefficients. When coordinates are requested with the **CPC**, **CEC**, or **CQC o-option**, \mathbf{b}' and \mathbf{R} are created from canonical coefficients.

If you specify the **POINT** expansion in the **MODEL** statement, **R** is an $m \times m$ identity matrix times the coefficient for the sums of squares (**_ISSQ_**) variable. If you specify the **EPOINT** expansion, **R** is an $m \times m$ diagonal matrix of coefficients from the squared variables. If you specify the **QPOINT** expansion, **R** is an $m \times m$ symmetric matrix of coefficients from the squared variables on the diagonal and crossproduct variables off the diagonal. The **MPC**, **MEC**, **MQC**, **CPC**, **CEC**, and **CQC** ideal point coordinates are defined as $-0.5\mathbf{b}'\mathbf{R}^{-1}$. When **R** is singular, the ideal point coordinates are infinitely far away and are set to missing, so you should try a simpler version of the model. The version that is simpler than the **POINT** model is the vector model, where no extra variables are created. In the vector model, designate all independent variables as **IDENTITY**. Then draw vectors from the origin to the **COEFFICIENTS** points.

Typically, when you request ideal point coordinates, the **MODEL** statement should consist of a single transformation for the dependent variables (usually **IDENTITY**, **MONOTONE**, or **MSPLINE**) and a single expansion for the independent variables (one of **POINT**, **EPOINT**, or **QPOINT**).

Redundancy Analysis

Redundancy analysis (Stewart and Love 1968) is a principal component analysis of multivariate regression predicted values. These first steps show the redundancy analysis results produced by **PROC TRANSREG**. The specification **TSTANDARD=Z** sets all variables to mean zero and variance one. **METHOD=REDUNDANCY** specifies redundancy analysis and outputs the redundancy variables to the **OUT=** data set. The **MREDUNDANCY** *o-option* outputs two sets of redundancy analysis coefficients to the **OUT=** data set.

The following statements produce [Figure 97.61](#):

Optimal Scaling

An alternating least squares optimal scaling algorithm can be divided into two major stages. The first major stage estimates the parameters of the linear model. These parameters are used to create the predicted values or target for each variable that can be transformed. Each target minimizes squared error (as explained in the discussion of the algorithms in *SAS Technical Report R-108*). The definition of the target depends on many factors, such as whether a variable is independent or dependent, which algorithm is used (for example, regression, redundancy, CANALS, or principal components), and so on. The definition of the target is independent of the transformation family you specify for the variable. However, the target values for a variable typically do not fit the prescribed transformation family for the variable. They might not have the right category structure; they might not have the right order; they might not be a linear combination of the columns of a B-spline basis; and so on.

The second major stage is optimal scaling. Optimal scaling can be defined as a possibly constrained, least squares regression problem. When you specify an optimal transformation, or when missing data are estimated for any variable, the full representation of the variable is not simply a vector; it is a matrix with more than one column. The optimal scaling phase finds the vector that is a linear combination of the columns of this matrix that is closest to the target (in terms of minimum squared error), among those that do not violate any of the constraints imposed by the transformation family. Optimal scaling methods are independent of the data analysis method that generated the target. In all cases, optimal scaling can be accomplished by creating a design matrix based on the original scaling of the variable and the transformation family specified for that variable. The optimally scaled variable is a linear combination of the columns of the design matrix. The coefficients of the linear combination are found by using (possibly constrained) least squares. Many optimal scaling problems are solved without actually constructing design and projection matrices. The next two sections describe the algorithms used by PROC TRANSREG for optimal scaling. The first section discusses optimal scaling for **OPSCORE**, **MONOTONE**, **UNTIE**, and **LINEAR** transformations, including how missing values are handled. The second section addresses **SPLINE** and **MSPLINE** transformations.

OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations

Two vectors of information are needed to produce the optimally scaled variable: the initial variable scaling vector **x** and the target vector **y**. For convenience, both vectors are first sorted on the values of the initial scaling vector. If you request an **UNTIE** transformation, the target vector is sorted within ties in the initial

scaling vector. The normal SAS collating sequence for missing and nonmissing values is used. Sorting simply permits the constraints to be specified in terms of relationships among adjoining coefficients. The sorting process partitions \mathbf{x} and \mathbf{y} into missing and nonmissing parts $(\mathbf{x}'_m \mathbf{x}'_n)'$, and $(\mathbf{y}'_m \mathbf{y}'_n)'$.

Next, PROC TRANSREG determines category membership. Every ordinary missing value (.) forms a separate category. (Three ordinary missing values form three categories.) Every special missing value within the range specified in the `UNTIE= a-option` forms a separate category. (If `UNTIE= BC` and there are three .B and two .C missing values, five categories are formed from them.) For all other special missing values, a separate category is formed for each different value. (If there are four .A missing values, one category is formed from them.)

Each distinct nonmissing value forms a separate category for `OPSCORE` and `MONOTONE` transformations (1 1 1 2 2 3 form three categories). Each nonmissing value forms a separate category for all other transformations (1 1 1 2 2 3 form six categories). When category membership is determined, category means are computed. Here is an example:

x:	(. . .A .A .B 1 1 1 2 2 3 3 3 4)'
y:	(5 6 2 4 2 1 2 3 4 6 4 5 6 7)'
OPSCORE and	
MONOTONE means:	(5 6 3 2 2 5 5 7)'
other means:	(5 6 3 2 1 2 3 4 6 4 5 6 7)'

The category means are the coefficients of a category indicator design matrix. The category means are the Fisher (1938) optimal scores. For `MONOTONE` and `UNTIE` transformations, order constraints are imposed on the category means for the nonmissing partition by merging categories that are out of order. The algorithm checks upward until an order violation is found, and then averages downward until the order violation is averaged away. (The average of \bar{x}_1 computed from n_1 observations and \bar{x}_2 computed from n_2 observations is $(n_1 \bar{x}_1 + n_2 \bar{x}_2) / (n_1 + n_2)$.) The `MONOTONE` algorithm (Kruskal 1964, secondary approach to ties) for this example with means for the nonmissing values $(2\ 5\ 5\ 7)'$ would do the following checks: $2 < 5$: OK, $5 = 5$: OK, $5 < 7$: OK. The means are in the proper order, so no work is needed.

The `UNTIE` transformation (Kruskal 1964, primary approach to ties) uses the same algorithm on the means of the nonmissing values $(1\ 2\ 3\ 4\ 6\ 4\ 5\ 6\ 7)'$ but with different results for this example: $1 < 2$: OK, $2 < 3$: OK, $3 < 4$: OK, $4 < 6$: OK, $6 > 4$: average 6 and 4 and replace 6 and 4 by the average. The new means of the nonmissing values are $(1\ 2\ 3\ 4\ 5\ 5\ 6\ 7)'$. The check resumes: $4 < 5$: OK, $5 = 5$: OK, $5 = 5$: OK, $5 < 6$: OK, $6 < 7$: OK. If some of the special missing values are ordered, the upward-checking, downward-averaging algorithm is applied to them also, independently of the other missing and nonmissing partitions. When the means conform to any required category or order constraints, an optimally scaled vector is produced from the means. The following example results from a `MONOTONE` transformation:

x:	(. . .A .A .B 1 1 1 2 2 3 3 3 4)'
y:	(5 6 2 4 2 1 2 3 4 6 4 5 6 7)'
result:	(5 6 3 3 2 2 2 2 5 5 5 5 5 7)'

The upward-checking, downward-averaging algorithm is equivalent to creating a category indicator design matrix, solving for least squares coefficients with order constraints, and then computing the linear combination of design matrix columns.

For the optimal transformation `LINEAR` and for nonoptimal transformations, missing values are handled as just described. The nonmissing target values are regressed onto the matrix defined by the nonmissing initial

scaling values and an intercept. In this example, the target vector $y_n = (1\ 2\ 3\ 4\ 6\ 4\ 5\ 6\ 7)'$ is regressed onto the design matrix

$$\begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 2 & 2 & 3 & 3 & 3 & 4 \end{bmatrix}'$$

Although only a linear transformation is performed, the effect of a linear regression optimal scaling is not eliminated by the later standardization step (unless the variable has no missing values). In the presence of missing values, the linear regression is necessary to minimize squared error.

SPLINE and MSPLINE Transformations

The missing portions of variables subjected to **SPLINE** or **MSPLINE** transformations are handled the same way as for **OPSCORE**, **MONOTONE**, **UNTIE**, and **LINEAR** transformations (see the previous section). The nonmissing partition is handled by first creating a B-spline basis of the specified degree with the specified knots for the nonmissing partition of the initial scaling vector and then regressing the target onto the basis. The optimally scaled vector is a linear combination of the B-spline basis vectors. Ordinary least squares regression coefficients are used. An algorithm for generating the B-spline basis is given in de Boor (1978, pp. 134–135). B-splines are both a computationally accurate and efficient way of constructing a basis for piecewise polynomials; however, they are not the most natural method of describing splines.

Consider an initial scaling vector $x = (1\ 2\ 3\ 4\ 5\ 6\ 7\ 8\ 9)'$ and a degree-three spline with interior knots at 3.5 and 6.5. The B-spline basis for the transformation is the left matrix, and the natural piecewise polynomial spline basis is the right matrix.

B-Spline Basis						Piecewise Polynomial Splines					
1.000	0.000	0.000	0.000	0	0	1	1	1	1	0	0
0.216	0.608	0.167	0.009	0	0	1	2	4	8	0	0
0.008	0.458	0.461	0.073	0	0	1	3	9	27	0	0
0	0.172	0.585	0.241	0.001	0	1	4	16	64	0.125	0
0	0.037	0.463	0.463	0.037	0	1	5	25	125	3.375	0
0	0.001	0.241	0.585	0.172	0	1	6	36	216	15.625	0
0	0	0.073	0.461	0.458	0.008	1	7	49	343	42.875	0.125
0	0	0.009	0.167	0.608	0.216	1	8	64	512	91.125	3.375
0	0	0.000	0.000	0.000	1.000	1	9	81	729	166.375	15.625

The two matrices span the same column space. The natural basis has an intercept, a linear term, a quadratic term, a cubic term, and two more terms since there are two interior knots. These terms are generated (for knot k and x element x) by the formula $(x - k)^3 \times I_{(x > k)}$. The indicator variable $I_{(x > k)}$ evaluates to 1.0 if x is greater than k and to 0.0 otherwise. If knot k had been repeated, there would be a $(x - k)^2 \times I_{(x > k)}$ term also. Notice that the fifth column makes no contribution to the curve before 3.5, makes zero contribution at 3.5 (the transformation is continuous), and makes an increasing contribution beyond 3.5. The same pattern of results holds for the last term with knot 6.5. The coefficient of the fifth column represents the change in the cubic portion of the curve after 3.5. The coefficient of the sixth column represents the change in the cubic portion of the curve after 6.5.

The numbers in the B-spline basis do not have a simple interpretation like the numbers in the natural piecewise polynomial basis. The B-spline basis has a diagonally banded structure. The band shifts one column to the right after every knot. The number of entries in each row that can potentially be nonzero is one greater than the degree. The elements within a row always sum to one. The B-spline basis is accurate because of the smallness of the numbers and the lack of extreme collinearity inherent in the natural polynomials. B-splines are efficient because PROC TRANSREG can take advantage of the sparseness of the B-spline basis when it accumulates crossproducts. The number of required multiplications and additions to accumulate the crossproduct matrix does not increase with the number of knots but does increase with the degree of the spline, so it is much more computationally efficient to increase the number of knots than to increase the degree of the polynomial.

MSPLINE transformations are handled like SPLINE transformations except that constraints are placed on the coefficients to ensure monotonicity. When the coefficients of the B-spline basis are monotonically increasing, the transformation is monotonically increasing. When the polynomial degree is two or less, monotone coefficient splines, integrated splines (Winsberg and Ramsay 1980), and the general class of all monotone splines are equivalent.

Specifying the Number of Knots

Keep the number of knots small (usually less than 10, although you can specify more). A degree-three spline with nine knots, one at each decile, can closely follow a large variety of curves. Each spline transformation of degree p with q knots fits a model with $p + q$ parameters. The total number of parameters should be much less than the number of observations. Usually in regression analyses, it is recommended that there be at least five or ten observations for each parameter in order to get stable results. For example, when spline transformations of degree three with nine knots are requested for six variables, the number of observations in the data set should be at least 5 or 10 times 72 (since $6 \times (3 + 9)$ is the total number of parameters). The overall model can also have a parameter for the intercept and one or more parameters for each nonspline variable in the model.

Increasing the number of knots gives the spline more freedom to bend and follow the data. Increasing the degree also gives the spline more freedom, but to a lesser extent. Specifying a large number of knots is much better than increasing the degree beyond three.

When you specify `NKNOTS= q` for a variable with n observations, then each of the $q + 1$ segments of the spline contains $n/(q + 1)$ observations on the average. When you specify `KNOTS=number-list`, make sure that there is a reasonable number of observations in each interval.

The following statements find a cubic polynomial transformation of x and no transformation of y :

```
proc transreg;
  model identity(y)=spline(x);
  output;
run;
```

The following statements find a cubic-spline transformation for x that consists of the weighted sum of a single constant, a single straight line, a quadratic curve for the portion of the variable less than 3.0, a different quadratic curve for the portion greater than 3.0 (since the 3.0 knot is repeated), and a different cubic curve for each of the intervals: (minimum to 1.5), (1.5 to 2.4), (2.4 to 3.0), (3.0 to 4.0), and (4.0 to maximum):

```
proc transreg;
  model identity(y)=spline(x / knots=1.5 2.4 3.0 3.0 4.0);
  output;
run;
```

The transformation is continuous everywhere, its first derivative is continuous everywhere, its second derivative is continuous everywhere except at 3.0, and its third derivative is continuous everywhere except at 1.5, 2.4, 3.0, and 4.0.

The following statements find a quadratic spline transformation that consists of a polynomial $x_t = b_0 + b_1x + b_2x^2$ for the range ($x < 3.0$) and a completely different polynomial $x_t = b_3 + b_4x + b_5x^2$ for the range ($x > 3.0$):

```
proc transreg;
  model identity(y)=spline(x / knots=3 3 3 degree=2);
  output;
run;
```

The two curves are not required to be continuous at 3.0.

The following statements categorize y into 10 intervals and find a step-function transformation:

```
proc transreg;
  model identity(y)=spline(x / degree=0 nknots=9);
  output;
run;
```

One aspect of this transformation family is unlike all other optimal transformation families. The initial scaling of the data does not fit the restrictions imposed by the transformation family. This is because the initial variable can be continuous, but a discrete step-function transformation is sought. Zero-degree spline variables are categorized before the first iteration.

The following statements find a continuous, piecewise linear transformation of x :

```
proc transreg;
  model identity(y)=spline(x / degree=1 nknots=8);
  output;
run;
```

SPLINE, BSPLINE, and PSPLINE Comparisons

SPLINE is a transformation. It takes a variable as input and produces a transformed variable as output. Internally, with **SPLINE**, a B-spline basis is used to find the transformation, which is a linear combination of the columns of the B-spline basis. However, with **SPLINE**, the basis is not made available in any output.

BSPLINE is an expansion. It takes a variable as input and produces more than one variable as output. The output variables are the same B-spline basis that is used internally by **SPLINE**.

PSPLINE is an expansion. It takes a variable as input and produces more than one variable as output. The difference between **PSPLINE** and **BSPLINE** is that **PSPLINE** produces a piecewise polynomial, whereas **BSPLINE** produces a B-spline. A matrix consisting of a piecewise polynomial basis and an intercept spans the same space as the B-spline matrix, but the basis vectors are quite different. The numbers in the piecewise

polynomials can get quite large; the numbers in the B-spline basis range between 0 and 1. There are many more zeros in the B-spline basis.

Interchanging SPLINE, BSPLINE, and PSPLINE should have no effect on the fit of the overall model except for the fact that PSPLINE is much more prone to numerical problems. Similarly, interchanging a CLASS expansion and an OPSCORE transformation should have no effect on the fit of the overall model.

Hypothesis Tests

PROC TRANSREG has a set of options for testing hypotheses in models with a single dependent variable. The TEST *a-option* produces an ANOVA table. It tests the null hypothesis that the vector of coefficients for all of the transformations is zero. The SS2 *a-option* produces a regression table with Type II tests of the contribution of each transformation to the overall model. In some cases, exact tests are provided; in other cases, the tests are approximate, liberal, or conservative.

There are two reasons why it is typically not appropriate to test hypotheses by using the output from PROC TRANSREG as input to other procedures such as the REG procedure. First, PROC REG has no way of determining how many degrees of freedom were used for each transformation. Second, the Type II sums of squares for the tests of the individual regression coefficients are not correct for the transformation regression model because PROC REG, as it evaluates the effect of each variable, cannot change the transformations of the other variables. PROC TRANSREG uses the correct degrees of freedom and sums of squares.

In an ordinary univariate linear model, there is one parameter for each independent variable, including the intercept. In the transformation regression model, many of the “variables” are used internally in the bases for the transformations. Each basis column has one parameter or *scoring* coefficient, and each linearly independent column has one model degree of freedom associated with it. Coefficients applied to transformed variables, *model coefficients*, do not enter into the degrees-of-freedom calculations. They are byproducts of the standardizations and can be absorbed into the transformations by specifying the ADDITIVE *a-option*. The word *parameter* is reserved for model and scoring coefficients that have a degree of freedom associated with them.

For expansions, there is one model parameter for each variable created by the expansion (except for all missing CLASS columns and expansions that have an implicit intercept). Each IDENTITY variable has one model parameter. If there are m POINT variables, they expand to $m + 1$ variables and hence have $m + 1$ model parameters. For m EPOINT variables, there are $2m$ model parameters. For m QPOINT variables, there are $m(m + 3)/2$ model parameters. If a variable with m categories is designated CLASS, there are $m - 1$ parameters. For BSPLINE and PSPLINE variables of DEGREE= n with NKNOTS= k , there are $n + k$ parameters. Note that one of the $n + k + 1$ BSPLINE columns and one of the m CLASS(variable / ZERO=NONE) columns are not counted due to the implicit intercept.

There are scoring parameters for missing values in nonexcluded observations. Each ordinary missing value (.) has one scoring parameter. Each different special missing value (._ and .A through .Z) within each variable has one scoring parameter. Missing values specified in the UNTIE= and MONOTONE= options follow the rules for UNTIE and MONOTONE transformations, which are described later in this chapter.

For all nonoptimal transformations (LOG, LOGIT, ARSIN, POWER, EXP, RANK, BOXCOX), there is one parameter per variable in addition to any missing value scoring parameters.

For SPLINE, OPSCORE, and LINEAR transformations, the number of scoring parameters is the number of basis columns that are used internally to find the transformations minus 1 for the intercept. The number of

scoring parameters for SPLINE variables is the same as the number of model parameters for BSPLINE and PSPLINE variables. If DEGREE= n and NKNOTS= k , there are $n + k$ scoring parameters. The number of scoring parameters for OPSCORE, SMOOTH, and SSPLINE variables is the same as the number of model parameters for CLASS variables. If there are m categories, there are $m - 1$ scoring parameters. There is one parameter for each LINEAR variable. For SPLINE, OPSCORE, LINEAR, MONOTONE, UNTIE, and MSPLINE transformations, missing value scoring parameters are computed as described previously with the nonoptimal transformations.

The number of scoring parameters for MONOTONE, UNTIE, and MSPLINE transformations is less precise than for SPLINE, OPSCORE, and LINEAR transformations. One way of handling a MONOTONE transformation is to treat it as if it were the same as an OPSCORE transformation. If there are m categories, there are $m - 1$ potential scoring parameters. However, there are typically fewer than $m - 1$ unique parameter estimates, since some of those $m - 1$ scoring parameter estimates might be tied during the optimal scaling to impose the order constraints. Imposing ties on the scoring parameter estimates is equivalent to fitting a model with fewer parameters. So there are two available scoring parameter counts: $m - 1$ and a smaller number that is determined during the analysis. Using $m - 1$ as the model degrees of freedom for MONOTONE variables (treating OPSCORE and MONOTONE transformations the same way) is *conservative*, since the MONOTONE scoring parameter estimates are more restricted than the OPSCORE scoring parameter estimates. Using the smaller count (the number of scoring parameter estimates that are different, minus 1 for the intercept) in the model degrees of freedom is *liberal*, since the data and the model together are being used to determine the number of parameters. PROC TRANSREG reports tests that use both liberal and conservative degrees of freedom to provide lower and upper bounds on the “true” p -values.

For the UNTIE transformation, the conservative scoring parameter count is the number of distinct observations, whereas the liberal scoring parameter count is the number of scoring parameter estimates that are different, minus 1 for the intercept. Hence, when you specify UNTIE, conservative tests have zero error degrees of freedom unless there are replicated observations.

For MSPLINE variables of DEGREE= n and NKNOTS= k , the conservative scoring parameter count is $n + k$, whereas the liberal parameter count is the number of scoring parameter estimates that are different, minus 1 for the intercept. A liberal degrees of freedom of 1 does not necessarily imply a linear transformation. It implies only that n plus k minus the number of ties imposed equals 1. An example of a one-degree-of-freedom nonlinear transformation is a two-piece linear transformation in which the slope of one piece is 0.

The number of scoring parameters is determined during each iteration. After the last iteration, enough information is available for the TEST *a-option* to produce an ANOVA table that reports the overall fit of the model. If you specify the SS2 *a-option*, further iterations are necessary to test the contribution of each transformation to the overall model.

The liberal tests do not compensate for overparameterization. For example, requesting a spline transformation with k knots when a linear transformation will suffice results in “liberal” tests that are actually conservative because too many degrees of freedom are being used for the transformations. To avoid this problem, use as few knots as possible.

In ordinary multiple regression, an F test of the null hypothesis that the coefficient for variable x_j is zero can be constructed by comparing two linear models. One model is the full model with all parameters, and the other is a reduced model that has all parameters except the parameter for variable x_j . The difference between the model sum of squares for the full model and the model sum of squares for the reduced model is the Type II sum of squares for the test of the null hypothesis that the coefficient for variable x_j is 0. The numerator of the F test has one degree of freedom. The mean square error for the full model is the denominator of the

F test of variable x_j . Note that the estimates of the coefficients for the two models are not usually the same. When variable x_j is removed, the coefficients for the other variables change to compensate for the removal of x_j . In a transformation regression model, the transformations of the other variables must be permitted to change and the numerator degrees of freedom are not always ones. It is not correct to simply let the model coefficients for the transformed variables change and apply the new model coefficients to the old transformations computed with the old scoring parameter estimates. In a transformation regression model, further iteration is needed to test each transformation, because all the scoring parameter estimates for other variables must be permitted to change to test the effect of variable x_j . This can be quite time-consuming for a large model if the **SOLVE** *a-option* cannot be used to solve directly for the transformations.

Output Data Set

The **OUT=** output data set can contain a great deal of information; however, in most cases, the output data set contains a small portion of the entire range of available information.

Output Data Set Examples

This section provides three brief examples, illustrating some typical **OUT=** output data sets. See the section “**Output Data Set Contents**” on page 8310 for a complete list of the contents of the **OUT=** data set.

The first example shows the output data set from a two-way ANOVA model. The following statements produce [Figure 97.65](#):

```

9	x1ax2a	Num	8	x1 a * x2 a							
10	x1	Char	32								
11	x2	Char	32								

The `_TYPE_` variable indicates observation type: score, multiple regression coefficient (parameter estimates), and marginal means. The `_NAME_` variable contains the default observation labels, “ROW1”, “ROW2”, and so on, and contains the dependent variable name (y) for the remaining observations. If you specify an `ID` statement, `_NAME_` contains the values of the first ID variable for score observations. The y variable is the dependent variable, Py contains the predicted values, Ry contains the residuals, and the variables Intercept through x1ax2a contain the design matrix. The x1 and x2 variables are the original CLASS variables.

The next example shows the contents of the output data set from fitting a curve through a scatter plot. The following statements produce [Figure 97.66](#):

```

6	Intercept	Num	8	Intercept
7	x	Num	8	
8	TIntercept	Num	8	Intercept Transformation
9	Tx	Num	8	x Transformation

The **OUT=** data set contains **_TYPE_** and **_NAME_** variables. Since no coefficients or coordinates are requested, all observations are **_TYPE_='SCORE'**. The **y** variable is the original dependent variable, **Ty** is the transformed dependent variable, **Py** contains the predicted values, **x** is the original independent variable, and **Tx** is the transformed independent variable. The data set also contains an **Intercept** and transformed intercept **TIntercept** variable. (In this case, the transformed intercept is the same as the intercept. However, if you specify the **TSTANDARD=** and **ADDITIVE** options, these are not always the same.)

The following example shows the results from specifying **METHOD=MORALS** when there is more than one dependent variable:

```

15	x2	Char	32	

If you specify **METHOD=MORALS** with multiple dependent variables, PROC TRANSREG performs separate univariate analyses and stacks the results in the **OUT=** data set. For this example, the results of the first analysis are in the partition designated by **_DEPVAR_='Spline(y1)'** and the results of the second analysis are in the partition designated by **_DEPVAR_='Spline(y2)'**, which are the transformation and dependent variable names. Each partition has **_TYPE_='SCORE'** observations for the variables and a **_TYPE_='M COEFFI'** observation for the coefficients. In this example, an **ID** variable is specified, so the **_NAME_** variable contains the formatted values of the first ID variable. Since both dependent variables have to go into the same column, the dependent variable is given a new name, **_DEPEND_**. The dependent variable transformation is named **T_DEPEND_**, the predicted values variable is named **P_DEPEND_**, and the residuals variable is named **R_DEPEND_**.

The independent variables are character **OPSCORE** variables. By default, PROC TRANSREG replaces character **OPSCORE** variables with category numbers and discards the original character variables. To avoid this, the input variables are renamed from **x1** and **x2** to **n1** and **n2** and the original **x1** and **x2** are added to the data set as ID variables. The **n1** and **n2** variables contain the initial values for the **OPSCORE** transformations, and the **Tn1** and **Tn2** variables contain optimal scores. The data set also contains an Intercept and transformed intercept **TIntercept** variable. The regression coefficients are in the transformation columns, which also contain the variables to which they apply.

Output Data Set Contents

Table 97.7 summarizes the various matrices that can result from PROC TRANSREG processing and that appear in the **OUT=** data set. The exact contents of an **OUT=** data set depends on many options.

Table 97.7 PROC TRANSREG OUT= Data Set Contents

TYPE	Contents	Options, Default Prefix
SCORE	dependent variables	DREPLACE not specified
SCORE	independent variables	IREPLACE not specified
SCORE	transformed dependent variables	default, TDPREFIX=T
SCORE	transformed independent variables	default, TIPREFIX=T
SCORE	predicted values	PREDICTED, PPREFIX=P
SCORE	residuals	RESIDUALS, RDPREFIX=R
SCORE	leverage	LEVERAGE, LEVERAGE=Leverage
SCORE	lower individual confidence limits	CLI, LILPREFIX=LIL, CILPREFIX=CIL
SCORE	upper individual confidence limits	CLI, LIUPREFIX=LIU, CIUPREFIX=CIU
SCORE	lower mean confidence limits	CLM, LMLPREFIX=LML, CMLPREFIX=CML
SCORE	upper mean confidence limits	CLM, LMUPREFIX=LMU, CMUPREFIX=CMU
SCORE	dependent canonical variables	CANONICAL, CDPREFIX=Cand
SCORE	independent canonical variables	CANONICAL, CIPREFIX=Cani
SCORE	redundancy variables	REDUNDANCY, RPREFIX=Red
SCORE	ID, CLASS, BSPLINE variables	ID, CLASS, BSPLINE,
SCORE	independent variables approximations	IAPPROXIMATIONS, AIPREFIX=A
M COEFFI	multiple regression coefficients	COEFFICIENTS, MRC
C COEFFI	canonical coefficients	COEFFICIENTS, CCC
MEAN	marginal means	COEFFICIENTS, MEANS
M REDUND	multiple redundancy coefficients	MREDUNDANCY
R REDUND	multiple redundancy coefficients	MREDUNDANCY
M POINT	point coordinates	COORDINATES or MPC, POINT
M EPOINT	elliptical point coordinates	COORDINATES or MEC, EPOINT
M QPOINT	quadratic point coordinates	COORDINATES or MQC, QPOINT
C POINT	canonical point coordinates	COORDINATES or CPC, POINT
C EPOINT	canonical elliptical point coordinates	COORDINATES or CEC, EPOINT
C QPOINT	canonical quadratic point coordinates	COORDINATES or CQC, QPOINT

The independent and dependent variables are created from the original input data. Several potential differences exist between these variables and the actual input data. An intercept variable can be added, new variables can be added for **POINT**, **EPOINT**, **QPOINT**, **CLASS**, **IDENTITY**, **PSPLINE**, and **BSPLINE** variables, and category numbers are substituted for character **OPSCORE** variables. These matrices are not always what is input to the first iteration. After the expanded data set is stored for inclusion in the output data set, several things happen to the data before they are input to the first iteration: column means are substituted for missing values; zero-degree **SPLINE** and **MSPLINE** variables are transformed so that the iterative algorithms get step-function data as input, which conform to the zero-degree transformation family restrictions; and the nonoptimal transformations are performed.

Details for the UNIVARIATE Method

When you specify **METHOD=UNIVARIATE** (in the MODEL or PROC TRANSREG statement), PROC TRANSREG can perform several analyses, one for each dependent variable. While each dependent variable can be transformed, their independent variables are not transformed. The **OUT=** data set optionally contains all of the **_TYPE_='SCORE'** observations, optionally followed by coefficients or coordinates.

Details for the MORALS Method

When you specify **METHOD=MORALS** (in the MODEL or PROC TRANSREG statement), successive analyses are performed, one for each dependent variable. Each analysis transforms one dependent variable and the entire set of the independent variables. All information for the first dependent variable (scores then, optionally, coefficients) appears first. Then all information for the second dependent variable (scores then, optionally, coefficients) appears next. This arrangement is repeated for all dependent variables.

Details for the CANALS and REDUNDANCY Methods

For **METHOD=CANALS** and **METHOD=REDUNDANCY** (specified in either the MODEL or PROC TRANSREG statement), one analysis is performed that simultaneously transforms all dependent and independent variables. The **OUT=** data set optionally contains all of the **_TYPE_='SCORE'** observations, optionally followed by coefficients or coordinates.

Variable Names

As shown in the preceding examples, some variables in the output data set directly correspond to input variables, and some are created. All original optimal and nonoptimal transformation variable names are unchanged.

The names of the **POINT**, **QPOINT**, and **EPOINT** expansion variables are also left unchanged, but new variables are created. When independent **POINT** variables are present, the sum-of-squares variable **_ISSQ_** is added to the output data set. For each **EPOINT** and **QPOINT** variable, a new squared variable is created by appending “_2”. For example, **Dim1** and **Dim2** are expanded into **Dim1**, **Dim2**, **Dim1_2**, and **Dim2_2**. In addition, for each pair of **QPOINT** variables, a new crossproduct variable is created by combining the two names—for example, **Dim1Dim2**.

The names of the **CLASS** variables are constructed from original variable names and levels. Lengths are controlled by the **CPREFIX= a-option**. For example, when **x1** and **x2** both have values of 'a' and 'b', **CLASS(x1 | x2 / ZERO=NONE)** creates **x1** main-effect variable names **x1a x1b**, **x2** main-effect variable names **x2a x2b**, and interaction variable names **x1ax2a x1ax2b x1bx2a x1bx2b**.

PROC TRANSREG then uses these variable names when creating the transformed, predicted, and residual variable names by affixing the relevant prefix and dropping extra characters if necessary.

METHOD=MORALS Variable Names

When you specify **METHOD=MORALS** and only one dependent variable is present, the output data set is structured exactly as if **METHOD=REDUNDANCY** (see the section “[Details for the CANALS and REDUNDANCY Methods](#)” on page 8312). When more than one dependent variable is present, the dependent variables are output in the variable **_DEPEND_**, transformed dependent variables are output in the variable **T_DEPEND_**, predicted values are output in the variable **P_DEPEND_**, and residuals are output in the variable **R_DEPEND_**. You can partition the data set into **BY** groups, one per dependent variable, by referring to the character variable **_DEPVAR_**, which contains the original dependent variable names and transformations.

Duplicate Variable Names

When the same name is generated from multiple variables in the **OUT=** data set, new names are created by appending '2', '3', or '4', and so on, until a unique name is created. For 32-character names, the last character is replaced with a numeric suffix until a unique name is created. For example, if there are two output variables that otherwise would be named *x*, then *x* and *x2* are created instead. If there are two output variables that otherwise would be named *ThisIsAThirtyTwoCharacterVarName*, then *ThisIsAThirtyTwoCharacterVarName* and *ThisIsAThirtyTwoCharacterVarNam2* are created instead.

OUTTEST= Output Data Set

The **OUTTEST=** data set contains hypothesis test results. The **OUTTEST=** data set always contains ANOVA results. When you specify the **SS2 a-option**, regression tables are also output. When you specify the **UTILITIES a-option**, conjoint analysis part-worth utilities are also output. The **OUTTEST=** data set has the following variables:

DEPVAR	is a 42-character variable that contains the dependent variable transformation and name.
TYPE	is an 8-character variable that contains the table type. The first character is “U” for univariate or “M” for multivariate. The second character is blank. The third character is “A” for ANOVA, “2” for Type II sum of squares, or “U” for UTILITIES . The fourth character is blank. The fifth character is “L” for liberal tests, “C” for conservative tests, or “U” for the usual tests.
Title	is an 80-character variable that contains the table title.
Variable	is a 42-character variable that contains the independent variable transformations and names for regression tables and blanks for ANOVA tables.
Coefficient	contains the multiple regression coefficients for regression tables and underscore special missing values for ANOVA tables.
Statistic	is a 24-character variable that contains the names for statistics in other variables, such as Value .
Value	contains multivariate test statistics and all other information that does not fit in one of the other columns including R square, dependent mean, adjusted R square, and coefficient of variation. Whenever Value is not an underscore special missing value, the Statistic variable describes the contents of the Value variable.
NumDF	contains numerator degrees of freedom for <i>F</i> tests.
DenDF	contains denominator degrees of freedom for <i>F</i> tests.
SSq	contains sums of squares.
MeanSquare	contains mean squares.
F	contains <i>F</i> statistics.
NumericP	contains the <i>p</i> -value for the <i>F</i> statistic, stored in a numeric variable.
P	is a 9-character variable that contains the formatted <i>p</i> -value for the <i>F</i> statistic, including the appropriate ~, <=, >=, or blank symbols.
LowerLimit	contains lower confidence limits on the parameter estimates.

UpperLimit	contains upper confidence limits on the parameter estimates.
StdError	contains standard errors. For SS2 and UTILITIES tables, standard errors are output for each coefficient with one degree of freedom.
Importance	contains the relative importance of each factor for UTILITIES tables.
Label	is a 256-character variable that contains variable labels.

There are several possible tables in the **OUTTEST=** data set corresponding to combinations of univariate and multivariate tests; ANOVA and regression results; and liberal, conservative, and the usual tests. Each table is composed of only a subset of the variables. Numeric variables contain underscore special missing values when they are not a column in a table. Ordinary missing values (.) appear in variables that are part of a table when a nonmissing value cannot be produced. For example, the F is missing for a test with zero degrees of freedom.

Computational Resources

This section provides information about the computational resources required to use PROC TRANSREG.

Let

- n = number of observations
- q = number of expanded independent variables
- r = number of expanded dependent variables
- k = maximum spline degree
- p = maximum number of knots

More than $56(q + r)$ plus the maximum of the data matrix size, the optimal scaling work space, and the covariance matrix size bytes of array space are required. The data matrix size is $8n(q + r)$ bytes. The optimal scaling work space requires less than $8(6n + (p + k + 2)(p + k + 11))$ bytes. The covariance matrix size is $4(q + r)(q + r + 1)$ bytes.

PROC TRANSREG tries to store the original and transformed data in memory. If there is not enough memory, a utility data set is used, potentially resulting in a large increase in execution time. The amount of memory for the preceding data formulas is an underestimate of the amount of memory needed to handle most problems. These formulas give the absolute minimum amount of memory required. If a utility data set is used, and if memory can be used with perfect efficiency, then roughly the amount of memory stated previously is needed. In reality, most problems require at least two or three times the minimum.

PROC TRANSREG sorts the data once. The sort time is roughly proportional to $(q + r)n^{3/2}$.

One regression analysis per iteration is required to compute model parameters (or two canonical correlation analyses per iteration for **METHOD=CANALS**). The time required to accumulate the crossproducts matrix is roughly proportional to $n(q + r)^2$. The time required to compute the regression coefficients is roughly proportional to q^3 .

Each optimal scaling is a multiple regression problem, although some transformations are handled with faster special-case algorithms. The number of regressors for the optimal scaling problems depends on the

original values of the variable and the type of transformation. For each monotone spline transformation, an unknown number of multiple regressions is required to find a set of coefficients that satisfies the constraints. The B-spline basis is generated twice for each [SPLINE](#) and [MSPLINE](#) transformation for each iteration. The time required to generate the B-spline basis is roughly proportional to nk^2 .

Unbalanced ANOVA without CLASS Variables

This section illustrates that an analysis of variance model can be formulated as a simple regression model with optimal scoring. The purpose of the example is to explain one aspect of how PROC TRANSREG works, not to propose an alternative way of performing an analysis of variance.

Finding the overall fit of a large, unbalanced analysis of variance model can be handled as an optimal scoring problem without creating large, sparse design matrices. For example, consider an unbalanced full main-effects and interactions ANOVA model with six factors. Assume that a SAS data set is created with factor-level indicator variables c1 through c6 and dependent variable y. If each factor level consists of nonblank single characters, you can create a cell indicator in a DATA step with the statement as follows:

```
x=compress(c1||c2||c3||c4||c5||c6);
```

The following statements optimally score x (by using the [OPSCORE](#) transformation) and do not transform y:

```
proc transreg;
  model identity(y)=opscore(x);
  output;
run;
```

The final R square reported is the R square for the full analysis of variance model. This R square is the same R square that would be reported by both of the following PROC GLM steps:

```
proc glm;
  class x;
  model y=x;
run;

proc glm;
  class c1-c6;
  model y=c1|c2|c3|c4|c5|c6;
run;
```

PROC TRANSREG optimally scores the classes of x, within the space of a single variable with values linearly related to the cell means, so the full ANOVA problem is reduced to a simple regression problem with an optimal independent variable. PROC TRANSREG requires only one iteration to find the optimal scoring of x but, by default, performs a second iteration, which reports no data changes.

Hypothesis Tests for Simple Univariate Models

If the dependent variable has one parameter (**IDENTITY**, **LINEAR** with no missing values, and so on) and if there are no monotonicity constraints, PROC TRANSREG fits univariate models, which can also be fit with a DATA step and PROC REG. This is illustrated with the following artificial data set:

```
data htex;
  do i = 0.5 to 10 by 0.5;
    x1 = log(i);
    x2 = sqrt(i) + sin(i);
    x3 = 0.05 * i * i + cos(i);
    y = x1 - x2 + x3 + 3 * normal(7);
    x1 = x1 + normal(7);
    x2 = x2 + normal(7);
    x3 = x3 + normal(7);
    output;
  end;
run;
```

Both PROC TRANSREG and PROC REG are run to fit the same polynomial regression model as follows:

```
proc transreg data=htex ss2 short;
  title 'Fit a Polynomial Regression Model with PROC TRANSREG';
  model identity(y) = spline(x1);
run;

data htex2;
  set htex;
  x1_1 = x1;
  x1_2 = x1 * x1;
  x1_3 = x1 * x1 * x1;
run;

proc reg;
  title 'Fit a Polynomial Regression Model with PROC REG';
  model y = x1_1 - x1_3;
run; quit;
```

The ANOVA and regression tables from PROC TRANSREG are displayed in [Figure 97.68](#). The ANOVA and regression tables from PROC REG are displayed in [Figure 97.69](#). The **SHORT** *a-option* is specified with PROC TRANSREG to suppress the iteration history.

	Coeff Var	432.07258			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	1.22083	1.47163	0.83	0.4190
x1_1	1	0.79743	1.75129	0.46	0.6550
x1_2	1	-0.49381	1.50449	-0.33	0.7470
x1_3	1	0.04422	0.32956	0.13	0.8949

The PROC TRANSREG regression table differs in several important ways from the parameter estimate table produced by PROC REG. The REG procedure displays standard errors and t statistics. PROC TRANSREG displays Type II sums of squares, mean squares, and F statistics. The difference is because the numerator degrees of freedom are not always 1, so t tests are not uniformly appropriate. When the degrees of freedom for variable x_j is 1, the following relationships hold between the standard errors (s_{β_j}) and the Type II sums of squares (SS_j):

$$s_{\beta_j} = (\hat{\beta}_j^2 / F_j)^{1/2}$$

and

$$SS_j = \hat{\beta}_j^2 \times \text{MSE} / s_{\beta_j}^2$$

PROC TRANSREG does not provide tests of the individual terms that go into the transformation. (However, it could if **BSPLINE** or **PSPLINE** had been specified instead of **SPLINE**.) The test of **spline(x1)** is the same as the test of the overall model. The intercepts are different due to the different numbers of variables and their standardizations.

In the next example, both x_1 and x_2 are transformed in the first PROC TRANSREG step, and PROC TRANSREG is used instead of a DATA step to create the polynomials for PROC REG. Both PROC TRANSREG and PROC REG fit the same polynomial regression model. The following statements run PROC TRANSREG and PROC REG and produce Figure 97.70 and Figure 97.71:

```

title 'Two-Variable Polynomial Regression';

proc transreg data=htex ss2 solve;
  model identity(y) = spline(x1 x2);
run;

proc transreg noprint data=htex maxiter=0;
  /* Use PROC TRANSREG to prepare input to PROC REG */
  model identity(y) = pspline(x1 x2);
  output out=htex2;
run;

proc reg data=htex2;
  model y = x1_1-x1_3 x2_1-x2_3;
  test x1_1, x1_2, x1_3;
  test x2_1, x2_2, x2_3;
run; quit;

```

Univariate ANOVA Table Based on the Usual Degrees of Freedom

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	6	38.7478	6.45796	0.45	0.8306
Error	13	185.3960	14.26123		
Corrected Total	19	224.1438			

Root MSE	3.77640	R-Square	0.1729
Dependent Mean	0.85490	Adj R-Sq	-0.2089
Coeff Var	441.73431		

Univariate Regression Table Based on the Usual Degrees of Freedom

Variable	DF	Coefficient	Type II Sum of Squares	Mean Square	F Value	Pr > F
Intercept	1	3.5437125	35.2282	35.2282	2.47	0.1400
Spline(x1)	3	0.3644562	4.5682	1.5227	0.11	0.9546
Spline(x2)	3	-1.3551738	32.9112	10.9704	0.77	0.5315

There are three iteration histories: one for the overall model and two for the two independent variables. The first PROC TRANSREG iteration history shows the R square of 0.17287 for the fit of the overall model. The second is for the following model:

```
model identity(y) = spline(x2);
```

This model excludes `spline(x1)`. The third iteration history is for the following model:

```
model identity(y) = spline(x1);
```

This model excludes `spline(x2)`. The difference between the first and second R square times the total sum of squares is the model sum of squares for `spline(x1)`:

$$(0.17287 - 0.15249) \times 224.143800 = 4.568165$$

The difference between the first and third R square times the total sum of squares is the model sum of squares for **spline(x2)**:

$$(0.17287 - 0.02604) \times 224.143800 = 32.911247$$

Figure 97.71 displays the PROC REG results. The TEST statement in PROC REG tests the null hypothesis that the vector of parameters for $x1_1$ $x1_2$ $x1_3$ is zero. This is the same test as the **spline(x1)** test used by PROC TRANSREG. Similarly, the PROC REG test that the vector of parameters for $x2_1$ $x2_2$ $x2_3$ is zero is the same as the PROC TRANSREG **SPLINE(x2)** test. So for models with no monotonicity constraints and no dependent variable transformations, PROC TRANSREG provides little more than a different packaging of standard least squares methodology.

Hypothesis Tests with Monotonicity Constraints

Now consider a model with monotonicity constraints. This model has no counterpart in PROC REG. The following statements fit a monotone-spline model and produce Figure 97.72:

```
title 'Monotone Splines';

proc transreg data=htex ss2 short;
  model identity(y) = mspline(x1-x3 / nknots=3);
run;
```

The **SHORT** *a-option* is specified to suppress the iteration histories. Two ANOVA tables are displayed—one by using liberal degrees of freedom and one by using conservative degrees of freedom. All sums of squares and the R squares are the same for both tables. What differs are the degrees of freedom and statistics that use degrees of freedom. The liberal test has 8 model degrees of freedom and 11 error degrees of freedom, whereas the conservative test has 15 model degrees of freedom and only 4 error degrees of freedom. The “true” *p*-value is between 0.8462 and 0.9997, so clearly you would fail to reject the null hypothesis. Unfortunately, results are not always this clear. (See Figure 97.72.)

Hypothesis Tests with Dependent Variable Transformations

PROC TRANSREG can also provide approximate tests of hypotheses when the dependent variable is transformed, but the output is more complicated. When a dependent variable has more than one degree of freedom, the problem becomes multivariate. Hypothesis tests are performed in the context of a multivariate linear model with the number of dependent variables equal to the number of scoring parameters for the dependent variable transformation. The transformation regression model with a dependent variable transformation differs from the usual multivariate linear model in two important ways. First, the usual assumption of multivariate normality is always violated. This fact is simply ignored. This is one reason why all hypothesis tests in the presence of a dependent variable transformation should be considered approximate at best. Multivariate normality is assumed even though it is known that the assumption is violated.

The second difference concerns the usual multivariate test statistics: Pillai's trace, Wilks' lambda, Hotelling-Lawley trace, and Roy's greatest root. The first three statistics are defined in terms of all the squared canonical correlations. Here, there is only one linear combination (the transformation), and hence only one squared canonical correlation of interest, which is equal to the R square. It might seem that Roy's greatest root, which uses only the largest squared canonical correlation, is the only statistic of interest. Unfortunately, Roy's greatest root is very liberal and provides only a lower bound on the p -value. Approximate upper bounds are provided by adjusting the other three statistics for the one linear combination case. Wilks' lambda, Pillai's trace, and Hotelling-Lawley trace are a conservative adjustment of the usual statistics.

These statistics are normally defined in terms of the squared canonical correlations, which are the eigenvalues of the matrix $\mathbf{H}(\mathbf{H} + \mathbf{E})^{-1}$, where \mathbf{H} is the hypothesis sum-of-squares matrix and \mathbf{E} is the error sum-of-squares matrix. Here the R square is used for the first eigenvalue, and all other eigenvalues are set to 0 since only one linear combination is used. Degrees of freedom are computed assuming that all linear

combinations contribute to the lambda and trace statistics, so the F tests for those statistics are conservative. The p -values for the liberal and conservative statistics provide approximate lower and upper bounds on p . In practice, the adjusted Pillai's trace is very conservative—perhaps too conservative to be useful. Wilks' lambda is less conservative, and the Hotelling-Lawley trace seems to be the least conservative. The conservative statistics and the liberal Roy's greatest root provide a bound on the true p -value. Unfortunately, they sometimes report a bound of 0.0001 and 1.0000.

The following example has a dependent variable transformation and produces [Figure 97.73](#):

```
title 'Transform Dependent and Independent Variables';

proc transreg data=htex ss2 solve short;
  model spline(y) = spline(x1-x3);
run;
```

The univariate results match Roy's greatest root results. Clearly, the proper action is to fail to reject the null hypothesis. However, as stated previously, results are not always this clear.

Figure 97.73 Transform Dependent and Independent Variables

Figure 97.73 *continued*

Adjusted Multivariate ANOVA Table Based on the Usual Degrees of Freedom					
Dependent Variable Scoring Parameters=3			S=3	M=2.5	N=3
Statistic	Value	F Value	Num DF	Den DF	p
Wilks' Lambda	0.505308	0.23	27	24.006	<= 0.9998
Pillai's Trace	0.494692	0.22	27	30	<= 0.9999
Hotelling-Lawley Trace	0.978992	0.26	27	11.589	<= 0.9980
Roy's Greatest Root	0.978992	1.09	9	10	>= 0.4452

The Wilks' Lambda, Pillai's Trace, and Hotelling-Lawley Trace statistics are a conservative adjustment of the normal statistics. Roy's Greatest Root is liberal. These statistics are normally defined in terms of the squared canonical correlations which are the eigenvalues of the matrix $H \cdot \text{inv}(H+E)$. Here the R-Square is used for the first eigenvalue and all other eigenvalues are set to zero since only one linear combination is used. Degrees of freedom are computed assuming all linear combinations contribute to the Lambda and Trace statistics, so the F tests for those statistics are conservative. The p values for the liberal and conservative statistics provide approximate lower and upper bounds on p. A liberal test statistic with conservative degrees of freedom and a conservative test statistic with liberal degrees of freedom yield at best an approximate p value, which is indicated by a "~" before the p value.

Univariate Regression Table Based on the Usual Degrees of Freedom						
Variable	DF	Coefficient	Type II Sum of Squares	Mean Square	F Value	Liberal p
Intercept	1	6.9089087	117.452	117.452	10.37	>= 0.0092
Spline(x1)	3	-1.0832321	32.493	10.831	0.96	>= 0.4504
Spline(x2)	3	-2.1539191	45.251	15.084	1.33	>= 0.3184
Spline(x3)	3	0.4779207	10.139	3.380	0.30	>= 0.8259

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

Figure 97.73 continued

Adjusted Multivariate Regression Table Based on the Usual Degrees of Freedom								
Variable	Coefficient	Statistic	Value	F	Value	Num DF	Den DF	p

		Pillai's Trace	0.222928	0.27		9	30	<= 0.9787
		Hotelling-Lawley Trace	0.286883	0.24		9	9.8113	<= 0.9784
		Roy's Greatest Root	0.286883	0.96		3	10	>= 0.4504
Spline(x2)	-2.1539191	Wilks' Lambda	0.714529	0.32		9	19.621	<= 0.9572
		Pillai's Trace	0.285471	0.35		9	30	<= 0.9494
		Hotelling-Lawley Trace	0.399524	0.33		9	9.8113	<= 0.9424
		Roy's Greatest Root	0.399524	1.33		3	10	>= 0.3184
Spline(x3)	0.4779207	Wilks' Lambda	0.917838	0.08		9	19.621	<= 0.9998
		Pillai's Trace	0.082162	0.09		9	30	<= 0.9996
		Hotelling-Lawley Trace	0.089517	0.07		9	9.8113	<= 0.9997
		Roy's Greatest Root	0.089517	0.30		3	10	>= 0.8259
These statistics are adjusted in the same way as the multivariate statistics above.								

Hypothesis Tests with One-Way ANOVA

One-way ANOVA models are fit with either an explicit or implicit intercept. In implicit intercept models, the ANOVA table of PROC TRANSREG is the correct table for a model with an intercept, and the regression table is the correct table for a model that does not have a separate explicit intercept. The PROC TRANSREG implicit intercept ANOVA table matches the PROC REG table when the NOINT *a-option* is not specified, and the PROC TRANSREG implicit intercept regression table matches the PROC REG table when the NOINT *a-option* is specified. The following statements illustrate this relationship and produce Figure 97.74:

Using the DESIGN Output Option

This example uses PROC TRANSREG and the **DESIGN** *o-option* to prepare an input data set with classification variables for the LOGISTIC procedure. The DESIGN *o-option* specifies that the goal is design matrix creation, not analysis. When you specify DESIGN, dependent variables are not required. The **DEVIATIONS** (or **EFFECTS**) *t-option* requests a deviations-from-means (1, 0, -1) coding of the classification variables, which is the same coding the CATMOD procedure uses. PROC TRANSREG automatically creates a macro variable &_TrgInd that contains the list of independent variables created. This macro is used in the PROC LOGISTIC MODEL statement. (See Figure 97.75.) For comparison, the same analysis is also performed with PROC CATMOD. The following statements create Figure 97.75:

```

title 'Using PROC TRANSREG to Create a Design Matrix';

data a;
  do y = 1, 2;
    do a = 1 to 4;
      do b = 1 to 3;
        w = ceil(uniform(1) * 10 + 10);
        output;
      end;
    end;
  end;
run;

proc transreg data=a design;
  model class(a b / deviations);

Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO

A discrete choice experiment is constructed consisting of four product brands, each available at three different prices, \$1.49, \$1.99, \$2.49. In addition, each choice set contains a constant “other” alternative available at \$1.49. In the fifth choice set, price is constant. PROC TRANSREG is used to code the design, and the PHREG procedure fits the multinomial logit choice model (not shown). See http://support.sas.com/resources/papers/tnote/tnote_marketresearch.html (Kuhfeld 2005) for more information about discrete choice modeling and the multinomial logit model; look for the latest “Discrete Choice” report. The following statements produce Figure 97.76:

```

title 'Choice Model Coding';

data design;
  array p[4];
  input p1-p4 @@;
  set = _n_;
  do brand = 1 to 4;
    price = p[brand];
    output;
  end;

1.99 1.99 1.49 2.49 1.99 2.49 1.99 1.99 1.49 2.49 1.99 2.49
;

proc transreg data=design design norestoremisssing nozeroconstant;
  model class(brand / zero=none) identity(price);
  output out=coded;
  by set;
run;

proc print data=coded(firstobs=21 obs=25);
  var set brand &_trgind;
run;

```

In the interest of space, only the fifth choice set is displayed in Figure 97.76.

Figure 97.76 The Fifth Choice Set

Choice Model Coding							
Obs	set	brand	brand1	brand2	brand3	brand4	price
21	5	1	1	0	0	0	1.49
22	5	2	0	1	0	0	1.49
23	5	3	0	0	1	0	1.49
24	5	4	0	0	0	1	1.49
25	5	.	0	0	0	0	1.49

For the constant alternative (Brand = .), the brand coding is a row of zeros due to the **NORESTOREMISSING** *o-option*, and Price is a constant \$1.49 (instead of 0) due to the **NOZEROCONSTANT**.

The data set was coded by choice set (BY set;). This is a small problem. With very large problems, it might be necessary to restrict the number of observations that are coded at one time so that the procedure uses less time and memory. Coding by choice set is one option. When coding is performed after the data are merged in, coding by subject and choice set combinations is another option. Alternatively, you can specify **DESIGN=*n***, where *n* is the number of observations to code at one time. For example, you can specify **DESIGN=100** or **DESIGN=1000** to process the data set in blocks of 100 or 1000 observations. Specify the **NOZEROCONSTANT** *a-option* to ensure that constant variables within blocks are not zeroed. When you specify **DESIGN=*n***, or perform coding after the data are merged in, specify the dependent variable and any other variables needed for analysis as **ID** variables.

Centering

You can use transformation options to center and standardize the variables in several ways. For example, the following **MODEL** statement creates three independent variables, x , x^2 , and x^3 :

```
model identity(y) = pspline(x);
```

The variables are not centered.

When the **CENTER** *t-option* is specified, as in the following statement, the independent variable is centered before squaring and cubing:

```
model identity(y) = pspline(x / center);
```

The three independent variables are $x - \bar{x}$, $(x - \bar{x})^2$, and $(x - \bar{x})^3$.

Since operations such as squaring occur after the centering, the resulting variables are not always centered. The **CENTER** *t-option* is particularly useful with polynomials since centering before squaring and cubing can help reduce collinearity and numerical problems. For example, if one of your variables is year, with values all greater than 1900, squaring and cubing without centering first will create variables that are all essentially perfectly correlated.

When the **TSTANDARD=**CENTER *t-option* is specified, as in the following model, the three independent variables are squared and cubed and then centered:

```
model identity(y) = pspline(x / tstandard=center);
```

The three independent variables are $x - \bar{x}$, $x^2 - \bar{x}^2$, and $x^3 - \bar{x}^3$.

You can specify both the **CENTER** and **TSTANDARD=**CENTER *t-options* to center the variables, then square and cube them, and then center the results, as in the following statement:

```
model identity(y) = pspline(x / center tstandard=center);
```

The three independent variables are $x - \bar{x}$, $(x - \bar{x})^2 - \overline{(x - \bar{x})^2}$, and $(x - \bar{x})^3 - \overline{(x - \bar{x})^3}$.

Displayed Output

The display options control the amount of displayed output. The displayed output can contain the following:

- an iteration history and convergence status table (by default when there are iterations)
- an ANOVA table when the **TEST**, **SS2**, or **UTILITIES** *a-option* is specified
- a regression table when the **SS2** *a-option* is specified
- conjoint analysis part-worth utilities when the **UTILITIES** *a-option* is specified
- model details when the **DETAIL** *a-option* is specified
- a multivariate ANOVA table when the dependent variable is transformed and the **TEST** or **SS2** *a-option* is specified
- a multivariate regression table when the dependent variable is transformed and it is specified
- liberal and conservative ANOVA, multivariate ANOVA, regression, and multivariate regression tables when there is a **MONOTONE**, **UNTIE**, or **MSPLINE** transformation and the **TEST** or **SS2** *a-option* is specified

ODS Table Names

PROC TRANSREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 97.8. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 97.8 ODS Tables Produced by PROC TRANSREG

ODS Table Name	Description	Statement & Option
ANOVA	ANOVA	MODEL/PROC, TEST/SS2
BoxCox	Box-Cox transformation results	MODEL, BOXCOX
CANALS	CANALS iteration history	MODEL/PROC, METHOD= CANALS
ClassLevels	ANOVA	MODEL/PROC, TEST/SS2

Table 97.8 continued

ODS Table Name	Description	Statement & Option
Coef	Regression results	MODEL/PROC, SS2
ConservANOVA	ANOVA, *1	MODEL/PROC, TEST/SS2
ConservCoef	Regression results, *1	MODEL/PROC, SS2
ConservFitStatistics	Fit statistics, *1	MODEL/PROC, TEST/SS2
ConservMVANOVA	Multivariate ANOVA, *1, *2	MODEL/PROC, TEST/SS2
ConservMVCoef	Multivariate regression results, *1, *2	MODEL/PROC, SS2
ConservUtilities	Conjoint analysis utilities, *1	MODEL/PROC, UTILITIES
ConvergenceStatus	Convergence status	default
Details	Model Details	MODEL/PROC, DETAIL
Equation	Linear dependency equation	less-than-full-rank model
FitStatistics	Fit statistics like R square	MODEL/PROC, TEST/SS2
Footnotes	Iteration history footnotes	default
Formula	Fit plot formula (nonprinting)	PROC, PLOTS=FIT(FORMULA)
LiberalANOVA	ANOVA, *1	MODEL/PROC, TEST/SS2
LiberalCoef	Regression results, *1	MODEL/PROC, SS2
LiberalFitStatistics	Fit statistics, *1	MODEL/PROC, TEST/SS2

Univariate	Univariate iteration history	MODEL/PROC, METHOD=UNIVARIATE
Utilities	Conjoint analysis utilities	MODEL/PROC, UTILITIES

*1. Liberal and conservative test tables are produced when a [MONOTONE](#), [UNTIE](#), or [MSPLINE](#) transformation is requested.

*2. Multivariate tables are produced when the dependent variable is iteratively transformed.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

Some graphs are produced by default; other graphs are produced by using statements and options. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC TRANSREG generates are listed in [Table 97.9](#), along with the required statements and options.

Table 97.9 Graphs Produced by PROC TRANSREG

ODS Graph Name	Plot Description	Statement & Option
BoxCoxFPlot	Box-Cox $F = t^2$	MODEL & PROC, BOXCOX transform & PLOTS(UNPACK)
BoxCoxLogLikePlot	Box-Cox Log Likelihood	MODEL & PROC, BOXCOX transform & PLOTS(UNPACK)
BoxCoxPlot	Box-Cox t or $F = t^2$ & Log Likelihood	MODEL, BOXCOX transform
BoxCoxtPlot	Box-Cox t	MODEL & PROC, BOXCOX transform & PLOTS(UNPACK)=BOXCOX(T)
FitPlot	Simple Regression and Separate Group Regressions	MODEL, a dependent variable that is not transformed, one non-CLASS independent variable, and at most one CLASS variable
ObservedByPredicted	Dependent Variable by Predicted Values	MODEL, PLOTS =OBSERVEDBYPREDICTED
PBSplineCritPlot	Penalized B-Spline Criterion Plot	MODEL, PBSPLINE transform
PrefMapVecPlot	Preference Mapping Vector Plot	MODEL & PROC, IDENTITY transform & COORDINATES
PrefMapIdealPlot	Preference Mapping Ideal Point Plot	MODEL & PROC, POINT expansion & COORDINATES
ResidualPlot	Residuals	PROC, PLOTS =RESIDUALS
RMSEPlot	Box-Cox Root Mean Square Error	MODEL & PROC, BOXCOX transform & PLOTS =BOXCOX(RMSE)
ScatterPlot	Scatter Plot of Observed Data	MODEL, one non-CLASS independent variable, and at most one CLASS variable, PLOTS =SCATTER
TransformationPlot	Variable Transformations	PROC, PLOTS =TRANSFORMATION

The PLOTS(INTERPOLATE) Option

This section illustrates one use of the PLOTS(INTERPOLATE) option for use with ODS Graphics. The data set has two groups of observations, $c = 1$ and $c = 2$. Each group is sparse, having only five observations, so the plots of the transformations and fit functions are not smooth. A second DATA step adds additional observations to the data set, over the range of x , with y missing. These observations do not contribute to the analysis, but they are used in computations of transformed and predicted values. The resulting plots are much smoother in the latter case than in the former. The other results of the analysis are the same. The following statements produce [Figure 97.77](#) and [Figure 97.78](#):

```

title 'Smoother Interpolation with PLOTS(INTERPOLATE)';

data a;
  input c y x;
  output;
  datalines;
1 1 1
1 2 2
1 4 3
1 6 4
1 7 5
2 3 1
2 4 2
2 5 3
2 4 4
2 5 5
;

ods graphics on;

proc transreg data=a plots=(tran fit) ss2;
  model ide(y) = pbs(x) * class(c / zero=none);
run;

data b;
  set a end=eof;
  output;
  if eof then do;
    y = .;
    do x = 1 to 5 by 0.05;
      c = 1; output;
      c = 2; output;
    end;
  end;
run;

proc transreg data=b plots(interpolate)=(tran fit) ss2;
  model ide(y) = pbs(x) * class(c / zero=none);
run;

```

The results with no interpolation are shown in [Figure 97.77](#). The transformation and fit functions are not at all smooth. The results with interpolation are shown in [Figure 97.78](#). The transformation and fit functions are smooth in [Figure 97.78](#), because there are intermediate points to plot.

Examples: TRANSREG Procedure

Example 97.1: Transformation Regression of Exhaust Emissions Data

In this example, the data are from an experiment in which nitrogen oxide emissions from a single cylinder engine are measured for various combinations of fuel, compression ratio, and equivalence ratio. The data are provided by Brinkman (1981). This gas data set is available from the Sashelp library.

The equivalence ratio and nitrogen oxide variables are continuous and numeric, so spline transformations of these variables are requested. The spline transformation of the dependent variable is restricted to be monotonic. Each spline is degree three with nine knots (one at each decile) in order to give PROC TRANSREG a great deal of freedom in finding transformations. The compression ratio variable has only five discrete values, so an optimal scoring is requested with monotonicity constraints. The character variable Fuel is nominal, so it is optimally scored without any monotonicity constraints. Observations with missing values are excluded with the **NOMISS** *a-option*.

Error	147	14.1443	0.09622		
Corrected Total	168	340.1619			

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

Output 97.1.1 continued

Root MSE	0.31019	R-Square	0.9584
Dependent Mean	2.34593	Adj R-Sq	0.9525
Coeff Var	13.22262		

Output 97.1.1 continued

Output 97.1.1 continued

Output 97.1.1 continued

The squared multiple correlation for the initial model is approximately 0.05. PROC TRANSREG increases the R square to over 0.95 by transforming the variables. The transformation plots show how each variable is transformed. The transformation of compression ratio (TCpRatio) is nearly linear. The transformation of equivalence ratio (TEqRatio) is nearly parabolic. It can be seen from this plot that the optimal transformation of equivalence ratio is nearly uncorrelated with the original scoring. This suggests that the large increase in R square is due to this transformation. The transformation of nitrogen oxide (TNOx) is similar to a log transformation. The final plot shows the transformed dependent variable plotted as a function of the predicted values. This plot is reasonably linear, showing that the nonlinearities in the data are being accounted for fairly well by the TRANSREG model.

These results suggest the parametric model

$$\begin{aligned}\log(\text{NOx}) = & b_0 + b_1 \times \text{EqRatio} + b_2 \times \text{EqRatio}^2 + b_3 \times \text{CpRatio} \\ & + \sum_j b_j \text{class}_j(\text{Fuel}) + \text{error}\end{aligned}$$

You can perform this analysis with PROC TRANSREG. The following statements produce [Output 97.1.2](#):

```

title2 'Now fit log(NOx) = b0 + b1*EqRatio + b2*EqRatio**2 +';
title3 'b3*CpRatio + Sum b(j)*Fuel(j) + Error';

The **LOG** transformation computes the natural log. The **PSPLINE** expansion expands EqRatio into a linear term, EqRatio , and a squared term, EqRatio^2 . An identity transformation of CpRatio and an optimal scoring of Fuel is requested. These should provide a good parametric operationalization of the optimal transformations. The final model has an R square of 0.91 (smaller than before since the model has fewer parameters, but still quite good).

Example 97.2: Box-Cox Transformations

This example shows Box-Cox transformations with a yarn failure data set. For more information about Box-Cox transformations, including using a Box-Cox transformation in a model with no independent variable, to normalize the distribution of the data, see the section “**Box-Cox Transformations**” on page 8222. In this example, a simple 3^3 design was used to study the effects of different factors on the failure of a yarn manufacturing process. The design factors are as follows:

- the length of test specimens of yarn, with levels of 250, 300, and 350 mm
- the amplitude of the loading cycle, with levels of 8, 9, and 10 mmd
- the load with levels of 40, 45, and 50 grams

The measured response was time (in cycles) until failure. However, you could just as well have measured the inverse of time until failure (in other words, the failure rate). Hence, the correct metric with which to analyze the response is not apparent. You can use PROC TRANSREG to find an optimum power transformation for the analysis. The following statements create the input SAS data set:

```

title 'Yarn Strength';

proc format;
  value a -1 = 8 0 = 9 1 = 10;
  value l -1 = 250 0 = 300 1 = 350;
  value o -1 = 40 0 = 45 1 = 50;
run;

data yarn;
  input Fail Amplitude Length Load @@;

1140 1 1 -1      884 1 1 0      360 1 1 1
;

```

PROC TRANSREG is run to find the Box-Cox transformation. The lambda list is -2 TO 2 BY 0.05, which produces 81 lambdas, and a convenient lambda is requested. This many power parameters makes a nice graphical display with plenty of detail around the confidence interval. In the interest of space, only part of this table is displayed. The independent variables are designated with the QPOINT expansion. QPOINT, for quadratic point model, gets its name from PROC TRANSREG's ideal point modeling capabilities, which process variables for a response surface analysis. What QPOINT does is create a set of independent variables consisting of the following: the m original variables (Length Amplitude Load), the m original variables squared (Length_2 Amplitude_2 Load_2), and the $m \times (m - 1)/2 = 3$ pairs of products between the m variables (LengthAmplitude LengthLoad AmplitudeLoad). The following statements produce [Output 97.2.1](#):

```

ods graphics on;

proc transreg details data=yarn ss2
  plots=(transformation(dependent) obp);
  model BoxCox(fail / convenient lambda=-2 to 2 by 0.05) =
    qpoint(length amplitude load);
run;

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

Output 97.2.1 continued

Output 97.2.1 *continued*

The optimal power parameter is -0.20 , but since 0.0 is in the confidence interval, and since the **CONVENIENT** t -option was specified, the procedure chooses a log transformation. The $F = t^2$ plot shows in the vicinity of the optimal Box-Cox transformation, the parameters for the three original variables (Length Amplitude Load), particularly Length, are significant and the others become essentially zero.

Example 97.3: Penalized B-Spline

The ENSO data set contains measurements of monthly averaged atmospheric pressure differences between Easter Island and Darwin, Australia, for a period of 168 months (National Institute of Standards and Technology 1998). The ENSO data set is available from the Sashelp library.

You can fit a curve through these data by using a penalized B-spline (Eilers and Marx 1996) function and the following statements:

```
title 'Atmospheric Pressure Changes Between'
      'Easter Island & Darwin, Australia';
ods graphics on;

proc transreg data=sashelp.enso;
  model identity(pressure) = pbspline(year);
run;
```

The dependent variable Pressure is specified along with an **IDENTITY** transformation, so Pressure is analyzed as is, with no transformations. The independent variable Year is specified with a **PBSPLINE** transformation, so a penalized B-spline model is fit. By default, a **DEGREE=3** B-spline basis is used along with 100 evenly spaced knots and three evenly spaced exterior knots on each side of the data. The penalized spline function is typically much smoother than you would get by using a **SPLINE** transformation or a **BSPLINE** expansion since changes in the coefficients of the basis are penalized to make a smoother fit. The output is shown next in [Output 97.3.1](#).

Output 97.3.1 Change in Atmospheric Pressure, AICC

Output 97.3.1 continued

The results show a yearly cycle of pressure change. The procedure chose a smoothing parameter of $\lambda = 0.709$. With data such as these, with many peaks and valleys, it might be useful to perform another analysis, this time asking for a smoother plot. The Schwarz Bayesian criterion (SBC) is sometimes a better choice than the default criterion when you want a smoother plot. The following PROC TRANSREG step requests a penalized B-spline analysis minimizing the SBC criterion:

```
proc transreg data=sashelp.enso;
  model identity(pressure) = pbspline(year / sbc);
run;
```

The plot of SBC as a function of λ is shown in [Output 97.3.2](#).

Output 97.3.2 Change in Atmospheric Pressure, SBC

The fit plot (not shown) is essentially the same as the one shown in [Output 97.3.1](#) due to the similar choice of smoothing parameters: $\lambda = 0.709$ versus $\lambda = 1.14$. You can analyze these data again, this time forcing PROC TRANSREG to consider only larger smoothing parameters. The specification **LAMBDA=2 10000 RANGE** eliminates from consideration the two lambdas that you previously saw and considers only $2 \leq \lambda \leq 10,000$. The following statements produce [Output 97.3.3](#):

```
proc transreg data=sashelp.enso;
  model identity(pressure) = pbspline(year / sbc lambda=2 10000 range);
run;
```

Output 97.3.3 Change in Atmospheric Pressure, SBC, Lambda > 1

Output 97.3.3 continued

The results clearly show that there is a local minimum in the $SBC(\lambda)$ function at $\lambda = 1801.1$. Using this lambda results in a much smoother regression function with a longer cycle than you saw previously. This second cycle can be identified as the periodic warming of the Pacific Ocean known as “El Niño.” The $SBC(\lambda)$ function has at least two minima since there are at least two trends in the data. In the first analysis, PROC TRANSREG found what is probably the globally optimal solution, and in the second set of analyses, with a little nudging away from the global optimum, it found a very interesting locally optimal solution.

You can specify a list of lambdas to see SBC as a function of lambda over the range that includes both minima as follows:

```
proc transreg data=sashelp.enso;
  model identity(pressure) = pbspline(year / sbc lambda=.1 .5 1 5
                                     10 50 100 500 to 2500 by 500);
run;
```

The plot of SBC as a function of λ is shown in [Output 97.3.4](#).

Output 97.3.4 Change in Atmospheric Pressure, SBC, Over the Range of Both Minima

Example 97.4: Nonmetric Conjoint Analysis of Tire Data

This example uses PROC TRANSREG to perform a nonmetric conjoint analysis of tire preference data. Conjoint analysis decomposes rank-ordered evaluation judgments of products or services into components based on qualitative product attributes. For each level of each attribute of interest, a numerical “part-worth utility” value is computed. The sum of the part-worth utilities for each product is an estimate of the utility for that product. The goal is to compute part-worth utilities such that the product utilities are as similar as possible to the original rank ordering. (This example is a greatly simplified introductory example.)

The stimuli for the experiment are 18 hypothetical tires. The stimuli represent different brands (Goodstone, Pirogi, Machismo),¹ prices (\$69.99, \$74.99, \$79.99), expected tread life (50,000, 60,000, 70,000 miles), and road hazard insurance plans (Yes, No). There are $3 \times 3 \times 3 \times 2 = 54$ possible combinations. From these, 18 combinations are selected that form an efficient experimental design for a main-effects model. The combinations are then ranked from 1 (most preferred) to 18 (least preferred). In this simple example, there is one set of rankings. A real conjoint study would have many more.

First, the FORMAT procedure is used to specify the meanings of the factor levels, which are entered as numbers in the DATA step along with the ranks. PROC TRANSREG is used to perform the conjoint analysis. A maximum of 50 iterations is requested. The specification `monotone(Rank / reflect)` in the MODEL statement requests that the dependent variable Rank should be monotonically transformed and reflected so that positive utilities mean high preference. The variables Brand, Price, Life, and Hazard are

¹In real conjoint experiments, real brand names would be used.

designated as **CLASS** variables, and the part-worth utilities are constrained by **ZERO=SUM** to sum to zero within each factor. The **UTILITIES** *a-option* displays the conjoint analysis results.

The importance column of the utilities table shows that price is the most important attribute in determining preference (57%), followed by expected tread life (18%), brand (15%), and road hazard insurance (10%). Looking at the utilities table for the maximum part-worth utility within each attribute, you see from the results that the most preferred combination is Pirogi brand tires, at \$69.99, with a 70,000-mile expected tread life and road hazard insurance. This product is not actually in the data set. The sum of the part-worth utilities for this combination is as follows:

$$20.64 = 9.50 + 1.90 + 5.87 + 2.41 + 0.96$$

The following statements produce [Output 97.4.1](#).

Example 97.5: Metric Conjoint Analysis of Tire Data

This example, which is more detailed than the previous one, uses PROC TRANSREG to perform a metric conjoint analysis of tire preference data. Conjoint analysis can be used to decompose preference ratings of products or services into components based on qualitative product attributes. For each level of each attribute of interest, a numerical “part-worth utility” value is computed. The sum of the part-worth utilities for each product is an estimate of the utility for that product. The goal is to compute part-worth utilities such that the product utilities are as similar as possible to the original ratings. Metric conjoint analysis, as shown in this example, fits an ordinary linear model directly to data assumed to be measured on an interval scale. Nonmetric conjoint analysis, as shown in [Example 97.4](#), finds an optimal monotonic transformation of original data before fitting an ordinary linear model to the transformed data.

This example has three parts. In the first part, an experimental design is created. In the second part, a DATA step creates descriptions of the stimuli for the experiment. The third part of the example performs the conjoint analyses.

