7	2	COV	RunTime	-0.668	0.11456	-0.00313
8	2	COV	RunPulse	-0.419	-0.00313	0.00264

The following statements combine the results for the imputed data sets. The EDF= option is specified to request that the adjusted degrees of freedom be used in the analysis. For a regression model with three independent variables (including the Intercept) and 31 observations, the complete-data error degrees of freedom is 28.

```
proc mianalyze data=outreg edf=28;
  modeleffects Intercept RunTime RunPulse;
run;
```

Output 58.3.2 Variance Information

The MIANALYZE Procedure				
Variance Information				
Parameter	-----Variance-----			DF
	Between	Within	Total	
Intercept	45.529229	76.543614	131.178689	9.1917
RunTime	0.019390	0.106220	0.129487	18.311
RunPulse	0.001007	0.002537	0.003746	12.137
Variance Information				
Parameter	Relative Increase in Variance	Fraction Missing Information	Relative Efficiency	
Intercept	0.713777	0.461277	0.915537	
RunTime	0.219051	0.192620	0.962905	
RunPulse	0.476384	0.355376	0.933641	

The “Variance Information” table in [Output 58.3.2](#) displays the between-imputation, within-imputation, and total variances for combining complete-data inferences.

The “Parameter Estimates” table in [Output 58.3.3](#) displays the estimated mean and standard error of the regression coefficients. The inferences are based on the t distribution. The table also displays a 95% mean confidence interval and a t test with the associated p -value for the hypothesis that the regression coefficient is equal to zero. Since the p -value for RunPulse is 0.1597, this variable can be removed from the regression model.

Output 58.3.3 Parameter Estimates

Parameter Estimates					
Parameter	Estimate	Std Error	95% Confidence Limits		DF

Example 58.4: Reading Mixed Model Results from PARMS= and COVB= Data Sets

This example creates data sets that contains parameter estimates and covariance matrices computed by a mixed model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the parameters.

The following PROC MIXED statements generate the fixed-effect parameter estimates and covariance matrix for each imputed data set:

```
proc mixed data=outmi;
  model Oxygen= RunTime RunPulse RunTime*RunPulse/solution covb;
  by _Imputation_;
  ods output SolutionF=mixparms CovB=mixcovb;
run;
```

The following statements display (in [Output 58.4.1](#)) output parameter estimates from PROC MIXED for the first two imputed data sets:

```
proc print data=mixparms (obs=8);
  var _Imputation_ Effect Estimate StdErr;
  title 'MIXED Model Coefficients (First Two Imputations)';
run;
```

Output 58.4.1 PROC MIXED Model Coefficients

MIXED Model Coefficients (First Two Imputations)				
Obs	_Imputation_	Effect	Estimate	StdErr
1	1	Intercept	148.09	81.5231
2	1	RunTime	-8.8115	7.8794
3	1	RunPulse	-0.4123	0.4684
4	1	RunTime*RunPulse	0.03437	0.04517
5	2	Intercept	64.3607	64.6034
6	2	RunTime	-1.1270	6.4307
7	2	RunPulse	0.08160	0.3688
8	2	RunTime*RunPulse	-0.01069	0.03664

The following statements display (in [Output 58.4.2](#)) the output covariance matrices associated with the parameter estimates from PROC MIXED for the first two imputed data sets:

```
proc print data=mixcovb (obs=8);
  var _Imputation_ Row Effect Col1 Col2 Col3 Col4;
  title 'Covariance Matrices (First Two Imputations)';
run;
```

Output 58.4.2 PROC MIXED Covariance Matrices

Covariance Matrices (First Two Imputations)						
Obs	_Imputation_	Row Effect	Col1	Col2	Col3	Col4
1	1	1 Intercept	6646.01	-637.40	-38.1515	3.6542
2	1	2 RunTime	-637.40	62.0842	3.6548	-0.3556
3	1	3 RunPulse	-38.1515	3.6548	0.2194	-0.02099
4	1	4 RunTime*RunPulse	3.6542	-0.3556	-0.02099	0.002040
5	2	1 Intercept	4173.59	-411.46	-23.7889	2.3441
6	2	2 RunTime	-411.46	41.3545	2.3414	-0.2353
7	2	3 RunPulse	-23.7889	2.3414	0.1360	-0.01338
8	2	4 RunTime*RunPulse	2.3441	-0.2353	-0.01338	0.001343

Note that the variables Col1, Col2, Col3, and Col4 are used to identify the effects Intercept, RunTime, RunPulse, and RunTime*RunPulse, respectively, through the variable Row.

For univariate inference, only parameter estimates and their associated standard errors are needed. The following statements use the MIANALYZE procedure with the input PARMS= data set to produce univariate results:

```
proc mianalyze parms=mixparms edf=28;
  modeleffects Intercept RunTime RunPulse RunTime*RunPulse;
run;
```

The “Variance Information” table in [Output 58.4.3](#) displays the between-imputation, within-imputation, and total variances for combining complete-data inferences.

Output 58.4.3 Variance Information

The MIANALYZE Procedure

RunTime*RunPulse	0	0.56	0.5846	

Since each covariance matrix contains variables Row, Col1, Col2, Col3, and Col4 for parameters, the EFFECTVAR=ROWCOL option is needed when you specify the COVB= option. The following statements illustrate the use of the MIANALYZE procedure with input PARMS= and COVB(EFFECTVAR=ROWCOL)= data sets:

```
proc mianalyze parms=mixparms edf=28
      covb(effectvar=rowcol)=mixcovb;
      modeleffects Intercept RunTime RunPulse RunTime*RunPulse;
run;
```

Example 58.5: Reading Generalized Linear Model Results

This example creates data sets that contains parameter estimates and corresponding covariance matrices computed by a generalized linear model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC GENMOD to generate the parameter estimates and covariance matrix for each imputed data set:

```
proc genmod data=outmi;
  model Oxygen= RunTime RunPulse/covb;
  by _Imputation_;
  ods output ParameterEstimates=gmparms
             ParmInfo=gmpinfo
             CovB=gmcovb;
run;
```

The following statements print (in [Output 58.5.1](#)) the output parameter estimates and covariance matrix from PROC GENMOD for the first two imputed data sets:

```
proc print data=gmparms (obs=8);
  var _Imputation_ Parameter Estimate StdErr;
  title 'GENMOD Model Coefficients (First Two Imputations)';
run;
```

Output 58.5.1 PROC GENMOD Model Coefficients

GENMOD Model Coefficients (First Two Imputations)

7	2	Prm3	-0.378616	-0.002826	0.0023843
8	2	Scale	1.602E-14	1.755E-16	-1.02E-16

The following statements use the MIANALYZE procedure with input PARMS=, PARMINFO=, and COVB= data sets:

```
proc mianalyze parms=gmparms covb=gmcovb parminfo=gmpinfo;
  modeleffects Intercept RunTime RunPulse;
run;
```

Since the GENMOD procedure computes maximum likelihood estimates for the covariance matrix, the EDF= option is not used. The resulting model coefficients are identical to the estimates in [Output 58.3.3](#) in [Example 58.3](#). However, the standard errors are slightly different because in this example, maximum likelihood estimates for the standard errors are combined without the EDF= option, whereas in [Example 58.3](#), unbiased estimates for the standard errors are combined with the EDF= option.

Example 58.6: Reading GLM Results from PARMS= and XPXI= Data Sets

This example creates data sets that contains parameter estimates and corresponding $(X'X)^{-1}$ matrices computed by a general linear model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC GLM to generate the parameter estimates and $(X'X)^{-1}$ matrix for each imputed data set:

```
proc glm data=outmi;
  model Oxygen= RunTime RunPulse/inverse;
  by _Imputation_;
  ods output ParameterEstimates=glmparms
             InvXPX=glmxpxi;
quit;
```

The following statements display (in [Output 58.6.1](#)) the output parameter estimates and standard errors from PROC GLM for the first two imputed data sets:

```
proc print data=glmparms (obs=6);
  var _Imputation_ Parameter Estimate StdErr;
  title 'GLM Model Coefficients (First Two Imputations)';
run;
```

Output 58.6.1 PROC GLM Model Coefficients

GLM Model Coefficients (First Two Imputations)

The standard errors for the estimates in the output glmparms data set are needed to create the covariance matrix from the $(X'X)^{-1}$ matrix. The following statements use the MIANALYZE procedure with input PARMS= and XPXI= data sets to produce the same results as displayed in [Output 58.3.2](#) and [Output 58.3.3](#) in [Example 58.3](#):

```
proc mianalyze parms=glmparms xpxi=glmxpxi edf=28;
  modeleffects Intercept RunTime RunPulse;
run;
```

Example 58.7: Reading Logistic Model Results from PARMS= and COVB= Data Sets

This example creates data sets that contains parameter estimates and corresponding covariance matrices computed by a logistic regression analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC LOGISTIC to generate the parameter estimates and covariance matrix for each imputed data set:

```
proc logistic data=outfish;
  class Species;
  model Species= Height Width Height*Width/ covb;
  by _Imputation_;
  ods output ParameterEstimates=lgsparms
             CovB=lgscovb;
run;
```

The following statements display (in [Output 58.7.1](#)) the output logistic regression coefficients from PROC LOGISTIC for the first two imputed data sets:

```
proc print data=lgsparms (obs=8);
  title 'LOGISTIC Model Coefficients (First Two Imputations)';
run;
```

Output 58.7.1 PROC LOGISTIC Model Coefficients

Example 58.8: Reading Mixed Model Results with Classification Variables

This example creates data sets that contains parameter estimates and corresponding covariance matrices with classification variables computed by a mixed regression model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC MIXED to generate the parameter estimates and covariance matrix for each imputed data set:

```
proc mixed data=outfish;
  class Species;
  model Length= Species Height Width/ solution covb;
  by _Imputation_;
  ods output SolutionF=mxparms CovB=mxcovb;
run;
```

The following statements display (in [Output 58.8.1](#)) the output mixed model coefficients from PROC MIXED for the first two imputed data sets:

```
proc print data=mxparms (obs=10);
  var _Imputation_ Effect Species Estimate StdErr;
  title 'MIXED Model Coefficients (First Two Imputations)';
run;
```

Output 58.8.1 PROC MIXED Model Coefficients

MIXED Model Coefficients (First Two Imputations)

Example 58.9: Using a TEST statement

This example creates an EST-type data set that contains regression coefficients and their corresponding covariance matrices computed from imputed data sets. These estimates are then combined to generate valid statistical inferences about the regression model. A TEST statement is used to test linear hypotheses about the parameters.

The following statements use the REG procedure to generate regression coefficients:

```
proc reg data=outmi outest=outreg covout noprint;
  model Oxygen= RunTime RunPulse;
  by _Imputation_;
run;
```

The following statements combine the results for the imputed data sets. A TEST statement is used to test linear hypotheses of Intercept=0 and RunTime=RunPulse.

```
proc mianalyze data=outreg edf=28;
  modeleffects Intercept RunTime RunPulse;
  test Intercept, RunTime=RunPulse / mult;
run;
```

The “Test Specification” table in [Output 58.9.1](#) displays the **L** matrix and the **c** vector in a TEST statement. Since there is no label specified for the TEST statement, “Test 1” is used as the label.

Output 58.9.1 Test Specification

The MIANALYZE Procedure				
Test: Test 1				
Test Specification				
-----L Matrix-----				
Parameter	Intercept	RunTime	RunPulse	C
TestPrm1	1.000000	0	0	0
TestPrm2	0	1.000000	-1.000000	0

The “Variance Information” table in [Output 58.9.2](#) displays the between-imputation variance, within-imputation variance, and total variance for each univariate inference. A detailed description of these statistics is provided in the section “[Combining Inferences from Imputed Data Sets](#)” on page 4844 and the section “[Multiple Imputation Efficiency](#)” on page 4845.

Output 58.9.2 Variance Information

Variance Information				
-----Variance-----				
Parameter	Between	Within	Total	DF
TestPrm1	45.529229	76.543614	131.178689	9.1917
TestPrm2	0.014715	0.114324	0.131983	20.598

With the MULT option, the procedure assumes that the between-imputation covariance matrix is proportional to the within-imputation covariance matrix and displays a multivariate inference for all the linear components taken jointly in [Output 58.9.4](#).

Output 58.9.4 Multivariate Inference

Multivariate Inference					
Assuming Proportionality of Between/Within Covariance Matrices					
Avg Relative Increase in Variance	Num DF	Den DF	F for H0: Parameter=Theta0	Pr > F	
0.419868	2	35.053	60.34	<.0001	

Example 58.10: Combining Correlation Coefficients

This example combines sample correlation coefficients computed from a set of imputed data sets by using Fisher’s z transformation.

Fisher’s z transformation of the sample correlation r is

$$z = \frac{1}{2} \log \left(\frac{1+r}{1-r} \right)$$

The statistic z is approximately normally distributed with mean

$$\log\left(\frac{1+\rho}{1-\rho}\right)$$

and variance $1/(n-3)$, where ρ is the population correlation coefficient and n is the number of observations.

The following statements use the CORR procedure to compute the correlation r and its associated Fisher's z statistic between variables Oxygen and RunTime for each imputed data set. The ODS statement is used to save Fisher's z statistic in an output data set.

```
proc corr data=outmi fisher(biasadj=no);
  var Oxygen RunTime;
  by _Imputation_;
  ods output FisherPearsonCorr= outz;
run;
```

The following statements display the number of observations and Fisher's z statistic for each imputed data set in [Output 58.10.1](#):

```
proc print data=outz;
  title 'Fisher's Correlation Statistics';
  var _Imputation_ NObs ZVal;
run;
```

Output 58.10.1 Output z Statistics

Fisher's Correlation Statistics				
Obs	_Imputation_	NObs	ZVal	
1	1	31	-1.27869	
2	2	31	-1.30715	
3	3	31	-1.27922	
4	4	31	-1.39243	
5	5	31	-1.40146	

The following statements generate the standard error associated with the z statistic, $1/\sqrt{n-3}$:

```
data outz;
  set outz;
  StdZ= 1. / sqrt(NObs-3);
run;
```

The following statements use the MIANALYZE procedure to generate a combined parameter estimate \hat{z} and its variance, as shown in [Output 58.10.2](#). The ODS statement is used to save the parameter estimates in an output data set.

```
proc mianalyze data=outz;
  ods output ParameterEstimates=parms;
  modeleffects ZVal;
  stderr StdZ;
run;
```

Output 58.10.2 Combining Fisher's z Statistics

The MIANALYZE Procedure					
Parameter Estimates					
Parameter	Estimate	Std Error	95% Confidence Limits		DF
ZVal	-1.331787	0.200327	-1.72587	-0.93771	330.23
Parameter Estimates					
Parameter	Minimum	Maximum			
ZVal	-1.401459	-1.278686			
Parameter Estimates					
Parameter	Theta0	t for H0:			
		Parameter=Theta0	Pr > t		
ZVal	0	-6.65	<.0001		

In addition to the estimate for z , PROC MIANALYZE also generates 95% confidence limits for z , $\hat{z}_{.025}$ and $\hat{z}_{.975}$. The following statements print the estimate and 95% confidence limits for z in [Output 58.10.3](#):

```
proc print data=parms;
  title 'Parameter Estimates with 95% Confidence Limits';
  var Estimate LCLMean UCLMean;
run;
```

Output 58.10.3 Parameter Estimates with 95% Confidence Limits

Parameter Estimates with 95% Confidence Limits				
Obs	Estimate	LCLMean	UCLMean	
1	-1.331787	-1.72587	-0.93771	

An estimate of the correlation coefficient with its corresponding 95% confidence limits is then generated from the following inverse transformation as described in the section “[Correlation Coefficients](#)” on page 4849:

$$r = \tanh(z) = \frac{e^{2z} - 1}{e^{2z} + 1}$$

for $z = \hat{z}$, $\hat{z}_{.025}$, and $\hat{z}_{.975}$.

The following statements generate and display an estimate of the correlation coefficient and its 95% confidence limits, as shown in [Output 58.10.4](#):

```
data corr_ci;
  set parms;
  r=      tanh( Estimate);
  r_lower= tanh( LCLMean);
  r_upper= tanh( UCLMean);
run;
proc print data=corr_ci;
  title 'Estimated Correlation Coefficient '
        ' with 95% Confidence Limits';
  var r r_lower r_upper;
run;
```

Output 58.10.4 Estimated Correlation Coefficient

Estimated Correlation Coefficient with 95% Confidence Limits				
	Obs	r	r_lower	r_upper
	1	-0.86969	-0.93857	-0.73417

Overview: MIXED Procedure

The MIXED procedure fits a variety of mixed linear models to data and enables you to use these fitted models to make statistical inferences about the data. A *mixed linear model* is a generalization of the standard linear model used in the GLM procedure, the generalization being that the data are permitted to exhibit correlation and nonconstant variability. The mixed linear model, therefore, provides you with the flexibility of modeling not only the means of your data (as in the standard linear model) but their variances and covariances as well.

The primary assumptions underlying the analyses performed by PROC MIXED are as follows:

- The data are normally distributed (Gaussian).
- The means (expected values) of the data are linear in terms of a certain set of parameters.
- The variances and covariances of the data are in terms of a different set of parameters, and they exhibit a structure matching one of those available in PROC MIXED.

Since Gaussian data can be modeled entirely in terms of their means and variances/covariances, the two sets of parameters in a mixed linear model actually specify the complete probability distribution of the data. The parameters of the mean model are referred to as *fixed-effects parameters*, and the parameters of the variance-covariance model are referred to as *covariance parameters*.

The fixed-effects parameters are associated with known explanatory variables, as in the standard linear model. These variables can be either qualitative (as in the traditional analysis of variance) or quantitative (as in standard linear regression). However, the covariance parameters are what distinguishes the mixed linear model from the standard linear model.

The need for covariance parameters arises quite frequently in applications, the following being the two most typical scenarios:

- The experimental units on which the data are measured can be grouped into clusters, and the data from a common cluster are correlated.
- Repeated measurements are taken on the same experimental unit, and these repeated measurements are correlated or exhibit variability that changes.

The first scenario can be generalized to include one set of clusters nested within another. For example, if students are the experimental unit, they can be clustered into classes, which in turn can be clustered into schools. Each level of this hierarchy can introduce an additional source of variability and correlation. The second scenario occurs in longitudinal studies, where repeated measurements are taken over time. Alternatively, the repeated measures could be spatial or multivariate in nature.

PROC MIXED provides a variety of covariance structures to handle the previous two scenarios. The most common of these structures arises from the use of *random-effects parameters*, which are additional unknown random variables assumed to affect the variability of the data. The variances of the random-effects parameters, commonly known as *variance components*, become the covariance parameters for this particular structure. Traditional mixed linear models contain both fixed- and random-effects parameters, and, in fact, it is the combination of these two types of effects that led to the name *mixed model*. PROC MIXED fits not only these traditional variance component models but numerous other covariance structures as well.

PROC MIXED fits the structure you select to the data by using the method of *restricted maximum likelihood (REML)*, also known as *residual maximum likelihood*. It is here that the Gaussian assumption for the data is exploited. Other estimation methods are also available, including *maximum likelihood* and *MIVQUE0*. The details behind these estimation methods are discussed in subsequent sections.

After a model has been fit to your data, you can use it to draw statistical inferences via both the fixed-effects and covariance parameters. PROC MIXED computes several different statistics suitable for generating hypothesis tests and confidence intervals. The validity of these statistics depends upon the mean and variance-covariance model you select, so it is important to choose the model carefully. Some of the output from PROC MIXED helps you assess your model and compare it with others.

Basic Features

PROC MIXED provides easy accessibility to numerous mixed linear models that are useful in many common statistical analyses. In the style of the GLM procedure, PROC MIXED fits the specified mixed linear model and produces appropriate statistics.

Here are some basic features of PROC MIXED:

- covariance structures, including variance components, compound symmetry, unstructured, AR(1), Toeplitz, spatial, general linear, and factor analytic
- GLM-type grammar, by using **MODEL**, **RANDOM**, and **REPEATED** statements for model specification and **CONTRAST**, **ESTIMATE**, and **LSMEANS** statements for inferences
- appropriate standard errors for all specified estimable linear combinations of fixed and random effects, and corresponding *t* and *F* tests
- subject and group effects that enable blocking and heterogeneity, respectively
- REML and ML estimation methods implemented with a Newton-Raphson algorithm
- capacity to handle unbalanced data
- ability to create a SAS data set corresponding to any table

PROC MIXED uses the Output Delivery System (ODS), a SAS subsystem that provides capabilities for displaying and controlling the output from SAS procedures. ODS enables you to convert any of the output from PROC MIXED into a SAS data set. See the section “[ODS Table Names](#)” on page 4987.

The MIXED procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the statistical graphics available with the MIXED procedure, see the `PLOTS=` option in the `PROC MIXED` statement and the section “[ODS Graphics](#)” on page 4992.

Notation for the Mixed Model

This section introduces the mathematical notation used throughout this chapter to describe the mixed linear model. You should be familiar with basic matrix algebra (see Searle 1982). A more detailed description of the mixed model is contained in the section “[Mixed Models Theory](#)” on page 4958.

A statistical model is a mathematical description of how data are generated. The standard linear model, as used by the GLM procedure, is one of the most common statistical models:

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

In this expression, \mathbf{y} represents a vector of observed data, $\boldsymbol{\beta}$ is an unknown vector of fixed-effects parameters with known design matrix \mathbf{X} , and $\boldsymbol{\epsilon}$ is an unknown random error vector modeling the statistical noise around $\mathbf{X}\boldsymbol{\beta}$. The focus of the standard linear model is to model the mean of \mathbf{y} by using the fixed-effects parameters $\boldsymbol{\beta}$. The residual errors $\boldsymbol{\epsilon}$ are assumed to be independent and identically distributed Gaussian random variables with mean 0 and variance σ^2 .

The mixed model generalizes the standard linear model as follows:

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

Here, $\boldsymbol{\gamma}$ is an unknown vector of random-effects parameters with known design matrix \mathbf{Z} , and $\boldsymbol{\epsilon}$ is an unknown random error vector whose elements are no longer required to be independent and homogeneous.

To further develop this notion of variance modeling, assume that $\boldsymbol{\gamma}$ and $\boldsymbol{\epsilon}$ are Gaussian random variables that are uncorrelated and have expectations $\mathbf{0}$ and variances \mathbf{G} and \mathbf{R} , respectively. The variance of \mathbf{y} is thus

$$\mathbf{V} = \mathbf{ZGZ}' + \mathbf{R}$$

Note that, when $\mathbf{R} = \sigma^2\mathbf{I}$ and $\mathbf{Z} = \mathbf{0}$, the mixed model reduces to the standard linear model.

You can model the variance of the data, \mathbf{y} , by specifying the structure (or form) of \mathbf{Z} , \mathbf{G} , and \mathbf{R} . The model matrix \mathbf{Z} is set up in the same fashion as \mathbf{X} , the model matrix for the fixed-effects parameters. For \mathbf{G} and \mathbf{R} , you must select some *covariance structure*. Possible covariance structures include the following:

- variance components
- compound symmetry (common covariance plus diagonal)
- unstructured (general covariance)
- autoregressive

- spatial
- general linear
- factor analytic

By appropriately defining the model matrices **X** and **Z**, as well as the covariance structure matrices **G** and **R**, you can perform numerous mixed model analyses.

PROC MIXED Contrasted with Other SAS Procedures

PROC MIXED is a generalization of the GLM procedure in the sense that PROC GLM fits standard linear models, and PROC MIXED fits the wider class of mixed linear models. Both procedures have similar **CLASS**, **MODEL**, **CONTRAST**, **ESTIMATE**, and **LSMEANS** statements, but their **RANDOM** and **REPEATED** statements differ (see the following paragraphs). Both procedures use the non-full-rank model parameterization, although the sorting of classification levels can differ between the two. PROC MIXED computes only Type I–Type III tests of fixed effects, while PROC GLM computes Types I–IV.

The **RANDOM** statement in PROC MIXED incorporates random effects constituting the $\boldsymbol{\gamma}$ vector in the mixed model. However, in PROC GLM, effects specified in the **RANDOM** statement are still treated as fixed as far as the model fit is concerned, and they serve only to produce corresponding expected mean squares. These expected mean squares lead to the traditional ANOVA estimates of variance components. PROC MIXED computes REML and ML estimates of variance parameters, which are generally preferred to the ANOVA estimates (Searle 1988; Harville 1988; Searle, Casella, and McCulloch 1992). Optionally, PROC MIXED also computes MIVQUE0 estimates, which are similar to ANOVA estimates.

The **REPEATED** statement in PROC MIXED is used to specify covariance structures for repeated measurements on subjects, while the **REPEATED** statement in PROC GLM is used to specify various transformations with which to conduct the traditional univariate or multivariate tests. In repeated measures situations, the mixed model approach used in PROC MIXED is more flexible and more widely applicable than either the univariate or multivariate approach. In particular, the mixed model approach provides a larger class of covariance structures and a better mechanism for handling missing values (Wolfinger and Chang 1995).

PROC MIXED subsumes the VARCOMP procedure. PROC MIXED provides a wide variety of covariance structures, while PROC VARCOMP estimates only simple random effects. PROC MIXED carries out several analyses that are absent in PROC VARCOMP, including the estimation and testing of linear combinations of fixed and random effects.

The ARIMA and AUTOREG procedures provide more time series structures than PROC MIXED, although they do not fit variance component models. The CALIS procedure fits general covariance matrices, but the fixed effects structure of the model is formed differently than in PROC MIXED. The LATTICE and NESTED procedures fit special types of mixed linear models that can also be handled in PROC MIXED, although PROC MIXED might run slower because of its more general algorithm. The TSCSREG procedure analyzes time series cross-sectional data, and it fits some structures not available in PROC MIXED.

The GLIMMIX procedure fits generalized linear mixed models (GLMMs). Linear mixed models—where the data are normally distributed, given the random effects—are in the class of GLMMs. The MIXED procedure can estimate covariance parameters with ANOVA methods that are not available in the GLIMMIX procedure (see **METHOD=TYPE1**, **METHOD=TYPE2**, and **METHOD=TYPE3** in the **PROC MIXED**

statement). Also, PROC MIXED can perform a sampling-based Bayesian analysis through the **PRIOR** statement, and the procedure supports certain Kronecker-type covariance structures. These features are not available in the GLIMMIX procedure. The GLIMMIX procedure, on the other hand, accommodates nonnormal data and offers a broader array of post-processing features than the MIXED procedure.

Getting Started: MIXED Procedure

Clustered Data Example

Consider the following SAS data set as an introductory example:

```
data heights;
  input Family Gender$ Height @@;
  datalines;
1 F 67   1 F 66   1 F 64   1 M 71   1 M 72   2 F 63
2 F 63   2 F 67   2 M 69   2 M 68   2 M 70   3 F 63
3 M 64   4 F 67   4 F 66   4 M 67   4 M 67   4 M 69
;
```

The response variable Height measures the heights (in inches) of 18 individuals. The individuals are classified according to Family and Gender. You can perform a traditional two-way analysis of variance of these data with the following PROC MIXED statements:

```
proc mixed data=heights;
  class Family Gender;
  model Height = Gender Family Family*Gender;
run;
```

The **PROC MIXED** statement invokes the procedure. The **CLASS** statement instructs PROC MIXED to consider both Family and Gender as classification variables. Dummy (indicator) variables are, as a result, created corresponding to all of the distinct levels of Family and Gender. For these data, Family has four levels and Gender has two levels.

The **MODEL** statement first specifies the response (dependent) variable Height. The explanatory (independent) variables are then listed after the equal (=) sign. Here, the two explanatory variables are Gender and Family, and these are the main effects of the design. The third explanatory term, Family*Gender, models an interaction between the two main effects.

PROC MIXED uses the dummy variables associated with Gender, Family, and Family*Gender to construct the **X** matrix for the linear model. A column of 1s is also included as the first column of **X** to model a global intercept. There are no **Z** or **G** matrices for this model, and **R** is assumed to equal $\sigma^2\mathbf{I}$, where **I** is an 18×18 identity matrix.

The RUN statement completes the specification. The coding is precisely the same as with the GLM procedure. However, much of the output from PROC MIXED is different from that produced by PROC GLM.

The output from PROC MIXED is shown in [Figure 59.1](#)–[Figure 59.7](#).

The “Model Information” table in [Figure 59.1](#) describes the model, some of the variables that it involves, and the method used in fitting it. This table also lists the method (profile, factor, parameter, or none) for handling the residual variance.

Figure 59.1 Model Information

The Mixed Procedure	
Model Information	
Data Set	WORK.HEIGHTS
Dependent Variable	Height
Covariance Structure	Diagonal
Estimation Method	REML
Residual Variance Method	Profile
Fixed Effects SE Method	Model-Based
Degrees of Freedom Method	Residual

The “Class Level Information” table in [Figure 59.2](#) lists the levels of all variables specified in the **CLASS** statement. You can check this table to make sure that the data are correct.

Figure 59.2 Class Level Information

Class Level Information		
Class	Levels	Values
Family	4	1 2 3 4
Gender	2	F M

The “Dimensions” table in [Figure 59.3](#) lists the sizes of relevant matrices. This table can be useful in determining CPU time and memory requirements.

Figure 59.3 Dimensions

Dimensions	
Covariance Parameters	1

Number of Observations Not Used	0

The “Covariance Parameter Estimates” table in [Figure 59.5](#) displays the estimate of σ^2 for the model.

Figure 59.5 Covariance Parameter Estimates

Covariance Parameter Estimates	
Cov Parm	Estimate
Residual	2.1000

The “Fit Statistics” table in [Figure 59.6](#) lists several pieces of information about the fitted mixed model, including values derived from the computed value of the restricted/residual likelihood.

Figure 59.6 Fit Statistics

Fit Statistics	
-2 Res Log Likelihood	41.6
AIC (smaller is better)	43.6
AICC (smaller is better)	44.1
BIC (smaller is better)	43.9

The “Type 3 Tests of Fixed Effects” table in [Figure 59.7](#) displays significance tests for the three effects listed in the **MODEL** statement. The Type 3 F statistics and p -values are the same as those produced by the GLM procedure. However, because PROC MIXED uses a likelihood-based estimation scheme, it does not directly compute or display sums of squares for this analysis.

Figure 59.7 Tests of Fixed Effects

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
Gender	1	10	17.63	0.0018
Family	3	10	5.90	0.0139
Family*Gender	3	10	2.89	0.0889

The Type 3 test for Family*Gender effect is not significant at the 5% level, but the tests for both main effects are significant.

The important assumptions behind this analysis are that the data are normally distributed and that they are independent with constant variance. For these data, the normality assumption is probably realistic since the data are observed heights. However, since the data occur in clusters (families), it is very likely that observations from the same family are statistically correlated—that is, not independent.

The methods implemented in PROC MIXED are still based on the assumption of normally distributed data, but you can drop the assumption of independence by modeling statistical correlation in a variety of ways. You can also model variances that are heterogeneous—that is, nonconstant.

For the height data, one of the simplest ways of modeling correlation is through the use of *random effects*. Here the family effect is assumed to be normally distributed with zero mean and some unknown variance. This is in contrast to the previous model in which the family effects are just constants, or *fixed effects*. Declaring Family as a random effect sets up a common correlation among all observations having the same level of Family.

Declaring Family*Gender as a random effect models an additional correlation between all observations that have the same level of both Family and Gender. One interpretation of this effect is that a female in a certain family exhibits more correlation with the other females in that family than with the other males, and likewise for a male. With the height data, this model seems reasonable.

The statements to fit this correlation model in PROC MIXED are as follows:

```
proc mixed;
  class Family Gender;
  model Height = Gender;
  random Family Family*Gender;
run;
```

Note that Family and Family*Gender are now listed in the **RANDOM** statement. The dummy variables associated with them are used to construct the **Z** matrix in the mixed model. The **X** matrix now consists of a column of 1s and the dummy variables for Gender.

The **G** matrix for this model is diagonal, and it contains the variance components for both Family and Family*Gender. The **R** matrix is still assumed to equal $\sigma^2\mathbf{I}$, where **I** is an identity matrix.

The output from this analysis is as follows.

Figure 59.8 Model Information

The Mixed Procedure	
Model Information	
Data Set	WORK.HEIGHTS
Dependent Variable	Height
Covariance Structure	Variance Components
Estimation Method	REML
Residual Variance Method	Profile
Fixed Effects SE Method	Model-Based
Degrees of Freedom Method	Containment

The “Model Information” table in Figure 59.8 shows that the containment method is used to compute the degrees of freedom for this analysis. This is the default method when a **RANDOM** statement is used; see the description of the **DDFM=** option for more information.

Figure 59.9 Class Level Information

Class Level Information				
Class	Levels	Values		
Family	4	1	2	3 4
Gender	2	F	M	

The “Class Level Information” table in Figure 59.9 is the same as before. The “Dimensions” table in Figure 59.10 displays the new sizes of the **X** and **Z** matrices.

Figure 59.10 Dimensions and Number of Observations

Dimensions

Figure 59.11 *continued*

Convergence criteria met.

The “Covariance Parameter Estimates” table in [Figure 59.12](#) displays the results of the REML fit. The Estimate column contains the estimates of the variance components for Family and Family*Gender, as well as the estimate of σ^2 .

Figure 59.12 Covariance Parameter Estimates (REML)

Covariance Parameter Estimates	
Cov Parm	Estimate
Family	2.4010
Family*Gender	1.7657
Residual	2.1668

The “Fit Statistics” table in [Figure 59.13](#) contains basic information about the REML fit.

Figure 59.13 Fit Statistics

Fit Statistics	
-2 Res Log Likelihood	71.0
AIC (smaller is better)	77.0
AICC (smaller is better)	79.0
BIC (smaller is better)	75.2

The “Type 3 Tests of Fixed Effects” table in [Figure 59.14](#) contains a significance test for the lone fixed effect, Gender. Note that the associated p -value is not nearly as significant as in the previous analysis. This illustrates the importance of correctly modeling correlation in your data.

Figure 59.14 Type 3 Tests of Fixed Effects

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
Gender	1	3	7.95	0.0667

An additional benefit of the random effects analysis is that it enables you to make inferences about gender that apply to an entire population of families, whereas the inferences about gender from the analysis where Family and Family*Gender are fixed effects apply only to the particular families in the data set.

PROC MIXED thus offers you the ability to model correlation directly and to make inferences about fixed effects that apply to entire populations of random effects.

Syntax: MIXED Procedure

The following statements are available in the MIXED procedure:

```
PROC MIXED < options > ;
BY variables ;
CLASS variable < (REF= option) > ... < variable < (REF= option) > > < / global-options > ;
CODE < options > ;
ID variables ;
MODEL dependent = < fixed-effects > < / options > ;
RANDOM random-effects < / options > ;
REPEATED < repeated-effect > < / options > ;
PARMS (value-list) ... < / options > ;
PERFORMANCE < options > ;
PRIOR < distribution > < / options > ;
CONTRAST 'label' < fixed-effect values ... >
    < | random-effect values ... > , ... < / options > ;
ESTIMATE 'label' < fixed-effect values ... >
    < | random-effect values ... > < / options > ;
LSMEANS fixed-effects < / options > ;
LSMESTIMATE model-effect lsmestimate-specification < / options > ;
SLICE model-effect < / options > ;
STORE < OUT= > item-store-name < / LABEL= 'label' > ;
WEIGHT variable ;
```

Items within angle brackets (< >) are optional. The **CONTRAST**, **ESTIMATE**, **LSMEANS**, and **RANDOM** statements can appear multiple times; all other statements can appear only once.

The **PROC MIXED** and **MODEL** statements are required, and the **MODEL** statement must appear after the **CLASS** statement if a **CLASS** statement is included. The **CONTRAST**, **ESTIMATE**, **LSMEANS**, **RANDOM**, and **REPEATED** statements must follow the **MODEL** statement. The **CONTRAST** and **ESTIMATE** statements must also follow any **RANDOM** statements. The **LSMESTIMATE**, **SLICE**, and **STORE** statements are shared with many procedures. Summary descriptions of functionality and syntax for these statements are also given after the **PROC MIXED** statement in alphabetical order, but you can find full documentation on them in Chapter 19, “Shared Concepts and Topics.”

Table 59.1 summarizes the basic functions and important options of each PROC MIXED statement. The syntax of each statement in Table 59.1 is described in the following sections in alphabetical order after the description of the **PROC MIXED** statement.

Table 59.1 Summary of PROC MIXED Statements

Statement	Description	Options
PROC MIXED	Invokes the procedure	DATA= specifies input data set, METHOD= specifies estimation method

Table 59.1 *continued*

Statement	Description	Options
BY	Performs multiple PROC MIXED analyses in one invocation	None
CLASS	Declares qualitative variables that create indicator variables in design matrices	None
CODE	Requests that the procedure write SAS DATA step code to a file or catalog entry	FILE= names the file where the generated code is saved, CATALOG= names the catalog entry where the generated code is saved, IMPUTE imputes predicted values for observations with missing or invalid covariates, RESIDUAL computes residuals
ID	Lists additional variables to be included in predicted values tables	None
MODEL	Specifies dependent variable and fixed effects, setting up X	S requests solution for fixed-effects parameters, DDFM= specifies denominator degrees of freedom method, OUTP= outputs predicted values to a data set, INFLUENCE computes influence diagnostics
RANDOM	Specifies random effects, setting up Z and G	SUBJECT= creates block-diagonality, TYPE= specifies covariance structure, S requests solution for random-effects parameters, G displays estimated G
REPEATED	Sets up R	SUBJECT= creates block-diagonality, TYPE= specifies covariance structure, R displays estimated blocks of R, GROUP= enables between-subject heterogeneity, LOCAL adds a diagonal matrix to R
PARMS	Specifies a grid of initial values for the covariance parameters	HOLD= and NOITER hold the covariance parameters or their ratios constant, PARMSDATA= reads the initial values from a SAS data set
PERFORMANCE	Specifies the number of threads to use	NTHREADS=
PRIOR	Performs a sampling-based Bayesian analysis for variance component models	NSAMPLE= specifies the sample size, SEED= specifies the starting seed
CONTRAST	Constructs custom hypothesis tests	E displays the L matrix coefficients
ESTIMATE	Constructs custom scalar estimates	CL produces confidence limits

Table 59.1 *continued*

Statement	Description	Options
LSMEANS	Computes least squares means for classification fixed effects	DIFF computes differences of the least squares means, ADJUST= performs multiple comparisons adjustments, AT changes covariates, OM changes weighting, CL produces confidence limits, SLICE= tests simple effects
LSMESTIMATE	Provides custom hypothesis tests among the least squares means	ADJUST= determines the method for multiple comparison adjustment of LS-mean differences, JOINT requests a joint <i>F</i> or chi-square test for the rows of the estimate
SLICE	Performs a partitioned analysis of LS-means for an interaction	ADJUST= determines the method for multiple comparison adjustment of LS-mean differences, DIFF requests differences of LS-means
STORE	Saves the context and results of the analysis	LABEL= adds a custom label
WEIGHT	Specifies a variable by which to weight R	None

PROC MIXED Statement

PROC MIXED < options > ;

The PROC MIXED statement invokes the MIXED procedure. Table 59.2 summarizes the options available in the PROC MIXED statement. These and other options in the PROC MIXED statement are then described fully in alphabetical order.

Table 59.2 PROC MIXED Statement Options

Option	Description
Basic Options	
DATA=	Specifies input data set
METHOD=	Specifies the estimation method
NOPROFILE	Includes scale parameter in optimization
ORDER=	Determines the sort order of CLASS variables
Displayed Output	
ASYCORR	Displays asymptotic correlation matrix of covariance parameter estimates
ASYCOV	Displays asymptotic covariance matrix of covariance parameter estimates
CL	Requests confidence limits for covariance parameter estimates
COVTEST	Displays asymptotic standard errors and Wald tests for covariance parameters
IC	Displays a table of information criteria

Table 59.2 *continued*

Option	Description
ITDETAILS	Displays estimates and gradients added to “Iteration History”
LOGNOTE	Writes periodic status notes to the log
MMEQ	Displays mixed model equations
MMEQSOL	Displays the solution to the mixed model equations
NOCLPRINT	Suppresses “Class Level Information” completely or in parts
NOITPRINT	Suppresses “Iteration History” table
PLOTS=	Produces ODS statistical graphics
RATIO	Produces ratio of covariance parameter estimates with residual variance
Optimization Options	
MAXFUNC=	Specifies the maximum number of likelihood evaluations
MAXITER=	Specifies the maximum number of iterations
Computational Options	
CONVF	Requests and tunes the relative function convergence criterion
CONVG	Requests and tunes the relative gradient convergence criterion
CONVH	Requests and tunes the relative Hessian convergence criterion
DFBW	Selects between-within degree of freedom method
EMPIRICAL	Computes empirical (“sandwich”) estimators
NOBOUND	Unbounds covariance parameter estimates
RIDGE=	Specifies starting value for minimum ridge value
SCORING=	Applies Fisher scoring where applicable

You can specify the following *options*.

ABSOLUTE

makes the convergence criterion absolute. By default, it is relative (divided by the current objective function value). See the [CONVF](#), [CONVG](#), and [CONVH](#) options in this section for a description of various convergence criteria.

ALPHA=*number*

requests that confidence limits be constructed for the covariance parameter estimates with confidence level $1 - \textit{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

ANOVAF

The ANOVAF option computes *F* tests in models with REPEATED statement and without RANDOM statement by a method similar to that of Brunner, Domhof, and Langer (2002). The method consists of computing special *F* statistics and adjusting their degrees of freedom. The technique is a generalization of the Greenhouse-Geisser adjustment in MANOVA models (Greenhouse and Geisser 1959). For more details, see the section “[F Tests With the ANOVAF Option](#)” on page 4969.

ASYCORR

produces the asymptotic correlation matrix of the covariance parameter estimates. It is computed from the corresponding asymptotic covariance matrix (see the description of the [ASYCOV](#) option, which follows). The name of the “Asymptotic Correlation” table is AsyCorr.

ASYCOV

requests that the asymptotic covariance matrix of the covariance parameters be displayed. By default, this matrix is the observed inverse Fisher information matrix, which equals $2\mathbf{H}^{-1}$, where \mathbf{H} is the Hessian (second derivative) matrix of the objective function. See the section “[Covariance Parameter Estimates](#)” on page 4985 for more information about this matrix. When you use the **SCORING=** option and PROC MIXED converges without stopping the scoring algorithm, PROC MIXED uses the expected Hessian matrix to compute the covariance matrix instead of the observed Hessian. The ODS name of the “Asymptotic Covariance” table is AsyCov.

CL<=WALD>

requests confidence limits for the covariance parameter estimates. A Satterthwaite approximation is used to construct limits for all parameters that have a lower boundary constraint of zero. These limits take the form

$$\frac{\nu \hat{\sigma}^2}{\chi^2_{\nu, 1-\alpha/2}} \leq \sigma^2 \leq \frac{\nu \hat{\sigma}^2}{\chi^2_{\nu, \alpha/2}}$$

where $\nu = 2Z^2$, Z is the Wald statistic $\hat{\sigma}^2/\text{se}(\hat{\sigma}^2)$, and the denominators are quantiles of the χ^2 -distribution with ν degrees of freedom. See Milliken and Johnson (1992) and Burdick and Graybill (1992) for similar techniques.

For all other parameters, Wald Z-scores and normal quantiles are used to construct the limits. Wald limits are also provided for variance components if you specify the **NOBOUND** option. The optional **=WALD** specification requests Wald limits for all parameters.

The confidence limits are displayed as extra columns in the “Covariance Parameter Estimates” table. The confidence level is $1 - \alpha = 0.95$ by default; this can be changed with the **ALPHA=** option.

CONVF<=number>

requests the relative function convergence criterion with tolerance *number*. The relative function convergence criterion is

$$\frac{|f_k - f_{k-1}|}{|f_k|} \leq \text{number}$$

where f_k is the value of the objective function at iteration k . To prevent the division by $|f_k|$, use the **ABSOLUTE** option. The default convergence criterion is **CONVH**, and the default tolerance is 1E–8.

CONVG <=number>

requests the relative gradient convergence criterion with tolerance *number*. The relative gradient convergence criterion is

$$\frac{\max_j |g_{jk}|}{|f_k|} \leq \text{number}$$

where f_k is the value of the objective function, and g_{jk} is the j th element of the gradient (first derivative) of the objective function, both at iteration k . To prevent division by $|f_k|$, use the **ABSOLUTE** option. The default convergence criterion is **CONVH**, and the default tolerance is 1E–8.

CONVH<=*number*>

requests the relative Hessian convergence criterion with tolerance *number*. The relative Hessian convergence criterion is

$$\frac{\mathbf{g}_k' \mathbf{H}_k^{-1} \mathbf{g}_k}{|f_k|} \leq \text{number}$$

where f_k is the value of the objective function, \mathbf{g}_k is the gradient (first derivative) of the objective function, and \mathbf{H}_k is the Hessian (second derivative) of the objective function, all at iteration k .

If \mathbf{H}_k is singular, then PROC MIXED uses the following relative criterion:

$$\frac{\mathbf{g}_k' \mathbf{g}_k}{|f_k|} \leq \text{number}$$

To prevent the division by $|f_k|$, use the **ABSOLUTE** option. The default convergence criterion is **CONVH**, and the default tolerance is 1E–8.

COVTEST

produces asymptotic standard errors and Wald Z-tests for the covariance parameter estimates.

DATA=*SAS-data-set*

names the SAS data set to be used by PROC MIXED. The default is the most recently created data set.

DFBW

has the same effect as the **DDFM**=BW option in the **MODEL** statement.

EMPIRICAL

computes the estimated variance-covariance matrix of the fixed-effects parameters by using the asymptotically consistent estimator described in Huber (1967); White (1980); Liang and Zeger (1986); Diggle, Liang, and Zeger (1994). This estimator is commonly referred to as the “sandwich” estimator, and it is computed as follows:

$$(\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X})^{-1} \left(\sum_{i=1}^S \mathbf{X}_i' \widehat{\mathbf{V}}_i^{-1} \widehat{\boldsymbol{\epsilon}}_i \widehat{\boldsymbol{\epsilon}}_i' \widehat{\mathbf{V}}_i^{-1} \mathbf{X}_i \right) (\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X})^{-1}$$

Here, $\widehat{\boldsymbol{\epsilon}}_i = y_i - \mathbf{X}_i \widehat{\boldsymbol{\beta}}$, S is the number of subjects, and matrices with an i subscript are those for the i th subject. You must include the **SUBJECT**= option in either a **RANDOM** or **REPEATED** statement for this option to take effect.

When you specify the **EMPIRICAL** option, PROC MIXED adjusts all standard errors and test statistics involving the fixed-effects parameters. This changes output in the following tables (listed in [Table 59.26](#)): Contrast, CorrB, CovB, Diffs, Estimates, InvCovB, LSMeans, Slices, SolutionF, Tests1–Tests3. The **OUTP**= and **OUTPM**= data sets are also affected. Finally, the Satterthwaite and Kenward-Roger degrees of freedom methods are not available if you specify the **EMPIRICAL** option.

IC

displays a table of various information criteria. The criteria are all in smaller-is-better form, and are described in [Table 59.3](#).

Table 59.3 Information Criteria

Criterion	Formula	Reference
AIC	$-2\ell + 2d$	Akaike (1974)
AICC	$-2\ell + 2dn^*/(n^* - d - 1)$	Hurvich and Tsai (1989) Burnham and Anderson (1998)
HQIC	$-2\ell + 2d \log \log n$ for $n > 1$	Hannan and Quinn (1979)
BIC	$-2\ell + d \log n$ for $n > 0$	Schwarz (1978)
CAIC	$-2\ell + d(\log n + 1)$ for $n > 0$	Bozdogan (1987)

Here ℓ denotes the maximum value of the (possibly restricted) log likelihood, d the dimension of the model, and n the number of observations. In SAS 6 of SAS/STAT software, n equals the number of valid observations for maximum likelihood estimation and $n - p$ for restricted maximum likelihood estimation, where p equals the rank of \mathbf{X} . In later versions, n equals the number of effective subjects as displayed in the “Dimensions” table, unless this value equals 1, in which case n equals the number of levels of the first random effect you specify in a **RANDOM** statement. If the number of effective subjects equals 1 and you have no **RANDOM** statements, then n reverts to the SAS 6 values. For AICC (a finite-sample corrected version of AIC), n^* equals the SAS 6 values of n , unless this number is less than $d + 2$, in which case it equals $d + 2$. When $n \leq 1$, the value of the HQIC criterion is -2ℓ . When $n=0$, the values of the BIC and CAIC criteria are -2ℓ and $-2\ell + d$, respectively.

For restricted likelihood estimation, d equals q , the effective number of estimated covariance parameters. In SAS 6, when a parameter estimate lies on a boundary constraint, then it is still included in the calculation of d , but in later versions it is not. The most common example of this behavior is when a variance component is estimated to equal zero. For maximum likelihood estimation, d equals $q + p$. The value of d is displayed in the “Information Criteria” table as the value ofParms variable; see Table 59.27.

The ODS name of the “Information Criteria” table is InfoCrit.

INFO

is a default option. The creation of the “Model Information,” “Dimensions,” and “Number of Observations” tables can be suppressed by using the **NOINFO** option.

Note that in SAS 6 this option displays the “Model Information” and “Dimensions” tables.

ITDETAILS

displays the parameter values at each iteration and enables the writing of notes to the SAS log pertaining to “infinite likelihood” and “singularities” during Newton-Raphson iterations.

LOGNOTE

writes periodic notes to the log describing the current status of computations. It is designed for use with analyses requiring extensive CPU resources.

MAXFUNC=*number*

specifies the maximum number of likelihood evaluations in the optimization process. The default is 150.

MAXITER=number

specifies the maximum number of iterations. The default is 50.

METHOD=REML | ML | MIVQUE0 | TYPE1 | TYPE2 | TYPE3

specifies the estimation method for the covariance parameters. The REML specification performs residual (restricted) maximum likelihood, and it is the default method. The ML specification performs maximum likelihood, and the MIVQUE0 specification performs minimum variance quadratic unbiased estimation of the covariance parameters.

The METHOD=TYPE n specifications apply only to variance component models with no **SUBJECT=** effects and no **REPEATED** statement. An analysis of variance table is included in the output, and the expected mean squares are used to estimate the variance components (see Chapter 42, “[The GLM Procedure](#),” for further explanation). The resulting method-of-moment variance component estimates are used in subsequent calculations, including standard errors computed from **ESTIMATE** and **LSMEANS** statements. The ODS table names are Type1, Type2, and Type3, respectively.

MMEQ

requests that the coefficient matrix and the right-hand side of the mixed model equations be displayed. If $\hat{\mathbf{G}}$ is nonsingular, the coefficient matrix and the right-hand side have the following form:

$$\begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{Z} \\ \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z} + \hat{\mathbf{G}}^{-1} \end{bmatrix} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{y} \\ \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

If $\hat{\mathbf{G}}$ is singular, the coefficient matrix and right-hand side have the following modified form:

$$\begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{Z}\hat{\mathbf{G}} \\ \hat{\mathbf{G}}'\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \hat{\mathbf{G}}'\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z}\hat{\mathbf{G}} + \mathbf{G} \end{bmatrix} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\tau}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{y} \\ \hat{\mathbf{G}}'\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

See the section “[Estimating Fixed and Random Effects in the Mixed Model](#)” on page 4965 for further information about these equations.

MMEQSOL

requests that a solution to the mixed model equations be produced, in addition to the inverted coefficients matrix. If $\hat{\mathbf{G}}$ is nonsingular, the formula is the same as the preceding description of the **MMEQ** option. If $\hat{\mathbf{G}}$ is singular, $\hat{\boldsymbol{\beta}}$ and $\mathbf{G}\hat{\boldsymbol{\tau}}$ are displayed in addition to the inverse of the modified coefficient matrix.

See the section “[Estimating Fixed and Random Effects in the Mixed Model](#)” on page 4965 for further information about these equations and solution transformation.

NAMELEN=<number>

specifies the length to which long effect names are shortened. The default and minimum value is 20.

NOBOUND

has the same effect as the **NOBOUND** option in the **PARMS** statement.

NOCLPRINT=<number>

suppresses the display of the “Class Level Information” table if you do not specify *number*. If you do specify *number*, only levels with totals that are less than *number* are listed in the table.

NOINFO

suppresses the display of the “Model Information,” “Dimensions,” and “Number of Observations” tables.

NOITPRINT

suppresses the display of the “Iteration History” table.

NOPROFILE

includes the residual variance as part of the Newton-Raphson iterations. This option applies only to models that have a residual variance parameter. By default, this parameter is profiled out of the likelihood calculations, except when you have specified the **HOLD=** option in the **PARMS** statement.

ORD

displays ordinates of the relevant distribution in addition to p -values. The ordinate can be viewed as an approximate odds ratio of hypothesis probabilities.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement). This option applies to the levels for all classification variables, except when you use the (default) **ORDER=FORMATTED** option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The **ORDER=** option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, **ORDER=FORMATTED**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine-dependent. For more information about sort order, see the chapter on the **SORT** procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

PLOTS <(global-plot-options) > <=plot-request <(options) > >

PLOTS <(global-plot-options) > <= (plot-request<(options)><...plot-request<(options)> >)>

requests that the MIXED procedure produce statistical graphics via the Output Delivery System, provided that ODS Graphics is enabled.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc mixed data=heights plots=all;
  class Family Gender;
  model Height = Gender / residual;
  random Family Family*Gender;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

For examples of the basic statistical graphics produced by the MIXED procedure and aspects of their computation and interpretation, see the section “[ODS Graphics](#)” on page 4992.

The *global-plot-options* apply to all relevant plots generated by the MIXED procedure. The *global-plot-options* supported by the MIXED procedure follow.

Global Plot Options

OBSNO

uses the data set observation number to identify observations in tooltips, provided that the observation number can be determined. Otherwise, the number displayed in tooltips is the index of the observation as it is used in the analysis within the BY group.

ONLY

suppresses the default plots. Only the plots specifically requested are produced.

UNPACKPANEL

UNPACK

displays each graph separately. (By default, some graphs can appear together in a single panel.)

MAXPOINTS=NONE | *number*

specifies that plots with elements that require processing more than *number* points be suppressed. The default is MAXPOINTS=5000. No plots are suppressed if you specify MAXPOINTS=NONE.

Specific Plot Options

The following listing describes the specific plots and their options.

ALL

requests that all plots appropriate for the particular analysis be produced.

BOXPLOT <(boxplot-options)>

requests box plots for the effects in your model that consist of classification effects only. Note that these effects can involve more than one classification variable (interaction and nested effects), but they cannot contain any continuous variables. By default, the BOXPLOT request produces box plots based on (conditional) raw residuals for the qualifying effects in the [MODEL](#),

RANDOM, and **REPEATED** statements. See the discussion of the *boxplot-options* in a later section for information about how to tune your box plot request.

DISTANCE<(USEINDEX)>

requests a plot of the likelihood or restricted likelihood distance. When influence diagnostics are requested with set selection according to an effect, the **USEINDEX** option enables you to replace the formatted tick values on the horizontal axis with integer indices of the effect levels in order to reduce the space taken up by the horizontal plot axis.

INFLUENCEESTPLOT<(options)>

requests panels of the deletion estimates in an influence analysis, provided that the **INFLUENCE** option is specified in the **MODEL** statement. No plots are produced for fixed-effects parameters associated with singular columns in the **X** matrix or for covariance parameters associated with singularities in the **ASYCOV** matrix. By default, separate panels are produced for the fixed-effects and covariance parameters delete estimates. The **FIXED** and **RANDOM** options enable you to select these specific panels. The **UNPACK** option produces separate plots for each of the parameter estimates. The **USEINDEX** option replaces formatted tick values for the horizontal axis with integer indices.

INFLUENCESTATPANEL<(options)>

requests panels of influence statistics. For iterative influence analysis (see the **INFLUENCE** option in the **MODEL** statement), the panel shows the Cook's *D* and CovRatio statistics for fixed-effects and covariance parameters, enabling you to gauge impact on estimates and precision for both types of estimates. In noniterative analysis, only statistics for the fixed effects are plotted. The **UNPACK** option produces separate plots from the elements in the panel. The **USEINDEX** option replaces formatted tick values for the horizontal axis with integer indices.

RESIDUALPANEL <(residual-plot-options)>

requests a panel of raw residuals. By default, the conditional residuals are produced. See the discussion of *residual-plot-options* in a later section for information about how to tune this panel.

STUDENTPANEL <(residual-plot-options)>

requests a panel of studentized residuals. By default, the conditional residuals are produced. See the discussion of *residual-plot-options* in a later section for information about how to tune this panel.

PEARSONPANEL <(residual-plot-options)>

requests a panel of Pearson residuals. By default, the conditional residuals are produced. See the discussion of *residual-plot-options* in a later section for information about how to tune this panel.

PRESS<(USEINDEX)>

requests a plot of PRESS residuals or PRESS statistics. These are based on “leave-one-out” or “leave-set-out” prediction of the marginal mean. When influence diagnostics are requested with set selection according to an effect, the **USEINDEX** option enables you to replace the formatted tick values on the horizontal axis with integer indices of the effect levels in order to reduce the space taken up by the horizontal plot axis.

VCIRYPANEL <(residual-plot-options)>

requests a panel of residual graphics based on the scaled residuals. See the **VCIRY** option in the **MODEL** statement for details about these scaled residuals. Only the **UNPACK** and **BOX** options of the *residual-plot-options* are available for this type of residual panel.

NONE

suppresses all plots.

Residual Plot Options

The *residual-plot-options* determine both the composition of the panels and the type of residuals being plotted.

BOX**BOXPLOT**

replaces the inset of summary statistics in the lower-right corner of the panel with a box plot of the residual (the “PROC GLIMMIX look”).

CONDITIONAL**BLUP**

constructs plots from conditional residuals.

MARGINAL**NOBLUP**

constructs plots from marginal residuals.

UNPACK

produces separate plots from the elements of the panel. The inset statistics are not part of the unpack operation.

Box Plot Options

The *boxplot-options* determine whether box plots are produced for residuals or for residuals and observed values, and for which model effects the box plots are constructed. The available *boxplot-options* are as follows.

CONDITIONAL**BLUP**

constructs box plots from conditional residuals—that is, residuals using the estimated BLUPs of random effects.

FIXED

produces box plots for all fixed effects (**MODEL** statement) consisting entirely of classification variables

GROUP

produces box plots for all GROUP= effects (**RANDOM** and **REPEATED** statement) consisting entirely of classification variables

MARGINAL**NOBLUP**

constructs box plots from marginal residuals.

NPANEL=number

provides the ability to break a box plot into multiple graphics. If *number* is negative, no balancing of the number of boxes takes place and *number* is the maximum number of boxes per graphic. If *number* is positive, the number of boxes per graphic is balanced. For example, suppose variable A has 125 levels, and consider the following statements:

```
ods graphics on;
proc mixed plots=boxplot (npanel=20);
  class A;
  model y = A;
run;
```

The box balancing results in six plots with 18 boxes each and one plot with 17 boxes. If *number* is zero, and this is the default, all levels of the effect are displayed in a single plot.

OBSERVED

adds box plots of the observed data for the selected effects.

RANDOM

produces box plots for all random effects (**RANDOM** statement) consisting entirely of classification variables. This does not include effects specified in the **GROUP=** or **SUBJECT=** options of the **RANDOM** statement.

REPEATED

produces box plots for the repeated effects (**REPEATED** statement). This does not include effects specified in the **GROUP=** or **SUBJECT=** options of the **REPEATED** statement.

STUDENT

constructs box plots from studentized residuals rather than from raw residuals.

SUBJECT

produces box plots for all SUBJECT= effects (**RANDOM** and **REPEATED** statement) consisting entirely of classification variables.

USEINDEX

uses as the horizontal axis label the index of the effect level rather than the formatted value(s). For classification variables with many levels or model effects that involve multiple classification variables, the formatted values identifying the effect levels can take up too much space as axis tick values, leading to extensive thinning. The **USEINDEX** option replaces tick values constructed from formatted values with the internal level number.

Multiple Plot Requests

You can list a plot request one or more times with different options. For example, the following statements request a panel of marginal raw residuals, individual plots generated from a panel of the conditional raw residuals, and a panel of marginal studentized residuals:

```
ods graphics on;
proc mixed plots(only)=(
    ResidualPanel(marginal)
    ResidualPanel(unpack conditional)
    StudentPanel(marginal box));
```

The inset of residual statistics is replaced in this last panel by a box plot of the studentized residuals. Similarly, if you specify the **INFLUENCE** option in the **MODEL** statement, then the following statements request statistical graphics of fixed-effects deletion estimates (in a panel), covariance parameter deletion estimates (unpacked in individual plots), and box plots for the **SUBJECT=** and fixed classification effects based on residuals and observed values:

```
ods graphics on / imagefmt=staticmap;
proc mixed plots(only)=(
    InfluenceEstPlot(fixed)
    InfluenceEstPlot(random unpack)
    BoxPlot(observed fixed subject);
```

The **STATICMAP** image format enables tooltips that show, for example, values of influence diagnostics associated with a particular delete estimate.

This concludes the syntax section for the **PLOTS=** option in the **PROC MIXED** statement.

RATIO

produces the ratio of the covariance parameter estimates to the estimate of the residual variance when the latter exists in the model.

RIDGE=*number*

specifies the starting value for the minimum ridge value used in the Newton-Raphson algorithm. The default is 0.3125.

SCORING<=*number*>

requests that Fisher scoring be used in association with the estimation method up to iteration *number*, which is 0 by default. When you use the **SCORING=** option and **PROC MIXED** converges without stopping the scoring algorithm, **PROC MIXED** uses the expected Hessian matrix to compute approximate standard errors for the covariance parameters instead of the observed Hessian. The output from the **ASYCOV** and **ASYCORR** options is similarly adjusted.

SIGITER

is an alias for the **NOPROFILE** option.

UPDATE

is an alias for the **LOGNOTE** option.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC MIXED to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MIXED procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Because sorting the data changes the order in which PROC MIXED reads observations, the sort order for the levels of the **CLASS** variable might be affected if you have specified **ORDER=DATA** in the PROC MIXED statement. This, in turn, affects specifications in the **CONTRAST** or **ESTIMATE** statement.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable* < (**REF=** *option*) > ... < *variable* < (**REF=** *option*) > > < / *global-options* > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the **MODEL** statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the **ORDER=** option in the **PROC MIXED** statement. You can specify the following REF= option to indicate how the levels of an individual classification variable are to be ordered by enclosing it in parentheses after the variable name:

REF= 'level' | FIRST | LAST

specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC MIXED's singular parameterization. You can specify the *level* of the variable to use as the reference level; specify a value that corresponds to the formatted value of the variable if a format is assigned. Alternatively, you can specify REF=FIRST to designate that the first ordered level serve as the reference, or REF=LAST to designate that the last ordered level serve as the reference. To specify that REF=FIRST or REF=LAST be used for all classification variables, use the **REF= global-option** after the slash (/) in the CLASS statement.

You can specify the following *global-options* in the CLASS statement after a slash (/):

REF=FIRST | LAST

specifies a level of all classification variables to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC MIXED's singular parameterization. Specify REF=FIRST to designate that the first ordered level for each classification variable serve as the reference. Specify REF=LAST to designate that the last ordered level serve as the reference. This option applies to all the variables specified in the CLASS statement. To specify different reference levels for different classification variables, use **REF=** options for individual variables.

TRUNCATE

specifies that class levels be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

CODE Statement

CODE < options > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 59.4 summarizes the *options* available in the CODE statement.

Table 59.4 CODE Statement Options

Option	Description
CATALOG=	Names the catalog entry where the generated code is saved
DUMMIES	Retains the dummy variables in the data set
ERROR	Computes the error function
FILE=	Names the file where the generated code is saved
FORMAT=	Specifies the numeric format for the regression coefficients
GROUP=	Specifies the group identifier for array names and statement labels
IMPUTE	Imputes predicted values for observations with missing or invalid covariates
LINESIZE=	Specifies the line size of the generated code
LOOKUP=	Specifies the algorithm for looking up CLASS levels
RESIDUAL	Computes residuals

For details about the syntax of the CODE statement, see the section “CODE Statement” on page 390 in Chapter 19, “Shared Concepts and Topics.”

CONTRAST Statement

```
CONTRAST 'label' <fixed-effect values ... >
          <| random-effect values ... >, ... </options>;
```

The CONTRAST statement provides a mechanism for obtaining custom hypothesis tests. It is patterned after the CONTRAST statement in PROC GLM, although it has been extended to include random effects. This enables you to select an appropriate inference space (McLean, Sanders, and Stroup 1991).

You can test the hypothesis $\mathbf{L}'\boldsymbol{\phi} = \mathbf{0}$, where $\mathbf{L}' = (\mathbf{K}'\mathbf{M}')$ and $\boldsymbol{\phi}' = (\boldsymbol{\beta}'\boldsymbol{\gamma}')$, in several inference spaces. The inference space corresponds to the choice of \mathbf{M} . When $\mathbf{M} = \mathbf{0}$, your inferences apply to the entire population from which the random effects are sampled; this is known as the *broad* inference space. When all elements of \mathbf{M} are nonzero, your inferences apply only to the observed levels of the random effects. This is known as the *narrow* inference space, and you can also choose it by specifying all of the random effects as fixed. The GLM procedure uses the narrow inference space. Finally, by setting to zero the portions of \mathbf{M} corresponding to selected main effects and interactions, you can choose *intermediate* inference spaces. The broad inference space is usually the most appropriate, and it is used when you do not specify any random effects in the CONTRAST statement.

The CONTRAST statement has the following arguments:

<i>label</i>	identifies the contrast in the table. A label is required for every contrast specified. Labels can be up to 200 characters and must be enclosed in quotes.
<i>fixed-effect</i>	identifies an effect that appears in the MODEL statement. The keyword INTERCEPT can be used as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.
<i>random-effect</i>	identifies an effect that appears in the RANDOM statement. The first random effect must follow a vertical bar (); however, random effects do not have to be specified.
<i>values</i>	are constants that are elements of the \mathbf{L} matrix associated with the fixed and random effects.

The rows of \mathbf{L}' are specified in order and are separated by commas. The rows of the \mathbf{K}' component of \mathbf{L}' are specified on the left side of the vertical bars (|). These rows test the fixed effects and are, therefore, checked for estimability. The rows of the \mathbf{M}' component of \mathbf{L}' are specified on the right side of the vertical bars. They test the random effects, and no estimability checking is necessary.

If PROC MIXED finds the fixed-effects portion of the specified contrast to be nonestimable (see the **SINGULAR=** option), then it displays a message in the log.

The following CONTRAST statement reproduces the F test for the effect A in the split-plot example (see Example 59.1):

```
contrast 'A broad'
  A  1 -1 0    A*B  .5 .5 -.5 -.5 0 0 ,
  A  1 0 -1    A*B  .5 .5 0 0 -.5 -.5 / df=6;
```

Note that no random effects are specified in the preceding contrast; thus, the inference space is broad. The resulting F test has two numerator degrees of freedom because \mathbf{L}' has two rows. The denominator degrees of freedom is, by default, the residual degrees of freedom (9), but the `DF=` option changes the denominator degrees of freedom to 6.

The following CONTRAST statement reproduces the F test for A when Block and A*Block are considered fixed effects (the narrow inference space):

```
contrast 'A narrow'
  A      1 -1 0
  A*B    .5 .5 -.5 -.5 0 0 |
  A*Block .25 .25 .25 .25
        -.25 -.25 -.25 -.25
        0 0 0 0 ,
  A      1 0 -1
  A*B    .5 .5 0 0 -.5 -.5 |
  A*Block .25 .25 .25 .25
        0 0 0 0
        -.25 -.25 -.25 -.25 ;
```

The preceding contrast does not contain coefficients for B and Block, because they cancel out in estimated differences between levels of A. Coefficients for B and Block are necessary to estimate the mean of one of the levels of A in the narrow inference space (see [Example 59.1](#)).

If the elements of \mathbf{L} are not specified for an effect that contains a specified effect, then the elements of the specified effect are automatically “filled in” over the levels of the higher-order effect. This feature is designed to preserve estimability for cases where there are complex higher-order effects. The coefficients for the higher-order effect are determined by equitably distributing the coefficients of the lower-level effect, as in the construction of least squares means. In addition, if the intercept is specified, it is distributed over all classification effects that are not contained by any other specified effect. If an effect is not specified and does not contain any specified effects, then all of its coefficients in \mathbf{L} are set to 0. You can override this behavior by specifying coefficients for the higher-order effect.

If too many values are specified for an effect, the extra ones are ignored; if too few are specified, the remaining ones are set to 0. If no random effects are specified, the vertical bar can be omitted; otherwise, it must be present. If a `SUBJECT=` effect is used in the `RANDOM` statement, then the coefficients specified for the effects in the `RANDOM` statement are equitably distributed across the levels of the SUBJECT effect. You can use the `E` option to see exactly which \mathbf{L} matrix is used.

The `SUBJECT` and `GROUP` options in the CONTRAST statement are useful for the case when a `SUBJECT=` or `GROUP=` variable appears in the `RANDOM` statement, and you want to contrast different subjects or groups. By default, CONTRAST statement coefficients on random effects are distributed equally across subjects and groups.

PROC MIXED handles missing level combinations of classification variables similarly to the way PROC GLM does. Both procedures delete fixed-effects parameters corresponding to missing levels in order to preserve estimability. However, PROC MIXED does not delete missing level combinations for random-effects parameters because linear combinations of the random-effects parameters are always estimable. These conventions can affect the way you specify your CONTRAST coefficients.

The CONTRAST statement computes the statistic

$$F = \frac{\begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}' \mathbf{L}(\mathbf{L}'\hat{\mathbf{C}}\mathbf{L})^{-1}\mathbf{L}' \begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}}{r}$$

where $r = \text{rank}(\mathbf{L}'\hat{\mathbf{C}}\mathbf{L})$, and approximates its distribution with an F distribution. In this expression, $\hat{\mathbf{C}}$ is an estimate of the generalized inverse of the coefficient matrix in the mixed model equations. See the section “Inference and Test Statistics” on page 4968 for more information about this F statistic.

The numerator degrees of freedom in the F approximation are $r = \text{rank}(\mathbf{L}'\hat{\mathbf{C}}\mathbf{L})$, and the denominator degrees of freedom are taken from the “Tests of Fixed Effects” table and corresponds to the final effect you list in the CONTRAST statement. You can change the denominator degrees of freedom by using the **DF=** option.

You can specify the following *options* in the CONTRAST statement after a slash (/).

CHISQ

requests that chi-square tests be performed in addition to any F tests. A chi-square statistic equals its corresponding F statistic times the associate numerator degrees of freedom, and the same degrees of freedom are used to compute the p -value for the chi-square test. This p -value is always less than that for the F -test, as it effectively corresponds to an F test with infinite denominator degrees of freedom.

DF=*number*

specifies the denominator degrees of freedom for the F test. The default is the denominator degrees of freedom taken from the “Tests of Fixed Effects” table and corresponds to the final effect you list in the CONTRAST statement.

E

requests that the **L** matrix coefficients for the contrast be displayed. The ODS name of the “L Matrix Coefficients” table is Coef.

GROUP *coeffs*

GRP *coeffs*

sets up random-effect contrasts between different groups when a **GROUP=** variable appears in the **RANDOM** statement. By default, CONTRAST statement coefficients on random effects are distributed equally across groups.

SINGULAR=*number*

tunes the estimability checking. If \mathbf{v} is a vector, define $\text{ABS}(\mathbf{v})$ to be the absolute value of the element of \mathbf{v} with the largest absolute value. If $\text{ABS}(\mathbf{K}' - \mathbf{K}'\mathbf{T})$ is greater than $c*\text{number}$ for any row of \mathbf{K}' in the contrast, then \mathbf{K} is declared nonestimable. Here \mathbf{T} is the Hermite form matrix $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$, and c is $\text{ABS}(\mathbf{K}')$ except when it equals 0, and then c is 1. The value for *number* must be between 0 and 1; the default is 1E-4.

SUBJECT *coeffs*

SUB *coeffs*

sets up random-effect contrasts between different subjects when a **SUBJECT=** variable appears in the **RANDOM** statement. By default, CONTRAST statement coefficients on random effects are distributed equally across subjects.

ESTIMATE Statement

ESTIMATE *'label' <fixed-effect values ... >*
<| random-effect values ... > </options> ;

The ESTIMATE statement is exactly like a **CONTRAST** statement, except only one-row **L** matrices are permitted. The actual estimate, $L'\hat{p}$, is displayed along with its approximate standard error. An approximate *t* test that $L'\hat{p} = 0$ is also produced.

PROC MIXED selects the degrees of freedom to match those displayed in the “Tests of Fixed Effects” table for the final effect you list in the ESTIMATE statement. You can modify the degrees of freedom by using the **DF=** option.

If PROC MIXED finds the fixed-effects portion of the specified estimate to be nonestimable, then it displays “Non-est” for the estimate entries.

The following examples of ESTIMATE statements compute the mean of the first level of A in the split-plot example (see [Example 59.1](#)) for various inference spaces:

```
estimate 'A1 mean narrow'  intercept 1
                           A 1 B .5 .5 A*B .5 .5 |
                           block  .25 .25 .25 .25
                           A*Block .25 .25 .25 .25
                               0 0 0 0
                               0 0 0 0;

estimate 'A1 mean intermed' intercept 1
                           A 1 B .5 .5 A*B .5 .5 |
                           Block .25 .25 .25 .25;

estimate 'A1 mean broad'   intercept 1
                           A 1 B .5 .5 A*B .5 .5;
```

The construction of the **L** vector for an ESTIMATE statement follows the same rules as listed under the **CONTRAST** statement.

Table 59.5 summarizes the options available in the ESTIMATE statement.

Table 59.5 ESTIMATE Statement Options

Option	Description
ALPHA=	Specifies the confidence level
CL	Constructs <i>t</i> -type confidence limits
DF=	Specifies the degrees of freedom
DIVISOR=	Specifies a value by which to divide all coefficients
E	Displays the L matrix coefficients
GROUP	Sets up random-effect contrasts between different groups
LOWER	Performs lower-tailed tests
SINGULAR=	Tunes the estimability checking
SUBJECT	Sets up random-effect contrasts between different subjects
UPPER	Performs upper-tailed tests

You can specify the following *options* in the ESTIMATE statement after a slash (/).

ALPHA=number

requests that a t -type confidence interval be constructed with confidence level $1 - \text{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

CL

requests that t -type confidence limits be constructed. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

DF=number

specifies the degrees of freedom for the t test and confidence limits. The default is the denominator degrees of freedom taken from the “Tests of Fixed Effects” table and corresponds to the final effect you list in the ESTIMATE statement.

DIVISOR=number

specifies a value by which to divide all coefficients so that fractional coefficients can be entered as integer numerators.

E

requests that the **L** matrix coefficients be displayed. The ODS name of this “L Matrix Coefficients” table is “Coef.”

GROUP coeffs**GRP coeffs**

sets up random-effect contrasts between different groups when a **GROUP=** variable appears in the **RANDOM** statement. By default, ESTIMATE statement coefficients on random effects are distributed equally across groups.

LOWER**LOWERTAILED**

requests that the p -value for the t test be based only on values less than the t statistic. A two-tailed test is the default. A lower-tailed confidence limit is also produced if you specify the **CL** option.

SINGULAR=number

tunes the estimability checking as documented for the **SINGULAR=** option in the **CONTRAST** statement.

SUBJECT coeffs**SUB coeffs**

sets up random-effect contrasts between different subjects when a **SUBJECT=** variable appears in the **RANDOM** statement. By default, ESTIMATE statement coefficients on random effects are distributed equally across subjects. For example, the ESTIMATE statement in the following code from [Example 59.5](#) constructs the difference between the random slopes of the first two batches.

```
proc mixed data=rc;
  class batch;
  model y = month / s;
  random int month / type=un sub=batch s;
  estimate 'slope b1 - slope b2' | month 1 / subject 1 -1;
run;
```

UPPER**UPPERTAILED**

requests that the p -value for the t test be based only on values greater than the t statistic. A two-tailed test is the default. An upper-tailed confidence limit is also produced if you specify the **CL** option.

ID Statement

ID *variables* ;

The ID statement specifies which variables from the input data set are to be included in the **OUTP=** and **OUTPM=** data sets from the **MODEL** statement. If you do not specify an ID statement, then all variables are included in these data sets. Otherwise, only the variables you list in the ID statement are included. Specifying an ID statement with no variables prevents any variables from being included in these data sets.

LSMEANS Statement

LSMEANS *fixed-effects* < / *options* > ;

The LSMEANS statement computes least squares means (LS-means) of fixed effects. As in the GLM procedure, LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs. The **L** matrix constructed to compute them is the same as the **L** matrix formed in PROC GLM; however, the standard errors are adjusted for the covariance parameters in the model.

Each LS-mean is computed as $\mathbf{L}\hat{\boldsymbol{\beta}}$, where **L** is the coefficient matrix associated with the least squares mean and $\hat{\boldsymbol{\beta}}$ is the estimate of the fixed-effects parameter vector (see the section “Estimating Fixed and Random Effects in the Mixed Model” on page 4965). The approximate standard errors for the LS-mean is computed as the square root of $\mathbf{L}(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{L}'$.

LS-means can be computed for any effect in the **MODEL** statement that involves **CLASS** variables. You can specify multiple effects in one LSMEANS statement or in multiple LSMEANS statements, and all LSMEANS statements must appear after the **MODEL** statement. As in the **ESTIMATE** statement, the **L** matrix is tested for estimability, and if this test fails, PROC MIXED displays “Non-est” for the LS-means entries.

Assuming the LS-mean is estimable, PROC MIXED constructs an approximate t test to test the null hypothesis that the associated population quantity equals zero. By default, the denominator degrees of freedom for this test are the same as those displayed for the effect in the “Tests of Fixed Effects” table (see the section “Default Output” on page 4983).

Table 59.6 summarizes the options available in the LSMEANS statement. All LSMEANS options are subsequently discussed in alphabetical order.

Table 59.6 Summary of LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate value in computing LS-means

Table 59.6 *continued*

Option	Description
BYLEVEL	Computes separate margins
DIFF	Requests differences of LS-means
OM	Specifies weighting scheme for LS-mean computation
SINGULAR=	Tunes estimability checking
SLICE=	Partitions <i>F</i> tests (simple effects)
Degrees of Freedom and <i>p</i>-values	
ADJDFE=	Determines whether to compute row-wise denominator degrees of freedom with DDFM=SATTERTHWAITE or DDFM=KENWARDROGER
ADJUST=	Determines the method for multiple comparison adjustment of LS-mean differences
ALPHA= α	Determines the confidence level ($1 - \alpha$)
DF=	Assigns specific value to degrees of freedom for tests and confidence limits
Statistical Output	
CL	Constructs confidence limits for means and or mean differences
CORR	Displays correlation matrix of LS-means
COV	Displays covariance matrix of LS-means
E	Prints the L matrix

You can specify the following *options* in the LSMEANS statement after a slash (/).

ADJDFE=SOURCE

ADJDFE=ROW

specifies how denominator degrees of freedom are determined when *p*-values and confidence limits are adjusted for multiple comparisons with the **ADJUST=** option. When you do not specify the **ADJDFE=** option, or when you specify **ADJDFE=SOURCE**, the denominator degrees of freedom for multiplicity-adjusted results are the denominator degrees of freedom for the LS-mean effect in the “Type 3 Tests of Fixed Effects” table. When you specify **ADJDFE=ROW**, the denominator degrees of freedom for multiplicity-adjusted results correspond to the degrees of freedom displayed in the DF column of the “Differences of Least Squares Means” table.

The **ADJDFE=ROW** setting is particularly useful if you want multiplicity adjustments to take into account that denominator degrees of freedom are not constant across LS-mean differences. This can be the case, for example, when the **DDFM=SATTERTHWAITE** or **DDFM=KENWARDROGER** degrees-of-freedom method is in effect.

In one-way models with heterogeneous variance, combining certain **ADJUST=** options with the **ADJDFE=ROW** option corresponds to particular methods of performing multiplicity adjustments in the presence of heteroscedasticity. For example, the following statements fit a heteroscedastic one-way model and perform Dunnett’s T3 method (Dunnett 1980), which is based on the studentized maximum modulus (**ADJUST=SMM**):

```
proc mixed;
  class A;
  model y = A / ddfm=satterth;
  repeated / group=A;
  lsmeans A / adjust=smm adjdfe=row;
run;
```

If you combine the ADJDFE=ROW option with **ADJUST=SIDAK**, the multiplicity adjustment corresponds to the T2 method of Tamhane (1979), while **ADJUST=TUKEY** corresponds to the method of Games-Howell (Games and Howell 1976). Note that **ADJUST=TUKEY** gives the exact results for the case of fractional degrees of freedom in the one-way model, but it does not take into account that the degrees of freedom are subject to variability. A more conservative method, such as **ADJUST=SMM**, might protect the overall error rate better.

Unless the **ADJUST=** option of the LSMEANS statement is specified, the ADJDFE= option has no effect.

ADJUST=BON

ADJUST=DUNNETT

ADJUST=SCHEFFE

ADJUST=SIDAK

ADJUST=SIMULATE < (*sim-options*) >

ADJUST=SMM | GT2

ADJUST=TUKEY

requests a multiple comparison adjustment for the p -values and confidence limits for the differences of LS-means. By default, PROC MIXED adjusts all pairwise differences unless you specify **ADJUST=DUNNETT**, in which case PROC MIXED analyzes all differences with a control level. The **ADJUST=** option implies the **DIFF** option.

The **BON** (Bonferroni) and **SIDAK** adjustments involve correction factors described in Chapter 42, “**The GLM Procedure**,” and Chapter 61, “**The MULTTEST Procedure**,” also see Westfall and Young (1993) and Westfall et al. (1999). When you specify **ADJUST=TUKEY** and your data are unbalanced, PROC MIXED uses the approximation described in Kramer (1956). Similarly, when you specify **ADJUST=DUNNETT** and the LS-means are correlated, PROC MIXED uses the factor-analytic covariance approximation described in Hsu (1992). The preceding references also describe the **SCHEFFE** and **SMM** adjustments.

The **SIMULATE** adjustment computes adjusted p -values and confidence limits from the simulated distribution of the maximum or maximum absolute value of a multivariate t random vector. All covariance parameters except the residual variance are fixed at their estimated values throughout the simulation, potentially resulting in some underdispersion. The simulation estimates q , the true $(1 - \alpha)$ quantile, where $1 - \alpha$ is the confidence coefficient. The default α is 0.05, and you can change this value with the **ALPHA=** option in the LSMEANS statement.

The number of samples is set so that the tail area for the simulated q is within γ of $1 - \alpha$ with $100(1 - \epsilon)\%$ confidence. In equation form,

$$P(|F(\hat{q}) - (1 - \alpha)| \leq \gamma) = 1 - \epsilon$$

where \hat{q} is the simulated q and F is the true distribution function of the maximum; see Edwards and Berry (1987) for details. By default, $\gamma = 0.005$ and $\epsilon = 0.01$, placing the tail area of \hat{q} within 0.005 of 0.95 with 99% confidence. The `ACC=` and `EPS=` *sim-options* reset γ and ϵ , respectively; the `NSAMP=` *sim-option* sets the sample size directly; and the `SEED=` *sim-option* specifies an integer used to start the pseudo-random number generator for the simulation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock. For additional descriptions of these and other simulation options, see the section “[LSMEANS Statement](#)” on page 3293 in Chapter 42, “[The GLM Procedure](#).”

ALPHA=number

requests that a t -type confidence interval be constructed for each of the LS-means with confidence level $1 - \text{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

AT variable = value

AT (variable-list) = (value-list)

AT MEANS

enables you to modify the values of the covariates used in computing LS-means. By default, all covariate effects are set equal to their mean values for computation of standard LS-means. The AT option enables you to assign arbitrary values to the covariates. Additional columns in the output table indicate the values of the covariates.

If there is an effect containing two or more covariates, the AT option sets the effect equal to the product of the individual means rather than the mean of the product (as with standard LS-means calculations). The AT MEANS option sets covariates equal to their mean values (as with standard LS-means) and incorporates this adjustment to crossproducts of covariates.

As an example, consider the following invocation of PROC MIXED:

```
proc mixed;
  class A;
  model Y = A X1 X2 X1*X2;
  lsmeans A;
  lsmeans A / at means;
  lsmeans A / at X1=1.2;
  lsmeans A / at (X1 X2)=(1.2 0.3);
run;
```

For the first two LSMEANS statements, the LS-means coefficient for X1 is \bar{x}_1 (the mean of X1) and for X2 is \bar{x}_2 (the mean of X2). However, for the first LSMEANS statement, the coefficient for X1*X2 is $\bar{x}_1\bar{x}_2$, but for the second LSMEANS statement, the coefficient is $\bar{x}_1 \cdot \bar{x}_2$. The third LSMEANS statement sets the coefficient for X1 equal to 1.2 and leaves it at \bar{x}_2 for X2, and the final LSMEANS statement sets these values to 1.2 and 0.3, respectively.

If a WEIGHT variable is present, it is used in processing AT variables. Also, observations with missing dependent variables are included in computing the covariate means, unless these observations form a missing cell and the [FULLX](#) option in the [MODEL](#) statement is not in effect. You can use the [E](#) option in conjunction with the AT option to check that the modified LS-means coefficients are the ones you want.

The AT option is disabled if you specify the [BYLEVEL](#) option.

BYLEVEL

requests PROC MIXED to process the OM data set by each level of the LS-mean effect (LSMEANS effect) in question. For more details, see the **OM** option later in this section.

CL

requests that *t*-type confidence limits be constructed for each of the LS-means. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

CORR

displays the estimated correlation matrix of the least squares means as part of the “Least Squares Means” table.

COV

displays the estimated covariance matrix of the least squares means as part of the “Least Squares Means” table.

DF=number

specifies the degrees of freedom for the *t* test and confidence limits. The default is the denominator degrees of freedom taken from the “Tests of Fixed Effects” table corresponding to the LS-means effect unless the **DDFM=SATTERTHWAITE** or **DDFM=KENWARDROGER** option is in effect in the **MODEL** statement. For these DDFM= methods, degrees of freedom are determined separately for each test; see the **DDFM=** option for more information.

DIFF<=difftype>**PDIFF<=difftype>**

requests that differences of the LS-means be displayed. The optional *difftype* specifies which differences to produce, with possible values being ALL, CONTROL, CONTROLL, and CONTROLU. The *difftype* ALL requests all pairwise differences, and it is the default. The *difftype* CONTROL requests the differences with a control, which, by default, is the first level of each of the specified LSMEANS effects.

To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the keyword CONTROL. For example, if the effects A, B, and C are classification variables, each having two levels, 1 and 2, the following LSMEANS statement specifies the (1,2) level of A*B and the (2,1) level of B*C as controls:

```
lsmeans A*B B*C / diff=control('1' '2' '2' '1');
```

For multiple effects, the results depend upon the order of the list, and so you should check the output to make sure that the controls are correct.

Two-tailed tests and confidence limits are associated with the CONTROL *difftype*. For one-tailed results, use either the CONTROLL or CONTROLU *difftype*. The CONTROLL *difftype* tests whether the noncontrol levels are significantly smaller than the control; the upper confidence limits for the control minus the noncontrol levels are considered to be infinity and are displayed as missing. Conversely, the CONTROLU *difftype* tests whether the noncontrol levels are significantly larger than the control; the upper confidence limits for the noncontrol levels minus the control are considered to be infinity and are displayed as missing.

If you want to perform multiple comparison adjustments on the differences of LS-means, you must specify the **ADJUST=** option.

The differences of the LS-means are displayed in a table titled “Differences of Least Squares Means.” The ODS table name is `Diff`.

E

requests that the **L** matrix coefficients for all LSMEANS effects be displayed. The ODS name of this “L Matrix Coefficients” table is `Coef`.

OM<=*OM-data-set*>

OBSMARGINS<=*OM-data-set*>

specifies a potentially different weighting scheme for the computation of LS-means coefficients. The standard LS-means have equal coefficients across classification effects; however, the **OM** option changes these coefficients to be proportional to those found in *OM-data-set*. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins observed in *OM-data-set*.

By default, *OM-data-set* is the same as the analysis data set. You can optionally specify another data set that describes the population for which you want to make inferences. This data set must contain all model variables except for the dependent variable (which is ignored if it is present). In addition, the levels of all **CLASS** variables must be the same as those occurring in the analysis data set. Specifying an *OM-data-set* enables you to construct arbitrarily weighted LS-means.

In computing the observed margins, PROC MIXED uses all observations for which there are no missing or invalid independent variables, including those for which there are missing dependent variables. Also, if *OM-data-set* has a **WEIGHT** variable, PROC MIXED uses weighted margins to construct the LS-means coefficients. If *OM-data-set* is balanced, the LS-means are unchanged by the **OM** option.

The **BYLEVEL** option modifies the observed-margins LS-means. Instead of computing the margins across all of the *OM-data-set*, PROC MIXED computes separate margins for each level of the LSMEANS effect in question. In this case the resulting LS-means are actually equal to raw means for fixed-effects models and certain balanced random-effects models, but their estimated standard errors account for the covariance structure that you have specified. If the **AT** option is specified, the **BYLEVEL** option disables it.

You can use the **E** option in conjunction with either the **OM** or **BYLEVEL** option to check that the modified LS-means coefficients are the ones you want. It is possible that the modified LS-means are not estimable when the standard ones are, or vice versa. Nonestimable LS-means are noted as “Non-est” in the output.

PDIF

is the same as the **DIFF** option.

SINGULAR=*number*

tunes the estimability checking as documented for the **SINGULAR**= option in the **CONTRAST** statement.

SLICE= *fixed-effect*

SLICE= (*fixed-effects*)

specifies effects by which to partition interaction LSMEANS effects. This can produce what are known as tests of simple effects (Winer 1971). For example, suppose that **A*B** is significant, and you want to test the effect of **A** for each level of **B**. The appropriate LSMEANS statement is as follows:

```
lsmeans A*B / slice=B;
```

This code tests for the simple main effects of A for B, which are calculated by extracting the appropriate rows from the coefficient matrix for the A*B LS-means and by using them to form an F test. See the section “[Inference and Test Statistics](#)” for more information about this F test.

The SLICE option produces a table titled “Tests of Effect Slices.” The ODS table name is Slices.

LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
              < , ... <'label'> values <divisor=n> >
              </ options > ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 59.7 summarizes the options available in the LSMESTIMATE statement.

Table 59.7 LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
BYLEVEL	Computes separate margins
DIVISOR=	Specifies a list of values to divide the coefficients
OM=	Specifies the weighting scheme for LS-means computation as determined by a data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level ($1 - \alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiple-comparison p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference

Table 59.7 continued

Option	Description
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
ELSM	Prints the K matrix
JOINT	Produces a joint <i>F</i> or chi-square test for the LS-means and LS-means differences
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMESTIMATE statement, see the section “[LSMESTIMATE Statement](#)” on page 470 in Chapter 19, “[Shared Concepts and Topics](#).”

MODEL Statement

MODEL *dependent* = < fixed-effects > < / options > ;

The MODEL statement names a single dependent variable and the fixed effects, which determine the **X** matrix of the mixed model (see the section “[Parameterization of Mixed Models](#)” on page 4971 for details). The [specification of effects](#) is the same as in the GLM procedure; however, unlike PROC GLM, you do not specify random effects in the MODEL statement. The MODEL statement is required.

An intercept is included in the fixed-effects model by default. If no fixed effects are specified, only this intercept term is fit. The intercept can be removed by using the NOINT option.

Table 59.8 summarizes the options available in the MODEL statement. These are subsequently discussed in detail in alphabetical order.

Table 59.8 Summary of MODEL Statement Options

Option	Description
Model Building	
NOINT	Excludes fixed-effect intercept from model
Statistical Computations	
ALPHA= α	Determines the confidence level $(1 - \alpha)$ for fixed effects
ALPHAP= α	Determines the confidence level $(1 - \alpha)$ for predicted values
CHISQ	Requests chi-square tests
DDF=	Specifies denominator degrees of freedom (list)
DDFM=	Specifies the method for computing denominator degrees of freedom
HTYPE=	Selects the type of hypothesis test
INFLUENCE	Requests influence and case-deletion diagnostics

Table 59.8 *continued*

Option	Description
NOTEST	Suppresses hypothesis tests for the fixed effects
OUTP=	Specifies output data set for predicted values and related quantities
OUTPM=	Specifies output data set for predicted means and related quantities
RESIDUAL	Adds Pearson-type and studentized residuals to output data sets
VCIRY	Adds scaled marginal residual to output data sets
Statistical Output	
CL	Displays confidence limits for fixed-effects parameter estimates
CORRB	Displays correlation matrix of fixed-effects parameter estimates
COVB	Displays covariance matrix of fixed-effects parameter estimates
COVBI	Displays inverse covariance matrix of fixed-effects parameter estimates
E, E1, E2, E3	Displays L matrix coefficients
INTERCEPT	Adds a row for the intercept to test tables
SOLUTION	Displays fixed-effects parameter estimates (and scale parameter in GLM models)
Singularity Tolerances	
SINGCHOL=	Tunes sensitivity in computing Cholesky roots
SINGRES=	Tunes singularity criterion for residual variance
SINGULAR=	Tunes the sensitivity in sweeping
ZETA=	Tunes the sensitivity in forming Type 3 functions

You can specify the following *options* in the MODEL statement after a slash (/).

ALPHA=number

requests that a *t*-type confidence interval be constructed for each of the fixed-effects parameters with confidence level $1 - \text{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

ALPHAP=number

requests that a *t*-type confidence interval be constructed for the predicted values with confidence level $1 - \text{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

CHISQ

requests that chi-square tests be performed for all specified effects in addition to the *F* tests. Type 3 tests are the default; you can produce the Type 1 and Type 2 tests by using the **HTYPE=** option.

CL

requests that *t*-type confidence limits be constructed for each of the fixed-effects parameter estimates. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

CONTAIN

has the same effect as the **DDFM=CONTAIN** option.

CORRB

produces the approximate correlation matrix of the fixed-effects parameter estimates. The ODS name of this table is CorrB.

COVB

produces the approximate variance-covariance matrix of the fixed-effects parameter estimates $\hat{\beta}$. By default, this matrix equals $(X'\hat{V}^{-1}X)^{-1}$ and results from sweeping $(X y)'\hat{V}^{-1}(X y)$ on all but its last pivot and removing the y border. The **EMPIRICAL** option in the **PROC MIXED** statement changes this matrix into “empirical sandwich” form. The ODS name of this table is CovB. If the degrees-of-freedom method of Kenward and Roger (1997) is in effect (**DDFM=KENWARDROGER**), the COVB matrix changes because the method entails an adjustment of the variance-covariance matrix of the fixed effects by the method proposed by Prasad and Rao (1990); Harville and Jeske (1992). See also Kackar and Harville (1984).

COVBI

produces the inverse of the approximate variance-covariance matrix of the fixed-effects parameter estimates. The ODS name of this table is InvCovB.

DDF=*value-list*

enables you to specify your own denominator degrees of freedom for the fixed effects. The *value-list* specification is a list of numbers or missing values (.) separated by commas. The degrees of freedom should be listed in the order in which the effects appear in the “Tests of Fixed Effects” table. If you want to retain the default degrees of freedom for a particular effect, use a missing value for its location in the list. For example, the following statement assigns 3 denominator degrees of freedom to A and 4.7 to A*B, while those for B remain the same:

```
model Y = A B A*B / ddf=3, ., 4.7;
```

If you specify **DDFM=SATTERTHWAITE** or **DDFM=KENWARDROGER**, the DDF= option has no effect.

DDFM=

DDFM=CONTAIN

DDFM=BETWITHIN

DDFM=RESIDUAL

DDFM=SATTERTHWAITE

DDFM=KENWARDROGER<(FIRSTORDER)>

DDFM=KENWARDROGER<(LINEAR)>

specifies the method for computing the denominator degrees of freedom for the tests of fixed effects resulting from the **MODEL**, **CONTRAST**, **ESTIMATE**, and **LSMEANS** statements.

Table 59.9 lists syntax aliases for the degrees-of-freedom methods.

Table 59.9 Aliases for DDFM= Option

DDFM= Option	Alias
BETWITHIN	BW
CONTAIN	CON

Table 59.9 *continued*

DDFM= Option	Alias
KENWARDROGER	KENROG, KR
RESIDUAL	RES
SATTERTHWAITE	SATTERTH, SAT

The DDFM=CONTAIN option invokes the *containment method* to compute denominator degrees of freedom, and it is the default when you specify a **RANDOM** statement. The containment method is carried out as follows: Denote the fixed effect in question **A**, and search the **RANDOM** effect list for the effects that *syntactically* contain **A**. For example, the random effect **B(A)** contains **A**, but the random effect **C** does not, even if it has the same levels as **B(A)**.

Among the random effects that contain **A**, compute their rank contribution to the $(\mathbf{X} \mathbf{Z})$ matrix. The DDF assigned to **A** is the smallest of these rank contributions. If no effects are found, the DDF for **A** is set equal to the residual degrees of freedom, $N - \text{rank}(\mathbf{X} \mathbf{Z})$. This choice of DDF matches the tests performed for balanced split-plot designs and should be adequate for moderately unbalanced designs.

CAUTION: If you have a **Z** matrix with a large number of columns, the overall memory requirements and the computing time after convergence can be substantial for the containment method. If it is too large, you might want to use the DDFM=BETWITHIN option.

The DDFM=BETWITHIN option is the default for **REPEATED** statement specifications (with no **RANDOM** statements). It is computed by dividing the residual degrees of freedom into between-subject and within-subject portions. PROC MIXED then checks whether a fixed effect changes within any subject. If so, it assigns within-subject degrees of freedom to the effect; otherwise, it assigns the between-subject degrees of freedom to the effect (see Schluchter and Elashoff 1990). If there are multiple within-subject effects containing classification variables, the within-subject degrees of freedom are partitioned into components corresponding to the subject-by-effect interactions.

One exception to the preceding method is the case where you have specified no **RANDOM** statements and a **REPEATED** statement with the **TYPE=UN** option. In this case, all effects are assigned the between-subject degrees of freedom to provide for better small-sample approximations to the relevant sampling distributions. DDFM=KENWARDROGER might be a better option to try for this case.

The DDFM=RESIDUAL option performs all tests by using the residual degrees of freedom, $n - \text{rank}(\mathbf{X})$, where n is the number of observations.

The DDFM=SATTERTHWAITE option performs a general Satterthwaite approximation for the denominator degrees of freedom, computed as follows. Suppose $\boldsymbol{\theta}$ is the vector of unknown parameters in **V**, and suppose $\mathbf{C} = (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^-$, where $^-$ denotes a generalized inverse. Let $\hat{\mathbf{C}}$ and $\hat{\boldsymbol{\theta}}$ be the corresponding estimates.

Consider the one-dimensional case, and consider $\boldsymbol{\ell}$ to be a vector defining an estimable linear combination of $\boldsymbol{\beta}$. The Satterthwaite degrees of freedom for the t statistic

$$t = \frac{\boldsymbol{\ell}'\hat{\boldsymbol{\beta}}}{\sqrt{\boldsymbol{\ell}'\hat{\mathbf{C}}\boldsymbol{\ell}'}}$$

is computed as

$$\nu = \frac{2(\boldsymbol{\ell}'\hat{\mathbf{C}}\boldsymbol{\ell}')^2}{\mathbf{g}'\mathbf{A}\mathbf{g}}$$

where \mathbf{g} is the gradient of $\ell\mathbf{C}\ell'$ with respect to $\boldsymbol{\theta}$, evaluated at $\hat{\boldsymbol{\theta}}$, and \mathbf{A} is the asymptotic variance-covariance matrix of $\hat{\boldsymbol{\theta}}$ obtained from the second derivative matrix of the likelihood equations.

For the multidimensional case, let \mathbf{L} be an estimable contrast matrix and denote the rank of $\mathbf{L}\hat{\mathbf{C}}\mathbf{L}'$ as $q > 1$. The Satterthwaite denominator degrees of freedom for the F statistic

$$F = \frac{\hat{\boldsymbol{\beta}}'\mathbf{L}'(\mathbf{L}\hat{\mathbf{C}}\mathbf{L}')^{-1}\mathbf{L}\hat{\boldsymbol{\beta}}}{q}$$

are computed by first performing the spectral decomposition $\mathbf{L}\hat{\mathbf{C}}\mathbf{L}' = \mathbf{P}'\mathbf{D}\mathbf{P}$, where \mathbf{P} is an orthogonal matrix of eigenvectors and \mathbf{D} is a diagonal matrix of eigenvalues, both of dimension $q \times q$. Define ℓ_m to be the m th row of $\mathbf{P}\mathbf{L}$, and let

$$v_m = \frac{2(D_m)^2}{\mathbf{g}_m'\mathbf{A}\mathbf{g}_m}$$

where D_m is the m th diagonal element of \mathbf{D} and \mathbf{g}_m is the gradient of $\ell_m\mathbf{C}\ell'_m$ with respect to $\boldsymbol{\theta}$, evaluated at $\hat{\boldsymbol{\theta}}$. Then let

$$E = \sum_{m=1}^q \frac{v_m}{v_m - 2} I(v_m > 2)$$

where the indicator function eliminates terms for which $v_m \leq 2$. The degrees of freedom for F are then computed as

$$v = \frac{2E}{E - q}$$

provided $E > q$; otherwise v is set to zero.

This method is a generalization of the techniques described in Giesbrecht and Burns (1985); McLean and Sanders (1988); Fai and Cornelius (1996). The method can also include estimated random effects. In this case, append $\hat{\boldsymbol{\gamma}}$ to $\hat{\boldsymbol{\beta}}$ and change $\hat{\mathbf{C}}$ to be the inverse of the coefficient matrix in the mixed model equations. The calculations require extra memory to hold c matrices that are the size of the mixed model equations, where c is the number of covariance parameters. In the notation of Table 59.29, this is approximately $8q(p + g)(p + g)/2$ bytes. Extra computing time is also required to process these matrices. The Satterthwaite method implemented here is intended to produce an accurate F approximation; however, the results can differ from those produced by PROC GLM. Also, the small sample properties of this approximation have not been extensively investigated for the various models available with PROC MIXED.

The DDFM=KENWARDROGER option performs the degrees of freedom calculations detailed by Kenward and Roger (1997). This approximation involves inflating the estimated variance-covariance matrix of the fixed and random effects by the method proposed by Prasad and Rao (1990) and Harville and Jeske (1992), see also Kackar and Harville (1984). Satterthwaite-type degrees of freedom are then computed based on this adjustment. By default, the observed information matrix of the covariance parameter estimates is used in the calculations. For covariance structures that have nonzero second derivatives with respect to the covariance parameters, the Kenward-Roger covariance matrix adjustment includes a second-order term. This term can result in standard error shrinkage. Also, the resulting adjusted covariance matrix can then be indefinite and is not invariant under reparameterization. The FIRSTORDER or LINEAR suboption of the DDFM=KENWARDROGER option

eliminates the second derivatives from the calculation of the covariance matrix adjustment. The LINEAR suboption is an alias for FIRSTORDER. For the case of scalar estimable functions, the resulting estimator is referred to as the Prasad-Rao estimator \tilde{m}^{\circledast} in Harville and Jeske (1992). The following are examples of covariance structures that generally lead to nonzero second derivatives: TYPE=ANTE(1), TYPE=AR(1), TYPE=ARH(1), TYPE=ARMA(1,1), TYPE=CSH, TYPE=FA, TYPE=FA0(q), TYPE=TOEPH, TYPE=UNR, and all TYPE=SP() structures.

When the asymptotic variance matrix of the covariance parameters is found to be singular, a generalized inverse is used. Covariance parameters with zero variance then do not contribute to the degrees-of-freedom adjustment for DDFM=SATTERTHWAITE and DDFM=KENWARDROGER, and a message is written to the log.

This method changes output in the following tables (listed in Table 59.26): Contrast, CorrB, CovB, Diffs, Estimates, InvCovB, LSMeans, Slices, SolutionF, SolutionR, Tests1–Tests3. The OUTP= and OUTPM= data sets are also affected.

E

requests that Type 1, Type 2, and Type 3 L matrix coefficients be displayed for all specified effects. The ODS name of the table is Coef.

E1

requests that Type 1 L matrix coefficients be displayed for all specified effects. The ODS name of the table is Coef.

E2

requests that Type 2 L matrix coefficients be displayed for all specified effects. The ODS name of the table is Coef.

E3

requests that Type 3 L matrix coefficients be displayed for all specified effects. The ODS name of the table is Coef.

FULLX

requests that columns of the X matrix that consist entirely of zeros not be eliminated from X; otherwise, they are eliminated by default. For a column corresponding to a missing cell to be added to X, its particular levels must be present in at least one observation in the analysis data set along with a missing dependent variable. The use of the FULLX option can affect coefficient specifications in the CONTRAST and ESTIMATE statements, as well as covariate coefficients from LSMEANS statements specified with the AT MEANS option.

HTYPE=value-list

indicates the type of hypothesis test to perform on the fixed effects. Valid entries for values in the list are 1, 2, and 3; the default value is 3. You can specify several types by separating the values with a comma or a space. The ODS table names are “Tests1” for the Type 1 tests, “Tests2” for the Type 2 tests, and “Tests3” for the Type 3 tests.

INFLUENCE<(influence-options)>

specifies that influence and case deletion diagnostics are to be computed.

The INFLUENCE option computes influence diagnostics by noniterative or iterative methods. The noniterative diagnostics rely on recomputation formulas under the assumption that covariance parameters or their ratios remain fixed. With the possible exception of a profiled residual variance, no

covariance parameters are updated. This is the default behavior because of its computational efficiency. However, the impact of an observation on the overall analysis can be underestimated if its effect on covariance parameters is not assessed. Toward this end, iterative methods can be applied to gauge the overall impact of observations and to obtain influence diagnostics for the covariance parameter estimates.

If you specify the INFLUENCE option without further suboptions, PROC MIXED computes single-case deletion diagnostics and influence statistics for each observation in the data set by updating estimates for the fixed-effects parameter estimates, and also the residual variance, if it is profiled. The **EFFECT=**, **SELECT=**, **ITER=**, **SIZE=**, and **KEEP=** suboptions provide additional flexibility in the computation and reporting of influence statistics. Table 59.10 briefly describes important suboptions and their effect on the influence analysis.

Table 59.10 Summary of INFLUENCE Default and Suboptions

Description	Suboption
Compute influence diagnostics for individual observations	Default
Measure influence of sets of observations chosen according to a classification variable or effect	EFFECT=
Remove pairs of observations and report the results sorted by degree of influence	SIZE=2
Remove triples, quadruples of observations, etc.	SIZE=
Allow selection of individual observations, observations sharing specific levels of effects, and construction of tuples from specified subsets of observations	SELECT=
Update fixed effects and covariance parameters by refitting the mixed model, adding up to n iterations	ITER=$n > 0$
Compute influence diagnostics for the covariance parameters	ITER=$n > 0$
Update only fixed effects and the residual variance, if it is profiled	ITER=0
Add the reduced-data estimates to the data set created with ODS OUTPUT	ESTIMATES

The modifiers and their default values are discussed in the following paragraphs. The set of computed influence diagnostics varies with the suboptions. The most extensive set of influence diagnostics is obtained when **ITER= n** with $n > 0$.

You can produce statistical graphics of influence diagnostics when ODS Graphics is enabled. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the graphics available in the MIXED procedure, see the section “ODS Graphics” on page 4992.

You can specify the following *influence-options* in parentheses:

EFFECT=*effect*

specifies an effect according to which observations are grouped. Observations sharing the same level of the *effect* are removed from the analysis as a group. The *effect* must contain only classification variables, but they need not be contained in the model.

Removing observations can change the rank of the $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-}$ matrix. This is particularly likely to happen when multiple observations are eliminated from the analysis. If the rank of the estimated variance-covariance matrix of $\hat{\boldsymbol{\beta}}$ changes or its singularity pattern is altered, no influence diagnostics are computed.

ESTIMATES

EST

specifies that the updated parameter estimates should be written to the ODS output data set. The values are not displayed in the “Influence” table, but if you use ODS OUTPUT to create a data set from the listing, the estimates are added to the data set. If **ITER=0**, only the fixed-effects estimates are saved. In iterative influence analyses, fixed-effects and covariance parameters are stored. The p fixed-effects parameter estimates are named Parm1–Parm p , and the q covariance parameter estimates are named CovP1–CovP q . The order corresponds to that in the “Solution for Fixed Effects” and “Covariance Parameter Estimates” tables. If parameter updates fail—for example, because of a loss of rank or a nonpositive definite Hessian—missing values are reported.

ITER= n

controls the maximum number of additional iterations PROC MIXED performs to update the fixed-effects and covariance parameter estimates following data point removal. If you specify $n > 0$, then statistics such as DFFITS, MDFFITS, and the likelihood distances measure the impact of observation(s) on all aspects of the analysis. Typically, the influence will grow compared to values at **ITER=0**. In models without **RANDOM** or **REPEATED** effects, the **ITER=** option has no effect.

This documentation refers to analyses when $n > 0$ simply as iterative influence analysis, even if final covariance parameter estimates can be updated in a single step (for example, when **METHOD=MIVQUE0** or **METHOD=TYPE3**). This nomenclature reflects the fact that only if $n > 0$ are all model parameters updated, which can require additional iterations. If $n > 0$ and **METHOD=REML** (default) or **METHOD=ML**, the procedure updates fixed effects and variance-covariance parameters after removing the selected observations with additional Newton-Raphson iterations, starting from the converged estimates for the entire data. The process stops for each observation or set of observations if the convergence criterion is satisfied or the number of further iterations exceeds n . If $n > 0$ and **METHOD=TYPE1**, **TYPE2**, or **TYPE3**, ANOVA estimates of the covariance parameters are recomputed in a single step.

Compared to noniterative updates, the computations are more involved. In particular for large data sets or a large number of random effects (or both), iterative updates require considerably more resources. A one-step (**ITER=1**) or two-step update might be a good compromise. The output includes the number of iterations performed, which is less than n if the iteration converges. If the process does not converge in n iterations, you should be careful in interpreting the results, especially if n is fairly large.

Bounds and other restrictions on the covariance parameters carry over from the full-data model. Covariance parameters that are not iterated in the model fit to the full data (the **NOITER** or **HOLD=** option in the **PARMS** statement) are likewise not updated in the refit. In certain models, such as random-effects models, the ratios between the covariance parameters and the residual variance are maintained rather than the actual value of the covariance parameter estimate (see the section “Influence Diagnostics” on page 4977).

KEEP=*n*

determines how many observations are retained for display and in the output data set or how many tuples if you specify **SIZE=**. The output is sorted by an influence statistic as discussed for the **SIZE=** suboption.

SELECT=*value-list*

specifies which observations or effect levels are chosen for influence calculations. If the **SELECT=** suboption is not specified, diagnostics are computed as follows:

- for all observations, if **EFFECT=** or **SIZE=** are not given
- for all levels of the specified effect, if **EFFECT=** is specified
- for all tuples of size *k* formed from the observations in *value-list*, if **SIZE=*k*** is specified

When you specify an effect with the **EFFECT=** option, the values in *value-list* represent indices of the levels in the order in which PROC MIXED builds classification effects. Which observations in the data set correspond to this index depends on the order of the variables in the **CLASS** statement, not the order in which the variables appear in the interaction effect. See the section “Parameterization of Mixed Models” on page 4971 to understand precisely how the procedure indexes nested and crossed effects and how levels of classification variables are ordered. The actual values of the classification variables involved in the effect are shown in the output so you can determine which observations were removed.

If the **EFFECT=** suboption is not specified, the **SELECT=** value list refers to the sequence in which observations are read from the input data set or from the current BY group if there is a **BY** statement. This indexing is not necessarily the same as the observation numbers in the input data set, for example, if a **WHERE** clause is specified or during BY processing.

SIZE=*n*

instructs PROC MIXED to remove groups of observations formed as tuples of size *n*. For example, **SIZE=2** specifies all $n \times (n - 1) / 2$ unique pairs of observations. The number of tuples for **SIZE=*k*** is $n! / (k!(n - k)!)$ and grows quickly with *n* and *k*. Using the **SIZE=** option can result in considerable computing time. The MIXED procedure displays by default only the 50 tuples with the greatest influence. Use the **KEEP=** option to override this default and to retain a different number of tuples in the listing or ODS output data set. Regardless of the **KEEP=** specification, all tuples are evaluated and the results are ordered according to an influence statistic. This statistic is the (restricted) likelihood distance as a measure of overall influence if **ITER=*n* > 0** or when a residual variance is profiled. When likelihood distances are unavailable, the results are ordered by the PRESS statistic.

To reduce computational burden, the **SIZE=** option can be combined with the **SELECT=***value-list* modifier. For example, the following statements evaluate all $15 = 6 \times 5 / 2$ pairs formed from observations 13, 14, 18, 30, 31, and 33 and display the five pairs with the greatest influence:

```
proc mixed;
  class a m f;
  model penetration = a m /
                    influence(size=2 keep=5
                              select=13,14,18,30,31,33);
  random f(m);
run;
```

If any observation in a tuple contains missing values or has otherwise not contributed to the analysis, the tuple is not evaluated. This guarantees that the displayed results refer to the same number of observations, so that meaningful statistics are available by which to order the results. If computations fail for a particular tuple—for example, because the $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-}$ matrix changes rank or the \mathbf{G} matrix is not positive definite—no results are produced. Results are retained when the maximum number of iterative updates is exceeded in iterative influence analyses.

The `SIZE=` suboption cannot be combined with the `EFFECT=` suboption. As in the case of the `EFFECT=` suboption, the statistics being computed are those appropriate for removal of multiple data points, even if `SIZE=1`.

The ODS name of the “Influence Diagnostics” table is `Influence`. The variables in this table depend on whether you specify the `EFFECT=`, `SIZE=`, or `KEEP=` suboption and whether covariance parameters are iteratively updated. When `ITER=0` (the default), certain influence diagnostics are meaningful only if the residual variance is profiled. Table 59.11 and Table 59.12 summarize the statistics obtained depending on the model and modifiers. The last column in these tables gives the variable name in the ODS OUTPUT INFLUENCE= data set. Restricted likelihood distances are reported instead of the likelihood distance unless `METHOD=ML`. See the section “Influence Diagnostics” on page 4977 for details about the individual statistics.

Table 59.11 Statistics Computed with INFLUENCE Option, Noniterative Analysis (ITER=0)

Suboption	σ^2 Profiled	Statistic	Variable Name
Default	Yes	Observed value	Observed
		Predicted value	Predicted

INTERCEPT

adds a row to the tables for Type 1, 2, and 3 tests corresponding to the overall intercept.

LCOMPONENTS

requests an estimate for each row of the **L** matrix used to form tests of fixed effects. Components corresponding to Type 3 tests are the default; you can produce the Type 1 and Type 2 component estimates with the **HTYPE=** option.

Tests of fixed effects involve testing of linear hypotheses of the form $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$. The matrix **L** is constructed from Type 1, 2, or 3 estimable functions. By default the MIXED procedure constructs Type 3 tests. In many situations, the individual rows of the matrix **L** represent contrasts of interest. For example, in a one-way classification model, the Type 3 estimable functions define differences of factor-level means. In a balanced two-way layout, the rows of **L** correspond to differences of cell means.

For example, suppose factors **A** and **B** have *a* and *b* levels, respectively. The following statements produce (*a* – 1) one degree of freedom tests for the rows of **L** associated with the Type 1 and Type 3 estimable functions for factor **A**, (*b* – 1) tests for the rows of **L** associated with factor **B**, and a single test for the Type 1 and Type 3 coefficients associated with regressor **X**:

```
class A B;
model y = A B x / htype=1,3 lcomponents;
```

The denominator degrees of freedom associated with a row of **L** are the same as those in the corresponding “Tests of Fixed Effects” table, except for **DDFM=KENWARDROGER** and **DDFM=SATTERTHWAITE**. For these degree of freedom methods, the denominator degrees of freedom are computed separately for each row of **L**.

The ODS name of the table containing all requested component tests is **LComponents**. See [Example 59.9](#) for applications of the **LCOMPONENTS** option.

NOCONTAIN

has the same effect as the **DDFM=RESIDUAL** option.

NOINT

requests that no intercept be included in the model. An intercept is included by default.

NOTEST

specifies that no hypothesis tests be performed for the fixed effects.

OUTP=SAS-data-set**OUTPRED=SAS-data-set**

specifies an output data set containing predicted values and related quantities. This option replaces the **P** option from SAS 6.

Predicted values are formed by using the rows from $(\mathbf{X} \ \mathbf{Z})$ as **L** matrices. Thus, predicted values from the original data are $\mathbf{X}\hat{\boldsymbol{\beta}} + \mathbf{Z}\hat{\boldsymbol{\gamma}}$. Their approximate standard errors of prediction are formed from the quadratic form of **L** with $\hat{\mathbf{C}}$ defined in the section “[Statistical Properties](#)” on page 4967. The **L95** and **U95** variables provide a *t*-type confidence interval for the predicted values, and they correspond to the **L95M** and **U95M** variables from the GLM and REG procedures for fixed-effects models. The residuals are the observed minus the predicted values. Predicted values for data points other than those observed can be obtained by using missing dependent variables in your input data set.

Specifications that have a **REPEATED** statement with the **SUBJECT=** option and missing dependent variables compute predicted values by using empirical best linear unbiased prediction (EBLUP). Using hats ($\hat{\cdot}$) to denote estimates, the EBLUP formula is

$$\hat{\mathbf{m}} = \mathbf{X}_m \hat{\boldsymbol{\beta}} + \hat{\mathbf{C}}_m \hat{\mathbf{V}}^{-1}(\mathbf{y} - \mathbf{X} \hat{\boldsymbol{\beta}})$$

where \mathbf{m} represents a hypothetical realization of a missing data vector with associated design matrix \mathbf{X}_m . The matrix \mathbf{C}_m is the model-based covariance matrix between \mathbf{m} and the observed data \mathbf{y} , and other notation is as presented in the section “**Mixed Models Theory**” on page 4958.

The estimated prediction variance is as follows:

$$\widehat{\text{Var}}(\hat{\mathbf{m}} - \mathbf{m}) = \hat{\mathbf{V}}_m - \hat{\mathbf{C}}_m \hat{\mathbf{V}}^{-1} \hat{\mathbf{C}}_m' + [\mathbf{X}_m - \hat{\mathbf{C}}_m \hat{\mathbf{V}}^{-1} \mathbf{X}](\mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{X})^{-1} [\mathbf{X}_m - \hat{\mathbf{C}}_m \hat{\mathbf{V}}^{-1} \mathbf{X}]'$$

where \mathbf{V}_m is the model-based variance matrix of \mathbf{m} . For further details, see Henderson (1984) and Harville (1990). This feature can be useful for forecasting time series or for computing spatial predictions.

By default, all variables from the input data set are included in the **OUTP=** data set. You can select a subset of these variables by using the **ID** statement.

OUTPM=SAS-data-set

OUTPREDM=SAS-data-set

specifies an output data set containing predicted means and related quantities. This option replaces the **PM** option from SAS 6.

The output data set is of the same form as that resulting from the **OUTP=** option, except that the predicted values do not incorporate the EBLUP values $\mathbf{Z}\hat{\boldsymbol{\gamma}}$. They also do not use the EBLUPs for specifications that have a **REPEATED** statement with the **SUBJECT=** option and missing dependent variables. The predicted values are formed as $\mathbf{X}\hat{\boldsymbol{\beta}}$ in the **OUTPM=** data set, and standard errors are quadratic forms in the approximate variance-covariance matrix of $\hat{\boldsymbol{\beta}}$ as displayed by the **COVB** option.

By default, all variables from the input data set are included in the **OUTPM=** data set. You can select a subset of these variables by using the **ID** statement.

RESIDUAL

RESIDUALS

requests that Pearson-type and (internally) studentized residuals be added to the **OUTP=** and **OUTPM=** data sets. Studentized residuals are raw residuals standardized by their estimated standard error. When residuals are internally studentized, the data point in question has contributed to the estimation of the covariance parameter estimates on which the standard error of the residual is based. Externally studentized marginal residuals can be computed with the **INFLUENCE** option. Pearson-type residuals scale the residual by the standard deviation of the response.

The option has no effect unless the **OUTP=** or **OUTPM=** option is specified or unless **ODS Graphics** is enabled. For general information about **ODS Graphics**, see Chapter 21, “**Statistical Graphics Using ODS**.” For specific information about the graphics available in the **MIXED** procedure, see the section “**ODS Graphics**” on page 4992. For computational details about studentized and Pearson residuals in **MIXED**, see the section “**Residual Diagnostics**” on page 4976.

SINGCHOL=number

tunes the sensitivity in computing Cholesky roots. If a diagonal pivot element is less than $D \times \text{number}$ as PROC MIXED performs the Cholesky decomposition on a matrix, the associated column is declared to be linearly dependent upon previous columns and is set to 0. The value D is the original diagonal element of the matrix. The default for *number* is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

SINGRES=number

sets the tolerance for which the residual variance is considered to be zero. The default is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

SINGULAR=number

tunes the sensitivity in sweeping. If a diagonal pivot element is less than $D \times \text{number}$ as PROC MIXED sweeps a matrix, the associated column is declared to be linearly dependent upon previous columns, and the associated parameter is set to 0. The value D is the original diagonal element of the matrix. The default is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

SOLUTION**S**

requests that a solution for the fixed-effects parameters be produced. Using notation from the section “[Mixed Models Theory](#)” on page 4958, the fixed-effects parameter estimates are $\hat{\beta}$ and their approximate standard errors are the square roots of the diagonal elements of $(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}$. You can output this approximate variance matrix with the [COVB](#) option or modify it with the [EMPIRICAL](#) option in the PROC MIXED statement or the [DDFM=KENWARDROGER](#) option in the [MODEL](#) statement.

Along with the estimates and their approximate standard errors, a t statistic is computed as the estimate divided by its standard error. The degrees of freedom for this t statistic matches the one appearing in the “Tests of Fixed Effects” table under the effect containing the parameter. The “Pr > |t|” column contains the two-tailed p -value corresponding to the t statistic and associated degrees of freedom. You can use the [CL](#) option to request confidence intervals for all of the parameters; they are constructed around the estimate by using a radius of the standard error times a percentage point from the t distribution.

VCIRY

requests that responses and marginal residuals be scaled by the inverse Cholesky root of the marginal variance-covariance matrix. The variables ScaledDep and ScaledResid are added to the [OUTPM=](#) data set. These quantities can be important in bootstrapping of data or residuals. Examination of the scaled residuals is also helpful in diagnosing departures from normality. Notice that the results of this scaling operation can depend on the order in which the MIXED procedure processes the data.

The VCIRY option has no effect unless you also use the [OUTPM=](#) option or unless ODS Graphics is enabled. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the MIXED procedure, see the section “[ODS Graphics](#)” on page 4992.

XPVIX

is an alias for the [COVBI](#) option.

XPVIXI

is an alias for the [COVB](#) option.

ZETA=number

tunes the sensitivity in forming Type 3 functions. Any element in the estimable function basis with an absolute value less than *number* is set to 0. The default is 1E–8.

PARMS Statement

PARMS (*value-list*)...< / *options* > ;

The PARMS statement specifies initial values for the covariance parameters, or it requests a grid search over several values of these parameters. You must specify the values in the order in which they appear in the “Covariance Parameter Estimates” table.

The *value-list* specification can take any of several forms:

<i>m</i>	a single value
m_1, m_2, \dots, m_n	several values
<i>m</i> to <i>n</i>	a sequence where <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment equals 1
<i>m</i> to <i>n</i> by <i>i</i>	a sequence where <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment equals <i>i</i>
m_1, m_2 to m_3	mixed values and sequences

You can use the PARMS statement to input known parameters. Referring to the split-plot example ([Example 59.1](#)), suppose the three variance components are known to be 60, 20, and 6. The SAS statements to fix the variance components at these values are as follows:

```
proc mixed data=sp noprofile;
  class Block A B;
  model Y = A B A*B;
  random Block A*Block;
  parms (60) (20) (6) / noiter;
run;
```

The [NOPROFILE](#) option requests PROC MIXED to refrain from profiling the residual variance parameter during its calculations, thereby enabling its value to be held at 6 as specified in the PARMS statement. The [NOITER](#) option prevents any Newton-Raphson iterations so that the subsequent results are based on the given variance components. You can also specify known parameters of **G** by using the [GDATA=](#) option in the [RANDOM](#) statement.

If you specify more than one set of initial values, PROC MIXED performs a grid search of the likelihood surface and uses the best point on the grid for subsequent analysis. Specifying a large number of grid points can result in long computing times. The grid search feature is also useful for exploring the likelihood surface. (See [Example 59.3](#).)

The results from the PARMS statement are the values of the parameters on the specified grid (denoted by CovP1–CovP*n*), the residual variance (possibly estimated) for models with a residual variance parameter, and various functions of the likelihood.

The ODS name of the “Parameter Search” table is ParmSearch.

Table 59.13 summarizes the options available in the PARMS statement.

Table 59.13 PARMS Statement Options

Option	Description
HOLD=	Holds parameter values equal to the specified values
LOGDETH	Evaluates the log determinant of the Hessian matrix
LOWERB=	Specifies lower boundary constraints
NOBOUND	Removes boundary constraints on covariance parameters
NOITER	Performs inferences using the best value from the grid search
NOPRINT	Suppresses the “Parameter Search” table
NOPROFILE	Specifies a different computational method for the residual variance
OLS	Requests starting values corresponding to the usual general linear model
PARMSDATA=	Reads in covariance parameter values from a SAS data set
RATIOS	Indicates that ratios with the residual variance are specified
UPPERB=	Specifies upper boundary constraints

You can specify the following *options* in the PARMS statement after a slash (/).

HOLD=*value-list*

EQCONS=*value-list*

specifies which parameter values PROC MIXED should hold to equal the specified values. For example, the following statement constrains the first and third covariance parameters to equal 5 and 2, respectively:

```
parms (5) (3) (2) (3) / hold=1,3;
```

LOGDETH

evaluates the log determinant of the Hessian matrix for each point specified in the PARMS statement. A Log Det H column is added to the “Parameter Search” table.

LOWERB=*value-list*

enables you to specify lower boundary constraints on the covariance parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that PROC MIXED uses for the covariance parameters, and each number corresponds to the lower boundary constraint. A missing value instructs PROC MIXED to use its default constraint, and if you do not specify numbers for all of the covariance parameters, PROC MIXED assumes the remaining ones are missing.

An example for which this option is useful is when you want to constrain the **G** matrix to be positive definite in order to avoid the more computationally intensive algorithms required when **G** becomes singular. The corresponding statements for a random coefficients model are as follows:

```
proc mixed;
  class person;
  model y = time;
```

```

random int time / type=fa0(2) sub=person;
parms / lowerb=1e-4,.,1e-4;
run;

```

Here the **TYPE=FA0(2)** structure is used in order to specify a Cholesky root parameterization for the 2×2 unstructured blocks in **G**. This parameterization ensures that the **G** matrix is nonnegative definite, and the **PARMS** statement then ensures that it is positive definite by constraining the two diagonal terms to be greater than or equal to $1E-4$.

NOBOUND

requests the removal of boundary constraints on covariance parameters. For example, variance components have a default lower boundary constraint of 0, and the **NOBOUND** option allows their estimates to be negative.

NOITER

requests that no Newton-Raphson iterations be performed and that PROC MIXED use the best value from the grid search to perform inferences. By default, iterations begin at the best value from the **PARMS** grid search.

NOPRINT

suppresses the display of the “Parameter Search” table.

NOPROFILE

specifies a different computational method for the residual variance during the grid search. By default, PROC MIXED estimates this parameter by using the profile likelihood when appropriate. This estimate is displayed in the Variance column of the “Parameter Search” table. The **NOPROFILE** option suppresses the profiling and uses the actual value of the specified variance in the likelihood calculations.

OLS

requests starting values corresponding to the usual general linear model. Specifically, all variances and covariances are set to zero except for the residual variance, which is set equal to its ordinary least squares (OLS) estimate. This option is useful when the default **MIVQUE0** procedure produces poor starting values for the optimization process.

PARMSDATA=SAS-data-set

PDATA=SAS-data-set

reads in covariance parameter values from a SAS data set. The data set should contain the **Est** or **Covp1–Covpn** variables.

RATIOS

indicates that ratios with the residual variance are specified instead of the covariance parameters themselves. The default is to use the individual covariance parameters.

UPPERB=value-list

enables you to specify upper boundary constraints on the covariance parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that PROC MIXED uses for the covariance parameters, and each number corresponds to the upper boundary constraint. A missing value instructs PROC MIXED to use its default constraint, and if you do not specify numbers for all of the covariance parameters, PROC MIXED assumes that the remaining ones are missing.

PERFORMANCE Statement

PERFORMANCE < *performance-options* > ;

The PERFORMANCE statement defines performance parameters for multithreaded computing in solving large mixed model equations and other large matrix sweep operations.

You can specify the following *performance-options* in the PERFORMANCE statement:

CPUCOUNT=ACTUAL | num

specifies how many processors the procedure assumes to be available on the machine. You can specify any integer from 1 to 256 for *num*. CPUCOUNT=ACTUAL is equivalent to setting *num* to be the number of physical processors available. This number can be less than the physical number of CPUs if the SAS process has been restricted by system administration tools. Setting CPUCOUNT= to a number greater than the actual number of available CPUs might result in reduced performance. This option overrides the CPUCOUNT= SAS system option.

NTHREADS=*n*

specifies the number of threads for analytic computations and overrides the SAS system option THREADS | NOTHEADS. If you do not specify the NTHREADS= option, the number of threads are determined based on the number of CPUs on the machine by creating one thread per CPU for the analytic computations. The largest number that can be specified for *n* is 256.

By default, PROC MIXED executes in multiple concurrent threads unless you specify the NOTHEADS system option or you force single-threaded execution with NTHREADS=1 or the NOTHEADS options in the PERFORMANCE statement.

THREADS=YES | NO

specifies whether PROC MIXED executes in multiple concurrent threads. The default is YES.

NOTHEAD

turns off the multithreaded computation.

PRIOR Statement

PRIOR < *distribution* > < / *options* > ;

The PRIOR statement enables you to carry out a sampling-based Bayesian analysis in PROC MIXED. It currently operates only with variance component models. Other TYPE= structures are not supported. The analysis produces a SAS data set containing a pseudo-random sample from the joint posterior density of the variance components and other parameters in the mixed model.

The posterior analysis is performed after all other PROC MIXED computations. It begins with the “Posterior Sampling Information” table, which provides basic information about the posterior sampling analysis, including the prior densities, sampling algorithm, sample size, and random number seed. The ODS name of this table is Posterior.

By default, PROC MIXED uses an independence chain algorithm in order to generate the posterior sample (Tierney 1994). This algorithm works by generating a pseudo-random proposal from a convenient base distribution, chosen to be as close as possible to the posterior. The proposal is then retained in the sample

with probability proportional to the ratio of weights constructed by taking the ratio of the true posterior to the base density. If a proposal is not accepted, then a duplicate of the previous observation is added to the chain.

In selecting the base distribution, PROC MIXED makes use of the fact that the fixed-effects parameters can be analytically integrated out of the joint posterior, leaving the marginal posterior density of the variance components. In order to better approximate the marginal posterior density of the variance components, PROC MIXED transforms them by using the MIVQUE(0) equations. You can display the selected transformation with the **PTRANS** option or specify your own with the **TDATA=** option. The density of the transformed parameters is then approximated by a product of inverted gamma densities (see Gelfand et al. 1990).

To determine the parameters for the inverted gamma densities, PROC MIXED evaluates the logarithm of the posterior density over a grid of points in each of the transformed parameters, and you can display the results of this search with the **PSEARCH** option. PROC MIXED then performs a linear regression of these values on the logarithm of the inverted gamma density. The resulting base densities are displayed in the “Base Densities” table; for ODS purposes, the name of this table is “Base.” You can input different base densities with the **BDATA=** option.

At the end of the sampling, the “Acceptance Rates” table displays the acceptance rate computed as the number of accepted samples divided by the total number of samples generated. The ODS name of the “Acceptance Rates” table is **AccRates**.

The **OUT=** option specifies the output data set containing the posterior sample. PROC MIXED automatically includes all variance component parameters in this data set (labeled **COVP1–COVP_n**), the Type 3 *F* statistics constructed as in Ghosh (1992) discussing Schervish (1992) (labeled **T3Fn**), the log values of the posterior (labeled **LOGF**), the log of the base sampling density (labeled **LOGG**), and the log of their ratio (labeled **LOGRATIO**). If you specify the **SOLUTION** option in the **MODEL** statement, the data set also contains a random sample from the posterior density of the fixed-effects parameters (labeled **BETA_n**); and if you specify the **SOLUTION** option in the **RANDOM** statement, the table contains a random sample from the posterior density of the random-effects parameters (labeled **GAM_n**). PROC MIXED also generates additional variables corresponding to any **CONTRAST**, **ESTIMATE**, or **LSMEANS** statement that you specify.

Subsequently, you can use SAS/INSIGHT or the UNIVARIATE, CAPABILITY, or KDE procedure to analyze the posterior sample.

The prior density of the variance components is, by default, a noninformative version of Jeffreys’ prior (Box and Tiao 1973). You can also specify informative priors with the **DATA=** option or a flat (equal to 1) prior for the variance components. The prior density of the fixed-effects parameters is assumed to be flat (equal to 1), and the resulting posterior is conditionally multivariate normal (conditioning on the variance component parameters) with mean $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}^{-1}\mathbf{y}$ and variance $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$.

Table 59.14 summarizes the options available in the PRIOR statement.

Table 59.14 PRIOR Statement Options

Option	Description
DATA=	Inputs the prior densities of the variance components
JEFFREYS	Specifies a noninformative reference version of Jeffreys’ prior
FLAT	Specifies a prior density equal to 1 everywhere

Table 59.14 *continued*

Option	Description
ALG=	Specifies the algorithm used for generating the posterior sample
BDATA=	Inputs the base densities used by the sampling algorithm
GRID=	Specifies a grid of values over which to evaluate the posterior density
GRIDT=	Specifies a transformed grid of values over which to evaluate the posterior density
IFACTOR=	An alias for the SFACTOR= option
LOGNOTE=	Writes a note to the log after generating the sample
LOGRBOUND=	Specifies the bounding constant for rejection sampling
NSAMPLE=	Specifies the number of posterior samples to generate
NSEARCH=	Specifies the number of posterior evaluations
OUT=	Creates an output data set containing the sample from the posterior density
OUTG=	Creates an output data set from the grid evaluations
OUTGT=	Creates an output data set from the transformed grid evaluations
PSEARCH	Displays the search used to determine the parameters for the inverted gamma densities
PTRANS	Displays the transformation of the variance components
SEED=	Specifies an integer used to start the pseudo-random number generator
SFACTOR=	Adjusts the search range of the transformed parameters
TDATA=	Inputs the transformation used by the sampling algorithm
TRANS=	Specifies the algorithm that determines the transformation of the covariance parameters
UPDATE=	An alias for the LOGNOTE= option

The *distribution* argument in the PRIOR statement determines the prior density for the variance component parameters of your mixed model. Valid values are as follows.

DATA=

enables you to input the prior densities of the variance components used by the sampling algorithm. This data set must contain the Type and Parm1–Parm*n* variables, where *n* is the largest number of parameters among each of the base densities. The format of the DATA= data set matches that created by PROC MIXED in the “Base Densities” table, so you can output the densities from one run and use them as input for a subsequent run.

JEFFREYS

specifies a noninformative reference version of Jeffreys’ prior constructed by using the square root of the determinant of the expected information matrix as in (1.3.92) of Box and Tiao (1973). This is the default prior.

FLAT

specifies a prior density equal to 1 everywhere, making the likelihood function the posterior.

You can specify the following *options* in the PRIOR statement after a slash (/).

ALG=IC | INDCHAIN**ALG=IS | IMPSAMP****ALG=RS | REJSAMP****ALG=RWC | RWCHAIN**

specifies the algorithm used for generating the posterior sample. The ALG=IC option requests an independence chain algorithm, and it is the default. The option ALG=IS requests importance sampling, ALG=RS requests rejection sampling, and ALG=RWC requests a random walk chain. For more information about these techniques, see Ripley (1987); Smith and Gelfand (1992); Tierney (1994).

BDATA=

enables you to input the base densities used by the sampling algorithm. This data set must contain the Type and Parm1–Parm*n* variables, where *n* is the largest number of parameters among each of the base densities. The format of the BDATA= data set matches that created by PROC MIXED in the “Base Densities” table, so you can output the densities from one run and use them as input for a subsequent run.

GRID=(value-list)

specifies a grid of values over which to evaluate the posterior density. The *value-list* syntax is the same as in the **PARMS** statement, and you must specify an output data set name with the **OUTG=** option.

GRIDT=(value-list)

specifies a transformed grid of values over which to evaluate the posterior density. The *value-list* syntax is the same as in the **PARMS** statement, and you must specify an output data set name with the **OUTGT=** option.

IFACTOR=number

is an alias for the **SFACTOR=** option.

LOGNOTE=number

instructs PROC MIXED to write a note to the SAS log after it generates the sample corresponding to each multiple of *number*. This is useful for monitoring the progress of CPU-intensive runs.

LOGRBOUND=number

specifies the bounding constant for rejection sampling. The value of *number* equals the maximum of $\log\{f/g\}$ over the variance component parameter space, where *f* is the posterior density and *g* is the product inverted gamma densities used to perform rejection sampling.

When performing the rejection sampling, you might encounter the following message:

```
WARNING: The log ratio bound of LL was violated at sample XX.
```

When this occurs, PROC MIXED reruns an optimization algorithm to determine a new log upper bound and then restarts the rejection sampling. The resulting **OUT=** data set contains all observations that have been generated; therefore, assuming that you have requested *N* samples, you should retain only the final *N* observations in this data set for analysis purposes.

NSAMPLE=number

specifies the number of posterior samples to generate. The default is 1000, but more accurate results are obtained with larger samples such as 10000.

NSEARCH=number

specifies the number of posterior evaluations PROC MIXED makes for each transformed parameter in determining the parameters for the inverted gamma densities. The default is 20.

OUT=SAS-data-set

creates an output data set containing the sample from the posterior density.

OUTG=SAS-data-set

creates an output data set from the grid evaluations specified in the **GRID=** option.

OUTGT=SAS-data-set

creates an output data set from the transformed grid evaluations specified in the **GRIDT=** option.

PSEARCH

displays the search used to determine the parameters for the inverted gamma densities. The ODS name of the table is Search.

PTRANS

displays the transformation of the variance components. For ODS purposes, the name of the table is "Trans."

SEED=number

specifies an integer used to start the pseudo-random number generator for the simulation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer clock. You should use a positive seed (less than $2^{31} - 1$) whenever you want to duplicate the sample in another run of PROC MIXED.

SFACTOR=number

enables you to adjust the range over which PROC MIXED searches the transformed parameters in order to determine the parameters for the inverted gamma densities. PROC MIXED determines the range by first transforming the estimates from the standard PROC MIXED analysis (REML, ML, or MIVQUE0, depending upon which estimation method you select). It then multiplies and divides the transformed estimates by $2 \times \text{number}$ to obtain upper and lower bounds, respectively. Transformed values that produce negative variance components in the original scale are not included in the search. The default value is 1; *number* must be greater than 0.5.

TDATA=

enables you to input the transformation of the covariance parameters used by the sampling algorithm. This data set should contain the CovP1–CovP*n* variables. The format of the TDATA= data set matches that created by PROC MIXED in the "Trans" table, so you can output the transformation from one run and use it as input for a subsequent run.

TRANS=EXPECTED | MIVQUE0 | OBSERVED

specifies the particular algorithm used to determine the transformation of the covariance parameters. The default is MIVQUE0, indicating a transformation based on the MIVQUE(0) equations. The other two options indicate the type of Hessian matrix used in constructing the transformation via a Cholesky root.

UPDATE=numberis an alias for the **LOGNOTE=** option.

RANDOM Statement

RANDOM *random-effects* **</ options>** ;

The **RANDOM** statement defines the random effects constituting the $\boldsymbol{\gamma}$ vector in the mixed model. It can be used to specify traditional variance component models (as in the **VARCOMP** procedure) and to specify random coefficients. The random effects can be classification or continuous, and multiple **RANDOM** statements are possible.

Using notation from the section “**Mixed Models Theory**” on page 4958, the purpose of the **RANDOM** statement is to define the **Z** matrix of the mixed model, the random effects in the $\boldsymbol{\gamma}$ vector, and the structure of **G**. The **Z** matrix is constructed exactly as the **X** matrix for the fixed effects, and the **G** matrix is constructed to correspond with the effects constituting **Z**. The structure of **G** is defined by using the **TYPE=** option.

You can specify **INTERCEPT** (or **INT**) as a random effect to indicate the intercept. **PROC MIXED** does not include the intercept in the **RANDOM** statement by default as it does in the **MODEL** statement.

Table 59.15 summarizes the options available in the **RANDOM** statement. All options are subsequently discussed in alphabetical order.

Table 59.15 Summary of **RANDOM** Statement Options

Option	Description
Construction of Covariance Structure	
GDATA=	Requests that the G matrix be read from a SAS data set
GROUP=	Varies covariance parameters by groups
LDATA=	Specifies data set with coefficient matrices for TYPE=LIN
NOFULLZ	Eliminates columns in Z corresponding to missing values
RATIOS	Indicates that ratios are specified in the GDATA= data set
SUBJECT=	Identifies the subjects in the model
TYPE=	Specifies the covariance structure
Statistical Output	
ALPHA=α	Determines the confidence level ($1 - \alpha$)
CL	Requests confidence limits for predictors of random effects
G	Displays the estimated G matrix
GC	Displays the Cholesky root (lower) of estimated G matrix
GCI	Displays the inverse Cholesky root (lower) of estimated G matrix
GCORR	Displays the correlation matrix corresponding to estimated G matrix
GI	Displays the inverse of the estimated G matrix
SOLUTION	Displays solutions $\hat{\boldsymbol{\gamma}}$ of the G-side random effects
V	Displays blocks of the estimated V matrix
VC	Displays the lower-triangular Cholesky root of blocks of the estimated V matrix

Table 59.15 *continued*

Option	Description
VCI	Displays the inverse Cholesky root of blocks of the estimated V matrix
VCORR	Displays the correlation matrix corresponding to blocks of the estimated V matrix
VI	Displays the inverse of the blocks of the estimated V matrix

You can specify the following *options* in the RANDOM statement after a slash (/).

ALPHA=number

requests that a *t*-type confidence interval be constructed for each of the random-effect estimates with confidence level $1 - \text{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

CL

requests that *t*-type confidence limits be constructed for each of the random-effect estimates. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

G

requests that the estimated **G** matrix be displayed. PROC MIXED displays blanks for values that are 0. If you specify the **SUBJECT=** option, then the block of the **G** matrix corresponding to the first subject is displayed. For ODS purposes, the name of the table is “G.”

GC

displays the lower-triangular Cholesky root of the estimated **G** matrix according to the rules listed under the **G** option. The ODS name of the table is CholG.

GCI

displays the inverse Cholesky root of the estimated **G** matrix according to the rules listed under the **G** option. The ODS name of the table is InvCholG.

GCORR

displays the correlation matrix corresponding to the estimated **G** matrix according to the rules listed under the **G** option. The ODS name of the table is GCorr.

GDATA=SAS-data-set

requests that the **G** matrix be read in from a SAS data set. This **G** matrix is assumed to be known; therefore, only **R**-side parameters from effects in the **REPEATED** statement are included in the Newton-Raphson iterations. If no **REPEATED** statement is specified, then only a residual variance is estimated.

The information in the **GDATA=** data set can appear in one of two ways. The first is a sparse representation for which you include **Row**, **Col**, and **Value** variables to indicate the row, column, and value of **G**, respectively. All unspecified locations are assumed to be 0. The second representation is for dense matrices. In it you include **Row** and **Col1–Coln** variables to indicate, respectively, the row and columns of **G**, which is a symmetric matrix of order *n*. For both representations, you must specify effects in the RANDOM statement that generate a **Z** matrix that contains *n* columns. (See [Example 59.4.](#))

If you have more than one RANDOM statement, only one GDATA= option is required in any one of them, and the data set you specify must contain the entire **G** matrix defined by all of the RANDOM statements.

If the GDATA= data set contains variance ratios instead of the variances themselves, then use the **RATIOS** option.

Known parameters of **G** can also be input by using the PARMS statement with the **HOLD=** option.

GI

displays the inverse of the estimated **G** matrix according to the rules listed under the **G** option. The ODS name of the table is InvG.

GROUP=effect

GRP=effect

defines an effect specifying heterogeneity in the covariance structure of **G**. All observations having the same level of the group effect have the same covariance parameters. Each new level of the group effect produces a new set of covariance parameters with the same structure as the original group. You should exercise caution in defining the group effect, because strange covariance patterns can result from its misuse. Also, the group effect can greatly increase the number of estimated covariance parameters, which can adversely affect the optimization process.

Continuous variables are permitted as arguments to the GROUP= option. PROC MIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

LDATA=SAS-data-set

reads the coefficient matrices associated with the **TYPE=LIN(number)** option. The data set must contain the variables Parm, Row, Col1–Col n or Parm, Row, Col, Value. The Parm variable denotes which of the *number* coefficient matrices is currently being constructed, and the Row, Col1–Col n , or Row, Col, Value variables specify the matrix values, as they do with the **GDATA=** option. Unspecified values of these matrices are set equal to 0.

NOFULLZ

eliminates the columns in **Z** corresponding to missing levels of random effects involving **CLASS** variables. By default, these columns are included in **Z**.

RATIOS

indicates that ratios with the residual variance are specified in the **GDATA=** data set instead of the covariance parameters themselves. The default **GDATA=** data set contains the individual covariance parameters.

SOLUTION

S

requests that the solution for the random-effects parameters be produced. Using notation from the section “[Mixed Models Theory](#)” on page 4958, these estimates are the empirical best linear unbiased predictors (EBLUPs) $\hat{\mathbf{y}} = \hat{\mathbf{G}}\mathbf{Z}'\hat{\mathbf{V}}^{-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})$. They can be useful for comparing the random effects from different experimental units and can also be treated as residuals in performing diagnostics for your mixed model.

The numbers displayed in the SE Pred column of the “Solution for Random Effects” table are not the standard errors of the $\hat{\gamma}$ displayed in the Estimate column; rather, they are the standard errors of predictions $\hat{\gamma}_i - \gamma_i$, where $\hat{\gamma}_i$ is the i th EBLUP and γ_i is the i th random-effect parameter.

SUBJECT=*effect*

SUB=*effect*

identifies the subjects in your mixed model. Complete independence is assumed across subjects; thus, for the RANDOM statement, the SUBJECT= option produces a block-diagonal structure in **G** with identical blocks. The **Z** matrix is modified to accommodate this block diagonality. In fact, specifying a subject effect is equivalent to nesting all other effects in the RANDOM statement within the subject effect.

Continuous variables are permitted as arguments to the SUBJECT= option. PROC MIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

When you specify the SUBJECT= option and a classification random effect, computations are usually much quicker if the levels of the random effect are duplicated within each level of the SUBJECT= effect.

TYPE=*covariance-structure*

specifies the covariance structure of **G**. Valid values for *covariance-structure* and their descriptions are listed in Table 59.17 and Table 59.18. Although a variety of structures are available, most applications call for either **TYPE=VC** or **TYPE=UN**. The **TYPE=VC** (variance components) option is the default structure, and it models a different variance component for each random effect.

The **TYPE=UN** (unstructured) option is useful for correlated random coefficient models. For example, the following statement specifies a random intercept-slope model that has different variances for the intercept and slope and a covariance between them:

```
random intercept age / type=un subject=person;
```

You can also use **TYPE=FA0(2)** here to request a **G** estimate that is constrained to be nonnegative definite.

If you are constructing your own columns of **Z** with continuous variables, you can use the **TYPE=TOEP(1)** structure to group them together to have a common variance component. If you want to have different covariance structures in different parts of **G**, you must use multiple RANDOM statements with different TYPE= options.

V<=*value-list***>**

requests that blocks of the estimated **V** matrix be displayed. The first block determined by the **SUBJECT=** effect is the default displayed block. PROC MIXED displays entries that are 0 as blanks in the table.

You can optionally use the *value-list* specification, which indicates the subjects for which blocks of **V** are to be displayed. For example, the following statement displays block matrices for the first, third, and seventh persons:

```
random int time / type=un subject=person v=1,3,7;
```

The ODS table name is V.

VC<=*value-list*>

displays the Cholesky root of the blocks of the estimated **V** matrix. The *value-list* specification is the same as in the **V** option. The ODS table name is CholV.

VCI<=*value-list*>

displays the inverse of the Cholesky root of the blocks of the estimated **V** matrix. The *value-list* specification is the same as in the **V** option. The table name for ODS purposes is “InvCholV.”

VCORR<=*value-list*>

displays the correlation matrix corresponding to the blocks of the estimated **V** matrix. The *value-list* specification is the same as in the **V** option. The table name for ODS purposes is “VCorr.”

VI<=*value-list*>

displays the inverse of the blocks of the estimated **V** matrix. The *value-list* specification is the same as in the **V** option. The ODS table name is InvV.

REPEATED Statement

REPEATED < *repeated-effect* > < / *options* > ;

The REPEATED statement is used to specify the **R** matrix in the mixed model. Its syntax is different from that of the REPEATED statement in PROC GLM. If no REPEATED statement is specified, **R** is assumed to be equal to $\sigma^2\mathbf{I}$.

For many repeated measures models, no repeated effect is required in the REPEATED statement. Simply use the **SUBJECT=** option to define the blocks of **R** and the **TYPE=** option to define their covariance structure. In this case, the repeated measures data must be similarly ordered for each subject, and you must indicate all missing response variables with periods in the input data set unless they all fall at the end of a subject's repeated response profile. These requirements are necessary in order to inform PROC MIXED of the proper location of the observed repeated responses.

Specifying a repeated effect is useful when you do not want to indicate missing values with periods in the input data set. The repeated effect must contain only classification variables. Make sure that the levels of the repeated effect are different for each observation within a subject; otherwise, PROC MIXED constructs identical rows in **R** corresponding to the observations with the same level. This results in a singular **R** and an infinite likelihood.

Whether you specify a REPEATED effect or not, the rows of **R** for each subject are constructed in the order in which they appear in the input data set.

Table 59.16 summarizes the options available in the REPEATED statement. All options are subsequently discussed in alphabetical order.

Table 59.16 Summary of REPEATED Statement Options

Option	Description
Construction of Covariance Structure	
GROUP=	Defines an effect specifying heterogeneity in the R-side covariance structure
LDATA=	Specifies data set with coefficient matrices for TYPE=LIN
LOCAL	Requests that a diagonal matrix be added to R
LOCALW	Specifies that only the local effects are weighted
NONLOCALW	Specifies that only the nonlocal effects are weighted
SUBJECT=	Identifies the subjects in the R-side model
TYPE=	Specifies the R-side covariance structure
Statistical Output	
HLM	Produces a table of Hotelling-Lawley-McKeon statistics (McKeon 1974)
HLPS	Produces a table of Hotelling-Lawley-Pillai-Samson statistics (Pillai and Samson 1959)
R	Displays blocks of the estimated R matrix
RC	Display the Cholesky root (lower) of blocks of the estimated R matrix
RCI	Displays the inverse Cholesky root (lower) of blocks of the estimated R matrix
RCORR	Displays the correlation matrix corresponding to blocks of the estimated R matrix
RI	Displays the inverse of blocks of the estimated R matrix

You can specify the following *options* in the REPEATED statement after a slash (/).

GROUP=effect

GRP=effect

defines an effect that specifies heterogeneity in the covariance structure of **R**. All observations that have the same level of the **GROUP** effect have the same covariance parameters. Each new level of the **GROUP** effect produces a new set of covariance parameters with the same structure as the original group. You should exercise caution in properly defining the **GROUP** effect, because strange covariance patterns can result with its misuse. Also, the **GROUP** effect can greatly increase the number of estimated covariance parameters, which can adversely affect the optimization process.

Continuous variables are permitted as arguments to the **GROUP=** option. PROC MIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

HLM

produces a table of Hotelling-Lawley-McKeon statistics (McKeon 1974) for all fixed effects whose levels change across data having the same level of the **SUBJECT=** effect (the *within-subject* fixed effects). This option applies only when you specify a REPEATED statement with the **TYPE=UN**

option and no **RANDOM** statements. For balanced data, this model is equivalent to the multivariate model for repeated measures in PROC GLM.

The Hotelling-Lawley-McKeon statistic has a slightly better F approximation than the Hotelling-Lawley-Pillai-Samson statistic (see the description of the **HLPS** option, which follows). Both of the Hotelling-Lawley statistics can perform much better in small samples than the default F statistic (Wright 1994).

Separate tables are produced for Type 1, 2, and 3 tests, according to the ones you select. The ODS table names are HLM1, HLM2, and HLM3, respectively.

HLPS

produces a table of Hotelling-Lawley-Pillai-Samson statistics (Pillai and Samson 1959) for all fixed effects whose levels change across data having the same level of the **SUBJECT=** effect (the *within-subject* fixed effects). This option applies only when you specify a **REPEATED** statement with the **TYPE=UN** option and no **RANDOM** statements. For balanced data, this model is equivalent to the multivariate model for repeated measures in PROC GLM, and this statistic is the same as the Hotelling-Lawley Trace statistic produced by PROC GLM.

Separate tables are produced for Type 1, 2, and 3 tests, according to the ones you select. The ODS table names are HLPS1, HLPS2, and HLPS3, respectively.

LDATA=SAS-data-set

reads the coefficient matrices associated with the **TYPE=LIN**(*number*) option. The data set must contain the variables *Parm*, *Row*, *Col1–Coln* or *Parm*, *Row*, *Col*, *Value*. The *Parm* variable denotes which of the *number* coefficient matrices is currently being constructed, and the *Row*, *Col1–Coln*, or *Row*, *Col*, *Value* variables specify the matrix values, as they do with the **RANDOM** statement option **GDATA=**. Unspecified values of these matrices are set equal to 0.

LOCAL

LOCAL=POM(*POM-data-set*)

requests that a diagonal matrix be added to **R**. With just the **LOCAL** option, this diagonal matrix equals $\sigma^2 \mathbf{I}$, and σ^2 becomes an additional variance parameter that PROC MIXED profiles out of the likelihood provided that you do not specify the **NOPROFILE** option in the **PROC MIXED** statement. The **LOCAL** option is useful if you want to add an observational error to a time series structure (Jones and Boadi-Boateng 1991) or a nugget effect to a spatial structure Cressie (1993).

The **LOCAL=EXP**(*<effects>*) option produces exponential local effects, also known as dispersion effects, in a log-linear variance model. These local effects have the form

$$\sigma^2 \text{diag}[\exp(\mathbf{U}\boldsymbol{\delta})]$$

where **U** is the full-rank design matrix corresponding to the effects that you specify and $\boldsymbol{\delta}$ are the parameters that PROC MIXED estimates. An intercept is not included in **U** because it is accounted for by σ^2 . PROC MIXED constructs the full-rank **U** in terms of 1s and –1s for classification effects. Be sure to scale continuous effects in **U** sensibly.

The **LOCAL=POM**(*POM-data-set*) option specifies the power-of-the-mean structure. This structure possesses a variance of the form $\sigma^2 |\mathbf{x}_i' \boldsymbol{\beta}^*|^\theta$ for the i th observation, where \mathbf{x}_i is the i th row of **X** (the design matrix of the fixed effects) and $\boldsymbol{\beta}^*$ is an estimate of the fixed-effects parameters that you specify in *POM-data-set*.

The SAS data set specified by *POM-data-set* contains the numeric variable Estimate (in previous releases, the variable name was required to be EST), and it has at least as many observations as there are fixed-effects parameters. The first p observations of the Estimate variable in *POM-data-set* are taken to be the elements of β^* , where p is the number of columns of \mathbf{X} . You must order these observations according to the non-full-rank parameterization of the MIXED procedure. One easy way to set up *POM-data-set* for a β^* corresponding to ordinary least squares is illustrated by the following statements:

```
ods output SolutionF=sf;
proc mixed;
  class a;
  model y = a x / s;
run;

proc mixed;
  class a;
  model y = a x;
  repeated / local=pom(sf);
run;
```

Note that the generalized least squares estimate of the fixed-effects parameters from the second PROC MIXED step usually is not the same as your specified β^* . However, you can iterate the POM fitting until the two estimates agree. Continuing from the previous example, the statements for performing one step of this iteration are as follows:

```
ods output SolutionF=sf1;
proc mixed;
  class a;
  model y = a x / s;
  repeated / local=pom(sf);
run;

proc compare brief data=sf compare=sf1;
  var estimate;
run;

data sf;
  set sf1;
run;
```

Unfortunately, this iterative process does not always converge. For further details, see the description of pseudo-likelihood in Chapter 3 of Carroll and Ruppert (1988).

LOCALW

specifies that only the local effects and no others be weighted. By default, all effects are weighted. The LOCALW option is used in connection with the [WEIGHT](#) statement and the [LOCAL](#) option in the REPEATED statement.

NONLOCALW

specifies that only the nonlocal effects and no others be weighted. By default, all effects are weighted. The NONLOCALW option is used in connection with the **WEIGHT** statement and the **LOCAL** option in the **REPEATED** statement.

R<=value-list>

requests that blocks of the estimated **R** matrix be displayed. The first block determined by the **SUBJECT=** effect is the default displayed block. PROC MIXED displays blanks for value-lists that are 0.

The *value-list* indicates the subjects for which blocks of **R** are to be displayed. For example, the following statement displays block matrices for the first, third, and fifth persons:

```
repeated / type=cs subject=person r=1,3,5;
```

See the **PARMS** statement for the possible forms of *value-list*. The ODS table name is **R**.

RC<=value-list>

produces the Cholesky root of blocks of the estimated **R** matrix. The *value-list* specification is the same as with the **R** option. The ODS table name is **CholR**.

RCI<=value-list>

produces the inverse Cholesky root of blocks of the estimated **R** matrix. The *value-list* specification is the same as with the **R** option. The ODS table name is **InvCholR**.

RCORR<=value-list>

produces the correlation matrix corresponding to blocks of the estimated **R** matrix. The *value-list* specification is the same as with the **R** option. The table name for ODS purposes is “RCorr.”

RI<=value-list>

produces the inverse of blocks of the estimated **R** matrix. The *value-list* specification is the same as with the **R** option. The ODS table name is **InvR**.

SSCP

requests that an unstructured **R** matrix be estimated from the sum-of-squares-and-crossproducts matrix of the residuals. It applies only when you specify **TYPE=UN** and have no **RANDOM** statements. Also, you must have a sufficient number of subjects for the estimate to be positive definite.

This option is useful when the size of the blocks of **R** is large (for example, greater than 10) and you want to use or inspect an unstructured estimate that is much quicker to compute than the default REML estimate. The two estimates will agree for certain balanced data sets when you have a classification fixed effect defined across all time points within a subject.

SUBJECT=effect**SUB=effect**

identifies the subjects in your mixed model. Complete independence is assumed across subjects; therefore, the **SUBJECT=** option produces a block-diagonal structure in **R** with identical blocks. When the **SUBJECT=** effect consists entirely of classification variables, the blocks of **R** correspond to observations sharing the same level of that effect. These blocks are sorted according to this effect as well.

Continuous variables are permitted as arguments to the SUBJECT= option. PROC MIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

If you want to model nonzero covariance among all of the observations in your SAS data set, specify SUBJECT=INTERCEPT to treat the data as if they are all from one subject. However, be aware that in this case PROC MIXED manipulates an **R** matrix with dimensions equal to the number of observations. If no SUBJECT= effect is specified, then every observation is assumed to be from a different subject and **R** is assumed to be diagonal. For this reason, you usually want to use the SUBJECT= option in the REPEATED statement.

TYPE=covariance-structure

specifies the covariance structure of the **R** matrix. The SUBJECT= option defines the blocks of **R**, and the TYPE= option specifies the structure of these blocks. Valid values for *covariance-structure* and their descriptions are provided in Table 59.17 and Table 59.18. The default structure is VC.

Table 59.17 Covariance Structures

Structure	Description	Parms	(<i>i, j</i>) element
ANTE(1)	Antependence	$2t - 1$	$\sigma_i \sigma_j \prod_{k=i}^{j-1} \rho_k$
AR(1)	Autoregressive(1)	2	$\sigma^2 \rho^{ i-j }$
ARH(1)	Heterogeneous AR(1)	$t + 1$	$\sigma_i \sigma_j \rho^{ i-j }$
ARMA(1,1)	ARMA(1,1)	3	$\sigma^2 [\gamma \rho^{ i-j -1} 1(i \neq j) + 1(i = j)]$
CS	Compound symmetry	2	$\sigma_1 + \sigma^2 1(i = j)$
CSH	Heterogeneous CS	$t + 1$	$\sigma_i \sigma_j [\rho 1(i \neq j) + 1(i = j)]$
FA(<i>q</i>)	Factor analytic	$\frac{q}{2}(2t - q + 1) + t$	$\sum_{k=1}^{\min(i,j,q)} \lambda_{ik} \lambda_{jk} + \sigma_i^2 1(i = j)$
FA0(<i>q</i>)	No diagonal FA	$\frac{q}{2}(2t - q + 1)$	$\sum_{k=1}^{\min(i,j,q)} \lambda_{ik} \lambda_{jk}$
FA1(<i>q</i>)	Equal diagonal FA	$\frac{q}{2}(2t - q + 1) + 1$	$\sum_{k=1}^{\min(i,j,q)} \lambda_{ik} \lambda_{jk} + \sigma^2 1(i = j)$
HF	Huynh-Feldt	$t + 1$	$(\sigma_i^2 + \sigma_j^2)/2 + \lambda 1(i \neq j)$
LIN(<i>q</i>)	General linear	<i>q</i>	$\sum_{k=1}^q \theta_k \mathbf{A}_{ij}$
TOEP	Toeplitz	<i>t</i>	$\sigma_{ i-j +1}$
TOEP(<i>q</i>)	Banded Toeplitz	<i>q</i>	$\sigma_{ i-j +1} 1(i - j < q)$
TOEPH	Heterogeneous TOEP	$2t - 1$	$\sigma_i \sigma_j \rho_{ i-j }$
TOEPH(<i>q</i>)	Banded hetero TOEP	$t + q - 1$	$\sigma_i \sigma_j \rho_{ i-j } 1(i - j < q)$
UN	Unstructured	$t(t + 1)/2$	σ_{ij}
UN(<i>q</i>)	Banded	$\frac{q}{2}(2t - q + 1)$	$\sigma_{ij} 1(i - j < q)$
UNR	Unstructured corrs	$t(t + 1)/2$	$\sigma_i \sigma_j \rho_{\max(i,j) \min(i,j)}$
UNR(<i>q</i>)	Banded correlations	$\frac{q}{2}(2t - q + 1)$	$\sigma_i \sigma_j \rho_{\max(i,j) \min(i,j)}$
UN@AR(1)	Direct product AR(1)	$t_1(t_1 + 1)/2 + 1$	$\sigma_{i_1 j_1} \rho^{ i_2 - j_2 }$

Table 59.17 continued

Structure	Description	Parms	(i, j) element
UN@CS	Direct product CS	$t_1(t_1 + 1)/2 + 1$	$\begin{cases} \sigma_{i_1 j_1} & i_2 = j_2 \\ \sigma^2 \sigma_{i_1 j_1} & i_2 \neq j_2 \\ 0 \leq \sigma^2 \leq 1 \end{cases}$
UN@UN	Direct product UN	$t_1(t_1 + 1)/2 + t_2(t_2 + 1)/2 - 1$	$\sigma_{1,i_1 j_1} \sigma_{2,i_2 j_2}$
VC	Variance components	q	$\sigma_k^2 1(i = j)$ and i corresponds to k th effect

In Table 59.17, “Parms” is the number of covariance parameters in the structure, t is the overall dimension of the covariance matrix, and $1(A)$ equals 1 when A is true and 0 otherwise. For example, $1(i = j)$ equals 1 when $i = j$ and 0 otherwise, and $1(|i - j| < q)$ equals 1 when $|i - j| < q$ and 0 otherwise. For the **TYPE=TOEPH** structures, $\rho_0 = 1$, and for the **TYPE=UNR** structures, $\rho_{ii} = 1$ for all i . For the direct product structures, the subscripts “1” and “2” see the first and second structure in the direct product, respectively, and $i_1 = \text{int}((i + t_2 - 1)/t_2)$, $j_1 = \text{int}((j + t_2 - 1)/t_2)$, $i_2 = \text{mod}(i - 1, t_2) + 1$, and $j_2 = \text{mod}(j - 1, t_2) + 1$.

Table 59.18 Spatial Covariance Structures

Structure	Description	Parms	(i, j) element
SP(EXP)(c-list)	Exponential	2	$\sigma^2 \exp\{-d_{ij}/\theta\}$
SP(EXPA)(c-list)	Anisotropic exponential	$2c + 1$	$\sigma^2 \prod_{k=1}^c \exp\{-\theta_k d(i, j, k)^{p_k}\}$
SP(EXPGA)(c ₁ c ₂)	2D exponential, geometrically anisotropic	4	$\sigma^2 \exp\{-d_{ij}(\theta, \lambda)/\rho\}$
SP(GAU)(c-list)	Gaussian	2	$\sigma^2 \exp\{-d_{ij}^2/\rho^2\}$
SP(GAUGA)(c ₁ c ₂)	2D Gaussian, geometrically anisotropic	4	$\sigma^2 \exp\{-d_{ij}(\theta, \lambda)^2/\rho^2\}$
SP(LIN)(c-list)	Linear	2	$\sigma^2(1 - \rho d_{ij}) 1(\rho d_{ij} \leq 1)$
SP(LINL)(c-list)	Linear log	2	$\sigma^2(1 - \rho \log(d_{ij}))$ $\times 1(\rho \log(d_{ij}) \leq 1, d_{ij} > 0)$
SP(MATERN)(c-list)	Matérn	3	$\sigma^2 \frac{1}{\Gamma(v)} \left(\frac{d_{ij}}{2\rho}\right)^v 2K_v(d_{ij}/\rho)$
SP(MATHSW)(c-list)	Matérn (Handcock-Stein-Wallis)	3	$\sigma^2 \frac{1}{\Gamma(v)} \left(\frac{d_{ij}\sqrt{v}}{\rho}\right)^v 2K_v\left(\frac{2d_{ij}\sqrt{v}}{\rho}\right)$
SP(POW)(c-list)	Power	2	$\sigma^2 \rho^{d_{ij}}$
SP(POWA)(c-list)	Anisotropic power	$c + 1$	$\sigma^2 \rho_1^{d(i,j,1)} \rho_2^{d(i,j,2)} \dots \rho_c^{d(i,j,c)}$
SP(SPH)(c-list)	Spherical	2	$\sigma^2 [1 - (\frac{3d_{ij}}{2\rho}) + (\frac{d_{ij}^3}{2\rho^3})] 1(d_{ij} \leq \rho)$
SP(SPHGA)(c ₁ c ₂)	2D Spherical, geometrically anisotropic	4	$\sigma^2 [1 - (\frac{3d_{ij}(\theta, \lambda)}{2\rho}) + (\frac{d_{ij}(\theta, \lambda)^3}{2\rho^3})]$ $\times 1(d_{ij}(\theta, \lambda) \leq \rho)$

In Table 59.18, c -list contains the names of the numeric variables used as coordinates of the location of the observation in space, and d_{ij} is the Euclidean distance between the i th and j th vectors of these coordinates, which correspond to the i th and j th observations in the input data set. For SP(POWA) and SP(EXPA), c is the number of coordinates, and $d(i, j, k)$ is the absolute distance between the k th coordinate, $k = 1, \dots, c$, of the i th and j th observations in the input data set. For the geometrically anisotropic structures SP(EXPGA), SP(GAUGA), and SP(SPHGA), exactly two spatial coordinate variables must be specified as c_1 and c_2 . Geometric anisotropy is corrected by applying a rotation θ and scaling λ to the coordinate system, and $d_{ij}(\theta, \lambda)$ represents the Euclidean distance between two points in the transformed space. SP(MATERN) and SP(MATHSW) represent covariance structures in a class defined by Matérn (see Matérn 1986; Handcock and Stein 1993; Handcock and Wallis 1994). The function K_ν is the modified Bessel function of the second kind of (real) order $\nu > 0$; the parameter ν governs the smoothness of the process (see below for more details).

Table 59.19 lists some examples of the structures in Table 59.17 and Table 59.18.

Table 59.19 Covariance Structure Examples

Description	Structure	Example
Variance components	VC (default)	$\begin{bmatrix} \sigma_B^2 & 0 & 0 & 0 \\ 0 & \sigma_B^2 & 0 & 0 \\ 0 & 0 & \sigma_{AB}^2 & 0 \\ 0 & 0 & 0 & \sigma_{AB}^2 \end{bmatrix}$
Compound symmetry	CS	$\begin{bmatrix} \sigma^2 + \sigma_1 & \sigma_1 & \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma^2 + \sigma_1 & \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma_1 & \sigma^2 + \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma_1 & \sigma_1 & \sigma^2 + \sigma_1 \end{bmatrix}$
Unstructured	UN	$\begin{bmatrix} \sigma_1^2 & \sigma_{21} & \sigma_{31} & \sigma_{41} \\ \sigma_{21} & \sigma_2^2 & \sigma_{32} & \sigma_{42} \\ \sigma_{31} & \sigma_{32} & \sigma_3^2 & \sigma_{43} \\ \sigma_{41} & \sigma_{42} & \sigma_{43} & \sigma_4^2 \end{bmatrix}$
Banded main diagonal	UN(1)	$\begin{bmatrix} \sigma_1^2 & 0 & 0 & 0 \\ 0 & \sigma_2^2 & 0 & 0 \\ 0 & 0 & \sigma_3^2 & 0 \\ 0 & 0 & 0 & \sigma_4^2 \end{bmatrix}$
First-order autoregressive	AR(1)	$\sigma^2 \begin{bmatrix} 1 & \rho & \rho^2 & \rho^3 \\ \rho & 1 & \rho & \rho^2 \\ \rho^2 & \rho & 1 & \rho \\ \rho^3 & \rho^2 & \rho & 1 \end{bmatrix}$
Toeplitz	TOEP	$\begin{bmatrix} \sigma^2 & \sigma_1 & \sigma_2 & \sigma_3 \\ \sigma_1 & \sigma^2 & \sigma_1 & \sigma_2 \\ \sigma_2 & \sigma_1 & \sigma^2 & \sigma_1 \\ \sigma_3 & \sigma_2 & \sigma_1 & \sigma^2 \end{bmatrix}$
Toeplitz with two bands	TOEP(2)	$\begin{bmatrix} \sigma^2 & \sigma_1 & 0 & 0 \\ \sigma_1 & \sigma^2 & \sigma_1 & 0 \\ 0 & \sigma_1 & \sigma^2 & \sigma_1 \\ 0 & 0 & \sigma_1 & \sigma^2 \end{bmatrix}$

Table 59.19 continued

Description	Structure	Example
Spatial power	SP(POW)(c)	$\sigma^2 \begin{bmatrix} 1 & \rho^{d_{12}} & \rho^{d_{13}} & \rho^{d_{14}} \\ \rho^{d_{21}} & 1 & \rho^{d_{23}} & \rho^{d_{24}} \\ \rho^{d_{31}} & \rho^{d_{32}} & 1 & \rho^{d_{34}} \\ \rho^{d_{41}} & \rho^{d_{42}} & \rho^{d_{43}} & 1 \end{bmatrix}$

First-order antedependence	ANTE(1)	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho_1 & \sigma_1\sigma_3\rho_1\rho_2 \\ \sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_2\sigma_3\rho_2 \\ \sigma_3\sigma_1\rho_2\rho_1 & \sigma_3\sigma_2\rho_2 & \sigma_3^2 \end{bmatrix}$
Heterogeneous Toeplitz	TOEPH	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho_1 & \sigma_1\sigma_3\rho_2 & \sigma_1\sigma_4\rho_3 \\ \sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_2\sigma_3\rho_1 & \sigma_2\sigma_4\rho_2 \\ \sigma_3\sigma_1\rho_2 & \sigma_3\sigma_2\rho_1 & \sigma_3^2 & \sigma_3\sigma_4\rho_1 \\ \sigma_4\sigma_1\rho_3 & \sigma_4\sigma_2\rho_2 & \sigma_4\sigma_3\rho_1 & \sigma_4^2 \end{bmatrix}$
Unstructured correlations	UNR	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho_{21} & \sigma_1\sigma_3\rho_{31} & \sigma_1\sigma_4\rho_{41} \\ \sigma_2\sigma_1\rho_{21} & \sigma_2^2 & \sigma_2\sigma_3\rho_{32} & \sigma_2\sigma_4\rho_{42} \\ \sigma_3\sigma_1\rho_{31} & \sigma_3\sigma_2\rho_{32} & \sigma_3^2 & \sigma_3\sigma_4\rho_{43} \\ \sigma_4\sigma_1\rho_{41} & \sigma_4\sigma_2\rho_{42} & \sigma_4\sigma_3\rho_{43} & \sigma_4^2 \end{bmatrix}$
Direct product AR(1)	UN@AR(1)	$\begin{bmatrix} \sigma_1^2 & \sigma_{21} \\ \sigma_{21} & \sigma_2^2 \end{bmatrix} \otimes \begin{bmatrix} 1 & \rho & \rho^2 \\ \rho & 1 & \rho \\ \rho^2 & \rho & 1 \end{bmatrix} =$

Table 59.19 continued

Description	Structure	Example
		$\begin{bmatrix} \sigma_1^2 & \sigma_1^2\rho & \sigma_1^2\rho^2 & \sigma_{21} & \sigma_{21}\rho & \sigma_{21}\rho^2 \\ \sigma_1^2\rho & \sigma_1^2 & \sigma_1^2\rho & \sigma_{21}\rho & \sigma_{21} & \sigma_{21}\rho \\ \sigma_1^2\rho^2 & \sigma_1^2\rho & \sigma_1^2 & \sigma_{21}\rho^2 & \sigma_{21}\rho & \sigma_{21} \\ \sigma_{21} & \sigma_{21}\rho & \sigma_{21}\rho^2 & \sigma_2^2 & \sigma_2^2\rho & \sigma_2^2\rho^2 \\ \sigma_{21}\rho & \sigma_{21} & \sigma_{21}\rho & \sigma_2^2\rho & \sigma_2^2 & \sigma_2^2\rho \\ \sigma_{21}\rho^2 & \sigma_{21}\rho & \sigma_{21} & \sigma_2^2\rho^2 & \sigma_2^2\rho & \sigma_2^2 \end{bmatrix}$

The following provides some further information about these covariance structures:

TYPE=ANTE(1) specifies the first-order antedependence structure (see Kenward 1987; Patel 1991; Macchiavelli and Arnold 1994). In Table 59.17, σ_i^2 is the i th variance parameter, and ρ_k is the k th autocorrelation parameter satisfying $|\rho_k| < 1$.

TYPE=AR(1) specifies a first-order autoregressive structure. PROC MIXED imposes the constraint $|\rho| < 1$ for stationarity.

TYPE=ARH(1) specifies a heterogeneous first-order autoregressive structure. As with TYPE=AR(1), PROC MIXED imposes the constraint $|\rho| < 1$ for stationarity.

TYPE=ARMA(1,1) specifies the first-order autoregressive moving-average structure. In Table 59.17, ρ is the autoregressive parameter, γ models a moving-average component, and σ^2 is the residual variance. In the notation of Fuller (1976, p. 68), $\rho = \theta_1$ and

$$\gamma = \frac{(1 + b_1\theta_1)(\theta_1 + b_1)}{1 + b_1^2 + 2b_1\theta_1}$$

The example in Table 59.19 and $|b_1| < 1$ imply that

$$b_1 = \frac{\beta - \sqrt{\beta^2 - 4\alpha^2}}{2\alpha}$$

where $\alpha = \gamma - \rho$ and $\beta = 1 + \rho^2 - 2\gamma\rho$. PROC MIXED imposes the constraints $|\rho| < 1$ and $|\gamma| < 1$ for stationarity, although for some values of ρ and γ in this region the resulting covariance matrix is not positive definite. When the estimated value of ρ becomes negative, the computed covariance is multiplied by $\cos(\pi d_{ij})$ to account for the negativity.

TYPE=CS specifies the compound-symmetry structure, which has constant variance and constant covariance.

TYPE=CSH specifies the heterogeneous compound-symmetry structure. This structure has a different variance parameter for each diagonal element, and it uses the square roots of these parameters in the off-diagonal entries. In Table 59.17, σ_i^2 is the i th variance parameter, and ρ is the correlation parameter satisfying $|\rho| < 1$.

TYPE=FA(q) specifies the factor-analytic structure with q factors (Jennrich and Schluchter 1986). This structure is of the form $\mathbf{\Lambda}\mathbf{\Lambda}' + \mathbf{D}$, where $\mathbf{\Lambda}$ is a $t \times q$ rectangular matrix and \mathbf{D} is a $t \times t$ diagonal matrix with t different parameters. When $q > 1$, the elements of $\mathbf{\Lambda}$ in its upper-right corner (that is, the elements in the i th row and j th column for $j > i$) are set to zero to fix the rotation of the structure.

- TYPE=FA0(*q*)** is similar to the **FA(*q*)** structure except that no diagonal matrix **D** is included. When $q < t$ —that is, when the number of factors is less than the dimension of the matrix—this structure is nonnegative definite but not of full rank. In this situation, you can use it for approximating an unstructured **G** matrix in the **RANDOM** statement or for combining with the **LOCAL** option in the **REPEATED** statement. When $q = t$, you can use this structure to constrain **G** to be nonnegative definite in the **RANDOM** statement.
- TYPE=FA1(*q*)** is similar to the **TYPE=FA(*q*)** structure except that all of the elements in **D** are constrained to be equal. This offers a useful and more parsimonious alternative to the full factor-analytic structure.
- TYPE=HF** specifies the Huynh-Feldt covariance structure (Huynh and Feldt 1970). This structure is similar to the **TYPE=CSH** structure in that it has the same number of parameters and heterogeneity along the main diagonal. However, it constructs the off-diagonal elements by taking arithmetic rather than geometric means.
- You can perform a likelihood ratio test of the Huynh-Feldt conditions by running PROC MIXED twice, once with **TYPE=HF** and once with **TYPE=UN**, and then subtracting their respective values of -2 times the maximized likelihood.
- If PROC MIXED does not converge under your Huynh-Feldt model, you can specify your own starting values with the **PARMS** statement. The default MIVQUE(0) starting values can sometimes be poor for this structure. A good choice for starting values is often the parameter estimates corresponding to an initial fit that uses **TYPE=CS**.
- TYPE=LIN(*q*)** specifies the general linear covariance structure with q parameters. This structure consists of a linear combination of known matrices that are input with the **LDATA=** option. This structure is very general, and you need to make sure that the variance matrix is positive definite. By default, PROC MIXED sets the initial values of the parameters to 1. You can use the **PARMS** statement to specify other initial values.
- TYPE=LINEAR(*q*)** is an alias for **TYPE=LIN(*q*)**.
- TYPE=SIMPLE** is an alias for **TYPE=VC**.
- TYPE=SP(EXPA)(*c-list*)** specifies the spatial anisotropic exponential structure, where *c-list* is a list of variables indicating the coordinates. This structure has (i, j) element equal to

$$\sigma^2 \prod_{k=1}^c \exp\{-\theta_k d(i, j, k)^{p_k}\}$$

where c is the number of coordinates and $d(i, j, k)$ is the absolute distance between the k th coordinate ($k = 1, \dots, c$) of the i th and j th observations in the input data set. There are $2c + 1$ parameters to be estimated: θ_k , p_k ($k = 1, \dots, c$), and σ^2 .

You might want to constrain some of the EXPA parameters to known values. For example, suppose you have three coordinate variables C1, C2, and C3 and you want to constrain the powers p_k to equal 2, as in Sacks et al. (1989). Suppose further that you want to model covariance across the entire input data set and you suspect the θ_k and σ^2 estimates are close to 3, 4, 5, and 1, respectively. Then specify the following statements:

```

repeated / type=sp(expa) (c1 c2 c3)
      subject=intercept;
parms (3) (4) (5) (2) (2) (2) (1) /
      hold=4,5,6;

```

TYPE=SP(EXPGA)(c1 c2) specify modification of the isotropic SP(EXP) covariance structure.

TYPE=SP(GAUGA)(c1 c2) specify modification of the isotropic SP(GAU) covariance structure.

TYPE=SP(SPHGA)(c1 c2) specify modification of the isotropic SP(SPH) covariance structure.

These are structures that allow for geometric anisotropy in two dimensions. The coordinates are specified by the variables c1 and c2.

If the spatial process is geometrically anisotropic in $\mathbf{c} = [c_{i1}, c_{i2}]$, then it is isotropic in the coordinate system

$$\mathbf{Ac} = \begin{bmatrix} 1 & 0 \\ 0 & \lambda \end{bmatrix} \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \mathbf{c} = \mathbf{c}^*$$

for a properly chosen angle θ and scaling factor λ . Elliptical isocorrelation contours are thereby transformed to spherical contours, adding two parameters to the respective isotropic covariance structures. Euclidean distances (see Table 59.18) are expressed in terms of \mathbf{c}^* .

The angle θ of the clockwise rotation is reported in radians, $0 \leq \theta \leq 2\pi$. The scaling parameter λ represents the ratio of the range parameters in the direction of the major and minor axis of the correlation contours. In other words, following a rotation of the coordinate system by angle θ , isotropy is achieved by compressing or magnifying distances in one coordinate by the factor λ .

Fixing $\lambda = 1.0$ reduces the models to isotropic ones for any angle of rotation. If the scaling parameter is held constant at 1.0, you should also hold constant the angle of rotation, as in the following statements:

```

repeated / type=sp(expga) (gxc gyc)
      subject=intercept;
parms (6) (1.0) (0.0) (1) / hold=2,3;

```

If λ is fixed at any other value than 1.0, the angle of rotation can be estimated. Specifying a starting grid of angles and scaling factors can considerably improve the convergence properties of the optimization algorithm for these models. Only a single random effect with geometrically anisotropic structure is permitted.

TYPE=SP(MATERN)(c-list) | TYPE=SP(MATHSW)(c-list) specifies covariance structures in the Matérn class of covariance functions (Matérn 1986). Two observations for the same subject (block of \mathbf{R}) that are Euclidean distance d_{ij} apart have covariance

$$\sigma^2 \frac{1}{\Gamma(\nu)} \left(\frac{d_{ij}}{2\rho} \right)^\nu 2K_\nu(d_{ij}/\rho) \quad \nu > 0, \rho > 0$$

where K_ν is the modified Bessel function of the second kind of (real) order $\nu > 0$. The smoothness (continuity) of a stochastic process with covariance function in this class increases with ν . The Matérn class thus enables data-driven estimation

of the smoothness properties. The covariance is identical to the exponential model for $\nu = 0.5$ (TYPE=SP(EXP)(*c-list*)), while for $\nu = 1$ the model advocated by Whittle (1954) results. As $\nu \rightarrow \infty$ the model approaches the gaussian covariance structure (TYPE=SP(GAU)(*c-list*)).

The MATHSW structure represents the Matérn class in the parameterization of Handcock and Stein (1993) and Handcock and Wallis (1994),

$$\sigma^2 \frac{1}{\Gamma(\nu)} \left(\frac{d_{ij} \sqrt{\nu}}{\rho} \right)^\nu 2K_\nu \left(\frac{2d_{ij} \sqrt{\nu}}{\rho} \right)$$

Since computation of the function K_ν and its derivatives is numerically very intensive, fitting models with Matérn covariance structures can be more time-consuming than with other spatial covariance structures. Good starting values are essential.

TYPE=SP(POW)(*c-list*) | TYPE=SP(POWA)(*c-list*) specifies the spatial power structures. When the estimated value of ρ becomes negative, the computed covariance is multiplied by $\cos(\pi d_{ij})$ to account for the negativity.

TYPE=TOEP(<*q*>) specifies a banded Toeplitz structure. This can be viewed as a moving-average structure with order equal to $q - 1$. The TYPE=TOEP option is a full Toeplitz matrix, which can be viewed as an autoregressive structure with order equal to the dimension of the matrix. The specification TYPE=TOEP(1) is the same as $\sigma^2 I$, where I is an identity matrix, and it can be useful for specifying the same variance component for several effects.

TYPE=TOEPH(<*q*>) specifies a heterogeneous banded Toeplitz structure. In Table 59.17, σ_i^2 is the i th variance parameter and ρ_j is the j th correlation parameter satisfying $|\rho_j| < 1$. If you specify the order parameter q , then PROC MIXED estimates only the first q bands of the matrix, setting all higher bands equal to 0. The option TOEPH(1) is equivalent to both the TYPE=UN(1) and TYPE=UNR(1) options.

TYPE=UN(<*q*>) specifies a completely general (unstructured) covariance matrix parameterized directly in terms of variances and covariances. The variances are constrained to be nonnegative, and the covariances are unconstrained. This structure is not constrained to be nonnegative definite in order to avoid nonlinear constraints; however, you can use the TYPE=FA0 structure if you want this constraint to be imposed by a Cholesky factorization. If you specify the order parameter q , then PROC MIXED estimates only the first q bands of the matrix, setting all higher bands equal to 0.

TYPE=UNR(<*q*>) specifies a completely general (unstructured) covariance matrix parameterized in terms of variances and correlations. This structure fits the same model as the TYPE=UN(*q*) option but with a different parameterization. The i th variance parameter is σ_i^2 . The parameter ρ_{jk} is the correlation between the j th and k th measurements; it satisfies $|\rho_{jk}| < 1$. If you specify the order parameter r , then PROC MIXED estimates only the first q bands of the matrix, setting all higher bands equal to zero.

TYPE=UN@AR(1) | TYPE=UN@CS | TYPE=UN@UN specify direct (Kronecker) product structures designed for multivariate repeated measures (see Galecki 1994). These structures are constructed by taking the Kronecker product of an unstructured matrix

(modeling covariance across the multivariate observations) with an additional covariance matrix (modeling covariance across time or another factor). The upper-left value in the second matrix is constrained to equal 1 to identify the model. See the *SAS/IML User's Guide* for more details about direct products.

To use these structures in the REPEATED statement, you must specify two distinct REPEATED effects, both of which must be included in the CLASS statement. The first effect indicates the multivariate observations, and the second identifies the levels of time or some additional factor. Note that the input data set must still be constructed in “univariate” format; that is, all dependent observations are still listed observation-wise in one single variable. Although this construction provides for general modeling possibilities, it forces you to construct variables indicating both dimensions of the Kronecker product.

For example, suppose your observed data consist of heights and weights of several children measured over several successive years. Your input data set should then contain variables similar to the following:

- Y, all of the heights and weights, with a separate observation for each
- Var, indicating whether the measurement is a height or a weight
- Year, indicating the year of measurement
- Child, indicating the child on which the measurement was taken

Your PROC MIXED statements for a Kronecker AR(1) structure across years would then be as follows:

```
proc mixed;
  class Var Year Child;
  model Y = Var Year Var*Year;
  repeated Var Year / type=un@ar(1)
                    subject=Child;
run;
```

You should nearly always want to model different means for the multivariate observations; hence the inclusion of Var in the MODEL statement. The preceding mean model consists of cell means for all combinations of VAR and YEAR.

TYPE=VC

specifies standard variance components and is the default structure for both the RANDOM and REPEATED statements. In the RANDOM statement, a distinct variance component is assigned to each effect. In the REPEATED statement, this structure is usually used only with the GROUP= option to specify a heterogeneous variance model.

Jennrich and Schluchter (1986) provide general information about the use of covariance structures, and Wolfinger (1996) presents details about many of the heterogeneous structures. Modeling with spatial covariance structures is discussed in many sources (Marx and Thompson 1987; Zimmerman and Harville 1991; Cressie 1993; Brownie, Bowman, and Burton 1993; Stroup, Baenziger, and Mulitze 1994; Brownie and Gumpertz 1997; Gotway and Stroup 1997; Chilès and Delfiner 1999; Schabenberger and Gotway 2005; Littell et al. 2006).

SLICE Statement

SLICE *model-effect* < / options > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in Table 19.21. For details about the syntax of the SLICE statement, see the section “SLICE Statement” on page 498 in Chapter 19, “Shared Concepts and Topics.”

NOTE: Use the section “LSMEANS Statement” on page 453 of Chapter 19, “Shared Concepts and Topics.” only for definitions of the options that you can use with the SLICE statement. PROC MIXED uses a slightly different syntax for the LSMEANS, which is described in the section “LSMEANS Statement” on page 491.

STORE Statement

STORE < OUT= > *item-store-name* < / LABEL= 'label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

WEIGHT Statement

WEIGHT *variable* ;

If you do not specify a REPEATED statement, the WEIGHT statement operates exactly like the one in PROC GLM. In this case PROC MIXED replaces $X'X$ and $Z'Z$ with $X'WX$ and $Z'WZ$, where W is the diagonal weight matrix. If you specify a REPEATED statement, then the WEIGHT statement replaces R with LRL , where L is a diagonal matrix with elements $W^{-1/2}$. Observations with nonpositive or missing weights are not included in the PROC MIXED analysis.

If a computation in PROC MIXED involves R , then the WEIGHT statement replaces R with $W^{-1/2}RW^{-1/2}$. For example, the covariance matrix V for the observations usually have the form $V = ZGZ' + R$, which with the WEIGHT statement becomes $V = ZGZ' + W^{-1/2}RW^{-1/2}$.

Details: MIXED Procedure

Mixed Models Theory

This section provides an overview of a likelihood-based approach to general linear mixed models. This approach simplifies and unifies many common statistical analyses, including those involving repeated mea-

tures, random effects, and random coefficients. The basic assumption is that the data are linearly related to unobserved multivariate normal random variables. For extensions to nonlinear and nonnormal situations see the documentation of the GLIMMIX and NLMIXED procedures. Additional theory and examples are provided in Littell et al. (2006); Verbeke and Molenberghs (1997, 2000); Brown and Prescott (1999).

Matrix Notation

Suppose that you observe n data points y_1, \dots, y_n and that you want to explain them by using n values for each of p explanatory variables $x_{11}, \dots, x_{1p}, x_{21}, \dots, x_{2p}, \dots, x_{n1}, \dots, x_{np}$. The x_{ij} values can be either regression-type continuous variables or dummy variables indicating class membership. The standard linear model for this setup is

$$y_i = \sum_{j=1}^p x_{ij} \beta_j + \epsilon_i \quad i = 1, \dots, n$$

where β_1, \dots, β_p are unknown *fixed-effects* parameters to be estimated and $\epsilon_1, \dots, \epsilon_n$ are unknown independent and identically distributed normal (Gaussian) random variables with mean 0 and variance σ^2 .

The preceding equations can be written simultaneously by using vectors and a matrix, as follows:

$$\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1p} \\ x_{21} & x_{22} & \dots & x_{2p} \\ \vdots & \vdots & & \vdots \\ x_{n1} & x_{n2} & \dots & x_{np} \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_p \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_n \end{bmatrix}$$

For convenience, simplicity, and extendability, this entire system is written as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where \mathbf{y} denotes the vector of observed y_i 's, \mathbf{X} is the known matrix of x_{ij} 's, $\boldsymbol{\beta}$ is the unknown fixed-effects parameter vector, and $\boldsymbol{\epsilon}$ is the unobserved vector of independent and identically distributed Gaussian random errors.

In addition to denoting data, random variables, and explanatory variables in the preceding fashion, the subsequent development makes use of basic matrix operators such as transpose ($'$), inverse ($^{-1}$), generalized inverse ($^{-}$), determinant ($|\cdot|$), and matrix multiplication. See Searle (1982) for details about these and other matrix techniques.

Formulation of the Mixed Model

The previous general linear model is certainly a useful one (Searle 1971), and it is the one fitted by the GLM procedure. However, many times the distributional assumption about $\boldsymbol{\epsilon}$ is too restrictive. The mixed model extends the general linear model by allowing a more flexible specification of the covariance matrix of $\boldsymbol{\epsilon}$. In other words, it allows for both correlation and heterogeneous variances, although you still assume normality.

The mixed model is written as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

where everything is the same as in the general linear model except for the addition of the known design matrix, \mathbf{Z} , and the vector of unknown *random-effects parameters*, $\boldsymbol{\gamma}$. The matrix \mathbf{Z} can contain either continuous or dummy variables, just like \mathbf{X} . The name *mixed model* comes from the fact that the model contains both fixed-effects parameters, $\boldsymbol{\beta}$, and random-effects parameters, $\boldsymbol{\gamma}$. See Henderson (1990) and Searle, Casella, and McCulloch (1992) for historical developments of the mixed model.

A key assumption in the foregoing analysis is that $\boldsymbol{\gamma}$ and $\boldsymbol{\epsilon}$ are normally distributed with

$$\begin{aligned} E \begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\epsilon} \end{bmatrix} &= \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix} \\ \text{Var} \begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\epsilon} \end{bmatrix} &= \begin{bmatrix} \mathbf{G} & \mathbf{0} \\ \mathbf{0} & \mathbf{R} \end{bmatrix} \end{aligned}$$

The variance of \mathbf{y} is, therefore, $\mathbf{V} = \mathbf{ZGZ}' + \mathbf{R}$. You can model \mathbf{V} by setting up the random-effects design matrix \mathbf{Z} and by specifying covariance structures for \mathbf{G} and \mathbf{R} .

Note that this is a general specification of the mixed model, in contrast to many texts and articles that discuss only simple random effects. Simple random effects are a special case of the general specification with \mathbf{Z} containing dummy variables, \mathbf{G} containing variance components in a diagonal structure, and $\mathbf{R} = \sigma^2 \mathbf{I}_n$, where \mathbf{I}_n denotes the $n \times n$ identity matrix. The general linear model is a further special case with $\mathbf{Z} = \mathbf{0}$ and $\mathbf{R} = \sigma^2 \mathbf{I}_n$.

The following two examples illustrate the most common formulations of the general linear mixed model.

Example: Growth Curve with Compound Symmetry

Suppose that you have three growth curve measurements for s individuals and that you want to fit an overall linear trend in time. Your \mathbf{X} matrix is as follows:

$$\mathbf{X} = \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ 1 & 3 \\ \vdots & \vdots \\ 1 & 1 \\ 1 & 2 \\ 1 & 3 \end{bmatrix}$$

The first column (coded entirely with 1s) fits an intercept, and the second column (coded with times of 1, 2, 3) fits a slope. Here, $n = 3s$ and $p = 2$.

