0 0 0 1 3 7 14 16 11
;
```

The response `y` is a categorical variable that contains nine ordered levels. You can use PROC LOGISTIC to fit an ordinal model to investigate the effects of the cheese additive types on taste ratings. Suppose you also want to save the ordinal model into an item store so that you can make statistical inference later. You can use the following statements to perform the tasks:

```
proc logistic data=cheese;
  freq freq;
  class additive y / param=glm;
  model y=additive;
  store sasuser.cheese;
  title 'Ordinal Model on Cheese Additives';
run;
```

By default, PROC LOGISTIC uses the cumulative logit model for the ordered categorical response. The STORE statement saves the fitted model to a SAS item store named `sasuser.cheese`. The name is a two-level SAS name of the form `libname.membername`. If `libname` is not specified in the STORE statement, the fitted results are saved in `work.membername` and the item store is deleted after the current SAS session ends. With this example, the fitted model is saved to an item store named `sasuser.cheese` in the `Sasuser` library. It is not deleted after the current SAS session ends. You can use PROC PLM to restore the results later.

The following statements use PROC PLM to load the saved model context and results by specifying `RESTORE=` with the target item store `sasuser.cheese`. Then they use two SHOW statements to display separate information saved in the item store. The first SHOW statement with the PROGRAM option displays the program that was used to generate the item store `sasuser.cheese`. The second SHOW statement with the PARMS option displays parameter estimates and associated statistics of the fitted ordinal model.

```
proc plm restore=sasuser.cheese;
  show program;
  show parms;
run;
```

Output 69.2.1 displays the program that generated the item store `sasuser.cheese`. Except for the title information, it matches the original program.

Output 69.2.1 Program Information from sasuser.cheese

```
Ordinal Model on Cheese Additives

The PLM Procedure

SAS Program Information

proc logistic data=cheese;
  freq freq;
  class additive y / param=glm;
  model y=additive;
  store sasuser.cheese;
run;
```

Output 69.2.2 displays estimates of the intercept terms and covariates and associated statistics. The intercept terms correspond to eight cumulative logits defined on taste ratings; that is, the *i*th intercept for *i*th logit is

$$\log\left(\frac{\sum_{j \leq i} p_j}{1 - \sum_{j \leq i} p_j}\right)$$

Output 69.2.2 Parameter Estimates of the Ordinal Model

Parameter Estimates			
Parameter	Taste Rating	Estimate	Standard Error
Intercept	1	-7.0801	0.5624
Intercept	2	-6.0249	0.4755
Intercept	3	-4.9254	0.4272
Intercept	4	-3.8568	0.3902
Intercept	5	-2.5205	0.3431
Intercept	6	-1.5685	0.3086
Intercept	7	-0.06688	0.2658
Intercept	8	1.4930	0.3310
Additive 1		1.6128	0.3778
Additive 2		4.9645	0.4741
Additive 3		3.3227	0.4251
Additive 4		0	.

You can perform various statistical inference tasks from a saved item store, as long as the task is applicable under the model context. For example, you can perform group comparisons between different cheese additive types. See the next example for details.

Example 69.3: Group Comparisons in an Ordinal Model

This example continues the study of the effects on taste of various cheese additives. You have finished fitting an ordinal logistic model and saved it to an item store named `sasuser.cheese` in the previous example. Suppose you want to make comparisons between any pair of cheese additives. You can conduct the analysis by using the `ESTIMATE` statement and constructing an appropriate `L` matrix, or by using the `LSMEANS` statement to compute least squares means differences. For an ordinal logistic model with the cumulative logit link, the least squares means are predicted population margins of the cumulative logits. The following statements compute and display differences between least squares means of cheese additive:

```
ods graphics on;
proc plm restore=sasuser.cheese;
    lsmeans additive / cl diff oddsratio plot=diff;
run;
ods graphics off;
```

The `LSMEANS` statement contains four options. The `DIFF` option requests least squares means differences for cheese additives. Since the fitted model is an ordinal logistic model with the cumulative logit link, the least squares means differences represent log cumulative odds ratios. The `ODDSRATIO` option requests exponentiation of the LS-means differences which produces cumulative odds ratios. The `CL` option constructs confidence limits for the LS-means differences. When ODS Graphics is enabled, the `PLOTS=DIFF` option requests a display of all pairwise least squares means differences and their significance.

Output 69.3.1 displays the LS-means differences. The reported log odds ratios indicate the relative difference among the cheese additives. A negative log odds ratio indicates that the first category (displayed in the `Additive` column) having a lower taste rating is less likely than the second category (displayed in the `_Additive` column) having a lower taste rating. For example, the log odds ratio between cheese additive 1 and 2 is -3.3517 and the corresponding odds ratio is 0.035 . This means the odds of cheese additive 1 receiving a poor rating is 0.035 times the odds of cheese additive 2 receiving a poor rating. In addition to the highly significant p -value (< 0.0001), the confidence limits for both the log odds ratio and the odds ratio indicate that you can reject the null hypothesis that the odds of cheese additive 1 having a lower taste rating is the same as that of cheese additive 2 having a lower rating. Similarly, the odds of cheese additive 2 having a lower rating is 143.241 (with 95% confidence limits $(56.558, 362.777)$) times the odds of cheese additive 4 having a lower rating. With the same logic, you can conclude that the preference order for the four cheese types from the most favorable to the least favorable is: 4, 1, 3 and 2.

Output 69.3.1 LS-Means Differences of Additive

Ordinal Model on Cheese Additives						
The PLM Procedure						
Differences of Additive Least Squares Means						
Additive	_Additive	Estimate	Standard Error	z Value	Pr > z	Alpha
1	2	-3.3517	0.4235	-7.91	<.0001	0.05
1	3	-1.7098	0.3731	-4.58	<.0001	0.05
1	4	1.6128	0.3778	4.27	<.0001	0.05
2	3	1.6419	0.3738	4.39	<.0001	0.05
2	4	4.9645	0.4741	10.47	<.0001	0.05
3	4	3.3227	0.4251	7.82	<.0001	0.05
Differences of Additive Least Squares Means						
Additive	_Additive	Lower	Upper	Odds Ratio	Lower Confidence Limit for Odds Ratio	Upper Confidence Limit for Odds Ratio
1	2	-4.1818	-2.5216	0.035	0.015	0.080
1	3	-2.4410	-0.9787	0.181	0.087	0.376
1	4	0.8724	2.3532	5.017	2.393	10.520
2	3	0.9092	2.3746	5.165	2.482	10.746
2	4	4.0353	5.8938	143.241	56.558	362.777
3	4	2.4895	4.1558	27.734	12.055	63.805

Output 69.3.2 displays the DiffPlot. This shows that all pairs of LS-means differences, equivalent to log odds ratios in this case, are significant at the level of $\alpha = 0.05$. This means that the preference between any pair of the four cheese additive types are statistically significantly different.

Output 69.3.2 LS-Means Plot of Pairwise Differences

Example 69.4: Posterior Inference for Binomial Data

This example demonstrates how you can use PROC PLM to perform posterior inference from a Bayesian analysis. The data for this example are taken from Weisberg (1985) and concern the effect of small electrical currents on farm animals. The ultimate goal of the experiment was to understand the effects of high-voltage power lines on livestock and to better protect farm animals. Seven cows and six shock intensities were used in two experiments. In one experiment, each cow was given 30 electrical shocks with five at each shock intensity in random order. The number of shock responses was recorded for each cow at each shock level. The experiment was then repeated to investigate whether the response diminished due to fatigue of cows, or due to learning. So each cow received a total of 60 shocks. For the following analysis, the cow difference is ignored. The following DATA step lists the data where the variable `current` represents the shock level, the variable `response` represents the number of shock responses, the variable `trial` represents the total number of trials at each shock level, and the variable `experiment` represents the experiment number (1 for the initial experiment and 2 for the repeated one):

```

data cow;
    input current response trial experiment;
    datalines;
0  0 35 1
0  0 35 2
1  6 35 1
1  3 35 2
2 13 35 1
2  8 35 2
3 26 35 1
3 21 35 2
4 33 35 1
4 27 35 2
5 34 35 1
5 29 35 2
;

```

Suppose you are interested in modeling the distribution of the shock response based on the level of the current and the experiment number. You can use the GENMOD procedure to fit a frequentist logistic model for the data. However, if you have some prior information about parameter estimates, you can fit a Bayesian logistic regression model to take this prior information into account. In this case, suppose you believe the logit of response has a positive association with the shock level but you are uncertain about the ranges of other regression coefficients. To incorporate this prior information in the regression model, you can use the following statements:

```

data prior;
    input _type_$ current;
    datalines;
mean 100
var   50
;

proc genmod data=cow;
    class experiment;
    bayes coeffprior=normal(input=prior) seed=1;
    model response/trial = current|experiment / dist=binomial;
    store cowgmd;
    title 'Bayesian Logistic Model on Cow';
run;

```

The DATA step creates a data set prior that specifies the prior distribution for the variable current, which in this case is a normal distribution with mean 100 and variance 50. This reflects a rough belief in a positive coefficient in a moderate range for current. The prior distribution parameters are not specified for experiment and the interaction between experiment and current, and so PROC GENMOD assigns a default prior for them, which is a normal distribution with mean 0 and variance 1E6.

The BAYES statement in PROC GENMOD specifies that the regression coefficients follow a normal distribution with mean and variance specified in the input data set named prior. It also specifies 1 as the seed for the random number generator in the simulation of the posterior sample. The MODEL statement requests a logistic regression model with a logit link. The STORE statement requests that the fitted results be saved into an item store named cowgmd.

The convergence diagnostics in the output of PROC GENMOD indicate that the Markov chain has converged. [Output 69.4.1](#) displays summaries on the posterior sample of the regression coefficients. The posterior mean for the intercept is -3.5857 with a 95% HPD interval $(-4.5226, -2.6303)$. The posterior mean of the coefficient for current is 1.1893 with a 95% HPD interval $(0.8950, 1.4946)$, which indicates a positive association between the logit of response and the shock level. Further investigation about whether shock reaction was different between two experiment is warranted.

Output 69.4.1 Posterior Summaries on the Bayesian Logistic Model

Bayesian Logistic Model on Cow						
The GENMOD Procedure						
Bayesian Analysis						
Posterior Summaries						
Parameter	N	Mean	Standard Deviation	Percentiles		
				25%	50%	75%
Intercept	10000	-3.6047	0.4906	-3.9281	-3.5842	-3.2679
current	10000	1.1966	0.1561	1.0873	1.1927	1.2996
experiment1	10000	0.0350	0.7014	-0.4206	0.0347	0.4987
experiment1current	10000	0.3574	0.2503	0.1906	0.3520	0.5235
Posterior Intervals						
Parameter	Alpha	Equal-Tail Interval		HPD Interval		
Intercept	0.050	-4.6233	-2.7074	-4.5611	-2.6581	
current	0.050	0.9073	1.5152	0.9028	1.5064	
experiment1	0.050	-1.3651	1.4004	-1.2995	1.4370	
experiment1current	0.050	-0.1293	0.8580	-0.1287	0.8580	

Bayesian model fitting typically involves a large amount of simulation. Using the item store and PROC PLM, you do not need to refit the model to perform further posterior inference. Suppose you want to determine whether the shock reaction for the current level is different between the two experiments. You can use PROC PLM with the ESTIMATE statement in the following statements:

```
proc plm restore=cowgmd;
  estimate
    'Diff at current 0' experiment 1 -1 current*experiment [1, 0 1] [-1, 0 2],
    'Diff at current 1' experiment 1 -1 current*experiment [1, 1 1] [-1, 1 2],
    'Diff at current 2' experiment 1 -1 current*experiment [1, 2 1] [-1, 2 2],
    'Diff at current 3' experiment 1 -1 current*experiment [1, 3 1] [-1, 3 2],
    'Diff at current 4' experiment 1 -1 current*experiment [1, 4 1] [-1, 4 2],
    'Diff at current 5' experiment 1 -1 current*experiment [1, 5 1] [-1, 5 2]
  / exp cl;
run;
```

Each line in the ESTIMATE statement compares the fits between the two groups at each current level. The nonpositional syntax is used for the interaction effect current*experiment. For example, the first line requests coefficient 1 for the interaction effect at current level 0 for the initial experiment, and coefficient

–1 for the effect at current level 0 for the repeated experiment. The two terms are then added to derive the difference. For more details about the nonpositional syntax, see “[Positional and Nonpositional Syntax for Coefficients in Linear Functions](#)” on page 448 of Chapter 19, “[Shared Concepts and Topics](#).”

The EXP option exponentiates log odds ratios to produce odds ratios. The CL option requests that confidence limits be constructed for both log odds ratios and odds ratios. [Output 69.4.2](#) lists the posterior sample estimates for differences between experiments at different current levels.

Output 69.4.2 Comparisons between Experiments at Different Current Levels

Diff at current 4	3.1227	4.2885	5.9040	1.3083	9.6902	
Diff at current 5	3.8606	6.0976	9.5838	0.9081	19.4638	

The sample statistics are constructed from the posterior sample saved in the item store `cowgmd`. From the output, the odds of a cow showing shock reaction at level 0 in the initial experiment is 1.2811 (with a 95% HPD interval (0.07387, 3.1001)) times the odds in the repeated experiment. The HPD interval for the odds ratio is constructed based on the mean and variance of the sample of the exponentiated log odds ratios, instead of based on the exponentiated mean and variance of the posterior sample of log odds ratios. The HPD interval suggests that there is not much evidence that the cows responded differently at current level 0 between the two experiments. Similar conclusions can be drawn for current level 1, 2, and 5. However, there is strong evidence that cows responded differently at current level 3 and 4 between the two experiments. The possible explanation is that, if the current level is so small that cows could hardly feel it or the current level is so strong that cows could hardly bear it, cows would respond consistently in the two experiment. If the current level is moderate, cows might get used to it and their response diminished in the repeated experiment.

You can visualize the distribution of the posterior sample of log odds ratios by specifying the `PLOTS=` option in the `ESTIMATE` statement. In the following statements, ODS Graphics is enabled by the `ODS GRAPHICS ON` statement, the `PLOTS=BOXPLOT` option requests a box plot of posterior distribution of log odds ratios. The suboption `ORIENT=HORIZONTAL` specifies a horizontal orientation of the boxes.

```
ods graphics on;
proc plm restore=cowgmd;
  estimate
    'Diff at current 0' experiment 1 -1 current*experiment [1, 0 1] [-1, 0 2],
    'Diff at current 1' experiment 1 -1 current*experiment [1, 1 1] [-1, 1 2],
    'Diff at current 2' experiment 1 -1 current*experiment [1, 2 1] [-1, 2 2],
    'Diff at current 3' experiment 1 -1 current*experiment [1, 3 1] [-1, 3 2],
    'Diff at current 4' experiment 1 -1 current*experiment [1, 4 1] [-1, 4 2],
    'Diff at current 5' experiment 1 -1 current*experiment [1, 5 1] [-1, 5 2]
    / plots=boxplot(orient=horizontal);
run;
ods graphics off;
```

Output 69.4.3 displays the box plot of the posterior sample of log odds ratios. The two boxes for differences at current level 3 and 4 show that the corresponding log odds ratios are significantly larger than the reference value $x = 0$. This indicate that there is obvious evidence that the probability of cow response is larger in the initial experiment than in the repeated one at the two current levels. The other four boxes show that the corresponding log odds ratios are not significantly different from 0, which suggests that there is no obvious reaction difference at current level 0, 1, 2, and 5 between the two experiments.

Output 69.4.3 Box Plot of Difference between Two Experiments

Example 69.5: BY-Group Processing

This example uses a data set on a study of the analgesic effects of treatments on elderly patients with neuralgia. The purpose of this example is to show how PROC PLM behaves under different situations when BY-group processing is present. Two test treatments and a placebo are compared to test whether the patient reported pain or not. For each patient, the information of age, gender, and the duration of complaint before the treatment began were recorded. The following DATA step creates the data set named Neuralgia:

```

Data Neuralgia;
  input Treatment $ Sex $ Age Duration Pain $ @@;
  datalines;
P F 68 1 No B M 74 16 No P F 67 30 No
P M 66 26 Yes B F 67 28 No B F 77 16 No
A F 71 12 No B F 72 50 No B F 76 9 Yes
A M 71 17 Yes A F 63 27 No A F 69 18 Yes
B F 66 12 No A M 62 42 No P F 64 1 Yes
A F 64 17 No P M 74 4 No A F 72 25 No
P M 70 1 Yes B M 66 19 No B M 59 29 No
A F 64 30 No A M 70 28 No A M 69 1 No

```

```

B F 78 1 No P M 83 1 Yes B F 69 42 No
B M 75 30 Yes P M 77 29 Yes P F 79 20 Yes
A M 70 12 No A F 69 12 No B F 65 14 No
B M 70 1 No B M 67 23 No A M 76 25 Yes
P M 78 12 Yes B M 77 1 Yes B F 69 24 No
P M 66 4 Yes P F 65 29 No P M 60 26 Yes
A M 78 15 Yes B M 75 21 Yes A F 67 11 No
P F 72 27 No P F 70 13 Yes A M 75 6 Yes
B F 65 7 No P F 68 27 Yes P M 68 11 Yes
P M 67 17 Yes B M 70 22 No A M 65 15 No
P F 67 1 Yes A M 67 10 No P F 72 11 Yes
A F 74 1 No B M 80 21 Yes A F 69 3 No
;

```

The data set contains five variables. Treatment is a classification variable that has three levels: A and B represent the two test treatments, and P represents the placebo treatment. Sex is a classification variable that indicates each patient's gender. Age is a continuous variable that indicates the age in years of each patient when a treatment began. Duration is a continuous variable that indicates the duration of complaint in months. The last variable Pain is the response variable with two levels: 'Yes' if pain was reported, 'No' if no pain was reported.

Suppose there is some preliminary belief that the dependency of pain on the explanatory variables is different for male and female patients, leading to separate models between genders. You believe there might be redundant information for predicting the probability of Pain. Thus, you want to perform model selection to eliminate unnecessary effects. You can use the following statements:

```

proc sort data=Neuralgia;
  by sex;
run;

proc logistic data=Neuralgia;
  class Treatment / param=glm;
  model pain = Treatment Age Duration / selection=backward;
  by sex;
  store painmodel;
  title 'Logistic Model on Neuralgia';
run;

```

PROC SORT is called to sort the data by variable Sex. The LOGISTIC procedure is then called to fit the probability of no pain. Three variables are specified for the full model: Treatment, Age, and Duration. Backward elimination is used as the model selection method. The BY statement fits separate models for male and female patients. Finally, the STORE statement specifies that the fitted results be saved to an item store named painmodel.

[Output 69.5.1](#) lists parameter estimates from the two models after backward elimination is performed. From the model for female patients, Treatment is the only factor that affects the probability of no pain, and Treatment A and B have the same positive effect in predicting the probability of no pain. From the model for male patients, both Treatment and Age are included in the selected model. Treatment A and B have different positive effects, while Age has a negative effect in predicting the probability of no pain.

Output 69.5.1 Parameter Estimates for Male and Female Patients

Logistic Model on Neuralgia					
----- Sex=F -----					
The LOGISTIC Procedure					
Analysis of Maximum Likelihood Estimates					
Parameter	DF	Estimate	Standard Error	Wald Chi-Square	Pr > ChiSq
Intercept	1	-0.4055	0.6455	0.3946	0.5299
Treatment A	1	2.6027	1.2360	4.4339	0.0352
Treatment B	1	2.6027	1.2360	4.4339	0.0352
Treatment P	0	0	.	.	.
----- Sex=M -----					
Analysis of Maximum Likelihood Estimates					
Parameter	DF	Estimate	Standard Error	Wald Chi-Square	Pr > ChiSq
Intercept	1	20.6178	9.1638	5.0621	0.0245
Treatment A	1	3.9982	1.7333	5.3208	0.0211
Treatment B	1	4.5556	1.9252	5.5993	0.0180
Treatment P	0	0	.	.	.
Age	1	-0.3416	0.1408	5.8869	0.0153

Now the fitted models are saved to the item store `painmodel`. Suppose you want to use it to score several new observations. The following DATA steps create three data sets for scoring:

```
data score1;
  input Treatment $ Sex $ Age;
  datalines;
A F 20
B F 30
P F 40
A M 20
B M 30
P M 40
;

data score2;
  set score1(drop=sex);
run;

data score3;
  set score2(drop=Age);
run;
```

The first score data set `score1` contains six observations and all the variables that are specified in the full model. The second score data set `score2` is a duplicate of `score1` except that `Sex` is dropped. The third score data set `score3` is a duplicate of `score2` except that `Age` is dropped. You can use the following statements to score the three data sets:

```
proc plm restore=painmodel;
  score data=score1 out=score1out predicted;
  score data=score2 out=score2out predicted;
  score data=score3 out=score3out predicted;
run;
```

[Output 69.5.2](#) lists the store information that PROC PLM reads from the item store `painmodel`. The “Model Effects” entry lists all three variables that are specified in the full model before the BY-group processing.

Output 69.5.2 Item Store Information for `painmodel`

Distribution	Binary
Class Variables	Treatment Pain
Model Effects	Intercept Treatment Age Duration

With the three `SCORE` statements, three data sets are thus produced: `score1out`, `score2out`, and `score3out`. They contain the linear predictors in addition to all original variables. The data set `score1out` contains the values shown in [Output 69.5.3](#).

Output 69.5.3 Values of Data Set `score1out`

Logistic Model on Neuralgia				
Obs	Treatment	Sex	Age	Predicted
1	A	F	20	2.1972
2	B	F	30	2.1972
3	P	F	40	-0.4055
4	A	M	20	17.7850
5	B	M	30	14.9269
6	P	M	40	6.9557

Linear predictors are computed for all six observations. Because the BY variable `Sex` is available in `score1`, PROC PLM uses separate models to score observations of male and female patients. So an observation with the same `Treatment` and `Age` has different linear predictors for different genders.

The data set `score2out` contains the values shown in [Output 69.5.4](#).

Output 69.5.4 Values of Data Set `score2out`

Logistic Model on Neuralgia				
Obs	Sex	Treatment	Age	Predicted
1	F	A	20	2.1972
2	F	B	30	2.1972
3	F	P	40	-0.4055
4	F	A	20	2.1972
5	F	B	30	2.1972
6	F	P	40	-0.4055
7	M	A	20	17.7850
8	M	B	30	14.9269
9	M	P	40	6.9557
10	M	A	20	17.7850
11	M	B	30	14.9269
12	M	P	40	6.9557

The second score data set `score2` does not contain the BY variable `Sex`. PROC PLM continues to score the full data set two times. Each time the scoring is based on the fitted model for each corresponding BY-group. In the output data set, `Sex` is added at the first column as the BY-group indicator. The first six entries correspond to the model for female patients, and the next six entries correspond to the model for male patients. `Age` is not included in the first model, and `Treatment` A and B have the same parameter estimates, so observations 1, 2, 4, and 5 have the same linear predicted value.

The data set `score3out` contains the values shown in [Output 69.5.5](#).

Output 69.5.5 Values of Data Set `score3out`

Logistic Model on Neuralgia			
Obs	Sex	Treatment	Predicted
1	F	A	2.19722
2	F	B	2.19722
3	F	P	-0.40547
4	F	A	2.19722
5	F	B	2.19722
6	F	P	-0.40547
7	M	A	.
8	M	B	.
9	M	P	.
10	M	A	.
11	M	B	.
12	M	P	.

The third score data set `score3` does not contain the BY variable `Sex`. PROC PLM scores the full data twice with separate models. Furthermore, it does not contain the variable `Age`, which is a selected variable for predicting the probability of no pain for male patients. Thus, PROC PLM computes linear predictor values for `score3` by using the first model for female patients, and sets the linear predictor to missing when using the second model for male patients to score the data set.

Example 69.6: Comparing Multiple B-Splines

This example conducts an analysis similar to Example 15 in Chapter 41.33, “Examples: GLIMMIX Procedure.” It uses simulated data to perform multiple comparisons among predicted values in a model with group-specific trends that are modeled through regression splines. The estimable functions are formed using nonpositional syntax with constructed effects. Consider the data in the following DATA step. Each of the 100 observations for the continuous response variable `y` is associated with one of two groups.

```
data spline;
  input group y @@;
  x = _n_;
  datalines;
1    -.020 1    0.199 2    -1.36 1    -.026
2    -.397 1    0.065 2    -.861 1    0.251
1    0.253 2    -.460 2    0.195 2    -.108
1    0.379 1    0.971 1    0.712 2    0.811
2    0.574 2    0.755 1    0.316 2    0.961
2    1.088 2    0.607 2    0.959 1    0.653
1    0.629 2    1.237 2    0.734 2    0.299

2    1.996 2    2.028 2    2.321 2    2.479
2    2.337 1    4.516 2    2.326 2    2.144
2    2.474 2    2.221 1    4.867 2    2.453
1    5.253 2    3.024 2    2.403 1    5.498
;
```

The following statements fit a model with separate trends for the two groups; the trends are modeled as B-splines.

```

proc orthoreg data=spline;
  class group;
  effect spl = spline(x);
  model y = group spl*group / noint;
  store ortho_spline;
  title 'B-splines Comparisons';
run;

```

Results from this analysis are shown in [Output 69.6.1](#). The “Parameter Estimates” table shows the estimates for the spline coefficients in the two groups.

Output 69.6.1 Results for Group-Specific Spline Model

spl*group 7 1	0	0	.	.	.
spl*group 7 2	0	0	.	.	.

By default, the ORTHOREG procedure constructs B-splines with seven knots. Since B-spline coefficients satisfy a sum-to-one constraint and since the model contains group-specific intercepts, the last spline coefficient for each group is redundant and is set to 0.

The following statements make a prediction for the input data set by using the SCORE statement with PROC PLM and graph the observed and predicted values in the two groups:

```
proc plm restore=ortho_spline;
  score data=spline out=ortho_pred predicted=p;
run;

proc sgplot data=ortho_pred;
  series y=p x=x / group=group name="fit";
  scatter y=y x=x / group=group;
  keylegend "fit" / title="Group";
run;
```

The prediction plot in [Output 69.6.2](#) suggests that there is some separation of the group trends for small values of x and for values that exceed about $x = 40$.

Output 69.6.2 Observed Data and Predicted Values by Group

In order to determine the range on which the trends separate significantly, the PLM procedure is executed in the following statements with an [ESTIMATE](#) statement that applies group comparisons at a number of values for the spline variable x :

```

%macro GroupDiff;
  %do x=0 %to 75 %by 5;
    "Diff at x=&x" group 1 -1 group*spl [1,1 &x] [-1,2 &x],
  %end;
  'Diff at x=80' group 1 -1 group*spl [1,1 80] [-1,2 80]
%mend;

proc plm restore=ortho_spline;
  show effects;
  estimate %GroupDiff / adjust=simulate seed=1 stepdown;
run;

```

For example, the following ESTIMATE statement compares the trends between the two groups at $x = 25$:

```
estimate 'Diff at x=25' group 1 -1 group*spl [1,1 25] [-1,2 25];
```

The nonpositional syntax is used for the `group*spl` effect. For example, the specification `[-1, 2 25]` requests that the spline be computed at $x = 25$ for the second level of variable `group`. The resulting coefficients are added to the *L* vector for the estimate after being multiplied with -1 .

Because comparisons are made at a large number of values for x , a multiplicity correction is in order to adjust the p -values to reflect familywise error control. Simulated p -values with step-down adjustment are used here.

Output 69.6.3 displays the “Store Information” for the item store and information about the spline effect (the result of the `SHOW` statement).

Diff at x=75	1.2400	0.1326	86	9.35	<.0001	<.0001
Diff at x=80	1.5237	0.1281	86	11.89	<.0001	<.0001

Notice that the “Store Information” in [Output 69.6.3](#) displays the classification variables (from the CLASS statement in PROC ORTHOREG), the constructed effects (from the EFFECT statement in PROC ORTHOREG), and the model effects (from the MODEL statement in PROC ORTHOREG). [Output 69.6.4](#) shows that at the 5% significance level the trends are significantly different for $x \leq 10$ and for $x \geq 40$. Between those values you cannot reject the hypothesis of trend congruity.

To see this effect more clearly, you can filter the results by adding the a filtering statement to the previous PROC PLM step:

```
proc plm restore=ortho_spline;
  estimate %GroupDiff / adjust=simulate seed=1 stepdown;
  filter adjp > 0.05;
run;
```

This produces [Output 69.6.5](#), which displays the subset of the results in [Output 69.6.4](#) that meets the condition in the **FILTER** expression.

Output 69.6.5 Filtered Estimate Results

Example 69.7: Linear Inference with Arbitrary Estimates

Suppose that you have calculated a vector of parameter estimates of dimension $(p \times 1)$ and its associated variance-covariance matrix by some statistical method. You might want to use these results to perform linear inference, or to score a data set and calculate predicted values and their standard errors.

The following DATA steps create two SAS data sets. The first, called `parms`, contains six estimates that represent two uncorrelated groups. The data set `cov` contains the covariance matrix of the estimates. The lack of correlation between the two sets of three parameters is evident in the block-diagonal structure of the covariance matrix.

```

data parms;
    length name $6;
    input Name$ Value;
    datalines;
alpha1 -3.5671
beta1   0.4421
gamma1 -2.6230
alpha2 -3.0111
beta2   0.3977
gamma2 -2.4442
;

data cov;
    input Parm row col1-col6;
    datalines;
1 1  0.007462 -0.005222  0.010234  0.000000  0.000000  0.000000
1 2 -0.005222  0.048197 -0.010590  0.000000  0.000000  0.000000
1 3  0.010234 -0.010590  0.215999  0.000000  0.000000  0.000000
1 4  0.000000  0.000000  0.000000  0.031261 -0.009096  0.015785
1 5  0.000000  0.000000  0.000000 -0.009096  0.039487 -0.019996
1 6  0.000000  0.000000  0.000000  0.015785 -0.019996  0.126172
;

```

Suppose that you are interested in testing whether the parameters are homogeneous across groups—that is, whether $\alpha_1 = \alpha_2$, $\beta_1 = \beta_2$, $\gamma_1 = \gamma_2$. You are interested in testing the hypothesis jointly and separately with multiplicity adjustment.

To use the PLM procedure, you first need to create an item store that contains the necessary information as if the preceding parameter vector and covariance matrix were the result of a statistical modeling procedure. The following statements use the GLIMMIX procedure to create such an item store, by fitting a saturated linear model with the data set that contains the parameter estimates serving as the input data set:

```

proc glimmix data=parms order=data;
    class Name;
    model Value = Name / noint ddfm=none s;
    random _residual_ / type=lin(1) ldata=cov v;
    parms (1) / noiter;
    store ArtificialModel;
    title 'Linear Inference';
run;

```

The RANDOM statement is used to form the covariance structure for the estimates. The PARMS statement prevents iterative updates of the covariance parameters. The resulting marginal covariance matrix of the “data” is thus identical to the covariance matrix in the data set cov. The ORDER=DATA option in the PROC GLIMMIX statement is used to arrange the levels of the classification variable Name in the order in which they appear in the data set so that the order of the parameters matches that of the covariance matrix.

The results of this analysis are shown in [Output 69.7.1](#). Note that the parameter estimates are identical to the values passed in the input data set and their standard errors equal the square root of the diagonal elements of the cov data set.

Output 69.7.1 “Fitted” Parameter Estimates and Covariance Matrix

name	beta1	0.4421	0.2195	Infty	2.01	0.0440
name	gamma1	-2.6230	0.4648	Infty	-5.64	<.0001
name	alpha2	-3.0111	0.1768	Infty	-17.03	<.0001
name	beta2	0.3977	0.1987	Infty	2.00	0.0454
name	gamma2	-2.4442	0.3552	Infty	-6.88	<.0001

There are other ways to fit a saturated model with the GLIMMIX procedure. For example, you can use the TYPE=UN covariance structure in the RANDOM statement with a properly prepared input data set for the PDATA= option in the PARMS statement. See Example 17 in Chapter 41.33, “[Examples: GLIMMIX Procedure](#),” for details.

Once the item store exists, you can apply the linear inference capabilities of the PLM procedure. For example, the [ESTIMATE](#) statement in the following statements test the hypothesis of parameter homogeneity across groups:

```
proc plm restore=ArtificialModel;
  estimate
    'alpha1 = alpha2' Name 1 0 0 -1 0 0,
    'beta1 = beta2 ' Name 0 1 0 0 -1 0,
    'gamma1 = gamma2' Name 0 0 1 0 0 -1 /
    adjust=bon stepdown ftest(label='Homogeneity');
run;
```

Label	Num DF	Den DF	F Value	Pr > F		
Homogeneity	3	Infty	2.79	0.0389		

The F test in [Output 69.7.2](#) shows that the joint test of homogeneity is rejected. The individual tests with familywise control of the Type I error show that the overall difference is due to a significant change in the α parameters. The hypothesis of homogeneity across the two groups cannot be rejected for the β and γ parameters.

Overview: PLS Procedure

The PLS procedure fits models by using any one of a number of linear predictive methods, including *partial least squares* (PLS). Ordinary least squares regression, as implemented in SAS/STAT procedures such as PROC GLM and PROC REG, has the single goal of minimizing sample response prediction error, seeking linear functions of the predictors that explain as much variation in each response as possible. The techniques implemented in the PLS procedure have the additional goal of accounting for variation in the predictors, under the assumption that directions in the predictor space that are well sampled should provide better prediction for *new* observations when the predictors are highly correlated. All of the techniques implemented in the PLS procedure work by extracting successive linear combinations of the predictors, called *factors* (also called *components*, *latent vectors*, or *latent variables*), which optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, the method of partial least squares balances the two objectives, seeking factors that explain both response and predictor variation.

Note that the name “partial least squares” also applies to a more general statistical method that is *not* implemented in this procedure. The partial least squares method was originally developed in the 1960s by the econometrician Herman Wold (1966) for modeling “paths” of causal relation between any number of “blocks” of variables. However, the PLS procedure fits only *predictive* partial least squares models, with one “block” of predictors and one “block” of responses. If you are interested in fitting more general path models, you should consider using the CALIS procedure.

Basic Features

The techniques implemented by the PLS procedure are as follows:

- principal components regression, which extracts factors to explain as much predictor sample variation as possible
- reduced rank regression, which extracts factors to explain as much response variation as possible. This technique, also known as (maximum) redundancy analysis, differs from multivariate linear regression only when there are multiple responses.
- partial least squares regression, which balances the two objectives of explaining response variation and explaining predictor variation. Two different formulations for partial least squares are available: the original predictive method of Wold (1966) and the SIMPLS method of de Jong (1993).

The number of factors to extract depends on the data. Basing the model on more extracted factors improves the model fit to the observed data, but extracting too many factors can cause *overfitting*—that is, tailoring the model too much to the current data, to the detriment of future predictions. The PLS procedure enables you to choose the number of extracted factors by *cross validation*—that is, fitting the model to part of the data, minimizing the prediction error for the unfitted part, and iterating with different portions of the data in the roles of fitted and unfitted. Various methods of cross validation are available, including one-at-a-time validation and splitting the data into blocks. The PLS procedure also offers test set validation, where the model is fit to the entire primary input data set and the fit is evaluated over a distinct test data set.

You can use the general linear modeling approach of the GLM procedure to specify a model for your design, allowing for general polynomial effects as well as classification or ANOVA effects. You can save the model fit by the PLS procedure in a data set and apply it to new data by using the SCORE procedure.

The PLS procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the statistical graphics available with the PLS procedure, see the [PLOTS](#) options in the [PROC PLS](#) statements and the section “[ODS Graphics](#)” on page 5891.

Getting Started: PLS Procedure

Spectrometric Calibration

The example in this section illustrates basic features of the PLS procedure. The data are reported in Umetrics (1995); the original source is Lindberg, Persson, and Wold (1983). Suppose that you are researching pollution in the Baltic Sea, and you would like to use the spectra of samples of seawater to determine the amounts of three compounds present in samples from the Baltic Sea: lignin sulfonate (ls: pulp industry pollution), humic acids (ha: natural forest products), and optical whitener from detergent (dt). Spectrometric calibration is a type of problem in which partial least squares can be very effective. The predictors are the spectra emission intensities at different frequencies in sample spectrum, and the responses are the amounts of various chemicals in the sample.

For the purposes of calibrating the model, samples with known compositions are used. The calibration data consist of 16 samples of known concentrations of ls, ha, and dt, with spectra based on 27 frequencies (or, equivalently, wavelengths). The following statements create a SAS data set named Sample for these data.

```

Fitting a PLS Model

To isolate a few underlying spectral factors that provide a good predictive model, you can fit a PLS model to the 16 samples by using the following SAS statements:

```

proc pls data=sample;
  model ls ha dt = v1-v27;
run;

```

By default, the PLS procedure extracts at most 15 factors. The procedure lists the amount of variation accounted for by each of these factors, both individual and cumulative; this listing is shown in [Figure 70.1](#).

Figure 70.1 PLS Variation Summary

The PLS Procedure				
Percent Variation Accounted for by Partial Least Squares Factors				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	97.4607	97.4607	41.9155	41.9155
2	2.1830	99.6436	24.2435	66.1590
3	0.1781	99.8217	24.5339	90.6929
4	0.1197	99.9414	3.7898	94.4827
5	0.0415	99.9829	1.0045	95.4873
6	0.0106	99.9935	2.2808	97.7681
7	0.0017	99.9952	1.1693	98.9374
8	0.0010	99.9961	0.5041	99.4415
9	0.0014	99.9975	0.1229	99.5645
10	0.0010	99.9985	0.1103	99.6747
11	0.0003	99.9988	0.1523	99.8270
12	0.0003	99.9991	0.1291	99.9561
13	0.0002	99.9994	0.0312	99.9873
14	0.0004	99.9998	0.0065	99.9938
15	0.0002	100.0000	0.0062	100.0000

Note that all of the variation in both the predictors and the responses is accounted for by only 15 factors; this is because there are only 16 sample observations. More important, almost all of the variation is accounted for with even fewer factors—one or two for the predictors and three to eight for the responses.

Selecting the Number of Factors by Cross Validation

A PLS model is not complete until you choose the number of factors. You can choose the number of factors by using cross validation, in which the data set is divided into two or more groups. You fit the model to all groups except one, and then you check the capability of the model to predict responses for the group omitted. Repeating this for each group, you then can measure the overall capability of a given form of the model. The predicted residual sum of squares (PRESS) statistic is based on the residuals generated by this process.

To select the number of extracted factors by cross validation, you specify the **CV=** option with an argument that says which cross validation method to use. For example, a common method is split-sample validation, in which the different groups are composed of every n th observation beginning with the first, every n th observation beginning with the second, and so on. You can use the **CV=SPLIT** option to specify split-sample validation with $n = 7$ by default, as in the following SAS statements:

```
proc pls data=sample cv=split;
  model ls ha dt = v1-v27;
run;
```

The resulting output is shown in [Figure 70.2](#) and [Figure 70.3](#).

Percent Variation Accounted for by Partial Least Squares Factors				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	97.4607	97.4607	41.9155	41.9155
2	2.1830	99.6436	24.2435	66.1590
3	0.1781	99.8217	24.5339	90.6929
4	0.1197	99.9414	3.7898	94.4827
5	0.0415	99.9829	1.0045	95.4873
6	0.0106	99.9935	2.2808	97.7681

The absolute minimum PRESS is achieved with six extracted factors. Notice, however, that this is not much smaller than the PRESS for three factors. By using the [CVTEST](#) option, you can perform a statistical model comparison suggested by van der Voet (1994) to test whether this difference is significant, as shown in the following SAS statements:

```
proc pls data=sample cv=split cvtest(seed=12345);
  model ls ha dt = v1-v27;
run;
```

The model comparison test is based on a rerandomization of the data. By default, the seed for this randomization is based on the system clock, but it is specified here. The resulting output is shown in Figure 70.4 and Figure 70.5.

Figure 70.5 PLS Variation Summary for Tested Split-Sample Validated Model

Percent Variation Accounted for by Partial Least Squares Factors				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	97.4607	97.4607	41.9155	41.9155
2	2.1830	99.6436	24.2435	66.1590
3	0.1781	99.8217	24.5339	90.6929

The p -value of 0.1430 in comparing the cross validated residuals from models with 6 and 3 factors indicates that the difference between the two models is insignificant; therefore, the model with fewer factors is preferred. The variation summary shows that over 99% of the predictor variation and over 90% of the response variation are accounted for by the three factors.

Predicting New Observations

Now that you have chosen a three-factor PLS model for predicting pollutant concentrations based on sample spectra, suppose that you have two new samples. The following SAS statements create a data set containing the spectra for the new samples:

```
data newobs;
  input obsnam $ v1-v27 @@;
  datalines;
EM17  3933 4518 5637 6006 5721 5187 4641 4149 3789
      3579 3447 3381 3327 3234 3078 2832 2571 2274
      2040 1818 1629 1470 1350 1245 1134 1050  987
EM25  2904 2997 3255 3150 2922 2778 2700 2646 2571
      2487 2370 2250 2127 2052 1713 1419 1200  984
      795  648  525  426  351  291  240  204  162
;
```

You can apply the PLS model to these samples to estimate pollutant concentration. To do so, append the new samples to the original 16, and specify that the predicted values for all 18 be output to a data set, as shown in the following statements:

```
data all;
  set sample newobs;
run;

proc pls data=all nfac=3;
  model ls ha dt = v1-v27;
  output out=pred p=p_ls p_ha p_dt;
run;

proc print data=pred;
  where (obsnam in ('EM17','EM25'));
  var obsnam p_ls p_ha p_dt;
run;
```

The new observations are not used in calculating the PLS model, since they have no response values. Their predicted concentrations are shown in [Figure 70.6](#).

Figure 70.6 Predicted Concentrations for New Observations

Obs	obsnam	p_ls	p_ha	p_dt
17	EM17	2.54261	0.31877	81.4174
18	EM25	-0.24716	1.37892	46.3212

Finally, if ODS Graphics is enabled, PLS also displays by default a plot of the amount of variation accounted for by each factor, as well as a correlations loading plot that summarizes the first two dimensions of the PLS model. The following statements, which are the same as the previous split-sample validation analysis but with ODS Graphics enabled, additionally produce [Figure 70.7](#) and [Figure 70.8](#):

```
ods graphics on;

proc pls data=sample cv=split cvtest(seed=12345);
  model ls ha dt = v1-v27;
run;

ods graphics off;
```

Figure 70.7 Split-Sample Cross Validation Plot

Figure 70.8 Correlation Loadings Plot

The cross validation plot in [Figure 70.7](#) gives a visual representation of the selection of the optimum number of factors discussed previously. The correlation loadings plot is a compact summary of many features of the PLS model. For example, it shows that the first factor is highly positively correlated with all spectral values, indicating that it is approximately an average of them all; the second factor is positively correlated with the lowest frequencies and negatively correlated with the highest, indicating that it is approximately a contrast between the two ends of the spectrum. The observations, represented by their number in the data set on this plot, are generally spaced well apart, indicating that the data give good information about these first two factors. For more details on the interpretation of the correlation loadings plot, see the section “[ODS Graphics](#)” on page 5891 and [Example 70.1](#).

Syntax: PLS Procedure

The following statements are available in the PLS procedure. Items within the angle brackets are optional.

```
PROC PLS < options > ;
    BY variables ;
    CLASS variables < / option > ;
    EFFECT name=effect-type (variables < / options > ) ;
    ID variables ;
    MODEL dependent-variables = effects < / options > ;
    OUTPUT OUT=SAS-data-set < options > ;
```

To analyze a data set, you must use the **PROC PLS** and **MODEL** statements. You can use the other statements as needed. **CLASS** and **EFFECT** statements, if present, must precede the **MODEL** statement.

PROC PLS Statement

```
PROC PLS < options > ;
```

The PROC PLS statement invokes the PLS procedure. Optionally, you can also indicate the analysis data and method in the PROC PLS statement. [Table 70.1](#) summarizes the options available in the PROC PLS statement.

Table 70.1 PROC PLS Statement Options

Option	Description
CENSCALE	Displays the centering and scaling information
CV=ONE	Specifies the cross validation method to be used
CVTEST	Specifies that van der Voet's (1994) randomization-based model comparison test be performed
DATA=	Names the SAS data set
DETAILS	Displays the details of the fitted model
METHOD=PLS	Specifies the general factor extraction method to be used
MISSING=	Specifies how observations with missing values are to be handled in computing the fit
NFAC=	Specifies the number of factors to extract
NOCENTER	Suppresses centering of the responses and predictors before fitting
NOCVSTDIZE	Suppresses re-centering and rescaling of the responses and predictors when cross-validating
NOPRINT	Suppresses the normal display of results
NOSCALE	Suppresses scaling of the responses and predictors before fitting
PLOTS	Controls the plots produced through ODS Graphics
VARSCALE	Specifies that continuous model variables be centered and scaled
VARSS	Displays the amount of variation accounted for in each response and predictor

The following options are available.

CENSCALE

lists the centering and scaling information for each response and predictor.

CV=ONE

CV=SPLIT <(n)>

CV=BLOCK <(n)>

CV=RANDOM <(cv-random-opts)>

CV=TESTSET(SAS-data-set)

specifies the cross validation method to be used. By default, no cross validation is performed. The method CV=ONE requests one-at-a-time cross validation, CV=SPLIT requests that every n th observation be excluded, CV=BLOCK requests that n blocks of consecutive observations be excluded, CV=RANDOM requests that observations be excluded at random, and CV=TESTSET(SAS-data-set) specifies a test set of observations to be used for validation (formally, this is called “test set validation” rather than “cross validation”). You can, optionally, specify n for CV=SPLIT and CV=BLOCK; the default is $n = 7$. You can also specify the following optional *cv-random-options* in parentheses after the CV=RANDOM option:

NITER= n

specifies the number of random subsets to exclude. The default value is 10.

NTEST= n

specifies the number of observations in each random subset chosen for exclusion. The default value is one-tenth of the total number of observations.

SEED= n

specifies an integer used to start the pseudo-random number generator for selecting the random test set. If you do not specify a seed, or specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer’s clock.

CVTEST <(cvtest-options)>

specifies that van der Voet’s (1994) randomization-based model comparison test be performed to test models with different numbers of extracted factors against the model that minimizes the predicted residual sum of squares; see the section “[Cross Validation](#)” on page 5887 for more information. You can also specify the following *cv-test-options* in parentheses after the CVTEST option:

PVAL= n

specifies the cutoff probability for declaring an insignificant difference. The default value is 0.10.

STAT=test-statistic

specifies the test statistic for the model comparison. You can specify either T2, for Hotelling’s T^2 statistic, or PRESS, for the predicted residual sum of squares. The default value is T2.

NSAMP= n

specifies the number of randomizations to perform. The default value is 1000.

SEED=*n*

specifies the seed value for randomization generation (the clock time is used by default).

DATA=*SAS-data-set*

names the SAS data set to be used by PROC PLS. The default is the most recently created data set.

DETAILS

lists the details of the fitted model for each successive factor. The details listed are different for different extraction methods; see the section “[Displayed Output](#)” on page 5890 for more information.

METHOD=PLS < (*PLS-options*) >**METHOD=SIMPLS****METHOD=PCR****METHOD=RRR**

specifies the general factor extraction method to be used. The value PLS requests partial least squares, SIMPLS requests the SIMPLS method of de Jong (1993), PCR requests principal components regression, and RRR requests reduced rank regression. The default is METHOD=PLS. You can also specify the following optional *PLS-options* in parentheses after METHOD=PLS:

ALGORITHM=NIPALS | SVD | EIG | RLGW

names the specific algorithm used to compute extracted PLS factors. NIPALS requests the usual iterative NIPALS algorithm, SVD bases the extraction on the singular value decomposition of $\mathbf{X}'\mathbf{Y}$, EIG bases the extraction on the eigenvalue decomposition of $\mathbf{Y}'\mathbf{X}\mathbf{X}'\mathbf{Y}$, and RLGW is an iterative approach that is efficient when there are many predictors. ALGORITHM=SVD is the most accurate but least efficient approach; the default is ALGORITHM=NIPALS.

MAXITER=*n*

specifies the maximum number of iterations for the NIPALS and RLGW algorithms. The default value is 200.

EPSILON=*n*

specifies the convergence criterion for the NIPALS and RLGW algorithms. The default value is 10^{-12} .

MISSING=NONE**MISSING=AVG****MISSING=EM < (*EM-options*) >**

specifies how observations with missing values are to be handled in computing the fit. The default is MISSING=NONE, for which observations with any missing variables (dependent or independent) are excluded from the analysis. MISSING=AVG specifies that the fit be computed by filling in missing values with the average of the nonmissing values for the corresponding variable. If you specify MISSING=EM, then the procedure first computes the model with MISSING=AVG and then fills in missing values by their predicted values based on that model and computes the model again. For both methods of imputation, the imputed values contribute to the centering and scaling values, and the difference between the imputed values and their final predictions contributes to the percentage of variation explained. You can also specify the following optional *EM-options* in parentheses after MISSING=EM:

MAXITER=*n*

specifies the maximum number of iterations for the imputation/fit loop. The default value is 1. If you specify a large value of MAXITER=, then the loop will iterate until it converges (as controlled by the EPSILON= option).

EPSILON=*n*

specifies the convergence criterion for the imputation/fit loop. The default value is 10^{-8} . This option is effective only if you specify a large value for the MAXITER= option.

NFAC=*n*

specifies the number of factors to extract. The default is $\min\{15, p, N\}$, where p is the number of predictors (the number of dependent variables for METHOD=RRR) and N is the number of runs (observations). This is probably more than you need for most applications. Extracting too many factors can lead to an overfit model, one that matches the training data too well, sacrificing predictive ability. Thus, if you use the default NFAC= specification, you should also either use the CV= option to select the appropriate number of factors for the final model or consider the analysis to be preliminary and examine the results to determine the appropriate number of factors for a subsequent analysis.

NOCENTER

suppresses centering of the responses and predictors before fitting. This is useful if the analysis variables are already centered and scaled. See the section “[Centering and Scaling](#)” on page 5889 for more information.

NOCVSTDIZE

suppresses re-centering and rescaling of the responses and predictors before each model is fit in the cross validation. See the section “[Centering and Scaling](#)” on page 5889 for more information.

NOPRINT

suppresses the normal display of results. This is useful when you want only the output statistics saved in a data set. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#)” for more information.

NOSCALE

suppresses scaling of the responses and predictors before fitting. This is useful if the analysis variables are already centered and scaled. See the section “[Centering and Scaling](#)” on page 5889 for more information.

PLOTS <(global-plot-options)> <= plot-request <(options)>>

PLOTS <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses from around the plot request. For example:

```
plots=none
plots=cvplot
plots=(diagnostics cvplot)
plots(unpack)=diagnostics
plots(unpack)=(diagnostics corrload(trace=off))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc pls data=pentaTrain;
    model log_RAI = S1-S5 L1-L5 P1-P5;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC PLS produces by default a plot of the R-square analysis and a correlation loading plot summarizing the first two factors.

The global plot options include the following:

FLIP

interchanges the X-axis and Y-axis dimensions for the score, weight, and loading plots.

ONLY

suppresses the default plots. Only plots specifically requested are displayed.

UNPACKPANEL

UNPACK

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACKPANEL to get each plot in a separate panel. You can specify PLOTS(UNPACKPANEL) to unpack only the default plots. You can also specify UNPACKPANEL as a suboption for certain specific plots, as discussed in the following.

The plot requests include the following:

ALL

produces all appropriate plots. You can specify other options with ALL—for example, to request all plots and unpack only the residuals, specify PLOTS=(ALL RESIDUALS(UNPACK)).

CORRLOAD <(TRACE = ON | OFF)>

produces a correlation loading plot (default). The TRACE= option controls how points corresponding to the X-loadings in the correlation loadings plot are depicted. By default, these points are depicted by the name of the corresponding model effect if there are 20 or fewer of them; otherwise, they are depicted by a connected “trace” through the points. You can use this option to change this behavior.

CVPLOT

produces a cross validation and R-square analysis. This plot requires the CV= option to be specified, and is displayed by default in this case.

DIAGNOSTICS <(UNPACK)>

produces a summary panel of the fit for each dependent variable. The summary by default consists of a panel for each dependent variable, with plots depicting the distribution of residuals and predicted values. You can use the UNPACK suboption to specify that the subplots be produced separately.

DMOD

produces the DMODX, DMODY, and DMODXY plots.

DMODX

produces a plot of the distance of each observation to the X model.

DMODXY

produces plots of the distance of each observation to the X and Y models.

DMODY

produces a plot of the distance of each observation to the Y model.

FIT

produces both the fit diagnostic panel and the ParmProfiles plot.

NONE

suppresses the display of graphics.

PARMPROFILES

produces profiles of the regression coefficients.

SCORES <(UNPACK | FLIP)>

produces the XScores, YScores, XYScores, and DModXY plots. You can use the UNPACK suboption to specify that the subplots for scores be produced separately, and the FLIP option to interchange their default X-axis and Y-axis dimensions.

RESIDUALS <(UNPACK)>

plots the residuals for each dependent variable against each independent variable. Residual plots are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately.

VIP

produces profiles of variable importance factors.

WEIGHTS <(UNPACK | FLIP)>

produces all X and Y loading and weight plots, as well as the VIP plot. You can use the UNPACK suboption to specify that the subplots for weights and loadings be produced separately, and the FLIP option to interchange their default X-axis and Y-axis dimensions.

XLOADINGPLOT <(UNPACK | FLIP)>

produces a scatter plot matrix of X-loadings against each other. Loading scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

XLOADINGPROFILES

produces profiles of the X-loadings.

XSCORES <(UNPACK | FLIP)>

produces a scatter plot matrix of X-scores against each other. Score scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

XWEIGHTPLOT <(UNPACK | FLIP)>

produces a scatter plot matrix of X-weights against each other. Weight scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

XWEIGHTPROFILES

produces profiles of the X-weights.

XYScores <(UNPACK)>

produces a scatter plot matrix of X-scores against Y-scores. Score scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately.

YScores <(UNPACK | FLIP)>

produces a scatter plot matrix of Y-scores against each other. Score scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

YWEIGHTPLOT <(UNPACK | FLIP)>

produces a scatter plot matrix of Y-weights against each other. Weight scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

VARSCALE

specifies that continuous model variables be centered and scaled prior to centering and scaling the model effects in which they are involved. The rescaling specified by the VARSCALE option is sometimes more appropriate if the model involves crossproducts between model variables; however, the VARSCALE option still might not produce the model you expect. See the section “[Centering and Scaling](#)” on page 5889 for more information.

VARSS

lists, in addition to the average response and predictor sum of squares accounted for by each successive factor, the amount of variation accounted for in each response and predictor.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC PLS to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the NOTSORTED or DESCENDING option in the BY statement for the PLS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / **TRUNCATE** > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

EFFECT Statement

EFFECT *name=effect-type* (*variables*< / *options*>) ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 of Chapter 19, “Shared Concepts and Topics.”

The following *effect-types* are available.

COLLECTION

is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.

LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.
MULTIMEMBER MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 70.2 summarizes the *options* available in the EFFECT statement.

Table 70.2 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect
Lag Effects Options	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Multimember Effects Options	
NOEFFECT	Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

For further details about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “[EFFECT Statement](#)” on page 393 of Chapter 19, “[Shared Concepts and Topics](#).”

ID Statement

ID *variables* ;

The ID statement names variables whose values are used to label observations in plots. If you do not specify an ID statement, then each observations is labeled in plots by its corresponding observation number.

MODEL Statement

MODEL *response-variables = predictor-effects < / options >* ;

The MODEL statement names the responses and the predictors, which determine the **Y** and **X** matrices of the model, respectively. Usually you simply list the names of the predictor variables as the model effects, but you can also use the effects notation of PROC GLM to specify polynomial effects and interactions; see the section “[Specification of Effects](#)” on page 3324 in Chapter 42, “[The GLM Procedure](#)” for further details. The MODEL statement is required. You can specify only one MODEL statement (in contrast to the REG procedure, for example, which allows several MODEL statements in the same PROC REG run).

You can specify the following options in the MODEL statement after a slash (/).

INTERCEPT

By default, the responses and predictors are centered; thus, no intercept is required in the model. You can specify the INTERCEPT option to override the default.

SOLUTION

lists the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses based on the centered and scaled predictors are displayed, as well as the coefficients for predicting the raw responses based on the raw predictors.

OUTPUT Statement

OUTPUT **OUT=***SAS-data-set* **keyword=***names* < ... **keyword=***names* > ;

You use the OUTPUT statement to specify a data set to receive quantities that can be computed for every input observation, such as extracted factors and predicted values. The following *keywords* are available:

PREDICTED	predicted values for responses
YRESIDUAL	residuals for responses
XRESIDUAL	residuals for predictors
XSCORE	extracted factors (X-scores, latent vectors, latent variables, <i>T</i>)
YSCORE	extracted responses (Y-scores, <i>U</i>)
STDY	standardized (centered and scaled) responses

STDX	standardized (centered and scaled) predictors
H	approximate leverage
PRESS	approximate predicted residuals
TSQUARE	scaled sum of squares of score values
STDXSSE	sum of squares of residuals for standardized predictors
STDYSSE	sum of squares of residuals for standardized responses

Suppose that there are N_x predictors and N_y responses and that the model has N_f selected factors.

- The keywords XRESIDUAL and STDX define an output variable for each predictor, so N_x names are required after each one.
- The keywords PREDICTED, YRESIDUAL, STDY, and PRESS define an output variable for each response, so N_y names are required after each of these keywords.
- The keywords XSCORE and YSCORE specify an output variable for each selected model factor. For these keywords, you provide only one base name, and the variables corresponding to each successive factor are named by appending the factor number to the base name. For example, if $N_f = 3$, then a specification of XSCORE=T would produce the variables T1, T2, and T3.
- Finally, the keywords H, TSQUARE, STDXSSE, and STDYSSE each specify a single output variable, so only one name is required after each of these keywords.

Details: PLS Procedure

Regression Methods

All of the predictive methods implemented in PROC PLS work essentially by finding linear combinations of the predictors (factors) to use to predict the responses linearly. The methods differ only in how the factors are derived, as explained in the following sections.

Partial Least Squares

Partial least squares (PLS) works by extracting one factor at a time. Let $\mathbf{X} = \mathbf{X}_0$ be the centered and scaled matrix of predictors and let $\mathbf{Y} = \mathbf{Y}_0$ be the centered and scaled matrix of response values. The PLS method starts with a linear combination $\mathbf{t} = \mathbf{X}_0\mathbf{w}$ of the predictors, where \mathbf{t} is called a *score* vector and \mathbf{w} is its associated *weight* vector. The PLS method predicts both \mathbf{X}_0 and \mathbf{Y}_0 by regression on \mathbf{t} :

$$\begin{aligned}\hat{\mathbf{X}}_0 &= \mathbf{t}\mathbf{p}', \text{ where } \mathbf{p}' = (\mathbf{t}'\mathbf{t})^{-1}\mathbf{t}'\mathbf{X}_0 \\ \hat{\mathbf{Y}}_0 &= \mathbf{t}\mathbf{c}', \text{ where } \mathbf{c}' = (\mathbf{t}'\mathbf{t})^{-1}\mathbf{t}'\mathbf{Y}_0\end{aligned}$$

The vectors \mathbf{p} and \mathbf{c} are called the X- and Y-loadings, respectively.

The specific linear combination $\mathbf{t} = \mathbf{X}_0 \mathbf{w}$ is the one that has maximum covariance $\mathbf{t}'\mathbf{u}$ with some response linear combination $\mathbf{u} = \mathbf{Y}_0 \mathbf{q}$. Another characterization is that the X- and Y-weights \mathbf{w} and \mathbf{q} are proportional to the first left and right singular vectors of the covariance matrix $\mathbf{X}_0' \mathbf{Y}_0$ or, equivalently, the first eigenvectors of $\mathbf{X}_0' \mathbf{Y}_0 \mathbf{Y}_0' \mathbf{X}_0$ and $\mathbf{Y}_0' \mathbf{X}_0 \mathbf{X}_0' \mathbf{Y}_0$, respectively.

This accounts for how the first PLS factor is extracted. The second factor is extracted in the same way by replacing \mathbf{X}_0 and \mathbf{Y}_0 with the X- and Y-residuals from the first factor:

$$\begin{aligned}\mathbf{X}_1 &= \mathbf{X}_0 - \hat{\mathbf{X}}_0 \\ \mathbf{Y}_1 &= \mathbf{Y}_0 - \hat{\mathbf{Y}}_0\end{aligned}$$

These residuals are also called the *deflated* X and Y blocks. The process of extracting a score vector and deflating the data matrices is repeated for as many extracted factors as are wanted.

SIMPLS

Note that each extracted PLS factor is defined in terms of different X-variables \mathbf{X}_i . This leads to difficulties in comparing different scores, weights, and so forth. The SIMPLS method of de Jong (1993) overcomes these difficulties by computing each score $t_i = \mathbf{X} \mathbf{r}_i$ in terms of the original (centered and scaled) predictors \mathbf{X} . The SIMPLS X-weight vectors \mathbf{r}_i are similar to the eigenvectors of $\mathbf{S}\mathbf{S}' = \mathbf{X}'\mathbf{Y}\mathbf{Y}'\mathbf{X}$, but they satisfy a different orthogonality condition. The \mathbf{r}_1 vector is just the first eigenvector \mathbf{e}_1 (so that the first SIMPLS score is the same as the first PLS score), but whereas the second eigenvector maximizes

$$\mathbf{e}_1' \mathbf{S}\mathbf{S}' \mathbf{e}_2 \text{ subject to } \mathbf{e}_1' \mathbf{e}_2 = 0$$

the second SIMPLS weight \mathbf{r}_2 maximizes

$$\mathbf{r}_1' \mathbf{S}\mathbf{S}' \mathbf{r}_2 \text{ subject to } \mathbf{r}_1' \mathbf{X}' \mathbf{X} \mathbf{r}_2 = \mathbf{t}_1' \mathbf{t}_2 = 0$$

The SIMPLS scores are identical to the PLS scores for one response but slightly different for more than one response; see de Jong (1993) for details. The X- and Y-loadings are defined as in PLS, but since the scores are all defined in terms of \mathbf{X} , it is easy to compute the overall model coefficients \mathbf{B} :

$$\begin{aligned}\hat{\mathbf{Y}} &= \sum_i \mathbf{t}_i \mathbf{c}_i' \\ &= \sum_i \mathbf{X} \mathbf{r}_i \mathbf{c}_i' \\ &= \mathbf{X} \mathbf{B}, \text{ where } \mathbf{B} = \mathbf{R} \mathbf{C}'\end{aligned}$$

Principal Components Regression

Like the SIMPLS method, principal components regression (PCR) defines all the scores in terms of the original (centered and scaled) predictors \mathbf{X} . However, unlike both the PLS and SIMPLS methods, the PCR method chooses the X-weights/X-scores without regard to the response data. The X-scores are chosen to explain as much variation in \mathbf{X} as possible; equivalently, the X-weights for the PCR method are the eigenvectors of the predictor covariance matrix $\mathbf{X}'\mathbf{X}$. Again, the X- and Y-loadings are defined as in PLS; but, as in SIMPLS, it is easy to compute overall model coefficients for the original (centered and scaled) responses \mathbf{Y} in terms of the original predictors \mathbf{X} .

Reduced Rank Regression

As discussed in the preceding sections, partial least squares depends on selecting factors $\mathbf{t} = \mathbf{X}\mathbf{w}$ of the predictors and $\mathbf{u} = \mathbf{Y}\mathbf{q}$ of the responses that have maximum covariance, whereas principal components regression effectively ignores \mathbf{u} and selects \mathbf{t} to have maximum variance, subject to orthogonality constraints. In contrast, reduced rank regression selects \mathbf{u} to account for as much variation in the *predicted* responses as possible, effectively ignoring the predictors for the purposes of factor extraction. In reduced rank regression, the Y-weights \mathbf{q}_i are the eigenvectors of the covariance matrix $\hat{\mathbf{Y}}'_{LS}\hat{\mathbf{Y}}_{LS}$ of the responses predicted by ordinary least squares regression; the X-scores are the projections of the Y-scores $\mathbf{Y}\mathbf{q}_i$ onto the X space.

Relationships between Methods

When you develop a predictive model, it is important to consider not only the explanatory power of the model for current responses, but also how well sampled the predictive functions are, since this affects how well the model can extrapolate to future observations. All of the techniques implemented in the PLS procedure work by extracting successive factors, or linear combinations of the predictors, that optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, principal components regression selects factors that explain as much predictor variation as possible, reduced rank regression selects factors that explain as much response variation as possible, and partial least squares balances the two objectives, seeking for factors that explain both response and predictor variation.

To see the relationships between these methods, consider how each one extracts a single factor from the following artificial data set consisting of two predictors and one response:

```
data data;
  input x1 x2 y;
  datalines;
    3.37651  2.30716      0.75615
    0.74193 -0.88845      1.15285
    4.18747  2.17373      1.42392
    0.96097  0.57301      0.27433
   -1.11161 -0.75225     -0.25410
   -1.38029 -1.31343     -0.04728
    1.28153 -0.13751      1.00341
   -1.39242 -2.03615      0.45518
    0.63741  0.06183      0.40699
   -2.52533 -1.23726     -0.91080
    2.44277  3.61077     -0.82590
  ;

proc pls data=data nfac=1 method=rrr;
  model y = x1 x2;
run;

proc pls data=data nfac=1 method=pcr;
  model y = x1 x2;
run;

proc pls data=data nfac=1 method=pls;
  model y = x1 x2;
run;
```

The amount of model and response variation explained by the first factor for each method is shown in Figure 70.9 through Figure 70.11.

Figure 70.9 Variation Explained by First Reduced Rank Regression Factor

The PLS Procedure				
Percent Variation Accounted for by Reduced Rank Regression Factors				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	15.0661	15.0661	100.0000	100.0000

Figure 70.10 Variation Explained by First Principal Components Regression Factor

The PLS Procedure				
Percent Variation Accounted for by Principal Components				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	92.9996	92.9996	9.3787	9.3787

Figure 70.11 Variation Explained by First Partial Least Squares Regression Factor

The PLS Procedure				
Percent Variation Accounted for by Partial Least Squares Factors				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	88.5357	88.5357	26.5304	26.5304

Notice that, while the first reduced rank regression factor explains *all* of the response variation, it accounts for only about 15% of the predictor variation. In contrast, the first principal components regression factor accounts for most of the predictor variation (93%) but only 9% of the response variation. The first partial least squares factor accounts for only slightly less predictor variation than principal components but about three times as much response variation.

Figure 70.12 illustrates how partial least squares balances the goals of explaining response and predictor variation in this case.

Figure 70.12 Depiction of First Factors for Three Different Regression Methods

The ellipse shows the general shape of the 11 observations in the predictor space, with the contours of increasing y overlaid. Also shown are the directions of the first factor for each of the three methods. Notice that, while the predictors vary most in the $x_1 = x_2$ direction, the response changes most in the orthogonal $x_1 = -x_2$ direction. This explains why the first principal component accounts for little variation in the response and why the first reduced rank regression factor accounts for little variation in the predictors. The direction of the first partial least squares factor represents a compromise between the other two directions.

Cross Validation

None of the regression methods implemented in the PLS procedure fit the observed data any better than ordinary least squares (OLS) regression; in fact, all of the methods approach OLS as more factors are extracted. The crucial point is that, when there are many predictors, OLS can *overfit* the observed data; biased regression methods with fewer extracted factors can provide better predictability of *future* observations. However, as the preceding observations imply, the quality of the observed data fit cannot be used to choose the number of factors to extract; the number of extracted factors must be chosen on the basis of how well the model fits observations not involved in the modeling procedure itself.

One method of choosing the number of extracted factors is to fit the model to only part of the available data (the *training set*) and to measure how well models with different numbers of extracted factors fit the other part of the data (the *test set*). This is called *test set validation*. However, it is rare that you have enough data to make both parts large enough for pure test set validation to be useful. Alternatively, you can make several different divisions of the observed data into training set and test set. This is called *cross validation*, and there are several different types. In *one-at-a-time* cross validation, the first observation is held out as a single-element test set, with all other observations as the training set; next, the second observation is held out, then the third, and so on. Another method is to hold out successive blocks of observations as test sets—for example, observations 1 through 7, then observations 8 through 14, and so on; this is known as *blocked* validation. A similar method is *split-sample* cross validation, in which successive groups of widely separated observations are held out as the test set—for example, observations {1, 11, 21, ...}, then observations {2, 12, 22, ...}, and so on. Finally, test sets can be selected from the observed data randomly; this is known as *random sample* cross validation.

Which validation you should use depends on your data. Test set validation is preferred when you have enough data to make a division into a sizable training set and test set that represent the predictive population well. You can specify that the number of extracted factors be selected by test set validation by using the **CV=TESTSET**(*data set*) option, where *data set* is the name of the data set containing the test set. If you do not have enough data for test set validation, you can use one of the cross validation techniques. The most common technique is one-at-a-time validation (which you can specify with the **CV=ONE** option or just the **CV** option), unless the observed data are serially correlated, in which case either blocked or split-sample validation might be more appropriate (**CV=BLOCK** or **CV=SPLIT**); you can specify the number of test sets in blocked or split-sample validation with a number in parentheses after the **CV=** option. Note that **CV=ONE** is the most computationally intensive of the cross validation methods, since it requires a recomputation of the PLS model for every input observation. Also, note that using random subset selection with **CV=RANDOM** might lead two different researchers to produce different PLS models on the same data (unless the same seed is used).

Whichever validation method you use, the number of factors chosen is usually the one that minimizes the predicted residual sum of squares (PRESS); this is the default choice if you specify any of the CV methods with PROC PLS. However, often models with fewer factors have PRESS statistics that are only marginally larger than the absolute minimum. To address this, van der Voet (1994) has proposed a statistical test for comparing the predicted residuals from different models; when you apply van der Voet's test, the number of factors chosen is the fewest with residuals that are insignificantly larger than the residuals of the model with minimum PRESS.

To see how van der Voet's test works, let $R_{i,jk}$ be the j th predicted residual for response k for the model with i extracted factors; the PRESS statistic is $\sum_{jk} R_{i,jk}^2$. Also, let i_{\min} be the number of factors for which PRESS is minimized. The critical value for van der Voet's test is based on the differences between squared predicted residuals

$$D_{i,jk} = R_{i,jk}^2 - R_{i_{\min},jk}^2$$

One alternative for the critical value is $C_i = \sum_{jk} D_{i,jk}$, which is just the difference between the PRESS statistics for i and i_{\min} factors; alternatively, van der Voet suggests Hotelling's T^2 statistic $C_i = \mathbf{d}'_i \mathbf{S}_i^{-1} \mathbf{d}_i$, where \mathbf{d}_i is the sum of the vectors $\mathbf{d}_{i,j} = \{D_{i,j1}, \dots, D_{i,jN_y}\}'$ and \mathbf{S}_i is the sum of squares and crossproduct matrix

$$\mathbf{S}_i = \sum_j \mathbf{d}_{i,j} \mathbf{d}'_{i,j}$$

Virtually, the significance level for van der Voet's test is obtained by comparing C_i with the distribution of values that result from randomly exchanging $R_{i,jk}^2$ and $R_{i_{\min},jk}^2$. In practice, a Monte Carlo sample of such values is simulated and the significance level is approximated as the proportion of simulated critical values that are greater than C_i . If you apply van der Voet's test by specifying the **CVTEST** option, then, by default, the number of extracted factors chosen is the least number with an approximate significance level that is greater than 0.10.

Centering and Scaling

By default, the predictors and the responses are centered and scaled to have mean 0 and standard deviation 1. Centering the predictors and the responses ensures that the criterion for choosing successive factors is based on how much *variation* they explain, in either the predictors or the responses or both. (See the section “Regression Methods” on page 5883 for more details on how different methods explain variation.) Without centering, both the mean variable value and the variation around that mean are involved in selecting factors. Scaling serves to place all predictors and responses on an equal footing relative to their variation in the data. For example, if Time and Temp are two of the predictors, then scaling says that a change of std(Time) in Time is roughly equivalent to a change of std(Temp) in Temp.

Usually, both the predictors and responses should be centered and scaled. However, if their values already represent variation around a nominal or target value, then you can use the **NOCENTER** option in the **PROC PLS** statement to suppress centering. Likewise, if the predictors or responses are already all on comparable scales, then you can use the **NOSCALE** option to suppress scaling.

Note that, if the predictors involve crossproduct terms, then, by default, the variables are *not* standardized before standardizing the crossproduct. That is, if the i th values of two predictors are denoted x_i^1 and x_i^2 , then the default standardized i th value of the crossproduct is

$$\frac{x_i^1 x_i^2 - \text{mean}_j(x_j^1 x_j^2)}{\text{std}_j(x_j^1 x_j^2)}$$

If you want the crossproduct to be based instead on standardized variables

$$\frac{x_i^1 - m^1}{s^1} \times \frac{x_i^2 - m^2}{s^2}$$

where $m^k = \text{mean}_j(x_j^k)$ and $s^k = \text{std}_j(x_j^k)$ for $k = 1, 2$, then you should use the **VARSCALE** option in the **PROC PLS** statement. Standardizing the variables separately is usually a good idea, but unless the model also contains all crossproducts nested within each term, the resulting model might not be equivalent to a simple linear model in the same terms. To see this, note that a model involving the crossproduct of two standardized variables

$$\frac{x_i^1 - m^1}{s^1} \times \frac{x_i^2 - m^2}{s^2} = x_i^1 x_i^2 \frac{1}{s^1 s^2} - x_i^1 \frac{m^2}{s^1 s^2} - x_i^2 \frac{m^1}{s^1 s^2} + \frac{m^1 m^2}{s^1 s^2}$$

involves both the crossproduct term and the linear terms for the unstandardized variables.

When cross validation is performed for the number of effects, there is some disagreement among practitioners as to whether each cross validation training set should be retransformed. By default, **PROC PLS** does so, but you can suppress this behavior by specifying the **NOCVSTDIZE** option in the **PROC PLS** statement.

Missing Values

By default, PROC PLS handles missing values very simply. Observations with any missing independent variables (including all classification variables) are excluded from the analysis, and no predictions are computed for such observations. Observations with no missing independent variables but any missing dependent variables are also excluded from the analysis, but predictions are computed.

However, the **MISSING=** option in the **PROC PLS** statement provides more sophisticated ways of modeling in the presence of missing values. If you specify **MISSING=AVG** or **MISSING=EM**, then all observations in the input data set contribute to both the analysis and the **OUTPUT OUT=** data set. With **MISSING=AVG**, the fit is computed by filling in missing values with the average of the nonmissing values for the corresponding variable. With **MISSING=EM**, the procedure first computes the model with **MISSING=AVG**, then fills in missing values with their predicted values based on that model and computes the model again. Alternatively, you can specify **MISSING=EM(MAXITER=*n*)** with a large value of *n* in order to perform this imputation/fit loop until convergence.

Displayed Output

By default, PROC PLS displays just the amount of predictor and response variation accounted for by each factor.

If you perform a cross validation for the number of factors by specifying the **CV** option in the **PROC PLS** statement, then the procedure displays a summary of the cross validation for each number of factors, along with information about the optimal number of factors.

If you specify the **DETAILS** option in the **PROC PLS** statement, then details of the fitted model are displayed for each successive factor. These details for each number of factors include the following:

- the predictor loadings
- the predictor weights
- the response weights
- the coded regression coefficients (for **METHOD=SIMPLS**, **PCR**, or **RRR**)

If you specify the **CENSCALE** option in the **PROC PLS** statement, then centering and scaling information for each response and predictor is displayed.

If you specify the **VARSS** option in the **PROC PLS** statement, the procedure displays, in addition to the average response and predictor sum of squares accounted for by each successive factor, the amount of variation accounted for in each response and predictor.

If you specify the **SOLUTION** option in the **MODEL** statement, then PROC PLS displays the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses based on the centered and scaled predictors are displayed, as well as the coefficients for predicting the raw responses based on the raw predictors.

ODS Table Names

PROC PLS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 70.3](#). For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 70.3 ODS Tables Produced by PROC PLS

ODS Table Name	Description	Statement	Option
CVResults	Results of cross validation	PROC	CV
CenScaleParms	Parameter estimates for centered and scaled data	MODEL	SOLUTION
CodedCoef	Coded coefficients	PROC	DETAILS

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

When ODS Graphics is enabled, by default the PLS procedure produces a plot of the variation accounted for by each extracted factor, as well as a *correlation loading plot* for the first two extracted factors (if the final model has at least two factors). The plot of the variation accounted for can take several forms:

- If the PLS analysis does not include cross validation, then the plot shows the total R square for both model effects and the dependent variables against the number of factors.
- If you specify the **CV=** option to select the number of factors in the final model by cross validation, then the plot shows the R-square analysis discussed previously as well as the root mean PRESS from the cross validation analysis, with the selected number of factors identified by a vertical line.

The correlation loading plot for the first two factors summarizes many aspects of the two most significant dimensions of the model. It consists of overlaid scatter plots of the scores of the first two factors, the loadings of the model effects, and the loadings of the dependent variables. The loadings are scaled so that the amount of variation in the variables that is explained by the model is proportional to the distance from the origin; circles indicating various levels of explained variation are also overlaid on the correlation loading plot. Also, the correlation between the model approximations for any two variables is proportional to the length of the projection of the point corresponding to one variable on a line through the origin passing through the point corresponding to the other variable; the sign of the correlation corresponds to which side of the origin the projected point falls on.

The R square and the first two correlation loadings are plotted by default when ODS Graphics is enabled, but you can produce many other plots for the PROC PLS analysis.

ODS Graph Names

PROC PLS assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 70.4](#).

Table 70.4 Graphs Produced by PROC PLS

ODS Graph Name	Plot Description	Option
CorrLoadPlot	Correlation loading plot (default)	PLOT=CORRLOAD(<i>option</i>)
CVPlot	Cross validation and R-square analysis (default, as appropriate)	CV=
DModXPlot	Distance of each observation to the X model	PLOT=DMDX
DModXYPlot	Distance of each observation to the X and Y models	PLOT=DMDXY
DModYPlot	Distance of each observation to the Y model	PLOT=DMDY

Examples: PLS Procedure

Example 70.1: Examining Model Details

This example, from Umetrics (1995), demonstrates different ways to examine a PLS model. The data come from the field of drug discovery. New drugs are developed from chemicals that are biologically active. Testing a compound for biological activity is an expensive procedure, so it is useful to be able to predict biological activity from cheaper chemical measurements. In fact, computational chemistry makes it possible to calculate certain chemical measurements without even making the compound. These measurements include size, lipophilicity, and polarity at various sites on the molecule. The following statements create a data set named `pentaTrain`, which contains these data.

```

data pentaTrain;

```

You would like to study the relationship between these measurements and the activity of the compound, represented by the logarithm of the relative Bradykinin activating activity (log_RAI). Notice that these data consist of many predictors relative to the number of observations. Partial least squares is especially appropriate in this situation as a useful tool for finding a few underlying predictive factors that account for most of the variation in the response. Typically, the model is fit for part of the data (the “training” or “work” set), and the quality of the fit is judged by how well it predicts the other part of the data (the “test” or “prediction” set). For this example, the first 15 observations serve as the training set and the rest constitute the test set (see Ufkes et al. 1978, 1982).

When you fit a PLS model, you hope to find a few PLS factors that explain most of the variation in both predictors and responses. Factors that explain response variation provide good predictive models for new responses, and factors that explain predictor variation are well represented by the observed values of the predictors. The following statements fit a PLS model with two factors and save predicted values, residuals, and other information for each data point in a data set named `outpls`.

```
proc pls data=pentaTrain;
  model log_RAI = S1-S5 L1-L5 P1-P5;
run;
```

The PLS procedure displays a table, shown in [Output 70.1.1](#), showing how much predictor and response variation is explained by each PLS factor.

Output 70.1.1 Amount of Training Set Variation Explained

The PLS Procedure

15	0.0000	100.0000	0.0000	99.1179	

From [Output 70.1.1](#), note that 97% of the response variation is already explained by just two factors, but only 29% of the predictor variation is explained.

The graphics in PROC PLS, available when ODS Graphics is enabled, make it easier to see features of the PLS model.

If ODS Graphics is enabled, then in addition to the tables discussed previously, PROC PLS displays a graphical depiction of the R-square analysis as well as a correlation loadings plot summarizing the model based on the first two PLS factors. The following statements perform the previous analysis with ODS Graphics enabled, producing [Output 70.1.2](#) and [Output 70.1.3](#).

```
ods graphics on;

proc pls data=pentaTrain;
  model log_RAI = S1-S5 L1-L5 P1-P5;
run;
```

Output 70.1.2 Plot of Proportion of Variation Accounted For

Output 70.1.3 Correlation Loadings Plot

The plot in [Output 70.1.2](#) of the proportion of variation explained (or R square) makes it clear that there is a plateau in the response variation after two factors are included in the model. The correlation loading plot in [Output 70.1.3](#) summarizes many features of this two-factor model, including the following:

- The X-scores are plotted as numbers for each observation. You should look for patterns or clearly grouped observations. If you see a curved pattern, for example, you might want to add a quadratic term. Two or more groupings of observations indicate that it might be better to analyze the groups separately, perhaps by including classification effects in the model. This plot appears to show most of the observations close together, with a few being more spread out with larger positive X-scores for factor 2. There are no clear grouping patterns, but observation 13 stands out.
- The loadings show how much variation in each variable is accounted for by the first two factors, jointly by the distance of the corresponding point from the origin and individually by the distance for the projections of this point onto the horizontal and vertical axes. That the dependent variable is well explained by the model is reflected in the fact that the point for `log_RAI` is near the 100% circle.
- You can also use the projection interpretation to relate variables to each other. For example, projecting other variables' points onto the line that runs through the `log_RAI` point and the origin, you can see that the PLS approximation for the predictor `L3` is highly positively correlated with `log_RAI`, `S3` is

somewhat less correlated but in the negative direction, and several predictors including L1, L5, and S5 have very little correlation with log_RAI.

Other graphics enable you to explore more of the features of the PLS model. For example, you can examine the X-scores versus the Y-scores to explore how partial least squares chooses successive factors. For a good PLS model, the first few factors show a high correlation between the X- and Y-scores. The correlation usually decreases from one factor to the next. When ODS Graphics is enabled, you can plot the X-scores versus the Y-scores by using the `PLOT=XYSCORES` option, as shown in the following statements.

```
proc pls data=pentaTrain nfac=4 plot=XYScores;
  model log_RAI = S1-S5 L1-L5 P1-P5;
run;
```

The plot of the X-scores versus the Y-scores for the first four factors is shown in [Output 70.1.4](#).

Output 70.1.4 X-Scores versus Y-Scores

For this example, [Output 70.1.4](#) shows high correlation between X- and Y-scores for the first factor but somewhat lower correlation for the second factor and sharply diminishing correlation after that. This adds strength to the judgment that `NFAC=2` is the right number of factors for these data and this model. Note that observation 13 is again extreme in the first two plots. This run might be overly influential for the PLS analysis; thus, you should check to make sure it is reliable.

As explained earlier, you can draw some inferences about the relationship between individual predictors and the dependent variable from the correlation loading plot. However, the regression coefficient profile and the variable importance plot give a more direct indication of which predictors are most useful for predicting the dependent variable. The regression coefficients represent the importance each predictor has in the prediction of just the response. The variable importance plot, on the other hand, represents the contribution of each predictor in fitting the PLS model for both predictors and response. It is based on the *Variable Importance for Projection* (VIP) statistic of Wold (1994), which summarizes the contribution a variable makes to the model. If a predictor has a relatively small coefficient (in absolute value) *and* a small value of VIP, then it is a prime candidate for deletion. Wold in Umetrics (1995) considers a value less than 0.8 to be “small” for the VIP. The following statements fit a two-factor PLS model and display these two additional plots.

```
proc pls data=pentaTrain nfac=2 plot=(ParmProfiles VIP);
  model log_RAI = S1-S5 L1-L5 P1-P5;
run;

ods graphics off;
```

The additional graphics are shown in [Output 70.1.5](#) and [Output 70.1.6](#).

Output 70.1.5 Variable Importance Plots

Output 70.1.6 Regression Parameter Profile

In these two plots, the variables L1, L2, P2, S5, L5, and P5 have small absolute coefficients and small VIP. Looking back at the correlation loadings plot in [Output 70.1.2](#), you can see that these variables tend to be the ones near zero for both PLS factors. You should consider dropping these variables from the model.

Example 70.2: Examining Outliers

This example is a continuation of [Example 70.1](#).

Standard diagnostics for statistical models focus on the response, allowing you to look for patterns that indicate the model is inadequate or for outliers that do not seem to follow the trend of the rest of the data. However, partial least squares effectively models the predictors as well as the responses, so you should consider the pattern of the fit for both. The DModX and DModY statistics give the distance from each point to the PLS model with respect to the predictors and the responses, respectively, and ODS Graphics enables you to plot these values. No point should be dramatically farther from the model than the rest. If there is a group of points that are all farther from the model than the rest, they might have something in common, in which case they should be analyzed separately.

The following statements fit a reduced model to the data discussed in [Example 70.1](#) and plot a panel of standard diagnostics as well as the distances of the observations to the model.

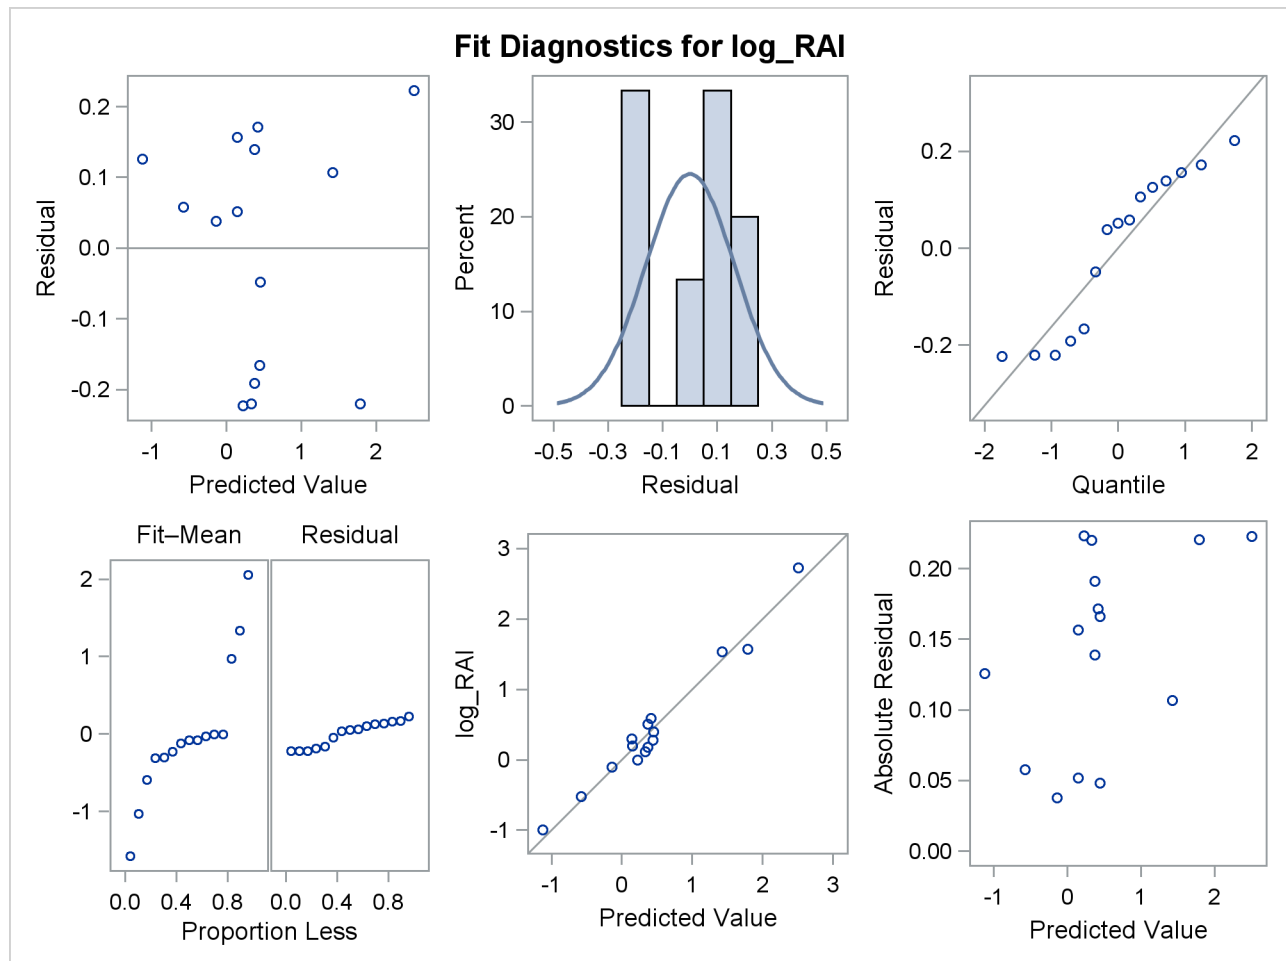

```
ods graphics on;

proc pls data=pentaTrain nfac=2 plot=(diagnostics dmod);
  model log_RAI = S1    P1
                S2
                S3 L3 P3
                S4 L4   ;
run;

ods graphics off;
```

The plots are shown in [Output 70.2.1](#) and [Output 70.2.2](#).

Output 70.2.1 Model Fit Diagnostics

Output 70.2.2 Predictor versus Response Distances to the Model

There appear to be no profound outliers in either the predictor space or the response space.

Example 70.3: Choosing a PLS Model by Test Set Validation

This example demonstrates issues in spectrometric calibration. The data (Umetrics 1995) consist of spectrographic readings on 33 samples containing known concentrations of two amino acids, tyrosine and tryptophan. The spectra are measured at 30 frequencies across the overall range of frequencies. For example, [Figure 70.3.1](#) shows the observed spectra for three samples, one with only tryptophan, one with only tyrosine, and one with a mixture of the two, all at a total concentration of 10^{-6} .

Output 70.3.1 Spectra for Three Samples of Tyrosine and Tryptophan

Of the 33 samples, 18 are used as a training set and 15 as a test set. The data originally appear in McAvoy et al. (1989).

These data were created in a lab, with the concentrations fixed in order to provide a wide range of applicability for the model. You want to use a linear function of the logarithms of the spectra to predict the logarithms of tyrosine and tryptophan concentration, as well as the logarithm of the total concentration. Actually, because of the possibility of zeros in both the responses and the predictors, slightly different transformations are used. The following statements create SAS data sets containing the training and test data, named `ftrain` and `ftest`, respectively.

```

10	0.0034	99.9952	0.1684	99.2707	

In order to choose the optimal number of PLS factors, you can explore how well models based on the training data with different numbers of factors fit the test data. To do so, use the [CV=TESTSET](#) option, with an argument pointing to the test data set `ftest`. The following statements also employ the ODS Graphics features in PROC PLS to display the cross validation results in a plot.

```

ods graphics on;

proc pls data=ftrain nfac=10 cv=testset(ftest)
  cvtest(stat=press seed=12345);

```

```

model tot_log tyr_log try_log = f1-f30;
run;

```

The tabular results of the test set validation are shown in [Output 70.3.3](#), and the graphical results are shown in [Output 70.3.4](#). They indicate that, although five PLS factors give the minimum predicted residual sum of squares, the residuals for four factors are insignificantly different from those for five. Thus, the smaller model is preferred.

Output 70.3.3 Test Set Validation for the Number of PLS Factors

The PLS Procedure

Output 70.3.4 Test Set Validation Plot

The factor loadings show how the PLS factors are constructed from the centered and scaled predictors. For spectral calibration, it is useful to plot the loadings against the frequency. In many cases, the physical meanings that can be attached to factor loadings help to validate the scientific interpretation of the PLS model. You can use ODS Graphics with PROC PLS to plot the loadings for the four PLS factors against frequency, as shown in the following statements.

```
proc pls data=ftrain nfac=4 plot=XLoadingProfiles;
  model tot_log tyr_log try_log = f1-f30;
run;

ods graphics off;
```

The resulting plot is shown in [Output 70.3.5](#).

Output 70.3.5 Predictor Loadings across Frequencies

Notice that all four factors handle frequencies below and above about 7 or 8 differently. For example, the first factor is very nearly a simple contrast between the averages of the two sets of frequencies, and the second factor appears to be approximately a weighted sum of only the frequencies in the first set.

Example 70.4: Partial Least Squares Spline Smoothing

The EFFECT statement makes it easy to construct a wide variety of linear models. In particular, you can use the spline effect to add smoothing terms to a model. A particular benefit of using spline effects in PROC PLS is that, when operating on spline basis functions, the partial least squares algorithm effectively chooses the amount of smoothing automatically, especially if you combine it with cross validation for the selecting the number of factors. This example employs the EFFECT statement to demonstrate partial least squares spline smoothing of agricultural data.

Weibe (1935) presents data from a study of uniformity of wheat yields over a certain rectangular plot of land. The following statements read these wheat yield measurements, indexed by row and column distances, into the SAS data set `Wheat`:

```

data Wheat;
  keep Row Column Yield;
  input Yield @@;
  iRow = int((_N-1)/12);
  iCol = mod(_N-1,12);
  Column = iCol*15 + 1; /* Column distance, in feet */
  Row     = iRow* 1 + 1; /* Row     distance, in feet */
  Row = 125 - Row + 1; /* Invert rows */
  datalines;

465 430 510 680 460 600 670 615 620 594 616 784
;

```

The following statements use the PLS procedure to smooth these wheat yields using two spline effects, one for rows and another for columns, in addition to their crossproduct. Each spline effect has, by default, seven basis columns; thus their crossproduct has $49 = 7^2$ columns, for a total of 63 parameters in the full linear model. However, the predictive PLS model does not actually need to have 63 degrees of freedom. Rather, the degree of smoothing is controlled by the number of PLS factors, which in this case is chosen automatically by random subset validation with the CV=RANDOM option.

```

ods graphics on;

proc pls data=Wheat cv=random(seed=1) cvtest(seed=12345)
  plot(only)=contourfit(obs=gradient);
  effect splCol = spline(Column);
  effect splRow = spline(Row );
  model Yield = splCol|splRow;
run;

ods graphics off;

```

These statements produce the output shown in [Output 70.4.1](#) through [Output 70.4.4](#).

Output 70.4.4 Default Spline Basis: Smoothed Yield

The cross validation results in [Output 70.4.2](#) point to a model with eight PLS factors; this is the smallest model whose predicted residual sum of squares (PRESS) is insignificantly different from the model with the absolute minimum PRESS. The variation summary in [Output 70.4.3](#) shows that this model accounts for about 60% of the variation in the Yield values. The OBS=GRADIENT suboption for the PLOT=CONTOURFIT option specifies that the observations in the resulting plot, [Output 70.4.4](#), be colored according to the same scheme as the surface of predicted yield. This coloration enables you to easily tell which observations are above the surface of predicted yield and which are below.

The surface of predicted yield is somewhat smoother than what Weibe (1935) settled on originally, with a predominance of simple, elliptically shaped contours. You can easily specify a potentially more granular model by increasing the number of knots in the spline bases. Even though the more granular model increases the number of predictor parameters, cross validation can still protect you from overfitting the data. The following statements are the same as those shown before, except that the spline effects now have twice as many basis functions:

```
ods graphics on;

proc pls data=Wheat cv=random(seed=1) cvtest(seed=12345)
    plot(only)=contourfit(obs=gradient);
    effect splCol = spline(Column / knotmethod=equal(14));
    effect splRow = spline(Row    / knotmethod=equal(14));
    model Yield = splCol|splRow;
run;

ods graphics off;
```

The resulting output is shown in [Output 70.4.5](#) through [Output 70.4.8](#).

Output 70.4.5 More Granular Spline Basis: Model and Data Information

The PLS Procedure	
Data Set	WORK.WHEAT
Factor Extraction Method	Partial Least Squares
PLS Algorithm	NIPALS
Number of Response Variables	1
Number of Predictor Parameters	360
Missing Value Handling	Exclude
Maximum Number of Factors	15
Validation Method	10-fold Random Subset Validation
Random Subset Seed	1
Validation Testing Criterion	Prob T**2 > 0.1
Number of Random Permutations	1000
Random Permutation Seed	12345
Number of Observations Read	1500
Number of Observations Used	1500

Output 70.4.6 More Granular Spline Basis: Random Subset Validated PRESS Statistics for Number of Factors

Random Subset Validation for the Number of Extracted Factors				
Number of Extracted Factors	Root Mean PRESS	T**2	Prob > T**2	
0	1.066355	247.9268	<.0001	
1	0.652658	20.68858	<.0001	
2	0.615087	0.074822	0.7740	
3	0.614128	0	1.0000	
4	0.615268	0.197678	0.6490	
5	0.618001	1.372038	0.2340	
6	0.622949	5.035504	0.0180	
7	0.626482	7.296797	0.0080	
8	0.633316	13.66045	<.0001	
9	0.635239	16.16922	<.0001	
10	0.636938	18.02295	<.0001	
11	0.636494	16.9881	<.0001	
12	0.63682	16.83341	<.0001	
13	0.637719	16.74157	<.0001	
14	0.637627	15.79342	<.0001	
15	0.638431	16.12327	<.0001	
Minimum root mean PRESS			0.6141	
Minimizing number of factors			3	
Smallest number of factors with p > 0.1			2	

Output 70.4.7 More Granular Spline Basis: PLS Variation Summary for Split-Sample Validated Model

Percent Variation Accounted for by Partial Least Squares Factors				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	1.7967	1.7967	64.7792	64.7792
2	1.3719	3.1687	6.3163	71.0955

Output 70.4.8 More Granular Spline Basis: Smoothed Yield

Output 70.4.5 shows that the model now has 360 parameters, many more than before. In Output 70.4.6 you can see that with more granular spline effects, fewer PLS factors are required—only two, in fact. However, Output 70.4.7 shows that this model now accounts for over 70% of the variation in the Yield values, and the contours of predicted values in Output 70.4.8 are less inclined to be simple elliptical shapes.

Overview: POWER Procedure

Power and sample size analysis optimizes the resource usage and design of a study, improving chances of conclusive results with maximum efficiency. The POWER procedure performs prospective power and sample size analyses for a variety of goals, such as the following:

- determining the sample size required to get a significant result with adequate probability (power)
- characterizing the power of a study to detect a meaningful effect
- conducting what-if analyses to assess sensitivity of the power or required sample size to other factors

Here *prospective* indicates that the analysis pertains to planning for a future study. This is in contrast to *retrospective* power analysis for a past study, which is not supported by the procedure.

A variety of statistical analyses are covered:

- *t* tests, equivalence tests, and confidence intervals for means
- tests, equivalence tests, and confidence intervals for binomial proportions
- multiple regression
- tests of correlation and partial correlation
- one-way analysis of variance
- rank tests for comparing two survival curves
- logistic regression with binary response
- Wilcoxon-Mann-Whitney (rank-sum) test

For more complex linear models, see Chapter 44, “[The GLMPOWER Procedure](#).”

Input for PROC POWER includes the components considered in study planning:

- design
- statistical model and test
- significance level (alpha)
- surmised effects and variability
- power
- sample size

You designate one of these components by a missing value in the input, in order to identify it as the result parameter. The procedure calculates this result value over one or more scenarios of input values for all other components. Power and sample size are the most common result values, but for some analyses the result can be something else. For example, you can solve for the sample size of a single group for a two-sample *t* test.

In addition to tabular results, PROC POWER produces graphs. You can produce the most common types of plots easily with default settings and use a variety of options for more customized graphics. For example, you can control the choice of axis variables, axis ranges, number of plotted points, mapping of graphical features (such as color, line style, symbol and panel) to analysis parameters, and legend appearance.

If ODS Graphics is enabled, then PROC POWER uses ODS Graphics to create graphs; otherwise, traditional graphs are produced.

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

For specific information about the statistical graphics and options available with the POWER procedure, see the [PLOT](#) statement and the section “[ODS Graphics](#)” on page 6081.

The POWER procedure is one of several tools available in SAS/STAT software for power and sample size analysis. PROC GLMPOWER supports more complex linear models. The Power and Sample Size application provides a user interface and implements many of the analyses supported in the procedures. See Chapter 44, “[The GLMPOWER Procedure](#),” and Chapter 72, “[The Power and Sample Size Application](#),” for details.

The following sections of this chapter describe how to use PROC POWER and discuss the underlying statistical methodology. The section “[Getting Started: POWER Procedure](#)” on page 5920 introduces PROC POWER with simple examples of power computation for a one-sample t test and sample size determination for a two-sample t test. The section “[Syntax: POWER Procedure](#)” on page 5927 describes the syntax of the procedure. The section “[Details: POWER Procedure](#)” on page 6018 summarizes the methods employed by PROC POWER and provides details on several special topics. The section “[Examples: POWER Procedure](#)” on page 6083 illustrates the use of the POWER procedure with several applications.

For an overview of methodology and SAS tools for power and sample size analysis, see Chapter 18, “[Introduction to Power and Sample Size Analysis](#).” For more discussion and examples, see O’Brien and Casteloe (2007); Casteloe (2000); Casteloe and O’Brien (2001); Muller and Benignus (1992); O’Brien and Muller (1993); Lenth (2001).

Getting Started: POWER Procedure

Computing Power for a One-Sample t Test

Suppose you want to improve the accuracy of a machine used to print logos on sports jerseys. The logo placement has an inherently high variability, but the horizontal alignment of the machine can be adjusted. The operator agrees to pay for a costly adjustment if you can establish a nonzero mean horizontal displacement in either direction with high confidence. You have 150 jerseys at your disposal to measure, and you want to determine your chances of a significant result (power) by using a one-sample t test with a two-sided $\alpha = 0.05$.

You decide that 8 mm is the smallest displacement worth addressing. Hence, you will assume a true mean of 8 in the power computation. Experience indicates that the standard deviation is about 40.

Use the [ONESAMPLEMEANS](#) statement in the POWER procedure to compute the power. Indicate power as the result parameter by specifying the [POWER=](#) option with a missing value (.). Specify your conjectures for the mean and standard deviation by using the [MEAN=](#) and [STDDEV=](#) options and for the sample size by using the [NTOTAL=](#) option. The statements required to perform this analysis are as follows:

```

proc power;
  onesamplemeans
    mean      = 8
    ntotal    = 150
    stddev    = 40
    power     = .;
run;

```

Default values for the **TEST=**, **DIST=**, **ALPHA=**, **NULLMEAN=**, and **SIDES=** options specify a two-sided t test for a mean of 0, assuming a normal distribution with a significance level of $\alpha = 0.05$.

Figure 71.1 shows the output.

Figure 71.1 Sample Size Analysis for One-Sample t Test

The POWER Procedure	
One-sample t Test for Mean	
Fixed Scenario Elements	
Distribution	Normal
Method	Exact
Mean	8
Standard Deviation	40
Total Sample Size	150
Number of Sides	2
Null Mean	0
Alpha	0.05
Computed Power	
Power	
0.682	

The power is about 0.68. In other words, there is about a 2/3 chance that the t test will produce a significant result demonstrating the machine's average off-center displacement. This probability depends on the assumptions for the mean and standard deviation.