The stimuli for the experiment are 18 hypothetical tires. The stimuli represent different brands (Goodstone, Pirogi, Machismo),² prices (\$69.99, \$74.99, \$79.99), expected tread life (50,000, 60,000, 70,000 miles), and road hazard insurance plans (Yes, No).

For a conjoint study such as this, you need to create an experimental design with 3 three-level factors, 1 two-level factor, and 18 combinations or *runs*. The easiest way to get this design is with the %MktEx autocall macro. The %MktEx macro requires you to specify the number of levels of each of the four factors, followed by N=18, the number of runs. Specifying a random number seed, while not strictly necessary, helps ensure that the design is reproducible. The %MktLab macro assigns the actual factor names instead of the default names x1, x2, and so on, and it assigns formats to the factor levels. The %MktEval macro helps you evaluate the design. It shows how correlated or independent the factors are, how often each factor level appears in the design, how often each pair occurs for every factor pair, and how often each product profile or run occurs in the design. See http://support.sas.com/resources/papers/tnote/tnote_marketresearch.html (Kuhfeld 2005) for more information about experimental design and conjoint analysis; look for the latest “Conjoint Analysis” report. The following statements create, evaluate, and display the design:

```

title 'Tire Study, Experimental Design';

proc format;
  value BrandF
    1 = 'Goodstone'
    2 = 'Pirogi   '
    3 = 'Machismo ';
  value PriceF
    1 = '$69.99'
    2 = '$74.99'
    3 = '$79.99';
  value LifeF
    1 = '50,000'
    2 = '60,000'
    3 = '70,000';
  value HazardF

```

²In real conjoint experiments, real brand names would be used.

```

1 = 'Yes'
2 = 'No ';

run;

%mktx(3 3 3 2, n=18, seed=448)

%mktlab(vars=Brand Price Life Hazard, out=sasuser.TireDesign,
         statements=format Brand BrandF9. Price PriceF9.
                     Life LifeF6. Hazard HazardF3.)

%mkteval;

proc print data=sasuser.TireDesign;
run;

```

The %MktEx macro (Kuhfeld 2005) output displayed in [Output 97.5.1](#) shows you that the design is 100% efficient, which means it is orthogonal and balanced. The %MktEval macro output displayed in [Output 97.5.2](#) shows you that all of the factors are uncorrelated or orthogonal, the design is balanced (each level occurs once), and every pair of factor levels occurs equally often (again showing that the design is orthogonal). The *n*-way frequencies show that each product profile occurs once (there are no duplicates). The design is shown in [Output 97.5.3](#). The design is automatically randomized (the profiles were sorted into a random order and the original levels are randomly reassigned). Orthogonality, balance, randomization, and other design concepts are discussed in detail in Kuhfeld (2005), in the “Experimental Design, Efficiency, Coding, and Choice Designs” report.

The %MktEx macro requires SAS/STAT, SAS/QC, and SAS/IML software. Alternatively, you can make a design for this experiment using the %MktDes macro, which requires only SAS/STAT and SAS/QC software. The %MktDes macro contains a small subset of the functionality of the %MktEx macro. It can be used as follows:

```
%mktdes(factors=Brand=3 Price=3 Life=3 Hazard=2, n=18)
```

The results of this step are not shown or used.

Next, the questionnaires are printed and given to the subjects, who are asked to rate the tires.

The following statements produce [Output 97.5.4](#):

```
data _null_;
  title;
  set sasuser.TireDesign;
  file print;
  if mod(_n_,4) eq 1 then do;
    put _page_;
    put +55 'Subject _____';
  end;
  length hazardstring $ 7.;
  if put(hazard, hazardf3.) = 'Yes'
    then hazardstring = 'with';
    else hazardstring = 'without';

  s = 3 + (_n_ >= 10);
  put // _n_ +(-1) ' ) For your next tire purchase, '
      'how likely are you to buy this product?'
      // +s Brand 'brand tires at ' Price +(-1) ', '
      / +s 'with a ' Life 'tread life guarantee, '
      / +s 'and ' hazardstring 'road hazard insurance.'
      // +s 'Definitely Would          Definitely Would'
      / +s 'Not Purchase              Purchase'
      // +s '1      2      3      4      5      6      7      8      9 ' ;
run;
```

This output in [Output 97.5.4](#) is abbreviated in the interest of conserving space; the statements actually produce stimuli for all combinations.

1 2 3 4 5 6 7 8 9

The third part of the example performs the conjoint analyses. The DATA step reads the data. Only the ratings are entered, one row per subject. Real conjoint studies have many more subjects than five. The TRANSPOSE procedure transposes this (5×18) data set into an (18×5) data set that can be merged with the factor level data set sasuser.TireDesign. The next DATA step does the merge. The PRINT procedure displays the input data set.

PROC TRANSREG fits the five individual conjoint models, one for each subject. The **UTILITIES** *a-option* displays the conjoint analysis results. The **SHORT** *a-option* suppresses the iteration histories, **OUTTEST=UTILS** creates an output data set with all of the conjoint results, and the **SEPARATORS=** option requests that the labels constructed for each category contain two blanks between the variable name and the level value. The ODS SELECT statement is used to limit the displayed output. The MODEL statement specifies **IDENTITY** for the ratings, which specifies a metric conjoint analysis—the ratings are not transformed. The variables Brand, Price, Life, and Hazard are designated as **CLASS** variables, and the part-worth utilities are constrained to sum to zero within each factor.

The following statements produce [Output 97.5.5](#):

```

The next steps summarize the results. Three tables are displayed, showing the following: all of the importance values, the average importance, and the part-worth utilities. The first DATA step selects the importance information from the UTILS data set. The final assignment statement stores just the variable name from the label, relying on the fact that the separator is two blanks. PROC TRANSPOSE creates the data set of importances, one row per subject, and PROC PRINT displays the results. The MEANS procedure displays the average importance of each attribute across the subjects. The next DATA step selects the part-worth utilities information from the UTILS data set. PROC TRANSPOSE creates the data set of utilities, one row per subject, and PROC PRINT displays the results. The following statements produce [Output 97.5.6](#):

Based on the importance values, price is the most important attribute for some of the respondents, but expected tread life is most important for others. On the average, price is most important, followed by expected tread life and brand. Road hazard insurance is less important. Each of the brands is preferred by some of the respondents. All respondents preferred a lower price over a higher price, a longer tread life, and road hazard insurance.

Example 97.6: Preference Mapping of Automobile Data

This example uses PROC TRANSREG to perform a preference mapping (PREFMAP) analysis (Carroll 1972) of automobile preference data after a PROC PRINQUAL principal component analysis. The PREFMAP analysis is a response surface regression that locates ideal points for each dependent variable in a space defined by the independent variables.

The data are ratings obtained from 25 judges of their preference for each of 17 automobiles. The ratings were made on a scale of zero (very weak preference) to nine (very strong preference). These judgments were made in 1980 about that year's products. There are two character variables that indicate the manufacturer and model of the automobile. The data set also contains three ratings: miles per gallon (MPG), projected reliability (Reliability), and quality of the ride (Ride). These ratings are on a scale of one (bad) to five (good). PROC PRINQUAL creates an **OUT=** data set containing standardized principal component scores (Prin1 and Prin2), along with the **ID** variables Model, MPG, Reliability, and Ride.

While this data set contains all of the information needed for the subsequent preference mapping, you can make slightly more informative plots by adding new variable labels to the principal component score variables. The default labels are 'Component 1', 'Component 2', and so on. These are by necessity rather generic since they are created before any data are read, and they must be appropriate across BY groups when a BY variable is specified. In contrast, the MDPREF plot in PROC PRINQUAL has axis labels of the form 'Component 1 (43.54%)' and 'Component 2 (23.4%)' that show the proportion of variance accounted for

by each component. You can create an output data set from the MDPREF plot by using the ODS OUTPUT statement and then use only the label information from it to reset the labels in the output data set from PROC PRINQUAL. In the DATA PLOT step, the SET statement for the MD data set is specified before the SET statement for the PRESULTS data set. The `if 0` ensures that no data are actually read from it, but nevertheless the properties of the Prin1 and Prin2 variables including the variable labels are set based on the properties of those variables in the MD data set.

The first PROC TRANSREG step fits univariate regression models for MPG and Reliability. All variables are designated **IDENTITY**. A vector drawn in the plot of Prin1 and Prin2 from the origin to the point defined by an attribute's regression coefficients approximately shows how the autos differ on that attribute. See Carroll (1972) for more information. The Prin1 and Prin2 columns of the TResult1 **OUT=** data set contain the automobile coordinates (`_Type_='SCORE'` observations) and endpoints of the MPG and Reliability vectors (`_Type_='M COEFFI'` observations).

The second PROC TRANSREG step fits a univariate regression model with Ride designated **IDENTITY**, and Prin1 and Prin2 designated **POINT**. The POINT expansion creates an additional independent variable `_ISSQ_`, which contains the sum of Prin1 squared and Prin2 squared. The **OUT=** data set TResult2 contains no `_Type_='SCORE'` observations, only ideal point (`_Type_='M POINT'`) coordinates for Ride. The coordinates of both the vectors and the ideal points are output by specifying **COORDINATES** in the OUTPUT statement in PROC TRANSREG.

A vector model is used for MPG and Reliability because perfectly efficient and reliable automobiles do not exist in the data set. The ideal points for MPG and Reliability are far removed from the plot of the automobiles. It is more likely that an ideal point for quality of the ride is in the plot, so an ideal point model is used for the ride variable. See Carroll (1972) and Schiffman, Reynolds, and Young (1981) for discussions of the vector model and point models (including the **EPOINT** and **QPOINT** versions of the point model that are not used in this example). For the vector model, the default coordinates stretch factor of 2.5 was used. This extends the vectors by a factor of 2.5 from their standard lengths, making a better graphical display. Sometimes the default vectors are short and near the origin, and they look better when they are extended.

Algorithm converged.					

Output 97.6.2 MDPREF Plot

Output 97.6.3 shows that an unreliable-to-reliable direction extends from the left and slightly below the origin to the right and slightly above the origin. The Japanese and European automobiles are rated, on the

average, as more reliable. A low MPG to good MPG direction extends from the top left of the plot to the bottom right. The smaller automobiles, on the average, get better gas mileage.

Output 97.6.3 Preference Mapping Vector Plot

Preference Mapping (PREFMAP) Analysis	
The TRANSREG Procedure	
The TRANSREG Procedure Hypothesis Tests for Identity(MPG)	
R-Square	0.5720
The TRANSREG Procedure Hypothesis Tests for Identity(Reliability)	
R-Square	0.5086

Output 97.6.3 continued

The ideal point for Ride in [Output 97.6.4](#) is in the top, just right of the center of the plot. Automobiles near the Ride ideal point tend to have a better ride than automobiles far away. It can be seen from the R squares that none of these ratings perfectly fits the model, so all of the interpretations are approximate.

Output 97.6.4 Preference Mapping Ideal Point Plot

Output 97.6.4 continued

The Ride point is a “negative-negative” ideal point. The point models assume that small ratings mean the object (automobile) is similar to the rating name and large ratings imply dissimilarity to the rating name. Because the opposite scoring is used, the interpretation of the Ride point must be reversed to a negative

ideal point (bad ride). However, the coefficient for the `_ISSQ_` variable in [Output 97.6.5](#) is negative, so the interpretation is reversed again, back to the original interpretation.

Overview: TREE Procedure

The TREE procedure reads a data set created by the CLUSTER or VARCLUS procedure and produces a tree diagram (also known as a *dendrogram* or *phenogram*), which displays the results of a hierarchical clustering analysis as a tree structure. The TREE procedure uses the data set to produce a diagram of the tree structure in the style of Johnson (1967), with the root at the top. Alternatively, the diagram can be oriented horizontally, with the root at the left. Any numeric variable in the output data set can be used to specify the heights of the clusters. PROC TREE can also create an output data set that contains a variable to indicate the disjoint clusters at a specified level in the tree.

Tree diagrams are discussed in the context of cluster analysis by Duran and Odell (1974); Hartigan (1975); Everitt (1980). Knuth (1973) provides a general treatment of tree diagrams in computer programming.

The literature on tree diagrams contains a mixture of botanical and genealogical terminology. The objects that are clustered are *leaves*. The cluster that contains all objects is the *root*. A cluster that contains at least two objects but not all of them is a *branch*. The general term for leaves, branches, and roots is *node*. If a cluster A is the union of clusters B and C, then A is the *parent* of B and C, and B and C are *children* of A. A leaf is thus a node with no children, and a root is a node with no parent. If every cluster has at most two children, the tree diagram is a *binary tree*. The CLUSTER procedure always produces binary trees. The VARCLUS procedure can produce tree diagrams with clusters that have many children.

Getting Started: TREE Procedure

The TREE procedure creates tree diagrams from a SAS data set that contains the tree structure. You can create this type of data set with the CLUSTER or VARCLUS procedure. See Chapter 31, “[The CLUSTER Procedure](#),” and Chapter 100, “[The VARCLUS Procedure](#),” for more information.

In the following example, the VARCLUS procedure is used to divide a set of variables into hierarchical clusters and to create the SAS data set that contains the tree structure. The TREE procedure then generates the tree diagrams.

The following data, from Hand et al. (1994), represent the amount of protein consumed from nine food groups for each of 25 European countries. The nine food groups are red meat (RedMeat), white meat (WhiteMeat), eggs (Eggs), milk (Milk), fish (Fish), cereal (Cereal), starch (Starch), nuts (Nuts), and fruits and vegetables (FruVeg).

The following SAS statements create the data set Protein:

```
data Protein;
  input Country $15. RedMeat WhiteMeat Eggs Milk
    Fish Cereal Starch Nuts FruVeg;
  datalines;
Albania      10.1  1.4  0.5   8.9  0.2  42.3  0.6  5.5  1.7
Austria      8.9 14.0  4.3  19.9  2.1  28.0  3.6  1.3  4.3
Belgium     13.5  9.3  4.1  17.5  4.5  26.6  5.7  2.1  4.0
Bulgaria      7.8  6.0  1.6   8.3  1.2  56.7  1.1  3.7  4.2
Czechoslovakia 9.7 11.4  2.8  12.5  2.0  34.3  5.0  1.1  4.0
Denmark     10.6 10.8  3.7  25.0  9.9  21.9  4.8  0.7  2.4
E Germany    8.4 11.6  3.7  11.1  5.4  24.6  6.5  0.8  3.6
Finland      9.5  4.9  2.7  33.7  5.8  26.3  5.1  1.0  1.4
France     18.0  9.9  3.3  19.5  5.7  28.1  4.8  2.4  6.5
Greece     10.2  3.0  2.8  17.6  5.9  41.7  2.2  7.8  6.5
Hungary      5.3 12.4  2.9   9.7  0.3  40.1  4.0  5.4  4.2
Ireland     13.9 10.0  4.7  25.8  2.2  24.0  6.2  1.6  2.9
Italy       9.0  5.1  2.9  13.7  3.4  36.8  2.1  4.3  6.7
Netherlands  9.5 13.6  3.6  23.4  2.5  22.4  4.2  1.8  3.7
Norway      9.4  4.7  2.7  23.3  9.7  23.0  4.6  1.6  2.7
Poland      6.9 10.2  2.7  19.3  3.0  36.1  5.9  2.0  6.6
Portugal     6.2  3.7  1.1   4.9 14.2  27.0  5.9  4.7  7.9
Romania      6.2  6.3  1.5  11.1  1.0  49.6  3.1  5.3  2.8
Spain       7.1  3.4  3.1   8.6  7.0  29.2  5.7  5.9  7.2
Sweden      9.9  7.8  3.5   4.7  7.5  19.5  3.7  1.4  2.0
Switzerland 13.1 10.1  3.1  23.8  2.3  25.6  2.8  2.4  4.9
UK          17.4  5.7  4.7  20.6  4.3  24.3  4.7  3.4  3.3
USSR        9.3  4.6  2.1  16.6  3.0  43.6  6.4  3.4  2.9
W Germany   11.4 12.5  4.1  18.8  3.4  18.6  5.2  1.5  3.8
Yugoslavia   4.4  5.0  1.2   9.5  0.6  55.9  3.0  5.7  3.2
;
```

The data set Protein contains the character variable Country and the nine numeric variables that represent the food groups. The \$15. in the INPUT statement specifies that the variable Country is a character variable with a length of 15.

The following statements cluster the variables in the data set Protein:

```
ods graphics on;

proc varclus data=Protein outtree=Tree centroid maxclusters=4
  plots=dendrogram(vertical height=ncl);
  var RedMeat--FruVeg;
run;
```

The OUTTREE= option creates an output data set named Tree to contain the tree structure. The CENTROID option specifies the centroid clustering method, and the MAXCLUSTERS= option specifies that the largest number of clusters desired is four. The VAR statement specifies that all numeric variables (RedMeat—FruVeg) are used by the procedure. Since ODS Graphics is enabled, PROC VARCLUS creates a dendrogram, which is displayed in [Figure 98.1](#). The option `plots=dendrogram(vertical height=ncl)` specifies a vertical dendrogram with the number of clusters on the vertical axis. The default is a horizontal dendrogram with, for this cluster analysis, the proportion of variance explained on the horizontal axis.

Figure 98.1 Dendrogram from PROC VARCLUS and ODS Graphics

The output data set *Tree*, created by the *OUTTREE=* option in the previous statements, contains the following variables:

<code>_NAME_</code>	the name of the cluster
<code>_PARENT_</code>	the parent of the cluster
<code>_NCL_</code>	the number of clusters
<code>_VAREXP_</code>	the amount of variance explained by the cluster
<code>_PROPOR_</code>	the proportion of variance explained by the clusters at the current level of the tree diagram
<code>_MINPRO_</code>	the minimum proportion of variance explained by a cluster
<code>_MAXEIGEN_</code>	the maximum second eigenvalue of a cluster

Figure 98.2 Graphical Tree Diagram from PROC TREE

The following statements use PROC TREE to produce tree diagrams of the clusters created by PROC VARCLUS:

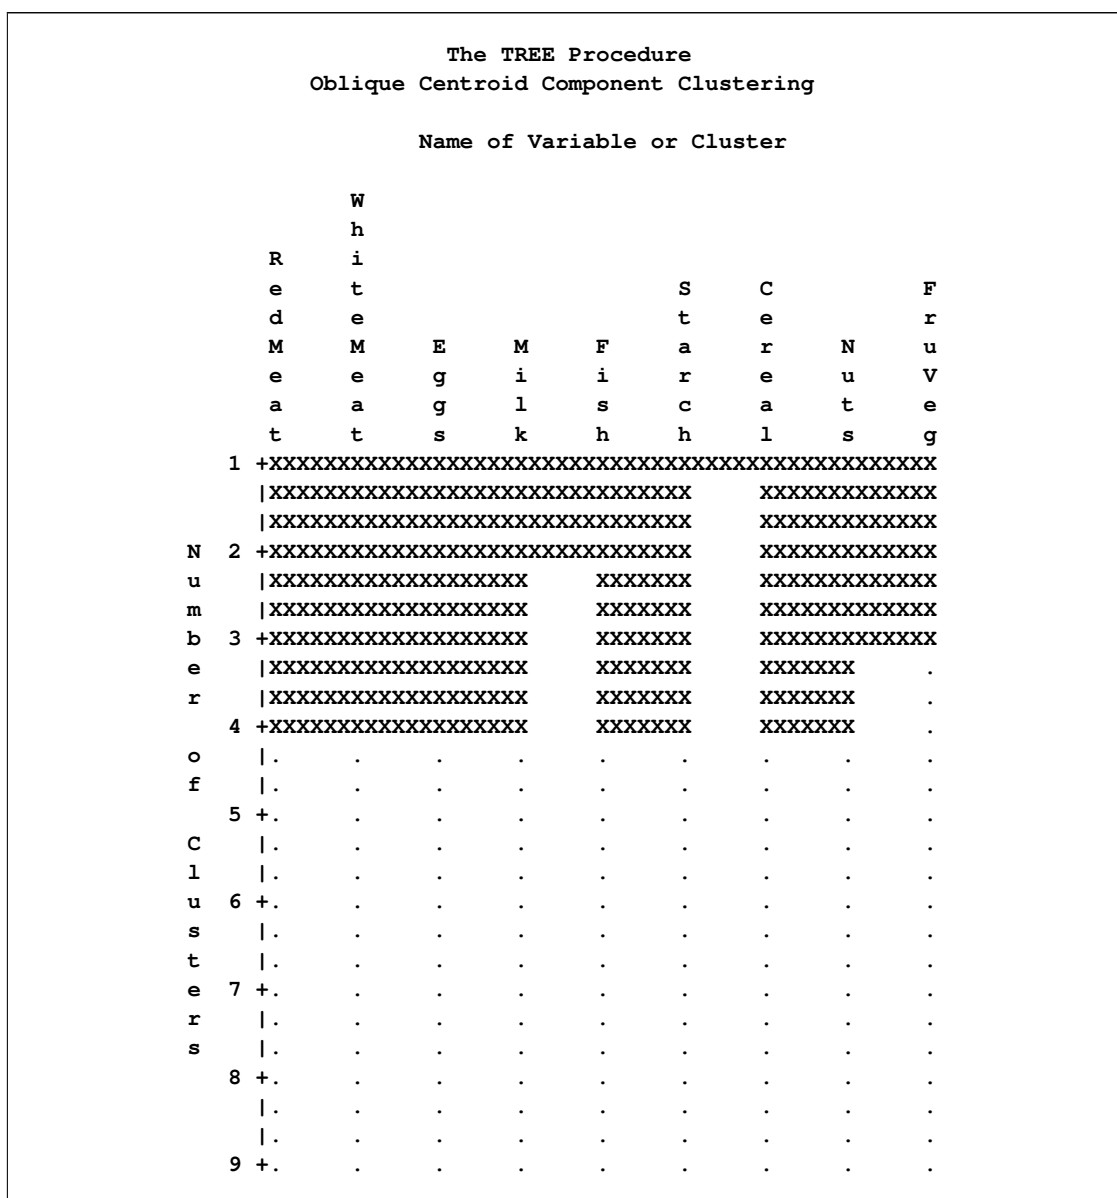

```
proc tree data=tree;
run;

proc tree data=tree lineprinter;
run;
```

PROC TREE is invoked twice. In the first invocation, the tree diagram is presented using the default graphical output. In the second invocation, the LINEPRINTER option specifies line printer output.

Figure 98.2 displays the default graphical representation of the tree diagram. Figure 98.3 displays the same information as Figure 98.2 by using line printer output.

Figure 98.3 Line Printer Representation of the Tree Diagram

In each diagram the name of the cluster is displayed on the horizontal axis and the number of clusters is displayed on the vertical (height) axis.

As you look up from the bottom of either diagram, clusters are progressively joined until a single, all-encompassing cluster is formed at the top (or root) of the tree. Clusters exist at each level of the diagram. For example, at the level where the diagram indicates three clusters, the clusters are as follows:

- Cluster 1: RedMeat WhiteMeat Eggs Milk
- Cluster 2: Fish Starch
- Cluster 3: Cereal Nuts FruVeg

As you proceed up the diagram one level, the number of clusters is two:

- Cluster 1: RedMeat WhiteMeat Eggs Milk Fish Starch
- Cluster 2: Cereal Nuts FruVeg

The following statements illustrate how you can specify the numeric variable that defines the height of each node (cluster) in the tree:

```
axis1 order=(0 to 1 by 0.2);
proc tree data=Tree horizontal haxis=axis1;
    height _PROPOR_;
run;
```

The ORDER= option in the AXIS1 statement (see *SAS/GRAPH: Reference*) specifies the data values in the order in which they are to appear on the axis. The HORIZONTAL option in the PROC TREE statement orients the tree diagram horizontally. The HAXIS= option specifies that the AXIS1 statement be used to customize the appearance of the horizontal axis. The HEIGHT statement specifies the variable _PROPOR_ (the proportion of variance explained) as the height variable.

The resulting tree diagram is shown in [Figure 98.4](#).

Figure 98.4 Horizontal Tree Diagram with `_PROPOR_` as the HEIGHT Variable

As you look from left to right in the diagram, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the tree.

Clusters exist at each level of the diagram, represented by horizontal line segments. Each vertical line segment represents a point where leaves and branches are connected into progressively larger clusters.

For example, three clusters are formed at the leftmost point along the axis where three horizontal line segments exist. At that point, where a vertical line segment connects the Cereal-Nuts and FruVeg clusters, the proportion of variance explained is about 0.6 (`_PROPOR_` = 0.6). At the next clustering level the variables Fish and Starch are clustered with variables RedMeat through Milk, resulting in a total of two clusters. The proportion of variance explained is about 0.45 at that point.

Syntax: TREE Procedure

The following statements are available in the TREE procedure:

```
PROC TREE < options > ;
  NAME variables ;
  HEIGHT variable ;
  PARENT variables ;
  BY variables ;
  COPY variables ;
  FREQ variable ;
  ID variable ;
```

If the input data set has been created by CLUSTER or VARCLUS, the only statement required is the PROC TREE statement. The BY, COPY, FREQ, HEIGHT, ID, NAME, and PARENT statements are described after the PROC TREE statement.

PROC TREE Statement

```
PROC TREE < options > ;
```

The PROC TREE statement invokes the TREE procedure.

Table 98.1 summarizes the options available in the PROC TREE statement.

Table 98.1 PROC TREE Statement Options

Option	Description
Data Sets	
DATA=	specifies input data set
DOCK=	specifies that small clusters not be counted in OUT= data set
LEVEL=	defines disjoint cluster in OUT= data set
NCLUSTERS=	specifies number of clusters in OUT= data set
OUT=	specifies output data set
ROOT=	displays root of a subtree
Cluster Heights	
HEIGHT=	specifies variable for the height axis
DISSIMILAR	specifies that height values indicate dissimilarity
SIMILAR	specifies that height values indicate similarity
Horizontal Trees	
HORIZONTAL	specifies that height axis be horizontal
Sort Order	
DESCENDING	reverses sort order
SORT	sorts children by HEIGHT variable
Displayed Output	
INC=	specifies increment between tick values

Table 98.1 *continued*

Option	Description
LINEPRINTER	displays tree by using line printer graphics
LIST	displays all nodes in tree
MAXHEIGHT=	specifies maximum value on axis
MINHEIGHT=	specifies minimum value on axis
NOPRINT	suppresses display of tree
NTICK=	specifies number of tick intervals
Graphics	
CFRAME=	specifies color of the frame
DESCRIPTION=	specifies catalog description
GOUT=	specifies catalog name
HAXIS=	customizes horizontal axis
HORDISPLAY=	displays horizontal tree with leaves on right
HPAGES=	specifies number of pages to expand tree horizontally
LINES=	specifies line color and thickness, dots at nodes
NAME=	specifies name of graph in catalog
VAXIS=	customizes vertical axis
VPAGES=	specifies number of pages to expand tree vertically
Line Printer Graphics	
PAGES=	specifies number of pages
POS=	specifies number of column positions
SPACES=	specifies number of spaces between objects
TICKPOS=	specifies number of column positions between ticks
FILLCHAR=	specifies fill character between unjoined leaves
JOINCHAR=	specifies character displayed between joined leaves
LEAFCHAR=	specifies character representing clusters with no children
TREECHAR=	specifies character representing clusters with children

CFRAME=*color*

specifies a color for the frame, which is the rectangle bounded by the axes.

DATA=*SAS-data-set*

specifies the input data set that defines the tree. If you omit the DATA= option, the most recently created SAS data set is used.

DESCENDING**DES**

reverses the sort order for the SORT option.

DESCRIPTION=*entry-description*

specifies a description for the graph in the GOUT= catalog. The default is “Proc Tree Graph Output.”

DISSIMILAR**DIS**

specifies that the values of the HEIGHT variable are dissimilarities; that is, a large height value means that the clusters are very dissimilar or far apart.

If neither the SIMILAR nor the DISSIMILAR option is specified, PROC TREE attempts to infer from the data whether the height values are similarities or dissimilarities. If PROC TREE cannot tell this from the data, it issues an error message and does not display a tree diagram.

DOCK=*n*

causes observations in the OUT= data set that have a frequency of *n* or less to be given missing values for the output variables CLUSTER and CLUSNAME. If the NCLUSTERS= option is also specified, DOCK= also prevents clusters with a frequency of *n* or less from being counted toward the number of clusters requested by the NCLUSTERS= option. By default, DOCK=0.

FILLCHAR='c'**FC='c'**

specifies the character displayed between leaves that are not joined into a cluster. The character should be enclosed in single quotes. The default is a blank. The LINEPRINTER option must also be specified.

GOUT=< libref.>member-name

specifies the catalog in which the generated graph is stored. The default is Work.Gseg.

HAXIS=AXIS*n*

specifies that the AXIS*n* statement be used to customize the appearance of the horizontal axis.

HEIGHT=name**H=name**

specifies certain conventional variables to be used for the height axis of the tree diagram. For many situations, the only option you need is the HEIGHT= option. Valid values for *name* and their meanings are as follows:

HEIGHT H	specifies the <code>_HEIGHT_</code> variable.
LENGTH L	defines the height of each node as its path length from the root. This can also be interpreted as the number of ancestors of the node.
MODE M	specifies the <code>_MODE_</code> variable.
NCL N	specifies the <code>_NCL_</code> (number of clusters) variable.
RSQ R	specifies the <code>_RSQ_</code> variable.

See also the section “[HEIGHT Statement](#)” on page 8408. The HEIGHT statement can specify any variable in the input data set to be used for the height axis. In rare cases, you might need to specify either the DISSIMILAR option or the SIMILAR option.

HORDISPLAY=RIGHT

specifies that the graph be oriented horizontally with the leaf nodes on the right side, when the HORIZONTAL option is also specified. By default, the leaf nodes are on the left side.

HORIZONTAL**HOR**

displays the tree diagram with the height axis oriented horizontally. The leaf nodes are on the side specified in the HORDISPLAY= option. If you do not specify the HORIZONTAL option, the height axis is vertical, with the root at the top. When the tree takes up more than one page, horizontal orientation can make the tree diagram considerably easier to read.

HPAGES=*n1*

specifies that the original graph be enlarged to cover *n1* pages. If you also specify the VPAGES=*n2* option, the original graph is enlarged to cover $n1 \times n2$ graphs. For example, if HPAGES=2 and VPAGES=3, then the original graph is generated, followed by $2 \times 3 = 6$ more graphs. In these six graphs, the original is enlarged by a factor of 2 in the horizontal direction and by a factor of 3 in the vertical direction. The graphs are generated in left-to-right and top-to-bottom order.

INC=*n*

specifies the increment between tick values on the height axis. If the HEIGHT variable is _NCL_, the default is usually 1, although a different value can be specified for consistency with other options. For any other HEIGHT variable, the default is some power of 10 times 1, 2, 2.5, or 5.

JOINCHAR='c'**JC='c'**

specifies the character displayed between leaves that are joined into a cluster. The character should be enclosed in single quotes. The default is 'X'. The LINEPRINTER option must also be specified.

LEAFCHAR='c'**LC='c'**

specifies the character used to represent clusters that have no children. The character should be enclosed in single quotes. The default is a period. The LINEPRINTER option must also be specified.

LEVEL=*n*

specifies the level of the tree that defines disjoint clusters for the OUT= data set. The LEVEL= option also causes only clusters between the root and a height of *n* to be displayed. The clusters in the output data set are those that exist at a height of *n* on the tree diagram. For example, if the HEIGHT variable is _NCL_ (number of clusters) and LEVEL=5 is specified, then the OUT= data set contains five disjoint clusters. If the HEIGHT variable is _RSQ_ (R square) and LEVEL=0.9 is specified, then the OUT= data set contains the smallest number of clusters that yields an R square of at least 0.9.

LINEPRINTER

specifies that the tree diagram be displayed using line printer graphics.

LINES=(< COLOR=*color* > < WIDTH=*n* > < DOTS >)

specifies the color and the thickness of the lines of the tree, and whether a dot is drawn at each leaf node. If the frame and the lines are specified to be the same color, PROC TREE selects a different color for the lines.

LIST

lists all the nodes in the tree, displaying the height, parent, and children of each node.

MAXHEIGHT=*n***MAXH=*n***

specifies the maximum value displayed on the height axis.

MINHEIGHT=*n***MINH=*n***

specifies the minimum value displayed on the height axis.

NAME=*name*

specifies the entry name for the generated graph in the GOUT= catalog. Each time another graph is generated with the same name, the name is modified by appending a number to make it unique.

NCLUSTERS=*n***NCL=*n*****N=*n***

specifies the number of clusters desired in the OUT= data set. The number of clusters obtained might not equal the number specified if (1) there are fewer than *n* leaves in the tree, (2) there are more than *n* unconnected trees in the data set, (3) a multiway tree does not contain a level with the specified number of clusters, or (4) the DOCK= option eliminates too many clusters.

The NCLUSTERS= option uses the `_NCL_` variable to determine the order in which the clusters are formed. If there is no `_NCL_` variable, the height variable (as determined by the HEIGHT statement or HEIGHT= option) is used instead.

NTICK=*n*

specifies the number of tick intervals on the height axis. The default depends on the values of other options.

NOPRINT

suppresses the display of the tree. Specify the NOPRINT option if you want only to create an OUT= data set.

OUT=*SAS-data-set*

creates an output data set that contains one observation for each object in the tree or subtree being processed and variables called CLUSTER and CLUSNAME that show cluster membership at any specified level in the tree. If you specify the OUT= option, you must also specify either the NCLUSTERS= or LEVEL= option in order to define the output partition level. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

PAGES=*n*

specifies the number of pages over which the tree diagram (from root to leaves) is to extend. The default is 1. The LINEPRINTER option must also be specified.

POS=*n*

specifies the number of column positions on the height axis. The default depends on the value of the PAGES= option, the orientation of the tree diagram, and the values specified by the PAGESIZE= and LINESIZE= options. The LINEPRINTER option must also be specified.

ROOT='name'

specifies the value of the NAME statement variable for the root of a subtree to be displayed if you do not want to display the entire tree. If you also specify the OUT= option, the output data set contains only objects that belong to the subtree specified by the ROOT= option.

SIMILAR**SIM**

specifies that the values of the HEIGHT variable represent similarities; that is, a large height value means that the clusters are very similar or close together.

If neither the SIMILAR nor the DISSIMILAR option is specified, PROC TREE attempts to infer from the data whether the height values are similarities or dissimilarities. If PROC TREE cannot tell this from the data, it issues an error message and does not display a tree diagram.

SORT

sorts the children of each node by the HEIGHT variable, in the order of cluster formation. See the **DESCENDING** option for details.

SPACES=s**S=s**

specifies the number of spaces between objects in the output. The default depends on the number of objects, the orientation of the tree diagram, and the values specified by the PAGESIZE= and LINE-SIZE= options. The LINEPRINTER option must also be specified.

TICKPOS=n

specifies the number of column positions per tick interval on the height axis. The default value is usually between 5 and 10, although a different value can be specified for consistency with other options.

TREECHAR='c'**TC='c'**

specifies the character used to represent clusters with children. The character should be enclosed in single quotes. The default is 'X'. The LINEPRINTER option must also be specified.

VAXIS=AXISn

specifies that the AXISn statement be used to customize the appearance of the vertical axis.

VPAGES=n2

specifies that the original graph be enlarged to cover $n2$ pages. If you also specify the HPAGES= $n1$ option, the original graph is enlarged to cover $n1 \times n2$ pages. For example, if HPAGES=2 and VPAGES=3, then the original graph is generated, followed by $2 \times 3 = 6$ more graphs. In these six graphs, the original is enlarged by a factor of 2 in the horizontal direction and by a factor of 3 in the vertical direction. The graphs are generated in left-to-right and top-to-bottom order.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC TREE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the TREE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

COPY Statement

COPY *variables* ;

The COPY statement specifies one or more character or numeric variables to be copied to the OUT= data set.

FREQ Statement

FREQ *variable* ;

The FREQ statement specifies one numeric variable that tells how many clustering observations belong to the cluster. If the FREQ statement is omitted, PROC TREE uses the variable _FREQ_ to specify the number of observations per cluster. If neither the FREQ statement nor the _FREQ_ variable is present, each leaf is assumed to represent one clustering observation, and the frequency for each internal node is found by summing the frequencies of its children.

HEIGHT Statement

HEIGHT *variable* ;

The HEIGHT statement specifies the name of a numeric variable to define the height of each node (cluster) in the tree. The height variable can also be specified by the HEIGHT= option in the PROC TREE statement. If both the HEIGHT statement and the HEIGHT= option are omitted, PROC TREE uses the variable _HEIGHT_. If the data set does not contain _HEIGHT_, PROC TREE uses the variable _NCL_. If _NCL_ is not present either, the height of each node is defined to be its path length from the root.

ID Statement

ID *variable* ;

The ID variable is used to identify the objects (leaves) in the tree on the output. The ID variable can be a character or numeric variable of any length. If the ID statement is omitted, the variable in the NAME statement is used instead. If both the ID and NAME statements are omitted, PROC TREE uses the variable _NAME_. If the _NAME_ variable is not found in the data set, PROC TREE issues an error message and stops. The ID variable is copied to the OUT= data set.

NAME Statement

NAME *variable* ;

The NAME statement specifies a character or numeric variable that identifies the node represented by each observation. The NAME statement variable and the PARENT statement variable jointly define the tree structure. If the NAME statement is omitted, PROC TREE uses the variable _NAME_. If the _NAME_ variable is not found in the data set, PROC TREE issues an error message and stops.

PARENT Statement

PARENT *variable* ;

The PARENT statement specifies a character or numeric variable that identifies the node in the tree that is the parent of each observation. The PARENT statement variable must have the same formatted length as the NAME statement variable. If the PARENT statement is omitted, PROC TREE uses the variable _PARENT_. If the _PARENT_ variable is not found in the data set, PROC TREE issues an error message and stops.

Details: TREE Procedure

Missing Values

An observation with a missing value for the NAME statement variable is omitted from processing. If the PARENT statement variable has a missing value but the NAME statement variable is present, the observation is treated as the root of a tree. A data set can contain several roots and, hence, several trees.

Missing values of the HEIGHT variable are set to upper or lower bounds determined from the nonmissing values under the assumption that the heights are monotonic with respect to the tree structure.

Missing values of the FREQ variable are inferred from nonmissing values where possible; otherwise, they are treated as zero.

Output Data Set

The OUT= data set contains one observation for each leaf in the tree or subtree being processed. The variables are as follows:

- the BY variables, if any
- the ID variable, or the NAME statement variable if the ID statement is not used
- the COPY variables
- a numeric variable CLUSTER that takes values from 1 to c , where c is the number of disjoint clusters. The cluster to which the first observation belongs is given the number 1, the cluster to which the next observation belongs that does not belong to cluster 1 is given the number 2, and so on.
- a character variable CLUSNAME that gives the value of the NAME statement variable of the cluster to which the observation belongs

The CLUSTER and CLUSNAME variables are missing if the corresponding leaf has a nonpositive frequency.

Displayed Output

The displayed output from the TREE procedure includes the following:

- the names of the objects in the tree
- the height axis
- the tree diagram.

The leaves of the tree diagram are displayed at the bottom of the graph. Horizontal lines connect the leaves into branches, while the topmost horizontal line indicates the root.

If the `LINEPRINTER` option is specified, the root (the cluster that contains all the objects) is indicated by a solid line of the character specified by the `TREECHAR=` option (the default character is 'X'). At each level of the tree, clusters are shown by unbroken lines of the `TREECHAR=` symbol with the `FILLCHAR=` symbol (the default is a blank) separating the clusters. The `LEAFCHAR=` symbol (the default character is a period) represents single-member clusters.

By default, the tree diagram is oriented with the height axis vertical and the object names at the top of the diagram. If the `HORIZONTAL` option is specified, then the height axis is horizontal and the object names are on the left.

ODS Table Names

PROC TREE assigns a name to each table it creates. You can use table names to refer to tables when using the Output Delivery System (ODS) to select tables and create output data sets. The name of PROC TREE's only table is listed in [Table 98.2](#). For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 98.2 ODS Tables Produced by PROC TREE

ODS Table Name	Description	Statement	Option
TreeListing	Listing of all nodes in the tree	PROC	LIST

Examples: TREE Procedure

Example 98.1: Mammals' Teeth

The following statements produce a data set that contains the numbers of different kinds of teeth for a variety of mammals:

```
data teeth;
  title 'Mammals' Teeth';
  input mammal & $16. v1-v8 @@;
  label v1='Right Top Incisors'
        v2='Right Bottom Incisors'
        v3='Right Top Canines'
        v4='Right Bottom Canines'
        v5='Right Top Premolars'
        v6='Right Bottom Premolars'
        v7='Right Top Molars'
        v8='Right Bottom Molars';
  datalines;
Brown Bat      2 3 1 1 3 3 3 3   Mole             3 2 1 0 3 3 3 3

;
```

The following statements use the CLUSTER procedure to cluster the mammals by average linkage and use ODS Graphics and the TREE procedure to produce a horizontal tree diagram that uses the average-linkage distance as its height axis:

```
ods graphics on;

proc cluster method=average std pseudo noeigen outtree=tree;
  id mammal;
  var v1-v8;
run;

proc tree horizontal;
run;
```

Output 98.1.1 displays the information about how the clusters are joined. For example, the cluster history shows that the mammals ‘Wolf’ and ‘Bear’ form cluster 29, which is merged with ‘Raccoon’ to form cluster 11.

Output 98.1.1 Output from PROC CLUSTER

Output 98.1.2 shows the tree diagram produced by PROC CLUSTER.

Output 98.1.2 Dendrogram from PROC CLUSTER

Output 98.1.3 shows the corresponding tree diagram produced by PROC TREE.

Output 98.1.3 Tree Diagram of Mammal Teeth Clusters

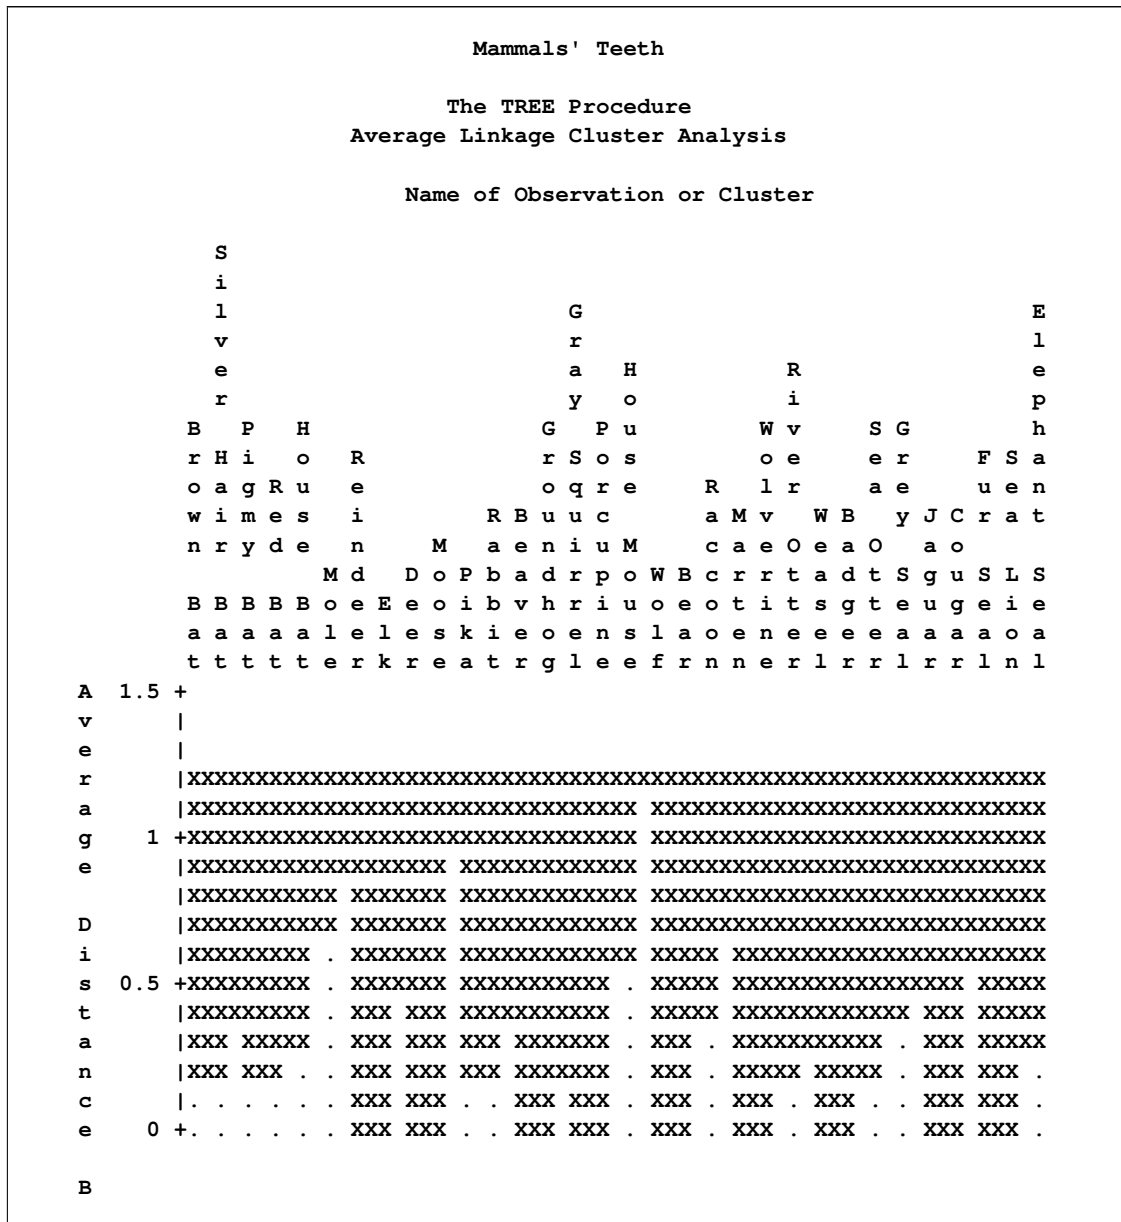

As you view the diagram in [Output 98.1.3](#) from left to right, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the tree. Clusters exist at each level of the diagram, and every vertical line connects leaves and branches into progressively larger clusters. For example, the five bats form a cluster at the 0.6 level, while the next cluster consists only of the mole. The mammals 'Reindeer', 'Elk', 'Deer', and 'Moose' form the next cluster at the 0.6 level, the mammals 'Pika' through 'House Mouse' are in the fourth cluster, the mammals 'Wolf', 'Bear', and 'Raccoon' form the fifth cluster, and the last cluster contains the mammals 'Marten' through 'Elephant Seal'.

The following statements create the same tree with line printer graphics in a vertical orientation:

```
proc tree lineprinter;
run;
```

The tree is displayed in [Output 98.1.4](#).

Output 98.1.4 PROC TREE with the LINEPRINTER Option

As you look up from the bottom of the diagram, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the top (or root) of the root. Clusters exist at each level of the diagram. For example, the unbroken line of Xs at the leftmost side of the 0.6 level indicates that the five bats have formed a cluster. The next cluster is represented by a period because it contains only one mammal, 'Mole'. The mammals 'Reindeer', 'Elk', 'Deer', and 'Moose' form the next cluster, indicated by Xs again. The mammals 'Pika' through 'House Mouse' are in the fourth cluster. The mammals 'Wolf', 'Bear', and 'Raccoon' form the fifth cluster, while the last cluster contains the mammals 'Marten' through 'Elephant Seal'.

The next statements sort the clusters at each branch in order of formation and use the number of clusters as the height axis:

```
proc tree sort height=n horizontal;
run;
```

The resulting tree is displayed in [Output 98.1.5](#).

Output 98.1.5 PROC TREE with SORT and HEIGHT= Options

Because the CLUSTER procedure always produces binary trees, the number of internal (root and branch) nodes in the tree is one less than the number of leaves. Therefore 31 clusters are formed from the 32 mammals in the input data set. These are represented by the 31 vertical line segments in the tree diagram, each at a different value along the horizontal axis.

As you examine the tree from left to right, the first vertical line segment is where 'Beaver' and 'Groundhog' are clustered and the number of clusters is 31. The next cluster is formed from 'Gray Squirrel' and 'Porcupine'. The third contains 'Wolf' and 'Bear'. Note how the tree graphically displays the clustering order information that was presented in tabular form by the CLUSTER procedure in [Output 98.1.1](#).

The same clusters as in [Output 98.1.3](#) and [Output 98.1.4](#) can be seen at the six-cluster level of the tree diagram in [Output 98.1.5](#), although the SORT and HEIGHT= options make them appear in a different order.

The following statements create these six clusters and save the result in the output data set part:

```
proc tree noprint out=part nclusters=6;
  id mammal;
  copy v1-v8;
run;

proc sort;
  by cluster;
run;
```

PROC TREE with the NOPRINT option displays no output but creates an output data set that indicates the cluster to which each observation belongs at the six-cluster level in the tree. The following statements print the data set part, with the results shown in [Output 98.1.6](#):

```
proc print label uniform;
  id mammal;
  var v1-v8;
  format v1-v8 1.;
  by cluster;
run;
```

Output 98.1.6 PROC TREE OUT= Data Set

Example 98.2: Iris Data

Fisher (1936)'s iris data give sepal and petal dimensions for three different species of iris. The data, which are available in the Sashelp library, are clustered by *k*th-nearest-neighbor density linkage by using the CLUSTER procedure with K=8. Observations are identified by species ('Setosa', 'Versicolor', or 'Virginica') in the tree diagram, which is oriented with the height axis horizontal.

The following statements produce the results shown in [Output 98.2.1](#) and [Output 98.2.2](#):

```
title 'Fisher (1936) Iris Data';
ods graphics on;

proc cluster data=sashelp.iris method=twostage print=10
            outtree=tree k=8 noeigen;
    var SepalLength SepalWidth PetalLength PetalWidth;
    copy Species;
run;

proc tree data=tree horizontal lineprinter pages=1 maxh=10;
    id species;
run;
```

The PAGES=1 option specifies that the tree diagram extend over one page from tree to root. Since the HORIZONTAL option is also specified, the horizontal extent of the diagram is one page. The number of vertical pages required for the diagram is dictated by the number of leaves in the tree.

The MAXH=10 limits the values displayed on the height axis to a maximum of 10. This prunes the tree diagram so that only the portion from the leaves to level 10 is displayed. You can see this pruning effect in [Output 98.2.2](#).

Output 98.2.1 Clustering of Fisher's Iris Data

Fisher (1936) Iris Data

Overview: TTEST Procedure

The TTEST procedure performs t tests and computes confidence limits for one sample, paired observations, two independent samples, and the AB/BA crossover design. Two-sided, TOST (two one-sided test) equivalence, and upper and lower one-sided hypotheses are supported for means, mean differences, and mean ratios for either normal or lognormal data.

Table 99.1 summarizes the designs, analysis criteria, hypotheses, and distributional assumptions supported in the TTEST procedure, along with the syntax used to specify them.

Table 99.1 Features Supported in the TTEST Procedure

Feature	Syntax
Design

Normal	PROC TTEST DIST=NORMAL
Lognormal	PROC TTEST DIST=LOGNORMAL

FREQ and WEIGHT statements are available. Data can be input in the form of observations or, in certain cases, summary statistics. Output includes summary statistics; confidence limits for means, standard deviations, and coefficients of variation; hypothesis tests; and a variety of graphical displays, including histograms, densities, box plots, confidence intervals, Q-Q plots, profiles, and agreement plots.

PROC TTEST uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the statistical graphics available with the TTEST procedure, see the PLOTS option in the PROC TTEST statement and the section “ODS Graphics” on page 8465.

Getting Started: TTEST Procedure

One-Sample t Test

A one-sample t test can be used to compare a sample mean to a given value. This example, taken from Huntsberger and Billingsley (1989, p. 290), tests whether the mean length of a certain type of court case is more than 80 days by using 20 randomly chosen cases. The data are read by the following DATA step:

```
data time;
  input time @@;
  datalines;
  43  90  84  87  116  95  86  99  93  92
  121  71  66  98  79  102  60  112  105  98
  ;
```

The only variable in the data set, time, is assumed to be normally distributed. The trailing at signs (@@) indicate that there is more than one observation on a line. The following statements invoke PROC TTEST for a one-sample t test:

```
ods graphics on;

proc ttest h0=80 plots(showh0) sides=u alpha=0.1;
  var time;
run;

ods graphics off;
```

The **VAR** statement indicates that the time variable is being studied, while the **H0=** option specifies that the mean of the time variable should be compared to the null value 80 rather than the default of 0. The **PLOTS(SHOWH0)** option requests that this null value be displayed on all relevant graphs. The **SIDES=U** option reflects the focus of the research question, namely whether the mean court case length is *greater than* 80 days, rather than *different than* 80 days (in which case you would use the default **SIDES=2** option). The **ALPHA=0.1** option requests 90% confidence intervals rather than the default 95% confidence intervals. The output is displayed in Figure 99.1.

Figure 99.1 One-Sample t Test Results

The TTEST Procedure					
Variable: time					
N	Mean	Std Dev	Std Err	Minimum	Maximum
20	89.8500	19.1456	4.2811	43.0000	121.0
Mean	90% CL Mean	Std Dev	90% CL Std Dev		
89.8500	84.1659 Infty	19.1456	15.2002 26.2374		

Figure 99.1 continued

DF	t Value	Pr > t
19	2.30	0.0164

Summary statistics appear at the top of the output. The sample size (N), mean, standard deviation, and standard error are displayed with the minimum and maximum values of the time variable. The 90% confidence limits for the mean and standard deviation are shown next. Due to the `SIDES=U` option, the interval for the mean is an upper one-sided interval with a finite lower bound (84.1659 days). The limits for the standard deviation are the equal-tailed variety, per the default `CI=EQUAL` option in the `PROC TTEST` statement. At the bottom of the output are the degrees of freedom, *t* statistic value, and *p*-value for the *t* test. At the 10% α level, this test indicates that the mean length of the court cases is significantly greater than from 80 days ($t = 2.30$, $p = 0.0164$).

The summary panel in Figure 99.2 shows a histogram with overlaid normal and kernel densities, a box plot, the 90% confidence interval for the mean, and the null value of 80 days.

Figure 99.2 Summary Panel

The confidence interval excludes the null value, consistent with the rejection of the null hypothesis at $\alpha = 0.1$.

The Q-Q plot in Figure 99.3 assesses the normality assumption.

Figure 99.3 Q-Q Plot

The curvilinear shape of the Q-Q plot suggests a possible slight deviation from normality. You could use the UNIVARIATE procedure with the NORMAL option to numerically check the normality assumptions.

Comparing Group Means

If you want to compare values obtained from two different groups, and if the groups are independent of each other and the data are normally or lognormally distributed in each group, then a group t test can be used. Examples of such group comparisons include the following:

- test scores for two third-grade classes, where one of the classes receives tutoring
- fuel efficiency readings of two automobile nameplates, where each nameplate uses the same fuel

- sunburn scores for two sunblock lotions, each applied to a different group of people
- political attitude scores of males and females

In the following example, the golf scores for males and females in a physical education class are compared. The sample sizes from each population are equal, but this is not required for further analysis. The scores are thought to be approximately normally distributed within gender. The data are read by the following statements:

```
data scores;
  input Gender $ Score @@;
  datalines;
f 75 f 76 f 80 f 77 f 80 f 77 f 73
m 82 m 80 m 85 m 85 m 78 m 87 m 82
;
```

The dollar sign (\$) following Gender in the INPUT statement indicates that Gender is a character variable. The trailing at signs (@@) enable the procedure to read more than one observation per line.

You can use a group *t* test to determine whether the mean golf score for the men in the class differs significantly from the mean score for the women. If you also suspect that the distributions of the golf scores of males and females have unequal variances, then you might want to specify the **COCHRAN** option in order to use the Cochran approximation (in addition to the Satterthwaite approximation, which is included by default). The following statements invoke PROC TTEST for the case of unequal variances, along with both types of confidence limits for the pooled standard deviation.

```
ods graphics on;

proc ttest cochran ci=equal umpu;
  class Gender;
  var Score;
run;

ods graphics off;
```

The **CLASS** statement contains the variable that distinguishes the groups being compared, and the **VAR** statement specifies the response variable to be used in calculations. The **COCHRAN** option produces *p*-values for the unequal variance situation by using the Cochran and Cox (1950) approximation. Equal-tailed and uniformly most powerful unbiased (UMPU) confidence intervals for σ are requested by the **CI=** option. Output from these statements is displayed in Figure 99.4 through Figure 99.7.

Figure 99.4 Simple Statistics

The TTEST Procedure						
Variable: Score						
Gender	N	Mean	Std Dev	Std Err	Minimum	Maximum
f	7	76.8571	2.5448	0.9619	73.0000	80.0000
m	7	82.7143	3.1472	1.1895	78.0000	87.0000
Diff (1-2)		-5.8571	2.8619	1.5298		

Simple statistics for the two populations being compared, as well as for the difference of the means between the populations, are displayed in [Figure 99.4](#). The Gender column indicates the population corresponding to the statistics in that row. The sample size (N), mean, standard deviation, standard error, and minimum and maximum values are displayed.

Confidence limits for means and standard deviations are shown in [Figure 99.5](#).

Figure 99.5 Simple Statistics

Gender	Method	Mean	95% CL Mean		Std Dev
f		76.8571	74.5036	79.2107	2.5448
m		82.7143	79.8036	85.6249	3.1472
Diff (1-2)	Pooled	-5.8571	-9.1902	-2.5241	2.8619
Diff (1-2)	Satterthwaite	-5.8571	-9.2064	-2.5078	

Gender	Method	95% CL Std Dev		95% UMPU CL Std Dev	
f		1.6399	5.6039	1.5634	5.2219
m		2.0280	6.9303	1.9335	6.4579
Diff (1-2)	Pooled	2.0522	4.7242	2.0019	4.5727
Diff (1-2)	Satterthwaite				

For the mean differences, both pooled (assuming equal variances for males and females) and Satterthwaite (assuming unequal variances) 95% intervals are shown. The confidence limits for the standard deviations are of the equal-tailed variety.

The test statistics, associated degrees of freedom, and p -values are displayed in [Figure 99.6](#).

Figure 99.6 t Tests

Method	Variances	DF	t Value	Pr > t
Pooled	Equal	12	-3.83	0.0024
Satterthwaite	Unequal	11.496	-3.83	0.0026
Cochran	Unequal	6	-3.83	0.0087

The Method column denotes which t test is being used for that row, and the Variances column indicates what assumption about variances is being made. The pooled test assumes that the two populations have equal variances and uses degrees of freedom $n_1 + n_2 - 2$, where n_1 and n_2 are the sample sizes for the two populations. The remaining two tests do not assume that the populations have equal variances. The Satterthwaite test uses the Satterthwaite approximation for degrees of freedom, while the Cochran test uses the Cochran and Cox approximation for the p -value. All three tests result in highly significant p -values, supporting the conclusion of a significant difference between males' and females' golf scores.

The "Equality of Variances" test in [Figure 99.7](#) reveals insufficient evidence of unequal variances (the Folded F statistic $F' = 1.53$, with $p = 0.6189$).

Figure 99.7 Tests of Equality of Variances

Equality of Variances				
Method	Num DF	Den DF	F Value	Pr > F
Folded F	6	6	1.53	0.6189

The summary panel in [Figure 99.8](#) shows comparative histograms, normal and kernel densities, and box plots, comparing the distribution of golf scores between genders.

Figure 99.8 Summary Panel

The Q-Q plots in [Output 99.9](#) assess the normality assumption for each gender.

Figure 99.9 Q-Q Plot

The plots for both males and females show no obvious deviations from normality. You can check the assumption of normality more rigorously by using PROC UNIVARIATE with the NORMAL option; if the assumption of normality is not reasonable, you should analyze the data with the nonparametric Wilcoxon rank sum test by using PROC NPAR1WAY.

Syntax: TTEST Procedure

The following statements are available in the TTEST procedure:

```
PROC TTEST < options > ;
  CLASS variable ;
  PAIRED variables ;
  BY variables ;
  VAR variables < / options > ;
  FREQ variable ;
  WEIGHT variable ;
```

No statement can be used more than once. There is no restriction on the order of the statements after the PROC TTEST statement.

PROC TTEST Statement

PROC TTEST < options > ;

The **PROC TTEST** statement invokes the TTEST procedure. Table 99.2 summarizes the options available in the **PROC TTEST** statement. The options are then described fully in alphabetical order.

Table 99.2 PROC TTEST Statement Options

Option	Description
Basic Options	
DATA=	Specifies input data set
ORDER=	Determines sort order of CLASS variable or CROSSOVER= treatment variables
Analysis Options	
ALPHA=	Specifies 1 – confidence level
DIST=	Specifies distributional assumption (normal or lognormal)
H0=	Specifies null value
SIDES=	Specifies number of sides and direction
TEST=	Specifies test criterion (difference or ratio)
TOST	Requests equivalence test and specifies bounds
Displayed Output	
CI=	Requests confidence interval for standard deviation or CV
COCHRAN	Requests Cochran <i>t</i> test
PLOTS	Produces ODS statistical graphics
Output Ordering	
BYVAR	Groups results by PAIRED or VAR variables
NOBYVAR	Groups results by tables

The following options can appear in the **PROC TTEST** statement.

ALPHA=*p*

specifies that confidence intervals (except test-based mean confidence intervals when the **TOST** option is used) are to be $100(1 - p)\%$ confidence intervals, where $0 < p < 1$. When the **TOST** option is used, the test-based mean confidence intervals are $100(1 - 2p)\%$ confidence intervals. By default, PROC TTEST uses **ALPHA=0.05**. If *p* is 0 or less, or 1 or more, an error message is printed.

BYVAR

groups the results by the **PAIRED** or **VAR** variables. The **BYVAR** option is enabled by default. Note that this represents a change from previous releases for how the results are grouped with respect to variables and tables. Prior to SAS 9.2, multiple variables were included in each table, similar to the new **NOBYVAR** option.

CI=EQUAL | UMPU | NONE**CL=EQUAL | UMPU | NONE**

specifies whether a confidence interval is displayed for σ and, if so, what kind. The **CI=EQUAL** option specifies an equal-tailed confidence interval, and it is the default. The **CI=UMPU** option specifies an interval based on the uniformly most powerful unbiased test of $H_0: \sigma = \sigma_0$. The **CI=NONE** option requests that no confidence interval be displayed for σ . The values **EQUAL** and **UMPU** together request that both types of confidence intervals be displayed. If the value **NONE** is specified with one or both of the values **EQUAL** and **UMPU**, **NONE** takes precedence. For more information, see the section “[Two-Independent-Sample Design](#)” on page 8455.

COCHRAN

requests the Cochran and Cox (1950) approximation of the probability level for the unequal variances situation. For more information, see the section “[Two-Independent-Sample Design](#)” on page 8455.

DATA=SAS-data-set

names the SAS data set for the procedure to use. By default, PROC TTEST uses the most recently created SAS data set. The input data set can contain summary statistics of the observations instead of the observations themselves. The number, mean, and standard deviation of the observations are required for each **BY** group (one sample and paired differences) or for each class within each **BY** group (two samples). For more information about the **DATA=** option, see the section “[Input Data Set of Statistics](#)” on page 8449.

DIST=LOGNORMAL | NORMAL

specifies the underlying distribution assumed for the data. The default is **NORMAL**, unless **TEST=RATIO** is specified, in which case the default is **LOGNORMAL**.

H0=m

requests tests against a null value of m , unless the **TOST** option is used, in which case m is merely used to derive the lower and upper equivalence bounds. For the crossover design, the value m applies for both treatment and period tests. By default, PROC TTEST uses **H0=0** when **TEST=DIFF** (or **DIST=NORMAL** for a one-sample design) and **H0=1** when **TEST=RATIO** (or **DIST=LOGNORMAL** for a one-sample design).

NOBYVAR

includes all **PAIRED** or **VAR** variables together in each output table. If the **NOBYVAR** option is not specified, then the **BYVAR** option is enabled, grouping the results by the **PAIRED** and **VAR** variables.

ORDER=DATA | FORMATTED | FREQ | INTERNAL | MIXED

specifies the order in which to sort the levels of the classification variables (which are specified in the **CLASS** statement) and treatment variables (which are specified in the **CROSSOVER=** option in the **VAR** statement). The default is **ORDER=MIXED**, which corresponds to the ordering in releases previous to SAS 9.2.

This option applies to the levels for all classification or treatment variables, except when you use the **ORDER=FORMATTED** option with numeric classification or treatment variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set.
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value.
FREQ	Descending frequency count; levels with the most observations come first in the order. In the event of a tie, ORDER=MIXED is used.
INTERNAL	Unformatted value.
MIXED	Same as ORDER=FORMATTED if the unformatted variable is character-valued; same as ORDER=INTERNAL otherwise (the unformatted variable is numeric-valued).

For FORMATTED and INTERNAL, the sort order is machine-dependent.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

PLOTS <(global-plot-options)> <= plot-request <(options)>>

PLOTS <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>)>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=(histogram boxplot interval qq profiles agreement)
plots(unpack)=summary
plots(showh0)=interval(type=pergroup)
plots=(summary(unpack) interval(type=period))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc ttest plots=all;
    var oxygen;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled but you do not specify the **PLOTS** option, then PROC TTEST produces a default set of plots. (**NOTE:** The graphical results are unavailable if your input data set contains summary statistics rather than observation values.)

For a one-sample design, the default plots are the following:

- summary plot (histogram with overlaid normal and kernel densities, box plot, and confidence interval band)
- Q-Q plot

For a two-independent-sample design, the default plots are the following:

- summary plot (comparative histograms with overlaid densities and box plots)
- Q-Q plot

For a paired design, the default plots are the following:

- summary plot (histogram, densities, box plot, and confidence interval) of the difference or ratio
- Q-Q plot of the difference or ratio
- profiles plot
- agreement plot

For a crossover design, the default plots are the following:

- comparative histograms with overlaid densities by treatment and period
- comparative box plots by treatment and period
- Q-Q plots by treatment and period
- profiles over treatment plot
- agreement of treatments plot

For more detailed descriptions of plots, see the section “[Interpreting Graphs](#)” on page 8466.

The global plot options include the following:

ONLY

suppresses the default plots. Only plots specifically requested are displayed.

SHOWH0

SHOWNULL

shows the null value (as specified by the **H0=** option in the **PROC TTEST** statement) in all relevant plots. For one-sample and paired designs, the null value can appear in **SUMMARY**, **BOX**, and **INTERVAL**. For two-independent-sample and crossover designs, the null value can appear only in **INTERVAL**.

UNPACKPANEL

UNPACK

suppresses paneling. By default, multiple plots can appear in some output panels. Specify **UNPACKPANEL** to get each plot in a separate panel. You can specify **PLOTS(UNPACKPANEL)** to unpack the default plots. You can also specify **UNPACK** as a suboption with **SUMMARY**.

The plot requests include the following:

ALL

produces all appropriate plots. You can specify other options with **ALL**; for example, to request all plots and specify that intervals should be for the period difference in a crossover design, specify **PLOTS=(ALL INTERVAL(TYPE=PERIOD))**.

AGREEMENT

AGREEMENTPLOT

requests an agreement plot. This plot is produced by default for paired and crossover designs, the only designs for which the **AGREEMENT** option is valid.

For paired designs, the second response in each pair is plotted against the first response. See the section “[Agreement Plots for Paired Designs](#)” on page 8466 for further details.

For crossover designs, the **AGREEMENT** plot request has the following options:

TYPE=PERIOD

plots the response in the second period against the response in the first period. See the section “[Period Agreement Plots for Crossover Designs](#)” on page 8466 for further details.

TYPE=TREATMENT

plots the response associated with the second treatment against the response associated with the first treatment. This is the default **TYPE=** option for crossover designs. See the section “[Treatment Agreement Plots for Crossover Designs](#)” on page 8467 for further details.

BOX

BOXPLOT

requests a box plot or comparative box plots. This plot is produced by default for crossover designs. For other designs, a box plot appears as part of the **SUMMARY** plot by default.

For one-sample and paired designs, a confidence interval for the mean is shown as a band in the background, along with the equivalence bounds if the **TOST** option is used in the **PROC TTEST** statement.

For a two-independent-sample design, comparative box plots (one for each class) are shown. For a crossover design, comparative box plots for all four combinations of the two treatments and two periods are shown.

See the section “[Box Plots](#)” on page 8467 for further details.

HISTOGRAM

HIST

HISTDENS

requests a histogram or comparative histograms with overlaid normal and kernel densities. This plot is produced by default for crossover designs. For other designs, it appears as part of the **SUMMARY** plot by default.

For one-sample and paired designs, the histogram and densities are based on the test criterion (which is the mean difference or ratio for a paired design). For a two-independent-sample design, comparative histograms (one for each class) are shown. For a crossover design, histograms for all four combinations of the two treatments and two periods are shown.

See the section “[Histograms](#)” on page 8467 for further details.

INTERVAL**INTERVALPLOT**

requests plots of confidence interval for means.

For a two-independent-sample design, the **INTERVAL** plot request has the following options:

TYPE=PERGROUP

shows two separate two-sided confidence intervals, one for each class. This option cannot be used along with the **SHOWH0** global plot option.

TYPE=TEST

shows pooled and Satterthwaite confidence intervals. This is the default **TYPE=** option for two-independent-sample designs.

For a crossover design, The **INTERVAL** plot request has the following options:

TYPE=PERGROUP

shows four separate two-sided intervals, one for each treatment-by-period combination. This option cannot be used along with the **SHOWH0** global plot option.

TYPE=PERIOD

shows pooled and Satterthwaite confidence intervals for the period difference or ratio. This option is invalid if the **IGNOREPERIOD** option is used in the **VAR** statement.

TYPE=TREATMENT

shows pooled and Satterthwaite confidence intervals for the treatment difference or ratio. This is the default **TYPE=** option for crossover designs.

See the section “[Confidence Intervals](#)” on page 8467 for further details.

NONE

suppresses all plots.

PROFILES**PROFILESPLOT**

requests a profiles plot. This plot is produced by default for paired and crossover designs, the only designs for which the **PROFILES** option is valid.

For paired designs, a line is drawn for each observation from left to right connecting the first response to the second response. See the section “[Profiles for Paired Designs](#)” on page 8468 for further details.

For crossover designs, the **PROFILES** plot request has the following options:

TYPE=PERIOD

shows response profiles over period, connecting the first period on the left to the second period on the right for each subject. See the section “[Profiles over Period for Crossover Designs](#)” on page 8468 for further details.

TYPE=TREATMENT

shows response profiles over treatment values, connecting the first treatment on the left to the second treatment on the right for each observation. This is the default **TYPE=** option for crossover designs. See the section “[Profiles over Treatment for Crossover Designs](#)” on page 8468 for further details.

QQ**QQPLOT**

requests a normal quantile-quantile (Q-Q) plot. This plot is produced by default for all designs.

For two-sample designs, separate plots are shown for each class in a single panel. For crossover design, separate plots are shown for each treatment-by-period combination in a single panel.

See the section “Q-Q Plots” on page 8468 for further details.

SUMMARY**SUMMARYPLOT**

requests **HISTOGRAM** and **BOX** plots together in a single panel, sharing common X axes. This plot is produced by default for one-sample, paired, and two-independent-sample designs, the only designs for which the **SUMMARY** option is valid. See the documentation for the **BOX** and **HISTOGRAM** plot requests for details. The **SUMMARY** plot request has the following option:

UNPACK

plots histograms with overlaid densities in one panel and box plots (along with confidence interval bands, if one-sample or paired design) in another. Note that specifying **PLOTS(ONLY)=SUMMARY(UNPACK)** is exactly the same as specifying **PLOTS(ONLY)=(BOX HISTOGRAM)**.

SIDES=2 | L | U

SIDED=2 | L | U

SIDE=2 | L | U

specifies the number of sides (or tails) and direction of the statistical tests and test-based confidence intervals. The values are interpreted as follows:

SIDES=2	(the default) specifies two-sided tests and confidence intervals for means.
SIDES=L	specifies lower one-sided tests, in which the alternative hypothesis indicates a mean less than the null value, and lower one-sided confidence intervals between minus infinity and the upper confidence limit.
SIDES=U	specifies upper one-sided tests, in which the alternative hypothesis indicates a mean greater than the null value, and upper one-sided confidence intervals between the lower confidence limit and infinity.

TEST=DIFF | RATIO

specifies the test criterion. Use **TEST=DIFF** to test the difference of means and **TEST=RATIO** to test the ratio of means. The default is **DIFF**, unless **DIST=LOGNORMAL** is specified, in which case the default is **RATIO**. This option is ignored for one-sample designs.

TOST (< lower , > upper)

requests Schuirmann's TOST equivalence test. The *upper* equivalence bound must be specified. If **TEST=DIFF**, then the default value for the *lower* equivalence bound is $2m - upper$, where m is the value of the **H0=** option. If **TEST=RATIO**, then the default value for *lower* is $m / upper$.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC TTEST to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the TTEST procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable* ;

A **CLASS** statement giving the name of the classification (or grouping) variable must accompany the **PROC TTEST** statement in the two-independent-sample case. It should be omitted for the one-sample, paired, and AB/BA crossover designs. If it is used without the **VAR** statement, all numeric variables in the input data set (except those that appear in the **CLASS**, **BY**, **FREQ**, or **WEIGHT** statement) are included in the analysis.

The classification variable must have two, and only two, levels. PROC TTEST divides the observations into the two groups for the *t* test by using the levels of this variable. You can use either a numeric or a character variable in the **CLASS** statement.

Class levels are determined from the formatted values of the **CLASS** variable. Thus, you can use formats to define group levels. See the discussions of the **FORMAT** procedure, the **FORMAT** statement, formats, and informats in *SAS Formats and Informats: Reference*.

FREQ Statement

FREQ *variable* ;

The *variable* in the **FREQ** statement identifies a variable that contains the frequency of occurrence of each observation. PROC TTEST treats each observation as if it appears *n* times, where *n* is the value of the **FREQ**

variable for the observation. If the value is not an integer, only the integer portion is used. If the frequency value is less than 1 or is missing, the observation is not used in the analysis. When the **FREQ** statement is not specified, each observation is assigned a frequency of 1. The **FREQ** statement cannot be used if the **DATA=** data set contains statistics instead of the original observations.

PAIRED Statement

PAIRED *pair-lists* ;

The *pair-lists* in the **PAIRED** statement identifies the variables to be compared in paired comparisons. You can use one or more *pair-lists*. Variables or lists of variables are separated by an asterisk (*) or a colon (:). The asterisk requests comparisons between each variable on the left with each variable on the right. The colon requests comparisons between the first variable on the left and the first on the right, the second on the left and the second on the right, and so forth. The number of variables on the left must equal the number on the right when the colon is used. The differences are calculated by taking the variable on the left minus the variable on the right for both the asterisk and colon. A pair formed by a variable with itself is ignored. Use the **PAIRED** statement only for paired comparisons. The **CLASS** and **VAR** statements cannot be used with the **PAIRED** statement.

Examples of the use of the asterisk and the colon are shown in Table 99.3.

Table 99.3 PAIRED Statement in the TTEST Procedure

These PAIRED statements...	yield these comparisons
PAIRED A*B;	A-B
PAIRED A*B C*D;	A-B and C-D
PAIRED (A B) * (C D) ;	A-C, A-D, B-C, and B-D
PAIRED (A B) * (C B) ;	A-C, A-B, and B-C
PAIRED (A1-A2) * (B1-B2) ;	A1-B1, A1-B2, A2-B1, and A2-B2
PAIRED (A1-A2) : (B1-B2) ;	A1-B1 and A2-B2

VAR Statement

VAR *variables* </ options> ;

The **VAR** statement names the variables to be used in the analyses. One-sample comparisons are conducted when the **VAR** statement is used without the **CROSSOVER=** option or **CLASS** statement. Two-independent-sample comparisons are conducted when the **VAR** statement is used with a **CLASS** statement.

An AB/BA crossover analysis is conducted when the **CROSSOVER=** option is used in the **VAR** statement. In this case, you must specify an even number of variables. Each set of two variables represents the responses in the first and second periods of the AB/BA crossover design. For example, if you use the **CROSSOVER=** option and specify **VAR x1 x2 x3 x4**, then you will get two analyses. One analysis will have x1 as the period 1 response and x2 as the period 2 response. The other analysis will have x3 as the period 1 response and x4 as the period 2 response.

The **VAR** statement cannot be used with the **PAIRED** statement. If the **VAR** statement is omitted, all numeric variables in the input data set (except a numeric variable appearing in the **BY**, **CLASS**, **FREQ**, or **WEIGHT** statement) are included in the analysis.

You can specify the following options after a slash (/):

CROSSOVER= (*variable1 variable2*)

specifies the variables representing the treatment applied in each of the two periods in an AB/BA crossover design. The treatment variables must have two, and only two, levels. For any given observation, the levels for the two variables must be different, due to the restrictions of the AB/BA crossover design. You can use either numeric or character variables.

Treatment levels are determined from the formatted values of the variables. Thus, you can use formats to define the treatment levels. See the discussions of the **FORMAT** procedure, the **FORMAT** statement, formats, and informats in *SAS Formats and Informats: Reference*.

IGNOREPERIOD

indicates that the period effect shall be ignored—that is, assumed to be equal to 0 (if **TEST=DIFF**) or 1 (if **TEST=RATIO**). This assumption increases the degrees of freedom for the test of the treatment difference by one and is usually more powerful, but it risks incorrect results if there is actually a period effect.

WEIGHT Statement

WEIGHT *variable* ;

The **WEIGHT** statement weights each observation in the input data set by the value of the **WEIGHT** variable. The values of the **WEIGHT** variable can be nonintegral, and they are not truncated. Observations with negative, zero, or missing values for the **WEIGHT** variable are not used in the analyses. Each observation is assigned a weight of 1 when the **WEIGHT** statement is not used. The **WEIGHT** statement cannot be used with an input data set of summary statistics.

Details: TTEST Procedure

Input Data Set of Statistics

PROC TTEST accepts data containing either observation values or summary statistics. Observation values are supported for all analyses, whereas summary statistics are supported only for a subset of analyses. If the analysis involves the paired design, the AB/BA crossover design, or the lognormal distributional assumption (**DIST=LOGNORMAL**), then observation values must be used. The graphical results are unavailable if your input data set contains summary statistics rather than raw observed values.

PROC TTEST assumes that the **DATA=** data set contains statistics if it contains a character variable with name **_TYPE_** or **_STAT_**. The TTEST procedure expects this character variable to contain the names of statistics. If both **_TYPE_** and **_STAT_** variables exist and are of type character, PROC TTEST expects **_TYPE_** to contain the names of statistics including 'N', 'MEAN', and 'STD' for each **BY** group (or for

each class within each **BY** group for two-sample t tests). If no 'N', 'MEAN', or 'STD' statistics exist, an error message is printed.

FREQ, **WEIGHT**, and **PAIRED** statements cannot be used with input data sets of statistics. **BY**, **CLASS**, and **VAR** statements are the same regardless of data set type. For paired comparisons, see the **_DIF_** values for the **_TYPE_=T** observations in output produced by the **OUTSTATS=** option in the **PROC COMPARE** statement (see the *Base SAS Procedures Guide*).

Missing Values

An observation is omitted from the calculations if it has a missing value for either the **CLASS** variable, a **CROSSOVER=** variable, a **PAIRED** variable, the variable to be tested (in a one-sample or two-independent-sample design), or either of the two response variables (in a crossover design). If more than one variable or pair of variables is listed in the **VAR** statement, a missing value in one variable or pair does not eliminate the observation from the analysis of other nonmissing variables or variable pairs.

Computational Methods

This section describes the computational formulas for the estimates, confidence limits, and tests for each analysis in the **TTEST** procedure. The first subsection defines some common notation. The second subsection discusses the distinction between arithmetic and geometric means. The third subsection explains the concept of the coefficient of variation. The following four subsections address the four supported designs (one-sample, paired, two-independent-sample, and AB/BA crossover). The content in each of those subsections is divided into separate discussions according to different values of the **DIST=** and **TEST=** options in the **PROC TTEST** statement. The last subsection describes TOST equivalence analyses.

Common Notation

Table 99.4 displays notation for some of the commonly used symbols.

Table 99.4 Common Notation

Symbol	Description
μ	Population value of (arithmetic) mean
μ_0	Null value of test (value of H0= option in PROC TTEST statement)
σ^2	Population variance
σ	Population value of standard deviation
γ	Population value of geometric mean
CV	Population value of coefficient of variation (ratio of population standard deviation and population arithmetic mean)
α	Value of ALPHA= option in PROC TTEST statement
$t_{p,v}$	p th percentile of t distribution with v degrees of freedom (df)
F_{p,v_1,v_2}	p th percentile of F distribution with v_1 numerator df and v_2 denominator df
$\chi^2_{p,v}$	p th percentile of chi-square distribution with v df

Arithmetic and Geometric Means

The *arithmetic mean* (more commonly called simply the *mean*) of the distribution of a random variable X is its expected value, $E(X)$. The arithmetic mean is the natural parameter of interest for a normal distribution because the distribution of the difference of normal random variables has a known normal distribution, and the arithmetic mean of a normal difference is equal to the difference of the individual arithmetic means. (No such convenient property holds for geometric means with normal data, with either differences or ratios.)

The usual estimate of an arithmetic mean is the sum of the values divided by the number of values:

$$\text{arithmetic mean} = \frac{1}{n} \sum_{i=1}^n y_i$$

The *geometric mean* of the distribution of a random variable X is $\exp(E(\log(X)))$, the exponentiation of the mean of the natural logarithm. The geometric mean is the natural parameter of interest for a lognormal distribution because the distribution of a ratio of lognormal random variables has a known lognormal distribution, and the geometric mean of a lognormal ratio is equal to the ratio of the individual geometric means. (No such convenient property holds for arithmetic means with lognormal data, with either differences or ratios.)

The usual estimate of a geometric mean is the product of the values raised to the power $1/n$, where n is the number of values:

$$\text{geometric mean} = \left(\prod_{i=1}^n y_i \right)^{\frac{1}{n}}$$

Coefficient of Variation

The *coefficient of variation* (abbreviated “CV”) of the distribution of a random variable X is the ratio of the standard deviation to the (arithmetic) mean, or $\sqrt{\text{Var}(X)}/E(X)$. Conceptually, it is a measure of the variability of X expressed in units corresponding to the mean of X .

For lognormal data, the CV is the natural measure of variability (rather than the standard deviation) because the CV is invariant to multiplication of a lognormal variable by a constant. For a two-independent-sample design, the assumption of equal CVs on a lognormal scale is analogous to the assumption of equal variances on the normal scale. When the CVs of two independent samples of lognormal data are assumed equal, the pooled estimate of variability is used.

One-Sample Design

Define the following notation:

n^* = number of observations in data set

y_i = value of i th observation, $i \in \{1, \dots, n^*\}$

f_i = frequency of i th observation, $i \in \{1, \dots, n^*\}$

w_i = weight of i th observation, $i \in \{1, \dots, n^*\}$

$$n = \text{sample size} = \sum_i^{n^*} f_i$$

Normal Data (DIST=NORMAL)

The mean estimate \bar{y} , standard deviation estimate s , and standard error SE are computed as follows:

$$\bar{y} = \frac{\sum_i^{n^*} f_i w_i y_i}{\sum_i^{n^*} f_i w_i}$$

$$s = \left(\frac{\sum_i^{n^*} f_i w_i (y_i - \bar{y})^2}{n - 1} \right)^{\frac{1}{2}}$$

$$SE = \frac{s}{\sum_i^{n^*} f_i w_i}$$

The $100(1 - \alpha)\%$ confidence interval for the mean μ is

$$\left(\bar{y} - t_{1-\frac{\alpha}{2}, n-1} SE, \bar{y} + t_{1-\frac{\alpha}{2}, n-1} SE \right), \text{ SIDES}=2$$

$$\left(-\infty, \bar{y} + t_{1-\alpha, n-1} SE \right), \text{ SIDES}=L$$

$$\left(\bar{y} - t_{1-\alpha, n-1} SE, \infty \right), \text{ SIDES}=U$$

The t value for the test is computed as

$$t = \frac{\bar{y} - \mu_0}{SE}$$

The p -value of the test is computed as

$$p\text{-value} = \begin{cases} P(t^2 > F_{1-\alpha, 1, n-1}) & , \quad 2\text{-sided} \\ P(t < t_{\alpha, n-1}) & , \quad \text{lower 1-sided} \\ P(t > t_{1-\alpha, n-1}) & , \quad \text{upper 1-sided} \end{cases}$$

The equal-tailed confidence interval for the standard deviation (**CI=EQUAL**) is based on the acceptance region of the test of $H_0: \sigma = \sigma_0$ that places an equal amount of area ($\frac{\alpha}{2}$) in each tail of the chi-square distribution:

$$\left\{ \chi_{\frac{\alpha}{2}, n-1}^2 \leq \frac{(n-1)s^2}{\sigma_0^2} \leq \chi_{\frac{1-\alpha}{2}, n-1}^2 \right\}$$

The acceptance region can be algebraically manipulated to give the following $100(1 - \alpha)\%$ confidence interval for σ^2 :

$$\left(\frac{(n-1)s^2}{\chi_{1-\frac{\alpha}{2}, n-1}^2}, \frac{(n-1)s^2}{\chi_{\frac{\alpha}{2}, n-1}^2} \right)$$

Taking the square root of each side yields the $100(1 - \alpha)\%$ **CI=EQUAL** confidence interval for σ :

$$\left(\left(\frac{(n-1)s^2}{\chi_{1-\frac{\alpha}{2}, n-1}^2} \right)^{\frac{1}{2}}, \left(\frac{(n-1)s^2}{\chi_{\frac{\alpha}{2}, n-1}^2} \right)^{\frac{1}{2}} \right)$$

The other confidence interval for the standard deviation (**CI=UMPU**) is derived from the uniformly most powerful unbiased test of $H_0: \sigma = \sigma_0$ (Lehmann 1986). This test has acceptance region

$$\left\{ c_1 \leq \frac{(n-1)s^2}{\sigma_0^2} \leq c_2 \right\}$$

where the critical values c_1 and c_2 satisfy

$$\int_{c_1}^{c_2} f_{n-1}(y) dy = 1 - \alpha$$

and

$$\int_{c_1}^{c_2} y f_{n-1}(y) dy = (n-1)(1 - \alpha)$$

where $f_\nu(y)$ is the PDF of the chi-square distribution with ν degrees of freedom. This acceptance region can be algebraically manipulated to arrive at

$$P \left\{ \frac{(n-1)s^2}{c_2} \leq \sigma^2 \leq \frac{(n-1)s^2}{c_1} \right\} = 1 - \alpha$$

where c_1 and c_2 solve the preceding two integrals. To find the area in each tail of the chi-square distribution to which these two critical values correspond, solve $c_1 = \chi_{1-\alpha_2, n-1}^2$ and $c_2 = \chi_{\alpha_1, n-1}^2$ for α_1 and α_2 ; the resulting α_1 and α_2 sum to α . Hence, a $100(1 - \alpha)\%$ confidence interval for σ^2 is given by

$$\left(\frac{(n-1)s^2}{\chi_{1-\alpha_2, n-1}^2}, \frac{(n-1)s^2}{\chi_{\alpha_1, n-1}^2} \right)$$

Taking the square root of each side yields the $100(1 - \alpha)\%$ **CI=UMPU** confidence interval for σ :

$$\left(\left(\frac{(n-1)s^2}{\chi_{1-\alpha_2, n-1}^2} \right)^{\frac{1}{2}}, \left(\frac{(n-1)s^2}{\chi_{\alpha_1, n-1}^2} \right)^{\frac{1}{2}} \right)$$

Lognormal Data (DIST=LOGNORMAL)

The **DIST=LOGNORMAL** analysis is handled by log-transforming the data and null value, performing a **DIST=NORMAL** analysis, and then transforming the results back to the original scale. This simple technique is based on the properties of the lognormal distribution as discussed in Johnson, Kotz, and Balakrishnan (1994, Chapter 14).

Taking the natural logarithms of the observation values and the null value, define

$$z_i = \log(y_i), \quad i \in \{1, \dots, n^*\}$$

$$\gamma_0 = \log(\mu_0)$$

First a **DIST=NORMAL** analysis is performed on z_i in place of y_i . The geometric mean estimate $\hat{\gamma}$ and CV estimate \widehat{CV} of the original lognormal data are computed as follows:

$$\hat{\gamma} = \exp(\bar{y})$$

$$\widehat{CV} = (\exp(s^2) - 1)^{\frac{1}{2}}$$

The t value and p -value remain the same. The confidence limits for the geometric mean and CV on the original lognormal scale are computed from the confidence limits for the arithmetic mean and standard deviation in the **DIST=NORMAL** analysis on the log-transformed data, in the same way that $\hat{\gamma}$ is derived from \bar{y} and \widehat{CV} is derived from s .

Paired Design

Define the following notation:

n^* = number of observations in data set

y_{1i} = value of i th observation for first PAIRED variable, $i \in \{1, \dots, n^*\}$

y_{2i} = value of i th observation for second PAIRED variable, $i \in \{1, \dots, n^*\}$

f_i = frequency of i th observation, $i \in \{1, \dots, n^*\}$

w_i = weight of i th observation, $i \in \{1, \dots, n^*\}$

$$n = \text{sample size} = \sum_i^{n^*} f_i$$

Normal Difference (DIST=NORMAL TEST=DIFF)

The analysis is the same as the analysis for the one-sample design in the section “Normal Data (DIST=NORMAL)” on page 8452 based on the differences

$$d_i = y_{1i} - y_{2i} \quad , \quad i \in \{1, \dots, n^*\}$$

Lognormal Ratio (DIST=LOGNORMAL TEST=RATIO)

The analysis is the same as the analysis for the one-sample design in the section “Lognormal Data (DIST=LOGNORMAL)” on page 8453 based on the ratios

$$r_i = y_{1i}/y_{2i} \quad , \quad i \in \{1, \dots, n^*\}$$

Normal Ratio (DIST=NORMAL TEST=RATIO)

The hypothesis $H_0: \mu_1/\mu_2 = \mu_0$, where μ_1 and μ_2 are the means of the first and second PAIRED variables, respectively, can be rewritten as $H_0: \mu_1 - \mu_0\mu_2 = 0$. The t value and p -value are computed in the same way as in the one-sample design in the section “Normal Data (DIST=NORMAL)” on page 8452 based on the transformed values

$$z_i = y_{1i} - \mu_0 y_{2i} \quad , \quad i \in \{1, \dots, n^*\}$$

Estimates and confidence limits are not computed for this situation.

Two-Independent-Sample Design

Define the following notation:

$$\begin{aligned}
 n_1^* &= \text{number of observations at first class level} \\
 n_2^* &= \text{number of observations at second class level} \\
 y_{1i} &= \text{value of } i\text{th observation at first class level, } i \in \{1, \dots, n_1^*\} \\
 y_{2i} &= \text{value of } i\text{th observation at second class level, } i \in \{1, \dots, n_2^*\} \\
 f_{1i} &= \text{frequency of } i\text{th observation at first class level, } i \in \{1, \dots, n_1^*\} \\
 f_{2i} &= \text{frequency of } i\text{th observation at second class level, } i \in \{1, \dots, n_2^*\} \\
 w_{1i} &= \text{weight of } i\text{th observation at first class level, } i \in \{1, \dots, n_1^*\} \\
 w_{2i} &= \text{weight of } i\text{th observation at second class level, } i \in \{1, \dots, n_2^*\} \\
 n_1 &= \text{sample size for first class level} = \sum_i^{n_1^*} f_{1i} \\
 n_2 &= \text{sample size for second class level} = \sum_i^{n_2^*} f_{2i}
 \end{aligned}$$

Normal Difference (DIST=NORMAL TEST=DIFF)

Observations at the first class level are assumed to be distributed as $N(\mu_1, \sigma_1^2)$, and observations at the second class level are assumed to be distributed as $N(\mu_2, \sigma_2^2)$, where μ_1 , μ_2 , σ_1 , and σ_2 are unknown.

The within-class-level mean estimates (\bar{y}_1 and \bar{y}_2), standard deviation estimates (s_1 and s_2), standard errors (SE_1 and SE_2), and confidence limits for means and standard deviations are computed in the same way as for the one-sample design in the section “Normal Data (DIST=NORMAL)” on page 8452.

The mean difference $\mu_1 - \mu_2 = \mu_d$ is estimated by

$$\bar{y}_d = \bar{y}_1 - \bar{y}_2$$

Under the assumption of equal variances ($\sigma_1^2 = \sigma_2^2$), the pooled estimate of the common standard deviation is

$$s_p = \left(\frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2} \right)^{\frac{1}{2}}$$

The pooled standard error (the estimated standard deviation of \bar{y}_d assuming equal variances) is

$$SE_p = s_p \left(\frac{1}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} + \frac{1}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} \right)^{\frac{1}{2}}$$

The pooled $100(1 - \alpha)\%$ confidence interval for the mean difference μ_d is

$$\begin{aligned}
 &(\bar{y}_d - t_{1-\frac{\alpha}{2}, n_1+n_2-2} SE_p, \bar{y}_d + t_{1-\frac{\alpha}{2}, n_1+n_2-2} SE_p), \text{ SIDES=2} \\
 &(-\infty, \bar{y}_d + t_{1-\alpha, n_1+n_2-2} SE_p), \text{ SIDES=L} \\
 &(\bar{y}_d - t_{1-\alpha, n_1+n_2-2} SE_p, \infty), \text{ SIDES=U}
 \end{aligned}$$

The t value for the pooled test is computed as

$$t_p = \frac{\bar{y}_d - \mu_0}{SE_p}$$

The p -value of the test is computed as

$$p\text{-value} = \begin{cases} P(t_p^2 > F_{1-\alpha, 1, n_1+n_2-2}) & , \quad 2\text{-sided} \\ P(t_p < t_{\alpha, n_1+n_2-2}) & , \quad \text{lower 1-sided} \\ P(t_p > t_{1-\alpha, n_1+n_2-2}) & , \quad \text{upper 1-sided} \end{cases}$$

Under the assumption of unequal variances (the Behrens-Fisher problem), the unpooled standard error is computed as

$$SE_u = \left(\frac{s_1^2}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} + \frac{s_2^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} \right)^{\frac{1}{2}}$$

Satterthwaite's (1946) approximation for the degrees of freedom, extended to accommodate weights, is computed as

$$df_u = \frac{SE_u^4}{\frac{s_1^4}{(n_1-1)\left(\sum_{i=1}^{n_1^*} f_{1i} w_{1i}\right)^2} + \frac{s_2^4}{(n_2-1)\left(\sum_{i=1}^{n_2^*} f_{2i} w_{2i}\right)^2}}$$

The unpooled Satterthwaite $100(1 - \alpha)\%$ confidence interval for the mean difference μ_d is

$$\begin{aligned} & \left(\bar{y}_d - t_{1-\frac{\alpha}{2}, df_u} SE_u, \bar{y}_d + t_{1-\frac{\alpha}{2}, df_u} SE_u \right), \text{ SIDES=2} \\ & \left(-\infty, \bar{y}_d + t_{1-\alpha, df_u} SE_u \right), \text{ SIDES=L} \\ & \left(\bar{y}_d - t_{1-\alpha, df_u} SE_u, \infty \right), \text{ SIDES=U} \end{aligned}$$

The t value for the unpooled Satterthwaite test is computed as

$$t_u = \frac{\bar{y}_d - \mu_0}{SE_u}$$

The p -value of the unpooled Satterthwaite test is computed as

$$p\text{-value} = \begin{cases} P(t_u^2 > F_{1-\alpha, 1, df_u}) & , \quad 2\text{-sided} \\ P(t_u < t_{\alpha, df_u}) & , \quad \text{lower 1-sided} \\ P(t_u > t_{1-\alpha, df_u}) & , \quad \text{upper 1-sided} \end{cases}$$

When the **COCHRAN** option is specified in the **PROC TTEST** statement, the Cochran and Cox (1950) approximation of the p -value of the t_u statistic is the value of p such that

$$t_u = \frac{\left(\frac{s_1^2}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} \right) t_1 + \left(\frac{s_2^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} \right) t_2}{\left(\frac{s_1^2}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} \right) + \left(\frac{s_2^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} \right)}$$

where t_1 and t_2 are the critical values of the t distribution corresponding to a significance level of p and sample sizes of n_1 and n_2 , respectively. The number of degrees of freedom is undefined when $n_1 \neq n_2$. In general, the Cochran and Cox test tends to be conservative (Lee and Gurland 1975).

The $100(1 - \alpha)\%$ **CI=EQUAL** and **CI=UMPU** confidence intervals for the common population standard deviation σ assuming equal variances are computed as discussed in the section “**Normal Data (DIST=NORMAL)**” on page 8452 for the one-sample design, except replacing s^2 by s_p^2 and $(n - 1)$ by $(n_1 + n_2 - 1)$.

The folded form of the F statistic, F' , tests the hypothesis that the variances are equal (Steel and Torrie 1980), where

$$F' = \frac{\max(s_1^2, s_2^2)}{\min(s_1^2, s_2^2)}$$

A test of F' is a two-tailed F test because you do not specify which variance you expect to be larger. The p -value gives the probability of a greater F value under the null hypothesis that $\sigma_1^2 = \sigma_2^2$. Note that this test is not very robust to violations of the assumption that the data are normally distributed, and thus it is not recommended without confidence in the normality assumption.

Lognormal Ratio (DIST=LOGNORMAL TEST=RATIO)

The **DIST=LOGNORMAL** analysis is handled by log-transforming the data and null value, performing a **DIST=NORMAL** analysis, and then transforming the results back to the original scale. See the section “**Normal Data (DIST=NORMAL)**” on page 8452 for the one-sample design for details on how the **DIST=NORMAL** computations for means and standard deviations are transformed into the **DIST=LOGNORMAL** results for geometric means and CVs. As mentioned in the section “**Coefficient of Variation**” on page 8451, the assumption of equal CVs on the lognormal scale is analogous to the assumption of equal variances on the normal scale.

Normal Ratio (DIST=NORMAL TEST=RATIO)

The distributional assumptions, equality of variances test, and within-class-level mean estimates (\bar{y}_1 and \bar{y}_2), standard deviation estimates (s_1 and s_2), standard errors (SE_1 and SE_2), and confidence limits for means and standard deviations are the same as in the section “**Normal Difference (DIST=NORMAL TEST=DIFF)**” on page 8455 for the two-independent-sample design.

The mean ratio $\mu_1/\mu_2 = \mu_r$ is estimated by

$$\hat{\mu}_r = \bar{y}_1/\bar{y}_2$$

No estimates or confidence intervals for the ratio of standard deviations are computed.

Under the assumption of equal variances ($\sigma_1^2 = \sigma_2^2$), the pooled confidence interval for the mean ratio is the Fieller (1954) confidence interval, extended to accommodate weights. Let

$$\begin{aligned} a_p &= \frac{s_p^2 t_{1-\frac{\alpha}{2}, n_1+n_2-2}^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} - \bar{y}_2^2 \\ b_p &= \bar{y}_1 \bar{y}_2 \\ c_p &= \frac{s_p^2 t_{1-\frac{\alpha}{2}, n_1+n_2-2}^2}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} - \bar{y}_1^2 \end{aligned}$$

where s_p is the pooled standard deviation defined in the section “Normal Difference (DIST=NORMAL TEST=DIFF)” on page 8455 for the two-independent-sample design. If $a_p \geq 0$ (which occurs when \bar{y}_2 is too close to zero), then the pooled two-sided $100(1 - \alpha)\%$ Fieller confidence interval for μ_r does not exist. If $a < 0$, then the interval is

$$\left(-\frac{b_p}{a_p} + \frac{(b_p^2 - a_p c_p)^{\frac{1}{2}}}{a_p}, -\frac{b_p}{a_p} - \frac{(b_p^2 - a_p c_p)^{\frac{1}{2}}}{a_p} \right)$$

For the one-sided intervals, let

$$a_p^* = \frac{s_p^2 t_{1-\alpha, n_1+n_2-2}^2 - \bar{y}_2^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}}$$

$$c_p^* = \frac{s_p^2 t_{1-\alpha, n_1+n_2-2}^2 - \bar{y}_1^2}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}}$$

which differ from a_p and c_p only in the use of α in place of $\alpha/2$. If $a_p^* \geq 0$, then the pooled one-sided $100(1 - \alpha)\%$ Fieller confidence intervals for μ_r do not exist. If $a_p^* < 0$, then the intervals are

$$\left(-\infty, -\frac{b_p}{a_p^*} - \frac{(b_p^2 - a_p^* c_p^*)^{\frac{1}{2}}}{a_p^*} \right), \text{ SIDES=L}$$

$$\left(-\frac{b_p}{a_p^*} + \frac{(b_p^2 - a_p^* c_p^*)^{\frac{1}{2}}}{a_p^*}, \infty \right), \text{ SIDES=U}$$

The pooled t test assuming equal variances is the Sasabuchi (1988a, b) test. The hypothesis $H_0: \mu_r = \mu_0$ is rewritten as $H_0: \mu_1 - \mu_0 \mu_2 = 0$, and the pooled t test in the section “Normal Difference (DIST=NORMAL TEST=DIFF)” on page 8455 for the two-independent-sample design is conducted on the original y_{1i} values ($i \in \{1, \dots, n_1^*\}$) and transformed values of y_{2i}

$$y_{2i}^* = \mu_0 y_{2i}, \quad i \in \{1, \dots, n_2^*\}$$

with a null difference of 0. The t value for the Sasabuchi pooled test is computed as

$$t_p = \frac{\bar{y}_1 - \mu_0 \bar{y}_2}{s_p \left(\frac{1}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} + \frac{\mu_0^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} \right)^{\frac{1}{2}}}$$

The p -value of the test is computed as

$$p\text{-value} = \begin{cases} P(t_p^2 > F_{1-\alpha, 1, n_1+n_2-2}) & , \quad 2\text{-sided} \\ P(t_p < t_{\alpha, n_1+n_2-2}) & , \quad \text{lower 1-sided} \\ P(t_p > t_{1-\alpha, n_1+n_2-2}) & , \quad \text{upper 1-sided} \end{cases}$$

Under the assumption of unequal variances, the unpooled Satterthwaite-based confidence interval for the mean ratio μ_r is computed according to the method in Dilba, Schaarschmidt, and Hothorn (2006), extended

to accommodate weights. The degrees of freedom are computed as

$$df_u = \frac{\left(\frac{s_1^2}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} + \frac{\hat{\mu}_r^2 s_2^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} \right)^2}{\frac{s_1^4}{(n_1-1) \left(\sum_{i=1}^{n_1^*} f_{1i} w_{1i} \right)^2} + \frac{\hat{\mu}_r^4 s_2^4}{(n_2-1) \left(\sum_{i=1}^{n_2^*} f_{2i} w_{2i} \right)^2}}$$

Note that the estimate $\hat{\mu}_r = \bar{y}_1 / \bar{y}_2$ is used in df_u . Let

$$\begin{aligned} a_u &= \frac{s_2^2 t_{1-\frac{\alpha}{2}, df_u}^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} - \bar{y}_2^2 \\ b_u &= \bar{y}_1 \bar{y}_2 \\ c_u &= \frac{s_1^2 t_{1-\frac{\alpha}{2}, df_u}^2}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} - \bar{y}_1^2 \end{aligned}$$

where s_1 and s_2 are the within-class-level standard deviations defined in the section “**Normal Difference (DIST=NORMAL TEST=DIFF)**” on page 8455 for the two-independent-sample design. If $a_u \geq 0$ (which occurs when \bar{y}_2 is too close to zero), then the unpooled Satterthwaite-based two-sided $100(1 - \alpha)\%$ confidence interval for μ_r does not exist. If $a_u < 0$, then the interval is

$$\left(-\frac{b_u}{a_u} + \frac{(b_u^2 - a_u c_u)^{\frac{1}{2}}}{a_u}, -\frac{b_u}{a_u} - \frac{(b_u^2 - a_u c_u)^{\frac{1}{2}}}{a_u} \right)$$

The t test assuming unequal variances is the test derived in Tamhane and Logan (2004). The hypothesis $H_0: \mu_r = \mu_0$ is rewritten as $H_0: \mu_1 - \mu_0 \mu_2 = 0$, and the Satterthwaite t test in the section “**Normal Difference (DIST=NORMAL TEST=DIFF)**” on page 8455 for the two-independent-sample design is conducted on the original y_{1i} values ($i \in \{1, \dots, n_1^*\}$) and transformed values of y_{2i}

$$y_{2i}^* = \mu_0 y_{2i}, \quad i \in \{1, \dots, n_2^*\}$$

with a null difference of 0. The degrees of freedom used in the unpooled t test differs from the df_u used in the unpooled confidence interval. The mean ratio μ_0 under the null hypothesis is used in place of the estimate $\hat{\mu}_r$:

$$df_u^* = \frac{\left(\frac{s_1^2}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} + \frac{\mu_0^2 s_2^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} \right)^2}{\frac{s_1^4}{(n_1-1) \left(\sum_{i=1}^{n_1^*} f_{1i} w_{1i} \right)^2} + \frac{\mu_0^4 s_2^4}{(n_2-1) \left(\sum_{i=1}^{n_2^*} f_{2i} w_{2i} \right)^2}}$$

The t value for the Satterthwaite-based unpooled test is computed as

$$t_u = \frac{\bar{y}_1 - \mu_0 \bar{y}_2}{\left(\frac{s_1^2}{\sum_{i=1}^{n_1^*} f_{1i} w_{1i}} + \frac{\mu_0^2 s_2^2}{\sum_{i=1}^{n_2^*} f_{2i} w_{2i}} \right)^{\frac{1}{2}}}$$

The p -value of the test is computed as

$$p\text{-value} = \begin{cases} P\left(t_u^2 > F_{1-\alpha, 1, df_u^*}\right) & , \quad \text{2-sided} \\ P\left(t_u < t_{\alpha, df_u^*}\right) & , \quad \text{lower 1-sided} \\ P\left(t_u > t_{1-\alpha, df_u^*}\right) & , \quad \text{upper 1-sided} \end{cases}$$

AB/BA Crossover Design

Let “A” and “B” denote the two treatment values. Define the following notation:

n_1^* = number of observations with treatment sequence AB

n_2^* = number of observations with treatment sequence BA

y_{11i} = response value of i th observation in sequence AB during period 1, $i \in \{1, \dots, n_1^*\}$

y_{12i} = response value of i th observation in sequence AB during period 2, $i \in \{1, \dots, n_1^*\}$

y_{21i} = response value of i th observation in sequence BA during period 1, $i \in \{1, \dots, n_2^*\}$

y_{22i} = response value of i th observation in sequence BA during period 2, $i \in \{1, \dots, n_2^*\}$

So $\{y_{11i}, \dots, y_{11n_1^*}\}$ and $\{y_{22i}, \dots, y_{22n_2^*}\}$ are all observed at treatment level A, and $\{y_{12i}, \dots, y_{12n_2^*}\}$ and $\{y_{21i}, \dots, y_{21n_1^*}\}$ are all observed at treatment level B.

Define the *period difference* for an observation as the difference between period 1 and period 2 response values:

$$pd_{kji} = y_{k1i} - y_{k2i}$$

for $k \in \{1, 2\}$ and $i \in \{1, \dots, n_k^*\}$. Similarly, the *period ratio* is the ratio between period 1 and period 2 response values:

$$pr_{kji} = y_{k1i} / y_{k2i}$$

The *crossover difference* for an observation is the difference between treatment A and treatment B response values:

$$cd_{kji} = \begin{cases} y_{k1i} - y_{k2i} & , \quad k = 1 \\ y_{k2i} - y_{k1i} & , \quad k = 2 \end{cases}$$

Similarly, the *crossover ratio* is the ratio between treatment A and treatment B response values:

$$cr_{kji} = \begin{cases} y_{k1i} / y_{k2i} & , \quad k = 1 \\ y_{k2i} / y_{k1i} & , \quad k = 2 \end{cases}$$

In the absence of the **IGNOREPERIOD** option in the **PROC TTEST** statement, the data are split into two groups according to treatment sequence and analyzed as a two-independent-sample design. If **DIST=NORMAL**, then the analysis of the treatment effect is based on the half period differences $\{pd_{kji}/2\}$, and the analysis for the period effect is based on the half crossover differences $\{cd_{kji}/2\}$. The computations for the normal difference analysis are the same as in the section “**Normal Difference (DIST=NORMAL TEST=DIFF)**” on page 8455 for the two-independent-sample design. The normal ratio analysis without the **IGNOREPERIOD** option is not supported for the AB/BA crossover design. If **DIST=LOGNORMAL**, then

the analysis of the treatment effect is based on the square root of the period ratios $\{\sqrt{pr_{kji}}\}$, and the analysis for the period effect is based on the square root of the crossover ratios $\{\sqrt{cr_{kji}}\}$. The computations are the same as in the section “[Lognormal Ratio \(DIST=LOGNORMAL TEST=RATIO\)](#)” on page 8457 for the two-independent-sample design.

If the **IGNOREPERIOD** option is specified, then the treatment effect is analyzed as a paired analysis on the (treatment A, treatment B) response value pairs, regardless of treatment sequence. So the set of pairs is taken to be the concatenation of $\{(y_{111}, y_{121}), \dots, (y_{11n_1^*}, y_{12n_1^*})\}$ and $\{(y_{221}, y_{211}), \dots, (y_{22n_2^*}, y_{21n_2^*})\}$. The computations are the same as in the section “[Paired Design](#)” on page 8454.

See Senn (2002, Chapter 3) for a more detailed discussion of the AB/BA crossover design.

TOST Equivalence Test

The hypotheses for an equivalence test are

$$\begin{aligned} H_0: \mu < \theta_L \quad \text{or} \quad \mu > \theta_U \\ H_1: \theta_L \leq \mu \leq \theta_U \end{aligned}$$

where θ_L and θ_U are the lower and upper bounds specified in the **TOST** option in the **PROC TTEST** statement, and μ is the analysis criterion (mean, mean ratio, or mean difference, depending on the analysis). Following the two one-sided tests (TOST) procedure of Schuirmann (1987), the equivalence test is conducted by performing two separate tests:

$$\begin{aligned} H_{a0}: \mu < \theta_L \\ H_{a1}: \mu \geq \theta_L \end{aligned}$$

and

$$\begin{aligned} H_{b0}: \mu > \theta_U \\ H_{b1}: \mu \leq \theta_U \end{aligned}$$

The overall p -value is the larger of the two p -values of those tests.

Rejection of H_0 in favor of H_1 at significance level α occurs if and only if the $100(1 - 2\alpha)\%$ confidence interval for μ is contained completely within (θ_L, θ_U) . So, the $100(1 - 2\alpha)\%$ confidence interval for μ is displayed in addition to the usual $100(1 - \alpha)\%$ interval.

For further discussion of equivalence testing for the designs supported in the **TTEST** procedure, see Phillips (1990); Diletti, Hauschke, and Steinijans (1991); Hauschke et al. (1999).

Displayed Output

For an AB/BA crossover design, the “CrossoverVarInfo” table shows the variables specified for the response and treatment values in each period of the design.

The summary statistics in the “Statistics” table and confidence limits in the “ConfLimits” table are displayed for certain variables and/or transformations or subgroups of the variables in the analysis, depending on the design. For a one-sample design, summary statistics are displayed for all variables in the analysis. For a paired design, statistics are displayed for the difference if you specify the **TEST=DIFF** option in the **PROC**

TTEST statement, or for the ratio if you specify **TEST=RATIO**. For a two-independent-sample design, the statistics for each of the two groups and for the difference (if **TEST=DIFF**) or ratio (if **TEST=RATIO**) are displayed. For an AB/BA crossover design, statistics are displayed for each of the four cells in the design (all four combinations of the two periods and two treatments). If the **IGNOREPERIOD** option is absent, then if **TEST=DIFF** is specified, statistics are displayed for the treatment difference within each sequence and overall, and also for the period difference. If **TEST=RATIO**, statistics are displayed for the treatment ratio within each sequence and overall, and also for the period ratio. If the **IGNOREPERIOD** option is specified in the **VAR** statement, then statistics are displayed for the overall treatment difference if **TEST=DIFF** or for the overall treatment ratio if **TEST=RATIO**.

The “Statistics” table displays the following summary statistics:

- the name of the variable(s), displayed if the **NOBYVAR** option is used in the **PROC TTEST** statement
- the name of the classification variable (if two-independent-sample design) or treatment and period (if AB/BA crossover design)
- N, the number of nonmissing values
- the (arithmetic) Mean, displayed if the **DIST=NORMAL** option is specified in the **PROC TTEST** statement
- the Geometric Mean, displayed if the **DIST=LOGNORMAL** option is specified in the **PROC TTEST** statement
- Std Dev, the standard deviation, displayed if the **DIST=NORMAL** option is specified in the **PROC TTEST** statement
- the Coefficient of Variation, displayed if the **DIST=LOGNORMAL** option is specified in the **PROC TTEST** statement
- Std Err, the standard error of the mean, displayed if the **DIST=NORMAL** option is specified in the **PROC TTEST** statement
- the Minimum value
- the Maximum value

The “ConfLimits” table displays the following:

- the name of the variable(s), displayed if the **NOBYVAR** option is used in the **PROC TTEST** statement
- the name of the classification variable (if two-independent-sample design) or treatment and period (if AB/BA crossover design)
- the (arithmetic) Mean, displayed if the **DIST=NORMAL** option is specified in the **PROC TTEST** statement
- the Geometric Mean, displayed if the **DIST=LOGNORMAL** option is specified in the **PROC TTEST** statement

- $100(1 - \alpha)\%$ CL Mean, the lower and upper confidence limits for the mean. Separate pooled and Satterthwaite confidence limits are shown for the difference or ratio transformations in two-independent-sample designs and AB/BA crossover designs without the **IGNOREPERIOD** option.
- Std Dev, the standard deviation, displayed if the **DIST=NORMAL** option is specified in the **PROC TTEST** statement
- the Coefficient of Variation, displayed if the **DIST=LOGNORMAL** option is specified in the **PROC TTEST** statement
- $100(1 - \alpha)\%$ CL Std Dev, the equal-tailed confidence limits for the standard deviation, displayed if the **DIST=NORMAL** and **CI=EQUAL** options are specified in the **PROC TTEST** statement
- $100(1 - \alpha)\%$ UMPU CL Std Dev, the UMPU confidence limits for the standard deviation, displayed if the **DIST=NORMAL** and **CI=UMPU** options are specified in the **PROC TTEST** statement
- $100(1 - \alpha)\%$ CL CV, the equal-tailed confidence limits for the coefficient of variation, displayed if the **DIST=LOGNORMAL** and **CI=EQUAL** options are specified in the **PROC TTEST** statement
- $100(1 - \alpha)\%$ UMPU CL CV, the UMPU confidence limits for the coefficient of variation, displayed if the **DIST=LOGNORMAL** and **CI=UMPU** options are specified in the **PROC TTEST** statement

The confidence limits in the “EquivLimits” table and test results in the “TTests” and “EquivTests” tables are displayed only for the test criteria—that is, the variables or transformations being tested. For a one-sample design, results are displayed for all variables in the analysis. For a paired design, results are displayed for the difference if you specify the **TEST=DIFF** option in the **PROC TTEST** statement, or for the ratio if you specify **TEST=RATIO**. For a two-independent-sample design, the results for the difference (if **TEST=DIFF**) or ratio (if **TEST=RATIO**) are displayed. For an AB/BA crossover design, results are displayed for the treatment difference (if **TEST=DIFF**) or ratio (if **TEST=RATIO**). If the **IGNOREPERIOD** option is absent, then results are also displayed for the period difference (if **TEST=DIFF**) or ratio (if **TEST=RATIO**).

The “EquivLimits” table, produced only if the **TOST** option is specified in the **PROC TTEST** statement, displays the following:

- the name of the variable(s), displayed if the **NOBYVAR** option is used in the **PROC TTEST** statement
- the (arithmetic) Mean, displayed if the **DIST=NORMAL** option is specified in the **PROC TTEST** statement
- the Geometric Mean, displayed if the **DIST=LOGNORMAL** option is specified in the **PROC TTEST** statement
- Lower Bound, the lower equivalence bound for the mean specified in the **TOST** option in the **PROC TTEST** statement
- $100(1 - 2\alpha)\%$ CL Mean, the lower and upper confidence limits for the mean relevant to the equivalence test. Separate pooled and Satterthwaite confidence limits are shown for two-independent-sample designs and AB/BA crossover designs without the **IGNOREPERIOD** option.
- Upper Bound, the upper equivalence bound for the mean specified in the **TOST** option in the **PROC TTEST** statement

- Assessment, the result of the equivalence test at the significance level specified by the ALPHA= option in the PROC TTEST statement, either “Equivalent” or “Not equivalent”

The “TTests” table is produced only if the TOST option is *not* specified in the PROC TTEST statement. Separate results for pooled and Satterthwaite tests (and also the Cochran and Cox test, if the COCHRAN option is specified in the PROC TTEST statement) are displayed for two-independent-sample designs and AB/BA crossover designs without the IGNOREPERIOD option. The table includes the following results:

- the name of the variable(s), displayed if the NOBYVAR option is used in the PROC TTEST statement
- t Value, the t statistic for comparing the mean to the null value as specified by the H0= option in the PROC TTEST statement
- DF, the degrees of freedom
- the p -value, the probability of obtaining a t statistic at least as extreme as the observed t value under the null hypothesis

The “EquivTests” table is produced only if the TOST option is specified in the PROC TTEST statement. Separate results for pooled and Satterthwaite tests are displayed for two-independent-sample designs and AB/BA crossover designs without the IGNOREPERIOD option. Each test consists of two separate one-sided tests. The overall p -value is the larger p -value from these two tests. The table includes the following results:

- the name of the variable(s), displayed if the NOBYVAR option is used in the PROC TTEST statement
- Null, the lower equivalence bound for the Upper test or the upper equivalence bound for the Lower test, as specified by the TOST option in the PROC TTEST statement
- t Value, the t statistic for comparing the mean to the Null value
- DF, the degrees of freedom
- the p -value, the probability of obtaining a t statistic at least as extreme as the observed t value under the null hypothesis

The “Equality” table gives the results of the test of equality of variances. It is displayed for two-independent-sample designs and AB/BA crossover designs without the IGNOREPERIOD option. The table includes the following results:

- the name of the variable(s), displayed if the NOBYVAR option is used in the PROC TTEST statement
- Num DF and Den DF, the numerator and denominator degrees of freedom
- F Value, the F' (folded) statistic
- Pr > F, the probability of a greater F' value. This is the two-tailed p -value.

ODS Table Names

PROC TTEST assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 99.5](#). For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 99.5 ODS Tables Produced by PROC TTEST

ODS Table Name	Description	Syntax
ConfLimits	100(1 – α)% confidence limits for means, standard deviations, and/or coefficients of variation	By default
Equality	Tests for equality of variance	CLASS statement or VAR / CROSSEVER=
EquivLimits	100(1 – 2 α)% confidence limits for means	PROC TTEST TOST
EquivTests	Equivalence <i>t</i> tests	PROC TTEST TOST
Statistics	Univariate summary statistics	By default
TTests	<i>t</i> tests	By default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

ODS Graph Names

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC TTEST generates are listed in [Table 99.6](#), along with the required statements and options.

Table 99.6 Graphs Produced by PROC TTEST

ODS Graph Name	Plot Description	Option
AgreementOfPeriods	Plot of period 2 against period 1 response values for an AB/BA crossover design	VAR / CROSSEVER= PLOTS=AGREEMENT(TYPE=PERIOD)
AgreementOfTreatments	Plot of second treatment against first treatment response values for an AB/BA crossover design	VAR / CROSSEVER= PLOTS=AGREEMENT

Table 99.6 *continued*

ODS Graph Name	Plot Description	Option
AgreementPlot	Plot of second response against first response for a paired design	PAIRED statement PLOTS=AGREEMENT
BoxPlot	Box plots, also with confidence band for one-sample or paired design	PLOTS=BOX PLOTS=SUMMARY(UNPACK)
Histogram	Histograms with overlaid kernel densities, and also normal densities if DIST=NORMAL	PLOTS=HISTOGRAM PLOTS=SUMMARY(UNPACK)
Interval	Confidence intervals for means	PLOTS=INTERVAL
ProfilesOverPrd	Plot of response profiles over periods 1 and 2 for an AB/BA crossover design	VAR / CROSSOVER= PLOTS=PROFILES(TYPE=PERIOD)
ProfilesOverTrt	Plot of response profiles over first and second treatments for an AB/BA crossover design	VAR / CROSSOVER= PLOTS=PROFILES
ProfilesPlot	Plot of response profiles over first and second response values for a paired design	PAIRED statement PLOTS=PROFILES
QQPlot	Normal quantile-quantile plots	PLOTS=QQ
SummaryPanel	Histograms with overlaid kernel densities (and also normal densities if DIST=NORMAL) and box plots (and also with confidence band for one-sample or paired design)	PLOTS=SUMMARY

Interpreting Graphs

Agreement Plots for Paired Designs

For paired designs, the second response of each pair is plotted against the first response, with the mean shown as a large bold symbol. If the **WEIGHT** statement is used, then the mean is the weighted mean. A diagonal line with slope=0 and y-intercept=1 is overlaid. The location of the points with respect to the diagonal line reveals the strength and direction of the difference or ratio. The tighter the clustering along the same direction as the line, the stronger the positive correlation of the two measurements for each subject. Clustering along a direction perpendicular to the line indicates negative correlation.

Period Agreement Plots for Crossover Designs

The response in the second period is plotted against the response in the first period, with plot symbols distinguishing the two treatment sequences and the two sequence means shown larger in bold. If the **WEIGHT**

statement is used, then the means are weighted means. A diagonal line with slope=0 and y-intercept=1 is overlaid.

In the absence of a strong period effect, the points from each sequence will appear as mirror images about the diagonal line, farther apart with stronger treatment effects. Deviations from symmetry about the diagonal line indicate a period effect. The spread of points within each treatment sequence is an indicator of between-subject variability. The tighter the clustering along the same direction as the line (within each treatment sequence), the stronger the positive correlation of the two measurements for each subject. Clustering along a direction perpendicular to the line indicates negative correlation.

The period agreement plot is usually less informative than the treatment agreement plot. The exception is when the period effect is stronger than the treatment effect.

Treatment Agreement Plots for Crossover Designs

The response associated with the second treatment is plotted against the response associated with the first treatment, with plot symbols distinguishing the two treatment sequences and the two sequence means shown larger in bold. If the **WEIGHT** statement is used, then the means are weighted means. A diagonal line with slope=0 and y-intercept=1 is overlaid.

The location of the points with respect to the diagonal line reveals the strength and direction of the treatment effect. Substantial location differences between the two sequences indicates a strong period effect. The spread of points within each treatment sequence is an indicator of between-subject variability. The tighter the clustering along the same direction as the line (within each treatment sequence), the stronger the positive correlation of the two measurements for each subject. Clustering along a direction perpendicular to the line indicates negative correlation.

Box Plots

The box is drawn from the 25th percentile (lower quartile) to the 75th percentile (upper quartile). The vertical line inside the box shows the location of the median. If **DIST=NORMAL**, then a diamond symbol shows the location of the mean. The whiskers extend to the minimum and maximum observations, and circles beyond the whiskers identify outliers.

For one-sample and paired designs, a confidence interval for the mean is shown as a band in the background. If the analysis is an equivalence analysis (with the **TOST** option in the **PROC TTEST** statement), then the interval is a $100(1 - 2\alpha)\%$ confidence interval shown along with the equivalence bounds. The inclusion of this interval completely within the bounds is indicative of a significant p -value. If the analysis is not an equivalence analysis, then the confidence level is $100(1 - \alpha)\%$. If the **SHOWHO** global plot option is used, then the null value for the test is shown. If the **WEIGHT** statement is used, then weights are incorporated in the confidence intervals.

Histograms

The **WEIGHT** statement is ignored in the computation of the normal and kernel densities.

Confidence Intervals

If the analysis is an equivalence analysis (with the **TOST** option in the **PROC TTEST** statement), then unless the **TYPE=PERGROUP** option is used, the interval is a $100(1 - 2\alpha)\%$ mean confidence interval shown along with the equivalence bounds. The inclusion of this interval completely within the bounds is indicative of a significant p -value.

If the analysis is not an equivalence analysis, or if the **TYPE=PERGROUP** option is used, then the confidence level is $100(1 - \alpha)\%$. If the **SHOWHO** global plot option is used, then the null value for the test is shown.

If the **SIDES=L** or **SIDES=U** option is used in the **PROC TTEST** statement, then the unbounded side of the one-sided interval is represented with an arrowhead. Note that the actual location of the arrowhead is irrelevant.

If the **WEIGHT** statement is used, then weights are incorporated in the confidence intervals.

Profiles for Paired Designs

For paired designs, a line is drawn for each observation from left to right connecting the first response to the second response. The mean first response and mean second response are connected with a bold line. If the **WEIGHT** statement is used, then the means are weighted means. The more extreme the slope, the stronger the effect. A wide spread of profiles indicates high between-subject variability. Consistent positive slopes indicate strong positive correlation. Widely varying slopes indicate lack of correlation, while consistent negative slopes indicate strong negative correlation.

Profiles over Period for Crossover Designs

For each observation, the response for the first period is connected to the response for second period, regardless of the treatment applied in each period. The means for each treatment sequence are shown in bold. If the **WEIGHT** statement is used, then the means are weighted means.

In the absence of a strong period effect, the profiles for each sequence will appear as mirror images about an imaginary horizontal line in the center. Deviations from symmetry about this imaginary horizontal line indicate a period effect. A wide spread of profiles within sequence indicates high between-subject variability.

The **TYPE=PERIOD** plot is usually less informative than the **TYPE=TREATMENT** plot. The exception is when the period effect is stronger than the treatment effect.

Profiles over Treatment for Crossover Designs

For each observation, the response for the first treatment is connected to the response for the second treatment, regardless of the periods in which they occur. The means for each treatment sequence are shown in bold. If the **WEIGHT** statement is used, then the means are weighted means.

In general, the more extreme the slope, the stronger the treatment effect. Slope differences between the two treatment sequences measure the period effect. A wide spread of profiles within sequence indicates high between-subject variability.

Q-Q Plots

Q-Q plots are useful for diagnosing violations of the normality and homoscedasticity assumptions. If the data in a Q-Q plot come from a normal distribution, the points will cluster tightly around the reference line. You can use the **UNIVARIATE** procedure with the **NORMAL** option to numerically check the normality assumption.

Examples: TTEST Procedure

Example 99.1: Using Summary Statistics to Compare Group Means

This example, taken from Huntsberger and Billingsley (1989), compares two grazing methods using 32 steers. Half of the steers are allowed to graze continuously while the other half are subjected to controlled grazing time. The researchers want to know if these two grazing methods affect weight gain differently. The data are read by the following DATA step:

```
data graze;
  length GrazeType $ 10;
  input GrazeType $ WtGain @@;
  datalines;
controlled 45    controlled 62
controlled 96    controlled 128
controlled 120   controlled 99
controlled 28    controlled 50
controlled 109   controlled 115
controlled 39    controlled 96
controlled 87    controlled 100
controlled 76    controlled 80
continuous 94    continuous 12
continuous 26    continuous 89
continuous 88    continuous 96
continuous 85    continuous 130
continuous 75    continuous 54
continuous 112   continuous 69
continuous 104   continuous 95
continuous 53    continuous 21
;
```

The variable `GrazeType` denotes the grazing method: “controlled” is controlled grazing and “continuous” is continuous grazing. The dollar sign (\$) following `GrazeType` makes it a character variable, and the trailing at signs (@@) tell the procedure that there is more than one observation per line.

If you have summary data—that is, just means and standard deviations, as computed by PROC MEANS—then you can still use PROC TTEST to perform a simple *t* test analysis. This example demonstrates this mode of input for PROC TTEST. Note, however, that graphics are unavailable when summary statistics are used as input.

The MEANS procedure is invoked to create a data set of summary statistics with the following statements:

```
proc sort;
  by GrazeType;
run;

proc means data=graze noprint;
  var WtGain;
  by GrazeType;
  output out=newgraze;
run;
```

The NOPRINT option eliminates all printed output from the MEANS procedure. The **VAR** statement tells PROC MEANS to compute summary statistics for the WtGain variable, and the **BY** statement requests a separate set of summary statistics for each level of GrazeType. The OUTPUT OUT= statement tells PROC MEANS to put the summary statistics into a data set called newgraze so that it can be used in subsequent procedures. This new data set is displayed in [Output 99.1.1](#) by using PROC PRINT as follows:

```
proc print data=newgraze;
run;
```

The **_STAT_** variable contains the names of the statistics, and the GrazeType variable indicates which group the statistic is from.

Output 99.1.1 Output Data Set of Summary Statistics

9	controlled	0	16	MEAN	83.125
10	controlled	0	16	STD	30.535

The following statements invoke PROC TTEST with the newgraze data set, as denoted by the **DATA=** option:

```
proc ttest data=newgraze;
  class GrazeType;
  var WtGain;
run;
```

The **CLASS** statement contains the variable that distinguishes between the groups being compared, in this case GrazeType. The summary statistics and confidence intervals are displayed first, as shown in [Output 99.1.2](#).

Output 99.1.2 Summary Statistics and Confidence Limits

The TTEST Procedure						
Variable: WtGain						
GrazeType	N	Mean	Std Dev	Std Err	Minimum	Maximum
continuous	16	75.1875	33.8117	8.4529	12.0000	130.0
controlled	16	83.1250	30.5350	7.6337	28.0000	128.0
Diff (1-2)		-7.9375	32.2150	11.3897		

Output 99.1.2 *continued*

GrazeType	Method	Mean	95% CL Mean		Std Dev
continuous		75.1875	57.1705	93.2045	33.8117
controlled		83.1250	66.8541	99.3959	30.5350
Diff (1-2)	Pooled	-7.9375	-31.1984	15.3234	32.2150
Diff (1-2)	Satterthwaite	-7.9375	-31.2085	15.3335	

GrazeType	Method	95% CL		Std Dev
continuous		24.9768	52.3300	
controlled		22.5563	47.2587	
Diff (1-2)	Pooled	25.7434	43.0609	
Diff (1-2)	Satterthwaite			

In **Output 99.1.2**, The GrazeType column specifies the group for which the statistics are computed. For each class, the sample size, mean, standard deviation and standard error, and maximum and minimum values are displayed. The confidence bounds for the mean are also displayed; however, since summary statistics are used as input, the confidence bounds for the standard deviation of the groups are not calculated.

Output 99.1.3 shows the results of tests for equal group means and equal variances.

Output 99.1.3 *t Tests*

Method	Variances	DF	t Value	Pr > t
Pooled	Equal	30	-0.70	0.4912
Satterthwaite	Unequal	29.694	-0.70	0.4913

Equality of Variances				
Method	Num DF	Den DF	F Value	Pr > F
Folded F	15	15	1.23	0.6981

A group test statistic for the equality of means is reported for both equal and unequal variances. Both tests indicate a lack of evidence for a significant difference between grazing methods ($t = -0.70$ and $p = 0.4912$ for the pooled test, $t = -0.70$ and $p = 0.4913$ for the Satterthwaite test). The equality of variances test does not indicate a significant difference in the two variances ($F' = 1.23$, $p = 0.6981$). Note that this test assumes that the observations in both data sets are normally distributed; this assumption can be checked in PROC UNIVARIATE by using the NORMAL option with the raw data.

Although the ability to use summary statistics as input is useful if you lack access to the original data, some of the output that would otherwise be produced in an analysis on the original data is unavailable. There are also limitations on the designs and distributional assumptions that can be used with summary statistics as input. For more information, see the section “[Input Data Set of Statistics](#)” on page 8449.

Example 99.2: One-Sample Comparison with the FREQ Statement

This example examines children's reading skills. The data consist of Degree of Reading Power (DRP) test scores from 44 third-grade children and are taken from Moore (1995, p. 337). Their scores are given in the following DATA step:

```
data read;
  input score count @@;
  datalines;
40 2   47 2   52 2   26 1   19 2
25 2   35 4   39 1   26 1   48 1
14 2   22 1   42 1   34 2   33 2
18 1   15 1   29 1   41 2   44 1
51 1   43 1   27 2   46 2   28 1
49 1   31 1   28 1   54 1   45 1
;
```

The following statements invoke the TTEST procedure to test if the mean test score is equal to 30.

```
ods graphics on;

proc ttest data=read h0=30;
  var score;
  freq count;
run;

ods graphics off;
```

The count variable contains the frequency of occurrence of each test score; this is specified in the **FREQ** statement. The output, shown in [Output 99.2.1](#), contains the results.

Output 99.2.1 TTEST Results

The TTEST Procedure					
Variable: score					
N	Mean	Std Dev	Std Err	Minimum	Maximum
44	34.8636	11.2303	1.6930	14.0000	54.0000
Mean	95% CL Mean	Std Dev		95% CL	Std Dev
34.8636	31.4493 38.2780	11.2303		9.2788	14.2291
DF t Value Pr > t					
43 2.87 0.0063					

The SAS log states that 30 observations and two variables have been read. However, the sample size given in the TTEST output is $N=44$. This is due to specifying the count variable in the **FREQ** statement. The test is significant ($t = 2.87$, $p = 0.0063$) at the 5% level, so you can conclude that the mean test score is different from 30.

The summary panel in [Output 99.2.2](#) shows a histogram with overlaid normal and kernel densities, a box plot, and the 95% confidence interval for the mean.

Output 99.2.2 Summary Panel

The Q-Q plot in [Output 99.2.3](#) assesses the normality assumption.

Output 99.2.3 Q-Q Plot

The tight clustering of the points around the diagonal line is consistent with the normality assumption. You could use the UNIVARIATE procedure with the NORMAL option to numerically check the normality assumption.

Example 99.3: Paired Comparisons

When it is not feasible to assume that two groups of data are independent, and a natural pairing of the data exists, it is advantageous to use an analysis that takes the correlation into account. Using this correlation results in higher power to detect existing differences between the means. The differences between paired observations are assumed to be normally distributed. Some examples of this natural pairing are as follows:

- pre- and post-test scores for a student receiving tutoring
- fuel efficiency readings of two fuel types observed on the same automobile
- sunburn scores for two sunblock lotions, one applied to the individual's right arm, one to the left arm
- political attitude scores of husbands and wives

In this example, taken from the *SUGI Supplemental Library User's Guide, Version 5 Edition*, a stimulus is being examined to determine its effect on systolic blood pressure. Twelve men participate in the study. Each man's systolic blood pressure is measured both before and after the stimulus is applied. The following statements input the data:

```
data pressure;
  input SBPbefore SBPafter @@;
  datalines;
120 128   124 131   130 131   118 127
140 132   128 125   140 141   135 137
126 118   130 132   126 129   127 135
;
```

The variables SBPbefore and SBPafter denote the systolic blood pressure before and after the stimulus, respectively.

The statements to perform the test follow:

```
ods graphics on;

proc ttest;
  paired SBPbefore*SBPafter;
run;

ods graphics off;
```

The **PAIRED** statement is used to test whether the mean change in systolic blood pressure is significantly different from zero. The tabular output is displayed in [Output 99.3.1](#).

Output 99.3.1 TTEST Results

The TTEST Procedure					
Difference: SBPbefore - SBPafter					
N	Mean	Std Dev	Std Err	Minimum	Maximum
12	-1.8333	5.8284	1.6825	-9.0000	8.0000
Mean	95% CL Mean	Std Dev	95% CL	Std Dev	
-1.8333	-5.5365	1.8698	5.8284	4.1288	9.8958
DF	t Value	Pr > t			
11	-1.09	0.2992			

The variables SBPbefore and SBPafter are the paired variables with a sample size of 12. The summary statistics of the difference are displayed (mean, standard deviation, and standard error) along with their confidence limits. The minimum and maximum differences are also displayed. The *t* test is not significant ($t = -1.09$, $p = 0.2992$), indicating that the stimuli did not significantly affect systolic blood pressure.

The summary panel in [Output 99.3.2](#) shows a histogram, normal and kernel densities, box plot, and $100(1 - \alpha)\% = 95\%$ confidence interval of the SBPbefore – SBPafter difference.

Output 99.3.2 Summary Panel

The agreement plot in [Output 99.3.3](#) reveals that only three men have higher blood pressure before the stimulus than after.

Output 99.3.3 Agreement of Treatments

But the differences for these men are relatively large, keeping the mean difference only slightly negative.

The profiles plot in [Output 99.3.4](#) is a different view of the same information contained in [Output 99.3.3](#), plotting the blood pressure from before to after the stimulus.

Output 99.3.4 Profiles over Treatments

The Q-Q plot in [Output 99.3.5](#) assesses the normality assumption.

Output 99.3.5 Q-Q Plot

The Q-Q plot shows no obvious deviations from normality. You can check the assumption of normality more rigorously by using PROC UNIVARIATE with the NORMAL option.

Example 99.4: AB/BA Crossover Design

Senn (2002, Chapter 3) discusses a study comparing the effectiveness of two bronchodilators, formoterol (“for”) and salbutamol (“sal”), in the treatment of childhood asthma. A total of 13 children are recruited for an AB/BA crossover design. A random sample of 7 of the children are assigned to the treatment sequence for/sal, receiving a dose of formoterol upon an initial visit (“period 1”) and then a dose of salbutamol upon a later visit (“period 2”). The other 6 children are assigned to the sequence sal/for, receiving the treatments in the reverse order but otherwise in a similar manner. Periods 1 and 2 are sufficiently spaced so that no carryover effects are suspected. After a child inhales a dose of a bronchodilator, peak expiratory flow (PEF) is measured. Higher PEF indicates greater effectiveness. The data are assumed to be approximately normally distributed.

The data set is generated with the following statements:

```
data asthma;
  input Drug1 $ Drug2 $ PEF1 PEF2 @@;
  datalines;
for sal 310 270   for sal 310 260   for sal 370 300
for sal 410 390   for sal 250 210   for sal 380 350
for sal 330 365
sal for 370 385   sal for 310 400   sal for 380 410
sal for 290 320   sal for 260 340   sal for 90  220
;
```

You can display the data by using the following statements, which produce [Output 99.4.1](#):

```
proc print data=asthma;
run;
```

Output 99.4.1 Asthma Study Data

Obs	Drug1	Drug2	PEF1	PEF2
1	for	sal	310	270
2	for	sal	310	260
3	for	sal	370	300
4	for	sal	410	390
5	for	sal	250	210
6	for	sal	380	350
7	for	sal	330	365
8	sal	for	370	385
9	sal	for	310	400
10	sal	for	380	410
11	sal	for	290	320
12	sal	for	260	340
13	sal	for	90	220

The variables PEF1 and PEF2 represent the responses for the first and second periods, respectively. The variables Drug1 and Drug2 represent the treatment in each period.

You can analyze this crossover design by using the **CROSSOVER=** option after a slash (/) in the **VAR** statement:

```
ods graphics on;

proc ttest data=asthma plots=interval;
  var PEF1 PEF2 / crossover= (Drug1 Drug2);
run;

ods graphics off;
```

With the default **PROC TTEST** options **TEST=DIFF** and **DIST=NORMAL** and the lack of the **IGNOREPERIOD** option in the **VAR** statement, both the treatment difference and the period difference are assessed. The **PROC TTEST** default options **H0=0**, **SIDES=2**, and **ALPHA=0.05** specify a two-sided analysis with 95% confidence limits comparing treatment and period differences to a default difference of zero. The default **CI=EQUAL** option in the **PROC TTEST** statement requests equal-tailed confidence intervals for

standard deviations. The **PLOTS=INTERVAL** option produces **TYPE=TREATMENT** confidence intervals, in addition to the default plots **AGREEMENT(TYPE=TREATMENT)**, **BOX**, **HISTOGRAM**, **PROFILES(TYPE=TREATMENT)**, and **QQ**.

Output 99.4.2 summarizes the response and treatment variables for each period.

Output 99.4.2 Crossover Variable Information

The TTEST Procedure		
Response Variables: PEF1, PEF2		
Crossover Variable Information		
Period	Response	Treatment
1	PEF1	Drug1
2	PEF2	Drug2

Output 99.4.3 displays basic summary statistics (sample size, mean, standard deviation, standard error, minimum, and maximum) for each of the four cells in the design, the treatment difference within each treatment sequence, the overall treatment difference, and the overall period difference.

Output 99.4.3 Statistics

Sequence	Treatment	Period	N	Mean	Std Dev	Std Err
1	for	1	7	337.1	53.7631	20.3206
2	for	2	6	345.8	70.8814	28.9372
2	sal	1	6	283.3	105.4	43.0245
1	sal	2	7	306.4	64.7247	24.4636
1	Diff (1-2)		7	30.7143	32.9682	12.4608
2	Diff (1-2)		6	62.5000	44.6934	18.2460
Both	Diff (1-2)			46.6071	19.3702	10.7766
Both		Diff (1-2)		-15.8929	19.3702	10.7766

Sequence	Treatment	Period	Minimum	Maximum
1	for	1	250.0	410.0
2	for	2	220.0	410.0
2	sal	1	90.0000	380.0
1	sal	2	210.0	390.0
1	Diff (1-2)		-35.0000	70.0000
2	Diff (1-2)		15.0000	130.0
Both	Diff (1-2)			
Both		Diff (1-2)		

The treatment difference “Diff (1-2)” corresponds to the “for” treatment minus the “sal” treatment, because “for” appears before “sal” in the output, according to the **ORDER=MIXED** default **PROC TTEST** option. Its mean estimate is 46.6071, favoring formoterol over salbutamol.

The standard deviation (Std Dev) reported for a “difference” is actually the pooled standard deviation across

both treatment sequence (for/sal and sal/for), assuming equal variances. The standard error (Std Err) is the standard deviation of the mean estimate.

The top half of the table in [Output 99.4.4](#) shows 95% two-sided confidence limits for the means for the same criteria addressed in the table in [Output 99.4.3](#).

Output 99.4.4 Confidence Limits

Sequence	Treatment	Period	Method	Mean	95% CL	Mean
1	for	1		337.1	287.4	386.9
2	for	2		345.8	271.4	420.2
2	sal	1		283.3	172.7	393.9
1	sal	2		306.4	246.6	366.3
1	Diff (1-2)			30.7143	0.2238	61.2048
2	Diff (1-2)			62.5000	15.5972	109.4
Both	Diff (1-2)		Pooled	46.6071	22.8881	70.3262
Both	Diff (1-2)		Satterthwaite	46.6071	21.6585	71.5558
Both		Diff (1-2)	Pooled	-15.8929	-39.6119	7.8262
Both		Diff (1-2)	Satterthwaite	-15.8929	-40.8415	9.0558
Sequence	Treatment	Period	Method	Std Dev	95% CL	Std Dev
1	for	1		53.7631	34.6446	118.4
2	for	2		70.8814	44.2447	173.8
2	sal	1		105.4	65.7841	258.5
1	sal	2		64.7247	41.7082	142.5
1	Diff (1-2)			32.9682	21.2445	72.5982
2	Diff (1-2)			44.6934	27.8980	109.6
Both	Diff (1-2)		Pooled	19.3702	13.7217	32.8882
Both	Diff (1-2)		Satterthwaite			
Both		Diff (1-2)	Pooled	19.3702	13.7217	32.8882
Both		Diff (1-2)	Satterthwaite			

For the mean differences, both pooled (assuming equal variances for both treatment sequences) and Satterthwaite (assuming unequal variances) intervals are shown. For example, the pooled confidence limits for the overall treatment mean difference (for – sal) assuming equal variances are 22.8881 and 70.3262.

The bottom half of [Output 99.4.4](#) shows 95% equal-tailed confidence limits for the standard deviations within each cell and for the treatment difference within each sequence. It also shows confidence limits for the pooled common standard deviation assuming equal variances. Note that the pooled standard deviation of 19.3702 and associated confidence limits 13.7217 and 32.8882 apply to both difference tests (treatment and period), since each of those tests involves the same pooled standard deviation.

[Output 99.4.5](#) shows the results of *t* tests of treatment and period differences.

Output 99.4.5 *t* Tests

Treatment	Period	Method	Variances	DF	t Value	Pr > t
Diff (1-2)		Pooled	Equal	11	4.32	0.0012
Diff (1-2)		Satterthwaite	Unequal	9.1017	4.22	0.0022
	Diff (1-2)	Pooled	Equal	11	-1.47	0.1683
	Diff (1-2)	Satterthwaite	Unequal	9.1017	-1.44	0.1838

Both pooled and Satterthwaite versions of the test of treatment difference are highly significant ($p = 0.0012$ and $p = 0.0022$), and both versions of the test of period difference are insignificant ($p = 0.1683$ and $p = 0.1838$).

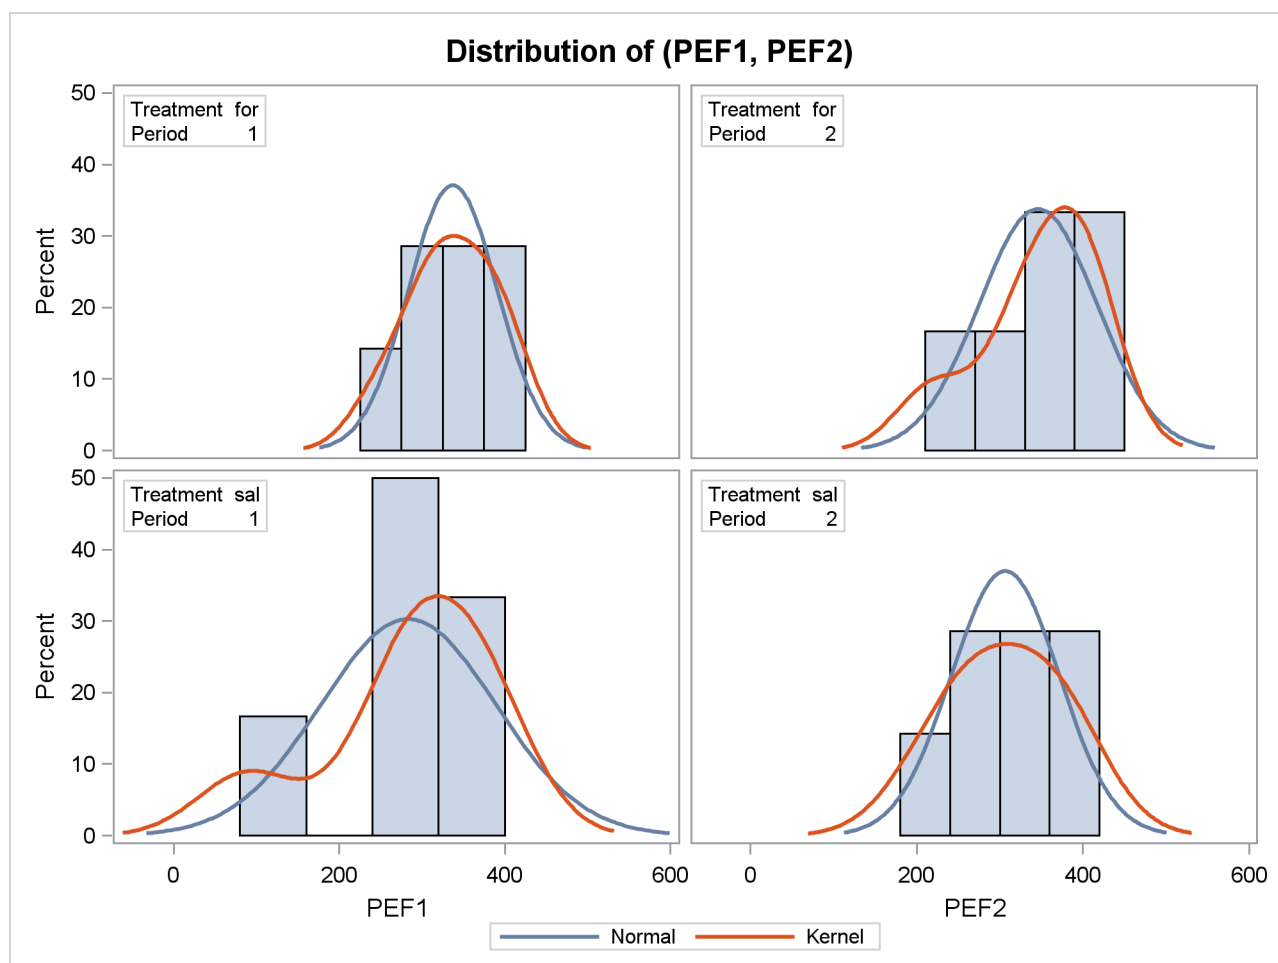

The folded F test of equal variances in each treatment sequence is shown in [Output 99.4.6](#).

Output 99.4.6 Equality of Variances Test

Equality of Variances				
Method	Num DF	Den DF	F Value	Pr > F
Folded F	5	6	1.84	0.4797

The insignificant result ($p = 0.48$) implies a lack of evidence for unequal variances. However, it does not demonstrate equal variances, and it is not very robust to deviations from normality.

[Output 99.4.7](#) shows the distribution of the response variables PEF1 and PEF2 within each of the four cells (combinations of two treatments and two periods) of the AB/BA crossover design, in terms of histograms and normal and kernel density estimates.

Output 99.4.7 Comparative Histograms

The distributions for the first treatment sequence (for/sal) appear to be somewhat symmetric, and the distributions for the sal/for sequence appear to be skewed to the left.

Output 99.4.8 shows a similar distributional summary but in terms of box plots.

Output 99.4.8 Comparative Box Plots

The relative locations of means and medians in each box plot corroborate the fact that the distributions for the sal/for sequence are skewed to the left. The distributions for the for/sal sequence appear to be skewed slightly to the right. The box plot for the salbutamol treatment in the first period shows an outlier (the circle on the far left side of the plot).

The treatment agreement plot in [Output 99.4.9](#) reveals that only a single observation has a higher peak expiratory flow for salbutamol.

Output 99.4.9 Agreement of Treatments Plot

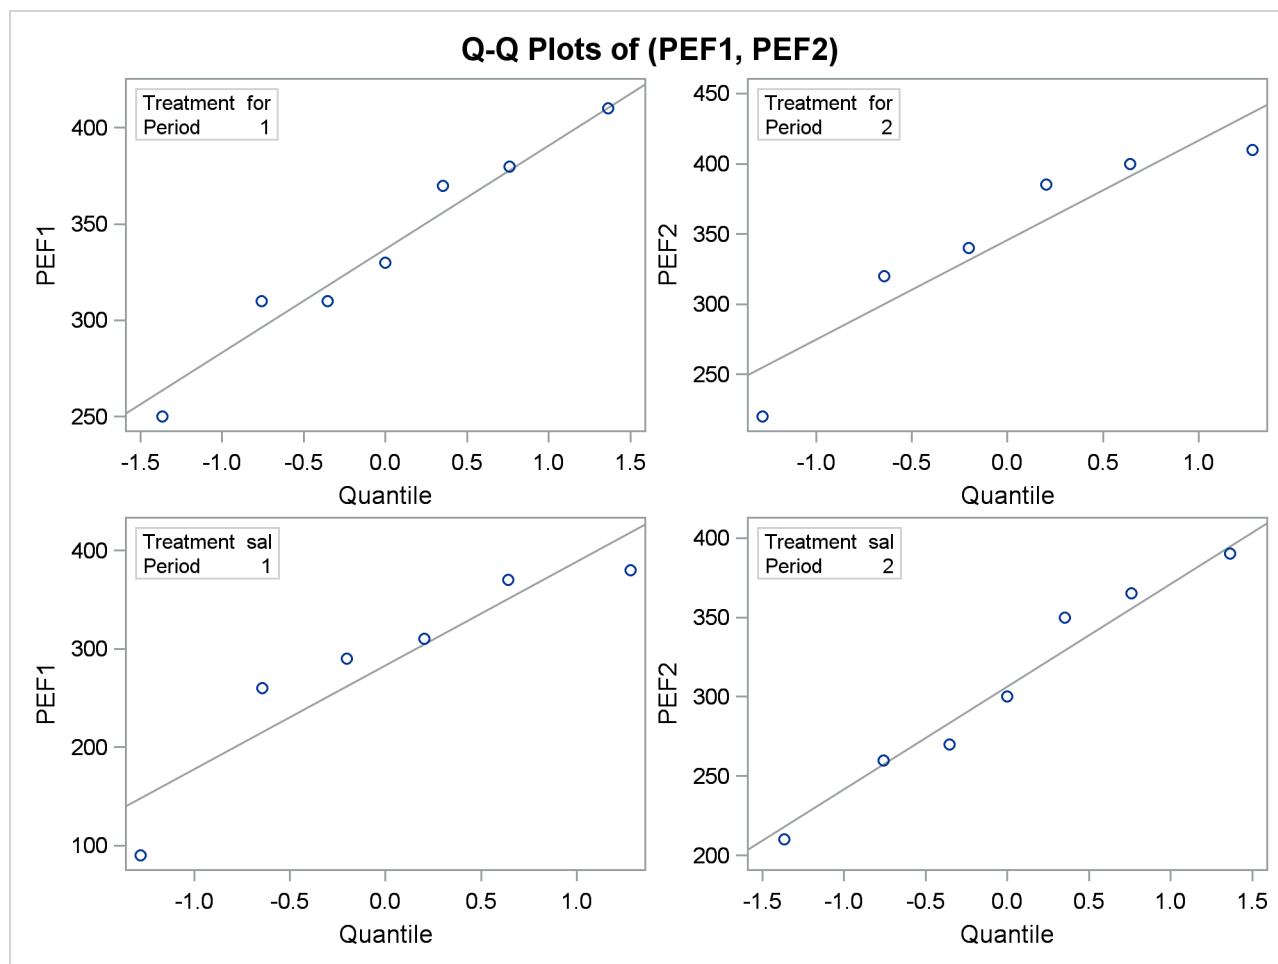

The mean for the sal/for treatment sequence is farther from the diagonal equivalence line, revealing that the treatment difference is more pronounced for the 6 observations in the sal/for sequence than for the 7 observations in the for/sal sequence. This fact is also seen numerically in [Output 99.4.3](#) and [Output 99.4.4](#), which show within-sequence treatment differences of 30.7 for for/sal and 62.5 for sal/for.

The profiles over treatment plot in [Output 99.4.10](#) is a different view of the same information contained in [Output 99.4.9](#), plotting the profiles from formoterol to salbutamol treatments. The lone observation for which the peak expiratory flow is higher for salbutamol appears as the only line with negative slope.

Output 99.4.10 Profiles over Treatment

The Q-Q plots in [Output 99.4.11](#) assess normality assumption within each of the four cells of the design.

Output 99.4.11 Q-Q Plots

The two Q-Q plots for the sal/for sequence (lower left and upper right) suggest some possible normality violations in the tails, but the sample size is too small to make any strong conclusions. You could use the UNIVARIATE procedure with the NORMAL option to numerically check the normality assumptions.

Finally, [Output 99.4.12](#) shows both pooled and Satterthwaite two-sided 95% confidence intervals for the treatment difference.

Output 99.4.12 Confidence Intervals for Treatment Difference

The pooled interval is slightly smaller than the Satterthwaite interval. (This is not always the case.)

Example 99.5: Equivalence Testing with Lognormal Data

Wellek (2003, p. 212) discusses an average bioequivalence study comparing the AUC (area under serum-concentration curve) measurements for two different drugs, denoted “Test” and “Reference,” over a period of 20 hours. This example looks at a portion of Wellek’s data, conducting an equivalence analysis with a paired design that uses AUC values on the original scale (assumed to be lognormally distributed). Each subject in the study received the Test drug upon one visit and then the Reference drug upon a later visit, sufficiently spaced so that no carryover effects would occur.

The goal is to test whether the geometric mean AUC ratio between Test and Reference is between 0.8 and 1.25, corresponding to the traditional FDA (80%, 125%) equivalence criterion. See the section “[Arithmetic and Geometric Means](#)” on page 8451 for a discussion of the use of geometric means for lognormal data.

The following SAS statements generate the data set:

```
data auc;
  input TestAUC RefAUC @@;
  datalines;
103.4 90.11 59.92 77.71 68.17 77.71 94.54 97.51
69.48 58.21 72.17 101.3 74.37 79.84 84.44 96.06
96.74 89.30 94.26 97.22 48.52 61.62 95.68 85.80
;
```

You can display the data by using the following statements, which produce [Output 99.5.1](#):

```
proc print data=auc;
run;
```

Output 99.5.1 AUC Data for Test and Reference Drugs

Obs	Test AUC	RefAUC
1	103.40	90.11
2	59.92	77.71
3	68.17	77.71
4	94.54	97.51
5	69.48	58.21
6	72.17	101.30
7	74.37	79.84
8	84.44	96.06
9	96.74	89.30
10	94.26	97.22
11	48.52	61.62
12	95.68	85.80

The TestAUC and RefAUC variables represent the AUC measurements for each subject under the Test and Reference drugs, respectively. Use the following SAS statements to perform the equivalence analysis:

```
ods graphics on;

proc ttest data=auc dist=lognormal tost(0.8, 1.25);
  paired TestAUC*RefAUC;
run;

ods graphics off;
```

The **DIST=LOGNORMAL** option specifies the lognormal distributional assumption and requests an analysis in terms of geometric mean and coefficient of variation. The **TOST** option specifies the equivalence bounds 0.8 and 1.25.

[Output 99.5.2](#) shows basic summary statistics for the ratio of TestAUC to RefAUC.

Output 99.5.2 Summary Statistics

The TTEST Procedure				
Ratio: TestAUC / RefAUC				
N	Geometric Mean	Coefficient of Variation	Minimum	Maximum
12	0.9412	0.1676	0.7124	1.1936

The geometric mean ratio of 0.9412 is the sample mean of the log-transformed data exponentiated to bring it

back to the original scale. So the plasma concentration over the 20-hour period is slightly lower for the Test drug than for the Reference drug. The CV of 0.1676 is the ratio of the standard deviation to the (arithmetic) mean.

Output 99.5.3 shows the $100(1 - \alpha)\% = 95\%$ confidence limits for the geometric mean ratio (0.8467 and 1.0462) and CV (0.1183 and 0.2884).

Output 99.5.3 Confidence Limits

Geometric Mean	95% CL Mean		Coefficient of Variation	95% CL CV	
0.9412	0.8467	1.0462	0.1676	0.1183	0.2884

Output 99.5.4 shows the $100(1 - 2\alpha)\% = 90\%$ confidence limits for the geometric mean ratio, 0.8634 and 1.0260.

Output 99.5.4 Equivalence Limits

Geometric Mean	Lower Bound	90% CL Mean		Upper Bound	Assessment
0.9412	0.8 <	0.8634	1.0260 <	1.25	Equivalent

The assessment of “Equivalent” reflects the fact that these limits are contained within the equivalence bounds 0.8 and 1.25. This result occurs if and only if the p -value of the test is less than the α value specified in the **ALPHA=** option in the **PROC TTEST** statement, and it is the reason that $100(1 - 2\alpha)\%$ confidence limits are shown in addition to the usual $100(1 - \alpha)\%$ limits.

Output 99.5.5 shows the p -values for the two one-sided tests against the upper and lower equivalence bounds.

Output 99.5.5 TOST Equivalence Test

Test	Null	DF	t Value	P-Value
Upper	0.8	11	3.38	0.0031
Lower	1.25	11	-5.90	<.0001
Overall				0.0031

The overall p -value of 0.0031, the larger of the two one-sided p -values, indicates significant evidence of equivalence between the Test and Reference drugs.

The summary panel in **Output 99.5.6** shows a histogram, kernel density, box plot, and $100(1 - 2\alpha)\% = 90\%$ confidence interval of the Test-to-Reference ratio of AUC, along with the equivalence bounds.

Output 99.5.6 Summary Panel

The confidence interval is closer to the lower equivalence bound than the upper bound and contained entirely within the bounds.

The agreement plot in [Output 99.5.7](#) reveals that the only four subjects with higher AUC for the Test drug are at the far lower or far upper end of the AUC distribution. This might merit further investigation.

Output 99.5.7 Agreement Plot

The profiles plot in [Output 99.5.8](#) is a different view of the same information contained in [Output 99.5.7](#), plotting the AUC from Test to Reference drug.

Output 99.5.8 Profiles Plot

Overview: VARCLUS Procedure

The VARCLUS procedure divides a set of numeric variables into disjoint or hierarchical clusters. Associated with each cluster is a linear combination of the variables in the cluster. This linear combination can be either the first principal component (the default) or the centroid component (if you specify the **CENTROID** option). The first principal component is a weighted average of the variables that explains as much variance as possible. See Chapter 73, “[The PRINCOMP Procedure](#),” for further details. Centroid components are unweighted averages of either the standardized variables (the default) or the raw variables (if you specify the **COVARIANCE** option). PROC VARCLUS tries to maximize the variance that is explained by the cluster components, summed over all the clusters.

The cluster components are oblique, not orthogonal, even when the cluster components are first principal components. In an ordinary principal component analysis, all components are computed from the same variables, and the first principal component is orthogonal to the second principal component and to every other principal component. In PROC VARCLUS, each cluster component is computed from a set of variables that is different from all the other cluster components. The first principal component of one cluster might be correlated with the first principal component of another cluster. Hence, the PROC VARCLUS algorithm is a type of oblique component analysis.

As in principal component analysis, either the correlation or the covariance matrix can be analyzed. If correlations are used, all variables are treated as equally important. If covariances are used, variables with larger variances have more importance in the analysis.

PROC VARCLUS displays a dendrogram (tree diagram of hierarchical clusters) by using ODS Graphics. PROC VARCLUS can also create an output data set that can be used by the TREE procedure to draw the dendrogram. A second output data set can be used with the SCORE procedure to compute component scores for each cluster.

PROC VARCLUS can be used as a variable-reduction method. A large set of variables can often be replaced by the set of cluster components with little loss of information. A given number of cluster components does not generally explain as much variance as the same number of principal components on the full set of variables, but the cluster components are usually easier to interpret than the principal components, even if the latter are rotated.

For example, an educational test might contain 50 items. PROC VARCLUS can be used to divide the items into, say, five clusters. Each cluster can then be treated as a subtest, with the subtest scores given by the cluster components. If the cluster components are centroid components of the covariance matrix, each subtest score is simply the sum of the item scores for that cluster.

The VARCLUS algorithm is both divisive and iterative. By default, PROC VARCLUS begins with all variables in a single cluster. It then repeats the following steps:

1. A cluster is chosen for splitting. Depending on the options specified, the selected cluster has either the smallest percentage of variation explained by its cluster component (using the PROPORTION= option) or the largest eigenvalue associated with the second principal component (using the MAX-EIGEN= option).
2. The chosen cluster is split into two clusters by finding the first two principal components, performing an orthoblique rotation (raw quartimax rotation on the eigenvectors; Harris and Kaiser 1964), and assigning each variable to the rotated component with which it has the higher squared correlation.
3. Variables are iteratively reassigned to clusters to try to maximize the variance accounted for by the cluster components. You can require the reassignment algorithms to maintain a hierarchical structure for the clusters.

The procedure stops splitting when either of the following conditions holds:

- The number of clusters is greater than or equal to the maximum number of clusters as specified by the MAXCLUSTERS= option is reached.
- Every cluster satisfies the stopping criteria specified by the PROPORTION= option (percentage of variation explained) or the MAXEIGEN= option (second eigenvalue) or both.

By default, VARCLUS stops splitting when every cluster has only one eigenvalue greater than one, thus satisfying the most popular criterion for determining the sufficiency of a single underlying dimension.

The iterative reassignment of variables to clusters proceeds in two phases. The first is a nearest component sorting (NCS) phase, similar in principle to the nearest centroid sorting algorithms described by Anderberg (1973). In each iteration, the cluster components are computed, and each variable is assigned to the component with which it has the highest squared correlation. The second phase involves a search algorithm in which each variable is tested to see if assigning it to a different cluster increases the amount of variance explained. If a variable is reassigned during the search phase, the components of the two clusters involved are recomputed before the next variable is tested. The NCS phase is much faster than the search phase but is more likely to be trapped by a local optimum.

If principal components are used, the NCS phase is an alternating least squares method and converges rapidly. The search phase can be very time-consuming for a large number of variables. But if the default initialization method is used, the search phase is rarely able to substantially improve the results of the NCS phase, so the search takes few iterations. If random initialization is used, the NCS phase might be trapped by a local optimum from which the search phase can escape.

If centroid components are used, the NCS phase is not an alternating least squares method and might not increase the amount of variance explained; therefore it is limited, by default, to one iteration.

You can have VARCLUS do the clustering hierarchically by restricting the reassignment of variables such that the clusters maintain a tree structure. In this case, when a cluster is split, a variable in one of the two resulting clusters can be reassigned to the other cluster that results from the split but not to a cluster that is not part of the original cluster (the one that is split).

Getting Started: VARCLUS Procedure

This example demonstrates how you can use PROC VARCLUS to cluster variables.

The following data are job ratings of police officers. The officers were rated by their supervisors on 13 job skills on a scale from 1 to 9. There is also an overall rating that is not used in this analysis. The following DATA step creates the SAS data set JobRat:

```

data JobRat;
  input
    (Communication_Skills
     Problem_Solving
     Learning_Ability
     Judgement_under_Pressure
     Observational_Skills
     Willingness_to_Confront_Problems
     Interest_in_People
     Interpersonal_Sensitivity
     Desire_for_Self_Improvement
     Appearance
     Dependability
     Physical_Ability
     Integrity
     Overall_Rating)
    (1.);
  datalines;
26838853879867
74758876857667
56757863775875
67869777988997
99997798878888

... more lines ...

99997899799799
99899899899899
76656399567486
;

```

The following statements cluster the variables:

```

proc varclus data=JobRat maxclusters=3;
  var Communication_Skills--Integrity;
run;

```

The DATA= option specifies the SAS data set JobRat as input.

The MAXCLUSTERS=3 option specifies that no more than three clusters be computed. By default, PROC VARCLUS splits and optimizes clusters until all clusters have a second eigenvalue less than one. In this example, the default setting would produce only two clusters, but going to three clusters produces a more interesting result.

The VAR statement lists the numeric variables (Communication_Skills -- Integrity) to be used in the analysis. The overall rating is omitted from the list of variables.

Although PROC VARCLUS displays output for one cluster, two clusters, and three clusters, the following figures display only the final analysis for three clusters.

For each cluster, [Figure 100.1](#) displays the number of variables in the cluster, the cluster variation, the total explained variation, and the proportion of the total variance explained by the variables in the cluster. The variance explained by the variables in a cluster is similar to the variance explained by a factor in

common factor analysis, but it includes contributions only from the variables in the cluster rather than from all variables.

The line labeled “Total variation explained” in Figure 100.1 gives the sum of the explained variation over all clusters. The final “Proportion” represents the total explained variation divided by the sum of cluster variation. This value, 0.6715, indicates that about 67% of the total variation in the data can be accounted for by the three cluster components.

Figure 100.1 Cluster Summary for Three Clusters from PROC VARCLUS

Oblique Principal Component Cluster Analysis					
Cluster Summary for 3 Clusters					
Cluster	Members	Cluster Variation	Variation Explained	Proportion Explained	Second Eigenvalue
1	6	6	3.771349	0.6286	0.7093
2	5	5	3.575933	0.7152	0.5035
3	2	2	1.382005	0.6910	0.6180
Total variation explained = 8.729286 Proportion = 0.6715					

Figure 100.2 shows how the variables are clustered. Figure 100.2 also displays the R-square value of each variable with its own cluster and the R-square value with its nearest cluster. The R-square value for a variable with the nearest cluster should be low if the clusters are well separated. The last column displays the ratio of $(1 - R_{own}^2)/(1 - R_{nearest}^2)$ for each variable. Small values of this ratio indicate good clustering.

Figure 100.2 R-Square Values from PROC VARCLUS

3 Clusters		R-squared with		
Cluster	Variable	Own Cluster	Next Closest	1-R**2 Ratio
Cluster 1	Communication_Skills	0.6403	0.3599	0.5620
	Problem_Solving	0.5412	0.2895	0.6458
	Learning_Ability	0.6561	0.1692	0.4139
	Observational_Skills	0.6889	0.2584	0.4194
	Willingness_to_Confront_Problems	0.6480	0.3402	0.5335

Figure 100.4 *continued*

Inter-Cluster Correlations			
Cluster	1	2	3
1	1.00000	0.60851	0.59223
2	0.60851	1.00000	0.48711
3	0.59223	0.48711	1.00000

PROC VARCLUS next displays the summary table of statistics for the cluster history (Figure 100.5). The first three columns give the number of clusters, the total variation explained by clusters, and the proportion of variation explained by clusters, respectively.

As displayed in the first row of Figure 100.5, the variation explained by the first principal component of all the variables is 6.547402, and the proportion of variation explained is 0.5036.

When the number of clusters is two, the total variation explained is 7.96775 and the proportion of variation explained by the two clusters is 0.6129. The larger second eigenvalue of the clusters is 0.937902; so by default, PROC VARCLUS would stop splitting clusters at this point. But because the MAXCLUSTERS=3 option was specified in this example, PROC VARCLUS continues to the three-cluster solution.

When the number of clusters increases to three, the total variation explained is 8.729286 and the proportion of variation explained by the two clusters is 0.6715. The largest second eigenvalue of the clusters is 0.709323. The statistical improvement from increasing the number of clusters from two to three seems modest, but the interpretability of the three clusters argues for the three-cluster solution.

Figure 100.5 also displays the minimum proportion of variance explained by a cluster, the minimum R^2 for a variable, and the maximum $(1 - R^2)$ ratio for a variable. The last quantity is the maximum ratio of the value $1 - R^2$ for a variable's own cluster to the value $1 - R^2$ for its nearest cluster.

Figure 100.5 Final Cluster Summary Table from PROC VARCLUS

Number of Clusters	Total Variation Explained by Clusters	Proportion of Variation Explained by Clusters	Minimum Proportion Explained by a Cluster	Maximum Second Eigenvalue in a Cluster	Minimum R-squared for a Variable	Maximum 1-R**2 Ratio for a Variable
1	6.547402	0.5036	0.5036	1.772715	0.2995	
2	7.967753	0.6129	0.5475	0.937902	0.3123	0.8026
3	8.729286	0.6715	0.6286	0.709323	0.5412	0.6875

Syntax: VARCLUS Procedure

The following statements are available in the VARCLUS procedure:

```
PROC VARCLUS < options > ;
    VAR variables ;
    SEED variables ;
    PARTIAL variables ;
    WEIGHT variables ;
    FREQ variables ;
    BY variables ;
```

Usually you need only the VAR statement in addition to the PROC VARCLUS statement. The following sections give detailed syntax information about each of the statements, beginning with the PROC VARCLUS statement. The remaining statements are listed in alphabetical order.

PROC VARCLUS Statement

```
PROC VARCLUS < options > ;
```

The PROC VARCLUS statement invokes the VARCLUS procedure. By default, VARCLUS clusters the numeric variables in the most recently created SAS data set, starting with one cluster and splitting clusters until all clusters have at most one eigenvalue greater than one.

Table 100.1 summarizes the options available in the PROC VARCLUS statement.

Table 100.1 Options Available in the PROC VARCLUS Statement

Option	Description
Data Sets	
DATA=	Specifies the input SAS data set
OUTSTAT=	Specifies the output SAS data set to contain statistics
OUTTREE=	Specifies the output SAS data set for use with PROC TREE
Input Data Processing	
COVARIANCE	Uses the covariance matrix instead of the correlation matrix
NOINT	Omits the intercept
VARDEF=	Specifies the divisor for variances
Number of Clusters	
MAXCLUSTERS=	Specifies the maximum number of clusters
MINCLUSTERS=	Specifies the minimum number of clusters
MAXEIGEN=	Specifies the maximum second eigenvalue in a cluster
PROPORTION=	Specifies the minimum proportion of variance explained by a cluster component
Clustering Methods	
CENTROID	Uses centroid components instead of principal components
HIERARCHY	Clusters hierarchically
INITIAL=	Specifies the initialization method

Table 100.1 *continued*

Option	Description
MAXITER=	Specifies the maximum iterations during the alternating least squares phase
MAXSEARCH=	Specifies the maximum iterations during the search phase
MULTIPLEGROUP	Performs a multiple group component analysis
RANDOM=	Specifies the random number seed
Control Displayed Output	
CORR	Displays the correlation matrix
NOPRINT	Suppresses displayed output
PLOTS=	Specifies ODS Graphics details
SHORT	Suppresses display of large matrices
SIMPLE	Displays means and standard deviations
SUMMARY	Suppresses all default displayed output except the final summary table
TRACE	Displays the cluster to which each variable is assigned during the iterations

VARCLUS chooses which cluster to split based on the MAXEIGEN= and PROPORTION= options.

1. If you specify *either* or *both* of these two options, then *only* the specified options affect the choice of the cluster to split.
2. If you specify *neither* of these options, the criterion for choice of cluster to split depends on the CENTROID option:
 - a) If you specify CENTROID, VARCLUS splits the cluster with the smallest percentage of variation explained by its cluster component, as if you had specified the PROPORTION= option.
 - b) If you do not specify CENTROID, VARCLUS splits the cluster with the largest eigenvalue associated with the second principal component, as if you had specified the MAXEIGEN= option.

The final number of clusters is controlled by three options: MAXCLUSTERS=, MAXEIGEN=, and PROPORTION=.

1. If you specify *any* of these three options, then *only* the options you specify affect the final number of clusters.
2. If you specify *none* of these options, VARCLUS continues to split clusters until the default splitting criterion is satisfied. The default splitting criterion depends on the CENTROID option:
 - a) If you specify CENTROID, the default splitting criterion is PROPORTION=0.75.
 - b) If you do not specify CENTROID, splitting is based on the MAXEIGEN= criterion, with a default depending on the COVARIANCE option:
 - i. For analyzing a correlation matrix (no COVARIANCE option), the default value for MAXEIGEN= is one.
 - ii. For analyzing a covariance matrix (using the COVARIANCE option), the default value for MAXEIGEN= is the average variance of the variables being clustered.

VARCLUS continues to split clusters until any of the following conditions holds:

- The number of cluster equals the value specified for MAXCLUSTERS=.
- No cluster qualifies for splitting according to the MAXEIGEN= or PROPORTION= criterion.
- A cluster was chosen for splitting, but after iteratively reassigning variables to clusters, one of the cluster has no members.

The following list gives details about the options.

CENTROID

uses centroid components rather than principal components. You should specify centroid components if you want the cluster components to be unweighted averages of the standardized variables (the default) or the unstandardized variables (if you specify the COVARIANCE option). It is possible to obtain locally optimal clusterings in which a variable is not assigned to the cluster component with which it has the highest squared correlation. You cannot specify both the CENTROID and MAXEIGEN= options.

CORR

C

displays the correlation matrix.

COVARIANCE

COV

analyzes the covariance matrix instead of the correlation matrix. The COVARIANCE option causes variables with a large variance to have more effect on the cluster components than variables with a small variance.

DATA=SAS-data-set

specifies the input data set to be analyzed. The data set can be an ordinary SAS data set or TYPE=CORR, UCORR, COV, UCOV, FACTOR, or SSCP. If you do not specify the DATA= option, the most recently created SAS data set is used. See Appendix A, “[Special SAS Data Sets](#),” for more information about types of SAS data sets.

HIERARCHY

HI

requires the clusters at different levels to maintain a hierarchical structure. To draw a tree diagram, enable ODS Graphics or use the OUTTREE= option and the TREE procedure.

INITIAL=GROUP

INITIAL=INPUT

INITIAL=RANDOM

INITIAL=SEED

specifies the method for initializing the clusters. If the INITIAL= option is omitted and the MINCLUSTERS= option is greater than 1, the initial cluster components are obtained by extracting the required number of principal components and performing an orthoblique rotation (raw quartimax rotation on the eigenvectors; Harris and Kaiser 1964). The following list describes the values for the INITIAL= option:

GROUP	obtains the cluster membership of each variable from an observation in the DATA= data set where the _TYPE_ variable has a value of 'GROUP'. In this observation, the variables to be clustered must each have an integer value ranging from one to the number of clusters. You can use this option only if the DATA= data set is a TYPE=CORR, UCORR, COV, UCOV, or FACTOR data set. You can use a data set created either by a previous run of PROC VARCLUS or in a DATA step.
INPUT	obtains scoring coefficients for the cluster components from observations in the DATA= data set where the _TYPE_ variable has a value of 'SCORE'. You can use this option only if the DATA= data set is a TYPE=CORR, UCORR, COV, UCOV, or FACTOR data set. You can use scoring coefficients from the FACTOR procedure or a previous run of PROC VARCLUS, or you can enter other coefficients in a DATA step.
RANDOM	assigns variables randomly to clusters.
SEED	initializes each cluster component to be one of the variables named in the SEED statement. Each variable listed in the SEED statement becomes the sole member of a cluster, and the other variables are initially unassigned. If you do not specify the SEED statement, the first MINCLUSTERS= variables in the VAR statement are used as seeds.

MAXCLUSTERS=*n***MAXC=*n***

specifies the largest number of clusters desired. The default value is the number of variables. VARCLUS stops splitting clusters after the number of clusters reaches the value of the MAXCLUSTERS= option, regardless of what other splitting options are specified.

MAXEIGEN=*n*

specifies that when choosing a cluster to split, VARCLUS should choose the cluster with the largest second eigenvalue, provided that its second eigenvalue is greater than the MAXEIGEN= value. The MAXEIGEN= option cannot be used with the CENTROID or MULTIPLEGROUP options.

If you do not specify MAXEIGEN=, the default behavior depends on other options as follows:

- If you specify PROPORTION=, CENTROID, or MULTIPLEGROUP, cluster splitting does not depend on the second eigenvalue.
- Otherwise, if you specify MAXCLUSTERS=, the default value for MAXEIGEN= is zero.
- Otherwise, the default value for MAXEIGEN= is either 1.0 if the correlation matrix is analyzed or the average variance if the COVARIANCE option is specified.

If you specify both MAXEIGEN= and MAXCLUSTERS=, the number of clusters will never exceed the value of the MAXCLUSTERS= option.

If you specify both MAXEIGEN= and PROPORTION=, VARCLUS first looks for a cluster to split based on the MAXEIGEN= criterion. If no cluster meets that criterion, VARCLUS then looks for a cluster to split based on the PROPORTION= criterion.

MAXITER=*n*

specifies the maximum number of iterations during the NCS phase. The default value is 1 if you specify the CENTROID option; the default is 10 otherwise.

MAXSEARCH=*n*

specifies the maximum number of iterations during the search phase. The default is 1,000 divided by the number of variables.

MINCLUSTERS=*n***MINC=*n***

specifies the smallest number of clusters desired. The default value is 2 for INITIAL=RANDOM or INITIAL=SEED; otherwise, VARCLUS begins with one cluster and tries to split it in accordance with the PROPORTION= option or the MAXEIGEN= option or both.

MULTIPLEGROUP**MG**

performs a multiple group component analysis (Harman 1976). You specify which variables belong to which clusters. No clusters are split, and no variables are reassigned to a different cluster. The input data set must be TYPE=CORR, UCORR, COV, UCOV, FACTOR, or SSCP and must contain an observation with _TYPE_='GROUP' that defines the variable groups. Specifying the MULTIPLE-GROUP option is equivalent to specifying all of the following options: INITIAL=GROUP, MINC=1, MAXITER=0, MAXSEARCH=0, PROPORTION=0, and MAXEIGEN=large number.

NOINT

requests that no intercept be used; covariances or correlations are not corrected for the mean. If you specify the NOINT option, the OUTSTAT= data set is TYPE=UCORR.

NOPRINT

suppresses displayed output. This option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, [“Using the Output Delivery System.”](#)

OUTSTAT=SAS-data-set

creates an output data set to contain statistics including means, standard deviations, correlations, cluster scoring coefficients, and the cluster structure. The OUTSTAT= data set is TYPE=UCORR if the NOINT option is specified. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For information about types of SAS data sets, see Appendix A, [“Special SAS Data Sets.”](#)

OUTTREE=SAS-data-set

creates an output data set to contain information about the tree structure that can be used by the TREE procedure to display a tree diagram. The OUTTREE= option implies the HIERARCHY option. See [Example 100.1](#) for use of the OUTTREE= option. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

PLOTS <(global-plot-options)> <= plot-request >

PLOTS < (*global-plot-options*) > <= (*plot-request* < ... *plot-request* >) >

controls the plots produced through ODS Graphics.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc varclus plots=dendrogram(height=ncl);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

By default, PROC VARCLUS produces a dendrogram.

The *global-plot-options*, UNPACK and ONLY, that are commonly used in the PLOTS= option in other procedures are accepted in PROC VARCLUS, but they currently have no effect since PROC VARCLUS produces only a dendrogram.

The following *plot-requests* can be specified:

ALL

produces all plots, which for PROC VARCLUS is only a dendrogram.

MAXPOINTS=*n*

MAXPTS=*n*

suppresses the dendrogram when the number of variables (clusters) exceeds the *n* value. This prevents an unreadable plot from being produced. The default is MAXPOINTS=200.

DENDROGRAM < (*dendrogram-options*) >

requests a dendrogram and specifies *dendrogram-options*.

Unlike most graphs, the size of the dendrogram can vary as a function of the number of objects that appear in the dendrogram. You can specify the following *dendrogram-options* to control the size and appearance of the dendrogram:

COMPUTEHEIGHT=*a b*

CH=*a b*

specifies the constants for computing the height of the dendrogram. For *n* points being clustered, intercept *a*, and slope *b*, the height is based in part on $a + bn$. For a horizontal dendrogram, the default (given in pixels) is COMPUTEHEIGHT=100 12, the default height in pixels is $\max(100 + 12n, 480)$, the default height in inches is $\max(1.04167 + 0.125n, 5)$, and the default height in centimeters is $\max(2.64583 + 0.3175n, 12.7)$. For a vertical dendrogram, the default height is 480 pixels. The default unit is pixels, and you can use the UNIT= *dendrogram-option* to change the unit to inches or centimeters for this option. Inches equals pixels divided by 96, and centimeters equals inches times 2.54.

COMPUTEWIDTH=*a b***CW=*a b***

specifies the constants for computing the width of the dendrogram. For n points being clustered, intercept a , and slope b , the width is based in part on $a + bn$. For a vertical dendrogram, the default (given in pixels) is COMPUTEWIDTH=100 12, the default width in pixels is $\max(100 + 12n, 640)$, the default width in inches is $\max(1.04167 + 0.125n, 6.66667)$, and the default width in centimeters is $\max(2.64583 + 0.3175n, 16.933)$. For a horizontal dendrogram, the default width is 640 pixels. The default unit is pixels, and you can use the UNIT= *dendrogram-option* to change the unit to inches or centimeters for this option. Inches equals pixels divided by 96, and centimeters equals inches times 2.54.

HEIGHT=PROPORTION | NCL | VAREXP**H=P | N | V**

specifies the method for drawing the height of the dendrogram. HEIGHT=PROPORTION is the default.

HEIGHT=PROPORTION specifies that the total proportion of variance explained by the clusters at the current level of the tree is used.

HEIGHT=NCL specifies that the number of clusters is used.

HEIGHT=VAREXP specifies that the total variance explained by the clusters at the current level of the tree is used.

HORIZONTAL | VERTICAL

specifies either a horizontal dendrogram with the objects on the vertical axis (HORIZONTAL) or a vertical dendrogram with the objects on the horizontal axis (VERTICAL). The default is HORIZONTAL.

SETHEIGHT=*height***SH=*height***

specifies the height of the dendrogram. By default, the height is based on the COMPUTEHEIGHT= option. The default unit is pixels, and you can use the UNIT= *dendrogram-option* to change the unit to inches or centimeters for this *dendrogram-option*.

SETWIDTH=*width***SW=*width***

specifies the width of the dendrogram. By default, the width is based on the COMPUTEWIDTH= option. The default unit is pixels, and you can use the UNIT= *dendrogram-option* to change the unit to inches or centimeters for this *dendrogram-option*.

UNIT=PX | IN | CM

specifies the unit (pixels, inches, or centimeters) for the SETHEIGHT=, SETWIDTH=, COMPUTEHEIGHT=, and COMPUTEWIDTH= *dendrogram-options*.

NONE

suppresses all plots.

The names of the graphs that PROC VARCLUS generates are listed in [Table 100.4](#), along with the required statements and options.

PROPORTION=*n***PERCENT=*n***

specifies that when choosing a cluster to split, VARCLUS should choose the cluster with the smallest proportion of variation explained, provided that the proportion of variation explained is less than the PROPORTION= value. Values greater than 1.0 are considered to be percentages, so PROPORTION=0.75 and PERCENT=75 are equivalent.

However, if you specify both MAXEIGEN= and PROPORTION=, VARCLUS first looks for a cluster to split based on the MAXEIGEN= criterion. If no cluster meets that criterion, VARCLUS then looks for a cluster to split based on the PROPORTION= criterion.

If you do not specify PROPORTION=, the default behavior depends on other options as follows:

- If you specify MAXEIGEN=, cluster splitting does not depend on the proportion of variation explained.
- Otherwise, if you specify CENTROID and MAXCLUSTERS=, the default value for PROPORTION= is 1.0.
- Otherwise, if you specify CENTROID without MAXCLUSTERS=, the default value is PROPORTION=0.75 or PERCENT=75.
- Otherwise, cluster splitting does not depend on the proportion of variation explained.

If you specify both PROPORTION= and MAXCLUSTERS=, the number of clusters will never exceed the value of the MAXCLUSTERS= option.

RANDOM=*n*

specifies a positive integer as a starting value for use with REPLACE=RANDOM. If you do not specify the RANDOM= option, the time of day is used to initialize the pseudorandom number sequence.

SHORT

suppresses display of the cluster structure, scoring coefficient, and intercluster correlation matrices.

SIMPLE**S**

displays means and standard deviations.

SUMMARY

suppresses all default displayed output except the final summary table.

TRACE

displays the cluster to which each variable is assigned during the iterations.

VARDEF=DF**VARDEF=N****VARDEF=WDF****VARDEF=WEIGHT | WGT**

specifies the divisor to be used in the calculation of variances and covariances. The default value is VARDEF=DF. The values and associated divisors are displayed in the following table.

Value	Divisor	Formula
DF	Degrees of freedom	$n - i$
N	Number of observations	n
WDF	Sum of weights minus one	$(\sum_j w_j) - 1$
WEIGHT WGT	Sum of weights	$\sum_j w_j$

In the preceding table, $i = 0$ if the NOINT option is specified, and $i = 1$ otherwise.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC VARCLUS to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the VARCLUS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

If a variable in your data set represents the frequency of occurrence for the other values in the observation, include the variable's name in a FREQ statement. The procedure then treats the data set as if each observation appears n times, where n is the value of the FREQ variable for the observation. If the value of the FREQ variable is less than 1, the observation is not used in the analysis. Only the integer portion of the value is used. The total number of observations is considered equal to the sum of the FREQ variable.

PARTIAL Statement

PARTIAL *variables* ;

If you want to base the clustering on partial correlations, list the variables to be partialled out in the PARTIAL statement.

SEED Statement

SEED *variables* ;

The SEED statement specifies variables to be used as seeds to initialize the clusters. It is not necessary to use INITIAL=SEED if the SEED statement is present, but if any other INITIAL= option is specified, the SEED statement is ignored.

VAR Statement

VAR *variables* ;

The VAR statement specifies the variables to be clustered. If you do not specify the VAR statement and do not specify TYPE=SSCP, all numeric variables not listed in other statements (except the SEED statement) are processed. The default VAR variable list does not include the variable INTERCEPT if the DATA= data set is TYPE=SSCP. If the variable INTERCEPT is explicitly specified in the VAR statement with a TYPE=SSCP data set, the NOINT option is enabled.

WEIGHT Statement

WEIGHT *variables* ;

If you want to specify relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances. The WEIGHT variable can take nonintegral values. An observation is used in the analysis only if the value of the WEIGHT variable is greater than zero.

Details: VARCLUS Procedure

Missing Values

Observations that contain missing values are omitted from the analysis.

Using the VARCLUS procedure

Default options for PROC VARCLUS often provide satisfactory results. If you want to change the final number of clusters, use one or more of the MAXCLUSTERS=, MAXEIGEN=, or PROPORTION= options. The MAXEIGEN= and PROPORTION= options usually produce similar results but occasionally cause different clusters to be selected for splitting. The MAXEIGEN= option tends to choose clusters with a large number of variables, while the PROPORTION= option is more likely to select a cluster with a small number of variables.

Execution Time

PROC VARCLUS usually requires more computer time than principal factor analysis, but it can be faster than some of the iterative factoring methods. If you have more than 30 variables, you might want to reduce execution time by one or more of the following methods:

- Specify the MINCLUSTERS= and MAXCLUSTERS= options if you know how many clusters you want.
- Specify the HIERARCHY option.
- Specify the SEED statement if you have some prior knowledge of what clusters to expect.

If computer time is not a limiting factor, you might want to try one of the following methods to obtain a better solution:

- If the clustering algorithm has not converged, specify larger values for MAXITER= and MAXSEARCH=.
- Try several factoring and rotation methods with PROC FACTOR to use as input to PROC VARCLUS.
- Run PROC VARCLUS several times, specifying INITIAL=RANDOM.

Output Data Sets

OUTSTAT= Data Set

The OUTSTAT= data set is TYPE=CORR, and it can be used as input to the SCORE procedure or a subsequent run of PROC VARCLUS. The OUTSTAT= data set contains the following variables:

- BY variables
- _NCL_, a numeric variable that gives the number of clusters
- _TYPE_, a character variable that indicates the type of statistic the observation contains
- _NAME_, a character variable that contains a variable name or a cluster name, which is of the form CLUS n , where n is the number of the cluster
- the variables that are clustered

The values of the _TYPE_ variable are listed in the following table.

Table 100.2 _TYPE_

TYPE	Contents
'MEAN'	Means
'STD'	Standard deviations
'USTD'	Uncorrected standard deviations, produced when the NOINT option is specified
'N'	Number of observations
'CORR'	Correlations
'UCORR'	Uncorrected correlation matrix, produced when the NOINT option is specified
'MEMBERS'	Number of members in each cluster
'VAREXP'	Variance explained by each cluster
'PROPOR'	Proportion of variance explained by each cluster
'GROUP'	Number of the cluster to which each variable belongs
'RSQUARED'	Squared multiple correlation of each variable with its cluster component
'SCORE'	Standardized scoring coefficients
'USCORE'	Scoring coefficients to be applied without subtracting the mean from the raw variables, produced when the NOINT option is specified
'STRUCTUR'	Cluster structure
'CCORR'	Correlations between cluster components

The observations with _TYPE_='MEAN', 'STD', 'N', and 'CORR' have missing values for the _NCL_ variable. All other values of the _TYPE_ variable are repeated for each cluster solution, with different solutions distinguished by the value of the _NCL_ variable. If you want to specify the OUTSTAT= data set with the SCORE procedure, you can use a DATA step to select observations with the _NCL_ variable missing or equal to the desired number of clusters as follows:

```
data Coef2;
  set Coef;
  if _ncl_ = . or _ncl_ = 3;
  drop _ncl_;
run;

proc score data=NewScore score=Coef2;
run;
```

PROC SCORE standardizes the new data by subtracting the original variable means that are stored in the _TYPE_='MEAN' observations and dividing by the original variable standard deviations from the _TYPE_='STD' observations. Then PROC SCORE multiplies the standardized variables by the coefficients from the _TYPE_='SCORE' observations to get the cluster scores.

OUTTREE= Data Set

The OUTTREE= data set contains one observation for each variable clustered plus one observation for each cluster of two or more variables—that is, one observation for each node of the cluster tree. The total number of output observations is between n and $2n - 1$, where n is the number of variables clustered.

The OUTTREE= data set contains the following variables:

- BY variables, if any
- `_NAME_`, a character variable that gives the name of the node. If the node is a cluster, the name is `CLUS n` , where n is the number of the cluster. If the node is a single variable, the variable name is used.
- `_PARENT_`, a character variable that gives the value of `_NAME_` of the parent of the node. If the node is the root of the tree, `_PARENT_` is blank.
- `_LABEL_`, a character variable that gives the label of the node. If the node is a cluster, the label is `CLUS n` , where n is the number of the cluster. If the node is a single variable, the variable label is used.
- `_NCL_`, the number of clusters
- `_VAREXP_`, the total variance explained by the clusters at the current level of the tree
- `_PROPOR_`, the total proportion of variance explained by the clusters at the current level of the tree
- `_MINPRO_`, the minimum proportion of variance explained by a cluster component
- `_MAXEIG_`, the maximum second eigenvalue of a cluster

Computational Resources

Let

- n = number of observations
- v = number of variables
- c = number of clusters

It is assumed that, at each stage of clustering, the clusters all contain the same number of variables.

Time

The time required for PROC VARCLUS to analyze a given data set varies greatly depending on the number of clusters requested, the number of iterations in both the alternating least squares and search phases, and whether centroid or principal components are used.

The time required to compute the correlation matrix is roughly proportional to nv^2 .

Default cluster initialization requires time roughly proportional to v^3 . Any other method of initialization requires time roughly proportional to cv^2 .

In the alternating least squares phase, each iteration requires time roughly proportional to cv^2 if centroid components are used or

$$\left(c + 5\frac{v}{c^2}\right)v^2$$

if principal components are used.

In the search phase, each iteration requires time roughly proportional to v^3/c if centroid components are used or v^4/c^2 if principal components are used. The HIERARCHY option speeds up each iteration after the first split by as much as $c/2$.

Memory

The amount of memory, in bytes, needed by PROC VARCLUS is approximately

$$v^2 + 2vc + 20v + 15c$$

Interpreting VARCLUS Procedure Output

Because the VARCLUS algorithm is a type of oblique component analysis, its output is similar to the output from the FACTOR procedure for oblique rotations. The scoring coefficients have the same meaning in both PROC VARCLUS and PROC FACTOR; they are coefficients applied to the standardized variables to compute component scores. The cluster structure is analogous to the factor structure that contains the correlations between each variable and each cluster component. A cluster pattern is not displayed because it would be the same as the cluster structure, except that zeros would appear in the same places in which zeros appear in the scoring coefficients. The intercluster correlations are analogous to interfactor correlations; they are the correlations among cluster components.

PROC VARCLUS also displays a cluster summary and a cluster listing. The cluster summary gives the number of variables in each cluster and the variation explained by the cluster component. The latter is similar to the variation explained by a factor but includes contributions from only the variables in that cluster rather than from all variables, as in PROC FACTOR. The proportion of variance explained is obtained by dividing the variance explained by the total variance of variables in the cluster. If the cluster contains two or more variables and the CENTROID option is omitted, the second largest eigenvalue of the cluster is also displayed.

The cluster listing gives the variables in each cluster. Two squared correlations are calculated for each cluster. The column labeled “Own Cluster” gives the squared correlation of the variable with its own cluster component. This value should be higher than the squared correlation with any other cluster unless an iteration limit has been exceeded or the CENTROID option has been used. The larger the squared correlation is, the better. The column labeled “Next Closest” contains the next-highest squared correlation of the variable with a cluster component. This value is low if the clusters are well separated. The column labeled “1-R**2 Ratio” gives the ratio of one minus the “Own Cluster” R square to one minus the “Next Closest” R square. A small “1-R**2 Ratio” indicates a good clustering.

Displayed Output

The following items are displayed for each cluster solution unless the NOPRINT or SUMMARY option is specified. The CLUSTER SUMMARY table includes the following columns:

- the Cluster number
- Members, the number of members in the cluster
- Cluster Variation of the variables in the cluster
- Variation Explained by the cluster component. This statistic is based only on the variables in the cluster rather than on all variables.
- Proportion Explained, the result of dividing the variation explained by the cluster variation
- Second Eigenvalue, the second largest eigenvalue of the cluster. This is displayed if the cluster contains more than one variable and the CENTROID option is not specified

PROC VARCLUS also displays the following:

- Total variation explained, the sum across clusters of the variation explained by each cluster
- Proportion, the total explained variation divided by the total variation of all the variables

The cluster listing includes the following columns:

- Variable, the variables in each cluster
- R square with Own Cluster (the squared correlation of the variable with its own cluster component), and R square with Next Closest (the next highest squared correlation of the variable with a cluster component). Own Cluster values should be higher than the R square with any other cluster unless an iteration limit is exceeded or you specify the CENTROID option. Next Closest should be a low value if the clusters are well separated.
- $1-R^2$ Ratio, the ratio of one minus the value in the Own Cluster column to one minus the value in the Next Closest column. The occurrence of low ratios indicates well-separated clusters.

If the SHORT option is not specified, PROC VARCLUS also displays the following tables:

- Standardized Scoring Coefficients, standardized regression coefficients for predicting cluster components from variables
- Cluster Structure, the correlations between each variable and each cluster component
- Inter-Cluster Correlations, the correlations between the cluster components

If the analysis includes partitions for two or more numbers of clusters, a final summary table is displayed. Each row of the table corresponds to one partition. The columns include the following:

- Number of Clusters
- Total Variation Explained by Clusters
- Proportion of Variation Explained by Clusters
- Minimum Proportion (of variation) Explained by a Cluster
- Maximum Second Eigenvalue in a Cluster
- Minimum R square for a Variable
- Maximum $1-R^2$ Ratio for a Variable

ODS Table Names

PROC VARCLUS assigns a name to each table it creates. You can use this name to refer to the table when using the Output Delivery System (ODS) to select tables and create output data sets. These ODS table names are listed in [Table 100.3](#). For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 100.3 ODS Tables Produced by PROC VARCLUS

ODS Table Name	Description	Option
ClusterQuality	Cluster quality	default
ClusterStructure	Cluster structure	default
ClusterSummary	Cluster summary	default
ConvergenceStatus	Convergence status	default
Corr	Correlations between variables	CORR
DataOptSummary	Data and options summary table	default
InterClusterCorr	Correlations between cluster components	default
IterHistory	Iteration history	TRACE
RSquare	R squares between variables and clusters	default
SimpleStatistics	Means and standard deviations	SIMPLE
StdScoreCoef	Standardized scoring coefficients	default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

By default, PROC VARCLUS produces a dendrogram.

You can refer to every graph produced through ODS Graphics with a name. The name of the graph that PROC VARCLUS generates is listed in [Table 100.4](#), along with the statement and option required to produce it.

Table 100.4 Graphs Produced by PROC VARCLUS

ODS Graph Name	Plot Description	Statement and Option
Dendrogram	Dendrogram (tree diagram)	PROC VARCLUS PLOTS=DENDROGRAM

Example: VARCLUS Procedure

Example 100.1: Correlations among Physical Variables

The data in this example are correlations among eight physical variables as given by Harman (1976). The first PROC VARCLUS run clusters on the basis of principal components. The second run clusters on the basis of centroid components. The third analysis is hierarchical, and the TREE procedure is used to display a tree diagram. The following statements create the data set and perform the analysis:

```
data phys8(type=corr);
  title 'Eight Physical Measurements on 305 School Girls';
  title2 'Harman: Modern Factor Analysis, 3rd Ed, p22';
  label ArmSpan='Arm Span'           Forearm='Length of Forearm'
        LowerLeg='Length of Lower Leg' BitDiam='Bitrochanteric Diameter'
        Girth='Chest Girth'          Width='Chest Width';
  input _Name_ $ 1-8
        (Height ArmSpan Forearm LowerLeg Weight BitDiam
         Girth Width) (7.);
  _Type_='corr';
  datalines;
Height      1.0      .846      .805      .859      .473      .398      .301      .382
ArmSpan      .846      1.0      .881      .826      .376      .326      .277      .415
Forearm      .805      .881      1.0      .801      .380      .319      .237      .345
LowerLeg      .859      .826      .801      1.0      .436      .329      .327      .365
Weight      .473      .376      .380      .436      1.0      .762      .730      .629
BitDiam      .398      .326      .319      .329      .762      1.0      .583      .577
Girth      .301      .277      .237      .327      .730      .583      1.0      .539
Width      .382      .415      .345      .365      .629      .577      .539      1.0
;
```

```
proc varclus data=phys8;
run;
```

The PROC VARCLUS statement invokes the procedure. By default, PROC VARCLUS clusters using principal components.

As displayed in [Output 100.1.1](#), when there is only one cluster, the cluster component (by default, the first principal component) explains 58.41% of the total variation of the eight variables.

The cluster is split because the second eigenvalue is greater than 1 (the default value of the MAXEIGEN option).

The two resulting cluster components explain 80.33% of the variation in the original variables. The cluster summary table shows that the variables Height, ArmSpan, Forearm, and LowerLeg have been assigned to the first cluster, and that the variables Weight, BitDiam, Girth, and Width have been assigned to the second cluster.

The standardized scoring coefficients in [Output 100.1.1](#) show that each cluster component has similar scores for each of its associated variables. This suggests that the principal cluster component solution should be similar to the centroid cluster component solution, which follows in the next PROC VARCLUS run.

The cluster structure table displays high correlations between the variables and their own cluster component. The correlations between the variables and the opposite cluster component are all moderate.

The intercluster correlation table shows that the two cluster components have a moderate correlation of 0.44513.

Output 100.1.1 Principal Component Clusters

In the following statements, the **CENTROID** option in the **PROC VARCLUS** statement specifies that cluster centroids be used as the basis for clustering:

```
proc varclus data=phys8 centroid;
run;
```

The first cluster component, which in the centroid method is an unweighted sum of the standardized variables, explains 57.89% of the variation in the data. This value is near the maximum possible variance explained, 58.41%, which is attained by the first principal component shown previously in [Output 100.1.1](#).

The default behavior in the centroid method is to split any cluster with less than 75% of the total cluster variance explained by the centroid component. Since the centroid component for the one-cluster solution explains only 57.89% of the variation as shown in [Output 100.1.2](#), the variables are split into two clusters. The resulting clusters are the same two clusters created by the principal component method. Recall that this outcome was suggested by the similar standardized scoring coefficients in the principal cluster component solution.

In the two-cluster solution, the centroid component of the second cluster explains only 72.75% of the total variation of the cluster. Since this percentage is less than 75%, the second cluster is split.

In the R-square table for two clusters, the **Width** variable has a weaker relation to its cluster than any other variable. In the three-cluster solution this variable is in a cluster of its own.

Each cluster component is an unweighted average of the cluster's standardized variables. Thus, the coefficients for each of the cluster's associated variables are identical in the centroid cluster component solution.

The centroid method stops at the three-cluster solution. The three centroid components account for 86.15% of the variability in the eight variables, and all cluster components account for at least 79.44% of the total variation in the corresponding cluster. Additionally, the smallest squared correlation between the variables and their own cluster component is 0.7482.

If the **PROPORTION=** option were set to a value between 0.5789 (the proportion of variance explained in the one-cluster solution) and 0.7275 (the minimum proportion of variance explained in the two-cluster

solution), PROC VARCLUS would stop at the two-cluster solution, and the centroid solution would find the same clusters as the principal components solution, although the cluster components would be slightly different.

8	8.000000	1.0000	1.0000	0.000000	1.0000	0.0000

The principal component method first separates the variables into the same two clusters that were created in the first PROC VARCLUS run. In creating the third cluster, the principal component method identifies the variable Width. This is the same variable that is put into its own cluster in the preceding centroid method example. The tree diagram in [Output 100.1.4](#) displays the cluster hierarchy.

Output 100.1.4 Dendrogram

It appears from the diagram that there are two, or possibly three, clusters present. However, the MAXC=8 option forces PROC VARCLUS to split the clusters until each variable is in its own cluster.

Overview: VARCOMP Procedure

The VARCOMP procedure handles general linear models that have random effects. Random effects are classification effects with levels that are assumed to be randomly selected from an infinite population of possible levels. PROC VARCOMP estimates the contribution of each of the random effects to the variance of the dependent variable.

A single MODEL statement specifies the dependent variables and the effects: main effects, interactions, and nested effects. The effects must be composed of classification variables; no continuous variables are allowed on the right side of the equal sign.

You can specify certain effects as fixed (nonrandom) by putting them first in the **MODEL** statement and indicating the number of fixed effects with the **FIXED=** option. An intercept is always fitted and assumed fixed. Except for the effects specified as fixed, all other effects are assumed to be random. Their contribution to the model can be thought of as an observation from a distribution that is normally and independently distributed.

The dependent variables are grouped based on the similarity of their missing values. Each group of dependent variables is then analyzed separately. The columns of the design matrix **X** are formed in the same order in which the effects are specified in the **MODEL** statement. A singular parameterization involving just 0–1 dummy variables is used, as in the GLM procedure.

You can specify four general methods of estimation in the PROC VARCOMP statement by using the **METHOD=** option. They are TYPE1 (based on computation of Type I sum of squares for each effect), MIVQUE0, maximum likelihood (**METHOD=ML**), and restricted maximum likelihood (**METHOD=REML**). A fifth method, **METHOD=GRR**, provides a specialized analysis for gauge repeatability and reproducibility (R&R) studies. See the section “[Gauge Repeatability and Reproducibility Analysis](#)” on page 8542 for further details. Note that this method, along with the **CL** option in the **MODEL** statement for confidence limits, applies only to certain designs, namely balanced one-way or two-way designs. The other four general methods apply to any random-effects model and design.

Other procedures, such as PROC GLM, PROC MIXED, and PROC GLIMMIX, fit similar random effects models. The VARCOMP procedure is usually more computationally efficient for certain special designs and models. See the section “[Relationship to PROC MIXED](#)” on page 8547 for a more precise comparison with the MIXED procedure in particular.

The GAUGE application in SAS/QC software provides a graphical interface for computing many of the same statistics as **METHOD=GRR** in PROC VARCOMP.

Getting Started: VARCOMP Procedure

Analyzing the Cure Rate of Rubber

This example, using data from Hicks (1973), concerns an experiment to determine the sources of variability in cure rates of rubber. The goal of the experiment was to find out if the different laboratories contributed more to the variance of cure rates than did the different batches of raw materials. This information would be useful in trying to control the cure rate of the final product because it would provide insight into the sources of the variability in cure rates. The rubber used was cured at three temperatures, which were taken to be fixed. Three laboratories were chosen at random, and three different batches of raw material were tested at each combination of temperature and laboratory. The following statements read the data into the SAS data set **Cure**.

```

data Cure;
  input Lab Temp Batch $ Cure @@;

;

```

The variables Lab, Temp, and Batch contain levels of laboratory, temperature, and batch, respectively. The Cure variable contains the response values.

The following SAS statements perform a restricted maximum likelihood variance component analysis.

```

title 'Analyzing the Cure Rate of Rubber';
proc varcomp method=reml data=cure;
  class temp lab batch;
  model cure=temp|lab batch(lab temp) / fixed=1;
run;

```

The FIXED=1 option indicates that the first factor, Temp, is fixed. The effect specification Temp|Lab is equivalent to putting the three terms Temp, Lab, and Temp*Lab in the model. Batch(Lab Temp) is equivalent to putting Batch(Temp*Lab) in the **MODEL** statement. The results of this analysis are displayed in Figure 101.1 through Figure 101.4.

Number of Observations Used					108
Dependent Variable: Cure					

Figure 101.1 provides information about the variables used in the analysis and the number of observations and specifies the dependent variable.

Figure 101.2 Iteration History

REML Iterations						
Iteration	Objective	Var (Lab)	Var (Temp*Lab)	Var (Batch (Temp* Lab))	Var (Error)	
0	13.4500060254	0.5094464340	0	2.4004888633	0.5787185225	
1	13.0898262160	0.3194348317	0	2.0869636935	0.6016005334	
2	13.0893125570	0.3176048001	0	2.0738906134	0.6026217204	
3	13.0893125555	0.3176017115	0	2.0738685461	0.6026234568	
Convergence criteria met.						

The “REML Iterations” table in Figure 101.2 displays the iteration history, which includes the value of the objective function associated with REML and the values of the variance components at each iteration.

Figure 101.3 REML Estimates

REML Estimates	
Variance Component	Estimate
Var (Lab)	0.31760
Var (Temp*Lab)	0
Var (Batch (Temp*Lab))	2.07387
Var (Error)	0.60262

Figure 101.3 displays the REML estimates of the variance components.

Figure 101.4 Covariance Matrix for REML Estimates

Asymptotic Covariance Matrix of Estimates		
	Var (Lab)	Var (Temp*Lab)
Var (Lab)	0.32452	0
Var (Temp*Lab)	0	0
Var (Batch (Temp*Lab))	-0.04998	0
Var (Error)	1.026E-12	0

Asymptotic Covariance Matrix of Estimates		
	Var (Batch (Temp*Lab))	Var (Error)
Var (Lab)	-0.04998	1.026E-12
Var (Temp*Lab)	0	0
Var (Batch (Temp*Lab))	0.45042	-0.0022417
Var (Error)	-0.0022417	0.0089668

The “Asymptotic Covariance Matrix of Estimates” table in Figure 101.4 displays the asymptotic covariance matrix of the REML estimates.

The results of the analysis show that the variance attributable to Batch(Temp*Lab) (with a variance component of 2.0739) is considerably larger than the variance attributable to Lab (0.3176). Therefore, attempts to reduce the variability of cure rates should concentrate on improving the homogeneity of the batches of raw material used rather than standardizing the practices or equipment within the laboratories. Also, note that since the Batch(Temp*Lab) variance is considerably larger than the experimental error (Var(Error)=0.6026), the Batch(Temp*Lab) variability plays an important part in the overall variability of the cure rates.

Syntax: VARCOMP Procedure

The following statements are available in the VARCOMP procedure:

```
PROC VARCOMP < options > ;
  CLASS variables ;
  MODEL dependent = < effects > < / options > ;
  BY variables ;
```

Only one MODEL statement is allowed. The BY, CLASS, and MODEL statements are described after the PROC VARCOMP statement.

PROC VARCOMP Statement

```
PROC VARCOMP < options > ;
```

The PROC VARCOMP statement invokes the VARCOMP procedure. [Table 101.1](#) summarizes the options available in the VARCOMP statement.

Table 101.1 PROC VARCOMP Statement Options

Option	Description
DATA=	Specifies the input SAS data set to use
EPSILON=	Specifies the convergence value of the objective function
MAXITER=	Specifies the maximum number of iterations for METHOD=ML or METHOD=REML
METHOD=	Specifies which of the five methods to use
SEED=	Specifies an unsigned integer used to start the pseudo-random number generator

You can specify the following options in the PROC VARCOMP statement.

DATA=SAS-data-set

specifies the input SAS data set to use. If this option is omitted, the most recently created SAS data set is used.

EPSILON=number

specifies the convergence value of the objective function for METHOD=ML or METHOD=REML. By default, EPSILON=1E-8.

MAXITER=number

specifies the maximum number of iterations for METHOD=ML or METHOD=REML. By default, MAXITER=50.

METHOD=TYPE1 | MIVQUE0 | ML | REML | GRR < (options) >

specifies which of the five methods (TYPE1, MIVQUE0, ML, REML, or GRR) you want to use. By default, METHOD=MIVQUE0. METHOD=GRR provides a specialized analysis only for certain

designs, whereas the other four methods apply to any random-effects model and design. You can specify the following options in parentheses after `METHOD=GRR`.

SPECLIMITS=(*LSL*,*USL*,<*k*>)

SL=(*LSL*,*USL*,<*k*>)

specifies the specification limits for the first random factor, which is regarded as the product being tested in the gauge R&R study. The lower limit (*LSL*) must be smaller than the upper limit (*USL*). The value *k* is optional. The default value is 6, which corresponds to the number of standard deviations between the “natural” tolerance limits containing the middle 99.73% of a normal process. *SPECLIMITS*=(*LSL*,*USL*,*k*) requests the estimates of the parameters *PTR*(*LSL*,*USL*,*k*) and *Cp*(*LSL*,*USL*,*k*) to be displayed.

RATIO

specifies that certain additional ratios of variance components should also be computed and displayed, such as proportion of total variance due to the process. These ratios are listed in Table 101.5.

For more information see the section “[Computational Methods](#)” on page 8540.

SEED=*n*

specifies an unsigned integer used to start the pseudo-random number generator. If you do not specify a seed or if you specify zero, the seed is generated from reading the time of day from the computer clock. You can use a SAS date as a seed. The random number generation is used in the computation of generalized confidence limits; see the section “[Confidence Limits](#)” on page 8544.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC VARCOMP to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the VARCOMP procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* ;

The CLASS statement specifies the classification variables to be used in the analysis. All effects in the MODEL statement must be composed of effects that appear in the CLASS statement. Classification variables can be either numeric or character; if they are character, only the first 16 characters are used.

Numeric classification variables are not restricted to integers since a variable's format determines the levels. For more information, see the discussion of the FORMAT statement in *SAS Formats and Informats: Reference*.

MODEL Statement

MODEL *dependent* = < *effects* > < / *options* > ;

The MODEL statement gives the dependent variables and independent effects. If you specify more than one dependent variable, a separate analysis is performed for each one. The independent effects are limited to main effects, interactions, and nested effects; no continuous effects are allowed. All independent effects must be composed of effects that appear in the CLASS statement. [Effects](#) are specified in the VARCOMP procedure in the same way as described for the ANOVA procedure. Only one MODEL statement is allowed.

The following options are available in the MODEL statement.

FIXED=*n*

specifies that the first *n* effects in the MODEL statement are fixed effects. The remaining effects are assumed to be random. By default, PROC VARCOMP assumes that all effects are random in the model. Keep in mind that if you use bar notation and, for example, specify Y=A|B / FIXED=2, then A*B is considered a random effect.

CL=

CL=MLS

CL=GCL< (*options*) >

specifies that confidence limits for all of the parameters of interest be computed and displayed. It also optionally specifies the method to use for computing the confidence limits. There are two methods: the modified large-sample (MLS) method and the generalized confidence limits (GCL) method. The default method is MLS. For more information about these two methods, see the section "[Confidence Limits](#)" on page 8544.

You can specify the following options in parentheses after CL=GCL.

NSAMPLE=*n*

specifies the sample size for generalized pivot quantities (GPQ) sampling. The default value is 12,605.

EPSILON=*number*

specifies a small positive value used in some GPQ computations. The default value is 0.001.

The CL option applies only to balanced one-way or two-way designs for **METHOD**=TYPE1 or GRR.

ALPHA= α

specifies the level of significance α for $(1 - \alpha)100\%$ two-sided confidence limits. The value of α must be between 0 and 1. By default, α is equal to 0.05.

Details: VARCOMP Procedure

Missing Values

If an observation has a missing value for any variable used in the independent effects, then the analyses of all dependent variables omit this observation. An observation is deleted from the analysis of a given dependent variable if the observation's value for that dependent variable is missing. Note that a missing value in one dependent variable does not eliminate an observation from the analysis of the other dependent variables.

During processing, PROC VARCOMP groups the dependent variables on their missing values across observations so that sums of squares and crossproducts can be computed in the most efficient manner.

Fixed and Random Effects

Central to the idea of variance components models is the idea of fixed and random effects. Each effect in a variance components model must be classified as either a fixed or a random effect. Fixed effects arise when the levels of an effect constitute the entire population in which you are interested. For example, if a plant scientist is comparing the yields of three varieties of soybeans, then *Variety* would be a fixed effect, providing that the scientist was concerned about making inferences about only these three varieties of soybeans. Similarly, if an industrial experiment focused on the effectiveness of two brands of a machine, *Machine* would be a fixed effect only if the experimenter's interest did not go beyond the two machine brands.

On the other hand, an effect is classified as a random effect when you want to make inferences about an entire population, and the levels in your experiment represent only a sample from that population. Psychologists comparing test results between different groups of subjects would consider *Subject* as a random effect. Depending on the psychologists' particular interest, the *Group* effect might be either fixed or random. For example, if the groups are based on the sex of the subject, then *Sex* would be a fixed effect. But if the psychologists are interested in the variability in test scores due to different teachers, then they might choose a random sample of teachers as being representative of the total population of teachers, and *Teacher* would be a random effect. Note that, in the soybean example presented earlier, if the scientists are interested in making inferences about the entire population of soybean varieties and randomly choose three varieties for testing, then *Variety* would be a random effect.

If all the effects in a model (except for the intercept) are considered random effects, then the model is called a *random-effects model*; likewise, a model with only fixed effects is called a *fixed-effects model*. The more common case, where some factors are fixed and others are random, is called a *mixed model*. In PROC VARCOMP, by default, effects are assumed to be random. You specify which effects are fixed by using the **FIXED=** option in the **MODEL** statement. In general, if an interaction or nested effect contains any effect that is random, then the interaction or nested effect should be considered a random effect as well.

In the linear model, each level of a fixed effect contributes a fixed amount to the expected value of the dependent variable. What makes a random effect different is that each level of a random effect contributes an amount that is viewed as a sample from a population of normally distributed variables, each with mean 0, and an unknown variance, much like the usual random error term that is a part of all linear models. The estimate of the variance associated with the random effect is known as the *variance component* because it measures the part of the overall variance contributed by that effect. Thus, PROC VARCOMP estimates the variance of the random variables that are associated with the random effects in your model, and the variance components tell you how much each of the random factors contributes to the overall variability in the dependent variable.

Negative Variance Component Estimates

The variance components estimated by PROC VARCOMP should theoretically be nonnegative because they are assumed to represent the variance of a random variable. Nevertheless, when you are using `METHOD=MIVQUE0`, `TYPE1`, or `GRR`, some estimates of variance components might become negative. (Due to the nature of the algorithms used for `METHOD=ML` and `METHOD=REML`, negative estimates are constrained to zero.) These negative estimates might arise for a variety of reasons:

- The variability in your data might be large enough to produce a negative estimate, even though the true value of the variance component is positive.
- Your data might contain outliers. See Hocking (1983) for a graphical technique for detecting outliers in variance components models by using the SAS System.
- A different model for interpreting your data might be appropriate. Under some statistical models for variance components analysis, negative estimates are an indication that observations in your data are negatively correlated. See Hocking (1984) for further information about these models.

Assuming you are satisfied that the model that PROC VARCOMP is using is appropriate for your data, it is common practice to treat negative variance components as if they are zero.

Computational Methods

Four methods of estimation can be specified in the PROC VARCOMP statement by using the `METHOD=` option. They are described in the following sections.

The Type I Method

This method (`METHOD=TYPE1`) computes the Type I sum of squares for each effect, equates each mean square involving only random effects to its expected value, and solves the resulting system of equations (Gaylor, Lucas, and Anderson 1970). The $\mathbf{X}'\mathbf{X} \mid \mathbf{X}'\mathbf{Y}$ matrix is computed and adjusted in segments whenever memory is not sufficient to hold the entire matrix.

The MIVQUE0 Method

Based on the technique suggested by Hartley, Rao, and LaMotte (1978), the MIVQUE0 method (METHOD=MIVQUE0) produces unbiased estimates that are invariant with respect to the fixed effects of the model and that are locally best quadratic unbiased estimates given that the true ratio of each component to the residual error component is zero. The technique is similar to TYPE1 except that the random effects are adjusted only for the fixed effects. This affords a considerable timing advantage over the TYPE1 method; thus, MIVQUE0 is the default method used in PROC VARCOMP. The $\mathbf{X}'\mathbf{X}|\mathbf{X}'\mathbf{Y}$ matrix is computed and adjusted in segments whenever memory is not sufficient to hold the entire matrix. Each element (i, j) of the form

$$\text{SSQ}(\mathbf{X}_i' \mathbf{M} \mathbf{X}_j)$$

is computed, where

$$\mathbf{M} = \mathbf{I} - \mathbf{X}_0(\mathbf{X}_0' \mathbf{X}_0)^{-1} \mathbf{X}_0'$$

and where \mathbf{X}_0 is part of the design matrix for the fixed effects, \mathbf{X}_i is part of the design matrix for one of the random effects, and SSQ is an operator that takes the sum of squares of the elements. For more information see Rao (1971, 1972) and Goodnight (1978).

The Maximum Likelihood Method

The maximum likelihood method (METHOD=ML) computes maximum likelihood estimates of the variance components; see Searle, Casella, and McCulloch (1992). The computing algorithm makes use of the W-transformation developed by Hemmerle and Hartley (1973) and Goodnight and Hemmerle (1979). The procedure uses a Newton-Raphson algorithm, iterating until the log-likelihood objective function converges.

The objective function for METHOD=ML is $\ln(|\mathbf{V}|) + \mathbf{r}'\mathbf{V}^{-1}\mathbf{r}$, where

$$\mathbf{V} = \sigma_0^2 \mathbf{I} + \sum_{i=1}^{n_r} \sigma_i^2 \mathbf{X}_i \mathbf{X}_i'$$

and where σ_0^2 is the residual variance, n_r is the number of random effects in the model, σ_i^2 represents the variance components, \mathbf{X}_i is part of the design matrix for one of the random effects, and

$$\mathbf{r} = \mathbf{y} - \mathbf{X}_0(\mathbf{X}_0' \mathbf{V}^{-1} \mathbf{X}_0)^{-1} \mathbf{X}_0' \mathbf{V}^{-1} \mathbf{y}$$

is the vector of residuals.

The Restricted Maximum Likelihood Method

The restricted maximum likelihood method (METHOD=REML) is similar to the maximum likelihood method, but it first separates the likelihood into two parts: one that contains the fixed effects and one that does not (Patterson and Thompson 1971). The procedure uses a Newton-Raphson algorithm, iterating until convergence is reached for the log-likelihood objective function of the portion of the likelihood that does not contain the fixed effects. Using notation from earlier methods, the objective function for METHOD=REML is $\ln(|\mathbf{V}|) + \mathbf{r}'\mathbf{V}^{-1}\mathbf{r} + \ln(|\mathbf{X}_0' \mathbf{V}^{-1} \mathbf{X}_0|)$. See Searle, Casella, and McCulloch (1992) for additional details.

The GRR Method

Based on the technique suggested by Burdick, Borror, and Montgomery (2005), the GRR method (METHOD=GRR) produces minimum variance unbiased estimators.

Gauge Repeatability and Reproducibility Analysis

In a typical gauge R&R experiment, each operator (O_j) makes multiple observations on each of several similar parts (P_i) from a monitored process. The statistical model used to describe the response variable is the balanced two-factor crossed random model with interaction

$$y_{ijk} = \mu_y + P_i + O_j + (PO)_{ij} + E_{ijk}$$

where $i = 1, \dots, p$, $j = 1, \dots, o$, $k = 1, \dots, r$, μ_y is an unknown constant, and $P_i, O_j, (PO)_{ij}, E_{ijk}$ are jointly independent normal random variables with means of zero and variances $\text{Var}(P), \text{Var}(O), \text{Var}(PO)$, and $\text{Var}(E)$, respectively. The corresponding SAS statements are as follows:

```
proc varcomp method=grr;
  class P O;
  model y = P|O;
run;
```

The first random effect in the MODEL statement is assumed to be the “Part” effect and the second is “Operator.”

The ANOVA table for the preceding model is shown in Table 101.2.

Table 101.2 GRR Analysis of Variance

Source	DF	Mean Square	Expected Mean Square
Parts(P)	$p - 1$	S_P^2	$\text{Var}(E) + r\text{Var}(PO) + or\text{Var}(P)$
Operators(O)	$o - 1$	S_O^2	$\text{Var}(E) + r\text{Var}(PO) + pr\text{Var}(O)$
P×O	$(p - 1)(o - 1)$	S_{PO}^2	$\text{Var}(E) + r\text{Var}(PO)$
Error(E)	$po(r - 1)$	S_E^2	$\text{Var}(E)$

The gauge R&R parameters of interest are given in Table 101.3 in terms of $\text{Var}(P), \text{Var}(O), \text{Var}(PO)$, and $\text{Var}(E)$.

Table 101.3 Gauge R&R Parameters

Parameter	Formula
Mean of population of measurements	$\mu_y = \bar{y}_{...} = \Sigma_{ijk} y_{ijk} / por$
Variance of the monitored process	$\gamma_P = \text{Var}(P)$
Variance of the measurement system	$\gamma_M = \text{Var}(O) + \text{Var}(PO) + \text{Var}(E)$
Total variance of the response variable	$\gamma_y = \text{Var}(y) = \gamma_P + \gamma_M$
Ratio of process variance to measurement variance	$\gamma_R = \gamma_P / \gamma_M$

Table 101.3 (continued)

Parameter	Formula
Proportion of total variance due to the process	$\rho_P = \gamma_P/\gamma_y = \frac{\gamma_R}{1+\gamma_R}$
Proportion of total variance due to the measurement	$\rho_M = \gamma_M/\gamma_y = 1 - \rho_P$
Signal-to-noise ratio	$\text{SNR} = \sqrt{2 \times \gamma_R}$
Discrimination ratio	$\text{DR} = 1 + 2\gamma_R$

For a one-way model, $\gamma_M = \text{Var}(E)$, and for a two-way model with no interaction, $\gamma_M = \text{Var}(O) + \text{Var}(E)$.

If you use the SPECLIMITS option to give specification limits, the two parameters in Table 101.4 will also be estimated and displayed.

Table 101.4 Gauge R&R Parameters Related to Specification Limits

Parameter	Formula
Precision-to-tolerance ratio	$\text{PTR}(\text{LSL}, \text{USL}, k) = k\sqrt{\gamma_M}/(\text{USL} - \text{LSL})$
Process capability ratio	$\text{Cp}(\text{LSL}, \text{USL}, k) = (\text{USL} - \text{LSL})/(k\sqrt{\gamma_P})$

Here, USL and LSL are the specification limits, and the value k corresponds to the number of standard deviations between the “natural” tolerance limits of a normal process.

If you use the RATIO option, the ratios in Table 101.5 will also be estimated and displayed.

Table 101.5 Gauge R&R Ratios

Ratio	Formula
Ratio of process variance to total variance	$\text{Var}(P)/\gamma_y$
Ratio of operator variance to total variance	$\text{Var}(O)/\gamma_y$
Ratio of process by operator variance to total variance	$\text{Var}(PO)/\gamma_y$
Ratio of process variance to residual variance	$\text{Var}(P)/\text{Var}(E)$
Ratio of operator variance to residual variance	$\text{Var}(O)/\text{Var}(E)$
Ratio of process by operator variance to residual variance	$\text{Var}(PO)/\text{Var}(E)$

Confidence Limits

When no exact confidence limits exist, it is common practice to use approximate confidence limits. Two such approximations are the modified large-sample (MLS) method and the generalized confidence limit (GCL) method as discussed in Burdick, Borror, and Montgomery (2005). When analyzing a balanced one-way or two-way design, if you specify the **CL=** option with **METHOD=TYPE1** or **GRR**, the VARCOMP procedure computes confidence limits by using either the MLS method (the default) or the GCL method. Generalized confidence limits are obtained by specifying the **CL=GCL** option in the **MODEL** statement.

MLS Confidence Limits

The method of MLS confidence limits was first introduced by Graybill and Wang (1980). It starts with approximate large-sample confidence limits; then it modifies the limits to be exact under certain parameter conditions.

For a balanced two-way crossed random model with interaction, formulas for the MLS method are given in Table 101.6. See Burdick, Borror, and Montgomery (2005) for the formulas for one-way or balanced two-way with no interaction models.

Confidence limits for parameters such as variances and their ratios might not contain the corresponding point estimates, because negative confidence bounds are increased to zero.

Table 101.6 100(1 – α)% MLS Confidence Limits

Parameter	Lower Bound	Upper Bound
μ_y	$\bar{y}_{...} - C \sqrt{\frac{K}{por}}$	$\bar{y}_{...} + C \sqrt{\frac{K}{por}}$
γ_P	$\hat{\gamma}_P - \sqrt{V_{LP}}/(or)$	$\hat{\gamma}_P + \sqrt{V_{UP}}/(or)$
γ_M	$\hat{\gamma}_M - \sqrt{V_{LM}}/(pr)$	$\hat{\gamma}_M + \sqrt{V_{UM}}/(pr)$
γ_y	$\hat{\gamma}_y - \sqrt{V_{LT}}/(por)$	$\hat{\gamma}_y + \sqrt{V_{UT}}/(por)$
γ_R	L_R	U_R
ρ_P	$L_R/(1 + L_R)$	$U_R/(1 + U_R)$
ρ_M	$1/(1 + U_R)$	$1/(1 + L_R)$

The terms in Table 101.6 are defined as follows:

$$\begin{aligned}
 V_{LP} &= G_1^2 S_P^4 + H_3^2 S_{PO}^4 + G_{13} S_P^2 S_{PO}^2 \\
 V_{UP} &= H_1^2 S_P^4 + G_3^2 S_{PO}^4 + H_{13} S_P^2 S_{PO}^2 \\
 V_{LM} &= G_2^2 S_O^4 + G_3^2 (p-1)^2 S_{PO}^4 + G_4^2 p^2 (r-1)^2 S_E^4 \\
 V_{UM} &= H_2^2 S_O^4 + H_3^2 (p-1)^2 S_{PO}^4 + H_4^2 p^2 (r-1)^2 S_E^4 \\
 V_{LT} &= G_1^2 p^2 S_P^4 + G_2^2 o^2 S_O^4 + G_3^2 (po - p - o)^2 S_{PO}^4 + G_4^2 (po)^2 (r-1)^2 S_E^4 \\
 V_{UT} &= H_1^2 p^2 S_P^4 + H_2^2 o^2 S_O^4 + H_3^2 (po - p - o)^2 S_{PO}^4 + H_4^2 (po)^2 (r-1)^2 S_E^4 \\
 L_R &= \frac{p(1 - G_1)(S_P^2 - F_1 S_{PO}^2)}{po(r-1)S_E^2 + o(1 - G_1)F_3 S_O^2 + o(p-1)S_{PO}^2} \\
 U_R &= \frac{p(1 + H_1)(S_P^2 - F_2 S_{PO}^2)}{po(r-1)S_E^2 + o(1 + H_1)F_4 S_O^2 + o(p-1)S_{PO}^2} \\
 G_1 &= 1 - F_{\alpha/2:\infty, p-1} \\
 G_2 &= 1 - F_{\alpha/2:\infty, o-1} \\
 G_3 &= 1 - F_{\alpha/2:\infty, (p-1)(o-1)} \\
 G_4 &= 1 - F_{\alpha/2:\infty, po(r-1)} \\
 H_1 &= F_{1-\alpha/2:\infty, p-1} - 1 \\
 H_2 &= F_{1-\alpha/2:\infty, o-1} - 1 \\
 H_3 &= F_{1-\alpha/2:\infty, (p-1)(o-1)} - 1 \\
 H_4 &= F_{1-\alpha/2:\infty, po(r-1)} - 1 \\
 F_1 &= F_{1-\alpha/2:p-1, (p-1)(o-1)} \\
 F_2 &= F_{\alpha/2:p-1, (p-1)(o-1)} \\
 F_3 &= F_{1-\alpha/2:p-1, o-1} \\
 F_4 &= F_{\alpha/2:p-1, o-1} \\
 G_{13} &= \frac{(F_1 - 1)^2 - G_1^2 F_1^2 - H_3^2}{F_1} \\
 H_{13} &= \frac{(1 - F_2)^2 - H_1^2 F_2^2 - G_3^2}{F_2} \\
 K &= s_P^2 + s_O^2 - s_{PO}^2 \\
 C &= \frac{s_P^2 \sqrt{F_{1-\alpha:1, p-1}} + s_O^2 \sqrt{F_{1-\alpha:1, o-1}} - s_{PO}^2 \sqrt{F_{1-\alpha:1, (p-1)(o-1)}}}{K}
 \end{aligned}$$

The symbol $F_{\alpha:df1, df2}$ represents the percentile of an F distribution with $df1$ and $df2$ degrees of freedom and area α to the left.

Generalized Confidence Limits

The method of generalized confidence limits was first introduced by Weerahandi (1993). The 100(1- α)% generalized confidence limits are determined as follows:

1. Initialize the random number generator with the seed. The seed value is specified by the **SEED=** option.
2. Sample N generalized pivot quantities (GPQ), defined to have a distribution that is independent of the parameters under study. The value N is specified by the **NSAMPLE=** option.
3. Define the lower and upper limits as the $\alpha/2$ and $1 - \alpha/2$ quantiles of the sampled GPQ values.

Formulas for generalized confidence limits are given in Table 101.7, where Z denotes a standard normal random variable and W_1 , W_2 , W_3 , and W_4 denote jointly independent chi-square random variables that are independent of Z with degrees of freedom $p - 1$, $o - 1$, $(p - 1)(o - 1)$ and $po(r - 1)$, respectively. The value of ϵ in Table 101.7 is specified by the **EPSILON=** option.

Table 101.7 100(1 - α)% Generalized Confidence Limits

Parameter	GPQ
μ_y	$\bar{y}_{...} - Z \sqrt{\max \left[\epsilon, \frac{(p-1)s_p^2}{porW_1} + \frac{(o-1)s_o^2}{porW_2} - \frac{(p-1)(o-1)s_{po}^2}{porW_3} \right]}$
γ_P	$\max \left[0, \frac{(p-1)s_p^2}{orW_1} - \frac{(p-1)(o-1)s_{po}^2}{prW_3} \right]$
γ_M	$\frac{(o-1)s_o^2}{prW_2} + \frac{(p-1)^2(o-1)s_{po}^2}{prW_3} + \frac{po(r-1)^2s_E^2}{rW_4}$
γ_y	$\frac{(p-1)s_p^2}{orW_1} + \frac{(o-1)s_o^2}{prW_2} + \frac{(po-p-o)(p-1)(o-1)s_{po}^2}{porW_3} + \frac{po(r-1)^2s_E^2}{rW_4}$
γ_R	$\frac{GPQ(\gamma_P)}{GPQ(\gamma_M)}$

In general, the GCL method provides a more accurate confidence interval with a shorter interval width than the MLS method. However, the greater accuracy comes at the cost of being somewhat nondeterministic, because of the reliance on simulation.

Displayed Output

PROC VARCOMP displays the following items:

- Class Level Information for verifying the levels in your data
- Number of observations read from the data set and number of observations used in the analysis
- for METHOD=TYPE1, an analysis-of-variance table with Source, DF, Type I Sum of Squares, Type I Mean Square, and Expected Mean Square, and a table of Type I variance component estimates
- for METHOD=MIVQUE0, the SSQ Matrix containing sums of squares of partitions of the $\mathbf{X}'\mathbf{X}$ crossproducts matrix adjusted for the fixed effects

- for METHOD=ML and METHOD=REML, the iteration history, including the objective function, a table of variance component estimates, and the estimated Asymptotic Covariance Matrix of the variance components
- for METHOD=GRR, an analysis-of-variance table with Source, DF, GRR Sum of Squares, GRR Mean Square, and Expected Mean Square, and a table of GRR parameter estimates. If the CL option is specified, confidence limits for each parameter estimate will also be displayed.

ODS Table Names

PROC VARCOMP assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 101.8. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 101.8 ODS Tables Produced by PROC VARCOMP

ODS Table Name	Description	Statement
ANOVA	Type 1 analysis of variance	METHOD=TYPE1 or GRR
AsyCov	Asymptotic covariance matrix of estimates	METHOD=ML or REML
ClassLevels	Class level information	default
ConvergenceStatus	Convergence status	METHOD=ML or REML
DepVar	Dependent variable	METHOD=TYPE1, REML, ML, or GRR
DependentInfo	Dependent variable info (multiple variables)	
Estimates	Variance component estimates	default
IterHistory	Iteration history	METHOD=ML or REML
NObs	Number of observations	default
SSCP	Sum of squares matrix	METHOD=MIVQUE0

In situations where multiple dependent variables are analyzed that differ in their missing value pattern, separate names for ANOVAn, AsyCovn, Estimatesn, IterHistoryn, and SSCPn tables are no longer required. The results are combined into a single output data set. For METHOD=TYPE1, ML, or REML, the variable Dependent in the output data set identifies the dependent variable. For METHOD=MIVQUE0, a variable is added to the output data set for each dependent variable.

Relationship to PROC MIXED

The MIXED procedure effectively performs the same analyzes as PROC VARCOMP and many others, including Type I, Type II, and Type III tests of fixed effects, confidence limits, customized contrasts, and least squares means. Furthermore, continuous variables are permitted as both fixed and random effects in PROC MIXED, and numerous other covariance structures besides variance components are available. The VARCOMP procedure is more computationally efficient for some special designs and models.

To translate PROC VARCOMP code into PROC MIXED code, move all random effects to the RANDOM statement in PROC MIXED. For example, the syntax for the example in the section “Getting Started: VARCOMP Procedure” on page 8532 is as follows:

```
proc mixed;
  class Temp Lab Batch;
  model Cure = Temp;
  random Lab Temp*Lab Batch(Lab Temp);
run;
```

REML is the default estimation method in PROC MIXED, and you can specify other methods by using the METHOD= option.

Examples: VARCOMP Procedure

Example 101.1: Using the Four General Estimation Methods

In this example, a and b are classification variables and y is the dependent variable. a is declared fixed, and b and a*b are random. Note that this design is unbalanced because the cell sizes are not all the same. PROC VARCOMP is invoked four times, once for each of the general estimation methods. The data are from Hemmerle and Hartley (1973). The following statements produce [Output 101.1.1](#).

```
data a;
  input a b y @@;
  datalines;
1 1 237   1 1 254   1 1 246   1 2 178   1 2 179
2 1 208   2 1 178   2 1 187   2 2 146   2 2 145   2 2 141
3 1 186   3 1 183   3 2 142   3 2 125   3 2 136
;

proc varcomp method=type1 data=a;
  class a b;
  model y=a|b / fixed=1;
run;
```

Output 101.1.1 VARCOMP Procedure: Method=TYPE1

Variance Components Estimation Procedure

Corrected Total	15	24270	
Type 1 Estimates			
		Variance Component	Estimate
		Var(b)	1448.4
		Var(a*b)	27.42659
		Var(Error)	78.63333

The “Class Level Information” table in [Output 101.1.1](#) displays the levels of each variable specified in the CLASS statement. You can check this table to make sure the data are input correctly.

The Type I analysis of variance in [Output 101.1.1](#) consists of a sequential partition of the total sum of squares. The mean square is the sum of squares divided by the degrees of freedom, and the expected mean square is the expected value of the mean square under the mixed model. The “Q” notation in the expected mean squares refers to a quadratic form in parameters of the parenthesized effect.

The Type I estimates of the variance components in [Output 101.1.1](#) result from solving the linear system of equations established by equating the observed mean squares to their expected values.

The following statements are the same as before, except that the estimation method is MIVQUE0 instead of the default TYPE1. They produce [Output 101.1.2](#).

```
proc varcomp method=mivque0 data=a;
  class a b;
  model y=a|b / fixed=1;
run;
```

Output 101.1.2 VARCOMP Procedure: Method=MIVQUE0

Variance Components Estimation Procedure				
MIVQUE(0) SSQ Matrix				
Source	b	a*b	Error	y
b	60.84000	20.52000	7.80000	89295.4
a*b	20.52000	20.52000	7.80000	30181.3
Error	7.80000	7.80000	13.00000	12533.5
MIVQUE(0) Estimates				
Variance Component		y		
Var(b)		1466.1		
Var(a*b)		-35.49170		
Var(Error)		105.73660		

The MIVQUE0 estimates in [Output 101.1.2](#) result from solving the equations established by the MIVQUE0 SSQ matrix. Note that the estimate of the variance component for the interaction effect, Var(a*b), is negative for this example.

The following statements use METHOD=ML to invoke maximum likelihood estimation. They produce [Output 101.1.3](#).

```
proc varcomp method=ml data=a;
  class a b;
  model y=a|b / fixed=1;
run;
```

Output 101.1.3 VARCOMP Procedure: Method=ML

Variance Components Estimation Procedure				
Maximum Likelihood Iterations				
Iteration	Objective	Var(b)	Var(a*b)	Var(Error)
0	78.3850371200	1031.49070	0	74.3909717935
1	78.2637043807	732.3606453635	0	77.4011688154
2	78.2635471161	723.6867470850	0	77.5301774839
3	78.2635471152	723.6658365289	0	77.5304926877
Convergence criteria met.				

Output 101.1.3 *continued*

Maximum Likelihood Estimates	
Variance Component	Estimate
Var(b)	723.66584
Var(a*b)	0
Var(Error)	77.53049

Asymptotic Covariance Matrix of Estimates			
	Var(b)	Var(a*b)	Var(Error)
Var(b)	537826.1	0	-107.33905
Var(a*b)	0	0	0
Var(Error)	-107.33905	0	858.71104

The “Maximum Likelihood Iterations” table in [Output 101.1.3](#) shows that the Newton-Raphson algorithm used by PROC VARCOMP requires three iterations to converge.

The ML estimate of Var(a*b) is zero for this example, and the other two estimates are smaller than their Type I and MIVQUE0 counterparts.

One benefit of using likelihood-based methods is that an approximate covariance matrix is available from the matrix of second derivatives evaluated at the ML solution. This covariance matrix is valid asymptotically and can be unreliable in small samples.

Here the variance component estimates for B and the Error are negatively correlated, and the elements for Var(a*b) are set to zero because the estimate equals zero. Also, the very large variance for Var(b) indicates a lot of uncertainty about the estimate for Var(b), and one contributing explanation is that B has only two levels in this data set.

Finally, the following statements use the restricted maximum likelihood (REML) for estimation. They produce [Output 101.1.4](#).

```
proc varcomp method=reml data=a;
  class a b;
  model y=a|b / fixed=1;
run;
```

Output 101.1.4 VARCOMP Procedure: Method=REML

Variance Components Estimation Procedure				
REML Iterations				
Iteration	Objective	Var(b)	Var (a*b)	Var (Error)
0	63.4134144942	1269.52701	0	91.5581191305
1	63.0446869787	1601.84199	32.7632417174	76.9355562461
2	63.0311530508	1468.82932	27.2258186561	78.7548276319
3	63.0311265148	1464.33646	26.9564053003	78.8431476502
4	63.0311265127	1464.36727	26.9588525177	78.8423898761
Convergence criteria met.				
REML Estimates				
Variance Component		Estimate		
Var(b)		1464.4		
Var(a*b)		26.95885		
Var(Error)		78.84239		
Asymptotic Covariance Matrix of Estimates				
	Var(b)	Var(a*b)	Var (Error)	
Var(b)	4401703.8	1.29359	-273.39651	
Var(a*b)	1.29359	3559.1	-502.85157	
Var(Error)	-273.39651	-502.85157	1249.7	

The “REML Iterations” table in [Output 101.1.4](#) shows that the REML optimization requires four iterations to converge.

The REML estimates in [Output 101.1.4](#) are all larger than the corresponding ML estimates (adjusting for potential downward bias) and are fairly similar to the Type I estimates.

The “Asymptotic Covariance Matrix of Estimates” table in [Output 101.1.4](#) shows that the Error variance component estimate is negatively correlated with the other two variance component estimates, and the estimated variances are all larger than their ML counterparts.

Example 101.2: Using the GRR Method

In this example from Houf and Burman (1988), the response variable is the thermal performance of a module measured in Celsius degrees per watt. Each of three operators measures 10 parts three times. It is assumed that parts and operators are selected at random from larger populations. The following statements produce [Output 101.2.1](#).

```

data Houf;
  input a b y @@;
  datalines;
1 1 37    1 1 38    1 1 37

10 2 35   10 2 35   10 2 34
10 3 35   10 3 34   10 3 35
;

proc varcomp data=Houf method=grr (speclimits=(18,58) ratio);
  class a b;
  model y=a|b|c|;
run;

```

You specify **METHOD=GRR** in this example to drive the VARCOMP procedure to produce a [gauge repeatability and reproducibility analysis](#). With the option **speclimits=(18 58)**, the parameters **PTR** and **Cp** are estimated and displayed. With the **RATIO** option, certain additional ratios of variance components are also estimated and displayed. Finally, the **CL=** option in the **MODEL** statement specifies that estimates of GRR quantities should have the corresponding confidence limits.

Output 101.2.1 Class Level Information Using Method=GRR

Variance Components Estimation Procedure												
Class Level Information												
Class	Levels		Values									
a	10		1	2	3	4	5	6	7	8	9	10
b	3		1	2	3							
Number of Observations Read											90	
Number of Observations Used											90	
Dependent Variable: y												

The “Class Level Information” table in [Output 101.2.1](#) displays the levels of each variable specified in the **CLASS** statement.

Output 101.2.2 Analysis of Variance Using Method=GRR

GRR Analysis of Variance			
Source	DF	Sum of Squares	Mean Square
a	9	3935.955556	437.328395
b	2	39.266667	19.633333
a*b	18	48.511111	2.695062
Error	60	30.666667	0.511111
Corrected Total	89	4054.400000	

GRR Analysis of Variance	
Source	Expected Mean Square
a	Var(Error) + 3 Var(a*b) + 9 Var(a)
b	Var(Error) + 3 Var(a*b) + 30 Var(b)
a*b	Var(Error) + 3 Var(a*b)
Error	Var(Error)
Corrected Total	

The GRR analysis of variance in [Output 101.2.2](#) is the same as for the Type I analysis when the design is balanced.

Finally, the estimates of the [GRR parameters](#) of interest and their [confidence limits](#) are displayed in [Output 101.2.3](#).

Output 101.2.3 Parameter Estimates Using Method=GRR

GRR Estimates			
Parameter	Estimate	95% Confidence Limits	
Mu Y	35.80000	30.49477	41.10523
Var (a)	48.29259	22.69452	161.63918
Var (b)	0.56461	0.07296	25.75077
Var (a*b)	0.72798	0.33273	1.79272
Var (Error)	0.51111	0.36816	0.75754
Gamma Y	50.09630	24.48844	166.22217
Gamma P	48.29259	22.69452	161.63918
Gamma M	1.80370	1.20623	27.01724
Gamma R	26.77413	1.69168	105.60895
SNR	7.31767	1.83939	14.53334
PTR (18, 58, 6)	0.20145	0.16474	0.77967
Cp (18, 58, 6)	0.95933	0.52437	1.39942
DR	54.54825	4.38336	212.21791
Rho P	0.96400	0.62848	0.99062
Rho M	0.03600	0.0093801	0.37152
Var (a) /Gamma Y	0.96400	0.62848	0.99062
Var (b) /Gamma Y	0.01127	0.0008700	0.34151
Var (a*b) /Gamma Y	0.01453	0.0027083	0.04744
Var (a) /Var (Error)	94.48551	40.19199	327.32469
Var (b) /Var (Error)	1.10467	0.13662	50.37744
Var (a*b) /Var (Error)	1.42432	0.55232	3.74691

You can draw the following inferences from the results of the analysis. Most of the variation is due to differences between parts because of the relative larger value of [Gamma R](#). The measurement system is nearly inadequate because the [PTR](#) exceeds 20%. However, the measurement system is of value in monitoring the process since the [SNR](#) is greater than five. See Burdick, Borror, and Montgomery (2003) for more information about interpreting gauge R&R studies.

The confidence limits in [Output 101.2.3](#) are based on large-sample asymptotic approximation. You can alternatively compute more accurate and usually smaller confidence intervals by using CL=GCL for generalized confidence limits. The following statements produce [Output 101.2.4](#):

```
proc varcomp data=Houf method=grr (speclimits=(18,58) ratio) seed=104;
  class a b;
  model y=a|b/cl=gcl;
run;
```

Output 101.2.4 Generalized Confidence Limits

Variance Components Estimation Procedure			
GRR Estimates			
Parameter	Estimate	95% Generalized Confidence Limits	
Mu Y	35.80000	30.48351	41.31148
Var (a)	48.29259	22.79316	168.91421

Gamma Y	50.09630	25.47092	180.85535
Gamma P	48.29259	22.79316	168.91421
Gamma M	1.80370	1.18494	25.76890
Gamma R	26.77413	1.91286	87.60026
SNR	7.31767	1.95594	13.23633
PTR (18, 58, 6)	0.20145	0.16328	0.76145
Cp (18, 58, 6)	0.95933	0.51295	1.39639
DR	54.54825	4.82572	176.20052
Rho P	0.96400	0.65669	0.98871
Rho M	0.03600	0.01129	0.34331
Var (a) / Gamma Y	0.96400	0.65669	0.98871
Var (b) / Gamma Y	0.01127	0.0010082	0.32122
Var (a*b) / Gamma Y	0.01453	0.0032088	0.04300
Var (a) / Var (Error)	94.48551	40.44585	336.50782
Var (b) / Var (Error)	1.10467	0.12886	47.19043
Var (a*b) / Var (Error)	1.42432	0.55232	3.74691

Note that the generalized confidence interval widths from [Output 101.2.4](#) for parameters γ_R and DR are 85.7 and 171.4, respectively. These widths are much shorter than the MLS-based widths, which are 103.9 and 207.8 from [Output 101.2.3](#).

In general, the GCL method provides a more accurate confidence interval with a shorter interval width than the MLS method. However, as discussed in the section “[Generalized Confidence Limits](#)” on page 8546, they are computationally intensive and somewhat nondeterministic, because they are based on an underlying Monte Carlo simulation.

Overview: VARIOGRAM Procedure

The VARIOGRAM procedure computes empirical measures of spatial continuity for two-dimensional spatial data. These measures are a function of the distances between the sample data pairs. When the data are free of nonrandom (or systematic) surface trends, the estimated continuity measures are the empirical semivariance and covariance. The procedure also fits permissible theoretical models to the empirical semivariograms, so that you can use them in subsequent analysis to perform spatial prediction. You can produce plots of the empirical semivariograms in addition to plots of the fitted models. Both isotropic and anisotropic continuity measures are available.

PROC VARIOGRAM also provides the Moran's I and Geary's c spatial autocorrelation statistics, in addition to the Moran scatter plot to visualize spatial associations within a specified neighborhood around observations. The procedure produces the OUTVAR=, OUTPAIR=, and OUTDISTANCE= data sets that contain information about the semivariogram analysis. Also, the OUTACWEIGHTS= and the OUTMORAN= output data sets contain information about the autocorrelation analysis.

The VARIOGRAM procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For more information about the graphics available in PROC VARIOGRAM, see the section “[ODS Graphics](#)” on page 8647.

Introduction to Spatial Prediction

Many activities in science and technology involve measurements of one or more quantities at given spatial locations, with the goal of predicting the measured quantities at unsampled locations. Application areas include reservoir prediction in mining and petroleum exploration, in addition to modeling in a broad spectrum of fields (for example, environmental health, environmental pollution, natural resources and energy, hydrology, and risk analysis). Often, the unsampled locations are on a regular grid, and the predictions are used to produce surface plots or contour maps.

The preceding tasks fall within the scope of *spatial prediction*, which, in general, is any prediction method that incorporates spatial dependence. The study of these tasks involves naturally occurring uncertainties that cannot be ignored. Stochastic analysis frameworks and methods are often used to account for these uncertainties. Hence, the terms *stochastic spatial prediction* and *stochastic modeling* are also used to characterize this type of analysis.

A popular method of spatial prediction is *ordinary kriging*, which produces both predicted values and associated standard errors. Ordinary kriging requires the complete specification (the form and parameter values) of the spatial dependence that characterizes the spatial process. For this purpose, models for the spatial dependence are expressed in terms of the distance between any two locations in the spatial domain of interest. These models take the form of a covariance or semivariance function.

Spatial prediction, then, involves two steps. First, you model the covariance or semivariance of the spatial process. These measures are typically not known in advance. This step involves computing an empirical estimate, in addition to determining both the mathematical form and the values of any parameters for a theoretical form of the dependence model. Second, you use this dependence model to solve the kriging system at a specified set of spatial points, resulting in predicted values and associated standard errors.

SAS/STAT software has two procedures that correspond to these steps for spatial prediction of two-dimensional data. The VARIOGRAM procedure is used in the first step (that is, calculating and modeling the dependence model), and the KRIGE2D procedure performs the kriging operations to produce the final predictions.

This introduction concludes with a note on terminology. You might commonly encounter the terms *estimation* and *prediction* used interchangeably by experts in different fields; this could be a source of confusion. A precise statistical vernacular uses the term *estimation* to refer to inferences about the value of fixed but unknown parameters, whereas *prediction* concerns inferences about the value of random variables—see, for example, Cressie (1993, p. 106). In light of these definitions, kriging methods are clearly predictive techniques, since they are concerned with making inferences about the value of a spatial random field at observed or unobserved locations. The SAS/STAT suite of procedures for spatial analysis and prediction (VARIOGRAM, KRIGE2D, and SIM2D) follows the statistical vernacular in the use of the terms *estimation* and *prediction*.

Getting Started: VARIOGRAM Procedure

PROC VARIOGRAM uses your data to compute the empirical semivariogram. This computation refers to the steps you take to derive the empirical semivariance from the data, and then to produce the corresponding semivariogram plot.

You can proceed further with the semivariogram analysis if the data are free of systematic trends. In that case, you can use the empirical outcome to determine a theoretical semivariogram model by using the automated methods provided by the VARIOGRAM procedure. The model characterizes the type of theoretical semivariance function you use to describe spatial dependence in your data set.

Graphical displays are requested by enabling ODS Graphics. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the VARIOGRAM procedure, see the section “[ODS Graphics](#)” on page 8647.

Preliminary Spatial Data Analysis

The following thick data set is available from the Sashelp library. The data set simulates measurements of coal seam thickness (in feet) taken over an approximately square area. The Thick variable has the thickness values in the thick data set. The coordinates are offsets from a point in the southwest corner of the measurement area, with the north and east distances in units of thousands of feet.

```

It is instructive to see the locations of the measured points in the area where you want to perform spatial prediction. It is desirable to have the sampling locations scattered evenly throughout the prediction area. If the locations are not scattered evenly, the prediction error might be unacceptably large where measurements are sparse.

You can run PROC VARIOGRAM in this preliminary analysis to determine potential problems. In the following statements, the **NOVARIOGRAM** option in the **COMPUTE** statement specifies that only the descriptive summaries and a plot of the raw data be produced.

```
ods graphics on;

proc variogram data=thick plots=pairs(thr=30);
  compute novariogram nhc=20;
  coordinates xc=East yc=North;
  var Thick;
run;
```

PROC VARIOGRAM produces the table in [Figure 102.1](#) that shows the number of Thick observations read and used. This table provides you with useful information in case you have missing values in the input data.

Figure 102.1 Number of Observations for the thick Data Set

Spatial Correlation Analysis with PROC VARIOGRAM	
The VARIOGRAM Procedure	
Dependent Variable: Thick	
Number of Observations Read	75
Number of Observations Used	75

Then, the scatter plot of the observed data is produced as shown in [Figure 102.2](#). According to the figure, although the locations are not ideally spread around the prediction area, there are not any extended areas lacking measurements. The same graph also provides the values of the measured variable by using colored markers.

Figure 102.2 Scatter Plot of the Observations Spatial Distribution

The following is a crucial step. Any obvious surface trend must be removed before you compute the empirical semivariogram and proceed to estimate a model of spatial dependence (the theoretical semivariogram model). You can observe in [Figure 102.2](#) the small-scale variation typical of spatial data, but a first inspection indicates no obvious major systematic trend.

Assuming, therefore, that the data are free of surface trends, you can work with the original thickness rather than residuals obtained from a trend removal process. The following analysis also assumes that the spatial characterization is independent of the direction of the line that connects any two equidistant pairs of data; this is a property known as isotropy. See “[Example 102.2: An Anisotropic Case Study with Surface Trend in the Data](#)” on page 8658 for a more detailed approach to trend analysis and the issue of anisotropy.

Following the previous exploratory analysis, you then need to classify each data pair as a member of a distance interval (lag). PROC VARIOGRAM performs this grouping with two required options for semivariogram computation: the `LAGDISTANCE=` and `MAXLAGS=` options. These options are based on your assessment of how to group the data pairs within distance classes.

The meaning of the required **LAGDISTANCE=** option is as follows. Classify all pairs of points into intervals according to their pairwise distance. The width of each distance interval is the **LAGDISTANCE=** value. The meaning of the required **MAXLAGS=** option is simply the number of intervals you consider. The problem is that given only the scatter plot of the measurement locations, it is not clear what values to give to the **LAGDISTANCE=** and **MAXLAGS=** options.

Ideally, you want a sufficient number of distance classes that capture the extent to which your data are correlated and you want each class to contain a minimum of data pairs to increase the accuracy in your computations. A rule of thumb used in semivariogram computations is that you should have at least 30 pairs per lag class. This is an empirical arbitrary threshold; see the section “Choosing the Size of Classes” on page 8623 for further details.

In the preliminary analysis, you use the option **NHCLASSES=** in the **COMPUTE** statement to help you experiment with these numbers and choose values for the **LAGDISTANCE=** and **MAXLAGS=** options. Here, in particular, you request **NHCLASSES=20** to preview a classification that uses 20 distance classes across your spatial domain. A zero lag class is always considered; therefore the output shows the number of distance classes to be one more than the number you specified.

Based on your selection of the **NHCLASSES=** option, the **NOVARIOGRAM** option produces a pairwise distances table from your observations shown in Figure 102.3, and the corresponding histogram in Figure 102.4. For illustration purposes, you also specify a threshold of minimum data pairs per distance class in the **PAIRS** option as **THR=30**. As a result, a reference line appears in the histogram so that you can visually identify any lag classes with pairs that fall below your specified threshold.

Figure 102.3 Pairwise Distance Intervals Table

Pairwise Distance Intervals				
Lag Class	-----Bounds-----		Number of Pairs	Percentage of Pairs
0	0.00	3.48	7	0.25%
1	3.48	10.45	81	2.92%
2	10.45	17.42	138	4.97%
3	17.42	24.39	167	6.02%
4	24.39	31.36	204	7.35%
5	31.36	38.33	210	7.57%
6	38.33	45.30	213	7.68%
7	45.30	52.27	253	9.12%
8	52.27	59.24	237	8.54%
9	59.24	66.20	280	10.09%
10	66.20	73.17	252	9.08%
11	73.17	80.14	230	8.29%
12	80.14	87.11	217	7.82%
13	87.11	94.08	154	5.55%
14	94.08	101.05	71	2.56%
15	101.05	108.02	41	1.48%
16	108.02	114.99	14	0.50%
17	114.99	121.96	5	0.18%
18	121.96	128.93	1	0.04%
19	128.93	135.89	0	0.00%
20	135.89	142.86	0	0.00%

The **NOVARIOGRAM** option also produces a table with useful facts about the pairs and the distances between the most remote data in selected directions, shown in [Figure 102.5](#). In particular, the lag distance value is calculated based on your selection of the **NHCLASSES=** option. The last three table entries report the overall maximum distance among your data pairs, in addition to the maximum distances in the main axes directions—that is, the vertical (N–S) axis and the horizontal (E–W) axis. This information is also provided in the inset of [Figure 102.4](#). When you specify a threshold in the **PAIRS** suboption of the **PLOTS** option, as in this example, the threshold also appears in the table. Then, the line that follows indicates the highest lag class with the following property: each one of the distance classes that lie farther away from this lag features a pairs population below the specified threshold.

With the preceding information you can determine appropriate values for the **LAGDISTANCE=** and **MAXLAGS=** options in the **COMPUTE** statement. In particular, the classification that uses 20 distance classes is satisfactory, and you can choose **LAGDISTANCE=7** after following the suggestion in [Figure 102.5](#).

Figure 102.4 Distribution of Pairwise Distances

Figure 102.5 Pairs Information Table

Pairs Information	
Number of Lags	21
Lag Distance	6.97
Minimum Pairs Threshold	30
Highest Lag With Pairs > Threshold	15
Maximum Data Distance in East	97.50
Maximum Data Distance in North	99.60
Maximum Data Distance	139.38

The **MAXLAGS=** option needs to be specified based on the spatial extent to which your data are correlated. Unless you know this size, in the present omnidirectional case you can assume the correlation extent to be roughly equal to half the overall maximum distance between data points.

The table in [Figure 102.5](#) suggests that this number corresponds to 139,380 feet, which is most likely on or close to a diagonal direction (that is, the northeast–southwest or northwest–southeast direction). Hence, you can expect the correlation extent in this scale to be around $139.4/2 = 69,700$ feet. Consequently, consider lag classes up to this distance for the empirical semivariogram computations. Given your lag size selection, [Figure 102.3](#) indicates that this distance corresponds to about 10 lags; hence you can set **MAXLAGS=10**.

Overall, for a specific **NHCLASSES=** choice of class count, you can expect your choice of **MAXLAGS=** to be approximately half the number of the lag classes (see the section “[Spatial Extent of the Empirical Semivariogram](#)” on page 8624 for more details).

After you have starting values for the **LAGDISTANCE=** and **MAXLAGS=** options, you can run the **VARIOGRAM** procedure multiple times to inspect and compare the results you get by specifying different values for these options.

Empirical Semivariogram Computation

Using the values of **LAGDISTANCE=7** and **MAXLAGS=10** computed previously, rerun **PROC VARIOGRAM** without the **NOVARIOGRAM** option in order to compute the empirical semivariogram. You specify the **CL** option in the **COMPUTE** statement to calculate the 95% confidence limits for the classical semivariance. The section “[COMPUTE Statement](#)” on page 8584 describes how to use the **ALPHA=** option to specify a different confidence level.

Also, you can request a robust version of the semivariance with the **ROBUST** option in the **COMPUTE** statement. **PROC VARIOGRAM** produces a plot that shows both the classical and the robust empirical semivariograms. See the details of the **PLOTS** option to specify different instances of plots of the empirical semivariogram. The following statements implement the preceding requests:

```
proc variogram data=thick outv=outv;
  compute lagd=7 maxlag=10 cl robust;
  coordinates xc=East yc=North;
  var Thick;
run;
```

Figure 102.6 displays the PROC VARIOGRAM output empirical semivariogram table for the preceding statements. The table displays a total of eleven lag classes, even though you specified `MAXLAGS=10`. The VARIOGRAM procedure always includes a zero lag class in the computations in addition to the `MAXLAGS` classes you request with the `MAXLAGS=` option. Hence, semivariance is actually computed at `MAXLAGS+1` lag classes; see the section “Distance Classification” on page 8619 for more details.

Figure 102.6 Output Table for the Empirical Semivariogram Analysis

Spatial Correlation Analysis with PROC VARIOGRAM							
The VARIOGRAM Procedure							
Dependent Variable: Thick							
Empirical Semivariogram							
Lag Class	Pair Count	Average Distance	-----Semivariance-----				
			Robust	Classical	Standard Error	95% Confidence Limits	
0	7	2.64	0.028	0.034	0.018	0	0.069
1	82	7.29	0.210	0.394	0.061	0.273	0.514
2	138	14.16	1.008	1.179	0.142	0.901	1.458
3	169	21.08	3.018	2.799	0.304	2.202	3.396
4	205	27.93	4.811	4.602	0.455	3.711	5.493
5	213	35.17	5.990	5.928	0.574	4.802	7.054
6	214	42.20	8.104	7.518	0.727	6.094	8.943
7	250	48.78	7.533	7.221	0.646	5.955	8.487
8	247	56.16	8.066	7.195	0.647	5.926	8.464
9	281	62.89	8.279	6.845	0.577	5.713	7.976
10	250	69.93	8.144	6.358	0.569	5.243	7.472

Figure 102.7 shows both the classical and robust empirical semivariograms. In addition, the plot features the approximate 95% confidence limits for the classical semivariance. The figure exhibits a typical behavior of the computed semivariance uncertainty, where in general the variance increases with distance from the origin at Distance=0.

Figure 102.7 Classical and Robust Empirical Semivariograms for Coal Seam Thickness Data

The needle plot in the lower part of the [Figure 102.7](#) provides the number of pairs that were used in the computation of the empirical semivariance for each lag class shown. In general, this is a pairwise distribution that is different from the distribution depicted in [Figure 102.4](#). First, the number of pairs shown in the needle plot depends on the particular criteria you specify in the **COMPUTE** statement of PROC VARIOGRAM. Second, the distances shown for each lag on the Distance axis are not the midpoints of the lag classes as in the pairwise distances plot, but rather the average distance from the origin Distance=0 of all pairs in a given lag class.

Autocorrelation Analysis

You can use the autocorrelation analysis features of PROC VARIOGRAM to compute the autocorrelation Moran's I and Geary's c statistics and to obtain the Moran scatter plot. In the following statements, you ask for the Moran's I and Geary's c statistics under the assumption of randomization using binary weights, in addition to the Moran scatter plot:

```
proc variogram data=thick outv=outv plots(only)=moran;
  compute lagd=7 maxlag=10 autocorr(assum=random);
  coordinates xc=East yc=North;
  var Thick;
run;
```

For the autocorrelation analysis with binary weights and the Moran scatter plot, the `LAGDISTANCE=` option indicates that you consider as neighbors of an observation all other observations within the specified distance from it.

Figure 102.8 shows the output from the requested autocorrelation analysis. This includes the observed (computed) Moran's I and Geary's c coefficients, the expected value and standard deviation for each coefficient, the corresponding Z score, and the p -value in the `Pr > |Z|` column. The low p -values suggest strong autocorrelation for both statistics types. A two-sided p -value is reported, which is the probability that the observed coefficient lies farther away from $|Z|$ on either side of the coefficient's expected value—that is, lower than $-Z$ or higher than Z . The sign of Z for both Moran's I and Geary's c coefficients indicates positive autocorrelation in the Thick data values; see the section “Interpretation” on page 8638 for more details.

Figure 102.8 Output Table for the Autocorrelation Statistics

Spatial Correlation Analysis with PROC VARIOGRAM						
The VARIOGRAM Procedure						
Dependent Variable: Thick						
Autocorrelation Statistics						
Assumption	Coefficient	Observed	Expected	Std Dev	Z	Pr > Z
Randomization	Moran's I	0.9240	-0.0244	0.145	6.53	<.0001
Randomization	Geary's c	0.0162	1.0000	0.175	-5.62	<.0001

The requested Moran scatter plot is shown in Figure 102.9. The plot includes all nonmissing observations that have neighbors within the specified `LAGDISTANCE=` distance. The horizontal axis displays the standardized Thick values, and the vertical axis displays the corresponding weighted average of their neighbors. The plot data points are concentrated in the upper right and lower left quadrants defined by the lines $x = 0$ and $y = 0$, and clearly around the axes' diagonal reference line $y = x$ of slope 1. This fact indicates strong positive spatial association in the thick data set observations. Therefore, for each observation its neighbors within the specified `LAGDISTANCE=` distance have overall similar Thick values to that observation. The plot also displays the linear regression slope, whose value is the Moran's I coefficient when the binary weights are row-averaged. See the section “The Moran Scatter Plot” on page 8639 for more details about the Moran scatter plot.

Figure 102.9 Moran Scatter Plot for Coal Seam Thickness Data

Theoretical Semivariogram Model Fitting

PROC VARIOGRAM features automated semivariogram fitting. In particular, the procedure selects a theoretical semivariogram model to fit the empirical semivariance and produces estimates of the model parameters in addition to a fit plot. You have the option to save these estimates in an item store, which is a binary file format that is defined by the SAS System and that you cannot modify. Then, you can retrieve this information at a later point from the item store for future analysis with PROC KRIGE2D or PROC SIM2D.

The coal seam thickness empirical semivariogram in Figure 102.7 shows first a slow, then rapid, rise from the origin. This behavior suggests that you can approximate the empirical semivariance with a Gaussian-type form

$$\gamma_z(h) = c_0 \left[1 - \exp \left(-\frac{h^2}{a_0^2} \right) \right]$$

as shown in the section “Theoretical Semivariogram Models” on page 8608. Based on this remark, you choose to fit a Gaussian model to your classical semivariogram. Run PROC VARIOGRAM again and

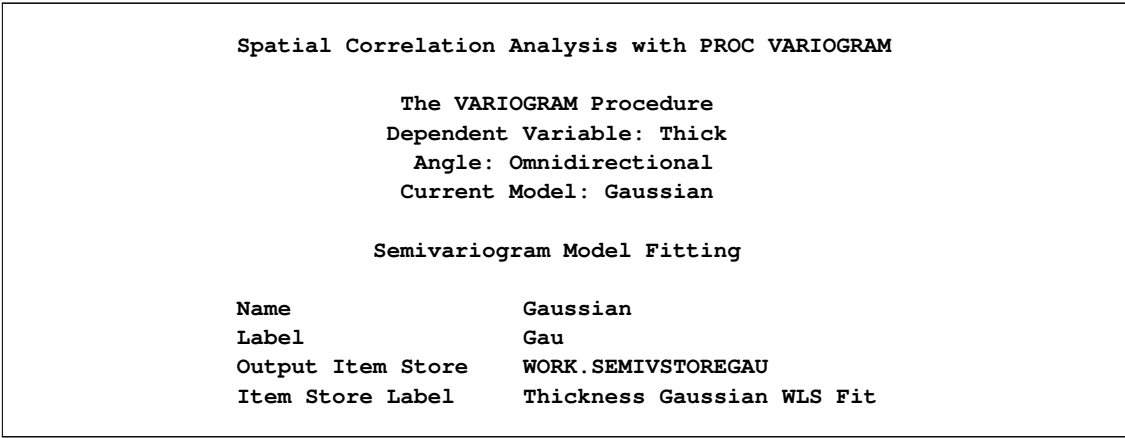

specify the **MODEL** statement with the **FORM=GAU** option. By default, PROC VARIOGRAM uses the weighted least squares (WLS) method to fit the specified model, although you can explicitly specify the **METHOD=** option to request the fitting method. You want additional information about the estimated parameters, so you specify the **CL** option in the **MODEL** statement to compute their 95% confidence limits and the **COVB** option of the **MODEL** statement to produce a table with their approximate covariances. You also specify the **STORE** statement to save the fitting outcome into an item store file with the name SemivStoreGau and a desired label. You run the following statements:

```
proc variogram data=thick outv=outv;
  store out=SemivStoreGau / label='Thickness Gaussian WLS Fit';
  compute lagd=7 maxlag=10;
  coordinates xc=East yc=North;
  model form=gau cl / covb;
  var Thick;
run;

ods graphics off;
```

After you run the procedure you get a series of output objects from the fitting analysis. In particular, Figure 102.10 shows first a model fitting table with the name and a short label of the model that you requested to use for the fit. The table also displays the name and label of the specified item store.

Figure 102.10 Semivariogram Model Fitting General Information

If you specify no parameters, as in the current example, then PROC VARIOGRAM initializes the model parameters for you with default values based on the empirical semivariance; for more details, see the section “Theoretical Semivariogram Model Fitting” on page 8627. The initial values provided by the VARIOGRAM procedure for the Gaussian model are displayed in the table in Figure 102.11.

Figure 102.11 Semivariogram Fitting Model Information

Model Information	
Parameter	Initial Value
Nugget	0
Scale	6.7992
Range	34.9635

Otherwise, in PROC VARIOGRAM you can specify initial values for parameters with the **PARMS** statement. Alternatively, you can specify fixed values for the model scale and range with the **SCALE=** and **RANGE=** options, respectively, in the **MODEL** statement. A nugget effect is always used in model fitting. Unless you explicitly specify a fixed nugget effect with the **NUGGET=** option in the **MODEL** statement or initialize the nugget parameter in the **PARMS** statement, the nugget effect is automatically initialized to zero. See the section “Syntax: VARIOGRAM Procedure” on page 8576 for more details about how the **MODEL** statement and the **PARMS** statement handle model parameters.

The output in Figure 102.12 comes from the optimization process that takes place during the model parameter estimation. The optimizer produces an optimization information table, information about the optimization technique that is used, optimization-related results, and notification about the optimization convergence.

Figure 102.12 Fitting Optimization Information

Convergence criterion (GCONV=1E-8) satisfied.			

The fitting process is successful, and the parameters converge to the estimated values shown in [Figure 102.13](#). For each parameter, the same table also displays the approximate standard error, the degrees of freedom, the t value, the approximate p -value, and the requested 95% confidence limits.

Figure 102.13 Semivariogram Fitting Parameter Estimates

Parameter Estimates

Scale	0.0000	0.0687	0.2326
Range	0.0000	0.2326	1.3094

The fitting summary table in [Figure 102.15](#) displays statistics about the quality of the fitting process. In particular, the table shows the weighted error sum of squares in the Weighted SSE column and the Akaike information criterion in the AIC column. See more information about the fitting criteria in section “Quality of Fit” on page 8632.

Figure 102.15 Semivariogram Model Fitting Summary

Fit Summary		
Model	Weighted SSE	AIC
Gau	11.43389	6.42556

Figure 102.16 demonstrates the fitted theoretical semivariogram against the empirical semivariance estimates with the weighted least squares method. The fit seems to be more accurate closer to the origin $h = 0$, and this is explained as follows: A smaller h corresponds to smaller semivariance; in turn, this corresponds to smaller semivariance variance, as shown in the section “Theoretical and Computational Details of the Semivariogram” on page 8613. By definition, the WLS optimization weights increase with decreasing variance, which leads to a more accurate fit for smaller distances h in the WLS fitting results.

Figure 102.16 Fitted Theoretical and Empirical Semivariogram for Coal Seam Thickness

Syntax: VARIOGRAM Procedure

The following statements are available in the VARIOGRAM procedure:

```
PROC VARIOGRAM options ;  
  BY variables ;  
  COMPUTE computation-options ;  
  COORDINATES coordinate-variables ;  
  DIRECTIONS directions-list ;  
  ID variable ;  
  MODEL model-options ;  
  PARMS parameters-list < / parameters-options > ;  
  NOPTIONS < options > ;  
  STORE store-options ;  
  VAR analysis-variables-list ;
```

The **COMPUTE** and **COORDINATES** statements are required. The **MODEL** and **PARMS** statements are hierarchical. If you specify a **PARMS** statement, it must follow a **MODEL** statement.

PROC VARIOGRAM Statement

```
PROC VARIOGRAM options ;
```

The PROC VARIOGRAM statement invokes the VARIOGRAM procedure. [Table 102.1](#) summarizes the options available in the PROC VARIOGRAM statement.

Table 102.1 PROC VARIOGRAM Statement Options

Option	Description
DATA=	Specifies the input data set
IDGLOBAL	Labels observations across BY groups using ascending observation numbers
IDNUM	Labels observations using the observation number
NOPRINT	Suppresses normal display of results
OUTACWEIGHTS=	Specifies a data set to store autocorrelation weights information
OUTDISTANCE=	Specifies a data set to store summary distance information
OUTMORAN=	Specifies a data set to store Moran scatter plot information
OUTPAIR=	Specifies a data set to store pairwise point information
OUTVAR=	Specifies a data set to store spatial continuity measures
PLOTS	Specifies the plot display and options

You can specify the following options in the PROC VARIOGRAM statement.

DATA=SAS-data-set
specifies a SAS data set that contains the *x* and *y* coordinate variables and the VAR statement variables.

IDGLOBAL

specifies that ascending observation numbers be used across BY groups for the observation labels in the appropriate output data sets and the **OBSERVATIONS** plot, instead of resetting the observation number in the beginning of each BY group. The IDGLOBAL option is ignored if no BY variables are specified. Also, if you specify the **ID** statement, then the IDGLOBAL option is ignored unless you also specify the IDNUM option in the **PROC VARIOGRAM** statement.

IDNUM

specifies that the observation number be used for the observation labels in the appropriate output data sets and the **OBSERVATIONS** plot. The IDNUM option takes effect when you specify the **ID** statement; otherwise, it is ignored.

NOPRINT

suppresses the normal display of results. The NOPRINT option is useful when you want only to create one or more output data sets with the procedure.

NOTE: This option temporarily disables the Output Delivery System (ODS); see the section “**ODS Graphics**” on page 8647 for more information.

OUTACWEIGHTS=SAS-data-set**OUTACW=SAS-data-set****OUTA=SAS-data-set**

specifies a SAS data set in which to store the autocorrelation weights information for each pair of points in the DATA= data set. Use this option with caution when the DATA= data set is large. If n denotes the number of observations in the DATA= data set, then the OUTACWEIGHTS= data set contains $[n(n - 1)]/2$ observations.

See the section “**OUTACWEIGHTS=SAS-data-set**” on page 8640 for details.

OUTDISTANCE=SAS-data-set**OUTDIST=SAS-data-set****OUTD=SAS-data-set**

specifies a SAS data set in which to store summary distance information. This data set contains a count of all pairs of data points within a given distance interval. The number of distance intervals is controlled by the **NHCLASSES=** option in the **COMPUTE** statement. The OUTDISTANCE= data set is useful for plotting modified histograms of the count data for determining appropriate lag distances. See the section “**OUTDIST=SAS-data-set**” on page 8641 for details.

OUTMORAN=SAS-data-set**OUTM=SAS-data-set**

specifies a SAS data set in which to store information that is illustrated in the Moran plot, namely the standardized value of each observation in the DATA= data set and the weighted average of its local neighbors. You must also specify the **LAGDISTANCE=** and **AUTOCORRELATION** options in the **COMPUTE** statement; otherwise, the OUTMORAN= data set request is ignored.

The OUTMORAN= data set is useful when you want to save the information that is illustrated in the Moran scatter plot. The data set can also contain entries of missing observations with neighbors, although these observations are not displayed in the Moran plot. However, if the only observations with neighbors in your input data set are observations with missing values, then the OUTMORAN= output data set is empty.

See the section “**OUTMORAN=SAS-data-set**” on page 8641 for details.

OUTPAIR=SAS-data-set

OUTP=SAS-data-set

specifies a SAS data set in which to store distance and angle information for each pair of points in the DATA= data set.

Use this option with caution when your DATA= data set is large. Assume that your DATA= data set has n observations. When you specify the **NOVARIOGRAM** option in the **COMPUTE** statement, the OUTPAIR= data set is populated with all $[n(n-1)]/2$ pairs that can be formed with the n observations.

If the **NOVARIOGRAM** option is not specified, then the OUTPAIR= data set contains only pairs of data that are located within a certain distance away from each other. Specifically, it contains pairs whose distance between observations belongs to a lag class up to the specified **MAXLAGS=** option in the **COMPUTE** statement. Then, depending on your specification of the **LAGDISTANCE=** and **MAXLAGS=** options, the OUTPAIR= data set might contain $[n(n-1)]/2$ or fewer pairs.

Finally, you can restrict the number of pairs in the OUTPAIR= data set with the **OUTPDISTANCE=** option in the **COMPUTE** statement. The **OUTPDISTANCE=** option in the **COMPUTE** statement excludes pairs of points when the distance between the pairs exceeds the **OUTPDISTANCE=** value.

See the section “**OUTPAIR=SAS-data-set**” on page 8642 for details.

OUTVAR=SAS-data-set

OUTVR=SAS-data-set

specifies a SAS data set in which to store the continuity measures.

See the section “**OUTVAR=SAS-data-set**” on page 8643 for details.

PLOTS <(global-plot-options)> <= plot-request <(options)>>

PLOTS <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=observ
plots=(observ semivar)
plots(unpack)=semivar
plots=(semivar(c1a unpack) semivar semivar(rob))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc variogram data=thick;
  compute novariogram;
  coordinates xc=East yc=North;
  var Thick;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “**Enabling and Disabling ODS Graphics**” on page 600 in Chapter 21, “**Statistical Graphics Using ODS.**”

If ODS Graphics is enabled but you omit the PLOTS option or have specified PLOTS=ALL, then PROC VARIOGRAM produces a default set of plots, which might be different for different **COMPUTE** statement options, as discussed in the following.

- If you specify **NOVARIOGRAM** in the **COMPUTE** statement, the VARIOGRAM procedure produces a scatter plot of your observations spatial distribution, in addition to the histogram of the pairwise distances of your data. For an example of the observations plot, see [Figure 102.2](#). For an example of the pairwise distances plot, see [Figure 102.4](#).
- If you omit **NOVARIOGRAM** in the **COMPUTE** statement, the VARIOGRAM procedure computes the empirical semivariogram for the specified **LAGDISTANCE=** and **MAXLAGS=** options. The observations plot appears by default in this case too. The VARIOGRAM procedure also produces a plot of the classical empirical semivariogram. If you also specify **ROBUST** in the **COMPUTE** statement, then the VARIOGRAM procedure instead produces a plot of both the classical and robust empirical semivariograms, in addition to the observations plot. For an example of the empirical semivariogram plot, see [Output 102.7](#). Moreover, if you specify the **MODEL** statement and perform model fitting, then PROC VARIOGRAM also produces a fit plot of the fitted semivariogram. An example of the fit plot is shown in [Figure 102.16](#).

The following *global-plot-options* are available:

ONLY

suppresses the default plots. Only plots that are specifically requested are displayed.

UNPACKPANEL

UNPACK

suppresses paneling. By default, multiple plots can appear in some output panels. Specify **UNPACKPANEL** to get each plot in a separate panel. You can specify **PLOTS(UNPACKPANEL)** to unpack the default plots. You can also specify **UNPACKPANEL** as a suboption with the **SEMIVAR** option.

The following individual *plot-requests* and *plot options* are available:

ALL

produces all appropriate plots. You can specify other *options* with **ALL**. For example, to request all default plots and an additional classical empirical semivariogram, specify **PLOTS=(ALL SEMIVAR(CLA))**.

EQUATE

specifies that all appropriate plots be produced in a way that the coordinates of the axes have equal size units.

FITPLOT <(fitplot-options)>

FIT <(fitplot-options)>

requests a plot that shows the model fitting results against the empirical semivariogram. By default, **FITPLOT** displays one plot of the fitted model (or a panel of plots for different angles in the anisotropic case).

If you specify the **FORM=AUTO** option in the **MODEL** statement, then each class of equivalent fitted models is displayed with a different curve on the plot. The best fitting model class is chosen based on the criteria that you specify in the **CHOOSE** option of the **MODEL** statement, and a

thicker line on top of any other curve is shown for it. The plot legend shows the ranked classes by displaying the label of the representative model of each class in the plot. If appropriate, the number of additional models in the same equivalence class also shows within parentheses.

You can specify the following *fitplot-options*:

NCLASSES=*number*

NCLASSES=ALL

specifies the maximum number of classes to display on the fit plot, where *number* is a positive integer. The default is NCLASSES=5 for nonpaneled plots and NCLASSES=3 for paneled plots. The option takes effect when you specify the **FORM=AUTO** option in the **MODEL** statement, and it is ignored when you fit one single model. If you specify NCLASSES=ALL or a larger number than the available classes, then all available classes are shown on the fit plot. If you specify multiple instances of the NCLASSES= option, then only the last specified instance is honored.

UNPACK

suppresses paneling in paneled fit plots. By default, fit plots appear in a panel, when appropriate.

MORAN < (*moran-options*) >

MOR < (*moran-options*) >

produces a Moran scatter plot of the observations with nonmissing values. For more details about this plot, see the section “[The Moran Scatter Plot](#)” on page 8639. In addition to the Moran scatter plot points, the plot also displays the fit line for the linear regression of the weighted average on the standardized observation values, the regression fit line slope, and a reference line with slope equal to 1. The MORAN plot has the following *moran-options*:

LABEL < (*label-options*) >

labels the observations. The label is the ID variable if the **ID** statement is specified; otherwise, it is the observation number. The *label-options* can be one or more of the following:

HH

specifies that labels show for observations in the upper right (high-high) plot quadrant of positive spatial association.

HL

specifies that labels show for observations in the lower right (high-low) plot quadrant of negative spatial association.

LH

specifies that labels show for observations in the upper left (low-high) plot quadrant of negative spatial association.

LL

specifies that labels show for observations in the lower left (low-low) plot quadrant of positive spatial association.

If you specify multiple instances of the MORAN option and you specify the LABEL suboption in any of those, then the resulting Moran scatter plot displays the observations labels. By default, when you specify none of the *label-options*, the PLOTS=MORAN(LABEL) request puts labels in all observations.

ROWAVG=*rowavg-option*

specifies the flag value for row-averaging of weights in the computation of the weighted average. The *rowavg-option* can be either of the following:

OFF

specifies that autocorrelation weights not be row-averaged.

ON

specifies that row-averaged autocorrelation weights be used.

The default behavior is ROWAVG=ON. If you specify the ROWAVG= option more than once in the same MORAN plot request, then the behavior is set to ROWAVG=ON unless any of the instances is ROWAVG=OFF.

When you specify the PLOTS=MORAN option, you must specify both the [AUTOCORRELATION](#) and the [LAGDISTANCE=](#) options in the [COMPUTE](#) statement to produce the Moran scatter plot. For more information about the plot, see the section “[The Moran Scatter Plot](#)” on page 8639.

NONE

suppresses all plots.

OBSERVATIONS < (*observations-plot-options*) >**OBSERV** < (*observations-plot-options*) >**OBS** < (*observations-plot-options*) >

produces the observed data plot. Only one observations plot is created if you specify the OBSERVATIONS option more than once within a PLOTS option.

The OBSERVATIONS option has the following suboptions:

GRADIENT

specifies that observations be displayed as circles colored by the observed measurement.

LABEL < (*label-option*) >

labels the observations. The label is the ID variable if the [ID](#) statement is specified; otherwise, it is the observation number. The *label-option* can be one of the following:

EQ=*number*

specifies that labels show for any observation whose value is equal to the specified *number*.

MAX=*number*

specifies that labels show for observations with values smaller than or equal to the specified *number*.

MIN=*number*

specifies that labels show for observations with values equal to or greater than the specified *number*.

If you specify multiple instances of the OBSERVATIONS option and you specify the LABEL suboption in any of those, then the resulting observations plot displays the observations labels. If more than one *label-option* is specified in multiple LABEL suboptions, then the prevailing *label-option* in the resulting OBSERVATIONS plot emerges by adhering to the choosing order: MIN, MAX, EQ.

OUTLINE

specifies that observations be displayed as circles with a border but with a completely transparent fill.

OUTLINEGRADIENT

is the same as `OBSERVATIONS(GRADIENT)` except that a border is shown around each observation.

SHOWMISSING

specifies that observations with missing values be displayed in addition to the observations with nonmissing values. By default, missing values locations are not shown on the plot. If you specify multiple instances of the `OBSERVATIONS` option and you specify the `SHOWMISSING` suboption in any of those, then the resulting observations plot displays the observations with missing values.

If you omit any of the `GRADIENT`, `OUTLINE`, and `OUTLINEGRADIENT` suboptions, the `OUTLINEGRADIENT` is the default suboption. If you specify multiple instances of the `OBSERVATIONS` option or multiple suboptions for `OBSERVATIONS`, then the resulting observations plot honors the last specified `GRADIENT`, `OUTLINE`, or `OUTLINEGRADIENT` suboption.

PAIRS <(pairs-plot-options)>

specifies that the pairwise distances histogram be produced. By default, the horizontal axis displays the lag class number. The vertical axis shows the frequency (count) of pairs in the lag classes. Notice that the zero lag class width is half the width of the other classes.

The `PAIRS` option has the following suboptions:

MIDPOINT**MID**

specifies that the plot that is created with the `PAIRS` option display the lag class midpoint value on the horizontal axis, rather than the default lag class number. The midpoint value is the actual distance of a lag class center from the assumed origin point at distance zero. See also the illustration in [Figure 102.22](#).

NOINSET**NOI**

specifies that the plot created with the `PAIRS` option be produced without the default inset that provides additional information about the pairs distribution.

THRESHOLD=*minimum pairs***THR**=*minimum pairs*

specifies that a reference line appear in the plot that is created with the `PAIRS` option to indicate the *minimum pairs* frequency of data pairs. You can use this line as an exploratory tool when you want to select lag classes that contain at least `THRESHOLD` point pairs. The option helps you to identify visually any portion of the `PAIRS` distribution that lies below the specified `THRESHOLD` value.

Only one pairwise distances histogram is created if you specify the `PAIRS` option within a `PLOTS` option. If you specify multiple instances of the `PAIRS` option, the resulting plot has the following features:

- If the MIDPOINT or NOINSET suboption has been specified in any of the instances, it is activated in the resulting plot.
- If you have specified the THRESHOLD= suboption more than once, then the THRESHOLD= value specified last prevails.

SEMIVARIOGRAM < (*semivar-plot-options*) >

SEMIVAR < (*semivar-plot-options*) >

specifies that the empirical semivariogram plot be produced. You can specify the SEMIVAR option multiple times in the same PLOTS option to request instances of plots with the following *semivar-plot-options*:

ALL | CLASSICAL | ROBUST

ALL | CLA | ROB

specifies a single type of empirical semivariogram (classical or robust) to plot, or specifies that all the available types be included in the same plot. The default is ALL.

UNPACKPANEL

UNPACK

specifies that paneled semivariogram plots be displayed separately. By default, plots appear in a panel, when appropriate.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC VARIOGRAM to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the VARIOGRAM procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

COMPUTE Statement

COMPUTE *computation-options* ;

The COMPUTE statement provides a number of options that control the computation of the semivariance, the robust semivariance, and the covariance.

Table 102.2 summarizes the options available in the COMPUTE statement.

Table 102.2 COMPUTE Statement Options

Option	Description
ALPHA=	Specifies the confidence level
ANGLETOLERANCE=	Specifies the tolerance
AUTOCORRELATION	Calculates autocorrelation statistics
BANDWIDTH=	Specifies the bandwidth
CL	Requests confidence limits
DEPSILON=	Specifies the distance value for declaring that two distinct points are zero distance apart
LAGDISTANCE=	Specifies the basic distance unit that defines the lags
LAGTOLERANCE=	Specifies the tolerance around the LAGDISTANCE= value
MAXLAGS=	Specifies the maximum number of lag classes to be used
NDIRECTIONS=	Specifies the number of angle classes to be used
NHCLASSES=	Specifies the number of distance classes to be used
NOVARIOGRAM	Prevents the computation of the continuity measures
OUTPDISTANCE=	Specifies the cutoff distance for writing observations to the OUTPAIR= data set
ROBUST	Calculates a robust version of the semivariance

ALPHA=*number*

specifies a parameter to obtain the confidence level for constructing confidence limits in the classical empirical semivariance estimation. The value of *number* must be in (0, 1), and the confidence level is $1 - \text{number}$. The default is ALPHA=0.05, which corresponds to the default confidence level of 95%. If the CL option is not specified, ALPHA= is ignored.

ANGLETOLERANCE=*angle-tolerance*

ANGLETOL=*angle-tolerance*

ATOL=*angle-tolerance*

specifies the tolerance, in degrees, around the angles determined by the NDIRECTIONS= specification. The default is $180^\circ / (2n_d)$, where n_d is the NDIRECTIONS= specification. If you do not specify the NDIRECTIONS= option or the DIRECTIONS statement, ANGLETOLERANCE= is ignored.

See the section “Theoretical and Computational Details of the Semivariogram” on page 8613 for further information.

AUTOCORRELATION < (*autocorrelation-options*) >

AUTOCORR < (*autocorrelation-options*) >

AUTOC < (*autocorrelation-options*) >

specifies that autocorrelation statistics be calculated. You can further specify the following *autocorrelation-options* in parentheses following the AUTOCORRELATION option.

ASSUMPTION <= *assumption-options* >

ASSUM <= *assumption-options* >

specifies the type of autocorrelation assumption to use. The *assumption-options* can be one of the following:

NORMALITY | NORMAL | NOR

specifies use of the normality assumption.

RANDOMIZATION | RANDOM | RAN

specifies use of the randomization assumption.

The default is ASSUMPTION=NORMALITY.

STATISTICS <= (*stats-options*) >

STATS <= (*stats-options*) >

specifies the autocorrelation statistics in detail. The *stats-options* can be one or more of the following:

ALL

applies all available types of autoregression statistics.

GEARY | GEA

specifies use of the Geary's *c* statistics.

MORAN | MOR

specifies use of the Moran's *I* statistics.

The default is STATISTICS=ALL.

WEIGHTS <= *weights-options* >

WEI <= *weights-options* >

specifies the scheme used for the computation of the autocorrelation weights. You can choose one of the following *weights-options*:

BINARY < (*binary-option*) >

specifies that binary weights be used. You also have the following *binary-option*:

ROWAVERAGING | ROWAVG | ROW

specifies that asymmetric autocorrelation weights be assigned to data pairs. For each observation, if there are nonzero weights, the ROWAVG option standardizes those weights so that they sum to 1. No row averaging is performed by default.

DISTANCE <(distance-options)>

specifies that autocorrelation weights be assigned based on the point pair distances. You also have the following *distance-options*:

NORMALIZE | **NORMAL** | **NOR**

specifies that normalized pair distances be used in the distance-based weights expression. The distances are normalized with respect to the maximum pairwise distance h_b , as it is defined in the section “[Computation of the Distribution Distance Classes](#)” on page 8621. By default, nonnormalized values are used in the computations.

POWER=number**POW**=number

specifies the power to which the pair distance is raised in the distance-based weights expression. POWER is a nonnegative number, and its default value is POWER=1.

ROWAVERAGING | **ROWAVG** | **ROW**

specifies that asymmetric autocorrelation weights be assigned to data pairs. For each observation, if there are nonzero weights, the ROWAVG option standardizes those weights so that they sum to 1. No row averaging is performed by default.

SCALE=number**SCA**=number

specifies the scaling factor in the distance-based weights expression. SCALE is a nonnegative number, and its default value is SCALE=1.

The default is WEIGHTS=BINARY. See the section “[Autocorrelation Statistics](#)” on page 8635 for further details about the autocorrelation weights.

When you specify the AUTOCORRELATION option with no *autocorrelation-options*, PROC VARIOGRAM computes by default both the Moran’s I and Geary’s c statistics with p -values computed under the normality assumption with binary weights.

If you specify more than one ASSUMPTION in the *autocorrelation-options*, all but the last specified ASSUMPTION are ignored. The same holds if you specify more than one POWER= or SCALE= parameter in the WEIGHT=DISTANCE *distance-options*.

If you specify the WEIGHT=BINARY option in the AUTOCORRELATION option and the **NOVARIOGRAM** option at the same time, then you must also specify the **LAGDISTANCE=** option in the **COMPUTE** statement. See the section “[Autocorrelation Weights](#)” on page 8635 for more information.

BANDWIDTH=bandwidth-distance**BANDW**=bandwidth-distance

specifies the bandwidth, or perpendicular distance cutoff for determining the angle class for a given pair of points. The distance classes define a series of cylindrically shaped areas, while the angle classes radially cut these cylindrically shaped areas. For a given angle class $(\theta_1 - \delta\theta_1, \theta_1 + \delta\theta_1)$, as you proceed out radially, the area encompassed by this angle class becomes larger. The BANDWIDTH= option restricts this area by excluding all points with a perpendicular distance from the line $\theta = \theta_1$ that is greater than the BANDWIDTH= value. See [Figure 102.23](#) for a visual representation of the bandwidth.

If you omit the `BANDWIDTH=` option, no restriction occurs. If you omit the `NDIRECTIONS=` option or the `DIRECTIONS` statement, `BANDWIDTH=` is ignored.

CL

requests confidence limits for the classical semivariance estimate. The lower bound of the confidence limits is always nonnegative, adhering to the behavior of the theoretical semivariance. You can control the confidence level with the `ALPHA=` option.

DEPSILON=*distance-value*

DEPS=*distance-value*

specifies the distance value for declaring that two distinct points are zero distance apart. Such pairs, if they occur, cause numeric problems. If you specify `DEPSILON= $\Delta\epsilon$` , then pairs of points P_1 and P_2 for which the distance between them $|P_1 P_2| < \Delta\epsilon$ are excluded from the continuity measure calculations. The default value of the `DEPSILON=` option is 100 times the machine precision; this product is approximately $1\text{E-}10$ on most computers.

LAGDISTANCE=*distance-unit*

LAGDIST=*distance-unit*

LAGD=*distance-unit*

specifies the basic distance unit that defines the lags. For example, a specification of `LAGDISTANCE= x` results in lag distance classes that are multiples of x . For a given pair of points P_1 and P_2 , the distance between them, denoted $|P_1 P_2|$, is calculated. If $|P_1 P_2| = x$, then this pair is in the first lag class. If $|P_1 P_2| = 2x$, then this pair is in the second lag class, and so on.

For irregularly spaced data, the pairwise distances are unlikely to fall exactly on multiples of the `LAGDISTANCE=` value. In this case, a distance tolerance of δx accommodates a spread of distances around multiples of x (the `LAGTOLERANCE=` option specifies the distance tolerance). For example, if $|P_1 P_2|$ is within $x \pm \delta x$, you would place this pair in the first lag class; if $|P_1 P_2|$ is within $2x \pm \delta x$, you would place this pair in the second lag class; and so on.

You can experiment and determine the candidate values for the `LAGDISTANCE=` option by plotting the pairwise distance histogram for different numbers of histogram classes, using the `NHCLASSES=` option.

A `LAGDISTANCE=` value is required for the semivariance and the autocorrelation computations. However, when you specify the `NOVARIOGRAM` option without the `AUTOCORRELATION` option, you need not specify the `LAGDISTANCE=` option.

See the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613 for more information.

LAGTOLERANCE=*tolerance-number*

LAGTOL=*tolerance-number*

LAGT=*tolerance-number*

specifies the tolerance around the `LAGDISTANCE=` value for grouping distance pairs into lag classes. See the description of the `LAGDISTANCE=` option for information about the use of the `LAGTOLERANCE=` option, and the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613 for more details.

If you omit the `LAGTOLERANCE=` option, a default value of $\frac{1}{2}$ times the `LAGDISTANCE=` value is used.

MAXLAGS=*number-of-lags***MAXLAG=***number-of-lags***MAXL=***number-of-lags*

specifies the maximum number of lag classes to be used in constructing the continuity measures in addition to a zero lag class; see also the section “[Distance Classification](#)” on page 8619. This option excludes any pair of points P_1 and P_2 for which the distance between them, $|P_1 P_2|$, exceeds the MAXLAGS= value times the [LAGDISTANCE=](#) value.

You can determine candidate values for the MAXLAGS= option by plotting or displaying the [OUT-DISTANCE=](#) data set.

A MAXLAGS= value is required unless you specify the [NOVARIOGRAM](#) option.

NDIRECTIONS=*number-of-directions***NDIR=***number-of-directions***ND=***number-of-directions*

specifies the number of angle classes to use in computing the continuity measures. This option is useful when there is potential anisotropy in the spatial continuity measures. Anisotropy is a field property in which the characterization of spatial continuity depends on the data pair orientation (or angle between the N–S direction and the axis defined by the data pair). Isotropy is the absence of this effect; that is, the description of spatial continuity depends only on the distance between the points, not the angle.

The angle classes formed from the NDIRECTIONS= option start from N–S and proceed clockwise. For example, NDIRECTIONS=3 produces three angle classes. In terms of compass points, these classes are centered at 0° (or its reciprocal, 180°), 60° (or its reciprocal, 240°), and 120° (or its reciprocal, 300°). For irregularly spaced data, the angles between pairs are unlikely to fall exactly in these directions, so an angle tolerance of $\delta\theta$ is used (the [ANGLETOLERANCE=](#) option specifies the angle tolerance). If NDIRECTIONS= n_d , the base angle is $\theta = 180^\circ/n_d$, and the angle classes are

$$(k\theta - \delta\theta, k\theta + \delta\theta) \quad k = 0, \dots, n_d - 1$$

If you omit the NDIRECTIONS= option, no angles are formed. This is the omnidirectional case where the spatial continuity measures are assumed to be isotropic.