Suppose further that you want to introduce a common correlation among the observations from a single individual, with correlation being the same for all individuals. One way of setting this up in the general mixed model is to eliminate the \mathbf{Z} and \mathbf{G} matrices and let the \mathbf{R} matrix be block diagonal with blocks corresponding to the individuals and with each block having the *compound-symmetry* structure. This structure has two unknown parameters, one modeling a common covariance and the other modeling a residual variance. The

form for \mathbf{R} would then be as follows:

$$\mathbf{R} = \begin{bmatrix} \sigma_1^2 + \sigma^2 & \sigma_1^2 & \sigma_1^2 & & & \\ \sigma_1^2 & \sigma_1^2 + \sigma^2 & \sigma_1^2 & & & \\ \sigma_1^2 & \sigma_1^2 & \sigma_1^2 + \sigma^2 & & & \\ & & & \ddots & & \\ & & & & \sigma_1^2 + \sigma^2 & \sigma_1^2 & \sigma_1^2 \\ & & & & \sigma_1^2 & \sigma_1^2 + \sigma^2 & \sigma_1^2 \\ & & & & \sigma_1^2 & \sigma_1^2 & \sigma_1^2 + \sigma^2 \end{bmatrix}$$

where blanks denote zeros. There are $3s$ rows and columns altogether, and the common correlation is $\sigma_1^2/(\sigma_1^2 + \sigma^2)$.

The PROC MIXED statements to fit this model are as follows:

```
proc mixed;
  class indiv;
  model y = time;
  repeated / type=cs subject=indiv;
run;
```

Here, *indiv* is a classification variable indexing individuals. The **MODEL** statement fits a straight line for time; the intercept is fit by default just as in PROC GLM. The **REPEATED** statement models the \mathbf{R} matrix: **TYPE=CS** specifies the compound symmetry structure, and **SUBJECT=INDIV** specifies the blocks of \mathbf{R} .

An alternative way of specifying the common intra-individual correlation is to let

$$\mathbf{Z} = \begin{bmatrix} 1 & & & & & \\ 1 & & & & & \\ 1 & & & & & \\ & 1 & & & & \\ & 1 & & & & \\ & 1 & & & & \\ & & \ddots & & & \\ & & & 1 & & \\ & & & 1 & & \\ & & & 1 & & \end{bmatrix}$$

$$\mathbf{G} = \begin{bmatrix} \sigma_1^2 & & & & \\ & \sigma_1^2 & & & \\ & & \ddots & & \\ & & & \sigma_1^2 & \end{bmatrix}$$

and $\mathbf{R} = \sigma^2 \mathbf{I}_n$. The \mathbf{Z} matrix has $3s$ rows and s columns, and \mathbf{G} is $s \times s$.

You can set up this model in PROC MIXED in two different but equivalent ways:

```
proc mixed;
  class indiv;
  model y = time;
  random indiv;
run;
```

```
proc mixed;
  class indiv;
  model y = time;
  random intercept / subject=indiv;
run;
```

Both of these specifications fit the same model as the previous one that used the **REPEATED** statement; however, the **RANDOM** specifications constrain the correlation to be positive, whereas the **REPEATED** specification leaves the correlation unconstrained.

Example: Split-Plot Design

The split-plot design involves two experimental treatment factors, A and B, and two different sizes of experimental units to which they are applied (see Winer 1971; Snedecor and Cochran 1980; Milliken and Johnson 1992; Steel, Torrie, and Dickey 1997). The levels of A are randomly assigned to the larger-sized experimental unit, called *whole plots*, whereas the levels of B are assigned to the smaller-sized experimental unit, the *subplots*. The subplots are assumed to be nested within the whole plots, so that a whole plot consists of a cluster of subplots and a level of A is applied to the entire cluster.

Such an arrangement is often necessary by nature of the experiment, the classical example being the application of fertilizer to large plots of land and different crop varieties planted in subdivisions of the large plots. For this example, fertilizer is the whole-plot factor A and variety is the subplot factor B.

The first example is a split-plot design for which the whole plots are arranged in a randomized block design. The appropriate PROC MIXED statements are as follows:

```
proc mixed;
  class a b block;
  model y = a|b;
  random block a*block;
run;
```

Here

$$\mathbf{R} = \sigma^2 \mathbf{I}_{24}$$

and **X**, **Z**, and **G** have the following form:

$$\mathbf{X} = \begin{bmatrix} 1 & 1 & & 1 & 1 & & & \\ 1 & 1 & & & 1 & 1 & & \\ 1 & & 1 & 1 & & & 1 & \\ 1 & & 1 & & 1 & & & 1 \\ 1 & & & 1 & 1 & & & 1 \\ 1 & & & 1 & 1 & & & \\ \vdots & \vdots & \vdots & & & \vdots & & \\ 1 & 1 & & 1 & 1 & & & \\ 1 & 1 & & & 1 & 1 & & \\ 1 & & 1 & 1 & & & 1 & \\ 1 & & 1 & & 1 & & & 1 \\ 1 & & & 1 & 1 & & & 1 \\ 1 & & & 1 & 1 & & & 1 \end{bmatrix}$$

$$\mathbf{Z} =$$

$$\mathbf{G} =$$

where σ_B^2 is the variance component for Block and σ_{AB}^2 is the variance component for A*Block. Changing the **RANDOM** statement as follows fits the same model, but with **Z** and **G** sorted differently:

```
random int a / subject=block;
```

In many situations, the best approach is to use *likelihood-based* methods, exploiting the assumption that \boldsymbol{y} and $\boldsymbol{\epsilon}$ are normally distributed (Hartley and Rao 1967; Patterson and Thompson 1971; Harville 1977; Laird and Ware 1982; Jennrich and Schluchter 1986). PROC MIXED implements two likelihood-based methods: *maximum likelihood* (ML) and *restricted/residual maximum likelihood* (REML). A favorable theoretical property of ML and REML is that they accommodate data that are missing at random (Rubin 1976; Little 1995).

PROC MIXED constructs an objective function associated with ML or REML and maximizes it over all unknown parameters. Using calculus, it is possible to reduce this maximization problem to one over only the parameters in \mathbf{G} and \mathbf{R} . The corresponding log-likelihood functions are as follows:

$$\begin{aligned}\text{ML : } l(\mathbf{G}, \mathbf{R}) &= -\frac{1}{2} \log |\mathbf{V}| - \frac{1}{2} \mathbf{r}' \mathbf{V}^{-1} \mathbf{r} - \frac{n}{2} \log(2\pi) \\ \text{REML : } l_R(\mathbf{G}, \mathbf{R}) &= -\frac{1}{2} \log |\mathbf{V}| - \frac{1}{2} \log |\mathbf{X}' \mathbf{V}^{-1} \mathbf{X}| - \frac{1}{2} \mathbf{r}' \mathbf{V}^{-1} \mathbf{r} - \frac{n-p}{2} \log(2\pi)\end{aligned}$$

where $\mathbf{r} = \mathbf{y} - \mathbf{X}(\mathbf{X}' \mathbf{V}^{-1} \mathbf{X})^{-1} \mathbf{X}' \mathbf{V}^{-1} \mathbf{y}$ and p is the rank of \mathbf{X} . PROC MIXED actually minimizes -2 times these functions by using a ridge-stabilized Newton-Raphson algorithm. Lindstrom and Bates (1988) provide reasons for preferring Newton-Raphson to the Expectation-Maximum (EM) algorithm (Dempster, Laird, and Rubin 1977; Laird, Lange, and Stram 1987), as well as analytical details for implementing a QR-decomposition approach to the problem. Wolfinger, Tobias, and Sall (1994) present the sweep-based algorithms that are implemented in PROC MIXED.

One advantage of using the Newton-Raphson algorithm is that the second derivative matrix of the objective function evaluated at the optima is available upon completion. Denoting this matrix \mathbf{H} , the asymptotic theory of maximum likelihood (see Serfling 1980) shows that $2\mathbf{H}^{-1}$ is an asymptotic variance-covariance matrix of the estimated parameters of \mathbf{G} and \mathbf{R} . Thus, tests and confidence intervals based on asymptotic normality can be obtained. However, these can be unreliable in small samples, especially for parameters such as variance components that have sampling distributions that tend to be skewed to the right.

If a residual variance σ^2 is a part of your mixed model, it can usually be *profiled* out of the likelihood. This means solving analytically for the optimal σ^2 and plugging this expression back into the likelihood formula (see Wolfinger, Tobias, and Sall 1994). This reduces the number of optimization parameters by one and can improve convergence properties. PROC MIXED profiles the residual variance out of the log likelihood whenever it appears reasonable to do so. This includes the case when \mathbf{R} equals $\sigma^2 \mathbf{I}$ and when it has blocks with a compound symmetry, time series, or spatial structure. PROC MIXED does not profile the log likelihood when \mathbf{R} has unstructured blocks, when you use the **HOLD=** or **NOITER** option in the **PARMS** statement, or when you use the **NOPROFILE** option in the **PROC MIXED** statement.

Instead of ML or REML, you can use the noniterative MIVQUE0 method to estimate \mathbf{G} and \mathbf{R} (Rao 1972; LaMotte 1973; Wolfinger, Tobias, and Sall 1994). In fact, by default PROC MIXED uses MIVQUE0 estimates as starting values for the ML and REML procedures. For variance component models, another estimation method involves equating Type 1, 2, or 3 expected mean squares to their observed values and solving the resulting system. However, Swallow and Monahan (1984) present simulation evidence favoring REML and ML over MIVQUE0 and other method-of-moment estimators.

Estimating Fixed and Random Effects in the Mixed Model

ML, REML, MIVQUE0, or Type1–Type3 provide estimates of \mathbf{G} and \mathbf{R} , which are denoted $\hat{\mathbf{G}}$ and $\hat{\mathbf{R}}$, respectively. To obtain estimates of $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$, the standard method is to solve the *mixed model equations* (Henderson 1984):

$$\begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{Z} \\ \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z} + \hat{\mathbf{G}}^{-1} \end{bmatrix} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{y} \\ \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

The solutions can also be written as

$$\begin{aligned} \hat{\boldsymbol{\beta}} &= (\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{y} \\ \hat{\boldsymbol{\gamma}} &= \hat{\mathbf{G}}\mathbf{Z}'\hat{\mathbf{V}}^{-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}) \end{aligned}$$

and have connections with empirical Bayes estimators (Laird and Ware 1982; Carlin and Louis 1996).

Note that the mixed model equations are extended normal equations and that the preceding expression assumes that $\hat{\mathbf{G}}$ is nonsingular. For the extreme case where the eigenvalues of $\hat{\mathbf{G}}$ are very large, $\hat{\mathbf{G}}^{-1}$ contributes very little to the equations and $\hat{\boldsymbol{\gamma}}$ is close to what it would be if $\boldsymbol{\gamma}$ actually contained fixed-effects parameters. On the other hand, when the eigenvalues of $\hat{\mathbf{G}}$ are very small, $\hat{\mathbf{G}}^{-1}$ dominates the equations and $\hat{\boldsymbol{\gamma}}$ is close to 0. For intermediate cases, $\hat{\mathbf{G}}^{-1}$ can be viewed as shrinking the fixed-effects estimates of $\boldsymbol{\gamma}$ toward 0 (Robinson 1991).

If $\hat{\mathbf{G}}$ is singular, then the mixed model equations are modified (Henderson 1984) as follows:

$$\begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{Z}\hat{\mathbf{G}} \\ \hat{\mathbf{G}}'\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \hat{\mathbf{G}}'\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z}\hat{\mathbf{G}} + \mathbf{G} \end{bmatrix} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\tau}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{y} \\ \hat{\mathbf{G}}'\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

Denote the generalized inverses of the nonsingular $\hat{\mathbf{G}}$ and singular $\hat{\mathbf{G}}$ forms of the mixed model equations by \mathbf{C} and \mathbf{M} , respectively. In the nonsingular case, the solution $\hat{\boldsymbol{\gamma}}$ estimates the random effects directly, but in the singular case the estimates of random effects are achieved through a back-transformation $\hat{\boldsymbol{\gamma}} = \hat{\mathbf{G}}\hat{\boldsymbol{\tau}}$ where $\hat{\boldsymbol{\tau}}$ is the solution to the modified mixed model equations. Similarly, while in the nonsingular case \mathbf{C} itself is the estimated covariance matrix for $(\hat{\boldsymbol{\beta}}, \hat{\boldsymbol{\gamma}})$, in the singular case the covariance estimate for $(\hat{\boldsymbol{\beta}}, \hat{\mathbf{G}}\hat{\boldsymbol{\tau}})$ is given by \mathbf{PMP} where

$$\mathbf{P} = \begin{bmatrix} \mathbf{I} & \\ & \hat{\mathbf{G}} \end{bmatrix}$$

An example of when the singular form of the equations is necessary is when a variance component estimate falls on the boundary constraint of 0.

Model Selection

The previous section on estimation assumes the specification of a mixed model in terms of \mathbf{X} , \mathbf{Z} , \mathbf{G} , and \mathbf{R} . Even though \mathbf{X} and \mathbf{Z} have known elements, their specific form and construction are flexible, and several possibilities can present themselves for a particular data set. Likewise, several different covariance structures for \mathbf{G} and \mathbf{R} might be reasonable.

Space does not permit a thorough discussion of model selection, but a few brief comments and references are in order. First, subject matter considerations and objectives are of great importance when selecting a model; see Diggle (1988) and Lindsey (1993).

Second, when the data themselves are looked to for guidance, many of the graphical methods and diagnostics appropriate for the general linear model extend to the mixed model setting as well (Christensen, Pearson, and Johnson 1992).

Finally, a likelihood-based approach to the mixed model provides several statistical measures for model adequacy as well. The most common of these are the likelihood ratio test and Akaike's and Schwarz's criteria (Bozdogan 1987; Wolfinger 1993; Keselman et al. 1998, 1999).

Statistical Properties

If \mathbf{G} and \mathbf{R} are known, $\hat{\boldsymbol{\beta}}$ is the *best linear unbiased estimator* (BLUE) of $\boldsymbol{\beta}$, and $\hat{\boldsymbol{\gamma}}$ is the *best linear unbiased predictor* (BLUP) of $\boldsymbol{\gamma}$ (Searle 1971; Harville 1988, 1990; Robinson 1991; McLean, Sanders, and Stroup 1991). Here, "best" means minimum mean squared error. The covariance matrix of $(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}, \hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma})$ is

$$\mathbf{C} = \begin{bmatrix} \mathbf{X}'\mathbf{R}^{-1}\mathbf{X} & \mathbf{X}'\mathbf{R}^{-1}\mathbf{Z} \\ \mathbf{Z}'\mathbf{R}^{-1}\mathbf{X} & \mathbf{Z}'\mathbf{R}^{-1}\mathbf{Z} + \mathbf{G}^{-1} \end{bmatrix}^{-}$$

where $^{-}$ denotes a generalized inverse (see Searle 1971).

However, \mathbf{G} and \mathbf{R} are usually unknown and are estimated by using one of the aforementioned methods. These estimates, $\hat{\mathbf{G}}$ and $\hat{\mathbf{R}}$, are therefore simply substituted into the preceding expression to obtain

$$\hat{\mathbf{C}} = \begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{Z} \\ \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z} + \hat{\mathbf{G}}^{-1} \end{bmatrix}^{-}$$

as the approximate variance-covariance matrix of $(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}, \hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma})$. In this case, the BLUE and BLUP acronyms no longer apply, but the word *empirical* is often added to indicate such an approximation. The appropriate acronyms thus become EBLUE and EBLUP.

McLean and Sanders (1988) show that $\hat{\mathbf{C}}$ can also be written as

$$\hat{\mathbf{C}} = \begin{bmatrix} \hat{\mathbf{C}}_{11} & \hat{\mathbf{C}}_{21}' \\ \hat{\mathbf{C}}_{21} & \hat{\mathbf{C}}_{22} \end{bmatrix}$$

where

$$\hat{\mathbf{C}}_{11} = (\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-}$$

$$\hat{\mathbf{C}}_{21} = -\hat{\mathbf{G}}\mathbf{Z}'\hat{\mathbf{V}}^{-1}\mathbf{X}\hat{\mathbf{C}}_{11}$$

$$\hat{\mathbf{C}}_{22} = (\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z} + \hat{\mathbf{G}}^{-1})^{-1} - \hat{\mathbf{C}}_{21}\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{Z}\hat{\mathbf{G}}$$

Note that $\hat{\mathbf{C}}_{11}$ is the familiar estimated generalized least squares formula for the variance-covariance matrix of $\hat{\boldsymbol{\beta}}$.

As a cautionary note, $\hat{\mathbf{C}}$ tends to underestimate the true sampling variability of $(\hat{\boldsymbol{\beta}}, \hat{\boldsymbol{\gamma}})$ because no account is made for the uncertainty in estimating \mathbf{G} and \mathbf{R} . Although inflation factors have been proposed (Kackar and Harville 1984; Kass and Steffey 1989; Prasad and Rao 1990), they tend to be small for data sets that are fairly well balanced. PROC MIXED does not compute any inflation factors by default, but rather accounts for the downward bias by using the approximate t and F statistics described subsequently. The `DDFM=KENWARDROGER` option in the `MODEL` statement prompts PROC MIXED to compute a specific inflation factor along with Satterthwaite-based degrees of freedom.

Inference and Test Statistics

For inferences concerning the covariance parameters in your model, you can use likelihood-based statistics. One common likelihood-based statistic is the *Wald Z*, which is computed as the parameter estimate divided by its asymptotic standard error. The asymptotic standard errors are computed from the inverse of the second derivative matrix of the likelihood with respect to each of the covariance parameters. The Wald *Z* is valid for large samples, but it can be unreliable for small data sets and for parameters such as variance components, which are known to have a skewed or bounded sampling distribution.

A better alternative is the likelihood ratio χ^2 statistic. This statistic compares two covariance models, one a special case of the other. To compute it, you must run PROC MIXED twice, once for each of the two models, and then subtract the corresponding values of -2 times the log likelihoods. You can use either ML or REML to construct this statistic, which tests whether the full model is necessary beyond the reduced model.

As long as the reduced model does not occur on the boundary of the covariance parameter space, the χ^2 statistic computed in this fashion has a large-sample χ^2 distribution that is χ^2 with degrees of freedom equal to the difference in the number of covariance parameters between the two models. If the reduced model does occur on the boundary of the covariance parameter space, the asymptotic distribution becomes a mixture of χ^2 distributions (Self and Liang 1987). A common example of this is when you are testing that a variance component equals its lower boundary constraint of 0.

A final possibility for obtaining inferences concerning the covariance parameters is to simulate or resample data from your model and construct empirical sampling distributions of the parameters. The SAS macro language and the ODS system are useful tools in this regard.

F and t Tests for Fixed- and Random-Effects Parameters

For inferences concerning the fixed- and random-effects parameters in the mixed model, consider estimable linear combinations of the following form:

$$\mathbf{L} \begin{bmatrix} \boldsymbol{\beta} \\ \boldsymbol{\gamma} \end{bmatrix}$$

The estimability requirement (Searle 1971) applies only to the $\boldsymbol{\beta}$ portion of \mathbf{L} , because any linear combination of $\boldsymbol{\gamma}$ is estimable. Such a formulation in terms of a general \mathbf{L} matrix encompasses a wide variety of common inferential procedures such as those employed with Type 1–Type 3 tests and LS-means. The **CONTRAST** and **ESTIMATE** statements in PROC MIXED enable you to specify your own \mathbf{L} matrices. Typically, inference on fixed effects is the focus, and, in this case, the $\boldsymbol{\gamma}$ portion of \mathbf{L} is assumed to contain all 0s.

Statistical inferences are obtained by testing the hypothesis

$$H : \mathbf{L} \begin{bmatrix} \boldsymbol{\beta} \\ \boldsymbol{\gamma} \end{bmatrix} = 0$$

or by constructing point and interval estimates.

When \mathbf{L} consists of a single row, a general *t* statistic can be constructed as follows (see McLean and Sanders 1988; Stroup 1989a):

$$t = \frac{\mathbf{L} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix}}{\sqrt{\mathbf{L} \hat{\mathbf{C}} \mathbf{L}'}}$$

Under the assumed normality of $\boldsymbol{\gamma}$ and $\boldsymbol{\epsilon}$, t has an exact t distribution only for data exhibiting certain types of balance and for some special unbalanced cases. In general, t is only approximately t -distributed, and its degrees of freedom must be estimated. See the **DDFM=** option for a description of the various degrees-of-freedom methods available in PROC MIXED.

With $\hat{\nu}$ being the approximate degrees of freedom, the associated confidence interval is

$$\mathbf{L} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix} \pm t_{\hat{\nu}, \alpha/2} \sqrt{\mathbf{L} \hat{\mathbf{C}} \mathbf{L}'}$$

where $t_{\hat{\nu}, \alpha/2}$ is the $(1 - \alpha/2)100$ percentile of the $t_{\hat{\nu}}$ distribution.

When the rank of \mathbf{L} is greater than 1, PROC MIXED constructs the following general F statistic:

$$F = \frac{\begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix}' \mathbf{L}' (\mathbf{L} \hat{\mathbf{C}} \mathbf{L}')^{-1} \mathbf{L} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix}}{r}$$

where $r = \text{rank}(\mathbf{L} \hat{\mathbf{C}} \mathbf{L}')$. Analogous to t , F in general has an approximate F distribution with r numerator degrees of freedom and $\hat{\nu}$ denominator degrees of freedom.

The t and F statistics enable you to make inferences about your fixed effects, which account for the variance-covariance model you select. An alternative is the χ^2 statistic associated with the likelihood ratio test. This statistic compares two fixed-effects models, one a special case of the other. It is computed just as when comparing different covariance models, although you should use ML and not REML here because the penalty term associated with restricted likelihoods depends upon the fixed-effects specification.

F Tests With the ANOVAF Option

The ANOVAF option computes F tests by the following method in models with **REPEATED** statement and without **RANDOM** statement. Let \mathbf{L} denote the matrix of estimable functions for the hypothesis $H: \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$, where $\boldsymbol{\beta}$ are the fixed-effects parameters. Let $\mathbf{M} = \mathbf{L}'(\mathbf{L}\mathbf{L}')^{-1}\mathbf{L}$, and suppose that $\hat{\mathbf{C}}$ denotes the estimated variance-covariance matrix of $\hat{\boldsymbol{\beta}}$ (see the section “**Statistical Properties**” for the construction of $\hat{\mathbf{C}}$).

The ANOVAF F statistics are computed as

$$F_A = \hat{\boldsymbol{\beta}}' \mathbf{L}' (\mathbf{L}\mathbf{L}')^{-1} \mathbf{L} \hat{\boldsymbol{\beta}} / t_1 = \hat{\boldsymbol{\beta}}' \mathbf{M} \hat{\boldsymbol{\beta}} / t_1$$

Notice that this is a modification of the usual F statistic where $(\mathbf{L} \hat{\mathbf{C}} \mathbf{L}')^{-1}$ is replaced with $(\mathbf{L}\mathbf{L}')^{-1}$ and $\text{rank}(\mathbf{L})$ is replaced with $t_1 = \text{trace}(\mathbf{M} \hat{\mathbf{C}})$; see, for example, Brunner, Domhof, and Langer (2002, Sec. 5.4). The p -values for this statistic are computed from either an F_{v_1, v_2} or an $F_{v_1, \infty}$ distribution. The respective degrees of freedom are determined by the MIXED procedure as follows:

$$\begin{aligned} v_1 &= \frac{t_1^2}{\text{trace}(\mathbf{M} \hat{\mathbf{C}} \mathbf{M} \hat{\mathbf{C}})} \\ v_2^* &= \frac{2t_1^2}{\mathbf{g}' \mathbf{A} \mathbf{g}} \\ v_2 &= \begin{cases} \max\{\min\{v_2^*, df_e\}, 1\} & \mathbf{g}' \mathbf{A} \mathbf{g} > 1\text{E}3 \times \text{MACEPS} \\ 1 & \text{otherwise} \end{cases} \end{aligned}$$

The term $\mathbf{g}'\mathbf{A}\mathbf{g}$ in the term ν_2^* for the denominator degrees of freedom is based on approximating $\text{Var}[\text{trace}(\widehat{\mathbf{M}\mathbf{C}})]$ based on a first-order Taylor series about the true covariance parameters. This generalizes results in the appendix of Brunner, Dette, and Munk (1997) to a broader class of models. The vector $\mathbf{g} = [g_1, \dots, g_q]$ contains the partial derivatives

$$\text{trace} \left(\mathbf{L}' (\mathbf{L}\mathbf{L}')^{-1} \mathbf{L} \frac{\partial \widehat{\mathbf{C}}}{\partial \theta_i} \right)$$

and \mathbf{A} is the asymptotic variance-covariance matrix of the covariance parameter estimates ([ASYCOV](#) option).

PROC MIXED reports ν_1 and ν_2 as “NumDF” and “DenDF” under the “ANOVA F” heading in the output. The corresponding p -values are denoted as “Pr > F(DDF)” for F_{ν_1, ν_2} and “Pr > F(infty)” for $F_{\nu_1, \infty}$, respectively.

P -values computed with the ANOVAF option can be identical to the nonparametric tests in Akritas, Arnold, and Brunner (1997) and in Brunner, Domhof, and Langer (2002), provided that the response data consist of properly created (and sorted) ranks and that the covariance parameters are estimated by MIVQUE0 in models with [REPEATED](#) statement and properly chosen [SUBJECT=](#) and/or [GROUP=](#) effects.

If you model an unstructured covariance matrix in a longitudinal model with one or more repeated factors, the ANOVAF results are identical to a multivariate MANOVA where degrees of freedom are corrected with the Greenhouse-Geisser adjustment (Greenhouse and Geisser 1959). For example, suppose that factor A has 2 levels and factor B has 4 levels. The following two sets of statements produce the same p -values:

```
proc mixed data=Mydata anovaf method=mivque0;
  class id A B;
  model score = A | B / chisq;
  repeated / type=un subject=id;
  ods select Tests3;
run;

proc transpose data=MyData out=tdata;
  by id;
  var score;
run;
proc glm data=tdata;
  model col: = / nouni;
  repeated A 2, B 4;
  ods output ModelANOVA=maov epsilons=eps;
run;
proc transpose data=eps (where=(substr(statistic,1,3)='Gre')) out=taps;
  var cvalue1;
run;

data aov; set maov;
  if (_n_ = 1) then merge taps;
  if (Source='A') then do;
    pFddf = ProbF;
    pFinf = 1 - probchi(df*Fvalue,df);
    output;
  end; else if (Source='B') then do;
    pFddf = ProbFGG;
```

```

        pFinf = 1 - probchi(df*col1*Fvalue,df*col1);
        output;
    end; else if (Source='A*B') then do;
        pfddf = ProbFGG;
        pFinf = 1 - probchi(df*col2*Fvalue,df*col2);
        output;
    end;
run;
proc print data=aov label noobs;
    label Source = 'Effect'
           df      = 'NumDF'
           Fvalue = 'Value'
           pFddf  = 'Pr > F(DDF)'
           pFinf  = 'Pr > F(infty)';
    var Source df Fvalue pFddf pFinf;
    format pF: pvalue6.;
run;

```

The PROC GLM code produces p -values that correspond to the ANOVA p -values shown as $\text{Pr} > \text{F(DDF)}$ in the MIXED output. The subsequent DATA step computes the p -values that correspond to $\text{Pr} > \text{F(infty)}$ in the PROC MIXED output.

Parameterization of Mixed Models

Recall that a mixed model is of the form

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

where \mathbf{y} represents univariate data, $\boldsymbol{\beta}$ is an unknown vector of fixed effects with known model matrix \mathbf{X} , $\boldsymbol{\gamma}$ is an unknown vector of random effects with known model matrix \mathbf{Z} , and $\boldsymbol{\epsilon}$ is an unknown random error vector.

PROC MIXED constructs a mixed model according to the specifications in the **MODEL**, **RANDOM**, and **REPEATED** statements. Each effect in the **MODEL** statement generates one or more columns in the model matrix \mathbf{X} , and each effect in the **RANDOM** statement generates one or more columns in the model matrix \mathbf{Z} . Effects in the **REPEATED** statement do not generate model matrices; they serve only to index observations within subjects. This section shows precisely how PROC MIXED builds \mathbf{X} and \mathbf{Z} .

Intercept

By default, all models automatically include a column of 1s in \mathbf{X} to estimate a fixed-effect intercept parameter μ . You can use the **NOINT** option in the **MODEL** statement to suppress this intercept. The **NOINT** option is useful when you are specifying a classification effect in the **MODEL** statement and you want the parameter estimate to be in terms of the mean response for each level of that effect, rather than in terms of a deviation from an overall mean.

By contrast, the intercept is not included by default in \mathbf{Z} . To obtain a column of 1s in \mathbf{Z} , you must specify in the **RANDOM** statement either the **INTERCEPT** effect or some effect that has only one level.

Regression Effects

Numeric variables, or polynomial terms involving them, can be included in the model as regression effects (covariates). The actual values of such terms are included as columns of the model matrices **X** and **Z**. You can use the bar operator with a regression effect to generate polynomial effects. For instance, $X|X|X$ expands to $X \ X^2 \ X^3$, a cubic model.

Main Effects

If a classification variable has m levels, PROC MIXED generates m columns in the model matrix for its main effect. Each column is an indicator variable for a given level. The order of the columns is the sort order of the values of their levels and can be controlled with the **ORDER=** option in the PROC MIXED statement. Table 59.20 is an example.

Table 59.20 Example of Main Effects

Data		I	A		B		
A	B	μ	A1	A2	B1	B2	B3
1	1	1	1	0	1	0	0
1	2	1	1	0	0	1	0
1	3	1	1	0	0	0	1
2	1	1	0	1	1	0	0
2	2	1	0	1	0	1	0
2	3	1	0	1	0	0	1

Typically, there are more columns for these effects than there are degrees of freedom for them. In other words, PROC MIXED uses an overparameterized model.

Interaction Effects

Often a model includes interaction (crossed) effects. With an interaction, PROC MIXED first reorders the terms to correspond to the order of the variables in the **CLASS** statement. Thus, $B*A$ becomes $A*B$ if **A** precedes **B** in the **CLASS** statement. Then, PROC MIXED generates columns for all combinations of levels that occur in the data. The order of the columns is such that the rightmost variables in the cross index faster than the leftmost variables (Table 59.21). Empty columns (that would contain all 0s) are not generated for **X**, but they are for **Z**.

Table 59.21 Example of Interaction Effects

Data		I	A		B			A*B					
A	B	μ	A1	A2	B1	B2	B3	A1B1	A1B2	A1B3	A2B1	A2B2	A2B3
1	1	1	1	0	1	0	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	1	0	0	0
2	1	1	0	1	1	0	0	0	0	0	1	0	0
2	2	1	0	1	0	1	0	0	0	0	0	1	0
2	3	1	0	1	0	0	1	0	0	0	0	0	1

In the preceding matrix, main-effects columns are not linearly independent of crossed-effects columns; in fact, the column space for the crossed effects contains the space of the main effect.

When your model contains many interaction effects, you might be able to code them more parsimoniously by using the bar operator (|). The bar operator generates all possible interaction effects. For example, $A|B|C$ expands to $A\ B\ A*B\ C\ A*C\ B*C\ A*B*C$. To eliminate higher-order interaction effects, use the at sign (@) in conjunction with the bar operator. For instance, $A|B|C|D\ @2$ expands to $A\ B\ A*B\ C\ A*C\ B*C\ D\ A*D\ B*D\ C*D$.

Nested Effects

Nested effects are generated in the same manner as crossed effects. Hence, the design columns generated by the following two statements are the same (but the ordering of the columns is different):

```
model Y=A B(A);
```

```
model Y=A A*B;
```

The nesting operator in PROC MIXED is more a notational convenience than an operation distinct from crossing. Nested effects are typically characterized by the property that the nested variables never appear as main effects. The order of the variables within nesting parentheses is made to correspond to the order of these variables in the **CLASS** statement. The order of the columns is such that variables outside the parentheses index faster than those inside the parentheses, and the rightmost nested variables index faster than the leftmost variables (Table 59.22).

Table 59.22 Example of Nested Effects

Data		I	A		B(A)					
A	B	μ	A1	A2	B1A1	B2A1	B3A1	B1A2	B2A2	B3A2
1	1	1	1	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	0
2	1	1	0	1	0	0	0	1	0	0
2	2	1	0	1	0	0	0	0	1	0
2	3	1	0	1	0	0	0	0	0	1

Note that nested effects are often distinguished from interaction effects by the implied randomization structure of the design. That is, they usually indicate random effects within a fixed-effects framework. The fact that random effects can be modeled directly in the **RANDOM** statement might make the specification of nested effects in the **MODEL** statement unnecessary.

Continuous-Nesting-Class Effects

When a continuous variable nests with a classification variable, the design columns are constructed by multiplying the continuous values into the design columns for the class effect (Table 59.23).

Table 59.23 Example of Continuous-Nesting-Class Effects

Data		I	A		X(A)	
X	A	μ	A1	A2	X(A1)	X(A2)
21	1	1	1	0	21	0
24	1	1	1	0	24	0
22	1	1	1	0	22	0
28	2	1	0	1	0	28
19	2	1	0	1	0	19
23	2	1	0	1	0	23

This model estimates a separate slope for X within each level of A.

Continuous-by-Class Effects

Continuous-by-class effects generate the same design columns as continuous-nesting-class effects. The two models are made different by the presence of the continuous variable as a regressor by itself, as well as a contributor to a compound effect. Table 59.24 shows an example.

Table 59.24 Example of Continuous-by-Class Effects

Data		I	X	A		X*A	
X	A	μ	X	A1	A2	X*A1	X*A2
21	1	1	21	1	0	21	0
24	1	1	24	1	0	24	0
22	1	1	22	1	0	22	0
28	2	1	28	0	1	0	28
19	2	1	19	0	1	0	19
23	2	1	23	0	1	0	23

You can use continuous-by-class effects to test for homogeneity of slopes.

General Effects

An example that combines all the effects is $X1*X2*A*B*C$ (D E). The continuous list comes first, followed by the crossed list, followed by the nested list in parentheses. You should be aware of the sequencing of parameters when you use the **CONTRAST** or **ESTIMATE** statement to compute some function of the parameter estimates.

Effects might be renamed by PROC MIXED to correspond to ordering rules. For example, $B*A(E D)$ might be renamed $A*B(D E)$ to satisfy the following:

- Classification variables that occur outside parentheses (crossed effects) are sorted in the order in which they appear in the **CLASS** statement.
- Variables within parentheses (nested effects) are sorted in the order in which they appear in the **CLASS** statement.

The sequencing of the parameters generated by an effect can be described by which variables have their levels indexed faster:

- Variables in the crossed list index faster than variables in the nested list.
- Within a crossed or nested list, variables to the right index faster than variables to the left.

For example, suppose a model includes four effects—A, B, C, and D—each having two levels, 1 and 2. Suppose the **CLASS** statement is as follows:

```
class A B C D;
```

Then the order of the parameters for the effect B*A(C D), which is renamed A*B (C D), is

$$\begin{aligned} A_1 B_1 C_1 D_1 &\rightarrow A_1 B_2 C_1 D_1 \rightarrow A_2 B_1 C_1 D_1 \rightarrow A_2 B_2 C_1 D_1 \rightarrow \\ A_1 B_1 C_1 D_2 &\rightarrow A_1 B_2 C_1 D_2 \rightarrow A_2 B_1 C_1 D_2 \rightarrow A_2 B_2 C_1 D_2 \rightarrow \\ A_1 B_1 C_2 D_1 &\rightarrow A_1 B_2 C_2 D_1 \rightarrow A_2 B_1 C_2 D_1 \rightarrow A_2 B_2 C_2 D_1 \rightarrow \\ A_1 B_1 C_2 D_2 &\rightarrow A_1 B_2 C_2 D_2 \rightarrow A_2 B_1 C_2 D_2 \rightarrow A_2 B_2 C_2 D_2 \end{aligned}$$

Note that first the crossed effects B and A are sorted in the order in which they appear in the **CLASS** statement so that A precedes B in the parameter list. Then, for each combination of the nested effects in turn, combinations of A and B appear. The B effect moves fastest because it is rightmost in the cross list. Then A moves next fastest, and D moves next fastest. The C effect is the slowest since it is leftmost in the nested list.

When numeric levels are used, levels are sorted by their character format, which might not correspond to their numeric sort sequence (for example, noninteger levels). Therefore, it is advisable to include a desired format for numeric levels or to use the **ORDER=INTERNAL** option in the **PROC MIXED** statement to ensure that levels are sorted by their internal values.

Implications of the Non-Full-Rank Parameterization

For models with fixed effects involving classification variables, there are more design columns in **X** constructed than there are degrees of freedom for the effect. Thus, there are linear dependencies among the columns of **X**. In this event, all of the parameters are not estimable; there is an infinite number of solutions to the mixed model equations. **PROC MIXED** uses a generalized inverse (a g_2 -inverse, Pringle and Rayner 1971) to obtain values for the estimates (Searle 1971). The solution values are not displayed unless you specify the **SOLUTION** option in the **MODEL** statement. The solution has the characteristic that estimates are 0 whenever the design column for that parameter is a linear combination of previous columns. With this parameterization, hypothesis tests are constructed to test linear functions of the parameters that are estimable.

Some procedures (such as the CATMOD procedure) reparameterize models to full rank by using restrictions on the parameters. **PROC GLM** and **PROC MIXED** do not reparameterize, making the hypotheses that are commonly tested more understandable. See Goodnight (1978) for additional reasons for not reparameterizing.

Missing Level Combinations

PROC MIXED handles missing level combinations of classification variables similarly to the way PROC GLM does. Both procedures delete fixed-effects parameters corresponding to missing levels in order to preserve estimability. However, PROC MIXED does not delete missing level combinations for random-effects parameters because linear combinations of the random-effects parameters are always estimable. These conventions can affect the way you specify your **CONTRAST** and **ESTIMATE** coefficients.

Residuals and Influence Diagnostics

Residual Diagnostics

Consider a residual vector of the form $\tilde{\mathbf{e}} = \mathbf{P}\mathbf{Y}$, where \mathbf{P} is a projection matrix, possibly an oblique projector. A typical element \tilde{e}_i with variance v_i and estimated variance \hat{v}_i is said to be *standardized* as

$$\frac{\tilde{e}_i}{\sqrt{\text{Var}[\tilde{e}_i]}} = \frac{\tilde{e}_i}{\sqrt{v_i}}$$

and *studentized* as

$$\frac{\tilde{e}_i}{\sqrt{\hat{v}_i}}$$

External studentization uses an estimate of $\text{Var}[\tilde{e}_i]$ that does not involve the i th observation. Externally studentized residuals are often preferred over internally studentized residuals because they have well-known distributional properties in standard linear models for independent data.

Residuals that are scaled by the estimated variance of the response, i.e., $\tilde{e}_i / \sqrt{\widehat{\text{Var}}[Y_i]}$, are referred to as Pearson-type residuals.

Marginal and Conditional Residuals

The marginal and conditional means in the linear mixed model are $E[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$ and $E[\mathbf{Y}|\boldsymbol{\gamma}] = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma}$, respectively. Accordingly, the vector \mathbf{r}_m of marginal residuals is defined as

$$\mathbf{r}_m = \mathbf{Y} - \mathbf{X}\hat{\boldsymbol{\beta}}$$

and the vector \mathbf{r}_c of conditional residuals is

$$\mathbf{r}_c = \mathbf{Y} - \mathbf{X}\hat{\boldsymbol{\beta}} - \mathbf{Z}\hat{\boldsymbol{\gamma}} = \mathbf{r}_m - \mathbf{Z}\hat{\boldsymbol{\gamma}}$$

Following Gregoire, Schabenberger, and Barrett (1995), let $\mathbf{Q} = \mathbf{X}(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{X}'$ and $\mathbf{K} = \mathbf{I} - \mathbf{Z}\hat{\mathbf{G}}\mathbf{Z}'\hat{\mathbf{V}}^{-1}$. Then

$$\widehat{\text{Var}}[\mathbf{r}_m] = \hat{\mathbf{V}} - \mathbf{Q}$$

$$\widehat{\text{Var}}[\mathbf{r}_c] = \mathbf{K}(\hat{\mathbf{V}} - \mathbf{Q})\mathbf{K}'$$

For an individual observation the raw, studentized, and Pearson-type residuals computed by the MIXED procedure are given in Table 59.25.

Table 59.25 Residual Types Computed by the MIXED Procedure

Type of Residual	Marginal	Conditional
Raw	$r_{mi} = Y_i - \mathbf{x}_i' \hat{\boldsymbol{\beta}}$	$r_{ci} = r_{mi} - \mathbf{z}_i' \hat{\boldsymbol{\gamma}}$
Studentized	$r_{mi}^{student} = \frac{r_{mi}}{\sqrt{\widehat{\text{Var}}[r_{mi}]}}$	$r_{ci}^{student} = \frac{r_{ci}}{\sqrt{\widehat{\text{Var}}[r_{ci}]}}$
Pearson	$r_{mi}^{pearson} = \frac{r_{mi}}{\sqrt{\widehat{\text{Var}}[Y_i]}}$	$r_{ci}^{pearson} = \frac{r_{ci}}{\sqrt{\widehat{\text{Var}}[Y_i \boldsymbol{\gamma}]}}$

When the **OUTPM=** option is specified in addition to the **RESIDUAL** option in the **MODEL** statement, $r_{mi}^{student}$ and $r_{mi}^{pearson}$ are added to the data set as variables **Resid**, **StudentResid**, and **PearsonResid**, respectively. When the **OUTP=** option is specified, $r_{ci}^{student}$ and $r_{ci}^{pearson}$ are added to the data set. Raw residuals are part of the **OUTPM=** and **OUTP=** data sets without the **RESIDUAL** option.

Scaled Residuals

For correlated data, a set of scaled quantities can be defined through the Cholesky decomposition of the variance-covariance matrix. Since fitted residuals in linear models are rank-deficient, it is customary to draw on the variance-covariance matrix of the data. If $\text{Var}[\mathbf{Y}] = \mathbf{V}$ and $\mathbf{C}'\mathbf{C} = \mathbf{V}$, then $\mathbf{C}'^{-1}\mathbf{Y}$ has uniform dispersion and its elements are uncorrelated.

Scaled residuals in a mixed model are meaningful for quantities based on the marginal distribution of the data. Let $\hat{\mathbf{C}}$ denote the Cholesky root of $\hat{\mathbf{V}}$, so that $\hat{\mathbf{C}}'\hat{\mathbf{C}} = \hat{\mathbf{V}}$, and define

$$\mathbf{Y}_c = \hat{\mathbf{C}}'^{-1}\mathbf{Y}$$

$$\mathbf{r}_{m(c)} = \hat{\mathbf{C}}'^{-1}\mathbf{r}_m$$

By analogy with other scalings, the inverse Cholesky decomposition can also be applied to the residual vector, $\hat{\mathbf{C}}'^{-1}\mathbf{r}_m$, although \mathbf{V} is not the variance-covariance matrix of \mathbf{r}_m .

To diagnose whether the covariance structure of the model has been specified correctly can be difficult based on \mathbf{Y}_c , since the inverse Cholesky transformation affects the expected value of \mathbf{Y}_c . You can draw on $\mathbf{r}_{m(c)}$ as a vector of (approximately) uncorrelated data with constant mean.

When the **OUTPM=** option in the **MODEL** statement is specified in addition to the **VCIRY** option, \mathbf{Y}_c is added as variable **ScaledDep** and $\mathbf{r}_{m(c)}$ is added as **ScaledResid** to the data set.

Influence Diagnostics

Basic Idea and Statistics

The general idea of quantifying the influence of one or more observations relies on computing parameter estimates based on all data points, removing the cases in question from the data, refitting the model, and computing statistics based on the change between full-data and reduced-data estimation. Influence statistics can be coarsely grouped by the aspect of estimation that is their primary target:

- overall measures compare changes in objective functions: (restricted) likelihood distance (Cook and Weisberg 1982, Ch. 5.2)
- influence on parameter estimates: Cook's D (Cook 1977, 1979), MDFFITS (Belsley, Kuh, and Welsch 1980, p. 32)

- influence on precision of estimates: CovRatio and CovTrace
- influence on fitted and predicted values: PRESS residual, PRESS statistic (Allen 1974), DFFITS (Belsley, Kuh, and Welsch 1980, p. 15)
- outlier properties: internally and externally studentized residuals, leverage

For linear models for uncorrelated data, it is not necessary to refit the model after removing a data point in order to measure the impact of an observation on the model. The change in fixed effect estimates, residuals, residual sums of squares, and the variance-covariance matrix of the fixed effects can be computed based on the fit to the full data alone. By contrast, in mixed models several important complications arise. Data points can affect not only the fixed effects but also the covariance parameter estimates on which the fixed-effects estimates depend. Furthermore, closed-form expressions for computing the change in important model quantities might not be available.

This section provides background material for the various influence diagnostics available with the MIXED procedure. See the section “[Mixed Models Theory](#)” on page 4958 for relevant expressions and definitions. The parameter vector θ denotes all unknown parameters in the \mathbf{R} and \mathbf{G} matrix.

The observations whose influence is being ascertained are represented by the set U and referred to simply as “the observations in U .” The estimate of a parameter vector, such as β , obtained from all observations except those in the set U is denoted $\hat{\beta}_{(U)}$. In case of a matrix \mathbf{A} , the notation $\mathbf{A}_{(U)}$ represents the matrix with the rows in U removed; these rows are collected in \mathbf{A}_U . If \mathbf{A} is symmetric, then notation $\mathbf{A}_{(U)}$ implies removal of rows and columns. The vector Y_U comprises the responses of the data points being removed, and $\mathbf{V}_{(U)}$ is the variance-covariance matrix of the remaining observations. When $k = 1$, lowercase notation emphasizes that single points are removed, such as $\mathbf{A}_{(u)}$.

Managing the Covariance Parameters

An important component of influence diagnostics in the mixed model is the estimated variance-covariance matrix $\mathbf{V} = \mathbf{ZGZ}' + \mathbf{R}$. To make the dependence on the vector of covariance parameters explicit, write it as $\mathbf{V}(\theta)$. If one parameter, σ^2 , is profiled or factored out of \mathbf{V} , the remaining parameters are denoted as θ^* . Notice that in a model where \mathbf{G} is diagonal and $\mathbf{R} = \sigma^2\mathbf{I}$, the parameter vector θ^* contains the ratios of each variance component and σ^2 (see Wolfinger, Tobias, and Sall 1994). When $\text{ITER}=0$, two scenarios are distinguished:

1. If the residual variance is not profiled, either because the model does not contain a residual variance or because it is part of the Newton-Raphson iterations, then $\hat{\theta}_{(U)} \equiv \hat{\theta}$.
2. If the residual variance is profiled, then $\hat{\theta}_{(U)}^* \equiv \hat{\theta}^*$ and $\hat{\sigma}_{(U)}^2 \neq \hat{\sigma}^2$. Influence statistics such as Cook’s D and internally studentized residuals are based on $\mathbf{V}(\hat{\theta})$, whereas externally studentized residuals and the DFFITS statistic are based on $\mathbf{V}(\hat{\theta}_U) = \sigma_{(U)}^2 \mathbf{V}(\hat{\theta}^*)$. In a random components model with uncorrelated errors, for example, the computation of $\mathbf{V}(\hat{\theta}_U)$ involves scaling of $\hat{\mathbf{G}}$ and $\hat{\mathbf{R}}$ by the full-data estimate $\hat{\sigma}^2$ and multiplying the result with the reduced-data estimate $\hat{\sigma}_{(U)}^2$.

Certain statistics, such as MDFFITS, CovRatio, and CovTrace, require an estimate of the variance of the fixed effects that is based on the reduced number of observations. For example, $\mathbf{V}(\hat{\theta}_U)$ is evaluated at the reduced-data parameter estimates but computed for the entire data set. The matrix $\mathbf{V}_{(U)}(\hat{\theta}_{(U)})$, on the other hand, has rows and columns corresponding to the points in U removed. The resulting matrix is evaluated at the delete-case estimates.

When influence analysis is iterative, the entire vector $\boldsymbol{\theta}$ is updated, whether the residual variance is profiled or not. The matrices to be distinguished here are $\mathbf{V}(\hat{\boldsymbol{\theta}})$, $\mathbf{V}(\hat{\boldsymbol{\theta}}_{(U)})$, and $\mathbf{V}_{(U)}(\hat{\boldsymbol{\theta}}_{(U)})$, with unambiguous notation.

Predicted Values, PRESS Residual, and PRESS Statistic

An unconditional predicted value is $\hat{y}_i = \mathbf{x}_i' \hat{\boldsymbol{\beta}}$, where the vector \mathbf{x}_i is the i th row of \mathbf{X} . The (raw) residual is given as $\hat{\epsilon}_i = y_i - \hat{y}_i$, and the PRESS *residual* is

$$\hat{\epsilon}_{i(U)} = y_i - \mathbf{x}_i' \hat{\boldsymbol{\beta}}_{(U)}$$

The PRESS *statistic* is the sum of the squared PRESS residuals,

$$PRESS = \sum_{i \in U} \hat{\epsilon}_{i(U)}^2$$

where the sum is over the observations in U .

If **EFFECT=**, **SIZE=**, or **KEEP=** is not specified, PROC MIXED computes the PRESS residual for each observation selected through **SELECT=** (or all observations if **SELECT=** is not given). If **EFFECT=**, **SIZE=**, or **KEEP=** is specified, the procedure computes PRESS.

Leverage

For the general mixed model, leverage can be defined through the projection matrix that results from a transformation of the model with the inverse of the Cholesky decomposition of \mathbf{V} , or through an oblique projector. The MIXED procedure follows the latter path in the computation of influence diagnostics. The leverage value reported for the i th observation is the i th diagonal entry of the matrix

$$\mathbf{H} = \mathbf{X}(\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}$$

which is the weight of the observation in contributing to its own predicted value, $\mathbf{H} = d\hat{\mathbf{Y}}/d\mathbf{Y}$.

While \mathbf{H} is idempotent, it is generally not symmetric and thus not a projection matrix in the narrow sense.

The properties of these leverages are generalizations of the properties in models with diagonal variance-covariance matrices. For example, $\hat{\mathbf{Y}} = \mathbf{H}\mathbf{Y}$, and in a model with intercept and $\mathbf{V} = \sigma^2\mathbf{I}$, the leverage values

$$h_{ii} = \mathbf{x}_i'(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_i$$

are $h_{ii}^l = 1/n \leq h_{ii} \leq 1 = h_{ii}^u$ and $\sum_{i=1}^n h_{ii} = \text{rank}(\mathbf{X})$. The lower bound for h_{ii} is achieved in an intercept-only model, and the upper bound is achieved in a saturated model. The trace of \mathbf{H} equals the rank of \mathbf{X} .

If v_{ij} denotes the element in row i , column j of \mathbf{V}^{-1} , then for a model containing only an intercept the diagonal elements of \mathbf{H} are

$$h_{ii} = \frac{\sum_{j=1}^n v_{ij}}{\sum_{i=1}^n \sum_{j=1}^n v_{ij}}$$

Because $\sum_{j=1}^n v_{ij}$ is a sum of elements in the i th row of the *inverse* variance-covariance matrix, h_{ii} can be negative, even if the correlations among data points are nonnegative. In case of a saturated model with $\mathbf{X} = \mathbf{I}$, $h_{ii} = 1.0$.

Internally and Externally Studentized Residuals

See the section “Residual Diagnostics” on page 4976 for the distinction between standardization, studentization, and scaling of residuals. Internally studentized marginal and conditional residuals are computed with the **RESIDUAL** option of the **MODEL** statement. The **INFLUENCE** option computes internally and externally studentized marginal residuals.

The computation of internally studentized residuals relies on the diagonal entries of $\mathbf{V}(\hat{\boldsymbol{\theta}}) - \mathbf{Q}(\hat{\boldsymbol{\theta}})$, where $\mathbf{Q}(\hat{\boldsymbol{\theta}}) = \mathbf{X}(\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X})^{-1}\mathbf{X}'$. Externally studentized residuals require iterative influence analysis or a profiled residual variance. In the former case the studentization is based on $\mathbf{V}(\hat{\boldsymbol{\theta}}_U)$; in the latter case it is based on $\sigma_{(U)}^2 \mathbf{V}(\hat{\boldsymbol{\theta}}^*)$.

Cook's *D*

Cook's *D* statistic is an invariant norm that measures the influence of observations in *U* on a vector of parameter estimates (Cook 1977). In case of the fixed-effects coefficients, let

$$\boldsymbol{\delta}_{(U)} = \hat{\boldsymbol{\beta}} - \hat{\boldsymbol{\beta}}_{(U)}$$

Then the MIXED procedure computes

$$D(\boldsymbol{\beta}) = \boldsymbol{\delta}_{(U)}' \widehat{\text{Var}}[\hat{\boldsymbol{\beta}}]^{-} \boldsymbol{\delta}_{(U)} / \text{rank}(\mathbf{X})$$

where $\widehat{\text{Var}}[\hat{\boldsymbol{\beta}}]^{-}$ is the matrix that results from sweeping $(\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X})^{-}$.

If \mathbf{V} is known, Cook's *D* can be calibrated according to a chi-square distribution with degrees of freedom equal to the rank of \mathbf{X} (Christensen, Pearson, and Johnson 1992). For estimated \mathbf{V} the calibration can be carried out according to an $F(\text{rank}(\mathbf{X}), n - \text{rank}(\mathbf{X}))$ distribution. To interpret *D* on a familiar scale, Cook (1979) and Cook and Weisberg (1982, p. 116) refer to the 50th percentile of the reference distribution. If *D* is equal to that percentile, then removing the points in *U* moves the fixed-effects coefficient vector from the center of the confidence region to the 50% confidence ellipsoid (Myers 1990, p. 262).

In the case of iterative influence analysis, the MIXED procedure also computes a *D*-type statistic for the covariance parameters. If $\boldsymbol{\Gamma}$ is the asymptotic variance-covariance matrix of $\hat{\boldsymbol{\theta}}$, then MIXED computes

$$D_{\boldsymbol{\theta}} = (\hat{\boldsymbol{\theta}} - \hat{\boldsymbol{\theta}}_{(U)})' \hat{\boldsymbol{\Gamma}}^{-1} (\hat{\boldsymbol{\theta}} - \hat{\boldsymbol{\theta}}_{(U)})$$

DFFITS and MDFFITS

A DFFIT measures the change in predicted values due to removal of data points. If this change is standardized by the externally estimated standard error of the predicted value in the full data, the DFFITS statistic of Belsley, Kuh, and Welsch (1980, p. 15) results:

$$\text{DFFITS}_i = (\hat{y}_i - \hat{y}_{i(u)}) / \text{ese}(\hat{y}_i)$$

The MIXED procedure computes DFFITS when the **EFFECT=** or **SIZE=** modifier of the **INFLUENCE** option is not in effect. In general, an external estimate of the estimated standard error is used. When **ITER** > 0, the estimate is

$$\text{ese}(\hat{y}_i) = \sqrt{\mathbf{x}_i' (\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}}_{(u)})^{-1}\mathbf{X})^{-1} \mathbf{x}_i}$$

When **ITER**=0 and σ^2 is profiled, then

$$\text{ese}(\hat{y}_i) = \hat{\sigma}_{(u)} \sqrt{\mathbf{x}_i' (\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}}^*)^{-1}\mathbf{X})^{-1} \mathbf{x}_i}$$

When the **EFFECT=**, **SIZE=**, or **KEEP=** modifier is specified, the MIXED procedure computes a multivariate version suitable for the deletion of multiple data points. The statistic, termed MDFFITS after the MDFFIT statistic of Belsley, Kuh, and Welsch (1980, p. 32), is closely related to Cook's D . Consider the case $\mathbf{V} = \sigma^2 \mathbf{V}(\boldsymbol{\theta}^*)$ so that

$$\text{Var}[\hat{\boldsymbol{\beta}}] = \sigma^2 (\mathbf{X}' \mathbf{V}(\boldsymbol{\theta}^*)^{-1} \mathbf{X})^{-}$$

and let $\widetilde{\text{Var}}[\hat{\boldsymbol{\beta}}_{(U)}]$ be an estimate of $\text{Var}[\hat{\boldsymbol{\beta}}_{(U)}]$ that does not use the observations in U . The MDFFITS statistic is then computed as

$$\text{MDFFITS}(\boldsymbol{\beta}) = \boldsymbol{\delta}'_{(U)} \widetilde{\text{Var}}[\hat{\boldsymbol{\beta}}_{(U)}]^{-} \boldsymbol{\delta}_{(U)} / \text{rank}(\mathbf{X})$$

If **ITER=0** and σ^2 is profiled, then $\widetilde{\text{Var}}[\hat{\boldsymbol{\beta}}_{(U)}]^{-}$ is obtained by sweeping

$$\hat{\sigma}^2_{(U)} (\mathbf{X}'_{(U)} \mathbf{V}_{(U)} (\hat{\boldsymbol{\theta}}^*)^{-} \mathbf{X}_{(U)})^{-}$$

The underlying idea is that if $\boldsymbol{\theta}^*$ were known, then

$$(\mathbf{X}'_{(U)} \mathbf{V}_{(U)} (\boldsymbol{\theta}^*)^{-1} \mathbf{X}_{(U)})^{-}$$

would be $\text{Var}[\hat{\boldsymbol{\beta}}]/\sigma^2$ in a generalized least squares regression with all but the data in U .

In the case of iterative influence analysis, $\widetilde{\text{Var}}[\hat{\boldsymbol{\beta}}_{(U)}]$ is evaluated at $\hat{\boldsymbol{\theta}}_{(U)}$. Furthermore, a MDFFITS-type statistic is then computed for the covariance parameters:

$$\text{MDFFITS}(\boldsymbol{\theta}) = (\hat{\boldsymbol{\theta}} - \hat{\boldsymbol{\theta}}_{(U)})' \widehat{\text{Var}}[\hat{\boldsymbol{\theta}}_{(U)}]^{-1} (\hat{\boldsymbol{\theta}} - \hat{\boldsymbol{\theta}}_{(U)})$$

Covariance Ratio and Trace

These statistics depend on the availability of an external estimate of \mathbf{V} , or at least of σ^2 . Whereas Cook's D and MDFFITS measure the impact of data points on a vector of parameter estimates, the covariance-based statistics measure impact on their precision. Following Christensen, Pearson, and Johnson (1992), the MIXED procedure computes

$$\text{CovTrace}(\boldsymbol{\beta}) = |\text{trace}(\widehat{\text{Var}}[\hat{\boldsymbol{\beta}}]^{-} \widetilde{\text{Var}}[\hat{\boldsymbol{\beta}}_{(U)}]) - \text{rank}(\mathbf{X})|$$

$$\text{CovRatio}(\boldsymbol{\beta}) = \frac{\det_{ns}(\widetilde{\text{Var}}[\hat{\boldsymbol{\beta}}_{(U)}])}{\det_{ns}(\widehat{\text{Var}}[\hat{\boldsymbol{\beta}}])}$$

where $\det_{ns}(\mathbf{M})$ denotes the determinant of the nonsingular part of matrix \mathbf{M} .

In the case of iterative influence analysis these statistics are also computed for the covariance parameter estimates. If q denotes the rank of $\text{Var}[\hat{\boldsymbol{\theta}}]$, then

$$\text{CovTrace}(\boldsymbol{\theta}) = |\text{trace}(\widehat{\text{Var}}[\hat{\boldsymbol{\theta}}]^{-} \widehat{\text{Var}}[\hat{\boldsymbol{\theta}}_{(U)}]) - q|$$

$$\text{CovRatio}(\boldsymbol{\theta}) = \frac{\det_{ns}(\widehat{\text{Var}}[\hat{\boldsymbol{\theta}}_{(U)}])}{\det_{ns}(\widehat{\text{Var}}[\hat{\boldsymbol{\theta}}])}$$

Likelihood Distances

The log-likelihood function l and restricted log-likelihood function l_R of the linear mixed model are given in the section “Estimating Covariance Parameters in the Mixed Model” on page 4964. Denote as ψ the collection of all parameters, i.e., the fixed effects β and the covariance parameters θ . Twice the difference between the (restricted) log-likelihood evaluated at the full-data estimates $\hat{\psi}$ and at the reduced-data estimates $\hat{\psi}_{(U)}$ is known as the (restricted) likelihood distance:

$$\begin{aligned} \text{RLD}_{(U)} &= 2\{l_R(\hat{\psi}) - l_R(\hat{\psi}_{(U)})\} \\ \text{LD}_{(U)} &= 2\{l(\hat{\psi}) - l(\hat{\psi}_{(U)})\} \end{aligned}$$

Cook and Weisberg (1982, Ch. 5.2) refer to these differences as *likelihood distances*, Beckman, Nachtsheim, and Cook (1987) call the measures *likelihood displacements*. If the number of elements in ψ that are subject to updating following point removal is q , then likelihood displacements can be compared against cutoffs from a chi-square distribution with q degrees of freedom. Notice that this reference distribution does not depend on the number of observations removed from the analysis, but rather on the number of model parameters that are updated. The likelihood displacement gives twice the amount by which the log likelihood of the full data changes if one were to use an estimate based on fewer data points. It is thus a global, summary measure of the influence of the observations in U jointly on all parameters.

Unless **METHOD=ML**, the MIXED procedure computes the likelihood displacement based on the residual (=restricted) log likelihood, even if **METHOD=MIVQUE0** or **METHOD=TYPE1**, **TYPE2**, or **TYPE3**.

Noniterative Update Formulas

Update formulas that do not require refitting of the model are available for the cases where $\mathbf{V} = \sigma^2\mathbf{I}$, \mathbf{V} is known, or \mathbf{V}^* is known. When **ITER=0** and these update formulas can be invoked, the MIXED procedure uses the computational devices that are outlined in the following paragraphs. It is then assumed that the variance-covariance matrix of the fixed effects has the form $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^-$. When **DDFM=KENWARDROGER**, this is not the case; the estimated variance-covariance matrix is then inflated to better represent the uncertainty in the estimated covariance parameters. Influence statistics when **DDFM=KENWARDROGER** should iteratively update the covariance parameters (**ITER** > 0). The dependence of \mathbf{V} on θ is suppressed in the sequel for brevity.

Updating the Fixed Effects Denote by \mathbf{U} the $(n \times k)$ matrix that is assembled from k columns of the identity matrix. Each column of \mathbf{U} corresponds to the removal of one data point. The point being targeted by the i th column of \mathbf{U} corresponds to the row in which a 1 appears. Furthermore, define

$$\begin{aligned} \mathbf{\Omega} &= (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^- \\ \mathbf{Q} &= \mathbf{X}\mathbf{\Omega}\mathbf{X}' \\ \mathbf{P} &= \mathbf{V}^{-1}(\mathbf{V} - \mathbf{Q})\mathbf{V}^{-1} \end{aligned}$$

The change in the fixed-effects estimates following removal of the observations in U is

$$\hat{\beta} - \hat{\beta}_{(U)} = \mathbf{\Omega}\mathbf{X}'\mathbf{V}^{-1}\mathbf{U}(\mathbf{U}'\mathbf{P}\mathbf{U})^{-1}\mathbf{U}'\mathbf{V}^{-1}(\mathbf{y} - \mathbf{X}\hat{\beta})$$

Using results in Cook and Weisberg (1982, A2) you can further compute

$$\tilde{\mathbf{\Omega}} = (\mathbf{X}'_{(U)}\mathbf{V}_{(U)}^{-1}\mathbf{X}_{(U)})^- = \mathbf{\Omega} + \mathbf{\Omega}\mathbf{X}'\mathbf{V}^{-1}\mathbf{U}(\mathbf{U}'\mathbf{P}\mathbf{U})^{-1}\mathbf{U}'\mathbf{V}^{-1}\mathbf{X}\mathbf{\Omega}$$

If \mathbf{X} is $(n \times p)$ of rank $m < p$, then $\mathbf{\Omega}$ is deficient in rank and the MIXED procedure computes needed quantities in $\tilde{\mathbf{\Omega}}$ by sweeping (Goodnight 1979). If the rank of the $(k \times k)$ matrix $\mathbf{U}'\mathbf{P}\mathbf{U}$ is less than k , the removal

of the observations introduces a new singularity, whether \mathbf{X} is of full rank or not. The solution vectors $\hat{\boldsymbol{\beta}}$ and $\hat{\boldsymbol{\beta}}_{(U)}$ then do not have the same expected values and should not be compared. When the MIXED procedure encounters this situation, influence diagnostics that depend on the choice of generalized inverse are not computed. The procedure also monitors the singularity criteria when sweeping the rows of $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-}$ and of $(\mathbf{X}'_{(U)}\mathbf{V}_{(U)}^{-1}\mathbf{X}_{(U)})^{-}$. If a new singularity is encountered or a former singularity disappears, no influence statistics are computed.

Residual Variance When σ^2 is profiled out of the marginal variance-covariance matrix, a closed-form estimate of σ^2 that is based on only the remaining observations can be computed provided $\mathbf{V}^* = \mathbf{V}(\hat{\boldsymbol{\theta}}^*)$ is known. Hurtado (1993, Thm. 5.2) shows that

$$(n - q - r)\hat{\sigma}_{(U)}^2 = (n - q)\hat{\sigma}^2 - \hat{\boldsymbol{\epsilon}}_U'(\hat{\sigma}^2\mathbf{U}'\mathbf{P}\mathbf{U})^{-1}\hat{\boldsymbol{\epsilon}}_U$$

and $\hat{\boldsymbol{\epsilon}}_U = \mathbf{U}'\mathbf{V}^{*-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})$. In the case of maximum likelihood estimation $q = 0$ and for REML estimation $q = \text{rank}(\mathbf{X})$. The constant r equals the rank of $(\mathbf{U}'\mathbf{P}\mathbf{U})$ for REML estimation and the number of effective observations that are removed if **METHOD=ML**.

Likelihood Distances For noniterative methods the following computational devices are used to compute (restricted) likelihood distances provided that the residual variance σ^2 is profiled.

The log likelihood function $l(\hat{\boldsymbol{\theta}})$ evaluated at the full-data and reduced-data estimates can be written as

$$\begin{aligned} l(\hat{\boldsymbol{\psi}}) &= -\frac{n}{2}\log(\hat{\sigma}^2) - \frac{1}{2}\log|\mathbf{V}^*| - \frac{1}{2}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})' \mathbf{V}^{*-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})/\hat{\sigma}^2 - \frac{n}{2}\log(2\pi) \\ l(\hat{\boldsymbol{\psi}}_{(U)}) &= -\frac{n}{2}\log(\hat{\sigma}_{(U)}^2) - \frac{1}{2}\log|\mathbf{V}^*| - \frac{1}{2}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{(U)})' \mathbf{V}^{*-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{(U)})/\hat{\sigma}_{(U)}^2 - \frac{n}{2}\log(2\pi) \end{aligned}$$

Notice that $l(\hat{\boldsymbol{\theta}}_{(U)})$ evaluates the log likelihood for n data points at the reduced-data estimates. It is not the log likelihood obtained by fitting the model to the reduced data. The likelihood distance is then

$$\text{LD}_{(U)} = n \log \left\{ \frac{\hat{\sigma}_{(U)}^2}{\hat{\sigma}^2} \right\} - n + (\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{(U)})' \mathbf{V}^{*-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{(U)})/\hat{\sigma}_{(U)}^2$$

Expressions for $\text{RLD}_{(U)}$ in noniterative influence analysis are derived along the same lines.

Default Output

The following sections describe the output PROC MIXED produces by default. This output is organized into various tables, and they are discussed in order of appearance.

Model Information

The “Model Information” table describes the model, some of the variables it involves, and the method used in fitting it. It also lists the method (profile, factor, parameter, or none) for handling the residual variance in the model. The *profile* method concentrates the residual variance out of the optimization problem, whereas the *parameter* method retains it as a parameter in the optimization. The *factor* method keeps the residual fixed, and *none* is displayed when a residual variance is not part of the model.

The “Model Information” table also has a row labeled Fixed Effects SE Method. This row describes the method used to compute the approximate standard errors for the fixed-effects parameter estimates and related functions of them. The two possibilities for this row are Model-Based, which is the default method, and Empirical, which results from using the **EMPIRICAL** option in the **PROC MIXED** statement.

The ODS name of the “Model Information” table is ModelInfo.

Class Level Information

The “Class Level Information” table lists the levels of every variable specified in the **CLASS** statement. You should check this information to make sure the data are correct. You can adjust the order of the **CLASS** variable levels with the **ORDER=** option in the **PROC MIXED** statement. The ODS name of the “Class Level Information” table is ClassLevels.

Dimensions

The “Dimensions” table lists the sizes of relevant matrices. This table can be useful in determining CPU time and memory requirements. The ODS name of the “Dimensions” table is Dimensions.

Number of Observations

The “Number of Observations” table shows the number of observations read from the data set and the number of observations used in fitting the model.

Iteration History

The “Iteration History” table describes the optimization of the **residual log likelihood or log likelihood**. The function to be minimized (the *objective function*) is $-2l$ for ML and $-2l_R$ for REML; the column name of the objective function in the “Iteration History” table is “-2 Log Like” for ML and “-2 Res Log Like” for REML. The minimization is performed by using a ridge-stabilized Newton-Raphson algorithm, and the rows of this table describe the iterations that this algorithm takes in order to minimize the objective function.

The Evaluations column of the “Iteration History” table tells how many times the objective function is evaluated during each iteration.

The Criterion column of the “Iteration History” table is, by default, a relative Hessian convergence quantity given by

$$\frac{\mathbf{g}_k' \mathbf{H}_k^{-1} \mathbf{g}_k}{|f_k|}$$

where f_k is the value of the objective function at iteration k , \mathbf{g}_k is the gradient (first derivative) of f_k , and \mathbf{H}_k is the Hessian (second derivative) of f_k . If \mathbf{H}_k is singular, then PROC MIXED uses the following relative quantity:

$$\frac{\mathbf{g}_k' \mathbf{g}_k}{|f_k|}$$

To prevent the division by $|f_k|$, use the **ABSOLUTE** option in the **PROC MIXED** statement. To use a relative function or gradient criterion, use the **CONVF** or **CONVG** option, respectively.

The Hessian criterion is considered superior to function and gradient criteria because it measures orthogonality rather than lack of progress (Bates and Watts 1988). Provided the initial estimate is feasible and the maximum number of iterations is not exceeded, the Newton-Raphson algorithm is considered to have converged when the criterion is less than the tolerance specified with the [CONVF](#), [CONVG](#), or [CONVH](#) option in the [PROC MIXED](#) statement. The default tolerance is $1\text{E}-8$. If convergence is not achieved, PROC MIXED displays the estimates of the parameters at the last iteration.

A convergence criterion that is missing indicates that a boundary constraint has been dropped; it is usually not a cause for concern.

If you specify the [ITDETAILS](#) option in the [PROC MIXED](#) statement, then the covariance parameter estimates at each iteration are included as additional columns in the “Iteration History” table.

The ODS name of the “Iteration History” table is IterHistory.

Convergence Status

The “Convergence Status” table informs about the status of the iterative estimation process at the end of the Newton-Raphson optimization. It appears as a message in the listing, and this message is repeated in the log. The ODS object “ConvergenceStatus” also contains several nonprinting columns that can be helpful in checking the success of the iterative process, in particular during batch processing or when analyzing BY groups. The Status variable takes on the value 0 for a successful convergence (even if the Hessian matrix might not be positive definite). The values 1 and 2 of the Status variable indicate lack of convergence and infeasible initial parameter values, respectively. The variables pdG and pdH can be used to check whether the G and H (Hessian) matrices are positive definite.

For models that are not fit iteratively, such as models without random effects or when the [NOITER](#) option is in effect, the “Convergence Status” is not produced.

Covariance Parameter Estimates

The “Covariance Parameter Estimates” table contains the estimates of the parameters in **G** and **R** (see the section “[Estimating Covariance Parameters in the Mixed Model](#)” on page 4964). Their values are labeled in the table along with Subject and Group information if applicable. The estimates are displayed in the Estimate column and are the results of one of the following estimation methods: REML, ML, MIVQUE0, SSCP, Type1, Type2, or Type3.

If you specify the [RATIO](#) option in the [PROC MIXED](#) statement, the Ratio column is added to the table listing the ratio of each parameter estimate to that of the residual variance.

Specifying the [COVTEST](#) option in the [PROC MIXED](#) statement produces the “Std Error,” “Z Value,” and “Pr Z” columns. The “Std Error” column contains the approximate standard errors of the covariance parameter estimates. These are the square roots of the diagonal elements of the observed inverse Fisher information matrix, which equals $2\mathbf{H}^{-1}$, where **H** is the Hessian matrix. The **H** matrix consists of the second derivatives of the objective function with respect to the covariance parameters; see Wolfinger, Tobias, and Sall (1994) for formulas. When you use the [SCORING=](#) option and PROC MIXED converges without stopping the scoring algorithm, PROC MIXED uses the expected Hessian matrix to compute the covariance matrix instead of the observed Hessian. The observed or expected inverse Fisher information matrix can be viewed as an asymptotic covariance matrix of the estimates.

The “Z Value” column is the estimate divided by its approximate standard error, and the “Pr Z” column is the one- or two-tailed area of the standard Gaussian density outside of the Z-value. The MIXED procedure

computes one-sided p -values for the residual variance and for covariance parameters with a lower bound of 0. The procedure computes two-sided p -values otherwise. These statistics constitute Wald tests of the covariance parameters, and they are valid only asymptotically.

CAUTION: Wald tests can be unreliable in small samples.

The ODS name of the “Covariance Parameter Estimates” table is CovParms.

Fit Statistics

The “Fit Statistics” table provides some statistics about the estimated mixed model. Expressions for the -2 times the log likelihood are provided in the section “[Estimating Covariance Parameters in the Mixed Model](#)” on page 4964. If the log likelihood is an extremely large number, then PROC MIXED has deemed the estimated \mathbf{V} matrix to be singular. In this case, all subsequent results should be viewed with caution.

In addition, the “Fit Statistics” table lists three information criteria: AIC, AICC, and BIC, all in smaller-is-better form. Expressions for these criteria are described under the **IC** option.

The ODS name of the “Model Fitting Information” table is FitStatistics.

Null Model Likelihood Ratio Test

If one covariance model is a submodel of another, you can carry out a likelihood ratio test for the significance of the more general model by computing -2 times the difference between their log likelihoods. Then compare this statistic to the χ^2 distribution with degrees of freedom equal to the difference in the number of parameters for the two models.

This test is reported in the “Null Model Likelihood Ratio Test” table to determine whether it is necessary to model the covariance structure of the data at all. The “Chi-Square” value is -2 times the log likelihood from the null model minus -2 times the log likelihood from the fitted model, where the null model is the one with only the fixed effects listed in the **MODEL** statement and $\mathbf{R} = \sigma^2 \mathbf{I}$. This statistic has an asymptotic χ^2 distribution with $q - 1$ degrees of freedom, where q is the effective number of covariance parameters (those not estimated to be on a boundary constraint). The “Pr > ChiSq” column contains the upper-tail area from this distribution. This p -value can be used to assess the significance of the model fit.

This test is not produced for cases where the null hypothesis lies on the boundary of the parameter space, which is typically for variance component models. This is because the standard asymptotic theory does not apply in this case (Self and Liang 1987, Case 5).

If you specify a **PARMS** statement, PROC MIXED constructs a likelihood ratio test between the best model from the grid search and the final fitted model and reports the results in the “Parameter Search” table.

The ODS name of the “Null Model Likelihood Ratio Test” table is LRT.

Type 3 Tests of Fixed Effects

The “Type 3 Tests of Fixed Effects” table contains hypothesis tests for the significance of each of the fixed effects—that is, those effects you specify in the **MODEL** statement. By default, PROC MIXED computes these tests by first constructing a Type 3 **L** matrix (see Chapter 15, “[The Four Types of Estimable Functions](#)”) for each effect. This **L** matrix is then used to compute the following F statistic:

$$F = \frac{\hat{\beta}' \mathbf{L}' [\mathbf{L}(\mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{X})^{-1} \mathbf{L}]^{-1} \mathbf{L} \hat{\beta}}{r}$$

where $r = \text{rank}(\mathbf{L}(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{L}')$. A p -value for the test is computed as the tail area beyond this statistic from an F distribution with NDF and DDF degrees of freedom. The numerator degrees of freedom (NDF) are the row rank of \mathbf{L} , and the denominator degrees of freedom are computed by using one of the methods described under the **DDFM=** option. Small values of the p -value (typically less than 0.05 or 0.01) indicate a significant effect.

You can use the **HTYPE=** option in the **MODEL** statement to obtain tables of Type 1 (sequential) tests and Type 2 (adjusted) tests in addition to or instead of the table of Type 3 (partial) tests.

You can use the **CHISQ** option in the **MODEL** statement to obtain Wald χ^2 tests of the fixed effects. These are carried out by using the numerator of the F statistic and comparing it with the χ^2 distribution with NDF degrees of freedom. It is more liberal than the F test because it effectively assumes infinite denominator degrees of freedom.

The ODS names of the “Type 1 Tests of Fixed Effects” through the “Type 3 Tests of Fixed Effects” tables are Tests1 through Tests3, respectively.

ODS Table Names

Each table created by PROC MIXED has a name associated with it, and you must use this name to reference the table when using ODS statements. These names are listed in Table 59.26.

Table 59.26 ODS Tables Produced by PROC MIXED

Table Name	Description	Required Statement / Option
AccRates	Acceptance rates for posterior sampling	PRIOR
AsyCorr	Asymptotic correlation matrix of covariance parameters	PROC MIXED ASYCORR
AsyCov	Asymptotic covariance matrix of covariance parameters	PROC MIXED ASYCOV
Base	Base densities used for posterior sampling	PRIOR
Bound	Computed bound for posterior rejection sampling	PRIOR
CholG	Cholesky root of the estimated \mathbf{G} matrix	RANDOM / GC
CholR	Cholesky root of blocks of the estimated \mathbf{R} matrix	REPEATED / RC
CholV	Cholesky root of blocks of the estimated \mathbf{V} matrix	RANDOM / VC
ClassLevels	Level information from the CLASS statement	Default output
Coef	\mathbf{L} matrix coefficients	E option in MODEL , CONTRAST , ESTIMATE , or LSMEANS
Contrasts	Results from the CONTRAST statements	CONTRAST

Table 59.26 continued

Table Name	Description	Required Statement / Option
ConvergenceStatus	Convergence status	Default
CorrB	Approximate correlation matrix of fixed-effects parameter estimates	MODEL / CORRB
CovB	Approximate covariance matrix of fixed-effects parameter estimates	MODEL / COVB
CovParms	Estimated covariance parameters	Default output
DiffS	Differences of LS-means	LSMEANS / DIFF (or PDIFF)
Dimensions	Dimensions of the model	Default output
Estimates	Results from ESTIMATE statements	ESTIMATE
FitStatistics	Fit statistics	Default
G	Estimated G matrix	RANDOM / G
GCorr	Correlation matrix from the estimated G matrix	RANDOM / GCORR
HLM1	Type 1 Hotelling-Lawley-McKeon tests of fixed effects	MODEL / HTYPE=1 and REPEATED / HLM TYPE=UN
HLM2	Type 2 Hotelling-Lawley-McKeon tests of fixed effects	MODEL / HTYPE=2 and REPEATED / HLM TYPE=UN
HLM3	Type 3 Hotelling-Lawley-McKeon tests of fixed effects	REPEATED / HLM TYPE=UN
HLPS1	Type 1 Hotelling-Lawley-Pillai-Samson tests of fixed effects	MODEL / HTYPE=1 and REPEATED / HLPS TYPE=UN
HLPS2	Type 2 Hotelling-Lawley-Pillai-Samson tests of fixed effects	MODEL / HTYPE=1 and REPEATED / HLPS TYPE=UN
HLPS3	Type 3 Hotelling-Lawley-Pillai-Samson tests of fixed effects	REPEATED / HLPS TYPE=UN
Influence	Influence diagnostics	MODEL / INFLUENCE
InfoCrit	Information criteria	PROC MIXED IC
InvCholG	Inverse Cholesky root of the estimated G matrix	RANDOM / GCI
InvCholR	Inverse Cholesky root of blocks of the estimated R matrix	REPEATED / RCI
InvCholV	Inverse Cholesky root of blocks of the estimated V matrix	RANDOM / VCI
InvCovB	Inverse of approximate covariance matrix of fixed-effects parameter estimates	MODEL / COVBI
InvG	Inverse of the estimated G matrix	RANDOM / GI
InvR	Inverse of blocks of the estimated R matrix	REPEATED / RI
InvV	Inverse of blocks of the estimated V matrix	RANDOM / VI
IterHistory	Iteration history	Default output

Table 59.26 *continued*

Table Name	Description	Required Statement / Option
LComponents	Single-degree-of-freedom estimates that correspond to rows of the L matrix for fixed effects	MODEL / LCOMPONENTS
LRT	Likelihood ratio test	Default output
LSMeans	LS-means	LSMEANS
MMEq	Mixed model equations	PROC MIXED MMEQ
MMEqSol	Mixed model equations solution	PROC MIXED MMEQSOL
ModelInfo	Model information	Default output
NObs	Number of observations read and used	Default output
ParmSearch	Parameter search values	PARMS
Posterior	Posterior sampling information	PRIOR
R	Blocks of the estimated R matrix	REPEATED / R
RCorr	Correlation matrix from blocks of the estimated R matrix	REPEATED / RCORR
Search	Posterior density search table	PRIOR / PSEARCH
Slices	Tests of LS-means slices	LSMEANS / SLICE=
SolutionF	Fixed-effects solution vector	MODEL / S
SolutionR	Random-effects solution vector	RANDOM / S
Tests1	Type 1 tests of fixed effects	MODEL / HTYPE=1
Tests2	Type 2 tests of fixed effects	MODEL / HTYPE=2
Tests3	Type 3 tests of fixed effects	Default output
Type1	Type 1 analysis of variance	PROC MIXED METHOD=TYPE1
Type2	Type 2 analysis of variance	PROC MIXED METHOD=TYPE2
Type3	Type 3 analysis of variance	PROC MIXED METHOD=TYPE3
Trans	Transformation of covariance parameters	PRIOR / PTRANS
V	Blocks of the estimated V matrix	RANDOM / V
VCorr	Correlation matrix from blocks of the estimated V matrix	RANDOM / VCORR

In Table 59.26, “Coef” refers to multiple tables produced by the **E**, **E1**, **E2**, or **E3** option in the **MODEL** statement and the **E** option in the **CONTRAST**, **ESTIMATE**, and **LSMEANS** statements. You can create one large data set of these tables with a statement similar to the following:

```
ods output Coef=c;
```

To create separate data sets, use the following statement:

```
ods output Coef(match_all)=c;
```

Here the resulting data sets are named **C**, **C1**, **C2**, etc. The same principles apply to data sets created from the “**R**,” “**CholR**,” “**InvCholR**,” “**RCorr**,” “**InvR**,” “**V**,” “**CholV**,” “**InvCholV**,” “**VCorr**,” and “**InvV**” tables.

In Table 59.26, the following changes have occurred from SAS 6. The “**Predicted**,” “**PredMeans**,” and “**Sample**” tables from SAS 6 no longer exist and have been replaced by output data sets; see descriptions

of the **MODEL** statement options **OUTP=** and **OUTPM=** and the **PRIOR** statement option **OUT=** for more details. The “ML” and “REML” tables from SAS 6 have been replaced by the “IterHistory” table. The “Tests,” “HLM,” and “HLPS” tables from SAS 6 have been renamed “Tests3,” “HLM3,” and “HLPS3,” respectively.

Table 59.27 lists the variable names associated with the data sets created when you use the ODS OUTPUT option in conjunction with the preceding tables. In Table 59.27, *n* is used to denote a generic number that depends on the particular data set and model you select, and it can assume a different value each time it is used (even within the same table). The phrase *model specific* appears in rows of the affected tables to indicate that columns in these tables depend on the variables you specify in the model.

CAUTION: There is a danger of name collisions with the variables in the *model specific* tables in Table 59.27 and variables in your input data set. You should avoid using input variables with the same names as the variables in these tables.

Table 59.27 Variable Names for the ODS Tables Produced in PROC MIXED

Table Name	Variables
AsyCorr	Row, CovParm, CovP1–CovPn
AsyCov	Row, CovParm, CovP1–CovPn
Base	Type, Parm1–Parmn

Some of the variables listed in [Table 59.27](#) are created only when you specify certain options in the relevant PROC MIXED statements.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Some graphs are produced by default; other graphs are produced by using statements and options.

ODS Graph Names

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC MIXED generates are listed in [Table 59.28](#), along with the required statements and options.

Table 59.28 Graphs Produced by PROC MIXED

ODS Graph Name	Plot Description	Statement or Option
Boxplot	Box plots	PLOTS=BOXPLOT
CovRatioPlot	CovRatio statistics for fixed effects or covariance parameters	PLOTS=INFLUENCESTATPANEL(UNPACK) and MODEL / INFLUENCE
CooksDPlot	Cook’s <i>D</i> for fixed effects or covariance parameters	PLOTS=INFLUENCESTATPANEL(UNPACK) and MODEL / INFLUENCE
DistancePlot	Likelihood or restricted likelihood distance	MODEL / INFLUENCE

Table 59.28 *continued*

ODS Graph Name	Plot Description	Statement or Option
InfluenceEstPlot	Panel of deletion estimates	MODEL / INFLUENCE(EST) or PLOTS=INFLUENCEESTPLOT and MODEL / INFLUENCE
InfluenceEstPlot	Parameter estimates after removing observation or sets of observations	PLOTS=INFLUENCEESTPLOT(UNPACK) and MODEL / INFLUENCE
InfluenceStatPanel	Panel of influence statistics	MODEL / INFLUENCE
PearsonBoxPlot	Box plot of Pearson residuals	PLOTS=PEARSONPANEL(UNPACK BOX)
PearsonByPredicted	Pearson residuals vs. predicted	PLOTS=PEARSONPANEL(UNPACK)
PearsonHistogram	Histogram of Pearson residuals	PLOTS=PEARSONPANEL(UNPACK)
PearsonPanel	Panel of Pearson residuals	MODEL / RESIDUAL
PearsonQQplot	<i>Q-Q</i> plot of Pearson residuals	PLOTS=PEARSONPANEL(UNPACK)
PressPlot	Plot of PRESS residuals or PRESS statistic	PLOTS=PRESS and MODEL / INFLUENCE
ResidualBoxplot	Box plot of (raw) residuals	PLOTS=RESIDUALPANEL(UNPACK BOX)
ResidualByPredicted	Residuals vs. predicted	PLOTS=RESIDUALPANEL(UNPACK)
ResidualHistogram	Histogram of raw residuals	PLOTS=RESIDUALPANEL(UNPACK)
ResidualPanel	Panel of (raw) residuals	MODEL / RESIDUAL
ResidualQQplot	<i>Q-Q</i> plot of raw residuals	PLOTS=RESIDUALPANEL(UNPACK)
ScaledBoxplot	Box plot of scaled residuals	PLOTS=VCIRYPANEL(UNPACK BOX)
ScaledByPredicted	Scaled residuals vs. predicted	PLOTS=VCIRYPANEL(UNPACK)
ScaledHistogram	Histogram of scaled residuals	PLOTS=VCIRYPANEL(UNPACK)
ScaledQQplot	<i>Q-Q</i> plot of scaled residuals	PLOTS=VCIRYPANEL(UNPACK)
StudentBoxplot	Box plot of studentized residuals	PLOTS=STUDENTPANEL(UNPACK BOX)
StudentByPredicted	Studentized residuals vs. predicted	PLOTS=STUDENTPANEL(UNPACK)
StudentHistogram	Histogram of studentized residuals	PLOTS=STUDENTPANEL(UNPACK)
StudentPanel	Panel of studentized residuals	MODEL / RESIDUAL
StudentQQplot	<i>Q-Q</i> plot of studentized residuals	PLOTS=STUDENTPANEL(UNPACK)
VCIRYPanel	Panel of scaled residuals	MODEL / VCIRY

Residual Plots

The MIXED procedure can generate panels of residual diagnostics. Each panel consists of a plot of residuals versus predicted values, a histogram with normal density overlaid, a Q-Q plot, and summary residual and fit statistics (Figure 59.15). The plots are produced even if the `OUTP=` and `OUTPM=` options in the `MODEL` statement are not specified. Residual panels can be generated for marginal and conditional raw, studentized, and Pearson residuals as well as for scaled residuals (see the section “Residual Diagnostics” on page 4976).

Recall the example in the section “Getting Started: MIXED Procedure” on page 4884. The following statements generate several 2×2 panels of residual graphs:

```
ods graphics on;
proc mixed data=heights plots=studentpanel(marginal conditional);
  class Family Gender;
  model Height = Gender / residual;
  random Family Family*Gender;
run;
ods graphics off;
```

The graphs are created when ODS Graphics is enabled. The panel of the studentized marginal residuals is shown in Figure 59.15, and the panel of the studentized conditional residuals is shown in Figure 59.16.

Figure 59.15 Panel of the Studentized (Marginal) Residuals

Since the fixed-effects part of the model comprises only an intercept and the gender effect, the marginal mean takes on only two values, one for each gender. The “Residual Statistics” inset in the lower-right corner provides descriptive statistics for the set of residuals that is displayed. Note that residuals in a mixed model do not necessarily sum to zero, even if the model contains an intercept.

Figure 59.16 Panel of the Conditional Studentized Residuals

Influence Plots

The graphical features of the MIXED procedure enable you to generate plots of influence diagnostics and of deletion estimates. The type and number of plots produced depend on your modifiers of the **INFLUENCE** option in the **MODEL** statement and on the **PLOTS=** option in the **PROC MIXED** statement. Plots related to covariance parameters are produced only when diagnostics are computed by iterative methods (**ITER=**). The estimates of the fixed effects—and covariance parameters when updates are iterative—are plotted when you specify the **ESTIMATES** modifier or when you request **PLOTS=INFLUENCEESTPLOT**.

Two basic types of influence panels are shown in Figure 59.17 and Figure 59.18. The diagnostics panel shows Cook’s *D* and CovRatio statistics for the fixed effects and the covariance parameters. For the SAS statements that produce these influence panels, see Example 59.8. In this example, the impact of subjects (Person) on the analysis is assessed. The Cook’s *D* statistic measures a subject’s impact on the estimates,

and the CovRatio statistic measures a subject's impact on the precision of the estimates. Separate statistics are computed for the fixed effects and the covariance parameters. The CovRatio statistic has a threshold of 1.0. Values larger than 1.0 indicate that precision of the estimates is lost by exclusion of the observations in question. Values smaller than 1.0 indicate that precision is gained by exclusion of the observations from the analysis. For example, it is evident from [Output 59.17](#) that person 20 has considerable impact on the covariance parameter estimates and moderate influence on the fixed-effects estimates. Furthermore, exclusion of this subject from the analysis increases the precision of the covariance parameters, whereas the effect on the precision of the fixed effects is minor.

[Output 59.18](#) shows another type of influence plot, a panel of the deletion estimates. Each plot within the panel corresponds to one of the model parameters. A reference line is drawn at the estimate based on the full data.

Figure 59.17 Influence Diagnostics

Figure 59.18 Deletion Estimates

Computational Issues

Computational Method

In addition to numerous matrix-multiplication routines, PROC MIXED frequently uses the sweep operator (Goodnight 1979) and the Cholesky root (Golub and Van Loan 1989). The routines perform a modified W transformation (Goodnight and Hemmerle 1979) for G-side likelihood calculations and a direct method for R-side likelihood calculations. For the Type 3 *F* tests, PROC MIXED uses the algorithm described in Chapter 42, “The GLM Procedure.”

PROC MIXED uses a ridge-stabilized Newton-Raphson algorithm to optimize either a full (ML) or residual (REML) likelihood function. The Newton-Raphson algorithm is preferred to the EM algorithm (Lindstrom and Bates 1988). PROC MIXED profiles the likelihood with respect to the fixed effects and also with respect to the residual variance whenever it appears reasonable to do so. The residual profiling can be avoided by using the NOPROFILE option of the PROC MIXED statement. PROC MIXED uses the MIVQUE0 method (Rao 1972; Giesbrecht 1989) to compute initial values.

The likelihoods that PROC MIXED optimizes are usually well-defined continuous functions with a single optimum. The Newton-Raphson algorithm typically performs well and finds the optimum in a few iterations. It is a quadratically converging algorithm, meaning that the error of the approximation near the optimum is squared at each iteration. The quadratic convergence property is evident when the convergence criterion drops to zero by factors of 10 or more.

Table 59.29 Notation for Order Calculations

Symbol	Number
p	Columns of X
g	Columns of Z
N	Observations
q	Covariance parameters
t	Maximum observations per subject
S	Subjects

Using the notation from Table 59.29, the following are estimates of the computational speed of the algorithms used in PROC MIXED. For likelihood calculations, the crossproducts matrix construction is of order $N(p + g)^2$ and the sweep operations are of order $(p + g)^3$. The first derivative calculations for parameters in **G** are of order qg^3 for ML and $q(g^3 + pg^2 + p^2g)$ for REML. If you specify a subject effect in the **RANDOM** statement and if you are not using the **REPEATED** statement, then replace g with g/S and q with qS in these calculations. The first derivative calculations for parameters in **R** are of order $qS(t^3 + gt^2 + g^2t)$ for ML and $qS(t^3 + (p + g)t^2 + (p^2 + g^2)t)$ for REML. For the second derivatives, replace q with $q(q + 1)/2$ in the first derivative expressions. When you specify both **G**- and **R**-side parameters (that is, when you use both the **RANDOM** and **REPEATED** statements), then additional calculations are required of an order equal to the sum of the orders for **G** and **R**. Considerable execution times can result in this case.

For further details about the computational techniques used in PROC MIXED, see Wolfinger, Tobias, and Sall (1994).

Parameter Constraints

By default, some covariance parameters are assumed to satisfy certain boundary constraints during the Newton-Raphson algorithm. For example, variance components are constrained to be nonnegative, and autoregressive parameters are constrained to be between -1 and 1 . You can remove these constraints with the **NOBOUND** option in the **PARMS** statement (or with the **NOBOUND** option in the **PROC MIXED** statement), but this can lead to estimates that produce an infinite likelihood. You can also introduce or change boundary constraints with the **LOWERB=** and **UPPERB=** options in the **PARMS** statement.

During the Newton-Raphson algorithm, a parameter might be set equal to one of its boundary constraints for a few iterations and then it might move away from the boundary. You see a missing value in the Criterion column of the “Iteration History” table whenever a boundary constraint is dropped.

For some data sets the final estimate of a parameter might equal one of its boundary constraints. This is usually not a cause for concern, but it might lead you to consider a different model. For instance, a variance component estimate can equal zero; in this case, you might want to drop the corresponding random effect from the model. However, be aware that changing the model in this fashion can affect degrees-of-freedom calculations.

Convergence Problems

For some data sets, the Newton-Raphson algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data.

It is also possible for PROC MIXED to converge to a point that is not the global optimum of the likelihood, although this usually occurs only with the spatial covariance structures.

If you experience convergence problems, the following points might be helpful:

- One useful tool is the **PARMS** statement, which lets you input initial values for the covariance parameters and performs a grid search over the likelihood surface.
- Sometimes the Newton-Raphson algorithm does not perform well when two of the covariance parameters are on a different scale—that is, when they are several orders of magnitude apart. This is because the Hessian matrix is processed jointly for the two parameters, and elements of it corresponding to one of the parameters can become close to internal tolerances in PROC MIXED. In this case, you can improve stability by rescaling the effects in the model so that the covariance parameters are on the same scale.
- Data that are extremely large or extremely small can adversely affect results because of the internal tolerances in PROC MIXED. Rescaling it can improve stability.
- For stubborn problems, you might want to specify **ODS OUTPUT COVPARMS=*data-set-name*** to output the “Covariance Parameter Estimates” table as a precautionary measure. That way, if the problem does not converge, you can read the final parameter values back into a new run with the **PARMSDATA=** option in the **PARMS** statement.
- Fisher scoring can be more robust than Newton-Raphson with poor **MIVQUE(0)** starting values. Specifying a **SCORING=** value of 5 or so might help to recover from poor starting values.
- Tuning the singularity options **SINGULAR=**, **SINGCHOL=**, and **SINGRES=** in the **MODEL** statement can improve the stability of the optimization process.
- Tuning the **MAXITER=** and **MAXFUNC=** options in the **PROC MIXED** statement can save resources. Also, the **ITDETAILS** option displays the values of all the parameters at each iteration.
- Using the **NOPROFILE** and **NOBOUND** options in the **PROC MIXED** statement might help convergence, although they can produce unusual results.
- Although the **CONVH** convergence criterion usually gives the best results, you might want to try **CONVF** or **CONVG**, possibly along with the **ABSOLUTE** option.
- If the convergence criterion reaches a relatively small value such as $1\text{E}-7$ but never gets lower than $1\text{E}-8$, you might want to specify **CONVH=1E-6** in the **PROC MIXED** statement to get results; however, interpret the results with caution.
- An infinite likelihood during the iteration process means that the Newton-Raphson algorithm has stepped into a region where either the **R** or **V** matrix is nonpositive definite. This is usually no cause for concern as long as iterations continue. If PROC MIXED stops because of an infinite likelihood, recheck your model to make sure that no observations from the same subject are producing identical rows in **R** or **V** and that you have enough data to estimate the particular covariance structure you have selected. Any time that the final estimated likelihood is infinite, subsequent results should be interpreted with caution.

- A nonpositive definite Hessian matrix can indicate a surface saddlepoint or linear dependencies among the parameters.
- A warning message about the singularities of \mathbf{X} changing indicates that there is some linear dependency in the estimate of $\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X}$ that is not found in $\mathbf{X}'\mathbf{X}$. This can adversely affect the likelihood calculations and optimization process. If you encounter this problem, make sure that your model specification is reasonable and that you have enough data to estimate the particular covariance structure you have selected. Rearranging effects in the **MODEL** statement so that the most significant ones are first can help, because PROC MIXED sweeps the estimate of $\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}$ in the order of the **MODEL** effects and the sweep is more stable if larger pivots are dealt with first. If this does not help, specifying starting values with the **PARMS** statement can place the optimization on a different and possibly more stable path.
- Lack of convergence can indicate model misspecification or a violation of the normality assumption.

Memory

Let p be the number of columns in \mathbf{X} , and let g be the number of columns in \mathbf{Z} . For large models, most of the memory resources are required for holding symmetric matrices of order p , g , and $p + g$. The approximate memory requirement in bytes is

$$40(p^2 + g^2) + 32(p + g)^2$$

If you have a large model that exceeds the memory capacity of your computer, see the suggestions listed under “Computing Time.”

Computing Time

PROC MIXED is computationally intensive, and execution times can be long. In addition to the CPU time used in collecting sums and crossproducts and in solving the mixed model equations (as in PROC GLM), considerable CPU time is often required to compute the likelihood function and its derivatives. These latter computations are performed for every Newton-Raphson iteration.

If you have a model that takes too long to run, the following suggestions can be helpful:

- Examine the “Model Information” table to find out the number of columns in the \mathbf{X} and \mathbf{Z} matrices. A large number of columns in either matrix can greatly increase computing time. You might want to eliminate some higher-order effects if they are too large.
- If you have a \mathbf{Z} matrix with a lot of columns, use the **DDFM=BW** option in the **MODEL** statement to eliminate the time required for the containment method.
- If possible, “factor out” a common effect from the effects in the **RANDOM** statement and make it the **SUBJECT=** effect. This creates a block-diagonal \mathbf{G} matrix and can often speed calculations.
- If possible, use the same or nested **SUBJECT=** effects in all **RANDOM** and **REPEATED** statements.
- If your data set is very large, you might want to analyze it in pieces. The **BY** statement can help implement this strategy.

- In general, specify random effects with a lot of levels in the **REPEATED** statement and those with a few levels in the **RANDOM** statement.
- The **METHOD=MIVQUE0** option runs faster than either the **METHOD=REML** or **METHOD=ML** option because it is noniterative.
- You can specify known values for the covariance parameters by using the **HOLD=** or **NOITER** option in the **PARMS** statement or the **GDATA=** option in the **RANDOM** statement. This eliminates the need for iteration.
- The **LOGNOTE** option in the **PROC MIXED** statement writes periodic messages to the SAS log concerning the status of the calculations. It can help you diagnose where the slowdown is occurring.

Examples: MIXED Procedure

The following are basic examples of the use of PROC MIXED. More examples and details can be found in Littell et al. (2006); Wolfinger (1997); Verbeke and Molenberghs (1997, 2000); Murray (1998); Singer (1998); Sullivan, Dukes, and Losina (1999), and Brown and Prescott (1999).

Example 59.1: Split-Plot Design

PROC MIXED can fit a variety of mixed models. One of the most common mixed models is the split-plot design. The split-plot design involves two experimental factors, A and B. Levels of A are randomly assigned to whole plots (main plots), and levels of B are randomly assigned to split plots (subplots) within each whole plot. The design provides more precise information about B than about A, and it often arises when A can be applied only to large experimental units. An example is where A represents irrigation levels for large plots of land and B represents different crop varieties planted in each large plot.

Consider the following data from Stroup (1989a), which arise from a balanced split-plot design with the whole plots arranged in a randomized complete-block design. The variable A is the whole-plot factor, and the variable B is the subplot factor. A traditional analysis of these data involves the construction of the whole-plot error (A*Block) to test A and the pooled residual error (B*Block and A*B*Block) to test B and A*B. To carry out this analysis with PROC GLM, you must use a TEST statement to obtain the correct *F* test for A.

Performing a mixed model analysis with PROC MIXED eliminates the need for the error term construction. PROC MIXED estimates variance components for Block, A*Block, and the residual, and it automatically incorporates the correct error terms into test statistics.

The following statements create a DATA set for a split-plot design with four blocks, three whole-plot levels, and two subplot levels:

```
data sp;
  input Block A B Y @@;
  datalines;
1 1 1 56 1 1 2 41
1 2 1 50 1 2 2 36
```

```

1 3 1 39 1 3 2 35
2 1 1 30 2 1 2 25
2 2 1 36 2 2 2 28
2 3 1 33 2 3 2 30
3 1 1 32 3 1 2 24
3 2 1 31 3 2 2 27
3 3 1 15 3 3 2 19
4 1 1 30 4 1 2 25
4 2 1 35 4 2 2 30
4 3 1 17 4 3 2 18
;

```

The following statements fit the split-plot model assuming random block effects:

```

proc mixed;
  class A B Block;
  model Y = A B A*B;
  random Block A*Block;
run;

```

The variables A, B, and Block are listed as classification variables in the **CLASS** statement. The columns of model matrix **X** consist of indicator variables corresponding to the levels of the fixed effects A, B, and A*B listed on the right side of the **MODEL** statement. The dependent variable Y is listed on the left side of the **MODEL** statement.

The columns of the model matrix **Z** consist of indicator variables corresponding to the levels of the random effects Block and A*Block. The **G** matrix is diagonal and contains the variance components of Block and A*Block. The **R** matrix is also diagonal and contains the residual variance.

The SAS statements produce [Output 59.1.1–Output 59.1.8](#).

The “Model Information” table in [Output 59.1.1](#) lists basic information about the split-plot model. REML is used to estimate the variance components, and the residual variance is profiled from the optimization.

Output 59.1.1 Results for Split-Plot Analysis

The Mixed Procedure	
Model Information	
Data Set	WORK.SP
Dependent Variable	Y
Covariance Structure	Variance Components
Estimation Method	REML
Residual Variance Method	Profile
Fixed Effects SE Method	Model-Based
Degrees of Freedom Method	Containment

The “Class Level Information” table in [Output 59.1.2](#) lists the levels of all variables specified in the **CLASS** statement. You can check this table to make sure that the data are correct.

Output 59.1.2 Split-Plot Example (*continued*)

Class Level Information		
Class	Levels	Values
A	3	1 2 3
B	2	1 2
Block	4	1 2 3 4

The “Dimensions” table in [Output 59.1.3](#) lists the magnitudes of various vectors and matrices. The **X** matrix is seen to be 24×12 , and the **Z** matrix is 24×16 .

Output 59.1.3 Split-Plot Example (*continued*)

Dimensions	
Covariance Parameters	3
Columns in X	12
Columns in Z	16
Subjects	1
Max Obs Per Subject	24

The “Number of Observations” table in [Output 59.1.4](#) shows that all observations read from the data set are used in the analysis.

Output 59.1.4 Split-Plot Example (*continued*)

Number of Observations	
Number of Observations Read	24
Number of Observations Used	24
Number of Observations Not Used	0

PROC MIXED estimates the variance components for Block, A*Block, and the residual by REML. The REML estimates are the values that maximize the likelihood of a set of linearly independent error contrasts, and they provide a correction for the downward bias found in the usual maximum likelihood estimates. The objective function is -2 times the logarithm of the restricted likelihood, and PROC MIXED minimizes this objective function to obtain the estimates.

The minimization method is the Newton-Raphson algorithm, which uses the first and second derivatives of the objective function to iteratively find its minimum. The “Iteration History” table in [Output 59.1.5](#) records the steps of that optimization process. For this example, only one iteration is required to obtain the estimates. The Evaluations column reveals that the restricted likelihood is evaluated once for each of the iterations. A criterion of 0 indicates that the Newton-Raphson algorithm has converged.

Output 59.1.5 Split-Plot Analysis (*continued*)

Iteration History			
Iteration	Evaluations	-2 Res Log Like	Criterion
0	1	139.81461222	
1	1	119.76184570	0.00000000
Convergence criteria met.			

The REML estimates for the variance components of Block, A*Block, and the residual are 62.40, 15.38, and 9.36, respectively, as listed in the Estimate column of the “Covariance Parameter Estimates” table in [Output 59.1.6](#).

Output 59.1.6 Split-Plot Analysis (*continued*)

Covariance Parameter Estimates	
Cov Parm	Estimate
Block	62.3958
A*Block	15.3819
Residual	9.3611

The “Fit Statistics” table in [Output 59.1.7](#) lists several pieces of information about the fitted mixed model, including the residual log likelihood. The Akaike (AIC) and Bayesian (BIC) information criteria can be used to compare different models; the ones with smaller values are preferred. The AICC information criteria is a small-sample bias-adjusted form of the Akaike criterion (Hurvich and Tsai 1989).

Output 59.1.7 Split-Plot Analysis (*continued*)

Fit Statistics	
-2 Res Log Likelihood	119.8
AIC (smaller is better)	125.8
AICC (smaller is better)	127.5
BIC (smaller is better)	123.9

Finally, the fixed effects are tested by using Type 3 estimable functions ([Output 59.1.8](#)).

Output 59.1.8 Split-Plot Analysis (*continued*)

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
A	2	6	4.07	0.0764
B	1	9	19.39	0.0017
A*B	2	9	4.02	0.0566

The tests match the one obtained from the following PROC GLM statements:

```
proc glm data=sp;
  class A B Block;
  model Y = A B A*B Block A*Block;
  test h=A e=A*Block;
run;
```

You can continue this analysis by producing solutions for the fixed and random effects and then testing various linear combinations of them by using the [CONTRAST](#) and [ESTIMATE](#) statements. If you use the same CONTRAST and ESTIMATE statements with PROC GLM, the test statistics correspond to the fixed-effects-only model. The test statistics from PROC MIXED incorporate the random effects.

The various “inference space” contrasts given by Stroup (1989a) can be implemented via the [ESTIMATE](#) statement. Consider the following examples:

```
proc mixed data=sp;
  class A B Block;
  model Y = A B A*B;
  random Block A*Block;
  estimate 'al mean narrow'
    intercept 1 A 1 B .5 .5 A*B .5 .5 |
    Block      .25 .25 .25 .25
    A*Block    .25 .25 .25 .25 0 0 0 0 0 0 0;

  estimate 'al mean intermed'
    intercept 1 A 1 B .5 .5 A*B .5 .5 |
    Block      .25 .25 .25 .25;

  estimate 'al mean broad'
    intercept 1 a 1 b .5 .5 A*B .5 .5;
run;
```

These statements result in [Output 59.1.9](#).

Output 59.1.9 Inference Space Results

The Mixed Procedure					
Estimates					
Label	Estimate	Standard Error	DF	t Value	Pr > t
a1 mean narrow	32.8750	1.0817	9	30.39	<.0001
a1 mean intermed	32.8750	2.2396	9	14.68	<.0001
a1 mean broad	32.8750	4.5403	9	7.24	<.0001

Note that all the estimates are equal, but their standard errors increase with the size of the inference space. The narrow inference space consists of the observed levels of Block and A*Block, and the t -statistic value of 30.39 applies only to these levels. This is the same t statistic computed by PROC GLM, because it computes standard errors from the narrow inference space. The intermediate inference space consists of the observed levels of Block and the entire population of levels from which A*Block are sampled. The t -statistic value of 14.68 applies to this intermediate space. The broad inference space consists of arbitrary random levels of both Block and A*Block, and the t -statistic value of 7.24 is appropriate. Note that the larger the inference space, the weaker the conclusion. However, the broad inference space is usually the one of interest, and even in this space conclusive results are common. The highly significant p -value for 'a1 mean broad' is an example. You can also obtain the 'a1 mean broad' result by specifying A in an **LSMEANS** statement. For more discussion of the inference space concept, see McLean, Sanders, and Stroup (1991).

The following statements illustrate another feature of the **RANDOM** statement. Recall that the basic statements for a split-plot design with whole plots arranged in randomized blocks are as follows.

```
proc mixed;
  class A B Block;
  model Y = A B A*B;
  random Block A*Block;
run;
```

An equivalent way of specifying this model is as follows:

```
proc mixed data=sp;
  class A B Block;
  model Y = A B A*B;
  random intercept A / subject=Block;
run;
```

In general, if all of the effects in the **RANDOM** statement can be nested within one effect, you can specify that one effect by using the **SUBJECT=** option. The subject effect is, in a sense, “factored out” of the random effects. The specification that uses the **SUBJECT=** effect can result in faster execution times for large problems because PROC MIXED is able to perform the likelihood calculations separately for each subject.

Example 59.2: Repeated Measures

The following data are from Pothoff and Roy (1964) and consist of growth measurements for 11 girls and 16 boys at ages 8, 10, 12, and 14. Some of the observations are suspect (for example, the third observation for person 20); however, all of the data are used here for comparison purposes.

The analysis strategy employs a linear growth curve model for the boys and girls as well as a variance-covariance model that incorporates correlations for all of the observations arising from the same person. The data are assumed to be Gaussian, and their likelihood is maximized to estimate the model parameters. For overviews of this approach to repeated measures, see Jennrich and Schluchter (1986); Louis (1988); Crowder and Hand (1990); Diggle, Liang, and Zeger (1994); Everitt (1995). Jennrich and Schluchter present results for the Pothoff and Roy data from various covariance structures. The PROC MIXED statements to fit an unstructured variance matrix (their Model 2) are as follows:

```
data pr;
  input Person Gender $ y1 y2 y3 y4;
  y=y1; Age=8; output;
  y=y2; Age=10; output;
  y=y3; Age=12; output;
  y=y4; Age=14; output;
  drop y1-y4;
  datalines;
1   F   21.0    20.0    21.5    23.0
2   F   21.0    21.5    24.0    25.5
3   F   20.5    24.0    24.5    26.0
4   F   23.5    24.5    25.0    26.5
5   F   21.5    23.0    22.5    23.5
6   F   20.0    21.0    21.0    22.5
7   F   21.5    22.5    23.0    25.0
8   F   23.0    23.0    23.5    24.0
9   F   20.0    21.0    22.0    21.5
10  F   16.5    19.0    19.0    19.5
11  F   24.5    25.0    28.0    28.0
12  M   26.0    25.0    29.0    31.0
13  M   21.5    22.5    23.0    26.5
14  M   23.0    22.5    24.0    27.5
15  M   25.5    27.5    26.5    27.0
16  M   20.0    23.5    22.5    26.0
17  M   24.5    25.5    27.0    28.5
18  M   22.0    22.0    24.5    26.5
19  M   24.0    21.5    24.5    25.5
20  M   23.0    20.5    31.0    26.0
21  M   27.5    28.0    31.0    31.5
22  M   23.0    23.0    23.5    25.0
23  M   21.5    23.5    24.0    28.0
24  M   17.0    24.5    26.0    29.5
25  M   22.5    25.5    25.5    26.0
26  M   23.0    24.5    26.0    30.0
27  M   22.0    21.5    23.5    25.0
;
```

```
proc mixed data=pr method=ml covtest;
  class Person Gender;
  model y = Gender Age Gender*Age / s;
  repeated / type=un subject=Person r;
run;
```

To follow Jennrich and Schluchter, this example uses maximum likelihood (**METHOD=ML**) instead of the default REML to estimate the unknown covariance parameters. The **COVTEST** option requests asymptotic tests of all the covariance parameters.

The **MODEL** statement first lists the dependent variable *Y*. The fixed effects are then listed after the equal sign. The variable *Gender* requests a different intercept for the girls and boys, *Age* models an overall linear growth trend, and *Gender*Age* makes the slopes different over time. It is actually not necessary to specify *Age* separately, but doing so enables PROC MIXED to carry out a test for heterogeneous slopes. The **SOLUTION** option requests the display of the fixed-effects solution vector.

The **REPEATED** statement contains no effects, taking advantage of the default assumption that the observations are ordered similarly for each subject. The **TYPE=UN** option requests an unstructured block for each **SUBJECT=Person**. The **R** matrix is, therefore, block diagonal with 27 blocks, each block consisting of identical 4×4 unstructured matrices. The 10 parameters of these unstructured blocks make up the covariance parameters estimated by maximum likelihood. The **R** option requests that the first block of **R** be displayed.

The results from this analysis are shown in [Output 59.2.1–Output 59.2.9](#).

Output 59.2.1 Repeated Measures Analysis with Unstructured Covariance Matrix

The Mixed Procedure	
Model Information	
Data Set	WORK.PR
Dependent Variable	y
Covariance Structure	Unstructured
Subject Effect	Person
Estimation Method	ML
Residual Variance Method	None
Fixed Effects SE Method	Model-Based
Degrees of Freedom Method	Between-Within

In [Output 59.2.1](#), the covariance structure is listed as “Unstructured,” and no residual variance is used with this structure. The default degrees-of-freedom method here is “Between-Within.”

Output 59.2.2 Repeated Measures Analysis (*continued*)

Class Level Information													
Class	Levels	Values											
Person	27	1	2	3	4	5	6	7	8	9	10	11	12
		13	14	15	16	17	18	19	20	21	22	23	24
		25	26	27									
Gender	2	F	M										

In [Output 59.2.2](#), note that Person has 27 levels and Gender has 2.

Output 59.2.3 Repeated Measures Analysis (*continued*)

Dimensions	
Covariance Parameters	10
Columns in X	6
Columns in Z	0
Subjects	27
Max Obs Per Subject	4

In [Output 59.2.3](#), the 10 covariance parameters result from the 4×4 unstructured blocks of **R**. There is no **Z** matrix for this model, and each of the 27 subjects has a maximum of 4 observations.

Output 59.2.4 Repeated Measures Analysis (*continued*)

Number of Observations			
Number of Observations Read		108	
Number of Observations Used		108	
Number of Observations Not Used		0	
Iteration History			
Iteration	Evaluations	-2 Log Like	Criterion
0	1	478.24175986	
1	2	419.47721707	0.00000152
2	1	419.47704812	0.00000000
Convergence criteria met.			

Three Newton-Raphson iterations are required to find the maximum likelihood estimates ([Output 59.2.4](#)). The default relative Hessian criterion has a final value less than $1\text{E}-8$, indicating the convergence of the Newton-Raphson algorithm and the attainment of an optimum.

Output 59.2.5 Repeated Measures Analysis (*continued*)

Estimated R Matrix for Person 1				
Row	Col1	Col2	Col3	Col4
1	5.1192	2.4409	3.6105	2.5222
2	2.4409	3.9279	2.7175	3.0624
3	3.6105	2.7175	5.9798	3.8235
4	2.5222	3.0624	3.8235	4.6180

The 4×4 matrix in [Output 59.2.5](#) is the estimated unstructured covariance matrix. It is the estimate of the first block of **R**, and the other 26 blocks all have the same estimate.

Output 59.2.6 Repeated Measures Analysis (*continued*)

Covariance Parameter Estimates					
Cov Parm	Subject	Estimate	Standard Error	Z Value	Pr > Z
UN(1,1)	Person	5.1192	1.4169	3.61	0.0002
UN(2,1)	Person	2.4409	0.9835	2.48	0.0131
UN(2,2)	Person	3.9279	1.0824	3.63	0.0001
UN(3,1)	Person	3.6105	1.2767	2.83	0.0047
UN(3,2)	Person	2.7175	1.0740	2.53	0.0114
UN(3,3)	Person	5.9798	1.6279	3.67	0.0001
UN(4,1)	Person	2.5222	1.0649	2.37	0.0179
UN(4,2)	Person	3.0624	1.0135	3.02	0.0025
UN(4,3)	Person	3.8235	1.2508	3.06	0.0022
UN(4,4)	Person	4.6180	1.2573	3.67	0.0001

The “Covariance Parameter Estimates” table in [Output 59.2.6](#) lists the 10 estimated covariance parameters in order; note their correspondence to the first block of **R** displayed in [Output 59.2.5](#). The parameter estimates are labeled according to their location in the block in the Cov Parm column, and all of these estimates are associated with Person as the subject effect. The Std Error column lists approximate standard errors of the covariance parameters obtained from the inverse Hessian matrix. These standard errors lead to approximate Wald Z statistics, which are compared with the standard normal distribution. The results of these tests indicate that all the parameters are significantly different from 0; however, the Wald test can be unreliable in small samples.

To carry out Wald tests of various linear combinations of these parameters, use the following procedure. First, run the statements again, adding the **ASYCOV** option and an ODS statement:

```
ods output CovParms=cp AsyCov=asy;
proc mixed data=pr method=ml covtest asycov;
  class Person Gender;
  model y = Gender Age Gender*Age / s;
  repeated / type=un subject=Person r;
run;
```

This creates two data sets, `cp` and `asy`, which contain the covariance parameter estimates and their asymptotic variance covariance matrix, respectively. Then read these data sets into the SAS/IML matrix programming language as follows:

```
proc iml;
  use cp;
  read all var {Estimate} into est;
  use asy;
  read all var ('CovP1':'CovP10') into asy;
```

You can then construct your desired linear combinations and corresponding quadratic forms with the `asy` matrix.

Output 59.2.7 Repeated Measures Analysis (*continued*)

Fit Statistics		
-2 Log Likelihood		419.5
AIC (smaller is better)		447.5
AICC (smaller is better)		452.0
BIC (smaller is better)		465.6
Null Model Likelihood Ratio Test		
DF	Chi-Square	Pr > ChiSq
9	58.76	<.0001

The null model likelihood ratio test (LRT) in [Output 59.2.7](#) is highly significant for this model, indicating that the unstructured covariance matrix is preferred to the diagonal matrix of the ordinary least squares null model. The degrees of freedom for this test is 9, which is the difference between 10 and the 1 parameter for the null model's diagonal matrix.

Output 59.2.8 Repeated Measures Analysis (*continued*)

Solution for Fixed Effects						
Effect	Gender	Estimate	Standard Error	DF	t Value	Pr > t
Intercept		15.8423	0.9356	25	16.93	<.0001
Gender	F	1.5831	1.4658	25	1.08	0.2904
Gender	M	0
Age		0.8268	0.07911	25	10.45	<.0001
Age*Gender	F	-0.3504	0.1239	25	-2.83	0.0091
Age*Gender	M	0

The “Solution for Fixed Effects” table in [Output 59.2.8](#) lists the solution vector for the fixed effects. The estimate of the boys’ intercept is 15.8423, while that for the girls is $15.8423 + 1.5831 = 17.0654$. Similarly, the estimate for the boys’ slope is 0.8268, while that for the girls is $0.8268 - 0.3504 = 0.4764$. Thus the

girls' starting point is larger than that for the boys, but their growth rate is about half that of the boys.

Note that two of the estimates equal 0; this is a result of the overparameterized model used by PROC MIXED. You can obtain a full-rank parameterization by using the following **MODEL** statement:

```
model y = Gender Gender*Age / noint s;
```

Here, the **NOINT** option causes the different intercepts to be fit directly as the two levels of Gender. However, this alternative specification results in different tests for these effects.

Output 59.2.9 Repeated Measures Analysis (*continued*)

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
Gender	1	25	1.17	0.2904
Age	1	25	110.54	<.0001
Age*Gender	1	25	7.99	0.0091

The “Type 3 Tests of Fixed Effects” table in **Output 59.2.9** displays Type 3 tests for all of the fixed effects. These tests are partial in the sense that they account for all of the other fixed effects in the model. In addition, you can use the **HTYPE=** option in the **MODEL** statement to obtain Type 1 (sequential) or Type 2 (also partial) tests of effects.

It is usually best to consider higher-order terms first, and in this case the **Age*Gender** test reveals a difference between the slopes that is statistically significant at the 1% level. Note that the p -value for this test (0.0091) is the same as the p -value in the “Age*Gender F” row in the “Solution for Fixed Effects” table (**Output 59.2.8**) and that the F statistic (7.99) is the square of the t statistic (−2.83), ignoring rounding error. Similar connections are evident among the other rows in these two tables.

The **Age** test is one for an overall growth curve accounting for possible heterogeneous slopes, and it is highly significant. Finally, the **Gender** row tests the null hypothesis of a common intercept, and this hypothesis cannot be rejected from these data.

As an alternative to the F tests shown here, you can carry out likelihood ratio tests of various hypotheses by fitting the reduced models, subtracting $-2 \log$ likelihoods, and comparing the resulting statistics with χ^2 distributions.

Since the different levels of the repeated effect represent different years, it is natural to try fitting a time series model to the data within each subject. To obtain time series structures in **R**, you can replace **TYPE=UN** with **TYPE=AR(1)** or **TYPE=TOEP** to obtain the first- or n th-order autoregressive covariance matrices, respectively. For example, the statements to fit an AR(1) structure are as follows:

```
/* first-order autoregressive */
proc mixed data=pr method=ml;
  class Person Gender;
  model y = Gender Age Gender*Age / s;
  repeated / type=ar(1) sub=Person r;
run;
```

To fit a random coefficients model, use the following statements:

```

/* random coefficients model */
proc mixed data=pr method=ml;
  class Person Gender;
  model y = Gender Age Gender*Age / s;
  random intercept Age / type=un sub=Person g;
run;

```

This specifies an unstructured covariance matrix for the random intercept and slope. In mixed model notation, **G** is block diagonal with identical 2×2 unstructured blocks for each person. By default, **R** becomes $\sigma^2\mathbf{I}$. See [Example 59.5](#) for further information about this model.

Finally, you can fit a compound symmetry structure by using **TYPE=CS**, as follows:

```

proc mixed data=pr method=ml covtest;
  class Person Gender;
  model y = Gender Age Gender*Age / s;
  repeated / type=cs subject=Person r;
run;

```

The results from this analysis are shown in [Output 59.2.10–Output 59.2.17](#).

The “Model Information” table in [Output 59.2.10](#) is the same as before except for the change in “Covariance Structure.”

Output 59.2.10 Repeated Measures Analysis with Compound Symmetry Structure

The Mixed Procedure	
Model Information	
Data Set	WORK.PR
Dependent Variable	y
Covariance Structure	Compound Symmetry
Subject Effect	Person
Estimation Method	ML
Residual Variance Method	Profile
Fixed Effects SE Method	Model-Based
Degrees of Freedom Method	Between-Within

The “Dimensions” table in [Output 59.2.11](#) shows that there are only two covariance parameters in the compound symmetry model; this covariance structure has common variance and common covariance.

Output 59.2.11 Analysis with Compound Symmetry (*continued*)

Class Level Information		
Class	Levels	Values
Person	27	1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27
Gender	2	F M

Output 59.2.11 *continued*

Columns in Z	0
Subjects	27
Max Obs Per Subject	4
Number of Observations	
Number of Observations Read	108
Number of Observations Used	108
Number of Observations Not Used	0

Since the data are balanced, only one step is required to find the estimates ([Output 59.2.12](#)).

Output 59.2.12 Analysis with Compound Symmetry (*continued*)

Iteration History			
Iteration	Evaluations	-2 Log Like	Criterion
0	1	478.24175986	
1	1	428.63905802	0.00000000
Convergence criteria met.			

[Output 59.2.13](#) displays the estimated **R** matrix for the first subject. Note the compound symmetry structure here, which consists of a common covariance with a diagonal enhancement.

Output 59.2.13 Analysis with Compound Symmetry (*continued*)

Estimated R Matrix for Person 1				
Row	Col1	Col2	Col3	Col4
1	4.9052	3.0306	3.0306	3.0306
2	3.0306	4.9052	3.0306	3.0306
3	3.0306	3.0306	4.9052	3.0306
4	3.0306	3.0306	3.0306	4.9052

The common covariance is estimated to be 3.0306, as listed in the CS row of the “Covariance Parameter Estimates” table in [Output 59.2.14](#), and the residual variance is estimated to be 1.8746, as listed in the Residual row. You can use these two numbers to estimate the intraclass correlation coefficient (ICC) for this model. Here, the ICC estimate equals $3.0306 / (3.0306 + 1.8746) = 0.6178$. You can also obtain this

number by adding the **RCORR** option to the **REPEATED** statement.

Output 59.2.14 Analysis with Compound Symmetry (*continued*)

Covariance Parameter Estimates					
Cov Parm	Subject	Estimate	Standard Error	Z Value	Pr > Z
CS	Person	3.0306	0.9552	3.17	0.0015
Residual		1.8746	0.2946	6.36	<.0001

In the case shown in [Output 59.2.15](#), the null model LRT has only one degree of freedom, corresponding to the common covariance parameter. The test indicates that modeling this extra covariance is superior to fitting the simple null model.

Output 59.2.15 Analysis with Compound Symmetry (*continued*)

Fit Statistics		
-2 Log Likelihood		428.6
AIC (smaller is better)		440.6
AICC (smaller is better)		441.5
BIC (smaller is better)		448.4
Null Model Likelihood Ratio Test		
DF	Chi-Square	Pr > ChiSq
1	49.60	<.0001

Note that the fixed-effects estimates and their standard errors ([Output 59.2.16](#)) are not very different from those in the preceding unstructured example ([Output 59.2.8](#)).

Output 59.2.16 Analysis with Compound Symmetry (*continued*)

Solution for Fixed Effects						
Effect	Gender	Estimate	Standard Error	DF	t Value	Pr > t
Intercept		16.3406	0.9631	25	16.97	<.0001
Gender	F	1.0321	1.5089	25	0.68	0.5003
Gender	M	0
Age		0.7844	0.07654	79	10.25	<.0001
Age*Gender	F	-0.3048	0.1199	79	-2.54	0.0130
Age*Gender	M	0

The F tests shown in [Output 59.2.17](#) are also similar to those from the preceding unstructured example ([Output 59.2.9](#)). Again, the slopes are significantly different but the intercepts are not.

Output 59.2.17 Analysis with Compound Symmetry (*continued*)

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
Gender	1	25	0.47	0.5003
Age	1	79	111.10	<.0001
Age*Gender	1	79	6.46	0.0130

You can fit the same compound symmetry model with the following specification by using the [RANDOM](#) statement:

```
proc mixed data=pr method=ml;
  class Person Gender;
  model y = Gender Age Gender*Age / s;
  random Person;
run;
```

Compound symmetry is the structure that Jennrich and Schluchter deemed best among the ones they fit. To carry the analysis one step further, you can use the [GROUP=](#) option as follows to specify heterogeneity of this structure across girls and boys:

```
proc mixed data=pr method=ml;
  class Person Gender;
  model y = Gender Age Gender*Age / s;
  repeated / type=cs subject=Person group=Gender;
run;
```

The results from this analysis are shown in [Output 59.2.18–Output 59.2.24](#). Note that in [Output 59.2.18](#) Gender is listed as a “Group Effect.”

Output 59.2.18 Repeated Measures Analysis with Heterogeneous Structures

The Mixed Procedure	
Model Information	
Data Set	WORK.PR
Dependent Variable	y
Covariance Structure	Compound Symmetry
Subject Effect	Person
Group Effect	Gender
Estimation Method	ML
Residual Variance Method	None
Fixed Effects SE Method	Model-Based
Degrees of Freedom Method	Between-Within

The four covariance parameters listed in [Output 59.2.19](#) result from the two compound symmetry structures corresponding to the two levels of Gender.

Output 59.2.19 Analysis with Heterogeneous Structures (*continued*)

Class Level Information														
Class	Levels	Values												
Person	27	1	2	3	4	5	6	7	8	9	10	11	12	13
		14	15	16	17	18	19	20	21	22	23			
		24	25	26	27									
Gender	2	F	M											
Dimensions														
Covariance Parameters												4		
Columns in X												6		
Columns in Z												0		
Subjects												27		
Max Obs Per Subject												4		
Number of Observations														
Number of Observations Read												108		
Number of Observations Used												108		
Number of Observations Not Used												0		

As [Output 59.2.20](#) shows, even with the heterogeneity, only one iteration is required for convergence.

Output 59.2.20 Analysis with Heterogeneous Structures (*continued*)

Iteration History			
Iteration	Evaluations	-2 Log Like	Criterion
0	1	478.24175986	
1	1	408.81297228	0.00000000
Convergence criteria met.			

The “Covariance Parameter Estimates” table in [Output 59.2.21](#) lists the heterogeneous estimates. Note that both the common covariance and the diagonal enhancement differ between girls and boys.

Output 59.2.21 Analysis with Heterogeneous Structures (*continued*)

Covariance Parameter Estimates			
Cov Parm	Subject	Group	Estimate
Variance	Person	Gender F	0.5900
CS	Person	Gender F	3.8804
Variance	Person	Gender M	2.7577
CS	Person	Gender M	2.4463

As [Output 59.2.22](#) shows, both Akaike's information criterion (424.8) and Schwarz's Bayesian information criterion (435.2) are smaller for this model than for the homogeneous compound symmetry model (440.6 and 448.4, respectively). This indicates that the heterogeneous model is more appropriate. To construct the likelihood ratio test between the two models, subtract the $-2 \log$ likelihood values: $428.6 - 408.8 = 19.8$. Comparing this value with the χ^2 distribution with two degrees of freedom yields a p -value less than 0.0001, again favoring the heterogeneous model.

Output 59.2.22 Analysis with Heterogeneous Structures (*continued*)

Fit Statistics	
-2 Log Likelihood	408.8
AIC (smaller is better)	424.8
AICC (smaller is better)	426.3
BIC (smaller is better)	435.2

Null Model Likelihood Ratio Test		
DF	Chi-Square	Pr > ChiSq
3	69.43	<.0001

Note that the fixed-effects estimates shown in [Output 59.2.23](#) are the same as in the homogeneous case, but the standard errors are different.

Output 59.2.23 Analysis with Heterogeneous Structures (*continued*)

Solution for Fixed Effects						
Effect	Gender	Estimate	Standard Error	DF	t Value	Pr > t
Intercept		16.3406	1.1130	25	14.68	<.0001
Gender	F	1.0321	1.3890	25	0.74	0.4644
Gender	M	0
Age		0.7844	0.09283	79	8.45	<.0001
Age*Gender	F	-0.3048	0.1063	79	-2.87	0.0053
Age*Gender	M	0

The fixed-effects tests shown in [Output 59.2.24](#) are similar to those from previous models, although the p -values do change as a result of specifying a different covariance structure. It is important for you to select a reasonable covariance structure in order to obtain valid inferences for your fixed effects.

Output 59.2.24 Analysis with Heterogeneous Structures (*continued*)

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
Gender	1	25	0.55	0.4644
Age	1	79	141.37	<.0001
Age*Gender	1	79	8.22	0.0053

Example 59.3: Plotting the Likelihood

The data for this example are from Hemmerle and Hartley (1973) and are also used for an example in the VARCOMP procedure. The response variable consists of measurements from an oven experiment, and the model contains a fixed effect A and random effects B and A*B.

The SAS statements are as follows:

```
data hh;
  input a b y @@;
  datalines;
1 1 237    1 1 254    1 1 246
1 2 178    1 2 179
2 1 208    2 1 178    2 1 187
2 2 146    2 2 145    2 2 141
3 1 186    3 1 183
3 2 142    3 2 125    3 2 136
;

ods output ParmSearch=parms;
proc mixed data=hh asycov mmeq mmeqsol covtest;
  class a b;
  model y = a / outp=predicted;
  random b a*b;
  lsmeans a;
  parms (17 to 20 by .1) (.3 to .4 by .005) (1.0);
run;
proc print data=predicted;
run;
```

The **ASYCOV** option in the **PROC MIXED** statement requests the asymptotic variance matrix of the covariance parameter estimates. This matrix is the observed inverse Fisher information matrix, which equals $2\mathbf{H}^{-1}$, where \mathbf{H} is the Hessian matrix of the objective function evaluated at the final covariance parameter estimates. The **MMEQ** and **MMEQSOL** options in the **PROC MIXED** statement request that the mixed model equations and their solution be displayed.

The **OUTP=** option in the **MODEL** statement produces the data set predicted, containing the predicted values. Least squares means (LSMEANS) are requested for A. The **PARMS** and **ODS** statements are used to construct a data set containing the likelihood surface.

The results from this analysis are shown in [Output 59.3.1–Output 59.3.13](#).

The “Model Information” table in [Output 59.3.1](#) lists details about this variance components model.

Output 59.3.1 Model Information

The Mixed Procedure	
Model Information	
Data Set	WORK.HH
Dependent Variable	Y
Covariance Structure	Variance Components
Estimation Method	REML
Residual Variance Method	Profile
Fixed Effects SE Method	Model-Based
Degrees of Freedom Method	Containment

The “Class Level Information” table in [Output 59.3.2](#) lists the levels for A and B.

Output 59.3.2 Class Level Information

Class Level Information		
Class	Levels	Values
a	3	1 2 3
b	2	1 2

The “Dimensions” table in [Output 59.3.3](#) reveals that **X** is 16×4 and **Z** is 16×8 . Since there are no **SUBJECT=** effects, PROC MIXED considers the data to be effectively from one subject with 16 observations.

Output 59.3.3 Model Dimensions and Number of Observations

To plot the likelihood surface by using ODS Graphics, use the following statements:

```
proc template;
  define statgraph surface;
    begingraph;
      layout overlay3d;
        surfaceplotparm x=CovP1 y=CovP2 z=ResLogLike;
      endlayout;
    endgraph;
  end;
run;
proc sgrender data=parms template=surface;
run;
```

The results from this plot are shown in Output 59.3.14. The peak of the surface is the REML estimates for the B and A*B variance components.

Output 59.3.14 Plot of Likelihood Surface

Example 59.4: Known G and R

This animal breeding example from Henderson (1984, p. 48) considers multiple traits. The data are artificial and consist of measurements of two traits on three animals, but the second trait of the third animal is missing. Assuming an additive genetic model, you can use PROC MIXED to predict the breeding value of both traits on all three animals and also to predict the second trait of the third animal. The data are as follows:

```
data h;
  input Trait Animal Y;
  datalines;
1 1 6
1 2 8
1 3 7
2 1 9
2 2 5
2 3 .
;
```

Both **G** and **R** are known.

$$\mathbf{G} = \begin{bmatrix} 2 & 1 & 1 & 2 & 1 & 1 \\ 1 & 2 & .5 & 1 & 2 & .5 \\ 1 & .5 & 2 & 1 & .5 & 2 \\ 2 & 1 & 1 & 3 & 1.5 & 1.5 \\ 1 & 2 & .5 & 1.5 & 3 & .75 \\ 1 & .5 & 2 & 1.5 & .75 & 3 \end{bmatrix}$$

$$\mathbf{R} = \begin{bmatrix} 4 & 0 & 0 & 1 & 0 & 0 \\ 0 & 4 & 0 & 0 & 1 & 0 \\ 0 & 0 & 4 & 0 & 0 & 1 \\ 1 & 0 & 0 & 5 & 0 & 0 \\ 0 & 1 & 0 & 0 & 5 & 0 \\ 0 & 0 & 1 & 0 & 0 & 5 \end{bmatrix}$$

In order to read **G** into PROC MIXED by using the **GDATA=** option in the **RANDOM** statement, perform the following DATA step:

```
data g;
  input Row Col1-Col6;
  datalines;
1 2 1 1 2 1
2 1 2 .5 1 2
3 1 .5 2 1 .5 2
4 2 1 1 3 1.5 1.5
5 1 2 .5 1.5 3 .75
6 1 .5 2 1.5 .75 3
;
```

The preceding data are in the dense representation for a **GDATA=** data set. You can also construct a data set with the sparse representation by using **Row**, **Col**, and **Value** variables, although this would require 21 observations instead of 6 for this example.

The PROC MIXED statements are as follows:

```
proc mixed data=h mmeq mmeqsol;
  class Trait Animal;
  model Y = Trait / noint s outp=predicted;
  random Trait*Animal / type=un gdata=g g gi s;
  repeated / type=un sub=Animal r ri;
  parms (4) (1) (5) / noiter;
run;
proc print data=predicted;
run;
```

The **MMEQ** and **MMEQSOL** options request the mixed model equations and their solution. The variables **Trait** and **Animal** are classification variables, and **Trait** defines the entire **X** matrix for the fixed-effects portion of the model, since the intercept is omitted with the **NOINT** option. The fixed-effects solution vector and predicted values are also requested by using the **S** and **OUTP=** options, respectively.

The random effect **Trait*Animal** leads to a **Z** matrix with six columns, the first five corresponding to the identity matrix and the last consisting of 0s. An unstructured **G** matrix is specified by using the **TYPE=UN**

option, and it is read into PROC MIXED from a SAS data set by using the `GDATA=G` specification. The `G` and `GI` options request the display of G and G^{-1} , respectively. The `S` option requests that the random-effects solution vector be displayed.

Note that the preceding R matrix is block diagonal if the data are sorted by animals. The `REPEATED` statement exploits this fact by requesting R to have unstructured 2×2 blocks corresponding to animals, which are the subjects. The `R` and `RI` options request that the estimated 2×2 blocks for the first animal and its inverse be displayed. The `PARMS` statement lists the parameters of this 2×2 matrix. Note that the parameters from G are not specified in the `PARMS` statement because they have already been assigned by using the `GDATA=` option in the `RANDOM` statement. The `NOITER` option prevents PROC MIXED from computing residual (restricted) maximum likelihood estimates; instead, the known values are used for inferences.

The results from this analysis are shown in [Output 59.4.1–Output 59.4.12](#).

The “Unstructured” covariance structure ([Output 59.4.1](#)) applies to both G and R here. The levels of Trait and Animal have been specified correctly.

Output 59.4.1 Model and Class Level Information

The Mixed Procedure		
Model Information		
Data Set		WORK.H
Dependent Variable		Y
Covariance Structure		Unstructured
Subject Effect		Animal
Estimation Method		REML
Residual Variance Method		None
Fixed Effects SE Method		Model-Based
Degrees of Freedom Method		Containment
Class Level Information		
Class	Levels	Values
Trait	2	1 2
Animal	3	1 2 3

The three covariance parameters indicated in [Output 59.4.2](#) correspond to those from the R matrix. Those from G are considered fixed and known because of the `GDATA=` option.

Output 59.4.2 Model Dimensions and Number of Observations

Dimensions	
Covariance Parameters	3
Columns in X	2
Columns in Z	6
Subjects	1
Max Obs Per Subject	6
Number of Observations	
Number of Observations Read	6
Number of Observations Used	5
Number of Observations Not Used	1

Because starting values for the covariance parameters are specified in the **PARMS** statement, the MIXED procedure prints the residual (restricted) log likelihood at the starting values. Because of the **NOITER** option in the **PARMS** statement, this is also the final log likelihood in this analysis (Output 59.4.3).

Output 59.4.3 REML Log Likelihood

Parameter Search				
CovP1	CovP2	CovP3	Res Log Like	-2 Res Log Like
4.0000	1.0000	5.0000	-7.3731	14.7463

The block of **R** corresponding to the first animal and the inverse of this block are shown in Output 59.4.4.

Output 59.4.4 Inverse R Matrix

Estimated R Matrix for Animal 1		
Row	Col1	Col2
1	4.0000	1.0000
2	1.0000	5.0000

3		-1.3333		
4	-0.6667	-0.6667		
5	1.3333			
6		1.3333		

The table of covariance parameter estimates in [Output 59.4.7](#) displays only the parameters in **R**. Because of the `GDATA=` option in the `RANDOM` statement, the G-side parameters do not participate in the pa-

parameter estimation process. Because of the **NOITER** option in the **PARMS** statement, however, the R-side parameters in this output are identical to their starting values.

Output 59.4.7 R-Side Covariance Parameters

Covariance Parameter Estimates		
Cov Parm	Subject	Estimate
UN(1,1)	Animal	4.0000
UN(2,1)	Animal	1.0000
UN(2,2)	Animal	5.0000

The coefficients of the mixed model equations in [Output 59.4.8](#) agree with Henderson (1984, p. 55). Recall from [Output 59.4.1](#) that there are 2 columns in **X** and 6 columns in **Z**. The first 8 columns of the mixed model equations correspond to the **X** and **Z** components. Column 9 represents the Y border.

Output 59.4.8 Mixed Model Equations with Y Border

Mixed Model Equations							
Row	Effect	Trait	Animal	Col1	Col2	Col3	Col4
1	Trait	1		0.7763	-0.1053	0.2632	0.2632

8	1.7756	1.4849	0.9930	2.7645	0.1276	

The solutions for the fixed and random effects in [Output 59.4.10](#) correspond to the last column in [Output 59.4.9](#). Note that the standard errors for the fixed effects and the prediction standard errors for the random effects are the square root values of the diagonal entries in the solution of the mixed model equations ([Output 59.4.9](#)).

Output 59.4.10 Solutions for Fixed and Random Effects

Solution for Fixed Effects						
Effect	Trait	Estimate	Standard Error	DF	t Value	Pr > t
Trait	1	6.9909	1.5971	3	4.38	0.0221
Trait	2	6.9959	2.1340	3	3.28	0.0465

Output 59.4.10 *continued*

Solution for Random Effects								
Effect	Trait	Animal	Estimate	Std Err		DF	t Value	Pr > t
					Pred			
Trait*Animal	1	1	0.05450	1.3521		0	0.04	.
Trait*Animal	1	2	-0.04955	1.3262		0	-0.04	.
Trait*Animal	1	3	0.02230	1.3346		0	0.02	.
Trait*Animal	2	1	0.2651	1.6589		0	0.16	.
Trait*Animal	2	2	-0.2601	1.6393		0	-0.16	.
Trait*Animal	2	3	0.1276	1.6627		0	0.08	.

The estimates for the two traits are nearly identical, but the standard error of the second trait is larger because of the missing observation.

The Estimate column in the “Solution for Random Effects” table lists the best linear unbiased predictions (BLUPs) of the breeding values of both traits for all three animals. The p -values are missing because the default containment method for computing degrees of freedom results in zero degrees of freedom for the random effects parameter tests.

Output 59.4.11 Significance Test Comparing Traits

Type 3 Tests of Fixed Effects				
Effect	Num	Den	F Value	Pr > F
	DF	DF		
Trait	2	3	10.59	0.0437

The two estimated traits are significantly different from zero at the 5% level ([Output 59.4.11](#)).

[Output 59.4.12](#) displays the predicted values of the observations based on the trait and breeding value estimates—that is, the fixed and random effects.

Output 59.4.12 Predicted Observations

Obs	Trait	Animal	Y	Pred	StdErr		Alpha	Lower	Upper	Resid
					Pred	DF				
1	1	1	6	7.04542	1.33027	0	0.05	.	.	-1.04542
2	1	2	8	6.94137	1.39806	0	0.05	.	.	1.05863
3	1	3	7	7.01321	1.41129	0	0.05	.	.	-0.01321
4	2	1	9	7.26094	1.72839	0	0.05	.	.	1.73906
5	2	2	5	6.73576	1.74077	0	0.05	.	.	-1.73576
6	2	3	.	7.12015	2.99088	0	0.05	.	.	.

The predicted values are not the predictions of future records in the sense that they do not contain a component corresponding to a new observational error. See Henderson (1984) for information about predicting future records. The Lower and Upper columns usually contain confidence limits for the predicted values; they are missing here because the random-effects parameter degrees of freedom equals 0.

Example 59.5: Random Coefficients

This example comes from a pharmaceutical stability data simulation performed by Obenchain (1990). The observed responses are replicate assay results, expressed in percent of label claim, at various shelf ages, expressed in months. The desired mixed model involves three batches of product that differ randomly in intercept (initial potency) and slope (degradation rate). This type of model is also known as a hierarchical or multilevel model (Singer 1998; Sullivan, Dukes, and Losina 1999).

The SAS statements are as follows:

```
data rc;
  input Batch Month @@;
  Monthhc = Month;
  do i = 1 to 6;
    input Y @@;
    output;
  end;

;

proc mixed data=rc;
  class Batch;
  model Y = Month / s;
  random Int Month / type=un sub=Batch s;
run;
```

In the DATA step, Monthhc is created as a duplicate of Month in order to enable both a continuous and a classification version of the same variable. The variable Monthhc is used in a subsequent [analysis](#)

In the PROC MIXED statements, Batch is listed as the only classification variable. The fixed effect Month in the **MODEL** statement is not declared as a classification variable; thus it models a linear trend in time. An intercept is included as a fixed effect by default, and the S option requests that the fixed-effects parameter estimates be produced.

The two random effects are Int and Month, modeling random intercepts and slopes, respectively. Note that Intercept and Month are used as both fixed and random effects. The **TYPE=UN** option in the **RANDOM** statement specifies an unstructured covariance matrix for the random intercept and slope effects. In mixed model notation, **G** is block diagonal with unstructured 2×2 blocks. Each block corresponds to a different level of Batch, which is the **SUBJECT=** effect. The unstructured type provides a mechanism for estimating the correlation between the random coefficients. The **S** option requests the production of the random-effects parameter estimates.

The results from this analysis are shown in **Output 59.5.1–Output 59.5.9**. The “Unstructured” covariance structure in **Output 59.5.1** applies to **G** here.

Output 59.5.1 Model Information in Random Coefficients Analysis

The Mixed Procedure	
Model Information	
Data Set	WORK.RC
Dependent Variable	Y
Covariance Structure	Unstructured
Subject Effect	Batch
Estimation Method	REML
Residual Variance Method	Profile
Fixed Effects SE Method	Model-Based
Degrees of Freedom Method	Containment

Batch is the only classification variable in this analysis, and it has three levels (**Output 59.5.2**).

Output 59.5.2 Random Coefficients Analysis (*continued*)

Class Level Information		
Class	Levels	Values
Batch	3	1 2 3

The “Dimensions” table in **Output 59.5.3** indicates that there are three subjects (corresponding to batches). The 24 observations not used correspond to the missing values of Y in the input data set.

Output 59.5.3 Random Coefficients Analysis (*continued*)

Dimensions	
Covariance Parameters	4
Columns in X	2
Columns in Z Per Subject	2
Subjects	3
Max Obs Per Subject	36
Number of Observations	
Number of Observations Read	108
Number of Observations Used	84
Number of Observations Not Used	24

As [Output 59.5.4](#) shows, only one iteration is required for convergence.

Output 59.5.4 Random Coefficients Analysis (*continued*)

Iteration History			
Iteration	Evaluations	-2 Res Log Like	Criterion
0	1	367.02768461	
1	1	350.32813577	0.00000000
Convergence criteria met.			

The Estimate column in [Output 59.5.5](#) lists the estimated elements of the unstructured 2×2 matrix comprising the blocks of **G**. Note that the random coefficients are negatively correlated.

Output 59.5.5 Random Coefficients Analysis (*continued*)

Covariance Parameter Estimates		
Cov Parm	Subject	Estimate
UN(1,1)	Batch	0.9768
UN(2,1)	Batch	-0.1045
UN(2,2)	Batch	0.03717
Residual		3.2932

The null model likelihood ratio test indicates a significant improvement over the null model consisting of no random effects and a homogeneous residual error ([Output 59.5.6](#)).

Output 59.5.6 Random Coefficients Analysis (*continued*)

Fit Statistics		
-2 Res Log Likelihood		350.3
AIC (smaller is better)		358.3
AICC (smaller is better)		358.8
BIC (smaller is better)		354.7
Null Model Likelihood Ratio Test		
DF	Chi-Square	Pr > ChiSq
3	16.70	0.0008

The fixed-effects estimates represent the estimated means for the random intercept and slope, respectively (Output 59.5.7).

Output 59.5.7 Random Coefficients Analysis (*continued*)

Solution for Fixed Effects					
Effect	Estimate	Standard Error	DF	t Value	Pr > t
Intercept	102.70	0.6456	2	159.08	<.0001
Month	-0.5259	0.1194	2	-4.41	0.0478

The random-effects estimates represent the estimated deviation from the mean intercept and slope for each batch (Output 59.5.8). Therefore, the intercept for the first batch is close to $102.7 - 1 = 101.7$, while the intercepts for the other two batches are greater than 102.7. The second batch has a slope less than the mean slope of -0.526 , while the other two batches have slopes greater than -0.526 .

Output 59.5.8 Random Coefficients Analysis (*continued*)

Solution for Random Effects						
Effect	Batch	Estimate	Std Err Pred	DF	t Value	Pr > t
Intercept	1	-1.0010	0.6842	78	-1.46	0.1474
Month	1	0.1287	0.1245	78	1.03	0.3047
Intercept	2	0.3934	0.6842	78	0.58	0.5669
Month	2	-0.2060	0.1245	78	-1.65	0.1021
Intercept	3	0.6076	0.6842	78	0.89	0.3772
Month	3	0.07731	0.1245	78	0.62	0.5365

The F statistic in the “Type 3 Tests of Fixed Effects” table in Output 59.5.9 is the square of the t statistic

used in the test of Month in the preceding “Solution for Fixed Effects” table (compare [Output 59.5.7](#) and [Output 59.5.9](#)). Both statistics test the null hypothesis that the slope assigned to Month equals 0, and this hypothesis can barely be rejected at the 5% level.

Output 59.5.9 Random Coefficients Analysis (*continued*)

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
Month	1	2	19.41	0.0478

It is also possible to fit a random coefficients model with error terms that follow a nested structure (Fuller and Battese 1973). The following SAS statements represent one way of doing this:

```
proc mixed data=rc;
  class Batch Monthc;
  model Y = Month / s;
  random Int Month Monthc / sub=Batch s;
run;
```

The variable Monthc is added to the **CLASS** and **RANDOM** statements, and it models the nested errors. Note that Month and Monthc are continuous and classification versions of the same variable. Also, the **TYPE=UN** option is dropped from the **RANDOM** statement, resulting in the default variance components model instead of correlated random coefficients. The results from this analysis are shown in [Output 59.5.10](#).

Output 59.5.10 Random Coefficients with Nested Errors Analysis

The Mixed Procedure	
Model Information	
Data Set	WORK.RC

Cov Parm	Subject	Estimate	
Intercept	Batch	0	
Month	Batch	0.01243	
Monthc	Batch	3.7411	
Residual		0.7969	

For this analysis, the Newton-Raphson algorithm requires five iterations and nine likelihood evaluations to achieve convergence. The missing value in the Criterion column in iteration 1 indicates that a boundary constraint has been dropped.

The estimate for the Intercept variance component equals 0. This occurs frequently in practice and indicates that the restricted likelihood is maximized by setting this variance component equal to 0. Whenever a zero variance component estimate occurs, the following note appears in the SAS log:

NOTE: Estimated G matrix is not positive definite.

The remaining variance component estimates are positive, and the estimate corresponding to the nested errors (MONTHC) is much larger than the other two.

A comparison of AIC and BIC for this model with those of the previous model favors the nested error model

(compare [Output 59.5.11](#) and [Output 59.5.6](#)). Strictly speaking, a likelihood ratio test cannot be carried out between the two models because one is not contained in the other; however, a cautious comparison of likelihoods can be informative.

Output 59.5.11 Random Coefficients with Nested Errors Analysis (*continued*)

Fit Statistics	
-2 Res Log Likelihood	276.9
AIC (smaller is better)	282.9
AICC (smaller is better)	283.2
BIC (smaller is better)	280.2

The better-fitting covariance model affects the standard errors of the fixed-effects parameter estimates more than the estimates themselves ([Output 59.5.12](#)).

Output 59.5.12 Random Coefficients with Nested Errors Analysis (*continued*)

Solution for Fixed Effects

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
Month	1	2	15.78	0.0579

The test of Month is similar to that from the previous model, although it is no longer significant at the 5% level (Output 59.5.14).

Example 59.6: Line-Source Sprinkler Irrigation

These data appear in Hanks et al. (1980); Johnson, Chaudhuri, and Kanemasu (1983); Stroup (1989b). Three cultivars (Cult) of winter wheat are randomly assigned to rectangular plots within each of three blocks (Block). The nine plots are located side by side, and a line-source sprinkler is placed through the middle. Each plot is subdivided into twelve subplots—six to the north of the line source, six to the south (Dir). The

two plots closest to the line source represent the maximum irrigation level (Irrig=6), the two next-closest plots represent the next-highest level (Irrig=5), and so forth.

This example is a case where both **G** and **R** can be modeled. One of Stroup's models specifies a diagonal **G** containing the variance components for **Block**, **Block*Dir**, and **Block*Irrig**, and a Toeplitz **R** with four bands. The SAS statements to fit this model and carry out some further analyses follow.

CAUTION: This analysis can require considerable CPU time.

The preceding statements use the bar operator (|) and the at sign (@) to specify all two-factor interactions between **Cult**, **Dir**, and **Irrig** as fixed effects.

The **RANDOM** statement sets up the **Z** and **G** matrices corresponding to the random effects **Block**, **Block*Dir**, and **Block*Irrig**.

In the **REPEATED** statement, the **TYPE=TOEP(4)** option sets up the blocks of the **R** matrix to be Toeplitz with four bands below and including the main diagonal. The subject effect is **Block*Cult**, and it produces

nine 12×12 blocks. The **R** option requests that the first block of **R** be displayed.

Least squares means (**LSMEANS**) are requested for **Cult**, **Irrig**, and **Cult*Irrig**, and a few **ESTIMATE** statements are specified to illustrate some linear combinations of the fixed effects.

The results from this analysis are shown in [Output 59.6.1](#).

The “Covariance Structures” row in [Output 59.6.1](#) reveals the two different structures assumed for **G** and **R**.

Output 59.6.6 lists the estimated covariance parameters from both **G** and **R**. The first three are the variance components making up the diagonal **G**, and the final four make up the Toeplitz structure in the blocks of **R**. The Residual row corresponds to the variance of the Toeplitz structure, and it represents the parameter profiled out during the optimization process.

Output 59.6.6 Estimated Covariance Parameters

Covariance Parameter Estimates		
Cov Parm	Subject	Estimate
Block		0.2194
Block*Dir		0.01768
Block*Irrig		0.03539
TOEP (2)	Block*Cult	0.007986
TOEP (3)	Block*Cult	0.001452
TOEP (4)	Block*Cult	-0.09253
Residual		0.2850

The “–2 Res Log Likelihood” value in [Output 59.6.7](#) is the same as the final value listed in the “Iteration History” table ([Output 59.6.4](#)).

Output 59.6.7 Fit Statistics Based on the Residual Log Likelihood

Fit Statistics	
–2 Res Log Likelihood	183.2
AIC (smaller is better)	197.2
AICC (smaller is better)	198.8
BIC (smaller is better)	190.9

Every fixed effect except for Dir and Cult*Irrig is significant at the 5% level ([Output 59.6.8](#)).

Output 59.6.8 Tests for Fixed Effects

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
Cult	2	68	7.98	0.0008
Dir	1	2	3.95	0.1852
Cult*Dir	2	68	3.44	0.0379
Irrig	5	10	102.60	<.0001
Cult*Irrig	10	68	1.91	0.0580
Dir*Irrig	5	68	6.12	<.0001

The “Estimates” table lists the results from the various linear combinations of fixed effects specified in the **ESTIMATE** statements ([Output 59.6.9](#)). Bridger is not significantly different from Luke, and Irrig possesses a strong linear component. This strength appears to be influencing the significance of the interaction.

Output 59.6.9 Estimates

Estimates					
Label	Estimate	Standard Error	DF	t Value	Pr > t
Bridger vs Luke	–0.03889	0.09524	68	–0.41	0.6843
Linear Irrig	30.6444	1.4412	10	21.26	<.0001
B vs L x Linear Irrig	–9.8667	2.7400	68	–3.60	0.0006

The least squares means shown in [Output 59.6.10](#) are useful in comparing the levels of the various fixed effects. For example, it appears that irrigation levels 5 and 6 have virtually the same effect.

Output 59.6.10 Least Squares Means for Cult, Irrig, and Their Interaction

Least Squares Means							
Effect	Cult	Irrig	Estimate	Standard Error	DF	t Value	Pr > t
Cult	Bridger		5.0306	0.2874	68	17.51	<.0001
Cult	Luke		5.0694	0.2874	68	17.64	<.0001

An interesting exercise is to fit other variance-covariance models to these data and to compare them to this one by using likelihood ratio tests, Akaike's information criterion, or Schwarz's Bayesian information criterion. In particular, some spatial models are worth investigating (Marx and Thompson 1987; Zimmerman and Harville 1991). The following is one example of spatial model statements:

```
proc mixed;
  class Block Cult Dir Irrig;
  model Y = Cult|Dir|Irrig@2;
  repeated / type=sp(pow) (Row Sbplt) sub=intercept;
run;
```

The **TYPE=SP(POW)**(Row Sbplt) option in the **REPEATED** statement requests the spatial power structure, with the two defining coordinate variables being Row and Sbplt. The **SUBJECT=INTERCEPT** option indicates that the entire data set is to be considered as one subject, thereby modeling **R** as a dense 108×108 covariance matrix. See Wolfinger (1993) for further discussion of this example and additional analyses.

Example 59.7: Influence in Heterogeneous Variance Model

In this example from Snedecor and Cochran (1976, p. 256), a one-way classification model with heterogeneous variances is fit. The data, shown in the following DATA step, represent amounts of different types of fat absorbed by batches of doughnuts during cooking, measured in grams.

```
data absorb;
  input FatType Absorbed @@;
  datalines;
1 164 1 172 1 168 1 177 1 156 1 195
2 178 2 191 2 197 2 182 2 185 2 177
3 175 3 193 3 178 3 171 3 163 3 176
4 155 4 166 4 149 4 164 4 170 4 168
;
```

The statistical model for these data can be written as

$$\begin{aligned}
 Y_{ij} &= \mu + \tau_i + \epsilon_{ij} \\
 i &= 1, \dots, t = 4 \\
 j &= 1, \dots, r = 6 \\
 \epsilon_{ij} &= N(0, \sigma_i^2)
 \end{aligned}$$

where Y_{ij} is the amount of fat absorbed by the j th batch of the i th fat type, and τ_i denotes the fat-type effects. A quick glance at the data suggests that observations 6, 9, 14, and 21 might be influential on the analysis, because these are extreme observations for the respective fat types.

The following SAS statements fit this model and request influence diagnostics for the fixed effects and covariance parameters. ODS Graphics is used to create plots of the influence diagnostics in addition to the tabular output. The **ESTIMATES** suboption requests plots of “leave-one-out” estimates for the fixed effects and group variances.

```
ods graphics on;

proc mixed data=absorb asycov;
  class FatType;
  model Absorbed = FatType / s
          influence(iter=10 estimates);
  repeated / group=FatType;
  ods output Influence=inf;
run;

ods graphics off;
```

The “Influence” table is output to the SAS data set inf so that parameter estimates can be printed subsequently. Results from this analysis are shown in [Output 59.7.1](#).

Output 59.7.1 Heterogeneous Variance Analysis

The Mixed Procedure		
Model Information		
Data Set	WORK.ABSORB	
Dependent Variable	Absorbed	
Covariance Structure	Variance Components	
Group Effect	FatType	
Estimation Method	REML	
Residual Variance Method	None	
Fixed Effects SE Method	Model-Based	
Degrees of Freedom Method	Between-Within	

Covariance Parameter Estimates		
Cov Parm	Group	Estimate
Residual	FatType 1	178.00
Residual	FatType 2	60.4000
Residual	FatType 3	97.6000
Residual	FatType 4	67.6000

Solution for Fixed Effects						
Effect	Fat Type	Estimate	Standard Error	DF	t Value	Pr > t
Intercept		162.00	3.3566	20	48.26	<.0001
FatType	1	10.0000	6.3979	20	1.56	0.1337
FatType	2	23.0000	4.6188	20	4.98	<.0001
FatType	3	14.0000	5.2472	20	2.67	0.0148
FatType	4	0

The fixed-effects solutions correspond to estimates of the following parameters:

Intercept : $\mu + \tau_4$

FatType1 : $\tau_1 - \tau_4$

FatType2 : $\tau_2 - \tau_4$

FatType3 : $\tau_3 - \tau_4$

FatType4 : 0

You can easily verify that these estimates are simple functions of the arithmetic means \bar{y}_i in the groups. For example, $\widehat{\mu + \tau_4} = \bar{y}_4 = 162.0$, $\widehat{\tau_1 - \tau_4} = \bar{y}_1 - \bar{y}_4 = 10.0$, and so forth. The covariance parameter estimates are the sample variances in the groups and are uncorrelated.

The variances in the four groups are shown in the “Covariance Parameter Estimates” table (Output 59.7.1). The estimated variance in the first group is two to three times larger than the variance in the other groups.

Output 59.7.2 Asymptotic Variances of Group Variance Estimates

Asymptotic Covariance Matrix of Estimates					
Row	Cov Parm	CovP1	CovP2	CovP3	CovP4
1	Residual	12674			
2	Residual		1459.26		
3	Residual			3810.30	
4	Residual				1827.90

In groups where the residual variance estimate is large, the precision of the estimate is also small (Output 59.7.2).

The following statements print the “leave-one-out” estimates for fixed effects and covariance parameters that were written to the inf data set with the **ESTIMATES** suboption (Output 59.7.3):

```
proc print data=inf label;
  var parm1-parm5 covp1-covp4;
run;
```

Output 59.7.3 Leave-One-Out Estimates

The graphical displays in [Output 59.7.4](#) and [Output 59.7.5](#) are created when ODS Graphics is enabled. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the MIXED procedure, see the section “[ODS Graphics](#)” on page 4992.

Output 59.7.4 Fixed-Effects Deletion Estimates

Output 59.7.5 Covariance Parameter Deletion Estimates

The estimate of the intercept is affected only when observations from the last group are removed. The estimate of the “FatType 1” effect reacts to removal of observations in the first and last group ([Output 59.7.4](#)).

While observations can affect one or more fixed-effects solutions in this model, they can affect only one covariance parameter, the variance in their group ([Output 59.7.5](#)). Observations 6, 9, 14, and 21, which are extreme in their group, reduce the group variance considerably.

Diagnostics related to residuals and predicted values are printed with the following statements:

```
proc print data=inf label;
  var observed predicted residual pressres
    student Rstudent;
run;
```

Output 59.7.6 Residual Diagnostics

Obs	Observed Value	Predicted Mean	Residual	PRESS Residual	Internally Studentized Residual	Externally Studentized Residual

22	164	162.0	2.000	2.400	0.2665	0.2401
23	170	162.0	8.000	9.600	1.0659	1.0845
24	168	162.0	6.000	7.200	0.7994	0.7657

Observations 6, 9, 14, and 21 have large studentized residuals ([Output 59.7.6](#)). That the externally studentized residuals are much larger than the internally studentized residuals for these observations indicates that the variance estimate in the group shrinks when the observation is removed. Also important to note is that comparisons based on raw residuals in models with heterogeneous variance can be misleading. Observation 5, for example, has a larger residual but a smaller studentized residual than observation 21. The variance for the first fat type is much larger than the variance in the fourth group. A “large” residual is more “surprising” in the groups with small variance.

A measure of the overall influence on the analysis is the (restricted) likelihood distance, shown in [Output 59.7.7](#). Observations 6, 9, 14, and 21 clearly displace the REML solution more than any other observations.

Output 59.7.7 Restricted Likelihood Distance

The following statements list the restricted likelihood distance and various diagnostics related to the fixed-effects estimates ([Output 59.7.8](#)):

```
proc print data=inf label;
  var leverage observed CookD DFFITS CovRatio RLD;
run;
```

Output 59.7.8 Restricted Likelihood Distance and Fixed-Effects Diagnostics

Obs	Leverage	Observed Value	Cook's D	DFFITS	COVRATIO	Restr. Likelihood Distance

23	0.167	170	0.05680	0.48500	1.1592	0.2383
24	0.167	168	0.03195	0.34245	1.3079	0.1353

In this example, observations with large likelihood distances also have large values for Cook's D and values of CovRatio far less than one ([Output 59.7.8](#)). The latter indicates that the fixed effects are estimated more precisely when these observations are removed from the analysis.

The following statements print the values of the D statistic and the CovRatio for the covariance parameters:

```
proc print data=inf label;
  var iter CookDCP CovRatioCP;
run;
```

The same conclusions as for the fixed-effects estimates hold for the covariance parameter estimates. Observations 6, 9, 14, and 21 change the estimates and their precision considerably ([Output 59.7.9](#), [Output 59.7.10](#)). All iterative updates converged within at most four iterations.

Output 59.7.9 Covariance Parameter Diagnostics

24	2	0.02020	1.4839

Output 59.7.10 displays the standard panel of influence diagnostics that is obtained when influence analysis is iterative. The Cook's D and CovRatio statistics are displayed for each deletion set for both fixed-effects and covariance parameter estimates. This provides a convenient summary of the impact on the analysis for each deletion set, since Cook's D statistic measures impact on the estimates and the CovRatio statistic measures impact on the precision of the estimates.

Output 59.7.10 Influence Diagnostics

Observations 6, 9, 14, and 21 have considerable impact on estimates and precision of fixed effects and covariance parameters. This is not necessarily the case. Observations can be influential on only some aspects of the analysis, as shown in the next example.

Example 59.8: Influence Analysis for Repeated Measures Data

This example revisits the repeated measures data of Pothoff and Roy (1964) that were analyzed in [Example 59.2](#). Recall that the data consist of growth measurements at ages 8, 10, 12, and 14 for 11 girls and 16 boys. The model being fit contains fixed effects for Gender and Age and their interaction.

The earlier analysis of these data indicated some unusual observations in this data set. Because of the clustered data structure, it is of interest to study the influence of clusters (children) on the analysis rather than the influence of individual observations. A cluster comprises the repeated measurements for each child.

The repeated measures are first modeled with an unstructured within-child variance-covariance matrix. A residual variance is not profiled in this model. A noniterative influence analysis will update the fixed effects only. The following statements request this noniterative maximum likelihood analysis and produce [Output 59.8.1](#):

```

proc mixed data=pr method=ml;
  class person gender;
  model y = gender age gender*age /
          influence(effect=person);
  repeated / type=un subject=person;
  ods select influence;
run;

```

27	4	20.2913	0.02523

Each observation in the “Influence Diagnostics for Levels of Person” table in [Output 59.8.1](#) represents the removal of four observations. The subjects 10, 15, and 24 have the greatest impact on the fixed effects (Cook’s D), and subject 10 and 21 have large PRESS statistics. The 21st child has a large PRESS statistic, and its D statistic is not that extreme. This is an indication that the model fits rather poorly for this child, whether it is part of the data or not.

The previous analysis does not take into account the effect on the covariance parameters when a subject is removed from the analysis. If you also update the covariance parameters, the impact of observations on

these can amplify or allay their effect on the fixed effects. To assess the overall influence of subjects on the analysis and to compute separate statistics for the fixed effects and covariance parameters, an iterative analysis is obtained by adding the **INFLUENCE** suboption **ITER=**, as follows:

```
ods graphics on;

proc mixed data=pr method=ml;
  class person gender;
  model y = gender age gender*age /
          influence(effect=person iter=5);
  repeated / type=un subject=person;
run;
```

The number of additional iterations following removal of the observations for a particular subject is limited to five. Graphical displays of influence diagnostics are created when ODS Graphics is enabled. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the MIXED procedure, see the section “[ODS Graphics](#)” on page 4992.

The MIXED procedure produces a plot of the restricted likelihood distance ([Output 59.8.2](#)) and a panel of diagnostics for fixed effects and covariance parameters ([Output 59.8.3](#)).

Output 59.8.2 Restricted Likelihood Distance

Output 59.8.3 Influence Diagnostics Panel

As judged by the restricted likelihood distance, subjects 20 and 24 clearly have the most influence on the overall analysis (Output 59.8.2).

Output 59.8.3 displays Cook's D and CovRatio statistics for the fixed effects and covariance parameters. Clearly, subject 20 has a dramatic effect on the estimates of variances and covariances. This subject also affects the precision of the covariance parameter estimates more than any other subject in Output 59.8.3 (CovRatio near 0).

The child who exerts the greatest influence on the fixed effects is subject 24. Maybe surprisingly, this subject affects the variance-covariance matrix of the fixed effects more than subject 20 (small CovRatio in Output 59.8.3).

The final model investigated for these data is a random coefficient model as in Stram and Lee (1994) with random effects for the intercept and age effect. The following statements examine the estimates for fixed effects and the entries of the unstructured 2×2 variance matrix of the random coefficients graphically:

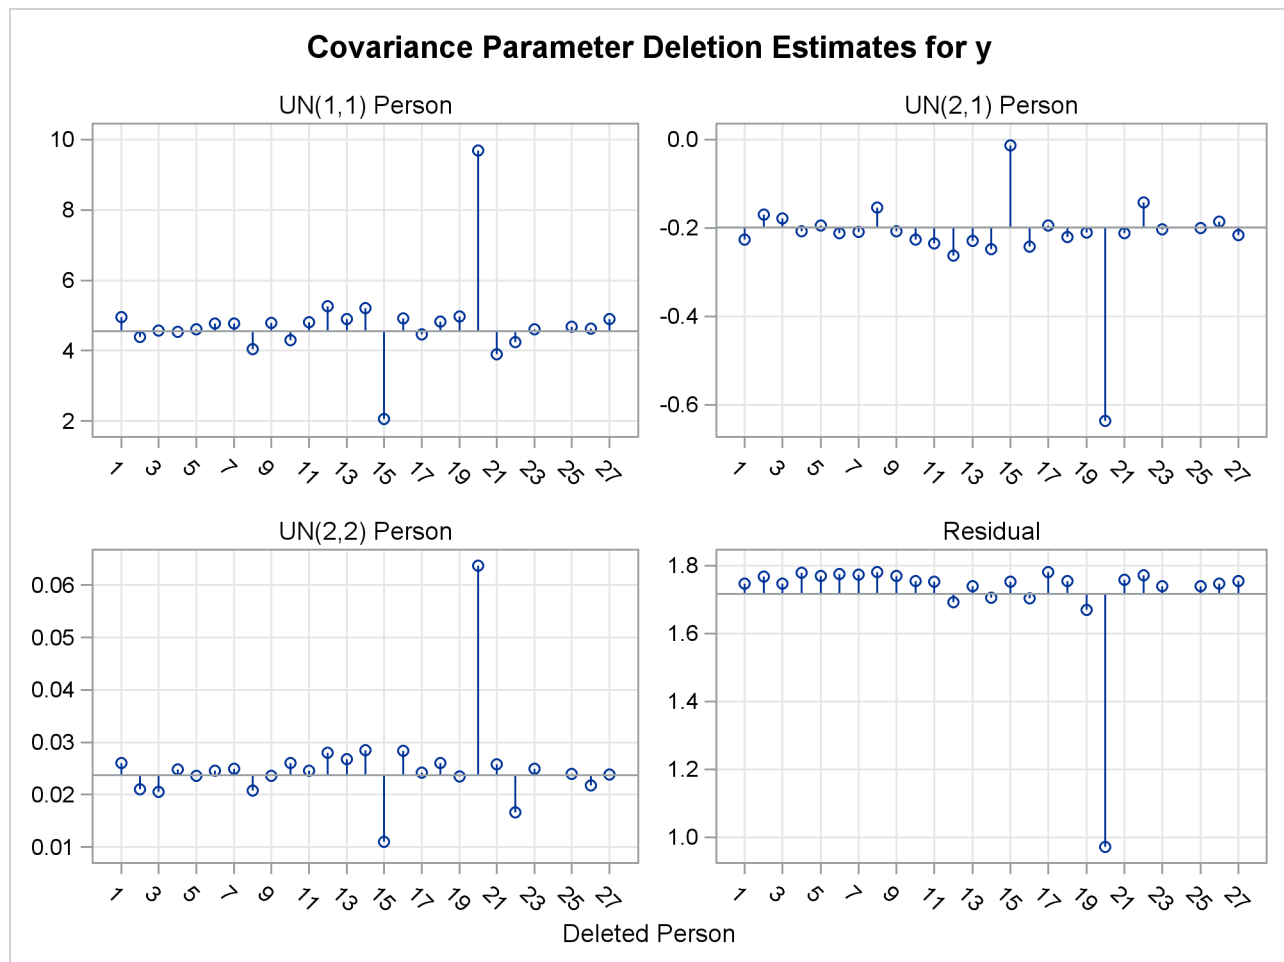

```
proc mixed data=pr method=ml
    plots(only)=InfluenceEstPlot;
    class person gender;
    model y = gender age gender*age /
```

```
influence(iter=5 effect=person est);
random intercept age / type=un subject=person;
run;
```

The **PLOTS(ONLY)=INFLUENCEESTPLOT** option restricts the graphical output from this PROC MIXED run to only the panels of deletion estimates ([Output 59.8.4](#) and [Output 59.8.5](#)).

Output 59.8.4 Fixed-Effects Deletion Estimates

Output 59.8.5 Covariance Parameter Deletion Estimates

The covariance parameter deletion estimates in [Output 59.8.5](#) show several important features.

- The panels do not contain information about subject 24. Estimation of the G matrix following removal of that child did not yield a positive definite matrix. As a consequence, covariance parameter diagnostics are not produced for this subject.
- Subject 20 has great impact on the four covariance parameters. Removing this child from the analysis increases the variance of the random intercept and random slope and reduces the residual variance by almost 80%. The repeated measurements of this child exhibit an up-and-down behavior.
- The variance of the random intercept and slope are reduced when child 15 is removed from the analysis. This child's growth measurements oscillate about 27.0 from age 10 on.

Examining observed and residual values by levels of classification variables is also a useful tool to diagnose the adequacy of the model and unusual observations. Box plots for effects in the model that consist of only classification variables can be requested with the **BOXPLOT** option of the **PLOTS=** option in the **PROC MIXED** statement. For example, the following statements produce box plots for the **SUBJECT=** effects in the model:

```
ods graphics on;
proc mixed data=pr method=ml
    plot=boxplot(observed marginal conditional subject);
    class person gender;
    model y = gender age gender*age;
    random intercept age / type=un subject=person;
run;
```

The specific boxplot options request a plot of the observed data (Output 59.8.6), the marginal residuals (Output 59.8.7), and the conditional residuals (Output 59.8.8). Box plots of the observed values show the variation within and between children clearly. The group of girls (subjects 1–11) is distinguishable from the group of boys by somewhat lesser average growth and lesser within-child variation (Output 59.8.6). After adjusting for overall (population-averaged) gender and age effects, the residual within-child variation is reduced but substantial differences in the means remain (Output 59.8.7). If child-specific inferences are desired, a model accounting for only Gender, Age, and Gender*Age effects is not adequate for these data.

Output 59.8.6 Distribution of Observed Values

Output 59.8.7 Distribution of Marginal Residuals

The conditional residuals incorporate the EBLUPs for each child and enable you to examine whether the subject-specific model is adequate (Output 59.8.8). By using each child “as its own control,” the residuals are now centered near zero. Subjects 20 and 24 stand out as unusual in all three sets of box plots.

Output 59.8.8 Distribution of Conditional Residuals

Example 59.9: Examining Individual Test Components

The **LCOMPONENTS** option in the **MODEL** statement enables you to perform single-degree-of-freedom tests for individual rows of the **L** matrix. Such tests are useful to identify interaction patterns. In a balanced layout, Type 3 components of **L** associated with **A*B** interactions correspond to simple contrasts of cell mean differences.

The first example revisits the data from the split-plot design by Stroup (1989a) that was analyzed in [Example 59.1](#). Recall that variables **A** and **B** in the following statements represent the whole-plot and subplot factors, respectively:

```
proc mixed data=sp;
  class a b block;
  model y = a b a*b / LComponents e3;
  random block a*block;
run;
```

The **MIXED** procedure constructs a separate **L** matrix for each of the three fixed-effects components. The matrices are displayed in [Output 59.9.1](#). The tests for fixed effects are shown in [Output 59.9.2](#).

Output 59.9.1 Coefficients of Type 3 Estimable Functions

The Mixed Procedure				
Type 3 Coefficients for A				
Effect	A	B	Row1	Row2
Intercept				
A	1		1	
A	2			1
A	3		-1	-1
B		1		
B		2		
A*B	1	1	0.5	
A*B	1	2	0.5	
A*B	2	1		0.5
A*B	2	2		0.5
A*B	3	1	-0.5	-0.5
A*B	3	2	-0.5	-0.5

Intercept				
A	1			
A	2			
A	3			
B		1		
B		2		
A*B	1	1	1	
A*B	1	2	-1	
A*B	2	1		1
A*B	2	2		-1
A*B	3	1	-1	-1
A*B	3	2	1	1

Output 59.9.2 Type 3 Tests in Split-Plot Example

Type 3 Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
A	2	6	4.07	0.0764
B	1	9	19.39	0.0017
A*B	2	9	4.02	0.0566

If $\mu_{i.}$ denotes a whole-plot main effect mean, $\mu_{.j}$ denotes a subplot main effect mean, and μ_{ij} denotes a cell mean, the five components shown in [Output 59.9.3](#) correspond to tests of the following:

- $H_0 : \mu_{1.} = \mu_{3.}$
- $H_0 : \mu_{2.} = \mu_{3.}$
- $H_0 : \mu_{.1} = \mu_{.2}$
- $H_0 : \mu_{11} - \mu_{12} = \mu_{31} - \mu_{32}$
- $H_0 : \mu_{21} - \mu_{22} = \mu_{31} - \mu_{32}$

Output 59.9.3 Type 3 L Components Table

L Components of Type 3 Tests of Fixed Effects						
Effect	L Index	Estimate	Standard Error	DF	t Value	Pr > t
A	1	7.1250	3.1672	6	2.25	0.0655
A	2	8.3750	3.1672	6	2.64	0.0383
B	1	5.5000	1.2491	9	4.40	0.0017
A*B	1	7.7500	3.0596	9	2.53	0.0321
A*B	2	7.2500	3.0596	9	2.37	0.0419

The first three components are comparisons of marginal means. The fourth component compares the effect of factor B at the first whole-plot level against the effect of B at the third whole-plot level. Finally, the last component tests whether the factor B effect changes between the second and third whole-plot level.

The Type 3 component tests can also be produced with these corresponding **ESTIMATE** statements:

```
proc mixed data=sp;
  class a b block ;
  model y = a b a*b;
  random block a*block;
  estimate 'a' 1' a 1 0 -1;
  estimate 'a' 2' a 0 1 -1;
  estimate 'b' 1' b 1 -1;
```

```

estimate 'a*b 1' a*b 1 -1 0 0 -1 1;
estimate 'a*b 2' a*b 0 0 1 -1 -1 1;
ods select Estimates;
run;

```

The results are shown in [Output 59.9.4](#).

Output 59.9.4 Results from ESTIMATE Statements

The Mixed Procedure						
Estimates						
Label		Estimate	Standard Error	DF	t Value	Pr > t
a	1	7.1250	3.1672	6	2.25	0.0655
a	2	8.3750	3.1672	6	2.64	0.0383
b	1	5.5000	1.2491	9	4.40	0.0017
a*b	1	7.7500	3.0596	9	2.53	0.0321
a*b	2	7.2500	3.0596	9	2.37	0.0419

A second useful application of the **LCOMPONENTS** option is in polynomial models, where Type 1 tests are often used to test the entry of model terms sequentially. The **SOLUTION** option in the **MODEL** statement displays the regression coefficients that correspond to a Type 3 analysis. That is, the coefficients represent the partial coefficients you would get by adding the regressor variable last in a model containing all other effects, and the tests are identical to those in the “Type 3 Tests of Fixed Effects” table.

Consider the following DATA step and the fit of a third-order polynomial regression model.

```

data polynomial;
  do x=1 to 20; input y@@; output; end;
  datalines;
1.092  1.758  1.997  3.154  3.880
3.810  4.921  4.573  6.029  6.032
6.291  7.151  7.154  6.469  7.137
6.374  5.860  4.866  4.155  2.711
;

proc mixed data=polynomial;
  model y = x x*x x*x*x / s lcomponents htype=1,3;
run;

```

The *t* tests displayed in the “Solution for Fixed Effects” table are Type 3 tests, sometimes referred to as partial tests. They measure the contribution of a regressor in the presence of all other regressor variables in the model.

Output 59.9.5 Parameter Estimates in Polynomial Model

The Mixed Procedure					
Solution for Fixed Effects					
Effect	Estimate	Standard Error	DF	t Value	Pr > t
Intercept	0.7837	0.3545	16	2.21	0.0420
x	0.3726	0.1426	16	2.61	0.0189
x*x	0.04756	0.01558	16	3.05	0.0076
x*x*x	-0.00306	0.000489	16	-6.27	<.0001

The Type 3 L components are identical to the tests in the “Solutions for Fixed Effects” table shown in [Output 59.9.5](#). The Type 1 table yields the following:

- sequential (Type 1) tests of regression variables that test the significance of a regressor given all other variables preceding it in the model list
- the regression coefficients for sequential submodels

Output 59.9.6 Type 1 and Type 3 L Components

L Components of Type 1 Tests of Fixed Effects						
Effect	L Index	Estimate	Standard Error	DF	t Value	Pr > t
x	1	0.1763	0.01259	16	14.01	<.0001
x*x	1	-0.04886	0.002449	16	-19.95	<.0001
x*x*x	1	-0.00306	0.000489	16	-6.27	<.0001

L Components of Type 3 Tests of Fixed Effects						
Effect	L Index	Estimate	Standard Error	DF	t Value	Pr > t
x	1	0.3726	0.1426	16	2.61	0.0189
x*x	1	0.04756	0.01558	16	3.05	0.0076
x*x*x	1	-0.00306	0.000489	16	-6.27	<.0001

The estimate of 0.1763 is the regression coefficient in a simple linear regression of Y on X. The estimate of -0.04886 is the partial coefficient for the quadratic term when it is added to a model containing only a linear component. Similarly, the value -0.00306 is the partial coefficient for the cubic term when it is added to a model containing a linear and quadratic component. The last Type 1 component is always identical to the corresponding Type 3 component.

Example 59.10: Isotonic Contrasts for Ordered Mean Values

It is often of interest to test whether the mean values of the dependent variable increases or decreases monotonically with certain factors. Hirotsu and Srivastava (2000) demonstrate one approach by using data (Moriguchi 1976). The data consist of ferrite cores subjected to four increasing temperatures. The response variable is the magnetic force of each core.

```
data FerriteCores;
  do Temp = 1 to 4;
    do rep = 1 to 5; drop rep;
      input MagneticForce @@;
      output;
    end;
  end;
  datalines;
10.8  9.9 10.7 10.4  9.7
10.7 10.6 11.0 10.8 10.9
11.9 11.2 11.0 11.1 11.3
11.4 10.7 10.9 11.3 11.7
;
```

The method presented by Hirotsu and Srivastava (2000) to test whether the magnetic force of the cores rises monotonically with temperature depends on the lower confidence limits of the *isotonic contrasts* of the force means at each temperature, adjusted for multiplicity. The corresponding isotonic contrast compares the average of a particular group and the preceding groups with the average of the succeeding groups. You can compute adjusted confidence intervals for isotonic contrasts by using the [LSMESTIMATE](#) statement.

The following statements analyze the FerriteCores data as a one-way design and multiplicity-adjusted lower confidence limits for the isotonic contrasts. For the multiplicity adjustment, the [LSMESTIMATE](#) statement employs simulation, which provides adjusted *p*-values and lower confidence limits that are exact up to Monte Carlo error.

```
proc mixed data=FerriteCores;
  class Temp;
  model MagneticForce = Temp;
  lsestimate Temp
    'avg(1:1)<avg(2:4)' -3  1  1  1 divisor=3,
    'avg(1:2)<avg(3:4)' -1 -1  1  1 divisor=2,
    'avg(1:3)<avg(4:4)' -1 -1 -1  3 divisor=3
    / adjust=simulate(seed=1) cl upper;
  ods select LSMestimates;
run;
```

The results are shown in [Output 59.10.1](#).

Output 59.10.1 Analysis of LS-Means with Isotonic Contrasts

The Mixed Procedure							
Least Squares Means Estimates							
Adjustment for Multiplicity: Simulated							
Effect	Label	Estimate	Standard Error	DF	t Value	Tails	Pr > t
Temp	avg(1:1) < avg(2:4)	0.8000	0.1906	16	4.20	Upper	0.0003
Temp	avg(1:2) < avg(3:4)	0.7000	0.1651	16	4.24	Upper	0.0003
Temp	avg(1:3) < avg(4:4)	0.4000	0.1906	16	2.10	Upper	0.0260
Least Squares Means Estimates							
Adjustment for Multiplicity: Simulated							
Effect	Label	Adj P	Alpha	Lower	Upper		
Temp	avg(1:1) < avg(2:4)	0.0010	0.05	0.4672	Infty		
Temp	avg(1:2) < avg(3:4)	0.0009	0.05	0.4118	Infty		
Temp	avg(1:3) < avg(4:4)	0.0625	0.05	0.06721	Infty		
Least Squares Means Estimates							
Adjustment for Multiplicity: Simulated							
Effect	Label	Adj Lower	Adj Upper				
Temp	avg(1:1) < avg(2:4)	0.3771	Infty				
Temp	avg(1:2) < avg(3:4)	0.3337	Infty				
Temp	avg(1:3) < avg(4:4)	-0.02291	Infty				

With an adjusted p -value of 0.001, the magnetic force at the first temperature is significantly less than the average of the other temperatures. Likewise, the average of the first two temperatures is significantly less than the average of the last two ($p = 0.0009$). However, the magnetic force at the last temperature is not significantly greater than the average magnetic force of the others ($p = 0.0625$). These results indicate a significant monotone increase over the first three temperatures, but not across all four temperatures.

Overview: MODECLUS Procedure

The MODECLUS procedure clusters observations in a SAS data set by using any of several algorithms based on nonparametric density estimates. The data can be numeric coordinates or distances. PROC MODECLUS can perform approximate significance tests for the number of clusters and can hierarchically join nonsignificant clusters. The significance tests are empirically validated by simulations with sample sizes ranging from 20 to 2000.

PROC MODECLUS produces output data sets containing density estimates and cluster membership, various cluster statistics including approximate p -values, and a summary of the number of clusters generated by various algorithms, smoothing parameters, and significance levels.

Most clustering methods are biased toward finding clusters possessing certain characteristics related to size (number of members), shape, or dispersion. Methods based on the least squares criterion (Sarle 1982), such as k -means and Ward's minimum variance method, tend to find clusters with roughly the same number of observations in each cluster. Average linkage (see Chapter 31, "The CLUSTER Procedure") is somewhat biased toward finding clusters of equal variance. Many clustering methods tend to produce compact, roughly hyperspherical clusters and are incapable of detecting clusters with highly elongated or irregular shapes. The methods with the least bias are those based on nonparametric density estimation (Silverman 1986, pp. 130–146; Scott 1992, pp. 125–190) such as density linkage (see Chapter 31, "The CLUSTER Procedure"), Wong and Lane (1983); Wong and Schaack (1982). The biases of many commonly used clustering methods are discussed in Chapter 11, "Introduction to Clustering Procedures."

PROC MODECLUS implements several clustering methods by using nonparametric density estimation. Such clustering methods are referred to hereafter as *nonparametric clustering methods*. The methods in PROC MODECLUS are related to, but not identical to, methods developed by Gitman (1973); Huizinga (1978); Koontz and Fukunaga (1972a, b); Koontz, Narendra, and Fukunaga (1976); Mizoguchi and Shimura (1980); Wong and Lane (1983).

Details of the algorithms are provided in the section "Clustering Methods" on page 5099.

For nonparametric clustering methods, a cluster is loosely defined as a region surrounding a local maximum of the probability density function (see the section "Significance Tests" on page 5101 for a more rigorous definition). Given a sufficiently large sample, nonparametric clustering methods are capable of detecting clusters of unequal size and dispersion and with highly irregular shapes. Nonparametric methods can also obtain good results for compact clusters of equal size and dispersion, but they naturally require larger sample sizes for good recovery than clustering methods that are biased toward finding such "nice" clusters.

For coordinate data, nonparametric clustering methods are less sensitive to changes in scale of the variables or to affine transformations of the variables than are most other commonly used clustering methods. Nevertheless, it is necessary to consider questions of scaling and transformation, since variables with large variances tend to have more of an effect on the resulting clusters than those with small variances. If two or more variables are not measured in comparable units, some type of standardization or scaling is necessary; otherwise, the distances used by the procedure might be based on inappropriate apples-and-oranges computations. For variables with comparable units of measurement, standardization or scaling might still be desirable if the scale estimates of the variables are not related to their expected importance for defining clusters. If you want two variables to have equal importance in the analysis, they should have roughly equal scale estimates. If you want one variable to have more of an effect than another, the former should be scaled to have a greater scale estimate than the latter. The STD option in the PROC MODECLUS statement scales all variables to equal variance. However, the variance is not necessarily the most appropriate scale estimate for cluster analysis. In particular, outliers should be removed before using PROC MODECLUS with the STD option. A variety of scale estimators including robust estimators are provided in the STDIZE procedure (for detailed information, see Chapter 87, "The STDIZE Procedure"). Additionally, the ACECLUS procedure provides another way to transform the variables to try to improve the separation of clusters.

Since clusters are defined in terms of local maxima of the probability density function, nonlinear transformations of the data can change the number of population clusters. The variables should be transformed so that equal differences are of equal practical importance. An interval scale of measurement is required. Or-

dinal or ranked data are generally inappropriate, since monotone transformations can produce any arbitrary number of modes.

Unlike the methods in the CLUSTER procedure, the methods in the MODECLUS procedure are not inherently hierarchical. However, PROC MODECLUS can do approximate nonparametric significance tests for the number of clusters by obtaining an approximate p -value for each cluster, and it can hierarchically join nonsignificant clusters.

Another important difference between the MODECLUS procedure and many other clustering methods is that you do not tell PROC MODECLUS how many clusters you want. Instead, you specify a *smoothing parameter* (see the section “[Density Estimation](#)” on page 5096) and, optionally, a significance level, and PROC MODECLUS determines the number of clusters. You can specify a list of smoothing parameters, and PROC MODECLUS performs a separate cluster analysis for each value in the list.

Getting Started: MODECLUS Procedure

This section illustrates how PROC MODECLUS can be used to examine the clusters of data in the following artificial data set.

```
data example;
  input x y @@;
  datalines;
18 18  20 22  21 20  12 23  17 12  23 25  25 20  16 27
20 13  28 22  80 20  75 19  77 23  81 26  55 21  64 24
72 26  70 35  75 30  78 42  18 52  27 57  41 61  48 64
59 72  69 72  80 80  31 53  51 69  72 81
;
```

It is a good practice to plot the data to check for obvious clusters or pathologies prior to the analysis. In this example, with only two variables and a small sample size, the SGPLOT procedure in the following statements produces a scatter plot:

```
proc sgplot;
  scatter y=y x=x;
run;
```

[Figure 60.1](#) suggests three clusters. Of these clusters, the one in the lower-left corner is the most compact, while the lower-right cluster is more dispersed.

The upper cluster is elongated and would be difficult for most clustering algorithms to identify as a single cluster. The plot also suggests that a Euclidean distance of 10 or 20 is a good initial guess for the neighborhood size in density estimation and clustering.

Figure 60.1 Scatter Plot of Data

To obtain a cluster analysis in PROC MODECLUS, you must specify the METHOD= option; for most purposes, METHOD=1 is recommended. The cluster analysis can be performed with a list of radii (R=10 15 35), as shown in the following PROC MODECLUS statement. An output data set containing the cluster membership is created with the OUT= option. The following statements produce Figure 60.2 through Figure 60.5:

```
proc modeclus data=example method=1 r=10 15 35 out=out;
run;
```

For each cluster solution, PROC MODECLUS produces a table of cluster statistics including the cluster number, the number of observations in the cluster, the maximum estimated density within the cluster, the number of observations in the cluster having a neighbor that belongs to a different cluster, and the estimated saddle density of the cluster. The results are displayed in Figure 60.2, Figure 60.3, and Figure 60.4 for three different radii. A smaller radius (R=10) yields a larger number of clusters (6), as displayed in Figure 60.2; a larger radius (R=35) includes all observations in a single cluster, as displayed in Figure 60.4. Note that all clusters in these three figures are “isolated” since their corresponding boundary frequencies are all zeros. Consequently, all the estimated saddle densities are missing. A table summarizing each cluster solution is then produced at the end, as displayed in Figure 60.5.

35	1	0

The OUT= data set contains a complete copy of the input data set for each cluster solution. By using a BY statement in the following PROC SGPLOT statement, you can examine the differences in cluster memberships for each radius as shown in [Figure 60.6](#) through [Figure 60.8](#):

```
proc sgplot data=out noautolegend;
  scatter y=y x=x / group=cluster markerchar=cluster;
  by _r_;
run;
```

Figure 60.7 Scatter Plots of Cluster Memberships with _R_=15**Figure 60.8** Scatter Plots of Cluster Memberships with _R_=35

Syntax: MODECLUS Procedure

The following statements are available in the MODECLUS procedure:

```
PROC MODECLUS < options > ;
    BY variables ;
    FREQ variable ;
    ID variable ;
    VAR variables ;
```

The PROC MODECLUS statement is required. All other statements are optional.

PROC MODECLUS Statement

```
PROC MODECLUS < options > ;
```

The PROC MODECLUS statement invokes the MODECLUS procedure. [Table 60.1](#) summarizes the options available in the PROC MODECLUS statement. These options are discussed in the following sections.