Now, suppose you want to account for some of your uncertainty in conjecturing the true mean and standard deviation by evaluating the power for four scenarios, using reasonable low and high values, 5 and 10 for the mean, and 30 and 50 for the standard deviation. Also, you might be able to measure more than 150 jerseys, and you would like to know under what circumstances you could get by with fewer. You want to plot power for sample sizes between 100 and 200 to visualize how sensitive the power is to changes in sample size for these four scenarios of means and standard deviations. The following statements perform this analysis:

```

ods listing style=htmlbluecml;
ods graphics on;

proc power;
  onesamplemeans
    mean    = 5 10
    ntotal  = 150
    stddev  = 30 50
    power   = .;
  plot x=n min=100 max=200;
run;

ods graphics off;

```

The new mean and standard deviation values are specified by using the **MEAN=** and **STDDEV=** options in the **ONESAMPLEMEANS** statement. The **PLOT** statement with **X=N** produces a plot with sample size on the X axis. (The result parameter, in this case the power, is always plotted on the other axis.) The **MIN=** and **MAX=** options in the **PLOT** statement determine the sample size range. The **ODS GRAPHICS ON** statement enables ODS Graphics. The **ODS LISTING STYLE=HTMLBLUECML** statement specifies the HTMLBLUECML style, which is suitable for use with PROC POWER because it allows both marker symbols and line styles to vary. See the section “ODS Styles Suitable for Use with PROC POWER” on page 6082 for more information.

Figure 71.2 shows the output, and Figure 71.3 shows the plot.

Figure 71.2 Sample Size Analysis for One-Sample *t* Test with Input Ranges

The POWER Procedure			
One-sample t Test for Mean			
Fixed Scenario Elements			
Distribution	Normal		
Method	Exact		
Total Sample Size	150		
Number of Sides	2		
Null Mean	0		
Alpha	0.05		
Computed Power			
Index	Mean	Std Dev	Power
1	5	30	0.527
2	5	50	0.229
3	10	30	0.982
4	10	50	0.682

Figure 71.3 Plot of Power versus Sample Size for One-Sample t Test with Input Ranges

The power ranges from about 0.23 to 0.98 for a sample size of 150 depending on the mean and standard deviation. In Figure 71.3, the line style identifies the mean, and the plotting symbol identifies the standard deviation. The locations of plotting symbols indicate computed powers; the curves are linear interpolations of these points. The plot suggests sufficient power for a mean of 10 and standard deviation of 30 (for any of the sample sizes) but insufficient power for the other three scenarios.

Determining Required Sample Size for a Two-Sample t Test

In this example you want to compare two physical therapy treatments designed to increase muscle flexibility. You need to determine the number of patients required to achieve a power of at least 0.9 to detect a group mean difference in a two-sample t test. You will use $\alpha = 0.05$ (two-tailed).

The mean flexibility with the standard treatment (as measured on a scale of 1 to 20) is well known to be about 13 and is thought to be between 14 and 15 with the new treatment. You conjecture three alternative scenarios for the means:

1. $\mu_1 = 13, \mu_2 = 14$
2. $\mu_1 = 13, \mu_2 = 14.5$
3. $\mu_1 = 13, \mu_2 = 15$

You conjecture two scenarios for the common group standard deviation:

1. $\sigma = 1.2$
2. $\sigma = 1.7$

You also want to try three weighting schemes:

1. equal group sizes (balanced, or 1:1)
2. twice as many patients with the new treatment (1:2)
3. three times as many patients with the new treatment (1:3)

This makes $3 \times 2 \times 3 = 18$ scenarios in all.

Use the **TWOSAMPLEMEANS** statement in the POWER procedure to determine the sample sizes required to give 90% power for each of these 18 scenarios. Indicate total sample size as the result parameter by specifying the **NTOTAL=** option with a missing value (.). Specify your conjectures for the means by using the **GROUPMEANS=** option. Using the “matched” notation (discussed in the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020), enclose the two group means for each scenario in parentheses. Use the **STDDEV=** option to specify scenarios for the common standard deviation. Specify the weighting schemes by using the **GROUPWEIGHTS=** option. You could again use the matched notation. But for illustrative purposes, specify the scenarios for each group weight separately by using the “crossed” notation, with scenarios for each group weight separated by a vertical bar (|). The statements that perform the analysis are as follows:

```
proc power;
  twosamplemeans
    groupmeans = (13 14) (13 14.5) (13 15)
    stddev     = 1.2 1.7
    groupweights = 1 | 1 2 3
    power      = 0.9
    ntotal     = .;
run;
```

Default values for the **TEST=**, **DIST=**, **NULLDIFF=**, **ALPHA=**, and **SIDES=** options specify a two-sided t test of group mean difference equal to 0, assuming a normal distribution with a significance level of $\alpha = 0.05$. The results are shown in [Figure 71.4](#).

Figure 71.4 Sample Size Analysis for Two-Sample t Test Using Group Means

The POWER Procedure						
Two-Sample t Test for Mean Difference						
Fixed Scenario Elements						
Distribution	Normal					
Method	Exact					
Group 1 Weight	1					
Nominal Power	0.9					
Number of Sides	2					
Null Difference	0					
Alpha	0.05					
Computed N Total						
Index	Mean1	Mean2	Std Dev	Weight2	Actual Power	N Total
1	13	14.0	1.2	1	0.907	64
2	13	14.0	1.2	2	0.908	72
3	13	14.0	1.2	3	0.905	84
4	13	14.0	1.7	1	0.901	124
5	13	14.0	1.7	2	0.905	141
6	13	14.0	1.7	3	0.900	164
7	13	14.5	1.2	1	0.910	30
8	13	14.5	1.2	2	0.906	33
9	13	14.5	1.2	3	0.916	40
10	13	14.5	1.7	1	0.900	56
11	13	14.5	1.7	2	0.901	63
12	13	14.5	1.7	3	0.908	76
13	13	15.0	1.2	1	0.913	18
14	13	15.0	1.2	2	0.927	21
15	13	15.0	1.2	3	0.922	24
16	13	15.0	1.7	1	0.914	34
17	13	15.0	1.7	2	0.921	39
18	13	15.0	1.7	3	0.910	44

The interpretation is that in the best-case scenario (large mean difference of 2, small standard deviation of 1.2, and balanced design), a sample size of $N = 18$ ($n_1 = n_2 = 9$) patients is sufficient to achieve a power of at least 0.9. In the worst-case scenario (small mean difference of 1, large standard deviation of 1.7, and a 1:3 unbalanced design), a sample size of $N = 164$ ($n_1 = 41, n_2 = 123$) patients is necessary. The Nominal Power of 0.9 in the “Fixed Scenario Elements” table represents the input target power, and the Actual Power column in the “Computed N Total” table is the power at the sample size (N Total) adjusted to achieve the specified sample weighting exactly.

Note the following characteristics of the analysis, and ways you can modify them if you want:

- The total sample sizes are rounded up to multiples of the weight sums (2 for the 1:1 design, 3 for the 1:2 design, and 4 for the 1:3 design) to ensure that each group size is an integer. To request raw fractional sample size solutions, use the **NFRACTIONAL** option.
- Only the group weight that varies (the one for group 2) is displayed as an output column, while the weight for group 1 appears in the “Fixed Scenario Elements” table. To display the group weights together in output columns, use the matched version of the value list rather than the crossed version.
- If you can specify only differences between group means (instead of their individual values), or if you want to display the mean differences instead of the individual means, use the **MEANDIFF=** option instead of the **GROUPMEANS=** option.

The following statements implement all of these modifications:

```
proc power;
  twosamplemeans
    nfractional
    meandiff      = 1 to 2 by 0.5
    stddev        = 1.2 1.7
    groupweights  = (1 1) (1 2) (1 3)
    power         = 0.9
    ntotal        = .;
run;
```

Figure 71.5 shows the new results.

5	1.0	1.7	1	2	138.598159	0.901	139
6	1.0	1.7	1	3	163.899094	0.900	164
7	1.5	1.2	1	1	28.961958	0.900	29
8	1.5	1.2	1	2	32.308867	0.906	33
9	1.5	1.2	1	3	37.893351	0.901	38
10	1.5	1.7	1	1	55.977156	0.900	56
11	1.5	1.7	1	2	62.717357	0.901	63
12	1.5	1.7	1	3	73.954291	0.900	74
13	2.0	1.2	1	1	17.298518	0.913	18
14	2.0	1.2	1	2	19.163836	0.913	20
15	2.0	1.2	1	3	22.282926	0.910	23
16	2.0	1.7	1	1	32.413512	0.905	33
17	2.0	1.7	1	2	36.195531	0.907	37
18	2.0	1.7	1	3	42.504535	0.903	43

Note that the Nominal Power of 0.9 applies to the raw computed sample size (Fractional N Total), and the Actual Power column applies to the rounded sample size (Ceiling N Total). Some of the adjusted sample sizes in Figure 71.5 are lower than those in Figure 71.4 because underlying group sample sizes are allowed to be fractional (for example, the first Ceiling N Total of 63 corresponding to equal group sizes of 31.5).

Syntax: POWER Procedure

The following statements are available in the POWER procedure:

```

PROC POWER < options > ;
  LOGISTIC < options > ;
  MULTREG < options > ;
  ONECORR < options > ;
  ONESAMPLEFREQ < options > ;
  ONESAMPLEMEANS < options > ;
  ONEWAYANOVA < options > ;
  PAIREDFREQ < options > ;
  PAIREDMEANS < options > ;
  PLOT < plot-options > < / graph-options > ;
  TWOSAMPLEFREQ < options > ;
  TWOSAMPLEMEANS < options > ;
  TWOSAMPLESURVIVAL < options > ;
  TWOSAMPLEWILCOXON < options > ;

```

The statements in the POWER procedure consist of the **PROC POWER** statement, a set of *analysis statements* (for requesting specific power and sample size analyses), and the **PLOT** statement (for producing graphs). The **PROC POWER** statement and at least one of the analysis statements are required. The analysis statements are **LOGISTIC**, **MULTREG**, **ONECORR**, **ONESAMPLEFREQ**, **ONESAMPLEMEANS**, **ONEWAYANOVA**, **PAIREDFREQ**, **PAIREDMEANS**, **TWOSAMPLEFREQ**, **TWOSAMPLEMEANS**, **TWOSAMPLESURVIVAL**, and **TWOSAMPLEWILCOXON**.

You can use multiple analysis statements and multiple **PLOT** statements. Each analysis statement produces a separate sample size analysis. Each **PLOT** statement refers to the previous analysis statement and generates a separate graph (or set of graphs).

The name of an analysis statement describes the framework of the statistical analysis for which sample size calculations are desired. You use options in the analysis statements to identify the result parameter to compute, to specify the statistical test and computational options, and to provide one or more scenarios for the values of relevant analysis parameters.

Table 71.1 summarizes the basic functions of each statement in PROC POWER. The syntax of each statement in Table 71.1 is described in the following pages.

Table 71.1 Statements in the POWER Procedure

Statement	Description
PROC POWER	Invokes the procedure
LOGISTIC	Likelihood ratio chi-square test of a single predictor in logistic regression with binary response
MULTREG	Tests of one or more coefficients in multiple linear regression
ONECORR	Fisher's z test and t test of (partial) correlation
ONESAMPLEFREQ	Tests, confidence interval precision, and equivalence tests of a single binomial proportion
ONESAMPLEMEANS	One-sample t test, confidence interval precision, or equivalence test
ONEWAYANOVA	One-way ANOVA including single-degree-of-freedom contrasts
PAIREDFREQ	McNemar's test for paired proportions
PAIREDMEANS	Paired t test, confidence interval precision, or equivalence test
PLOT	Displays plots for previous sample size analysis
TWOSAMPLEFREQ	Chi-square, likelihood ratio, and Fisher's exact tests for two independent proportions
TWOSAMPLEMEANS	Two-sample t test, confidence interval precision, or equivalence test
TWOSAMPLESURVIVAL	Log-rank, Gehan, and Tarone-Ware tests for comparing two survival curves
TWOSAMPLEWILCOXON	Wilcoxon-Mann-Whitney (rank-sum) test for 2 independent groups

See the section “Summary of Analyses” on page 6018 for a summary of the analyses available and the syntax required for them.

PROC POWER Statement

PROC POWER < options > ;

The **PROC POWER** statement invokes the POWER procedure. You can specify the following option.

PLOTONLY

specifies that only graphical results from the **PLOT** statement should be produced.

LOGISTIC Statement

LOGISTIC < options > ;

The **LOGISTIC** statement performs power and sample size analyses for the likelihood ratio chi-square test of a single predictor in binary logistic regression, possibly in the presence of one or more covariates that might be correlated with the tested predictor.

Summary of Options

Table 71.2 summarizes the options available in the LOGISTIC statement.

Table 71.2 LOGISTIC Statement Options

Option	Description
Define analysis	
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
COVARIATES=	Specifies the distributions of predictor variables
TESTPREDICTOR=	Specifies the distribution of the predictor variable being tested
VARDIST=	Defines a distribution for a predictor variable
Specify effects	
CORR=	Specifies the multiple correlation between the predictor and the covariates
COVODDSRATIOS=	Specifies the odds ratios for the covariates
COVREGCOEFFS=	Specifies the regression coefficients for the covariates
DEFAULTUNIT=	Specifies the default change in the predictor variables
INTERCEPT=	Specifies the intercept
RESPONSEPROB=	Specifies the response probability
TESTODDSRATIO=	Specifies the odds ratio being tested
TESTREGCOEFF=	Specifies the regression coefficient for the predictor variable
UNITS=	Specifies the changes in the predictor variables
Specify sample size	
NFRACTIONAL	Enables fractional input and output for sample sizes
NTOTAL=	Specifies the sample size
Specify power	
POWER=	Specifies the desired power of the test

Table 71.2 *continued*

Option	Description
Specify computational method	
DEFAULTNBINS=	Specifies the default number of categories for each predictor variable
NBINS=	Specifies the number of categories for predictor variables
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.3 summarizes the valid result parameters in the LOGISTIC statement.

Table 71.3 Summary of Result Parameters in the LOGISTIC Statement

Analyses	Solve For	Syntax
TEST=LRCHI	Power Sample size	POWER=. NTOTAL=.

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

CORR=*number-list*

specifies the multiple correlation (ρ) between the tested predictor and the covariates. If you also specify the COVARIATES= option, then the sample size is either multiplied (if you are computing power) or divided (if you are computing sample size) by a factor of $(1 - \rho^2)$. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

COVARIATES=*grouped-name-list*

specifies the distributions of any predictor variables in the model but not being tested, using labels specified with the VARDIST= option. The distributions are assumed to be independent of each other and of the tested predictor. If this option is omitted, then the tested predictor specified by the TEST= option is assumed to be the only predictor in the model. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-name-list*.

COVODDSRATIOS=*grouped-number-list*

specifies the odds ratios for the covariates in the full model (including variables in the TEST= and COVARIATES= options). The ordering of the values corresponds to the ordering in the COVARIATES= option. If the response variable is coded as $Y = 1$ for success and $Y = 0$ for failure, then the odds ratio for each covariate X is the odds of $Y = 1$ when $X = a$ divided by the odds of $Y = 1$ when $X = b$, where a and b are determined from the DEFAULTUNIT= and UNITS= options. Values must be greater than zero. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

COVREGCOEFFS=*grouped-number-list*

specifies the regression coefficients for the covariates in the full model including the test predictor (as specified by the **TESTPREDICTOR=** option). The ordering of the values corresponds to the ordering in the **COVARIATES=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

DEFAULTNBINS=*number*

specifies the default number of categories (or “bins”) into which the distribution for each predictor variable is divided in internal calculations. Higher values increase computational time and memory requirements but generally lead to more accurate results. Each test predictor or covariate that is absent from the **NBINS=** option derives its bin number from the **DEFAULTNBINS=** option. The default value is **DEFAULTNBINS=10**.

There are two variable distributions for which the number of bins can be overridden internally:

- For an ordinal distribution, the number of ordinal values is always used as the number of bins.
- For a binomial distribution, if the requested number of bins is larger than $n + 1$, where n is the sample size parameter of the binomial distribution, then exactly $n + 1$ bins are used.

DEFAULTUNIT=*change-spec*

specifies the default change in the predictor variables assumed for odds ratios specified with the **COVODDSRATIOS=** and **TESTODDSRATIO=** options. Each test predictor or covariate that is absent from the **UNITS=** option derives its change value from the **DEFAULTUNIT=** option. The value must be nonzero. The default value is **DEFAULTUNIT=1**. This option can be used only if at least one of the **COVODDSRATIOS=** and **TESTODDSRATIO=** options is used.

Valid specifications for *change-spec* are as follows:

number defines the odds ratio as the ratio of the response variable odds when $X = a$ to the odds when $X = a - \textit{number}$ for any constant a .

<+|->SD defines the odds ratio as the ratio of the odds when $X = a$ to the odds when $X = a - \sigma$ (or $X = a + \sigma$, if SD is preceded by a minus sign (–)) for any constant a , where σ is the standard deviation of X (as determined from the **VARDIST=** option).

*multiple**SD defines the odds ratio as the ratio of the odds when $X = a$ to the odds when $X = a - \textit{multiple} * \sigma$ for any constant a , where σ is the standard deviation of X (as determined from the **VARDIST=** option).

PERCENTILES(*p1*, *p2*) defines the odds ratio as the ratio of the odds when X is equal to its $p2 * 100$ th percentile to the odds when X is equal to its $p1 * 100$ th percentile (where the percentiles are determined from the distribution specified in the **VARDIST=** option). Values for $p1$ and $p2$ must be strictly between 0 and 1.

INTERCEPT=*number-list*

specifies the intercept in the full model (including variables in the **TESTPREDICTOR=** and **COVARIATES=** options). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NBINS=(*"name" = number <... "name" = number >*)

specifies the number of categories (or “bins”) into which the distribution for each predictor variable (identified by its *name* from the **VARDIST=** option) is divided in internal calculations. Higher values increase computational time and memory requirements but generally lead to more accurate results. Each predictor variable that is absent from the **NBINS=** option derives its bin number from the **DEFAULTNBINS=** option.

There are two variable distributions for which the **NBINS=** value can be overridden internally:

- For an ordinal distribution, the number of ordinal values is always used as the number of bins.
- For a binomial distribution, if the requested number of bins is larger than $n + 1$, where n is the sample size parameter of the binomial distribution, then exactly $n + 1$ bins are used.

NFRACTIONAL**NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NTOTAL=*number-list*

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). Values must be at least one. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **DEFAULTNBINS=**
- **NBINS=**
- **ALPHA=**
- **RESPONSEPROB=**
- **INTERCEPT=**
- **TESTPREDICTOR=**
- **TESTODDSRATIO=**
- **TESTREGCOEFF=**
- **COVARIATES=**
- **COVODDSRATIOS=**
- **COVREGCOEFFS=**
- **CORR=**
- **NTOTAL=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **LOGISTIC** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **LOGISTIC** statement.

POWER=number-list

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

RESPONSEPROB=number-list

specifies the response probability in the full model when all predictor variables (including variables in the **TESTPREDICTOR=** and **COVARIATES=** options) are equal to their means. The log odds of this probability are equal to the intercept in the full model where all predictor are centered at their means. If the response variable is coded as $Y = 1$ for success and $Y = 0$ for failure, then this probability is equal to the mean of Y in the full model when all X s are equal to their means. Values must be strictly between zero and one. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

TEST=LRCHI

specifies the likelihood ratio chi-square test of a single model parameter in binary logistic regression. This is the default test option.

TESTODDSRATIO=number-list

specifies the odds ratio for the predictor variable being tested in the full model (including variables in the **TESTPREDICTOR=** and **COVARIATES=** options). If the response variable is coded as $Y = 1$ for success and $Y = 0$ for failure, then the odds ratio for the X being tested is the odds of $Y = 1$ when $X = a$ divided by the odds of $Y = 1$ when $X = b$, where a and b are determined from the **DEFAULTUNIT=** and **UNITS=** options. Values must be greater than zero. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

TESTPREDICTOR=name-list

specifies the distribution of the predictor variable being tested, using labels specified with the **VARDIST=** option. This distribution is assumed to be independent of the distributions of the covariates as defined in the **COVARIATES=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *name-list*.

TESTREGCOEFF=number-list

specifies the regression coefficient for the predictor variable being tested in the full model including the covariates specified by the **COVARIATES=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

UNITS=(“name” = change-spec <... “name” = change-spec >)

specifies the changes in the predictor variables assumed for odds ratios specified with the **COVODDSRATIOS=** and **TESTODDSRATIO=** options. Each predictor variable whose *name* (from the **VARDIST=** option) is absent from the **UNITS** option derives its change value from the **DEFAULTUNIT=** option. This option can be used only if at least one of the **COVODDSRATIOS=** and **TESTODDSRATIO=** options is used.

Valid specifications for *change-spec* are as follows:

number defines the odds ratio as the ratio of the response variable odds when $X = a$ to the odds when $X = a - \text{number}$ for any constant a .

<+|->SD defines the odds ratio as the ratio of the odds when $X = a$ to the odds when $X = a - \sigma$ (or $X = a + \sigma$, if SD is preceded by a minus sign (-)) for any constant a , where σ is the standard deviation of X (as determined from the **VARDIST=** option).

multiple*SD defines the odds ratio as the ratio of the odds when $X = a$ to the odds when $X = a - multiple * \sigma$ for any constant a , where σ is the standard deviation of X (as determined from the **VARDIST=** option).

PERCENTILES($p1, p2$) defines the odds ratio as the ratio of the odds when X is equal to its $p2 * 100$ th percentile to the odds when X is equal to its $p1 * 100$ th percentile (where the percentiles are determined from the distribution specified in the **VARDIST=** option). Values for $p1$ and $p2$ must be strictly between 0 and 1.

Each unit value must be nonzero.

VARDIST("label")=distribution (parameters)
defines a distribution for a predictor variable.

For the **VARDIST=** option,

label identifies the variable distribution in the output and with the **COVARIATES=** and **TESTPREDICTOR=** options.

distribution specifies the distributional form of the variable.

parameters specifies one or more parameters associated with the distribution.

Choices for distributional forms and their parameters are as follows:

ORDINAL ((*values*) : (*probabilities*)) is an ordered categorical distribution. The *values* are any numbers separated by spaces. The *probabilities* are numbers between 0 and 1 (inclusive) separated by spaces. Their sum must be exactly 1. The number of *probabilities* must match the number of *values*.

BETA ($a, b <, l, r >$) is a beta distribution with shape parameters a and b and optional location parameters l and r . The values of a and b must be greater than 0, and l must be less than r . The default values for l and r are 0 and 1, respectively.

BINOMIAL (p, n) is a binomial distribution with probability of success p and number of independent Bernoulli trials n . The value of p must be greater than 0 and less than 1, and n must be an integer greater than 0. If $n = 1$, then the distribution is binary.

EXPONENTIAL (λ) is an exponential distribution with scale λ , which must be greater than 0.

GAMMA (a, λ) is a gamma distribution with shape a and scale λ . The values of a and λ must be greater than 0.

LAPLACE (θ, λ) is a Laplace distribution with location θ and scale λ . The value of λ must be greater than 0.

LOGISTIC (θ, λ) is a logistic distribution with location θ and scale λ . The value of λ must be greater than 0.

LOGNORMAL (θ, λ) is a lognormal distribution with location θ and scale λ . The value of λ must be greater than 0.

NORMAL (θ, λ) is a normal distribution with mean θ and standard deviation λ . The value of λ must be greater than 0.

POISSON (m) is a Poisson distribution with mean m . The value of m must be greater than 0.

UNIFORM (l, r) is a uniform distribution on the interval $[l, r]$, where $l < r$.

Restrictions on Option Combinations

To specify the intercept in the full model, choose one of the following two parameterizations:

- intercept (using the **INTERCEPT=** options)
- Prob($Y = 1$) when all predictors are equal to their means (using the **RESPONSEPROB=** option)

To specify the effect associated with the predictor variable being tested, choose one of the following two parameterizations:

- odds ratio (using the **TESTODDSRATIO=** options)
- regression coefficient (using the **TESTREGCOEFFS=** option)

To describe the effects of the covariates in the full model, choose one of the following two parameterizations:

- odds ratios (using the **COVODDSRATIOS=** options)
- regression coefficients (using the **COVREGCOEFFS=** options)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **LOGISTIC** statement.

Likelihood Ratio Chi-Square Test for One Predictor

You can express effects in terms of response probability and odds ratios, as in the following statements:

```
proc power;
  logistic
    vardist("x1a") = normal(0, 2)
    vardist("x1b") = normal(0, 3)
    vardist("x2") = poisson(7)
    vardist("x3a") = ordinal((-5 0 5) : (.3 .4 .3))
    vardist("x3b") = ordinal((-5 0 5) : (.4 .3 .3))
    testpredictor = "x1a" "x1b"
    covariates = "x2" | "x3a" "x3b"
    responseprob = 0.15
    testoddsratio = 1.75
    covoddsratios = (2.1 1.4)
    ntotal = 100
    power = .;
run;
```

The **VARDIST=** options define the distributions of the predictor variables. The **TESTPREDICTOR=** option specifies two scenarios for the test predictor distribution, Normal(10,2) and Normal(10,3). The **COVARIATES=** option specifies two covariates, the first with a Poisson(7) distribution. The second covariate has an ordinal distribution on the values -5, 0, and 5 with two scenarios for the associated probabilities: (.3, .4, .3) and (.4, .3, .3). The response probability in the full model with all variables equal to zero is specified by the **RESPONSEPROB=** option as 0.15. The odds ratio for a unit decrease in the tested predictor is specified by the **TESTODDSRATIO=** option to be 1.75. Corresponding odds ratios for the two covariates in the full model are specified by the **COVODDSRATIOS=** option to be 2.1 and 1.4. The **POWER=.** option requests a solution for the power at a sample size of 100 as specified by the **NTOTAL=** option.

Default values of the **TEST=** and **ALPHA=** options specify a likelihood ratio test of the first predictor with a significance level of 0.05. The default of **DEFAULTUNIT=1** specifies that all odds ratios are defined in terms of unit changes in predictors. The default of **DEFAULTNBINS=10** specifies that each of the three predictor variables is discretized into a distribution with 10 categories in internal calculations.

You can also express effects in terms of regression coefficients, as in the following statements:

```
proc power;
  logistic
    vardist("x1a") = normal(0, 2)
    vardist("x1b") = normal(0, 3)
    vardist("x2") = poisson(7)
    vardist("x3a") = ordinal((-5 0 5) : (.3 .4 .3))
    vardist("x3b") = ordinal((-5 0 5) : (.4 .3 .3))
    testpredictor = "x1a" "x1b"
    covariates = "x2" | "x3a" "x3b"
    intercept = -6.928162
    testregcoeff = 0.5596158
    covregcoeffs = (0.7419373 0.3364722)
    ntotal = 100
    power = .;
run;
```

The regression coefficients for the tested predictor (**TESTREGCOEFF=0.5596158**) and covariates (**COVREGCOEFFS=(0.7419373 0.3364722)**) are determined by taking the logarithm of the corresponding odds ratios. The intercept in the full model is specified as -6.928162 by the **INTERCEPT=** option. This number is calculated according to the formula at the end of “Analyses in the LOGISTIC Statement” on page 6029, which expresses the intercept in terms of the response probability, regression coefficients, and predictor means:

$$\text{Intercept} = \log\left(\frac{0.15}{1 - 0.15}\right) - (0.5596158(0) + 0.7419373(7) + 0.3364722(0))$$

MULTREG Statement

MULTREG <options> ;

The **MULTREG** statement performs power and sample size analyses for Type III *F* tests of sets of predictors in multiple linear regression, assuming either fixed or normally distributed predictors.

Summary of Options

Table 71.4 summarizes the options available in the MULTREG statement.

Table 71.4 MULTREG Statement Options

Option	Description
Define analysis	
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
MODEL=	Specifies the assumed distribution of the predictors
NFULLPREDICTORS=	Specifies the number of predictors in the full model
NOINT	Specifies a no-intercept model
NREDUCEDPREDICTORS=	Specifies the number of predictors in the reduced model
NTESTPREDICTORS=	Specifies the number of predictors being tested
Specify effects	
PARTIALCORR=	Specifies the partial correlation
RSQUAREDIFF=	Specifies the difference in R^2
RSQUAREFULL=	Specifies the R^2 of the full model
RSQUAREREDUCED=	Specifies the R^2 of the reduced model
Specify sample size	
NFRACTIONAL	Enables fractional input and output for sample sizes
NTOTAL=	Specifies the sample size
Specify power	
POWER=	Specifies the desired power
Control ordering in output	
OUTPUTORDER=	Controls the order of parameters

Table 71.5 summarizes the valid result parameters in the MULTREG statement.

Table 71.5 Summary of Result Parameters in the MULTREG Statement

Analyses	Solve For	Syntax
TEST=TYPE3	Power	POWER=.
	Sample size	NTOTAL=.

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

MODEL=keyword-list

specifies the assumed distribution of the tested predictors. **MODEL=FIXED** indicates a fixed predictor distribution. **MODEL=RANDOM** (the default) indicates a joint multivariate normal distribution for the response and tested predictors. You can use the aliases **CONDITIONAL** for **FIXED** and **UNCONDITIONAL** for **RANDOM**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*.

FIXED fixed predictors

RANDOM random (multivariate normal) predictors

NFRACTIONAL**NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NFULLPREDICTORS=number-list**NFULLPRED=number-list**

specifies the number of predictors in the full model, not counting the intercept. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NOINT

specifies a no-intercept model (for both full and reduced models). By default, the intercept is included in the model. If you want to test the intercept, you can specify the **NOINT** option and simply consider the intercept to be one of the predictors being tested. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NREDUCEDPREDICTORS=number-list**NREDUCEDPRED=number-list****NREDPRED=number-list**

specifies the number of predictors in the reduced model, not counting the intercept. This is the same as the difference between values of the **NFULLPREDICTORS=** and **NTESTPREDICTORS=** options. Note that supplying a value of 0 is the same as specifying an *F* test of a Pearson correlation. This option cannot be used at the same time as the **NTESTPREDICTORS=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NTESTPREDICTORS=number-list**NTESTPRED=number-list**

specifies the number of predictors being tested. This is the same as the difference between values of the **NFULLPREDICTORS=** and **NREDUCEDPREDICTORS=** options. Note that supplying identical values for the **NTESTPREDICTORS=** and **NFULLPREDICTORS=** options is the same as specifying an *F* test of a Pearson correlation. This option cannot be used at the same time as the **NREDUCEDPREDICTORS=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NTOTAL=number-list

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). The minimum acceptable value for the sample size depends on the **MODEL=**, **NOINT**, **NFULLPREDICTORS=**, **NTESTPREDICTORS=**, and **NREDUCEDPREDICTORS=** options. It ranges from $p + 1$ to $p + 3$, where p is the value of the **NFULLPREDICTORS** option. See Table 71.30 for further information about minimum **NTOTAL** values, and see the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **MODEL=**
- **NFULLPREDICTORS=**
- **NTESTPREDICTORS=**
- **NREDUCEDPREDICTORS=**
- **ALPHA=**
- **PARTIALCORR=**
- **RSQUAREFULL=**
- **RSQUAREREDUCED=**
- **RSQUAREDIFF=**
- **NTOTAL=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **MULTREG** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **MULTREG** statement.

PARTIALCORR=number-list**PCORR=number-list**

specifies the partial correlation between the tested predictors and the response, adjusting for any other predictors in the model. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

POWER=number-list

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

RSQUAREDIFF=number-list**RSQDIFF=number-list**

specifies the difference in R^2 between the full and reduced models. This is equivalent to the proportion of variation explained by the predictors you are testing. It is also equivalent to the squared semipartial correlation of the tested predictors with the response. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

RSQUAREFULL=*number-list*

RSQFULL=*number-list*

specifies the R^2 of the full model, where R^2 is the proportion of variation explained by the model. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

RSQUAREREDUCED=*number-list*

RSQREDUCED=*number-list*

RSQRED=*number-list*

specifies the R^2 of the reduced model, where R^2 is the proportion of variation explained by the model. If the reduced model is an empty or intercept-only model (in other words, if **NREDUCEDPREDICTORS=0** or **NTESTPREDICTORS=NFULLPREDICTORS**), then **RSQUAREREDUCED=0** is assumed. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

TEST=TYPE3

specifies a Type III F test of a set of predictors adjusting for any other predictors in the model. This is the default test option.

Restrictions on Option Combinations

To specify the number of predictors, use any two of these three options:

- the number of predictors in the full model (**NFULLPREDICTORS=**)
- the number of predictors in the reduced model (**NREDUCEDPREDICTORS=**)
- the number of predictors being tested (**NTESTPREDICTORS=**)

To specify the effect, choose one of the following parameterizations:

- partial correlation (by using the **PARTIALCORR=** option)
- R^2 for the full and reduced models (by using any two of **RSQUAREDIFF=**, **RSQUAREFULL=**, and **RSQUAREREDUCED=**)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **MULTREG** statement.

Type III F Test of a Set of Predictors

You can express effects in terms of partial correlation, as in the following statements. Default values of the **TEST=**, **MODEL=**, and **ALPHA=** options specify a Type III F test with a significance level of 0.05, assuming normally distributed predictors.

```

proc power;
  multreg
    model = random
    nfullpredictors = 7
    ntestpredictors = 3
    partialcorr = 0.35
    ntotal = 100
    power = .;
run;

```

You can also express effects in terms of R^2 :

```

proc power;
  multreg
    model = fixed
    nfullpredictors = 7
    ntestpredictors = 3
    rsquarefull = 0.9
    rsquarediff = 0.1
    ntotal = .
    power = 0.9;
run;

```

ONECORR Statement

ONECORR <options> ;

The **ONECORR** statement performs power and sample size analyses for tests of simple and partial Pearson correlation between two variables. Both Fisher's z test and the t test are supported.

Summary of Options

Table 71.6 summarizes the options available in the **ONECORR** statement.

Table 71.6 ONECORR Statement Options

Option	Description
Define analysis	
DIST=	Specifies the underlying distribution assumed for the test statistic
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
MODEL=	Specifies the assumed distribution of the variables
NPARTIALVARS=	Specifies the number of variables adjusted for in the correlation
NULLCORR=	Specifies the null value of the correlation
SIDES=	Specifies the number of sides and the direction of the statistical test
Specify effects	
CORR=	Specifies the correlation

Table 71.6 continued

Option	Description
Specify sample size	
NFRACTIONAL	Enables fractional input and output for sample sizes
NTOTAL=	Specifies the sample size
Specify power	
POWER=	Specifies the desired power of the test
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.7 summarizes the valid result parameters in the **ONECORR** statement.

Table 71.7 Summary of Result Parameters in the ONECORR Statement

Analyses	Solve For	Syntax
TEST=PEARSON	Power Sample size	POWER=. NTOTAL=.

Dictionary of Options

ALPHA=number-list
specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

CORR=number-list
specifies the correlation between two variables, possibly adjusting for other variables as determined by the **NPARTIALVARS=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

DIST=FISHERZ
DIST=T
specifies the underlying distribution assumed for the test statistic. FISHERZ corresponds to Fisher’s *z* normalizing transformation of the correlation coefficient. T corresponds to the *t* transformation of the correlation coefficient. Note that **DIST=T** is equivalent to analyses in the **MULTREG** statement with **NTESTPREDICTORS=1**. The default value is FISHERZ.

MODEL=keyword-list
specifies the assumed distribution of the first variable when **DIST=T**. The second variable is assumed to have a normal distribution. **MODEL=FIXED** indicates a fixed distribution. **MODEL=RANDOM** (the default) indicates a joint bivariate normal distribution with the second variable. You can use the aliases **CONDITIONAL** for **FIXED** and **UNCONDITIONAL** for **RANDOM**. This option can be used only for **DIST=T**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*.

FIXED fixed variables

RANDOM random (bivariate normal) variables

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NPARTIALVARS=*number-list*

NPVARS=*number-list*

specifies the number of variables adjusted for in the correlation between the two primary variables. The default value is 0, corresponding to a simple correlation. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NTOTAL=*number-list*

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). Values for the sample size must be at least $p + 3$ when **DIST=T** and **MODEL=CONDITIONAL**, and at least $p + 4$ when either **DIST=FISHER** or when **DIST=T** and **MODEL=UNCONDITIONAL**, where p is the value of the **NPARTIALVARS** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLCORR=*number-list*

NULLC=*number-list*

specifies the null value of the correlation. The default value is 0. This option can be used only with the **DIST=FISHERZ** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **MODEL=**
- **SIDES=**
- **NULL=**
- **ALPHA=**
- **NPARTIALVARS=**
- **CORR=**
- **NTOTAL=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **ONECORR** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **ONECORR** statement.

POWER=number-list

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

SIDES=keyword-list

specifies the number of sides (or tails) and the direction of the statistical test. Valid keywords are

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

The default value is 2.

TEST=PEARSON

specifies a test of the Pearson correlation coefficient between two variables, possibly adjusting for other variables. This is the default test option.

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **ONECORR** statement.

Fisher's z Test for Pearson Correlation

The following statements demonstrate a power computation for Fisher's z test for correlation. Default values of **TEST=PEARSON**, **ALPHA=0.05**, **SIDES=2**, and **NPARTIALVARS=0** are assumed.

```
proc power;
  onecorr dist=fisherz
    nullcorr = 0.15
    corr = 0.35
    ntotal = 180
    power = .;
run;
```

t Test for Pearson Correlation

The following statements demonstrate a sample size computation for the *t* test for correlation. Default values of **TEST=PEARSON**, **MODEL=RANDOM**, **ALPHA=0.05**, and **SIDES=2** are assumed.

```
proc power;
  onecorr dist=t
    npartialvars = 4
    corr = 0.45
    ntotal = .
    power = 0.85;
run;
```

ONESAMPLEFREQ Statement

ONESAMPLEFREQ <options> ;

The **ONESAMPLEFREQ** statement performs power and sample size analyses for exact and approximate tests (including equivalence, noninferiority, and superiority) and confidence interval precision for a single binomial proportion.

Summary of Options

Table 71.8 summarizes the options available in the **ONESAMPLEFREQ** statement.

Table 71.8 ONESAMPLEFREQ Statement Options

Option	Description
Define analysis	
CI=	Specifies an analysis of precision of a confidence interval
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
EQUIVBOUNDS=	Specifies the lower and upper equivalence bounds
LOWER=	Specifies the lower equivalence bound
MARGIN=	Specifies the equivalence or noninferiority or superiority margin
NULLPROPORTION=	Specifies the null proportion
SIDES=	Specifies the number of sides and the direction of the statistical test
UPPER=	Specifies the upper equivalence bound
Specify effect	
HALFWIDTH=	Specifies the desired confidence interval half-width
PROPORTION=	Specifies the binomial proportion
Specify variance estimation	
VAREST=	Specifies how the variance is computed
Specify sample size	
NFRACTIONAL	Enables fractional input and output for sample sizes
NTOTAL=	Specifies the sample size
Specify power and related probabilities	
POWER=	Specifies the desired power of the test
PROBWIDTH=	Specifies the probability of obtaining a confidence interval half-width less than or equal to the value specified by HALFWIDTH=
Choose computational method	
METHOD=	Specifies the computational method
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.9 summarizes the valid result parameters for different analyses in the **ONESAMPLEFREQ** statement.

Table 71.9 Summary of Result Parameters in the **ONESAMPLEFREQ** Statement

Analyses	Solve For	Syntax
CI=WILSON	Prob(width)	PROBWIDTH=.

TEST=EXACT	Power	POWER=.
TEST=Z METHOD=EXACT	Power	POWER=.
TEST=Z METHOD=NORMAL	Power	POWER=.
	Sample size	NTOTAL=.

Dictionary of Options

ALPHA=number-list

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. If the **CI=** and **SIDES=1** options are used, then the value must be less than 0.5. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

CI

CI=AGRESTICOULL | **AC**

CI=JEFFREYS

CI=EXACT | **CLOPPERPEARSON** | **CP**

CI=WALD

CI=WALD_CORRECT

CI=WILSON | **SCORE**

specifies an analysis of precision of a confidence interval for the sample binomial proportion.

The value of the **CI=** option specifies the type of confidence interval. The **CI=AGRESTICOULL** option is a generalization of the “Adjusted Wald / add 2 successes and 2 failures” interval of Agresti and Coull (1998) and is presented in Brown, Cai, and DasGupta (2001). It corresponds to the **TABLES / BINOMIAL (AGRESTICOULL)** option in PROC FREQ. The **CI=JEFFREYS** option specifies the equal-tailed Jeffreys prior Bayesian interval, corresponding to the **TABLES / BINOMIAL (JEFFREYS)** option in PROC FREQ. The **CI=EXACT** option specifies the exact Clopper-Pearson confidence interval based on enumeration, corresponding to the **TABLES / BINOMIAL (EXACT)** option in PROC FREQ. The **CI=WALD** option specifies the confidence interval based on the Wald test (also commonly called the z test or normal-approximation test), corresponding to the **TABLES / BINOMIAL (WALD)** option in PROC FREQ. The **CI=WALD_CORRECT** option specifies the confidence interval based on the Wald test with continuity correction, corresponding to the **TABLES / BINOMIAL (CORRECT WALD)** option in PROC FREQ. The **CI=WILSON** option (the default) specifies the confidence interval based on the score statistic, corresponding to the **TABLES / BINOMIAL (WILSON)** option in PROC FREQ.

Instead of power, the relevant probability for this analysis is the probability of achieving a desired precision. Specifically, it is the probability that the half-width of the confidence interval will be at most the value specified by the **HALFWIDTH=** option.

EQUIVBOUNDS=*grouped-number-list*

specifies the lower and upper equivalence bounds, representing the same information as the combination of the **LOWER=** and **UPPER=** options but grouping them together. The **EQUIVBOUNDS=** option can be used only with equivalence analyses (**TEST=EQUIV_ADJZ | EQUIV_EXACT | EQUIV_Z**). Values must be strictly between 0 and 1. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

HALFWIDTH=*number-list*

specifies the desired confidence interval half-width. The half-width for a two-sided interval is the length of the confidence interval divided by two. This option can be used only with the **CI=** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

LOWER=*number-list*

specifies the lower equivalence bound for the binomial proportion. The **LOWER=** option can be used only with equivalence analyses (**TEST=EQUIV_ADJZ | EQUIV_EXACT | EQUIV_Z**). Values must be strictly between 0 and 1. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

MARGIN=*number-list*

specifies the equivalence or noninferiority or superiority margin, depending on the analysis.

The **MARGIN=** option can be used with one-sided analyses (**SIDES = 1 | U | L**), in which case it specifies the margin added to the null proportion value in the hypothesis test, resulting in a noninferiority or superiority test (depending on the agreement between the effect and hypothesis directions and the sign of the margin). A test with a null proportion p_0 and a margin m is the same as a test with null proportion $p_0 + m$ and no margin.

The **MARGIN=** option can also be used with equivalence analyses (**TEST=EQUIV_ADJZ | EQUIV_EXACT | EQUIV_Z**) when the **NULLPROPORTION=** option is used, in which case it specifies the lower and upper equivalence bounds as $p_0 - m$ and $p_0 + m$, where p_0 is the value of the **NULLPROPORTION=** option and m is the value of the **MARGIN=** option.

The **MARGIN=** option cannot be used in conjunction with the **SIDES=2** option. (Instead, specify an equivalence analysis by using **TEST=EQUIV_ADJZ** or **TEST=EQUIV_EXACT** or **TEST=EQUIV_Z**). Also, the **MARGIN=** option cannot be used with the **CI=** option.

Values must be strictly between -1 and 1 . In addition, the sum of **NULLPROPORTION** and **MARGIN** must be strictly between 0 and 1 for one-sided analyses, and the derived lower equivalence bound ($2 * \text{NULLPROPORTION} - \text{MARGIN}$) must be strictly between 0 and 1 for equivalence analyses.

See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

METHOD=EXACT

METHOD=NORMAL

specifies the computational method. **METHOD=EXACT** (the default) computes exact results by using the binomial distribution. **METHOD=NORMAL** computes approximate results by using the normal approximation to the binomial distribution.

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. This option is invalid when the **METHOD=EXACT** option is specified. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRAC-TIONAL** option.

NTOTAL=number-list

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLPROPORTION=number-list

NULLP=number-list

specifies the null proportion. A value of 0.5 corresponds to the sign test. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **SIDES=**
- **NULLPROPORTION=**
- **ALPHA=**
- **PROPORTION=**
- **NTOTAL=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **ONESAMPLEFREQ** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **ONESAMPLEFREQ** statement.

POWER=*number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

PROBWIDTH=*number-list*

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the **HALFWIDTH=** option. A missing value (**PROBWIDTH=.**) requests a solution for this probability. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can be used only with the **CI=** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

PROPORTION=*number-list*

P=*number-list*

specifies the binomial proportion—that is, the expected proportion of successes in the hypothetical binomial trial. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and the direction of the statistical test. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords are as follows:

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

If the effect size is zero, then **SIDES=1** is not permitted; instead, specify the direction of the test explicitly in this case with either **SIDES=L** or **SIDES=U**. The default value is 2.

TEST

TEST= ADJZ

TEST= EQUIV_ADJZ

TEST= EQUIV_EXACT

TEST= EQUIV_Z

TEST= EXACT

TEST= Z

specifies the statistical analysis. **TEST=ADJZ** specifies a normal-approximate *z* test with continuity adjustment. **TEST=EQUIV_ADJZ** specifies a normal-approximate two-sided equivalence test based on the *z* statistic with continuity adjustment and a TOST (two one-sided tests) procedure.

TEST=EQUIV_EXACT specifies the exact binomial two-sided equivalence test based on a TOST (two one-sided tests) procedure. **TEST=EQUIV_Z** specifies a normal-approximate two-sided equivalence test based on the z statistic without any continuity adjustment, which is the same as the chi-square statistic, and a TOST (two one-sided tests) procedure. **TEST** or **TEST=EXACT** (the default) specifies the exact binomial test. **TEST=Z** specifies a normal-approximate z test without any continuity adjustment, which is the same as the chi-square test when **SIDES=2**.

UPPER=number-list

specifies the upper equivalence bound for the binomial proportion. The **UPPER=** option can be used only with equivalence analyses (**TEST=EQUIV_ADJZ** | **EQUIV_EXACT** | **EQUIV_Z**). Values must be strictly between 0 and 1. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

VAREST=keyword-list

specifies how the variance is computed in the test statistic for the **TEST=Z**, **TEST=ADJZ**, **TEST=EQUIV_Z**, and **TEST=EQUIV_ADJZ** analyses. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *keyword-list*. Valid keywords are as follows:

NULL (the default) estimates the variance by using the null proportion(s) (specified by some combination of the **NULLPROPORTION=**, **MARGIN=**, **LOWER=**, and **UPPER=** options). For **TEST=Z** and **TEST=ADJZ**, the null proportion is the value of the **NULLPROPORTION=** option plus the value of the **MARGIN=** option (if it is used). For **TEST=EQUIV_Z** and **TEST=EQUIV_ADJZ**, there are two null proportions, corresponding to the lower and upper equivalence bounds, one for each test in the TOST (two one-sided tests) procedure.

SAMPLE estimates the variance by using the observed sample proportion.

This option is ignored if the analysis is one other than **TEST=Z**, **TEST=ADJZ**, **TEST=EQUIV_Z**, or **TEST=EQUIV_ADJZ**.

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **ONESAMPLEFREQ** statement.

Exact Test of a Binomial Proportion

The following statements demonstrate a power computation for the exact test of a binomial proportion. Defaults for the **SIDES=** and **ALPHA=** options specify a two-sided test with a 0.05 significance level.

```
proc power;
  onesamplefreq test=exact
    nullproportion = 0.2
    proportion = 0.3
    ntotal = 100
    power = .;
run;
```

z Test

The following statements demonstrate a sample size computation for the z test of a binomial proportion. Defaults for the **SIDES=**, **ALPHA=**, and **VAREST=** options specify a two-sided test with a 0.05 significance level that uses the null variance estimate.

```
proc power;
  onesamplefreq test=z method=normal
    nullproportion = 0.8
    proportion = 0.85
    sides = u
    ntotal = .
    power = .9;
run;
```

z Test with Continuity Adjustment

The following statements demonstrate a sample size computation for the z test of a binomial proportion with a continuity adjustment. Defaults for the **SIDES=**, **ALPHA=**, and **VAREST=** options specify a two-sided test with a 0.05 significance level that uses the null variance estimate.

```
proc power;
  onesamplefreq test=adjz method=normal
    nullproportion = 0.15
    proportion = 0.1
    sides = l
    ntotal = .
    power = .9;
run;
```

Exact Equivalence Test for a Binomial Proportion

You can specify equivalence bounds by using the **EQUIVBOUNDS=** option, as in the following statements:

```
proc power;
  onesamplefreq test=equiv_exact
    proportion = 0.35
    equivbounds = (0.2 0.4)
    ntotal = 50
    power = .;
run;
```

You can also specify the combination of **NULLPROPORTION=** and **MARGIN=** options:

```
proc power;
  onesamplefreq test=equiv_exact
    proportion = 0.35
    nullproportion = 0.3
    margin = 0.1
    ntotal = 50
    power = .;
run;
```

Finally, you can specify the combination of **LOWER=** and **UPPER=** options:

```
proc power;
  onesamplefreq test=equiv_exact
    proportion = 0.35
    lower = 0.2
    upper = 0.4
    ntotal = 50
    power = .;
run;
```

Note that the three preceding analyses are identical.

Exact Noninferiority Test for a Binomial Proportion

A noninferiority test corresponds to an upper one-sided test with a negative-valued margin, as demonstrated in the following statements:

```
proc power;
  onesamplefreq test=exact
    sides = U
    proportion = 0.15
    nullproportion = 0.1
    margin = -0.02
    ntotal = 130
    power = .;
run;
```

Exact Superiority Test for a Binomial Proportion

A superiority test corresponds to an upper one-sided test with a positive-valued margin, as demonstrated in the following statements:

```
proc power;
  onesamplefreq test=exact
    sides = U
    proportion = 0.15
    nullproportion = 0.1
    margin = 0.02
    ntotal = 130
    power = .;
run;
```

Confidence Interval Precision

The following statements performs a confidence interval precision analysis for the Wilson score-based confidence interval for a binomial proportion. The default value of the **ALPHA=** option specifies a confidence level of 0.95.

```
proc power;
  onesamplefreq ci=wilson
    halfwidth = 0.1
    proportion = 0.3
    ntotal = 70
    probwidth = .;
run;
```

Restrictions on Option Combinations

To specify the equivalence bounds for **TEST=EQUIV_ADJZ**, **TEST=EQUIV_EXACT**, and **TEST=EQUIV_Z**, use any of these three option sets:

- lower and upper equivalence bounds, using the **EQUIVBOUNDS=** option
- lower and upper equivalence bounds, using the **LOWER=** and **UPPER=** options
- null proportion (**NULLPROPORTION=**) and margin (**MARGIN=**)

ONESAMPLEMEANS Statement

ONESAMPLEMEANS < options > ;

The **ONESAMPLEMEANS** statement performs power and sample size analyses for *t* tests, equivalence tests, and confidence interval precision involving one sample.

Summary of Options

Table 71.10 summarizes the options available in the **ONESAMPLEMEANS** statement.

Table 71.10 ONESAMPLEMEANS Statement Options

Option	Description
Define analysis	
CI=	Specifies an analysis of precision of the confidence interval for the mean
DIST=	Specifies the underlying distribution assumed for the test statistic
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
LOWER=	Specifies the lower equivalence bound for the mean
NULLMEAN=	Specifies the null mean
SIDES=	Specifies the number of sides and the direction of the statistical test
UPPER=	Specifies the upper equivalence bound for the mean
Specify effect	
HALFWIDTH=	Specifies the desired confidence interval half-width
MEAN=	Specifies the mean
Specify variability	
CV=	Specifies the coefficient of variation
STDDEV=	Specifies the standard deviation
Specify sample size	
NFRACTIONAL	Enables fractional input and output for sample sizes
NTOTAL=	Specifies the sample size

Table 71.10 *continued*

Option	Description
Specify power and related probabilities	
POWER=	Specifies the desired power of the test
PROBTYPE=	Specifies the type of probability for the PROBWIDTH= option
PROBWIDTH=	Specifies the probability of obtaining a confidence interval half-width less than or equal to the value specified by HALFWIDTH=
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.11 summarizes the valid result parameters for different analyses in the **ONESAMPLEMEANS** statement.

Table 71.11 Summary of Result Parameters in the ONESAMPLEMEANS Statement

Analyses	Solve For	Syntax
TEST=T DIST=NORMAL	Power	POWER=.
	Sample size	NTOTAL=.
	Alpha	ALPHA=.
	Mean	MEAN=.
	Standard Deviation	STDDEV=.
TEST=T DIST=LOGNORMAL	Power	POWER=.
	Sample size	NTOTAL=.
TEST=EQUIV	Power	POWER=.
	Sample size	NTOTAL=.
CI=T	Prob(width)	PROBWIDTH=.
	Sample size	NTOTAL=.

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test or requests a solution for alpha with a missing value (**ALPHA=.**). The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. If the **CI=** and **SIDES=1** options are used, then the value must be less than 0.5. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

CI

CI=T

specifies an analysis of precision of the confidence interval for the mean. Instead of power, the relevant probability for this analysis is the probability of achieving a desired precision. Specifically, it is the probability that the half-width of the confidence interval will be at most the value specified by the **HALFWIDTH=** option. If neither the **CI=** option nor the **TEST=** option is used, the default is **TEST=T**.

CV=number-list

specifies the coefficient of variation, defined as the ratio of the standard deviation to the mean. You can use this option only with **DIST=LOGNORMAL**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

DIST=LOGNORMAL**DIST=NORMAL**

specifies the underlying distribution assumed for the test statistic. **NORMAL** corresponds to the normal distribution, and **LOGNORMAL** corresponds to the lognormal distribution. The default value is **NORMAL**.

HALFWIDTH=number-list

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can be used only with the **CI=T** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

LOWER=number-list

specifies the lower equivalence bound for the mean. This option can be used only with the **TEST=EQUIV** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

MEAN=number-list

specifies the mean, in the original scale, or requests a solution for the mean with a missing value (**MEAN=.**). The mean is arithmetic if **DIST=NORMAL** and geometric if **DIST=LOGNORMAL**. This option can be used only with the **TEST=T** and **TEST=EQUIV** analyses. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NFRACTIONAL**NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NTOTAL=number-list

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLMEAN=number-list**NULLM=number-list**

specifies the null mean, in the original scale (whether **DIST=NORMAL** or **DIST=LOGNORMAL**). The default value is 0 when **DIST=NORMAL** and 1 when **DIST=LOGNORMAL**. This option can be used only with the **TEST=T** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **SIDES=**
- **NULLMEAN=**
- **LOWER=**
- **UPPER=**
- **ALPHA=**
- **MEAN=**
- **HALFWIDTH=**
- **STDDEV=**
- **CV=**
- **NTOTAL=**
- **POWER=**
- **PROBTYPE=**
- **PROBWIDTH=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **ONESAMPLEMEANS** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **ONESAMPLEMEANS** statement.

POWER=number-list

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option can be used only with the **TEST=T** and **TEST=EQUIV** analyses. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

PROBTYPE=keyword-list

specifies the type of probability for the **PROBWIDTH=** option. A value of **CONDITIONAL** (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the **HALFWIDTH=** option, given that the true mean is captured by the confidence interval. A value of **UNCONDITIONAL** indicates the unconditional probability that the confidence interval half-width is at most the value specified by the **HALFWIDTH=** option. You can use the alias **GIVENVALIDITY** for **CONDITIONAL**. The **PROBTYPE=** option can be used only with the **CI=T** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*.

CONDITIONAL width probability conditional on interval containing the mean

UNCONDITIONAL unconditional width probability

PROBWIDTH=number-list

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the **HALFWIDTH=** option. A missing value (**PROBWIDTH=.**) requests a solution for this probability. The type of probability is controlled with the **PROBTYPE=** option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can be used only with the **CI=T** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

SIDES=keyword-list

specifies the number of sides (or tails) and the direction of the statistical test or confidence interval. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords and their interpretation for the **TEST=** analyses are as follows:

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

For confidence intervals, **SIDES=U** refers to an interval between the lower confidence limit and infinity, and **SIDES=L** refers to an interval between minus infinity and the upper confidence limit. For both of these cases and **SIDES=1**, the confidence interval computations are equivalent. The **SIDES=** option can be used only with the **TEST=T** and **CI=T** analyses. The default value is 2.

STDDEV=number-list**STD=number-list**

specifies the standard deviation, or requests a solution for the standard deviation with a missing value (**STDDEV=.**). You can use this option only with **DIST=NORMAL**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

TEST**TEST=EQUIV****TEST=T**

specifies the statistical analysis. **TEST=EQUIV** specifies an equivalence test of the mean by using a two one-sided tests (TOST) analysis (Schuirmann 1987). **TEST** or **TEST=T** (the default) specifies a *t* test on the mean. If neither the **TEST=** option nor the **CI=** option is used, the default is **TEST=T**.

UPPER=number-list

specifies the upper equivalence bound for the mean, in the original scale (whether **DIST=NORMAL** or **DIST=LOGNORMAL**). This option can be used only with the **TEST=EQUIV** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (by using the **TEST=** option)
- confidence interval precision (by using the **CI=** option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **ONESAMPLEMEANS** statement.

One-Sample *t* Test

The following statements demonstrate a power computation for the one-sample *t* test. Default values for the **DIST=**, **SIDES=**, **NULLMEAN=**, and **ALPHA=** options specify a two-sided test for zero mean with a normal distribution and a significance level of 0.05.

```
proc power;
  onesamplemeans test=t
    mean = 7
    stddev = 3
    ntotal = 50
    power = .;
run;
```

One-Sample *t* Test with Lognormal Data

The following statements demonstrate a sample size computation for the one-sample *t* test for lognormal data. Default values for the **SIDES=**, **NULLMEAN=**, and **ALPHA=** options specify a two-sided test for unit mean with a significance level of 0.05.

```
proc power;
  onesamplemeans test=t dist=lognormal
    mean = 7
    cv = 0.8
    ntotal = .
    power = 0.9;
run;
```

Equivalence Test for Mean of Normal Data

The following statements demonstrate a power computation for the TOST equivalence test for a normal mean. Default values for the **DIST=** and **ALPHA=** options specify a normal distribution and a significance level of 0.05.

```
proc power;
  onesamplemeans test=equiv
    lower = 2
    upper = 7
    mean = 4
    stddev = 3
    ntotal = 100
    power = .;
run;
```

Equivalence Test for Mean of Lognormal Data

The following statements demonstrate a sample size computation for the TOST equivalence test for a log-normal mean. The default of `ALPHA=0.05` specifies a significance level of 0.05.

```
proc power;
  onesamplemeans test=equiv dist=lognormal
    lower = 1
    upper = 5
    mean = 3
    cv = 0.6
    ntotal = .
    power = 0.85;
run;
```

Confidence Interval for Mean

By default `CI=T` analyzes the conditional probability of obtaining the desired precision, given that the interval contains the true mean, as in the following statements. The defaults of `SIDES=2` and `ALPHA=0.05` specify a two-sided interval with a confidence level of 0.95.

```
proc power;
  onesamplemeans ci = t
    halfwidth = 14
    stddev = 8
    ntotal = 50
    probwidth = .;
run;
```

ONEWAYANOVA Statement

ONEWAYANOVA <options> ;

The **ONEWAYANOVA** statement performs power and sample size analyses for one-degree-of-freedom contrasts and the overall *F* test in one-way analysis of variance.

Summary of Options

Table 71.12 summarizes the options available in the **ONEWAYANOVA** statement.

Table 71.12 ONEWAYANOVA Statement Options

Option	Description
Define analysis	
<code>TEST=</code>	Specifies the statistical analysis
Specify analysis information	
<code>ALPHA=</code>	Specifies the significance level
<code>CONTRAST=</code>	Specifies coefficients for single-degree-of-freedom hypothesis tests
<code>NULLCONTRAST=</code>	Specifies the null value of the contrast
<code>SIDES=</code>	Specifies the number of sides and the direction of the statistical test

Table 71.12 continued

Option	Description
Specify effect	
GROUPMEANS=	Specifies the group means
Specify variability	
STDDEV=	Specifies the error standard deviation
Specify sample size and allocation	
GROUPNS=	Specifies the group sample sizes
GROUPWEIGHTS=	Specifies the sample size allocation weights for the groups
NFRACTIONAL	Enables fractional input and output for sample sizes
NPERGROUP=	Specifies the common sample size per group
NTOTAL=	Specifies the sample size
Specify power	
POWER=	Specifies the desired power of the test
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.13 summarizes the valid result parameters for different analyses in the **ONEWAYANOVA** statement.

Table 71.13 Summary of Result Parameters in the ONEWAYANOVA Statement

Analyses	Solve For	Syntax
TEST=CONTRAST	Power	POWER=.
	Sample size	NTOTAL=. NPERGROUP==.
TEST=OVERALL	Power	POWER=.
	Sample size	NTOTAL=. NPERGROUP==.

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

CONTRAST= (*values*) < (... *values*) >

specifies coefficients for single-degree-of-freedom hypothesis tests. You must provide a coefficient for every mean appearing in the **GROUPMEANS=** option. Specify multiple contrasts either with additional sets of coefficients or with additional **CONTRAST=** options. For example, you can specify two different contrasts of five means by using the following:

```
CONTRAST = (1 -1 0 0 0) (1 0 -1 0 0)
```

GROUPMEANS=*grouped-number-list*

GMEANS=*grouped-number-list*

specifies the group means. This option is used to implicitly set the number of groups. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPNS=*grouped-number-list*

GNS=*grouped-number-list*

specifies the group sample sizes. The number of groups represented must be the same as with the **GROUPMEANS**= option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPWEIGHTS=*grouped-number-list*

GWEIGHTS=*grouped-number-list*

specifies the sample size allocation weights for the groups. This option controls how the total sample size is divided between the groups. Each set of values across all groups represents relative allocation weights. Additionally, if the **NFRACTIONAL** option is not used, the total sample size is restricted to be equal to a multiple of the sum of the group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). The number of groups represented must be the same as with the **GROUPMEANS**= option. Values must be integers unless the **NFRACTIONAL** option is used. The default value is 1 for each group, amounting to a balanced design. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NPARGROUP=*number-list*

NPERG=*number-list*

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (**NPERGROUP**=.). Use of this option implicitly specifies a balanced design. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NTOTAL=*number-list*

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL**=.). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLCONTRAST=*number-list*

NULLC=*number-list*

specifies the null value of the contrast. The default value is 0. This option can be used only with the **TEST=CONTRAST** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **CONTRAST=**
- **SIDES=**
- **NULLCONTRAST=**
- **ALPHA=**
- **GROUPMEANS=**
- **STDDEV=**
- **GROUPWEIGHTS=**
- **NTOTAL=**
- **NPERGROUP=**
- **GROUPNS=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **ONEWAYANOVA** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **ONEWAYANOVA** statement.

POWER=number-list

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

SIDES=keyword-list

specifies the number of sides (or tails) and the direction of the statistical test. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords are as follows:

- | | |
|---|---|
| 1 | one-sided with alternative hypothesis in same direction as effect |
| 2 | two-sided |
| U | upper one-sided with alternative greater than null value |
| L | lower one-sided with alternative less than null value |

This option can be used only with the **TEST=CONTRAST** analysis. The default value is 2.

STDDEV=number-list**STD=number-list**

specifies the error standard deviation. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

TEST=CONTRAST**TEST=OVERALL**

specifies the statistical analysis. **TEST=CONTRAST** specifies a one-degree-of-freedom test of a contrast of means. The test is the usual F test for the two-sided case and the usual t test for the one-sided case. **TEST=OVERALL** specifies the overall F test of equality of all means. The default is **TEST=CONTRAST** if the **CONTRAST=** option is used, and **TEST=OVERALL** otherwise.

Restrictions on Option Combinations

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (by using the **NPERGROUP=** option)
- total sample size and allocation weights (by using the **NTOTAL=** and **GROUPWEIGHTS=** options)
- individual group sample sizes (by using the **GROUPNS=** option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **ONEWAYANOVA** statement.

One-Degree-of-Freedom Contrast

You can use the **NPERGROUP=** option in a balanced design, as in the following statements. Default values for the **SIDES=**, **NULLCONTRAST=**, and **ALPHA=** options specify a two-sided test for a contrast value of 0 with a significance level of 0.05.

```
proc power;
  onewayanova test=contrast
    contrast = (1 0 -1)
    groupmeans = 3 | 7 | 8
    stddev = 4
    npergroup = 50
    power = .;
run;
```

You can also specify an unbalanced design with the **NTOTAL=** and **GROUPWEIGHTS=** options:

```
proc power;
  onewayanova test=contrast
    contrast = (1 0 -1)
    groupmeans = 3 | 7 | 8
    stddev = 4
    groupweights = (1 2 2)
    ntotal = .
    power = 0.9;
run;
```

Another way to specify the sample sizes is with the **GROUPNS=** option:

```
proc power;
  onewayanova test=contrast
    contrast = (1 0 -1)
    groupmeans = 3 | 7 | 8
    stddev = 4
    groupns = (20 40 40)
    power = .;
run;
```

Overall F Test

The following statements demonstrate a power computation for the overall F test in a one-way ANOVA. The default of **ALPHA=0.05** specifies a significance level of 0.05.

```
proc power;
  onewayanova test=overall
    groupmeans = 3 | 7 | 8
    stddev = 4
    npergroup = 50
    power = .;
run;
```

PAIREDFREQ Statement

PAIREDFREQ <options> ;

The **PAIREDFREQ** statement performs power and sample size analyses for McNemar's test for paired proportions.

Summary of Options

Table 71.14 summarizes the options available in the **PAIREDFREQ** statement.

Table 71.14 PAIREDFREQ Statement Options

Option	Description
Define analysis	
DIST=	Specifies the underlying distribution assumed for the test statistic
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
NULLDISCPRORATIO=	Specifies the null value of the ratio of discordant proportions
SIDES=	Specifies the number of sides and the direction of the statistical test or confidence interval
Specify effects	
CORR=	Specifies the correlation ϕ between members of a pair
DISCPRORPDIFF=	Specifies the discordant proportion difference $p_{01} - p_{10}$
DISCPRORPORTIONS=	Specifies the two discordant proportions, p_{10} and p_{01}

Table 71.14 continued

Option	Description
DISCPRORATIO=	Specifies the ratio p_{01}/p_{10}
ODDSRATIO=	Specifies the odds ratio $[p_{\cdot 1}/(1 - p_{\cdot 1})] / [p_{1 \cdot}/(1 - p_{1 \cdot})]$
PAIREDPROPORTIONS=	Specifies the two paired proportions, $p_{1\cdot}$ and $p_{\cdot 1}$
PROPORTIONDIFF=	Specifies the proportion difference $p_{\cdot 1} - p_{1\cdot}$
REFPROPORTION=	Specifies either the reference first proportion $p_{1\cdot}$ or the reference discordant proportion p_{10}
RELATIVERISK=	Specifies the relative risk $p_{\cdot 1}/p_{1\cdot}$
TOTALPROPDISC=	Specifies the discordant proportion sum, $p_{10} + p_{01}$
Specify sample size	
NFRACTIONAL	Enables fractional input and output for sample sizes
NPAIRS=	Specifies the total number of proportion pairs
Specify power	
POWER=	Specifies the desired power of the test
Choose computational method	
METHOD=	Specifies the computational method
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.15 summarizes the valid result parameters in the PAIREFREQ statement.

Table 71.15 Summary of Result Parameters in the PAIREFREQ Statement

Analyses	Solve For	Syntax
TEST=MCNEMAR METHOD=CONNOR	Power Sample size	POWER=. NPAIRS=.
TEST=MCNEMAR METHOD=EXACT	Power	POWER=.
TEST=MCNEMAR METHOD=MIETTINEN	Power Sample size	POWER=. NPAIRS=.

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

CORR=*number-list*

specifies the correlation ϕ between members of a pair. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

DISCPROPORTIONS=*grouped-number-list*

DISCPS=*grouped-number-list*

specifies the two discordant proportions, p_{10} and p_{01} . See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

DISCPROPDIFF=*number-list*

DISCPDIFF=*number-list*

specifies the difference $p_{01} - p_{10}$ between discordant proportions. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

DISCPRORATIO=*number-list*

DISCPRATIO=*number-list*

specifies the ratio p_{01}/p_{10} of discordant proportions. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

DIST=EXACT_COND

DIST=NORMAL

specifies the underlying distribution assumed for the test statistic. EXACT_COND corresponds to the exact conditional test, based on the exact binomial distribution of the two types of discordant pairs given the total number of discordant pairs. NORMAL corresponds to the conditional test based on the normal approximation to the binomial distribution of the two types of discordant pairs given the total number of discordant pairs. The default value is EXACT_COND.

METHOD=CONNOR

METHOD=EXACT

METHOD=MIETTINEN

specifies the computational method. **METHOD=EXACT** (the default) uses the exact binomial distributions of the total number of discordant pairs and the two types of discordant pairs. **METHOD=CONNOR** uses an approximation from Connor (1987), and **METHOD=MIETTINEN** uses an approximation from Miettinen (1968). The CONNOR and MIETTINEN methods are valid only for **DIST=NORMAL**.

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option. This option cannot be used with **METHOD=EXACT**.

NPAIRS=*number-list*

specifies the total number of proportion pairs (concordant and discordant) or requests a solution for the number of pairs with a missing value (**NPAIRS=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLDISCPRORATIO=*number-list*

NULLDISCRATIO=*number-list*

NULLRATIO=*number-list*

NULLR=*number-list*

specifies the null value of the ratio of discordant proportions. The default value is 1. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

ODDSRATIO=*number-list*

OR=*number-list*

specifies the odds ratio $[p_{1.}/(1 - p_{1.})] / [p_{1.}/(1 - p_{1.})]$. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **SIDES=**
- **NULLDISCPRORATIO=**
- **ALPHA=**
- **PAIREDPROPORTIONS=**
- **PROPORTIONDIFF=**
- **ODDSRATIO=**
- **RELATIVERISK=**
- **CORR=**
- **DISCPROPORTIONS=**
- **DISCPROPDIFF=**
- **TOTALPROPDISC=**
- **REFPROPORTION=**
- **DISCPRORATIO=**
- **NPAIRS=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **PAIREDFREQ** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **PAIREDFREQ** statement.

PAIREDPROPORTIONS=*grouped-number-list*

PPROPORTIONS=*grouped-number-list*

PAIREDPS=*grouped-number-list*

PPS=*grouped-number-list*

specifies the two paired proportions, $p_{1.}$ and $p_{.1}$. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

POWER=*number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

PROPORTIONDIFF=*number-list*

PDIF=*number-list*

specifies the proportion difference $p_{.1} - p_{1.}$. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

REFPROPORTION=*number-list*

REFP=*number-list*

specifies either the reference first proportion $p_{1.}$ (when used in conjunction with the **PROPORTIONDIFF=**, **ODDSRATIO=**, or **RELATIVERISK=** option) or the reference discordant proportion p_{10} (when used in conjunction with the **DISCPROPDIF=** or **DISCPROPRATIO=** option). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

RELATIVERISK=*number-list*

RR=*number-list*

specifies the relative risk $p_{.1} / p_{1.}$. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and the direction of the statistical test or confidence interval. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords and their interpretation are as follows:

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

If the effect size is zero, then **SIDES=1** is not permitted; instead, specify the direction of the test explicitly in this case with either **SIDES=L** or **SIDES=U**. The default value is 2.

TEST=MCNEMAR

specifies the McNemar test of paired proportions. This is the default test option.

TOTALPROPDISC=*number-list*

TOTALPDISC=*number-list*

PDISC=*number-list*

specifies the sum of the two discordant proportions, $p_{10} + p_{01}$. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

Restrictions on Option Combinations

To specify the proportions, choose one of the following parameterizations:

- discordant proportions (using the **DISCPROPORTIONS=** option)
- difference and sum of discordant proportions (using the **DISCPROPDIFF=** and **TOTALPROPDISC=** options)
- difference of discordant proportions and reference discordant proportion (using the **DISCPROPDIFF=** and **REFPROPORTION=** options)
- ratio of discordant proportions and reference discordant proportion (using the **DISCPROPRATIO=** and **REFPROPORTION=** options)
- ratio and sum of discordant proportions (using the **DISCPROPRATIO=** and **TOTALPROPDISC=** options)
- paired proportions and correlation (using the **PAIREDPROPORTIONS=** and **CORR=** options)
- proportion difference, reference proportion, and correlation (using the **PROPORTIONDIFF=**, **REFPROPORTION=**, and **CORR=** options)
- odds ratio, reference proportion, and correlation (using the **ODDSRATIO=**, **REFPROPORTION=**, and **CORR=** options)
- relative risk, reference proportion, and correlation (using the **RELATIVERISK=**, **REFPROPORTION=**, and **CORR=** options)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **PAIREDFREQ** statement.

McNemar Exact Conditional Test

You can express effects in terms of the individual discordant proportions, as in the following statements. Default values for the **TEST=**, **SIDES=**, **ALPHA=**, and **NULLDISCPROPRATIO=** options specify a two-sided McNemar test for no effect with a significance level of 0.05.

```
proc power;
  pairedfreq dist=exact_cond
    discproportions = 0.15 | 0.45
    npairs = 80
    power = .;
run;
```

You can also express effects in terms of the difference and sum of discordant proportions:

```
proc power;
  pairedfreq dist=exact_cond
    discpropdiff = 0.3
    totalpropdisc = 0.6
    npairs = 80
    power = .;
run;
```

You can also express effects in terms of the difference of discordant proportions and the reference discordant proportion:

```
proc power;
  pairedfreq dist=exact_cond
    discpropdiff = 0.3
    refproportion = 0.15
    npairs = 80
    power = .;
run;
```

You can also express effects in terms of the ratio of discordant proportions and the denominator of the ratio:

```
proc power;
  pairedfreq dist=exact_cond
    discpropratio = 3
    refproportion = 0.15
    npairs = 80
    power = .;
run;
```

You can also express effects in terms of the ratio and sum of discordant proportions:

```
proc power;
  pairedfreq dist=exact_cond
    discpropratio = 3
    totalpropdisc = 0.6
    npairs = 80
    power = .;
run;
```

You can also express effects in terms of the paired proportions and correlation:

```
proc power;
  pairedfreq dist=exact_cond
    pairedproportions = 0.6 | 0.8
    corr = 0.4
    npairs = 45
    power = .;
run;
```

You can also express effects in terms of the proportion difference, reference proportion, and correlation:

```
proc power;
  pairedfreq dist=exact_cond
    proportiondiff = 0.2
    refproportion = 0.6
```

```

        corr = 0.4
        npairs = 45
        power = .;
run;

```

You can also express effects in terms of the odds ratio, reference proportion, and correlation:

```

proc power;
    pairedfreq dist=exact_cond
        oddsratio = 2.66667
        refproportion = 0.6
        corr = 0.4
        npairs = 45
        power = .;
run;

```

You can also express effects in terms of the relative risk, reference proportion, and correlation:

```

proc power;
    pairedfreq dist=exact_cond
        relativerisk = 1.33333
        refproportion = 0.6
        corr = 0.4
        npairs = 45
        power = .;
run;

```

McNemar Normal Approximation Test

The following statements demonstrate a sample size computation for the normal-approximate McNemar test. The default value for the **METHOD=** option specifies an exact sample size computation. Default values for the **TEST=**, **SIDES=**, **ALPHA=**, and **NULLDISCPRORATIO=** options specify a two-sided McNemar test for no effect with a significance level of 0.05.

```

proc power;
    pairedfreq dist=normal method=connor
        discproportions = 0.15 | 0.45
        npairs = .
        power = .9;
run;

```

PAIREDMEANS Statement

PAIREDMEANS <options> ;

The **PAIREDMEANS** statement performs power and sample size analyses for *t* tests, equivalence tests, and confidence interval precision involving paired samples.

Summary of Options

Table 71.14 summarizes the options available in the **PAIREDMEANS** statement.

Table 71.16 PAIREDMEANS Statement Options

Option	Description
Define analysis	
CI=	Specifies an analysis of precision of the confidence interval for the mean difference
DIST=	Specifies the underlying distribution assumed for the test statistic
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
LOWER=	Specifies the lower equivalence bound
NULLDIFF=	Specifies the null mean difference
NULLRATIO=	Specifies the null mean ratio
SIDES=	Specifies the number of sides and the direction of the statistical test or confidence interval
UPPER=	Specifies the upper equivalence bound
Specify effects	
HALFWIDTH=	Specifies the desired confidence interval half-width
MEANDIFF=	Specifies the mean difference
MEANRATIO=	Specifies the geometric mean ratio, γ_2/γ_1
PAIREDMEANS=	Specifies the two paired means
Specify variability	
CORR=	Specifies the correlation between members of a pair
CV=	Specifies the common coefficient of variation
PAIREDCVS=	Specifies the coefficient of variation for each member of a pair
PAIREDSTDDEVS=	Specifies the standard deviation of each member of a pair
STDDEV=	Specifies the common standard deviation
Specify sample size	
NFRACTIONAL	Enables fractional input and output for sample sizes
NPAIRS=	Specifies the number of pairs
Specify power and related probabilities	
POWER=	Specifies the desired power of the test
PROBTYPE=	Specifies the type of probability for the PROBWIDTH= option
PROBWIDTH=	Specifies the probability of obtaining a confidence interval half-width less than or equal to the value specified by the HALFWIDTH=
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.17 summarizes the valid result parameters for different analyses in the **PAIREDMEANS** statement.

Table 71.17 Summary of Result Parameters in the PAIREDMEANS Statement

Analyses	Solve For	Syntax
TEST=DIFF	Power Sample size	POWER=. NPAIRS=.
TEST=RATIO	Power Sample size	POWER=. NPAIRS=.
TEST=EQUIV_DIFF	Power Sample size	POWER=. NPAIRS=.
TEST=EQUIV_RATIO	Power Sample size	POWER=. NPAIRS=.
CI=DIFF	Prob(width) Sample size	PROBWIDTH=. NPAIRS=.

Dictionary of Options

ALPHA=number-list

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. If the **CI=** and **SIDES=1** options are used, then the value must be less than 0.5. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

CI

CI=DIFF

specifies an analysis of precision of the confidence interval for the mean difference. Instead of power, the relevant probability for this analysis is the probability of achieving a desired precision. Specifically, it is the probability that the half-width of the observed confidence interval will be at most the value specified by the **HALFWIDTH=** option. If neither the **CI=** option nor the **TEST=** option is used, the default is **TEST=DIFF**.

CORR=number-list

specifies the correlation between members of a pair. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

CV=number-list

specifies the coefficient of variation assumed to be common to both members of a pair. The coefficient of variation is defined as the ratio of the standard deviation to the mean. You can use this option only with **DIST=LOGNORMAL**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

DIST=LOGNORMAL**DIST=NORMAL**

specifies the underlying distribution assumed for the test statistic. NORMAL corresponds to the normal distribution, and LOGNORMAL corresponds to the lognormal distribution. The default value (also the only acceptable value in each case) is NORMAL for **TEST=DIFF**, **TEST=EQUIV_DIFF**, and **CI=DIFF**; and LOGNORMAL for **TEST=RATIO** and **TEST=EQUIV_RATIO**.

HALFWIDTH=number-list

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can be used only with the **CI=DIFF** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

LOWER=number-list

specifies the lower equivalence bound for the mean difference or mean ratio, in the original scale (whether **DIST=NORMAL** or **DIST=LOGNORMAL**). This option can be used only with the **TEST=EQUIV_DIFF** and **TEST=EQUIV_RATIO** analyses. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

MEANDIFF=number-list

specifies the mean difference, defined as the mean of the difference between the second and first members of a pair, $\mu_2 - \mu_1$. This option can be used only with the **TEST=DIFF** and **TEST=EQUIV_DIFF** analyses. When **TEST=EQUIV_DIFF**, the mean difference is interpreted as the treatment mean minus the reference mean. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

MEANRATIO=number-list

specifies the geometric mean ratio, defined as γ_2/γ_1 . This option can be used only with the **TEST=RATIO** and **TEST=EQUIV_RATIO** analyses. When **TEST=EQUIV_RATIO**, the mean ratio is interpreted as the treatment mean divided by the reference mean. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NFRACTIONAL**NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NPAIRS=number-list

specifies the number of pairs or requests a solution for the number of pairs with a missing value (**NPAIRS=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLDIFF=number-list**NULLD=number-list**

specifies the null mean difference. The default value is 0. This option can be used only with the **TEST=DIFF** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLRATIO=*number-list*

NULLR=*number-list*

specifies the null mean ratio. The default value is 1. This option can be used only with the **TEST=RATIO** analysis. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **SIDES=**
- **NULLDIFF=**
- **NULLRATIO=**
- **LOWER=**
- **UPPER=**
- **ALPHA=**
- **PAIREDMEANS=**
- **MEANDIFF=**
- **MEANRATIO=**
- **HALFWIDTH=**
- **STDDEV=**
- **PAIREDSTDDEVS=**
- **CV=**
- **PAIREDCVS=**
- **CORR=**
- **NPAIRS=**
- **POWER=**
- **PROBTYPE=**
- **PROBWIDTH=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **PAIREDMEANS** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **PAIREDMEANS** statement.

PAIREDCVS=*grouped-number-list*

specifies the coefficient of variation for each member of a pair. Unlike the **CV=** option, the **PAIREDCVS=** option supports different values for each member of a pair. Values must be nonnegative (unless both are equal to zero, which is permitted). This option can be used only with **DIST=LOGNORMAL**. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *grouped-number-list*.

PAIREDMEANS=*grouped-number-list*

PMEANS=*grouped-number-list*

specifies the two paired means, in the original scale. The means are arithmetic if **DIST**=NORMAL and geometric if **DIST**=LOGNORMAL. This option cannot be used with the **CI**=DIFF analysis. When **TEST**=EQUIV_DIFF, the means are interpreted as the reference mean (first) and the treatment mean (second). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

PAIREDSTDDEVS=*grouped-number-list*

PAIREDSTDS=*grouped-number-list*

PSTDDEVS=*grouped-number-list*

PSTDS=*grouped-number-list*

specifies the standard deviation of each member of a pair. Unlike the **STDDEV**= option, the **PAIREDSTDDEVS**= option supports different values for each member of a pair. This option can be used only with **DIST**=NORMAL. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

POWER=*number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER**=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option cannot be used with the **CI**=DIFF analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

PROBTYPE=*keyword-list*

specifies the type of probability for the **PROBWIDTH**= option. A value of CONDITIONAL (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the **HALFWIDTH**= option, given that the true mean difference is captured by the confidence interval. A value of UNCONDITIONAL indicates the unconditional probability that the confidence interval half-width is at most the value specified by the **HALFWIDTH**= option. you can use the alias GIVENVALIDITY for CONDITIONAL. The **PROBTYPE**= option can be used only with the **CI**=DIFF analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*.

CONDITIONAL width probability conditional on interval containing the mean

UNCONDITIONAL unconditional width probability

PROBWIDTH=*number-list*

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the **HALFWIDTH**= option. A missing value (**PROBWIDTH**=.) requests a solution for this probability. The type of probability is controlled with the **PROBTYPE**= option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can be used only with the **CI**=DIFF analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and the direction of the statistical test or confidence interval. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords and their interpretation for the **TEST**= analyses are as follows:

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

For confidence intervals, **SIDES=U** refers to an interval between the lower confidence limit and infinity, and **SIDES=L** refers to an interval between minus infinity and the upper confidence limit. For both of these cases and **SIDES=1**, the confidence interval computations are equivalent. The **SIDES=** option cannot be used with the **TEST=EQUIV_DIFF** and **TEST=EQUIV_RATIO** analyses. The default value is 2.

STDDEV=number-list

STD=number-list

specifies the standard deviation assumed to be common to both members of a pair. This option can be used only with **DIST=NORMAL**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

TEST

TEST=DIFF

TEST=EQUIV_DIFF

TEST=EQUIV_RATIO

TEST=RATIO

specifies the statistical analysis. **TEST** or **TEST=DIFF** (the default) specifies a paired *t* test on the mean difference. **TEST=EQUIV_DIFF** specifies an additive equivalence test of the mean difference by using a two one-sided tests (TOST) analysis (Schuirmann 1987). **TEST=EQUIV_RATIO** specifies a multiplicative equivalence test of the mean ratio by using a TOST analysis. **TEST=RATIO** specifies a paired *t* test on the geometric mean ratio. If neither the **TEST=** option nor the **CI=** option is used, the default is **TEST=DIFF**.

UPPER=number-list

specifies the upper equivalence bound for the mean difference or mean ratio, in the original scale (whether **DIST=NORMAL** or **DIST=LOGNORMAL**). This option can be used only with the **TEST=EQUIV_DIFF** and **TEST=EQUIV_RATIO** analyses. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (by using the **TEST=** option)
- confidence interval precision (by using the **CI=** option)

To specify the means, choose one of the following parameterizations:

- individual means (by using the **PAIREDMEANS=** option)
- mean difference (by using the **MEANDIFF=** option)
- mean ratio (by using the **MEANRATIO=** option)

To specify the coefficient of variation, choose one of the following parameterizations:

- common coefficient of variation (by using the **CV=** option)
- individual coefficients of variation (by using the **PAIREDCVS=** option)

To specify the standard deviation, choose one of the following parameterizations:

- common standard deviation (by using the **STDDEV=** option)
- individual standard deviations (by using the **PAIREDSTDDEVS=** option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **PAIREDMEANS** statement.

Paired *t* Test

You can express effects in terms of the mean difference and variability in terms of a correlation and common standard deviation, as in the following statements. Default values for the **DIST=**, **SIDES=**, **NULLDIFF=**, and **ALPHA=** options specify a two-sided test for no difference with a normal distribution and a significance level of 0.05.

```
proc power;
  pairedmeans test=diff
    meandiff = 7
    corr = 0.4
    stddev = 12
    npairs = 50
    power = .;
run;
```

You can also express effects in terms of individual means and variability in terms of correlation and individual standard deviations:

```
proc power;
  pairedmeans test=diff
    pairedmeans = 8 | 15
    corr = 0.4
    pairedstddevs = (7 12)
    npairs = .
    power = 0.9;
run;
```

Paired *t* Test of Mean Ratio with Lognormal Data

You can express variability in terms of correlation and a common coefficient of variation, as in the following statements. Defaults for the **DIST=**, **SIDES=**, **NULLRATIO=** and **ALPHA=** options specify a two-sided test of mean ratio = 1 assuming a lognormal distribution and a significance level of 0.05.

```
proc power;
    pairedmeans test=ratio
        meanratio = 7
        corr = 0.3
        cv = 1.2
        npairs = 30
        power = .;
run;
```

You can also express variability in terms of correlation and individual coefficients of variation:

```
proc power;
    pairedmeans test=ratio
        meanratio = 7
        corr = 0.3
        pairedcvs = 0.8 | 0.9
        npairs = 30
        power = .;
run;
```

Additive Equivalence Test for Mean Difference with Normal Data

The following statements demonstrate a sample size computation for a TOST equivalence test for a normal mean difference. Default values for the [DIST=](#) and [ALPHA=](#) options specify a normal distribution and a significance level of 0.05.

```
proc power;
    pairedmeans test=equiv_diff
        lower = 2
        upper = 5
        meandiff = 4
        corr = 0.2
        stddev = 8
        npairs = .
        power = 0.9;
run;
```

Multiplicative Equivalence Test for Mean Ratio with Lognormal Data

The following statements demonstrate a power computation for a TOST equivalence test for a lognormal mean ratio. Default values for the [DIST=](#) and [ALPHA=](#) options specify a lognormal distribution and a significance level of 0.05.

```
proc power;
    pairedmeans test=equiv_ratio
        lower = 3
        upper = 7
        meanratio = 5
        corr = 0.2
        cv = 1.1
        npairs = 50
        power = .;
run;
```

Confidence Interval for Mean Difference

By default **CI=DIFF** analyzes the conditional probability of obtaining the desired precision, given that the interval contains the true mean difference, as in the following statements. The defaults of **SIDES=2** and **ALPHA=0.05** specify a two-sided interval with a confidence level of 0.95.

```
proc power;
  pairedmeans ci = diff
    halfwidth = 4
    corr = 0.35
    stddev = 8
    npairs = 30
    probwidth = .;
run;
```

PLOT Statement

PLOT *<plot-options>* *</graph-options>* ;

The **PLOT** statement produces a graph or set of graphs for the sample size analysis defined by the previous analysis statement. The *plot-options* define the plot characteristics, and the *graph-options* are SAS/GRAPH-style options. If ODS Graphics is enabled, then the **PLOT** statement uses ODS Graphics to create graphs. For example:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power;
  onesamplemeans
    mean    = 5 10
    ntotal  = 150
    stddev  = 30 50
    power   = .;
  plot x=n min=100 max=200;
run;

ods graphics off;
```

Otherwise, traditional graphics are produced. For example:

```
ods graphics off;

proc power;
  onesamplemeans
    mean    = 5 10
    ntotal  = 150
    stddev  = 30 50
    power   = .;
  plot x=n min=100 max=200;
run;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The ODS LISTING STYLE=HTMLBLUECML statement specifies the HTMLBLUECML style, which is suitable for use with PROC POWER because it allows both marker symbols and line styles to vary. See the section “ODS Styles Suitable for Use with PROC POWER” on page 6082 for more information.

Options

You can specify the following *plot-options* in the PLOT statement.

INTERPOL=JOIN | NONE

specifies the type of curve to draw through the computed points. The INTERPOL=JOIN option connects computed points by straight lines. The INTERPOL=NONE option leaves computed points unconnected.

KEY=BYCURVE <(bycurve-options)>

KEY=BYFEATURE <(byfeature-options)>

KEY=ONCURVES

specifies the style of key (or “legend”) for the plot. The default is KEY=BYFEATURE, which specifies a key with a column of entries for each plot feature (line style, color, and/or symbol). Each entry shows the mapping between a value of the feature and the value(s) of the analysis parameter(s) linked to that feature. The KEY=BYCURVE option specifies a key with each row identifying a distinct curve in the plot. The KEY=ONCURVES option places a curve-specific label adjacent to each curve.

You can specify the following *byfeature-options* in parentheses after the KEY=BYCURVE option.

NUMBERS=OFF | ON

specifies how the key should identify curves. If NUMBERS=OFF, then the key includes symbol, color, and line style samples to identify the curves. If NUMBERS=ON, then the key includes numbers matching numeric labels placed adjacent to the curves. The default is NUMBERS=ON.

POS=BOTTOM | INSET

specifies the position of the key. The POS=BOTTOM option places the key below the X axis. The POS=INSET option places the key inside the plotting region and attempts to choose the least crowded corner. The default is POS=BOTTOM.

You can specify the following *byfeature-options* in parentheses after KEY=BYFEATURE option.

POS=BOTTOM | INSET

specifies the position of the key. The POS=BOTTOM option places the key below the X axis. The POS=INSET option places the key inside the plotting region and attempts to choose the least crowded corner. The default is POS=BOTTOM.

MARKERS=ANALYSIS | COMPUTED | NICE | NONE

specifies the locations for plotting symbols.

The MARKERS=ANALYSIS option places plotting symbols at locations corresponding to the values of the relevant input parameter from the analysis statement preceding the PLOT statement.

The MARKERS=COMPUTED option (the default) places plotting symbols at the locations of actual computed points from the sample size analysis.

The MARKERS=NICE option places plotting symbols at tick mark locations (corresponding to the argument axis).

The MARKERS=NONE option disables plotting symbols.

MAX=number | DATAMAX

specifies the maximum of the range of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). The default is DATAMAX, which specifies the maximum value that occurs for this parameter in the analysis statement that precedes the **PLOT** statement.

MIN=number | DATAMIN

specifies the minimum of the range of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). The default is DATAMIN, which specifies the minimum value that occurs for this parameter in the analysis statement that precedes the **PLOT** statement.

NPOINTS=number**NPTS=number**

specifies the number of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). You cannot use the **NPOINTS=** and **STEP=** options simultaneously. The default value for typical situations is 20.

STEP=number

specifies the increment between values of the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). You cannot use the **STEP=** and **NPOINTS=** options simultaneously. By default, the **NPOINTS=** option is used instead of the **STEP=** option.

VARY (feature < BY parameter-list > < , ... , feature < BY parameter-list > >)

specifies how plot features should be linked to varying analysis parameters. Available plot *features* are COLOR, LINESTYLE, PANEL, and SYMBOL. A “panel” refers to a separate plot with a heading identifying the subset of values represented in the plot.

The *parameter-list* is a list of one or more names separated by spaces. Each name must match the name of an analysis option used in the analysis statement preceding the **PLOT** statement. Also, the name must be the *primary* name for the analysis option—that is, the one listed first in the syntax description.

If you omit the < BY *parameter-list* > portion for a feature, then one or more multivalued parameters from the analysis will be automatically selected for you.

X=EFFECT N POWER

specifies a plot with the requested type of parameter on the X axis and the parameter being solved for on the Y axis. When **X=EFFECT**, the parameter assigned to the X axis is the one most representative of “effect size.” When **X=N**, the parameter assigned to the X axis is the sample size. When **X=POWER**, the parameter assigned to the X axis is the one most representative of “power” (either power itself or a similar probability, such as Prob(Width) for confidence interval analyses). You cannot use the **X=** and **Y=** options simultaneously. The default is **X=POWER**, unless the result parameter is power or Prob(Width), in which case the default is **X=N**.

You can use the **X=N** option only when a scalar sample size parameter is used as input in the analysis. For example, **X=N** can be used with total sample size or sample size per group, or with two group sample sizes when one is being solved for.

Table 71.18 summarizes the parameters representing effect size in different analyses.

Table 71.18 Effect Size Parameters for Different Analyses

Analysis Statement and Options	Effect Size Parameters
LOGISTIC	None
MULTREG	Partial correlation or R^2 difference
ONECORR	Correlation
ONESAMPLEFREQ TEST	Proportion
ONESAMPLEFREQ CI	CI half-width
ONESAMPLEMEANS TEST=T, ONESAMPLEMEANS TEST=EQUIV	Mean
ONESAMPLEMEANS CI=T	CI half-width
ONEWAYANOVA	None
PAIREDFREQ	Discordant proportion difference or ratio
PAIREDMEANS TEST=DIFF, PAIREDMEANS TEST=EQUIV_DIFF	Mean difference
PAIREDMEANS TEST=RATIO, PAIREDMEANS TEST=EQUIV_RATIO	Mean ratio
PAIREDMEANS CI=DIFF	CI half-width
TWOSAMPLEFREQ	Proportion difference, odds ratio, or relative risk
TWOSAMPLEMEANS TEST=DIFF, TWOSAMPLEMEANS TEST=DIFF_SATT, TWOSAMPLEMEANS TEST=EQUIV_DIFF	Mean difference
TWOSAMPLEMEANS TEST=RATIO, TWOSAMPLEMEANS TEST=EQUIV_RATIO	Mean ratio
TWOSAMPLEMEANS CI=DIFF	CI half-width
TWOSAMPLESURVIVAL	Hazard ratio if used, else none
TWOSAMPLEWILCOXON	None

XOPTS=(*x-options*)

specifies plot characteristics pertaining to the X axis.

You can specify the following *x-options* in parentheses.

CROSSREF=NO | YES

specifies whether the reference lines defined by the **REF=** *x-option* should be crossed with a reference line on the Y axis that indicates the solution point on the curve.

REF=number-list

specifies locations for reference lines extending from the X axis across the entire plotting region. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

Y=EFFECT N POWER

specifies a plot with the requested type of parameter on the Y axis and the parameter being solved for on the X axis. When **Y=EFFECT**, the parameter assigned to the Y axis is the one most representative of “effect size.” When **Y=N**, the parameter assigned to the Y axis is the sample size. When **Y=POWER**, the parameter assigned to the Y axis is the one most representative of “power” (either power itself or a similar probability, such as Prob(Width) for confidence interval analyses). You cannot use the **Y=** and **X=** options simultaneously. By default, the **X=** option is used instead of the **Y=** option.

YOPTS=(y-options)

specifies plot characteristics pertaining to the Y axis.

You can specify the following *y-options* in parentheses.

CROSSREF=NO | YES

specifies whether the reference lines defined by the **REF= y-option** should be crossed with a reference line on the X axis that indicates the solution point on the curve.

REF=number-list

specifies locations for reference lines extending from the Y axis across the entire plotting region. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

You can specify the following *graph-options* in the **PLOT** statement after a slash (/).

DESCRIPTION='string'

specifies a descriptive string of up to 40 characters that appears in the “Description” field of the graphics catalog. The description does not appear on the plots. By default, PROC POWER assigns a description either of the form “Y versus X” (for a single-panel plot) or of the form “Y versus X (S),” where Y is the parameter on the Y axis, X is the parameter on the X axis, and S is a description of the subset represented on the current panel of a multipanel plot.

NAME='string'

specifies a name of up to eight characters for the catalog entry for the plot. The default name is **PLOTn**, where *n* is the number of the plot statement within the current invocation of PROC POWER. If the name duplicates the name of an existing entry, SAS/GRAPH software adds a number to the duplicate name to create a unique entry—for example, **PLOT11** and **PLOT12** for the second and third panels of a multipanel plot generated in the first **PLOT** statement in an invocation of PROC POWER.

TWO SAMPLE FREQ Statement

TWO SAMPLE FREQ < options > ;

The **TWO SAMPLE FREQ** statement performs power and sample size analyses for tests of two independent proportions. Pearson's chi-square, Fisher's exact, and likelihood ratio chi-square tests are supported.

Summary of Options

Table 71.19 summarizes the options available in the **TWO SAMPLE FREQ** statement.

Table 71.19 TWO SAMPLE FREQ Statement Options

Option	Description
Define analysis	
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
NULLODDSRATIO=	Specifies the null odds ratio
NULLPROPORTIONDIFF=	Specifies the null proportion difference
NULLRELATIVERISK=	Specifies the null relative risk
SIDES=	Specifies the number of sides and the direction of the statistical test or confidence interval
Specify effects	
GROUPPROPORTIONS=	Specifies the two independent proportions, p_1 and p_2
ODDSRATIO=	Specifies the odds ratio $[p_2/(1 - p_2)] / [p_1/(1 - p_1)]$
PROPORTIONDIFF=	Specifies the proportion difference $p_2 - p_1$
REFPROPORTION=	Specifies the reference proportion p_1
RELATIVERISK=	Specifies the relative risk p_2/p_1
Specify sample size and allocation	
GROUPNS=	Specifies the two group sample sizes
GROUPWEIGHTS=	Specifies the sample size allocation weights for the two groups
NFRACTIONAL	Enables fractional input and output for sample sizes
NPERGROUP=	Specifies the common sample size per group
NTOTAL=	Specifies the sample size
Specify power	
POWER=	Specifies the desired power of the test
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.20 summarizes the valid result parameters for different analyses in the **TWOSAMPLEFREQ** statement.

Table 71.20 Summary of Result Parameters in the TWOSAMPLEFREQ Statement

Analyses	Solve For	Syntax
TEST=FISHER	Power	POWER=.
	Sample size	NTOTAL=.
TEST=LRCHI	Power	NPERGROUP=.
	Sample size	POWER=.
TEST=PCHI	Power	NTOTAL=.
	Sample size	NPERGROUP=.

Dictionary of Options

ALPHA=number-list

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

GROUPPROPORTIONS=grouped-number-list

GPROPORTIONS=grouped-number-list

GROUPPS=grouped-number-list

GPS=grouped-number-list

specifies the two independent proportions, p_1 and p_2 . See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPNS=grouped-number-list

GNS=grouped-number-list

specifies the two group sample sizes. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPWEIGHTS=grouped-number-list

GWEIGHTS=grouped-number-list

specifies the sample size allocation weights for the two groups. This option controls how the total sample size is divided between the two groups. Each pair of values for the two groups represents relative allocation weights. Additionally, if the **NFRACTIONAL** option is not used, the total sample size is restricted to be equal to a multiple of the sum of the two group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). Values must be integers unless the **NFRACTIONAL** option is used. The default value is (1 1), a balanced design with a weight of 1 for each group. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

NFRACTIONAL**NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NPERGROUP=number-list**NPERG=number-list**

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (**NPERGROUP=.**). Use of this option implicitly specifies a balanced design. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NTOTAL=number-list

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLODDSRATIO=number-list**NULLOR=number-list**

specifies the null odds ratio. The default value is 1. This option can be used only with the **ODDSRATIO=** option in the **TEST=PCHI** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLPROPORTIONDIFF=number-list**NULLPDIFF=number-list**

specifies the null proportion difference. The default value is 0. This option can be used only with the **GROUPPROPORTIONS=** or **PROPORTIONDIFF=** option in the **TEST=PCHI** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLRELATIVERISK=number-list**NULLRR=number-list**

specifies the null relative risk. The default value is 1. This option can be used only with the **RELATIVERISK=** option in the **TEST=PCHI** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

ODDSRATIO=number-list**OR=number-list**

specifies the odds ratio $[p_2/(1 - p_2)] / [p_1/(1 - p_1)]$. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- SIDES=
- NULLPROPORTIONDIFF=
- NULLODDSRATIO=
- NULLRELATIVERISK=
- ALPHA=
- GROUPPROPORTIONS=
- REFPROPORTION=
- PROPORTIONDIFF=
- ODDSRATIO=
- RELATIVERISK=
- GROUPWEIGHTS=
- NTOTAL=
- NPERGROUP=
- GROUPNS=
- POWER=

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **TWOSAMPLEFREQ** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **TWOSAMPLEFREQ** statement.

POWER=number-list

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

PROPORTIONDIFF=number-list

PDIF=number-list

specifies the proportion difference $p_2 - p_1$. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

REFPROPORTION=number-list

REFP=number-list

specifies the reference proportion p_1 . See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

RELATIVERISK=number-list

RR=number-list

specifies the relative risk p_2 / p_1 . See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

SIDES=keyword-list

specifies the number of sides (or tails) and the direction of the statistical test or confidence interval. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords and their interpretation are as follows:

- | | |
|---|---|
| 1 | one-sided with alternative hypothesis in same direction as effect |
| 2 | two-sided |

- U upper one-sided with alternative greater than null value
 L lower one-sided with alternative less than null value

If the effect size is zero, then **SIDES=1** is not permitted; instead, specify the direction of the test explicitly in this case with either **SIDES=L** or **SIDES=U**. The default value is 2.

TEST=FISHER

TEST=LRCHI

TEST=PCHI

specifies the statistical analysis. **TEST=FISHER** specifies Fisher's exact test. **TEST=LRCHI** specifies the likelihood ratio chi-square test. **TEST=PCHI** (the default) specifies Pearson's chi-square test.

Restrictions on Option Combinations

To specify the proportions, choose one of the following parameterizations:

- individual proportions (by using the **GROUPPROPORTIONS=** option)
- difference between proportions and reference proportion (by using the **PROPORTIONDIFF=** and **REFPROPORTION=** options)
- odds ratio and reference proportion (by using the **ODDSRATIO=** and **REFPROPORTION=** options)
- relative risk and reference proportion (by using the **RELATIVERISK=** and **REFPROPORTION=** options)

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (by using the **NPERGROUP=** option)
- total sample size and allocation weights (by using the **NTOTAL=** and **GROUPWEIGHTS=** options)
- individual group sample sizes (by using the **GROUPNS=** option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **TWOSAMPLEFREQ** statement.