The NDIRECTIONS= option is useful for exploring possible anisotropy. The [DIRECTIONS](#) statement, described in the section “[DIRECTIONS Statement](#)” on page 8590, provides greater control over the angle classes.

See the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613 for more information.

NHCLASSES=*number-of-histogram-classes***NHCLASS=***number-of-histogram-classes***NHC=***number-of-histogram-classes*

specifies the number of distance classes to consider in the spatial domain in the exploratory stage of the empirical semivariogram computation. The actual number of classes is one more than the NHCLASSES= value, since a special lag zero class is also computed. The NHCLASSES= option is used to produce the distance intervals table, the histogram of pairwise distances, and the [OUT-DISTANCE=](#) data set. See the [OUTDISTANCE=](#) option, the section “[OUTDIST=SAS-data-set](#)”

on page 8641, and the section “Theoretical and Computational Details of the Semivariogram” on page 8613 for more information.

The default value is NHCLASSES=10.

NOVARIOGRAM

prevents the computation of the continuity measures. This option is useful for preliminary analysis, or when you require only the **OUTDISTANCE=** or **OUTPAIR=** data sets.

OUTPDISTANCE=*distance-limit*

OUTPDIST=*distance-limit*

OUTPD=*distance-limit*

specifies the cutoff distance for writing observations to the **OUTPAIR=** data set. If you specify **OUTPDISTANCE=** d_{max} , the distance $|P_1 P_2|$ between each pair of points P_1 and P_2 is checked against d_{max} . If $|P_1 P_2| > d_{max}$, the observation for this pair is not written to the **OUTPAIR=** data set. If you omit the **OUTPDISTANCE=** option, all distinct pairs are written. This option is ignored if you omit the **OUTPAIR=** data set.

ROBUST

requests that a robust version of the semivariance be calculated in addition to the classical semivariance.

COORDINATES Statement

COORDINATES *coordinate-variables* ;

The following two options give the names of the variables in the **DATA=** data set that contains the values of the x and y coordinates of the data.

Only one **COORDINATES** statement is allowed, and it is applied to all the analysis variables. In other words, it is assumed that all the **VAR** variables have the same x and y coordinates.

XCOORD=*(variable-name)*

XC=*(variable-name)*

X=*(variable-name)*

gives the name of the variable that contains the x coordinate of the data in the **DATA=** data set.

YCOORD=*(variable-name)*

YC=*(variable-name)*

Y=*(variable-name)*

gives the name of the variable that contains the y coordinate of the data in the **DATA=** data set.

DIRECTIONS Statement

DIRECTIONS *directions-list* ;

You use the DIRECTIONS statement to define angle classes. You can specify angle classes as a list of angles, separated by commas, with optional angle tolerances and bandwidths within parentheses following the angle. You must specify at least one angle.

If you do not specify the optional angle tolerance, the default value of 45° is used. If you do not specify the optional bandwidth, no bandwidth is checked. If you specify a bandwidth, you must also specify an angle tolerance.

For example, suppose you want to compute three separate semivariograms at angles $\theta_1 = 0^\circ$, $\theta_2 = 60^\circ$, and $\theta_3 = 120^\circ$, with corresponding angle tolerances $\delta\theta_1 = 22.5^\circ$, $\delta\theta_2 = 12.5^\circ$, and $\delta\theta_3 = 22.5^\circ$, with bandwidths 50 and 40 distance units on the first two angle classes and no bandwidth check on the last angle class.

The appropriate DIRECTIONS statement is as follows:

```
directions 0.0(22.5,50), 60.0(12.5,40),120(22.5);
```

ID Statement

ID *variable* ;

The ID statement specifies which variable to include for identification of the observations in the **OUTPAIR=** and the **OUTACWEIGHTS=** output data sets. The ID statement variable is also used for the labels and tool tips in the **OBSERVATIONS** plot.

In the VARIOGRAM procedure you can specify only one ID variable in the ID statement. If no ID statement is given, then PROC VARIOGRAM uses the observation number in the data sets and the **OBSERVATIONS** plot.

MODEL Statement

MODEL *fitting-options* < / *model-options* > ;

You specify the MODEL statement if you want to fit a theoretical semivariogram model to the empirical semivariogram data that are produced in the **COMPUTE** statement. You must have nonmissing empirical semivariogram estimates at a minimum of three lags to perform model fitting.

Table 102.3 summarizes the options available in the MODEL statement.

Table 102.3 MODEL Statement Options

Option	Description
Fitting Options	
ALPHA=	Specifies confidence level
CHOOSE=	Ranks the fitted models and chooses the optimally fit model
CL	Constructs a <i>t</i> -type confidence interval
EQUIVTOL=	Specifies a positive upper value tolerance
FIT=	Specifies which type of empirical semivariogram to fit
FORM=	Specifies the functional form (type) of the semivariogram model
MDATA=	Specifies the input data set
METHOD=	Fits a theoretical model to the empirical semivariance
NEPSILON=	Adds a minimal nugget effect
NUGGET=	Specifies the nugget effect
RANGE=	Specifies the range parameter
RANGELAG=	Uses consecutive nonmissing empirical semivariance lags to fit model
RANKEPS=	Specifies the minimum threshold to compare fit quality
SCALE=	Specifies the scale parameter in semivariogram models
SMOOTH=	Specifies the positive smoothness parameter ν
Model Options	
COVB	Requests the covariance matrix
CORRB	Requests the approximate correlation matrix
DETAILS	Produces different levels of output
GRADIENT	Displays the gradient of the objective function
MTOGTOL=	Specifies a threshold value for the smoothness parameter
NOFIT	Suppresses the model fitting process
NOITPRINT	Suppresses the display of the iteration history table

You can choose to perform a fully automated fitting or to fit one model with specific forms. In the first case you simply specify a list of forms or no forms at all. All suitable combinations are tested, and the result is the model that produces the best fit according to specified criteria. In the second case you specify one theoretical semivariogram model, and you have more control over its parameters for the fitting process.

Furthermore, you can specify a theoretical semivariogram model in two ways:

- You explicitly specify the **FORM** option and any of the options **SCALE**, **RANGE**, and **NUGGET** in the MODEL statement.
- You can specify an **MDATA=** data set. This data set contains variables that correspond to the **FORM** option and to any of the options **SCALE**, **RANGE**, **NUGGET**, and **SMOOTH**. You can also use an **MDATA=** data set to request a fully automated fitting.

The two methods are exclusive; either you specify all parameters explicitly, or they all are read from the **MDATA=** data set.

The MODEL statement has the following *fitting-options*:

ALPHA=*number*

requests that a *t*-type confidence interval be constructed for each of the fitting parameters with confidence level $1 - \textit{number}$. The value of *number* must be in (0, 1); the default is 0.05 which corresponds to the default confidence level of 95%. If the CL option of the MODEL statement is not specified, then ALPHA= is ignored.

CHOOSE=*criterion*

CHOOSE=(*criterion1* ... *criterionk*)

specifies that if the fitting task has more than one model to fit, then PROC VARIOGRAM ranks the fitted models and chooses the optimally fit model according to one or more available criteria.

If you want to use multiple fitting criteria, then the order in which you specify them in the CHOOSE= option defines how they are applied. This feature is useful when fitting suggests that two or more models perform equally well according to a certain criterion. For example, if two models are equivalent according to *criterioni*, then they are further ranked in the list based on the next criterion, *criterionj*, where $j = i + 1$.

Each *criterion* can be one of the following:

AIC

specifies Akaike's information criterion.

SSE

specifies the weighted sum of squares error for each fitted model when METHOD=WLS, and the residual sum of squares error for each fitted model when METHOD=OLS.

STATUS

classifies models based on their fitting process convergence status. CHOOSE=STATUS places on top models for which the fitting process is successful.

By default, the models are ranked in the fit summary table with the best fitted model at the top of the list, based on the criteria that you specify in the CHOOSE= option. This model is the fit choice of PROC VARIOGRAM for the particular fitting task. If you omit the CHOOSE= option, then the default behavior is CHOOSE=(SSE AIC).

Regardless of the specified fitting criteria, models for which the fitting process is unsuccessful always appear at the bottom of the fit summary table. For more details about the fitting criteria, see the section "Fitting Criteria" on page 8632. After multiple models are ranked, they are further categorized in classes of equivalence depending on whether any two models calculate the same semivariance value at the same distance for a series of different distances. For more details, see the section "Classes of Equivalence" on page 8634.

If you specify the same criterion multiple times in the CHOOSE= option, then only the first instance is used for the ranking process and any additional ones are ignored. If you specify only one model to fit in the MODEL statement and you specify the CHOOSE= option, then the option is ignored.

CL

requests that *t*-type confidence limits be constructed for each of the fitting parameters estimates. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option of the **MODEL** statement.

EQUIVTOL=etol-value**ETOL=etol-value**

specifies a positive upper value tolerance to use when categorizing multiple models in classes of equivalence. For this categorization, the VARIOGRAM procedure computes the sum of absolute differences of semivariances for pairs of consecutively ranked models. If the sum is lower than the EQUIVTOL= value for any such model pair, then these two models are deemed to be equivalent. As a result, the EQUIVTOL= option can affect the number and size of classes of equivalence in the fit summary table. Smaller values of the EQUIVTOL= parameter result in a more strict model comparison and can lead to a higher number of classes of equivalence. For more details, see the section “Classes of Equivalence” on page 8634.

The default value for the EQUIVTOL= parameter is 10^{-3} . The EQUIVTOL= option applies when you fit multiple models with the **FORM=AUTO** option of the **MODEL** statement; otherwise, it is ignored.

The EQUIVTOL= option is independent of the ranking results from the **RANKEPS=** option of the **MODEL** statement. This means that you could possibly have models listed but not ranked in the fit summary table, and still have equivalence classes assigned according to the order in which the models appear in the table.

FIT=fit-type-options

specifies which type of empirical semivariogram to fit. You can choose between the following *fit-type-options*:

CLASSICAL**CLA**

fits a model for the classical empirical semivariance.

ROBUST**ROB**

fits a model for the robust empirical semivariance. This option can be used only when the **ROBUST** option is specified in the **COMPUTE** statement.

The default value is FIT=CLASSICAL.

FORM=form**FORM=(form1, ..., formk)****FORM=AUTO** (*auto-options*)

specifies the functional form (type) of the semivariogram model. The supported structures are two-parameter models that use the sill and range as parameters. The Matérn model is an exception that makes use of a third smoothing parameter ν .

The **FORM=** option is required when you specify the **MODEL** statement. You can perform fitting of a theoretical semivariogram model either explicitly or in an automated manner. For the explicit specification you specify suitable model forms in the **FORM=** option. For an automated fit you specify the **FORM=****AUTO** option which has the **AUTO(MLIST=)** and **AUTO(NEST=)** suboptions. You can read more details in the following two subsections.

Explicit Model Specification

You can explicitly specify a theoretical semivariogram model to fit by using any combination of one, two, or three forms. Use the syntax with the single *form* to specify a non-nested model. Use the syntax with *k* structures *form_i*, $i = 1, \dots, k$, to specify up to three nested structures ($k \leq 3$) in a semivariogram model. Each of the forms can be any of the following:

**CUBIC | EXPONENTIAL | GAUSSIAN | MATERN |
PENTASPHERICAL | POWER | SINEHOLEEFFECT | SPHERICAL
CUB | EXP | GAU | MAT | PEN | POW | SHE | SPH**
specify a form.

All of these forms are presented in more detail in the section “Theoretical Semivariogram Models” on page 8608. In addition, you can optionally specify a nugget effect for your model with the **NUGGET** option in the **MODEL** statement.

For example, the syntax

FORM=GAU

specifies a model with a single Gaussian structure. Also, the syntax

FORM= (EXP , SHE , MAT)

specifies a nested model with an exponential, a sine hole effect, and a Matérn structure. Finally

FORM= (EXP , EXP)

specifies a nested model with two structures both of which are exponential.

NOTE: In the documentation, models are named either by using their full names or by using the first three letters of their structures. Also, the names of different structures in a nested model are separated by a hyphen (-). According to this convention, the previous examples illustrate how to specify a GAU, an EXP-SHE-MAT, and an EXP-EXP model, respectively, with the **FORM=** option.

When you explicitly specify the types of structures, you can fix parameter values or ask PROC VARIOGRAM to select default initial values for the forms parameters by using the **SCALE**, **RANGE**, **NUGGET**, and **SMOOTH** options. You can set your own, non-default initial parameter values by using the **PARMS** statement in combination with an explicitly specified semivariogram model in the **MODEL** statement.

Automated Model Selection

Use the **FORM=****AUTO** option to request the highest level of automation in the best fit selection of the parameters. If you specify **FORM=****AUTO**, any of the **SCALE**, **RANGE**, or **SMOOTH** options that are also specified are ignored. When you specify the **FORM=****AUTO** option, you cannot specify the **PARMS**

statement for the corresponding [MODEL](#) statement. As a result, when you use the FORM=AUTO option, you cannot fix any of the model parameters and PROC VARIOGRAM sets initial values for them.

The AUTO option has the following *auto-options*:

MLIST=*mform*

MLIST=(*mform1*, ..., *mformp*)

specifies one or more different model forms to use in combinations during the model fitting process. If you omit the MLIST= suboption, then combinations are made among all available model types. The *mform* can be any of the following eight forms:

**CUBIC | EXPONENTIAL | GAUSSIAN | MATERN |
PENTASPHERICAL | POWER | SINEHOLEEFFECT | SPHERICAL
CUB | EXP | GAU | MAT | PEN | POW | SHE | SPH**
specify a form.

If you use more than one *mform*, then each *mform_i*, $i = 1, \dots, p$ must be different from the others in the group of $p \leq 8$ forms that you specify.

NEST=*nest-list*

specifies the number of nested structures to use for the fitting. You can choose between the following to specify the *nest-list*:

n a single value

m TO *n* a sequence in which *m* equals the starting value and *n* equals the ending value

For example,

NEST=1

produces the best fit with one single model among all model types specified in the [MLIST=](#) suboption. Also,

NEST=2 TO 3

produces the best fit among all combinations of the model types specified in the [MLIST=](#) suboption that result in nested models with two or three structures. The combinations that are tested include repetitions. Hence, if you specify, for example,

MODEL FORM=AUTO (MLIST=(EXP, SPH) NEST=1 TO 2)

then the different models that are tested are equivalent to the specifications FORM=EXP, FORM=SPH, FORM=(EXP,EXP), FORM=(EXP,SPH), FORM=(SPH,SPH) and FORM=(SPH,EXP). **NOTE:** The models EXP-SPH and SPH-EXP are taken as two separate models. Although they are mathematically equivalent (see the section “[Nested Models](#)” on page 8613), PROC VARIOGRAM assigns different initial values to the model structures in each case, which can lead to different fitting results. (See the section “[Example 102.1: Aspects of Semivariogram Model Fitting](#)” on page 8648.)

If you omit the NEST suboption, then by default PROC VARIOGRAM searches for the best fit with up to three nested structures in a model. The default behavior is equivalent to

```
NEST=1 TO 3
```

In the VARIOGRAM procedure you can use a maximum of three nested structures to fit an empirical semivariogram; that is, $n \leq 3$.

You can use the AUTO value for the form in the **MDATA=** data set, and also in the **FORM=** option. However, in the former case the automation functionality is limited compared to the latter case and the *auto-options* of the **FORM=AUTO** option. In particular, when you specify the form to be AUTO in the **MDATA=** data set, then PROC VARIOGRAM follows only the default behavior and searches among all available forms for the best fit with up to three nested structures in a model.

MDATA=SAS-data-set

specifies the input data set that contains parameter values for the covariance or semivariogram model. The **MDATA=** data set must contain a variable named **FORM**, and it can optionally include any of the variables **SCALE**, **RANGE**, **NUGGET**, and **SMOOTH**.

The **FORM** variable must be a character variable. It accepts only the **AUTO** value or the *form* values that can be specified in the **FORM=** option in the **MODEL** statement. The **RANGE**, **SCALE**, **NUGGET**, and **SMOOTH** variables must be numeric or missing.

The number of observations present in the **MDATA=** data set corresponds to the level of nesting of the semivariogram model. Each observation line describes a structure of the model you submit for fitting.

If you specify the **AUTO** value for the **FORM** variable in an observation, then you cannot specify additional nested structures in the same data set, and any parameters you specify in the same structure are ignored. In that case, PROC VARIOGRAM performs a crude automated search among all available forms to obtain the best fit with up to three nested structures in a model. You can refine this type of search with additional suboptions when you perform it with the **FORM=AUTO** option instead of the **MDATA=** option in the **MODEL** statement.

When you have a nested model, you might want to specify parameter values for only some of the nested structures. In this case, you must specify the corresponding parameter values for the remaining model structures as missing values.

For example, you can use the following **DATA** step to specify a non-nested model that uses a spherical covariance within an **MDATA=** data set:

```
data mdl;
  input scale range form $;
  datalines;
25 10 SPH
;
```

Then, you can use the `md1` data in the **MODEL** statement of PROC VARIOGRAM as shown in the following statements:

```
proc variogram data=...;
  compute ...;
  model mdata=md1;
run;
```

This is equivalent to the following explicit specification of the semivariance model parameters:

```
proc variogram data=...;
  compute ...;
  model form=sph scale=25 range=10;
run;
```

The following data set `md2` is an example of a nested model:

```
data md2;
  input form $ scale range nugget smooth;
  datalines;
SPH 20 8 5 .
MAT 12 3 5 0.7
GAU . 1 5 .
;
```

This specification is equivalent to the following explicit specification of the semivariance model parameters:

```
proc variogram data=...;
  compute ....;
  model form=(sph,mat,gau)
        scale=(20,12,.) range=(8,3,1) smooth=0.7 nugget=5;
run;
```

Use the **SMOOTH** variable column in the `MDATA=` data set to specify the smoothing parameter ν in the Matérn semivariogram models. The **SMOOTH** variable values must be positive and no greater than 1,000,000. PROC VARIOGRAM sets this upper limit for numerical and performance reasons. In any case, if the fitting process leads the smoothness value to exceed the default threshold value 10,000, then the VARIOGRAM procedure converts the Matérn form into a Gaussian form and repeats the model fitting. To adjust the switching threshold value, you can use the **MTOGTOL=** option in the **MODEL** statement.

If you specify a **SMOOTH** column in the `MDATA=` data set, then its elements are ignored except for the rows in which the corresponding **FORM** is Matérn.

The **NUGGET** variable value is the same for all nested structures. This is the way to specify a nugget effect in the `MDATA=` data set. If you specify more than one nugget value for different structures, then the last nugget value specified is used.

METHOD=*method-options*

must be specified in the MODEL statement to fit a theoretical model to the empirical semivariance. The METHOD option has the following suboptions:

OLS

specifies that ordinary least squares be used for the fitting.

WLS

specifies that weighted least squares be used for the fitting.

The default is METHOD=WLS.

NEPSILON=*min-nugget-factor***NEPS=***min-nugget-factor*

specifies that a minimal nugget effect be added to the theoretical semivariance in the unlikely occasion that the theoretical semivariance becomes zero during fitting with weighted least squares. As explained in the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613, the theoretical semivariance is always positive for any distance larger than zero. If a conflicting situation emerges as a result of numerical fitting issues, then the NEPSILON= option can help you alleviate the problem by adding a minimal variance at the distance lag where the issue is encountered. For more details, see the section “[Parameter Initialization](#)” on page 8630.

If you omit the NEPSILON= option, then PROC VARIOGRAM sets a default value of 10^{-6} . If a minimal nugget effect is used, its value is case-specific and is based on the *min-nugget-factor*. Specifically, its value is defined as *min-nugget-factor* times the sample variance of the input data set, or as *min-nugget-factor* when the sample variance is equal to zero.

NUGGET=*number*

specifies the nugget effect for the model. The nugget effect is due to a discontinuity in the semivariogram as determined by plotting the sample semivariogram; see “[Theoretical Semivariogram Models](#)” on page 8608 for more details. The NUGGET= parameter is a nonnegative number. If you specify a nonmissing value, then it is used as a fixed parameter in the fitting process.

PROC VARIOGRAM assigns a default initial value for the nugget effect in the following cases:

- if you specify a missing value.
- if you omit the NUGGET= option and you do not specify an associated [PARMS](#) statement with initial values for the nugget.

The NUGGET= option is incompatible with the specification of the [PARMS](#) statement for the corresponding [MODEL](#) statement.

RANGE=*range***RANGE=***(range1, ..., rangek)*

specifies the range parameter in semivariogram models. The RANGE= option is optional. However, if you specify the RANGE= option, then you must provide range values for all structures that you have specified explicitly in the [FORM=](#) option. All nonmissing range values are considered as fixed parameters. PROC VARIOGRAM assigns a default initial value to any of the model structures for which you specify a missing range value. PROC VARIOGRAM assigns default initial values to all model structures if you omit the RANGE= option, unless you specify an associated [PARMS](#) statement and initial values for the range in it.

The range parameter is a positive number, has the units of distance, and is related to the correlation scale of the underlying spatial process.

NOTE: If you specify this parameter for a power model, then it does not correspond to a range. For power models, the parameter you specify in the RANGE option is a dimensionless power exponent whose value must range within [0,2) so that the power model is a valid semivariance function.

The RANGE= option is ignored when you specify the FORM=AUTO option. The RANGE= option is incompatible with the specification of the PARMS statement for the corresponding MODEL statement.

RANGELAG=*rlag-list*

RLAG=*rlag-list*

specifies that you prefer to use the range of consecutive nonmissing empirical semivariance lags in the *rlag-list* for the semivariogram fitting process, instead of using all MAXLAGS+1 lag classes by default. You can specify *rlag-list* in either of the following forms:

- | | |
|----------------------|--|
| <i>k</i> | a single value that designates the width of the selected lag range by starting at lag zero. You must use at least three lags to perform model fitting, so you can specify <i>k</i> within [3, . . . , MAXLAGS+1]. |
| <i>m</i> TO <i>n</i> | a sequence in which <i>m</i> equals the starting lag and <i>n</i> equals the ending lag. The parameters <i>m</i> and <i>n</i> must be nonnegative integer numbers to designate lag classes between zero and MAXLAGS. Use at least three lags for model fitting; hence it holds that $n - m \geq 2$. |

The following two brief examples exhibit the use of the RANGELAG option. These examples assume that you have set the MAXLAGS= option to 9 or higher to indicate nonmissing empirical semivariance estimates at 10 lags or more.

In the first example,

RANGELAG=8

uses the empirical semivariance in the first eight lags to fit a theoretical model. Hence, RANGELAG=8 uses only the lag classes zero to seven. This approach enables you to account only for the correlation behavior described by the first *k* empirical semivariogram lag classes.

In the second example,

RANGELAG=2 TO 9

specifies that the empirical semivariance values at lag classes zero, one, and after lag class nine are excluded from the model fitting process.

RANKEPS=*reps-value*

REPS=*reps-value*

specifies the minimum threshold to compare fit quality of two models for a specific criterion. Beyond this threshold the criterion values become insensitive to comparison. In particular, when you fit multiple models, PROC VARIOGRAM computes for each one the value of the fitting criterion specified in the **CHOOSE=** option of the **MODEL** statement. These values are examined in pairs at the sorting stage. If the difference of a given pair exceeds the *reps-value*, then the sort order of the corresponding models is reversed; otherwise, the two models retain their relative order in the rankings. Hence, the **RANKEPS=** option can affect model ranking in the fit summary table.

The default value for the **RANKEPS=** parameter is 10^{-6} and accounts for the default optimization convergence tolerance at the fitting stage prior to model ranking. The convergence tolerance itself limits the accuracy that you can use to compare two models under a given criterion. As a result, smaller values of the **RANKEPS=** parameter might not lead to a sensible and more strict model comparison because for a smaller *reps-value*, ranking could depend on digits beyond the accuracy limit.

In the opposite end, if the specified *reps-value* turns out to be large compared to the criterion value differences, then it can make the sorting process insensitive to the specified sorting criterion. When this happens, the fit summary table ranking reflects only the order in which different models are examined in the procedure flow. You can tell whether the criterion is bypassed; if it is, then one or more values of the specified criterion might not appear to be sorted in the fit summary table.

The **RANKEPS=** parameter must be a positive number. The **RANKEPS=** option applies when you fit multiple models with the **FORM=AUTO** option of the **MODEL** statement; otherwise, it is ignored.

SCALE=*scale*

SCALE=(*scale1*, ..., *scalek*)

specifies the scale parameter in semivariogram models. The **SCALE=** option is optional. However, if you specify the **SCALE=** option, then you must provide sill values for all structures that you have specified explicitly in the **FORM=** option. All nonmissing scale values are considered as fixed parameters. PROC VARIOGRAM assigns a default initial value to any of the model structures for which you specify a missing scale value. PROC VARIOGRAM assigns default initial values to all model structures if you omit the **SCALE=** option, unless you specify an associated **PARMS** statement with initial values for scale.

The scale parameter is a positive number. It has the same units as the variance of the variable in the **VAR** statement. The scale of each structure in a semivariogram model represents the variance contribution of the structure to the total model variance.

In power models the **SCALE=** parameter does not correspond to a sill because the power model has no sill. Instead, PROC VARIOGRAM uses the **SCALE=** option to designate the slope (or scaling factor) in power model forms. The power model slope has the same variance units as the variable in the **VAR** statement.

The **SCALE=** option is ignored when you specify the **FORM=AUTO** option. The **SCALE=** option is incompatible with the specification of the **PARMS** statement for the corresponding **MODEL** statement.

SMOOTH=*smooth*

SMOOTH=(*smooth1*, ..., *smoothm*)

specifies the positive smoothness parameter ν in the Matérn type of semivariance structures. The special case $\nu = 0.5$ is equivalent to the exponential model, whereas the theoretical limit $\nu \rightarrow \infty$ gives the Gaussian model.

The SMOOTH= option is optional. When you specify an explicit model in the **FORM=** option with m Matérn structures, you can provide up to m smoothness values. You can specify a value for *smoothi*, $i = 1, \dots, m$ that is positive and no greater than 1,000,000. PROC VARIOGRAM sets this upper limit for the SMOOTH= option values for numerical and performance reasons. In any case, if the fitting process leads the smoothness value to exceed the default threshold value 10,000, then the VARIOGRAM procedure converts the Matérn form into a Gaussian form and repeats the model fitting. To adjust the switching threshold value, you can use the **MTOGTOL=** option in the **MODEL** statement.

If you specify fewer than m values, then the remaining Matérn structures have their smoothness parameters initialized to missing values. If you specify more than m values, then values in excess are ignored.

All nonmissing smoothness values are considered as fixed parameters of the corresponding Matérn structures. PROC VARIOGRAM assigns a default initial value to any of the model Matérn structures, if any, for which you specify a missing smoothness value. PROC VARIOGRAM assigns default initial values to all model Matérn structures if you omit the SMOOTH= option, unless you specify an associated **PARMS** statement and initial values for smoothness in it.

The SMOOTH= option is ignored when you specify the **FORM=AUTO** option. The SMOOTH= option is incompatible with the specification of the **PARMS** statement for the corresponding **MODEL** statement.

In addition to the *fitting-options*, you can specify the following *model-options* after a slash (/) in the **MODEL** statement.

COVB

requests the approximate covariance matrix for the parameter estimates of the model fitting. The COVB option is ignored when you also specify the **DETAILS=ALL** option.

When you specify an explicit model with the **FORM=** option in the **MODEL** statement, the COVB option produces the requested approximate covariance matrix. When you specify the **FORM=AUTO** option in the **MODEL** statement, by default the COVB option produces output only for the selected model, where the choice is based on the criteria that you specify in the **CHOOSE=** option of the **MODEL** statement. If you specify the **DETAILS** option in addition to **FORM=AUTO** in the **MODEL** statement, then the COVB option produces output for each one of the fitted models.

CORRB

requests the approximate correlation matrix for the parameter estimates of the model fitting. The CORRB option is ignored when you also specify the **DETAILS=ALL** option.

When you specify an explicit model with the **FORM=** option in the **MODEL** statement, the CORRB option produces the requested approximate correlation matrix. When you specify the **FORM=AUTO** option in the **MODEL** statement, by default the CORRB option produces output only for the selected model, where the choice is based on the criteria that you specify in the **CHOOSE=** option of the **MODEL** statement. If you specify the **DETAILS** option in addition to **FORM=AUTO** in the **MODEL** statement, then the CORRB option produces output for each one of the fitted models.

DETAILS *<= detail-level>*

requests different levels of output to be produced during the fitting process. You can specify any of the following *detail-level* arguments:

MOD

specifies that the default output for all candidate models be produced when the **FORM=**[AUTO](#) option is specified in the **MODEL** statement. If you fit only one explicit model, then the **DETAILS=MOD** option has no effect and is ignored.

ITR

requests that a complete iteration history be produced in addition to the default output. The output for **DETAILS=ITR** includes the current values of the parameter estimates, their gradients, and additional optimization statistics.

ALL

requests the most detailed level of output when fitting a model. Specifically, except for the default output, the **DETAILS=ALL** option produces optimization statistics in addition to the combined output of the **DETAILS=ITR**, **COVB**, and **CORRB** options.

When you fit multiple models with the **FORM=**[AUTO](#) option in the **MODEL** statement, only the selected model default output is produced. The model selection is based on the criteria that you specify in the **CHOOSE=** option of the **MODEL** statement. With the **DETAILS** option you can produce ODS tables with information about the fitting process of all the models that you fit. Moreover, you can produce output at different levels of detail that you can specify with the *detail-level* argument.

Omitting the **DETAILS** option or specifying the **DETAILS** option without any argument is equivalent to specifying **DETAILS=MOD**.

GRADIENT

displays the gradient of the objective function with respect to the parameter estimates in the “Parameter Estimates” table.

MTOGTOL=*number***MTOL=***number*

specifies a threshold value for the smoothness parameter of the Matérn form. Above this threshold, a Matérn form in a model switches to the Gaussian form. The *number* value must be positive and no greater than 1,000,000, which is the smoothness upper bound set by the VARIOGRAM procedure.

By default, if the fitting process progressively increases the Matérn smoothness parameter ν without converging to a smoothness estimate, then PROC VARIOGRAM converts the Matérn form into a Gaussian form when smoothness exceeds the default value 10,000. If you specify the *number* value to be greater than the 1,000,000 boundary value, then it is ignored and reset to the default threshold value. For more details about the Matérn-to-Gaussian form conversion, see the section “[Fitting with Matérn Forms](#)” on page 8634.

NOFIT

suppresses the model fitting process.

NOITPRINT

suppresses the display of the iteration history table when you have also specified the **DETAILS=ITR** or **DETAILS=ALL** option in the **MODEL** statement. Otherwise, the **NOITPRINT** option is ignored.

PARMS Statement

PARMS (*value-list*)...< / *options* > ;

The PARMS statement specifies initial values for the semivariance parameters of a single specified model in the **MODEL** statement. Alternatively, the PARMS statement can request a grid search over several values of these parameters. You must specify the values by starting with the nugget effect parameter. You continue in the order in which semivariogram forms are specified in the **FORM=** option of the **MODEL** statement by specifying for each structure the values for its scale, range, and any other parameters as applicable.

The PARMS statement is optional and must follow the associated **MODEL** statement.

The *value-list* specification can take any of several forms:

<i>m</i>	a single value
m_1, m_2, \dots, m_n	several values
<i>m</i> to <i>n</i>	a sequence in which <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment equals 1
<i>m</i> to <i>n</i> by <i>i</i>	a sequence in which <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment equals <i>i</i>
m_1, m_2 to m_3	mixed values and sequences

You can use the PARMS statement to input fixed values for parameters and also initial values that you want to optimize.

Suppose that you want to fit a semivariogram model with a Matérn component of scale 3, range 20, smoothing parameter 4.5, and an exponential component of unspecified scale and range 15. Assume that you also want to fix all the specified parameter values for the optimization. Including the nugget effect, you have a model with six parameters.

In terms of the PARMS statement, your specifications mean that you have initial values for the second, third, fourth, and sixth parameter in the parameter list. Also, the same specifications imply that you provide no initial values for the first parameter (which corresponds to the nugget effect) and the fifth parameter (which corresponds to the exponential model scale). For these parameters you prefer that PROC VARIOGRAM selects initial values, instead. Since you must specify values for all model parameters in the PARMS statement, you simply specify missing values for the first and fifth parameter. This is the way to request that PROC VARIOGRAM assigns default initial values to parameters. The SAS statements to implement these specifications are as follows:

```
proc variogram data=FirstData;
  < other VARIOGRAM statements >
  model form=(mat,exp);
  parms (.) (3) (20) (4.5) (.) (15) / hold=(2 to 4,6);
run;
```

NOTE: The preceding statements are equivalent to the following ones in which the PARMS statement is omitted:

```
proc variogram data=FirstData;
  < other VARIOGRAM statements >
  model form=(mat,exp) scale=(3,.) range(20,15) smooth=4.5;
run;
```

This example might suggest that you can always use either the PARMS or the [MODEL](#) statement to specify the same fitting parameters in the VARIOGRAM procedure. However, the PARMS statement gives you more flexibility in two ways:

- You can set non-default initial parameter values by using the PARMS statement, whereas in the [MODEL](#) statement you can request default initial values only by setting parameters to missing values. For this reason the PARMS statement cannot be specified when the [FORM=AUTO](#) option is specified in the associated [MODEL](#) statement. As an example, the following statements do not have an equivalent without using the PARMS statement, because the first parameter in the PARMS statement list (which corresponds to the [NUGGET](#) parameter) is set to the specific initial value of 2.1 and the fifth parameter (which corresponds to the exponential structure scale) is set to the specific initial value of 0.3.

```
proc variogram data=FirstData;
  < other VARIOGRAM statements >
  model form=(mat,exp);
  parms (2.1) (3) (20) (4.5) (0.3) (15) / hold=(2 to 4,6);
run;
```

- In the [MODEL](#) statement all the nonmissing parameter values that you specify remain fixed. Instead, the PARMS statement considers all values in the specified parameter sets to be subjected to optimization unless you force values to be fixed with the [HOLD=](#) option. In the previous example, you can specify that you want to optimize all of your parameters by skipping the [HOLD=](#) option as shown in the following modified statements:

```
proc variogram data=FirstData;
  < other VARIOGRAM statements >
  model form=(mat,exp);
  parms (2.1) (3) (20) (4.5) (1) (15);
run;
```

When you omit the PARMS statement list and the [PDATA=](#) data set in a PARMS statement, the specification is equivalent to a PARMS statement list where all the parameters have missing initial values. However, if you specify no other option in the PARMS statement, then the PARMS statement is ignored.

In order to avoid ambiguity, you cannot specify the PARMS statement if any of the scale, range, nugget, or smoothness parameters has been specified in the associated [MODEL](#) statement either explicitly or in the [MDATA=](#) data set. This condition is in effect even when you specify an empty PARMS statement.

If you specify more than one set of initial values, a grid of initial values sets is created. PROC VARIOGRAM seeks among the specified sets for the one that gives the lowest objective function value. Then, the procedure uses the initial values in the selected set for the fitting optimization.

The results from the PARMS statement are the values of the parameters on the specified grid. The ODS name of the “Parameter Search” table is ParmSearch.

You can specify the following options after a slash (/) in the PARMS statement:

HOLD=*value-list*

EQCONS=*value-list*

specifies which parameter values be constrained to equal the specified values. For example, the following statement constrains the first and third semivariance parameters to equal 0.5 and 12, respectively. The fourth parameter is fixed to the default initial value that is assigned to it by PROC VARIOGRAM.

```
parms (0.5) (3) (12) (.) / hold=1,3,4;
```

The HOLD= option accepts only nonmissing values in its list. If you specify more than the available parameters in the HOLD= option list, then the ones in excess are ignored. If the HOLD= option list has integer values that do not correspond to variables in the [PARMS](#) list, then they are also ignored. Noninteger values are rounded to the closest integer and evaluated accordingly.

When you specify more than one set of parameter initial values, the HOLD= option list applies to the set that gives the lowest objective function value before this set is sent to the optimizer for the fitting.

LOWERB=*value-list*

specifies lower boundary constraints on the semivariance parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that PROC VARIOGRAM uses for the semivariance parameters, and each number corresponds to the lower boundary constraint. A missing value instructs PROC VARIOGRAM to use its default constraint.

If you do not specify lower bounds for all of the semivariance parameters, then PROC VARIOGRAM assumes that the remaining parameters are not bounded. If you specify more lower bounds in the *value-list* than the available parameters, then the numbers in excess are ignored. If you specify lower bounds for parameters with missing initial values, then the VARIOGRAM procedure enforces the specified bounds in the fitting process. By default, the lower bound for all parameters is zero.

When you specify the [HOLD=](#) option together with the LOWERB= option, the lower bounds in the LOWERB= option *value-list* that correspond to fixed parameters are ignored. When you specify the [NOBOUND](#) option together with the LOWERB= option, the LOWERB= option is ignored.

MAXSCALE=*maxscale*

specifies a positive upper threshold for the fitted semivariogram sill. This option imposes a linear constraint on the optimization of the nonfixed semivariogram scale and nugget parameters so that the sum of all scale and nugget parameters does not exceed the specified MAXSCALE= value. The MAXSCALE= constraint is ignored if all the semivariogram scale and nugget parameters are fixed.

NOBOUND

requests the removal of boundary constraints on semivariance parameters. For example, semivariance parameters have a default zero lower boundary constraint since they have a physical meaning only for positive values. The NOBOUND option enables the fitting process to derive negative estimates; hence, you need to be cautious with the outcome when you specify this option.

The NOBOUND option has no effect on the power model exponent parameter. The exponent must range within $[0,2)$ so that the model is a valid semivariance function. Also, the NOBOUND option has no effect on the Matérn smoothness parameter. The options LOWERB= and UPPERB= are ignored if either of them is specified together with the NOBOUND option in the PARMS statement.

PARMSDATA=SAS-data-set

PDATA=SAS-data-set

specifies that semivariance parameters values be read from a SAS data set. The data set should contain the values in the sequence required by the PARMS statement in either of the following two ways:

- Specify one single column under the variable Estimate (or Est) that contains all the parameter values.
- Use one column for each parameter, and place the n columns under the Parm1–Parm n variables.

For example, the following two data sets are valid and equivalent ways to specify initial values for the nugget effect and the parameters of the Matérn and exponential structures that have been used in the previous examples in the PARMS statement section:

```
data parData1;
  input Estimate @@;
  datalines;
. 3 20 4.5 . 15
;
```

```
data parData2;
  input Parm1 Parm2 Parm3 Parm4 Parm5 Parm6;
  datalines;
. 3 20 4.5 . 15
;
```

If you have the parData1 data set, then you can import this information into the PARMS statement as follows:

```
proc variogram data=FirstData;
  < other VARIOGRAM statements >
  model form=(mat,exp);
  parms / pdata=parData1 hold=(2 to 4,6);
run;
```

You can specify more than one set of initial values in the PDATA= data set by following the preceding guidelines. PROC VARIOGRAM seeks among the specified sets for the one that gives the lowest objective function value. Then, the procedure uses the initial values in the selected set for the fitting optimization.

You can explicitly specify initial parameter values in the PARMS statement or use the PDATA= option, but you cannot use both at the same time.

UPPERB=*value-list*

specifies upper boundary constraints on the semivariance parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that PROC VARIOGRAM uses for the semivariance parameters, and each number corresponds to the upper boundary constraint. A missing value instructs PROC VARIOGRAM to use its default constraint.

If you do not specify upper bounds for all of the semivariance parameters, then PROC VARIOGRAM assumes that the remaining parameters are not bounded. If you specify more upper bounds in the *value-list* than the available parameters, then the numbers in excess are ignored. If you specify upper bounds for parameters with missing initial values, then the VARIOGRAM procedure enforces the specified bounds in the fitting process. By default, the scale, range, nugget, and Matérn smoothness parameters have no upper bounds, whereas the power model exponent parameter is lower than two.

When you specify the **HOLD=** option together with the **UPPERB=** option, the upper bounds in the **UPPERB=** option *value-list* that correspond to fixed parameters are ignored. When you specify the **NOBOUND** option together with the **UPPERB=** option, the **UPPERB=** option is ignored.

NLOPTIONS Statement

NLOPTIONS < *options* > ;

By default, PROC VARIOGRAM uses the technique **TECH=NRRIDG**, which corresponds to Newton-Raphson optimization with ridging. For more information about the **NLOPTIONS**, see the section “**NLOPTIONS Statement**” on page 482 in Chapter 19, “**Shared Concepts and Topics**.”

STORE Statement

STORE OUT=*store-name* < / *option* > ;

The **STORE** statement requests that the procedure save the context and results of the semivariogram model fitting analysis in an item store. An item store is a binary file defined by the SAS System. You cannot modify the contents of an item store. The contents of item stores produced by PROC VARIOGRAM can be processed only with the **KRIGE2D** or the **SIM2D** procedure. After you save results in an item store, you can use them at a later time without having to fit the model again.

The *store-name* is a usual one- or two-level SAS name, as for SAS data sets. If you specify a one-level name, then the item store resides in the Work library and is deleted at the end of the SAS session. Since item stores are often used for postprocessing tasks, typical usage specifies a two-level name of the form *libname.membername*. If an item store by the same name as specified in the **STORE** statement already exists, the existing store is replaced.

You can specify the following option in the STORE statement after a slash (/):

LABEL=*store-label*

specifies a custom label for the item store that is produced by PROC VARIOGRAM. When another procedure processes an item store, the label appears in the procedure's output along with other identifying information.

VAR Statement

VAR *analysis-variables-list* ;

Use the VAR statement to specify the analysis variables. You can specify only numeric variables. If you omit the VAR statement, all numeric variables in the **DATA=** data set that are not in the **COORDINATES** statement are used.

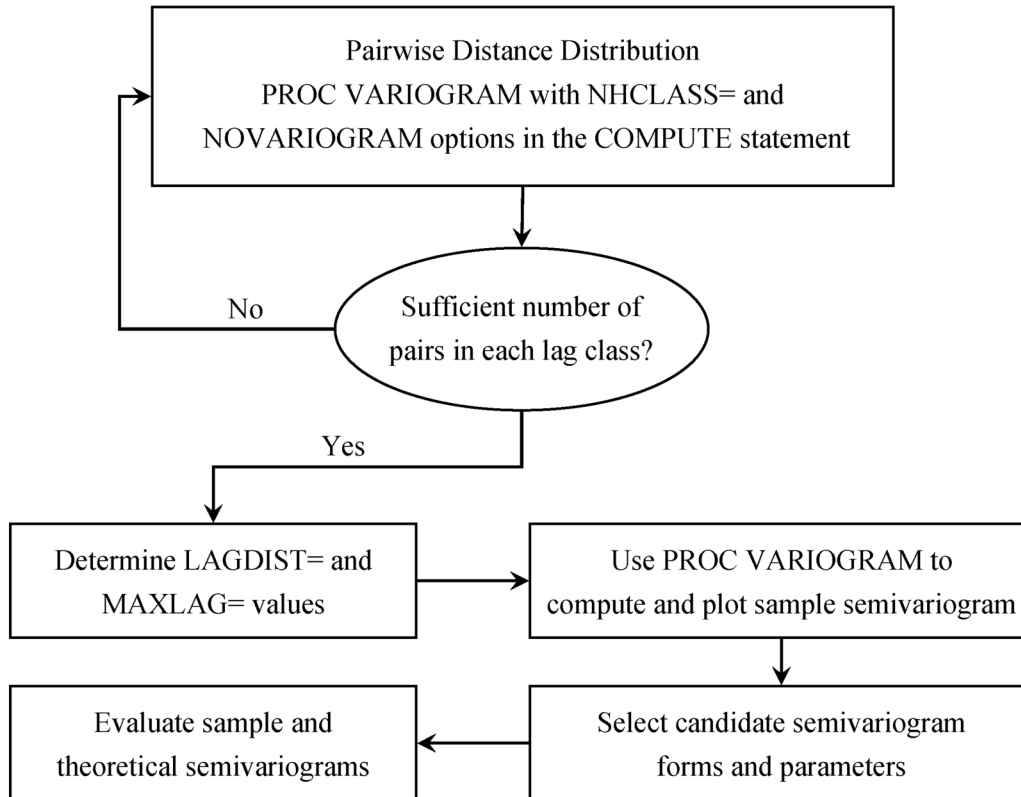

Details: VARIOGRAM Procedure

Theoretical Semivariogram Models

The VARIOGRAM procedure computes the empirical (also known as *sample* or *experimental*) semivariogram from a set of point measurements. Semivariograms are used in the first steps of spatial prediction as tools that provide insight into the spatial continuity and structure of a random process. Naturally occurring randomness is accounted for by describing a process in terms of the *spatial random field* (SRF) concept (Christakos 1992). An SRF is a collection of random variables throughout your spatial domain of prediction. For some of them you already have measurements, and your data set constitutes part of a single realization of this SRF. Based on your sample, spatial prediction aims to provide you with values of the SRF at locations where no measurements are available.

Prediction of the SRF values at unsampled locations by techniques such as ordinary kriging requires the use of a theoretical semivariogram or covariance model. Due to the randomness involved in stochastic processes, the theoretical semivariance cannot be computed. Instead, it is possible that the empirical semivariance can provide an estimate of the theoretical semivariance, which then characterizes the spatial structure of the process.

The VARIOGRAM procedure follows a general flow of investigation that leads you from a set of spatial observations to an expression of theoretical semivariance to characterize the SRF continuity. Specifically, the empirical semivariogram is computed after a suitable choice is made for the **LAGDISTANCE=** and **MAXLAGS=** options. For computations in more than one direction you can further use the **NDIRECTIONS=** option or the **DIRECTIONS** statement. Potential theoretical models (which can also incorporate nesting, anisotropy, and the nugget effect) can be fitted to the empirical semivariance by using the **MODEL** statement, and then plotted against the empirical semivariogram. The flow of this analytical process is illustrated in Figure 102.17. After a suitable theoretical model is determined, it is used in PROC KRIGE2D for the prediction stage. The prediction analysis is presented in detail in the section “Details of Ordinary Kriging” on page 3839 in the KRIGE2D procedure documentation.

Figure 102.17 Flowchart for Semivariogram Selection

It is critical to note that the empirical semivariance provides an estimate of its theoretical counterpart only when the SRF satisfies stationarity conditions. These conditions imply that the SRF has a constant (or zero) expected value. Consequently, your data need to be sampled from a trend-free random field and need to have a constant mean, as assumed in “[Getting Started: VARIOGRAM Procedure](#)” on page 8561. Equivalently, your data could be residuals of an initial sample that has had a surface trend removed, as portrayed in “[Example 102.2: An Anisotropic Case Study with Surface Trend in the Data](#)” on page 8658. For a closer look at stationarity, see the section “[Stationarity](#)” on page 8615. For details about different stationarity types and conditions see, for example, Chilès and Delfiner (1999, section 1.1.4).

Characteristics of Semivariogram Models

When you obtain a valid empirical estimate of the theoretical semivariance, it is then necessary to choose a type of theoretical semivariogram model based on that estimate. Commonly used theoretical semivariogram shapes rise monotonically as a function of distance. The shape is typically characterized in terms of particular parameters; these are the *range* a_0 , the *sill* (or *scale*) c_0 , and the *nugget effect* c_n . [Figure 102.18](#) displays a theoretical semivariogram of a spherical semivariance model and points out the semivariogram characteristics.

Figure 102.18 A Theoretical Semivariogram of Spherical Type and Its Characteristics

Specifically, the sill is the semivariogram upper bound. The range a_0 denotes the distance at which the semivariogram reaches the sill. When the semivariogram increases asymptotically toward its sill value, as occurs in the exponential and Gaussian semivariogram models, the term *effective* (or *practical*) range is also used. The effective range r_ϵ is defined as the distance at which the semivariance value achieves 95% of the sill. In particular, for these models the relationship between the range and effective range is $r_\epsilon = 3a_0$ (exponential model) and $r_\epsilon = \sqrt{3}a_0$ (Gaussian model).

The nugget effect c_n represents a discontinuity of the semivariogram that can be present at the origin. It is typically attributed to microscale effects or measurement errors. The semivariance is always 0 at distance $h = 0$; hence, the nugget effect demonstrates itself as a jump in the semivariance as soon as $h > 0$ (note in Figure 102.18 the discontinuity of the function at $h = 0$ in the presence of a nugget effect).

The sill c_0 consists of the nugget effect, if present, and the *partial sill* σ_0^2 ; that is, $c_0 = c_n + \sigma_0^2$. If the SRF $Z(s)$ is second-order stationary (see the section “Stationarity” on page 8615), the estimate of the sill is an estimate of the constant variance $\text{Var}[Z(s)]$ of the field. Nonstationary processes have variances that depend on the location s . Their semivariance increases with distance; hence their semivariograms have no sill.

Not every function is a suitable candidate for a theoretical semivariogram model. The semivariance function $\gamma_z(h)$, as defined in the following section, is a so-called *conditionally negative-definite* function that satisfies (Cressie 1993, p. 60)

$$\sum_{i=1}^m \sum_{j=i}^m q_i q_j \gamma_z(s_i - s_j) \leq 0$$

for any number m of locations s_i, s_j in \mathcal{R}^2 with $h = s_i - s_j$, and any real numbers q_i such that $\sum_{i=1}^m q_i = 0$. PROC VARIOGRAM can use a variety of permissible theoretical semivariogram models.

Specifically, Table 102.4 shows a list of such models that you can use for fitting in the **MODEL** statement of the VARIOGRAM procedure.

Table 102.4 Permissible Theoretical Semivariogram Models ($a_0 > 0$, unless noted otherwise)

Model Type	Semivariance
Exponential	$\gamma_z(\mathbf{h}) = \begin{cases} 0 & \text{if } \mathbf{h} = 0 \\ c_n + \sigma_0^2 \left[1 - \exp\left(-\frac{ \mathbf{h} }{a_0}\right) \right] & \text{if } 0 < \mathbf{h} \end{cases}$
Gaussian	$\gamma_z(\mathbf{h}) = \begin{cases} 0 & \text{if } \mathbf{h} = 0 \\ c_n + \sigma_0^2 \left[1 - \exp\left(-\frac{ \mathbf{h} ^2}{a_0^2}\right) \right] & \text{if } 0 < \mathbf{h} \end{cases}$
Power	$\gamma_z(\mathbf{h}) = \begin{cases} 0 & \text{if } \mathbf{h} = 0 \\ c_n + \sigma_0^2 \mathbf{h}^{a_0} & \text{if } 0 < \mathbf{h} , 0 \leq a_0 < 2 \end{cases}$
Spherical	$\gamma_z(\mathbf{h}) = \begin{cases} 0 & \text{if } \mathbf{h} = 0 \\ c_n + \sigma_0^2 \left[\frac{3}{2} \frac{ \mathbf{h} }{a_0} - \frac{1}{2} \left(\frac{ \mathbf{h} }{a_0} \right)^3 \right] & \text{if } 0 < \mathbf{h} \leq a_0 \\ c_0 & \text{if } a_0 < \mathbf{h} \end{cases}$
Cubic	$\gamma_z(\mathbf{h}) = \begin{cases} 0 & \text{if } \mathbf{h} = 0 \\ c_n + \sigma_0^2 \left[7 \left(\frac{ \mathbf{h} }{a_0} \right)^2 - \frac{35}{4} \left(\frac{ \mathbf{h} }{a_0} \right)^3 + \frac{7}{2} \left(\frac{ \mathbf{h} }{a_0} \right)^5 - \frac{3}{4} \left(\frac{ \mathbf{h} }{a_0} \right)^7 \right] & \text{if } 0 < \mathbf{h} \leq a_0 \\ c_0 & \text{if } a_0 < \mathbf{h} \end{cases}$
Pentaspherical	$\gamma_z(\mathbf{h}) = \begin{cases} 0 & \text{if } \mathbf{h} = 0 \\ c_n + \sigma_0^2 \left[\frac{15}{8} \frac{ \mathbf{h} }{a_0} - \frac{5}{4} \left(\frac{ \mathbf{h} }{a_0} \right)^3 + \frac{3}{8} \left(\frac{ \mathbf{h} }{a_0} \right)^5 \right] & \text{if } 0 < \mathbf{h} \leq a_0 \\ c_0 & \text{if } a_0 < \mathbf{h} \end{cases}$
Sine hole effect	$\gamma_z(\mathbf{h}) = \begin{cases} 0 & \text{if } \mathbf{h} = 0 \\ c_n + \sigma_0^2 \left[1 - \frac{\sin(\pi \mathbf{h} /a_0)}{\pi \mathbf{h} /a_0} \right] & \text{if } 0 < \mathbf{h} \end{cases}$
Matérn class	$\gamma_z(\mathbf{h}) = \begin{cases} 0 & \text{if } \mathbf{h} = 0 \\ c_n + \sigma_0^2 \left[1 - \frac{2}{\Gamma(\nu)} \left(\frac{ \mathbf{h} \sqrt{\nu}}{a_0} \right)^\nu K_\nu \left(2 \frac{ \mathbf{h} \sqrt{\nu}}{a_0} \right) \right] & \text{if } 0 < \mathbf{h} , \nu > 0 \end{cases}$

All of these models, except for the power model, are transitive. A transitive model characterizes a random process whose variation reaches the sill value c_0 within a specific range from any location in the field.

The power model is nontransitive and applies to processes whose variance increases with distance. It has no scale and range; instead, it quantifies the process variation by using a positive slope parameter and a dimensionless power exponent α that indicate how fast the variance increases. The expression for the power model is a valid semivariogram only when the exponent parameter ranges within $0 \leq \alpha < 2$. For convenience, PROC VARIOGRAM registers the power model slope parameter under the **SCALE=** option parameters in the **MODEL** statement. For the same reason, the scale and power slope parameters are represented with the common symbol σ_0^2 in Table 102.4. Also for convenience, PROC VARIOGRAM registers the power model exponent parameter under the **RANGE=** option parameters. The range and the power exponent parameters are represented with the common symbol a_0 in Table 102.4.

The power model is a generalized case of the linear model, which is not included explicitly in the model set of PROC VARIOGRAM. The linear model is derived from the power model when you specify the exponent $\alpha = 1$.

Among the models displayed in Table 102.4, the Matérn (or K -Bessel) class is a class of semivariance models that distinguish from each other by means of the positive smoothing parameter ν . Different values of ν correspond to different correlation models. Most notably, for $\nu = 0.5$ the Matérn semivariance is equivalent to the exponential model, whereas $\nu \rightarrow \infty$ gives the Gaussian model. Also, Table 102.4 shows that the Matérn semivariance computations use the gamma function $\Gamma(\nu)$ and the second kind Bessel function K_ν .

In PROC VARIOGRAM, you can input the model parameter values either explicitly as arguments of options, or as lists of values. In the latter case, you are expected to provide the values in the order the models are specified in the SAS statements, and furthermore in the sequential order of the scale, range, and smoothing parameter for each model as appropriate, and always starting with the nugget effect. If the parameter values are specified through an input file, then the total of n parameters should be provided either as one variable named Estimate or as many variables with the respective names Parm1–Parm n .

You can review in further detail the models shown in Table 102.4 in the section “Theoretical Semivariogram Models” on page 3823 in the KRIGE2D procedure documentation.

The theoretical semivariogram models are used to describe the spatial structure of random processes. Based on their shape and characteristics, the semivariograms of these models can provide a plethora of information (Christakos 1992, section 7.3):

- Examination of the semivariogram variation in different directions provides information about the isotropy of the random process. (See also the discussion about isotropy in the following section.)
- The semivariogram range determines the zone of influence that extends from any given location. Values at surrounding locations within this zone are correlated with the value at the specific location by means of the particular semivariogram.
- The semivariogram behavior at large distances indicates the degree of stationarity of the process. In particular, an asymptotic behavior suggests a stationary process, whereas either a linear increase and slow convergence to the sill or a fast increase is an indicator of nonstationarity.
- The semivariogram behavior close to the origin indicates the degree of regularity of the process variation. Specifically, a parabolic behavior at the origin implies a very regular spatial variation, whereas a linear behavior characterizes a nonsmooth process. The presence of a nugget effect is additional evidence of irregularity in the process.
- The semivariogram behavior within the range provides description of potential periodicities or anomalies in the spatial process.

A brief note on terminology: In some fields (for example, geostatistics) the term homogeneity is sometimes used instead of stationarity in spatial analysis; however, in statistics homogeneity is defined differently (Banerjee, Carlin, and Gelfand 2004, section 2.1.3). In particular, the alternative terminology characterizes as homogeneous the stationary SRF in \mathcal{R}^n , $n > 1$, whereas it retains the term stationary for such SRF in \mathcal{R}^1 (SRF in \mathcal{R}^1 are also known as *random processes*). Often, studies in a single dimension refer to temporal processes; hence, you might see time-stationary random processes called “temporally stationary” or simply stationary, and stationary SRF in \mathcal{R}^n , $n > 1$, characterized as “spatially homogeneous” or simply homogeneous. This distinction made by the alternative nomenclature is more evident in spatiotemporal

random fields (S/TRF), where the different terms clarify whether stationarity applies in the spatial or the temporal part of the S/TRF.

Nested Models

When you try to represent an empirical semivariogram by fitting a theoretical model, you might find that using a combination of theoretical models results in a more accurate fit onto the empirical semivariance than using a single model. This is known as model nesting. The semivariance models that result as the sum of two or more semivariance structures are called *nested* models.

In general, a linear combination of permissible semivariance models produces a new permissible semivariance model. Nested models are based on this premise. You can include in a sum any combination of the models presented in Table 102.4. For example, a nested semivariance $\gamma_z(\mathbf{h})$ that contains two structures, one exponential $\gamma_{z,\text{EXP}}(\mathbf{h})$ and one spherical $\gamma_{z,\text{SPH}}(\mathbf{h})$, can be expressed as

$$\gamma_z(\mathbf{h}) = \gamma_{z,\text{EXP}}(\mathbf{h}) + \gamma_{z,\text{SPH}}(\mathbf{h})$$

If you have a nested model and a nugget effect, then the nugget effect c_n is a single parameter that is considered jointly for all the nested structures.

Nested models, anisotropic models, and the nugget effect increase the scope of theoretical models available. You can find additional discussion about these concepts in the section “Theoretical Semivariogram Models” on page 3823 in the KRIGE2D procedure documentation.

Theoretical and Computational Details of the Semivariogram

Let $\{Z(\mathbf{s}), \mathbf{s} \in D \subset \mathcal{R}^2\}$ be a spatial random field (SRF) with n measured values $z_i = Z(\mathbf{s}_i)$ at respective locations $\mathbf{s}_i, i = 1, \dots, n$. You use the VARIOGRAM procedure because you want to gain insight into the spatial continuity and structure of $Z(\mathbf{s})$. A good measure of the spatial continuity of $Z(\mathbf{s})$ is defined by means of the variance of the difference $Z(\mathbf{s}_i) - Z(\mathbf{s}_j)$, where \mathbf{s}_i and \mathbf{s}_j are locations in D . Specifically, if you consider \mathbf{s}_i and \mathbf{s}_j to be spatial increments such that $\mathbf{h} = \mathbf{s}_j - \mathbf{s}_i$, then the variance function based on the increments \mathbf{h} is independent of the actual locations $\mathbf{s}_i, \mathbf{s}_j$. Most commonly, the continuity measure used in practice is one half of this variance, better known as the *semivariance* function,

$$\gamma_z(\mathbf{h}) = \frac{1}{2} \text{Var}[Z(\mathbf{s} + \mathbf{h}) - Z(\mathbf{s})]$$

or, equivalently,

$$\gamma_z(\mathbf{h}) = \frac{1}{2} (\text{E}\{[Z(\mathbf{s} + \mathbf{h}) - Z(\mathbf{s})]^2\} - \{\text{E}[Z(\mathbf{s} + \mathbf{h})] - \text{E}[Z(\mathbf{s})]\}^2)$$

The plot of semivariance as a function of \mathbf{h} is the *semivariogram*. You might also commonly see the term *semivariogram* used instead of the term *semivariance*.

Assume that the SRF $Z(\mathbf{s})$ is free of nonrandom (or systematic) surface trends. Then, the expected value $\text{E}[Z(\mathbf{s})]$ of $Z(\mathbf{s})$ is a constant for all $\mathbf{s} \in \mathcal{R}^2$, and the semivariance expression is simplified to the following:

$$\gamma_z(\mathbf{h}) = \frac{1}{2} \text{E}\{[Z(\mathbf{s} + \mathbf{h}) - Z(\mathbf{s})]^2\}$$

Given the preceding assumption, you can compute an estimate $\hat{\gamma}_z(\mathbf{h})$ of the semivariance $\gamma_z(\mathbf{h})$ from a finite set of points in a practical way by using the formula

$$\hat{\gamma}_z(\mathbf{h}) = \frac{1}{2 |N(\mathbf{h})|} \sum_{N(\mathbf{h})} [Z(s_i) - Z(s_j)]^2$$

where the sets $N(\mathbf{h})$ contain all the neighboring pairs at distance \mathbf{h} ,

$$N(\mathbf{h}) = \{i, j : s_i - s_j = \mathbf{h}\}$$

and $|N(\mathbf{h})|$ is the number of such pairs (i, j) .

The expression for $\hat{\gamma}_z(\mathbf{h})$ is called the *empirical semivariance* (Matheron 1963). This is the quantity that PROC VARIOGRAM computes, and its corresponding plot is the *empirical semivariogram*.

The empirical semivariance $\hat{\gamma}_z(\mathbf{h})$ is also referred to as *classical*. This name is used so that it can be distinguished from the *robust semivariance* estimate $\bar{\gamma}_z(\mathbf{h})$ and the corresponding *robust semivariogram*. The robust semivariance was introduced by Cressie and Hawkins (1980) to weaken the effect that outliers in the observations might have on the semivariance. It is described by Cressie (1993, p. 75) as

$$\bar{\gamma}_z(\mathbf{h}) = \frac{\Psi^4(\mathbf{h})}{2[0.457 + 0.494/N(\mathbf{h})]}$$

In the preceding expression the parameter $\Psi(\mathbf{h})$ is defined as

$$\Psi(\mathbf{h}) = \frac{1}{N(\mathbf{h})} \sum_{P_i P_j \in N(\mathbf{h})} [Z(s_i) - Z(s_j)]^{\frac{1}{2}}$$

According to Cressie (1985), the estimate $\hat{\gamma}_z(\mathbf{h})$ has approximate variance

$$\text{Var}[\hat{\gamma}_z(\mathbf{h})] \simeq \frac{2[\gamma_z(\mathbf{h})]^2}{N(\mathbf{h})}$$

This approximation is possible by assuming $Z(s)$ to be a Gaussian SRF, and by further assuming the squared differences in empirical semivariances to be uncorrelated for different distances \mathbf{h} . Typically, semivariance estimates are correlated because of the underlying spatial correlation among the observations, and also because the same observation pairs might be used for the estimation of more than one semivariogram point, as described in the following subsections. Despite these restrictive assumptions, the approximate variance provides an idea about the semivariance estimate variance and enables fitting of a theoretical model to the empirical semivariance; see the section “[Theoretical Semivariogram Model Fitting](#)” on page 8627 for more details about the fitting process.

NOTE: If your data include a surface trend, then the empirical semivariance $\hat{\gamma}_z(\mathbf{h})$ is not an estimate of the theoretical semivariance function $\gamma_z(\mathbf{h})$. Instead, rather than the spatial increments variance, it represents a different quantity known as *pseudo-semivariance*, and its corresponding plot is a *pseudo-semivariogram*. In principle, pseudo-semivariograms do not provide measures of the spatial continuity. They can thus lead to misinterpretations of the $Z(s)$ spatial structure, and are consequently unsuitable for the purpose of spatial prediction. For further information, see the detailed discussion in the section “[Empirical Semivariograms and Surface Trends](#)” on page 8626. Under certain conditions you might be able to gain some insight about the spatial continuity with a pseudo-semivariogram. This case is presented in “[Example 102.3: Analysis without Surface Trend Removal](#)” on page 8672.

Stationarity

In the combined presence of the previous two assumptions—that is, when $E[Z(s)]$ is constant and spatial increments define $\gamma_z(\mathbf{h})$ —the SRF $Z(s)$ is characterized as *intrinsically stationary* (Cressie 1993, p. 40).

The expected value $E[Z(s)]$ is the first statistical moment of the SRF $Z(s)$. The second statistical moment of the SRF $Z(s)$ is the *covariance* function between two points s_i and s_j in $Z(s)$, and it is defined as

$$C_z(s_i, s_j) = E([Z(s_i) - E[Z(s_i)]] [Z(s_j) - E[Z(s_j)]])$$

When $s_i = s_j = s$, the covariance expression provides the variance at s .

The assumption of a constant $E[Z(s)] = m$ means that the expected value is invariant with respect to translations of the spatial location s . The covariance is considered invariant to such translations when it depends only on the distance $\mathbf{h} = s_i - s_j$ between any two points s_i and s_j . If both of these conditions are true, then the preceding expression becomes

$$C_z(s_i, s_j) = C_z(s_i - s_j) = C_z(\mathbf{h}) = E([Z(s) - m][Z(s + \mathbf{h}) - m])$$

When both $E[Z(s)]$ and $C(s_i, s_j)$ are invariant to spatial translations, the SRF $Z(s)$ is characterized as *second-order stationary* (Cressie 1993, p. 53).

In a second-order stationary SRF the quantity $C(\mathbf{h})$ is the same for any two points that are separated by distance \mathbf{h} . Based on the preceding formula, for $\mathbf{h} = 0$ you can see that the variance is constant throughout a second-order stationary SRF. Hence, second-order stationarity is a stricter condition than intrinsic stationarity.

Under the assumption of second-order stationarity, the semivariance definition at the beginning of this section leads to the conclusion that

$$\gamma_z(\mathbf{h}) = C(0) - C(\mathbf{h})$$

which relates the theoretical semivariance and covariance. Keep in mind that the empirical estimates of these quantities are not related in exactly the same way, as indicated in Schabenberger and Gotway (2005, section 4.2.1).

Ergodicity

In addition to the constant $E[Z(s)]$ and the assumption of intrinsic stationarity, *ergodicity* is a necessary third hypothesis to estimate the empirical semivariance. Assume that for the SRF $Z(s)$ you have measurements z_i whose sample mean is estimated by \bar{Z} . The hypothesis of ergodicity dictates that $\bar{Z} = E[Z(s)]$.

In general, an SRF $Z(s)$ is characterized as ergodic if the statistical moments of its realizations coincide with the corresponding ones of the SRF. In spatial analysis you are often interested in the first two statistical moments, and consequently a more relaxed ergodicity assumption is made only for them. See Christakos (1992, section 2.12) for the use of the ergodicity hypothesis in SRF, and Cressie (1993, p. 57) for a more detailed discussion of ergodicity.

The semivariogram analysis makes implicit use of the ergodicity hypothesis. The VARIOGRAM procedure works with the residual centered values $V(s_i) = v_i = z_i - \bar{Z}$, $i = 1, \dots, n$, where it is assumed that the sample mean \bar{Z} is the constant expected value $E[Z(s)]$ of $Z(s)$. This is equivalent to using the original values, since $V(s_i) - V(s_j) = Z(s_i) - Z(s_j)$, which shows the property of the semivariance to filter out the mean. See the section “[Semivariance Computation](#)” on page 8625 for the exact expressions PROC VARIOGRAM uses to compute the empirical classical $\hat{\gamma}_z(\mathbf{h})$ and robust $\bar{\gamma}_z(\mathbf{h})$ semivariances.

Anisotropy

Semivariance is defined on the basis of the spatial increment vector \mathbf{h} . If the variance characteristics of $Z(\mathbf{s})$ are independent of the spatial direction, then $Z(\mathbf{s})$ is called *isotropic*; if not, then $Z(\mathbf{s})$ is called *anisotropic*. In the case of isotropy, the semivariogram depends only on the length h of \mathbf{h} and $\gamma_z(\mathbf{h}) = \gamma_z(h)$. Anisotropy is characterized as *geometric*, when the range a_0 of the semivariogram varies in different directions, and *zonal*, when the semivariogram sill c_0 depends on the spatial direction. Either type or both types of anisotropy can be present.

In the more general case, an SRF can be anisotropic. For an accurate characterization of the spatial structure it is necessary to perform individual analyses in multiple directions. Goovaerts (1997, p. 98) suggests an initial investigation in at least one direction more than the working spatial dimensions—for example, at least three different directions in \mathcal{R}^2 . Olea (2006) supports exploring as many directions as possible when the data set allows.

You might not know in advance whether you have anisotropy or not. If the semivariogram characteristics remain unchanged in different directions, then you assume the SRF is isotropic. If your directional analysis reveals anisotropic behavior in particular directions, then you proceed to focus your analysis on these directions. For example, in an anisotropic SRF in \mathcal{R}^2 you should expect to find two distinct directions where you observe the *major axis* and the *minor axis* of anisotropy. Typically, these two directions are perpendicular, although they might be at other than right angles when zonal anisotropy is present.

If you can distinguish a maximum and a minimum sill in different directions, then you have a case of zonal anisotropy. The SRF exhibits strongest continuity in the direction of the lowest sill, which is the direction of the major anisotropy axis. If the sill does not change across directions, then the major axis direction of strongest continuity is the one in which the semivariogram has maximum range. See “[Example 102.2: An Anisotropic Case Study with Surface Trend in the Data](#)” on page 8658 for a detailed demonstration of a case with anisotropy when you use PROC VARIOGRAM.

You can find additional information about anisotropy analysis in the section “[Anisotropic Models](#)” on page 3832 in the KRIGE2D procedure documentation.

Pair Formation

The basic starting point in computing the empirical semivariance is the enumeration of pairs of points for the spatial data. [Figure 102.19](#) shows the spatial domain D and the set of n measurements $z_i, i = 1, \dots, n$, that have been sampled at the indicated locations in D . Two data points P_1 and P_2 , with coordinates $\mathbf{s}_1 = (x_1, y_1)$ and $\mathbf{s}_2 = (x_2, y_2)$, respectively, are selected for illustration.

A vector, or directed line segment, is drawn between these points. If the length

$$|P_i P_j| = |\mathbf{s}_2 - \mathbf{s}_1| = (x_2 - x_1)^2 + (y_2 - y_1)^2$$

of this vector is smaller than the specified `DEPSILON=` value, then the pair is excluded from the continuity measure calculations because the two points P_1 and P_2 are considered to be at zero distance apart (or *collocated*). Spatial collocation might appear due to different scales in sampling, observations made at the same spatial location at different time instances, and errors in the data sets. PROC VARIOGRAM excludes such pairs from the pairwise distance and semivariance computations because they can cause numeric problems in spatial analysis.

If this pair is not discarded on the basis of collocation, it is then classified—first by orientation of the directed line segment $\mathbf{s}_2 - \mathbf{s}_1$, and then by its length $|P_i P_j|$. For example, it is unlikely for actual data that the

distance $|P_i P_j|$ between any pair of data points P_i and P_j located at s_i and s_j , respectively, would exactly satisfy $|P_i P_j| = |h| = h$ in the preceding computation of $\hat{\gamma}_z(h)$. A similar argument can be made for the orientation of the segment $s_2 - s_1$. Consequently, the pair $P_1 P_2$ is placed into an angle and distance class.

The following subsections give more details about the nature of these classifications. You can also find extensive discussions about the size and the number of classes to consider for the computation of the empirical semivariogram.

Figure 102.19 Selection of Points P_1 and P_2 in Spatial Domain D

Angle Classification

Suppose you specify `NDIRECTIONS=3` in the `COMPUTE` statement in `PROC VARIOGRAM`. This results in three angle classes defined by midpoint angles between 0° and 180° : $0^\circ \pm \delta\theta$, $60^\circ \pm \delta\theta$, and $120^\circ \pm \delta\theta$, where $\delta\theta$ is the angle tolerance. If you do not specify an angle tolerance by using the `ANGLETOLERANCE=` option in the `COMPUTE` statement, the following default value is used:

$$\delta\theta = \frac{180^\circ}{2 \times \text{NDIR}}$$

For example, if `NDIRECTIONS=3`, the default angle tolerance is $\delta\theta = 30^\circ$. When the directed line segment $P_1 P_2$ in Figure 102.19 is superimposed on the coordinate system that shows the angle classes, its angle is approximately 45° , measured clockwise from north. In particular, it falls within $[60^\circ - \delta\theta, 60^\circ + \delta\theta) = [30^\circ, 90^\circ)$, the second angle class (Figure 102.20).

NOTE: If the designated points P_1 and P_2 are labeled in the opposite order, the orientation is in the opposite direction—that is, approximately 225° instead of approximately 45° . This does not affect angle class selection; the angle classes $[60^\circ - \delta\theta, 60^\circ + \delta\theta)$ and $[240^\circ - \delta\theta, 240^\circ + \delta\theta)$ are the same.

Figure 102.20 Selected Pair $P_1 P_2$ Falls within the Second Angle Class

If you specify an angle tolerance less than the default, such as $ATOL=15^\circ$, some point pairs might be excluded. For example, the selected point pair $P_1 P_2$ in Figure 102.20, while closest to the 60° axis, might lie outside $[60 - \delta\theta, 60 + \delta\theta) = [45^\circ, 75^\circ)$. In this case, the point pair $P_1 P_2$ would be excluded from the semivariance computation. This setting can be desirable if you want to reduce interference between neighboring angles. An angle tolerance that is too small might result in too few point pairs in some distance classes for the empirical semivariance estimation (see also the discussion in the section “Choosing the Size of Classes” on page 8623).

On the other hand, you can specify an angle tolerance *greater* than the default. This can result in a point pair being counted in more than one angle classes. This has a smoothing effect on the variogram and is useful when only a small amount of data is present or the available data are sparsely located. However, in cases of anisotropy the smoothing effect might have the side effect of amplifying weaker anisotropy in some direction and weakening stronger anisotropy in another (Deutsch and Journel 1992, p. 59).

Changes in the values of the **BANDWIDTH=** option have a similar effect. See the section “Bandwidth Restriction” on page 8620 for an explanation of how **BANDWIDTH=** functions.

An alternative way to specify angle classes and angle tolerances is with the **DIRECTIONS** statement. The **DIRECTIONS** statement is useful when angle classes are not equally spaced. When you use the **DIRECTIONS** statement, consider specifying the angle tolerance too. The default value of the angle tolerance is 45° when a **DIRECTIONS** statement is used instead of the **NDIRECTIONS=** option in the **COMPUTE**

statement. This might not be appropriate for a particular set of angle classes. See the section “[DIRECTIONS Statement](#)” on page 8590 for more details.