Table 60.1 Summary of PROC MODECLUS Statement Options

Option	Description
Specify input and output data sets	
DATA=	Specifies input data set name
OUT=	Specifies output data set name for observations
OUTCLUS=	Specifies output data set name for clusters
OUTSUM=	Specifies output data set name for cluster solutions
Specify variables in output data sets	
CLUSTER=	Specifies variable in the OUT= and OUTCLUS= data sets identifying clusters
DENSITY=	Specifies variable in the OUT= data set containing density estimates
OUTLENGTH=	Specifies length of variables in the output data sets
Summarize and process coordinate data before clustering	
SIMPLE	Requests simple statistics
STANDARD	Standardizes the variables to mean 0 and standard deviation 1
Specify smoothing parameters	
DK=	Specifies number of neighbors to use for <i>k</i> th-nearest-neighbor density estimation
CK=	Specifies number of neighbors to use for clustering
K=	Specifies number of neighbors to use for <i>k</i> th-nearest-neighbor density estimation and clustering
DR=	Specifies radius of the sphere of support for uniform-kernel density estimation
CR=	Specifies radius of the neighborhood for clustering
R=	Specifies radius of the sphere of support for uniform-kernel density estimation and the neighborhood clustering
Specify density estimation options	
CASCADE=	Specifies number of times the density estimates are to be cascaded

Table 60.1 *continued*

Option	Description
DIMENSION=	Specifies dimensionality to be used when computing density estimates
AM	Uses arithmetic means for cascading density estimates
HM	Uses harmonic means for cascading density estimates
SUM	Uses sums for cascading density estimates
Specify clustering methods and options	
DOCK=	Dissolves clusters with n or fewer members
EARLY	Stops the analysis after obtaining a solution with either no cluster or a single cluster
JOIN=	Requests that nonsignificant clusters be hierarchically joined
MAXCLUSTERS=	Specifies maximum number of clusters to be obtained with METHOD=6
METHOD=	Specifies clustering method to use
MODE=	Specifies minimum members for either cluster to be designated a modal cluster when two clusters are joined using METHOD=5
POWER=	Specifies power of the density used with METHOD=6
TEST	Specifies approximate significance tests for the number of clusters
THRESHOLD=	Specifies assignment threshold used with METHOD=6
Specify the output display options	
ALL	Produces all optional output
BOUNDARY	Displays the density and cluster membership of observations with neighbors belonging to a different cluster
CORE	Retains the neighbor lists for each observation in memory
CROSS	Displays the estimated cross validated log density of each observation
CROSSLIST	Displays the estimated density and cluster membership of each observation
LOCAL	Displays estimates of local dimensionality and writes them to the OUT=data set
NEIGHBOR	Displays the neighbors of each observation
NOPRINT	Suppresses the display of the output
NOSUMMARY	Suppresses the display of the summary of the number of clusters, number of unassigned observations, and maximum p -value for each analysis
SHORT	Suppresses the display of statistics for each cluster
TRACE	Traces the cluster assignments when METHOD=6

You can specify at least one of the following options for smoothing parameters for density estimation: DK=, K=, DR=, or R=. To obtain a cluster analysis, you can specify the METHOD= option and at least one of the following smoothing parameters for clustering: CK=, K=, CR=, or R=. If you want significance tests for the number of clusters, you should specify either the DR= or R= option. If none of the smoothing parameters is specified, the MODECLUS procedure provides a default value for the R= option. See the section “[Density Estimation](#)” on page 5096 for the formula of a reasonable first guess for R= and a discussion of smoothing parameters.

You can specify lists of values for the DK=, CK=, K=, DR=, CR=, and R= options. Numbers in the lists can be separated by blanks or commas. You can include in the lists one or more items of the form *start TO stop BY increment*. Each list can contain either one value or the same number of values as in every other list that contains more than one value. If a list has only one value, that value is used in combination with all

the values in longer lists. If two or more lists have more than one value, then one analysis is done by using the first value in each list, another analysis is done by using the second value in each list, and so on.

You can specify the following options in the PROC MODECLUS statement.

ALL

produces all optional output.

AM

specifies arithmetic means for cascading density estimates. See the description of the CASCADE= option.

BOUNDARY

displays the density and cluster membership of observations with neighbors belonging to a different cluster.

CASCADE=*n*

CASC=*n*

specifies the number of times the density estimates are to be cascaded (see the section “[Density Estimation](#)” on page 5096). The default value 0 performs no cascading.

You can specify a list of values for the CASCADE= option. Each value in the list is combined with each combination of smoothing parameters to produce a separate analysis.

CK=*n*

specifies the number of neighbors to use for clustering. The number of neighbors should be at least two but less than the number of observations. See the section “[Density Estimation](#)” on page 5096 for details.

CLUSTER=*name*

provides a name for the variable in the OUT= and OUTCLUS= data sets identifying clusters. The default name is CLUSTER.

CORE

keeps the neighbor lists for each observation in the computer memory to make small problems run faster.

CR=*n*

specifies the radius of the neighborhood for clustering. See the section “[Density Estimation](#)” on page 5096 for details.

CROSS

computes the likelihood cross validation criterion (Silverman 1986, pp. 52–55). This option appears to be of limited usefulness. See the section “[Density Estimation](#)” on page 5096 for details.

CROSSLIST

displays the cross validated log density of each observation.

DATA=*SAS-data-set*

specifies the input data set containing observations to be clustered. If you omit the DATA= option, the most recently created SAS data set is used.

If the data set is TYPE=DISTANCE, the data are interpreted as a distance matrix. The number of variables must equal the number of observations in the data set or in each BY group. The distances are assumed to be Euclidean, but the procedure accepts other types of distances or dissimilarities. Unlike the CLUSTER procedure, PROC MODECLUS uses the entire distance matrix, not just the lower triangle; the distances are not required to be symmetric. The neighbors of a given observation are determined solely from the distances in that observation. Missing values are considered infinite. Various distance measures can be computed from coordinate data by using the DISTANCE procedure (for detailed information, see Chapter 34, “[The DISTANCE Procedure](#)”).

If the data set is not TYPE=DISTANCE, the data are interpreted as coordinates in a Euclidean space, and Euclidean distances are computed. The variables can be discrete or continuous and should be at the interval level of measurement.

Data set types such as TYPE=DISTANCE do not persist when you copy or modify a data set. You must specify the TYPE= data set option for the new data set, as in the following example:

```
data dist2(type=distance);
  set dist;
run;
```

If you do not specify the TYPE=DISTANCE data set option, the new data set is the default TYPE=DATA. If you use the new data set in a procedure that accepts both TYPE=DATA or TYPE=DISTANCE data sets (such as PROC CLUSTER or PROC MODECLUS), the results will be incorrect.

DENSITY=*name*

provides a name for the variable in the OUT= data set containing density estimates. The default name is DENSITY.

DIMENSION=*n*

DIM=*n*

specifies the dimensionality to be used when computing density estimates. The default is the number of variables if the data are coordinates; the default is 1 if the data are distances.

DK=*n*

specifies the number of neighbors to use for *k*th-nearest-neighbor density estimation. The number of neighbors should be at least two but less than the number of observations. See the section “[Density Estimation](#)” on page 5096 for details.

DOCK=*n*

dissolves clusters with *n* or fewer members by making the members unassigned.

DR=*n*

specifies the radius of the sphere of support for uniform-kernel density estimation. See the section “[Density Estimation](#)” on page 5096 for details.

EARLY

stops the cluster analysis after obtaining either a solution with no cluster or a solution with one cluster to which all observations are assigned. The smoothing parameters should be specified in increasing order. This can reduce the computer time required for the analysis but might occasionally miss some multiple-cluster solutions.

HM

uses harmonic means for cascading density estimates. See the description of the `CASCADE=` option for details.

JOIN=<=p>

requests that nonsignificant clusters be hierarchically joined. The `JOIN` option implies the `TEST` option. After each solution is obtained, the cluster with the largest approximate p -value is either joined to a neighboring cluster or, if there is no neighboring cluster, dissolved by making all of its members unassigned. After two clusters are joined, an analysis of the remaining clusters is displayed.

If you do not specify a p -value with the `JOIN=` option, joining continues until only one cluster remains, and the results are written to the output data sets after each analysis. If you specify a p -value with the `JOIN=` option, joining continues until the greatest approximate p -value is less than the value given in the `JOIN=` option, and only if there is more than one cluster are the results for that analysis written to the output data sets.

Any value of p less than $1E-8$ is set to $1E-8$.

K=n

specifies the number of neighbors to use for k th-nearest-neighbor density estimation and clustering. The number of neighbors should be at least two but less than the number of observations. Specifying `K=n` is equivalent to specifying both `DK=n` and `CK=n`. See the section “[Density Estimation](#)” on page 5096 for details.

LIST

displays the estimated density and cluster membership of each observation.

LOCAL

requests estimates of local dimensionality (Tukey and Tukey 1981, pp. 236–237).

MAXCLUSTERS=n**MAXC=n**

specifies the maximum number of clusters to be obtained with the `METHOD=6` option. By default, there is no fixed limit.

METHOD=n**MET=n****M=n**

specifies what clustering method to use. Since these methods do not have widely recognized names, the methods are indicated by numbers from 0 to 6. The methods are described in the section “[Clustering Methods](#)” on page 5099. For most purposes, `METHOD=1` is recommended, although `METHOD=6` might occasionally produce better results in return for considerably greater computer time and space requirements. `METHOD=1` is not good for discrete coordinate data with only a few equally spaced values. In this case, `METHOD=6` or `METHOD=3` works better. `METHOD=4` or `METHOD=5` is less desirable than other methods when there are ties, since a general characteristic of agglomerative hierarchical clustering methods is that the results are indeterminate in the presence of ties.

You must specify the `METHOD=` option to obtain a cluster analysis.

You can specify a list of values for the `METHOD=` option. Each value in the list is combined with each combination of smoothing and cascading parameters to produce a separate cluster analysis.

MODE=*n*

specifies that when two clusters are joined using the METHOD=5 option (no other methods are affected by the MODE= option), each must have at least *n* members for either cluster to be designated a modal cluster. In any case, each cluster must also have a maximum density greater than the fusion density for either cluster to be designated a modal cluster. If you specify the K= option, the default value of the MODE= option is the same as the value of the K= option because the use of *k*th-nearest-neighbor density estimation limits the resolution that can be obtained for clusters with fewer than *k* members. If you do not specify the K= option, the default is MODE=2. If you specify MODE=0, the default value is used instead of 0. If you specify a FREQ statement, the MODE= value is compared to the number of observations in each cluster, not to the sum of the frequencies.

NEIGHBOR

displays the neighbors of each observation in a table called “Nearest Neighbor List.” See [Nearest Neighbor List](#) for information displayed in the table.

NOPRINT

suppresses the display of the output. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

NOSUMMARY

suppresses the display of the summary of the number of clusters, number of unassigned observations, and maximum *p*-value for each analysis.

OUT=SAS-data-set

specifies the output data set containing the input data plus density estimates, cluster membership, and variables identifying the type of solution. There is an output observation corresponding to each input observation for each solution. Therefore, the OUT= data set can be very large.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For details about OUT= data sets, see the section “[Output Data Sets](#)” on page 5107.

OUTCLUS=SAS-data-set**OUTC=SAS-data-set**

specifies the output data set containing an observation corresponding to each cluster in each solution. The variables identify the solution and contain statistics describing the clusters.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For details about OUTCLUS= data sets, see the section “[Output Data Sets](#)” on page 5107.

OUTSUM=SAS-data-set**OUTS=SAS-data-set**

specifies the output data set containing an observation corresponding to each cluster solution, giving the number of clusters and the number of unclassified observations for that solution.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For details about OUTSUM= data sets, see the section “[Output Data Sets](#)” on page 5107.

OUTLENGTH=*n***OUTL=*n***

specifies the length of those output variables that are not copied from the input data set but are created by PROC MODECLUS.

The OUTLENGTH= option applies only to the following variables that appear in all of the output data sets: `_K_`, `_DK_`, `_CK_`, `_R_`, `_DR_`, `_CR_`, `_CASCAD_`, `_METHOD_`, `_NJOIN_`, and `_LOCAL_`.

The minimum value is 2 or 3, depending on the operating system. The maximum value is 8. The default value is 8.

POWER=*n***POW=*n***

specifies the power of the density used with the METHOD=6 option. The default value is 2.

R=*n*

specifies the radius of the sphere of support for uniform-kernel density estimation and the neighborhood for clustering. Specifying R=*n* is equivalent to specifying both DR=*n* and CR=*n*. See the section “[Density Estimation](#)” on page 5096 for details.

SHORT

suppresses the display of statistics for each cluster.

SIMPLE**S**

displays means, standard deviations, skewness, kurtosis, and a coefficient of bimodality. The SIMPLE option applies only to coordinate data.

STANDARD**STD**

standardizes the variables to mean 0 and standard deviation 1. The STANDARD option applies only to coordinate data.

SUM

uses sums for cascading density estimates. See the description of the [CASCADE=](#) option for details.

TEST

performs approximate significance tests for the number of clusters. The R= or DR= option must also be specified with a nonzero value to obtain significance tests.

The significance tests performed by PROC MODECLUS are valid only for simple random samples, and they require at least 20 observations per cluster to have enough power to be of any use. See the section “[Significance Tests](#)” on page 5101 for details.

THRESHOLD=*n***THR=*n***

specifies the assignment threshold used with the METHOD=6 option. The default is 0.5.

TRACE

traces the process of cluster assignments when METHOD=6 is specified.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC MODECLUS to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MODECLUS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC MODECLUS then treats the data set as if each observation appeared n times, where n is the value of the FREQ variable for the observation. Nonintegral values of the FREQ variable are truncated to the largest integer less than the FREQ value.

ID Statement

ID *variable* ;

The values of the ID variable identify observations in the displayed results and in the OUT= data set. If you omit the ID statement, each observation is identified by its observation number, and a variable called `_OBS_` is written to the OUT= data set containing the original observation numbers.

VAR Statement

VAR *variables* ;

The VAR statement specifies numeric variables to be used in the cluster analysis. If you omit the VAR statement, all numeric variables not specified in other statements are used.

Details: MODECLUS Procedure

Density Estimation

See Silverman (1986) or Scott (1992) for an introduction to nonparametric density estimation.

PROC MODECLUS uses hyperspherical uniform kernels of fixed or variable radius. The density estimate at a point is computed by dividing the number of observations within a sphere centered at the point by the product of the sample size and the volume of the sphere. The size of the sphere is determined by the smoothing parameters that you are required to specify.

For fixed-radius kernels, specify the radius as a Euclidean distance with either the DR= or R= option. For variable-radius kernels, specify the number of neighbors desired within the sphere with either the DK= or K= option; the radius is then the smallest radius that contains at least the specified number of observations including the observation at which the density is being estimated. If you specify both the DR= or R= option and the DK= or K= option, the radius used is the maximum of the two indicated radii; this is useful for dealing with outliers.

It is convenient to refer to the sphere of support of the kernel at observation x_i as the *neighborhood* of x_i . The observations within the neighborhood of x_i are the *neighbors* of x_i . In some contexts, x_i is considered a neighbor of itself, but in other contexts it is not. The following notation is used in this chapter:

x_i	the i th observation
$d(x,y)$	the distance between points x and y
n	the total number of observations in the sample
n_i	the number of observations within the neighborhood of x_i , including x_i itself
n_i^-	the number of observations within the neighborhood of x_i , not including x_i itself
N_i	the set of indices of neighbors of x_i , including i
N_i^-	the set of indices of neighbors of x_i , not including i
v_i	the volume of the neighborhood of x_i
r_i	the radius of the neighborhood of x_i

\hat{f}_i	the estimated density at x_i
\hat{f}_i^-	the cross validated density estimate at x_i
C_k	the set of indices of observations assigned to cluster k
v	the number of variables or the dimensionality
s_l	standard deviation of the l th variable

The estimated density at x_i is

$$\hat{f}_i = \frac{n_i}{nv_i}$$

which indicates the number of neighbors of x_i divided by the product of the sample size and the volume of the neighborhood at x_i , where

$$v_i = \frac{\pi^{\frac{v}{2}} r_i^v}{\Gamma(\frac{v}{2} + 1)}$$

and Γ can be computed in a DATA step by using the GAMMA function. Note that $v = 1$ for distance data.

The density estimates provided by uniform kernels are not quite as good as those provided by some other types of kernels, but they are quite satisfactory for clustering. The significance tests for the number of clusters require the use of fixed-size uniform kernels.

There is no simple answer to the question of which smoothing parameter to use (Silverman 1986, pp. 43–61, 84–88, 98–99). It is usually necessary to try several different smoothing parameters. A reasonable first guess for the K= option is in the range of 0.1 to 1 times $n^{4/(v+4)}$, smaller values being suitable for higher dimensionalities. A reasonable first guess for the R= option in many coordinate data sets is given by

$$\left[\frac{2^{v+2}(v+2)\Gamma(\frac{v}{2} + 1)}{nv^2} \right]^{1/(v+4)} \sqrt{\sum_{l=1}^v s_l^2}$$

which can be computed in a DATA step by using the GAMMA function for Γ . The MODECLUS procedure also provides this first guess as a default smoothing parameter if none of the options (DR=, CR=, R=, DK=, CK=, and K=) is specified. This formula is derived under the assumption that the data are sampled from a multivariate normal distribution and, therefore, tend to be too large (oversmooth) if the true distribution is multimodal. Robust estimates of the standard deviations might be preferable if there are outliers. If the data are distances, the factor $\sqrt{\sum s_l^2}$ can be replaced by an average root-mean-squared Euclidean distance divided by $\sqrt{2}$. To prevent outliers from appearing as separate clusters, you can also specify K=2 or CK=2 or, more generally, K= m or CK= m , $m \geq 2$, which in most cases forces clusters to have at least m members.

If the variables all have unit variance (for example, if you specify the STD option), you can use [Table 60.2](#) to obtain an initial guess for the R= option.

Table 60.2 Reasonable First Guess for R= for Standardized Data

Number of Obs	Number of Variables									
	1	2	3	4	5	6	7	8	9	10
20	1.01	1.36	1.77	2.23	2.73	3.25	3.81	4.38	4.98	5.60
35	0.91	1.24	1.64	2.08	2.56	3.08	3.62	4.18	4.77	5.38
50	0.84	1.17	1.56	1.99	2.46	2.97	3.50	4.06	4.64	5.24
75	0.78	1.09	1.47	1.89	2.35	2.85	3.38	3.93	4.50	5.09
100	0.73	1.04	1.41	1.82	2.28	2.77	3.29	3.83	4.40	4.99
150	0.68	0.97	1.33	1.73	2.18	2.66	3.17	3.71	4.27	4.85
200	0.64	0.93	1.28	1.67	2.11	2.58	3.09	3.62	4.17	4.75
350	0.57	0.85	1.18	1.56	1.98	2.44	2.93	3.45	4.00	4.56
500	0.53	0.80	1.12	1.49	1.91	2.36	2.84	3.35	3.89	4.45
750	0.49	0.74	1.06	1.42	1.82	2.26	2.74	3.24	3.77	4.32
1000	0.46	0.71	1.01	1.37	1.77	2.20	2.67	3.16	3.69	4.23
1500	0.43	0.66	0.96	1.30	1.69	2.11	2.57	3.06	3.57	4.11
2000	0.40	0.63	0.92	1.25	1.63	2.05	2.50	2.99	3.49	4.03

One data-based method for choosing the smoothing parameter is likelihood cross validation (Silverman 1986, pp. 52–55). The cross validated density estimate at an observation is obtained by omitting the observation from the computations:

$$\hat{f}_i^- = \frac{n_i^-}{nv_i}$$

The (log) likelihood cross validation criterion is then computed as

$$\sum_{i=1}^n \log \hat{f}_i^-$$

The suggested smoothing parameter is the one that maximizes this criterion. With fixed-radius kernels, likelihood cross validation oversmooths long-tailed distributions; for purposes of clustering, it tends to undersmooth short-tailed distributions. With k -nearest-neighbor density estimation, likelihood cross validation is useless because it almost always indicates $k=2$.

Cascaded density estimates are obtained by computing initial kernel density estimates and then, at each observation, taking the arithmetic mean, harmonic mean, or sum of the initial density estimates of the observations within the neighborhood. The cascaded density estimates can, in turn, be cascaded, and so on. Let ${}_k\hat{f}_i$ be the density estimate at x_i cascaded k times. For all types of cascading, ${}_0\hat{f}_i = \hat{f}_i$. If the cascading is done by arithmetic means, then, for $k \geq 0$,

$${}_{k+1}\hat{f}_i = \sum_{j \in N_i} {}_k\hat{f}_j / n_i$$

For harmonic means,

$${}_{k+1}\hat{f}_i = \left(\sum_{j \in N_i} {}_k\hat{f}_j^{-1} / n_i \right)^{-1}$$

and for sums,

$${}_{k+1}\hat{f}_i = \left(\sum_{j \in N_i} {}_k\hat{f}_j^{k+1} \right)^{\frac{1}{k+2}}$$

To avoid cluttering formulas, the symbol \hat{f}_i is used in the rest of the chapter to denote the density estimate at x_i whether cascaded or not, since the clustering methods and significance tests do not depend on the degree of cascading.

Cascading increases the smoothness of the estimates with less computation than would be required by increasing the smoothing parameters to yield a comparable degree of smoothness. For population densities with bounded support and discontinuities at the boundaries, cascading improves estimates near the boundaries. Cascaded estimates, especially using sums, might be more sensitive to the local covariance structure of the distribution than are the uncascaded kernel estimates. Cascading seems to be useful for detecting very nonspherical clusters. Cascading was suggested by Tukey and Tukey (1981, p. 237). Additional research into the properties of cascaded density estimates is needed.

Clustering Methods

The number of clusters is a function of the smoothing parameters. The number of clusters tends to decrease as the smoothing parameters increase, but the relationship is not strictly monotonic. Generally, you should specify several different values of the smoothing parameters to see how the number of clusters varies.

The clustering methods used by PROC MODECLUS use spherical clustering neighborhoods of fixed or variable radius that are similar to the spherical kernels used for density estimation. For fixed-radius neighborhoods, specify the radius as a Euclidean distance with either the CR= or R= option. For variable-radius neighborhoods, specify the number of neighbors desired within the sphere with either the CK= or K= option; the radius is then the smallest radius that contains at least the specified number of observations including the observation for which the neighborhood is being determined. However, in the following descriptions of clustering methods, an observation is not considered to be one of its own neighbors. If you specify both the CR= or R= option and the CK= or K= option, the radius used is the maximum of the two indicated radii; this is useful for dealing with outliers. In this section, the symbols N_i , N_i^- , n_i , and n_i^- refer to clustering neighborhoods, not density estimation neighborhoods.

METHOD=0

Begin with each observation in a separate cluster. For each observation and each of its neighbors, join the cluster to which the observation belongs with the cluster to which the neighbor belongs. This method does not use density estimates. With a fixed clustering radius, the clusters are those obtained by cutting the single linkage tree at the specified radius (see Chapter 31, “The CLUSTER Procedure”).

METHOD=1

Begin with each observation in a separate cluster. For each observation, find the nearest neighbor with a greater estimated density. If such a neighbor exists, join the cluster to which the observation belongs with the cluster to which the specified neighbor belongs.

Next, consider each observation with density estimates equal to that of one or more neighbors but not less than the estimate at any neighbor. Join the cluster containing the observation with (1) each cluster containing a neighbor of the observation such that the maximum density estimate in the cluster equals the density estimate at the observation and (2) the cluster containing the nearest neighbor of the observation such that the maximum density estimate in the cluster exceeds the density estimate at the observation.

This method is similar to the classification or assignment stage of algorithms described by Gitman (1973) and Huizinga (1978).

METHOD=2

Begin with each observation in a separate cluster. For each observation, find the neighbor with the greatest estimated density exceeding the estimated density of the observation. If such a neighbor exists, join the cluster to which the observation belongs with the cluster to which the specified neighbor belongs.

Observations with density estimates equal to that of one or more neighbors but not less than the estimate at any neighbor are treated the same way as they are in METHOD=1.

This method is similar to the first stage of an algorithm proposed by Mizoguchi and Shimura (1980).

METHOD=3

Begin with each observation in a separate cluster. For each observation, find the neighbor with greater estimated density such that the slope of the line connecting the point on the estimated density surface at the observation with the point on the estimated density surface at the neighbor is a maximum. That is, for observation x_i , find a neighbor x_j such that $(\hat{f}_j - \hat{f}_i)/d(x_j, x_i)$ is a maximum. If this slope is positive, join the cluster to which observation x_i belongs with the cluster to which the specified neighbor x_j belongs. This method was invented by Koontz, Narendra, and Fukunaga (1976).

Observations with density estimates equal to that of one or more neighbors but not less than the estimate at any neighbor are treated the same way as they are in METHOD=1. The algorithm suggested for this situation by Koontz, Narendra, and Fukunaga (1976) might fail for flat areas in the estimated density that contain four or more observations.

METHOD=4

This method is equivalent to the first stage of two-stage density linkage (see Chapter 31, “[The CLUSTER Procedure](#)”) without the use of the MODE=option.

METHOD=5

This method is equivalent to the first stage of two-stage density linkage (see Chapter 31, “[The CLUSTER Procedure](#)”) with the use of the MODE=option.

METHOD=6

Begin with all observations unassigned.

Step 1: Form a list of seeds, each seed being a single observation such that the estimated density of the observation is not less than the estimated density of any of its neighbors. If you specify the MAXCLUSTERS= n option, retain only the n seeds with the greatest estimated densities.

Step 2: Consider each seed in decreasing order of estimated density, as follows:

1. If the current seed has already been assigned, proceed to the next seed. Otherwise, form a new cluster consisting of the current seed.
2. Add to the cluster any unassigned seed that is a neighbor of a member of the cluster or that shares a neighbor with a member of the cluster; repeat until no unassigned seed satisfies these conditions.
3. Add to the cluster all neighbors of seeds that belong to the cluster.
4. Consider each unassigned observation. Compute the ratio of the sum of the $p - 1$ powers of the estimated density of the neighbors that belong to the current cluster to the sum of the $p - 1$ powers of the estimated density of all of its neighbors, where p is specified by the POWER= option and is 2 by default. Let x_i be the current observation, and let k be the index of the current cluster. Then this ratio is

$$r_{ik} = \frac{\sum_{j \in N_i \cap C_k} \hat{f}_j^{p-1}}{\sum_{j \in N_i} \hat{f}_j^{p-1}}$$

(The sum of the $p - 1$ powers of the estimated density of the neighbors of an observation is an estimate of the integral of the p th power of the density over the neighborhood.) If r_{ik} exceeds the maximum of 0.5 and the value of the THRESHOLD= option, add the observation x_i to the current cluster k . Repeat until no more observations can be added to the current cluster.

Step 3: (This step is performed only if the value of the THRESHOLD= option is less than 0.5.) Form a list of unassigned observations in decreasing order of estimated density. Repeat the following actions until the list is empty:

1. Remove the first observation from the list, such as observation x_i .
2. For each cluster k , compute r_{ik} .
3. If the maximum over clusters of r_{ik} exceeds the value of the THRESHOLD= option, assign observation x_i to the corresponding cluster and insert all observations of which the current observation is a neighbor into the list, keeping the list in decreasing order of estimated density.

METHOD=6 is related to a method invented by Koontz and Fukunaga (1972a) and discussed by Koontz and Fukunaga (1972b).

Significance Tests

Significance tests require that a fixed-radius kernel be specified for density estimation via the DR= or R= option. You can also specify the DK= or K= option, but only the fixed radius is used for the significance tests.

The purpose of the significance tests is as follows: given a simple random sample of objects from a population, obtain an estimate of the number of clusters in the population such that the probability in repeated sampling that the estimate exceeds the true number of clusters is not much greater than α , $1\% \leq \alpha \leq 10\%$. In other words, a sequence of null hypotheses of the form

$H_0^{(i)}$: The number of population clusters is i or less

where $i = 1, 2, \dots, n$, is tested against the alternatives such as

$H_a^{(i)}$: The number of population clusters exceeds i

with a maximum experimentwise error rate of approximately α . The tests protect you from overestimating the number of population clusters. It is impossible to protect against underestimating the number of population clusters without introducing much stronger assumptions than are used here, since the number of population clusters could conceivably exceed the sample size.

The method for conducting significance tests is as follows:

1. Estimate densities by using fixed-radius uniform kernels.
2. Obtain preliminary clusters by a “valley-seeking” method. Other clustering methods could be used but would yield less power.
3. Compute an approximate p -value for each cluster by comparing the estimated maximum density in the cluster with the estimated maximum density on the cluster boundary.
4. Repeatedly join the least significant cluster with a neighboring cluster until all remaining clusters are significant.
5. Estimate the number of population clusters as the number of significant sample clusters.
6. The preceding steps can be repeated for any number of different radii, and the estimate of the number of population clusters can be taken to be the maximum number of significant sample clusters for any radius.

This method has the following useful features:

- No distributional assumptions are required.
- The choice of smoothing parameter is not critical since you can try any number of different values.
- The data can be coordinates or distances.
- Time and space requirements for the significance tests are no worse than those for obtaining the clusters.
- The power is high enough to be useful for practical purposes.

The method for computing the p -values is based on a series of plausible approximations. There are as yet no rigorous proofs that the method is infallible. Neither are there any asymptotic results. However, simulations for sample sizes ranging from 20 to 2000 indicate that the p -values are almost always conservative. The only case discovered so far in which the p -values are liberal is a uniform distribution in one dimension for

which the simulated error rates exceed the nominal significance level only slightly for a limited range of sample sizes.

To make inferences regarding population clusters, it is first necessary to define what is meant by a cluster. For clustering methods that use nonparametric density estimation, a cluster is usually loosely defined as a region surrounding a local maximum of the probability density function or a maximal connected set of local maxima. This definition might not be satisfactory for very rough densities with many local maxima. It is not applicable at all to discrete distributions for which the density does not exist. As another example in which this definition is not intuitively reasonable, consider a uniform distribution in two dimensions with support in the shape of a figure eight (including the interior). This density might be considered to contain two clusters even though it does not have two distinct modes.

These difficulties can be avoided by defining clusters in terms of the local maxima of a smoothed probability density or mass function. For example, define the neighborhood distribution function (NDF) with radius r at a point x as the probability that a randomly selected point will lie within a radius r of x —that is, the probability integral over a hypersphere of radius r centered at x :

$$s(x) = P(d(x, X) \leq r)$$

where X is the random variable being sampled, r is a user-specified radius, and $d(x, y)$ is the distance between points x and y .

The NDF exists for all probability distributions. You can select the radius according to the degree of resolution required. The minimum-variance unbiased estimate of the NDF at a point x is proportional to the uniform-kernel density estimate with corresponding support.

You can define a *modal region* as a maximal connected set of local maxima of the NDF. A cluster is a connected set containing exactly one modal region. This definition seems to give intuitively reasonable results in most cases. An exception is a uniform density on the perimeter of a square. The NDF has four local maxima. There are eight local maxima along the perimeter, but running PROC MODECLUS with the `R=` option would yield four clusters since the two local maxima at each corner are separated by a distance equal to the radius. While this density does indeed have four distinctive features (the corners), it is not obvious that each corner should be considered a cluster.

The number of population clusters depends on the radius of the NDF. The significance tests in PROC MODECLUS protect against overestimating the number of clusters at any specified radius. It is often useful to look at the clustering results across a range of radii. A plot of the number of sample clusters as a function of the radius is a useful descriptive display, especially for high-dimensional data (Wong and Schaack 1982).

If a population has two clusters, it must have two modal regions. If there are two modal regions, there must be a “valley” between them. It seems intuitively desirable that the boundary between the two clusters should follow the bottom of this valley. All the clustering methods in PROC MODECLUS are designed to locate the estimated cluster boundaries in this way, although methods 1 and 6 seem to be much more successful at this than the others. Regardless of the precise location of the cluster boundary, it is clear that the maximum of the NDF along the boundary between two clusters must be strictly less than the value of the NDF in either modal region; otherwise, there would be only a single modal region; according to Hartigan and Hartigan (1985), there must be a “dip” between the two modes. PROC MODECLUS assesses the significance of a sample cluster by comparing the NDF in the modal region with the maximum of the NDF along the cluster boundary. If the NDF has second-order derivatives in the region of interest and if the boundary between the two clusters is indeed at the bottom of the valley, then the maximum value of the NDF along the boundary

occurs at a saddle point. Hence, this test is called a *saddle test*. This term is intended to describe any test for clusters that compares modal densities with saddle densities, not just the test currently implemented in the MODECLUS procedure.

The obvious estimate of the maximum NDF in a sample cluster is the maximum estimated NDF at an observation in the cluster. Let $m(k)$ be the index of the observation for which the maximum is attained in cluster k .

Estimating the maximum NDF on the cluster boundary is more complicated. One approach is to take the maximum NDF estimate at an observation in the cluster that has a neighbor belonging to another cluster. This method yields excessively large estimates when the neighborhood is large. Another approach is to try to choose an object closer to the boundary by taking the observation with the maximum sum of estimated densities of neighbors belonging to a different cluster. After some experimentation, it is found that a combination of these two methods works well. Let B_k be the set of indices of observations in cluster k that have neighbors belonging to a different cluster, and compute

$$\max_{i \in B_k} \left(0.2 \hat{f}_i n_i + \sum_{j \in N_i - C_k} \hat{f}_j \right)$$

Let $s(k)$ be the index of the observation for which the maximum is attained.

Using the notation $\#(S)$ for the cardinality of set S , let

$$\begin{aligned} n_{ij}^- &= \#(N_i^- \cap N_j^-) \\ c_m(k) &= n_{m(k)}^- - n_{m(k)s(k)}^- \\ c_s(k) &= n_{s(k)}^- - n_{m(k)s(k)}^- \text{ if } B_k \neq \emptyset, \\ &= 0 \text{ otherwise} \\ q_k &= 1/2 \text{ if } B_k \neq \emptyset, \\ &= 2/3 \text{ otherwise} \\ z_k &= \frac{c_m(k) - q_k(c_m(k) + c_s(k)) - 1/2}{\sqrt{q_k(1 - q_k)(c_m(k) + c_s(k))}} \\ u &= \left\lceil (0.2 + 0.05\sqrt{n}) \sum_{i: n_i > 1} \frac{1}{n_i + 1} \right\rceil \end{aligned}$$

Let $R(u)$ be a random variable distributed as the range of a random sample of u observations from a standard normal distribution. Then the approximate p -value p_k for cluster k is

$$p_k = \Pr(z_k > R(u)/\sqrt{2})$$

If points $m(k)$ and $s(k)$ are fixed a priori, z_k would be the usual approximately normal test statistic for comparing two binomial random variables. In fact, $m(k)$ and $s(k)$ are selected in such a way that $c_m(k)$ tends to be large and $c_s(k)$ tends to be small. For this reason, and because there might be a large number of clusters, each with its own z_k to be tested, each z_k is referred to the distribution of $R(u)$ instead of a

standard normal distribution. If the tests are conducted for only one radius and if u is chosen equal to n , then the p -values are very conservative because (1) you are not making all possible pairwise comparisons of observations in the sample and (2) n_i^- and n_j^- are positively correlated if the neighborhoods overlap. In the formula for u , the summation overcorrects somewhat for the conservativeness due to correlated n_i^- 's. The factor $0.2 + 0.05\sqrt{n}$ is empirically estimated from simulation results to adjust for the use of more than one radius.

If the JOIN option is specified, the least significant cluster (the cluster with the smallest z_k) is either dissolved or joined with a neighboring cluster. If no members of the cluster have neighbors belonging to a different cluster, all members of the cluster are unassigned. Otherwise, the cluster is joined to the neighboring cluster such that the sum of density estimates of neighbors of the estimated saddle point belonging to it is a maximum. Joining clusters increases the power of the saddle test. For example, consider a population with two well-separated clusters. Suppose that, for a certain radius, each population cluster is divided into two sample clusters. None of the four sample clusters is likely to be significant, but after the two sample clusters corresponding to each population cluster are joined, the remaining two clusters can be highly significant.

The saddle test implemented in PROC MODECLUS has been evaluated by simulation from known distributions. Some results are given in the following three tables. In Table 60.3, samples of 20 to 2000 observations are generated from a one-dimensional uniform distribution. For sample sizes of 1000 or less, 2000 samples are generated and analyzed by PROC MODECLUS. For a sample size of 2000, only 1000 samples are generated. The analysis is done with at least 20 different values of the R= option spread across the range of radii most likely to yield significant results. The six central columns of the table give the observed error rates at the nominal error rates (α) at the head of each column. The standard errors of the observed error rates are given at the bottom of the table. The observed error rates are conservative for $\alpha \leq 5\%$, but they increase with α and become slightly liberal for sample sizes in the middle of the range tested.

Table 60.3 Observed Error Rates (%) for Uniform Distribution

Sample Size	Nominal Type 1 Error Rate						Number of Simulations
	1	2	5	10	15	20	
20	0.00	0.00	0.00	0.60	11.65	27.05	2000
50	0.35	0.70	4.50	10.95	20.55	29.80	2000
100	0.35	0.85	3.90	11.05	18.95	28.05	2000
200	0.30	1.35	4.00	10.50	18.60	27.05	2000
500	0.45	1.05	4.35	9.80	16.55	23.55	2000
1000	0.70	1.30	4.65	9.55	15.45	19.95	2000
2000	0.40	1.10	3.00	7.40	11.50	16.70	1000
Standard	0.22	0.31	0.49	0.67	0.80	0.89	2000
Error	0.31	0.44	0.69	0.95	1.13	1.26	1000

All unimodal distributions other than the uniform that have been tested, including normal, Cauchy, and exponential distributions and uniform mixtures, have produced much more conservative results. Table 60.4 displays results from a unimodal mixture of two normal distributions with equal variances and equal sampling probabilities and with means separated by two standard deviations. Any greater separation would produce a bimodal distribution. The observed error rates are quite conservative.

Table 60.4 Observed Error Rates (%) for Normal Mixture with 2σ Separation

Sample Size	Nominal Type 1 Error Rate						Number of Simulations
	1	2	5	10	15	20	
100	0.0	0.0	0.0	1.0	2.0	4.0	200
200	0.0	0.0	0.0	2.0	3.0	3.0	200
500	0.0	0.0	0.5	0.5	0.5	0.5	200

All distributions in two or more dimensions that have been tested yield extremely conservative results. For example, a uniform distribution on a circle yields observed error rates that are never more than one-tenth of the nominal error rates for sample sizes up to 1000. This conservatism is due to the fact that, as the dimensionality increases, more and more of the probability lies in the tails of the distribution (Silverman 1986, p. 92), and the saddle test used by PROC MODECLUS is more conservative for distributions with pronounced tails. This applies even to a uniform distribution on a hypersphere because, although the density does not have tails, the NDF does.

Since the formulas for the significance tests do not involve the dimensionality, no problems are created when the data are linearly dependent. Simulations of data in nonlinear subspaces (the circumference of a circle or surface of a sphere) have also yielded conservative results.

Table 60.5 displays results in terms of power for identifying two clusters in samples from a bimodal mixture of two normal distributions with equal variances and equal sampling probabilities separated by four standard deviations. In this simulation, PROC MODECLUS never indicated more than two significant clusters.

Table 60.5 Power (%) for Normal Mixture with 4σ Separation

Sample Size	Nominal Type 1 Error Rate						Number of Simulations
	1	2	5	10	15	20	
20	0.0	0.0	0.0	2.0	37.5	68.5	200
35	0.0	13.5	38.5	48.5	64.0	75.5	200
50	17.5	26.0	51.5	67.0	78.5	84.0	200
75	25.5	36.0	58.5	77.5	85.5	89.5	200
100	40.0	54.5	72.5	84.5	91.5	92.5	200
150	70.5	80.0	92.0	97.0	100.0	100.0	200
200	89.0	96.0	99.5	100.0	100.0	100.0	200

The saddle test is not as efficient as excess-mass tests for multimodality (Müller and Sawitzki 1991; Polonik 1993). However, there is not yet a general approximation for the distribution of excess-mass statistics to circumvent the need for simulations to do significance tests. See Minnotte (1992) for a review of tests for multimodality.

Computational Resources

The MODECLUS procedure stores coordinate data in memory if there is enough space. For distance data, only one observation at a time is in memory.

PROC MODECLUS constructs lists of the neighbors of each observation. The total space required is $12 \sum n_i$ bytes, where n_i is based on the largest neighborhood required by any analysis. The lists are stored

in a SAS utility data set unless you specify the CORE option. You might get an error message from the SAS System or from the operating system if there is not enough disk space for the utility data set. Clustering method 6 requires a second list that is always stored in memory.

For coordinate data, the time required to construct the neighbor lists is roughly proportional to $v(\log n)(\sum n_i) \log(\sum n_i/n)$. For distance data, the time is roughly proportional to $n^2 \log(\sum n_i/n)$.

The time required for density estimation is proportional to $\sum n_i$ and is usually small compared to the time required for constructing the neighbor lists.

Clustering methods 0 through 3 are quite efficient, requiring time proportional to $\sum n_i$. Methods 4 and 5 are slower, requiring time roughly proportional to $(\sum n_i) \log(\sum n_i)$. Method 6 can also be slow, but the time requirements depend very much on the data and the particular options specified. Methods 4, 5, and 6 also require more memory than the other methods.

The time required for significance tests is roughly proportional to $g \sum n_i$, where g is the number of clusters.

PROC MODECLUS can process data sets of several thousand observations if you specify reasonable smoothing parameters. Very small smoothing values produce many clusters, whereas very large values produce many neighbors; either case can require excessive time or space.

Missing Values

If the data are coordinates, observations with missing values are excluded from the analysis.

If the data are distances, missing values are treated as infinite. The neighbors of each observation are determined solely by the distances in that observation. The distances are not required to be symmetric, and there is no check for symmetry; the neighbors of each observation are determined only from the distances in that observation. This treatment of missing values is quite different from that of the CLUSTER procedure, which ignores the upper triangle of the distance matrix.

Output Data Sets

The OUT= data set contains one complete copy of the input data set for each cluster solution. There are additional variables identifying each solution and giving information about individual observations. Solutions with only one remaining cluster when JOIN= p is specified are omitted from the OUT= data set (see the description of the JOIN= option). The OUT= data set can be extremely large, so it is advisable to specify the DROP= data set option to exclude unnecessary variables.

The OUTCLUS= or OUTC= data set contains one observation for each cluster in each cluster solution. The variables identify the solution and provide statistics describing the cluster.

The OUTSUM= or OUTS= data set contains one observation for each cluster solution. The variables identify the solution and provide information about the solution as a whole.

The following variables can appear in all of the output data sets:

- `_K_`, which is the value of the K= option for the current solution. This variable appears only if you specify the K= option.

- `_DK_`, which is the value of the `DK=` option for the current solution. This variable appears only if you specify the `DK=` option.
- `_CK_`, which is the value of the `CK=` option for the current solution. This variable appears only if you specify the `CK=` option.
- `_R_`, which is the value of the `R=` option for the current solution. This variable appears only if you specify the `R=` option.
- `_DR_`, which is the value of the `DR=` option for the current solution. This variable appears only if you specify the `DR=` option.
- `_CR_`, which is the value of the `CR=` option for the current solution. This variable appears only if you specify the `CR=` option.
- `_CASCAD_`, which is the number of times the density estimates have been cascaded for the current solution. This variable appears only if you specify the `CASCADE=` option.
- `_METHOD_`, which is the value of the `METHOD=` option for the current solution. This variable appears only if you specify the `METHOD=` option.
- `_NJOIN_`, which is the number of clusters that are joined or dissolved in the current solution. This variable appears only if you specify the `JOIN` option.
- `_LOCAL_`, which is the local dimensionality estimate of the observation. This variable appears only if you specify the `LOCAL` option.

The `OUT=` data set contains the following variables:

- the variables from the input data set
- `_OBS_`, which is the observation number from the input data set. This variable appears only if you omit the `ID` statement.
- `DENSITY`, which is the estimated density at the observation. This variable can be renamed by the `DENSITY=` option.
- `CLUSTER`, which is the number of the cluster to which the observation is assigned. This variable can be renamed by the `CLUSTER=` option.

The `OUTCLUS=` data set contains the following variables:

- the `BY` variables, if any
- `_NCLUS_`, which is the number of clusters in the solution
- `CLUSTER`, which is the number of the current cluster
- `_FREQ_`, which is the number of observations in the cluster
- `_MODE_`, which is the maximum estimated density in the cluster
- `_BFREQ_`, which is the number of observations in the cluster with neighbors belonging to a different cluster

- `_SADDLE_`, which is the estimated saddle density for the cluster
- `_MC_`, which is the number of observations within the fixed-radius density-estimation neighborhood of the modal observation. This variable appears only if you specify the TEST or JOIN option.
- `_SC_`, which is the number of observations within the fixed-radius density-estimation neighborhood of the saddle observation. This variable appears only if you specify the TEST or JOIN option.
- `_OC_`, which is the number of observations within the overlap of the two previous neighborhoods. This variable appears only if you specify the TEST or JOIN option.
- `_Z_`, which is the approximate z statistic for the cluster. This variable appears only if you specify the TEST or JOIN option.
- `_P_`, which is the approximate p -value for the cluster. This variable appears only if you specify the TEST or JOIN option.

The OUTSUM= data set contains the following variables:

- the BY variables, if any
- `_NCLUS_`, which is the number of clusters in the solution
- `_UNCL_`, which is the number of unclassified observations
- `_CROSS_`, which is the likelihood cross validation criterion if you specify the CROSS or CROSSLIST option

Displayed Output

If you specify the SIMPLE option and the data are coordinates, PROC MODECLUS displays the following simple descriptive statistics for each variable:

- the mean
- the standard deviation
- the skewness
- the kurtosis
- a coefficient of bimodality (see Chapter 31, “[The CLUSTER Procedure](#)”)

If you specify the NEIGHBOR option, PROC MODECLUS displays a list of neighbors for each observation. The table contains the following items:

- the observation number or ID value of the observation
- the observation number or ID value of each of its neighbors
- the distance to each neighbor

If you specify the CROSSLIST option, PROC MODECLUS produces a table of information regarding cross validation of the density estimates. Each table has a row for each observation. For each observation, the following are displayed:

- the observation number or ID value of the observation
- the radius of the neighborhood
- the number of neighbors
- the estimated log density
- the estimated cross validated log density

If you specify the LOCAL option, PROC MODECLUS produces a table of information regarding estimates of local dimensionality. Each table has a row for each observation. For each observation, the following are displayed:

- the observation number or ID value of the observation
- the radius of the neighborhood
- the estimated local dimensionality

If you specify the LIST option, PROC MODECLUS produces a table listing the observations within each cluster. The table includes the following items:

- the cluster number
- the observation number or ID value of the observation
- the estimated density
- the sum of the density estimates of observations within the neighborhood that belong to the same cluster
- the sum of the density estimates of observations within the neighborhood that belong to a different cluster
- the sum of the density estimates of all the observations within the neighborhood
- the ratio of the sum of the density estimates for the same cluster to the sum of all the density estimates in the neighborhood

If you specify the LIST option and there are unassigned objects, PROC MODECLUS produces a table listing those observations. The table includes the following items:

- the observation number or ID value of the observation
- the estimated density
- the ratio of the sum of the density estimates for the same cluster to the sum of the density estimates in the neighborhood for all other clusters

If you specify the BOUNDARY option, PROC MODECLUS produces a table listing the observations in each cluster that have a neighbor belonging to a different cluster. The table includes the following items:

- the observation number or ID value of the observation
- the estimated density

- the cluster number
- the ratio of the sum of the density estimates for the same cluster to the sum of the density estimates in the neighborhood for all other clusters

If you do not specify the SHORT option, PROC MODECLUS produces a table of cluster statistics including the following items:

- the cluster number
- the cluster frequency (the number of observations in the cluster)
- the maximum estimated density within the cluster
- the number of observations in the cluster having a neighbor that belongs to a different cluster
- the estimated saddle density of the cluster

If you specify the TEST or JOIN option, the table of cluster statistics includes the following items pertaining to the saddle test:

- the number of observations within the fixed-radius density-estimation neighborhood of the modal observation
- the number of observations within the fixed-radius density-estimation neighborhood of the saddle observation
- the number of observations within the overlap of the two preceding neighborhoods
- the z statistic for comparing the preceding counts
- the approximate p -value

If you do not specify the NOSUMMARY option, PROC MODECLUS produces a table summarizing each cluster solution containing the following items:

- the smoothing parameters and cascade value
- the number of clusters
- the frequency of unclassified objects
- the likelihood cross validation criterion if you specify the CROSS or CROSSLIST option

If you specify the JOIN option, the summary table also includes the following items:

- the number of clusters joined
- the maximum p -value of any cluster in the solution

If you specify the TRACE option, PROC MODECLUS produces a table for each cluster solution that lists each observation along with its cluster membership as it is reassigned from the “Old” cluster to the “New” cluster. This reassignment is described in **Step 1** through **Step 3** of the section “**METHOD=6**” on page 5100. Each table has a row for each observation. For each observation, the following are displayed:

- the observation number or ID value of the observation

- the estimated density
- the “Old” cluster membership. 0 represents an unassigned observation and –1 represents a seed.
- the “New” cluster membership
- “Ratio,” which is documented in the section “**METHOD=6**” on page 5100. The following character values can also be displayed:

“M” means the observation is a mode

“S” means the observation is a seed

“N” means the neighbor of a mode or seed, for which the ratio is not computed

ODS Table Names

PROC MODECLUS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 60.6](#).

For more information about ODS, see Chapter 20, “[Using the Output Delivery System.](#)”

All of the ODS tables in [Table 60.6](#) are created by specifying the PROC MODECLUS statement.

Table 60.6 ODS Tables Produced by PROC MODECLUS

ODS Table Name	Description	Option
BoundaryFreq	Boundary objects information	BOUNDARY or ALL
ClusterList	Cluster listing, cluster ID, frequency, density etc.	LIST or ALL
ClusterStats	Cluster statistics	default
	Cluster statistics, significance test statistics	TEST, JOIN, or ALL
ClusterSummary	Cluster summary	default
	Cluster summary, crossvalidation criterion	CROSS, CROSSLIS, or ALL
	Cluster summary, clusters joined information	JOIN or ALL
CrossList	Cross validated log density	CROSSLIST
ListLocal	Local dimensionality estimates	LOCAL
Neighbor	Nearest neighbor list	NEIGHBOR or ALL
SimpleStatistics	Simple statistics	SIMPLE or ALL
Trace	Trace of clustering algorithm (METHOD=6 only)	TRACE or ALL when METHOD=6
UnassignObjects	Information about unassigned objects	LIST or ALL

Examples: MODECLUS Procedure

Example 60.1: Cluster Analysis of Samples from Univariate Distributions

This example uses pseudo-random samples from a uniform distribution, an exponential distribution, and a bimodal mixture of two normal distributions. Results are presented in [Output 60.1.1](#) through [Output 60.1.18](#) as plots displaying both the true density and the estimated density, as well as cluster membership.

The following statements produce [Output 60.1.1](#) through [Output 60.1.4](#):

```

title 'Modeclus Example with Univariate Distributions';
title2 'Uniform Distribution';

data uniform;

Example 60.2: Cluster Analysis of Flying Mileages between Ten American Cities

This example uses distance data and illustrates the use of the TRANSPOSE procedure and the DATA step to fill in the upper triangle of the distance matrix. A data set containing a table of flying mileages between 10 U.S. cities is available in the Sashelp library. The results are displayed in [Output 60.2.1](#) through [Output 60.2.3](#).

The following statements produce [Output 60.2.1](#):

```

title 'Modeclus Analysis of 10 American Cities';
title2 'Based on Flying Mileages';

*-----Fill in Upper Triangle of Distance Matrix-----;
proc transpose data=sashelp.mileages out=tran;
  copy city;
run;

data mileages(type=distance drop=col: _: i);
  merge sashelp.mileages tran;
  array var[10] atlanta--washingtondc;
  array col[10];
  do i = 1 to 10;
    var[i] = sum(var[i], col[i]);
  end;
run;

*-----Clustering with K-Nearest-Neighbor Density Estimates-----;
proc modeclus data=mileages all m=1 k=3;
  id CITY;
run;

```

Example 60.3: Cluster Analysis with Significance Tests

This example uses artificial data containing two clusters. One cluster is from a circular bivariate normal distribution. The other is a ring-shaped cluster that completely surrounds the first cluster. Without significance tests, the ring is divided into several sample clusters for any degree of smoothing that yields reasonable density estimates. The JOIN= option puts the ring back together. [Output 60.3.1](#) displays a short summary generated from the first PROC MODECLUS statement. [Output 60.3.2](#) contains a series of tables produced from the second PROC MODECLUS statement. The lack of p -value in the JOIN= option makes joining continue until only one cluster remains (see the description of the JOIN= option). The cluster memberships are then plotted as displayed in [Output 60.3.1](#) through [Output 60.3.8](#).

The following statements produce [Output 60.3.1](#) through [Output 60.3.8](#):

```

title 'Modeclus Analysis with the JOIN= option';
title2 'A Normal Cluster Surrounded by a Ring Cluster';

data circle; keep x y;
  c=1;
  do n=1 to 30;
    x=rannor(5);
    y=rannor(5);
    output;
  end;

  c=2;
  do n=1 to 300;
    x=rannor(5);
    y=rannor(5);
    z=rannor(5)+8;
    l=z/sqrt(x**2+y**2);
    x=x*l;
    y=y*l;
    output;
  end;
run;
```

```

Output 60.3.8 Cluster Memberships When Number of Clusters Joined=5**Example 60.4: Cluster Analysis: Hertzsprung-Russell Plot**

This example uses computer-generated data to mimic a Hertzsprung-Russell plot (Struve and Zeberg 1962, p. 259) of the temperature and luminosity of stars. The data are plotted and displayed in [Output 60.4.1](#). It appears that there are two main groups of stars and a collection of isolated stars. The long straggling group of points appearing diagonally across the figure represents the main group of stars; the more compact group in the top-right corner contains giant stars. The JOIN= option is specified at a 0.05 significance level with various smoothing parameters. The CK=5 option is specified in order to prevent the numerous outliers from forming separate clusters. The results from PROC MODECLUS is displayed in [Output 60.4.2](#). The cluster memberships are then plotted by PROC SGPLOT, as displayed in [Output 60.4.3](#) through [Output 60.4.5](#).

Note that the graphic output from PROC SGPLOT in [Output 60.4.3](#) is not available when `_R_ = 2.5` because only one cluster remains after joining at a 5% significance level, and the results are not written to the OUT= data set. See the description of the JOIN= option). for more information.

The following statements produce [Output 60.4.1](#) through [Output 60.4.5](#):

```

Example 60.5: Using the TRACE Option When METHOD=6

To illustrate how the TRACE option can help you to understand the clustering process when METHOD=6 is specified, the following data set is created with 12 observations:

```
data test;
  input x @@;
  datalines;
1 2 3 4 5 7.5 9 11.5 13 14.5 15 16
;
```

The first five observations seem to be close to each other, and the last five observations seem to be close to each other. Observation 6 is separated from the first five observations with a (Euclidean) distance of 2.5, and the same distance separates observation 7 from the last five observations. Observations 6 and 7 differ by 1.5.

Suppose METHOD=6 with a radius of 2.5 is chosen for the cluster analysis. You can specify the TRACE option to understand how each observation is assigned.

The following statements produce [Output 60.5.1](#) and [Output 60.5.2](#):

```
/*-- METHOD=6 with TRACE and THRESHOLD=0.5 (default) --*/
title 'METHOD=6 with TRACE and THRESHOLD=0.5 (default)';

proc modeclus data=test method=6 r=2.5 trace short out=out;
  var x;
run;
```

```

title2 'Plot of DENSITY*X=CLUSTER';

proc sgplot data=out;
  scatter y=density x=x / group=cluster datalabel=_obs_;
run;

```

Output 60.5.1 Partial Output of METHOD=6 with TRACE and Default THRESHOLD=

METHOD=6 with TRACE and THRESHOLD=0.5 (default)

The MODECLUS Procedure

Overview: MULTTEST Procedure

The MULTTEST procedure addresses the multiple testing problem. This problem arises when you perform many hypothesis tests on the same data set. Carrying out multiple tests is often reasonable because of the cost of obtaining data, the discovery of new aspects of the data, and the many alternative statistical methods. However, a disadvantage of multiple testing is the greatly increased probability of declaring false significances.

For example, suppose you carry out 10 hypothesis tests at the 5% level, and you assume that the distributions of the p -values from these tests are uniform and independent. Then, the probability of declaring a particular test significant under its null hypothesis is 0.05, but the probability of declaring at least 1 of the 10 tests significant is 0.401. If you perform 20 hypothesis tests, the latter probability increases to 0.642. These high chances illustrate the danger of multiple testing.

PROC MULTTEST approaches the multiple testing problem by adjusting the p -values from a family of hypothesis tests. An adjusted p -value is defined as the smallest significance level for which the given hypothesis would be rejected, when the entire family of tests is considered. The decision rule is to reject the null hypothesis when the adjusted p -value is less than α . For most methods, this decision rule controls the *familywise error rate* at or below the α level. However, the *false discovery rate* controlling procedures control the false discovery rate at or below the α level.

PROC MULTTEST provides the following p -value adjustments:

- Bonferroni
- Šidák
- step-down methods
- Hochberg
- Hommel
- Fisher and Stouffer combination
- bootstrap
- permutation
- adaptive methods
- false discovery rate
- positive FDR

The Bonferroni and Šidák adjustments are simple functions of the raw p -values. They are computationally quick, but they can be too conservative. Step-down methods remove some conservativeness, as do the step-up methods of Hochberg (1988), and the adaptive methods. The bootstrap and permutation adjustments resample the data with and without replacement, respectively, to approximate the distribution of the minimum p -value of all tests. This distribution is then used to adjust the individual raw p -values. The bootstrap and permutation methods are computationally intensive but appealing in that, unlike the other methods, correlations and distributional characteristics are incorporated into the adjustments (Westfall and Young 1989; Westfall et al. 1999).

PROC MULTTEST handles data arising from a multivariate one-way ANOVA model, possibly stratified, with continuous and discrete response variables; it can also accept raw p -values as input data. You can perform a t test for the mean for continuous data with or without a homogeneity assumption, and the following statistical tests for discrete data:

- Cochran-Armitage linear trend test
- Freeman-Tukey double arcsine test
- Peto mortality-prevalence (log-rank) test
- Fisher exact test

The Cochran-Armitage and Peto tests have exact versions that use permutation distributions and asymptotic versions that use an optional continuity correction. Also, with the exception of the Fisher exact test, you can use a stratification variable to construct Mantel-Haenszel-type tests. All of the previously mentioned tests can be one- or two-sided.

As in the GLM procedure, you can specify linear contrasts that compare means or proportions of the treated groups. The output contains summary statistics and regular and multiplicity-adjusted p -values. You can create output data sets containing raw and adjusted p -values, test statistics and other intermediate calculations, permutation distributions, and resampling information.

The MULTTEST procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).”

The GLIMMIX, GLM, MIXED, and LIFETEST procedures, and other procedures that implement the ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements, also adjust their results for multiple tests. For more information, see the documentation for these procedures and statements, and Westfall et al. (1999).

Getting Started: MULTTEST Procedure

Drug Example

Suppose you conduct a small study to test the effect of a drug on 15 subjects. You randomly divide the subjects into three balanced groups receiving 0 mg, 1 mg, and 2 mg of the drug, respectively. You carry out the experiment and record the presence or absence of 10 side effects for each subject. Your data set is as follows:

```
data Drug;
  input Dose$ SideEff1-SideEff10;
  datalines;
0MG 0 0 1 0 0 1 0 0 0 0
0MG 0 0 0 0 0 0 0 0 0 1
0MG 0 0 0 0 0 0 0 0 1 0
0MG 0 0 0 0 0 0 0 0 0 0
0MG 0 1 0 0 0 0 0 0 0 0
1MG 1 0 0 1 0 1 0 0 1 0
1MG 0 0 0 1 1 0 0 1 0 1
1MG 0 1 0 0 0 0 1 0 0 0
1MG 0 0 1 0 0 0 0 0 0 1
1MG 1 0 1 0 0 0 0 1 0 0
2MG 0 1 1 1 0 1 1 1 0 1
2MG 1 1 1 1 1 1 0 1 1 0
2MG 1 0 0 1 0 1 1 0 1 0
2MG 0 1 1 1 1 0 1 1 1 1
```

```

2MG  1   0   1   0   1   1   1   0   0   1
;

```

The increasing incidence of 1s for higher dosages in the preceding data set provides an initial visual indication that the drug has an effect. To explore this statistically, you perform an analysis in which the possibility of side effects increases linearly with drug level. You can analyze the data for each side effect separately, but you are concerned that, with so many tests, there might be a high probability of incorrectly declaring some drug effects significant. You want to correct for this multiplicity problem in a way that accounts for the discreteness of the data and for the correlations between observations on the same unit.

PROC MULTTEST addresses these concerns by processing all of the data simultaneously and adjusting the p -values. The following statements perform a typical analysis:

```

ods graphics on;
proc multtest bootstrap nsample=20000 seed=41287 notables
    plots=PByTest(vref=0.05 0.1);
    class Dose;
    test ca(SideEff1-SideEff10);
    contrast 'Trend' 0 1 2;
run;
ods graphics off;

```

This analysis uses the **BOOTSTRAP** option to adjust the p -values. The **NSAMPLE=** option requests 20,000 samples for the bootstrap analysis, and the starting seed for the random number generator is 41287. The **NOTABLES** option suppresses the display of summary statistics for each side effect and drug level combination. The **PLOTS=** option displays a visual summary of the unadjusted and adjusted p -values against each test, and the **VREF=** option adds reference lines to the display.

The **CLASS** statement is used to specify the grouping variable, Dose. The **ca(sideeff1-sideeff10)** specification in the **TEST** statement requests a Cochran-Armitage linear trend test for all 10 characteristics. The **CONTRAST** statement gives the coefficients for the linear trend test.

The “Model Information” table in Figure 61.1 describes the statistical tests performed by PROC MULTTEST. For this example, PROC MULTTEST carries out a two-tailed Cochran-Armitage linear trend test with no continuity correction or strata adjustment. This test is performed on the raw data and on 20,000 bootstrap samples.

Figure 61.1 Output Summary for the MULTTEST Procedure

The Multtest Procedure	
Model Information	
Test for discrete variables	Cochran-Armitage
Z-score approximation used	Everywhere
Continuity correction	0
Tails for discrete tests	Two-tailed
Strata weights	None
P-value adjustment	Bootstrap
Number of resamples	20000
Seed	41287

The “Contrast Coefficients” table in [Figure 61.2](#) displays the coefficients for the Cochran-Armitage test. They are 0, 1, and 2, as specified in the **CONTRAST** statement.

Figure 61.2 Coefficients Used in the MULTTEST Procedure

Contrast Coefficients			
Contrast	Dose		
	0MG	1MG	2MG
Trend	0	1	2

The “p-Values” table in [Figure 61.3](#) lists the p -values for the drug example. The Raw column lists the p -values for the Cochran-Armitage test on the original data, and the Bootstrap column provides the bootstrap adjustment of the raw p -values.

Note that the raw p -values lead you to reject the null hypothesis of no linear trend for 3 of the 10 characteristics at the 5% level and 7 of the 10 characteristics at the 10% level. The bootstrap p -values, however, lead to this conclusion for 0 of the 10 characteristics at the 5% level and only 2 of the 10 characteristics at the 10% level; you can also see this in [Figure 61.4](#).

Figure 61.3 Summary of p -Values for the MULTTEST Procedure

p-Values			
Variable	Contrast	Raw	Bootstrap
SideEff1	Trend	0.0519	0.3388
SideEff2	Trend	0.1949	0.8403
SideEff3	Trend	0.0662	0.5190
SideEff4	Trend	0.0126	0.0884
SideEff5	Trend	0.0382	0.2408
SideEff6	Trend	0.0614	0.4383
SideEff7	Trend	0.0095	0.0514
SideEff8	Trend	0.0519	0.3388
SideEff9	Trend	0.1949	0.8403
SideEff10	Trend	0.2123	0.9030

Figure 61.4 Adjusted p -Values

The bootstrap adjustment gives the probability of observing a p -value as extreme as each given p -value, considering all 10 tests simultaneously. This adjustment incorporates the correlation of the raw p -values, the discreteness of the data, and the multiple testing problem. Failure to account for these issues can certainly lead to misleading inferences for these data.

Syntax: MULTTEST Procedure

The following statements are available in the MULTTEST procedure:

```

PROC MULTTEST < options > ;
  BY variables ;
  CLASS variable ;
  CONTRAST 'label' values ;
  FREQ variable ;
  ID variables ;
  STRATA variable ;
  TEST name (variables < / options >) ;

```

Statements that follow the PROC MULTTEST statement can appear in any order. The **CLASS** and **TEST** statements are required unless the **INPVALUES=** option is specified in the **PROC MULTTEST** statement.

The following sections describe the PROC MULTTEST statement and then describe the other statements in alphabetical order.

PROC MULTTEST Statement

PROC MULTTEST <options> ;

The PROC MULTTEST statement invokes the MULTTEST procedure. It also specifies the p -value adjustments. Table 61.1 summarizes the options available in the PROC MULTTEST statement. These options are described in alphabetical order following the table.

Table 61.1 PROC MULTTEST Statement Options by Function

Option	Description
FWE-Controlling p-Value Adjustments	
ADAPTIVEHOLM	Computes the adaptive step-down Bonferroni adjustment
ADAPTIVEHOCHBERG	Computes the adaptive step-up Bonferroni adjustment
BONFERRONI	Computes the Bonferroni adjustment
BOOTSTRAP	Computes the bootstrap min- p adjustment
FISHER_C	Computes Fisher's combination adjustment
HOCHBERG	Computes the step-up Bonferroni adjustment
HOMMEL	Computes Hommel's adjustment
HOLM	Computes the step-down Bonferroni adjustment
PERMUTATION	Computes the permutation min- p adjustment
SIDAK	Computes Šidák's adjustment
STEPBON	Computes the step-down Bonferroni adjustment
STEPBOOT	Computes the step-down bootstrap adjustment
STEPPERM	Computes the step-down permutation adjustment
STEPSID	Computes the step-down Šidák adjustment
STOUFFER	Computes the Stouffer-Liptak combination adjustment
FDR-Controlling p-Value Adjustments	
ADAPTIVEFDR	Computes the adaptive linear step-up adjustment
DEPENDENTFDR	Computes the linear step-up adjustment under dependence
FDR	Computes the linear step-up adjustment
FDRBOOT	Computes the linear step-up bootstrap min- p adjustment
FDRPERM	Computes the linear step-up permutation min- p adjustment
PFDR	Computes the positive FDR adjustment
Input/Output Data Sets	
DATA=	Names the input data set
INPVALUES=	Names the input data set of raw p -values
OUT=	Names the output data set
OUTPERM=	Names the output permutation data set
OUTSAMP=	Names the output resample data set

Table 61.1 *continued*

Option	Description
Displayed Output Options	
<code>NOPRINT</code>	Suppresses all tables
<code>NOTABLES</code>	Suppresses variable tables
<code>NOZEROS</code>	Suppresses zero tables for CLASS variables
<code>NOPVALUE</code>	Suppresses the “p-Values” table
<code>PLOTS</code>	Requests ODS Graphics
Resampling Options	
<code>CENTER</code>	Mean-centers continuous variables before resampling
<code>NOCENTER</code>	Does not mean-center continuous variables before resampling
<code>NSAMPLE=</code>	Specifies the number of resamples
<code>RANUNI</code>	Specifies a different random number generator
<code>SEED=</code>	Specifies the seed for resampling
CLASS Variable Options	
<code>NOZEROS</code>	Suppresses zero tables for CLASS variables
<code>ORDER=</code>	Specifies CLASS variable order
Computational Options	
<code>EPSILON=</code>	Specifies the comparison value
<code>NTRUENULL=</code>	Specifies the estimation method for the number of true nulls
<code>PTRUENULL=</code>	Specifies the estimation method for the proportion of true nulls

You can specify the following options in the PROC MULTTEST statement.

ADAPTIVEHOCHBERG

AHOC

requests adjusted p -values by using the Hochberg and Benjamini (1990) adaptive step-up Bonferroni method. See the section “[Adaptive Adjustments](#)” on page 5200 for more details.

ADAPTIVEHOLM

AHOLM

requests adjusted p -values by using the Hochberg and Benjamini (1990) adaptive step-down Bonferroni method. See the section “[Adaptive Adjustments](#)” on page 5200 for more details.

ADAPTIVEFDR<(UNRESTRICT)>

AFDR<(UNRESTRICT)>

requests adjusted p -values by using the Benjamini and Hochberg (2000) adaptive linear step-up method (AFDR). The UNRESTRICT option estimates the AFDR as defined in Benjamini and Hochberg (2000), which allows the adjustment to reduce the raw p -value. By default, the AFDR is constrained to be greater than or equal to the raw p -value. See the section “[Adaptive False Discovery Rate](#)” on page 5202 for more details.

BONFERRONI

BON

specifies that the Bonferroni adjustments (number of tests $\times p$ -value) be computed for each test. These adjustments can be extremely conservative and should be viewed with caution. When exact tests are specified via the `PERMUTATION=` option in the `TEST` statement, the actual permutation

distributions are used, resulting in a much less conservative version of this procedure (Westfall and Wolfinger 1997). See the section “[Bonferroni](#)” on page 5197 for more details.

BOOTSTRAP

BOOT

specifies that the p -values be adjusted by using the bootstrap method to resample vectors (Westfall and Young 1993). Resampling is performed with replacement and independently within levels of the [STRATA](#) variable. Continuous variables are mean-centered by default prior to resampling; specify the [NOCENTER](#) option to change this. See the section “[Bootstrap](#)” on page 5197 for more details. The BOOTSTRAP option is not allowed with the Peto test.

If the [PERMUTATION=](#) suboption is used with the [CA](#) test in the [TEST](#) statement, the exact permutation distribution is recomputed for each bootstrap sample. **CAUTION:** This can be very time-consuming. It is preferable to use permutation resampling when permutation base tests are used.

CENTER

requests that continuous variables be mean-centered prior to resampling. The default action is to mean-center for bootstrap resampling and not to mean-center for permutation resampling.

DATA=SAS-data-set

names the input SAS data set to be used by PROC MULTTEST. The default is to use the most recently created data set. The DATA= and [INPVALUES=](#) options cannot both be specified.

DEPENDENTFDR

DFDR

requests adjusted p -values by using the method of Benjamini and Yekateuli (2001). See the section “[Dependent False Discovery Rate](#)” on page 5201 for more details.

EPSILON=number

specifies the amount by which two p -values must differ to be declared unequal. The value *number* must be between 0 and 1; the default value is 1000 times the machine epsilon, which is approximately $1\text{E}-12$. For SAS 9.1 and earlier releases the default value was $1\text{E}-8$. See Westfall and Young (1993, pp. 165–166) for more information.

FDR

LSU

requests adjusted p -values by using the linear step-up method of Benjamini and Hochberg (1995). These p -values do not control the familywise error rate, but they do control the false discovery rate in some cases. See the section “[False Discovery Rate Controlling Adjustments](#)” on page 5200 for more details.

FDRBOOT< (β) >

A bootstrap-resampling false discovery rate controlling method due to Yekateuli and Benjamini (1999). This method uses the same resampling algorithm as the [BOOTSTRAP](#) option. Every resample is saved in order to compute a quantile of the resampled p -values; therefore, this method can use a lot of memory. The parameter β designates that a $100(1 - \beta)$ quantile is used in the computations for determining the adjustments; by default, $\beta = 0.05$. See the section “[False Discovery Rate Resampling Adjustments](#)” on page 5201 for details.

FDRPERM<(β)>

A permutation-resampling false discovery rate controlling method due to Yekateuli and Benjamini (1999). This method uses the same resampling algorithm as the **PERMUTATION** option. Every resample is saved in order to compute a quantile of the resampled p -values; therefore, this method can use a lot of memory. The parameter β designates that a $100(1 - \beta)$ quantile is used in the computations for determining the adjustments; by default, $\beta = 0.05$. See the section “[False Discovery Rate Resampling Adjustments](#)” on page 5201 for details.

FISHER_C**FIC**

requests adjusted p -values by using Fisher’s combination method. See the section “[Fisher Combination](#)” on page 5199 for more details.

HOCHBERG**HOC**

requests adjusted p -values by using the step-up Bonferroni method due to Hochberg (1988). See the section “[Hochberg](#)” on page 5199 for more details.

HOMMEL**HOM**

requests adjusted p -values by using the method of Hommel (1988). See the section “[Hommel](#)” on page 5199 for more details.

HOLM

is an alias for the [STEPBON](#) adjustment.

INPVALUES<(pvalue-name)>=SAS-data-set

names an input SAS data set that includes a variable containing raw p -values. The MULTTEST procedure adjusts the collection of raw p -values for multiplicity. Resampling-based adjustments are not permitted with this type of data input. The **CLASS**, **CONTRAST**, **FREQ**, **STRATA**, and **TEST** statements are ignored when an INPVALUES= data set is specified. The INPVALUES= and **DATA=** options cannot both be specified. The *pvalue-name* enables you to specify the name of the p -value column from your data set. By default, *pvalue-name*=‘raw_p’. The INPVALUES= data set can contain variables in addition to the raw p -values variable; see [Example 61.5](#) for an example.

LIPTAK

is an alias for the [STOUFFER](#) adjustment.

NOCENTER

requests that continuous variables not be mean-centered prior to resampling. The default action is to mean-center for bootstrap resampling and not to mean-center for permutation resampling.

NOPRINT

suppresses the normal display of results. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

NOPVALUE

suppresses the display of the “p-Values” table of raw and adjusted p -values. This option is most useful when you are adjusting many tests and need to create only an **OUT=** data set or display graphics.

NOTABLES

suppresses display of the “Discrete Variable Tabulations” and “Continuous Variable Tabulations” tables.

NOZEROS

suppresses display of tables having zero occurrences for all **CLASS** levels.

NSAMPLE=number**N=number**

specifies the number of resamples for use with the resampling methods. The value *number* must be a positive integer; by default, 20,000 resamples are used. Large values of *number* (20,000 or more) are usually recommended for accuracy, but long execution times can result, particularly with large data sets.

NTRUENULL=keyword | value**M0=keyword | value**

Controls the method used to estimate the number of true NULL hypotheses (m_0) for the adaptive methods. This option is ignored unless one of the adaptive methods is specified. By default, PROC MULTTEST uses the **DECREASESLOPE** method for the **ADAPTIVEHOLM** and **ADAPTIVEHOCHBERG** adjustments, and the **LOWESTSLOPE** method for **ADAPTIVEFDR** adjustment. For the **PFDR** adjustment, the **SPLINE** method is attempted first. If the estimate is nonpositive or if the slope of the spline at the last λ is greater than 0.1 times the range of the fitted spline values, then the **BOOTSTRAP** method is used.

You can specify a positive integer as the *value*, or you can specify one of the *keywords* in the following list. Alternatively, you can specify the proportion of true NULL hypotheses by using the **PTRUENULL=** option. Suppose you have m tests with ordered p -values $p_{(1)} \leq \dots \leq p_{(m)}$, and define $q_{(i)} = 1 - p_{(i)}$.

BOOTSTRAP<(bootstrap-options)>

uses the bootstrap method of Storey and Tibshirani (2003). Compute the proportion of true null hypotheses $\hat{\pi}_0(\lambda) = \frac{m - N(\lambda) + f}{(1 - \lambda)m}$ for $\lambda \in L = \{0, 0.05, \dots, 0.95\}$, where $N(\lambda)$ is the number of p -values less than or equal to λ , and $f = 1$ for the finite-sample case; otherwise $f = 0$. For each λ , bootstrap on the p -values to form B bootstrap versions $\hat{\pi}_0^b(\lambda)$, $b = 1, \dots, B$, and choose the λ that yields the minimum $\widehat{\text{MSE}}(\lambda) = \frac{1}{B} \sum_{b=1}^B (\hat{\pi}_0^b(\lambda) - \min_{\lambda' \in L} \hat{\pi}_0(\lambda'))^2$. The available *bootstrap-options* are as follows:

FINITE

the finite-sample case of the **PFDR** option, described on page 5178.

NBOOT=B

bootstrap resamples of the raw p -values for the λ computations. **NBOOT**=10,000 by default; B must be a positive integer.

NLAMBDA=n

“optimal” λ is the value in $\{0, \frac{1}{n}, \dots, \frac{n-1}{n}\}$ that minimizes the MSE. **NLAMBDA**=20 by default; n must be an integer greater than 1.

DECREASESLOPE

Schweder and Spjøtvoll (1982) as modified by Hochberg and Benjamini (1990). Let b_i be the slope of the least squares line fit to $\{q_{(m)}, \dots, q_{(m-i+1)}\}$ and through the origin, for $i = 1, \dots, m$. Find the first $i = m-1, m-2, \dots, 1$ such that $b_i < b_{i+1}$. Then $\hat{m}_0 = \text{ceil}(\frac{1}{b_{i+1}} - 1)$.

KSTEST<(β)>

uses the Kolmogorov-Smirnov uniformity test method of Turkheimer, Smith, and Schmidt (2001). Let $k_{\min} = 1, k_{\max} = m$, and the Kolmogorov-Smirnov statistic $D = \max(q_{(i)} - i/(m+1)(\sqrt{k} + 0.12 + 0.11/\sqrt{k}))$. If D is greater than the upper-tail probability (Press et al. 1992), then $k_{\max} = k, k = \text{floor}((k_{\min} + k)/2)$; otherwise, let $k_{\min} = k, k = \text{floor}((k + k_{\max})/2)$. Repeat until $k = k_{\min}$. Next compute the slope b of the weighted least squares regression line on the k smallest $q_{(i)}$ by using weights $w_i = i(k-i+1)/((k+1)^2(k+2))$. Then $\hat{m}_0 = \text{ceil}(\frac{1}{b} - 1)$.

LEASTSQUARES

uses a linear least squares method to search for the correct cutpoint. For each $i = 0, \dots, m$ compute the SSE of the least squares line through the origin fitting $\{q_{(m)}, \dots, q_{(m-i+1)}\}$, let b_i be the slope of this line, and add the SSE of the unconstrained least squares line through the rest of the q s. For $i = 0$ compute the SSE for the unconstrained line. The argument i that minimizes the SSE is the cutpoint: if $i = 0$ then $\hat{m}_0 = 0$; if $i = m$ then $\hat{m}_0 = m$; otherwise $\hat{m}_0 = \text{ceil}(\frac{1}{b_i} - 1)$.

LOWESTSLOPE

uses the lowest slope method of Benjamini and Hochberg (2000). Find the first $i = 1, \dots, m$ such that $b_i = q_{(i)}/(m-i+1)$ decreases. Then $\hat{m}_0 = \text{floor}(\min(\frac{1}{b_i} + 1, m))$.

MEANDIFF

uses the mean of differences method of Hsueh, Chen, and Kodell (2003). Let $\bar{d}_i = \frac{q_{(m-i+1)}}{i}$ and estimate $\hat{m}_0^i = \frac{1}{\bar{d}_i} - 1$. Start from $i = m$ and proceed downward until the first time $\hat{m}_0^{i-1} \geq \hat{m}_0^i$ occurs.

SPLINE<(spline-options)>

uses the cubic spline method of Storey and Tibshirani (2003). For each $\lambda \in \{0, \frac{1}{n}, \frac{2}{n}, \dots, \frac{n-1}{n}\}$ compute $\hat{\pi}_0(\lambda) = \frac{\#\{p_i > \lambda\}}{m(1-\lambda)}$. Let $\hat{f}(\lambda)$ be the natural cubic spline with 3 degrees of freedom of $\hat{\pi}_0(\lambda)$ versus λ . Estimate $\hat{\pi}_0$ by taking the spline value at the last λ : $\hat{\pi}_0 = \hat{\pi}_0(\frac{n-1}{n})$, so that $\hat{m}_0 = m\hat{\pi}_0$. The available *spline-options* are as follows:

DF= df

sets the degrees of freedom of the spline, where df is a nonnegative integer. The default is DF=3.

DFCONV= $number$

specifies the absolute change in spline degrees of freedom value for concluding convergence. If $|df_i - df_{i+1}| < number$ (or if the **SPCONV=** criterion is satisfied), then convergence is declared. *number* must be between 0 and 1; by default, *number* is 1000 times the square root of machine epsilon, which is about 1E-5.

FINITE

computations for the finite-sample case of the [PFDR](#) option, described on page 5178.

MAXITER=*n*

specifies the maximum number of golden-search iterations used to find a spline with $DF=df$ degrees of freedom. By default, MAXITER=100; *number* must be a nonnegative integer.

NLAMBDA=*n*

$\hat{\pi}_0(\lambda)$ for $\lambda \in \{0, \frac{1}{n}, \frac{2}{n}, \dots, \frac{n-1}{n}\}$ for the spline fit. By default, NLAMBDA=20; *number* must be an integer greater than 1.

SPCONV=*number*

specifies the absolute change in smoothing parameter value for concluding convergence of the spline. If $|sp_i - sp_{i+1}| < \text{number}$ (or if the [DFCONV=](#) criterion is satisfied), then convergence is declared. By default, *number* equals the square root of the machine epsilon, which is about 1E–8.

In all cases \hat{m}_0 is constrained to lie between 0 and m ; if the computed $\hat{m}_0 = 0$, then the adaptive adjustments do not produce results. If you specify $\hat{m}_0 > m$, then it is reduced to m . Values of \hat{m}_0 are displayed in the “Estimated Number of True Null Hypotheses” table.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the classification variables (which are specified in the [CLASS](#) statement). This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

OUT=SAS-data-set

names the output SAS data set containing variable names, contrast names, intermediate calculations, and all associated *p*-values. See “[OUT= Data Set](#)” on page 5204 for more information.

OUTPERM=SAS-data-set

names the output SAS data set containing entire permutation distributions (upper-tail probabilities) for all tests when the **PERMUTATION=** option is specified. See “**OUTPERM= Data Set**” on page 5205 for more information. **CAUTION:** This data set can be very large.

OUTSAMP=SAS-data-set

names the output SAS data set containing information from the resampled data sets when resampling is performed. See “**OUTSAMP= Data Set**” on page 5205 for more information. **CAUTION:** This data set can be very large.

PDATA=SAS-data-set

is an alias for the **INPVALUES=** option.

PERMUTATION**PERM**

computes adjusted p -values in identical fashion as the **BOOTSTRAP** option, with the exception that PROC MULTTEST resamples without replacement rather than with replacement. Resampling is performed independently within levels of the **STRATA** variable. Continuous variables are not mean-centered prior to resampling; specify the **CENTER** to change this. See the section “**Bootstrap**” on page 5197 for more details. The **PERMUTATION** option is not allowed with the Peto test.

PFDR<(options)>

computes the “ q -values” $\hat{q}_\lambda(p_i)$ of Storey (2002) and Storey, Taylor, and Siegmund (2004). PROC MULTTEST treats these “ q -values” as adjusted p -values. The computations depend on selecting a parameter λ and an estimation method for the false discovery rate; see the section “**Positive False Discovery Rate**” on page 5202 for computational details. The available *options* for choosing the method are as follows:

FINITE

estimates the false discovery rate with $\widehat{\text{pFDR}}$ or $\widehat{\text{FDR}}$ for the finite-sample case with independent null p -values.

POSITIVE

estimates the false discovery rate with $\widehat{\text{pFDR}}$ instead of the default $\widehat{\text{FDR}}$.

UNRESTRICT

estimates the false discovery rate as defined in Storey (2002), which allows the adjustment to reduce the raw p -value. By default, the PFDR is constrained to be greater than or equal to the raw p -value.

The available options for controlling the λ search are the *bootstrap-options* (page 5175), the *spline-options* (page 5176), and the following options:

LAMBDA=number

specifies a $\lambda \in [0, 1)$ and does not perform the bootstrap or spline searches for an “optimal” λ .

MAXLAMBDA=number

stops the NLAMBDA= search sequence for the *bootstrap* and *spline* searches when this *number* is reached. The *number* must be in $[0, 1]$. This option is ignored if the **LAMBDA=** option is specified.

PLOTS< (*global-plot-options*) >=*plot-request*< (*options*) >

PLOTS< (*global-plot-options*) >=(*plot-request*< (*options*) >< . . . *plot-request*< (*options*) >>)

controls the plots produced through ODS Graphics. If you specify only one *plot-request*, you can omit the parentheses. For example, the following statements are valid specifications of the PLOTS= option:

```
plots = all
plots = (rawprob adjusted)
plots(sigonly) = (rawprob adjusted(unpack))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc multtest plots=adjusted inpvalues=a pfdr;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

By default, no graphs are created; you must specify the PLOTS= option to make graphs. You need at least two tests to produce a graph. If you are not using an **INPVALUES=** data set, then each test is given a name constructed as “variable-name contrast-label”. If you specify a **MEAN** test in the **TEST** statement, the *t*-test names are prefixed with “Mean:”. See [Example 61.6](#) for examples of the ODS graphical displays.

The following *global-plot-options* are available:

UNPACKPANELS | UNPACK

suppresses paneling. By default, the plots produced with the **ADJUSTED** and **RAWPROB** options are grouped in a single display, called a *panel*. Specify **UNPACK** to display each plot separately.

SIGONLY<=*number*>

displays only those tests with adjusted *p*-values \leq *number*, where $0 \leq \textit{number} \leq 1$. By default, *number* = 0.05.

The following *plot-requests* are available:

ADJUSTED< (**UNPACK**) >

displays a 2×2 panel of adjusted *p*-value plots similar to those Storey and Tibshirani (2003) developed for use with the **PFDR** *p*-value adjustment method. The plots of the adjusted *p*-values by the raw *p*-values and the adjusted *p*-values by their rank show the effect of the adjustments. The plot of the proportion of adjusted *p*-values \leq each adjusted *p*-value and the plot of the expected number of false positives (the proportion significant multiplied by the adjusted *p*-value) versus the proportion significant show the effect of choosing different significance levels. The **UNPACK** option unpanels the display.

ALL

produces all appropriate plots. You can specify other options with ALL; for example, to display all plots and unpack the **RAWPROB** plots you can specify **plots=(all rawprob(unpack))**.

LAMBDA

displays plots of the MSE and the estimated number of true nulls against the λ parameter when the **NTRUENULL=SPLINE** or **NTRUENULL=BOOTSTRAP** option is in effect.

MANHATTAN<(options)>

displays the Manhattan plot (a plot of $-\log_{10}$ of the adjusted p -values versus the tests). You can specify the following *options*:

GROUP=variable

specifies a variable to group the adjusted p -values in the display.

LABEL <=OBS>

labels the observations that have adjusted p -values that are less than the value specified in the **VREF=** option. By default, labels are created as follows: if an **INPVALUES=** data set and an **ID** statement are specified, then the observations are labeled with the ID values; if a **DATA=** data set is specified, then the observations are labeled with their constructed test name; otherwise, the observation or test number is displayed.

NOTESTNAME

displays the number of the test instead of the test name on the X-axis, which is useful when you have many tests.

UNPACK

suppresses paneling. By default, Manhattan plots are created for each requested p -value adjustment, and the results are grouped in a single display, called a *panel*. Specify **UNPACK** to display each plot separately.

VREF=number | NONE

displays a reference line at $-\log_{10}(\text{number})$. The *number* must be between 0 and 1. By default, a reference line at $-\log_{10}(0.05)$ is displayed; it can be suppressed by specifying **VREF=0** or **VREF=NONE**. If the **LABEL** option is also specified, then observations above this line are labeled with their ID variables, their observation number, their test name, or their test number.

NONE

suppresses all plots.

PBYTEST<(options)>

displays the adjusted p -values for each test. The available options are as follows:

NOTESTNAME

displays the number of the test instead of the test name on the axis, which is useful when you have many tests.

VREF=

number-list displays reference lines at the p -values specified in the *number-list*. The values in the *number-list* must be between 0 and 1; otherwise they are ignored. You can specify a single value or a list of values; for example, **vref=0.1 0 to 0.05 by 0.01** displays reference lines at each of the values {0.01, 0.02, 0.03, 0.04, 0.05, and 0.1}.

RAWPROB<(UNPACK)>

displays a uniform probability plot of 1 minus the raw p -values (Schweder and Spjøtvoll 1982) along with a histogram. If m_0 is the number of true null hypotheses among the m tests, the points on the left side of the plot should be approximately linear with slope $\frac{1}{m_0+1}$. This graphic is displayed when an adaptive p -value adjustment method is requested in order to see if the **NTRUENULL=** estimate is appropriate. The UNPACK option unpanels the display.

PTRUENULL=*keyword* | *value*

PI0=*keyword* | *value*

is alias for the **NTRUENULL=** option, except that you can specify the proportion of true null hypotheses as a *value* between 0 and 1, instead of specifying the number of true null hypotheses. The available *keywords* are also the **NTRUENULL=** options described on page 5175.

RANUNI

requests the random number generator used in releases prior to SAS 9.2. Beginning with SAS 9.2, the random number generator is the Mersenne Twister, which has better performance when bootstrapping. Changes in the **bootstrap-** or **permutation-**adjusted p -values from prior releases are due to unimportant sampling differences.

SEED=*number*

S=*number*

specifies the initial seed for the random number generator used for resampling. The value for *number* must be an integer. If you do not specify a seed, or if you specify a value less than or equal to zero, then PROC MULTTEST uses the time of day from the computer's clock to generate an initial seed. For more details about seed values, see *SAS Language Reference: Concepts*.

SIDAK**SID**

computes the Šidák adjustment for each test. These adjustments take the form

$$1 - (1 - p)^m$$

where p is the raw p -value and m is the number of tests. These are slightly less conservative than the Bonferroni adjustments, but they still should be viewed with caution. When exact tests are specified via the **PERMUTATION=** option in the **TEST** statement, the actual permutation distributions are used, resulting in a much less conservative version of this procedure (Westfall and Wolfinger 1997). See the section “Šidák” on page 5197 for more details.

STEPBON**HOLM**

requests adjusted p -values by using the step-down Bonferroni method of Holm (1979). See the section “Step-Down Methods” on page 5198 for more details.

STEPBOOT

requests that adjusted p -values be computed by using bootstrap resampling as described under the **BOOTSTRAP** option, but in step-down fashion. See the section “[Step-Down Methods](#)” on page 5198 for more details.

STEPPER

requests that adjusted p -values be computed by using permutation resampling as described under the **PERMUTATION** option, but in step-down fashion. See the section “[Step-Down Methods](#)” on page 5198 for more details.

STEPSID

requests adjusted p -values by using the Šidák method as described in the **SIDAK** option, but in step-down fashion. See the section “[Step-Down Methods](#)” on page 5198 for more details.

STOUFFER**LIPTAK**

requests adjusted p -values by using the Stouffer-Liptak combination method. See the section “[Stouffer-Liptak Combination](#)” on page 5199 for more details.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC MULTTEST to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MULTTEST procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

You can specify one or more *variables* in the input data set on the BY statement.

Since sorting the data changes the order in which PROC MULTTEST reads observations, this can affect the sort order for the levels of the **CLASS** variable if you have specified ORDER=DATA in the PROC MULTTEST statement. This, in turn, affects specifications in the **CONTRAST** statements.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable* < / **TRUNCATE** > ;

The CLASS statement is required unless the **INPVALUES=** option is specified. The CLASS statement specifies a single variable (character or numeric) used to identify the groups for the analysis. For example, if the variable *Treatment* defines different levels of a treatment that you want to compare, then you would specify the following statements:

```
class Treatment;
```

The CLASS variable can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variable. The order of the class levels used by PROC MULTTEST corresponds to the order of their formatted values; this order can be changed with the **ORDER=** option in the PROC MULTTEST statement.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior you can specify the **TRUNCATE** option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the **FORMAT** procedure in the *Base SAS Procedures Guide* and the discussions of the **FORMAT** statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the **ORDER=** option in the PROC MULTTEST statement. You need to be aware of the order when using the **CONTRAST** statement, and you should check the “Contrast Coefficients” table to verify that it is suitable.

You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

CONTRAST Statement

CONTRAST *'label'* *values* ;

This statement is used to identify tests between the levels of the **CLASS** variable; in particular, it is used to specify the coefficients for the trend tests. The *label* is a string naming the contrast; it contains a maximum of 21 characters. The *values* are scoring coefficients across the **CLASS** variable levels.

You can specify multiple CONTRAST statements, thereby specifying multiple contrasts for each variable. Multiplicity adjustments are computed for all contrasts and all variables simultaneously. The coefficients are applied to the ordered **CLASS** variables; this order can be changed with the **ORDER=** option in the PROC MULTTEST statement. For example, consider a four-group experiment with **CLASS** variable levels A1, A2, B1, and B2 denoting two levels of two treatments. The following statements produce three linear trend tests for each variable identified in the **TEST** statement. PROC MULTTEST computes the multiplicity adjustments over the entire collection of tests, which is three times the number of variables.

```
contrast 'a vs b'      -1 -1  1  1;
contrast 'a linear'    -1  1  0  0;
contrast 'b linear'     0  0 -1  1;
```

As another example, consider an animal carcinogenicity experiment with dose levels 0, 4, 8, 16, and 50. You can specify a trend test with the indicated scoring coefficients by using the following statement:

```
contrast 'arithmetic trend' 0 4 8 16 50;
```

Multiplicity-adjusted p -values are then computed over the collection of variables identified in the **TEST** statement. See Lagakos and Louis (1985) for guidelines on the selection of contrast-scoring values.

When a Fisher test is specified in the **TEST** statement, the **CONTRAST** statement coefficients are used to group the **CLASS** variable's levels. Groups with a -1 contrast coefficient are combined and compared with groups with a 1 contrast coefficient for each test, and groups with a 0 coefficient are not included in the contrast. For example, the following statements compute Fisher exact tests for (a) control versus the combined treatment groups, (b) control versus the first treatment group, and (c) control versus the third treatment group:

```
contrast 'c vs all'  1 -1 -1 -1;
contrast 'c vs t1'   1 -1  0  0;
contrast 'c vs t3'   1  0  0 -1;
```

Multiplicity adjustments are then computed over the entire collection of tests and variables. Only -1 , 1 , and 0 are acceptable **CONTRAST** coefficients when the Fisher test is specified; PROC MULTTEST ignores the **CONTRAST** statement if any other coefficients appear.

If you specify the **FISHER** test and no **CONTRAST** statements, then all contrasts of control versus treatment are automatically generated, with the first level of the **CLASS** variable deemed to be the control. In this case, the control level is assigned the value 1 in each contrast and the other treatment levels are assigned -1 . You should therefore use the **LOWERTAILED** option to test for higher success rates in the treatment groups.

For tests other than **FISHER**, **CONTRAST** values are $0, 1, 2, \dots$ by default. If you specify the **CA** or **PETO** test with the **PERMUTATION=** option, then your **CONTRAST** coefficients must be integer valued.

For t tests for the mean of continuous data (and for the **FT** tests), the contrast coefficients are centered to have mean $= 0$. The resulting centered scoring coefficients are then applied to the sample means (or to the double-arcsine-transformed proportions in the case of the **FT** tests).

FREQ Statement

FREQ *variable* ;

The **FREQ** statement names a variable that provides frequencies for each observation in the **DATA=** data set. Specifically, if n is the value of the **FREQ** variable for a given observation, then that observation is used n times.

If the value of the **FREQ** variable is missing or is less than 1 , the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

ID Statement

ID *variables* ;

The ID statement names one or more variables for identifying observations in the output and in the plots. The statement requires an **INPVALUES=** data set. All ID variables are displayed in the “pValues” table. The ID variables are used as the X axis for the plots requested by the **PLOTS=PBYPTEST** and **PLOTS=MANHATTAN** options in the PROC MULTTEST statement; they are also used to label points on the Manhattan plots. This option has no effect on the **OUT=** data set.

STRATA Statement

STRATA *variable* ;

The STRATA statement identifies a single variable to use as a stratification variable in the analysis. This yields tests similar to those discussed in Mantel and Haenszel (1959) and Hoel and Walburg (1972) for binary data and pooled-means tests for continuous data. For example, when you test for prevalence in a carcinogenicity study, it is common to stratify on intervals of the time of death; the first level of the stratification variable might represent weeks 0–52, the second might represent weeks 53–80, and so on. In multicenter clinical studies, each level of the stratification variable might represent a particular center.

The following option is available in the STRATA statement after a slash (/):

WEIGHT=*keyword*

specifies the type of strata weighting to use when computing the Freeman-Tukey and *t* tests. Valid *keywords* are SAMPLESIZE, HARMONIC, and EQUAL. SAMPLESIZE requests weights proportional to the within-stratum sample sizes, and is the default method even if the WEIGHT= option is not specified. HARMONIC sets up weights equal to the harmonic mean of the nonmissing within-stratum CLASS sizes, and is similar to a Type 2 analysis in PROC GLM. EQUAL specifies equal weights, and is similar to a Type 3 analysis in PROC GLM.

TEST Statement

TEST *name (variables < / options>)* ;

The TEST statement is required unless the **INPVALUES=** option is specified. The TEST statement identifies statistical tests to be performed and the discrete and continuous variables to be tested. [Table 61.2](#) summarizes the names and options available in the TEST statement.

Table 61.2 TEST Statement Names and Options

Option	Description
TEST Names	
CA	Requests the Cochran-Armitage linear trend tests for group comparisons
FISHER	Requests Fisher exact tests
FT	Requests Z-score CA tests based upon the Freeman-Tukey double arcsine transformation
MEAN	Requests the t test for the mean
PETO	Requests the Peto mortality-prevalence test
TEST Options	
BINOMIAL	Uses the binomial variance estimate for CA and Peto tests
CONTINUITY=	Specifies a continuity correction
DDFM=	Specifies whether to use homogeneous or heterogeneous variances
LOWERTAILED	Makes all tests lower-tailed
PERMUTATION=	Computes p -values for the CA and Peto tests by using exact permutation distributions
TIME=	Identifies the Peto test variable containing the age at death
UPPERTAILED	Makes all tests upper-tailed

The following tests are permitted as *name* in the TEST statement.

CA

requests the Cochran-Armitage linear trend tests for group comparisons. The test variables should take the value 0 for a failure and 1 for a success. **PERMUTATION=** option can be used to request an exact permutation test; otherwise, a Z-score approximation is used. The **CONTINUITY=** option can be used to specify a continuity correction for the Z-score approximation.

FISHER

requests Fisher exact tests for comparing two treatment groups. The test variables should take the value 0 for a failure and 1 for a success.

FT

requests Z-score CA tests based upon the Freeman-Tukey double arcsine transformation of the frequencies. The test variables should take the value 0 for a failure and 1 for a success.

MEAN

requests the t test for the mean. The test variables can take on any numeric values.

PETO

requests the Peto mortality-prevalence test. The test variables should take the value 0 for a nonoccurrence, 1 for an incidental occurrence, and 2 for a fatal occurrence. The **TIME=** option should be used with the Peto test to specify an integer-valued variable giving the age at death. The **CONTINUITY=** option can be used to specify a continuity correction for the test.

If the value of a TEST variable is invalid, the observation is not used in the analysis. You can specify two tests only if one of them is **MEAN**. For example, the following statement is valid:

```
test ca(d1-d2) mean(c1-c2);
```

But specifying both CA and FT, as shown in the following statement, is invalid:

```
test ca(d1-d2) ft(d1-d2);
```

You can specify the following options in the TEST statement (some apply to only one test).

BINOMIAL

uses the binomial variance estimate for CA and Peto tests in their asymptotic normal approximations. The default is to use the hypergeometric variance.

CONTINUITY=number

C=number

specifies *number* as a particular continuity correction for the Z-score approximation in the CA and Peto tests. The default is 0.

LOWERTAILED

LOWER

is used to make all tests lower-tailed. All tests are two-tailed by default.

PERMUTATION=number

PERM=number

computes *p*-values for the CA and Peto tests by using exact permutation distributions when marginal success or failure totals within a stratum are *number* or less. You can specify *number* as a nonnegative integer. For totals greater than *number* (or when the PERMUTATION= option is omitted), PROC MULTTEST uses standard normal approximations with a continuity correction chosen to approximate the permutation distribution. PROC MULTTEST computes the appropriate convolution distributions when you use the [STRATA](#) statement along with the PERMUTATION= option.

DDFM= POOLED | SATTERTHWAITE

specifies whether the [MEAN](#) test uses a homogeneity assumption (DDFM=POOLED, the default) or deals with heterogeneous variances (DDFM=SATTERTHWAITE). See “[t Test for the Mean](#)” on page 5194 for more information.

TIME=variable

identifies the Peto test variable containing the age at death, which must be integer valued. If the TIME= option is omitted, all ages are assumed to equal 1.

UPPERTAILED

UPPER

is used to make all tests upper-tailed. All tests are two-tailed by default.

Details: MULTTEST Procedure

Statistical Tests

The following section discusses the statistical tests performed in the MULTTEST procedure. For continuous data, a t test for the mean (**MEAN**) is available. For discrete variables, available tests are the Cochran-Armitage linear trend test (**CA**), the Freeman-Tukey double arcsine test (**FT**), the Peto mortality-prevalence test (**PETO**), and the Fisher exact test (**FISHER**).

Throughout this section, the discrete and continuous variables are denoted by S_{vgsr} and X_{vgsr} , respectively, where v is the variable, g is the treatment group, s is the stratum, and r is the replication. Let m_{vgs} denote the sample size for a binary variable v within group g and stratum s . A plus sign (+) subscript denotes summation over an index. Note that the tests are invariant to the location and scale of the contrast coefficients t_g .

Cochran-Armitage Linear Trend Test

The Cochran-Armitage linear trend test (Cochran 1954; Armitage 1955; Agresti 2002) is implemented by using a Z -score approximation, an exact permutation distribution, or a combination of both.

Z-Score Approximation

The pooled probability estimate for variable v and stratum s is

$$p_{vs} = \frac{S_{v+s+}}{m_{v+s}}$$

The expected value (under constant within-stratum treatment probabilities) for variable v , group g , and stratum s is

$$E_{vgs} = m_{vgs} p_{vs}$$

Letting t_g denote the contrast trend coefficients specified by the **CONTRAST** statement, the test statistic for variable v has numerator

$$N_v = \sum_s \sum_g t_g (S_{vgs+} - E_{vgs})$$

The binomial variance estimate for this statistic is

$$V_v = \sum_s p_{vs} (1 - p_{vs}) \sum_g m_{vgs} (t_g - \bar{t}_{vs})^2$$

where

$$\bar{t}_{vs} = \sum_g \frac{m_{vgs} t_g}{m_{v+s}}$$

The hypergeometric variance estimate (the default) is

$$V_v = \sum_s \{m_{v+s} / (m_{v+s} - 1)\} p_{vs} (1 - p_{vs}) \sum_g m_{vgs} (t_g - \bar{t}_{vs})^2$$

For any strata s with $m_{v+s} \leq 1$, the contribution to the variance is taken to be zero.

PROC MULTTEST computes the Z -score statistic

$$Z_v = \frac{N_v}{\sqrt{V_v}}$$

The p -value for this statistic comes from the standard normal distribution. Whenever a 0 is computed for the denominator, the p -value is set to 1. This p -value approximates the probability obtained from the exact permutation distribution, discussed in the following text.

The Z -score statistic can be continuity-corrected to better approximate the permutation distribution. With continuity correction c , the upper-tailed p -value is computed from

$$Z_v = \frac{N_v - c}{\sqrt{V_v}}$$

For two-tailed, noncontinuity-corrected tests, PROC MULTTEST reports the p -value as $2 \min(p, 1 - p)$, where p is the upper-tailed p -value. The same formula holds for the continuity-corrected test, with the exception that when the noncontinuity-corrected Z and the continuity-corrected Z have opposite signs, the two-tailed p -value is 1.

When the **PERMUTATION=** option is specified and no **STRATA** variable is specified, PROC MULTTEST uses a continuity correction selected to optimally approximate the upper-tail probability of permutation distributions with smaller marginal totals (Westfall and Lin 1988). Otherwise, the continuity correction is specified by the **CONTINUITY=** option in the **TEST** statement.

The **CA** Z -score statistic is the Hoel-Walburg (Mantel-Haenszel) statistic reported by Dinse (1985).

Exact Permutation Test

When you use the **PERMUTATION=** option for **CA** in the **TEST** statement, PROC MULTTEST computes the exact permutation distribution of the trend score

$$T_v = \sum_s \sum_g t_g S_{vgs+}$$

where the contrast trend coefficients t_g must be integer valued. The observed value of this trend is compared to the permutation distribution to obtain the p -value

$$p_v = \Pr(X \geq \text{observed } T_v)$$

where X is a random variable from the permutation distribution and where upper-tailed tests are requested. This probability can be viewed as a binomial probability, where the within-stratum probabilities are constant and where the probability is conditional with respect to the marginal totals S_{v+s+} . It also can be considered a rerandomization probability.

Because the computations can be quite time-consuming with large data sets, specifying the **PERMUTATION=number** option in the **TEST** statement limits the situations where PROC MULTTEST computes the exact permutation distribution. When marginal total success or total failure frequencies exceed *number* for a particular stratum, the permutation distribution is approximated by a continuity-corrected normal distribution. You should be cautious when using the **PERMUTATION=** option in conjunction with bootstrap resampling because the permutation distribution is recomputed for each bootstrap sample. This recomputation is not necessary with permutation resampling.

The permutation distribution is computed in two steps:

1. The permutation distributions of the trend scores are computed within each stratum.
2. The distributions are convolved to obtain the distribution of the total trend.

As long as the total success or failure frequency does not exceed *number* for any stratum, the computed distributions are exact. In other words, if $S_{v+s+} \leq \text{number}$ or $(m_{v+s} - S_{v+s+}) \leq \text{number}$ for all s , then the permutation trend distribution for variable v is computed exactly.

In step 1, the distribution of the within-stratum trend

$$\sum_g t_g S_{vg s+}$$

is computed by using the multivariate hypergeometric distribution of the $S_{vg s+}$, provided *number* is not exceeded. This distribution can be written as

$$\Pr(S_{v1s+}, S_{v2s+}, \dots, S_{vGs+}) = \prod_{g=1}^G \frac{\binom{m_{vgs}}{S_{vgs+}}}{\binom{m_{v+s}}{S_{v+s+}}}$$

The distribution of the within-stratum trend is then computed by summing these probabilities over appropriate configurations. For further information about this technique, see Bickis and Krewski (1986) and Westfall and Lin (1988). In step 2, the exact convolution distribution is obtained for the trend statistic summed over all strata having totals that meet the threshold criterion. This distribution is obtained by applying the fast Fourier transform to the exact within-stratum distributions. A description of this general method can be found in Pagano and Tritchler (1983) and Good (1987).

The convolution distribution of the overall trend is then computed by convolving the exact distribution with the distribution of the continuity-corrected standard normal approximation. To be more specific, let S_1 denote the subset of stratum indices that satisfy the threshold criterion, and let S_2 denote the subset of indices that do not satisfy the criterion. Let T_{v1} denote the combined trend statistic from the set S_1 , which has an exact distribution obtained from Fourier analysis as previously outlined, and let T_{v1} denote the combined trend statistic from the set S_2 . Then the distribution of the overall trend $T_v = T_{v1} + T_{v2}$ is obtained by convolving the analytic distribution of T_{v1} with the continuity-corrected normal approximation for T_{v2} . Using the notation from the section “Z-Score Approximation” on page 5188, this convolution can be written as

$$\begin{aligned} \Pr(T_{v1} + T_{v2} \geq u) &= \sum_{u1} \Pr(T_{v1} + T_{v2} \geq u \mid T_{v1} = u1) \Pr(T_{v1} = u1) \\ &\approx \sum_{u1} \Pr(Z \geq z) \Pr(T_{v1} = u1) \end{aligned}$$

where Z is a standard normal random variable, and

$$z = \frac{1}{\sqrt{V_v}} \left(u - u1 - \sum_{S_2} p_{vs} \sum_g t_g m_{vgs} - c \right)$$

In this expression, the summation of s in V_v is over S_2 , and c is the continuity correction discussed under the Z-score approximation.

When a two-tailed test is requested, the expected trend is computed

$$E_v = \sum_s \sum_g t_g E_{vgs}$$

The two-tailed p -value is reported as the permutation tail probability for the observed trend T_v plus the permutation tail probability for $2E_v - T_v$, the reflected trend.

Freeman-Tukey Double Arcsine Test

For this test, the contrast trend coefficients t_1, \dots, t_G are centered to the values c_1, \dots, c_G , where $c_g = t_g - \bar{t}$, $\bar{t} = \sum_g t_g / G$, and G is the number of groups. The numerator of this test statistic is

$$N_v = \sum_s w_{vs} \sum_g c_g f(S_{vgs+}, m_{vgs})$$

where the weights w_{vs} take on three different types of values depending upon your specification of the **WEIGHT=** option in the **STRATA** statement. The default value is the within-strata sample size m_{v+s} , ensuring comparability with the ordinary CA trend statistic. **WEIGHT=HARMONIC** sets w_{vs} equal to the harmonic mean

$$\left[\left(\sum_g \frac{1}{m_{vgs}} \right) / G^* \right]^{-1}$$

where G^* is the number of nonmissing groups and the summation is over only the nonmissing elements. The harmonic means analysis places more weight on the smaller sample sizes than does the default sample size method, and is similar to a Type 2 analysis in PROC GLM. **WEIGHT=EQUAL** sets $w_{vs} = 1$ for all v and s , and is similar to a Type 3 analysis in PROC GLM.

The function $f(r, n)$ is the double arcsine transformation:

$$f(r, n) = \arcsin \left(\sqrt{\frac{r}{n+1}} \right) + \arcsin \left(\sqrt{\frac{r+1}{n+1}} \right)$$

The variance estimate is

$$V_v = \sum_s w_{vs}^2 \sum_g \frac{c_g^2}{m_{vgs} + \frac{1}{2}}$$

The test statistic is

$$Z_v = \frac{N_v}{\sqrt{V_v}}$$

The Freeman-Tukey transformation and its variance are described by Freeman and Tukey (1950) and Miller (1978). Since its variance is not weighted by the pooled probabilities, as is the CA test, the **FT** test can be more useful than the CA test for tests involving only a subset of the groups.

Peto Mortality-Prevalence Trend Test

The Peto test is a modified Cochran-Armitage procedure incorporating mortality and prevalence information. The Peto test is computed like two Cochran-Armitage Z-score approximations, one for prevalence and one for mortality (Peto, Pike, and Day 1980). It represents a special case in PROC MULTTEST because the data structure requirements are different, and the resampling methods used for adjusting p -values are not valid. The **TIME=** option variable is required to specify “death” times or, more generally, times of occurrence. In addition, the test variables must assume one of the following three values:

- 0 = no occurrence
- 1 = incidental occurrence
- 2 = fatal occurrence

Use the **TIME=** option variable to define the mortality strata, and use the **STRATA** statement variable to define the prevalence strata.

In the following notation, the subscript v represents the variable, g represents the treatment group, s represents the stratum, and t represents the time. Recall that a plus sign (+) in a subscript location denotes summation over that subscript.

Let S_{vgs}^P be the number of incidental occurrences, and let m_{vgs}^P be the total sample size for variable v in group g , stratum s , excluding fatal tumors.

Let S_{vgt}^F be the number of fatal occurrences in time period t , and let m_{vgt}^F be the number of patients alive at the end of time $t - 1$.

The pooled probability estimates are given by

$$p_{vs}^P = \frac{S_{v+s}^P}{m_{v+s}^P}$$

$$p_{vt}^F = \frac{S_{v+t}^F}{m_{v+t}^F}$$

The expected values are

$$E_{vgs}^P = m_{vgs}^P p_{vs}^P$$

$$E_{vgt}^F = m_{vgt}^F p_{vt}^F$$

Let t_g denote a contrast trend coefficient, and define the numerator terms as follows:

$$N_v^P = \sum_s \sum_g t_g (S_{vgs}^P - E_{vgs}^P)$$

$$N_v^F = \sum_t \sum_g t_g (S_{vgt}^F - E_{vgt}^F)$$

Define the denominator variance terms by using the binomial variance:

$$V_v^P = \sum_s p_{vs}^P (1 - p_{vs}^P) \left[\left(\sum_g m_{vgs}^P t_g^2 \right) - \frac{1}{m_{v+s}^P} \left(\sum_g m_{vgs}^P t_g \right)^2 \right]$$

$$V_v^F = \sum_s p_{vt}^F (1 - p_{vt}^F) \left[\left(\sum_g m_{vgt}^F t_g^2 \right) - \frac{1}{m_{v+t}^F} \left(\sum_g m_{vgt}^F t_g \right)^2 \right]$$

The hypergeometric variances (the default) are calculated by weighting the within-strata variances as discussed in the section “[Z-Score Approximation](#)” on page 5188.

The Peto statistic is computed as

$$Z_v = \frac{N_v^P + N_v^F - c}{\sqrt{V_v^P + V_v^F}}$$

where c is a continuity correction. The p -value is determined from the standard normal distribution unless the `PERMUTATION=number` option is used. When you use the `PERMUTATION=` option for `PETO` in the `TEST` statement, PROC MULTTEST computes the “discrete approximation” permutation distribution described by Mantel (1980) and Soper and Tonkonoh (1993). Specifically, the permutation distribution of $\sum_s \sum_g t_g S_{vgs}^P + \sum_t \sum_g t_g S_{vgt}^F$ is computed, assuming that $\{\sum_g t_g S_{vgs}^P\}$ and $\{\sum_g t_g S_{vgt}^F\}$ are independent over all s and t . Note that the contrast trend coefficients t_g must be integer valued. The p -values are exact under this independence assumption. However, the independence assumption is valid only asymptotically, which is why these p -values are called “approximate.”

An exact permutation distribution is available only under the assumption of equal risk of censoring in all treatment groups; even then, computing this distribution can be cumbersome. Soper and Tonkonoh (1993) describe situations where the discrete approximation distribution closely fits the exact permutation distribution.

Fisher Exact Test

The `CONTRAST` statement in PROC MULTTEST enables you to compute Fisher exact tests for two-group comparisons. No stratification variable is allowed for this test. Note, however, that the `FISHER` exact test is a special case of the exact permutation tests performed by PROC MULTTEST and that these permutation tests allow a stratification variable. Recall that contrast coefficients can be -1 , 0 , or 1 for the Fisher test. The frequencies and sample sizes of the groups scored as -1 are combined, as are the frequencies and sample sizes of the groups scored as 1 . Groups scored as 0 are excluded. The -1 group is then compared with the 1 group by using the Fisher exact test.

Letting x and m denote the frequency and sample size of the 1 group, and letting y and n denote those of the -1 group, the p -value is calculated as

$$\Pr(X \geq x \mid X + Y = x + y) = \sum_{i=x}^m \frac{\binom{m}{i} \binom{n}{x+y-i}}{\binom{m+n}{x+y}}$$

where X and Y are independent binomially distributed random variables with sample sizes m and n and common probability parameters. The hypergeometric distribution is used to determine the stated probability; Yates (1984) discusses this technique. PROC MULTTEST computes the two-tailed p -values by adding probabilities from both tails of the hypergeometric distribution. The first tail is from the observed x and y , and the other tail is chosen so that the resulting probability is as large as possible without exceeding the probability from the first tail. If the variable being tested has only one level, then the p -value is set to 1.

***t* Test for the Mean**

For continuous variables, PROC MULTTEST automatically centers the contrast trend coefficients, as in the Freeman-Tukey test. These centered coefficients c_g are then used to form a t statistic contrasting the within-group means. Let n_{vgs} denote the sample size within group g and stratum s ; it depends on variable v only when there are missing values. Determine the weights w_{vs} as in the Freeman-Tukey test with n_{vgs} replacing m_{vgs} . Define

$$\bar{X}_{vgs+} = \frac{1}{n_{vgs}} \sum_r X_{vgsr}$$

as the sample mean within a group-and-stratum combination, and let μ_{vgs} denote the treatment means. Write the null hypothesis as

$$\sum_s w_{vs} \sum_g c_g \mu_{vgs} = 0$$

Also define

$$s_v^2 = \frac{\sum_s \sum_g \sum_r (X_{vgsr} - \bar{X}_{vgs+})^2}{\sum_s \sum_g (n_{vgs} - 1)}$$

as the pooled sample variance.

Homogeneous Variance

Assuming constant variance for all group-and-stratum combinations, the t statistic for the mean is

$$M_v = \frac{\sum_s w_{vs} \sum_g c_g \bar{X}_{vgs+}}{\sqrt{s_v^2 \left(\sum_s w_{vs}^2 \sum_g \frac{c_g^2}{n_{vgs}} \right)}}$$

Then under the null hypothesis and assuming normality, independence, and homoscedasticity, M_v follows a t distribution with $df_p = \sum_s \sum_g (n_{vgs} - 1)$ degrees of freedom.

Whenever a denominator of 0 is computed, the p -value is set to 1. When missing data force $n_{vgs} = 0$, the contribution to the denominator of the pooled variance is 0 and not -1 . This is also true for the degrees of freedom.

Heterogeneous Variance

If you do not assume constant variance for all group-and-stratum combinations, then the approximate t test is

$$M_v = \frac{\sum_s w_{vs} \sum_g c_g \bar{X}_{vgs} +}{\sqrt{\sum_s w_{vs}^2 \sum_g c_g^2 \frac{s_{vgs}^2}{n_{vgs}}}}$$

Under the null hypothesis and assuming normality and independence, the Satterthwaite (1946) approximation for the degrees of freedom of the t test is given by

$$df_s = \frac{\left(\sum_s w_{vs}^2 \sum_g c_g^2 \frac{s_{vgs}^2}{n_{vgs}} \right)^2}{\sum_s \sum_g \frac{\left(w_{vs}^2 c_g^2 \frac{s_{vgs}^2}{n_{vgs}} \right)^2}{n_{vgs} - 1}}$$

under the restriction $1 \leq df_s \leq \sum_s \sum_g n_{vgs}$.

Whenever a denominator of 0 for M_v is computed, the p -value is set to 1. If the denominator for df_s is computed as 0, then set $df_s = df_p$. When missing data force $n_{vgs} \leq 1$, that group-and-stratum combination does not contribute to the df_s computation.

p-Value Adjustments

Suppose you test m null hypotheses, H_{01}, \dots, H_{0m} , and obtain the p -values p_1, \dots, p_m . Denote the ordered p -values as $p_{(1)} \leq \dots \leq p_{(m)}$ and order the tests appropriately: $H_{0(1)}, \dots, H_{0(m)}$. Suppose you know m_0 of the null hypotheses are true and $m_1 = m - m_0$ are false. Let R indicate the number of null hypotheses rejected by the tests, where V of these are incorrectly rejected (that is, V tests are Type I errors) and $R - V$ are correctly rejected (so $m_1 - R + V$ tests are Type II errors). This information is summarized in the following table:

	Null is Rejected	Null is Not Rejected	Total
Null is True	V	$m_0 - V$	m_0
Null is False	$R - V$	$m_1 - R + V$	m_1
Total	R	$m - R$	m

The *familywise error rate* (FWE) is the overall Type I error rate for all the comparisons (possibly under some restrictions); that is, it is the maximum probability of incorrectly rejecting one or more null hypotheses:

$$\text{FWE} = \Pr(V > 0)$$

The FWE is also known as the *maximum experimentwise error rate* (MEER), as discussed in the section “Pairwise Comparisons” on page 3351 of Chapter 42, “The GLM Procedure.”

The *false discovery rate* (FDR) is the expected proportion of incorrectly rejected hypotheses among all rejected hypotheses:

$$\begin{aligned} \text{FDR} &= E\left(\frac{V}{R}\right) \quad \text{where } \frac{V}{R} = 0 \text{ when } V = R = 0 \\ &= E\left(\frac{V}{R} \mid R > 0\right) \Pr(R > 0) \end{aligned}$$

Under the overall null hypothesis (all the null hypotheses are true), the FDR=FWE since $V = R$ gives $E\left(\frac{V}{R}\right) = 1 \times \Pr\left(\frac{V}{R} = 1\right) = \Pr(V > 0)$. Otherwise, FDR is always less than FWE, and an FDR-controlling adjustment also controls the FWE. Another definition used is the *positive* false discovery rate:

$$\text{pFDR} = E\left(\frac{V}{R} \mid R > 0\right)$$

The p -value adjustment methods discussed in the following sections attempt to correct the raw p -values while controlling either the FWE or the FDR. Note that the methods might impose some restrictions in order to achieve this; restrictions are discussed along with the methods in the following sections. Discussions and comparisons of some of these methods are given in Dmitrienko et al. (2005), Dudoit, Shaffer, and Boldrick (2003), Westfall et al. (1999), and Brown and Russell (1997).

Familywise Error Rate Controlling Adjustments

PROC MULTTEST provides several p -value adjustments to control the familywise error rate. *Single-step* adjustment methods are computed without reference to the other hypothesis tests under consideration. The available single-step methods are the Bonferroni and Šidák adjustments, which are simple functions of the raw p -values that try to distribute the significance level α across all the tests, and the bootstrap and permutation resampling adjustments, which require the raw data. The Bonferroni and Šidák methods are calculated from the permutation distributions when exact permutation tests are used with the [CA](#) or [Peto](#) test.

Stepwise tests, or *sequentially rejective* tests, order the hypotheses in *step-up* (least significant to most significant) or *step-down* fashion, then sequentially determine acceptance or rejection of the nulls. These tests are more powerful than the single-step tests, and they do not always require you to perform every test. However, PROC MULTTEST still adjusts every p -value. PROC MULTTEST provides the following stepwise p -value adjustments: step-down Bonferroni (Holm), step-down Šidák, step-down bootstrap and permutation resampling, Hochberg's (1988) step-up, Hommel's (1988), Fisher's combination method, and the Stouffer-Liptak combination method. Adaptive versions of Holm's step-down Bonferroni and Hochberg's step-up Bonferroni methods, which require an estimate of the number of true null hypotheses, are also available.

Liu (1996) shows that all single-step and stepwise tests based on marginal p -values can be used to construct a *closed* test (Marcus, Peritz, and Gabriel 1976; Dmitrienko et al. 2005). Closed testing methods not only control the familywise error rate at size α , but are also more powerful than the tests on which they are based. Westfall and Wolfinger (2000) note that several of the methods available in PROC MULTTEST are closed—namely, the [step-down methods](#), [Hommel's method](#), and [Fisher's combination](#); see that reference for conditions and exceptions.

All methods except the resampling methods are calculated by simple functions of the raw p -values or marginal permutation distributions; the permutation and bootstrap adjustments require the raw data. Because the resampling techniques incorporate distributional and correlational structures, they tend to be less conservative than the other methods.

When a resampling (bootstrap or permutation) method is used with only one test, the adjusted p -value is the bootstrap or permutation p -value for that test, with no adjustment for multiplicity, as described by Westfall and Soper (1994).

Bonferroni

The Bonferroni p -value for test i , $i = 1, \dots, m$ is simply $\tilde{p}_i = mp_i$. If the adjusted p -value exceeds 1, it is set to 1. The Bonferroni test is conservative but always controls the familywise error rate.

If the unadjusted p -values are computed by using exact permutation distributions, then the Bonferroni adjustment for p_i is $\tilde{p}_i = p_1^* + \dots + p_m^*$, where p_j^* is the largest p -value from the permutation distribution of test j satisfying $p_j^* \leq p_i$, or 0 if all permutational p -values of test j are greater than p_i . These adjustments are much less conservative than the ordinary Bonferroni adjustments because they incorporate the discrete distributional characteristics. However, they remain conservative in that they do not incorporate correlation structures between multiple contrasts and multiple variables (Westfall and Wolfinger 1997).

Šidák

A technique slightly less conservative than Bonferroni is the Šidák p -value (Šidák 1967), which is $\tilde{p}_i = 1 - (1 - p_i)^m$. It is exact when all of the p -values are uniformly distributed and independent, and it is conservative when the test statistics satisfy the positive orthant dependence condition (Holland and Copenhaver 1987).

If the unadjusted p -values are computed by using exact permutation distributions, then the Šidák adjustment for p_i is $\tilde{p}_i = 1 - (1 - p_1^*) \dots (1 - p_m^*)$, where the p_j^* are as described previously. These adjustments are less conservative than the corresponding Bonferroni adjustments, but they do not incorporate correlation structures between multiple contrasts and multiple variables (Westfall and Wolfinger 1997).

Bootstrap

The bootstrap method creates pseudo-data sets by sampling observations with replacement from each within-stratum pool of observations. An entire data set is thus created, and p -values for all tests are computed on this pseudo-data set. A counter records whether the minimum p -value from the pseudo-data set is less than or equal to the actual p -value for each base test. (If there are m tests, then there are m such counters.) This process is repeated a large number of times, and the proportion of resampled data sets where the minimum pseudo- p -value is less than or equal to an actual p -value is the adjusted p -value reported by PROC MULTTEST. The algorithms are described in Westfall and Young (1993).

In the case of continuous data, the pooling of the groups is not likely to re-create the shape of the null hypothesis distribution, since the pooled data are likely to be multimodal. For this reason, PROC MULTTEST automatically mean-centers all continuous variables prior to resampling. Such mean-centering is akin to resampling residuals in a regression analysis, as discussed by Freedman (1981). You can specify the **NO-CENTER** option if you do not want to center the data.

The bootstrap method implicitly incorporates all sources of correlation, from both the multiple contrasts and the multivariate structure. The adjusted p -values incorporate all correlations and distributional characteristics. This method always provides weak control of the familywise error rate, and it provides strong control when the *subset pivotality* condition holds; that is, for any subset of the null hypotheses, the joint distribution of the p -values for the subset is identical to that under the complete null (Westfall and Young 1993).

Permutation

The permutation-style-adjusted p -values are computed in identical fashion as the [bootstrap](#)-adjusted p -values, with the exception that the within-stratum resampling is performed without replacement instead of with replacement. This produces a rerandomization analysis such as in Brown and Fears (1981) and Heyse and Rom (1988). In the spirit of rerandomization analyses, the continuous variables are not centered prior to resampling. This default can be overridden by using the [CENTER](#) option.

The permutation method implicitly incorporates all sources of correlation, from both the multiple contrasts and the multivariate structure. The adjusted p -values incorporate all correlations and distributional characteristics. This method always provides weak control of the familywise error rate, and it provides strong control of the familywise error rate under the *subset pivotality* condition, as described in the preceding section.

Step-Down Methods

Step-down testing is available for the Bonferroni, Šidák, bootstrap, and permutation methods. The benefit of using step-down methods is that the tests are made more powerful (smaller adjusted p -values) while, in most cases, maintaining strong control of the familywise error rate. The step-down method was pioneered by Holm (1979) and further developed by Shaffer (1986), Holland and Copenhaver (1987), and Hochberg and Tamhane (1987).

The Bonferroni step-down (Holm) p -values $\tilde{p}_{(1)}, \dots, \tilde{p}_{(m)}$ are obtained from

$$\tilde{p}_{(i)} = \begin{cases} mp_{(1)} & \text{for } i = 1 \\ \max(\tilde{p}_{(i-1)}, (m - i + 1)p_{(i)}) & \text{for } i = 2, \dots, m \end{cases}$$

As always, if any adjusted p -value exceeds 1, it is set to 1.

The Šidák step-down p -values are determined similarly:

$$\tilde{p}_{(i)} = \begin{cases} 1 - (1 - p_{(1)})^m & \text{for } i = 1 \\ \max(\tilde{p}_{(i-1)}, 1 - (1 - p_{(i)})^{m-i+1}) & \text{for } i = 2, \dots, m \end{cases}$$

Step-down Bonferroni adjustments that use exact tests are defined as

$$\tilde{p}_{(i)} = \begin{cases} p_{(1)}^* + \dots + p_{(m)}^* & \text{for } i = 1 \\ \max(\tilde{p}_{(i-1)}, p_{(i)}^* + \dots + p_{(m)}^*) & \text{for } i = 2, \dots, m \end{cases}$$

where the p_j^* are defined as before. Note that p_j^* is taken from the permutation distribution corresponding to the j th-smallest unadjusted p -value. Also, any \tilde{p}_j greater than 1.0 is reduced to 1.0.

Step-down Šidák adjustments for exact tests are defined analogously by substituting $1 - (1 - p_{(j)}^*) \dots (1 - p_{(m)}^*)$ for $p_{(j)}^* + \dots + p_{(m)}^*$.

The resampling-style step-down methods are analogous to the preceding step-down methods; the most extreme p -value is adjusted according to all m tests, the second-most extreme p -value is adjusted according to $(m - 1)$ tests, and so on. The difference is that all correlational and distributional characteristics are incorporated when you use resampling methods. More specifically, assuming the same ordering of p -values as discussed previously, the resampling-style step-down-adjusted p -value for test i is the probability that the minimum pseudo- p -value of tests i, \dots, m is less than or equal to p_i .

This probability is evaluated by using Monte Carlo simulation, as are the previously described resampling-style-adjusted *p*-values. In fact, the computations for step-down-adjusted *p*-values are essentially no more time-consuming than the computations for the non-step-down-adjusted *p*-values. After Monte Carlo, the step-down-adjusted *p*-values are corrected to ensure monotonicity; this correction leaves the first adjusted *p*-values alone, then corrects the remaining ones as needed. The step-down method approximately controls the familywise error rate, and it is described in more detail by Westfall and Young (1993), Westfall et al. (1999), and Westfall and Wolfinger (2000).

Hommel

Hommel's (1988) method is a closed testing procedure based on Simes' test (Simes 1986). The Simes *p*-value for a joint test of any set of *S* hypotheses with *p*-values $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(S)}$ is $\min((S/1)p_{(1)}, (S/2)p_{(2)}, \dots, (S/S)p_{(S)})$. The Hommel-adjusted *p*-value for test *j* is the maximum of all such Simes *p*-values, taken over all joint tests that include *j* as one of their components.

Hochberg-adjusted *p*-values are always as large or larger than Hommel-adjusted *p*-values. Sarkar and Chang (1997) shows that Simes' method is valid under independent or positively dependent *p*-values, so Hommel's and Hochberg's methods are also valid in such cases by the closure principle.

Hochberg

Assuming *p*-values are independent and uniformly distributed under their respective null hypotheses, Hochberg (1988) demonstrates that Holm's step-down adjustments control the familywise error rate even when calculated in *step-up* fashion. Since the adjusted *p*-values are uniformly smaller for Hochberg's method than for Holm's method, the Hochberg method is more powerful. However, this improved power comes at the cost of having to make the assumption of independence. Hochberg's method can be derived from Hommel's (Liu 1996), and is thus also derived from Simes' test (Simes 1986).

Hochberg-adjusted *p*-values are always as large or larger than Hommel-adjusted *p*-values. Sarkar and Chang (1997) showed that Simes' method is valid under independent or positively dependent *p*-values, so Hommel's and Hochberg's methods are also valid in such cases by the closure principle.

The Hochberg-adjusted *p*-values are defined in reverse order of the step-down Bonferroni:

$$\tilde{p}_{(i)} = \begin{cases} p_{(m)} & \text{for } i = m \\ \min(\tilde{p}_{(i+1)}, (m - i + 1)p_{(i)}) & \text{for } i = m - 1, \dots, 1 \end{cases}$$

Fisher Combination

The **FISHER_C** option requests adjusted *p*-values by using closed tests, based on the idea of Fisher's combination test. The Fisher combination test for a joint test of any set of *S* hypotheses with *p*-values uses the chi-square statistic $\chi^2 = -2 \sum \log(p_i)$, with $2S$ degrees of freedom. The FISHER_C adjusted *p*-value for test *j* is the maximum of all *p*-values for the combination tests, taken over all joint tests that include *j* as one of their components. Independence of *p*-values is required for the validity of this method.

Stouffer-Liptak Combination

The **STOUFFER** option requests adjusted *p*-values by using closed tests, based on the Stouffer-Liptak combination test. The Stouffer combination joint test of any set of *S* one-sided hypotheses with *p*-values, p_1, \dots, p_S , yields the *p*-value, $1 - \Phi\left(\frac{1}{\sqrt{S}} \sum_i \Phi^{-1}(1 - p_i)\right)$. The STOUFFER adjusted *p*-value for test *j* is the maximum of all *p*-values for the combination tests, taken over all joint tests that include *j* as one of their components.

Independence of the one-sided p -values is required for the validity of this method. Westfall (2005) shows that the Stouffer-Liptak adjustment might have more power than the [Fisher combination](#) and [Simes'](#) adjustments when the test results reinforce each other.

Adaptive Adjustments

Adaptive adjustments modify the FWE- and FDR-controlling procedures by taking an estimate of the number m_0 or proportion π_0 of true null hypotheses into account. The adjusted p -values for Holm's and Hochberg's methods involve the number of unadjusted p -values larger than (i), $m - i + 1$. So the minimal significance level at which the i th ordered p -value is rejected implies that the number of true null hypotheses is $m - i + 1$. However, if you know m_0 , then you can replace $m - i + 1$ with $\min(m_0, m - i + 1)$, thereby obtaining more power while maintaining the original α -level significance.

Since m_0 is unknown, there are several methods used to estimate the value—see the [NTRUENULL=](#) option for more information. The estimation method described by Hochberg and Benjamini (1990) considers the graph of $1 - p_{(i)}$ versus i , where the $p_{(i)}$ are the ordered p -values of your tests. See [Output 61.6.4](#) for an example. If all null hypotheses are actually true ($m_0 = m$), then the p -values behave like a sample from a uniform distribution and this graph should be a straight line through the origin. However, if points in the upper-right corner of this plot do not follow the initial trend, then some of these null hypotheses are probably false and $0 < m_0 < m$.

The [ADAPTIVEHOLM](#) option uses this estimate of m_0 to adjust the step-up Bonferroni method while the [ADAPTIVEHOCHBERG](#) option adjusts the step-down Bonferroni method. Both of these methods are due to Hochberg and Benjamini (1990). When m_0 is known, these procedures control the familywise error rate in the same manner as their nonadaptive versions but with more power; however, since m_0 must be estimated, the FWE control is only approximate. The [ADAPTIVEFDR](#) and [PFDR](#) options also use \hat{m}_0 , and are described in the following section.

The adjusted p -values for the [ADAPTIVEHOLM](#) method are computed by

$$\tilde{p}_{(i)} = \begin{cases} \min(m, \hat{m}_0) p_{(1)} & \text{for } i = 1 \\ \max[\tilde{p}_{(i-1)}, \min(m - i + 1, \hat{m}_0) p_{(i)}] & \text{for } i = 2, \dots, m \end{cases}$$

The adjusted p -values for the [ADAPTIVEHOCHBERG](#) method are computed by

$$\tilde{p}_{(i)} = \begin{cases} \min(1, \hat{m}_0) p_{(m)} & \text{for } i = m \\ \min[\tilde{p}_{(i+1)}, \min(m - i + 1, \hat{m}_0) p_{(i)}] & \text{for } i = m - 1, \dots, 1 \end{cases}$$

False Discovery Rate Controlling Adjustments

Methods that control the *false discovery rate* (FDR) were described by Benjamini and Hochberg (1995). These adjustments do not necessarily control the familywise error rate (FWE). However, FDR-controlling methods are more powerful and more liberal, and hence reject more null hypotheses, than adjustments protecting the FWE. FDR-controlling methods are often used when you have a large number of null hypotheses. To control the FDR, Benjamini and Hochberg's (1995) linear step-up method is provided, as well as an adaptive version, a dependence version, and bootstrap and permutation resampling versions. Storey's (2002) pFDR methods are also provided.

The [FDR](#) option requests p -values that control the “false discovery rate” described by Benjamini and Hochberg (1995). These *linear step-up* adjustments are potentially much less conservative than the [Hochberg](#) adjustments.

The FDR-adjusted *p*-values are defined in step-up fashion, like the Hochberg adjustments, but with less conservative multipliers:

$$\tilde{p}_{(i)} = \begin{cases} p_{(m)} & \text{for } i = m \\ \min(\tilde{p}_{(i+1)}, \frac{m}{i} p_{(i)}) & \text{for } i = m-1, \dots, 1 \end{cases}$$

The **FDR** method is guaranteed to control the false discovery rate at level $\leq \frac{m_0}{m} \alpha \leq \alpha$ when you have independent *p*-values that are uniformly distributed under their respective null hypotheses. Benjamini and Yekateuli (2001) show that the false discovery rate is also controlled at level $\leq \frac{m_0}{m} \alpha$ when the *positive regression dependent* condition holds on the set of the true null hypotheses, and they provide several examples where this condition is true.

NOTE: The positive regression dependent condition on the set of the true null hypotheses holds if the joint distribution of the test statistics $\mathbf{X} = (X_1, \dots, X_m)$ for the null hypotheses H_{01}, \dots, H_{0m} satisfies: $\Pr(\mathbf{X} \in A | X_i = x)$ is nondecreasing in x for each X_i where H_{0i} is true, for any increasing set A . The set A is increasing if $\mathbf{x} \in A$ and $\mathbf{y} \geq \mathbf{x}$ implies $\mathbf{y} \in A$.

Dependent False Discovery Rate

The **DEPENDENTFDR** option requests a false discovery rate controlling method that is always valid for *p*-values under any kind of dependency (Benjamini and Yekateuli 2001), but is thus quite conservative. Let $\gamma = \sum_{i=1}^m \frac{1}{i}$. The **DEPENDENTFDR** procedure always controls the false discovery rate at level $\leq \frac{m_0}{m} \alpha \gamma$. The adjusted *p*-values are computed as

$$\tilde{p}_{(i)} = \begin{cases} \gamma p_{(m)} & \text{for } i = m \\ \min(\tilde{p}_{(i+1)}, \gamma \frac{m}{i} p_{(i)}) & \text{for } i = m-1, \dots, 1 \end{cases}$$

False Discovery Rate Resampling Adjustments

Bootstrap and permutation resampling methods to control the false discovery rate are available with the **FDRBOOT** and **FDRPERM** options (Yekateuli and Benjamini 1999). These methods approximately control the false discovery rate when the *subset pivotality* condition holds, as discussed in the section “**Bootstrap**” on page 5197, and when the *p*-values corresponding to the true null hypotheses are independent of those for the false null hypotheses.

The resampling methodology for the **BOOTSTRAP** and **PERMUTATION** methods is used to create B resamples. For the b th resample, let $R^b(p)$ denote the number of *p*-values that are less than or equal to the observed *p*-value p . Let $r_\beta(p)$ be the $100(1 - \beta)$ quantile of $\{R^1(p) \dots R^b(p) \dots R^B(p)\}$, and let $r(p)$ be the number of observed *p*-values less than or equal to p . Compute one of the following estimators:

$$\begin{aligned} \text{local estimator} \quad Q_1(p) &= \begin{cases} \frac{1}{B} \sum_{b=1}^B \frac{R^b(p)}{R^b(p) + r(p) - pm} & \text{if } r(p) - r_\beta(p) \geq pm \\ \#\{R^b(p) \geq 1\}/B & \text{otherwise} \end{cases} \\ \text{upper limit estimator} \quad Q_\beta(p) &= \begin{cases} \sup_{x \in [0, p]} \left(\frac{1}{B} \sum_{b=1}^B \frac{R^b(x)}{R^b(x) + r(x) - r_\beta(x)} \right) & \text{if } r(x) - r_\beta(x) \geq 0 \\ \#\{R^b(p) \geq 1\}/B & \text{otherwise} \end{cases} \end{aligned}$$

where m is the number of tests and B is the number of resamples. Then for $Q = Q_1$ or Q_β , the adjusted p -values are computed as

$$\tilde{p}_{(i)} = \begin{cases} Q(p_{(m)}) & \text{for } i = m \\ \min(\tilde{p}_{(i+1)}, Q(p_{(i)})) & \text{for } i = m-1, \dots, 1 \end{cases}$$

Adaptive False Discovery Rate

Since the **FDR** method controls the false discovery rate at $\leq \frac{m_0}{m}\alpha \leq \alpha$, knowledge of m_0 allows improvement of the power of the adjustment while still maintaining control of the false discovery rate. The **ADAPTIVEFDR** option requests adaptive adjusted p -values for approximate control of the false discovery rate, as discussed in Benjamini and Hochberg (2000). See the section “**Adaptive Adjustments**” on page 5200 for more details. These adaptive adjustments are also defined in step-up fashion but use an estimate \hat{m}_0 of the number of true null hypotheses:

$$\tilde{p}_{(i)} = \begin{cases} \frac{\hat{m}_0}{m} p_{(m)} & \text{for } i = m \\ \min(\tilde{p}_{(i+1)}, \frac{\hat{m}_0}{i} p_{(i)}) & \text{for } i = m-1, \dots, 1 \end{cases}$$

Since $\hat{m}_0 \leq m$, the larger p -values are adjusted down. This means that, as defined, controlling the false discovery rate enables you to reject these tests at a level less than the observed p -value. However, by default, this reduction is prevented with an additional restriction: $\tilde{p}_{(i)} = \max\{\tilde{p}_{(i)}, p_{(i)}\}$.

To use this adjustment, Benjamini and Hochberg (2000) suggest first specifying the **FDR** option—if at least one test is rejected at your level, then apply the **ADAPTIVEFDR** adjustment. Alternatively, Benjamini, Krieger, and Yekutieli (2006) apply the **FDR** adjustment at level $\frac{\alpha}{\alpha+1}$, then specify the resulting number of true hypotheses with the **NTRUENULL=** option and apply the **ADAPTIVEFDR** adjustment; they show that this *two-stage linear step-up* procedure controls the false discovery rate at level α for independent test statistics.

Positive False Discovery Rate

The **PFDR** option computes the “ q -values” $\hat{q}_\lambda(p_i)$ (Storey 2002; Storey, Taylor, and Siegmund 2004), which are adaptive adjusted p -values for strong control of the false discovery rate when the p -values corresponding to the true null hypotheses are independent and uniformly distributed. There are four versions of the **PFDR** available. Let $N(\lambda)$ be the number of observed p -values that are less than or equal to λ ; let m be the number of tests; let $f = 1$ if the **FINITE** option is specified, and otherwise set $f = 0$; and denote the estimated proportion of true null hypotheses by

$$\hat{\pi}_0(\lambda) = \frac{m - N(\lambda) + f}{(1 - \lambda)m}$$

The default estimate of FDR is

$$\widehat{\text{FDR}}_\lambda(p) = \frac{\hat{\pi}_0(\lambda)p}{\max(N(p), 1)/m}$$

If you set $\lambda = 0$, then this is identical to the **FDR** adjustment.

The positive FDR is estimated by

$$\widehat{\text{pFDR}}_\lambda(p) = \frac{\widehat{\text{FDR}}_\lambda(p)}{1 - (1 - p)^m}$$

The finite-sample versions of these two estimators for independent null p -values are given by

$$\widehat{\text{FDR}}_{\lambda}^*(p) = \begin{cases} \frac{\hat{\pi}_0^*(\lambda)p}{\max(N(p), 1)/m} & \text{if } p \leq \lambda \\ 1 & \text{if } p > \lambda \end{cases}$$

$$\widehat{\text{pFDR}}_{\lambda}^*(p) = \frac{\widehat{\text{FDR}}_{\lambda}^*(p)}{1 - (1 - p)^m}$$

Finally, the adjusted p -values are computed as

$$\tilde{p}_i = \hat{q}_{\lambda}(p_i) = \inf_{p \geq p_i} \widehat{\text{FDR}}_{\lambda}(p) \quad i = 1, \dots, m$$

This method can produce adjusted p -values that are smaller than the raw p -values. This means that, as defined, controlling the false discovery rate enables you to reject these tests at a level less than the observed p -value. However, by default, this reduction is prevented with an additional restriction: $\tilde{p}_i = \max\{\tilde{p}_i, p_i\}$.

Missing Values

If a **CLASS** or **STRATA** variable has a missing value, then PROC MULTTEST removes that observation from the analysis.

When there are missing values for test variables, the within-group-and-stratum sample sizes can differ from variable to variable. In most cases this is not a problem; however, it is possible for all data to be missing for a particular group within a particular stratum. For continuous variables and Freeman-Tukey tests, PROC MULTTEST re-centers the contrast trend coefficients within strata where all data for a particular group are missing. Re-centering the **MEAN** tests could redefine your t tests in an undesirable fashion; for example, if you specify coefficients to contrast the first and third groups (**contrast -1 0 1**) but the third group is missing, then the re-centered coefficients become -0.5 and 0.5 , thus contrasting the first and second groups. If this is the case, you can run your t tests in separate PROC MULTTEST invocations, then combine the data and adjust the p -values by using the **INPVALUES=** option. However, you might find this re-centering acceptable for the Freeman-Tukey trend tests, since the contrast still tests for an increasing trend. The Cochran-Armitage and Peto tests are unaffected by this situation.

PROC MULTTEST uses missing values for resampling if they exist in the original data set. If all variables have missing values for any observation, then PROC MULTTEST removes the observation prior to resampling. Otherwise, PROC MULTTEST treats all missing values as ordinary observations in the resampling. This means that different resampled data sets can have different group sizes. In some cases it means that a resampled data set can have all missing values for a particular variable in a particular group/stratum combination, even when values exist for that combination in the original data. For this reason, PROC MULTTEST recomputes all quantities within each pseudo-data set, including such items as centered scoring coefficients and degrees of freedom for p -values.

While PROC MULTTEST does provide analyses in missing value cases, you should not feel that it completely solves the missing-value problem. If you are concerned about the adverse effects of missing data on a particular analysis, you should consider using imputation and sensitivity analyses to assess the effects of the missing data.

Computational Resources

PROC MULTTEST keeps all of the data in memory to expedite resampling. A large portion of the memory requirement is thus $8 \times \text{NOBS} \times \text{NVAR}$ bytes, where NOBS is the number of observations in the data set, and NVAR is the number of variables analyzed, including CLASS, FREQ, and STRATA variables.

If you specify PERMUTATION=number (for exact permutation distributions), then PROC MULTTEST requires additional memory. This requirement is approximately $4 \times \text{NTEST} \times \text{NSTRATA} \times \text{CMAX} \times \text{number} \times (\text{number} + 1)$ bytes, where NTEST is the number of contrasts, NSTRATA is the number of STRATA levels, and CMAX is the maximum contrast coefficient.

If you specify the FDRBOOT or FDRPERM option, then saving all the resamples in memory requires $8 \times \text{NSAMPLE} \times \text{NOBS}$ bytes, where NSAMPLE is the number of resamples used.

The execution time is linear in the number of resamples; that is, 10,000 resamples will take 10 times longer than 1,000 resamples. The execution time is also linear in the sample size; that is, 100 resamples of size N will take 10 times longer than 100 resamples of size $10N$.

Output Data Sets

OUT= Data Set

The OUT= data set contains contrast names (_test_), variable names (_var_), the contrast label (_contrast_), raw p -values (raw_p or the value specified in the INPVALUES= option), and all requested adjusted p -values (bon_p, sid_p, boot_p, perm_p, stpbbon_p, stpsid_p, stpbootp, stppermp, hom_p, hoc_p, fic_p, stouffer_p, aholm_p, ahoc_p, fdr_p, dfdr_p, fdrbootp, ufdbootp, fdrpermp, ufdpermp, afdr_p, or pfdr_p).

If a resampling-based adjusted p -value is requested, then the simulation standard error is included as either sim_se, stpsimse, fdrsimse, or ufdsimse, depending on whether single-step, step-down, or FDR adjustments are requested. The simulation standard errors are used to bound the true resampling-based adjusted p -value. For example, if the resampling-based estimate is 0.0312 and the simulation standard error is 0.00123, then a 95% confidence interval for the true adjusted p -value is $0.0312 \pm 1.96(0.00123)$, or 0.0288 to 0.0336.

Intermediate statistics used to calculate the p -values are also written to the OUT= data set. The statistics are separated by the _strat_ level. When _strat_ is reported as missing, the statistics refer to the pooled analysis over all _strat_ levels. The p -values are provided only for the pooled analyses and are therefore reported as missing for the strata-specific statistics.

For the Peto test, an additional variable, _tstrat_, is included to indicate whether the stratum is an incidental occurrence stratum (_tstrat_=0) or a fatal occurrence stratum (_tstrat_=1).

The statistic _value_ is the per-strata contribution to the numerator of the overall test statistic. In the case of the MEAN test, this is the contrast function of the sample means multiplied by the total number of observations within the stratum. For the FT test, _value_ is the contrast function of the double-arcsine transformed proportions, again multiplied by the total number of observations within the stratum. For the CA and Peto tests, _value_ is the observed value of the trend statistic within that stratum.

When either PETO or CA is requested, the variable _exp_ is included; this variable contains the expected value of the trend statistic for the given stratum.

The statistic _se_ is the square root of the variance of the per-strata _value_ statistic for any of the tests.

For **MEAN** tests, the variable `_nval_` is included. When reported with an individual stratum level (that is, when the `_strat_` value is nonmissing), the value `_nval_` refers to the within-stratum sample size. For the combined analysis (that is, the value of the `_strat_` is missing), the value `_nval_` contains degrees of freedom of the t distribution used to compute the unadjusted p -value.

When the **FISHER** test is requested, the `OUT=` data set contains the variables `_xval_`, `_mval_`, `_yval_`, and `_nval_`, which define observations and sample sizes in the two groups defined by the **CONTRAST** statement.

For example, the `OUT=` data set from the drug example in the section “**Getting Started: MULTTEST Procedure**” on page 5167 is displayed in [Figure 61.5](#).

Figure 61.5 Output Data for the MULTTEST Procedure

OUTPERM= Data Set

The `OUTPERM=` data set contains contrast names (`_contrast_`), variable names (`_var_`), and the associated permutation distributions (`_value_` and `upper_p`). PROC MULTTEST computes the permutation distributions when you use the **PERMUTATION=** option with the **CA** or Peto test. The `_value_` variable represents the support of the distributions, and `upper_p` represents their cumulative upper-tail probabilities. The size of this data set depends on the number of variables and the support of their permutation distributions.

For information about how this distribution is computed, see the section “**Exact Permutation Test**” on page 5189. For an illustration, see [Example 61.1](#).

OUTSAMP= Data Set

The `OUTSAMP=` data set contains the data sets used in the resampling analysis, if such an analysis is requested. The variable `_sample_` indicates the number of the resampled data set. This variable ranges from 1 to the value of the **NSAMPLE=** option. For each value of the `_sample_` variable, an entire resampled data set is included, with `_stratum_`, `_class_`, and all other variables in the original data set. The values of the original variables are mean-centered for the mean test, if requested. The variable `_obs_` indicates the observation’s position in the original data set.

Each new data set is randomly drawn from the original data set, either with (bootstrap) or without (permutation) replacement. The size of this data set is, thus, the number of observations in the original data set times the number of samples.

Displayed Output

The output produced by PROC MULTTEST is divided into several tables. If the **DATA=** data set is specified, then the following tables are displayed:

- The “Model Information” table provides a list of the options and settings used for that particular invocation of the procedure. This table is not displayed if the **INPVALUES=** data set is specified. Included in this list are the following items:
 - statistical tests
 - support of the exact permutation distribution for the **CA** and **Peto** tests
 - continuity corrections used for the **CA** test
 - test tails
 - strata adjustment
 - *p*-value adjustments and specified suboptions
 - centering of continuous variables
 - number of samples and seed
- The “Contrast Coefficients” table lists the coefficients used in constructing the statistical tests. These coefficients are either specified in **CONTRAST** statements or generated by default. The coefficients apply to the levels of the **CLASS** statement variable. If a **MEAN** or **FT** test is specified in the **TEST** statement, the centered coefficients are displayed. Patterns of missing values in your data set might affect the coefficients used in your analysis; the displayed contrasts take missing value patterns into account. See the section “**Missing Values**” on page 5203 for more information.
- The “Variable Tabulations” tables provide summary statistics for each variable listed in the **TEST** statement. Included for discrete variables are the count, sample size, and percentage of occurrences. For continuous variables, the mean, sample standard deviation, and sample size are displayed. All of the previously mentioned statistics are computed for distinct combinations of the **CLASS** and **STRATA** statement variables.

If the **INPVALUES=** data set is specified, then the following tables are displayed:

- The “P-Value Adjustment Information” table provides a list of the specified *p*-value adjustments. If an adaptive adjustment is specified (see section “**Adaptive Adjustments**” on page 5200), then the following settings are also displayed when appropriate:
 - whether the finite-sample version of the PFDR is used (**FINITE**)
 - the number of tuning parameters to check (**NLAMBDA=**), the maximum tuning parameter (**MAXLAMBDA=**), or the specified tuning parameter (**LAMBDA=**)
 - the degrees of freedom of the spline (**DF=**) and the smoothing parameter
 - the number of bootstrap resamples (**NBOOT=**) and the seed (**SEED=**)

- If the **bootstrap** or **spline** method for estimating the number of true null hypotheses m_0 is used and the **PLOTS=** option is specified, the “Lambda Values” table displays the m_0 estimates as a function of the tuning parameter λ . If the **bootstrap** method is used, the table also displays the mean-squared errors, the minimum of which is used to select a specific λ . This table contains the values used in the “Lambda Functions” plot.
- The “Estimated Number of True Null Hypotheses” table displays the p -value adjustment, the method used to estimate the number of true nulls, and an estimate of the number and proportion of true null hypotheses in the data set.

The following table is displayed unless the **NOPVALUE** option is specified:

- The “p-Values” table is a collection of the raw and adjusted p -values from the run of PROC MULTTEST. The p -values are identified by variable and test.

ODS Table Names

PROC MULTTEST assigns a name to each table it creates, and you must use this name to reference the table when using the Output Delivery System (ODS). These names are listed in the following table. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 61.3 ODS Tables Produced by PROC MULTTEST

ODS Table Name	Description	Statement or Option
Continuous	Continuous variable tabulations	TEST with MEAN
Contrasts	Contrast coefficients	default
Discrete	Discrete variable tabulations	TEST with CA, FT, PETO, or FISHER
LambdaValues	True null estimates	AHOLM, AHOC, AFDR, or PFDR
ModelInfo	Model information	default
NumTrueNull	Estimates of number of true nulls	AHOLM, AHOC, AFDR, or PFDR
pValues	p -values from the tests	default
pValueInfo	p -value adjustment information	INPVALUES=

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

You must also specify the options in the PROC MULTTEST statement that are indicated in Table 61.4.

PROC MULTTEST assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 61.4.

Table 61.4 Graphs Produced by PROC MULTTEST

ODS Graph Name	Plot Description	Option
AdjPlots	Panel of adjusted p -value plots	PLOTS=ADJUSTED
AdjByRawRank	Adjusted by rank of raw p -values	PLOTS=ADJUSTED(UNPACK)
AdjbyRawP	Adjusted by raw p -values	PLOTS=ADJUSTED(UNPACK)
AdjBySignificant	Proportion significant by adjusted	PLOTS=ADJUSTED(UNPACK)
FalsePosBySignificant	Expected number of false positives by proportion significant	PLOTS=ADJUSTED(UNPACK)
PByTest	p -values by test	PLOTS=PBYTEST
LambdaPlot	MSE or NTRUENULL by lambda	PLOTS=LAMBDA and (NTRUENULL=BOOTSTRAP or NTRUENULL=SPLINE or PFDR)
ManhattanPlots	$-\log_{10}$ (adjusted p -values) by test	PLOTS=MANHATTAN
ManhattanPanel	Panel of Manhattan plots	PLOTS=MANHATTAN
RawUniformPlot	Raw p -values by rank and histogram	PLOTS=RAWPROB or AHOLM or AHOC or AFDR or PFDR
RawUniformPlot	Raw p -values by rank	PLOTS=RAWPROB(UNPACK) and AHOLM or AHOC or AFDR or PFDR
RawUniformHist	Histogram of raw p -values	PLOTS=RAWPROB(UNPACK) and AHOLM or AHOC or AFDR or PFDR

Examples: MULTTEST Procedure

Example 61.1: Cochran-Armitage Test with Permutation Resampling

This example, from Keith Soper at Merck, illustrates the exact permutation Cochran-Armitage test carried out on permutation resamples. In the following data set, each observation represents an animal. The binary variables S1 and S2 indicate two tumor types, with 0s indicating no tumor (failure) and 1 indicating a tumor (success); note that they have perfect negative association. The grouping variable is Dose.

```
data a;
  input S1 S2 Dose @@;
  datalines;
0 1 1    1 0 1    0 1 1
0 1 1    0 1 1    1 0 1
1 0 2    1 0 2    0 1 2
1 0 2    0 1 2    1 0 2
```

```

1 0 3   1 0 3   1 0 3
0 1 3   0 1 3   1 0 3
;

proc multtest data=a permutation nsample=10000 seed=36607 outperm=pmt;
  test ca(S1 S2 / permutation=10 uppertailed);
  class Dose;
  contrast 'CA Linear Trend' 0 1 2;
run;
proc print data=pmt;
run;

```

The PROC MULTTEST statement requests 10,000 permutation resamples. The **OUTPERM=** option creates an output SAS data set **pmt** used for the exact permutation distribution computed for the **CA** test.

The **TEST** statement specifies an upper-tailed Cochran-Armitage linear trend test for **S1** and **S2**. The cutoff for exact permutation calculations is 10, as specified with the **PERMUTATION=** option in the **TEST** statement. Since **S1** and **S2** have 10 and 8 successes, respectively, PROC MULTTEST uses exact permutation distributions to compute the *p*-values for both variables.

The groups for the **CA** test are the levels of **Dose** from the **CLASS** statement. The trend coefficients applied to these groups are 0, 1, and 2, respectively, as specified in the **CONTRAST** statement.

Finally, the PROC PRINT statement displays the SAS data set **pmt**, which contains the permutation distributions.

The results from this analysis are displayed in [Output 61.1.1](#) through [Output 61.1.5](#). You should check the “Model Information” table to verify that the analysis specifications are correct.

Output 61.1.1 Cochran-Armitage Test with Permutation Resampling

The Multtest Procedure	
Model Information	
Test for discrete variables	Cochran-Armitage
Exact permutation distribution used	Everywhere
Tails for discrete tests	Upper-tailed
Strata weights	None
P-value adjustment	Permutation
Number of resamples	10000
Seed	36607

The label and coefficients from the **CONTRAST** statement are shown in [Output 61.1.2](#).

Output 61.1.2 Contrast Coefficients

Contrast Coefficients			
	Dose		
Contrast	1	2	3
CA Linear Trend	0	1	2

Output 61.1.3 displays summary statistics for the two test variables, S1 and S2. The Count column lists the number of successes for each level of the CLASS variable, Dose. The NumObs column lists the sample size, and the Percent column lists the percentage of successes in the sample.

Output 61.1.3 Summary Statistics

Discrete Variable Tabulations				
Variable	Dose	Count	NumObs	Percent
S1	1	2	6	33.33
S1	2	4	6	66.67
S1	3	4	6	66.67
S2	1	4	6	66.67
S2	2	2	6	33.33
S2	3	2	6	33.33

The Raw column in Output 61.1.4 contains the p -values from the CA test, and the Permutation column contains the permutation-adjusted p -values.

Output 61.1.4 Resulting p -Values

p-Values			
Variable	Contrast	Raw	Permutation
S1	CA Linear Trend	0.1993	0.4009
S2	CA Linear Trend	0.9220	1.0000

This table shows that, for S1, the adjusted p -value is approximately twice the raw p -value. In fact, resamples with small (large) p -values for S1 have large (small) p -values for S2 due to the perfect negative association of the variables, and hence the permutation-adjusted p -value for S1 should be $2 \times 0.1993 = 0.3986$; the difference is due to resampling error. For the same reason, since the raw p -value for S2 is 0.9220, the adjusted p -value equals 1. The permutation p -values for S1 and S2 also happen to be the Bonferroni-adjusted p -values for this example.

The OUTPERM= data set is displayed in Output 61.1.5, which contains the exact permutation distributions for S1 and S2 in terms of cumulative probabilities.

Output 61.1.5 Exact Permutation Distribution

Obs	_contrast_	_var_	_value_	upper_p
1	CA Linear Trend	S1	0	1.00000
2	CA Linear Trend	S1	1	1.00000

Example 61.2: Freeman-Tukey and t Tests with Bootstrap Resampling

The data for this example are the same as for [Example 61.1](#), except that a continuous variable T , which indicates the time of death of the animal, has been added.

```
data a;
  input S1 S2 T Dose @@;
  datalines;
0 1 104 1 1 0 80 1 0 1 104 1
0 1 104 1 0 1 100 1 1 0 104 1
1 0 85 2 1 0 60 2 0 1 89 2
1 0 96 2 0 1 96 2 1 0 99 2
1 0 60 3 1 0 50 3 1 0 80 3
0 1 98 3 0 1 99 3 1 0 50 3
;

proc multtest data=a bootstrap nsample=10000 seed=37081 outsamp=res;
  test ft(S1 S2 / lowertailed) mean(T / lowertailed);
  class Dose;
  contrast 'Linear Trend' 0 1 2;
run;

proc print data=res(obs=36);
run;
```

The **BOOTSTRAP** option in the PROC MULTTEST statement requests bootstrap resampling, and **NSAMPLE=10000** requests 10,000 bootstrap samples. The **SEED=37081** option provides a starting value for the random number generator. The **OUTSAMP=res** option creates an output SAS data set `res` containing the 10,000 bootstrap samples.

The **TEST** statement specifies the Freeman-Tukey test for $S1$ and $S2$ and specifies the t test for T . Both tests are lower-tailed. The grouping variable in the **CLASS** statement is `Dose`, and the coefficients across the levels of `Dose` are 0, 1, and 2, as specified in the **CONTRAST** statement. The PROC PRINT statement displays the first 36 observations of the `res` data set containing the bootstrap samples.

The results from this analysis are listed in [Output 61.2.1](#) through [Output 61.2.5](#).

The “Model Information” table in [Output 61.2.1](#) corresponds to the specifications in the invocation of PROC MULTTEST.

Output 61.2.1 FT and *t* tests with Bootstrap Resampling

The Multtest Procedure	
Model Information	
Test for discrete variables	Freeman-Tukey
Test for continuous variables	Mean t-test
Degrees of Freedom Method	Pooled
Tails for discrete tests	Lower-tailed
Tails for continuous tests	Lower-tailed
Strata weights	None
P-value adjustment	Bootstrap
Center continuous variables	Yes
Number of resamples	10000
Seed	37081

The “Contrast Coefficients” table in [Output 61.2.2](#) shows the coefficients from the **CONTRAST** statement after centering, and they model a linear trend.

Output 61.2.2 Contrast Coefficients

Contrast Coefficients				
		Dose		
Contrast		1	2	3
Linear Trend	Centered	-1	0	1

The summary statistics are displayed in [Output 61.2.3](#). The values for the discrete variables S1 and S2 are the same as those from [Example 61.1](#). The mean, standard deviation, and sample size for the continuous variable T at each level of Dose are displayed in the “Continuous Variable Tabulations” table.

Output 61.2.3 Summary Statistics

Discrete Variable Tabulations				
Variable	Dose	Count	NumObs	Percent
S1	1	2	6	33.33
S1	2	4	6	66.67
S1	3	4	6	66.67
S2	1	4	6	66.67
S2	2	2	6	33.33
S2	3	2	6	33.33

Output 61.2.3 *continued*

Continuous Variable Tabulations				
Variable	Dose	NumObs	Mean	Standard Deviation
T	1	6	99.3333	9.6056
T	2	6	87.5000	14.4326
T	3	6	72.8333	22.7017

The p -values, displayed in [Output 61.2.4](#), are from the Freeman-Tukey test for S1 and S2, and are from the t test for T.

Output 61.2.4 p -Values

p-Values			
Variable	Contrast	Raw	Bootstrap
S1	Linear Trend	0.8547	1.0000
S2	Linear Trend	0.1453	0.4605
T	Linear Trend	0.0070	0.0281

The Raw column in [Output 61.2.4](#) contains the results from the tests on the original data, while the Bootstrap column contains the bootstrap resampled adjustment to raw_p. Note that the adjusted p -values are larger than the raw p -values for all three variables. The adjusted p -values more accurately reflect the correlation of the raw p -values, the small size of the data, and the multiple testing.

[Output 61.2.5](#) displays the first 36 observations of the SAS data set resulting from the OUTSAMP=RES option in the PROC MULTTEST statement. The entire data set has 180,000 observations, which is 10,000 times the number of observations in the data set.

Output 61.2.5 Resampling Data Set

Obs	_sample_	_class_	_obs_	S1	S2	T
1	1	1	17	0	1	26.1667

15	1	3	14	1	0	-22.8333
16	1	3	15	1	0	7.1667
17	1	3	15	1	0	7.1667
18	1	3	6	1	0	4.6667
19	2	1	6	1	0	4.6667
20	2	1	17	0	1	26.1667
21	2	1	8	1	0	-27.5000
22	2	1	13	1	0	-12.8333
23	2	1	9	0	1	1.5000
24	2	1	8	1	0	-27.5000
25	2	2	9	0	1	1.5000
26	2	2	18	1	0	-22.8333
27	2	2	15	1	0	7.1667
28	2	2	14	1	0	-22.8333
29	2	2	9	0	1	1.5000
30	2	2	17	0	1	26.1667
31	2	3	16	0	1	25.1667
32	2	3	11	0	1	8.5000
33	2	3	14	1	0	-22.8333
34	2	3	18	1	0	-22.8333
35	2	3	18	1	0	-22.8333
36	2	3	10	1	0	8.5000

The `_sample_` variable is the sample indicator and `_class_` indicates the resampling group—that is, the level of the `CLASS` variable Dose assigned to the new observation. The number of the observation in the original data set is represented by `_obs_`. Also listed are the values of the original test variables, S1 and S2, and the mean-centered values of T.

Example 61.3: Peto Mortality-Prevalence Test

This example illustrates the use of the Peto mortality-prevalence test. The test is a combination of analyses about the prevalence of incidental tumors in the population and mortality due to fatal tumors.

In the following data set, each observation represents an animal. The variables S1–S3 are three tumor types, with a value of 0 indicating no tumor, 1 indicating an incidental (nonlethal) tumor, and 2 indicating a lethal tumor. The time variable T indicates the time of death of the animal, a strata variable B is constructed from T, and the grouping variable Dose is drug dosage.

```
data a;
  input S1-S3 T Dose @@;
  if T<=90 then B=1; else B=2;
  datalines;
0 0 0 104 0    2 0 1 80 0    0 0 1 104 0
0 0 0 104 0    0 2 0 100 0    1 0 0 104 0
2 0 0 85 1    2 1 0 60 1    0 1 0 89 1
2 0 1 96 1    0 0 0 96 1    2 0 1 99 1
2 1 1 60 2    2 0 0 50 2    2 0 1 80 2
0 0 2 98 2    0 0 1 99 2    2 1 1 50 2
;

proc multtest data=a notables out=p stepsid;
  test peto(S1-S3 / permutation=20 time=T uppertailed);
  class Dose;
  strata B;
  contrast 'mort-prev' 0 1 2;
run;
proc print data=p;
run;
```

The **NOTABLES** option in the PROC MULTTEST statement suppresses the display of the summary statistics for each variable. The **OUT=** option creates an output SAS data set p containing all *p*-values and intermediate statistics. The **STEPSID** option is used to adjust the *p*-values.

The **TEST** statement specifies an upper-tailed Peto test for S1–S3. The mortality strata are defined by **TIME=T**, the death times. The **CLASS** statement contains the grouping variable Dose. The prevalence strata are defined by the **STRATA** statement as the blocking variable B. The **CONTRAST** statement lists the default linear trend coefficients. The PROC PRINT statement displays the requested *p*-value data set.

The results from this analysis are listed in [Output 61.3.1](#) through [Output 61.3.4](#).

The “Model Information” table in [Output 61.3.1](#) displays information corresponding to the PROC MULTTEST invocation. In this case the totals for all prevalence and fatality strata are less than 20, so exact permutation tests are used everywhere, and the STEPSID adjustments are computed from these permutation distributions.

Output 61.3.1 Peto Test

The Multtest Procedure	
Model Information	
Test for discrete variables	Peto
Exact permutation distribution used	Everywhere
Tails for discrete tests	Upper-tailed
Strata weights	Sample size
P-value adjustment	Stepdown Sidak

The contrast trend coefficients are listed in [Output 61.3.2](#). They happen to be the same as the levels of the Dose variable.

Output 61.3.2 Contrast Coefficients

Contrast Coefficients			
		Dose	
Contrast	0	1	2
mort-prev	0	1	2

In the “*p*-Values” table in [Output 61.3.3](#), the *p*-values for the Peto tests are listed in the Raw column, and the step-down Šidák adjusted *p*-values are in the Stepdown Šidák column.

Output 61.3.3 *p*-Values

p-Values			
Variable	Contrast	Raw	Stepdown Sidak
S1	mort-prev	0.0681	0.0814
S2	mort-prev	0.5000	0.5000
S3	mort-prev	0.0363	0.0781

Significant *p*-values in the preceding table support the claim that higher dosage levels lead to higher mortality and prevalence. The raw Peto test is significant at the 5% level for S3, but the adjusted S3 test is no longer significant at 5%. The raw and adjusted *p*-values for S2 are the same because of the step-down technique.

The OUT= data set is displayed in [Output 61.3.4](#).

Output 61.3.4 OUT= Data Set

The first 30 observations correspond to intermediate statistics used to compute the Peto p -values. The `_test_` variable lists the name of the test, the `_var_` variable lists the name of the **TEST** variables, and the `_contrast_` variable lists the **CONTRAST** label. The `_strat_` variable lists the level of the **STRATA** variable, and the `_tstrat_` variable indicates whether or not the stratum corresponds to values of the **TIME=** variable. The `_value_` variable is the observed contrast for a stratum, and the `_exp_` variable is its expected value. The variable `_se_` contains the square root of the variance terms summed to form the denominator of the Peto statistics.

The final three observations correspond to the three Peto tests, with their p -values listed under the `raw_p` variable. The `stpsid_p` variable contains the step-down Šidák-adjusted p -values.

Example 61.4: Fisher Test with Permutation Resampling

The following data, from Brown and Fears (1981), are the results of an 80-week carcinogenesis bioassay with female mice. Six tissue sites are examined at necropsy; 1 indicates the presence of a tumor and 0 the absence. A frequency variable Freq is included. A control and four different doses of a drug (in parts per milliliter) make up the levels of the grouping variable Dose.

  test fisher(Liver Lung Lymph Cardio Pitui Ovary /
    lowertailed);
  class Dose;
  freq Freq;
run;
proc print data=p;
run;
```

In the PROC MULTTEST statement, the **ORDER=DATA** option is required to keep the levels of Dose in the order in which they appear in the data set. Without this option, the levels are sorted by their formatted value, resulting in an alphabetic ordering. The **NOTABLES** option suppresses the display of summary statistics, and the **OUT=** option produces an output data set p containing the *p*-values. The **PERMUTATION** option specifies permutation resampling, **NSAMPLE=1000** requests 1000 samples, and **SEED=764511** option provides a starting value for the random number generator. You should specify a seed if you need to duplicate resampling results.

To test for higher rates of tumor occurrence in the treatment groups compared to the control group, the **LOWERTAILED** option is specified in the **FISHER** option of the **TEST** statement to produce a lower-tailed Fisher exact test for the six tissue sites. The Fisher test is appropriate for comparing a treatment and a control, but multiple testing can be a problem. Brown and Fears (1981) use a multivariate permutation to evaluate the entire collection of tests. PROC MULTTEST adjusts the p -values by simulation.

The treatments make up the levels of the grouping variable **Dose**, listed in the **CLASS** statement. Since no **CONTRAST** statement is specified, PROC MULTTEST uses the default pairwise contrasts with the first level of **Dose**. The **FREQ** statement is used since these are summary data containing frequency counts of occurrences.

The results from this analysis are listed in [Output 61.4.1](#) through [Output 61.4.4](#). First, the PROC MULTTEST specifications are displayed in [Output 61.4.1](#).

Output 61.4.1 Fisher Test with Permutation Resampling

The Multtest Procedure	
Model Information	
Test for discrete variables	Fisher
Tails for discrete tests	Lower-tailed
Strata weights	None
P-value adjustment	Permutation
Number of resamples	1000
Seed	764511

The default contrasts for the Fisher test are displayed in [Output 61.4.2](#). Note that each dose is compared with the control.

Output 61.4.2 Default Contrast Coefficients

Contrast Coefficients

As noted by Brown and Fears, only one of the 24 tests is significant at the 5% level (Lymph, CTRL vs. 16PPM). Brown and Fears report a 12% chance of observing at least one significant raw *p*-value for 16PPM and a 9% chance of observing at least one significant raw *p*-value for Lymph (both at the 5% level). Adjusted *p*-values exhibit much lower chances of false significances. For this example, none of the adjusted *p*-values are close to significant.

The OUT= data set is displayed in [Output 61.4.4](#).

The `_test_`, `_var_`, and `_contrast_` variables provide the **TEST** name, **TEST** variable, and **CONTRAST** label, respectively. The `_xval_`, `_mval_`, `_yval_`, and `_nval_` variables contain the components used to compute the Fisher exact tests from the hypergeometric distribution. The `raw_p` variable contains the p -values from the Fisher exact tests, and the `perm_p` variable contains their permutation-based adjustments. The variable `sim_se` is the simulation standard error from the permutation resampling.

Example 61.5: Inputting Raw p -Values

This example illustrates how to use PROC MULTTEST to multiplicity-adjust a collection of raw p -values obtained from some other source. This is a valuable option for those cases where PROC MULTTEST cannot compute the raw p -values directly. The data set `a`, which follows, contains the unadjusted p -values computed in [Example 61.4](#). Note that the data set needs to have one variable containing the p -values, but the data set can contain other variables as well.

```
data a;

24	0.3689	1.0000	0.9437	0.9243

Note that the adjusted *p*-values for the Hochberg method are less than or equal to those for the Holm (Step-down Bonferroni) method. In turn, the adjusted *p*-values for the FDR method (False Discovery Rate) are less than or equal to those for the Hochberg method. These comparisons hold generally for all *p*-value configurations. The FDR method controls the false discovery rate and not the familywise error rate. The Hochberg method controls the familywise error rate under independence. The Holm method controls the familywise error rate without assuming independence.

Example 61.6: Adaptive Adjustments and ODS Graphics

An experiment was performed using Affymetrix[®] gene chips on the CD4 lymphocyte white blood cells of patients with and without a hereditary allergy (atopy) and possibly with asthma. The Asthma-Atopy microarray data set and analysis are discussed in Gibson and Wolfinger (2004): a one-way ANOVA model of the log2mas5 variable ($\log_2(\text{MAS 5.0 summary statistics})$) is fit against a classification variable trt describing different asthma-atopy combinations in the patients, and the least squares means of the trt variable are computed.

For this example, a 1% random sample of least squares means having p -values exceeding $1E-6$ is taken. The resulting data are recorded in the test data set, where the Probe_Set_ID variable identifies the probe and the Probt variable contains the p -values for the $m = 121$ tests, as follows:

```
data test;
  length Probe_Set_ID $9.;
  input Probe_Set_ID $ Probt @@;

The following statements adjust the p -values in the test data set by using the adaptive adjustments ([ADAPTIVEHOLM](#), [ADAPTIVEHOCHBERG](#), [ADAPTIVEFDR](#), and [PFDR](#)), which require an estimate of the number of true null hypotheses (\hat{m}_0) or proportion of true null hypotheses ($\hat{\pi}_0$). This example illustrates some of the features and graphics for computing and evaluating these estimates. The [NOPVALUE](#) option is specified to suppress the display of the “p-Values” table.

```
ods graphics on;
proc multtest invalues(Probt)=test plots=all seed=518498000
  aholm ahoc afdr pfdr(positive) nopvalue;
  id Probe_Set_ID;
run;
ods graphics off;
```

Output 61.6.1 lists the requested p -value adjustments, along with the selected value of the “Lambda” tuning parameter and the seed (specified with the `SEED=` option) used in the `bootstrap` method of estimating the number of true null hypotheses. The “Lambda Values” table lists the estimated number of true nulls for each value of λ , where you can see that the minimum MSE (0.002315) occurs at $\lambda = 0.4$. Output 61.6.2 shows that the `SPLINE` method failed due to a large slope at $\lambda = 0.95$, so the bootstrap method is used and the MSE plot is displayed.

Output 61.6.1 p and Lambda Values

Output 61.6.2 Tuning Parameter Plots

Output 61.6.3 also shows that the bootstrap estimate is used for the PFDR adjustment. The other adjustments have different default methods for estimating the number of true nulls.

Output 61.6.3 Adjustments and Their Default Estimation Method

Estimated Number of True Null Hypotheses			
P-Value Adjustment	Method	Estimate	Proportion
Adaptive Holm	Decreased Slope	26	0.21488
Adaptive Hochberg	Decreased Slope	26	0.21488
Adaptive FDR	Lowest Slope	43	0.35537
Positive FDR	Bootstrap	23.3333	0.19284

Output 61.6.4 displays the estimated number of true nulls \hat{m}_0 against a uniform probability plot of the unadjusted p -values (if the p -values are distributed uniformly, the points on the plot will all lie on a straight line). According to Schweder and Spjøtvoll (1982) and Hochberg and Benjamini (1990), the points on the

left side of the plot should be approximately linear with slope $\frac{1}{m_0+1}$, so you can use this plot to evaluate whether your estimate of \hat{m}_0 seems reasonable.

Output 61.6.4 p -Value Distribution

The **NTRUENULL=** option provides several methods for estimating the number of true null hypotheses; the following table displays each method and its estimate for this example:

NTRUENULL=	Estimate
BOOTSTRAP	23.3
DECREASESLOPE	26
KSTEST	35
LEASTSQUARES	28
LOWESTSLOPE	43
MEANDIFF	42
SPLINE	50.1

Another method of estimating the number of true null hypotheses fits a finite mixture model (mixing a uniform with a beta) to the distribution of the unadjusted p -values (Allison et al. 2002). Osborne (2006) provides the following PROC NLMIXED statements to fit this model:

```
proc nlmixed data=test;
  parameters pi0=0.5 a=.1 b=.1;
  pi1= 1-pi0;
  bounds 0 <= pi0 <= 1;
  loglikelihood= log(pi0+pi1*pdf('beta',Probt,a,b));
  model Probt ~ general(loglikelihood);
run;
```

You might have to change the initial parameter values in the PARAMETERS statement to achieve convergence; see Chapter 64, “[The NLMIXED Procedure](#),” for more information. This mixture model estimates $\hat{\pi}_0 = 0$, meaning that the distribution of p -values is completely specified by a single beta distribution. If the estimate were, say, $\hat{\pi}_0 = 0.10$, you could then specify it as follows:

```
proc multtest invalues(Probt)=test ptruennull=0.10
  aholm ahoc afdr pfdr(positive) nopvalue;
  id Probe_Set_ID;
run;
```

A plot of the unadjusted and adjusted p -values for each test is also produced. Due to the large number of tests and adjustments, the plot is not very informative and is not displayed here.

The top two plots in [Output 61.6.5](#) show how the adjusted values compare with each other and the unadjusted p -values. The PFDR and AFDR adjustments are eventually smaller than the unadjusted p -values since they control the false discovery rate. The adaptive Holm and Hochberg adjustments are almost identical, so the adaptive Holm values are mostly obscured in all four plots. The plot of the Proportion Significant versus the Adjusted p -values tells you how many of the tests are significant for each cutoff, while the plot of the number of false positives (FPN) versus the Proportion Significant tells you how many false positives you can expect for that cutoff.

Output 61.6.5 Adjustment Diagnostics

A Manhattan plot displays $-\log_{10}$ of the adjusted p -values, so the most significant tests stand out at the top of the plot. The default plot is not displayed here. The following statements create a Manhattan plot of the adaptive FDR p -values, with the most significant tests labeled with their observation number. The ID values are displayed on the X axis, and the `VREF=` option specifies the significance level. This plot is typically created with many more p -values, and special ODS Graphics options such as the `LABELMAX=` option might be required to display the graph. If memory usage is an issue, you might want to store your p -values and use the `SGPLOT` procedure to create a similar graph.

```
ods graphics on / labelmax=1000;
proc multtest invalues(Probt)=test afdr nopvalue
  plots=Manhattan(label=obs vref=0.0001);
  id Probe_Set_ID;
run;
ods graphics off;
```

Output 61.6.6 Manhattan Plot

If you have a lot of tests, the “Raw and Adjusted p -Values” and “P-Value Adjustment Diagnostics” plots can be more informative if you suppress some of the tests. In the following statements, the `SIGONLY=0.001` option selects tests with adjusted p -values < 0.001 for display. [Output 61.6.7](#) displays tests with their “significant” adjusted p -values:

```
ods graphics on;
proc multtest invalues(Probt)=test plots(sigonly=0.001)=PByTest
      aholm ahoc afdr pfdr(positive) nopvalue;
run;
ods graphics off;
```

Output 61.6.7 Raw and Adjusted p -Values

Overview: NESTED Procedure

The NESTED procedure performs random-effects analysis of variance for data from an experiment with a nested (hierarchical) structure.¹ A random-effects model for data from a completely nested design with two factors has the form

$$y_{ijr} = \mu + \alpha_i + \beta_{ij} + \epsilon_{ijr}$$

¹PROC NESTED is modeled after the General Purpose Nested Analysis of Variance program of the Dairy Cattle Research Branch of the United States Department of Agriculture. That program was originally written by M. R. Swanson, Statistical Reporting Service, United States Department of Agriculture.

where

- y_{ijr} is the value of the dependent variable observed at the r th replication with the first factor at its i th level and the second factor at its j th level.
- μ is the overall (fixed) mean of the sampling population.
- $\alpha_i, \beta_{ij}, \epsilon_{ijr}$ are mutually uncorrelated random effects with zero means and respective variances $\sigma_\alpha^2, \sigma_\beta^2$, and σ_ϵ^2 (the variance components).

This model is appropriate for an experiment with a multistage nested sampling design. An example of this is given in [Example 62.1](#), where four turnip plants are randomly chosen (the first factor), then three leaves are randomly chosen from each plant (the second factor nested within the first), and then two samples are taken from each leaf (the different replications at fixed levels of the two factors).

Note that PROC NESTED is appropriate for models with only classification effects; it does not handle models that contain continuous covariates. For random effects models with covariates, use either the GLM or MIXED procedure.

Contrasted with Other SAS Procedures

The NESTED procedure performs a computationally efficient analysis of variance for data with a nested design, estimating the different components of variance and also testing for their significance if the design is balanced (see the section “[Unbalanced Data](#)” on page 5243). Although other procedures (such as GLM and MIXED) provide similar analyses, PROC NESTED is both easier to use and computationally more efficient for this special type of design. This is especially true when the design involves a large number of factors, levels, or observations.

For example, to specify a four-factor completely nested design in the GLM procedure, you use the following form:

```
class a b c d;
model y=a b(a) c(a b) d(a b c);
```

However, to specify the same design in PROC NESTED, you simply use the following form:

```
class a b c d;
var y;
```

In addition, other procedures require TEST statements to perform appropriate tests, whereas the NESTED procedure produces the appropriate tests automatically. However, PROC NESTED makes one assumption about the input data that the other procedures do not: **PROC NESTED assumes that the input data set is sorted by the classification (CLASS) variables defining the effects.** If you use PROC NESTED on data that are not sorted by the CLASS variables, then the results might not be valid.

Getting Started: NESTED Procedure

Reliability of Automobile Models

A study is performed to compare the reliability of several models of automobiles. Three different automobile models (Model) from each of four U.S. automobile manufacturers (Make) are tested. Three different cars of each make and model are subjected to a reliability test and given a score between 1 and 100 (Score), where higher scores indicate greater reliability.

The following statements create the SAS data set auto.

```

title1 'Reliability of Automobile Models';
data auto;
    input Make $ Model Score @@;
    datalines;
a 1 62  a 2 77  a 3 59
a 1 67  a 2 73  a 3 64
a 1 60  a 2 79  a 3 60
b 1 72  b 2 58  b 3 80
b 1 75  b 2 63  b 3 84
b 1 69  b 2 57  b 3 89
c 1 94  c 2 76  c 3 81
c 1 90  c 2 75  c 3 85
c 1 88  c 2 78  c 3 85
d 1 69  d 2 73  d 3 90
d 1 72  d 2 88  d 3 87
d 1 76  d 2 87  d 3 92
;

```

The Make variable contains the make of the automobile, represented here by 'a', 'b', 'c', or 'd', while the Model variable represents the automobile model with a '1', '2', or '3'. The Score variable contains the reliability scores given to the three sampled cars from each Make-Model group. Since the automobile models are nested within their makes, the NESTED procedure is used to analyze these data. The NESTED procedure requires the data to be sorted by Make and, within Make, by Model, so the following statements execute a PROC SORT before completing the analysis.

```

proc sort data=auto;
    by Make Model;
run;

title1 'Reliability of Automobile Models';
proc nested data=auto;
    class Make Model;
    var Score;
run;

```

The Model variable appears after the Make variable in the CLASS statement because it is nested within Make. The VAR statement specifies the response variable. The output is displayed in [Figure 62.1](#).

Figure 62.1 Output from PROC NESTED

Reliability of Automobile Models								
The NESTED Procedure								
Coefficients of Expected Mean Squares								
Source		Make		Model		Error		
Make		9		3		1		
Model		0		3		1		
Error		0		0		1		
Nested Random Effects Analysis of Variance for Variable Score								
Variance Source	DF	Sum of Squares	F Value	Pr > F	Error Term	Mean Square	Variance Component	Percent of Total
Total	35	4177.888889				119.368254	131.876543	100.0000
Make	3	1709.000000	2.15	0.1719	Model	569.666667	33.867284	25.6811
Model	8	2118.888889	18.16	<.0001	Error	264.861111	83.425926	63.2606
Error	24	350.000000				14.583333	14.583333	11.0583
Score Mean						75.94444444		
Standard Error of Score Mean						3.97794848		

Figure 62.1 first displays the coefficients of the variance components that make up each of the expected mean squares, and then it displays the ANOVA table. The results do not indicate significant variation between the different automobile makes ($F = 2.15$, $p = 0.1719$). However, they do suggest that there is significant variation between the different models within the makes ($F = 18.16$, $p < 0.0001$). This is evident in the fact that the make of car accounts for only 25.7% of the total variation in the data, while the car model accounts for 63.3% (as shown in the Percent of Total column). The estimated variance components are shown in the Variance Component column.

Syntax: NESTED Procedure

The following statements are available in the NESTED procedure:

```
PROC NESTED < options > ;
  CLASS variables < / option > ;
  VAR variables ;
  BY variables ;
```

The PROC NESTED and CLASS statements are required. The BY, CLASS, and VAR statements are described after the PROC NESTED statement.

PROC NESTED Statement

PROC NESTED < options > ;

The PROC NESTED statement invokes the NESTED procedure. Table 62.1 summarizes the options available in the PROC NESTED statement.

Table 62.1 PROC NESTED Statement Options

Option	Description
AOV	Displays only the analysis of variance statistics
DATA=	Names the SAS data set

The PROC NESTED statement has the following options:

AOV

displays only the analysis of variance statistics when there is more than one dependent variable. The “analysis of covariation” statistics are suppressed (see the section “[Analysis of Covariation](#)” on page 5244).

DATA=SAS-data-set

names the SAS data set to be used by PROC NESTED. By default, the procedure uses the most recently created SAS data set.

BY Statement

BY variables ;

You can specify a BY statement with PROC NESTED to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the NESTED procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / *option* > ;

You must include a CLASS statement with PROC NESTED specifying the classification variables for the analysis.

Values of a variable in the CLASS statement denote the levels of an effect. The name of that variable is also the name of the corresponding effect. The second effect is assumed to be nested within the first effect, the third effect is assumed to be nested within the second effect, and so on.

By default, class levels are determined from the entire formatted values of the CLASS variables. Note that this represents a slight change from previous releases in the way in which class levels are determined. Prior to SAS 9, class levels were determined using no more than the first eight characters of the formatted values, except for numeric variables with no explicit format, for which class levels were determined from the raw numeric values. If you want to revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement. In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide*, and the discussions for the FORMAT statement and SAS formats in *SAS Statements: Reference*.

NOTE: The data set must be sorted by the classification variables in the order in which they are given in the CLASS statement. Use PROC SORT to sort the data if they are not already sorted.

You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

VAR Statement

VAR *variables* ;

The VAR statement lists the dependent variables for the analysis. The dependent variables must be numeric variables. If you do not specify a VAR statement, PROC NESTED performs an analysis of variance for all numeric variables in the data set, except those already specified in the CLASS statement.

Details: NESTED Procedure

Missing Values

An observation with missing values for any of the variables used by PROC NESTED is omitted from the analysis. Blank values of CLASS character variables are treated as missing values.

Unbalanced Data

A completely nested design is defined to be unbalanced if the groups corresponding to the levels of some classification variable are not all of the same size. The NESTED procedure can compute unbiased estimates for the variance components in an unbalanced design, but because the sums of squares on which these estimates are based no longer have χ^2 distributions under a Gaussian model for the data, F tests for the significance of the variance components cannot be computed. PROC NESTED checks to see that the design is balanced. If it is not, a warning to that effect appears in the log, and the columns corresponding to the F tests in the analysis of variance are left blank.

General Random-Effects Model

A random-effects model for data from a completely nested design with n factors has the general form

$$y_{i_1 i_2 \dots i_n r} = \mu + \alpha_{i_1} + \beta_{i_1 i_2} + \dots + \epsilon_{i_1 i_2 \dots i_n r}$$

where

$y_{i_1 i_2 \dots i_n r}$ is the value of the dependent variable observed at the r th replication with factor j at level i_j , for $j = 1, \dots, n$.

μ is the overall (fixed) mean of the sampled population.

$\alpha_{i_1}, \beta_{i_1 i_2}, \dots, \epsilon_{i_1 i_2 \dots i_n r}$ are mutually uncorrelated random effects with zero means and respective variances $\sigma_\alpha^2, \sigma_\beta^2, \dots, \sigma_\epsilon^2$.

Analysis of Covariation

When you specify more than one dependent variable, the NESTED procedure produces a descriptive analysis of the covariance between each pair of dependent variables in addition to a separate analysis of variance for each variable. The analysis of covariation is computed under the basic random-effects model for each pair of dependent variables:

$$\begin{aligned} y_{i_1 i_2 \dots i_n r} &= \mu + \alpha_{i_1} + \beta_{i_1 i_2} + \dots + \epsilon_{i_1 i_2 \dots i_n r} \\ y'_{i_1 i_2 \dots i_n r} &= \mu' + \alpha'_{i_1} + \beta'_{i_1 i_2} + \dots + \epsilon'_{i_1 i_2 \dots i_n r} \end{aligned}$$

where the notation is the same as that used in the preceding general random-effects model.

There is an additional assumption that all the random effects in the two models are mutually uncorrelated except for corresponding effects, for which

$$\begin{aligned} \text{Corr}(\alpha_{i_1}, \alpha'_{i_1}) &= \rho_\alpha \\ \text{Corr}(\beta_{i_1 i_2}, \beta'_{i_1 i_2}) &= \rho_\beta \\ &\vdots \\ \text{Corr}(\epsilon_{i_1 i_2 \dots i_n r}, \epsilon'_{i_1 i_2 \dots i_n r}) &= \rho_\epsilon \end{aligned}$$

Error Terms in *F* Tests

Random-effects ANOVAs are distinguished from fixed-effects ANOVAs by which error mean squares are used as the denominator for *F* tests. Under a fixed-effects model, there is only one true error term in the model, and the corresponding mean square is used as the denominator for all tests. This is how the usual analysis is computed in PROC ANOVA, for example. However, in a random-effects model for a nested experiment, mean squares are compared sequentially. The correct denominator in the test for the first factor is the mean square due to the second factor; the correct denominator in the test for the second factor is the mean square due to the third factor; and so on. Only the mean square due to the last factor, the one at the bottom of the nesting order, should be compared to the error mean square.

Computational Method

The building blocks of the analysis are the sums of squares for the dependent variables for each classification variable within the factors that precede it in the model, corrected for the factors that follow it. For example, for a two-factor nested design, PROC NESTED computes the following sums of squares:

$$\begin{aligned}\text{Total SS} & \sum_{ijr} (y_{ijr} - y_{...})^2 \\ \text{SS for Factor 1} & \sum_i n_{i.} \left(\frac{y_{i.}}{n_{i.}} - \frac{y_{...}}{n_{..}} \right)^2 \\ \text{SS for Factor 2 within Factor 1} & \sum_{ij} n_{ij} \left(\frac{y_{ij.}}{n_{ij.}} - \frac{y_{i.}}{n_{i.}} \right)^2 \\ \text{Error SS} & \sum_{ijr} \left(y_{ijr} - \frac{y_{ij.}}{n_{ij}} \right)^2\end{aligned}$$

where y_{ijr} is the r th replication, n_{ij} is the number of replications at level i of the first factor and level j of the second, and a dot as a subscript indicates summation over the corresponding index. If there is more than one dependent variable, PROC NESTED also computes the corresponding sums of crossproducts for each pair. The expected value of the sum of squares for a given classification factor is a linear combination of the variance components corresponding to this factor and to the factors that are nested within it. For each factor, the coefficients of this linear combination are computed. (The efficiency of PROC NESTED is partly due to the fact that these various sums can be accumulated with just one pass through the data, assuming that the data have been sorted by the classification variables.) Finally, estimates of the variance components are derived as the solution to the set of linear equations that arise from equating the mean squares to their expected values.

Displayed Output

PROC NESTED displays the following items for each dependent variable:

- Coefficients of Expected Mean Squares, which are the coefficients of the $n + 1$ variance components making up the expected mean square. Denoting the element in the i th row and j th column of this matrix by C_{ij} , the expected value of the mean square due to the i th classification factor is

$$C_{i1}\sigma_1^2 + \cdots + C_{in}\sigma_n^2 + C_{i,n+1}\sigma_\epsilon^2$$

C_{ij} is always zero for $i > j$, and if the design is balanced, C_{ij} is equal to the common size of all classification groups of the j th factor for $i \leq j$. Finally, the mean square for error is always an unbiased estimate of σ_ϵ^2 . In other words, $C_{n+1,n+1} = 1$.

For every dependent variable, PROC NESTED displays an analysis of variance table. Each table contains the following:

- each Variance Source in the model (the different components of variance) and the total variance
- degrees of freedom (DF) for the corresponding sum of squares
- Sum of Squares for each classification factor. The sum of squares for a given classification factor is the sum of squares in the dependent variable within the factors that precede it in the model, corrected for the factors that follow it. (See the section “[Computational Method](#)” on page 5245.)
- *F* Value for a factor, which is the ratio of its mean square to the appropriate error mean square. The next column, labeled *PR > F*, gives the significance levels that result from testing the hypothesis that each variance component equals zero.
- the appropriate Error Term for an *F* test, which is the mean square due to the next classification factor in the nesting order. (See the section “[Error Terms in F Tests](#)” on page 5244.)
- Mean Square due to a factor, which is the corresponding sum of squares divided by the degrees of freedom
- estimates of the Variance Components. These are computed by equating the mean squares to their expected values and solving for the variance terms. (See the section “[Computational Method](#)” on page 5245.)
- Percent of Total, the proportion of variance due to each source. For the *i*th factor, the value is

$$100 \times \frac{\text{source variance component}}{\text{total variance component}}$$

- Mean, the overall average of the dependent variable. This gives an unbiased estimate of the mean of the population. Its variance is estimated by a certain linear combination of the estimated variance components, which is identical to the mean square due to the first factor in the model divided by the total number of observations when the design is balanced.

If there is more than one dependent variable, then the NESTED procedure displays an “analysis of covariation” table for each pair of dependent variables (unless the AOV option is specified in the PROC NESTED statement). See the section “[Analysis of Covariation](#)” on page 5244 for details. For each source of variation, this table includes the following:

- Degrees of Freedom
- Sum of Products

- Mean Products
- Covariance Component, the estimate of the covariance component

Items in the analysis of covariation table are computed analogously to their counterparts in the analysis of variance table. The analysis of covariation table also includes the following:

- Variance Component Correlation for a given factor. This is an estimate of the correlation between corresponding effects due to this factor. This correlation is the ratio of the covariance component for this factor to the square root of the product of the variance components for the factor for the two different dependent variables. (See the section “[Analysis of Covariation](#)” on page 5244.)
- Mean Square Correlation for a given classification factor. This is the ratio of the Mean Products for this factor to the square root of the product of the Mean Squares for the factor for the two different dependent variables.

ODS Table Names

PROC NESTED assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 62.2 ODS Tables Produced by PROC NESTED

ODS Table Name	Description	Statement
ANCOVA	Analysis of covariance	default with more than one dependent variable
ANOVA	Analysis of variance	default
EMSCoef	Coefficients of expected mean squares	default
Statistics	Overall statistics for fit	default

Example: NESTED Procedure

Example 62.1: Variability of Calcium Concentration in Turnip Greens

In the following example from Snedecor and Cochran (1976), an experiment is conducted to study the variability of calcium concentration in turnip greens. Four plants are selected at random; then three leaves are randomly selected from each plant. Two 100-mg samples are taken from each leaf. The amount of calcium is determined by microchemical methods.

Because the data are read in sorted order, it is not necessary to use PROC SORT on the CLASS variables. Leaf is nested in Plant; Sample is nested in Leaf and is left for the residual term. All the effects are random effects. The following statements read the data and invoke PROC NESTED. These statements produce [Output 62.1.1](#).