Pearson Chi-Square Test for Two Proportions

You can use the **NPERGROUP=** option in a balanced design and express effects in terms of the individual proportions, as in the following statements. Default values for the **SIDES=** and **ALPHA=** options specify a two-sided test with a significance level of 0.05.

```
proc power;
  twosamplefreq test=pchi
    groupproportions = (.15 .25)
    nullproportiondiff = .03
    npergroup = 50
    power = .;
run;
```

You can also specify an unbalanced design by using the `NTOTAL=` and `GROUPWEIGHTS=` options and express effects in terms of the odds ratio. The default value of the `NULLODDSRATIO=` option specifies a test of no effect.

```
proc power;
  twosamplefreq test=pchi
    oddsratio = 2.5
    refproportion = 0.3
    groupweights = (1 2)
    ntotal = .
    power = 0.8;
run;
```

You can also specify sample sizes with the `GROUPNS=` option and express effects in terms of relative risks. The default value of the `NULLRELATIVERISK=` option specifies a test of no effect.

```
proc power;
  twosamplefreq test=pchi
    relativerisk = 1.5
    refproportion = 0.2
    groupns = 40 | 60
    power = .;
run;
```

You can also express effects in terms of the proportion difference. The default value of the `NULLPROPORTIONDIFF=` option specifies a test of no effect, and the default value of the `GROUPWEIGHTS=` option specifies a balanced design.

```
proc power;
  twosamplefreq test=pchi
    proportiondiff = 0.15
    refproportion = 0.4
    ntotal = 100
    power = .;
run;
```

Fisher's Exact Conditional Test for Two Proportions

The following statements demonstrate a power computation for Fisher's exact conditional test for two proportions. Default values for the `SIDES=` and `ALPHA=` options specify a two-sided test with a significance level of 0.05.

```
proc power;
  twosamplefreq test=fisher
    groupproportions = (.35 .15)
    npergroup = 50
    power = .;
run;
```

Likelihood Ratio Chi-Square Test for Two Proportions

The following statements demonstrate a sample size computation for the likelihood ratio chi-square test for two proportions. Default values for the **SIDES=** and **ALPHA=** options specify a two-sided test with a significance level of 0.05.

```
proc power;
  twosamplefreq test=lrchi
    oddsratio = 2
    refproportion = 0.4
    npergroup = .
    power = 0.9;
run;
```

TWOSAMPLEMEANS Statement

TWOSAMPLEMEANS <options> ;

The **TWOSAMPLEMEANS** statement performs power and sample size analyses for pooled and unpooled *t* tests, equivalence tests, and confidence interval precision involving two independent samples.

Summary of Options

Table 71.21 summarizes the options available in the **TWOSAMPLEMEANS** statement.

Table 71.21 TWOSAMPLEMEANS Statement Options

Option	Description
Define analysis	
CI=	Specifies an analysis of precision of the confidence interval
DIST=	Specifies the underlying distribution assumed for the test statistic
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
LOWER=	Specifies the lower equivalence bound
NULLDIFF=	Specifies the null mean difference
NULLRATIO=	Specifies the null mean ratio
SIDES=	Specifies the number of sides and the direction of the statistical test or confidence interval
UPPER=	Specifies the upper equivalence bound
Specify effects	
HALFWIDTH=	Specifies the desired confidence interval half-width
GROUPMEANS=	Specifies the two group means
MEANDIFF=	Specifies the mean difference
MEANRATIO=	Specifies the geometric mean ratio, γ_2/γ_1
Specify variability	
CV=	Specifies the common coefficient of variation

Table 71.21 *continued*

Option	Description
GROUPSTDDEVS=	Specifies the standard deviation of each group
STDDEV=	Specifies the common standard deviation
Specify sample size and allocation	
GROUPNS=	Specifies the two group sample sizes
GROUPWEIGHTS=	Specifies the sample size allocation weights for the two groups
NFRACTIONAL	Enables fractional input and output for sample sizes
NPERGROUP=	Specifies the common sample size per group
NTOTAL=	Specifies the sample size
Specify power and related probabilities	
POWER=	Specifies the desired power of the test
PROBTYPE=	Specifies the type of probability for the PROBWIDTH= option
PROBWIDTH=	Specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.22 summarizes the valid result parameters for different analyses in the **TWOSAMPLEMEANS** statement.

TEST=EQUIV_RATIO	Power Sample size	POWER=. NTOTAL=. NPERGROUP=.
CI=DIFF	Prob(width) Sample size	PROBWIDTH=. NTOTAL=. NPERGROUP=.

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test or requests a solution for alpha with a missing value (ALPHA=.). The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. If the CI= and SIDES=1 options are used, then the value must be less than 0.5. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

CI

CI=DIFF

specifies an analysis of precision of the confidence interval for the mean difference, assuming equal variances. Instead of power, the relevant probability for this analysis is the probability that the interval half-width is at most the value specified by the HALFWIDTH= option. If neither the TEST= option nor the CI= option is used, the default is TEST=DIFF.

CV=*number-list*

specifies the coefficient of variation assumed to be common to both groups. The coefficient of variation is defined as the ratio of the standard deviation to the mean. You can use this option only with DIST=LOGNORMAL. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

DIST=LOGNORMAL

DIST=NORMAL

specifies the underlying distribution assumed for the test statistic. NORMAL corresponds to the normal distribution, and LOGNORMAL corresponds to the lognormal distribution. The default value (also the only acceptable value in each case) is NORMAL for TEST=DIFF, TEST=DIFF_SATT, TEST=EQUIV_DIFF, and CI=DIFF; and LOGNORMAL for TEST=RATIO and TEST=EQUIV_RATIO.

GROUPMEANS=*grouped-number-list*

GMEANS=*grouped-number-list*

specifies the two group means or requests a solution for one group mean given the other. Means are in the original scale. They are arithmetic if **DIST**=NORMAL and geometric if **DIST**=LOGNORMAL. This option cannot be used with the **CI**=DIFF analysis. When **TEST**=EQUIV_DIFF, the means are interpreted as the reference mean (first) and the treatment mean (second). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPNS=*grouped-number-list*

GNS=*grouped-number-list*

specifies the two group sample sizes or requests a solution for one group sample size given the other. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPSTDDEVS=*grouped-number-list*

GSTDDEVS=*grouped-number-list*

GROUPSTDS=*grouped-number-list*

GSTD=*grouped-number-list*

specifies the standard deviation of each group. Unlike the **STDDEV**= option, the **GROUPSTDDEVS**= option supports different values for each group. It is valid only for the Satterthwaite *t* test (**TEST**=DIFF_SATT **DIST**=NORMAL). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPWEIGHTS=*grouped-number-list*

GWEIGHTS=*grouped-number-list*

specifies the sample size allocation weights for the two groups, or requests a solution for one group weight given the other. This option controls how the total sample size is divided between the two groups. Each pair of values for the two groups represents relative allocation weights. Additionally, if the **NFRACTIONAL** option is not used, the total sample size is restricted to be equal to a multiple of the sum of the two group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). Values must be integers unless the **NFRACTIONAL** option is used. The default value is (1 1), a balanced design with a weight of 1 for each group. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

HALFWIDTH=*number-list*

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can be used only with the **CI**=DIFF analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

LOWER=*number-list*

specifies the lower equivalence bound for the mean difference or mean ratio, in the original scale (whether **DIST**=NORMAL or **DIST**=LOGNORMAL). Values must be greater than 0 when **DIST**=LOGNORMAL. This option can be used only with the **TEST**=EQUIV_DIFF and **TEST**=EQUIV_RATIO analyses. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

MEANDIFF=number-list

specifies the mean difference, defined as $\mu_2 - \mu_1$, or requests a solution for the mean difference with a missing value (**MEANDIFF=.**). This option can be used only with the **TEST=DIFF**, **TEST=DIFF_SATT**, and **TEST=EQUIV_DIFF** analyses. When **TEST=EQUIV_DIFF**, the mean difference is interpreted as the treatment mean minus the reference mean. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

MEANRATIO=number-list

specifies the geometric mean ratio, defined as γ_2/γ_1 . This option can be used only with the **TEST=RATIO** and **TEST=EQUIV_RATIO** analyses. When **TEST=EQUIV_RATIO**, the mean ratio is interpreted as the treatment mean divided by the reference mean. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NFRACTIONAL**NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NPERGROUP=number-list**NPERG=number-list**

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (**NPERGROUP=.**). Use of this option implicitly specifies a balanced design. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NTOTAL=number-list

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLDIFF=number-list**NULLD=number-list**

specifies the null mean difference. The default value is 0. This option can be used only with the **TEST=DIFF** and **TEST=DIFF_SATT** analyses. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NULLRATIO=number-list**NULLR=number-list**

specifies the null mean ratio. The default value is 1. This option can be used only with the **TEST=RATIO** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- SIDES=
- NULLDIFF=
- NULLRATIO=
- LOWER=
- UPPER=
- ALPHA=
- GROUPMEANS=
- MEANDIFF=
- MEANRATIO=
- HALFWIDTH=
- STDDEV=
- GROUPSTDDEVS==
- CV=
- GROUPWEIGHTS=
- NTOTAL=
- NPERGROUP=
- GROUPNS=
- POWER=
- PROBTTYPE=
- PROBWIDTH=

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **TWOSAMPLEMEANS** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **TWOSAMPLEMEANS** statement.

POWER=number-list

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option cannot be used with the **CI=DIFF** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

PROBTTYPE=keyword-list

specifies the type of probability for the **PROBWIDTH=** option. A value of **CONDITIONAL** (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the **HALFWIDTH=** option, given that the true mean difference is captured by the confidence interval. A value of **UNCONDITIONAL** indicates the unconditional probability that the confidence interval half-width is at most the value specified by the **HALFWIDTH=** option. you can use the alias **GIVENVALIDITY** for **CONDITIONAL**. The **PROBTTYPE=** option can be used only with the **CI=DIFF** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*.

CONDITIONAL width probability conditional on interval containing the mean

UNCONDITIONAL unconditional width probability

PROBWIDTH=number-list

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the **HALFWIDTH=** option. A missing value (**PROBWIDTH=.**) requests a solution for this probability. The type of probability is controlled with the **PROBTYPE=** option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can be used only with the **CI=DIFF** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

SIDES=keyword-list

specifies the number of sides (or tails) and the direction of the statistical test or confidence interval. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords and their interpretation for the **TEST=** analyses are as follows:

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

For confidence intervals, **SIDES=U** refers to an interval between the lower confidence limit and infinity, and **SIDES=L** refers to an interval between minus infinity and the upper confidence limit. For both of these cases and **SIDES=1**, the confidence interval computations are equivalent. The **SIDES=** option cannot be used with the **TEST=EQUIV_DIFF** and **TEST=EQUIV_RATIO** analyses. The default value is 2.

STDDEV=number-list**STD=number-list**

specifies the standard deviation assumed to be common to both groups, or requests a solution for the common standard deviation with a missing value (**STDDEV=.**). This option can be used only with **DIST=NORMAL**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

TEST**TEST=DIFF****TEST=DIFF_SATT****TEST=EQUIV_DIFF****TEST=EQUIV_RATIO****TEST=RATIO**

specifies the statistical analysis. **TEST** or **TEST=DIFF** (the default) specifies a pooled *t* test on the mean difference, assuming equal variances. **TEST=DIFF_SATT** specifies a Satterthwaite unpooled *t* test on the mean difference, assuming unequal variances. **TEST=EQUIV_DIFF** specifies an additive equivalence test of the mean difference by using a two one-sided tests (TOST) analysis (Schuirmann 1987). **TEST=EQUIV_RATIO** specifies a multiplicative equivalence test of the mean ratio by using a TOST analysis. **TEST=RATIO** specifies a pooled *t* test on the mean ratio, assuming equal coefficients of variation. If neither the **TEST=** option nor the **CI=** option is used, the default is **TEST=DIFF**.

UPPER=number-list

specifies the upper equivalence bound for the mean difference or mean ratio, in the original scale (whether **DIST=NORMAL** or **DIST=LOGNORMAL**). This option can be used only with the **TEST=EQUIV_DIFF** and **TEST=EQUIV_RATIO** analyses. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (by using the **TEST=** option)
- confidence interval precision (by using the **CI=** option)

To specify the means, choose one of the following parameterizations:

- individual group means (by using the **GROUPMEANS=** option)
- mean difference (by using the **MEANDIFF=** option)
- mean ratio (by using the **MEANRATIO=** option)

To specify standard deviations in the Satterthwaite *t* test (**TEST=DIFF_SATT**), choose one of the following parameterizations:

- common standard deviation (by using the **STDDEV=** option)
- individual group standard deviations (by using the **GROUPSTDDEVS==** option)

To specify the sample sizes and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (by using the **NPERGROUP=** option)
- total sample size and allocation weights (by using the **NTOTAL=** and **GROUPWEIGHTS=** options)
- individual group sample sizes (by using the **GROUPNS=** option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **TWOSAMPLEMEANS** statement.

Two-Sample *t* Test Assuming Equal Variances

You can use the **NPERGROUP=** option in a balanced design and express effects in terms of the mean difference, as in the following statements. Default values for the **DIST=**, **SIDES=**, **NULLDIFF=**, and **ALPHA=** options specify a two-sided test for no difference with a normal distribution and a significance level of 0.05.

```

proc power;
  twosamplemeans test=diff
    meandiff = 7
    stddev = 12
    npergroup = 50
    power = .;
run;

```

You can also specify an unbalanced design by using the **NTOTAL=** and **GROUPWEIGHTS=** options and express effects in terms of individual group means:

```

proc power;
  twosamplemeans test=diff
    groupmeans = 8 | 15
    stddev = 4
    groupweights = (2 3)
    ntotal = .
    power = 0.9;
run;

```

Another way to specify the sample sizes is with the **GROUPNS=** option:

```

proc power;
  twosamplemeans test=diff
    groupmeans = 8 | 15
    stddev = 4
    groupns = (25 40)
    power = .;
run;

```

Two-Sample Satterthwaite t Test Assuming Unequal Variances

The following statements demonstrate a power computation for the two-sample Satterthwaite t test allowing unequal variances. Default values for the **DIST=**, **SIDES=**, **NULLDIFF=**, and **ALPHA=** options specify a two-sided test for no difference with a normal distribution and a significance level of 0.05.

```

proc power;
  twosamplemeans test=diff_satt
    meandiff = 3
    groupstddevs = 5 | 8
    groupweights = (1 2)
    ntotal = 60
    power = .;
run;

```

Two-Sample Pooled t Test of Mean Ratio with Lognormal Data

The following statements demonstrate a power computation for the pooled t test of a lognormal mean ratio. Default values for the **DIST=**, **SIDES=**, **NULLRATIO=**, and **ALPHA=** options specify a two-sided test of mean ratio = 1 assuming a lognormal distribution and a significance level of 0.05.

```

proc power;
  twosamplemeans test=ratio
    meanratio = 7
    cv = 0.8
    groupns = 50 | 70
    power = .;
run;

```

Additive Equivalence Test for Mean Difference with Normal Data

The following statements demonstrate a sample size computation for the TOST equivalence test for a normal mean difference. A default value of **GROUPWEIGHTS**=(1 1) specifies a balanced design. Default values for the **DIST**= and **ALPHA**= options specify a significance level of 0.05 and an assumption of normally distributed data.

```

proc power;
  twosamplemeans test=equiv_diff
    lower = 2
    upper = 5
    meandiff = 4
    stddev = 8
    ntotal = .
    power = 0.9;
run;

```

Multiplicative Equivalence Test for Mean Ratio with Lognormal Data

The following statements demonstrate a power computation for the TOST equivalence test for a lognormal mean ratio. Default values for the **DIST**= and **ALPHA**= options specify a significance level of 0.05 and an assumption of lognormally distributed data.

```

proc power;
  twosamplemeans test=equiv_ratio
    lower = 3
    upper = 7
    meanratio = 5
    cv = 0.75
    npergroup = 50
    power = .;
run;

```

Confidence Interval for Mean Difference

By default **CI**=DIFF analyzes the conditional probability of obtaining the desired precision, given that the interval contains the true mean difference, as in the following statements. The defaults of **SIDES**=2 and **ALPHA**=0.05 specify a two-sided interval with a confidence level of 0.95.

```

proc power;
  twosamplemeans ci = diff
    halfwidth = 4
    stddev = 8
    groupns = (30 35)
    probwidth = .;
run;

```

TWOSAMPLESURVIVAL Statement

TWOSAMPLESURVIVAL <options> ;

The **TWOSAMPLESURVIVAL** statement performs power and sample size analyses for comparing two survival curves. The log-rank, Gehan, and Tarone-Ware rank tests are supported.

Summary of Options

Table 71.23 summarizes the options available in the **TWOSAMPLESURVIVAL** statement.

Table 71.23 TWOSAMPLESURVIVAL Statement Options

Option	Description
Define analysis	
TEST=	Specifies the statistical analysis
Specify analysis information	
ACCRUALTIME=	Specifies the accrual time
ALPHA=	Specifies the significance level
FOLLOWUPTIME=	Specifies the follow-up time
SIDES=	Specifies the number of sides and the direction of the statistical test or confidence interval
TOTALTIME=	Specifies the total time
Specify effects	
CURVE=	Defines a survival curve
GROUPMEDSURVTIMES=	Specifies the median survival times in each group
GROUPSURVEXPHAZARDS=	Specifies exponential hazard rates of the survival curve for each group
GROUPSURVIVAL=	Specifies the survival curve for each group
HAZARDRATIO=	Specifies the hazard ratio
REFSURVEXPHAZARD=	Specifies the exponential hazard rate of the survival curve for the reference group
REFSURVIVAL=	Specifies the survival curve for the reference group
Specify loss information	
GROUPLOSS=	Specifies the exponential loss survival curve for each group
GROUPLOSSEXPHAZARDS=	Specifies the exponential hazards of the loss in each group
GROUPMEDLOSTIMES=	Specifies the median times of the loss in each group
Specify sample size and allocation	
ACCRUALRATEPERGROUP=	Specifies the common accrual rate per group
ACCRUALRATETOTAL=	Specifies the total accrual rate
EVENTSTOTAL=	Specifies the expected total number of events
GROUPACCRUALRATES=	Specifies the accrual rate for each group
GROUPNS=	Specifies the two group sample sizes
GROUPWEIGHTS=	Specifies the sample size allocation weights for the two groups
NFRACTIONAL	Enables fractional input and output for sample sizes
NPERGROUP=	Specifies the common sample size per group
NTOTAL=	Specifies the sample size

Table 71.23 *continued*

Option	Description
Specify power <code>POWER=</code>	Specifies the desired power of the test
Specify computational method <code>NSUBINTERVAL=</code>	Specifies the number of subintervals per unit time
Control ordering in output <code>OUTPUTORDER=</code>	Controls the output order of parameters

Table 71.24 summarizes the valid result parameters for different analyses in the `TWOSAMPLESURVIVAL` statement.

Table 71.24 Summary of Result Parameters in the `TWOSAMPLESURVIVAL` Statement

Analyses	Solve For	Syntax
<code>TEST=GEHAN</code>	Power Sample size	<code>POWER=.</code> <code>NTOTAL=.</code> <code>NPERGROUP=.</code> <code>EVENTSTOTAL=.</code> <code>ACCRUALRATETOTAL=.</code> <code>ACCRUALRATEPERGROUP=.</code>
<code>TEST=LOGRANK</code>	Power Sample size	<code>POWER=.</code> <code>NTOTAL=.</code> <code>NPERGROUP=.</code> <code>EVENTSTOTAL=.</code> <code>ACCRUALRATETOTAL=.</code> <code>ACCRUALRATEPERGROUP=.</code>
<code>TEST=TARONEWARE</code>	Power Sample size	<code>POWER=.</code> <code>NTOTAL=.</code> <code>NPERGROUP=.</code> <code>EVENTSTOTAL=.</code> <code>ACCRUALRATETOTAL=.</code> <code>ACCRUALRATEPERGROUP=.</code>

Dictionary of Options

`ACCRUALRATEPERGROUP=number-list`

`ACCRUALRATEPERG=number-list`

`ARPERGROUP=number-list`

`ARPERG=number-list`

specifies the common accrual rate per group or requests a solution for the common accrual rate per group with a missing value (`ACCRUALRATEPERGROUP=.`). The accrual rate per group is the number of subjects in each group that enters the study per time unit during the accrual period. Use of this option implicitly specifies a balanced design. The `NFRACTIONAL` option is automatically

enabled when the `ACCRUALRATEPERGROUP=` option is used. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

ACCRUALRATETOTAL=*number-list*

ARTOTAL=*number-list*

specifies the total accrual rate or requests a solution for the accrual rate with a missing value (`ACCRUALRATETOTAL=.`). The total accrual rate is the total number of subjects that enter the study per time unit during the accrual period. The `NFRACTIONAL` option is automatically enabled when the `ACCRUALRATETOTAL=` option is used. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

ACCRUALTIME=*number-list* | **MAX**

ACCTIME=*number-list* | **MAX**

ACCRUALT=*number-list* | **MAX**

ACCT=*number-list* | **MAX**

specifies the accrual time. Accrual is assumed to occur uniformly from time 0 to the time specified by the `ACCRUALTIME=` option. If the `GROUPSURVIVAL=` or `REFSURVIVAL=` option is used, then the value of the total time (the sum of accrual and follow-up times) must be less than or equal to the largest time in *each* multipoint (piecewise linear) survival curve. If the `ACCRUALRATEPERGROUP=`, `ACCRUALRATETOTAL=`, or `GROUPACCRUALRATES=` option is used, then the accrual time must be greater than 0. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

`ACCRUALTIME=MAX` can be used when each scenario in the analysis contains at least one piecewise linear survival curve (in the `GROUPSURVIVAL=` or `REFSURVIVAL=` option). It causes the accrual time to be automatically set, separately for each scenario, to the maximum possible time supported by the piecewise linear survival curve(s) in that scenario. It is not compatible with the `FOLLOWUPTIME=MAX` option or the `TOTALTIME=` option.

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

CURVE("label")=*points*

defines a survival curve.

For the `CURVE=` option,

label identifies the curve in the output and with the `GROUPLOSS=`, `GROUPSURVIVAL=`, and `REFSURVIVAL=` options.

points specifies one or more (time, survival) pairs on the curve, where the survival value denotes the probability of surviving until at least the specified time.

A single-point curve is interpreted as exponential, and a multipoint curve is interpreted as piecewise linear. Points can be expressed in either of two forms:

- a series of time:survival pairs separated by spaces. For example:

1:0.9 2:0.7 3:0.6

- a DOLIST of times enclosed in parentheses, followed by a colon (:), followed by a DOLIST of survival values enclosed in parentheses. For example:

(1 to 3 by 1):(0.9 0.7 0.6)

The DOLIST format is the same as in the DATA step.

Points can also be expressed as combinations of the two forms. For example:

1:0.9 2:0.8 (3 to 6 by 1):(0.7 0.65 0.6 0.55)

The points have the following restrictions:

- The time values must be nonnegative and strictly increasing.
- The survival values must be strictly decreasing.
- The survival value at a time of 0 must be equal to 1.
- If there is only one point, then the time must be greater than 0, and the survival value cannot be 0 or 1.

EVENTSTOTAL=*number-list*

EVENTTOTAL=*number-list*

EETOTAL=*number-list*

specifies the expected total number of events—that is, deaths, whether observed or censored—during the entire study period, or requests a solution for this parameter with a missing value (**EVENTSTOTAL=.**). The **NFRACTIONAL** option is automatically enabled when the **EVENTSTOTAL=** option is used. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

FOLLOWUPTIME=*number-list* | **MAX**

FUTIME=*number-list* | **MAX**

FOLLOWUPT=*number-list* | **MAX**

FUT=*number-list* | **MAX**

specifies the follow-up time, the amount of time in the study past the accrual time. If the **GROUPSURVIVAL=** or **REFSURVIVAL=** option is used, then the value of the total time (the sum of accrual and follow-up times) must be less than or equal to the largest time in *each* multipoint (piecewise linear) survival curve. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

FOLLOWUPTIME=MAX can be used when each scenario in the analysis contains at least one piecewise linear survival curve (in the **GROUPSURVIVAL=** or **REFSURVIVAL=** option). It causes the follow-up time to be automatically set, separately for each scenario, to the maximum possible time supported by the piecewise linear survival curve(s) in that scenario. It is not compatible with the **ACCRUALTIME=MAX** option or the **TOTALTIME=** option.

GROUPACCRUALRATES=*grouped-number-list*

GACCRUALRATES=*grouped-number-list*

GROUPARS=*grouped-number-list*

GARS=*grouped-number-list*

specifies the accrual rate for each group. The groupwise accrual rates are the numbers of subjects in each group that enters the study per time unit during the accrual period. The [NFRATIONAL](#) option is automatically enabled when the [GROUPACCRUALRATES](#)= option is used. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPLOSS=*grouped-name-list*

GLOSS=*grouped-name-list*

specifies the exponential loss survival curve for each group, by using labels specified with the [CURVE](#)= option. Loss is assumed to follow an exponential curve, indicating the expected rate of censoring (in other words, loss to follow-up) over time. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-name-list*.

GROUPLOSSEXPHAZARDS=*grouped-number-list*

GLOSSEXPHAZARDS=*grouped-number-list*

GROUPLOSSEXPHS=*grouped-number-list*

GLOSSEXPHS=*grouped-number-list*

specifies the exponential hazards of the loss in each group. Loss is assumed to follow an exponential curve, indicating the expected rate of censoring (in other words, loss to follow-up) over time. If none of the [GROUPLOSSEXPHAZARDS](#)=, [GROUPLOSS](#)=, and [GROUPMEDLOSSTIMES](#)= options are used, the default of [GROUPLOSSEXPHAZARDS](#)=(0 0) indicates no loss to follow-up. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPMEDLOSSTIMES=*grouped-number-list*

GMEDLOSSTIMES=*grouped-number-list*

GROUPMEDLOSSTS=*grouped-number-list*

GMEDLOSSTS=*grouped-number-list*

specifies the median times of the loss in each group. Loss is assumed to follow an exponential curve, indicating the expected rate of censoring (in other words, loss to follow-up) over time. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPMEDSURVTIMES=*grouped-number-list*

GMEDSURVTIMES=*grouped-number-list*

GROUPMEDSURVTS=*grouped-number-list*

GMEDSURVTS=*grouped-number-list*

specifies the median survival times in each group. When the [GROUPMEDSURVTIMES](#)= option is used, the survival curve in each group is assumed to be exponential. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPNS=*grouped-number-list*

GNS=*grouped-number-list*

specifies the two group sample sizes. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPSURVEXPHAZARDS=*grouped-number-list*

GSURVEXPHAZARDS=*grouped-number-list*

GROUPSURVEXPHS=*grouped-number-list*

GEXPHS=*grouped-number-list*

specifies exponential hazard rates of the survival curve for each group. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

GROUPSURVIVAL=*grouped-name-list*

GSURVIVAL=*grouped-name-list*

GROUPSURV=*grouped-name-list*

GSURV=*grouped-name-list*

specifies the survival curve for each group, by using labels specified with the **CURVE=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-name-list*.

GROUPWEIGHTS=*grouped-number-list*

GWEIGHTS=*grouped-number-list*

specifies the sample size allocation weights for the two groups. This option controls how the total sample size is divided between the two groups. Each pair of values for the two groups represents relative allocation weights. Additionally, if the **NFRACTIONAL** option is not used, the total sample size is restricted to be equal to a multiple of the sum of the two group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). Values must be integers unless the **NFRACTIONAL** option is used. The default value is (1 1), a balanced design with a weight of 1 for each group. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

HAZARDRATIO=*number-list*

HR=*number-list*

specifies the hazard ratio of the second group’s survival curve to the first group’s survival curve. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. This option is automatically enabled when any of the following options are used: **ACCRUALRATEPERGROUP=**, **ACCRUALRATETOTAL=**, **EVENTSTOTAL=**, and **GROUPACCRUALRATES=**. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NPARGROUP=*number-list*

NPARG=*number-list*

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (**NPARGROUP=.**). Use of this option implicitly specifies a balanced design. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NSUBINTERVAL=*number-list*

NSUBINTERVALS=*number-list*

NSUB=*number-list*

NSUBS=*number-list*

specifies the number of subintervals per unit time to use in internal calculations. Higher values increase computational time and memory requirements but generally lead to more accurate results. The default value is 12. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NTOTAL=*number-list*

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **SIDES=**
- **ACCRUALTIME=**
- **FOLLOWUPTIME=**
- **TOTALTIME=**
- **NSUBINTERVAL=**
- **ALPHA=**
- **REFSURVIVAL=**
- **GROUPSURVIVAL=**
- **REFSURVEXPHAZARD=**
- **HAZARDRATIO=**
- **GROUPSURVEXPHAZARDS=**
- **GROUPMEDSURVTIMES=**
- **GROUPLOSSEXPHAZARDS=**
- **GROUPLOSS=**
- **GROUPMEDLOSSTIMES=**
- **GROUPWEIGHTS=**
- **NTOTAL=**
- **ACCRUALRATETOTAL=**
- **EVENTSTOTAL=**
- **NPARGROUP=**

- **ACCRUALRATEPERGROUP=**
- **GROUPNS=**
- **GROUPACCRUALRATES=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **TWOSAMPLESURVIVAL** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **TWOSAMPLESURVIVAL** statement.

POWER=*number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

REFSURVEXPHAZARD=*number-list*

REFSURVEXPH=*number-list*

specifies the exponential hazard rate of the survival curve for the first (reference) group. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

REFSURVIVAL=*name-list*

REFSURV=*name-list*

specifies the survival curve for the first (reference) group, by using labels specified with the **CURVE=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *name-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and the direction of the statistical test or confidence interval. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords and their interpretation are as follows:

- | | |
|---|---|
| 1 | one-sided with alternative hypothesis in same direction as effect |
| 2 | two-sided |
| U | upper one-sided with the alternative hypothesis favoring better survival in the second group |
| L | lower one-sided with the alternative hypothesis favoring better survival in the first (reference) group |

The default value is 2.

TEST=GEHAN

TEST=LOGRANK

TEST=TARONEWARE

specifies the statistical analysis. **TEST=GEHAN** specifies the Gehan rank test. **TEST=LOGRANK** (the default) specifies the log-rank test. **TEST=TARONEWARE** specifies the Tarone-Ware rank test.

TOTALTIME=*number-list* | **MAX**

TOTALT=*number-list* | **MAX**

specifies the total time, which is equal to the sum of accrual and follow-up times. If the **GROUPSURVIVAL=** or **REFSURVIVAL=** option is used, then the value of the total time must be less than or equal to the largest time in *each* multipoint (piecewise linear) survival curve. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

TOTALTIME=MAX can be used when each scenario in the analysis contains at least one piecewise linear survival curve (in the **GROUPSURVIVAL=** or **REFSURVIVAL=** option). It causes the total time to be automatically set, separately for each scenario, to the maximum possible time supported by the piecewise linear survival curve(s) in that scenario. It is not compatible with the **ACCRUALTIME=MAX** option or the **FOLLOWUPTIME=MAX** option.

Restrictions on Option Combinations

To specify the survival curves, choose one of the following parameterizations:

- arbitrary piecewise linear or exponential curves (by using the **CURVE=** and **GROUPSURVIVAL=** options)
- curves with proportional hazards (by using the **CURVE=**, **REFSURVIVAL=**, and **HAZARDRATIO=** options)
- exponential curves, by using one of the following parameterizations:
 - median survival times (by using the **GROUPMEDSURVTIMES=** option)
 - the hazard ratio and the hazard of the reference curve (by using the **HAZARDRATIO=** and **REFSURVEXPHAZARD=** options)
 - the individual hazards (by using the **GROUPSURVEXPHAZARDS=** option)

To specify the study time, use any two of the following three options:

- accrual time (by using the **ACCRUALTIME=** option)
- follow-up time (by using the **FOLLOWUPTIME=** option)
- total time, the sum of accrual and follow-up times (by using the **TOTALTIME=** option)

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (by using the **NPERGROUP=** option)
- accrual rate per group in a balanced design (by using the **ACCRUALRATEPERGROUP=** option)
- total sample size and allocation weights (by using the **NTOTAL=** and **GROUPWEIGHTS=** options)
- total accrual rate and allocation weights (by using the **ACCRUALRATETOTAL=** and **GROUPWEIGHTS=** options)

- expected total number of events and allocation weights (by using the `EVENTSTOTAL=` and `GROUPWEIGHTS=` options)
- individual group sample sizes (by using the `GROUPNS=` option)
- individual group accrual rates (by using the `GROUPACCRUALRATES=` option)

The values of parameters that involve expected number of events or accrual rate are converted internally to the analogous sample size parameterization (that is, the `NPERGROUP=`, `NTOTAL=`, or `GROUPNS=` option) for the purpose of sample size adjustments according to the presence or absence of the `NFRAC-TIONAL` option.

To specify the exponential loss curves, choose one of the following parameterizations:

- a point on the loss curve of each group (by using the `CURVE=` and `GROUPLOSS=` options)
- median loss times (by using the `GROUPMEDLOSSTIMES=` option)
- the individual loss hazards (by using the `GROUPLOSSEXPHAZARDS=` option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the `TWOSAMPLESURVIVAL` statement.

Log-Rank Test for Two Survival Curves

You can use the `NPERGROUP=` option in a balanced design and specify piecewise linear or exponential survival curves by using the `CURVE=` and `GROUPSURVIVAL=` options, as in the following statements. Default values for the `SIDES=`, `ALPHA=`, `NSUBINTERVAL=`, and `GROUPLOSSEXPHAZARDS=` options specify a two-sided test with a significance level of 0.05, an assumption of no loss to follow-up, and the use of 12 subintervals per unit time in computations.

```
proc power;
  twosamplesurvival test=logrank
    curve("Control")    = (1 2 3):(0.8 0.7 0.6)
    curve("Treatment")  = (5):(.6)
    groupsurvival = "Control" | "Treatment"
    accrualtime = 2
    followuptime = 1
    npergroup = 50
    power = .;
run;
```

In the preceding example, the “Control” curve is piecewise linear (since it has more than one point), and the “Treatment” curve is exponential (since it has only one point).

You can also specify an unbalanced design by using the `NTOTAL=` and `GROUPWEIGHTS=` options and specify piecewise linear or exponential survival curves with proportional hazards by using the `CURVE=`, `REFSURVIVAL=`, and `HAZARDRATIO=` options:

```

proc power;
  twosamplesurvival test=logrank
    curve("Control")    = (1 2 3):(0.8 0.7 0.6)
    refsurvival = "Control"
    hazardratio = 1.5
    accrualtime = 2
    followuptime = 1
    groupweights = (1 2)
    ntotal = .
    power = 0.8;
run;

```

Instead of computing sample size, you can compute the accrual rate by using the [ACCRUALRATETOTAL=](#) option:

```

proc power;
  twosamplesurvival test=logrank
    curve("Control")    = (1 2 3):(0.8 0.7 0.6)
    refsurvival = "Control"
    hazardratio = 1.5
    accrualtime = 2
    followuptime = 1
    groupweights = (1 2)
    accrualratetotal = .
    power = 0.8;
run;

```

or the expected number of events by using the [EVENTSTOTAL=](#) option:

```

proc power;
  twosamplesurvival test=logrank
    curve("Control")    = (1 2 3):(0.8 0.7 0.6)
    refsurvival = "Control"
    hazardratio = 1.5
    accrualtime = 2
    followuptime = 1
    groupweights = (1 2)
    eventstotal = .
    power = 0.8;
run;

```

You can also specify sample sizes with the [GROUPNS=](#) option and specify exponential survival curves in terms of median survival times:

```

proc power;
  twosamplesurvival test=logrank
    groupmedsurvtimes = (16 22)
    accrualtime = 6
    totaltime = 18
    groupns = 40 | 60
    power = .;
run;

```

You can also specify exponential survival curves in terms of the hazard ratio and reference hazard. The default value of the **GROUPWEIGHTS=** option specifies a balanced design.

```
proc power;
  twosamplesurvival test=logrank
    hazardratio = 1.2
    refsurvexpazard = 0.7
    accrualtime = 2
    totaltime = 4
    ntotal = 100
    power = .;
run;
```

You can also specify exponential survival curves in terms of the individual hazards, as in the following statements:

```
proc power;
  twosamplesurvival test=logrank
    groupsurvexpazards = 0.7 | 0.84
    accrualtime = 2
    totaltime = 4
    ntotal = .
    power = 0.9;
run;
```

Gehan Rank Test for Two Survival Curves

In addition to the log-rank test, you can also specify the Gehan tank test, as in the following statements. Default values for the **SIDES=**, **ALPHA=**, **NSUBINTERVAL=**, and **GROUPLOSSEXPHAZARDS=** options specify a two-sided test with a significance level of 0.05, an assumption of no loss to follow-up, and the use of 12 subintervals per unit time in computations.

```
proc power;
  twosamplesurvival test=gehan
    groupmedsurvtimes = 5 | 7
    accrualtime = 3
    totaltime = 6
    npergroup = .
    power = 0.8;
run;
```

Tarone-Ware Rank Test for Two Survival Curves

You can also specify the Tarone-Ware tank test, as in the following statements. Default values for the **SIDES=**, **ALPHA=**, **NSUBINTERVAL=**, and **GROUPLOSSEXPHAZARDS=** options specify a two-sided test with a significance level of 0.05, an assumption of no loss to follow-up, and the use of 12 subintervals per unit time in computations.

```

proc power;
  twosamplesurvival test=taroneware
    groupmedsurvtimes = 5 | 7
    accrualtime = 3
    totaltime = 6
    npergroup = 100
    power = .;
run;

```

TWOSAMPLEWILCOXON Statement

TWOSAMPLEWILCOXON <options> ;

The **TWOSAMPLEWILCOXON** statement performs power and sample size analyses for the Wilcoxon-Mann-Whitney test (also called the Wilcoxon rank-sum test, Mann-Whitney-Wilcoxon test, or Mann-Whitney U test) for two independent groups.

Note that the O'Brien-Castelloe approach to computing power for the Wilcoxon test is approximate, based on asymptotic behavior as the total sample size gets large. The quality of the power approximation degrades for small sample sizes; conversely, the quality of the sample size approximation degrades if the two distributions are far apart, so that only a small sample is needed to detect a significant difference. But this degradation is rarely a problem in practical situations, in which experiments are usually performed for relatively close distributions.

Summary of Options

Table 71.25 summarizes the options available in the **TWOSAMPLEWILCOXON** statement.

Table 71.25 TWOSAMPLEWILCOXON Statement Options

Option	Description
Define analysis	
TEST=	Specifies the statistical analysis
Specify analysis information	
ALPHA=	Specifies the significance level
SIDES=	Specifies the number of sides and the direction of the statistical test
Specify distributions	
VARDIST=	Defines a distribution for a variable
VARIABLES=	Specifies the distributions of two or more variables
Specify sample size and allocation	
GROUPNS=	Specifies the two group sample sizes
GROUPWEIGHTS=	Specifies the sample size allocation weights for the two groups
NFRACTIONAL	Enables fractional input and output for sample sizes
NPERGROUP=	Specifies the common sample size per group
NTOTAL=	Specifies the sample size
Specify power	
POWER=	Specifies the desired power of the test

Table 71.25 continued

Option	Description
Specify computational options	
NBINS=	Specifies the number of categories for each variable
Control ordering in output	
OUTPUTORDER=	Controls the output order of parameters

Table 71.26 summarizes the valid result parameters in the TWOSAMPLEWILCOXON statement.

Table 71.26 Summary of Result Parameters in the TWOSAMPLEWILCOXON Statement

Analyses	Solve For	Syntax
TEST=WMW	Power Sample size	POWER=. NTOTAL=. NPERGROUP=.

Dictionary of Options

- ALPHA=number-list**
specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.
- GROUPNS=grouped-number-list**
- GNS=grouped-number-list**
specifies the two group sample sizes. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *grouped-number-list*.
- GROUPWEIGHTS=grouped-number-list**
- GWEIGHTS=grouped-number-list**
specifies the sample size allocation weights for the two groups. This option controls how the total sample size is divided between the two groups. Each pair of values for the two groups represents relative allocation weights. Additionally, if the **NFRACTIONAL** option is not used, the total sample size is restricted to be equal to a multiple of the sum of the two group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). Values must be integers unless the **NFRACTIONAL** option is used. The default value is (1 1), a balanced design with a weight of 1 for each group. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *grouped-number-list*.
- NBINS=number-list**
specifies the number of categories (or “bins”) each variable’s distribution is divided into (unless it is ordinal, in which case the categories remain intact) in internal calculations. Higher values increase computational time and memory requirements but generally lead to more accurate results. However, if the value is too high, then numerical instability can occur. The default value is 1000. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

NFRACTIONAL**NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NPERGROUP=number-list**NPERG=number-list**

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (**NPERGROUP=.**). Use of this option implicitly specifies a balanced design. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

NTOTAL=number-list

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- SIDES
- NBINS=
- ALPHA=
- VARIABLES=
- GROUPWEIGHTS=
- NTOTAL=
- NPERGROUP=
- GROUPNS=
- POWER=

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **TWOSAMPLEWILCOXON** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **TWOSAMPLEWILCOXON** statement.

POWER=number-list

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

SIDES=keyword-list

specifies the number of sides (or tails) and the direction of the statistical test. Valid keywords are as follows:

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

The default value is 2.

TEST=WMW

specifies the Wilcoxon-Mann-Whitney test for two independent groups. This is the default test option.

VARDIST("label")=distribution (parameters)

defines a distribution for a variable.

For the **VARDIST=** option,

- label* identifies the variable distribution in the output and with the **VARIABLES=** option.
- distribution* specifies the distributional form of the variable.
- parameters* specifies one or more parameters associated with the distribution.

Choices for distributional forms and their parameters are as follows:

ORDINAL ((*values*) : (*probabilities*)) is an ordered categorical distribution. The *values* are any numbers separated by spaces. The *probabilities* are numbers between 0 and 1 (inclusive) separated by spaces. Their sum must be exactly 1. The number of *probabilities* must match the number of *values*.

BETA (*a*, *b* <, *l*, *r* >) is a beta distribution with shape parameters *a* and *b* and optional location parameters *l* and *r*. The values of *a* and *b* must be greater than 0, and *l* must be less than *r*. The default values for *l* and *r* are 0 and 1, respectively.

BINOMIAL (*p*, *n*) is a binomial distribution with probability of success *p* and number of independent Bernoulli trials *n*. The value of *p* must be greater than 0 and less than 1, and *n* must be an integer greater than 0. If *n* = 1, then the distribution is binary.

EXPONENTIAL (*λ*) is an exponential distribution with scale *λ*, which must be greater than 0.

GAMMA (*a*, *λ*) is a gamma distribution with shape *a* and scale *λ*. The values of *a* and *λ* must be greater than 0.

LAPLACE (*θ*, *λ*) is a Laplace distribution with location *θ* and scale *λ*. The value of *λ* must be greater than 0.

LOGISTIC (*θ*, *λ*) is a logistic distribution with location *θ* and scale *λ*. The value of *λ* must be greater than 0.

LOGNORMAL (*θ*, *λ*) is a lognormal distribution with location *θ* and scale *λ*. The value of *λ* must be greater than 0.

NORMAL (*θ*, *λ*) is a normal distribution with mean *θ* and standard deviation *λ*. The value of *λ* must be greater than 0.

POISSON (m) is a Poisson distribution with mean m . The value of m must be greater than 0.

UNIFORM (l, r) is a uniform distribution on the interval $[l, r]$, where $l < r$.

VARIABLES=*grouped-name-list*

VAR=*grouped-name-list*

specifies the distributions of two or more variables, using labels specified with the **VARDIST=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-name-list*.

Restrictions on Option Combinations

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (using the **NPERGROUP=** option)
- total sample size and allocation weights (using the **NTOTAL=** and **GROUPWEIGHTS=** options)
- individual group sample sizes (using the **GROUPNS=** option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **TWO SAMPLE WILCOXON** statement.

Wilcoxon-Mann-Whitney Test for Comparing Two Distributions

The following statements perform a power analysis for Wilcoxon-Mann-Whitney tests comparing an ordinal variable with each other type of distribution. Default values for the **ALPHA=**, **NBINS=**, **SIDES=**, and **TEST=** options specify a two-sided test with a significance level of 0.05 and the use of 1000 categories per distribution when discretization is needed.

```
proc power;
  twosamplewilcoxon
    vardist("myordinal") = ordinal ((0 1 2) : (.2 .3 .5))
    vardist("mybeta1") = beta (1, 2)
    vardist("mybeta2") = beta (1, 2, 0, 2)
    vardist("mybinomial") = binomial (.3, 3)
    vardist("myexponential") = exponential (2)
    vardist("mygamma") = gamma (1.5, 2)
    vardist("mylaplace") = laplace (1, 2)
    vardist("mylogistic") = logistic (1, 2)
    vardist("mylognormal") = lognormal (1, 2)
    vardist("mynormal") = normal (3, 2)
    vardist("mypoisson") = poisson (2)
    vardist("myuniform") = uniform (0, 2)
    variables = "myordinal" | "mybeta1" "mybeta2" "mybinomial"
                  "myexponential" "mygamma" "mylaplace"
                  "mylogistic" "mylognormal" "mynormal"
                  "mypoisson" "myuniform"

    ntotal = 40
    power = .;
run;
```

Details: POWER Procedure

Overview of Power Concepts

In statistical hypothesis testing, you typically express the belief that some effect exists in a population by specifying an alternative hypothesis H_1 . You state a null hypothesis H_0 as the assertion that the effect does *not* exist and attempt to gather evidence to reject H_0 in favor of H_1 . Evidence is gathered in the form of sample data, and a statistical test is used to assess H_0 . If H_0 is rejected but there really is *no* effect, this is called a *Type I error*. The probability of a Type I error is usually designated “alpha” or α , and statistical tests are designed to ensure that α is suitably small (for example, less than 0.05).

If there really is an effect in the population but H_0 is *not* rejected in the statistical test, then a *Type II error* has been made. The probability of a Type II error is usually designated “beta” or β . The probability $1 - \beta$ of avoiding a Type II error—that is, correctly rejecting H_0 and achieving statistical significance—is called the *power*. (NOTE: Another more general definition of power is the probability of rejecting H_0 for any given set of circumstances, even those corresponding to H_0 being true. The POWER procedure uses this more general definition.)

An important goal in study planning is to ensure an acceptably high level of power. Sample size plays a prominent role in power computations because the focus is often on determining a sufficient sample size to achieve a certain power, or assessing the power for a range of different sample sizes.

Some of the analyses in the POWER procedure focus on *precision* rather than power. An analysis of confidence interval precision is analogous to a traditional power analysis, with “CI Half-Width” taking the place of effect size and “Prob(Width)” taking the place of power. The *CI Half-Width* is the margin of error associated with the confidence interval, the distance between the point estimate and an endpoint. The *Prob(Width)* is the probability of obtaining a confidence interval with *at most* a target half-width.

Summary of Analyses

Table 71.27 gives a summary of the analyses supported in the POWER procedure. The name of the analysis statement reflects the type of data and design. The TEST=, CI=, and DIST= options specify the focus of the statistical hypothesis (in other words, the criterion on which the research question is based) and the test statistic to be used in data analysis.

Table 71.27 Summary of Analyses

Specifying Value Lists in Analysis Statements

To specify one or more scenarios for an analysis parameter (or set of parameters), you provide a list of values for the statement option that corresponds to the parameter(s). To identify the parameter you want to solve for, you place missing values in the appropriate list.

There are five basic types of such lists: *keyword-lists*, *number-lists*, *grouped-number-lists*, *name-lists*, and *grouped-name-lists*. Some parameters, such as the direction of a test, have values represented by one or more keywords in a *keyword-list*. Scenarios for scalar-valued parameters, such as power, are represented by a *number-list*. Scenarios for groups of scalar-valued parameters, such as group sample sizes in a multi-group design, are represented by a *grouped-number-list*. Scenarios for named parameters, such as reference survival curves, are represented by a *name-list*. Scenarios for groups of named parameters, such as group survival curves, are represented by a *grouped-name-list*.

The following subsections explain these five basic types of lists.

Keyword-Lists

A *keyword-list* is a list of one or more keywords separated by spaces. For example, you can specify both two-sided and upper-tailed versions of a one-sample *t* test:

```
SIDES = 2 U
```

Number-Lists

A *number-list* can be one of two things: a series of one or more numbers expressed in the form of one or more DOLISTS, or a missing value indicator (.).

The DOLIST format is the same as in the DATA step language. For example, for the one-sample t test you can specify four scenarios (30, 50, 70, and 100) for a total sample size in any of the following ways.

```
NTOTAL = 30 50 70 100
NTOTAL = 30 to 70 by 20 100
```

A missing value identifies a parameter as the result parameter; it is valid only with options representing parameters you can solve for in a given analysis. For example, you can request a solution for NTOTAL:

```
NTOTAL = .
```

Grouped-Number-Lists

A *grouped-number-list* specifies multiple scenarios for numeric values in two or more groups, possibly including missing value indicators to solve for a specific group. The list can assume one of two general forms, a “crossed” version and a “matched” version.

Crossed Grouped-Number-Lists

The crossed version of a grouped number list consists of a series of *number-lists* (see the section “[Number-Lists](#)” on page 6021), one representing each group, with groups separated by a vertical bar (|). The values for each group represent multiple scenarios for that group, and the scenarios for each individual group are crossed to produce the set of all scenarios for the analysis option. For example, you can specify the following six scenarios for the sizes (n_1, n_2) of two groups

```
(20, 30)(20, 40)(20, 50)
(25, 30)(25, 40)(25, 50)
```

as follows:

```
GROUPNS = 20 25 | 30 40 50
```

If the analysis can solve for a value in one group given the other groups, then one of the *number-lists* in a *crossed grouped-number-list* can be a missing value indicator (.). For example, in a two-sample t test you can posit three scenarios for the group 2 sample size while solving for the group 1 sample size:

```
GROUPNS = . | 30 40 50
```

Some analyses can involve more than two groups. For example, you can specify $2 \times 3 \times 1 = 6$ scenarios for the means of three groups in a one-way ANOVA as follows:

```
GROUPMEANS = 10 12 | 10 to 20 by 5 | 24
```

Matched Grouped-Number-Lists

The matched version of a grouped number list consists of a series of numeric lists, each enclosed in parentheses. Each list consists of a value for each group and represents a single scenario for the analysis option. Multiple scenarios for the analysis option are represented by multiple lists. For example, you can express the crossed grouped-number-list

```
GROUPNS = 20 25 | 30 40 50
```

alternatively in a matched format:

```
GROUPNS = (20 30) (20 40) (20 50) (25 30) (25 40) (25 50)
```

The matched version is particularly useful when you want to include only a subset of all combinations of individual group values. For example, you might want to pair 20 only with 50, and 25 only with 30 and 40:

```
GROUPNS = (20 50) (25 30) (25 40)
```

If the analysis can solve for a value in one group given the other groups, then you can replace the value for that group with a missing value indicator (.). If used, the missing value indicator must occur in the same group in every scenario. For example, you can solve for the group 1 sample size (as in the section “[Crossed Grouped-Number-Lists](#)” on page 6021) by using a matched format:

```
GROUPNS = (. 30) (. 40) (. 50)
```

Some analyses can involve more than two groups. For example, you can specify two scenarios for the means of three groups in a one-way ANOVA:

```
GROUPMEANS = (15 24 32) (12 25 36)
```

Name-Lists

A *name-list* is a list of one or more names in single or double quotes, separated by spaces. For example, you can specify two scenarios for the reference survival curve in a log-rank test:

```
REFSURVIVAL = "Curve A" "Curve B"
```

Grouped-Name-Lists

A *grouped-name-list* specifies multiple scenarios for names in two or more groups. The list can assume one of two general forms, a “crossed” version and a “matched” version.

Crossed Grouped-Name-Lists

The crossed version of a grouped name list consists of a series of *name-lists* (see the section “Name-Lists” on page 6022), one representing each group, with groups separated by a vertical bar (|). The values for each group represent multiple scenarios for that group, and the scenarios for each individual group are crossed to produce the set of all scenarios for the analysis option. For example, you can specify the following six scenarios for the survival curves (c_1, c_2) of two groups

```
(“Curve A”, “Curve C”)(“Curve A”, “Curve D”)(“Curve A”, “Curve E”)
(“Curve B”, “Curve C”)(“Curve B”, “Curve D”)(“Curve B”, “Curve E”)
```

as follows:

```
GROUPSURVIVAL = "Curve A" "Curve B" | "Curve C" "Curve D"
                  "Curve E"
```

Matched Grouped-Name-Lists

The matched version of a grouped name list consists of a series of name lists, each enclosed in parentheses. Each list consists of a name for each group and represents a single scenario for the analysis option. Multiple scenarios for the analysis option are represented by multiple lists. For example, you can express the crossed grouped-name-list

```
GROUPSURVIVAL = "Curve A" "Curve B" | "Curve C" "Curve D"
                  "Curve E"
```

alternatively in a matched format:

```
GROUPSURVIVAL = ("Curve A" "Curve C")
                  ("Curve A" "Curve D")
                  ("Curve A" "Curve E")
                  ("Curve B" "Curve C")
                  ("Curve B" "Curve D")
                  ("Curve B" "Curve E")
```

The matched version is particularly useful when you want to include only a subset of all combinations of individual group values. For example, you might want to pair “Curve A” only with “Curve C”, and “Curve B” only with “Curve D” and “Curve E”:

```
GROUPSURVIVAL = ("Curve A" "Curve C")
                  ("Curve B" "Curve D")
                  ("Curve B" "Curve E")
```

Sample Size Adjustment Options

By default, PROC POWER rounds sample sizes conservatively (down in the input, up in the output) so that all total sizes (and individual group sample sizes, if a multigroup design) are integers. This is generally considered conservative because it selects the closest realistic design providing *at most* the power of the

(possibly fractional) input or mathematically optimized design. In addition, in a multigroup design, all group sizes are adjusted to be multiples of the corresponding group weights. For example, if GROUPWEIGHTS = (2 6), then all group 1 sample sizes become multiples of 2, and all group 2 sample sizes become multiples of 6 (and all total sample sizes become multiples of 8).

With the NFRACTIONAL option, sample size input is not rounded, and sample size output (whether total or groupwise) are reported in two versions, a raw “fractional” version and a “ceiling” version rounded up to the nearest integer.

Whenever an input sample size is adjusted, both the original (“nominal”) and adjusted (“actual”) sample sizes are reported. Whenever computed output sample sizes are adjusted, both the original input (“nominal”) power and the achieved (“actual”) power at the adjusted sample size are reported.

Error and Information Output

The Error column in the main output table provides reasons for missing results and flags numerical results that are bounds rather than exact answers. For example, consider the sample size analysis implemented by the following statements:

```
proc power;
  twosamplefreq test=pchi
    method=normal
    oddsratio= 1.0001
    refproportion=.4
    nulloddsratio=1
    power=.9
    ntotal=.;
run;
```

Figure 71.6 continued

Computed N Total		
Actual Power	N Total	Error
0.206	2.15E+09	Solution is a lower bound

The output in Figure 71.6 reveals that the sample size to achieve a power of 0.9 could not be computed, but that the sample size 2.15E+09 achieves a power of 0.206.

The Info column provides further details about Error column entries, warnings about any boundary conditions detected, and notes about any adjustments to input. Note that the Info column is hidden by default in the main output. You can view it by using the ODS OUTPUT statement to save the output as a data set and the PRINT procedure. For example, the following SAS statements print both the Error and Info columns for a power computation in a two-sample *t* test:

```
proc power;
  twosamplemeans
    meandiff= 0 7
    stddev=2
    ntotal=2 5
    power=.;
  ods output output=Power;
run;

proc print noobs data=Power;
  var MeanDiff NominalNTotal NTotal Power Error Info;
run;
```

The output is shown in Figure 71.7.

Figure 71.7 Error and Info Columns

Mean Diff	Nominal NTotal	NTotal	Power	Error	Info
0	2	2	.	Invalid input	N too small / No effect
0	5	4	0.050		Input N adjusted / No effect
7	2	2	.	Invalid input	N too small
7	5	4	0.477		Input N adjusted

The mean difference of 0 specified with the MEANDIFF= option leads to a “No effect” message to appear in the Info column. The sample size of 2 specified with the NTOTAL= option leads to an “Invalid input” message in the Error column and an “NTotal too small” message in the Info column. The sample size of 5 leads to an “Input N adjusted” message in the Info column because it is rounded down to 4 to produce integer group sizes of 2 per group.

Displayed Output

If you use the **PLOTONLY** option in the **PROC POWER** statement, the procedure displays only graphical output. Otherwise, the displayed output of the POWER procedure includes the following:

- the “Fixed Scenario Elements” table, which shows all applicable single-valued analysis parameters, in the following order: distribution, method, parameters input explicitly, and parameters supplied with defaults
- an output table showing the following when applicable (in order): the index of the scenario, all multivalued input, ancillary results, the primary computed result, and error descriptions
- plots (if requested)

For each input parameter, the order of the input values is preserved in the output.

Ancillary results include the following:

- Actual Power, the achieved power, if it differs from the input (Nominal) power value
- Actual Prob(Width), the achieved precision probability, if it differs from the input (Nominal) probability value
- Actual Alpha, the achieved significance level, if it differs from the input (Nominal) alpha value
- fractional sample size, if the **NFRACTIONAL** option is used in the analysis statement

If sample size is the result parameter and the **NFRACTIONAL** option is used in the analysis statement, then both “Fractional” and “Ceiling” sample size results are displayed. Fractional sample sizes correspond to the “Nominal” values of power or precision probability. Ceiling sample sizes are simply the fractional sample sizes rounded up to the nearest integer; they correspond to “Actual” values of power or precision probability.

ODS Table Names

PROC POWER assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 71.28](#). For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 71.28 ODS Tables Produced by PROC POWER

ODS Table Name	Description	Statement
FixedElements	Factoid with single-valued analysis parameters	Default*
Output	All input and computed analysis parameters, error messages, and information messages for each scenario	Default
PlotContent	Data contained in plots, including analysis parameters and indices identifying plot features. (NOTE: This table is saved as a data set and not displayed in PROC POWER output.)	PLOT

*Depends on input.

Computational Resources

Memory

In the **TWOSAMPLESURVIVAL** statement, the amount of required memory is roughly proportional to the product of the number of subintervals (specified by the **NSUBINTERVAL=** option) and the total time of the study (specified by the **ACCRUALTIME=**, **FOLLOWUPTIME=**, and **TOTALTIME=** options). If you run out of memory, then you can try either specifying a smaller number of subintervals, changing the time scale to a use a longer time unit (for example, years instead of months), or both.

CPU Time

In the Satterthwaite t test analysis (**TWOSAMPLEMEANS TEST=DIFF_SATT**), the required CPU time grows as the mean difference decreases relative to the standard deviations. In the **PAIREDFREQ** statement, the required CPU time for the exact power computation (**METHOD=EXACT**) grows with the sample size.

Computational Methods and Formulas

This section describes the approaches used in PROC POWER to compute power for each analysis. The first subsection defines some common notation. The following subsections describe the various power analyses, including discussions of the data, statistical test, and power formula for each analysis. Unless otherwise indicated, computed values for parameters besides power (for example, sample size) are obtained by solving power formulas for the desired parameters.

Common Notation

Table 71.29 displays notation for some of the more common parameters across analyses. The Associated Syntax column shows examples of relevant analysis statement options, where applicable.

Table 71.29 Common Notation

Symbol	Description	Associated Syntax
α	Significance level	ALPHA=
N	Total sample size	NTOTAL=, NPAIRS=
n_i	Sample size in i th group	NPERGROUP=, GROUPNS=
w_i	Allocation weight for i th group (standardized to sum to 1)	GROUPWEIGHTS=
μ	(Arithmetic) mean	MEAN=
μ_i	(Arithmetic) mean in i th group	GROUPMEANS=, PAIREDMEANS=
μ_{diff}	(Arithmetic) mean difference, $\mu_2 - \mu_1$ or $\mu_T - \mu_R$	MEANDIFF=
μ_0	Null mean or mean difference (arithmetic)	NULL=, NULLDIFF=
γ	Geometric mean	MEAN=
γ_i	Geometric mean in i th group	GROUPMEANS=, PAIREDMEANS=
γ_0	Null mean or mean ratio (geometric)	NULL=, NULLRATIO=
σ	Standard deviation (or common standard deviation per group)	STDDEV=
σ_i	Standard deviation in i th group	GROUPSTDDEVS=, PAIREDSTDDEVS=
σ_{diff}	Standard deviation of differences	
CV	Coefficient of variation, defined as the ratio of the standard deviation to the (arithmetic) mean	CV=, PAIREDCVS=
ρ	Correlation	CORR=
μ_T, μ_R	Treatment and reference (arithmetic) means for equivalence test	GROUPMEANS=, PAIREDMEANS=
γ_T, γ_R	Treatment and reference geometric means for equivalence test	GROUPMEANS=, PAIREDMEANS=
θ_L	Lower equivalence bound	LOWER=
θ_U	Upper equivalence bound	UPPER=
$t(\nu, \delta)$	t distribution with df ν and noncentrality δ	
$F(\nu_1, \nu_2, \lambda)$	F distribution with numerator df ν_1 , denominator df ν_2 , and noncentrality λ	
$t_{p;\nu}$	p th percentile of t distribution with df ν	
$F_{p;\nu_1,\nu_2}$	p th percentile of F distribution with numerator df ν_1 and denominator df ν_2	
$\text{Bin}(N, p)$	Binomial distribution with sample size N and proportion p	

A “lower one-sided” test is associated with SIDES=L (or SIDES=1 with the effect smaller than the null value), and an “upper one-sided” test is associated with SIDES=U (or SIDES=1 with the effect larger than the null value).

Owen (1965) defines a function, known as Owen's Q , that is convenient for representing terms in power formulas for confidence intervals and equivalence tests:

$$Q_v(t, \delta; a, b) = \frac{\sqrt{2\pi}}{\Gamma(\frac{v}{2})2^{\frac{v-2}{2}}} \int_a^b \Phi\left(\frac{tx}{\sqrt{v}} - \delta\right) x^{v-1} \phi(x) dx$$

where $\phi(\cdot)$ and $\Phi(\cdot)$ are the density and cumulative distribution function of the standard normal distribution, respectively.

Analyses in the LOGISTIC Statement

Likelihood Ratio Chi-Square Test for One Predictor (TEST=LRCHI)

The power computing formula is based on Shieh and O'Brien (1998); Shieh (2000); Self, Mauritsen, and Ohara (1992), and Hsieh (1989).

Define the following notation for a logistic regression analysis:

- N = # subjects (NTOTAL)
- K = # predictors (not counting intercept)
- $\mathbf{x} = (x_1, \dots, x_K)'$ = random variables for predictor vector
- $\mathbf{x}_{-1} = (x_2, \dots, x_K)'$
- $\boldsymbol{\mu} = (\mu_1, \dots, \mu_K)' = E\mathbf{x}$ = mean predictor vector
- $\mathbf{x}_i = (x_{i1}, \dots, x_{iK})'$ = predictor vector for subject i ($i \in 1, \dots, N$)
- Y = random variable for response (0 or 1)
- Y_i = response for subject i ($i \in 1, \dots, N$)
- $p_i = \text{Prob}(Y_i = 1 | \mathbf{x}_i)$ ($i \in 1, \dots, N$)
- $\phi = \text{Prob}(Y_i = 1 | \mathbf{x}_i = \boldsymbol{\mu})$ (RESPONSEPROB)
- U_j = unit change for j th predictor (UNITS)
- $\text{OR}_j = \text{Odds}(Y_i = 1 | x_{ij} = c) / \text{Odds}(Y_i = 1 | x_{ij} = c - U_j)$ (c arbitrary, $i \in 1, \dots, N$, $j \in 1, \dots, K$) (TESTODDSRATIO if $j = 1$, COVODDSRATIOS if $j > 1$)
- Ψ_0 = intercept in full model (INTERCEPT)
- $\boldsymbol{\Psi} = (\Psi_1, \dots, \Psi_K)'$ = regression coefficients in full model
($\Psi_1 = \text{TESTREGCOEFF}$, others = COVREGCOEFFS)
- $\rho = \text{Corr}(\mathbf{x}_{-1}, x_1)$ (CORR)
- c_j = # distinct possible values of x_{ij} ($j \in 1, \dots, K$) (for any i) (NBINS)
- x_{gj}^* = g th possible value of x_{ij} ($g \in 1, \dots, c_j$) ($j \in 1, \dots, K$)
(for any i) (VARDIST)
- $\pi_{gj} = \text{Prob}(x_{ij} = x_{gj}^*)$ ($g \in 1, \dots, c_j$) ($j \in 1, \dots, K$)
(for any i) (VARDIST)
- $C = \prod_{j=1}^K c_j$ = # possible values of \mathbf{x}_i (for any i)
- \mathbf{x}_m^* = m th possible value of \mathbf{x}_i ($m \in 1, \dots, C$)
- $\pi_m = \text{Prob}(\mathbf{x}_i = \mathbf{x}_m^*)$ ($m \in 1, \dots, C$)

The logistic regression model is

$$\log\left(\frac{p_i}{1-p_i}\right) = \Psi_0 + \Psi' \mathbf{x}_i$$

The hypothesis test of the first predictor variable is

$$H_0: \Psi_1 = 0$$

$$H_1: \Psi_1 \neq 0$$

Assuming independence among all predictor variables, π_m is defined as follows:

$$\pi_m = \prod_{j=1}^K \pi_{h(m,j)j} \quad (m \in 1, \dots, C)$$

where $h(m, j)$ is calculated according to the following algorithm:

```

z = m;
do  j = K  to  1;
    h(m, j) = mod(z - 1, c_j) + 1;
    z = floor((z - 1)/c_j) + 1;
end;
```

This algorithm causes the elements of the transposed vector $\{h(m, 1), \dots, h(m, K)\}$ to vary fastest to slowest from right to left as m increases, as shown in the following table of $h(m, j)$ values:

$h(m, j)$		j				
		1	2	\dots	$K-1$	K
	1	1	1	\dots	1	1
	1	1	1	\dots	1	2
	\vdots				\vdots	
	\vdots	1	1	\dots	1	c_K
	\vdots	1	1	\dots	2	1
	\vdots	1	1	\dots	2	2
	\vdots				\vdots	
m	\vdots	1	1	\dots	2	c_K
	\vdots				\vdots	
	\vdots	c_1	c_2	\dots	c_{K-1}	1
	\vdots	c_1	c_2	\dots	c_{K-1}	2
	\vdots				\vdots	
	C	c_1	c_2	\dots	c_{K-1}	c_K

The \mathbf{x}_m^* values are determined in a completely analogous manner.

The discretization is handled as follows (unless the distribution is ordinal, or binomial with sample size parameter at least as large as requested number of bins): for x_j , generate c_j quantiles at evenly spaced probability values such that each such quantile is at the midpoint of a bin with probability $\frac{1}{c_j}$. In other words,

$$x_{gj}^* = \left(\frac{g - 0.5}{c_j} \right) \text{th quantile of relevant distribution,}$$

$$(g \in 1, \dots, c_j)(j \in 1, \dots, K)$$

$$\pi_{gj} = \frac{1}{c_j} \quad (\text{same for all } g)$$

The primary noncentrality for the power computation is

$$\Delta^* = 2 \sum_{m=1}^C \pi_m [b'(\theta_m) (\theta_m - \theta_m^*) - (b(\theta_m) - b(\theta_m^*))]$$

where

$$b'(\theta) = \frac{\exp(\theta)}{1 + \exp(\theta)}$$

$$b(\theta) = \log(1 + \exp(\theta))$$

$$\theta_m = \Psi_0 + \Psi' \mathbf{x}_m^*$$

$$\theta_m^* = \Psi_0^* + \Psi^{*'} \mathbf{x}_m^*$$

where

$$\Psi_0^* = \Psi_0 + \Psi_1 \mu_1 = \text{intercept in reduced model, absorbing the tested predictor}$$

$$\Psi^* = (0, \Psi_2, \dots, \Psi_K)' = \text{coefficients in reduced model}$$

The power is

$$\text{power} = P(\chi^2(1, \Delta^* N(1 - \rho^2)) \geq \chi_{1-\alpha}^2(1))$$

The factor $(1 - \rho^2)$ is the adjustment for correlation between the predictor that is being tested and other predictors, from Hsieh (1989).

Alternative input parameterizations are handled by the following transformations:

$$\Psi_0 = \log\left(\frac{\phi}{1 - \phi}\right) - \Psi' \mu$$

$$\Psi_j = \frac{\log(\text{OR}_j)}{U_j} \quad (j \in 1, \dots, K)$$

Analyses in the MULTREG Statement

Type III F Test in Multiple Regression (TEST=TYPE3)

Maxwell (2000) discusses a number of different ways to represent effect sizes (and to compute exact power based on them) in multiple regression. PROC POWER supports two of these, multiple partial correlation and R^2 in full and reduced models.

Let p denote the total number of predictors in the full model (excluding the intercept), and let Y denote the response variable. You are testing that the coefficients of $p_1 \geq 1$ predictors in a set X_1 are 0, controlling for all of the other predictors X_{-1} , which consists of $p - p_1 \geq 0$ variables.

The hypotheses can be expressed in two different ways. The first is in terms of $\rho_{YX_1|X_{-1}}$, the multiple partial correlation between the predictors in X_1 and the response Y adjusting for the predictors in X_{-1} :

$$H_0: \rho_{YX_1|X_{-1}}^2 = 0$$

$$H_1: \rho_{YX_1|X_{-1}}^2 > 0$$

The second is in terms of the multiple correlations in full ($\rho_{Y|(X_1, X_{-1})}$) and reduced ($\rho_{Y|X_{-1}}$) nested models:

$$H_0: \rho_{Y|(X_1, X_{-1})}^2 - \rho_{Y|X_{-1}}^2 = 0$$

$$H_1: \rho_{Y|(X_1, X_{-1})}^2 - \rho_{Y|X_{-1}}^2 > 0$$

Note that the squared values of $\rho_{Y|(X_1, X_{-1})}$ and $\rho_{Y|X_{-1}}$ are the population R^2 values for full and reduced models.

The test statistic can be written in terms of the sample multiple partial correlation $R_{YX_1|X_{-1}}$,

$$F = \begin{cases} (N - 1 - p) \frac{R_{YX_1|X_{-1}}^2}{1 - R_{YX_1|X_{-1}}^2}, & \text{intercept} \\ (N - p) \frac{R_{YX_1|X_{-1}}^2}{1 - R_{YX_1|X_{-1}}^2}, & \text{no intercept} \end{cases}$$

or the sample multiple correlations in full ($R_{Y|(X_1, X_{-1})}$) and reduced ($R_{Y|X_{-1}}$) models,

$$F = \begin{cases} (N - 1 - p) \frac{R_{Y|(X_1, X_{-1})}^2 - R_{Y|X_{-1}}^2}{1 - R_{Y|(X_1, X_{-1})}^2}, & \text{intercept} \\ (N - p) \frac{R_{Y|(X_1, X_{-1})}^2 - R_{Y|X_{-1}}^2}{1 - R_{Y|(X_1, X_{-1})}^2}, & \text{no intercept} \end{cases}$$

The test is the usual Type III F test in multiple regression:

$$\text{Reject } H_0 \text{ if } \begin{cases} F \geq F_{1-\alpha}(p_1, N - 1 - p), & \text{intercept} \\ F \geq F_{1-\alpha}(p_1, N - p), & \text{no intercept} \end{cases}$$

Although the test is invariant to whether the predictors are assumed to be random or fixed, the power is affected by this assumption. If the response and predictors are assumed to have a joint multivariate normal

distribution, then the exact power is given by the following formula:

$$\begin{aligned} \text{power} &= \begin{cases} P \left[\left(\frac{N-1-p}{p_1} \right) \left(\frac{R_{YX_1|X_{-1}}^2}{1-R_{YX_1|X_{-1}}^2} \right) \geq F_{1-\alpha}(p_1, N-1-p) \right], & \text{intercept} \\ P \left[\left(\frac{N-p}{p_1} \right) \left(\frac{R_{YX_1|X_{-1}}^2}{1-R_{YX_1|X_{-1}}^2} \right) \geq F_{1-\alpha}(p_1, N-p) \right], & \text{no intercept} \end{cases} \\ &= \begin{cases} P \left[R_{YX_1|X_{-1}}^2 \geq \frac{F_{1-\alpha}(p_1, N-1-p)}{F_{1-\alpha}(p_1, N-1-p) + \frac{N-1-p}{p_1}} \right], & \text{intercept} \\ P \left[R_{YX_1|X_{-1}}^2 \geq \frac{F_{1-\alpha}(p_1, N-p)}{F_{1-\alpha}(p_1, N-p) + \frac{N-p}{p_1}} \right], & \text{no intercept} \end{cases} \end{aligned}$$

The distribution of $R_{YX_1|X_{-1}}^2$ (for any $\rho_{YX_1|X_{-1}}^2$) is given in Chapter 32 of Johnson, Kotz, and Balakrishnan (1995). Sample size tables are presented in Gatsonis and Sampson (1989).

If the predictors are assumed to have fixed values, then the exact power is given by the noncentral F distribution. The noncentrality parameter is

$$\lambda = N \frac{\rho_{YX_1|X_{-1}}^2}{1 - \rho_{YX_1|X_{-1}}^2}$$

or equivalently,

$$\lambda = N \frac{\rho_{Y|(X_1, X_{-1})}^2 - \rho_{Y|X_{-1}}^2}{1 - \rho_{Y|(X_1, X_{-1})}^2}$$

The power is

$$\text{power} = \begin{cases} P(F(p_1, N-1-p, \lambda) \geq F_{1-\alpha}(p_1, N-1-p)), & \text{intercept} \\ P(F(p_1, N-p, \lambda) \geq F_{1-\alpha}(p_1, N-p)), & \text{no intercept} \end{cases}$$

The minimum acceptable input value of N depends on several factors, as shown in Table 71.30.

Table 71.30 Minimum Acceptable Sample Size Values in the MULTREG Statement

Predictor Type	Intercept in Model?	$p_1 = 1$?	Minimum N
Random	Yes	Yes	$p + 3$
Random	Yes	No	$p + 2$
Random	No	Yes	$p + 2$
Random	No	No	$p + 1$
Fixed	Yes	Yes or No	$p + 2$
Fixed	No	Yes or No	$p + 1$

Analyses in the ONECORR Statement

Fisher's z Test for Pearson Correlation (TEST=PEARSON DIST=FISHERZ)

Fisher's z transformation (Fisher 1921) of the sample correlation $R_{Y|(X_1, X_{-1})}$ is defined as

$$z = \frac{1}{2} \log \left(\frac{1 + R_{Y|(X_1, X_{-1})}}{1 - R_{Y|(X_1, X_{-1})}} \right)$$

Fisher's z test assumes the approximate normal distribution $N(\mu, \sigma^2)$ for z , where

$$\mu = \frac{1}{2} \log \left(\frac{1 + \rho_{Y|(X_1, X_{-1})}}{1 - \rho_{Y|(X_1, X_{-1})}} \right) + \frac{\rho_{Y|(X_1, X_{-1})}}{2(N - 1 - p^*)}$$

and

$$\sigma^2 = \frac{1}{N - 3 - p^*}$$

where p^* is the number of variables partialled out (Anderson 1984, pp. 132–133) and $\rho_{Y|(X_1, X_{-1})}$ is the partial correlation between Y and X_1 adjusting for the set of zero or more variables X_{-1} .

The test statistic

$$z^* = (N - 3 - p^*)^{\frac{1}{2}} \left[z - \frac{1}{2} \log \left(\frac{1 + \rho_0}{1 - \rho_0} \right) - \frac{\rho_0}{2(N - 1 - p^*)} \right]$$

is assumed to have a normal distribution $N(\delta, \nu)$, where ρ_0 is the null partial correlation and δ and ν are derived from Section 16.33 of Stuart and Ord (1994):

$$\begin{aligned} \delta &= (N - 3 - p^*)^{\frac{1}{2}} \left[\frac{1}{2} \log \left(\frac{1 + \rho_{Y|(X_1, X_{-1})}}{1 - \rho_{Y|(X_1, X_{-1})}} \right) + \frac{\rho_{Y|(X_1, X_{-1})}}{2(N - 1 - p^*)} \left(1 + \frac{5 + \rho_{Y|(X_1, X_{-1})}^2}{4(N - 1 - p^*)} + \right. \right. \\ &\quad \left. \left. \frac{11 + 2\rho_{Y|(X_1, X_{-1})}^2 + 3\rho_{Y|(X_1, X_{-1})}^4}{8(N - 1 - p^*)^2} \right) - \frac{1}{2} \log \left(\frac{1 + \rho_0}{1 - \rho_0} \right) - \frac{\rho_0}{2(N - 1 - p^*)} \right] \\ \nu &= \frac{N - 3 - p^*}{N - 1 - p^*} \left[1 + \frac{4 - \rho_{Y|(X_1, X_{-1})}^2}{2(N - 1 - p^*)} + \frac{22 - 6\rho_{Y|(X_1, X_{-1})}^2 - 3\rho_{Y|(X_1, X_{-1})}^4}{6(N - 1 - p^*)^2} \right] \end{aligned}$$

The approximate power is computed as

$$\text{power} = \begin{cases} \Phi \left(\frac{\delta - z_{1-\alpha}}{\nu^{\frac{1}{2}}} \right), & \text{upper one-sided} \\ \Phi \left(\frac{-\delta - z_{1-\alpha}}{\nu^{\frac{1}{2}}} \right), & \text{lower one-sided} \\ \Phi \left(\frac{\delta - z_{1-\frac{\alpha}{2}}}{\nu^{\frac{1}{2}}} \right) + \Phi \left(\frac{-\delta - z_{1-\frac{\alpha}{2}}}{\nu^{\frac{1}{2}}} \right), & \text{two-sided} \end{cases}$$

Because the test is biased, the achieved significance level might differ from the nominal significance level. The actual alpha is computed in the same way as the power except with the correlation $\rho_{Y|(X_1, X_{-1})}$ replaced by the null correlation ρ_0 .

***t* Test for Pearson Correlation (TEST=PEARSON DIST=T)**

The two-sided case is identical to multiple regression with an intercept and $p_1 = 1$, which is discussed in the section “Analyses in the MULTREG Statement” on page 6032.

Let p^* denote the number of variables partialled out. For the one-sided cases, the test statistic is

$$t = (N - 2 - p^*)^{\frac{1}{2}} \frac{R_{YX_1|X_{-1}}}{\left(1 - R_{YX_1|X_{-1}}^2\right)^{\frac{1}{2}}}$$

which is assumed to have a null distribution of $t(N - 2 - p^*)$.

If the X and Y variables are assumed to have a joint multivariate normal distribution, then the exact power is given by the following formula:

$$\begin{aligned} \text{power} &= \begin{cases} P \left[(N - 2 - p^*)^{\frac{1}{2}} \frac{R_{YX_1|X_{-1}}}{\left(1 - R_{YX_1|X_{-1}}^2\right)^{\frac{1}{2}}} \geq t_{1-\alpha}(N - 2 - p^*) \right], & \text{upper one-sided} \\ P \left[(N - 2 - p^*)^{\frac{1}{2}} \frac{R_{YX_1|X_{-1}}}{\left(1 - R_{YX_1|X_{-1}}^2\right)^{\frac{1}{2}}} \leq t_{\alpha}(N - 2 - p^*) \right], & \text{lower one-sided} \end{cases} \\ &= \begin{cases} P \left[R_{Y|(X_1, X_{-1})} \geq \frac{t_{1-\alpha}(N - 2 - p^*)}{(t_{1-\alpha}^2(N - 2 - p^*) + N - 2 - p^*)^{\frac{1}{2}}} \right], & \text{upper one-sided} \\ P \left[R_{Y|(X_1, X_{-1})} \leq \frac{t_{\alpha}(N - 2 - p^*)}{(t_{\alpha}^2(N - 2 - p^*) + N - 2 - p^*)^{\frac{1}{2}}} \right], & \text{lower one-sided} \end{cases} \end{aligned}$$

The distribution of $R_{Y|(X_1, X_{-1})}$ (given the underlying true correlation $\rho_{Y|(X_1, X_{-1})}$) is given in Chapter 32 of Johnson, Kotz, and Balakrishnan (1995).

If the X variables are assumed to have fixed values, then the exact power is given by the noncentral t distribution $t(N - 2 - p^*, \delta)$, where the noncentrality is

$$\delta = N^{\frac{1}{2}} \frac{\rho_{YX_1|X_{-1}}}{\left(1 - \rho_{YX_1|X_{-1}}^2\right)^{\frac{1}{2}}}$$

The power is

$$\text{power} = \begin{cases} P(t(N - 2 - p^*, \delta) \geq t_{1-\alpha}(N - 2 - p^*)), & \text{upper one-sided} \\ P(t(N - 2 - p^*, \delta) \leq t_{\alpha}(N - 2 - p^*)), & \text{lower one-sided} \end{cases}$$

Analyses in the ONESAMPLEFREQ Statement

Exact Test of a Binomial Proportion (TEST=EXACT)

Let X be distributed as $\text{Bin}(N, p)$. The hypotheses for the test of the proportion p are as follows:

$$H_0: p = p_0$$

$$H_1: \begin{cases} p \neq p_0, & \text{two-sided} \\ p > p_0, & \text{upper one-sided} \\ p < p_0, & \text{lower one-sided} \end{cases}$$

The exact test assumes binomially distributed data and requires $N \geq 1$ and $0 < p_0 < 1$. The test statistic is

$$X = \text{number of successes} \sim \text{Bin}(N, p)$$

The significance probability α is split symmetrically for two-sided tests, in the sense that each tail is filled with as much as possible up to $\alpha/2$.

Exact power computations are based on the binomial distribution and computing formulas such as the following from Johnson, Kotz, and Kemp (1992, equation 3.20):

$$P(X \geq C | N, p) = P\left(F_{v_1, v_2} \leq \frac{v_2 p}{v_1(1-p)}\right) \quad \text{where } v_1 = 2C \text{ and } v_2 = 2(N - C + 1)$$

Let C_L and C_U denote lower and upper critical values, respectively. Let α_a denote the achieved (actual) significance level, which for two-sided tests is the sum of the favorable major tail (α_M) and the opposite minor tail (α_m).

For the upper one-sided case,

$$C_U = \min\{C : P(X \geq C | p_0) \leq \alpha\}$$

$$\text{Reject } H_0 \text{ if } X \geq C_U$$

$$\alpha_a = P(X \geq C_U | p_0)$$

$$\text{power} = P(X \geq C_U | p)$$

For the lower one-sided case,

$$C_L = \max\{C : P(X \leq C | p_0) \leq \alpha\}$$

$$\text{Reject } H_0 \text{ if } X \leq C_L$$

$$\alpha_a = P(X \leq C_L | p_0)$$

$$\text{power} = P(X \leq C_L | p)$$

For the two-sided case,

$$C_L = \max\{C : P(X \leq C | p_0) \leq \frac{\alpha}{2}\}$$

$$C_U = \min\{C : P(X \geq C | p_0) \leq \frac{\alpha}{2}\}$$

$$\text{Reject } H_0 \text{ if } X \leq C_L \text{ or } X \geq C_U$$

$$\alpha_a = P(X \leq C_L \text{ or } X \geq C_U | p_0)$$

$$\text{power} = P(X \leq C_L \text{ or } X \geq C_U | p)$$

z Test for Binomial Proportion Using Null Variance (TEST=Z VAREST=NULL)

For the normal approximation test, the test statistic is

$$Z(X) = \frac{X - Np_0}{[Np_0(1 - p_0)]^{\frac{1}{2}}}$$

For the METHOD=EXACT option, the computations are the same as described in the section “[Exact Test of a Binomial Proportion \(TEST=EXACT\)](#)” on page 6036 except for the definitions of the critical values.

For the upper one-sided case,

$$C_U = \min\{C : Z(C) \geq z_{1-\alpha}\}$$

For the lower one-sided case,

$$C_L = \max\{C : Z(C) \leq z_\alpha\}$$

For the two-sided case,

$$C_L = \max\{C : Z(C) \leq z_{\frac{\alpha}{2}}\}$$

$$C_U = \min\{C : Z(C) \geq z_{1-\frac{\alpha}{2}}\}$$

For the METHOD=NORMAL option, the test statistic $Z(X)$ is assumed to have the normal distribution

$$N\left(\frac{N^{\frac{1}{2}}(p - p_0)}{[p_0(1 - p_0)]^{\frac{1}{2}}}, \frac{p(1 - p)}{p_0(1 - p_0)}\right)$$

The approximate power is computed as

$$\text{power} = \begin{cases} \Phi\left(\frac{z_\alpha + \sqrt{N} \frac{p - p_0}{\sqrt{p_0(1 - p_0)}}}{\sqrt{\frac{p(1 - p)}{p_0(1 - p_0)}}}\right), & \text{upper one-sided} \\ \Phi\left(\frac{z_\alpha - \sqrt{N} \frac{p - p_0}{\sqrt{p_0(1 - p_0)}}}{\sqrt{\frac{p(1 - p)}{p_0(1 - p_0)}}}\right), & \text{lower one-sided} \\ \Phi\left(\frac{z_{\frac{\alpha}{2}} + \sqrt{N} \frac{p - p_0}{\sqrt{p_0(1 - p_0)}}}{\sqrt{\frac{p(1 - p)}{p_0(1 - p_0)}}}\right) + \Phi\left(\frac{z_{\frac{\alpha}{2}} - \sqrt{N} \frac{p - p_0}{\sqrt{p_0(1 - p_0)}}}{\sqrt{\frac{p(1 - p)}{p_0(1 - p_0)}}}\right), & \text{two-sided} \end{cases}$$

The approximate sample size is computed in closed form for the one-sided cases by inverting the power equation,

$$N = \left(\frac{z_{\text{power}} \sqrt{p(1 - p)} + z_{1-\alpha} \sqrt{p_0(1 - p_0)}}{p - p_0}\right)^2$$

and by numerical inversion for the two-sided case.

z Test for Binomial Proportion Using Sample Variance (TEST=Z VAREST=SAMPLE)

For the normal approximation test using the sample variance, the test statistic is

$$Z_s(X) = \frac{X - Np_0}{[N\hat{p}(1 - \hat{p})]^{1/2}}$$

where $\hat{p} = X/N$.

For the METHOD=EXACT option, the computations are the same as described in the section “[Exact Test of a Binomial Proportion \(TEST=EXACT\)](#)” on page 6036 except for the definitions of the critical values.

For the upper one-sided case,

$$C_U = \min\{C : Z_s(C) \geq z_{1-\alpha}\}$$

For the lower one-sided case,

$$C_L = \max\{C : Z_s(C) \leq z_\alpha\}$$

For the two-sided case,

$$\begin{aligned} C_L &= \max\{C : Z_s(C) \leq z_{\frac{\alpha}{2}}\} \\ C_U &= \min\{C : Z_s(C) \geq z_{1-\frac{\alpha}{2}}\} \end{aligned}$$

For the METHOD=NORMAL option, the test statistic $Z_s(X)$ is assumed to have the normal distribution

$$N\left(\frac{N^{1/2}(p - p_0)}{[p(1 - p)]^{1/2}}, 1\right)$$

(see Chow, Shao, and Wang (2003, p. 82)).

The approximate power is computed as

$$\text{power} = \begin{cases} \Phi\left(z_\alpha + \sqrt{N} \frac{p - p_0}{\sqrt{p(1 - p)}}\right), & \text{upper one-sided} \\ \Phi\left(z_\alpha - \sqrt{N} \frac{p - p_0}{\sqrt{p(1 - p)}}\right), & \text{lower one-sided} \\ \Phi\left(z_{\frac{\alpha}{2}} + \sqrt{N} \frac{p - p_0}{\sqrt{p(1 - p)}}\right) + \Phi\left(z_{\frac{\alpha}{2}} - \sqrt{N} \frac{p - p_0}{\sqrt{p(1 - p)}}\right), & \text{two-sided} \end{cases}$$

The approximate sample size is computed in closed form for the one-sided cases by inverting the power equation,

$$N = p(1 - p) \left(\frac{z_{\text{power}} + z_{1-\alpha}}{p - p_0} \right)^2$$

and by numerical inversion for the two-sided case.

z Test for Binomial Proportion with Continuity Adjustment Using Null Variance (TEST=ADJZ VAREST=NULL)

For the normal approximation test with continuity adjustment, the test statistic is (Pagano and Gauvreau 1993, p. 295):

$$Z_c(X) = \frac{X - Np_0 + 0.5(1_{\{X < Np_0\}}) - 0.5(1_{\{X > Np_0\}})}{[Np_0(1 - p_0)]^{\frac{1}{2}}}$$

For the METHOD=EXACT option, the computations are the same as described in the section “Exact Test of a Binomial Proportion (TEST=EXACT)” on page 6036 except for the definitions of the critical values.

For the upper one-sided case,

$$C_U = \min\{C : Z_c(C) \geq z_{1-\alpha}\}$$

For the lower one-sided case,

$$C_L = \max\{C : Z_c(C) \leq z_{\alpha}\}$$

For the two-sided case,

$$C_L = \max\{C : Z_c(C) \leq z_{\frac{\alpha}{2}}\}$$

$$C_U = \min\{C : Z_c(C) \geq z_{1-\frac{\alpha}{2}}\}$$

For the METHOD=NORMAL option, the test statistic $Z_c(X)$ is assumed to have the normal distribution $N(\mu, \sigma^2)$, where μ and σ^2 are derived as follows.

For convenience of notation, define

$$k = \frac{1}{2\sqrt{Np_0(1 - p_0)}}$$

Then

$$E[Z_c(X)] = 2kNp - 2kNp_0 + kP(X < Np_0) - kP(X > Np_0)$$

and

$$\begin{aligned} \text{Var}[Z_c(X)] &= 4k^2Np(1 - p) + k^2[1 - P(X = Np_0)] - k^2[P(X < Np_0) - P(X > Np_0)]^2 \\ &\quad + 4k^2[E(X1_{\{X < Np_0\}}) - E(X1_{\{X > Np_0\}})] - 4k^2Np[P(X < Np_0) - P(X > Np_0)] \end{aligned}$$

The probabilities $P(X = Np_0)$, $P(X < Np_0)$, and $P(X > Np_0)$ and the truncated expectations $E(X1_{\{X < Np_0\}})$ and $E(X1_{\{X > Np_0\}})$ are approximated by assuming the normal-approximate distribution of X , $N(Np, Np(1 - p))$. Letting $\phi(\cdot)$ and $\Phi(\cdot)$ denote the standard normal PDF and CDF, respectively, and defining d as

$$d = \frac{Np_0 - Np}{[Np(1 - p)]^{\frac{1}{2}}}$$

the terms are computed as follows:

$$\begin{aligned}
 P(X = Np_0) &= 0 \\
 P(X < Np_0) &= \Phi(d) \\
 P(X > Np_0) &= 1 - \Phi(d) \\
 E(X1_{\{X < Np_0\}}) &= Np\Phi(d) - [Np(1-p)]^{\frac{1}{2}}\phi(d) \\
 E(X1_{\{X > Np_0\}}) &= Np[1 - \Phi(d)] + [Np(1-p)]^{\frac{1}{2}}\phi(d)
 \end{aligned}$$

The mean and variance of $Z_c(X)$ are thus approximated by

$$\mu = k[2Np - 2Np_0 + 2\Phi(d) - 1]$$

and

$$\sigma^2 = 4k^2 \left[Np(1-p) + \Phi(d)(1 - \Phi(d)) - 2(Np(1-p))^{\frac{1}{2}}\phi(d) \right]$$

The approximate power is computed as

$$\text{power} = \begin{cases} \Phi\left(\frac{z_{\alpha} + \mu}{\sigma}\right), & \text{upper one-sided} \\ \Phi\left(\frac{z_{\alpha} - \mu}{\sigma}\right), & \text{lower one-sided} \\ \Phi\left(\frac{z_{\frac{\alpha}{2}} + \mu}{\sigma}\right) + \Phi\left(\frac{z_{\frac{\alpha}{2}} - \mu}{\sigma}\right), & \text{two-sided} \end{cases}$$

The approximate sample size is computed by numerical inversion.

z Test for Binomial Proportion with Continuity Adjustment Using Sample Variance (TEST=ADJZ VAREST=SAMPLE)

For the normal approximation test with continuity adjustment using the sample variance, the test statistic is

$$Z_{cs}(X) = \frac{X - Np_0 + 0.5(1_{\{X < Np_0\}}) - 0.5(1_{\{X > Np_0\}})}{[N\hat{p}(1 - \hat{p})]^{\frac{1}{2}}}$$

where $\hat{p} = X/N$.

For the METHOD=EXACT option, the computations are the same as described in the section “[Exact Test of a Binomial Proportion \(TEST=EXACT\)](#)” on page 6036 except for the definitions of the critical values.

For the upper one-sided case,

$$C_U = \min\{C : Z_{cs}(C) \geq z_{1-\alpha}\}$$

For the lower one-sided case,

$$C_L = \max\{C : Z_{cs}(C) \leq z_{\alpha}\}$$

For the two-sided case,

$$C_L = \max\{C : Z_{cs}(C) \leq z_{\frac{\alpha}{2}}\}$$

$$C_U = \min\{C : Z_{cs}(C) \geq z_{1-\frac{\alpha}{2}}\}$$

For the METHOD=NORMAL option, the test statistic $Z_{cs}(X)$ is assumed to have the normal distribution $N(\mu, \sigma^2)$, where μ and σ^2 are derived as follows.

For convenience of notation, define

$$k = \frac{1}{2\sqrt{Np(1-p)}}$$

Then

$$E[Z_{cs}(X)] \approx 2kNp - 2kNp_0 + kP(X < Np_0) - kP(X > Np_0)$$

and

$$\begin{aligned} \text{Var}[Z_{cs}(X)] \approx & 4k^2Np(1-p) + k^2[1 - P(X = Np_0)] - k^2[P(X < Np_0) - P(X > Np_0)]^2 \\ & + 4k^2[E(X1_{\{X < Np_0\}}) - E(X1_{\{X > Np_0\}})] - 4k^2Np[P(X < Np_0) - P(X > Np_0)] \end{aligned}$$

The probabilities $P(X = Np_0)$, $P(X < Np_0)$, and $P(X > Np_0)$ and the truncated expectations $E(X1_{\{X < Np_0\}})$ and $E(X1_{\{X > Np_0\}})$ are approximated by assuming the normal-approximate distribution of X , $N(Np, Np(1-p))$. Letting $\phi(\cdot)$ and $\Phi(\cdot)$ denote the standard normal PDF and CDF, respectively, and defining d as

$$d = \frac{Np_0 - Np}{[Np(1-p)]^{\frac{1}{2}}}$$

the terms are computed as follows:

$$\begin{aligned} P(X = Np_0) &= 0 \\ P(X < Np_0) &= \Phi(d) \\ P(X > Np_0) &= 1 - \Phi(d) \\ E(X1_{\{X < Np_0\}}) &= Np\Phi(d) - [Np(1-p)]^{\frac{1}{2}}\phi(d) \\ E(X1_{\{X > Np_0\}}) &= Np[1 - \Phi(d)] + [Np(1-p)]^{\frac{1}{2}}\phi(d) \end{aligned}$$

The mean and variance of $Z_{cs}(X)$ are thus approximated by

$$\mu = k[2Np - 2Np_0 + 2\Phi(d) - 1]$$

and

$$\sigma^2 = 4k^2 \left[Np(1-p) + \Phi(d)(1 - \Phi(d)) - 2(Np(1-p))^{\frac{1}{2}}\phi(d) \right]$$

The approximate power is computed as

$$\text{power} = \begin{cases} \Phi\left(\frac{z_{\alpha} + \mu}{\sigma}\right), & \text{upper one-sided} \\ \Phi\left(\frac{z_{\alpha} - \mu}{\sigma}\right), & \text{lower one-sided} \\ \Phi\left(\frac{z_{\frac{\alpha}{2}} + \mu}{\sigma}\right) + \Phi\left(\frac{z_{\frac{\alpha}{2}} - \mu}{\sigma}\right), & \text{two-sided} \end{cases}$$

The approximate sample size is computed by numerical inversion.

Exact Equivalence Test of a Binomial Proportion (TEST=EQUIV_EXACT)

The hypotheses for the equivalence test are

$$H_0: p < \theta_L \quad \text{or} \quad p > \theta_U$$

$$H_1: \theta_L \leq p \leq \theta_U$$

where θ_L and θ_U are the lower and upper equivalence bounds, respectively.

The analysis is the two one-sided tests (TOST) procedure as described in Chow, Shao, and Wang (2003) on p. 84, but using exact critical values as on p. 116 instead of normal-based critical values.

Two different hypothesis tests are carried out:

$$H_{a0}: p < \theta_L$$

$$H_{a1}: p \geq \theta_L$$

and

$$H_{b0}: p > \theta_U$$

$$H_{b1}: p \leq \theta_U$$

If H_{a0} is rejected in favor of H_{a1} and H_{b0} is rejected in favor of H_{b1} , then H_0 is rejected in favor of H_1 .

The test statistic for each of the two tests (H_{a0} versus H_{a1} and H_{b0} versus H_{b1}) is

$$X = \text{number of successes} \sim \text{Bin}(N, p)$$

Let C_U denote the critical value of the exact upper one-sided test of H_{a0} versus H_{a1} , and let C_L denote the critical value of the exact lower one-sided test of H_{b0} versus H_{b1} . These critical values are computed in the section “Exact Test of a Binomial Proportion (TEST=EXACT)” on page 6036. Both of these tests are rejected if and only if $C_U \leq X \leq C_L$. Thus, the exact power of the equivalence test is

$$\begin{aligned} \text{power} &= P(C_U \leq X \leq C_L) \\ &= P(X \geq C_U) - P(X \geq C_L + 1) \end{aligned}$$

The probabilities are computed using Johnson and Kotz (1970, equation 3.20).

z Equivalence Test for Binomial Proportion Using Null Variance (TEST=EQUIV_Z VAREST=NULL)

The hypotheses for the equivalence test are

$$H_0: p < \theta_L \quad \text{or} \quad p > \theta_U$$

$$H_1: \theta_L \leq p \leq \theta_U$$

where θ_L and θ_U are the lower and upper equivalence bounds, respectively.

The analysis is the two one-sided tests (TOST) procedure as described in Chow, Shao, and Wang (2003) on p. 84, but using the null variance instead of the sample variance.

Two different hypothesis tests are carried out:

$$H_{a0}: p < \theta_L$$

$$H_{a1}: p \geq \theta_L$$

and

$$H_{b0}: p > \theta_U$$

$$H_{b1}: p \leq \theta_U$$

If H_{a0} is rejected in favor of H_{a1} and H_{b0} is rejected in favor of H_{b1} , then H_0 is rejected in favor of H_1 .

The test statistic for the test of H_{a0} versus H_{a1} is

$$Z_L(X) = \frac{X - N\theta_L}{[N\theta_L(1 - \theta_L)]^{\frac{1}{2}}}$$

The test statistic for the test of H_{b0} versus H_{b1} is

$$Z_U(X) = \frac{X - N\theta_U}{[N\theta_U(1 - \theta_U)]^{\frac{1}{2}}}$$

For the METHOD=EXACT option, let C_U denote the critical value of the exact upper one-sided test of H_{a0} versus H_{a1} using $Z_L(X)$. This critical value is computed in the section “[z Test for Binomial Proportion Using Null Variance \(TEST=Z VAREST=NULL\)](#)” on page 6037. Similarly, let C_L denote the critical value of the exact lower one-sided test of H_{b0} versus H_{b1} using $Z_U(X)$. Both of these tests are rejected if and only if $C_U \leq X \leq C_L$. Thus, the exact power of the equivalence test is

$$\begin{aligned} \text{power} &= P(C_U \leq X \leq C_L) \\ &= P(X \geq C_U) - P(X \geq C_L + 1) \end{aligned}$$

The probabilities are computed using Johnson and Kotz (1970, equation 3.20).

For the METHOD=NORMAL option, the test statistic $Z_L(X)$ is assumed to have the normal distribution

$$N\left(\frac{N^{\frac{1}{2}}(p - \theta_L)}{[\theta_L(1 - \theta_L)]^{\frac{1}{2}}}, \frac{p(1 - p)}{\theta_L(1 - \theta_L)}\right)$$

and the test statistic $Z_U(X)$ is assumed to have the normal distribution

$$N\left(\frac{N^{\frac{1}{2}}(p - \theta_U)}{[\theta_U(1 - \theta_U)]^{\frac{1}{2}}}, \frac{p(1 - p)}{\theta_U(1 - \theta_U)}\right)$$

(see Chow, Shao, and Wang (2003, p. 84)). The approximate power is computed as

$$\text{power} = \Phi\left(\frac{z_\alpha - \sqrt{N} \frac{p - \theta_U}{\sqrt{\theta_U(1 - \theta_U)}}}{\sqrt{\frac{p(1 - p)}{\theta_U(1 - \theta_U)}}}\right) + \Phi\left(\frac{z_\alpha + \sqrt{N} \frac{p - \theta_L}{\sqrt{\theta_L(1 - \theta_L)}}}{\sqrt{\frac{p(1 - p)}{\theta_L(1 - \theta_L)}}}\right) - 1$$

The approximate sample size is computed by numerically inverting the power formula, using the sample size estimate N_0 of Chow, Shao, and Wang (2003, p. 85) as an initial guess:

$$N_0 = p(1 - p) \left(\frac{z_{1-\alpha} + z_{(1+\text{power})/2}}{0.5(\theta_U - \theta_L) - |p - 0.5(\theta_L + \theta_U)|} \right)^2$$

z Equivalence Test for Binomial Proportion Using Sample Variance (TEST=EQUIV_Z VAREST=SAMPLE)

The hypotheses for the equivalence test are

$$H_0: p < \theta_L \quad \text{or} \quad p > \theta_U$$

$$H_1: \theta_L \leq p \leq \theta_U$$

where θ_L and θ_U are the lower and upper equivalence bounds, respectively.

The analysis is the two one-sided tests (TOST) procedure as described in Chow, Shao, and Wang (2003) on p. 84.

Two different hypothesis tests are carried out:

$$H_{a0}: p < \theta_L$$

$$H_{a1}: p \geq \theta_L$$

and

$$H_{b0}: p > \theta_U$$

$$H_{b1}: p \leq \theta_U$$

If H_{a0} is rejected in favor of H_{a1} and H_{b0} is rejected in favor of H_{b1} , then H_0 is rejected in favor of H_1 .

The test statistic for the test of H_{a0} versus H_{a1} is

$$Z_{sL}(X) = \frac{X - N\theta_L}{[N\hat{p}(1 - \hat{p})]^{\frac{1}{2}}}$$

where $\hat{p} = X/N$.

The test statistic for the test of H_{b0} versus H_{b1} is

$$Z_{sU}(X) = \frac{X - N\theta_U}{[N\hat{p}(1 - \hat{p})]^{\frac{1}{2}}}$$

For the METHOD=EXACT option, let C_U denote the critical value of the exact upper one-sided test of H_{a0} versus H_{a1} using $Z_{sL}(X)$. This critical value is computed in the section “[z Test for Binomial Proportion Using Sample Variance \(TEST=Z VAREST=SAMPLE\)](#)” on page 6038. Similarly, let C_L denote the critical value of the exact lower one-sided test of H_{b0} versus H_{b1} using $Z_{sU}(X)$. Both of these tests are rejected if and only if $C_U \leq X \leq C_L$. Thus, the exact power of the equivalence test is

$$\begin{aligned}\text{power} &= P(C_U \leq X \leq C_L) \\ &= P(X \geq C_U) - P(X \geq C_L + 1)\end{aligned}$$

The probabilities are computed using Johnson and Kotz (1970, equation 3.20).