Distance Classification

The distance class for a point pair P_1P_2 is determined as follows. The directed line segment P_1P_2 is superimposed on the coordinate system that shows the distance or lag classes. These classes are determined by the `LAGDISTANCE=` option in the `COMPUTE` statement. Denoting the length of the line segment by $|P_1P_2|$ and the `LAGDISTANCE=` value by Δ , the lag class L is determined by

$$L(P_1P_2) = \left\lfloor \frac{|P_1P_2|}{\Delta} + 0.5 \right\rfloor$$

where $\lfloor x \rfloor$ denotes the largest integer $\leq x$.

When the directed line segment P_1P_2 is superimposed on the coordinate system that shows the distance classes, it is seen to fall in the first lag class; see [Figure 102.21](#) for an illustration for $\Delta = 1$.

Figure 102.21 Selected Pair P_1P_2 Falls within the First Lag Class

Pairwise distances are positive. Therefore, the line segment $|P_1P_2|$ might belong to one of the `MAXLAG` lag classes or it could be shorter than half the length of the `LAGDISTANCE=` value. In the last case the segment is said to belong to the lag class zero. Hence, lag class zero is smaller than lag classes $1, \dots, \text{MAXLAGS}$. The definition of lag classes in this manner means that when you specify the `MAXLAGS=` parameter, PROC VARIOGRAM produces a semivariogram with a total of `MAXLAGS+1` lag classes including the zero lag class. For example, if you specify `LAGDISTANCE=1` and `MAXLAGS=10` and you do not specify a `LAGTOLERANCE=` value in the `COMPUTE` statement in PROC VARIOGRAM, the 11 lag classes generated by the preceding equation are

$$[0, 0.5), [0.5, 1.5), [1.5, 2.5), \dots, [9.5, 10.5)$$

The preceding lag classes description is correct under the assumption of the default lag tolerance, which is half the **LAGDISTANCE=** value. Using the default lag tolerance results in no gaps between the distance class intervals, as shown in Figure 102.22.

Figure 102.22 Lag Distance Axis Showing Lag Classes

On the other hand, if you do specify a distance tolerance with the **LAGTOLERANCE=** option in the **COMPUTE** statement, a further check is performed to see whether the point pair falls within this tolerance of the nearest lag. In the preceding example, if you specify **LAGDISTANCE=1** and **MAXLAGS=10** (as before) and also specify **LAGTOLERANCE=0.25**, the intervals become

$$[0, 0.25), [0.75, 1.25), [1.75, 2.25), \dots, [9.75, 10.25)$$

You might want to avoid this specification because it results in gaps in the lag classes. For example, if a point pair $P_1 P_2$ falls in an interval such as

$$|P_1 P_2| \in [1.25, 1.75)$$

then it is excluded from the semivariance calculation. The maximum **LAGTOLERANCE=** value allowed is half the **LAGDISTANCE=** value; no overlap of the distance classes is allowed.

See the section “Computation of the Distribution Distance Classes” on page 8621 for a more extensive discussion of practical aspects in the specification of the **LAGDISTANCE=** and **MAXLAGS=** options.

Bandwidth Restriction

Because the areal segments that are generated from the angle and distance classes increase in area as the lag distance increases, it is sometimes desirable to restrict this area (Deutsch and Journel 1992, p. 45). If you specify the **BANDWIDTH=** option in the **COMPUTE** statement, the lateral, or perpendicular, distance from the axis that defines the angle classes is fixed.

For example, suppose two points P_3 , P_4 are picked from the domain in Figure 102.19 and are superimposed on the grid that defines distance and angle classes, as shown in Figure 102.23.

The endpoint of vector $P_3 P_4$ falls within the angle class around 60° and the fifth lag class; however, it falls outside the restricted area that is defined by the bandwidth. Hence, it is excluded from the semivariance calculation.

Figure 102.23 Selected Pair P_3P_4 Falls outside Bandwidth Limit

Finally, a pair $P_i P_j$ that falls in a lag class larger than the value of the **MAXLAGS=** option is excluded from the semivariance calculation.

The **BANDWIDTH=** option complements the angle and lag tolerances in determining how point pairs are included in distance classes. Clearly, the number of pairs within each angle/distance class is strongly affected by the angle and lag tolerances and whether **BANDWIDTH=** has been specified. See also the section “**Angle Classification**” on page 8617 for more details about the effects these rules can have, since **BANDWIDTH=** operates in a manner similar to the **ANGLETOLERANCE=** option.

Computation of the Distribution Distance Classes

This section deals with theoretical considerations and practical aspects when you specify the **LAGDISTANCE=** and **MAXLAGS=** options. In principle, these values depend on the amount and spatial distribution of your experimental data.

The value of the **LAGDISTANCE=** option regulates how many pairs of data are contained within each distance class. In effect, this information defines the pairwise distance distribution (see the following subsection). Your choice of **MAXLAGS=** specifies how many of these lags you want to include in the empirical semivariogram computation. Adjusting the values of these parameters is a crucial part of your analysis. Based on your observations sample, they determine whether you have sufficient points for a descriptive empirical semivariogram, and they can affect the accuracy of the estimated semivariance, too.

The simplest way of determining the distribution of pairwise distances is to determine the maximum distance h_{max} between any pair of points in your data, and then to divide this distance by some number N of intervals to produce distance classes of length $\delta = h_{max}/N$. The distance $|P_1 P_2|$ between each pair of points P_1, P_2 is computed, and the pair $P_1 P_2$ is counted in the k th distance class if $|P_1 P_2| \in [(k-1)\delta, k\delta)$ for $k = 1, \dots, N$.

The actual computation is a slight variation of this. A bound, rather than the actual maximum distance, is computed. This bound is the length of the diagonal of a bounding rectangle for the data points. This bounding rectangle is found by using the maximum and minimum x and y coordinates, x_{max} , x_{min} , y_{max} , y_{min} , and forming the rectangle determined by the following points:

$$\begin{array}{cc} (x_{min}, y_{max}) & (x_{max}, y_{max}) \\ (x_{min}, y_{min}) & (x_{max}, y_{min}) \end{array}$$

See Figure 102.24 for an illustration of the bounding rectangle applied to the data of the domain D in Figure 102.19. PROC VARIOGRAM provides you with the sizes of $x_{max} - x_{min}$, $y_{max} - y_{min}$, and h_b . For example, in Figure 102.4 in the preliminary analysis, the specified parameters named “Max Data Distance in East,” “Max Data Distance in North,” and “Max Data Distance” correspond to the lengths $x_{max} - x_{min}$, $y_{max} - y_{min}$, and h_b , respectively.

Figure 102.24 Bounding Rectangle to Determine Maximum Pairwise Distance in Domain D

The pairwise distance bound, denoted by h_b , is given by

$$h_b = \sqrt{(x_{max} - x_{min})^2 + (y_{max} - y_{min})^2}$$

Using h_b , the interval $(0, h_b]$ is divided into $N + 1$ subintervals, where N is the value of the **NHCLASSES=** option specified in the **COMPUTE** statement, or $N = 10$ (default) if the **NHCLASSES=** option is not specified. The basic distance unit is $h_0 = \frac{h_b}{N}$; the distance intervals are centered on $h_0, 2h_0, \dots, Nh_0$, with a distance tolerance of $\pm \frac{h_0}{2}$. The extra subinterval is $(0, h_0/2)$ and corresponds to lag class zero. It is half

the length of the remaining subintervals, and it often contains the smallest number of pairs. Figure 102.22 shows an example where the lag classes correspond to $h_0 = 1$. This method of partitioning the interval $(0, h_b]$ is used in the empirical semivariogram computation.

Choosing the Size of Classes

When you start with a data sample, the VARIOGRAM procedure computes all the distinct point pairs in the sample. The OUTPAIR= output data set, described in the section “OUTPAIR=SAS-data-set” on page 8642, contains information about these pairs. The point pairs are then categorized in classes. The size of each class depends on the common distance that separates consecutive classes. In PROC VARIOGRAM you need to provide this distance value with the LAGDISTANCE= option. Practically, you can define the distance between classes to be about the size of the average sampling distance (Olea 2006).

Under a more scrutinized approach, before you specify a value for the LAGDISTANCE= option, it is helpful to be aware of two issues. First, estimate how many classes of data pairs you might need. Each class contributes one point to the empirical semivariogram. Therefore, you need enough classes for an adequate number of points, so that your empirical semivariogram can suggest a suitable theoretical model shape for the description of the spatial continuity. Second, keep in mind that a larger number of data pairs in a class can contribute to a more accurate estimate of the corresponding semivariogram point.

The first consideration is a more general issue, and both this and the following subsection address it in detail. Based on the second consideration, the class size problem translates into having a sufficient number of data pairs in each class to produce an accurate semivariance estimate. However, only empirical rules of thumb exist to guide you with this choice. Examples of minimum-pairs empirical rules include the suggestion by Journel and Huijbregts (1978, p. 194) to use at least 30 point pairs for each lag class. Also, in a different approach, Chilès and Delfiner (1999, p. 38) increase this number to 50 point pairs.

Obviously, smaller data samples provide fewer data pairs in the sample. According to Olea (2006), it is difficult to properly estimate a semivariogram with fewer than 50 measurements. The preceding minimum-pairs practical rules are useful in cases where small samples are involved. When you work with a relatively small sample, the key is to specify the value of LAGDISTANCE= such that you can strike a balance between the number of the classes you can form and their pairs count. In the coal seam thickness example of the section “Preliminary Spatial Data Analysis” on page 8562, it is not possible to create a desirable large number of classes and maintain an adequate size for each one. On the other hand, there is no practical need to invoke these rules in the case of the much larger sample of ozone concentrations in “Example 102.2: An Anisotropic Case Study with Surface Trend in the Data” on page 8658.

The spatial distribution of the sample might also affect the grouping of pairs into classes. For example, data that are sampled in clusters might prove difficult to classify according to the preceding practical rules. One strategy to address this problem is to accept fewer than 30 pairs for the underpopulated distance classes. Then, at the stage when you determine what theoretical semivariogram model to use, either disregard the corresponding empirical semivariogram points or use them and accept the increased uncertainty.

The VARIOGRAM procedure can help you decide on a suitable class size before you proceed with the empirical semivariogram computation. First, provide a number for the class count by specifying the NHCLASSES= value. Run the procedure with the option NOVARIogram in the COMPUTE statement and examine the distribution data pairs. Use different values of NHCLASSES= to investigate how this parameter affects the data pairs distribution in each distance class. The pairwise distance intervals table (for example, Figure 102.3) shows the number of pairs in each distance class in the “Number of Pairs” column, and you can use the preceding rule of thumb to adjust the NHCLASSES= value accordingly.

PROC VARIOGRAM displays a rounded value of the distance between the lag bounds as the “Lag Distance” parameter in the pairs information table (see Figure 102.5) or the pairwise distances histogram (see Figure 102.4), which you can use for the `LAGDISTANCE=` specification. However, this is only one tool. For the semivariogram computation you can specify your own `LAGDISTANCE=` value based on your experience. Smaller `LAGDISTANCE=` values result in fewer data pairs in the classes. In that sense, you might find smaller values useful when you work with large samples so that you obtain more semivariogram points. Also, if the `LAGDISTANCE=` value is too large, you might end up “wasting” too many point pairs in fewer classes at the expense of computing fewer semivariogram points and no significant accuracy gains in the estimation.

As explained earlier, depending on the sample size and its spatial distribution you might have classes with fewer points than what the practical rules advise. Most commonly, the deficient distance classes are the limiting ones close to the origin $h = 0$ and the most remote ones at large h . The classes near the origin correspond to lags 0 and 1. These lags are crucial because the empirical semivariogram in small distances h characterizes the process smoothness and can help you detect the presence of a nugget effect. However, as discussed in the section “Distance Classification” on page 8619, lag zero is half the size of the rest of the classes by definition, so it can be expected to violate the rule of thumb for the number of pairs in a class.

The classes located at higher and extreme distances within a spatial domain are often not accounted for in the empirical semivariogram. The fewer pairs that can be formed in these distances do not allow for an accurate assessment of the spatial correlation, as is explained in the following section.

Spatial Extent of the Empirical Semivariogram

Given your choice for the `LAGDISTANCE=` value in your spatial domain, the following paragraphs provide guidelines on how many classes to consider when you compute the empirical semivariogram.

Obviously, you want to include no more classes beyond the limit where the pairs count falls below the minimum-pairs empirical rule threshold, as discussed in the preceding subsection. PROC VARIOGRAM provides you with a visual way to inspect this upper limit, if you decide to make use of the minimum-pairs empirical rule. In particular, specify your threshold choice for the minimum pairs per class by using the `THRESHOLD=` parameter for the `PLOTS=PAIRS` option.

Then, the procedure produces in the pairwise distances histogram a reference line at the specified `THRESHOLD=` value, which leaves below the line all lags whose pairs count is lower than the threshold value; see, for example, Figure 102.4. The last lag class whose pair population is above the `THRESHOLD=` value is reported in the pairs information table as “Highest Lag With Pairs > Threshold.” This value is not a recommendation for the `MAXLAGS=` option, but rather is an upper limit for your choice. Detailed information about the pairs count in each class is displayed in the corresponding pairwise distance intervals table, as Figure 102.3 demonstrates.

The preceding suggests that you have an upper limit indication, but you still need some criterion to decide how many lags to include in the semivariogram estimation. The criterion is the extent of spatial dependence in your domain.

Spatial dependence can exist beyond your domain limits. However, you have no data past your domain scale to define a range for larger-scale spatial dependencies. As you look for pairs of data that are gradually farther apart, the number of pairs naturally decreases with distance. The pairs at the more distant classes might be so few that they are likely to be independent with respect to the spatial dependence scale that you can detect. If you include the largest distances in your empirical semivariogram plot, then these pairs only contribute added noise. In the same sense, you cannot explore in detail spatial dependencies in scales

smaller than an average minimum distance between your data. The nugget effect represents then microscale correlations whose effect is evident in your working scale.

You specify the spatial dependence extent with commonly used measures such as the *correlation range* (or *correlation length*) ϵ and the *correlation radius* h_c . Both are defined in a similar manner. The correlation range ϵ is the distance at which the covariance is 5% of its value at $\mathbf{h} = 0$, and shows that beyond ϵ the covariance is considered to be negligible. The correlation radius h_c is the distance at which the covariance is about half the variance at $\mathbf{h} = 0$, and indicates the distance over which significant correlations prevail (Christakos 1992, p. 76). The physical meanings of these measures are similar to that of the semivariogram range. Also, the effective range r_ϵ used in asymptotically increasing semivariance models has essentially the same definition as the correlation range ϵ (see the section “Theoretical Semivariogram Models” on page 8608).

A rough estimate of the correlation extent measures might be available from previous studies of a similar site, or from prior information about related measurements. In such an event, you typically want to consider a maximum pairwise distance that does not exceed the length of two or three correlation radii, or one and a half correlation ranges. You can then specify the **MAXLAGS=** value on the basis of the lags that fit in that distance.

When you have no estimates of correlation extent measures, you can use first use a crude measure to get started with your analysis: you can typically expect **MAXLAGS=** to be about half of the lag classes shown in the pairwise distances histogram.

Then, if necessary, you can refine your **MAXLAGS=** choice by using the following maximum lags rule of thumb: Journel and Huijbregts (1978, p. 194) advise considering lags up to about half of the extreme distance between data in the direction of interest. The VARIOGRAM procedure assists you in this task by providing the overall extreme data distance h_b , in addition to the extreme data distances in the vertical and horizontal axes directions. For example, h_b is reported in the pairs information table as “Maximum Data Distance” (see Figure 102.5), and in the pairwise distances histogram as “Max Data Distance” (see Figure 102.4).

Overall, avoid significant deviations from the maximum lags rule of thumb. As was stated earlier, a **MAXLAGS=** value that takes you well beyond the half-extreme distance between data in a given direction might give you limited accuracy in the empirical semivariance estimates at higher distances. At the other end, a value of **MAXLAGS=** that is too small might lead you to omit important information about the spatial structure that potentially lies within the range of distances you skipped.

Semivariance Computation

With the classification of a point pair $P_i P_j$ into an angle/distance class, as shown earlier in this section, the semivariance computation proceeds as follows.

Denote all pairs that $P_i P_j$ belong to angle class $[\theta_k - \delta\theta_k, \theta_k + \delta\theta_k)$ and distance class $L = L(P_i P_j)$ as $N(\theta_k, L)$. For example, based on Figure 102.20 and Figure 102.21, $P_1 P_2$ belongs to $N(60^\circ, 1)$.

Let $|N(\theta_k, L)|$ denote the *number* of such pairs. The component of the standard (or method of moments) semivariance that correspond to angle/distance class $N(\theta_k, L)$ is given by

$$\hat{\gamma}(h_k) = \frac{1}{2 |N(\theta_k, L)|} \sum_{P_i P_j \in N(\theta_k, L)} [V(s_i) - V(s_j)]^2$$

where h_k is the average distance in class $N(\theta_k, L)$; that is,

$$h_k = \frac{1}{|N(\theta_k, L)|} \sum_{P_i P_j \in N(\theta_k, L)} |P_i P_j|$$

The robust version of the semivariance is given by

$$\bar{\gamma}(h_k) = \frac{\Psi^4(h_k)}{2[0.457 + 0.494/N(\theta_k, L)]}$$

where

$$\Psi(h_k) = \frac{1}{N(\theta_k, L)} \sum_{P_i P_j \in N(\theta_k, L)} [V(s_i) - V(s_j)]^{\frac{1}{2}}$$

This robust version of the semivariance is computed when you specify the **ROBUST** option in the **COMPUTE** statement in PROC VARIOGRAM.

PROC VARIOGRAM computes and writes to the **OUTVAR=** data set the quantities h_k , θ_k , L , $N(\theta_k, L)$, $\hat{\gamma}(h)$, and $\bar{\gamma}(h)$.

Empirical Semivariograms and Surface Trends

It was stressed in the beginning of the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613 that if your data are not free of nonrandom surface trends, then the empirical semivariance $\hat{\gamma}_z(\mathbf{h})$ you obtain from PROC VARIOGRAM represents a pseudo-semivariance rather than an estimate of the theoretical semivariance $\gamma_z(\mathbf{h})$.

In practice, two major difficulties appear. First, you might have no knowledge of underlying surface trends in your SRF $Z(s)$. It can be possible to have this information when you deal with a repetitive phenomenon (Chilès and Delfiner 1999, p. 123), or if you work within a subdomain of a broader region with known characteristics; often, though, this is not the case. Second, even if you suspect the existence of an underlying nonrandom trend, its precise nature might be unknown (Cressie 1993, p. 114, 162).

Based on the last remark, the criteria to define the exact form of a surface trend can be subjective. However, statistical methods can identify the presence and remove an estimate of such a trend. Different trend forms can be estimated in your SRF depending on the trend estimation model that you choose. This choice can lead to different degrees of smoothing in the residual random fluctuations. It might also have an effect on the residuals spatial structure characterization, because trend removals with different models are essentially different operations acting upon the values of your original observations. Following the comment by Chilès and Delfiner (1999, section 2.7.3), there are as many semivariograms of residuals as there are ways of estimating the trend. The same source also examines the introduction of bias in the semivariance of the residuals as a side effect of trend removal processes. This bias is small when you examine distances close to the origin $\mathbf{h} = 0$, and it can increase with distance.

Keeping in mind the preceding remarks, an approach you can take is to use one of the many predictive modeling tools in SAS/STAT software to estimate the unknown trend. Then you use PROC VARIOGRAM to analyze the residuals after you remove the trend. If the resulting model does not require too many degrees of freedom (such as if you use a low-order polynomial), then this approach might be sufficient. The

section “[Analysis with Surface Trend Removal](#)” on page 8662 demonstrates how to use PROC GLM (see Chapter 42, “[The GLM Procedure](#)”) for that purpose.

Apart from the standard semivariogram analysis, you can attempt to fit a theoretical semivariogram model to your empirical semivariogram if (a) either the analysis itself or your knowledge of the SRF does not clearly suggest the presence of any surface trend, or (b) the analysis can indicate a potentially trend-free direction, along which your data have a constant mean.

For example, you might observe overall similar values in your data. This can be an indication that your data are free of nonrandom trends, or that a very mild trend is present. The case falls under the preceding option (a). A very mild trend still allows a good determination of the semivariance at short distances according to Chilès and Delfiner (1999, p. 125), and this can be sufficient for your spatial prediction goal. An analysis of this type is assumed in the section “[Preliminary Spatial Data Analysis](#)” on page 8562.

If you observe similar values locally across a particular direction, this is an instance of option (b). Olea (2006) suggests recognizing a trend-free direction as being perpendicular to the axis of the maximum dip in the values of $Z(s)$. If you suspect that at least one such direction exists for your data, then run PROC VARIOGRAM for a series of directions in the angular vicinity. The trend-free direction, if it exists, coincides with the one whose pseudo-semivariogram exhibits minimal increase with distance; see “[Example 102.3: Analysis without Surface Trend Removal](#)” on page 8672 for a demonstration of this approach. However, you cannot test $Z(s)$ for anisotropy in this case, because you can investigate the semivariogram only in the single trend-free direction (Olea 1999, p. 76). Chilès and Delfiner (1999, section 2.7.4) suggest fitting a theoretical model in a trend-free direction only if the hypothesis of an isotropic semivariogram appears reasonable in your analysis.

As a result, you need to be very cautious when you choose to perform semivariogram analysis on data you have not previously examined for surface trends. In this event, both of the options (a) and (b) that were reviewed in the preceding paragraphs rely mostly on empirical and subjective criteria. As noted in this section, a degree of subjectivity exists in the selection of the surface trend itself. This fact suggests that a significant part of the semivariogram analysis is based on metastatistical decisions and on your understanding of your data and the physical considerations that govern your study. In any case, as shown in the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613, your semivariogram analysis relies fundamentally on the use of trend-free data.

Theoretical Semivariogram Model Fitting

You can choose between two approaches to select a theoretical semivariogram model and fit the empirical semivariance. The first one is manual fitting, in which a theoretical semivariogram model is selected based on visual inspection of the empirical semivariogram. For example, see Hohn (1988, p. 25) and comments from defendants of this approach in Olea (1999, p. 82). The second approach is to perform model fitting in an automated manner. For this task you can use methods such as least squares, maximum likelihood, and robust methods (Cressie 1993, section 2.6).

The VARIOGRAM procedure features automated semivariogram model fitting that uses the weighted least squares (WLS) or the ordinary least squares (OLS) method. Use the **MODEL** statement to request that specific model forms or an array of candidate models be tested for optimal fitting to the empirical semivariance.

Assume that you compute first the empirical semivariance $\gamma_z^*(\mathbf{h})$ at **MAXLAGS**= k distance classes, where $\gamma_z^*(\mathbf{h})$ can be either the classical estimate $\hat{\gamma}_z(\mathbf{h})$ or the robust estimate $\tilde{\gamma}_z(\mathbf{h})$, as shown in the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613. In fitting based on least

squares, you want to estimate the parameters vector θ of the theoretical semivariance $\gamma_z(\mathbf{h})$ that minimizes the sum of square differences $R(\theta)$ given by the expression

$$R(\theta) = \sum_{i=1}^k w_i^2 [\gamma_z^*(\mathbf{h}_i) - \gamma_z(\mathbf{h}_i; \theta)]^2$$

For $i = 1, \dots, k$, the weights are $w_i^2 = 1/\text{Var}[\gamma_z^*(\mathbf{h}_i)]$ in the case of WLS and $w_i^2 = 1$ in the case of OLS. Therefore, the parameters θ are estimated in OLS by minimizing

$$R(\theta)_{OLS} = \sum_{i=1}^k [\gamma_z^*(\mathbf{h}_i) - \gamma_z(\mathbf{h}_i; \theta)]^2$$

For WLS, Cressie (1985) investigated approximations for the variance of both the classical and robust empirical semivariances. Then, under the assumptions of normally distributed observations and uncorrelated squared differences in the empirical semivariance, the approximate weighted least squares estimate of the parameters θ can be obtained by minimizing

$$R(\theta)_{WLS} = \frac{1}{2} \sum_{i=1}^k N(\mathbf{h}_i) \left[\frac{\gamma_z^*(\mathbf{h}_i)}{\gamma_z(\mathbf{h}_i; \theta)} - 1 \right]^2$$

where $N(\mathbf{h}_i)$ is the number of pairs of points in the i th distance lag.

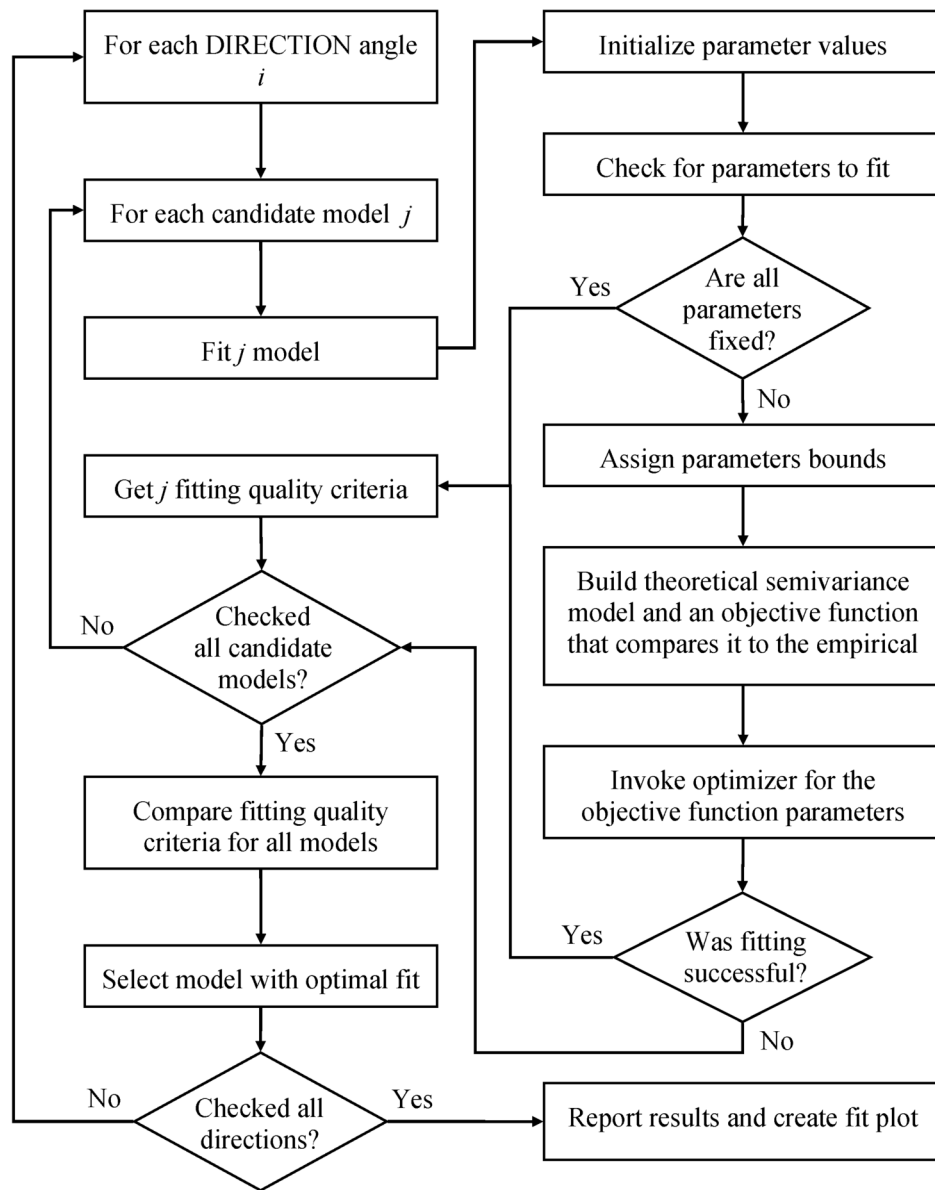

PROC VARIOGRAM relies on nonlinear optimization to minimize the least squares objective function $R(\theta)$. The outcome is the model that best fits the empirical semivariogram according to your criteria. The fitting process flow is displayed in [Figure 102.25](#). Goovaerts (1997, section 4.2.4) suggests that fitting a theoretical model should aim to capture the major spatial features. An accurate fit is desirable, but overfitting does not offer advantages, because you might find yourself trying to model possibly spurious details of the empirical semivariogram. At the same time, it is important to describe the correlation behavior accurately near the semivariogram origin. As pointed out by Chilès and Delfiner (1999, pp. 104–105), a poor description of spatial continuity at small lags can lead to loss of optimality in kriging predictions and erroneous reproduction of the variability in conditional simulations.

The significance of achieving better accuracy near the semivariogram origin is an advantage of the WLS method compared to OLS. In particular, the semivariance variance decreases when you get closer the origin $\mathbf{h} = 0$, as suggested in the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613. The WLS weights are expressed as the inverse of this variance; as a result, WLS fitting is more accurate for distances \mathbf{h} near the semivariogram origin. In contrast, the OLS approach performs a least squares overall best fit because it assumes constant variance at all distances \mathbf{h} . Another advantage of WLS over OLS is that OLS falsely assumes that the differences in the optimization process are normally distributed and independent. However, WLS has the disadvantage that the weights depend on the fitting parameters.

Depending on your application, you can use WLS or OLS with PROC VARIOGRAM to fit classical semivariance. Other fitting methods include maximum likelihood approaches that rely crucially on the normality assumption for the data distribution, and the generalized least squares method that offers better accuracy but is computationally more demanding. You can find extensive discussions about these issues in Cressie (1993, section 2.3), Jian, Olea, and Yu (1996), Stein (1988), and Schabenberger and Gotway (2005).

The sections “[Parameter Initialization](#)” on page 8630 and “[Quality of Fit](#)” on page 8632 provide details and insight about semivariogram fitting, in addition to ways to cope with poor fits or no fit at all. These strategies can help you reach a meaningful description of spatial correlation in your problem.

Figure 102.25 Semivariogram Fitting Process Flowchart

Parameter Initialization

An important stage when you prepare for the model fitting process is initialization of the model parameters. As stated earlier, nonlinear optimization techniques are used in the fitting process. These techniques assist in the estimation of the model parameters, and being nonlinear means they can be very sensitive to selection of the initial values.

You can specify initial values close to the expected estimates when you have a relatively simple problem, such as in the example of the section “[Getting Started: VARIOGRAM Procedure](#)” on page 8561. In the case of nested models the selection of initial values can be more challenging because you have to assess the level of contribution for each one of the nested components.

The VARIOGRAM procedure features automatic selection of initial values based on the recommendations in Jian, Olea, and Yu (1996). Specifically, if you compute the estimated empirical semivariogram $\hat{\gamma}_z(\mathbf{h})$ at k lags, then:

- The default initial nugget effect $c_{n,0}$ is

$$c_{n,0} = \text{Max} \left[0, \hat{\gamma}_z(\mathbf{h}_1) - \frac{\mathbf{h}_1}{\mathbf{h}_2 - \mathbf{h}_1} [\hat{\gamma}_z(\mathbf{h}_2) - \hat{\gamma}_z(\mathbf{h}_1)] \right]$$

- The default initial slope $\sigma_{0,0}^2$ and initial exponent $a_{0,0}$ for the power model are

$$\sigma_{0,0}^2 = \frac{[\hat{\gamma}_z(\mathbf{h}_{k-2}) + \hat{\gamma}_z(\mathbf{h}_{k-1}) + \hat{\gamma}_z(\mathbf{h}_k)] / 3 - c_{n,0}}{\mathbf{h}_k - \mathbf{h}_1}$$

$$a_{0,0} = 1$$

- The default initial scale $\sigma_{0,0}^2$ and initial range $a_{0,0}$ for all other models are

$$\sigma_{0,0}^2 = \frac{[\hat{\gamma}_z(\mathbf{h}_{k-2}) + \hat{\gamma}_z(\mathbf{h}_{k-1}) + \hat{\gamma}_z(\mathbf{h}_k)]}{3} - c_{n,0}$$

$$a_{0,0} = 0.5\mathbf{h}_k$$

When you use the Matérn form, PROC VARIOGRAM sets the default initial value for the Matérn smoothness to $\nu_0 = 1$.

These rules are observed in the case of single, non-nested model fitting, and they are slightly modified to apply for nested model fitting as follows: Assume that you want to fit a nested model composed of m structures. As stated in the section “[Nested Models](#)” on page 8613, the nugget effect is a single parameter and is independent of the number of nested structures in a model. Also, the sum of the nested structure scales and the nugget effect, if any, must be equal to the total variance. For this reason, PROC VARIOGRAM simply divides the initial scale value it would assign to a non-nested model into m components $\sigma_{0,0,1}^2, \dots, \sigma_{0,0,m}^2$. For the range parameter, the VARIOGRAM procedure sets the initial range $a_{0,0,1}$ of the first nested structure equal to the value it would assign to a non-nested model initial range. Then, the initial range $a_{0,0,m}$ of the m -component is set recursively to half the value of the initial range $a_{0,0,m-1}$ of the $(m-1)$ -component.

Your empirical semivariogram must have nonmissing estimates at least at three lags so that you can use the automated fitting feature in PROC VARIOGRAM. Overall, if you specify a model form with q parameters to fit to an empirical semivariogram with nonmissing estimates at k lags, then the fitting problem is well-defined only when the degrees of freedom are $DF = k - q \geq 0$.

A potential numerical issue is that fitting could momentarily lead the fitting parameters to near-zero semivariance values at lags away from zero distance. The theoretical semivariance is always positive for any distance larger than zero, and this is also a requirement for the numerical computation of $R(\theta)_{WLS}$ in weighted least squares fitting. Such numerical issues are unlikely but possible, depending on the data set you use and the parameter initial values. If an event of nonpositive semivariance at a given lag occurs during an iteration, then PROC VARIOGRAM transparently adds a minimal amount of variance at that lag for the specific iteration. You can control this amount of variance with the `NEPSILON=` option of the `MODEL` statement. It is recommended that you leave this parameter at its default value.

The section concludes with a reminder of the fitting process sensitivity to the initial parameter values selection. The VARIOGRAM procedure facilitates this selection for you by using the simple rules shown earlier. However, the suggested initial values might not always be the best choice. In simple cases, such as the introductory example in the section “Getting Started: VARIOGRAM Procedure” on page 8561, this approach is very convenient and effective.

In principle, you are strongly encouraged to experiment with initial values. You want to make sure that the fitting process leads the model parameters to converge to estimates that make sense for your problem. When a parameter estimate seems unreasonable on the basis of your problem specification (for example, a model scale might be estimated to be 10 times the size of your sample variance, or the estimate of a range might be zero), PROC VARIOGRAM produces a note to let you know about a potentially ambiguous fit. These issues are examined in more detail in the section “Quality of Fit” on page 8632.

Parameter Estimates

When the fit process is complete, the VARIOGRAM procedure produces the “Parameter Estimates” table with information about the fitted model parameters. The table includes estimates of the parameters, their approximate standard error, the statistical degrees of freedom DF, the corresponding t statistic, and its approximate p -value. For a model with q parameters that fits an empirical semivariogram of k nonmissing lags, $DF = k - q$.

NOTE: Parameter estimates might have nonzero standard errors even in the rather extreme case where $DF = 0$. This can typically occur when there are active optimization constraints in the fitting process.

You can request the confidence intervals for the parameter estimates of a fitted model by specifying the `CL` option of the `MODEL` statement. These confidence intervals are computed using the Wald-based formula

$$\hat{\beta}_i \pm \text{stderr}_i \times t(k - q, 1 - \alpha/2)$$

where $\hat{\beta}_i$ is the i th parameter estimate, stderr_i is its estimated approximate standard error, $t(k - q, 1 - \alpha/2)$ is the t statistic with $DF = k - q$ degrees of freedom. The confidence intervals are only asymptotically valid. The significance level α used in the construction of these confidence limits can be set with the `ALPHA=` option of the `MODEL` statement; the default value is $\alpha = 0.05$.

Specify the `COVB` and the `CORRB` options in the `MODEL` statement to request the approximate covariance and approximate correlation matrices of the fitted parameters, respectively. These matrices are based on the optimization process results. In agreement with reporting similar optimization output in SAS/STAT software, parameters with active restraints have zeros in the corresponding rows and columns in the covariance and correlation matrices, and display 1 in the correlation matrix diagonal.

Quality of Fit

The VARIOGRAM procedure produces a fit summary table to report about the goodness of fit. When you specify multiple models to fit with the **FORM=**[AUTO](#) option in the **MODEL** statement, the VARIOGRAM procedure uses two processes to rank the fitted models: The first one depends on your choice among available fitting criteria. The second one is based on an operational classification of equivalent models in classes. The two processes are described in more detail in the following subsections.

Overall, no absolutely correct way exists to rank and classify multiple models. Your choice of ranking criteria could depend on your study specifications, physical considerations, or even your personal assessment of fitting performance. The VARIOGRAM procedure provides you with fitting and comparison features to facilitate and help you better understand the fitting process.

Fitting Criteria

The fit summary table ranks multiple models on the basis of one or more fitting criteria that you can specify with the **CHOOSE=** option of the **MODEL** statement, as explained in the section “[Syntax: VARIOGRAM Procedure](#)” on page 8576. Currently, the VARIOGRAM procedure offers two numerical criteria (for which a smaller value indicates a better fit) and a qualitative criterion:

- The residual sum of squares error (SSE) is based on the objective function of the fitting process. When the specified method is weighted least squares, the sum of squares of the weighted differences (WSSE) is computed according to the expression

$$\text{WSSE} = \sum_{i=1}^k w_i^2 [\gamma_z^*(\mathbf{h}_i) - \gamma_z(\mathbf{h}_i; \boldsymbol{\theta})]^2$$

where $\gamma_z^*(\mathbf{h}_i)$ can be either the classical or robust semivariance estimate of the theoretical semivariance $\gamma_z(\mathbf{h}_i; \boldsymbol{\theta})$ at the i th lag and the weights w_i^2 are taken at lags $i = 1, \dots, k$. When you specify the **METHOD=**[OLS](#) option in the **MODEL**, the weights $w_i^2 = 1$ for $i = 1, \dots, k$, and the SSE is expressed as

$$\text{SSE} = \sum_{i=1}^k [\gamma_z^*(\mathbf{h}_i) - \gamma_z(\mathbf{h}_i; \boldsymbol{\theta})]^2$$

- Akaike’s information criterion (AIC) is included in the fit summary table when there is at least one nonfixed parameter. In its strict definition, AIC assumes that the model errors are normally and independently distributed. This assumption is not correct in the semivariance fitting analysis. However, the AIC can be also defined in an operational manner on the basis of the weighted squared error sum WSSE as

$$\text{AIC} = k \ln \left(\frac{\text{WSSE}}{k} \right) + 2q$$

for k lags and q model parameters; see, for example, Olea (1999, p. 84). The operational definition of the AIC is provided as an additional criterion for the comparison of fitted models in PROC VARIOGRAM.

The AIC expression suggests that when you specify multiple models with the **FORM=**[AUTO](#) option in the **MODEL** statement, all models with the same number of parameters are ranked in the same way by the AIC and the WSSE criteria. Among models with the same WSSE value, AIC ranks higher the ones with fewer parameters.

- The third qualitative criterion enables you to classify multiple models based on their convergence status. A model is sent to the bottom of the ranking table if the parameter estimation optimization fails to converge or fitting is unsuccessful due to any other issue. These two cases are distinguished by the different notes they produce in the fit summary ODS table. If you specify the [STORE](#) statement to save the fitting output in an item store, then models that have failed to fit are not passed to the item store.

With respect to convergence status, PROC VARIOGRAM ranks higher those models that have successfully completed the fitting process. It might occur that the selection of parameter initial values, physical considerations about the forms that are used for the fit, or numerical aspects of the nonlinear optimization could result in ambiguous fits. For example, you might see that model parameters converge at or near their boundary values, or that parameters have unreasonably high estimates when compared to the empirical semivariogram characteristics. Then, the fit summary table designates such fits as questionable.

You might not need to take any action if you are satisfied with the fitting results and the selected model. You can investigate questionable fits in one or more of the following ways:

- If a form in a nested model makes no contribution to the model due to a parameter at or near its boundary value, then you could have a case of a degenerate fit. When you fit multiple models, a model with degenerate fit can collapse to the more simple model that does not include the noncontributing form. The VARIOGRAM procedure includes in its fit summary all models that are successfully fit. In such cases you can ignore degenerate fits. You can also try subsequent fits of individual models and exclude noncontributing forms or use different initial values.
- Unreasonably low or high parameter estimates might be an indication that the current initial values are not a good guess for the nonlinear optimizer. In most cases, fitting an empirical semivariogram gives you the advantage of a fair understanding about the value range of your parameters. Then, you can use the [PARMS](#) statement to specify a different set of initial values and try the fit again.
- Try replacing the problematic form with another one. A clear example is that you can expect a very poor fit if you specify an exponential model to fit an empirical semivariogram that suggests linear behavior.

Eventually, if none of the aforementioned issues exist, then a model is ranked in the highest positions of the fit summary table. You can combine two or more of the fitting criteria to manage classification of multiple fitted models in a more detailed manner.

In some cases you might still experience a poor quality of fit or no fit at all. If none of the earlier suggestions results in a satisfactory fit, then you could decide to re-estimate the empirical semivariogram for your same input data. The following actions can produce different empirical semivariograms to fit a theoretical model to:

- If you compute the semivariogram for different angles and you experience optimization failures, try specifying explicitly the same direction angles with different tolerance or bandwidth value in the [DIRECTIONS](#) statement.
- Modify slightly the [LAGDISTANCE=](#) option in the [COMPUTE](#) statement to obtain a different empirical semivariogram.

Finally, it is possible to have models in the fitting summary table ranked in a way that seemingly contradicts the specification in the **CHOOSE=** option of the **MODEL** statement. Consider an example with the default behavior **CHOOSE=(SSE AIC)**, where you might observe that models have the same SSE values but are not ranked further as expected by the AIC criterion. A closer examination of such cases typically reduces this issue to a matter of the accuracy shown in the table. That is, the displayed accuracy of the SSE values might hide additional decimal digits that justify the given ranking.

In such scenarios, discrimination of models at the limits of numerical accuracy might suggest that you choose a model of questionable fit or a nested structure over a more simple one. You can then review the candidate models and exercise your judgment to select the model that works best for you. If all values of a criterion are equal, then the ranking order is simply the order in which models are examined unless more criteria follow that can affect the ranking.

Classes of Equivalence

The fit summary that is produced after fitting multiple models further categorizes the ranked models in classes of equivalence. Equivalence classification is an additional investigation that is unrelated to the ranking criteria presented in the previous subsection; it is an operational criterion that provides you with a qualitative overview of multiple model fit performance under given fitting conditions.

To examine model equivalence, the VARIOGRAM procedure computes the semivariances for each one of the fitted models at a set of distances. For any pair of consecutively ranked models, if the sum of their semivariance absolute differences at all designated distances is smaller than the tolerance specified by the **EQUIVTOL=** parameter, then the two models are deemed equivalent and placed in the same class; otherwise, they are placed in different classes. Equivalence classification depends on the existing ranking; hence the resulting classes can differ when you specify different ranking criteria in the **CHOOSE=** option of the **MODEL** statement.

The equivalence class numbers start at 1 for the top-ranked model in the fit summary table. You can consider the top model of each equivalence class to be a representative of the class behavior. When you specify that fit plots be produced and there are equivalence classes, the plot displays the equivalence classes and the legend designates each one by its representative model.

Consequently, if an equivalence class contains multiple members after a fit, then all of its members produce in general the exact same semivariogram. A typical reason could be that the fitting process estimates of scale parameters are at or close to their zero boundaries in one or more nested forms in a model. In such cases, the behavior of this model reduces to the behavior of its nested components with nonzero parameters. When one or more models share this situation or have the same contributing nested forms, they could end up as members of the same equivalence class depending on the ranking criteria.

It is not necessary for all models in the same equivalence class to produce the exact same semivariogram. If a fit of two obviously different forms involves semivariance values that are small enough for the equivalence criterion to be satisfied by the default value of the **EQUIVTOL=** option, then you might need to specify an even smaller value in the **EQUIVTOL=** option to rank these two models in separate equivalence classes.

Fitting with Matérn Forms

When you use a Matérn form in the fitting process, it is possible that the fitting optimizer might encounter numerical difficulties if it tries to push the smoothing parameter ν towards increasingly high values. The VARIOGRAM procedure addresses this issue by imposing an amply elevated upper bound of 1,000,000 on the smoothness values it processes. The section “[Characteristics of Semivariogram Models](#)” on page 8609

mentions that $\nu \rightarrow \infty$ gives the Gaussian model. In the scenario of progressively increasing smoothness values, PROC VARIOGRAM acknowledges that the Matérn form behavior tends asymptotically to become Gaussian and replaces automatically the Matérn with a Gaussian form in the model. Subsequently, fitting resumes with the resulting model.

If you explore fitting of multiple models, then any duplicate models that might occur due to Matérn-to-Gaussian form conversions are fitted only once. Also, if a nested model has more than one Matérn form, then the fitting process checks one of them at a time about whether they need to be replaced by a Gaussian form. Consequently, following the switch of one Matérn form, the fitting process starts anew with the resulting model before any decisions for additional form conversions are made.

Replacement of the Matérn form with the Gaussian form occurs by default when $\nu > 10,000$. However, you can control this threshold value with the `MTOGTOL=` parameter of the `MODEL` statement. Practically, the Matérn form starts to resemble the Gaussian behavior for ν values that are about $\nu > 10$. If you encounter such conversions of the Matérn form into Gaussian and you prefer to set a lower ν threshold for the conversion than the default, you might experience improved code performance because computation of the Matérn semivariance can be numerically demanding.

Autocorrelation Statistics

Spatial autocorrelation measures offer you additional insight into the interdependence of spatial data. These measures quantify the correlation of an SRF $Z(s)$ with itself at different locations, and they can be very useful whether you have information at exact locations (point-referenced data) or measurements that characterize an area type such as counties, census tracts, zip codes, and so on (areal data).

As in the semivariogram computation, a key issue for the autocorrelation statistics is that you work with a set z_i of measurements, $i = 1, \dots, n$, that are free of nonrandom surface trends and have a constant mean.

Autocorrelation Weights

In general, the choice of a weighting scheme is subjective. You can obtain different results by using different schemes, options, and parameters. PROC VARIOGRAM offers you considerable flexibility in choosing weights that are appropriate for prior considerations such as different hypotheses about neighboring areas, definition of the neighborhood structure, and accounting for natural barriers or other spatial characteristics; see the discussion in Cliff and Ord (1981, p. 17). As stressed for all types of spatial analysis, it is important to have good knowledge of your data. In the autocorrelation statistics, this knowledge can help you avoid spurious correlations when you choose the weights.

The starting point is to assign individual weights to each one of the n data values z_i , $i = 1, \dots, n$, with respect to the rest. An $n \times n$ matrix of weights is thus defined, such that for any two locations s_i and s_j , the weight w_{ij} denotes the effect of the value z_i at location s_i on the value z_j at location s_j . Depending on the nature of your study, the weights w_{ij} need not be symmetric; that is, it can be true that $w_{ij} \neq w_{ji}$.

Binary and Nonbinary Weights

The weights w_{ij} can be either binary or nonbinary values. Binary values of 1 or 0 are assigned if the SRF $Z(s_i)$ at one location s_i is deemed to be connected or not, respectively, to its value $Z(s_j)$ at another location s_j . Nonbinary values can be used in the presence of more refined measures of connectivity between any two data points P_i and P_j . PROC VARIOGRAM offers a choice between a binary and a distance-based nonbinary weighting scheme.

In the binary weighting scheme the weight $w_{ij} = 1$ if the data pair at s_i and s_j is closer than the user-defined distance that is defined by the **LAGDISTANCE=** option, and $w_{ij} = 0$ if $i = j$ or in any other case. For that reason, in the **COMPUTE** statement, if you specify the **WEIGHTS=BINARY** suboption of the **AUTOCORRELATION** option when the **NOVARIOGRAM** option is also specified, then you must also specify the **LAGDISTANCE=** option.

The nonbinary weighting scheme is based on the pair distances and is invoked with the **WEIGHTS=DISTANCE** suboption of the **AUTOCORRELATION** option. PROC VARIOGRAM uses a variation of the Pareto form functional to set the weights. Namely, the autocorrelation weight for every point pair P_i and P_j located at s_i and s_j , respectively, is defined as

$$w_{ij} = s \frac{1}{1 + |\mathbf{h}|^p}$$

where $\mathbf{h} = s_i - s_j$ and $p \geq 0$ and $s \geq 0$ are user-defined parameters for the adjustment of the weights.

In particular, the power parameter p is specified in the **POWER=** option of the **DISTANCE** suboption within the **AUTOCORRELATION** option. The default value for this parameter is $p = 1$. Also, the scaling parameter s is specified by the **SCALE=** option in the **DISTANCE** suboption of the **AUTOCORRELATION** option. The default value for the scaling parameter is $s = 1$. You can use the p and s parameters to adjust the actual values of the weights according to your needs. Variations in the scaling parameter s do not affect the computed values of the Moran's I and Geary's c autocorrelation coefficients that are introduced in the section “Autocorrelation Statistics Types” on page 8637.

Nonbinary Weights with Normalized Distances

PROC VARIOGRAM offers additional flexibility in the **DISTANCE** weighting scheme through an option to use normalized pair distances. You can invoke this feature by specifying the **NORMALIZE** option in the **DISTANCE** suboption of the **AUTOCORRELATION** option. In this case, the distances used in the definition of the weights are normalized by the maximum pairwise distance h_b (see the section “Computation of the Distribution Distance Classes” on page 8621 and Figure 102.24); the weights are then defined as $w_{ij} = s/[1 + (|\mathbf{h}|/h_b)^p]$.

Most likely, h_b has a different value for different data sets. Hence, it is suggested that you avoid using the weights you obtain from the preceding equation and one data set for comparisons with the weights you derive from different data sets.

Symmetric and Asymmetric Weights

The weighting schemes presented in the preceding paragraphs are symmetric; that is, $w_{ij} = w_{ji}$ for every data pair at locations s_i and s_j . However, you can also define asymmetric weights w'_{ij} such that

$$\sum_{j \in J} w'_{ij} = 1$$

for $i = 1, 2, \dots, n$, where $w'_{ij} = w_{ij} / \sum_{j \in J} w_{ij}$, $i = 1, 2, \dots, n$. In the distance-based scheme, J is the set of all locations that form point pairs with the point at s_i . In the binary scheme, J is the set of the locations that are connected to s_i based on your selection of the **LAGDISTANCE=** option; see Cliff and Ord (1981, p. 18). The weights w'_{ij} are *row-averaged* (or *standardized* by the count of their connected neighbors). You can apply row averaging in weights when you specify the **ROWAVG** option within either the **BINARY** or **DISTANCE** suboptions in the **AUTOCORRELATION** option.

Autocorrelation Statistics Types

One measure of spatial autocorrelation provided by PROC VARIOGRAM is Moran's I statistic, which was introduced by Moran (1950) and is defined as

$$I = \frac{n}{(n-1)S^2W} \sum_i \sum_j w_{ij} v_i v_j$$

where $S^2 = (n-1)^{-1} \sum_i v_i^2$, and $W = \sum_i \sum_{j \neq i} w_{ij}$.

Another measure of spatial autocorrelation in PROC VARIOGRAM is Geary's c statistic (Geary 1954), defined as

$$c = \frac{1}{2S^2W} \sum_i \sum_j w_{ij} (z_i - z_j)^2$$

These expressions indicate that Moran's I coefficient makes use of the centered variable, whereas the Geary's c expression uses the noncentered values in the summation.

Inference on these two statistic types comes from approximate tests based on the asymptotic distribution of I and c , which both tend to a normal distribution as n increases. To this end, PROC VARIOGRAM calculates the means and variances of I and c . The outcome depends on the assumption made regarding the distribution $Z(s)$. In particular, you can choose to investigate any of the statistics under the *normality* (also known as *Gaussianity*) or the *randomization* assumption. Cliff and Ord (1981) provided the equations for the means and variances of the I and c distributions, as described in the following.

The normality assumption asserts that the random field $Z(s)$ follows a normal distribution of constant mean (\bar{Z}) and variance, from which the z_i values are drawn. In this case, the I statistics yield

$$E_g[I] = -\frac{1}{n-1}$$

and

$$E_g[I^2] = \frac{1}{(n+1)(n-1)W^2} (n^2 S_1 - n S_2 + 3W^2)$$

where $S_1 = 0.5 \sum_i \sum_{j \neq i} (w_{ij} + w_{ji})^2$ and $S_2 = \sum_i (\sum_j w_{ij} + \sum_j w_{ji})^2$. The corresponding moments for the c statistics are

$$E_g[c] = 1$$

and

$$\text{Var}_g[c] = \frac{(2S_1 + S_2)(n-1) - 4W^2}{2(n+1)W^2}$$

According to the randomization assumption, the I and c observations are considered in relation to all the different values that I and c could take, respectively, if the n z_i values were repeatedly randomly permuted around the domain D . The moments for the I statistics are now

$$E_r[I] = -\frac{1}{n-1}$$

and

$$E_r[I^2] = \frac{A_1 + A_2}{(n-1)(n-2)(n-3)W^2}$$

where $A_1 = n[(n^2 - 3n + 3)S_1 - nS_2 + 3W^2]$, $A_2 = -b_2[n(n-1)S_1 - 2nS_2 + 6W^2]$. The factor $b_2 = m_4/(m_2^2)$ is the coefficient of kurtosis that uses the sample moments $m_k = \frac{1}{n} \sum_i v_i^k$ for $k = 2, 4$. Finally, the c statistics under the randomization assumption are given by

$$E_r[c] = 1$$

and

$$\text{Var}_r[c] = \frac{B_1 + B_2 + B_3}{n(n-2)(n-3)W^2}$$

with $B_1 = (n-1)S_1[n^2 - 3n + 3 - (n-1)b_2]$, $B_2 = -\frac{1}{4}(n-1)S_2[n^2 + 3n - 6 - (n^2 - n + 2)b_2]$, and $B_3 = W^2[n^2 - 3 - b_2(n-1)^2]$.

If you specify `LAGDISTANCE=` to be larger than the maximum data distance in your domain, the binary weighting scheme used by the VARIOGRAM procedure leads to all weights $w_{ij} = 1$, $i \neq j$. In this extreme case the preceding definitions can show that the variances of the I and c statistics become zero under either the normality or the randomization assumption.

A similar effect might occur when you have collocated observations (see the section “[Pair Formation](#)” on page 8616). The Moran’s I and Geary’s c statistics allow for the inclusion of such pairs in the computations. Hence, contrary to the semivariance analysis, PROC VARIOGRAM does not exclude pairs of collocated data from the autocorrelation statistics.

Interpretation

For Moran’s I coefficient, $I > E[I]$ indicates positive autocorrelation. Positive autocorrelation suggests that neighboring values s_i and s_j tend to have similar feature values z_i and z_j , respectively. When $I < E[I]$, this is a sign of negative autocorrelation, or dissimilar values at neighboring locations. A measure of strength of the autocorrelation is the size of the absolute difference $|I - E[I]|$.

Geary’s c coefficient interpretation is analogous to that of Moran’s I . The only difference is that $c > E[c]$ indicates negative autocorrelation and dissimilarity, whereas $c < E[c]$ signifies positive autocorrelation and similarity of values.

The VARIOGRAM procedure uses the mathematical definitions in the preceding section to provide the observed and expected values, and the standard deviation of the autocorrelation coefficients in the autocorrelation statistics table. The Z scores for each type of statistics are computed as

$$Z_I = \frac{I - E[I]}{\sqrt{\text{Var}[I]}}$$

for Moran’s I coefficient, and

$$Z_c = \frac{c - E[c]}{\sqrt{\text{Var}[c]}}$$

for Geary's c coefficient. PROC VARIOGRAM also reports the two-sided p -value for each coefficient under the null hypothesis that the sample values are not autocorrelated. Smaller p -values correspond to stronger autocorrelation for both the I and c statistics. However, the p -value does not tell you whether the autocorrelation is positive or negative. Based on the preceding remarks, you have positive autocorrelation when $Z_I > 0$ or $Z_c < 0$, and you have negative autocorrelation when $Z_I < 0$ or $Z_c > 0$.

The Moran Scatter Plot

The Moran scatter plot (Anselin 1996) is a useful visual tool for exploratory analysis, because it enables you to assess how similar an observed value is to its neighboring observations. Its horizontal axis is based on the values of the observations and is also known as the response axis. The vertical Y axis is based on the weighted average or spatial lag of the corresponding observation on the horizontal X axis. **NOTE:** The term *spatial lag* in the current context is unrelated to the concept of the semivariogram lag presented in the section “[Distance Classification](#)” on page 8619.

The Moran scatter plot provides a visual representation of spatial associations in the neighborhood around each observation. You specify a neighborhood size with the `LAGDISTANCE=` option in the `COMPUTE` statement. The observations are represented by their standardized values; therefore only nonmissing observations are shown in the plot. For each one of those, the VARIOGRAM procedure computes the weighted average, which is the weighted mean value of its neighbors. Then, the centered weighted average is plotted against the standardized observations. As a result, the scatter plot is centered on the coordinates (0, 0), and distances in the plot are expressed in deviations from the origin (0, 0).

Depending on their position on the plot, the Moran plot data points express the level of spatial association of each observation with its neighboring ones. Conceptually, these characteristics differentiate the Moran plot from the semivariogram. The latter is typically used in geostatistics to depict spatial associations across the whole domain as a continuous function of a distance metric.

You can find the data points on the Moran scatter plot in any of the four quadrants defined by the horizontal line $y = 0$ and the vertical line $x = 0$. Points in the upper right (or high-high) and lower left (or low-low) quadrants indicate positive spatial association of values that are higher and lower than the sample mean, respectively. The lower right (or high-low) and upper left (or low-high) quadrants include observations that exhibit negative spatial association; that is, these observed values carry little similarity to their neighboring ones.

When you use binary, row-averaged weights for the creation of the Moran scatter plot and in autocorrelation statistics, Moran's I coefficient is equivalent to the regression slope of the Moran scatter plot. That is, when you specify

```
PLOTS=MORAN (ROWAVG=ON)
```

in the `PROC VARIOGRAM` statement and

```
AUTOCORR (WEIGHTS=BINARY (ROWAVERAGING) )
```

in the `COMPUTE` statement, then the regression line slope of the Moran scatter plot is the Moran's I coefficient shown in the section “[Autocorrelation Statistics Types](#)” on page 8637. In this sense, the Moran's I coefficient has a global character, whereas the Moran scatter plot provides you with a more detailed exploratory view of the autocorrelation behavior of the individual observations.

This detailed view can reveal outliers with respect to the regression line slope of the Moran scatter plot. Outliers, if present, can function as leverage points that affect the value of Moran's I coefficient. As noted by Anselin (1996), such extremes indicate local instability in spatial association. This instability can be caused either by problems with the autocorrelation weights matrix or by fine-scale characteristics of the spatial structure, which are beneath the current observation structure.

Computational Resources

The fundamental computation of the VARIOGRAM procedure is binning: for each pair of observations in the input data set, a distance class and an angle class are determined and recorded. Let N_d denote the number of distance classes, N_a denote the number of angle classes, and N_v denote the number of VAR variables. The memory requirements for these operations are proportional to $N_d \times N_a \times N_v$. This is typically small.

The CPU time required for the computations is proportional to the number of pairs of observations, or to $N^2 \times N_v$, where N is the number of observations in the input data set.

Output Data Sets

The VARIOGRAM procedure produces four data sets: the OUTACWEIGHTS=*SAS-data-set*, the OUTDIST=*SAS-data-set*, the OUTPAIR=*SAS-data-set*, and the OUTVAR=*SAS-data-set*. These data sets are described in the following sections.

OUTACWEIGHTS=*SAS-data-set*

The OUTACWEIGHTS= data set contains one observation for each pair of points P_1, P_2 in the original data set, where P_1 is different from P_2 , with information about the data distance and autocorrelation weight of each point pair.

The OUTACWEIGHTS= data set can be very large, even for a moderately sized DATA= data set. For example, if the DATA= data set has NOBS=500, then the OUTACWEIGHTS= data set has $\text{NOBS}(\text{NOBS} - 1)/2 = 124,750$ observations.

When you perform autocorrelation computations, the OUTACWEIGHTS= data set is a practical way to save the autocorrelation weights for further use.

The OUTACWEIGHTS= data set contains the following variables:

- ACWGHT12, the autocorrelation weight for the pair P_1, P_2
- ACWGHT21, the autocorrelation weight for the pair P_2, P_1
- DISTANCE, the distance between the data in the pair
- ID1, the ID variable value or observation number for the first point in the pair
- ID2, the ID variable value or observation number for the second point in the pair
- V1, the variable value for the first point in the pair
- V2, the variable value for the second point in the pair

- VARNAME, the variable name for the current VAR variable
- X1, the x coordinate of the first point in the pair
- X2, the x coordinate of the second point in the pair
- Y1, the y coordinate of the first point in the pair
- Y2, the y coordinate of the second point in the pair

When the autocorrelation weights are symmetric, the pair P_1, P_2 has the same weight as the pair P_2, P_1 . For this reason, in the case of symmetric weights the OUTACWEIGHTS= data set contains only the autocorrelation weights ACWGHT12.

If no ID statement is specified, then the corresponding observation number is assigned to each one of the variables ID1 and ID2, instead.

OUTDIST=SAS-data-set

The OUTDIST= data set contains counts for a modified histogram that shows the distribution of pairwise distances. This data set provides you with information related to the choice of values for the LAGDISTANCE= option in the COMPUTE statement.

To request an OUTDIST= data set, specify the OUTDIST= data set in the PROC VARIOGRAM statement and the NOVARIOGRAM option in the COMPUTE statement. The NOVARIOGRAM option prevents any semivariogram or covariance computation from being performed.

The following variables are written to the OUTDIST= data set:

- COUNT, the number of pairs that fall into this lag class
- LAG, the lag class value
- LB, the lower bound of the lag class interval
- UB, the upper bound of the lag class interval
- PER, the percent of all pairs that fall in this lag class
- VARNAME, the name of the current VAR variable

OUTMORAN=SAS-data-set

The OUTMORAN= data set contains the standardized value (or response) of each observation and the weighted average of its N neighbors, based on a neighborhood within a LAGDISTANCE= distance from the observation. To request this data set, specify the OUTMORAN= data set in the PROC VARIOGRAM statement, in addition to the AUTOCORRELATION and LAGDISTANCE= options in the COMPUTE statement.

The following variables are written to the OUTMORAN= data set:

- DISTANCE, the value of the neighborhood radius, which is specified with the LAGDISTANCE= option
- ID, the ID variable value or observation number for the current observation
- N, the number of neighbors within the specified DISTANCE from the current observation
- RESPONSE, the standardized value of the current observation
- STDWAVG, the standardized weighted average of the neighbors for the current observation
- V, the variable value of the current observation
- VARNAME, the variable name for the current VAR variable
- X, the x coordinate of the current observation
- Y, the y coordinate of the current observation
- WAVG, the weighted average of the neighbors for the current observation

For zero neighbors in the neighborhood of a nonmissing observation, the corresponding value of the variable N=0 and the variables STDWAVG and WAVG are assigned missing values. Observations with missing values are included in the OUTMORAN= data set if they have neighbors and only if nonmissing observations with neighbors also exist in the same data set.

OUTPAIR=SAS-data-set

When you specify the NOVARIOGRAM option in the COMPUTE statement, the OUTPAIR= data set contains one observation for each distinct pair of points P_1, P_2 in the original data set. Otherwise, the OUTPAIR= data set might have fewer observations, depending on the values you specify in the LAGDISTANCE= and MAXLAGS= options and whether you specify the OUTPDISTANCE= option in the COMPUTE statement.

If the NOVARIOGRAM option is not specified in the COMPUTE statement, then the OUTPAIR= data set contains one observation for each distinct pair of points that are up to a distance within MAXLAGS= away from each other. If you also specify the OUTPDISTANCE= D_{max} option in the COMPUTE statement, then all pairs P_1, P_2 in the original data set that satisfy the relation $|P_1 P_2| \leq D_{max}$ are written to the OUTPAIR= data set.

Given the aforementioned specifications, note that the OUTPAIR= data set can be very large even for a moderately sized DATA= data set. For example, if the DATA= data set has NOBS=500, then the OUTPAIR= data could have up to $\text{NOBS}(\text{NOBS} - 1)/2 = 124,750$ observations if no OUTPDISTANCE= restriction is given in the COMPUTE statement.

The OUTPAIR= data set contains information about the distance and orientation of each point pair, and you can use it for specialized continuity measure calculations.

The OUTPAIR= data set contains the following variables:

- AC, the angle class value
- COS, the cosine of the angle between pairs
- DC, the distance (lag) class
- DISTANCE, the distance between the data in pairs
- ID1, the ID variable value or observation number for the first point in the pair
- ID2, the ID variable value or observation number for the second point in the pair
- V1, the variable value for the first point in the pair
- V2, the variable value for the second point in the pair
- VARNAME, the variable name for the current **VAR** variable
- X1, the x coordinate of the first point in the pair
- X2, the x coordinate of the second point in the pair
- Y1, the y coordinate of the first point in the pair
- Y2, the y coordinate of the second point in the pair

If no **ID** statement is specified, then the corresponding observation number is assigned to each one of the variables ID1 and ID2, instead.

OUTVAR=SAS-data-set

The OUTVAR= data set contains the standard and robust versions of the sample semivariance, the covariance, and other information in each lag class.

The OUTVAR= data set contains the following variables:

- ANGLE, the angle class value (clockwise from N to S)
- ATOL, the angle tolerance for the lag or angle class
- AVERAGE, the average variable value for the lag or angle class
- BANDW, the bandwidth for the lag or angle class
- COUNT, the number of pairs in the lag or angle class
- COVAR, the covariance value for the lag or angle class
- DISTANCE, the average lag distance for the lag or angle class
- LAG, the lag class value (in **LAGDISTANCE=** units)
- RVARIO, the sample robust semivariance value for the lag or angle class

- STDERR, the approximate standard error of the sample semivariance estimate
- VARIOG, the sample semivariance value for the lag or angle class
- VARNAME, the name of the current VAR variable

The robust semivariance estimate, RVARIO, is not included in the data set if you omit the option ROBUST in the COMPUTE statement.

The bandwidth variable, BANDW, is not included in the data set if no bandwidth specification is given in the COMPUTE statement or in a DIRECTIONS statement.

The OUTVAR= data set contains a line where the LAG variable is -1 . The AVERAGE variable in this line displays the sample mean value \bar{Z} of the SRF $Z(s)$, and the COVAR variable shows the sample variance $\text{Var}[Z(s)]$.

Displayed Output

In addition to the output data sets, the VARIOGRAM procedure produces a variety of output objects. Most of these are produced depending on whether you specify either NOVARIogram or LAGDISTANCE= and MAXLAGS= in the COMPUTE statement. The VARIOGRAM procedure output objects are the following:

- a default “Number of Observations” table that displays the number of observations read from the input data set and the number of observations used in the analysis
- a default map that shows the spatial distribution of the observations of the current variable in the VAR statement. The observations are displayed by default with circled markers whose color indicates the VAR value at the corresponding location.
- a table with basic information about the lags and the extreme distance between data pairs, when NOVARIogram is specified
- a table that describes the distribution of data pairs in distance intervals, when NOVARIogram is specified
- a histogram plot of the pairwise distance distribution, when NOVARIogram is specified). The plot also displays a reference line at a user-specified pairs frequency threshold when you specify the THRESHOLD= parameter in the PLOTS=PAIRS option. The option PLOTS=PAIRS(NOINSET) forces the informational inset that appears in the plot to hide.
- empirical semivariogram details, when NOVARIogram is not specified and LAGDISTANCE= and MAXLAGS= are specified. This table also includes the semivariance estimate variance and confidence limits when CL is specified, and estimates of the robust semivariance when ROBUST is specified.

- plots of the appropriate empirical semivariograms, when **NOVARIOGRAM** is not specified and **LAGDISTANCE=** and **MAXLAGS=** are specified. If you perform the analysis in more than one direction simultaneously, the output is a panel that contains the empirical semivariogram plots for the specified angles. If the semivariograms are nonpaneled, then each plot includes in the lower part a needle plot of the contributing pairs distribution.
- a table that provides autocorrelation statistics, when the options **AUTOCORRELATION** and **LAGDISTANCE=** are specified
- the Moran scatter plot of the standardized observation values against the weighted averages of their neighbors, when the options **PLOTS=MORAN**, **AUTOCORRELATION**, and **LAGDISTANCE=** are specified

When you specify the **MODEL** statement and request a fit of a theoretical model to the empirical semivariogram, the **VARIOGRAM** procedure also produces the following default output:

- a table with some general fitting information, in addition to the output item store if you have specified one with the **STORE** statement
- a table with more specific information about the selected model's parameters and their initial values
- a table with general information about the optimization that provides the fitting parameters of the selected model
- a table with the optimization process output and a table with the convergence status of the optimization process, if you have specified a single model to fit
- a "Parameter Estimates" table with information about the fitted parameters estimates
- a "Fit Summary" table that reports the fit quality of all models you requested to fit
- plots of fitted theoretical semivariogram models. If you perform model fitting in more than one direction angle or for more than one variable in your **DATA=** data set, then the output is a panel that contains all fitted models for the respective directions or variables.

Additional output can be produced in model fitting if you specify a higher level of output detail with the **DETAILS** option in the **MODEL** statement. This output can be information tables for each separate model when you specify multiple models to fit, tables with more details about the optimization process, and the covariance and correlation matrices of the model parameter estimates. The complete listing of the PROC **VARIOGRAM** output follows in the section "**ODS Table Names**" on page 8646 and the section "**ODS Graph Names**" on page 8647.

ODS Table Names

Each table created by PROC VARIOGRAM has a name associated with it, and you must use this name to refer to the table when using ODS Graphics. These names are listed in Table 102.6.

Table 102.6 ODS Tables Produced by PROC VARIOGRAM

ODS Table Name	Description	Required Statement	Option
AutoCorrStats	Autocorrelation statistics information	COMPUTE	AUTOCORRELATION
ConvergenceStatus	Status of optimization at conclusion	MODEL	Default output
CorrB	Approximate correlation matrix of model parameter estimates	MODEL	CORRB
CovB	Approximate covariance matrix of model parameter estimates	MODEL	COVB
DistanceIntervals	Pairwise distances matrix	COMPUTE	NOVARIOGRAM
FitGenInfo	General fitting information	MODEL	Default output
FitSummary	Fitting process summary	MODEL	Default output
InputOptions	Optimization input options	MODEL	DETAILS=ALL
IterHist	Iteration history	MODEL	DETAILS=ITR
IterStop	Optimization-related results	MODEL	Default output
Lagrange	Information about Lagrange multipliers	MODEL	DETAILS=ALL
ModelInfo	Model information	MODEL	Default output
NObs	Number of observations read and used	PROC	Default output
OptInfo	Optimization information	MODEL	Default output
PairsInformation	General information about the pairs distribution in classes and data maximum distances in selected directions	COMPUTE	NOVARIOGRAM
ParameterEstimates	Model fitting solution and statistics	MODEL	Default output
ParameterEstimatesResults	Parameter estimates and gradient information	MODEL	DETAILS=ALL
ParameterEstimatesStart	More detailed model information	MODEL	DETAILS=ITR
ParmSearch	Parameter search values	MODEL	Default output
ProblemDescription	Information at the optimization start	MODEL	DETAILS=ITR
ProjGrad	Projected gradient information	MODEL	DETAILS=ALL
SemivariogramTable	Empirical semivariance classes, parameters, and estimates	COMPUTE	LAGD=, MAXLAGS=

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

For additional control of the graphics that are displayed, see the [PLOTS](#) option in the section “[PROC VARIOGRAM Statement](#)” on page 8576.

ODS Graph Names

PROC VARIOGRAM assigns a name to each graph it creates by using ODS Graphics. You can use this name to refer to the graph when using ODS Graphics. You must also specify the [PLOTS=](#) option indicated in [Table 102.7](#).

Table 102.7 Graphs Produced by PROC VARIOGRAM

ODS Graph Name	Plot Description	Statement	Option
FitPanel	Panel of one or more classes of fitted semivariograms in different angles	PROC	PLOTS=FIT
FitPlot	Plot of one or more classes of fitted semivariograms	PROC	PLOTS=FIT
MoranPlot	Scatter plot of standardized observed values against weighted averages	PROC	PLOTS=MORAN
ObservationsPlot	Scatter plot of observed data and colored markers that indicates observed values	PROC	PLOTS=OBSERV
PairDistPlot	Histogram of the pairwise distance distribution	PROC	PLOTS=PAIRS
Semivariogram	Plots of empirical classical and robust (optional) semivariograms	PROC	PLOTS=SEMIVAR
SemivariogramPanel	Panel of empirical classical and robust (optional) semivariogram plots	PROC	PLOTS=SEMIVAR

Examples: VARIOGRAM Procedure

Example 102.1: Aspects of Semivariogram Model Fitting

This example helps you explore aspects of automated semivariogram fitting with PROC VARIOGRAM. The test case is a spatial study of arsenic (As) concentration in drinking water.

Arsenic is a toxic pollutant that can occur in drinking water because of human activity or, typically, due to natural release from the sediments in water aquifers. The World Health Organization has a standard that allows As concentration up to a maximum of 10 $\mu\text{g/l}$ (micrograms per liter) in drinking water.

In general, natural release of arsenic into groundwater is very slow. Arsenic concentration in water might exhibit no significant temporal fluctuations over a period of a few months. For this reason, it is acceptable to perform a spatial study of arsenic with input from time-aggregated pollutant concentrations. This example makes use of this assumption for its data set `logAsData`. The data set consists of 138 simulated observations from wells across a square area of 500 km \times 500 km. The variable `logAs` in the `logAsData` data set is the natural logarithm of arsenic concentration. Often, the natural logarithm of arsenic concentration (`logAs`) is used as the random variable to facilitate the analysis because its distribution tends to resemble the normal distribution.