```

title 'Calcium Concentration in Turnip Leaves--Nested Random Model';
title2 'Snedecor and Cochran, 'Statistical Methods', 1976, p. 286';
data Turnip;
  do Plant=1 to 4;
    do Leaf=1 to 3;
      do Sample=1 to 2;
        input Calcium @@;

Output 62.1.1 Analysis of Calcium Concentration in Turnip Greens Using PROC NESTED

Calcium Concentration in Turnip Leaves--Nested Random Model
Snedecor and Cochran, 'Statistical Methods', 1976, p. 286

The NESTED Procedure

Coefficients of Expected Mean Squares

Source	Plant	Leaf	Error
Plant	6	2	1
Leaf	0	2	1
Error	0	0	1

Output 62.1.1 *continued*

Nested Random Effects Analysis of Variance for Variable Calcium								
Variance Source	DF	Sum of Squares	F Value	Pr > F	Error Term	Mean Square	Variance Component	Percent of Total
Total	23	10.270396				0.446539	0.532938	100.0000
Plant	3	7.560346	7.67	0.0097	Leaf	2.520115	0.365223	68.5302
Leaf	8	2.630200	49.41	<.0001	Error	0.328775	0.161060	30.2212
Error	12	0.079850				0.006654	0.006654	1.2486
Calcium Mean						3.01208333		
Standard Error of Calcium Mean						0.32404445		

The results indicate that there is significant (nonzero) variation from plant to plant ($\text{Pr} > F$ is 0.0097) and from leaf to leaf within a plant ($\text{Pr} > F$ is less than 0.0001). Notice that the variance component for Plant uses the Leaf mean square as an error term in the model rather than the error mean square.

Overview: NLIN Procedure

The NLIN procedure fits nonlinear regression models and estimates the parameters by nonlinear least squares or weighted nonlinear least squares. You specify the model with programming statements. This gives you great flexibility in modeling the relationship between the response variable and independent (regressor) variables. It does, however, require additional coding compared to model specifications in linear modeling procedures such as the REG, GLM, and MIXED procedures.

Estimating parameters in a nonlinear model is an iterative process that commences from starting values. You need to declare the parameters in your model and supply their initial values for the NLIN procedure. You do not need to specify derivatives of the model equation with respect to the parameters. Although facilities for specifying first and second derivatives exist in the NLIN procedure, it is not recommended that you specify derivatives this way. Obtaining derivatives from user-specified expressions predates the high-quality automatic differentiator that is now used by the NLIN procedure.

Nonlinear least-squares estimation involves finding those values in the parameter space that minimize the (weighted) residual sum of squares. In a sense, this is a “distribution-free” estimation criterion since the distribution of the data does not need to be fully specified. Instead, the assumption of homoscedastic and uncorrelated model errors with zero mean is sufficient. You can relax the homoscedasticity assumption by using a weighted residual sum of squares criterion. The assumption of uncorrelated errors (independent observations) cannot be relaxed in the NLIN procedure. In summary, the primary assumptions for analyses with the NLIN procedure are as follows:

- The structure in the response variable can be decomposed additively into a mean function and an error component.
- The model errors are uncorrelated and have zero mean. Unless a weighted analysis is performed, the errors are also assumed to be homoscedastic (have equal variance).
- The mean function consists of known regressor (independent) variables and unknown constants (the parameters).

Fitting nonlinear models can be a difficult undertaking. There is no closed-form solution for the parameter estimates, and the process is iterative. There can be one or more local minima in the residual sum of squares surface, and the process depends on the starting values supplied by the user. You can reduce the dependence on the starting values and reduce the chance to arrive at a local minimum by specifying a grid of starting values. The NLIN procedure then computes the residual sum of squares at each point on the grid and starts the iterative process from the point that yields the lowest sum of squares. Even in this case, however, convergence does not guarantee that a global minimum has been found.

The numerical behavior of a model and a model–data combination can depend on the way in which you parameterize the model—for example, whether parameters are expressed on the logarithmic scale or not. Parameterization also has bearing on the interpretation of the estimated quantities and the statistical properties of the parameter estimators. Inferential procedures in nonlinear regression models are typically approximate in that they rely on the asymptotic properties of the parameter estimators that are obtained as the sample size grows without bound. Such asymptotic inference can be questionable in small samples, especially if the behavior of the parameter estimators is “far-from-linear.” Reparameterization of the model can yield parameters whose behavior is akin to that of estimators in linear models. These parameters exhibit close-to-linear behavior.

The NLIN procedure solves the nonlinear least squares problem by one of the following four algorithms (methods):

- steepest-descent or gradient method
- Newton method
- modified Gauss-Newton method
- Marquardt method

These methods use derivatives or approximations to derivatives of the SSE with respect to the parameters to guide the search for the parameters producing the smallest SSE. Derivatives computed automatically by the NLIN procedure are analytic, unless the model contains functions for which an analytic derivative is not available.

Using PROC NLIN, you can also do the following:

- confine the estimation procedure to a certain range of values of the parameters by imposing bounds on the estimates
- produce new SAS data sets containing predicted values, parameter estimates, residuals and other model diagnostics, estimates at each iteration, and so forth.

You can use the NLIN procedure for segmented models (see [Example 63.1](#)) or robust regression (see [Example 63.2](#)). You can also use it to compute maximum-likelihood estimates for certain models (see Jennrich and Moore 1975; Charnes, Frome, and Yu 1976). For maximum likelihood estimation in a model with a linear predictor and binomial error distribution, see the LOGISTIC, PROBIT, GENMOD, GLIMMIX, and CATMOD procedures. For a linear model with a Poisson, gamma, or inverse Gaussian error distribution, see the GENMOD and GLIMMIX procedures. For likelihood estimation in a linear model with a normal error distribution, see the MIXED, GENMOD, and GLIMMIX procedures. The PHREG and LIFEREG procedures fit survival models by maximum likelihood. For general maximum likelihood estimation, see the NLP procedure in the *SAS/OR User's Guide: Mathematical Programming* and the NLMIXED procedure. These procedures are recommended over the NLIN procedure for solving maximum likelihood problems.

PROC NLIN uses the Output Delivery System (ODS). ODS enables you to convert any of the output from PROC NLIN into a SAS data set. See the section “[ODS Table Names](#)” on page 5305 for a listing of the ODS tables that are produced by the NLIN procedure.

In addition, PROC NLIN can produce graphs when ODS Graphics is enabled. For more information, see the [PLOTS](#) option and the section “[ODS Graphics](#)” on page 5305 for a listing of the ODS graphs.

Getting Started: NLIN Procedure

Nonlinear or Linear Model

The NLIN procedure performs univariate nonlinear regression by using the least squares method. Nonlinear regression analysis is indicated when the functional relationship between the response variable and the predictor variables is nonlinear. Nonlinearity in this context refers to a nonlinear relationship in the *parameters*. Many linear regression models exhibit a relationship in the regressor (predictor) variables that is not simply a straight line. This does not make the models nonlinear. A model is nonlinear in the parameters if the derivative of the model with respect to a parameter depends on this or other parameters.

Consider, for example the models

$$E[Y|x] = \beta_0 + \beta_1 x$$

$$E[Y|x] = \beta_0 + \beta_1 x + \beta_2 x^2$$

$$E[Y|x] = \beta + x/\alpha$$

In these expressions, $E[Y|x]$ denotes the expected value of the response variable Y at the fixed value of x . (The conditioning on x simply indicates that the predictor variables are assumed to be non-random in models fit by the NLIN procedure. Conditioning is often omitted for brevity in this chapter.)

Only the third model is a nonlinear model. The first model is a simple linear regression. It is linear in the parameters β_0 and β_1 since the model derivatives do not depend on unknowns:

$$\frac{\partial}{\partial \beta_0} (\beta_0 + \beta_1 x) = 1$$

$$\frac{\partial}{\partial \beta_1} (\beta_0 + \beta_1 x) = x$$

The model is also linear in its relationship with x (a straight line). The second model is also linear in the parameters, since

$$\frac{\partial}{\partial \beta_0} (\beta_0 + \beta_1 x + \beta_2 x^2) = 1$$

$$\frac{\partial}{\partial \beta_1} (\beta_0 + \beta_1 x + \beta_2 x^2) = x$$

$$\frac{\partial}{\partial \beta_2} (\beta_0 + \beta_1 x + \beta_2 x^2) = x^2$$

It is a *curvilinear* model since it exhibits a curved relationship when plotted against x . The third model, finally, is a nonlinear model since

$$\frac{\partial}{\partial \beta} (\beta + x/\alpha) = 1$$

$$\frac{\partial}{\partial \alpha} (\beta + x/\alpha) = -\frac{x}{\alpha^2}$$

The second of these derivatives depends on a parameter α . A model is nonlinear if it is not linear in at least one parameter.

Notation for Nonlinear Regression Models

This section briefly introduces the basic notation for nonlinear regression models that applies in this chapter. Additional notation is introduced throughout as needed.

The $(n \times 1)$ vector of observed responses is denoted as \mathbf{y} . This vector is the realization of an $(n \times 1)$ random vector \mathbf{Y} . The NLIN procedure assumes that the variance matrix of this random vector is $\sigma^2 \mathbf{I}$. In other words, the observations have equal variance (are homoscedastic) and are uncorrelated. By defining the special variable `_WEIGHT_` in your NLIN programming statements, you can introduce heterogeneous variances. If a `_WEIGHT_` variable is present, then $\text{Var}[\mathbf{Y}] = \sigma^2 \mathbf{W}^{-1}$, where \mathbf{W} is a diagonal matrix containing the values of the `_WEIGHT_` variable.

The mean of the random vector is represented by a nonlinear model that depends on parameters β_1, \dots, β_p and regressor (independent) variables z_1, \dots, z_k :

$$E[Y_i] = f(\beta_1, \beta_2, \dots, \beta_p; z_{i1}, \dots, z_{ik})$$

In contrast to linear models, the number of regressor variables (k) does not necessarily equal the number of parameters (p) in the mean function $f(\cdot)$. For example, the model fitted in the next subsection contains a single regressor and two parameters.

To represent the mean of the vector of observations, boldface notation is used in an obvious extension of the previous equation:

$$E[\mathbf{Y}] = \mathbf{f}(\boldsymbol{\beta}; \mathbf{z}_1, \dots, \mathbf{z}_k)$$

The vector \mathbf{z}_1 , for example, is an $(n \times 1)$ vector of the values for the first regressor variables. The explicit dependence of the mean function on $\boldsymbol{\beta}$ and/or the \mathbf{z} vectors is often omitted for brevity.

In summary, the stochastic structure of models fit with the NLIN procedure is mathematically captured by

$$\begin{aligned} \mathbf{Y} &= \mathbf{f}(\boldsymbol{\beta}; \mathbf{z}_1, \dots, \mathbf{z}_k) + \boldsymbol{\epsilon} \\ E[\boldsymbol{\epsilon}] &= \mathbf{0} \\ \text{Var}[\boldsymbol{\epsilon}] &= \sigma^2 \mathbf{I} \end{aligned}$$

Note that the residual variance σ^2 is typically also unknown. Since it is not estimated in the same fashion as the other p parameters, it is often not counted in the number of parameters of the nonlinear regression. An estimate of σ^2 is obtained after the model fit by the method of moments based on the residual sum of squares.

A matrix that plays an important role in fitting nonlinear regression models is the $(n \times p)$ matrix of the first partial derivatives of the mean function \mathbf{f} with respect to the p model parameters. It is frequently denoted as

$$\mathbf{X} = \frac{\partial \mathbf{f}(\boldsymbol{\beta}; \mathbf{z}_1, \dots, \mathbf{z}_k)}{\partial \boldsymbol{\beta}}$$

The use of the symbol \mathbf{X} —common in linear statistical modeling—is no accident here. The first derivative matrix plays a similar role in nonlinear regression to that of the \mathbf{X} matrix in a linear model. For example, the

asymptotic variance of the nonlinear least-squares estimators is proportional to $(\mathbf{X}'\mathbf{X})^{-1}$, and projection-type matrices in nonlinear regressions are based on $\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'$. Also, fitting a nonlinear regression model can be cast as an iterative process where a nonlinear model is approximated by a series of linear models in which the derivative matrix is the regressor matrix. An important difference between linear and nonlinear models is that the derivatives in a linear model do not depend on any parameters (see previous subsection). In contrast, the derivative matrix $\partial \mathbf{f}(\boldsymbol{\beta})/\partial \boldsymbol{\beta}$ is a function of at least one element of $\boldsymbol{\beta}$. It is this dependence that lies at the core of the fact that estimating the parameters in a nonlinear model cannot be accomplished in closed form, but it is an iterative process that commences with user-supplied starting values and attempts to continually improve on the parameter estimates.

Estimating the Parameters in the Nonlinear Model

As an example of a nonlinear regression analysis, consider the following theoretical model of enzyme kinetics. The model relates the initial velocity of an enzymatic reaction to the substrate concentration.

$$f(\mathbf{x}, \boldsymbol{\theta}) = \frac{\theta_1 x_i}{\theta_2 + x_i}, \quad \text{for } i = 1, 2, \dots, n$$

where x_i represents the amount of substrate for n trials and $f(\mathbf{x}, \boldsymbol{\theta})$ is the velocity of the reaction. The vector $\boldsymbol{\theta}$ contains the rate parameters. This model is known as the Michaelis-Menten model in biochemistry (Ratkowsky 1990, p. 59). The model exists in many parameterizations. In the form shown here, θ_1 is the maximum velocity of the reaction that is theoretically attainable. The parameter θ_2 is the substrate concentration at which the velocity is 50% of the maximum.

Suppose that you want to study the relationship between concentration and velocity for a particular enzyme/substrate pair. You record the reaction rate (velocity) observed at different substrate concentrations.

A SAS data set is created for this experiment in the following DATA step:

```
data Enzyme;
  input Concentration Velocity @@;
  datalines;
0.26 124.7    0.30 126.9
0.48 135.9    0.50 137.6
0.54 139.6    0.68 141.1
0.82 142.8    1.14 147.6
1.28 149.8    1.38 149.4
1.80 153.9    2.30 152.5
2.44 154.5    2.48 154.7
;
```

The SAS data set Enzyme contains the two variables Concentration (substrate concentration) and Velocity (reaction rate). The following statements fit the Michaelis-Menten model by nonlinear least squares:

```
proc nlin data=Enzyme method=marquardt hougard;
  parms theta1=155
        theta2=0 to 0.07 by 0.01;
  model Velocity = theta1*Concentration / (theta2 + Concentration);
run;
```

The **DATA=** option specifies that the SAS data set *Enzyme* be used in the analysis. The **METHOD=** option directs PROC NLIN to use the MARQUARDT iterative method. The **HOUGAARD** option requests that a skewness measure be calculated for the parameters.

The **PARMS** statement declares the parameters and specifies their initial values. Suppose that V represents the velocity and C represents the substrate concentration. In this example, the initial estimates listed in the **PARMS** statement for θ_1 and θ_2 are obtained as follows:

θ_1 : Because the model is a monotonic increasing function in C , and because

$$\lim_{C \rightarrow \infty} \left(\frac{\theta_1 C}{\theta_2 + C} \right) = \theta_1$$

you can take the largest observed value of the variable *Velocity* (154.7) as the initial value for the parameter *Theta1*. Thus, the **PARMS** statement specifies 155 as the initial value for *Theta1*, which is approximately equal to the maximum observed velocity.

θ_2 : To obtain an initial value for the parameter θ_2 , first rearrange the model equation to solve for θ_2 :

$$\theta_2 = \frac{\theta_1 C}{V} - C$$

By substituting the initial value of *Theta1* for θ_1 and taking each pair of observed values of *Concentration* and *Velocity* for C and V , respectively, you obtain a set of possible starting values for *Theta2* ranging from about 0.01 to 0.07.

You can choose any value within this range as a starting value for *Theta2*, or you can direct PROC NLIN to perform a preliminary search for the best initial *Theta2* value within that range of values. The **PARMS** statement specifies a range of values for *Theta2*, resulting in a search over the grid points from 0 to 0.07 in increments of 0.01.

The **MODEL** statement specifies the enzymatic reaction model

$$V = \frac{\theta_1 C}{\theta_2 + C}$$

in terms of the data set variables *Velocity* and *Concentration* and in terms of the parameters in the **PARMS** statement.

The results from this PROC NLIN invocation are displayed in the following figures.

PROC NLIN evaluates the model at each point on the specified grid for the *Theta2* parameter. [Figure 63.1](#) displays the calculations resulting from the grid search.

Figure 63.1 Nonlinear Least-Squares Grid Search

The NLIN Procedure		
Dependent Variable Velocity		
Grid Search		
theta1	theta2	Sum of Squares
155.0	0	3075.4
155.0	0.0100	2074.1
155.0	0.0200	1310.3
155.0	0.0300	752.0
155.0	0.0400	371.9
155.0	0.0500	147.2
155.0	0.0600	58.1130
155.0	0.0700	87.9662

The parameter Theta1 is held constant at its specified initial value of 155, the grid is traversed, and the residual sum of squares is computed at each point. The “best” starting value is the point that corresponds to the smallest value of the residual sum of squares. The best set of starting values is obtained for $\theta_1 = 155$, $\theta_2 = 0.06$ (Figure 63.1). PROC NLIN uses this point from which to start the following, iterative phase of nonlinear least-squares estimation.

Figure 63.2 displays the iteration history. Note that the first entry in the “Iterative Phase” table echoes the starting values and the residual sum of squares for the best value combination in Figure 63.1. The subsequent rows of the table show the updates of the parameter estimates and the improvement (decrease) in the residual sum of squares. For this data-and-model combination, the first iteration yielded a large improvement in the sum of squares (from 58.113 to 19.7017). Further steps were necessary to improve the estimates in order to achieve the convergence criterion. The NLIN procedure by default determines convergence by using R , the relative offset measure of Bates and Watts (1981). Convergence is declared when this measure is less than 10^{-5} —in this example, after three iterations.

Figure 63.2 Iteration History and Convergence Status

The NLIN Procedure			
Dependent Variable Velocity			
Method: Marquardt			
Iterative Phase			
Iter	theta1	theta2	Sum of Squares
0	155.0	0.0600	58.1130
1	158.0	0.0736	19.7017
2	158.1	0.0741	19.6606
3	158.1	0.0741	19.6606

NOTE: Convergence criterion met.

Figure 63.3 Estimation Summary

Estimation Summary	
Method	Marquardt
Iterations	3
R	5.861E-6
PPC(theta2)	8.569E-7
RPC(theta2)	0.000078
Object	2.902E-7
Objective	19.66059
Observations Read	14
Observations Used	14
Observations Missing	0

A summary of the estimation including several convergence measures (R, PPC, RPC, and Object) is displayed in [Figure 63.3](#).

The “R” measure in [Figure 63.3](#) is the relative offset convergence measure of Bates and Watts. A “PPC” value of 8.569E-7 indicates that the parameter Theta2 (which has the largest PPC value of the parameters) would change by that relative amount, if PROC NLIN were to take an additional iteration step. The “RPC” value indicates that Theta2 changed by 0.000078, relative to its value in the last iteration. These changes are measured before step length adjustments are made. The “Object” measure indicates that the objective function changed by 2.902E-7 in relative value from the last iteration.

[Figure 63.4](#) displays the analysis of variance table for the model. The table displays the degrees of freedom, sums of squares, and mean squares along with the model F test.

Figure 63.4 Nonlinear Least-Squares Analysis of Variance

NOTE: An intercept was not specified for this model.					
Source	DF	Sum of Squares	Mean Square	F Value	Approx Pr > F
Model	2	290116	145058	88537.2	<.0001
Error	12	19.6606	1.6384		
Uncorrected Total	14	290135			

Figure 63.5 Parameter Estimates and Approximate 95% Confidence Intervals

Parameter	Estimate	Approx Std Error	Approximate 95% Confidence Limits		Skewness
theta1	158.1	0.6737	156.6	159.6	0.0152
theta2	0.0741	0.00313	0.0673	0.0809	0.0362

[Figure 63.5](#) displays the estimates for each parameter, the associated asymptotic standard error, and the upper and lower values for the asymptotic 95% confidence interval. PROC NLIN also displays the asymptotic

correlations between the estimated parameters (not shown).

The skewness measures of 0.0152 and 0.0362 indicate that the parameter estimators exhibit close-to-linear behavior and that their standard errors and confidence intervals can be safely used for inferences.

Thus, the estimated nonlinear model relating reaction velocity and substrate concentration can be written as

$$\hat{V} = \frac{158.1C}{0.0741 + C}$$

where \hat{V} represents the predicted velocity or rate of the reaction, and C represents the substrate concentration.

PARAMETERS < parameter-specification > < , ... , parameter-specification >
    < / PDATA=SAS-data-set > ;
PROFILE parameter < ... parameter > < / options > ;
RETAIN variable < =values > < ... variable < =values > > ;
Programming statements ;
```

The statements in the NLIN procedure, in addition to the **PROC NLIN** statement, are as follows:

BOUNDS	constrains the parameter estimates within specified bounds
BY	specifies variables to define subgroups for the analysis
DER	specifies the first or second partial derivatives
ID	specifies additional variables to add to the output data set
MODEL	defines the relationship between the dependent and independent variables (the mean function)
OUTPUT	creates an output data set containing observation-wise statistics
PARAMETERS	identifies parameters to be estimated and their starting values
PROFILE	identifies parameters to be profiled
<i>Programming Statements</i>	includes assignment statements, ARRAY statements, DO loops, and other program control statements. These are valid SAS expressions that can appear in

the DATA step. PROC NLIN enables you to create new variables within the procedure and use them in the nonlinear analysis. These programming statements can appear anywhere in the PROC NLIN code, but new variables must be created before they appear in other statements. The NLIN procedure automatically creates several variables that are also available for use in the analysis. See the section “[Special Variables](#)” on page 5291 for more information.

The PROC NLIN, PARAMETERS, and MODEL statements are required.

PROC NLIN Statement

PROC NLIN < options > ;

The PROC NLIN statement invokes the NLIN procedure.

Table 63.1 summarizes the options available in the PROC NLIN statement. All options are subsequently discussed in alphabetical order.

Table 63.1 Summary of Options in PROC NLIN Statement

Option	Description
Options Related to Data Sets	
DATA=	Specifies the input data set
OUTEST=	Specifies the output data set for parameter estimates, covariance matrix, and so on
SAVE	Requests that final estimates be added to the OUTEST= data set
Optimization Options	
BEST=	Limits display of grid search
METHOD=	Chooses the optimization method
MAXITER=	Specifies the maximum number of iterations
MAXSUBIT=	Specifies the maximum number of step halvings
NOHALVE	Allows the objective function to increase between iterations
RHO=	Controls the step-size search
SMETHOD=	Specifies the step-size search method
TAU=	Controls the step-size search
G4	Uses the Moore-Penrose inverse
UNCORRECTEDDF	Does not expense degrees of freedom when bounds are active
SIGSQ=	Specifies the fixed value for residual variance
Singularity and Convergence Criteria	
CONVERGE=	Tunes the convergence criterion
CONVERGEOBJ=	Uses the change in loss function as the convergence criterion and tunes its value
CONVERGEPARM=	Uses the maximum change in parameter estimates as the convergence criterion and tunes its value
SINGULAR=	Tunes the singularity criterion used in matrix inversions

Table 63.1 *continued*

Option	Description
ODS Graphics Options	
PLOTS=	Produces ODS graphical displays
Displayed Output	
HOUGAARD	Adds Hougaard's skewness measure to the "Parameter Estimates" table
BIAS	Adds Box's bias measure to the "Parameter Estimates" table
NOITPRINT	Suppresses the "Iteration History" table
NOPRINT	Suppresses displayed output
LIST	Displays the model program and variable list
LISTALL	Selects the LIST , LISTDEP , LISTDER , and LISTCODE options
LISTCODE	Displays the model program code
LISTDEP	Displays dependencies of model variables
LISTDER	Displays the derivative table
NLINMEASURES	Displays the global nonlinearity measures table
TOTALSS	Adds the uncorrected or corrected total sum of squares to the analysis of variance table
XREF	Displays the cross-reference of variables
Trace Model Execution	
FLOW	Displays execution messages for program statements
PRINT	Displays results of statements in model program
TRACE	Displays results of operations in model program

ALPHA= α

specifies the level of significance α used in the construction of $100(1 - \alpha)\%$ confidence intervals. The value must be strictly between 0 and 1; the default value of $\alpha = 0.05$ results in 95% intervals. This value is used as the default confidence level for limits computed in the "Parameter Estimates" table and with the **LCLM**, **LCL**, **UCLM**, and **UCL** options in the **OUTPUT** statement.

BEST= n

requests that PROC NLIN display the residual sums of squares only for the best n combinations of possible starting values from the grid. If you do not specify the **BEST=** option, PROC NLIN displays the residual sum of squares for every combination of possible parameter starting values.

BIAS

adds Box's bias and percentage bias measures to the "Parameter Estimates" table (Box 1971). Box's bias measure, along with Hougaard's measure of skewness, is used for assessing a parameter estimator's close-to-linear behavior (Ratkowsky 1983, 1990). Hence, it is useful for identifying problematic parameters (Seber and Wild 1989, sec. 4.7.1). When you specify the **BIAS** option, Box's bias measure (Box 1971) and the percentage bias (the bias expressed as a percentage of the least-squares estimator) are added for each parameter to the "Parameter Estimates" table. Ratkowsky (1983, p. 21) takes a percentage bias in excess of 1% to be a good rule of thumb for indicating nonlinear behavior.

See the section "Box's Measure of Bias" on page 5286 for further details. [Example 63.4](#) shows how to use this measure, along with Hougaard's measure of skewness, to evaluate changes in the

parameterization of a nonlinear model. Computation of the Box's bias measure requires first and second derivatives. If you do not provide derivatives with the **DER** statement—and it is recommended that you do not—the analytic derivatives are computed for you.

CONVERGE=c

specifies the convergence criterion for PROC NLIN. For all iterative methods the relative offset convergence measure of Bates and Watts is used by default to determine convergence. This measure is labeled “R” in the “Estimation Summary” table. The iterations are said to have converged for **CONVERGE=c** if

$$\sqrt{\frac{\mathbf{r}'\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{r}}{\text{LOSS}^{(i)}}} < c$$

where \mathbf{r} is the residual vector and \mathbf{X} is the $(n \times p)$ matrix of first derivatives with respect to the parameters. The default LOSS function is the sum of squared errors (SSE), and $\text{LOSS}^{(i)}$ denotes the value of the loss function at the i th iteration. By default, **CONVERGE**= 10^{-5} . The R convergence measure cannot be computed accurately in the special case of a perfect fit (residuals close to zero). When the SSE is less than the value of the **SINGULAR=** criterion, convergence is assumed.

CONVERGEOBJ=c

uses the change in the LOSS function as the convergence criterion and tunes the criterion. The iterations are said to have converged for **CONVERGEOBJ=c** if

$$\frac{|\text{LOSS}^{(i-1)} - \text{LOSS}^{(i)}|}{|\text{LOSS}^{(i-1)} + 10^{-6}|} < c$$

where $\text{LOSS}^{(i)}$ is the LOSS for the i th iteration. The default LOSS function is the sum of squared errors (SSE), the residual sum of squares. The constant c should be a small positive number. For more details about the LOSS function, see the section “[Special Variable Used to Determine Convergence Criteria](#)” on page 5292. For more details about the computational methods in the NIN procedure, see the section “[Computational Methods](#)” on page 5294.

Note that in SAS 6 the **CONVERGE=** and **CONVERGEOBJ=** options both requested that convergence be tracked by the relative change in the loss function. If you specify the **CONVERGEOBJ=** option in newer releases, the **CONVERGE=** option is disabled. This enables you to track convergence as in SAS 6.

CONVERGEPARM=c

uses the maximum change among parameter estimates as the convergence criterion and tunes the criterion. The iterations are said to have converged for **CONVERGEPARM=c** if

$$\max_j \left(\frac{|\beta_j^{(i-1)} - \beta_j^{(i)}|}{|\beta_j^{(i-1)}|} \right) < c$$

where $\beta_j^{(i)}$ is the value of the j th parameter at the i th iteration.

The default convergence criterion is **CONVERGE**. If you specify **CONVERGEPARM=c**, the maximum change in parameters is used as the convergence criterion. If you specify both the **CONVERGEOBJ=** and **CONVERGEPARM=** options, PROC NLIN continues to iterate until the decrease in LOSS is sufficiently small (as determined by the **CONVERGEOBJ=** option) and the maximum change among the parameters is sufficiently small (as determined by the **CONVERGEPARM=** option).

DATA=SAS-data-set

specifies the input SAS data set to be analyzed by PROC NLIN. If you omit the DATA= option, the most recently created SAS data set is used.

FLOW

displays a message for each statement in the model program as it is executed. This debugging option is rarely needed, and it produces large amounts of output.

G4

uses a Moore-Penrose inverse (g_4 -inverse) in parameter estimation. See Kennedy and Gentle (1980) for details.

HOUGAARD

adds Hougaard's measure of skewness to the "Parameter Estimates" table (Hougaard 1982, 1985). The skewness measure is one method of assessing a parameter estimator's close-to-linear behavior in the sense of Ratkowsky (1983, 1990). The behavior of estimators that are close to linear approaches that of least squares estimators in linear models, which are unbiased and have minimum variance. When you specify the HOUGAARD option, the standardized skewness measure of Hougaard (1985) is added for each parameter to the "Parameter Estimates" table. Because of the linkage between nonlinear behavior of a parameter estimator in nonlinear regression and the nonnormality of the estimator's sampling distribution, Ratkowsky (1990, p. 28) provides the following rules to interpret the (standardized) Hougaard skewness measure:

- Values less than 0.1 in absolute value indicate very close-to-linear behavior.
- Values between 0.1 and 0.25 in absolute value indicate reasonably close-to-linear behavior.
- The nonlinear behavior is apparent for absolute values above 0.25 and is considerable for absolute values above 1.

See the section "[Hougaard's Measure of Skewness](#)" on page 5286 for further details. [Example 63.4](#) shows how to use this measure to evaluate changes in the parameterization of a nonlinear model. Computation of the Hougaard skewness measure requires first and second derivatives. If you do not provide derivatives with the [DER](#) statement—and it is recommended that you do not—the analytic derivatives are computed for you.

LIST

displays the model program and variable lists, including the statements added by macros. Note that the expressions displayed by the LIST option do not necessarily represent the way the expression is actually calculated—because intermediate results for common subexpressions can be reused—but are shown in expanded form. To see how the expression is actually evaluated, use the [LISTCODE](#) option.

LISTALL

selects the [LIST](#), [LISTDEP](#), [LISTDER](#), and [LISTCODE](#) options.

LISTCODE

displays the derivative tables and the compiled model program code. The LISTCODE option is a debugging feature and is not normally needed.

LISTDEP

produces a report that lists, for each variable in the model program, the variables that depend on it and the variables on which it depends.

LISTDER

displays a table of derivatives. The derivatives table lists each nonzero derivative computed for the problem. The derivative listed can be a constant, a variable in the model program, or a special derivative variable created to hold the result of an expression.

MAXITER=*n*

specifies the maximum number *n* of iterations in the optimization process. The default is *n* = 100.

MAXSUBIT=*n*

places a limit on the number of step halvings. The value of MAXSUBIT must be a positive integer and the default value is *n* = 30.

METHOD=GAUSS**METHOD=MARQUARDT****METHOD=NEWTON****METHOD=GRADIENT**

specifies the iterative method employed by the NLIN procedure in solving the nonlinear least squares problem. The GAUSS, MARQUARDT, and NEWTON methods are more robust than the GRADIENT method. If you omit the METHOD= option, METHOD=GAUSS is used. See the section “[Computational Methods](#)” on page 5294 for more information.

NLINMEASURES

displays the global nonlinearity measures table. These measures include the maximum intrinsic and parameter-effects curvatures (Bates and Watts 1980), the root mean square (RMS) intrinsic and parameter-effects curvatures and the critical curvature value (Bates and Watts 1980). In addition, the variances of the ordinary and projected residuals are included. According to Bates and Watts (1980), both intrinsic and parameter-effects curvatures are deemed negligible if they are less than the critical curvature value. This critical value is given by $1/(\sqrt{F})$ where $F = F(p, n - p; \alpha)$. The value $1/\sqrt{F}$ can be considered as the radius of curvature of the 100(1 - α) percent confidence region (Bates and Watts 1980).

NOITPRINT

suppresses the display of the “Iteration History” table.

NOHALVE

removes the restriction that the objective value must decrease at every iteration. Step halving is still used to satisfy [BOUNDS](#) and to ensure that the number of observations that can be evaluated does not decrease. The NOHALVE option can be useful in weighted nonlinear least squares problems where the weights depend on the parameters, such as in iteratively reweighted least squares (IRLS) fitting. See [Example 63.2](#) for an application of IRLS fitting.

NOPRINT

suppresses the display of the output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, “[Using the Output Delivery System](#).”

OUTEST=SAS-data-set

specifies an output data set that contains the parameter estimates produced at each iteration. See the section “[Output Data Sets](#)” for details. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

PLOTS <(global-plot-option)> <= (plot-request <(options)> <... plot-request <(options)> >)>

controls most of the plots that are produced through ODS Graphics (other plots are controlled by the [PROFILE](#) statement). When you specify only one *plot-request*, you can omit the parentheses around it. Here are some examples:

```
plots
plots          = none
plots          = diagnostics(unpack)
plots          = fit(stats=none)
plots          = residuals(residualtype=proj unpack smooth)
plots(stats=all) = (diagnostics(stats=(maxincurv maxpecurv)) fit)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc nlin plots=diagnostics(stats=all);
  model y = alpha - beta*(gamma**x);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled and if you specify the PLOTS option without any *global-plot-option* or *plot-requests*, PROC NLIN produces the plots listed in [Table 63.2](#) with the default set of statistics and options. If you do not specify the PLOTS option, PROC NLIN does not produce any of these graphs.

Table 63.2 Graphs Produced When the PLOTS Option Is Specified

Plot	Conditional On
ContourFitPlot	Model with two regressors
FitDiagnosticsPanel	Unconditional
FitPlot	Model with one regressor
LeveragePlot	Unconditional
LocalInfluencePlot	Unconditional
ResidualPanel	Unconditional

You can request additional plots by specifying *plot-requests*. For a listing of all the plots that PROC NLIN produces, see the section “[ODS Graphics](#)” on page 5305. Each *global-plot-option* applies to all plots that are generated by the NLIN procedure except for plots that are controlled by the **PROFILE** statement. The *global-plot-option* can be overridden by a specific *option* after a *plot-request*.

The following *global-plot-options* are available:

RESIDUALTYPE=RAW | PROJ | BOTH

specifies the residual type to be plotted in the fit diagnostics and residual plots. RESIDUALTYPE=RAW requests that only the ordinary residuals be included in the plots; RESIDUALTYPE=PROJ sets the choice to projected residuals. By default, both residual types are included, which can also be effected by setting RESIDUALTYPE=BOTH. See the section “[Residuals in Nonlinear Regression](#)” on page 5289 for details about the properties of ordinary and projected residuals in nonlinear regression.

STATS=ALL | DEFAULT | NONE | (*plot-statistics*)

requests the statistics to be included in all plots, except the ResidualPlots and the unpacked diagnostics plots. [Table 63.3](#) lists the statistics that you can request. STATS=ALL requests all these statistics, STATS=NONE suppresses all statistics, and STATS=DEFAULT selects the default statistics. You request statistics in addition to the default set by including the keyword DEFAULT in the *plot-statistics* list.

Table 63.3 Statistics Available in Plots

Keyword	Default	Description
DEFAULT		All default statistics
MAXINCURV		Maximum intrinsic curvature
MAXPECURV		Maximum parameter-effects curvature
MSE	x	Mean squared error, estimated or set by the SIGSQ option
NOBS	x	Number of observations used
NPARM	x	Number of parameters in the model
PVAR	x	Estimated variance of the projected residuals
RMSNINCURV		Root mean square intrinsic curvature
RMSPECURV		Root mean square parameter-effects curvature
VAR	x	Estimated variance of the ordinary residuals

Along with the maximum intrinsic and parameter-effects curvatures, the critical curvature (CURVCRIT) value, $1/\sqrt{F}$ where $F = F(p, n - p; \alpha)$, is also displayed. You do not need to specify any option for it. See the section “[Relative Curvature Measures of Nonlinearity](#)” on page 5287 for details about curvature measures of nonlinearity.

UNPACK

suppresses paneling.

You can specify the following *plot-requests* in the PLOTS= option:

ALL

produces all appropriate plots.

NONE

suppresses all plots.

DIAGNOSTICS < (*diagnostics-options*) >

produces a summary panel of fit diagnostics, leverage plots, and local-influence plots. The fit diagnostics panel includes:

- histogram of the ordinary residuals
- histogram of the projected residuals
- response variable values versus the predicted values
- expectation or mean of the ordinary residuals versus the predicted values
- ordinary and projected residuals versus the predicted values
- standardized ordinary and projected residuals versus the predicted values
- standardized ordinary and projected residuals versus the tangential leverage
- standardized ordinary and projected residuals versus the Jacobian leverage
- box plot of the ordinary and projected residuals if you specify the STATS=NONE suboption

The leverage and local influence plots are produced separately. The leverage plot is an index plot of the tangential and Jacobian leverages (by observation), and the local-influence plot contains the local influence by observation for a perturbation of the response variable. See the sections “[Leverage in Nonlinear Regression](#)” on page 5288 and “[Local Influence in Nonlinear Regression](#)” on page 5288 for some details about leverages and local-influence in nonlinear regression.

You can specify the following *diagnostics-options*:

RESIDUALTYPE=RAW | PROJ | BOTH

specifies the residual type to be plotted in the panel. See the RESIDUALTYPE= *global-plot-option* for details. This *diagnostics-option* overrides the PLOTS RESIDUALTYPE *global-plot-option*. Only the plots that overlay both ordinary and projected residuals in the same plot are affected by this option.

LEVERAGETYPE=TAN | JAC | BOTH

specifies the leverage type to be plotted in the leverage plot. LEVERAGETYPE=TAN specifies that only the tangential leverage be included in the leverage plot, and LEVERAGETYPE=JAC specifies that only the Jacobian leverage be included. By default, both are displayed in the leverage plot. The same result can be effected by setting LEVERAGETYPE=BOTH. Only the leverage plot is affected by this option.

LABELOBS

specifies that the leverage and local-influence plots be labeled with the observation number. Only these two plots are affected by this option.

STATS=stats-options

determines which statistics are included in the panel. See the `STATS= global-plot-option` for details. This *diagnostics-option* overrides the `PLOTS STATS global-plot-option`.

UNPACK

produces the plots in the diagnostics panel as individual plots. The statistics panel is not included in the individual plots, even if `STATS= global-plot-option` or `STATS= diagnostics-option` or both are specified.

FITPLOT | FIT <(fit-options)>

produces, depending on the number of regressors, a scatter or contour fit plot. For a single-regressor model, a scatter plot of the data overlaid with the regression curve, confidence, and prediction bands is produced. For two-regressor models, a contour fit plot of the model with overlaid data is produced. If the model contains more than two regressors, no fit plot is produced.

You can specify the following *fit-options*:

NOCLI

suppresses the prediction limits for single-regressor models.

NOCLM

suppresses the confidence limits for single-regressor models.

NOLIMITS

suppresses the confidence and prediction limits for single-regressor models.

OBS=GRADIENT | NONE | OUTLINE | OUTLINEGRADIENT

controls how the observations are displayed. The suboptions are as follows:

`OBS=GRADIENT` specifies that observations be displayed as circles colored by the observed response. The same color gradient is used to display the fitted surface and the observations. Observations for which the predicted response is close to the observed response have similar colors—the greater the contrast between the color of an observation and the surface, the larger the residual is at that point. `OBS=GRADIENT` is the default.

`OBS=NONE` suppresses the observations.

`OBS=OUTLINE` specifies that observations be displayed as circles with a border but with a completely transparent fill.

`OBS=OUTLINEGRADIENT` is the same as `OBS=GRADIENT` except that a border is shown around each observation. This option is useful for identifying the location observations for which the residuals are small, because at these points the color of the observations and the color of the surface are indistinguishable.

CONTLEG

specifies that a continuous legend be included in the contour fit plot of a two-regressor model.

STATS=stats-options

determines which model fit statistics are included in the panel. See the **STATS= global-plot-option** for details. This *fit-option* overrides the **PLOTS STATS global-plot-option**.

RESIDUALS < residual-options >

produces panels of the ordinary and projected residuals versus the regressors in the model. Each panel contains at most six plots, and multiple panels are used in the case where there are more than six regressors in the model.

The following *residual-options* are available:

RESIDUALTYPE=RAW | PROJ | BOTH

specifies the residual type to be plotted in the panel. See the **RESIDUALTYPE= global-plot-option** for details. This *residual-option* overrides the **PLOTS RESIDUALTYPE global-plot-option**.

SMOOTH

requests a nonparametric smooth of the residuals for each regressor. Each nonparametric fit is a loess fit that uses local linear polynomials, linear interpolation, and a smoothing parameter selected that yields a local minimum of the corrected Akaike information criterion (AICC). See Chapter 53, “[The LOESS Procedure](#),” for details.

UNPACK

suppresses paneling.

PRINT

displays the result of each statement in the program as it is executed. This option is a debugging feature that produces large amounts of output and is normally not needed.

RHO=value

specifies a value that controls the step-size search. By default **RHO=0.1**, except when **METHOD=MARQUARDT**. In that case, **RHO=10**. See the section “[Step-Size Search](#)” on page 5299 for more details.

SAVE

specifies that, when the iteration limit is exceeded, the parameter estimates from the final iteration be output to the **OUTEST=** data set. These parameter estimates are associated with the observation for which **_TYPE_** = “FINAL”. If you omit the **SAVE** option, the parameter estimates from the final iteration are not output to the data set unless convergence has been attained.

SIGSQ=value

specifies a value to use as the estimate of the residual variance in lieu of the estimated mean-squared error. This value is used in computing the standard errors of the estimates. Fixing the value of the residual variance can be useful, for example, in maximum likelihood estimation.

SINGULAR=s

specifies the singularity criterion, **s**, which is the absolute magnitude of the smallest pivot value allowed when inverting the Hessian or the approximation to the Hessian. The default value is 1E4 times the machine epsilon; this product is approximately 1E-12 on most computers.

SMETHOD=HALVE

SMETHOD=GOLDEN

SMETHOD=CUBIC

specifies the step-size search method. The default is **SMETHOD=HALVE**. See the section “[Step-Size Search](#)” on page 5299 for details.

TAU=value

specifies a value that is used to control the step-size search. The default is **TAU=1**, except when **METHOD=MARQUARDT**. In that case the default is **TAU=0.01**. See the section “[Step-Size Search](#)” on page 5299 for details.

TOTALSS

adds to the analysis of variance table the uncorrected total sum of squares in models that have an (implied) intercept, and adds the corrected total sum of squares in models that do not have an (implied) intercept.

TRACE

displays the result of each operation in each statement in the model program as it is executed, in addition to the information displayed by the **FLOW** and **PRINT** options. This debugging option is needed very rarely, and it produces even more output than the **FLOW** and **PRINT** options.

XREF

displays a cross-reference of the variables in the model program showing where each variable is referenced or given a value. The XREF listing does not include derivative variables.

UNCORRECTEDDF

specifies that no degrees of freedom be lost when a bound is active. When the **UNCORRECTEDDF** option is not specified, an active bound is treated as if a restriction were applied to the set of parameters, so one parameter degree of freedom is deducted.

BOUNDS Statement

BOUNDS *inequality* < , ... , *inequality* > ;

The **BOUNDS** statement restricts the parameter estimates so that they lie within specified regions. In each **BOUNDS** statement, you can specify a series of boundary values separated by commas. The series of bounds is applied simultaneously. Each boundary specification consists of a list of parameters, an inequality comparison operator, and a value. In a single-bounded expression, these three elements follow one another in the order described. The following are examples of valid single-bounded expressions:

```
bounds a1-a10 <= 20;
bounds c > 30;
bounds a b c > 0;
```

Multiple-bounded expressions are also permitted. For example:

```
bounds 0 <= B<= 10;
bounds 15 < x1 <= 30;
bounds r <= s <= p < q;
```

If you need to restrict an expression involving several parameters (for example, $\alpha + \beta < 1$), you can reparameterize the model so that the expression becomes a parameter or so that the boundary constraint can be expressed as a simple relationship between two parameters. For example, the boundary constraint $\alpha + \beta < 1$ in the model

```
model y = alpha + beta*x;
```

can be achieved by parameterizing $\theta = 1 - \beta$ as follows:

```
bounds alpha < theta;
model y = alpha + (1-theta)*x;
```

Starting with SAS 7.01, Lagrange multipliers are reported for all bounds that are enforced (active) when the estimation terminates. In the “Parameter Estimates” table, the Lagrange multiplier estimates are identified with names *Bound1*, *Bound2*, and so forth. An active bound is treated as if a restriction were applied to the set of parameters so that one parameter degree of freedom is deducted. You can use the [UNCORRECTEDDF](#) option to prevent the loss of degrees of freedom when bounds are active.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC NLIN to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the NLIN procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CONTROL Statement

CONTROL *variable* <=*values*> <... *variable* <=*values*>> ;

The CONTROL statement declares control variables and specifies their values. A control variable is like a retained variable (see the section “[RETAIN Statement](#)” on page 5282) except that it is retained *across* iterations, and the derivative of the model with respect to a control variable is always zero.

DER Statement

DER. *parameter=expression ;*

DER. *parameter.parameter=expression ;*

The DER statement specifies first or second partial derivatives. By default, analytical derivatives are automatically computed. However, you can specify the derivatives yourself by using the DER.parm syntax. Use the first form shown to specify first partial derivatives, and use the second form to specify second partial derivatives. Note that the DER.parm syntax is retained for backward compatibility. The automatic analytical derivatives are, in general, a better choice. For additional information about automatic analytical derivatives, see the section “[Automatic Derivatives](#)” on page 5284.

For most of the computational methods, you need only specify the first partial derivative with respect to each parameter to be estimated. For the NEWTON method, specify both the first and the second derivatives. If any needed derivatives are not specified, they are automatically computed.

The expression can be an algebraic representation of the partial derivative of the expression in the [MODEL](#) statement with respect to the parameter or parameters that appear on the left side of the [DER](#) statement. Numerical derivatives can also be used. The expression in the DER statement must conform to the rules for a valid SAS expression, and it can include any quantities that the [MODEL](#) statement expression contains.

ID Statement

ID *variables ;*

The ID statement specifies additional variables to place in the output data set created by the [OUTPUT](#) statement. Any variable on the left side of any assignment statement is eligible. Also, the special variables created by the procedure can be specified. Variables in the input data set do not need to be specified in the ID statement since they are automatically included in the output data set.

MODEL Statement

MODEL *dependent = expression ;*

The MODEL statement defines the prediction equation by declaring the dependent variable and defining an expression that evaluates predicted values. The expression can be any valid SAS expression that yields a numeric result. The expression can include parameter names, variables in the data set, and variables created by programming statements in the NLIN procedure. Any operators or functions that can be used in a DATA step can also be used in the MODEL statement.

A statement such as

```
model y=expression;
```

is translated into the form

```
model.y=expression;
```

using the compound variable name `model.y` to hold the predicted value. You can use this assignment directly as an alternative to the `MODEL` statement. Either a `MODEL` statement or an assignment to a compound variable such as `model.y` must appear.

OUTPUT Statement

OUTPUT **OUT**=SAS-data-set keyword=names <... keyword=names> </ options> ;

The `OUTPUT` statement specifies an output data set to contain statistics calculated for each observation. For each statistic, specify the keyword, an equal sign, and a variable name for the statistic in the output data set. All of the names appearing in the `OUTPUT` statement must be valid SAS names, and none of the new variable names can match a variable already existing in the data set to which `PROC NLIN` is applied.

If an observation includes a missing value for one of the independent variables, both the predicted value and the residual value are missing for that observation. If the iterations fail to converge, all the values of all the variables named in the `OUTPUT` statement are missing values.

Table 63.4 summarizes the options available in the `OUTPUT` statement.

Table 63.4 OUTPUT Statement Options

Option	Description
Output data set and OUTPUT statement options	
<code>ALPHA=</code>	Specifies the level of significance α
<code>DER</code>	Saves the first derivatives of the model
<code>OUT=</code>	Specifies the output data set
Keyword options	
<code>H=</code>	Specifies the tangential leverage
<code>J=</code>	Specifies the Jacobian leverage
<code>L95=</code>	Specifies the lower bound of an approximate 95% prediction interval
<code>L95M=</code>	Specifies the lower bound of an approximate 95% confidence interval for the mean
<code>LCL=</code>	Specifies the lower bound of an approximate $100(1 - \alpha)\%$ prediction interval
<code>LCLM=</code>	Specifies the lower bound of an approximate $100(1 - \alpha)\%$ confidence interval for the mean
<code>LMAX=</code>	Specifies the direction of maximum local influence
<code>PARMS=</code>	Specifies the parameter estimates
<code>PREDICTED=</code>	Specifies the predicted values
<code>PROJRES=</code>	Specifies the projected residuals
<code>PROJSTUDENT=</code>	Specifies the standardized projected residuals
<code>RESEXPEC=</code>	Specifies the mean of the residuals
<code>RESIDUAL=</code>	Specifies the residuals
<code>SSE=</code>	Specifies the residual sum of squares
<code>STDI=</code>	Specifies the standard error of the individual predicted value
<code>STDP=</code>	Specifies the standard error of the mean predicted value
<code>STDR=</code>	Specifies the standard error of the residual
<code>STUDENT=</code>	Specifies the standardized residuals

Table 63.4 *continued*

Option	Description
U95=	Specifies the upper bound of an approximate 95% prediction interval
U95M=	Specifies the upper bound of an approximate 95% confidence interval for the mean
UCL=	Specifies the upper bound of an approximate $100(1 - \alpha)\%$ prediction interval
UCLM=	Specifies the upper bound of an approximate $100(1 - \alpha)\%$ confidence interval for the mean
WEIGHT=	Specifies the special variable <code>_WEIGHT_</code>

You can specify the following options in the OUTPUT statement. For a description of computational formulas, see Chapter 4, “[Introduction to Regression Procedures](#).”

OUT=SAS-data-set

specifies the SAS data set to be created by PROC NLIN when an OUTPUT statement is included. The new data set includes the variables in the input data set. Also included are any **ID** variables specified in the **ID** statement, plus new variables with names that are specified in the OUTPUT statement.

The following values can be calculated and output to the new data set.

H=name

specifies a variable that contains the tangential leverage. See the section “[Leverage in Nonlinear Regression](#)” on page 5288 for details.

J=name

specifies a variable that contains the Jacobian leverage. See the section “[Leverage in Nonlinear Regression](#)” on page 5288 for details.

L95=name

specifies a variable that contains the lower bound of an approximate 95% confidence interval for an individual prediction. This includes the variance of the error as well as the variance of the parameter estimates. See also the description for the **U95=** option later in this section.

L95M=name

specifies a variable that contains the lower bound of an approximate 95% confidence interval for the expected value (mean). See also the description for the **U95M=** option later in this section.

LCL=name

specifies a variable that contains the lower bound of an approximate $100(1 - \alpha)\%$ confidence interval for an individual prediction. The α level is equal to the value of the **ALPHA=** option in the OUTPUT statement or, if this option is not specified, to the value of the **ALPHA=** option in the **PROC NLIN** statement. If neither of these options is specified, then $\alpha = 0.05$ by default, resulting in a lower bound for an approximate 95% confidence interval. For the corresponding upper bound, see the **UCL** keyword.

LCLM=*name*

specifies a variable that contains the lower bound of an approximate $100(1 - \alpha)\%$ confidence interval for the expected value (mean). The α level is equal to the value of the **ALPHA=** option in the **OUTPUT** statement or, if this option is not specified, to the value of the **ALPHA=** option in the **PROC NLIN** statement. If neither of these options is specified, then $\alpha = 0.05$ by default, resulting in a lower bound for an approximate 95% confidence interval. For the corresponding lower bound, see the **UCLM** keyword.

LMAX=*name*

specifies a variable that contains the direction of maximum local influence of an additive perturbation of the response variable. See the section “[Local Influence in Nonlinear Regression](#)” on page 5288 for details.

PARMS=*names*

specifies variables in the output data set that contains parameter estimates. These can be the same variable names that are listed in the **PARAMETERS** statement; however, you can choose new names for the parameters identified in the sequence from the parameter estimates table. A note in the log indicates which variable in the output data set is associated with which parameter name. Note that, for each of these new variables, the values are the same for every observation in the new data set.

PREDICTED=*name***P=***name*

specifies a variable in the output data set that contains the predicted values of the dependent variable.

PROJRES=*name*

specifies a variable that contains the projected residuals obtained by projecting the residuals (ordinary residuals) into the null space of $(X|H)$. For the ordinary residuals, see the **RESIDUAL=** option later in this section. The section “[Residuals in Nonlinear Regression](#)” on page 5289 describes the statistical properties of projected residuals in nonlinear regression.

PROJSTUDENT=*name*

specifies a variable that contains the standardized projected residuals. See the section “[Residuals in Nonlinear Regression](#)” on page 5289 for details and the **STUDENT=** option later in this section.

RESEXPEC=*name*

specifies a variable that contains the mean of the residuals. In contrast to linear regressions where the mean of the residuals is zero, in nonlinear regression the residuals have a nonzero mean value and show a negative covariance with the mean response. See the section “[Residuals in Nonlinear Regression](#)” on page 5289 for details.

RESIDUAL=*name***R=***name*

specifies a variable in the output data set that contains the residuals. See also the description of **PROJRES=** option stated previously in this section and the section “[Residuals in Nonlinear Regression](#)” on page 5289 for the statistical properties of residuals and projected residuals.

SSE=*name*

ESS=*name*

specifies a variable in the output data set that contains the residual sum of squares finally determined by the procedure. The value of the variable is the same for every observation in the new data set.

STDI=*name*

specifies a variable that contains the standard error of the individual predicted value.

STDP=*name*

specifies a variable that contains the standard error of the mean predicted value.

STDR=*name*

specifies a variable that contains the standard error of the residual.

STUDENT=*name*

specifies a variable that contains the standardized residuals. These are residuals divided by their estimated standard deviation. See the **PROJSTUDENT=** option defined previously in this section and the section “[Residuals in Nonlinear Regression](#)” on page 5289 for the statistical properties of residuals and projected residuals.

U95=*name*

specifies a variable that contains the upper bound of an approximate 95% confidence interval for an individual prediction. See also the description for the **L95=** option.

U95M=*name*

specifies a variable that contains the upper bound of an approximate 95% confidence interval for the expected value (mean). See also the description for the **L95M=** option.

UCL=*name*

specifies a variable that contains the upper bound of an approximate $100(1 - \alpha)\%$ confidence interval for an individual prediction. The α level is equal to the value of the **ALPHA=** option in the **OUTPUT** statement or, if this option is not specified, to the value of the **ALPHA=** option in the **PROC NLIN** statement. If neither of these options is specified, then $\alpha = 0.05$ by default, resulting in an upper bound for an approximate 95% confidence interval. For the corresponding lower bound, see the **LCL** keyword.

UCLM=*name*

specifies a variable that contains the upper bound of an approximate $100(1 - \alpha)\%$ confidence interval for the expected value (mean). The α level is equal to the value of the **ALPHA=** option in the **OUTPUT** statement or, if this option is not specified, to the value of the **ALPHA=** option in the **PROC NLIN** statement. If neither of these options is specified, then $\alpha = 0.05$ by default, resulting in an upper bound for an approximate 95% confidence interval. For the corresponding lower bound, see the **LCLM** keyword.

WEIGHT=*name*

specifies a variable in the output data set that contains values of the special variable **_WEIGHT_**.

You can specify the following options in the **OUTPUT** statement after a slash (/):

ALPHA= α

specifies the level of significance α for $100(1 - \alpha)\%$ confidence intervals. By default, α is equal to the value of the **ALPHA=** option in the **PROC NLIN** statement or 0.05 if that option is not specified. You can supply values that are strictly between 0 and 1.

DER

saves the first derivatives of the model with respect to the parameters to the OUTPUT data set. The derivatives are named DER_parmname, where “parmname” is the name of the model parameter in your NLIN statements. You can use the DER option to extract the $\mathbf{X} = \partial \mathbf{f} / \partial \boldsymbol{\beta}$ matrix into a SAS data set. For example, the following statements create the data set nlinX, which contains the \mathbf{X} matrix:

```
proc nlin;
  parms theta1=155 theta3=0.04;
  model V = theta1*c / (theta3 + c);
  output out=nlinout / der;
run;

data nlinX;
  set nlinout (keep=DER_);
run;
```

The derivatives are evaluated at the final parameter estimates.

PARAMETERS Statement

PARAMETERS *< parameter-specification >* *<, ..., parameter-specification >*
< / PDATA=SAS-data-set > ;

PARMS *< parameter-specification >* *<, ..., parameter-specification >*
< / PDATA=SAS-data-set > ;

A PARAMETERS (or PARMS) statement is required. The purpose of this statement is to provide starting values for the NLIN procedure. You can provide values that define a point in the parameter space or a set of points.

All parameters must be assigned starting values through the PARAMETERS statement. The NLIN procedure does not assign default starting values to parameters in your model that do not appear in the PARAMETERS statement. However, it is not necessary to supply parameters and starting values explicitly through a *parameter-specification*. Starting values can also be provided through a data set. The names assigned to parameters must be valid SAS names and must not coincide with names of variables in the input data set (see the **DATA=** option in the **PROC NLIN** statement). Parameters that are assigned starting values through the PARAMETERS statement can be omitted from the estimation, for example, if the expression in the **MODEL** statement does not depend on them.

Assigning Starting Values with Parameter-Specification

A *parameter-specification* has the general form

name = value-list

where *name* identifies the parameter and *value-list* provides the set of starting values for the parameter.

Very often, the *value-list* contains only a single value, but more general and flexible list specifications are possible:

<i>m</i>	a single value
<i>m1, m2, ..., mn</i>	several values
<i>m TO n</i>	a sequence where <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment equals 1
<i>m TO n BY i</i>	a sequence where <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment is <i>i</i>
<i>m1, m2 TO m3</i>	mixed values and sequences

When you specify more than one value for a parameter, PROC NLIN sorts the values in ascending sequence and removes duplicate values from the parameter list before forming the grid for the parameter search. If you specify several values for each parameter, PROC NLIN evaluates the model at each point on the grid. The iterations then commence from the point on the grid that yields the smallest objective function value.

For example, the following PARMS statement specifies five parameters and sets their possible starting values as shown in the table:

```
parms  b0 = 0
       b1 = 4 to 8
       b2 = 0 to .6 by .2
       b3 = 1, 10, 100
       b4 = 0, .5, 1 to 4;
```

Possible starting values				
B0	B1	B2	B3	B4
0	4	0.0	1	0.0
	5	0.2	10	0.5
	6	0.4	100	1.0
	7	0.6		2.0
	8			3.0
				4.0

Residual sums of squares are calculated for each of the $1 \times 5 \times 4 \times 3 \times 6 = 360$ combinations of possible starting values. (Specifying a large grid of values can take considerable computing time.)

If you specify a starting value with a *parameter-specification*, any starting values provided for this parameter through the PDATA= data set are ignored. The *parameter-specification* overrides the information in the PDATA= data set. When you specify a **BY** statement, the same *parameter-specification* is applied in each **BY** group. To vary starting values with **BY** groups, use the PDATA= option in the PARAMETERS statement as described in the following paragraphs.

Assigning Starting Values from a SAS Data Set

The `PDATA=` option in the `PARAMETERS` statement enables you to assign starting values for parameters through a SAS data set. The data set must contain at least two variables that identify the parameter and contain starting values, respectively. The *character* variable identifying the parameters must be named `Parameter` or `Parm`. The *numeric* variable containing the starting value must be named `Estimate` or `Est`. This enables you, for example, to use the contents of the “ParameterEstimates” table from one PROC NLIN run to supply starting values for a subsequent run, as in the following example:

```
proc nlin data=FirstData;
  parameters alpha=100 beta=3 gamma=4;
  < other NLIN statements >
  model y = ... ;
  ods output ParameterEstimates=pest;
run;

proc nlin data=SecondData;
  parameters / pdata=pest;
  Switch = 1/(1+gamma*exp(beta*log(dose)));
  model y = alpha*Switch;
run;
```

You can specify multiple values for a parameter in the `PDATA=` data set, and the parameters can appear in any order. The starting values are collected by parameter and arranged in ascending order, and duplicate values are removed. The parameter names in the `PDATA=` data set are not case sensitive. For example, the following DATA step defines starting values for three parameters and a starting grid with $1 \times 3 \times 1 = 3$ points:

```
data test;
  input Parameter $ Estimate;
  datalines;
alpha 100
BETA 4
beta 4.1
beta 4.2
beta 4.1
gamma 30
;
```

If starting values for a parameter are provided through the `PDATA=` data set and through an explicit *parameter-specification*, the latter takes precedence.

When you specify a **BY** statement, you can control whether the same starting values are applied to each BY group or whether the starting values are varied. If the **BY** variables are not present in the `PDATA=` data set, the entire contents of the `PDATA=` data set are applied in each **BY** group. If the **BY** variables are present in the `PDATA=` data set, then **BY**-group-specific starting values are assigned.

PROFILE Statement

PROFILE *parameter* <...*parameter*> </*options*> ;

A PROFILE statement selects parameters for profiling to assess their nonlinear characteristics. It can also gauge the influence of each observation on the selected parameters. To produce the plots that are controlled by the PROFILE statement, ODS Graphics must be enabled. PROC NLIN ignores PROFILE statements for nonconvergent and singular models.

Table 63.6 summarizes the *options* available in the PROFILE statement.

Table 63.6 Summary of Options in PROFILE Statement

Option	Description
ALL	Produces all profiling related plots and statistics
CONFCURV	Produces confidence curves for the listed parameters
JACKKNIFE	Produces plots of the absolute relative percentage change by observation for the listed parameters
PROFDATA=	Specifies the profile output data set
RANGE=	Specifies a profiling range
TPLOT	Produces profile <i>t</i> plots for the listed parameters

ALL

produces all appropriate plots for the parameters that are listed in the PROFILE statement. This option overrides all other *options*. If the PROFDATA= option is specified, the values of the corresponding statistics are written to the data set.

CONFCURV

produces confidence curves for each parameter listed in the PROFILE statement. If the PROFDATA= option is specified, the values of the corresponding statistics are written to the data set. See the section “[Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates](#)” on page 5290 for details.

JACKKNIFE

produces, for each parameter listed in the PROFILE statement, plots of absolute relative percentage change in the value of the parameter that results from a fit to a jackknife-resampled datum versus observation number. The jackknife resampling is performed with a leave-one-out method. If the PROFDATA= option is specified, the values of the corresponding statistics are written to the data set. See the section “[Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates](#)” on page 5290 for details.

PROFDATA=SAS-data-set

specifies the SAS data set to be created by PROC NLIN when a PROFILE statement is included. See the section “[Output Data Sets](#)” on page 5299 for details about this data set.

RANGE= β_f to β_t by β_b

specifies a profiling range for each parameter listed in the PROFILE statement. β_f , β_t and β_b represent the starting, final, and consecutive incremental values of the range in terms of the standard errors of the parameters to be profiled. If you do not specify the RANGE= option, PROC NLIN uses -2, 2, and 0.2 as default values for β_f , β_t , and β_b , respectively. For example, if parameter θ is in the PROFILE statement, then during the profiling of θ , PROC NLIN performs approximately $(\beta_t - \beta_f)/\beta_b$ number of constrained optimizations. At the i th constrained optimization, the value of θ is constrained to θ_i ,

$$\theta_i = \hat{\theta} + \text{stderr}_{\theta} \left(\beta_f + i \frac{(\beta_t - \beta_f)}{\beta_b} \right)$$

and the rest of the parameters are freely optimized. In the preceding expression, $\hat{\theta}$ and stderr_{θ} are the estimated value and standard error, respectively, for θ . If parameter bounds are specified with BOUNDS statements, PROC NLIN enforces those bounds during the profiling optimizations.

NOTE: The profiling optimizations are performed using quasi-Newton algorithm. During these optimizations, any optimization options specified in the PROC NLIN statement and the _LOSS_ variable are ignored.

TPLOT

produces profile t plots for each parameter listed in the PROFILE statement. If the PROFDATA= option is specified, the values of the corresponding statistics are written to the data set. See the section “Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates” on page 5290 for details.

RETAIN Statement

RETAIN *variable* <=values> <... *variable* <=values>> ;

The RETAIN statement declares retained variables and specifies their values. A retained variable is like a control variable (see the section “CONTROL Statement” on page 5272) except that it is retained only *within* iterations. An iteration involves a single pass through the data set.

Other Programming Statements

PROC NLIN supports many statements that are similar to SAS programming statements used in a DATA step. However, there are some differences in capabilities; for additional information, see also the section “Incompatibilities with SAS 6.11 and Earlier Versions of PROC NLIN” on page 5303.

Several SAS programming statements can be used after the PROC NLIN statement. These statements can appear anywhere in the PROC NLIN code, but new variables must be created before they appear in other statements. For example, the following statements are valid since they create the variable temp before it is used in the MODEL statement:

```
proc nlin;
  parms b0=0 to 2 by 0.5 b1=0.01 to 0.09 by 0.01;
  temp = exp(-b1*x);
  model y=b0*(1-temp);
run;
```

The following statements result in missing values for y because the variable temp is undefined before it is used:

```
proc nlin;
  parms b0=0 to 2 by 0.5 b1=0.01 to 0.09 by 0.01;
  model y = b0*(1-temp);
  temp = exp(-b1*x);
run;
```

PROC NLIN can process assignment statements, explicitly or implicitly subscripted ARRAY statements, explicitly or implicitly subscripted array references, IF statements, SAS functions, and program control statements. You can use programming statements to create new SAS variables for the duration of the procedure. These variables are not included in the data set to which PROC NLIN is applied. Program statements can include variables in the [DATA=](#) data set, parameter names, variables created by preceding programming statements within PROC NLIN, and special variables used by PROC NLIN. The following SAS programming statements can be used in PROC NLIN:

```
ABORT;
ARRAY arrayname <[ dimensions ]> <$> <variables-and-constants>;
CALL name <(expression < , expression ... >)>;
DELETE;
DO < variable = expression < TO expression > < BY expression > >
    < , expression < TO expression > < BY expression > > ...
    < WHILE expression > < UNTIL expression >;
END;
GOTO statement-label;
IF expression;
IF expression THEN program-statement;
    ELSE program-statement;
variable = expression;
variable + expression;
LINK statement-label;
PUT < variable > < = > ...;
RETURN;
SELECT < (expression) >;
STOP;
SUBSTR(variable, index, length)= expression;
WHEN (expression)program-statement;
    OTHERWISE program-statement;
```

These statements can use the special variables created by PROC NLIN. See the section “[Special Variables](#)” on page 5291 for more information.

Details: NLIN Procedure

Automatic Derivatives

Depending on the optimization method you select, analytical first- and second-order derivatives are computed automatically. Derivatives can still be supplied using the DER.parm syntax. These DER.parm derivatives are not verified by the differentiator. If any needed derivatives are not supplied, they are computed and added to the programming statements. To view the computed derivatives, use the [LISTDER](#) or [LIST](#) option.

The following model is solved using Newton’s method. Analytical first- and second-order derivatives are automatically computed. The compiled program code is shown in [Figure 63.6](#).

```
proc nlin data=Enzyme method=newton list;
  parms x1=4 x2=2;
  model Velocity = x1 * exp (x2 * Concentration);
run;
```

Figure 63.6 Model and Derivative Code Output

The NLIN Procedure		
Listing of Compiled Program Code		
Stmt	Line:Col	Statement as Parsed
1	1429:4	MODEL.Velocity = x1 * EXP(x2
		* Concentration);
1	1429:4	@MODEL.Velocity/@x1 = EXP(x2
		* Concentration);
1	1429:4	@MODEL.Velocity/@x2 = x1 * Concentration
		* EXP(x2 * Concentration);
1	1429:4	@@MODEL.Velocity/@x1/@x2 = Concentration
		* EXP(x2 * Concentration);
1	1429:4	@@MODEL.Velocity/@x2/@x1 = Concentration
		* EXP(x2 * Concentration);
1	1429:4	@@MODEL.Velocity/@x2/@x2 = x1
		* Concentration * Concentration
		* EXP(x2 * Concentration);

Note that all the derivatives require the evaluation of EXP(X2 * Concentration). The actual machine-level code is displayed if you specify the [LISTCODE](#) option, as in the following statements:

```
proc nlin data=Enzyme method=newton listcode;
  parms x1=4 x2=2;
  model Velocity = x1 * exp (x2 * Concentration);
run;
```

Note that, in the generated code, only one exponentiation is performed ([Figure 63.7](#)). The generated code reuses previous operations to be more efficient.

Measures of Nonlinearity and Diagnostics

A “close-to-linear” nonlinear regression model, in the sense of Ratkowsky (1983, 1990), is a model in which parameter estimators have properties similar to those in a linear regression model. That is, the least squares estimators of the parameters are close to being unbiased and normally distributed, and they have minimum variance.

A nonlinear regression model sometimes fails to be close to linear due to the properties of one or several parameters. When this occurs, bias in the parameter estimates can render inferences that use the reported standard errors and confidence limits invalid.

PROC NLIN provides various measures of nonlinearity. To assess the nonlinearity of a model-data combination, you can use both of the following complementary sets of measures:

- Box’s bias (Box 1971) and Hougaard’s skewness (Hougaard 1982, 1985) of the least squares parameter estimates
- curvature measures of nonlinearity (Bates and Watts 1980).

Furthermore, PROC NLIN provides residual, leverage, and local-influence diagnostics (St. Laurent and Cook 1993).

In the following several sections, these nonlinearity measures and diagnostics are discussed. For this material, several basic definitions are required. Let \mathbf{X} be the Jacobian matrix for the model, $\mathbf{X} = \frac{\partial \mathbf{f}}{\partial \boldsymbol{\beta}}$, and let \mathbf{Q} and \mathbf{R} be the components of the QR decomposition of $\mathbf{X} = \mathbf{QR}$ of \mathbf{X} , where \mathbf{Q} is an $(n \times n)$ orthogonal matrix. Finally, let \mathbf{B} be the inverse of the matrix constructed from the first p rows of the $(n \times p)$ dimensional matrix \mathbf{R} (that is, $\mathbf{B} = \mathbf{R}_p^{-1}$). Next define

$$\begin{aligned} [\mathbf{H}_j]_{kl} &= \frac{\partial^2 \mathbf{f}_j}{\partial \boldsymbol{\beta}_k \partial \boldsymbol{\beta}_l} \\ [\mathbf{U}_j]_{kl} &= \sum_{mn} \mathbf{B}'_{km} [\mathbf{H}_j]_{mn} \mathbf{B}_{nl} \\ [\mathbf{A}_j]_{kl} &= \sqrt{p \times \text{mse}} \sum_m \mathbf{Q}'_{jm} [\mathbf{U}_m]_{kl}, \end{aligned}$$

where \mathbf{H} , \mathbf{U} and the acceleration array \mathbf{A} are three-dimensional $(n \times p \times p)$ matrices. The first p faces of the acceleration array constitute a $(p \times p \times p)$ parameter-effects array and the last $(n - p)$ faces constitute the $(n - p \times p \times p)$ intrinsic curvature array (Bates and Watts 1980). The previous and subsequent quantities are computed at the least squares parameter estimators.

Box's Measure of Bias

The degree to which parameter estimators exhibit close-to-linear behavior can be assessed with Box's bias (Box 1971) and Hougaard's measure of skewness (Hougaard 1982, 1985). The bias and percentage bias measures are available through the **BIAS** option in the **PROC NLIN** statement. Box's bias measure is defined as

$$\hat{\mathbf{E}}[\hat{\boldsymbol{\theta}} - \boldsymbol{\theta}] = -\frac{\sigma^2}{2} (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \sum_{i=1}^n w_i \mathbf{x}'_i \text{Tr}((\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} [\mathbf{H}_i])$$

where $\sigma^2 = \text{mse}$ if the **SIGSQ** option is not set. Otherwise, σ^2 is the value you set with the **SIGSQ** option. \mathbf{W} is the diagonal weight matrix specified with the **_WEIGHT_** variable (or the identity matrix if **_WEIGHT_** is not defined) and $[\mathbf{H}_i]$ is the $(p \times p)$ Hessian matrix at the i th observation. In the case of unweighted least squares, the bias formula can be expressed in terms of the acceleration array \mathbf{A} ,

$$\hat{\mathbf{E}}[\hat{\theta}_i - \theta_i] = -\frac{\sigma^2}{2p \times \text{mse}} \sum_{j,k=1}^p \mathbf{B}_{ij} [\mathbf{A}_j]_{kk}$$

As the preceding formulas illustrate, the bias depends solely on the parameter-effects array, thereby permitting its reduction through reparameterization. **Example 63.4** shows how changing the parameterization of a four-parameter logistic model can reduce the bias. Ratkowsky (1983, p. 21) recommends that you consider reparameterization if the percentage bias exceeds 1%.

Hougaard's Measure of Skewness

In addition to Box's bias, Hougaard's measure of skewness, g_{1i} (Hougaard 1982, 1985), is also provided in PROC NLIN to assess the close-to-linear behavior of parameter estimators. This measure is available

through the **HOUGAARD** option in the **PROC NLIN** statement. Hougaard's skewness measure for the i th parameter is based on the third central moment, defined as

$$E \left[\hat{\theta}_i - E(\hat{\theta}_i) \right]^3 = -(\sigma^2)^2 \sum_{jkl} [\mathbf{L}]_{ij} [\mathbf{L}]_{ik} [\mathbf{L}]_{il} ([\mathbf{V}_j]_{kl} + [\mathbf{V}_k]_{jl} + [\mathbf{V}_l]_{jk})$$

where the sum is a triple sum over the number of parameters and

$$\mathbf{L} = (\mathbf{X}'\mathbf{X})^{-1} = \left(\frac{\partial \mathbf{f}}{\partial \boldsymbol{\beta}'} \frac{\partial \mathbf{f}}{\partial \boldsymbol{\beta}} \right)^{-1}$$

The term $[\mathbf{L}]_{ij}$ denotes the value in row i , column j of the matrix \mathbf{L} . (Hougaard (1985) uses superscript notation to denote elements in this inverse.) The matrix \mathbf{V} is a three-dimensional ($p \times p \times p$) array

$$[\mathbf{V}_j]_{kl} = \sum_{m=1}^n \frac{\partial F_m}{\partial \beta_j} \frac{\partial^2 F_m}{\partial \beta_k \partial \beta_l}$$

The third central moment is then normalized using the standard error as

$$G_{1i} = E \left[\hat{\theta}_i - E(\hat{\theta}_i) \right]^3 / (\sigma^2 \times [\mathbf{L}]_{ii})^{3/2}$$

The previous expressions depend on the unknown values of the parameters and on the residual variance σ^2 . In order to evaluate the Hougaard measure in a particular data set, the NLIN procedure computes

$$\begin{aligned} g_{1i} &= \hat{E} \left[\hat{\theta}_i - E(\hat{\theta}_i) \right]^3 / (\text{mse} \times [\hat{\mathbf{L}}]_{ii})^{3/2} \\ \hat{E} \left[\hat{\theta}_i - E(\hat{\theta}_i) \right]^3 &= -\text{mse}^2 \sum_{jkl} [\hat{\mathbf{L}}]_{ij} [\hat{\mathbf{L}}]_{ik} [\hat{\mathbf{L}}]_{il} ([\hat{\mathbf{V}}_j]_{kl} + [\hat{\mathbf{V}}_k]_{jl} + [\hat{\mathbf{V}}_l]_{jk}) \end{aligned}$$

Following Ratkowsky (1990, p. 28), the parameter θ_i is considered to be very close to linear, reasonably close, skewed, or quite nonlinear according to the absolute value of the Hougaard measure $|g_{1i}|$ being less than 0.1, between 0.1 and 0.25, between 0.25 and 1, or greater than 1, respectively.

Relative Curvature Measures of Nonlinearity

Bates and Watts (1980) formulated the maximum parameter-effects and maximum intrinsic curvature measures of nonlinearity to assess the close-to-linear behavior of nonlinear models. Ratkowsky (1990) notes that of the two curvature components in a nonlinear model, the parameter-effects curvature is typically larger. It is this component that you can affect by changing the parameterization of a model. PROC NLIN provides these two measures of curvature both through the **STATS plot-option** and through the **NLINMEASURES** option in the **PROC NLIN** statement.

The maximum parameter-effects and intrinsic curvatures are defined, in a compact form, as

$$\begin{aligned} \mathbf{T}^\tau &= \max_{\boldsymbol{\theta}} \left\| \boldsymbol{\theta}' \mathbf{A}^\tau \boldsymbol{\theta} \right\| \\ \mathbf{T}^\eta &= \max_{\boldsymbol{\theta}} \left\| \boldsymbol{\theta}' \mathbf{A}^\eta \boldsymbol{\theta} \right\| \end{aligned}$$

where \mathbf{T}^τ and \mathbf{T}^η denote the maximum parameter-effects and intrinsic curvatures, while \mathbf{A}^τ and \mathbf{A}^η stand for the parameter-effects and intrinsic curvature arrays. The maximization is carried out over a unit-vector

of the parameter values (Bates and Watts 1980). In line with Bates and Watts (1980), PROC NLIN takes 10^{-4} as the convergence tolerance for the maximum intrinsic and parameter-effects curvatures. Note that the preceding matrix products involve contraction of the faces of the three-dimensional acceleration arrays with the normalized parameter vector, θ . The corresponding expressions for the RMS (root mean square) parameter-effects and intrinsic curvatures can be found in Bates and Watts (1980).

The statistical significance of T^τ and T^η and the corresponding RMS values can be assessed by comparing these values with $1/\sqrt{F}$, where F is the upper $\alpha \times 100\%$ quantile of an F distribution with p and $n - p$ degrees of freedom (Bates and Watts 1980).

One motivation for fitting a nonlinear model in a different parameterization is to obtain a particular interpretation and to give parameter estimators more close-to-linear behavior. [Example 63.4](#) shows how changing the parameterization of a four-parameter logistic model can reduce the parameter-effects curvature and can yield a useful parameter interpretation at the same time. In addition, [Example 63.6](#) shows a nonlinear model with a high intrinsic curvature and the corresponding diagnostics.

Leverage in Nonlinear Regression

In contrast to linear regression, there are several measures of leverage in nonlinear regression. Furthermore, in nonlinear regression, the effect of a change in the i th response on the i th predicted value might depend on both the size of the change and the i th response itself (St. Laurent and Cook 1992). As a result, some observations might show superleverage —namely, leverages in excess of one (St. Laurent and Cook 1992).

PROC NLIN provides two measures of leverages: tangential and Jacobian leverages through the **PLOTS** option in the **PROC NLIN** statement and the **H=** and **J=** options of **OUTPUT** statement. Tangential leverage, H_i , is based on approximating the nonlinear model with a linear model that parameterizes the tangent plane at the least squares parameter estimators. In contrast, Jacobian leverage, J_i , is simply defined as the instantaneous rate of change in the i th predicted value with respect to the i th response (St. Laurent and Cook 1992).

The mathematical formulas for tangential and Jacobian leverages are

$$H_i = w_i \mathbf{x}_i (\mathbf{X}' \mathbf{W} \mathbf{X})^{-1} \mathbf{x}_i'$$

$$J_i = w_i \mathbf{x}_i (\mathbf{X}' \mathbf{W} \mathbf{X} - [\mathbf{W} \mathbf{e}][\mathbf{H}])^{-1} \mathbf{x}_i',$$

where \mathbf{e} is the vector of residuals, \mathbf{W} is the diagonal weight matrix if you specify the special variable `_WEIGHT_` and otherwise the identity matrix, and i indexes the corresponding quantities for the i th observation. The brackets $[\cdot][\cdot]$ indicate column multiplication as defined in Bates and Watts (1980). The preceding formula for tangential leverage holds if the gradient, Marquardt, or Gauss methods are used. For the Newton method, the tangential leverage is set equal to the Jacobian leverage.

In a model with a large intrinsic curvature, the Jacobian and tangential leverages can be very different. In fact, the two leverages are identical only if the model provides an exact fit to the data ($\mathbf{e} = 0$) or the model is intrinsically linear (St. Laurent and Cook 1993). This is also illustrated by the leverage plot and nonlinearity measures provided in [Example 63.6](#).

Local Influence in Nonlinear Regression

St. Laurent and Cook (1993) suggest using l_{\max} , the direction that yields the maximum normal curvature, to assess the local influence of an additive perturbation to the response variable on the estimation of the

parameters and variance of a nonlinear model. Defining the normal curvature components

$$C_\theta = \max_l \frac{2}{\sigma^2} l' \mathbf{J} l$$

$$C_\sigma = \max_l \frac{4}{\sigma^2} l' \mathbf{P}_e l$$

where \mathbf{J} is the Jacobian leverage matrix and $\mathbf{P}_e = \mathbf{e}\mathbf{e}'/(\mathbf{e}'\mathbf{e})$, you choose the l_{\max} that results in the maximum of the two curvature components (St. Laurent and Cook 1993). PROC NLIN provides l_{\max} through the **PLOTS** option in the **PROC NLIN** statement and the **LMAX=** option in the **OUTPUT** statement. Example 63.6 shows a plot of l_{\max} for a model with high intrinsic curvature.

Residuals in Nonlinear Regression

If a nonlinear model is intrinsically nonlinear, using the residuals $\mathbf{e} = \mathbf{y} - \hat{\mathbf{y}}$ for diagnostics can be misleading (Cook and Tsai 1985). This is due to the fact that in correctly specified intrinsically nonlinear models, the residuals have nonzero means and different variances, even when the original error terms have identical variances. Furthermore, the covariance between the residuals and the predicted values tends to be negative semidefinite, complicating the interpretation of plots based on \mathbf{e} (Cook and Tsai 1985).

Projected residuals are proposed by Cook and Tsai (1985) to overcome these shortcomings of residuals, which are henceforth called raw (ordinary) residuals to differentiate them from their projected counterparts. Projected residuals have zero means and are uncorrelated with the predicted values. In fact, projected residuals are identical to the raw residuals in intrinsically linear models.

PROC NLIN provides raw and projected residuals, along with their standardized forms. In addition, the mean or expectation of the raw residuals is available. These can be accessed with the **PLOTS** option in the **PROC NLIN** statement and the **OUTPUT** statement options **PROJRES=**, **PROJSTUDENT=**, **RESEXPEC=**, **RESIDUAL=** and **STUDENT=**.

Denote the projected residuals by \mathbf{e}_p and the expectation of the raw residuals by $E[\mathbf{e}]$. Then

$$\mathbf{e}_p = (\mathbf{I}_n - \mathbf{P}_{xh}) \mathbf{e}$$

$$E[\mathbf{e}_i] = -\frac{\sigma^2}{2} \sum_{j=1}^n \tilde{\mathbf{P}}_{x,ij} \text{Tr} \left([\mathbf{H}_j] (\mathbf{X}'\mathbf{X})^{-1} \right)$$

where \mathbf{e}_i is the i th observation raw residual, \mathbf{I}_n is an n -dimensional identity matrix, \mathbf{P}_{xh} is the projector onto the column space of $(\mathbf{X}|\mathbf{H})$, and $\tilde{\mathbf{P}}_x = \mathbf{I}_n - \mathbf{P}_x$. The preceding formulas are general with the projectors defined accordingly to take the weighting into consideration. In unweighted least squares, $E[\mathbf{e}]$ reduces to

$$E[\mathbf{e}] = -\frac{1}{2} \sigma^2 \tilde{\mathbf{Q}} \mathbf{a}$$

with $\tilde{\mathbf{Q}}$ being the last $n - p$ columns of the \mathbf{Q} matrix in the QR decomposition of \mathbf{X} and the $(n - p)$ dimensional vector \mathbf{a} being defined in terms of the intrinsic acceleration array

$$\mathbf{a}_i = \sum_{j=1}^p [\mathbf{A}_{i+p}]_{jj}$$

Standardization of the projected residuals requires the variance of the projected residuals. This is estimated using the formula (Cook and Tsai 1985)

$$\sigma_p^2 = \frac{\mathbf{e}_p' \mathbf{e}_p}{\text{Tr}(\mathbf{I}_n - \mathbf{P}_{xh})}$$

The standardized raw and projected residuals, denoted by \tilde{e} and \tilde{e}_p respectively, are given by

$$\tilde{e} = \frac{\sqrt{w_i} \mathbf{e}}{\sigma \sqrt{1 - \mathbf{P}_{x,ii}}}$$

$$\tilde{e}_p = \frac{\sqrt{w_i} \mathbf{e}_p}{\sigma \sqrt{1 - \mathbf{P}_{xh,ii}}}$$

The use of raw and projected residuals for diagnostics in nonlinear regression is illustrated in [Example 63.6](#).

Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates

The global measures of nonlinearity, discussed in the preceding section, are very useful for assessing the overall nonlinearity of the model. However, the impact of global nonlinearity on inference regarding subsets of the parameter set cannot be easily determined (Cook and Tsai 1985). The impact of the nonlinearity on the uncertainty of individual parameters can be efficiently described by profile t plots and confidence curves (Bates and Watts 1988; Cook and Weisberg 1990).

A profile t plot for parameter θ is a plot of the likelihood ratio pivotal statistic, $\tau(\theta)$, and the corresponding Wald pivotal statistic, $\sigma(\theta)$ (Bates and Watts 1988). The likelihood ratio pivotal statistic is defined as

$$\tau(\theta) = \text{sign}(\theta - \hat{\theta}) L(\theta)$$

with

$$L(\theta) = \left(\frac{\text{SSE}(\theta, \tilde{\Theta}) - \text{SSE}(\hat{\theta}, \hat{\Theta})}{\text{mse}} \right)^{1/2}$$

where θ is the profile parameter and Θ refers to the remaining parameters. $\text{SSE}(\theta, \tilde{\Theta})$ is the sum of square errors where the profile parameter θ is constrained at a given value and $\tilde{\Theta}$ is the least squares estimate of Θ conditional on a given value of θ . In contrast, $\text{SSE}(\hat{\theta}, \hat{\Theta})$ is the sum of square errors for the full model. For linear models, $\tau(\theta)$ matches $\sigma(\theta)$, which is defined as

$$\sigma(\theta) = \frac{\theta - \hat{\theta}}{\text{stderr}_{\theta}}$$

where θ is the constrained value, $\hat{\theta}$ is the estimated value for the parameter, and stderr_{θ} is the standard error for the parameter. Usually a profile t plot is overlaid with a reference line that passes through the origin and has a slope of 1. PROC NLIN follows this convention.

A confidence curve for a particular parameter is useful for validating Wald-based confidence intervals for the parameter against likelihood-based confidence intervals (Cook and Weisberg 1990). A confidence curve contains a scatter plot of the constrained parameter value versus $L(\theta)$. The Wald-based confidence intervals are overlaid as two straight lines that pass through $(0, \hat{\theta})$ with a slope of $\pm \text{stderr}_{\theta}$. Hence, for different levels of significance, you can easily compare the Wald-based confidence intervals against the corresponding confidence intervals that are based on the likelihood ratio. Cook and Weisberg (1990) recommend that you report a single Wald-based confidence interval only if there is a good agreement between the Wald and likelihood intervals up to at least the 99% confidence level.

Compared to local influence, the leave-one-out method performs a more complete analysis of the influence of observations on the values of parameter estimates. In this method, jackknife resampling removes each

observation in turn and fits the model to the remaining data set. Hence, a data set with n observations will have n corresponding data sets with $n-1$ observations. The impact of each observation on a parameter is assessed by the absolute relative percentage change in the value of the parameter compared with the reference value from the full data.

Missing Values

If the value of any one of the SAS variables involved in the model is missing from an observation, that observation is omitted from the analysis. If only the value of the dependent variable is missing, that observation has a predicted value calculated for it when you use an **OUTPUT** statement and specify the **PREDICTED=** option.

If an observation includes a missing value for one of the independent variables, both the predicted value and the residual value are missing for that observation. If the iterations fail to converge, the values for all variables named in the **OUTPUT** statement are set to missing.

Special Variables

Several special variables are created automatically and can be used in PROC NLIN programming statements.

Special Variables with Values That Are Set by PROC NLIN

The values of the following six special variables are set by PROC NLIN and should not be reset to a different value by programming statements:

ERROR	is set to 1 if a numerical error or invalid argument to a function occurs during the current execution of the program. It is reset to 0 before each new execution.
ITER	represents the current iteration number. The variable _ITER_ is set to -1 during the grid search phase.
MODEL	is set to 1 for passes through the data when only the predicted values are needed, and not the derivatives. It is 0 when both predicted values and derivatives are needed. If your derivative calculations consume a lot of time, you can save resources by using the following statement after your MODEL statement but before your derivative calculations:

```
if _model_ then return;
```

The derivatives generated by PROC NLIN do this automatically.

N	indicates the number of times the PROC NLIN step has been executed. It is never reset for successive passes through the data set.
OBS	indicates the observation number in the data set for the current program execution. It is reset to 1 to start each pass through the data set (unlike the _N_ variable).
SSE	contains the error sum of squares of the last iteration. During the grid search phase, the _SSE_ variable is set to 0. For iteration 0, the _SSE_ variable is set to the SSE associated with the point chosen from the grid search.

`_P_WEIGHTED_SSE_` contains the error sum of squares for the optimization tasks that are required for profiling parameters and assessing the influence of each observation on the estimate of each profiled parameter.

Special Variable Used to Determine Convergence Criteria

The special variable `_LOSS_` can be used to determine the criterion function for convergence and step shortening. PROC NLIN looks for the variable `_LOSS_` in the programming statements and, if it is defined, uses the (weighted) sum of this value instead of the residual sum of squares to determine the criterion function for convergence and step shortening. This feature is useful in certain types of maximum-likelihood estimation.

NOTE: Even if you specify the `_LOSS_` variable in your programming statements, the NLIN procedure continues to solve a least squares problem. The specified `_LOSS_` variable does **not** define or alter the objective function for parameter estimation.

Weighted Regression with the Special Variable `_WEIGHT_`

To obtain weighted nonlinear least squares estimates of parameters, make an assignment to the `_WEIGHT_` variable as in the following statement:

```
_weight_ = expression;
```

When this statement is included, the expression on the right side of the assignment statement is evaluated for each observation in the data set. The values multiplied by $1/\sigma^2$ are then taken as inverse elements of the diagonal variance-covariance matrix of the dependent variable.

When a variable name is given after the equal sign, the values of the variable are taken as the inverse elements of the variance-covariance matrix. The larger the `_WEIGHT_` value, the more importance the observation is given.

The `_WEIGHT_` variable can be a function of the estimated parameters. For estimation purposes, the derivative of the `_WEIGHT_` variable with respect to the parameters is not included in the gradient and the Hessian of the loss function. This is normally the desired approach for iteratively reweighted least squares estimation. When the `_WEIGHT_` variable is a function of the parameters, the gradient and the Hessian used can lead to poor convergence or nonconvergence of the requested estimation. To have the derivative of the `_WEIGHT_` variable with respect to the parameters included in the gradient and the Hessian of the loss function, do not use the `_WEIGHT_` variable. Instead, redefine the model as

$$(y - f(x, \beta)) \times \sqrt{\text{wgt}(\beta)}$$

where y is the original dependent variable, $f(x, \beta)$ is the nonlinear model, and $\text{wgt}(\beta)$ is the weight that is a function of the parameters.

If the `_WEIGHT_ =` statement is not used, the default value of 1 is used, and regular least squares estimates are obtained.

Troubleshooting

This section describes a number of problems that might occur in your analysis with PROC NLIN.

Excessive Computing Time

If you specify a grid of starting values that contains many points, the analysis might take excessive time since the procedure must go through the entire data set for each point on the grid.

The analysis might also take excessive time if your problem takes many iterations to converge, since each iteration requires as much time as a linear regression with predicted values and residuals calculated.

Dependencies

The matrix of partial derivatives can be singular, possibly indicating an overparameterized model. For example, if b_0 starts at zero in the following model, the derivatives for b_1 are all zero for the first iteration:

```
parms b0=0 b1=.022;
model pop=b0*exp(b1*(year-1790));
der.b0=exp(b1*(year-1790));
der.b1=(year-1790)*b0*exp(b1*(year-1790));
```

The first iteration changes a subset of the parameters; then the procedure can make progress in succeeding iterations. This singularity problem is local. The next example displays a global problem. The term b_2 in the exponent is not identifiable since it trades roles with b_0 .

```
parms b0=3.9 b1=.022 b2=0;
model pop=b0*exp(b1*(year-1790)+b2);
der.b0 = exp(b1*(year-1790)+b2);
der.b1 = (year-1790)*b0*exp(b1*(year-1790)+b2);
der.b2 = b0*exp(b1*(year-1790)+b2);
```

Unable to Improve

The method can lead to steps that do not improve the estimates even after a series of step halvings. If this happens, the procedure issues a message stating that it is unable to make further progress, but it then displays the following warning message:

```
PROC NLIN failed to converge
```

Then it displays the results. This often means that the procedure has not converged at all. If you provided your own derivatives, check them carefully and then examine the residual sum of squares surface. If PROC NLIN has not converged, try a different set of starting values, a different METHOD= specification, the G4 option, or a different model.

Divergence

The iterative process might diverge, resulting in overflows in computations. It is also possible that parameters enter a space where arguments to such functions as LOG and SQRT become invalid. For example, consider the following model:

```
parms b=0;
model y = x / b;
```

Suppose that y contains only zeros, and suppose that the values for variable x are not zero. There is no least squares estimate for b since the SSE declines as b approaches infinity or minus infinity. To avoid the problem, the same model could be parameterized as $y = a \cdot x$.

If you have divergence problems, try reparameterizing the model, selecting different starting values, increasing the maximum allowed number of iterations (the `MAXITER=` option), specifying an alternative `METHOD=` option, or including a `BOUNDS` statement.

Local Minimum

The program might converge to a local rather than a global minimum. For example, consider the following model:

```
parms a=1 b=-1;
model y=(1-a*x)*(1-b*x);
```

Once a solution is found, an equivalent solution with the same SSE can be obtained by swapping the values of a and b .

Discontinuities

The computational methods assume that the model is a continuous and smooth function of the parameters. If this is not true, the method does not work. For example, the following models do not work:

```
model y=a+int(b*x);

model y=a+b*x+4*(z>c);
```

Responding to Trouble

PROC NLIN does not necessarily produce a good solution the first time. Much depends on specifying good initial values for the parameters. You can specify a grid of values in the `PARMS` statement to search for good starting values. While most practical models should give you no trouble, other models can require switching to a different iteration method or a different computational method for matrix inversion. Specifying the option `METHOD=MARQUARDT` sometimes works when the default method (Gauss-Newton) does not work.

Computational Methods

Nonlinear Least Squares

Recall the basic notation for the nonlinear regression model from the section “[Notation for Nonlinear Regression Models](#)” on page 5255. The parameter vector β belongs to Ω , a subset of R^p . Two points of this set are of particular interest: the true value $\tilde{\beta}$ and the least squares estimate $\hat{\beta}$. The general nonlinear model fit with the NLIN procedure is represented by the equation

$$Y = f(\tilde{\beta}_0, \tilde{\beta}_1, \dots, \tilde{\beta}_p; z_1, z_2, \dots, z_k) + \epsilon = f(\tilde{\beta}; z_1, z_2, \dots, z_k) + \epsilon$$

where z_j denotes the $(n \times 1)$ vector of the j th regressor (independent) variable, $\tilde{\beta}$ is the true value of the parameter vector, and ϵ is the $(n \times 1)$ vector of homoscedastic and uncorrelated model errors with zero mean.

To write the model for the i th observation, the i th elements of $\mathbf{z}_1, \dots, \mathbf{z}_k$ are collected in the row vector \mathbf{z}'_i , and the model equation becomes

$$Y_i = f(\boldsymbol{\beta}; \mathbf{z}'_i) + \epsilon_i$$

The shorthand $f_i(\boldsymbol{\beta})$ will also be used throughout to denote the mean of the i th observation.

For any given value $\boldsymbol{\beta}$ we can compute the residual sum of squares

$$\begin{aligned} \text{SSE}(\boldsymbol{\beta}) &= \sum_{i=1}^n (y_i - f(\boldsymbol{\beta}; \mathbf{z}'_i))^2 \\ &= \sum_{i=1}^n (y_i - f_i(\boldsymbol{\beta}))^2 = \mathbf{r}(\boldsymbol{\beta})' \mathbf{r}(\boldsymbol{\beta}) \end{aligned}$$

The aim of nonlinear least squares estimation is to find the value $\hat{\boldsymbol{\beta}}$ that minimizes $\text{SSE}(\boldsymbol{\beta})$. Because \mathbf{f} is a nonlinear function of $\boldsymbol{\beta}$, a closed-form solution does not exist for this minimization problem. An iterative process is used instead. The iterative techniques that PROC NLIN uses are similar to a series of linear regressions involving the matrix \mathbf{X} and the residual vector $\mathbf{r} = \mathbf{y} - \mathbf{f}(\boldsymbol{\beta})$, evaluated at the current values of $\boldsymbol{\beta}$.

It is more insightful, however, to describe the algorithms in terms of their approach to minimizing the residual sum of squares and in terms of their updating formulas. If $\hat{\boldsymbol{\beta}}^{(u)}$ denotes the value of the parameter estimates at the u th iteration, and $\hat{\boldsymbol{\beta}}^{(0)}$ are your starting values, then the NLIN procedure attempts to find values k and $\boldsymbol{\Delta}$ such that

$$\hat{\boldsymbol{\beta}}^{(u+1)} = \hat{\boldsymbol{\beta}}^{(u)} + k \boldsymbol{\Delta}$$

and

$$\text{SSE}(\hat{\boldsymbol{\beta}}^{(u+1)}) < \text{SSE}(\hat{\boldsymbol{\beta}}^{(u)})$$

The various methods to fit a nonlinear regression model—which you can select with the `METHOD=` option in the `PROC NLIN` statement—differ in the calculation of the update vector $\boldsymbol{\Delta}$.

The gradient and Hessian of the residual sum of squares with respect to individual parameters and pairs of parameters are, respectively,

$$\begin{aligned} \mathbf{g}(\boldsymbol{\beta})_j &= \frac{\partial \text{SSE}(\boldsymbol{\beta})}{\partial \beta_j} = -2 \sum_{i=1}^n (y_i - f_i(\boldsymbol{\beta})) \frac{\partial f_i(\boldsymbol{\beta})}{\partial \beta_j} \\ [\mathbf{H}(\boldsymbol{\beta})]_{jk} &= \frac{\partial^2 \text{SSE}(\boldsymbol{\beta})}{\partial \beta_j \partial \beta_k} = 2 \sum_{i=1}^n \frac{\partial f_i(\boldsymbol{\beta})}{\partial \beta_j} \frac{\partial f_i(\boldsymbol{\beta})}{\partial \beta_k} - (y_i - f_i(\boldsymbol{\beta})) \frac{\partial^2 f_i(\boldsymbol{\beta})}{\partial \beta_j \partial \beta_k} \end{aligned}$$

Denote as $\mathbf{H}_i^*(\boldsymbol{\beta})$ the Hessian matrix of the mean function,

$$[\mathbf{H}_i^*(\boldsymbol{\beta})]_{jk} = \left[\frac{\partial^2 f_i(\boldsymbol{\beta})}{\partial \beta_j \partial \beta_k} \right]_{jk}$$

Collecting the derivatives across all parameters leads to the expressions

$$\mathbf{g}(\boldsymbol{\beta}) = \frac{\partial \text{SSE}(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} = -2\mathbf{X}'\mathbf{r}(\boldsymbol{\beta})$$

$$\mathbf{H}(\boldsymbol{\beta}) = \frac{\partial^2 \text{SSE}(\boldsymbol{\beta})}{\partial \boldsymbol{\beta} \partial \boldsymbol{\beta}'} = 2 \left(\mathbf{X}'\mathbf{X} - \sum_{i=1}^n r_i(\boldsymbol{\beta}) \mathbf{H}_i^*(\boldsymbol{\beta}) \right)$$

The change in the vector of parameter estimates is computed as follows, depending on the estimation method:

$$\text{Gauss-Newton: } \boldsymbol{\Delta} = (-\mathbf{E}[\mathbf{H}(\boldsymbol{\beta})])^{-1} \mathbf{g}(\boldsymbol{\beta}) = (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}'\mathbf{r}$$

$$\text{Marquardt: } \boldsymbol{\Delta} = (\mathbf{X}'\mathbf{X} + \lambda \text{diag}(\mathbf{X}'\mathbf{X}))^{-1} \mathbf{X}'\mathbf{r}$$

$$\text{Newton: } \boldsymbol{\Delta} = -\mathbf{H}(\boldsymbol{\beta})^{-1} \mathbf{g}(\boldsymbol{\beta}) = \mathbf{H}(\boldsymbol{\beta})^{-1} \mathbf{X}'\mathbf{r}$$

$$\text{Steepest descent: } \boldsymbol{\Delta} = -\frac{1}{2} \frac{\partial \text{SSE}(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} = \mathbf{X}'\mathbf{r}$$

The Gauss-Newton and Marquardt iterative methods regress the residuals onto the partial derivatives of the model with respect to the parameters until the estimates converge. You can view the Marquardt algorithm as a Gauss-Newton algorithm with a ridging penalty. The Newton iterative method regresses the residuals onto a function of the first and second derivatives of the model with respect to the parameters until the estimates converge. Analytical first- and second-order derivatives are automatically computed as needed.

The default method used to compute $(\mathbf{X}'\mathbf{X})^{-1}$ is the sweep (Goodnight 1979). It produces a reflexive generalized inverse (a g_2 -inverse, Pringle and Rayner 1971). In some cases it might be preferable to use a Moore-Penrose inverse (a g_4 -inverse) instead. If you specify the **G4** option in the **PROC NLIN** statement, a g_4 -inverse is used to calculate $\boldsymbol{\Delta}$ on each iteration.

The four algorithms are now described in greater detail.

Algorithmic Details

Gauss-Newton and Newton Methods

From the preceding set of equations you can see that the Marquardt method is a ridged version of the Gauss-Newton method. If the ridge parameter λ equals zero, the Marquardt step is identical to the Gauss-Newton step. An important difference between the Newton methods and the Gauss-Newton-type algorithms lies in the use of second derivatives. To motivate this distinctive element between Gauss-Newton and the Newton method, focus first on the objective function in nonlinear least squares. To numerically find the minimum of

$$\text{SSE}(\boldsymbol{\beta}) = \mathbf{r}(\boldsymbol{\beta})'\mathbf{r}(\boldsymbol{\beta})$$

you can approach the problem by approximating the sum of squares criterion by a criterion for which you can compute a closed-form solution. Following Seber and Wild (1989, Sect. 2.1.3), we can achieve that by doing the following:

- approximating the model and substituting the approximation into $SSE(\beta)$
- approximating $SSE(\beta)$ directly

The first method, approximating the nonlinear model with a first-order Taylor series, is the purview of the Gauss-Newton method. Approximating the residual sum of squares directly is the realm of the Newton method.

The first-order Taylor series of the residual $r(\beta)$ at the point $\hat{\beta}$ is

$$r(\beta) \approx r(\hat{\beta}) - \hat{X}(\beta - \hat{\beta})$$

Substitution into $SSE(\beta)$ leads to the objective function for the Gauss-Newton step:

$$SSE(\beta) \approx S_G(\beta) = r(\hat{\beta})' - 2r'(\hat{\beta})\hat{X}(\beta - \hat{\beta}) + (\beta - \hat{\beta})'(\hat{X}'\hat{X})(\beta - \hat{\beta})$$

“Hat” notation is used here to indicate that the quantity in question is evaluated at $\hat{\beta}$.

To motivate the Newton method, take a second-order Taylor series of $SSE(\beta)$ around the value $\hat{\beta}$:

$$SSE(\beta) \approx S_N(\beta) = SSE(\hat{\beta}) + g(\hat{\beta})'(\beta - \hat{\beta}) + \frac{1}{2}(\beta - \hat{\beta})'H(\hat{\beta})(\beta - \hat{\beta})$$

Both $S_G(\beta)$ and $S_N(\beta)$ are quadratic functions in β and are easily minimized. The minima occur when

$$\text{Gauss-Newton: } \beta - \hat{\beta} = (\hat{X}'\hat{X})^{-1} \hat{X}'r(\hat{\beta})$$

$$\text{Newton: } \beta - \hat{\beta} = -H(\hat{\beta})^{-1}g(\hat{\beta})$$

and these terms define the preceding Δ update vectors.

Gauss-Newton Method

Since the Gauss-Newton method is based on an approximation of the model, you can also derive the update vector by first considering the “normal” equations of the nonlinear model

$$X'f(\beta) = X'Y$$

and then substituting the Taylor approximation

$$f(\beta) \approx f(\hat{\beta}) + X(\beta - \hat{\beta})$$

for $f(\beta)$. This leads to

$$X'(f(\hat{\beta}) + X(\beta - \hat{\beta})) = X'Y$$

$$(X'X)(\beta - \hat{\beta}) = X'Y - X'f(\hat{\beta})$$

$$(X'X)\Delta = X'r(\hat{\beta})$$

and the update vector becomes

$$\Delta = (X'X)^{-1} X'r(\hat{\beta})$$

NOTE: If $X'X$ is singular or becomes singular, PROC NLIN computes Δ by using a generalized inverse for the iterations after singularity occurs. If $X'X$ is still singular for the last iteration, the solution should be examined.

Newton Method

The Newton method uses the second derivatives and solves the equation

$$\Delta = H^{-1}X'r$$

If the automatic variables `_WEIGHT_`, `_WGTJPJ_`, and `_RESID_` are used, then

$$\Delta = H^{-1}X'W^{SSE}r^*$$

is the direction, where

$$H = X'W^{XPX}X - \sum_{i=1}^n H_i^*(\beta)w_i^{XPX}r_i^*$$

and

W^{SSE} is an $n \times n$ diagonal matrix with elements w_i^{SSE} of weights from the `_WEIGHT_` variable. Each element w_i^{SSE} contains the value of `_WEIGHT_` for the i th observation.

W^{XPX} is an $n \times n$ diagonal matrix with elements w_i^{XPX} of weights from the `_WGTJPJ_` variable. Each element w_i^{XPX} contains the value of `_WGTJPJ_` for the i th observation.

r^* is a vector with elements r_i^* from the `_RESID_` variable. Each element r_i^* contains the value of `_RESID_` evaluated for the i th observation.

Marquardt Method

The updating formula for the Marquardt method is as follows:

$$\Delta = (X'X + \lambda \text{diag}(X'X))^{-1}X'e$$

The Marquardt method is a compromise between the Gauss-Newton and steepest descent methods (Marquardt 1963). As $\lambda \rightarrow 0$, the direction approaches Gauss-Newton. As $\lambda \rightarrow \infty$, the direction approaches steepest descent.

Marquardt's studies indicate that the average angle between Gauss-Newton and steepest descent directions is about 90° . A choice of λ between 0 and infinity produces a compromise direction.

By default, PROC NLIN chooses $\lambda = 10^{-7}$ to start and computes Δ . If $SSE(\beta_0 + \Delta) < SSE(\beta_0)$, then $\lambda = \lambda/10$ for the next iteration. Each time $SSE(\beta_0 + \Delta) > SSE(\beta_0)$, then $\lambda = 10\lambda$.

NOTE: If the SSE decreases on each iteration, then $\lambda \rightarrow 0$, and you are essentially using the Gauss-Newton method. If SSE does not improve, then λ is increased until you are moving in the steepest descent direction.

Marquardt's method is equivalent to performing a series of ridge regressions, and it is useful when the parameter estimates are highly correlated or the objective function is not well approximated by a quadratic.

Steepest Descent (Gradient) Method

The steepest descent method is based directly on the gradient of $0.5r(\beta)'r(\beta)$:

$$\frac{1}{2} \frac{\partial SSE(\beta)}{\partial \beta} = -X'r$$

The quantity $-\mathbf{X}'\mathbf{r}$ is the gradient along which $\epsilon'\epsilon$ increases. Thus $\mathbf{\Delta} = \mathbf{X}'\mathbf{r}$ is the direction of steepest descent.

If the automatic variables `_WEIGHT_` and `_RESID_` are used, then

$$\mathbf{\Delta} = \mathbf{X}'\mathbf{W}^{\text{SSE}}\mathbf{r}^*$$

is the direction, where

\mathbf{W}^{SSE} is an $n \times n$ diagonal matrix with elements w_i^{SSE} of weights from the `_WEIGHT_` variable. Each element w_i^{SSE} contains the value of `_WEIGHT_` for the i th observation.

\mathbf{r}^* is a vector with elements r_i^* from `_RESID_`. Each element r_i^* contains the value of `_RESID_` evaluated for the i th observation.

Using the method of steepest descent, let

$$\boldsymbol{\beta}^{(k+1)} = \boldsymbol{\beta}^{(k)} + \alpha \mathbf{\Delta}$$

where the scalar α is chosen such that

$$\text{SSE}(\boldsymbol{\beta}_i + \alpha \mathbf{\Delta}) < \text{SSE}(\boldsymbol{\beta}_i)$$

NOTE: The steepest-descent method can converge very slowly and is therefore not generally recommended. It is sometimes useful when the initial values are poor.

Step-Size Search

The default method of finding the step size k is step halving by using `SMETHOD=HALVE`. If $\text{SSE}(\boldsymbol{\beta}^{(u)} + \mathbf{\Delta}) > \text{SSE}(\boldsymbol{\beta}^{(u)})$, compute $\text{SSE}(\boldsymbol{\beta}^{(u)} + 0.5\mathbf{\Delta})$, $\text{SSE}(\boldsymbol{\beta}^{(u)} + 0.25\mathbf{\Delta})$, \dots , until a smaller SSE is found.

If you specify `SMETHOD=GOLDEN`, the step size k is determined by a golden section search. The parameter `TAU` determines the length of the initial interval to be searched, with the interval having length `TAU` (or $2 \times \text{TAU}$), depending on $\text{SSE}(\boldsymbol{\beta}^{(u)} + \mathbf{\Delta})$. The `RHO` parameter specifies how fine the search is to be. The SSE at each endpoint of the interval is evaluated, and a new subinterval is chosen. The size of the interval is reduced until its length is less than `RHO`. One pass through the data is required each time the interval is reduced. Hence, if `RHO` is very small relative to `TAU`, a large amount of time can be spent determining a step size. For more information about the golden section search, see Kennedy and Gentle (1980).

If you specify `SMETHOD=CUBIC`, the NLIN procedure performs a cubic interpolation to estimate the step size. If the estimated step size does not result in a decrease in SSE, step halving is used.

Output Data Sets

The data set produced by the `OUTEST=` option in the `PROC NLIN` statement contains the parameter estimates on each iteration, including the grid search.

The variable `_ITER_` contains the iteration number. The variable `_TYPE_` denotes whether the observation contains iteration parameter estimates (“ITER”), final parameter estimates (“FINAL”), or covariance estimates (“COVB”). The variable `_NAME_` contains the parameter name for covariances, and the variable

`_SSE_` contains the objective function value for the parameter estimates. The variable `_STATUS_` indicates whether the estimates have converged.

The data set produced by the `OUTPUT` statement contains statistics calculated for each observation. In addition, the data set contains the variables from the input data set and any `ID` variables that are specified in the `ID` statement.

The data set that is produced by the `PROFDATA=` option in the `PROFILE` statement contains statistics that are calculated during parameter profiling. The variable `_TYPE_` denotes whether the observation is from a profiling task (set as `PROF`) or jackknife resampling task (set as `JACK`). The variable `_PROF_PARM_` refers to the name of the profiled parameter for profiling tasks. The variable `_OBS_INF_MEAS_` is the observation index of the deleted observation for jackknife resampling tasks, and the variables `_L_STAT_` and `_W_STAT_` contain the likelihood ratio pivotal statistic and the Wald pivotal statistic, respectively. The rest of the variables are the parameter estimates.

Confidence Intervals

Parameter Confidence Intervals

The parameter confidence intervals are computed using the Wald-based formula:

$$\hat{\beta}_i \pm \text{stderr}_i \times t(n - p, 1 - \alpha/2)$$

where $\hat{\beta}_i$ is the i th parameter estimate, stderr_i is its estimated approximate standard error, $t(n - p, 1 - \alpha/2)$ is a t statistic with $n - p$ degrees of freedom, n is the number of observations, and p is the number of parameters. You can specify the significance level α used in the construction of these confidence limits with the `ALPHA=` option in the `PROC NLIN` statement; the default value is $\alpha = 0.05$. Because Wald-based confidence intervals are only asymptotically valid, you should use confidence curves for a more accurate and complete inference on confidence intervals. See the section “[Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates](#)” on page 5290 for details.

Model Confidence Intervals

Model confidence intervals are output when an `OUT=` data set is specified and one or more of the keywords `LCLM`, `UCLM`, `LCL`, `UCL`, `L95M=`, `U95M=`, `L95=`, and `U95=` is specified. The expressions for these terms are as follows:

$$\text{LCLM} = f(\boldsymbol{\beta}, \mathbf{z}_i) - \sqrt{\text{MSE} \times h_i / w_i} \times t(n - p, 1 - \alpha/2)$$

$$\text{UCLM} = f(\boldsymbol{\beta}, \mathbf{z}_i) + \sqrt{\text{MSE} \times h_i / w_i} \times t(n - p, 1 - \alpha/2)$$

$$\text{LCL} = f(\boldsymbol{\beta}, \mathbf{z}_i) - \sqrt{\text{MSE}(h_i + 1/w_i)} \times t(n - p, 1 - \alpha/2)$$

$$\text{UCL} = f(\boldsymbol{\beta}, \mathbf{z}_i) + \sqrt{\text{MSE}(h_i + 1/w_i)} \times t(n - p, 1 - \alpha/2)$$

$$\text{L95M} = f(\boldsymbol{\beta}, \mathbf{z}_i) - \sqrt{\text{MSE} \times h_i / w_i} \times t(n - p, 1 - 0.05/2)$$

$$\text{U95M} = f(\boldsymbol{\beta}, \mathbf{z}_i) + \sqrt{\text{MSE} \times h_i / w_i} \times t(n - p, 1 - 0.05/2)$$

$$\text{L95} = f(\boldsymbol{\beta}, \mathbf{z}_i) - \sqrt{\text{MSE}(h_i + 1/w_i)} \times t(n - p, 1 - 0.05/2)$$

$$\text{U95} = f(\boldsymbol{\beta}, \mathbf{z}_i) + \sqrt{\text{MSE}(h_i + 1/w_i)} \times t(n - p, 1 - 0.05/2)$$

where $h_i = w_i x_i (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \mathbf{x}_i'$ is the leverage, $\mathbf{X} = \partial \mathbf{f} / \partial \boldsymbol{\beta}$, and \mathbf{x}_i is the i th row of \mathbf{X} . These results are derived for linear systems. The intervals are approximate for nonlinear models. The value α in the preceding formulas for **LCLM**, **UCLM**, **LCL**, and **UCL** can be set with the **ALPHA=** option in the **PROC NLIN** statement or with the **ALPHA=** option in the **OUTPUT** statement. If both **ALPHA=** options are specified, the option in the **OUTPUT** takes precedence.

Covariance Matrix of Parameter Estimates

For unconstrained estimates (no active bounds), the covariance matrix of the parameter estimates is

$$\text{mse} \times (\mathbf{X}'\mathbf{X})^{-1}$$

for the gradient, Marquardt, and Gauss methods and

$$\text{mse} \times \mathbf{H}^{-1}$$

for the Newton method. Recall that \mathbf{X} is the matrix of the first partial derivatives of the nonlinear model with respect to the parameters. The matrices are evaluated at the final parameter estimates. The mean squared error, the estimate of the residual variance σ^2 , is computed as

$$\text{mse} = \mathbf{r}'\mathbf{r} / (n - p)$$

where n is the number of nonmissing (used) observations and p is the number of estimable parameters. The standard error reported for the parameter estimates is the square root of the corresponding diagonal element of this matrix. If you specify a value for the residual variance with the **SIGSQ=** option, then that value replaces mse in the preceding expressions.

Now suppose that restrictions or bounds are active. Equality restrictions can be written as a vector function, $h(\boldsymbol{\theta}) = \mathbf{0}$. Inequality restrictions are either active or inactive. When an inequality restriction is active, it is treated as an equality restriction.

Assume that the vector $h(\boldsymbol{\theta})$ contains the current active restrictions. The constraint matrix \mathbf{A} is then

$$\mathbf{A}(\hat{\boldsymbol{\theta}}) = \frac{\partial h(\hat{\boldsymbol{\theta}})}{\partial \hat{\boldsymbol{\theta}}}$$

The covariance matrix for the restricted parameter estimates is computed as

$$\mathbf{Z}(\mathbf{Z}'\mathbf{H}\mathbf{Z})^{-1}\mathbf{Z}'$$

where \mathbf{H} is the Hessian (or approximation to the Hessian) and \mathbf{Z} collects the last $(p - n_c)$ columns of \mathbf{Q} from an LQ factorization of the constraint matrix. Further, n_c is the number of active constraints, and p denotes the number of parameters. See Gill, Murray, and Wright (1981) for more details about the LQ factorization. The covariance matrix for the Lagrange multipliers is computed as

$$(\mathbf{A}\mathbf{H}^{-1}\mathbf{A}')^{-1}$$

Convergence Measures

The NLIN procedure computes and reports four convergence measures, labeled R, PPC, RPC, and OBJECT.

R is the primary convergence measure for the parameters. It measures the degree to which the residuals are orthogonal to the columns of \mathbf{X} , and it approaches 0 as the gradient of the objective function becomes small. R is defined as

$$\sqrt{\frac{\mathbf{r}'\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{r}}{\text{LOSS}^i}}$$

PPC is the prospective parameter change measure. PPC measures the maximum relative change in the parameters implied by the parameter-change vector computed for the next iteration. At the k th iteration, PPC is the maximum over the parameters

$$\frac{|\widehat{\theta}_i^{(k+1)} - \widehat{\theta}_i^{(k)}|}{|\widehat{\theta}_i^{(k)}| + 1\text{E} - 6}$$

where $\widehat{\theta}_i^{(k)}$ is the current value of the i th parameter and $\widehat{\theta}_i^{(k+1)}$ is the prospective value of this parameter after adding the change vector computed for the next iteration. These changes are measured before step length adjustments are made. The parameter with the maximum prospective relative change is displayed with the value of PPC, unless the PPC is nearly 0.

RPC is the retrospective parameter change measure. RPC measures the maximum relative change in the parameters from the previous iteration. At the k th iteration, RPC is the maximum over i of

$$\frac{|\widehat{\theta}_i^{(k)} - \widehat{\theta}_i^{(k-1)}|}{|\widehat{\theta}_i^{(k-1)}| + 1\text{E} - 6}$$

where $\widehat{\theta}_i^{(k)}$ is the current value of the i th parameter and $\widehat{\theta}_i^{(k-1)}$ is the previous value of this parameter. These changes are measured before step length adjustments are made. The name of the parameter with the maximum retrospective relative change is displayed with the value of RPC, unless the RPC is nearly 0.

OBJECT measures the relative change in the objective function value between iterations:

$$\frac{|O^{(k)} - O^{(k-1)}|}{|O^{(k-1)}| + 1\text{E} - 6}$$

where $O^{(k-1)}$ is the value of the objective function ($O^{(k)}$) from the previous iteration. This is the old **CONVERGEOBJ=** criterion.

Displayed Output

In addition to the output data sets, PROC NLIN also produces the following output objects:

- the residual sums of squares associated with all or some of the combinations of possible starting values of the parameters
- the estimates of the parameters and the residual sums of squares at each iteration
- the estimation summary table, which displays information about the estimation method, the number of observations in the analysis, the objective function, and convergence measures
- the analysis of variance table, including sums of squares for the “Model,” “Residual,” and “Total” sources of variation (“Corrected Total” or “Uncorrected Total”), and the model F test. Note that beginning in SAS[®] 9, only the uncorrected total SS is reported and the respective F test is based on the uncorrected total SS if PROC NLIN determines the model does not include an intercept. If PROC NLIN determines the model does include an intercept, only the corrected total SS is reported and the respective F test is based on the corrected total SS.
- the table of parameter estimates, which contains for each parameter in the model its estimate, the approximate standard error of the estimate, and a 95% confidence interval based on the approximate standard error. The confidence level can be changed with the [ALPHA=](#) option in the [PROC NLIN](#) statement. The [HOUGAARD](#) option in the [PROC NLIN](#) statement requests that Hougaard’s skewness measure be added for each parameter. The standard errors and confidence limits are labeled approximate because they are valid asymptotically as the number of observations grows. If your model is linear in the parameters, the standard errors and confidence intervals are not approximate.
- the approximate correlation matrix of the parameter estimates. This correlation matrix is labeled approximate because it is computed from the approximate covariance matrix of the parameter estimates. If your model is linear in the parameters, the correlation matrix is not approximate.

Incompatibilities with SAS 6.11 and Earlier Versions of PROC NLIN

The NLIN procedure now uses a compiler that is different from the DATA step compiler. The compiler was changed so that analytical derivatives could be computed automatically. For the most part, the syntax accepted by the old NLIN procedure can be used in the new NLIN procedure. However, there are several differences that should be noted:

- You cannot specify a character index variable in the DO statement, and you cannot specify a character test in the IF statement. Thus `do i=1,2,3;` is supported, but `do i='ONE','TWO','THREE';` is not supported. And `if 'THIS' < 'THAT' then ...;` is supported, but `if 'THIS' THEN ...;` is not supported.
- The PUT statement, which is used mostly for program debugging in PROC NLIN, supports only some of the features of the DATA step PUT statement, and it has some new features that the DATA step PUT statement does not.

- The PUT statement does not support line pointers, factored lists, iteration factors, overprinting, the `_INFILE_` option, the `‘:’` format modifier, or the symbol `‘$’`.
 - The PUT statement does support expressions inside of parentheses. For example, `put (sqrt(x));` produces the square root of X.
 - The PUT statement also supports the option `_PDV_` to display a formatted listing of all the variables in the program. The statement `put _pdv_;` prints a much more readable listing of the variables than `put _all_;` does.
- You cannot use the `‘*’` subscript, but you can specify an array name in a PUT statement without subscripts. Thus, `array a ...; put a;` is acceptable, but `put a[*];` is not. The statement `put a;` displays all the elements of the array a. The `put a=;` statement displays all the elements of A with each value labeled by the name of the element variable.
 - You cannot specify arguments in the ABORT statement.
 - You can specify more than one target statement in the WHEN and OTHERWISE statements. That is, DO/END groups are not necessary for multiple WHEN statements, such as `select; when(exp1); stmt1; stmt2; when(exp2); stmt3; stmt4; end;.`
 - You can specify only the options LOG, PRINT, and LIST in the FILE statement.
 - The RETAIN statement retains only values across one pass through the data set. If you need to retain values across iterations, use the CONTROL statement to make a control variable.

The ARRAY statement in PROC NLIN is similar to, but not the same as, the ARRAY statement in the DATA step. The ARRAY statement is used to associate a name (of no more than 8 characters) with a list of variables and constants. The array name can then be used with subscripts in the program to refer to the items in the list.

The ARRAY statement supported by PROC NLIN does not support all the features of the DATA step ARRAY statement. You cannot specify implicit indexing variables; all array references must have explicit subscript expressions. You can specify simple array dimensions; lower bound specifications are not supported. A maximum of six dimensions are accepted.

On the other hand, the ARRAY statement supported by PROC NLIN does accept both variables and constants as array elements. In the following statements, b is a constant array and c is a variable array. Note that the constant array elements cannot be changed with assignment statements.

```
proc nlin data=nld;
array b[4] 1 2 3 4;      /* Constant array */
array c[4] ( 1 2 3 4 ); /* Numeric array with initial values */

b[1] = 2;                /* This is an ERROR, b is a constant array*/
c[2] = 7.5;              /* This is allowed */
```

Both dimension specification and the list of elements are optional, but at least one must be specified. When the list of elements is not specified, or fewer elements than the size of the array are listed, array variables are created by suffixing element numbers to the array name to complete the element list.

If the array is used as a pure array in the program rather than a list of symbols (the individual symbols of the array are not referenced in the code), the array is converted to a numerical array. A pure array is literally

a vector of numbers that are accessed only by index. Using these types of arrays results in faster derivatives and compiled code. The assignment to `c1` in the following statements forces the array to be treated as a list of symbols:

```
proc nlin data=nld;
array c[4] ( 1 2 3 4 ); /* Numeric array with initial values */

c[2] = 7.5;              /* This is C used as a pure array */
c1 = -92.5;              /* This forces C to be a list of symbols */
```

ODS Table Names

PROC NLIN assigns a name to each table it creates. You can use these names to refer to the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 63.7](#). For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 63.7 ODS Tables Produced by PROC NLIN

ODS Table Name	Description	Statement
ANOVA	Analysis of variance	default
CodeDependency	Variable cross reference	LISTDEP
CodeList	Listing of program statements	LISTCODE
ConvergenceStatus	Convergence status	default
CorrB	Correlation of the parameters	default
EstSummary	Summary of the estimation	default
FirstDerivatives	First derivative table	LISTDER
IterHistory	Iteration output	default
MissingValues	Missing values generated by the program	default
NonlinearityMeasures	Global nonlinearity measures	NLINMEASURES
ParameterEstimates	Parameter estimates	default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

PROC NLIN assigns a name to each graph it creates using ODS. You can use these names to refer to the graphs when using ODS. The graphs that are controlled by the **PLOTS** option in the **PROC NLIN** statement are listed in Table 63.8 and those that are controlled by the options in **PROFILE** statement are in Table 63.9.

Table 63.8 Graphs Controlled by the PLOTS option in the PROC NLIN Statement

ODS Graph Name	Plot Description	PLOTS Option
ContourFitPlot	Contour fit plot for models with two regressors	FIT
FitPlot	Fit plot for models with one regressor	FIT
FitDiagnosticsPanel	Panel of fit diagnostics	DIAGNOSTICS
LeveragePlot	Tangential and Jacobian leverages versus observation number	DIAGNOSTICS
LocalInfluencePlot	Local influence versus observation number	DIAGNOSTICS
ObservedByPredictedPlot	Dependent variable versus predicted values	DIAGNOSTICS(UNPACK)
ProjectedResidualHistogram	A histogram of the projected residuals	DIAGNOSTICS(UNPACK)
RawResidualExpectationPlot	Raw residual expectation versus predicted values	DIAGNOSTICS(UNPACK)
RawResidualHistogram	A histogram of the raw residuals	DIAGNOSTICS(UNPACK)
ResidualBoxPlot	A box plot of the raw and projected residuals	DIAGNOSTICS(UNPACK)
ResidualPanel	A panel of the raw and projected residuals versus the regressors	RESIDUALS
ResidualPlot	A plot of the raw and projected residuals versus the regressors	RESIDUALS(UNPACK)
ResidualByPredictedPlot	Raw and projected residuals versus the predicted values	DIAGNOSTICS(UNPACK)
RStudentByJacLeveragePlot	Standardized raw and projected residuals versus Jacobian leverage	DIAGNOSTICS(UNPACK)
RStudentByPredictedPlot	Standardized raw and projected residuals versus the predicted values	DIAGNOSTICS(UNPACK)
RStudentByTanLeveragePlot	Standardized raw and projected residuals versus tangential leverage	DIAGNOSTICS(UNPACK)

Table 63.9 Graphs Controlled by the PROFILE Statement

ODS Graph Name	Plot Description	PROFILE Option
ConfidenceCurve	Parameter value versus t value	CONF CURV
JackknifePlot	Absolute relative percentage difference versus observation number	JACKKNIFE
ProfiletPlot	Likelihood ratio pivotal statistic versus Wald pivotal statistic	TPLOT

Convergence Status Table

The “Convergence Status” table can be used to programmatically check the status of an estimation. This table contains the Status variable that takes on the value 0, 1, 2, or 3. If Status takes on a value less than 3, the convergence criterion was met. Specifically, the values mean the following:

Status=0	indicates that the convergence criterion was met and no warning or error messages were issued during the PROC NLIN run. Also, no notes that could indicate a problem with the model were issued.
Status=1	indicates that the convergence criterion was met and notes were written to the log that might indicate a problem with the model.
Status=2	indicates that the convergence criterion was met and one or more warning messages were produced during the PROC NLIN run.
Status=3	indicates that the convergence criterion was not met.

The following sample program demonstrates how the “Convergence Status” table can be used:

```
ods output ConvergenceStatus=ConvStatus;
proc nlin data=YourData;
  parameters a=1 b=1 c=1;
  model wgt = a + x / (b*y+c*z);
run;

data _null_;
  set ConvStatus;
  if status > 0 then put "A problem occurred";
run;
```

Examples: NLIN Procedure

Example 63.1: Segmented Model

Suppose you are interested in fitting a model that consists of two segments that connect in a smooth fashion. For example, the following model states that for values of x less than x_0 the mean of Y is a quadratic function in x , and for values of x greater than x_0 the mean of Y is constant:

$$E[Y|x] = \begin{cases} \alpha + \beta x + \gamma x^2 & \text{if } x < x_0 \\ c & \text{if } x \geq x_0 \end{cases}$$

In this model equation α , β , and γ are the coefficients of the quadratic segment, and c is the plateau of the mean function. The NLIN procedure can fit such a segmented model even when the join point, x_0 , is unknown.

We also want to impose conditions on the two segments of the model. First, the curve should be continuous—that is, the quadratic and the plateau section need to meet at x_0 . Second, the curve should be smooth—that is, the first derivative of the two segments with respect to x need to coincide at x_0 .

The continuity condition requires that

$$p = E[Y|x_0] = \alpha + \beta x_0 + \gamma x_0^2$$

The smoothness condition requires that

$$\frac{\partial E[Y|x_0]}{\partial x} = \beta + 2\gamma x_0 \equiv 0$$

If you solve for x_0 and substitute into the expression for c , the two conditions jointly imply that

$$x_0 = -\beta/2\gamma$$

$$c = \alpha - \beta^2/4\gamma$$

Although there are apparently four unknowns, the model contains only three parameters. The continuity and smoothness restrictions together completely determine one parameter given the other three.

The following DATA step creates the SAS data set for this example:

```
data a;
  input y x @@;
  datalines;
.46 1  .47 2  .57 3  .61 4  .62 5  .68 6  .69 7
.78 8  .70 9  .74 10 .77 11 .78 12 .74 13 .80 13
.80 15 .78 16
;
```

The following PROC NLIN statements fit this segmented model:

```
title 'Quadratic Model with Plateau';
proc nlin data=a;
  parms alpha=.45 beta=.05 gamma=-.0025;

  x0 = -.5*beta / gamma;

  if (x < x0) then
    mean = alpha + beta*x + gamma*x*x;
  else mean = alpha + beta*x0 + gamma*x0*x0;
  model y = mean;

  if _obs_=1 and _iter_= . then do;
    plateau =alpha + beta*x0 + gamma*x0*x0;
    put / x0= plateau= ;
  end;
  output out=b predicted=yp;
run;
```

The parameters of the model are α , β , and γ , respectively. They are represented in the PROC NLIN statements by the variables alpha, beta, and gamma, respectively. In order to model the two segments, a conditional statement is used that assigns the appropriate expression to the mean function depending on the value of x_0 . A PUT statement is used to print the constrained parameters every time the program is executed for the first observation. The [OUTPUT](#) statement computes predicted values for plotting and saves them to data set b.

Note that there are other ways in which you can write the conditional expressions for this model. For example, you could formulate a condition with two model statements, as follows:

```
proc nlin data=a;
  parms alpha=.45 beta=.05 gamma=-.0025;
  x0 = -.5*beta / gamma;
  if (x < x0) then
    model y = alpha+beta*x+gamma*x*x;
  else model y = alpha+beta*x0+gamma*x0*x0;
run;
```

Or you could use a single expression with a conditional evaluation, as in the following statements:

```
proc nlin data=a;
  parms alpha=.45 beta=.05 gamma=-.0025;
  x0 = -.5*beta / gamma;
  model y = (x <x0)*(alpha+beta*x +gamma*x*x) +
            (x>=x0)*(alpha+beta*x0+gamma*x0*x0);
run;
```

The results from fitting this model with PROC NLIN are shown in [Output 63.1.1–Output 63.1.3](#). The iterative optimization converges after six iterations ([Output 63.1.1](#)). [Output 63.1.1](#) indicates that the join point is 12.747 and the plateau value is 0.777.

  scatter y=y x=x;
  series y=yp x=x;
run;
```

Output 63.1.4 Observed and Predicted Values for the Quadratic Model

If you want to estimate the join point directly, you can use the relationship between the parameters to change the parameterization of the model in such a way that the mean function depends directly on x_0 . Using the smoothness condition that relates x_0 to γ ,

$$x_0 = -\beta/2\gamma$$

you can express γ as a function of β and x_0 :

$$\gamma = -\beta/(2x_0)$$

Substituting for γ in the model equation

$$E[Y|x] = \begin{cases} \alpha + \beta x + \gamma x^2 & \text{if } x < x_0 \\ \alpha - \beta^2/(4\gamma) & \text{if } x \geq x_0 \end{cases}$$

yields the reparameterized model

$$E[Y|x] = \begin{cases} \alpha + \beta x(1 - x/(2x_0)) & \text{if } x < x_0 \\ \alpha + \beta x_0/2 & \text{if } x \geq x_0 \end{cases}$$

This model is fit with the following PROC NLIN statements:

```

proc nlin data=a;
  parms alpha=.45 beta=.05 x0=10;
  if (x<x0) then
    mean = alpha + beta*x *(1-x/(2*x0));
  else mean = alpha + beta*x0/2;
  model y = mean;
run;

```

Output 63.1.5 Results from Reparameterized Model

The analysis of variance table in the reparameterized model is the same as in the earlier analysis (compare [Output 63.1.5](#) and [Output 63.1.3](#)). Changing the parameterization of a model does not affect the fit. The “Parameter Estimates” table now shows x_0 as a parameter in the model. The estimate agrees with the earlier result that uses the PUT statement ([Output 63.1.2](#)). Since x_0 is now a model parameter, the NLIN procedure also reports its asymptotic standard error and its approximate 95% confidence interval.

Example 63.2: Iteratively Reweighted Least Squares

With the NLIN procedure you can perform weighted nonlinear least squares regression in situations where the weights are functions of the parameters. To minimize a weighted sum of squares, you assign an expression to the `_WEIGHT_` variable in your PROC NLIN statements. When the `_WEIGHT_` variable depends on the model parameters, the estimation technique is known as iteratively reweighted least squares (IRLS). In this situation you should employ the `NOHALVE` option in the `PROC NLIN` statement. Because the weights change from iteration to iteration, it is not reasonable to expect the *weighted* residual sum of squares to decrease between iterations. The `NOHALVE` option removes that restriction.

Examples where IRLS estimation is used include robust regression via M-estimation (Huber 1964, 1973), generalized linear models (McCullagh and Nelder 1989), and semivariogram fitting in spatial statistics (Schabenberger and Pierce 2002, Sect. 9.2). There are dedicated SAS/STAT procedures for robust regression (the `ROBUSTREG` procedure) and generalized linear models (the `GENMOD` and `GLIMMIX` procedures). Examples of weighted least squares fitting of a semivariogram function can be found in Chapter 102, “[The VARIOGRAM Procedure](#).”

In this example we show an application of PROC NLIN for M-estimation only to illustrate the connection between robust regression and weighted least squares. The `ROBUSTREG` procedure is the appropriate tool to fit these models with SAS/STAT software.

M-estimation was introduced by Huber (1964, 1973) to estimate location parameters robustly. Beaton and Tukey (1974) applied the idea of M-estimation in regression models and introduced the biweight (or bisquare) weight function. See Holland and Welsch (1977) for this and other robust methods. Consider a linear regression model of the form

$$E[Y_i|x] = \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i$$

In weighted least squares estimation you seek the parameters $\hat{\boldsymbol{\beta}}$ that minimize

$$\sum_{i=1}^n w_i (y_i - \mathbf{x}_i' \boldsymbol{\beta})^2 = \sum_{i=1}^n w_i e_i^2$$

where w_i is the weight associated with the i th observation. The *normal* equations of this minimization problem can be written as

$$\sum_{i=1}^n w_i e_i \mathbf{x}_i = \mathbf{0}$$

In M-estimation the corresponding equations take on the form

$$\sum_{i=1}^n \psi(e_i) \mathbf{x}_i = \mathbf{0}$$

where $\psi(\cdot)$ is a weighing function. The Beaton-Tukey biweight, for example, can be written as

$$\psi(e_i) = \begin{cases} e_i \left(1 - \left(\frac{e_i}{\sigma k}\right)^2\right)^2 & |e_i/\sigma| \leq k \\ 0 & |e_i/\sigma| > k \end{cases}$$

Substitution into the estimating equation for M-estimation yields weighted least squares equations

$$\sum_{i=1}^n \psi(e_i) \mathbf{x}_i = \sum_{i=1}^n w_i e_i \mathbf{x}_i = \mathbf{0}$$

$$w_i = \begin{cases} \left(1 - \left(\frac{e_i}{\sigma k}\right)^2\right)^2 & |e_i/\sigma| \leq k \\ 0 & |e_i/\sigma| > k \end{cases}$$

The biweight function involves two constants, σ and k . The scale σ can be fixed or estimated from the fit in the previous iteration. If σ is estimated, a robust estimator of scale is typically used. In this example σ is fixed at 2. A common value for the constant k is $k = 4.685$.

The following DATA step creates a SAS data set of the population of the United States (in millions), recorded at 10-year intervals starting in 1790 and ending in 1990. The aim is to fit a quadratic linear model to the population over time.

```
title 'U.S. Population Growth';

226542 248710
;
```

The PROC NLIN code that follows fits this linear model by M-estimation and IRLS. The weight function is set to a zero or nonzero value depending on the value of the scaled residual. The **NOHALVE** option removes the requirement that the (weighted) residual sum of squares must decrease between iterations.

```
title 'Beaton/Tukey Biweight Robust Regression using IRLS';
proc nlin data=uspop nohalve;
    parms b0=20450.43 b1=-22.7806 b2=.0063456;
    model pop=b0+b1*year+b2*year*year;
    resid = pop-model.pop;
    sigma = 2;
    k      = 4.685;
    if abs(resid/sigma)<=k then _weight_=(1-(resid / (sigma*k))**2)**2;
    else _weight_=0;
    output out=c r=rbi;
run;
```

Parameter estimates from this fit are shown in [Output 63.2.1](#), and the computed weights at the final iteration are displayed in [Output 63.2.2](#). The observations for 1940 and 1950 are highly discounted because of their large residuals.

21	248.710	1990	3960100	-1.33067	2	4.685	0.96007

You can obtain this analysis more conveniently with PROC ROBUSTREG. The procedure re-estimates the scale parameter robustly between iterations. To obtain an analysis with a fixed scale parameter as in this example, use the following PROC ROBUSTREG statements:

```

proc robustreg data=uspop method=m(scale=2);
  model pop = year year*year;
  output out=weights weight=w;
run;

proc print data=weights;
run;

```

Note that the computation of standard errors in the ROBUSTREG procedure is different from the calculations in the NLIN procedure.

Example 63.3: Probit Model with Likelihood Function

The data in this example, taken from Lee (1974), consist of patient characteristics and a variable indicating whether cancer remission occurred. This example demonstrates how to use PROC NLIN with a likelihood function. In this case, twice the negative of the log-likelihood function is to be minimized. This is the objective function for the analysis:

$$-2 \log L = -2 \sum_{i=1}^n \log \{ \pi_i(y_i, \mathbf{x}_i) \}$$

In this expression, π_i denotes the success probability of the n Bernoulli trials, and $\log L$ is the log likelihood of n independent binary (Bernoulli) observations. The probability π_i depends on the observations through the linear predictor η_i ,

$$\pi_i(y_i, \mathbf{x}_i) = \begin{cases} 1 - \Phi(\eta_i) & y_i = 1 \\ \Phi(\eta_i) & y_i = 0 \end{cases}$$

The linear predictor takes the form of a regression equation that is linear in the parameters,

$$\eta_i = \beta_0 + \beta_1 z_{1i} + \beta_2 z_{2i} + \cdots \beta_k z_{ki} = \mathbf{z}_i \boldsymbol{\beta}$$

Despite this linearity of η in the z variables, the probit model is nonlinear, because the linear predictor appears inside the nonlinear probit function.

In order to use the NLIN procedure to minimize the function, the estimation problem must be cast in terms of a nonlinear least squares problem with objective function

$$\sum_{i=1}^n (y_i - f(\boldsymbol{\beta}, \mathbf{z}'_i))^2$$

This can be accomplished by setting $y_i = 0$ and $f(\boldsymbol{\beta}, \mathbf{z}'_i) = \sqrt{-2 \log \{ \pi_i \}}$. Because $0 \leq \pi \leq 1$, the function $-2 \log \{ \pi_i \}$ is strictly positive and the square root can be taken safely.

The following DATA step creates the data for the probit analysis. The variable `like` is created in the DATA step, and it contains the value 0 throughout. This variable serves as the “dummy” response variable in the PROC NLIN step. The variable `remiss` indicates whether cancer remission occurred. It is the binary outcome variable of interest and is used to determine the relevant probability for observation i as the success or failure probability of a Bernoulli experiment.

```

1 1 .69 .69 0.9 0.398 .986
0 1 .73 .73 0.7 0.398 .986
;

```

The following NLIN statements fit the probit model:

```

proc nlin data=remiss method=newton sigsq=1;
  parms int=-10 a = -2 b = -1 c=6;

  linp = int + a*cell + b*li + c*temp;
  p = probnorm(linp);

  if (remiss = 1) then pi = 1-p;
  else pi = p;

  model.like = sqrt(- 2 * log(pi));
  output out=p p=predict;
run;

```

The assignment to the variable linp creates the linear predictor of the generalized linear model,

$$\eta = \beta_0 + \beta_1 \text{cell}_i + \beta_2 \text{li}_i + \beta_3 * \text{temp}_i$$

In this example, the variables cell, li, and temp are used as regressors.

By default, the NLIN procedure computes the covariance matrix of the parameter estimates based on the nonlinear least squares assumption. That is, the procedure computes the estimate of the residual variance as the mean squared error and uses that to multiply the inverse crossproduct matrix or the inverse Hessian matrix. (See the section “[Covariance Matrix of Parameter Estimates](#)” on page 5301 for details.) In the probit model, there is no residual variance. In addition, standard errors in maximum likelihood estimation are based on the inverse Hessian matrix. The **METHOD=NEWTON** option in the **PROC NLIN** statement is used to employ the Hessian matrix in computing the covariance matrix of the parameter estimates. The **SIGSQ=1** option replaces the residual variance estimate that PROC NLIN would use by default as a multiplier of the inverse Hessian with the value 1.0.

Output 63.3.1 shows the results of this analysis. The analysis of variance table shows an apparently strange result. The total sum of squares is zero, and the model sum of squares is negative. Recall that the values of the response variable were set to zero and the mean function was constructed as $-2 \log\{\pi_i\}$ in order for the NLIN procedure to minimize a log-likelihood function in terms of a nonlinear least squares problem. The value 21.9002 shown as the “Error” sum of squares is the value of the function $-2 \log L$.

Output 63.3.1 Nonlinear Least-Squares Analysis from PROC NLIN

run;

proc genmod data=remiss;
  model remiss = cell li temp / dist=bin link=probit;
run;

proc logistic data=remiss;
  model remiss = cell li temp / link=probit technique=newton;
run;
```

Example 63.4: Affecting Curvature through Parameterization

The work of Ratkowsky (1983, 1990) has brought into focus the importance of close-to-linear behavior of parameters in nonlinear regression models. The curvature in a nonlinear model consists of two components: the intrinsic curvature and the parameter-effects curvature. See the section “[Relative Curvature Measures of Nonlinearity](#)” on page 5287 for details. Intrinsic curvature expresses the degree to which the nonlinear model bends as values of the *parameters* change. This is not the same as the curviness of the model as a function of the covariates (the x variables). Intrinsic curvature is a function of the type of model you are fitting and the data. This curvature component cannot be affected by reparameterization of the model. According to Ratkowsky (1983), the intrinsic curvature component is typically smaller than the parameter-effects curvature, which can be affected by altering the parameterization of the model.

In models with low curvature, the nonlinear least squares parameter estimators behave similarly to least squares estimators in linear regression models, which have a number of desirable properties. If the model is correct, they are best linear unbiased estimators and are normally distributed if the model errors are normal (otherwise they are asymptotically normal). As you lower the curvature of a nonlinear model, you can expect that the parameter estimators approach the behavior of the linear regression model estimators: they behave “close to linear.”

This example uses a simple data set and a commonly applied model for dose-response relationships to examine how the parameter-effects curvature can be reduced. The statistics by which an estimator’s behavior is judged are Box’s bias (Box 1971) and Hougaard’s measure of skewness (Hougaard 1982, 1985).

The log-logistic model

$$E[Y|x] = \delta + \frac{\alpha - \delta}{1 + \gamma \exp\{\beta \ln(x)\}}$$

is a popular model to express the response Y as a function of dose x . The response is bounded between the asymptotes α and δ . The term in the denominator governs the transition between the asymptotes and depends on two parameters, γ and β . The log-logistic model can be viewed as a member of a broader class of dose-response functions, those relying on *switch-on* or *switch-off* mechanisms (see, for example, Schabenberger and Pierce 2002, sec. 5.8.6). A switch function is usually a monotonic function $S(x, \theta)$ that takes values between 0 and 1. A switch-on function increases in x ; a switch-off function decreases in x . In the log-logistic case, the function

$$S(x, [\beta, \gamma]) = \frac{1}{1 + \gamma \exp\{\beta \ln(x)\}}$$

is a switch-off function for $\beta > 0$ and a switch-on function for $\beta < 0$. You can write general dose-response functions with asymptotes simply as

$$E[Y|x] = \mu_{\min} + (\mu_{\max} - \mu_{\min})S(x, \theta)$$

The following DATA step creates a small data set from a dose-response experiment with response y:

```
data logistic;
  input dose y;
  logdose = log(dose);
  datalines;
0.009 106.56
0.035  94.12
0.07  89.76
0.15  60.21
0.20  39.95
0.28  21.88
0.50   7.46
;
```

A graph of these data is produced with the following statements:

```
proc sgplot data=logistic;
  scatter y=y x=dose;
  xaxis type=log logstyle=linear;
run;
```

Output 63.4.1 Observed Data in Dose-Response Experiment

When dose is expressed on the log scale, the sigmoidal shape of the dose-response relationship is clearly visible ([Output 63.4.1](#)). The log-logistic switching model in the preceding parameterization is fit with the following statements in the NLIN procedure:

```
proc nlin data=logistic bias hougaard nlinmeasures;
  parameters alpha=100 beta=3 gamma=300;
  delta = 0;
  Switch = 1/(1+gamma*exp(beta*log(dose)));
  model y = delta + (alpha - delta)*Switch;
run;
```

The lower asymptote δ is assumed to be 0 in this case. Since δ is not listed in the **PARAMETERS** statement and is assigned a value in the program, it is assumed to be constant. Note that the term Switch is the switch-off function in the log-logistic model. The **BIAS** and **HOUGAARD** options in the **PROC NLIN** statement request that Box's bias, percentage bias, and Hougaard's skewness measure be added to the table of parameter estimates, and the **NLINMEASURES** option requests that the global nonlinearity measures be produced.

The NLIN procedure converges after 10 iterations and achieves a residual mean squared error of 15.1869 (Output 63.4.2). This value is not that important by itself, but it is worth noting since this model fit is compared to the fit with other parameterizations later on.

The table of parameter estimates displays the estimates of the three model parameters, their approximate standard errors, 95% confidence limits, Hougaard's skewness measure, Box's bias, and percentage bias (Output 63.4.3). Parameters for which the skewness measure is less than 0.1 in absolute value and with percentage bias less than 1% exhibit very close-to-linear behavior, and skewness values less than 0.25 in absolute value indicate reasonably close-to-linear behavior (Ratkowsky 1990). According to these rules, the estimators $\hat{\beta}$ and $\hat{\gamma}$ suffer from substantial curvature. The estimator $\hat{\gamma}$ is especially "far-from-linear." Inferences that involve $\hat{\gamma}$ and rely on the reported standard errors or confidence limits (or both) for this parameter might be questionable.

Output 63.4.3 Parameter Estimates, Hougaard's Skewness, and Box's Bias

Parameter	Estimate	Approx Std Error	Approximate 95% Confidence Limits	Skewness	Bias	Percent Bias

The related global nonlinearity measures output table (Output 63.4.4) shows that both the maximum and RMS parameter-effects curvature are substantially larger than the critical curvature value recommended by Bates and Watts (1980). In contrast, the intrinsic curvatures of the model are less than the critical value. This implies that most of the nonlinearity can be removed by reparameterization.

Output 63.4.4 Global Nonlinearity Measures

Global Nonlinearity Measures	
Max Intrinsic Curvature	0.2397
RMS Intrinsic Curvature	0.1154
Max Parameter-Effects Curvature	4.0842
RMS Parameter-Effects Curvature	1.8198
Curvature Critical Value	0.3895
Raw Residual Variance	15.187
Projected Residual Variance	5.922

One method of reducing the parameter-effects curvature, and thereby reduce the bias and skewness of the parameter estimators, is to replace a parameter with its expected-value parameterization. Schabenberger et al. (1999) and Schabenberger and Pierce (2002, sec. 5.7.2) refer to this method as *reparameterization through defining relationships*. A defining relationship is obtained by equating the mean response at a chosen value of x (say, x^*) to the model:

$$E[Y|x^*] = \delta + \frac{\alpha - \delta}{1 + \gamma \exp\{\beta \ln(x^*)\}}$$

This equation is then solved for a parameter that is subsequently replaced in the original equation. This method is particularly useful if x^* has an interesting interpretation. For example, let λ_K denote the value that reduces the response by $K \times 100\%$,

$$E[Y|\lambda_K] = \delta + \left(\frac{100 - K}{100}\right)(\alpha - \delta)$$

Because γ exhibits large bias and skewness, it is the target in the first round of reparameterization. Setting the expression for the conditional mean at λ_K equal to the mean function when $x = \lambda_K$ yields the following expression:

$$\delta + \left(\frac{100 - K}{100}\right)(\alpha - \delta) = \delta + \frac{\alpha - \delta}{1 + \gamma \exp\{\beta \ln(\lambda_K)\}}$$

This expression is solved for γ , and the result is substituted back into the model equation. This leads to a log-logistic model in which γ is replaced by the parameter λ_K , the dose at which the response was reduced by $K \times 100\%$. The new model equation is

$$E[Y|x] = \delta + \frac{\alpha - \delta}{1 + K/(100 - K) \exp\{\beta \ln(x/\lambda_K)\}}$$

A particularly interesting choice is $K = 50$, since λ_{50} is the dose at which the response is halved. In studies of mortality, this concentration is also known as the LD50. For the special case of λ_{50} the model equation becomes

$$E[Y|x] = \delta + \frac{\alpha - \delta}{1 + \exp\{\beta \ln(x/\lambda_{50})\}}$$

You can fit the model in the LD50 parameterization with the following statements:

```
proc nlin data=logistic bias hougard;
  parameters alpha=100 beta=3 LD50=0.15;
  delta = 0;
  Switch = 1/(1+exp(beta*log(dose/LD50)));
  model y = delta + (alpha - delta)*Switch;
  output out=nlinout pred=p lcl=lcl ucl=ucl;
run;
```

Partial results from this NLIN run are shown in [Output 63.4.5](#). The analysis of variance tables in [Output 63.4.2](#) and [Output 63.4.5](#) are identical. Changing the parameterization of a model does not affect the model fit. It does, however, affect the interpretation of the parameters and the statistical properties (close-to-linear behavior) of the parameter estimators. The skewness and bias measures of the parameter LD50 is considerably reduced compared to those values for the parameter γ in the previous parameterization. Also, γ has been replaced by a parameter with a useful interpretation, the dose that yields a 50% reduction in mean response. Also notice that the bias and skewness measures of α and β are not affected by the $\gamma \rightarrow$ LD50 reparameterization.

Output 63.4.5 ANOVA Table and Parameter Estimates in LD50 Parameterization

To reduce the parameter-effects curvature of the β parameter, you can use the technique of defining relationships again. This can be done generically, by solving

$$\mu^* = \delta + \frac{\alpha - \delta}{1 + \exp\{\beta \ln(x/\lambda)\}}$$

for β , treating μ^* as the new parameter (in lieu of β), and choosing a value for x^* that leads to low skewness. This results in the expected-value parameterization of β . Solving for β yields

$$\beta = \frac{\log\left(\frac{\alpha - \mu^*}{\mu^* - \delta}\right)}{\log(x^*/\lambda)}$$

The interpretation of the parameter μ^* that replaces β in the model equation is simple: it is the mean dose response when the dose is x^* . Fixing $x^* = 0.3$, the following PROC NLIN statements fit this model:

```
proc nlin data=logistic bias houggaard nlinmeasures;
  parameters alpha=100 mustar=20 LD50=0.15;
  delta      = 0;
  xstar      = 0.3;
  beta       = log((alpha - mustar)/(mustar - delta)) / log(xstar/LD50);
  Switch     = 1/(1+exp(beta*log(dose/LD50)));
  model y = delta + (alpha - delta)*Switch;
  output out=nlinout pred=p lcl=lcl ucl=ucl;
run;
```

Note that the switch-off function continues to be written in terms of β and the LD50. The only difference from the previous model is that β is now expressed as a function of the parameter μ^* . Using expected-value parameterizations is a simple mechanism to lower the curvature in a model and to arrive at starting values. The starting value for μ^* can be gleaned from [Output 63.4.1](#) at $x = 0.3$.

[Output 63.4.6](#) shows selected results from this NLIN run. The ANOVA table is again unaffected by the change in parameterization. The skewness for μ^* is significantly reduced in comparison to those of the β parameter in the previous model (compare [Output 63.4.6](#) and [Output 63.4.5](#)), while its bias remains on the same scale from [Output 63.4.5](#) to [Output 63.4.6](#). Also note the substantial reduction in the parameter-effects curvature values. As expected, the intrinsic curvature values remain intact.

Example 63.5: Comparing Nonlinear Trends among Groups

When you model nonlinear trends in the presence of group (classification) variables, two questions often arise: whether the trends should be varied by group, and how to decide which parameters should be varied across groups. A large battery of tools is available on linear statistical models to test hypotheses involving the model parameters, especially to test linear hypotheses. To test similar hypotheses in nonlinear models, you can draw on analogous tools. Especially important in this regard are comparisons of nested models by contrasting their residual sums of squares.

In this example, a two-group model from a pharmacokinetic application is fit to data that are in part based on the theophylline data from Pinheiro and Bates (1995) and the first example in the documentation for the NLMIXED procedure. In a pharmacokinetic application you study how a drug is dispersed through a living organism. The following data represent concentrations of the drug theophylline over a 25-hour period following oral administration. The data are derived by collapsing and averaging the subject-specific data from Pinheiro and Bates (1995) in a particular, yet unimportant, way. The purpose of arranging the data in this way is purely to demonstrate the methodology.

The following code plots the theophylline concentration data over time for the two groups (Output 63.5.1). In each group the concentration tends to rise sharply right after the drug is administered, followed by a prolonged tapering of the concentration.

```
proc sgplot data=theop;
  scatter x=time y=conc / group=group;
  yaxis label='Concentration';
  xaxis label='Time';
  run;
```

Output 63.5.1 Observed Responses in Two Groups

In the context of nonlinear mixed models, Pinheiro and Bates (1995) consider a first-order compartment model for these data. In terms of two fixed treatment groups, the model can be written as

$$C_{it} = \frac{Dk_{e_i}k_{a_i}}{Cl_i(k_{a_i} - k_{e_i})} [\exp(-k_{e_i}t) - \exp(-k_{a_i}t)] + \epsilon_{it}$$

where C_{it} is the observed concentration in group i at time t , D is the dose of theophylline, k_{e_i} is the elimination rate in group i , k_{a_i} is the absorption rate in group i , Cl_i is the clearance in group i , and ϵ_{it}

denotes the model error. Because the rates and the clearance must be positive, you can parameterize the model in terms of log rates and the log clearance:

$$\begin{aligned} Cl_i &= \exp\{\beta_{1i}\} \\ k_{a_i} &= \exp\{\beta_{2i}\} \\ k_{e_i} &= \exp\{\beta_{3i}\} \end{aligned}$$

In this parameterization the model contains six parameters, and the rates and clearance vary by group. This produces two separate response profiles, one for each group. On the other extreme, you could model the trends as if there were no differences among the groups:

$$\begin{aligned} Cl_i &= \exp\{\beta_1\} \\ k_{a_i} &= \exp\{\beta_2\} \\ k_{e_i} &= \exp\{\beta_3\} \end{aligned}$$

In between these two extremes lie other models, such as a model where both groups have the same absorption and elimination rate, but different clearances. The question then becomes how to go about building a model in an organized manner.

To test hypotheses about nested nonlinear models, you can apply the idea of a “Sum of Squares Reduction Test.” A reduced model is nested within a full model if you can impose q constraints on the full model to obtain the reduced model. Then, if SSE_r and SSE_f denote the residual sum of squares in the reduced and the full model, respectively, the test statistic is

$$F_R = \frac{(SSE_r - SSE_f) / q}{SSE_f / (n - p)} = \frac{(SSE_r - SSE_f) / q}{MSE_f}$$

where n are the number of observations used and p are the number of parameters in the full model. The numerator of the F_R statistic is the average reduction in residual sum of squares per constraint. The mean squared error of the full model is used to scale this average because it is less likely to be a biased estimator of the residual variance than the variance estimate from a constrained (reduced) model. The F_R statistic is then compared against quantiles from an F distribution with q numerator and $n - p$ denominator degrees of freedom. Schabenberger and Pierce (2002) discuss the justification for this test and compare it to other tests in nonlinear models.

In the present application we might phrase the initial question akin to the overall F test for a factor in a linear model: Should any parameters be varied between the two groups? The corresponding null hypothesis is

$$H: \begin{cases} \beta_{11} = \beta_{12} \\ \beta_{21} = \beta_{22} \\ \beta_{31} = \beta_{32} \end{cases}$$

where the first subscript identifies the type of the parameter and the second subscript identifies the group. Note that this hypothesis implies

$$H: \begin{cases} Cl_1 = Cl_2 \\ k_{a_1} = k_{a_2} \\ k_{e_1} = k_{e_2} \end{cases}$$

If you fail to reject this hypothesis, there is no need to further examine individual parameter differences.

The reduced model—the model subject to the null hypothesis—is fit with the following PROC NLIN statements:

```
proc nlin data=theop;
  parms beta1=-3.22 beta2=0.47 beta3=-2.45;
  c1  = exp(beta1);
  ka  = exp(beta2);
  ke  = exp(beta3);
  mean = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/c1/(ka-ke);
  model conc = mean;
  ods output Anova=aovred(rename=(ss=ssred ms=msred df=dfred));
run;
```

The clearance, the rates, and the mean function are formed independently of the group membership. The analysis of variance table is saved to the data set aovred, and some of its variables are renamed. This is done so that the data set can be merged easily with the analysis of variance table for the full model (see following).

The converged model has a residual sum of square of $SSE_r = 286.4$ and a mean squared error of 3.0142 (Output 63.5.2). The table of parameter estimates gives the values for the estimated log clearance ($\hat{\beta}_1 = -3.2991$), the estimated log absorption rate ($\hat{\beta}_2 = 0.4769$), and the estimated log elimination rate ($\hat{\beta}_3 = -2.5555$).

Output 63.5.2 Fit Results for the Reduced Model

The NLIN Procedure					
Dependent Variable conc					
Method: Gauss-Newton					
NOTE: Convergence criterion met.					
NOTE: An intercept was not specified for this model.

Error	95	286.4	3.0142		
Uncorrected Total	98	3386.8			
Parameter	Estimate	Approx Std Error	Approximate 95% Confidence Limits		
beta1	-3.2991	0.0956	-3.4888	-3.1094	
beta2	0.4769	0.1640	0.1512	0.8025	
beta3	-2.5555	0.1410	-2.8354	-2.2755	

The full model, in which all three parameters are varied by group, can be fit with the following statements in the NLIN procedure:

```

proc nlin data=theop;
  parms beta1_1=-3.22 beta2_1=0.47 beta3_1=-2.45
        beta1_2=-3.22 beta2_2=0.47 beta3_2=-2.45;
  if (group=1) then do;
    cl  = exp(beta1_1);
    ka  = exp(beta2_1);
    ke  = exp(beta3_1);
  end; else do;
    cl  = exp(beta1_2);
    ka  = exp(beta2_2);
    ke  = exp(beta3_2);
  end;
  mean = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/cl/(ka-ke);
  model conc = mean;
  ods output Anova=aovfull;
run;

```

Separate parameters for the groups are now specified in the **PARMS** statement, and the value of the model variables *cl*, *ka*, and *ke* is assigned conditional on the group membership of an observation. Notice that the same expression as in the previous run can be used to model the mean function.

The results from this PROC NLIN run are shown in [Output 63.5.3](#). The residual sum of squares in the full model is only $SSE_f = 138.9$, compared to $SSE_r = 286.4$ in the reduced model ([Output 63.5.3](#)).

Output 63.5.3 Fit Results for the Full Model

beta3_2	-2.4442	0.1618	-2.7655	-2.1229

Whether this reduction in sum of squares is sufficient to declare that the full model provides a significantly better fit than the reduced model depends on the number of constraints imposed on the full model and on the variability in the data. In other words, before drawing any conclusions, you have to take into account how many parameters have been dropped from the model and how much variation around the regression trends the data exhibit. The F_R statistic sets these quantities into relation. The following macro merges the analysis of variance tables from the full and reduced model, and computes F_R and its p -value:

```
%macro SSReductionTest;
  data aov; merge aovred aovfull;
    if (Source='Error') then do;
      Fstat = ((SSred-SS)/(dfred-df))/ms;
      pvalue = 1-ProbF(Fstat,dfred-df,df);
      output;
    end;
  run;
proc print data=aov label noobs;
  label Fstat = 'F Value'
        pValue = 'Prob > F';
  format pvalue pvalue8.;
  var Fstat pValue;

F Value	Prob > F
32.5589	<.000001

There is clear evidence that the model with separate trends fits these data significantly better (Output 63.5.4). To decide whether all parameters should be varied between the groups or only one or two of them, we first refit the model in a slightly different parameterization:

```
proc nlin data=theop;
  parms beta1_1=-3.22 beta2_1=0.47 beta3_1=-2.45
        beta1_diff=0 beta2_diff=0 beta3_diff=0;
  if (group=1) then do;
    c1 = exp(beta1_1);
    ka = exp(beta2_1);
    ke = exp(beta3_1);
  end; else do;
    c1 = exp(beta1_1 + beta1_diff);
    ka = exp(beta2_1 + beta2_diff);
    ke = exp(beta3_1 + beta3_diff);
  end;
  mean = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/c1/(ka-ke);
  model conc = mean;
run;
```

In the preceding statements, the parameters in the second group were expressed using offsets from parameters in the first group. For example, the parameter `beta1_diff` measures the change in log clearance between group 2 and group 1.

This simple reparameterization does not affect the model fit. The analysis of variance tables in [Output 63.5.5](#) and [Output 63.5.3](#) are identical. It does, however, affect the interpretation of the estimated quantities. Since the parameter `beta1_diff` measures the change in the log clearance rates between the groups, you can use the approximate 95% confidence limits in [Output 63.5.5](#) to assess whether that quantity in the pharmacokinetic equation varies between groups. Only the confidence interval for the difference in the log clearances excludes 0. The intervals for `beta2_diff` and `beta3_diff` include 0.

Output 63.5.5 Fit Results for the Full Model in Difference Parameterization

The NLIN Procedure					
Dependent Variable conc					
Method: Gauss-Newton					
NOTE: Convergence criterion met.					
NOTE: An intercept was not specified for this model.					
Source	DF	Sum of Squares	Mean Square	F Value	Approx Pr > F
Model	6	3247.9	541.3	358.56	<.0001
Error	92	138.9	1.5097		
Uncorrected Total	98	3386.8			

Parameter	Estimate	Approx Std Error	Approximate 95% Confidence Limits	
beta1_1	-3.5671	0.0864	-3.7387	-3.3956
beta2_1	0.4421	0.1349	0.1742	0.7101
beta3_1	-2.6230	0.1265	-2.8742	-2.3718
beta1_diff	0.5560	0.1368	0.2842	0.8278
beta2_diff	-0.0444	0.2402	-0.5214	0.4326
beta3_diff	0.1788	0.2054	-0.2291	0.5866

This suggests as the final model one where the absorption and elimination rates are the same for both groups and only the clearances are varied. The following statements fit this model and perform the sum of squares reduction test:

```
proc nlin data=theop;
  parms beta1_1=-3.22 beta2_1=0.47 beta3_1=-2.45
        beta1_diff=0;
  ka = exp(beta2_1);
  ke = exp(beta3_1);
  if (group=1) then do;
    cl = exp(beta1_1);
  end; else do;
    cl = exp(beta1_1 + beta1_diff);
  end;
  mean = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/cl/(ka-ke);
  model conc = mean;
  ods output Anova=aovred(rename=(ss=ssred ms=msred df=dfred));
```

```

output out=predvals predicted=p;
run;
%SSReductionTest;

```

The results for this model with common absorption and elimination rates are shown in [Output 63.5.6](#). The sum-of-squares reduction test comparing this model against the full model with six parameters shows—as expected—that the full model does not fit the data significantly better ($p = 0.6193$, [Output 63.5.7](#)).

Output 63.5.6 Fit Results for Model with Common Rates

The NLIN Procedure					
Dependent Variable conc

beta1_diff	0.4346	0.0454	0.3444	0.5248	

Output 63.5.7 F Statistic and P-value for Hypothesis of Common Rates

F Value	Prob > F
0.48151	0.619398

A plot of the observed and predicted values for this final model is obtained with the following statements:

```

proc sgplot data=predvals;
  scatter x=time y=conc / group=group;
  series x=time y=p / group=group name='fit';
  keylegend 'fit' / across=2 title='Group';
  yaxis label='Concentration';
  xaxis label='Time';
run;

```

The plot is shown in [Output 63.5.8](#).

Output 63.5.8 Observed and Fitted Values for Theophylline Data

The sum-of-squares reduction test is not the only possibility of performing linear-model style hypothesis testing in nonlinear models. You can also perform Wald-type testing of linear hypotheses about the parameter estimates. See [Example 41.17](#) in Chapter 41, “[The GLIMMIX Procedure](#),” for an application of this example that uses the NLIN and GLIMMIX procedures to compare the parameters across groups and adjusts p -values for multiplicity.

Example 63.6: ODS Graphics and Diagnostics

The model in this example, taken from St. Laurent and Cook (1993), shows an unusual behavior in that the intrinsic curvature is substantially larger than the parameter-effects curvature. This example demonstrates how the diagnostics features of PROC NLIN can be used to perform postconvergence diagnostics.

The model takes the form

$$E[Y|x_1, x_2] = \alpha x_1 + \exp\{\gamma x_2\}$$

The following DATA step creates a small data set to be used in this example:

```

data contrived;
  input x1 x2 y;
  datalines;
-4.0   -2.5  -10.0
-3.0   -2.0   -5.0
-2.0   -1.5   -2.0
-1.0   -1.0   -1.0
 0.0    0.0    1.5
 1.0    1.0    4.0
 2.0    1.5    5.0
 3.0    2.0    6.0
 4.0    2.5    7.0
-3.5   -2.2   -7.1
-3.5   -1.7   -5.1
 3.5    0.7    6.1
 2.5    1.2    7.5
;

```

The model is fit with the following statements in the NLIN procedure:

```

ods graphics on;
proc nlin data=contrived bias hougard
  NLINMEASURES plots(stats=all)=(diagnostics);
  parms alpha=2.0
        gamma=0.0;
  model y = alpha*x1 + exp(gamma*x2);
run;
ods graphics off;

```

Output 63.6.1 Bias, Skewness, and Global Nonlinearity Measures

The NLIN Procedure							
Parameter	Estimate	Approx Std Error	Approximate 95% Confidence Limits		Skewness	Bias	Percent Bias
alpha	1.9378	0.4704	0.9024	2.9733	6.6491	0.5763	29.7
gamma	0.0718	0.7923	-1.6720	1.8156	-7.5596	-0.9982	-1390
Global Nonlinearity Measures							
Max Intrinsic Curvature					6.6007		
RMS Intrinsic Curvature					4.0421		
Max Parameter-Effects Curvature					3.5719		
RMS Parameter-Effects Curvature					2.1873		
Curvature Critical Value					0.5011		
Raw Residual Variance					2.1722		
Projected Residual Variance					1.4551		

The bias, skewness, and both the maximum and RMS intrinsic curvatures, compared to the critical curvature value, show that the model is highly nonlinear (Output 63.6.1). As such, performing diagnostics with the

raw residuals can be problematic because they might have undesirable statistical properties: a nonzero mean and a negative semidefinite (instead of zero) covariance with the predicted values and different variances. In addition, the use of tangential leverage is questionable in this case.

The partial results from this NLIN run are shown in [Output 63.6.2](#), [Output 63.6.3](#), and [Output 63.6.4](#). The diagnostics plots corroborate the previously mentioned expectations: highly correlated raw residuals (with the predicted values), significant differences between tangential and Jacobian leverages and projected residuals which overcome some of the shortcomings of the raw residuals. Finally, considering the large intrinsic curvature, reparameterization might not make the model close-to-linear, perhaps necessitating the construction of another model.

Output 63.6.2 Diagnostics Panel

Output 63.6.3 Leverage Plots

Output 63.6.4 Local Influence Plot

Example 63.7: Parameter Profiling

The following model, taken from Clarke (1987a), demonstrates the benefits of parameter profiling and confidence curves to identify the nonlinear characteristics of parameters that occur in the model. The profiling is also augmented with a plot that shows the influence of each observation on the parameter estimates.

The model takes the form

$$E[Y|x] = \theta_3 + \theta_2 \exp\{\theta_1 x\}$$

The data set used in this example is taken from Clarke (1987a). The following DATA step creates this data set:

```
data clarke1987a;
  input  x y;
  datalines;
1      3.183
2      3.059
3      2.871
4      2.622
5      2.541
6      2.184
7      2.110
8      2.075
9      2.018
10     1.903
11     1.770
12     1.762
13     1.550
;
```

The model is fit with the following statements in the NLIN procedure:

```
ods graphics on;
proc nlin data=clarke1987a plots(stats=none)=diagnostics;
  parms theta1=-0.15
        theta2=2.0
        theta3=0.80;
  profile theta3 / range = -6 to 2 by 0.2 all;
  model y = theta3 + theta2*exp(theta1*x);
run;
ods graphics off;
```

The profile t plot, [Output 63.7.1](#), for parameter θ_3 shows a definite deviation from the linear reference line that has a slope of 1 and passes through the origin. Hence, Wald-based inference for θ_3 is not appropriate. The confidence curve for θ_3 validates this conclusion.

[Output 63.7.2](#) shows the confidence curve for θ_3 . You can see that there is a significant difference between the Wald-based confidence interval and the corresponding likelihood-based interval. In such cases, the likelihood-based intervals are preferred because their coverage rate is much closer to the nominal values than the coverage rate of the Wald-based intervals (Donaldson and Schnabel 1987; Cook and Weisberg 1990). Furthermore, this example shows that the adequacy of a linear approximation with regards to a certain parameter cannot be inferred directly from the model. If it could, θ_3 , which enters the model linearly,

would have a completely linear behavior. For a detailed discussion about this issue, see Cook and Weisberg (1990).

Finally, [Output 63.7.3](#) depicts the influence of each observation on the value of θ_3 . Observations 6 and 13 have the most influence on the value of this parameter. The plot is generated using the leave-one-out method and should be contrasted with the local influence plot, [Output 63.7.4](#), which is based on assessing the influence of an additive perturbation of the response variable.

Output 63.7.1 Profile t Plot

Output 63.7.2 Confidence Curve

Output 63.7.3 Observation Influence on Parameter Estimate

Output 63.7.4 Local Influence Plot

Overview: NLMIXED Procedure

Introduction

The NLMIXED procedure fits nonlinear mixed models—that is, models in which both fixed and random effects enter nonlinearly. These models have a wide variety of applications, two of the most common being pharmacokinetics and overdispersed binomial data. PROC NLMIXED enables you to specify a conditional distribution for your data (given the random effects) having either a standard form (normal, binomial, Poisson) or a general distribution that you code using SAS programming statements.

PROC NLMIXED fits nonlinear mixed models by maximizing an approximation to the likelihood integrated over the random effects. Different integral approximations are available, the principal ones being adaptive Gaussian quadrature and a first-order Taylor series approximation. A variety of alternative optimization techniques are available to carry out the maximization; the default is a dual quasi-Newton algorithm.

Successful convergence of the optimization problem results in parameter estimates along with their approximate standard errors based on the second derivative matrix of the likelihood function. PROC NLMIXED enables you to use the estimated model to construct predictions of arbitrary functions by using empirical Bayes estimates of the random effects. You can also estimate arbitrary functions of the nonrandom parameters, and PROC NLMIXED computes their approximate standard errors by using the delta method.

Literature on Nonlinear Mixed Models

Davidian and Giltinan (1995) and Vonesh and Chinchilli (1997) provide good overviews as well as general theoretical developments and examples of nonlinear mixed models. Pinheiro and Bates (1995) is a primary reference for the theory and computational techniques of PROC NLMIXED. They describe and compare several different integrated likelihood approximations and provide evidence that adaptive Gaussian quadrature is one of the best methods. Davidian and Gallant (1993) also use Gaussian quadrature for nonlinear mixed models, although the smooth nonparametric density they advocate for the random effects is currently not available in PROC NLMIXED.

Traditional approaches to fitting nonlinear mixed models involve Taylor series expansions, expanding around either zero or the empirical best linear unbiased predictions of the random effects. The former is the basis for the well-known first-order method (Beal and Sheiner 1982, 1988; Sheiner and Beal 1985),

and it is optionally available in PROC NLMIXED. The latter is the basis for the estimation method of Lindstrom and Bates (1990), and it is not available in PROC NLMIXED. However, the closely related Laplacian approximation is an option; it is equivalent to adaptive Gaussian quadrature with only one quadrature point. The Laplacian approximation and its relationship to the Lindstrom-Bates method are discussed by: Beal and Sheiner (1992); Wolfinger (1993); Vonesh (1992, 1996); Vonesh and Chinchilli (1997); Wolfinger and Lin (1997).

A parallel literature exists in the area of generalized linear mixed models, in which random effects appear as a part of the linear predictor inside a link function. Taylor-series methods similar to those just described are discussed in articles such as: Harville and Mee (1984); Stiratelli, Laird, and Ware (1984); Gilmour, Anderson, and Rae (1985); Goldstein (1991); Schall (1991); Engel and Keen (1992); Breslow and Clayton (1993); Wolfinger and O'Connell (1993); McGilchrist (1994), but such methods have not been implemented in PROC NLMIXED because they can produce biased results in certain binary data situations (Rodriguez and Goldman 1995; Lin and Breslow 1996). Instead, a numerical quadrature approach is available in PROC NLMIXED, as discussed in: Pierce and Sands (1975); Anderson and Aitkin (1985); Hedeker and Gibbons (1994); Crouch and Spiegelman (1990); Longford (1994); McCulloch (1994); Liu and Pierce (1994); Diggle, Liang, and Zeger (1994).

Nonlinear mixed models have important applications in pharmacokinetics, and Roe (1997) provides a wide-ranging comparison of many popular techniques. Yuh et al. (1994) provide an extensive bibliography on nonlinear mixed models and their use in pharmacokinetics.

PROC NLMIXED Compared with Other SAS Procedures and Macros

The models fit by PROC NLMIXED can be viewed as generalizations of the random coefficient models fit by the MIXED procedure. This generalization allows the random coefficients to enter the model nonlinearly, whereas in PROC MIXED they enter linearly. With PROC MIXED you can perform both maximum likelihood and restricted maximum likelihood (REML) estimation, whereas PROC NLMIXED implements only maximum likelihood. This is because the analog to the REML method in PROC NLMIXED would involve a high-dimensional integral over all of the fixed-effects parameters, and this integral is typically not available in closed form. Finally, PROC MIXED assumes the data to be normally distributed, whereas PROC NLMIXED enables you to analyze data that are normal, binomial, or Poisson or that have any likelihood programmable with SAS statements.

PROC NLMIXED does not implement the same estimation techniques available with the NLINMIX macro or the default estimation method of the GLIMMIX procedure. These are based on the estimation methods of: Lindstrom and Bates (1990); Breslow and Clayton (1993); Wolfinger and O'Connell (1993), and they iteratively fit a set of generalized estimating equations (see Chapters 14 and 15 of Littell et al. 2006; Wolfinger 1997). In contrast, PROC NLMIXED directly maximizes an approximate integrated likelihood. This remark also applies to the SAS/IML macros MIXNLIN (Vonesh and Chinchilli 1997) and NLMEM (Galecki 1998).

The GLIMMIX procedure also fits mixed models for nonnormal data with nonlinearity in the conditional mean function. In contrast to the NLMIXED procedure, PROC GLIMMIX assumes that the model contains a linear predictor that links covariates to the conditional mean of the response. The NLMIXED procedure is designed to handle general conditional mean functions, whether they contain a linear component or not. As mentioned earlier, the GLIMMIX procedure by default estimates parameters in generalized linear mixed models by pseudo-likelihood techniques, whereas PROC NLMIXED by default performs maximum likeli-

hood estimation by adaptive Gauss-Hermite quadrature. This estimation method is also available with the GLIMMIX procedure (METHOD=QUAD in the PROC GLIMMIX statement).

PROC NLMIXED has close ties with the NLP procedure in SAS/OR software. PROC NLMIXED uses a subset of the optimization code underlying PROC NLP and has many of the same optimization-based options. Also, the programming statement functionality used by PROC NLMIXED is the same as that used by PROC NLP and the MODEL procedure in SAS/ETS software.

Getting Started: NLMIXED Procedure

Nonlinear Growth Curves with Gaussian Data

As an introductory example, consider the orange tree data of Draper and Smith (1981). These data consist of seven measurements of the trunk circumference (in millimeters) on each of five orange trees. You can input these data into a SAS data set as follows:

```
data tree;
    input tree day y;
    datalines;
1  118   30
1  484   58
1  664   87

... more lines ...

5 1582  177
;
```

Lindstrom and Bates (1990) and Pinheiro and Bates (1995) propose the following logistic nonlinear mixed model for these data:

$$y_{ij} = \frac{b_1 + u_{i1}}{1 + \exp[-(d_{ij} - b_2)/b_3]} + e_{ij}$$

Here, y_{ij} represents the j th measurement on the i th tree ($i = 1, \dots, 5$; $j = 1, \dots, 7$), d_{ij} is the corresponding day, b_1, b_2, b_3 are the fixed-effects parameters, u_{i1} are the random-effect parameters assumed to be iid $N(0, \sigma_u^2)$, and e_{ij} are the residual errors assumed to be iid $N(0, \sigma_e^2)$ and independent of the u_{i1} . This model has a logistic form, and the random-effect parameters u_{i1} enter the model linearly.

The statements to fit this nonlinear mixed model are as follows:

```
proc nlmixed data=tree;
    parms b1=190 b2=700 b3=350 s2u=1000 s2e=60;
    num = b1+u1;
    ex  = exp(-(day-b2)/b3);
    den = 1 + ex;
    model y ~ normal(num/den, s2e);
    random u1 ~ normal(0, s2u) subject=tree;
run;
```

The **PROC NLMIXED** statement invokes the procedure and inputs the tree data set. The **PARMS** statement identifies the unknown parameters and their starting values. Here there are three fixed-effects parameters (b_1 , b_2 , b_3) and two variance components (s^2_u , s^2_e).

The next three statements are SAS programming statements specifying the logistic mixed model. A new variable u_1 is included to identify the random effect. These statements are evaluated for every observation in the data set when the NLMIXED procedure computes the log likelihood function and its derivatives.

The **MODEL** statement defines the dependent variable and its conditional distribution given the random effects. Here a normal (Gaussian) conditional distribution is specified with mean num/den and variance s^2_e .

The **RANDOM** statement defines the single random effect to be u_1 , and specifies that it follow a normal distribution with mean 0 and variance s^2_u . The **SUBJECT=** argument in the **RANDOM** statement defines a variable indicating when the random effect obtains new realizations; in this case, it changes according to the values of the *tree* variable. PROC NLMIXED assumes that the input data set is clustered according to the levels of the *tree* variable; that is, all observations from the same tree occur sequentially in the input data set.

The output from this analysis is as follows.

Figure 64.1 Model Specifications

The NLMIXED Procedure	
Specifications	
Data Set	WORK.TREE
Dependent Variable	Y
Distribution for Dependent Variable	Normal
Random Effects	u1
Distribution for Random Effects	Normal
Subject Variable	tree
Optimization Technique	Dual Quasi-Newton
Integration Method	Adaptive Gaussian Quadrature

The “Specifications” table lists basic information about the nonlinear mixed model you have specified (Figure 64.1). Included are the input data set, the dependent and subject variables, the random effects, the relevant distributions, and the type of optimization. The “Dimensions” table lists various counts related to the model, including the number of observations, subjects, and parameters (Figure 64.2). These quantities are useful for checking that you have specified your data set and model correctly. Also listed is the number of quadrature points that PROC NLMIXED has selected based on the evaluation of the log likelihood at the starting values of the parameters. Here, only one quadrature point is necessary because the random-effect parameters u_{i1} enter the model linearly. (The Gauss-Hermite quadrature with a single quadrature point results in the Laplace approximation of the log likelihood.)

Figure 64.2 Dimensions Table for Growth Curve Model

Dimensions

Figure 64.3 Starting Values of Parameter Estimates and Negative Log Likelihood

Parameters					
b1	b2	b3	s2u	s2e	NegLogLike
190	700	350	1000	60	132.491787

The “Parameters” table lists the parameters to be estimated, their starting values, and the negative log likelihood evaluated at the starting values (Figure 64.3).

Figure 64.4 Iteration History for Growth Curve Model

Iteration History					
Iter	Calls	NegLogLike	Diff	MaxGrad	Slope
1	4	131.686742	0.805045	0.010269	-0.633
2	6	131.64466	0.042082	0.014783	-0.0182
3	8	131.614077	0.030583	0.009809	-0.02796
4	10	131.572522	0.041555	0.001186	-0.01344
5	11	131.571895	0.000627	0.0002	-0.00121
6	13	131.571889	5.549E-6	0.000092	-7.68E-6
7	15	131.571888	1.096E-6	6.097E-6	-1.29E-6
NOTE: GCONV convergence criterion satisfied.					

The “Iteration History” table records the history of the minimization of the negative log likelihood (Figure 64.4). For each iteration of the quasi-Newton optimization, values are listed for the number of function calls, the value of the negative log likelihood, the difference from the previous iteration, the absolute value of the largest gradient, and the slope of the search direction. The note at the bottom of the table indicates that the algorithm has converged successfully according to the **GCONV** convergence criterion, a standard criterion computed using a quadratic form in the gradient and the inverse Hessian.

The final maximized value of the log likelihood as well as the information criterion of Akaike (AIC), its small sample bias corrected version (AICC), and the Bayesian information criterion (BIC) in the “smaller is better” form appear in the “Fit Statistics” table (Figure 64.5). These statistics can be used to compare different nonlinear mixed models.

Figure 64.5 Fit Statistics for Growth Curve Model

Fit Statistics	
-2 Log Likelihood	263.1
AIC (smaller is better)	273.1
AICC (smaller is better)	275.2
BIC (smaller is better)	271.2

Figure 64.6 Parameter Estimates at Convergence

Parameter Estimates							
Parameter	Estimate	Standard Error	DF	t Value	Pr > t	Alpha	Lower
b1	192.05	15.6473	4	12.27	0.0003	0.05	148.61
b2	727.90	35.2472	4	20.65	<.0001	0.05	630.04
b3	348.07	27.0790	4	12.85	0.0002	0.05	272.88
s2u	999.88	647.44	4	1.54	0.1974	0.05	-797.70
s2e	61.5139	15.8831	4	3.87	0.0179	0.05	17.4153
Parameter Estimates							
	Parameter	Upper	Gradient				
	b1	235.50	1.154E-6				
	b2	825.76	5.289E-6				
	b3	423.25	-6.1E-6				
	s2u	2797.45	-3.84E-6				
	s2e	105.61	2.892E-6				

The maximum likelihood estimates of the five parameters and their approximate standard errors computed using the final Hessian matrix are displayed in the “Parameter Estimates” table (Figure 64.6). Approximate t -values and Wald-type confidence limits are also provided, with degrees of freedom equal to the number of subjects minus the number of random effects. You should interpret these statistics cautiously for variance parameters like s2u and s2e. The final column in the output shows the gradient vector at the optimization solution. Each element appears to be sufficiently small to indicate a stationary point.

Since the random-effect parameters u_{i1} enter the model linearly, you can obtain equivalent results by using the first-order method (specify **METHOD=FIRO** in the **PROC NL MIXED** statement).

Logistic-Normal Model with Binomial Data

This example analyzes the data from Beitler and Landis (1985), which represent results from a multi-center clinical trial investigating the effectiveness of two topical cream treatments (active drug, control) in curing an infection. For each of eight clinics, the number of trials and favorable cures are recorded for each treatment. The SAS data set is as follows.