For the METHOD=NORMAL option, the test statistic $Z_{sL}(X)$ is assumed to have the normal distribution

$$N\left(\frac{N^{\frac{1}{2}}(p - \theta_L)}{[p(1-p)]^{\frac{1}{2}}}, 1\right)$$

and the test statistic $Z_{sU}(X)$ is assumed to have the normal distribution

$$N\left(\frac{N^{\frac{1}{2}}(p - \theta_U)}{[p(1-p)]^{\frac{1}{2}}}, 1\right)$$

(see Chow, Shao, and Wang (2003), p. 84).

The approximate power is computed as

$$\text{power} = \Phi\left(z_\alpha - \sqrt{N} \frac{p - \theta_U}{\sqrt{p(1-p)}}\right) + \Phi\left(z_\alpha + \sqrt{N} \frac{p - \theta_L}{\sqrt{p(1-p)}}\right) - 1$$

The approximate sample size is computed by numerically inverting the power formula, using the sample size estimate N_0 of Chow, Shao, and Wang (2003, p. 85) as an initial guess:

$$N_0 = p(1-p) \left(\frac{z_{1-\alpha} + z_{(1+\text{power})/2}}{0.5(\theta_U - \theta_L) - |p - 0.5(\theta_L + \theta_U)|} \right)^2$$

z Equivalence Test for Binomial Proportion with Continuity Adjustment Using Null Variance (TEST=EQUIV_ADJZ VAREST=NULL)

The hypotheses for the equivalence test are

$$\begin{aligned}H_0: p < \theta_L \quad \text{or} \quad p > \theta_U \\ H_1: \theta_L \leq p \leq \theta_U\end{aligned}$$

where θ_L and θ_U are the lower and upper equivalence bounds, respectively.

The analysis is the two one-sided tests (TOST) procedure as described in Chow, Shao, and Wang (2003) on p. 84, but using the null variance instead of the sample variance.

Two different hypothesis tests are carried out:

$$\begin{aligned}H_{a0}: p < \theta_L \\ H_{a1}: p \geq \theta_L\end{aligned}$$

and

$$H_{b0}: p > \theta_U$$

$$H_{b1}: p \leq \theta_U$$

If H_{a0} is rejected in favor of H_{a1} and H_{b0} is rejected in favor of H_{b1} , then H_0 is rejected in favor of H_1 .

The test statistic for the test of H_{a0} versus H_{a1} is

$$Z_{cL}(X) = \frac{X - N\theta_L + 0.5(1_{\{X < N\theta_L\}}) - 0.5(1_{\{X > N\theta_L\}})}{\left[N\hat{\theta}_L(1 - \hat{\theta}_L) \right]^{\frac{1}{2}}}$$

where $\hat{p} = X/N$.

The test statistic for the test of H_{b0} versus H_{b1} is

$$Z_{cU}(X) = \frac{X - N\theta_U + 0.5(1_{\{X < N\theta_U\}}) - 0.5(1_{\{X > N\theta_U\}})}{\left[N\hat{\theta}_U(1 - \hat{\theta}_U) \right]^{\frac{1}{2}}}$$

For the METHOD=EXACT option, let C_U denote the critical value of the exact upper one-sided test of H_{a0} versus H_{a1} using $Z_{cL}(X)$. This critical value is computed in the section “z Test for Binomial Proportion with Continuity Adjustment Using Null Variance (TEST=ADJZ VAREST=NULL)” on page 6039. Similarly, let C_L denote the critical value of the exact lower one-sided test of H_{b0} versus H_{b1} using $Z_{cU}(X)$. Both of these tests are rejected if and only if $C_U \leq X \leq C_L$. Thus, the exact power of the equivalence test is

$$\begin{aligned} \text{power} &= P(C_U \leq X \leq C_L) \\ &= P(X \geq C_U) - P(X \geq C_L + 1) \end{aligned}$$

The probabilities are computed using Johnson and Kotz (1970, equation 3.20).

For the METHOD=NORMAL option, the test statistic $Z_{cL}(X)$ is assumed to have the normal distribution $N(\mu_L, \sigma_L^2)$, and $Z_{cU}(X)$ is assumed to have the normal distribution $N(\mu_U, \sigma_U^2)$, where μ_L , μ_U , σ_L^2 , and σ_U^2 are derived as follows.

For convenience of notation, define

$$\begin{aligned} k_L &= \frac{1}{2\sqrt{N\theta_L(1 - \theta_L)}} \\ k_U &= \frac{1}{2\sqrt{N\theta_U(1 - \theta_U)}} \end{aligned}$$

Then

$$\begin{aligned} E[Z_{cL}(X)] &\approx 2k_L Np - 2k_L N\theta_L + k_L P(X < N\theta_L) - k_L P(X > N\theta_L) \\ E[Z_{cU}(X)] &\approx 2k_U Np - 2k_U N\theta_U + k_U P(X < N\theta_U) - k_U P(X > N\theta_U) \end{aligned}$$

and

$$\begin{aligned}\text{Var}[Z_{cL}(X)] &\approx 4k_L^2 Np(1-p) + k_L^2 [1 - P(X = N\theta_L)] - k_L^2 [P(X < N\theta_L) - P(X > N\theta_L)]^2 \\ &\quad + 4k_L^2 [E(X1_{\{X < N\theta_L\}}) - E(X1_{\{X > N\theta_L\}})] - 4k_L^2 Np [P(X < N\theta_L) - P(X > N\theta_L)] \\ \text{Var}[Z_{cU}(X)] &\approx 4k_U^2 Np(1-p) + k_U^2 [1 - P(X = N\theta_U)] - k_U^2 [P(X < N\theta_U) - P(X > N\theta_U)]^2 \\ &\quad + 4k_U^2 [E(X1_{\{X < N\theta_U\}}) - E(X1_{\{X > N\theta_U\}})] - 4k_U^2 Np [P(X < N\theta_U) - P(X > N\theta_U)]\end{aligned}$$

The probabilities $P(X = N\theta_L)$, $P(X < N\theta_L)$, $P(X > N\theta_L)$, $P(X = N\theta_U)$, $P(X < N\theta_U)$, and $P(X > N\theta_U)$ and the truncated expectations $E(X1_{\{X < N\theta_L\}})$, $E(X1_{\{X > N\theta_L\}})$, $E(X1_{\{X < N\theta_U\}})$, and $E(X1_{\{X > N\theta_U\}})$ are approximated by assuming the normal-approximate distribution of X , $N(Np, Np(1-p))$. Letting $\phi(\cdot)$ and $\Phi(\cdot)$ denote the standard normal PDF and CDF, respectively, and defining d_L and d_U as

$$\begin{aligned}d_L &= \frac{N\theta_L - Np}{[Np(1-p)]^{\frac{1}{2}}} \\ d_U &= \frac{N\theta_U - Np}{[Np(1-p)]^{\frac{1}{2}}}\end{aligned}$$

the terms are computed as follows:

$$\begin{aligned}P(X = N\theta_L) &= 0 \\ P(X = N\theta_U) &= 0 \\ P(X < N\theta_L) &= \Phi(d_L) \\ P(X < N\theta_U) &= \Phi(d_U) \\ P(X > N\theta_L) &= 1 - \Phi(d_L) \\ P(X > N\theta_U) &= 1 - \Phi(d_U) \\ E(X1_{\{X < N\theta_L\}}) &= Np\Phi(d_L) - [Np(1-p)]^{\frac{1}{2}}\phi(d_L) \\ E(X1_{\{X < N\theta_U\}}) &= Np\Phi(d_U) - [Np(1-p)]^{\frac{1}{2}}\phi(d_U) \\ E(X1_{\{X > N\theta_L\}}) &= Np[1 - \Phi(d_L)] + [Np(1-p)]^{\frac{1}{2}}\phi(d_L) \\ E(X1_{\{X > N\theta_U\}}) &= Np[1 - \Phi(d_U)] + [Np(1-p)]^{\frac{1}{2}}\phi(d_U)\end{aligned}$$

The mean and variance of $Z_{cL}(X)$ and $Z_{cU}(X)$ are thus approximated by

$$\begin{aligned}\mu_L &= k_L [2Np - 2N\theta_L + 2\Phi(d_L) - 1] \\ \mu_U &= k_U [2Np - 2N\theta_U + 2\Phi(d_U) - 1]\end{aligned}$$

and

$$\begin{aligned}\sigma_L^2 &= 4k_L^2 [Np(1-p) + \Phi(d_L)(1 - \Phi(d_L)) - 2(Np(1-p))^{\frac{1}{2}}\phi(d_L)] \\ \sigma_U^2 &= 4k_U^2 [Np(1-p) + \Phi(d_U)(1 - \Phi(d_U)) - 2(Np(1-p))^{\frac{1}{2}}\phi(d_U)]\end{aligned}$$

The approximate power is computed as

$$\text{power} = \Phi\left(\frac{z_\alpha - \mu_U}{\sigma_U}\right) + \Phi\left(\frac{z_\alpha + \mu_L}{\sigma_L}\right) - 1$$

The approximate sample size is computed by numerically inverting the power formula.

**z Equivalence Test for Binomial Proportion with Continuity Adjustment Using Sample Variance
(TEST=EQUIV_ADJZ VAREST=SAMPLE)**

The hypotheses for the equivalence test are

$$H_0: p < \theta_L \quad \text{or} \quad p > \theta_U$$

$$H_1: \theta_L \leq p \leq \theta_U$$

where θ_L and θ_U are the lower and upper equivalence bounds, respectively.

The analysis is the two one-sided tests (TOST) procedure as described in Chow, Shao, and Wang (2003) on p. 84.

Two different hypothesis tests are carried out:

$$H_{a0}: p < \theta_L$$

$$H_{a1}: p \geq \theta_L$$

and

$$H_{b0}: p > \theta_U$$

$$H_{b1}: p \leq \theta_U$$

If H_{a0} is rejected in favor of H_{a1} and H_{b0} is rejected in favor of H_{b1} , then H_0 is rejected in favor of H_1 .

The test statistic for the test of H_{a0} versus H_{a1} is

$$Z_{csL}(X) = \frac{X - N\theta_L + 0.5(1_{\{X < N\theta_L\}}) - 0.5(1_{\{X > N\theta_L\}})}{[N\hat{p}(1 - \hat{p})]^{\frac{1}{2}}}$$

where $\hat{p} = X/N$.

The test statistic for the test of H_{b0} versus H_{b1} is

$$Z_{csU}(X) = \frac{X - N\theta_U + 0.5(1_{\{X < N\theta_U\}}) - 0.5(1_{\{X > N\theta_U\}})}{[N\hat{p}(1 - \hat{p})]^{\frac{1}{2}}}$$

For the METHOD=EXACT option, let C_U denote the critical value of the exact upper one-sided test of H_{a0} versus H_{a1} using $Z_{csL}(X)$. This critical value is computed in the section “z Test for Binomial Proportion with Continuity Adjustment Using Sample Variance (TEST=ADJZ VAREST=SAMPLE)” on page 6040. Similarly, let C_L denote the critical value of the exact lower one-sided test of H_{b0} versus H_{b1} using $Z_{csU}(X)$. Both of these tests are rejected if and only if $C_U \leq X \leq C_L$. Thus, the exact power of the equivalence test is

$$\begin{aligned} \text{power} &= P(C_U \leq X \leq C_L) \\ &= P(X \geq C_U) - P(X \geq C_L + 1) \end{aligned}$$

The probabilities are computed using Johnson and Kotz (1970, equation 3.20).

For the METHOD=NORMAL option, the test statistic $Z_{csL}(X)$ is assumed to have the normal distribution $N(\mu_L, \sigma_L^2)$, and $Z_{csU}(X)$ is assumed to have the normal distribution $N(\mu_U, \sigma_U^2)$, where μ_L , μ_U , σ_L^2 and σ_U^2 are derived as follows.

For convenience of notation, define

$$k = \frac{1}{2\sqrt{Np(1-p)}}$$

Then

$$E[Z_{csL}(X)] \approx 2kNp - 2kN\theta_L + kP(X < N\theta_L) - kP(X > N\theta_L)$$

$$E[Z_{csU}(X)] \approx 2kNp - 2kN\theta_U + kP(X < N\theta_U) - kP(X > N\theta_U)$$

and

$$\begin{aligned} \text{Var}[Z_{csL}(X)] &\approx 4k^2Np(1-p) + k^2[1 - P(X = N\theta_L)] - k^2[P(X < N\theta_L) - P(X > N\theta_L)]^2 \\ &\quad + 4k^2[E(X1_{\{X < N\theta_L\}}) - E(X1_{\{X > N\theta_L\}})] - 4k^2Np[P(X < N\theta_L) - P(X > N\theta_L)] \\ \text{Var}[Z_{csU}(X)] &\approx 4k^2Np(1-p) + k^2[1 - P(X = N\theta_U)] - k^2[P(X < N\theta_U) - P(X > N\theta_U)]^2 \\ &\quad + 4k^2[E(X1_{\{X < N\theta_U\}}) - E(X1_{\{X > N\theta_U\}})] - 4k^2Np[P(X < N\theta_U) - P(X > N\theta_U)] \end{aligned}$$

The probabilities $P(X = N\theta_L)$, $P(X < N\theta_L)$, $P(X > N\theta_L)$, $P(X = N\theta_U)$, $P(X < N\theta_U)$, and $P(X > N\theta_U)$ and the truncated expectations $E(X1_{\{X < N\theta_L\}})$, $E(X1_{\{X > N\theta_L\}})$, $E(X1_{\{X < N\theta_U\}})$, and $E(X1_{\{X > N\theta_U\}})$ are approximated by assuming the normal-approximate distribution of X , $N(Np, Np(1-p))$. Letting $\phi(\cdot)$ and $\Phi(\cdot)$ denote the standard normal PDF and CDF, respectively, and defining d_L and d_U as

$$\begin{aligned} d_L &= \frac{N\theta_L - Np}{[Np(1-p)]^{\frac{1}{2}}} \\ d_U &= \frac{N\theta_U - Np}{[Np(1-p)]^{\frac{1}{2}}} \end{aligned}$$

the terms are computed as follows:

$$\begin{aligned} P(X = N\theta_L) &= 0 \\ P(X = N\theta_U) &= 0 \\ P(X < N\theta_L) &= \Phi(d_L) \\ P(X < N\theta_U) &= \Phi(d_U) \\ P(X > N\theta_L) &= 1 - \Phi(d_L) \\ P(X > N\theta_U) &= 1 - \Phi(d_U) \\ E(X1_{\{X < N\theta_L\}}) &= Np\Phi(d_L) - [Np(1-p)]^{\frac{1}{2}}\phi(d_L) \\ E(X1_{\{X < N\theta_U\}}) &= Np\Phi(d_U) - [Np(1-p)]^{\frac{1}{2}}\phi(d_U) \\ E(X1_{\{X > N\theta_L\}}) &= Np[1 - \Phi(d_L)] + [Np(1-p)]^{\frac{1}{2}}\phi(d_L) \\ E(X1_{\{X > N\theta_U\}}) &= Np[1 - \Phi(d_U)] + [Np(1-p)]^{\frac{1}{2}}\phi(d_U) \end{aligned}$$

The mean and variance of $Z_{csL}(X)$ and $Z_{csU}(X)$ are thus approximated by

$$\begin{aligned}\mu_L &= k [2Np - 2N\theta_L + 2\Phi(d_L) - 1] \\ \mu_U &= k [2Np - 2N\theta_U + 2\Phi(d_U) - 1]\end{aligned}$$

and

$$\begin{aligned}\sigma_L^2 &= 4k^2 \left[Np(1-p) + \Phi(d_L)(1-\Phi(d_L)) - 2(Np(1-p))^{\frac{1}{2}}\phi(d_L) \right] \\ \sigma_U^2 &= 4k^2 \left[Np(1-p) + \Phi(d_U)(1-\Phi(d_U)) - 2(Np(1-p))^{\frac{1}{2}}\phi(d_U) \right]\end{aligned}$$

The approximate power is computed as

$$\text{power} = \Phi\left(\frac{z_\alpha - \mu_U}{\sigma_U}\right) + \Phi\left(\frac{z_\alpha + \mu_L}{\sigma_L}\right) - 1$$

The approximate sample size is computed by numerically inverting the power formula.

Wilson Score Confidence Interval for Binomial Proportion (CI=WILSON)

The two-sided $100(1-\alpha)\%$ confidence interval for p is

$$\frac{X + \frac{z_{1-\alpha/2}^2}{2}}{N + z_{1-\alpha/2}^2} \pm \frac{z_{1-\alpha/2} N^{\frac{1}{2}}}{N + z_{1-\alpha/2}^2} \left(\hat{p}(1-\hat{p}) + \frac{z_{1-\alpha/2}^2}{4N} \right)^{\frac{1}{2}}$$

So the half-width for the two-sided $100(1-\alpha)\%$ confidence interval is

$$\text{half-width} = \frac{z_{1-\alpha/2} N^{\frac{1}{2}}}{N + z_{1-\alpha/2}^2} \left(\hat{p}(1-\hat{p}) + \frac{z_{1-\alpha/2}^2}{4N} \right)^{\frac{1}{2}}$$

Prob(Width) is calculated exactly by adding up the probabilities of observing each $X \in \{1, \dots, N\}$ that produces a confidence interval whose half-width is at most a target value h :

$$\text{Prob(Width)} = \sum_{i=0}^N P(X = i) 1_{\text{half-width} < h}$$

For references and more details about this and all other confidence intervals associated with the **CI=** option, see “[Binomial Proportion](#)” on page 2565 of Chapter 38, “[The FREQ Procedure](#).”

Agresti-Coull “Add k Successes and Failures” Confidence Interval for Binomial Proportion (CI=AGRESTICOULL)

The two-sided $100(1 - \alpha)\%$ confidence interval for p is

$$\frac{X + \frac{z_{1-\alpha/2}^2}{2}}{N + z_{1-\alpha/2}^2} \pm z_{1-\alpha/2} \left(\frac{\frac{X + \frac{z_{1-\alpha/2}^2}{2}}{N + z_{1-\alpha/2}^2} \left(1 - \frac{X + \frac{z_{1-\alpha/2}^2}{2}}{N + z_{1-\alpha/2}^2} \right)}{N + z_{1-\alpha/2}^2} \right)^{\frac{1}{2}}$$

So the half-width for the two-sided $100(1 - \alpha)\%$ confidence interval is

$$\text{half-width} = z_{1-\alpha/2} \left(\frac{\frac{X + \frac{z_{1-\alpha/2}^2}{2}}{N + z_{1-\alpha/2}^2} \left(1 - \frac{X + \frac{z_{1-\alpha/2}^2}{2}}{N + z_{1-\alpha/2}^2} \right)}{N + z_{1-\alpha/2}^2} \right)^{\frac{1}{2}}$$

Prob(Width) is calculated exactly by adding up the probabilities of observing each $X \in \{1, \dots, N\}$ that produces a confidence interval whose half-width is at most a target value h :

$$\text{Prob(Width)} = \sum_{i=0}^N P(X = i) 1_{\text{half-width} < h}$$

Jeffreys Confidence Interval for Binomial Proportion (CI=JEFFREYS)

The two-sided $100(1 - \alpha)\%$ confidence interval for p is

$$[L_J(X), U_J(X)]$$

where

$$L_J(X) = \begin{cases} 0, & X = 0 \\ \text{Beta}_{\alpha/2; X+1/2, N-X+1/2}, & X > 0 \end{cases}$$

and

$$U_J(X) = \begin{cases} \text{Beta}_{1-\alpha/2; X+1/2, N-X+1/2}, & X < N \\ 1, & X = N \end{cases}$$

The half-width of this two-sided $100(1 - \alpha)\%$ confidence interval is defined as half the width of the full interval:

$$\text{half-width} = \frac{1}{2} (U_J(X) - L_J(X))$$

Prob(Width) is calculated exactly by adding up the probabilities of observing each $X \in \{1, \dots, N\}$ that produces a confidence interval whose half-width is at most a target value h :

$$\text{Prob(Width)} = \sum_{i=0}^N P(X = i) 1_{\text{half-width} < h}$$

Exact Clopper-Pearson Confidence Interval for Binomial Proportion (CI=EXACT)

The two-sided $100(1 - \alpha)\%$ confidence interval for p is

$$[L_E(X), U_E(X)]$$

where

$$L_E(X) = \begin{cases} 0, & X = 0 \\ \text{Beta}_{\alpha/2; X, N-X+1}, & X > 0 \end{cases}$$

and

$$U_E(X) = \begin{cases} \text{Beta}_{1-\alpha/2; X+1, N-X}, & X < N \\ 1, & X = N \end{cases}$$

The half-width of this two-sided $100(1 - \alpha)\%$ confidence interval is defined as half the width of the full interval:

$$\text{half-width} = \frac{1}{2} (U_E(X) - L_E(X))$$

Prob(Width) is calculated exactly by adding up the probabilities of observing each $X \in \{1, \dots, N\}$ that produces a confidence interval whose half-width is at most a target value h :

$$\text{Prob(Width)} = \sum_{i=0}^N P(X = i) 1_{\text{half-width} < h}$$

Wald Confidence Interval for Binomial Proportion (CI=WALD)

The two-sided $100(1 - \alpha)\%$ confidence interval for p is

$$\hat{p} \pm z_{1-\alpha/2} \left(\frac{\hat{p}(1 - \hat{p})}{N} \right)^{\frac{1}{2}}$$

So the half-width for the two-sided $100(1 - \alpha)\%$ confidence interval is

$$\text{half-width} = z_{1-\alpha/2} \left(\frac{\hat{p}(1 - \hat{p})}{N} \right)^{\frac{1}{2}}$$

Prob(Width) is calculated exactly by adding up the probabilities of observing each $X \in \{1, \dots, N\}$ that produces a confidence interval whose half-width is at most a target value h :

$$\text{Prob(Width)} = \sum_{i=0}^N P(X = i) 1_{\text{half-width} < h}$$

Continuity-Corrected Wald Confidence Interval for Binomial Proportion (CI=WALD_CORRECT)

The two-sided $100(1 - \alpha)\%$ confidence interval for p is

$$\hat{p} \pm \left[z_{1-\alpha/2} \left(\frac{\hat{p}(1 - \hat{p})}{N} \right)^{\frac{1}{2}} + \frac{1}{2N} \right]$$

So the half-width for the two-sided $100(1 - \alpha)\%$ confidence interval is

$$\text{half-width} = z_{1-\alpha/2} \left(\frac{\hat{p}(1 - \hat{p})}{N} \right)^{\frac{1}{2}} + \frac{1}{2N}$$

Prob(Width) is calculated exactly by adding up the probabilities of observing each $X \in \{1, \dots, N\}$ that produces a confidence interval whose half-width is at most a target value h :

$$\text{Prob(Width)} = \sum_{i=0}^N P(X = i) 1_{\text{half-width} < h}$$

Analyses in the ONESAMPLEMEANS Statement

One-Sample t Test (TEST=T)

The hypotheses for the one-sample t test are

$$H_0: \mu = \mu_0$$

$$H_1: \begin{cases} \mu \neq \mu_0, & \text{two-sided} \\ \mu > \mu_0, & \text{upper one-sided} \\ \mu < \mu_0, & \text{lower one-sided} \end{cases}$$

The test assumes normally distributed data and requires $N \geq 2$. The test statistics are

$$t = N^{\frac{1}{2}} \left(\frac{\bar{x} - \mu_0}{s} \right) \sim t(N - 1, \delta)$$

$$t^2 \sim F(1, N - 1, \delta^2)$$

where \bar{x} is the sample mean, s is the sample standard deviation, and

$$\delta = N^{\frac{1}{2}} \left(\frac{\mu - \mu_0}{\sigma} \right)$$

The test is

$$\text{Reject } H_0 \quad \text{if} \quad \begin{cases} t^2 \geq F_{1-\alpha}(1, N - 1), & \text{two-sided} \\ t \geq t_{1-\alpha}(N - 1), & \text{upper one-sided} \\ t \leq t_{\alpha}(N - 1), & \text{lower one-sided} \end{cases}$$

Exact power computations for t tests are discussed in O'Brien and Muller (1993, Section 8.2), although not specifically for the one-sample case. The power is based on the noncentral t and F distributions:

$$\text{power} = \begin{cases} P(F(1, N - 1, \delta^2) \geq F_{1-\alpha}(1, N - 1)), & \text{two-sided} \\ P(t(N - 1, \delta) \geq t_{1-\alpha}(N - 1)), & \text{upper one-sided} \\ P(t(N - 1, \delta) \leq t_{\alpha}(N - 1)), & \text{lower one-sided} \end{cases}$$

Solutions for N , α , and δ are obtained by numerically inverting the power equation. Closed-form solutions for other parameters, in terms of δ , are as follows:

$$\mu = \delta \sigma N^{-\frac{1}{2}} + \mu_0$$

$$\sigma = \begin{cases} \delta^{-1} N^{\frac{1}{2}} (\mu - \mu_0), & |\delta| > 0 \\ \text{undefined}, & \text{otherwise} \end{cases}$$

One-Sample t Test with Lognormal Data (TEST=T DIST=LOGNORMAL)

The lognormal case is handled by reexpressing the analysis equivalently as a normality-based test on the log-transformed data, by using properties of the lognormal distribution as discussed in Johnson, Kotz, and Balakrishnan (1994, Chapter 14). The approaches in the section “One-Sample t Test (TEST=T)” on page 6054 then apply.

In contrast to the usual t test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means. This is because the transformation of a null arithmetic mean of lognormal data to the normal scale depends on the unknown coefficient of variation, resulting in an ill-defined hypothesis on the log-transformed data. Geometric means transform cleanly and are more natural for lognormal data.

The hypotheses for the one-sample t test with lognormal data are

$$H_0: \frac{\gamma}{\gamma_0} = 1$$

$$H_1: \begin{cases} \frac{\gamma}{\gamma_0} \neq 1, & \text{two-sided} \\ \frac{\gamma}{\gamma_0} > 1, & \text{upper one-sided} \\ \frac{\gamma}{\gamma_0} < 1, & \text{lower one-sided} \end{cases}$$

Let μ^* and σ^* be the (arithmetic) mean and standard deviation of the normal distribution of the log-transformed data. The hypotheses can be rewritten as follows:

$$H_0: \mu^* = \log(\gamma_0)$$

$$H_1: \begin{cases} \mu^* \neq \log(\gamma_0), & \text{two-sided} \\ \mu^* > \log(\gamma_0), & \text{upper one-sided} \\ \mu^* < \log(\gamma_0), & \text{lower one-sided} \end{cases}$$

where $\mu^* = \log(\gamma)$.

The test assumes lognormally distributed data and requires $N \geq 2$.

The power is

$$\text{power} = \begin{cases} P(F(1, N-1, \delta^2) \geq F_{1-\alpha}(1, N-1)), & \text{two-sided} \\ P(t(N-1, \delta) \geq t_{1-\alpha}(N-1)), & \text{upper one-sided} \\ P(t(N-1, \delta) \leq t_{\alpha}(N-1)), & \text{lower one-sided} \end{cases}$$

where

$$\delta = N^{\frac{1}{2}} \left(\frac{\mu^* - \log(\gamma_0)}{\sigma^*} \right)$$

$$\sigma^* = [\log(\text{CV}^2 + 1)]^{\frac{1}{2}}$$

Equivalence Test for Mean of Normal Data (TEST=EQUIV DIST=NORMAL)

The hypotheses for the equivalence test are

$$H_0: \mu < \theta_L \quad \text{or} \quad \mu > \theta_U$$

$$H_1: \theta_L \leq \mu \leq \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987). The test assumes normally distributed data and requires $N \geq 2$. Phillips (1990) derives an expression for the exact power assuming a two-sample balanced design; the results are easily adapted to a one-sample design:

$$\text{power} = Q_{N-1} \left((-t_{1-\alpha}(N-1)), \frac{\mu - \theta_U}{\sigma N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) - \\ Q_{N-1} \left((t_{1-\alpha}(N-1)), \frac{\mu - \theta_L}{\sigma N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right)$$

where $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the section "Common Notation" on page 6027.

Equivalence Test for Mean of Lognormal Data (TEST=EQUIV DIST=LOGNORMAL)

The lognormal case is handled by reexpressing the analysis equivalently as a normality-based test on the log-transformed data, by using properties of the lognormal distribution as discussed in Johnson, Kotz, and Balakrishnan (1994, Chapter 14). The approaches in the section "Equivalence Test for Mean of Normal Data (TEST=EQUIV DIST=NORMAL)" on page 6055 then apply.

In contrast to the additive equivalence test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means. This is because the transformation of an arithmetic mean of lognormal data to the normal scale depends on the unknown coefficient of variation, resulting in an ill-defined hypothesis on the log-transformed data. Geometric means transform cleanly and are more natural for lognormal data.

The hypotheses for the equivalence test are

$$H_0: \gamma \leq \theta_L \quad \text{or} \quad \gamma \geq \theta_U \\ H_1: \theta_L < \gamma < \theta_U$$

$$\text{where } 0 < \theta_L < \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987) on the log-transformed data. The test assumes lognormally distributed data and requires $N \geq 2$. Diletti, Hauschke, and Steinijans (1991) derive an expression for the exact power assuming a crossover design; the results are easily adapted to a one-sample design:

$$\text{power} = Q_{N-1} \left((-t_{1-\alpha}(N-1)), \frac{\log(\gamma) - \log(\theta_U)}{\sigma^* N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) - \\ Q_{N-1} \left((t_{1-\alpha}(N-1)), \frac{\log(\gamma) - \log(\theta_L)}{\sigma^* N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right)$$

where

$$\sigma^* = [\log(CV^2 + 1)]^{\frac{1}{2}}$$

is the standard deviation of the log-transformed data, and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the section "Common Notation" on page 6027.

Confidence Interval for Mean (CI=T)

This analysis of precision applies to the standard t -based confidence interval:

$$\begin{cases} \left[\bar{x} - t_{1-\frac{\alpha}{2}}(N-1)\frac{s}{\sqrt{N}}, \bar{x} + t_{1-\frac{\alpha}{2}}(N-1)\frac{s}{\sqrt{N}} \right], & \text{two-sided} \\ \left[\bar{x} - t_{1-\alpha}(N-1)\frac{s}{\sqrt{N}}, \infty \right), & \text{upper one-sided} \\ \left(-\infty, \bar{x} + t_{1-\alpha}(N-1)\frac{s}{\sqrt{N}} \right], & \text{lower one-sided} \end{cases}$$

where \bar{x} is the sample mean and s is the sample standard deviation. The “half-width” is defined as the distance from the point estimate \bar{x} to a finite endpoint,

$$\text{half-width} = \begin{cases} t_{1-\frac{\alpha}{2}}(N-1)\frac{s}{\sqrt{N}}, & \text{two-sided} \\ t_{1-\alpha}(N-1)\frac{s}{\sqrt{N}}, & \text{one-sided} \end{cases}$$

A “valid” confidence interval captures the true mean. The exact probability of obtaining at most the target confidence interval half-width h , unconditional or conditional on validity, is given by Beal (1989):

$$\begin{aligned} \Pr(\text{half-width} \leq h) &= \begin{cases} P\left(\chi^2(N-1) \leq \frac{h^2 N(N-1)}{\sigma^2(t_{1-\frac{\alpha}{2}}^2(N-1))}\right), & \text{two-sided} \\ P\left(\chi^2(N-1) \leq \frac{h^2 N(N-1)}{\sigma^2(t_{1-\alpha}^2(N-1))}\right), & \text{one-sided} \end{cases} \\ \Pr(\text{half-width} \leq h \mid \text{validity}) &= \begin{cases} \left(\frac{1}{1-\alpha}\right) 2 \left[Q_{N-1}\left((t_{1-\frac{\alpha}{2}}(N-1)), 0; 0, b_1\right) - Q_{N-1}(0, 0; 0, b_1) \right], & \text{two-sided} \\ \left(\frac{1}{1-\alpha}\right) Q_{N-1}((t_{1-\alpha}(N-1)), 0; 0, b_1), & \text{one-sided} \end{cases} \end{aligned}$$

where

$$b_1 = \frac{h(N-1)^{\frac{1}{2}}}{\sigma(t_{1-\frac{\alpha}{c}}(N-1))N^{-\frac{1}{2}}}$$

c = number of sides

and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen’s Q function, defined in the section “Common Notation” on page 6027.

A “quality” confidence interval is both sufficiently narrow (half-width $\leq h$) and valid:

$$\begin{aligned} \Pr(\text{quality}) &= \Pr(\text{half-width} \leq h \text{ and validity}) \\ &= \Pr(\text{half-width} \leq h \mid \text{validity})(1 - \alpha) \end{aligned}$$

Analyses in the ONEWAYANOVA Statement**One-Degree-of-Freedom Contrast (TEST=CONTRAST)**

The hypotheses are

$$\begin{aligned} H_0: c_1\mu_1 + \cdots + c_G\mu_G &= c_0 \\ H_1: \begin{cases} c_1\mu_1 + \cdots + c_G\mu_G \neq c_0, & \text{two-sided} \\ c_1\mu_1 + \cdots + c_G\mu_G > c_0, & \text{upper one-sided} \\ c_1\mu_1 + \cdots + c_G\mu_G < c_0, & \text{lower one-sided} \end{cases} \end{aligned}$$

where G is the number of groups, $\{c_1, \dots, c_G\}$ are the contrast coefficients, and c_0 is the null contrast value.

The test is the usual F test for a contrast in one-way ANOVA. It assumes normal data with common group variances and requires $N \geq G + 1$ and $n_i \geq 1$.

O'Brien and Muller (1993, Section 8.2.3.2) give the exact power as

$$\text{power} = \begin{cases} P(F(1, N - G, \delta^2) \geq F_{1-\alpha}(1, N - G)), & \text{two-sided} \\ P(t(N - G, \delta) \geq t_{1-\alpha}(N - G)), & \text{upper one-sided} \\ P(t(N - G, \delta) \leq t_{\alpha}(N - G)), & \text{lower one-sided} \end{cases}$$

where

$$\delta = N^{\frac{1}{2}} \left(\frac{\sum_{i=1}^G c_i \mu_i - c_0}{\sigma \left(\sum_{i=1}^G \frac{c_i^2}{w_i} \right)^{\frac{1}{2}}} \right)$$

Overall F Test (TEST=OVERALL)

The hypotheses are

$$H_0: \mu_1 = \mu_2 = \dots = \mu_G$$

$$H_1: \mu_i \neq \mu_j \text{ for some } i, j$$

where G is the number of groups.

The test is the usual overall F test for equality of means in one-way ANOVA. It assumes normal data with common group variances and requires $N \geq G + 1$ and $n_i \geq 1$.

O'Brien and Muller (1993, Section 8.2.3.1) give the exact power as

$$\text{power} = P(F(G - 1, N - G, \lambda) \geq F_{1-\alpha}(G - 1, N - G))$$

where the noncentrality is

$$\lambda = N \left(\frac{\sum_{i=1}^G w_i (\mu_i - \bar{\mu})^2}{\sigma^2} \right)$$

and

$$\bar{\mu} = \sum_{i=1}^G w_i \mu_i$$

Analyses in the PAIREDFREQ Statement

Overview of Conditional McNemar tests

Notation:

		Case		
		Failure	Success	
Control	Failure	n_{00}	n_{01}	$n_{0\cdot}$
	Success	n_{10}	n_{11}	$n_{1\cdot}$
		$n_{\cdot 0}$	$n_{\cdot 1}$	N

$$n_{00} = \#\{\text{control}=\text{failure}, \text{case}=\text{failure} \}$$

$$n_{01} = \#\{\text{control}=\text{failure}, \text{case}=\text{success} \}$$

$$n_{10} = \#\{\text{control}=\text{success}, \text{case}=\text{failure} \}$$

$$n_{11} = \#\{\text{control}=\text{success}, \text{case}=\text{success} \}$$

$$N = n_{00} + n_{01} + n_{10} + n_{11}$$

$$n_D = n_{01} + n_{10} \equiv \# \text{ discordant pairs}$$

$$\hat{\pi}_{ij} = \frac{n_{ij}}{N}$$

$$\pi_{ij} = \text{theoretical population value of } \hat{\pi}_{ij}$$

$$\pi_{1\cdot} = \pi_{10} + \pi_{11}$$

$$\pi_{\cdot 1} = \pi_{01} + \pi_{11}$$

$$\phi = \text{Corr}(\text{control observation}, \text{case observation}) \quad (\text{within a pair})$$

$$\text{DPR} = \text{“discordant proportion ratio”} = \frac{\pi_{01}}{\pi_{10}}$$

$$\text{DPR}_0 = \text{null DPR}$$

Power formulas are given here in terms of the discordant proportions π_{10} and π_{01} . If the input is specified in terms of $\{\pi_{1\cdot}, \pi_{\cdot 1}, \phi\}$, then it can be converted into values for $\{\pi_{10}, \pi_{01}\}$ as follows:

$$\pi_{01} = \pi_{\cdot 1}(1 - \pi_{1\cdot}) - \phi((1 - \pi_{1\cdot})\pi_{1\cdot}(1 - \pi_{\cdot 1})\pi_{\cdot 1})^{\frac{1}{2}}$$

$$\pi_{10} = \pi_{01} + \pi_{1\cdot} - \pi_{\cdot 1}$$

All McNemar tests covered in PROC POWER are *conditional*, meaning that n_D is assumed fixed at its observed value.

For the usual $\text{DPR}_0 = 1$, the hypotheses are

$$H_0: \pi_{\cdot 1} = \pi_{1\cdot}$$

$$H_1: \begin{cases} \pi_{\cdot 1} \neq \pi_{1\cdot}, & \text{two-sided} \\ \pi_{\cdot 1} > \pi_{1\cdot}, & \text{upper one-sided} \\ \pi_{\cdot 1} < \pi_{1\cdot}, & \text{lower one-sided} \end{cases}$$

The test statistic for both tests covered in PROC POWER (DIST=EXACT_COND and DIST=NORMAL) is the McNemar statistic Q_M , which has the following form when $DPR_0 = 1$:

$$Q_{M_0} = \frac{(n_{01} - n_{10})^2}{n_{01} + n_{10}}$$

For the conditional McNemar tests, this is equivalent to the square of the $Z(X)$ statistic for the test of a single proportion (normal approximation to binomial), where the proportion is $\frac{\pi_{01}}{\pi_{01} + \pi_{10}}$, the null is 0.5, and “ N ” is n_D (see, for example, Schork and Williams 1980):

$$\begin{aligned} Z(X) &= \frac{n_{01} - n_D(0.5)}{[n_D 0.5(1 - 0.5)]^{\frac{1}{2}}} \sim N \left(\frac{n_D^{\frac{1}{2}} (\frac{\pi_{01}}{\pi_{01} + \pi_{10}} - 0.5)}{[0.5(1 - 0.5)]^{\frac{1}{2}}}, \frac{\frac{\pi_{01}}{\pi_{01} + \pi_{10}} (1 - \frac{\pi_{01}}{\pi_{01} + \pi_{10}})}{0.5(1 - 0.5)} \right) \\ &= \frac{n_{01} - (n_{01} + n_{10})(0.5)}{[(n_{01} + n_{10})0.5(1 - 0.5)]^{\frac{1}{2}}} \\ &= \frac{n_{01} - n_{10}}{[n_{01} + n_{10}]^{\frac{1}{2}}} \\ &= \sqrt{Q_{M_0}} \end{aligned}$$

This can be generalized to a custom null for $\frac{\pi_{01}}{\pi_{01} + \pi_{10}}$, which is equivalent to specifying a custom null DPR:

$$\left[\frac{\pi_{01}}{\pi_{01} + \pi_{10}} \right]_0 \equiv \left[\frac{1}{1 + \frac{1}{\frac{\pi_{01}}{\pi_{10}}}} \right]_0 \equiv \frac{1}{1 + \frac{1}{DPR_0}}$$

So, a conditional McNemar test (asymptotic or exact) with a custom null is equivalent to the test of a single proportion $p_1 \equiv \frac{\pi_{01}}{\pi_{01} + \pi_{10}}$ with a null value $p_0 \equiv \frac{1}{1 + \frac{1}{DPR_0}}$, with a sample size of n_D :

$$\begin{aligned} H_0: p_1 &= p_0 \\ H_1: \begin{cases} p_1 \neq p_0, & \text{two-sided} \\ p_1 > p_0, & \text{one-sided U} \\ p_1 < p_0, & \text{one-sided L} \end{cases} \end{aligned}$$

which is equivalent to

$$\begin{aligned} H_0: DPR &= DPR_0 \\ H_1: \begin{cases} DPR \neq DPR_0, & \text{two-sided} \\ DPR > DPR_0, & \text{one-sided U} \\ DPR < DPR_0, & \text{one-sided L} \end{cases} \end{aligned}$$

The general form of the test statistic is thus

$$Q_M = \frac{(n_{01} - n_D p_0)^2}{n_D p_0 (1 - p_0)}$$

The two most common conditional McNemar tests assume either the exact conditional distribution of Q_M (covered by the DIST=EXACT_COND analysis) or a standard normal distribution for Q_M (covered by the DIST=NORMAL analysis).

McNemar Exact Conditional Test (TEST=MCNEMAR DIST=EXACT_COND)

For DIST=EXACT_COND, the power is calculated assuming that the test is conducted by using the exact conditional distribution of Q_M (conditional on n_D). The power is calculated by first computing the conditional power for each possible n_D . The unconditional power is computed as a weighted average over all possible outcomes of n_D :

$$\text{power} = \sum_{n_D=0}^N P(n_D) P(\text{Reject } p_1 = p_0 | n_D)$$

where $n_D \sim \text{Bin}(\pi_{01} + \pi_{10}, N)$, and $P(\text{Reject } p_1 = p_0 | n_D)$ is calculated by using the exact method in the section “Exact Test of a Binomial Proportion (TEST=EXACT)” on page 6036.

The achieved significance level, reported as “Actual Alpha” in the analysis, is computed in the same way except by using the actual alpha of the one-sample test in place of its power:

$$\text{actual alpha} = \sum_{n_D=0}^N P(n_D) \alpha^*(p_1, p_0 | n_D)$$

where $\alpha^*(p_1, p_0 | n_D)$ is the actual alpha calculated by using the exact method in the section “Exact Test of a Binomial Proportion (TEST=EXACT)” on page 6036 with proportion p_1 , null p_0 , and sample size n_D .

McNemar Normal Approximation Test (TEST=MCNEMAR DIST=NORMAL)

For DIST=NORMAL, power is calculated assuming the test is conducted by using the normal-approximate distribution of Q_M (conditional on n_D).

For the METHOD=EXACT option, the power is calculated in the same way as described in the section “McNemar Exact Conditional Test (TEST=MCNEMAR DIST=EXACT_COND)” on page 6061, except that $P(\text{Reject } p_1 = p_0 | n_D)$ is calculated by using the exact method in the section “z Test for Binomial Proportion Using Null Variance (TEST=Z VAREST=NULL)” on page 6037. The achieved significance level is calculated in the same way as described at the end of the section “McNemar Exact Conditional Test (TEST=MCNEMAR DIST=EXACT_COND)” on page 6061.

For the METHOD=MIETTINEN option, approximate sample size for the one-sided cases is computed according to equation (5.6) in Miettinen (1968):

$$N = \frac{\left\{ z_{1-\alpha}(p_{10} + p_{01}) + z_{\text{power}} \left[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01}) \right]^{\frac{1}{2}} \right\}^2}{(p_{10} + p_{01})(p_{01} - p_{10})^2}$$

Approximate power for the one-sided cases is computed by solving the sample size equation for power, and approximate power for the two-sided case follows easily by summing the one-sided powers each at $\alpha/2$:

$$\text{power} = \begin{cases} \Phi \left(\frac{(p_{01} - p_{10})[N(p_{10} + p_{01})]^{\frac{1}{2}} - z_{1-\alpha}(p_{10} + p_{01})}{[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01})]^{\frac{1}{2}}} \right), & \text{upper one-sided} \\ \Phi \left(\frac{-(p_{01} - p_{10})[N(p_{10} + p_{01})]^{\frac{1}{2}} - z_{1-\alpha}(p_{10} + p_{01})}{[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01})]^{\frac{1}{2}}} \right), & \text{lower one-sided} \\ \Phi \left(\frac{(p_{01} - p_{10})[N(p_{10} + p_{01})]^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}}(p_{10} + p_{01})}{[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01})]^{\frac{1}{2}}} \right) + \\ \Phi \left(\frac{-(p_{01} - p_{10})[N(p_{10} + p_{01})]^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}}(p_{10} + p_{01})}{[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01})]^{\frac{1}{2}}} \right), & \text{two-sided} \end{cases}$$

The two-sided solution for N is obtained by numerically inverting the power equation.

In general, compared to METHOD=CONNOR, the METHOD=MIETTINEN approximation tends to be slightly more accurate but can be slightly anticonservative in the sense of underestimating sample size and overestimating power (Lachin 1992, p. 1250).

For the METHOD=CONNOR option, approximate sample size for the one-sided cases is computed according to equation (3) in Connor (1987):

$$N = \frac{\left\{ z_{1-\alpha}(p_{10} + p_{01})^{\frac{1}{2}} + z_{power} [p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}} \right\}^2}{(p_{01} - p_{10})^2}$$

Approximate power for the one-sided cases is computed by solving the sample size equation for power, and approximate power for the two-sided case follows easily by summing the one-sided powers each at $\alpha/2$:

$$\text{power} = \begin{cases} \Phi \left(\frac{(p_{01} - p_{10})N^{\frac{1}{2}} - z_{1-\alpha}(p_{10} + p_{01})^{\frac{1}{2}}}{[p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}}} \right), & \text{upper one-sided} \\ \Phi \left(\frac{-(p_{01} - p_{10})N^{\frac{1}{2}} - z_{1-\alpha}(p_{10} + p_{01})^{\frac{1}{2}}}{[p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}}} \right), & \text{lower one-sided} \\ \Phi \left(\frac{(p_{01} - p_{10})N^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}}(p_{10} + p_{01})^{\frac{1}{2}}}{[p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}}} \right) + \\ \Phi \left(\frac{-(p_{01} - p_{10})N^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}}(p_{10} + p_{01})^{\frac{1}{2}}}{[p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}}} \right), & \text{two-sided} \end{cases}$$

The two-sided solution for N is obtained by numerically inverting the power equation.

In general, compared to METHOD=MIETTINEN, the METHOD=CONNOR approximation tends to be slightly less accurate but slightly conservative in the sense of overestimating sample size and underestimating power (Lachin 1992, p. 1250).

Analyses in the PAIREDMEANS Statement

Paired t Test (TEST=DIFF)

The hypotheses for the paired t test are

$$\begin{aligned} H_0: \mu_{\text{diff}} &= \mu_0 \\ H_1: \begin{cases} \mu_{\text{diff}} \neq \mu_0, & \text{two-sided} \\ \mu_{\text{diff}} > \mu_0, & \text{upper one-sided} \\ \mu_{\text{diff}} < \mu_0, & \text{lower one-sided} \end{cases} \end{aligned}$$

The test assumes normally distributed data and requires $N \geq 2$. The test statistics are

$$\begin{aligned} t &= N^{\frac{1}{2}} \left(\frac{\bar{d} - \mu_0}{s_d} \right) \sim t(N - 1, \delta) \\ t^2 &\sim F(1, N - 1, \delta^2) \end{aligned}$$

where \bar{d} and s_d are the sample mean and standard deviation of the differences and

$$\delta = N^{\frac{1}{2}} \left(\frac{\mu_{\text{diff}} - \mu_0}{\sigma_{\text{diff}}} \right)$$

and

$$\sigma_{\text{diff}} = (\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2)^{\frac{1}{2}}$$

The test is

$$\text{Reject } H_0 \quad \text{if } \begin{cases} t^2 \geq F_{1-\alpha}(1, N-1), & \text{two-sided} \\ t \geq t_{1-\alpha}(N-1), & \text{upper one-sided} \\ t \leq t_{\alpha}(N-1), & \text{lower one-sided} \end{cases}$$

Exact power computations for t tests are given in O'Brien and Muller (1993, Section 8.2.2):

$$\text{power} = \begin{cases} P(F(1, N-1, \delta^2) \geq F_{1-\alpha}(1, N-1)), & \text{two-sided} \\ P(t(N-1, \delta) \geq t_{1-\alpha}(N-1)), & \text{upper one-sided} \\ P(t(N-1, \delta) \leq t_{\alpha}(N-1)), & \text{lower one-sided} \end{cases}$$

Paired t Test for Mean Ratio with Lognormal Data (TEST=RATIO)

The lognormal case is handled by reexpressing the analysis equivalently as a normality-based test on the log-transformed data, by using properties of the lognormal distribution as discussed in Johnson, Kotz, and Balakrishnan (1994, Chapter 14). The approaches in the section “Paired t Test (TEST=DIFF)” on page 6062 then apply.

In contrast to the usual t test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means.

The hypotheses for the paired t test with lognormal pairs $\{Y_1, Y_2\}$ are

$$H_0: \frac{\gamma_2}{\gamma_1} = \gamma_0$$

$$H_1: \begin{cases} \frac{\gamma_2}{\gamma_1} \neq \gamma_0, & \text{two-sided} \\ \frac{\gamma_2}{\gamma_1} > \gamma_0, & \text{upper one-sided} \\ \frac{\gamma_2}{\gamma_1} < \gamma_0, & \text{lower one-sided} \end{cases}$$

Let μ_1^* , μ_2^* , σ_1^* , σ_2^* , and ρ^* be the (arithmetic) means, standard deviations, and correlation of the bivariate normal distribution of the log-transformed data $\{\log Y_1, \log Y_2\}$. The hypotheses can be rewritten as follows:

$$H_0: \mu_2^* - \mu_1^* = \log(\gamma_0)$$

$$H_1: \begin{cases} \mu_2^* - \mu_1^* \neq \log(\gamma_0), & \text{two-sided} \\ \mu_2^* - \mu_1^* > \log(\gamma_0), & \text{upper one-sided} \\ \mu_2^* - \mu_1^* < \log(\gamma_0), & \text{lower one-sided} \end{cases}$$

where

$$\begin{aligned}\mu_1^* &= \log \gamma_1 \\ \mu_2^* &= \log \gamma_2 \\ \sigma_1^* &= [\log(CV_1^2 + 1)]^{\frac{1}{2}} \\ \sigma_2^* &= [\log(CV_2^2 + 1)]^{\frac{1}{2}} \\ \rho^* &= \frac{\log \{\rho CV_1 CV_2 + 1\}}{\sigma_1^* \sigma_2^*}\end{aligned}$$

and CV_1 , CV_2 , and ρ are the coefficients of variation and the correlation of the original untransformed pairs $\{Y_1, Y_2\}$. The conversion from ρ to ρ^* is shown in Jones and Miller (1966).

The test assumes lognormally distributed data and requires $N \geq 2$. The power is

$$\text{power} = \begin{cases} P(F(1, N-1, \delta^2) \geq F_{1-\alpha}(1, N-1)), & \text{two-sided} \\ P(t(N-1, \delta) \geq t_{1-\alpha}(N-1)), & \text{upper one-sided} \\ P(t(N-1, \delta) \leq t_{\alpha}(N-1)), & \text{lower one-sided} \end{cases}$$

where

$$\delta = N^{\frac{1}{2}} \left(\frac{\mu_1^* - \mu_2^* - \log(\gamma_0)}{\sigma^*} \right)$$

and

$$\sigma^* = (\sigma_1^{*2} + \sigma_2^{*2} - 2\rho^* \sigma_1^* \sigma_2^*)^{\frac{1}{2}}$$

Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)

The hypotheses for the equivalence test are

$$H_0: \mu_{\text{diff}} < \theta_L \quad \text{or} \quad \mu_{\text{diff}} > \theta_U$$

$$H_1: \theta_L \leq \mu_{\text{diff}} \leq \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987). The test assumes normally distributed data and requires $N \geq 2$. Phillips (1990) derives an expression for the exact power assuming a two-sample balanced design; the results are easily adapted to a paired design:

$$\begin{aligned}\text{power} &= Q_{N-1} \left((-t_{1-\alpha}(N-1)), \frac{\mu_{\text{diff}} - \theta_U}{\sigma_{\text{diff}} N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma_{\text{diff}} N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) - \\ &\quad Q_{N-1} \left((t_{1-\alpha}(N-1)), \frac{\mu_{\text{diff}} - \theta_L}{\sigma_{\text{diff}} N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma_{\text{diff}} N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right)\end{aligned}$$

where

$$\sigma_{\text{diff}} = (\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2)^{\frac{1}{2}}$$

and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the section “Common Notation” on page 6027.

Multiplicative Equivalence Test for Mean Ratio with Lognormal Data (TEST=EQUIV_RATIO)

The lognormal case is handled by reexpressing the analysis equivalently as a normality-based test on the log-transformed data, by using properties of the lognormal distribution as discussed in Johnson, Kotz, and Balakrishnan (1994, Chapter 14). The approaches in the section “Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)” on page 6064 then apply.

In contrast to the additive equivalence test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means.

The hypotheses for the equivalence test are

$$H_0: \frac{\gamma_T}{\gamma_R} \leq \theta_L \quad \text{or} \quad \frac{\gamma_T}{\gamma_R} \geq \theta_U$$

$$H_1: \theta_L < \frac{\gamma_T}{\gamma_R} < \theta_U$$

$$\text{where } 0 < \theta_L < \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987) on the log-transformed data. The test assumes lognormally distributed data and requires $N \geq 2$. Diletti, Hauschke, and Steinijans (1991) derive an expression for the exact power assuming a crossover design; the results are easily adapted to a paired design:

$$\begin{aligned} \text{power} = & Q_{N-1} \left((-t_{1-\alpha}(N-1)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_U)}{\sigma^* N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) - \\ & Q_{N-1} \left((t_{1-\alpha}(N-1)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_L)}{\sigma^* N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) \end{aligned}$$

where σ^* is the standard deviation of the differences between the log-transformed pairs (in other words, the standard deviation of $\log(Y_T) - \log(Y_R)$, where Y_T and Y_R are observations from the treatment and reference, respectively), computed as

$$\sigma^* = (\sigma_R^{*2} + \sigma_T^{*2} - 2\rho^* \sigma_R^* \sigma_T^*)^{\frac{1}{2}}$$

$$\sigma_R^* = [\log(\text{CV}_R^2 + 1)]^{\frac{1}{2}}$$

$$\sigma_T^* = [\log(\text{CV}_T^2 + 1)]^{\frac{1}{2}}$$

$$\rho^* = \frac{\log\{\rho \text{CV}_R \text{CV}_T + 1\}}{\sigma_R^* \sigma_T^*}$$

where CV_R , CV_T , and ρ are the coefficients of variation and the correlation of the original untransformed pairs $\{Y_T, Y_R\}$, and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function. The conversion from ρ to ρ^* is shown in Jones and Miller (1966), and Owen's Q function is defined in the section “Common Notation” on page 6027.

Confidence Interval for Mean Difference (CI=DIFF)

This analysis of precision applies to the standard t -based confidence interval:

$$\begin{aligned} & \left[\bar{d} - t_{1-\frac{\alpha}{2}}(N-1) \frac{s_d}{\sqrt{N}}, \quad \bar{d} + t_{1-\frac{\alpha}{2}}(N-1) \frac{s_d}{\sqrt{N}} \right], & \text{two-sided} \\ & \left[\bar{d} - t_{1-\alpha}(N-1) \frac{s_d}{\sqrt{N}}, \quad \infty \right), & \text{upper one-sided} \\ & \left(-\infty, \quad \bar{d} + t_{1-\alpha}(N-1) \frac{s_d}{\sqrt{N}} \right], & \text{lower one-sided} \end{aligned}$$

where \bar{d} and s_d are the sample mean and standard deviation of the differences. The “half-width” is defined as the distance from the point estimate \bar{d} to a finite endpoint,

$$\text{half-width} = \begin{cases} t_{1-\frac{\alpha}{2}}(N-1) \frac{s_d}{\sqrt{N}}, & \text{two-sided} \\ t_{1-\alpha}(N-1) \frac{s_d}{\sqrt{N}}, & \text{one-sided} \end{cases}$$

A “valid” confidence interval captures the true mean difference. The exact probability of obtaining at most the target confidence interval half-width h , unconditional or conditional on validity, is given by Beal (1989):

$$\begin{aligned} \Pr(\text{half-width} \leq h) &= \begin{cases} P\left(\chi^2(N-1) \leq \frac{h^2 N(N-1)}{\sigma_{\text{diff}}^2(t_{1-\frac{\alpha}{2}}^2(N-1))}\right), & \text{two-sided} \\ P\left(\chi^2(N-1) \leq \frac{h^2 N(N-1)}{\sigma_{\text{diff}}^2(t_{1-\alpha}^2(N-1))}\right), & \text{one-sided} \end{cases} \\ \Pr(\text{half-width} \leq h \mid \text{validity}) &= \begin{cases} \left(\frac{1}{1-\alpha}\right) 2 \left[Q_{N-1}\left((t_{1-\frac{\alpha}{2}}(N-1)), 0; 0, b_1\right) - Q_{N-1}(0, 0; 0, b_1) \right], & \text{two-sided} \\ \left(\frac{1}{1-\alpha}\right) Q_{N-1}((t_{1-\alpha}(N-1)), 0; 0, b_1), & \text{one-sided} \end{cases} \end{aligned}$$

where

$$\begin{aligned} \sigma_{\text{diff}} &= (\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2)^{\frac{1}{2}} \\ b_1 &= \frac{h(N-1)^{\frac{1}{2}}}{\sigma_{\text{diff}}(t_{1-\frac{\alpha}{c}}(N-1))N^{-\frac{1}{2}}} \\ c &= \text{number of sides} \end{aligned}$$

and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen’s Q function, defined in the section “[Common Notation](#)” on page 6027.

A “quality” confidence interval is both sufficiently narrow (half-width $\leq h$) and valid:

$$\begin{aligned} \Pr(\text{quality}) &= \Pr(\text{half-width} \leq h \text{ and validity}) \\ &= \Pr(\text{half-width} \leq h \mid \text{validity})(1 - \alpha) \end{aligned}$$

Analyses in the TWOSAMPLEFREQ Statement

Overview of the 2×2 Table

Notation:

		Outcome		
		Failure	Success	
Group	1	$n_1 - x_1$	x_1	n_1
	2	$n_2 - x_2$	x_2	n_2
		$N - m$	m	N

$$\begin{aligned}
x_1 &= \# \text{ successes in group 1} \\
x_2 &= \# \text{ successes in group 2} \\
m &= x_1 + x_2 = \text{total \# successes} \\
\hat{p}_1 &= \frac{x_1}{n_1} \\
\hat{p}_2 &= \frac{x_2}{n_2} \\
\hat{p} &= \frac{m}{N} = w_1 \hat{p}_1 + w_2 \hat{p}_2
\end{aligned}$$

The hypotheses are

$$\begin{aligned}
H_0: p_2 - p_1 &= p_0 \\
H_1: \begin{cases} p_2 - p_1 \neq p_0, & \text{two-sided} \\ p_2 - p_1 > p_0, & \text{upper one-sided} \\ p_2 - p_1 < p_0, & \text{lower one-sided} \end{cases}
\end{aligned}$$

where p_0 is constrained to be 0 for all but the unconditional Pearson chi-square test.

Internal calculations are performed in terms of p_1 , p_2 , and p_0 . An input set consisting of OR, p_1 , and OR_0 is transformed as follows:

$$\begin{aligned}
p_2 &= \frac{(OR)p_1}{1 - p_1 + (OR)p_1} \\
p_{10} &= p_1 \\
p_{20} &= \frac{OR_0 p_{10}}{1 - p_{10} + (OR_0)p_{10}} \\
p_0 &= p_{20} - p_{10}
\end{aligned}$$

An input set consisting of RR, p_1 , and RR_0 is transformed as follows:

$$\begin{aligned}
p_2 &= (RR)p_1 \\
p_{10} &= p_1 \\
p_{20} &= (RR_0)p_{10} \\
p_0 &= p_{20} - p_{10}
\end{aligned}$$

Note that the transformation of either OR_0 or RR_0 to p_0 is not unique. The chosen parameterization fixes the null value p_{10} at the input value of p_1 .

Pearson Chi-Square Test for Two Proportions (TEST=PCHI)

The usual Pearson chi-square test is unconditional. The test statistic

$$z_P = \frac{\hat{p}_2 - \hat{p}_1 - p_0}{\left[\hat{p}(1 - \hat{p}) \left(\frac{1}{n_1} + \frac{1}{n_2} \right) \right]^{\frac{1}{2}}} = [Nw_1w_2]^{\frac{1}{2}} \frac{\hat{p}_2 - \hat{p}_1 - p_0}{\hat{p}(1 - \hat{p})}$$

is assumed to have a null distribution of $N(0, 1)$.

Sample size for the one-sided cases is given by equation (4) in Fleiss, Tytun, and Ury (1980). One-sided power is computed as suggested by Diegert and Diegert (1981) by inverting the sample size formula. Power for the two-sided case is computed by adding the lower-sided and upper-sided powers each with $\alpha/2$, and sample size for the two-sided case is obtained by numerically inverting the power formula. A custom null value p_0 for the proportion difference $p_2 - p_1$ is also supported.

$$\text{power} = \begin{cases} \Phi \left(\frac{(p_2 - p_1 - p_0)(N w_1 w_2)^{\frac{1}{2}} - z_{1-\alpha} [(w_1 p_1 + w_2 p_2)(1 - w_1 p_1 - w_2 p_2)]^{\frac{1}{2}}}{[w_2 p_1 (1 - p_1) + w_1 p_2 (1 - p_2)]^{\frac{1}{2}}} \right), & \text{upper one-sided} \\ \Phi \left(\frac{-(p_2 - p_1 - p_0)(N w_1 w_2)^{\frac{1}{2}} - z_{1-\alpha} [(w_1 p_1 + w_2 p_2)(1 - w_1 p_1 - w_2 p_2)]^{\frac{1}{2}}}{[w_2 p_1 (1 - p_1) + w_1 p_2 (1 - p_2)]^{\frac{1}{2}}} \right), & \text{lower one-sided} \\ \Phi \left(\frac{(p_2 - p_1 - p_0)(N w_1 w_2)^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}} [(w_1 p_1 + w_2 p_2)(1 - w_1 p_1 - w_2 p_2)]^{\frac{1}{2}}}{[w_2 p_1 (1 - p_1) + w_1 p_2 (1 - p_2)]^{\frac{1}{2}}} \right) + \\ \Phi \left(\frac{-(p_2 - p_1 - p_0)(N w_1 w_2)^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}} [(w_1 p_1 + w_2 p_2)(1 - w_1 p_1 - w_2 p_2)]^{\frac{1}{2}}}{[w_2 p_1 (1 - p_1) + w_1 p_2 (1 - p_2)]^{\frac{1}{2}}} \right), & \text{two-sided} \end{cases}$$

For the one-sided cases, a closed-form inversion of the power equation yield an approximate total sample size

$$N = \frac{\left[z_{1-\alpha} \{ (w_1 p_1 + w_2 p_2)(1 - w_1 p_1 - w_2 p_2) \}^{\frac{1}{2}} + z_{\text{power}} \{ w_2 p_1 (1 - p_1) + w_1 p_2 (1 - p_2) \}^{\frac{1}{2}} \right]^2}{w_1 w_2 (p_2 - p_1 - p_0)^2}$$

For the two-sided case, the solution for N is obtained by numerically inverting the power equation.

Likelihood Ratio Chi-Square Test for Two Proportions (TEST=LRCHI)

The usual likelihood ratio chi-square test is unconditional. The test statistic

$$z_{\text{LR}} = (-1_{\{p_2 < p_1\}}) \sqrt{2N \sum_{i=1}^2 \left[w_i \hat{p}_i \log \left(\frac{\hat{p}_i}{\hat{p}} \right) + w_i (1 - \hat{p}_i) \log \left(\frac{1 - \hat{p}_i}{1 - \hat{p}} \right) \right]}$$

is assumed to have a null distribution of $N(0, 1)$ and an alternative distribution of $N(\delta, 1)$, where

$$\delta = N^{\frac{1}{2}} (-1_{\{p_2 < p_1\}}) \sqrt{2 \sum_{i=1}^2 \left[w_i p_i \log \left(\frac{p_i}{w_1 p_1 + w_2 p_2} \right) + w_i (1 - p_i) \log \left(\frac{1 - p_i}{1 - (w_1 p_1 + w_2 p_2)} \right) \right]}$$

The approximate power is

$$\text{power} = \begin{cases} \Phi(\delta - z_{1-\alpha}), & \text{upper one-sided} \\ \Phi(-\delta - z_{1-\alpha}), & \text{lower one-sided} \\ \Phi(\delta - z_{1-\frac{\alpha}{2}}) + \Phi(-\delta - z_{1-\frac{\alpha}{2}}), & \text{two-sided} \end{cases}$$

For the one-sided cases, a closed-form inversion of the power equation yield an approximate total sample size

$$N = \left(\frac{z_{\text{power}} + z_{1-\alpha}}{\delta} \right)^2$$

For the two-sided case, the solution for N is obtained by numerically inverting the power equation.

Fisher's Exact Conditional Test for Two Proportions (Test=FISHER)

Fisher's exact test is conditional on the observed total number of successes m . Power and sample size computations are based on a test with similar power properties, the continuity-adjusted arcsine test. The test statistic

$$z_A = (4Nw_1w_2)^{\frac{1}{2}} \left[\arcsin \left(\left[\hat{p}_2 + \frac{1}{2Nw_2} (1_{\{\hat{p}_2 < \hat{p}_1\}} - 1_{\{\hat{p}_2 > \hat{p}_1\}}) \right]^{\frac{1}{2}} \right) - \arcsin \left(\left[\hat{p}_1 + \frac{1}{2Nw_1} (1_{\{\hat{p}_1 < \hat{p}_2\}} - 1_{\{\hat{p}_1 > \hat{p}_2\}}) \right]^{\frac{1}{2}} \right) \right]$$

is assumed to have a null distribution of $N(0, 1)$ and an alternative distribution of $N(\delta, 1)$, where

$$\delta = (4Nw_1w_2)^{\frac{1}{2}} \left[\arcsin \left(\left[p_2 + \frac{1}{2Nw_2} (1_{\{p_2 < p_1\}} - 1_{\{p_2 > p_1\}}) \right]^{\frac{1}{2}} \right) - \arcsin \left(\left[p_1 + \frac{1}{2Nw_1} (1_{\{p_1 < p_2\}} - 1_{\{p_1 > p_2\}}) \right]^{\frac{1}{2}} \right) \right]$$

The approximate power for the one-sided balanced case is given by Walters (1979) and is easily extended to the unbalanced and two-sided cases:

$$\text{power} = \begin{cases} \Phi(\delta - z_{1-\alpha}), & \text{upper one-sided} \\ \Phi(-\delta - z_{1-\alpha}), & \text{lower one-sided} \\ \Phi\left(\delta - z_{1-\frac{\alpha}{2}}\right) + \Phi\left(-\delta - z_{1-\frac{\alpha}{2}}\right), & \text{two-sided} \end{cases}$$

Analyses in the TWOSAMPLEMEANS Statement**Two-Sample t Test Assuming Equal Variances (TEST=DIFF)**

The hypotheses for the two-sample t test are

$$H_0: \mu_{\text{diff}} = \mu_0$$

$$H_1: \begin{cases} \mu_{\text{diff}} \neq \mu_0, & \text{two-sided} \\ \mu_{\text{diff}} > \mu_0, & \text{upper one-sided} \\ \mu_{\text{diff}} < \mu_0, & \text{lower one-sided} \end{cases}$$

The test assumes normally distributed data and common standard deviation per group, and it requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$. The test statistics are

$$t = N^{\frac{1}{2}}(w_1w_2)^{\frac{1}{2}} \left(\frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{s_p} \right) \sim t(N-2, \delta)$$

$$t^2 \sim F(1, N-2, \delta^2)$$

where \bar{x}_1 and \bar{x}_2 are the sample means and s_p is the pooled standard deviation, and

$$\delta = N^{\frac{1}{2}}(w_1w_2)^{\frac{1}{2}} \left(\frac{\mu_{\text{diff}} - \mu_0}{\sigma} \right)$$

The test is

$$\text{Reject } H_0 \quad \text{if } \begin{cases} t^2 \geq F_{1-\alpha}(1, N-2), & \text{two-sided} \\ t \geq t_{1-\alpha}(N-2), & \text{upper one-sided} \\ t \leq t_{\alpha}(N-2), & \text{lower one-sided} \end{cases}$$

Exact power computations for t tests are given in O'Brien and Muller (1993, Section 8.2.1):

$$\text{power} = \begin{cases} P(F(1, N-2, \delta^2) \geq F_{1-\alpha}(1, N-2)), & \text{two-sided} \\ P(t(N-2, \delta) \geq t_{1-\alpha}(N-2)), & \text{upper one-sided} \\ P(t(N-2, \delta) \leq t_{\alpha}(N-2)), & \text{lower one-sided} \end{cases}$$

Solutions for N , n_1 , n_2 , α , and δ are obtained by numerically inverting the power equation. Closed-form solutions for other parameters, in terms of δ , are as follows:

$$\begin{aligned} \mu_{\text{diff}} &= \delta \sigma (N w_1 w_2)^{-\frac{1}{2}} + \mu_0 \\ \mu_1 &= \delta \sigma (N w_1 w_2)^{-\frac{1}{2}} + \mu_0 - \mu_2 \\ \mu_2 &= \delta \sigma (N w_1 w_2)^{-\frac{1}{2}} + \mu_0 - \mu_1 \\ \sigma &= \begin{cases} \delta^{-1} (N w_1 w_2)^{\frac{1}{2}} (\mu_{\text{diff}} - \mu_0), & |\delta| > 0 \\ \text{undefined}, & \text{otherwise} \end{cases} \\ w_1 &= \begin{cases} \frac{1}{2} \pm \frac{1}{2} \left[1 - \frac{4\delta^2 \sigma^2}{N(\mu_{\text{diff}} - \mu_0)^2} \right]^{\frac{1}{2}}, & 0 < |\delta| \leq \frac{1}{2} N^{\frac{1}{2}} \frac{|\mu_{\text{diff}} - \mu_0|}{\sigma} \\ \text{undefined}, & \text{otherwise} \end{cases} \\ w_2 &= \begin{cases} \frac{1}{2} \pm \frac{1}{2} \left[1 - \frac{4\delta^2 \sigma^2}{N(\mu_{\text{diff}} - \mu_0)^2} \right]^{\frac{1}{2}}, & 0 < |\delta| \leq \frac{1}{2} N^{\frac{1}{2}} \frac{|\mu_{\text{diff}} - \mu_0|}{\sigma} \\ \text{undefined}, & \text{otherwise} \end{cases} \end{aligned}$$

Finally, here is a derivation of the solution for w_1 :

Solve the δ equation for w_1 (which requires the quadratic formula). Then determine the range of δ given w_1 :

$$\begin{aligned} \min_{w_1}(\delta) &= \begin{cases} 0, & \text{when } w_1 = 0 \text{ or } 1, \text{ if } (\mu_{\text{diff}} - \mu_0) \geq 0 \\ \frac{1}{2} N^{\frac{1}{2}} \frac{(\mu_{\text{diff}} - \mu_0)}{\sigma}, & \text{when } w_1 = \frac{1}{2}, \text{ if } (\mu_{\text{diff}} - \mu_0) < 0 \end{cases} \\ \max_{w_1}(\delta) &= \begin{cases} 0, & \text{when } w_1 = 0 \text{ or } 1, \text{ if } (\mu_{\text{diff}} - \mu_0) < 0 \\ \frac{1}{2} N^{\frac{1}{2}} \frac{(\mu_{\text{diff}} - \mu_0)}{\sigma}, & \text{when } w_1 = \frac{1}{2}, \text{ if } (\mu_{\text{diff}} - \mu_0) \geq 0 \end{cases} \end{aligned}$$

This implies

$$|\delta| \leq \frac{1}{2} N^{\frac{1}{2}} \frac{|\mu_{\text{diff}} - \mu_0|}{\sigma}$$

Two-Sample Satterthwaite t Test Assuming Unequal Variances (TEST=DIFF_SATT)

The hypotheses for the two-sample Satterthwaite t test are

$$H_0: \mu_{\text{diff}} = \mu_0$$

$$H_1: \begin{cases} \mu_{\text{diff}} \neq \mu_0, & \text{two-sided} \\ \mu_{\text{diff}} > \mu_0, & \text{upper one-sided} \\ \mu_{\text{diff}} < \mu_0, & \text{lower one-sided} \end{cases}$$

The test assumes normally distributed data and requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$. The test statistics are

$$t = \frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{\left[\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2} \right]^{\frac{1}{2}}} = N^{\frac{1}{2}} \frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{\left[\frac{s_1^2}{w_1} + \frac{s_2^2}{w_2} \right]^{\frac{1}{2}}}$$

$$F = t^2$$

where \bar{x}_1 and \bar{x}_2 are the sample means and s_1 and s_2 are the sample standard deviations.

DiSantostefano and Muller (1995, p. 585) state, the test is based on assuming that under H_0 , F is distributed as $F(1, \nu)$, where ν is given by Satterthwaite's approximation (Satterthwaite 1946),

$$\nu = \frac{\left[\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2} \right]^2}{\frac{\left[\frac{\sigma_1^2}{n_1} \right]^2}{n_1-1} + \frac{\left[\frac{\sigma_2^2}{n_2} \right]^2}{n_2-1}} = \frac{\left[\frac{\sigma_1^2}{w_1} + \frac{\sigma_2^2}{w_2} \right]^2}{\frac{\left[\frac{\sigma_1^2}{w_1} \right]^2}{Nw_1-1} + \frac{\left[\frac{\sigma_2^2}{w_2} \right]^2}{Nw_2-1}}$$

Since ν is unknown, in practice it must be replaced by an estimate

$$\hat{\nu} = \frac{\left[\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2} \right]^2}{\frac{\left[\frac{s_1^2}{n_1} \right]^2}{n_1-1} + \frac{\left[\frac{s_2^2}{n_2} \right]^2}{n_2-1}} = \frac{\left[\frac{s_1^2}{w_1} + \frac{s_2^2}{w_2} \right]^2}{\frac{\left[\frac{s_1^2}{w_1} \right]^2}{Nw_1-1} + \frac{\left[\frac{s_2^2}{w_2} \right]^2}{Nw_2-1}}$$

So the test is

$$\text{Reject } H_0 \text{ if } \begin{cases} F \geq F_{1-\alpha}(1, \hat{\nu}), & \text{two-sided} \\ t \geq t_{1-\alpha}(\hat{\nu}), & \text{upper one-sided} \\ t \leq t_{\alpha}(\hat{\nu}), & \text{lower one-sided} \end{cases}$$

Exact solutions for power for the two-sided and upper one-sided cases are given in Moser, Stevens, and Watts (1989). The lower one-sided case follows easily by using symmetry. The equations are as follows:

$$\text{power} = \begin{cases} \int_0^\infty P(F(1, N-2, \lambda) > h(u) F_{1-\alpha}(1, v(u)) | u) f(u) du, & \text{two-sided} \\ \int_0^\infty P\left(t(N-2, \lambda^{\frac{1}{2}}) > [h(u)]^{\frac{1}{2}} t_{1-\alpha}(v(u)) | u\right) f(u) du, & \text{upper one-sided} \\ \int_0^\infty P\left(t(N-2, \lambda^{\frac{1}{2}}) < [h(u)]^{\frac{1}{2}} t_{\alpha}(v(u)) | u\right) f(u) du, & \text{lower one-sided} \end{cases}$$

where

$$h(u) = \frac{\left(\frac{1}{n_1} + \frac{u}{n_2}\right) (n_1 + n_2 - 2)}{\left[(n_1 - 1) + (n_2 - 1) \frac{u \sigma_1^2}{\sigma_2^2}\right] \left(\frac{1}{n_1} + \frac{\sigma_2^2}{\sigma_1^2 n_2}\right)}$$

$$v(u) = \frac{\left(\frac{1}{n_1} + \frac{u}{n_2}\right)^2}{\frac{1}{n_1^2(n_1-1)} + \frac{u^2}{n_2^2(n_2-1)}}$$

$$\lambda = \frac{(\mu_{\text{diff}} - \mu_0)^2}{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}$$

$$f(u) = \frac{\Gamma\left(\frac{n_1+n_2-2}{2}\right)}{\Gamma\left(\frac{n_1-1}{2}\right) \Gamma\left(\frac{n_2-1}{2}\right)} \left[\frac{\sigma_1^2(n_2-1)}{\sigma_2^2(n_1-1)}\right]^{\frac{n_2-1}{2}} u^{\frac{n_2-3}{2}} \left[1 + \left(\frac{n_2-1}{n_1-1}\right) \frac{u \sigma_1^2}{\sigma_2^2}\right]^{-\left(\frac{n_1+n_2-2}{2}\right)}$$

The density $f(u)$ is obtained from the fact that

$$\frac{u \sigma_1^2}{\sigma_2^2} \sim F(n_2 - 1, n_1 - 1)$$

Two-Sample Pooled t Test of Mean Ratio with Lognormal Data (TEST=RATIO)

The lognormal case is handled by reexpressing the analysis equivalently as a normality-based test on the log-transformed data, by using properties of the lognormal distribution as discussed in Johnson, Kotz, and Balakrishnan (1994, Chapter 14). The approaches in the section “Two-Sample t Test Assuming Equal Variances (TEST=DIFF)” on page 6069 then apply.

In contrast to the usual t test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means. The test assumes equal coefficients of variation in the two groups.

The hypotheses for the two-sample t test with lognormal data are

$$H_0: \frac{\gamma_2}{\gamma_1} = \gamma_0$$

$$H_1: \begin{cases} \frac{\gamma_2}{\gamma_1} \neq \gamma_0, & \text{two-sided} \\ \frac{\gamma_2}{\gamma_1} > \gamma_0, & \text{upper one-sided} \\ \frac{\gamma_2}{\gamma_1} < \gamma_0, & \text{lower one-sided} \end{cases}$$

Let μ_1^* , μ_2^* , and σ^* be the (arithmetic) means and common standard deviation of the corresponding normal distributions of the log-transformed data. The hypotheses can be rewritten as follows:

$$H_0: \mu_2^* - \mu_1^* = \log(\gamma_0)$$

$$H_1: \begin{cases} \mu_2^* - \mu_1^* \neq \log(\gamma_0), & \text{two-sided} \\ \mu_2^* - \mu_1^* > \log(\gamma_0), & \text{upper one-sided} \\ \mu_2^* - \mu_1^* < \log(\gamma_0), & \text{lower one-sided} \end{cases}$$

where

$$\mu_1^* = \log \gamma_1$$

$$\mu_2^* = \log \gamma_2$$

The test assumes lognormally distributed data and requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$.

The power is

$$\text{power} = \begin{cases} P(F(1, N-2, \delta^2) \geq F_{1-\alpha}(1, N-2)), & \text{two-sided} \\ P(t(N-2, \delta) \geq t_{1-\alpha}(N-2)), & \text{upper one-sided} \\ P(t(N-2, \delta) \leq t_{\alpha}(N-2)), & \text{lower one-sided} \end{cases}$$

where

$$\delta = N^{\frac{1}{2}}(w_1 w_2)^{\frac{1}{2}} \left(\frac{\mu_2^* - \mu_1^* - \log(\gamma_0)}{\sigma^*} \right)$$

$$\sigma^* = [\log(\text{CV}^2 + 1)]^{\frac{1}{2}}$$

Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)

The hypotheses for the equivalence test are

$$H_0: \mu_{\text{diff}} < \theta_L \quad \text{or} \quad \mu_{\text{diff}} > \theta_U$$

$$H_1: \theta_L \leq \mu_{\text{diff}} \leq \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987). The test assumes normally distributed data and requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$. Phillips (1990) derives an expression for the exact power assuming a balanced design; the results are easily adapted to an unbalanced design:

$$\text{power} = Q_{N-2} \left((-t_{1-\alpha}(N-2)), \frac{\mu_{\text{diff}} - \theta_U}{\sigma N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}}; 0, \frac{(N-2)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}(t_{1-\alpha}(N-2))} \right) -$$

$$Q_{N-2} \left((t_{1-\alpha}(N-2)), \frac{\mu_{\text{diff}} - \theta_L}{\sigma N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}}; 0, \frac{(N-2)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}(t_{1-\alpha}(N-2))} \right)$$

where $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the section "Common Notation" on page 6027.

Multiplicative Equivalence Test for Mean Ratio with Lognormal Data (TEST=EQUIV_RATIO)

The lognormal case is handled by reexpressing the analysis equivalently as a normality-based test on the log-transformed data, by using properties of the lognormal distribution as discussed in Johnson, Kotz, and Balakrishnan (1994, Chapter 14). The approaches in the section “Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)” on page 6073 then apply.

In contrast to the additive equivalence test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means.

The hypotheses for the equivalence test are

$$H_0: \frac{\gamma_T}{\gamma_R} \leq \theta_L \quad \text{or} \quad \frac{\gamma_T}{\gamma_R} \geq \theta_U$$

$$H_1: \theta_L < \frac{\gamma_T}{\gamma_R} < \theta_U$$

$$\text{where } 0 < \theta_L < \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987) on the log-transformed data. The test assumes lognormally distributed data and requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$. Diletti, Hauschke, and Steinijans (1991) derive an expression for the exact power assuming a crossover design; the results are easily adapted to an unbalanced two-sample design:

$$\text{power} = Q_{N-2} \left((-t_{1-\alpha}(N-2)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_U)}{\sigma^* N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}}; 0, \frac{(N-2)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}(t_{1-\alpha}(N-2))} \right) -$$

$$Q_{N-2} \left((t_{1-\alpha}(N-2)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_L)}{\sigma^* N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}}; 0, \frac{(N-2)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}(t_{1-\alpha}(N-2))} \right)$$

where

$$\sigma^* = [\log(\text{CV}^2 + 1)]^{\frac{1}{2}}$$

is the (assumed common) standard deviation of the normal distribution of the log-transformed data, and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the section “Common Notation” on page 6027.

Confidence Interval for Mean Difference (CI=DIFF)

This analysis of precision applies to the standard t -based confidence interval:

$$\left[(\bar{x}_2 - \bar{x}_1) - t_{1-\frac{\alpha}{2}}(N-2) \frac{s_p}{\sqrt{N w_1 w_2}}, \right. \\ \left. (\bar{x}_2 - \bar{x}_1) + t_{1-\frac{\alpha}{2}}(N-2) \frac{s_p}{\sqrt{N w_1 w_2}} \right], \quad \text{two-sided}$$

$$\left[(\bar{x}_2 - \bar{x}_1) - t_{1-\alpha}(N-2) \frac{s_p}{\sqrt{N w_1 w_2}}, \quad \infty \right), \quad \text{upper one-sided}$$

$$\left(-\infty, \quad (\bar{x}_2 - \bar{x}_1) + t_{1-\alpha}(N-2) \frac{s_p}{\sqrt{N w_1 w_2}} \right], \quad \text{lower one-sided}$$

where \bar{x}_1 and \bar{x}_2 are the sample means and s_p is the pooled standard deviation. The “half-width” is defined as the distance from the point estimate $\bar{x}_2 - \bar{x}_1$ to a finite endpoint,

$$\text{half-width} = \begin{cases} t_{1-\frac{\alpha}{2}}(N-2) \frac{s_p}{\sqrt{Nw_1w_2}}, & \text{two-sided} \\ t_{1-\alpha}(N-2) \frac{s_p}{\sqrt{Nw_1w_2}}, & \text{one-sided} \end{cases}$$

A “valid” confidence interval captures the true mean. The exact probability of obtaining at most the target confidence interval half-width h , unconditional or conditional on validity, is given by Beal (1989):

$$\begin{aligned} \Pr(\text{half-width} \leq h) &= \begin{cases} P\left(\chi^2(N-2) \leq \frac{h^2 N(N-2)(w_1w_2)}{\sigma^2(t_{1-\frac{\alpha}{2}}^2(N-2))}\right), & \text{two-sided} \\ P\left(\chi^2(N-2) \leq \frac{h^2 N(N-2)(w_1w_2)}{\sigma^2(t_{1-\alpha}^2(N-2))}\right), & \text{one-sided} \end{cases} \\ \Pr(\text{half-width} \leq h \mid \text{validity}) &= \begin{cases} \left(\frac{1}{1-\alpha}\right) 2 \left[Q_{N-2}\left((t_{1-\frac{\alpha}{2}}(N-2)), 0; 0, b_2\right) - Q_{N-2}(0, 0; 0, b_2) \right], & \text{two-sided} \\ \left(\frac{1}{1-\alpha}\right) Q_{N-2}((t_{1-\alpha}(N-2)), 0; 0, b_2), & \text{one-sided} \end{cases} \end{aligned}$$

where

$$b_2 = \frac{h(N-2)^{\frac{1}{2}}}{\sigma(t_{1-\frac{\alpha}{c}}(N-2))N^{-\frac{1}{2}}(w_1w_2)^{-\frac{1}{2}}}$$

$c = \text{number of sides}$

and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen’s Q function, defined in the section “[Common Notation](#)” on page 6027.

A “quality” confidence interval is both sufficiently narrow ($\text{half-width} \leq h$) and valid:

$$\begin{aligned} \Pr(\text{quality}) &= \Pr(\text{half-width} \leq h \text{ and validity}) \\ &= \Pr(\text{half-width} \leq h \mid \text{validity})(1 - \alpha) \end{aligned}$$

Analyses in the TWOSAMPLESURVIVAL Statement

Rank Tests for Two Survival Curves (TEST=LOGRANK, TEST=GEHAN, TEST=TARONEWARE)

The method is from Lakatos (1988) and Cantor (1997, pp. 83–92).

Define the following notation:

- $X_j(i)$ = i th input time point on survival curve for group j
- $S_j(i)$ = input survivor function value corresponding to $X_j(i)$
- $h_j(t)$ = hazard rate for group j at time t
- $\Psi_j(t)$ = loss hazard rate for group j at time t
- λ_j = exponential hazard rate for group j
- R = hazard ratio of group 2 to group 1 \equiv (assumed constant) value of $\frac{h_2(t)}{h_1(t)}$
- m_j = median survival time for group j
- b = number of subintervals per time unit
- T = accrual time
- τ = follow-up time after accrual
- L_j = exponential loss rate for group j
- XL_j = input time point on loss curve for group j
- SL_j = input survivor function value corresponding to XL_j
- mL_j = median survival time for group j
- r_i = rank for i th time point

Each survival curve can be specified in one of several ways.

- For exponential curves:
 - a single point $(X_j(1), S_j(1))$ on the curve
 - median survival time
 - hazard rate
 - hazard ratio (for curve 2, with respect to curve 1)
- For piecewise linear curves with proportional hazards:
 - a set of points $\{(X_1(1), S_1(1)), (X_1(2), S_1(2)), \dots\}$ (for curve 1)
 - hazard ratio (for curve 2, with respect to curve 1)
- For arbitrary piecewise linear curves:
 - a set of points $\{(X_j(1), S_j(1)), (X_j(2), S_j(2)), \dots\}$

A total of $M + 1$ evenly spaced time points $\{t_0 = 0, t_1, t_2, \dots, t_M = T + \tau\}$ are used in calculations, where

$$M = \text{floor}((T + \tau)b)$$

The hazard function is calculated for each survival curve at each time point. For an exponential curve, the (constant) hazard is given by one of the following, depending on the input parameterization:

$$h_j(t) = \begin{cases} \lambda_j \\ \lambda_1 R \\ \frac{-\log(\frac{1}{2})}{m_j} \\ \frac{-\log(S_j(1))}{X_j(1)} \\ \frac{-\log(S_1(1))}{X_1(1)} R \end{cases}$$

For a piecewise linear curve, define the following additional notation:

$$\begin{aligned} t_i^- &= \text{largest input time } X \text{ such that } X \leq t_i \\ t_i^+ &= \text{smallest input time } X \text{ such that } X > t_i \end{aligned}$$

The hazard is computed by using linear interpolation as follows:

$$h_j(t_i) = \frac{S_j(t_i^-) - S_j(t_i^+)}{[S_j(t_i^+) - S_j(t_i^-)][t_i - t_i^-] + S_j(t_i^-)[t_i^+ - t_i^-]}$$

With proportional hazards, the hazard rate of group 2's curve in terms of the hazard rate of group 1's curve is

$$h_2(t) = h_1(t)R$$

Hazard function values $\{\Psi_j(t_i)\}$ for the loss curves are computed in an analogous way from $\{L_j, XL_j, SL_j, mL_j\}$.

The expected number at risk $N_j(i)$ at time i in group j is calculated for each group and time points 0 through $M - 1$, as follows:

$$\begin{aligned} N_j(0) &= Nw_j \\ N_j(i + 1) &= N_j(i) \left[1 - h_j(t_i) \left(\frac{1}{b} \right) - \Psi_j(t_i) \left(\frac{1}{b} \right) - \left(\frac{1}{b(T + \tau - t_i)} \right) 1_{\{t_i > \tau\}} \right] \end{aligned}$$

Define θ_i as the ratio of hazards and ϕ_i as the ratio of expected numbers at risk for time t_i :

$$\begin{aligned} \theta_i &= \frac{h_2(t_i)}{h_1(t_i)} \\ \phi_i &= \frac{N_2(i)}{N_1(i)} \end{aligned}$$

The expected number of deaths in each subinterval is calculated as follows:

$$D_i = [h_1(t_i)N_1(i) + h_2(t_i)N_2(i)] \left(\frac{1}{b} \right)$$

The rank values are calculated as follows according to which test statistic is used:

$$r_i = \begin{cases} 1, & \text{log-rank} \\ N_1(i) + N_2(i), & \text{Gehan} \\ \sqrt{N_1(i) + N_2(i)}, & \text{Tarone-Ware} \end{cases}$$

The distribution of the test statistic is approximated by $N(E, 1)$ where

$$E = \frac{\sum_{i=0}^{M-1} D_i r_i \left[\frac{\phi_i \theta_i}{1 + \phi_i \theta_i} - \frac{\phi_i}{1 + \phi_i} \right]}{\sqrt{\sum_{i=0}^{M-1} D_i r_i^2 \frac{\phi_i}{(1 + \phi_i)^2}}}$$

Note that $N^{\frac{1}{2}}$ can be factored out of the mean E , and so it can be expressed equivalently as

$$E = N^{\frac{1}{2}} E^* = N^{\frac{1}{2}} \left[\frac{\sum_{i=0}^{M-1} D_i^* r_i^* \left[\frac{\phi_i \theta_i}{1 + \phi_i \theta_i} - \frac{\phi_i}{1 + \phi_i} \right]}{\sqrt{\sum_{i=0}^{M-1} D_i^* r_i^{*2} \frac{\phi_i}{(1 + \phi_i)^2}}} \right]$$

where E^* is free of N and

$$\begin{aligned} D_i^* &= [h_1(t_i)N_1^*(i) + h_2(t_i)N_2^*(i)] \left(\frac{1}{b} \right) \\ r_i^* &= \begin{cases} 1, & \text{log-rank} \\ N_1^*(i) + N_2^*(i), & \text{Gehan} \\ \sqrt{N_1^*(i) + N_2^*(i)}, & \text{Tarone-Ware} \end{cases} \\ N_j^*(0) &= w_j \\ N_j^*(i+1) &= N_j^*(i) \left[1 - h_j(t_i) \left(\frac{1}{b} \right) - \Psi_j(t_i) \left(\frac{1}{b} \right) - \left(\frac{1}{b(T + \tau - t_i)} \right) 1_{\{t_i > \tau\}} \right] \end{aligned}$$

The approximate power is

$$\text{power} = \begin{cases} \Phi \left(-N^{\frac{1}{2}} E^* - z_{1-\alpha} \right), & \text{upper one-sided} \\ \Phi \left(N^{\frac{1}{2}} E^* - z_{1-\alpha} \right), & \text{lower one-sided} \\ \Phi \left(-N^{\frac{1}{2}} E^* - z_{1-\frac{\alpha}{2}} \right) + \Phi \left(N^{\frac{1}{2}} E^* - z_{1-\frac{\alpha}{2}} \right), & \text{two-sided} \end{cases}$$

Note that the upper and lower one-sided cases are expressed differently than in other analyses. This is because $E^* > 0$ corresponds to a higher survival curve in group 1 and thus, by the convention used in PROC power for two-group analyses, the lower side.

For the one-sided cases, a closed-form inversion of the power equation yield an approximate total sample size

$$N = \left(\frac{z_{\text{power}} + z_{1-\alpha}}{E^*} \right)^2$$

For the two-sided case, the solution for N is obtained by numerically inverting the power equation.

Accrual rates are converted to and from sample sizes according to the equation $a_j = n_j/T$, where a_j is the accrual rate for group j .

Expected numbers of events—that is, deaths, whether observed or censored—are converted to and from sample sizes according to the equation

$$e_j = \begin{cases} n_j [1 - S_j(\tau)], & T = 0 \\ n_j \left[1 - \frac{1}{T} \int_0^T S_j(T + \tau - t) dt \right], & T > 0 \end{cases}$$

where e_j is the expected number of events in group j . For an exponential curve, the equation simplifies to

$$e_j = \begin{cases} n_j [1 - \exp(-\lambda_j \tau)], & T = 0 \\ n_j \left[1 - \frac{1}{\lambda_j T} (\exp(-\lambda_j \tau) - \exp(-\lambda_j (T + \tau))) \right], & T > 0 \end{cases}$$

For a piecewise linear curve, first define K_j as the number of time points in the following collection: τ , $T + \tau$, and input time points for group j strictly between τ and $T + \tau$. Denote the ordered set of these points as $\{u_{j1}, \dots, u_{jK_j}\}$. The survival function values $S_j(\tau)$ and $S_j(T + \tau)$ are calculated by linear interpolation between adjacent input time points if they do not coincide with any input time points. Then the equation for a piecewise linear curve simplifies to

$$e_j = \begin{cases} n_j [1 - S_j(\tau)], & T = 0 \\ n_j \left[1 - \frac{1}{2T} \sum_{i=1}^{K_j-1} (u_{j,i+1} - u_{ji}) (S_j(u_{ji}) + S_j(u_{j,i+1})) \right], & T > 0 \end{cases}$$

Analyses in the TWOSAMPLEWILCOXON Statement

Wilcoxon-Mann-Whitney Test for Comparing Two Distributions (TEST=WMW)

The power approximation in this section is applicable to the Wilcoxon-Mann-Whitney (WMW) test as invoked with the WILCOXON option in the PROC NPAR1WAY statement of the NPAR1WAY procedure. The approximation is based on O'Brien and Casteloe (2006) and an estimator called $\widehat{WMW}_{\text{odds}}$. See O'Brien and Casteloe (2006) for a definition of $\widehat{WMW}_{\text{odds}}$, which need not be derived in detail here for purposes of explaining the power formula.

Let Y_1 and Y_2 be independent observations from any two distributions that you want to compare using the WMW test. For purposes of deriving the asymptotic distribution of $\widehat{WMW}_{\text{odds}}$ (and consequently the power computation as well), these distributions must be formulated as ordered categorical (“ordinal”) distributions.

If a distribution is continuous, it can be discretized using a large number of categories with negligible loss of accuracy. Each nonordinal distribution is divided into b categories, where b is the value of the NBINS parameter, with breakpoints evenly spaced on the probability scale. That is, each bin contains an equal probability $1/b$ for that distribution. Then the breakpoints across both distributions are pooled to form a collection of C bins (heretofore called “categories”), and the probabilities of bin membership for each distribution are recalculated. The motivation for this method of binning is to avoid degenerate representations of the distributions—that is, small handfuls of large probabilities among mostly empty bins—as can be caused by something like an evenly spaced grid across raw values rather than probabilities.

After the discretization process just mentioned, there are now two ordinal distributions, each with a set of probabilities across a common set of C ordered categories. For simplicity of notation, assume (without loss of generality) the response values to be $1, \dots, C$. Represent the conditional probabilities as

$$\tilde{p}_{ij} = \text{Prob}(Y_i = j \mid \text{group} = i), i \in \{1, 2\} \quad \text{and} \quad j \in \{1, \dots, C\}$$

and the group allocation weights as

$$w_i = \frac{n_i}{N} = \text{Prob}(\text{group} = i), \quad i \in \{1, 2\}$$

The joint probabilities can then be calculated simply as

$$p_{ij} = \text{Prob}(\text{group} = i, Y_i = j) = w_i \tilde{p}_{ij}, i \in \{1, 2\} \quad \text{and} \quad j \in \{1, \dots, C\}$$

The next step in the power computation is to compute the probabilities that a randomly chosen pair of observations from the two groups is concordant, discordant, or tied. It is useful to define these probabilities as functions of the terms Rs_{ij} and Rd_{ij} , defined as follows, where Y is a random observation drawn from the joint distribution across groups and categories:

$$\begin{aligned} Rs_{ij} &= \text{Prob}(Y \text{ is concordant with cell}(i, j)) + \frac{1}{2} \text{Prob}(Y \text{ is tied with cell}(i, j)) \\ &= \text{Prob}((\text{group} < i \text{ and } Y < j) \text{ or } (\text{group} > i \text{ and } Y > j)) + \\ &\quad \frac{1}{2} \text{Prob}(\text{group} \neq i \text{ and } Y = j) \\ &= \sum_{g=1}^2 \sum_{c=1}^C w_g \tilde{p}_{gc} \left[I_{(g-i)(c-j) > 0} + \frac{1}{2} I_{g \neq i, c=j} \right] \end{aligned}$$

and

$$\begin{aligned} Rd_{ij} &= \text{Prob}(Y \text{ is discordant with cell}(i, j)) + \frac{1}{2} \text{Prob}(Y \text{ is tied with cell}(i, j)) \\ &= \text{Prob}((\text{group} < i \text{ and } Y > j) \text{ or } (\text{group} > i \text{ and } Y < j)) + \\ &\quad \frac{1}{2} \text{Prob}(\text{group} \neq i \text{ and } Y = j) \\ &= \sum_{g=1}^2 \sum_{c=1}^C w_g \tilde{p}_{gc} \left[I_{(g-i)(c-j) < 0} + \frac{1}{2} I_{g \neq i, c=j} \right] \end{aligned}$$

For an independent random draw Y_1, Y_2 from the two distributions,

$$\begin{aligned} P_c &= \text{Prob}(Y_1, Y_2 \text{ concordant}) + \frac{1}{2} \text{Prob}(Y_1, Y_2 \text{ tied}) \\ &= \sum_{i=1}^2 \sum_{j=1}^C w_i \tilde{p}_{ij} Rs_{ij} \end{aligned}$$

and

$$\begin{aligned} P_d &= \text{Prob}(Y_1, Y_2 \text{ discordant}) + \frac{1}{2} \text{Prob}(Y_1, Y_2 \text{ tied}) \\ &= \sum_{i=1}^2 \sum_{j=1}^C w_i \tilde{p}_{ij} Rd_{ij} \end{aligned}$$

Then

$$\text{WMW}_{\text{odds}} = \frac{P_c}{P_d}$$

Proceeding to compute the theoretical standard error associated with WMW_{odds} (that is, the population analogue to the sample standard error),

$$SE(WMW_{\text{odds}}) = \frac{2}{P_d} \left[\sum_{i=1}^2 \sum_{j=1}^C w_i \tilde{p}_{ij} (WMW_{\text{odds}} R d_{ij} - R s_{ij})^2 / N \right]^{\frac{1}{2}}$$

Converting to the natural log scale and using the delta method,

$$SE(\log(WMW_{\text{odds}})) = \frac{SE(WMW_{\text{odds}})}{WMW_{\text{odds}}}$$

The next step is to produce a “smoothed” version of the $2 \times C$ cell probabilities that conforms to the null hypothesis of the Wilcoxon-Mann-Whitney test (in other words, independence in the $2 \times C$ contingency table of probabilities). Let $SE_{H_0}(\log(WMW_{\text{odds}}))$ denote the theoretical standard error of $\log(WMW_{\text{odds}})$ assuming H_0 .

Finally we have all of the terms needed to compute the power, using the noncentral chi-square and normal distributions:

$$\text{power} = \begin{cases} P \left(Z \geq \frac{SE_{H_0}(\log(WMW_{\text{odds}}))}{SE(\log(WMW_{\text{odds}}))} z_{1-\alpha} - \delta^* N^{\frac{1}{2}} \right), & \text{upper one-sided} \\ P \left(Z \leq \frac{SE_{H_0}(\log(WMW_{\text{odds}}))}{SE(\log(WMW_{\text{odds}}))} z_{\alpha} - \delta^* N^{\frac{1}{2}} \right), & \text{lower one-sided} \\ P \left(\chi^2(1, (\delta^*)^2 N) \geq \left[\frac{SE_{H_0}(\log(WMW_{\text{odds}}))}{SE(\log(WMW_{\text{odds}}))} \right]^2 \chi^2_{1-\alpha}(1) \right), & \text{two-sided} \end{cases}$$

where

$$\delta^* = \frac{\log(WMW_{\text{odds}})}{N^{\frac{1}{2}} SE(\log(WMW_{\text{odds}}))}$$

is the primary noncentrality—that is, the “effect size” that quantifies how much the two conjectured distributions differ. Z is a standard normal random variable, $\chi^2(df, nc)$ is a noncentral χ^2 random variable with degrees of freedom df and noncentrality nc , and N is the total sample size.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is not enabled, then PROC POWER creates traditional graphics.

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC POWER generates are listed in [Table 71.31](#), along with the required statements and options.

Table 71.31 Graphs Produced by PROC POWER

ODS Graph Name	Plot Description	Option
PowerPlot	Plot with two of the following three parameters on the X and Y axes: power, sample size, and effect size	PLOT
PowerAbort	Empty plot that shows an error message when a plot could not be produced	PLOT

ODS Styles Suitable for Use with PROC POWER

ODS styles control the appearance of graphs produced by PROC POWER. ODS provides over 50 styles, but most are not suitable for use in PROC POWER. PROC POWER requires a style that distinguishes curves based on a combination of color, line style, and symbol marker. Styles that are well-suited for use in PROC POWER include: STATISTICAL, ANALYSIS, DEFAULT, LISTING, and HTMLBLUECML. The HTMLBLUE and PLATEAU styles are commonly used, but they are not well-suited for use with PROC POWER because they rely primarily on color to distinguish curves rather than a combination of color, line style, and symbol marker.

In this chapter, a style is explicitly specified at the start of each example that uses ODS Graphics to remind you to use one of the suitable styles. Styles are specified in an ODS destination statement. Destinations include LISTING, HTML, RTF, PDF, and many others. You can set the style and the destination as follows:

```
ods html style=htmlbluecml;
ods graphics on;

proc power;
  onesamplemeans
    mean      = 5 10
    ntotal    = 150
    stddev    = 30 50
    power     = .;
  plot x=n min=100 max=200;
run;

ods graphics off;
ods html close;
```

For more information about ODS and ODS destinations, see Chapter 20, “Using the Output Delivery System.” For more information ODS styles, see Chapter 21, “Statistical Graphics Using ODS.”

Examples: POWER Procedure

Example 71.1: One-Way ANOVA

This example deals with the same situation as in [Example 44.1](#) of Chapter 44, “The GLMPOWER Procedure.”

Hocking (1985, p. 109) describes a study of the effectiveness of electrolytes in reducing lactic acid buildup for long-distance runners. You are planning a similar study in which you will allocate five different fluids to runners on a 10-mile course and measure lactic acid buildup immediately after the run. The fluids consist of water and two commercial electrolyte drinks, EZDure and LactoZap, each prepared at two concentrations, low (EZD1 and LZ1) and high (EZD2 and LZ2).