The goal is to explore spatial continuity in the `logAs` observations. The following statements read the `logAs` values from the `logAsData` data set:

```

;

```

First you want to inspect the `logAs` data for surface trends and the pairwise distribution. You run the `VARIOGRAM` procedure with the `NOVARIogram` option in the `COMPUTE` statement. You also request the `PLOTS=PAIRS(MID)` option, which prompts the pair distance plot to display the actual distance between pairs, rather than the lag number itself, in the midpoint of the lags. You use the following statements:

```

ods graphics on;

proc variogram data=logAsData plots=pairs(mid);
  compute novariogram nhc=50;
  coord xc=East yc=North;
  var logAs;
run;

```

The observations scatter plot in [Output 102.1.1](#) shows a rather uniform distribution of the locations in the study domain. Reasonably, neighboring values of `logAs` seem to exhibit some correlation. There seems to be no definite sign of an overall surface trend in the `logAs` values. You can consider that the observations are trend-free, and proceed with estimation of the empirical semivariance.

Output 102.1.1 logAs Observation Data Scatter Plot

The observed logAs values go as high as 3.28091, which corresponds to a concentration of $26.6 \mu\text{g/l}$. In fact, only three observations exceed the health standard of $10 \mu\text{g/l}$ (or about 2.3 in the log scale), and they are situated in relatively neighboring locations to the east of the domain center.

Based on the discussion in section “[Preliminary Spatial Data Analysis](#)” on page 8562, the pair distance plot in [Output 102.1.2](#) suggests that you could consider pairs that are anywhere around up to half the maximum pairwise distance of about 700 km.

Output 102.1.2 Distribution of Pairwise Distances for logAs Data

After some experimentation with values for the `LAGDISTANCE=` and `MAXLAGS=` options, you actually find that a lag distance of 5 km over 40 lags can provide a clear representation of the logAs semivariance. With respect to [Output 102.1.2](#), this finding indicates that in the current example it is sufficient to consider pairs separated by a distance of up to 200 km. You run the following statements to obtain the empirical semivariogram:

```
proc variogram data=logAsData plots(only)=semivar;
  compute lagd=5 maxlag=40;
  coord xc=East yc=North;
  var logAs;
run;
```

The first few lag classes of the logAs empirical semivariance table are shown in [Output 102.1.3](#).

Output 102.1.3 Partial Output of the Empirical Semivariogram Table for logAs Data

Semivariogram Model Fitting of Log-Arsenic Concentration			
The VARIOGRAM Procedure			
Dependent Variable: logAs			
Empirical Semivariogram			
Lag Class	Pair Count	Average Distance	Semivariance
0	1	1.9	0.111
1	5	4.9	0.145
2	6	9.7	0.286
3	11	14.6	0.545
4	27	20.0	0.900

[Output 102.1.3](#) and [Output 102.1.4](#) indicate that the logarithm of arsenic spatial correlation starts with a small nugget effect around 0.11 and rises to a sill value that is most likely between 1.4 and 1.8. The rise could be of exponential type, although the smooth increase of semivariance close to the origin could also suggest Gaussian behavior. You suspect that a Matérn form might also work, since its smoothness parameter ν can regulate the form to exhibit an intermediate behavior between the exponential and Gaussian forms.

Output 102.1.4 Empirical Semivariogram for logAs Data

You can investigate all of the preceding clues with the model fitting features of PROC VARIOGRAM. The simplest way to fit a model is to specify its form in the **MODEL** statement. In this case, you have the added complexity of having more than one possible candidate. For this reason, you use the **FORM=AUTO** option that picks the best fit out of a list of candidates. Within this option you specify the **MLIST=** suboption to use the exponential, Gaussian, and Matérn forms. You also specify the **NEST=** suboption to request fitting of a model with up to two nested structures. Eventually, you specify the **PLOTS=FIT** option to produce a plot of the fitted models. The **STORE** statement saves the fitting output into an item store you name **SemivAsStore** for future use. You apply these specifications with the following statements:

```
proc variogram data=logAsData plots(only)=fit;
  store out=SemivAsStore / label='LogAs Concentration Models';
  compute lagd=5 maxlag=40;
  coord xc=East yc=North;
  model form=auto(mlist=(exp,gau,mat) nest=1 to 2);
  var logAs;
run;

ods graphics off;
```

The table of general information about fitting is shown in [Output 102.1.5](#). The table lets you know that 12 model combinations are to be tested for weighted least squares fitting, based on the three forms that you specified.

Output 102.1.5 Semivariogram Model Fitting General Information

Semivariogram Model Fitting of Log-Arsenic Concentration	
The VARIOGRAM Procedure	
Dependent Variable: logAs	
Angle: Omnidirectional	
Semivariogram Model Fitting	
Model	Selection from 12 form combinations
Output Item Store	WORK.SEMIVASSTORE
Item Store Label	LogAs Concentration Models

The combinations include repetitions. For example, you specified the GAU form; hence the GAU-GAU form is tested, too. The model combinations also include permutations. For example, you specified the GAU and the EXP forms; hence the GAU-EXP and EXP-GAU models are fitted separately. According to the section “[Nested Models](#)” on page 8613, it might seem that the same model is fitted twice. However, in each of these two cases, each structure starts the fitting process with different parameter initial values. This can lead GAU-EXP to a different fit than EXP-GAU leads to, as seen in the fitting summary table in [Output 102.1.6](#). The table shows all the model combinations that were tested and fitted. By default, the ordering is based on the weighted sum of squares error criterion, and you can see that the lowest values in the Weighted SSE column are in top slots of the list.

Output 102.1.6 Semivariogram Model Fitting Summary

Fit Summary			
Class	Model	Weighted SSE	AIC
1	Gau-Gau	25.42435	-9.59246
	Gau-Mat	25.42482	-7.59169
2	Exp-Gau	25.97835	-8.70865
3	Exp-Mat	26.36846	-6.09754
4	Mat	26.37519	-10.08708
5	Gau	26.78629	-11.45296
6	Exp	28.01200	-9.61851
	Exp-Exp	28.01200	-5.61850
	Mat-Exp	28.01200	-3.61850
	Gau-Exp	28.01200	-5.61850

Note the leftmost Class column in [Output 102.1.6](#). As explained in detail in section “Classes of Equivalence” on page 8634, when you fit more than one model, all fitted models that compute the same semi-variance are placed in the same class of equivalence. For example, in this fitting example the top ranked GAU-GAU and GAU-MAT nested models produce indistinguishable semivariograms; for that reason they are both placed in the same class 1 of equivalence. The same occurs with the EXP, GAU-EXP, EXP-EXP, and MAT-EXP models in the bottom of the table. By default, PROC VARIOGRAM uses the AIC as a secondary classification criterion; hence models in each equivalence class are already ordered based on their AIC values.

Another remark in [Output 102.1.6](#) is that despite submitting 12 model combinations for fitting, the table shows only 10. You can easily see that the combinations MAT-GAU and MAT-MAT are not among the listed models in the fit summary. This results from the behavior of the VARIOGRAM procedure in the following situation: A parameter optimization takes place during the fitting process. In the present case the optimizer keeps increasing the Matérn smoothness parameter ν in the MAT-GAU model. At the limit of an infinite ν parameter, the Matérn form becomes the Gaussian form. For that reason, when the parameter ν is driven towards very high values, PROC VARIOGRAM automatically replaces the Matérn form with the Gaussian. This switch converts the MAT-GAU model into a GAU-GAU model. However, a GAU-GAU model already exists among the specified forms; consequently, the duplicate GAU-GAU model is skipped, and the fitted model list is reduced by one model. A similar explanation justifies the omission of the MAT-MAT model from the fit summary table.

In our example, the nested Gaussian-Gaussian model is the fitting selection of the procedure based on the default ranking criteria. [Output 102.1.7](#) displays additional information about the selected model. In particular, you see the table with general information about the Gaussian-Gaussian model, the initial values used for its parameters, and information about the optimization process for the fitting.

Output 102.1.7 Fitting and Optimization Information for Gaussian-Gaussian Model

Semivariogram Model Fitting	
Name	Gaussian-Gaussian
Label	Gau-Gau
Model Information	
Parameter	Initial Value
Nugget	0.0903
GauScale1	0.6709
GauRange1	100.0
GauScale2	0.6709
GauRange2	50.0230
Optimization Information	
Optimization Technique	Dual Quasi-Newton
Parameters in Optimization	5
Lower Boundaries	5
Upper Boundaries	0
Starting Values From	PROC

The estimated parameter values of the selected Gaussian-Gaussian model are shown in [Output 102.1.8](#).

Output 102.1.8 Parameter Estimates of the Fitting Selected Model

Parameter Estimates					
Parameter	Estimate	Approx Std Error	DF	t Value	Approx Pr > t
Nugget	0.08308	0.05097	36	1.63	0.1118
GauScale1	0.3277	0.2077	36	1.58	0.1234
GauRange1	62.3127	19.8488	36	3.14	0.0034
GauScale2	1.2615	0.2070	36	6.10	<.0001
GauRange2	21.4596	3.2722	36	6.56	<.0001

By default, when you specify more than one model to fit, PROC VARIOGRAM produces a fit plot that compares the first five classes of the successfully fit candidate models. The model that is selected according to the specified fitting criteria is shown with a thicker line in the plot.

You can modify the number of displayed equivalence classes with the [NCLASSES=](#) suboption of the [PLOTS=FIT](#) option. When you have such comparison plots, PROC VARIOGRAM displays the representative model from each class of equivalence.

The default fit plot for the current model comparison is shown in [Output 102.1.9](#). The legend informs you there is one more model in the first class of equivalence, as the fitting summary table indicated earlier in [Output 102.1.6](#).

Output 102.1.9 Fitted Theoretical and Empirical logAs Concentration Semivariograms for the Specified Models

In the present example, all fitted models in the first five classes have very similar semivariograms. The selected Gaussian-Gaussian model seems to have a relatively larger range than the rest of the displayed models, but you can expect any of these models to exhibit a near-identical behavior in terms of spatial correlation. As a result, all models in the displayed classes are likely to lead to very similar output, if you proceed to use any of them for spatial prediction.

In that sense, semivariogram fitting is a partially subjective process, for which there might not exist only one single correct answer to solve your problem. In the context of the example, on one hand you might conclude that the selected Gaussian-Gaussian model is exactly sufficient to describe spatial correlation in the arsenic study. On the other hand, the similar performance of all models might prompt you to choose instead a more simple non-nested model for prediction like the Matérn or the Gaussian model.

Regardless of whether you might opt to sacrifice the statistically best fit (depending on your selected criteria) to simplicity, eventually you are the one to decide which approach serves your study optimally. The model fitting features of PROC VARIOGRAM offer you significant assistance so that you can assess your options efficiently.

Example 102.2: An Anisotropic Case Study with Surface Trend in the Data

This example shows how to examine data for nonrandom surface trends and anisotropy. You use simulated data where the variable is atmospheric ozone (O_3) concentrations measured in Dobson units (DU). The coordinates are offsets from a point in the southwest corner of the measurement area, with the east and north distances in units of kilometers (km). You work with the ozoneSet data set that contains 300 measurements in a square area of 100 km \times 100 km.

The following statements read the data set:

```

title 'Semivariogram Analysis in Anisotropic Case With Trend Removal';

data ozoneSet;
  input East North Ozone @@;
  datalines;

;

```

The initial step is to explore the data set by inspecting the data spatial distribution. Run PROC VARIOGRAM, specifying the **NOVARIogram** option in the **COMPUTE** statement as follows:

```

ods graphics on;

proc variogram data=ozoneSet;
  compute novariogram nhc=35;
  coord xc=East yc=North;
  var Ozone;
run;

```

The result is a scatter plot of the observed data shown in [Output 102.2.1](#). The scatter plot suggests an almost uniform spread of the measurements throughout the prediction area. No direct inference can be made about the existence of a surface trend in the data. However, the apparent stratification of ozone values in the northeast–southwest direction might indicate a nonrandom trend.

Output 102.2.1 Ozone Observation Data Scatter Plot

You need to define the size and count of the data classes by specifying suitable values for the `LAGDISTANCE=` and `MAXLAGS=` options, respectively. Compared to the smaller sample of thickness data used in “[Getting Started: VARIOGRAM Procedure](#)” on page 8561, the larger size of the `ozoneSet` data results in more densely populated distance classes for the same value of the `NHCLASSES=` option. After you experiment with a variety of values for the `NHCLASSES=` option, you can adjust `LAGDISTANCE=` to have a relatively small number. Then you can account for a large value of `MAXLAGS=` so that you obtain many sample semivariogram points within your data correlation range. Specifying these values requires some exploration, for which you might need to return to this point from a later stage in your semivariogram analysis. For illustration purposes you now specify `NHCLASSES=35`.

Your choice of `NHCLASSES=35` yields the pairwise distance intervals table in [Output 102.2.2](#) and the corresponding histogram in [Output 102.2.3](#).

Output 102.2.2 Pairwise Distance Intervals Table

Pairwise Distance Intervals				
Lag Class	-----Bounds-----		Number of Pairs	Percentage of Pairs
0	0.00	2.01	52	0.12%
1	2.01	6.03	420	0.94%
2	6.03	10.06	815	1.82%
3	10.06	14.08	1143	2.55%
4	14.08	18.10	1518	3.38%
5	18.10	22.12	1680	3.75%
6	22.12	26.15	1931	4.31%
7	26.15	30.17	2135	4.76%
8	30.17	34.19	2285	5.09%
9	34.19	38.21	2408	5.37%
10	38.21	42.24	2551	5.69%
11	42.24	46.26	2444	5.45%
12	46.26	50.28	2535	5.65%
13	50.28	54.30	2487	5.55%
14	54.30	58.33	2460	5.48%
15	58.33	62.35	2391	5.33%
16	62.35	66.37	2302	5.13%
17	66.37	70.39	2285	5.09%
18	70.39	74.41	2079	4.64%
19	74.41	78.44	1786	3.98%
20	78.44	82.46	1640	3.66%
21	82.46	86.48	1493	3.33%
22	86.48	90.50	1243	2.77%
23	90.50	94.53	925	2.06%
24	94.53	98.55	710	1.58%
25	98.55	102.57	421	0.94%
26	102.57	106.59	274	0.61%
27	106.59	110.62	200	0.45%
28	110.62	114.64	120	0.27%
29	114.64	118.66	55	0.12%
30	118.66	122.68	35	0.08%
31	122.68	126.71	14	0.03%
32	126.71	130.73	11	0.02%
33	130.73	134.75	2	0.00%
34	134.75	138.77	0	0.00%
35	138.77	142.80	0	0.00%

Notice the overall high pair count in the majority of classes in [Output 102.2.2](#). You can see that even for higher values of `NHCLASSES=` the classes are still sufficiently populated for your semivariogram analysis according to the rule of thumb stated in the section “[Choosing the Size of Classes](#)” on page 8623. Based on the displayed information in [Output 102.2.3](#), you specify `LAGDISTANCE=4` km. You can further experiment with smaller lag sizes to obtain more points in your sample semivariogram.

You can focus on the `MAXLAGS=` specification at a later point. The important step now is to investigate the presence of trends in the measurement. The following section makes a suggestion about how to remove surface trends from your data and then continues the semivariogram analysis with the detrended data.

Output 102.2.3 Distribution of Pairwise Distances for Ozone Observation Data

Analysis with Surface Trend Removal

You can use a SAS/STAT predictive modeling procedure to extract surface trends from your original data. If your goal is spatial prediction, you can continue processing the detrended data for the prediction tasks, and at the end you can reinstate the trend at the prediction locations to report your analysis results.

In general, the exact form of the trend is unknown, as discussed in the section “[Empirical Semivariograms and Surface Trends](#)” on page 8626. In this case, the spatial distribution of the measurements shown in [Figure 102.2.1](#) suggests that you can use a quadratic model to describe the surface trend like the one that follows:

$$T(\text{East}, \text{North}) = f_0 + f_1 [\text{East}] + f_2 [\text{East}]^2 + f_3 [\text{North}] + f_4 [\text{North}]^2$$

The following statements show how to invoke the GLM procedure for your ozone data and how to extract the preceding trend from them:

```
proc glm data=ozoneSet plots=none;
  model ozone = East East*East North North*North;
  output out=gmout predicted=pred residual=ResidualOzone;
run;
```

Among other output, PROC GLM produces estimates for the parameters f_0, \dots, f_4 in the preceding trend model. [Output 102.2.4](#) shows the table with the parameter estimates. In this table, the coefficient f_0 corresponds to the intercept estimate, and the rest of the coefficients correspond to their matching variables; for example, the estimate in the line of “East*East” refers to f_2 in the preceding model. For more information about the syntax and the PROC GLM output, see Chapter 42, “[The GLM Procedure](#).”

Output 102.2.4 Parameter Estimates for the Surface Trend Model

Semivariogram Analysis in Anisotropic Case With Trend Removal				
The GLM Procedure				
Dependent Variable: Ozone				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	270.6798273	0.40595731	666.77	<.0001
East	0.0065148	0.01360281	0.48	0.6323
East*East	0.0010726	0.00012987	8.26	<.0001
North	-0.0369159	0.01297491	-2.85	0.0047
North*North	0.0035587	0.00012659	28.11	<.0001

The detrending process leaves you with the GMOUT data set, which contains the ResidualOzone data residuals. This time you run PROC VARIOGRAM again with the [NOVARIOGRAM](#) option to inspect the detrended residuals, and with a request only for the observations plot, as follows:

```
proc variogram data=gmout plots(only)=observ;
  compute novariogram nhc=35;
  coord xc=East yc=North;
  var ResidualOzone;
run;
```

The requested observations plot is shown in [Output 102.2.5](#).

Output 102.2.5 Ozone Residual Observation Data Scatter Plot

Before you proceed with the empirical semivariogram computation and model fitting, examine your data for anisotropy. This investigation is necessary to portray the spatial structure of your SRF accurately. If anisotropy exists, it manifests itself as different ranges or sills or both for the empirical semivariograms in different directions.

You want detail in your analysis, so you ask for the empirical semivariance in 12 directions by specifying `NDIRECTIONS=12`. Based on the `NDIRECTIONS=` option, empirical semivariograms are produced in increments of the base angle $\theta = 180^\circ/12 = 15^\circ$.

You also choose `ANGLETOLERANCE=22.5` and `BANDWIDTH=20`. A different choice of values produces different empirical semivariograms, because these options can regulate the number of pairs that are included in a class. Avoid assigning values that are too small to these parameters so that you can allow for an adequate number of point pairs per class. At the same time, the higher the values of these parameters are, the more data pairs that come from closely neighboring directions are included in each lag. Therefore, values for the `ANGLETOLERANCE=` and `BANDWIDTH=` options that are too high pose a risk of losing information along the particular direction. The side effect occurs because you incorporate data pairs from a broader spectrum of angles; thus, you potentially amplify weaker anisotropy or weaken stronger anisotropy, as noted in the section “Angle Classification” on page 8617. You can experiment with different `ANGLETOLERANCE=` and `BANDWIDTH=` values to reach this balance with your data, if necessary.

With the following statements you ask to display only the SEMIVAR plots in the specified number of directions. Multiple empirical semivariograms are placed by default in panels, as [Output 102.2.6](#) shows. If you want an individual plot for each angle, then you need to further specify the plot option SEMIVAR(UNPACK).

```
proc variogram data=gmount plot(only)=semivar;
  compute lagd=4 maxlag=16 ndir=12 atol=22.5 bandw=20;
  coord xc=East yc=North;
  var ResidualOzone;
run;
```

Output 102.2.6 Ozone Empirical Semivariograms with $0^\circ \leq \theta < 180^\circ$ and $\delta\theta = 15^\circ$

Output 102.2.6 *continued*

Output 102.2.6 *continued*

The panels in [Output 102.2.6](#) suggest that in some of the directions, such as for $\theta = 0^\circ$, the directional plots tend to exhibit a somewhat noisy structure. This behavior can be due to the pairs distribution across the particular direction. Specifically, based on the `LAGDISTANCE=` choice there might be insufficient pairs present in a class. Also, depending on the `ANGLETOLERANCE=` and `BANDWIDTH=` values, too many pairs might be considered from neighboring angles that potentially follow a modified structure. These are factors that can increase the variability in the semivariance estimate. A different explanation might lie in the existence of outliers in the data set; this aspect is further explored in “[Example 102.5: A Box Plot of the Square Root Difference Cloud](#)” on page 8684.

This behavior is relatively mild here and should not obstruct your goal to study anisotropy in your data. You can also perform individual computations in any direction. By doing so, you can fine-tune the computation parameters and attempt to obtain smoother estimates of the sample semivariance.

Further in this study, the directional plots in [Output 102.2.6](#) suggest that during shifting from $\theta = 0^\circ$ to $\theta = 90^\circ$, the empirical semivariogram range increases. Beyond the angle $\theta = 90^\circ$, the range starts decreasing again until the whole circle is traversed at 180° and small range values are encountered around the N–S direction at $\theta = 0^\circ$. The sill seems to remain overall the same. This analysis suggests the presence of anisotropy in the ozone concentrations, with the major axis oriented at about $\theta = 90^\circ$ and the minor axis situated perpendicular to the major axis at $\theta = 0^\circ$.

The multidirectional analysis requires that for a given `LAGDISTANCE=` you also specify a `MAXLAGS=` value. Since the ozone correlation range might be unknown (as assumed here), you can apply the rule of thumb that suggests use of the half-extreme data distance in the direction of interest, as explained in the section “[Spatial Extent of the Empirical Semivariogram](#)” on page 8624. Following the information displayed in [Output 102.2.3](#), for different directions this distance varies between $99.4/2 = 49.7$ and $140.8/2 = 70.4$ km. In turn, the pairwise distances table in [Output 102.2.2](#) indicates that within this range of distances you can specify `MAXLAGS=` to be between 12 and 17 lags. In this example you specify `MAXLAGS=16`.

At this point you are ready to continue with fitting theoretical semivariogram models to the empirical semivariogram in the selected directions of $\theta = 0^\circ$ and $\theta = 90^\circ$. By trying out different models, you see that an exponential one is suitable for your empirical data:

$$\gamma_z(h) = c_0 \left[1 - \exp \left(-\frac{h}{a_0} \right) \right]$$

For the purpose of the present example, it is reasonable to assume a constant nugget effect equal to zero, based on the empirical semivariograms shown in [Output 102.2.6](#). The same output suggests that the model scale is likely to be above 2, and that the range might be relatively small in $\theta = 0^\circ$. You specify the `PARMS` statement to set initial values for the exponential model parameters and account for these considerations.

In particular, you assign an initial value of zero to the nugget effect. Then you request a grid search for the range and scale parameters, so that the optimal initial values set is selected for the parameter estimation in each of the two angles $\theta = 0^\circ$ and $\theta = 90^\circ$. By inspecting the empirical semivariograms in [Output 102.2.6](#), you specify the value list 2, 2.5, and 3 for the scale, and the values from 5 to 25 with a step of 10 for the range. In addition, you specify the parameter 1 in the `HOLD=` option to designate the nugget effect parameter as a constant. According to these specifications, you use the following statements:

```
proc variogram data=gmount plot(only)=fit;
  compute lagd=4 maxlag=16;
  directions 0(22.5,10) 90(22.5,10);
  coord xc=East yc=North;
```

```

model form=exp;
parms (0.) (2 to 3 by 0.5) (5 to 25 by 10) / hold=(1);
var ResidualOzone;
run;

ods graphics off;

```

The VARIOGRAM procedure repeats the fitting process for each one of the selected directions. First, in $\theta = 0^\circ$ the parameter search table in [Output 102.2.7](#) shows you which value combinations are tested initially to choose the one that gives the lowest objective function value.

Output 102.2.7 Parameter Search for the Selected Direction $\theta = 0^\circ$

Semivariogram Analysis in Anisotropic Case With Trend Removal				
The VARIOGRAM Procedure				
Dependent Variable: ResidualOzone				
Angle: 0				
Current Model: Exponential				
Parameter Search				
Set	Nugget	Scale	Range	Objective Function
1	0	2	5	391.06593
2	0	2	15	1740.0

The fitted and empirical semivariograms for the selected directions are displayed in the panel of [Output 102.2.12](#).

Output 102.2.12 Fitted Theoretical and Empirical Semivariogram for the Ozone Data in the $\theta = 0^\circ$ and $\theta = 90^\circ$ Directions

Conclusively, your semivariogram analysis on the detrended ozone data suggests that the ozone SRF exhibits anisotropy in the perpendicular directions of N–S ($\theta = 0^\circ$) and E–W ($\theta = 90^\circ$).

The sills in the two directions of anisotropy are similar in size. By inspecting again the empirical semivariograms in [Output 102.2.6](#), you could make the reasonable assumption that you have a case of geometric anisotropy, where the range in the major axis is about 4.5 times larger than the minor axis range. If you would like to use these PROC VARIOGRAM results for predictions, then you would need to specify a single scale value for the geometric anisotropy sill. In this case you could choose an arbitrary value for the constant scale from the narrow interval formed by the estimated scales in the previous results. For example, you can

specify the **PARMS** statement modified as shown in the following statement to approximate a common scale for the semivariance in all directions:

```
parms (0.) (2.7) (5 to 25 by 10) / hold=(1,2);
```

As an alternative, you can use PROC VARIOGRAM to fit an exponential model to all different angles examined in this example, and then select the constant scale value to be the mean of the scales across all directions.

Example 102.3: Analysis without Surface Trend Removal

This example uses PROC VARIOGRAM without removing potential surface trends in a data set in order to investigate a distinguished spatial direction in the data. In doing so, this example also serves as a guide to examine under which circumstances you might be able to bypass the effect of a trend on a semivariogram. Typically though, for theoretical semivariogram estimations you follow the analysis presented in “[Example 102.2: An Anisotropic Case Study with Surface Trend in the Data](#)” on page 8658.

As explained in the section “[Details: VARIOGRAM Procedure](#)” on page 8608, when you compute the empirical semivariance for data that contain underlying surface trends, the outcome is the pseudo-semivariance. Pseudo-semivariograms are not estimates of the theoretical semivariogram; hence, they provide no information about the spatial continuity of your SRF.

However, in the section “[Empirical Semivariograms and Surface Trends](#)” on page 8626 it is mentioned that you might still be able to perform a semivariogram analysis with potentially non-trend-free data, if you suspect that your measurements might be trend-free across one or more specific directions. The example demonstrates this approach.

Reconsider the ozone data presented at the beginning of “[Example 102.2: An Anisotropic Case Study with Surface Trend in the Data](#)” on page 8658. The spatial distribution of the data is shown in [Figure 102.2.1](#), and the pairwise distance distribution for NHCLASSES=35 is illustrated in [Figure 102.2.3](#). This exploratory analysis suggested a LAGDISTANCE=4 km, and [Figure 102.2.2](#) indicated that for this LAGDISTANCE= you can consider a value of MAXLAGS=16.

Recall from the section “[Empirical Semivariograms and Surface Trends](#)” on page 8626 that you need to investigate the empirical semivariogram of the data in a few different directions in order to identify a trend-free direction. If such a direction exists, then you can proceed with this special type of analysis. The following statements employ NDIRECTIONS=8 to examine eight directions:

```
ods graphics on;

proc variogram data=ozoneSet plot(only)=semivar;
  compute lagd=4 maxlag=16 ndirections=8 robust;
  coord xc=East yc=North;
  var Ozone;
run;
```

By default, the range of 180° is divided into eight equally distanced angles: $\theta = 0^\circ$, $\theta = 22.5^\circ$, $\theta = 45^\circ$, $\theta = 67.5^\circ$, $\theta = 90^\circ$, $\theta = 112.5^\circ$, $\theta = 135^\circ$, and $\theta = 157.5^\circ$. The resulting empirical semivariograms for these angles are shown in [Output 102.3.1](#).

Output 102.3.1 Ozone Empirical Semivariograms with $0^\circ \leq \theta < 180^\circ$ and $\delta\theta = 22.5^\circ$

Output 102.3.1 continued

The figures in [Output 102.3.1](#) suggest an overall continuing increase with distance of the semivariance in all directions. As explained in the section “[Theoretical Semivariogram Models](#)” on page 8608, this can be an indication of systematic trends in the data. However, the direction of $\theta = 112.5^\circ$ clearly indicates that the increase rate, if any, is smaller than the corresponding rates across the rest of the directions. You then want to search whether there exists a trend-free direction in the neighborhood of this angle.

Run PROC VARIOGRAM again, specifying several directions within an interval of angles where you want to close in and you suspect the existence of a trend-free direction. In the following step you specify ANGLETOL=15°, which is smaller than the default value of 22.5°, and you also specify BANDWIDTH=10 km. The smaller values help with minimization of the interference with neighboring directions, as discussed in the section “[Angle Classification](#)” on page 8617.

The aforementioned considerations are addressed in the following statements:

```
proc variogram data=ozoneSet plot(only)=semivar(c1a);
  compute lagd=4 maxlag=16 robust;
  directions 100(15,10) 103(15,10)
             106(15,10) 108(15,10)
             110(15,10) 112(15,10)
             115(15,10) 118(15,10);
  coord xc=East yc=North;
  var Ozone;
run;
```

Your analysis has brought you to examine a narrow strip of angles within $\theta = 100^\circ$ and $\theta = 118^\circ$. The pseudo-semivariograms in [Output 102.3.2](#) and [Output 102.3.3](#) indicate that at the boundaries of this strip, the angles display increasing semivariance with distance. On the other hand, within this interval there are directions across which the semivariance is tentatively reaching a sill, and these are potential candidates to be trend-free directions.

Output 102.3.2 Ozone Empirical Semivariograms in 100° , 103° , 106° , and 108°

Output 102.3.3 Ozone Empirical Semivariograms in 110°, 112°, 115°, and 118°

You can further investigate this angle spectrum in more detail. For example, you can monitor additional angles in between, or use a smaller `LAGDISTANCE=` and increased `MAXLAGS=` values to single out the most qualified candidate. For the purpose of this example, you can consider the direction $\theta = 108^\circ$ to very likely be the trend-free one you are looking for.

From a physical standpoint, the trend-free direction, if it exists, is expected to be perpendicular to the direction of the maximum dip in the values of the ozone field, as mentioned in the section “[Empirical Semivariograms and Surface Trends](#)” on page 8626. If you cross-examine the ozone data distribution in [Output 102.2.1](#), the figure suggests that this direction exists and is slightly tilted clockwise with respect to the E–W axis. This direction emerges from the mild stratification of the ozone values in your data distribution. The ozone concentrations across it are similar when compared to surrounding directions, and as such, it has been identified as a trend-free direction.

Your next step is to obtain the empirical semivariogram in the suspected trend-free direction of $\theta = 108^\circ$ and to perform a theoretical model fit.

The semivariance in [Output 102.3.2](#) exhibits a slow, almost linear rise at short distances and seems to be reaching the sill fast, rather than asymptotically. You can accommodate this behavior by using the spherical model

$$\gamma_z(h) = \begin{cases} c_n + \sigma_0^2 \left[\frac{3}{2} \frac{h}{a_0} - \frac{1}{2} \left(\frac{h}{a_0} \right)^3 \right], & \text{for } 0 < h \leq a_0 \\ c_0, & \text{for } a_0 < h \end{cases}$$

where $\gamma_z(0) = 0$ and $a_0 > 0$. The empirical semivariograms also suggest that there does not seem to be a nugget effect. Assume that in this example you are interested in what the fitting process concludes about the nugget effect, so you skip the `NUGGET=` option in the `MODEL` statement. You also let PROC VARIOGRAM provide initial values for the rest of the model parameters. Eventually, you use the `PLOTS` option to inspect the classical and robust empirical semivariograms in the selected direction and to produce a plot of the fitted model. The following statements implement these considerations:

```
proc variogram data=ozoneSet plot(only)=(semivar fit);
  compute lagd=4 maxlag=16 robust cl;
  directions 108(15,10);
  coord xc=East yc=North;
  model form=sph;
  var ozone;
run;

ods graphics off;
```

The classical and robust empirical semivariograms in the selected direction $\theta = 108^\circ$ are displayed in Figure 102.3.4.

Output 102.3.4 Ozone Classical and Robust Empirical Semivariograms in $\theta = 108^\circ$

The output continues with information about the fitting process, which terminates successfully and produces the estimated parameters and the fit summary tables shown in [Output 102.3.5](#). The near-zero nugget parameter estimate indicates that you can consider the process to be practically free of nugget effect.

The fitted and empirical semivariograms for the selected direction $\theta = 108^\circ$ are displayed in [Output 102.3.6](#).

Output 102.3.6 Fitted Theoretical and Empirical Semivariogram for the Ozone Data in $\theta = 108^\circ$

A comparative look at the empirical and fitted semivariograms in [Output 102.3.6](#) and [Output 102.2.12](#) suggests that the analysis of the trend-free ResidualOzone produces a different outcome from that of the original Ozone values. In fact, a more suitable comparison can be made between the semivariograms in the assumed trend-free direction $\theta = 108^\circ$ of the current scenario and the one shown in [Output 102.2.6](#) in the nearly identical direction $\theta = 105^\circ$. It might seem unreasonable that these two semivariograms are produced both in the same ozone study and in a narrow band of directions free of apparent surface trends, yet they bear no resemblance. However, the lack of similarity in these plots stems from operating on two different data sets where the outcome depends on the actual data values.

More specifically, the semivariogram analysis treats the trend-free ozone set and the original ozone measurements as different quantities. The process of detrending the original Ozone values is a transformation of these values into the trend-free values of ResidualOzone. Any existing spatial correlation in the original data is not necessarily retained within the transformed data. Depending on the transformation features, the emerging data set has its own characteristics, as demonstrated in this example.

A final remark concerns the issue of isotropy. Based on the details presented in the section “[Empirical Semivariograms and Surface Trends](#)” on page 8626, your knowledge of the spatial structure of the ozoneSet data set is limited to the selected trend-free direction you indicated in the present example. You can generalize this outcome for all spatial directions only if you consider the hypothesis of isotropy in the ozone field to be reasonable. However, you cannot infer the assumption of anisotropy in the present example based on the analysis in the section “[Analysis with Surface Trend Removal](#)” on page 8662. Again, the reason is that you currently use the observed Ozone values, whereas the ResidualOzone data in the previous example emerged from a transformation of the current data. Hence, you have essentially two data sets that do not necessarily share the same properties.

Example 102.4: Covariogram and Semivariogram

The covariance that was reviewed in the section “[Stationarity](#)” on page 8615 is an alternative measure of spatial continuity that can be used instead of the semivariance. In a similar manner to the empirical semivariance that was presented in the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613, you can also compute the empirical covariance. The covariograms are plots of this quantity and can be used to fit permissible theoretical covariance models, in correspondence to the semivariogram analysis presented in the section “[Theoretical Semivariogram Models](#)” on page 8608. This example displays a comparative view of the empirical covariogram and semivariogram, and examines some additional aspects of these two measures.

You consider 500 simulations of an SRF $Z(s)$ in a square domain of 100×100 (10^6 km²). The following DATA step defines the data locations:

```
title 'Covariogram and Semivariogram';

data dataCoord;
  retain seed 837591;
  do i=1 to 100;
    East = round(100*ranuni(seed),0.1);
    North = round(100*ranuni(seed),0.1);
    output;
  end;
run;
```

For the simulations you use PROC SIM2D, which produces Gaussian simulations of SRFs with user-specified covariance structure—see Chapter 85, “[The SIM2D Procedure](#).” The Gaussian SRF implies full knowledge of the SRF expected value $E[Z(s)]$ and variance $\text{Var}[Z(s)]$ at every location s . The following statements simulate an isotropic, second-order stationary SRF with constant expected value and variance throughout the simulation domain:

```
proc sim2d outsim=dataSims;
  simulate numreal=500 seed=79750
          nugget=2 scale=6 range=10 form=exp;
  mean 30;
  grid gdata=dataCoord xc=East yc=North;
run;
```

Here, the SIMULATE statement accommodates the simulation parameters. The NUMREAL= option specifies that you want to perform 500 simulations, and the SEED= option specifies the seed for the simulation random number generator. You use the MEAN statement to specify the expected value $E[Z(s)] = 30$ units of Z . You also specify two variance components. The first is the nugget effect, and you use the NUGGET= option to set it to $c_n = 2$. The second is the partial sill $\sigma_0^2 = 6$ that you specify with the SCALE= option. The two variance components make up the total SRF variance $\text{Var}[Z(s)] = c_n + \sigma_0^2 = 8$. You assume an exponential covariance structure to describe the field spatial continuity, where σ_0^2 is the sill value and its range $a_0 = 10$ km (effective range $a_e = 3a_0 = 30$ km) is specified by the RANGE= option. The option FORM= specifies the covariance structure type.

The empirical semivariance and covariance are computed by the VARIOGRAM procedure, and are available either in the ODS output semivariogram table (as variables Semivariance and Covariance, respectively) or in the [OUTVAR=](#) data set. In the following statements you obtain these variables by using the [OUTVAR=](#) data set of the VARIOGRAM procedure:

```
proc variogram data=dataSims outv=outv noprint;
  compute lagd=3 maxlag=18;
  coord xc=gxc yc=gyc;
  by _ITER_;
  var sval;
run;
```

For each distance lag you take the average of the empirical measures over the number of simulations. PROC SORT prepares the input data for PROC MEANS, which produces these averages and stores them in the dataAvgs data set. This sequence is performed with the following statements:

```
proc sort data=outv;
  by lag;
run;

proc means data=outv n mean noprint;
  var Distance variog covar;
  by lag;
  output out=dataAvgs mean(variog)=Semivariance
                    mean(covar)=Covariance
                    mean(Distance)=Distance;
run;
```

The SGPLOT procedure creates the plot of the average empirical semivariogram and covariogram, as in the following statements:

```
proc sgplot data=dataAvgs;
  title "Empirical Semivariogram and Covariogram";
  xaxis label = "Distance" grid;
  yaxis label = "Semivariance" min=-0.5 max=9 grid;
  y2axis label = "Covariance" min=-0.5 max=9;
  scatter y=Semivariance x=Distance /
    markerattrs = GraphData1
    name='Semivar'
    legendlabel='Semivariance';
  scatter y=Covariance x=Distance /
    y2axis
    markerattrs = GraphData2
    name='Covar'
    legendlabel='Covariance';
  discretelegend 'Semivar' 'Covar';
run;
```

The plot of the average empirical semivariance and covariance of the preceding analysis is shown in [Output 102.4.1](#). The high number of simulations led to averages of empirical continuity measures that accurately approximate the simulated SRF characteristics. Specifically, the empirical semivariogram and covariogram both exhibit clearly exponential behavior. The semivariogram sill is approximately at the specified variance $\text{Var}[Z(s)] = 8$ of the SRF.

The simulated SRF is second-order stationary, so you expect at each lag the sum of the empirical semivariance and covariance to approximate the field variance $\text{Var}[Z(s)]$, as explained in the section “[Stationarity](#)” on page 8615. This behavior is evident in [Output 102.4.1](#).

This example concludes with a discussion of basic reasons why the empirical semivariogram analysis is commonly preferred to the empirical covariance analysis. A first reason comes from the assumptions that are necessary to compute each of these two measures. The condition of intrinsic stationarity that is required in order to define the empirical semivariogram is less restrictive than the condition of second-order stationarity that is required in order to consider the covariance function as a parameter of the process.

Also, an empirical semivariogram can indicate whether a nugget effect is present in your data sample, whereas the empirical covariogram itself might not reveal this information. This point is illustrated in [Output 102.4.1](#), where you expect to see that $C(\mathbf{0}) = \text{Var}[Z(s)]$, but the empirical covariogram cannot have a point at exactly $\mathbf{h} = \mathbf{0}$. A practical way to investigate for a nugget effect when you use empirical covariograms is as follows: recall that the **OUTVAR=** data set provides you with the sample variance (shown in the COVAR column for LAG=-1), as the following statement shows:

```
/* Obtain the sample variance from the data set -----*/

proc print data=dataAvgs (obs=1);
run;
```

Output 102.4.1 Average Empirical Semivariogram and Covariogram from 500 Simulations

Output 102.4.2 is a partial output of the `dataAvgs` data set, which contains averages of the `OUTVAR=` data set and shows the computed average $C(0)$ in the `Covariance` column. The combination of the empirical covariogram and the $C(0)$ value can help you fit a theoretical covariance model that includes any nugget effect, if present. See also the discussion in Schabenberger and Gotway (2005, section 4.2.2) about the Matérn definition of the covariance function that is related to this issue. In particular, this definition provides for an additional variance component in the covariance expression at $h = 0$ to account for the corresponding nugget effect in the semivariogram.

Output 102.4.2 Partial Outcome of the `dataAvgs` Data Set

Empirical Semivariogram and Covariogram						
Obs	LAG	_TYPE_	_FREQ_	Semivariance	Covariance	Distance
1	-1	0	500	.	7.74832	.

In addition to the preceding points, if the SRF is nonstationary, the empirical semivariogram indicates that the SRF variance increases with distance h , as [Output 102.3.1](#) shows in “[Example 102.3: Analysis without Surface Trend Removal](#)” on page 8672. In that case it makes no sense to compute the empirical covariogram. Specifically, the covariogram could provide you with an estimate of the sample variance, which is not sufficient to indicate that the SRF might not be stationary (see also Chilès and Delfiner 1999, p. 31).

Finally, the definitions of the empirical semivariance and covariance in the section “[Theoretical and Computational Details of the Semivariogram](#)” on page 8613 clearly show that the sample mean \bar{Z} and the SRF expected value $E[Z(s)]$ are not important for the computation of the semivariance, but either one is necessary for the covariance. Hence, the semivariance expression filters the mean, and this behavior is especially useful when the mean is unknown. On the other hand, if $E[Z(s)]$ is unknown and the empirical covariance is computed based on the sample mean \bar{Z} , this can induce additional bias in the covariance computation.

Example 102.5: A Box Plot of the Square Root Difference Cloud

The Gaussian form selected for the semivariogram in the section “[Getting Started: VARIOGRAM Procedure](#)” on page 8561 is based on consideration of the plots of the sample semivariogram. For the coal thickness data, the Gaussian form appears to be a reasonable choice.

However, it can often happen that a plot of the sample variogram shows so much scatter that no particular form is evident. The cause of this scatter can be one or more outliers in the pairwise differences of the measured quantities.

A method of identifying potential outliers is discussed in Cressie (1993, section 2.2.2). This example illustrates how to use the `OUTPAIR=` data set from PROC VARIOGRAM to produce a square root difference cloud, which is useful in detecting outliers.

For the SRF $Z(s)$, $s \in \mathcal{R}^2$, the square root difference cloud for a particular direction e is given by

$$| Z(s_i + he) - Z(s_i) |^{\frac{1}{2}}$$

for a given lag distance h . In the actual computation, all pairs $P_1 P_2$ of points P_1 , P_2 within a distance tolerance around h and an angle tolerance around the direction e are used. This generates a number of point pairs for each lag class h . The spread of these values gives an indication of outliers.

Following the example in the section “[Getting Started: VARIOGRAM Procedure](#)” on page 8561, this example uses a basic `LAGDISTANCE=7`, with a distance tolerance of 3.5, and a direction of N–S, with an angle tolerance `ATOL=30°`.

First, use PROC VARIOGRAM to produce an `OUTPAIR=` data set. Then use a DATA step to subset this data by choosing pairs within 30° of N–S. In addition, compute lag class and square root difference variables, as the following statements show:

```

title 'Square Root Difference Cloud Example';

data thick;
  input East North Thick @@;
  label Thick='Coal Seam Thickness';

;

proc variogram data=thick outp=outp noprint;
  compute novariogram;
  coordinates xc=East yc=North;
  var Thick;
run;

data sqroot;
  set outp;
  /* Include only points +/- 30 degrees of N-S -----*/
  where abs(cos) < 0.5;
  /* Unit lag of 7, distance tolerance of 3.5 -----*/
  lag_class=int(distance/7 + 0.5000001);
  sqr_diff=sqrt(abs(v1-v2));
run;

proc sort data=sqroot;
  by lag_class;
run;

```

Next, summarize the results by using the MEANS procedure:

```
proc means data=sqroot noprint n mean std;
  var sqr_diff;
  by lag_class;
  output out=msqrt n=n mean=mean std=std;
run;
title2 'Summary of Results';

proc print data=msqrt;
  id lag_class;
  var n mean std;
run;
```

The preceding statements produce [Output 102.5.1](#).

Output 102.5.1 Summary of Results

Square Root Difference Cloud Example Summary of Results				
lag_				
class	n	mean	std	
0	5	0.47300	0.14263	
1	31	0.77338	0.41467	
2	51	1.17052	0.47800	
3	58	1.52287	0.51454	
4	65	1.68625	0.58465	
5	65	1.66963	0.68582	
6	80	1.79693	0.62929	
7	88	1.73334	0.73191	
8	83	1.75528	0.68767	
9	108	1.72901	0.58274	
10	80	1.48268	0.48695	
11	84	1.19242	0.47037	
12	68	0.89765	0.42510	
13	38	0.84223	0.44249	
14	7	1.05653	0.42548	
15	3	1.35076	0.11472	

Finally, present the results in a box plot by using the SGPLOT procedure. The box plot facilitates the detection of outliers. The statements are as follows:

```
proc sgplot data=sqroot;
  xaxis label = "Lag Class";
  yaxis label = "Square Root Difference";
  title "Box Plot of the Square Root Difference Cloud";
  vbox sqr_diff / category=lag_class;
run;
```

Output 102.5.2 suggests that outliers, if any, do not appear to be adversely affecting the empirical semivariogram in the N–S direction for the coal seam thickness data. The conclusion from Output 102.5.2 is consistent with our previous semivariogram analysis of the same data set in the section “Getting Started: VARIOGRAM Procedure” on page 8561. The effect of the isolated outliers in lag classes 6 and 10–12 in Output 102.5.2 is demonstrated as the divergence between the classical and robust empirical semivariance estimates in the higher distances in Output 102.7. The difference in these estimates comes from the definition of the robust semivariance estimator $\hat{\gamma}_z(\mathbf{h})$ (see the section “Theoretical and Computational Details of the Semivariogram” on page 8613), which imposes a smoothing effect on the outlier influence.

Output 102.5.2 Box Plot of the Square Root Difference Cloud

Introduction to Special SAS Data Sets

All SAS/STAT procedures create SAS data sets. Any table generated by a procedure can be saved to a data set by using the Output Delivery System (ODS), and many procedures also have syntax that enables you to save other statistics to data sets. Some of these data sets are organized according to certain conventions so that they can be read by a SAS/STAT procedure for further analysis. Such specially organized data sets are recognized by the TYPE= data set attribute.

The CORR procedure (see the *Base SAS Procedures Guide: Statistical Procedures*), for example, can create a data set with the attribute TYPE=CORR containing a correlation matrix. This TYPE=CORR data set can

be read by the REG or FACTOR procedure, among others. If the original data set is large, using a special SAS data set in this way can save computer time by avoiding the recomputation of the correlation matrix in subsequent analyses.

PROC REG, for example, can create a TYPE=EST data set containing estimated regression coefficients. If you need to make predictions for new observations, you can use the SCORE procedure to read both the TYPE=EST data set and a data set containing the new observations. PROC SCORE can then compute predicted values or residuals without repeating the entire regression analysis. See Chapter 82, “[The SCORE Procedure](#),” for an example.

A special SAS data set might contain different kinds of statistics. A special variable called `_TYPE_` is used to distinguish the various statistics. For example, in a TYPE=CORR data set, an observation in which `_TYPE_='MEAN'` contains the means of the variables in the analysis, and an observation in which `_TYPE_='STD'` contains the standard deviations. Correlations appear in observations with `_TYPE_='CORR'`. Another special variable, `_NAME_`, is needed to identify the row of the correlation matrix. Thus, the correlation between variables X and Y is given by the value of the variable X in the observation for which `_TYPE_='CORR'` and `_NAME_='Y'`, or by the value of the variable Y in the observation for which `_TYPE_='CORR'` and `_NAME_='X'`.

The special data sets created by SAS/STAT procedures can generally be used directly by other procedures without modification. However, if you create an output data set with PROC CORR and use the NOCORR option to omit the correlation matrix from the OUT= data set, you need to set the TYPE= option either in parentheses following the OUT= data set name in the PROC CORR statement or in parentheses following the DATA= option in any other procedure that recognizes the special TYPE= attribute. In either case, the TYPE= option should be set to COV, CSSCP, or SSCP according to what type of matrix is stored in the data set and what data set types are accepted as input by the other procedures you plan to use. If you do not follow these steps and you use the TYPE=CORR data set with no correlation matrix as input to another procedure, the procedure might issue an error message indicating that the correlation matrix is missing from the data set.

You can create special SAS data sets directly in a DATA step by specifying the TYPE= option in parentheses after the data set name in the DATA statement. See “[Example A.2: Creating a TYPE=CORR Data Set in a DATA Step](#)” on page 8696 for an example. If you use a DATA step with a SET statement to modify a special SAS data set, you must specify the TYPE= option in the DATA statement. The TYPE= attribute of the data set in the SET statement is *not* automatically copied to the data set being created. You can determine the TYPE= attribute of a data set by using the CONTENTS procedure (see “[Example A.1: A TYPE=CORR Data Set Produced by PROC CORR](#)” on page 8695 and the *Base SAS Procedures Guide* for details).

[Table A.1](#) summarizes the TYPE= data sets that can be used as input to SAS/STAT procedures. [Table A.2](#) summarizes the TYPE= data sets that are created by SAS/STAT procedures and the statements each procedure uses to create its special output data sets. Most procedures accept ordinary SAS data sets and create ordinary output SAS data sets with no TYPE= specification in addition to the special data sets shown in the tables. When you specify a data set with a type that the procedure does not recognize, the procedure prints an error message and stops executing.

Table A.1 SAS/STAT Procedures That Accept Special Input Data Sets Types

Procedure	Special TYPE= Data Sets Accepted
ACECLUS	ACE, CORR, COV, SSCP, UCORR, UCOV
BOXPLOT	BOXPLOT, CHARTSUM

Special SAS Data Sets

TYPE=ACE Data Sets

A TYPE=ACE data set is created by the ACECLUS procedure, and it contains the approximate within-cluster covariance estimate, as well as eigenvalues and eigenvectors from a canonical analysis, among other statistics. It can be used as input to the ACECLUS procedure to initialize another execution of PROC ACECLUS. It can also be used to compute canonical variable scores with PROC SCORE and as input to PROC FACTOR, specifying METHOD=SCORE, to rotate the canonical variables. See Chapter 23, “[The ACECLUS Procedure](#),” for details.

TYPE=BOXPLOT Data Sets

A TYPE=BOXPLOT data set is created by and used by the BOXPLOT procedure. The data set contains the group summary statistics and outlier values required for constructing a schematic box plot. Each observation in a TYPE=BOXPLOT data set records the value of a single feature of one group’s box-and-whiskers plot, such as its mean. Consequently, a TYPE=BOXPLOT data set contains multiple observations per group. These must appear consecutively in the data set. The _TYPE_ variable identifies the feature whose value is recorded in a given observation. _TYPE_ values of ‘N’, ‘MIN’, ‘Q1’, ‘MEDIAN’, ‘MEAN’, ‘Q3’, and ‘MAX’ are required for each group. See Chapter 26, “[The BOXPLOT Procedure](#),” for details.

TYPE=CALISFIT Data Sets

PROC CALIS creates a TYPE=CALISFIT data set. This data set contains the names of the model fit indices and their values. A TYPE=CALISFIT data set is intended to save all the fit index values for future use, especially when the customized fit summary table shows only a small number of fit indices. See Chapter 27, “[The CALIS Procedure](#),” for details.

TYPE=CALISMDL Data Sets

PROC CALIS creates and accepts as input a TYPE=CALISMDL data set. This data set contains the model specification and the computed parameter estimates. A TYPE=CALISMDL data set is intended to be reused as an input data set to specify good initial values in subsequent analyses by PROC CALIS. See Chapter 27, “[The CALIS Procedure](#),” for details.

TYPE=CHARTSUM Data Sets

A TYPE=CHARTSUM data set is created by and used by the BOXPLOT procedure. The data set contains group summary statistics associated with box-and-whiskers plots. See Chapter 26, “[The BOXPLOT Procedure](#),” for details.

TYPE=CORR Data Sets

A TYPE=CORR data set usually contains a correlation matrix and possibly other statistics including means, standard deviations, and the number of observations in the original SAS data set from which the correlation matrix was computed. Using PROC CORR with an output data set option (OUTP=, OUTS=, OUTK=, OUTH=, or OUT=) produces a TYPE=CORR data set. (For a complete description of the CORR procedure, see the *Base SAS Procedures Guide: Statistical Procedures*.) The CALIS, CANCORR, CANDISC, DISCRIM, PRINCOMP, and VARCLUS procedures can also create a TYPE=CORR data set with additional statistics (the CORR option is needed in PROC CALIS). A TYPE=CORR data set containing a correlation matrix can be used as input for the ACECLUS, CALIS, CANCORR, CANDISC, DISCRIM, FACTOR, PRINCOMP, REG, SCORE, STEPDISC, and VARCLUS procedures. The variables in a TYPE=CORR data set are as follows:

- the BY variable or variables, if a BY statement is used with the procedure
- `_TYPE_`, a character variable of length eight with values identifying the type of statistic in each observation, such as 'MEAN', 'STD', 'N', and 'CORR'
- `_NAME_`, a character variable with values identifying the variable with which a given row of the correlation matrix is associated
- other variables that were analyzed by the CORR procedure or other procedures

The usual values of the `_TYPE_` variable are as follows:

<code>_TYPE_</code>	Contents
MEAN	mean of each variable analyzed
STD	standard deviation of each variable
N	number of observations used in the analysis. PROC CORR records the number of nonmissing values for each variable unless the NOMISS option is used. If the NOMISS option is specified, or if the CALIS, CANCORR, CANDISC, PRINCOMP, or VARCLUS procedure is used to create the data set, observations with one or more missing values are omitted from the analysis, so this value is the same for each variable and provides the number of observations with no missing values. If a FREQ statement is used with the procedure that creates the data set, the number of observations is the sum of the relevant values of the variable in the FREQ statement. Procedures that read a TYPE=CORR data set use the smallest value in the observation with <code>_TYPE_='N'</code> as the number of observations in the analysis.
SUMWGT	sum of the observation weights if a WEIGHT statement is used with the procedure that creates the data set. The values are determined analogously to those of the <code>_TYPE_='N'</code> observation.
CORR	correlations with the variable named by the <code>_NAME_</code> variable

There might be additional observations in a TYPE=CORR data set depending on the particular procedure and options used.

If you create a TYPE=CORR data set yourself, the data set need not contain the observations with `_TYPE_='MEAN'`, 'STD', 'N', or 'SUMWGT', unless you intend to use one of the discriminant procedures. Procedures assume that all of the means are 0.0 and that the standard deviations are 1.0 if this information is not in the TYPE=CORR data set. If `_TYPE_='N'` does not appear, most procedures assume that the number of observations is 10,000; significance tests and other statistics that depend on the number

of observations are, of course, meaningless. In the CALIS and CANCELL procedures, you can use the EDF= option instead of including a _TYPE_='N' observation.

A correlation matrix is symmetric; that is, the correlation between X and Y is the same as the correlation between Y and X. The CALIS, CANCELL, CANDISC, CORR, DISCRIM, PRINCOMP, and VARCLUS procedures output the entire correlation matrix. If you create the data set yourself, you need to include only one of the two occurrences of the correlation between two variables; the other can be given a missing value.

If you create a TYPE=CORR data set yourself, the _TYPE_ and _NAME_ variables are not necessary except for use with the discriminant procedures and PROC SCORE. If there is no _TYPE_ variable, then all observations are assumed to contain correlations. If there is no _NAME_ variable, the first observation is assumed to correspond to the first variable in the analysis, the second observation to the second variable, and so on. However, if you omit the _NAME_ variable, you will not be able to analyze arbitrary subsets of the variables or list the variables in a VAR or MODEL statement in a different order.

Example A.1: A TYPE=CORR Data Set Produced by PROC CORR

See Figure A.1 for an example of a TYPE=CORR data set produced by the following SAS statements. Figure A.2 displays partial output from PROC CONTENTS, which indicates that the “Data Set Type” is ‘CORR’.

Example A.2: Creating a TYPE=CORR Data Set in a DATA Step

This example creates a TYPE=CORR data set by reading a correlation matrix in a DATA step. Figure A.3 shows the resulting data set.

TYPE=COV Data Sets

A TYPE=COV data set is similar to a TYPE=COV data set except that it has `_TYPE_='COV'` observations containing covariances instead of or in addition to `_TYPE_='CORR'` observations containing correlations. The CALIS and PRINCOMP procedures create a TYPE=COV data set (the COV option is needed in PROC PRINCOMP). You can also create a TYPE=COV data set by using PROC CORR with the COV and NO-CORR options and specifying the data set option TYPE=COV in parentheses following the name of the output data set. You can use only the OUTP= or OUT= option to create a TYPE=COV data set with PROC CORR. Another way to create a TYPE=COV data set is to read a covariance matrix in a data set, in the same manner as shown in “[Example A.2: Creating a TYPE=COV Data Set in a DATA Step](#)” on page 8696 for a TYPE=COV data set. TYPE=COV data sets are used by the same procedures that use TYPE=COV data sets.

TYPE=CSSCP Data Sets

A TYPE=CSSCP data set contains a corrected sum of squares and crossproducts (CSSCP) matrix. TYPE=CSSCP data sets are created by using the CORR procedure with the CSSCP option and specifying the data set option TYPE=CSSCP in parentheses following the name of the OUTP= or OUT= data set. You can also create TYPE=CSSCP data sets in a DATA step; in this case, TYPE=CSSCP must be specified as a data set option. The variables in a TYPE=CSSCP data set are the same as those found in a TYPE=SSCP data set, except that there is not a variable called Intercept or a row with `_NAME_='Intercept'`. TYPE=CSSCP data sets are read by only the CANDISC, DISCRIM, and STEPDISC procedures. Formulas useful for illustrating differences between corrected and uncorrected matrices in some special SAS data sets are shown in the section “[Definitional Formulas](#)” on page 8702.

TYPE=DISTANCE Data Sets

PROC DISTANCE creates a TYPE=DISTANCE or TYPE=SIMILAR data set, depending on the METHOD= option. TYPE=DISTANCE can be used as an input data set to PROC MODECLUS or

PROC CLUSTER, but TYPE=SIMILAR cannot be used as an input to any procedures. The proximity measures are stored as a lower triangular matrix or a square matrix in the OUT= data set (depending on the SHAPE= option). See Chapter 34, “[The DISTANCE Procedure](#),” for details. You can also create a TYPE=DISTANCE data set in a DATA step by reading or computing a lower triangular or symmetric matrix of dissimilarity values, such as a chart of mileage between cities. The number of observations must be equal to the number of variables used in the analysis. This type of data set is used as input by the CLUSTER and MODECLUS procedures. PROC CLUSTER ignores the upper triangular portion of a TYPE=DISTANCE data set and assumes that all main diagonal values are zero, even if they are missing. PROC MODECLUS uses the entire distance matrix and does not require the matrix to be symmetric. See Chapter 31, “[The CLUSTER Procedure](#),” and Chapter 60, “[The MODECLUS Procedure](#),” for examples and details.

TYPE=EST Data Sets

A TYPE=EST data set contains parameter estimates. The CALIS, CATMOD, LIFEREG, LOGISTIC, NLIN, ORTHOREG, PHREG, PROBIT, and REG procedures create TYPE=EST data sets when the OUT=EST= option is specified. A TYPE=EST data set produced by PROC LIFEREG, PROC ORTHOREG, or PROC REG can be used with PROC SCORE to compute residuals or predicted values. The variables in a TYPE=EST data set include the following:

- the BY variables, if a BY statement is used
- `_TYPE_`, a character variable of length eight, that indicates the type of estimate. The values depend on which procedure created the data set. Usually a value of 'PARM' or 'PARMS' indicates estimated regression coefficients, and a value of 'COV' or 'COVB' indicates estimated covariances of the parameter estimates. Some procedures, such as PROC NLIN, have other values of `_TYPE_` for special purposes.
- `_NAME_`, a character variable that contains the values of the names of the rows of the covariance matrix when the procedure outputs the covariance matrix of the parameter estimates
- variables that contain the parameter estimates, usually the same variables that appear in the VAR statement or in any MODEL statement. See Chapter 27, “[The CALIS Procedure](#),” Chapter 30, “[The CATMOD Procedure](#),” and Chapter 63, “[The NLIN Procedure](#),” for details on the variable names used in output data sets created by those procedures.

Other variables can be included depending on the particular procedure and options used.

Example A.3: A TYPE=EST Data Set Produced by PROC REG

Figure A.4 shows the TYPE=EST data set produced by the following statements:

```
proc reg data=SocEcon outest=regest covout;
  full:  model house=pop school employ services / noprint;
  empser: model house=employ services / noprint;
run; quit;
```

```
proc print data=regest;
run;
```

10	.	.	-6.41	134.49	.	

TYPE=FACTOR Data Sets

A TYPE=FACTOR data set is created by PROC FACTOR when the OUTSTAT= option is specified. The CALIS, CANCELL, FACTOR, PRINCOMP, SCORE, and VARCLUS procedures can use TYPE=FACTOR data sets as input. The variables are the same as in a TYPE=CORR data set. The statistics include means, standard deviations, sample size, correlations, eigenvalues, eigenvectors, factor patterns, residual correlations, scoring coefficients, and others depending on the options specified. See Chapter 35, “The FACTOR Procedure,” for details. When the NOINT option is used with the OUTSTAT= option in PROC FACTOR, the value of the _TYPE_ variable is set to 'USCORE' instead of 'SCORE' to indicate that the scoring coefficients have not been corrected for the mean. If this data set is used with PROC SCORE, the value of the _TYPE_ variable tells PROC SCORE whether or not to subtract the mean from the scoring coefficients.

TYPE=LINEAR Data Sets

A TYPE=LINEAR data set contains the coefficients of a linear function of the variables in observations with `_TYPE_='LINEAR'`. PROC DISCRIM stores linear discriminant function coefficients in a TYPE=LINEAR data set when you specify `METHOD=NORMAL` (the default method), `POOL=YES`, and an `OUTSTAT=` data set; the data set can be used in a subsequent invocation of PROC DISCRIM to classify additional observations. Many other statistics can be included depending on the options used. See Chapter 33, “[The DISCRIM Procedure](#),” for details.

TYPE=LOGISMOD Data Sets

A TYPE=LOGISMOD data set contains information about a logistic regression model fit by PROC LOGISTIC. PROC LOGISTIC both creates and reads TYPE=LOGISMOD data sets. See Chapter 54, “[The LOGISTIC Procedure](#),” for details.

TYPE=MIXED Data Sets

A TYPE=MIXED data set contains coefficients of either a linear or a quadratic function, or both if there are BY groups. PROC DISCRIM produces a TYPE=MIXED data set when you specify `METHOD=NORMAL` (the default method), `POOL=TEST`, and an `OUTSTAT=` data set. See Chapter 33, “[The DISCRIM Procedure](#),” for details.

TYPE=QUAD Data Sets

A TYPE=QUAD data set contains the coefficients of a quadratic function of the variables in observations with `_TYPE_='QUAD'`. PROC DISCRIM stores quadratic discriminant function coefficients in a TYPE=QUAD data set when you specify `METHOD=NORMAL` (the default method), `POOL=NO`, and an `OUTSTAT=` data set; the data set can be used in a subsequent invocation of PROC DISCRIM to classify additional observations. Many other statistics can be included depending on the options used. See Chapter 33, “[The DISCRIM Procedure](#),” for details.

TYPE=SSCP Data Sets

A TYPE=SSCP data set contains an uncorrected sum of squares and crossproducts (SSCP) matrix. TYPE=SSCP data sets are produced by PROC REG when the `OUTSSCP=` option is specified in the PROC REG statement. You can also create a TYPE=SSCP data set by using PROC CORR with the SSCP option and specifying the data set option `TYPE=SSCP` in parentheses following the name of the `OUTP=` or `OUT=` data set. You can also create TYPE=SSCP data sets in a DATA step; in this case, TYPE=SSCP must be specified as a data set option.

The variables in a TYPE=SSCP data set include those found in a TYPE=CORR data set. In addition, there is a variable called `Intercept` that contains crossproducts for the intercept (sums of the variables). The

SSCP matrix is stored in observations with `_TYPE_='SSCP'`, including a row with `_NAME_='Intercept'`. PROC REG also outputs an observation with `_TYPE_='N'`. PROC CORR includes observations with `_TYPE_='MEAN'` and `_TYPE_='STD'` as well. TYPE=SSCP data sets are used by the same procedures that use TYPE=CORR data sets.

Example A.4: A TYPE=SSCP Data Set Produced by PROC REG

The following statements create a TYPE=SSCP data set from the SocEcon input data set created in “Example A.1: A TYPE=CORR Data Set Produced by PROC CORR” on page 8695:

```
proc reg data=SocEcon outsscp=regsscp;
    model house=pop school employ services / noprint;
run; quit;

proc print data=regsscp;
run;
```

The data set is created by PROC REG and is displayed in Figure A.5.

Figure A.5 A TYPE=SSCP Data Set Produced by PROC REG

7	N		12.0	12	12.00	12	12	12

TYPE=TREE Data Sets

Some clustering procedures produce TYPE=TREE data sets. For example, in PROC CLUSTER, a TYPE=TREE data set contains one observation for each observation in the input data set, plus one observation for each cluster of two or more observations (that is, one observation for each node of the cluster tree). The total number of output observations is usually $2n - 1$, where n is the number of input observations. The density methods might produce fewer output observations when the number of clusters cannot be reduced to one.

In PROC VARCLUS, the OUTTREE= data set contains one observation for each variable clustered plus one observation for each cluster of two or more variables—that is, one observation for each node of the cluster tree. The total number of output observations is between n and $2n - 1$, where n is the number of variables clustered. See Chapter 31, “The CLUSTER Procedure,” and Chapter 100, “The VARCLUS Procedure,” for details.

TYPE=UCORR Data Sets

A TYPE=UCORR data set is almost identical to a TYPE=CORR data set, except that the correlations are uncorrected for the mean. The corresponding value of the `_TYPE_` variable is 'UCORR' instead of 'CORR'. Uncorrected standard deviations are in observations with `_TYPE_='USTD'`. A TYPE=UCORR data set can be used as input for every SAS/STAT procedure that uses a TYPE=CORR data set, except for the CANDISC, DISCRIM, and STEPDISC procedures. TYPE=UCORR data sets can be created by the CANCORR, PRINCOMP, and VARCLUS procedures.

TYPE=UCOV Data Sets

A TYPE=UCOV data set is similar to a TYPE=COV data set, except that the covariances are uncorrected for the mean. Also, the corresponding value of the `_TYPE_` variable is 'UCOV' instead of 'COV'. A TYPE=UCOV data set can be used as input for every SAS/STAT procedure that uses a TYPE=COV data set, except for the CANDISC, DISCRIM, and STEPDISC procedures. TYPE=UCOV data sets can be created by the PRINCOMP procedure.

TYPE=WEIGHT Data Sets

The CALIS procedure creates and accepts as input a TYPE=WEIGHT data set. This data set contains the weight matrix used in generalized, weighted, or diagonally weighted least squares estimation. See Chapter 27, “[The CALIS Procedure](#),” for details.

Definitional Formulas

This section contrasts corrected and uncorrected SSCP, COV, and CORR matrices by showing how these matrices can be computed. In the following formulas, assume that the data consist of two variables, X and Y , with n observations.

$$\text{SSCP} = \begin{bmatrix} n & \sum X & \sum Y \\ \sum X & \sum X^2 & \sum XY \\ \sum Y & \sum XY & \sum Y^2 \end{bmatrix}$$

$$\text{CSSCP} = \begin{bmatrix} \sum (X - \bar{X})^2 & \sum (X - \bar{X})(Y - \bar{Y}) \\ \sum (X - \bar{X})(Y - \bar{Y}) & \sum (Y - \bar{Y})^2 \end{bmatrix}$$

$$\text{COV} = \frac{\text{CSSCP}}{n-1} = \frac{1}{n-1} \begin{bmatrix} \sum (X - \bar{X})^2 & \sum (X - \bar{X})(Y - \bar{Y}) \\ \sum (X - \bar{X})(Y - \bar{Y}) & \sum (Y - \bar{Y})^2 \end{bmatrix}$$

$$\text{UCOV} = \frac{1}{n} \begin{bmatrix} \sum X^2 & \sum XY \\ \sum XY & \sum Y^2 \end{bmatrix}$$

$$\text{CORR} = \begin{bmatrix} 1 & \frac{\sum (X - \bar{X})(Y - \bar{Y})}{\sqrt{\sum (X - \bar{X})^2 \sum (Y - \bar{Y})^2}} \\ \frac{\sum (X - \bar{X})(Y - \bar{Y})}{\sqrt{\sum (X - \bar{X})^2 \sum (Y - \bar{Y})^2}} & 1 \end{bmatrix}$$

$$\text{UCORR} = \begin{bmatrix} 1 & \frac{\sum XY}{\sqrt{\sum X^2 \sum Y^2}} \\ \frac{\sum XY}{\sqrt{\sum X^2 \sum Y^2}} & 1 \end{bmatrix}$$

Overview of Sashelp Data Sets

SAS provides over 200 data sets in the Sashelp library. These data sets are available for you to use for examples and for testing code. For example, the following step uses the Sashelp.Class data set:

```
proc reg data=sashelp.class;  
    model weight = height;  
run; quit;
```

You do not need to provide a DATA step to use Sashelp data sets.

The following steps list all of the data sets that are available in Sashelp:

```
ods listing close;  
proc contents data=sashelp._all_;  
    ods output members=m;  
run;  
ods listing;  
  
proc print;  
    where memtype = 'DATA';  
run;
```

The results of these steps (over 200 data set names) are not displayed.

The following steps provide detailed information about the Sashelp data sets:

```
proc contents data=sashelp._all_;  
run;
```

The results of this step (hundreds of pages of PROC CONTENTS information) are not displayed.

Eight data sets are frequently used in SAS/STAT documentation, and information about these data sets is displayed in the next sections:

Sashelp.BMT	Bone marrow transplant data
Sashelp.Class	Class data
Sashelp.ENS0	El Niño southern oscillation data
Sashelp.Fish	Finland's Lake Laengelmavesi fish catch data
Sashelp.Gas	Exhaust emissions data
Sashelp.Iris	Fisher (1936) iris data
Sashelp.Thick	Coal seam thickness data
Sashelp.Mileages	Flying mileages between five U.S. cities data

Bone Marrow Transplant Data

The following steps display information about the data set Sashelp.BMT and create [Figure B.1](#):

```

title 'Bone Marrow Transplant Data';
proc contents data=sashelp.bmt varnum;
    ods select position;
run;

title 'The First Five Observations Out of 137';
proc print data=sashelp.bmt (obs=5);
run;

title 'The Risk Group Variable';
proc freq data=sashelp.bmt;
    tables group;
run;

```

2	Ethanol	12	0.761	2.295
3	Ethanol	12	1.108	1.498
4	Ethanol	12	1.016	2.881
5	Ethanol	12	1.189	0.760

Figure B.5 *continued*

The Fuel Type Variable				
Fuel	Frequency	Percent	Cumulative Frequency	Cumulative Percent
82rongas	9	5.26	9	5.26
94%Eth	25	14.62	34	19.88
Ethanol	90	52.63	124	72.51
Gasohol	13	7.60	137	80.12
Indolene	22	12.87	159	92.98
Methanol	12	7.02	171	100.00

Fisher (1936) Iris Data

The following steps display information about the data set Sashelp.Iris and create [Figure B.6](#):

```

title 'Fisher (1936) Iris Data';
proc contents data=sashelp.iris varnum;
    ods select position;
run;

title 'The First Five Observations Out of 150';
proc print data=sashelp.iris(obs=5);
run;

title 'The Iris Species Variable';
proc freq data=sashelp.iris;
    tables species;
run;

```

Figure B.6 Fisher (1936) Iris Data

Fisher (1936) Iris Data				
Variables in Creation Order				
#	Variable	Type	Len	Label
1	Species	Char	10	Iris Species
2	SepalLength	Num	8	Sepal Length (mm)
3	SepalWidth	Num	8	Sepal Width (mm)
4	PetalLength	Num	8	Petal Length (mm)
5	PetalWidth	Num	8	Petal Width (mm)

The First Five Observations Out of 150					
Obs	Species	Sepal Length	Sepal Width	Petal Length	Petal Width
1	Setosa	50	33	14	2
2	Setosa	46	34	14	3
3	Setosa	46	36	10	2
4	Setosa	51	33	17	5
5	Setosa	55	35	13	2

Figure B.6 *continued*

The Iris Species Variable				
Iris Species				
Species	Frequency	Percent	Cumulative Frequency	Cumulative Percent
Setosa	50	33.33	50	33.33
Versicolor	50	33.33	100	66.67
Virginica	50	33.33	150	100.00

Coal Seam Thickness Data

The following steps display information about the data set Sashelp.Thick and create [Figure B.7](#):

```
title 'Coal Seam Thickness Data';
proc contents data=sashelp.thick varnum;
  ods select position;
run;

title 'The First Five Observations Out of 75';
proc print data=sashelp.thick(obs=5);
run;
```

Figure B.7 Coal Seam Thickness Data

Coal Seam Thickness Data				
Variables in Creation Order				
#	Variable	Type	Len	Label
1	East	Num	8	
2	North	Num	8	
3	Thick	Num	8	Coal Seam Thickness
The First Five Observations Out of 75				
Obs	East	North	Thick	
1	0.7	59.6	34.1	
2	2.1	82.7	42.2	
3	4.7	75.1	39.5	
4	4.8	52.8	34.3	
5	5.9	67.1	37.0	

Flying Mileages between Five U.S. Cities Data

The following steps display information about the data set Sashelp.Mileages and create Figure B.8:

```

title 'Flying Mileages between Five US Cities Data';
proc contents data=sashelp.mileages varnum;
    ods select position;
run;

title 'The Full Data Set';
proc print data=sashelp.mileages label;
    id city;
run;

```

Your Turn

We welcome your feedback.

- If you have comments about this book, please send them to **`yourturn@sas.com`**. Include the full title and page numbers (if applicable).
- If you have comments about the software, please send them to **`suggest@sas.com`**.

SAS® Publishing Delivers!

Whether you are new to the work force or an experienced professional, you need to distinguish yourself in this rapidly changing and competitive job market. SAS® Publishing provides you with a wide range of resources to help you set yourself apart. Visit us online at support.sas.com/bookstore.

SAS® Press

Need to learn the basics? Struggling with a programming problem? You'll find the expert answers that you need in example-rich books from SAS Press. Written by experienced SAS professionals from around the world, SAS Press books deliver real-world insights on a broad range of topics for all skill levels.

support.sas.com/saspress

SAS® Documentation

To successfully implement applications using SAS software, companies in every industry and on every continent all turn to the one source for accurate, timely, and reliable information: SAS documentation. We currently produce the following types of reference documentation to improve your work experience:

- Online help that is built into the software.
- Tutorials that are integrated into the product.
- Reference documentation delivered in HTML and PDF – **free** on the Web.
- Hard-copy books.