```
data infection;
  input clinic t x n;
  datalines;
1 1 11 36
1 0 10 37
2 1 16 20
2 0 22 32
3 1 14 19
3 0 7 19
4 1 2 16
4 0 1 17
5 1 6 17
5 0 0 12
6 1 1 11
6 0 0 10
7 1 1 5
7 0 1 9
8 1 4 6
8 0 6 7
;
```

Suppose n_{ij} denotes the number of trials for the i th clinic and the j th treatment ($i = 1, \dots, 8; j = 0, 1$), and x_{ij} denotes the corresponding number of favorable cures. Then a reasonable model for the preceding data is the following logistic model with random effects:

$$x_{ij}|u_i \sim \text{Binomial}(n_{ij}, p_{ij})$$

and

$$\eta_{ij} = \log \left(\frac{p_{ij}}{1 - p_{ij}} \right) = \beta_0 + \beta_1 t_j + u_i$$

The notation t_j indicates the j th treatment, and the u_i are assumed to be iid $N(0, \sigma_u^2)$.

The PROC NLMIXED statements to fit this model are as follows:

```
proc nlmixed data=infection;
  parms beta0=-1 beta1=1 s2u=2;
  eta    = beta0 + beta1*t + u;
  expeta = exp(eta);
  p      = expeta/(1+expeta);
  model x ~ binomial(n,p);
  random u ~ normal(0,s2u) subject=clinic;
  predict eta out=eta;
  estimate '1/beta1' 1/beta1;
run;
```

The **PROC NLMIXED** statement invokes the procedure, and the **PARMS** statement defines the parameters and their starting values. The next three statements define p_{ij} , and the **MODEL** statement defines the conditional distribution of x_{ij} to be binomial. The **RANDOM** statement defines u to be the random effect with subjects defined by the clinic variable.

The **PREDICT** statement constructs predictions for each observation in the input data set. For this example, predictions of η_{ij} and approximate standard errors of prediction are output to a data set named eta. These predictions include empirical Bayes estimates of the random effects u_i .

The **ESTIMATE** statement requests an estimate of the reciprocal of β_1 .

The output for this model is as follows.

Figure 64.7 Model Information and Dimensions for Logistic-Normal Model

The NLMIXED Procedure	
Specifications	
Data Set	WORK.INFECTION
Dependent Variable	x
Distribution for Dependent Variable	Binomial
Random Effects	u
Distribution for Random Effects	Normal
Subject Variable	clinic
Optimization Technique	Dual Quasi-Newton
Integration Method	Adaptive Gaussian Quadrature
Dimensions	
Observations Used	16
Observations Not Used	0
Total Observations	16
Subjects	8
Max Obs Per Subject	2
Parameters	3
Quadrature Points	5

The “Specifications” table provides basic information about the nonlinear mixed model (Figure 64.7). For example, the distribution of the response variable, conditional on normally distributed random effects, is binomial. The “Dimensions” table provides counts of various variables. You should check this table to make sure the data set and model have been entered properly. PROC NLMIXED selects five quadrature points to achieve the default accuracy in the likelihood calculations.

Figure 64.8 Starting Values of Parameter Estimates

Parameters			
beta0	beta1	s2u	NegLogLike
-1	1	2	37.5945925

The “Parameters” table lists the starting point of the optimization and the negative log likelihood at the starting values (Figure 64.8).

Figure 64.9 Iteration History and Fit Statistics for Logistic-Normal Model

Iteration History					
Iter	Calls	NegLogLike	Diff	MaxGrad	Slope
1	2	37.3622692	0.232323	2.882077	-19.3762
2	3	37.1460375	0.216232	0.921926	-0.82852
3	5	37.0300936	0.115944	0.315897	-0.59175
4	6	37.0223017	0.007792	0.01906	-0.01615
5	7	37.0222472	0.000054	0.001743	-0.00011
6	9	37.0222466	6.57E-7	0.000091	-1.28E-6
7	11	37.0222466	5.38E-10	2.078E-6	-1.1E-9

NOTE: GCONV convergence criterion satisfied.

Fit Statistics	
-2 Log Likelihood	74.0
AIC (smaller is better)	80.0
AICC (smaller is better)	82.0
BIC (smaller is better)	80.3

The “Iteration History” table indicates successful convergence in seven iterations (Figure 64.9). The “Fit Statistics” table lists some useful statistics based on the maximized value of the log likelihood.

Figure 64.10 Parameter Estimates for Logistic-Normal Model

Parameter Estimates							
Parameter	Estimate	Standard Error	DF	t Value	Pr > t	Alpha	Lower
beta0	-1.1974	0.5561	7	-2.15	0.0683	0.05	-2.5123
beta1	0.7385	0.3004	7	2.46	0.0436	0.05	0.02806
s2u	1.9591	1.1903	7	1.65	0.1438	0.05	-0.8554

Parameter Estimates		
Parameter	Upper	Gradient
beta0	0.1175	-3.1E-7
beta1	1.4488	-2.08E-6
s2u	4.7736	-2.48E-7

The “Parameter Estimates” table indicates marginal significance of the two fixed-effects parameters (Figure 64.10). The positive value of the estimate of β_1 indicates that the treatment significantly increases the chance of a favorable cure.

Figure 64.11 Table of Additional Estimates

Additional Estimates								
Label	Estimate	Standard Error	DF	t Value	Pr > t	Alpha	Lower	Upper
1/beta1	1.3542	0.5509	7	2.46	0.0436	0.05	0.05146	2.6569

The “Additional Estimates” table displays results from the `ESTIMATE` statement (Figure 64.11). The estimate of $1/\beta_1$ equals $1/0.7385 = 1.3542$ and its standard error equals $0.3004/0.7385^2 = 0.5509$ by the delta method (Billingsley 1986; Cox 1998). Note that this particular approximation produces a t -statistic identical to that for the estimate of β_1 .

Not shown is the eta data set, which contains the original 16 observations and predictions of the η_{ij} .

Syntax: NLMIXED Procedure

The following statements are available in the NLMIXED procedure:

```

PROC NLMIXED < options > ;
  ARRAY array-specification ;
  BOUNDS boundary-constraints ;
  BY variables ;
  CONTRAST 'label' expression < , expression > < options > ;
  ESTIMATE 'label' expression < options > ;
  ID names ;
  MODEL model-specification ;
  PARMS parameters-and-starting-values ;
  PREDICT expression OUT=SAS-data-set < options > ;
  RANDOM random-effects-specification ;
  REPLICATE variable ;
  Programming statements ;

```

The following sections provide a detailed description of each of these statements.

PROC NLMIXED Statement

```

PROC NLMIXED < options > ;

```

The `PROC NLMIXED` statement invokes the NLMIXED procedure. Table 64.1 summarizes the options available in the `PROC NLMIXED` statement.

Table 64.1 PROC NLMIXED Statement Options

Option	Description
Basic Options	
DATA=	Specifies the input data set
METHOD=	Specifies the integration method
Displayed Output Specifications	
ALPHA=	Specifies α for confidence limits
CORR	Requests the correlation matrix
COV	Requests the covariance matrix
DF=	Specifies the degrees of freedom for p -values and confidence limits
ECORR	Requests the correlation matrix of additional estimates
ECOV	Requests the covariance matrix of additional estimates
EDER	Requests derivatives of additional estimates
EMPIRICAL	Requests the empirical (“sandwich”) estimator of covariance matrix
HESS	Requests the Hessian matrix
ITDETAILS	Requests iteration details
START	Specifies the gradient at starting values
Debugging Output	
FLOW	Displays the model execution messages
LISTCODE	Displays compiled model program
LISTDEP	Produces a model dependency listing
LISTDER	Displays the model derivatives
LIST	Displays the model program and variables
TRACE	Displays detailed model execution messages
XREF	Displays the model cross references
Quadrature Options	
NOADSCALE	Requests no adaptive scaling
NOAD	Requests no adaptive centering
OUTQ=	Displays output data set
QFAC=	Specifies the search factor
QMAX=	Specifies the maximum points
QPOINTS=	Specifies the number of points
QSCALEFAC=	Specifies the scale factor
QTOL=	Specifies the tolerance
Empirical Bayes Options	
EBOPT	Requests comprehensive optimization
EBSSFRAC=	Specifies the step-shortening fraction
EBSTOL=	Specifies the step-shortening tolerance
EBSTEPS=	Specifies the number of Newton steps
EBSUBSTEPS=	Specifies the number of substeps
EBTOL=	Specifies the convergence tolerance
EBZSTART	Requests zero as the starting values

Table 64.1 *continued*

Option	Description
Optimization Specifications	
HESCAL=	Specifies the type of Hessian scaling
INHESIAN<=>	Specifies the start for approximated Hessian
LINESEARCH=	Specifies the line-search method
LSPRECISION=	Specifies the line-search precision
OPTCHECK<=>	Checks optimality in a neighborhood
RESTART=	Specifies the iteration number for update restart
TECHNIQUE=	Specifies the minimization technique
UPDATE=	Specifies the update technique
Derivatives Specifications	
DIAHES	Uses only the diagonal of Hessian
FDHESSIAN<=>	Specifies the finite-difference second derivatives
FD<=>	Specifies the finite-difference derivatives
Constraint Specifications	
LCDEACT=	Specifies the Lagrange multiplier tolerance for deactivating
LCEPSILON=	Specifies the range for active constraints
LCSINGULAR=	Specifies the tolerance for dependent constraints
Termination Criteria Specifications	
ABSCONV=	Specifies the absolute function convergence criterion
ABSFCNV=	Specifies the absolute function difference convergence criterion
ABSGCONV=	Specifies the absolute gradient convergence criterion
ABSXCONV=	Specifies the absolute parameter convergence criterion
FCONV=	Specifies the relative function convergence criterion
FCONV2=	Specifies another relative function convergence criterion
FDIGITS=	Specifies the number accurate digits in objective function
FSIZE=	Specifies the FSIZE parameter of the relative function and relative gradient termination criteria
GCONV=	Specifies the relative gradient convergence criterion
MAXFUNC=	Specifies the maximum number of function calls
MAXITER=	Specifies the maximum number of iterations
MAXTIME=	Specifies the upper limit seconds of CPU time
MINITER=	Specifies the minimum number of iterations
XCONV=	Specifies the relative parameter convergence criterion
XSIZE=	Used in XCONV criterion
Step Length Specifications	
DAMPSTEP<=>	Specifies the damped steps in line search
INSTEP=	Specifies the initial trust-region radius
MAXSTEP=	Specifies the maximum trust-region radius
Singularity Tolerances	
SINGCHOL=	Specifies the tolerance for Cholesky roots

Table 64.1 *continued*

Option	Description
SINGHESS=	Specifies the tolerance for Hessian
SINGSWEEP=	Specifies the tolerance for sweep
SINGVAR=	Specifies the tolerance for variances
Covariance Matrix Tolerances	
ASINGULAR=	Specifies the absolute singularity for inertia
CFACTOR=	Specifies the multiplication factor for COV matrix
COVSING=	Specifies the tolerance for singular COV matrix
G4=	Specifies the threshold for Moore-Penrose inverse
MSINGULAR=	Specifies the relative M singularity for inertia
VSINGULAR=	Specifies the relative V singularity for inertia

These options are described in alphabetical order. For a description of the mathematical notation used in the following sections, see the section “[Modeling Assumptions and Notation](#)” on page 5383.

ABSCONV=*r*

ABSTOL=*r*

specifies an absolute function convergence criterion. For minimization, termination requires $f(\boldsymbol{\theta}^{(k)}) \leq r$. The default value of *r* is the negative square root of the largest double-precision value, which serves only as a protection against overflows.

ABSFCNV=*r*<[*n*]>

ABSFTOL=*r*<[*n*]>

specifies an absolute function difference convergence criterion. For all techniques except NMSIMP, termination requires a small change of the function value in successive iterations:

$$|f(\boldsymbol{\theta}^{(k-1)}) - f(\boldsymbol{\theta}^{(k)})| \leq r$$

The same formula is used for the NMSIMP technique, but $\boldsymbol{\theta}^{(k)}$ is defined as the vertex with the lowest function value, and $\boldsymbol{\theta}^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value is *r* = 0. The optional integer value *n* specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSGCONV=*r*<[*n*]>

ABSGTOL=*r*<[*n*]>

specifies an absolute gradient convergence criterion. Termination requires the maximum absolute gradient element to be small:

$$\max_j |g_j(\boldsymbol{\theta}^{(k)})| \leq r$$

This criterion is not used by the NMSIMP technique. The default value is *r* = 1E–5. The optional integer value *n* specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSXCONV= $r < [n] >$ **ABSXTOL**= $r < [n] >$

specifies an absolute parameter convergence criterion. For all techniques except NMSIMP, termination requires a small Euclidean distance between successive parameter vectors,

$$\| \boldsymbol{\theta}^{(k)} - \boldsymbol{\theta}^{(k-1)} \|_2 \leq r$$

For the NMSIMP technique, termination requires either a small length $\alpha^{(k)}$ of the vertices of a restart simplex,

$$\alpha^{(k)} \leq r$$

or a small simplex size,

$$\delta^{(k)} \leq r$$

where the simplex size $\delta^{(k)}$ is defined as the L1 distance from the simplex vertex $\boldsymbol{\xi}^{(k)}$ with the smallest function value to the other n simplex points $\boldsymbol{\theta}_l^{(k)} \neq \boldsymbol{\xi}^{(k)}$:

$$\delta^{(k)} = \sum_{\boldsymbol{\theta}_l^{(k)} \neq \boldsymbol{\xi}^{(k)}} \| \boldsymbol{\theta}_l^{(k)} - \boldsymbol{\xi}^{(k)} \|_1$$

The default is $r = 1\text{E-}8$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

ALPHA= α

specifies the alpha level to be used in computing confidence limits. The default value is 0.05.

ASINGULAR= r **ASING**= r

specifies an absolute singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is the square root of the smallest positive double-precision value.

CFACTOR= f

specifies a multiplication factor f for the estimated covariance matrix of the parameter estimates.

COV

requests the approximate covariance matrix for the parameter estimates.

CORR

requests the approximate correlation matrix for the parameter estimates.

COVSING= $r > 0$

specifies a nonnegative threshold that determines whether the eigenvalues of a singular Hessian matrix are considered to be zero.

DAMPSTEP=<=r>**DS=<=r>**

specifies that the initial step-size value $\alpha^{(0)}$ for each line search (used by the QUANEW, CONGRA, or NEWRAP technique) cannot be larger than r times the step-size value used in the former iteration. If you specify the DAMPSTEP option without factor r , the default value is $r = 2$. The DAMPSTEP= r option can prevent the line-search algorithm from repeatedly stepping into regions where some objective functions are difficult to compute or where they could lead to floating-point overflows during the computation of objective functions and their derivatives. The DAMPSTEP= r option can save time-costly function calls that result in very small step sizes α . For more details on setting the start values of each line search, see the section “[Restricting the Step Length](#)” on page 5398.

DATA=SAS-data-set

specifies the input data set. Observations in this data set are used to compute the log likelihood function that you specify with PROC NLMIXED statements.

NOTE: If you are using a [RANDOM](#) statement, the input data set must be clustered according to the [SUBJECT=](#) variable. One easy way to accomplish this is to sort your data by the [SUBJECT=](#) variable prior to calling PROC NLMIXED. PROC NLMIXED does not sort the input data set for you.

DF=d

specifies the degrees of freedom to be used in computing p values and confidence limits. The default value is the number of subjects minus the number of random effects for random effects models, and the number of observations otherwise.

DIAHES

specifies that only the diagonal of the Hessian is used.

EBOPT

requests that a more comprehensive optimization be carried out if the default empirical Bayes optimization fails to converge.

EBSSFRAC=<=r> 0

specifies the step-shortening fraction to be used while computing empirical Bayes estimates of the random effects. The default value is 0.8.

EBSTOL=<=r> ≥ 0

specifies the objective function tolerance for determining the cessation of step-shortening while computing empirical Bayes estimates of the random effects. The default value is $r = 1\text{E}-8$.

EBSTEPS=<=n> ≥ 0

specifies the maximum number of Newton steps for computing empirical Bayes estimates of random effects. The default value is $n = 50$.

EBSUBSTEPS=<=n> ≥ 0

specifies the maximum number of step-shortenings for computing empirical Bayes estimates of random effects. The default value is $n = 20$.

EBTOL=<=r> ≥ 0

specifies the convergence tolerance for empirical Bayes estimation. The default value is $r = \epsilon\text{E}4$, where ϵ is the machine precision. This default value equals approximately $1\text{E}-12$ on most machines.

EBZSTART

requests that a zero be used as starting values during empirical Bayes estimation. By default, the starting values are set equal to the estimates from the previous iteration (or zero for the first iteration).

ECOV

requests the approximate covariance matrix for all expressions specified in [ESTIMATE](#) statements.

ECORR

requests the approximate correlation matrix for all expressions specified in [ESTIMATE](#) statements.

EDER

requests the derivatives of all expressions specified in [ESTIMATE](#) statements with respect to each of the model parameters.

EMPIRICAL

requests that the covariance matrix of the parameter estimates be computed as a likelihood-based empirical (“sandwich”) estimator (White 1982). If $f(\boldsymbol{\theta}) = -\log\{m(\boldsymbol{\theta})\}$ is the objective function for the optimization and $m(\boldsymbol{\theta})$ denotes the marginal log likelihood (see the section “[Modeling Assumptions and Notation](#)” on page 5383 for notation and further definitions) the empirical estimator is computed as

$$\mathbf{H}(\hat{\boldsymbol{\theta}})^{-1} \left(\sum_{i=1}^s \mathbf{g}_i(\hat{\boldsymbol{\theta}}) \mathbf{g}_i(\hat{\boldsymbol{\theta}})' \right) \mathbf{H}(\hat{\boldsymbol{\theta}})^{-1}$$

where \mathbf{H} is the second derivative matrix of f and \mathbf{g}_i is the first derivative of the contribution to f by the i th subject. If you choose the EMPIRICAL option, this estimator of the covariance matrix of the parameter estimates replaces the model-based estimator $\mathbf{H}(\hat{\boldsymbol{\theta}})^{-1}$ in subsequent calculations. You can output the subject-specific gradients \mathbf{g}_i to a SAS data set with the [SUBGRADIENT](#) option in the [PROC NLMIXED](#) statement.

The EMPIRICAL option requires the presence of a [RANDOM](#) statement and is available for [METHOD=GAUSS](#) and [METHOD=ISAMP](#) only.

FCONV= $r < [n] >$ **FTOL= $r < [n] >$**

specifies a relative function convergence criterion. For all techniques except NMSIMP, termination requires a small relative change of the function value in successive iterations,

$$\frac{|f(\boldsymbol{\theta}^{(k)}) - f(\boldsymbol{\theta}^{(k-1)})|}{\max(|f(\boldsymbol{\theta}^{(k-1)})|, \text{FSIZE})} \leq r$$

where FSIZE is defined by the [FSIZE=](#) option. The same formula is used for the NMSIMP technique, but $\boldsymbol{\theta}^{(k)}$ is defined as the vertex with the lowest function value, and $\boldsymbol{\theta}^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default is $r = 10^{-\text{FDIGITS}}$, where FDIGITS is the value of the [FDIGITS=](#) option. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

FCNV2= $r < [n] >$ **FTOL2= $r < [n] >$**

specifies another function convergence criterion. For all techniques except NMSIMP, termination requires a small predicted reduction

$$df^{(k)} \approx f(\boldsymbol{\theta}^{(k)}) - f(\boldsymbol{\theta}^{(k)} + \mathbf{s}^{(k)})$$

of the objective function. The predicted reduction

$$\begin{aligned} df^{(k)} &= -\mathbf{g}^{(k)'} \mathbf{s}^{(k)} - \frac{1}{2} \mathbf{s}^{(k)'} \mathbf{H}^{(k)} \mathbf{s}^{(k)} \\ &= -\frac{1}{2} \mathbf{s}^{(k)'} \mathbf{g}^{(k)} \\ &\leq r \end{aligned}$$

is computed by approximating the objective function f by the first two terms of the Taylor series and substituting the Newton step:

$$\mathbf{s}^{(k)} = -[\mathbf{H}^{(k)}]^{-1} \mathbf{g}^{(k)}$$

For the NMSIMP technique, termination requires a small standard deviation of the function values of the $n + 1$ simplex vertices $\boldsymbol{\theta}_l^{(k)}$, $l = 0, \dots, n$,

$$\sqrt{\frac{1}{n+1} \sum_l \left[f(\boldsymbol{\theta}_l^{(k)}) - \bar{f}(\boldsymbol{\theta}^{(k)}) \right]^2} \leq r$$

where $\bar{f}(\boldsymbol{\theta}^{(k)}) = \frac{1}{n+1} \sum_l f(\boldsymbol{\theta}_l^{(k)})$. If there are n_{act} boundary constraints active at $\boldsymbol{\theta}^{(k)}$, the mean and standard deviation are computed only for the $n + 1 - n_{act}$ unconstrained vertices. The default value is $r = 1\text{E-}6$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

FD <= FORWARD | CENTRAL | $r >$

specifies that all derivatives be computed using finite difference approximations. The following specifications are permitted:

FD is equivalent to FD=100.

FD=CENTRAL uses central differences.

FD=FORWARD uses forward differences.

FD= r uses central differences for the initial and final evaluations of the gradient and for the Hessian. During iteration, start with forward differences and switch to a corresponding central-difference formula during the iteration process when one of the following two criteria is satisfied:

- The absolute maximum gradient element is less than or equal to r times the **ABSGCONV=** threshold.
- The normalized predicted function reduction (see the **GTOL** option) is less than or equal to $\max(1\text{E-}6, r \times \text{GTOL})$. The $1\text{E-}6$ ensures that the switch is done, even if you set the GTOL threshold to zero.

Note that the FD and FDHESSIAN options cannot apply at the same time. The FDHESSIAN option is ignored when only first-order derivatives are used. See the section “[Finite-Difference Approximations of Derivatives](#)” on page 5393 for more information.

FDHESSIAN<=FORWARD | CENTRAL>

FDHES<=FORWARD | CENTRAL>

FDH<=FORWARD | CENTRAL>

specifies that second-order derivatives be computed using finite difference approximations based on evaluations of the gradients.

FDHESSIAN=FORWARD uses forward differences.

FDHESSIAN=CENTRAL uses central differences.

FDHESSIAN uses forward differences for the Hessian except for the initial and final output.

Note that the FD and FDHESSIAN options cannot apply at the same time. See the section “[Finite-Difference Approximations of Derivatives](#)” on page 5393 for more information.

FDIGITS=*r*

specifies the number of accurate digits in evaluations of the objective function. Fractional values such as FDIGITS=4.7 are allowed. The default value is $r = -\log_{10} \epsilon$, where ϵ is the machine precision. The value of r is used to compute the interval size h for the computation of finite-difference approximations of the derivatives of the objective function and for the default value of the [FCONV](#)= option.

FLOW

displays a message for each statement in the model program as it is executed. This debugging option is very rarely needed and produces voluminous output.

FSIZE=*r*

specifies the FSIZE parameter of the relative function and relative gradient termination criteria. The default value is $r = 0$. For more details, see the [FCONV](#)= and [GCONV](#)= options.

G4= $n > 0$

specifies a dimension to determine the type of generalized inverse to use when the approximate covariance matrix of the parameter estimates is singular. The default value of n is 60. See the section “[Covariance Matrix](#)” on page 5402 for more information.

GCONV= $r < [n] >$

GTOL= $r < [n] >$

specifies a relative gradient convergence criterion. For all techniques except CONGRA and NMSIMP, termination requires that the normalized predicted function reduction is small,

$$\frac{\mathbf{g}(\boldsymbol{\theta}^{(k)})' [\mathbf{H}^{(k)}]^{-1} \mathbf{g}(\boldsymbol{\theta}^{(k)})}{\max(|f(\boldsymbol{\theta}^{(k)})|, \text{FSIZE})} \leq r$$

where FSIZE is defined by the FSIZE= option. For the CONGRA technique (where a reliable Hessian estimate H is not available), the following criterion is used:

$$\frac{\|\mathbf{g}(\boldsymbol{\theta}^{(k)})\|_2^2 \quad \|\mathbf{s}(\boldsymbol{\theta}^{(k)})\|_2}{\|\mathbf{g}(\boldsymbol{\theta}^{(k)}) - \mathbf{g}(\boldsymbol{\theta}^{(k-1)})\|_2 \max(|f(\boldsymbol{\theta}^{(k)})|, \text{FSIZE})} \leq r$$

This criterion is not used by the NMSIMP technique.

The default value is $r = 1\text{E-}8$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

HESCAL=0|1|2|3

HS=0|1|2|3

specifies the scaling version of the Hessian matrix used in NRRIDG, TRUREG, NEWRAP, or DBLDOG optimization.

If HS is not equal to 0, the first iteration and each restart iteration sets the diagonal scaling matrix $\mathbf{D}^{(0)} = \text{diag}(d_i^{(0)})$:

$$d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)}$$

where $H_{i,i}^{(0)}$ are the diagonal elements of the Hessian. In every other iteration, the diagonal scaling matrix $\mathbf{D}^{(0)} = \text{diag}(d_i^{(0)})$ is updated depending on the HS option:

HS=0 specifies that no scaling is done.

HS=1 specifies the Moré (1978) scaling update:

$$d_i^{(k+1)} = \max \left[d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

HS=2 specifies the Dennis, Gay, and Welsch (1981) scaling update:

$$d_i^{(k+1)} = \max \left[0.6 * d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

HS=3 specifies that d_i is reset in each iteration:

$$d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}$$

In each scaling update, ϵ is the relative machine precision. The default value is HS=0. Scaling of the Hessian can be time-consuming in the case where general linear constraints are active.

HESS

requests the display of the final Hessian matrix after optimization. If you also specify the [START](#) option, then the Hessian at the starting values is also printed.

INHESIAN=<r>

INHES=<r>

specifies how the initial estimate of the approximate Hessian is defined for the quasi-Newton techniques QUANEW and DBLDOG. There are two alternatives:

- If you do not use the r specification, the initial estimate of the approximate Hessian is set to the Hessian at $\theta^{(0)}$.
- If you do use the r specification, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix, $r\mathbf{I}$.

By default, if you do not specify the option INHESIAN= r , the initial estimate of the approximate Hessian is set to the multiple of the identity matrix $r\mathbf{I}$, where the scalar r is computed from the magnitude of the initial gradient.

INSTEP=*r*

reduces the length of the first trial step during the line search of the first iterations. For highly nonlinear objective functions, such as the EXP function, the default initial radius of the trust-region algorithm TRUREG or DBLDOG or the default step length of the line-search algorithms can result in arithmetic overflows. If this occurs, you should specify decreasing values of $0 < r < 1$ such as INSTEP=1E-1, INSTEP=1E-2, INSTEP=1E-4, and so on, until the iteration starts successfully.

- For trust-region algorithms (TRUREG, DBLDOG), the INSTEP= option specifies a factor $r > 0$ for the initial radius $\Delta^{(0)}$ of the trust region. The default initial trust-region radius is the length of the scaled gradient. This step corresponds to the default radius factor of $r = 1$.
- For line-search algorithms (NEWRAP, CONGRA, QUANEW), the INSTEP= option specifies an upper bound for the initial step length for the line search during the first five iterations. The default initial step length is $r = 1$.
- For the Nelder-Mead simplex algorithm, using TECH=NMSIMP, the INSTEP=*r* option defines the size of the start simplex.

For more details, see the section “[Computational Problems](#)” on page 5399.

ITDETAILS

requests a more complete iteration history, including the current values of the parameter estimates, their gradients, and additional optimization statistics. For further details, see the section “[Iterations](#)” on page 5405.

LCDEACT=*r***LCD=*r***

specifies a threshold *r* for the Lagrange multiplier that determines whether an active inequality constraint remains active or can be deactivated. During minimization, an active inequality constraint can be deactivated only if its Lagrange multiplier is less than the threshold value $r < 0$. The default value is

$$r = -\min(0.01, \max(0.1 \times \text{ABSGCONV}, 0.001 \times \text{gmax}^{(k)}))$$

where ABSGCONV is the value of the absolute gradient criterion, and $\text{gmax}^{(k)}$ is the maximum absolute element of the (projected) gradient $\mathbf{g}^{(k)}$ or $\mathbf{Z}'\mathbf{g}^{(k)}$. (See the section “[Active Set Methods](#)” for a definition of \mathbf{Z} .)

LCEPSILON=*r* > 0**LCEPS=*r* > 0****LCE=*r* > 0**

specifies the range for active and violated boundary constraints. The default value is $r = 1\text{E}-8$. During the optimization process, the introduction of rounding errors can force PROC NLMIXED to increase the value of *r* by a factor of 10, 100, If this happens, it is indicated by a message displayed in the log.

LCSINGULAR= $r > 0$ **LCSING= $r > 0$** **LCS= $r > 0$**

specifies a criterion r , used in the update of the QR decomposition, that determines whether an active constraint is linearly dependent on a set of other active constraints. The default value is $r = 1\text{E-}8$. The larger r becomes, the more the active constraints are recognized as being linearly dependent. If the value of r is larger than 0.1, it is reset to 0.1.

LINESEARCH= i **LIS= i**

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques. See Fletcher (1987) for an introduction to line-search techniques. The value of i can be $1, \dots, 8$. For CONGRA, QUANEW and NEWRAP, the default value is $i = 2$.

- | | |
|-------|---|
| LIS=1 | specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is similar to one used by the Harwell subroutine library. |
| LIS=2 | specifies a line-search method that needs more function than gradient calls for quadratic and cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option. |
| LIS=3 | specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option. |
| LIS=4 | specifies a line-search method that needs the same number of function and gradient calls for stepwise extrapolation and cubic interpolation. |
| LIS=5 | specifies a line-search method that is a modified version of LIS=4. |
| LIS=6 | specifies golden section line search (Polak 1971), which uses only function values for linear approximation. |
| LIS=7 | specifies bisection line search (Polak 1971), which uses only function values for linear approximation. |
| LIS=8 | specifies the Armijo line-search technique (Polak 1971), which uses only function values for linear approximation. |

LIST

displays the model program and variable lists. The LIST option is a debugging feature and is not normally needed.

LISTCODE

displays the derivative tables and the compiled program code. The LISTCODE option is a debugging feature and is not normally needed.

LISTDEP

produces a report that lists, for each variable in the program, the variables that depend on it and on which it depends. The LISTDEP option is a debugging feature and is not normally needed.

LISTDER

displays a table of derivatives. This table lists each nonzero derivative computed for the problem. The LISTDER option is a debugging feature and is not normally needed.

LOGNOTE<=*n*>

writes periodic notes to the log that describe the current status of computations. It is designed for use with analyses requiring extensive CPU resources. The optional integer value *n* specifies the desired level of reporting detail. The default is *n* = 1. Choosing *n* = 2 adds information about the objective function values at the end of each iteration. The most detail is obtained with *n* = 3, which also reports the results of function evaluations within iterations.

LSPRECISION=*r***LSP=*r***

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3. Usually an imprecise line search is inexpensive and successful. For more difficult optimization problems, a more precise and expensive line search might be necessary (Fletcher 1987). The second line-search method (which is the default for the NEWRAP, QUANEW, and CONGRA techniques) and the third line-search method approach exact line search for small LSPRECISION= values. If you have numerical problems, you should try to decrease the LSPRECISION= value to obtain a more precise line search. The default values are shown in the following table.

TECH=	UPDATE=	LSP default
QUANEW	DBFGS, BFGS	<i>r</i> = 0.4
QUANEW	DDFP, DFP	<i>r</i> = 0.06
CONGRA	all	<i>r</i> = 0.1
NEWRAP	no update	<i>r</i> = 0.9

For more details, see Fletcher (1987).

MAXFUNC=*i***MAXFU=*i***

specifies the maximum number *i* of function calls in the optimization process. The default values are as follows:

- TRUREG, NRRIDG, NEWRAP: 125
- QUANEW, DBLDOG: 500
- CONGRA: 1000
- NMSIMP: 3000

Note that the optimization can terminate only after completing a full iteration. Therefore, the number of function calls that is actually performed can exceed the number that is specified by the MAXFUNC= option.

MAXITER=*i***MAXIT=*i***

specifies the maximum number *i* of iterations in the optimization process. The default values are as follows:

- TRUREG, NRRIDG, NEWRAP: 50
- QUANEW, DBLDOG: 200
- CONGRA: 400
- NMSIMP: 1000

These default values are also valid when *i* is specified as a missing value.

MAXSTEP=*r*<[*n*]>

specifies an upper bound for the step length of the line-search algorithms during the first *n* iterations. By default, *r* is the largest double-precision value and *n* is the largest integer available. Setting this option can improve the speed of convergence for the CONGRA, QUANEW, and NEWRAP techniques.

MAXTIME=*r*

specifies an upper limit of *r* seconds of CPU time for the optimization process. The default value is the largest floating-point double representation of your computer. Note that the time specified by the MAXTIME= option is checked only once at the end of each iteration. Therefore, the actual running time can be much longer than that specified by the MAXTIME= option. The actual running time includes the rest of the time needed to finish the iteration and the time needed to generate the output of the results.

METHOD=*value*

specifies the method for approximating the integral of the likelihood over the random effects. Valid values are as follows:

FIRO

specifies the first-order method of Beal and Sheiner (1982). When using METHOD=FIRO, you must specify the NORMAL distribution in the **MODEL** statement and you must also specify a **RANDOM** statement.

GAUSS

specifies adaptive Gauss-Hermite quadrature (Pinheiro and Bates 1995). You can prevent the adaptation with the **NOAD** option or prevent adaptive scaling with the **NOADSCALE** option. This is the default integration method.

HARDY

specifies Hardy quadrature based on an adaptive trapezoidal rule. This method is available only for one-dimensional integrals; that is, you must specify only one random effect.

ISAMP

specifies adaptive importance sampling (Pinheiro and Bates 1995). You can prevent the adaptation with the **NOAD** option or prevent adaptive scaling with the **NOADSCALE** option. You can use the **SEED=** option to specify a starting seed for the random number generation used in the importance sampling. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock.

MINITER=*i***MINIT**=*i*

specifies the minimum number of iterations. The default value is 0. If you request more iterations than are actually needed for convergence to a stationary point, the optimization algorithms can behave strangely. For example, the effect of rounding errors can prevent the algorithm from continuing for the required number of iterations.

MSINGULAR=*r* > 0**MSING**=*r* > 0

specifies a relative singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is 1E–12 if you do not specify the SINGHESS= option; otherwise, the default value is $\max(10\epsilon, (1E-4) \times \text{SINGHESS})$. See the section “[Covariance Matrix](#)” on page 5402 for more information.

NOAD

requests that the Gaussian quadrature be nonadaptive; that is, the quadrature points are centered at zero for each of the random effects and the current random-effects variance matrix is used as the scale matrix.

NOADSCALE

requests nonadaptive scaling for adaptive Gaussian quadrature; that is, the quadrature points are centered at the empirical Bayes estimates for the random effects, but the current random-effects variance matrix is used as the scale matrix. By default, the observed Hessian from the current empirical Bayes estimates is used as the scale matrix.

OPTCHECK<=*r* > 0 >

computes the function values $f(\theta_l)$ of a grid of points θ_l in a ball of radius of *r* about θ^* . If you specify the OPTCHECK option without factor *r*, the default value is *r* = 0.1 at the starting point and *r* = 0.01 at the terminating point. If a point θ_l^* is found with a better function value than $f(\theta^*)$, then optimization is restarted at θ_l^* .

OUTQ=*SAS-data-set*

specifies an output data set containing the quadrature points used for numerical integration.

QFAC=*r* > 0

specifies the additive factor used to adaptively search for the number of quadrature points. For **METHOD**=GAUSS, the search sequence is 1, 3, 5, 7, 9, 11, 11 + *r*, 11 + 2*r*, ..., where the default value of *r* is 10. For **METHOD**=ISAMP, the search sequence is 10, 10 + *r*, 10 + 2*r*, ..., where the default value of *r* is 50.

QMAX=*r* > 0

specifies the maximum number of quadrature points permitted before the adaptive search is aborted. The default values are 31 for adaptive Gaussian quadrature, 61 for nonadaptive Gaussian quadrature, 160 for adaptive importance sampling, and 310 for nonadaptive importance sampling.

QPOINTS=*n* > 0

specifies the number of quadrature points to be used during evaluation of integrals. For **METHOD**=GAUSS, *n* equals the number of points used in each dimension of the random effects, resulting in a total of n^r points, where *r* is the number of dimensions. For **METHOD**=ISAMP, *n* specifies the total number of quadrature points regardless of the dimension of the random effects.

By default, the number of quadrature points is selected adaptively, and this option disables the adaptive search.

QSCALEFAC= $r > 0$

specifies a multiplier for the scale matrix used during quadrature calculations. The default value is 1.0.

QTOL= $r > 0$

specifies the tolerance used to adaptively select the number of quadrature points. When the relative difference between two successive likelihood calculations is less than r , then the search terminates and the lesser number of quadrature points is used during the subsequent optimization process. The default value is 1E-4.

RESTART= $i > 0$

REST= $i > 0$

specifies that the QUANEW or CONGRA algorithm is restarted with a steepest descent/ascent search direction after, at most, i iterations. Default values are as follows:

- CONGRA: UPDATE=PB: restart is performed automatically, i is not used.
- CONGRA: UPDATE \neq PB: $i = \min(10n, 80)$, where n is the number of parameters.
- QUANEW: i is the largest integer available.

SEED= i

specifies the random number seed for **METHOD=ISAMP**. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock. The value must be less than $2^{31} - 1$.

SINGCHOL= $r > 0$

specifies the singularity criterion r for Cholesky roots of the random-effects variance matrix and scale matrix for adaptive Gaussian quadrature. The default value is 1E4 times the machine epsilon; this product is approximately 1E-12 on most computers.

SINGHESS= $r > 0$

specifies the singularity criterion r for the inversion of the Hessian matrix. The default value is 1E-8. See the ASINGULAR, MSINGULAR=, and VSINGULAR= options for more information.

SINGSWEEP= $r > 0$

specifies the singularity criterion r for inverting the variance matrix in the first-order method and the empirical Bayes Hessian matrix. The default value is 1E4 times the machine epsilon; this product is approximately 1E-12 on most computers.

SINGVAR= $r > 0$

specifies the singularity criterion r below which statistical variances are considered to equal zero. The default value is 1E4 times the machine epsilon; this product is approximately 1E-12 on most computers.

START

requests that the gradient of the log likelihood at the starting values be displayed. If you also specify the **HESS** option, then the starting Hessian is displayed as well.

SUBGRADIENT=SAS-data-set

SUBGRAD=SAS-data-set

specifies a SAS data set to save in models with **RANDOM** statement the subject-specific gradients of the integrated, marginal log-likelihood with respect to all parameters. The sum of the subject-specific gradients equals the gradient reported in the “Parameter Estimates” table. The data set contains a variable identifying the subjects.

In models without **RANDOM** statement the **SUBGRADIENT=** data set contains the observation-wise gradient. The variable identifying the **SUBJECT=** is then replaced with the **Observation**. This observation counter includes observations not used in the analysis and is reset in each **BY**-group.

Saving disaggregated gradient information with the **SUBGRADIENT=** option requires **METHOD=GAUSS** or **METHOD=ISAMP**.

TECHNIQUE=value

TECH=value

specifies the optimization technique. By default, **TECH** = **QUANEW**. Valid values are as follows:

- **CONGRA**
performs a conjugate-gradient optimization, which can be more precisely specified with the **UPDATE=** option and modified with the **LINESEARCH=** option. When you specify this option, **UPDATE=PB** by default.
- **DBLDOG**
performs a version of double-dogleg optimization, which can be more precisely specified with the **UPDATE=** option. When you specify this option, **UPDATE=DBFGS** by default.
- **NMSIMP**
performs a Nelder-Mead simplex optimization.
- **NONE**
does not perform any optimization. This option can be used as follows:
 - to perform a grid search without optimization
 - to compute estimates and predictions that cannot be obtained efficiently with any of the optimization techniques
- **NEWRAP**
performs a Newton-Raphson optimization combining a line-search algorithm with ridging. The line-search algorithm **LIS=2** is the default method.
- **NRRIDG**
performs a Newton-Raphson optimization with ridging.
- **QUANEW**
performs a quasi-Newton optimization, which can be defined more precisely with the **UPDATE=** option and modified with the **LINESEARCH=** option. This is the default estimation method.
- **TRUREG**
performs a trust region optimization.

TRACE

displays the result of each operation in each statement in the model program as it is executed. This debugging option is very rarely needed, and it produces voluminous output.

UPDATE=method**UPD=method**

specifies the update method for the quasi-Newton, double-dogleg, or conjugate-gradient optimization technique. Not every update method can be used with each optimizer. See the section “[Optimization Algorithms](#)” on page 5388 for more information.

Valid methods are as follows:

- **BFGS**
performs the original Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the inverse Hessian matrix.
- **DBFGS**
performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default update method.
- **DDFP**
performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- **DFP**
performs the original DFP update of the inverse Hessian matrix.
- **PB**
performs the automatic restart update method of Powell (1977) and Beale (1972).
- **FR**
performs the Fletcher-Reeves update (Fletcher 1987).
- **PR**
performs the Polak-Ribiere update (Fletcher 1987).
- **CD**
performs a conjugate-descent update of Fletcher (1987).

VSINGULAR= $r > 0$ **VSING= $r > 0$**

specifies a relative singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is $r = 1\text{E-}8$ if the **SINGHESS=** option is not specified, and it is the value of **SINGHESS=** option otherwise. See the section “[Covariance Matrix](#)” on page 5402 for more information.

XCONV= $r < [n] >$ **XTOL= $r < [n] >$**

specifies the relative parameter convergence criterion. For all techniques except NMSIMP, termination requires a small relative parameter change in subsequent iterations:

$$\frac{\max_j |\theta_j^{(k)} - \theta_j^{(k-1)}|}{\max(|\theta_j^{(k)}|, |\theta_j^{(k-1)}|, \text{XSIZE})} \leq r$$

For the NMSIMP technique, the same formula is used, but $\theta^{(k)}$ is defined as the vertex with the lowest function value and $\theta^{(k-1)}$ is defined as the vertex with the highest function value in the simplex.

The default value is $r = 1\text{E-}8$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

XREF

displays a cross-reference of the variables in the program showing where each variable is referenced or given a value. The XREF listing does not include derivative variables. This option is a debugging feature and is not normally needed.

XSIZE= $r > 0$

specifies the XSIZE parameter of the relative parameter termination criterion. The default value is $r = 0$. For more details, see the [XCONV=](#) option.

ARRAY Statement

ARRAY *arrayname* [*dimensions*] <\$> <*variables-and-constants*> ;

The ARRAY statement is similar to, but not exactly the same as, the ARRAY statement in the SAS DATA step, and it is exactly the same as the ARRAY statements in the NLIN, NLP, and MODEL procedures. The ARRAY statement is used to associate a name (of no more than eight characters) with a list of variables and constants. The array name is used with subscripts in the program to refer to the array elements. The following statements illustrate this:

```
array r[8] r1-r8;

do i = 1 to 8;
    r[i] = 0;
end;
```

The ARRAY statement does not support all the features of the ARRAY statement in the DATA step. It cannot be used to assign initial values to array elements. Implicit indexing of variables cannot be used; all array references must have explicit subscript expressions. Only exact array dimensions are allowed; lower-bound specifications are not supported. A maximum of six dimensions is allowed.

On the other hand, the ARRAY statement does allow both variables and constants to be used as array elements. (Constant array elements cannot have values assigned to them.) Both dimension specification and the list of elements are optional, but at least one must be specified. When the list of elements is not specified or fewer elements than the size of the array are listed, array variables are created by suffixing element numbers to the array name to complete the element list.

BOUNDS Statement

BOUNDS *b-con* <, *b-con* ... >;

where *b-con* := number *operator* parameter_list *operator* number
 or *b-con* := number *operator* parameter_list
 or *b-con* := parameter_list *operator* number
 and *operator* := <=, <, >=, or >

Boundary constraints are specified with a BOUNDS statement. One- or two-sided boundary constraints are allowed. The list of boundary constraints are separated by commas. For example:

```
bounds 0 <= a1-a9 x <= 1, -1 <= c2-c5;
bounds b1-b10 y >= 0;
```

You can specify more than one BOUNDS statement. If you specify more than one lower (upper) bound for the same parameter, the maximum (minimum) of these is taken.

If the maximum l_j of all lower bounds is larger than the minimum of all upper bounds u_j for the same parameter θ_j , the boundary constraint is replaced by $\theta_j := l_j := \min(u_j)$ defined by the minimum of all upper bounds specified for θ_j .

BY Statement

BY *variables* ;

You can specify a BY statement with PROC NLMIXED to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the NLMIXED procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

An optimization problem is solved for each BY group separately unless the **TECH=NONE** option is specified.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CONTRAST Statement

CONTRAST *'label' expression < , expression > < options > ;*

The CONTRAST statement enables you to conduct a statistical test that several expressions simultaneously equal zero. The expressions are typically contrasts—that is, differences whose expected values equal zero under the hypothesis of interest.

In the CONTRAST statement you must provide a quoted string to identify the contrast and then a list of valid SAS expressions separated by commas. Multiple CONTRAST statements are permitted, and results from all statements are listed in a common table. PROC NLMIXED constructs approximate F tests for each statement using the delta method (Cox 1998) to approximate the variance-covariance matrix of the constituent expressions.

The following option is available in the CONTRAST statement:

DF= d

specifies the denominator degrees of freedom to be used in computing p values for the F statistics. The default value corresponds to the **DF**= option in the PROC NLMIXED statement.

ESTIMATE Statement

ESTIMATE *'label' expression < options > ;*

The ESTIMATE statement enables you to compute an additional estimate that is a function of the parameter values. You must provide a quoted string to identify the estimate and then a valid SAS expression. Multiple ESTIMATE statements are permitted, and results from all statements are listed in a common table. PROC NLMIXED computes approximate standard errors for the estimates using the delta method (Billingsley 1986). It uses these standard errors to compute corresponding t statistics, p -values, and confidence limits.

The **ECOV** option in the PROC NLMIXED statement produces a table containing the approximate covariance matrix of all the additional estimates you specify. The **ECORR** option produces the corresponding correlation matrix. The **EDER** option produces a table of the derivatives of the additional estimates with respect to each of the model parameters.

The following options are available in the ESTIMATE statement:

ALPHA= α

specifies the alpha level to be used in computing confidence limits. The default value corresponds to the **ALPHA**= option in the PROC NLMIXED statement.

DF= d

specifies the degrees of freedom to be used in computing p -values and confidence limits. The default value corresponds to the **DF**= option in the PROC NLMIXED statement.

ID Statement

ID *names* ;

The ID statement identifies additional quantities to be included in the **OUT=** data set of the **PREDICT** statement. These can be any symbols you have defined with SAS programming statements.

MODEL Statement

MODEL *dependent-variable* \sim *distribution* ;

The MODEL statement is the mechanism for specifying the conditional distribution of the data given the random effects. You must specify a single dependent variable from the input data set, a tilde \sim , and then a distribution with its parameters. Valid distributions are as follows.

- *normal*(*m*,*v*) specifies a normal (Gaussian) distribution with mean *m* and variance *v*.
- *binary*(*p*) specifies a binary (Bernoulli) distribution with probability *p*.
- *binomial*(*n*,*p*) specifies a binomial distribution with count *n* and probability *p*.
- *gamma*(*a*,*b*) specifies a gamma distribution with shape *a* and scale *b*.
- *negbin*(*n*,*p*) specifies a negative binomial distribution with count *n* and probability *p*.
- *poisson*(*m*) specifies a Poisson distribution with mean *m*.
- *general*(*ll*) specifies a general log likelihood function that you construct using SAS programming statements.

The MODEL statement must follow any SAS programming statements you specify for computing parameters of the preceding distributions. See the section “[Built-in Log-Likelihood Functions](#)” on page 5386 for expressions of the built-in conditional log-likelihood functions.

PARMS Statement

PARMS *< name-list <=numbers> > <, name-list <=numbers> ... >*
</ options> ;

The PARMS statement lists names of parameters and specifies initial values, possibly over a grid. You can specify the parameters and values directly in a list, or you can provide the name of a SAS data set that contains them by using the **DATA=** option.

While the PARMS statement is not required, you are encouraged to use it to provide PROC NLMIXED with accurate starting values. Parameters not listed in the PARMS statement are assigned an initial value of 1.

PROC NLMIXED considers all symbols not assigned values to be parameters, so you should specify your modeling statements carefully and check the output from the “Parameters” table to make sure the proper parameters are identified.

A list of parameter names in the PARMS statement is not separated by commas and is followed by an equal sign and a list of numbers. If the number list consists of only one number, this number defines the initial value for all the parameters listed to the left of the equal sign.

If the number list consists of more than one number, these numbers specify the grid locations for each of the parameters listed to the left of the equal sign. You can use the TO and BY keywords to specify a number list for a grid search. If you specify a grid of points in a PARMS statement, PROC NLMIXED computes the objective function value at each grid point and chooses the best (feasible) grid point as an initial point for the optimization process. You can use the BEST= option to save memory for the storing and sorting of all grid point information.

The following options are available in the PARMS statement after a slash (/):

BEST=*i* > 0

specifies the maximum number of points displayed in the “Parameters” table, selected as the points with the maximum likelihood values. By default, all grid values are displayed.

BYDATA

enables you to assign different starting values for each **BY** group by using the DATA=SAS-*data-set* option during **BY** processing. By default, **BY** groups are ignored in the PARMS data set. For the BYDATA option to be effective, the DATA= data set must contain the BY variables and the same BY groups as the primary input data set. When you supply a grid of starting values with the DATA= data set and the BYDATA option is in effect, the size of the grid is determined by the first **BY** group.

DATA=SAS-*data-set*

specifies a SAS data set containing parameter names and starting values. The data set should be in one of two forms: narrow or wide. The narrow-form data set contains the variables Parameter and Estimate, with parameters and values listed as distinct observations. The wide-form data set has the parameters themselves as variables, and each observation provides a different set of starting values. By default, **BY** groups are ignored in this data set, so the same starting grid is evaluated for each **BY** group. You can vary the starting values for **BY** groups by using the BYDATA option.

PREDICT Statement

PREDICT *expression* **OUT=SAS-*data-set*** < *options* > ;

The PREDICT statement enables you to construct predictions of an expression across all of the observations in the input data set. Any valid SAS programming expression involving the input data set variables, parameters, and random effects is valid. Predicted values are computed using the parameter estimates and empirical Bayes estimates of the random effects. Standard errors of prediction are computed using the delta method (Billingsley 1986; Cox 1998). Results are placed in an output data set that you specify with the **OUT=** option. Besides all variables from the input data set, the OUT= data set contains the following variables: Pred, StdErrPred, DF, tValue, Probt, Alpha, Lower, Upper. You can also add other computed quantities to this data set with the ID statement.

The following options are available in the PREDICT statement:

ALPHA= α

specifies the alpha level to be used in computing t statistics and intervals. The default value corresponds to the **ALPHA=** option in the **PROC NLMIXED** statement.

DER

requests that derivatives of the predicted expression with respect to all parameters be included in the OUT= data set. The variable names for the derivatives are the same as the parameter names with the prefix “Der_” appended. All of the derivatives are evaluated at the final estimates of the parameters and the empirical Bayes estimates of the random effects.

DF= d

specifies the degrees of freedom to be used in computing t statistics and intervals in the OUT= data set. The default value corresponds to the **DF=** option in the **PROC NLMIXED** statement.

RANDOM Statement

RANDOM *random-effects* ~ *distribution* **SUBJECT=***variable* < *options* > ;

The RANDOM statement defines the random effects and their distribution. The random effects must be represented by symbols that appear in your SAS programming statements. They typically influence the mean value of the distribution specified in the **MODEL** statement. The RANDOM statement consists of a list of the random effects (usually just one or two symbols), a tilde ~, the distribution for the random effects, and then a **SUBJECT=** variable.

NOTE: The input data set must be clustered according to the **SUBJECT=** variable. One easy way to accomplish this is to sort your data by the **SUBJECT=** variable prior to calling PROC NLMIXED. PROC NLMIXED does not sort the input data set for you; rather, it processes the data sequentially and considers an observation to be from a new subject whenever the value of its **SUBJECT=** variable changes from the previous observation.

The only distribution available for the random effects is normal(m,v) with mean m and variance v .

This syntax is illustrated as follows for one effect:

```
random u ~ normal(0,s2u) subject=clinic;
```

For multiple effects, you should specify bracketed vectors for m and v , the latter consisting of the lower triangle of the random-effects variance matrix listed in row order. This is illustrated for two and three random effects as follows:

```
random b1 b2 ~ normal([0,0],[g11,g21,g22]) subject=person;
random b1 b2 b3 ~ normal([0,0,0],[g11,g21,g22,g31,g32,g33])
    subject=person;
```

The **SUBJECT=** variable determines when new realizations of the random effects are assumed to occur. PROC NLMIXED assumes that a new realization occurs whenever the value of the **SUBJECT=** variable changes from the previous observation, so your input data set should be clustered according to this variable. One easy way to accomplish this is to run PROC SORT prior to calling PROC NLMIXED by using the **SUBJECT=** variable as the BY variable.

Only one RANDOM statement is permitted, so multilevel nonlinear mixed models are not accommodated. However, you can specify certain nested random effects structure with a single RANDOM statement (see Chapter 15 of Littell et al. (2006) for an example).

The following options are available in the RANDOM statement:

ALPHA= α

specifies the alpha level to be used in computing t statistics and intervals. The default value corresponds to the ALPHA= option in the PROC NLMIXED statement.

DF= d

specifies the degrees of freedom to be used in computing t statistics and intervals in the OUT= data set. The default value corresponds to the DF= option in the PROC NLMIXED statement.

OUT=SAS-data-set

requests an output data set containing empirical Bayes estimates of the random effects and their approximate standard errors of prediction.

REPLICATE Statement

REPLICATE *variable* ;

The REPLICATE statement provides a way to accommodate models in which different subjects have identical data. This occurs most commonly when the dependent variable is binary. When you specify a REPLICATE variable, PROC NLMIXED treats its value as the number of subjects that have data identical to the data for the current value of the SUBJECT= variable (specified in the RANDOM statement). Only the last observation of the REPLICATE variable for each subject is used, and the replicate variable must have only positive values.

The function of a REPLICATE statement is related to but not quite the same as the function of either a FREQ or a WEIGHT statement in other statistical modeling procedures, such as the GLM, GENMOD, GLIMMIX, and LOGISTIC procedures. A FREQ or a WEIGHT value essentially multiplies the log likelihood or sum of squares contribution for each observation. On the other hand, a REPLICATE value multiplies the log likelihood contribution of each subject, which consists of one or more observations. When no SUBJECT= variable is specified, the REPLICATE value behaves like a weight, multiplying each observation's log likelihood contribution.

Programming Statements

This section lists the programming statements used to code the log-likelihood function in PROC NLMIXED. It also documents the differences between programming statements in PROC NLMIXED and programming statements in the SAS DATA step. The syntax of programming statements used in PROC NLMIXED is identical to that used in the CALIS and GENMOD procedures (see Chapter 27 and Chapter 40, respectively), and the MODEL procedure (see the *SAS/ETS User's Guide*). Most of the programming statements that can be used in the SAS DATA step can also be used in the NLMIXED procedure. See *SAS Language Reference: Dictionary* for a description of SAS programming statements. The following are valid statements:

```

ABORT;
ARRAY arrayname < [ dimensions ] > < $ > < variables-and-constants >;
CALL name < (expression < , expression ... >) >;
DELETE;
DO < variable = expression < TO expression > < BY expression > >
    < , expression < TO expression > < BY expression > > ...
    < WHILE expression > < UNTIL expression >;
END;
GOTO statement-label;
IF expression;
IF expression THEN program-statement;
    ELSE program-statement;
variable = expression;
variable + expression;
LINK statement-label;
PUT < variable > < = > ...;
RETURN;
SELECT < (expression) >;
STOP;
SUBSTR(variable, index, length) = expression;
WHEN (expression) program-statement;
    OTHERWISE program-statement;

```

For the most part, the SAS programming statements work the same as they do in the SAS DATA step, as documented in *SAS Language Reference: Concepts*; however, there are the following differences:

- The ABORT statement does not allow any arguments.
- The DO statement does not allow a character index variable. Thus

```
do i = 1,2,3;
```

is supported, but the following statement is not supported:

```
do i = 'A', 'B', 'C';
```

- The LAG function does work appropriately with PROC NLMIXED, but you can use the ZLAG function instead.
- The PUT statement, used mostly for program debugging in PROC NLMIXED, supports only some of the features of the DATA step PUT statement, and it has some new features that the DATA step PUT statement does not.
 - The PROC NLMIXED PUT statement does not support line pointers, factored lists, iteration factors, overprinting, _INFILE_, the colon (:) format modifier, or “\$”.
 - The PROC NLMIXED PUT statement does support expressions, but the expression must be enclosed in parentheses. For example, the following statement displays the square root of x:

```
put (sqrt(x));
```

- The PROC NLMIXED PUT statement supports the item `_PDV_` to display a formatted listing of all variables in the program. For example, the following statement displays a much more readable listing of the variables than the `_ALL_` print item:

```
put _pdv_;
```

- The WHEN and OTHERWISE statements enable you to specify more than one target statement. That is, DO/END groups are not necessary for multiple statement WHENs. For example, the following syntax is valid:

```
select;
  when (exp1) stmt1;
               stmt2;
  when (exp2) stmt3;
               stmt4;
end;
```

When coding your programming statements, you should avoid defining variables that begin with an underscore (`_`), because they might conflict with internal variables created by PROC NLMIXED. The **MODEL** statement must come after any SAS programming statements that define or modify terms used in the construction of the log-likelihood.

Details: NLMIXED Procedure

This section contains details about the underlying theory and computations of PROC NLMIXED.

Modeling Assumptions and Notation

PROC NLMIXED operates under the following general framework for nonlinear mixed models. Assume that you have an observed data vector \mathbf{y}_i for each of i subjects, $i = 1, \dots, s$. The \mathbf{y}_i are assumed to be independent across i , but within-subject covariance is likely to exist because each of the elements of \mathbf{y}_i is measured on the same subject. As a statistical mechanism for modeling this within-subject covariance, assume that there exist latent random-effect vectors \mathbf{u}_i of small dimension (typically one or two) that are also independent across i . Assume also that an appropriate model linking \mathbf{y}_i and \mathbf{u}_i exists, leading to the joint probability density function

$$p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) q(\mathbf{u}_i | \boldsymbol{\xi})$$

where \mathbf{X}_i is a matrix of observed explanatory variables and $\boldsymbol{\phi}$ and $\boldsymbol{\xi}$ are vectors of unknown parameters.

Let $\boldsymbol{\theta} = [\boldsymbol{\phi}, \boldsymbol{\xi}]$ and assume that it is of dimension n . Then inferences about $\boldsymbol{\theta}$ are based on the marginal likelihood function

$$m(\boldsymbol{\theta}) = \prod_{i=1}^s \int p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) q(\mathbf{u}_i | \boldsymbol{\xi}) d\mathbf{u}_i$$

In particular, the function

$$f(\boldsymbol{\theta}) = -\log m(\boldsymbol{\theta})$$

is minimized over $\boldsymbol{\theta}$ numerically in order to estimate $\boldsymbol{\theta}$, and the inverse Hessian (second derivative) matrix at the estimates provides an approximate variance-covariance matrix for the estimate of $\boldsymbol{\theta}$. The function $f(\boldsymbol{\theta})$ is referred to both as the negative log likelihood function and as the objective function for optimization.

As an example of the preceding general framework, consider the nonlinear growth curve example in the section “Getting Started: NLMIXED Procedure” on page 5350. Here, the conditional distribution $p(y_i | \mathbf{X}_i, \boldsymbol{\phi}, u_i)$ is normal with mean

$$\frac{b_1 + u_{i1}}{1 + \exp[-(d_{ij} - b_2)/b_3]}$$

and variance σ_e^2 ; thus $\boldsymbol{\phi} = [b_1, b_2, b_3, \sigma_e^2]$. Also, u_i is a scalar and $q(u_i | \xi)$ is normal with mean 0 and variance σ_u^2 ; thus $\xi = \sigma_u^2$.

The following additional notation is also found in this chapter. The quantity $\boldsymbol{\theta}^{(k)}$ refers to the parameter vector at the k th iteration, the vector $\mathbf{g}(\boldsymbol{\theta})$ refers to the gradient vector $\nabla f(\boldsymbol{\theta})$, and the matrix $\mathbf{H}(\boldsymbol{\theta})$ refers to the Hessian $\nabla^2 f(\boldsymbol{\theta})$. Other symbols are used to denote various constants or option values.

Integral Approximations

An important part of the marginal maximum likelihood method described previously is the computation of the integral over the random effects. The default method in PROC NLMIXED for computing this integral is adaptive Gaussian quadrature as described in Pinheiro and Bates (1995). Another approximation method is the first-order method of Beal and Sheiner (1982, 1988). A description of these two methods follows.

Adaptive Gaussian Quadrature

A quadrature method approximates a given integral by a weighted sum over predefined abscissas for the random effects. A good approximation can usually be obtained with an adequate number of quadrature points as well as appropriate centering and scaling of the abscissas. Adaptive Gaussian quadrature for the integral over \mathbf{u}_i centers the integral at the empirical Bayes estimate of \mathbf{u}_i , defined as the vector $\hat{\mathbf{u}}_i$ that minimizes

$$-\log [p(y_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)q(\mathbf{u}_i | \xi)]$$

with $\boldsymbol{\phi}$ and ξ set equal to their current estimates. The final Hessian matrix from this optimization can be used to scale the quadrature abscissas.

Suppose $(z_j, w_j; j = 1, \dots, p)$ denote the standard Gauss-Hermite abscissas and weights (Golub and Welsch 1969, or Table 25.10 of Abramowitz and Stegun 1972). The adaptive Gaussian quadrature integral approximation is as follows:

$$\int p(y_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)q(\mathbf{u}_i | \xi) d\mathbf{u}_i \approx 2^{r/2} |\boldsymbol{\Gamma}(\mathbf{X}_i, \boldsymbol{\theta})|^{-1/2} \sum_{j_1=1}^p \cdots \sum_{j_r=1}^p \left[p(y_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{a}_{j_1, \dots, j_r})q(\mathbf{a}_{j_1, \dots, j_r} | \xi) \prod_{k=1}^r w_{j_k} \exp z_{j_k}^2 \right]$$

where r is the dimension of u_i , $\Gamma(\mathbf{X}_i, \boldsymbol{\theta})$ is the Hessian matrix from the empirical Bayes minimization, $\mathbf{z}_{j_1, \dots, j_r}$ is a vector with elements $(z_{j_1}, \dots, z_{j_r})$, and

$$\mathbf{a}_{j_1, \dots, j_r} = \hat{\mathbf{u}}_i + 2^{1/2} \Gamma(\mathbf{X}_i, \boldsymbol{\theta})^{-1/2} \mathbf{z}_{j_1, \dots, j_r}$$

PROC NLMIXED selects the number of quadrature points adaptively by evaluating the log-likelihood function at the starting values of the parameters until two successive evaluations have a relative difference less than the value of the **QTOL=** option. The specific search sequence is described under the **QFAC=** option. Using the **QPOINTS=** option, you can adjust the number of quadrature points p to obtain different levels of accuracy. Setting $p = 1$ results in the Laplacian approximation as described in: Beal and Sheiner (1992); Wolfinger (1993); Vonesh (1992, 1996); Vonesh and Chinchilli (1997); Wolfinger and Lin (1997).

The **NOAD** option in the **PROC NLMIXED** statement requests nonadaptive Gaussian quadrature. Here all $\hat{\mathbf{u}}_i$ are set equal to zero, and the Cholesky root of the estimated variance matrix of the random effects is substituted for $\Gamma(\mathbf{X}_i, \boldsymbol{\theta})^{-1/2}$ in the preceding expression for $\mathbf{a}_{j_1, \dots, j_r}$. In this case derivatives are computed using the algorithm of Smith (1995). The **NOADSCALE** option requests the same scaling substitution but with the empirical Bayes $\hat{\mathbf{u}}_i$.

PROC NLMIXED computes the derivatives of the adaptive Gaussian quadrature approximation when carrying out the default dual quasi-Newton optimization.

First-Order Method

Another integral approximation available in PROC NLMIXED is the first-order method of Beal and Sheiner (1982, 1988) and Sheiner and Beal (1985). This approximation is used only in the case where $p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)$ is normal—that is,

$$p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) = (2\pi)^{-n_i/2} |\mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})|^{-1/2} \exp \left\{ -(1/2) [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)]' \mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})^{-1} [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)] \right\}$$

where n_i is the dimension of \mathbf{y}_i , \mathbf{R}_i is a diagonal variance matrix, and \mathbf{m}_i is the conditional mean vector of \mathbf{y}_i .

The first-order approximation is obtained by expanding $\mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)$ with a one-term Taylor series expansion about $\mathbf{u}_i = \mathbf{0}$, resulting in the approximation

$$p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) \approx (2\pi)^{-n_i/2} |\mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})|^{-1/2} \exp \left\{ -(1/2) [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{0}) - \mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi}) \mathbf{u}_i]' \mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})^{-1} [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{0}) - \mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi}) \mathbf{u}_i] \right\}$$

where $\mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi})$ is the Jacobian matrix $\partial \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) / \partial \mathbf{u}_i$ evaluated at $\mathbf{u}_i = \mathbf{0}$.

Assuming that $q(\mathbf{u}_i | \boldsymbol{\xi})$ is normal with mean $\mathbf{0}$ and variance matrix $\mathbf{G}(\boldsymbol{\xi})$, the first-order integral approximation is computable in closed form after completing the square:

$$\int p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) q(\mathbf{u}_i | \boldsymbol{\xi}) d\mathbf{u}_i \approx (2\pi)^{-n_i/2} |\mathbf{V}_i(\mathbf{X}_i, \boldsymbol{\theta})|^{-1/2} \exp \left\{ -(1/2) [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{0})]' \mathbf{V}_i(\mathbf{X}_i, \boldsymbol{\theta})^{-1} [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{0})] \right\}$$

where $\mathbf{V}_i(\mathbf{X}_i, \boldsymbol{\theta}) = \mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi}) \mathbf{G}(\boldsymbol{\xi}) \mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi})' + \mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})$. The resulting approximation for $f(\boldsymbol{\theta})$ is then minimized over $\boldsymbol{\theta} = [\boldsymbol{\phi}, \boldsymbol{\xi}]$ to obtain the first-order estimates. PROC NLMIXED uses finite-difference derivatives of the first-order integral approximation when carrying out the default dual quasi-Newton optimization.

Built-in Log-Likelihood Functions

This section displays the basic formulas used by the NLMIXED procedure to compute the conditional log-likelihood functions of the data given the random effects. Note, however, that in addition to these basic equations, the NLMIXED procedure employs a number of checks for missing values and floating-point arithmetic. You can see the entire program used by the NLMIXED procedure to compute the conditional log-likelihood functions $l(\phi; y)$ by adding the **LIST** debugging option to the **PROC NLMIXED** statement.

$Y \sim \text{normal}(m, v)$

$$l(m, v; y) = -\frac{1}{2} \left(\log\{2\pi\} + \frac{(y - m)^2}{v} + \log\{v\} \right)$$

$$E[Y] = m$$

$$\text{Var}[Y] = v$$

$$v > 0$$

$Y \sim \text{binary}(p)$

$$l_1(p; y) = \begin{cases} y \log\{p\} & y > 0 \\ 0 & \text{otherwise} \end{cases}$$

$$l_2(p; y) = \begin{cases} (1 - y) \log\{1 - p\} & y < 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(p; y) = l_1(p; y) + l_2(p; y)$$

$$E[Y] = p$$

$$\text{Var}[Y] = p(1 - p)$$

$$0 < p < 1$$

$Y \sim \text{binomial}(n, p)$

$$l_c = \log\{\Gamma(n + 1)\} - \log\{\Gamma(y + 1)\} - \log\{\Gamma(n - y + 1)\}$$

$$l_1(n, p; y) = \begin{cases} y \log\{p\} & y > 0 \\ 0 & \text{otherwise} \end{cases}$$

$$l_2(n, p; y) = \begin{cases} (n - y) \log\{1 - p\} & n - y > 0 \\ 0 & \text{otherwise} \end{cases}$$

$$l(n, p; y) = l_c + l_1(n, p; y) + l_2(n, p; y)$$

$$E[Y] = n p$$

$$\text{Var}[Y] = n p(1 - p)$$

$$0 < p < 1$$

$Y \sim \text{gamma}(a, b)$

$$l(a, b; y) = -a \log\{b\} - \log\{\Gamma(a)\} + (a - 1) \log\{y\} - y/b$$

$$E[Y] = ab$$

$$\text{Var}[Y] = ab^2$$

$$a > 0$$

$$b > 0$$

This parameterization of the gamma distribution differs from the parameterization used in the GLIMMIX and GENMOD procedures. The following statements show the equivalent reparameterization in the NLMIXED procedure that fits a generalized linear model for gamma-distributed data in the parameterization of the GLIMMIX procedure:

```
proc glimmix;
  model y = x / dist=gamma s;
run;

proc nlmixed;
  parms b0=1 b1=0 scale=14;
  linp = b0 + b1*x;
  mu   = exp(linp);
  b    = mu/scale;
  model y ~ gamma(scale,b);
run;
```

$$Y \sim \text{negbin}(n, p)$$

$$\begin{aligned}
 l(n, p; y) &= \log\{\Gamma(n + y)\} - \log\{\Gamma(n)\} - \log\{\Gamma(y + 1)\} \\
 &\quad + n \log\{p\} + y \log\{1 - p\} \\
 E[Y] &= nP = n \left(\frac{1 - p}{p} \right) \\
 \text{Var}[Y] &= nP(1 - P) = n \left(\frac{1 - p}{p} \right) \frac{1}{p} \\
 n &\geq 0 \\
 0 < p < 1
 \end{aligned}$$

This form of the negative binomial distribution is one of the many parameterizations in which the mass function or log-likelihood function appears. Another common parameterization uses

$$\begin{aligned}
 l(n, p; y) &= \log\{\Gamma(n + y)\} - \log\{\Gamma(n)\} - \log\{\Gamma(y + 1)\} \\
 &\quad + n \log\{1 - P/(1 + P)\} + y \log\{P/(1 + P)\}
 \end{aligned}$$

with $P = (1 - p)/p$, $P > 0$.

Note that the parameter n can be real-numbered; it does not have to be integer-valued. The parameterization of the negative binomial distribution in the NLMIXED procedure differs from that in the GLIMMIX and GENMOD procedures. The following statements show the equivalent formulations for maximum likelihood estimation in the GLIMMIX and NLMIXED procedures in a negative binomial regression model:

```
proc glimmix;
  model y = x / dist=negbin s;
run;
```

```

proc nlmixed;
  parms b0=3, b1=1, k=0.8;
  linp = b0 + b1*x;
  mu = exp(linp);
  p = 1/(1+mu*k);
  model y ~ negbin(1/k,p);
run;

```

$Y \sim \text{Poisson}(m)$

$$l(m; y) = y \log\{m\} - m - \log\{\Gamma(y + 1)\}$$

$$E[Y] = m$$

$$\text{Var}[Y] = m$$

$$m > 0$$

Optimization Algorithms

There are several optimization techniques available in PROC NLMIXED. You can choose a particular optimizer with the **TECH=** option in the **PROC NLMIXED** statement.

Algorithm	TECH=
trust region method	TRUREG
Newton-Raphson method with line search	NEWRAP
Newton-Raphson method with ridging	NRRIDG
quasi-Newton methods (DBFGS, DDFP, BFGS, DFP)	QUANEW

conjugate gradient methods (PB, FR, PR, CD)	CONGRA
Nelder-Mead simplex method	NMSIMP

No algorithm for optimizing general nonlinear functions exists that always finds the global optimum for a general nonlinear minimization problem in a reasonable amount of time. Since no single optimization technique is invariably superior to others, PROC NLMIXED provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in PROC NLMIXED can find the correct solution. Moreover, nonlinear optimization can be computationally expensive in terms of time and memory, so you must be careful when matching an algorithm to a problem.

All optimization techniques in PROC NLMIXED use $O(n^2)$ memory except the conjugate gradient methods, which use only $O(n)$ of memory and are designed to optimize problems with many parameters. Since the techniques are iterative, they require the repeated computation of the following:

- the function value (optimization criterion)
- the gradient vector (first-order partial derivatives)
- for some techniques, the (approximate) Hessian matrix (second-order partial derivatives)

However, since each of the optimizers requires different derivatives, some computational efficiencies can be gained. The following table shows, for each optimization technique, which derivatives are required (FOD: first-order derivatives; SOD: second-order derivatives).

Algorithm	FOD	SOD
TRUREG	x	x
NEWRAP	x	x
NRRIDG	x	x
QUANEW	x	-
DBLDOG	x	-
CONGRA	x	-
NMSIMP	-	-

Each optimization method employs one or more convergence criteria that determine when it has converged. The various termination criteria are listed and described in the “**PROC NLMIXED Statement**” section. An algorithm is considered to have converged when any one of the convergence criteria is satisfied. For example, under the default settings, the QUANEW algorithm will converge if `ABSGCONV` < 1E–5, `FCONV` < 10^{–FDIGITS}, or `GCONV` < 1E–8.

Choosing an Optimization Algorithm

The factors that go into choosing a particular optimization technique for a particular problem are complex and can involve trial and error.

For many optimization problems, computing the gradient takes more computer time than computing the function value, and computing the Hessian sometimes takes *much* more computer time and memory than computing the gradient, especially when there are many decision variables. Unfortunately, optimization techniques that do not use some kind of Hessian approximation usually require many more iterations than techniques that do use a Hessian matrix, and as a result the total run time of these techniques is often longer. Techniques that do not use the Hessian also tend to be less reliable. For example, they can more easily terminate at stationary points rather than at global optima.

A few general remarks about the various optimization techniques follow:

- The second-derivative methods TRUREG, NEWRAP, and NRRIDG are best for small problems where the Hessian matrix is not expensive to compute. Sometimes the NRRIDG algorithm can be faster than the TRUREG algorithm, but TRUREG can be more stable. The NRRIDG algorithm requires only one matrix with $n(n + 1)/2$ double words; TRUREG and NEWRAP require two such matrices.
- The first-derivative methods QUANEW and DBLDOG are best for medium-sized problems where the objective function and the gradient are much faster to evaluate than the Hessian. The QUANEW and DBLDOG algorithms, in general, require more iterations than TRUREG, NRRIDG, and NEWRAP, but each iteration can be much faster. The QUANEW and DBLDOG algorithms require only the gradient to update an approximate Hessian, and they require slightly less memory than TRUREG or NEWRAP (essentially one matrix with $n(n + 1)/2$ double words). QUANEW is the default optimization method.

- The first-derivative method CONGRA is best for large problems where the objective function and the gradient can be computed much faster than the Hessian and where too much memory is required to store the (approximate) Hessian. The CONGRA algorithm, in general, requires more iterations than QUANEW or DBLDOG, but each iteration can be much faster. Since CONGRA requires only a factor of n double-word memory, many large applications of PROC NLMIXED can be solved only by CONGRA.
- The no-derivative method NMSIMP is best for small problems where derivatives are not continuous or are very difficult to compute.

Algorithm Descriptions

Some details about the optimization techniques follow.

Trust Region Optimization (TRUREG)

The trust region method uses the gradient $\mathbf{g}(\boldsymbol{\theta}^{(k)})$ and the Hessian matrix $\mathbf{H}(\boldsymbol{\theta}^{(k)})$; thus, it requires that the objective function $f(\boldsymbol{\theta})$ have continuous first- and second-order derivatives inside the feasible region.

The trust region method iteratively optimizes a quadratic approximation to the nonlinear objective function within a hyperelliptic trust region with radius Δ that constrains the step size corresponding to the quality of the quadratic approximation. The trust region method is implemented using: Dennis, Gay, and Welsch (1981); Gay (1983); Moré and Sorensen (1983).

The trust region method performs well for small- to medium-sized problems, and it does not need many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

Newton-Raphson Optimization with Line Search (NEWRAP)

The NEWRAP technique uses the gradient $\mathbf{g}(\boldsymbol{\theta}^{(k)})$ and the Hessian matrix $\mathbf{H}(\boldsymbol{\theta}^{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region. If second-order derivatives are computed efficiently and precisely, the NEWRAP method can perform well for medium-sized to large problems, and it does not need many function, gradient, and Hessian calls.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. Otherwise, a combination of ridging and line search is performed to compute successful steps. If the Hessian is not positive definite, a multiple of the identity matrix is added to the Hessian matrix to make it positive definite (Eskow and Schnabel 1991).

In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation (LINESEARCH=2).

Newton-Raphson Ridge Optimization (NRRIDG)

The NRRIDG technique uses the gradient $\mathbf{g}(\boldsymbol{\theta}^{(k)})$ and the Hessian matrix $\mathbf{H}(\boldsymbol{\theta}^{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. If at least one of these two conditions is not satisfied, a multiple of the identity matrix is added to the Hessian matrix.

The NRRIDG method performs well for small- to medium-sized problems, and it does not require many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

Since the NRRIDG technique uses an orthogonal decomposition of the approximate Hessian, each iteration of NRRIDG can be slower than that of the NEWRAP technique, which works with Cholesky decomposition. Usually, however, NRRIDG requires fewer iterations than NEWRAP.

Quasi-Newton Optimization (QUANEW)

The (dual) quasi-Newton method uses the gradient $g(\theta^{(k)})$, and it does not need to compute second-order derivatives since they are approximated. It works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian; but, in general, it requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which compute second-order derivatives. QUANEW is the default optimization algorithm because it provides an appropriate balance between the speed and stability required for most nonlinear mixed model applications.

The QUANEW technique is one of the following, depending on the value of the `UPDATE=` option.

- the original quasi-Newton algorithm, which updates an approximation of the inverse Hessian
- the dual quasi-Newton algorithm, which updates the Cholesky factor of an approximate Hessian (default)

You can specify four update formulas with the `UPDATE=` option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- BFGS performs the original BFGS update of the inverse Hessian matrix.
- DFP performs the original DFP update of the inverse Hessian matrix.

In each iteration, a line search is performed along the search direction to find an approximate optimum. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit of the step size. Violating the left-side Goldstein condition can affect the positive definiteness of the quasi-Newton update. In that case, either the update is skipped or the iterations are restarted with an identity matrix, resulting in the steepest descent or ascent search direction. You can specify line-search algorithms other than the default with the `LINESEARCH=` option.

The QUANEW algorithm uses its own line-search technique. No options and parameters (except the `INSTEP=` option) controlling the line search in the other algorithms apply here. In several applications, large steps in the first iterations are troublesome. You can use the `INSTEP=` option to impose an upper bound for the step size α during the first five iterations. You can also use the `INHESIAN= r` option to specify a different starting approximation for the Hessian. If you specify only the `INHESIAN` option, the Cholesky factor of a (possibly ridged) finite difference approximation of the Hessian is used to initialize the quasi-Newton update process. The values of the `LCSINGULAR=`, `LCEPSILON=`, and `LCDEACT=`

options, which control the processing of linear and boundary constraints, are valid only for the quadratic programming subroutine used in each iteration of the QUANEW algorithm.

Double-Dogleg Optimization (DBLDOG)

The double-dogleg optimization method combines the ideas of the quasi-Newton and trust region methods. In each iteration, the double-dogleg algorithm computes the step $s^{(k)}$ as the linear combination of the steepest descent or ascent search direction $s_1^{(k)}$ and a quasi-Newton search direction $s_2^{(k)}$:

$$s^{(k)} = \alpha_1 s_1^{(k)} + \alpha_2 s_2^{(k)}$$

The step is requested to remain within a prespecified trust region radius; see Fletcher (1987, p. 107). Thus, the DBLDOG subroutine uses the dual quasi-Newton update but does not perform a line search. You can specify two update formulas with the **UPDATE=** option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell update of the Cholesky factor of the Hessian matrix.

The double-dogleg optimization technique works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian. The implementation is based on Dennis and Mei (1979) and Gay (1983), but it is extended for dealing with boundary and linear constraints. The DBLDOG technique generally requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which require second-order derivatives; however, each of the DBLDOG iterations is computationally cheap. Furthermore, the DBLDOG technique requires only gradient calls for the update of the Cholesky factor of an approximate Hessian.

Conjugate Gradient Optimization (CONGRA)

Second-order derivatives are not required by the CONGRA algorithm and are not even approximated. The CONGRA algorithm can be expensive in function and gradient calls, but it requires only $O(n)$ memory for unconstrained optimization. In general, many iterations are required to obtain a precise solution, but each of the CONGRA iterations is computationally cheap. You can specify four different update formulas for generating the conjugate directions by using the **UPDATE=** option:

- PB performs the automatic restart update method of Powell (1977) and Beale (1972). This is the default.
- FR performs the Fletcher-Reeves update (Fletcher 1987).
- PR performs the Polak-Ribiere update (Fletcher 1987).
- CD performs a conjugate-descent update of Fletcher (1987).

The default, **UPDATE=PB**, behaved best in most test examples. You are advised to avoid the option **UPDATE=CD**, which behaved worst in most test examples.

The CONGRA subroutine should be used for optimization problems with large n . For the unconstrained or boundary constrained case, CONGRA requires only $O(n)$ bytes of working memory, whereas all other

optimization methods require order $O(n^2)$ bytes of working memory. During n successive iterations, uninterrupted by restarts or changes in the working set, the conjugate gradient algorithm computes a cycle of n conjugate search directions. In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit for the step size. Other line-search algorithms can be specified with the `LINESEARCH=` option.

Nelder-Mead Simplex Optimization (NMSIMP)

The Nelder-Mead simplex method does not use any derivatives and does not assume that the objective function has continuous derivatives. The objective function itself needs to be continuous. This technique is quite expensive in the number of function calls, and it might be unable to generate precise results for $n \gg 40$.

The original Nelder-Mead simplex algorithm is implemented and extended to boundary constraints. This algorithm does not compute the objective for infeasible points, but it changes the shape of the simplex adapting to the nonlinearities of the objective function, which contributes to an increased speed of convergence. It uses a special termination criterion.

Finite-Difference Approximations of Derivatives

The `FD=` and `FDHESSIAN=` options specify the use of finite-difference approximations of the derivatives. The `FD=` option specifies that all derivatives are approximated using function evaluations, and the `FDHESSIAN=` option specifies that second-order derivatives are approximated using gradient evaluations.

Computing derivatives by finite-difference approximations can be very time-consuming, especially for second-order derivatives based only on values of the objective function (`FD=` option). If analytical derivatives are difficult to obtain (for example, if a function is computed by an iterative process), you might consider one of the optimization techniques that use first-order derivatives only (`QUANEW`, `DBLDOG`, or `CONGRA`). In the expressions that follow, θ denotes the parameter vector, h_i denotes the step size for the i th parameter, and e_i is a vector of zeros with a 1 in the i th position.

Forward-Difference Approximations

The forward-difference derivative approximations consume less computer time, but they are usually not as precise as approximations that use central-difference formulas.

- For first-order derivatives, n additional function calls are required:

$$g_i = \frac{\partial f}{\partial \theta_i} \approx \frac{f(\theta + h_i e_i) - f(\theta)}{h_i}$$

- For second-order derivatives based on function calls only (Dennis and Schnabel 1983, p. 80), $n + n^2/2$ additional function calls are required for dense Hessian:

$$\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{f(\theta + h_i e_i + h_j e_j) - f(\theta + h_i e_i) - f(\theta + h_j e_j) + f(\theta)}{h_i h_j}$$

- For second-order derivatives based on gradient calls (Dennis and Schnabel 1983, p. 103), n additional gradient calls are required:

$$\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{g_i(\boldsymbol{\theta} + h_j \mathbf{e}_j) - g_i(\boldsymbol{\theta})}{2h_j} + \frac{g_j(\boldsymbol{\theta} + h_i \mathbf{e}_i) - g_j(\boldsymbol{\theta})}{2h_i}$$

Central-Difference Approximations

Central-difference approximations are usually more precise, but they consume more computer time than approximations that use forward-difference derivative formulas.

- For first-order derivatives, $2n$ additional function calls are required:

$$g_i = \frac{\partial f}{\partial \theta_i} \approx \frac{f(\boldsymbol{\theta} + h_i \mathbf{e}_i) - f(\boldsymbol{\theta} - h_i \mathbf{e}_i)}{2h_i}$$

- For second-order derivatives based on function calls only (Abramowitz and Stegun 1972, p. 884), $2n + 4n^2/2$ additional function calls are required.

$$\frac{\partial^2 f}{\partial \theta_i^2} \approx \frac{-f(\boldsymbol{\theta} + 2h_i \mathbf{e}_i) + 16f(\boldsymbol{\theta} + h_i \mathbf{e}_i) - 30f(\boldsymbol{\theta}) + 16f(\boldsymbol{\theta} - h_i \mathbf{e}_i) - f(\boldsymbol{\theta} - 2h_i \mathbf{e}_i)}{12h_i^2}$$

$$\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{f(\boldsymbol{\theta} + h_i \mathbf{e}_i + h_j \mathbf{e}_j) - f(\boldsymbol{\theta} + h_i \mathbf{e}_i - h_j \mathbf{e}_j) - f(\boldsymbol{\theta} - h_i \mathbf{e}_i + h_j \mathbf{e}_j) + f(\boldsymbol{\theta} - h_i \mathbf{e}_i - h_j \mathbf{e}_j)}{4h_i h_j}$$

- For second-order derivatives based on gradient calls, $2n$ additional gradient calls are required:

$$\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{g_i(\boldsymbol{\theta} + h_j \mathbf{e}_j) - g_i(\boldsymbol{\theta} - h_j \mathbf{e}_j)}{4h_j} + \frac{g_j(\boldsymbol{\theta} + h_i \mathbf{e}_i) - g_j(\boldsymbol{\theta} - h_i \mathbf{e}_i)}{4h_i}$$

You can use the **FDIGITS=** option to specify the number of accurate digits in the evaluation of the objective function. This specification is helpful in determining an appropriate interval size h to be used in the finite-difference formulas.

The step sizes h_j , $j = 1, \dots, n$ are defined as follows:

- For the forward-difference approximation of first-order derivatives that use function calls and second-order derivatives that use gradient calls, $h_j = \sqrt[3]{\eta}(1 + |\theta_j|)$.
- For the forward-difference approximation of second-order derivatives that use only function calls and all central-difference formulas, $h_j = \sqrt[3]{\eta}(1 + |\theta_j|)$.

The value of η is defined by the **FDIGITS=** option:

- If you specify the number of accurate digits by using **FDIGITS= r** , η is set to 10^{-r} .
- If you do not specify the **FDIGITS=** option, η is set to the machine precision ϵ .

Hessian Scaling

The rows and columns of the Hessian matrix can be scaled when you use the trust region, Newton-Raphson, and double-dogleg optimization techniques. Each element $H_{i,j}$, $i, j = 1, \dots, n$ is divided by the scaling factor $d_i d_j$, where the scaling vector $d = (d_1, \dots, d_n)$ is iteratively updated in a way specified by the **HESCAL=i** option, as follows:

$i = 0$: No scaling is done (equivalent to $d_i = 1$).

$i \neq 0$: First iteration and each restart iteration sets:

$$d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)}$$

$i = 1$: See Moré (1978):

$$d_i^{(k+1)} = \max \left[d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

$i = 2$: See Dennis, Gay, and Welsch (1981):

$$d_i^{(k+1)} = \max \left[0.6d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

$i = 3$: d_i is reset in each iteration:

$$d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}$$

In the preceding equations, ϵ is the relative machine precision or, equivalently, the largest double-precision value that, when added to 1, results in 1.

Active Set Methods

The parameter vector $\theta \in \mathcal{R}^n$ can be subject to a set of m linear equality and inequality constraints:

$$\begin{aligned} \sum_{j=1}^n a_{ij} \theta_j &= b_i & i &= 1, \dots, m_e \\ \sum_{j=1}^n a_{ij} \theta_j &\geq b_i & i &= m_e + 1, \dots, m \end{aligned}$$

The coefficients a_{ij} and right-hand sides b_i of the equality and inequality constraints are collected in the $m \times n$ matrix **A** and the m vector **b**.

The m linear constraints define a feasible region \mathcal{G} in \mathcal{R}^n that must contain the point θ_* that minimizes the problem. If the feasible region \mathcal{G} is empty, no solution to the optimization problem exists.

In PROC NLMIXED, all optimization techniques use *active set methods*. The iteration starts with a feasible point $\theta^{(0)}$, which you can provide or which can be computed by the Schittkowski and Stoer (1979) algorithm

implemented in PROC NLMIXED. The algorithm then moves from one feasible point $\theta^{(k-1)}$ to a better feasible point $\theta^{(k)}$ along a feasible search direction $s^{(k)}$,

$$\theta^{(k)} = \theta^{(k-1)} + \alpha^{(k)} s^{(k)}, \quad \alpha^{(k)} > 0$$

Theoretically, the path of points $\theta^{(k)}$ never leaves the feasible region \mathcal{G} of the optimization problem, but it can reach its boundaries. The active set $\mathcal{A}^{(k)}$ of point $\theta^{(k)}$ is defined as the index set of all linear equality constraints and those inequality constraints that are satisfied at $\theta^{(k)}$. If no constraint is active at $\theta^{(k)}$, the point is located in the interior of \mathcal{G} , and the active set $\mathcal{A}^{(k)} = \emptyset$ is empty. If the point $\theta^{(k)}$ in iteration k hits the boundary of inequality constraint i , this constraint i becomes active and is added to $\mathcal{A}^{(k)}$. Each equality constraint and each active inequality constraint reduce the dimension (degrees of freedom) of the optimization problem.

In practice, the active constraints can be satisfied only with finite precision. The `LCEPSILON= r` option specifies the range for active and violated linear constraints. If the point $\theta^{(k)}$ satisfies the condition

$$\left| \sum_{j=1}^n a_{ij} \theta_j^{(k)} - b_i \right| \leq t$$

where $t = r(|b_i| + 1)$, the constraint i is recognized as an active constraint. Otherwise, the constraint i is either an inactive inequality or a violated inequality or equality constraint. Due to rounding errors in computing the projected search direction, error can be accumulated so that an iterate $\theta^{(k)}$ steps out of the feasible region.

In those cases, PROC NLMIXED might try to pull the iterate $\theta^{(k)}$ back into the feasible region. However, in some cases the algorithm needs to increase the feasible region by increasing the `LCEPSILON= r` value. If this happens, a message is displayed in the log output.

If the algorithm cannot improve the value of the objective function by moving from an active constraint back into the interior of the feasible region, it makes this inequality constraint an equality constraint in the next iteration. This means that the active set $\mathcal{A}^{(k+1)}$ still contains the constraint i . Otherwise, it releases the active inequality constraint and increases the dimension of the optimization problem in the next iteration.

A serious numerical problem can arise when some of the active constraints become (nearly) linearly dependent. PROC NLMIXED removes linearly dependent equality constraints before starting optimization. You can use the `LCSINGULAR= r` option to specify a criterion r used in the update of the QR decomposition that determines whether an active constraint is linearly dependent relative to a set of other active constraints.

If the solution θ^* is subjected to n_{act} linear equality or active inequality constraints, the QR decomposition of the $n \times n_{act}$ matrix $\hat{\mathbf{A}}'$ of the linear constraints is computed by $\hat{\mathbf{A}}' = \mathbf{Q}\mathbf{R}$, where \mathbf{Q} is an $n \times n$ orthogonal matrix and \mathbf{R} is an $n \times n_{act}$ upper triangular matrix. The n columns of matrix \mathbf{Q} can be separated into two matrices, $\mathbf{Q} = [\mathbf{Y}, \mathbf{Z}]$, where \mathbf{Y} contains the first n_{act} orthogonal columns of \mathbf{Q} and \mathbf{Z} contains the last $n - n_{act}$ orthogonal columns of \mathbf{Q} . The $n \times (n - n_{act})$ column-orthogonal matrix \mathbf{Z} is also called the *null-space matrix* of the active linear constraints $\hat{\mathbf{A}}'$. The $n - n_{act}$ columns of the $n \times (n - n_{act})$ matrix \mathbf{Z} form a basis orthogonal to the rows of the $n_{act} \times n$ matrix $\hat{\mathbf{A}}$.

At the end of the iterating, PROC NLMIXED computes the *projected gradient* \mathbf{g}_Z ,

$$\mathbf{g}_Z = \mathbf{Z}'\mathbf{g}$$

In the case of boundary-constrained optimization, the elements of the projected gradient correspond to the gradient elements of the free parameters. A necessary condition for θ^* to be a local minimum of the optimization problem is

$$\mathbf{g}_Z(\theta^*) = \mathbf{Z}'\mathbf{g}(\theta^*) = \mathbf{0}$$

The symmetric $n_{act} \times n_{act}$ matrix \mathbf{G}_Z ,

$$\mathbf{G}_Z = \mathbf{Z}'\mathbf{G}\mathbf{Z}$$

is called a *projected Hessian matrix*. A second-order necessary condition for $\boldsymbol{\theta}^*$ to be a local minimizer requires that the projected Hessian matrix is positive semidefinite.

Those elements of the n_{act} vector of first-order estimates of *Lagrange multipliers*,

$$\lambda = (\hat{\mathbf{A}}\hat{\mathbf{A}}')^{-1}\hat{\mathbf{A}}\mathbf{Z}\mathbf{Z}'\mathbf{g}$$

that correspond to active inequality constraints indicate whether an improvement of the objective function can be obtained by releasing this active constraint. For minimization, a significant negative Lagrange multiplier indicates that a possible reduction of the objective function can be achieved by releasing this active linear constraint. The **LCDEACT=*r*** option specifies a threshold *r* for the Lagrange multiplier that determines whether an active inequality constraint remains active or can be deactivated. (In the case of boundary-constrained optimization, the Lagrange multipliers for active lower (upper) constraints are the negative (positive) gradient elements corresponding to the active parameters.)

Line-Search Methods

In each iteration *k*, the (dual) quasi-Newton, conjugate gradient, and Newton-Raphson minimization techniques use iterative line-search algorithms that try to optimize a linear, quadratic, or cubic approximation of *f* along a feasible descent search direction $\mathbf{s}^{(k)}$,

$$\boldsymbol{\theta}^{(k+1)} = \boldsymbol{\theta}^{(k)} + \alpha^{(k)}\mathbf{s}^{(k)}, \quad \alpha^{(k)} > 0$$

by computing an approximately optimal scalar $\alpha^{(k)}$.

Therefore, a line-search algorithm is an iterative process that optimizes a nonlinear function $f(\alpha)$ of one parameter (α) within each iteration *k* of the optimization technique. Since the outside iteration process is based only on the approximation of the objective function, the inside iteration of the line-search algorithm does not have to be perfect. Usually, it is satisfactory that the choice of α significantly reduces (in a minimization) the objective function. Criteria often used for termination of line-search algorithms are the Goldstein conditions (see Fletcher 1987).

You can select various line-search algorithms by specifying the **LINESEARCH=** option. The line-search method **LINESEARCH=2** seems to be superior when function evaluation consumes significantly less computation time than gradient evaluation. Therefore, **LINESEARCH=2** is the default method for Newton-Raphson, (dual) quasi-Newton, and conjugate gradient optimizations.

You can modify the line-search methods **LINESEARCH=2** and **LINESEARCH=3** to be exact line searches by using the **LSPRECISION=** option and specifying the σ parameter described in Fletcher (1987). The line-search methods **LINESEARCH=1**, **LINESEARCH=2**, and **LINESEARCH=3** satisfy the left-side and right-side Goldstein conditions (see Fletcher 1987). When derivatives are available, the line-search methods **LINESEARCH=6**, **LINESEARCH=7**, and **LINESEARCH=8** try to satisfy the right-side Goldstein condition; if derivatives are not available, these line-search algorithms use only function calls.

Restricting the Step Length

Almost all line-search algorithms use iterative extrapolation techniques that can easily lead them to (feasible) points where the objective function f is no longer defined or is difficult to compute. Therefore, PROC NLMIXED provides options restricting the step length α or trust region radius Δ , especially during the first main iterations.

The inner product $\mathbf{g}'\mathbf{s}$ of the gradient \mathbf{g} and the search direction \mathbf{s} is the slope of $f(\alpha) = f(\boldsymbol{\theta} + \alpha\mathbf{s})$ along the search direction \mathbf{s} . The default starting value $\alpha^{(0)} = \alpha^{(k,0)}$ in each line-search algorithm ($\min_{\alpha>0} f(\boldsymbol{\theta} + \alpha\mathbf{s})$) during the main iteration k is computed in three steps:

1. The first step uses either the difference $|\Delta f| = |f^{(k)} - f^{(k-1)}|$ of the function values during the last two consecutive iterations or the final step-size value α^- of the last iteration $k - 1$ to compute a first value of $\alpha_1^{(0)}$.

- If the **DAMPSTEP** option is not used,

$$\alpha_1^{(0)} = \begin{cases} \text{step} & \text{if } 0.1 \leq \text{step} \leq 10 \\ 10 & \text{if } \text{step} > 10 \\ 0.1 & \text{if } \text{step} < 0.1 \end{cases}$$

with

$$\text{step} = \begin{cases} |\Delta f|/|\mathbf{g}'\mathbf{s}| & \text{if } |\mathbf{g}'\mathbf{s}| \geq \epsilon \max(100 \times |\Delta f|, 1) \\ 1 & \text{otherwise} \end{cases}$$

This value of $\alpha_1^{(0)}$ can be too large and can lead to a difficult or impossible function evaluation, especially for highly nonlinear functions such as the EXP function.

- If the **DAMPSTEP=r** option is used,

$$\alpha_1^{(0)} = \min(1, r\alpha^-)$$

The initial value for the new step length can be no larger than r times the final step length α^- of the former iteration. The default value is $r = 2$.

2. During the first five iterations, the second step enables you to reduce $\alpha_1^{(0)}$ to a smaller starting value $\alpha_2^{(0)}$ by using the **INSTEP=r** option:

$$\alpha_2^{(0)} = \min(\alpha_1^{(0)}, r)$$

After more than five iterations, $\alpha_2^{(0)}$ is set to $\alpha_1^{(0)}$.

3. The third step can further reduce the step length by

$$\alpha_3^{(0)} = \min(\alpha_2^{(0)}, \min(10, u))$$

where u is the maximum length of a step inside the feasible region.

The `INSTEP=r` option enables you to specify a smaller or larger radius Δ of the trust region used in the first iteration of the trust region and double-dogleg algorithms. The default initial trust region radius $\Delta^{(0)}$ is the length of the scaled gradient (Moré 1978). This step corresponds to the default radius factor of $r = 1$. In most practical applications of the TRUREG and DBLDOG algorithms, this choice is successful. However, for bad initial values and highly nonlinear objective functions (such as the EXP function), the default start radius can result in arithmetic overflows. If this happens, you can try decreasing values of `INSTEP=r`, $0 < r < 1$, until the iteration starts successfully. A small factor r also affects the trust region radius $\Delta^{(k+1)}$ of the next steps because the radius is changed in each iteration by a factor $0 < c \leq 4$, depending on the ratio ρ expressing the goodness of quadratic function approximation. Reducing the radius Δ corresponds to increasing the ridge parameter λ , producing smaller steps aimed more closely toward the (negative) gradient direction.

Computational Problems

Floating-Point Errors and Overflows

Numerical optimization of a numerically integrated function is a difficult task, and the computation of the objective function and its derivatives can lead to arithmetic exceptions and overflows. A typical cause of these problems is parameters with widely varying scales. If the scaling of your parameters varies by more than a few orders of magnitude, the numerical stability of the optimization problem can be seriously reduced and can result in computational difficulties. A simple remedy is to rescale each parameter so that its final estimated value has a magnitude near 1.

If parameter rescaling does not help, consider the following actions:

- Specify the `ITDETAILS` option in the `PROC NLMIXED` statement to obtain more detailed information about when and where the problem is occurring.
- Provide different initial values or try a grid search of values.
- Use boundary constraints to avoid the region where overflows can happen.
- Delete outlying observations or subjects from the input data, if this is reasonable.
- Change the algorithm (specified in programming statements) that computes the objective function.

The line-search algorithms that work with cubic extrapolation are especially sensitive to arithmetic overflows. If an overflow occurs during a line search, you can use the `INSTEP=` option to reduce the length of the first trial step during the first five iterations, or you can use the `DAMPSTEP` or `MAXSTEP` option to restrict the step length of the initial α in subsequent iterations. If an arithmetic overflow occurs in the first iteration of the trust region or double-dogleg algorithm, you can use the `INSTEP=` option to reduce the default trust region radius of the first iteration. You can also change the optimization technique or the line-search method.

Long Run Times

`PROC NLMIXED` can take a long time to run for problems involving complex models, many parameters, or large input data sets. Although the optimization techniques used by `PROC NLMIXED` are some of the best ones available, they are not guaranteed to converge quickly for all problems. Ill-posed or misspecified

models can cause the algorithms to use more extensive calculations designed to achieve convergence, and this can result in longer run times. So first make sure that your model is specified correctly, that your parameters are scaled to be of the same order of magnitude, and that your data reasonably match the model you are contemplating.

If you are using the default adaptive Gaussian quadrature algorithm and no iteration history is printing at all, then PROC NLMIXED might be bogged down trying to determine the number of quadrature points at the first set of starting values. Specifying the `QPOINTS=` option will bypass this stage and proceed directly to iterations; however, be aware that the likelihood approximation might not be accurate if there are too few quadrature points.

PROC NLMIXED can also have difficulty determining the number of quadrature points if the initial starting values are far from the optimum values. To obtain more accurate starting values for the model parameters, one easy method is to fit a model with no `RANDOM` statement. You can then use these estimates as starting values, although you will still need to specify values for the random-effects distribution. For normal-normal models, another strategy is to use `METHOD=FIRO`. If you can obtain estimates by using this approximate method, then they can be used as starting values for more accurate likelihood approximations.

If you are running PROC NLMIXED multiple times, you will probably want to include a statement like the following in your program:

```
ods output ParameterEstimates=pe;
```

This statement creates a SAS data set named PE upon completion of the run. In your next invocation of PROC NLMIXED, you can then specify

```
parms / data=pe;
```

to read in the previous estimates as starting values.

To speed general computations, you should double-check your programming statements to minimize the number of floating-point operations. Using auxiliary variables and factoring amenable expressions can be useful changes in this regard.

Problems Evaluating Code for Objective Function

The starting point $\theta^{(0)}$ must be a point for which the programming statements can be evaluated. However, during optimization, the optimizer might iterate to a point $\theta^{(k)}$ where the objective function or its derivatives cannot be evaluated. In some cases, the specification of boundary for parameters can avoid such situations. In many other cases, you can indicate that the point $\theta^{(0)}$ is a bad point simply by returning an extremely large value for the objective function. In these cases, the optimization algorithm reduces the step length and stays closer to the point that has been evaluated successfully in the former iteration.

No Convergence

There are a number of things to try if the optimizer fails to converge.

- Change the initial values by using a grid search specification to obtain a set of good feasible starting values.
- Change or modify the update technique or the line-search algorithm.

This method applies only to **TECH=QUANEW** and **TECH=CONGRA**. For example, if you use the default update formula and the default line-search algorithm, you can do the following:

- change the update formula with the **UPDATE=** option
 - change the line-search algorithm with the **LINESEARCH=** option
 - specify a more precise line search with the **LSPRECISION=** option, if you use **LINESEARCH=2** or **LINESEARCH=3**
- Change the optimization technique.
For example, if you use the default option, **TECH=QUANEW**, you can try one of the second-derivative methods if your problem is small or the conjugate gradient method if it is large.
 - Adjust finite-difference derivatives.
The forward-difference derivatives specified with the **FD=** or **FDHESSIAN=** option might not be precise enough to satisfy strong gradient termination criteria. You might need to specify the more expensive central-difference formulas. The finite-difference intervals might be too small or too big, and the finite-difference derivatives might be erroneous.
 - Double-check the data entry and program specification.

Convergence to Stationary Point

The gradient at a stationary point is the null vector, which always leads to a zero search direction. This point satisfies the first-order termination criterion. Search directions that are based on the gradient are zero, so the algorithm terminates. There are two ways to avoid this situation:

- Use the **PARMS** statement to specify a grid of feasible initial points.
- Use the **OPTCHECK=r** option to avoid terminating at the stationary point.

The signs of the eigenvalues of the (reduced) Hessian matrix contain the following information regarding a stationary point:

- If all of the eigenvalues are positive, the Hessian matrix is positive definite, and the point is a minimum point.
- If some of the eigenvalues are positive and all remaining eigenvalues are zero, the Hessian matrix is positive semidefinite, and the point is a minimum or saddle point.
- If all of the eigenvalues are negative, the Hessian matrix is negative definite, and the point is a maximum point.
- If some of the eigenvalues are negative and all remaining eigenvalues are zero, the Hessian matrix is negative semidefinite, and the point is a maximum or saddle point.
- If all of the eigenvalues are zero, the point can be a minimum, maximum, or saddle point.

Precision of Solution

In some applications, PROC NLMIXED can result in parameter values that are not precise enough. Usually, this means that the procedure terminated at a point too far from the optimal point. The termination criteria define the size of the termination region around the optimal point. Any point inside this region can be accepted for terminating the optimization process. The default values of the termination criteria are set to satisfy a reasonable compromise between the computational effort (computer time) and the precision of the computed estimates for the most common applications. However, there are a number of circumstances in which the default values of the termination criteria specify a region that is either too large or too small.

If the termination region is too large, then it can contain points with low precision. In such cases, you should determine which termination criterion stopped the optimization process. In many applications, you can obtain a solution with higher precision simply by using the old parameter estimates as starting values in a subsequent run in which you specify a smaller value for the termination criterion that was satisfied at the former run.

If the termination region is too small, the optimization process might take longer to find a point inside such a region, or it might not even find such a point due to rounding errors in function values and derivatives. This can easily happen in applications in which finite-difference approximations of derivatives are used and the **GCONV** and **ABSGCONV** termination criteria are too small to respect rounding errors in the gradient values.

Covariance Matrix

The estimated covariance matrix of the parameter estimates is computed as the inverse Hessian matrix, and for unconstrained problems it should be positive definite. If the final parameter estimates are subjected to $n_{act} > 0$ active linear inequality constraints, the formulas of the covariance matrices are modified similar to Gallant (1987) and Cramer (1986, p. 38) and additionally generalized for applications with singular matrices.

There are several steps available that enable you to tune the rank calculations of the covariance matrix.

1. You can use the **ASINGULAR=**, **MSINGULAR=**, and **VSINGULAR=** options to set three singularity criteria for the inversion of the Hessian matrix **H**. The singularity criterion used for the inversion is

$$|d_{j,j}| \leq \max(\text{ASING}, \text{VSING} * |H_{j,j}|, \text{MSING} * \max(|H_{1,1}|, \dots, |H_{n,n}|))$$

where $d_{j,j}$ is the diagonal pivot of the matrix **H**, and **ASING**, **VSING**, and **MSING** are the specified values of the **ASINGULAR=**, **VSINGULAR=**, and **MSINGULAR=** options, respectively. The default values are as follows:

- **ASING**: the square root of the smallest positive double-precision value
- **MSING**: 1E-12 if you do not specify the **SINGHESS=** option and $\max(10\epsilon, 1E - 4 \times \text{SINGHESS})$ otherwise, where ϵ is the machine precision
- **VSING**: 1E-8 if you do not specify the **SINGHESS=** option and the value of **SINGHESS** otherwise

Note that, in many cases, a normalized matrix $\mathbf{D}^{-1}\mathbf{A}\mathbf{D}^{-1}$ is decomposed, and the singularity criteria are modified correspondingly.

2. If the matrix \mathbf{H} is found to be singular in the first step, a generalized inverse is computed. Depending on the `G4=` option, either a generalized inverse satisfying all four Moore-Penrose conditions is computed (a g_4 -inverse) or a generalized inverse satisfying only two Moore-Penrose conditions is computed (a g_2 -inverse, Pringle and Rayner 1971). If the number of parameters n of the application is less than or equal to `G4=i`, a g_4 -inverse is computed; otherwise, only a g_2 -inverse is computed. The g_4 -inverse is computed by the (computationally very expensive but numerically stable) eigenvalue decomposition, and the g_2 -inverse is computed by Gauss transformation. The g_4 -inverse is computed using the eigenvalue decomposition $\mathbf{A} = \mathbf{Z}\mathbf{\Lambda}\mathbf{Z}'$, where \mathbf{Z} is the orthogonal matrix of eigenvectors and $\mathbf{\Lambda}$ is the diagonal matrix of eigenvalues, $\mathbf{\Lambda} = \text{diag}(\lambda_1, \dots, \lambda_n)$. The g_4 -inverse of \mathbf{H} is set to

$$\mathbf{A}^- = \mathbf{Z}\mathbf{\Lambda}^-\mathbf{Z}'$$

where the diagonal matrix $\mathbf{\Lambda}^- = \text{diag}(\lambda_1^-, \dots, \lambda_n^-)$ is defined using the `COVSING=` option:

$$\lambda_i^- = \begin{cases} 1/\lambda_i & \text{if } |\lambda_i| > \text{COVSING} \\ 0 & \text{if } |\lambda_i| \leq \text{COVSING} \end{cases}$$

If you do not specify the `COVSING=` option, the nr smallest eigenvalues are set to zero, where nr is the number of rank deficiencies found in the first step.

For optimization techniques that do not use second-order derivatives, the covariance matrix is computed using finite-difference approximations of the derivatives.

Prediction

The nonlinear mixed model is a useful tool for statistical prediction. Assuming a prediction is to be made regarding the i th subject, suppose that $f(\boldsymbol{\theta}, \mathbf{u}_i)$ is a differentiable function predicting some quantity of interest. Recall that $\boldsymbol{\theta}$ denotes the vector of unknown parameters and \mathbf{u}_i denotes the vector of random effects for the i th subject. A natural point prediction is $f(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i)$, where $\hat{\boldsymbol{\theta}}$ is the maximum likelihood estimate of $\boldsymbol{\theta}$ and $\hat{\mathbf{u}}_i$ is the empirical Bayes estimate of \mathbf{u}_i described previously in the section “Integral Approximations” on page 5384.

An approximate prediction variance matrix for $(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i)$ is

$$\mathbf{P} = \begin{bmatrix} \hat{\mathbf{H}}^{-1} & \hat{\mathbf{H}}^{-1} \left(\frac{\partial \hat{\mathbf{u}}_i}{\partial \boldsymbol{\theta}} \right)' \\ \left(\frac{\partial \hat{\mathbf{u}}_i}{\partial \boldsymbol{\theta}} \right) \hat{\mathbf{H}}^{-1} & \hat{\mathbf{\Gamma}}^{-1} + \left(\frac{\partial \hat{\mathbf{u}}_i}{\partial \boldsymbol{\theta}} \right) \hat{\mathbf{H}}^{-1} \left(\frac{\partial \hat{\mathbf{u}}_i}{\partial \boldsymbol{\theta}} \right)' \end{bmatrix}$$

where $\hat{\mathbf{H}}$ is the approximate Hessian matrix from the optimization for $\hat{\boldsymbol{\theta}}$, $\hat{\mathbf{\Gamma}}$ is the approximate Hessian matrix from the optimization for $\hat{\mathbf{u}}_i$, and $(\partial \hat{\mathbf{u}}_i / \partial \boldsymbol{\theta})$ is the derivative of $\hat{\mathbf{u}}_i$ with respect to $\boldsymbol{\theta}$, evaluated at $(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i)$. The approximate variance matrix for $\hat{\boldsymbol{\theta}}$ is the standard one discussed in the previous section, and that for $\hat{\mathbf{u}}_i$ is an approximation to the conditional mean squared error of prediction described by Booth and Hobert (1998).

The prediction variance for a general scalar function $f(\boldsymbol{\theta}, \mathbf{u}_i)$ is defined as the expected squared difference $E[f(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i) - f(\boldsymbol{\theta}, \mathbf{u}_i)]^2$. PROC NLMIXED computes an approximation to it as follows. The derivative of $f(\boldsymbol{\theta}, \mathbf{u}_i)$ is computed with respect to each element of $(\boldsymbol{\theta}, \mathbf{u}_i)$ and evaluated at $(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i)$. If \mathbf{a}_i is the resulting vector, then the approximate prediction variance is $\mathbf{a}_i' \mathbf{P} \mathbf{a}_i$. This approximation is known as the delta method (Billingsley 1986; Cox 1998).

Computational Resources

Since nonlinear optimization is an iterative process that depends on many factors, it is difficult to estimate how much computer time is necessary to find an optimal solution satisfying one of the termination criteria. You can use the **MAXTIME=**, **MAXITER=**, and **MAXFUNC=** options to restrict the amount of CPU time, the number of iterations, and the number of function calls in a single run of PROC NLMIXED.

In each iteration k , the NRRIDG technique uses a symmetric Householder transformation to decompose the $n \times n$ Hessian matrix \mathbf{H} ,

$$\mathbf{H} = \mathbf{V}'\mathbf{T}\mathbf{V}, \quad \mathbf{V}: \text{orthogonal}, \quad \mathbf{T}: \text{tridiagonal}$$

to compute the (Newton) search direction \mathbf{s} ,

$$\mathbf{s}^{(k)} = -[\mathbf{H}^{(k)}]^{-1}\mathbf{g}^{(k)} \quad k = 1, 2, 3, \dots$$

The TRUREG and NEWRAP techniques use the Cholesky decomposition to solve the same linear system while computing the search direction. The QUANEW, DBLDOG, CONGRA, and NMSIMP techniques do not need to invert or decompose a Hessian matrix; thus, they require less computational resources than the other techniques.

The larger the problem, the more time is needed to compute function values and derivatives. Therefore, you might want to compare optimization techniques by counting and comparing the respective numbers of function, gradient, and Hessian evaluations.

Finite-difference approximations of the derivatives are expensive because they require additional function or gradient calls:

- forward-difference formulas
 - For first-order derivatives, n additional function calls are required.
 - For second-order derivatives based on function calls only, for a dense Hessian, $n + n^2/2$ additional function calls are required.
 - For second-order derivatives based on gradient calls, n additional gradient calls are required.
- central-difference formulas
 - For first-order derivatives, $2n$ additional function calls are required.
 - For second-order derivatives based on function calls only, for a dense Hessian, $2n + 2n^2$ additional function calls are required.
 - For second-order derivatives based on gradient calls, $2n$ additional gradient calls are required.

Many applications need considerably more time for computing second-order derivatives (Hessian matrix) than for computing first-order derivatives (gradient). In such cases, a dual quasi-Newton technique is recommended, which does not require second-order derivatives.

Displayed Output

This section describes the displayed output from PROC NLMIXED. See the section “ODS Table Names” on page 5407 for details about how this output interfaces with the Output Delivery System.

Specifications

The NLMIXED procedure first displays the “Specifications” table, listing basic information about the non-linear mixed model that you have specified. It includes the principal variables and estimation methods.

Dimensions

The “Dimensions” table lists counts of important quantities in your nonlinear mixed model, including the number of observations, subjects, parameters, and quadrature points.

Parameters

The “Parameters” table displays the information you provided with the **PARMS** statement and the value of the negative log-likelihood function evaluated at the starting values.

Starting Gradient and Hessian

The **START** option in the **PROC NLMIXED** statement displays the gradient of the negative log-likelihood function at the starting values of the parameters. If you also specify the **HESS** option, then the starting Hessian is displayed as well.

Iterations

The iteration history consists of one line of output for each iteration in the optimization process. The iteration history is displayed by default because it is important that you check for possible convergence problems. The default iteration history includes the following variables:

- Iter, the iteration number
- Calls, the number of function calls
- NegLogLike, the value of the objective function
- Diff, the difference between adjacent function values
- MaxGrad, the maximum of the absolute (projected) gradient components (except NMSIMP)
- Slope, the slope g' s of the search direction s at the current parameter iterate $\theta^{(k)}$ (QUANEW only)
- Rho, the ratio between the achieved and predicted values of Diff (NRRIDG only)
- Radius, the radius of the trust region (TRUREG only)
- StdDev, the standard deviation of the simplex values (NMSIMP only)
- Delta, the vertex length of the simplex (NMSIMP only)
- Size, the size of the simplex (NMSIMP only)

For the QUANEW method, the value of Slope should be significantly negative. Otherwise, the line-search algorithm has difficulty reducing the function value sufficiently. If this difficulty is encountered, an asterisk (*) appears after the iteration number. If there is a tilde ~ after the iteration number, the BFGS update is skipped, and very high values of the Lagrange function are produced. A backslash (\) after the iteration number indicates that Powell's correction for the BFGS update is used.

For methods using second derivatives, an asterisk (*) after the iteration number means that the computed Hessian approximation was singular and had to be ridged with a positive value.

For the NMSIMP method, only one line is displayed for several internal iterations. This technique skips the output for some iterations because some of the termination tests (StdDev and Size) are rather time-consuming compared to the simplex operations, and they are performed only every five simplex operations.

The **ITDETAILS** option in the **PROC NLMIXED** statement provides a more detailed iteration history. Besides listing the current values of the parameters and their gradients, the **ITDETAILS** option provides the following values in addition to the default output:

- Restart, the number of iteration restarts
- Active, the number of active constraints
- Lambda, the value of the Lagrange multiplier (TRUREG and DBLDOG only)
- Ridge, the ridge value (NRRIDG only)
- Alpha, the line-search step size (QUANEW only)

An apostrophe (') trailing the number of active constraints indicates that at least one of the active constraints was released from the active set due to a significant Lagrange multiplier.

Convergence Status

The "Convergence Status" table contains a status message describing the reason for termination of the optimization. The ODS name of this table is **ConvergenceStatus**, and you can query the nonprinting numeric variable **Status** to check for a successful optimization. This is useful in batch processing, or when processing BY groups, for example, in simulations. Successful convergence is indicated by **Status=0**.

Fitting Information

The "Fitting Information" table lists the final minimized value of -2 times the log likelihood as well as the information criteria of Akaike (AIC) and Schwarz (BIC), as well as a finite-sample corrected version of AIC (AICC). The criteria are computed as follows:

$$\text{AIC} = 2f(\hat{\theta}) + 2p$$

$$\text{AICC} = 2f(\hat{\theta}) + 2pn/(n - p - 1)$$

$$\text{BIC} = 2f(\hat{\theta}) + p \log(s)$$

where $f()$ is the negative of the marginal log-likelihood function, $\hat{\theta}$ is the vector of parameter estimates, p is the number of parameters, n is the number of observations, and s is the number of subjects. See Hurvich and Tsai (1989) and Burnham and Anderson (1998) for additional details.

Parameter Estimates

The “Parameter Estimates” table lists the estimates of the parameter values after successful convergence of the optimization problem or the final values of the parameters under nonconvergence. If the problem did converge, standard errors are computed from the final Hessian matrix. The ratio of the estimate with its standard error produces a t value, with approximate degrees of freedom computed as the number of subjects minus the number of random effects. A p -value and confidence limits based on this t distribution are also provided. Finally, the gradient of the negative log-likelihood function is displayed for each parameter, and you should verify that they each are sufficiently small for unconstrained parameters.

Covariance and Correlation Matrices

Following standard maximum likelihood theory (for example, Serfling 1980), the asymptotic variance-covariance matrix of the parameter estimates equals the inverse of the Hessian matrix. You can display this matrix with the **COV** option in the **PROC NLMIXED** statement. The corresponding correlation form is available with the **CORR** option.

Additional Estimates

The “Additional Estimates” table displays the results of all **ESTIMATE** statements that you specify, with the same columns as the “Parameter Estimates” table. The **ECOV** and **ECORR** options in the **PROC NLMIXED** statement produce tables displaying the approximate covariance and correlation matrices of the additional estimates. They are computed using the delta method (Billingsley 1986; Cox 1998). The **EDER** option in the **PROC NLMIXED** statement produces a table that displays the derivatives of the additional estimates with respect to the model parameters evaluated at their final estimated values.

ODS Table Names

PROC NLMIXED assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 64.2. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 64.2 ODS Tables Produced by **PROC NLMIXED**

ODS Table Name	Description	Statement or Option
AdditionalEstimates	Results from ESTIMATE statements	ESTIMATE

Examples: NLMIXED Procedure

Example 64.1: One-Compartment Model with Pharmacokinetic Data

A popular application of nonlinear mixed models is in the field of pharmacokinetics, which studies how a drug disperses through a living individual. This example considers the theophylline data from Pinheiro and Bates (1995). Serum concentrations of the drug theophylline are measured in 12 subjects over a 25-hour period after oral administration. The data are as follows.

```
data theoph;
  input subject time conc dose wt;
  datalines;
1  0.00  0.74  4.02  79.6
1  0.25  2.84  4.02  79.6
1  0.57  6.57  4.02  79.6
1  1.12 10.50  4.02  79.6
1  2.02  9.66  4.02  79.6
1  3.82  8.58  4.02  79.6
1  5.10  8.36  4.02  79.6
1  7.03  7.47  4.02  79.6

... more lines ...

12 24.15  1.17  5.30  60.5
;
```

Pinheiro and Bates (1995) consider the following first-order compartment model for these data:

$$C_{it} = \frac{Dk_{e_i}k_{a_i}}{Cl_i(k_{a_i} - k_{e_i})}[\exp(-k_{e_i}t) - \exp(-k_{a_i}t)] + e_{it}$$

where C_{it} is the observed concentration of the i th subject at time t , D is the dose of theophylline, k_{e_i} is the elimination rate constant for subject i , k_{a_i} is the absorption rate constant for subject i , Cl_i is the clearance for subject i , and e_{it} are normal errors. To allow for random variability between subjects, they assume

$$Cl_i = \exp(\beta_1 + b_{i1})$$

$$k_{a_i} = \exp(\beta_2 + b_{i2})$$

$$k_{e_i} = \exp(\beta_3)$$

where the β s denote fixed-effects parameters and the b_i s denote random-effects parameters with an unknown covariance matrix.

The PROC NLMIXED statements to fit this model are as follows:

```
proc nlmixed data=theoph;
  parms beta1=-3.22 beta2=0.47 beta3=-2.45
        s2b1=0.03  cb12=0    s2b2=0.4 s2=0.5;
  cl  = exp(beta1 + b1);
  ka  = exp(beta2 + b2);
  ke  = exp(beta3);
  pred = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/cl/(ka-ke);
  model conc ~ normal(pred,s2);
  random b1 b2 ~ normal([0,0],[s2b1,cb12,s2b2]) subject=subject;
run;
```

The **PARMS** statement specifies starting values for the three β s and four variance-covariance parameters. The clearance and rate constants are defined using SAS programming statements, and the conditional model for the data is defined to be normal with mean *pred* and variance *s2*. The two random effects are *b1* and *b2*, and their joint distribution is defined in the **RANDOM** statement. Brackets are used in defining their mean vector (two zeros) and the lower triangle of their variance-covariance matrix (a general 2×2 matrix). The **SUBJECT=** variable is *subject*.

The results from this analysis are as follows.

Output 64.1.1 Model Specification for One-Compartment Model

The NLMIXED Procedure	
Specifications	
Data Set	WORK.THEOPH
Dependent Variable	conc
Distribution for Dependent Variable	Normal
Random Effects	b1 b2
Distribution for Random Effects	Normal
Subject Variable	subject
Optimization Technique	Dual Quasi-Newton
Integration Method	Adaptive Gaussian Quadrature

The “Specifications” table lists the setup of the model (Output 64.1.1). The “Dimensions” table indicates that there are 132 observations, 12 subjects, and 7 parameters. PROC NLMIXED selects 5 quadrature points for each random effect, producing a total grid of 25 points over which quadrature is performed (Output 64.1.2).

Output 64.1.2 Dimensions Table for One-Compartment Model

Dimensions	
Observations Used	132
Observations Not Used	0
Total Observations	132
Subjects	12
Max Obs Per Subject	11
Parameters	7
Quadrature Points	5

The “Parameters” table lists the 7 parameters, their starting values, and the initial evaluation of the negative log likelihood using adaptive Gaussian quadrature (Output 64.1.3). The “Iteration History” table indicates that 10 steps are required for the dual quasi-Newton algorithm to achieve convergence.

Output 64.1.3 Starting Values and Iteration History

Parameters						
beta1	beta2	beta3	s2b1	cb12	s2b2	s2 NegLogLike
-3.22	0.47	-2.45	0.03	0	0.4	0.5 177.789945

Iteration History

NOTE: GCONV convergence criterion satisfied.

Output 64.1.4 Fit Statistics for One-Compartment Model

Fit Statistics	
-2 Log Likelihood	355.5
AIC (smaller is better)	369.5
AICC (smaller is better)	370.4
BIC (smaller is better)	372.9

The “Fit Statistics” table lists the final optimized values of the log-likelihood function and information criteria in the “smaller is better” form ([Output 64.1.4](#)).

Output 64.1.5 Parameter Estimates for One-Compartment Model

Parameter Estimates							
Parameter	Estimate	Standard Error	DF	t Value	Pr > t	Alpha	Lower
beta1	-3.2268	0.05950	10	-54.23	<.0001	0.05	-3.3594
beta2	0.4806	0.1989	10	2.42	0.0363	0.05	0.03745
beta3	-2.4592	0.05126	10	-47.97	<.0001	0.05	-2.5734
s2b1	0.02803	0.01221	10	2.30	0.0445	0.05	0.000833
cb12	-0.00127	0.03404	10	-0.04	0.9710	0.05	-0.07712
s2b2	0.4331	0.2005	10	2.16	0.0560	0.05	-0.01353
s2	0.5016	0.06837	10	7.34	<.0001	0.05	0.3493

Parameter Estimates		
Parameter	Upper	Gradient
beta1	-3.0942	-0.00009
beta2	0.9238	3.645E-7
beta3	-2.3449	0.000039
s2b1	0.05523	-0.00014
cb12	0.07458	-0.00007
s2b2	0.8798	-6.98E-6
s2	0.6540	6.133E-6

The “Parameter Estimates” table contains the maximum likelihood estimates of the parameters ([Output 64.1.5](#)). Both s2b1 and s2b2 are marginally significant, indicating between-subject variability in the clearances and absorption rate constants, respectively. There does not appear to be a significant covariance between them, as seen by the estimate of cb12.

The estimates of β_1 , β_2 , and β_3 are close to the adaptive quadrature estimates listed in Table 3 of Pinheiro and Bates (1995). However, Pinheiro and Bates use a Cholesky-root parameterization for the random-effects variance matrix and a logarithmic parameterization for the residual variance. The PROC NL MIXED statements using their parameterization are as follows, and results are similar.

```

proc nlmixed data=theoph;
  parms l11=-1.5 l2=0 l13=-0.1 beta1=-3 beta2=0.5 beta3=-2.5 ls2=-0.7;
  s2    = exp(ls2);
  l1    = exp(l11);
  l3    = exp(l13);
  s2b1  = l1*l1*s2;
  cb12  = l2*l1*s2;
  s2b2  = (l2*l2 + l3*l3)*s2;
  c1    = exp(beta1 + b1);
  ka    = exp(beta2 + b2);
  ke    = exp(beta3);
  pred  = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/c1/(ka-ke);
  model conc ~ normal(pred,s2);
  random b1 b2 ~ normal([0,0],[s2b1,cb12,s2b2]) subject=subject;
run;

```

Example 64.2: Probit-Normal Model with Binomial Data

For this example, consider the data from Weil (1970), also studied by: Williams (1975); Ochi and Prentice (1984); McCulloch (1994). In this experiment 16 pregnant rats receive a control diet and 16 receive a chemically treated diet, and the litter size for each rat is recorded after 4 and 21 days. The SAS data set follows:

```

data rats;
  input trt $ m x @@;
  if (trt='c') then do;
    x1 = 1;
    x2 = 0;
  end;
  else do;
    x1 = 0;
    x2 = 1;
  end;
  litter = _n_;
  datalines;
c 13 13   c 12 12   c 9 9   c 9 9   c 8 8   c 8 8   c 13 12   c 12 11
c 10 9    c 10 9    c 9 8    c 13 11   c 5 4    c 7 5    c 10 7    c 10 7
t 12 12   t 11 11   t 10 10   t 9 9    t 11 10   t 10 9    t 10 9    t 9 8
t 9 8     t 5 4     t 9 7    t 7 4    t 10 5    t 6 3    t 10 3    t 7 0
;

```

Here, *m* represents the size of the litter after 4 days, and *x* represents the size of the litter after 21 days. Also, indicator variables *x*₁ and *x*₂ are constructed for the two treatment levels.

Following McCulloch (1994), assume a latent survival model of the form

$$y_{ijk} = t_i + \alpha_{ij} + e_{ijk}$$

where *i* indexes treatment, *j* indexes litter, and *k* indexes newborn rats within a litter. The *t_i* represent treatment means, the α_{ij} represent random litter effects assumed to be iid $N(0, s_i^2)$, and the *e_{ijk}* represent iid residual errors, all on the latent scale.

Instead of observing the survival times *y_{ijk}*, assume that only the binary variable indicating whether *y_{ijk}* exceeds 0 is observed. If *x_{ij}* denotes the sum of these binary variables for the *i*th treatment and the *j*th litter,

then the preceding assumptions lead to the following generalized linear mixed model:

$$x_{ij}|\alpha_{ij} \sim \text{Binomial}(m_{ij}, p_{ij})$$

where m_{ij} is the size of each litter after 4 days and

$$p_{ij} = \Phi(t_i + \alpha_{ij})$$

The PROC NLMIXED statements to fit this model are as follows:

```
proc nlmixed data=rats;
  parms t1=1 t2=1 s1=.05 s2=1;
  eta = x1*t1 + x2*t2 + alpha;
  p   = probnorm(eta);
  model x ~ binomial(m,p);
  random alpha ~ normal(0,x1*s1*s1+x2*s2*s2) subject=litter;
  estimate 'gamma2' t2/sqrt(1+s2*s2);
  predict p out=p;
run;
```

As in [Example 64.1](#), the PROC NLMIXED statement invokes the procedure and the PARMS statement defines the parameters. The parameters for this example are the two treatment means, t_1 and t_2 , and the two random-effect standard deviations, s_1 and s_2 .

The indicator variables x_1 and x_2 are used in the program to assign the proper mean to each observation in the input data set as well as the proper variance to the random effects. Note that programming expressions are permitted inside the distributional specifications, as illustrated by the random-effects variance specified here.

The **ESTIMATE** statement requests an estimate of $\gamma_2 = t_2/\sqrt{1+s_2^2}$, which is a location-scale parameter from Ochi and Prentice (1984).

The **PREDICT** statement constructs predictions for each observation in the input data set. For this example, predictions of p and approximate standard errors of prediction are output to a SAS data set named P. These predictions are functions of the parameter estimates and the empirical Bayes estimates of the random effects α_i .

The output for this model is as follows.

Output 64.2.1 Specifications, Dimensions, and Starting Values

The NLMIXED Procedure	
Specifications	
Data Set	WORK.RATS
Dependent Variable	x
Distribution for Dependent Variable	Binomial
Random Effects	alpha
Distribution for Random Effects	Normal
Subject Variable	litter
Optimization Technique	Dual Quasi-Newton
Integration Method	Adaptive Gaussian Quadrature

Output 64.2.1 *continued*

Dimensions				
Observations Used				32
Observations Not Used				0
Total Observations				32
Subjects				32
Max Obs Per Subject				1
Parameters				4
Quadrature Points				7
Parameters				
t1	t2	s1	s2	NegLogLike
1	1	0.05	1	54.9362323

The “Specifications” table provides basic information about this nonlinear mixed model ([Output 64.2.1](#)). The “Dimensions” table provides counts of various variables. Note that each observation in the data comprises a separate subject. Using the starting values in the “Parameters” table, PROC NLMIXED determines that the log-likelihood function can be approximated with sufficient accuracy with a seven-point quadrature rule.

Output 64.2.2 Iteration History for Probit-Normal Model

Iteration History					
Iter	Calls	NegLogLike	Diff	MaxGrad	Slope
1	2	53.9933934	0.942839	11.03261	-81.9428
2	3	52.875353	1.11804	2.148952	-2.86277
3	5	52.6350386	0.240314	0.329957	-1.05049
4	6	52.6319939	0.003045	0.122926	-0.00672
5	8	52.6313583	0.000636	0.028246	-0.00352
6	11	52.6313174	0.000041	0.013551	-0.00023
7	13	52.6313115	5.839E-6	0.000603	-0.00001
8	15	52.6313115	9.45E-9	0.000022	-1.68E-8
NOTE: GCONV convergence criterion satisfied.					

The “Iteration History” table indicates successful convergence in 8 iterations ([Output 64.2.2](#)).

Output 64.2.3 Fit Statistics for Probit-Normal Model

Fit Statistics	
-2 Log Likelihood	105.3
AIC (smaller is better)	113.3
AICC (smaller is better)	114.7
BIC (smaller is better)	119.1

The “Fit Statistics” table lists useful statistics based on the maximized value of the log likelihood (Output 64.2.3).

Output 64.2.4 Parameter Estimates for Probit-Normal Model

Parameter Estimates							
Parameter	Estimate	Standard Error	DF	t Value	Pr > t	Alpha	Lower
t1	1.3063	0.1685	31	7.75	<.0001	0.05	0.9626
t2	0.9475	0.3055	31	3.10	0.0041	0.05	0.3244
s1	0.2403	0.3015	31	0.80	0.4315	0.05	-0.3746
s2	1.0292	0.2988	31	3.44	0.0017	0.05	0.4198

Parameter Estimates		
Parameter	Upper	Gradient
t1	1.6499	-0.00002
t2	1.5705	9.283E-6
s1	0.8552	0.000014
s2	1.6385	-3.16E-6

The “Parameter Estimates” table indicates significance of all the parameters except S1 (Output 64.2.4).

Output 64.2.5 Additional Estimates

Additional Estimates								
Label	Estimate	Standard Error	DF	t Value	Pr > t	Alpha	Lower	Upper
gamma2	0.6603	0.2165	31	3.05	0.0047	0.05	0.2186	1.1019

The “Additional Estimates” table displays results from the **ESTIMATE** statement (Output 64.2.5). The estimate of γ_2 equals 0.66, agreeing with that obtained by McCulloch (1994). The standard error 0.22 is computed using the delta method (Billingsley 1986; Cox 1998).

Not shown is the P data set, which contains the original 32 observations and predictions of the p_{ij} .

Example 64.3: Probit-Normal Model with Ordinal Data

The data for this example are from Ezzet and Whitehead (1991), who describe a crossover experiment on two groups of patients using two different inhaler devices (A and B). Patients from group 1 used device A for one week and then device B for another week. Patients from group 2 used the devices in reverse order. The data entered as a SAS data set are as follows:

```
data inhaler;
  input clarity group time freq @@;
  gt = group*time;
  sub = floor((_n_+1)/2);
  datalines;
1 0 0 59 1 0 1 59 1 0 0 35 2 0 1 35 1 0 0 3 3 0 1 3 1 0 0 2
4 0 1 2 2 0 0 11 1 0 1 11 2 0 0 27 2 0 1 27 2 0 0 2 3 0 1 2
2 0 0 1 4 0 1 1 4 0 0 1 1 0 1 1 4 0 0 1 2 0 1 1 1 1 0 63
1 1 1 63 1 1 0 13 2 1 1 13 2 1 0 40 1 1 1 40 2 1 0 15 2 1 1 15
3 1 0 7 1 1 1 7 3 1 0 2 2 1 1 2 3 1 0 1 3 1 1 1 4 1 0 2
1 1 1 2 4 1 0 1 3 1 1 1
;
```

The response measurement, clarity, is the patients' assessment on the clarity of the leaflet instructions for the devices. The clarity variable is on an ordinal scale, with 1=easy, 2=only clear after rereading, 3=not very clear, and 4=confusing. The group variable indicates the treatment group, and the time variable indicates the time of measurement. The freq variable indicates the number of patients with exactly the same responses. A variable gt is created to indicate a group-by-time interaction, and a variable sub is created to indicate patients.

As in the previous example and in Hedeker and Gibbons (1994), assume an underlying latent continuous variable, here with the form

$$y_{ij} = \beta_0 + \beta_1 g_i + \beta_2 t_j + \beta_3 g_i t_j + u_i + e_{ij}$$

where i indexes patient and j indexes the time period, g_i indicates groups, t_j indicates time, u_i is a patient-level normal random effect, and e_{ij} are iid normal errors. The β s are unknown coefficients to be estimated.

Instead of observing y_{ij} , however, you observe only whether it falls in one of the four intervals: $(-\infty, 0)$, $(0, I1)$, $(I1, I1 + I2)$, or $(I1 + I2, \infty)$, where $I1$ and $I2$ are both positive. The resulting category is the value assigned to the clarity variable.

The following code sets up and fits this ordinal probit model:

```
proc nlmixed data=inhaler corr ecorr;
  parms b0=0 b1=0 b2=0 b3=0 sd=1 i1=1 i2=1;
  bounds i1 > 0, i2 > 0;
  eta = b0 + b1*group + b2*time + b3*gt + u;
  if (clarity=1) then p = probnorm(-eta);
  else if (clarity=2) then
    p = probnorm(i1-eta) - probnorm(-eta);
  else if (clarity=3) then
    p = probnorm(i1+i2-eta) - probnorm(i1-eta);
  else p = 1 - probnorm(i1+i2-eta);
  if (p > 1e-8) then ll = log(p);
  else ll = -1e20;
```

```

model clarity ~ general(11);
random u ~ normal(0,sd*sd) subject=sub;
replicate freq;
estimate 'thresh2' i1;
estimate 'thresh3' i1 + i2;
estimate 'icc' sd*sd/(1+sd*sd);
run;

```

The **PROC NLMIXED** statement specifies the input data set and requests correlations both for the parameter estimates (**CORR** option) and for the additional estimates specified with **ESTIMATE** statements (**ECORR** option).

The parameters as defined in the **PARMS** statement are as follows: **b0** (overall intercept), **b1** (group main effect), **B2** (time main effect), **b3** (group-by-time interaction), **sd** (standard deviation of the random effect), **i1** (increment between first and second thresholds), and **i2** (increment between second and third thresholds). The **BOUND**s statement restricts **i1** and **i2** to be positive.

The SAS programming statements begin by defining the linear predictor **eta**, which is a linear combination of the **b** parameters and a single random effect **u**. The next statements define the ordinal likelihood according to the **clarity** variable, **eta**, and the increment variables. An error trap is included in case the likelihood becomes too small.

A general log-likelihood specification is used in the **MODEL** statement, and the **RANDOM** statement defines the random effect **u** to have standard deviation **sd** and subject variable **sub**. The **REPLICATE** statement indicates that data for each subject should be replicated according to the **freq** variable.

The **ESTIMATE** statements specify the second and third thresholds in terms of the increment variables (the first threshold is assumed to equal zero for model identifiability). Also computed is the intraclass correlation.

The output is as follows.

Output 64.3.1 Specifications for Ordinal Data Model

The NLMIXED Procedure	
Specifications	
Data Set	WORK.INHALER
Dependent Variable	clarity
Distribution for Dependent Variable	General
Random Effects	u
Distribution for Random Effects	Normal
Subject Variable	sub
Replicate Variable	freq
Optimization Technique	Dual Quasi-Newton
Integration Method	Adaptive Gaussian Quadrature

The “Specifications” table echoes some primary information specified for this nonlinear mixed model (Output 64.3.1). Because the log-likelihood function was expressed with SAS programming statements, the distribution is displayed as *General* in the “Specifications” table.

The “Dimensions” table reveals a total of 286 subjects, which is the sum of the values of the FREQ variable for the second time point. Five quadrature points are selected for log-likelihood evaluation ([Output 64.3.2](#)).

Output 64.3.2 Dimensions Table for Ordinal Data Model

Dimensions	
Observations Used	38
Observations Not Used	0
Total Observations	38
Subjects	286
Max Obs Per Subject	2
Parameters	7
Quadrature Points	5

Output 64.3.3 Parameter Starting Values and Negative Log Likelihood

Parameters							
b0	b1	b2	b3	sd	i1	i2	NegLogLike
0	0	0	0	1	1	1	538.484276

The “Parameters” table lists the simple starting values for this problem ([Output 64.3.3](#)). The “Iteration History” table indicates successful convergence in 13 iterations ([Output 64.3.4](#)).

Output 64.3.4 Iteration History

Iteration History					
Iter	Calls	NegLogLike	Diff	MaxGrad	Slope

The “Additional Estimates” table displays results from the ESTIMATE statements ([Output 64.3.7](#)).

Example 64.4: Poisson-Normal Model with Count Data

This example uses the pump failure data of Gaver and O’Muircheartaigh (1987). The number of failures and the time of operation are recorded for 10 pumps. Each of the pumps is classified into one of two groups corresponding to either continuous or intermittent operation. The data are as follows:

```
data pump;
  input y t group;
  pump = _n_;
  logtstd = log(t) - 2.4564900;
  datalines;
5  94.320 1
1  15.720 2
5  62.880 1
14 125.760 1
3   5.240 2
19 31.440 1
1   1.048 2
1   1.048 2
4   2.096 2
22 10.480 2
;
```

Each row denotes data for a single pump, and the variable logtstd contains the centered operation times.

Letting y_{ij} denote the number of failures for the j th pump in the i th group, Draper (1996) considers the following hierarchical model for these data:

$$\begin{aligned}
 y_{ij} | \lambda_{ij} &\sim \text{Poisson}(\lambda_{ij}) \\
 \log \lambda_{ij} &= \alpha_i + \beta_i (\log t_{ij} - \overline{\log t}) + e_{ij} \\
 e_{ij} | \sigma^2 &\sim \text{Normal}(0, \sigma^2)
 \end{aligned}$$

The model specifies different intercepts and slopes for each group, and the random effect is a mechanism for accounting for overdispersion.

The corresponding PROC NLMIXED statements are as follows:

```
proc nlmixed data=pump;
  parms logsig 0 beta1 1 beta2 1 alpha1 1 alpha2 1;
  if (group = 1) then eta = alpha1 + beta1*logtstd + e;
  else eta = alpha2 + beta2*logtstd + e;
  lambda = exp(eta);
  model y ~ poisson(lambda);
  random e ~ normal(0,exp(2*logsig)) subject=pump;
  estimate 'alpha1-alpha2' alpha1-alpha2;
  estimate 'beta1-beta2' beta1-beta2;
run;
```

The selected output is as follows.

Output 64.4.1 Dimensions Table for Poisson-Normal Model

The NLMIXED Procedure	
Dimensions	
Observations Used	10
Observations Not Used	0
Total Observations	10
Subjects	10
Max Obs Per Subject	1
Parameters	5
Quadrature Points	5

The “Dimensions” table indicates that data for 10 pumps are used with one observation for each (Output 64.4.1).

Output 64.4.2 Iteration History for Poisson-Normal Model

Iteration History					
Iter	Calls	NegLogLike	Diff	MaxGrad	Slope

The “Parameter Estimates” and “Additional Estimates” tables list the maximum likelihood estimates for each of the parameters and two differences (Output 64.4.4). The point estimates for the mean parameters agree fairly closely with the Bayesian posterior means reported by Draper (1996); however, the likelihood-based standard errors are roughly half the Bayesian posterior standard deviations. This is most likely due to the fact that the Bayesian standard deviations account for the uncertainty in estimating σ^2 , whereas the likelihood values plug in its estimated value. This downward bias can be corrected somewhat by using the t_9 distribution shown here.

Example 64.5: Failure Time and Frailty Model

In this example an accelerated failure time model with proportional hazard is fitted with and without random effects. The data are from the “Getting Started” example of PROC LIFEREG; see Chapter 51, “The LIFEREG Procedure.” Thirty-eight patients are divided into two groups of equal size, and different pain relievers are assigned to each group. The outcome reported is the time in minutes until headache relief. The variable *sensor* indicates whether relief was observed during the course of the observation period (*sensor* = 0) or whether the observation is censored (*sensor* = 1). The SAS DATA step for these data is as follows:

```
data headache;
  input minutes group sensor @@;
  patient = _n_;
  datalines;
11 1 0    12 1 0    19 1 0    19 1 0
19 1 0    19 1 0    21 1 0    20 1 0
21 1 0    21 1 0    20 1 0    21 1 0
20 1 0    21 1 0    25 1 0    27 1 0
30 1 0    21 1 1    24 1 1    14 2 0
16 2 0    16 2 0    21 2 0    21 2 0
23 2 0    23 2 0    23 2 0    23 2 0
25 2 1    23 2 0    24 2 0    24 2 0
26 2 1    32 2 1    30 2 1    30 2 0
32 2 1    20 2 1
;
```

In modeling survival data, censoring of observations must be taken into account carefully. In this example, only right censoring occurs. If $g(t, \boldsymbol{\beta})$, $h(t, \boldsymbol{\beta})$, and $G(t, \boldsymbol{\beta})$ denote the density of failure, the hazard function, and the survival distribution function at time t , respectively, then the log likelihood can be written as

$$\begin{aligned} l(\boldsymbol{\beta}; \mathbf{t}) &= \sum_{i \in U_u} \log g(t_i, \boldsymbol{\beta}) + \sum_{i \in U_c} \log G(t_i, \boldsymbol{\beta}) \\ &= \sum_{i \in U_u} \log h(t_i, \boldsymbol{\beta}) + \sum_{i=1}^n \log G(t_i, \boldsymbol{\beta}) \end{aligned}$$

(See Cox and Oakes 1984, Ch. 3.) In these expressions U_u is the set of uncensored observations, U_c is the set of censored observations, and n denotes the total sample size.

The proportional hazards specification expresses the hazard in terms of a baseline hazard, multiplied by a constant. In this example the hazard is that of a Weibull model and is parameterized as $h(t, \boldsymbol{\beta}) = \gamma \alpha (\alpha t)^{\gamma-1}$ and $\alpha = \exp\{-\mathbf{x}'\boldsymbol{\beta}\}$.

The linear predictor is set equal to the intercept in the reference group (group = 2); this defines the baseline hazard. The corresponding distribution of survival past time t is $G(t, \beta) = \exp\{-(\alpha t)^\gamma\}$. See Cox and Oakes (1984, Table 2.1) and the section “Supported Distributions” in Chapter 51, “The LIFEREG Procedure,” for this and other survival distribution models and various parameterizations.

The following NLMIXED statements fit this accelerated failure time model and estimate the cumulative distribution function of time to headache relief:

```
proc nlmixed data=headache;
  bounds gamma > 0;
  lnp = b0 - b1*(group-2);
  alpha = exp(-lnp);
  G_t = exp(-(alpha*minutes)**gamma);
  g = gamma*alpha*((alpha*minutes)**(gamma-1))*G_t;
  ll = (censor=0)*log(g) + (censor=1)*log(G_t);
  model minutes ~ general(ll);
  predict 1-G_t out=cdf;
run;
```

Output 64.5.1 Specifications Table for Fixed-Effects Failure Time Model

The NLMIXED Procedure	
Specifications	
Data Set	WORK.HEADACHE
Dependent Variable	minutes
Distribution for Dependent Variable	General
Optimization Technique	Dual Quasi-Newton
Integration Method	None

The “Specifications” table shows that no integration is required, since the model does not contain random effects (Output 64.5.1).

Output 64.5.2 Negative Log Likelihood with Default Starting Values

Parameters			
gamma	b0	b1	NegLogLike
1	1	1	263.990327

No starting values were given for the three parameters. The NLMIXED procedure assigns the default value of 1.0 in this case. The negative log likelihood based on these starting values is shown in Output 64.5.2.

Output 64.5.3 Iteration History for Fixed-Effects Failure Time Model

Iteration History					
Iter	Calls	NegLogLike	Diff	MaxGrad	Slope

17	34	99.8736351	6.1E-10	4.768E-6	-1.23E-9

NOTE: GCONV convergence criterion satisfied.

The “Iteration History” table shows that the procedure converges after 17 iterations and 34 evaluations of the objective function (Output 64.5.3).

Output 64.5.4 Fit Statistics and Parameter Estimates

Fit Statistics							
-2 Log Likelihood				199.7			
AIC (smaller is better)				205.7			
AICC (smaller is better)				206.5			
BIC (smaller is better)				210.7			

Parameter Estimates							
Parameter	Estimate	Standard Error	DF	t Value	Pr > t	Alpha	Lower
gamma	4.7128	0.6742	38	6.99	<.0001	0.05	3.3479
b0	3.3091	0.05885	38	56.23	<.0001	0.05	3.1900
b1	-0.1933	0.07856	38	-2.46	0.0185	0.05	-0.3523

Parameter Estimates		
Parameter	Upper	Gradient
gamma	6.0777	5.327E-8
b0	3.4283	-4.77E-6
b1	-0.03426	-1.22E-6

The parameter estimates and their standard errors shown in [Output 64.5.4](#) are identical to those obtained with the LIFEREG procedure and the following statements:

```
proc lifereg data=headache;
  class group;
  model minutes*censor(1) = group / dist=weibull;
  output out=new cdf=prob;
run;
```

The t statistic and confidence limits are based on 38 degrees of freedom. The LIFEREG procedure computes z intervals for the parameter estimates.

For the two groups you obtain

$$\begin{aligned}\hat{\alpha}(\text{group} = 1) &= \exp\{-3.3091 + 0.1933\} = 0.04434 \\ \hat{\alpha}(\text{group} = 2) &= \exp\{-3.3091\} = 0.03655\end{aligned}$$

The probabilities of headache relief by t minutes are estimated as

$$\begin{aligned}1 - G(t, \text{group} = 1) &= 1 - \exp\{-(0.04434 * t)^{4.7128}\} \\ 1 - G(t, \text{group} = 2) &= 1 - \exp\{-(0.03655 * t)^{4.7128}\}\end{aligned}$$

These probabilities, calculated at the observed times, are shown for the two groups in [Output 64.5.5](#) and printed with the following statements:

```
proc print data=cdf;
  var group censor patient minutes pred;
run;
```

Since the slope estimate is negative with p -value of 0.0185, you can infer that pain reliever 1 leads to overall significantly faster relief, but the estimated probabilities give no information about patient-to-patient variation within and between groups. For example, while pain reliever 1 provides faster relief overall, some patients in group 2 might respond more quickly than some patients in group 1. A frailty model enables you to accommodate and estimate patient-to-patient variation in health status by introducing random effects into a subject's hazard function.

The following statements model the hazard for patient i in terms of $\alpha_i = \exp\{-\mathbf{x}_i' \boldsymbol{\beta} - z_i\}$, where z_i is a (normal) random patient effect. Notice that the only difference from the previous NLMIXED statements are the **RANDOM** statement and the addition of z in the linear predictor. The empirical Bayes estimates of the random effect (**RANDOM** statement), the parameter estimates (ODS OUTPUT statement), and the estimated cumulative distribution function (**PREDICT** statement) are saved to subsequently graph the patient-specific distribution functions.

```

ods output ParameterEstimates=est;
proc nlmixed data=headache;
  bounds gamma > 0;
  linp = b0 - b1*(group-2) + z;
  alpha = exp(-linp);
  G_t   = exp(-(alpha*minutes)**gamma);
  g     = gamma*alpha*((alpha*minutes)**(gamma-1))*G_t;
  ll = (censor=0)*log(g) + (censor=1)*log(G_t);
  model minutes ~ general(ll);
  random z ~ normal(0,exp(2*logsig)) subject=patient out=EB;
  predict 1-G_t out=cdf;
run;

```

Output 64.5.6 Specifications for Random Frailty Model

The NLMIXED Procedure	
Specifications	
Data Set	WORK.HEADACHE
Dependent Variable	minutes
Distribution for Dependent Variable	General
Random Effects	z
Distribution for Random Effects	Normal
Subject Variable	patient
Optimization Technique	Dual Quasi-Newton
Integration Method	Adaptive Gaussian Quadrature

The “Specifications” table shows that the objective function is computed by adaptive Gaussian quadrature because of the presence of random effects (compare [Output 64.5.6](#) and [Output 64.5.1](#)). The “Dimensions” table reports that nine quadrature points are being used to integrate over the random effects ([Output 64.5.7](#)).

15	31	99.2444957	9.147E-8	0.000271	-1.84E-7

NOTE: GCONV convergence criterion satisfied.

The procedure converges after 15 iterations ([Output 64.5.8](#)). The achieved -2 log likelihood is only 1.2 less than that in the model without random effects (compare [Output 64.5.9](#) and [Output 64.5.4](#)). Compared to a chi-square distribution with one degree of freedom, the addition of the random effect appears not to improve the model significantly. You must exercise care, however, in interpreting likelihood ratio tests when the value under the null hypothesis falls on the boundary of the parameter space (see, for example, Self and Liang 1987).

Output 64.5.9 Fit Statistics for Random Frailty Model

Fit Statistics

33	33	z	0.07618	0.14132
34	34	z	0.16292	0.16460
35	35	z	0.13193	0.15528
36	36	z	0.06327	0.12124
37	37	z	0.16292	0.16460
38	38	z	0.02074	0.14160

The predicted values and patient-specific survival distributions can be plotted with the SAS code that follows:

```
proc transpose data=est (keep=estimate)
    out=trest(rename=(col1=gamma col2=b0 col3=b1));
run;

data pred;
    merge eb(keep=estimate) headache(keep=patient group);
    array pp{2} pred1-pred2;
    if _n_ = 1 then set trest(keep=gamma b0 b1);
    do time=11 to 32;
        linp      = b0 - b1*(group-2) + estimate;
        pp{group} = 1-exp(- (exp(-linp)*time)**gamma);
        symbolid  = patient+1;
        output;
    end;
    keep pred1 pred2 time patient;
run;

data pred;
    merge pred
        cdf(where = (group=1)
            rename = (pred=pcdf1 minutes=minutes1)
            keep   = pred minutes group)
        cdf(where = (group=2)
            rename = (pred=pcdf2 minutes=minutes2)
            keep   = pred minutes group);
    drop group;
run;

proc sgplot data=pred noautolegend;
    label minutes1='Minutes to Headache Relief'
          pcdf1    ='Estimated Patient-specific CDF';
    series x=time      y=pred1 /
          group=patient
          lineattrs=(pattern=solid color=black);
    series x=time      y=pred2 /
          group=patient
          lineattrs=(pattern=dash color=black);
    scatter x=minutes1 y=pcdf1 /
          markerattrs=(symbol=CircleFilled size=9);
    scatter x=minutes2 y=pcdf2 /
          markerattrs=(symbol=Circle      size=9);
run;
```

The separation of the distribution functions by groups is evident in [Output 64.5.12](#). Most of the distributions of patients in the first group are to the left of the distributions in the second group. The separation is not complete, however. Several patients who are assigned the second pain reliever experience headache relief more quickly than patients assigned to the first group.

Output 64.5.12 Patient-Specific CDFs and Predicted Values. Pain Reliever 1: Solid Lines, Closed Circles; Pain Reliever 2: Dashed Lines, Open Circles.

Overview: NPAR1WAY Procedure

The NPAR1WAY procedure performs nonparametric tests for location and scale differences across a one-way classification. PROC NPAR1WAY also provides a standard analysis of variance on the raw data and tests based on the empirical distribution function.

PROC NPAR1WAY performs tests for location and scale differences based on the following scores of a response variable: Wilcoxon, median, Van der Waerden (normal), Savage, Siegel-Tukey, Ansari-Bradley, Klotz, Mood, and Conover. Additionally, PROC NPAR1WAY provides tests that use the raw input data as scores. When the data are classified into two samples, tests are based on simple linear rank statistics. When the data are classified into more than two samples, tests are based on one-way ANOVA statistics. Both asymptotic and exact p -values are available for these tests. PROC NPAR1WAY also provides Hodges-Lehmann estimation, including exact confidence limits for the location shift.

PROC NPAR1WAY computes empirical distribution function (EDF) statistics, which test whether the distribution of a variable is the same across different groups. These include the Kolmogorov-Smirnov test, the Cramer-von Mises test, and, when the data are classified into only two samples, the Kuiper test. Exact p -values are available for the two-sample Kolmogorov-Smirnov test.

PROC NPAR1WAY uses the Output Delivery System (ODS), a SAS subsystem that provides capabilities for displaying and controlling the output from SAS procedures. ODS enables you to convert any of the output from PROC NPAR1WAY into a SAS data set. See the section “[ODS Table Names](#)” on page 5493 for more information.

PROC NPAR1WAY uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the statistical graphics available with the NPAR1WAY procedure, see the `PLOTS=` option in the PROC NPAR1WAY statement and the section “[ODS Graphics](#)” on page 5495.

Getting Started: NPAR1WAY Procedure

This example illustrates how you can use PROC NPAR1WAY to perform a one-way nonparametric analysis. The data from Halverson and Sherwood (1930) consist of weight gain measurements for five different levels of gossypol additive in animal feed. Gossypol is a substance contained in cottonseed shells, and these data were collected to study the effect of gossypol on animal nutrition.

The following DATA step statements create the SAS data set Gossypol:

```
data Gossypol;
  input Dose n;
  do i=1 to n;
    input Gain @@;
    output;
  end;
  datalines;
0 16
228 229 218 216 224 208 235 229 233 219 224 220 232 200 208 232
.04 11
186 229 220 208 228 198 222 273 216 198 213
.07 12
179 193 183 180 143 204 114 188 178 134 208 196
.10 17
130 87 135 116 118 165 151 59 126 64 78 94 150 160 122 110 178
.13 11
154 130 130 118 118 104 112 134 98 100 104
;
```

The data set Gossypol contains the variable Dose, which represents the amount of gossypol additive, and the variable Gain, which represents the weight gain.

Researchers are interested in whether there is a difference in weight gain among animals receiving the different dose levels of gossypol. The following statements invoke the NPAR1WAY procedure to perform a nonparametric analysis of this problem:

```
proc npar1way data=Gossypol;
  class Dose;
  var Gain;
run;
```

The variable Dose is the CLASS variable, and the VAR statement specifies the variable Gain is the response variable. The CLASS statement is required, and you must name only one CLASS variable. You can name one or more analysis variables in the VAR statement. If you omit the VAR statement, PROC NPAR1WAY analyzes all numeric variables in the data set except for the CLASS variable, the FREQ variable, and the BY variables.

When no analysis options are specified in the PROC NPAR1WAY statement, the ANOVA, WILCOXON, MEDIAN, VW, SAVAGE, and EDF options are invoked by default. The tables in the following figures show the results of these analyses.

The tables in Figure 65.1 are produced with the ANOVA option. For each level of the CLASS variable Dose, PROC NPAR1WAY displays the number of observations and the mean of the analysis variable Gain. PROC NPAR1WAY displays a standard analysis of variance on the raw data. This gives the same results as the GLM and ANOVA procedures. The p -value for the F test is <0.0001 , which indicates that Dose accounts for a significant portion of the variability of the dependent variable Gain.

Figure 65.1 Analysis of Variance

The NPAR1WAY Procedure					
Analysis of Variance for Variable Gain					
Classified by Variable Dose					
Dose		N	Mean		
0		16	222.187500		
0.04		11	217.363636		
0.07		12	175.000000		
0.1		17	120.176471		
0.13		11	118.363636		
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Among	4	140082.986077	35020.74652	55.8143	<.0001
Within	62	38901.998997	627.45160		
Average scores were used for ties.					

The WILCOXON option produces the output in Figure 65.2. PROC NPAR1WAY first provides a summary of the Wilcoxon scores for the analysis variable Gain by class level. For each level of the CLASS variable Dose, PROC NPAR1WAY displays the following information: number of observations, sum of the Wilcoxon scores, expected sum under the null hypothesis of no difference among class levels, standard deviation under the null hypothesis, and mean score.

Next PROC NPAR1WAY displays the one-way ANOVA statistic, which for Wilcoxon scores is known as the Kruskal-Wallis test. The statistic equals 52.6656, with four degrees of freedom, which is the number of class levels minus one. The p -value (probability of a larger statistic under the null hypothesis) is <0.0001 . This leads to rejection of the null hypothesis that there is no difference in location for Gain among the levels of Dose. This p -value is asymptotic, computed from the asymptotic chi-square distribution of the test statistic. For certain data sets it might also be useful to compute the exact p -value—for example, for small data sets or for data sets that are sparse, skewed, or heavily tied. You can use the EXACT statement to request exact p -values for any of the location or scale tests available in PROC NPAR1WAY.

Figure 65.2 Wilcoxon Score Analysis

Wilcoxon Scores (Rank Sums) for Variable Gain Classified by Variable Dose					
Dose	N	Sum of Scores	Expected Under H0	Std Dev Under H0	Mean Score
0	16	890.50	544.0	67.978966	55.656250
0.04	11	555.00	374.0	59.063588	50.454545
0.07	12	395.50	408.0	61.136622	32.958333
0.1	17	275.50	578.0	69.380741	16.205882
0.13	11	161.50	374.0	59.063588	14.681818
Average scores were used for ties.					
Kruskal-Wallis Test					
		Chi-Square	52.6656		
		DF	4		
		Pr > Chi-Square	<.0001		

Figure 65.3 through Figure 65.5 display the analyses produced by the MEDIAN, VW, and SAVAGE options. For each score type, PROC NPAR1WAY provides a summary of scores and the one-way ANOVA statistic, as previously described for Wilcoxon scores. Other score types available in PROC NPAR1WAY are Siegel-Tukey, Ansari-Bradley, Klotz, and Mood, which can be used to test for scale differences. Conover scores can be used to test for differences in both location and scale. Additionally, you can specify the SCORES=DATA option, which uses the input data as scores. This option gives you the flexibility to construct any scores for your data with the DATA step and then analyze these scores with PROC NPAR1WAY.

Figure 65.3 Median Score Analysis

Median Scores (Number of Points Above Median) for Variable Gain Classified by Variable Dose					
Dose	N	Sum of Scores	Expected Under H0	Std Dev Under H0	Mean Score
0	16	16.0	7.880597	1.757902	1.00
0.04	11	11.0	5.417910	1.527355	1.00
0.07	12	6.0	5.910448	1.580963	0.50
0.1	17	0.0	8.373134	1.794152	0.00
0.13	11	0.0	5.417910	1.527355	0.00
Average scores were used for ties.					
Median One-Way Analysis					
		Chi-Square	54.1765		
		DF	4		
		Pr > Chi-Square	<.0001		

Figure 65.4 Van der Waerden (Normal) Score Analysis

Van der Waerden Scores (Normal) for Variable Gain Classified by Variable Dose					
Dose	N	Sum of Scores	Expected Under H0	Std Dev Under H0	Mean Score
0	16	16.116474	0.0	3.325957	1.007280

		Pr > Chi-Square	<.0001		

The tables in Figure 65.6 display the empirical distribution function statistics, comparing the distribution of Gain for the different levels of Dose. These tables are produced by the EDF option, and they include Kolmogorov-Smirnov statistics and Cramér-von Mises statistics.

Figure 65.6 Empirical Distribution Function Analysis

Kolmogorov-Smirnov Test for Variable Gain Classified by Variable Dose

PROC NPAR1WAY uses ODS Graphics to create graphs as part of its output. The following statements produce a box plot of Wilcoxon scores for Gain classified by Dose. ODS Graphics must be enabled before producing graphs.

```
ods graphics on;
proc npar1way data=Gossypol plots(only)=wilcoxonboxplot;
  class Dose;
  var Gain;
run;
ods graphics off;
```

Figure 65.7 displays the box plot of Wilcoxon scores. This graph corresponds to the Wilcoxon scores analysis shown in Figure 65.2. To remove the p -value from the box plot display, you can specify the NOSTATS plot option in parentheses following the WILCOXONBOXPLOT option.

Box plots are available for all PROC NPAR1WAY score types except median scores, which are displayed in a stacked bar chart. If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC NPAR1WAY produces all plots that are associated with the analyses that you request.

Figure 65.7 Box Plot of Wilcoxon Scores

In the preceding example, the CLASS variable Dose has five levels, and the analyses examine possible differences among these five levels (samples). The following statements invoke the NPAR1WAY procedure to perform a nonparametric analysis of the two lowest levels of Dose:

```
proc npar1way data=Gossypol;
  where Dose <= .04;
  class Dose;
  var Gain;
run;
```

The tables in the following figures show the results of this two-sample analysis. The tables in [Figure 65.8](#) are produced by the ANOVA option.

Figure 65.8 Analysis of Variance for Two-Sample Data

The NPAR1WAY Procedure					
Analysis of Variance for Variable Gain					
Classified by Variable Dose					
Dose		N	Mean		
0		16	222.187500		
0.04		11	217.363636		
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Among	1	151.683712	151.683712	0.5587	0.4617
Within	25	6786.982955	271.479318		
Average scores were used for ties.					

[Figure 65.9](#) displays the output produced by the WILCOXON option. PROC NPAR1WAY provides a summary of the Wilcoxon scores for the analysis variable Gain for each of the two class levels. Since there are only two levels, PROC NPAR1WAY displays the two-sample test, based on the simple linear rank statistic with Wilcoxon scores. The normal approximation includes a continuity correction. To remove the continuity correction, you can specify the CORRECT=NO option. PROC NPAR1WAY also gives a *t* approximation for the Wilcoxon two-sample test. Like the multisample analysis, PROC NPAR1WAY computes a one-way ANOVA statistic, which for Wilcoxon scores is known as the Kruskal-Wallis test. All these *p*-values show no difference in Gain for the two Dose levels at the 0.05 level of significance.

[Figure 65.10](#) through [Figure 65.12](#) display the two-sample analyses produced by the MEDIAN, VW, and SAVAGE options.

Figure 65.9 Wilcoxon Two-Sample Analysis

Wilcoxon Scores (Rank Sums) for Variable Gain Classified by Variable Dose					
Dose	N	Sum of Scores	Expected Under H0	Std Dev Under H0	Mean Score
0	16	253.50	224.0	20.221565	15.843750
0.04	11	124.50	154.0	20.221565	11.318182

Average scores were used for ties.

Wilcoxon Two-Sample Test

The tables in [Figure 65.13](#) display the empirical distribution function statistics, comparing the distribution of Gain for the two levels of Dose. The p -value for the Kolmogorov-Smirnov two-sample test is 0.6199, which indicates no rejection of the null hypothesis that the Gain distributions are identical for the two levels of Dose.

Syntax: NPAR1WAY Procedure

The following statements are available in the NPAR1WAY procedure:

```
PROC NPAR1WAY < options > ;
  BY variables ;
  CLASS variable ;
  EXACT statistic-options < / computation-options > ;
  FREQ variable ;
  OUTPUT < OUT=SAS-data-set > < options > ;
  VAR variables ;
```

The **PROC NPAR1WAY** statement invokes the NPAR1WAY procedure. The **PROC NPAR1WAY** and **CLASS** statements are required. Table 65.1 summarizes the statements available in the NPAR1WAY procedure.

The rest of this section gives detailed syntax information for the **BY**, **CLASS**, **EXACT**, **FREQ**, **OUTPUT**, and **VAR** statements in alphabetical order after the description of the **PROC NPAR1WAY** statement.

Table 65.1 Summary of PROC NPAR1WAY Statements

Statement	Description
BY	Provides separate analyses for each BY group
CLASS	Identifies the classification variable
EXACT	Requests exact tests
FREQ	Identifies a frequency variable
OUTPUT	Requests an output data set
VAR	Identifies analysis variables

PROC NPAR1WAY Statement

```
PROC NPAR1WAY < options > ;
```

The **PROC NPAR1WAY** statement invokes the NPAR1WAY procedure. Optionally, it identifies the input data set and requests analyses. By default, the procedure uses the most recently created SAS data set and omits missing values from the analysis. If you do not specify any analysis *options*, **PROC NPAR1WAY** performs an analysis of variance (**ANOVA** option), tests for location differences (**WILCOXON**, **MEDIAN**, **SAVAGE**, and **VW** options), and empirical distribution function tests (**EDF** option).

Table 65.2 summarizes the *options* available in the **PROC NPAR1WAY** statement. Descriptions of the *options* follow in alphabetical order.

Table 65.2 PROC NPAR1WAY Statement Options

Option	Description
Input Data Set	
DATA=	Names the input SAS data set
Missing Values	
MISSING	Treats missing CLASS values as a valid class
Analyses	
AB	Requests analysis of Ansari-Bradley scores
ANOVA	Requests standard analysis of variance
CONOVER	Requests analysis of Conover scores
D	Requests one-sided Kolmogorov-Smirnov statistics
DSCF	Requests pairwise multiple comparison analysis
EDF	Requests empirical distribution function statistics
FP	Requests the Fligner-Policello test
HL	Requests Hodges-Lehmann estimation for two-sample data
KLOTZ	Requests analysis of Klotz scores
MEDIAN	Requests analysis of median scores
MOOD	Requests analysis of Mood scores
SAVAGE	Requests analysis of Savage scores
SCORES=DATA	Requests analysis of input data scores
ST	Requests analysis of Siegel-Tukey scores
VW NORMAL	Requests analysis of Van der Waerden (normal) scores
WILCOXON	Requests analysis of Wilcoxon scores
Analysis Details	
ADJUST	Requests median adjustment for scale analyses
ALPHA=	Specifies the confidence level for Hodges-Lehmann estimation
CORRECT=NO	Suppresses the continuity correction for Wilcoxon and Siegel-Tukey two-sample tests
Displayed Output	
NOPRINT	Suppresses the display of all output
Plots	
PLOTS=	Requests plots from ODS Graphics

You can specify the following *options* in the PROC NPAR1WAY statement.

AB < (ADJUST) >

requests an analysis of Ansari-Bradley scores. See the section “[Ansari-Bradley Scores](#)” on page 5472 for more information. The ADJUST option subtracts class medians from the input observations before performing the analysis.

ADJUST

adjusts for location differences among classes before performing tests for scale differences. The ADJUST option applies to the following analyses: Ansari-Bradley ([AB](#)), Klotz ([KLOTZ](#)), Mood ([MOOD](#)), and Siegel-Tukey ([ST](#)). If you specify the ADJUST option, PROC NPAR1WAY subtracts the corresponding class median from each observation before scoring the data and performing the scale tests that you request.

You can also request adjustment for an individual scale test by specifying ADJUST in parentheses after the scale test option; for example, you can specify [ST\(ADJUST\)](#) to adjust by class medians before performing the Siegel-Tukey test.

ALPHA= α

specifies the level of the confidence limits for location shift, which you request with the [HL](#) option. The value of α must be between 0 and 1, and the default is 0.05. A confidence level of α produces $100(1 - \alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits for the Hodges-Lehmann estimate.

ANOVA

requests a standard analysis of variance on the raw data.

CONOVER

requests an analysis of Conover scores. See the section “[Conover Scores](#)” on page 5472 for more information.

CORRECT=NO

suppresses the continuity correction for the Wilcoxon two-sample test and the Siegel-Tukey two-sample test. See the section “[Continuity Correction](#)” on page 5469 for more information.

D

requests the one-sided Kolmogorov-Smirnov $D+$ and $D-$ statistics and their asymptotic p -values, in addition to the two-sided D statistic produced by the [EDF](#) option for two-sample data. The D option invokes the [EDF](#) option. The statistics $D+$ and $D-$ are provided by default if you request exact Kolmogorov-Smirnov statistics with the KS option in the [EXACT](#) statement for two-sample data. See the section “[Tests Based on the Empirical Distribution Function](#)” on page 5477 for details about Kolmogorov-Smirnov statistics.

DATA=SAS-data-set

names the SAS data set to be analyzed by PROC NPAR1WAY. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

DSCF

requests the Dwass, Steel, Critchlow-Fligner multiple comparison procedure, which is based on pairwise two-sample rankings. This procedure is available for multisample data, where the number of [CLASS](#) variable levels is greater than 2. See the section “[Multiple Comparisons Based on Pairwise Rankings](#)” on page 5476 for more information.

EDF

requests statistics based on the empirical distribution function. These include the Kolmogorov-Smirnov and Cramér-von Mises tests and, if there are only two classification levels, the Kuiper test. See the section “[Tests Based on the Empirical Distribution Function](#)” on page 5477 for more information.

The EDF option produces the Kolmogorov-Smirnov D statistic for two-sample data. You can request the one-sided $D+$ and $D-$ statistics for two-sample data with the **D** option.

FP < (REFCLASS = class-number | 'class-value') >

requests the Fligner-Policello test for two-sample data. See the section “[Fligner-Policello Test](#)” on page 5475 for more information.

The REFCLASS= option specifies which of the two **CLASS** variable levels (samples) to use as the reference class X for the difference between class placement sums, $P_Y - P_X$. REFCLASS=1 refers to the first class that is listed in the “Fligner-Policello Placements” table, and REFCLASS=2 refers to the second class listed. The table displays class levels in the order in which they appear in the input data set. REFCLASS=*class-value* identifies the reference class by the formatted value of the **CLASS** variable. By default, the reference class is the second class listed in the “Fligner-Policello Placements” table (REFCLASS=2).

HL < (REFCLASS = class-number | 'class-value') >

requests Hodges-Lehmann estimation of the location shift for two-sample data. The HL option provides asymptotic confidence limits for the location shift. These are sometimes known as Moses confidence limits. See the section “[Hodges-Lehmann Estimation of Location Shift](#)” on page 5473 for details. You can specify the level of the confidence limits by using the **ALPHA=** option. The default of ALPHA=0.5 produces 95% confidence limits for the location shift.

The REFCLASS= option specifies which of the two **CLASS** variable levels (samples) to use as the reference class X for the location shift, $Y - X$. REFCLASS=1 refers to the first class that is listed in the “Wilcoxon Scores” table, and REFCLASS=2 refers to the second class listed. The table displays class levels in the order in which they appear in the input data set. REFCLASS=*class-value* identifies the reference class by the formatted value of the **CLASS** variable.

By default, PROC NPAR1WAY uses the larger of the two classes as the reference class X to compute the Hodges-Lehmann location shift, $Y - X$. If both class have the same number of observations, PROC NPAR1WAY uses the class that appears second in the input data set as the reference class.

KLOTZ < (ADJUST) >

requests an analysis of Klotz scores. See the section “[Klotz Scores](#)” on page 5472 for more information. The ADJUST option subtracts class medians from the input observations before performing the analysis.

MEDIAN

requests an analysis of median scores. When there are two classification levels, this option produces the two-sample median test. When there are more than two samples, this option produces the multi-sample median test, which is also known as the Brown-Mood test. See the section “[Median Scores](#)” on page 5471 for more information.

MISSING

treats missing values of the **CLASS** variable as a valid class level.

MOOD < (ADJUST) >

requests an analysis of Mood scores. See the section “[Mood Scores](#)” on page 5472 for more information. The ADJUST option subtracts class medians from the input observations before performing the analysis.

NOPRINT

suppresses the display of all output. You can use the NOPRINT option when you only want to create an output data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, “[Using the Output Delivery System.](#)”

PLOTS < (*global-plot-options*) > < = *plot-request* < (*plot-option*) > >

PLOTS < (*global-plot-options*) > < = (*plot-request* < (*plot-option*) > < ... *plot-request* < (*plot-option*) > >) >

controls the plots that are produced through ODS Graphics. *Plot-requests* specify the plots to produce, and *plot-options* control the appearance and content of the plots. You can specify *plot-options* in parentheses after a *plot-request*. A *global-plot-option* applies to all plots for which it is available, unless it is altered by a specific *plot-option*. You can specify *global-plot-options* in parentheses after the PLOTS option.

When you specify only one *plot-request*, you can omit the parentheses around the request. For example:

```
plots=all
plots=wilcoxonboxplot
plots=(wilcoxonboxplot edfplot)
plots(only)=(medianplot normalboxplot)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc npar1way plots=wilcoxonboxplot;
  variable response;
  class treatment;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

If ODS Graphics is enabled but you do not specify the PLOTS= option, PROC NPAR1WAY produces all plots that are associated with the analyses that you request. If you request a plot with the PLOTS= option but do not request the corresponding analysis, PROC NPAR1WAY automatically invokes that analysis. For example, if you specify PLOTS=CONOVERBOXPLOT but do not also specify the CONOVER option in the PROC NPAR1WAY statement, PROC NPAR1WAY produces the Conover scores analysis in addition to the box plot.

You can suppress default plots and request specific plots by using the **PLOTS(ONLY)=** option; PLOTS(ONLY)=(*plot-requests*) produces only the plots that are specified as *plot-requests*. You can suppress all plots with the **PLOTS=NONE** option. The PLOTS= option has no effect when you specify the **NOPRINT** option.

PROC NPAR1WAY provides box plots of scored data, median plots, and empirical distribution plots. See [Figure 65.7](#), [Output 65.1.2](#), [Output 65.1.4](#), and [Output 65.2.2](#) for examples of plots that PROC NPAR1WAY produces. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS.](#)”

Global Plot Options

A *Global-plot-option* applies to all plots for which the option is available unless it is altered by a specific *plot-option*. You can specify the following *global-plot-options* in parentheses after the PLOTS option. You cannot specify both STATS and NOSTATS as *global-plot-options* in the same statement.

NOSTATS

suppresses the p -values that are displayed by default in the plots.

ONLY

suppresses the default plots and requests only the plots that are specified as *plot-requests*.

STATS

displays p -values in the plots. This is the default.

Plot Requests

The following *plot-requests* are available with the PLOTS= option.

ABBOXPLOT | AB

requests a box plot of Ansari-Bradley scores. This plot is associated with the Ansari-Bradley analysis, which you request by specifying the [AB](#) option.

ALL

requests all plots that are associated with the specified analyses. This is the default if you do not specify the [ONLY](#) *global-plot-option*.

ANOVABOXPLOT | ANOVA

requests a box plot of the raw data. This plot is associated with the analysis of variance based on the raw data, which you request by specifying the [ANOVA](#) option.

CONOVERBOXPLOT | CONOVER

requests a box plot of Conover scores. This plot is associated with the Conover analysis, which you request by specifying the [CONOVER](#) option.

DATAScoresBOXPLOT | DATAScores

requests a box plot of raw data scores. This plot is associated with the analysis that uses input data as scores, which you request by specifying the [SCORES=DATA](#) option.

EDFPLOT | EDF

requests an empirical distribution plot. This plot is associated with the analyses based on the empirical distribution function, which you request by specifying the [EDF](#) option.

FPBOXPLOT | FP

requests a box plot of Fligner-Policello placements. This plot is associated with the Fligner-Policello analysis, which you request by specifying the [FP](#) option.

KLOTZBOXPLOT | KLOTZ

requests a box plot of Klotz scores. This plot is associated with the Klotz analysis, which you request by specifying the [KLOTZ](#) option.

MEDIANPLOT | MEDIAN

requests a stacked bar chart showing the frequencies above and below the overall median. This plot is associated with the median score analysis, which you request by specifying the **MEDIAN** option.

MOODBOXPLOT | MOOD

requests a box plot of Mood scores. This plot is associated with the Mood analysis, which you request by specifying the **MOOD** option.

NONE

suppresses all plots.

SAVAGEBOXPLOT | SAVAGE

requests a box plot of Savage scores. This plot is associated with the Savage analysis, which you request by specifying the **SAVAGE** option.

STBOXPLOT | ST

requests a box plot of Siegel-Tukey scores. This plot is associated with the Siegel-Tukey analysis, which you request by specifying the **ST** option.

VWBOXPLOT | VW**NORMALBOXPLOT | NORMAL**

requests a box plot of Van der Waerden (normal) scores. This plot is associated with the Van der Waerden analysis, which you request by specifying the **VW** or **NORMAL** option.

WILCOXONBOXPLOT | WILCOXON

requests a box plot of Wilcoxon scores. This plot is associated with the Wilcoxon analysis, which you request by specifying the **WILCOXON** option.

Plot Options

The following *plot-options* are available for any *plot-request*. You cannot specify both **STATS** and **NOSTATS** as *plot-options* for the same plot. If you specify **NOSTATS** as a *global-plot-option*, specifying **STATS** as an individual *plot-option* overrides the *global-plot-option* for the individual plot and displays statistics in the plot.

NOSTATS

suppresses the *p*-values that are displayed in the plot by default.

STATS

displays *p*-values in the plot. This is the default.

SAVAGE

requests an analysis of Savage scores. See the section “[Savage Scores](#)” on page 5471 for more information.

SCORES=DATA

requests an analysis that uses input data as scores. This option gives you the flexibility to construct any scores for your data with the **DATA** step and then analyze these scores with PROC NPAR1WAY. See the section “[Scores for Linear Rank and One-Way ANOVA Tests](#)” on page 5470 for more information.

To produce the two-sample permutation test that is known as Pitman's test, provide raw (unscored) data in the input data set and specify the SCORES=DATA option in the **EXACT** statement. See the section “[Exact Tests](#)” on page 5479 for more information.

ST < (ADJUST) >

requests an analysis of Siegel-Tukey scores. See the section “[Siegel-Tukey Scores](#)” on page 5472 for more information. The ADJUST option subtracts class medians from the input observations before performing the analysis.

VW | NORMAL

requests an analysis of Van der Waerden (normal) scores. See the section “[Van der Waerden \(Normal\) Scores](#)” on page 5471 for more information.

WILCOXON

requests an analysis of Wilcoxon scores. When there are two classification levels (samples), this option produces the Wilcoxon rank-sum test. For any number of classification levels, this option produces the Kruskal-Wallis test. See the section “[Wilcoxon Scores](#)” on page 5471 for more information.

BY Statement

BY variables ;

You can specify a BY statement with PROC NPARIWAY to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the NPARIWAY procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable* ;

The CLASS statement, which is required, names one and only one classification variable. The variable can be character or numeric. The CLASS variable identifies groups (samples) in the data, and PROC NPAR1WAY provides analyses to examine differences among these groups. There can be two or more groups in the data.

EXACT Statement

EXACT *statistic-options* < / *computation-options* > ;

The EXACT statement requests exact tests and confidence limits for selected statistics. The *statistic-options* identify which statistics to compute, and the *computation-options* specify options for computing exact statistics. See the section “Exact Tests” on page 5479 for details.

NOTE: PROC NPAR1WAY computes exact tests by using fast and efficient algorithms that are superior to direct enumeration. Exact tests are appropriate when a data set is small, sparse, skewed, or heavily tied. For some large problems, computation of exact tests might require a large amount of time and memory. Consider using asymptotic tests for such problems. Alternatively, when asymptotic methods might not be sufficient for such large problems, consider using Monte Carlo estimation of exact *p*-values. You can request Monte Carlo estimation by specifying the **MC** *computation-option* in the EXACT statement. See the section “Computational Resources” on page 5481 for more information.

Statistic Options

The *statistic-options* specify which exact tests to compute. Table 65.3 lists the available *statistic-options* and the exact statistics that are computed. Descriptions of the *statistic-options* follow Table 65.3 in alphabetical order.

Exact *p*-values are available for all nonparametric tests of location and scale differences that are produced by PROC NPAR1WAY. These include tests based on the following scores: Wilcoxon, median, Van der Waerden (normal), Savage, Siegel-Tukey, Ansari-Bradley, Klotz, Mood, and Conover. Additionally, exact *p*-values are available for tests that use the raw input data as scores. The procedure computes exact *p*-values when the data are classified into two levels (two-sample tests) and when the data are classified into more than two levels (multisample tests). Two-sample tests are based on simple linear rank statistics. Multisample tests are based on one-way ANOVA statistics.

Exact *p*-values are also available for the two-sample Kolmogorov-Smirnov test. Exact confidence limits are available for the Hodges-Lehmann estimate of location shift.

If you list no *statistic-options* in the EXACT statement, then PROC NPAR1WAY computes all available exact *p*-values for those tests that you request in the PROC NPAR1WAY statement.

Table 65.3 EXACT Statement Statistic Options

Statistic Option	Exact Test
AB	Ansari-Bradley test
CONOVER	Conover test
HL	Hodges-Lehmann confidence limits
KLOTZ	Klotz test
KS EDF	Two-sample Kolmogorov-Smirnov test
MEDIAN	Median test
MOOD	Mood test
SAVAGE	Savage test
SCORES=DATA	Test with input data as scores
ST	Siegel-Tukey test
VW NORMAL	Van der Waerden (normal scores) test
WILCOXON	Wilcoxon test for two-sample data or Kruskal-Wallis test for multisample data

You can specify the following *statistic-options* in the EXACT statement.

AB

requests the exact Ansari-Bradley test. See the sections “[Ansari-Bradley Scores](#)” on page 5472 and “[Exact Tests](#)” on page 5479 for details. The **AB** option in the PROC NPAR1WAY statement provides Ansari-Bradley score analysis and asymptotic tests.

CONOVER

requests the exact Conover test. See the sections “[Conover Scores](#)” on page 5472 and “[Exact Tests](#)” on page 5479 for details. The **CONOVER** option in the PROC NPAR1WAY statement provides Conover score analysis and asymptotic tests.

HL

requests exact Hodges-Lehmann confidence limits for the location shift for two-sample data. See the section “[Hodges-Lehmann Estimation of Location Shift](#)” on page 5473 for details. The **HL** option in the PROC NPAR1WAY statement provides asymptotic Hodges-Lehmann confidence limits.

You can specify the level of the confidence limits by using the **ALPHA=** option in the PROC NPAR1WAY statement. The default of ALPHA=0.5 produces 95% confidence limits for the location shift.

KLOTZ

requests the exact Klotz test. See the sections “[Klotz Scores](#)” on page 5472 and “[Exact Tests](#)” on page 5479 for details. The **KLOTZ** option in the PROC NPAR1WAY statement provides Klotz score analysis and asymptotic tests.

KS | EDF

requests the exact Kolmogorov-Smirnov two-sample test. See the section “[Tests Based on the Empirical Distribution Function](#)” on page 5477 for details. The **EDF** option in the PROC NPAR1WAY statement provides the asymptotic Kolmogorov-Smirnov test and other statistics that are based on the empirical distribution function. The **D** option in the PROC NPAR1WAY statement provides the asymptotic one-sided Kolmogorov-Smirnov tests for two-sample data.

MEDIAN

requests the exact median test. See the sections “[Median Scores](#)” on page 5471 and “[Exact Tests](#)” on page 5479 for details. The **MEDIAN** option in the PROC NPAR1WAY statement provides median score analysis and asymptotic tests.

MOOD

requests the exact Mood test. See the sections “[Mood Scores](#)” on page 5472 and “[Exact Tests](#)” on page 5479 for details. The **MOOD** option in the PROC NPAR1WAY statement provides Mood score analysis and asymptotic tests.

SAVAGE

requests the exact Savage test. See the sections “[Savage Scores](#)” on page 5471 and “[Exact Tests](#)” on page 5479 for details. The **SAVAGE** option in the PROC NPAR1WAY statement provides Savage score analysis and asymptotic tests.

SCORES=DATA

requests the exact test that uses the input data as scores. For two-sample data, the test is based on the rank-sum statistic. For multisample data, the test is based on the one-way ANOVA statistic. See the sections “[Scores for Linear Rank and One-Way ANOVA Tests](#)” on page 5470 and “[Exact Tests](#)” on page 5479 for details. The **SCORES=DATA** option in the PROC NPAR1WAY statement provides analysis of the data scores and the corresponding asymptotic test.

ST

requests the exact Siegel-Tukey test. See the sections “[Siegel-Tukey Scores](#)” on page 5472 and “[Exact Tests](#)” on page 5479 for details. The **ST** option in the PROC NPAR1WAY statement provides analysis of Siegel-Tukey scores and asymptotic tests.

VW | NORMAL

requests the exact Van der Waerden (normal scores) test. See the sections “[Van der Waerden \(Normal\) Scores](#)” on page 5471 and “[Exact Tests](#)” on page 5479 for details. The **VW** option in the PROC NPAR1WAY statement provides analysis of Van der Waerden (normal) scores and asymptotic tests.

WILCOXON

requests the exact Wilcoxon test. When the data consist of two classification levels (samples), the exact test is based on the Wilcoxon rank-sum statistic. When the data consist of more than two levels (multisample data), the exact test is based on the one-way ANOVA statistic for Wilcoxon scores, which is the Kruskal-Wallis statistic. See the sections “[Wilcoxon Scores](#)” on page 5471 and “[Exact Tests](#)” on page 5479 for details. The **WILCOXON** option in the PROC NPAR1WAY statement provides analysis of Wilcoxon scores and the asymptotic Wilcoxon and Kruskal-Wallis tests.

Computation Options

Computation-options specify options for computing exact statistics. You can specify the following *computation-options* in the EXACT statement after a slash (/).

ALPHA= α

specifies the level of the confidence limits for Monte Carlo p -value estimates. The value of α must be between 0 and 1, and the default is 0.01. A confidence level of α produces $100(1 - \alpha)\%$ confidence limits. The default of ALPHA=0.01 produces 99% confidence limits for the Monte Carlo estimates.

The ALPHA= option invokes the **MC** option.

MAXTIME=*value*

specifies the maximum clock time (in seconds) that PROC NPAR1WAY can use to compute an exact p -value. If the procedure does not complete the computation within the specified time, the computation terminates. The value of MAXTIME= must be a positive number. The MAXTIME= option is valid for Monte Carlo estimation of exact p -values as well as direct exact p -value computation. See the section “[Computational Resources](#)” on page 5481 for more information.

MC

requests Monte Carlo estimation of exact p -values instead of direct exact p -value computation. Monte Carlo estimation can be useful for large problems that require a considerable amount of time and memory for exact computations but for which asymptotic approximations might not be sufficient. See the section “[Monte Carlo Estimation](#)” on page 5481 for more information.

The MC option is available for all EXACT *statistic-options* except the [HL](#) option, which produces exact Hodges-Lehmann confidence limits. The [ALPHA=](#), [N=](#), and [SEED=](#) options also invoke the MC option.

N=*n*

specifies the number of samples for Monte Carlo estimation. The value of n must be a positive integer, and the default is 10,000 samples. Larger values of n produce more precise estimates of exact p -values. Because larger values of n generate more samples, the computation time increases.

The N= option invokes the [MC](#) option.

POINT

requests exact point probabilities for the test statistics.

The POINT option is available for all EXACT statement *statistic-options* except the [HL](#) option, which produces exact Hodges-Lehmann confidence limits. The POINT option is not available with the [MC](#) option.

SEED=*number*

specifies the initial seed for random number generation for Monte Carlo estimation. The value of the SEED= option must be an integer. If you do not specify the SEED= option or if the SEED= value is negative or zero, PROC NPAR1WAY uses the time of day from the computer’s clock to obtain the initial seed.

The SEED= option invokes the [MC](#) option.

FREQ Statement

FREQ *variable* ;

The FREQ statement names a numeric variable that provides a frequency for each observation in the input data set. If you use a FREQ statement, PROC NPAR1WAY assumes that an observation occurs n times, where n is the value of the FREQ variable for the observation. The sum of the FREQ variable values represents the total number of observations, and the analysis is based on this expanded number of observations.

If the value of the FREQ variable is missing or is less than one, PROC NPAR1WAY does not use that observation in the analysis. If the value of the FREQ variable is not an integer, PROC NPAR1WAY uses only the integer portion as the frequency of the observation.

OUTPUT Statement

OUTPUT < **OUT**=*SAS-data-set* > < *output-options* > ;

The OUTPUT statement creates a SAS data set that contains statistics that PROC NPAR1WAY computes. Table 65.4 lists the statistics that can be stored in the output data set. You identify which statistics to include by specifying *output-options*.

The output data set contains one observation for each analysis variable that you name in the VAR statement. If you use a BY statement, the output data set contains an observation or set of observations for each BY group. See the section “Contents of the Output Data Set” on page 5483 for more information.

As an alternative to the OUTPUT statement, you can use the Output Delivery System (ODS) to store statistics that PROC NPAR1WAY computes. ODS can create a SAS data set from any table that PROC NPAR1WAY produces. For more information, see the section “ODS Table Names” on page 5493 and Chapter 20, “Using the Output Delivery System.”

You can specify the following *options* in the OUTPUT statement:

OUT=*SAS-data-set*

names the output data set. When you use an OUTPUT statement but do not specify the OUT= option, PROC NPAR1WAY creates a data set and names it by using the *DATA**n* convention.

output-options

specifies the statistics to include in the output data set. Table 65.4 lists the *output-options* that are available in the OUTPUT statement. Descriptions of the *output-options* follow the table in alphabetical order.

When you specify an *output-option*, the output data set includes the test statistic and associated values from the analysis that you specify. The associated values might include standardized statistics, one- and two-sided *p*-values, exact *p*-values, degrees of freedom, and confidence limits. See the section “Contents of the Output Data Set” on page 5483 for a list of output data set variables that each *output-option* produces.

If you do not specify any *output-options* in the OUTPUT statement, the output data set includes all available statistics from the analyses that you request in the PROC NPAR1WAY statement. If you request a statistic in the OUTPUT statement but do not request the corresponding analysis in the PROC NPAR1WAY statement, PROC NPAR1WAY performs the corresponding analysis.

Table 65.4 OUTPUT Statement Output Options

Output Option	Output Data Set Statistics
AB	Ansari-Bradley test
ANOVA	Analysis of variance
CONOVER	Conover test
EDF	Kolmogorov-Smirnov test, Cramér-von Mises test, and Kuiper test for two-sample data
FP	Fligner-Policello test
HL	Hodges-Lehmann estimates
KLOTZ	Klotz test
MEDIAN	Median test
MOOD	Mood test
SAVAGE	Savage test
SCORES=DATA	Test with input data as scores
ST	Siegel-Tukey test
VW NORMAL	Van der Waerden (normal scores) test
WILCOXON	Wilcoxon test for two-sample data and Kruskal-Wallis test

You can specify the following *output-options* in the OUTPUT statement.

AB

includes statistics from the Ansari-Bradley analysis in the output data set. The **AB** option in the PROC NPAR1WAY statement requests analysis of Ansari-Bradley scores. See the section “[Ansari-Bradley Scores](#)” on page 5472 for more information.

ANOVA

includes analysis of variance statistics in the output data set. The **ANOVA** option in the PROC NPAR1WAY statement requests a standard analysis of variance for the raw data.

CONOVER

includes statistics from the Conover analysis in the output data set. The **CONOVER** option in the PROC NPAR1WAY statement requests analysis of Conover scores. See the section “[Conover Scores](#)” on page 5472 for more information.

EDF

includes empirical distribution function statistics in the output data set. The **EDF** option in the PROC NPAR1WAY statement requests computation of these statistics, which include the Kolmogorov-Smirnov test, the Cramér-von Mises test, and the Kuiper test for two sample-data. See the section “[Tests Based on the Empirical Distribution Function](#)” on page 5477 for more information.

FP

includes the Fligner-Policello test in the output data set. The **FP** option in the PROC NPAR1WAY statement requests the Fligner-Policello test, which is available for two-sample data. See the section “[Fligner-Policello Test](#)” on page 5475 for more information.

HL

includes the Hodges-Lehmann estimate and confidence limits in the output data set. The **HL** option in the PROC NPAR1WAY statement requests Hodges-Lehmann estimation, which is available for two-sample data. See the section “[Hodges-Lehmann Estimation of Location Shift](#)” on page 5473 for more information.

KLOTZ

includes statistics from the Klotz analysis in the output data set. The **KLOTZ** option in the PROC NPAR1WAY statement requests analysis of Klotz scores. See the section “[Klotz Scores](#)” on page 5472 for more information.

MEDIAN

includes statistics from the median analysis in the output data set. The **MEDIAN** option in the PROC NPAR1WAY statement requests analysis of median scores. See the section “[Median Scores](#)” on page 5471 for more information.

MOOD

includes statistics from the Mood analysis in the output data set. The **MOOD** option in the PROC NPAR1WAY statement requests analysis of Mood scores. See the section “[Mood Scores](#)” on page 5472 for more information.

SAVAGE

includes statistics from the Savage analysis in the output data set. The **SAVAGE** option in the PROC NPAR1WAY statement requests analysis of SAVAGE scores. See the section “[Savage Scores](#)” on page 5471 for more information.

SCORES=DATA

includes statistics from the analysis of data scores in the output data set. The **SCORES=DATA** option in the PROC NPAR1WAY statement requests an analysis that uses the raw input data as scores.

ST

includes statistics from the Siegel-Tukey analysis in the output data set. The **ST** option in the PROC NPAR1WAY statement requests analysis of Siegel-Tukey scores. See the section “[Siegel-Tukey Scores](#)” on page 5472 for more information.

VW | NORMAL

includes statistics from the Van der Waerden (normal scores) analysis in the output data set. The **VW** option in the PROC NPAR1WAY statement requests analysis of Van der Waerden scores. See the section “[Van der Waerden \(Normal\) Scores](#)” on page 5471 for more information.

WILCOXON

includes statistics from the Wilcoxon analysis in the output data set. The **WILCOXON** option in the PROC NPAR1WAY statement requests analysis of Wilcoxon scores. For two-sample data, this analysis includes the Wilcoxon rank-sum test. For all data (two-sample and multisample), the analysis includes the Kruskal-Wallis test. See the section “[Wilcoxon Scores](#)” on page 5471 for more information.

VAR Statement

VAR *variables* ;

The VAR statement names the response (dependent) variables to be included in the analysis. These variables must be numeric. If you omit the VAR statement, the procedure includes all numeric variables in the data set except for the **CLASS** variable, the **FREQ** variable, and the **BY** variables.

Details: NPAR1WAY Procedure

Missing Values

If an observation has a missing value for a response (**VAR**) variable, PROC NPAR1WAY excludes that observation from the analysis. Any observation with a missing or nonpositive value for the **FREQ** variable is also excluded from the analysis.

By default, PROC NPAR1WAY also excludes observations with missing values of the **CLASS** variable. If you specify the **MISSING** option, PROC NPAR1WAY treats missing values of the **CLASS** variable as a valid class level and includes these observations in the analysis.

PROC NPAR1WAY treats missing **BY** variable values like any other **BY** variable value. The missing values form a separate, valid **BY** group.

Tied Values

Tied values occur when two or more observations are equal, whether the observations occur in the same sample or in different samples. In theory, nonparametric tests were developed for continuous distributions where the probability of a tie is zero. In practice, however, ties often occur. PROC NPAR1WAY uses the same method to handle ties for all score types. The procedure computes the scores as if there were no ties, averages the scores for tied observations, and assigns this average score to each observation with the same value.

When there are tied values, PROC NPAR1WAY first sorts the observations in ascending order and assigns ranks as if there were no ties. Then the procedure computes the scores based on these ranks by using the formula for the specified score type. The procedure averages the scores for tied observations and assigns this average score to each of the tied observations. Thus, all equal data values have the same score value. PROC NPAR1WAY then computes the test statistic from these scores.

Note that the asymptotic tests might be less accurate when the distribution of the data is heavily tied. For such data, it might be appropriate to use the exact tests provided by PROC NPAR1WAY as described in the section “**Exact Tests**” on page 5479.

When computing empirical distribution function statistics for data with ties, PROC NPAR1WAY uses the formulas given in the section “**Tests Based on the Empirical Distribution Function**” on page 5477. No special handling of ties is necessary.

PROC NPAR1WAY bases its computations on the internal numeric values of the analysis variables; the procedure does not format or round these values before analysis. When values differ in their internal representation, even slightly, PROC NPAR1WAY does not treat them as tied values. If this is a concern for your data, then round the analysis variables by an appropriate amount before invoking PROC NPAR1WAY. For information about the ROUND function, see the discussion in *SAS Language Reference: Dictionary*.

Statistical Computations

Simple Linear Rank Tests for Two-Sample Data

Statistics of the form

$$S = \sum_{j=1}^n c_j a(R_j)$$

are called *simple linear rank statistics*, where

R_j is the rank of observation j

$a(R_j)$ is the score based on the rank of observation j

c_j is an indicator variable denoting the class to which the j th observation belongs

n is the total number of observations

For two-sample data (where the observations are classified into two levels), PROC NPAR1WAY calculates simple linear rank statistics for the scores that you specify. The section “[Scores for Linear Rank and One-Way ANOVA Tests](#)” on page 5470 describes the available scores, which you can use to test for differences in location and differences in scale.

To compute the linear rank statistic S , PROC NPAR1WAY sums the scores of the observations in the smaller of the two samples. If both samples have the same number of observations, PROC NPAR1WAY sums those scores for the sample that appears first in the input data set.

For each score that you specify, PROC NPAR1WAY computes an asymptotic test of the null hypothesis of no difference between the two classification levels. Exact tests are also available for these two-sample linear rank statistics. PROC NPAR1WAY computes exact tests for each score type that you specify in the [EXACT](#) statement. See the section “[Exact Tests](#)” on page 5479 for details.