You conjecture that the standard deviation of lactic acid measurements given any particular fluid is about 3.75, and that the expected lactic acid values will correspond roughly to those in [Table 71.32](#). You are least familiar with the LZ1 drink and hence decide to consider a range of reasonable values for that mean.

Table 71.32 Mean Lactic Acid Buildup by Fluid

Water	EZD1	EZD2	LZ1	LZ2
35.6	33.7	30.2	29 or 28	25.9

You are interested in four different comparisons, shown in [Table 71.33](#) with appropriate contrast coefficients.

Table 71.33 Planned Comparisons

Comparison	Contrast Coefficients				
	Water	EZD1	EZD2	LZ1	LZ2
Water versus electrolytes	4	−1	−1	−1	−1
EZD versus LZ	0	1	1	−1	−1
EZD1 versus EZD2	0	1	−1	0	0
LZ1 versus LZ2	0	0	0	1	−1

For each of these contrasts you want to determine the sample size required to achieve a power of 0.9 for detecting an effect with magnitude in accord with [Table 71.32](#). You are not yet attempting to choose a single sample size for the study, but rather checking the range of sample sizes needed for individual contrasts. You plan to test each contrast at $\alpha = 0.025$. In the interests of reducing costs, you will provide twice as many runners with water as with any of the electrolytes; in other words, you will use a sample size weighting scheme of 2:1:1:1:1. Use the [ONEWAYANOVA](#) statement in the POWER procedure to compute the sample sizes.

The statements required to perform this analysis are as follows:

```
proc power;
  onewayanova
    groupmeans = 35.6 | 33.7 | 30.2 | 29 28 | 25.9
    stddev = 3.75
    groupweights = (2 1 1 1 1)
    alpha = 0.025
    ntotal = .
    power = 0.9
    contrast = (4 -1 -1 -1 -1) (0 1 1 -1 -1)
              (0 1 -1 0 0) (0 0 0 1 -1);
run;
```

The **NTOTAL=** option with a missing value (.) indicates total sample size as the result parameter. The **GROUPMEANS=** option with values from Table 71.32 specifies your conjectures for the means. With only one mean varying (the LZ1 mean), the “crossed” notation is simpler, showing scenarios for each group mean, separated by vertical bars (|). See the section “Specifying Value Lists in Analysis Statements” on page 6020 for more details on crossed and matched notations for grouped values. The contrasts in Table 71.33 are specified with the **CONTRAST=** option, by using the “matched” notation with each contrast enclosed in parentheses. The **STDDEV=**, **ALPHA=**, and **POWER=** options specify the error standard deviation, significance level, and power. The **GROUPWEIGHTS=** option specifies the weighting schemes. Default values for the **NULLCONTRAST=** and **SIDES=** options specify a two-sided *t* test of the contrast equal to 0. See Output 71.1.1 for the results.

Output 71.1.1 Sample Sizes for One-Way ANOVA Contrasts

The POWER Procedure												
Single DF Contrast in One-Way ANOVA												
Fixed Scenario Elements												
Method						Exact						
Alpha						0.025						
Standard Deviation						3.75						
Group Weights						2 1 1 1 1						
Nominal Power						0.9						
Number of Sides						2						
Null Contrast Value						0						
Computed N Total												
Index	-----Contrast-----					-----Means-----					Actual Power	N Total
1	4	-1	-1	-1	-1	35.6	33.7	30.2	29	25.9	0.947	30
2	4	-1	-1	-1	-1	35.6	33.7	30.2	28	25.9	0.901	24
3	0	1	1	-1	-1	35.6	33.7	30.2	29	25.9	0.929	60
4	0	1	1	-1	-1	35.6	33.7	30.2	28	25.9	0.922	48
5	0	1	-1	0	0	35.6	33.7	30.2	29	25.9	0.901	174
6	0	1	-1	0	0	35.6	33.7	30.2	28	25.9	0.901	174
7	0	0	0	1	-1	35.6	33.7	30.2	29	25.9	0.902	222
8	0	0	0	1	-1	35.6	33.7	30.2	28	25.9	0.902	480

The sample sizes in [Output 71.1.1](#) range from 24 for the comparison of water versus electrolytes to 480 for the comparison of LZ1 versus LZ2, both assuming the smaller LZ1 mean. The sample size for the latter comparison is relatively large because the small mean difference of $28 - 25.9 = 2.1$ is hard to detect.

The Nominal Power of 0.9 in the “Fixed Scenario Elements” table in [Output 71.1.1](#) represents the input target power, and the Actual Power column in the “Computed N Total” table is the power at the sample size (N Total) adjusted to achieve the specified sample weighting. Note that all of the sample sizes are rounded up to multiples of 6 to preserve integer group sizes (since the group weights add up to 6). You can use the `NFRACTIONAL` option in the `ONEWAYANOVA` statement to compute raw fractional sample sizes.

Suppose you want to plot the required sample size for the range of power values from 0.5 to 0.95. First, define the analysis by specifying the same statements as before, but add the `PLOTONLY` option to the `PROC POWER` statement to disable the nongraphical results. Next, specify the `PLOT` statement with `X=POWER` to request a plot with power on the X axis. (The result parameter, here sample size, is always plotted on the other axis.) Use the `MIN=` and `MAX=` options in the `PLOT` statement to specify the power range. The following statements produce the plot shown in [Output 71.1.2](#).

```
ods listing style=htmlbluecml;
ods graphics on;

proc power plotonly;
  onewayanova
    groupmeans = 35.6 | 33.7 | 30.2 | 29 28 | 25.9
    stddev = 3.75
    groupweights = (2 1 1 1 1)
    alpha = 0.025
    ntotal = .
    power = 0.9
    contrast = (4 -1 -1 -1 -1) (0 1 1 -1 -1)
               (0 1 -1 0 0) (0 0 0 1 -1);
  plot x=power min=.5 max=.95;
run;
```

The `ODS LISTING STYLE=HTMLBLUECML` statement specifies the `HTMLBLUECML` style, which is suitable for use with `PROC POWER` because it allows both marker symbols and line styles to vary. See the section “[ODS Styles Suitable for Use with PROC POWER](#)” on page 6082 for more information.

Output 71.1.2 Plot of Sample Size versus Power for One-Way ANOVA Contrasts

In [Output 71.1.2](#), the line style identifies the contrast, and the plotting symbol identifies the group means scenario. The plot shows that the required sample size is highest for the (0 0 0 1 -1) contrast, corresponding to the test of LZ1 versus LZ2 that was previously found to require the most resources, in either cell means scenario.

Note that some of the plotted points in [Output 71.1.2](#) are unevenly spaced. This is because the plotted points are the *rounded* sample size results at their corresponding *actual* power levels. The range specified with the `MIN=` and `MAX=` values in the `PLOT` statement corresponds to *nominal* power levels. In some cases, actual power is substantially higher than nominal power. To obtain plots with evenly spaced points (but with *fractional* sample sizes at the computed points), you can use the `NFRACTIONAL` option in the analysis statement preceding the `PLOT` statement.

Finally, suppose you want to plot the power for the range of sample sizes you will likely consider for the study (the range of 24 to 480 that achieves 0.9 power for different comparisons). In the `ONEWAYANOVA` statement, identify power as the result (`POWER=.`), and specify `NTOTAL=24`. The following statements produce the plot:

```
proc power plotonly;
  onewayanova
    groupmeans = 35.6 | 33.7 | 30.2 | 29 28 | 25.9
    stddev = 3.75
    groupweights = (2 1 1 1 1)
    alpha = 0.025
    ntotal = 24
    power = .
    contrast = (4 -1 -1 -1 -1) (0 1 1 -1 -1)
              (0 1 -1 0 0) (0 0 0 1 -1);
  plot x=n min=24 max=480;
run;

ods graphics off;
```

The `X=N` option in the `PLOT` statement requests a plot with sample size on the X axis.

Note that the value specified with the `NTOTAL=24` option is not used. It is overridden in the plot by the `MIN=` and `MAX=` options in the `PLOT` statement, and the `PLOTONLY` option in the `PROC POWER` statement disables nongraphical results. But the `NTOTAL=` option (along with a value) is still needed in the `ONEWAYANOVA` statement as a placeholder, to identify the desired parameterization for sample size.

Output 71.1.3 shows the resulting plot.

Output 71.1.3 Plot of Power versus Sample Size for One-Way ANOVA Contrasts

Although [Output 71.1.2](#) and [Output 71.1.3](#) surface essentially the same computations for practical power ranges, they each provide a different quick visual assessment. [Output 71.1.2](#) reveals the range of required sample sizes for powers of interest, and [Output 71.1.3](#) reveals the range of achieved powers for sample sizes of interest.

Example 71.2: The Sawtooth Power Function in Proportion Analyses

For many common statistical analyses, the power curve is monotonically increasing: the more samples you take, the more power you achieve. However, in statistical analyses of discrete data, such as tests of proportions, the power curve is often nonmonotonic. A small increase in sample size can result in a *decrease* in power, a decrease that is sometimes substantial. The explanation is that the actual significance level (in other words, the achieved Type I error rate) for discrete tests strays below the target level and varies with sample size. The power loss from a decrease in the Type I error rate can outweigh the power gain from an increase in sample size. The example discussed here demonstrates this “sawtooth” phenomenon. For additional discussion on the topic, see Chernick and Liu (2002).

Suppose you have a new scheduling system for an airline, and you want to determine how many flights you must observe to have at least an 80% chance of establishing an improvement in the proportion of late arrivals on a specific travel route. You will use a one-sided exact binomial proportion test with a null proportion of 30%, the frequency of late arrivals under the previous scheduling system, and a nominal significance level of $\alpha = 0.05$. Well-supported predictions estimate the new late arrival rate to be about 20%, and you will base your sample size determination on this assumption.

The POWER procedure does not currently compute exact sample size directly for the exact binomial test. But you can get an initial estimate by computing the approximate sample size required for a z test. Use the `ONESAMPLEFREQ` statement in the POWER procedure with `TEST=Z` and `METHOD=NORMAL` to compute the approximate sample size to achieve a power of 0.8 by using the z test. The following statements perform the analysis:

```
proc power;
  onesamplefreq test=z method=normal
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.3
    proportion     = 0.2
    ntotal         = .
    power          = 0.8;
run;
```

The `NTOTAL=` option with a missing value (.) indicates sample size as the result parameter. The `SIDES=1` option specifies a one-sided test. The `ALPHA=`, `NULLPROPORTION=`, and `POWER=` options specify the significance level of 0.05, null value of 0.3, and target power of 0.8, respectively. The `PROPORTION=` option specifies your conjecture of 0.3 for the true proportion.

Output 71.2.1 Approximate Sample Size for z Test of a Proportion

The POWER Procedure		
Z Test for Binomial Proportion		
Fixed Scenario Elements		
Method	Normal approximation	
Number of Sides	1	
Null Proportion	0.3	
Alpha	0.05	
Binomial Proportion	0.2	
Nominal Power	0.8	
Variance Estimate	Null Variance	
Computed N Total		
Actual	N	
Power	Total	
0.800	119	

The results, shown in [Output 71.2.1](#), indicate that you need to observe about $N = 119$ flights to have an 80% chance of rejecting the hypothesis of a late arrival proportion of 30% or higher, if the true proportion is 20%,

by using the z test. A similar analysis (Output 71.2.2) reveals an approximate sample size of $N = 129$ for the z test with continuity correction, which is performed by using `TEST=ADJZ`:

```
proc power;
  onesamplefreq test=adjz method=normal
    sides          = 1
    alpha           = 0.05
    nullproportion  = 0.3
    proportion      = 0.2
    ntotal          = .
    power           = 0.8;
run;
```

Output 71.2.2 Approximate Sample Size for z Test with Continuity Correction

The POWER Procedure		
Z Test for Binomial Proportion with Continuity Adjustment		
Fixed Scenario Elements		
Method	Normal approximation	
Number of Sides		1
Null Proportion		0.3
Alpha		0.05
Binomial Proportion		0.2
Nominal Power		0.8
Variance Estimate	Null Variance	
Computed N Total		
Actual	N	
Power	Total	
0.801	129	

Based on the approximate sample size results, you decide to explore the power of the exact binomial test for sample sizes between 110 and 140. The following statements produce the plot:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power plotonly;
  onesamplefreq test=exact
    sides          = 1
    alpha           = 0.05
    nullproportion  = 0.3
    proportion      = 0.2
    ntotal          = 119
    power           = .;
  plot x=n min=110 max=140 step=1
    yopts=(ref=.8) xopts=(ref=119 129);
run;
```

The ODS LISTING STYLE=HTMLBLUECML statement specifies the HTMLBLUECML style, which is suitable for use with PROC POWER because it allows both marker symbols and line styles to vary. See the section “ODS Styles Suitable for Use with PROC POWER” on page 6082 for more information.

The TEST=EXACT option in the ONESAMPLEFREQ statement specifies the exact binomial test, and the missing value (.) for the POWER= option indicates power as the result parameter. The PLOTONLY option in the PROC POWER statement disables nongraphical output. The PLOT statement with X=N requests a plot with sample size on the X axis. The MIN= and MAX= options in the PLOT statement specify the sample size range. The YOPTS=(REF=) and XOPTS=(REF=) options add reference lines to highlight the approximate sample size results. The STEP=1 option produces a point at each integer sample size. The sample size value specified with the NTOTAL= option in the ONESAMPLEFREQ statement is overridden by the MIN= and MAX= options in the PLOT statement. Output 71.2.3 shows the resulting plot.

Output 71.2.3 Plot of Power versus Sample Size for Exact Binomial Test

Note the sawtooth pattern in Output 71.2.3. Although the power surpasses the target level of 0.8 at $N = 119$, it decreases to 0.79 with $N = 120$ and further to 0.76 with $N = 122$ before rising again to 0.81 with $N = 123$. Not until $N = 130$ does the power stay above the 0.8 target. Thus, a more conservative sample size recommendation of 130 might be appropriate, depending on the precise goals of the sample size determination.

In addition to considering alternative sample sizes, you might also want to assess the sensitivity of the power to inaccuracies in assumptions about the true proportion. The following statements produce a plot including true proportion values of 0.18 and 0.22. They are identical to the previous statements except for

the additional true proportion values specified with the **PROPORTION=** option in the **ONESAMPLEFREQ** statement.

```
proc power plotonly;
  onesamplefreq test=exact
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.3
    proportion      = 0.18 0.2 0.22
    ntotal         = 119
    power          = .;
  plot x=n min=110 max=140 step=1
    yopts=(ref=.8) xopts=(ref=119 129);
run;
```

Output 71.2.4 shows the resulting plot.

Output 71.2.4 Plot for Assessing Sensitivity to True Proportion Value

The plot reveals a dramatic sensitivity to the true proportion value. For $N=119$, the power is about 0.92 if the true proportion is 0.18, and as low as 0.62 if the proportion is 0.22. Note also that the power jumps occur at the same sample sizes in all three curves; the curves are only shifted and stretched vertically. This is because spikes and valleys in power curves are invariant to the true proportion value; they are due to changes in the critical value of the test.

A closer look at some ancillary output from the analysis sheds light on this property of the sawtooth pattern. You can add an ODS OUTPUT statement to save the plot content corresponding to [Output 71.2.3](#) to a data set:

```
proc power plotonly;
  ods output plotcontent=PlotData;
  onesamplefreq test=exact
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.3
    proportion     = 0.2
    ntotal         = 119
    power          = .;
  plot x=n min=110 max=140 step=1
       yopts=(ref=.8) xopts=(ref=119 129);
run;
```

The PlotData data set contains parameter values for each point in the plot. The parameters include underlying characteristics of the putative test. The following statements print the critical value and actual significance level along with sample size and power:

```
proc print data=PlotData;
  var NTotal LowerCritVal Alpha Power;
run;
```

Output 71.2.5 shows the plot data.

Output 71.2.5 Numerical Content of Plot

Obs	NTotal	Lower CritVal	Alpha	Power
1	110	24	0.0356	0.729
2	111	24	0.0313	0.713
3	112	25	0.0446	0.771
4	113	25	0.0395	0.756
5	114	25	0.0349	0.741
6	115	26	0.0490	0.795
7	116	26	0.0435	0.781
8	117	26	0.0386	0.767
9	118	26	0.0341	0.752
10	119	27	0.0478	0.804
11	120	27	0.0425	0.790
12	121	27	0.0377	0.776
13	122	27	0.0334	0.762
14	123	28	0.0465	0.812
15	124	28	0.0414	0.799
16	125	28	0.0368	0.786
17	126	28	0.0327	0.772
18	127	29	0.0453	0.820
19	128	29	0.0404	0.807
20	129	29	0.0359	0.794
21	130	30	0.0493	0.838
22	131	30	0.0441	0.827
23	132	30	0.0394	0.815
24	133	30	0.0351	0.803
25	134	31	0.0480	0.845
26	135	31	0.0429	0.834
27	136	31	0.0384	0.823
28	137	31	0.0342	0.811
29	138	32	0.0466	0.851
30	139	32	0.0418	0.841
31	140	32	0.0374	0.830

Note that whenever the critical value changes, the actual α jumps up to a value close to the nominal $\alpha=0.05$, and the power also jumps up. Then while the critical value stays constant, the actual α and power slowly decrease. The critical value is independent of the true proportion value. So you can achieve a locally maximal power by choosing a sample size corresponding to a spike on the sawtooth curve, and this choice is locally optimal *regardless* of the unknown value of the true proportion. Locally optimal sample sizes in this case include 115, 119, 123, 127, 130, and 134.

As a point of interest, the power does not always jump sharply and decrease gradually. The shape of the sawtooth depends on the direction of the test and the location of the null proportion relative to 0.5. For example, if the direction of the hypothesis in this example is reversed (by switching true and null proportion values) so that the rejection region is in the upper tail, then the power curve exhibits sharp decreases and gradual increases. The following statements are similar to those producing the plot in [Output 71.2.3](#) but with values of the `PROPORTION=` and `NULLPROPORTION=` options switched:

```

proc power plotonly;
  onesamplefreq test=exact
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.2
    proportion      = 0.3
    ntotal         = 119
    power          = .;
  plot x=n min=110 max=140 step=1;
run;

```

The resulting plot is shown in [Output 71.2.6](#).

Output 71.2.6 Plot of Power versus Sample Size for Another One-sided Test

Finally, two-sided tests can lead to even more irregular power curve shapes, since changes in lower and upper critical values affect the power in different ways. The following statements produce a plot of power versus sample size for the scenario of a two-sided test with high alpha and a true proportion close to the null value:

```

proc power plotonly;
  onesamplefreq test=exact
    sides          = 2
    alpha          = 0.2
    nullproportion = 0.1
    proportion     = 0.09
    ntotal         = 10
    power          = .;
  plot x=n min=2 max=100 step=1;
run;

ods graphics off;

```

Output 71.2.7 shows the resulting plot.

Output 71.2.7 Plot of Power versus Sample Size for a Two-Sided Test

Due to the irregular shapes of power curves for proportion tests, the question “Which sample size should I use?” is often insufficient. A sample size solution produced directly in PROC POWER reveals the smallest possible sample size to achieve your target power. But as the examples in this section demonstrate, it is helpful to consult graphs for answers to questions such as the following:

- Which sample size will guarantee that all higher sample sizes also achieve my target power?
- Given a candidate sample size, can I increase it slightly to achieve locally maximal power, or perhaps even decrease it and get higher power?

Example 71.3: Simple AB/BA Crossover Designs

Crossover trials are experiments in which each subject is given a sequence of different treatments. They are especially common in clinical trials for medical studies. The reduction in variability from taking multiple measurements on a subject allows for more precise treatment comparisons. The simplest such design is the AB/BA crossover, in which each subject receives each of two treatments in a randomized order.

Under certain simplifying assumptions, you can test the treatment difference in an AB/BA crossover trial by using either a paired or two-sample t test (or equivalence test, depending on the hypothesis). This example will demonstrate when and how you can use the **PAIREDMEANS** statement in PROC POWER to perform power analyses for AB/BA crossover designs.

Senn (1993, Chapter 3) discusses a study comparing the effects of two bronchodilator medications in treatment of asthma, by using an AB/BA crossover design. Suppose you want to plan a similar study comparing two new medications, “Xilodol” and “Brantium.” Half of the patients would be assigned to sequence AB, getting a dose of Xilodol in the first treatment period, a wash-out period of one week, and then a dose of Brantium in the second treatment period. The other half would be assigned to sequence BA, following the same schedule but with the drugs reversed. In each treatment period you would administer the drugs in the morning and then measure peak expiratory flow (PEF) at the end of the day, with higher PEF representing better lung function.

You conjecture that the mean and standard deviation of PEF are about $\mu_A = 330$ and $\sigma_A = 40$ for Xilodol and $\mu_B = 310$ and $\sigma_B = 55$ for Brantium, and that each pair of measurements on the same subject will have a correlation of about 0.3. You want to compute the power of both one-sided and two-sided tests of mean difference, with a significance level of $\alpha = 0.01$, for a sample size of 100 patients and also plot the power for a range of 50 to 200 patients. Note that the allocation ratio of patients to the two sequences is irrelevant in this analysis.

The choice of statistical test depends on which assumptions are reasonable. One possibility is a t test. A paired or two-sample t test is valid when there is no carryover effect and no interactions between patients, treatments, and periods. See Senn (1993, Chapter 3) for more details. The choice between a paired or a two-sample test depends on what you assume about the period effect. If you assume no period effect, then a paired t test is the appropriate analysis for the design, with the first member of each pair being the Xilodol measurement (regardless of which sequence the patient belongs to). Otherwise, the two-sample t test approach is called for, since this analysis adjusts for the period effect by using an extra degree of freedom.

Suppose you assume no period effect. Then you can use the **PAIREDMEANS** statement in PROC POWER with the **TEST=DIFF** option to perform a sample size analysis for the paired t test. Indicate power as the result parameter by specifying the **POWER=** option with a missing value (.). Specify the conjectured means and standard deviations for each drug by using the **PAIREDMEANS=** and **PAIREDSTDDEVS=** options and the correlation by using the **CORR=** option. Specify both one- and two-sided tests by using the **SIDES=** option, the significance level by using the **ALPHA=** option, and the sample size (in terms of number of pairs) by using the **NPAIRS=** option. Generate a plot of power versus sample size by specifying the **PLOT**

statement with `X=N` to request a plot with sample size on the X axis. (The result parameter, here power, is always plotted on the other axis.) Use the `MIN=` and `MAX=` options in the `PLOT` statement to specify the sample size range (as numbers of pairs).

The following statements perform the sample size analysis:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power;
  pairedmeans test=diff
    pairedmeans    = (330 310)
    pairedstddevs  = (40 55)
    corr           = 0.3
    sides          = 1 2
    alpha          = 0.01
    npairs         = 100
    power          = .;
  plot x=n min=50 max=200;
run;

ods graphics off;
```

The `ODS LISTING STYLE=HTMLBLUECML` statement specifies the `HTMLBLUECML` style, which is suitable for use with `PROC POWER` because it allows both marker symbols and line styles to vary. See the section “[ODS Styles Suitable for Use with PROC POWER](#)” on page 6082 for more information.

Default values for the `NULLDIFF=` and `DIST=` options specify a null mean difference of 0 and the assumption of normally distributed data. The output is shown in [Output 71.3.1](#) and [Output 71.3.2](#).

Output 71.3.1 Power for Paired *t* Analysis of Crossover Design

The POWER Procedure		
Paired t Test for Mean Difference		
Fixed Scenario Elements		
Distribution	Normal	
Method	Exact	
Alpha	0.01	
Mean 1	330	
Mean 2	310	
Standard Deviation 1	40	
Standard Deviation 2	55	
Correlation	0.3	
Number of Pairs	100	
Null Difference	0	
Computed Power		
Index	Sides	Power
1	1	0.865
2	2	0.801

Output 71.3.2 Plot of Power versus Sample Size for Paired t Analysis of Crossover Design

The “Computed Power” table in [Output 71.3.1](#) shows that the power with 100 patients is about 0.8 for the two-sided test and 0.87 for the one-sided test with the alternative of larger Brantium mean. In [Output 71.3.2](#), the line style identifies the number of sides of the test. The plotting symbols identify locations of actual computed powers; the curves are linear interpolations of these points. The plot demonstrates how much higher the power is in the one-sided test than in the two-sided test for the range of sample sizes.

Suppose now that instead of detecting a difference between Xilodol and Brantium, you want to establish that they are similar—in particular, that the absolute mean PEF difference is at most 35. You might consider this goal if, for example, one of the drugs has fewer side effects and if a difference of no more than 35 is considered clinically small. Instead of a standard t test, you would conduct an *equivalence test* of the treatment mean difference for the two drugs. You would test the hypothesis that the true difference is less than -35 or more than 35 against the alternative that the mean difference is between -35 and 35 , by using an additive model and a two one-sided tests (“TOST”) analysis.

Assuming no period effect, you can use the `PAIREDMEANS` statement with the `TEST=EQUIV_DIFF` option to perform a sample size analysis for the paired equivalence test. Indicate power as the result parameter by specifying the `POWER=` option with a missing value (.). Use the `LOWER=` and `UPPER=` options to specify the equivalence bounds of -35 and 35 . Use the `PAIREDMEANS=`, `PAIREDSTDDEVS=`, `CORR=`, and `ALPHA=` options in the same way as in the t test at the beginning of this example to specify the remaining parameters.

The following statements perform the sample size analysis:

```
proc power;
  pairedmeans test=equiv_add
    lower      = -35
    upper      = 35
    pairedmeans = (330 310)
    pairedstddevs = (40 55)
    corr       = 0.3
    alpha      = 0.01
    npairs     = 100
    power      = .;
run;
```

The default option **DIST=NORMAL** specifies an assumption of normally distributed data. The output is shown in [Output 71.3.3](#).

Output 71.3.3 Power for Paired Equivalence Test for Crossover Design

The POWER Procedure	
Equivalence Test for Paired Mean Difference	
Fixed Scenario Elements	
Distribution	Normal
Method	Exact
Lower Equivalence Bound	-35
Upper Equivalence Bound	35
Alpha	0.01
Reference Mean	330
Treatment Mean	310
Standard Deviation 1	40
Standard Deviation 2	55
Correlation	0.3
Number of Pairs	100
Computed Power	
Power	0.598

The power for the paired equivalence test with 100 patients is about 0.6.

Example 71.4: Noninferiority Test with Lognormal Data

The typical goal in noninferiority testing is to conclude that a new treatment or process or product is not appreciably worse than some standard. This is accomplished by convincingly rejecting a one-sided null hypothesis that the new treatment is appreciably worse than the standard. When designing such studies, investigators must define precisely what constitutes “appreciably worse.”

You can use the POWER procedure for sample size analyses for a variety of noninferiority tests, by specifying custom, one-sided null hypotheses for common tests. This example illustrates the strategy (often called Blackwelder's scheme; Blackwelder 1982) by comparing the means of two independent lognormal samples. The logic applies to one-sample, two-sample, and paired-sample problems involving normally distributed measures and proportions.

Suppose you are designing a study hoping to show that a new (less expensive) manufacturing process does not produce appreciably more pollution than the current process. Quantifying “appreciably worse” as 10%, you seek to show that the mean pollutant level from the new process is less than 110% of that from the current process. In standard hypothesis testing notation, you seek to reject

$$H_0: \frac{\mu_{\text{new}}}{\mu_{\text{current}}} \geq 1.10$$

in favor of

$$H_A: \frac{\mu_{\text{new}}}{\mu_{\text{current}}} < 1.10$$

This is described graphically in Figure 71.8. Mean ratios below 100% are better levels for the new process; a ratio of 100% indicates absolute equivalence; ratios of 100–110% are “tolerably” worse; and ratios exceeding 110% are appreciably worse.

Figure 71.8 Hypotheses for the Pollutant Study

An appropriate test for this situation is the common two-group t test on log-transformed data. The hypotheses become

$$H_0: \log(\mu_{\text{new}}) - \log(\mu_{\text{current}}) \geq \log(1.10)$$

$$H_A: \log(\mu_{\text{new}}) - \log(\mu_{\text{current}}) < \log(1.10)$$

Measurements of the pollutant level will be taken by using laboratory models of the two processes and will be treated as independent lognormal observations with a coefficient of variation (σ/μ) between 0.5 and 0.6 for both processes. You will end up with 300 measurements for the current process and 180 for the new one. It is important to avoid a Type I error here, so you set the Type I error rate to 0.01. Your theoretical work suggests that the new process will actually reduce the pollutant by about 10% (to 90% of current), but you need to compute and graph the power of the study if the new levels are actually between 70% and 120% of current levels.

Implement the sample size analysis by using the **TWOSAMPLEMEANS** statement in PROC POWER with the **TEST=RATIO** option. Indicate power as the result parameter by specifying the **POWER=** option with a missing value (.). Specify a series of scenarios for the mean ratio between 0.7 and 1.2 by using the **MEANRATIO=** option. Use the **NULLRATIO=** option to specify the null mean ratio of 1.10. Specify **SIDES=L** to indicate a one-sided test with the alternative hypothesis stating that the mean ratio is *lower* than the null value. Specify the significance level, scenarios for the coefficient of variation, and the group

sample sizes by using the **ALPHA=**, **CV=**, and **GROUPNS=** options. Generate a plot of power versus mean ratio by specifying the **PLOT** statement with the **X=EFFECT** option to request a plot with mean ratio on the X axis. (The result parameter, here power, is always plotted on the other axis.) Use the **STEP=** option in the **PLOT** statement to specify an interval of 0.05 between computed points in the plot.

The following statements perform the desired analysis:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power;
  twosamplemeans test=ratio
    meanratio = 0.7 to 1.2 by 0.1
    nullratio = 1.10
    sides      = L
    alpha      = 0.01
    cv         = 0.5 0.6
    groupns    = (300 180)
    power      = .;
  plot x=effect step=0.05;
run;

ods graphics off;
```

The ODS LISTING STYLE=HTMLBLUECML statement specifies the HTMLBLUECML style, which is suitable for use with PROC POWER because it allows both marker symbols and line styles to vary. See the section “[ODS Styles Suitable for Use with PROC POWER](#)” on page 6082 for more information.

Note the use of **SIDES=L**, which forces computations for cases that need a rejection region that is opposite to the one providing the most one-tailed power; in this case, it is the lower tail. Such cases will show power that is less than the prescribed Type I error rate. The default option **DIST=LOGNORMAL** specifies the assumption of lognormally distributed data. The default **MIN=** and **MAX=** options in the plot statement specify an X axis range identical to the effect size range in the **TWOSAMPLEMEANS** statement (mean ratios between 0.7 and 1.2).

[Output 71.4.1](#) and [Output 71.4.2](#) show the results.

Output 71.4.1 Power for Noninferiority Test of Ratio

The POWER Procedure	
Two-Sample t Test for Mean Ratio	
Fixed Scenario Elements	
Distribution	Lognormal
Method	Exact
Number of Sides	L
Null Geometric Mean Ratio	1.1
Alpha	0.01
Group 1 Sample Size	300
Group 2 Sample Size	180

Output 71.4.1 continued

Computed Power				
Index	Geo Mean Ratio	CV	Power	
1	0.7	0.5	>.999	
2	0.7	0.6	>.999	
3	0.8	0.5	>.999	
4	0.8	0.6	>.999	
5	0.9	0.5	0.985	
6	0.9	0.6	0.933	
7	1.0	0.5	0.424	
8	1.0	0.6	0.306	
9	1.1	0.5	0.010	
10	1.1	0.6	0.010	
11	1.2	0.5	<.001	
12	1.2	0.6	<.001	

Output 71.4.2 Plot of Power versus Mean Ratio for Noninferiority Test

The “Computed Power” table in [Output 71.4.1](#) shows that power exceeds 0.90 if the true mean ratio is 90% or less, as surmised. But power is unacceptably low (0.31–0.42) if the processes happen to be truly equivalent. Note that the power is identical to the alpha level (0.01) if the true mean ratio is 1.10 and below 0.01 if the true mean ratio is appreciably worse (>110%). In [Output 71.4.2](#), the line style identifies the coefficient of variation. The plotting symbols identify locations of actual computed powers; the curves are linear interpolations of these points.

Example 71.5: Multiple Regression and Correlation

You are working with a team of preventive cardiologists investigating whether elevated serum homocysteine levels are linked to atherosclerosis (plaque buildup) in coronary arteries. The planned analysis is an ordinary least squares regression to assess the relationship between total homocysteine level (tHcy) and a plaque burden index (PBI), adjusting for six other variables: age, gender, plasma levels of folate, vitamin B₆, vitamin B₁₂, and a serum cholesterol index. You will regress PBI on tHcy and the six other predictors (plus the intercept) and use a Type III *F* test to assess whether tHcy is a significant predictor after adjusting for the others. You wonder whether 100 subjects will provide adequate statistical power.

This is a correlational study at a single time. Subjects will be screened so that about half will have had a heart problem. All eight variables will be measured during one visit. Most clinicians are familiar with simple correlations between two variables, so you decide to pose the statistical problem in terms of estimating and testing the partial correlation between $X_1 = \text{tHcy}$ and $Y = \text{PBI}$, controlling for the six other predictor variables ($R_{YX_1|X_{-1}}$). This greatly simplifies matters, especially the elicitation of the conjectured effect.

You use partial regression plots like that shown in [Figure 71.9](#) to teach the team that the partial correlation between PBI and tHcy is the correlation of two sets of residuals obtained from ordinary regression models, one from regressing PBI on the six covariates and the other from regressing tHcy on the same covariates. Thus each subject has “expected” tHcy and PBI values based on the six covariates. The cardiologists believe that subjects whose tHcy is relatively higher than expected will also have a PBI that is relatively higher than expected. The partial correlation quantifies that adjusted association just as a standard simple correlation does with the unadjusted linear association between two variables.

Figure 71.9 Partial Regression Plot

Based on previously published studies of various coronary risk factors and after viewing a set of scatterplots showing various correlations, the team surmises that the true partial correlation is likely to be at least 0.35.

You want to compute the statistical power for a sample size of $N = 100$ by using $\alpha = 0.05$. You also want to plot power for sample sizes between 50 and 150. Use the **MULTREG** statement to compute the power and the **PLOT** statement to produce the graph. Since the predictors are observed rather than fixed in advanced, and a joint multivariate normal assumption seems tenable, use **MODEL=**RANDOM. The following statements perform the power analysis:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power;
  multreg
    model = random
    nfullpredictors = 7
    ntestpredictors = 1
    partialcorr = 0.35
    ntotal = 100
    power = .;
  plot x=n min=50 max=150;
run;

ods graphics off;
```

The **ODS LISTING STYLE=HTMLBLUECML** statement specifies the **HTMLBLUECML** style, which is suitable for use with **PROC POWER** because it allows both marker symbols and line styles to vary. See the section “**ODS Styles Suitable for Use with PROC POWER**” on page 6082 for more information.

The **POWER=.** option identifies power as the parameter to compute. The **NFULLPREDICTORS=** option specifies seven total predictors (not including the intercept), and the **NTESTPREDICTORS=** option indicates that one of those predictors is being tested. The **PARTIALCORR=** and **NTOTAL=** options specify the partial correlation and sample size, respectively. The default value for the **ALPHA=** option sets the significance level to 0.05. The **X=N** option in the plot statement requests a plot of sample size on the X axis, and the **MIN=** and **MAX=** options specify the sample size range.

Output 71.5.1 shows the output, and Output 71.5.2 shows the plot.

Output 71.5.1 Power Analysis for Multiple Regression

The POWER Procedure	
Type III F Test in Multiple Regression	
Fixed Scenario Elements	
Method	Exact
Model	Random X
Number of Predictors in Full Model	7
Number of Test Predictors	1
Partial Correlation	0.35
Total Sample Size	100
Alpha	0.05

Output 71.5.1 *continued*

Computed Power
Power
0.939

Output 71.5.2 Plot of Power versus Sample Size for Multiple Regression

For the sample size $N = 100$, the study is almost balanced with respect to Type I and Type II error rates, with $\alpha = 0.05$ and $\beta = 1 - 0.937 = 0.063$. The study thus seems well designed at this sample size.

Now suppose that in a follow-up meeting with the cardiologists, you discover that their specific intent is to demonstrate that the (partial) correlation between PBI and tHcy is greater than 0.2. You suggest changing the planned data analysis to a one-sided Fisher's z test with a null correlation of 0.2. The following statements perform a power analysis for this test:

```

proc power;
  onecorr dist=fisherz
    npvars = 6
    corr = 0.35
    nullcorr = 0.2
    sides = 1
    ntotal = 100
    power = .;
run;

```

The **DIST=FISHERZ** option in the **ONECORR** statement specifies Fisher's z test. The **NPARTIALVARS=** option specifies that six additional variables are adjusted for in the partial correlation. The **CORR=** option specifies the conjectured correlation of 0.35, and the **NULLCORR=** option indicates the null value of 0.2. The **SIDES=** option specifies a one-sided test.

Output 71.5.3 shows the output.

Output 71.5.3 Power Analysis for Fisher's z Test

The POWER Procedure		
Fisher's z Test for Pearson Correlation		
Fixed Scenario Elements		
Distribution	Fisher's z transformation of r	
Method	Normal approximation	
Number of Sides		1
Null Correlation		0.2
Number of Variables Partialled Out		6
Correlation		0.35
Total Sample Size		100
Nominal Alpha		0.05
Computed Power		
Actual		
Alpha	Power	
0.05	0.466	

The power for Fisher's z test is less than 50%, the decrease being mostly due to the smaller effect size (relative to the null value). When asked for a recommendation for a new sample size goal, you compute the required sample size to achieve a power of 0.95 (to balance Type I and Type II errors) and 0.85 (a threshold deemed to be minimally acceptable to the team). The following statements perform the sample size determination:

```

proc power;
  onecorr dist=fisherz
    npvars = 6
    corr = 0.35
    nullcorr = 0.2
    sides = 1
    ntotal = .
    power = 0.85 0.95;
run;

```

The **NTOTAL=.** option identifies sample size as the parameter to compute, and the **POWER=** option specifies the target powers.

Output 71.5.4 Sample Size Determination for Fisher's z Test

The POWER Procedure				
Fisher's z Test for Pearson Correlation				
Fixed Scenario Elements				
Distribution	Fisher's z transformation of r			
Method	Normal approximation			
Number of Sides				1
Null Correlation				0.2
Number of Variables Partialled Out				6
Correlation				0.35
Nominal Alpha				0.05
Computed N Total				
Index	Nominal Power	Actual Alpha	Actual Power	N Total
1	0.85	0.05	0.850	280
2	0.95	0.05	0.950	417

The results in [Output 71.5.4](#) reveal a required sample size of 417 to achieve a power of 0.95 and a required sample size of 280 to achieve a power of 0.85.

Example 71.6: Comparing Two Survival Curves

You are consulting for a clinical research group planning a trial to compare survival rates for proposed and standard cancer treatments. The planned data analysis is a log-rank test to nonparametrically compare the overall survival curves for the two treatments. Your goal is to determine an appropriate sample size to achieve a power of 0.8 for a two-sided test with $\alpha = 0.05$ by using a balanced design.

The survival curve for patients on the standard treatment is well known to be approximately exponential with a median survival time of five years. The research group conjectures that the new proposed treatment will yield a (nonexponential) survival curve similar to the dashed line in [Figure 71.6.1](#).

Patients will be accrued uniformly over two years and then followed for an additional three years past the accrual period. Some loss to follow-up is expected, with roughly exponential rates that would result in about 50% loss with the standard treatment within 10 years. The loss to follow-up with the proposed treatment is more difficult to predict, but 50% loss would be expected to occur sometime between years 5 and 20.

Output 71.6.1 Survival Curves

Use the **TWOSAMPLESURVIVAL** statement with the **TEST=LOGRANK** option to compute the required sample size for the log-rank test. The following statements perform the analysis:

```
proc power;
  twosamplesurvival test=logrank
    curve("Standard") = 5 : 0.5
    curve("Proposed") = (1 to 5 by 1):(0.95 0.9 0.75 0.7 0.6)
    groupsurvival = "Standard" | "Proposed"
    accrualtime = 2
    followuptime = 3
    groupmedlosstimes = 10 | 20 5
    power = 0.8
    npergroup = .;
run;
```

The **CURVE=** option defines the two survival curves. The “Standard” curve has only one point, specifying an exponential form with a survival probability of 0.5 at year 5. The “Proposed” curve is a piecewise linear curve defined by the five points shown in Figure 71.6.1. The **GROUPSURVIVAL=** option assigns the survival curves to the two groups, and the **ACCRUALTIME=** and **FOLLOWUPTIME=** options specify the accrual and follow-up times. The **GROUPMEDLOSSTIMES=** option specifies the years at which 50% loss is expected to occur. The **POWER=** option specifies the target power, and the **NPERGROUP=** option identifies sample size per group as the parameter to compute. Default values for the **SIDES=** and **ALPHA=** options specify a two-sided test with $\alpha = 0.05$.

Output 71.6.2 shows the results.

Output 71.6.2 Sample Size Determination for Log-Rank Test

The POWER Procedure				
Log-Rank Test for Two Survival Curves				
Fixed Scenario Elements				
Method	Lakatos normal approximation			
Accrual Time				2
Follow-up Time				3
Group 1 Survival Curve			Standard	
Form of Survival Curve 1			Exponential	
Group 2 Survival Curve			Proposed	
Form of Survival Curve 2			Piecewise Linear	
Group 1 Median Loss Time				10
Nominal Power				0.8
Number of Sides				2
Number of Time Sub-Intervals				12
Alpha				0.05
Computed N Per Group				
Index	Median Loss Time	Actual Power	N Per Group	
1	20	0.800	228	
2	5	0.801	234	

The required sample size per group to achieve a power of 0.8 is 228 if the median loss time is 20 years for the proposed treatment. Only six more patients are required in each group if the median loss time is as short as five years.

Example 71.7: Confidence Interval Precision

An investment firm has hired you to help plan a study to estimate the success of a new investment strategy called “IntuiVest.” The study involves complex simulations of market conditions over time, and it tracks the balance of a hypothetical brokerage account starting with \$50,000. Each simulation is very expensive in terms of computing time. You are asked to determine an appropriate number of simulations to estimate

the average change in the account balance at the end of three years. The goal is to have a 95% chance of obtaining a 90% confidence interval whose half-width is at most \$1,000. That is, the firm wants to have a 95% chance of being able to correctly claim at the end of the study that “Our research shows with 90% confidence that IntuiVest yields a profit of \$X \pm \$1,000 at the end of three years on an initial investment of \$50,000 (under simulated market conditions).”

The probability of achieving the desired precision (that is, a small interval width) can be calculated either unconditionally or conditionally given that the true mean is captured by the interval. You decide to use the conditional form, considering two of its advantages:

- The conditional probability is usually lower than the unconditional probability for the same sample size, meaning that the conditional form is generally conservative.
- The overall probability of achieving the desired precision *and* capturing the true mean is easily computed as the product of the half-width probability and the confidence level. In this case, the overall probability is $0.95 \times 0.9 = 0.855$.

Based on some initial simulations, you expect a standard deviation between \$25,000 and \$45,000 for the ending account balance. You will consider both of these values in the sample size analysis.

As mentioned in the section “[Overview of Power Concepts](#)” on page 6018, an analysis of confidence interval precision is analogous to a traditional power analysis, with “CI Half-Width” taking the place of effect size and “Prob(Width)” taking the place of power. In this example, the target CI Half-Width is 1000, and the desired Prob(Width) is 0.95.

In addition to computing sample sizes for a half-width of \$1,000, you are asked to plot the required number of simulations for a range of half-widths between \$500 and \$2,000. Use the [ONESAMPLEMEANS](#) statement with the [CI=T](#) option to implement the sample size determination. The following statements perform the analysis:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power;
  onesamplemeans ci=t
    alpha = 0.1
    halfwidth = 1000
    stddev = 25000 45000
    probwidth = 0.95
    ntotal = .;
  plot x=effect min=500 max=2000;
run;

ods graphics off;
```

The ODS LISTING STYLE=HTMLBLUECML statement specifies the HTMLBLUECML style, which is suitable for use with PROC POWER because it allows both marker symbols and line styles to vary. See the section “[ODS Styles Suitable for Use with PROC POWER](#)” on page 6082 for more information.

The [NTOTAL=](#) option identifies sample size as the parameter to compute. The [ALPHA=0.1](#) option specifies a confidence level of $1 - \alpha = 0.9$. The [HALFWIDTH=](#) option specifies the target half-width, and the [STDDEV=](#) option specifies the conjectured standard deviation values. The [PROBWIDTH=](#) option specifies

the desired probability of achieving the target precision. The default value **PROBTYPE=CONDITIONAL** specifies that this probability is conditional on the true mean being captured by the interval. The default of **SIDES=2** indicates a two-sided interval.

Output 71.7.1 shows the output, and Output 71.7.2 shows the plot.

Output 71.7.1 Sample Size Determination for Confidence Interval Precision

The POWER Procedure			
Confidence Interval for Mean			
Fixed Scenario Elements			
Distribution	Normal		
Method	Exact		
Alpha	0.1		
CI Half-Width	1000		
Nominal Prob(Width)	0.95		
Number of Sides	2		
Prob Type	Conditional		
Computed N Total			
Index	Std Dev	Actual Prob (Width)	N Total
1	25000	0.951	1788
2	45000	0.950	5652

Output 71.7.2 Plot of Sample Size versus Confidence Interval Half-Width

The number of simulations required in order to have a 95% chance of obtaining a half-width of at most 1000 is between 1788 and 5652, depending on the standard deviation. The plot reveals that more than 20,000 simulations would be required for a half-width of 500, assuming the higher standard deviation.

Example 71.8: Customizing Plots

This example demonstrates various ways you can modify and enhance plots:

- assigning analysis parameters to axes
- fine-tuning a sample size axis
- adding reference lines
- linking plot features to analysis parameters
- choosing key (legend) styles
- modifying symbol locations

The example plots are all based on a sample size analysis for a two-sample t test of group mean difference. You start by computing the sample size required to achieve a power of 0.9 by using a two-sided test with $\alpha = 0.05$, assuming the first mean is 12, the second mean is either 15 or 18, and the standard deviation is either 7 or 9.

Use the **TWOSAMPLEMEANS** statement with the **TEST=DIFF** option to compute the required sample sizes. Indicate total sample size as the result parameter by supplying a missing value (.) with the **NTOTAL=** option. Use the **GROUPMEANS=**, **STDDEV=**, and **POWER=** options to specify values of the other parameters. The following statements perform the sample size computations:

```
proc power;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev         = 7 9
    power          = 0.9
    ntotal         = .;
run;
```

Default values for the **NULLDIFF=**, **SIDES=**, **GROUPWEIGHTS=**, and **DIST=** options specify a null mean difference of 0, two-sided test, balanced design, and assumption of normally distributed data, respectively.

Output 71.8.1 shows that the required sample size ranges from 60 to 382, depending on the unknown standard deviation and second mean.

Output 71.8.1 Computed Sample Sizes

The POWER Procedure				
Two-Sample t Test for Mean Difference				
Fixed Scenario Elements				
Distribution	Normal			
Method	Exact			
Group 1 Mean	12			
Nominal Power	0.9			
Number of Sides	2			
Null Difference	0			
Alpha	0.05			
Group 1 Weight	1			
Group 2 Weight	1			
Computed N Total				
Index	Mean2	Std Dev	Actual Power	N Total
1	15	7	0.902	232
2	15	9	0.901	382
3	18	7	0.904	60
4	18	9	0.904	98

Assigning Analysis Parameters to Axes

Use the **PLOT** statement to produce plots for all power and sample size analyses in PROC POWER. For the sample size analysis described at the beginning of this example, suppose you want to plot the required sample size on the Y axis against a range of powers between 0.5 and 0.95 on the X axis. The **X=** and **Y=** options specify which parameter to plot against the result and which axis to assign to this parameter. You can use either the **X=** or the **Y=** option, but not both. Use the **X=POWER** option in the **PLOT** statement to request a plot with power on the X axis. The result parameter, here total sample size, is always plotted on the other axis. Use the **MIN=** and **MAX=** options to specify the range of the axis indicated with either the **X=** or the **Y=** option. Here, specify **MIN=0.5** and **MAX=0.95** to specify the power range. The following statements produce the plot:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev        = 7 9
    power         = 0.9
    ntotal        = .;
  plot x=power min=0.5 max=0.95;
run;
```

The ODS LISTING STYLE=HTMLBLUECML statement specifies the HTMLBLUECML style, which is suitable for use with PROC POWER because it allows both marker symbols and line styles to vary. See the section “ODS Styles Suitable for Use with PROC POWER” on page 6082 for more information.

Note that the value (0.9) of the POWER= option in the TWOSAMPLEMEANS statement is only a placeholder when the PLOTONLY option is used and both the MIN= and MAX= options are used, because the values of the MIN= and MAX= options override the value of 0.9. But the POWER= option itself is still required in the TWOSAMPLEMEANS statement, to provide a complete specification of the sample size analysis.

The resulting plot is shown in Output 71.8.2.

Output 71.8.2 Plot of Sample Size versus Power

The line style identifies the group means scenario, and the plotting symbol identifies the standard deviation scenario. The locations of plotting symbols indicate computed sample sizes; the curves are linear interpolations of these points. By default, each curve consists of approximately 20 computed points (sometimes slightly more or less, depending on the analysis).

If you would rather plot power on the Y axis versus sample size on the X axis, you have two general strategies to choose from. One strategy is to use the Y= option instead of the X= option in the PLOT statement:

```
plot y=power min=0.5 max=0.95;
```

Output 71.8.3 Plot of Power versus Sample Size using First Strategy

Note that the resulting plot ([Output 71.8.3](#)) is essentially a mirror image of [Output 71.8.2](#). The axis ranges are set such that each curve in [Output 71.8.3](#) contains similar values of Y instead of X. Each plotted point represents the computed value of the X axis at the input value of the Y axis.

A second strategy for plotting power versus sample size (when originally solving for sample size) is to invert the analysis and base the plot on computed power for a given range of sample sizes. This strategy works well for monotonic power curves (as is the case for the t test and most other continuous analyses). It is advantageous in the sense of preserving the traditional role of the Y axis as the computed parameter. A common way to implement this strategy is as follows:

- Determine the range of sample sizes sufficient to cover at the desired power range for all curves (where each “curve” represents a scenario for standard deviation and second group mean).
- Use this range for the X axis of a plot.

To determine the required sample sizes for target powers of 0.5 and 0.95, change the values in the **POWER=** option as follows to reflect this range:

```

proc power;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev        = 7 9
    power         = 0.5 0.95
    ntotal        = .;
run;

```

Output 71.8.4 reveals that a sample size range of 24 to 470 is approximately sufficient to cover the desired power range of 0.5 to 0.95 for all curves (“approximately” because the actual power at the rounded sample size of 24 is slightly higher than the nominal power of 0.5).

Output 71.8.4 Computed Sample Sizes

The POWER Procedure					
Two-Sample t Test for Mean Difference					
Fixed Scenario Elements					
Distribution			Normal		
Method			Exact		
Group 1 Mean			12		
Number of Sides			2		
Null Difference			0		
Alpha			0.05		
Group 1 Weight			1		
Group 2 Weight			1		
Computed N Total					
Index	Mean2	Std Dev	Nominal Power	Actual Power	N Total
1	15	7	0.50	0.502	86
2	15	7	0.95	0.951	286
3	15	9	0.50	0.505	142
4	15	9	0.95	0.950	470
5	18	7	0.50	0.519	24
6	18	7	0.95	0.953	74
7	18	9	0.50	0.516	38
8	18	9	0.95	0.952	120

To plot power on the Y axis for sample sizes between 20 and 500, use the **X=N** option in the **PLOT** statement with **MIN=20** and **MAX=500**:

```

proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev        = 7 9
    power         = .
    ntotal        = 200;
  plot x=n min=20 max=500;
run;

```

Each curve in the resulting plot in [Output 71.8.5](#) covers at least a power range of 0.5 to 0.95.

Output 71.8.5 Plot of Power versus Sample Size Using Second Strategy

Finally, suppose you want to produce a plot of sample size versus effect size for a power of 0.9. In this case, the “effect size” is defined to be the mean difference. You need to reparameterize the analysis by using the **MEANDIFF=** option instead of the **GROUPMEANS=** option to produce a plot, since each plot axis must be represented by a scalar parameter. Use the **X=EFFECT** option in the **PLOT** statement to assign the mean difference to the X axis. The following statements produce a plot of required sample size to detect mean differences between 3 and 6:

```
proc power plotonly;
  twosamplemeans test=diff
    meandiff      = 3 6
    stddev        = 7 9
    power         = 0.9
    ntotal        = .;
  plot x=effect min=3 max=6;
run;
```

The resulting plot [Output 71.8.6](#) shows how the required sample size decreases with increasing mean difference.

Output 71.8.6 Plot of Sample Size versus Mean Difference

Fine-Tuning a Sample Size Axis

Consider the following plot request for a sample size analysis similar to the one in [Output 71.8.1](#) but with only a single scenario, and with unbalanced sample size allocation of 2:1:

```
proc power plotonly;
  ods output plotcontent=PlotData;
  twosamplemeans test=diff
    groupmeans    = 12 | 18
    stddev        = 7
    groupweights  = 2 | 1
    power         = .
    ntotal        = 20;
  plot x=n min=20 max=50 npoints=20;
run;
```

The `MIN=`, `MAX=`, and `NPOINTS=` options in the `PLOT` statement request a plot with 20 points between 20 and 50. But the resulting plot ([Output 71.8.7](#)) appears to have only 11 points, and they range from 18 to 48.

Output 71.8.7 Plot with Overlapping Points

The reason that this plot has fewer points than usual is due to the rounding of sample sizes. If you do not use the **NFRACTIONAL** option in the analysis statement (here, the **TWOSAMPLEMEANS** statement), then the set of sample size points determined by the **MIN=**, **MAX=**, **NPOINTS=**, and **STEP=** options in the **PLOT** statement can be rounded to satisfy the allocation weights. In this case, they are rounded down to the nearest multiples of 3 (the sum of the weights), and many of the points overlap. To see the overlap, you can print the **NominalNTotal** (unadjusted) and **NTotal** (rounded) variables in the **PlotContent** ODS object (here saved to a data set called **PlotData**):

```
proc print data=PlotData;
  var NominalNTotal NTotal;
run;
```

The output is shown in [Output 71.8.8](#).

Output 71.8.8 Sample Sizes

Obs	Nominal NTotal	NTotal
1	18.0	18
2	19.6	18
3	21.2	21
4	22.7	21
5	24.3	24
6	25.9	24
7	27.5	27
8	29.1	27
9	30.6	30
10	32.2	30
11	33.8	33
12	35.4	33
13	36.9	36
14	38.5	36
15	40.1	39
16	41.7	39
17	43.3	42
18	44.8	42
19	46.4	45
20	48.0	48

Besides overlapping of sample size points, another peculiarity that might occur without the [NFRAC-TIONAL](#) option is unequal spacing—for example, in the plot in [Output 71.8.9](#), created with the following statements:

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 18
    stddev        = 7
    groupweights  = 2 | 1
    power         = .
    ntotal        = 20;
  plot x=n min=20 max=50 npoints=5;
run;
```

Output 71.8.9 Plot with Unequally Spaced Points

If you want to guarantee evenly spaced, nonoverlapping sample size points in your plots, you can either (1) use the **NFRACTIONAL** option in the analysis statement preceding the **PLOT** statement or (2) use the **STEP=** option and provide values for the **MIN=**, **MAX=**, and **STEP=** options in the **PLOT** statement that are multiples of the sum of the allocation weights. Note that this sum is simply 1 for one-sample and paired designs and 2 for balanced two-sample designs. So any integer step value works well for one-sample and paired designs, and any even step value works well for balanced two-sample designs. Both of these strategies will avoid rounding adjustments.

The following statements implement the first strategy to create the plot in [Output 71.8.10](#), by using the **NFRACTIONAL** option in the **TWOSAMPLEMEANS** statement:

```
proc power plotonly;
  twosamplemeans test=diff
    nfractional
    groupmeans    = 12 | 18
    stddev        = 7
    groupweights  = 2 | 1
    power         = .
    ntotal        = 20;
  plot x=n min=20 max=50 npoints=20;
run;
```

Output 71.8.10 Plot with Fractional Sample Sizes

To implement the second strategy, use multiples of 3 for the **STEP=**, **MIN=**, and **MAX=** options in the **PLOT** statement (because the sum of the allocation weights is $2 + 1 = 3$). The following statements use **STEP=3**, **MIN=18**, and **MAX=48** to create a plot that looks identical to the plot in [Output 71.8.7](#) but suffers no overlapping of points:

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 18
    stddev        = 7
    groupweights  = 2 | 1
    power         = .
    ntotal        = 20;
  plot x=n min=18 max=48 step=3;
run;
```

Adding Reference Lines

Suppose you want to add reference lines to highlight power=0.8 and power=0.9 on the plot in [Output 71.8.5](#). You can add simple reference lines by using the **YOPTS=** option and **REF=** suboption in the **PLOT** statement to produce [Output 71.8.11](#), with the following statements:

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev        = 7 9
    power         = .
    ntotal        = 100;
  plot x=n min=20 max=500
      yopts=(ref=0.8 0.9);
run;
```

Output 71.8.11 Plot with Simple Reference Lines on Y Axis

Or you can specify **CROSSREF=**YES to add reference lines that intersect each curve and cross over to the other axis:

```
plot x=n min=20 max=500
     yopts=(ref=0.8 0.9 crossref=yes);
```

The resulting plot is shown in [Output 71.8.12](#).

Output 71.8.12 Plot with CROSSREF=YES Style Reference Lines from Y Axis

You can also add reference lines for the X axis by using the **XOPTS=** option instead of the **YOPTS=** option. For example, the following **PLOT** statement produces [Output 71.8.13](#), which has crossing reference lines highlighting the sample size of 100:

```
plot x=n min=20 max=500
     xopts=(ref=100 crossref=yes);
```

Note that the values that label the reference lines at the X axis in [Output 71.8.12](#) and at the Y axis in [Output 71.8.13](#) are linearly interpolated from two neighboring points on the curves. Thus they might not exactly match corresponding values that are computed directly from the methods in the section “[Computational Methods and Formulas](#)” on page 6027—that is, computed by PROC POWER in the absence of a PLOT statement. The two ways of computing these values generally differ by a negligible amount.

Output 71.8.13 Plot with CROSSREF=YES Style Reference Lines from X Axis

Linking Plot Features to Analysis Parameters

You can use the **VARY** option in the **PLOT** statement to specify which of the following features you want to associate with analysis parameters.

- line style
- plotting symbol
- color
- panel

You can specify mappings between each of these features and one or more analysis parameters, or you can simply choose a subset of these features to use (and rely on default settings to associate these features with multiple-valued analysis parameters).

Suppose you supplement the sample size analysis in [Output 71.8.5](#) to include three values of alpha, by using the following statements:

```

proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev        = 7 9
    alpha         = 0.01 0.025 0.1
    power         = .
    ntotal        = 100;
  plot x=n min=20 max=500;
run;

```

The defaults for the **VARY** option in the **PLOT** statement specify line style varying by the **ALPHA=** parameter, plotting symbol varying by the **GROUPMEANS=** parameter, panel varying by the **STDDEV=** parameter, and color remaining constant. The resulting plot, consisting of two panels, is shown in [Output 71.8.14](#).

Output 71.8.14 Plot with Default VARY Settings

Output 71.8.14 *continued*

Suppose you want to produce a plot with only one panel that varies color in addition to line style and plotting symbol. Include the `LINESTYLE`, `SYMBOL`, and `COLOR` keywords in the **VARY** option in the **PLOT** statement, as follows, to produce the plot in [Output 71.8.15](#):

```
plot x=n min=20 max=500
      vary (linestyle, symbol, color);
```

Output 71.8.15 Plot with Varying Color Instead of Panel

Finally, suppose you want to specify which features are used *and* which analysis parameters they are linked to. The following **PLOT** statement produces a two-panel plot (shown in [Output 71.8.16](#)) in which line style varies by standard deviation, plotting symbol varies by both alpha and sides, and panel varies by means:

```
plot x=n min=20 max=500
    vary (linestyle by stddev,
          symbol by alpha sides,
          panel by groupmeans);
```

Output 71.8.16 Plot with Features Explicitly Linked to Parameters

Output 71.8.16 continued

Choosing Key (Legend) Styles

The default style for the key (or “legend”) is one that displays the association between levels of features and levels of analysis parameters, located below the X axis. For example, [Output 71.8.5](#) demonstrates this style of key.

You can reproduce [Output 71.8.5](#) with the same key but a different location, inside the plotting region, by using the `POS=INSET` option within the `KEY=BYFEATURE` option in the `PLOT` statement. The following statements product the plot in [Output 71.8.17](#):

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev        = 7 9
    power         = .
    ntotal        = 200;
  plot x=n min=20 max=500
    key = byfeature(pos=inset);
run;
```

Output 71.8.17 Plot with a By-Feature Key inside the Plotting Region

Alternatively, you can specify a key that identifies each individual curve separately by number by using the **KEY=BYCURVE** option in the **PLOT** statement:

```
plot x=n min=20 max=500
    key = bycurve;
```

The resulting plot is shown in [Output 71.8.18](#).

Output 71.8.18 Plot with a Numbered By-Curve Key

Use the **NUMBERS=OFF** option within the **KEY=BYCURVE** option to specify a nonnumbered key that identifies curves with samples of line styles, symbols, and colors:

```
plot x=n min=20 max=500
    key = bycurve(numbers=off pos=inset);
```

The **POS=INSET** suboption places the key within the plotting region. The resulting plot is shown in [Output 71.8.19](#).

Output 71.8.19 Plot with a Nonnumbered By-Curve Key

Finally, you can attach labels directly to curves with the `KEY=ONCURVES` option. The following `PLOT` statement produces [Output 71.8.20](#):

```
plot x=n min=20 max=500
     key = oncurves;
```

Output 71.8.20 Plot with Directly Labeled Curves

Modifying Symbol Locations

The default locations for plotting symbols are the points computed directly from the power and sample size algorithms. For example, [Output 71.8.5](#) shows plotting symbols corresponding to computed points. The curves connecting these points are interpolated (as indicated by the `INTERPOL=` option in the `PLOT` statement).

You can modify the locations of plotting symbols by using the `MARKERS=` option in the `PLOT` statement. The `MARKERS=ANALYSIS` option places plotting symbols at locations corresponding to the input specified in the analysis statement preceding the `PLOT` statement. You might prefer this as an alternative to using reference lines to highlight specific points. For example, you can reproduce [Output 71.8.5](#), but with the plotting symbols located at the sample sizes shown in [Output 71.8.1](#), by using the following statements:

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev         = 7 9
    power          = .
    ntotal         = 232 382 60 98;
```

```

plot x=n min=20 max=500
     markers=analysis;
run;

```

The analysis statement here is the **TWOSAMPLEMEANS** statement. The **MARKERS=ANALYSIS** option in the **PLOT** statement causes the plotting symbols to occur at sample sizes specified by the **NTOTAL=** option in the **TWOSAMPLEMEANS** statement: 232, 382, 60, and 98. The resulting plot is shown in [Output 71.8.21](#).

Output 71.8.21 Plot with **MARKERS=ANALYSIS**

You can also use the **MARKERS=NICE** option to align symbols with the tick marks on one of the axes (the X axis when the **X=** option is used, or the Y axis when the **Y=** option is used):

```

plot x=n min=20 max=500
     markers=nice;

```

The plot created by this **PLOT** statement is shown in [Output 71.8.22](#).

Output 71.8.22 Plot with MARKERS=NICE

Note that the plotting symbols are aligned with the tick marks on the X axis because the `X=` option is specified.

Example 71.9: Binary Logistic Regression with Independent Predictors

Suppose you are planning an industrial experiment similar to the analysis in “Getting Started: LOGISTIC Procedure” on page 4166 of Chapter 54, “The LOGISTIC Procedure,” but for a different type of ingot. The primary test of interest is the likelihood ratio chi-square test of the effect of heating time on the readiness of the ingots for rolling. Ingot will be randomized independently into one of four different heating times (5, 10, 15, and 20 minutes) with allocation ratios 2:3:3:2 and three different soaking times (2, 4, and 6 minutes) with allocation ratios 2:2:1. The mass of each ingot will be measured as a covariate.

You want to know how many ingots you must sample to have a 90% chance of detecting an odds ratio as small as 1.2 for a five-minute heating time increase. The odds ratio is defined here as the odds of the ingot not being ready given a heating time of h minutes divided by the odds given a heating time of $h - 5$ minutes, for any time h . You will use a significance level of $\alpha = 0.1$ to balance Type I and Type II errors since you consider their importance to be roughly equal.

The distributions of heating time and soaking time are determined by the design, but you must conjecture the distribution of ingot mass. Suppose you expect its distribution to be approximately normal with mean 4 kg and standard deviation between 1 kg and 2 kg.

You are powering the study for an odds ratio of 1.2 for the heating time, but you must also conjecture odds ratios for soaking time and mass. You suspect that the odds ratio for a unit increase in soaking time is about 1.4, and the odds ratio for a unit increase in mass is between 1 and 1.3.

Finally, you must provide a guess for the average probability of an ingot not being ready for rolling, averaged across all possible design profiles. Existing data suggest that this probability lies between 0.15 and 0.25.

You decide to evaluate sample size at the two extremes of each parameter for which you conjectured a range. Use the following statements to perform the sample size determination:

```
proc power;
  logistic
    vardist("Heat") = ordinal((5 10 15 20) : (0.2 0.3 0.3 0.2))
    vardist("Soak") = ordinal((2 4 6) : (0.4 0.4 0.2))
    vardist("Mass1") = normal(4, 1)
    vardist("Mass2") = normal(4, 2)
    testpredictor = "Heat"
    covariates = "Soak" | "Mass1" "Mass2"
    responseprob = 0.15 0.25
    testoddsratio = 1.2
    units= ("Heat" = 5)
    covoddsratios = 1.4 | 1 1.3
    alpha = 0.1
    power = 0.9
    ntotal = .;
run;
```

The **VARDIST=** option is used to define the distributions of the predictor variables. The distributions of heating and soaking times are defined by the experimental design, with ordinal probabilities derived from the allocation ratios. The two conjectured standard deviations for the ingot mass are represented in the Mass1 and Mass2 distributions. The **TESTPREDICTOR=** option identifies the predictor being tested, and the **COVARIATES=** option specifies the scenarios for the remaining predictors in the model (soaking time and mass). The **RESPONSEPROB=** option specifies the overall response probability, and the **TESTODDSRATIO=** and **UNITS=** options indicate the odds ratio and increment for heating time. The **COVODDSRATIOS=** option specifies the scenarios for the odds ratios of soaking time and mass. The default **DEFAULTUNIT=1** option specifies a unit change for both of these odds ratios. The **ALPHA=** option sets the significance level, and the **POWER=** option defines the target power. Finally, the **NTOTAL=** option with a missing value (.) identifies the parameter to solve for.

Output 71.9.1 shows the results.

Output 71.9.1 Sample Sizes for Test of Heating Time in Logistic Regression

The POWER Procedure										
Likelihood Ratio Chi-Square Test for One Predictor										
Fixed Scenario Elements										
Method		Shieh-O'Brien approximation								
Alpha		0.1								
Test Predictor		Heat								
Odds Ratio for Test Predictor		1.2								
Unit for Test Pred Odds Ratio		5								
Nominal Power		0.9								
Computed N Total										
Index	Response		-Covariates-	--Cov ORs--		-Cov Units-	Total		N	Total
	Prob			Bins	Actual Power					
1	0.15	Soak	Mass1	1.4	1.0	1	1	120	0.900	1878
2	0.15	Soak	Mass1	1.4	1.3	1	1	120	0.900	1872
3	0.15	Soak	Mass2	1.4	1.0	1	1	120	0.900	1878
4	0.15	Soak	Mass2	1.4	1.3	1	1	120	0.900	1857
5	0.25	Soak	Mass1	1.4	1.0	1	1	120	0.900	1342
6	0.25	Soak	Mass1	1.4	1.3	1	1	120	0.900	1348
7	0.25	Soak	Mass2	1.4	1.0	1	1	120	0.900	1342
8	0.25	Soak	Mass2	1.4	1.3	1	1	120	0.900	1369

The required sample size ranges from 1342 to 1878, depending on the unknown true values of the overall response probability, mass standard deviation, and soaking time odds ratio. The overall response probability clearly has the largest influence among these parameters, with a sample size increase of almost 40% going from 0.25 to 0.15.

Example 71.10: Wilcoxon-Mann-Whitney Test

Consider a hypothetical clinical trial to treat interstitial cystitis (IC), a painful, chronic inflammatory condition of the bladder with no known cause that most commonly affects women. Two treatments will be compared: lidocaine alone ("lidocaine") versus lidocaine plus a fictitious experimental drug called Mironel ("Mir+lido"). The design is balanced, randomized, double-blind, and female-only. The primary outcome is a measure of overall improvement at week 4 of the study, measured on a seven-point Likert scale as shown in Table 71.34.

Table 71.34 Self-Report Improvement Scale

Compared to when I started this study, my condition is:	
Much worse	−3
Worse	−2
Slightly worse	−1
The same	0
Slightly better	+1
Better	+2
Much better	+3

The planned data analysis is a one-sided Wilcoxon-Mann-Whitney test with $\alpha = 0.05$ where the alternative hypothesis represents greater improvement for “Mir+lido.”

You are asked to graphically assess the power of the planned trial for sample sizes between 100 and 250, assuming that the conditional outcome probabilities given treatment are equal to the values in [Table 71.35](#).

Table 71.35 Conjectured Conditional Probabilities

Treatment	Response						
	−3	−2	−1	0	+1	+2	+3
Lidocaine	0.01	0.04	0.20	0.50	0.20	0.04	0.01
Mir+lido	0.01	0.03	0.15	0.35	0.30	0.10	0.06

Use the following statements to compute the power at sample sizes of 100 and 250 and generate a power curve:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power;
  twosamplewilcoxon
    vardist("lidocaine") = ordinal ((−3 −2 −1 0 1 2 3) :
                                   (.01 .04 .20 .50 .20 .04 .01))
    vardist("Mir+lido") = ordinal ((−3 −2 −1 0 1 2 3) :
                                   (.01 .03 .15 .35 .30 .10 .06))
    variables = "lidocaine" | "Mir+lido"
    sides = u
    ntotal = 100 250
    power = .;
    plot step=10;
run;

ods graphics off;
```

The ODS LISTING STYLE=HTMLBLUECML statement specifies the HTMLBLUECML style, which is suitable for use with PROC POWER because it allows both marker symbols and line styles to vary. See the section “[ODS Styles Suitable for Use with PROC POWER](#)” on page 6082 for more information.

The **VARDIST=** option is used to define the distribution for each treatment, and the **VARIABLES=** option specifies the distributions to compare. The **SIDES=U** option corresponds to the alternative hypothesis that the second distribution ("Mir+lido") is more favorable. The **NTOTAL=** option specifies the total sample sizes of interest, and the **POWER=** option with a missing value (.) identifies the parameter to solve for. The default **GROUPWEIGHTS=** and **ALPHA=** options specify a balanced design and significance level $\alpha = 0.05$.

The **STEP=10** option in the **PLOT** statement requests a point for each sample size increment of 10. The default values for the **X=**, **MIN=**, and **MAX=** plot options specify a sample size range of 100 to 250 (the same as in the analysis) for the X axis.

The tabular and graphical results are shown in [Output 71.10.1](#) and [Output 71.10.2](#), respectively.

Output 71.10.1 Power Values for Wilcoxon-Mann-Whitney Test

The POWER Procedure		
Wilcoxon-Mann-Whitney Test		
Fixed Scenario Elements		
Method	O'Brien-Castelloe approximation	
Number of Sides	U	
Group 1 Variable	lidocaine	
Group 2 Variable	Mir+lido	
Pooled Number of Bins	7	
Alpha	0.05	
Group 1 Weight	1	
Group 2 Weight	1	
NBins Per Group	1000	
Computed Power		
	N	
Index	Total	Power
1	100	0.651
2	250	0.939

Output 71.10.2 Plot of Power versus Sample Size for Wilcoxon Power Analysis

The achieved power ranges from 0.651 to 0.939, increasing with sample size.

Overview: PSS Application

SAS Power and Sample Size

The SAS Power and Sample Size application (PSS) is a desktop application that provides easy access to power analysis and sample size determination techniques. The application is intended for students and researchers as well as experienced SAS users and statisticians.

Figure 72.1 shows the graphical user interface. PSS relies on the SAS/STAT procedures POWER and GLMPower for its computations.

Figure 72.1 PSS Application

Help Calculate

This section describes the statistical tasks that are available with the application as well as its principal features.

Analyses

PSS provides power and sample size computations for a variety of statistical analyses. Included are t tests for means; equivalence tests and confidence intervals for means and proportions; exact binomial, chi-square, Fisher's exact, and McNemar tests for proportions; correlation and regression (multiple and logistic); one-way analysis of variance; linear models; tests of distribution; and rank tests for comparing survival curves.

Table 72.1 lists the analyses that are available.

Table 72.1 Available Analyses

Category	Analysis
Means	One-sample t test
	Paired t test
	Two-sample t test
Confidence intervals	One proportion
	One-sample means
	Paired means
	Two-sample means
	Two-sample means
Equivalence tests	One proportion
	One-sample means
	Paired means
	Two-sample means
Proportions	One proportion
	Two correlated proportions
	Two independent proportions
Correlation and regression	Pearson correlation coefficient
	Logistic regression with a binary response
	Multiple regression
Analysis of variance and linear models	One-way ANOVA
	General linear univariate models
Survival analysis	Two-sample survival rank tests
Distribution tests	Wilcoxon Mann-Whitney test for two distributions

Features

PSS provides multiple input parameter options, stores the results in a project format, displays power curves, and produces narratives for the results. Narratives are descriptions of the input parameters and include a statement about the computed power or sample size. The SAS log and SAS code are also available.

All analyses offer computation of power or sample size. Some analyses offer computation of sample size per group as well as total sample size.

Where appropriate, several alternate ways of entering values for certain parameters are offered. For example, in the two-sample t test analysis, means can be entered for individual groups or as a difference. The null mean difference can be specified as a default of zero or can be explicitly entered.

Information about existing analyses is stored in a project format. You can access each project to review the results or to edit your input parameters and produce another analysis.

Getting Started: PSS Application

Overview

This section is intended to get you off to a quick start with PSS. More detailed information about using the application is found in “[How to Use: PSS Application](#)” on page 6166 and in the example sections.

To start the application on a PC using the Windows operating system, select **Start►Programs►SAS►SAS Power and Sample Size 3.1** (or the latest release).

When you first use the application for a release, you are asked some configuration questions. For more information see the section “[Configuration](#)” on page 6182.

As an initial step, you also must define a SAS connection. If you have Foundation SAS software installed on the PC that you are using for PSS, this step can be done for you automatically. To define a connection or to determine whether one has already been defined, see the section “[SAS Connections](#)” on page 6166.

The Basic Steps

Here are the basic steps that you follow to use PSS.

1. Start a new project by selecting **File►New** on the menu bar or clicking the **New** icon on the toolbar.
2. In the New window, select the desired analysis type and click **OK**.
A project window for the analysis type appears with the Edit Properties page displayed. (The tabs on the Edit Properties page and their content vary according to the analysis type.)
3. Click each tab to enter the relevant data for the analysis. (For more information about the types of data to enter, see the example sections.)
4. After you have entered all the data, click the **Calculate** button.
5. After PSS calculates the results, the project window displays the View Results page with the Summary Table tab displayed by default.
6. To view other results or to review the SAS code or the SAS log, click any of the tabs on the left side of the View Results page.
7. To print any results page, select **File►Print** on the menu bar.

The remainder of this section takes you through a simple example.

A Simple Example

Suppose you want to determine the power for a new marketing study. You want to compare car sales in the southeastern region to the national average of 1.0 car per salesperson per day. You believe that the actual average for the region is 1.6 cars per salesperson per day. You want to test if the mean for a single group is larger than a specific value, so the one-sample t test is the appropriate analysis. The conjectured mean is 1.6 and the null mean is 1.0. You intend to use a significance level of 0.05 for the one-sided test. You want to calculate power for two standard deviations, 0.5 and 0.75, and two sample sizes, 10 and 20 dealerships.

First, open a new project by selecting **File►New** on the menu bar or clicking the **New** icon on the toolbar. The New window appears. Then, select the appropriate analysis.

Figure 72.2 New Window

For this example, the selected analysis is the **One-sample t test** in the **Means** section, as shown at the top of Figure 72.2. Select the analysis from the list and click **OK**. The **One-sample t test** project window appears with the Edit Properties page displayed, as shown in Figure 72.3.

Figure 72.3 Edit Properties Page

Regional car sales versus the national average

Analysis: One-sample t Test

Project: Regional car sales versus the national average

Properties

Standard Deviation | Sample Size | Results | **Solve For** | Distribution | Hypothesis | Alpha | Means

Select a quantity to solve for

☒ Power

☐ Sample size

◀ Previous tab | Next tab ▶

Enter a descriptive label of the project in the **Project:** field. For the example, change the description to Regional car sales versus the national average. The description is used to identify the project when you reopen it from the Open window.

Select **File►Save** to save the description change. Note in [Figure 72.3](#) that the title bar of the window contains your project description after you have saved the change.

Properties of the project are displayed on several tabs. You can change from tab to tab by clicking a tab or by clicking the **Next tab** or **Previous tab** buttons. To display help about the properties for a tab, click the **Help** button at the bottom of the Edit Properties page.

Entering Parameter Values

First, click the **Solve For** tab and choose to calculate power or sample size. For this example, select the **Power** option, as shown in [Figure 72.3](#).

Next, you must provide values for two analysis options and four parameters. These parameters are set in separate tabs on the Edit Properties page and are labeled **Distribution**, **Hypothesis**, **Alpha**, **Mean**, **Standard Deviation**, and **Sample Size**.

Distribution

Click the **Distribution** tab to select a **Normal** or **Lognormal** distribution. For the example, you are using means rather than mean ratios, so select **Normal**, as shown in [Figure 72.4](#).

Figure 72.4 Distribution Tab

Analysis: One-sample t Test

Project:

Properties

Standard Deviation	Sample Size	Results
Solve For	Distribution	Hypothesis
	Alpha	Means

Select the distribution of the test

☐ Lognormal

☒ Normal

Hypothesis

Click the **Hypothesis** tab to select a one- or two-sided test. Because you are interested only in whether the southeastern region produces higher daily car sales than the national average, select **One-sided test**, as shown in [Figure 72.5](#).

Figure 72.5 Hypothesis Tab

Analysis: One-sample t Test

Project:

Properties

Standard Deviation	Sample Size	Results
Solve For	Distribution	Hypothesis
		Alpha
		Means

Select a one or two-sided hypothesis test

☒ One-sided test
 ☐ Lower one-sided test
 ☐ Upper one-sided test

☐ Two-sided test

There are three one-sided test options: **One-sided test**, **Upper one-sided test**, and **Lower one-sided test**. The **Upper one-sided test** option would also be appropriate for this example.

Alpha

Click the **Alpha** tab to specify one or more significance levels. Enter 0.05, as shown in [Figure 72.6](#).

Figure 72.6 Alpha Tab

Properties

Standard Deviation	Sample Size	Results
Solve For	Distribution	Hypothesis
		Alpha
		Means

Specify one or more significance levels

Alpha
0.05

Rows

This value will be the default unless the default has been changed in the Preferences window. To set preferences, select **Tools►Preferences** on the menu bar. For more information about setting preferences, see the section “[Setting Preferences](#)” on page 6169.

Mean

Click the **Means** tab to enter one or more means and null means. For the example, enter 1.6 in the Mean table and 1.0 in the Null Mean table. [Figure 72.7](#) shows the entered values.

Figure 72.7 Means Tab

Properties

Standard Deviation Sample Size Results

Solve For Distribution Hypothesis Alpha Means

Enter one or more values for the mean and null mean

Mean
1.6

Null Mean
1.0

Rows

Rows

Note that additional input rows are available if you want to enter additional sets of parameters. You can also append and delete rows using the and buttons beneath the table. In addition, by selecting a row and right-clicking, you can choose to insert and delete rows in the body of the table from a pop-up menu.

Standard Deviation

Click the **Standard Deviation** tab to enter standard deviations. You are interested in two standard deviations, 0.5 and 0.75. Enter them in the table, as shown in [Figure 72.8](#).

Figure 72.8 Standard Deviation Tab

The screenshot shows the 'Properties' dialog box with the 'Standard Deviation' tab selected. The 'Solve For' tab is also highlighted. The 'Distribution' tab is active, and the 'Hypothesis' tab is selected. The 'Alpha' and 'Means' tabs are also visible. The 'Sample Size' and 'Results' tabs are at the bottom. The main area contains the text 'Enter one or more standard deviations'. Below this is a list box labeled 'Std. Dev.' containing the values '0.5' and '0.75'. At the bottom, there is a 'Rows' section with two buttons: a green plus sign and a red minus sign.

Sample Size

You want to be able to sample between 10 and 20 dealerships. Click the **Sample Size** tab and enter these two values, as shown in Figure 72.9.

Figure 72.9 Sample Size Tab

The screenshot shows the 'Properties' dialog box with the 'Sample Size' tab selected. The 'Solve For' tab is also highlighted. The 'Distribution' tab is active, and the 'Hypothesis' tab is selected. The 'Alpha' and 'Means' tabs are also visible. The 'Standard Deviation' and 'Results' tabs are at the bottom. The main area contains the text 'Enter one or more values for total sample size'. Below this is a list box labeled 'Total N' containing the values '10' and '20'. At the bottom, there is a 'Rows' section with two buttons: a green plus sign and a red minus sign. Below the 'Rows' section is a section labeled 'Fractional Sample Sizes' with a checkbox labeled 'Allow fractional sample sizes'.

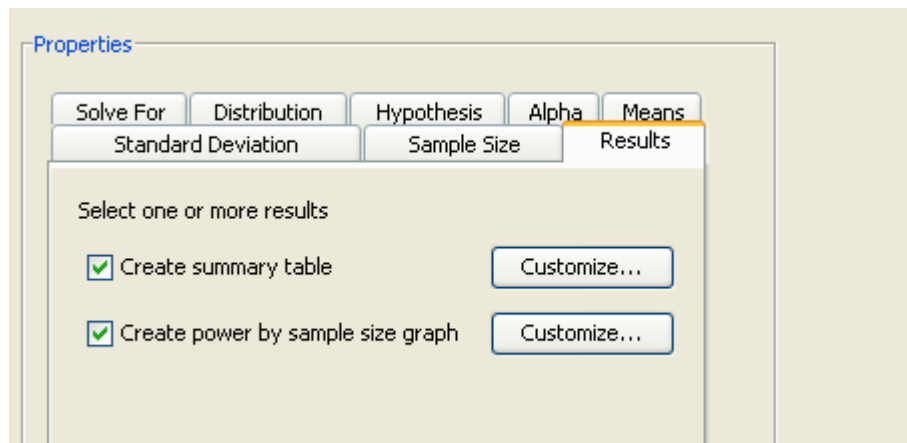

Scenarios

The input values are combined into one or more scenarios. In this case, each of the two standard deviations is combined with each of the two sample sizes for a total of four scenarios. Then power is computed for each scenario. In this example, only a single value or setting is present for the mean, null mean, and alpha level, so they are common to all scenarios.

Results Options

Click the **Results** tab to select results options including a Summary Table and a Power by Sample Size graph.

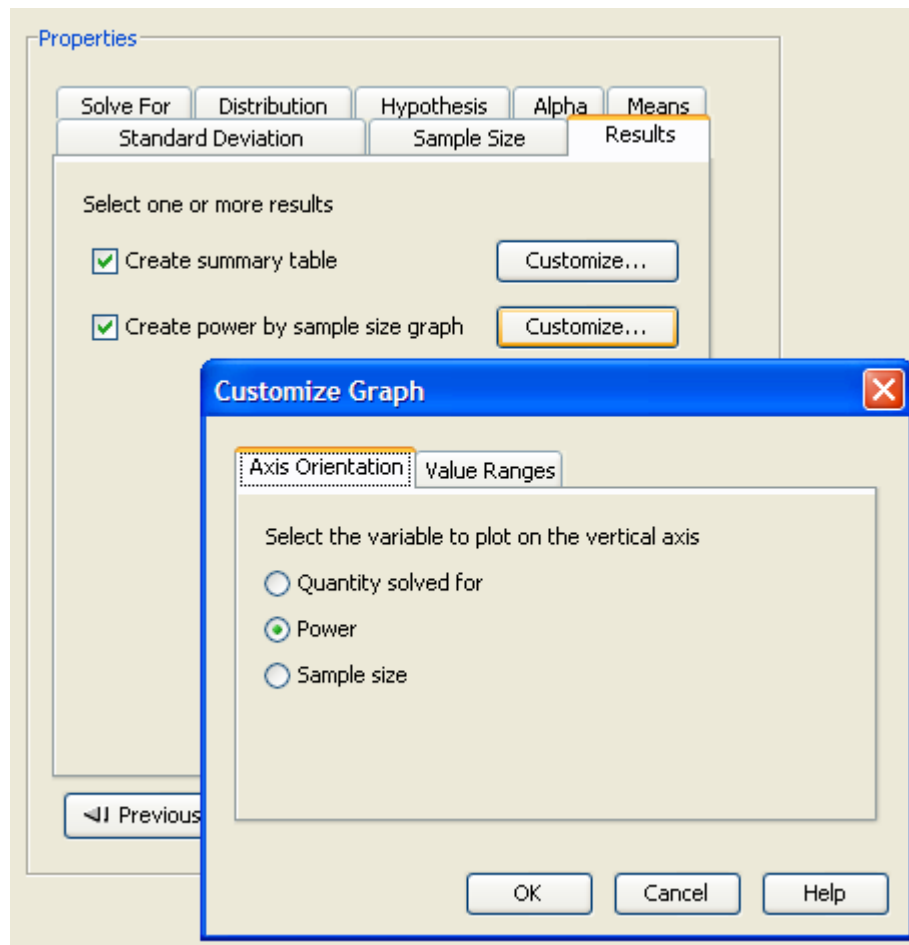

Figure 72.10 Results Tab

For this example, select both results check boxes: **Create summary table** and **Create power by sample size graph**, as shown in Figure 72.10. These selections can also be set as preferences; see the section “Setting Preferences” on page 6169.

Customizing the Power by Sample Size Graph

Click the **Customize** button beside the **Create power by sample size graph** check box to customize the graph. The Customize Graph window contains two tabs: **Axis Orientation** and **Value Ranges**, as shown in Figure 72.11.

Figure 72.11 Customize Graph Window with Axis Orientation Tab

Click the **Axis Orientation** tab to select which quantity you would like to plot on the vertical axis. You can choose to display the quantity solved for (either power or sample size) on the vertical axis or you can choose to display power or sample size on the vertical axis with the other quantity appearing on the horizontal axis. The default is **Quantity solved for** (or power) on the vertical axis, which is appropriate for this graph.

The summary table is created using the two sample sizes specified in the Sample Size table, 10 and 20. If you want to create a graph that contains more than these two sample sizes, you can do so by customizing the value ranges for the graph. Click the **Value Ranges** tab to set the axis range for sample sizes, as shown in Figure 72.12.

Figure 72.12 Customize Graph Window with Value Ranges Tab

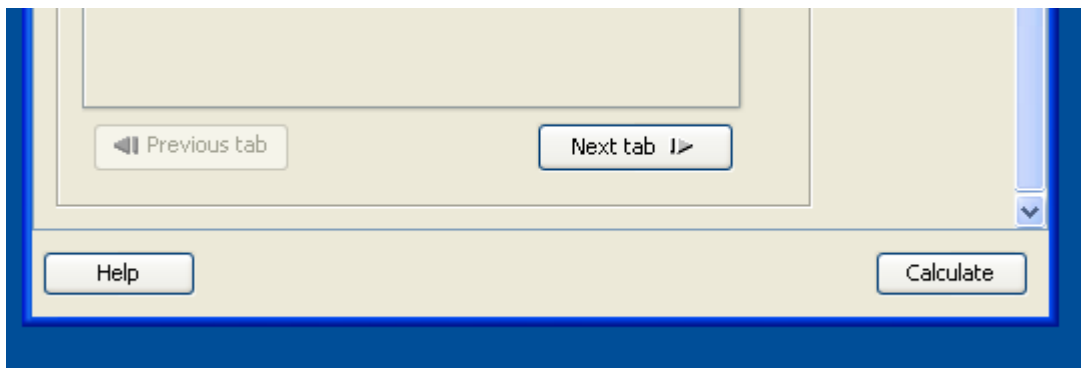

Enter 5 for the minimum and 30 for the maximum. Also, select **Interval between points** in the drop-down list and enter a value of 1. These values set the sample size axis to range from 5 to 30 in increments of 1. The completed Value Ranges section of the window is shown in [Figure 72.12](#).

When you solve for power, you can set a range for sample size values, but not for the powers; and vice versa when you solve for sample size. That is, you cannot set the range of axis values for the quantity that you are solving for.

Click **OK** to save the values that you have entered and return to the Edit Properties page.

Performing the Analysis

You have now specified all of the necessary input values. Click **Calculate** to perform the analysis, as shown in [Figure 72.13](#).

Figure 72.13 Calculate Button on the Edit Properties Page

Alternatively, you could choose to save the information that you have entered by selecting **File►Save** from the menu bar or clicking the **Save** toolbar icon, and perform the analysis at another time. No error checking is done when you save the project.

You can close the project by selecting **File►Close** on the menu bar or clicking the window close **X** in the upper right corner of the project window. You can reopen a project by selecting **File►Open** on the menu bar or clicking the **Open** toolbar icon.

For this example, click **Calculate**.

Viewing the Results

Results appear on the View Results page and are viewable in separate tabs. The tabs include **Summary Table**, **Graph**, **Narratives**, **SAS Log**, and **SAS Code** (located on the left side of the View Results page). The **Summary Table** and **Graph** tabs appear if you selected those options on the **Results** tab of the Edit Properties page. The other tabs always appear.

Summary Table

Click the **Summary Table** tab to view the summary table.

Figure 72.14 Summary Table Tab with Fixed Scenario Elements and Computed Power Tables

The Summary table consists of two subtables, as shown in Figure 72.14. The `Fixed Scenario Elements` table includes the parameters or options that have a single value for the analysis. The `Computed Power` table contains the input parameters that have been given more than one value, and it shows the computed quantity, power.

Thus, the `Computed Power` table contains four rows for the four combinations of standard deviation and sample size. From the table you can see that all four powers are high. The smallest value of power, 0.754, is associated with the largest standard deviation and the smallest sample size. In other words, the probability of rejecting the null hypothesis is greater than 75% in all four scenarios.

Power by Sample Size Graph

Click the **Graph** tab to view the power by sample size graph.

The power by sample size graph in Figure 72.15 contains one curve for each standard deviation. For a standard deviation of 0.5 (the upper curve), increasing sample size above 10 does not lead to much increase in power. If you are satisfied with a power of 0.75 or greater, 10 samples would be adequate for standard deviations between 0.5 and 0.75.

Figure 72.15 Graph Tab with Power by Sample Size Graph

Narratives

Click the **Narratives** tab to display a facility for creating narratives.

Narratives are descriptions of the values that compose each scenario and include a statement about the computed power or sample size.

To create narratives, choose one or more scenarios in the table at the bottom of the tab. A narrative for each selected scenario is displayed in the top portion of the tab. See Figure 72.16.

Figure 72.16 Narrative Tab

Regional car sales versus the national average

Edit Properties View Results

Summary Table
Graph
Narratives
SAS Log
SAS Code

Narratives

For a one-sample t test of a normal mean with a one-sided significance level of 0.05 and null mean 1, assuming a standard deviation of 0.5, a sample size of 10 has a power of 0.967 to detect a mean of 1.6.

Create Narratives

Select one or more scenarios

Select	Index	Sides	NullMean	Alpha	Mean	StdDev	NTotal	Power	Error	Info
<input checked="" type="checkbox"/>	1	1	1	0.05	1.6	0.50	10	0.96747525		
<input type="checkbox"/>	2	1	1	0.05	1.6	0.50	20	0.99978391		
<input type="checkbox"/>	3	1	1	0.05	1.6	0.75	10	0.75442476		
<input type="checkbox"/>	4	1	1	0.05	1.6	0.75	20	0.9641728		

☐ Hide columns with constant input values

Clear all selections

For the example, select the first row in the table. The following narrative is displayed for the scenario with a standard deviation of 0.5 and a sample size of 10:

For a one-sample t test of a normal mean with a one-sided significance level of 0.05 and null mean 1, assuming a standard deviation of 0.5, a sample size of 10 has a power of 0.967 to detect a mean of 1.6.

You can select several rows in the table. As you select each one, a corresponding narrative is created and displayed in the top portion of the table. Selecting a second scenario (the third row) produces the following output, where the narrative for the first row is followed by the narrative for the third row:

For a one-sample t test of a normal mean with a one-sided significance level of 0.05 and null mean 1, assuming a standard deviation of 0.5, a sample size of 10 has a power of 0.967 to detect a mean of 1.6.

For a one-sample t test of a normal mean with a one-sided significance level of 0.05 and null mean 1, assuming a standard deviation of 0.75, a sample size of 10 has a power of 0.754 to detect a mean of 1.6.

Other Results

Other results include the SAS log and the SAS code.

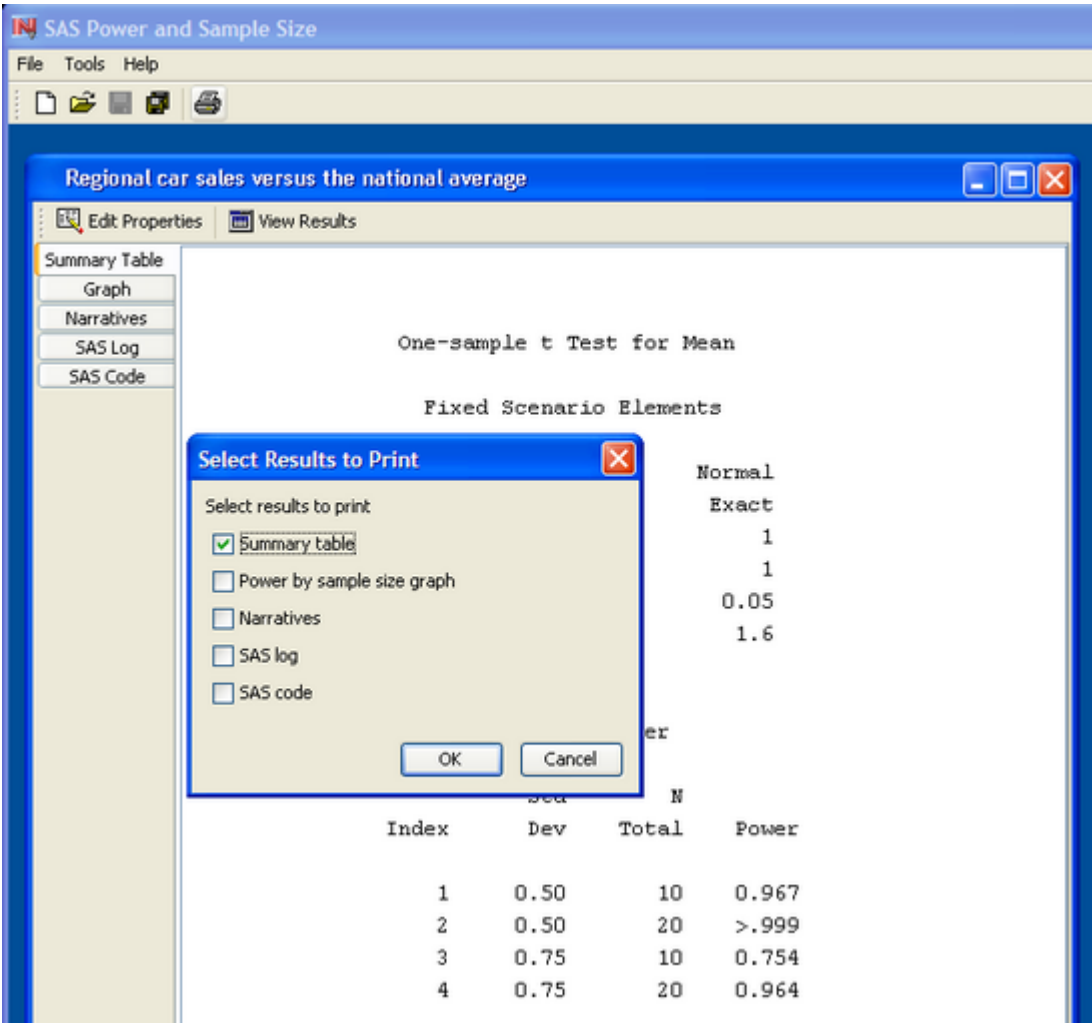

The SAS log that was produced when the **Calculate** button was last clicked appears on the **SAS Log** tab.

The SAS statements that produced the results appear on the **SAS Code** tab.

Printing Results

To print one or more results, select **File►Print** from the menu bar or click the **Print** toolbar icon. A window is displayed that lists all available results, as shown in [Figure 72.17](#). Select the results that you want to print and click **OK**.

Figure 72.17 Print Selection Window

Changing Properties

If you want to change some values of the properties and rerun the analysis, change to the Edit Properties page and continue. The icons for selecting the Edit Properties and View Results pages are in the command bar just below the project window title.

Closing the Project

When you are finished working with a project, close it by clicking the **X** in the upper right corner of the project window or selecting **File►Close** on the menu bar. If you have not saved the project, you will be asked if you want to save it before closing.

Opening a Project

You can reopen existing projects using the Open window. Select **File►Open** on the menu bar or click the **Open** toolbar icon.

Figure 72.18 Open Window Containing the Analysis Created in the Example

As shown in Figure 72.18, the analysis that you just completed is listed in the table. The label that you assigned to it, `Regional car sales versus the national average`, appears in the **Project** column of the table. The table also contains the date that the analysis was last modified. If you do not see the project that you are looking for, change the value of the **Display projects by date** box to `All` by selecting `All` from the drop-down list, and click the **Change display** button.

You can sort the projects in the table by clicking the header of the desired column. The sort direction is indicated by arrows displayed in the column header.

Select the project that you want to open and click **OK**. You can also double-click the project entry to open it.

Changing Values and Rerunning the Analysis

After viewing the graph, you might want to re-create the graph with a different range for sample sizes. On the **Results** tab of the Edit Properties page, click the **Customize** button for the power by sample size graph. The **Customize Graph** window is displayed.

On the **Value Ranges** tab of the window, change the Maximum value in the Sample Size table from 30 to 20. Click **OK**.

Rerun the analysis by clicking **Calculate**. The View Results page is displayed again and the graph now has the new maximum value for the sample size axis.

How to Use: PSS Application

Overview

The PSS application is an application that resides on your desktop. It requires a connection to SAS software either on your desktop machine or a remote machine. You can set default values for several parameters and options as preferences. More detail on creating and editing projects is provided. Projects can be imported and exported.

SAS Connections

Connections to SAS servers are defined in the Preferences window. To access the Preferences window, select **Tools►Preferences** on the menu bar.

Click the **SAS Connection** tab to select or define a connection to a SAS server. A connection to a SAS server is required in order to calculate results. The server can be on your local (desktop) machine or on a remote machine.

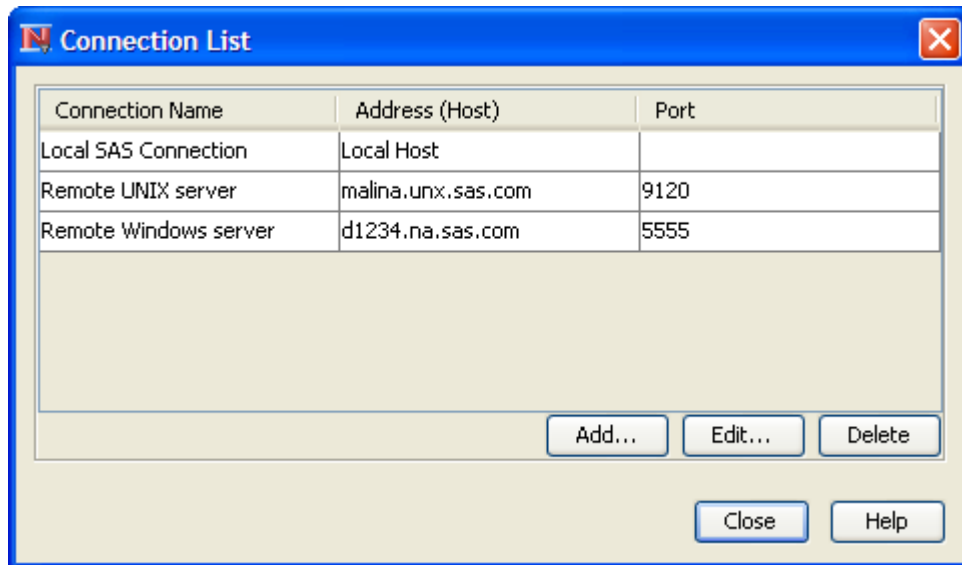

You can define several SAS connections and choose the one you want to use. To select a previously defined connection, choose it from the **Connection** list on the **SAS Connection** tab; see [Figure 72.19](#).

Figure 72.19 SAS Connection Tab

To define a SAS connection, click the **Define connection** button. The Connection List window appears, as shown in [Figure 72.20](#). To create a new connection, click **Add**. To edit an existing connection, select it in the Connection List and click **Edit**.

Figure 72.20 Connection List

Defining a SAS Connection

After you click the **Add** or **Edit** button, the Define SAS Connection window appears, as shown in [Figure 72.21](#). If you clicked **Edit**, the previously defined information is available for editing.

Figure 72.21 Define Connection Window

Define SAS Connection

Connection Label

Label:

SAS Connection Configuration

Are the SAS server and SAS Power and Sample Size running on the same machine?

☒ Yes ☐ No

Local Server Properties

Enter the full pathname of the SAS command

Pathname:

Remote Server Properties

Platform

☐ UNIX ☐ Windows

Connection Product

☒ SAS/Connect

SAS Server Properties

Name: Port:

☐ User id and password are required

Enter a descriptive label for the connection. The label is used to distinguish among the connections in the connections list.

Then, select **Yes** or **No** to specify whether the SAS connection is to the local machine (that is, the one on which PSS is running) or to a remote machine, respectively.

Defining a Local Connection

To define a connection to the local machine, enter the full path name of (or browse for) the SAS executable file (*sas.exe* on Microsoft Windows).

Test the SAS connection by clicking the **Test SAS Connection** button.

Defining a Remote Connection

To define a connection to a remote machine, select either the **UNIX** or **Windows** option to indicate that the remote SAS server is on a machine running the UNIX or Microsoft Windows operating systems, respectively. Then, specify the machine name and port number that the SAS/Connect spawner is using on the remote machine. Contact the SAS server administrator for this information.

If the remote machine is running Microsoft Windows, select the **User id and password are required** if authentication is required to access the SAS server (that is, if the SAS **-security** option is used). By default, authentication is required for SAS servers running on UNIX operating systems.

Test the SAS connection by clicking the **Test SAS Connection** button.