To compute an asymptotic test for a linear rank sum statistic, PROC NPAR1WAY uses a standardized test statistic z , which has an asymptotic standard normal distribution under the null hypothesis. The standardized test statistic is computed as

$$z = (S - E_0(S)) / \sqrt{\text{Var}_0(S)}$$

where $E_0(S)$ is the expected value of S under the null hypothesis, and $\text{Var}_0(S)$ is the variance under the null hypothesis. As shown in Randles and Wolfe (1979),

$$E_0(S) = \frac{n_1}{n} \sum_{j=1}^n a(R_j)$$

where n_1 is the number of observations in the first (smaller) class level (sample), n_2 is the number of observations in the other class level, and

$$\text{Var}_0(S) = \frac{n_1 n_2}{n(n-1)} \sum_{j=1}^n (a(R_j) - \bar{a})^2$$

where \bar{a} is the average score,

$$\bar{a} = \frac{1}{n} \sum_{j=1}^n a(R_j)$$

Definition of p -Values

PROC NPAR1WAY computes one-sided and two-sided asymptotic p -values for each two-sample linear rank test. When the test statistic z is greater than its null hypothesis expected value of zero, PROC NPAR1WAY computes the right-sided p -value, which is the probability of a larger value of the statistic occurring under the null hypothesis. When the test statistic is less than or equal to zero, PROC NPAR1WAY computes the left-sided p -value, which is the probability of a smaller value of the statistic occurring under the null hypothesis. The one-sided p -value $P_1(z)$ can be expressed as

$$P_1(z) = \begin{cases} \text{Prob}(Z > z) & \text{if } z > 0 \\ \text{Prob}(Z < z) & \text{if } z \leq 0 \end{cases}$$

where Z has a standard normal distribution. The two-sided p -value $P_2(z)$ is computed as

$$P_2(z) = \text{Prob}(|Z| > |z|)$$

Continuity Correction

PROC NPAR1WAY uses a continuity correction for the asymptotic two-sample Wilcoxon and Siegel-Tukey tests by default. You can remove the continuity correction by specifying the **CORRECT=NO** option. PROC NPAR1WAY incorporates the continuity correction when computing the standardized test statistic z by subtracting 0.5 from the numerator ($S - E_0(S)$) if it is greater than zero. If the numerator is less than zero, PROC NPAR1WAY adds 0.5. Some sources recommend a continuity correction for nonparametric tests that use a continuous distribution to approximate a discrete distribution. (See Sheskin 1997.)

If you specify **CORRECT=NO**, PROC NPAR1WAY does not use a continuity correction for any test.

One-Way ANOVA Tests

PROC NPAR1WAY computes a one-way ANOVA test for each score type that you specify. Under the null hypothesis of no difference among class levels (samples), this test statistic has an asymptotic chi-square distribution with $r - 1$ degrees of freedom, where r is the number of class levels. For Wilcoxon scores, this test is known as the Kruskal-Wallis test.

Exact one-way ANOVA tests are also available for multisample data (where the data are classified into more than two levels). For two-sample data, exact simple linear rank tests are available. PROC NPAR1WAY computes exact tests for each score type that you specify in the **EXACT** statement. See the section “[Exact Tests](#)” on page 5479 for details.

PROC NPAR1WAY computes the one-way ANOVA test statistic as

$$C = \left(\sum_{i=1}^r (T_i - E_0(T_i))^2 / n_i \right) / S^2$$

where T_i is the total of scores for class level i , $E_0(T_i)$ is the expected total for level i under the null hypothesis of no difference among levels, n_i is the number of observations in level i , and S^2 is the sample variance of the scores. The total of scores for class level i is given by

$$T_i = \sum_{j=1}^n c_{ij} a(R_j)$$

where $a(R_j)$ is the score for observation j , and c_{ij} indicates whether observation j is in level i . The expected total of scores for class level i under the null hypothesis is equal to

$$E_0(T_i) = \frac{n_i}{n} \sum_{j=1}^n a(R_j)$$

The sample variance of the scores is computed as

$$S^2 = \frac{1}{(n-1)} \sum_{j=1}^n (a(R_j) - \bar{a})^2$$

where \bar{a} is the average score,

$$\bar{a} = \frac{1}{n} \sum_{j=1}^n a(R_j)$$

Scores for Linear Rank and One-Way ANOVA Tests

For each score type that you specify, PROC NPAR1WAY computes a one-way ANOVA statistic and also a linear rank statistic for two-sample data. The following score types are used primarily to test for differences in location: Wilcoxon, median, Van der Waerden (normal), and Savage. The following scores types are used to test for scale differences: Siegel-Tukey, Ansari-Bradley, Klotz, and Mood. Conover scores can be used to test for differences in both location and scale. This section gives formulas for the score types available in PROC NPAR1WAY. For further information about the formulas and the applicability of each score, see Randles and Wolfe (1979); Gibbons and Chakraborti (2010); Conover (1999); Hollander and Wolfe (1999).

In addition to the score types described in this section, you can specify the **SCORES=DATA** option to use the input data observations as scores. This enables you to produce a wide variety of tests. You can construct any scores by using the DATA step, and then you can use PROC NPAR1WAY to compute the corresponding linear rank and one-way ANOVA tests for these scores. You can also analyze raw (unscored) data with the **SCORES=DATA** option; for two-sample data, the corresponding exact test is a permutation test that is known as Pitman's test.

Wilcoxon Scores

Wilcoxon scores are the ranks of the observations, which can be written as

$$a(R_j) = R_j$$

where R_j is the rank of observation j , and $a(R_j)$ is the score of observation j .

Using Wilcoxon scores in the linear rank statistic for two-sample data produces the rank sum statistic of the Mann-Whitney-Wilcoxon test. Using Wilcoxon scores in the one-way ANOVA statistic produces the Kruskal-Wallis test. Wilcoxon scores are locally most powerful for location shifts of a logistic distribution.

When computing the asymptotic Wilcoxon two-sample test, PROC NPAR1WAY uses a continuity correction by default, as described in the section “[Continuity Correction](#)” on page 5469. If you specify the **CORRECT=NO** option in the PROC NPAR1WAY statement, the procedure does not use a continuity correction.

Median Scores

Median scores equal 1 for observations greater than the median, and 0 otherwise. In terms of the observation ranks, median scores are defined as

$$a(R_j) = \begin{cases} 1 & \text{if } R_j > (n+1)/2 \\ 0 & \text{if } R_j \leq (n+1)/2 \end{cases}$$

Using median scores in the linear rank statistic for two-sample data produces the two-sample median test. The one-way ANOVA statistic with median scores is equivalent to the Brown-Mood test. Median scores are particularly powerful for distributions that are symmetric and heavy-tailed.

Van der Waerden (Normal) Scores

Van der Waerden scores are the quantiles of a standard normal distribution and are also known as *quantile normal scores*. Van der Waerden scores are computed as

$$a(R_j) = \Phi^{-1} \left(\frac{R_j}{n+1} \right)$$

where Φ is the cumulative distribution function of a standard normal distribution. These scores are powerful for normal distributions.

Savage Scores

Savage scores are expected values of order statistics from the exponential distribution, with 1 subtracted to center the scores around 0. Savage scores are computed as

$$a(R_j) = \sum_{i=1}^{R_j} \left(\frac{1}{n-i+1} \right) - 1$$

Savage scores are powerful for comparing scale differences in exponential distributions or location shifts in extreme value distributions (Hajek 1969, p. 83).

Siegel-Tukey Scores

Siegel-Tukey scores are defined as

$$\begin{aligned} a(1) &= 1, & a(n) &= 2, & a(n-1) &= 3, & a(2) &= 4, \\ a(3) &= 5, & a(n-2) &= 6, & a(n-3) &= 7, & a(4) &= 8, \dots \end{aligned}$$

where the score values continue to increase in this pattern toward the middle ranks until all observations have been assigned a score.

When computing the asymptotic Siegel-Tukey two-sample test, PROC NPAR1WAY uses a continuity correction by default, as described in the section “[Continuity Correction](#)” on page 5469. If you specify the **CORRECT=NO** option in the PROC NPAR1WAY statement, the procedure does not use a continuity correction.

Ansari-Bradley Scores

Ansari-Bradley scores are similar to Siegel-Tukey scores, but Ansari-Bradley scoring assigns the same score value to corresponding extreme ranks. (Siegel-Tukey scores are a permutation of the ranks $1, 2, \dots, n$.) Ansari-Bradley scores are defined as

$$\begin{aligned} a(1) &= 1, & a(n) &= 1, \\ a(2) &= 2, & a(n-1) &= 2, \dots \end{aligned}$$

Equivalently, Ansari-Bradley scores are equal to

$$a(R_j) = \frac{n+1}{2} - \left| R_j - \frac{n+1}{2} \right|$$

Klotz Scores

Klotz scores are the squares of the Van der Waerden (normal) scores. Klotz scores are computed as

$$a(R_j) = \left(\Phi^{-1} \left(\frac{R_j}{n+1} \right) \right)^2$$

where Φ is the cumulative distribution function of a standard normal distribution.

Mood Scores

Mood scores are computed as the square of the difference between the observation rank and the average rank. Mood scores can be written as

$$a(R_j) = \left(R_j - \frac{n+1}{2} \right)^2$$

Conover Scores

Conover scores are based on the squared ranks of the absolute deviations from the sample means. For observation j the absolute deviation from the mean is computed as

$$U_j = |X_{j(i)} - \bar{X}_i|$$

where $X_{j(i)}$ is the value of observation j , observation j belongs to sample i , and \bar{X}_i is the mean of sample i . The values of U_j are ranked, and the Conover score for observation j is computed as

$$Score_j = (\text{Rank}(U_j))^2$$

Following Conover (1999), when there are ties among the values of U_j , PROC NPAR1WAY assigns the average rank to each of the tied observations. To compute the average rank, PROC NPAR1WAY ranks the U_j as if there were no ties, and then averages the ranks of the tied observations.

The Conover score test is also known as the squared ranks test for variances. See Conover (1999) for more information.

Hodges-Lehmann Estimation of Location Shift

If you specify the **HL** option, PROC NPAR1WAY computes the Hodges-Lehmann estimate of location shift for two-sample data. PROC NPAR1WAY also provides confidence limits for the location shift. These confidence limits are sometimes called Moses confidence limits. You can set the level of the confidence limits with the **ALPHA=** option. The default is **ALPHA=0.05**, which produces 95% confidence limits. Additionally, you can request exact confidence limits for the location shift by specifying the **HL** option in the **EXACT** statement.

The Hodges-Lehmann estimator of location shift is associated with the Wilcoxon linear rank statistic. See Hollander and Wolfe (1999) and Hodges and Lehmann (1983) for details.

PROC NPAR1WAY computes the Hodges-Lehmann estimate $\hat{\Delta}$ as the median of all paired differences between observations in the two samples (classes), which can be written as

$$\hat{\Delta} = \text{median} \left((Y_j - X_i) \text{ where } j = 1, 2, \dots, n_1; i = 1, 2, \dots, n_2 \right)$$

The Y_j are observations in class 1, the X_i are observations in class 2, and n_1 and n_2 denote the number of observations in class 1 and class 2, respectively.

By default, PROC NPAR1WAY uses the larger of the two classes as the reference class X (class 2). If both class have the same number of observations, PROC NPAR1WAY uses the class that appears second in the input data set as the reference class. You can specify the reference class by using the **HL(REFCLASS=)** option. **REFCLASS=1** refers to the first class that is listed in the “Wilcoxon Scores” table, and **REFCLASS=2** refers to the second class in the table. **REFCLASS=class-value** identifies the reference class by the formatted value of the **CLASS** variable.

Let m denote the total number of differences ($n_1 \times n_2$), and let $U^{(k)}$ denote the k th value of $(Y_j - X_i)$ among the ordered differences. When m is an odd number, then the median difference is the value with rank $(m + 1)/2$,

$$\hat{\Delta} = U^{(k)} \text{ where } k = (m + 1)/2$$

When m is an even number, the median difference is the average of the values with ranks $(m/2)$ and $((m/2) + 1)$,

$$\hat{\Delta} = (U^{(k)} + U^{(k+1)})/2 \text{ where } k = m/2$$

Following Hollander and Wolfe (1999), the asymptotic lower and upper confidence limits for the location shift are

$$\left(\Delta_L = U^{(C_\alpha)}, \Delta_U = U^{(m+1-C_\alpha)} \right)$$

where C_α is the largest integer less than or equal to C_α^* , which is computed as

$$C_\alpha^* = E_0(S) - z_{\alpha/2} \sqrt{\text{Var}_0(S)}$$

where $E_0(S)$ and $\text{Var}_0(S)$ are the expected value and variance, respectively, of the Wilcoxon statistic S under the null hypothesis (as described in the section “[Simple Linear Rank Tests for Two-Sample Data](#)” on page 5468), and $z_{\alpha/2}$ is the $100(1 - \alpha/2)$ percentile of the standard normal distribution. For Wilcoxon rank scores,

$$E_0(S) = n_1 n_2 / 2$$

When there are no tied values, $\text{Var}_0(S)$ for Wilcoxon scores equals

$$\text{Var}_0(S) = n_1 n_2 (n_1 + n_2 + 1) / 12$$

PROC NPAR1WAY displays the midpoint of the confidence interval (Δ_L, Δ_U) , which can also be used as an estimate of location shift. See Lehmann (1963) for details. Additionally, PROC NPAR1WAY provides an estimate of the asymptotic standard error of $\hat{\Delta}$ based on the length of the confidence interval, which is computed as

$$\text{se}(\hat{\Delta}) = (\Delta_U - \Delta_L) / (2 z_{\alpha/2})$$

Exact Confidence Limits

If you specify the HL option in the EXACT statement, PROC NPAR1WAY computes exact confidence limits for the location shift between the two samples. As for the asymptotic confidence limits, you can set the confidence level with the ALPHA= option. The default is ALPHA=0.05, which produces 95% confidence limits.

PROC NPAR1WAY computes exact confidence limits for the location shift as described in Randles and Wolfe (1979, p. 180). PROC NPAR1WAY first generates the exact conditional distribution of the Mann-Whitney U statistic, which equals the number of pairwise differences $(Y_i - X_j)$ that are positive, plus half the number of pairwise differences that are zero. The Mann-Whitney statistic is defined as

$$MW = \sum_{i=1}^{n_1} \sum_{j=i}^{n_2} \phi(Y_i - X_j)$$

where

$$\phi(Y_i, X_j) = \begin{cases} 1 & \text{if } Y_i > X_j \\ 1/2 & \text{if } Y_i = X_j \\ 0 & \text{otherwise} \end{cases}$$

From the exact conditional distribution of the Mann-Whitney statistic MW , PROC NPAR1WAY chooses $C_{L,\alpha}^*$ as the largest value such that $\text{Prob}(MW \geq C_{L,\alpha}^*) \geq \alpha/2$. Rounding $C_{L,\alpha}^*$ up to the nearest integer $C_{L,\alpha}$, the lower confidence limit equals the difference $(Y_i - X_j)$ that has a rank of $(n_1 n_2 - C_{L,\alpha} + 1)$.

To find the upper confidence limit, PROC NPAR1WAY chooses $C_{U,\alpha}^*$ as the smallest value such that $\text{Prob}(MW \leq C_{U,\alpha}^*) \geq \alpha/2$. Rounding $C_{U,\alpha}^*$ down to the nearest integer $C_{U,\alpha}$, the upper confidence limit equals the difference $(Y_i - X_j)$ that has a rank of $(n_1 n_2 - C_{U,\alpha})$.

Because this is a discrete problem, the confidence coefficient for these exact confidence limits is not exactly $(1 - \alpha)$ but is at least $(1 - \alpha)$. Thus, these confidence limits are conservative.

Fligner-Policello Test

If you specify the **FP** option, PROC NPAR1WAY computes the Fligner-Policello location test for two-sample data (Fligner and Policello 1981). The null hypothesis for the test is $H_0 : \theta_X = \theta_Y$, where θ_X and θ_Y are the population medians of the two classes. The Fligner-Policello test assumes that the distribution in each class is symmetric around the class median, but it does not require that the two class distributions have the same form or that the class variances be equal. See Hollander and Wolfe (1999) and Juneau (2007) for more information.

The Fligner-Policello test is based on placement scores (Orban and Wolfe 1979). The placement of an observation X_i from class X , $P(X_i)$, is defined as the number of observations in class Y that are less than X_i . If there are ties, the placement of X_i is adjusted by adding half the number of observations in class Y that are equal to X_i . The placement of an observation Y_j from class Y , $P(Y_j)$, is defined in the same way. The placements can be expressed as

$$P(X_i) = \sum_{j=1}^{n_y} (I(Y_j < X_i) + 0.5I(Y_j = X_i))$$

$$P(Y_j) = \sum_{i=1}^{n_x} (I(X_i < Y_j) + 0.5I(X_i = Y_j))$$

where $I(\cdot)$ is an indicator function and n_x and n_y denote the number of observations in class X and class Y , respectively.

The average placements for class X and class Y are computed as

$$\bar{P}_x = \left(\sum_{i=1}^{n_x} P(X_i) \right) / n_x$$

$$\bar{P}_y = \left(\sum_{j=1}^{n_y} P(Y_j) \right) / n_y$$

The Fligner-Policello test statistic is computed as

$$z = \left(\sum_{j=1}^{n_y} P(Y_j) - \sum_{i=1}^{n_x} P(X_i) \right) / \left(2\sqrt{V_x + V_y + \bar{P}_x \bar{P}_y} \right)$$

where

$$V_x = \sum_{i=1}^{n_x} (P(X_i) - \bar{P}_x)^2$$

$$V_y = \sum_{j=1}^{n_y} (P(Y_j) - \bar{P}_y)^2$$

and the standard deviation of the placements is $\sqrt{V_x/(n_x - 1)}$ for class X and $\sqrt{V_y/(n_y - 1)}$ for class Y .

Under the null hypothesis, the Fligner-Policello statistic has an asymptotic standard normal distribution. PROC NPAR1WAY provides one- and two-sided asymptotic p -values for the Fligner-Policello test. For the one-sided test, PROC NPAR1WAY displays the right-sided p -value when the test statistic z is greater than its null hypothesis expected value of zero. PROC NPAR1WAY displays the left-sided p -value when the test statistic z is less than or equal to zero. The one-sided p -value $P_1(z)$ can be expressed as

$$P_1(z) = \begin{cases} \text{Prob}(Z > z) & \text{if } z > 0 \\ \text{Prob}(Z < z) & \text{if } z \leq 0 \end{cases}$$

where Z has a standard normal distribution. The two-sided p -value $P_2(z)$ is computed as $\text{Prob}(|Z| > |z|)$.

When you specify the FP option, PROC NPAR1WAY displays a “Fligner-Policello Placements” table and a “Fligner-Policello Test” table. The “Fligner-Policello Placements” table contains the following information for each of the two classes: number of observations, sum of the placements, average placement, and standard deviation of the placements. The “Fligner-Policello Test” table contains the test statistic z and the corresponding one- and two-sided p -values. This table also displays the difference between the class placement sums, which is the numerator of the test statistic. When ODS Graphics is enabled and you specify the FP or PLOTS=FPBOXPLOT option, PROC NPAR1WAY provides a box plot of the Fligner-Policello placements.

PROC NPAR1WAY computes the Fligner-Policello difference (the numerator of the test statistic) as the placement sum for class Y minus the placement sum for class X (the reference class). By default, PROC NPAR1WAY uses the first class that is listed in the “Fligner-Policello Placements” table as class Y and the second class as the reference class X . The table displays class levels in the order in which they appear in the input data set. To use the first class (instead of the second class) as the reference class for the Fligner-Policello test, you can specify the FP(REFCLASS=1) option. Or you can specify the FP(REFCLASS=*class-value*) option to identify the reference class by the formatted value of the **CLASS** variable.

Multiple Comparisons Based on Pairwise Rankings

If you specify the DSCF option, PROC NPAR1WAY computes the Dwass, Steel, Critchlow-Fligner (DSCF) multiple comparison analysis, which is based on pairwise two-sample Wilcoxon comparisons (Dwass 1960; Steel 1960; Critchlow and Fligner 1991). The DSCF analysis is available when the number of **CLASS** variable levels (samples) is greater than 2. There are $r(r-1)/2$ pairs of samples, where r is the total number of samples.

For each pair of samples, PROC NPAR1WAY ranks the observations and computes the standardized Wilcoxon test statistic, which is described in the sections “[Simple Linear Rank Tests for Two-Sample Data](#)” on page 5468 and “[Wilcoxon Scores](#)” on page 5471. The procedure does not include a continuity correction in the Wilcoxon test statistics that it computes for the DSCF analysis. The DSCF statistic for a pair of samples is computed as $\sqrt{2} z$, where z is the two-sample standardized Wilcoxon statistic. Under the null hypothesis of no location differences among the r samples, the distribution of the DSCF statistics can be approximated by the studentized range distribution for r independent standard normal variables. The p -value for a two-sample DSCF comparison is the percentile of the studentized range distribution that corresponds to the value of the DSCF statistic. See Hollander and Wolfe (1999) and Juneau (2007, 2004) for more information.

When you specify the DSCF option, PROC NPAR1WAY displays the “Pairwise Two-Sided Multiple Comparison Analysis” table, which contains the following information for each two-sample comparison: comparison identification (two class variable levels), two-sample Wilcoxon test statistic, DSCF statistic, and

two-sided DSCF p -value. You can store these statistics in a SAS data set by using the Output Delivery System (ODS). The ODS name for this table is DSCF. For more information, see the section “ODS Table Names” on page 5493 and Chapter 20, “Using the Output Delivery System.”

Tests Based on the Empirical Distribution Function

If you specify the **EDF** option, PROC NPAR1WAY computes tests based on the empirical distribution function. These include the Kolmogorov-Smirnov and Cramér-von Mises tests, and also the Kuiper test for two-sample data. This section gives formulas for these test statistics. For further information about the formulas and the interpretation of EDF statistics, see Hollander and Wolfe (1999) and Gibbons and Chakraborti (2010). For details about the k -sample analogs of the Kolmogorov-Smirnov and Cramér-von Mises statistics, see Kiefer (1959).

The *empirical distribution function* (EDF) of a sample $\{x_j\}$, $j = 1, 2, \dots, n$, is defined as

$$F(x) = \frac{1}{n}(\text{number of } x_j \leq x) = \frac{1}{n} \sum_{j=1}^n I(x_j \leq x)$$

where $I(\cdot)$ is an indicator function. PROC NPAR1WAY uses the subsample of values within the i th class level to generate an EDF for the class, F_i . The EDF for the overall sample, pooled over classes, can also be expressed as

$$F(x) = \frac{1}{n} \sum_i (n_i F_i(x))$$

where n_i is the number of observations in the i th class level, and n is the total number of observations.

Kolmogorov-Smirnov Test

The Kolmogorov-Smirnov statistic measures the maximum deviation of the EDF within the classes from the pooled EDF. PROC NPAR1WAY computes the Kolmogorov-Smirnov statistic as

$$KS = \max_j \sqrt{\frac{1}{n} \sum_i n_i (F_i(x_j) - F(x_j))^2} \quad \text{where } j = 1, 2, \dots, n$$

The asymptotic Kolmogorov-Smirnov statistic is computed as

$$KS_a = KS \times \sqrt{n}$$

For each class level i and overall, PROC NPAR1WAY displays the value of F_i at the maximum deviation from F and the value $\sqrt{n_i} (F_i - F)$ at the maximum deviation from F . PROC NPAR1WAY also gives the observation where the maximum deviation occurs.

If there are only two class levels, PROC NPAR1WAY computes the two-sample Kolmogorov-Smirnov test statistic D as

$$D = \max_j |F_1(x_j) - F_2(x_j)| \quad \text{where } j = 1, 2, \dots, n$$

The p -value for this test is the probability that D is greater than the observed value d under the null hypothesis of no difference between class levels (samples). PROC NPAR1WAY computes the asymptotic p -value for

D with the approximation

$$\text{Prob}(D > d) = 2 \sum_{i=1}^{\infty} (-1)^{(i-1)} e^{(-2i^2 z^2)}$$

where

$$z = d \sqrt{n_1 n_2 / n}$$

See Hodges (1957) for information about this approximation.

If you specify the **D** option, or if you request exact Kolmogorov-Smirnov p -values with the **KS** option in the **EXACT** statement, PROC NPAR1WAY also computes the one-sided Kolmogorov-Smirnov statistics $D+$ and $D-$ for two-sample data as

$$D+ = \max_j (F_1(x_j) - F_2(x_j)) \quad \text{where } j = 1, 2, \dots, n$$

$$D- = \max_j (F_2(x_j) - F_1(x_j)) \quad \text{where } j = 1, 2, \dots, n$$

The asymptotic probability that $D+$ is greater than the observed value d^+ , under the null hypothesis of no difference between the two class levels, is computed as

$$\text{Prob}(D+ > d^+) = e^{-2z^2} \quad \text{where } z = d^+ \sqrt{n_1 n_2 / n}$$

Similarly, the asymptotic probability that $D-$ is greater than the observed value d^- is computed as

$$\text{Prob}(D- > d^-) = e^{-2z^2} \quad \text{where } z = d^- \sqrt{n_1 n_2 / n}$$

To request exact p -values for the Kolmogorov-Smirnov statistics, you can specify the **KS** option in the **EXACT** statement. See the section “Exact Tests” on page 5479 for more information.

Cramér-von Mises Test

The Cramér-von Mises statistic is defined as

$$CM = \frac{1}{n^2} \sum_i \left(n_i \sum_{j=1}^p t_j (F_i(x_j) - F(x_j))^2 \right)$$

where t_j is the number of ties at the j th distinct value and p is the number of distinct values. The asymptotic value is computed as

$$CM_a = CM \times n$$

PROC NPAR1WAY displays the contribution of each class level to the sum CM_a .

Kuiper Test

For data with two class levels, PROC NPAR1WAY computes the Kuiper statistic, its scaled value for the asymptotic distribution, and the asymptotic p -value. The Kuiper statistic is computed as

$$K = \max_j (F_1(x_j) - F_2(x_j)) - \min_j (F_1(x_j) - F_2(x_j)) \quad \text{where } j = 1, 2, \dots, n$$

The asymptotic value is

$$K_a = K \sqrt{n_1 n_2 / n}$$

PROC NPAR1WAY displays the value of $(\max_j |F_1(x_j) - F_2(x_j)|)$ for each class level.

The p -value for the Kuiper test is the probability of observing a larger value of K_a under the null hypothesis of no difference between the two classes. PROC NPAR1WAY computes this p -value according to Owen (1962, p. 441).

Exact Tests

PROC NPAR1WAY provides exact p -values for tests for location and scale differences based on the following scores: Wilcoxon, median, van der Waerden (normal), Savage, Siegel-Tukey, Ansari-Bradley, Klotz, Mood, and Conover. Additionally, PROC NPAR1WAY provides exact p -values for tests that use the raw data as scores. Exact tests are available for two-sample and multisample data. When the data are classified into two samples, tests are based on simple linear rank statistics. When the data are classified into more than two samples, tests are based on one-way ANOVA statistics.

Exact tests can be useful in situations where the asymptotic assumptions are not met and the asymptotic p -values are not close approximations for the true p -values. Standard asymptotic methods involve the assumption that the test statistic follows a particular distribution when the sample size is sufficiently large. When the sample size is not large, asymptotic results might not be valid, with the asymptotic p -values differing perhaps substantially from the exact p -values. Asymptotic results might also be unreliable when the distribution of the data is sparse, skewed, or heavily tied. See Agresti (2007) and Bishop, Fienberg, and Holland (1975). Exact computations are based on the statistical theory of exact conditional inference for contingency tables, reviewed by Agresti (1992).

In addition to computation of exact p -values, PROC NPAR1WAY provides the option of estimating exact p -values by Monte Carlo simulation. This can be useful for problems that are so large that exact computations require a great amount of time and memory, but for which asymptotic approximations might not be sufficient.

The following sections summarize the exact computational algorithms, define the exact p -values that PROC NPAR1WAY computes, discuss the computational resource requirements, and describe the Monte Carlo estimation option.

Computational Algorithms

PROC NPAR1WAY computes exact p -values by using the network algorithm developed by Mehta and Patel (1983). This algorithm provides a substantial advantage over direct enumeration, which can be very time-consuming and feasible only for small problems. See Agresti (1992) for a review of algorithms for computation of exact p -values, and see Mehta, Patel, and Tsiatis (1984) and Mehta, Patel, and Senchaudhuri (1991) for information about the performance of the network algorithm.

PROC NPAR1WAY constructs a contingency table from the input data, with rows formed by the levels of the classification variable and columns formed by the response variable values. The reference set for a given contingency table is the set of all contingency tables with the observed marginal row and column sums. Corresponding to this reference set, the network algorithm forms a directed acyclic network consisting of nodes in a number of stages. A path through the network corresponds to a distinct table in the reference set. The distances between nodes are defined so that the total distance of a path through the network is the corresponding value of the test statistic. At each node, the algorithm computes the shortest and longest path distances for all the paths that pass through that node. For the two-sample linear rank statistics, which can be expressed as linear combinations of cell frequencies multiplied by increasing row and column scores, PROC NPAR1WAY computes shortest and longest path distances by using the algorithm given by Agresti, Mehta, and Patel (1990). For the multisample one-way test statistics, PROC NPAR1WAY computes an upper bound for the longest path and a lower bound for the shortest path by following the approach of Valz and Thompson (1994).

The longest and shortest path distances (bounds) for a node are compared to the value of the test statistic to determine whether all paths through the node contribute to the p -value, none of the paths through the node contribute to the p -value, or neither of these situations occurs. If all paths through the node contribute, the p -value is incremented accordingly, and these paths are eliminated from further analysis. If no paths contribute, these paths are eliminated from the analysis. Otherwise, the algorithm continues, still processing this node and the associated paths. The algorithm finishes when all nodes have been accounted for.

In applying the network algorithm, PROC NPAR1WAY uses full numerical precision to represent all statistics, row and column scores, and other quantities involved in the computations. Although it is possible to use rounding to improve the speed and memory requirements of the algorithm, PROC NPAR1WAY does not do this because it can result in reduced accuracy of the p -values.

Definition of p -Values

For two-sample linear rank tests, PROC NPAR1WAY computes exact one-sided and two-sided p -values for each test that is specified in the EXACT statement. For the one-sided test, PROC NPAR1WAY displays the right-sided p -value when the observed value of the test statistic is greater than its expected value. The right-sided p -value is the sum of probabilities for those tables having a test statistic greater than or equal to the observed test statistic. Otherwise, when the test statistic is less than or equal to its expected value, PROC NPAR1WAY displays the left-sided p -value. The left-sided p -value is the sum of probabilities for those tables having a test statistic less than or equal to the one observed. The one-sided p -value P_1 can be expressed as

$$P_1(t) = \begin{cases} \text{Prob}(\text{Test Statistic} \geq t) & \text{if } t > E_0(T) \\ \text{Prob}(\text{Test Statistic} \leq t) & \text{if } t \leq E_0(T) \end{cases}$$

where t is the observed value of the test statistic and $E_0(T)$ is the expected value of the test statistic under the null hypothesis. PROC NPAR1WAY computes the two-sided p -value as the sum of the one-sided p -value and the corresponding area in the opposite tail of the distribution of the statistic, equidistant from the expected value. The two-sided p -value P_2 can be expressed as

$$P_2(t) = \text{Prob}(|\text{Test Statistic} - E_0(T)| \geq |t - E_0(T)|)$$

For multisample data, the tests are based on one-way ANOVA statistics. For a test of this form, large values of the test statistic indicate a departure from the null hypothesis; the test is inherently two-sided. The exact

p -value is the sum of probabilities for those tables having a test statistic greater than or equal to the value of the observed test statistic.

If you specify the **POINT** option in the EXACT statement, PROC NPAR1WAY also displays exact point probabilities for the test statistics. The exact point probability is the exact probability that the test statistic equals the observed value.

Computational Resources

PROC NPAR1WAY uses relatively fast and efficient algorithms for exact computations. These algorithms, together with improvements in computer power, now make it feasible to perform exact computations for data sets where previously only asymptotic methods could be applied. Nevertheless, there are still large problems that might require a prohibitive amount of time and memory for exact computations, depending on the speed and memory available on your computer. For large problems, consider whether exact methods are really needed or whether asymptotic methods might give results quite close to the exact results while requiring much less computer time and memory. When asymptotic methods might not be sufficient for such large problems, consider using Monte Carlo estimation of exact p -values, as described in the section “**Monte Carlo Estimation**” on page 5481.

A formula does not exist that can predict in advance how much time and memory are needed to compute an exact p -value for a certain problem. The time and memory required depend on several factors, including which test is being performed, the total sample size, the number of rows and columns, and the specific arrangement of the observations into table cells. Generally, larger problems (in terms of total sample size, number of rows, and number of columns) tend to require more time and memory. Additionally, for a fixed total sample size, time and memory requirements tend to increase as the number of rows and columns increase, since this corresponds to an increase in the number of tables in the reference set. Also for a fixed sample size, time and memory requirements increase as the marginal row and column totals become more homogeneous. See Agresti, Mehta, and Patel (1990) and Gail and Mantel (1977) for details.

At any time while PROC NPAR1WAY is computing exact p -values, you can terminate the computations by pressing the system interrupt key sequence (see the *SAS Companion* for your system) and choosing to stop computations. After you terminate exact computations, PROC NPAR1WAY completes all other remaining tasks. The procedure produces the requested output and reports missing values for any exact p -values not computed by the time of termination.

You can also use the **MAXTIME=** option in the EXACT statement to limit the amount of time PROC NPAR1WAY uses for exact computations. You specify a MAXTIME= value that is the maximum amount of time (in seconds) that PROC NPAR1WAY can use to compute an exact p -value. If PROC NPAR1WAY does not finish computing the exact p -value within that time, it terminates the computation and completes all other remaining tasks.

Monte Carlo Estimation

If you specify the **MC** option in the EXACT statement, PROC NPAR1WAY computes Monte Carlo estimates of the exact p -values instead of directly computing the exact p -values. Monte Carlo estimation can be useful for large problems that require a great amount of time and memory for exact computations but for which asymptotic approximations might not be sufficient. To describe the precision of each Monte Carlo estimate, PROC NPAR1WAY provides the asymptotic standard error and $100(1 - \alpha)\%$ confidence limits. The confidence level α is determined by the **ALPHA=** option in the EXACT statement, which, by default, equals 0.01 and produces 99% confidence limits. The **N=** option in the EXACT statement specifies the

number of samples PROC NPAR1WAY uses for Monte Carlo estimation; the default is 10,000 samples. You can specify a larger value for n to improve the precision of the Monte Carlo estimates. Because larger values of n generate more samples, the computation time increases. Or you can specify a smaller value of n to reduce the computation time.

To compute a Monte Carlo estimate of an exact p -value, PROC NPAR1WAY generates a random sample of tables with the same total sample size, row totals, and column totals as the observed table. PROC NPAR1WAY uses the algorithm of Agresti, Wackerly, and Boyett (1979), which generates tables in proportion to their hypergeometric probabilities conditional on the marginal frequencies. For each sample table, PROC NPAR1WAY computes the value of the test statistic and compares it to the value for the observed table. When estimating a right-sided p -value, PROC NPAR1WAY counts all sample tables for which the test statistic is greater than or equal to the observed test statistic. Then the p -value estimate equals the number of these tables divided by the total number of tables sampled, which can be written as

$$\begin{aligned}\hat{P}_{MC} &= M / N \\ M &= \text{number of samples with (Test Statistic} \geq t) \\ N &= \text{total number of samples} \\ t &= \text{observed Test Statistic}\end{aligned}$$

PROC NPAR1WAY computes left-sided and two-sided p -value estimates in a similar manner. For left-sided p -values, PROC NPAR1WAY evaluates whether the test statistic for each sampled table is less than or equal to the observed test statistic. For two-sided p -values, PROC NPAR1WAY examines the sample test statistics according to the expression for $P_2(t)$ given in the section “[Definition of \$p\$ -Values](#)” on page 5480.

The variable M is a binomial variable with N trials and success probability p . It follows that the asymptotic standard error of the Monte Carlo estimate is

$$se(\hat{P}_{MC}) = \sqrt{\hat{P}_{MC} (1 - \hat{P}_{MC}) / (N - 1)}$$

PROC NPAR1WAY constructs asymptotic confidence limits for the p -values according to

$$\hat{P}_{MC} \pm \left(z_{\alpha/2} \times se(\hat{P}_{MC}) \right)$$

where $z_{\alpha/2}$ is the $100(1 - \alpha/2)$ percentile of the standard normal distribution, and the confidence level α is determined by the ALPHA= option in the EXACT statement.

When the Monte Carlo estimate \hat{P}_{MC} equals 0, PROC NPAR1WAY computes confidence limits for the p -value as

$$(0, 1 - \alpha^{(1/N)})$$

When the Monte Carlo estimate \hat{P}_{MC} equals 1, PROC NPAR1WAY computes the confidence limits as

$$(\alpha^{(1/N)}, 1)$$

Contents of the Output Data Set

The **OUTPUT** statement creates a SAS data set that contains statistics that PROC NPAR1WAY computes. You identify which statistics to store in the output data set by specifying *output-options* in the OUTPUT statement. See the description of the **OUTPUT** statement for more information.

The output data set contains one observation for each analysis variable for each **BY** group. (You can specify the analysis variables in the **VAR** statement.) The OUTPUT data set includes the following variables:

- BY variables, if you use a **BY** statement
- **_VAR_**, which identifies the analysis variable
- variables that contain the statistics

When you specify an *output-option* in the OUTPUT statement, the output data set contains the test statistic and associated values from the analysis that you specify. The associated values might include standardized statistics, one- and two-sided *p*-values, exact *p*-values, degrees of freedom, and confidence limits. If you request an exact test for the specified analysis by using the **EXACT** statement, the output data set includes the exact *p*-values. The statistics that are included also depend on the classification of the data. Some statistics are available only for two-sample data (where the **CLASS** variable groups the data into two classes); other statistics are available only for multisample data.

Table 65.5 lists variable names and descriptions for the statistics that are available in the output data set.

Monte Carlo estimates of exact *p*-values are not available in this output data set. You can store Monte Carlo estimates in a SAS data set by using the Output Delivery System (ODS). ODS can create a SAS data set from any table that PROC NPAR1WAY produces. For more information, see the section “**ODS Table Names**” on page 5493 and Chapter 20, “**Using the Output Delivery System**.”

Table 65.5 Output Data Set Variable Names and Descriptions

Output Option	Output Variables	Variable Descriptions
AB	_AB_	* Two-sample Ansari-Bradley statistic
	Z_AB	* Ansari-Bradley statistic, standardized
	PL_AB	* <i>p</i> -value (left-sided), Ansari-Bradley test
	PR_AB	* <i>p</i> -value (right-sided), Ansari-Bradley test
	P2_AB	* <i>p</i> -value (two-sided), Ansari-Bradley test
	XPL_AB	* Exact <i>p</i> -value (left-sided), Ansari-Bradley test

*Statistic included only for two-sample cases.

**Statistic included only for multisample cases.

Displayed Output

If you specify the **ANOVA** option, PROC NPAR1WAY displays a “Class Means” table and an “Analysis of Variance” table for each response variable. The “Class Means” table includes the following information for each **CLASS** variable value (level):

- N, which is the number of observations
- Mean of the response variable

The “Analysis of Variance” table includes the following information for each Source of variation (Among classes and Within classes):

- DF, which is the degrees of freedom associated with the source
- Sum of Squares
- Mean Square, which is the sum of squares divided by the degrees of freedom

The “Analysis of Variance” table also includes the following:

- F Value for testing the hypothesis that the class means are equal, which is computed by dividing the Mean Square (Among) by the Mean Square (Within)
- $Pr > F$, which is the significance probability corresponding to the F Value

For each score type that you specify, PROC NPAR1WAY displays a “Class Scores” table. The available score types include Wilcoxon, median, Van der Waerden (normal), Savage, Siegel-Tukey, Ansari-Bradley, Klotz, Mood, Conover, and raw data scores. PROC NPAR1WAY computes the scores for the response variable values and classifies the scored observations according to the **CLASS** variable values. The “Class Scores” table includes the following information for each CLASS variable level:

- N, which is the number of observations
- Sum of Scores
- Expected Under H0, which is the expected sum of scores under the null hypothesis of no difference among classes
- Std Dev Under H0, which is the standard deviation under the null hypothesis
- Mean Score

When there are two levels of the **CLASS** variable, PROC NPAR1WAY displays a “Two-Sample Test” table for each analysis of scores. The “Two-Sample Test” table includes the following information:

- Statistic, which is the sum of scores for the class with the smaller sample size
- Z, which is the standardized test statistic and has an asymptotic standard normal distribution under the null hypothesis
- One-Sided $Pr < Z$ or One-Sided $Pr > Z$, which is the asymptotic one-sided p -value. This is displayed as $Pr < Z$ or $Pr > Z$, depending on whether Z is ≤ 0 or > 0 .
- Two-Sided $Pr > |Z|$, which is the asymptotic two-sided p -value

For Wilcoxon scores, the “Two-Sample Test” table also includes a t Approximation for the Wilcoxon two-sample test.

If you request an exact test by specifying the score type in the **EXACT** statement, the “Two-Sample Test” table also includes the following exact p -values:

- One-Sided $Pr \leq S$ or One-Sided $Pr \geq S$, which is the exact one-sided p -value. This is displayed as $Pr \leq S$ or $Pr \geq S$, depending on whether $S \leq \text{Mean}$ or $S > \text{Mean}$, where S is the test statistic and Mean is its expected value under the null hypothesis.

- Point $Pr = S$, which is the point probability. This is displayed if you specify the **POINT** option in the EXACT statement.
- Two-Sided $Pr \geq |S - \text{Mean}|$, which is the exact two-sided p -value

If you request Monte Carlo estimates for a two-sample exact test by specifying the **MC** option in the **EXACT** statement, PROC NPAR1WAY displays the “Monte Carlo Estimates for the Exact Test” table, which includes the following information:

- Estimate of One-Sided $Pr \leq S$ or One-Sided $Pr \geq S$, which is the exact one-sided p -value, together with its Lower and Upper Confidence Limits
- Estimate of Two-Sided $Pr \geq |S - \text{Mean}|$, which is the exact two-sided p -value, together with its Lower and Upper Confidence Limits
- Number of Samples used to compute the Monte Carlo estimates
- Initial Seed used to compute the Monte Carlo estimates

For both two-sample and multisample data, PROC NPAR1WAY displays a “One-Way Analysis” table, which includes the following information:

- Chi-Square, which is the one-way ANOVA statistic for testing the null hypothesis of no difference among classes
- DF, which is the degrees of freedom
- $Pr > \text{Chi-Square}$, which is the asymptotic p -value

For multisample data, if you request an exact test by specifying the score type in the **EXACT** statement, the “One-Way Analysis” table also displays the exact p -value as follows:

- Exact $Pr \geq \text{Chi-Square}$
- Exact $Pr = \text{Chi-Square}$, which is the point probability. This is displayed if you specify the **POINT** option in the EXACT statement.

For multisample data, if you specify the **MC** option in the **EXACT** statement, PROC NPAR1WAY displays the following information in the “Monte Carlo Estimate for the Exact Test” table:

- Estimate of Exact $Pr \geq \text{Chi-Square}$, together with its Lower and Upper Confidence Limits
- Number of Samples used to compute the Monte Carlo estimate
- Initial Seed used to compute the Monte Carlo estimate

If you specify the **HL** option for two-sample data, PROC NPAR1WAY produces a “Hodges-Lehmann Estimation” table, which includes the following information:

- Location Shift estimate
- Confidence Limits for the Location Shift
- Confidence Interval Midpoint
- Asymptotic Standard Error estimate, which is based on the confidence interval

If you request exact Hodges-Lehmann confidence limits by specifying the HL option in the **EXACT** statement, the “Hodges-Lehmann Estimation” table also includes Exact Confidence Limits and the exact Interval Midpoint.

If you specify the **FP** option for two-sample data, PROC NPAR1WAY produces the “Fligner-Policello Placements” table and the “Fligner-Policello Test” table. The “Fligner-Policello Placements” table includes the following information for each **CLASS** variable level:

- N, which is the number of observations
- Sum, which is the sum of the placements
- Mean, which is the average placement
- Std Dev, which is the standard deviation of the placements

The “Fligner-Policello Test” table includes the following information:

- Difference, which is the difference in placement sums between the two **CLASS** levels (samples)
- Statistic (Z), which is the standardized test statistic and has an asymptotic standard normal distribution under the null hypothesis
- One-Sided $\Pr < Z$ or One-Sided $\Pr > Z$, which is the one-sided p -value. This is displayed as $\Pr < Z$ or $\Pr > Z$, depending on whether Z is ≤ 0 or > 0 .
- Two-Sided $\Pr > |Z|$, which is the two-sided p -value

If you specify the **DSCF** option for multisample data, PROC NPAR1WAY produces the “Pairwise Two-Sided Multiple Comparison Analysis” table, which includes the following information for each two-sample comparison:

- Comparison, which identifies the two **CLASS** levels that are compared
- Wilcoxon Z, which is the standardized two-sample Wilcoxon statistic
- DSCF Value, which is the Dwass, Steel, Critchlow-Fligner statistic
- $\Pr > \text{DSCF}$, which is the two-sided p -value

If you specify the **EDF** option, PROC NPAR1WAY produces tables for the Kolmogorov-Smirnov test, the Cramér-von Mises test, and for two-sample data only, the Kuiper test.

The “Kolmogorov-Smirnov Test” table includes the following information for each **CLASS** variable level:

- N, which is the number of observations
- EDF at Maximum, which is the value of the class EDF (empirical distribution function) at its maximum deviation from the pooled EDF
- Deviation from Mean at Maximum, which is the value of $\sqrt{n_i} \sqrt{F_i - \bar{F}}$ at its maximum, where n_i is the class sample size, F_i is the class EDF, and \bar{F} is the pooled EDF

The “Kolmogorov-Smirnov Test” table displays the following statistics:

- KS, which is the Kolmogorov-Smirnov statistic
- KSa, which is the asymptotic Kolmogorov-Smirnov statistic, $KSa = \sqrt{n} KS$

For two-sample data, the “Kolmogorov-Smirnov Test” table also displays the following statistics:

- $Pr > KSa$, which is the asymptotic p -value for KSa and equals $Pr > D$
- D, which is the two-sample Kolmogorov-Smirnov statistic, $\max_j |F_1(x_j) - F_2(x_j)|$

If you specify the **D** option for two-sample data, PROC NPAR1WAY displays the following one-sided Kolmogorov-Smirnov statistics and their asymptotic p -values in the “Kolmogorov-Smirnov Two-Sample Test” table:

- D+, which is $\max_j (F_1(x_j) - F_2(x_j))$
- $Pr > D+$
- D-, which is $\max_j (F_2(x_j) - F_1(x_j))$
- $Pr > D-$

For two-sample data, if you request an exact Kolmogorov-Smirnov test by specifying the **KS** option in the **EXACT** statement, PROC NPAR1WAY displays the following exact p -values in the “Kolmogorov-Smirnov Two-Sample Test” table:

- Exact $Pr \geq D$
- Exact $Pr \geq D+$
- Exact $Pr \geq D-$
- Exact Point $Pr = D$, Exact Point $Pr = D+$, and Exact Point $Pr = D-$, if you specify the **POINT** option in the **EXACT** statement

If you request Monte Carlo estimates for the two-sample exact Kolmogorov-Smirnov test, PROC NPAR1WAY displays the following information in the “Kolmogorov-Smirnov Two-Sample Test” table:

- Estimate of Exact $\Pr \geq D$, together with its Lower and Upper Confidence Limits
- Estimate of Exact $\Pr \geq D+$, together with its Lower and Upper Confidence Limits
- Estimate of Exact $\Pr \geq D-$, together with its Lower and Upper Confidence Limits
- Number of Samples used to compute the Monte Carlo estimates
- Initial Seed used to compute the Monte Carlo estimates

The “Cramér–von Mises Test” table includes the following information for each CLASS variable level:

- N, which is the number of observations
- Summed Deviation from Mean, which is $(n_i/n) \sum_{j=1}^p t_j (F_i(x_j) - F(x_j))^2$

The “Cramér–von Mises Statistics” table displays the following statistics:

- CM, which is the Cramér–von Mises statistic
- CMa, which is the asymptotic Cramér–von Mises statistic, $\text{CMa} = n \text{ CM}$

For two-sample data, PROC NPAR1WAY displays the “Kuiper Test” table, which includes the following information for each CLASS variable level:

- N, which is the number of observations
- Deviation from Mean, which is $\max_j |F_1(x_j) - F_2(x_j)|$

The “Kuiper Two-Sample Statistics” table displays the following statistics:

- K, which is the Kuiper two-sample test statistic
- Ka, which is the asymptotic Kuiper two-sample test statistic, $\text{Ka} = K \sqrt{n_1 n_2 / n}$
- $\Pr > \text{Ka}$

ODS Table Names

PROC NPAR1WAY assigns a name to each table that it creates. You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 65.6 lists the ODS table names together with their descriptions and the options required to produce the tables. If you do not specify any analysis options in the PROC NPAR1WAY statement, the procedure provides the [ANOVA](#), [WILCOXON](#), [MEDIAN](#), [VW \(NORMAL\)](#), [SAVAGE](#), and [EDF](#) analyses by default.

Table 65.6 ODS Tables Produced by PROC NPAR1WAY

ODS Table Name	Description	Statement	Option

*PROC NPAR1WAY produces this table only for two-sample data.

**PROC NPAR1WAY produces this table only for multisample data.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

When ODS Graphics is enabled, you can request specific plots with the **PLOTS=** option in the PROC NPAR1WAY statement. If you do not specify the PLOTS= option but have enabled ODS Graphics, PROC NPAR1WAY produces all plots that are associated with the analyses that you request.

PROC NPAR1WAY assigns a name to each graph that it creates with ODS Graphics. You can use these names to refer to the graphs. Table 65.7 lists the names of the graphs that PROC NPAR1WAY generates together with their descriptions and the options that are required to produce the graphs.

Table 65.7 Graphs Produced by PROC NPAR1WAY

ODS Graph Name	Description	Option
ABBoxPlot	Box plot of Ansari-Bradley scores	AB
ANOVABoxPlot	Box plot of raw data	ANOVA
ConoverBoxPlot	Box plot of Conover scores	CONOVER
DataScoresBoxPlot	Box plot of data scores	SCORES=DATA
EDFPlot	Empirical distribution function plot	EDF
FPBoxPlot	Box plot of Fligner-Policello placements	FP
KlotzBoxPlot	Box plot of Klotz scores	KLOTZ
MedianPlot	Median plot	MEDIAN
MoodBoxPlot	Box plot of Mood scores	MOOD

STBoxPlot	Box plot of Siegel-Tukey scores	ST
VWBoxPlot	Box plot of Van der Waerden scores	VW NORMAL
WilcoxonBoxPlot	Box plot of Wilcoxon scores	WILCOXON

Examples: NPAR1WAY Procedure

Example 65.1: Two-Sample Location Tests and Plots

Fifty-nine female patients with rheumatoid arthritis who participated in a clinical trial were assigned to two groups, active and placebo. The response status (excellent=5, good=4, moderate=3, fair=2, poor=1) of each patient was recorded.

The following SAS statements create the data set *Arthritis*, which contains the observed status values for all the patients. The variable *Treatment* denotes the treatment received by a patient, and the variable *Response* contains the response status of the patient. The variable *Freq* contains the frequency of the observation, which is the number of patients with the *Treatment* and *Response* combination.

```
data Arthritis;
  input Treatment $ Response Freq @@;
  datalines;
Active 5 5 Active 4 11 Active 3 5 Active 2 1 Active 1 5
Placebo 5 2 Placebo 4 4 Placebo 3 7 Placebo 2 7 Placebo 1 12
;
```

The following PROC NPAR1WAY statements test the null hypothesis that there is no difference in the patient response status against the alternative hypothesis that the patient response status differs in the two treatment groups. The WILCOXON option requests the Wilcoxon test for difference in location, and the MEDIAN option requests the median test for difference in location. The variable *Treatment* is the CLASS variable, and the VAR statement specifies that the variable *Response* is the analysis variable.

The PLOTS= option requests a box plot of the Wilcoxon scores and a median plot for Response classified by Treatment. ODS Graphics must be enabled before producing plots.

```
ods graphics on;
proc npar1way data=Arthritis wilcoxon median
      plots=(wilcoxonboxplot medianplot);
  class Treatment;
  var Response;
  freq Freq;
run;
ods graphics off;
```

Output 65.1.1 shows the results of the Wilcoxon analysis. The Wilcoxon two-sample test statistic equals 999.0, which is the sum of the Wilcoxon scores for the smaller sample (Active). This sum is greater than 810.0, which is the expected value under the null hypothesis of no difference between the two samples, Active and Placebo. The one-sided p -value is 0.0016, which indicates that the patient response for the Active treatment is significantly more than for the Placebo group.

Output 65.1.1 Wilcoxon Two-Sample Test

The NPAR1WAY Procedure					
Wilcoxon Scores (Rank Sums) for Variable Response Classified by Variable Treatment					
Treatment	N	Sum of Scores	Expected Under H0	Std Dev Under H0	Mean Score
Active	27	999.0	810.0	63.972744	37.000000
Placebo	32	771.0	960.0	63.972744	24.093750
Average scores were used for ties.					
Wilcoxon Two-Sample Test					
Statistic		999.0000			
Normal Approximation					
Z		2.9466			
One-Sided Pr > Z		0.0016			
Two-Sided Pr > Z		0.0032			
t Approximation					
One-Sided Pr > Z		0.0023			
Two-Sided Pr > Z		0.0046			
Z includes a continuity correction of 0.5.					
Kruskal-Wallis Test					
Chi-Square		8.7284			
DF		1			
Pr > Chi-Square		0.0031			

Output 65.1.2 displays the box plot of Wilcoxon scores classified by Treatment, which corresponds to the Wilcoxon analysis in Output 65.1.1. To remove the p -values from the box plot display, you can specify the NOSTATS plot option in parentheses after the WILCOXONBOXPLOT option.

Output 65.1.2 Box Plot of Wilcoxon Scores

Output 65.1.3 shows the results of the median two-sample test. The test statistic equals 18.9167, and its standardized Z value is 3.2667. The one-sided p -value $\Pr > Z$ equals 0.0005. This supports the alternative hypothesis that the effect of the Active treatment is greater than that of the Placebo.

Output 65.1.4 displays the median plot for the analysis of Response classified by Treatment. The median plot is a stacked bar chart showing the frequencies above and below the overall median. This plot corresponds to the median scores analysis in Output 65.1.3.

Output 65.1.3 Median Two-Sample Test

Median Scores (Number of Points Above Median) for Variable Response Classified by Variable Treatment					
Treatment	N	Sum of Scores	Expected Under H0	Std Dev Under H0	Mean Score
Active	27	18.916667	13.271186	1.728195	0.700617

Example 65.2: EDF Statistics and EDF Plot

This example uses the SAS data set *Arthritis* created in [Example 65.1](#). The data set contains the variable *Treatment*, which denotes the treatment received by a patient, and the variable *Response*, which contains the response status of the patient. The variable *Freq* contains the frequency of the observation, which is the number of patients with the *Treatment* and *Response* combination.

The following statements request empirical distribution function (EDF) statistics, which test whether the distribution of a variable is the same across different groups. The *EDF* option requests the EDF analysis. The variable *Treatment* is the *CLASS* variable, and the variable *Response* specified in the *VAR* statement is the analysis variable. The *FREQ* statement names *Freq* as the frequency variable.

The *PLOTS=* option requests an EDF plot for *Response* classified by *Treatment*. ODS Graphics must be enabled before producing plots.

```
ods graphics on;
proc npar1way edf plots=edfplot data=Arthritis;
  class Treatment;
  var Response;
  freq Freq;
run;
ods graphics off;
```

[Output 65.2.1](#) shows EDF statistics that compare the two levels of *Treatment*, *Active* and *Placebo*. The asymptotic *p*-value for the Kolmogorov-Smirnov test is 0.0164. This supports rejection of the null hypothesis that the distributions are the same for the two samples.

[Output 65.2.2](#) shows the EDF plot for *Response* classified by *Treatment*.

Output 65.2.1 Empirical Distribution Function Statistics

The NPAR1WAY Procedure			
Kolmogorov-Smirnov Test for Variable Response Classified by Variable Treatment			
Treatment	N	EDF at Maximum	Deviation from Mean at Maximum
Active	27	0.407407	-1.141653
Placebo	32	0.812500	1.048675
Total	59	0.627119	
Maximum Deviation Occurred at Observation 3 Value of Response at Maximum = 3.0			
Kolmogorov-Smirnov Two-Sample Test (Asymptotic)			
KS	0.201818	D	0.405093
KSa	1.550191	Pr > KSa	0.0164

Output 65.2.2 Empirical Distribution Function Plot

Example 65.3: Exact Wilcoxon Two-Sample Test

Researchers conducted an experiment to compare the effects of two stimulants. Thirteen randomly selected subjects received the first stimulant, and six randomly selected subjects received the second stimulant. The reaction times (in minutes) were measured while the subjects were under the influence of the stimulants.

The following SAS statements create the data set `React`, which contains the observed reaction times for each stimulant. The variable `Stim` represents Stimulant 1 or 2. The variable `Time` contains the reaction times observed for subjects under the stimulant.

```
data React;
  input Stim Time @@;
  datalines;
1 1.94 1 1.94 1 2.92 1 2.92 1 2.92 1 2.92 1 3.27
1 3.27 1 3.27 1 3.27 1 3.70 1 3.70 1 3.74
2 3.27 2 3.27 2 3.27 2 3.70 2 3.70 2 3.74
;
```

The following statements request a Wilcoxon test of the null hypothesis that there is no difference between the effects of the two stimulants. `Stim` is the CLASS variable, and `Time` is the analysis variable. The

WILCOXON option requests an analysis of Wilcoxon scores. The CORRECT=NO option removes the continuity correction from the computation of the standardized z test statistic. The WILCOXON option in the EXACT statement requests exact p -values for the Wilcoxon test. Because the sample size is small, the large-sample normal approximation might not be adequate, and it is appropriate to compute the exact test. These statements produce the results shown in [Output 65.3.1](#).

```
proc npar1way wilcoxon correct=no data=React;
  class Stim;
  var Time;
  exact wilcoxon;
run;
```

[Output 65.3.1](#) displays the results of the Wilcoxon two-sample test. The Wilcoxon statistic equals 79.50. Since this value is greater than 60.0, the expected value under the null hypothesis, PROC NPAR1WAY displays the right-sided p -values. The normal approximation for the Wilcoxon two-sample test yields a one-sided p -value of 0.0382 and a two-sided p -value of 0.0764. For the exact Wilcoxon test, the one-sided p -value is 0.0527, and the two-sided p -value is 0.1054.

Output 65.3.1 Wilcoxon Two-Sample Test

The NPAR1WAY Procedure					
Wilcoxon Scores (Rank Sums) for Variable Time Classified by Variable Stim					
Stim	N	Sum of Scores	Expected Under H0	Std Dev Under H0	Mean Score
1	13	110.50	130.0	11.004784	8.500
2	6	79.50	60.0	11.004784	13.250
Average scores were used for ties.

Example 65.4: Hodges-Lehmann Estimation

This example uses the SAS data set `React` created in [Example 65.3](#). The data set contains the variable `Stim`, which represents Stimulant 1 or 2, and the variable `Time`, which contains the reaction times observed for subjects under the stimulant.

The following statements request Hodges-Lehmann estimation of the location shift between the two groups. `Stim` is the CLASS variable, and `Time` is the analysis variable. The `HL` option requests Hodges-Lehmann estimation. The `ALPHA=` option sets the confidence level for the Hodges-Lehmann confidence limits. The `HL` option in the `EXACT` statement requests exact confidence limits for the estimate of location shift. The `ODS SELECT` statement selects which tables to display. [Output 65.4.1](#) shows the Hodges-Lehmann results.

```
proc npar1way hl alpha=.02 data=React;
  class Stim;
  var Time;
  exact hl;
  ods select WilcoxonScores HodgesLehmann;
run;
```

The `HL` option invokes the `WILCOXON` option, which produces a table of Wilcoxon scores ([Output 65.4.1](#)). The Hodges-Lehmann estimate of location shift is 0.35, and the asymptotic confidence limits are 0.00 and 0.82. The confidence interval midpoint equals 0.41, which can also be used as an estimate of the location shift. The ASE estimate of 0.1762 is based on the length of the confidence interval. The exact confidence limits are 0.00 and 1.33.

Output 65.4.1 Hodges-Lehmann Estimate of Location Shift

The NPAR1WAY Procedure					
Wilcoxon Scores (Rank Sums) for Variable Time Classified by Variable Stim					
Stim	N	Sum of Scores	Expected Under H0	Std Dev Under H0	Mean Score
1	13	110.50	130.0	11.004784	8.500
2	6	79.50	60.0	11.004784	13.250
Average scores were used for ties.					
Hodges-Lehmann Estimation					
Location Shift (2 - 1)				0.3500	
Type	98% Confidence Limits		Interval Midpoint	Asymptotic Standard Error	
Asymptotic (Moses)	0.0000	0.8200	0.4100	0.1762	
Exact	0.0000	1.3300	0.6650		

Example 65.5: Exact Savage Multisample Test

A researcher conducting a laboratory experiment randomly assigned 15 mice to receive one of three drugs. The survival time (in days) was then recorded.

The following SAS statements create the data set `Mice`, which contains the observed survival times for the mice. The variable `Treatment` denotes the treatment received. The variable `Days` contains the number of days the mouse survived.

```
data Mice;
  input Treatment $ Days @@;
  datalines;
1 1 1 1 1 3 1 3 1 4
2 3 2 4 2 4 2 4 2 15
3 4 3 4 3 10 3 10 3 26
;
```

The following statements request a Savage test of the null hypothesis that there is no difference in survival time among the three drugs. `Treatment` is the CLASS variable, and `Days` is the analysis variable. The SAVAGE option requests an analysis of Savage scores. The SAVAGE option in the EXACT statement requests exact p -values for the Savage test. Because the sample size is small, the large-sample normal approximation might not be adequate, and it is appropriate to compute the exact test.

PROC NPAR1WAY tests the null hypothesis that there is no difference in the survival times among the three drugs against the alternative hypothesis of difference among the drugs. The SAVAGE option specifies an analysis based on Savage scores. The variable `Treatment` is the CLASS variable, and the variable `Days` is the response variable. The EXACT statement requests the exact Savage test.

```
proc npar1way savage data=Mice;
  class Treatment;
  var Days;
  exact savage;
run;
```

Output 65.5.1 shows the results of the Savage test. The exact p -value is 0.0445, which supports a difference in survival times among the drugs at the 0.05 level. The asymptotic p -value based on the chi-square approximation is 0.0638.

Output 65.5.1 Savage Multisample Exact Test

The NPAR1WAY Procedure					
Savage Scores (Exponential) for Variable Days Classified by Variable Treatment					
Treatment	N	Sum of Scores	Expected Under H0	Std Dev Under H0	Mean Score
1	5	-3.367980	0.0	1.634555	-0.673596
2	5	0.095618	0.0	1.634555	0.019124
3	5	3.272362	0.0	1.634555	0.654472
Average scores were used for ties.

Overview: ORTHOREG Procedure

The ORTHOREG procedure fits general linear models by the method of least squares. Other SAS/STAT software procedures, such as the GLM and REG procedures, fit the same types of models, but PROC

ORTHOREG can produce more accurate estimates than other regression procedures when your data are ill-conditioned. Instead of collecting crossproducts, PROC ORTHOREG uses Gentleman-Givens transformations to update and compute the upper triangular matrix **R** of the QR decomposition of the data matrix, with special care for scaling (Gentleman 1972, 1973). This method has the advantage over other orthogonalization methods (for example, Householder transformations) of not requiring the data matrix to be stored in memory.

The standard SAS regression procedures (PROC REG and PROC GLM) are very accurate for most problems. However, if you have very ill-conditioned data, these procedures can produce estimates that yield an error sum of squares very close to the minimum but still different from the exact least squares estimates. Normally, this coincides with estimates that have very high standard errors. In other words, the numerical error is much smaller than the statistical standard error.

PROC ORTHOREG fits models by the method of linear least squares, minimizing the sum of the squared residuals for predicting the responses—that is, the distance between the regression line and the observed *Y*s. The “ORTHO” in the name of the procedure refers to the orthogonalization approach to solving the least squares equations. In particular, PROC ORTHOREG does *not* perform the modeling method known as “orthogonal regression,” which minimizes a different criterion (namely, the distance between the regression line and the *X/Y* points taken together.)

Getting Started: ORTHOREG Procedure

Longley Data

The labor statistics data set of Longley (1967) is noted for being ill-conditioned. Both the ORTHOREG and GLM procedures are applied for comparison (only portions of the PROC GLM results are shown).

NOTE: The results from this example vary from machine to machine, depending on floating-point configuration.

The following statements read the data into the SAS data set Longley:

```

title 'PROC ORTHOREG used with Longley data';
data Longley;
    input Employment Prices GNP Jobless Military PopSize Year;
    datalines;
60323  83.0 234289 2356 1590 107608 1947

68655 112.6 482704 3813 2552 123366 1959

```

```

69564 114.2 502601 3931 2514 125368 1960
69331 115.7 518173 4806 2572 127852 1961
70551 116.9 554894 4007 2827 130081 1962
;

```

The data set contains one dependent variable, Employment (total derived employment), and six independent variables: Prices (GNP implicit price deflator normalized to the value 100 in 1954), GNP (gross national product), Jobless (unemployment), Military (size of armed forces), PopSize (noninstitutional population aged 14 and over), and Year (year).

The following statements use the ORTHOREG procedure to model the Longley data by using a quadratic model in each independent variable, without interaction:

```

proc orthoreg data=Longley;
    model Employment = Prices    Prices*Prices
                      GNP       GNP*GNP
                      Jobless   Jobless*Jobless
                      Military   Military*Military
                      PopSize    PopSize*PopSize
                      Year       Year*Year;
run;

```

Figure 66.1 shows the resulting analysis.

PopSize	1	-0.0303997234299	5.9272538242	-0.01	0.9962
PopSize**2	1	-1.212511414607E-6	0.0000237262	-0.05	0.9625
Year	1	-194907.139041839	157739.28757	-1.24	0.3045
Year**2	1	50.8067603538501	40.279878943	1.26	0.2963

The estimates in Figure 66.1 compare very well with the best estimates available; for additional information, see Longley (1967) and Beaton, Rubin, and Barone (1976).

The following statements request the same analysis from the GLM procedure:

```
proc glm data=Longley;
  model Employment = Prices    Prices*Prices
                    GNP       GNP*GNP
                    Jobless   Jobless*Jobless
                    Military   Military*Military
                    PopSize    PopSize*PopSize
                    Year       Year*Year;
  ods select OverallANOVA
             FitStatistics
             ParameterEstimates
             Notes;
run;
```

Figure 66.2 contains the overall ANOVA table and the parameter estimates produced by PROC GLM. Notice that the PROC ORTHOREG fit achieves a somewhat smaller root mean square error (RMSE) and also that the GLM procedure detects spurious singularities.

Figure 66.2 Partial PROC GLM Results

PROC ORTHOREG used with Longley data					
The GLM Procedure					
Dependent Variable: Employment					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F

Year*Year	1.038	0.419	2.48	0.0683	
NOTE: The X'X matrix has been found to be singular, and a generalized inverse was used to solve the normal equations. Terms whose estimates are followed by the letter 'B' are not uniquely estimable.					

Syntax: ORTHOREG Procedure

The following statements are available in the ORTHOREG procedure:

```

PROC ORTHOREG < options > ;
  CLASS variables < / option > ;
  MODEL dependent-variable = independent-effects < / option > ;
  BY variables ;
  EFFECT name = effect-type (variables < / options >) ;
  EFFECTPLOT < plot-type < (plot-definition-options) > > < / options > ;
  ESTIMATE < 'label' > estimate-specification < / options > ;
  LSMEANS < model-effects > < / options > ;
  LSMESTIMATE model-effect lsmestimate-specification < / options > ;
  SLICE model-effect < / options > ;
  STORE < OUT= > item-store-name < / LABEL= 'label' > ;
  TEST < model-effects > < / options > ;
  WEIGHT variable ;

```

The **BY**, **CLASS**, **MODEL**, and **WEIGHT** statements are described in full after the **PROC ORTHOREG** statement in alphabetical order. The **EFFECT**, **EFFECTPLOT**, **ESTIMATE**, **LSMEANS**, **LSMESTIMATE**, **SLICE**, **STORE**, and **TEST** statements are common to many procedures. Summary descriptions of functionality and syntax for these statements are also given after the **PROC ORTHOREG** statement in alphabetical order, and full documentation about them is available in Chapter 19, “Shared Concepts and Topics.”

PROC ORTHOREG Statement

```
PROC ORTHOREG < options > ;
```

The **PROC ORTHOREG** statement invokes the ORTHOREG procedure. Table 66.1 summarizes the options available in the **PROC ORTHOREG** statement.

Table 66.1 PROC ORTHOREG Statement Options

Option	Description
DATA=	Specifies the input SAS data set
NOPRINT	Suppresses the normal display of results
ORDER=	Specifies the order in which to sort class levels
OUTEST=	Produces an output data set
SINGULAR=	Specifies the singularity criterion

The **PROC ORTHOREG** statement has the following options:

DATA=SAS-data-set

specifies the input SAS data set to use. By default, the procedure uses the most recently created SAS data set. The data set specified cannot be a **TYPE=**CORR, **TYPE=**COV, or **TYPE=**SSCP data set.

NOPRINT

suppresses the normal display of results. This option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#)” for more information.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the classification variables (which are specified in the [CLASS](#) statement). This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option may be useful when you use [ESTIMATE](#) statement. This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

OUTEST=SAS-data-set

produces an output data set that contains the parameter estimates, the [BY](#) variables, and the special variables _TYPE_ (value “**PARMS**”), _NAME_ (blank), and _RMSE_ (root mean squared error).

SINGULAR=s

specifies a singularity criterion ($s \geq 0$) for the inversion of the triangular matrix **R**. By default, SINGULAR=1E-12.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC ORTHOREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the ORTHOREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable* <(REF= *option*)> ... <*variable* <(REF= *option*)>> </ *global-options*> ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC ORTHOREG statement. You can specify the following REF= option to indicate how the levels of an individual classification variable are to be ordered by enclosing it in parentheses after the variable name:

REF= '*level*' | FIRST | LAST

specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC ORTHOREG's singular parameterization. You can specify the *level* of the variable to use as the reference level; specify a value that corresponds to the formatted value of the variable if a format is assigned. Alternatively, you can specify REF=FIRST to designate that the first ordered level serve as the reference, or REF=LAST to designate that the last ordered level serve as the reference. To specify that REF=FIRST or REF=LAST be used for all classification variables, use the REF= *global-option* after the slash (/) in the CLASS statement.

You can specify the following *global-options* in the CLASS statement after a slash (/):

REF=FIRST | LAST

specifies a level of all classification variables to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC ORTHOREG's singular parameterization. Specify REF=FIRST to designate that the first ordered level for each classification variable serve as the reference. Specify REF=LAST to designate that the last ordered level serve as the reference. This option applies to all the variables specified in the CLASS statement. To specify different reference levels for different classification variables, use [REF=](#) options for individual variables.

TRUNCATE

specifies that class levels be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

EFFECT Statement

EFFECT *name=effect-type* (*variables* < / *options* >) ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “[GLM Parameterization of Classification Variables and Effects](#)” on page 383 in Chapter 19, “[Shared Concepts and Topics](#).”

You can specify the following *effect-types*:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.
MULTIMEMBER MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 66.2 summarizes the *options* available in the EFFECT statement.

Table 66.2 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect

Table 66.2 *continued*

Option	Description
Lag Effects Options	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Multimember Effects Options	
NOEFFECT	Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “**EFFECT Statement**” on page 393 in Chapter 19, “**Shared Concepts and Topics**.”

EFFECTPLOT Statement

EFFECTPLOT < *plot-type* < (*plot-definition-options*) > > < / *options* > ;

The EFFECTPLOT statement produces a display of the fitted model and provides options for changing and enhancing the displays. Table 66.3 describes the available *plot-types* and their *plot-definition-options*.

Table 66.3 *Plot-Types and Plot-Definition-Options*

Plot-Type and Description	Plot-Definition-Options
BOX Displays a box plot of continuous response data at each level of a CLASS effect, with predicted values superimposed and connected by a line. This is an alternative to the INTERACTION <i>plot-type</i> .	PLOTBY= variable or CLASS effect X= CLASS variable or effect
CONTOUR Displays a contour plot of predicted values against two continuous covariates.	PLOTBY= variable or CLASS effect X= continuous variable Y= continuous variable
FIT Displays a curve of predicted values versus a continuous variable.	PLOTBY= variable or CLASS effect X= continuous variable
INTERACTION Displays a plot of predicted values (possibly with error bars) versus the levels of a CLASS effect. The predicted values are connected with lines and can be grouped by the levels of another CLASS effect.	PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= CLASS variable or effect
SLICEFIT Displays a curve of predicted values versus a continuous variable grouped by the levels of a CLASS effect.	PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= continuous variable

For full details about the syntax and options of the EFFECTPLOT statement, see the section “**EFFECTPLOT Statement**” on page 411 in Chapter 19, “**Shared Concepts and Topics**.”

ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
      < , ... <'label'> estimate-specification <(divisor=n)> >
      </ options> ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form $\mathbf{L}\boldsymbol{\beta}$. You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 66.4 summarizes the options available in the ESTIMATE statement.

Table 66.4 ESTIMATE Statement Options

Option	Description
Construction and Computation of Estimable Functions	
DIVISOR=	Specifies a list of values to divide the coefficients
NOFILL	Suppresses the automatic fill-in of coefficients for higher-order effects
SINGULAR=	Tunes the estimability checking difference
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple comparison adjustment of estimates
ALPHA= α	Determines the confidence level $(1 - \alpha)$
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiplicity-corrected p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits
CORR	Displays the correlation matrix of estimates
COV	Displays the covariance matrix of estimates
E	Prints the \mathbf{L} matrix
JOINT	Produces a joint F or chi-square test for the estimable functions
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 in Chapter 19, “Shared Concepts and Topics.”

LSMEANS Statement

LSMEANS < *model-effects* > < / *options* > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 66.5 summarizes the options available in the LSMEANS statement.

Table 66.5 LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies the covariate value in computing LS-means
BYLEVEL	Computes separate margins
DIFF	Requests differences of LS-means
OM=	Specifies the weighting scheme for LS-means computation as determined by the input data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and <i>p</i>-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level ($1 - \alpha$)
STEPDOWN	Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
LINES	Produces a “Lines” display for pairwise LS-means differences
MEANS	Prints the LS-means
PLOTS=	Requests graphs of means and mean comparisons
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMEANS statement, see the section “[LSMEANS Statement](#)” on page 453 in Chapter 19, “[Shared Concepts and Topics](#).”

LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
              <,...<'label'> values <divisor=n>>
              </options>;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 66.6 summarizes the options available in the LSMESTIMATE statement.

Table 66.6 LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
BYLEVEL	Computes separate margins
DIVISOR=	Specifies a list of values to divide the coefficients
OM=	Specifies the weighting scheme for LS-means computation as determined by a data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level $(1 - \alpha)$
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiple-comparison p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
ELSM	Prints the K matrix
JOINT	Produces a joint F or chi-square test for the LS-means and LS-means differences
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMESTIMATE statement, see the section “[LSMESTIMATE Statement](#)” on page 470 in Chapter 19, “[Shared Concepts and Topics](#).”

MODEL Statement

MODEL *dependent-variable* = *independent-effects* < / *option* > ;

The MODEL statement names the dependent variable and the independent effects. Only one MODEL statement is allowed. The [specification of effects](#) and the parameterization of the linear model are the same as in the GLM procedure; see Chapter 42, “[The GLM Procedure](#)” for further details.

The following option can be used in the MODEL statement:

NOINT

omits the intercept term from the model. Often, this omission also changes the total sum of squares in the ANOVA and the value of R square to forms of these statistics that are not corrected for the mean. However, if the model is determined to contain an implicit intercept, in the sense that the all-ones intercept vector is in the column space of the design, then the usual mean-corrected forms of these statistics are used.

SLICE Statement

SLICE *model-effect* < / *options* > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the [LSMEANS](#) statement, which are summarized in [Table 19.21](#). For details about the syntax of the SLICE statement, see the section “[SLICE Statement](#)” on page 498 in Chapter 19, “[Shared Concepts and Topics](#).”

STORE Statement

STORE < **OUT=** > *item-store-name* < / **LABEL=** 'label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “[STORE Statement](#)” on page 501 in Chapter 19, “[Shared Concepts and Topics](#).”

TEST Statement

TEST < *model-effects* > < / *options* > ;

The TEST statement enables you to perform F tests for model effects that test Type I, Type II, or Type III hypotheses. See Chapter 15, “[The Four Types of Estimable Functions](#),” for details about the construction of Type I, II, and III estimable functions.

[Table 66.7](#) summarizes the options available in the TEST statement.

Table 66.7 TEST Statement Options

Option	Description
CHISQ	Requests chi-square tests
DDF=	Specifies denominator degrees of freedom for fixed effects
E	Requests Type I, Type II, and Type III coefficients
E1	Requests Type I coefficients
E2	Requests Type II coefficients
E3	Requests Type III coefficients
HTYPE=	Indicates the type of hypothesis test to perform
INTERCEPT	Adds a row that corresponds to the overall intercept

For details about the syntax of the TEST statement, see the section “[TEST Statement](#)” on page 502 in Chapter 19, “[Shared Concepts and Topics](#).”

WEIGHT Statement

WEIGHT *variable* ;

A WEIGHT statement names a variable in the input data set whose values are relative weights for a weighted least squares regression. If the weight value is proportional to the reciprocal of the variance for each observation, the weighted estimates are the best linear unbiased estimates (BLUE). For a more complete description of the WEIGHT statement, see the section “[WEIGHT Statement](#)” on page 3323 in the GLM procedure.

Details: ORTHOREG Procedure

Missing Values

If there is a missing value for any model variable in an observation, the entire observation is dropped from the analysis.

Output Data Set

The **OUTEST=** option produces a TYPE=EST output SAS data set that contains the BY variables, parameter estimates, and four special variables. For each new value of the BY variables, PROC ORTHOREG outputs an observation to the OUTEST= data set. The variables in the data set are as follows:

- parameter estimates for all variables listed in the [MODEL](#) statement
- BY variables
- `_TYPE_`, which is a character variable with the value PARMS for every observation

- `_NAME_`, which is a character variable left blank for every observation
- `_RMSE_`, which is the root mean square error (the estimate of the standard deviation of the true errors)
- Intercept, which is the estimated intercept. This variable does not exist in the OUTEST= data set if the `NOINT` option is specified.

Displayed Output

PROC ORTHOREG displays the parameter estimates and associated statistics. These include the following:

- overall model analysis of variance, including the error mean square, which is an estimate of σ^2 (the variance of the true errors), and the overall F test for a model effect.
- root mean square error, which is an estimate of the standard deviation of the true errors. It is calculated as the square root of the mean squared error.
- R square (R^2) measures how much variation in the dependent variable can be accounted for by the model. R square, which can range from 0 to 1, is the ratio of the sum of squares for the model to the corrected total sum of squares. In general, the larger the value of R square, the better the model's fit.
- estimates for the parameters in the linear model

The table of parameter estimates consists of the following:

- the terms used as regressors, including the intercept.
- degrees of freedom (DF) for the variable. There is one degree of freedom for each parameter being estimated unless the model is not full rank.
- estimated linear coefficients.
- estimates of the standard errors of the parameter estimates.
- the critical t values for testing whether the parameters are This is computed as the parameter estimate divided by its standard error.
- the two-sided p -value for the t test, which is the probability that a t statistic would obtain a greater absolute value than that observed given that the true parameter is zero.

ODS Table Names

PROC ORTHOREG assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 66.8. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Each of the EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements also creates tables, which are not listed in [Table 66.8](#). For information about these tables, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

Table 66.8 ODS Tables Produced by PROC ORTHOREG

ODS Table Name	Description	Statement
ANOVA	Analysis of variance	Default
FitStatistics	Overall statistics for fit	Default
Levels	Table of class levels	CLASS statement
ParameterEstimates	Parameter estimates	Default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

When ODS Graphics is enabled, then each of the EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots associated with their analyses. For information about these plots, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

Examples: ORTHOREG Procedure

Example 66.1: Precise Analysis of Variance

The data for the following example are from Powell, Murphy, and Gramlich (1982). In order to calibrate an instrument for measuring atomic weight, 24 replicate measurements of the atomic weight of silver (chemical symbol Ag) are made with the new instrument and with a reference instrument.

NOTE: The results from this example vary from machine to machine, depending on floating-point configuration.

The following statements read the measurements for the two instruments into the SAS data set AgWeight:

```

title 'Atomic Weight of Silver by Two Different Instruments';
data AgWeight;
  input Instrument AgWeight @@;
  datalines;
1 107.8681568    1 107.8681465    1 107.8681572    1 107.8681785
1 107.8681446    1 107.8681903    1 107.8681526    1 107.8681494
1 107.8681616    1 107.8681587    1 107.8681519    1 107.8681486
1 107.8681419    1 107.8681569    1 107.8681508    1 107.8681672
1 107.8681385    1 107.8681518    1 107.8681662    1 107.8681424
1 107.8681360    1 107.8681333    1 107.8681610    1 107.8681477
2 107.8681079    2 107.8681344    2 107.8681513    2 107.8681197

;

```

Notice that the variation in the atomic weight measurements is several orders of magnitude less than their mean. This is a situation that can be difficult for standard, regression-based analysis-of-variance procedures to handle correctly.

The following statements invoke the ORTHOREG procedure to perform a simple one-way analysis of variance, testing for differences between the two instruments:

```

proc orthoreg data=AgWeight;
  class Instrument;
  model AgWeight = Instrument;
run;

```

Output 66.1.1 shows the resulting analysis.

Output 66.1.1 PROC ORTHOREG Results for Atomic Weight Example

Atomic Weight of Silver by Two Different Instruments		
The ORTHOREG Procedure		
Class Level Information		
Factor	Levels	-Values-
Instrument	2	1 2

Output 66.1.1 continued

Atomic Weight of Silver by Two Different Instruments					
The ORTHOREG Procedure					
Dependent Variable: AgWeight					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	3.6383419E-9	3.6383419E-9	15.95	0.0002
Error	46	1.0495173E-8	2.281559E-10		
Corrected Total	47	1.4133515E-8			
		Root MSE	0.0000151048		
		R-Square	0.2574265445		
Parameter	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	107.868136354166	3.0832608E-6	3.499E7	<.0001
(Instrument='1')	1	0.00001741249999	4.3603893E-6	3.99	0.0002
(Instrument='2')	0	0	.	.	.

The mean difference between instruments is about 1.74×10^{-5} (the value of the (Instrument='1') parameter in the parameter estimates table), whereas the level of background variation in the measurements is about 1.51×10^{-5} (the value of the root mean square error). At this level of error, the difference is significant, with a p -value of 0.0002.

The National Institute of Standards and Technology (1998) has provided certified ANOVA values for this data set. The following statements use ODS to examine the ANOVA values produced by both the ORTHOREG and GLM procedures more precisely for comparison with the NIST-certified values:

```

ods listing close;

proc orthoreg data=AgWeight;
  class Instrument;
  model AgWeight = Instrument;
  ods output ANOVA          = OrthoregANOVA
             FitStatistics = OrthoregFitStat;
run;

proc glm data=AgWeight;
  class Instrument;
  model AgWeight = Instrument;
  ods output OverallANOVA = GLMANOVA
             FitStatistics = GLMFitStat;
run;
ods listing;

data _null_;
  set OrthoregANOVA (in=inANOVA)
      OrthoregFitStat(in=inFitStat);
  if (inANOVA) then do;
    if (Source = 'Model') then put "Model SS: " ss e20.;
    if (Source = 'Error') then put "Error SS: " ss e20.;
  end;
  if (inFitStat) then do;
    if (Statistic = 'Root MSE') then
      put "Root MSE: " nValue1 e20.;
    if (Statistic = 'R-Square') then
      put "R-Square: " nValue1 best20.;
  end;
run;

data _null_;
  set GLMANOVA (in=inANOVA)
      GLMFitStat(in=inFitStat);
  if (inANOVA) then do;
    if (Source = 'Model') then put "Model SS: " ss e20.;
    if (Source = 'Error') then put "Error SS: " ss e20.;
  end;
  if (inFitStat) then put "Root MSE: " RootMSE e20.;
  if (inFitStat) then put "R-Square: " RSquare best20.;
run;

```

In SAS/STAT software prior to SAS 8, PROC GLM gave much less accurate results than PROC ORTHOREG. [Table 66.9](#) and [Table 66.10](#) compare the ANOVA values certified by NIST with those produced by the two procedures.

Table 66.9 Accuracy Comparison for Sums of Squares

Values	Model SS	Error SS
NIST-certified	3.6383418750000E-09	1.0495172916667E-08
ORTHOREG	3.6383418747907E-09	1.0495172916797E-08

Table 66.9 *continued*

Values	Model SS	Error SS
GLM, since SAS 8	3.6383418747907E-09	1.0495172916797E-08
GLM, before SAS 8	0	1.0331496763990E-08

Table 66.10 Accuracy Comparison for Fit Statistics

Values	Root MSE	R Square
NIST-certified	1.5104831444641E-05	0.25742654453832
ORTHOREG	1.5104831444735E-05	0.25742654452494
GLM, since SAS 8	1.5104831444735E-05	0.25742654452494
GLM, before SAS 8	1.4986585859992E-05	0

Although the PROC ORTHOREG values and the PROC GLM values for the current version are quite close to the certified ones, the PROC GLM values for releases prior to SAS 8 are not. In fact, since the model sum of squares is so small, in prior releases the GLM procedure set it (and consequently R square) to zero.

Example 66.2: Wampler Data

This example applies the ORTHOREG procedure to a collection of data sets noted for being ill-conditioned. The `OUTEST=` data set is used to collect the results for comparison with values certified to be correct by the National Institute of Standards and Technology (1998).

NOTE: The results from this example vary from machine to machine, depending on floating-point configuration.

The data are from Wampler (1970). The independent variates for all five data sets are x^i , $i = 1, \dots, 5$, for $x = 0, 1, \dots, 20$. Two of the five dependent variables are exact linear functions of the independent terms:

$$\begin{aligned} y_1 &= 1 + x + x^2 + x^3 + x^4 + x^5 \\ y_2 &= 1 + 0.1x + 0.01x^2 + 0.001x^3 + 0.0001x^4 + 0.00001x^5 \end{aligned}$$

The other three dependent variables have the same mean value as y_1 , but with nonzero errors:

$$\begin{aligned} y_3 &= y_1 + e \\ y_4 &= y_1 + 100e \\ y_5 &= y_1 + 10000e \end{aligned}$$

where e is a vector of values with standard deviation ~ 2044 , chosen to be orthogonal to the mean model for y_1 .

The following statements create a SAS data set Wampler that contains the Wampler data, run a SAS macro program that uses PROC ORTHOREG to fit a fifth-order polynomial in x to each of the Wampler dependent variables, and collect the results in a data set named ParmEst:

```
data Wampler;
  do x=0 to 20;
    input e @@;
    y1 = 1 +      x      +      x**2 +      x**3
          +      x**4 +      x**5;
    y2 = 1 + .1  *x      + .01  *x**2 + .001*x**3
          + .0001*x**4 + .00001*x**5;
    y3 = y1 +      e;
    y4 = y1 +    100*e;
    y5 = y1 + 10000*e;
    output;
  end;
  datalines;
759 -2048 2048 -2048 2523 -2048 2048 -2048 1838 -2048 2048
-2048 1838 -2048 2048 -2048 2523 -2048 2048 -2048 759
;

%macro WTest;
  data ParmEst; if (0); run;
  %do i = 1 %to 5;
    proc orthoreg data=Wampler outest=ParmEst&i noprint;
      model y&i = x x*x x*x*x x*x*x*x x*x*x*x*x;
      data ParmEst&i; set ParmEst&i; Dep = "y&i";
      data ParmEst; set ParmEst ParmEst&i;
      label Col1='x'      Col2='x**2' Col3='x**3'
            Col4='x**4' Col5='x**5';
    run;
  %end;
%mend;
%WTest;
```

Instead of displaying the raw values of the RMSE and parameter estimates, use an additional DATA step as follows to compute the deviations from the values certified to be correct by the National Institute of Standards and Technology (1998):

```
data ParmEst; set ParmEst;
  if      (Dep = 'y1') then
    _RMSE_ = _RMSE_ - 0.000000000000000;
  else if (Dep = 'y2') then
    _RMSE_ = _RMSE_ - 0.000000000000000;
  else if (Dep = 'y3') then
    _RMSE_ = _RMSE_ - 2360.14502379268;
  else if (Dep = 'y4') then
    _RMSE_ = _RMSE_ - 236014.502379268;
  else if (Dep = 'y5') then
    _RMSE_ = _RMSE_ - 23601450.2379268;
  if (Dep ^= 'y2') then do;
```

```

Intercept = Intercept - 1.000000000000000;
Col1      = Col1      - 1.000000000000000;
Col2      = Col2      - 1.000000000000000;
Col3      = Col3      - 1.000000000000000;
Col4      = Col4      - 1.000000000000000;
Col5      = Col5      - 1.000000000000000;
end;
else do;
Intercept = Intercept - 1.000000000000000;
Col1      = Col1      - 0.100000000000000;
Col2      = Col2      - 0.100000000000000e-1;
Col3      = Col3      - 0.100000000000000e-2;
Col4      = Col4      - 0.100000000000000e-3;
Col5      = Col5      - 0.100000000000000e-4;
end;
run;

proc print data=ParmEst label noobs;
  title 'Wampler data: Deviations from Certified Values';
  format _RMSE_ Intercept Col1-Col5 e9.;
  var Dep _RMSE_ Intercept Col1-Col5;
run;

```

The results, shown in [Output 66.2.1](#), indicate that the values computed by PROC ORTHOREG are quite close to the NIST-certified values.

Output 66.2.1 Wampler Data: Deviations from Certified Values

Wampler data: Deviations from Certified Values							
Dep	_RMSE_	Intercept	x	x**2	x**3	x**4	x**5
y1	0.00E+00	5.46E-12	-9.82E-11	1.55E-11	-5.68E-13	3.55E-14	-6.66E-16

y4	-4.07E-10	-5.38E-10	8.99E-10	-3.29E-10	4.23E-11	-2.27E-12	4.35E-14
y5	-3.35E-08	-4.10E-08	8.07E-08	-2.77E-08	3.54E-09	-1.90E-10	3.64E-12

Example 66.3: Fitting Polynomials

The extra accuracy of the regression algorithm used by PROC ORTHOREG is most useful when the model contains near-singularities that you want to be able to distinguish from true singularities. This example demonstrates this usefulness in the context of fitting polynomials of high degree.

NOTE: The results from this example vary from machine to machine, depending on floating-point configuration.

The following DATA step computes a response y as an exact ninth-degree polynomial function of a predictor x evaluated at 0, 0.01, 0.02, ..., 1.

```

title 'Polynomial Data';
data Polynomial;
  do i = 1 to 101;
    x = (i-1)/(101-1);
    y = 10**(9/2);
    do j = 0 to 8;
      y = y * (x - j/8);
    end;
    output;
  end;
run;

```

The polynomial is constructed in such a way that its zeros lie at $x = i/8$ for $i = 0, \dots, 8$. The following statements use the EFFECT statement to fit a ninth-degree polynomial to this data with PROC ORTHOREG. The EFFECT statement makes it easy to specify complicated polynomial models.

```

ods graphics on;

proc orthoreg data=Polynomial;
  effect xMod = polynomial(x / degree=9);
  model y = xMod;
  effectplot fit / obs;
  store OStore;
run;

ods graphics off;

```

The effect xMod defined by the EFFECT statement refers to all nine degrees of freedom in the ninth-degree polynomial (excluding the intercept term). The resulting output is shown in [Output 66.3.1](#). Note that the R square for the fit is 1, indicating that the ninth-degree polynomial has been correctly fit.

Output 66.3.1 PROC ORTHOREG Results for Ninth-Degree Polynomial

Polynomial Data					
The ORTHOREG Procedure					
Dependent Variable: y					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F

Corrected Total	100	15.527180055			
		Root MSE	1.02156E-11		
		R-Square	1		

Output 66.3.1 continued

Parameter	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	-3.24572035915E-11	8.114115E-12	-4.00	0.0001
x	1	75.9977312440678	4.898326E-10	1.55E11	<.0001
x^2	1	-1652.40781362191	9.5027919E-9	-174E9	<.0001
x^3	1	14249.4539769783	8.3110512E-8	1.71E11	<.0001
x^4	1	-64932.461575205	3.8997072E-7	-167E9	<.0001
x^5	1	173315.359360779	1.066611E-6	1.62E11	<.0001
x^6	1	-280158.03646002	1.7523078E-6	-16E10	<.0001
x^7	1	269781.812887653	1.7021134E-6	1.58E11	<.0001
x^8	1	-142302.494710055	9.0027891E-7	-158E9	<.0001
x^9	1	31622.7766022468	1.997493E-7	1.58E11	<.0001

The fit plot produced by the EFFECTPLOT statement, [Output 66.3.2](#), also demonstrates the perfect fit.

Output 66.3.2 PROC ORTHOREG Fit Plot for Ninth-Degree Polynomial

Finally, you can use the PLM procedure with the fit model saved by the STORE statement in the item store

OStore to check the predicted values for the known zeros of the polynomial, as shown in the following statements:

```
data Zeros(keep=x);
  do j = 0 to 8;
    x = j/8;
    output;
  end;
run;

proc plm restore=OStore noprint;
  score data=Zeros out=OZeros pred=OPred;
run;

proc print noobs;
run;
```

The predicted values of the zeros, shown in [Output 66.3.3](#), are again all miniscule.

Output 66.3.3 Predicted Zeros for Ninth-Degree Polynomial

Polynomial Data	
x	OPred
0.000	-3.2457E-11
0.125	-2.1262E-11
0.250	-9.5867E-12
0.375	-2.2895E-11
0.500	-5.2154E-11
0.625	-1.2329E-10
0.750	-2.5329E-10
0.875	-3.9836E-10
1.000	-5.9663E-10

To compare these results with those from a least squares fit produced by an alternative algorithm, consider fitting a polynomial to this data using the GLM procedure. PROC GLM does not have an EFFECT statement, but the familiar bar notation can still be used to specify a ninth-degree polynomial fairly succinctly, as shown in the following statements:

```
proc glm data=Polynomial;
  model y = x|x|x|x|x|x|x|x|x;
  store GStore;
run;
```

Partial results are shown in [Output 66.3.4](#). In this case, the R square for the fit is only about 0.83, indicating that the full ninth-degree polynomial was not correctly fit.

Output 66.3.4 PROC GLM for Ninth-Degree Polynomial

Polynomial Data					
The GLM Procedure					
Dependent Variable: y					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	8	12.91166643	1.61395830	56.77	<.0001
Error	92	2.61551363	0.02842950		
Corrected Total	100	15.52718006			
	R-Square	Coeff Var	Root MSE	y Mean	
	0.831553	-6.6691E17	0.168610	-0.000000	

The following statements, which use the PLM procedure to compute predictions based on the GLM fit at the true zeros of the polynomial, also confirm that PROC GLM is not able to correctly fit a polynomial of this degree, as shown in [Output 66.3.5](#).

```
proc plm restore=GStore noprint;
  score data=Zeros out=GZeros pred=GPred;
run;

data Zeros;
  merge OZeros GZeros;
run;

proc print noobs;
run;
```

Output 66.3.5 Predicted Zeros for Ninth-Degree Polynomial

Overview: PHREG Procedure

The analysis of survival data requires special techniques because the data are almost always incomplete and familiar parametric assumptions might be unjustifiable. Investigators follow subjects until they reach a prespecified endpoint (for example, death). However, subjects sometimes withdraw from a study, or the study is completed before the endpoint is reached. In these cases, the survival times (also known as failure times) are *censored*; subjects survived to a certain time beyond which their status is unknown. The uncensored survival times are sometimes referred to as *event* times. Methods of survival analysis must account for both censored and uncensored data.

Many types of models have been used for survival data. Two of the more popular types of models are the accelerated failure time model (Kalbfleisch and Prentice 1980) and the Cox proportional hazards model (Cox 1972). Each has its own assumptions about the underlying distribution of the survival times. Two closely related functions often used to describe the distribution of survival times are the survivor function and the hazard function. See the section “[Failure Time Distribution](#)” on page 5608 for definitions. The accelerated failure time model assumes a parametric form for the effects of the explanatory variables and usually assumes a parametric form for the underlying survivor function. The Cox proportional hazards model also assumes a parametric form for the effects of the explanatory variables, but it allows an unspecified form for the underlying survivor function.

The PHREG procedure performs regression analysis of survival data based on the Cox proportional hazards model. Cox’s semiparametric model is widely used in the analysis of survival data to explain the effect of explanatory variables on hazard rates.

The survival time of each member of a population is assumed to follow its own hazard function, $\lambda_i(t)$, expressed as

$$\lambda_i(t) = \lambda(t; \mathbf{Z}_i) = \lambda_0(t) \exp(\mathbf{Z}_i' \boldsymbol{\beta})$$

where $\lambda_0(t)$ is an arbitrary and unspecified baseline hazard function, \mathbf{Z}_i is the vector of explanatory variables for the i th individual, and $\boldsymbol{\beta}$ is the vector of unknown regression parameters that is associated with the explanatory variables. The vector $\boldsymbol{\beta}$ is assumed to be the same for all individuals. The survivor function can be expressed as

$$S(t; \mathbf{Z}_i) = [S_0(t)]^{\exp(\mathbf{Z}_i' \boldsymbol{\beta})}$$

where $S_0(t) = \exp(-\int_0^t \lambda_0(u) du)$ is the baseline survivor function. To estimate $\boldsymbol{\beta}$, Cox (1972, 1975) introduced the partial likelihood function, which eliminates the unknown baseline hazard $\lambda_0(t)$ and accounts for censored survival times.

The partial likelihood of Cox also allows time-dependent explanatory variables. An explanatory variable is time-dependent if its value for any given individual can change over time. Time-dependent variables have many useful applications in survival analysis. You can use a time-dependent variable to model the effect of subjects changing treatment groups. Or you can include time-dependent variables such as blood pressure or blood chemistry measures that vary with time during the course of a study. You can also use time-dependent variables to test the validity of the proportional hazards model.

An alternative way to fit models with time-dependent explanatory variables is to use the counting process style of input. The counting process formulation enables PROC PHREG to fit a superset of the Cox model,

known as the multiplicative hazards model. This extension also includes recurrent events data and left-truncation of failure times. The theory of these models is based on the counting process pioneered by Andersen and Gill (1982), and the model is often referred to as the Andersen-Gill model.

Multivariate failure-time data arise when each study subject can potentially experience several events (for example, multiple infections after surgery) or when there exists some natural or artificial clustering of subjects (for example, a litter of mice) that induces dependence among the failure times of the same cluster. Data in the former situation are referred to as multiple events data, which include recurrent events data as a special case; data in the latter situation are referred to as clustered data. You can use PROC PHREG to carry out various methods of analyzing these data.

The population under study can consist of a number of subpopulations, each of which has its own baseline hazard function. PROC PHREG performs a stratified analysis to adjust for such subpopulation differences. Under the stratified model, the hazard function for the j th individual in the i th stratum is expressed as

$$\lambda_{ij}(t) = \lambda_{i0}(t) \exp(\mathbf{Z}_{ij}'\boldsymbol{\beta})$$

where $\lambda_{i0}(t)$ is the baseline hazard function for the i th stratum and \mathbf{Z}_{ij} is the vector of explanatory variables for the individual. The regression coefficients are assumed to be the same for all individuals across all strata.

Ties in the failure times can arise when the time scale is genuinely discrete or when survival times that are generated from the continuous-time model are grouped into coarser units. The PHREG procedure includes four methods of handling ties. The *discrete* logistic model is available for discrete time-scale data. The other three methods apply to continuous time-scale data. The *exact* method computes the exact conditional probability under the model that the set of observed tied event times occurs before all the censored times with the same value or before larger values. *Breslow* and *Efron* methods provide approximations to the exact method.

Variable selection is a typical exploratory exercise in multiple regression when the investigator is interested in identifying important prognostic factors from a large number of candidate variables. The PHREG procedure provides four selection methods: forward selection, backward elimination, stepwise selection, and best subset selection. The best subset selection method is based on the likelihood score statistic. This method identifies a specified number of best models that contain one, two, or three variables and so on, up to the single model that contains all of the explanatory variables.

The PHREG procedure also enables you to do the following: include an offset variable in the model; weight the observations in the input data; test linear hypotheses about the regression parameters; perform conditional logistic regression analysis for matched case-control studies; output survivor function estimates, residuals, and regression diagnostics; and estimate and plot the survivor function for a new set of covariates.

PROC PHREG can also be used to fit the multinomial logit choice model to discrete choice data. See http://support.sas.com/resources/papers/tnote/tnote_marketresearch.html for more information about discrete choice modeling and the multinomial logit model. Look for the “Discrete Choice” report.

The PHREG procedure uses ODS Graphics to create graphs as part of its output. For example, the ASSESS statement uses a graphical method that uses ODS Graphics to check the adequacy of the model. See Chapter 21, “[Statistical Graphics Using ODS](#),” for general information about ODS Graphics.

For both the BASELINE and OUTPUT statements, the default method of estimating a survivor function has changed to the Breslow (1972) estimator—that is, METHOD=CH. The option NOMEAN that was available

in the BASELINE statement prior to SAS/STAT 9.2 has become obsolete—that is, requested statistics at the sample average values of the covariates are no longer computed and added to the OUT= data set. However, if the COVARIATES= data set is not specified, the requested statistics are computed and output for the covariate set that consists of the reference levels for the CLASS variables and sample averages for the continuous variable. In addition to the requested statistics, the OUT= data set also contains all variables in the COVARIATES= data set.

The remaining sections of this chapter contain information about how to use PROC PHREG, information about the underlying statistical methodology, and some sample applications of the procedure. The section “Getting Started: PHREG Procedure” on page 5543 introduces PROC PHREG with two examples. The section “Syntax: PHREG Procedure” on page 5553 describes the syntax of the procedure. The section “Details: PHREG Procedure” on page 5608 summarizes the statistical techniques used in PROC PHREG. The section “Examples: PHREG Procedure” on page 5678 includes eight additional examples of useful applications. Experienced SAS/STAT software users might decide to proceed to the “Syntax” section, while other users might choose to read both the “Getting Started” and “Examples” sections before proceeding to “Syntax” and “Details.”

Getting Started: PHREG Procedure

This section uses the two-sample vaginal cancer mortality data from Kalbfleisch and Prentice (1980, p. 2) in two examples to illustrate some of the basic features of PROC PHREG. The first example carries out a classical Cox regression analysis and the second example performs a Bayesian analysis of the Cox model.

Two groups of rats received different pretreatment regimes and then were exposed to a carcinogen. Investigators recorded the survival times of the rats from exposure to mortality from vaginal cancer. Four rats died of other causes, so their survival times are censored. Interest lies in whether the survival curves differ between the two groups.

The following DATA step creates the data set Rats, which contains the variable Days (the survival time in days), the variable Status (the censoring indicator variable: 0 if censored and 1 if not censored), and the variable Group (the pretreatment group indicator).

```
data Rats;
  label Days = 'Days from Exposure to Death';
  input Days Status Group @@;
  datalines;
143 1 0   164 1 0   188 1 0   188 1 0
190 1 0   192 1 0   206 1 0   209 1 0
213 1 0   216 1 0   220 1 0   227 1 0
230 1 0   234 1 0   246 1 0   265 1 0
304 1 0   216 0 0   244 0 0   142 1 1
156 1 1   163 1 1   198 1 1   205 1 1
232 1 1   232 1 1   233 1 1   233 1 1
233 1 1   233 1 1   239 1 1   240 1 1
261 1 1   280 1 1   280 1 1   296 1 1
296 1 1   323 1 1   204 0 1   344 0 1
;
```

By using ODS Graphics, PROC PHREG allows you to plot the survival curve for Group=0 and the survival curve for Group=1, but first you must save these two covariate values in a SAS data set as in the following DATA step:

```
data Regimes;
  Group=0;
  output;
  Group=1;
  output;
run;
```

Classical Method of Maximum Likelihood

PROC PHREG fits the Cox model by maximizing the partial likelihood and computes the baseline survivor function by using the Breslow (1972) estimate. The following statements produce [Figure 67.1](#) and [Figure 67.2](#):

```
ods graphics on;
proc phreg data=Rats plot(overlay)=survival;
  model Days*Status(0)=Group;
  baseline covariates=regimes out=_null_;
run;
ods graphics off;
```

In the MODEL statement, the response variable, Days, is crossed with the censoring variable, Status, with the value that indicates censoring is enclosed in parentheses. The values of Days are considered censored if the value of Status is 0; otherwise, they are considered event times.

Graphs are produced when ODS Graphics is enabled. The survival curves for the two observations in the data set Regime, specified in the COVARIATES= option in the BASELINE statement, are requested through the PLOTS= option with the OVERLAY option for overlaying both survival curves in the same plot.

[Figure 67.2](#) shows a typical printed output of a classical analysis. Since Group takes only two values, the null hypothesis for no difference between the two groups is identical to the null hypothesis that the regression coefficient for Group is 0. All three tests in the “Testing Global Null Hypothesis: BETA=0” table (see the section “[Testing the Global Null Hypothesis](#)” on page 5625) suggest that the survival curves for the two pretreatment groups might not be the same. In this model, the hazard ratio (or risk ratio) for Group, defined as the exponentiation of the regression coefficient for Group, is the ratio of the hazard functions between the two groups. The estimate is 0.551, implying that the hazard function for Group=1 is smaller than that for Group=0. In other words, rats in Group=1 lived longer than those in Group=0. This conclusion is also revealed in the plot of the survivor functions in [Figure 67.2](#).

Figure 67.2 Survivorship for the Two Pretreatment Regimes

In this example, the comparison of two survival curves is put in the form of a proportional hazards model. This approach is essentially the same as the log-rank (Mantel-Haenszel) test. In fact, if there are no ties in the survival times, the likelihood score test in the Cox regression analysis is identical to the log-rank test. The advantage of the Cox regression approach is the ability to adjust for the other variables by including them in the model. For example, the present model could be expanded by including a variable that contains the initial body weights of the rats.

Next, consider a simple test of the validity of the proportional hazards assumption. The proportional hazards model for comparing the two pretreatment groups is given by the following:

$$\lambda(t) = \begin{cases} \lambda_0(t) & \text{if GROUP} = 0 \\ \lambda_0(t)e^{\beta_1} & \text{if GROUP} = 1 \end{cases}$$

The ratio of hazards is e^{β_1} , which does not depend on time. If the hazard ratio changes with time, the proportional hazards model assumption is invalid. Simple forms of departure from the proportional hazards model can be investigated with the following time-dependent explanatory variable $x = x(t)$:

$$x(t) = \begin{cases} 0 & \text{if GROUP} = 0 \\ \log(t) - 5.4 & \text{if GROUP} = 1 \end{cases}$$

Here, $\log(t)$ is used instead of t to avoid numerical instability in the computation. The constant, 5.4, is the average of the logs of the survival times and is included to improve interpretability. The hazard ratio in the two groups then becomes $e^{\beta_1 - 5.4\beta_2 t^{\beta_2}}$, where β_2 is the regression parameter for the time-dependent variable x . The term e^{β_1} represents the hazard ratio at the geometric mean of the survival times. A nonzero value of β_2 would imply an increasing ($\beta_2 > 0$) or decreasing ($\beta_2 < 0$) trend in the hazard ratio with time.

The following statements implement this simple test of the proportional hazards assumption. The MODEL statement includes the time-dependent explanatory variable X, which is defined subsequently by the programming statement. At each event time, subjects in the risk set (those alive just before the event time) have their X values changed accordingly.

```
proc phreg data=Rats;
  model Days*Status(0)=Group X;
  X=Group*(log(Days) - 5.4);
run;
```

The analysis of the parameter estimates is displayed in Figure 67.3. The Wald chi-square statistic for testing the null hypothesis that $\beta_2 = 0$ is 0.0158. The statistic is not statistically significant when compared to a chi-square distribution with one degree of freedom ($p = 0.8999$). Thus, you can conclude that there is no evidence of an increasing or decreasing trend over time in the hazard ratio.

Figure 67.3 A Simple Test of Trend in the Hazard Ratio

The PHREG Procedure						
Analysis of Maximum Likelihood Estimates						
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
Group	1	-0.59976	0.34837	2.9639	0.0851	0.549
X	1	-0.22952	1.82489	0.0158	0.8999	0.795

Bayesian Analysis

PROC PHREG uses the partial likelihood of the Cox model as the likelihood and generates a chain of posterior distribution samples by the Gibbs Sampler. Summary statistics, convergence diagnostics, and diagnostic plots are provided for each parameter. The following statements generate Figure 67.4–Figure 67.10:

```
ods graphics on;
proc phreg data=Rats;
  model Days*Status(0)=Group;
  bayes seed=1 outpost=Post;
run;
ods graphics off;
```

The BAYES statement invokes the Bayesian analysis. The SEED= option is specified to maintain reproducibility; the OUTPOST= option saves the posterior distribution samples in a SAS data set for post-

processing; no other options are specified in the BAYES statement. By default, a uniform prior distribution is assumed on the regression coefficient Group. The uniform prior is a flat prior on the real line with a distribution that reflects ignorance of the location of the parameter, placing equal probability on all possible values the regression coefficient can take. Using the uniform prior in the following example, you would expect the Bayesian estimates to resemble the classical results of maximizing the likelihood. If you can elicit an informative prior on the regression coefficients, you should use the COEFFPRIOR= option to specify it.

You should make sure that the posterior distribution samples have achieved convergence before using them for Bayesian inference. PROC PHREG produces three convergence diagnostics by default. If ODS Graphics is enabled before calling PROC PHREG as in the preceding program, diagnostics plots are also displayed.

The results of this analysis are shown in the following figures.

The “Model Information” table in [Figure 67.4](#) summarizes information about the model you fit and the size of the simulation.

Figure 67.4 Model Information

The PHREG Procedure		
Bayesian Analysis		
Model Information		
Data Set	WORK.RATS	
Dependent Variable	Days	Days from Exposure to Death
Censoring Variable	Status	
Censoring Value(s)	0	
Model	Cox	
Ties Handling	BRESLOW	
Sampling Algorithm	ARMS	
Burn-In Size	2000	
MC Sample Size	10000	
Thinning	1	

PROC PHREG first fits the Cox model by maximizing the partial likelihood. The only parameter in the model is the regression coefficient of Group. The maximum likelihood estimate (MLE) of the parameter and its 95% confidence interval are shown in [Figure 67.5](#).

Figure 67.5 Classical Parameter Estimates

Maximum Likelihood Estimates					
Parameter	DF	Estimate	Standard Error	95% Confidence Limits	
Group	1	-0.5959	0.3484	-1.2788	0.0870

Since no prior is specified for the regression coefficient, the default uniform prior is used. This information is displayed in the “Uniform Prior for Regression Coefficients” table in [Figure 67.6](#).

Figure 67.6 Coefficient Prior

Uniform Prior for Regression Coefficients	
Parameter	Prior
Group	Constant

The “Fit Statistics” table in [Figure 67.7](#) lists information about the fitted model. The table displays the DIC (deviance information criterion) and pD (effective number of parameters). See the section “[Fit Statistics](#)” on page 5662 for details.

Figure 67.7 Fit Statistics

Fit Statistics	
DIC (smaller is better)	203.444
pD (Effective Number of Parameters)	1.003

Summary statistics of the posterior samples are displayed in the “Posterior Summaries” table and “Posterior Intervals” table as shown in [Figure 67.8](#). Note that the mean and standard deviation of the posterior samples are comparable to the MLE and its standard error, respectively, due to the use of the uniform prior.

Figure 67.8 Summary Statistics

The PHREG Procedure						
Bayesian Analysis						
Posterior Summaries						
Parameter	N	Mean	Standard Deviation	25%	Percentiles 50%	75%
Group	10000	-0.5998	0.3511	-0.8326	-0.5957	-0.3670
Posterior Intervals						
Parameter	Alpha	Equal-Tail Interval		HPD Interval		
Group	0.050	-1.3042	0.0721	-1.2984	0.0756	

PROC PHREG provides diagnostics to assess the convergence of the generated Markov chain. [Figure 67.9](#) shows three of these diagnostics: the lag1, lag5, lag10, and lag50 autocorrelations; the Geweke diagnostic; and the effective sample size. There is no indication that the Markov chain has not reached convergence. See the section “[Statistical Diagnostic Tests](#)” on page 144 for information about interpreting these diagnostics.

Figure 67.9 Convergence Diagnostics

The PHREG Procedure				
Bayesian Analysis				
Posterior Autocorrelations				
Parameter	Lag 1	Lag 5	Lag 10	Lag 50
Group	-0.0079	0.0091	-0.0161	0.0101
Geweke Diagnostics				
Parameter	z	Pr > z		
Group	0.0149	0.9881		
Effective Sample Sizes				
Parameter	ESS	Autocorrelation		Efficiency
		Time		
Group	10000.0	1.0000	1.0000	

You can also assess the convergence of the generated Markov chain by examining the trace plot, the autocorrelation function plot, and the posterior density plot. [Figure 67.10](#) displays a panel of these three plots for the parameter Group. This graphical display is automatically produced when ODS Graphics is enabled. Note that the trace of the samples centers on -0.6 with only small fluctuations, the autocorrelations are quite small, and the posterior density appears bell-shaped—all exemplifying the behavior of a converged Markov chain.

Figure 67.10 Diagnostic Plots

The proportional hazards model for comparing the two pretreatment groups is

$$\lambda(t) = \begin{cases} \lambda_0(t) & \text{if Group}=0 \\ \lambda_0(t)e^{\beta} & \text{if Group}=1 \end{cases}$$

The probability that the hazard of Group=0 is greater than that of Group=1 is

$$\Pr(\lambda_0(t) > \lambda_0(t)e^{\beta}) = \Pr(\beta < 0)$$

This probability can be enumerated from the posterior distribution samples by computing the fraction of samples with a coefficient less than 0. The following DATA step and PROC MEANS perform this calculation:

```
data New;
  set Post;
  Indicator=(Group < 0);
  label Indicator='Group < 0';
run;
proc means data=New(keep=Indicator) n mean;
run;
```

Figure 67.11 Prob(Hazard(Group=0) > Hazard(Group=1))

The MEANS Procedure	
Analysis Variable : Indicator Group < 0	
N	Mean
10000	0.9581000

The PROC MEANS results are displayed in [Figure 67.11](#). There is a 95.8% chance that the hazard rate of Group=0 is greater than that of Group=1. The result is consistent with the fact that the average survival time of Group=0 is less than that of Group=1.

Syntax: PHREG Procedure

The following statements are available in the PHREG procedure. Items within *< >* are optional.

```

PROC PHREG < options > ;
  ASSESS keyword </ options > ;
  BASELINE < OUT=SAS-data-set > < COVARIATES=SAS-data-set >
    < keyword=name ... keyword=name > </ options > ;
  BAYES < options > ;
  BY variables ;
  CLASS variable < (options) > < ... variable < (options) > > </ options > ;
  CONTRAST < 'label' > effect values < , ... , effect values > </ options > ;
  FREQ variable ;
  EFFECT name = effect-type (variables </ options >) ;
  ESTIMATE < 'label' > estimate-specification </ options > ;
  HAZARDRATIO < 'label' > variable </ options > ;
  ID variables ;
  LSMEANS < model-effects > </ options > ;
  LSMESTIMATE model-effect lsestimate-specification </ options > ;
  MODEL response < * censor(list) > = < effects > </ options > ;
  OUTPUT < OUT=SAS-data-set > < keyword=name ... keyword=name > </ options > ;
  Programming statements ;
  RANDOM variable </ options > ;
  SLICE model-effect </ options > ;
  STORE < OUT= > item-store-name </ LABEL='label' > ;
  STRATA variable < (list) > < ... variable < (list) > > </ option > ;
  < label: > TEST equation < , ... , equation > </ options > ;
  WEIGHT variable </ option > ;

```

The PROC PHREG and MODEL statements are required. The CLASS statement, if present, must precede the MODEL statement, and the ASSESS or CONTRAST statement, if present, must come after the MODEL statement. The BAYES statement, that invokes a Bayesian analysis, is not compatible with the ASSESS, CONTRAST, ID, OUTPUT, and TEST statements, as well as a number of options in the PROC PHREG and MODEL statements. See the section “[Specifics for Bayesian Analysis](#)” on page 5653 for details.

The rest of this section provides detailed syntax information for each statement, beginning with the PROC PHREG statement. The remaining statements are covered in alphabetical order.

PROC PHREG Statement

PROC PHREG < options > ;

The PROC PHREG statement invokes the PHREG procedure. Table 67.1 summarizes the options available in the PROC PHREG statement.

Table 67.1 PROC PHREG Statement Options

Option	Description
ALPHA=	Specifies the level of significance
ATRISK	Displays a table that contains the number of units and the corresponding number of events in the risk sets
COVM	Uses the model-based covariance matrix in the analysis
COVOUT	Adds the estimated covariance matrix to the OUTEST= data set
COVSANDWICH	Requests the robust sandwich estimate for the covariance matrix
DATA=	Names the SAS data set to be analyzed
INEST=	Names the SAS data set that contains initial estimates
MULTIPASS	Recompiles the risk sets
NAMELEN=	Specifies the length of effect names
NOPRINT	Suppresses all displayed output
NOSUMMARY	Suppresses the summary display observation frequencies
OUTEST=	Creates an output SAS data set containing estimates of the regression coefficients
PLOTS	Controls the plots produced through ODS Graphics
SIMPLE	Displays simple descriptive statistics

You can specify the following *options* in the PROC PHREG statement.

ALPHA=*number*

specifies the level of significance α for $100(1 - \alpha)\%$ confidence intervals. The value *number* must be between 0 and 1; the default value is 0.05, which results in 95% intervals. This value is used as the default confidence level for limits computed by the BASELINE, BAYES, CONTRAST, HAZARDRATIO, and MODEL statements. You can override this default by specifying the ALPHA= option in the separate statements.

ATRISK

displays a table that contains the number of units at risk at each event time and the corresponding number of events in the risk sets. For example, the following risk set information is displayed if the ATRISK option is specified in the example in the section “Getting Started: PHREG Procedure” on page 5543.

Risk Set Information		
Number of Units		
Days	At Risk	Event
142	40	1
143	39	1
156	38	1
⋮	⋮	⋮
296	5	2
304	3	1
323	2	1

COVOUT

adds the estimated covariance matrix of the parameter estimates to the OUTEST= data set. The COVOUT option has no effect unless the OUTEST= option is specified.

COVM

requests that the model-based covariance matrix (which is the inverse of the observed information matrix) be used in the analysis if the COVS option is also specified. The COVM option has no effect if the COVS option is not specified.

COVSANDWICH <(AGGREGATE)>**COVS <(AGGREGATE)>**

requests the robust sandwich estimate of Lin and Wei (1989) for the covariance matrix. When this option is specified, this robust sandwich estimate is used in the Wald tests for testing the global null hypothesis, null hypotheses of individual parameters, and the hypotheses in the CONTRAST and TEST statements. In addition, a modified score test is computed in the testing of the global null hypothesis, and the parameter estimates table has an additional StdErrRatio column, which contains the ratios of the robust estimate of the standard error relative to the corresponding model-based estimate. Optionally, you can specify the keyword AGGREGATE enclosed in parentheses after the COVSANDWICH (or COVS) option, which requests a summing up of the score residuals for each distinct ID pattern in the computation of the robust sandwich covariance estimate. This AGGREGATE option has no effect if the ID statement is not specified.

DATA=SAS-data-set

names the SAS data set that contains the data to be analyzed. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

INEST=SAS-data-set

names the SAS data set that contains initial estimates for all the parameters in the model. BY-group processing is allowed in setting up the INEST= data set. See the section “[INEST= Input Data Set](#)” on page 5665 for more information.

MULTIPASS

requests that, for each Newton-Raphson iteration, PROC PHREG recompile the risk sets corresponding to the event times for the (start,stop) style of response and recomputes the values of the time-dependent variables defined by the programming statements for each observation in the risk sets. If the MULTIPASS option is not specified, PROC PHREG computes all risk sets and all the variable values and saves them in a utility file. The MULTIPASS option decreases required disk space at the

expense of increased execution time; however, for very large data, it might actually save time since it is time-consuming to write and read large utility files. This option has an effect only when the (start,stop) style of response is used or when there are time-dependent explanatory variables.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

NOPRINT

suppresses all displayed output. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

NOSUMMARY

suppresses the summary display of the event and censored observation frequencies.

OUTEST=SAS-data-set

creates an output SAS data set that contains estimates of the regression coefficients. The data set also contains the convergence status and the log likelihood. If you use the COVOUT option, the data set also contains the estimated covariance matrix of the parameter estimators. See the section “[OUTEST= Output Data Set](#)” on page 5664 for more information.

PLOTS<(global-plot-options)> = plot-request

PLOTS<(global-plot-options)> = (plot-request <...<plot-request> >)

controls the baseline functions plots produced through ODS Graphics. Each observation in the COVARIATES= data set in the BASELINE statement represents a set of covariates for which a curve is produced for each *plot-request* and for each stratum. You can use the ROWID= option in the BASELINE statement to specify a variable in the COVARIATES= data set for identifying the curves produced for the covariate sets. If the ROWID= option is not specified, the curves produced are identified by the covariate values if there is only a single covariate or by the observation numbers of the COVARIATES= data set if the model has two or more covariates. If the COVARIATES= data set is not specified, a reference set of covariates consisting of the reference levels for the CLASS variables and the average values for the continuous variables is used. For plotting more than one curve, you can use the OVERLAY= option to group the curves in separate plots. When you specify one *plot-request*, you can omit the parentheses around the plot request. Here are some examples:

```
plots=survival
plots=(survival cumhaz)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc phreg plots(cl)=survival;
  model Time*Status(0)=X1-X5;
  baseline covariates=One;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The *global-plot-options* include the following:

CL=<EQTAIL | HPD>

displays the pointwise interval limits for the specified curves. For the classical analysis, CL displays the confidence limits. For the Bayesian analysis, CL=EQTAIL displays the equal-tail credible limits and CL=HPD displays the HPD limits. Specifying just CL in a Bayesian analysis defaults to CL=HPD.

OVERLAY <=overlay-option>

specifies how the curves for the various strata and covariate sets are overlaid. If the STRATA statement is not specified, specifying OVERLAY without any option will overlay the curves for all the covariate sets. The available *overlay-options* are as follows:

BYGROUP

GROUP

overlays, for each stratum, all curves for the covariate sets that have the same **GROUP=** value in the COVARIATES= data set in the same plot.

INDIVIDUAL

IND

displays, for each stratum, a separate plot for each covariate set.

BYROW

ROW

displays, for each covariate set, a separate plot containing the curves for all the strata.

BYSTRATUM

STRATUM

displays, for each stratum, a separate plot containing the curves for all sets of covariates.

The default is OVERLAY=BYGROUP if the **GROUP=** option is specified in the BASELINE statement or if the COVARIATES= data set contains the **_GROUP_** variable; otherwise the default is OVERLAY=INDIVIDUAL.

TIMERANGE=(<min> <,max>)

TIMERANGE=<min> <,max>

RANGE=(<min> <,max>)

RANGE=<min> <,max>

specifies the range of values on the time axis to clip the display. The *min* and *max* values are the lower and upper bounds of the range. By default, *min* is 0 and *max* is the largest event time.

The *plot-requests* include the following:

CUMHAZ

plots the estimated cumulative hazard function for each set of covariates in the COVARIATES= data set in the BASELINE statement. If the COVARIATES= data set is not specified, the estimated cumulative hazard function is plotted for the reference set of covariates consisting of reference levels for the CLASS variables and average values for the continuous variables.

MCF

plots the estimated mean cumulative function for each set of covariates in the COVARIATES= data set in the BASELINE statement. If the COVARIATES= data set is not specified, the estimated mean cumulative function is plotted for the reference set of covariates consisting of reference levels for the CLASS variables and average values for the continuous variables.

NONE

suppresses all the plots in the procedure. Specifying this option is equivalent to disabling ODS Graphics for the entire procedure.

SURVIVAL

plots the estimated survivor function for each set of covariates in the COVARIATES= data set in the BASELINE statement. If COVARIATES= data set is not specified, the estimated survivor function is plotted for the reference set of covariates consisting of reference levels for the CLASS variables and average values for the continuous variables.

SIMPLE

displays simple descriptive statistics (mean, standard deviation, minimum, and maximum) for each explanatory variable in the MODEL statement.

ASSESS Statement

ASSESS <VAR=(list)> <PH> </ options> ;

The ASSESS statement performs the graphical and numerical methods of Lin, Wei, and Ying (1993) for checking the adequacy of the Cox regression model. The methods are derived from cumulative sums of martingale residuals over follow-up times or covariate values. You can assess the functional form of a covariate or you can check the proportional hazards assumption for each covariate in the Cox model. PROC PHREG uses ODS Graphics for the graphical displays. You must specify at least one of the following options to create an analysis.

VAR=(variable-list)

specifies the list of explanatory variables for which their functional forms are assessed. For each variable on the list, the observed cumulative martingale residuals are plotted against the values of the explanatory variable along with 20 (or n if NPATHS= n is specified) simulated residual patterns.

PROPORTIONALHAZARDS**PH**

requests the checking of the proportional hazards assumption. For each explanatory variable in the model, the observed score process component is plotted against the follow-up time along with 20 (or n if NPATHS= n is specified) simulated patterns.

The following options can be specified after a slash (/):

NPATHS= n

specifies the number of simulated residual patterns to be displayed in a cumulative martingale residual plot or a score process plot. The default is $n=20$.

CRPANEL

requests that a plot with four panels, each containing the observed cumulative martingale residuals and two simulated residual patterns, be created.

RESAMPLE *<=n>*

requests that the Kolmogorov-type supremum test be computed on 1,000 simulated patterns or on *n* simulated patterns if *n* is specified.

SEED=*n*

specifies an integer seed for the random number generator used in creating simulated realizations for plots and for the Kolmogorov-type supremum tests. Specifying a seed enables you to reproduce identical graphs and *p*-values for the model assessments from the same PHREG specification. If the SEED= option is not specified, or if you specify a nonpositive seed, a random seed is derived from the time of day.

BASELINE Statement

BASELINE *<OUT=SAS-data-set>* *<OUTDIFF=SAS-data-set>* *<COVARIATES=SAS-data-set>*
<TIMELIST=list> *<keyword=name . . . keyword=name>* *</options>* ;

The BASELINE statement creates a SAS data set (named by the OUT= option) that contains the baseline function estimates at the event times of each stratum for every set of covariates in the COVARIATES= data set. If the COVARIATES= data set is not specified, a reference set of covariates consisting of the reference levels for the CLASS variables and the average values for the continuous variables is used. You can use the DIRADJ option to obtain the direct adjusted survival curve that averages the estimated survival curves for the observations in the COVARIATES= data set. No BASELINE data set is created if the model contains a time-dependent variable defined by means of programming statement.

Table 67.2 summarizes the options available in the BASELINE statement.

Table 67.2 BASELINE Statement Options

Option	Description
Data Set and Time List Options	
OUT=	Specifies the output BASELINE data set
OUTDIFF=	Specifies the output data set that contains differences of direct adjusted survival curves
COVARIATES=	Specifies the SAS data set that contains the explanatory variables
TIMELIST=	Specifies a list of time points for Bayesian computation of survival estimates.
Keyword Options	
CMF=	Specifies the cumulative mean function estimate
CUMHAZ=	Specifies the cumulative hazard function estimate
LOGLOGS=	Specifies the log of the negative log of SURVIVAL
LOGSURV=	Specifies the log of SURVIVAL
LOWERCMF=	Specifies the lower pointwise confidence limit for CMF
LOWERCUMHAZ=	specifies the lower pointwise confidence limit for CUMHAZ

Table 67.2 continued

Options	Description
LOWERHPDCUMHAZ=	Specifies the lower limit of the HPD interval for CUMHAZ
LOWERHPD=	Specifies the lower limit of the HPD interval for SURVIVAL
LOWER=	Specifies the lower pointwise confidence limit for SURVIVAL
STDCMF=	Specifies the estimated standard error of CMF
STDCUMHAZ=	Specifies the estimated standard error of CUMHAZ
STDERR=	Specifies the standard error of SURVIVAL
STDXBETA=	Specifies the estimated standard error of the linear predictor estimator
SURVIVAL=	Specifies the survivor function estimate
UPPERCMF=	Specifies the upper pointwise confidence limit for CMF
UPPERCUMHAZ=	Specifies the upper pointwise confidence limit for CUMHAZ
UPPERHPDCUMHAZ=	Specifies the upper limit of the HPD interval for CUMHAZ
UPPERHPD=	Specifies the upper limit of the HPD interval for SURVIVAL
UPPER=	Specifies the upper pointwise confidence limit for SURVIVAL
XBETA=	Specifies the estimate of the linear predictor $\mathbf{x}'\boldsymbol{\beta}$
Other Options	
ALPHA=	Specifies the significance level of the confidence interval for the survivor function
CLTYPE=	Specifies the method used to compute the confidence limits
DIRADJ	Computes direct adjusted survival curves
GROUP=	Names a variable whose values are used to identify or group the survival curves
METHOD=	Specifies the method used to compute the survivor function estimates
ROWID=	Names the variable in the COVARIATES= data set for identifying the baseline functions curves in the plots

The following options are available in the BASELINE statement.

OUT=SAS-data-set

names the output BASELINE data set. If you omit the OUT= option, the data set is created and given a default name by using the *DATA**n* convention. See the section “[OUT= Output Data Set in the BASELINE Statement](#)” on page 5665 for more information.

OUTDIFF=SAS-data-set

names the output data set that contains all pairwise differences of direct adjusted probabilities between groups if the **GROUP=** variable is specified, or between strata if the **GROUP=** variable is not specified. It is required that the **DIRADJ** option be specified to use the OUTDIFF= option.

COVARIATES=SAS-data-set

names the SAS data set that contains the sets of explanatory variable values for which the quantities of interest are estimated. All variables in the COVARIATES= data set are copied to the OUT= data set. Thus, any variable in the COVARIATES= data set can be used to identify the covariate sets in the OUT= data set.

TIMELIST=*list*

specifies a list of time points at which the survival function estimates and cumulative hazard function estimates are computed. The following specifications are equivalent:

```
timelist=5,20 to 50 by 10
timelist=5 20 30 40 50
```

If the TIMELIST= option is not specified, the default is to carry out the prediction at all event times and at time 0. This option can be used only for the Bayesian analysis.

keyword=*name*

specifies the statistics to be included in the OUT= data set and assigns names to the variables that contain these statistics. Specify a *keyword* for each desired statistic, an equal sign, and the name of the variable for the statistic. Not all *keywords* listed in [Table 67.3](#) (and discussed in the text that follows) are appropriate for both the classical analysis and the Bayesian analysis; and the table summarizes the choices for each analysis.

Table 67.3 Summary of the Keyword Choices

Keyword	Classical	Bayesian
Survivor Function		
SURVIVAL=	X	X
STDERR=	X	X
LOWER=	X	X
UPPER=	X	X
LOWERHPD=		X
UPPERHPD=		X
Cumulative Hazard Function		
CUMHAZ=	X	X
STDCUMHAZ=	X	X
LOWERCUMHAZ=	X	X
UPPERCUMHAZ=	X	X
LOWERHPDCUMHAZ=		X
UPPERHPDCUMHAZ=		X
Cumulative Mean Function		
CMF=	X	
STDCMF=	X	
LOWERCMF=	X	
UPPERCMF=	X	
Others		
XBETA=	X	X
STDXBETA=	X	X
LOGSURV=	X	
LOGLOGS=	X	

The available *keywords* are as follows.

CMF=

MCF=

specifies the cumulative mean function estimate for recurrent events data. Specifying **CMF=_ALL_** is equivalent to specifying **CMF=CMF**, **STDCMF=StdErrCMF**, **LOWERCMF=LowerCMF**, and **UPPERCMF=UpperCMF**. Nelson (2002) refers to the mean function estimate as MCF (mean cumulative function).

CUMHAZ=

specifies the cumulative hazard function estimate. Specifying **CUMHAZ=_ALL_** is equivalent to specifying **CUMHAZ=CumHaz**, **STDCUMHAZ=StdErrCumHaz**, **LOWERCUMHAZ=LowerCumHaz**, and **UPPERCUMHAZ=UpperCumHaz**. For a Bayesian analysis, **CUMHAZ=_ALL_** also includes **LOWERHPDCUMHAZ=LowerHPDCumHaz** and **UpperHPDCUMHAZ=UpperHPDCumHaz**.

LOGLOGS=

specifies the log of the negative log of **SURVIVAL**.

LOGSURV=

specifies the log of **SURVIVAL**.

LOWER=

L=

specifies the lower pointwise confidence limit for the survivor function. For a Bayesian analysis, this is the lower limit of the equal-tail credible interval for the survivor function. The confidence level is determined by the **ALPHA=** option.

LOWERCMF=

LOWERMCF=

specifies the lower pointwise confidence limit for the cumulative mean function. The confidence level is determined by the **ALPHA=** option.

LOWERHPD=

specifies the lower limit of the HPD interval for the survivor function. The confidence level is determined by the **ALPHA=** option.

LOWERHPDCUMHAZ=

specifies the lower limit of the HPD interval for the cumulative hazard function. The confidence level is determined by the **ALPHA=** option.

LOWERCUMHAZ=

specifies the lower pointwise confidence limit for the cumulative hazard function. For a Bayesian analysis, this is the lower limit of the equal-tail credible interval for the cumulative hazard function. The confidence level is determined by the **ALPHA=** option.

STDERR=

specifies the standard error of the survivor function estimator. For a Bayesian analysis, this is the standard deviation of the posterior distribution of the survivor function.

STDCMF=

STDMCF=

specifies the estimated standard error of the cumulative mean function estimator.

STDCUMHAZ=

specifies the estimated standard error of the cumulative hazard function estimator. For a Bayesian analysis, this is the standard deviation of the posterior distribution of the cumulative hazard function.

STDXBETA=

specifies the estimated standard error of the linear predictor estimator. For a Bayesian analysis, this is the standard deviation of the posterior distribution of the linear predictor.

SURVIVAL=

specifies the survivor function ($S(t) = [S_0(t)]^{\exp(\beta'x)}$) estimate. Specifying SURVIVAL=_ALL_ is equivalent to specifying SURVIVAL=Survival, STDERR=StdErrSurvival, LOWER=LowerSurvival, and UPPER=UpperSurvival; and for a Bayesian analysis, SURVIVAL=_ALL_ also specifies LOWERHPD= LowerHPDSurvival and UPPERHPD=UpperHPDSurvival.

UPPER=

U=

specifies the upper pointwise confidence limit for the survivor function. For a Bayesian analysis, this is the upper limit of the equal-tail credible interval for the survivor function. The confidence level is determined by the ALPHA= option.

UPPERCMF=

UPPERMCF=

specifies the upper pointwise confidence limit for the cumulative mean function. The confidence level is determined by the ALPHA= option.

UPPERCUMHAZ=

specifies the upper pointwise confidence limit for the cumulative hazard function. For a Bayesian analysis, this is the upper limit of the equal-tail credible interval for the cumulative hazard function. The confidence level is determined by the ALPHA= option.

UPPERHPD=

specifies the upper limit of the equal-tail credible interval for the survivor function. The confidence level is determined by the ALPHA= option.

UPPERHPDCUMHAZ=

specifies the upper limit of the equal-tail credible interval for the cumulative hazard function. The confidence level is determined by the ALPHA= option.

XBETA=

specifies the estimate of the linear predictor $x'\beta$.

The following options can appear in the BASELINE statement after a slash (/). The METHOD= and CLTYPE= options apply only to the estimate of the survivor function in the classical analysis. For the Bayesian analysis, the survivor function is estimated by the Breslow (1972) method.

ALPHA=*value*

specifies the significance level of the confidence interval for the survivor function. The value must be between 0 and 1. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified.

CLTYPE=*method*

specifies the method used to compute the confidence limits for $S(t, \mathbf{z})$, the survivor function for a subject with a fixed covariate vector \mathbf{z} at event time t . The CLTYPE= option can take the following values:

LOG

specifies that the confidence limits for $\log(S(t, \mathbf{z}))$ be computed using the normal theory approximation. The confidence limits for $S(t, \mathbf{z})$ are obtained by back-transforming the confidence limits for $\log(S(t, \mathbf{z}))$. The default is CLTYPE=LOG.

LOGLOG

specifies that the confidence limits for the $\log(-\log(S(t, \mathbf{z})))$ be computed using normal theory approximation. The confidence limits for $S(t, \mathbf{z})$ are obtained by back-transforming the confidence limits for $\log(-\log(S(t, \mathbf{z})))$.

NORMAL

<LINEAR> specifies that the confidence limits for $S(t, \mathbf{z})$ be computed directly using normal theory approximation.

DIRADJ

computes direct adjusted survival curves (Makuch 1982; Gail and Byar 1986; Zhang et al. 2007) by averaging the estimated survival curves for the observations in the COVARIATES= data set. See the section “[Direct Adjusted Survival Curves](#)” on page 5646 and [Example 67.8](#) for the computation and specific details. If the COVARIATES= data set is not specified, the input data set specified in the DATA= option in the PROC PHREG statement is used instead. If you also specify the [GROUP=](#) option, PROC PHREG computes an adjusted survival curve for each value of the [GROUP=](#) variable.

GROUP=*variable*

names a variable whose values identify or group the estimated survival curves. The behavior of this option depends on whether you also specify the [DIRADJ](#) option:

- If you also specify the [DIRADJ](#) option, *variable* must be a CLASS variable in the model. A direct adjusted survival curve is computed for each value of *variable* in the input data. The *variable* does not have to be a variable in the COVARIATES= data set. Each direct adjusted survival curve is the average of the survival curves of all individuals in the COVARIATES= data set with their value of *variable* set to a specific value.
- If you do not specify the [DIRADJ](#) option, *variable* is required to be a numeric variable in the COVARIATES= data set. Survival curves for the observations with the same value of the *variable* are overlaid in the same plot.

METHOD=*method*

specifies the method used to compute the survivor function estimates. See the section “[Survivor Function Estimators](#)” on page 5643 for details. You can specify the following *methods*:

BRESLOW**CH****EMP**

specifies that the Breslow (1972) estimator be used to compute the survivor function—that is, that the survivor function be estimated by exponentiating the negative empirical cumulative hazard function.

FH

specifies that the Fleming-Harrington (FH) estimates be computed. The FH estimator is a tie-breaking modification of the Breslow estimator. If there are no tied event times, this estimator is the same as the Breslow estimator.

PL

specifies that the product-limit estimates of the survivor function be computed. This estimator is not available if you use the model syntax that allows two time variables for counting process style of input; in such a case the Breslow estimator (METHOD=BRESLOW) is used instead.

The default is METHOD=BRESLOW.

ROWID=*variable*

ID=*variable*

ROW=*variable*

names a variable in the COVARIATES= data set for identifying the baseline function curves in the plots. This option has no effect if the PLOTS= option in the PROC PHREG statement is not specified. Values of this variable are used to label the curves for the corresponding rows in the COVARIATES= data set. You can specify ROWID=_OBS_ to use the observation numbers in the COVARIATES= data set for identification.

For recurrent events data, both CMF= and CUMHAZ= statistics are the Nelson estimators, but their standard error are not the same. Confidence limits for the cumulative mean function and cumulative hazard function are based on the log transform.

BAYES Statement

BAYES < *options* > ;

The BAYES statement requests a Bayesian analysis of the regression model by using Gibbs sampling. The Bayesian posterior samples (also known as the chain) for the regression parameters can be output to a SAS data set. [Table 67.4](#) summarizes the options available in the BAYES statement.

Table 67.4 BAYES Statement Options

Option	Description
Monte Carlo Options	
INITIAL=	Specifies initial values of the chain
NBI=	Specifies the number of burn-in iterations
NMC=	Specifies the number of iterations after burn-in
SAMPLING=	Specifies the sampling algorithm

Table 67.4 continued

Option	Description
SEED=	Specifies the random number generator seed
THINNING=	Controls the thinning of the Markov chain
Model and Prior Options	
COEFFPRIOR=	Specifies the prior of the regression coefficients
DISPERSIONPRIOR=	Specifies the prior of the dispersion parameter for frailties
PIECEWISE=	Specifies details of the piecewise exponential model
Summaries and Diagnostics of the Posterior Samples	
DIAGNOSTICS=	Displays convergence diagnostics
PLOTS=	Displays diagnostic plots
STATISTICS=	Displays summary statistics
Posterior Samples	
OUTPOST=	Names a SAS data set for the posterior samples

The following list describes these options and their suboptions.

COEFFPRIOR=UNIFORM | NORMAL <(normal-option)> | **ZELLNER** <(zellner-option)>

CPRIOR=UNIFORM | NORMAL <(normal-option)> | **ZELLNER** <(zellner-option)>

COEFF=UNIFORM | NORMAL <(normal-option)> | **ZELLNER** <(zellner-option)>

specifies the prior distribution for the regression coefficients. The default is COEFFPRIOR=UNIFORM. The following prior distributions are available:

UNIFORM

specifies a flat prior—that is, the prior that is proportional to a constant ($p(\beta_1, \dots, \beta_k) \propto 1$ for all $-\infty < \beta_i < \infty$).

NORMAL<(normal-option)>

specifies a normal distribution. The *normal-options* include the following:

INPUT=SAS-data-set

specifies a SAS data set that contains the mean and covariance information of the normal prior. The data set must contain the `_TYPE_` variable to identify the observation type, and it must contain a variable to represent each regression coefficient. If the data set also contains the `_NAME_` variable, values of this variable are used to identify the covariances for the `_TYPE_='COV'` observations; otherwise, the `_TYPE_='COV'` observations are assumed to be in the same order as the explanatory variables in the MODEL statement. PROC PHREG reads the mean vector from the observation with `_TYPE_='MEAN'` and the covariance matrix from observations with `_TYPE_='COV'`. For an independent normal prior, the variances can be specified with `_TYPE_='VAR'`; alternatively, the precisions (inverse of the variances) can be specified with `_TYPE_='PRECISION'`.

RELVAR <=c>

specifies a normal prior $N(\mathbf{0}, c\mathbf{J})$, where \mathbf{J} is a diagonal matrix with diagonal elements equal to the variances of the corresponding ML estimator. By default, `c=1E6`.

VAR=c

specifies the normal prior $N(\mathbf{0}, c\mathbf{I})$, where \mathbf{I} is the identity matrix.

If you do not specify a *normal-option*, the normal prior $N(\mathbf{0}, 10^6\mathbf{I})$, where \mathbf{I} is the identity matrix, is used. See the section “[Normal Prior](#)” on page 5658 for details.

ZELLNER<(zellner-option)>

specifies the Zellner g-prior for the regression coefficients. The g-prior is a normal prior distribution with mean zero and covariance matrix equal to $(g\mathbf{X}'\mathbf{X})^{-1}$, where \mathbf{X} is the design matrix and g can be a constant or a parameter with a gamma prior. The *zellner-options* include the following:

G=number

specifies a constant *number* for g .

GAMMA <(SHAPE=a ISCALE=b)>

specifies that g has a gamma prior distribution $G(a, b)$ with density $f(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}$. By default, $a=b=1\text{E-}4$.

If you do not specify a *zellner-option*, the default is ZELLNER($g=1\text{E-}6$).

DISPERSIONPRIOR=GAMMA<(gamma-options)> | IGAMMA<(igamma-options)> | IMPROPER**DPRIOR=GAMMA<(gamma-options)> | IGAMMA<(igamma-options)> | IMPROPER**

specifies the prior distribution of the dispersion parameter. For gamma frailty, the dispersion parameter is the variance of the gamma frailty; for lognormal frailty, the dispersion parameter is the variance of the normal random component. The default is DISPERSIONPRIOR=IMPROPER.

You can specify the following values for this options:

GAMMA<(gamma-options)>

specifies the gamma prior. A gamma prior $G(a, b)$ with hyperparameters a and b has density $f(\theta) = \frac{b^a \theta^{a-1} e^{-b\theta}}{\Gamma(a)}$, where a is the shape parameter and b is the inverse-scale parameter. You can use the following *gamma-options* enclosed in parentheses to specify the hyperparameters:

SHAPE=a**ISCALE=b**

results in a $G(a, b)$ prior when both *gamma-options* are specified.

SHAPE=c

results in a $G(c, c)$ prior when specified alone.

ISCALE=c

results in a $G(c, c)$ prior when specify alone.

The default is SHAPE=1E-4 and ISCALE=1E-4.

IGAMMA<(igamma-options)>

specifies the inverse-gamma prior. An inverse-gamma prior $IG(a, b)$ with hyperparameters a and b has a density $f(\theta) = \frac{b^a \theta^{-(a+1)} e^{-\frac{b}{\theta}}}{\Gamma(a)}$, where a is the shape parameter and b is the scale parameter. You can use the following *igamma-options* enclosed in parentheses to specify the hyperparameters:

SHAPE=*a***SCALE=*b***results in a $IG(a, b)$ prior when both *igamma-options* are specified.**SHAPE=*c***results in a $IG(c, c)$ prior when specified alone.**SCALE=*c***results in a $IG(c, c)$ prior when specified alone.

The default is SHAPE=2.001 AND SCALE=0.01.

IMPROPERspecifies the improper prior, which has a density $f(\theta)$ proportional to θ^{-1} .**DIAGNOSTICS=ALL | NONE | keyword | (keyword-list)****DIAG=ALL | NONE | keyword | (keyword-list)**

controls the number of diagnostics produced. You can request all the diagnostics in the following list by specifying DIAGNOSTICS=ALL. If you do not want any of these diagnostics, you specify DIAGNOSTICS=NONE. If you want some but not all of the diagnostics, or if you want to change certain settings of these diagnostics, you specify a subset of the following keywords. The default is DIAGNOSTICS=([AUTOCORR GEWEKE ESS](#)).

AUTOCORR <(LAGS= numeric-list)>

computes the autocorrelations of lags given by LAGS= list for each parameter. Elements in the list are truncated to integers and repeated values are removed. If the LAGS= option is not specified, autocorrelations of lags 1, 5, 10, and 50 are computed for each variable. See the section “[Autocorrelations](#)” on page 152 for details.

ESS

computes the effective sample size of Kass et al. (1998), the correlation time, and the efficiency of the chain for each parameter. See the section “[Effective Sample Size](#)” on page 152 for details.

MCSE**MCERROR**

computes the Monte Carlo standard error for each parameter. The Monte Carlo standard error, which measures the simulation accuracy, is the standard error of the posterior mean estimate and is calculated as the posterior standard deviation divided by the square root of the effective sample size. See the section “[Standard Error of the Mean Estimate](#)” on page 153 for details.

HEIDELBERGER <(heidel-options)>

computes the Heidelberg and Welch tests for each parameter. See the section “[Heidelberg and Welch Diagnostics](#)” on page 148 for details. The tests consist of a stationary test and a halfwidth test. The former tests the null hypothesis that the sample values form a stationary process. If the stationarity test is passed, a halfwidth test is then carried out. Optionally, you can specify one or more of the following *heidel-options*:

SALPHA=*value*

specifies the α level ($0 < \alpha < 1$) for the stationarity test. The default is the value of the **ALPHA=** option in the PROC PHREG statement, or 0.05 if that option is not specified.

HALPHA=*value*

specifies the α level ($0 < \alpha < 1$) for the halfwidth test. The default is the value of the **ALPHA=** option in the PROC PHREG statement, or 0.05 if that option is not specified.

EPS=*value*

specifies a small positive number ϵ such that if the halfwidth is less than ϵ times the sample mean of the retaining samples, the halfwidth test is passed.

GELMAN <(gelman-options)>

computes the Gelman and Rubin convergence diagnostics. See the section “[Gelman and Rubin Diagnostics](#)” on page 145 for details. You can specify one or more of the following *gelman-options*:

NCHAIN=*number***N=***number*

specifies the number of parallel chains used to compute the diagnostic and has to be 2 or larger. The default is NCHAIN=3. The NCHAIN= option is ignored when the INITIAL= option is specified in the BAYES statement, and in such a case, the number of parallel chains is determined by the number of valid observations in the INITIAL= data set.

ALPHA=*value*

specifies the significance level for the upper bound. The default is the value of the **ALPHA=** option in the PROC PHREG statement, or 0.05 if that option is not specified (resulting in a 97.5% bound).

GEWEKE <(geweke-options)>

computes the Geweke diagnostics. See the section “[Geweke Diagnostics](#)” on page 146 for details. The diagnostic is essentially a two-sample t -test between the first f_1 portion and the last f_2 portion of the chain. The default is $f_1=0.1$ and $f_2=0.5$, but you can choose other fractions by using the following *geweke-options*:

FRAC1=*value*

specifies the early f_1 fraction of the Markov chain.

FRAC2=*value*

specifies the latter f_2 fraction of the Markov chain.

RAFTERY <(raftery-options)>

computes the Raftery and Lewis diagnostics. See the section “[Raftery and Lewis Diagnostics](#)” on page 149 for details. The diagnostic evaluates the accuracy of the estimated quantile ($\hat{\theta}_Q$ for a given $Q \in (0, 1)$) of a chain. $\hat{\theta}_Q$ can achieve any degree of accuracy when the chain is allowed to run for a long time. A stopping criterion is when the estimated probability $\hat{P}_Q = \Pr(\theta \leq \hat{\theta}_Q)$ reaches within $\pm R$ of the value Q with probability S ; that is, $\Pr(Q - R \leq \hat{P}_Q \leq Q + R) = S$. The following *raftery-options* enable you to specify Q , R , S , and a precision level ϵ for a stationary test.

QUANTILE=*value***Q=***value*

specifies the order (a value between 0 and 1) of the quantile of interest. The default is 0.025.

ACCURACY=*value***R=***value*

specifies a small positive number as the margin of error for measuring the accuracy of estimation of the quantile. The default is 0.005.

PROBABILITY=*value***S=***value*

specifies the probability of attaining the accuracy of the estimation of the quantile. The default is 0.95.

EPSILON=*value***EPS=***value*

specifies the tolerance level (a small positive number) for the test. The default is 0.001.

INITIAL=*SAS-data-set*

specifies the SAS data set that contains the initial values of the Markov chains. The INITIAL= data set must contain a variable for each parameter in the model. You can specify multiple rows as the initial values of the parallel chains for the Gelman-Rubin statistics, but posterior summary statistics, diagnostics, and plots are computed only for the first chain.

NBI=*number*

specifies the number of burn-in iterations before the chains are saved. The default is 2000.

NMC=*number*

specifies the number of iterations after the burn-in. The default is 10000.

OUTPOST=*SAS-data-set***OUT=***SAS-data-set*names the SAS data set that contains the posterior samples. See the section “[OUTPOST= Output Data Set in the BAYES Statement](#)” on page 5665 for more information. Alternatively, you can output the posterior samples into a data set, as shown in the following example in which the data set is named PostSamp.

```
ODS OUTPUT PosteriorSample = PostSamp;
```

PIECEWISE <=*keyword* <(< **NINTERVAL=***number* > < **INTERVALS=**(*numeric-list*) > < **PRIOR=***option* >) >>specifies that the piecewise constant baseline hazard model be used in the Bayesian analysis. You can specify one of the following two *keywords*:**HAZARD**

models the baseline hazard parameters in the original scale. The hazard parameters are named Lambda1, Lambda2, . . . , and so on.

LOGHAZARD

models the baseline hazard parameters in the log scale. The log-hazard parameters are named Alpha1, Alpha2, . . . , and so on.

Specifying **PIECEWISE** by itself is the same as specifying **PIECEWISE=LOGHAZARD**.

You can choose one of the following two options to specify the partition of the time axis into intervals of constant baseline hazards:

NINTERVAL=*number*

N=*number*

specifies the number of intervals with constant baseline hazard rates. PROC PHREG partitions the time axis into the given number of intervals with approximately equal number of events in each interval.

INTERVALS=(*numeric-list*)

INTERVAL=(*numeric-list*)

specifies the list of numbers that partition the time axis into disjoint intervals with constant baseline hazard in each interval. For example, **INTERVALS**=(100, 150, 200, 250, 300) specifies a model with a constant hazard in the intervals [0,100), [100,150), [150,200), [200,250), [250,300), and [300,∞). Each interval must contain at least one event; otherwise, the posterior distribution can be improper, and inferences cannot be derived from an improper posterior distribution.

If neither **NINTERVAL=** nor **INTERVAL=** is specified, the default is **NINTERVAL=8**.

To specify the prior for the baseline hazards $(\lambda_1, \dots, \lambda_J)$ in the original scale, you specify the following:

PRIOR = IMPROPER | UNIFORM | GAMMA<(*gamma-option*)> | **ARGAMMA**<(*arggamma-option*)>

The default is **PRIOR=IMPROPER**. The available prior options include the following:

IMPROPER

specifies the noninformative and improper prior $p(\lambda_1, \dots, \lambda_J) \propto \prod_i \lambda_i^{-1}$ for all $\lambda_i > 0$.

UNIFORM

specifies a uniform prior on the real line; that is, $p(\lambda_i) \propto 1$ for all $\lambda_i > 0$.

GAMMA <(*gamma-option*)>

specifies an independent gamma prior $G(a, b)$ with density $f(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}$, which can be followed by one of the following *gamma-options* enclosed in parentheses. The hyperparameters a and b are the shape and inverse-scale parameters of the gamma distribution, respectively. See the section “[Independent Gamma Prior](#)” on page 5657 for details. The default is $G(10^{-4}, 10^{-4})$ for each λ_j , setting the prior mean to 1 with variance 1E4. This prior is proper and reasonably noninformative.

INPUT=SAS-data-set

specifies a data set containing the hyperparameters of the independent gamma prior. The data set must contain the `_TYPE_` variable to identify the observation type, and it must contain the variables named Lambda1, Lambda2, . . . , and so forth, to represent

the hazard parameters. The observation with `_TYPE_='SHAPE'` identifies the shape parameters, and the observation with `_TYPE_='ISCALE'` identifies the inverse-scale parameters.

RELSHAPE=<c>

specifies independent $G(c\hat{\lambda}_j, c)$ distribution, where $\hat{\lambda}_j$'s are the MLEs of the hazard rates. This prior has mean $\hat{\lambda}_j$ and variance $\frac{\hat{\lambda}_j}{c}$. By default, $c=1E-4$.

SHAPE=a and ISCALE=b

together specify the $G(a, b)$ prior.

SHAPE=c

ISCALE=c

specifies the $G(c, c)$ prior.

ARGAMMA <(argamma-option)>

specifies an autoregressive gamma prior of order 1, which can be followed by one of the following *argamma-options*. See the section “AR1 Prior” on page 5657 for details.

INPUT=SAS-data-set

specifies a data set containing the hyperparameters of the correlated gamma prior. The data set must contain the `_TYPE_` variable to identify the observation type, and it must contain the variables named `Lambda1`, `Lambda2`, ..., and so forth, to represent the hazard parameters. The observation with `_TYPE_='SHAPE'` identifies the shape parameters, and the observation with `_TYPE_='ISCALE'` identifies the *relative* inverse-scale parameters; that is, if a_j and b_j are, respectively, the SHAPE and ISCALE values for λ_j , $1 \leq j \leq J$, then $\lambda_1 \sim G(a_1, b_1)$, and $\lambda_j \sim G(a_j, b_j/\lambda_{j-1})$ for $2 \leq j \leq J$.

SHAPE=a and SCALE=b

together specify that $\lambda_1 \sim G(a, b)$ and $\lambda_j \sim G(a, b/\lambda_{j-1})$ for $2 \leq j \leq J$.

SHAPE=c

ISCALE=c

specifies that $\lambda_1 \sim G(c, c)$ and $\lambda_j \sim G(c, c/\lambda_{j-1})$ for $2 \leq j \leq J$.

To specify the prior for $\alpha_1, \dots, \alpha_J$, the hazard parameters in the log scale, you specifying the following:

PRIOR=UNIFORM | NORMAL<(normal-option)>

specifies the prior for the loghazard parameters. The default is `PRIOR=UNIFORM`. The available `PRIOR=` options are as follows:

UNIFORM

specifies the uniform prior on the real line; that is, $\alpha_i \propto 1$ for all $-\infty < \alpha_i < \infty$.

NORMAL<(normal-option)>

specifies a normal prior distribution on the log-hazard parameters. The *normal-options* include the following. If you do not specify a *normal-option*, the normal prior $N(0, 10^6 \mathbf{I})$, where \mathbf{I} is the identity matrix, is used.

INPUT=SAS-data-set

specifies a SAS data set containing the mean and covariance information of the normal prior. The data set must contain the `_TYPE_` variable to identify the observation type, and it must contain variables named Alpha1, Alpha2, ..., and so forth, to represent the log-hazard parameters. If the data set also contains the `_NAME_` variable, the value of this variable will be used to identify the covariances for the `_TYPE_='COV'` observations; otherwise, the `_TYPE_='COV'` observations are assumed to be in the same order as the explanatory variables in the MODEL statement. PROC PHREG reads the mean vector from the observation with `_TYPE_='MEAN'` and the covariance matrix from observations with `_TYPE_='COV'`. See the section “[Normal Prior](#)” on page 5658 for details. For an independent normal prior, the variances can be specified with `_TYPE_='VAR'`; alternatively, the precisions (inverse of the variances) can be specified with `_TYPE_='PRECISION'`.

If you have a joint normal prior for the log-hazard parameters and the regression coefficients, specify the same data set containing the mean and covariance information of the multivariate normal distribution in both the `COEFFPRIOR=NORMAL(INPUT=)` and the `PIECEWISE=LOGHAZARD(PRIOR=NORMAL(INPUT=))` options. See the section “[Joint Multivariate Normal Prior for Log-Hazards and Regression Coefficients](#)” on page 5658 for details.

RELVAR <=c>

specifies the normal prior $N(0, c\mathbf{J})$, where \mathbf{J} is a diagonal matrix with diagonal elements equal to the variances of the corresponding ML estimator. By default, $c=1E6$.

VAR=c

specifies the normal prior $N(0, c\mathbf{I})$, where \mathbf{I} is the identity matrix.

PLOTS <(global-plot-options)> = plot-request**PLOTS <(global-plot-options)> = (plot-requests)**

controls the diagnostic plots produced through ODS Graphics. Three types of plots can be requested: trace plots, autocorrelation function plots, and kernel density plots. By default, the plots are displayed in panels unless the global plot option UNPACK is specified. If you specify more than one type of plots, the plots are displayed by parameters unless the global plot option GROUPBY=TYPE is specified. When you specify only one plot request, you can omit the parentheses around the plot request. For example:

```
plots=none
plots(unpack)=trace
plots=(trace autocorr)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc phreg;
  model y=x;
  bayes plots=trace;
run;
ods graphics off;
```

If ODS Graphics is enabled but you do not specify the `PLOTS=` option in the `BAYES` statement, then PROC PHREG produces, for each parameter, a panel that contains the trace plot, the autocorrelation function plot, and the density plot. This is equivalent to specifying `plots=(trace autocorr density)`.

The *global-plot-options* include the following:

FRINGE

creates a fringe plot on the X axis of the density plot.

GROUPBY = PARAMETER | TYPE

specifies how the plots are to be grouped when there is more than one type of plots. The choices are as follows:

TYPE

specifies that the plots be grouped by type.

PARAMETER

specifies that the plots be grouped by parameter.

`GROUPBY=PARAMETER` is the default.

SMOOTH

displays a fitted penalized B-spline curve each trace plot.

UNPACKPANEL

UNPACK

specifies that all paneled plots be unpacked, meaning that each plot in a panel is displayed separately.

The *plot-requests* include the following:

ALL

specifies all types of plots. `PLOTS=ALL` is equivalent to specifying `PLOTS=(TRACE AUTOCORR DENSITY)`.

AUTOCORR

displays the autocorrelation function plots for the parameters.

DENSITY

displays the kernel density plots for the parameters.

NONE

suppresses all diagnostic plots.

TRACE

displays the trace plots for the parameters. See the section “[Visual Analysis via Trace Plots](#)” on page 139 for details.

Consider a model with four parameters, `X1–X4`. Displays for various specification are depicted as follows.

1. PLOTS=(TRACE AUTOCORR) displays the trace and autocorrelation plots for each parameter side by side with two parameters per panel:

Display 1	Trace(X1)	Autocorr(X1)
	Trace(X2)	Autocorr(X2)

Display 2	Trace(X3)	Autocorr(X3)
	Trace(X4)	Autocorr(X4)

2. PLOTS(GROUPBY=TYPE)=(TRACE AUTOCORR) displays all the paneled trace plots, followed by panels of autocorrelation plots:

Display 1	Trace(X1)
	Trace(X2)

Display 2	Trace(X3)
	Trace(X4)

Display 3	Autocorr(X1)	Autocorr(X2)
	Autocorr(X3)	Autocorr(X4)

3. PLOTS(UNPACK)=(TRACE AUTOCORR) displays a separate trace plot and a separate correlation plot, parameter by parameter:

Display 1	Trace(X1)
-----------	-----------

Display 2	Autocorr(X1)
-----------	--------------

Display 3	Trace(X2)
-----------	-----------

Display 4	Autocorr(X2)
-----------	--------------

Display 5	Trace(X3)
-----------	-----------

Display 6	Autocorr(X3)
-----------	--------------

Display 7	Trace(X4)
-----------	-----------

Display 8	Autocorr(X4)
-----------	--------------

4. PLOTS(UNPACK GROUPBY=TYPE) = (TRACE AUTOCORR) displays all the separate trace plots followed by the separate autocorrelation plots:

Display 1	Trace(X1)
Display 2	Trace(X2)
Display 3	Trace(X3)
Display 4	Trace(X4)
Display 5	Autocorr(X1)
Display 6	Autocorr(X2)
Display 7	Autocorr(X3)
Display 8	Autocorr(X4)

SAMPLING=keyword

specifies the sampling algorithm used in the Markov chain Monte Carlo (MCMC) simulations. Two sampling algorithms are available:

ARMS**GIBBS**

requests the use of the adaptive rejection Metropolis sampling (ARMS) algorithm to draw the Gibbs samples. `ALGORITHM=ARMS` is the default.

RWM

requests the use of the random walk Metropolis (RWM) algorithm to draw the samples.

For details about the MCMC sampling algorithms, see the section “[Markov Chain Monte Carlo Method](#)” on page 133 in Chapter 7, “[Introduction to Bayesian Analysis Procedures](#).”

SEED=number

specifies an integer seed ranging from 1 to $2^{31}-1$ for the random number generator in the simulation. Specifying a seed enables you to reproduce identical Markov chains for the same specification. If the `SEED=` option is not specified, or if you specify a nonpositive seed, a random seed is derived from the time of day.

STATISTICS <(global-options)> = ALL | NONE | keyword | (keyword-list)**STATS <(global-statoptions)> = ALL | NONE | keyword | (keyword-list)**

controls the number of posterior statistics produced. Specifying `STATISTICS=ALL` is equivalent to specifying `STATISTICS=(SUMMARY INTERVAL COV CORR)`. If you do not want any posterior statistics, you specify `STATISTICS=NONE`. The default is `STATISTICS=(SUMMARY INTERVAL)`. See the section “[Summary Statistics](#)” on page 153 for details. The *global-options* include the following:

ALPHA=*numeric-list*

controls the probabilities of the credible intervals. The ALPHA= values must be between 0 and 1. Each ALPHA= value produces a pair of 100(1–ALPHA)% equal-tail and HPD intervals for each parameters. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified (yielding the 95% credible intervals for each parameter).

PERCENT=*numeric-list*

requests the percentile points of the posterior samples. The PERCENT= values must be between 0 and 100. The default is PERCENT= 25, 50, 75, which yield the 25th, 50th, and 75th percentile points for each parameter.

You can specify the following values for a *keyword* or as part of a *keyword-list*. To specify a list, place parentheses around multiple keywords that are separated by spaces.

CORR

produces the posterior correlation matrix.

COV

produces the posterior covariance matrix.

SUMMARY

produces the means, standard deviations, and percentile points for the posterior samples. The default is to produce the 25th, 50th, and 75th percentile points, but you can use the global PERCENT= option to request specific percentile points.

INTERVAL

produces equal-tail credible intervals and HPD intervals. The default is to produce the 95% equal-tail credible intervals and 95% HPD intervals, but you can use the global ALPHA= option to request intervals of any probabilities.

THINNING=*number***THIN=***number*

controls the thinning of the Markov chain. Only one in every k samples is used when THINNING= k , and if NBI= n_0 and NMC= n , the number of samples kept is

$$\left[\frac{n_0 + n}{k} \right] - \left[\frac{n_0}{k} \right]$$

where $[a]$ represents the integer part of the number a . The default is THINNING=1.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC PHREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the PHREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable* < (*options*) > ... < *variable* < (*options*) > > < / *global-options* > ;

The CLASS statement names the classification variables to be used as explanatory variables in the analysis.

The CLASS statement must precede the **MODEL** statement. Most options can be specified either as individual variable *options* or as *global-options*. You can specify *options* for each variable by enclosing the options in parentheses after the variable name. You can also specify *global-options* for the CLASS statement by placing them after a slash (/). *Global-options* are applied to all the variables specified in the CLASS statement. If you specify more than one CLASS statement, the *global-options* specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *options* override the *global-options*. You can specify the following values for either an *option* or a *global-option*:

CPREFIX=*n*

specifies that, at most, the first *n* characters of a CLASS variable name be used in creating names for the corresponding design variables. The default is $32 - \min(32, \max(2, f))$, where *f* is the formatted length of the CLASS variable.

DESCENDING

DESC

reverses the sort order of the classification variable. If both the DESCENDING and **ORDER=** options are specified, PROC PHREG orders the categories according to the ORDER= option and then reverses that order.

LPREFIX=*n*

specifies that, at most, the first *n* characters of a CLASS variable label be used in creating labels for the corresponding design variables. The default is $256 - \min(256, \max(2, f))$, where *f* is the formatted length of the CLASS variable.

MISSING

treats missing values ('.', '_', 'A', ..., 'Z' for numeric variables and blanks for character variables) as valid values for the CLASS variable.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option can be useful when you use the CONTRAST statement. By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. When ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows how PROC PHREG interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted values, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) values
FREQ	Descending frequency count; levels with more observations come earlier in the order
INTERNAL	Unformatted value

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

PARAM=keyword

specifies the parameterization method for the classification variable or variables. You can specify any of the *keywords* shown in the following table; the default is PARAM=REF. Design matrix columns are created from CLASS variables according to the corresponding coding schemes:

Value of PARAM=	Coding
EFFECT	Effect coding
GLM	Less-than-full-rank reference cell coding (this <i>keyword</i> can be used only in a global option)
ORDINAL THERMOMETER	Cumulative parameterization for an ordinal CLASS variable
POLYNOMIAL POLY	Polynomial coding
REFERENCE REF	Reference cell coding
ORTHEFFECT	Orthogonalizes PARAM=EFFECT coding
ORTHORDINAL ORTHOTHERM	Orthogonalizes PARAM=ORDINAL coding
ORTHPOLY	Orthogonalizes PARAM=POLYNOMIAL coding
ORTHREF	Orthogonalizes PARAM=REFERENCE coding

All parameterizations are full rank, except for the GLM parameterization. The **REF=** option in the CLASS statement determines the reference level for EFFECT and REFERENCE coding and for their orthogonal parameterizations. It also indirectly determines the reference level for a singular GLM parameterization through the order of levels.

If **PARAM=ORTHPOLY** or **PARAM=POLY** and the classification variable is numeric, then the **ORDER=** option in the CLASS statement is ignored, and the internal unformatted values are used. See the section “[Other Parameterizations](#)” on page 387 of Chapter 19, “[Shared Concepts and Topics](#),” for further details.

REF= *'level' | keyword*

specifies the reference level for **PARAM=EFFECT**, **PARAM=REFERENCE**, and their orthogonalizations. For **PARAM=GLM**, the **REF=** option specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the linear estimates with a singular parameterization.

For an individual variable **REF=** option (but not for a global **REF=** option), you can specify the *level* of the variable to use as the reference level. Specify the formatted value of the variable if a format is assigned. For a global or individual variable **REF=** option, you can use one of the following *keywords*. The default is **REF=LAST**.

FIRST designates the first ordered level as reference.

LAST designates the last ordered level as reference.

TRUNCATE *<=n>*

specifies the length *n* of CLASS variable values to use in determining CLASS variable levels. The default is to use the full formatted length of the CLASS variable. If you specify **TRUNCATE** without the length *n*, the first 16 characters of the formatted values are used. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases before SAS 9. The **TRUNCATE** option is available only as a global option.

Class Variable Naming Convention

Parameter names for a CLASS predictor variable are constructed by concatenating the CLASS variable name with the CLASS levels. However, for the POLYNOMIAL and orthogonal parameterizations, parameter names are formed by concatenating the CLASS variable name and keywords that reflect the parameterization. See the section “[Other Parameterizations](#)” on page 387 in Chapter 19, “[Shared Concepts and Topics](#),” for examples and further details.

Class Variable Parameterization with Unbalanced Designs

PROC PHREG initially parameterizes the CLASS variables by looking at the levels of the variables across the complete data set. If you have an *unbalanced* replication of levels across variables or BY groups, then the design matrix and the parameter interpretation might be different from what you expect. For instance, suppose you have a model with one CLASS variable A with three levels (1, 2, and 3), and another CLASS variable B with two levels (1 and 2). If the third level of A occurs only with the first level of B, if you use the EFFECT parameterization, and if your model contains the effect A(B) and an intercept, then the design for A within the second level of B is not a differential effect. In particular, the design looks like the following:

		Design Matrix			
B	A	A(B=1)		A(B=2)	
		A1	A2	A1	A2
1	1	1	0	0	0
1	2	0	1	0	0
1	3	-1	-1	0	0
2	1	0	0	1	0
2	2	0	0	0	1

PROC PHREG detects linear dependency among the last two design variables and sets the parameter for A2(B=2) to zero, resulting in an interpretation of these parameters as if they were reference- or dummy-coded. The REFERENCE or GLM parameterization might be more appropriate for such problems.

CONTRAST Statement

CONTRAST *'label'* *row-description* < , ... *row-description* > < / *options* > ;

The CONTRAST statement provides a mechanism for obtaining customized hypothesis tests. It is similar to the CONTRAST statement in PROC GLM and PROC CATMOD, depending on the coding schemes used with any categorical variables involved.

The CONTRAST statement enables you to specify a matrix, \mathbf{L} , for testing the hypothesis $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$. You must be familiar with the details of the model parameterization that PROC PHREG uses (for more information, see the PARAM= option in the section “[CLASS Statement](#)” on page 5578). Optionally, the CONTRAST statement enables you to estimate each row, $\mathbf{L}'_i\boldsymbol{\beta}$, of $\mathbf{L}\boldsymbol{\beta}$ and test the hypothesis $\mathbf{L}'_i\boldsymbol{\beta} = 0$. Computed statistics are based on the asymptotic chi-square distribution of the Wald statistic.

There is no limit to the number of CONTRAST statements that you can specify, but they must appear after the MODEL statement.

The syntax of a *row-description* is:

effect values < , ... , *effect values* >

The following parameters are specified in the CONTRAST statement:

- label* identifies the contrast on the output. A label is required for every contrast specified, and it must be enclosed in quotes.
- effect* identifies an effect that appears in the MODEL statement. You do not need to include all effects that are included in the MODEL statement.
- values* are constants that are elements of the \mathbf{L} matrix associated with the effect. To correctly specify your contrast, it is crucial to know the ordering of parameters within each effect and the variable levels associated with any parameter. The “Class Level Information” table shows the ordering of levels within variables. The E option, described later in this section, enables you to verify the proper correspondence of *values* to parameters.

The rows of \mathbf{L} are specified in order and are separated by commas. Multiple degree-of-freedom hypotheses can be tested by specifying multiple *row-descriptions*. For any of the full-rank parameterizations, if an effect

is not specified in the CONTRAST statement, all of its coefficients in the **L** matrix are set to 0. If too many values are specified for an effect, the extra ones are ignored. If too few values are specified, the remaining ones are set to 0.

When you use effect coding (by specifying PARAM=EFFECT in the CLASS statement), all parameters are directly estimable (involve no other parameters). For example, suppose an effect coded CLASS variable **A** has four levels. Then there are three parameters ($\alpha_1, \alpha_2, \alpha_3$) representing the first three levels, and the fourth parameter is represented by

$$-\alpha_1 - \alpha_2 - \alpha_3$$

To test the first versus the fourth level of **A**, you would test

$$\alpha_1 = -\alpha_1 - \alpha_2 - \alpha_3$$

or, equivalently,

$$2\alpha_1 + \alpha_2 + \alpha_3 = 0$$

which, in the form $\mathbf{L}\boldsymbol{\beta} = 0$, is

$$\begin{bmatrix} 2 & 1 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1 vs. 4' A 2 1 1;
```

To contrast the third level with the average of the first two levels, you would test

$$\frac{\alpha_1 + \alpha_2}{2} = \alpha_3$$

or, equivalently,

$$\alpha_1 + \alpha_2 - 2\alpha_3 = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1&2 vs. 3' A 1 1 -2;
```

Other CONTRAST statements involving classification variables with PARAM=EFFECT are constructed similarly. For example:

```
contrast '1 vs. 2' A 1 -1 0;
contrast '1&2 vs. 4' A 3 3 2;
contrast '1&2 vs. 3&4' A 2 2 0;
contrast 'Main Effect' A 1 0 0,
                        A 0 1 0,
                        A 0 0 1;
```

When you use the less-than-full-rank parameterization (by specifying `PARAM=GLM` in the `CLASS` statement), each row is checked for estimability. If `PROC PHREG` finds a contrast to be nonestimable, it displays missing values in corresponding rows in the results. `PROC PHREG` handles missing level combinations of categorical variables in the same manner as `PROC GLM`. Parameters corresponding to missing level combinations are not included in the model. This convention can affect the way in which you specify the **L** matrix in your `CONTRAST` statement. If the elements of **L** are not specified for an effect that contains a specified effect, then the elements of the specified effect are distributed over the levels of the higher-order effect just as the `GLM` procedure does for its `CONTRAST` and `ESTIMATE` statements. For example, suppose that the model contains effects *A* and *B* and their interaction *A*B*. If you specify a `CONTRAST` statement involving *A* alone, the **L** matrix contains nonzero terms for both *A* and *A*B*, since *A*B* contains *A*.

The Cox model contains no explicit intercept parameter, so it is not valid to specify one in the `CONTRAST` statement. As a consequence, you can test or estimate only homogeneous linear combinations (those with zero-intercept coefficients, such as contrasts that represent group differences) for the `GLM` parameterization.

The degrees of freedom are the number of linearly independent constraints implied by the `CONTRAST` statement—that is, the rank of **L**.

You can specify the following *options* after a slash (/).

ALPHA= *p*

specifies the level of significance *p* for the $100(1 - p)\%$ confidence interval for each contrast when the `ESTIMATE` option is specified. The value *p* must be between 0 and 1. By default, *p* is equal to the value of the `ALPHA=` option in the `PROC PHREG` statement, or 0.05 if that option is not specified.

E

requests that the **L** matrix be displayed.

ESTIMATE=*keyword*

requests that each individual contrast (that is, each row, $l'_i\beta$, of **L** β) or exponentiated contrast ($e^{l'_i\beta}$) be estimated and tested. `PROC PHREG` displays the point estimate, its standard error, a Wald confidence interval, and a Wald chi-square test for each contrast. The significance level of the confidence interval is controlled by the `ALPHA=` option. You can estimate the contrast or the exponentiated contrast ($e^{l'_i\beta}$), or both, by specifying one of the following *keywords*:

PARM	specifies that the contrast itself be estimated.
EXP	specifies that the exponentiated contrast be estimated.
BOTH	specifies that both the contrast and the exponentiated contrast be estimated.

SINGULAR=*number*

tunes the estimability check. This option is ignored when the full-rank parameterization is used. If **v** is a vector, define $\text{ABS}(\mathbf{v})$ to be the largest absolute value of the elements of **v**. For a row vector l' of the contrast matrix **L**, define *c* to be equal to $\text{ABS}(\mathbf{l})$ if $\text{ABS}(\mathbf{l})$ is greater than 0; otherwise, *c* equals 1. If $\text{ABS}(\mathbf{l}' - \mathbf{l}'\mathbf{T})$ is greater than $c * \text{number}$, then *l* is declared nonestimable. The **T** matrix is the Hermite form matrix $\mathbf{I}_0^{-1}\mathbf{I}_0$, where \mathbf{I}_0^{-1} represents a generalized inverse of the information matrix \mathbf{I}_0 of the null model. The value for *number* must be between 0 and 1; the default value is 1E-4.

TEST<(keywords)>

requests a Type 3 test for each contrast. The default is to use the Wald statistic, but you can request other statistics by specifying one or more of the following *keywords*:

ALL

requests the likelihood ratio tests, the score tests, and the Wald tests. Specifying TEST(ALL) is equivalent to specifying TEST=(LR SCORE WALD).

NONE

suppresses the Type 3 analysis. Even if the TEST option is not specified, PROC PHREG displays the Wald test results for each model effect if a CLASS variable is involved in a MODEL effect. The NONE option can be used to suppress such display.

LR

requests the likelihood ratio tests. This request is not honored if the COVS option is also specified.

SCORE

requests the score tests. This request is not honored if the COVS option is also specified.

WALD

requests the Wald tests.

*

EFFECT Statement

EFFECT *name=effect-type (variables </ options>)* ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.
MULTIMEMBER MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 67.5 summarizes the *options* available in the EFFECT statement.

Table 67.5 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect
Lag Effects Options	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Multimember Effects Options	
NOEFFECT	Specifies that observations with all missing levels for the multi-member variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
    <,<'label'> estimate-specification <(divisor=n)>> <,<...>
    </options>;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form $\mathbf{L}\boldsymbol{\beta}$. You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 67.6 summarizes *options* available in the ESTIMATE statement. If the BAYES statement is specified, the ADJUST=, STEPDOWN, TESTVALUE, LOWER, UPPER, and JOINT options are ignored. The PLOTS= option is not available for the maximum likelihood analysis. It is available only for the Bayesian analysis.

Table 67.6 ESTIMATE Statement Options

Option	Description
Construction and Computation of Estimable Functions	
DIVISOR=	Specifies a list of values to divide the coefficients
NOFILL	Suppresses the automatic fill-in of coefficients for higher-order effects
SINGULAR=	Tunes the estimability checking difference
Degrees of Freedom and <i>p</i>-values	
ADJUST=	Determines the method for multiple comparison adjustment of estimates
ALPHA= α	Determines the confidence level $(1 - \alpha)$
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiplicity-corrected <i>p</i> -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits
CORR	Displays the correlation matrix of estimates
COV	Displays the covariance matrix of estimates
E	Prints the \mathbf{L} matrix
JOINT	Produces a joint <i>F</i> or chi-square test for the estimable functions
PLOTS=	Requests ODS statistical graphics if the analysis is sampling-based
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 of Chapter 19, “Shared Concepts and Topics.”

FREQ Statement

FREQ *variable* < / *option* > ;

The FREQ statement identifies the *variable* (in the input data set) that contains the frequency of occurrence of each observation. PROC PHREG treats each observation as if it appears n times, where n is the value of the FREQ variable for the observation. If not an integer, the frequency value is truncated to an integer. If the frequency value is missing, the observation is not used in the estimation of the regression parameters.

The following option can be specified in the FREQ statement after a slash (/):

NOTRUNCATE

NOTRUNC

specifies that frequency values are not truncated to integers.

HAZARDRATIO Statement

HAZARDRATIO < '*label*' > *variable* < / *options* > ;

The HAZARDRATIO statement enables you to request hazard ratios for any variable in the model at customized settings. For example, if the model contains the interaction of a CLASS variable A and a continuous variable X, the following specification displays a table of hazard ratios comparing the hazards of each pair of levels of A at X=3:

```
hazardratio A / at (X=3) diff=ALL;
```

The HAZARDRATIO statement identifies the variable whose hazard ratios are to be evaluated. If the variable is a continuous variable, the hazard ratio compares the hazards for a given change (by default, a increase of 1 unit) in the variable. For a CLASS variable, a hazard ratio compares the hazards of two levels of the variable. More than one HAZARDRATIO statement can be specified, and an optional label (specified as a quoted string) helps identify the output.

Table 67.7 summarizes the options available in the HAZARDRATIO statement.

Table 67.7 HAZARDRATIO Statement Options

Option	Description
ALPHA=	Specifies the alpha level
AT	Specifies the variables that interact with the variable of interest
CL=	Specifies confidence limits
DIFF=	Specifies which differences to consider
E	Displays the log-hazard ratio
PLCONV=	Controls the convergence criterion
PLMAXIT=	Specifies the maximum number of iterations to achieve the convergence
PLSINGULAR=	Specifies the tolerance for testing the singularity
UNITS=	Specifies the units of change

Options for the HAZARDRATIO statement are as follows.

ALPHA=number

specifies the alpha level of the interval estimates for the hazard ratios. The value must be between 0 and 1. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified.

AT (variable=ALL | REF | list < ... variable=ALL | REF | list >)

specifies the variables that interact with the variable of interest and the corresponding values of the interacting variables. If the interacting variable is continuous and a numeric list is specified after the equal sign, hazard ratios are computed for each value in the list. If the interacting variable is a CLASS variable, you can specify, after the equal sign, a list of quoted strings corresponding to various levels of the CLASS variable, or you can specify the keyword ALL or REF. Hazard ratios are computed at each value of the list if the list is specified, or at each level of the interacting variable if ALL is specified, or at the reference level of the interacting variable if REF is specified.

If this option is not specified, PROC PHREG finds all the variables that interact with the variable of interest. If an interacting variable is a CLASS variable, *variable= ALL* is the default; if the interacting variable is continuous, *variable=m* is the default, where *m* is the average of all the sampled values of the continuous variable.

Suppose the model contains two interactions: an interaction A*B of CLASS variables A and B, and another interaction A*X of A with a continuous variable X. If 3.5 is the average of the sampled values of X, the following two HAZARDRATIO statements are equivalent:

```
hazardratio A;
hazardratio A / at (B=ALL X=3.5);
```

CL=WALD | PL | BOTH

specifies whether to create the Wald or profile-likelihood confidence limits, or both for the classical analysis. By default, Wald confidence limits are produced. This option is not applicable to a Bayesian analysis.

DIFF=ALL | REF

specifies which differences to consider for the level comparisons of a CLASS variable. The default is DIFF=ALL. This option is ignored in the estimation of hazard ratios for a continuous variable. DIFF=ALL requests all differences, and DIFF=REF requests comparisons between the reference level and all other levels of the CLASS variable.

E

displays the vector **h** of linear coefficients such that $\mathbf{h}'\boldsymbol{\beta}$ is the log-hazard ratio, with $\boldsymbol{\beta}$ being the vector of regression coefficients.

PLCONV=value

controls the convergence criterion for the profile-likelihood confidence limits. The quantity *value* must be a positive number, with a default value of 1E-4. The PLCONV= option has no effect if profile-likelihood confidence intervals (CL=PL) are not requested.

PLMAXIT=*n*

specifies the maximum number of iterations to achieve the convergence of the profile-likelihood confidence limits. By default, PLMAXITER=25. If convergence is not attained in *n* iterations, the corresponding profile-likelihood confidence limit for the hazard ratio is set to missing. The PLMAXITER= option has no effect if profile-likelihood confidence intervals (CL=PL) are not requested.

PLSINGULAR=*value*

specifies the tolerance for testing the singularity of the Hessian matrix in the computation of the profile-likelihood confidence limits. The test requires that a pivot for sweeping this matrix be at least this number times a norm of the matrix. Values of the PLSINGULAR= option must be numeric. By default, *value* is the machine epsilon times 1E7, which is approximately 1E–9. The PLSINGULAR= option has no effect if profile-likelihood confidence intervals (CL=PL) are not requested.

UNITS=*value*

specifies the units of change in the continuous explanatory variable for which the customized hazard ratio is estimated. The default is UNITS=1. This option is ignored in the computation of the hazard ratios for a CLASS variable.

ID Statement

ID *variables* ;

The ID statement specifies additional variables for identifying observations in the input data. These variables are placed in the OUT= data set created by the OUTPUT statement. In the computation of the COVSANDWICH estimate, you can aggregate over distinct values of these ID variables.

Only variables in the input data set can be included in the ID statement.

LSMEANS Statement

LSMEANS < *model-effects* > < / *options* > ;

The LSMEANS statement compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 67.8 summarizes the options available in the LSMEANS statement. If the BAYES statement is specified, the ADJUST=, STEPDOWN, and LINES options are ignored. The PLOTS= option is not available for the maximum likelihood analysis. It is available only for the Bayesian analysis.

Table 67.8 LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies the covariate value in computing LS-means
BYLEVEL	Computes separate margins
DIFF	Requests differences of LS-means
OM=	Specifies the weighting scheme for LS-means computation as determined by the input data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level ($1 - \alpha$)
STEPDOWN	Adjusts multiple-comparison p -values further in a step-down fashion
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
LINES	Produces a “Lines” display for pairwise LS-means differences
MEANS	Prints the LS-means
PLOTS=	Requests graphs of means and mean comparisons
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMEANS statement, see the section “[LSMEANS Statement](#)” on page 453 of Chapter 19, “[Shared Concepts and Topics](#).”

LSMESTIMATE Statement

```
LSMESTIMATE model-effect < 'label' > values < divisor=n >
              < , < 'label' > values < divisor=n > > < , ... >
              < / options > ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 67.9 summarizes the options available in the LSMESTIMATE statement. If the BAYES statement is specified, the ADJUST=, STEPDOWN, TESTVALUE, LOWER, UPPER, and JOINT options are ignored. The PLOTS= option is not available for the maximum likelihood analysis. It is available only for the Bayesian analysis.

Table 67.9 LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
BYLEVEL	Computes separate margins
DIVISOR=	Specifies a list of values to divide the coefficients
OM=	Specifies the weighting scheme for LS-means computation as determined by a data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level ($1 - \alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiple-comparison p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
ELSM	Prints the K matrix
JOINT	Produces a joint F or chi-square test for the LS-means and LS-means differences
PLOTS=	Requests graphs of means and mean comparisons
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMESTIMATE statement, see the section “[LSMESTIMATE Statement](#)” on page 470 of Chapter 19, “[Shared Concepts and Topics](#).”

MODEL Statement

MODEL *response* < * *censor* (*list*) > = *effects* < / *options* > ;

MODEL (*t1*, *t2*) < * *censor* (*list*) > = *effects* < / *options* > ;

The MODEL statement identifies the variables to be used as the failure time variables, the optional censoring variable, and the explanatory effects, including covariates, main effects, interactions, nested effects; see the section “[Specification of Effects](#)” on page 3324 of Chapter 42, “[The GLM Procedure](#),” for more information. A note of caution: specifying the effect T*A in the MODEL statement, where T is the time variable and A is

a CLASS variable, does not make the effect time-dependent. See the section “[Time and CLASS Variables Usage](#)” on page 5609 for more information.

Two forms of MODEL syntax can be specified; the first form allows one time variable, and the second form allows two time variables for the counting process style of input (see the section “[Counting Process Style of Input](#)” on page 5615 for more information).

In the first MODEL statement, the name of the failure time variable precedes the equal sign. This name can optionally be followed by an asterisk, the name of the censoring variable, and a list of censoring values (separated by blanks or commas if there is more than one) enclosed in parentheses. If the censoring variable takes on one of these values, the corresponding failure time is considered to be censored. Following the equal sign are the explanatory effects (sometimes called independent variables or covariates) for the model.

Instead of a single failure-time variable, the second MODEL statement identifies a pair of failure-time variables. Their names are enclosed in parentheses, and they signify the endpoints of a semiclosed interval $(t1, t2]$ during which the subject is at risk. If the censoring variable takes on one of the censoring values, the time $t2$ is considered to be censored.

The censoring variable must be numeric and the failure-time variables must contain nonnegative values. Any observation with a negative failure time is excluded from the analysis, as is any observation with a missing value for any of the variables listed in the MODEL statement. Failure-time variables with a SAS date format are not recommended because the dates might be translated into negative numbers and consequently the corresponding observation would be discarded.

[Table 67.10](#) summarizes the *options* available in the MODEL statement. These *options* can be specified after a slash (/). Four convergence criteria are allowed for the maximum likelihood optimization: ABSFCONV=, FCONV=, GCONV=, and XCONV=. If you specify more than one convergence criterion, the optimization is terminated as soon as one of the criteria is satisfied. If none of the criteria is specified, the default is GCONV=1E-8.

Table 67.10 MODEL Statement Options

Option	Description
Model Specification Options	
NOFIT	Suppresses model fitting
OFFSET=	Specifies offset variable
SELECTION=	Specifies effect selection method
Effect Selection Options	
BEST=	Controls the number of models displayed for SCORE selection
DETAILS	Requests detailed results at each step
HIERARCHY=	Specifies whether and how hierarchy is maintained and whether a single effect or multiple effects are allowed to enter or leave the model per step
INCLUDE=	Specifies number of effects included in every model
MAXSTEP=	Specifies maximum number of steps for STEPWISE selection
SEQUENTIAL	Adds or deletes effects in sequential order
SLENTRY=	Specifies significance level for entering effects
SLSTAY=	Specifies significance level for removing effects

Table 67.10 *continued*

Option	Description
START=	Specifies number of variables in first model
STOP=	Specifies number of variables in final model
STOPRES	Adds or deletes variables by residual chi-square criterion
Maximum Likelihood Optimization Options	
ABSFCONV=	Specifies absolute function convergence criterion
FCONV=	Specifies relative function convergence criterion
FIRTH	Specifies Firth's penalized likelihood method
GCONV=	Specifies relative gradient convergence criterion
XCONV=	Specifies relative parameter convergence criterion
MAXITER=	Specifies maximum number of iterations
RIDGEINIT=	Specifies the initial ridging value
RIDGING=	Specifies the technique to improve the log likelihood function when its value is worse than that of the previous step
SINGULAR=	Specifies tolerance for testing singularity
Confidence Interval Options	
ALPHA=	Specifies α for the $100(1 - \alpha)\%$ confidence intervals
PLCONV=	Specifies profile-likelihood convergence criterion
RISKLIMITS=	Computes confidence intervals for hazard ratios
Display Options	
CORRB	Displays correlation matrix
COVB	Displays covariance matrix
ITPRINT	Displays iteration history
NODUMMYPRINT	Suppresses "Class Level Information" table
TYPE1	Displays Type 1 analysis
TYPE3	Displays Type 3 analysis
Miscellaneous Options	
ENTRYTIME=	Specifies the delayed entry time variable
TIES=	Specifies the method of handling ties in failure times

ALPHA=value

sets the significance level used for the confidence limits for the hazard ratios. The quantity *value* must be between 0 and 1. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified. This option has no effect unless the RISKLIMITS option is specified.

ABSFCONV=value**CONVERGELIKE=value**

specifies the absolute function convergence criterion. Termination requires a small change in the objective function (log partial likelihood function) in subsequent iterations,

$$|l_k - l_{k-1}| < \text{value}$$

where l_k is the value of the objective function at iteration k .

BEST=*n*

is used exclusively with the SCORE model selection method. The BEST=*n* option specifies that *n* models with the highest-score chi-square statistics are to be displayed for each model size. If the option is omitted and there are no more than 10 explanatory variables, then all possible models are listed for each model size. If the option is omitted and there are more than 10 explanatory variables, then the number of models selected for each model size is, at most, equal to the number of explanatory variables listed in the MODEL statement.

See [Example 67.2](#) for an illustration of the SCORE selection method and the BEST= option.

CORRB

displays the estimated correlation matrix of the parameter estimates.

COVB

displays the estimated covariance matrix of the parameter estimates.

DETAILS

produces a detailed display at each step of the model-building process. It produces an “Analysis of Variables Not in the Model” table before displaying the variable selected for entry for FORWARD or STEPWISE selection. For each model fitted, it produces the “Analysis of Maximum Likelihood Estimates” table.

See [Example 67.1](#) for a discussion of these tables.

ENTRYTIME=variable**ENTRY=variable**

specifies the name of the variable that represents the left-truncation time. This option has no effect when the counting process style of input is specified. See the section “[Left-Truncation of Failure Times](#)” on page 5617 for more information.

FCONV=value

specifies the relative function convergence criterion. Termination requires a small relative change in the objective function (log partial likelihood function) in subsequent iterations,

$$\frac{|l_k - l_{k-1}|}{|l_{k-1}| + 1\text{E} - 6} < \text{value}$$

where l_k is the value of the objective function at iteration k .

FIRTH

performs Firth’s penalized maximum likelihood estimation to reduce bias in the parameter estimates (Heinze and Schemper 2001; Firth 1993). This method is useful when the likelihood is monotone—that is, the likelihood converges to finite value while at least one estimate diverges to infinity.

GCONV=value

specifies the relative gradient convergence criterion. Termination requires that the normalized prediction function reduction is small,

$$\frac{\mathbf{g}_k \mathbf{H}_k^{-1} \mathbf{g}_k}{|l_k| + 1\text{E} - 6} < \text{value}$$

where l_k is the log partial likelihood, \mathbf{g}_k is the gradient vector (first partial derivatives of the log partial likelihood), and \mathbf{H}_k is the negative Hessian matrix (second partial derivatives of the log partial likelihood), all at iteration k .

HIERARCHY=*keyword*

HIER=*keyword*

specifies whether and how the model hierarchy requirement is applied and whether a single effect or multiple effects are allowed to enter or leave the model in one step. You can specify that only CLASS variable effects, or both CLASS and continuous variable effects, be subject to the hierarchy requirement. The HIERARCHY= option is ignored unless you also specify the FORWARD, BACKWARD, or STEPWISE selection method.

Model hierarchy refers to the requirement that, for any term to be in the model, all effects contained in the term must be present in the model. For example, in order for the interaction A*B to enter the model, the main effects A and B must be in the model. Likewise, neither effect A nor B can leave the model while the interaction A*B is in the model.

You can specify any of the following *keywords* in the HIERARCHY= option:

NONE

indicates that the model hierarchy is not maintained. Any single effect can enter or leave the model at any given step of the selection process.

SINGLE

indicates that only one effect can enter or leave the model at one time, subject to the model hierarchy requirement. For example, suppose that you specify the main effects A and B and the interaction of A*B in the model. In the first step of the selection process, either A or B can enter the model. In the second step, the other main effect can enter the model. The interaction effect can enter the model only when both main effects have already been entered. Also, before A or B can be removed from the model, the A*B interaction must first be removed. All effects (CLASS and continuous variables) are subject to the hierarchy requirement.

SINGLECLASS

is the same as HIERARCHY=SINGLE except that only CLASS effects are subject to the hierarchy requirement.

MULTIPLE

indicates that more than one effect can enter or leave the model at one time, subject to the model hierarchy requirement. In a forward selection step, a single main effect can enter the model, or an interaction can enter the model together with all the effects that are contained in the interaction. In a backward elimination step, an interaction itself, or the interaction together with all the effects that the interaction contains, can be removed. All effects (CLASS and continuous variable) are subject to the hierarchy requirement.

MULTIPLECLASS

is the same as HIERARCHY=MULTIPLE except that only CLASS effects are subject to the hierarchy requirement.

The default value is HIERARCHY=SINGLE, which means that model hierarchy is to be maintained for all effects (that is, both CLASS and continuous variable effects) and that only a single effect can enter or leave the model at each step.

INCLUDE=*n*

includes the first *n* effects in the MODEL statement in every model. By default, INCLUDE=0. The INCLUDE= option has no effect when SELECTION=NONE.

ITPRINT

displays the iteration history, including the last evaluation of the gradient vector.

MAXITER=*n*

specifies the maximum number of iterations allowed. The default value for *n* is 25. If convergence is not attained in *n* iterations, the displayed output and all data sets created by PROC PHREG contain results that are based on the last maximum likelihood iteration.

MAXSTEP=*n*

specifies the maximum number of times the explanatory variables can move in and out of the model before the STEPWISE model-building process ends. The default value for *n* is twice the number of explanatory variables in the MODEL statement. The option has no effect for other model selection methods.

NODUMMYPRINT**NODESIGNPRINT****NODP**

suppresses the “Class Level Information” table, which shows how the design matrix columns for the CLASS variables are coded.

NOFIT

performs the global score test, which tests the joint significance of all the explanatory variables in the MODEL statement. No parameters are estimated. If the NOFIT option is specified along with other MODEL statement options, NOFIT takes precedence, and all other options are ignored except the TIES= option.

OFFSET=*name*

specifies the name of an offset variable, which is an explanatory variable with a regression coefficient fixed as one. This option can be used to incorporate risk weights for the likelihood function.

PLCONV=*value*

controls the convergence criterion for confidence intervals based on the profile-likelihood function. The quantity *value* must be a positive number, with a default value of 1E–4. The PLCONV= option has no effect if profile-likelihood based confidence intervals are not requested.

RIDGING=*keyword*

specifies the technique to improve the log likelihood when its value is worse than that of the previous step. The available *keywords* are as follows:

ABSOLUTE

specifies that the diagonal elements of the negative (expected) Hessian be inflated by adding the ridge value.

RELATIVE

specifies that the diagonal elements be inflated by the factor equal to 1 plus the ridge value.

NONE

specifies the crude line-search method of taking half a step be used instead of ridging.

The default is RIDGING=RELATIVE.

RIDGEINIT=*value*

specifies the initial ridge value. The maximum ridge value is 2000 times the maximum of 1 and the initial ridge value. The initial ridge value is raised to 1E-4 if it is less than 1E-4. By default, RIDGEINIT=1E-4. This option has no effect for RIDGING=ABSOLUTE.

RISKLIMITS<=*keyword*>**RL**<=*keyword*>

produces confidence intervals for hazard ratios of main effects not involved in interactions or nestings. Computation of these confidence intervals is based on the profile likelihood or based on individual Wald tests. The confidence coefficient can be specified with the [ALPHA=](#) option. You can specify one of the following keywords:

PL

requests profile-likelihood confidence limits.

WALD

requests confidence limits based on the Wald tests.

BOTH

request both profile-likelihood and Wald confidence limits.

Classification main effects that use parameterizations other than REF, EFFECT, or GLM are ignored. If you need to compute hazard ratios for an effect involved in interactions or nestings, or using some other parameterization, then you should specify a [HAZARDRATIO statement](#) for that effect.

SELECTION=*method*

specifies the method used to select the model. The *methods* available are as follows:

BACKWARD**B**

requests backward elimination.

FORWARD**F**

requests forward selection.

NONE**N**

fits the complete model specified in the MODEL statement. This is the default value.

SCORE

requests best subset selection. It identifies a specified number of models with the highest-score chi-square statistic for all possible model sizes ranging from one explanatory variable to the total number of explanatory variables listed in the MODEL statement. This option is not allowed if an explanatory effect in the MODEL statement contains a CLASS variable.

STEPWISE**S**

requests stepwise selection.

For more information, see the section “[Effect Selection Methods](#)” on page 5648.

SEQUENTIAL

forces variables to be added to the model in the order specified in the MODEL statement or to be eliminated from the model in the reverse order of that specified in the MODEL statement.

SINGULAR=value

specifies the singularity criterion for determining linear dependencies in the set of explanatory variables. The default value is 1E-12.

SLENTY=value**SLE=value**

specifies the significance level (a value between 0 and 1) for entering an explanatory variable into the model in the FORWARD or STEPWISE method. For all variables not in the model, the one with the smallest p -value is entered if the p -value is less than or equal to the specified significance level. The default value is 0.05.

SLSTAY=value**SLS=value**

specifies the significance level (a value between 0 and 1) for removing an explanatory variable from the model in the BACKWARD or STEPWISE method. For all variables in the model, the one with the largest p -value is removed if the p -value exceeds the specified significance level. The default value is 0.05.

START=n

begins the FORWARD, BACKWARD, or STEPWISE selection process with the first n effects listed in the MODEL statement. The value of n ranges from 0 to s , where s is the total number of effects in the MODEL statement. The default value of n is s for the BACKWARD method and 0 for the FORWARD and STEPWISE methods. Note that $\text{START}=n$ specifies only that the first n effects appear in the first model, while $\text{INCLUDE}=n$ requires that the first n effects be included in every model. For the SCORE method, $\text{START}=n$ specifies that the smallest models contain n effects, where n ranges from 1 to s ; the default value is 1. The $\text{START}=$ option has no effect when $\text{SELECTION}=\text{NONE}$.

STOP=n

specifies the maximum (FORWARD method) or minimum (BACKWARD method) number of effects to be included in the final model. The effect selection process is stopped when n effects are found. The value of n ranges from 0 to s , where s is the total number of effects in the MODEL statement. The default value of n is s for the FORWARD method and 0 for the BACKWARD method. For the SCORE method, $\text{STOP}=n$ specifies that the smallest models contain n effects, where n ranges from 1 to s ; the default value of n is s . The $\text{STOP}=$ option has no effect when $\text{SELECTION}=\text{NONE}$ or STEPWISE.

STOPRES**SR**

specifies that the addition and deletion of variables be based on the result of the likelihood score test for testing the joint significance of variables not in the model. This score chi-square statistic is referred to as the residual chi-square. In the FORWARD method, the STOPRES option enters the explanatory variables into the model one at a time until the residual chi-square becomes insignificant (that is, until the p -value of the residual chi-square exceeds the SLENTY= value). In the BACKWARD method, the STOPRES option removes variables from the model one at a time until the residual chi-square becomes significant (that is, until the p -value of the residual chi-square becomes less than the SLSTAY= value). The STOPRES option has no effect for the STEPWISE method.

TYPE1

requests that a Type 1 (sequential) analysis of likelihood ratio test be performed. This consists of sequentially fitting models, beginning with the null model and continuing up to the model specified in the MODEL statement. The likelihood ratio statistic for each successive pair of models is computed and displayed in a table.

TYPE3 <(keywords)>

requests a Type 3 test for each effect that is specified in the MODEL statement. The default is to use the Wald statistic, but you can request other statistics by specifying one or more of the following keywords:

ALL

requests the likelihood ratio tests, the score tests, and the Wald tests. Specifying TYPE3(ALL) is equivalent to specifying TYPE3=(LR SCORE WALD).

NONE

suppresses the Type 3 analysis. Even if the TYPE3 option is not specified, PROC PHREG displays the Wald test results for each model effect if a CLASS variable is involved in a MODEL effect. The NONE option can be used to suppress such display.

LR

requests the likelihood ratio tests. This request is not honored if the COVS option is also specified.

SCORE

requests the score tests. This request is not honored if the COVS option is also specified.

WALD

requests the Wald tests.

TIES=method

specifies how to handle ties in the failure time. The following *methods* are available:

BRESLOW

uses the approximate likelihood of Breslow (1974). This is the default value.

DISCRETE

replaces the proportional hazards model by the discrete logistic model

$$\frac{\lambda(t; \mathbf{z})}{1 - \lambda(t; \mathbf{z})} = \frac{\lambda_0(t)}{1 - \lambda_0(t)} \exp(\mathbf{z}'\boldsymbol{\beta})$$

where $\lambda_0(t)$ and $h(t; \mathbf{z})$ are discrete hazard functions.

EFRON

uses the approximate likelihood of Efron (1977).

EXACT

computes the exact conditional probability under the proportional hazards assumption that all tied event times occur before censored times of the same value or before larger values. This is equivalent to summing all terms of the marginal likelihood for β that are consistent with the observed data (Kalbfleisch and Prentice 1980; DeLong, Guirguis, and So 1994).

The EXACT method can take a considerable amount of computer resources. If ties are not extensive, the EFRON and BRESLOW methods provide satisfactory approximations to the EXACT method for the continuous time-scale model. In general, Efron's approximation gives results that are much closer to the EXACT method results than Breslow's approximation does. If the time scale is genuinely discrete, you should use the DISCRETE method. The DISCRETE method is also required in the analysis of case-control studies when there is more than one case in a matched set. If there are no ties, all four methods result in the same likelihood and yield identical estimates. The default, TIES=BRESLOW, is the most efficient method when there are no ties.

XCONV=*value*

CONVEREPARM=*value*

specifies the relative parameter convergence criterion. Termination requires a small relative parameter change in subsequent iterations,

$$\max_i |\delta_k^{(i)}| < \text{value}$$

where

$$\delta_k^{(i)} = \begin{cases} \theta_k^{(i)} - \theta_{k-1}^{(i)} & |\theta_{k-1}^{(i)}| < .01 \\ \frac{\theta_k^{(i)} - \theta_{k-1}^{(i)}}{\theta_{k-1}^{(i)}} & \text{otherwise} \end{cases}$$

where $\theta_k^{(i)}$ is the estimate of the i th parameter at iteration k .

OUTPUT Statement

OUTPUT < **OUT=***SAS-data-set* > < **keyword=***name* ... **keyword=***name* > < / *options* > ;

The OUTPUT statement creates a new SAS data set containing statistics calculated for each observation. These can include the estimated linear predictor ($\mathbf{z}'_j \hat{\beta}$) and its standard error, survival distribution estimates, residuals, and influence statistics. In addition, this data set includes the time variable, the explanatory variables listed in the MODEL statement, the censoring variable (if specified), and the BY, STRATA, FREQ, and ID variables (if specified).

For observations with missing values in the time variable or any explanatory variables, the output statistics are set to missing. However, for observations with missing values only in the censoring variable or the FREQ variable, survival estimates are still computed. Therefore, by adding observations with missing values in the FREQ variable or the censoring variable, you can compute the survivor function estimates for new observations or for settings of explanatory variables not present in the data without affecting the model fit.

No OUTPUT data set is created if the model contains a time-dependent variable defined by means of programming statements.

The following list explains specifications in the OUTPUT statement.

OUT=SAS-data-set

names the output data set. If you omit the OUT= option, the OUTPUT data set is created and given a default name by using the `DATAn` convention. See the section “[OUT= Output Data Set in the OUTPUT Statement](#)” on page 5665 for more information.

keyword=name

specifies the statistics included in the OUTPUT data set and names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and either a variable or a list of variables to contain the statistic. The keywords that accept a list of variables are DFBETA, RESSCH, RESSCO, and WTRESSCH. For these keywords, you can specify as many names in *name* as the number of explanatory variables specified in the MODEL statement. If you specify k names and k is less than the total number of explanatory variables, only the changes for the first k parameter estimates are output. The keywords and the corresponding statistics are as follows:

ATRISK

specifies the number of subjects at risk at the observation time τ_j (or at the right endpoint of the at-risk interval when a counting process MODEL specification is used).

DFBETA

specifies the approximate changes in the parameter estimates ($\hat{\beta} - \hat{\beta}_{(j)}$) when the j th observation is omitted. These variables are a weighted transform of the score residual variables and are useful in assessing local influence and in computing robust variance estimates.

LD

specifies the approximate likelihood displacement when the observation is left out. This diagnostic can be used to assess the impact of each observation on the overall fit of the model.

LMAX

specifies the relative influence of observations on the overall fit of the model. This diagnostic is useful in assessing the sensitivity of the fit of the model to each observation.

LOGLOGS

specifies the log of the negative log of [SURVIVAL](#).

LOGSURV

specifies the log of [SURVIVAL](#).

RESDEV

specifies the deviance residual \hat{D}_j . This is a transform of the martingale residual to achieve a more symmetric distribution.

RESMART

specifies the martingale residual \hat{M}_j . The residual at the observation time τ_j can be interpreted as the difference over $[0, \tau_j]$ in the observed number of events minus the expected number of events given by the model.

RESSCH

specifies the Schoenfeld residuals. These residuals are useful in assessing the proportional hazards assumption.

RESSCO

specifies the score residuals. These residuals are a decomposition of the first partial derivative of the log likelihood. They can be used to assess the leverage exerted by each subject in the parameter estimation. They are also useful in constructing robust sandwich variance estimators.

STDXBETA

specifies the standard error of the **XBETA** predictor, $\sqrt{\mathbf{z}'_j \hat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) \mathbf{z}_j}$.

SURVIVAL

specifies the survivor function estimate $\hat{S}_j = [\hat{S}_0(\tau_j)]^{\exp(\mathbf{z}'_j \hat{\boldsymbol{\beta}})}$, where τ_j is the observation time.

WTRESSCH

specifies the weighted Schoenfeld residuals. These residuals are useful in investigating the nature of nonproportionality if the proportional hazard assumption does not hold.

XBETA

specifies the estimate of the linear predictor, $\mathbf{z}'_j \hat{\boldsymbol{\beta}}$.

The following *options* can appear in the OUTPUT statement after a slash (/) as follows:

ORDER=*value*

specifies the order of the observations in the OUTPUT data set. The following *values* are available:

- | | |
|--------|--|
| DATA | requests that the output observations be sorted the same as the input data set. |
| SORTED | requests that the output observations be sorted by strata and descending order of the time variable within each stratum. |

The default is ORDER=DATA.

METHOD=*method*

specifies the method used to compute the survivor function estimates. See the section “[Survivor Function Estimators](#)” on page 5643 for details. The following *methods* are available:

BRESLOW**CH****EMP**

specifies that the empirical cumulative hazard function estimate of the survivor function be computed; that is, the survivor function is estimated by exponentiating the negative empirical cumulative hazard function.

FH

specifies that the Fleming-Harrington (FH) estimates be computed. The FH estimator is a tie-breaking modification of the Breslow estimator. If there are no tied event times, this estimator is the same as the Breslow estimator.

PL

specifies that the product-limit estimates of the survivor function be computed. This estimator is not available if you use the model syntax that allows two time variables for the counting process style of input; in such a case, the Breslow estimator (METHOD=BRESLOW) is used instead.

The default is METHOD=BRESLOW.

Programming Statements

Programming statements are used to create or modify the values of the explanatory variables in the MODEL statement. They are especially useful in fitting models with time-dependent explanatory variables. Programming statements can also be used to create explanatory variables that are not time dependent. For example, you can create indicator variables from a categorical variable and incorporate them into the model. PROC PHREG programming statements cannot be used to create or modify the values of the response variable, the censoring variable, the frequency variable, or the strata variables.

The following DATA step statements are available in PROC PHREG:

```
ABORT;
ARRAY arrayname <[ dimensions ]> <$> <variables-and-constants>;
CALL name <(expression <, expression ... >)>;
DELETE;
DO <variable = expression <TO expression> <BY expression>>
    < , expression <TO expression> <BY expression>> ...
    <WHILE expression> <UNTIL expression>;
END;
GOTO statement-label;
IF expression;
IF expression THEN program-statement;
    ELSE program-statement;
variable = expression;
variable + expression;
LINK statement-label;
PUT <variable> <=> ...;
RETURN;
SELECT <(expression)>;
STOP;
SUBSTR(variable, index, length)= expression;
WHEN (expression)program-statement;
    OTHERWISE program-statement;
```

By default, the PUT statement in PROC PHREG writes results to the Output window instead of the Log window. If you want the results of the PUT statements to go to the Log window, add the following statement before the PUT statements:

```
FILE LOG;
```

DATA step functions are also available. Use these programming statements the same way you use them in the DATA step. For detailed information, see *SAS Statements: Reference*.

Consider the following example of using programming statements in PROC PHREG. Suppose blood pressure is measured at multiple times during the course of a study investigating the effect of blood pressure on some survival time. By treating the blood pressure as a time-dependent explanatory variable, you are able to use the value of the most recent blood pressure at each specific point of time in the modeling process rather than using the initial blood pressure or the final blood pressure. The values of the following variables are recorded for each patient, if they are available. Otherwise, the variables contain missing values.

Time	survival time
Censor	censoring indicator (with 0 as the censoring value)
BP0	blood pressure on entry to the study
T1	time 1
BP1	blood pressure at T1
T2	time 2
BP2	blood pressure at T2

The following programming statements create a variable BP. At each time T, the value of BP is the blood pressure reading for that time, if available. Otherwise, it is the last blood pressure reading.

```
proc phreg;
  model Time*Censor(0)=BP;
  BP = BP0;
  if Time>=T1 and T1^=. then BP=BP1;
  if Time>=T2 and T2^=. then BP=BP2;
run;
```

For other illustrations of using programming statements, see the section “[Classical Method of Maximum Likelihood](#)” on page 5544 and [Example 67.6](#).

RANDOM Statement

RANDOM *variable* </ options> ;

The RANDOM statement enables you to fit a shared frailty model for clustered data (see the section “[The Frailty Model](#)” on page 5618 for details). The *variable* that represents the clusters must be a CLASS variable (declared in the CLASS statement).

The following *options* can be specified in the RANDOM statement:

ABSPCONV=*r*

specifies an absolute variance estimate convergence criterion for the doubly iterative estimation process. The PHREG procedure applies this criterion to the variance parameter estimate of the random effects. Suppose $\hat{\theta}^{(j)}$ denotes the estimate of the variance parameter at the *j*th optimization. By default, PROC PHREG examines the relative change in the variance estimate between optimizations (see the **PCONV=** option). The purpose of the ABSPCONV= criterion is to stop the doubly iterative process when the absolute change $|\hat{\theta}^{(j)} - \hat{\theta}^{(j-1)}|$ is less than the tolerance criterion *r*. This convergence criterion does not affect the convergence criteria applied within any individual optimization. In order to change the convergence behavior within an individual optimization, you can use the

ABSCONV=, ABSFCONV=, ABSGCONV=, ABSXCONV=, FCONV=, or GCONV= option in the NLOPTIONS statement.

ALPHA=value

specifies the α level of the confidence limits for the random effects. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified. This option is ignored if the SOLUTION option is not also specified.

DIST=GAMMA | LOGNORMAL

specifies the distribution of the shared frailty. DIST=GAMMA specifies a gamma frailty model. DIST=LOGNORMAL specifies a lognormal frailty model; that is, the log-frailty random variable has a normal distribution with mean zero. The default is DIST=LOGNORMAL.

METHOD=REML | ML

specifies the estimation method for the variance parameter of the normal random effects. METHOD=REML performs the residual maximum likelihood; METHOD=ML performs maximum likelihood. This option is ignored for the gamma frailty model. The default is METHOD=REML.

NOCLPRINT

suppresses the display of the “Class Level Information for Random Effects” table.

PCONV=r

specifies the variance estimate convergence criterion for the doubly iterative estimation process. The PHREG procedure applies this criterion to the variance estimate of the random effects. Suppose $\hat{\theta}^{(j)}$ denotes the estimate of variance at the j th optimization. The procedure terminates the doubly iterative process if the relative change

$$2 \times \frac{|\hat{\theta}^{(j)} - \hat{\theta}^{(j-1)}|}{|\hat{\theta}^{(j)}| + |\hat{\theta}^{(j-1)}|}$$

is less than r . To check an absolute convergence criterion in addition, you can specify the ABSPCONV= option in the RANDOM statement. The default value for r is 1E-4. This convergence criterion does not affect the convergence criteria applied within any individual optimization. In order to change the convergence behavior within an individual optimization, you can use the ABSCONV=, ABSFCONV=, ABSGCONV=, ABSXCONV=, FCONV=, or GCONV= option in the NLOPTIONS statement.

SOLUTION <(number-list)>

displays statistical measures of the random-effect parameters. The behavior of this option depends on whether you also specify the BAYES statement:

- When you do not specify a BAYES statement, this option displays point estimates and confidence intervals for the random components and for the frailties.
- When you also specify a BAYES statement, this option displays the summary statistics and diagnostics of the random-effect parameters. Optionally, you can specify a *number-list* of indices of the random-effect parameters for which the summary statistics and diagnostics are to be displayed. For example, to display the summary statistics and diagnostics for the second to the fifth random-effect parameters, specify

SOLUTION(2 to 5)

If you specify SOLUTION without a list, summary statistics and diagnostics are displayed for each random-effect parameter.

INITIALVARIANCE=*value*

INITIAL=*value*

specifies an initial value of the dispersion parameter. For the lognormal frailty model, the dispersion parameter represents the variance of the normal random effect; for the gamma frailty model, it represents the variance of the gamma frailty. The default is INITIAL=1.

STRATA Statement

STRATA *variable* <(*list*)> <... *variable* <(*list*)>> </ *option*> ;

The proportional hazards assumption might not be realistic for all data. If so, it might still be reasonable to perform a stratified analysis. The STRATA statement names the variables that determine the stratification. Strata are formed according to the nonmissing values of the STRATA variables unless the MISSING option is specified. In the STRATA statement, *variable* is a variable with values that are used to determine the strata levels, and *list* is an optional list of values for a numeric variable. Multiple variables can appear in the STRATA statement.

The values for *variable* can be formatted or unformatted. If the variable is a character variable, or if the variable is numeric and no list appears, then the strata are defined by the unique values of the variable. If the variable is numeric and is followed by a list, then the levels for that variable correspond to the intervals defined by the list. The corresponding strata are formed by the combination of levels and unique values. The list can include numeric values separated by commas or blanks, *value* to *value* by *value* range specifications, or combinations of these.

For example, the specification

```
strata age (5, 10 to 40 by 10) sex;
```

indicates that the levels for *age* are to be less than 5, 5 to 10, 10 to 20, 20 to 30, 30 to 40, and greater than 40. (Note that observations with exactly the cutpoint value fall into the interval preceding the cutpoint.) Thus, with the *sex* variable, this STRATA statement specifies 12 strata altogether.

The following option can be specified in the STRATA statement after a slash (/):

MISSING

allows missing values (‘.’ for numeric variables and blanks for character variables) as valid STRATA variable values. Otherwise, observations with missing STRATA variable values are deleted from the analysis.

SLICE Statement

SLICE *model-effect* </ *options*> ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in [Table 19.21](#). For details about the syntax of the SLICE statement, see the section “[SLICE Statement](#)” on page 498 in Chapter 19, “[Shared Concepts and Topics](#).”

STORE Statement

STORE <OUT=>*item-store-name* </ LABEL='label'> ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

TEST Statement

<label:> **TEST** *equation* <, ..., *equation*> </ options> ;

The TEST statement tests linear hypotheses about the regression coefficients. PROC PHREG performs a Wald test for the joint hypothesis specified in a single TEST statement. Each equation specifies a linear hypothesis; multiple equations (rows of the joint hypothesis) are separated by commas. The *label*, which must be a valid SAS name, is used to identify the resulting output and should always be included. You can submit multiple TEST statements.

The form of an equation is as follows:

term < ± *term* ... > < = < ± *term* < ± *term* ... > > >

where *term* is a variable or a constant or a constant times a variable. The variable is any explanatory variable in the MODEL statement. When no equal sign appears, the expression is set to 0. The following program illustrates possible uses of the TEST statement:

```
proc phreg;
  model time= A1 A2 A3 A4;
  Test1: test A1, A2;
  Test2: test A1=0,A2=0;
  Test3: test A1=A2=A3;
  Test4: test A1=A2,A2=A3;
run;
```

Note that the first and second TEST statements are equivalent, as are the third and fourth TEST statements.

The following *options* can be specified in the TEST statement after a slash (/):

AVERAGE

enables you to assess the average effect of the variables in the given TEST statement. An overall estimate of the treatment effect is computed as a weighted average of the treatment coefficients as illustrated in the following statement:

TREATMENT: test trt1, trt2, trt3, trt4 / average;

Let $\beta_1, \beta_2, \beta_3$, and β_4 be corresponding parameters for trt1, trt2, trt3, and trt4, respectively. Let $\hat{\beta} = (\hat{\beta}_1, \hat{\beta}_2, \hat{\beta}_3, \hat{\beta}_4)'$ be the estimated coefficient vector and let $\hat{V}(\hat{\beta})$ be the corresponding variance estimate. Assuming $\beta_1 = \beta_2 = \beta_3 = \beta_4$, let $\bar{\beta}$ be the average treatment effect. The effect is

estimated by $\mathbf{c}'\hat{\boldsymbol{\beta}}$, where $\mathbf{c} = [\mathbf{1}_4'\hat{\mathbf{V}}^{-1}(\hat{\boldsymbol{\beta}})\mathbf{1}_4]^{-1}\hat{\mathbf{V}}^{-1}(\hat{\boldsymbol{\beta}})\mathbf{1}_4$ and $\mathbf{1}_4 = (1, 1, 1, 1)'$. A test of the null hypothesis $H_0 : \tilde{\boldsymbol{\beta}} = 0$ is also included, which is more sensitive than the multivariate test for testing the null hypothesis $H_0 : \beta_1 = \beta_2 = \beta_3 = \beta_4 = 0$.

E

specifies that the linear coefficients and constants be printed. When the AVERAGE option is specified along with the E option, the optimal weights of the average effect are also printed in the same tables as the coefficients.

PRINT

displays intermediate calculations. This includes $\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}'$ bordered by $(\mathbf{L}\hat{\boldsymbol{\beta}} - \mathbf{c})$, and $[\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}']^{-1}$ bordered by $[\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}']^{-1}(\mathbf{L}\hat{\boldsymbol{\beta}} - \mathbf{c})$, where \mathbf{L} is a matrix of linear coefficients and \mathbf{c} is a vector of constants.

See the section “Using the TEST Statement to Test Linear Hypotheses” on page 5628 for details.

WEIGHT Statement

WEIGHT *variable* </option> ;

The *variable* in the WEIGHT statement identifies the variable in the input data set that contains the case weights. When the WEIGHT statement appears, each observation in the input data set is weighted by the value of the WEIGHT variable. The WEIGHT values can be nonintegral and are not truncated. Observations with negative, zero, or missing values for the WEIGHT variable are not used in the model fitting. When the WEIGHT statement is not specified, each observation is assigned a weight of 1. The WEIGHT statement is available for TIES=BRESLOW and TIES=EFRON only.

The following *option* can be specified in the WEIGHT statement after a slash (/):

NORMALIZE**NORM**

causes the weights specified by the WEIGHT *variable* to be normalized so that they add up the actual sample size. With this option, the estimated covariance matrix of the parameter estimators is invariant to the scale of the WEIGHT variable.

Details: PHREG Procedure

Failure Time Distribution

Let T be a nonnegative random variable representing the failure time of an individual from a homogeneous population. The survival distribution function (also known as the survivor function) of T is written as

$$S(t) = \Pr(T \geq t)$$

A mathematically equivalent way of specifying the distribution of T is through its hazard function. The hazard function $\lambda(t)$ specifies the instantaneous failure rate at t . If T is a continuous random variable, $\lambda(t)$ is expressed as

$$\lambda(t) = \lim_{\Delta t \rightarrow 0^+} \frac{\Pr(t \leq T < t + \Delta t \mid T \geq t)}{\Delta t} = \frac{f(t)}{S(t)}$$

where $f(t)$ is the probability density function of T . If T is discrete with masses at $x_1 < x_2 < \dots$, then survivor function is given by

$$S(t) = \sum_{x_j \leq t} \Pr(T = x_j) = \sum_j \Pr(T = j) \delta(t - x_j)$$

where $\delta(u)=0$ if $u < 0$ and $\delta(u)=1$ otherwise. The discrete hazards are given by

$$\lambda_j = \Pr(T = x_j \mid T \geq x_j) = \frac{\Pr(T = x_j)}{S(x_j)} \quad j = 1, 2, \dots$$

Time and CLASS Variables Usage

The following DATA step creates an artificial data set, `Test`, to be used in this section. There are four variables in `Test`: the variable `T` contains the failure times; the variable `Status` is the censoring indicator variable with the value 1 for an uncensored failure time and the value 0 for a censored time; the variable `A` is a categorical variable with values 1, 2, and 3 representing three different categories; and the variable `MirrorT` is an exact copy of `T`.

```
data Test;
  input T Status A @@;
  MirrorT = T;
  datalines;
23      1      1      7      0      1
23      1      1     10      1      1
20      0      1     13      0      1
24      1      1     10      1      1
18      1      2      6      1      2
18      0      2      6      1      2
13      0      2     13      1      2
 9      0      2     15      1      2
 8      1      3      6      1      3
12      0      3      4      1      3
11      1      3      8      1      1
 6      1      3      7      1      3
 7      1      3     12      1      3
 9      1      2     15      1      2
 3      1      2     14      0      3
 6      1      1     13      1      2
;
```

Time Variable on the Right Side of the MODEL Statement

When the time variable is explicitly used in an explanatory effect in the MODEL statement, the effect is *not* time-dependent. In the following specification, T is the time variable, but T does not play the role of the time variable in the explanatory effect T*A:

```
proc phreg data=Test;
  class A;
  model T*Status(0)=T*A;
run;
```

The parameter estimates of this model are shown in Figure 67.12.

Figure 67.12 T*A Effect

The PHREG Procedure								
Analysis of Maximum Likelihood Estimates								
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio	Label	
T*A	1 1	-0.16549	0.05042	10.7734	0.0010	.	A 1 * T	
T*A	2 1	-0.11852	0.04181	8.0344	0.0046	.	A 2 * T	

To verify that the effect T*A in the MODEL statement is not time-dependent, T is replaced by MirrorT, which is an exact copy of T, as in the following statements:

```
proc phreg data=Test;
  class A;
  model T*Status(0)=A*MirrorT;
run;
```

The results of fitting this model (Figure 67.13) are identical to those of the previous model (Figure 67.12), except for the parameter names and labels. The effect A*MirrorT is not time-dependent, so neither is A*T.

CLASS Variables and Programming Statements

In PROC PHREG, the levels of CLASS variables are determined by the CLASS statement and the input data and are not affected by user-supplied programming statements. Consider the following statements, which produce the results in [Figure 67.14](#). Variable A is declared as a CLASS variable in the CLASS statement. By default, the reference parameterization is used with A=3 as the reference level. Two regression coefficients are estimated for the two dummy variables of A.

```
proc phreg data=Test;
  class A;
  model T*Status(0)=A;
run;
```

[Figure 67.14](#) shows the dummy variables of A and the regression coefficients estimates.

Analysis of Maximum Likelihood Estimates							
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio	Label
A	1	-1.40925	0.64802	4.7293	0.0297	0.244	A 1
A	2	-0.65705	0.51764	1.6112	0.2043	0.518	A 2

Now consider the programming statement that attempts to change the value of the CLASS variable A as in the following specification:

```
proc phreg data=Test;
  class A;
  model T*Status(0)=A;
  if A=3 then A=2;
run;
```

Results of this analysis are shown in Figure 67.15 and are identical to those in Figure 67.14. The `if A=3 then A=2` programming statement has no effects on the design variables for A, which have already been determined.

Figure 67.15 Design Variable and Regression Coefficient Estimates

The PHREG Procedure								
Class Level Information								
			Class	Value	Design Variables			
			A	1	1	0		
				2	0	1		
				3	0	0		
Analysis of Maximum Likelihood Estimates								
Parameter	DF		Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio	Label
A	1	1	-1.40925	0.64802	4.7293	0.0297	0.244	A 1
A	2	1	-0.65705	0.51764	1.6112	0.2043	0.518	A 2

Additionally any variable used in a programming statement that has already been declared in the CLASS statement is *not* treated as a collection of the corresponding design variables. Consider the following statements:

```

proc phreg data=Test;
  class A;
  model T*Status(0)=A X;
  X=T*A;
run;

```

The CLASS variable A generates two design variables as explanatory variables. The variable X created by the `X=T*A` programming statement is a single time-dependent covariate whose values are evaluated using the exact values of A given in the data, not the dummy-coded values that represent the levels of A. In data set Test, A assumes the values of 1, 2, and 3, and these are the exact values that are used in producing X. If A were a character variable with values ‘Bird’, ‘Cat’, and ‘Dog’, the programming statement `X=T*A` would have produced an error in the attempt to multiply a number with a character value.

Figure 67.16 Single Time-Dependent Variable X*A

The PHREG Procedure							
Analysis of Maximum Likelihood Estimates							
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio	Label
A	1	0.15798	1.69338	0.0087	0.9257	1.171	A 1
A	2	0.00898	0.87573	0.0001	0.9918	1.009	A 2
X	1	0.09268	0.09535	0.9448	0.3311	1.097	

To generalize the simple test of proportional hazard assumption for the design variables of A (as in the section the “[Classical Method of Maximum Likelihood](#)” on page 5544), you specify the following statements, which are not the same as in the preceding program or as in the specification in the section “[Time Variable on the Right Side of the MODEL Statement](#)” on page 5610:

```

proc phreg data=Test;
  class A;
  model T*Status(0)=A X1 X2;
  X1= T*(A=1);
  X2= T*(A=2);
run;

```

The Boolean parenthetical expressions (A=1) and (A=2) resolve to a value of 1 or 0, depending on whether the expression is true or false, respectively.

Results of this test are shown in [Figure 67.17](#).

Figure 67.17 Simple Test of Proportional Hazards Assumption

The PHREG Procedure								
Analysis of Maximum Likelihood Estimates								
Parameter	DF		Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio	Label
A	1	1	-0.00766	1.69435	0.0000	0.9964	0.992	A 1
A	2	1	-0.88132	1.64298	0.2877	0.5917	0.414	A 2
X1		1	-0.15522	0.20174	0.5920	0.4417	0.856	
X2		1	0.01155	0.18858	0.0037	0.9512	1.012	

In general, when your model contains a categorical explanatory variable that is time-dependent, it might be necessary to use hardcoded dummy variables to represent the categories of the categorical variable. Alternatively, you might consider using the counting-process style of input where you break up the covariate history of an individual into a number of records with nonoverlapping start and stop times and declare the categorical time-dependent variable in the CLASS statement.

Partial Likelihood Function for the Cox Model

Let $\mathbf{Z}_l(t)$ denote the vector explanatory variables for the l th individual at time t . Let $t_1 < t_2 < \dots < t_k$ denote the k distinct, ordered event times. Let d_i denote the multiplicity of failures at t_i ; that is, d_i is the size of the set \mathcal{D}_i of individuals that fail at t_i . Let w_l be the weight associated with the l th individual. Using this notation, the likelihood functions used in PROC PHREG to estimate $\boldsymbol{\beta}$ are described in the following sections.

Continuous Time Scale

Let \mathcal{R}_i denote the risk set just before the i th ordered event time t_i . Let \mathcal{R}_i^* denote the set of individuals whose event or censored times exceed t_i or whose censored times are equal to t_i .

Exact Likelihood

$$L_1(\boldsymbol{\beta}) = \prod_{i=1}^k \left\{ \int_0^\infty \prod_{j \in \mathcal{D}_i} \left[1 - \exp \left(- \frac{e^{\boldsymbol{\beta}' \mathbf{Z}_j(t_i)}}{\sum_{l \in \mathcal{R}_i^*} e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} t} \right) \right] \exp(-t) dt \right\}$$

Breslow Likelihood

$$L_2(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} \mathbf{Z}_j(t_i)}}{\left[\sum_{l \in \mathcal{R}_i} e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} \right]^{d_i}}$$

Incorporating weights, the Breslow likelihood becomes

$$L_2(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} w_j \mathbf{Z}_j(t_i)}}{\left[\sum_{l \in \mathcal{R}_i} w_l e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} \right]^{\sum_{j \in \mathcal{D}_i} w_j}}$$

Efron Likelihood

$$L_3(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} \mathbf{Z}_j(t_i)}}{\prod_{j=1}^{d_i} \left(\sum_{l \in \mathcal{R}_i} e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} - \frac{j-1}{d_i} \sum_{l \in \mathcal{D}_i} e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} \right)}$$

Incorporating weights, the Efron likelihood becomes

$$L_3(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} w_j \mathbf{Z}_j(t_i)}}{\left[\prod_{j=1}^{d_i} \left(\sum_{l \in \mathcal{R}_i} w_l e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} - \frac{j-1}{d_i} \sum_{l \in \mathcal{D}_i} w_l e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} \right) \right]^{\frac{1}{d_i} \sum_{j \in \mathcal{D}_i} w_j}}$$

Discrete Time Scale

Let \mathcal{Q}_i denote the set of all subsets of d_i individuals from the risk set \mathcal{R}_i . For each $\mathbf{q} \in \mathcal{Q}_i$, \mathbf{q} is a d_i -tuple $(q_1, q_2, \dots, q_{d_i})$ of individuals who might have failed at t_i .

Discrete Logistic Likelihood

$$L_4(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} \mathbf{Z}_j(t_i)}}{\sum_{\mathbf{q} \in \mathcal{Q}_i} e^{\boldsymbol{\beta}' \sum_{l=1}^{d_i} \mathbf{Z}_{q_l}(t_i)}}$$

The computation of $L_4(\boldsymbol{\beta})$ and its derivatives is based on an adaptation of the recurrence algorithm of Gail, Lubin, and Rubinstein (1981) to the logarithmic scale. When there are no ties on the event times (that is, $d_i \equiv 1$), all four likelihood functions $L_1(\boldsymbol{\beta})$, $L_2(\boldsymbol{\beta})$, $L_3(\boldsymbol{\beta})$, and $L_4(\boldsymbol{\beta})$ reduce to the same expression. In a stratified analysis, the partial likelihood is the product of the partial likelihood functions for the individual strata.

Counting Process Style of Input

In the counting process formulation, data for each subject are identified by a triple $\{N, Y, \mathbf{Z}\}$ of counting, at-risk, and covariate processes. Here, $N(t)$ indicates the number of events that the subject experiences over the time interval $(0, t]$; $Y(t)$ indicates whether the subject is at risk at time t (one if at risk and zero otherwise);

and $\mathbf{Z}(t)$ is a vector of explanatory variables for the subject at time t . The sample path of N is a step function with jumps of size +1 at the event times, and $N(0) = 0$. Unless $\mathbf{Z}(t)$ changes continuously with time, the data for each subject can be represented by multiple observations, each identifying a semiclosed time interval $(t_1, t_2]$, the values of the explanatory variables over that interval, and the event status at t_2 . The subject remains at risk during the interval $(t_1, t_2]$, and an event might occur at t_2 . Values of the explanatory variables for the subject remain unchanged in the interval. This style of data input was originated by Therneau (1994).

For example, a patient has a tumor recurrence at weeks 3, 10, and 15 and is followed up to week 23. Consider three fixed explanatory variables Trt (treatment), Number (initial tumor number), and Size (initial tumor size), and one time-dependent covariate Z that represents a hormone level. The value of Z might change during the follow-up period. The data for this patient are represented by the following four observations:

T1	T2	Status	Trt	Number	Size	Z
0	3	1	1	1	3	12.3
3	10	1	1	1	3	14.7
10	15	1	1	1	3	13.8
15	23	0	1	1	3	15.5

Here (T1,T2] contains the at-risk intervals. The variable Event indicates whether a recurrence has occurred at T2; a value of 1 indicates a tumor recurrence, and a value of 0 indicates nonrecurrence. The following statements fit a multiplicative hazards model with baseline covariates Trt, Number, and Size, and a time-varying covariate Z.

```
proc phreg;
  model (T1,T2) * Status(0) = Trt Z1 Z2 Z3;
run;
```

Another useful application of the counting process formulation is delayed entry of subjects into the risk set. For example, in studying the mortality of workers exposed to a carcinogen, the survival time is chosen to be the worker's age at death by malignant neoplasm. Any worker joining the workplace at a later age than a given event failure time is not included in the corresponding risk set. The variables of a worker consist of Entry (age at which the worker entered the workplace), Age (age at death or age censored), Status (an indicator of whether the observation time is censored, with the value 0 identifying a censored time), and X1 and X2 (explanatory variables thought to be related to survival). The specification for such an application is as follows:

```
proc phreg;
  model (Entry, Age) * Status(0) = X1 X2;
run;
```

Alternatively, you can use a time-dependent variable to control the risk set, as illustrated in the following specification:

```
proc phreg;
  model Age * Status(0) = X1 X2;
  if Age < Entry then X1= .;
run;
```

Here, X1 becomes a time-dependent variable. At a given death time t , the value of X1 is reevaluated for each subject with $\text{Age} \geq t$; subjects with $\text{Entry} > t$ are given a missing value in X1 and are subsequently removed

from the risk set. Computationally, this approach is not as efficient as the one that uses the counting process formulation.

Left-Truncation of Failure Times

Left-truncation occurs when individuals are not observed at the natural time origin of the phenomenon under study but come under observation at some known later time (called the left-truncation time). The risk set just prior to an event time does not include individuals whose left-truncation times exceed the given event time. Thus, any contribution to the likelihood must be conditional on the truncation limit having been exceeded.

You use the `ENTRY=` option to specify the variable that represents the left-truncation time. Suppose T_1 and T_2 represent the left-truncation time and the survival time, respectively. To account for left-truncation, you specify the following statements:

```
proc phreg;
  model T2*Dead(0)=X1-X10/entry=T1;
  title 'The ENTRY= option is Specified';
run;
```

Equivalently, you can use the counting process style of input for left-truncation:

```
proc phreg;
  model (T1, T2)*Dead(0)=X1-X10;
  title 'Counting Process Style of Input';
run;
```

Since the product-limit estimator of the survivor function is not available for the counting process style of input, you cannot use PROC PHREG to obtain the product-limit estimate of the survivor function if you have data with left-truncation times. In the preceding PROC PHREG calls, if you also specify `METHOD=PL` in a `BASELINE` statement or an `OUTPUT` statement, it is defaulted to `METHOD=BRESLOW`.

The Multiplicative Hazards Model

Consider a set of n subjects such that the counting process $N_i \equiv \{N_i(t), t \geq 0\}$ for the i th subject represents the number of observed events experienced over time t . The sample paths of the process N_i are step functions with jumps of size $+1$, with $N_i(0) = 0$. Let β denote the vector of unknown regression coefficients. The multiplicative hazards function $\Lambda(t, \mathbf{Z}_i(t))$ for N_i is given by

$$Y_i(t)d\Lambda(t, \mathbf{Z}_i(t)) = Y_i(t) \exp(\beta' \mathbf{Z}_i(t))d\Lambda_0(t)$$

where

- $Y_i(t)$ indicates whether the i th subject is at risk at time t (specifically, $Y_i(t) = 1$ if at risk and $Y_i(t) = 0$ otherwise)
- $\mathbf{Z}_i(t)$ is the vector of explanatory variables for the i th subject at time t
- $\Lambda_0(t)$ is an unspecified baseline hazard function

See Fleming and Harrington (1991) and Andersen et al. (1992). The Cox model is a special case of this multiplicative hazards model, where $Y_i(t) = 1$ until the first event or censoring, and $Y_i(t) = 0$ thereafter.

The partial likelihood for n independent triplets $(N_i, Y_i, \mathbf{Z}_i), i = 1, \dots, n$, has the form

$$\mathcal{L}(\boldsymbol{\beta}) = \prod_{i=1}^n \prod_{t \geq 0} \left\{ \frac{Y_i(t) \exp(\boldsymbol{\beta}' \mathbf{Z}_i(t))}{\sum_{j=1}^n Y_j(t) \exp(\boldsymbol{\beta}' \mathbf{Z}_j(t))} \right\}^{\Delta N_i(t)}$$

where $\Delta N_i(t) = 1$ if $N_i(t) - N_i(t-) = 1$, and $\Delta N_i(t) = 0$ otherwise.

The Frailty Model

You can use the frailty model to model correlations between failures of the same cluster. The hazard rate for the j th individual in the i th cluster is

$$\lambda_{ij}(t) = \lambda_0(t) e^{\boldsymbol{\beta}' \mathbf{Z}_{ij}(t) + \gamma_i}$$

where $\lambda_0(t)$ is an arbitrary baseline hazard rate, \mathbf{Z}_{ij} is the vector of (fixed-effect) covariates, $\boldsymbol{\beta}$ is the vector of regression coefficients, and γ_i is the random effect for cluster i .

Frailties are the exponential transformations of the random components, and the frailty model can be written as

$$\lambda_{ij}(t) = \lambda_0(t) e^{\gamma_i} e^{\boldsymbol{\beta}' \mathbf{Z}_{ij}(t)}$$

The random components $\gamma_1, \dots, \gamma_s$ (alternatively, the frailties $e^{\gamma_1}, \dots, e^{\gamma_s}$) are assumed to be independent and identically distributed. Modeling is based on the random effects rather than on the frailties.

Two frailty distributions are available in PROC PHREG: gamma and lognormal. Use the DIST= option in the RANDOM statement to choose the distribution. Let θ be an unknown parameter. The frailty distributions are listed in Table 67.11.

Table 67.11 Frailty Distributions

Frailty Option	Distribution	Density $f(\gamma_i)$	Mean and Variance
DIST=GAMMA	$e^{\gamma_i} \sim G\left(\frac{1}{\theta}, \frac{1}{\theta}\right)$	$\frac{\exp(\frac{\gamma_i}{\theta}) \exp\left(-\frac{\exp(\gamma_i)}{\theta}\right)}{\theta^{\frac{1}{\theta}} \Gamma(\frac{1}{\theta})}$	$E(e^{\gamma_i})=1 \quad V(e^{\gamma_i})=\theta$
DIST=LOGNORMAL	$\gamma_i \sim N(0, \theta)$	$\frac{1}{\sqrt{(2\pi\theta)}} \exp\left(-\frac{\gamma_i^2}{2\theta}\right)$	$E(\gamma_i)=0 \quad V(\gamma_i)=\theta$

The unknown parameter θ is a dispersion parameter. Each frailty distribution has a central tendency of 1 (the gamma frailty has a mean of 1, and the lognormal frailty has a median of 1). Thus, you can infer that individuals in cluster i with frailty $e^{\gamma_i} > 1$ (or $e^{\gamma_i} < 1$) tend to fail at a faster (or slower) rate than they fail under an independence model.

PROC PHREG estimates the regression coefficients $\boldsymbol{\beta}$, the random effects $\gamma_1, \dots, \gamma_s$, and the dispersion parameter θ . The RANDOM statement in PROC PHREG enables you to fit a shared frailty model by a

penalized partial likelihood approach. If you also specify the BAYES statement, PROC PHREG performs a Bayesian analysis of the shared frailty model.

If the RANDOM statement is specified, any ASSESS, BASELINE, and OUTPUT statements are ignored. Also ignored are the COVS options in the PROC PHREG statement and the following options in the MODEL statement: BEST=, DETAILS, HIERARCHY=, INCLUDE=, NOFIT, PLCONV=, SELECTION=, SEQUENTIAL, SLENTY=, SLSTAY=, TYPE1, and TYPE3(ALL, LR, SCORE). Profile likelihood confidence intervals for the hazard ratios are not available for the frailty model analysis.

Hazard Ratios

Consider a dichotomous risk factor variable X that takes the value 1 if the risk factor is present and 0 if the risk factor is absent. The log-hazard function is given by

$$\log[\lambda(t|X)] = \log[\lambda_0(t)] + \beta_1 X$$

where $\lambda_0(t)$ is the baseline hazard function.

The hazard ratio ψ is defined as the ratio of the hazard for those with the risk factor ($X = 1$) to the hazard without the risk factor ($X = 0$). The log of the hazard ratio is given by

$$\log(\psi) \equiv \log[\psi(X = 1, X = 0)] = \log[\lambda(t|X = 1)] - \log[\lambda(t|X = 0)] = \beta_1$$

In general, the hazard ratio can be computed by exponentiating the difference of the log-hazard between any two population profiles. This is the approach taken by the [HAZARDRATIO statement](#), so the computations are available regardless of parameterization, interactions, and nestings. However, as shown in the preceding equation for $\log(\psi)$, hazard ratios of main effects can be computed as functions of the parameter estimates, and the remainder of this section is concerned with this methodology.

The parameter, β_1 , associated with X represents the change in the log-hazard from $X = 0$ to $X = 1$. So the hazard ratio is obtained by simply exponentiating the value of the parameter associated with the risk factor. The hazard ratio indicates how the hazard change as you change X from 0 to 1. For instance, $\psi = 2$ means that the hazard when $X = 1$ is twice the hazard when $X = 0$.

Suppose the values of the dichotomous risk factor are coded as constants a and b instead of 0 and 1. The hazard when $X = a$ becomes $\lambda(t) \exp(a\beta_1)$, and the hazard when $X = b$ becomes $\lambda(t) \exp(b\beta_1)$. The hazard ratio corresponding to an increase in X from a to b is

$$\psi = \exp[(b - a)\beta_1] = [\exp(\beta_1)]^{b-a} \equiv [\exp(\beta_1)]^c$$

Note that for any a and b such that $c = b - a = 1$, $\psi = \exp(\beta_1)$. So the hazard ratio can be interpreted as the change in the hazard for any increase of one unit in the corresponding risk factor. However, the change in hazard for some amount other than one unit is often of greater interest. For example, a change of one pound in body weight might be too small to be considered important, while a change of 10 pounds might be more meaningful. The hazard ratio for a change in X from a to b is estimated by raising the hazard ratio estimate for a unit change in X to the power of $c = b - a$ as shown previously.

For a polytomous risk factor, the computation of hazard ratios depends on how the risk factor is parameterized. For illustration, suppose that Cell is a risk factor with four categories: Adeno, Large, Small, and Squamous.

For the effect parameterization scheme ([PARAM=EFFECT](#)) with Squamous as the reference group, the design variables for Cell are as follows:

Cell	Design Variables		
	X_1	X_2	X_3
Adeno	1	0	0
Large	0	1	0
Small	0	0	1
Squamous	-1	-1	-1

The log-hazard for Adeno is

$$\begin{aligned}\log[\lambda(t|\text{Adeno})] &= \log[\lambda_0(t)] + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) \\ &= \lambda_0(t) + \beta_1\end{aligned}$$

The log-hazard for Squamous is

$$\begin{aligned}\log[\lambda(t|\text{Squamous})] &= \log[\lambda_0(t)] + \beta_1(X_1 = -1) + \beta_2(X_2 = -1) + \beta_3(X_3 = -1) \\ &= \log[\lambda_0(t)] - \beta_1 - \beta_2 - \beta_3\end{aligned}$$

Therefore, the log-hazard ratio of Adeno versus Squamous

$$\begin{aligned}\log[\psi(\text{Adeno}, \text{Squamous})] &= \log[\lambda(t|\text{Adeno})] - \log[\lambda(t|\text{Squamous})] \\ &= 2\beta_1 + \beta_2 + \beta_3\end{aligned}$$

For the reference cell parameterization scheme (**PARAM=REF**) with Squamous as the reference cell, the design variables for Cell are as follows:

Cell	Design Variables		
	X_1	X_2	X_3
Adeno	1	0	0
Large	0	1	0
Small	0	0	1
Squamous	0	0	0

The log-hazard ratio of Adeno versus Squamous is given by

$$\begin{aligned}\log(\psi(\text{Adeno}, \text{Squamous})) &= \log[\lambda(t|\text{Adeno})] - \log[\lambda(t|\text{Squamous})] \\ &= (\log[\lambda_0(t)] + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) - \\ &\quad (\log[\lambda_0(t)] + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) \\ &= \beta_1\end{aligned}$$

For the GLM parameterization scheme (**PARAM=GLM**), the design variables are as follows:

Cell	Design Variables			
	X_1	X_2	X_3	X_4
Adeno	1	0	0	0
Large	0	1	0	0
Small	0	0	1	0
Squamous	0	0	0	1

The log-hazard ratio of Adeno versus Squamous is

$$\begin{aligned}
 & \log(\psi(\text{Adeno}, \text{Squamous})) \\
 &= \log[\lambda(t|\text{Adeno})] - \log[\lambda(t|\text{Squamous})] \\
 &= \log[\lambda_0(t)] + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 0) - \\
 & \quad (\log(\lambda_0(t)) + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 1)) \\
 &= \beta_1 - \beta_4
 \end{aligned}$$

Consider Cell as the only risk factor in the Cox regression in [Example 67.3](#). The computation of hazard ratio of Adeno versus Squamous for various parameterization schemes is tabulated in [Table 67.12](#).

Table 67.12 Hazard Ratio Comparing Adeno to Squamous

PARAM=	Parameter Estimates				Hazard Ratio Estimates
	$\hat{\beta}_1$	$\hat{\beta}_2$	$\hat{\beta}_3$	$\hat{\beta}_4$	
EFFECT	0.5772	-0.2115	0.2454		$\exp(2 \times 0.5772 - 0.2115 + 0.2454) = 3.281$
REF	1.8830	0.3996	0.8565		$\exp(1.8830) = 3.281$
GLM	1.8830	0.3996	0.8565	0.0000	$\exp(1.8830) = 3.281$

The fact that the log-hazard ratio ($\log(\psi)$) is a linear function of the parameters enables the **HAZARDRATIO statement** to compute the hazard ratio of the main effect even in the presence of interactions and nest effects. The section “[Hazard Ratios](#)” on page 5619 details the estimation of the hazard ratios in a classical analysis.

To customize hazard ratios for specific units of change for a continuous risk factor, you can use the **UNITS=** option in a **HAZARDRATIO statement** to specify a list of relevant units for each explanatory variable in the model. Estimates of these customized hazard ratios are given in a separate table. Let (L_j, U_j) be a confidence interval for $\log(\psi)$. The corresponding lower and upper confidence limits for the customized hazard ratio $\exp(c\beta_j)$ are $\exp(cL_j)$ and $\exp(cU_j)$, respectively (for $c > 0$), or $\exp(cU_j)$ and $\exp(cL_j)$, respectively (for $c < 0$).

Proportional Rates/Means Models for Recurrent Events

Let $N(t)$ be the number of events experienced by a subject over the time interval $(0, t]$. Let $dN(t)$ be the increment of the counting process N over $[t, t + dt)$. The rate function is given by

$$d\mu_{\mathbf{Z}}(t) = E[dN(t)|\mathbf{Z}(t)] = e^{\beta'\mathbf{Z}(t)} d\mu_0(t)$$

where $\mu_0(\cdot)$ is an unknown continuous function. If the \mathbf{Z} are time independent, the rate model is reduced to the mean model

$$\mu_{\mathbf{Z}}(t) = e^{\boldsymbol{\beta}'\mathbf{Z}} \mu_0(t)$$

The partial likelihood for n independent triplets (N_i, Y_i, \mathbf{Z}_i) , $i = 1, \dots, n$, of counting, at-risk, and covariate processes is the same as that of the multiplicative hazards model. However, a robust sandwich estimate is used for the covariance matrix of the parameter estimator instead of the model-based estimate.

Let T_{ki} be the k th event time of the i th subject. Let C_i be the censoring time of the i th subject. The at-risk indicator and the failure indicator are, respectively,

$$Y_i(t) = I(C_i \geq t) \text{ and } \Delta_{ki} = I(T_{ki} \leq C_i)$$

Denote

$$S^{(0)}(\boldsymbol{\beta}, t) = \sum_{i=1}^n Y_i(t) e^{\boldsymbol{\beta}'\mathbf{Z}_i(t)} \text{ and } \bar{\mathbf{Z}}(\boldsymbol{\beta}, t) = \frac{\sum_{i=1}^n Y_i(t) e^{\boldsymbol{\beta}'\mathbf{Z}_i(t)} \mathbf{Z}_i(t)}{S^{(0)}(\boldsymbol{\beta}, t)}$$

Let $\hat{\boldsymbol{\beta}}$ be the maximum likelihood estimate of $\boldsymbol{\beta}$, and let $\mathcal{I}(\hat{\boldsymbol{\beta}})$ be the observed information matrix. The robust sandwich covariance matrix estimate is given by

$$\mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) \sum_{i=1}^n \left[W_i(\hat{\boldsymbol{\beta}}) W_i'(\hat{\boldsymbol{\beta}}) \right] \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})$$

where

$$W_i(\boldsymbol{\beta}) = \sum_k \Delta_{ki} \left\{ Z_i(T_{ki}) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, T_{ki}) \right\} - \sum_{l=1}^n \sum_l \frac{\Delta_{lj} Y_i(T_{lj}) e^{\boldsymbol{\beta}'\mathbf{Z}_i(T_{lj})}}{S^{(0)}(\boldsymbol{\beta}, T_{lj})} \left\{ Z_i(T_{lj}) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, T_{lj}) \right\}$$

For a given realization of the covariates $\boldsymbol{\xi}$, the Nelson estimator is used to predict the mean function

$$\hat{\mu}_{\boldsymbol{\xi}}(t) = e^{\hat{\boldsymbol{\beta}}'\boldsymbol{\xi}} \sum_{i=1}^n \sum_k \frac{I(T_{ki} \leq t) \Delta_{ki}}{S^{(0)}(\hat{\boldsymbol{\beta}}, T_{ki})}$$

with standard error estimate given by

$$\hat{\sigma}^2(\hat{\mu}_{\boldsymbol{\xi}}(t)) = \sum_{i=1}^n \left(\frac{1}{n} \hat{\psi}_i(t, \boldsymbol{\xi}) \right)^2$$

where

$$\begin{aligned} \frac{1}{n} \hat{\psi}_i(t, \boldsymbol{\xi}) = & e^{\hat{\boldsymbol{\beta}}'\boldsymbol{\xi}} \left\{ \sum_k \frac{I(T_{ki} \leq t) \Delta_{ik}}{S^{(0)}(\hat{\boldsymbol{\beta}}, T_{ki})} - \sum_{j=1}^n \sum_k \frac{Y_i(T_{kj}) e^{\hat{\boldsymbol{\beta}}'\mathbf{Z}_i(T_{kj})} I(T_{kj} \leq t) \Delta_{kj}}{[S^{(0)}(\hat{\boldsymbol{\beta}}, T_{kj})]^2} - \right. \\ & \left[\sum_{i=1}^n \sum_k \frac{I(T_{ki} \leq t) \Delta_{ik} [\bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, T_{ki}) - \boldsymbol{\xi}]}{S^{(0)}(\hat{\boldsymbol{\beta}}, T_{ki})} \right] \\ & \left. \times \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) \int_0^t [\mathbf{Z}_i(u) - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, u)] d\hat{M}_i(u) \right\} \end{aligned}$$

Since the cumulative mean function is always nonnegative, the log transform is used to compute confidence intervals. The $100(1 - \alpha)\%$ pointwise confidence limits for $\mu_{\xi}(t)$ are

$$\hat{\mu}_{\xi}(t)e^{\pm z_{\alpha/2} \frac{\hat{\sigma}(\hat{\mu}_{\xi}(t))}{\hat{\mu}_{\xi}(t)}}$$

where $z_{\alpha/2}$ is the upper $100\alpha/2$ percentage point of the standard normal distribution.

Newton-Raphson Method

Let $L(\boldsymbol{\beta})$ be one of the likelihood functions described in the previous subsections. Let $l(\boldsymbol{\beta}) = \log L(\boldsymbol{\beta})$. Finding $\boldsymbol{\beta}$ such that $L(\boldsymbol{\beta})$ is maximized is equivalent to finding the solution $\hat{\boldsymbol{\beta}}$ to the likelihood equations

$$\frac{\partial l(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} = 0$$

With $\hat{\boldsymbol{\beta}}^0 = \mathbf{0}$ as the initial solution, the iterative scheme is expressed as

$$\hat{\boldsymbol{\beta}}^{j+1} = \hat{\boldsymbol{\beta}}^j - \left[\frac{\partial^2 l(\hat{\boldsymbol{\beta}}^j)}{\partial \boldsymbol{\beta}^2} \right]^{-1} \frac{\partial l(\hat{\boldsymbol{\beta}}^j)}{\partial \boldsymbol{\beta}}$$

The term after the minus sign is the Newton-Raphson step. If the likelihood function evaluated at $\hat{\boldsymbol{\beta}}^{j+1}$ is less than that evaluated at $\hat{\boldsymbol{\beta}}^j$, then $\hat{\boldsymbol{\beta}}^{j+1}$ is recomputed using half the step size. The iterative scheme continues until convergence is obtained—that is, until $\hat{\boldsymbol{\beta}}_{j+1}$ is sufficiently close to $\hat{\boldsymbol{\beta}}^j$. Then the maximum likelihood estimate of $\boldsymbol{\beta}$ is $\hat{\boldsymbol{\beta}} = \hat{\boldsymbol{\beta}}_{j+1}$.

The model-based variance estimate of $\hat{\boldsymbol{\beta}}$ is obtained by inverting the information matrix $\mathcal{I}(\hat{\boldsymbol{\beta}})$

$$\hat{\mathbf{V}}_m(\hat{\boldsymbol{\beta}}) = \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) = - \left[\frac{\partial^2 l(\hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\beta}^2} \right]^{-1}$$

Firth's Modification for Maximum Likelihood Estimation

In fitting a Cox model, the phenomenon of monotone likelihood is observed if the likelihood converges to a finite value while at least one parameter diverges (Heinze and Schemper 2001).

Let $\mathbf{x}_l(t)$ denote the vector explanatory variables for the l th individual at time t . Let $t_1 < t_2 < \dots < t_m$ denote the k distinct, ordered event times. Let d_j denote the multiplicity of failures at t_j ; that is, d_j is the size of the set \mathcal{D}_j of individuals that fail at t_j . Let \mathcal{R}_j denote the risk set just before t_j . Let $\boldsymbol{\beta} = (\beta_1, \dots, \beta_k)'$ be the vector of regression parameters. The Breslow log partial likelihood is given by

$$l(\boldsymbol{\beta}) = \log L(\boldsymbol{\beta}) = \sum_{j=1}^m \left\{ \boldsymbol{\beta}' \sum_{l \in \mathcal{D}_j} \mathbf{x}_l(t_j) - d_j \log \sum_{h \in \mathcal{R}_j} e^{\boldsymbol{\beta}' \mathbf{x}_h(t_j)} \right\}$$

Denote

$$\mathbf{S}_j^{(a)}(\boldsymbol{\beta}) = \sum_{h \in \mathcal{R}_j} e^{\boldsymbol{\beta}' \mathbf{x}_h(t_j)} [\mathbf{x}_h(t_j)]^{\otimes a} \quad a = 0, 1, 2$$

Then the score function is given by

$$\begin{aligned} \mathbf{U}(\boldsymbol{\beta}) &\equiv (U(\beta_1), \dots, U(\beta_k))' \\ &= \frac{\partial l(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} \\ &= \sum_{j=1}^m \left\{ \sum_{l \in \mathcal{D}_j} \mathbf{x}_l(t_j) - d_j \frac{\mathbf{S}_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right\} \end{aligned}$$

and the Fisher information matrix is given by

$$\begin{aligned} \mathcal{I}(\boldsymbol{\beta}) &= -\frac{\partial^2 l(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}^2} \\ &= \sum_{j=1}^m d_j \left\{ \frac{\mathbf{S}_j^{(2)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} - \left[\frac{\mathbf{S}_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right] \left[\frac{\mathbf{S}_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right]' \right\} \end{aligned}$$

Heinze (1999); Heinze and Schemper (2001) applied the idea of Firth (1993) by maximizing the penalized partial likelihood

$$l^*(\boldsymbol{\beta}) = l(\boldsymbol{\beta}) + 0.5 \log(|\mathcal{I}(\boldsymbol{\beta})|)$$

The score function $\mathbf{U}(\boldsymbol{\beta})$ is replaced by the modified score function by $\mathbf{U}^*(\boldsymbol{\beta}) \equiv (U^*(\beta_1), \dots, U^*(\beta_k))'$, where

$$U^*(\beta_r) = U(\beta_r) + 0.5 \text{tr} \left\{ \mathcal{I}^{-1}(\boldsymbol{\beta}) \frac{\partial \mathcal{I}(\boldsymbol{\beta})}{\partial \beta_r} \right\} \quad r = 1, \dots, k$$

The Firth estimate is obtained iteratively as

$$\boldsymbol{\beta}^{(s+1)} = \boldsymbol{\beta}^{(s)} + \mathcal{I}^{-1}(\boldsymbol{\beta}^{(s)}) \mathbf{U}^*(\boldsymbol{\beta}^{(s)})$$

The covariance matrix $\hat{\mathbf{V}}$ is computed as $\mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})$, where $\hat{\boldsymbol{\beta}}$ is the maximum penalized partial likelihood estimate.

Explicit formulae for $\frac{\partial \mathcal{I}(\boldsymbol{\beta})}{\partial \beta_r}$, $r = 1, \dots, k$

Denote

$$\begin{aligned} \mathbf{x}_h(t) &= (x_{h1}(t), \dots, x_{hk}(t))' \\ \mathbf{Q}_{jr}^{(a)}(\boldsymbol{\beta}) &= \sum_{h \in \mathcal{R}_j} e^{\boldsymbol{\beta}' \mathbf{x}_h(t_j)} x_{hr}(t_j) [\mathbf{x}_h(t_j)]^{\otimes a} \quad a = 0, 1, 2; r = 1, \dots, k \end{aligned}$$

Then

$$\begin{aligned} \frac{\partial \mathcal{I}(\boldsymbol{\beta})}{\partial \beta_r} = & \sum_{j=1}^m d_j \left\{ \left[\frac{\mathbf{Q}_{jr}^{(2)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} - \frac{\mathbf{Q}_{jr}^{(0)}(\boldsymbol{\beta}) S_j^{(2)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta}) S_j^{(0)}(\boldsymbol{\beta})} \right] - \right. \\ & \left[\frac{\mathbf{Q}_{jr}^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} - \frac{\mathbf{Q}_{jr}^{(0)}(\boldsymbol{\beta}) S_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta}) S_j^{(0)}(\boldsymbol{\beta})} \right] \left[\frac{S_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right]' - \\ & \left. \left[\frac{S_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right] \left[\frac{\mathbf{Q}_{jr}^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} - \frac{\mathbf{Q}_{jr}^{(0)}(\boldsymbol{\beta}) S_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta}) S_j^{(0)}(\boldsymbol{\beta})} \right]' \right\} \quad r = 1, \dots, k \end{aligned}$$

Robust Sandwich Variance Estimate

For the i th subject, $i = 1, \dots, n$, let X_i , w_i , and $\mathbf{Z}_i(t)$ be the observed time, weight, and the covariate vector at time t , respectively. Let Δ_i be the event indicator and let $Y_i(t) = I(X_i \geq t)$. Let

$$S^{(r)}(\boldsymbol{\beta}, t) = \sum_{j=1}^n w_j Y_j(t) e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \mathbf{Z}_j^{\otimes r}(t), \quad r = 0, 1$$

Let $\bar{\mathbf{Z}}(\boldsymbol{\beta}, t) = \frac{S^{(1)}(\boldsymbol{\beta}, t)}{S^{(0)}(\boldsymbol{\beta}, t)}$. The score residual for the i th subject is

$$\mathbf{L}_i(\boldsymbol{\beta}) = \Delta_i \left\{ \mathbf{Z}_i(X_i) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, X_i) \right\} - \sum_{j=1}^n \Delta_j \frac{w_j Y_j(X_j) e^{\boldsymbol{\beta}' \mathbf{Z}_j(X_j)}}{S^{(0)}(\boldsymbol{\beta}, X_j)} \left\{ \mathbf{Z}_j(X_j) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, X_j) \right\}$$

For TIES=EFRON, the computation of the score residuals is modified to comply with the Efron partial likelihood. See the section “[Residuals](#)” on page 5639 for more information.

The robust sandwich variance estimate of $\hat{\boldsymbol{\beta}}$ derived by Binder (1992), who incorporated weights into the analysis, is

$$\hat{\mathbf{V}}_s(\hat{\boldsymbol{\beta}}) = \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) \left[\sum_{j=1}^n (w_j \mathbf{L}_j(\hat{\boldsymbol{\beta}}))^{\otimes 2} \right] \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})$$

where $\mathcal{I}(\hat{\boldsymbol{\beta}})$ is the observed information matrix, and $\mathbf{a}^{\otimes 2} = \mathbf{a}\mathbf{a}'$. Note that when $w_i \equiv 1$,

$$\hat{\mathbf{V}}_s(\hat{\boldsymbol{\beta}}) = \mathbf{D}'\mathbf{D}$$

where \mathbf{D} is the matrix of DFBETA residuals. This robust variance estimate was proposed by Lin and Wei (1989) and Reid and Cr  peau (1985).

Testing the Global Null Hypothesis

The following statistics can be used to test the global null hypothesis $H_0: \boldsymbol{\beta} = \mathbf{0}$. Under mild assumptions, each statistic has an asymptotic chi-square distribution with p degrees of freedom given the null hypothesis. The value p is the dimension of $\boldsymbol{\beta}$. For clustered data, the likelihood ratio test, the score test, and the Wald test assume independence of observations within a cluster, while the robust Wald test and the robust score test do not need such an assumption.

Likelihood Ratio Test

$$\chi^2_{\text{LR}} = 2 \left[l(\hat{\beta}) - l(0) \right]$$

Score Test

$$\chi^2_S = \left[\frac{\partial l(0)}{\partial \beta} \right]' \left[-\frac{\partial^2 l(0)}{\partial \beta^2} \right]^{-1} \left[\frac{\partial l(0)}{\partial \beta} \right]$$

Wald's Test

$$\chi^2_W = \hat{\beta}' \left[-\frac{\partial^2 l(\hat{\beta})}{\partial \beta^2} \right] \hat{\beta}$$

Robust Score Test

$$\chi^2_{\text{RS}} = \left[\sum_i \mathbf{L}_i^0 \right]' \left[\sum_i \mathbf{L}_i^0 \mathbf{L}_i^{0'} \right]^{-1} \left[\sum_i \mathbf{L}_i^0 \right]$$

where \mathbf{L}_i^0 is the score residual of the i th subject at $\beta = 0$; that is, $\mathbf{L}_i^0 = \mathbf{L}_i(0, \infty)$, where the score process $\mathbf{L}_i(\beta, t)$ is defined in the section “[Residuals](#)” on page 5639.

Robust Wald's Test

$$\chi^2_{\text{RW}} = \hat{\beta}' [\hat{\mathbf{V}}_s(\hat{\beta})]^{-1} \hat{\beta}$$

where $\hat{\mathbf{V}}_s(\hat{\beta})$ is the sandwich variance estimate (see the section “[Robust Sandwich Variance Estimate](#)” on page 5625 for details).

Type 3 Tests

The following statistics can be used to test the null hypothesis $H_{0L}: \mathbf{L}\beta = \mathbf{0}$, where \mathbf{L} is a matrix of known coefficients. Under mild assumptions, each of the following statistics has an asymptotic chi-square distribution with p degrees of freedom, where p is the rank of \mathbf{L} . Let $\tilde{\beta}_L$ be the maximum likelihood of β under the null hypothesis H_{0L} ; that is,

$$l(\tilde{\beta}_L) = \max_{\mathbf{L}\beta = \mathbf{0}} l(\beta)$$

Likelihood Ratio Statistic

$$\chi^2_{\text{LR}} = 2 \left[l(\hat{\beta}) - l(\tilde{\beta}_L) \right]$$

Score Statistic

$$\chi_S^2 = \left[\frac{\partial l(\tilde{\boldsymbol{\beta}}_L)}{\partial \boldsymbol{\beta}} \right]' \left[-\frac{\partial^2 l(\tilde{\boldsymbol{\beta}}_L)}{\partial \boldsymbol{\beta}^2} \right]^{-1} \left[\frac{\partial l(\tilde{\boldsymbol{\beta}}_L)}{\partial \boldsymbol{\beta}} \right]$$

Wald's Statistic

$$\chi_W^2 = (\mathbf{L}\hat{\boldsymbol{\beta}})' [\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}']^{-1} (\mathbf{L}\hat{\boldsymbol{\beta}})$$

where $\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})$ is the estimated covariance matrix, which can be the model-based covariance matrix $\left[-\frac{\partial^2 l(\hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\beta}^2} \right]^{-1}$ or the sandwich covariance matrix $V_S(\hat{\boldsymbol{\beta}})$ (see the section “[Robust Sandwich Variance Estimate](#)” on page 5625 for details).

Confidence Limits for a Hazard Ratio

Let \mathbf{e}_j be the j th unit vector—that is, the j th entry of the vector is 1 and all other entries are 0. The hazard ratio for the explanatory variable with regression coefficient $\beta_j = \mathbf{e}_j' \boldsymbol{\beta}$ is defined as $\exp(\beta_j)$. In general, a log-hazard ratio can be written as $\mathbf{h}' \boldsymbol{\beta}$, a linear combination of the regression coefficients, and the hazard ratio $\exp(\mathbf{h}' \boldsymbol{\beta})$ is obtained by replacing \mathbf{e}_j with \mathbf{h} .

Point Estimate

The hazard ratio $\exp(\mathbf{e}_j' \boldsymbol{\beta})$ is estimated by $\exp(\mathbf{e}_j' \hat{\boldsymbol{\beta}})$, where $\hat{\boldsymbol{\beta}}$ is the maximum likelihood estimate of the $\boldsymbol{\beta}$.

Wald's Confidence Limits

The $100(1 - \alpha)\%$ confidence limits for the hazard ratio are calculated as

$$\exp \left(\mathbf{e}_j' \hat{\boldsymbol{\beta}} \pm z_{\alpha/2} \sqrt{\mathbf{e}_j' \hat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) \mathbf{e}_j} \right)$$

where $\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})$ is estimated covariance matrix, and $z_{\alpha/2}$ is the $100(1 - \alpha/2)$ percentile point of the standard normal distribution.

Profile-Likelihood Confidence Limits

The construction of the profile-likelihood-based confidence interval is derived from the asymptotic χ^2 distribution of the generalized likelihood ratio test of Venzon and Moolgavkar (1988). Suppose that the parameter vector is $\boldsymbol{\beta} = (\beta_1, \dots, \beta_k)'$ and you want to compute a confidence interval for β_j . The profile-likelihood function for $\beta_j = \gamma$ is defined as

$$l_j^*(\gamma) = \max_{\boldsymbol{\beta} \in \mathcal{B}_j(\gamma)} l(\boldsymbol{\beta})$$

where $\mathcal{B}_j(\gamma)$ is the set of all $\boldsymbol{\beta}$ with the j th element fixed at γ , and $l(\boldsymbol{\beta})$ is the log-likelihood function for $\boldsymbol{\beta}$. If $l_{\max} = l(\hat{\boldsymbol{\beta}})$ is the log likelihood evaluated at the maximum likelihood estimate $\hat{\boldsymbol{\beta}}$, then $2(l_{\max} - l_j^*(\beta_j))$

has a limiting chi-square distribution with one degree of freedom if β_j is the true parameter value. Let $l_0 = l_{\max} - 0.5\chi_1^2(1 - \alpha)$, where $\chi_1^2(1 - \alpha)$ is the $100(1 - \alpha)$ percentile of the chi-square distribution with one degree of freedom. A $100(1 - \alpha)\%$ confidence interval for β_j is

$$\{\gamma : l_j^*(\gamma) \geq l_0\}$$

The endpoints of the confidence interval are found by solving numerically for values of β_j that satisfy equality in the preceding relation. To obtain an iterative algorithm for computing the confidence limits, the log-likelihood function in a neighborhood of β is approximated by the quadratic function

$$\tilde{l}(\beta + \delta) = l(\beta) + \delta'g + \frac{1}{2}\delta'V\delta$$

where $g = g(\beta)$ is the gradient vector and $V = V(\beta)$ is the Hessian matrix. The increment δ for the next iteration is obtained by solving the likelihood equations

$$\frac{d}{d\delta}\{\tilde{l}(\beta + \delta) + \lambda(e_j'\delta - \gamma)\} = 0$$

where λ is the Lagrange multiplier, e_j is the j th unit vector, and γ is an unknown constant. The solution is

$$\delta = -V^{-1}(g + \lambda e_j)$$

By substituting this δ into the equation $\tilde{l}(\beta + \delta) = l_0$, you can estimate λ as

$$\lambda = \pm \left(\frac{2(l_0 - l(\beta) + \frac{1}{2}g'V^{-1}g)}{e_j'V^{-1}e_j} \right)^{\frac{1}{2}}$$

The upper confidence limit for β_j is computed by starting at the maximum likelihood estimate of β and iterating with positive values of λ until convergence is attained. The process is repeated for the lower confidence limit, using negative values of λ .

Convergence is controlled by value ϵ specified with the PLCONV= option in the MODEL statement (the default value of ϵ is 1E-4). Convergence is declared on the current iteration if the following two conditions are satisfied:

$$|l(\beta) - l_0| \leq \epsilon$$

and

$$(g + \lambda e_j)'V^{-1}(g + \lambda e_j) \leq \epsilon$$

The profile-likelihood confidence limits for the hazard ratio $\exp(e_j'\beta)$ are obtained by exponentiating these confidence limits.

Using the TEST Statement to Test Linear Hypotheses

Linear hypotheses for β are expressed in matrix form as

$$H_0: L\beta = c$$

where L is a matrix of coefficients for the linear hypotheses, and c is a vector of constants. The Wald chi-square statistic for testing H_0 is computed as

$$\chi_W^2 = (L\hat{\beta} - c)' [L\hat{V}(\hat{\beta})L']^{-1} (L\hat{\beta} - c)$$

where $\hat{V}(\hat{\beta})$ is the estimated covariance matrix. Under H_0 , χ_W^2 has an asymptotic chi-square distribution with r degrees of freedom, where r is the rank of L .

Optimal Weights for the AVERAGE option in the TEST Statement

Let $\beta_0 = (\beta_{i_1}, \dots, \beta_{i_s})'$, where $\{\beta_{i_1}, \dots, \beta_{i_s}\}$ is a subset of s regression coefficients. For any vector $\mathbf{e} = (e_1, \dots, e_s)'$ of length s ,

$$\mathbf{e}'\hat{\beta}_0 \sim N(\mathbf{e}'\beta_0, \mathbf{e}'\hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e})$$

To find \mathbf{e} such that $\mathbf{e}'\hat{\beta}_0$ has the minimum variance, it is necessary to minimize $\mathbf{e}'\hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e}$ subject to $\sum_{i=1}^s e_i = 1$. Let $\mathbf{1}_s$ be a vector of 1's of length s . The expression to be minimized is

$$\mathbf{e}'\hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e} - \lambda(\mathbf{e}'\mathbf{1}_s - 1)$$

where λ is the Lagrange multiplier. Differentiating with respect to \mathbf{e} and λ , respectively, yields

$$\begin{aligned}\hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e} - \lambda\mathbf{1}_s &= \mathbf{0} \\ \mathbf{e}'\mathbf{1}_s - 1 &= 0\end{aligned}$$

Solving these equations gives

$$\mathbf{e} = [\mathbf{1}_s'\hat{\mathbf{V}}^{-1}(\hat{\beta}_0)\mathbf{1}_s]^{-1}\hat{\mathbf{V}}^{-1}(\hat{\beta}_0)\mathbf{1}_s$$

This provides a one degree-of-freedom test for testing the null hypothesis $H_0 : \beta_{i_1} = \dots = \beta_{i_s} = 0$ with normal test statistic

$$Z = \frac{\mathbf{e}'\hat{\beta}_0}{\sqrt{\mathbf{e}'\hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e}}}$$

This test is more sensitive than the multivariate test specified by the TEST statement

Multivariate: test X1, ..., Xs;

where X1, ..., Xs are the variables with regression coefficients $\beta_{i_1}, \dots, \beta_{i_s}$, respectively.

Analysis of Multivariate Failure Time Data

Multivariate failure time data arise when each study subject can potentially experience several events (for instance, multiple infections after surgery) or when there exists some natural or artificial clustering of subjects (for instance, a litter of mice) that induces dependence among the failure times of the same cluster. Data in the former situation are referred to as multiple events data, and data in the latter situation are referred to as clustered data. The multiple events data can be further classified into ordered and unordered data. For ordered data, there is a natural ordering of the multiple failures within a subject, which includes recurrent events data as a special case. For unordered data, the multiple event times result from several concurrent failure processes.

Multiple events data can be analyzed by the Wei, Lin, and Weissfeld (1989), or WLW, method based on the marginal Cox models. For the special case of recurrent events data, you can fit the intensity model (Andersen and Gill 1982), the proportional rates/means model (Pepe and Cai 1993; Lawless and Nadeau 1995; Lin et al. 2000), or the stratified models for total time and gap time proposed by Prentice, Williams,

and Peterson (1981), or PWP. For clustered data, you can carry out the analysis of Lee, Wei, and Amato (1992) based on the marginal Cox model. To use PROC PHREG to perform these analyses correctly and effectively, you have to array your data in a specific way to produce the correct risk sets.

All examples described in this section can be found in the program *phrmult.sas* in the SAS/STAT sample library. Furthermore, the “Examples” section in this chapter contains two examples to illustrate the methods of analyzing recurrent events data and clustered data.

Marginal Cox Models for Multiple Events Data

Suppose there are n subjects and each subject can experience up to K potential events. Let $\mathbf{Z}_{ki}(\cdot)$ be the covariate process associated with the k th event for the i th subject. The marginal Cox models are given by

$$\lambda_k(t; \mathbf{Z}_{ki}) = \lambda_{k0} e^{\boldsymbol{\beta}'_k \mathbf{Z}_{ki}(t)}, k = 1, \dots, K; i = 1, \dots, n$$

where $\lambda_{k0}(t)$ is the (event-specific) baseline hazard function for the k th event and $\boldsymbol{\beta}_k$ is the (event-specific) column vector of regression coefficients for the k th event. WLW estimates $\boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_K$ by the maximum partial likelihood estimates $\hat{\boldsymbol{\beta}}_1, \dots, \hat{\boldsymbol{\beta}}_K$, respectively, and uses a robust sandwich covariance matrix estimate for $(\hat{\boldsymbol{\beta}}'_1, \dots, \hat{\boldsymbol{\beta}}'_K)'$ to account for the dependence of the multiple failure times.

By using a properly prepared input data set, you can estimate the regression parameters for all the marginal Cox models and compute the robust sandwich covariance estimates in one PROC PHREG invocation. For convenience of discussion, suppose each subject can potentially experience $K = 3$ events and there are two explanatory variables Z1 and Z2. The event-specific parameters to be estimated are $\boldsymbol{\beta}_1 = (\beta_{11}, \beta_{21})'$ for the first marginal model, $\boldsymbol{\beta}_2 = (\beta_{12}, \beta_{22})'$ for the second marginal model, and $\boldsymbol{\beta}_3 = (\beta_{13}, \beta_{23})'$ for the third marginal model. Inference of these parameters is based on the robust sandwich covariance matrix estimate of the parameter estimators. It is necessary that each row of the input data set represent the data for a potential event of a subject. The input data set should contain the following:

- an ID variable for identifying the subject so that all observations of the same subject have the same ID value
- an Enum variable to index the multiple events. For example, Enum=1 for the first event, Enum=2 for the second event, and so on.
- a Time variable to represent the observed time from some time origin for the event. For recurrence events data, it is the time from the study entry to each recurrence.
- a Status variable to indicate whether the Time value is a censored or uncensored time. For example, Status=1 indicates an uncensored time and Status=0 indicates a censored time.
- independent variables (Z1 and Z2)

The WLW analysis can be carried out by specifying the following:

```
proc phreg covs(aggregate);
  model Time*Status(0)=Z11 Z12 Z13 Z21 Z22 Z23;
  strata Enum;
  id ID;
  Z11= Z1 * (Enum=1);
  Z12= Z1 * (Enum=2);
```

```

Z13= Z1 * (Enum=3);
Z21= Z2 * (Enum=1);
Z22= Z2 * (Enum=2);
Z23= Z2 * (Enum=3);
run;

```

The variable Enum is specified in the STRATA statement so that there is one marginal Cox model for each distinct value of Enum. The variables Z11, Z12, Z13, Z21, Z22, and Z23 in the MODEL statement are event-specific variables derived from the independent variables Z1 and Z2 by the given programming statements. In particular, the variables Z11, Z12, and Z13 are event-specific variables for the explanatory variable Z1; the variables Z21, Z22, and Z23 are event-specific variables for the explanatory variable Z2. For $j = 1, 2$, and $k = 1, 2, 3$, variable Zjk contains the same values as the explanatory variable Zj for the rows that correspond to k th marginal model and the value 0 for all other rows; as such, β_{jk} is the regression coefficient for Zjk. You can avoid using the programming statements in PROC PHREG if you create these event-specific variables in the input data set by using the same programming statements in a DATA step.

The option COVS(AGGREGATE) is specified in the PROC PHREG statement to obtain the robust sandwich estimate of the covariance matrix, and the score residuals used in computing the middle part of the sandwich estimate are aggregated over identical ID values. You can also include TEST statements in the PROC PHREG code to test various linear hypotheses of the regression parameters based on the robust sandwich covariance matrix estimate.

Consider the AIDS study data in Wei, Lin, and Weissfeld (1989) from a randomized clinical trial to assess the antiretroviral capacity of ribavirin over time in AIDS patients. Blood samples were collected at weeks 4, 8, and 12 from each patient in three treatment groups (placebo, low dose of ribavirin, and high dose). For each serum sample, the failure time is the number of days before virus positivity was detected. If the sample was contaminated or it took a longer period of time than was achievable in the laboratory, the sample was censored. For example:

- Patient #1 in the placebo group has uncensored times 9, 6, and 7 days (that is, it took 9 days to detect viral positivity in the first blood sample, 6 days for the second blood sample, and 7 days for the third blood sample).
- Patient #14 in the low-dose group of ribavirin has uncensored times of 16 and 17 days for the first and second sample, respectively, and a censored time of 21 days for the third blood sample.
- Patient #28 in the high-dose group has an uncensored time of 21 days for the first sample, no measurement for the second blood sample, and a censored time of 25 days for the third sample.

For a full-rank parameterization, two design variables are sufficient to represent three treatment groups. Based on the reference coding with placebo as the reference, the values of the two dummy explanatory variables Z1 and Z2 representing the treatments are as follows:

Treatment Group	Z1	Z2
Placebo	0	0
Low dose ribavirin	1	0
High dose ribavirin	0	1

The bulk of the task in using PROC PHREG to perform the WLW analysis lies in the preparation of the input data set. As discussed earlier, the input data set should contain the ID, Enum, Time, and Status variables,

and event-specific independent variables Z11, Z12, Z13, Z21, Z22, and Z23. Data for the three patients described earlier are arrayed as follows:

ID	Time	Status	Enum	Z1	Z2
1	9	1	1	0	0
1	6	1	2	0	0
1	7	1	3	0	0
14	16	1	1	1	0
14	17	1	2	1	0
14	21	0	3	1	0
28	21	1	1	0	1
28	25	0	3	0	1

The first three rows are data for Patient #1 with event times at 9, 6, and 7 days, one row for each event. The next three rows are data for Patient #14, who has an uncensored time of 16 days for the first serum sample, an uncensored time of 17 days for the second sample, and a censored time of 21 days for the third sample. The last two rows are data for Patient #28 of the high-dose group (Z1=0 and Z2=1). Since the patient did not have a second serum sample, there are only two rows of data.

To perform the WLW analysis, you specify the following statements:

```
proc phreg covs(aggregate);
  model Time*Status(0)=Z11 Z12 Z13 Z21 Z22 Z23;
  strata Enum;
  id ID;
  Z11= Z1 * (Enum=1);
  Z12= Z1 * (Enum=2);
  Z13= Z1 * (Enum=3);
  Z21= Z2 * (Enum=1);
  Z22= Z2 * (Enum=2);
  Z23= Z2 * (Enum=3);
  EqualLowDose: test Z11=Z12, Z12=Z23;
  AverageLow: test Z11,Z12,Z13 / e average;
run;
```

Two linear hypotheses are tested using the TEST statements. The specification

```
EqualLowDose: test Z11=Z12, Z12=Z13;
```

tests the null hypothesis $\beta_{11} = \beta_{12} = \beta_{13}$ of identical low-dose effects across three marginal models. The specification

```
AverageLow: test Z11,Z12,Z13 / e average;
```

tests the null hypothesis of no low-dose effects (that is, $\beta_{11} = \beta_{12} = \beta_{13} = 0$). The AVERAGE option computes the optimal weights for estimating the average low-dose effect $\beta_1^* = \beta_{11} = \beta_{12} = \beta_{13}$ and performs a 1 DF test for testing the null hypothesis that $\beta_1^* = 0$. The E option displays the coefficients for the linear hypotheses, including the optimal weights.

Marginal Cox Models for Clustered Data

Suppose there are n clusters with K_i members in the i th cluster, $i = 1, \dots, n$. Let $\mathbf{Z}_{ki}(\cdot)$ be the covariate process associated with the k th member of the i th cluster. The marginal Cox model is given by

$$\lambda(t; \mathbf{Z}_{ki}) = \lambda_0(t) e^{\boldsymbol{\beta}' \mathbf{Z}_{ki}(t)} \quad k = 1, \dots, K_i; i = 1, \dots, n$$

where $\lambda_0(t)$ is an arbitrary baseline hazard function and $\boldsymbol{\beta}$ is the vector of regression coefficients. Lee, Wei, and Amato (1992) estimate $\boldsymbol{\beta}$ by the maximum partial likelihood estimate $\hat{\boldsymbol{\beta}}$ under the independent working assumption, and use a robust sandwich covariance estimate to account for the intracluster dependence.

To use PROC PHREG to analyze the clustered data, each member of a cluster is represented by an observation in the input data set. The input data set to PROC PHREG should contain the following:

- an ID variable to identify the cluster so that members of the same cluster have the same ID value
- a Time variable to represent the observed survival time of a member of a cluster
- a Status variable to indicate whether the Time value is an uncensored or censored time. For example, Status=1 indicates an uncensored time and Status=0 indicates a censored time.
- the explanatory variables thought to be related to the failure time

Consider a tumor study in which one of three female rats of the same litter was randomly subjected to a drug treatment. The failure time is the time from randomization to the detection of tumor. If a rat died before the tumor was detected, the failure time was censored. For example:

- In litter #1, the drug-treated rat has an uncensored time of 101 days, one untreated rat has a censored time of 49 days, and the other untreated rat has a failure time of 104 days.
- In litter #3, the drug-treated rat has a censored time of 104 days, one untreated rat has a censored time of 102 days, and the other untreated rat has a censored time of 104 days.

In this example, a litter is a cluster and the rats of the same litter are members of the cluster. Let Trt be a 0-1 variable representing the treatment a rat received, with value 1 for drug treatment and 0 otherwise. Data for the two litters of rats described earlier contribute six observations to the input data set:

Litter	Time	Status	Trt
1	101	1	1
1	49	0	0
1	104	1	0
3	104	0	1
3	102	0	0
3	104	0	0

The analysis of Lee, Wei, and Amato (1992) can be performed by PROC PHREG as follows:

```
proc phreg covs(aggregate);
  model Time*Status(0)=Treatment;
  id Litter;
run;
```

Intensity and Rate/Mean Models for Recurrent Events Data

Suppose each subject experiences recurrences of the same phenomenon. Let $N(t)$ be the number of events a subject experiences over the interval $[0, t]$ and let $\mathbf{Z}(\cdot)$ be the covariate process of the subject.

The intensity model (Andersen and Gill 1982) is given by

$$\lambda_{\mathbf{Z}}(t)dt = E\{dN(t)|\mathcal{F}_{t-}\} = \lambda_0(t)e^{\boldsymbol{\beta}'\mathbf{Z}(t)}dt$$

where \mathcal{F}_t represents all the information of the processes N and \mathbf{Z} up to time t , $\lambda_0(t)$ is an arbitrary baseline intensity function, and $\boldsymbol{\beta}$ is the vector of regression coefficients. This model consists of two components: (1) all the influence of the prior events on future recurrences, if there is any, is mediated through the time-dependent covariates, and (2) the covariates have multiplicative effects on the instantaneous rate of the counting process. If the covariates are time invariant, the risk of recurrences is unaffected by the past events.

The proportional rates and means models (Pepe and Cai 1993; Lawless and Nadeau 1995; Lin et al. 2000) assume that the covariates have multiplicative effects on the mean and rate functions of the counting process. The rate function is given by

$$d\mu_{\mathbf{Z}}(t) = E\{dN(t)|\mathbf{Z}(t)\} = e^{\boldsymbol{\beta}'\mathbf{Z}(t)}d\mu_0(t)$$

where $\mu_0(t)$ is an unknown continuous function and $\boldsymbol{\beta}$ is the vector of regression parameters. If \mathbf{Z} is time invariant, the mean function is given by

$$\mu_{\mathbf{Z}}(t) = E\{N(t)|\mathbf{Z}\} = e^{\boldsymbol{\beta}'\mathbf{Z}}\mu_0(t)$$

For both the intensity and the proportional rates/means models, estimates of the regression coefficients are obtained by solving the partial likelihood score function. However, the covariance matrix estimate for the intensity model is computed as the inverse of the observed information matrix, while that for the proportional rates/means model is given by a sandwich estimate. For a given pattern of fixed covariates, the Nelson estimate for the cumulative intensity function is the same for the cumulative mean function, but their standard errors are not the same.

To fit the intensity or rate/mean model by using PROC PHREG, the counting process style of input is needed. A subject with K events contributes $K + 1$ observations to the input data set. The k th observation of the subject identifies the time interval from the $(k - 1)$ event or time 0 (if $k = 1$) to the k th event, $k = 1, \dots, K$. The $(K + 1)$ observation represents the time interval from the K th event to time of censorship. The input data set should contain the following variables:

- a TStart variable to represent the $(k - 1)$ recurrence time or the value 0 if $k = 1$
- a TStop variable to represent the k th recurrence time or the follow-up time if $k = K + 1$

- a **Status** variable indicating whether the TStop time is a recurrence time or a censored time; for example, Status=1 for a recurrence time and Status=0 for censored time
- explanatory variables thought to be related to the recurrence times

If the rate/mean model is used, the input data should also contain an ID variable for identifying the subjects.

Consider the chronic granulomatous disease (CGD) data listed in Fleming and Harrington (1991). The disease is a rare disorder characterized by recurrent pyrogenic infections. The study is a placebo-controlled randomized clinical trial conducted by the International CGD Cooperative Study to assess the effect of gamma interferon to reduce the rate of infection. For each study patient the times of recurrent infections along with a number of prognostic factors were collected. For example:

- Patient #17404, age 38, in the gamma interferon group had a follow-up time of 293 without any infection.
- Patient #204001, age 12, in the placebo group had an infection at 219 days, a recurrent infection at 373 days, and was followed up to 414 days.

Let **Trt** be the variable representing the treatment status with value 1 for gamma interferon and value 2 for placebo. Let **Age** be a covariate representing the age of the CGD patient. Data for the two CGD patients described earlier are given in the following table.

ID	TStart	TStop	Status	Trt	Age
174054	0	293	0	1	38
204001	0	219	1	2	12
204001	219	373	1	2	12
204001	373	414	0	2	12

Since Patient #174054 had no infection through the end of the follow-up period (293 days), there is only one observation representing the period from time 0 to the end of the follow-up. Data for Patient #204001 are broken into three observations, since there are two infections. The first observation represents the period from time 0 to the first infection, the second observation represents the period from the first infection to the second infection, and the third time period represents the period from the second infection to the end of the follow-up.

The following specification fits the intensity model:

```
proc phreg;
  model (TStart,TStop)*Status(0)=Trt Age;
run;
```

You can predict the cumulative intensity function for a given pattern of fixed covariates by specifying the CUMHAZ= option in the BASELINE statement. Suppose you are interested in two fixed patterns, one for patients of age 30 in the gamma interferon group and the other for patients of age 1 in the placebo group. You first create the SAS data set as follows:

```

data Pattern;
  Trt=1; Age=30;
  output;
  Trt=2; Age=1;
  output;
run;

```

You then include the following BASELINE statement in the PROC PHREG specification. The CUMHAZ=_all_ option produces the cumulative hazard function estimates, the standard error estimates, and the lower and upper pointwise confidence limits.

```
baseline covariates=Pattern out=out1 cumhaz=_all_;
```

The following specification of PROC PHREG fits the mean model and predicts the cumulative mean function for the two patterns of covariates in the Pattern data set:

```

proc phreg covs(aggregate);
  model (Tstart,Tstop)*Status(0)=Trt Age;
  baseline covariates=Pattern out=out2 cmf=_all_;
  id ID;
run;

```

The COV(AGGREGATE) option, along with the ID statement, computes the robust sandwich covariance matrix estimate. The CMF=_ALL_ option adds the cumulative mean function estimates, the standard error estimates, and the lower and upper pointwise confidence limits to the OUT=Out2 data set.

PWP Models for Recurrent Events Data

Let $N(t)$ be the number of events a subject experiences by time t . Let $\mathbf{Z}(t)$ be the covariate vectors of the subject at time t . For a subject who has K events before censorship takes place, let $t_0 = 0$, let t_k be the k th recurrence time, $k = 1, \dots, K$, and let t_{K+1} be the censored time. Prentice, Williams, and Peterson (1981) consider two time scales, a total time from the beginning of the study and a gap time from immediately preceding failure. The PWP models are stratified Cox-type models that allow the shape of the hazard function to depend on the number of preceding events and possibly on other characteristics of $\{N(t)$ and $\mathbf{Z}(t)\}$. The total time and gap time models are given, respectively, as follows:

$$\begin{aligned}\lambda(t|\mathcal{F}_{t-}) &= \lambda_{0k}(t)e^{\beta'_k \mathbf{Z}(t)}, & t_{k-1} < t \leq t_k \\ \lambda(t|\mathcal{F}_{t-}) &= \lambda_{0k}(t - t_{k-1})e^{\beta'_k \mathbf{Z}(t)}, & t_{k-1} < t \leq t_k\end{aligned}$$

where λ_{0k} is an arbitrary baseline intensity functions, and β_k is a vector of stratum-specific regression coefficients. Here, a subject moves to the k th stratum immediately after his $(k - 1)$ recurrence time and remains there until the k th recurrence occurs or until censorship takes place. For instance, a subject who experiences only one event moves from the first stratum to the second stratum after the event occurs and remains in the second stratum until the end of the follow-up.

You can use PROC PHREG to carry out the analyses of the PWP models, but you have to prepare the input data set to provide the correct risk sets. The input data set for analyzing the total time is the same as the AG model with an additional variable to represent the stratum that the subject is in. A subject with K events contributes $K + 1$ observations to the input data set, one for each stratum that the subject moves to. The input data should contain the following variables:

- a TStart variable to represent the $(k - 1)$ recurrence time or the value 0 if $k = 1$
- a TStop variable to represent the k th recurrence time or the time of censorship if $k = K + 1$
- a Status variable with value 1 if the Time value is a recurrence time and value 0 if the Time value is a censored time
- an Enum variable representing the index of the stratum that the subject is in. For a subject who has only one event at t_1 and is followed to time t_c , Enum=1 for the first observation (where Time= t_1 and Status=1) and Enum=2 for the second observation (where Time= t_c and Status=0).
- explanatory variables thought to be related to the recurrence times

To analyze gap times, the input data set should also include a GapTime variable that is equal to (TStop – TStart).

Consider the data of two subjects in CGD data described in the previous section:

- Patients #174054, age 38, in the gamma interferon group had a follow-up time of 293 without any infection.
- Patient #204001, age 12, in the placebo group had an infection at 219 days, a recurrent infection at 373 days, and a follow-up time of 414 days.

To illustrate, suppose all subjects have at most two observed events. The data for the two subjects in the input data set are as follows:

ID	TStart	TStop	Gaptime	Status	Enum	Trt	Age
174054	0	293	293	0	1	1	38
204001	0	219	219	1	1	2	12
204001	219	373	154	1	2	2	12
204001	373	414	41	0	3	2	12

Subject #174054 contributes only one observation to the input data, since there is no observed event. Subject #204001 contributes three observations, since there are two observed events.

To fit the total time model of PWP with stratum-specific slopes, either you can create the stratum-specific explanatory variables (Trt1, Trt2, and Trt3 for Trt, and Age1, Age2, and Age3 for Age) in a DATA step, or you can specify them in PROC PHREG by using programming statements as follows:

```
proc phreg;
  model (TStart,TStop)*Status(0)=Trt1 Trt2 Trt3 Age1 Age2 Age3;
  strata Enum;
  Trt1= Trt * (Enum=1);
  Trt2= Trt * (Enum=2);
  Trt3= Trt * (Enum=3);
  Age1= Age * (Enum=1);
  Age2= Age * (Enum=2);
  Age3= Age * (Enum=3);
run;
```

To fit the total time model of PWP with the common regression coefficients, you specify the following:

```
proc phreg;
  model (TStart,TStop)*Status(0)=Trt Age;
  strata Enum;
run;
```

To fit the gap time model of PWP with stratum-specific regression coefficients, you specify the following:

```
proc phreg;
  model Gaptime*Status(0)=Trt1 Trt2 Trt3 Age1 Age2 Age3;
  strata Enum;
  Trt1= Trt * (Enum=1);
  Trt2= Trt * (Enum=2);
  Trt3= Trt * (Enum=3);
  Age1= Age * (Enum=1);
  Age2= Age * (Enum=2);
  Age3= Age * (Enum=3);
run;
```

To fit the gap time model of PWP with common regression coefficients, you specify the following:

```
proc phreg;
  model Gaptime*Status(0)=Trt Age;
  strata Enum;
run;
```

Model Fit Statistics

Suppose the model contains p regression parameters. Let Δ_j and f_j be the event indicator and the frequency, respectively, of the j th observation. The three criteria displayed by the PHREG procedure are calculated as follows:

- -2 Log Likelihood:

$$-2 \text{ Log L} = -2 \log(L_n(\hat{\beta}))$$

where $L_n(\cdot)$ is a partial likelihood function for the corresponding TIES= option as described in the section “[Partial Likelihood Function for the Cox Model](#)” on page 5614, and $\hat{\beta}$ is the maximum likelihood estimate of the regression parameter vector.

- Akaike’s Information Criterion:

$$\text{AIC} = -2 \text{ Log L} + 2p$$

- Schwarz Bayesian (Information) Criterion:

$$\text{SBC} = -2 \text{ Log L} + p \log\left(\sum_j f_j \Delta_j\right)$$

The -2 Log Likelihood statistic has a chi-square distribution under the null hypothesis (that all the explanatory effects in the model are zero) and the procedure produces a p -value for this statistic. The AIC and SBC statistics give two different ways of adjusting the -2 Log Likelihood statistic for the number of terms in the model and the number of observations used. These statistics should be used when comparing different models for the same data (for example, when you use the METHOD=STEPWISE option in the MODEL statement); lower values of the statistic indicate a more desirable model.

Residuals

This section describes the computation of residuals (RESMART=, RESDEV=, RESSCH=, and RESSCO=) in the OUTPUT statement.

First, consider TIES=BRESLOW. Let

$$\begin{aligned} S^{(0)}(\boldsymbol{\beta}, t) &= \sum_i Y_i(t) e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} \\ S^{(1)}(\boldsymbol{\beta}, t) &= \sum_i Y_i(t) e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} \mathbf{Z}_i(t) \\ \bar{\mathbf{Z}}(\boldsymbol{\beta}, t) &= \frac{S^{(1)}(\boldsymbol{\beta}, t)}{S^{(0)}(\boldsymbol{\beta}, t)} \\ d\Lambda_0(\boldsymbol{\beta}, t) &= \sum_i \frac{dN_i(t)}{S^{(0)}(\boldsymbol{\beta}, t)} \\ dM_i(\boldsymbol{\beta}, t) &= dN_i(t) - Y_i(t) e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} d\Lambda_0(\boldsymbol{\beta}, t) \end{aligned}$$

The martingale residual at t is defined as

$$\hat{M}_i(t) = \int_0^t dM_i(\hat{\boldsymbol{\beta}}, s) = N_i(t) - \int_0^t Y_i(s) e^{\hat{\boldsymbol{\beta}}' \mathbf{Z}_i(s)} d\Lambda_0(\hat{\boldsymbol{\beta}}, s)$$

Here $\hat{M}_i(t)$ estimates the difference over $(0, t]$ between the observed number of events for the i th subject and a conditional expected number of events. The quantity $\hat{M}_i \equiv \hat{M}_i(\infty)$ is referred to as the martingale residual for the i th subject. When the counting process MODEL specification is used, the RESMART= variable contains the component $(\hat{M}_i(t_2) - \hat{M}_i(t_1))$ instead of the martingale residual at t_2 . The martingale residual for a subject can be obtained by summing up these component residuals within the subject. For the Cox model with no time-dependent explanatory variables, the martingale residual for the i th subject with observation time t_i and event status Δ_i is

$$\hat{M}_i = \Delta_i - e^{\hat{\boldsymbol{\beta}}' \mathbf{Z}_i} \int_0^{t_i} d\Lambda_0(\hat{\boldsymbol{\beta}}, s)$$

The deviance residuals D_i are a transform of the martingale residuals:

$$D_i = \text{sign}(\hat{M}_i) \sqrt{2 \left[-\hat{M}_i - N_i(\infty) \log \left(\frac{N_i(\infty) - \hat{M}_i}{N_i(\infty)} \right) \right]}$$

The square root shrinks large negative martingale residuals, while the logarithmic transformation expands martingale residuals that are close to unity. As such, the deviance residuals are more symmetrically distributed around zero than the martingale residuals. For the Cox model, the deviance residual reduces to the form

$$D_i = \text{sign}(\hat{M}_i) \sqrt{2[-\hat{M}_i - \Delta_i \log(\Delta_i - \hat{M}_i)]}$$

When the counting process MODEL specification is used, values of the RESDEV= variable are set to missing because the deviance residuals can be calculated only on a per-subject basis.

The Schoenfeld (1982) residual vector is calculated on a per-event-time basis. At the j th event time t_{ij} of the i th subject, the Schoenfeld residual

$$\hat{U}_i(t_{ij}) = \mathbf{Z}_i(t_{ij}) - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, t_{ij})$$

is the difference between the i th subject covariate vector at t_{ij} and the average of the covariate vectors over the risk set at t_{ij} . Under the proportional hazards assumption, the Schoenfeld residuals have the sample path of a random walk; therefore, they are useful in assessing time trend or lack of proportionality. Harrell (1986) proposed a z -transform of the Pearson correlation between these residuals and the rank order of the failure time as a test statistic for nonproportional hazards. Therneau, Grambsch, and Fleming (1990) considered a Kolmogorov-type test based on the cumulative sum of the residuals.

The score process for the i th subject at time t is

$$\mathbf{L}_i(\boldsymbol{\beta}, t) = \int_0^t [\mathbf{Z}_i(s) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, s)] dM_i(\boldsymbol{\beta}, s)$$

The vector $\hat{\mathbf{L}}_i \equiv \mathbf{L}_i(\hat{\boldsymbol{\beta}}, \infty)$ is the score residual for the i th subject. When the counting process MODEL specification is used, the RESSCO= variables contain the components of $(\mathbf{L}_i(\hat{\boldsymbol{\beta}}, t_2) - \mathbf{L}_i(\hat{\boldsymbol{\beta}}, t_1))$ instead of the score process at t_2 . The score residual for a subject can be obtained by summing up these component residuals within the subject.

The score residuals are a decomposition of the first partial derivative of the log likelihood. They are useful in assessing the influence of each subject on individual parameter estimates. They also play an important role in the computation of the robust sandwich variance estimators of Lin and Wei (1989) and Wei, Lin, and Weissfeld (1989).

For TIES=EFRON, the preceding computation is modified to comply with the Efron partial likelihood. For a given time t , let $\Delta_i(t)=1$ if the t is an event time of the i th subject and 0 otherwise. Let $d(t) = \sum_i \Delta_i(t)$, which is the number of subjects that have an event at t . For $1 \leq k \leq d(t)$, let

$$\begin{aligned} S^{(0)}(\boldsymbol{\beta}, k, t) &= \sum_i Y_i(t) \left\{ 1 - \frac{k-1}{d(t)} \Delta_i(t) \right\} e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} \\ S^{(1)}(\boldsymbol{\beta}, k, t) &= \sum_i Y_i(t) \left\{ 1 - \frac{k-1}{d(t)} \Delta_i(t) \right\} e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} \mathbf{Z}_i(t) \\ \bar{\mathbf{Z}}(\boldsymbol{\beta}, k, t) &= \frac{S^{(1)}(\boldsymbol{\beta}, k, t)}{S^{(0)}(\boldsymbol{\beta}, k, t)} \\ d\Lambda_0(\boldsymbol{\beta}, k, t) &= \sum_i \frac{dN_i(t)}{S^{(0)}(\boldsymbol{\beta}, k, t)} \\ dM_i(\boldsymbol{\beta}, k, t) &= dN_i(t) - Y_i(t) \left(1 - \Delta_i(t) \frac{k-1}{d(t)} \right) e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} d\Lambda_0(\boldsymbol{\beta}, k, t) \end{aligned}$$

The martingale residual at t for the i th subject is defined as

$$\hat{M}_i(t) = \int_0^t \frac{1}{d(s)} \sum_{k=1}^{d(s)} dM_i(\hat{\beta}, k, s) = N_i(t) - \int_0^t \frac{1}{d(s)} \sum_{k=1}^{d(s)} Y_i(s) \left(1 - \Delta_i(s) \frac{k-1}{d(s)} \right) e^{\hat{\beta}' \mathbf{Z}_i(s)} d\Lambda_0(\hat{\beta}, k, s)$$

Deviance residuals are computed by using the same transform on the corresponding martingale residuals as in TIES=BRESLOW.

The Schoenfeld residual vector for the i th subject at event time t_{ij} is

$$\hat{\mathbf{U}}_i(t_{ij}) = \mathbf{Z}_i(t_{ij}) - \frac{1}{d(t_{ij})} \sum_{k=1}^{d(t_{ij})} \bar{\mathbf{Z}}(\hat{\beta}, k, t_{ij})$$

The score process for the i th subject at time t is given by

$$\mathbf{L}_i(\beta, t) = \int_0^t \frac{1}{d(s)} \sum_{k=1}^{d(s)} \left(\mathbf{Z}_i(s) - \bar{\mathbf{Z}}(\beta, k, s) \right) dM_i(\beta, k, s)$$

For TIES=DISCRETE or TIES=EXACT, it is difficult to come up with modifications that are consistent with the corresponding partial likelihood. Residuals for these TIES= methods are computed by using the same formulae as in TIES=BRESLOW.

Diagnostics Based on Weighted Residuals

The vector of weighted Schoenfeld residuals, \mathbf{r}_i , is computed as

$$\mathbf{r}_i = n_e \mathcal{I}^{-1}(\hat{\beta}) \hat{\mathbf{U}}_i(t_i)$$

where n_e is the total number of events and $\hat{\mathbf{U}}_i(t_i)$ is the vector of Schoenfeld residuals at the event time t_i . The components of \mathbf{r}_i are output to the WTRESSCH= variables.

The weighted Schoenfeld residuals are useful in assessing the proportional hazards assumption. The idea is that most of the common alternatives to the proportional hazards can be cast in terms of a time-varying coefficient model

$$\lambda(t, \mathbf{Z}) = \lambda_0(t) \exp(\beta_1(t)Z_1 + \beta_2(t)Z_2 + \dots)$$

where $\lambda(t, \mathbf{Z})$ and $\lambda_0(t)$ are hazard rates. Let $\hat{\beta}_j$ and r_{ij} be the j th component of $\hat{\beta}$ and \mathbf{r}_i , respectively. Grambsch and Therneau (1994) suggest using a smoothed plot of $(\hat{\beta}_j + r_{ij})$ versus t_i to discover the functional form of the time-varying coefficient $\beta_j(t)$. A zero slope indicates that the coefficient is not varying with time.

The weighted score residuals are used more often than their unscaled counterparts in assessing local influence. Let $\hat{\beta}_{(i)}$ be the estimate of β when the i th subject is left out, and let $\delta \hat{\beta}_i = \hat{\beta} - \hat{\beta}_{(i)}$. The j th component of $\delta \hat{\beta}_i$ can be used to assess any untoward effect of the i th subject on $\hat{\beta}_j$. The exact computation of $\delta \hat{\beta}_i$

involves refitting the model each time a subject is omitted. Cain and Lange (1984) derived the following approximation of Δ_i as weighted score residuals:

$$\delta\hat{\beta}_i = \mathcal{I}^{-1}(\hat{\beta})\hat{\mathbf{L}}_i$$

Here, $\hat{\mathbf{L}}_i$ is the vector of the score residuals for the i th subject. Values of $\delta\hat{\beta}_i$ are output to the DFBETA= variables. Again, when the counting process MODEL specification is used, the DFBETA= variables contain the component $\mathcal{I}^{-1}(\hat{\beta})(\mathbf{L}_i(\hat{\beta}, t_2) - \mathbf{L}_i(\hat{\beta}, t_1))$, where the score process $\mathbf{L}_i(\beta, t)$ is defined in the section “Residuals” on page 5639. The vector $\delta\hat{\beta}_i$ for the i th subject can be obtained by summing these components within the subject.

Note that these DFBETA statistics are a transform of the score residuals. In computing the robust sandwich variance estimators of Lin and Wei (1989) and Wei, Lin, and Weissfeld (1989), it is more convenient to use the DFBETA statistics than the score residuals (see Example 67.10).

Influence of Observations on Overall Fit of the Model

The LD statistic approximates the likelihood displacement, which is the amount by which minus twice the log likelihood ($-2 \log L(\hat{\beta})$), under a fitted model, changes when each subject in turn is left out. When the i th subject is omitted, the likelihood displacement is

$$2 \log L(\hat{\beta}) - 2 \log L(\hat{\beta}_{(i)})$$

where $\hat{\beta}_{(i)}$ is the vector of parameter estimates obtained by fitting the model without the i th subject. Instead of refitting the model without the i th subject, Pettitt and Bin Daud (1989) propose that the likelihood displacement for the i th subject be approximated by

$$\text{LD}_i = \hat{\mathbf{L}}_i' \mathcal{I}^{-1}(\hat{\beta}) \hat{\mathbf{L}}_i$$

where $\hat{\mathbf{L}}_i$ is the score residual vector of the i th subject. This approximation is output to the LD= variable.

The LMAX statistic is another global influence statistic. This statistic is based on the symmetric matrix

$$\mathbf{B} = \mathbf{L} \mathcal{I}^{-1}(\hat{\beta}) \mathbf{L}'$$

where \mathbf{L} is the matrix with rows that are the score residual vectors $\hat{\mathbf{L}}_i$. The elements of the eigenvector associated with the largest eigenvalue of the matrix \mathbf{B} , standardized to unit length, give a measure of the sensitivity of the fit of the model to each observation in the data. The influence of the i th subject on the global fit of the model is proportional to the magnitude of ζ_i , where ζ_i is the i th element of the vector $\boldsymbol{\zeta}$ that satisfies

$$\mathbf{B}\boldsymbol{\zeta} = \lambda_{\max}\boldsymbol{\zeta} \quad \text{and} \quad \boldsymbol{\zeta}'\boldsymbol{\zeta} = 1$$

with λ_{\max} being the largest eigenvalue of \mathbf{B} . The sign of ζ_i is irrelevant, and its absolute value is output to the LMAX= variable.

When the counting process MODEL specification is used, the LD= and LMAX= variables are set to missing, because these two global influence statistics can be calculated on a per-subject basis only.

Survivor Function Estimators

Three estimators of the survivor function are available: the Breslow (1972) estimator, which is based on the empirical cumulative hazard function, the Fleming and Harrington (1984) estimator, which is a tie-breaking modification of the Breslow estimator, and the product-limit estimator (Kalbfleisch and Prentice 1980, pp. 84–86).

Let $\{t_1 < \dots < t_k\}$ be the distinct uncensored times of the survival data.

Breslow Estimator

To select this estimator, specify the METHOD=BRESLOW option in the BASELINE statement or OUTPUT statement. For the j th subject, let $\{(X_j, \Delta_j, \mathbf{Z}_j(\cdot))\}$ represent the failure time, the event indicator, and the vector of covariate values, respectively. For $t \geq 0$, let

$$\begin{aligned} Y_j(t) &= I(X_j \geq t) \\ \Delta_j(t) &= \begin{cases} 1 & X_j = t \text{ \& } \Delta_j = 1 \\ 0 & \text{otherwise} \end{cases} \\ d(t) &= \sum_j \Delta_j(t) \end{aligned}$$

Note that $d(t)$ is the number of subjects that have an event at t . Let

$$\begin{aligned} S^{(0)}(\boldsymbol{\beta}, t) &= \sum_j Y_j(t) e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \\ S^{(1)}(\boldsymbol{\beta}, t) &= \sum_j Y_j(t) e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \mathbf{Z}_j(t) \\ \bar{\mathbf{Z}}(\boldsymbol{\beta}, t) &= \frac{S^{(1)}(\boldsymbol{\beta}, t)}{S^{(0)}(\boldsymbol{\beta}, t)} \end{aligned}$$

For a given realization of the explanatory variables $\boldsymbol{\xi}$, the cumulative hazard function estimator at $\boldsymbol{\xi}$ is

$$\hat{\Lambda}_B(t, \boldsymbol{\xi}) = e^{\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \frac{d(t_i)}{S^{(0)}(\hat{\boldsymbol{\beta}}, t_i)}$$

with variance estimated by

$$\hat{\sigma}^2(\hat{\Lambda}_B(t, \boldsymbol{\xi})) = e^{2\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \frac{d(t_i)}{[S^{(0)}(\hat{\boldsymbol{\beta}}, t_i)]^2} + H(t, \boldsymbol{\xi})' [\mathcal{I}(\hat{\boldsymbol{\beta}})]^{-1} H(t, \boldsymbol{\xi})$$

where

$$H(t, \boldsymbol{\xi}) = e^{\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \frac{d(t_i)}{S^{(0)}(\hat{\boldsymbol{\beta}}, t_i)} \left(\bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, t_i) - \boldsymbol{\xi} \right)$$

For the marginal model, the variance estimator computation follows Spiekerman and Lin (1998).

The Breslow estimate of the survivor function for $\mathbf{Z} = \boldsymbol{\xi}$ is

$$\hat{S}_B(t, \boldsymbol{\xi}) = \exp(-\hat{\Lambda}_B(t, \boldsymbol{\xi}))$$

By the delta method, the standard error of $\hat{S}_B(t, \boldsymbol{\xi})$ is approximated by

$$\hat{\sigma}(\hat{S}_B(t, \boldsymbol{\xi})) = \hat{S}_B(t, \boldsymbol{\xi}) \hat{\sigma}(\hat{\Lambda}_B(t, \boldsymbol{\xi}))$$

Fleming-Harrington Estimator

To select this estimator, specify the METHOD=FH option in the BASELINE statement or OUTPUT statement. With $Y_j(t)$ and $d(t)$ as defined in the section “Breslow Estimator” on page 5643 and for $1 \leq k \leq d(t)$, let

$$\begin{aligned} S_E^{(0)}(\boldsymbol{\beta}, k, t) &= \sum_j Y_j(t) \left\{ 1 - \frac{k-1}{d(t)} \Delta_j(t) \right\} e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \\ S_E^{(1)}(\boldsymbol{\beta}, k, t) &= \sum_j Y_j(t) \left\{ 1 - \frac{k-1}{d(t)} \Delta_j(t) \right\} e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \mathbf{Z}_j(t) \\ \bar{\mathbf{Z}}_E \boldsymbol{\beta}, k, t &= \frac{S_E^{(1)}(\boldsymbol{\beta}, k, t)}{S_E^{(0)}(\boldsymbol{\beta}, k, t)} \end{aligned}$$

For a given realization of the explanatory variables, the Fleming-Harrington adjustment of the cumulative hazard function is

$$\hat{\Lambda}_F(t, \boldsymbol{\xi}) = e^{\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \left\{ \sum_{k=1}^{d(t_i)} \frac{1}{S_E^{(0)}(\hat{\boldsymbol{\beta}}, k, t_i)} \right\}$$

with variance estimated by

$$\hat{\sigma}^2(\hat{\Lambda}_F(t, \boldsymbol{\xi})) = e^{2\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \left\{ \sum_{k=1}^{d(t_i)} \frac{1}{[S_E^{(0)}(\hat{\boldsymbol{\beta}}, k, t_i)]^2} \right\} + H_E(t, \boldsymbol{\xi})' [\mathcal{I}(\hat{\boldsymbol{\beta}})]^{-1} H_E(t, \boldsymbol{\xi})$$

where

$$H_E(t, \boldsymbol{\xi}) = e^{\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \left\{ \left[\sum_{t_i \leq t} \sum_{k=1}^{d(t_i)} \frac{1}{S_E^{(0)}(\hat{\boldsymbol{\beta}}, k, t_i)} \bar{\mathbf{Z}}_E(\hat{\boldsymbol{\beta}}, k, t_i) \right] - \hat{\Lambda}_F(t, \mathbf{0}) \boldsymbol{\xi} \right\}$$

The Fleming-Harrington estimate of the survivor function for $\mathbf{Z} = \boldsymbol{\xi}$ is

$$\hat{S}_F(t, \boldsymbol{\xi}) = \exp(-\hat{\Lambda}_F(t, \boldsymbol{\xi}))$$

By the delta method, the standard error of $\hat{S}_F(t, \boldsymbol{\xi})$ is approximated by

$$\hat{\sigma}(\hat{S}_F(t, \boldsymbol{\xi})) = \hat{S}_F(t, \boldsymbol{\xi}) \hat{\sigma}(\hat{\Lambda}_F(t, \boldsymbol{\xi}))$$

Product-Limit Estimator

To select this estimator, specify the METHOD=PL option in the BASELINE statement or OUTPUT statement. Let \mathcal{D}_i denote the set of individuals that fail at t_i . Let \mathcal{C}_i denote the set of individuals that are censored in the half-open interval $[t_i, t_{i+1})$, where $t_0 = 0$ and $t_{k+1} = \infty$. Let γ_l denote the censoring times in $[t_i, t_{i+1})$, where l ranges over \mathcal{C}_i .

The likelihood function for all individuals is given by

$$\mathcal{L} = \prod_{i=0}^k \left\{ \prod_{l \in \mathcal{D}_i} \left([S_0(t_i)]^{\exp(\mathbf{Z}'_l \boldsymbol{\beta})} - [S_0(t_i + 0)]^{\exp(\mathbf{Z}'_l \boldsymbol{\beta})} \right) \prod_{l \in \mathcal{C}_i} [S_0(\gamma_l + 0)]^{\exp(\mathbf{Z}'_l \boldsymbol{\beta})} \right\}$$

where \mathcal{D}_0 is empty. The likelihood \mathcal{L} is maximized by taking $S_0(t) = S_0(t_i + 0)$ for $t_i < t \leq t_{i+1}$ and allowing the probability mass to fall only on the observed event times t_1, \dots, t_k . By considering a discrete model with hazard contribution $1 - \alpha_i$ at t_i , you take $S_0(t_i) = S_0(t_{i-1} + 0) = \prod_{j=0}^{i-1} \alpha_j$, where $\alpha_0 = 1$. Substitution into the likelihood function produces

$$\mathcal{L} = \prod_{i=0}^k \left\{ \prod_{j \in \mathcal{D}_i} \left(1 - \alpha_i^{\exp(\mathbf{Z}'_j \boldsymbol{\beta})} \right) \prod_{l \in \mathcal{R}_i - \mathcal{D}_i} \alpha_i^{\exp(\mathbf{Z}'_l \boldsymbol{\beta})} \right\}$$

If you replace $\boldsymbol{\beta}$ with $\hat{\boldsymbol{\beta}}$ estimated from the partial likelihood function and then maximize with respect to $\alpha_1, \dots, \alpha_k$, the maximum likelihood estimate $\hat{\alpha}_i$ of α_i becomes a solution of

$$\sum_{j \in \mathcal{D}_i} \frac{\exp(\mathbf{Z}'_j \hat{\boldsymbol{\beta}})}{1 - \hat{\alpha}_i^{\exp(\mathbf{Z}'_j \hat{\boldsymbol{\beta}})}} = \sum_{l \in \mathcal{R}_i} \exp(\mathbf{Z}'_l \hat{\boldsymbol{\beta}})$$

When only a single failure occurs at t_i , $\hat{\alpha}_i$ can be found explicitly. Otherwise, an iterative solution is obtained by the Newton method.

The baseline survival function is estimated by

$$\hat{S}_0(t) = \hat{S}_0(t_{i-1} + 0) = \prod_{j=0}^{i-1} \hat{\alpha}_j, t_{i-1} < t \leq t_i$$

For a given realization of the explanatory variables $\boldsymbol{\xi}$, the product-limit estimate of the survival function at $\mathbf{Z} = \boldsymbol{\xi}$ is

$$\hat{S}_P(t, \boldsymbol{\xi}) = [\hat{S}_0(t)]^{\exp(\boldsymbol{\beta}' \boldsymbol{\xi})}$$

Approximating the variance of $-\log(\hat{S}_P(t, \boldsymbol{\xi}))$ by the variance estimate of the Breslow estimator of the cumulative hazard function, the variance of the product-limit estimator at $\mathbf{Z} = \boldsymbol{\xi}$ is given by

$$\hat{\sigma}(\hat{S}_P(t, \boldsymbol{\xi})) = \hat{S}_P(t, \boldsymbol{\xi}) \hat{\sigma}(\hat{\Lambda}_B(t, \boldsymbol{\xi}))$$

Direct Adjusted Survival Curves

Consider the Breslow estimator of the survival function. For $j = 1, \dots, n$, let ξ_j represent the covariate set of the j th patient. The direct adjusted survival curve averages the estimated survival curves for each patient:

$$\bar{S}(t) = \frac{1}{n} \sum_{j=1}^n \hat{S}(t, \xi_j)$$

The variance of $\bar{S}(t)$ can be estimated by

$$\hat{\sigma}^2(\bar{S}(t)) = \frac{1}{n^2} \left(V^{(1)}(t) + V^{(2)}(t) \right)$$

where

$$\begin{aligned} V^{(1)}(t) &= \left(\sum_{j=1}^n e^{\hat{\beta}' \xi_j} \hat{S}(t, \xi_j) \right)^2 \sum_{t_i \leq t} \frac{d(t_i)}{[S^{(0)}(\hat{\beta}, t_i)]^2} \\ V^{(2)}(t) &= \left(\sum_{j=1}^n \hat{S}(t, \xi_j) H(t, \xi_j) \right)' \left[\mathcal{I}(\hat{\beta}) \right]^{-1} \left(\sum_{j=1}^n \hat{S}(t, \xi_j) H(t, \xi_j) \right) \end{aligned}$$

Comparison of Direct Adjusted Probabilities of Two Strata

For a stratified Cox model, let k index the strata. For the j th patient, let $\hat{S}_k(t, \xi_j)$ and $H_k(t, \xi_j)$ be the estimated survival function and the \mathbf{H} vector for the k th stratum. The direct adjusted survival curve for the k th stratum is

$$\bar{S}_k(t) = \frac{1}{n} \sum_{j=1}^n \hat{S}_k(t, \xi_j)$$

The variance of $\bar{S}_1(t) - \bar{S}_2(t)$ can be estimated by

$$\hat{\sigma}^2(\bar{S}_1(t) - \bar{S}_2(t)) = \frac{1}{n^2} \left(U_1^{(1)}(t) + U_2^{(1)} + U_{12}^{(2)}(t) \right)$$

where

$$\begin{aligned} U_k^{(1)}(t) &= \left(\sum_{j=1}^n e^{\hat{\beta}' \xi_j} \hat{S}_k(t, \xi_j) \right)^2 \sum_{t_i \leq t} \frac{d(t_i)}{[S^{(0)}(\hat{\beta}, t_i)]^2} \quad k = 1, 2 \\ U_{12}^{(2)}(t) &= \left\{ \sum_{j=1}^n \left[\hat{S}_1(t, \xi_j) H_1(t, \xi_j) - \hat{S}_2(t, \xi_j) H_2(t, \xi_j) \right] \right\}' \mathcal{I}^{-1}(\hat{\beta}) \\ &\quad \left\{ \sum_{j=1}^n \left[\hat{S}_1(t, \xi_j) H_2(t, \xi_j) - \hat{S}_2(t, \xi_j) H_1(t, \xi_j) \right] \right\} \end{aligned}$$

Comparison of Direct Adjusted Survival Probabilities of Two Treatments

For $j = 1, \dots, n$, let ξ_{jk} represent the covariate set of the j th patient with the k th treatment, $k = 1, 2$. The direct adjusted survival curve for the k th treatment is

$$\bar{S}_k(t) = \frac{1}{n} \sum_{i=j}^n \hat{S}(t, \xi_{jk})$$

The variance of $\bar{S}_1(t) - \bar{S}_2(t)$ can be estimated by

$$\hat{\sigma}^2(\bar{S}_1(t) - \bar{S}_2(t)) = \frac{1}{n^2} \left(V_{12}^{(1)}(t) + V_{12}^{(2)}(t) \right)$$

where

$$\begin{aligned} V_{12}^{(1)}(t) &= \left\{ \sum_{j=1}^n \left[e^{\beta' \xi_{1j}} \hat{S}(t, \xi_{1j}) - e^{\beta' \xi_{2j}} \hat{S}(t, \xi_{2j}) \right] \right\}^2 \sum_{t_i \leq t} \frac{d(t_i)}{[S^{(0)}(\hat{\beta}, t_i)]^2} \\ V_{12}^{(2)}(t) &= \left\{ \sum_{j=1}^n \left[\hat{S}(t, \xi_{1j}) H(t, \xi_{1j}) - \hat{S}(t, \xi_{2j}) H(t, \xi_{2j}) \right] \right\}' \mathcal{I}^{-1}(\hat{\beta}) \\ &\quad \left\{ \sum_{j=1}^n \left[\hat{S}(t, \xi_{1j}) H(t, \xi_{1j}) - \hat{S}(t, \xi_{2j}) H(t, \xi_{2j}) \right] \right\} \end{aligned}$$

Confidence Intervals for the Survivor Function

When the computation of confidence limits for the survivor function $S(t)$ is based on the asymptotic normality of the survival estimator $\hat{S}(t)$ —which can be the Breslow estimator $\hat{S}_B(t)$, the Fleming-Harrington estimator $\hat{S}_F(t)$, or the product-limit estimator $\hat{S}_P(t)$ —the approximate confidence interval might include impossible values outside the range $[0, 1]$ at extreme values of t . This problem can be avoided by applying the asymptotic normality to a transformation of $S(t)$ for which the range is unrestricted. In addition, certain transformed confidence intervals for $S(t)$ perform better than the usual linear confidence intervals (Borgan and Liestøl 1990). The CLTYPE= option in the BASELINE statement enables you to choose one of the following transformations: the log-log function, the log function, and the linear function.

Let g be the transformation that is being applied to the survivor function $S(t)$. By the delta method, the standard error of $g(\hat{S}(t))$ is estimated by

$$\tau(t) = \hat{\sigma} \left[g(\hat{S}(t)) \right] = g'(\hat{S}(t)) \hat{\sigma}[\hat{S}(t)]$$

where g' is the first derivative of the function g . The $100(1-\alpha)\%$ confidence interval for $S(t)$ is given by

$$g^{-1} \left\{ g[\hat{S}(t)] \pm z_{\alpha/2} g'[\hat{S}(t)] \hat{\sigma}[\hat{S}(t)] \right\}$$

where g^{-1} is the inverse function of g . The choices for the transformation g are as follows:

- CLTYPE=NORMAL specifies linear transformation, which is the same as having no transformation in which g is the identity. The $100(1-\alpha)\%$ confidence interval for $S(t)$ is given by

$$\hat{S}(t) - z_{\frac{\alpha}{2}} \hat{\sigma} \left[\hat{S}(t) \right] \leq S(t) \leq \hat{S}(t) + z_{\frac{\alpha}{2}} \hat{\sigma} \left[\hat{S}(t) \right]$$

- CLTYPE=LOG specifies log transformation. The estimated variance of $\log(\hat{S}(t))$ is $\hat{\tau}^2(t) = \frac{\hat{\sigma}^2(\hat{S}(t))}{\hat{S}^2(t)}$. The $100(1-\alpha)\%$ confidence interval for $S(t)$ is given by

$$\hat{S}(t) \exp \left(-z_{\frac{\alpha}{2}} \hat{\tau}(t) \right) \leq S(t) \leq \hat{S}(t) \exp \left(z_{\frac{\alpha}{2}} \hat{\tau}(t) \right)$$

- CLTYPE=LOGLOG specifies log-log transformation. The estimated variance of $\log(-\log(\hat{S}(t)))$ is $\hat{\tau}^2(t) = \frac{\hat{\sigma}^2[\hat{S}(t)]}{[\hat{S}(t) \log(\hat{S}(t))]^2}$. The $100(1-\alpha)\%$ confidence interval for $S(t)$ is given by

$$\left[\hat{S}(t) \right]^{\exp \left(z_{\frac{\alpha}{2}} \hat{\tau}(t) \right)} \leq S(t) \leq \left[\hat{S}(t) \right]^{\exp \left(-z_{\frac{\alpha}{2}} \hat{\tau}(t) \right)}$$

Effect Selection Methods

Five effect selection methods are available. The simplest method (and the default) is SELECTION=NONE, for which PROC PHREG fits the complete model as specified in the MODEL statement. The other four methods are FORWARD for forward selection, BACKWARD for backward elimination, STEPWISE for stepwise selection, and SCORE for best subsets selection. These methods are specified with the SELECTION= option in the MODEL statement and are based on the score test or Wald test as described in the section “Type 3 Tests” on page 5626.

When SELECTION=FORWARD, PROC PHREG first estimates parameters for effects that are forced into the model. These are the first n effects in the MODEL statement, where n is the number specified by the START= or INCLUDE= option in the MODEL statement (n is zero by default). Next, the procedure computes the score statistic for each effect that is not in the model. Each score statistic is the chi-square statistic of the score test for testing the null hypothesis that the corresponding effect that is not in the model is null. If the largest of these statistics is significant at the SLSENTRY= level, the effect with the largest score statistic is added to the model. After an effect is entered in the model, it is never removed from the model. The process is repeated until none of the remaining effects meet the specified level for entry or until the STOP= value is reached.

When SELECTION=BACKWARD, parameters for the complete model as specified in the MODEL statement are estimated unless the START= option is specified. In that case, only the parameters for the first n effects in the MODEL statement are estimated, where n is the number specified by the START= option. Next, the procedure computes the Wald statistic of each effect in the model. Each Wald's statistic is the chi-square statistic of the Wald test for testing the null hypothesis that the corresponding effect is null. If the smallest of these statistics is not significant at the SLSTAY= level, the effect with the smallest Wald statistic is removed. After an effect is removed from the model, it remains excluded. The process is repeated until no other variable in the model meets the specified level for removal or until the STOP= value is reached.

The SELECTION=STEPWISE option is similar to the SELECTION=FORWARD option except that effects already in the model do not necessarily remain. Effects are entered into and removed from the model in such

a way that each forward selection step can be followed by one or more backward elimination steps. The stepwise selection process terminates if no further effect can be added to the model or if the effect just entered into the model is the only effect that is removed in the subsequent backward elimination.

For `SELECTION=SCORE`, `PROC PHREG` uses the branch-and-bound algorithm of Furnival and Wilson (1974) to find a specified number of models with the highest score (chi-square) statistic for all possible model sizes, from 1, 2, or 3 variables, and so on, up to the single model that contains all of the explanatory variables. The number of models displayed for each model size is controlled by the `BEST=` option. You can use the `START=` option to impose a minimum model size, and you can use the `STOP=` option to impose a maximum model size. For instance, with `BEST=3`, `START=2`, and `STOP=5`, the `SCORE` selection method displays the best three models (that is, the three models with the highest score chi-squares) that contain 2, 3, 4, and 5 variables. One of the limitations of the branch-and-bound algorithm is that it works only when each explanatory effect contains exactly one parameter—the `SELECTION=SCORE` option is not allowed when an explanatory effect in the `MODEL` statement contains a `CLASS` variable.

The `SEQUENTIAL` and `STOPRES` options can alter the default criteria for adding variables to or removing variables from the model when they are used with the `FORWARD`, `BACKWARD`, or `STEPWISE` selection method.

Assessment of the Proportional Hazards Model

The proportional hazards model specifies that the hazard function for the failure time T associated with a $p \times 1$ column covariate vector \mathbf{Z} takes the form

$$\lambda(t; \mathbf{Z}) = \lambda_0(t) e^{\boldsymbol{\beta}' \mathbf{Z}}$$

where $\lambda_0(\cdot)$ is an unspecified baseline hazard function and $\boldsymbol{\beta}$ is a $p \times 1$ column vector of regression parameters. Lin, Wei, and Ying (1993) present graphical and numerical methods for model assessment based on the cumulative sums of martingale residuals and their transforms over certain coordinates (such as covariate values or follow-up times). The distributions of these stochastic processes under the assumed model can be approximated by the distributions of certain zero-mean Gaussian processes whose realizations can be generated by simulation. Each observed residual pattern can then be compared, both graphically and numerically, with a number of realizations from the null distribution. Such comparisons enable you to assess objectively whether the observed residual pattern reflects anything beyond random fluctuation. These procedures are useful in determining appropriate functional forms of covariates and assessing the proportional hazards assumption. You use the `ASSESS` statement to carry out these model-checking procedures.

For a sample of n subjects, let $(X_i, \Delta_i, \mathbf{Z}_i)$ be the data of the i th subject; that is, X_i represents the observed failure time, Δ_i has a value of 1 if X_i is an uncensored time and 0 otherwise, and $\mathbf{Z}_i = (Z_{1i}, \dots, Z_{pi})'$ is a p -vector of covariates. Let $N_i(t) = \Delta_i I(X_i \leq t)$ and $Y_i(t) = I(X_i \geq t)$. Let

$$S^{(0)}(\boldsymbol{\beta}, t) = \sum_{i=1}^n Y_i(t) e^{\boldsymbol{\beta}' \mathbf{Z}_i} \quad \text{and} \quad \mathbf{Z}(\boldsymbol{\beta}, t) = \frac{\sum_{i=1}^n Y_i(t) e^{\boldsymbol{\beta}' \mathbf{Z}_i} \mathbf{Z}_i}{S^{(0)}(\boldsymbol{\beta}, t)}$$

Let $\hat{\boldsymbol{\beta}}$ be the maximum partial likelihood estimate of $\boldsymbol{\beta}$, and let $\mathcal{I}(\hat{\boldsymbol{\beta}})$ be the observed information matrix.

The martingale residuals are defined as

$$\hat{M}_i(t) = N_i(t) - \int_0^t Y_i(u) e^{\hat{\boldsymbol{\beta}}' \mathbf{Z}_i} d\hat{\Lambda}_0(u), \quad i = 1, \dots, n$$

where $\hat{\Lambda}_0(t) = \int_0^t \frac{\sum_{i=1}^n dN_i(u)}{S^{(0)}(\hat{\beta}, u)}$.

The empirical score process $\mathbf{U}(\hat{\beta}, t) = (U_1(\hat{\beta}, t), \dots, U_p(\hat{\beta}, t))'$ is a transform of the martingale residuals:

$$\mathbf{U}(\hat{\beta}, t) = \sum_{i=1}^n \mathbf{Z}_i \hat{M}_i(t)$$

Checking the Functional Form of a Covariate

To check the functional form of the j th covariate, consider the partial-sum process of $\hat{M}_i = \hat{M}_i(\infty)$:

$$W_j(z) = \sum_{i=1}^n I(Z_{ji} \leq z) \hat{M}_i$$

Under that null hypothesis that the model holds, $W_j(z)$ can be approximated by the zero-mean Gaussian process

$$\begin{aligned} \hat{W}_j(z) = & \sum_{l=1}^n \Delta_l \left\{ I(Z_{jl} \leq z) - \frac{\sum_{i=1}^n Y_i(X_l) e^{\hat{\beta}' \mathbf{Z}_i} I(Z_{il} \leq z)}{S^{(0)}(\hat{\beta}, X_l)} \right\} G_l - \\ & \sum_{k=1}^n \int_0^\infty Y_k(s) e^{\hat{\beta}' \mathbf{Z}_k} I(Z_{jk} \leq z) [\mathbf{Z}_k - \bar{\mathbf{Z}}(\hat{\beta}, s)]' d\hat{\Lambda}_0(s) \\ & \times \mathcal{I}^{-1}(\hat{\beta}) \sum_{l=1}^n \Delta_l [\mathbf{Z}_l - \bar{\mathbf{Z}}(\hat{\beta}, X_l)] G_l \end{aligned}$$

where (G_1, \dots, G_n) are independent standard normal variables that are independent of $(X_i, \Delta_i, \mathbf{Z}_i)$, $i = 1, \dots, n$.

You can assess the functional form of the j th covariate by plotting a small number of realizations (the default is 20) of $\hat{W}_j(z)$ on the same graph as the observed $W_j(z)$ and visually comparing them to see how typical the observed pattern of $W_j(z)$ is of the null distribution samples. You can supplement the graphical inspection method with a Kolmogorov-type supremum test. Let s_j be the observed value of $S_j = \sup_z |W_j(z)|$ and let $\hat{S}_j = \sup_z |\hat{W}_j(z)|$. The p -value $\Pr(S_j \geq s_j)$ is approximated by $\Pr(\hat{S}_j \geq s_j)$, which in turn is approximated by generating a large number of realizations (1000 is the default) of $\hat{W}_j(\cdot)$.

Checking the Proportional Hazards Assumption

Consider the standardized empirical score process for the j th component of \mathbf{Z}

$$U_j^*(t) = [\mathcal{I}^{-1}(\hat{\beta})_{jj}]^{\frac{1}{2}} U_j(\hat{\beta}, t),$$

Under the null hypothesis that the model holds, $U_j^*(t)$ can be approximated by

$$\begin{aligned}\hat{U}_j^*(t) &= [\mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})_{jj}]^{\frac{1}{2}} \left\{ \sum_{l=1}^n I(X_l \leq t) \Delta_l [Z_{jl} - \bar{Z}_j(\hat{\boldsymbol{\beta}}, t)] G_l - \right. \\ &\quad \sum_{k=1}^n \int_0^t Y_k(s) e^{\hat{\boldsymbol{\beta}}' \mathbf{Z}_k} Z_{jk} [\mathbf{Z}_k - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, s)]' d\hat{\Lambda}_0(s) \\ &\quad \left. \times \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) \sum_{l=1}^n \Delta_l [\mathbf{Z}_l - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, X_l)] G_l \right\}\end{aligned}$$

where $\bar{Z}_j(\hat{\boldsymbol{\beta}}, t)$ is the j th component of $\bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, t)$, and (G_1, \dots, G_n) are independent standard normal variables that are independent of $(X_i, \Delta_i, \mathbf{Z}_i, (i = 1, \dots, n))$.

You can assess the proportional hazards assumption for the j th covariate by plotting a few realizations of $\hat{U}_j^*(t)$ on the same graph as the observed $U_j^*(t)$ and visually comparing them to see how typical the observed pattern of $U_j^*(t)$ is of the null distribution samples. Again you can supplement the graphical inspection method with a Kolmogorov-type supremum test. Let s_j^* be the observed value of $S_j^* = \sup_t |U_j^*(t)|$ and let $\hat{S}_j^* = \sup_t |\hat{U}_j^*(t)|$. The p -value $\Pr[S_j^* \geq s_j^*]$ is approximated by $\Pr[\hat{S}_j^* \geq s_j^*]$, which in turn is approximated by generating a large number of realizations (1000 is the default) of $\hat{U}_j^*(\cdot)$.

The Penalized Partial Likelihood Approach for Fitting Frailty Models

Let $\boldsymbol{\gamma} = (\gamma_1, \dots, \gamma_s)'$ be the vector of random components for the s clusters.

Gamma Frailty Model

Assume each e^{γ_i} has an independent and identically distributed gamma distribution with mean 1 and a common unknown variance θ ; that is, e^{γ_i} is iid $G(\frac{1}{\theta}, \frac{1}{\theta})$. The penalty function is

$$-\frac{1}{\theta} \sum_{i=1}^s \left(\gamma_i - e^{\gamma_i} \right)$$

plus a function of θ . The penalized partial log likelihood is given by

$$l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta) = l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma}) + \frac{1}{\theta} \sum_{i=1}^s \left(\gamma_i - e^{\gamma_i} \right)$$

where $l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})$ is the log of any of the partial likelihoods in the sections “[Partial Likelihood Function for the Cox Model](#)” on page 5614 and “[The Multiplicative Hazards Model](#)” on page 5617.

The profile marginal log-likelihood of this shared frailty model (Therneau and Grambsch 2000, pp. 257–258) is

$$l_m(\theta) = l_p(\hat{\boldsymbol{\beta}}(\theta), \hat{\boldsymbol{\gamma}}(\theta), \theta) + \sum_{i=1}^s \left\{ \theta^{-1} - (\theta^{-1} + d_i) \log[\theta^{-1} + d_i] + \theta^{-1} \log(\theta^{-1}) + \log \left[\frac{\Gamma(\theta^{-1} + d_i)}{\Gamma(\theta^{-1})} \right] \right\}$$

where d_i is the number of events in the i th cluster.

The maximization of this approximate likelihood is a doubly iterative process that alternates between the following two steps:

- For a provisional value of θ , the best linear unbiased predictors (BLUP) of $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ are computed by maximizing the penalized partial log-likelihood $l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)$. The marginal likelihood is evaluated. This constitutes the inner loop.
- A new value of θ is obtained by the golden section search based on the marginal likelihood of all the previous iterations. This constitutes the outer loop.

The outer loop is iterated until the bracketing interval of θ is small.

Lognormal Frailty Model

With each γ_i having a zero-mean normal distribution and a common variance θ , the penalty function is

$$\frac{1}{2\theta} \boldsymbol{\gamma}' \boldsymbol{\gamma}$$

plus a function of θ . The penalized partial log likelihood is given by

$$l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta) = l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma}) - \frac{1}{2\theta} \boldsymbol{\gamma}' \boldsymbol{\gamma}$$

where $l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})$ is the log of any of the partial likelihoods in the sections “[Partial Likelihood Function for the Cox Model](#)” on page 5614 and “[The Multiplicative Hazards Model](#)” on page 5617.

For a given θ , let \mathbf{H} be the negative Hessian of the penalized partial log likelihood $l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)$; that is,

$$\mathbf{H} = \mathbf{H}(\boldsymbol{\beta}, \boldsymbol{\gamma}) = \begin{bmatrix} \mathbf{H}_{11} & \mathbf{H}_{12} \\ \mathbf{H}_{21} & \mathbf{H}_{22} \end{bmatrix}$$

where $\mathbf{H}_{11} = -\frac{\partial^2 l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)}{\partial \boldsymbol{\beta}^2}$, $\mathbf{H}_{12} = \mathbf{H}_{21}' = -\frac{\partial^2 l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)}{\partial \boldsymbol{\beta} \partial \boldsymbol{\gamma}}$, and $\mathbf{H}_{22} = -\frac{\partial^2 l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)}{\partial \boldsymbol{\gamma}^2}$.

The marginal log likelihood of this shared frailty model is

$$l_m(\boldsymbol{\beta}, \theta) = -\frac{1}{2} \log(\theta^s) + \log \left[\int e^{l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)} d\boldsymbol{\gamma} \right]$$

Using a Laplace approximation to the integral as in Breslow and Clayton (1993), an approximate marginal log likelihood (Ripatti and Palmgren 2000; Therneau and Grambsch 2000) is given by

$$l_m(\boldsymbol{\beta}, \theta) \approx -\frac{1}{2} \log(\theta^s) - \frac{1}{2} \log(|\mathbf{H}_{22}(\boldsymbol{\beta}, \tilde{\boldsymbol{\gamma}}, \theta)|) - l_p(\boldsymbol{\beta}, \tilde{\boldsymbol{\gamma}}, \theta)$$

The maximization of this approximate likelihood is a doubly iterative process that alternates between the following two steps:

- For a provisional value of θ , PROC PHREG computes the best linear unbiased predictors (BLUP) of $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ by maximizing the penalized partial log likelihood $l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)$. This constitutes the inner loop.

- For $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ fixed at the BLUP values, PROC PHREG estimates θ by maximizing the approximate marginal likelihood $l_m(\boldsymbol{\beta}, \theta)$. This constitutes the outer loop.

The outer loop is iterated until the difference between two successive estimates of θ is small.

The ML estimate of θ is

$$\hat{\theta} = \frac{\hat{\boldsymbol{\gamma}}' \hat{\boldsymbol{\gamma}} + \text{trace}(\mathbf{H}_{22}^{-1})}{s}$$

The variance for $\hat{\theta}$ is

$$\text{var}(\hat{\theta}) = 2\hat{\theta} \left[s + \frac{1}{\hat{\theta}^2} \text{trace}(\mathbf{H}_{22}^{-1} \mathbf{H}_{22}^{-1}) - \frac{2}{\hat{\theta}} \text{trace}(\mathbf{H}_{22}^{-1}) \right]^{-1}$$

The REML estimation of θ is obtained by replacing $(\mathbf{H}_{22})^{-1}$ by $(\mathbf{H}^{-1})_{22}$.

The inverse of the final \mathbf{H} matrix is used as the variance estimate of $(\hat{\boldsymbol{\beta}}, \hat{\boldsymbol{\gamma}})'$.

The final BLUP estimates of the random components $\gamma_1, \dots, \gamma_s$ can be displayed by using the SOLUTION option in the RANDOM statement. Also displayed are estimates of the lognormal frailties, which are the exponentiated estimates of the BLUP estimates.

Wald-Type Tests for Penalized Models

Let \mathbf{I} be the negative Hessian of the partial log likelihood $l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})$:

$$\mathbf{I} = \begin{bmatrix} \mathbf{I}_{11} & \mathbf{I}_{12} \\ \mathbf{I}_{21} & \mathbf{I}_{22} \end{bmatrix}$$

where $\mathbf{I}_{11} = -\frac{\partial^2 l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})}{\partial \boldsymbol{\beta}^2}$, $\mathbf{I}_{12} = \mathbf{I}_{21}' = -\frac{\partial^2 l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})}{\partial \boldsymbol{\beta} \partial \boldsymbol{\gamma}}$, and $\mathbf{I}_{22} = -\frac{\partial^2 l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})}{\partial \boldsymbol{\gamma}^2}$. Write $\boldsymbol{\tau}' = (\boldsymbol{\beta}', \boldsymbol{\gamma}')'$. The Wald-type chi-square statistic for testing $H_0 : \mathbf{C}\boldsymbol{\tau} = \mathbf{0}$ is

$$(\mathbf{C}\hat{\boldsymbol{\tau}})'(\mathbf{C}\mathbf{H}^{-1}\mathbf{C}')^{-1}(\mathbf{C}\hat{\boldsymbol{\tau}})$$

Let \mathbf{H} be the negative Hessian of the penalized partial log likelihood $l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)$ at the ML estimate θ ; that is, $\mathbf{H} = \frac{\partial^2}{\partial \boldsymbol{\beta} \partial \boldsymbol{\gamma}} l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \hat{\theta})$. Let $\mathbf{V} = \mathbf{H}^{-1} \mathbf{I} \mathbf{H}^{-1}$. Gray (1992) recommends the following generalized degrees of freedom for the Wald test:

$$\text{DF} = \text{trace}[(\mathbf{C}\mathbf{H}^{-1}\mathbf{C}')^{-1} \mathbf{C}\mathbf{V}\mathbf{C}']$$

See Therneau and Grambsch (2000, Section 5.8) for a discussion of this Wald-type test.

PROC PHREG uses the label "Adjusted DF" to represent this generalized degrees of freedom in the output.

Specifics for Bayesian Analysis

To request a Bayesian analysis, you specify the new BAYES statement in addition to the PROC PHREG statement and the MODEL statement. You include a CLASS statement if you have effects that involve categorical variables. The FREQ or WEIGHT statement can be included if you have a frequency or weight

variable, respectively, in the input data. The STRATA statement can be used to carry out a stratified analysis for the Cox model, but it is not allowed in the piecewise constant baseline hazard model. Programming statements can be used to create time-dependent covariates for the Cox model, but they are not allowed in the piecewise constant baseline hazard model. However, you can use the counting process style of input to accommodate time-dependent covariates that are not continuously changing with time for the piecewise constant baseline hazard model and the Cox model as well. The HAZARDRATIO statement enables you to request a hazard ratio analysis based on the posterior samples. The ASSESS, CONTRAST, ID, OUTPUT, and TEST statements, if specified, are ignored. Also ignored are the COVM and COVS options in the PROC PHREG statement and the following options in the MODEL statement: BEST=, CORRB, COVB, DETAILS, HIERARCHY=, INCLUDE=, MAXSTEP=, NOFIT, PLCONV=, SELECTION=, SEQUENTIAL, SLENTY=, and SLSTAY=.

Piecewise Constant Baseline Hazard Model

Single Failure Time Variable

Let $\{(t_i, \mathbf{x}_i, \delta_i), i = 1, 2, \dots, n\}$ be the observed data. Let $a_0 = 0 < a_1 < \dots < a_{J-1} < a_J = \infty$ be a partition of the time axis.

Hazards in Original Scale The hazard function for subject i is

$$h(t|\mathbf{x}_i; \boldsymbol{\theta}) = h_0(t) \exp(\boldsymbol{\beta}'\mathbf{x}_i)$$

where

$$h_0(t) = \lambda_j \text{ if } a_{j-1} \leq t < a_j, j = 1, \dots, J$$

The baseline cumulative hazard function is

$$H_0(t) = \sum_{j=1}^J \lambda_j \Delta_j(t)$$

where

$$\Delta_j(t) = \begin{cases} 0 & t < a_{j-1} \\ t - a_{j-1} & a_{j-1} \leq t < a_j \\ a_j - a_{j-1} & t \geq a_j \end{cases}$$

The log likelihood is given by

$$\begin{aligned} l(\boldsymbol{\lambda}, \boldsymbol{\beta}) &= \sum_{i=1}^n \delta_i \left[\sum_{j=1}^J I(a_{j-1} \leq t_i < a_j) \log \lambda_j + \boldsymbol{\beta}'\mathbf{x}_i \right] - \sum_{i=1}^n \left[\sum_{j=1}^J \Delta_j(t_i) \lambda_j \right] \exp(\boldsymbol{\beta}'\mathbf{x}_i) \\ &= \sum_{j=1}^J d_j \log \lambda_j + \sum_{i=1}^n \delta_i \boldsymbol{\beta}'\mathbf{x}_i - \sum_{j=1}^J \lambda_j \left[\sum_{i=1}^n \Delta_j(t_i) \exp(\boldsymbol{\beta}'\mathbf{x}_i) \right] \end{aligned}$$

where $d_j = \sum_{i=1}^n \delta_i I(a_{j-1} \leq t_i < a_j)$.

Note that for $1 \leq j \leq J$, the full conditional for λ_j is log-concave only when $d_j > 0$, but the full conditionals for the β 's are always log-concave.

For a given β , $\frac{\partial l}{\partial \lambda} = 0$ gives

$$\tilde{\lambda}_j(\beta) = \frac{d_j}{\sum_{i=1}^n \Delta_j(t_i) \exp(\beta' \mathbf{x}_i)}, \quad j = 1, \dots, J$$

Substituting these values into $l(\lambda, \beta)$ gives the profile log likelihood for β

$$l_p(\beta) = \sum_{i=1}^n \delta_i \beta' \mathbf{x}_i - \sum_{j=1}^J d_j \log \left[\sum_{l=1}^n \Delta_j(t_l) \exp(\beta' \mathbf{x}_l) \right] + c$$

where $c = \sum_j (d_j \log d_j - d_j)$. Since the constant c does not depend on β , it can be discarded from $l_p(\beta)$ in the optimization.

The MLE $\hat{\beta}$ of β is obtained by maximizing

$$l_p(\beta) = \sum_{i=1}^n \delta_i \beta' \mathbf{x}_i - \sum_{j=1}^J d_j \log \left[\sum_{l=1}^n \Delta_j(t_l) \exp(\beta' \mathbf{x}_l) \right]$$

with respect to β , and the MLE $\hat{\lambda}$ of λ is given by

$$\hat{\lambda} = \tilde{\lambda}(\hat{\beta})$$

For $j = 1, \dots, J$, let

$$\begin{aligned} \mathbf{S}_j^{(r)}(\beta) &= \sum_{l=1}^n \Delta_j(t_l) e^{\beta' \mathbf{x}_l} \mathbf{x}_l^{\otimes r}, \quad r = 0, 1, 2 \\ \mathbf{E}_j(\beta) &= \frac{\mathbf{S}_j^{(1)}(\beta)}{S_j^{(0)}(\beta)} \end{aligned}$$

The partial derivatives of $l_p(\beta)$ are

$$\begin{aligned} \frac{\partial l_p(\beta)}{\partial \beta} &= \sum_{i=1}^n \delta_i \mathbf{x}_i - \sum_{j=1}^J d_j \mathbf{E}_j(\beta) \\ -\frac{\partial^2 l_p(\beta)}{\partial \beta^2} &= \sum_{j=1}^J d_j \left\{ \frac{\mathbf{S}_j^{(2)}(\beta)}{S_j^{(0)}(\beta)} - \left[\mathbf{E}_j(\beta) \right] \left[\mathbf{E}_j(\beta) \right]' \right\} \end{aligned}$$

The asymptotic covariance matrix for $(\hat{\lambda}, \hat{\beta})$ is obtained as the inverse of the information matrix given by

$$\begin{aligned} -\frac{\partial^2 l(\hat{\lambda}, \hat{\beta})}{\partial \lambda^2} &= \mathcal{D} \left(\frac{d_1}{\hat{\lambda}_1^2}, \dots, \frac{d_J}{\hat{\lambda}_J^2} \right) \\ -\frac{\partial^2 l(\hat{\lambda}, \hat{\beta})}{\partial \beta^2} &= \sum_{j=1}^J \hat{\lambda}_j \mathbf{S}_j^{(2)}(\hat{\beta}) \\ -\frac{\partial^2 l(\hat{\lambda}, \hat{\beta})}{\partial \lambda \partial \beta} &= (\mathbf{S}_1^{(1)}(\hat{\beta}), \dots, \mathbf{S}_J^{(1)}(\hat{\beta})) \end{aligned}$$

See Example 6.5.1 in Lawless (2003) for details.

Hazards in Log Scale By letting

$$\alpha_j = \log(\lambda_j), \quad j = 1, \dots, J$$

you can build a prior correlation among the λ_j 's by using a correlated prior $\boldsymbol{\alpha} \sim N(\boldsymbol{\alpha}_0, \Sigma_\alpha)$, where $\boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_J)'$.

The log likelihood is given by

$$l(\boldsymbol{\alpha}, \boldsymbol{\beta}) = \sum_{j=1}^J d_j \alpha_j + \sum_{i=1}^n \delta_i \boldsymbol{\beta}' \mathbf{x}_i - \sum_{j=1}^J e^{\alpha_j} S_j^{(0)}(\boldsymbol{\beta})$$

Then the MLE of λ_j is given by

$$e^{\hat{\alpha}_j} = \hat{\lambda}_j = \frac{d_j}{S_j^0(\hat{\boldsymbol{\beta}})}$$

Note that the full conditionals for α 's and β 's are always log-concave.

The asymptotic covariance matrix for $(\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\beta}})$ is obtained as the inverse of the information matrix formed by

$$\begin{aligned} -\frac{\partial^2 l(\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\alpha}^2} &= \mathcal{D}\left(e^{\hat{\alpha}_1} S_1^0(\hat{\boldsymbol{\beta}}), \dots, e^{\hat{\alpha}_J} S_J^0(\hat{\boldsymbol{\beta}})\right) \\ -\frac{\partial^2 l(\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\beta}^2} &= \sum_{j=1}^J e^{\hat{\alpha}_j} \mathbf{S}_j^{(2)}(\hat{\boldsymbol{\beta}}) \\ -\frac{\partial^2 l(\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\alpha} \partial \boldsymbol{\beta}} &= (e^{\hat{\alpha}_1} \mathbf{S}_1^{(1)}(\hat{\boldsymbol{\beta}}), \dots, e^{\hat{\alpha}_J} \mathbf{S}_J^{(1)}(\hat{\boldsymbol{\beta}})) \end{aligned}$$

Counting Process Style of Input

Let $\{(s_i, t_i], \mathbf{x}_i, \delta_i), i = 1, 2, \dots, n\}$ be the observed data. Let $a_0 = 0 < a_1 < \dots < a_k$ be a partition of the time axis, where $a_k > t_i$ for all $i = 1, 2, \dots, n$.

Replacing $\Delta_j(t_i)$ with

$$\Delta_j((s_i, t_i]) = \begin{cases} 0 & t_i < a_{j-1} \vee s_i > a_j \\ t_i - \max(s_i, a_{j-1}) & a_{j-1} \leq t_i < a_j \\ a_j - \max(s_i, a_{j-1}) & t_i \geq a_j \end{cases}$$

the formulation for the single failure time variable applies.

Priors for Model Parameters

For a Cox model, the model parameters are the regression coefficients. For a piecewise exponential model, the model parameters consist of the regression coefficients and the hazards or log-hazards. The priors for the hazards and the priors for the regression coefficients are assumed to be independent, while you can have a joint multivariate normal prior for the log-hazards and the regression coefficients.

Hazard Parameters

Let $\lambda_1, \dots, \lambda_J$ be the constant baseline hazards.

Improper Prior The joint prior density is given by

$$p(\lambda_1, \dots, \lambda_J) = \prod_{j=1}^J \frac{1}{\lambda_j}, \forall \lambda_j > 0$$

This prior is improper (nonintegrable), but the posterior distribution is proper as long as there is at least one event time in each of the constant hazard intervals.

Uniform Prior The joint prior density is given by

$$p(\lambda_1, \dots, \lambda_J) \propto 1, \forall \lambda_j > 0$$

This prior is improper (nonintegrable), but the posteriors are proper as long as there is at least one event time in each of the constant hazard intervals.

Gamma Prior The gamma distribution $G(a, b)$ has a PDF

$$f_{a,b}(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}, t > 0$$

where a is the shape parameter and b^{-1} is the scale parameter. The mean is $\frac{a}{b}$ and the variance is $\frac{a}{b^2}$.

Independent Gamma Prior Suppose for $j = 1, \dots, J$, λ_j has an independent $G(a_j, b_j)$ prior. The joint prior density is given by

$$p(\lambda_1, \dots, \lambda_J) \propto \prod_{j=1}^J \left\{ \lambda_j^{a_j-1} e^{-b_j \lambda_j} \right\}, \forall \lambda_j > 0$$

AR1 Prior $\lambda_1, \dots, \lambda_J$ are correlated as follows:

$$\begin{aligned} \lambda_1 &\sim G(a_1, b_1) \\ \lambda_2 &\sim G\left(a_2, \frac{b_2}{\lambda_1}\right) \\ \dots &\dots \\ \lambda_J &\sim G\left(a_J, \frac{b_J}{\lambda_{J-1}}\right) \end{aligned}$$

The joint prior density is given by

$$p(\lambda_1, \dots, \lambda_J) \propto \lambda_1^{a_1-1} e^{-b_1 \lambda_1} \prod_{j=2}^J \left(\frac{b_j}{\lambda_{j-1}} \right)^{a_j} \lambda_j^{a_j-1} e^{-\frac{b_j}{\lambda_{j-1}} \lambda_j}$$

Log-Hazard Parameters

Write $\alpha = (\alpha_1, \dots, \alpha_J)' \equiv (\log \lambda_1, \dots, \log \lambda_J)'$.

Uniform Prior The joint prior density is given by

$$p(\alpha_1 \dots \alpha_J) \propto 1, \forall -\infty < \alpha_i < \infty$$

Note that the uniform prior for the log-hazards is the same as the improper prior for the hazards.

Normal Prior Assume α has a multivariate normal prior with mean vector α_0 and covariance matrix Ψ_0 . The joint prior density is given by

$$p(\alpha) \propto e^{-\frac{1}{2}(\alpha - \alpha_0)' \Psi_0^{-1} (\alpha - \alpha_0)}$$

Regression Coefficients

Let $\beta = (\beta_1, \dots, \beta_k)'$ be the vector of regression coefficients.

Uniform Prior The joint prior density is given by

$$p(\beta_1, \dots, \beta_k) \propto 1, \forall -\infty < \beta_i < \infty$$

This prior is improper, but the posterior distributions for β are proper.

Normal Prior Assume β has a multivariate normal prior with mean vector β_0 and covariance matrix Σ_0 . The joint prior density is given by

$$p(\beta) \propto e^{-\frac{1}{2}(\beta - \beta_0)' \Sigma_0^{-1} (\beta - \beta_0)}$$

Joint Multivariate Normal Prior for Log-Hazards and Regression Coefficients Assume $(\alpha', \beta')'$ has a multivariate normal prior with mean vector $(\alpha'_0, \beta'_0)'$ and covariance matrix Φ_0 . The joint prior density is given by

$$p(\alpha, \beta) \propto e^{-\frac{1}{2}[(\alpha - \alpha_0)', (\beta - \beta_0)'] \Phi_0^{-1} [(\alpha - \alpha_0)', (\beta - \beta_0)']}$$

Zellner's g-Prior Assume β has a multivariate normal prior with mean vector $\mathbf{0}$ and covariance matrix $(g\mathbf{X}'\mathbf{X})^{-1}$, where \mathbf{X} is the design matrix and g is either a constant or it follows a gamma prior with density $f(\tau) = \frac{b(b\tau)^{a-1}e^{-b\tau}}{\Gamma(a)}$ where a and b are the SHAPE= and ISCALE= parameters. Let k be the rank of \mathbf{X} . The joint prior density with g being a constant c is given by

$$p(\beta) \propto c^{\frac{k}{2}} e^{-\frac{1}{2}\beta'(c\mathbf{X}'\mathbf{X})^{-1}\beta}$$

The joint prior density with g having a gamma prior is given by

$$p(\beta, \tau) \propto \tau^{\frac{k}{2}} e^{-\frac{1}{2}\beta'(\tau\mathbf{X}'\mathbf{X})^{-1}\beta} \frac{b(b\tau)^{a-1}e^{-b\tau}}{\Gamma(a)}$$

Dispersion Parameter for Frailty Model**Improper Prior** The density is

$$p(\theta) = \frac{1}{\theta}$$

Inverse Gamma Prior The inverse gamma distribution $IG(a, b)$ has a density

$$p(\theta|a, b) = \frac{b^a \theta^{-(a+1)} e^{-\frac{b}{\theta}}}{\Gamma(a)}$$

where a and b are the SHAPE= and SCALE= parameters.**Gamma Prior** The gamma distribution $G(a, b)$ has a density

$$p(\theta|a, b) = \frac{b^a \theta^{a-1} e^{-b\theta}}{\Gamma(a)}$$

where a and b are the SHAPE= and ISCALE= parameters.**Posterior Distribution**Denote the observed data by D .**Cox Model**

$$\pi(\boldsymbol{\beta}|D) \propto \underbrace{L(D|\boldsymbol{\beta})}_{\text{partial likelihood}} \underbrace{p(\boldsymbol{\beta})}_{\text{prior}}$$

Frailty Model

Based on the framework of Sargent (1998),

$$\pi(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta|D) \propto \underbrace{L(D|\boldsymbol{\beta}, \boldsymbol{\gamma})}_{\text{partial likelihood}} \underbrace{\overbrace{g(\boldsymbol{\gamma}|\theta)}^{\text{random effects}}}_{\text{priors}} \underbrace{p(\boldsymbol{\beta})p(\theta)}_{\text{priors}}$$

where the joint density of the random effects $\boldsymbol{\gamma} = (\gamma_1, \dots, \gamma_s)'$ is given by

$$g(\boldsymbol{\gamma}|\theta) \propto \begin{cases} \prod_i \exp\left(\frac{\gamma_i}{\theta}\right) \exp\left(-\exp\left(\frac{\gamma_i}{\theta}\right)\right) & \text{gamma frailty} \\ \prod_i \exp\left(-\frac{\gamma_i^2}{2\theta}\right) & \text{lognormal frailty} \end{cases}$$

Piecewise Exponential Model Hazard Parameters

$$\pi(\lambda, \beta | D) \propto L_H(D | \lambda, \beta) p(\lambda) p(\beta)$$

where $L_H(D | \lambda, \beta)$ is the likelihood function with hazards λ and regression coefficients β as parameters.

Log-Hazard Parameters

$$\pi(\alpha, \beta | D) \propto \begin{cases} L_{LH}(D | \alpha, \beta) p(\alpha, \beta) & \text{if } (\alpha', \beta')' \sim \text{MVN} \\ L_{LH}(D | \alpha, \beta) p(\alpha) p(\beta) & \text{otherwise} \end{cases}$$

where $L_{LH}(D | \alpha, \beta)$ is the likelihood function with log-hazards α and regression coefficients β as parameters.

Sampling from the Posterior Distribution

For the Gibbs sampler, PROC PHREG uses the ARMS (adaptive rejection Metropolis sampling) algorithm of Gilks, Best, and Tan (1995) to sample from the full conditionals. This is the default sampling scheme. Alternatively, you can request the random walk Metropolis (RWM) algorithm to sample an entire parameter vector from the posterior distribution. For a general discussion of these algorithms, see section “[Markov Chain Monte Carlo Method](#)” on page 133.

You can output these posterior samples into a SAS data set by using the OUTPOST= option in the BAYES statement, or you can use the following SAS statement to output the posterior samples into the SAS data set Post:

```
ods output PosteriorSample=Post;
```

The output data set also includes the variables LogLike and LogPost, which represent the log of the likelihood and the log of the posterior log density, respectively.

Let $\theta = (\theta_1, \dots, \theta_k)'$ be the parameter vector. For the Cox model, the θ_i 's are the regression coefficients β_i 's, and for the piecewise constant baseline hazard model, the θ_i 's consist of the baseline hazards λ_i 's (or log baseline hazards α_i 's) and the regression coefficients β_j 's. Let $L(D | \theta)$ be the likelihood function, where D is the observed data. Note that for the Cox model, the likelihood contains the infinite-dimensional baseline hazard function, and the gamma process is perhaps the most commonly used prior process (Ibrahim, Chen, and Sinha 2001). However, Sinha, Ibrahim, and Chen (2003) justify using the partial likelihood as the likelihood function for the Bayesian analysis. Let $p(\theta)$ be the prior distribution. The posterior $f\pi(\theta | D)$ is proportional to the joint distribution $L(D | \theta)p(\theta)$.

Gibbs Sampler

The full conditional distribution of θ_i is proportional to the joint distribution; that is,

$$\pi(\theta_i | \theta_j, i \neq j, D) \propto L(D | \theta) p(\theta)$$

For example, the one-dimensional conditional distribution of θ_1 , given $\theta_j = \theta_j^*, 2 \leq j \leq k$, is computed as

$$\pi(\theta_1 | \theta_j = \theta_j^*, 2 \leq j \leq k, D) = L(D | \theta = (\theta_1, \theta_2^*, \dots, \theta_k^*)') p(\theta = (\theta_1, \theta_2^*, \dots, \theta_k^*)')$$

Suppose you have a set of arbitrary starting values $\{\theta_1^{(0)}, \dots, \theta_k^{(0)}\}$. Using the ARMS algorithm, an iteration of the Gibbs sampler consists of the following:

- draw $\theta_1^{(1)}$ from $\pi(\theta_1|\theta_2^{(0)}, \dots, \theta_k^{(0)}, D)$
- draw $\theta_2^{(1)}$ from $\pi(\theta_2|\theta_1^{(1)}, \theta_3^{(0)}, \dots, \theta_k^{(0)}, D)$
- \vdots
- draw $\theta_k^{(1)}$ from $\pi(\theta_k|\theta_1^{(1)}, \dots, \theta_{k-1}^{(1)}, D)$

After one iteration, you have $\{\theta_1^{(1)}, \dots, \theta_k^{(1)}\}$. After n iterations, you have $\{\theta_1^{(n)}, \dots, \theta_k^{(n)}\}$. Cumulatively, a chain of n samples is obtained.

Random Walk Metropolis Algorithm

PROC PHREG uses a multivariate normal proposal distribution $q(.|\theta)$ centered at θ . With an initial parameter vector $\theta^{(0)}$, a new sample $\theta^{(1)}$ is obtained as follows:

- sample θ^* from $q(.|\theta^{(0)})$
- calculate the quantity $r = \min \left\{ \frac{\pi(\theta^*|D)}{\pi(\theta^{(0)}|D)}, 1 \right\}$
- sample u from the uniform distribution $U(0, 1)$
- set $\theta^{(1)} = \theta^*$ if $u < r$; otherwise set $\theta^{(1)} = \theta^{(0)}$

With $\theta^{(1)}$ taking the role of $\theta^{(0)}$, the previous steps are repeated to generate the next sample $\theta^{(2)}$. After n iterations, a chain of n samples $\{\theta^{(1)}, \dots, \theta^{(n)}\}$ is obtained.

Starting Values of the Markov Chains

When the BAYES statement is specified, PROC PHREG generates one Markov chain that contains the approximate posterior samples of the model parameters. Additional chains are produced when the Gelman-Rubin diagnostics are requested. Starting values (initial values) can be specified in the INITIAL= data set in the BAYES statement. If the INITIAL= option is not specified, PROC PHREG picks its own initial values for the chains based on the maximum likelihood estimates of θ and the prior information of θ .

Denote $[x]$ as the integral value of x .

Constant Baseline Hazards λ_i 's

For the first chain that the summary statistics and diagnostics are based on, the initial values are

$$\lambda_i^{(0)} = \hat{\lambda}_i$$

For subsequent chains, the starting values are picked in two different ways according to the total number of chains specified. If the total number of chains specified is less than or equal to 10, initial values of the r th chain ($2 \leq r \leq 10$) are given by

$$\lambda_i^{(0)} = \hat{\lambda}_i e^{\pm \left(\left[\frac{r}{2} \right] + 2 \right) \hat{s}(\hat{\lambda}_i)}$$

with the plus sign for odd r and minus sign for even r . If the total number of chains is greater than 10, initial values are picked at random over a wide range of values. Let u_i be a uniform random number between 0 and 1; the initial value for λ_i is given by

$$\lambda_i^{(0)} = \hat{\lambda}_i e^{16(u_i - 0.5)\hat{s}(\hat{\lambda}_i)}$$

Regression Coefficients and Log-Hazard Parameters θ_i 's

The θ_i 's are the regression coefficients β_i 's, and in the piecewise exponential model, include the log-hazard parameters α_i 's. For the first chain that the summary statistics and regression diagnostics are based on, the initial values are

$$\theta_i^{(0)} = \hat{\theta}_i$$

If the number of chains requested is less than or equal to 10, initial values for the r th chain ($2 \leq r \leq 10$) are given by

$$\theta_i^{(0)} = \hat{\theta}_i \pm \left(2 + \left\lceil \frac{r}{2} \right\rceil\right) \hat{s}(\hat{\theta}_i)$$

with the plus sign for odd r and minus sign for even r . When there are more than 10 chains, the initial value for the θ_i is picked at random over the range $(\hat{\theta}_i - 8\hat{s}(\hat{\theta}_i), \hat{\theta}_i + 8\hat{s}(\hat{\theta}_i))$; that is,

$$\theta_i^{(0)} = \hat{\theta}_i + 16(u_i - 0.5)\hat{s}(\hat{\theta}_i)$$

where u_i is a uniform random number between 0 and 1.

Fit Statistics

Denote the observed data by D . Let θ be the vector of parameters of length k . Let $L(D|\theta)$ be the likelihood. The deviance information criterion (DIC) proposed in Spiegelhalter et al. (2002) is a Bayesian model assessment tool. Let $\text{Dev}(\theta) = -2 \log L(D|\theta)$. Let $\overline{\text{Dev}(\theta)}$ and $\bar{\theta}$ be the corresponding posterior means of $\text{Dev}(\theta)$ and θ , respectively. The deviance information criterion is computed as

$$\text{DIC} = 2\overline{\text{Dev}(\theta)} - \text{Dev}(\bar{\theta})$$

Also computed is

$$pD = \overline{\text{Dev}(\theta)} - \text{Dev}(\bar{\theta})$$

where pD is interpreted as the effective number of parameters.

Note that $\text{Dev}(\theta)$ defined here does not have the standardizing term as in the section “[Deviance Information Criterion \(DIC\)](#)” on page 155. Nevertheless, the DIC calculated here is still useful for variable selection.

Posterior Distribution for Quantities of Interest

Let $\theta = (\theta_1, \dots, \theta_k)'$ be the parameter vector. For the Cox model, the θ_i 's are the regression coefficients β_i 's; for the piecewise constant baseline hazard model, the θ_i 's consist of the baseline hazards λ_i 's (or log baseline hazards α_i 's) and the regression coefficients β_j 's. Let $\mathcal{S} = \{\theta^{(r)}, r = 1, \dots, N\}$ be the chain that represents the posterior distribution for θ .

Consider a quantity of interest τ that can be expressed as a function $f(\theta)$ of the parameter vector θ . You can construct the posterior distribution of τ by evaluating the function $f(\theta^{(r)})$ for each $\theta^{(r)}$ in \mathcal{S} . The posterior chain for τ is $\{f(\theta^{(r)}), r = 1, \dots, N\}$. Summary statistics such as mean, standard deviation, percentiles, and credible intervals are used to describe the posterior distribution of τ .

Hazard Ratio

As shown in the section “**Hazard Ratios**” on page 5619, a log-hazard ratio is a linear combination of the regression coefficients. Let \mathbf{h} be the vector of linear coefficients. The posterior sample for this hazard ratio is the set $\{\exp(\mathbf{h}'\boldsymbol{\beta}^{(r)}), r = 1, \dots, N\}$.

Survival Distribution

Let \mathbf{x} be a covariate vector of interest.

Cox Model Let $\{(t_i, \mathbf{z}_i, \delta_i), i = 1, 2, \dots, n\}$ be the observed data. Define

$$Y_i(t) = \begin{cases} 1 & t < t_i \\ 0 & \text{otherwise} \end{cases}$$

Consider the r th draw $\boldsymbol{\beta}^{(r)}$ of \mathcal{S} . The baseline cumulative hazard function at time t is given by

$$H_0(t|\boldsymbol{\beta}^{(r)}) = \sum_{i:t_i \leq t} \frac{\delta_i}{\sum_{l=1}^n Y_l(t_i) \exp(\mathbf{z}_l' \boldsymbol{\beta}^{(r)})}$$

For the given covariate vector \mathbf{x} , the cumulative hazard function at time t is

$$H(t; \mathbf{x}|\boldsymbol{\beta}^{(r)}) = H_0(t|\boldsymbol{\beta}^{(r)}) \exp(\mathbf{x}' \boldsymbol{\beta}^{(r)})$$

and the survival function at time t is

$$S(t; \mathbf{x}|\boldsymbol{\beta}^{(r)}) = \exp[-H(t; \mathbf{x}|\boldsymbol{\beta}^{(r)})]$$

Piecewise Exponential Model Let $0 = a_0 < a_1 < \dots < a_J < \infty$ be a partition of the time axis. Consider the r th draw $\boldsymbol{\theta}^{(r)}$ in \mathcal{S} , where $\boldsymbol{\theta}^{(r)}$ consists of $\boldsymbol{\lambda}^{(r)} = (\lambda_1^{(r)}, \dots, \lambda_J^{(r)})'$ and $\boldsymbol{\beta}^{(r)}$. The baseline cumulative hazard function at time t is

$$H_0(t|\boldsymbol{\lambda}^{(r)}) = \sum_{j=1}^J \lambda_j^{(r)} \Delta_j(t)$$

where

$$\Delta_j(t) = \begin{cases} 0 & t < a_{j-1} \\ t - a_{j-1} & a_{j-1} \leq t < a_j \\ a_j - a_{j-1} & t \geq a_j \end{cases}$$

For the given covariate vector \mathbf{x} , the cumulative hazard function at time t is

$$H(t; \mathbf{x}|\boldsymbol{\lambda}^{(r)}, \boldsymbol{\beta}^{(r)}) = H_0(t|\boldsymbol{\lambda}^{(r)}) \exp(\mathbf{x}' \boldsymbol{\beta}^{(r)})$$

and the survival function at time t is

$$S(t; \mathbf{x}|\boldsymbol{\lambda}^{(r)}, \boldsymbol{\beta}^{(r)}) = \exp[-H(t; \mathbf{x}|\boldsymbol{\lambda}^{(r)}, \boldsymbol{\beta}^{(r)})]$$

Computational Resources

Let n be the number of observations in a BY group. Let p be the number of explanatory variables. The minimum working space (in bytes) needed to process the BY group is

$$\max\{12n, 24p^2 + 160p\}$$

Extra memory is needed for certain TIES= options. Let k be the maximum multiplicity of tied times. The TIES=DISCRETE option requires extra memory (in bytes) of

$$4k(p^2 + 4p)$$

The TIES=EXACT option requires extra memory (in bytes) of

$$24(k^2 + 5k)$$

If sufficient space is available, the input data are also kept in memory. Otherwise, the input data are reread from the utility file for each evaluation of the likelihood function and its derivatives, with the resulting execution time substantially increased.

Input and Output Data Sets

OUTEST= Output Data Set

The **OUTEST=** data set contains one observation for each BY group containing the maximum likelihood estimates of the regression coefficients. If you also use the **COVOUT** option in the PROC PHREG statement, there are additional observations containing the rows of the estimated covariance matrix. If you specify **SELECTION=FORWARD**, **BACKWARD**, or **STEPWISE**, only the estimates of the parameters and covariance matrix for the final model are output to the **OUTEST=** data set.

Variables in the OUTEST= Data Set

The **OUTEST=** data set contains the following variables:

- any BY variables specified
- **_TIES_**, a character variable of length 8 with four possible values: BRESLOW, DISCRETE, EFRON, and EXACT. These are the four values of the **TIES=** option in the MODEL statement.
- **_TYPE_**, a character variable of length 8 with two possible values: PARMS for parameter estimates or COV for covariance estimates. If both the **COVM** and **COVS** options are specified in the PROC PHREG statement along with the **COVOUT** option, **_TYPE_='COVM'** for the model-based covariance estimates and **_TYPE_='COVS'** for the robust sandwich covariance estimates.
- **_STATUS_**, a character variable indicating whether the estimates have converged
- **_NAME_**, a character variable containing the name of the TIME variable for the row of parameter estimates and the name of each explanatory variable to label the rows of covariance estimates

- one variable for each regression coefficient and one variable for the offset variable if the **OFFSET=** option is specified. If an explanatory variable is not included in the final model in a variable selection process, the corresponding parameter estimates and covariances are set to missing.
- **_LNLIKE_**, a numeric variable containing the last computed value of the log likelihood

Parameter Names in the **OUTEST=** Data Set

For continuous explanatory variables, the names of the parameters are the same as the corresponding variables. For CLASS variables, the parameter names are obtained by concatenating the corresponding CLASS variable name with the CLASS category; see the **PARAM=** option in the **CLASS** statement for more details. For interaction and nested effects, the parameter names are created by concatenating the names of each component effect.

INEST= Input Data Set

You can specify starting values for the maximum likelihood iterative algorithm in the **INEST=** data set. The **INEST=** data set has the same structure as the **OUTEST=** data set but is not required to have all the variables or observations that appear in the **OUTEST=** data set.

The **INEST=** data set must contain variables that represent the regression coefficients of the model. If BY processing is used, the **INEST=** data set should also include the BY variables, and there must be one observation for each BY group. If the **INEST=** data set also contains the **_TYPE_** variable, only observations with **_TYPE_** value 'PARMS' are used as starting values.

OUT= Output Data Set in the **OUTPUT** Statement

The **OUT=** data set in the **OUTPUT** statement contains all the variables in the input data set, along with statistics you request by specifying *keyword=name* options. The new variables contain a variety of diagnostics that are calculated for each observation in the input data set.

OUT= Output Data Set in the **BASELINE** Statement

The **OUT=** data set in the **BASELINE** statement contains all the variables in the **COVARIATES=** data set, along with statistics you request by specifying *keyword=name* options. For unstratified input data, there are $1 + n$ observations in the **OUT=** data set for each observation in the **COVARIATES=** data set, where n is the number of distinct event times in the input data. For input data that are stratified into k strata, with n_i distinct events in the i th stratum, $i = 1, \dots, k$, there are $1 + n_i$ observations for the i th stratum in the **OUT=** data set for each observation in the **COVARIATES=** data set.

OUTDIFF= Output Data Set in the **BASELINE** Statement

The **OUTDIFF=** data set contains the differences of the direct adjusted survival probabilities between two treatments or two strata and their standard errors.

OUTPOST= Output Data Set in the **BAYES** Statement

The **OUTPOST=** data set contains the generated posterior samples. There are $3 + n$ variables, where n is the number of model parameters. The variable **Iteration** represents the iteration number, the variable **LogLike** contains the log-likelihood values, and the variable **LogPost** contains the log-posterior-density values. The other n variables represent the draws of the Markov chain for the model parameters.

Displayed Output

If you use the NOPRINT option in the PROC PHREG statement, the procedure does not display any output. Otherwise, PROC PHREG displays results of the analysis in a collection of tables. The tables are listed separately for the maximum likelihood analysis and for the Bayesian analysis.

Maximum Likelihood Analysis Displayed Output

Model Information

The “Model Information” table displays the two-level name of the input data set, the name and label of the failure time variable, the name and label of the censoring variable and the values indicating censored times, the model (either the Cox model or the piecewise constant baseline hazard model), the name and label of the OFFSET variable, the name and label of the FREQ variable, the name and label of the WEIGHT variable, and the method of handling ties in the failure time for the Cox model. The ODS name of the “Model Information” table is ModelInfo.

Number of Observations

The “Number of Observations” table displays the number of observations read and used in the analysis. The ODS name of the “Number of Observations” is NObs.

Class Level Information

The “Class Level Information” table is displayed when there are CLASS variables in the model. The table lists the categories of every CLASS variable that is used in the model and the corresponding design variable values. The ODS name of the “Class Level Information” table is ClassLevelInfo.

Class Level Information for Random Effects

The “Class Level Information for Random Effects” table is displayed when the RANDOM statement is specified. The table lists the categories of the classification variable specified in the RANDOM statement. The ODS name of the “Class Level Information for Random Effects” table is ClassLevelInfoR.

Summary of the Number of Event and Censored Values

The “Summary of the Number of Event and Censored Values” table displays, for each stratum, the breakdown of the number of events and censored values. The ODS name of the “Summary of the Number of Event and Censored Values” table is CensoredSummary.

Risk Sets Information

The “Risk Sets Information” table is displayed if you specify the ATRISK option in the PROC PHREG statement. The table displays, for each event time, the number of units at-risk and the number of units that experience the event. The ODS name of the “Risk Sets Information” table is RiskSetInfo.

Descriptive Statistics for Continuous Explanatory Variables

The “Simple Statistics for Continuous Explanatory Variables” table is displayed when you specify the SIMPLE option in the PROC PHREG statement. The table contains, for each stratum, the mean, standard deviation, and minimum and maximum for each continuous explanatory variable in the MODEL statement. For ODS purposes, the name of the “Descriptive Statistics for Continuous Explanatory Variables” table is “SimpleStatistics.”

Frequency Distribution of CLASS Variables

The “Frequency Distribution of CLASS Variables” table is displayed if you specify the SIMPLE option in the PROC PHREG statement and there are CLASS variables in the model. The table lists the frequency of the levels of the CLASS variables. The ODS name of the “Frequency Distribution of CLASS Variables” table is ClassLevelFreq.

Maximum Likelihood Iteration History

The “Maximum Likelihood Iteration History” table is displayed if you specify the ITPRINT option in the MODEL statement. The table contains the iteration number, ridge value or step size, log likelihood, and parameter estimates at each iteration. The ODS name of the “Maximum Likelihood Iteration History” table is IterHistory.

Gradient of Last Iteration

The “Gradient of Last Iteration” table is displayed if you specify the ITPRINT option in the MODEL statement. The ODS name of the “Gradient of Last Iteration” table is LastGradient.

Convergence Status

The “Convergence Status” table displays the convergence status of the Newton-Raphson maximization. The ODS name of the “Convergence Status” table is ConvergenceStatus.

Model Fit Statistics

The “Model Fit Statistics” table displays the values of -2 log likelihood for the null model and the fitted model, the AIC, and SBC. The ODS name of the “Model Fit Statistics” table is FitStatistics.

Covariance Parameter Estimates

The “Covariance Parameter Estimates” table displays the estimate of the variance parameter of the random effect and the standard error estimate of the variance parameter estimator. The ODS name of the “Covariance Parameter Estimates” table is CovParms.

Testing Global Null Hypothesis: BETA=0

The “Testing Global Null Hypothesis: BETA=0” table displays results of the likelihood ratio test, the score test, and the Wald test for testing the hypothesis that all parameters are zero. For the frailty model, the score test is not displayed and an adjusted degrees of freedom is used (see the section “[Wald-Type Tests for Penalized Models](#)” on page 5653 for more information.) For ODS purpose, the name of the “Testing Global Null Hypothesis: BETA=0” table is “GlobalTests.”

Likelihood Ratio Statistics for Type 1 Analysis

The “Likelihood Ratio Statistics for Type 1 Analysis” table is displayed if the TYPE1 option is specified in the MODEL statement. The table displays the degrees of freedom, the likelihood ratio chi-square statistic, and the p -value for each effect in the model. The ODS name of “Likelihood Ratio Statistics for Type 1 Analysis” is Type1.

Type 3 Tests

The “Type 3 Tests” table is displayed if the model contains a CLASS variable or if the TYPE3 option is specified in the MODEL statement. The table displays, for each specified statistic, the Type 3 chi-square, the degrees of freedom, and the p -value for each effect in the model. For the frailty model, the table also

displays the adjusted Wald-type test results (see the section “Wald-Type Tests for Penalized Models” on page 5653 for details.) The ODS name of “Type 3 Tests” is Type3.

Analysis of Maximum Likelihood Estimates

The “Analysis of Maximum Likelihood Estimates” table displays the maximum likelihood estimate of the parameter; the estimated standard error, computed as the square root of the corresponding diagonal element of the estimated covariance matrix; the ratio of the robust standard error estimate to the model-based standard error estimate if you specify the COVS option in the PROC PHREG statement; the Wald Chi-Square statistic, computed as the square of the parameter estimate divided by its standard error estimate; the degrees of freedom of the Wald chi-square statistic, which has a value of 1 unless the corresponding parameter is redundant or infinite, in which case the value is 0; the p -value of the Wald chi-square statistic with respect to a chi-square distribution with one degree of freedom; the hazard ratio estimate; and the confidence limits for the hazard ratio if you specified the RISKLIMITS option in the MODEL statement. The ODS name of the “Analysis of Maximum Likelihood Estimates” table is ParameterEstimates.

Solution for Random Effects

The “Solution for Random Effects” table displays the BLUP estimates of the random effects, the estimated standard errors, the confidence intervals for the random effects, the exponentiated values of the BLUP estimates, and confidence intervals for the exponentiated random effects. The ODS name of the “Solution for Random Effects” table is SolutionR.

Regression Models Selected by Score Criterion

The “Regression Models Selected by Score Criterion” table is displayed if you specify SELECTION=SCORE in the MODEL statement. The table contains the number of explanatory variables in each model, the score chi-square statistic, and the names of the variables included in the model. The ODS name of the “Regression Models Selected by Score Criterion” table is BestSubsets.

Analysis of Effects Eligible for Entry

The “Analysis of Effects Eligible for Entry” table is displayed if you use the FORWARD or STEPWISE selection method and you specify the DETAILS option in the MODEL statement. The table contains the score chi-square statistic for testing the significance of each variable not in the model (after adjusting for the variables already in the model), and the p -value of the chi-square statistic with respect to a chi-square distribution with one degree of freedom. This table is produced before a variable is selected for entry in a forward selection step. The ODS name of the “Analysis of Effects Eligible for Entry” table is EffectsToEntry.

Analysis of Effects Eligible for Removal

The “Analysis of Effects Eligible for Removal” table is displayed if you use the BACKWARD or STEPWISE selection method and you specify the DETAILS option in the MODEL statement. The table contains the Wald chi-square statistic for testing the significance of each candidate effect for removal, the degrees of freedom of the Wald chi-square, and the corresponding p -value. This table is produced before an effect is selected for removal. The ODS name of the “Analysis of Effects Eligible for Removal” table is EffectsToRemoval.

Summary of Backward Elimination

The “Summary of Backward Elimination” table is displayed if you specify the SELECTION=BACKWARD option in the MODEL statement. The table contains the step number, the effects removed at each step, the

corresponding chi-square statistic, the degrees of freedom, and the p -value. For ODS purpose, the name of the “Summary of Backward Elimination” table is “ModelBuildingSummary.”

Summary of Forward Selection

The “Summary of Forward Selection” table is displayed if you specify the SELECTION=FORWARD option in the MODEL statement. The table contains the step number, the effects entered at each step, the corresponding chi-square statistic, the degrees of freedom, and the p -value. For ODS purpose, the name of the “Summary of Forward Selection” table is “ModelBuildingSummary.”

Summary of Stepwise Selection

The “Summary of Stepwise Selection” table is displayed if you specify SELECTION=STEPWISE is specified in the MODEL statement. The table contains the step number, the effects entered or removed at each step, the corresponding chi-square statistic, the degrees of freedom, and the corresponding p -value. For ODS purpose, the name of the “Summary of Stepwise Selection” table is “ModelBuildingSummary.”

Covariance Matrix

The “Covariance Matrix” table is displayed if you specify the COVB option in the MODEL statement. The table contains the estimated covariance matrix for the parameter estimates. For ODS purposes, the name of the “Covariance Matrix” table is “CovB.”

Correlation Matrix

The “Correlation Matrix” table is displayed if you specify the COVB option in the MODEL statement. The table contains the estimated correlation matrix for the parameter estimates. For ODS purposes, the name of the “Correlation Matrix” table is “CorrB.”

Hazard Ratios for *label*

The “Hazard Ratios for *label*” table is displayed if you specify the HAZARDRATIO statement. The table displays the estimate and confidence limits for each hazard ratio. The ODS name of the “Hazard Ratios for *label*” table is HazardRatios.