Additional Settings

Click the **Settings** button on the Define SAS Connection window to access some additional settings for a remote connection to a SAS server. For the most part these settings are prompts that PSS expects to receive from the SAS/CONNECT spawner on the remote machine, as shown in [Figure 72.22](#).

If the remote SAS server is on a UNIX machine, you must specify the full pathname of the SAS command. Contact the SAS server administrator for this information.

Figure 72.22 Connection Settings Window

The screenshot shows a 'Settings' dialog box with a blue title bar and a close button (X). The dialog is divided into two main sections: 'UNIX' and 'Windows'. The 'UNIX' section contains five input fields: 'Command prompt:' with the text 'Hello>', 'User ID prompt:' with 'Username:', 'Password prompt:' with 'Password:', 'SAS command:' which is empty, and 'SAS options:' with the text '-dmr -noterminal -comamid tcp'. The 'Windows' section contains two input fields: 'User ID prompt:' with 'Username:' and 'Password prompt:' with 'Password:'. At the bottom of the dialog are three buttons: 'OK', 'Cancel', and 'Reset'.

Setting Preferences

In the Preferences window you can set default values for options that are used by all analyses.

To access the Preferences window, select **Tools►Preferences** on the menu bar. [Figure 72.23](#) shows the Preferences window.

Figure 72.23 Preferences Window

Preference values are used as the defaults for each newly opened project (that is, those that are opened from the New window). For a specific project, each of these default values can be overridden on the Edit Properties page.

Changes in preferences do not change the state of an existing analysis (that is, one that is accessed from the Open window).

Selecting the Quantity to Solve For

Click the **Solve For** tab to select **Power** or **Sample Size** as the default value to be solved for; see [Figure 72.23](#). For confidence interval analyses, selecting **Power** is equivalent to selecting **Prob(Width)**.

For analyses that offer both **Sample size per group** and **Total sample size**, the **Sample size** option on this page corresponds to total sample size.

Setting Alphas

Click the **Alpha** tab to enter one or more values for alpha. Alpha is the significance level (false positive probability). For confidence interval analyses, alpha values are transformed into confidence levels by $(1 - \alpha)$. For example, an alpha of 0.05 would represent a confidence level of 0.95.

To set default values of alpha, enter one or more values in the **Alpha** data entry table. See Figure 72.24. It is not necessary to have any default values for alpha. Add more rows to the table as needed using the  button at the bottom of the table.

Figure 72.24 Alpha Preference Tab

Setting Powers

Click the **Power** tab to enter one or more values for power. It is not necessary to have any default values for power. For confidence interval analyses, power values are treated as `prob(width)` values.

To set default values of power, enter one or more values in the **Power** data entry table; see Figure 72.25.

Figure 72.25 Power Preference Tab

Setting Results Options

Click the **Results** tab to make default selections for the summary table and the power by sample size graph options; see Figure 72.26.

Figure 72.26 Results Options Preferences Tab

The summary table consists of the input parameter values and the calculated quantity (power or sample size). Select the **Create summary table** check box to create the table by default.

To request that an analysis create a power by sample size graph by default, select the **Create power by sample size graph** check box.

Creating and Editing PSS Projects

A PSS project is an instance of an analysis. The first decision in using PSS is to choose the appropriate test or design. Select the **File►New** on the menu bar or click the **New** icon on the toolbar. The New window appears with a list of the available analyses. Select the type of analysis that you want from the list and click **OK**.

When the project is first opened, the Edit Properties page is displayed. It is described in the section “[Editing Properties](#)” on page 6174.

After the properties have been specified and the analysis is performed, the View Results page is displayed. See the section “[Viewing the Results](#)” on page 6178.

A project that has been saved and closed can be reopened from the Open window. Select **File►Open** on the menu bar or click the **Open** icon on the toolbar.

Editing Properties

The Edit Properties page consists of several analysis options and input parameters that are relevant to the particular analysis. These options and parameters are organized on several tabs, as shown in Figure 72.27.

Figure 72.27 Edit Properties Page

The screenshot shows the SAS Power and Sample Size application window. The main title bar reads "SAS Power and Sample Size". Below it is a menu bar with "File", "Tools", and "Help". A toolbar contains icons for file operations. The main window has a title bar that says "One-sample t test" with standard window controls. Inside, there are two tabs: "Edit Properties" (active) and "View Results". The "Edit Properties" tab contains the following elements:

- Analysis: One-sample t Test**
- Project:** A text box containing "One-sample t test".
- Properties** section with a scrollable area containing:
 - Four tabs: "Standard Deviation", "Sample Size", "Results", and "Solve For". The "Solve For" tab is active.
 - Under the "Solve For" tab, there are two sub-tabs: "Distribution" and "Hypothesis".
 - Below the sub-tabs, there are two radio buttons:
 - ☒ Power
 - ☐ Sample size
- At the bottom of the "Properties" section are two buttons: "Previous tab" and "Next tab".
- At the bottom of the window are two buttons: "Help" and "Calculate".

The Edit Properties page contains various controls by which you can enter values or select choices. In addition to the usual data entry controls such as text fields and check boxes, several specialized controls are present: data entry tables and the Alternate Forms control. More detailed descriptions follow.

Using Data Tables

Data entry tables are composed of data entry fields for one or more rows and columns. [Figure 72.28](#) shows a two-row, two-column table.

Figure 72.28 Two-Column Data Entry Table with Controls

Group 1	Group 2

Rows

Type an appropriate value in each field. It is not necessary to type data in all rows or to delete empty rows. However, if a table has more than one column, the cells of a row must be completely filled or completely blank. Rows with values in some but not all cells are not allowed.

To append more rows, click the button beneath the table. To delete the last row of the table, click the button.

Also, you can display a pop-up menu to perform additional actions such as inserting and deleting rows. First, select the row to insert before or delete, then right-click to display the pop-menu and select the desired action.

Using Alternate Forms

For some input parameters, there are several ways in which data may be entered. For example, in the two-sample t test analysis, group means can be entered as either individual means or a difference between means.

The alternate forms are displayed in a drop-down list with an adjacent button, as shown in [Figure 72.29](#). The button enables you to cycle through the alternatives, displaying each one in turn. To see what forms are available, you can open the drop-down list and select the one you want or you can click the button until the form that you want is displayed.

Figure 72.29 Select a form Drop-Down List and Button

The screenshot shows the 'Properties' dialog box with the 'Solve For' tab selected. Under 'Solve For', the 'Means' sub-tab is active. A drop-down menu for 'Select a form:' is open, showing a list of options: 'Group means', 'Difference between means', 'Group means', 'Difference between means, Null difference', and 'Group means, Null difference'. The 'Group means, Null difference' option is highlighted. Below the drop-down, there is a table with a header 'Group 1' and an empty column. At the bottom, there are 'Rows' buttons with '+' and '-' icons.

The alternate form last used for an analysis is saved and displayed as the default when a new instance of the analysis is opened.

Customizing Graphs

The Edit Properties page for all analyses contains a **Results** tab. You can choose to create a graph, and you can optionally choose to customize the graph by clicking the **Customize** button that is beside the **Create power and sample size graph** choice.

As shown in Figure 72.30, the Customize Graph window consists of an **Axis Orientation** tab and a **Value Ranges** tab. Use the **Axis Orientation** options to specify which axes you want used for power and for sample size. Use the **Value Ranges** settings to specify the axis range for the non-target quantity (that is, the power axis if you are solving for sample size or the sample size axis if you are solving for power).

Figure 72.30 Customize Graph Window

When specifying a value range, you can specify a minimum value and a maximum value. Also, you can select either the **Number of points** or the **Interval between points** choice for the axis and specify a value. All of these values are optional; specify only the ones you want.

Scenarios

A scenario is one instance of a complete set of values for an analysis. For example, if two alpha values and two total sample size values are specified with all other input parameters taking only a single value, there would be four scenarios—the four combinations of two alphas and two sample sizes.

Performing the Analysis

To perform the analysis, click **Calculate** at the lower right of the Edit Properties page. The input parameters are checked for validity, and the analysis is performed. The View Results page is then displayed.

Viewing the Results

The results appear in separate tabs on the View Results Page. These tabs include **Summary Table**, **Graph**, **Narratives**, **SAS Log**, and **SAS Code**.

Viewing the Summary Table

Click the **Summary Table** tab to view the summary table. It consists of two subtables, as shown in Figure 72.31. The **Fixed Scenario Elements** table includes the options and parameter values that are constant for the analysis. The **Computed Power** table includes the calculated power or sample size values and the values for input parameters that have multiple values specified for the analysis.

Figure 72.31 View Results Page with Summary Table

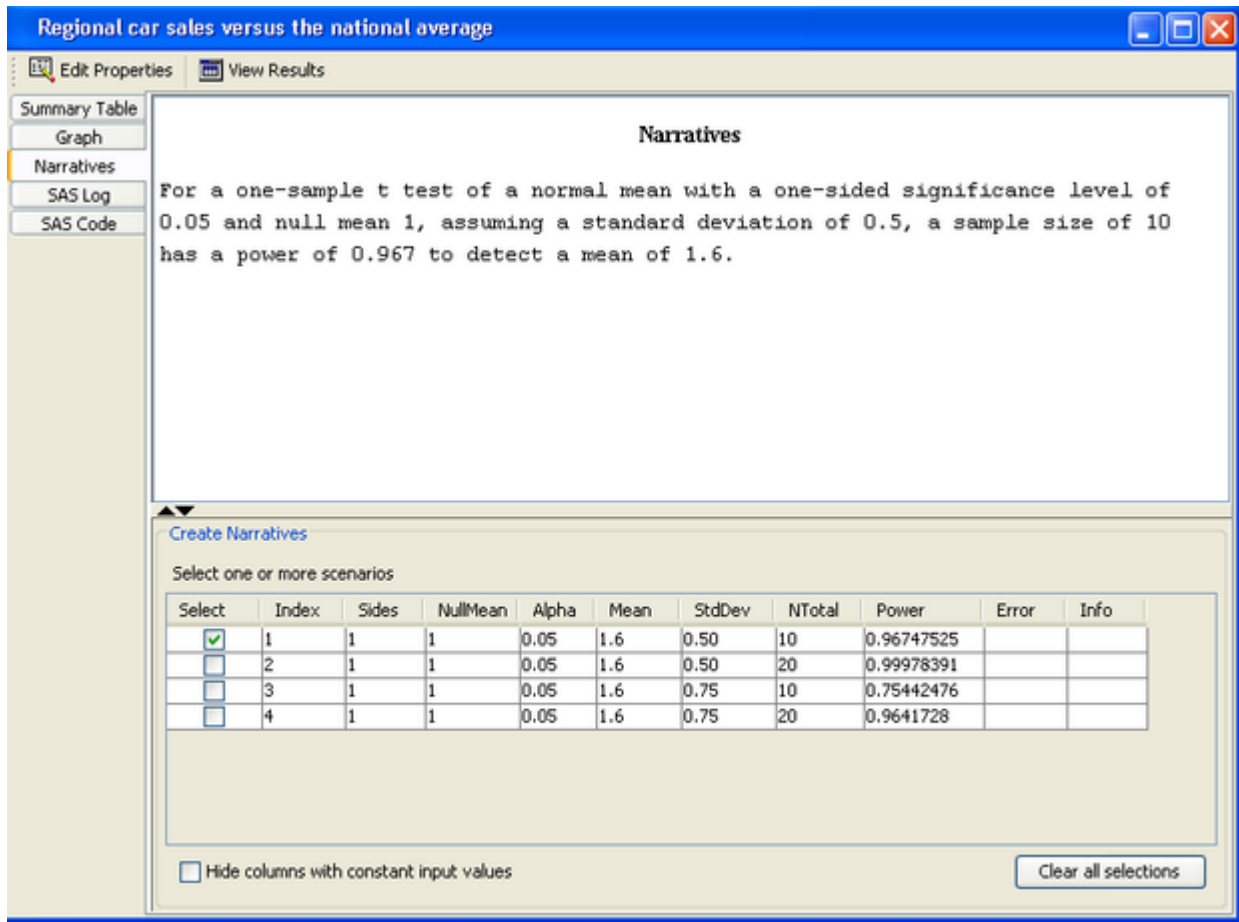

Creating Narratives

Click the **Narratives** tab to display a facility to create narratives. Narratives are descriptions of the input parameter values and calculated quantities in sentence or paragraph form. Each narrative corresponds to one calculated quantity value.

The **Narratives** tab is divided into a narrative selector panel and a narrative display panel. To create a narrative, select the row in the narrative selector panel that corresponds to it. You can select as many rows as you want. See Figure 72.32.

Figure 72.32 Narrative Selector and Display

The narrative selector table often contains columns whose values do not vary. For example, in Figure 72.32, the Sides, NullMean, Alpha, and Mean columns contain values that do not vary. You can hide these columns by selecting the **Hide columns with constant input values** check box.

Viewing the SAS Log and Code

Click the **SAS Code** tab to view the SAS statements that are used to generate the analysis results. Click the **SAS Log** tab to view the SAS log that corresponds to the analysis.

The SAS code differs slightly from the statements in the SAS log. Statements that are used to place the results in the location maintained by the application are not included. This is done to prevent you from overwriting the results stored by the application if you run the SAS code outside of the application.

Printing Results

To print one or more results, click the **Print** icon on the toolbar or select **File►Print** on the menu bar. The Select Results to Print window is displayed. You can choose to print one or more of the results by selecting the corresponding options here.

Saving the Project

To save a project, click the **Save** toolbar icon or select **File►Save** from the menu bar. Projects can be saved even if some of the information is invalid. Error checking is performed when the **Calculate** button is clicked.

Closing the Project

To close a project, click the **X** in the upper right corner of the project window or select **File►Close** from the menu bar.

Importing and Exporting Projects

PSS projects can be imported from the same machine or a different machine. Also, the active project (the project that is open and on top of any other open projects) can be exported.

Importing Projects

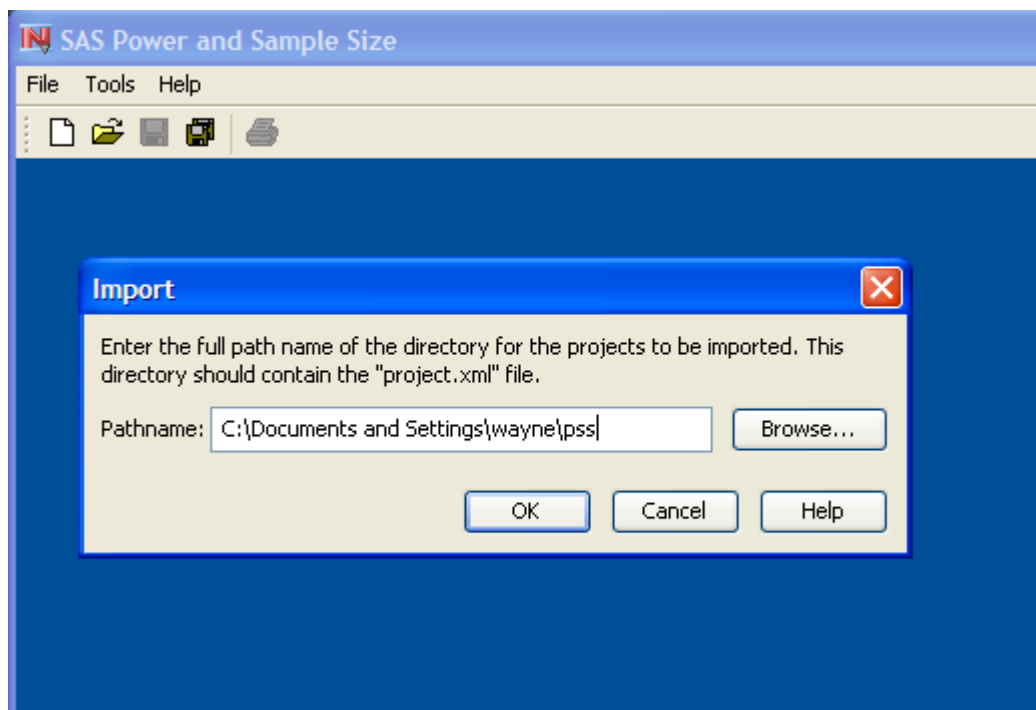

A PSS project that was created on another machine or by another user can be imported and used. Also, importing projects is the recommended way of moving existing PSS projects that were created with PSS release 2.0 (a Web application) to PSS release 3.1 (a desktop application).

PSS files are stored in a folder entitled *pss*. The *pss* folder contains a *project.xml* file and individual folders for each project. See [Figure 72.33](#).

Figure 72.33 PSS Directory Structure

If PSS files are on another machine, they must first be copied to a temporary location on the desktop machine that is running PSS. The entire *pss* folder should be copied.

To import projects, select **File►Import** from the menu bar. Then, specify the full pathname of the *pss* folder.

Figure 72.34 Import Projects Window

To import PSS 2.0 files, you need to find the *pss* folder. The easiest way to do this is to search for the *project.xml* file. If you find several files with this name, you need to decide which one or more to import.

Exporting the Active Project

If you want to send a PSS project to someone, you can export the active project. The active project is the one that is open and that has focus (is displayed on top of any other open projects). Select **File►Export active project** and specify a temporary directory to hold the exported project.

The recipient must import the project using PSS.

Details: PSS Application

Software Requirements

PSS is available in SAS 9.2 or later for the following platforms: Microsoft Windows 7, Vista, and XP.

Two configurations are available for SAS connections: local and remote. With the local configuration, PSS and SAS must reside on the same machine. With the remote configuration, PSS and SAS can reside on different machines. SAS connections are defined and selected on the **SAS Connection** tab on the Preferences window. More information about SAS connections is found in the section “[SAS Connections](#)” on page 6166.

For both configurations, Base SAS and SAS/STAT software must be installed and SAS/GRAPH software is recommended.

For the remote configuration, SAS/CONNECT and SAS/IntrNet software must also be installed. For more information about configuring the remote SAS server, click **Help►Contents** on the menu bar and then click **Configuring a Remote SAS Server** under **Special Topics** in the table of contents.

Installation

SAS Power and Sample Size is installed separately from the SAS/STAT product. Contact your SAS site representative to have the application installed.

SAS Power and Sample Size is installed using the SAS Software Deployment Wizard. It is listed as an available product with, but separate from, Foundation SAS which contains the SAS/STAT and SAS/GRAPH products that are required for using the application.

Configuration

When you first run SAS Power and Sample Size 3.1 (PSS), you are asked to provide configuration information.

First, you are asked for the name of a directory to contain the your power and sample size projects. A folder named *pss* is created in the specified directory, and projects are stored in the *pss* folder. This directory cannot be the same as the one used by PSS 2.0. If it is, PSS requires that another folder name be provided.

Then, if the appropriate release of the SAS System is available on the desktop machine, you are asked whether a connection should be automatically created to it. If you respond **No**, then PSS informs you that a connection to the SAS server is necessary and asks if you want to select one now or later. A connection to a SAS server is not necessary to use the application until the **Calculate** button on the Edit Properties page of a project is clicked. More information about connections is available in the section “[Setting Preferences](#)” on page 6169.

Then, PSS displays a wizard to help you import existing PSS projects from either a previous release (PSS 2.0) or the current one (PSS 3.1). More information is available in the section “[Importing Projects](#)” on page 6180.

Example: Two-Sample t Test

Overview

The one-sample t test compares the mean of a sample to a given value. The two-sample t test compares the means of two samples. The paired t test compares the mean of the differences in the observations to a given number. PSS provides power and sample size computations for all of these types of t tests. For more information about power and sample size analysis for t tests, see Chapter 71, “[The POWER Procedure](#).”

The two-sample t test tests for differences or ratios between means for two groups. The groups are assumed to be independent. This example describes three examples using the two-sample t test: for equal variances, for unequal variances, and for mean ratios.

Test of Two Independent Means for Equal Variances

Suppose you are interested in testing whether an experimental drug produces a lower systolic blood pressure than a placebo does. Will 25 subjects per treatment group yield a satisfactory power for this test? From previous work, you expect that the blood pressure is 132 for the control group and 120 for the drug treatment group and that the standard deviation is 15 for both groups. You want to use a one-sided test with a significance level of 0.05. Because there are two independent groups and you are assuming that blood pressure is normally distributed, the two-sample t test is an appropriate analysis.

Start by creating a new project. Select **File►New**. In the New window, select **Two-sample t test** from the list. The Two-Sample t test project window appears, with the Edit Properties page displayed.

Editing Properties

On this page enter a name to describe the project and enter project properties. Click each tab on the Edit Properties page to enter the desired properties. You can also change tabs by clicking the **Next tab** or **Previous tab** buttons. See [Figure 72.3](#).

Figure 72.35 Two-Sample t Test

Two-sample t test

Edit Properties View Results

Analysis: Two-sample t test

Project: Experimental blood pressure drug with two groups

Properties

Alpha	Means	Standard Deviation	Sample Size	Results
Solve For	Distribution	Hypothesis	Test	

Select a quantity to solve for

☒ Power

☐ Sample size per group

☐ Total sample size

Project Description

The description is used to identify this particular project in the Open and Delete windows. Type a description for your project in the **Project:** text box.

For this example, change the description to `Experimental blood pressure drug with two groups`, as shown in Figure 72.35.

Solve For

For the two-sample t test analysis, you can choose to solve for power, sample size per group, or total sample size. Specify the desired quantity type on the **Solve For** tab.

Click the **Solve For** tab and select the **Power** option as shown in Figure 72.35. For information about solving for sample size, see the section “Solving for Sample Size” on page 6204.

Distribution

Click the **Distribution** tab to select a distribution option that specifies the underlying distribution for the test statistic, as shown in Figure 72.36.

Figure 72.36 Distribution Tab

Analysis: Two-sample t test

Project:

Properties

Alpha	Means	Standard Deviation	Sample Size	Results
Solve For	Distribution	Hypothesis	Test	

Select the distribution of the test

☐ Lognormal

☒ Normal

For this example, you are interested in means rather than mean ratios, so select the **Normal** option.

Hypothesis

Click the **Hypothesis** tab to select the type of test; see [Figure 72.37](#).

Figure 72.37 Hypothesis Tab

Analysis: Two-sample t test

Project:

Properties

Alpha	Means	Standard Deviation	Sample Size	Results
Solve For	Distribution	Hypothesis	Test	

Select a one or two-sided hypothesis test

☒ One-sided test ☐ Lower one-sided test

☐ Two-sided test ☐ Upper one-sided test

You can choose either a one- or two-sided test. If you do not know the direction of the effect (that is, whether it is positive or negative), the two-sided test is appropriate. If you know the effect's direction, the one-sided test is appropriate. For the one-sided test, the alternative hypothesis is assumed to be in the same direction as the effect. If you specify a one-sided test and the effect is in the unexpected direction, the results of the analysis are invalid.

The **One-sided test** option assumes that you know the correct direction of the test. Select the **Lower one-sided test** and **Upper one-sided test** options to explicitly indicate the direction of the one-sided test.

Because you are interested only in whether the experimental drug lowers blood pressure, select the **One-sided test** option on the **Hypothesis** tab.

Test

Click the **Test** tab to select either the pooled t test or the Satterthwaite t test.

Figure 72.38 Test Tab

Analysis: Two-sample t test

Project: Experimental blood pressure drug with two groups

Properties

Alpha	Means	Standard Deviation	Sample Size	Results
Solve For		Distribution	Hypothesis	Test

Select a test

☒ Pooled t test

☐ Satterthwaite t test

With the independent variances that the example uses, select **Pooled t test** option. The Satterthwaite t test is used with unequal variances; it is available only with the normal distribution.

Alpha

Click the **Alpha** tab to specify one or more significance levels, as shown in [Figure 72.39](#).

Figure 72.39 Alpha Tab

Analysis: Two-sample t test

Project:

Properties

Solve For	Distribution	Hypothesis	Test
Alpha	Standard Deviation	Sample Size	Results

Specify one or more significance levels

Alpha
0.05

Rows

Alpha is the significance level (that is, the probability of falsely rejecting the null hypothesis). If you frequently use the same values for alpha, set them as defaults in the Preferences window. See the section “[Setting Preferences](#)” on page 6169 for more information about setting preferences.

Type the desired significance level of 0.05 in the first cell of the Alpha table (if it is not already the default value).

Means

Click the **Means** tab to select one of four possible ways to enter the means and the null mean difference, as shown in [Figure 72.40](#).

Figure 72.40 Means Tab

Properties

Solve For: Means | Distribution: Standard Deviation | Hypothesis: Power | Test: Sample Size | Alpha: Results

Select a form: Group means

Enter one or more rows of group means

Group 1	Group 2
132	120

Rows

Select one of the following forms from the **Select A Form** list. The four available forms are:

Difference between means

Enter the difference between the group means. The null mean difference is assumed to be 0.

Group means

Enter the means for each group. The null mean difference is assumed to be 0. The difference is formed by subtracting the mean for group 1 from the mean for group 2.

Difference between means, Null difference

Enter the difference between the group means and a null mean difference.

Group means, Null difference

Enter the means for each group and a null mean difference. The difference is formed by subtracting the mean for group 1 from the mean for group 2.

For this analysis, you can enter the means for the two groups either individually or as a difference. If your null mean difference is not zero, enter that value in the Null Mean table. (The Null Mean table is displayed only for the **Group means**, **Null Difference** and **Difference between means, Null difference** forms.)

For this example, a null mean difference of 0 is reasonable, so select the **Group means** form from the list, as shown in Figure 72.40. Enter the control mean of 132 in the first row of the first column and the experimental mean of 120 in the first row of the second column.

Standard Deviation

Click the **Standard Deviation** tab to enter the standard deviation for the two groups. It is assumed to be equal for both groups.

For the example, enter a single value of 15, as shown in [Figure 72.41](#).

Figure 72.41 Standard Deviation Tab

The screenshot shows the 'Properties' dialog box with the 'Standard Deviation' tab selected. The 'Solve For' section has 'Means' selected. The 'Distribution' section has 'Standard Deviation' selected. The 'Hypothesis' section has 'Power' selected. The 'Test' section has 'Sample Size' selected. The 'Alpha' section has 'Results' selected. The main area is titled 'Enter one or more standard deviations' and contains a table with one row: 'Std. Dev.' with the value '15'. Below the table are 'Rows' buttons: a green plus icon and a red minus icon.

Sample Size

Click the **Sample Size** tab to select one of three possible ways to enter the sample sizes, as shown in [Figure 72.40](#).

Select one of the following forms from the **Select A Form** list:

Sample size per group

Enter the sample size for one of the two groups. The group sizes are assumed to be equal.

Group sample sizes

Enter the sample size for each of the two groups. The group sizes can be equal or unequal.

Total N, Group weights

Enter the total sample size for the two groups and the relative sample sizes for each group. For more information about using relative sample sizes, see the section [“Using Unequal Group Sizes”](#) on page 6205.

Examine the alternatives by clicking the **Select a form** down arrow. For this example, select the **Sample size per group** form. You want to examine a curve of powers in the power by sample size graph, so enter the values 20, 25, and 30 in the Sample Size table, as shown in [Figure 72.42](#). If you need to add more rows to the table, add them by clicking the button beneath the table.

Figure 72.42 Sample Size Tab

Summary of Properties

Table 72.2 contains the values of the input parameters for the example.

Table 72.2 Summary of Input Properties

Parameter	Value
Solve for	Power
Distribution	Normal
Hypothesis	One-sided test
Test	Pooled t test
Alpha	0.05
Means form	Group means
Means	132, 120
Standard deviation	15
Sample size form	Sample size per group
Sample size	20, 25, 30

Results

Click the **Results** tab to request desired results. Summary table and power by sample size graph options are available.

For the example, select the **Create summary table** and **Create power by sample size graph** check boxes.

Click **Calculate** to perform the analysis. If there are no errors in the input values, the View Results page appears. If there are errors in the input parameter values, you are prompted to correct them.

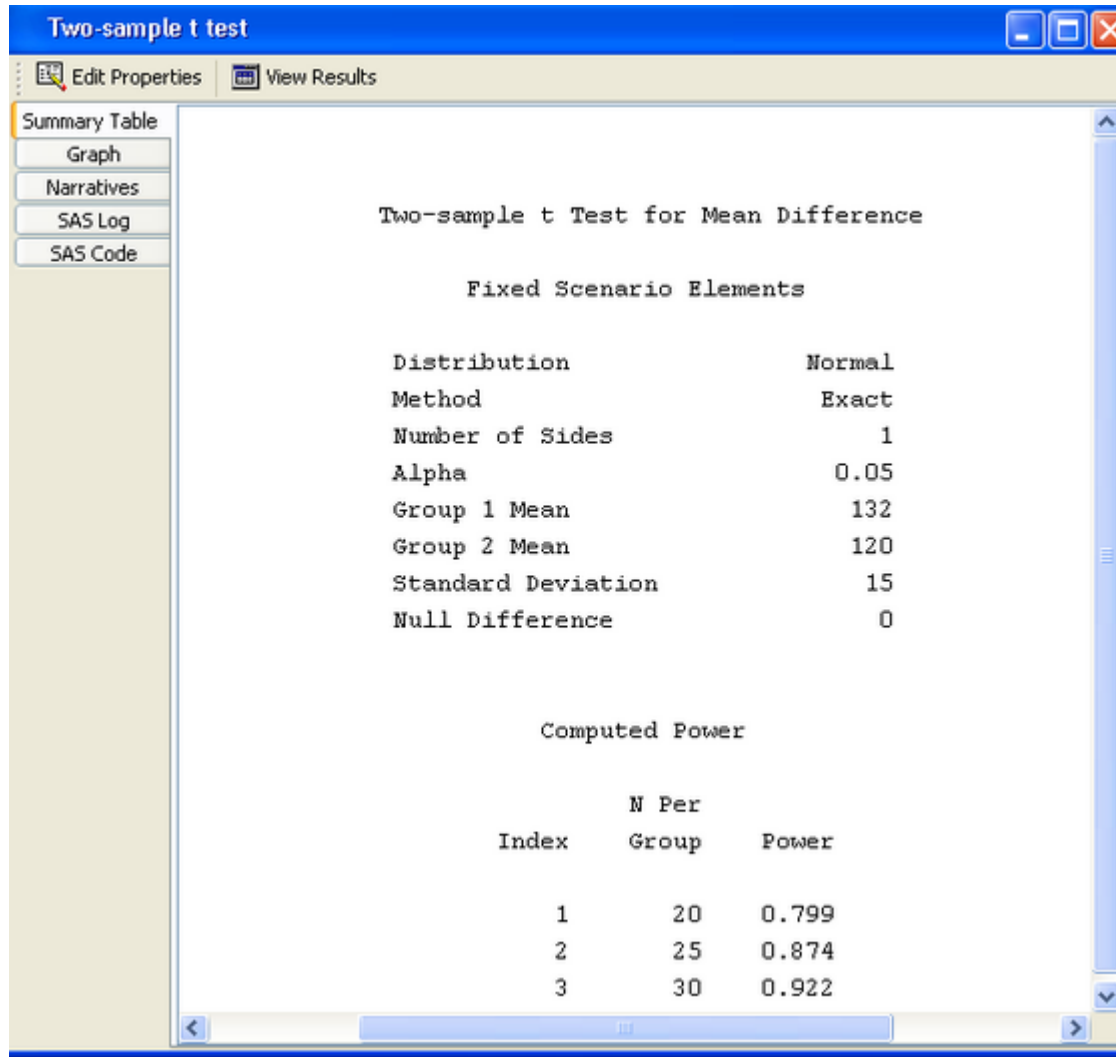

Viewing Results

The results are listed on separate tabs on the View Results page. Click the tab of each result that you want to view.

Summary Table

Click the **Summary Table** tab to view a table that includes the values of the input parameters and the computed quantity (in this example, power). See Figure 72.43.

Figure 72.43 Results Page with Summary Table

The table consists of two subtables: the `Fixed Scenario Elements` table that contains the input parameters that have only one value for the analysis, and the `Computed Power` table that contains the input parameters that have more than one value for the analysis and the corresponding power. Only the N per group parameter appears in the `Computed Power` table; all of the other input parameters have a single value. The computed power for a sample size per group of 25 is 0.874. Thus, you have a probability of 0.87 that the study will find the expected result if the assumptions and conjectured values are correct.

Power by Sample Size Graph

Click the **Graph** tab to view a power by sample size graph that displays power on the vertical axis and sample size per group on the horizontal axis. See [Figure 72.44](#).

Figure 72.44 Power by Sample Size Graph

The range of values for the horizontal axis is 20 to 30, which were the smallest and largest values, respectively, that you entered on the **Sample Size** tab. You can customize the graph by specifying the values for the sample size axis (see the section “[Customizing Graphs](#)” on page 6176).

Narratives

Click the **Narratives** tab to create and display a sentence- or paragraph-length text summary of the input parameter values and the computed quantity for combinations of the input parameter values; see [Figure 72.45](#).

Figure 72.45 Narrative Selector and Display

Narratives

For a two-sample pooled t test of a normal mean difference with a one-sided significance level of 0.05, assuming a common standard deviation of 15, a sample size of 20 per group has a power of 0.799 to detect a difference between the means 132 and 120.

Create Narratives

Select one or more scenarios

Select	Index	Sides	Alpha	Mean1	Mean2	StdDev	NPerGroup	NullDiff	Power	Error	Info
<input checked="" type="checkbox"/>	1	1	0.05	132	120	15	20	0	0.79940818		
<input type="checkbox"/>	2	1	0.05	132	120	15	25	0	0.87355245		
<input type="checkbox"/>	3	1	0.05	132	120	15	30	0	0.92176938		

To create a narrative, selected the desired scenario (row) in the narrative selector table at the bottom of the **Narratives** tab.

In this example, select the narrative for the sample size per group of 20, which yields a power of 0.799. The following text summary is displayed:

For a two-sample pooled t test of a normal mean difference with a one-sided significance level of 0.05, assuming a common standard deviation of 15, a sample size of 20 per group has a power of 0.799 to detect a difference between the means 132 and 120.

To create other narratives, select the desired rows in the narrative selector table. If you also select the second row for the sample size of 25, another text summary is displayed below the first one:

For a two-sample pooled t test of a normal mean difference with a one-sided significance level of 0.05, assuming a common standard deviation of 15, a sample size of 20 per group has a power of 0.799 to detect a difference between the means 132 and 120.

For a two-sample pooled t test of a normal mean difference with a one-sided significance level of 0.05, assuming a common standard deviation of 15, a sample size of 25 per group has a power of 0.874 to detect a difference between the means 132 and 120.

To change some values of the analysis and rerun it, select the Edit Properties page, change the desired properties, and click the **Calculate** button again.

Test of Two Independent Means for Unequal Variances

In the preceding example, you assumed that the population standard deviations were equal. If you believe that the population standard deviations are not equal, use the same two-sample t test analysis as with the preceding example, but change the test option and enter group standard deviations.

You can use the previous example to demonstrate this test. If the project is not already open, open it by selecting **File►Open** on the menu bar, and then selecting the project that you have been using.

Make a copy of the project by selecting **File►Save As**. Enter a different project description, Experimental blood pressure drug with two groups for unequal variances. Click **OK**.

The copy of the project is opened, and the current project is closed.

Editing Properties

Test

On the **Test** tab of the copied project, change the test to **Satterthwaite t test**, as shown in Figure 72.46.

Figure 72.46 Satterthwaite t Test Option

Specifying Group Standard Deviations

Click the **Standard Deviation** tab and enter the group standard deviations of 12 and 15 on a single row, as shown in Figure 72.47.

Figure 72.47 Group Standard Deviations

Properties

Solve For: Alpha Means **Distribution** Hypothesis Test

Standard Deviation Sample Size Results

Enter one or more rows of standard deviations

Group 1	Group 2
12	15

Rows

Summary of Input Parameters

Table 72.3 contains the values of the input parameters for the example.

Table 72.3 Summary of Input Parameters

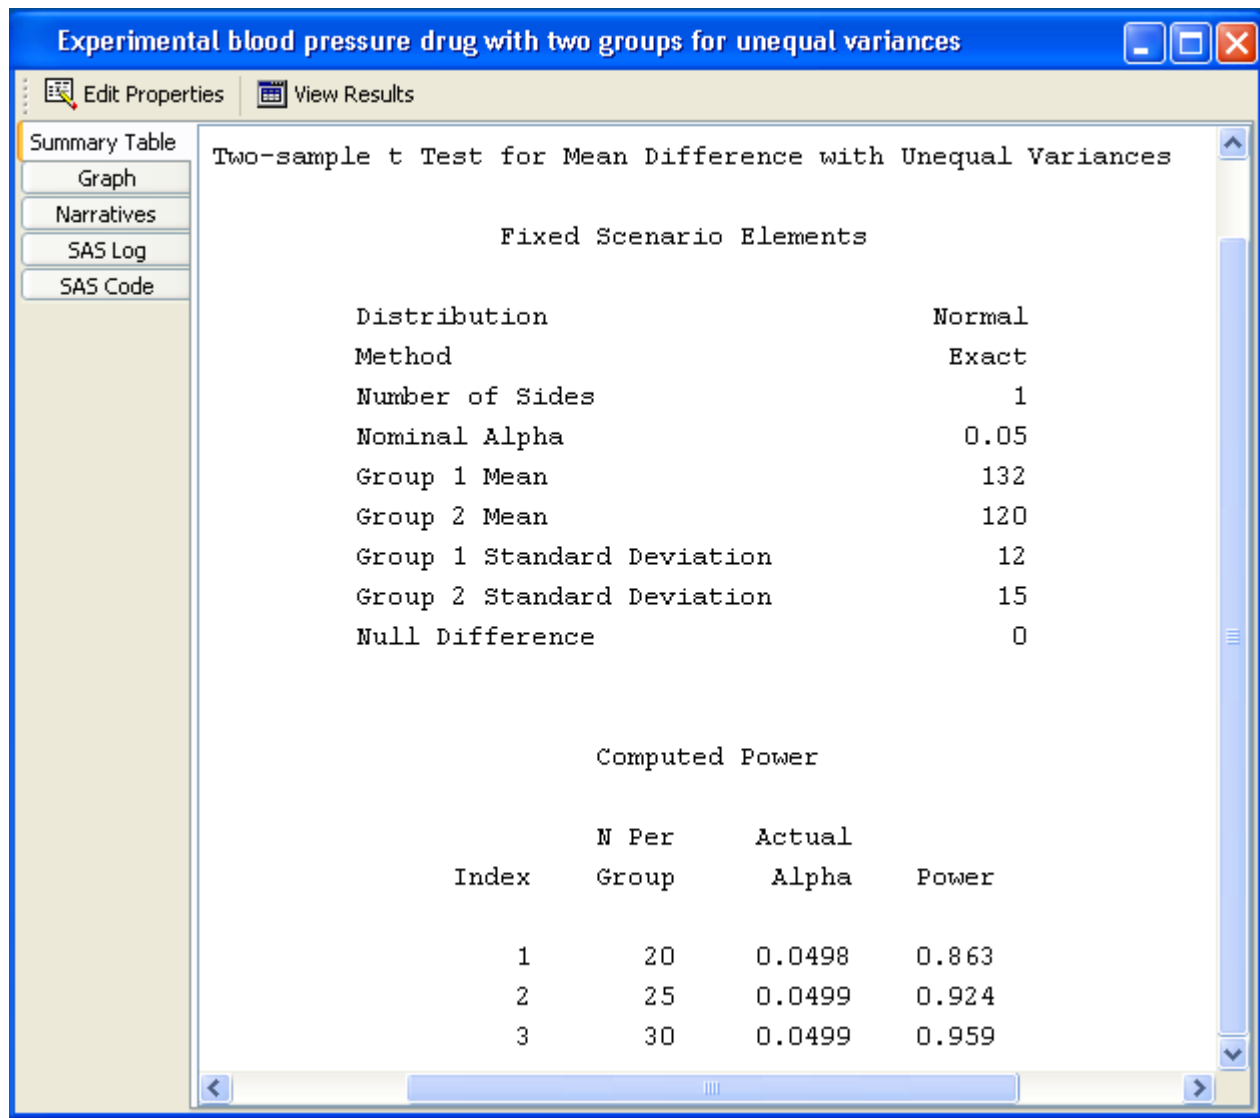

Parameter	Value
Distribution	Normal
Hypothesis	One-sided test
Test	Satterthwaite t test
Alpha	0.05
Means form	Group means
Means	132, 120
Standard deviation	12, 15
Sample size form	Sample size per group
Sample size	20, 25, 30

Click **Calculate** to run the analysis.

Viewing Results

The power for a sample size per group of 25 is 0.924, as shown in Figure 72.48. Notice that the actual alpha is 0.0499. This is because the Satterthwaite t test is (slightly) biased.

Figure 72.48 Satterthwaite Test Results

If you modified the previous example, when you select the **Narratives** tab, the following message is displayed:

Previously selected narratives have been cleared because one or more input parameter values have changed.

In the previous analysis, you created narratives for two scenarios. Because this analysis uses group standard deviations, those selected narratives were cleared. The message would also have appeared if you had changed the number of scenarios.

Use the narrative selector table to create other narratives.

Test of Mean Ratios

Instead of comparing means for a control and drug treatment group, you might want to investigate whether the blood pressure of the treatment group is lowered by a given percentage of the control group, say 10 percent. That is, you expect the ratio of the treatment group to the control group to be 90% or less.

PSS provides a two-sample t test of a mean ratio when the data are lognormally distributed.

For mean ratios, the coefficient of variation (CV) is used instead of standard deviation. In this example, you can expect the CV to be between 0.5 and 0.6. You also want to compare an equally weighted sampling of groups with an overweighted sampling in which the control group contains twice as many subjects as the treatment group: 50 and 25, respectively.

Make a copy of the project by selecting **File►Save As**. Enter a different project description, `Percent improvement with blood pressure drug`.

The copy of the project is opened.

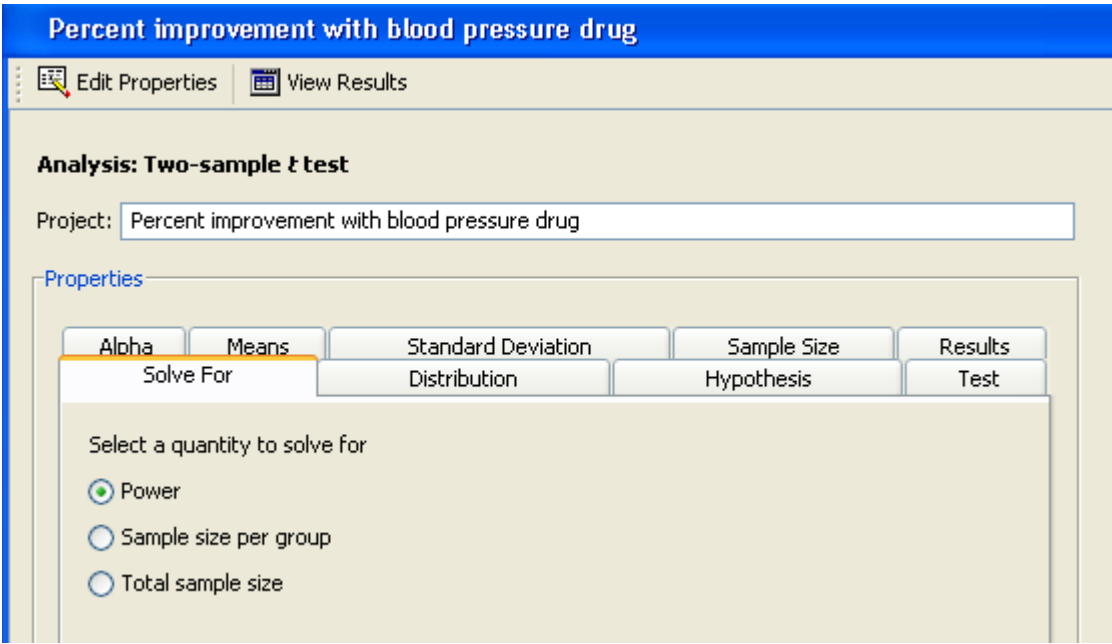

Editing Properties

Several of the input parameters for the test of mean ratios differ from the ones described in the section “[Test of Two Independent Means for Equal Variances](#)” on page 6183. Mean ratios and coefficients of variation are used instead of mean differences and standard deviations. These two parameters are discussed in detail in this section. For the input parameters and options that have been discussed previously in this example, only the values for this example are given.

Solve For Tab

Click the **Solve For** tab to select the **Power** option as the quantity to be solved for, as shown in [Figure 72.49](#).

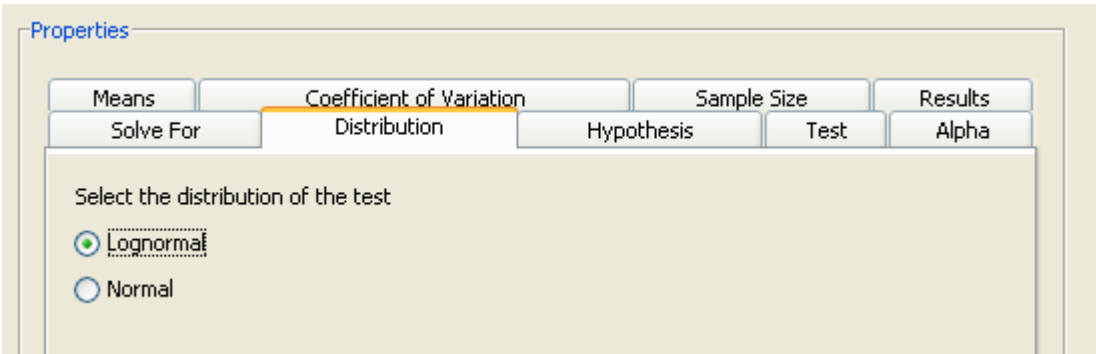

Figure 72.49 Project Description, Solve for Tab

Distribution

You are interested in mean ratios rather than means, so select the **Lognormal** option on the **Distribution** tab, as shown in Figure 72.50.

Figure 72.50 Distribution Tab with Lognormal Option

Hypothesis and Alpha

Click the **Hypothesis** tab and select the **One-sided test** option.

Click the **Alpha** tab and type 0.05 as the significance level in the first cell of the table, if it is not already there.

Means

Click the **Means** tab to select the input form for entering mean ratios. There are four alternate forms for entering means or mean ratios:

Mean ratio

Enter the ratio of the two group means—that is, the treatment mean divided by the reference mean. The null ratio is assumed to be 1.

Group means

Enter the means for each group. The ratio of the means is formed by dividing the mean for group 2 by the mean for group 1. The null ratio is assumed to be 1.

Mean ratio, Null ratio

Enter the ratio of the two group means—that is, the treatment mean divided by the reference mean. Enter the null ratio.

Group means, Null ratio

Enter the means for each group. The ratio of the means is formed by dividing the mean for group 2 by the mean for group 1. Enter the null ratio.

As shown in [Figure 72.51](#), select the **Mean ratio** form which uses a default null ratio of 1. Enter a single mean ratio value of 0.9.

Figure 72.51 Means Tab with Mean Ratio Form and Values

The screenshot shows a software window titled "Properties" with a "Means" tab selected. The "Solve For" dropdown is set to "Means". Below the tabs, there is a "Select a form:" dropdown menu with "Mean ratio" selected. To the right of this dropdown is a small icon of a document with a red 'X'. Below the dropdown, the text "Enter one or more mean ratios" is displayed. A table with one row and one column is shown, with the value "0.9" entered in the cell. The table has a "Ratio" header. Below the table, there are two buttons: a green plus sign and a red minus sign, both labeled "Rows".

Coefficient of Variation

On the **Coefficient of Variation** tab, enter the coefficients of variation. They are assumed to be equal for the two groups.

For this example, enter 0.5 and 0.6, as shown in Figure 72.52.

Figure 72.52 Coefficient of Variation Tab

The screenshot shows a software window titled "Properties" with several tabs: "Solve For", "Distribution", "Hypothesis", "Test", and "Alpha". The "Coefficient of Variation" tab is selected. Below the tabs, there is a section labeled "Enter one or more coefficients of variation". It contains a table with two rows. The first row has a value of 0.5, and the second row has a value of 0.6. Below the table, there are two buttons labeled "Rows" with a plus sign and a minus sign.

CV
0.5
0.6

Sample Size

On the **Sample Size** tab, select the **Group sample sizes** form and enter two sets of values: 25 and 25 in the first row and 25 and 50 in the second row, as shown in Figure 72.53.

Figure 72.53 Sample Sizes

The screenshot shows the same software window with the "Sample Size" tab selected. Below the tabs, there is a section labeled "Select a form:" with a dropdown menu set to "Group sample sizes" and a button with a circular arrow icon. Below this, there is a section labeled "Enter one or more rows of group sample sizes". It contains a table with two columns, "Group 1" and "Group 2", and two rows. The first row has values 25 and 25, and the second row has values 25 and 50. Below the table, there are two buttons labeled "Rows" with a plus sign and a minus sign.

Group 1	Group 2
25	25
25	50

Summary of Input Parameters

Table 72.4 contains the values of the input parameters for the example.

Table 72.4 Summary of Input Parameters

Parameter	Value
Hypothesis	One-sided test
Distribution	Lognormal
Alpha	0.05
Means form	Mean ratio
Mean ratio	0.9
Coefficients of variation	0.5, 0.6
Sample size form	Group sample sizes
Sample Size	(25, 25), (25, 50)

Results

On the **Results** tab, select the **Create summary table** and **Create power by sample size graph** check boxes.

Click **Calculate** to perform the analysis.

In this case, the following message is displayed:

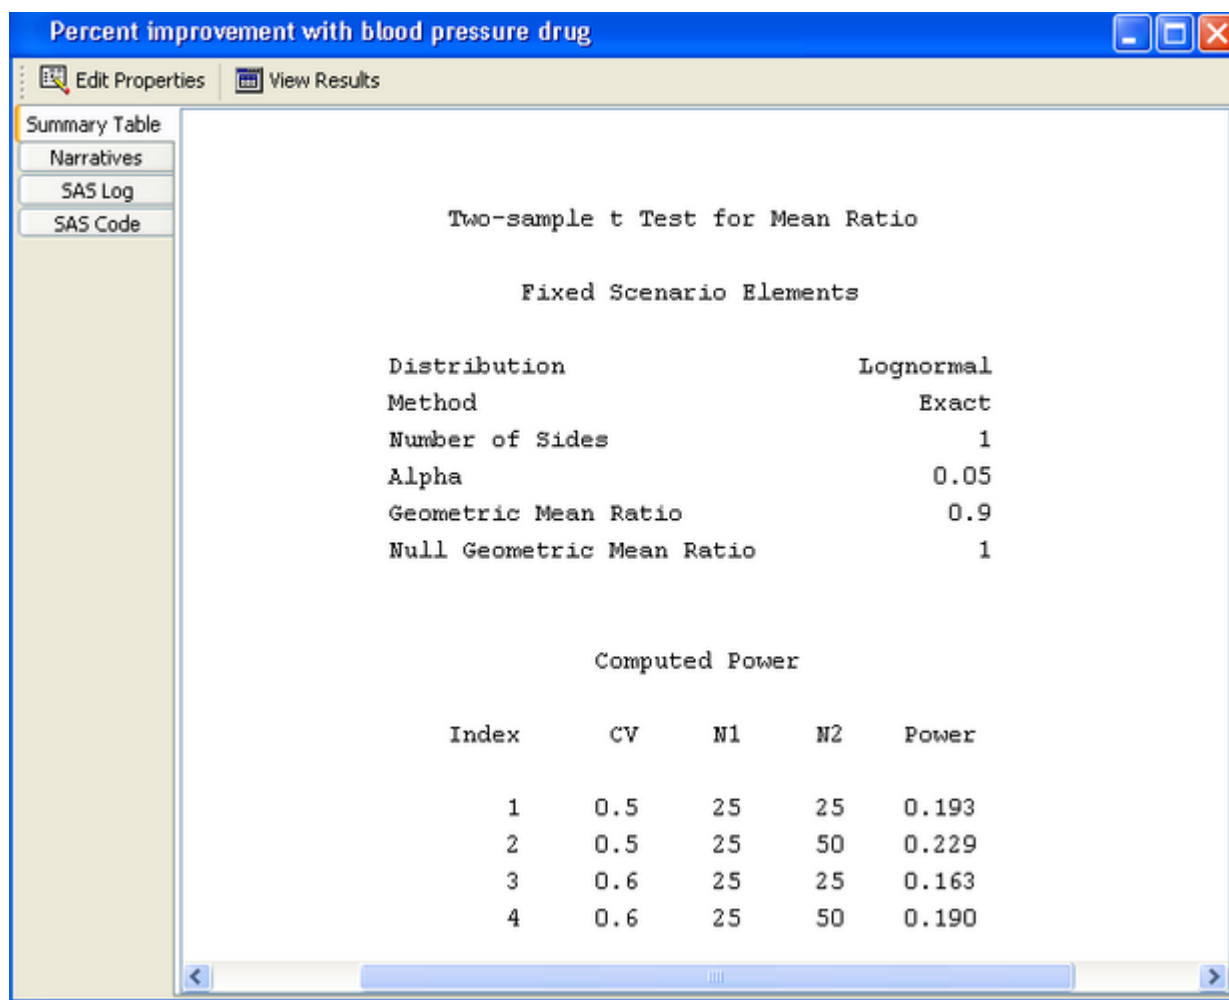

The power by sample size graph is not available when specifying sample sizes for two groups.

If you want a power by sample size graph, you can choose to plot total sample size instead by using the **Total N, Group weights** sample size form on the **Sample Size** tab. For more information about using this input form, see the section “[Using Unequal Group Sizes](#)” on page 6205.

Viewing Results

The first thing that you notice from the summary table in [Figure 72.54](#) is that the calculated powers are quite low—they range from 0.163 to 0.229. You have less than a 25% probability of detecting the difference that you are looking for. Clearly, this set of parameter values leads to insufficient power. To increase power, you might choose a larger sample size or a larger alpha.

Figure 72.54 Summary Table

You can also see that oversampling the control group improves power slightly, 0.229 versus 0.193 for the coefficient of variation of 0.5. However, this is a marginal increase that is probably not worth the added expense.

For the example, use larger sample sizes with equal cell sizes. Return to the Edit Properties page by clicking the **Edit Properties** icon near the top of the window.

Then, on the **Sample size** tab, change to the **Sample size per group** form. Specify sample sizes of 50, 100, 150, and 200, as shown in Figure 72.55.

Figure 72.55 Modified Sample Size Values

Properties

Solve For: **Sample size per group**

Distribution: **Coefficient of Variation**

Hypothesis: **Test**

Alpha: **Results**

Select a form: **Sample size per group**

Enter one or more values for sample size per group

N Per Group

3	0.5	150	0.611
4	0.5	200	0.720
5	0.6	50	0.242
6	0.6	100	0.380
7	0.6	150	0.499
8	0.6	200	0.599

Additional Topics

Solving for Sample Size

Several types of analysis enable you to solve for either total sample size or sample size per group. The sample size per group choice assumes equal group sizes. When solving for total sample size, the group sizes can be equal or unequal. Select the desired quantity on the **Solve For** tab. An example of these options is shown in Figure 72.57.

Figure 72.57 Solve For Tab with Sample Size Selected

The image shows a software window titled "Properties" with a tabbed interface. The tabs are: Means, Coefficient of Variation, Power, Sample Size, and Results. The "Solve For" sub-tab is active, showing a "Solve For" section with three radio buttons: "Power", "Sample size per group" (which is selected and has a dashed border), and "Total sample size". Below the tabs, there are additional sub-tabs: "Distribution", "Hypothesis", "Test", and "Alpha".

For either of the two sample size options, you must specify one or more values for power on the **Power** tab. If you frequently use the same values for power, set them as the default in the Preferences window, which is accessed by **Tools►Preferences**. Changing preferences affects only projects that you create after the change; existing projects are not affected.

If you select total sample size, you must specify whether the group sizes are equal or unequal. Select the appropriate option on the **Sample Size** tab. For unequal group sizes, you must specify the relative sample sizes for the two groups. For information about providing relative sample sizes, see the section “[Using Unequal Group Sizes](#)” on page 6205.

Using Unequal Group Sizes

When solving for either power or total sample size, you might have unequal group sizes. If so, you must provide relative sample sizes for the groups. Weights must be greater than 0 but do not have to sum to 1.

Select the **Total N, Group weights** form on the **Sample Size** tab. Enter total sample sizes of 30 and 60 in the **Total N** table. Select the **Unequal group sizes** option and click **Enter Relative Sample Sizes**, as seen in [Figure 72.58](#).

Figure 72.58 Sample Size Tab with Group Weights Form

The screenshot shows the 'Properties' window with the 'Sample Size' tab selected. The 'Solve For' dropdown is set to 'Total N, Group weights'. Under 'Select equal or unequal group sizes', the 'Unequal group sizes' radio button is selected. A button labeled 'Enter Relative Sample Sizes...' is visible. To the right, a list box titled 'Total N' contains the values 30 and 60. Below this list box are 'Rows' controls with '+' and '-' buttons.

Figure 72.59 displays the window in which you can enter relative sample sizes. As an example, enter 2 for the first group and 1 for the second. In this case, you are sampling the drug treatment group twice as often as the control group.

Figure 72.59 Relative Sample Sizes Window

The screenshot shows the 'Relative Sample Sizes' dialog box overlaid on the 'Properties' window. The dialog box has a title bar with a red 'X' button. Inside, the text 'Enter one or more rows of relative sample sizes' is displayed. Below this is a table with two columns: 'Group 1' and 'Group 2'. The first row contains the values 2 and 1. Below the table are 'Rows' controls with '+' and '-' buttons. At the bottom of the dialog box are 'OK', 'Cancel', and 'Help' buttons.

Group 1	Group 2
2	1

The weights control how the total sample size is divided between the two groups. In the example, the sample size for groups 1 and 2 is 20 and 10, respectively, for a total sample size of 30.

Click **OK** to save the values and return to the Edit Properties page.

Example: Analysis of Variance

Overview

PSS offers power and sample size calculations for analysis of variance in two tasks: one-way ANOVA and general linear univariate models. Optional contrasts are available in both tasks.

In the one-way ANOVA task, you can solve for sample size per group as well as total sample size. The contrast facility for the one-way ANOVA task enables you to select orthogonal polynomials as well as to specify contrast coefficients. For more information about power and sample size analysis for one-way ANOVA, see Chapter 71, “[The POWER Procedure](#).”

In the general linear univariate models task, you specify linear models for a single dependent variable. Type III tests and contrasts of fixed effects are included, and the model can include covariates. For more information about power and sample size analysis for linear univariate models, see Chapter 44, “[The GLMPOWER Procedure](#).”

The Example

Suppose you are interested in testing how two experimental drugs affect systolic blood pressure relative to a standard drug. You want to include both men and women in the study. You have a two-factor design: a drug factor with three levels and a gender factor with two levels. You choose a main-effects-only model because you do not expect a drug by gender interaction. You want to calculate the sample size that will produce a power of 0.9 using a significance level of 0.05. You believe that the error standard deviation is between 5 and 7 mm pressure. This is a two-way analysis of variance, so the general linear univariate models task is the appropriate one.

Editing Properties

Start by opening the New window (**File►New**). In the **Analysis of Variance and Linear models** section of the New window, select **General linear univariate models**. The **General univariate linear models** project appears, with the Edit Properties page displayed.

Project Description

For the example, change the project description to Three blood pressure drugs and gender.

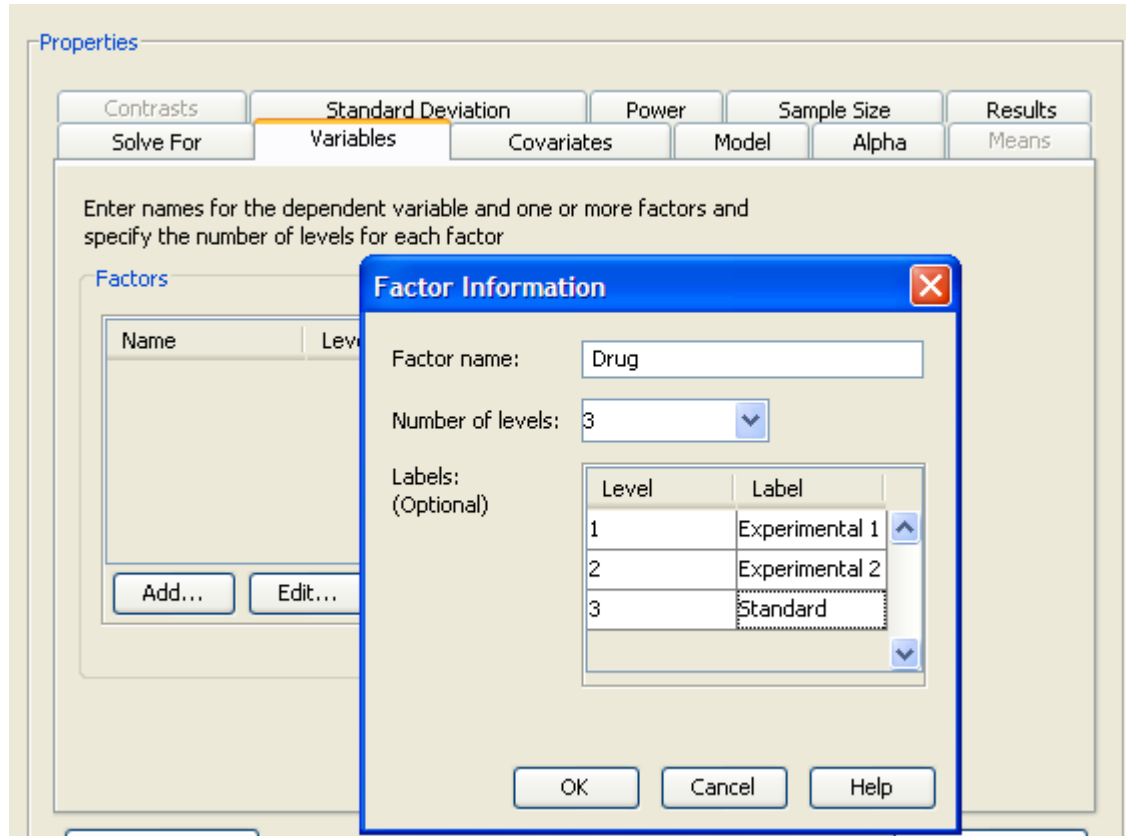

Solve For

Click the **Solve For** tab and select the **Sample size** option.

Variables

Click the **Variables** tab to enter the names of the factors in the design. Click the **Add** button. The Factor Definition window appears, as shown in Figure 72.60.

Figure 72.60 Factor Definition Window

Enter the name for the first factor, *Drug*, and enter the number of factor levels in the **Number of levels:** list box. There are three levels for this factor. Optionally, you can provide a label for each factor level. This label is used to identify factor levels on other tabs of the Edit Properties page. For this example enter the labels *Experimental 1*, *Experimental 2*, and *Standard* for the three levels of the *Drug* factor. Click **OK** when you are finished.

Click the **Add** button again and repeat the process for the second factor, *Gender* with two levels and labels *Female* and *Male*.

Factors can contain blanks and other special characters. Do not use an asterisk (*) because a factor name with an asterisk might be confused with an interaction effect. Factor names can be any length, but they must be distinct from one another in the first 32 characters.

On the **Variables** tab, you can also specify the name of the dependent variable; in this example, *Blood pressure* is used.

The completed **Variables** tab is shown in [Figure 72.61](#).

Figure 72.61 Variables Tab with Factors and Number of Levels

The screenshot shows the 'Properties' dialog box with the 'Variables' tab selected. The 'Factors' section contains a table with the following data:

Name	Levels
Drug	3
Gender	2

Below the table are buttons for 'Add...', 'Edit...', and 'Delete'. The 'Dependent Variable' section shows 'Blood pressure' entered in the 'Name' field.

Model

Click the **Model** tab, then choose from three model options:

Main effects

Only the main effects are included in the model.

Main effects and all interactions

The main effects and all possible interactions are included in the model.

Custom model

Selected effects are included in the model. The effects are selected in a model builder that is displayed when this model is selected. For more information about specifying a custom model, see the section “[Specifying a Custom Model](#)” on page 6220.

For this example, choose the default **Main effects** model, as shown in [Figure 72.62](#).

Figure 72.62 Model Tab with Main Effects Selected

Alpha

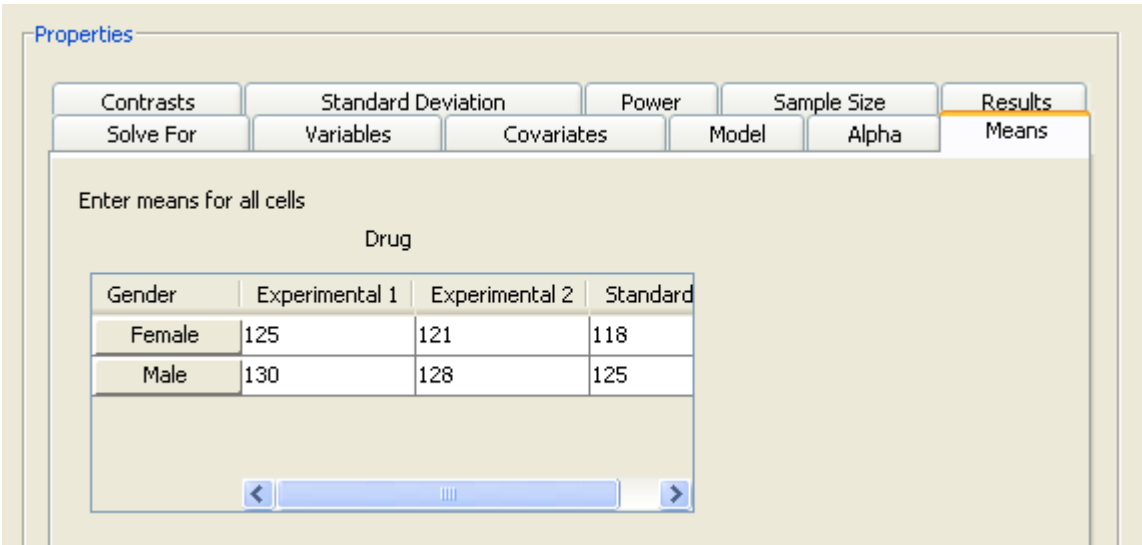

Click the **Alpha** tab to specify one or more significance levels. For the example, specify a single significance level of 0.05.

Alpha is the significance level (that is, the probability of falsely rejecting the null hypothesis). If you frequently use the same values for alpha, set them as the defaults in the Preferences window (**Tools►Preferences**).

Means

Click the **Means** tab to enter projected cell means for each cell of the design. The completed means for the example are shown in Figure 72.63.

Figure 72.63 Means Tab with Cell Means

Standard Deviation

Click the **Standard Deviation** tab to specify one or more conjectured error standard deviations. The standard deviation is the same as the root mean squared error. For this example, enter two standard deviations, 5 and 7, as shown in Figure 72.64.

Figure 72.64 Standard Deviations Tab

Properties

Select equal or unequal cell sizes

☒ Equal cell sizes
☐ Unequal cell sizes

Enter Relative Sample Sizes...

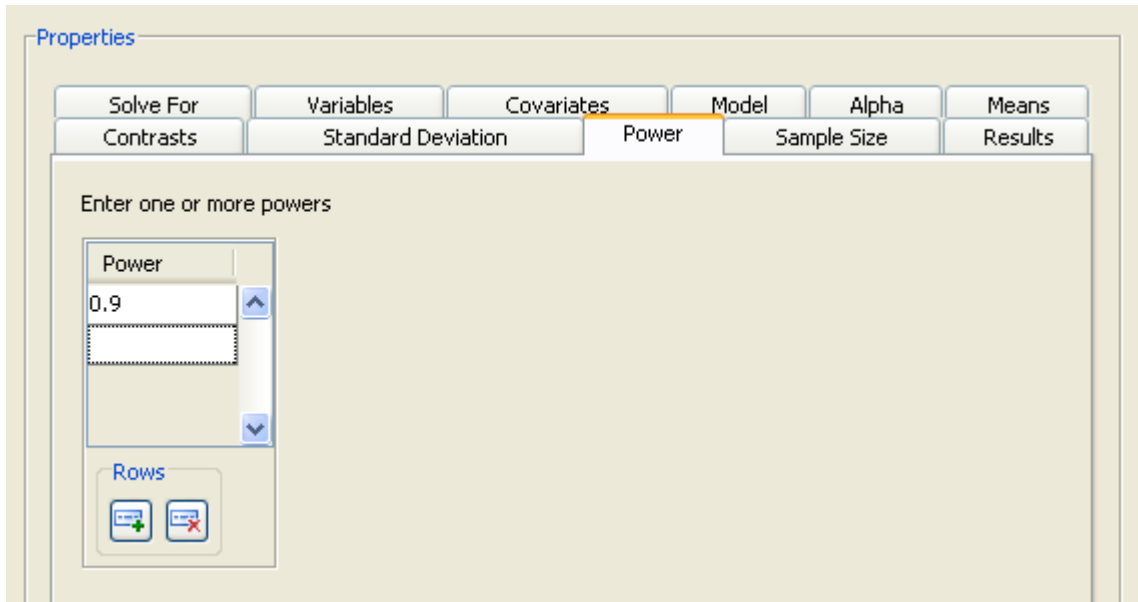

For the example, select the **Equal cell sizes** option, as shown in Figure 72.65.

When solving for sample size, it is necessary to specify whether the cell sample sizes are equal or unequal. If cell sizes are unequal, relative sample size weights must also be specified. For more information about providing sample size weights, see the section “Using Unequal Cell Sizes” on page 6217.

Power

Click the **Power** tab to specify one or more powers. For this example, enter a single power of 0.9, as shown in Figure 72.66.

Figure 72.66 Power Tab

Summary of Input Parameters

Table 72.6 contains the values of the input parameters for the example.

Table 72.6 Summary of Input Parameters

Parameter	Value
Model	Main effects
Alpha	0.05
Means	See Table 72.7
Standard deviation	5, 7
Relative sample sizes	Equal cell sizes
Power	0.9

Table 72.7 Cell Means

Gender	Drug		Standard
	Experimental 1	Experimental 2	
Female	125	121	118
Male	130	128	125

Results Options

Click the **Results** tab to select desired results. For the example, select both the **Create summary table** and **Create power by sample size graph** check boxes.

The graph consists of four points, one for each of the four scenarios that were created by combining the two factor main effects with the two standard deviations. This graph is not very informative, so specify a range of powers for the horizontal power axis. To change the power axis of the graph, click the **Customize** button beside the **Create power by sample size graph** check box to open the Customize Graph window.

Figure 72.67 Value Ranges on Customize Graph Window

Click the **Value Ranges** tab and enter a minimum power of 0.75 and a maximum power of 0.95, as shown in Figure 72.67. Click **OK** to close the window.

Now, click **Calculate** to perform the analysis.

Viewing Results

The results are displayed in separate tabs on the View Results page.

Click the **Summary Table** tab to view the summary table. In the `Computed N Total` table, sample sizes are listed for each combination of factor and standard deviation (Figure 72.68). You need a total sample size between 60 and 108 to yield a power of 0.9 for the `Drug` effect if the standard deviation is between 5 and 7. You need a sample size of half that for the `Gender` effect.

Figure 72.68 Summary Table

Click the **Graph** tab to view the power by sample size graph, as shown in Figure 72.69. One approximately linear curve is displayed for each standard deviation and factor combination.

Figure 72.69 Power by Sample Size Graph

Click the **Narratives** tab to create narratives of one or more scenarios. Select the first scenario, the Drug effect with the standard deviation of 5, in the narrative selector table. Note that the cell means are not included in the following narrative description:

For the usual F test of the Drug effect in the general linear univariate model with fixed class effects [Blood pressure = Drug Gender] using a significance level of 0.05, assuming the specified cell means and an error standard deviation of 5, a total sample size of 60 assuming a balanced design is required to obtain a power of at least 0.9. The actual power is 0.921.

For more information about using the narrative facility, see the section “[Creating Narratives](#)” on page 6179.

Additional Topics

Adding Contrasts

Click the **Contrasts** tab to define one or more contrasts. Contrasts are optional. PSS allows contrasts to be added when using either a main effects model or a main effects and interactions model. At least two factors must have been specified in order to be able to enter contrasts. The contrast tab appears in [Figure 72.70](#).

Figure 72.70 Contrast Tab with Coefficients

Properties

Solve For Variables Covariates Model Alpha Means **Contrasts** Standard Deviation Power Sample Size Results

Contrasts are optional. Select a contrast, then enter contrast coefficients for each required effect

Experime...	Experime...	Standard
0.5	0.5	-1.0

Rows

Clear

☐ Use single degree of freedom for multiple effects

☒ Warn if coefficients in a row do not sum to zero

To create a contrast, click the **New** button. Then, select the newly created contrast (Contrast 1) from the list.

Specify a label for the contrast in the **Label** field. The label should be different from all of the factor names and all interactions in the model, as well as other contrast labels.

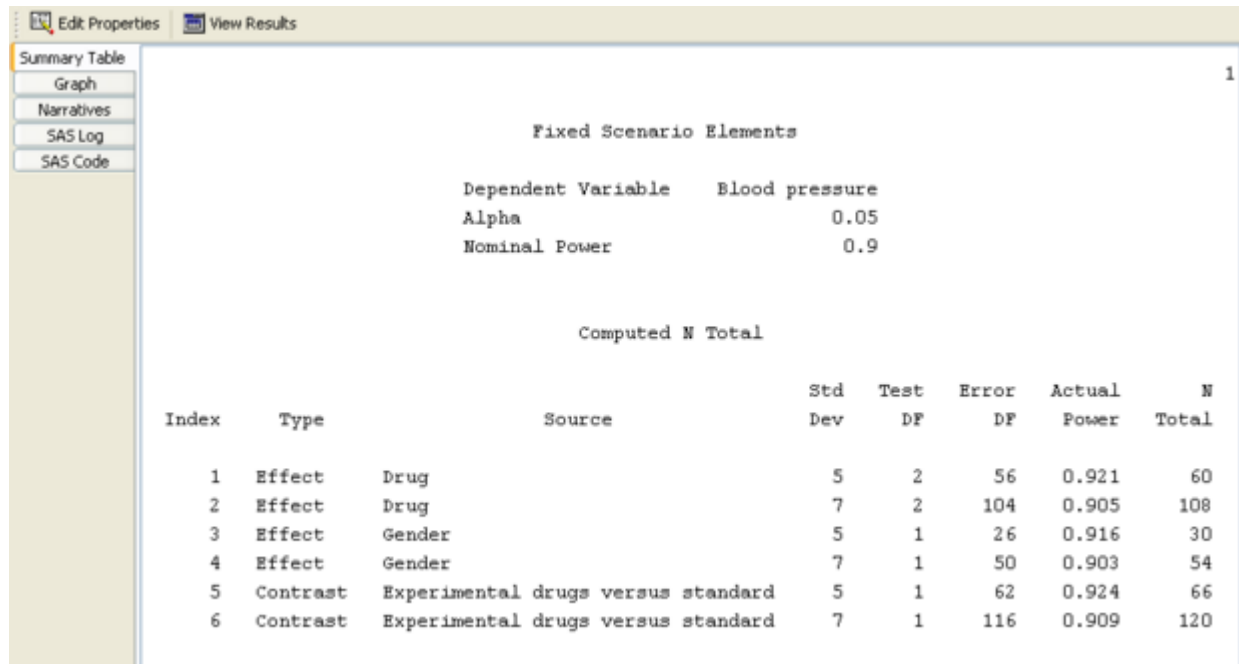

Then, for each term you want to include in the contrast, select the term in the **Effects** list and enter at least two coefficients per term. It is not necessary to enter zeros; blanks are considered to be zeros.

To clear all of the contrast coefficients for a term, click the **Clear** button. To remove a previously defined contrast, select it from the **Contrasts** list and click the **Remove** button.

In this example, you are interested in comparing the two experimental drugs to the standard drug. As shown in [Figure 72.70](#), the contrast coefficients are 0.5, 0.5, and -1 for the three levels of the Drug effect.

Figure 72.71 shows the two scenarios for the contrast at the bottom of the `Computed N Total` table. The two scenarios also appear in the graph but the graph is not shown here.

Figure 72.71 Computed N Total Table for the Contrast

Contrasts Standard Deviation Power **Sample Size** Results

Select equal or unequal cell sizes

☐ Equal cell sizes

☒ Unequal cell sizes

Enter Relative Sample Sizes...

For the example, select the **Unequal cell sizes** option, as seen in Figure 72.72, and then click the **Enter Relative Sample Sizes** button.

Figure 72.73 shows the window in which you can enter relative sample sizes. As an example, enter the sample size weights from Table 72.8.

Table 72.8 Sample Size Weights

Gender	Drug		
	Experimental 1	Experimental 2	Standard
Males	1	1	2
Females	1	1	2

If you have unequal cell sizes, you must enter relative sample size weights for the cells. Weights do not have to sum to 1 across the cells. Some weights can be zero, but enough weights must be greater than zero so that the effects and contrasts are estimable.

In this case, you want the sample size of the standard group to be twice that of each of the two experimental groups. Click **OK** to save the values and return to the Edit Properties page.

Figure 72.73 Relative Sample Sizes Window

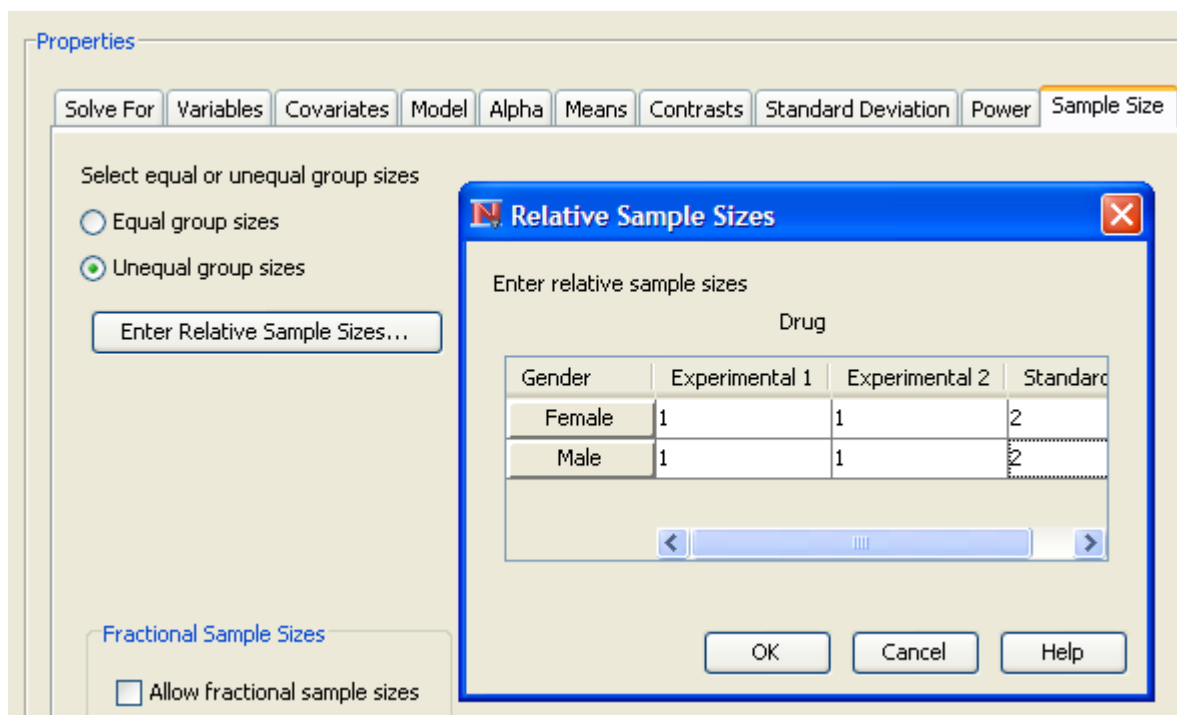

Figure 72.74 shows the summary table for the Drug by Gender example.

Figure 72.74 Summary Table for Unbalanced Design Example

Solving for Power

In addition to solving for sample size, you can also solve for power. Figure 72.75 shows the two options. Click the **Solve For** tab to select the **Power** option.

Figure 72.75 Solve For Tab with Power Option Selected

Properties

Solve For Variables Covariates Model Alpha Means Contrasts Standard Deviation Sample Size Re

Select a quantity to solve for

☒ Power

☐ Sample size

When solving for power, you must provide sample size information. For the general linear univariate model analysis, you provide this information by using one of two alternate forms. To choose the desired alternate form, select the desired form from the **Select a form** list box on the **Sample Size** tab. The alternate forms are:

Sample size per cell

Enter the sample size for a cell. Cell sizes are assumed to be equal. Sample size is reported in the summary table as total sample size.

Total N, Cell weights

Enter the total sample size and specify whether cell sizes are to be equal or unequal. Select the **Equal cell sizes** or **Unequal cell sizes** option. For unequal cell sizes, you also enter cell weights. Click the **Enter Relative Sample Sizes** button to display a window that is used to enter the data. For more information about using unequal cell sizes, see the section “[Using Unequal Cell Sizes](#)” on page 6217.

Specifying a Custom Model

Click the **Model** tab to select from three types of models: a **Main effects** model, a **Main effects and all interactions** model, and a **Custom model**.

To specify a custom model, select the **Custom model** option; then a model building facility is displayed.

The facility displays a list of the factors on the left. Construct the desired model using the **Add**, **Cross**, and **Factorial** buttons. The example shown in [Figure 72.76](#) has the three main effects and one of the four possible interactions.

Figure 72.76 Model Tab with Custom Model Builder Displayed

Remove All

Model Effects

A
B
C
A * C

Add the three main effects (A, B, C) by selecting them in the **Terms** list and clicking the **Add** button. Add the A*B interaction by selecting the A and B factors in the **Terms** list and clicking the **Cross** button.

To create the complete factorial design of several factors, select the factors in the **Terms** list, then click the **Factorial** button. All possible main effects and interactions are added to the **Model Effects** list.

To remove effects, select them in the **Model Effects** list and click the **Remove** button. Clicking the **Remove All** button removes all effects in the model.

Including Covariates

Click the **Covariates** tab to enter covariate information.

Figure 72.77 Covariates Tab with Proportional Reduction in Variance Form

Properties

Covariates are optional. Select the number of covariates

Number of covariates: 4

Select a form: Proportional reduction in variance

Enter one or more proportional reduction in variance values

Reduction
0.3

Rows

+ -

Figure 72.77 illustrates four covariates and a proportional reduction in variation of 0.3. The results for the analysis are not shown.

Covariates are optional. If you have covariates, include the total number of degrees of freedom for all covariates. To do this, add the number of continuous covariates and the sum of the degrees of freedom of the classification covariates, and enter this total in the **Number of Covariates** list box. For example, with two continuous covariates and a single classification covariate factor with three levels, the total would be $2 + (3 - 1) = 4$.

Also, you must enter the correlation between the dependent variable and the set of covariates. Two alternate forms are available: **Multiple correlation** and **Proportional reduction in variance**. Select the desired form and enter one or more values.

The multiple correlation is between the set of covariates and the dependent variable. Proportional reduction in variation is how much the variance of the dependent variable is reduced by the inclusion of the covariates, expressed as a proportion between 0 and 1.

Example: Two-Sample Survival Rank Tests

Overview

Survival analysis often involves the comparison of survival curves. PSS provides sample size and power calculations for two-sample survival rank analyses. Several rank tests are available: Gehan, log-rank, and Tarone-Ware. There are also several ways to specify the survival functions. For more information about power and sample size analysis for survival rank tests, see Chapter 71, “[The POWER Procedure](#).”

The Example

Suppose you want to compare survival rates for an existing cancer treatment and a new treatment. You intend to use a log-rank test to compare the overall survival curves for the two treatments. You want to determine a sample size to achieve a power of 0.8 for a two-sided test using a balanced design, with a significance level of 0.05.

The survival curve of patients for the existing treatment is known to be approximately exponential with a median survival time of five years. You think that the proposed treatment will yield a survival curve described by the times and probabilities listed in [Table 72.9](#). Patients are to be accrued uniformly over two years and followed for three years.

Table 72.9 Survival Probabilities for Proposed Treatment

Time	Probability
1	0.95
2	0.90
3	0.75
4	0.70
5	0.60

To create a new survival analysis project, select **File►New**. Then, under the **Survival Analysis** section, select **Two-sample survival rank tests** and click **OK**. The **Two-sample survival rank tests** project appears with the Edit Properties page displayed.

Editing Properties

Project Description

For the example, change the project description to Comparing cancer treatments using two-sample survival rank test.

Figure 72.78 Project Description and Solve For Tab

Solve For

Click the **Solve For** tab to select the quantity to solve for. For this example, select the **Sample size per group** option, as shown in Figure 72.78. For information about calculating total sample size, see the section “Solving for Sample Size” on page 6204.

In this analysis you can solve for power, sample size per group, or total sample size.

Test

Click the **Test** tab to select a rank test. For this example, select the **Log-rank** option, as shown in Figure 72.79.

Figure 72.79 Test Tab

Analysis: Two-sample Survival Rank Tests

Project:

Properties

Survival Functions	Accrual Times	Power	Sample Size	Results
Solve For	Test	Hypothesis	Alpha	

Select a test

☐ Gehan rank

☒ Log-rank

☐ Tarone-Ware rank

Several rank tests are available: Gehan, log-rank, and Tarone-Ware. The Gehan test is most sensitive to survival differences near the beginning of the study period, the log-rank test is uniformly sensitive throughout the study period, and the Tarone-Ware test is somewhere in between.

Hypothesis

Click the **Hypothesis** tab to select a one- or two-sided test. For the example, select the **Two-sided test** option, as shown in Figure 72.80.

Figure 72.80 Hypothesis Tab

Analysis: Two-sample Survival Rank Tests

Project:

Properties

Survival Functions	Accrual Times	Power	Sample Size	Results
Solve For	Test	Hypothesis	Alpha	

Select a one or two-sided hypothesis test

☐ One-sided test ☐ Lower one-sided test

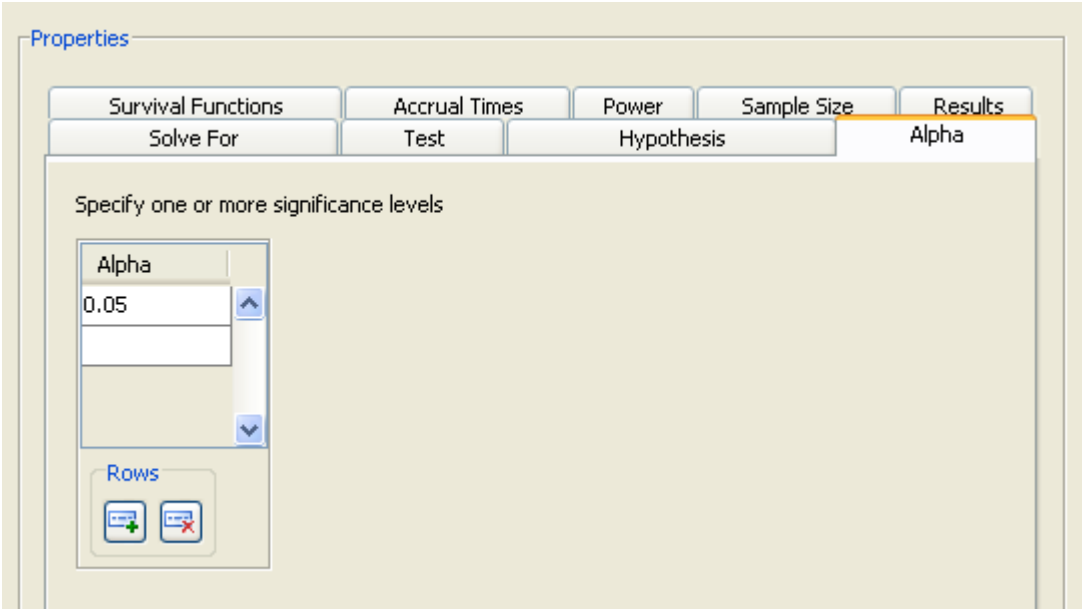

☒ Two-sided test ☐ Upper one-sided test

You can choose either a one- or two-sided test. For the one-sided test, the alternative hypothesis is assumed to be in the same direction as the effect. If you do not know the direction of the effect (that is, whether it is positive or negative), the two-sided test is appropriate. If you know the effect’s direction, the one-sided test is appropriate. If you specify a one-sided test and the effect is in the unexpected direction, the results of the analysis are invalid.

Alpha

Click the **Alpha** tab to enter one or more values for the significance level. For the example, enter the desired significance level of 0.05 in the first cell of the Alpha table, as shown in [Figure 72.81](#), if it is not already the default value.

Figure 72.81 Alpha Tab

The significance level is the probability of falsely rejecting the null hypothesis. If you frequently use the same values for alpha, set them as the defaults in the Preferences window.

Survival Functions

Click the **Survival Functions** tab to select the input form for the survival functions.

Figure 72.82 Survival Functions Tab with Number of Curves

Function 1
Function 2

Define Curve

Label: **Function 1**

Group: ☒ 1 ☐ 2

Time	Probability

Rows

Examine the input alternatives available in the **Select a form** list. There are four alternate forms for entering survival functions. The first three apply only to exponential curves; the fourth applies to both piecewise linear and exponential curves.

Group median survival times

Enter median survival times for the two groups.

Group hazards

Enter hazards for the two groups.

Hazards, Hazard ratios

Enter hazards for the reference group and hazard ratios.

Survival curves

Enter survival probabilities and their associated times for each of several curves. Select or enter the number of curves from the drop-down list; at least two curves are required. Then, for each curve, select it in the left-hand list, select the Group 1 or Group 2 option, and then define the survival curve by entering pairs of times and probabilities. Enter a time and probability pair only if the probability is less than that of the previous pair.

For information about using the other forms, see the section “[Using the Other Survival Curve Forms](#)” on page 6236.

For each survival curve, select the curve in the left-hand list. Then, enter a descriptive label and select which group it is for. The labels should be unique. Finally, enter pairs of survival times and probabilities.

When you enter probabilities, enter a time and probability pair only when the probability for a survival curve changes. For example, if the probability for curve 1 at time 1 and 2 is 0.9 and at time 3 is 0.8, enter 0.9 for time 1 and 0.8 for time 3.

To specify an exponential survival curve, enter a single time and probability pair. In the example, the exponential curve for the existing treatment is defined by a probability of 0.5 at time 5.

The units of time for the survival curves must correspond to the units for the accrual, follow-up, and total times, which are described in the section “[Accrual Times](#)” on page 6229.

You can also compare several survival curves. For example, if you have two scenarios, A and B, for group 1’s curve and two scenarios, C and D, for group 2’s curve, then specify probabilities for the four curves and assign A and B to group 1 and C and D to group 2.

For the example, select the **Survival curves** form, as shown in [Figure 72.82](#). Enter the value, 2, in the **Number of survival curves** list box.

For the example enter the following values:

- For the first survival curve, enter a label of `Existing treatment` and select the **Group 1** option. For the first curve, enter a time of 5 and a probability of 0.5. [Figure 72.83](#) shows the resulting values.

Figure 72.83 Survival Times and Probabilities for Curve 1

The screenshot shows the 'Properties' dialog box with the 'Solve For' tab selected. The 'Survival Functions' sub-tab is active. The 'Select a form:' dropdown is set to 'Survival curves'. Below it, the instruction reads 'Select the number of curves; specify times and probabilities for each curve'. The 'Curves' section shows 'Number of survival curves:' set to 2. A list box contains 'Function 1' and 'Function 2'. The 'Define Curve' section shows 'Label:' set to 'Existing treatment' and 'Group:' with radio buttons for '1' (selected) and '2'. A table with columns 'Time' and 'Probability' contains one row with '5' and '0.5'. Below the table are 'Rows' buttons with '+' and '-' icons.

Time	Probability
5	0.5

- For the second curve select `Function 2` in the selection list on the left side of the tab. Enter a label of `Proposed treatment` and select the **Group 2** option. Then, enter time values of 1 through 5 and

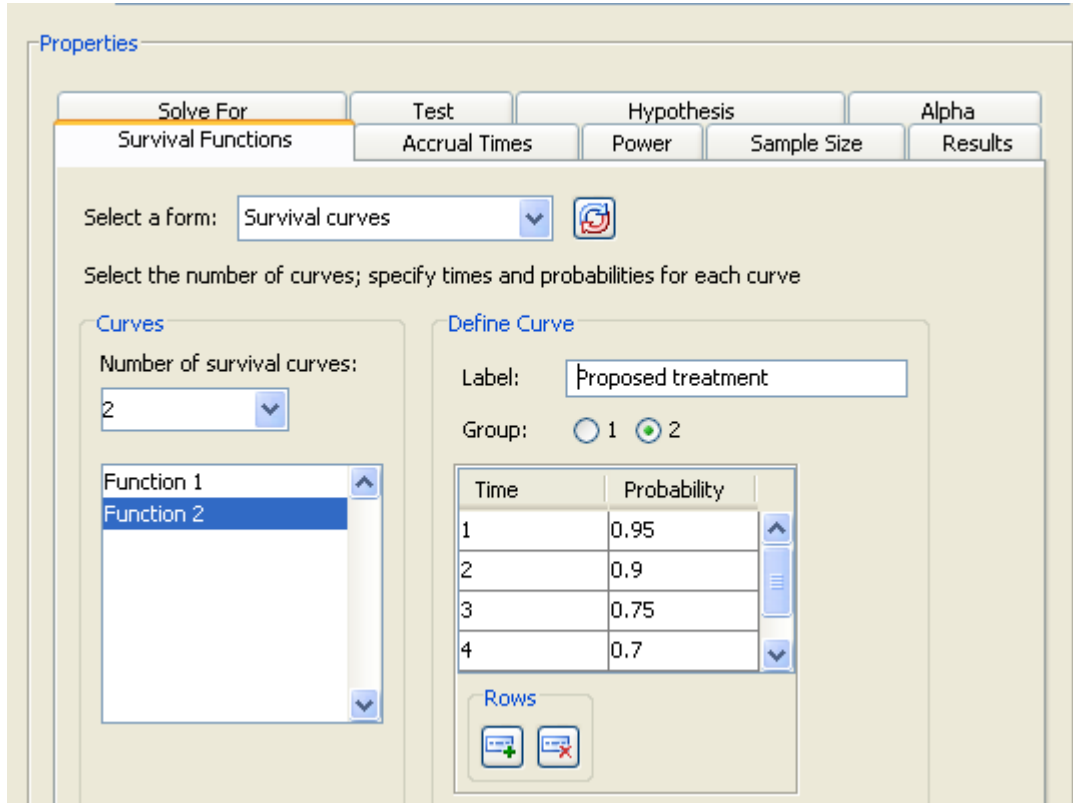

the corresponding probabilities of 0.95, 0.9, 0.75, 0.7, and 0.6. To add rows to the table, click the  button beneath the table.

Figure 72.84 shows these values; the last row of the time and probability table is not displayed.

Accrual Times

Click the **Accrual times** tab to select an input form for accrual times and to enter the times.

Figure 72.85 Accrual Times Tab

Properties

Solve For: Survival Functions

Test: **Accrual Times**

Hypothesis: Power

Alpha: Results

Select a form: Accrual times, Follow-up times

Enter one or more accrual and follow-up times

Accrual	Follow-up
2	3

Rows: + -

Examine the alternatives available in the **Select a form** list.

Accrual time is the period during which subjects are brought into the study. Follow-up time is the period during which subjects are observed after all subjects have been included in the study. Total time is the sum of accrual and follow-up time. The units of time for the accrual, follow-up, and total times must correspond to the units you used specified for the survival curves.

When you enter survival curves, the sum of the accrual and follow-up times must be less than the largest time for each survival curve. This does not apply to survival curves represented by a single time, which represent exponential curves.

On the **Accrual Times** tab, there are three alternate forms for entering accrual and follow-up times:

Accrual times, Follow-up times

Enter accrual and follow-up times.

Accrual times, Total times

Enter accrual and total times.

Follow-up times, Total times

Enter follow-up and total times.

For the example, select the **Accrual times, Follow-up times** form. Then enter a single value of 2 in the Accrual table and a value of 3 in the Follow-up table, as shown in [Figure 72.85](#).

Power

Click the **Power** tab to enter one or more power values. For the example, enter a single value of 0.8.

When you calculate sample size, it is necessary to specify one or more powers.

Summary of Input Parameters

Table 72.10 contains the values of the input parameters for the example.

Table 72.10 Summary of Input Parameters

Parameter	Value
Solve for	Sample size per group
Test	Log-rank
Hypothesis	Two-sided test
Alpha	0.05
Survival function form	Survival curves
Survival curves	See Table 72.11 and Table 72.12
Accrual and follow-up times form	Accrual time, Follow-up times
Accrual times	2
Follow-up times	3
Power	0.8

Table 72.11 and Table 72.12 contain times and probabilities for the two survival curves, respectively.

Table 72.11 Survival Times and Probabilities for Existing Treatment (Survival Curve 1)

Time	Probability
5	0.5

Table 72.12 Survival Times and Probabilities for Proposed Treatment (Survival Curve 2)

Time	Probability
1	0.95
2	0.90
3	0.75
4	0.70
5	0.60

Result Options

Click the **Results** tab to specify the desired result options. For the example, request both results by selecting both the **Create summary table** and **Create power by sample size graph** check boxes.

Specifying only one power (as in this example) produces a graph with a single point. You might be interested in a plot of sample sizes for a range of powers—say, between 0.75 and 0.85. You can customize the graph by specifying the values for the power axis. Also, you might want to change the appearance of the graph to have sample size (per group) on the vertical axis and power on the horizontal axis.

Click the **Customize** button beside the **Create power by sample size graph** check box to customize the graph. The Customize Graph window is displayed, as shown in Figure 72.86.

Figure 72.86 Customize Graph Window with Axis Orientation Tab

Click the **Axis Orientation** tab to select which variable to plot on the vertical axis. For the example, select the **Quantity solved for** option, as shown in Figure 72.86. This option plots sample size on the vertical axis and power on the horizontal axis. You could also have chosen the **Sample size** option.

Click the **Value Ranges** tab to enter minimum and maximum values for a plot axis. For the example, enter a minimum of 0.75 and a maximum of 0.85 in the Powers text boxes. This sets the range of values on the axis for powers. The completed Value Ranges tab of the window is displayed in Figure 72.87. You can set the axis values only for the quantity that is not being solved for.

Figure 72.87 Customize Graph Window with Value Ranges Tab

Click **OK** to save the values that you have entered and return to the Edit Properties page.

Then, click **Calculate** to perform the analysis. If there are no errors in the input parameter values, the View Results page appears. If there are errors in the input parameter values, you are prompted to correct them.

Viewing Results

The results appear in separate tabs on the View Results page of the project. Select the tab of each result that you want to view.

Summary Table

Click the **Summary Table** tab to view the summary table. It is composed of two subtables. As shown in [Figure 72.88](#), the **Fixed Scenario Elements** and **Computed N Per Group** tables include the values of the input parameters and the computed quantity (in this case, sample size per group, *N per group*). The sample size per group for the single requested scenario is 226.

Figure 72.88 Summary Table

**Power by Sample Size Graph**

Click the **Graph** tab to view the power by sample size graph.

Figure 72.89 Power by Sample Size Graph

As you can see in [Figure 72.89](#), the graph is curved slightly upward with larger powers associated with larger sample sizes. Sample size is plotted on the vertical axis as requested in the Customize Graph window.

Narratives

Click the **Narratives** tab to create one or more narratives. To generate a narrative, select the single scenario in the narrative selector table at the bottom of the tab. The narrative for this task does not include the survival times and probabilities for the survival curves:

For a log-rank test comparing two survival curves with a two-sided significance level of 0.05, assuming uniform accrual with an accrual time of 2 and a follow-up time of 3, a sample size of 226 per group is required to obtain a power of at least 0.8 for the exponential curve, “Existing treatment,” and the piecewise linear curve, “Proposed treatment.” The actual power is 0.800.

For information about selecting additional narratives when multiple scenarios are present, see the section [“Creating Narratives”](#) on page 6179.

Additional Topics

Using the Other Survival Curve Forms

Survival functions can be specified as median survival times, hazards, or a combination of hazards for one group and hazard ratios. These all assume exponential curves.

Suppose you are interested in comparing the proposed and existing treatments using their median survival times. The survival times are five years and four years for the two groups, respectively.

Figure 72.90 Median Survival Times and List of Alternate Forms

Properties

Solve For: Survival Functions

Test: Accrual Times

Hypothesis: Power

Overview: PRINCOMP Procedure

The PRINCOMP procedure performs principal component analysis. As input you can use raw data, a correlation matrix, a covariance matrix, or a sum-of-squares-and-crossproducts (SSCP) matrix. You can create output data sets containing eigenvalues, eigenvectors, and standardized or unstandardized principal component scores.

Principal component analysis is a multivariate technique for examining relationships among several quantitative variables. The choice between using factor analysis and using principal component analysis depends in part on your research objectives. You should use the PRINCOMP procedure if you are interested in summarizing data and detecting linear relationships. You can use principal components to reduce the number of

variables in regression, clustering, and so on. See Chapter 9, “[Introduction to Multivariate Procedures](#),” for a detailed comparison of the PRINCOMP and FACTOR procedures.

You can use ODS Graphics to display the scree plot, component pattern plot, component pattern profile plot, matrix plot of component scores, and component score plots. These plots are especially valuable tools in exploratory data analysis.

Principal component analysis was originated by Pearson (1901) and later developed by Hotelling (1933). The application of principal components is discussed by Rao (1964); Cooley and Lohnes (1971); Gnanadesikan (1977). Excellent statistical treatments of principal components are found in Kshirsagar (1972); Morrison (1976); Mardia, Kent, and Bibby (1979).

Given a data set with p numeric variables, you can compute p principal components. Each principal component is a linear combination of the original variables, with coefficients equal to the eigenvectors of the correlation or covariance matrix. The eigenvectors are customarily taken with unit length. The principal components are sorted by descending order of the eigenvalues, which are equal to the variances of the components.

Principal components have a variety of useful properties (Rao 1964; Kshirsagar 1972):

- The eigenvectors are orthogonal, so the principal components represent jointly perpendicular directions through the space of the original variables.
- The principal component scores are jointly uncorrelated. Note that this property is quite distinct from the previous one.
- The first principal component has the largest variance of any unit-length linear combination of the observed variables. The j th principal component has the largest variance of any unit-length linear combination orthogonal to the first $j - 1$ principal components. The last principal component has the smallest variance of any linear combination of the original variables.
- The scores on the first j principal components have the highest possible generalized variance of any set of unit-length linear combinations of the original variables.
- The first j principal components provide a least squares solution to the model

$$\mathbf{Y} = \mathbf{XB} + \mathbf{E}$$

where \mathbf{Y} is an $n \times p$ matrix of the centered observed variables; \mathbf{X} is the $n \times j$ matrix of scores on the first j principal components; \mathbf{B} is the $j \times p$ matrix of eigenvectors; \mathbf{E} is an $n \times p$ matrix of residuals; and you want to minimize $\text{trace}(\mathbf{E}'\mathbf{E})$, the sum of all the squared elements in \mathbf{E} . In other words, the first j principal components are the best linear predictors of the original variables among all possible sets of j variables, although any nonsingular linear transformation of the first j principal components would provide equally good prediction. The same result is obtained if you want to minimize the determinant or the Euclidean (Schur, Frobenius) norm of $\mathbf{E}'\mathbf{E}$ rather than the trace.