Coefficients of Contrast *label*

The “Coefficients of Contrast *label*” table is displayed if you specify the E option in the CONTRAST statement. The table displays the parameter names and the corresponding coefficients of each row of contrast *label*. The ODS name of the “Coefficients of Contrast *label*” table is ContrastCoeff.

Contrast Test Results

The “Contrast Test Results” table is displayed if you specify the CONTRAST statement. The table displays the degrees of freedom, test statistics, and the p -values for testing each contrast. The ODS name of the “Contrast Test Results” table is ContrastTest.

Contrast Estimation and Testing Results by Row

The “Contrast Estimation and Testing Results by Row” table is displayed if you specify the ESTIMATE option in the CONTRAST statement. The table displays, for each row, the estimate of the linear function of the coefficients, its standard error, and the confidence limits for the linear function. The ODS name of the “Contrast Estimation and Testing Results by Row” table is ContrastEstimate.

Linear Coefficients for *label*

The “Linear Coefficients *label*” table is displayed if you specify the E option in the TEST statement with *label* being the TEST statement label. The table contains the coefficients and constants of the linear hypothesis. For ODS purposes, the name of the “Linear Coefficients for *label*” table is “TestCoeff.”

L[cov(b)]L' and Lb-c

The “L[cov(b)]L' and Lb-c” table is displayed if you specified the PRINT option in a TEST statement with *label* being the TEST statement label. The table displays the intermediate calculations of the Wald test. The ODS name of the “L[cov(b)]L' and Lb-c” table is TestPrint1.

Ginv(L[cov(b)]L') and Ginv(L[cov(b)]L')(Lb-c)

The “Ginv(L[cov(b)]L') and Ginv(L[cov(b)]L')(Lb-c)” table is displayed if you specified the PRINT option in a TEST statement with *label* being the TEST statement label. The table displays the intermediate calculations of the Wald test. The ODS name of the “Ginv(L[cov(b)]L') and Ginv(L[cov(b)]L')(Lb-c)” table is TestPrint2.

***label* Test Results**

The “*label* Test Results” table is displayed if you specify a TEST statement with *label* being the TEST statement label. The table contains the Wald chi-square statistic, the degrees of freedom, and the *p*-value. The ODS name of “*label* Test Results” table is TestStmts.

Average Effect for *label*

The “Average Effect for *label*” table is displayed if the AVERAGE option is specified in a TEST statement with *label* being the TEST statement label. The table contains the weighted average of the parameter estimates for the variables in the TEST statement, the estimated standard error, the z-score, and the *p*-value. The ODS name of the “Average Effect for *label*” is TestAverage.

Reference Set of Covariates for Plotting

The “Reference Set of Covariates for Plotting” table is displayed if the PLOTS= option is requested without specifying the COVARIATES= data set in the BASELINE statement. The tables contains the values of the covariates for the reference set, where the reference levels are used for the CLASS variables and the sample averages for the continuous variables.

Bayesian Analysis Displayed Output**Model Information**

The “Model Information” table displays the two-level name of the input data set, the name and label of the failure time variable, the name and label of the censoring variable and the values indicating censored times, the model (either the Cox model or the piecewise constant baseline hazard model), the name and label of the OFFSET variable, the name and label of the FREQ variable, the name and label of the WEIGHT variable, the method of handling ties in the failure time, the number of burn-in iterations, the number of iterations after the burn-in, and the number of thinning iterations. The ODS name of the “Model Information” table is ModelInfo.

Number of Observations

The “Number of Observations” table displays the number of observations read and used in the analysis. The ODS name of the “Number of Observations” is NObs.

Summary of the Number of Event and Censored Values

The “Summary of the Number of Event and Censored Values” table displays, for each stratum, the breakdown of the number of events and censored values. This table is not produced if the NONSUMMARY option is specified in the PROC PHREG statement. The ODS name of the “Summary of the Number of Event and Censored Values” table is CensoredSummary.

Descriptive Statistics for Continuous Explanatory Variables

The “Simple Statistics for Continuous Explanatory Variables” table is displayed when you specify the SIMPLE option in the PROC PHREG statement. The table contains, for each stratum, the mean, standard deviation, and minimum and maximum for each continuous explanatory variable in the MODEL statement. For ODS purposes, the name of the “Descriptive Statistics for Continuous Explanatory Variables” table is “SimpleStatistics.”

Class Level Information

The “Class Level Information” table is displayed if there are CLASS variables in the model. The table lists the categories of every CLASS variable in the model and the corresponding design variable values. The ODS name of the “Class Level Information” table is ClassLevelInfo.

Frequency Distribution of CLASS Variables

The “Frequency Distribution of CLASS Variables” table is displayed if you specify the SIMPLE option in the PROC PHREG statement and there are CLASS variables in the model. The table lists the frequency of the levels of the CLASS variables. The ODS name of the “Frequency Distribution of CLASS Variables” table is ClassLevelFreq.

Regression Parameter Information

The “Regression Parameter Information” table displays the names of the parameters and the corresponding level information of effects containing the CLASS variables. The ODS name of the “Regression Parameter Information” table is ParmInfo.

Constant Baseline Hazard Time Intervals

The “Constant Baseline Hazard Time Intervals” table displays the intervals of constant baseline hazard and the corresponding numbers of failure times and event times. This table is produced only if you specify the PIECEWISE option in the BAYES statement. The ODS name of the “Constant Baseline Hazard Time Intervals” table is Interval.

Maximum Likelihood Estimates

The “Maximum Likelihood Estimates” table displays, for each parameter, the maximum likelihood estimate, the estimated standard error, and the 95% confidence limits. The ODS name of the “Maximum Likelihood Estimates” table is ParameterEstimates.

Hazard Prior

The “Hazard Prior” table is displayed if you specify the PIECEWISE=HAZARD option in the BAYES statement. It describes the prior distribution of the hazard parameters. The ODS name of the “Hazard Prior” table is HazardPrior.

Log-Hazard Prior

The “Log-Hazard Prior” table is displayed if you specify the `PIECEWISE=LOGHAZARD` option in the `BAYES` statement. It describes the prior distribution of the log-hazard parameters. The ODS name of the “Log-Hazard Prior” table is `HazardPrior`.

Coefficient Prior

The “Coefficient Prior” table displays the prior distribution of the regression coefficients. The ODS name of the “Coefficient Prior” table is `CoeffPrior`.

Initial Values

The “Initial Values” table is displayed if you specify the `INITIAL` option in the `BAYES` statement. The table contains the initial values of the parameters for the Gibbs sampling. The ODS name of the “Initial Values” table is `InitialValues`.

Fit Statistics

The “Fit Statistics” table displays the DIC and pD statistics for each parameter. The ODS name of the “Fit Statistics” table is `FitStatistics`.

Posterior Summaries

The “Posterior Summaries” table displays the size of the posterior sample, the mean, the standard error, and the percentiles for each model parameter. The ODS name of the “Posterior Summaries” table is `PostSummaries`.

Posterior Intervals

The “Posterior Intervals” table displays the equal-tail interval and the HPD interval for each model parameter. The ODS name of the “Posterior Intervals” table is `PostIntervals`.

Posterior Covariance Matrix

The “Posterior Covariance Matrix” table is produced if you include `COV` in the `SUMMARY=` option in the `BAYES` statement. This table displays the sample covariance of the posterior samples. The ODS name of the “Posterior Covariance Matrix” table is `Cov`.

Posterior Correlation Matrix

The “Posterior Correlation Matrix” table is displayed if you include `CORR` in the `SUMMARY=` option in the `BAYES` statement. The table contains the sample correlation of the posterior samples. The ODS name of the “Posterior Correlation Matrix” table is `Corr`.

Posterior Autocorrelations

The “Posterior Autocorrelations” table displays the lag 1, lag 5, lag 10, and lag 50 autocorrelations for each parameter. The ODS name of the “Posterior Autocorrelations” table is `AutoCorr`.

Gelman-Rubin Diagnostics

The “Gelman-Rubin Diagnostics” table is produced if you include `GELMAN` in the `DIAGNOSTIC=` option in the `BAYES` statement. This table displays the estimate of the potential scale reduction factor and its 97.5% upper confidence limit for each parameter. The ODS name of the “Gelman-Rubin Diagnostics” table is `Gelman`.

Geweke Diagnostics

The “Geweke Diagnostics” table displays the Geweke statistic and its p -value for each parameter. The ODS name of the “Geweke Diagnostics” table is Geweke.

Raftery-Lewis Diagnostics

The “Raftery-Lewis Diagnostics” tables is produced if you include RAFTERY in the DIAGNOSTIC= option in the BAYES statement. This table displays the Raftery and Lewis diagnostics for each variable. For ODS purposes, the name of the “Raftery-Diagnostics” table is “Raftery.”

Heidelberger-Welch Diagnostics

The “Heidelberger-Welch Diagnostics” table is displayed if you include HEIDELBERGER in the DIAGNOSTIC= option in the BAYES statement. This table describes the results of a stationary test and a halfwidth test for each parameter. The ODS name of the “Heidelberger-Welch Diagnostics” table is Heidelberg.

Effective Sample Sizes

The “Effective Sample Sizes” table displays, for each parameter, the effective sample size, the correlation time, and the efficiency. The ODS name of the “Effective Sample Sizes” table is ESS.

Hazard Ratios for label

The “Hazard Ratios for *label*” table is displayed if you specify the HAZARDRATIO statement. The table displays the posterior summary for each hazard ratio. The summary includes the mean, standard error, quartiles, and equal-tailed and HPD intervals. The ODS name of the “Hazard Ratios for *label*” table is HazardRatios.

Reference Set of Covariates for Plotting

The “Reference Set of Covariates for Plotting” table is displayed if the PLOTS= option is requested without specifying the COVARIATES= data set in the BASELINE statement. The table contains the values of the covariates for the reference set, where the reference levels are used for the CLASS variables and the sample averages for the continuous variables.

ODS Table Names

PROC PHREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed separately in [Table 67.13](#) for the maximum likelihood analysis and in [Table 67.14](#) for the Bayesian analysis. For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Each of the EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements creates ODS tables, which are not listed in [Table 67.13](#) and [Table 67.14](#). For information about these tables, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

Table 67.13 ODS Tables for a Maximum Likelihood Analysis Produced by PROC PHREG

ODS Table Name	Description	Statement / Option
BestSubsets	Best subset selection	MODEL / SELECTION=SCORE

Table 67.13 continued

ODS Table Name	Description	Statement / Option
CensoredSummary	Summary of event and censored observations	Default
ClassLevelFreq	Frequency distribution of CLASS variables	CLASS, PROC / SIMPLE
ClassLevelInfo	CLASS variable levels and design variables	CLASS
ClassLevelInfoR	Class levels for random effects	RANDOM
ContrastCoeff	L matrix for contrasts	CONTRAST / E
ContrastEstimate	Individual contrast estimates	CONTRAST / ESTIMATE=
ContrastTest	Wald test for contrasts	CONTRAST
ConvergenceStatus	Convergence status	Default
CorrB	Estimated correlation matrix of parameter estimators	MODEL / CORRB
CovB	Estimated covariance matrix of parameter estimators	MODEL / COVB
CovParms	Variance estimates of the random effects	RANDOM
EffectsToEnter	Analysis of effects for entry	MODEL / SELECTION=FIS
EffectsToRemove	Analysis of effects for removal	MODEL / SELECTION=BIS
FitStatistics	Model fit statistics	Default
FunctionalFormSupTest	Supremum test for functional form	ASSESS / VAR=
GlobalScore	Global chi-square test	MODEL / NOFIT
GlobalTests	Tests of the global null hypothesis	Default
HazardRatios	Hazard ratios and confidence limits	HAZARDRATIO
IterHistory	Iteration history	MODEL / ITPRINT
LastGradient	Last evaluation of gradient	MODEL / ITPRINT
ModelBuildingSummary	Summary of model building	MODEL / SELECTION=BIFIS
ModelInfo	Model information	Default
NObs	Number of observations	Default
ParameterEstimates	Maximum likelihood estimates of model parameters	Default
ProportionalHazardsSupTest	Supremum test for proportional hazards assumption	ASSESS / PH
ResidualChiSq	Residual chi-square	MODEL / SELECTION=FIB
ReferenceSet	Reference set of covariates for plotting	PROC / PLOTS=
RiskSetInfo	Risk set information	PROC / ATRISK
SimpleStatistics	Summary statistics of input continuous explanatory variables	PROC / SIMPLE
SolutionR	Solutions for random effects	RANDOM / SOLUTION
TestAverage	Average effect for test	TEST / AVERAGE
TestCoeff	Coefficients for linear hypotheses	TEST / E
TestPrint1	$L[\text{cov}(\mathbf{b})]L'$ and $L\mathbf{b}-\mathbf{c}$	TEST / PRINT

Table 67.13 *continued*

ODS Table Name	Description	Statement / Option
TestPrint2	$G_{\text{inv}}(\mathbf{L}[\text{cov}(\mathbf{b})]\mathbf{L}')$ and $G_{\text{inv}}(\mathbf{L}[\text{cov}(\mathbf{b})]\mathbf{L}')(\mathbf{Lb}-\mathbf{c})$	TEST / PRINT
TestStmts	Linear hypotheses testing results	TEST
Type1	Type 1 likelihood ratio tests	MODEL / TYPE1
Type3	Type 3 chi-square tests	MODEL / TYPE3 CLASS

Table 67.14 ODS Table for a Bayesian Analysis Produced by PROC PHREG

ODS Table Name	Description	Statement / Option
AutoCorr	Autocorrelations of the posterior samples	BAYES
CensoredSummary	Numbers of the event and censored observations	PROC
ClassLevelFreq	Frequency distribution of CLASS variables	CLASS, PROC / SIMPLE
ClassLevelInfo	CLASS variable levels and design variables	CLASS
CoeffPrior	Prior distribution of the regression coefficients	BAYES
Corr	Posterior correlation matrix	BAYES / SUMMARY=CORR
Cov	Posterior covariance Matrix	BAYES / SUMMARY=COV
ESS	Effective sample sizes	BAYES / DIAGNOSTICS=ESS
FitStatistics	Fit statistics	BAYES
Gelman	Gelman-Rubin convergence diagnostics	BAYES / DIAGNOSTICS=GELMAN
Geweke	Geweke convergence diagnostics	BAYES
HazardPrior	Prior distribution of the baseline hazards	BAYES / PIECEWISE
HazardRatios	Posterior summary statistics for hazard ratios	HAZARDRATIO
Heidelberger	Heidelberger-Welch convergence diagnostics	BAYES / DIAGNOSTICS=HEIDELBERGER
InitialValues	Initial values of the Markov chains	BAYES
ModelInfo	Model information	Default
NObs	Number of observations	Default
MError	Monte Carlo standard errors	BAYES / DIAGNOSTICS=MCERROR
ParameterEstimates	Maximum likelihood estimates of model parameters	Default
ParmInfo	Names of regression coefficients	CLASS,BAYES
Partition	Partition of constant baseline hazard intervals	BAYES / PIECEWISE

Table 67.14 *continued*

ODS Table Name	Description	Statement / Option
PostIntervals	Equal-tail and high probability density intervals of the posterior samples	BAYES
PosteriorSample	Posterior samples	BAYES / (for ODS output data set only)
PostSummaries	Summary statistics of the posterior samples	BAYES
Raftery	Raftery-Lewis convergence diagnostics	BAYES / DIAGNOSTICS=RAFTERY
ReferenceSet	Reference set of covariates for plotting	PROC / PLOTS=
SimpleStatistics	Summary statistics of input continuous explanatory variables	PROC / SIMPLE

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC PHREG generates are listed separately in [Table 67.15](#) for the maximum likelihood analysis and in [Table 67.16](#) for the Bayesian analysis. When the ODS Graphics are in effect in a Bayesian analysis, each of the ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots associated with their analyses. For information of these plots, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

Table 67.15 Graphs for a Maximum Likelihood Analysis Produced by PROC PHREG

ODS Graph Name	Plot Description	Statement / Option
CumhazPlot	Cumulative hazard function plot	PROC / PLOTS=CUMHAZ
CumulativeResiduals	Cumulative martingale residual plot	ASSESS / VAR=
CumResidPanel	Panel plot of cumulative martingale residuals	ASSESS / VAR=, CRPANEL
MCFPlot	Mean cumulative function plot	PROC / PLOTS=MCF
ScoreProcess	Standardized score process plot	ASSESS / PH
SurvivalPlot	Survivor function plot	PROC / PLOTS=SURVIVAL

Table 67.16 Graphs for a Bayesian Analysis Produced by PROC PHREG

TracePlot	Trace plot	BAYES / PLOTS(UNPACK)=TRACE

Examples: PHREG Procedure

This section contains 14 examples of PROC PHREG applications. The first 12 examples use the classical method of maximum likelihood, while the last two examples illustrate the Bayesian methodology.

Example 67.1: Stepwise Regression

Krall, Uthoff, and Harley (1975) analyzed data from a study on multiple myeloma in which researchers treated 65 patients with alkylating agents. Of those patients, 48 died during the study and 17 survived. The following DATA step creates the data set Myeloma. The variable Time represents the survival time in months from diagnosis. The variable VStatus consists of two values, 0 and 1, indicating whether the patient was alive or dead, respectively, at the end of the study. If the value of VStatus is 0, the corresponding value of Time is censored. The variables thought to be related to survival are LogBUN (log(BUN) at diagnosis), HGB (hemoglobin at diagnosis), Platelet (platelets at diagnosis: 0=abnormal, 1=normal), Age (age at diagnosis, in years), LogWBC (log(WBC) at diagnosis), Frac (fractures at diagnosis: 0=none, 1=present), LogPBM (log percentage of plasma cells in bone marrow), Protein (proteinuria at diagnosis), and SCalc (serum calcium at diagnosis). Interest lies in identifying important prognostic factors from these nine explanatory variables.

```

The stepwise selection process consists of a series of alternating forward selection and backward elimination steps. The former adds variables to the model, while the latter removes variables from the model.

The following statements use PROC PHREG to produce a stepwise regression analysis. Stepwise selection is requested by specifying the SELECTION=STEPWISE option in the MODEL statement. The option SLENTRY=0.25 specifies that a variable has to be significant at the 0.25 level before it can be entered into the model, while the option SLSTAY=0.15 specifies that a variable in the model has to be significant at the 0.15 level for it to remain in the model. The DETAILS option requests detailed results for the variable selection process.

```

proc phreg data=Myeloma;
  model Time*VStatus(0)=LogBUN HGB Platelet Age LogWBC
    Frac LogPBM Protein SCalc
    / selection=stepwise slentry=0.25
    slstay=0.15 details;
run;

```

Results of the stepwise regression analysis are displayed in [Output 67.1.1](#) through [Output 67.1.7](#).

Individual score tests are used to determine which of the nine explanatory variables is first selected into the model. In this case, the score test for each variable is the global score test for the model containing that variable as the only explanatory variable. [Output 67.1.1](#) displays the chi-square statistics and the corresponding p -values. The variable LogBUN has the largest chi-square value (8.5164), and it is significant ($p = 0.0035$) at the SLENTY=0.25 level. The variable LogBUN is thus entered into the model.

Output 67.1.1 Individual Score Test Results for All Variables

The PHREG Procedure			
Model Information			
Data Set	WORK.MYELOMA		
Dependent Variable	Time	Survival Time	
Censoring Variable	VStatus	0=Alive 1=Dead	
Censoring Value(s)	0		
Ties Handling	BRESLOW		
Summary of the Number of Event and Censored Values			
Total	Event	Percent Censored	
65	48	26.15	
Analysis of Effects Eligible for Entry			
Effect	DF	Score Chi-Square Pr > ChiSq	
LogBUN	1	8.5164	0.0035
HGB	1	5.0664	0.0244
Platelet	1	3.1816	0.0745
Age	1	0.0183	0.8924

Frac	1	0.9151	0.3388
LogPBM	1	0.5846	0.4445
Protein	1	0.1466	0.7018
SCalc	1	1.1109	0.2919

Output 67.1.1 *continued*

Residual Chi-Square Test		
Chi-Square	DF	Pr > ChiSq
18.4550	9	0.0302

Output 67.1.2 displays the results of the first model. Since the Wald chi-square statistic is significant ($p = 0.0039$) at the SLSTAY=0.15 level, LogBUN stays in the model.

Output 67.1.2 First Model in the Stepwise Selection Process

Step 1. Effect LogBUN is entered. The model contains the following effects:						
LogBUN						
Convergence Status						
Convergence criterion (GCONV=1E-8) satisfied.						
Model Fit Statistics						
Criterion		Without Covariates		With Covariates		
-2 LOG L		309.716		301.959		
AIC		309.716		303.959		
SBC		309.716		305.830		
Testing Global Null Hypothesis: BETA=0						
Test		Chi-Square	DF	Pr > ChiSq		
Likelihood Ratio		7.7572	1	0.0053		
Score		8.5164	1	0.0035		
Wald		8.3392	1	0.0039		
Analysis of Maximum Likelihood Estimates						
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
LogBUN	1	1.74595	0.60460	8.3392	0.0039	5.731

The next step consists of selecting another variable to add to the model. **Output 67.1.3** displays the chi-square statistics and p -values of individual score tests (adjusted for LogBUN) for the remaining eight variables. The score chi-square for a given variable is the value of the likelihood score test for testing the

significance of the variable in the presence of LogBUN. The variable HGB is selected because it has the highest chi-square value (4.3468), and it is significant ($p = 0.0371$) at the SLENTY=0.25 level.

Output 67.1.3 Score Tests Adjusted for the Variable LogBUN

Analysis of Effects Eligible for Entry			
Effect	DF	Score	
		Chi-Square	Pr > ChiSq
HGB	1	4.3468	0.0371

LogPBM	1	1.0334	0.3094
Protein	1	0.5214	0.4703
SCalc	1	1.4150	0.2342

Residual Chi-Square Test		
Chi-Square	DF	Pr > ChiSq
9.3164	8	0.3163

Output 67.1.4 displays the fitted model containing both LogBUN and HGB. Based on the Wald statistics, neither LogBUN nor HGB is removed from the model.

Output 67.1.4 Second Model in the Stepwise Selection Process

Step 2. Effect HGB is entered. The model contains the following effects:		
LogBUN HGB		
Convergence Status		
Convergence criterion (GCONV=1E-8) satisfied.		
Model Fit Statistics		
Criterion	Without Covariates	With Covariates
-2 LOG L	309.716	297.767
AIC	309.716	301.767
SBC	309.716	305.509

Output 67.1.4 *continued*

HGB	1	-0.11899	0.05751	4.2811	0.0385	0.888

Output 67.1.6 *continued*

NOTE: Model building terminates because the effect to be entered is the effect that was removed in the last step.

The procedure also displays a summary table of the steps in the stepwise selection process, as shown in [Output 67.1.7](#).

Output 67.1.7 Model Selection Summary

Summary of Stepwise Selection							
Step	Effect		DF	Number		Score	
	Entered	Removed		In	Chi-Square	Wald Chi-Square	Pr > ChiSq
1	LogBUN		1	1	8.5164		0.0035
2	HGB		1	2	4.3468		0.0371
3	SCalc		1	3	1.8225		0.1770
4		SCalc	1	2		1.8127	0.1782

The stepwise selection process results in a model with two explanatory variables, LogBUN and HGB.

Example 67.2: Best Subset Selection

An alternative to stepwise selection of variables is best subset selection. This method uses the branch-and-bound algorithm of Furnival and Wilson (1974) to find a specified number of best models containing one, two, or three variables, and so on, up to the single model containing all of the explanatory variables. The criterion used to determine the “best” subset is based on the global score chi-square statistic. For two models A and B, each having the same number of explanatory variables, model A is considered to be better than model B if the global score chi-square statistic for A exceeds that for B.

In the following statements, best subset selection analysis is requested by specifying the `SELECTION=SCORE` option in the `MODEL` statement. The `BEST=3` option requests the procedure to identify only the three best models for each size. In other words, `PROC PHREG` will list the three models having the highest score statistics of all the models possible for a given number of covariates.

```
proc phreg data=Myeloma;
  model Time*VStatus(0)=LogBUN HGB Platelet Age LogWBC
    Frac LogPBM Protein SCalc
    / selection=score best=3;
run;
```

[Output 67.2.1](#) displays the results of this analysis. The number of explanatory variables in the model is given in the first column, and the names of the variables are listed on the right. The models are listed in descending order of their score chi-square values within each model size. For example, among all models containing two explanatory variables, the model that contains the variables LogBUN and HGB has the largest score value (12.7252), the model that contains the variables LogBUN and Platelet has the second-largest score

value (11.1842), and the model that contains the variables LogBUN and SCalc has the third-largest score value (9.9962).

Output 67.2.1 Best Variable Combinations

The PHREG Procedure			
Regression Models Selected by Score Criterion			
Number of Variables	Score Chi-Square	Variables Included in Model	
1	8.5164	LogBUN

Example 67.3: Modeling with Categorical Predictors

Consider the data for the Veterans Administration lung cancer trial presented in Appendix 1 of Kalbfleisch and Prentice (1980). In this trial, males with advanced inoperable lung cancer were randomized to a standard therapy and a test chemotherapy. The primary endpoint for the therapy comparison was time to death in days, represented by the variable Time. Negative values of Time are censored values. The data include information about a number of explanatory variables: Therapy (type of therapy: standard or test), Cell (type

of tumor cell: adeno, large, small, or squamous), Prior (prior therapy: 0=no, 10=yes), Age (age, in years), Duration (months from diagnosis to randomization), and Kps (Karnofsky performance scale). A censoring indicator variable, Censor, is created from the data, with the value 1 indicating a censored time and the value 0 indicating an event time. The following DATA step saves the data in the data set VALung.

```
proc format;
  value yesno 0='no' 10='yes';
run;

data VALung;
  drop check m;
  retain Therapy Cell;
  infile cards column=column;
  length Check $ 1;
  label Time='time to death in days'
        Kps='Karnofsky performance scale'
        Duration='months from diagnosis to randomization'
        Age='age in years'
        Prior='prior therapy'
        Cell='cell type'
        Therapy='type of treatment';
  format Prior yesno.;
  M=Column;
  input Check $ @@;
  if M>Column then M=1;
  if Check='s'|Check='t' then do;
    input @M Therapy $ Cell $;
    delete;
  end;
  else do;
    input @M Time Kps Duration Age Prior @@;
    Status=(Time>0);
    Time=abs(Time);
  end;

```

The following statements use the PHREG procedure to fit the Cox proportional hazards model to these data. The variables `Prior`, `Cell`, and `Therapy`, which are categorical variables, are declared in the `CLASS` statement. By default, PROC PHREG parameterizes the `CLASS` variables by using the reference coding with the last category as the reference category. However, you can explicitly specify the reference category of your choice. Here, `Prior=no` is chosen as the reference category for prior therapy, `Cell=large` is chosen as the reference category for type of tumor cell, and `Therapy=standard` is chosen as the reference category for the type of therapy. In the `MODEL` statement, the term `Prior|Therapy` is just another way of specifying the main effects `Prior`, `Therapy`, and the `Prior*Therapy` interaction.

```

proc phreg data=VALung;
  class Prior(ref='no') Cell(ref='large') Therapy(ref='standard');
  model Time*Status(0) = Kps Duration Age Cell Prior|Therapy;
run;

```

Coding of the `CLASS` variables is displayed in [Output 67.3.1](#). There is one dummy variable for `Prior` and one for `Therapy`, since both variables are binary. The dummy variable has a value of 0 for the reference category (`Prior=no`, `Therapy=standard`). The variable `Cell` has four categories and is represented by three dummy variables. Note that the reference category, `Cell=large`, has a value of 0 for all three dummy variables.

Output 67.3.1 Reference Coding of CLASS Variables

The PHREG Procedure				
Class Level Information				
Class	Value	Design Variables		
Prior	no	0		
	yes	1		
Cell	adeno	1	0	0
	large	0	0	0
	small	0	1	0
	squamous	0	0	1
Therapy	standard	0		
	test	1		

The test results of individual model effects are shown in [Output 67.3.2](#). There is a strong prognostic effect of Kps on patient's survivorship ($p < 0.0001$), and the survival times for patients of different Cell types differ significantly ($p = 0.0003$). The Prior*Therapy interaction is marginally significant ($p = 0.0416$)—that is, prior therapy might play a role in whether one treatment is more effective than the other.

Output 67.3.2 Wald Tests of Individual Effects

Type 3 Tests			
Effect	DF	Wald Chi-Square	Pr > ChiSq
Kps	1	35.5051	<.0001
Duration	1	0.1159	0.7335
Age	1	1.9772	0.1597
Cell	3	18.5339	0.0003
Prior	1	2.5296	0.1117
Therapy	1	5.2349	0.0221
Prior*Therapy	1	4.1528	0.0416

In the Cox proportional hazards model, the effects of the covariates are to act multiplicatively on the hazard of the survival time, and therefore it is a little easier to interpret the corresponding hazard ratios than the regression parameters. For a parameter that corresponds to a continuous variable, the hazard ratio is the ratio of hazard rates for a increase of one unit of the variable. From [Output 67.3.3](#), the hazard ratio estimate for Kps is 0.968, meaning that an increase of 10 units in Karnofsky performance scale will shrink the hazard rate by $1 - (0.968)^{10} = 28\%$. For a CLASS variable parameter, the hazard ratio presented in the [Output 67.3.3](#) is the ratio of the hazard rates between the given category and the reference category. The hazard rate of

Cell=adeno is 219% that of Cell=large, the hazard rate of Cell=small is 62% that of Cell=large, and the hazard rate of Cell=squamous is only 66% that of Cell=large. Hazard ratios for Prior and Therapy are missing since the model contains the Prior*Therapy interaction. You can use the HAZARDRATIO statement to obtain the hazard ratios for a main effect in the presence of interaction as shown later in this example.

Output 67.3.3 Parameters Estimates with Reference Coding

Analysis of Maximum Likelihood Estimates					
Parameter		DF	Parameter Estimate	Standard Error	Chi-Square Pr > ChiSq

Prior*Therapy	yes test	prior therapy yes * type of treatment test

The following PROC PHREG statements illustrate the use of the backward elimination process to identify the effects that affect the survivorship of the lung cancer patients. The option **SELECTION=BACKWARD** is specified to carry out the backward elimination. The option **SLSTAY=0.1** specifies the significant level for retaining the effects in the model.

```
proc phreg data=VALung;
  class Prior(ref='no') Cell(ref='large') Therapy(ref='standard');
  model Time*Status(0) = Kps Duration Age Cell Prior|Therapy
    / selection=backward slstay=0.1;
run;
```

Results of the backward elimination process are summarized in [Output 67.3.4](#). The effect Duration was eliminated first and was followed by Age.

Output 67.3.4 Effects Eliminated from the Model

The PHREG Procedure					
Summary of Backward Elimination					
Step	Effect Removed	DF	Number In	Wald Chi-Square	Pr > ChiSq
1	Duration	1	6	0.1159	0.7335

Finally, the following statements refit the previous model and computes hazard ratios at settings beyond those displayed in the “Analysis of Maximum Likelihood Estimates” table. You can use either the HAZARDRATIO statement or the CONTRAST statement to obtain hazard ratios. Using the CONTRAST statement to compute hazard ratios for CLASS variables can be a daunting task unless you are familiar with the parameterization schemes (see the section “[Parameterization of Model Effects](#)” on page 383 of Chapter 19, “[Shared Concepts and Topics](#),” for details), but you have control over which specific hazard ratios you want to compute. HAZARDRATIO statements, on the other hand, are designed specifically to provide hazard ratios. They are easy to use and you can also request both the Wald confidence limits and the profile-likelihood confidence limits; the latter is not available for the CONTRAST statements. Three HAZARDRATIO statements are specified; each has the CL=BOTH option to request both the Wald confidence limits and the profile-likelihood limits. The first HAZARDRATIO statement, labeled ‘H1’, estimates the hazard ratio for an increase of 10 units in the KPS; the UNITS= option specifies the number of units increase. The second HAZARDRATIO statement, labeled ‘H2’ computes the hazard ratios for comparing any pairs of tumor Cell

types. The third HAZARDRATIO statement, labeled 'H3', compares the test therapy with the standard therapy. The DIFF=REF option specifies that each nonreference category is compared to the reference category. The purpose of using DIFF=REF here is to ensure that the hazard ratio is comparing the test therapy to the standard therapy instead of the other way around. Three CONTRAST statements, labeled 'C1', 'C2', and 'C3', parallel to the HAZARDRATIO statements 'H1', 'H2', and 'H3', respectively, are specified. The ESTIMATE=EXP option specifies that the linear predictors be estimated in the exponential scale, which are precisely the hazard ratios.

```
proc phreg data=VALung;
  class Prior(ref='no') Cell(ref='large') Therapy(ref='standard');
  model Time*Status(0) = Kps Cell Prior|Therapy;
  hazardratio 'H1' Kps / units=10 cl=both;
  hazardratio 'H2' Cell / cl=both;
  hazardratio 'H3' Therapy / diff=ref cl=both;
  contrast 'C1' Kps 10 / estimate=exp;
  contrast 'C2' cell 1 0 0, /* adeno vs large */
               cell 1 -1 0, /* adeno vs small */
               cell 1 0 -1, /* adeno vs squamous */
               cell 0 -1 0, /* large vs small */
               cell 0 0 -1, /* large vs Squamous */
               cell 0 1 -1 /* small vs squamous */
               / estimate=exp;
  contrast 'C3' Prior 0 Therapy 1 Prior*Therapy 0,
               Prior 0 Therapy 1 Prior*Therapy 1 / estimate=exp;
run;
```

Output 67.3.6 displays the results of the three HAZARDRATIO statements in separate tables. Results of the three CONTRAST statements are shown in one table in Output 67.3.7. However, point estimates and the Wald confidence limits for the hazard ratio agree in between the two outputs.

Output 67.3.6 Results from HAZARDRATIO Statements

The PHREG Procedure					
H1: Hazard Ratios for Kps

Example 67.4: Firth's Correction for Monotone Likelihood

In fitting the Cox regression model by maximizing the partial likelihood, the estimate of an explanatory variable X will be infinite if the value of X at each uncensored failure time is the largest of all the values of X in the risk set at that time (Tsiatis 1981; Bryson and Johnson 1981). You can exploit this information to artificially create a data set that has the condition of monotone likelihood for the Cox regression. The following DATA step modifies the Myeloma data in [Example 67.1](#) to create a new explanatory variable, Contrived, which has the value 1 if the observed time is less than or equal to 65 and has the value 0 otherwise. The phenomenon of monotone likelihood will be demonstrated in the new data set Myeloma2.

```
data Myeloma2;
  set Myeloma;
  Contrived= (Time <= 65);
run;
```

For illustration purposes, consider a Cox model with three explanatory variables, one of which is the variable Contrived. The following statements invoke PROC PHREG to perform the Cox regression. The IPRINT option is specified in the MODEL statement to print the iteration history of the optimization.

```
proc phreg data=Myeloma2;
  model Time*Vstatus(0)=LOGbun HGB Contrived / itprint;
run;
```

The symptom of monotonicity is demonstrated in [Output 67.4.1](#). The log likelihood converges to the value of -136.56 while the coefficient for Contrived diverges. Although the Newton-Raphson optimization process did not fail, it is obvious that convergence is questionable. A close examination of the standard errors in the “Analysis of Maximum Likelihood Estimates” table reveals a very large value for the coefficient of Contrived. This is very typical of a diverged estimate.

Output 67.4.1 Monotone Likelihood Behavior Displayed

Analysis of Maximum Likelihood Estimates						
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
LogBUN	1	1.71884	0.58376	8.6697	0.0032	5.578
HGB	1	-0.11238	0.06090	3.4053	0.0650	0.894
Contrived	1	17.04170	1080	0.0002	0.9874	25183399

Next, the Firth correction was applied as shown in the following statements. Also, the profile-likelihood confidence limits for the hazard ratios are requested by using the RISKLIMITS=PL option.

```
proc phreg data=Myeloma2;
  model Time*Vstatus(0)=LogBUN HGB Contrived /
    firth risklimits=pl itprint;
run;
```

PROC PHREG uses the penalized likelihood maximum to obtain a finite estimate for the coefficient of Contrived (Output 67.4.2). The much preferred profile-likelihood confidence limits, as shown in (Heinze and Schemper 2001), are also displayed.

Output 67.4.2 Convergence Obtained with the Firth Correction

Example 67.5: Conditional Logistic Regression for m:n Matching

Conditional logistic regression is used to investigate the relationship between an outcome and a set of prognostic factors in matched case-control studies. The outcome is whether the subject is a case or a control. If there is only one case and one control, the matching is 1:1. The $m:n$ matching refers to the situation in which there is a varying number of cases and controls in the matched sets. You can perform conditional logistic regression with the PHREG procedure by using the discrete logistic model and forming a stratum for each matched set. In addition, you need to create dummy survival times so that all the cases in a matched set have the same event time value, and the corresponding controls are censored at later times.

Consider the following set of low infant birth-weight data extracted from Appendix 1 of Hosmer and Lemeshow (1989). These data represent 189 women, of whom 59 had low-birth-weight babies and 130

had normal-weight babies. Under investigation are the following risk factors: weight in pounds at the last menstrual period (LWT), presence of hypertension (HT), smoking status during pregnancy (Smoke), and presence of uterine irritability (UI). For HT, Smoke, and UI, a value of 1 indicates a “yes” and a value of 0 indicates a “no.” The woman’s age (Age) is used as the matching variable. The SAS data set LBW contains a subset of the data corresponding to women between the ages of 16 and 32.

;

```

The variable Low is used to determine whether the subject is a case (Low=1, low-birth-weight baby) or a control (Low=0, normal-weight baby). The dummy time variable Time takes the value 1 for cases and 2 for controls.

The following statements produce a conditional logistic regression analysis of the data. The variable Time is the response, and Low is the censoring variable. Note that the data set is created so that all the cases have the same event time and the controls have later censored times. The matching variable Age is used in the STRATA statement so that each unique age value defines a stratum. The variables LWT, Smoke, HT, and UI are specified as explanatory variables. The TIES=DISCRETE option requests the discrete logistic model.

```
proc phreg data=LBW;
  model Time*Low(0)= LWT Smoke HT UI / ties=discrete;
  strata Age;
run;
```

The procedure displays a summary of the number of event and censored observations for each stratum. These are the number of cases and controls for each matched set shown in [Output 67.5.1](#).

Output 67.5.1 Summary of Number of Case and Controls

The PHREG Procedure					
Model Information					
Data Set		WORK.LBW			
Dependent Variable		Time			
Censoring Variable		Low			
Censoring Value(s)		0			
Ties Handling		DISCRETE			
Summary of the Number of Event and Censored Values					
Stratum	Age	Total	Event	Censored	Percent Censored
1	16	7	1	6	85.71
2	17	12	5	7	58.33
3	18	10	2	8	80.00
4	19	16	3	13	81.25
5	20	18	8	10	55.56
6	21	12	5	7	58.33
7	22	13	2	11	84.62
8	23	13	5	8	61.54

13	28	9	2	7	77.78
14	29	7	1	6	85.71
15	30	7	1	6	85.71
16	31	5	1	4	80.00
17	32	6	1	5	83.33

Total		174	54	120	68.97

Results of the conditional logistic regression analysis are shown in [Output 67.5.2](#). Based on the Wald test for individual variables, the variables LWT, Smoke, and HT are statistically significant while UI is marginal.

The hazard ratios, computed by exponentiating the parameter estimates, are useful in interpreting the results of the analysis. If the hazard ratio of a prognostic factor is larger than 1, an increment in the factor increases the hazard rate. If the hazard ratio is less than 1, an increment in the factor decreases the hazard rate. Results indicate that women were more likely to have low-birth-weight babies if they were underweight in the last menstrual cycle, were hypertensive, smoked during pregnancy, or suffered uterine irritability.

Output 67.5.2 Conditional Logistic Regression Analysis for the Low-Birth-Weight Study

For matched case-control studies with one case per matched set (1:n matching), the likelihood function for the conditional logistic regression reduces to that of the Cox model for the continuous time scale. For this situation, you can use the default TIES=BRESLOW.

Example 67.6: Model Using Time-Dependent Explanatory Variables

Time-dependent variables can be used to model the effects of subjects transferring from one treatment group to another. One example of the need for such strategies is the Stanford heart transplant program. Patients are accepted if physicians judge them suitable for heart transplant. Then, when a donor becomes available, physicians choose transplant recipients according to various medical criteria. A patient's status can be changed during the study from waiting for a transplant to being a transplant recipient. Transplant status can be defined by the time-dependent covariate function $z = z(t)$ as

$$z(t) = \begin{cases} 0 & \text{if the patient has not received the transplant at time } t \\ 1 & \text{if the patient has received the transplant at time } t \end{cases}$$

The Stanford heart transplant data that appear in Crowley and Hu (1977) consist of 103 patients, 69 of whom received transplants. The data are saved in a SAS data set called Heart in the following DATA step. For each patient in the program, there is a birth date (Bir_Date), a date of acceptance (Acc_Date), and a date last seen (Ter_Date). The survival time (Time) in days is defined as $\text{Time} = \text{Ter_Date} - \text{Acc_Date}$. The survival time is said to be uncensored (Status=1) or censored (Status=0), depending on whether Ter_Date is the date of death or the closing date of the study. The age, in years, at acceptance into the program is $\text{Acc_Age} = (\text{Acc_Date} - \text{Bir_Date}) / 365$. Previous open-heart surgery for each patient is indicated by the variable PrevSurg. For each transplant recipient, there is a date of transplant (Xpl_Date) and three measures (NMismatch, Antigen, Mismatch) of tissue-type mismatching. The waiting period (WaitTime) in days for a transplant recipient is calculated as $\text{WaitTime} = \text{Xpl_Date} - \text{Acc_Date}$, and the age (in years) at transplant is $\text{Xpl_Age} = (\text{Xpl_Date} - \text{Bir_Date}) / 365$. For those who do not receive heart transplants, the WaitTime, Xpl_Age, NMismatch, Antigen, and Mismatch variables contain missing values.

The input data contain dates that have a two-digit year representation. The SAS option YEARCUTOFF=1900 is specified to ensure that a two-digit year xx is year 19xx.

```
options yearcutoff=1900;

```

Crowley and Hu (1977) have presented a number of analyses to assess the effects of various explanatory variables on the survival of patients. This example fits two of the models that they have considered.

The first model consists of two explanatory variables—the transplant status and the age at acceptance. The transplant status (XStatus) is a time-dependent variable defined by the programming statements between the MODEL statement and the RUN statement. The XStatus variable takes the value 1 or 0 at time t (measured from the date of acceptance), depending on whether or not the patient has received a transplant at that time. Note that the value of XStatus changes for subjects in each risk set (subjects still alive just before each distinct event time); therefore, the variable cannot be created in the DATA step. The variable

Acc_Age, which is not time dependent, accounts for the possibility that pretransplant risks vary with age. The following statements fit this model:

```
proc phreg data= Heart;
  model Time*Status(0)= XStatus Acc_Age;
  if (WaitTime = . or Time < WaitTime) then XStatus=0.;
  else XStatus= 1.0;
run;
```

Results of this analysis are shown in [Output 67.6.1](#). Transplantation appears to be associated with a slight decrease in risk, although the effect is not significant ($p = 0.8261$). The age at acceptance as a pretransplant risk factor adds significantly to the model ($p = 0.0289$). The risk increases significantly with age at acceptance.

Analysis of Maximum Likelihood Estimates						
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
XStatus	1	-0.06720	0.30594	0.0482	0.8261	0.935
Acc_Age	1	0.03158	0.01446	4.7711	0.0289	1.032

The second model consists of three explanatory variables—the transplant status, the transplant age, and the mismatch score. Four transplant recipients who were not typed have no Mismatch values; they are excluded from the analysis by the use of a WHERE clause. The transplant age (XAge) and the mismatch score (XScore) are also time dependent and are defined in a fashion similar to that of XStatus. While the patient is waiting for a transplant, XAge and XScore have a value of 0. After the patient has migrated to the recipient population, XAge takes on the value of Xpl_Age (transplant age for the recipient), and XScore takes on the value of Mismatch (a measure of the degree of dissimilarity between donor and recipient). The following statements fit this model:

```
proc phreg data= Heart;
  model Time*Status(0)= XStatus XAge XScore;
  where NotTyped ^= 'y';
  if (WaitTime = . or Time < WaitTime) then do;
    XStatus=0.;
    XAge=0.;
    XScore= 0.;
  end;
  else do;
    XStatus= 1.0;
    XAge= Xpl_Age;
    XScore= Mismatch;
  end;
run;
```

Results of the analysis are shown in [Output 67.6.2](#). Note that only 99 patients are included in this analysis, instead of 103 patients as in the previous analysis, since four transplant recipients who were not typed are excluded. The variable XAge is statistically significant ($p = 0.0143$), with a hazard ratio exceeding 1. Therefore, patients who had a transplant at younger ages lived longer than those who received a transplant later in their lives. The variable XScore has only minimal effect on the survival ($p = 0.1121$).

Example 67.7: Time-Dependent Repeated Measurements of a Covariate

Repeated determinations can be made during the course of a study of variables thought to be related to survival. Consider an experiment to study the dosing effect of a tumor-promoting agent. Forty-five rodents initially exposed to a carcinogen were randomly assigned to three dose groups. After the first death of an animal, the rodents were examined every week for the number of papillomas. Investigators were interested in determining the effects of dose on the carcinoma incidence after adjusting for the number of papillomas.

The input data set TUMOR consists of the following 19 variables:

- ID (subject identification)
- Time (survival time of the subject)
- Dead (censoring status where 1=dead and 0=censored)
- Dose (dose of the tumor-promoting agent)
- P1–P15 (number of papillomas at the 15 times that animals died. These 15 death times are weeks 27, 34, 37, 41, 43, 45, 46, 47, 49, 50, 51, 53, 65, 67, and 71. For instance, subject 1 died at week 47; it had no papilloma at week 27, five papillomas at week 34, six at week 37, eight at week 41, and 10 at weeks 43, 45, 46, and 47. For an animal that died before week 71, the number of papillomas is missing for those times beyond its death.)

The following SAS statements create the data set TUMOR:

```
data Tumor;
  infile datalines missover;
  input ID Time Dead Dose P1-P15;
  label ID='Subject ID';
  datalines;
1 47 1 1.0 0 5 6 8 10 10 10 10

;

```

The number of papillomas (NPap) for each animal in the study was measured repeatedly over time. One way of handling time-dependent repeated measurements in the PHREG procedure is to use programming statements to capture the appropriate covariate values of the subjects in each risk set. In this example, NPap is a time-dependent explanatory variable with values that are calculated by means of the programming statements shown in the following SAS statements:

```

proc phreg data=Tumor;
  model Time*Dead(0)=Dose NPap;
  array pp{*} P1-P14;
  array tt{*} t1-t15;
  t1=27; t2=34; t3=37; t4=41; t5=43;
  t6=45; t7=46; t8=47; t9=49; t10=50;
  t11=51; t12=53; t13=65; t14=67; t15=71;
  if Time < tt[1] then NPap=0;
  else if time >= tt[15] then NPap=P15;
  else do i=1 to dim(pp);
    if tt[i] <= Time < tt[i+1] then NPap= pp[i];
  end;
run;

```

At each death time, the NPap value of each subject in the risk set is recalculated to reflect the actual number of papillomas at the given death time. For instance, subject one in the data set Tumor was in the risk sets at weeks 27 and 34; at week 27, the animal had no papilloma, while at week 34, it had five papillomas. Results of the analysis are shown in [Output 67.7.1](#). After the number of papillomas is adjusted for, the dose effect of the tumor-promoting agent is not statistically significant.

Output 67.7.1 Cox Regression Analysis on the Survival of Rodents

Another way to handle time-dependent repeated measurements in the PHREG procedure is to use the counting process style of input. Multiple records are created for each subject, one record for each distinct pattern of the time-dependent measurements. Each record contains a T1 value and a T2 value representing the time interval (T1,T2] during which the values of the explanatory variables remain unchanged. Each record also contains the censoring status at T2.

One advantage of using the counting process formulation is that you can easily obtain various residuals and influence statistics that are not available when programming statements are used to compute the values of the time-dependent variables. On the other hand, creating multiple records for the counting process formulation requires extra effort in data manipulation.

Consider a counting process style of input data set named Tumor1. It contains multiple observations for each subject in the data set Tumor. In addition to variables ID, Time, Dead, and Dose, four new variables are generated:

- T1 (left endpoint of the risk interval)
- T2 (right endpoint of the risk interval)
- NPap (number of papillomas in the time interval (T1,T2])
- Status (censoring status at T2)

For example, five observations are generated for the rodent that died at week 47 and that had no papilloma at week 27, five papillomas at week 34, six at week 37, eight at week 41, and 10 at weeks 43, 45, 46, and 47. The values of T1, T2, NPap, and Status for these five observations are (0,27,0,0), (27,34,5,0), (34,37,6,0), (37,41,8,0), and (41,47,10,1). Note that the variables ID, Time, and Dead are not needed for the estimation of the regression parameters, but they are useful for plotting the residuals.

The following SAS statements create the data set Tumor1:

```
data Tumor1(keep=ID Time Dead Dose T1 T2 NPap Status);
  array pp{*} P1-P14;
  array qq{*} P2-P15;
  array tt{1:15} _temporary_
    (27 34 37 41 43 45 46 47 49 50 51 53 65 67 71);
  set Tumor;
  T1 = 0;
  T2 = 0;
  Status = 0;
  if ( Time = tt[1] ) then do;
    T2 = tt[1];
    NPap = p1;
    Status = Dead;
    output;
  end;
  else do _i_=1 to dim(pp);
    if ( tt[_i_] = Time ) then do;
      T2= Time;
      NPap = pp[_i_];
      Status = Dead;
      output;
    end;
  end;
```

```

        else if (tt[_i_] < Time ) then do;
            if (pp[_i_] ^= qq[_i_] ) then do;
                if qq[_i_] = . then T2= Time;
                else
                    T2= tt[_i_];
                NPap= pp[_i_];
                Status= 0;
                output;
                T1 = T2;
            end;
        end;
    end;
    if ( Time >= tt[15] ) then do;
        T2 = Time;
        NPap = P15;
        Status = Dead;
        output;
    end;
run;

```

In the following SAS statements, the counting process MODEL specification is used. The DFBETA statistics are output to a SAS data set named Out1. Note that Out1 contains multiple observations for each subject—that is, one observation for each risk interval (T1,T2].

```

proc phreg data=Tumor1;
    model (T1,T2)*Status(0)=Dose NPap;
    output out=Out1 resmart=Mart dfbeta=db1-db2;
    id ID Time Dead;
run;

```

The output from PROC PHREG (not shown) is identical to [Output 67.7.1](#) except for the “Summary of the Number of Event and Censored Values” table. The number of event observations remains unchanged between the two specifications of PROC PHREG, but the number of censored observations differs due to the splitting of each subject’s data into multiple observations for the counting process style of input.

Next, the MEANS procedure sums up the component statistics for each subject and outputs the results to a SAS data set named Out2:

```

proc means data=Out1 noprint;
    by ID Time Dead;
    var Mart db1-db2;
    output out=Out2 sum=Mart db_Dose db_NPap;
run;

```

Finally, DFBETA statistics are plotted against subject ID for easy identification of influential points:

```

title 'DfBetas for Dose';
proc sgplot data=Out2;
  yaxis label="DfBeta" grid;
  refline 0 / axis=y;
  scatter y=db_Dose x=ID;
run;
title 'DfBetas for NPap';
proc sgplot data=Out2;
  yaxis label="DfBeta" grid;
  refline 0 / axis=y;
  scatter y=db_NPap x=ID;
run;

```

The plots of the DFBETA statistics are shown in [Output 67.7.2](#) and [Output 67.7.3](#). Subject 30 appears to have a large influence on both the Dose and NPap coefficients. Subjects 31 and 35 have considerable influences on the DOSE coefficient, while subjects 22 and 44 have rather large influences on the NPap coefficient.

Output 67.7.2 Plot of DFBETA Statistic for DOSE versus Subject Number

Output 67.7.3 Plot of DFBETA Statistic for NPAP versus Subject Number

Example 67.8: Survival Curves

You might want to use your regression analysis results to predict the survivorship of subjects of specific covariate values. The `COVARIATES=` data set in the `BASELINE` statement enables you to specify the sets of covariate values for the prediction. On the other hand, you might want to summarize the survival experience of an average patient for a given population. The `DIRADJ` option in the `BASELINE` statement computes the direct adjusted survival curve that averages the estimated survival curves for patients whose covariates are represented in the `COVARIATES=` data set. By using the `PLOTS=` option in the `PROC PHREG` statement, you can use ODS Graphics to display the predicted survival curves. You can elect to output the predicted survival curves in a SAS data set by optionally specifying the `OUT=` option in the `BASELINE` statement. This example illustrates how to obtain the covariate-specific survival curves and the direct adjusted survival curve by using the Myeloma data set in [Example 67.1](#), where variables `LogBUN` and `HGB` were identified as the most important prognostic factors.

Suppose you want to compute the predicted survival curves for two sets of covariate values: (LogBUN=1.0, HGB=10) and (LogBUN=1.8, HGB=12). These values are saved in the data set `Inrisks` in the following DATA step. Also created in this data set is the variable `Id`, whose values will be used in identifying the covariate sets in the survival plot.

```
data Inrisks;
    length Id $20;
    input LogBUN HGB Id $12-31;
    datalines;
1.00 10.0  logBUN=1.0 HGB=10
1.80 12.0  logBUN=1.8 HGB=12
;
```

The following statements plot the survival functions in [Output 67.8.1](#) and save the survival estimates in the data set `Pred1`:

```
ods graphics on;
proc phreg data=Myeloma plots(overlay)=survival;
    model Time*VStatus(0)=LogBUN HGB;
    baseline covariates=Inrisks out=Pred1 survival=_all_/rowid=Id;
run;
```

The `COVARIATES=` option in the `BASELINE` statement specifies the data set that contains the set of covariates of interest. The `PLOTS=` option in the `PROC PHREG` statement creates the survival plot. The `OVERLAY` suboption overlays the two curves in the same plot. If the `OVERLAY` suboption is not specified, each curve is displayed in a separate plot. The `ROWID=` option in the `BASELINE` statement specifies that the values of the variable `Id` in the `COVARIATES=` data set be used to identify the curves in the plot. The `SURVIVAL=_ALL_` option in the `BASELINE` statement requests that the estimated survivor function, standard error, and lower and upper confidence limits for the survivor function be output into the SAS data set that is specified in the `OUT=` option.

The survival Plot ([Output 67.8.1](#)) contains two curves, one for each of row of covariates in the data set `Inrisks`.

Output 67.8.1 Estimated Survivor Function Plot

The following statements print out the observations in the data set `Pred1` for the realization `LogBUN=1.00` and `HGB=10.0`:

```
proc print data=Pred1(where=(logBUN=1 and HGB=10));
run;
```

As shown in [Output 67.8.2](#), 32 observations represent the survivor function for the realization `LogBUN=1.00` and `HGB=10.0`. The first observation has survival time 0 and survivor function estimate 1.0. Each of the remaining 31 observations represents a distinct event time in the input data set `Myeloma`. These observations are presented in ascending order of the event times. Note that all the variables in the `COVARIATES=InRisks` data set are included in the `OUT=Pred1` data set. Likewise, you can print out the observations that represent the survivor function for the realization `LogBUN=1.80` and `HGB=12.0`.

Output 67.8.2 Survivor Function Estimates for LogBUN=1.0 and HGB=10.0

Obs	Id	Log BUN	HGB	Time	Survival	StdErr Survival	Lower Survival	Upper Survival

Next, the DIRADJ option in the BASELINE statement is used to request a survival curve that represents the survival experience of an average patient in the population in which the COVARIATES= data set is sampled. When the DIRADJ option is specified, PROC PHREG computes the direct adjusted survival function by averaging the predicted survival functions for the rows in the COVARIATES= data set. The following statements plot the direct adjusted survival function in [Output 67.8.3](#).

```
proc phreg data=Myeloma plots=survival;
  model Time*VStatus(0)=LogBUN HGB;
  baseline covariates=Myeloma survival=_all_/diradj;
run;
```

When the DIRADJ option is specified in the BASELINE statement, the default COVARIATES= data set is the input data set. For clarity, the COVARIATES=MYELOMA is specified in the BASELINE statement in the preceding PROC PHREG call.

Output 67.8.3 Average Survival Function for the Myeloma Data

If neither the COVARIATES= data set nor the DIRADJ option is specified in the BASELINE statement, PROC PHREG computes a predicted survival curve based on $\bar{\mathbf{Z}}$, the average values of the covariate vectors in the input data (Neuberger et al. 1986). This curve represents the survival experience of a patient with an average prognostic index $\beta'\bar{\mathbf{Z}}$ equal to the average prognostic index of all patients. This approach has a couple of drawbacks: it is possible that no patient could ever have such an average index, and it does not account for the variability in the prognostic factor from patient to patient.

The DIRADJ option is particularly useful if the model contains a categorical explanatory variable that represents different treatments of interest. By specifying this categorical variable in the GROUP= option, you obtain a direct adjusted survival curve for each category of the variable. In addition, you can use the OUTDIFF= option to save all pairwise differences of these direct adjusted survival probabilities in a data set. For illustration, consider a model that also includes the categorical variable Frac, which has a value 0 if a patient did not have a fracture at diagnosis and 1 otherwise, as an explanatory variable. The following statements plot the adjusted survival curves in [Output 67.8.4](#) and save the differences of the direct adjusted survival probabilities in the data set Diff1:

```
proc phreg data=Myeloma plots(overlay)=survival;
  class Frac;
  model Time*VStatus(0)=LogBUN HGB Frac;
  baseline covariates=Myeloma outdiff=Diff1 survival=_all_/diradj group=Frac;
run;
```

Because the CLASS variable Frac is specified as the GROUP= variable, a separate direct adjusted survival curve is computed for each value of the variable Frac. Each direct adjusted survival curve is the average of the predicted survival curves for all the patients in the entire Myeloma data set with their Frac value set to a specific constant. For example, the direct adjusted survival curve for Frac=0 (no fracture at diagnosis) is computed as follows:

1. The value of the variable Frac is set to 0 for all observations in the Myeloma data set.
2. The survival curve for each observation in the modified data set is computed.
3. All the survival curves computed in step 2 are averaged.

Output 67.8.4 Average Survival by Fracture Status

Output 67.8.4 shows that patients without fracture at diagnosis have better survival than those with fractures. Differences in the survival probabilities and their standard errors are displayed in Output 67.8.5.

```
proc print data=Diff1;
run;
ods graphics off;
```

Output 67.8.5 Differences in the Survival between Fracture and Nonfracture

Example 67.9: Analysis of Residuals

Residuals are used to investigate the lack of fit of a model to a given subject. You can obtain martingale and deviance residuals for the Cox proportional hazards regression analysis by requesting that they be included in the OUTPUT data set. You can plot these statistics and look for outliers.

Consider the stepwise regression analysis performed in [Example 67.1](#). The final model included variables LogBUN and HGB. You can generate residual statistics for this analysis by refitting the model containing those variables and including an OUTPUT statement as in the following invocation of PROC PHREG. The keywords XBETA, RESMART, and RESDEV identify new variables that contain the linear predictor scores $z_j'\hat{\beta}$, martingale residuals, and deviance residuals. These variables are xb, mart, and dev, respectively.

```
proc phreg data=Myeloma noprint;
  model Time*Vstatus(0)=LogBUN HGB;
  output out=Outp xbeta=Xb resmart=Mart resdev=Dev;
run;
```

The following statements plot the residuals against the linear predictor scores:

```
title "Myeloma Study";
proc sgplot data=Outp;
  yaxis grid;
  refline 0 / axis=y;
  scatter y=Mart x=Xb;
run;
proc sgplot data=Outp;
  yaxis grid;
  refline 0 / axis=y;
  scatter y=Dev x=Xb;
run;
```

The resulting plots are shown in [Output 67.9.1](#) and [Output 67.9.2](#). The martingale residuals are skewed because of the single event setting of the Cox model. The martingale residual plot shows an isolation point (with linear predictor score 1.09 and martingale residual -3.37), but this observation is no longer distinguishable in the deviance residual plot. In conclusion, there is no indication of a lack of fit of the model to individual observations.

Output 67.9.1 Martingale Residual Plot

Output 67.9.2 Deviance Residual Plot

Example 67.10: Analysis of Recurrent Events Data

Recurrent events data consist of times to a number of repeated events for each sample unit—for example, times of recurrent episodes of a disease in patients. Various ways of analyzing recurrent events data are described in the section “[Analysis of Multivariate Failure Time Data](#)” on page 5629. The bladder cancer data listed in Wei, Lin, and Weissfeld (1989) are used here to illustrate these methods.

The data consist of 86 patients with superficial bladder tumors, which were removed when the patients entered the study. Of these patients, 48 were randomized into the placebo group, and 38 were randomized into the group receiving thiotepa. Many patients had multiple recurrences of tumors during the study, and new tumors were removed at each visit. The data set contains the first four recurrences of the tumor for each patient, and each recurrence time was measured from the patient’s entry time into the study.

The data consist of the following eight variables:

- Trt, treatment group (1=placebo and 2=thiotepa)
- Time, follow-up time
- Number, number of initial tumors
- Size, initial tumor size
- T1, T2, T3, and T4, times of the four potential recurrences of the bladder tumor. A patient with only two recurrences has missing values in T3 and T4.

In the data set *Bladder*, four observations are created for each patient, one for each of the four potential tumor recurrences. In addition to values of Trt, Number, and Size for the patient, each observation contains the following variables:

- ID, patient’s identification (which is the sequence number of the subject)
- Visit, visit number (with value k for the k th potential tumor recurrence)
- TStart, time of the $(k - 1)$ recurrence for Visit= k , or the entry time 0 if VISIT=1, or the follow-up time if the $(k - 1)$ recurrence does not occur
- TStop, time of the k th recurrence if Visit= k or follow-up time if the k th recurrence does not occur
- Status, event status of TStop (1=recurrence and 0=censored)

For instance, a patient with only one recurrence time at month 6 who was followed until month 10 will have values for Visit, TStart, TStop, and Status of (1,0,6,1), (2,6,10,0), (3,10,10,0), and (4,10,10,0), respectively. The last two observations are redundant for the intensity model and the proportional means model, but they are important for the analysis of the marginal Cox models. If the follow-up time is beyond the time of the fourth tumor recurrence, it is tempting to create a fifth observation with the time of the fourth tumor recurrence as the TStart value, the follow-up time as the TStop value, and a Status value of 0. However, Therneau and Grambsch (2000, Section 8.5) have warned against incorporating such observations into the analysis.

The following SAS statements create the data set Bladder:

```

data Bladder;
  keep ID TStart TStop Status Trt Number Size Visit;
  retain ID TStart 0;
  array tt T1-T4;
  infile datalines missover;
  input Trt Time Number Size T1-T4;
  ID + 1;
  TStart=0;
  do over tt;
    Visit=_i_;
    if tt = . then do;
      TStop=Time;
      Status=0;
    end;
    else do;
      TStop=tt;
      Status=1;
    end;
    output;
    TStart=TStop;
  end;
  if (TStart < Time) then delete;

First, consider fitting the intensity model (Andersen and Gill 1982) and the proportional means model (Lin et al. 2000). The counting process style of input is used in the PROC PHREG specification. For the proportional means model, inference is based on the robust sandwich covariance estimate, which is requested by the COVS(AGGREGATE) option in the PROC PHREG statement. The COVM option is specified for the analysis of the intensity model to use the model-based covariance estimate. Note that some of the observations in the data set `Bladder` have a degenerated interval of risk. The presence of these observations does not affect the results of the analysis since none of these observations are included in any of the risk sets. However, the procedure will run more efficiently without these observations; consequently, in the following SAS statements, the WHERE clause is used to eliminate these redundant observations:

```

title 'Intensity Model and Proportional Means Model';
proc phreg data=Bladder covm covs(aggregate);
  model (TStart, TStop) * Status(0) = Trt Number Size;
  id id;
  where TStart < TStop;
run;

```

Results of fitting the intensity model and the proportional means model are shown in [Output 67.10.1](#) and [Output 67.10.2](#), respectively. The robust sandwich standard error estimate for `Trt` is larger than its model-based counterpart, rendering the effect of thiotepa less significant in the proportional means model ($p = 0.0747$) than in the intensity model ($p = 0.0215$).

Output 67.10.1 Analysis of the Intensity Model

Next, consider the conditional models of Prentice, Williams, and Peterson (1981). In the PWP models, the risk set for the $(k + 1)$ recurrence is restricted to those patients who have experienced the first k recurrences. For example, a patient who experienced only one recurrence is an event observation for the first recurrence; this patient is a censored observation for the second recurrence and should not be included in the risk set for the third or fourth recurrence. The following DATA step eliminates those observations that should not be in the risk sets, forming a new input data set (named `Bladder2`) for fitting the PWP models. The variable `Gaptime`, representing the gap times between successive recurrences, is also created.

```
data Bladder2(drop=LastStatus);
  retain LastStatus;
  set Bladder;
  by ID;
  if first.id then LastStatus=1;
  if (Status=0 and LastStatus=0) then delete;
  LastStatus=Status;
  Gaptime=Tstop-Tstart;
run;
```

The following statements fit the PWP total time model. The variables `Trt1`, `Trt2`, `Trt3`, and `Trt4` are visit-specific variables for `Trt`; the variables `Number1`, `Number2`, `Number3`, and `Number4` are visit-specific variables for `Number`; and the variables `Size1`, `Size2`, `Size3`, and `Size4` are visit-specific variables for `Size`.

```
title 'PWP Total Time Model with Noncommon Effects';
proc phreg data=Bladder2;
  model (Tstart,Tstop) * Status(0) = Trt1-Trt4 Number1-Number4
                                         Size1-Size4;

  Trt1= Trt * (Visit=1);
  Trt2= Trt * (Visit=2);
  Trt3= Trt * (Visit=3);
  Trt4= Trt * (Visit=4);
  Number1= Number * (Visit=1);
  Number2= Number * (Visit=2);
  Number3= Number * (Visit=3);
  Number4= Number * (Visit=4);
  Size1= Size * (Visit=1);
  Size2= Size * (Visit=2);
  Size3= Size * (Visit=3);
  Size4= Size * (Visit=4);
  strata Visit;
run;
```

Results of the analysis of the PWP total time model are shown in [Output 67.10.3](#). There is no significant treatment effect on the total time in any of the four tumor recurrences.

run;

```

Results of the analysis of the PWP gap-time model are shown in [Output 67.10.4](#). Note that the regression coefficients for the first tumor recurrence are the same as those of the total time model, since the total time and the gap time are the same for the first recurrence. There is no significant treatment effect on the gap times for any of the four tumor recurrences.

You can fit the PWP total time model with common effects by using the following SAS statements. However, the analysis is not shown here.

```

title2 'PWP Total Time Model with Common Effects';
proc phreg data=Bladder2;
  model (tstart,tstop) * status(0) = Trt Number Size;
  strata Visit;
run;

```

You can fit the PWP gap-time model with common effects by using the following statements. Again, the analysis is not shown here.

```

title2 'PWP Gap Time Model with Common Effects';
proc phreg data=Bladder2;
  model Gaptime * Status(0) = Trt Number Size;
  strata Visit;
run;

```

Recurrent events data are a special case of multiple events data in which the recurrence times are regarded as multivariate failure times and the marginal approach of Wei, Lin, and Weissfeld (1989) can be used. WLW fits a Cox model to each of the component times and makes statistical inference of the regression parameters based on a robust sandwich covariance matrix estimate. No specific correlation structure is imposed on the multivariate failure times. For the k th marginal model, let β_k denote the row vector of regression parameters, let $\hat{\beta}_k$ denote the maximum likelihood estimate of β_k , let \hat{A}_k denote the covariance matrix obtained by inverting the observed information matrix, and let R_k denote the matrix of score residuals. WLW showed that the joint distribution of $(\hat{\beta}_1, \dots, \hat{\beta}_4)'$ can be approximated by a multivariate normal distribution with mean vector $(\beta_1, \dots, \beta_4)'$ and robust covariance matrix

$$\begin{pmatrix} V_{11} & V_{12} & V_{13} & V_{14} \\ V_{21} & V_{22} & V_{23} & V_{24} \\ V_{31} & V_{32} & V_{33} & V_{34} \\ V_{41} & V_{42} & V_{43} & V_{44} \end{pmatrix}$$

with the submatrix V_{ij} given by

$$V_{ij} = \hat{A}_i (R_i' R_j) \hat{A}_j$$

In this example, there are four marginal proportional hazards models, one for each potential recurrence time. Instead of fitting one model at a time, you can fit all four marginal models in one analysis by using the STRATA statement and model-specific covariates as in the following statements. Using Visit as the STRATA variable on the input data set Bladder, PROC PHREG simultaneously fits all four marginal models, one for each Visit value. The COVS(AGGREGATE) option is specified to compute the robust sandwich variance estimate by summing up the score residuals for each distinct pattern of ID value. The TEST statement TREATMENT is used to perform the global test of no treatment effect for each tumor recurrence, the AVERAGE option is specified to estimate the parameter for the common treatment effect, and the E option displays the optimal weights for the common treatment effect.

```

title 'Wei-Lin-Weissfeld Model';

Out of the 86 patients, 47 patients have only one tumor recurrence, 29 patients have two recurrences, 22 patients have three recurrences, and 14 patients have four recurrences (Output 67.10.5). Parameter estimates for the four marginal models are shown in Output 67.10.6. The 4 DF Wald test (Output 67.10.7) indicates a lack of evidence of a treatment effect in any of the four recurrences ($p = 0.4105$). The optimal weights for estimating the parameter of the common treatment effect are 0.67684, 0.25723, -0.07547 , and 0.14140 for Trt1, Trt2, Trt3, and Trt4, respectively, which gives a parameter estimate of -0.5489 with a standard error estimate of 0.2853. A more sensitive test for a treatment effect is the 1 DF test based on this common parameter; however, there is still insufficient evidence for such effect at the 0.05 level ($p = 0.0543$).

Example 67.11: Analysis of Clustered Data

When experimental units are naturally or artificially clustered, failure times of experimental units within a cluster are correlated. Two approaches can be taken to adjust for the intracluster correlation. In the marginal Cox model approach, Lee, Wei, and Amato (1992) estimate the regression parameters in the Cox model by the maximum partial likelihood estimates under an independent working assumption and use a robust sandwich covariance matrix estimate to account for the intracluster dependence. Lin (1994) illustrates this methodology by using a subset of data from the Diabetic Retinopathy Study (DRS). An alternative approach to account for the within-cluster correlation is to use a shared frailty model where cluster effects are incorporated into the model as independent and identically distributed random variables.

The following DATA step creates the data set Blind that represents 197 diabetic patients who have a high risk of experiencing blindness in both eyes as defined by DRS criteria. One eye of each patient is treated with laser photocoagulation. The hypothesis of interest is whether the laser treatment delays the occurrence of blindness. Since juvenile and adult diabetes have very different courses, it is also desirable to examine how the age of onset of diabetes might affect the time of blindness. Since there are no biological differences between the left eye and the right eye, it is natural to assume a common baseline hazard function for the failure times of the left and right eyes.

Each patient is a cluster that contributes two observations to the input data set, one for each eye. The following variables are in the input data set Blind:

- ID, patient's identification
- Time, time to blindness
- Status, blindness indicator (0:censored and 1:blind)
- Treat, treatment received (Laser or Others)
- Type, type of diabetes (Juvenile: onset at age ≤ 20 or Adult: onset at age > 20)

```
proc format;
    value type 0='Juvenile' 1='Adult';
    value Rx   1='Laser' 0='Others';
run;

The following statements use PROC PHREG to carry out the analysis of Lee, Wei, and Amato (1992). The explanatory variables in this Cox model are Treat, Type, and the Treat \times Type interaction. The COVS(AGGREGATE) option is specified to compute the robust sandwich covariance matrix estimate. The ID statement identifies the variable that represents the clusters. The HAZARDRATIO statement requests hazard ratios for the treatments be displayed.

```
proc phreg data=Blind covs(aggregate);
  class Treat Type;
  model Time*Status(0)=Treat|Type;
  id ID;
  hazardratio 'Marginal Model Analysis' Treat;
run;
```

Results of the marginal model analysis are displayed in [Output 67.11.2](#). The robust standard error estimates are smaller than the model-based counterparts, since the ratio of the robust standard error estimate relative to the model-based estimate is less than 1 for each parameter. Laser photocoagulation appears to be effective ($p = 0.0217$) in delaying the occurrence of blindness, although there is also a significant interaction effect between treatment and type of diabetes ($p = 0.0053$).

Output 67.11.2 Inference Based the Marginal Model

The PHREG Procedure						
Analysis of Maximum Likelihood Estimates						
Parameter		DF	Parameter Estimate	Standard Error	StdErr Ratio	Chi-Square
Treat	Laser	1	-0.42467	0.18497	0.850	5.2713
Type	Adult	1	0.34084	0.19558	0.982	3.0371
Treat*Type	Laser Adult	1	-0.84566	0.30353	0.865	7.7622
Analysis of Maximum Likelihood Estimates						
Parameter		Pr > ChiSq	Hazard Ratio	Label		
Treat	Laser	0.0217	.	Treat Laser		
Type	Adult	0.0814	.	Type Adult		
Treat*Type	Laser Adult	0.0053	.	Treat Laser * Type Adult		

Hazard ratio estimates of the laser treatment relative to nonlaser treatment are displayed in [Output 67.11.3](#). For both types of diabetes, the 95% confidence interval for the hazard ratio lies below 1. This indicates that laser-photocoagulation treatment is more effective in delaying blindness regardless of the type of diabetes. However, the effect is more prominent for adult-onset diabetes than for juvenile-onset diabetes since the hazard ratio estimates for the former are less than those of the latter.

Output 67.11.3 Hazard Ratio Estimates for Marginal Model

Marginal Model Analysis: Hazard Ratios for Treat			
Description	Point Estimate	95% Wald Robust Confidence Limits	
Treat Laser vs Others At Type=Adult	0.281	0.175	0.451
Treat Laser vs Others At Type=Juvenile	0.654	0.455	0.940

Next, you analyze the same data by using a shared frailty model. The following statements use PROC PHREG to fit a shared frailty model to the Blind data set. The RANDOM statement identifies the variable ID as the variable that represents the clusters. You must declare the cluster variable as a classification variable in the CLASS statement.

```
proc phreg data=Blind;
  class ID Treat Type;
  model Time*Status(0)=Treat|Type;
  random ID;
  hazardratio 'Frailty Model Analysis' Treat;
run;
```

Selected results of this analysis are displayed in [Output 67.11.4](#) to [Output 67.11.6](#).

The “Random Class Level Information” table in [Output 67.11.4](#) displays the 197 ID values of the patients. You can suppress the display of this table by using the NOCLPRINT option in the RANDOM statement.

Output 67.11.4 Unique Cluster Identification Values

The PHREG Procedure

Example 67.12: Model Assessment Using Cumulative Sums of Martingale Residuals

The Mayo liver disease example of Lin, Wei, and Ying (1993) is reproduced here to illustrate the checking of the functional form of a covariate and the assessment of the proportional hazards assumption. The data represent 418 patients with primary biliary cirrhosis (PBC), among whom 161 had died as of the date of data listing. A subset of the variables is saved in the SAS data set Liver. The data set contains the following variables:

- Time, follow-up time, in years
- Status, event indicator with value 1 for death time and value 0 for censored time
- Age, age in years from birth to study registration
- Albumin, serum albumin level, in gm/dl
- Bilirubin, serum bilirubin level, in mg/dl
- Edema, edema presence
- Protime, prothrombin time, in seconds

The following statements create the data set Liver:

```
data Liver;
  input Time Status Age Albumin Bilirubin Edema Protime @@;
  label Time="Follow-up Time in Years";

Consider fitting a Cox model for the survival time of the PCB patients with the covariates Bilirubin, log(Protime), log(Albumin), Age, and Edema. The log transform, which is often applied to blood chemistry measurements, is deliberately not employed for Bilirubin. It is of interest to assess the functional form of the variable Bilirubin in the Cox model. The specifications are as follows:

```
ods graphics on;
proc phreg data=Liver;
  model Time*Status(0)=Bilirubin logProtime logAlbumin Age Edema;
  logProtime=log(Protime);
  logAlbumin=log(Albumin);
  assess var=(Bilirubin) / resample seed=7548;
run;
```

The ASSESS statement creates a plot of the cumulative martingale residuals against the values of the covariate Bilirubin, which is specified in the VAR= option. The RESAMPLE option computes the p -value of a Kolmogorov-type supremum test based on a sample of 1,000 simulated residual patterns.

Parameter estimates of the model fit are shown in [Output 67.12.1](#). The plot in [Output 67.12.2](#) displays the observed cumulative martingale residual process for Bilirubin together with 20 simulated realizations from the null distribution. When ODS Graphics is enabled, this graphical display is requested by specifying the ASSESS statement. It is obvious that the observed process is atypical compared to the simulated realizations. Also, none of the 1,000 simulated realizations has an absolute maximum exceeding that of the observed cumulative martingale residual process. Both the graphical and numerical results indicate that a transform is deemed necessary for Bilirubin in the model.

Output 67.12.1 Cox Model with Bilirubin as a Covariate

The PHREG Procedure						
Analysis of Maximum Likelihood Estimates						
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
Bilirubin	1	0.11733	0.01298	81.7567	<.0001	1.124
logProtime	1	2.77581	0.71482	15.0794	0.0001	16.052
logAlbumin	1	-3.17195	0.62945	25.3939	<.0001	0.042
Age	1	0.03779	0.00805	22.0288	<.0001	1.039
Edema	1	0.84772	0.28125	9.0850	0.0026	2.334

Output 67.12.2 Cumulative Martingale Residuals vs Bilirubin

The cumulative martingale residual plots in [Output 67.12.3](#) provide guidance in suggesting a more appropriate functional form for a covariate. The four curves were created from simple forms of misspecification by using 10,000 simulated times from a exponential model with 20% censoring. The true and fitted models are shown in [Table 67.17](#). The following statements produce [Output 67.12.3](#).

[illegible]

```

        x1 = 1 + ( x1 - 1 ) / 10;

Output 67.12.3 Typical Cumulative Residual Plot Patterns**Table 67.17** Model Misspecifications

Plot	Data	Fitted Model
(a)	$\log(X)$	X
(b)	$\{X, X^2\}$	X
(c)	$\{X, X^2, X^3\}$	$\{X, X^2\}$
(d)	$I(X > 5)$	X

The curve of observed cumulative martingale residuals in [Output 67.12.2](#) most resembles the behavior of the curve in plot (a) of [Output 67.12.3](#), indicating that $\log(\text{Bilirubin})$ might be a more appropriate term in the model than Bilirubin.

Next, the analysis of the natural history of the PBC is repeated with $\log(\text{Bilirubin})$ replacing Bilirubin, and the functional form of $\log(\text{Bilirubin})$ is assessed. Also assessed is the proportional hazards assumption for the Cox model. The analysis is carried out by the following statements:

```

proc phreg data=Liver;
  model Time*Status(0)=logBilirubin logProtime logAlbumin Age Edema;
  logBilirubin=log(Bilirubin);
  logProtime=log(Protime);
  logAlbumin=log(Albumin);
  assess var=(logBilirubin) ph / crpanel resample seed=19;
run;
ods graphics off;

```

The SEED= option specifies a integer seed for generating random numbers. The CRPANEL option in the ASSESS statement requests a panel of four plots. Each plot displays the observed cumulative martingale residual process along with two simulated realizations. The PH option checks the proportional hazards assumption of the model by plotting the observed standardized score process with 20 simulated realizations for each covariate in the model.

Output 67.12.4 displays the parameter estimates of the fitted model. The cumulative martingale residual plots in Output 67.12.5 and Output 67.12.6 show that the observed martingale residual process is more typical of the simulated realizations. The *p*-value for the Kolmogorov-type supremum test based on 1,000 simulations is 0.052, indicating that the log transform is a much improved functional form for Bilirubin.

Output 67.12.4 Model with log(Bilirubin) as a Covariate

The PHREG Procedure						
Analysis of Maximum Likelihood Estimates						
Parameter	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
logBilirubin	1	0.87072	0.08263	111.0484	<.0001	2.389
logProtime	1	2.37789	0.76674	9.6181	0.0019	10.782
logAlbumin	1	-2.53264	0.64819	15.2664	<.0001	0.079
Age	1	0.03940	0.00765	26.5306	<.0001	1.040
Edema	1	0.85934	0.27114	10.0447	0.0015	2.362

Output 67.12.5 Panel Plot of Cumulative Martingale Residuals versus $\log(\text{Bilirubin})$

Output 67.12.6 Cumulative Martingale Residuals versus log(Bilirubin)

Output 67.12.7 and Output 67.12.8 display the results of proportional hazards assumption assessment for log(Bilirubin) and log(Protime), respectively. The latter plot reveals nonproportional hazards for log(Protime).

Output 67.12.7 Standardized Score Process for log(Bilirubin)

[

Output 67.12.8 Standardized Score Process for log(Protime)

Plots for log(Albumin), Age, and Edema are not shown here. The Kolmogorov-type supremum test results for all the covariates are shown in [Output 67.12.9](#). In addition to log(Protime), the proportional hazards assumption appears to be violated for Edema.

Output 67.12.9 Kolmogorov-Type Supremum Tests for Proportional Hazards Assumption

Supremum Test for Proportionals Hazards Assumption				
Variable	Maximum Absolute Value	Replications	Seed	Pr > MaxAbsVal
logBilirubin	1.0880	1000	19	0.1450

Edema	1.4350	1000	19	0.0330

Example 67.13: Bayesian Analysis of the Cox Model

This example illustrates the use of an informative prior. Hazard ratios, which are transformations of the regression parameters, are useful for interpreting survival models. This example also demonstrates the use of the HAZARDRATIO statement to obtain customized hazard ratios.

Consider the VALung data set in [Example 67.3](#). In this example, the Cox model is used for the Bayesian analysis. The parameters are the coefficients of the continuous explanatory variables (Kps, Duration, and Age) and the coefficients of the design variables for the categorical explanatory variables (Prior, Cell, and Therapy). You use the CLASS statement in PROC PHREG to specify the categorical variables and their reference levels. Using the default reference parameterization, the design variables for the categorical variables are Prioryes (for Prior with Prior='no' as reference), Celladeno, Cellsmall, Cellsquamous (for Cell with Cell='large' as reference), and Therapytest (for Therapy='standard' as reference).

Consider the explanatory variable Kps. The Karnofsky performance scale index enables patients to be classified according to their functional impairment. The scale can range from 0 to 100—0 for dead, and 100 for a normal, healthy person with no evidence of disease. Recall that a flat prior was used for the regression coefficient in the example in the section “[Bayesian Analysis](#)” on page 5547. A flat prior on the Kps coefficient implies that the coefficient is as likely to be 0.1 as it is to be -100000 . A coefficient of -5 means that a decrease of 20 points in the scale increases the hazard by $e^{-20 \times -5} (=2.68 \times 10^{43})$ -fold, which is a rather unreasonable and unrealistic expectation for the effect of the Karnofsky index, much less than the value of -100000 . Suppose you have a more realistic expectation: the effect is somewhat small and is more likely to be negative than positive, and a decrease of 20 points in the Karnofsky index will change the hazard from 0.9-fold (some minor positive effect) to 4-fold (a large negative effect). You can convert this opinion to a more informative prior on the Kps coefficient β_1 . Mathematically,

$$0.9 < e^{-20\beta_1} < 4$$

which is equivalent to

$$-0.0693 < \beta_1 < 0.0053$$

This becomes the plausible range that you believe the Kps coefficient can take. Now you can find a normal distribution that best approximates this belief by placing the majority of the prior distribution mass within this range. Assuming this interval is $\mu \pm 2\sigma$, where μ and σ are the mean and standard deviation of the normal prior, respectively, the hyperparameters μ and σ are computed as follows:

$$\begin{aligned}\mu &= \frac{-0.0693 + 0.0053}{2} = -0.032 \\ \sigma &= \frac{0.0053 - (-0.0693)}{4} = 0.0186\end{aligned}$$

Note that a normal prior distribution with mean -0.0320 and standard deviation 0.0186 indicates that you believe, before looking at the data, that a decrease of 20 points in the Karnofsky index will probably change the hazard rate by 0.9-fold to 4-fold. This does not rule out the possibility that the Kps coefficient can take a more extreme value such as -5 , but the probability of having such extreme values is very small.

Assume the prior distributions are independent for all the parameters. For the coefficient of Kps, you use a normal prior distribution with mean -0.0320 and variance $0.0186^2 (=0.00035)$. For other parameters, you resort to using a normal prior distribution with mean 0 and variance $1E6$, which is fairly noninformative. Means and variances of these independent normal distributions are saved in the data set Prior as follows:

```

In the following BAYES statement, COEFFPRIOR=NORMAL(INPUT=Prior) specifies the normal prior distribution for the regression coefficients with details contained in the data set Prior. Summary statistics of the posterior distribution are produced by default. Autocorrelations and effective sample size are requested as convergence diagnostics as well as the trace plots for visual analysis. For comparisons of hazards, three HAZARDRATIO statements are specified—one for the variable Therapy, one for the variable Age, and one for the variable Cell.

```

ods graphics on;

PROC PHREG computes the maximum likelihood estimates of regression parameters (Output 67.13.3). These estimates are used as the starting values for the simulation of posterior samples.

Output 67.13.3 Parameter Estimates

Maximum Likelihood Estimates					
Parameter	DF	Estimate	Standard Error	95% Confidence Limits	
Kps	1	-0.0326	0.00551	-0.0434	-0.0218
Duration	1	-0.00009	0.00913	-0.0180	0.0178
Age	1	-0.00855	0.00930	-0.0268	0.00969

The first HAZARDRATIO statement compares the hazards between the standard therapy and the test therapy. Summaries of the posterior distribution of the corresponding hazard ratio are shown in [Output 67.13.11](#). There is a 95% chance that the hazard ratio of standard therapy versus test therapy lies between 0.5 and 1.1.

Output 67.13.11 Hazard Ratio for Treatment

Hazard Ratio Statement 1: Hazard Ratios for Therapy						
Description			N	Mean	Standard Deviation	
Therapy standard vs test			10000	0.7645	0.1573	
Hazard Ratio Statement 1: Hazard Ratios for Therapy						
Quantiles			95% Equal-Tail Interval		95% HPD Interval	
25%	50%	75%				
0.6544	0.7488	0.8583	0.5001	1.1143	0.4788	1.0805

The second HAZARDRATIO statement assesses the change of hazards for an increase in Age of 10 years. Summaries of the posterior distribution of the corresponding hazard ratio are shown in [Output 67.13.12](#).

Output 67.13.12 Hazard Ratio for Age

Hazard Ratio Statement 2: Hazard Ratios for Age						
Description	N	Mean	Standard Deviation	25%	Quantiles 50%	75%
Age Unit=10	10000	0.9230	0.0859	0.8635	0.9195	0.9782
Hazard Ratio Statement 2: Hazard Ratios for Age

Example 67.14: Bayesian Analysis of Piecewise Exponential Model

This example illustrates using a piecewise exponential model in a Bayesian analysis. Consider the Rats data set in the section “[Getting Started: PHREG Procedure](#)” on page 5543. In the following statements, PROC PHREG is used to carry out a Bayesian analysis for the piecewise exponential model. In the BAYES statement, the option `PIECEWISE` stipulates a piecewise exponential model, and `PIECEWISE=HAZARD` requests that the constant hazards be modeled in the original scale. By default, eight intervals of constant hazards are used, and the intervals are chosen such that each has roughly the same number of events.

```
data Rats;
  label Days  ='Days from Exposure to Death';
  input Days Status Group @@;
  datalines;
143 1 0   164 1 0   188 1 0   188 1 0
190 1 0   192 1 0   206 1 0   209 1 0
213 1 0   216 1 0   220 1 0   227 1 0
230 1 0   234 1 0   246 1 0   265 1 0
304 1 0   216 0 0   244 0 0   142 1 1
156 1 1   163 1 1   198 1 1   205 1 1
232 1 1   232 1 1   233 1 1   233 1 1
233 1 1   233 1 1   239 1 1   240 1 1
261 1 1   280 1 1   280 1 1   296 1 1
296 1 1   323 1 1   204 0 1   344 0 1
;

proc phreg data=Rats;
  model Days*Status(0)=Group;
  bayes seed=1 piecewise=hazard;
run;
```

The “Model Information” table in [Output 67.14.1](#) shows that the piecewise exponential model is being used.

Output 67.14.1 Model Information

The PHREG Procedure		
Bayesian Analysis		
Model Information		
Data Set	WORK.RATS	
Dependent Variable	Days	Days from Exposure to Death
Censoring Variable	Status	
Censoring Value(s)	0	
Model	Piecewise Exponential	
Sampling Algorithm	ARMS	
Burn-In Size	2000	
MC Sample Size	10000	
Thinning	1	

By default the time axis is partitioned into eight intervals of constant hazard. [Output 67.14.2](#) details the number of events and observations in each interval. Note that the constant hazard parameters are named Lambda1, ..., Lambda8. You can supply your own partition by using the INTERVALS= suboption within the PIECEWISE=HAZARD option.

Output 67.14.2 Interval Partition

Constant Hazard Time Intervals				
Interval [Lower, Upper)		N	Event	Hazard Parameter
0	176	5	5	Lambda1
176	201.5	5	5	Lambda2
201.5	218	7	5	Lambda3
218	232.5	5	5	Lambda4
232.5	233.5	4	4	Lambda5
233.5	253.5	5	4	Lambda6
253.5	288	4	4	Lambda7
288	Infty	5	4	Lambda8

The model parameters consist of the eight hazard parameters Lambda1, ..., Lambda8, and the regression coefficient Group. The maximum likelihood estimates are displayed in [Output 67.14.3](#). Again, these estimates are used as the starting values for simulation of the posterior distribution.

Output 67.14.3 Maximum Likelihood Estimates

Maximum Likelihood Estimates					
Parameter	DF	Estimate	Standard Error	95% Confidence Limits	
Lambda1	1	0.000953	0.000443	0.000084	0.00182
Lambda2	1	0.00794	0.00371	0.000672	0.0152
Lambda3	1	0.0156	0.00734	0.00120	0.0300
Lambda4	1	0.0236	0.0115	0.00112	0.0461
Lambda5	1	0.3669	0.1959	-0.0172	0.7509
Lambda6	1	0.0276	0.0148	-0.00143	0.0566
Lambda7	1	0.0262	0.0146	-0.00233	0.0548
Lambda8	1	0.0545	0.0310	-0.00626	0.1152
Group	1	-0.6223	0.3468	-1.3020	0.0573

Without using the PRIOR= suboption within the PIECEWISE=HAZARD option to specify the prior of the hazard parameters, the default is to use the noninformative and improper prior displayed in [Output 67.14.4](#).

Output 67.14.4 Hazard Prior

Improper Prior for Hazards	
Parameter	Prior
Lambda1	1 / Lambda1
Lambda2	1 / Lambda2
Lambda3	1 / Lambda3
Lambda4	1 / Lambda4
Lambda5	1 / Lambda5
Lambda6	1 / Lambda6
Lambda7	1 / Lambda7
Lambda8	1 / Lambda8

The noninformative uniform prior is used for the regression coefficient Group ([Output 67.14.5](#)), as in the section “[Bayesian Analysis](#)” on page 5547.

Output 67.14.5 Coefficient Prior

Uniform Prior for Regression Coefficients	
Parameter	Prior
Group	Constant

Summary statistics for all model parameters are shown in [Output 67.14.6](#) and [Output 67.14.7](#).

Output 67.14.6 Summary Statistics

Overview: PLAN Procedure

The PLAN procedure constructs designs and randomizes plans for factorial experiments, especially nested and crossed experiments and randomized block designs. PROC PLAN can also be used for generating lists of permutations and combinations of numbers. The PLAN procedure can construct the following types of experimental designs:

- full factorial designs, with and without randomization
- certain balanced and partially balanced incomplete block designs
- generalized cyclic incomplete block designs
- Latin square designs

For other kinds of experimental designs, especially fractional factorial, response surface, and orthogonal array designs, see the FACTEX and OPTTEX procedures and the ADX Interface in SAS/QC software.

PROC PLAN generates designs by first generating a selection of the levels for the first factor. Then, for the second factor, PROC PLAN generates a selection of its levels for each level of the first factor. In general, for a given factor, the PLAN procedure generates a selection of its levels for all combinations of levels for the factors that precede it.

The selection can be done in five different ways:

- randomized selection, for which the levels are returned in a random order
- ordered selection, for which the levels are returned in a standard order every time a selection is generated
- cyclic selection, for which the levels returned are computed by cyclically permuting the levels of the previous selection
- permuted selection, for which the levels are a permutation of the integers $1, \dots, n$
- combination selection, for which the m levels are selected as a combination of the integers $1, \dots, n$ taken m at a time

The randomized selection method can be used to generate randomized plans. Also, by appropriate use of cyclic selection, any of the designs in the very wide class of generalized cyclic block designs (Jarrett and Hall 1978) can be generated.

There is no limit to the depth to which the different factors can be nested, and any number of randomized plans can be generated.

You can also declare a list of factors to be selected simultaneously with the lowest (that is, the most nested) factor. The levels of the factors in this list can be seen as constituting the treatment to be applied to the cells of the design. For this reason, factors in this list are called *treatments*. With this list, you can generate and randomize plans in one run of PROC PLAN.

Getting Started: PLAN Procedure

Three Replications with Four Factors

Suppose you want to determine if the order in which four drugs are given affects the response of a subject. If you have only three subjects to test, you can use the following statements to design the experiment.

```
proc plan seed=27371;
  factors Replicate=3 ordered Drug=4;
run;
```

These statements produce a design with three replicates of the four levels of the factor Drug arranged in random order. The three levels of Replicate are arranged in order, as shown in [Figure 68.1](#).

Figure 68.1 Three Replications and Four Factors

The PLAN Procedure			
Factor	Select	Levels	Order
Replicate	3	3	Ordered
Drug	4	4	Random
Replicate --Drug--			
	1	3 2 4 1	
	2	1 2 4 3	
	3	4 1 2 3	

You might also want to apply one of four different treatments to each cell of this plan (for example, applying different amounts of each drug). The following additional statements create the output shown in [Figure 68.2](#):

```
  factors Replicate=3 ordered Drug=4;
  treatments Treatment=4;
run;
```

Figure 68.2 Using the TREATMENTS Statement

The PLAN Procedure			
Plot Factors			
Factor	Select	Levels	Order
Replicate	3	3	Ordered
Drug	4	4	Random
Treatment Factors			
Factor	Select	Levels	Order
Treatment	4	4	Random

Figure 68.2 *continued*

Replicate	--Drug--	--Treatment--			
1	3 1 2 4	2	1	3	4
2	4 3 2 1	4	1	2	3
3	3 2 4 1	1	4	2	3

Randomly Assigning Subjects to Treatments

You can use the PLAN procedure to design a completely randomized design. Suppose you have 12 experimental units, and you want to assign one of two treatments to each unit. Use a DATA step to store the unrandomized design in a SAS data set, and then call PROC PLAN to randomize it by specifying one factor with the default type of RANDOM, having 12 levels. The following statements produce Figure 68.3 and Figure 68.4:

```

title 'Completely Randomized Design';
/* The unrandomized design */

data Unrandomized;
  do Unit=1 to 12;
    if (Unit <= 6) then Treatment=1;
    else               Treatment=2;
    output;
  end;
run;

/* Randomize the design */

proc plan seed=27371;
  factors Unit=12;
  output data=Unrandomized out=Randomized;
run;

proc sort data=Randomized;
  by Unit;
run;
proc print;
run;

```

Figure 68.3 shows that the 12 levels of the unit factor have been randomly reordered and then lists the new ordering.

Figure 68.3 A Completely Randomized Design for Two Treatments

Completely Randomized Design			
The PLAN Procedure			
Factor	Select	Levels	Order
Unit	12	12	Random
-----Unit-----			
8	5	1	4
6	2	12	7
3	9	10	11

After the data set is sorted by the unit variable, the randomized design is displayed (Figure 68.4).

Figure 68.4 A Completely Randomized Design for Two Treatments

Completely Randomized Design		
Obs	Unit	Treatment
1	1	1
2	2	1
3	3	2
4	4	1
5	5	1
6	6	1
7	7	2
8	8	1
9	9	2
10	10	2
11	11	2
12	12	2

You can also generate the plan by using a **TREATMENTS** statement instead of a DATA step. The following statements generate the same plan.

```
proc plan seed=27371;
  factors Unit=12;
  treatments Treatment=12 cyclic (1 1 1 1 1 1 2 2 2 2 2 2);
  output out=Randomized;
run;
```

Syntax: PLAN Procedure

The following statements are available in the PLAN procedure:

```
PROC PLAN < options > ;
FACTORS factor-selections < / NOPRINT > ;
OUTPUT OUT=SAS-data-set < factor-value-settings > ;
TREATMENTS factor-selections ;
```

To use PROC PLAN, you need to specify the **PROC PLAN** statement and at least one **FACTORS** statement before the first RUN statement. The **TREATMENTS** statement, **OUTPUT** statement, and additional **FACTORS** statements can appear either before the first RUN statement or after it.

The rest of this section gives detailed syntax information for each of the statements, beginning with the **PROC PLAN** statement. The remaining statements are described in alphabetical order.

You can use PROC PLAN interactively by specifying multiple groups of statements, separated by RUN statements. For details, see the section “Using PROC PLAN Interactively” on page 5782.

PROC PLAN Statement

```
PROC PLAN < options > ;
```

The PROC PLAN statement invokes the PLAN procedure. Optionally, you can also specify a random number seed or a default method for selecting levels of factors. By default, the procedure uses a random number seed generated from reading the time of day from the computer’s clock and randomly selects levels of factors. These defaults can be modified with the **SEED=** and **ORDERED** options, respectively. Unlike many SAS/STAT procedures, the PLAN procedure does not have a **DATA=** option in the PROC PLAN statement; in this procedure, both the input and output data sets are specified in the **OUTPUT** statement.

Table 68.1 summarizes the options available in the PROC PLAN statement.

Table 68.1 PROC PLAN Statement Options

Option	Description
ORDERED	Selects the levels of the factor as the integers 1, 2, . . . , m , in order
SEED=	Specifies an integer used to start the pseudo-random number generator

You can specify the following options in the PROC PLAN statement:

ORDERED

selects the levels of the factor as the integers 1, 2, . . . , m , in order. For more detail, see “[Selection-Types](#)” on page 5777 and “[Specifying Factor Structures](#)” on page 5784.

SEED=number

specifies an integer used to start the pseudo-random number generator for selecting factor levels randomly. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer’s clock.

FACTORS Statement

FACTORS *factor-selections* </ **NOPRINT** > ;

The FACTORS statement specifies the factors of the plan and generates the plan. Taken together, the *factor-selections* specify the plan to be generated; more than one *factor-selection* request can be used in a FACTORS statement. The form of a *factor-selection* is

name = *m* < **OF** *n* > < *selection-type* > ;

where

<i>name</i>	is a valid SAS name. This gives the name of a factor in the design.
<i>m</i>	is a positive integer that gives the number of values to be selected. If <i>n</i> is specified, the value of <i>m</i> must be less than or equal to <i>n</i> .
<i>n</i>	is a positive integer that gives the number of values to be selected from.
<i>selection-type</i>	specifies one of five methods for selecting <i>m</i> values. Possible values are COMB, CYCLIC, ORDERED, PERM, and RANDOM. The CYCLIC <i>selection-type</i> has additional optional specifications that enable you to specify an initial block of numbers to be cyclically permuted and an increment used to permute the numbers. By default, the <i>selection-type</i> is RANDOM, unless you use the ORDERED option in the PROC PLAN statement. In this case, the default <i>selection-type</i> is ORDERED. For details, see the following section, “ Selection-Types ”; for examples, see the section “ Syntax Examples ” on page 5778.

The following option can appear in the FACTORS statement after the slash:

NOPRINT

suppresses the display of the plan. This is particularly useful when you require only an output data set. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

Selection-Types

PROC PLAN interprets *selection-type* as follows:

RANDOM	selects the <i>m</i> levels of the factor randomly without replacement from the integers 1, 2, . . . , <i>n</i> . Or, if <i>n</i> is not specified, RANDOM selects levels by randomly ordering the integers 1, 2, . . . , <i>m</i> .
ORDERED	selects the levels of the factor as the integers 1, 2, . . . , <i>m</i> , in that order.
PERM	selects the <i>m</i> levels of the factor as a permutation of the integers 1, . . . , <i>m</i> according to an algorithm that cycles through all <i>m</i> ! permutations. The permutations are produced in a sorted standard order; see Example 68.6 .
COMB	selects the <i>m</i> levels of the factor as a combination of the integers 1, . . . , <i>n</i> taken <i>m</i> at a time, according to an algorithm that cycles through all $n!/(m!(n - m)!)$ combinations. The combinations are produced in a sorted standard order; see Example 68.6 .

CYCLIC *<(initial-block)>* *<increment>* selects the levels of the factor by cyclically permuting the integers $1, 2, \dots, n$. Wrapping occurs at m if n is not specified, and at n if n is specified. Additional optional specifications are as follows.

With the *selection-type* CYCLIC, you can optionally specify an *initial-block* and an *increment*. The *Argument* *initial-block* must be specified within parentheses, and it specifies the block of numbers to permute. The first permutation is the block you specify, the second is the block permuted by 1 (or by the *increment* you specify), and so on. By default, the *initial-block* is the integers $1, 2, \dots, m$. If you specify an *initial-block*, it must have m values. Values specified in the *initial-block* do not have to be given in increasing order.

The *increment* specifies the increment by which to permute the block of numbers. By default, the *increment* is 1.

Syntax Examples

This section gives some simple syntax examples. For more complex examples and details on how to generate various designs, see “[Specifying Factor Structures](#)” on page 5784. The examples in this section assume that you use the default random selection method and do not use the **ORDERED** option in the **PROC PLAN** statement.

The following specification generates a random permutation of the numbers 1, 2, 3, 4, and 5.

```
factors A=5;
```

The following specification generates a random permutation of five of the integers from 1 to 8, selected without replacement.

```
factors A=5 of 8;
```

Adding the **ORDERED** *selection-type* to the two previous specifications generates an ordered list of the integers 1 to 5. The following specification cyclically permutes the integers 1, 2, 3, and 4.

```
factors A=4 cyclic;
```

Since this simple request generates only one permutation of the numbers, the procedure generates an ordered list of the integers 1 to 4. The following specification cyclically permutes the integers 5 to 8.

```
factors A=4 of 8 cyclic (5 6 7 8);
```

In this case, since only one permutation is performed, the procedure generates an ordered list of the integers 5 to 8. The following specification produces an ordered list for A, with values 1 and 2.

```
factors A=2 ordered B=4 of 8 cyclic (5 6 7 8) 2;
```

The associated factor levels for B are 5, 6, 7, 8 for level 1 of A, and 7, 8, 1, 2 for level 2 of A.

Handling More Than One Factor-Selection

For cases with more than one *factor-selection* in the same **FACTORS** statement, **PROC PLAN** constructs the design as follows:

1. **PROC PLAN** first generates levels for the first *factor-selection*. These levels are permutations of integers (1, 2, and so on) appropriate for the selection type chosen. If you do not specify a selection

type, PROC PLAN uses the default (RANDOM); if you specify the **ORDERED** option in the **PROC PLAN** statement, the procedure uses **ORDERED** as the default selection type.

2. For every integer generated for the first *factor-selection*, levels are generated for the second *factor-selection*. These levels are generated according to the specifications following the second equal sign.
3. This process is repeated until levels for all *factor-selections* have been generated.

The following statements give an example of generating a design with two random factors:

```
proc plan;
  factors One=4 Two=3;
run;
```

The procedure first generates a random permutation of the integers 1 to 4 and then, for each of these, generates a random permutation of the integers 1 to 3. You can think of factor Two as being nested within factor One, where the levels of factor One are to be randomly assigned to 4 units.

As another example, six random permutations of the numbers 1, 2, 3 can be generated by specifying the following statements:

```
proc plan;
  factors a=6 ordered b=3;
run;
```

OUTPUT Statement

OUTPUT **OUT=SAS-data-set** < **DATA=SAS-data-set** > < *factor-value-settings* > ;

The OUTPUT statement applies only to the last plan generated. If you use PROC PLAN interactively, the OUTPUT statement for a given plan must be immediately preceded by the **FACTORS** statement (and the **TREATMENTS** statement, if appropriate) for the plan.

See “[Output Data Sets](#)” on page 5783 for more information about how output data sets are constructed.

You can specify the following options in the OUTPUT statement:

OUT=SAS-data-set

DATA=SAS-data-set

You can use the OUTPUT statement both to output the last plan generated and to use the last plan generated to randomize another SAS data set.

When you specify only the OUT= option in the OUTPUT statement, PROC PLAN saves the last plan generated to the specified data set. The output data set contains one variable for each factor in the plan and one observation for each cell in the plan. The value of a variable in a given observation is the level of the corresponding factor for that cell. The OUT= option is required.

When you specify both the DATA= and OUT= options in the OUTPUT statement, then PROC PLAN uses the last plan generated to randomize the input data set (DATA=), saving the results to the output data set (OUT=). The output data set has the same form as the input data set but has modified values for the variables that correspond to factors (see the section “[Output Data Sets](#)” on page 5783 for details). Values for variables not corresponding to factors are transferred without change.

factor-value-settings

specify the values input or output for the factors in the design. The form for *factor-value-settings* is different when only an OUT= data set is specified and when both OUT= and DATA= data sets are specified.

Both forms are discussed in the following section.

Factor-Value-Settings with Only an OUT= Data Set

When you specify only an OUT= data set, the form for each *factor-value-setting* specification is one of the following:

factor-name < **NVALS**=*list-of-n-numbers* > < **ORDERED** | **RANDOM** > ;

or

factor-name < **CVALS**=*list-of-n-strings* > < **ORDERED** | **RANDOM** > ;

where

- factor-name* is a factor in the last **FACTORS** statement preceding the OUTPUT statement.
- NVALS=** lists *n* numeric values for the factor. By default, the procedure uses NVALS=(1 2 3 \cdots *n*).
- CVALS=** lists *n* character strings for the factor. Each string can have up to 40 characters, and each string must be enclosed in quotes. **CAUTION:** When you use the CVALS= option, the variable created in the output data set has a length equal to the length of the longest string given as a value; shorter strings are padded with trailing blanks. For example, the values output for the first level of a two-level factor with the following two different specifications are not the same.

```
CVALS=('String 1' "String 2")
```

```
CVALS=('String 1' "A longer string")
```

The value output with the second specification is 'String 1' followed by seven blanks. In order to match two such values (for example, when merging two plans), you must use the TRIM function in the DATA step (see *SAS Functions and CALL Routines: Reference*).

ORDERED | RANDOM specifies how values (those given with the NVALS= or CVALS= option, or the default values) are associated with the levels of a factor (the integers 1, 2, \dots , *n*). The default association type is ORDERED, for which the first value specified is output for a factor level setting of 1, the second value specified is output for a level of 2, and so on. You can also specify an association type of RANDOM, for which the levels are associated with the values in a random order. Specifying RANDOM is useful for randomizing crossed experiments (see the section “[Randomizing Designs](#)” on page 5786).

The following statements give an example of using the OUTPUT statement with only an OUT= data set and with both the NVALS= and CVALS= specifications.

```
proc plan;
  factors a=6 ordered b=3;
  output out=design a nvals=(10 to 60 by 10)
           b cvals=('HSX' 'SB2' 'DNY');
run;
```

The DESIGN data set contains two variables, a and b. The values of the variable a are 10 when factor a equals 1, 20 when factor a equals 2, and so on. Values of the variable b are 'HSX' when factor b equals 1, 'SB2' when factor b equals 2, and 'DNY' when factor b equals 3.

Factor-Value-Settings with OUT= and DATA= Data Sets

If you specify an input data set with **DATA=**, then PROC PLAN assumes that each factor in the last plan generated corresponds to a variable in the input set. If the variable name is different from the name of the factor to which it corresponds, the two can be associated in the values specification by

input-variable-name = factor-name ;

Then, the **NVALS=** or **CVALS=** specification can be used. The values given by **NVALS=** or **CVALS=** specify the input values as well as the output values for the corresponding variable.

Since the procedure assumes that the collection of input factor values constitutes a plan position description (see the section “[Output Data Sets](#)” on page 5783), the values must correspond to integers less than or equal to *m*, the number of values selected for the associated factor. If any input values do not correspond, then the collection does not define a plan position, and the corresponding observation is output without changing the values of any of the factor variables.

The following statements demonstrate the use of *factor-value-settings*. The input SAS data set a contains variables Block and Plot, which are renamed Day and Hour, respectively.

```
proc plan;
  factors Day=7 Hour=6;
  output data=a out=b
    Block = Day cvals=('Mon' 'Tue' 'Wed' 'Thu'
                      'Fri' 'Sat' 'Sun'      )
    Plot  = Hour;
run;
```

For another example of using both a **DATA=** and **OUT=** data set, see the section “[Randomly Assigning Subjects to Treatments](#)” on page 5774.

TREATMENTS Statement

TREATMENTS *factor-selections ;*

The TREATMENTS statement specifies the treatments of the plan to generate, but it does not generate a plan. If you supply several **FACTORS** and TREATMENTS statements before the first RUN statement, the procedure uses only the last TREATMENTS specification and applies it to the plans that are generated by each of the **FACTORS** statements. The TREATMENTS statement must follow a **FACTORS** statement. The TREATMENTS statement has the same syntax as the **FACTORS** statement. The individual *factor-selections* also have the same form as in the **FACTORS** statement:

`name = m <OF n> <selection-type> ;`

The procedure generates each treatment simultaneously with the lowest (that is, the most nested) factor in the last **FACTORS** statement. The *m* value for each treatment must be at least as large as the *m* for the most nested factor.

The following statements use both a **FACTORS** and a **TREATMENTS** statement. First the **FACTORS** statement sets up the rows and columns of a 3 × 3 square (factors *r* and *c*). Then, the **TREATMENTS** statement augments the square with two cyclic treatments. The resulting design is a 3 × 3 Graeco-Latin square, a type of design useful in main-effects factorial experiments.

```
proc plan;
  factors r=3 ordered c=3 ordered;
  treatments a=3 cyclic
            b=3 cyclic 2;
run;
```

The resulting Graeco-Latin square design is shown in [Figure 68.5](#). Notice how the values of *r* and *c* are ordered (1, 2, 3) as requested.

Figure 68.5 A 3 × 3 Graeco-Latin Square

The PLAN Procedure

Details: PLAN Procedure

Using PROC PLAN Interactively

After specifying a design with a **FACTORS** statement and running PROC PLAN with a **RUN** statement, you can generate additional plans and output data sets without invoking PROC PLAN again.

In PROC PLAN, all statements can be used interactively. You can execute statements singly or in groups by following the single statement or group of statements with a **RUN** statement.

If you use PROC PLAN interactively, you can end the procedure with a **DATA** step, another **PROC** step, an **ENDSAS** statement, or a **QUIT** statement. The syntax of the **QUIT** statement is

```
quit;
```

When you use PROC PLAN interactively, additional **RUN** statements do not end the procedure but tell PROC PLAN to execute additional statements.

Output Data Sets

To understand how PROC PLAN creates output data sets, you need to look at how the procedure represents a plan. A plan is a list of values for all the factors, the values being chosen according to the *factor-selection* requests you specify. For example, consider the plan produced by the following statements:

```
proc plan seed=12345;
  factors a=3 b=2;
run;
```

The plan as displayed by PROC PLAN is shown in [Figure 68.6](#).

Figure 68.6 A Simple Plan

The PLAN Procedure			
Factor	Select	Levels	Order
a	3	3	Random
b	2	2	Random
a -b-			
	2	2 1	
	1	1 2	
	3	2 1	

The first cell of the plan has a=2 and b=2, the second has a=2 and b=1, the third has a=1 and b=1, and so on. If you output the plan to a data set with the OUTPUT statement, by default the output data set contains a numeric variable with that factor's name; the values of this numeric variable are the numbers of the successive levels selected for the factor in the plan. For example, the following statements produce [Figure 68.7](#).

```
proc plan seed=12345;
  factors a=3 b=2;
  output out=out;
run;
proc print data=out;
run;
```

Figure 68.7 Output Data Set from Simple Plan

Obs	a	b
1	2	2
2	2	1
3	1	1
4	1	2
5	3	2
6	3	1

Alternatively, you can specify the values that are output for a factor with the **CVALS=** or **NVALS=** option. Also, you can specify that the internal values be associated with the output values in random order with the **RANDOM** option. See the section “**OUTPUT Statement**” on page 5779.

If you also specify an input data set (**DATA=**), each factor is associated with a variable in the **DATA=** data set. This occurs either implicitly by the factor and variable having the same name or explicitly as described in the specifications for the **OUTPUT** statement. In this case, the values of the variables corresponding to the factors are first read and then interpreted as describing the position of a cell in the plan. Then the respective values taken by the factors at that position are assigned to the variables in the **OUT=** data set. For example, consider the data set defined by the following statements.

```
data in;
  input a b;
  datalines;
1 1
2 1
3 1
;
```

Suppose you specify this data set as an input data set for the **OUTPUT** statement.

```
proc plan seed=12345;
  factors a=3 b=2;
  output out=out data=in;
run;
proc print data=out;
run;
```

PROC PLAN interprets the first observation as referring to the cell in the first row and column of the plan, since **a=1** and **b=1**; likewise, the second observation is interpreted as the cell in the second row and first column, and the third observation as the cell in the third row and first column. In the output data set, **a** and **b** have the values they have in the plan at these positions, as shown in Figure 68.8.

Figure 68.8 Output Form of Input Data Set from Simple Plan

Obs	a	b
1	2	2
2	1	1
3	3	2

When the factors are random, this has the effect of randomizing the input data set in the same manner as the plan produced (see the sections “**Randomizing Designs**” on page 5786 and “**Randomly Assigning Subjects to Treatments**” on page 5774).

Specifying Factor Structures

By appropriately combining features of the PLAN procedure, you can construct an extensive set of designs. The basic tools are the *factor-selections*, which are used in the **FACTORS** and **TREATMENTS** statements.

Table 68.2 summarizes how the procedure interprets various *factor-selections* (assuming that the **ORDERED** option is not specified in the **PROC PLAN** statement).

Table 68.2 *Factor-Selection Interpretation*

Form of Request	Interpretation	Example	Results
<i>name=m</i>	produce a random permutation of the integers $1, 2, \dots, m$	t=15	lists a random ordering of the numbers $1, 2, \dots, 15$
<i>name=m</i> cyclic	cyclically permute the integers $1, 2, \dots, m$	t=5 cyclic	selects the integers 1 to 5. On the next iteration, selects 2,3,4,5,1; then 3,4,5,1,2; and so on.
<i>name=m</i> of <i>n</i>	choose a random sample of <i>m</i> integers (without replacement) from the set of integers $1, 2, \dots, n$	t=5 of 15	lists a random selection of 5 numbers from 1 to 15. First, the procedure selects 5 numbers and then arranges them in random order.
<i>name=m</i> of <i>n</i> ordered	has the same effect as <i>name=m</i> ordered	t=5 of 15 ordered	lists the integers 1 to 5 in increasing order (same as t=5 ordered)
<i>name=m</i> of <i>n</i> cyclic	permute <i>m</i> of the <i>n</i> integers	t=5 of 30 cyclic	selects the integers 1 to 5. On the next iteration, selects 2,3,4,5,6; then 3,4,5,6,7; and so on. The 30th iteration produces 30,1,2,3,4; the 31st iteration produces 1,2,3,4,5; and so on.
<i>name=m</i> perm	produce a list of all permutations of <i>m</i> integers	t=5 perm	lists the integers 1,2,3,4,5 on the first iteration; on the second lists 1,2,3,5,4; on the 119th iteration lists 5,4,3,1,2; and on the last (120th) lists 5,4,3,2,1.
<i>name=m</i> of <i>n</i> comb	choose combinations of <i>m</i> integers from <i>n</i> integers	t=3 of 5 comb	lists all combinations of 5 choose 3 integers. The first iteration is 1,2,3; the second is 1,2,4; the third is 1,2,5; and so on until the last iteration 3,4,5.
<i>name=m</i> of <i>n</i> cyclic (<i>initial-block</i>)	permute <i>m</i> of the <i>n</i> integers, starting with the values specified in the <i>initial-block</i>	t=4 of 30 cyclic (2 10 15 18)	selects the integers 2,10,15,18. On the next iteration, selects 3,11,16,19; then 4,12,17,20; and so on. The thirteenth iteration is 14,22,27,30; the fourteenth iteration is 15,23,28,1; and so on.
<i>name=m</i> of <i>n</i> cyclic (<i>initial-block</i>) <i>increment</i>	permute <i>m</i> of the <i>n</i> integers. Start with the values specified in the <i>initial-block</i> , then add the <i>increment</i> to each value.	t=4 of 30 cyclic (2 10 15 18) 2	selects the integers 2,10,15,18. On the next iteration, selects 4,12,17,20; then 6,14,19,22; and so on. The wrap occurs at the eighth iteration. The eighth iteration is 16,24,29,2; and so on.

In Table 68.2, in order for more than one iteration to appear in the plan, another *name=j* factor selection (with $j > 1$) must precede the example factor selection. For example, the following statements produce six of the iterations described in the last entry of Table 68.2.

```
proc plan;
  factors c=6 ordered t=4 of 30 cyclic (2 10 15 18) 2;
run;
```

The following statements create a randomized complete block design and output the design to a data set.

```
proc plan ordered;
  factors blocks=3 cell=5;
  treatments t=5 random;
  output out=rcdb;
run;
```

Randomizing Designs

In many situations, proper randomization is crucial for the validity of any conclusions to be drawn from an experiment. Randomization is used both to neutralize the effect of any unknown systematic biases that might be involved in the design and to provide a basis for the assumptions underlying the analysis.

You can use PROC PLAN to randomize an already existing design: one produced by a previous call to PROC PLAN, perhaps, or a more specialized design taken from a standard reference such as Cochran and Cox (1957). The method is to specify the appropriate block structure in the **FACTORS** statement and then to specify the data set where the design is stored with the **DATA=** option in the **OUTPUT** statement. For an illustration of this method, see the section “Randomly Assigning Subjects to Treatments” on page 5774).

Two sorts of randomization are provided for, corresponding to the **RANDOM** factor selection and association types in the **FACTORS** and **OUTPUT** statements, respectively. Designs in which factors are completely nested (for example, block designs) should be randomized by specifying that the selection type of each factor is **RANDOM** in the **FACTORS** statement, which is the default (see Example 68.3). On the other hand, if the factors are crossed (for example, row-and-column designs), they should be randomized by one random reassignment of their values for the whole design. To do this, specify that the association type of each factor is **RANDOM** in the **OUTPUT** statement (see Example 68.4).

Displayed Output

The PLAN procedure displays the following output:

- the *m* value for each factor, which is the number of values to be selected
- the *n* value for each factor, which is the number of values to be selected from
- the selection type for each factor, as specified in the **FACTORS** statement
- the initial block and increment number for cyclic factors
- the *factor-value-selections* making up each plan

In addition, notes are written to the log that give the starting and ending values of the random number seed for each call to PROC PLAN.

ODS Table Names

PROC PLAN assigns a name to each table it creates. You can use these names to reference the table in the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, “[Using the Output Delivery System.](#)”

Table 68.3 ODS Tables Produced by PROC PLAN

ODS Table Name	Description	Statements
FInfo	General factor information	FACTORS and no TREATMENTS
PInfo	Plot factor information	FACTORS and TREATMENTS
Plan	Computed plan	default
TInfo	Treatment factor information	FACTORS and TREATMENTS

Examples: PLAN Procedure

Example 68.1: A Split-Plot Design

This plan is appropriate for a split-plot design with main plots forming a randomized complete block design. In this example, there are three blocks, four main plots per block, and two subplots per main plot. First, three random permutations (one for each of the blocks) of the integers 1, 2, 3, and 4 are produced. The four integers correspond to the four levels of the main plot factor *a*; the permutation determines how the levels of *a* are assigned to the main plots within a block. For each of these 12 numbers (four numbers per block for three blocks), a random permutation of the integers 1 and 2 is produced. Each two-integer permutation determines the assignment of the two levels of the subplot factor *b* within a main plot. The following statements produce [Output 68.1.1](#):

```
title 'Split Plot Design';
proc plan seed=37277;
  factors Block=3 ordered a=4 b=2;
run;
```

Output 68.1.1 A Split-Plot Design

Split Plot Design

		2	1 2
3		4	2 1
		2	2 1
		3	2 1
		1	2 1

Example 68.2: A Hierarchical Design

In this example, three plants are nested within four pots, which are nested within three houses. The **FAC-TORS** statement requests a random permutation of the numbers 1, 2, and 3 to choose Houses randomly. The second step requests a random permutation of the numbers 1, 2, 3, and 4 for each of those first three numbers to randomly assign Pots to Houses. Finally, the **FACTORS** statement requests a random permutation of 1, 2, and 3 for each of the 12 integers in the second set of permutations. This last step randomly assigns Plants to Pots. The following statements produce [Output 68.2.1](#):

```

title 'Hierarchical Design';
proc plan seed=17431;
  factors Houses=3 Pots=4 Plants=3 / noprint;
  output out=nested;
run;

proc print data=nested;
run;

```

Example 68.3: An Incomplete Block Design

Jarrett and Hall (1978) give an example of a generalized cyclic design with good efficiency characteristics. The design consists of two replicates of 52 treatments in 13 blocks of size 8. The following statements use the PLAN procedure to generate this design in an appropriately randomized form and store it in a SAS data set GCBD. Then the design is sorted and transposed to display in randomized order. The following statements produce [Output 68.3.1](#) and [Output 68.3.2](#):

```

title 'Generalized Cyclic Block Design';
proc plan seed=33373;
  factors Block=13 Plot=8;
  treatments Treatment=8 of 52 cyclic (1 2 3 4 32 43 46 49) 4;
  output out=G CBD;
quit;

proc sort data=G CBD out=G CBD;
  by Block Plot;
run;

proc transpose data= G CBD(rename=(Plot=_NAME_))
  out =tG CBD(drop=_NAME_);
  by Block;
  var Treatment;
run;

proc print data=tG CBD noobs;
run;

```

13	47	35	45	24	46	38	41	48

Example 68.4: A Latin Square Design

All of the preceding examples involve designs with completely nested block structures, for which PROC PLAN was especially designed. However, by appropriate coordination of its facilities, PROC PLAN can accommodate a much wider class of designs. A Latin square design is based on experimental units that have a row-and-column block structure. The following statements use the **CYCLIC** option in the **TREATMENTS** statement to generate a simple 4×4 Latin square. The **RANDOM** option in the **OUTPUT** statement randomizes the generated Latin square by randomly permuting the row, column, and treatment values independently. This example also uses *factor-value-settings* in the **OUTPUT** statement.

```

title 'Latin Square Design';
proc plan seed=37430;
  factors Row=4 ordered Col=4 ordered / noprint;
  treatments Tmt=4 cyclic;
  output out=LatinSquare
    Row cvals=('Day 1' 'Day 2' 'Day 3' 'Day 4') random
    Col cvals=('Lab 1' 'Lab 2' 'Lab 3' 'Lab 4') random
    Tmt nvals=(      0      100      250      450) random;
quit;

proc sort data=LatinSquare out=LatinSquare;
  by Row Col;
run;
proc transpose data= LatinSquare(rename=(Col=_NAME_))
  out =tLatinSquare(drop=_NAME_);
  by Row;
  var Tmt;
run;
proc print data=tLatinSquare noobs;
run;

```

The preceding statements produce [Output 68.4.1](#).

Output 68.4.1 A Randomized Latin Square Design

Latin Square Design				
Row	Lab_1	Lab_2	Lab_3	Lab_4
Day 1	0	250	100	450
Day 2	250	450	0	100
Day 3	100	0	450	250
Day 4	450	100	250	0

You can use the PLAN procedure to randomize Latin squares from any transformation sets. See Kempthorne (1952) for definitions of transformation sets. In particular, the following DATA step and PROC PLAN statements demonstrate how to randomize a Latin square from the second transformation set defined in Kempthorne (1952). The following DATA step creates a 4×4 Latin square from the transformation set 2:

```
data Unrandomized;
  do Row = 1 to 4;
    do Col = 1 to 4;
      input Tmt @@;
      output;
    end;
  end;
  datalines;
1 2 3 4
2 1 4 3
3 4 1 2
4 3 2 1
;
```

The following PROC PLAN statements permute the rows and columns and randomly assign treatment levels.

```
proc plan;
  factors Row = 4;
  output data= Unrandomized out=Randomized1;
run;
  factors Col = 4;
  output data= Randomized1 out=Randomized2;
run;
  factors Tmt = 4;
  output data= Randomized2 out=Randomized3;
run;

proc sort data=Randomized3;
  by Row Col;
run;
proc transpose data= Randomized3 out =tLatinSquare2(drop=_NAME_);
  by Row;
  var Tmt;
run;
proc print data=tLatinSquare2 noobs;
run;
```

Output 68.4.2 A Randomized Latin Square from a Different Transformation Set

3	3	1	4	2
4	1	3	2	4

Example 68.5: A Generalized Cyclic Incomplete Block Design

The following statements depict how to create an appropriately randomized generalized cyclic incomplete block design for v treatments (given by the value of t) in b blocks (given by the value of b) of size k (with values of p indexing the cells within a block) with initial block $(e_1 e_2 \cdots e_k)$ and increment number i .

```
factors b=b p=k ;
treatments t=k of v cyclic (e1 e2 ⋯ ek) i ;
```

For example, the specification

```
proc plan seed=37430;
  factors b=10 p=4;
  treatments t=4 of 30 cyclic (1 3 4 26) 2;
run;
```

generates the generalized cyclic incomplete block design given in Example 1 of Jarrett and Hall (1978), which is given by the rows and columns of the plan associated with the treatment factor *t* in [Output 68.5.1](#).

Output 68.5.1 A Generalized Cyclic Incomplete Block Design

The PLAN Procedure				
Plot Factors				
Factor	Select	Levels	Order	
b	10	10	Random	
p	4	4	Random	
Treatment Factors				
Factor	Select	Levels	Order	Initial Block / Increment
t	4	30	Cyclic	(1 3 4 26) / 2
b ---p--- -----t-----				
2	2 3 1 4	1	3	4 26
1	3 2 4 1	3	5	6 28
3	2 3 4 1	5	7	8 30
10	4 2 3 1	7	9	10 2
9	4 1 2 3	9	11	12 4
4	1 3 2 4	11	13	14 6
5	1 2 4 3	13	15	16 8
8	3 2 4 1	15	17	18 10
7	2 4 1 3	17	19	20 12
6	2 1 4 3	19	21	22 14

Example 68.6: Permutations and Combinations

Occasionally, you might need to generate all possible permutations of *n* things, or all possible combinations of *n* things taken *m* at a time.

For example, suppose you are planning an experiment in cognitive psychology where you want to present four successive stimuli to each subject. You want to observe each permutation of the four stimuli. The following statements use PROC PLAN to create a data set containing all possible permutations of four numbers in random order.

```

title 'All Permutations of 1,2,3,4';
proc plan seed=60359;
    factors      Subject  = 24
                Order    = 4  ordered;
    treatments Stimulus = 4  perm;
    output out=Psych;
run;

proc sort data=Psych out=Psych;
    by Subject Order;
run;

proc transpose data= Psych(rename=(Order=_NAME_))
               out =tPsych(drop=_NAME_);
    by Subject;
    var Stimulus;
run;

proc print data=tPsych noobs;
run;

```

The variable Subject is set at 24 levels because there are $4! = 24$ total permutations to be listed. If Subject > 24, the list repeats. [Output 68.6.1](#) displays the PROC PLAN output. Note that the variable Subject is listed in random order.

Output 68.6.1 List of Permutations

All Permutations of 1,2,3,4			
The PLAN Procedure			
Plot Factors

18	1 2 3 4	3 2 4 1
21	1 2 3 4	3 4 1 2
9	1 2 3 4	3 4 2 1
22	1 2 3 4	4 1 2 3
10	1 2 3 4	4 1 3 2
7	1 2 3 4	4 2 1 3
11	1 2 3 4	4 2 3 1
3	1 2 3 4	4 3 1 2
20	1 2 3 4	4 3 2 1

The output data set **Psych** contains 96 observations of the 3 variables (Subject, Order, and Stimulus). Sorting the output data set by Subject and by Order within Subject results in all possible permutations of Stimulus in random order. PROC TABULATE displays these permutations in [Output 68.6.2](#).

Output 68.6.2 Randomized Permutations

All Permutations of 1,2,3,4				
Subject	_1	_2	_3	_4
1	1	3	4	2
2	2	4	3	1
3	4	3	1	2
4	1	2	3	4
5	1	4	2	3
6	2	3	1	4
7	4	2	1	3
8	2	4	1	3
9	3	4	2	1
10	4	1	3	2
11	4	2	3	1
12	3	2	1	4
13	3	1	2	4
14	2	1	4	3
15	1	2	4	3
16	3	1	4	2
17	1	4	3	2
18	3	2	4	1
19	2	1	3	4
20	4	3	2	1
21	3	4	1	2
22	4	1	2	3
23	2	3	4	1
24	1	3	2	4

As another example, suppose you have six alternative treatments, any four of which can occur together in a block (in no particular order). The following statements use PROC PLAN to create a data set containing all possible combinations of six numbers taken four at a time. In this case, you use ODS to create the data set.

```

title 'All Combinations of (6 Choose 4) Integers';
proc plan;
  factors Block=15 ordered
    Treat= 4 of 6 comb;
  ods output Plan=Combinations;
run;

proc print data=Combinations noobs;
run;

```

The variable Block has 15 levels since there are a total of $6!/(4!2!) = 15$ combinations of four integers chosen from six integers. The data set formed by ODS from the displayed plan has one row for each block, with the four values of Treat corresponding to four different variables, as shown in [Output 68.6.3](#) and [Output 68.6.4](#).

Output 68.6.3 List of Combinations

All Combinations of (6 Choose 4) Integers

The PLAN Procedure

Factor	Select	Levels	Order
Block	15	15	Ordered
Treat	4	6	Comb

Block	-Treat-
-------	---------

1	1 2 3 4
2	1 2 3 5
3	1 2 3 6
4	1 2 4 5
5	1 2 4 6
6	1 2 5 6
7	1 3 4 5
8	1 3 4 6
9	1 3 5 6
10	1 4 5 6
11	2 3 4 5
12	2 3 4 6
13	2 3 5 6
14	2 4 5 6
15	3 4 5 6

Output 68.6.4 Combinations Data Set Created by ODS

All Combinations of (6 Choose 4) Integers

Block	Treat1	Treat2	Treat3	Treat4
1	1	2	3	4
2	1	2	3	5
3	1	2	3	6

12	2	3	4	6
13	2	3	5	6
14	2	4	5	6
15	3	4	5	6

Example 68.7: Crossover Designs

In *crossover* experiments, the same experimental units or subjects are given multiple treatments in sequence, and the model for the response at any one period includes an effect for the treatment applied in the previous period. A good design for a crossover experiment is therefore one that balances how often each treatment is preceded by each other treatment. Cox (1992) gives the following example of a balanced crossover experiment for paper production. In this experiment, the subjects are production runs of the mill, with the treatments being six different concentrations of pulp used in sequence. The following statements construct this design in a standard form:

```
proc plan;
  factors Run=6 ordered Period=6 ordered;
  treatments Treatment=6 cyclic (1 2 6 3 5 4);
run;
```

Output 68.7.1 shows the results of the preceding statements.

Output 68.7.1 Crossover Design for Six Treatments

The PLAN Procedure				
Plot Factors				
Factor	Select	Levels	Order	
Run	6	6	Ordered	
Period	6	6	Ordered	
Treatment Factors				
Factor	Select	Levels	Order	Initial Block / Increment
Treatment	6	6	Cyclic	(1 2 6 3 5 4) / 1
Run	---Period---		-Treatment-	
1	1	2	3	4
2	1	2	3	4
3	1	2	3	4
4	1	2	3	4
5	1	2	3	4
6	1	2	3	4

The construction method for this example is due to Williams (1949). The initial block for the treatment variable Treatment is defined as follows for $n = 6$:

$$(1 \quad 2 \quad n \quad 3 \quad n-1 \quad \dots \quad n/2 \quad n/2+2 \quad n/2)$$

This general form serves to generate a balanced crossover design for n treatments and n subjects in n periods when n is even. When n is odd, $2n$ subjects are required, with the following initial blocks, respectively for odd and even n :

$$\begin{pmatrix} 1 & 2 & n & 3 & n-1 & \dots & n/2+1 & n/2 \\ n/2 & n/2+1 & \dots & n-1 & 3 & n & 2 & 1 \end{pmatrix}$$

In order to randomize Williams' crossover designs, the following statements randomly permute the subjects and treatments:

```
proc plan seed=136149876;
  factors Run=6 ordered Period=6 ordered / noprint;
  treatments Treatment=6 cyclic (1 2 6 3 5 4);
  output out=RandomizedDesign
    Run      random
    Treatment random
    ;
run;

/*
/ Relabel Period to obtain the same design as in Cox (1992) .
/-----*/
data RandomizedDesign;
  set RandomizedDesign;
  Period = mod(Period+2,6)+1;
run;

proc sort data=RandomizedDesign;
  by Run Period;
run;

proc transpose data=RandomizedDesign out=tDesign(drop=_name_);
  by notsorted Run;
  var Treatment;
run;

data tDesign;
  set tDesign;
  rename COL1-COL6 = Period_1-Period_6;
run;

proc print data=tDesign noobs;
run;
```

In the preceding statements, Run and Treatment are randomized by using the [RANDOM](#) option in the [OUTPUT](#) statement, and new labels for Period are obtained in a subsequent DATA step. This Period relabeling is not necessary and might not be valid for Williams' designs in general; it is used in this example only to match results with those of Cox (1992). The SORT and TRANSPOSE steps then prepare the design to be printed in a standard form, shown in [Output 68.7.2](#).

Output 68.7.2 Randomized Crossover Design

Run	Period_1	Period_2	Period_3	Period_4	Period_5	Period_6
1	3	6	2	5	4	1
2	5	3	4	6	1	2
3	1	4	5	2	6	3
4	2	1	6	4	3	5
5	6	5	1	3	2	4
6	4	2	3	1	5	6

The analysis of a crossover experiment requires for each observation a *carryover* variable whose values are the treatment in the preceding period. The following statements add such a variable to the randomized design constructed previously:

```
proc sort data=RandomizedDesign;
  by Run Period;
run;
data RandomizedDesign;
  set RandomizedDesign;
  by Run period;
  LagTreatment = lag(Treatment);
  if (first.Run) then LagTreatment = .;
run;

proc transpose data=RandomizedDesign out=tDesign(drop=_name_);
  by notsorted Run;
  var LagTreatment;
run;
data tDesign;
  set tDesign;
  rename COL1-COL6 = Period_1-Period_6;
run;
proc print data=tDesign noobs;
run;
```

Output 68.7.3 displays the values of the carryover variable for each run and period.

Output 68.7.3 Lag Treatment Effect in Crossover Design

Run	Period_1	Period_2	Period_3	Period_4	Period_5	Period_6
1	.	3	6	2	5	4
2	.	5	3	4	6	1
3	.	1	4	5	2	6
4	.	2	1	6	4	3
5	.	6	5	1	3	2
6	.	4	2	3	1	5

Of course, the carryover variable has no effect in the first period, which is why it is coded with a missing value in this case.

The experimental LAG effect in the EFFECT statement in PROC ORTHOREG provides a convenient mechanism for incorporating the carryover effect into the analysis. The following statements first add the observed data to the design to create the Mills data set. Then PROC ORTHOREG is invoked, and the carryover effect is defined as a lag effect with the relevant period and subject information specified. ODS is used to trim down the results to show only the parts that are usually of interest in crossover analysis. For more information about the EFFECTS statement in PROC ORTHOREG, see the section “[EFFECT Statement](#)” on page 5517.

6	Avg	-0.8167	0.3284	15	-2.49	0.0252

The Type I analysis of variance indicates that all effects are significant—in particular, both the direct and the carryover effects of the treatment. In the presence of carryover effects, the LS-means need to be defined

with some care. The LS-means for treatments computed using balanced margins for the carryover effect are inestimable; so the OBSMARGINS option is specified in the LSMEANS statement in order to use the observed margins instead. The observed margins take the absence of a carryover effect in the first period into account. Note that the LS-means themselves of the carryover effect are inestimable, but their differences are estimable. The LS-means of the direct effect of the treatment and the ANOM differences for the LS-means of their carryover effect match the “adjusted direct effects” and “adjusted residual effects,” respectively, of Cox (1992).

Overview: PLM Procedure

The PLM procedure performs postfitting statistical analyses for the contents of a SAS item store that was previously created with the STORE statement in some other SAS/STAT procedure. An item store is a special SAS-defined binary file format used to store and restore information with a hierarchical structure.

The statements available in the PLM procedure are designed to reveal the contents of the source item store via the Output Delivery System (ODS) and to perform postfitting tasks such as the following:

- testing hypotheses
- computing confidence intervals
- producing prediction plots
- scoring a new data set

The use of item stores and PROC PLM enables you to separate common postprocessing tasks, such as testing for treatment differences and predicting new observations under a fitted model, from the process of model building and fitting. A numerically expensive model fitting technique can be applied once to produce a source item store. The PLM procedure can then be called multiple times and the results of the fitted model analyzed without incurring the model fitting expenditure again.

The PLM procedure offers the most advanced postprocessing techniques available in SAS/STAT software. These techniques include step-down multiplicity adjustments for p -values, F tests with order restrictions, analysis of means (ANOM), and sampling-based linear inference based on Bayes posterior estimates.

The following procedures support the STORE statement for the generation of item stores that can be processed with the PLM procedure: GENMOD, GLIMMIX, GLM, GLMSELECT, LIFEREG, LOGISTIC, MIXED, ORTHOREG, PHREG, PROBIT, SURVEYLOGISTIC, SURVEYPHREG, and SURVEYREG. The RELIABILITY procedure in SAS/QC software also supports the STORE statement. For details about the STORE statement, see the section “[STORE Statement](#)” on page 501 of Chapter 19, “[Shared Concepts and Topics](#).”

Basic Features

The PLM procedure, unlike most SAS/STAT procedures, does not operate primarily on an input data set. Instead, the procedure requires you to specify an item store with the [RESTORE=](#) option in the [PROC PLM](#) statement. The item store contains the necessary information and context about the statistical model that was fit when the store was created. SAS data sets are used only to provide input information in some circumstances. For example, when scoring a data set or when computing least squares means with specially defined population margins. In other words, instead of reading raw data and fitting a model, the PLM procedure reads the results of a model having been fit.

In order to interact with the item store and to reveal its contents, the PLM procedure supports the [SHOW](#) statement which converts item store information into standard ODS tables for viewing and further processing.

The PLM procedure is sensitive to the contents of the item store. For example, if a BAYES statement was in effect when the item store was created, the posterior parameter estimates are saved to the item store so that the PLM procedure can perform postprocessing tasks by taking the posterior distribution of estimable functions into account. As another example, for item stores that are generated by a mixed model procedure using the Satterthwaite or Kenward-Roger (Kenward and Roger 1997) degrees-of-freedom method, these methods continue to be available when the item store contents are processed with the PLM procedure.

Because the PLM procedure does not read data and does not fit a model, the processing time of this procedure is usually considerably less than the processing time of the procedure that generates the item store.

PROC PLM Contrasted with Other SAS Procedures

In contrast to other analytic procedures in SAS/STAT software, the PLM procedure does not use an input data set. Instead, it retrieves information from an item store.

Some of the statements in the PLM procedure are also available as postprocessing statements in other procedures. Table 69.1 lists SAS/STAT procedures that support the same postprocessing statements as PROC PLM does.

Table 69.1 SAS/STAT Procedures with Postprocessing Statements Similar to PROC PLM

	EFFECTPLOT	ESTIMATE	LSMEANS	LSMESTIMATE	SLICE	TEST
GENMOD	✓	✓*	✓	✓	✓	
GLIMMIX		✓*	✓*	✓*	✓

SURVEYPHREG		✓	✓	✓	✓	✓
SURVEYREG		✓	✓	✓	✓	✓

Table entries marked with ✓ indicate procedures that support statements with the same functionality as in PROC PLM. Those entries marked with ✓* indicate procedures that support statements with same names but different syntaxes from PROC PLM. You can find the most comprehensive set of features for these statements in the PLM procedure. For example, the LSMEANS statement is available in all of the listed procedures. For example, the ESTIMATE statement available in the GENMOD, GLIMMIX, GLM and MIXED procedures does not support all options that PROC PLM supports, such as multiple rows and multiplicity adjustments.

The WHERE statement in other procedures enables you to conditionally select a subset of the observations from the input data set so that the procedure processes only the observations that meet the specified conditions. Since the PLM procedure does not use an input data set, the WHERE statement in the PLM procedure has different functionality. If the item store contains information about BY groups—that is, a BY statement

was in effect when the item store was created—you can use the [WHERE](#) statement to select specific BY groups for the analysis. You can also use the [FILTER](#) statement in the PLM procedure to filter results from the ODS output and output data sets.

Getting Started: PLM Procedure

The following DATA step creates a data set from a randomized block experiment with a factorial treatment structure of factors A and B:

```
data BlockDesign;
  input block a b y @@;
  datalines;
  1 1 1 56 1 1 2 41
  1 2 1 50 1 2 2 36
  1 3 1 39 1 3 2 35
  2 1 1 30 2 1 2 25
  2 2 1 36 2 2 2 28
  2 3 1 33 2 3 2 30
  3 1 1 32 3 1 2 24
  3 2 1 31 3 2 2 27
  3 3 1 15 3 3 2 19
  4 1 1 30 4 1 2 25
  4 2 1 35 4 2 2 30
  4 3 1 17 4 3 2 18
  ;
```

The GLM procedure is used in the following statements to fit the model and to create a source item store for the PLM procedure:

```
proc glm data=BlockDesign;
  class block a b;
  model y = block a b a*b / solution;
  store sasuser.BlockAnalysis / label='PLM: Getting Started';
run;
```

The CLASS statement identifies the variables Block, A, and B as classification variables. The MODEL statement specifies the response variable and the model effects. The block effect models the design effect, and the a, b, and a*b effects model the factorial treatment structure. The STORE statement requests that the context and results of this analysis be saved to an item store named sasuser.BlockAnalysis. Because the SASUSER library is specified as the library name of the item store, the store will be available after the SAS session completes. The optional label in the STORE statement identifies the store in subsequent analyses with the PLM procedure.

Note that having BlockDesign as the name of the output store would not create a conflict with the input data set name, because data sets and item stores are saved as files of different types.

Figure 69.1 displays the results from the GLM procedure. The “Class Level Information” table shows the number of levels and their values for the three classification variables. The “Parameter Estimates” table shows the estimates and their standard errors along with *t* tests.

Figure 69.1 Class Variable Information, Fit Statistics, and Parameter Estimates

a*b 3 2	0.00000000 B		.	.	.

The following statements invoke the PLM procedure and use `sasuser.BlockAnalysis` as the source item store:

```
proc plm restore=sasuser.BlockAnalysis;
run;
```

These statements produce [Figure 69.2](#). The “Store Information” table displays information that is gleaned from the source item store. For example, the store was created by the GLM procedure at the indicated time and date, and the input data set for the analysis was `WORK.BLOCKDESIGN`. The label used earlier in the `STORE` statement of the GLM procedure also appears as a descriptor in [Figure 69.2](#).

a	3	1 2 3
b	2	1 2

The “Store Information” table also echoes partial information about the variables and model effects that are used in the analysis. The “Class Level Information” table is produced by the PLM procedure by default whenever the model contains effects that depend on CLASS variables.

The following statements request a display of the fit statistics and the parameter estimates from the source item store and a test of the treatment main effects and their interactions:

```
proc plm restore=sasuser.BlockAnalysis;
  show fit parms;
  test a b a*b;
run;
```

The statements produce [Figure 69.3](#). Notice that the estimates and standard errors in the “Parameter Estimates” table agree with the results displayed earlier by the GLM procedure, except for small differences in formatting.

Figure 69.3 Fit Statistics, Parameter Estimates, and Tests of Effects

The PLM Procedure	
Fit Statistics	
MSE	21.66667
Error df	15

Figure 69.3 continued

Parameter Estimates					
Effect	block	a	b	Estimate	Standard Error
Intercept				20.4167	2.8504
block	1			17.0000	2.6874
block	2			4.5000	2.6874
block	3			-1.1667	2.6874
block	4			0	.
a		1		3.2500	3.2914
a		2		4.7500	3.2914
a		3		0	.
b			1	0.5000	3.2914
b			2	0	.
a*b		1	1	7.7500	4.6547
a*b		1	2	0	.
a*b		2	1	7.2500	4.6547
a*b		2	2	0	.
a*b		3	1	0	.
a*b		3	2	0	.

Type III Tests of Model Effects				
Effect	Num DF	Den DF	F Value	Pr > F
a	2	15	7.54	0.0054
b	1	15	8.38	0.0111
a*b	2	15	1.74	0.2097

Since the main effects, but not the interaction are significant in this experiment, the subsequent analysis focuses on the main effects, in particular on the effect of variable A.

The following statements request the least squares means of the A effect along with their pairwise differences:

```
proc plm restore=sasuser.BlockAnalysis seed=3;
  lsmeans      a      / diff;
  lsmestimate a -1 1,
              1 1 -2 / uppertailed ftest;
run;
```

The **LSMESTIMATE** statement tests two linear combinations of the A least squares means: equality of the first two levels and whether the sum of the first two level effects equals twice the effect of the third level. The **FTEST** option in the **LSMESTIMATE** statement requests a joint *F* test for this two-row contrast. The **UPPERTAILED** option requests that the *F* test also be carried out under one-sided order restrictions. Since *F* tests under order restrictions (chi-bar-square statistic) require a simulation-based approach for the calculation of *p*-values, the random number stream is initialized with a seed value through the **SEED=** option in the **PROC PLM** statement.

The results of the **LSMEANS** and the **LSMESTIMATE** statement are shown in Figure 69.4.

Figure 69.4 LS-Means Related Inference for A Effect

The PLM Procedure							
a Least Squares Means							
a		Estimate	Standard Error	DF	t Value	Pr > t	
1		32.8750	1.6457	15	19.98	<.0001	
2		34.1250	1.6457	15	20.74	<.0001	
3		25.7500	1.6457	15	15.65	<.0001	
Differences of a Least Squares Means							
a	_a	Estimate	Standard Error	DF	t Value	Pr > t	
1	2	-1.2500	2.3274	15	-0.54	0.5991	
1	3	7.1250	2.3274	15	3.06	0.0079	
2	3	8.3750	2.3274	15	3.60	0.0026	
Least Squares Means Estimates							
Effect	Label	Estimate	Standard Error	DF	t Value	Tails	Pr > t
a	Row 1	1.2500	2.3274	15	0.54	Upper	0.2995
a	Row 2	15.5000	4.0311	15	3.85	Upper	0.0008
F Test for Least Squares Means Estimates							
Effect	Num DF	Den DF	F Value	Pr > F	ChiBar Sq Value	Pr > ChiBarSq	
a	2	15	7.54	0.0054	15.07	0.0001	

The least squares means for the three levels of variable A are 32.875, 34.125, and 25.75. The differences between the third level and the first and second levels are statistically significant at the 5% level (p -values of 0.0079 and 0.0026, respectively). There is no significant difference between the first two levels. The first row of the “Least Squares Means Estimates” table also displays the difference between the first two levels of factor A. Although the (absolute value of the) estimate and its standard error are identical to those in the “Differences of a Least Squares Means” table, the p -values do not agree because one-sided tests were requested in the LSMESTIMATE statement.

The “F Test” table in Figure 69.4 shows the two degree-of-freedom test for the linear combinations of the LS-means. The F value of 7.54 with p -value of 0.0054 represents the usual (two-sided) F test. Under the one-sided right-tailed order restriction imposed by the UPPERTAILED option, the ChiBarSq value of 15.07 represents the observed value of the chi-bar-square statistic of Silvapulle and Sen (2004). The associated p -value of 0.0001 was obtained by simulation.

Now suppose that you are interested in analyzing the relationship of the interaction cell means. (Typically this would not be the case in this example since the $a*b$ interaction is not significant; see [Figure 69.3](#).) The **SLICE** statement in the following PROC PLM run produces an F test of equality and all pair-wise differences of the interaction means for the subset (partition) where variable B is at level ‘1’. With ODS Graphics enabled, the pairwise differences are displayed in a diffogram.

```
ods graphics on;
proc plm restore=sasuser.BlockAnalysis;
  slice a*b / sliceby(b='1') diff;
run;
ods graphics off;
```

The results are shown in [Figure 69.5](#). Since variable A has three levels, the test of equality of the A means at level ‘1’ of B is a two-degree comparison. This comparison is statistically significant (p -value equals 0.0040). You can conclude that the three levels of A are not the same for the first level of B.

Figure 69.5 Results from Analyzing an Interaction Partition

The PLM Procedure							
F Test for a*b Least Squares Means Slice							
Slice	Num DF	Den DF	F Value	Pr > F			
b 1	2	15	8.18	0.0040			
Simple Differences of a*b Least Squares Means							
Slice	a	_a	Estimate	Standard Error	DF	t Value	Pr > t
b 1	1	2	-1.0000	3.2914	15	-0.30	0.7654
b 1	1	3	11.0000	3.2914	15	3.34	0.0045
b 1	2	3	12.0000	3.2914	15	3.65	0.0024

The table of “Simple Differences” was produced by the DIFF option in the **SLICE** statement. As is the case with the marginal comparisons in [Figure 69.4](#), there are significant differences against the third level of A if variable B is held fixed at ‘1’.

[Figure 69.6](#) shows the diffogram that displays the three pairwise least squares mean differences and their significance. Each line segment corresponds to a comparison. It centers at the least squares means in the pair with its length corresponding to the projected width of a confidence interval for the difference. If the variable B is held fixed at ‘1’, both the first two levels are significantly different from the third level, but the difference between the first and the second level is not significant.

Figure 69.6 LS-Means Difference Diffogram

Syntax: PLM Procedure

The following statements are available in the PLM procedure:

```

PROC PLM RESTORE=item-store-specification < options > ;
CODE < options > ;
EFFECTPLOT < plot-type < (plot-definition-options) > > < / options > ;
ESTIMATE < 'label' > estimate-specification < (divisor=n) >
    < , ... < 'label' > estimate-specification < (divisor=n) > > < / options > ;
FILTER expression ;
LSMEANS < model-effects > < / options > ;
LSMESTIMATE model-effect < 'label' > values < divisor=n >
    < , ... < 'label' > values < divisor=n > > < / options > ;
SCORE DATA=SAS-data-set < OUT=SAS-data-set >
    < keyword<=name> > ...
    < keyword<=name> > < / options > ;
SHOW options ;
SLICE model-effect < / options > ;
TEST < model-effects > < / options > ;
WHERE expression ;

```

With the exception of the **PROC PLM** statement and the **FILTER** statement, any statement can appear multiple times and in any order. The default order in which the statements are processed by the PLM procedure depends on the specification in the item store and can be modified with the **STMTORDER=** option in the **PROC PLM** statement.

In contrast to many other SAS/STAT modeling procedures, the PLM procedure does not have common modeling statements such as the **CLASS** and **MODEL** statements. This is because the information about classification variables and model effects is contained in the source item store that is passed to the procedure in the **PROC PLM** statement. All subsequent statements are checked for consistency with the stored model. For example, the statement

```
lsmeans c / diff;
```

is detected as not valid unless one of the following conditions was true at the time when the source store was created:

- The effect C was used in the model.
- C was specified in the **CLASS** statement.
- The **CLASS** variables in the model had a GLM parameterization.

The **FILTER**, **SCORE**, **SHOW**, and **WHERE** statements are described in full after the **PROC PLM** statement in alphabetical order. The **CODE**, **EFFECTPLOT**, **ESTIMATE**, **LSMEANS**, **LSMESTIMATE**, **SLICE**, and **TEST** statements are also used by many other procedures. Summary descriptions of functionality and syntax for these statements are also given after the **PROC PLM** statement in alphabetical order, but full documentation about them is available in Chapter 19, “Shared Concepts and Topics.”

PROC PLM Statement

PROC PLM RESTORE=*item-store-specification* < options > ;

The PROC PLM statement invokes the PLM procedure. The **RESTORE=** option with *item-store-specification* is required. Table 69.2 summarizes the options available in the PROC PLM statement.

Table 69.2 PROC PLM Statement Options

Option	Description
Basic Options	
RESTORE=	Specifies the source item store for processing
SEED=	Specifies the random number seed
STMTORDER=	Affects the order in which statements are grouped during processing
FORMAT=	Specifies how the PLM procedure handles user-defined formats
WHEREFORMAT	Specifies the constants (literals) in terms of the formatted values of the BY variables
Computational Options	
ALPHA=	Specifies the nominal significance level
DDFMETHOD=	Specifies the method for determining denominator degrees of freedom
PERCENTILES=	Supplies a list of percentiles for the construction of HPD intervals
Displayed Output	
MAXLEN=	Determines the maximum length of informational strings
NOCLPRINT	Suppresses the display of the “Class Level Information” table
NOINFO	Suppresses the display of the “Store Information” table
NOPRINT	Suppresses tabular and graphical output
PLOT	Controls the plots produced through ODS Graphics
Singularity Tolerances	
ESTEPS=	Specifies the tolerance value used in determining the estimability of linear functions
SINGCHOL=	Tunes the singularity criterion in Cholesky decompositions
SINGRES=	Sets the tolerance for which the residual variance or scale parameter is considered to be zero
SINGULAR=	Tunes the general singularity criterion
ZETA=	Tunes the sensitivity in forming Type III functions

You can specify the following *options*:

ALPHA= α

specifies the nominal significance level for multiplicity corrections and for the construction of confidence intervals. The value of α must be between 0 and 1. The default is the value specified in the source item store, or 0.05 if the item store does not provide a value. The confidence level based on α is $1 - \alpha$.

DDFMETHOD=RESIDUAL | RES | ERROR

DDFMETHOD=NONE

DDFMETHOD=KENROG | KR | KENWARDROGER

DDFMETHOD=SATTERTH | SAT | SATTERTHWAITE

specifies the method for determining denominator degrees of freedom for tests and confidence intervals. The default degree-of-freedom method is determined by the contents of the item store. You can override the default to some extent with the DDFMETHOD= option.

If you choose DDFMETHOD=NONE, then infinite denominator degrees of freedom are assumed for tests and confidence intervals. This essentially produces z tests and intervals instead of t tests and intervals and chi-square tests instead of F tests.

The KENWARDROGER and SATTERTHWAITE methods require that the source item store contain information about these methods. This information is currently available for item stores that were created with the MIXED or GLIMMIX procedures when the appropriate DDFM= option was in effect.

ESTEPS= ϵ

specifies the tolerance value used in determining the estimability of linear functions. The default value is determined by the contents of the source item store; it is usually 1E-4.

FORMAT=NOLOAD | RELOAD

specifies how the PLM procedure handles user-defined formats, which are not permanent. When the item store is created, user-defined formats are stored. When the PLM procedure opens an item store, it uses this option as follows. If FORMAT=RELOAD (the default), the stored formats are loaded again from the item store and formats that already exist in your SAS session are replaced by the reloaded formats. If FORMAT=NOLOAD, stored formats are not loaded from the item store and existing formats are not replaced.

With FORMAT=NOLOAD, you prevent the PLM procedure from reloading the format from the item store. As a consequence, PLM statements might fail if a format was present at the item store creation and is not available in your SAS session. Also, if you modify the format that was used in the item store creation and use FORMAT=NOLOAD, you might obtain unexpected results because levels of classification variables are remapped.

The “Class Level Information” table always displays the formatted values of classification variables that were used in fitting the model, regardless of the FORMAT= option. For more details about using formats with the PLM procedure, see [“User-Defined Formats and the PLM Procedure”](#) on page 5834.

MAXLEN= n

determines the maximum length of informational strings in the “Store Information” table. This table displays, for example, lists of classification or BY variables and lists of model effects. The value of n determines the truncation length for these strings. The minimum and maximum values for n are 20 and 256, respectively. The default is $n = 100$.

NOCLPRINT<= $number$ >

suppresses the display of the “Class Level Information” table if you do not specify *number*. If you specify *number*, only levels with totals that are less than *number* are listed in the table. The PLM procedure produces the “Class Level Information” table by default when the model contains effects that depend on classification variables.

NOINFO

suppresses the display of the “Store Information” table.

NOPRINT

suppresses the generation of tabular and graphical output. When the NOPRINT option is in effect, ODS tables are also not produced.

PERCENTILES=*value-list***PERCENTILE=***value-list*

supplies a list of percentiles for the construction of highest posterior density (HPD) intervals when the PLM procedure performs a sampling-based analysis (for example, when processing an item store that contains posterior parameter estimates from a Bayesian analysis). The default set of percentiles depends on the contents of the source item store; it is typically PERCENTILES=25, 50, 75. The entries in *value-list* must be strictly between 0 and 100.

PLOTS <(*global-plot-option*)> <=*specific-plot-options*>

controls the plots produced through ODS Graphics. ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc plm plots=all;
    lsmeans a/diff;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

Global Plot Option

The following *global-plot-option* applies to all plots produced by [PROC PLM](#).

UNPACKPANEL**UNPACK**

suppresses paneling. (By default, multiple plots can appear in some output panels.) Specify UNPACK to display each plot separately.

Specific Plot Options

You can specify the following *specific-plot-options*:

ALL

requests that all the appropriate plots be produced.

NONE

suppresses all plots.

SEED=number

specifies the random number seed for analyses that depend on a random number stream. You can also specify the random number seed through some PLM statements (for example, through the SEED= options in the ESTIMATE, LSMEANS, and LSMESTIMATE statements). However, note that there is only a single random number stream per procedure run. Specifying the SEED= option in the PROC PLM statement initializes the stream for all subsequent statements. If you do not specify a random number seed, the source item store might supply one for you. If a seed is in effect when the PLM procedure opens the source store, the “Store Information” table displays its value.

If the random number seed is less than or equal to zero, the seed is generated from reading the time of day from the computer clock and a log message indicates the chosen seed value.

SINGCHOL=number

tunes the singularity criterion in Cholesky decompositions. The default value depends on the contents of the source item store. The default value is typically 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

SINGRES=number

sets the tolerance for which the residual variance or scale parameter is considered to be zero. The default value depends on the contents of the source item store. The default value is typically 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

SINGULAR=number

tunes the general singularity criterion applied by the PLM procedure in divisions and inversions. The default value used by the PLM procedure depends on the contents of the item store. The default value is typically 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

RESTORE=item-store-specification

specifies the source item store for processing. This option is required because, in contrast to SAS data sets, there is no default item store. An *item-store-specification* consists of a one- or two-level name as with SAS data sets. As with data sets, the default library association of an item store is with the WORK library, and any stores created in this library are deleted when the SAS session concludes.

STMTORDER=SYNTAX | GROUP**STMT=SYNTAX | GROUP**

affects the order in which statements are grouped during processing. The default behavior depends on the contents of the source item store and can be modified with the STMTORDER= option. If STMTORDER=SYNTAX is in effect, the statements are processed in the order in which they appear. Note that this precludes the hierarchical grouping of ODS objects. If STMTORDER=GROUP is in effect, the statements are processed in groups and in the following order: [SHOW](#), [TEST](#), [LSMEANS](#), [SLICE](#), [LSMESTIMATE](#), [ESTIMATE](#), [SCORE](#), [EFFECTPLOT](#), and [CODE](#).

WHEREFORMAT

specifies that the constants (literals) specified in [WHERE](#) expressions for group selection are in terms of the formatted values of the BY variables. By default, WHERE expressions are specified in terms of the unformatted (raw) values of the BY variables, as in the SAS DATA step.

ZETA=number

tunes the sensitivity in forming Type III functions. Any element in the estimable function basis with an absolute value less than *number* is set to 0. The default depends on the contents of the source item store; it usually is 1E–8.

CODE Statement

CODE < *options* > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 69.3 summarizes the *options* available in the CODE statement.

Table 69.3 CODE Statement Options

Option	Description
CATALOG=	Names the catalog entry where the generated code is saved
DUMMIES	Retains the dummy variables in the data set
ERROR	Computes the error function
FILE=	Names the file where the generated code is saved
FORMAT=	Specifies the numeric format for the regression coefficients
GROUP=	Specifies the group identifier for array names and statement labels
IMPUTE	Imputes predicted values for observations with missing or invalid covariates
LINESIZE=	Specifies the line size of the generated code
LOOKUP=	Specifies the algorithm for looking up CLASS levels
RESIDUAL	Computes residuals

For details about the syntax of the CODE statement, see the section “CODE Statement” on page 390 in Chapter 19, “Shared Concepts and Topics.”

EFFECTPLOT Statement

EFFECTPLOT < *plot-type* < (*plot-definition-options*) > > < / *options* > ;

The EFFECTPLOT statement produces a display of the fitted model and provides options for changing and enhancing the displays. Table 69.4 describes the available *plot-types* and their *plot-definition-options*.

Table 69.4 *Plot-Types and Plot-Definition-Options*

Plot-Type and Description	Plot-Definition-Options
BOX Displays a box plot of continuous response data at each level of a CLASS effect, with predicted values superimposed and connected by a line. This is an alternative to the INTERACTION <i>plot-type</i> .	PLOTBY= variable or CLASS effect X= CLASS variable or effect
CONTOUR Displays a contour plot of predicted values against two continuous covariates.	PLOTBY= variable or CLASS effect X= continuous variable Y= continuous variable
FIT Displays a curve of predicted values versus a continuous variable.	PLOTBY= variable or CLASS effect X= continuous variable
INTERACTION Displays a plot of predicted values (possibly with error bars) versus the levels of a CLASS effect. The predicted values are connected with lines and can be grouped by the levels of another CLASS effect.	PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= CLASS variable or effect
SLICEFIT Displays a curve of predicted values versus a continuous variable grouped by the levels of a CLASS effect.	PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= continuous variable

For full details about the syntax and options of the EFFECTPLOT statement, see the section “**EFFECTPLOT Statement**” on page 411 in Chapter 19, “**Shared Concepts and Topics**.”

ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
      < , ... <'label'> estimate-specification <(divisor=n)> >
      </ options> ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form $\mathbf{L}\boldsymbol{\beta}$. You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 69.5 summarizes the options available in the ESTIMATE statement.

Table 69.5 ESTIMATE Statement Options

Option	Description
Construction and Computation of Estimable Functions	
DIVISOR=	Specifies a list of values to divide the coefficients
NOFILL	Suppresses the automatic fill-in of coefficients for higher-order effects
SINGULAR=	Tunes the estimability checking difference
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple comparison adjustment of estimates
ALPHA= α	Determines the confidence level ($1 - \alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPPDOWN	Adjusts multiplicity-corrected p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits
CORR	Displays the correlation matrix of estimates
COV	Displays the covariance matrix of estimates
E	Prints the L matrix
JOINT	Produces a joint F or chi-square test for the estimable functions
PLOTS=	Requests ODS statistical graphics if the analysis is sampling-based
SEED=	Specifies the seed for computations that depend on random numbers
Generalized Linear Modeling	
CATEGORY=	Specifies how to construct estimable functions with multinomial data
EXP	Exponentiates and displays estimates
ILINK	Computes and displays estimates and standard errors on the inverse linked scale

For details about the syntax of the ESTIMATE statement, see the section “[ESTIMATE Statement](#)” on page 437 in Chapter 19, “[Shared Concepts and Topics](#).”

FILTER Statement

FILTER *expression* ;

The FILTER statement enables you to filter the results of the PLM procedure, specifically the contents of ODS tables and the output data sets. There can be at most one FILTER statement per PROC PLM run, and the filter is applied to all BY groups and to all queries generated through [WHERE](#) expressions.

A filter *expression* follows the same pattern as a *where-expression* in the [WHERE](#) statement. The expressions consist of operands and operators. For more information about specifying *where-expressions*, see the [WHERE](#) statement for the PLM procedure and *SAS Language Reference: Concepts*.

Valid keywords for the formation of operands in the FILTER statement are shown in [Table 69.6](#).

Table 69.6 Keywords for Filtering Results

Keyword	Description
Prob	Regular (unadjusted) p -values from t , F , or chi-square tests
ProbChi	Regular (unadjusted) p -values from chi-square tests
ProbF	Regular (unadjusted) p -values from F tests
ProbT	Regular (unadjusted) p -values from t tests
AdjP	Adjusted p -values
Estimate	Results displayed in “Estimates” column of ODS tables
Pred	Predicted values in SCORE output data sets
Resid	Residuals in SCORE output data sets.
Std	Standard errors in ODS tables and in SCORE results
Mu	Results displayed in the “Mean” column of ODS tables (this column is typically produced by the ILINK option)
tValue	The value of the usual t statistic
FValue	The value of the usual F statistic
Chisq	The value of the chi-square statistic
testStat	The value of the test statistic (a generic keyword for the ‘tValue’, ‘FValue’, and ‘Chisq’ tokens)
Lower	The lower confidence limit displayed in ODS tables
Upper	The upper confidence limit displayed in ODS tables
AdjLower	The adjusted lower confidence limit displayed in ODS tables
AdjUpper	The adjusted upper confidence limit displayed in ODS tables
LowerMu	The lower confidence limit for the mean displayed in ODS tables
UpperMu	The upper confidence limit for the mean displayed in ODS tables
AdjLowerMu	The adjusted lower confidence limit for the mean displayed in ODS tables
AdjUpperMu	The adjusted upper confidence limit for the mean displayed in ODS tables

When you write filtering expressions, be advised that filtering variables that are not used in the results are typically set to missing values. For example, the following statements select all results (filter nothing) because no adjusted p -values are computed:

```
proc plm restore=MyStore;
  lsmeans a / diff;
  filter adjp < 0.05;
run;
```

If the adjusted p -values are set to missing values, the condition `adjp < 0.05` is true in each case (missing values always compare smaller than the smallest nonmissing value).

See “[Example 69.6: Comparing Multiple B-Splines](#)” on page 5853 for an example of using the `FILTER` statement.

Filtering results has no effect on the item store contents that are displayed with the `SHOW` statement. However, BY-group selection with the `WHERE` statement can limit the amount of information that is displayed by the `SHOW` statements.

LSMEANS Statement

LSMEANS < *model-effects* > < / *options* > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 69.7 summarizes the options available in the LSMEANS statement.

Table 69.7 LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
<code>AT</code>	Modifies the covariate value in computing LS-means
<code>BYLEVEL</code>	Computes separate margins
<code>DIFF</code>	Requests differences of LS-means
<code>OM=</code>	Specifies the weighting scheme for LS-means computation as determined by the input data set
<code>SINGULAR=</code>	Tunes estimability checking
Degrees of Freedom and <i>p</i>-values	
<code>ADJUST=</code>	Determines the method for multiple-comparison adjustment of LS-means differences
<code>ALPHA=α</code>	Determines the confidence level $(1 - \alpha)$
<code>STEPDOWN</code>	Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion
Statistical Output	
<code>CL</code>	Constructs confidence limits for means and mean differences
<code>CORR</code>	Displays the correlation matrix of LS-means
<code>COV</code>	Displays the covariance matrix of LS-means
<code>E</code>	Prints the L matrix
<code>LINES</code>	Produces a “Lines” display for pairwise LS-means differences
<code>MEANS</code>	Prints the LS-means
<code>PLOTS=</code>	Requests graphs of means and mean comparisons
<code>SEED=</code>	Specifies the seed for computations that depend on random numbers

Table 69.7 *continued*

Option	Description
Generalized Linear Modeling	
EXP	Exponentiates and displays estimates of LS-means or LS-means differences
ILINK	Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale
ODDSRATIO	Reports (simple) differences of least squares means in terms of odds ratios if permitted by the link function

For details about the syntax of the LSMEANS statement, see the section “[LSMEANS Statement](#)” on page 453 in Chapter 19, “[Shared Concepts and Topics](#).”

LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
              < , ... <'label'> values <divisor=n> >
              </ options> ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 69.8 summarizes the options available in the LSMESTIMATE statement.

Table 69.8 LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
BYLEVEL	Computes separate margins
DIVISOR=	Specifies a list of values to divide the coefficients
OM=	Specifies the weighting scheme for LS-means computation as determined by a data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and <i>p</i>-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level $(1 - \alpha)$
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference

Table 69.8 *continued*

Option	Description
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
ELSM	Prints the K matrix
JOINT	Produces a joint <i>F</i> or chi-square test for the LS-means and LS-means differences
PLOTS=	Requests graphs of means and mean comparisons
SEED=	Specifies the seed for computations that depend on random numbers
Generalized Linear Modeling	
CATEGORY=	Specifies how to construct estimable functions with multinomial data
EXP	Exponentiates and displays LS-means estimates
ILINK	Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale

For details about the syntax of the LSMESTIMATE statement, see the section “[LSMESTIMATE Statement](#)” on page 470 in Chapter 19, “[Shared Concepts and Topics](#).”

SCORE Statement

```
SCORE DATA=SAS-data-set <OUT=SAS-data-set>
    <keyword<=name>> ...
    <keyword<=name>> </options> ;
```

The SCORE statement applies the contents of the source item store to compute predicted values and other observation-wise statistics for a SAS data set.

You can specify the following syntax elements in the SCORE statement before the option slash (/):

DATA=SAS-data-set

specifies the input data set for scoring. This option is required, and the data set is examined for congruity with the previously fitted (and stored) model. For example, all necessary variables to form a row of the **X** matrix must be present in the input data set and must be of the correct type and format. The following variables do not have to be present in the input data set:

- the response variable
- the *events* and *trials* variables used in the *events/trials* syntax for binomial data
- variables used in WEIGHT or FREQ statements

OUT=SAS-data-set

specifies the name of the output data set. If you do not specify an output data set with the OUT= option, the PLM procedure uses the *DATA**n* convention to name the output data set.

keyword<=name>

specifies a statistic to be included in the OUT= data set and optionally assigns the statistic the variable name *name*. Table 69.9 lists the keywords and the default names assigned by the PLM procedure if you do not specify a *name*.

Table 69.9 Keywords for Output Statistics

Keyword	Description	Expression	Name
PREDICTED	Linear predictor	$\hat{\eta} = \mathbf{x}\hat{\boldsymbol{\beta}}$	Predicted
STDERR	Standard deviation of linear predictor	$\sqrt{\text{Var}(\hat{\eta})}$	StdErr
RESIDUAL	Residual	$y - g^{-1}(\hat{\eta})$	Resid
LCLM	Lower confidence limit for the linear predictor		LCLM
UCLM	Upper confidence limit for the linear predictor		UCLM
LCL	Lower prediction limit for the linear predictor		LCL
UCL	Upper prediction limit for the linear predictor		UCL

Prediction limits (LCL, UCL) are available only for statistical models that allow such limits, typically regression-type models for normally distributed data with an identity link function.

You can specify the following options in the SCORE statement after a slash (/):

ALPHA=number

determines the coverage probability for two-sided confidence and prediction intervals. The coverage probability is computed as $1 - \text{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

DF=number

specifies the degrees of freedom to use in the construction of prediction and confidence limits.

ILINK

requests that predicted values be inversely linked to produce predictions on the data scale. By default, predictions are produced on the linear scale where covariate effects are additive.

NOUNIQUE

requests that names not be made unique in the case of naming conflicts. By default, the PLM procedure avoids naming conflicts by assigning a unique name to each output variable. If you specify the NOUNIQUE option, variables with conflicting names are not renamed. In that case, the first variable added to the output data set takes precedence.

NOVAR

requests that variables from the input data set not be added to the output data set.

OBSCAT

requests that statistics in models for multinomial data be written to the output data set only for the response level that corresponds to the observed level of the observation.

SAMPLE

requests that the sample of parameter estimates in the item store be used to form scoring statistics. This option is useful when the item store contains the results of a Bayesian analysis and a posterior sample of parameter estimates. The predicted value is then computed as the average predicted value across the posterior estimates, and the standard error measures the standard deviation of these estimates. For example, let $\hat{\beta}_1, \dots, \hat{\beta}_k$ denote the k posterior sample estimates of β , and let \mathbf{x}_i denote the \mathbf{x} -vector for the i th observation in the scoring data set. If the **SAMPLE** option is in effect, the output statistics for the predicted value, the standard error, and the residual of the i th observation are computed as

$$\begin{aligned}\eta_{ij} &= \mathbf{x}_i \hat{\beta}_j \\ \text{PRED}_i &= \bar{\eta}_i = \frac{1}{k} \sum_{j=1}^k \eta_{ij} \\ \text{STDERR}_i &= \left(\frac{1}{k-1} \sum_{j=1}^k (\eta_{ij} - \bar{\eta}_i)^2 \right)^{1/2} \\ \text{RESIDUAL}_i &= y_i - g^{-1}(\bar{\eta}_i)\end{aligned}$$

where $g^{-1}(\cdot)$ denotes the inverse link function.

If, in addition, the **ILINK** option is in effect, the calculations are as follows:

$$\begin{aligned}\eta_{ij} &= \mathbf{x}_i \hat{\beta}_j \\ \text{PRED}_i &= \frac{1}{k} \sum_{j=1}^k g^{-1}(\eta_{ij}) \\ \text{STDERR}_i &= \left(\frac{1}{k-1} \sum_{j=1}^k (g^{-1}(\eta_{ij}) - \text{PRED}_i)^2 \right)^{1/2} \\ \text{RESIDUAL}_i &= y_i - \text{PRED}_i\end{aligned}$$

The LCL and UCL statistics are not available with the **SAMPLE** option. When the LCLM and UCLM statistics are requested, the **SAMPLE** option yields the lower $100 \times \alpha/2\%$ and upper $100 \times (1 - \alpha/2)\%$ percentiles of the predicted values under the sample (posterior) distribution. When you request residuals with the **SAMPLE** option, the calculation depends on whether the **ILINK** option is specified.

SHOW Statement

SHOW *options* ;

The SHOW statement uses the Output Delivery System to display contents of the item store. This statement is useful for verifying that the contents of the item store apply to the analysis and for generating ODS tables. Table 69.10 summarizes the options available in the SHOW statement.

Table 69.10 SHOW Statement Options

Option	Description
ALL	Displays all applicable contents
BYVAR	Displays information about the BY variables
CLASSLEVELS	Displays the “Class Level Information” table
CORRELATION	Produces the correlation matrix of the parameter estimates
COVARIANCE	Produces the covariance matrix of the parameter estimates
EFFECTS	Displays information about the constructed effects
FITSTATS	Displays the fit statistics
HESSIAN	Displays the Hessian matrix
HERMITE	Generates the Hermite matrix $\mathbf{H} = (\mathbf{X}'\mathbf{X})^{-1}(\mathbf{X}'\mathbf{X})$
PARAMETERS	Displays the parameter estimates
PROGRAM	Displays the SAS program that generated the item store
XPX	Displays the crossproduct matrix $\mathbf{X}'\mathbf{X}$
XPXI	Displays the generalized inverse of the crossproduct matrix $\mathbf{X}'\mathbf{X}$

You can specify the following options after the SHOW statement:

ALL | _ALL_

displays all applicable contents.

BYVAR | BY

displays information about the BY variables in the source item store. If a BY statement was present when the item store was created, the PLM procedure performs the analysis separately for each BY group.

CLASSLEVELS | CLASS

displays the “Class Level Information” table. This table is produced by the PLM procedure by default if the model contains effects that depend on classification variables.

CORRELATION | CORR | CORRB

produces the correlation matrix of the parameter estimates. If the source item store contains a posterior sample of parameter estimates, the computed matrix is the correlation matrix of the sample covariance matrix.

COVARIANCE | COV | COVB

produces the covariance matrix of the parameter estimates. If the source item store contains a posterior sample of parameter estimates, the PLM procedure computes the empirical sample covariance matrix from the posterior estimates. You can convert this matrix into a sample correlation matrix with the CORRELATION option in the SHOW statement.

EFFECTS

displays information about the constructed effects in the model. Constructed effects are those that were created with the EFFECT statement in the procedure run that generated the source item store.

FITSTATS | FIT

displays the fit statistics from the item store.

HESSIAN | HESS

displays the Hessian matrix.

HERMITE | HERM

generates the Hermite matrix $\mathbf{H} = (\mathbf{X}'\mathbf{X})^{-}(\mathbf{X}'\mathbf{X})$. The PLM procedure chooses a reflexive, g_2 -inverse for the generalized inverse of the crossproduct matrix $\mathbf{X}'\mathbf{X}$. See [“Important Linear Algebra Concepts”](#) on page 44 of Chapter 3, [“Introduction to Statistical Modeling with SAS/STAT Software,”](#) for information about generalized inverses and the sweep operator.

PARAMETERS<=n>**PARMS<=n>**

displays the parameter estimates. The structure of the display depends on whether a posterior sample of parameter estimates is available in the source item store. If such a sample is present, up to the first 20 parameter vectors are shown in wide format. You can modify this number with the n argument.

If no posterior sample is present, the single vector of parameter estimates is shown in narrow format. If the store contains information about the covariance matrix of the parameter estimates, then standard errors are added.

PROGRAM<(WIDTH=n)>**PROG<(WIDTH=n)>**

displays the SAS program that generated the item store, provided that this was stored at store generation time. The program does not include comments, titles, or some other global statements. The optional width parameter n determines the display width of the source code.

XPX | CROSSPRODUCT

displays the crossproduct matrix $\mathbf{X}'\mathbf{X}$.

XPXI

displays the generalized inverse of the crossproduct matrix $\mathbf{X}'\mathbf{X}$. The PLM procedure obtains a reflexive g_2 -inverse by sweeping. See [“Important Linear Algebra Concepts”](#) on page 44 of Chapter 3, [“Introduction to Statistical Modeling with SAS/STAT Software,”](#) for information about generalized inverses and the sweep operator.

SLICE Statement

SLICE *model-effect* </ options> ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in [Table 19.21](#). For details about the syntax of the SLICE statement, see the section [“SLICE Statement”](#) on page 498 in Chapter 19, [“Shared Concepts and Topics.”](#)

TEST Statement

TEST *< model-effects > < / options > ;*

The TEST statement enables you to perform F tests for model effects that test Type I, Type II, or Type III hypotheses. See Chapter 15, “[The Four Types of Estimable Functions](#),” for details about the construction of Type I, II, and III estimable functions.

Table 69.11 summarizes the options available in the TEST statement.

Table 69.11 TEST Statement Options

Option	Description
CHISQ	Requests chi-square tests
DDF=	Specifies denominator degrees of freedom for fixed effects
E	Requests Type I, Type II, and Type III coefficients
E1	Requests Type I coefficients
E2	Requests Type II coefficients
E3	Requests Type III coefficients
HTYPE=	Indicates the type of hypothesis test to perform
INTERCEPT	Adds a row that corresponds to the overall intercept

For details about the syntax of the TEST statement, see the section “[TEST Statement](#)” on page 502 in Chapter 19, “[Shared Concepts and Topics](#).”

WHERE Statement

WHERE *expression ;*

You can use the WHERE statement in the PLM procedure when the item store contains BY-variable information and you want to apply the PROC PLM statements to only a subset of the BY groups.

A WHERE expression is a type of SAS expression that defines a condition. In the DATA step and in procedures that use SAS data sets as the input source, the WHERE expression is used to select observations for inclusion in the DATA step or in the analysis. In the PLM procedure, which does not accept a SAS data set but rather takes an item store that was created by a qualifying SAS/STAT procedure, the WHERE statement is also used to specify conditions. The conditional selection does not apply to observations in PROC PLM, however. Instead, you use the WHERE statement in the PLM procedure to select a subset of BY groups from the item store to which to apply the PROC PLM statements.

The general syntax of the WHERE statement is

WHERE *operand < operator operand > < AND | OR operand < operator operand > . . . > ;*

where

operand is something to be operated on. The operand can be the name of a BY variable in the item store, a SAS function, a constant, or a predefined name to identify columns in result tables.

operator is a symbol that requests a comparison, logical operation, or arithmetic calculation. All SAS expression operators are valid for a WHERE expression.

For more details about how to specify general WHERE expressions, see *SAS Language Reference: Concepts*. Notice that the **FILTER** statement accepts similar expressions that are specified in terms of predefined keywords. Expressions in the WHERE statement of the PLM procedure are written in terms of BY variables.

There is no limit to the number of WHERE statements in the PLM procedure. When you specify multiple WHERE statements, the statements are *not* cumulative. Each WHERE statement is executed separately. You can think of each selection WHERE statement as one analytic query to the item store: the WHERE statement defines the query, and the PLM procedure is the querying engine. For example, suppose that the item store contains results for the numeric BY variables A and B. The following statements define two separate queries of the item store:

```
WHERE a = 4;
WHERE (b < 3) and (a > 4);
```

The PLM procedure first applies the requested analysis to all BY groups where a equals 4 (irrespective of the value of variable b). The analysis is then repeated for all BY groups where b is less than 3 and a is greater than 4.

Group selection with WHERE statements is possible only if the item store contains BY variables. You can use the **BYVAR** option in the **SHOW** statement to display the BY variables in the item store.

Note that WHERE expressions in the SAS DATA step and in many procedures are specified in terms of the unformatted values of data set variables, even if a format was applied to the variable. If you specify the **WHEREFORMAT** option in the **PROC PLM** statement, the PLM procedure evaluates WHERE expressions for BY variables in terms of the formatted values. For example, assume that the following format was applied to the variable tx when the item store was created:

```
proc format;
  value bf 1 = 'Control'
           2 = 'Treated';
run;
```

Then the following two PROC PLM runs are equivalent:

```
proc plm restore=MyStore;
  show parms;
  where b = 2;
run;

proc plm restore=MyStore whereformat;
  show parms;
  where b = 'Treated';
run;
```

Details: PLM Procedure

BY Processing and the PLM Procedure

When a BY statement is in effect for the analysis that creates an item store, the information about BY variables and BY-group-specific modeling results are transferred to the item store. In this case, the PLM procedure automatically assumes a processing mode for the item store that is akin to BY processing, with the PLM statements being applied in turn for each of the BY groups. Also, you can then obtain a table of BY groups with the **BYVAR** option in the **SHOW** statement. The “Source Information” table also displays the variable names of the BY variables if BY groups are present. The **WHERE** statement can be used to restrict the analysis to specific BY groups that meet the conditions of the WHERE expression.

See [Example 69.4](#) for an example that uses BY-group-specific information in the source item store.

As with procedures that operate on input data sets, the BY variable information is added automatically to any output data sets and ODS tables produced by the PLM procedure.

When you score a data set with the **SCORE** statement and the item store contains BY variables, three situations can arise:

- None of the BY variables are present in the scoring data set. In this situation the results of the BY groups in the item store are applied in turn to the entire scoring data set. For example, if the scoring data set contains 50 observations and no BY-variable information, the number of observations in the output data set of the **SCORE** statement equals 50 times the number of BY groups.
- The scoring data set contains only a part of the BY variables, or the variables have different type or format. The PLM procedure does not process such an incompatible scoring data set.
- All BY variables are in the scoring data set in the same type and format as when the item store was created. The BY-group-specific results are applied to each observation in the scoring data set. The scoring data set does not have to be sorted or grouped by the BY variables. However, it is computationally more efficient if the scoring data set is arranged by groups of the BY variables.

Analysis Based on Posterior Estimates

If an item store is saved from a Bayesian analysis (by PROC GENMOD or PROC PHREG or PROC LIFEREG), then PROC PLM can perform sampling-based inference based on Bayes posterior estimates that are saved in the item store. For example, the following statements request a Bayesian analysis and save the results to an item store named `sasuser.gmd`. For the Bayesian analysis, the random number generator seed is set to 1. By default, a noninformative distribution is set as the prior distribution for the regression coefficients and the posterior sample size is 10,000.

```
proc genmod data=gs;
  class a b;
  model y = a b;
  bayes seed=1;
  store sasuser.gmd / label='Bayesian Analysis';
run;
```

When the PLM procedure opens the item store `sasuser.gmd`, it detects that the results were saved from a Bayesian analysis. The posterior sample of regression coefficient estimates are then loaded to perform statistical inference tasks.

The majority of postprocessing tasks involve inference based on an estimable linear function $\mathbf{L}\hat{\boldsymbol{\beta}}$, which often requires its mean and variance. When the standard frequentist analyses are performed, the mean and variance have explicit forms because the parameter estimate $\hat{\boldsymbol{\beta}}$ is analytically tractable. However, explicit forms are not usually available when Bayesian models are fitted. Instead, empirical means and variance-covariance matrices for the estimable function are constructed from the posterior sample.

Let $\hat{\boldsymbol{\beta}}_i, i = 1, \dots, N_p$ denote the N_p vectors of posterior sample estimates of $\boldsymbol{\beta}$ saved in `sasuser.gmd`. Use these vectors to construct the posterior sample of estimable functions $\mathbf{L}\hat{\boldsymbol{\beta}}_i$. The posterior mean of the estimable function is thus

$$\overline{\mathbf{L}\hat{\boldsymbol{\beta}}} = \frac{1}{N_p} \sum_{i=1}^{N_p} \mathbf{L}\hat{\boldsymbol{\beta}}_i$$

and the posterior variance of the estimable function is

$$\mathbf{V}(\mathbf{L}\hat{\boldsymbol{\beta}}) = \frac{1}{N_p - 1} \sum_{i=1}^{N_p} (\mathbf{L}\hat{\boldsymbol{\beta}}_i - \overline{\mathbf{L}\hat{\boldsymbol{\beta}}})^2$$

Sometimes statistical inference on a transformation of $\mathbf{L}\hat{\boldsymbol{\beta}}$ is requested. For example, the EXP option for the ESTIMATE and LSMESTIMATE statements requests analysis based on $\exp(\mathbf{L}\hat{\boldsymbol{\beta}})$, exponentiation of the estimable function. If this type of analysis is requested, the posterior sample of transformed estimable functions is constructed by transforming each of the estimable function evaluated at the posterior sample: $f(\mathbf{L}\hat{\boldsymbol{\beta}}_i), i = 1, \dots, N_p$. The posterior mean and variance for $f(\mathbf{L}\hat{\boldsymbol{\beta}})$ are then computed from the constructed sample to make the inference:

$$\overline{f(\mathbf{L}\hat{\boldsymbol{\beta}})} = \frac{1}{N_p} \sum_{i=1}^{N_p} f(\mathbf{L}\hat{\boldsymbol{\beta}}_i)$$

$$\mathbf{V}(f(\mathbf{L}\hat{\boldsymbol{\beta}})) = \frac{1}{N_p - 1} \sum_{i=1}^{N_p} (f(\mathbf{L}\hat{\boldsymbol{\beta}}_i) - \overline{f(\mathbf{L}\hat{\boldsymbol{\beta}})})^2$$

After obtaining the posterior mean and variance, the PLM procedure proceeds to perform statistical inference based on them.

User-Defined Formats and the PLM Procedure

The PLM procedure does not support a FORMAT statement because it operates without an input data set, and also because changing the format properties of variables could alter the interpretation of parameter estimates, thus creating a dissonance with variable properties in effect when the item store was created. Instead, user-defined formats that are applied to classification variables when the item store is created are saved to the store and are by default reloaded by the PLM procedure. When the PLM procedure loads a format, notes are issued to the log.

You can change the load behavior for formats with the **FORMAT=** option in the **PROC PLM** statement.

User-defined formats do not need to be supplied in a new SAS session. However, when a user-defined format with the same name as a stored format exists and the default **FORMAT=RELOAD** option is in effect, the format definition loaded from the item store replaces the format currently in effect.

In the following statements, the format **AFORM** is created and applied to the variable **a** in the **PROC GLM** step. This format definition is transferred to the item store **sasuser.glm** through the **STORE** statement.

```
proc format;
  value aform 1='One' 2='Two' 3='Three';
run;
proc glm data=sp;
  format a aform.;
  class block a b;
  model y = block a b x;
  store sasuser.glm;
  weight x;
run;
```

The following statements replace the format definition of the **AFORM** format. The **PLM** step then reloads the **AFORM** format (from the item store) and thereby restores its original state.

```
proc format;
  value aform 1='Un' 2='Deux' 3='Trois';
run;
proc plm restore=sasuser.glm;
  show class;
  score data=sp out=plmout lcl lclm ucl uclm;
run;
```

The following notes, issued by the **PLM** procedure, inform you that the procedure loaded the format, the format already existed, and the existing format was replaced:

```
NOTE: The format AFORM was loaded from item store SASUSER.GLM.
NOTE: Format AFORM is already on the library.
NOTE: Format AFORM has been output.
```

After the **PROC PLM** run, the definition that is in effect for the format **AFORM** corresponds to the following SAS statements:

```
proc format;
  value aform 1='One' 2='Two' 3='Three';
run;
```

ODS Table Names

PROC PLM assigns a name to each table it creates. You can use these names to refer to the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 69.12](#). For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Each of the EFFECTPLOT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements also creates tables, which are not listed in Table 69.12. For information about these tables, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

Table 69.12 ODS Tables Produced by PROC PLM

Table Name	Description	Required Option
ByVarInfo	Information about BY variables in source item store (if present)	SHOW BYVAR
ClassLevels	Level information from the CLASS statement	Default output when model effects depend on CLASS variables
Corr	Correlation matrix of parameter estimates	SHOW CORR
Cov	Covariance matrix of parameter estimates	SHOW COV
FitStatistics	Fit statistics	SHOW FIT
Hessian	Hessian matrix	SHOW HESSIAN
Hermite	Hermite matrix	SHOW HERMITE
ParameterEstimates	Parameter estimates	SHOW PARMS
ParameterSample	Sampled (posterior) parameter estimates	SHOW PARMS
Program	Originating source code	SHOW PROGRAM
StoreInfo	Information about source item store	Default
XpX	$\mathbf{X}'\mathbf{X}$ matrix	SHOW XPX
XpXI	$(\mathbf{X}'\mathbf{X})^{-1}$ matrix	SHOW XPXI

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, then each of the EFFECTPLOT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots associated with their analyses. For information about these plots, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

Examples: PLM Procedure

Example 69.1: Scoring with PROC PLM

Logistic regression with model selection is often used to extract useful information and build interpretable models for classification problems with many variables. This example demonstrates how you can use PROC LOGISTIC to build a spline model on a simulated data set and how you can later use the fitted model to classify new observations.

The following DATA step creates a data set named SimuData, which contains 5,000 observations and 100 continuous variables:

```
%let nObs    = 5000;
%let nVars   = 100;
data SimuData;
    array x{&nVars};
    do obsNum=1 to &nObs;
        do j=1 to &nVars;
            x{j}=ranuni(1);
        end;

        linp = 10 + 11*x1 - 10*sqrt(x2) + 2/x3 - 8*exp(x4) + 7*x5*x5
              - 6*x6**1.5 + 5*log(x7) - 4*sin(3.14*x8) + 3*x9 - 2*x10;
        TrueProb = 1/(1+exp(-linp));

        if ranuni(1) < TrueProb then y=1;
                                   else y=0;

        output;
    end;
run;
```

The response is binary based on the inversely transformed logit values. The true logit is a function of only 10 of the 100 variables, including nonlinear transformations of seven variables, as follows:

$$\text{logit}(p) = 10 + 11x_1 - 10\sqrt{x_2} + \frac{2}{x_3} - 8 \exp(x_4) + 7x_5^2 - 6x_6^{1.5} + 5 \log(x_7) - 4 \sin(3.14x_8) + 3x_9 - 2x_{10}$$

Now suppose the true model is not known. With some exploratory data analysis, you determine that the dependency of the logit on some variables is nonlinear. Therefore, you decide to use splines to model this nonlinear dependence. Also, you want to use stepwise regression to remove unimportant variable transformations. The following statements perform the task:

```
proc logistic data=SimuData;
    effect splines = spline(x1-x&nVars/separate);
    model y = splines/selection=stepwise;
    store sasuser.SimuModel;
run;
```

By default, PROC LOGISTIC models the probability that $y = 0$. The EFFECT statement requests an effect named splines constructed by all predictors in the data. The SEPARATE option specifies that the spline

basis for each variable be treated as a separate set so that model selection applies to each individual set. The `SELECTION=STEPWISE` specifies the stepwise regression as the model selection technique. The `STORE` statement requests that the fitted model be saved to an item store `sasuser.SimuModel`. See “[Example 69.2: Working with Item Stores](#)” on page 5838 for an example with more details about working with item stores.

The spline effect for each predictor produces seven columns in the design matrix, making stepwise regression computationally intensive. For example, a typical Pentium 4 workstation takes around ten minutes to run the preceding statements. Real data sets for classification can be much larger. See examples at UCI Machine Learning Repository (Asuncion and Newman 2007). If new observations about which you want to make predictions are available at model fitting time, you can add the `SCORE` statement in the `LOGISTIC` procedure. Consider the case in which observations to predict become available after fitting the model. With `PROC PLM`, you do not have to repeat the computationally intensive model-fitting processes multiple times. You can use the `SCORE` statement in the `PLM` procedure to score new observations based on the item store `sasuser.SimuModel` that was created during the initial model building. For example, to compute the probability of $y = 0$ for one new observation with all predictor values equal to 0.15 in the data set `test`, you can use the following statements:

```
data test;
  array x{&nVars};
  do j=1 to &nVars;
    x{j}=0.15;
  end;
  drop j;
  output;
run;

proc plm restore=sasuser.SimuModel;
  score data=test out=testout predicted / ilink;
run;
```

The `ILINK` option in the `SCORE` statement requests that predicted values be inversely transformed to the response scale. In this case, it is the predicted probability of $y = 0$. [Output 69.1.1](#) shows the predicted probability for the new observation.

Output 69.1.1 Predicted Probability for One New Observation

Obs	Predicted
1	0.56649

Example 69.2: Working with Item Stores

This example demonstrates how procedures save statistical analysis context and results into item stores and how you can use `PROC PLM` to make post hoc inference based on saved item stores. The data are taken from McCullagh and Nelder (1989) and concern the effects on taste of various cheese additives. Four cheese additives were tested, and 52 response ratings for each additive were obtained. The response was measured on a scale of nine categories that range from strong dislike (1) to excellent taste (9). The following program

saves the data in the data set `Cheese`. The variable `y` contains the taste rating, the variable `Additive` contains cheese additive types, and the variable `freq` contains the frequencies with which each additive received each rating.

```
data Cheese;
  do Additive = 1 to 4;
    do y = 1 to 9;
      input freq @@;
      output;
    end;
  end;
  label y='Taste Rating';