- In geometric terms, the j -dimensional linear subspace spanned by the first j principal components provides the best possible fit to the data points as measured by the sum of squared perpendicular distances from each data point to the subspace. This is in contrast to the geometric interpretation of least squares regression, which minimizes the sum of squared vertical distances. For example, suppose you have two variables. Then, the first principal component minimizes the sum of squared perpendicular distances from the points to the first principal axis. This is in contrast to least squares, which would minimize the sum of squared vertical distances from the points to the fitted line.

Principal component analysis can also be used for exploring polynomial relationships and for multivariate outlier detection (Gnanadesikan 1977), and it is related to factor analysis, correspondence analysis, allometry, and biased regression techniques (Mardia, Kent, and Bibby 1979).

Getting Started: PRINCOMP Procedure

The following data provide crime rates per 100,000 people in seven categories for each of the 50 states in 1977. Since there are seven numeric variables, it is impossible to plot all the variables simultaneously. Principal components can be used to summarize the data in two or three dimensions, and they help to visualize the data. The following statements produce [Figure 73.1](#) through [Figure 73.5](#).

```

Figure 73.1 displays the PROC PRINCOMP output, beginning with simple statistics followed by the correlation matrix. The PROC PRINCOMP statement requests by default principal components computed from the correlation matrix, so the total variance is equal to the number of variables, 7.

Figure 73.1 Number of Observations and Simple Statistics from the PRINCOMP Procedure

Crime Rates per 100,000 Population by State				
The PRINCOMP Procedure				
	Observations	50		
	Variables	7		
Simple Statistics				
	Murder	Rape	Robbery	Assault
Mean	7.444000000	25.73400000	124.0920000	211.3000000
Std	3.866768941	10.75962995	88.3485672	100.2530492
Simple Statistics				
	Burglary	Larceny	Auto_Theft	
Mean	1291.904000	2671.288000	377.5260000	
Std	432.455711	725.908707	193.3944175	

Figure 73.1 *continued*

Correlation Matrix							
	Murder	Rape	Robbery	Assault	Burglary	Larceny	Auto_Theft
Murder	1.0000	0.6012	0.4837	0.6486	0.3858	0.1019	0.0688
Rape	0.6012	1.0000	0.5919	0.7403	0.7121	0.6140	0.3489
Robbery	0.4837	0.5919	1.0000	0.5571	0.6372	0.4467	0.5907
Assault	0.6486	0.7403	0.5571	1.0000	0.6229	0.4044	0.2758
Burglary	0.3858	0.7121	0.6372	0.6229	1.0000	0.7921	0.5580
Larceny	0.1019	0.6140	0.4467	0.4044	0.7921	1.0000	0.4442
Auto_Theft	0.0688	0.3489	0.5907	0.2758	0.5580	0.4442	1.0000

Figure 73.2 displays the eigenvalues. The first principal component explains about 58.8% of the total variance, the second principal component explains about 17.7%, and the third principal component explains about 10.4%. Note that the eigenvalues sum to the total variance.

The eigenvalues indicate that two or three components provide a good summary of the data, two components accounting for 76% of the total variance and three components explaining 87%. Subsequent components contribute less than 5% each.

Figure 73.2 Results of Principal Component Analysis: PROC PRINCOMP

Eigenvalues of the Correlation Matrix				
	Eigenvalue	Difference	Proportion	Cumulative
1	4.11495951	2.87623768	0.5879	0.5879
2	1.23872183	0.51290521	0.1770	0.7648
3	0.72581663	0.40938458	0.1037	0.8685
4	0.31643205	0.05845759	0.0452	0.9137
5	0.25797446	0.03593499	0.0369	0.9506
6	0.22203947	0.09798342	0.0317	0.9823
7	0.12405606		0.0177	1.0000

Figure 73.3 displays the eigenvectors. From the eigenvectors matrix, you can represent the first principal component Prin1 as a linear combination of the original variables:

$$\begin{aligned}
 \text{Prin1} = & 0.300279 \times (\text{Murder}) \\
 & + 0.431759 \times (\text{Rape}) \\
 & + 0.396875 \times (\text{Robbery}) \\
 & \cdot \\
 & \cdot \\
 & \cdot \\
 & + 0.295177 \times (\text{Auto_Theft})
 \end{aligned}$$

Similarly, the second principal component Prin2 is

$$\begin{aligned}\text{Prin2} = & -0.629174 \times (\text{Murder}) \\ & - 0.169435 \times (\text{Rape}) \\ & + 0.042247 \times (\text{Robbery}) \\ & \cdot \\ & \cdot \\ & \cdot \\ & - 0.502421 \times (\text{Auto_Theft})\end{aligned}$$

where the variables are standardized.

Figure 73.3 Results of Principal Component Analysis: PROC PRINCOMP

	Eigenvectors						
	Prin1	Prin2	Prin3	Prin4	Prin5	Prin6	Prin7
Murder	0.300279	-.629174	0.178245	-.232114	0.538123	0.259117	0.267593
Rape	0.431759	-.169435	-.244198	0.062216	0.188471	-.773271	-.296485
Robbery	0.396875	0.042247	0.495861	-.557989	-.519977	-.114385	-.003903
Assault	0.396652	-.343528	-.069510	0.629804	-.506651	0.172363	0.191745
Burglary	0.440157	0.203341	-.209895	-.057555	0.101033	0.535987	-.648117
Larceny	0.357360	0.402319	-.539231	-.234890	0.030099	0.039406	0.601690
Auto_Theft	0.295177	0.502421	0.568384	0.419238	0.369753	-.057298	0.147046

The first component is a measure of the overall crime rate since the first eigenvector shows approximately equal loadings on all variables. The second eigenvector has high positive loadings on variables Auto_Theft and Larceny and high negative loadings on variables Murder and Assault. There is also a small positive loading on Burglary and a small negative loading on Rape. This component seems to measure the preponderance of property crime over violent crime. The interpretation of the third component is not obvious.

The ODS GRAPHICS statement enables the PRINCOMP procedure to produce statistical graphs by using ODS Graphics. See Chapter 21, “[Statistical Graphics Using ODS](#),” for more information. PLOTS=SCORE(ELLIPSE NCOMP=3) in the PROC PRINCOMP statement requests the pairwise component score plots for the first three components with a 95% prediction ellipse overlaid on each of the scatter plot. [Figure 73.4](#) shows the plot of the first two components. It is possible to identify regional trends on the plot of the first two components. Nevada and California are at the extreme right, with high overall crime rates but an average ratio of property crime to violent crime. North and South Dakota are at the extreme left, with low overall crime rates. Southeastern states tend to be at the bottom of the plot, with a higher-than-average ratio of violent crime to property crime. New England states tend to be in the upper part of the plot, with a higher-than-average ratio of property crime to violent crime. Assuming the first two components are from a bivariate normal distribution, the ellipse identifies Nevada as a possible outlier.

Figure 73.4 Plot of the First Two Component Scores

[Figure 73.5](#) shows the plot of the first and third components. Assuming the first and the third components are from a bivariate normal distribution, the ellipse identifies Nevada, Massachusetts, and New York as possible outliers.

Figure 73.5 Plot of the First and Third Component Scores

The most striking feature of the plot of the first and third principal components is that Massachusetts and New York are outliers on the third component.

Syntax: PRINCOMP Procedure

The following statements are available in the PRINCOMP procedure:

```

PROC PRINCOMP < options > ;
  BY variables ;
  FREQ variable ;
  ID variables ;
  PARTIAL variables ;
  VAR variables ;
  WEIGHT variable ;

```

Usually only the VAR statement is used in addition to the PROC PRINCOMP statement. The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC PRINCOMP statement. The remaining statements are described in alphabetical order.

PROC PRINCOMP Statement

PROC PRINCOMP < options > ;

The PROC PRINCOMP statement invokes the PRINCOMP procedure. Optionally, it also identifies input and output data sets, specifies the analyses performed, and controls displayed output. [Table 73.1](#) summarizes the options available in the PROC PRINCOMP statement.

Table 73.1 Summary of PROC PRINCOMP Statement Options

Option	Description
Specify data sets	
DATA=	Specifies input data set name
OUT=	Specifies output data set name
OUTSTAT=	Specifies output data set name containing various statistics
Specify details of analysis	
COV	Computes the principal components from the covariance matrix
N=	Specifies the number of principal components to be computed
NOINT	Omits the intercept from the model
PREFIX=	Specifies a prefix for naming the principal components
PARPREFIX=	Specifies a prefix for naming the residual variables
SINGULAR=	Specifies the singularity criterion
STD	Standardizes the principal component scores
VARDEF=	Specifies the divisor used in calculating variances and standard deviations
Suppress the display of output	
NOPRINT	Suppresses the display of all output
Specify ODS Graphics details	
PLOTS=	Specifies options that control the details of the plots

The following list provides details about these options.

COVARIANCE

COV

computes the principal components from the covariance matrix. If you omit the COV option, the correlation matrix is analyzed. Use of the COV option causes variables with large variances to be more strongly associated with components with large eigenvalues and causes variables with small variances to be more strongly associated with components with small eigenvalues. You should not specify the COV option unless the units in which the variables are measured are comparable or the variables are standardized in some way.

DATA=SAS-data-set

specifies the SAS data set to be analyzed. The data set can be an ordinary SAS data set or a TYPE=ACE, TYPE=CORR, TYPE=COV, TYPE=FACTOR, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV data set (see Appendix A, “[Special SAS Data Sets](#)”). Also, the PRINCOMP procedure can read the _TYPE_='COVB' matrix from a TYPE=EST data set. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

N=number

specifies the number of principal components to be computed. The default is the number of variables. The value of the N= option must be an integer greater than or equal to zero.

NOINT

omits the intercept from the model. In other words, the NOINT option requests that the covariance or correlation matrix not be corrected for the mean. When you use the PRINCOMP procedure with the NOINT option, the covariance matrix and, hence, the standard deviations are not corrected for the mean. If you are interested in the standard deviations corrected for the mean, you can get them by using a procedure such as the MEANS procedure.

If you use a TYPE=SSCP data set as input to the PRINCOMP procedure and list the variable Intercept in the VAR statement, the procedure acts as if you had also specified the NOINT option. If you use NOINT and also create an OUTSTAT= data set, the data set is TYPE=UCORR or TYPE=UCOV rather than TYPE=CORR or TYPE=COV.

NOPRINT

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, “[Using the Output Delivery System](#).”

OUT=SAS-data-set

creates an output SAS data set that contains all the original data as well as the principal component scores.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For details about OUT= data sets, see the section “[Output Data Sets](#)” on page 6253.

OUTSTAT=SAS-data-set

creates an output SAS data set that contains means, standard deviations, number of observations, correlations or covariances, eigenvalues, and eigenvectors. If you specify the COV option, the data set is TYPE=COV or TYPE=UCOV, depending on the NOINT option, and it contains covariances; otherwise, the data set is TYPE=CORR or TYPE=UCORR, depending on the NOINT option, and it contains correlations. If you specify the PARTIAL statement, the OUTSTAT= data set contains R squares as well.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For details about OUTSTAT= data sets, see the section “[Output Data Sets](#)” on page 6253.

PLOTS *<(global-plot-options)> <= plot-request <(options)>>*

PLOTS *<(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>*

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=(scatter pattern)
plots(unpack)=scree
plots(ncomp=3 flip)=(pattern(circles=0.5 1.0) score)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc princomp plots=all;
  var x1--x10;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled, but do not specify the PLOTS= option, PROC PRINCOMP produces the scree plot by default.

The global plot options include the following:

FLIP

flips or interchanges the X-axis and Y-axis dimension for the component score plots and the component pattern plots. For example, if there are three components, the default plots ($y * x$) are Component 2 * Component 1, Component 3 * Component 1, and Component 3 * Component 2. When you specify PLOTS(FILP), the plots are Component 1 * Component 2, Component 1 * Component 3, and Component 2 * Component 3.

NCOMP= n

specifies the number of components n (≥ 2) to be plotted for the component pattern plots and the component score plots. If the NCOMP= option is again specified in an individual plot, such as PLOTS=SCORE(NCOMP= m), the value m will determine the number of components to be plotted in the component score plots. Be aware that the number of plots $(n \times (n - 1) / 2)$ produced grows quadratically when n increases. The default is 5 or the total number of components m (≥ 2), whichever is smaller. If $n > m$, NCOMP= m will be used.

ONLY

suppresses the default plots. Only plots specifically requested are displayed.

UNPACKPANEL

UNPACK

suppresses paneling in the scree plot. By default, multiple plots can appear in an output panel. Specify UNPACKPANEL to get each plot in a separate panel. You can specify PLOTS(UNPACKPANEL) to unpack the default plots. You can also specify UNPACKPANEL as a suboption with SCREE (such as PLOTS=SCREE(UNPACKPANEL)).

The plot requests include the following:

ALL

produces all appropriate plots. You can specify other options with ALL; for example, to request all plots and unpack only the scree plot, specify `PLOTS=(ALL SCREE(UNPACKPANEL))`.

EIGEN | EIGENVALUE | SCREE < (UNPACKPANEL) >

produces the scree plot of eigenvalues and proportion variance explained. By default, both plots are output in a panel. Specify `PLOTS= SCREE(UNPACKPANEL)` to get each plot in a separate panel.

MATRIX

produces the matrix plot of principal component scores.

NONE

suppresses the display of all graphics output.

PATTERN < (pattern-options) >

produces the pairwise component pattern plots. Each variable is plotted as an observation whose coordinates are correlations between the variable and the two corresponding components on the plot. Use the `NCOMP=` option (for instance, `PLOTS=PATTERN(NCOMP=3)`) described in the following to control the number of plots to be displayed.

The available *pattern-options* are as follows:

CIRCLES < = number list >

plots the variance percentage circles. Each number in the list must be greater than 0. If the number is greater than or equal to 1, it is interpreted as a percentage and divided by 100; `CIRCLES=0.05` and `CIRCLES=5` are equivalent. For each number (*c*) specified, a ($c \times 100\%$) variance circle is created.

By default, there is no circle for the scatter pattern plot (`PLOTS=PATTERN`) and a unit circle with a 100% variance circle is plotted for the vector pattern plot (`PLOTS=PATTERN (VECTOR)`). You can display multiple circles by specifying `PLOTS=PATTERN(CIRCLES=)`. For example, specifying `PLOTS=PATTERN(CIRCLES=.3 .6 1.0)` will display the 30%, 60%, and 100% variance circles in the pattern plots.

FLIP

flips or interchanges the X-axis and Y-axis dimensions for the component pattern plots. Specify `PLOTS=PATTERN(FLIP)` to flip the X-axis and Y-axis dimensions.

NCOMP=*n*

specifies the number of components $n (\geq 2)$ to be plotted. The default is 5 or the total number of components $m (\geq 2)$, whichever is smaller. If $n > m$, `NCOMP= m` will be used. Be aware that the number of plots $(n \times (n - 1)/2)$ produced grows quadratically when n increases.

VECTOR

plots pattern in a vector form.

PATTERNPROFILE | PROFILE

produces the pattern profile plot. There is a profile for each component. The Y-axis value represents the correlation between the variable (corresponding to the X-axis value) and the profiled principal component.

SCORE < (score-options) >

produces the pairwise component score plots. Use the NCOMP= option (for instance, PLOTS=SCORE(NCOMP=3)) described in the following to control the number of plots to be displayed.

The available *score-options* are as follows:

ALPHA=number list

specifies a list of numbers for the prediction ellipses to be displayed in the score plots. Each value (α) in the list must be greater than 0. If α is greater than or equal to 1, it is interpreted as a percentage and divided by 100; ALPHA=0.05 and ALPHA=5 are equivalent.

ELLIPSE

requests prediction ellipses for the principal component scores of a new observation to be created in the principal component score plots. See the section “Confidence and Prediction Ellipses” in “The CORR Procedure” (*Base SAS Procedures Guide: Statistical Procedures*), for details about the computation of a prediction ellipse.

FLIP

flips or interchanges the X-axis and Y-axis dimensions for the component score plots. Specify PLOTS=SCORE(FLIP) to flip the X-axis and Y-axis dimensions.

NCOMP=*n*

specifies the number of components $n(\geq 2)$ to be plotted. The default is 5 or the total number of components $m(\geq 2)$, whichever is smaller. If $n > m$, NCOMP= m will be used. Be aware that the number of plots $(n \times (n - 1)/2)$ produced grows quadratically when n increases.

PAINT <=position>

creates plots of component i versus component j , painted by component k . When there are at least three components, the PLOTS=SCORE option is specified, and the PAINT option is not specified, a painted score plot for component 3 versus component 2, painted by component 1 is produced. Use the PAINT option when you want to create painted score plots involving other triples of components.

PLOTS=SCORE(PAINT), PLOTS=SCORE(PAINT=F), and PLOTS=SCORE(PAINT=FIRST) are all equivalent and create painted plots of $i \times j$, painted by k for triples (i, j, k) where $k < j < i$.

PLOTS=SCORE(PAINT=L) and PLOTS=SCORE(PAINT=LAST) are equivalent and create painted plots of $i \times j$, painted by k for triples (i, j, k) where $j < i < k$.

PLOTS=SCORE(PAINT=M) and PLOTS=SCORE(PAINT=MIDDLE) are equivalent and create painted plots of $i \times j$, painted by k for triples (i, j, k) where $j < k < i$.

PREFIX=name

specifies a prefix for naming the principal components. By default, the names are Prin1, Prin2, ..., Prin*n*. If you specify PREFIX=ABC, the components are named ABC1, ABC2, ABC3, and so on. The number of characters in the prefix plus the number of digits required to designate the variables should not exceed the current name length defined by the VALIDVARNAME= system option.

PARPREFIX=name**PPREFIX=name****RPREFIX=name**

specifies a prefix for naming the residual variables in the OUT= data set and the OUTSTAT= data set. By default, the prefix is R_. The number of characters in the prefix plus the maximum length of the variable names should not exceed the current name length defined by the VALIDVARNAME= system option.

SINGULAR=p**SING=p**

specifies the singularity criterion, where $0 < p < 1$. If a variable in a PARTIAL statement has an R square as large as $1 - p$ when predicted from the variables listed before it in the statement, the variable is assigned a standardized coefficient of 0. By default, SINGULAR=1E-8.

STANDARD**STD**

standardizes the principal component scores in the OUT= data set to unit variance. If you omit the STANDARD option, the scores have variance equal to the corresponding eigenvalue. Note that STANDARD has no effect on the eigenvalues themselves.

VARDEF=DF | N | WDF | WEIGHT | WGT

specifies the divisor used in calculating variances and standard deviations. By default, VARDEF=DF. The following table displays the values and associated divisors.

Value	Divisor	Formula	
DF	error degrees of freedom	$n - i$	(before partialing)
		$n - p - i$	(after partialing)
N	number of observations	n	
WEIGHT WGT	sum of weights	$\sum_{j=1}^n w_j$	
WDF	sum of weights minus one	$\left(\sum_{j=1}^n w_j\right) - i$	(before partialing)
		$\left(\sum_{j=1}^n w_j\right) - p - i$	(after partialing)

In the formulas for VARDEF=DF and VARDEF=WDF, p is the number of degrees of freedom of the variables in the PARTIAL statement, and i is 0 if the NOINT option is specified and 1 otherwise.

BY Statement

BY variables ;

You can specify a BY statement with PROC PRINCOMP to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the PRINCOMP procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ variable ;

The FREQ statement specifies a variable that provides frequencies for each observation in the DATA= data set. Specifically, if n is the value of the FREQ variable for a given observation, then that observation is used n times.

The analysis produced using a FREQ statement reflects the expanded number of observations. The total number of observations is considered equal to the sum of the FREQ variable. You could produce the same analysis (without the FREQ statement) by first creating a new data set that contains the expanded number of observations. For example, if the value of the FREQ variable is 5 for the first observation, the first 5 observations in the new data set would be identical. Each observation in the old data set would be replicated n_j times in the new data set, where n_j is the value of the FREQ variable for that observation.

If the value of the FREQ variable is missing or is less than one, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

ID Statement

ID variables ;

The ID statement labels observations with values from the first ID variable in the principal component score plot. If one or more ID variables are specified, their values are displayed in tooltips of the component score plot and the matrix plot of component scores.

PARTIAL Statement

PARTIAL *variables* ;

If you want to analyze a partial correlation or covariance matrix, specify the names of the numeric variables to be partialled out in the PARTIAL statement. The PRINCOMP procedure computes the principal components of the residuals from the prediction of the VAR variables by the PARTIAL variables. If you request an OUT= or OUTSTAT= data set, the residual variables are named by prefixing the characters R_ by default or the string specified in the PARPREFIX= option to the VAR variables.

VAR Statement

VAR *variables* ;

The VAR statement lists the numeric variables to be analyzed. If you omit the VAR statement, all numeric variables not specified in other statements are analyzed. If, however, the DATA= data set is TYPE=SSCP, the default set of variables used as VAR variables does not include Intercept so that the correlation or covariance matrix is constructed correctly. If you want to analyze Intercept as a separate variable, you should specify it in the VAR statement.

WEIGHT Statement

WEIGHT *variable* ;

If you want to use relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances.

The observation is used in the analysis only if the value of the WEIGHT statement variable is nonmissing and is greater than zero.

Details: PRINCOMP Procedure

Missing Values

Observations with missing values for any variable in the VAR, PARTIAL, FREQ, or WEIGHT statement are omitted from the analysis and are given missing values for principal component scores in the OUT= data set. If a correlation, covariance, or SSCP matrix is read, it can contain missing values as long as every pair of variables has at least one nonmissing entry.

Output Data Sets

OUT= Data Set

The OUT= data set contains all the variables in the original data set plus new variables containing the principal component scores. The N= option determines the number of new variables. The names of the new variables are formed by concatenating the value given by the PREFIX= option (or Prin if PREFIX= is omitted) and the numbers 1, 2, 3, and so on. The new variables have mean 0 and variance equal to the corresponding eigenvalue, unless you specify the STANDARD option to standardize the scores to unit variance. Also, if you specify the COV option, the procedure computes the principal component scores from the corrected or the uncorrected (if the NOINT option is specified) variables rather than the standardized variables.

If you use a PARTIAL statement, the OUT= data set also contains the residuals from predicting the VAR variables from the PARTIAL variables.

An OUT= data set cannot be created if the DATA= data set is TYPE=ACE, TYPE=CORR, TYPE=COV, TYPE=EST, TYPE=FACTOR, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV.

OUTSTAT= Data Set

The OUTSTAT= data set is similar to the TYPE=CORR data set produced by the CORR procedure. The following table relates the TYPE= value for the OUTSTAT= data set to the options specified in the PROC PRINCOMP statement.

Options	TYPE=
(default)	CORR
COV	COV
NOINT	UCORR
COV NOINT	UCOV

Note that the default (neither the COV nor NOINT option) produces a TYPE=CORR data set.

The new data set contains the following variables:

- the BY variables, if any
- two new variables, _TYPE_ and _NAME_, both character variables
- the variables analyzed (that is, those in the VAR statement); or, if there is no VAR statement, all numeric variables not listed in any other statement; or, if there is a PARTIAL statement, the residual variables as described under the OUT= data set

Each observation in the new data set contains some type of statistic as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are as follows:

MEAN mean of each variable. If you specify the PARTIAL statement, this observation is omitted.

STD	standard deviations. If you specify the COV option, this observation is omitted, so the SCORE procedure does not standardize the variables before computing scores. If you use the PARTIAL statement, the standard deviation of a variable is computed as its root mean squared error as predicted from the PARTIAL variables.
USTD	uncorrected standard deviations. When you specify the NOINT option in the PROC PRINCOMP statement, the OUTSTAT= data set contains standard deviations not corrected for the mean. However, if you also specify the COV option in the PROC PRINCOMP statement, this observation is omitted.
N	number of observations on which the analysis is based. This value is the same for each variable. If you specify the PARTIAL statement and the value of the VARDEF= option is DF or unspecified, then the number of observations is decremented by the degrees of freedom for the PARTIAL variables.
SUMWGT	the sum of the weights of the observations. This value is the same for each variable. If you specify the PARTIAL statement and VARDEF=WDF, then the sum of the weights is decremented by the degrees of freedom for the PARTIAL variables. This observation is output only if the value is different from that in the observation with _TYPE_='N'.
CORR	correlations between each variable and the variable specified by the _NAME_ variable. The number of observations with _TYPE_='CORR' is equal to the number of variables being analyzed. If you specify the COV option, no _TYPE_='CORR' observations are produced. If you use the PARTIAL statement, the partial correlations, not the raw correlations, are output.
UCORR	uncorrected correlation matrix. When you specify the NOINT option without the COV option in the PROC PRINCOMP statement, the OUTSTAT= data set contains a matrix of correlations not corrected for the means. However, if you also specify the COV option in the PROC PRINCOMP statement, this observation is omitted.
COV	covariances between each variable and the variable specified by the _NAME_ variable. _TYPE_='COV' observations are produced only if you specify the COV option. If you use the PARTIAL statement, the partial covariances, not the raw covariances, are output.
UCOV	uncorrected covariance matrix. When you specify the NOINT and COV options in the PROC PRINCOMP statement, the OUTSTAT= data set contains a matrix of covariances not corrected for the means.
EIGENVAL	eigenvalues. If the N= option requested fewer than the maximum number of principal components, only the specified number of eigenvalues are produced, with missing values filling out the observation.
SCORE	eigenvectors. The _NAME_ variable contains the name of the corresponding principal component as constructed from the PREFIX= option. The number of observations with _TYPE_='SCORE' equals the number of principal components computed. The eigenvectors have unit length unless you specify the STD option, in which case the unit-length eigenvectors are divided by the square roots of the eigenvalues to produce scores with unit standard deviations. To obtain the principal component scores, if the COV option is not specified, these coefficients should be multiplied by the standardized data. With the COV option, these coefficients should be multiplied by the centered data. Means obtained from the observation with _TYPE_='MEAN' and standard deviations obtained from the observation with _TYPE_='STD' should be used for centering and standardizing the data.

USCORE	scoring coefficients to be applied without subtracting the mean from the raw variables. _TYPE_='USCORE' observations are produced when you specify the NOINT option in the PROC PRINCOMP statement. To obtain the principal component scores, these coefficients should be multiplied by the data that are standardized by the uncorrected standard deviations obtained from the observation with _TYPE_='USTD'.
RSQUARED	R squares for each VAR variable as predicted by the PARTIAL variables
B	regression coefficients for each VAR variable as predicted by the PARTIAL variables. This observation is produced only if you specify the COV option.
STB	standardized regression coefficients for each VAR variable as predicted by the PARTIAL variables. If you specify the COV option, this observation is omitted.

The data set can be used with the SCORE procedure to compute principal component scores, or it can be used as input to the FACTOR procedure specifying METHOD=SCORE to rotate the components. If you use the PARTIAL statement, the scoring coefficients should be applied to the residuals, not the original variables.

Computational Resources

Let

- n = number of observations
- v = number of VAR variables
- p = number of PARTIAL variables
- c = number of components

- The minimum allocated memory required (in bytes) is

$$232v + 120p + 48c + \max(8cv, 8vp + 4(v + p)(v + p + 1))$$

- The time required to compute the correlation matrix is roughly proportional to

$$n(v + p)^2 + \frac{p}{2}(v + p)(v + p + 1)$$

- The time required to compute eigenvalues is roughly proportional to v^3 .
- The time required to compute eigenvectors is roughly proportional to cv^2 .

Displayed Output

The PRINCOMP procedure displays the following items if the DATA= data set is not TYPE=CORR, TYPE=COV, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV:

- simple statistics, including the mean and std (standard deviation) for each variable. If you specify the NOINT option, the uncorrected standard deviation (ustd) is displayed.
- the correlation or, if you specify the COV option, the covariance matrix

The PRINCOMP procedure displays the following items if you use the PARTIAL statement:

- regression statistics, giving the R square and RMSE (root mean squared error) for each VAR variable as predicted by the PARTIAL variables (not shown)
- standardized regression coefficients or, if you specify the COV option, regression coefficients for predicting the VAR variables from the PARTIAL variables (not shown)
- the partial correlation matrix or, if you specify the COV option, the partial covariance matrix (not shown)

The PRINCOMP procedure displays the following item if you specify the COV option:

- the total variance

The PRINCOMP procedure displays the following items unless you specify the NOPRINT option:

- eigenvalues of the correlation or covariance matrix, as well as the difference between successive eigenvalues, the proportion of variance explained by each eigenvalue, and the cumulative proportion of variance explained
- the eigenvectors

ODS Table Names

PROC PRINCOMP assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 73.2](#). For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

All of the tables are created with the specification of the PROC PRINCOMP statement; a few tables need an additional PARTIAL statement.

Table 73.2 ODS Tables Produced by PROC PRINCOMP

ODS Table Name	Description	Statement / Option
Corr	Correlation matrix	default

Table 73.2 *Continued*

ODS Table Name	Description	Statement and Option
Cov	Covariance matrix	COV
Eigenvalues	Eigenvalues	default
Eigenvectors	Eigenvectors	default
NObsNVar	Number of observations, variables, and partial variables	default
ParCorr	Partial correlation matrix	PARTIAL statement
ParCov	Uncorrected partial covariance matrix	PARTIAL statement and COV
RegCoef	Regression coefficients	PARTIAL statement and COV
RSquareRMSE	Regression statistics: R squares and RMSEs	PARTIAL statement
SimpleStatistics	Simple statistics	default
StdRegCoef	Standardized regression coefficients	PARTIAL statement
TotalVariance	Total variance	COV

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Some graphs are produced by default; other graphs are produced by using statements and options. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC PRINCOMP generates are listed in [Table 73.3](#), along with the required statements and options.

Table 73.3 Graphs Produced by PROC PRINCOMP

ODS Graph Name	Plot Description	Statement and Option
PaintedScorePlot	Score plot of component i versus component j , painted by component k	PLOTS=SCORE when number of variables ≥ 3
PatternPlot	Component pattern plot	PLOTS=PATTERN
PatternProfilePlot	Component pattern profile plot	PLOTS=PATTERNPROFILE
ScoreMatrixPlot	Matrix plot of component scores	PLOTS=MATRIX
ScorePlot	Component score plot	PLOTS=SCORE
ScreePlot	Scree and variance plots	default and PLOTS=SCREE
VariancePlot	Variance proportion explained plot	PLOTS=SCREE(UNPACKPANEL)

Examples: PRINCOMP Procedure

Example 73.1: Temperatures

This example analyzes mean daily temperatures in selected cities in January and July. Both the raw data and the principal components are plotted to illustrate how principal components are orthogonal rotations of the original variables.

The following statements create the Temperature data set.

```
data Temperature;
  length Cityid $ 2;
  title 'Mean Temperature in January and July for Selected Cities ';
  input City $1-15 January July;
  Cityid = substr(City,1,2);
  datalines;
Mobile          51.2 81.6
Phoenix         51.2 91.2
Little Rock     39.5 81.4
Sacramento     45.1 75.2
Denver          29.9 73.0

... more lines ...

Cheyenne        26.6 69.1
;
```

The following statements plot the temperature data set. The Cityid variable instead of City is used as a data label in the scatter plot for possible label clashing.

```
title 'Mean Temperature in January and July for Selected Cities';
proc sgplot data=Temperature;
  scatter x=July y=January / datalabel=Cityid;
run;
```

The results are displayed in [Output 73.1.1](#), which shows a scatter diagram of the 64 pairs of data points with July temperatures plotted against January temperatures.

Output 73.1.1 Plot of Raw Data

The following step requests a principal component analysis on the Temperature data set:

```
ods graphics on;

title 'Mean Temperature in January and July for Selected Cities';
proc princomp data=Temperature cov plots=score(ellipse);
  var July January;
  id Cityid;
run;
```

Output 73.1.2 displays the PROC PRINCOMP output. The standard deviation of January (11.712) is higher than the standard deviation of July (5.128). The COV option in the PROC PRINCOMP statement requests the principal components to be computed from the covariance matrix. The total variance is 163.474. The first principal component explains about 94% of the total variance, and the second principal component explains only about 6%. The eigenvalues sum to the total variance.

Note that January receives a higher loading on Prin1 because it has a higher standard deviation than July, and the PRINCOMP procedure calculates the scores by using the centered variables rather than the standardized variables.

Output 73.1.2 Results of Principal Component Analysis

Mean Temperature in January and July for Selected Cities				
The PRINCOMP Procedure				
	Observations	64		
	Variables	2		
Simple Statistics				
		July	January	
Mean		75.60781250	32.09531250	
StD		5.12761910	11.71243309	
Covariance Matrix				
		July	January	
July		26.2924777	46.8282912	
January		46.8282912	137.1810888	
Total Variance		163.47356647		
Eigenvalues of the Covariance Matrix				
	Eigenvalue	Difference	Proportion	Cumulative
1	154.310607	145.147647	0.9439	0.9439
2	9.162960		0.0561	1.0000
Eigenvectors				
		Prin1	Prin2	
	July	0.343532	0.939141	
	January	0.939141	-.343532	

PLOTS=SCORE in the PROC PRINCOMP statement requests a plot of the second principal component against the first principal component as shown in [Output 73.1.3](#). It is clear from this plot that the principal components are orthogonal rotations of the original variables and that the first principal component has a larger variance than the second principal component. In fact, the first component has a larger variance than either of the original variables July and January. The ellipse indicates that Miami, Phoenix, and Portland are possible outliers.

Output 73.1.3 Plot of Component 2 by Component 1

Example 73.2: Basketball Data

The data in this example are rankings of 35 college basketball teams. The rankings were made before the start of the 1985–86 season by 10 news services.

The purpose of the principal component analysis is to compute a single variable that best summarizes all 10 of the preseason rankings.

Note that the various news services rank different numbers of teams, varying from 20 through 30 (there is a missing rank in one of the variables, `WashPost`). And, of course, not all services rank the same teams, so there are missing values in these data. Each of the 35 teams is ranked by at least one news service.

The PRINCOMP procedure omits observations with missing values. To obtain principal component scores for all of the teams, it is necessary to replace the missing values. Since it is the best teams that are ranked, it is not appropriate to replace missing values with the mean of the nonmissing values. Instead, an ad hoc method is used that replaces missing values with the mean of the unassigned ranks. For example, if 20 teams are ranked by a news service, then ranks 21 through 35 are unassigned. The mean of ranks 21 through 35 is 28, so missing values for that variable are replaced by the value 28. To prevent the method of missing-value replacement from having an undue effect on the analysis, each observation is weighted according to the

number of nonmissing values it has. See [Example 74.2](#) in Chapter 74, “The PRINQUAL Procedure,” for an alternative analysis of these data.

Since the first principal component accounts for 78% of the variance, there is substantial agreement among the rankings. The eigenvector shows that all the news services are about equally weighted; this is also suggested by the nearly horizontal line of the pattern profile plot in [Output 73.2.3](#). So a simple average would work almost as well as the first principal component. The following statements produce [Output 73.2.1](#).

```

/*-----*/
/*
/* Pre-season 1985 College Basketball Rankings
/* (rankings of 35 teams by 10 news services)
/*
/* Note: (a) news services rank varying numbers of teams;
/*        (b) not all teams are ranked by all news services;
/*        (c) each team is ranked by at least one service;
/*        (d) rank 20 is missing for UPI.
/*

Example 73.3: Job Ratings

This example uses the PRINCOMP procedure to analyze job performance. Police officers were rated by their supervisors in 14 categories as part of standard police departmental administrative procedure.

The following statements create the Jobratings data set:

```
options validvarname=any;
data Jobratings;
    input 'Communication Skills'n      'Problem Solving'n
          'Learning Ability'n          'Judgment Under Pressure'n
          'Observational Skills'n      'Willingness to Confront Problems'n
          'Interest in People'n        'Interpersonal Sensitivity'n
          'Desire for Self-Improvement'n 'Appearance'n
          'Dependability'n             'Physical Ability'n
          'Integrity'n                'Overall Rating'n;
    datalines;
2 6 8 3 8 8 5 3 8 7 9 8 6 7 7 4 7 5 8 8 7 6 8 5 7 6 6 7 5 6 7 5 7 8 6 3 7 7 5
8 7 5 6 7 8 6 9 7 7 7 9 8 8 9 9 7 9 9 9 9 7 7 9 8 8 7 8 8 8 8 8 9 8 9 7 8 9 9
8 8 8 7 9 9 8 9 9 9 9 8 8 9 8 9 9 7 9 8 8 7 7 9 4 7 9 8 4 6 8 8 8 6 3 5 6 5 2

... more lines ...

7 8 9 9 7 9 9 7 9 9 9 9 8 9 9 8 9 9 8 9 9 8 9 9 7 6 6 5 6 3 9 9 5 6 7 4 8 6
;
```

The data set Jobratings contains 14 variables. Each variable contains the job ratings, using a scale measurement from 1 to 10 (1=fail to comply, 10=exceptional). The last variable Overall Rating contains a score as an overall index on how each officer performs.

The following statements request a principal component analysis on the Jobratings data set, output the scores to the Scores data set (OUT= Scores), and produce default plots. Note that variable Overall Rating is excluded from the analysis.

```
ods graphics on;

proc princomp data=Jobratings(drop='Overall Rating'n);
run;
```

Figure 73.3.1 and Figure 73.3.2 display the PROC PRINCOMP output, beginning with simple statistics followed by the correlation matrix. By default, the PROC PRINCOMP statement requests principal components computed from the correlation matrix, so the total variance is equal to the number of variables, 13. In this example, it would also be reasonable to use the COV option, which would cause variables with a high variance (such as Dependability) to have more influence on the results than variables with a low variance (such as Learning Ability). If you used the COV option, scores would be computed from centered rather than standardized variables.

Output 73.3.1 Simple Statistics and Correlation Matrix from the PRINCOMP Procedure

Figure 73.3.2 displays the eigenvalues. The first principal component explains about 50% of the total variance, the second principal component explains about 13.6%, and the third principal component explains about 7.7%. Note that the eigenvalues sum to the total variance. The eigenvalues indicate that three to five components provide a good summary of the data, with three components accounting for about 71.7% of the total variance and five components explaining about 82.7%. Subsequent components contribute less than 5% each.

Output 73.3.2 Eigenvalues and Eigenvectors from the PRINCOMP Procedure

PROC PRINCOMP produces the scree plot as shown in [Figure 73.3.3](#) by default when ODS Graphics is enabled. You can obtain more plots by specifying the PLOTS= option in the PROC PRINCOMP statement.

The “Scree Plot” on the left shows that the eigenvalue of the first component is approximately 6.5 and the eigenvalue of the second component is largely decreased to under 2.0. The “Variance Explained” plot on the right shows that you can explain a near 80% of total variance with the first four principal components.

Output 73.3.3 Scree Plot from the PRINCOMP Procedure

The first component reflects overall performance since the first eigenvector shows approximately equal loadings on all variables. The second eigenvector has high positive loadings on the variables Observational Skills and Willingness to Confront Problems but even higher negative loadings on the variables Interest in People and Interpersonal Sensitivity. This component seems to reflect the ability to take action, but it also reflects a lack of interpersonal skills. The third eigenvector has a very high positive loading on the variable Physical Ability and high negative loadings on the variables Problem Solving and Learning Ability. This component seems to reflect physical strength, but also shows poor learning and problem-solving skills.

In short, the three components represent the following:

First Component:	overall performance
Second Component:	smart, tough, and introverted
Third Component:	superior strength and average intellect

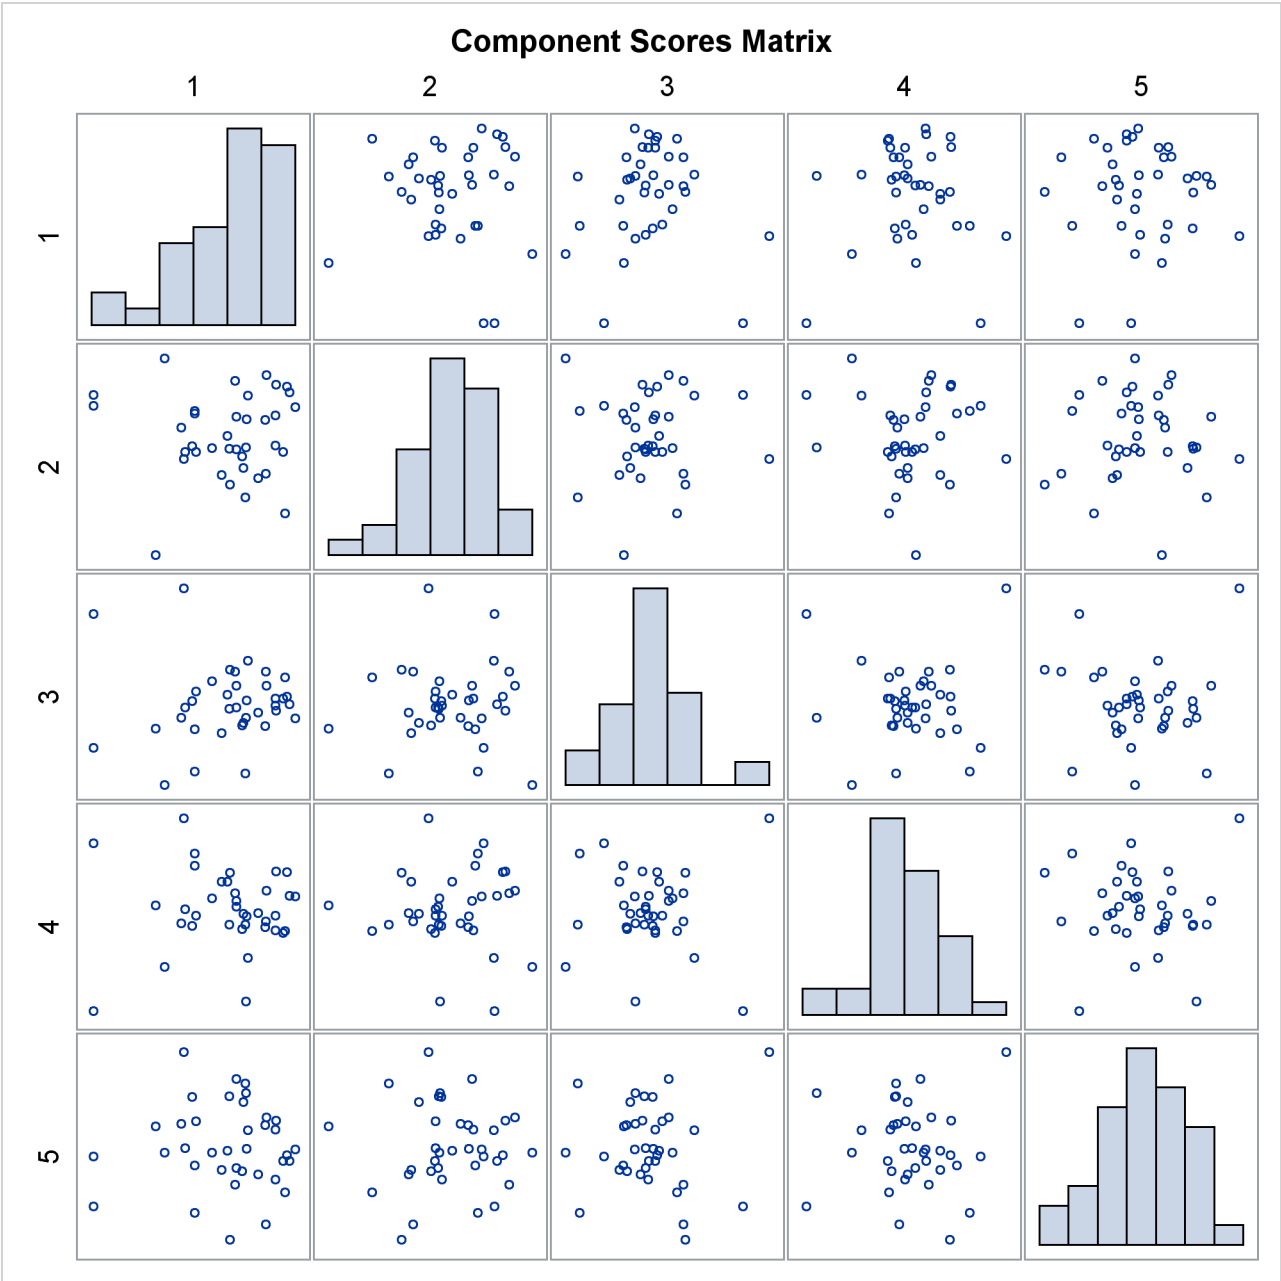

PROC PRINCOMP also produces other plots besides the scree plot, which are helpful while interpreting the results. The following statements request plots from the PRINCOMP procedure:

```
proc princomp data=Jobratings (drop='Overall Rating'n)
    plots (ncomp=3)=all n=5;
run;
```

PLOTS=ALL(NCOMP=3) in the PROC PRINCOMP statement requests all plots to be produced but limits the number of components to be plotted in the component pattern plots and the component score plots to three. The N=5 option sets the number of principal components to be computed to five. Besides a scree plot similar to the one shown before, the rest of plots are displayed in the following context.

Output 73.3.4 shows a matrix plot of component scores between the first five principal components. The histogram of each component is displayed in the diagonal element of the matrix. The histograms indicate that the first principal component is skewed to the left and the second principal component is slightly skewed to the right.

Output 73.3.4 Matrix Plot of Component Scores

The pairwise component pattern plots are shown in [Output 73.3.5](#) to [Output 73.3.7](#). The pattern plots show the following:

- All variables positively and evenly correlate with the first principal component ([Output 73.3.5](#) and [Output 73.3.6](#)).
- The variables Observational Skills and Willingness to Confront Problems correlate highly with the second component, and the variables Interest in People and Interpersonal Sensitivity correlate highly but negatively with the second component ([Output 73.3.5](#)).
- The variable Physical Ability correlates highly with the third component, and the variables Problem Solving and Learning Ability correlate highly but negatively with the third component ([Output 73.3.6](#)).
- The variable Observational Skills, Willingness to Confront Problems, Interest in People, and Interpersonal Sensitivity correlate highly (either positively or negatively) with the second component, but all have very low correlations with the third component; the variables Physical Ability and Problem Solving correlate highly (either positively or negatively) with the third component, but both have very low correlations with the second component ([Output 73.3.7](#)).

Output 73.3.5 Pattern Plot of Component 2 by Component 1

Output 73.3.6 Pattern Plot of Component 3 by Component 1

Output 73.3.7 Pattern Plot of Component 3 by Component 2

Output 73.3.8 shows a component pattern profile. As it was shown in the pattern plots, the nearly horizontal profile from the first component indicates that the first component is mostly correlated evenly across all variables.

Output 73.3.8 Component Pattern Profile Plot from the PRINCOMP Procedure

Output 73.3.9 through Output 73.3.11 display the pairwise component score plots. Observation numbers are used as the plotting symbol.

Output 73.3.9 shows a scatter plot of the first and third components. Observations 82, 9, and 84 seem like outliers on the first component; Observations 16 and 59 can be potential outliers on the second component.

Output 73.3.9 Component 2 versus Component 1

Output 73.3.10 shows a scatter plot of the first and third components. Observations 82, 9, and 84 seem like outliers on the first component.

Output 73.3.10 Component 3 versus Component 1

Output 73.3.11 shows a scatter plot of the second and third components. Observations 95, 15, 16, and 59 can be potential outliers on the second component.

Output 73.3.11 Component 3 versus Component 2

Output 73.3.12 shows a scatter plot of the second and third components, displaying the first component with color. Color interpolation in the HTMLBLUE style ranges from red (minimum) to blue (middle) and to green (maximum).

Output 73.3.12 Component 3 versus Component 2, Painted by Component 1

Overview: PRINQUAL Procedure

The PRINQUAL procedure performs principal component analysis (PCA) of qualitative, quantitative, or mixed data. PROC PRINQUAL is based on the work of Kruskal and Shepard (1974); Young, Takane, and de Leeuw (1978); Young (1981); Winsberg and Ramsay (1983). PROC PRINQUAL finds linear and nonlinear transformations of variables, using the method of alternating least squares, that optimize properties of the transformed variables' correlation or covariance matrix. Nonoptimal transformations such as logarithm and rank are also available. You can use ODS Graphics to display the results. You can use PROC PRINQUAL to do the following:

- fit metric and nonmetric principal component analyses
- perform metric and nonmetric multidimensional preference (MDPREF) analyses (Carroll 1972)
- transform data prior to their use in other analyses
- reduce the number of variables for subsequent use in regression analyses, cluster analyses, and other analyses
- detect nonlinear relationships

PROC PRINQUAL provides three methods, each of which seeks to optimize a different property of the transformed variables' covariance or correlation matrix. These methods are as follows:

- maximum total variance, or MTV
- minimum generalized variance, or MGW
- maximum average correlation, or MAC

The MTV method is based on a PCA model, and it is the most commonly used method. All three methods attempt to find transformations that decrease the rank of the covariance matrix computed from the transformed variables. Transforming the variables to maximize the total variance accounted for by a few linear combinations locates the observations in a space with a dimensionality that approximates the stated number of linear combinations as much as possible, given the transformation constraints. Transforming the variables to minimize their generalized variance or maximize the average correlations also reduces the dimensionality, but without a stated target for the final dimensionality. See the section [“The Three Methods of Variable Transformation”](#) on page 6311 for more information about all three methods.

The data can contain variables measured on nominal, ordinal, interval, and ratio scales of measurement (Siegel 1956). Any mix is allowed with all methods. PROC PRINQUAL can do the following:

- transform nominal variables by optimally scoring the categories (Fisher 1938)
- transform ordinal variables monotonically by scoring the ordered categories so that order is weakly preserved (adjacent categories can be merged) and the covariance matrix is optimized. You can undo ties optimally or leave them tied (Kruskal 1964). You can also transform ordinal variables to ranks.
- transform interval and ratio scale of measurement variables linearly, or transform them nonlinearly with spline transformations (de Boor 1978; van Rijckevorsel 1982) or monotone spline transformations (Winsberg and Ramsay 1983). In addition, nonoptimal transformations for logarithm, rank, exponential, power, logit, and inverse trigonometric sine are available.
- estimate missing data without constraint, with category constraints (missing values within the same group get the same value), and with order constraints (missing value estimates in adjacent groups can be tied to preserve a specified ordering). See Gifi (1990) and Young (1981).

The transformed qualitative (nominal and ordinal) variables can be thought of as being quantified by the analysis, with the quantification done in the context set by the algorithm. The data are quantified so that the proportion of variance accounted for by a stated number of principal components is locally maximized, the generalized variance of the variables is locally minimized, or the average of the correlations is locally maximized.

The PROC PRINQUAL iterations produce a set of transformed variables. Each variable's new scoring satisfies a set of constraints based on the original scoring of the variable and the specified transformation type. First, all variables are required to satisfy standardization constraints; that is, all variables have a fixed mean and variance. The other constraints include linear constraints, weak order constraints, category constraints, and smoothness constraints. The new set of scores is selected from the sets of possible scorings that do not violate the constraints so that the method criterion is locally optimized.

Getting Started: PRINQUAL Procedure

PROC PRINQUAL can be used to fit a principal component model with nonlinear transformations of the variables and graphically display the results. This example finds monotonic transformations of ratings of automobiles.

```

;

ods graphics on;

proc prinqual data=cars plots=all maxiter=100;
  transform monotone(mpg -- cargo);
  id model;
run;

```

The PROC PRINQUAL statement names the input data set Cars. The ODS GRAPHICS statement, along with the PLOTS=ALL option, requests all graphical displays. The MDPREF option requests the PCA plot with the scores (automobiles) represented as points and the structure (variables) represented as vectors. By default, the vector lengths are increased by a factor of 2.5 to produce a better graphical display. If instead you were to specify MDPREF=1, you would get the actual vectors, and they would all be short and would end near the origin where there are a lot of points. It is often the case that increasing the vector lengths by a factor of 2 or 3 makes a better graphical display, so by default the vector lengths are increased by a factor of 2.5. Up to 100 iterations are requested with the MAXITER= option. All of the numeric variable are specified with a MONOTONE transformation, so their original values, 1 to 5, are optimally rescored to maximize fit to a two-component model while preserving the original order. The Model variable provides the labels for the row points in the plot.

The iteration history table is shown in [Figure 74.1](#). The monotonic transformations allow the PCA to account for 5% more variance in two principal components than the ordinary PCA model applied to the untransformed data.

Algorithm converged.

The PCA biplot in [Figure 74.2](#) shows the transformed automobile ratings projected into the two-dimensional plane of the analysis. The automobiles on the left tend to be smaller than the autos on the right, and the autos at the top tend to be cheaper than the autos at the bottom. The vectors can help you interpret the plot of the scores. Longer vectors show the variables that better fit the two-dimensional model. A larger component of them is in the plane of the plot. In contrast, shorter vectors show the variables that do not fit the two-dimensional model as well. They tend to be located less in the plot and more away from the plot; hence their projection into the plot is shorter. To envision this, lay a pencil on your desk directly under a light, and slowly rotate it up to form a 90-degree angle with your desk. As you do so, the shadow or projection of the pencil onto your desk will get progressively shorter. The results show, for example, that the Chevette would be expected to do well on gas mileage but not well on quiet and acceleration. In contrast, the Corvette and the Firebird have the opposite pattern.

Figure 74.2 Automobile Ratings PCA Biplot

There are many patterns shown in the transformations in [Figure 74.3](#). The transformation of Braking, for example, is not very different from the original scoring. The optimal scoring for other variables, such as Acceleration and Handling, is binary. Automobiles are differentiated by high versus everything else or low versus everything else.

Figure 74.3 Automobile Ratings Transformations

Syntax: PRINQUAL Procedure

The following statements are available in the PRINQUAL procedure:

```
PROC PRINQUAL < options > ;
  TRANSFORM transform(variables < / t-options >)
             < transform(variables < / t-options >). . . > ;
  ID variables ;
  FREQ variable ;
  WEIGHT variable ;
  BY variables ;
```

To use PROC PRINQUAL, you need the PROC PRINQUAL and TRANSFORM statements. You can abbreviate all *options* and *t-options* to their first three letters. This is a special feature of PROC PRINQUAL and is not generally true of other SAS/STAT procedures.

The rest of this section provides detailed syntax information about each of the preceding statements, beginning with the PROC PRINQUAL statement. The remaining statements are described in alphabetical order.

PROC PRINQUAL Statement

```
PROC PRINQUAL < options > ;
```

The PROC PRINQUAL statement invokes the PRINQUAL procedure. Optionally, this statement identifies an input data set, creates an output data set, specifies the algorithm and other computational details, and controls displayed output. [Table 74.1](#) summarizes the options available in the PROC PRINQUAL statement.

Table 74.1 Summary of PROC PRINQUAL Statement Options

Option	Description
Input Data Set Options	
DATA=	Specifies input SAS data set
Output Data Set Details	
APPROXIMATIONS	Outputs approximations to transformed variables
APREFIX=	Specifies prefix for approximation variables
CORRELATIONS	Outputs correlations and component structure matrix
MDPREF=	Specifies a multidimensional preference analysis
OUT=	Specifies output data set
PREFIX=	Specifies prefix for principal component scores
REPLACE	Replaces raw data with transformed data
SCORES	Outputs principal component scores
STANDARD	Standardizes principal component scores
TPREFIX=	Specifies prefix for transformed variables
TSTANDARD=	Specifies transformation standardization

Table 74.1 *continued*

Option	Description
Method and Iterations	
CCONVERGE=	Specifies minimum criterion change
CHANGE=	Specifies number of first iteration to be displayed
CONVERGE=	Specifies minimum data change
COVARIANCE	Analyzes covariances
DUMMY	Initializes using dummy variables
INITITER=	Specifies number of MAC initialization iterations
MAXITER=	Specifies maximum number of iterations
METHOD=	Specifies iterative algorithm
NOCHECK	Suppresses numerical error checking
N	Specifies number of principal components
REFRESH=	Specifies number of MGv models before refreshing
REITERATE	Restarts iterations
SINGULAR=	Specifies singularity criterion
TYPE=	Specifies input observation type
Missing Data Handling	
MONOTONE=	Includes monotone special missing values
NOMISS	Excludes observations with missing values
UNTIE=	Unties special missing values
Control Displayed Output	
NOPRINT	Suppresses displayed output
PLOTS=	Specifies ODS Graphics details

The following list describes these options in alphabetical order.

APREFIX=*name*

APR=*name*

specifies a prefix for naming the approximation variables. By default, APREFIX=A. Specifying the APREFIX= option also implies the APPROXIMATIONS option.

APPROXIMATIONS

APPROX

APP

includes principal component approximations to the transformed variables (Eckart and Young 1936) in the output data set. Variable names are constructed from the value of the APREFIX= option and the input variable names. If you specify the APREFIX= option, then approximations are automatically included. If you specify the APPROXIMATIONS option and not the APREFIX= option, then the APPROXIMATIONS option uses the default, APREFIX=A, to construct the variable names.

CCONVERGE=*n***CCO=*n***

specifies the minimum change in the criterion being optimized that is required to continue iterating. By default, CCONVERGE=0.0. The CCONVERGE= option is ignored for METHOD=MAC. For the MGVS method, specify CCONVERGE=-2 to ensure data convergence.

CHANGE=*n***CHA=*n***

specifies the number of the first iteration to be displayed in the iteration history table. The default is CHANGE=1. When you specify a larger value for *n*, the first *n* - 1 iterations are not displayed, thus speeding up the analysis. The CHANGE= option is most useful with the MGVS method, which is much slower than the other methods.

CONVERGE=*n***CON=*n***

specifies the minimum average absolute change in standardized variable scores that is required to continue iterating. By default, CONVERGE=0.00001. Average change is computed over only those variables that can be transformed by the iterations—that is, all LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE variables and nonoptimal transformation variables with missing values. For more information, see the section “[Optimal Transformations](#)” on page 6306.

COVARIANCE**COV**

computes the principal components from the covariance matrix. The variables are always centered to mean zero. If you do not specify the COVARIANCE option, the variables are also standardized to variance one, which means the analysis is based on the correlation matrix.

CORRELATIONS**COR**

includes correlations and the component structure matrix in the output data set. By default, this information is not included.

DATA=SAS-*data-set*

specifies the SAS data set to be analyzed. The data set must be an ordinary SAS data set; it cannot be a TYPE=CORR or TYPE=COV data set. If you omit the DATA= option, PROC PRINQUAL uses the most recently created SAS data set.

DUMMY**DUM**

expands variables specified for OPSCORE optimal transformations to dummy variables for the initialization (Tenenhaus and Vachette 1977). By default, the initial values of OPSCORE variables are the actual data values. The dummy variable nominal initialization requires considerable time and memory, so it might not be possible to use the DUMMY option with large data sets. No separate report of the initialization is produced. Initialization results are incorporated into the first iteration displayed in the iteration history table. For details, see the section “[Optimal Transformations](#)” on page 6306.

INITITER=*n***INI=*n***

specifies the number of MAC iterations required to initialize the data before starting MTV or MGW iterations. By default, INITITER=0. The INITITER= option is ignored if METHOD=MAC.

MAXITER=*n***MAX=*n***

specifies the maximum number of iterations. By default, MAXITER=30.

MDPREF<=*n*>**MDP<=*n*>**

specifies a multidimensional preference analysis by implying the STANDARD, SCORES, and CORRELATIONS options. This option also suppresses warnings when there are more variables than observations.

When ODS Graphics is enabled, an MDPREF plot is produced with points for each row and vectors for each column. Often, the vectors are short, and a better graphical display is produced when the vectors are stretched. The absolute lengths of each vector can optionally be changed by specifying MDPREF=*n*. Then the vector coordinates are all multiplied by *n*. Usually, *n* will be a value such as 2, 2.5, or 3. The default is 2.5. Specify MDPREF=1 to see the vectors without any stretching. The relative lengths of the different vectors is important and interpretable, and these are preserved by the stretching.

METHOD=MAC | MGW | MTV**MET=MAC | MGW | MTV**

specifies the optimization method. By default, METHOD=MTV. Values of the METHOD= option are MTV, for maximum total variance; MGW, for minimum generalized variance; and MAC, for maximum average correlation. You can use the MAC method when all variables are positively correlated or when no monotonicity constraints are placed on any transformations. See the section “[The Three Methods of Variable Transformation](#)” on page 6311 for more information.

MONOTONE=*two-letters***MON=*two-letters***

specifies the first and last special missing value in the list of those special missing values to be estimated using within-variable order and category constraints. By default, there are no order constraints on missing value estimates. The *two-letters* value must consist of two letters in alphabetical order. For example, MONOTONE=DF means that the estimate of .D must be less than or equal to the estimate of .E, which must be less than or equal to the estimate of .F; no order constraints are placed on estimates of ._, .A through .C, and .G through .Z. For details, see the sections “[Missing Values](#)” on page 6316 and “[Optimal Scaling](#)” on page 8298 in Chapter 97, “[The TRANSREG Procedure](#).”

N=*n*

specifies the number of principal components to be computed. By default, N=2.

NOCHECK**NOC**

turns off computationally intensive numerical error checking for the MGCV method. If you do not specify the NOCHECK option, the procedure computes R square from the squared length of the predicted values vector and compares this value to the R square computed from the error sum of squares that is a byproduct of the sweep algorithm (Goodnight 1978). If the two values of R square differ by more than the square root of the value of the SINGULAR= option, a warning is displayed, the value of the REFRESH= option is halved, and the model is refit after refreshing. Specifying the NOCHECK option slightly speeds up the algorithm. Note that other less computationally intensive error checking is always performed.

NOMISS**NOM**

excludes all observations with missing values from the analysis, but does not exclude them from the OUT= data set. If you omit the NOMISS option, PROC PRINQUAL simultaneously computes the optimal transformations of the nonmissing values and estimates the missing values that minimize squared error.

Casewise deletion of observations with missing values occurs when you specify the NOMISS option, when there are missing values in IDENTITY variables, when there are weights less than or equal to 0, or when there are frequencies less than 1. Excluded observations are output with a blank value for the _TYPE_ variable, and they have a weight of 0. They do not contribute to the analysis but are scored and transformed as *supplementary* or passive observations. See the sections “[Passive Observations](#)” on page 6322 and “[Missing Values](#)” on page 6316 for more information about excluded observations and missing data.

NOPRINT**NOP**

suppresses the display of all output. This option disables the Output Delivery System (ODS), including ODS Graphics, for the duration of the procedure. For more information, see Chapter 20, “[Using the Output Delivery System](#).”

OUT=SAS-data-set

specifies an output SAS data set that contains results of the analysis. If you omit the OUT= option, PROC PRINQUAL still creates an output data set and names it by using the DATA n convention. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. You can use the REPLACE, APPROXIMATIONS, SCORES, and CORRELATIONS options to control what information is included in the output data set. For details, see the section “[Output Data Set](#)” on page 6318.

PLOTS <(global-plot-options)> <= plot-request <(options)>>

PLOTS <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses from around the plot request. Here are some examples:

```
plots=none
plots=transformation
plots(unpack)=transformation
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc prinqual plots=all;
    transformation spline(x1-x10);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled, but do not specify the PLOTS= option, then PROC PRINQUAL produces an MDPREF plot when the MDPREF option is specified.

The global plot options include the following:

FLIP

FLI

flips or interchanges the X-axis and Y-axis dimensions for MDPREF plots. The FLIP option can be specified either as a global plot option (for example, PLOTS(FLIP)) or with the MDPREF option (for example, PLOTS=MDPREF(FLIP)).

INTERPOLATE

INT

uses observations that are excluded from the analysis for interpolation in the fit and transformation plots. By default, observations with zero weight are excluded from all plots. These include observations with a zero, negative, or missing weight or frequency and observations excluded due to missing and invalid values. You can specify PLOTS(INTERPOLATE)=(*plot-requests*) to include some of these observations in the plots. You can use this option, for example, with sparse data sets to show smoother functions over the range of the data (see the section “[The PLOTS\(INTERPOLATE\) Option](#)” on page 8340 in Chapter 97, “[The TRANSREG Procedure](#)”).

ONLY

ONL

suppresses the default plots. Only plots specifically requested are displayed.

UNPACKPANEL**UNPACK****UNP**

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACKPANEL to get each plot in a separate panel.

The plot requests include the following:

ALL

produces all appropriate plots.

TRANSFORMATION**TRA****TRANSFORMATION(UNPACK)****TRA(UNP)**

plots the variable transformations. By default, multiple plots can appear in some output panels. Specify UNPACKPANEL to display each plot in a separate panel.

MDPREF**MDP**

plots multidimensional preference analysis results. The MDPREF plot can also be requested by specifying the [MDPREF](#) option in the PROC PRINQUAL statement outside the PLOTS= option.

NONE

suppresses all plots.

PREFIX=*name***PRE=***name*

specifies a prefix for naming the principal components. By default, PREFIX=Prin. As a result, the principal component default names are Prin1, Prin2, . . . , Prin*n*.

REFRESH=*n***REF=***n*

specifies the number of variables to scale in the MGCV method before computing a new inverse. By default, REFRESH=5. PROC PRINQUAL uses the REFRESH= option in the sweep algorithm of the MGCV method. Large values for the REFRESH= option make the method run faster but with more numerical error. Small values make the method run more slowly but with more numerical accuracy.

REITERATE**REI**

enables PROC PRINQUAL to use previous transformations as starting points. The REITERATE option affects only variables that are iteratively transformed (specified as LINEAR, SPLINE, MSPLINE, SSPLINE, UNTIE, OPSCORE, and MONOTONE). For iterative transformations, the REITERATE option requests a search in the input data set for a variable that consists of the value of the TPREFIX= option followed by the original variable name. If such a variable is found, it is used to provide the initial values for the first iteration. The final transformation is a member of the transformation family defined by the original variable, not the transformation family defined by the initialization variable. See the section “[REITERATE Option Usage](#)” on page 6321.

REPLACE**REP**

replaces the original data with the transformed data in the output data set. The names of the transformed variables in the output data set correspond to the names of the original variables in the input data set. If you do not specify the REPLACE option, both original variables and transformed variables (with names constructed from the TPREFIX= option and the original variable names) are included in the output data set.

SCORES**SCO**

includes principal component scores in the output data set. By default, scores are not included.

SINGULAR=*n***SIN=*n***

specifies the largest value within rounding error of zero. By default, SINGULAR=1E-8. PROC PRINQUAL uses the value of the SINGULAR= option for checking $(1 - R^2)$ when constructing full-rank matrices of predictor variables, checking denominators before dividing, and so on.

STANDARD**STD**

standardizes the principal component scores in the output data set to mean zero and variance one instead of the default mean zero and variance equal to the corresponding eigenvalue. See the [SCORES](#) option.

TPREFIX=*name***TPR=*name***

specifies a prefix for naming the transformed variables. By default, TPREFIX=T. The TPREFIX= option is ignored if you specify the REPLACE option.

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z**TST=CEN | NOM | ORI | Z**

specifies the standardization of the transformed variables in the OUT= data set. By default, TSTANDARD=ORIGINAL. When you specify the TSTANDARD= option in the PROC PRINQUAL statement, it is the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization just for selected variables.

CENTER centers the output variables to mean zero, but the variances are the same as the variances of the input variables.

NOMISS sets the means and variances of the transformed variables in the OUT= data set, computed over all output values that correspond to nonmissing values in the input data set, to the means and variances computed from the nonmissing observations of the original variables. The TSTANDARD=NOMISS specification is useful with missing data. When a variable is linearly transformed, the final variable contains the original nonmissing values and the missing value estimates. In other words, the nonmissing values are unchanged. If your data have no missing values, TSTANDARD=NOMISS and TSTANDARD=ORIGINAL produce the same results.

ORIGINAL sets the means and variances of the transformed variables to the means and variances of the original variables. This is the default.

Z standardizes the variables to mean zero, variance one.

For nonoptimal variable transformations, the means and variances of the original variables are actually the means and variances of the nonlinearly transformed variables, unless you specify the **ORIGINAL** nonoptimal *t-option* in the **TRANSFORM** statement. For example, if a variable *X* with no missing values is specified as **LOG**, then, by default, the final transformation of *X* is simply $\text{LOG}(X)$, not $\text{LOG}(X)$ standardized to the mean of *X* and variance of *X*.

TYPE=*'text'* | *name*

TYP=*'text'* | *name*

specifies the valid value for the `_TYPE_` variable in the input data set. If PROC PRINQUAL finds an input `_TYPE_` variable, it uses only observations with a `_TYPE_` value that matches the **TYPE**= value. This enables a PROC PRINQUAL **OUT**= data set containing correlations to be used as input to PROC PRINQUAL without requiring a **WHERE** statement to exclude the correlations. If a `_TYPE_` variable is not in the data set, all observations are used. The default is **TYPE**=**'SCORE'**, so if you do not specify the **TYPE**= option, only observations with `_TYPE_` = **'SCORE'** are used.

PROC PRINQUAL displays a note when it reads observations with blank values of `_TYPE_`, but it does not automatically exclude those observations. Data sets created by the TRANSREG and PRINQUAL procedures have blank `_TYPE_` values for those observations that were excluded from the analysis due to nonpositive weights, nonpositive frequencies, or missing data. When these observations are read again, they are excluded for the same reason that they were excluded from their original analysis, not because their `_TYPE_` value is blank.

UNTIE=*two-letters*

UNT=*two-letters*

specifies the first and last special missing values in the list of those special missing values that are to be estimated with within-variable order constraints but no category constraints. The *two-letters* value must consist of two letters in alphabetical order. By default, there are category constraints but no order constraints on special missing value estimates. For details, see the section “[Missing Values](#)” on page 6316. Also, see the section “[Optimal Scaling](#)” on page 8298 in Chapter 97, “[The TRANSREG Procedure](#).”

BY Statement

BY *variables* ;

You can specify a **BY** statement with PROC PRINQUAL to obtain separate analyses of observations in groups that are defined by the **BY** variables. When a **BY** statement appears, the procedure expects the input data set to be sorted in order of the **BY** variables. If you specify more than one **BY** statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the **SORT** procedure with a similar **BY** statement.
- Specify the **NOTSORTED** or **DESCENDING** option in the **BY** statement for the PRINQUAL procedure. The **NOTSORTED** option does not mean that the data are unsorted but rather that the data are

arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, list the variable's name in a FREQ statement. PROC PRINQUAL then treats the data set as if each observation appeared n times, where n is the value of the FREQ variable for the observation. Noninteger values of the FREQ variable are truncated to the largest integer less than the FREQ value. The observation is used in the analysis only if the value of the FREQ statement variable is greater than or equal to 1.

ID Statement

ID *variables* ;

The ID statement includes additional character or numeric variables in the output data set. The variables must be contained in the input data set.

TRANSFORM Statement

TRANSFORM *transform*(*variables* < / *t-options* >)< *transform*(*variables* < / *t-options* >)... > ;

The TRANSFORM statement lists the variables to be analyzed (*variables*) and specifies the transformation (*transform*) to apply to each variable listed. You must specify a transformation for each variable list in the TRANSFORM statement. The variables are variables in the data set. The *t-options* are transformation options that provide details for the transformation; these depend on the *transform* chosen. The *t-options* are listed after a slash in the parentheses that enclose the variables.

For example, the following statements find a quadratic polynomial transformation of all variables in the data set:

```
proc prinqual;
  transform spline(_all_ / degree=2);
run;
```

Or, if N1 through N10 are nominal variables and M1 through M10 are ordinal variables, you can use the following statements:

```
proc prinqual;  
  transform opscore (N1-N10) monotone (M1-M10) ;  
run;
```

The following sections describe the transformations available (specified with *transform*) and the options available for some of the transformations (specified with *t-options*).

Families of Transformations

There are three types of transformation families: nonoptimal, optimal, and other. The families are described as follows:

- Nonoptimal transformations preprocess the specified variables, replacing each one with a single new nonoptimal, nonlinear transformation.
- Optimal transformations replace the specified variables with new, iteratively derived optimal transformation variables that fit the specified model better than the original variable (except in contrived cases where the transformation fits the model exactly as well as the original variable).
- Other transformations are the IDENTITY and SSPLINE transformations. These do not fit into either of the preceding categories.

Table 74.2 summarizes the transformations in each family.

Table 74.2 Transformation Families

Transformation	Description
Nonoptimal Transformations	
ARSIN	Inverse trigonometric sine
EXP	Exponential
LOG	Logarithm
LOGIT	Logit
POWER	Raises variables to specified power
RANK	Transforms to ranks
Optimal Transformations	
LINEAR	Linear
MONOTONE	Monotonic, ties preserved
MSPLINE	Monotonic B-spline
OPSCORE	Optimal scoring
SPLINE	B-spline
UNTIE	Monotonic, ties not preserved
Other Transformations	
IDENTITY	Identity, no transformation
SSPLINE	Iterative smoothing spline

The *transform* is followed by a variable (or list of variables) enclosed in parentheses. Optionally, depending on the *transform*, the parentheses can also contain *t-options*, which follow the variables and a slash. For

example, the following statement computes the LOG transformation of X and Y:

```
transform log(X Y);
```

A more complex example follows:

```
transform spline(Y / nknots=2) log(X1 X2 X3);
```

The preceding statement uses the SPLINE transformation of the variable Y and the LOG transformation of the variables X1, X2, and X3. In addition, it uses the NKNOTS= option with the SPLINE transformation and specifies two knots.

The rest of this section provides syntax details for members of the three families of transformations. The *t-options* are discussed in the section “[Transformation Options \(t-options\)](#)” on page 6307.

Nonoptimal Transformations

Nonoptimal transformations are computed before the iterative algorithm begins. Nonoptimal transformations create a single new transformed variable that replaces the original variable. The new variable is not transformed by the subsequent iterative algorithms (except for a possible linear transformation and missing value estimation).

The following list provides syntax and details for nonoptimal variable transformations.

ARSIN

ARS

finds an inverse trigonometric sine transformation. Variables specified in the ARSIN *transform* must be numeric and in the interval $(-1.0 \leq x \leq 1.0)$, and they are typically continuous.

EXP

exponentiates variables (x is transformed to a^x). To specify the value of a , use the [PARAMETER=](#) *t-option*. By default, a is the mathematical constant $e = 2.718\dots$. Variables specified with the EXP *transform* must be numeric, and they are typically continuous.

LOG

transforms variables to logarithms (x is transformed to $\log_a(x)$). To specify the base of the logarithm, use the [PARAMETER=](#) *t-option*. The default is a natural logarithm with base $e = 2.718\dots$. Variables specified with the LOG *transform* must be numeric and positive, and they are typically continuous.

LOGIT

finds a logit transformation on the variables. The logit of x is $\log(x/(1 - x))$. Unlike other transformations, LOGIT does not have a three-letter abbreviation. Variables specified with the LOGIT *transform* must be numeric and in the interval $(0.0 < x < 1.0)$, and they are typically continuous.

POWER

POW

raises variables to a specified power (x is transformed to x^a). You must specify the power parameter a by specifying the [PARAMETER=](#) *t-option* following the variables.

```
power(variable / parameter=number)
```

You can use POWER for squaring variables (PARAMETER=2), reciprocal transformations (PARAMETER=-1), square roots (PARAMETER=0.5), and so on. Variables specified with the POWER *transform* must be numeric, and they are typically continuous.

RANK**RAN**

transforms variables to ranks. Ranks are averaged within ties. The smallest input value is assigned the smallest rank. Variables specified with the RANK *transform* must be numeric.

Optimal Transformations

Optimal transformations are iteratively derived. Missing values for these types of variables can be optimally estimated (see the section “Missing Values” on page 6316). See the sections “OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations” on page 8298 and “SPLINE and MSPLINE Transformations” on page 8300 in Chapter 97, “The TRANSREG Procedure,” for more information about the optimal transformations.

The following list provides syntax and details for optimal transformations.

LINEAR**LIN**

finds an optimal linear transformation of each variable. For variables with no missing values, the transformed variable is the same as the original variable. For variables with missing values, the transformed nonmissing values have a different scale and origin than the original values. Variables specified with the LINEAR *transform* must be numeric.

MONOTONE**MON**

finds a monotonic transformation of each variable, with the restriction that ties are preserved. The Kruskal (1964) secondary least squares monotonic transformation is used. This transformation weakly preserves order and category membership (ties). Variables specified with the MONOTONE *transform* must be numeric, and they are typically discrete.

MSPLINE**MSP**

finds a monotonically increasing B-spline transformation with monotonic coefficients (de Boor 1978; de Leeuw 1986) of each variable. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY= *t-options* with MSPLINE. By default, PROC PRINQUAL uses a quadratic spline. Variables specified with the MSPLINE *transform* must be numeric, and they are typically continuous.

OPSCORE**OPS**

finds an optimal scoring of each variable. The OPSCORE transformation assigns scores to each class (level) of the variable. The Fisher (1938) optimal scoring method is used. Variables specified with the OPSCORE *transform* can be either character or numeric; numeric variables should be discrete.

SPLINE**SPL**

finds a B-spline transformation (de Boor 1978) of each variable. By default, PROC PRINQUAL uses a cubic polynomial transformation. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY *t-options* with SPLINE. Variables specified with the SPLINE *transform* must be numeric, and they are typically continuous.

UNTIE**UNT**

finds a monotonic transformation of each variable without the restriction that ties are preserved. PROC PRINQUAL uses the Kruskal (1964) primary least squares monotonic transformation method. This transformation weakly preserves order but not category membership (it might untie some previously tied values). Variables specified with the UNTIE *transform* must be numeric, and they are typically discrete.

Other Transformations**IDENTITY****IDE**

specifies variables that are not changed by the iterations. The IDENTITY transformation is used for variables when no transformation and no missing data estimation are desired. However, the REFLECT, ADDITIVE, TSTANDARD=Z, and TSTANDARD=CENTER options can linearly transform all variables, including IDENTITY variables, after the iterations. Observations with missing values in IDENTITY variables are excluded from the analysis, and no optimal scores are computed for missing values in IDENTITY variables. Variables specified with the IDENTITY *transform* must be numeric.

SSPLINE**SSP**

finds an iterative smoothing spline transformation of each variable. The SSPLINE transformation does not generally minimize squared error. You can specify the smoothing parameter with either the SM= *t-option* or the PARAMETER= *t-option*. The default smoothing parameter is SM=0. Variables specified with the SSPLINE *transform* must be numeric, and they are typically continuous.

Transformation Options (t-options)

If you use a nonoptimal, optimal, or other transformation, you can use *t-options*, which specify additional details of the transformation. The *t-options* are specified within the parentheses that enclose variables and are listed after a slash. For example:

```
proc prinqual;
  transform spline(X Y / nknots=3);
run;
```

The preceding statements find an optimal variable transformation (SPLINE) of the variables X and Y and use a *t-option* to specify the number of knots (NKNOTS=). The following is a more complex example:

```
proc prinqual;
  transform spline(Y / nknots=3) spline(X1 X2 / nknots=6);
run;
```

These statements use the SPLINE transformation for all three variables and use *t-options* as well; the NKNOTS= option specifies the number of knots for the spline.

The following sections discuss the *t-options* available for nonoptimal, optimal, and other transformations.

Table 74.3 summarizes the *t-options*.

Table 74.3 Transformation Options

Option	Description
Nonoptimal Transformation	
ORIGINAL	Uses original mean and variance
Parameter Specification	
PARAMETER=	Specifies miscellaneous parameters
SM	Specifies smoothing parameter
Spline	
DEGREE=	Specifies the degree of the spline
EVENLY	Spaces the knots evenly
KNOTS=	Specifies the interior knots or break points
NKNOTS=	Creates n knots
Other t-options	
NAME=	Renames variables
REFLECT	Reflects the variable around the mean
TSTANDARD=	Specifies transformation standardization

Nonoptimal Transformation t-options**ORIGINAL****ORI**

matches the variable's final mean and variance to the mean and variance of the original variable. By default, the mean and variance are based on the transformed values. The ORIGINAL *t-option* is available for all of the nonoptimal transformations.

Parameter t-options**PARAMETER=number****PAR=number**

specifies the transformation parameter. The PARAMETER= *t-option* is available for the EXP, LOG, POWER, SMOOTH, and SSPLINE transformations. For EXP, the parameter is the value to be exponentiated; for LOG, the parameter is the base value; and for POWER, the parameter is the power. For SMOOTH and SSPLINE, the parameter is the raw smoothing parameter. (See the SM= option for an alternative way to specify the smoothing parameter.) The default for the PARAMETER= *t-option* for the LOG and EXP transformations is $e = 2.718 \dots$. The default parameter for SSPLINE is computed from SM=0. For the POWER transformation, you must specify the PARAMETER= *t-option*; there is no default.

SM= n

specifies a smoothing parameter in the range 0 to 100, just like PROC GPLOT uses. For example, SM=50 in PROC PRINQUAL is equivalent to I=SM50 on the SYMBOL statement with PROC GPLOT. You can specify the SM= *t-option* only with the SSPLINE transformation. The smoothness of the function increases as the value of the smoothing parameter increases. By default, SM=0.

Spline *t*-options

The following *t*-options are available with the SPLINE and MSPLINE optimal transformations.

DEGREE=*n*

DEG=*n*

specifies the degree of the B-spline transformation. The degree must be a nonnegative integer. The defaults are DEGREE=3 for SPLINE variables and DEGREE=2 for MSPLINE variables.

The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

EVENLY<=*n*>

EVE<=*n*>

is used with the NKNOTS= *t*-option to space the knots evenly. The differences between adjacent knots are constant. If you specify NKNOTS=*k*, *k* knots are created at

$$\text{minimum} + i((\text{maximum} - \text{minimum})/(k + 1))$$

for $i = 1, \dots, k$. For example, if you specify

spline(X / knots=2 evenly)

and the variable *X* has a minimum of 4 and a maximum of 10, then the two interior knots are 6 and 8. Without the EVENLY *t*-option, the NKNOTS= *t*-option places knots at percentiles, so the knots are not evenly spaced.

By default for the SPLINE and MSPLINE transformations, the smaller exterior knots are all the same and just a little smaller than the minimum. Similarly, by default, the larger exterior knots are all the same and just a little larger than the maximum. However, if you specify EVENLY=*n*, then the *n* exterior knots are evenly spaced as well. The number of exterior knots must be greater than or equal to the degree. You can specify values larger than the degree when you want to interpolate slightly beyond the range of your data. The exterior knots must be less than the minimum or greater than the maximum, and hence the knots across all sets are not precisely equally spaced. For example, with data ranging from 0 to 10, and with EVENLY=3 and NKNOTS=4, the first exterior knots are -4.000000000001, -2.000000000001, and -0.000000000001, the interior knots are 2, 4, 6, and 8, and the second exterior knots are 10.000000000001, 12.000000000001, and 14.000000000001.

KNOTS=number-list | *n* TO *m* BY *p*

KNO=number-list | *n* TO *m* BY *p*

specifies the interior knots or break points. By default, there are no knots. The first time you specify a value in the knot list, it indicates a discontinuity in the *n*th (from DEGREE=*n*) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the (*n* - 1) derivative of the transformation function at the value of the knot. Knots can be repeated any number of times to decrease the smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the KNOTS= *t*-option with the NKNOTS= *t*-option. You should keep the number of knots small. (See the section “Specifying the Number of Knots” on page 8301 in Chapter 97, “The TRANSREG Procedure.”)

NKNOTS=*n***NKN=*n***

creates *n* knots, the first at the $100/(n + 1)$ percentile, the second at the $200/(n + 1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the 25th percentile, the median, and the 75th percentile. By default, NKNOTS=0. The NKNOTS= *t-option* must be ≥ 0 .

You cannot use the NKNOTS= *t-option* with the KNOTS= *t-option*. You should keep the number of knots small. (See the section “[Specifying the Number of Knots](#)” on page 8301 in Chapter 97, “[The TRANSREG Procedure](#).”)

Other *t-options*

The following *t-options* are available for all transformations.

NAME=(*variable-list*)**NAM=(*variable-list*)**

renames variables as they are used in the TRANSFORM statement. This option allows a variable to be used more than once. For example, if the variable X is a character variable, then the following step stores both the original character variable X and a numeric variable XC that contains category numbers in the output data set.

```
proc prinqual data=A n=1 out=B;
  transform linear(Y) opscore(X / name=(XC));
  id X;
run;
```

REFLECT**REF**

reflects the transformation

$$y = -(y - \bar{y}) + \bar{y}$$

after the iterations are completed and before the final standardization and results calculations.

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z**TST=CEN | NOM | ORI | Z**

specifies the standardization of the transformed variables in the OUT= data set. By default, TSTANDARD=ORIGINAL. When the TSTANDARD= option is specified in the PROC PRINQUAL statement, it specifies the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization only for selected variables.

WEIGHT Statement
WEIGHT *variable* ;

When you use a WEIGHT statement, a weighted residual sum of squares is minimized. The WEIGHT statement has no effect on degrees of freedom or number of observations, but the weights affect most other calculations. The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than 0.

Details: PRINQUAL Procedure

The Three Methods of Variable Transformation

The three methods of variable transformation provided by PROC PRINQUAL are discussed in the following sections.

The Maximum Total Variance (MTV) Method

The MTV method (Young, Takane, and de Leeuw 1978) is based on the principal component model, and it attempts to maximize the sum of the first r eigenvalues of the covariance matrix. This method transforms variables to be (in a least squares sense) as similar to linear combinations of r principal component score variables as possible, where r can be much smaller than the number of variables. This maximizes the total variance of the first r components (the trace of the covariance matrix of the first r principal components). See *SAS Technical Report R-108*.

On each iteration, the MTV algorithm alternates classical principal component analysis (Hotelling 1933) with optimal scaling (Young 1981). When all variables are ordinal preference ratings, this corresponds to MDPREF analysis (Carroll 1972). You can request the dummy variable initialization method suggested by Tenenhaus and Vachette (1977), who independently propose the same iterative algorithm for nominal and interval scale-of-measurement variables.

The Minimum Generalized Variance (MGV) Method

The MGV method (Sarle 1984) uses an iterated multiple regression algorithm in an attempt to minimize the determinant of the covariance matrix of the transformed variables. This method transforms each variable to be (in a least squares sense) as similar to linear combinations of the remaining variables as possible. This locally minimizes the generalized variance of the transformed variables, the determinant of the covariance matrix, the volume of the parallelepiped defined by the transformed variables, and the sphericity (the extent to which a quadratic form in the optimized covariance matrix defines a sphere). See *SAS Technical Report R-108*.

On each iteration for each variable, the MGV algorithm alternates multiple regression with optimal scaling. The multiple regression involves predicting the selected variable from all other variables. You can request a dummy variable initialization by using a modification of the Tenenhaus and Vachette (1977) method that is appropriate with a regression algorithm. This method can be viewed as a way of investigating the nature of the linear and nonlinear dependencies in, and the rank of, a data matrix containing variables that can be nonlinearly transformed. This method tries to create a less-than-full-rank data matrix. The matrix contains the transformation of each variable that is most similar to what the other transformed variables predict.

The Maximum Average Correlation (MAC) Method

The MAC method (de Leeuw 1985) uses an iterated constrained multiple regression algorithm in an attempt to maximize the average of the elements of the correlation matrix. This method transforms each variable to be (in a least squares sense) as similar to the average of the remaining variables as possible.

On each iteration for each variable, the MAC algorithm alternates computing an equally weighted average of the other variables with optimal scaling. The MAC method is similar to the MGV method in that each

variable is scaled to be as similar to a linear combination of the other variables as possible, given the constraints on the transformation. However, optimal weights are not computed. You can use the MAC method when all variables are positively correlated or when no monotonicity constraints are placed on any transformations. Do not use this method with negatively correlated variables when some optimal transformations are constrained to be increasing because the signs of the correlations are not taken into account. The MAC method is useful as an initialization method for the MTV and MGV methods.

Understanding How PROC PRINQUAL Works

In the following example, PROC PRINQUAL uses the MTV method to linearize a curved scatter plot. Let

$$\begin{aligned} X_1 &= -1 \text{ to } 1 \text{ by } 0.02 \\ X_2 &= X_1^3 + \epsilon \\ X_3 &= X_2^5 + \epsilon \end{aligned}$$

where ϵ is normal error.

These three variables define a curved swarm of points in three-dimensional space. First, the SGSCATTER procedure is used to display two-dimensional views of these data. Next, PROC PRINQUAL is used to straighten the scatter plot, making it more one-dimensional by finding a smooth transformation of each variable. The N=1 option in the PROC PRINQUAL statement requests one principal component. The TRANSFORM statement requests a cubic spline transformation with nine knots. *Splines* are curves, which are usually required to be continuous and smooth. See the section “[Splines](#)” on page 6315 for more information about splines. See Smith (1979) for an excellent introduction to splines.

PROC PRINQUAL transforms each variable to be as much as possible like the first principal component (or more generally, to be close to the space defined by the first N= principal components). One component accounts for 92 percent of the variance of the untransformed data and over 99 percent of the variance of the transformed data (see [Figure 74.5](#)). Note that the results did not converge in the default 50 iterations, so more iterations were requested using the MAXITER= option. The transformations are requested by specifying PLOTS=TRANSFORMATION and are displayed in [Figure 74.6](#).

PROC PRINQUAL creates an output data set that contains both the original and transformed variables. The original variables are named X1, X2, and X3, and the transformed variables are named TX1, TX2, and TX3. The transformed variables are displayed using the SGSCATTER procedure in [Figure 74.7](#).

The following statements produce [Figure 74.4](#) through [Figure 74.7](#):

```
ods graphics on;

* Generate Three-Dimensional Data;
data X;
  do X1 = -1 to 1 by 0.02;
    X2 = X1 ** 3 + 0.05 * normal(7);
    X3 = X1 ** 5 + 0.05 * normal(7);
    output;
  end;
run;
```

```

proc sgscatter data=x;
  plot x1*x2 x1*x3 x3*x2;
run;

* Try to Straighten the Scatter Plot;
proc prinqual data=X n=1 maxiter=2000 plots=transformation out=results;
  title 'Linearize the Scatter Plot';
  transform spline(X1-X3 / nknots=9);
run;

* Plot the Linearized Scatter Plot;
proc sgscatter data=results;
  plot tx1*tx2 tx1*tx3 tx3*tx2;
run;

```

The three-dimensional data in Figure 74.4 and Figure 74.7 are displayed in three two-dimensional plots, arrayed as if they were three faces of a cube that was flattened as you might flatten a box.

Figure 74.4 Three-Dimensional Scatter Plot

Figure 74.5 PRINQUAL Iteration History

Figure 74.6 Transformations

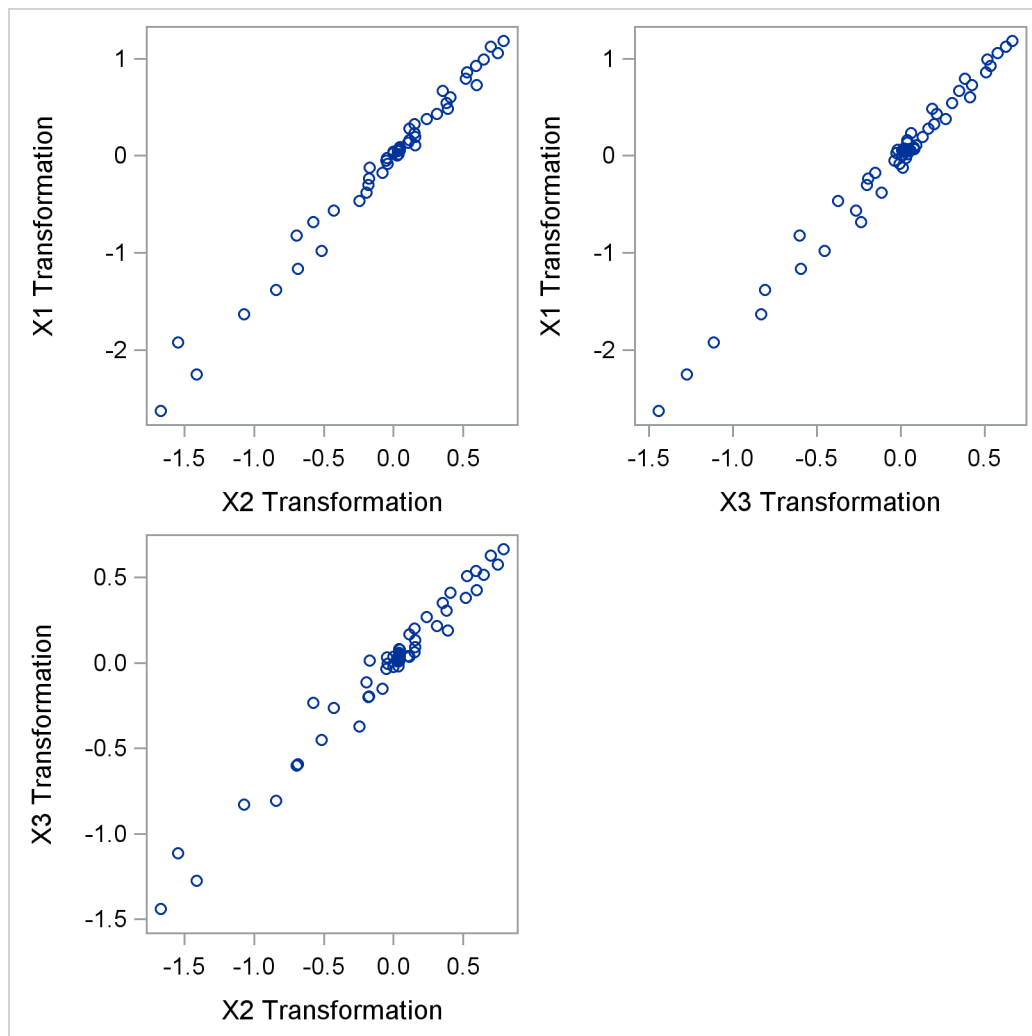

Figure 74.7 Linearized Scatter Plot

Splines

Splines are curves, and they are usually required to be continuous and smooth. Splines are usually defined as piecewise polynomials of degree n with function values and first $n - 1$ derivatives that agree at the points where they join. The abscissa values of the join points are called *knots*. The term “spline” is also used for polynomials (splines with no knots) and piecewise polynomials with more than one discontinuous derivative. Splines with no knots are generally smoother than splines with knots, which are generally smoother than splines with multiple discontinuous derivatives. Splines with few knots are generally smoother than splines with many knots; however, increasing the number of knots usually increases the fit of the spline function to the data. Knots give the curve freedom to bend to follow the data more closely. See Smith (1979) for an excellent introduction to splines. There are many examples and detailed discussions of splines in Chapter 97, “[The TRANSREG Procedure](#).” See the sections “[Linear and Nonlinear Regression Functions](#)” on page 8250, “[Smoothing Splines](#)” on page 8263, “[SPLINE and MSPLINE Transformations](#)” on page 8300, “[Specifying the Number of Knots](#)” on page 8301, “[SPLINE, BSPLINE, and PSPLINE Comparisons](#)” on page 8302, “[Linear and Nonlinear Regression Functions](#)” on page 8250, “[Simultaneously Fitting](#)

Two Regression Functions” on page 8254, and examples “Using Splines and Knots” on page 8233 and Example 97.1.

Missing Values

PROC PRINQUAL can estimate missing values, subject to optional constraints, so that the covariance matrix is optimized. The procedure provides several approaches for handling missing data. When you specify the NOMISS option in the PROC PRINQUAL statement, observations with missing values are excluded from the analysis. Otherwise, missing data are estimated, using variable means as initial estimates. Missing values for OPSCORE character variables are treated the same as any other category during the initialization. See the section “Missing Values” on page 8289 in Chapter 97, “The TRANSREG Procedure,” for more information about missing data estimation.

Controlling the Number of Iterations

Several options in the PROC PRINQUAL statement control the number of iterations performed. Iteration terminates when any one of the following conditions is satisfied:

- The number of iterations equals the value of the MAXITER= option.
- The average absolute change in variable scores from one iteration to the next is less than the value of the CONVERGE= option.
- The criterion change is less than the value of the CCONVERGE= option.

With the MTV method, the change in the proportion of variance criterion can become negative when the data have converged so that it is numerically impossible, within machine precision, to increase the criterion. Because the MTV algorithm is convergent, a negative criterion change is the result of very small amounts of rounding error. The MGCV method displays the average squared multiple correlation (which is not the criterion being optimized), so the criterion change can become negative well before convergence. The MAC method criterion (average correlation) is never computed, so the CCONVERGE= option is ignored for METHOD=MAC. You can specify a negative value for either convergence option if you want to define convergence only in terms of the other convergence option.

With the MGCV method, iterations minimize the generalized variance (determinant), but the generalized variance is not reported for two reasons. First, in most data sets, the generalized variance is almost always near zero (or will be after one or two iterations), which is its minimum. This does not mean that iteration is complete; it simply means that at least one multiple correlation is at or near one. The algorithm continues minimizing the determinant in $(m - 1)$, $(m - 2)$ dimensions, and so on. Because the generalized variance is almost always near zero, it does not provide a good indication of how the iterations are progressing. The mean R square provides a better indication of convergence. The second reason for not reporting the generalized variance is that almost no additional time is required to compute R square values for each step. This is because the error sum of squares is a byproduct of the algorithm at each step. Computing the determinant at the end of each iteration adds more computations to an already computationally intensive algorithm.

You can increase the number of iterations to ensure convergence by increasing the value of the MAXITER= option and decreasing the value of the CONVERGE= option. Because the average absolute change in standardized variable scores seldom decreases below $1E-11$, you typically do not specify a value for the CONVERGE= option less than $1E-8$ or $1E-10$. Most of the data changes occur during the first few iterations, but the data can still change after 50 or even 100 iterations. You can try different combinations of values for the CONVERGE= and MAXITER= options to ensure convergence without extreme overiteration. If the data do not converge with the default specifications, specify the REITERATE option, or try CONVERGE= $1E-8$ and MAXITER=50, or CONVERGE= $1E-10$ and MAXITER=200.

Performing a Principal Component Analysis of Transformed Data

PROC PRINQUAL produces an iteration history table that displays (for each iteration) the iteration number, the maximum and average absolute change in standardized variable scores computed over the iteratively transformed variables, the criterion being optimized, and the criterion change. In order to examine the results of the analysis in more detail, you can analyze the information in the output data set by using other SAS procedures.

Specifically, use the PRINCOMP procedure to perform a principal components analysis on the transformed data. PROC PRINCOMP accepts the raw data from PROC PRINQUAL but issues a warning, because the PROC PRINQUAL output data set has `_NAME_` and `_TYPE_` variables but is not a TYPE=CORR data set. You can ignore this warning.

If the output data set contains both scores and correlations, you must subset it for analysis with PROC PRINCOMP. Otherwise, the correlation observations are treated as ordinary observations and the PROC PRINCOMP results are incorrect. For example, consider the following statements:

```
proc prinqual data=a out=b correlations replace;
    transform spline(var1-var50 / nknots=3);
run;

proc princomp data=b;
    where _TYPE_='SCORE';
run;
```

Also note that the proportion of variance accounted for, as reported by PROC PRINCOMP, can exceed the proportion of variance accounted for in the last PROC PRINQUAL iteration. This is because PROC PRINQUAL reports the variance accounted for by the components analysis that generated the current scaling of the data, not a components analysis of the current scaling of the data.

Using the MAC Method

You can use the MAC algorithm alone by specifying METHOD=MAC, or you can use it as an initialization algorithm for METHOD=MTV and METHOD=MGV analyses by specifying the iteration option INITITER=. If any variables are negatively correlated, do not use the MAC algorithm with monotonic transformations (MONOTONE, UNTIE, and MSPLINE) because the signs of the correlations among the variables are not used when computing variable approximations. If an approximation is negatively correlated with the original variable, monotone constraints would make the optimally scaled variable a constant, which is not allowed (see the section “[Avoiding Constant Transformations](#)” on page 6321). When used

with other transformations, the MAC algorithm can reverse the scoring of the variables. So, for example, if variable X is designated $\text{LOG}(X)$ with $\text{METHOD}=\text{MAC}$ and $\text{TSTANDARD}=\text{ORIGINAL}$, the final transformation (for example, TX) might not be $\text{LOG}(X)$. If TX is not $\text{LOG}(X)$, it has the same mean as $\text{LOG}(X)$ and the same variance as $\text{LOG}(X)$, and it is perfectly negatively correlated with $\text{LOG}(X)$. PROC PRINQUAL displays a note for every variable that is reversed in this manner.

You can use the $\text{METHOD}=\text{MAC}$ algorithm to reverse the scorings of some rating variables before a factor analysis. The correlations among bipolar ratings such as 'like - dislike', 'hot - cold', and 'fragile - monumental' are typically both positive and negative. If some items are reversed to say 'dislike - like', 'cold - hot', and 'monumental - fragile', some of the negative signs can be eliminated, and the factor pattern matrix would be cleaner. You can use PROC PRINQUAL with $\text{METHOD}=\text{MAC}$ and LINEAR transformations to reverse some items, maximizing the average of the intercorrelations.

Output Data Set

PROC PRINQUAL produces an output data set by default. By specifying the $\text{OUT}=\text{, APPROXIMATIONS, SCORES, REPLACE, and CORRELATIONS}$ options in the PROC PRINQUAL statement, you can name this data set and control its contents.

By default, the procedure creates an output data set that contains variables with $\text{_TYPE_}=\text{'SCORE'}$. These observations contain original variables, transformed variables, components, or data approximations. If you specify the CORRELATIONS option in the PROC PRINQUAL statement, the data set also contains observations with $\text{_TYPE_}=\text{'CORR'}$; these observations contain correlations or component structure information.

Structure and Content

The output data set can have 16 different forms, depending on the specified combinations of the $\text{REPLACE, SCORES, APPROXIMATIONS, and CORRELATIONS}$ options. You can specify any combination of these options. To illustrate, assume that the data matrix consists of N observations and m variables, and n components are computed. Then define the following:

- D** the $N \times m$ matrix of original data with variable names that correspond to the names of the variables in the input data set. However, when you use the OPSCORE transformation on character variables, those variables are replaced by numeric variables that contain category numbers.
- T** the $N \times m$ matrix of transformed data with variable names constructed from the value of the TPREFIX= option (if you do not specify the REPLACE option) and the names of the variables in the input data set
- S** the $N \times n$ matrix of component scores with variable names constructed from the value of the PREFIX= option and integers
- A** the $N \times m$ matrix of data approximations with variable names constructed from the value of the APREFIX= option and the names of the variables in the input data set
- R_{TD}** the $m \times m$ matrix of correlations between the transformed variables and the original variables with variable names that correspond to the names of the variables in the input data set. When missing values exist, casewise deletion is used to compute the correlations.
- R_{TT}** the $m \times m$ matrix of correlations among the transformed variables with the variable names constructed from the value of the TPREFIX= option (if you do not specify the REPLACE option) and the names of the variables in the input data set

- R_{TS}** the $m \times n$ matrix of correlations between the transformed variables and the principal component scores (component structure matrix) with variable names constructed from the value of the **PRE-FIX=** option and integers
- R_{TA}** the $m \times m$ matrix of correlations between the transformed variables and the variable approximations with variable names constructed from the value of the **APREFIX=** option and the names of the variables in the input data set

To create a data set **Work.A** that contains all information, specify the following options in the **PROC PRINQUAL** statement:

```
proc prinqual scores approximations correlations out=a;
```

Also use a **TRANSFORM** statement appropriate for your data. Then the **Work.A** data set contains the following:

```

D      T      S      A
RTD  RTT  RTS  RTA
```

To eliminate the bottom partitions that contain the correlations and component structure, do not specify the **CORRELATIONS** option. For example, use the following **PROC PRINQUAL** statement with an appropriate **TRANSFORM** statement:

```
proc prinqual scores approximations out=a;
```

Then the **Work.A** data set contains the following:

```
D T S A
```

Suppose you use the following **PROC PRINQUAL** statement (with an appropriate **TRANSFORM** statement):

```
proc prinqual out=a;
```

This creates a data set **Work.A** of the following form:

```
D T
```

To output transformed data and component scores only, specify the following options in the **PROC PRINQUAL** statement:

```
proc prinqual replace scores out=a;
```

Then the **Work.A** data set contains the following:

```
T S
```

`_TYPE_` and `_NAME_` Variables

In addition to the preceding information, the output data set contains two character variables, the variable `_TYPE_` (length 8) and the variable `_NAME_` (length 32).

The `_TYPE_` variable has the value 'SCORE' if the observation contains variables, transformed variables, components, or data approximations; the `_TYPE_` variable has the value 'CORR' if the observation contains correlations or component structure.

By default, the `_NAME_` variable has values 'ROW1', 'ROW2', and so on, for the observations with `_TYPE_='SCORE'`. If you use an ID statement, the variable `_NAME_` contains the formatted ID variable for SCORES observations. The values of the variable `_NAME_` for observations with `_TYPE_='CORR'` are the names of the transformed variables.

Certain procedures, such as PROC PRINCOMP, which can use the PROC PRINQUAL output data set, issue a warning that the PROC PRINQUAL data set contains `_NAME_` and `_TYPE_` variables but is not a TYPE=CORR data set. You can ignore this warning.

Variable Names

The TPREFIX=, APREFIX=, and PREFIX= options specify prefixes for the transformed and approximation variable names and for principal component score variables, respectively. PROC PRINQUAL constructs transformed and approximation variable names from a prefix and the first characters of the original variable name. The number of characters in the prefix plus the number of characters in the original variable name (including the final digits, if any) required to uniquely designate the new variables should not exceed 32. For example, if the APREFIX= parameter that you specify is one character, PROC PRINQUAL adds the first 31 characters of the original variable name; if your prefix is four characters, only the first 28 characters of the original variable name are added.

Effect of the TSTANDARD= and COVARIANCE Options

The values in the output data set are affected by the TSTANDARD= and COVARIANCE options. If you specify TSTANDARD=NOMISS, the NOMISS standardization is performed on the transformed data after the iterations have been completed, but before the output data set is created. The new means and variances are used in creating the output data set. Then, if you do not specify the COVARIANCE option, the data are transformed to mean zero and variance one. The principal component scores and data approximations are computed from the resulting matrix. The data are then linearly transformed to have the mean and variance specified by the TSTANDARD= option. The data approximations are transformed so that the means within each pair of a transformed variable and its approximation are the same. The ratio of the variance of a variable approximation to the variance of the corresponding transformed variable equals the proportion of the variance of the variable that is accounted for by the components model.

If you specify the COVARIANCE option and do not specify TSTANDARD=Z, you can input the transformed data to PROC PRINCOMP, again specifying the COVARIANCE option, to perform a components analysis of the results of PROC PRINQUAL. Similarly, if you do not specify the COVARIANCE option with PROC PRINQUAL and you input the transformed data to PROC PRINCOMP without the COVARIANCE option, you receive the same report. However, some combinations of PROC PRINQUAL options, such as COVARIANCE and TSTANDARD=Z, while valid, produce approximations and scores that cannot be reproduced by PROC PRINCOMP.

The component scores in the output data set are computed from the correlations among the transformed variables, or from the covariances if you specified the COVARIANCE option. The component scores are

computed after the TSTANDARD=NOMISS transformation, if specified. The means of the component scores in the output data set are always zero. The variances equal the corresponding eigenvalues, unless you specify the STANDARD option; then the variances are set to one.

Avoiding Constant Transformations

There are times when the optimal scaling produces a constant transformed variable. This can happen with the MONOTONE, UNTIE, and MSPLINE transformations when the target is negatively correlated with the original input variable. It can happen with all transformations when the target is uncorrelated with the original input variable. When this happens, the procedure modifies the target to avoid a constant transformation. This strategy avoids certain nonoptimal solutions.

If the transformation is monotonic and a constant transformed variable results, the procedure multiplies the target by -1 and tries the optimal scaling again. If the transformation is not monotonic or if the multiplication by -1 did not help, the procedure tries using a random target. If the transformation is still constant, the previous nonconstant transformation is retained. When a constant transformation is avoided by any strategy, this message is displayed: “A constant transformation was avoided for *name*.”

Constant Variables

Constant and almost constant variables are zeroed and ignored.

Character OPSCORE Variables

Character OPSCORE variables are replaced by a numeric variable containing category numbers before the iterations, and the character values are discarded. Only the first eight characters are considered in determining category membership. If you want the original character variable in the output data set, give it a different name in the OPSCORE specification (OPSCORE(x / name=(x2)) and name the original variable in the ID statement (ID x;).

REITERATE Option Usage

You can use the REITERATE option to perform additional iterations when PROC PRINQUAL stops before the data have adequately converged. For example, suppose you execute the following code:

```
proc prinqual data=A cor out=B;
    transform mspline(X1-X5);
run;
```

If the transformations do not converge in the default 30 iterations, you can perform more iterations without repeating the first 30 iterations, as follows:

```
proc prinqual data=B reiterate cor out=B;
  transform mspline(X1-X5);
run;
```

Note that a WHERE statement is not necessary to exclude the correlation observations. They are automatically excluded because their `_TYPE_` variable value is not 'SCORE'.

You can also use the REITERATE option to specify starting values other than the original values for the transformations. Providing alternate starting points might avoid local optima. Here are two examples.

```
proc prinqual data=A out=B;
  transform rank(X1-X5);
run;

proc prinqual data=B reiterate out=C;
  /* Use ranks as the starting point. */
  transform monotone(X1-X5);
run;

data B;
  set A;
  array TXS[5] TX1-TX5;
  do j = 1 to 5;
    TXS[j] = normal(0);
  end;
run;

proc prinqual data=B reiterate out=C;
  /* Use a random starting point. */
  transform monotone(X1-X5);
run;
```

Note that divergence with the REITERATE option, particularly in the second iteration, is not an error since the initial transformation is not required to be a valid member of the transformation family. When you specify the REITERATE option, the iteration does not terminate when the criterion change is negative during the first 10 iterations.

Passive Observations

Observations can be excluded from the analysis for several reasons, including zero weight, zero frequency, missing values in variables designated as IDENTITY, or missing values with the NOMISS option specified. These observations are passive in that they do not contribute to determining transformations, R square, total variance, and so on. However, some information can be computed for them, such as approximations, principal component scores, and transformed values. Passive observations in the output data set have a blank value for the variable `_TYPE_`.

Missing value estimates for passive observations might converge slowly with METHOD=MTV. In the following example, the missing value estimates should be 2, 5, and 8. Since the nonpassive observations do not change, the procedure converges in one iteration but the missing value estimates do not converge. The extra iterations produced by specifying CONVERGE=-1 and CCONVERGE=-1, as shown in the second PROC PRINQUAL step that follows, generate the expected results.

```

data A;
    input X Y;
    datalines;
1 1
2 .
3 3
4 4
5 .

;

proc prinqual nomiss data=A nomiss n=1 out=B method=mtv;
    transform lin(X Y);
run;

proc print;
run;

proc prinqual nomiss data=A nomiss n=1 out=B method=mtv converge=-1 cconverge=-1;
    transform lin(X Y);
run;

proc print;
run;

```

Computational Resources

This section provides information about the computational resources required to run PROC PRINQUAL.

Let

- N = number of observations
- m = number of variables
- n = number of principal components
- k = maximum spline degree
- p = maximum number of knots

- For the MTV algorithm, more than

$$56m + 8Nm + 8(6N + (p + k + 2)(p + k + 11))$$

bytes of array space are required.

- For the MGCV and MAC algorithms, more than $56m$ plus the maximum of the data matrix size and the optimal scaling work space bytes of array space are required. The data matrix size is $8Nm$ bytes. The optimal scaling work space requires less than $8(6N + (p + k + 2)(p + k + 1))$ bytes.
- For the MTV and MGCV algorithms, more than $56m + 4m(m + 1)$ bytes of array space are required.
- PROC PRINQUAL tries to store the original and transformed data in memory. If there is not enough memory, a utility data set is used, potentially resulting in a large increase in execution time. The amount of memory for the preceding data formulas is an underestimate of the amount of memory needed to handle most problems. These formulas give an absolute minimum amount of memory required. If a utility data set is used, and if memory could be used with perfect efficiency, then roughly the amount of memory stated previously would be needed. In reality, most problems require at least two or three times the minimum.
- PROC PRINQUAL sorts the data once. The sort time is roughly proportional to $mN^{3/2}$.
- For the MTV algorithm, the time required to compute the variable approximations is roughly proportional to $2Nm^2 + 5m^3 + nm^2$.
- For the MGCV algorithm, one regression analysis per iteration is required to compute model parameter estimates. The time required to accumulate the crossproduct matrix is roughly proportional to Nm^2 . The time required to compute the regression coefficients is roughly proportional to m^3 . For each variable for each iteration, the swept crossproduct matrix is updated with time roughly proportional to $m(N+m)$. The swept crossproduct matrix is updated for each variable with time roughly proportional to m^2 , until computations are refreshed, requiring all sweeps to be performed again.
- The only computationally intensive part of the MAC algorithm is the optimal scaling, since variable approximations are simple averages.
- Each optimal scaling is a multiple regression problem, although some transformations are handled with faster special-case algorithms. The number of regressors for the optimal scaling problems depends on the original values of the variable and the type of transformation. For each monotone spline transformation, an unknown number of multiple regressions is required to find a set of coefficients that satisfies the constraints. The B-spline basis is generated twice for each SPLINE and MSPLINE transformation for each iteration. The time required to generate the B-spline basis is roughly proportional to Nk^2 .

Displayed Output

The main output from PROC PRINQUAL is the output data set. However, the procedure does produce displayed output in the form of an iteration history table that includes the following:

- iteration number
- the criterion being optimized
- criterion change
- maximum and average absolute change in standardized variable scores computed over variables that can be iteratively transformed
- notes
- final convergence status

ODS Table Names

PROC PRINQUAL assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 74.4](#) along with the PROC PRINQUAL statement options needed to produce the table. For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 74.4 ODS Tables Produced by PROC PRINQUAL

ODS Table Name	Description	Option
ConvergenceStatus	Convergence Status	default
Footnotes	Iteration History Footnotes	default
MAC	MAC Iteration History	METHOD=MAC
MGV	MGV Iteration History	METHOD=MGV
MTV	MTV Iteration History	METHOD=MTV
PctVar	Percentage of Variance	nonprinting

The nonprinting “PctVar” table is not displayed and does not appear in the ODS trace output unless you specify it in an ODS OUTPUT statement, as in the following example:

```
ods output pctvar=pvardataset;
```

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The plots are produced only when you specify the options shown in the table. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC PRINQUAL generates are listed in [Table 74.5](#), along with the required statements and options.

Table 74.5 Graphs Produced by PROC PRINQUAL

ODS Graph Name	Plot Description	Option
MDPrefPlot	Multidimensional preference analysis	MDPREF
TransformationPlot	Variable transformation	PLOTS=TRANSFORMATION

Examples: PRINQUAL Procedure

Example 74.1: Multidimensional Preference Analysis of Automobile Data

This example uses PROC PRINQUAL to perform a nonmetric multidimensional preference (MDPREF) analysis (Carroll 1972). MDPREF analysis is a principal component analysis of a data matrix with columns that correspond to people and rows that correspond to objects. The data are ratings or rankings of each person's preference for each object. The data are the transpose of the usual multivariate data matrix. (In other words, the columns are people; in the more typical matrix the rows represent people.) The final result of an MDPREF analysis is a biplot (Gabriel 1981) of the resulting preference space. A biplot displays the judges and objects in a single plot by projecting them onto the plane in the transformed variable space that accounts for the most variance.

In 1980, 25 judges gave their preferences for each of 17 new automobiles. The ratings were made on a 0 to 9 scale, with 0 meaning very weak preference and 9 meaning very strong preference for the automobile. The following statements create a SAS data set with the manufacturer and model of each automobile along with the ratings:

```

```

The following statements run PROC PRINCOMP and create a scree plot. The results of this step are shown in [Output 74.1.1](#).

```

ods graphics on;
* Principal Component Analysis of the Original Data;
proc princomp data=CarPref;
  ods select ScreePlot;
  var '1'n-'25'n;
run;

```

Output 74.1.1 Eigenvalue Plot

The scree or eigenvalue plot in [Output 74.1.1](#) shows that two principal components should be retained. There is a clear separation between the first two components and the remaining components. There are eight eigenvalues that are precisely zero because there are eight fewer observations than variables in the data matrix. One additional eigenvalue is zero, for a total of nine zero eigenvalues, since the correlation matrix is based on centered data. The following statements create the data set and perform a principal component analysis of the original data.

PROC PRINQUAL fits the nonmetric MDPREF model. PROC PRINQUAL monotonically transforms the raw judgments to maximize the proportion of variance accounted for by the first two principal components. The MONOTONE option is specified in the TRANSFORM statement to request a nonmetric MDPREF analysis; alternatively, you can instead specify the IDENTITY option for a metric analysis. Several options are used in the PROC PRINQUAL statement. The option DATA=CarPref specifies the input data set, OUT=Results creates an output data set, and N=2 and the default METHOD=MTV transform the data to better fit a two-component model. The REPLACE option replaces the original data with the monotonically transformed data in the OUT= data set. The MDPREF option standardizes the component scores to variance one so that the geometry of the biplot is correct, and it creates two variables in the OUT= data set named Prin1 and Prin2. These variables contain the standardized principal component scores and structure matrix, which are used to make the biplot. If the variables in data matrix \mathbf{X} are standardized to mean zero and variance one, and n is the number of rows in \mathbf{X} , then $\mathbf{X} = \mathbf{V}\mathbf{\Lambda}^{1/2}\mathbf{W}'$ is the principal component model, where $\mathbf{X}'\mathbf{X}/(n-1) = \mathbf{W}\mathbf{\Lambda}\mathbf{W}'$. The \mathbf{W} and $\mathbf{\Lambda}$ contain the eigenvectors and eigenvalues of the correlation matrix of \mathbf{X} . The first two columns of \mathbf{V} , the standardized component scores, and $\mathbf{W}\mathbf{\Lambda}^{1/2}$, which is the structure matrix, are output. The advantage of creating a biplot based on principal components is that coordinates do not depend on the sample size. The following statements transform the data and produce [Output 74.1.2](#).

```
* Transform the Data to Better Fit a Two Component Model;
proc prinqual data=CarPref out=Results n=2 replace mdpref;
  title2 'Multidimensional Preference (MDPREF) Analysis';
  title3 'Optimal Monotonic Transformation of Preference Data';
  id model;
  transform monotone('1'n-'25'n);
run;
```

30	0.00027	0.00454	0.82995	0.00000	Not Converged
WARNING: Failed to converge, however criterion change is less than 0.0001.					

The iteration history displayed by PROC PRINQUAL indicates that the proportion of variance is increased from an initial 0.66946 to 0.82995. The proportion of variance accounted for by PROC PRINQUAL on the first iteration equals the cumulative proportion of variance shown by PROC PRINCOMP for the first two principal components. PROC PRINQUAL's initial iteration performs a standard principal component analysis of the raw data. The columns labeled Average Change, Maximum Change, and Criterion Change contain values that always decrease, indicating that PROC PRINQUAL is improving the transformations at a monotonically decreasing rate over the iterations. This does not always happen, and when it does not, it suggests that the analysis might be converging to a degenerate solution. See [Example 74.2](#) for a discussion

of a degenerate solution. The algorithm does not converge in 30 iterations. However, the criterion change is small, indicating that more iterations are unlikely to have much effect on the results.

The biplot, shown in [Output 74.1.3](#), is automatically displayed by PROC PRINQUAL when ODS Graphics is enabled and the MDPREF option is specified.

Output 74.1.3 Biplot Made with PRINQUAL

The second PROC PRINCOMP analysis is performed on the transformed data. The WHERE statement is used to retain only the monotonically transformed judgments. The scree plot shows that the first two eigenvalues are now much larger than the remaining smaller eigenvalues. The second eigenvalue has increased markedly at the expense of the next several eigenvalues. Two principal components seem to be necessary and sufficient to adequately describe these judges' preferences for these automobiles. The cumulative proportion of variance displayed by PROC PRINCOMP for the first two principal components is 0.83. The following statements perform the analysis and produce [Output 74.1.4](#):

```

* Final Principal Component Analysis;
proc princomp data=Results;
  ods select ScreePlot;
  var '1'n-'25'n;
  where _TYPE_='SCORE';
run;

```

Output 74.1.4 Transformed Data Eigenvalue Plot

The remainder of the example discusses the MDPREF biplot. A biplot is a plot that displays the relation between the row points and the columns of a data matrix. The rows of \mathbf{V} , the standardized component scores, and $\mathbf{W}\mathbf{\Lambda}^{1/2}$, the structure matrix, contain enough information to reproduce \mathbf{X} . The (i, j) element of \mathbf{X} is the product of row i of \mathbf{V} and row j of $\mathbf{W}\mathbf{\Lambda}^{1/2}$. If all but the first two columns of \mathbf{V} and $\mathbf{W}\mathbf{\Lambda}^{1/2}$ are discarded, the (i, j) element of \mathbf{X} is approximated by the product of row i of \mathbf{V} and row j of $\mathbf{W}\mathbf{\Lambda}^{1/2}$.

Since the MDPREF analysis is based on a principal component model, the dimensions of the MDPREF biplot are the first two principal components. The first principal component is the longest dimension through the MDPREF biplot. The first principal component is overall preference, which is the most salient dimension in the preference judgments. One end points in the direction that is on the average preferred most by the judges, and the other end points in the least preferred direction. The second principal component is orthogonal to the first principal component, and it is the orthogonal direction that is the second most salient. The interpretation of the second dimension varies from example to example.

With an MDPREF biplot, it is geometrically appropriate to represent each automobile (object) by a point and each judge by a vector. The automobile points have coordinates that are the scores of the automobile on the first two principal components. The judge vectors emanate from the origin of the space and go through a point whose coordinates are the coefficients of the judge (variable) on the first two principal components.

The absolute length of a vector is arbitrary. However, the relative lengths of the vectors indicate fit, with the squared lengths being proportional to the communalities that you can get in PROC FACTOR output. The direction of the vector indicates the direction that is most preferred by the individual judge, with preference increasing as the vector moves from the origin. Let \mathbf{v}' be row i of \mathbf{V} , \mathbf{u}' be row j of $\mathbf{U} = \mathbf{W}\mathbf{\Lambda}^{1/2}$, $\|\mathbf{v}\|$

be the length of \mathbf{v} , $\|\mathbf{u}\|$ be the length of \mathbf{u} , and θ be the angle between \mathbf{v} and \mathbf{u} . The predicted degree of preference that an individual judge has for an automobile is $\mathbf{u}'\mathbf{v} = \|\mathbf{u}\| \|\mathbf{v}\| \cos \theta$. Each automobile point can be orthogonally projected onto the vector. The projection of automobile i on vector j is $\mathbf{u}((\mathbf{u}'\mathbf{v})/(\mathbf{u}'\mathbf{u}))$, and the length of this projection is $\|\mathbf{v}\| \cos \theta$. The automobile that projects farthest along a vector in the direction it points is that judge's most preferred automobile, since the length of this projection, $\|\mathbf{v}\| \cos \theta$, differs from the predicted preference, $\|\mathbf{u}\| \|\mathbf{v}\| \cos \theta$, only by $\|\mathbf{u}\|$, which is constant for each judge.

To interpret the biplot, look for directions through the plot that show a continuous change in some attribute of the automobiles, or look for regions in the plot that contain clusters of automobile points and determine what attributes the automobiles have in common. Points that are tightly clustered in a region of the plot represent automobiles that have the same preference patterns across the judges. Vectors that point in roughly the same direction represent judges who have similar preference patterns.

In the biplot, American automobiles are located at the left of the space, while European and Japanese automobiles are located at the right. At the top of the space are expensive American automobiles (Cadillac Eldorado, Lincoln Continental), while at the bottom are inexpensive ones (Ford Pinto, Chevrolet Chevette). The first principal component differentiates American from imported automobiles, and the second arranges automobiles by price and other associated characteristics.

The two expensive American automobiles form a cluster, the sporty automobile (Pontiac Firebird) is by itself, the Volvo DL is by itself, and the remaining imported autos form a cluster, as do the remaining American autos. It seems there are 5 prototypical automobiles in this set of 17, in terms of preference patterns among the 25 judges.

Most of the judges prefer the imported automobiles, especially the Volvo. There is also a fairly large minority that prefer the expensive autos, whether or not they are American (those with vectors that point toward one o'clock), or simply prefer expensive American automobiles (vectors that point toward eleven o'clock). There are two judges who prefer anything except expensive American autos (five o'clock vectors), and one who prefers inexpensive American autos (seven o'clock vector).

Several vectors point toward the upper-right corner of the plot, toward a region with no automobiles. This is the region between the European and Japanese autos at the right and the luxury autos at the top. This suggests that there is a market for luxury Japanese and European automobiles.

The next part of this example modifies the graph template for the MDPREF plot to display group information (the make of the automobile) in the MDPREF plot. First you need to run the PROC PRINQUAL step with ODS trace output enabled to find the name of the graph template for the MDPREF plot:

```
ods trace on;
proc prinqual data=CarPref out=Results n=2 replace mdpref;
  title2 'Multidimensional Preference (MDPREF) Analysis';
  title3 'Optimal Monotonic Transformation of Preference Data';
  id model;
  transform monotone('1'n-'25'n);
run;
```

The results are as follows:

Output Added:

```
-----
Name:      MDPrefPlot
Label:     2 by 1
Template:  Stat.Prinqual.Graphics.MDPref
Path:     Prinqual.MDPREF.MDPrefPlot
-----
```

The following step displays the template:

```
proc template;
  source Stat.Prinqual.Graphics.MDPref;
run;
```

The following template is displayed:

```
define statgraph Stat.Prinqual.Graphics.MDPref;
  notes "Multidimensional Preference Analysis Plot";
  dynamic xVar yVar xVec yVec ylab xlab yshortlab xshortlab xOri yOri
    stretch;
  begingraph;
  entrytitle "Multidimensional Preference Analysis";
  layout overlayequated / equatetype=fit xaxisopts=(label=XLAB shortlabel
    =XSHORTLAB offsetmin=0.1 offsetmax=0.1) yaxisopts=(label=YLAB
    shortlabel=YSHORTLAB offsetmin=0.1 offsetmax=0.1);
  scatterplot y=YVAR x=XVAR / datalabel=IDLAB1 rolename=( _tip1=
    OBSNUMVAR _id2=IDLAB2 _id3=IDLAB3 _id4=IDLAB4 _id5=IDLAB5 _id6=
    IDLAB6 _id7=IDLAB7 _id8=IDLAB8 _id9=IDLAB9 _id10=IDLAB10 _id11=
    IDLAB11 _id12=IDLAB12 _id13=IDLAB13 _id14=IDLAB14 _id15=IDLAB15
    _id16=IDLAB16 _id17=IDLAB17 _id18=IDLAB18 _id19=IDLAB19 _id20=
    IDLAB20) tip=(y x datalabel _tip1 _id2 _id3 _id4 _id5 _id6 _id7
    _id8 _id9 _id10 _id11 _id12 _id13 _id14 _id15 _id16 _id17 _id18
    _id19 _id20) datalabelattrs=GRAPHVALUETEXT (color=
    GraphData1:ContrastColor) markerattrs=GRAPHDATA1;
  vectorplot y=YVEC x=XVEC xorigin=0 yorigin=0 / datalabel=LABEL2VAR
    shaftprotected=false rolename=( _tip1=VNAME _tip2=VLABEL _tip3=
    YORI _tip4=XORI _tip5=LENGTH _tip6=LENGTH2) tip=(y x datalabel
    _tip1 _tip2 _tip3 _tip4 _tip5 _tip6) datalabelattrs=
    GRAPHVALUETEXT (color=GraphData2:ContrastColor) lineattrs=
    GRAPHDATA2 (pattern=solid) primary=true;
  if (0)
    entry "Vector Stretch = " STRETCH / autoalign=(topright topleft
      bottomright bottomleft right left top bottom);
  endif;
  endlayout;
endgraph;
end;
```

The following step adds a PROC PRINQUAL statement and a RUN statement, removes attribute options from the SCATTERPLOT statement, adds a GROUP=IDLAB2 option to use the second ID variable as a group variable, and adds a NAME='s' option along with a DISCRETELEGEND statement to display the groups in a legend:

```

proc template;
  define statgraph Stat.Prinqual.Graphics.MDPref;
    notes "Multidimensional Preference Analysis Plot";
    dynamic xVar yVar xVec yVec ylab xlab yshortlab xshortlab xOri yOri
      stretch;
    begingraph;
    entrytitle "Multidimensional Preference Analysis";
    layout overlayequated / equatetype=fit xaxisopts=(label=XLAB shortlabel
      =XSHORTLAB offsetmin=0.1 offsetmax=0.1) yaxisopts=(label=YLAB
      shortlabel=YSHORTLAB offsetmin=0.1 offsetmax=0.1);
    scatterplot y=YVAR x=XVAR / datalabel=IDLAB1 rolname=(_tip1=
      OBSNUMVAR _id2=IDLAB2 _id3=IDLAB3 _id4=IDLAB4 _id5=IDLAB5 _id6=
      IDLAB6 _id7=IDLAB7 _id8=IDLAB8 _id9=IDLAB9 _id10=IDLAB10 _id11=
      IDLAB11 _id12=IDLAB12 _id13=IDLAB13 _id14=IDLAB14 _id15=IDLAB15
      _id16=IDLAB16 _id17=IDLAB17 _id18=IDLAB18 _id19=IDLAB19 _id20=
      IDLAB20) tip=(y x datalabel _tip1 _id2 _id3 _id4 _id5 _id6 _id7
      _id8 _id9 _id10 _id11 _id12 _id13 _id14 _id15 _id16 _id17 _id18
      _id19 _id20)

      group=idlab2 name='s'; *<==== add the group variable ====<<<<;

    vectorplot y=YVEC x=XVEC xorigin=0 yorigin=0 / datalabel=LABEL2VAR
      shaftprotected=false rolname=(_tip1=VNAME _tip2=VLABEL _tip3=
      YORI _tip4=XORI _tip5=LENGTH _tip6=LENGTH2) tip=(y x datalabel
      _tip1 _tip2 _tip3 _tip4 _tip5 _tip6) datalabelattrs=
      GRAPHVALUETEXT (color=GraphData2:ContrastColor) lineattrs=
      GRAPHDATA2 (pattern=solid) primary=true;

    discretelegend 's'; *<==== add a legend ====<<<<;

    if (0)
      entry "Vector Stretch = " STRETCH / autoalign=(topright topleft
        bottomright bottomleft right left top bottom);
    endif;
    endlayout;
  endgraph;
end;
run;

```

The following step creates the MDPREF plot with the make of the automobile added as a second ID variable and displayed in the graph as a group variable:

```

proc prinqual data=CarPref out=Results n=2 replace mdpref;
  title2 'Multidimensional Preference (MDPREF) Analysis';
  title3 'Optimal Monotonic Transformation of Preference Data';
  id model make;
  transform monotone('1'n-'25'n);
run;

```

The results are displayed in [Output 74.1.5](#).

Output 74.1.5 Biplot with a Group Variable

The following step restores the default template:

```
proc template;
  delete Stat.Prinqual.Graphics.MDPref / store=sasuser.templat;
run;
```

Example 74.2: Principal Components of Basketball Rankings

The data in this example are 1985–1986 preseason rankings of 35 U.S. college basketball teams by 10 different news services. The services do not all rank the same teams or the same number of teams, so there are missing values in these data. Each of the 35 teams in the data set is ranked by at least one news service. One way of summarizing these data is with a principal component analysis, since the rankings should all be related to a single underlying variable, the first principal component.

You can use PROC PRINQUAL to estimate the missing ranks and compute scores for all observations. You can formulate a PROC PRINQUAL analysis that assumes that the observed ranks are ordinal variables and replaces the ranks with new numbers that are monotonic with the ranks and better fit the one prin-

pical component model. The missing rank estimates need to be constrained since a news service would have positioned the unranked teams below the teams it ranked. PROC PRINQUAL should impose order constraints within the nonmissing values and between the missing and nonmissing values, but not within the missing values. PROC PRINQUAL has sophisticated missing data handling facilities; however, these facilities cannot directly handle this problem. The solution requires reformulating the problem.

By performing some preliminary data manipulations, specifying the N=1 option in the PROC PRINQUAL statement, and specifying the UNTIE transformation in the TRANSFORM statement, you can make the missing value estimates conform to the requirements. The PROC MEANS step finds the largest rank for each variable. The next DATA step replaces missing values with a value that is one larger than the largest observed rank. The PROC PRINQUAL N=1 option specifies that the variables should be transformed to make them as one-dimensional as possible. The UNTIE transformation in the TRANSFORM statement monotonically transforms the ranks, untying any ties in an optimal way. Because the only ties are for the values that replace the missing values, and because these values are larger than the observed values, the rescaling of the data satisfies the preceding requirements.

The following statements create the data set and perform the transformations discussed previously. These statements produce [Output 74.2.1](#) and [Output 74.2.2](#).

```
* Preseason 1985 College Basketball Rankings
* (rankings of 35 teams by 10 news services)
*
* Note: (a) Various news services rank varying numbers of teams.
*       (b) Not all 35 teams are ranked by all news services.
*       (c) Each team is ranked by at least one service.
*       (d) Rank 20 is missing for UPI.;

Output 74.2.2 Transformations

An alternative approach is to use the pairwise deletion option of the CORR procedure to compute the correlation matrix and then use PROC PRINCOMP or PROC FACTOR to perform the principal component analysis. This approach has several disadvantages. The correlation matrix might not be positive semidefinite (PSD), an assumption required for principal component analysis. PROC PRINQUAL always produces a PSD correlation matrix. Even with pairwise deletion, PROC CORR removes the six observations that have only a single nonmissing value from this data set. Finally, it is still not possible to calculate scores on the principal components for those teams that have missing values.

You can compute the composite ranking by using PROC PRINCOMP and some preliminary data manipulations, similar to those discussed previously.

Chapter 73, “[The PRINCOMP Procedure](#),” contains an example where the average of the unused ranks in each poll is substituted for the missing values, and each observation is weighted by the number of nonmissing values. This method has much to recommend it. It is much faster and simpler than using PROC PRINQUAL. It is also much less prone to degeneracies and capitalization on chance. However, PROC PRINCOMP does not allow the nonmissing ranks to be monotonically transformed and the missing values untied to optimize fit.

PROC PRINQUAL monotonically transforms the observed ranks and estimates the missing ranks (within the constraints given previously) to account for almost 95 percent of the variance of the transformed data by just one dimension. PROC FACTOR is then used to report details of the principal component analysis of the transformed data. As shown by the Factor Pattern values in [Output 74.2.3](#), nine of the ten news services have a correlation of 0.95 or larger with the scores on the first principal component after the data are optimally transformed. The scores are sorted and the composite ranking is displayed following the PROC FACTOR output. More confidence can be placed in the stability of the scores for teams that are ranked by the majority of the news services than in scores for teams that are seldom ranked.

The monotonic transformations are plotted for each of the ten news services. See [Output 74.2.2](#). These plots show the values of the raw ranks (with the missing ranks replaced by the maximum rank plus one) versus the rescored (transformed) ranks. The transformations are the step functions that maximize the fit of the data to the principal component model. Smoother transformations could be found by using MSPLINE transformations, but MSPLINE transformations would not correctly handle the missing data problem.

34	St. Joseph's	3.39259
35	Houston	4.69614

The ordinary PROC PRINQUAL missing data handling facilities do not work for these data because they do not constrain the missing data estimates properly. If you code the missing ranks as missing and specify linear transformations, then you can compute least squares estimates of the missing values without transforming the observed values. The first principal component then accounts for 92 percent of the variance after 20 iterations. However, Virginia Tech is ranked number 11 by its score even though it appeared in only one poll (Inside Sports ranked it number 13, anchoring it firmly in the middle). Specifying monotone transformations is also inappropriate since they too allow unranked teams to move in between ranked teams.

With these data, the combination of monotone transformations and the freedom to score the missing ranks without constraint leads to degenerate transformations. PROC PRINQUAL tries to merge the 35 points

into two points, producing a perfect fit in one dimension. There is evidence for this after 20 iterations when the Average Change, Maximum Change, and Criterion Change values are all increasing, instead of the more stable decreasing change rate seen in the analysis shown. The change rates all stop increasing after 41 iterations, and it is clear by 70 or 80 iterations that one component will account for 100 percent of the transformed variables variance after sufficient iteration. While this might seem desirable (after all, it is a perfect fit), you should, in fact, be on guard when this happens. Whenever convergence is slow, the rates of change increase, or the final data perfectly fit the model, the solution is probably degenerating because of too few constraints on the scorings.

PROC PRINQUAL can account for 100 percent of the variance by scoring Montana and UCLA with one positive value on all variables and scoring all the other teams with one negative value on all variables. This inappropriate analysis suggests that all ranked teams are equally good except for two teams that are less good. Both of these two teams are ranked by only one news service, and their only nonmissing rank is last in the poll. This accounts for the degeneracy.

Overview: PROBIT Procedure

The PROBIT procedure calculates maximum likelihood estimates of regression parameters and the natural (or threshold) response rate for quantal response data from biological assays or other discrete event data. This includes probit, logit, ordinal logistic, and extreme value (or gompit) regression models.

Probit analysis developed from the need to analyze qualitative (dichotomous or polytomous) dependent variables within the regression framework. Many response variables are binary by nature (yes/no), while others are measured ordinally rather than continuously (degree of severity). Researchers have shown ordinary least squares (OLS) regression to be inadequate when the dependent variable is discrete (Collett 2003; Agresti 2002). Probit or logit analyses are more appropriate in this case.

The PROBIT procedure computes maximum likelihood estimates of the parameters β and C of the probit equation by using a modified Newton-Raphson algorithm. When the response Y is binary, with values 0 and 1, the probit equation is

$$p = \Pr(Y = 0) = C + (1 - C)F(\mathbf{x}'\beta)$$

where

- β is a vector of parameter estimates
- F is a cumulative distribution function (normal, logistic, or extreme value)
- \mathbf{x} is a vector of explanatory variables
- p is the probability of a response
- C is the natural (threshold) response rate

Notice that PROC PROBIT, by default, models the probability of the *lower* response levels. The choice of the distribution function F (normal for the probit model, logistic for the logit model, and extreme value or Gompertz for the gompit model) determines the type of analysis. For most problems, there is relatively little difference between the normal and logistic specifications of the model. Both distributions are symmetric about the value zero. The extreme value (or Gompertz) distribution, however, is not symmetric, approaching 0 on the left more slowly than it approaches 1 on the right. You can use the extreme value distribution where such asymmetry is appropriate.

For ordinal response models, the response, Y , of an individual or an experimental unit can be restricted to one of a (usually small) number, $k + 1$ ($k \geq 1$), of ordinal values, denoted for convenience by $1, \dots, k, k + 1$. For example, the severity of coronary disease can be classified into three response categories as 1=no disease, 2=angina pectoris, and 3=myocardial infraction. The PROBIT procedure fits a common slopes cumulative model, which is a parallel-lines regression model based on the cumulative probabilities of the response categories rather than on their individual probabilities. The cumulative model has the form

$$\Pr(Y \leq 1 \mid \mathbf{x}) = F(\mathbf{x}'\boldsymbol{\beta})$$

$$\Pr(Y \leq i \mid \mathbf{x}) = F(\alpha_i + \mathbf{x}'\boldsymbol{\beta}), \quad 2 \leq i \leq k$$

where $\alpha_2, \dots, \alpha_k$ are $k - 1$ intercept parameters. By default, the covariate vector \mathbf{x} contains an overall intercept term.

You can set or estimate the natural (threshold) response rate C . Estimation of C can begin either from an initial value that you specify or from the rate observed in a control group. By default, the natural response rate is fixed at zero.

An observation in the data set analyzed by the PROBIT procedure might contain the response and explanatory values for one subject. Alternatively, it might provide the number of observed events from a number of subjects at a particular setting of the explanatory variables. In this case, PROC PROBIT models the probability of an event.

The PROBIT procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the PROBIT procedure, see the section “[ODS Graphics](#)” on page 6415.

Getting Started: PROBIT Procedure

The following example illustrates how you can use the PROBIT procedure to compute the threshold response rate and regression parameter estimates for quantal response data.

Estimating the Natural Response Threshold Parameter

Suppose you want to test the effect of a drug at 12 dosage levels. You randomly divide 180 subjects into 12 groups of 15—one group for each dosage level. You then conduct the experiment and, for each subject, record the presence or absence of a positive response to the drug. You summarize the data by counting the number of subjects responding positively in each dose group. Your data set is as follows:

```
data study;
  input Dose Respond @@;
  Number = 15;
  datalines;
0      3    1.1    4    1.3    4    2.0    3    2.2    5    2.8    4
3.7    5    3.9    9    4.4    8    4.8   11    5.9   12    6.8   13
;
```

The variable `dose` represents the amount of drug administered. The first group, receiving a dose level of 0, is the control group. The variable `number` represents the number of subjects in each group. All groups are equal in size; hence, `number` has the value 15 for all observations. The variable `respond` represents the number of subjects responding to the associated drug dosage.

You can model the probability of positive response as a function of dosage by using the following statements:

```
ods graphics on;

proc probit data=study log10 optc plots=(predpplot ipplot);
  model respond/number=dose;
  output out=new p=p_hat;
run;
```

The `DATA=` option specifies that PROC PROBIT analyze the SAS data set `study`. The `LOG10` option replaces the first continuous independent variable (`dose`) with its common logarithm. The `OPTC` option estimates the natural response rate. When you use the `LOG10` option with the `OPTC` option, any observations with a dose value less than or equal to zero are used in the estimation as a control group.

The `PLOTS=` option in the PROC PROBIT statement, together with the ODS GRAPHICS statement, requests two plots for the estimated probability values and dosage levels. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the graphics available in the PROBIT procedure, see the section “ODS Graphics” on page 6415.

The MODEL statement specifies a proportional response by using the variables `respond` and `number` in *events/trials* syntax. The variable `dose` is the stimulus or explanatory variable.

The OUTPUT statement creates a new data set, `new`, that contains all the variables in the original data set, and a new variable, `p_hat`, that represents the predicted probabilities.

The results from this analysis are displayed in the following figures.

Figure 75.1 displays background information about the model fit. Included are the name of the input data set, the response variables used, and the number of observations, events, and trials. The last line in Figure 75.1 shows the final value of the log-likelihood function.

Figure 75.2 displays the table of parameter estimates for the model. The parameter C , which is the natural response threshold or the proportion of individuals responding at zero dose, is estimated to be 0.2409. Since both the intercept and the slope coefficient have significant p -values (0.0020, 0.0010), you can write the model for

$$\text{Pr}(\text{response}) = C + (1 - C)F(\mathbf{x}'\beta)$$

as

$$\text{Pr}(\text{response}) = 0.2409 + 0.7591(\Phi(-4.1439 + 6.2308 \times \log_{10}(\text{dose})))$$

where Φ is the normal cumulative distribution function.

Finally, PROC PROBIT specifies the resulting tolerance distribution by providing the mean MU and scale parameter SIGMA as well as the covariance matrix of the distribution parameters in Figure 75.3.

Figure 75.1 Model Fitting Information for the PROBIT Procedure

Figure 75.3 Tolerance Distribution Estimates for the PROBIT Procedure

Estimated Covariance Matrix for Tolerance Parameters			
	MU	SIGMA	_C_
MU	0.001158	-0.000493	0.000954
SIGMA	-0.000493	0.002394	-0.000999
C	0.000954	-0.000999	0.002731

The PLOT=PREDPLOT option creates the plot in [Figure 75.4](#), showing the relationship between dosage level, observed response proportions, and estimated probability values. The dashed lines represent pointwise confidence bands for the fitted probabilities, and a reference line is plotted at the estimated threshold value of 0.24.

The PLOT=IPPPLOT option creates the plot in [Figure 75.5](#), showing the inverse relationship between dosage level and observed response proportions/estimated probability values. The dashed lines represent pointwise fiducial limits for the predicted values of the dose variable, and a reference line is also plotted at the estimated threshold value of 0.24.

The two plot options can be put together with the PLOTS= option, as shown in the PROC PROBIT statement.

Figure 75.4 Plot of Observed and Fitted Probabilities versus Dose Level

Figure 75.5 Inverse Predicted Probability Plot with Fiducial Limits

Syntax: PROBIT Procedure

The following statements are available in the PROBIT procedure:

```

PROC PROBIT < options > ;
  BY variables ;
  CDFPLOT < VAR=variable > < options > ;
  CLASS variables ;
  ESTIMATE < 'label' > estimate-specification < (divisor=n) >
    < , ... < 'label' > estimate-specification < (divisor=n) > > < / options > ;
  EFFECTPLOT < plot-type < (plot-definition-options) > > < / options > ;
  INSET < keyword-list > < / options > ;
  IPPPLOT < VAR=variable > < options > ;
  LPREDPLOT < VAR=variable > < options > ;
  LSMEANS < model-effects > < / options > ;
  LSMESTIMATE model-effect < 'label' > values < (divisor=n) >
    < , ... < 'label' > values < (divisor=n) > > < / options > ;
  MODEL response = independents < / options > ;
  OUTPUT < OUT=SAS-data-set > < options > ;
  PREDPPLOT < VAR=variable > < options > ;
  SLICE model-effect < / options > ;
  STORE < OUT= > item-store-name < / LABEL='label' > ;
  TEST < model-effects > < / options > ;
  WEIGHT variable ;

```

A MODEL statement is required. Only a single MODEL statement can be used with one invocation of the PROBIT procedure. If multiple MODEL statements are present, only the last one is used. Main effects and higher-order terms can be specified in the MODEL statement, as in the GLM procedure. If a CLASS statement is used, it must precede the MODEL statement.

The CDFPLOT, INSET, IPPPLOT, LPREDPLOT, and PREDPPLOT statements are used to produce graphical output. You can use any appropriate combination of the graphical statements after the MODEL statement.

The ESTIMATE, EFFECTPLOT, LSMEANS, LSMESTIMATE, SLICE, STORE, and TEST statements are common to many procedures. Summary descriptions of functionality and syntax for these statements are also given after the PROC PROBIT statement in alphabetical order, and full documentation about them is available in Chapter 19, “Shared Concepts and Topics.”

PROC PROBIT Statement

```

PROC PROBIT < options > ;

```

The PROC PROBIT statement invokes the PROBIT procedure. Table 75.1 summarizes the options available in the PROC PROBIT statement.

Table 75.1 PROC PROBIT Statement Options

Option	Description
COVOUT	Writes the parameter estimate covariance matrix to the OUTEST= data set
C=	Controls how the natural response is handled
DATA=	Specifies the SAS data set to be used
GOUT=	Specifies a graphics catalog in which to save graphics output
HPROB=	Specifies a minimum probability level for the Pearson's chi-square
INEST=	Specifies an input SAS data set that contains initial estimates
INVERSECL	Computes confidence limits
LACKFIT	Performs two goodness-of-fit tests
LOG	Replaces the first continuous independent variable with its natural logarithm
LOG10	Replaces the first continuous independent variable with log to the base 10
NAMELEN=	Specifies the length of effect names to be <i>n</i> characters
NOPRINT	Suppresses the display of all output including graphics
OPTC	Controls how the natural response is handled
ORDER=	Specifies the sort order for the levels of the classification variables
OUTEST=	Specifies a SAS data set to contain the parameter estimates
PLOT PLOTS	Controls the plots produced through ODS Graphics
XDATA=	Specifies an input SAS data set that contains values for all the independent variables

You can specify the following *options* in the PROC PROBIT statement.

COVOUT

writes the parameter estimate covariance matrix to the OUTEST= data set.

C=*rate*

OPTC

controls how the natural response is handled. Specify the OPTC option to request that the natural response rate *C* be estimated. Specify the C=*rate* option to set the natural response rate or to provide the initial estimate of the natural response rate. The natural response rate value must be a number between 0 and 1.

- If you specify neither the OPTC nor the C= option, a natural response rate of zero is assumed.
- If you specify both the OPTC and the C= option, the C= option should be a reasonable initial estimate of the natural response rate. For example, you could use the ratio of the number of responses to the number of subjects in a control group.
- If you specify the C= option but not the OPTC option, the natural response rate is set to the specified value and not estimated.
- If you specify the OPTC option but not the C= option, PROC PROBIT's action depends on the response variable, as follows:
 - If you specify either the LN or LOG10 option and some subjects have the first independent variable (dose) values less than or equal to zero, these subjects are treated as a control group. The initial estimate of *C* is then the ratio of the number of responses to the number of subjects in this group.

- If you do not specify the LN or LOG10 option or if there is no control group, then one of the following occurs:
 - If all responses are greater than zero, the initial estimate of the natural response rate is the minimal response rate (the ratio of the number of responses to the number of subjects in a dose group) across all dose levels.
 - If one or more of the responses is zero (making the response rate zero in that dose group), the initial estimate of the natural rate is the reciprocal of twice the largest number of subjects in any dose group in the experiment.

DATA=SAS-data-set

specifies the SAS data set to be used by PROC PROBIT. By default, the procedure uses the most recently created SAS data set.

GOUT=graphics-catalog

specifies a graphics catalog in which to save graphics output.

HPROB=p

specifies a minimum probability level for the Pearson's chi-square to indicate a good fit. The default value is 0.10. The LACKFIT option must also be specified for this option to have any effect. For Pearson's goodness-of-fit chi-square values with probability greater than the HPROB= value, the fiducial limits, if requested with the INVERSECL option, are computed by using a critical value of 1.96. For chi-square values with probability less than the value of the HPROB= option, the critical value is a 0.95 two-sided quantile value taken from the t distribution with degrees of freedom equal to $(k - 1) \times m - q$, where k is the number of levels for the response variable, m is the number of different sets of independent variable values, and q is the number of parameters fit in the model. Note that the HPROB= option can also appear in the MODEL statement.

INEST=SAS-data-set

specifies an input SAS data set that contains initial estimates for all the parameters in the model. See the section "[INEST= SAS-data-set](#)" on page 6407 for a detailed description of the contents of the INEST= data set.

INVERSECL<(PROB=rates)>

computes confidence limits for the values of the first continuous independent variable (such as dose) that yield selected response rates. You can optionally specify a list of response rates as *rates*. The response rates must be between zero and one, and can be a list separated by blanks, commas, or in the form of a DO list.

For example,

```
PROB = .1 TO .9 by .1
PROB = .1 .2 .3 .4
PROB = .01, .25, .75, .9
```

are valid lists of response rates.

If the algorithm fails to converge (this can happen when C is nonzero), missing values are reported for the confidence limits. See the section "[Inverse Confidence Limits](#)" on page 6410 for details. Note that the INVERSECL option can also appear in the MODEL statement.

LACKFIT

performs two goodness-of-fit tests (a Pearson's chi-square test and a log-likelihood ratio chi-square test) for the fitted model.

To compute the test statistics, proper grouping of the observations into subpopulations is needed. You can use the AGGREGATE or AGGREGATE= option for this end. See the entry for the AGGREGATE and AGGREGATE= options under the MODEL statement. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the *events/trials* syntax.

NOTE: This test is not appropriate if the data are very sparse, with only a few values at each set of the independent variable values.

If the Pearson's chi-square test statistic is significant, then the covariance estimates and standard error estimates are adjusted. See the section "[Lack-of-Fit Tests](#)" on page 6408 for a description of the tests. Note that the LACKFIT option can also appear in the MODEL statement.

LOG**LN**

analyzes the data by replacing the first continuous independent variable with its natural logarithm. This variable is usually the level of some treatment such as dosage. In addition to the usual output given by the INVERSECL option, the estimated dose values and 95% fiducial limits for dose are also displayed. If you specify the OPTC option, any observations with a dose value less than or equal to zero are used in the estimation as a control group. If you do not specify the OPTC option with the LOG or LN option, then any observations with the first continuous independent variable values less than or equal to zero are ignored.

LOG10

specifies an analysis like that of the LN or LOG option, except that the common logarithm (log to the base 10) of the dose value is used rather than the natural logarithm.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

NOPRINT

suppresses the display of all output including graphics. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, "[Using the Output Delivery System](#)."

OPTC

controls how the natural response is handled. See the description of the [C= option](#) on page 6353 for details.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the classification variables (which are specified in the [CLASS](#) statement). This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent.

This order also applies to the levels of the response variable. Response level ordering is important because PROC PROBIT always models the probability of response levels at the beginning of the ordering. See the section “[Response Level Ordering](#)” on page 6404 for further details.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

OUTEST=SAS-data-set

specifies a SAS data set to contain the parameter estimates and, if the COVOUT option is specified, their estimated covariances. If you omit this option, the output data set is not created. The contents of the data set are described in the section “[OUTEST= SAS-data-set](#)” on page 6411.

PLOT | PLOTS <=plot-request >

PLOT | PLOTS <=(plot-request < ...plot-request >)>

specifies options that control details of the plots created by ODS Graphics. These plots are related to a dose variable, which is identified as the first single continuous independent variable in the MODEL statement. If there are interaction terms with this variable in the model, the PROBIT procedure will not produce any plot.

You can specify more than one plot request within the parentheses after PLOTS=. For a single plot request, you can omit the parentheses.

ODS Graphics must be enabled before plots can be requested. For example:

```
proc probit plots=predplot;
  model r/n = dose;
run;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The following plot requests are available.

ALL

creates all appropriate plots.

CDFPLOT<(LEVEL=(character-list))>

requests the plot of predicted cumulative distribution function (CDF) of the multinomial response variable as a function of a single continuous independent variable (dose variable). This single continuous independent variable must be the first single continuous independent variable listed in the MODEL statement. You can request this plot only with a multinomial model.

The LEVEL= suboption specifies the levels of the multinomial response variable for which the CDF curves are requested. There are $k - 1$ curves for a k -level multinomial response variable (for the highest level, it is the constant line 1). You can specify any of them to be plotted by the LEVEL= suboption.

IPPPLOT

requests the inverse plot of the predicted probability against the first single continuous variable (dose variable) in the MODEL statement for the binomial model. You can request this plot only with a binomial model. The confidence limits for the predicted values of the dose variable are the computed fiducial limits, not the inverse of the confidence limits of the predicted probabilities. See the section “[Inverse Confidence Limits](#)” on page 6410 for more details.

LPREDPLOT<(LEVEL=(character-list))>

requests the plot of the linear predictor $\mathbf{x}'\mathbf{b}$ against the first single continuous variable (dose variable) in the MODEL statement for either the binomial model or the multinomial model. The confidence limits for the predicted values are available only for the binomial model.

For the multinomial model, you can use the LEVEL= suboption to specify the levels for which the linear predictor lines are plotted.

NONE

suppresses all plots.

PREDPPLOT<(LEVEL=(character-list))>

requests the plot of the predicted probability against the first single continuous variable (dose variable) in the MODEL statement for both the binomial model and the multinomial model. Confidence limits are available only for the binomial model.

For the multinomial model, you can use the LEVEL= suboption to specify the levels for which the linear predictor lines are plotted.

XDATA=SAS-data-set

specifies an input SAS data set that contains values for all the independent variables in the MODEL statement and variables in the CLASS statement. If there are covariates specified in a MODEL statement, you specify fixed values for the effects in the MODEL statement by the XDATA= data set when predicted values and/or fiducial limits for a single continuous variable (dose variable) are required. These specified values for the effects in the MODEL statement are also used for generating plots. See the section “[XDATA= SAS-data-set](#)” on page 6411 for a detailed description of the contents of the XDATA= data set.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC PROBIT to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the PROBIT procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CDFPLOT Statement

CDFPLOT < **VAR=***variable* > < *options* > ;

The CDFPLOT statement plots the predicted cumulative distribution function (CDF) of the multinomial response variable as a function of a single continuous independent variable (dose variable). You can use this statement only after a multinomial model statement.

VAR=*variable*

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= *variable* is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

The predicted cumulative distribution function is defined as

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}})$$

where $j = 1, \dots, k$ are the indexes of the k levels of the multinomial response variable, F is the CDF of the distribution used to model the cumulative probabilities, $\hat{\mathbf{b}}$ is the vector of estimated parameters, \mathbf{x} is the covariate vector, \hat{a}_j are estimated ordinal intercepts with $\hat{a}_1 = 0$, and C is the threshold parameter, either known or estimated from the model. Let x_1 be the covariate corresponding to the dose variable and \mathbf{x}_{-1} be the vector of the rest of the covariates. Let the corresponding estimated parameters be \hat{b}_1 and $\hat{\mathbf{b}}_{-1}$. Then

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + x_1\hat{b}_1 + \mathbf{x}'_{-1}\hat{\mathbf{b}}_{-1})$$

To plot \hat{F}_j as a function of x_1 , \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

specify the levels of the multinomial response variable for which the CDF curves are requested, and add features to the plot. There are $k - 1$ curves for a k -level multinomial response variable (for the highest level, it is the constant line 1). You can specify any of them to be plotted by the LEVEL= option in the CDFPLOT statement. See the LEVEL= option for how to specify the levels.

An attached box on the right side of the plot is used to label these curves with the names of their levels. You can specify the color of this box by using the CLABBOX= option.

You can use options in the CDFPLOT statement to do the following:

- superimpose specification limits
- specify the levels for which the CDF curves are requested
- specify graphical enhancements (such as color or text height)

Summary of Options

Table 75.2 through Table 75.8 summarize the *options* available in the CDFPLOT statement. The “[Dictionary of Options](#)” on page 6362 describes each option in detail.

CDF Options

Table 75.2 Options for CDFPLOT

LEVEL=(<i>character-list</i>)	Specifies the names of the levels for which the CDF curves are requested
NOTHRESH	Suppresses the threshold line
THRESHLABPOS= <i>value</i>	Specifies the position for the label of the threshold line

General Options**Table 75.3** Color Options

<i>CAXIS=color</i>	Specifies color for axis
<i>CFIT=color</i>	Specifies color for fitted curves
<i>CFRAME=color</i>	Specifies color for frame
<i>CGRID=color</i>	Specifies color for grid lines
<i>CHREF=color</i>	Specifies color for HREF= lines
<i>CLABBOX=color</i>	Specifies color for label box
<i>CTEXT=color</i>	Specifies color for text
<i>CVREF=color</i>	Specifies color for VREF= lines

Table 75.4 Options to Enhance Plots Produced on Graphics Devices

<i>ANNOTATE=</i> <i>SAS-data-set</i>	Specifies an Annotate data set
<i>INBORDER</i>	Requests a border around plot
<i>LFIT=linetype</i>	Specifies line style for fitted curves
<i>LGRID=linetype</i>	Specifies line style for grid lines
<i>NOFRAME</i>	Suppresses the frame around plotting areas
<i>NOGRID</i>	Suppresses grid lines
<i>NOFIT</i>	Suppresses CDF curves
<i>NOHLABEL</i>	Suppresses horizontal labels
<i>NOHTICK</i>	Suppresses horizontal ticks
<i>NOVTICK</i>	Suppresses vertical ticks
<i>TURNVLABELS</i>	Vertically strings out characters in vertical labels
<i>WFIT=n</i>	Specifies thickness for fitted curves
<i>WGRID=n</i>	Specifies thickness for grids
<i>WREFL=n</i>	Specifies thickness for reference lines

Table 75.5 Axis Options

HAXIS= <i>value1 to value2</i> < by <i>value3</i> >	Specifies tick mark values for horizontal axis
HOFFSET= <i>value</i>	Specifies offset for horizontal axis
HLOWER= <i>value</i>	Specifies lower limit on horizontal axis scale
HUPPER= <i>value</i>	Specifies upper limit on horizontal axis scale
NHTICK= <i>n</i>	Specifies number of ticks for horizontal axis
NVTICK= <i>n</i>	Specifies number of ticks for vertical axis
VAXIS= <i>value1 to value2</i> < by <i>value3</i> >	Specifies tick mark values for vertical axis
VAXISLABEL=' <i>label</i> '	Specifies label for vertical axis
VOFFSET= <i>value</i>	Specifies offset for vertical axis
VLOWER= <i>value</i>	Specifies lower limit on vertical axis scale
VUPPER= <i>value</i>	Specifies upper limit on vertical axis scale
WAXIS= <i>n</i>	Specifies thickness for axis

Table 75.6 Graphics Catalog Options

DESCRIPTION=' <i>string</i> '	Specifies description for graphics catalog member
NAME=' <i>string</i> '	Specifies name for plot in graphics catalog

Table 75.7 Options for Text Enhancement

FONT= <i>font</i>	Specifies software font for text
HEIGHT= <i>value</i>	Specifies height of text outside framed areas
INHEIGHT= <i>value</i>	Specifies height of text inside framed areas

Table 75.8 Options for Reference Lines

HREF < (INTERSECT) > =value-list	Requests horizontal reference line
HREFLABELS = (‘label1’,...,‘labeln’)	Specifies labels for HREF= lines
HREFLABPOS = <i>n</i>	Specifies vertical position of labels for HREF= lines
LHREF = <i>linetype</i>	Specifies line style for HREF= lines
LVREF = <i>linetype</i>	Specifies line style for VREF= lines
VREF < (INTERSECT) > =value-list	Requests vertical reference line
VREFLABELS = (‘label1’,...,‘labeln’)	Specifies labels for VREF= lines
VREFLABPOS = <i>n</i>	Specifies horizontal position of labels for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the CDFPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an Annotate data set, as described in *SAS/GRAPH: Reference*, that enables you to add features to the CDF plot. The ANNOTATE= data set you specify in the CDFPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted CDF curves. The default is the first color in the device color list.

CFRAME=*color*

CFR=*color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CLABBOX=*color*

specifies the color for the area enclosed by the label box for CDF curves. This area is not shaded by default.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*

CV=*color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION=*"string"*

DES=*"string"*

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the horizontal axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists follow:

```
haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10
```

HEIGHT=*value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies offset for horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=*'label1', ..., 'labeln'***HREFLABEL=***'label1', ..., 'labeln'***HREFLAB=***'label1', ..., 'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Top
2	Staggered from top
3	Bottom
4	Staggered from bottom
5	Alternating from top
6	Alternating from bottom

INBORDER

requests a border around CDF plots.

INHEIGHT=*value*

Specifies height of text inside framed areas.

LEVEL=*(character-list)***ORDINAL=***(character-list)*

specifies the names of the levels for which CDF curves are requested. Names should be quoted and separated by space. If there is no correct name provided, no CDF curve is plotted.

LFIT=*linetype*

specifies a line style for fitted curves. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1).

LGRID=*linetype*

specifies a line style for all grid lines. *linetype* is between 1 and 46. The default is 35.

LHREF=*linetype*

LH=*linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype*

LV=*linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME='string'

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NHTICK=*n*

Specifies number of ticks for horizontal axis.

NVTICK=*n*

Specifies number of ticks for vertical axis.

NOFIT

suppresses the fitted CDF curves.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

TURNVLABELS

vertically strings out characters in vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESHLABPOS=*n*

specifies the horizontal position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Left
2	Right

VAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the vertical axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists follow:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL=*'string'*

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VOFFSET=*value*

specifies the offset for the vertical axis.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=*'label1', ..., 'labeln'***VREFLABEL=***'label1', ..., 'labeln'***VREFLAB=***'label1', ..., 'labeln'*

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Left
2	Right

VUPPER=*value*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *value* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*

specifies line thickness for fitted curves. The default value is 1.

WGRID=*n*

specifies line thickness for grids. The default value is 1.

WREFL=*n*

specifies line thickness for reference lines. The default value is 1.

CLASS Statement

CLASS *variables* < / **TRUNCATE** > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the **MODEL** statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the **ORDER=** option in the **PROC PROBIT** statement. You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

EFFECTPLOT Statement

EFFECTPLOT < *plot-type* < (*plot-definition-options*) > > < / *options* > ;

The EFFECTPLOT statement produces a display of the fitted model and provides options for changing and enhancing the displays. [Table 75.9](#) describes the available *plot-types* and their *plot-definition-options*.

Table 75.9 Plot-Types and Plot-Definition-Options

Plot-Type and Description	Plot-Definition-Options
BOX Displays a box plot of continuous response data at each level of a CLASS effect, with predicted values superimposed and connected by a line. This is an alternative to the INTERACTION plot-type.	PLOTBY= variable or CLASS effect X= CLASS variable or effect
CONTOUR Displays a contour plot of predicted values against two continuous covariates.	PLOTBY= variable or CLASS effect X= continuous variable Y= continuous variable
FIT Displays a curve of predicted values versus a continuous variable.	PLOTBY= variable or CLASS effect X= continuous variable
INTERACTION Displays a plot of predicted values (possibly with error bars) versus the levels of a CLASS effect. The predicted values are connected with lines and can be grouped by the levels of another CLASS effect.	PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= CLASS variable or effect
SLICEFIT Displays a curve of predicted values versus a continuous variable grouped by the levels of a CLASS effect.	PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= continuous variable

For full details about the syntax and options of the EFFECTPLOT statement, see the section “**EFFECTPLOT Statement**” on page 411 in Chapter 19, “**Shared Concepts and Topics**.”

ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
      < , ... <'label'> estimate-specification <(divisor=n)> >
      </ options> ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form $\mathbf{L}\boldsymbol{\beta}$. You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 75.10 summarizes the options available in the ESTIMATE statement.

Table 75.10 ESTIMATE Statement Options

Option	Description
Construction and Computation of Estimable Functions	
DIVISOR=	Specifies a list of values to divide the coefficients
NOFILL	Suppresses the automatic fill-in of coefficients for higher-order effects
SINGULAR=	Tunes the estimability checking difference
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple comparison adjustment of estimates
ALPHA= α	Determines the confidence level ($1 - \alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiplicity-corrected p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits
CORR	Displays the correlation matrix of estimates
COV	Displays the covariance matrix of estimates
E	Prints the L matrix
JOINT	Produces a joint F or chi-square test for the estimable functions
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the ESTIMATE statement, see the section “[ESTIMATE Statement](#)” on page 437 in Chapter 19, “[Shared Concepts and Topics](#).”

INSET Statement

INSET < keyword-list > < / options > ;

The box or table of summary information produced on plots made with the [CDFPLOT](#), [IPPPLOT](#), [LPREDPLOT](#), or [PREDPPLOT](#) statement is called an *inset*. You can use the INSET statement to customize both the information that is printed in the inset box and the appearance of the inset box. To supply the information that is displayed in the inset box, you specify *keywords* corresponding to the information you want shown. For example, the following statements produce a predicted probability plot with the number of trials, the number of events, the name of the distribution, and the estimated optimum natural threshold in the inset.

```
proc probit data=epidemic;
  model r/n = dose;
  predpplot;
  inset nobs ntrials nevents dist optc;
run;
```

By default, inset entries are identified with appropriate labels. However, you can provide a customized label by specifying the *keyword* for that entry followed by the equal sign (=) and the label in quotes. For example, the following INSET statement produces an inset containing the number of observations and the name of the distribution, labeled “Sample Size” and “Distribution” in the inset.

```
inset nobs='Sample Size' dist='Distribution';
```

If you specify a keyword that does not apply to the plot you are creating, then the keyword is ignored.

The *options* control the appearance of the box.

If you specify more than one INSET statement, only the first one is used.

Keywords Used in the INSET Statement

Table 75.11 and Table 75.12 list keywords available in the INSET statement to display summary statistics, distribution parameters, and distribution fitting information.

Table 75.11 Summary Statistics

NOBS	Number of observations
NTRIALS	Number of trials
NEVENTS	Number of events
C	User-input threshold
OPTC	Estimated natural threshold
NRESPLEV	Number of levels of the response variable

Table 75.12 General Information

CONFIDENCE	Confidence coefficient for all confidence intervals
DIST	Name of the distribution

Options Used in the INSET Statement

Table 75.13 and Table 75.14 list the options available in the INSET statement.

Table 75.13 Color and Pattern Options

CFILL= <i>color</i>	Specifies color for filling box
CFILLH= <i>color</i>	Specifies color for filling box header
CFRAME= <i>color</i>	Specifies color for frame
CHEADER= <i>color</i>	Specifies color for text in header
CTEXT= <i>color</i>	Specifies color for text

Table 75.14 General Appearance Options

FONT= <i>font</i>	Specifies software font for text
HEIGHT= <i>value</i>	Specifies height of text
HEADER= <i>'quoted string'</i>	Specifies text for header or box title
NOFRAME	Omits frame around box
POS= <i>value</i> <DATA PERCENT>	Determines the position of the inset. The <i>value</i> can be a compass point (N, NE, E, SE, S, SW, W, NW) or a pair of coordinates (x, y) enclosed in parentheses. The coordinates can be specified in axis percentage units or axis data units.
REFPOINT= <i>name</i>	Specifies the reference point for an inset that is positioned by a pair of coordinates with the POS= option. You use the REFPOINT= option in conjunction with the POS= coordinates. The REFPOINT= option specifies which corner of the inset frame you have specified with coordinates (x, y), and it can take the value of BR (bottom right), BL (bottom left), TR (top right), or TL (top left). The default is REFPOINT=BL. If the inset position is specified as a compass point, then the REFPOINT= option is ignored.

IPPLOT Statement

IPPLOT < *variable* > < *options* > ;

The IPPLOT statement plots the inverse of the predicted probability (IPP) against a single continuous variable (dose variable) in the MODEL statement for the binomial model. You can only use this statement after a binomial model statement. The confidence limits for the predicted values of the dose variable are the computed fiducial limits, not the inverse of the confidence limits of the predicted probabilities. See the section “[Inverse Confidence Limits](#)” on page 6410 for more details.

VAR= *variable*

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

For the binomial model, the response variable is a probability. An estimate of the dose level \hat{x}_1 needed for a response of p is given by

$$\hat{x}_1 = (F^{-1}(p) - \mathbf{x}_{-1}'\hat{\mathbf{b}}_{-1})/\hat{b}_1$$

where F is the cumulative distribution function used to model the probability, \mathbf{x}_{-1} is the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ is the vector of the estimated parameters corresponding to \mathbf{x}_{-1} , and \hat{b}_1 is the estimated parameter for the dose variable of interest.

To plot \hat{x}_1 as a function of p , x_{-1} must be specified. You can use the XDATA= option to provide the values of x_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

add features to the plot.

You can use options in the IPPPLOT statement to do the following:

- superimpose specification limits
- suppress or add the observed data points on the plot
- suppress or add the fiducial limits on the plot
- specify graphical enhancements (such as color or text height)

Summary of Options

Table 75.15 through Table 75.21 summarize the *options* available in the IPPPLOT statement. The “Dictionary of Options” on page 6374 describes each option in detail.

IPP Options

Table 75.15 Plot Layout Options for IPPPLOT

NOCONF	Suppresses fiducial limits
NODATA	Suppresses observed data points on the plot
NOTHRESH	Suppresses the threshold line
THRESHLABPOS= <i>value</i>	Specifies the position for the label of the threshold line

General Options

Table 75.16 Color Options

CAXIS= <i>color</i>	Specifies color for axis
CFIT= <i>color</i>	Specifies color for fitted curves
CFRAME= <i>color</i>	Specifies color for frame
CGRID= <i>color</i>	Specifies color for grid lines
CHREF= <i>color</i>	Specifies color for HREF= lines
CTEXT= <i>color</i>	Specifies color for text
CVREF= <i>color</i>	Specifies color for VREF= lines

Table 75.17 Options to Enhance Plots Produced on Graphics Devices

ANNOTATE= <i>SAS-data-set</i>	Specifies an Annotate data set
INBORDER	Requests a border around plot
LFIT= <i>linetype</i>	Specifies line style for fitted curves and confidence limits
LGRID= <i>linetype</i>	Specifies line style for grid lines
NOFRAME	Suppresses the frame around plotting areas
NOGRID	Suppresses grid lines
NOFIT	Suppresses fitted curves
NOHLABEL	Suppresses horizontal labels
NOHTICK	Suppresses horizontal ticks
NOVTICK	Suppresses vertical ticks
TURNVLABELS	Vertically strings out characters in vertical labels
WFIT= <i>n</i>	Specifies thickness for fitted curves
WGRID= <i>n</i>	Specifies thickness for grids
WREFL= <i>n</i>	Specifies thickness for reference lines

Table 75.18 Axis Options

HAXIS= <i>value1 to value2</i> < by <i>value3</i> >	Specifies tick mark values for horizontal axis
HOFFSET= <i>value</i>	Specifies offset for horizontal axis
HLOWER= <i>value</i>	Specifies lower limit on horizontal axis scale
HUPPER= <i>value</i>	Specifies upper limit on horizontal axis scale
NHTICK= <i>n</i>	Specifies number of ticks for horizontal axis
NVTICK= <i>n</i>	Specifies number of ticks for vertical axis
VAXIS= <i>value1 to value2</i> < by <i>value3</i> >	Specifies tick mark values for vertical axis
VAXISLABEL= <i>'label'</i>	Specifies label for vertical axis
VOFFSET= <i>value</i>	Specifies offset for vertical axis
VLOWER= <i>value</i>	Specifies lower limit on vertical axis scale
VUPPER= <i>value</i>	Specifies upper limit on vertical axis scale
WAXIS= <i>n</i>	Specifies thickness for axis

Table 75.19 Options for Reference Lines

HREF <(INTERSECT)> <i>=value-list</i>	Requests horizontal reference line
HREFLABELS = (<i>'label1'</i> , ..., <i>'labeln'</i>)	Specifies labels for HREF= lines
HREFLABPOS = <i>n</i>	Specifies vertical position of labels for HREF= lines
LHREF = <i>linetype</i>	Specifies line style for HREF= lines
LVREF = <i>linetype</i>	Specifies line style for VREF= lines
VREF <(INTERSECT)> <i>=value-list</i>	Requests vertical reference line
VREFLABELS = (<i>'label1'</i> , ..., <i>'labeln'</i>)	Specifies labels for VREF= lines
VREFLABPOS = <i>n</i>	Specifies horizontal position of labels for VREF= lines

Table 75.20 Graphics Catalog Options

DESCRIPTION = <i>'string'</i>	Specifies description for graphics catalog member
NAME = <i>'string'</i>	Specifies name for plot in graphics catalog

Table 75.21 Options for Text Enhancement

FONT = <i>font</i>	Specifies software font for text
HEIGHT = <i>value</i>	Specifies height of text used outside framed areas
INHEIGHT = <i>value</i>	Specifies height of text inside framed areas

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the IPPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an Annotate data set, as described in *SAS/GRAPH: Reference*, that enables you to add features to the IPP plot. The ANNOTATE= data set you specify in the IPPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted IPP curves. The default is the first color in the device color list.

CFRAME=*color***CFR=***color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=*color***CH=***color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color***CV=***color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION='*string*'**DES=**'*string*'

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the horizontal axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists follow:

```
haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10
```

HEIGHT=*value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies offset for horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=*'label1', ..., 'labeln'***HREFLABEL=***'label1', ..., 'labeln'***HREFLAB=***'label1', ..., 'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Top
2	Staggered from top
3	Bottom
4	Staggered from bottom
5	Alternating from top
6	Alternating from bottom

INBORDER

requests a border around IPP plots.

INHEIGHT=*value*

Specifies height of text inside framed areas.

LFIT=*linetype*

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1) and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

LGRID=*linetype*

specifies a line style for all grid lines. The value for *linetype* must be between 1 and 46. The default is 35.

LHREF=*linetype***LH=***linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype***LV=***linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME='string'

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NHTICK=*n*

Specifies number of ticks for horizontal axis.

NVTICK=*n*

Specifies number of ticks for vertical axis.

NOCONF

suppresses fiducial limits from the plot.

NODATA

suppresses observed data points from the plot.

NOFIT

suppresses the fitted IPP curves.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

TURNVLABELS

vertically strings out characters in vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESHLABPOS=*n*

specifies the vertical position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Top
2	Bottom

VAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the vertical axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists follow:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL=*'string'*

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VOFFSET=*value*

specifies the offset for the vertical axis.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=*'label1',...,'labeln'***VREFLABEL=*'label1',...,'labeln'*****VREFLAB=*'label1',...,'labeln'***

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Left
2	Right

VUPPER=*value*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *value* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*

specifies line thickness for fitted curves. The default value is 1.

WGRID=*n*

specifies line thickness for grids. The default value is 1.

WREFL=*n*

specifies line thickness for reference lines. The default value is 1.

LPREDPLOT Statement

LPREDPLOT < VAR=*variable* > < options > ;

The LPREDPLOT statement plots the linear predictor (LPRED) $\mathbf{x}'\mathbf{b}$ against a single continuous variable (dose variable) in the MODEL statement for either the binomial model or the multinomial model. The confidence limits for the predicted values are available only for the binomial model.

VAR= *variable*

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement for which the linear predictor plot is plotted. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

Let x_1 be the covariate of the dose variable, \mathbf{x}_{-1} be the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ be the vector of estimated parameters corresponding to \mathbf{x}_{-1} , and \hat{b}_1 be the estimated parameter for the dose variable of interest.

To plot $\hat{\mathbf{x}}'\mathbf{b}$ as a function of x_1 , \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

add features to the plot.

For the multinomial model, you can use the LEVEL= option to specify the levels for which the linear predictor lines are plotted. The lines are labeled by the names of their levels in the middle.

You can use options in the LPREDPLOT statement to do the following:

- superimpose specification limits
- suppress or add the observed data points on the plot for the binomial model
- suppress or add the confidence limits for the binomial model
- specify the levels for which the linear predictor lines are requested for the multinomial model
- specify graphical enhancements (such as color or text height)

Summary of Options

Table 75.22 through Table 75.28 list all *options* by function. The “Dictionary of Options” on page 6382 describes each option in detail.

LPRED Options

Table 75.22 Plot Layout Options for LPREDPLOT

LEVEL=(<i>character-list</i>)	Specifies the names of the levels for which the linear predictor lines are requested (only for the multinomial model)
NOCONF	Suppresses fiducial limits (only for the binomial model)
NODATA	Suppresses observed data points on the plot (only for the binomial model)
NOTHRESH	Suppresses the threshold line
THRESHLABPOS= <i>value</i>	Specifies the position for the label of the threshold line

General Options

Table 75.23 Color Options

CAXIS= <i>color</i>	Specifies color for axis
CFIT= <i>color</i>	Specifies color for fitted curves
CFRAME= <i>color</i>	Specifies color for frame
CGRID= <i>color</i>	Specifies color for grid lines
CHREF= <i>color</i>	Specifies color for HREF= lines
CTEXT= <i>color</i>	Specifies color for text
CVREF= <i>color</i>	Specifies color for VREF= lines

Table 75.24 Options to Enhance Plots Produced on Graphics Devices

ANNOTATE= <i>SAS-data-set</i>	Specifies an Annotate data set
INBORDER	Requests a border around plot

INHEIGHT=value	Specifies height of text inside framed areas

Table 75.28 Options for Reference Lines

HREF<(INTERSECT)> =value-list	Requests horizontal reference line
HREFLABELS= (‘label1’,...,‘labeln’)	Specifies labels for HREF= lines
HREFLABPOS=n	Specifies vertical position of labels for HREF= lines
LHREF=linetype	Specifies line style for HREF= lines
LVREF=linetype	Specifies line style for VREF= lines
VREF<(INTERSECT)> =value-list	Requests vertical reference line
VREFLABELS= (‘label1’,...,‘labeln’)	Specifies labels for VREF= lines
VREFLABPOS=n	Specifies horizontal position of labels for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the LPREDPLOT statement.

ANNOTATE=SAS-data-set

ANNO=SAS-data-set

specifies an Annotate data set, as described in *SAS/GRAPH: Reference*, that enables you to add features to the LPRED plot. The ANNOTATE= data set you specify in the LPREDPLOT statement is used for all plots created by the statement.

CAXIS=color

CAXES=color

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=color

specifies the color for the fitted LPRED lines. The default is the first color in the device color list.

CFRAME=color

CFR=color

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=*color***CH=***color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color***CV=***color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION='*string*'**DES=**'*string*'

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the horizontal axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists follow:

```
haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10
```

HEIGHT=*value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies offset for horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=*'label1', ..., 'labeln'***HREFLABEL=***'label1', ..., 'labeln'***HREFLAB=***'label1', ..., 'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Top
2	Staggered from top
3	Bottom
4	Staggered from bottom
5	Alternating from top
6	Alternating from bottom

INBORDER

requests a border around LPRED plots.

INHEIGHT=*value*

Specifies height of text inside framed areas.

LEVEL=*(character-list)***ORDINAL=***(character-list)*

specifies the names of the levels for which linear predictor lines are requested. Names should be quoted and separated by space. If there is no correct name provided, no LPRED line is plotted.

LFIT=*linetype*

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1) and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

LGRID=*linetype*

specifies a line style for all grid lines. The value for *linetype* is between 1 and 46. The default is 35.

LHREF=*linetype***LH=***linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype***LV=***linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME='string'

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NHTICK=*n*

Specifies number of ticks for horizontal axis.

NVTICK=*n*

Specifies number of ticks for vertical axis.

NOCONF

suppresses confidence limits from the plot. This works only for the binomial model. Confidence limits are not plotted for the multinomial model.

NODATA

suppresses observed data points from the plot. This works only for the binomial model. Data points are not plotted for the multinomial model.

NOFIT

suppresses the fitted LPRED lines.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

TURNVLABELS

vertically strings out characters in vertical labels.

THRESLABPOS=*n*

specifies the horizontal position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Left
2	Right

VAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the vertical axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists follow:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL=*'string'*

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VOFFSET=*value*

specifies the offset for the vertical axis.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=*'label1',...,'labeln'*

VREFLABEL=*'label1',...,'labeln'*

VREFLAB=*'label1',...,'labeln'*

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Left
2	Right

VUPPER=*number*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *number* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*

specifies line thickness for fitted lines. The default value is 1.

WGRID=*n*

specifies line thickness for grids. The default value is 1.

WREFL=*n*

specifies line thickness for reference lines. The default value is 1.

LSMEANS Statement

LSMEANS < *model-effects* > < / *options* > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 75.29 summarizes the options available in the LSMEANS statement.

Table 75.29 LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies the covariate value in computing LS-means
BYLEVEL	Computes separate margins
DIFF	Requests differences of LS-means
OM=	Specifies the weighting scheme for LS-means computation as determined by the input data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level $(1 - \alpha)$
STEPDOWN	Adjusts multiple-comparison p -values further in a step-down fashion
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
LINES	Produces a “Lines” display for pairwise LS-means differences
MEANS	Prints the LS-means
PLOTS=	Requests graphs of means and mean comparisons
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMEANS statement, see the section “[LSMEANS Statement](#)” on page 453 in Chapter 19, “[Shared Concepts and Topics](#).”

LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
              < , ... <'label'> values <divisor=n> >
              </options> ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 75.30 summarizes the options available in the LSMESTIMATE statement.

Table 75.30 LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
BYLEVEL	Computes separate margins
DIVISOR=	Specifies a list of values to divide the coefficients
OM=	Specifies the weighting scheme for LS-means computation as determined by a data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level ($1 - \alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiple-comparison p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
ELSM	Prints the K matrix
JOINT	Produces a joint F or chi-square test for the LS-means and LS-means differences
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMESTIMATE statement, see the section “[LSMESTIMATE Statement](#)” on page 470 in Chapter 19, “[Shared Concepts and Topics](#).”

MODEL Statement

< label > **MODEL** *response* = *effects* *< / options >* ;

< label > **MODEL** *events/trials* = *effects* *< / options >* ;

The MODEL statement names the variables used as the response and the independent variables. Additionally, you can specify the distribution used to model the response, as well as other options. Only a single MODEL statement can be used with one invocation of the PROBIT procedure. If multiple MODEL statements are present, only the last is used. Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure.

The optional *label*, which must be a valid SAS name, is used to label output from the matching MODEL statement.

The *response* can be a single variable with a value that is used to indicate the level of the observed response. For example, the response might be a variable called *Symptoms* that takes on the values ‘None,’ ‘Mild,’ or ‘Severe.’ Note that, for dichotomous response variables, the probability of the lower sorted value is modeled by default (see the section “[Details: PROBIT Procedure](#)” on page 6404). Because the model fit by the PROBIT procedure requires ordered response levels, you might need to use either the ORDER=DATA option in the PROC PROBIT statement or a numeric coding of the response to get the desired ordering of levels.

Alternatively, the response can be specified as a pair of variable names separated by a slash (/). The value of the first variable, *events*, is the number of positive responses (or events). The value of the second variable, *trials*, is the number of trials. Both variables must be numeric and nonnegative, and the ratio of the first variable value to the second variable value must be between 0 and 1, inclusive. For example, the variables might be *hits*, a variable containing the number of hits for a baseball player, and *AtBats*, a variable containing the number of times at bat. A model for hitting proportion (batting average) as a function of age could be specified as

```
model hits/AtBats=age;
```

The *effects* following the equal sign are the covariates in the model. Higher-order effects, such as interactions and nested terms, are allowed in the list, as in the GLM procedure. Variable names and combinations of variable names representing higher-order terms are allowed to appear in this list. Classification variables can be used as effects, and indicator variables are generated for the class levels. If you do not specify any covariates following the equal sign, an intercept-only model is fit.

Table 75.31 summarizes the options available in the MODEL statement.

Table 75.31 MODEL Statement Options

Option	Description
AGGREGATE	Specifies the subpopulations
ALPHA=	Sets the significance level
CONVERGE=	Specifies the convergence criterion
CORRB	Displays the estimated correlation matrix
COVB	Displays the estimated covariance matrix
DISTRIBUTION=	Specifies the cumulative distribution function
HPROB=	Specifies a minimum probability level
INITIAL=	Sets initial values for the parameters
INTERCEPT=	Initializes the intercept parameter
INVERSECL	Computes confidence limits
ITPRINT	Displays the iteration history, the final evaluation of the gradient, and the second derivative matrix
LACKFIT	Performs two goodness-of-fit tests
MAXITER=	Specifies the maximum number of iterations
NOINT	Fits a model with no intercept parameter
SCALE=	Specifies the method for estimating the dispersion parameter
SINGULAR=	Specifies the singularity criterion

The following options are available in the MODEL statement.

AGGREGATE

AGGREGATE=*variable-list*

specifies the subpopulations on which the Pearson's chi-square test statistic and the log-likelihood ratio chi-square test statistic (deviance) are calculated if the LACKFIT option is specified. See the section "[Rescaling the Covariance Matrix](#)" on page 6409 for details of Pearson's chi-square and deviance calculations.

Observations with common values in the given list of variables are regarded as coming from the same subpopulation. Variables in the list can be any variables in the input data set. Specifying the AGGREGATE option is equivalent to specifying the AGGREGATE= option with a variable list that includes all independent variables in the MODEL statement. The PROBIT procedure sorts the input data set according to the variables specified in this list. Information for the sorted data set is reported in the "Response-Covariate Profile" table.

The deviance and Pearson's goodness-of-fit statistics are calculated if the LACKFIT option is specified in the MODEL statement. The calculated results are reported in the "Goodness-of-Fit" table. If the Pearson's chi-square test is significant with the test level specified by the HPROB= option, the fiducial limits, if required with the INVERSECL option in the MODEL statement, are modified (see the section "[Inverse Confidence Limits](#)" on page 6410 for details). Also, the covariance matrix is rescaled by the dispersion parameter when the SCALE= option is specified.

ALPHA=*value*

sets the significance level for the confidence intervals for regression parameters, fiducial limits for the predicted values, and confidence intervals for the predicted probabilities. The value must be between 0 and 1. The default value is ALPHA=0.05.

CONVERGE=*value*

specifies the convergence criterion. Convergence is declared when the maximum change in the parameter estimates between Newton-Raphson steps is less than the value specified. The change is a relative change if the parameter is greater than 0.01 in absolute value; otherwise, it is an absolute change.

By default, CONVERGE=1.0E-8.

CORRB

displays the estimated correlation matrix of the parameter estimates.

COVB

displays the estimated covariance matrix of the parameter estimates.

DISTRIBUTION=*distribution-type*

DIST=*distribution-type*

D=*distribution-type*

specifies the cumulative distribution function used to model the response probabilities. The distributions are described in the section "[Details: PROBIT Procedure](#)" on page 6404. Valid values for *distribution-type* are as follows:

NORMAL the normal distribution for the probit model
 LOGISTIC the logistic distribution for the logit model
 EXTREMEVALUE | EXTREME | GOMPERTZ the extreme value, or Gompertz distribution for the gompit model

By default, DISTRIBUTION=NORMAL.

HPROB=*p*

specifies a minimum probability level for the Pearson's chi-square to indicate a good fit. The default value is 0.10. The LACKFIT option must also be specified for this option to have any effect. For Pearson's goodness-of-fit chi-square values with probability greater than the HPROB= value, the fiducial limits, if requested with the INVERSECL option, are computed by using a critical value of 1.96. For chi-square values with probability less than the value of the HPROB= option, the critical value is a 0.95 two-sided quantile value taken from the *t* distribution with degrees of freedom equal to $(k - 1) \times m - q$, where *k* is the number of levels for the response variable, *m* is the number of different sets of independent variable values, and *q* is the number of parameters fit in the model. If you specify the HPROB= option in both the PROC PROBIT and MODEL statements, the MODEL statement option takes precedence.

INITIAL=*values*

sets initial values for the parameters in the model other than the intercept. The values must be given in the order in which the variables are listed in the MODEL statement. If some of the independent variables listed in the MODEL statement are classification variables, then there must be as many values given for that variable as there are classification levels minus 1. The INITIAL option can be specified as follows.

Type of List	Specification
List separated by blanks	initial=3 4 5
List separated by commas	initial=3,4,5

By default, all parameters have initial estimates of zero.

NOTE: The INITIAL= option is overwritten by the INEST= option in the PROC PROBIT statement.

INTERCEPT=*value*

initializes the intercept parameter to *value*. By default, INTERCEPT=0.

INVERSECL<(PROB=*rates*)>

computes confidence limits for the values of the first continuous independent variable (such as dose) that yield selected response rates. You can optionally specify a list of response rates as *rates*. The response rates must be between zero and one; they can be a list separated by blanks, commas, or in the form of a DO list. For example, the following expressions are all valid lists of response rates:

```
PROB = .1 TO .9 by .1
PROB = .1 .2 .3 .4
PROB = .01, .25, .75, .9
```

If the algorithm fails to converge (this can happen when *C* is nonzero), missing values are reported for the confidence limits. See the section “[Inverse Confidence Limits](#)” on page 6410 for details.

ITPRINT

displays the iteration history, the final evaluation of the gradient, and the second derivative matrix (Hessian).

LACKFIT

performs two goodness-of-fit tests (a Pearson's chi-square test and a log-likelihood ratio chi-square test) for the fitted model.

To compute the test statistics, proper grouping of the observations into subpopulations is needed. You can use the AGGREGATE or AGGREGATE= option for this purpose. See the entry for the AGGREGATE and AGGREGATE= options under the MODEL statement. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the *events/trials* syntax.

NOTE: This test is not appropriate if the data are very sparse, with only a few values at each set of the independent variable values.

If the Pearson's chi-square test statistic is significant, then the covariance estimates and standard error estimates are adjusted. See the section "[Lack-of-Fit Tests](#)" on page 6408 for a description of the tests. Note that the LACKFIT option can also appear in the PROC PROBIT statement. See the section "[PROC PROBIT Statement](#)" on page 6352 for details.

MAXITER=*value***MAXIT=***value*

specifies the maximum number of iterations to be performed in estimating the parameters. By default, MAXITER=50.

NOINT

fits a model with no intercept parameter. If the INTERCEPT= option is also specified, the intercept is fixed at the specified value; otherwise, it is set to zero. This is most useful when the response is binary. When the response has k levels, then $k - 1$ intercept parameters are fit. The NOINT option sets the intercept parameter corresponding to the lowest response level equal to zero. A Lagrange multiplier, or score, test for the restricted model is computed when the NOINT option is specified.

SCALE=*scale*

enables you to specify the method for estimating the dispersion parameter. To correct for overdispersion or underdispersion, the covariance matrix is multiplied by the estimate of the dispersion parameter. Valid values for *scale* are as follows:

D DEVIANCE	specifies that the dispersion parameter be estimated by the deviance divided by its degrees of freedom.
P PEARSON	specifies that the dispersion parameter be estimated by the Pearson's chi-square statistic divided by its degrees of freedom. This is set as the default method for estimating the dispersion parameter.

You can use the AGGREGATE= option to define the subpopulations for calculating the Pearson's chi-square statistic and the deviance.

The "Goodness-of-Fit" table includes the Pearson's chi-square statistic, the deviance, their degrees of freedom, the ratio of each statistic divided by its degrees of freedom, and the corresponding p -value.

SINGULAR=value

specifies the singularity criterion for determining linear dependencies in the set of independent variables. The sum of squares and crossproducts matrix of the independent variables is formed and swept. If the relative size of a pivot becomes less than the value specified, then the variable corresponding to the pivot is considered to be linearly dependent on the previous set of variables considered. By default, *value*=1E-12.

OUTPUT Statement

OUTPUT < **OUT=SAS-data-set** *keyword=name* ... *keyword=name* > ;

The OUTPUT statement creates a new SAS data set containing all variables in the input data set and, optionally, the fitted probabilities, the estimate of $\mathbf{x}'\boldsymbol{\beta}$, and the estimate of its standard error. Estimates of the probabilities, $\mathbf{x}'\boldsymbol{\beta}$, and the standard errors are computed for observations with missing response values as long as the values of all the explanatory variables are nonmissing. This enables you to compute these statistics for additional settings of the explanatory variables that are of interest but for which responses are not observed.

You can specify multiple OUTPUT statements. Each OUTPUT statement creates a new data set and applies only to the preceding MODEL statement. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

Details on the specifications in the OUTPUT statement are as follows:

keyword=name specifies the statistics to include in the output data set and assigns names to the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

PROB | P cumulative probability estimates

$$p = C + (1 - C)F(a_j + \mathbf{x}'\boldsymbol{\beta})$$

STD standard error estimates of $a_j + \mathbf{x}'\mathbf{b}$

XBETA estimates of $a_j + \mathbf{x}'\boldsymbol{\beta}$

OUT=SAS-data-set names the output data set. By default, the new data set is named by using the *DATA**n* convention.

When the *single variable response* syntax is used, the `_LEVEL_` variable is added to the output data set, and there are $k - 1$ output observations for each input observation, where k is the number of response levels. There is no observation output corresponding to the highest response level. For each of the $k - 1$ observations, the PROB variable contains the fitted probability of obtaining a response level up to the level indicated by the `_LEVEL_` variable, the XBETA variable contains $a_j + \mathbf{x}'\mathbf{b}$, where j references the levels ($a_1 = 0$), and the STD variable contains the standard error estimate of the XBETA variable. See the section “[Details: PROBIT Procedure](#)” on page 6404 for the formulas for the parameterizations.

PREDPPLOT Statement

PREDPPLOT < VAR=variable > < options > ;

The PREDPPLOT statement plots the predicted probability against a single continuous variable (dose variable) in the MODEL statement for both the binomial model and the multinomial model. Confidence limits are available only for the binomial model. An attached box on the right side of the plot is used to label predicted probability curves with the names of their levels for the multinomial model. You can specify the color of this box by using the CLABBOX= option.

VAR=variable

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

The predicted probability is

$$\hat{p} = C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}})$$

for the binomial model and

$$\begin{aligned}\hat{p}_1 &= C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}}) \\ \hat{p}_j &= (1 - C)(F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}}) - F(\hat{a}_{j-1} + \mathbf{x}'\hat{\mathbf{b}})) \quad j = 2, \dots, k - 1 \\ \hat{p}_k &= (1 - C)(1 - F(\hat{a}_{k-1} + \mathbf{x}'\hat{\mathbf{b}}))\end{aligned}$$

for the multinomial model with k response levels, where F is the cumulative distribution function used to model the probability, \mathbf{x}' is the vector of the covariates, \hat{a}_j are the estimated ordinal intercepts with $\hat{a}_1 = 0$, C is the threshold parameter, either known or estimated from the model, and $\hat{\mathbf{b}}'$ is the vector of estimated parameters.

To plot \hat{p} (or \hat{p}_j) as a function of a continuous variable x_1 , the remaining covariates \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

enable you to plot the observed data and add features to the plot.

You can use options in the PREDPPLOT statement to do the following:

- superimpose specification limits
- suppress or add observed data points for the binomial model
- suppress or add confidence limits for the binomial model
- specify the levels for which predicted probability curves are requested for the multinomial model
- specify graphical enhancements (such as color or text height)

Summary of Options

Table 75.32 through Table 75.38 list all *options* by function. The “Dictionary of Options” on page 6398 describes each option in detail.

PREDPLOT Options

Table 75.32 Plot Layout Options for PREDPLOT

LEVEL=(<i>character-list</i>)	Specifies the names of the levels for which the predicted probability curves are requested (only for the multinomial model)
NOCONF	Suppresses confidence limits
NODATA	Suppresses observed data points on the plot
NOTHRESH	Suppresses the threshold line
THRESHLABPOS= <i>value</i>	Specifies the position for the label of the threshold line

General Options

Table 75.33 Color Options

CAXIS= <i>color</i>	Specifies color for the axes
CFIT= <i>color</i>	Specifies color for fitted curves
CFRAME= <i>color</i>	Specifies color for frame
CGRID= <i>color</i>	Specifies color for grid lines
CHREF= <i>color</i>	Specifies color for HREF= lines
CLABBOX= <i>color</i>	Specifies color for label box
CTEXT= <i>color</i>	Specifies color for text
CVREF= <i>color</i>	Specifies color for VREF= lines

Table 75.34 Options to Enhance Plots Produced on Graphics Devices

ANNOTATE= <i>SAS-data-set</i>	Specifies an Annotate data set
INBORDER	Requests a border around plot
LFIT= <i>linetype</i>	Specifies line style for fitted curves and confidence limits
LGRID= <i>linetype</i>	Specifies line style for grid lines
NOFRAME	Suppresses the frame around plotting areas
NOGRID	Suppresses grid lines
NOFIT	Suppresses fitted curves
NOHLABEL	Suppresses horizontal labels
NOHTICK	Suppresses horizontal ticks
NOVTICK	Suppresses vertical ticks
TURNVLABELS	Vertically strings out characters in vertical labels
WFIT= <i>n</i>	Specifies thickness for fitted curves
WGRID= <i>n</i>	Specifies thickness for grids
WREFL= <i>n</i>	Specifies thickness for reference lines

Table 75.35 Axis Options

HAXIS= <i>value1 to value2</i> < by <i>value3</i> >	Specifies tick mark values for horizontal axis
HOFFSET= <i>value</i>	Specifies offset for horizontal axis
HLOWER= <i>value</i>	Specifies lower limit on horizontal axis scale
HUPPER= <i>value</i>	Specifies upper limit on horizontal axis scale
NHTICK= <i>n</i>	Specifies number of ticks for horizontal axis
NVTICK= <i>n</i>	Specifies number of ticks for vertical axis
VAXIS= <i>value1 to value2</i> < by <i>value3</i> >	Specifies tick mark values for vertical axis
VAXISLABEL= <i>'label'</i>	Specifies label for vertical axis
VOFFSET= <i>value</i>	Specifies offset for vertical axis
VLOWER= <i>value</i>	Specifies lower limit on vertical axis scale
VUPPER= <i>value</i>	Specifies upper limit on vertical axis scale
WAXIS= <i>n</i>	Specifies thickness for axis

Table 75.36 Graphics Catalog Options

DESCRIPTION= <i>'string'</i>	Specifies description for graphics catalog member
NAME= <i>'string'</i>	Specifies name for plot in graphics catalog

Table 75.37 Options for Text Enhancement

FONT=font	Specifies software font for text
HEIGHT=value	Specifies height of text used outside framed areas
INHEIGHT=value	Specifies height of text inside framed areas

Table 75.38 Options for Reference Lines

HREF<(INTERSECT)> =value-list	Requests horizontal reference line
HREFLABELS= (‘label1’,...,‘labeln’)	Specifies labels for HREF= lines
HREFLABPOS=n	Specifies vertical position of labels for HREF= lines
LHREF=linetype	Specifies line style for HREF= lines
LVREF=linetype	Specifies line style for VREF= lines
VREF<(INTERSECT)> =value-list	Requests vertical reference line
VREFLABELS= (‘label1’,...,‘labeln’)	Specifies labels for VREF= lines
VREFLABPOS=n	Specifies horizontal position of labels for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the PREDPPLOT statement.

ANNOTATE=SAS-data-set

ANNO=SAS-data-set

specifies an Annotate data set, as described in *SAS/GRAPH: Reference*, that enables you to add features to the predicted probability plot. The ANNOTATE= data set you specify in the PREDPPLOT statement is used for all plots created by the statement.

CAXIS=color

CAXES=color

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=color

specifies the color for the fitted predicted probability curves. The default is the first color in the device color list.

CFRAME=color

CFR=color

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*

CV=*color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION='*string*'

DES='*string*'

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the horizontal axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists follow:

```
haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10
```

HEIGHT=*value*

specifies the height of text used outside framed areas.

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies the offset for the horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=*'label1', ..., 'labeln'***HREFLABEL=***'label1', ..., 'labeln'***HREFLAB=***'label1', ..., 'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Top
2	Staggered from top
3	Bottom
4	Staggered from bottom
5	Alternating from top
6	Alternating from bottom

INBORDER

requests a border around predicted probability plots.

INHEIGHT=*value*

Specifies height of text inside framed areas.

LEVEL=*(character-list)***ORDINAL=***(character-list)*

specifies the names of the levels for which predicted probability curves are requested. Names should be quoted and separated by space. If there is no correct name provided, no fitted probability curve is plotted.

LFIT=*linetype*

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1) and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

LGRID=*linetype*

specifies a line style for all grid lines. The value for *linetype* is between 1 and 46. The default is 35.

LHREF=*linetype*

LH=*linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype*

LV=*linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME='string'

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NHTICK=*n*

Specifies number of ticks for horizontal axis.

NVTICK=*n*

Specifies number of ticks for vertical axis.

NOCONF

suppresses confidence limits from the plot. This works only for the binomial model. Confidence limits are not plotted for the multinomial model.

NODATA

suppresses observed data points from the plot. This works only for the binomial model. The data points are not plotted for the multinomial model.

NOFIT

suppresses the fitted predicted probability curves.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

TURNVLABELS

vertically strings out characters in vertical labels.

THRESHLABPOS=*n*

specifies the horizontal position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Left
2	Right

VAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the vertical axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists follow:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL=*'string'*

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VOFFSET=*value*

specifies the offset for the vertical axis.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=*'label1', ..., 'labeln'***VREFLABEL=*'label1', ..., 'labeln'*****VREFLAB=*'label1', ..., 'labeln'***

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	Label Placement
1	Left
2	Right

VUPPER=*value*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *value* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*

specifies line thickness for fitted curves. The default value is 1.

WGRID=*n*

specifies line thickness for grids. The default value is 1.

WREFL=*n*

specifies line thickness for reference lines. The default value is 1.

SLICE Statement

SLICE *model-effect* < / *options* > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in [Table 19.21](#). For details about the syntax of the SLICE statement, see the section “[SLICE Statement](#)” on page 498 in Chapter 19, “[Shared Concepts and Topics](#).”

STORE Statement

STORE < **OUT=** > *item-store-name* < / **LABEL=** '*label*' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “[STORE Statement](#)” on page 501 in Chapter 19, “[Shared Concepts and Topics](#).”

TEST Statement

TEST < model-effects > < / options > ;

The TEST statement enables you to perform chi-square tests for model effects that test Type I, Type II, or Type III hypotheses. By default, the Type III tests are performed. For more information, see Chapter 19, “Shared Concepts and Topics.”

WEIGHT Statement

WEIGHT variable ;

A WEIGHT statement can be used with PROC PROBIT to weight each observation by the value of the variable specified. The contribution of each observation to the likelihood function is multiplied by the value of the weight variable. Observations with zero, negative, or missing weights are not used in model estimation.

Details: PROBIT Procedure

Missing Values

PROC PROBIT does not use any observations having missing values for any of the independent variables, the response variables, or the weight variable. If only the response variables are missing, statistics requested in the OUTPUT statement are computed.

Response Level Ordering

For binary response data, PROC PROBIT fits the following model by default:

$$\Phi^{-1} \left(\frac{p - C}{1 - C} \right) = \mathbf{x}'\boldsymbol{\beta}$$

where p is the probability of the response level identified as the first level in the “Response Profile” table in the output and Φ is the normal cumulative distribution function. By default, the covariate vector \mathbf{x} contains an intercept term. This is sometimes called Abbot’s formula.

Because of the symmetry of the normal (and logistic) distribution, the effect of reversing the order of the two response values is to change the signs of $\boldsymbol{\beta}$ in the preceding equation.

By default, response levels appear in ascending, sorted order (that is, the lowest level appears first, and then the next lowest, and so on). There are a number of ways that you can control the sort order of the response categories and, therefore, which level is assigned the first ordered level. One of the most common sets of response levels is $\{0,1\}$, with 1 representing the event with the probability that is to be modeled.

Consider the example where Y takes the values 1 and 0 for event and nonevent, respectively, and EXPOSURE is the explanatory variable. By default, PROC PROBIT assigns the first ordered level to response level 0, causing the probability of the nonevent to be modeled. There are several ways to change this.

Besides recoding the variable Y , you can do the following:

- assign a format to Y such that the first formatted value (when the formatted values are put in sorted order) corresponds to the event. For the following example, $Y=0$ could be assigned formatted value 'nonevent' and $Y=1$ could be assigned formatted value 'event.' Since ORDER=FORMATTED by default, $Y=1$ becomes the first ordered level. See [Example 75.3](#) for an illustration of this method.

```
proc format;
  value disease 1='event' 0='nonevent';
run;
proc probit;
  model y=exposure;
  format y disease.;
run;
```

- arrange the input data set so that $Y=1$ appears first and use the ORDER=DATA option in the PROC PROBIT statement. Since ORDER=DATA sorts levels in order of their appearance in the data set, $Y=1$ becomes the first ordered level. Note that this option causes classification variables to be sorted by their order of appearance in the data set, also.

Computational Method

The log-likelihood function is maximized by means of a ridge-stabilized Newton-Raphson algorithm. Initial regression parameter estimates are set to zero. The INITIAL= and INTERCEPT= options in the MODEL statement can be used to give nonzero initial estimates.

The log-likelihood function, L , is computed as

$$L = \sum_i w_i \ln(p_i)$$

where the sum is over the observations in the data set, w_i is the weight for the i th observation, and p_i is the modeled probability of the observed response. In the case of the events/trials syntax in the MODEL statement, each observation contributes two terms corresponding to the probability of the event and the probability of its complement:

$$L = \sum_i w_i [r_i \ln(p_i) + (n_i - r_i) \ln(1 - p_i)]$$

where r_i is the number of events and n_i is the number of trials for observation i . This log-likelihood function differs from the log-likelihood function for a binomial or multinomial distribution by additive terms consisting of the log of binomial or multinomial coefficients. These terms are parameter-independent and do not affect the model estimation or the standard errors and tests.

The estimated covariance matrix, V , of the parameter estimates is computed as the negative inverse of the information matrix of second derivatives of L with respect to the parameters evaluated at the final parameter estimates. Thus, the estimated covariance matrix is derived from the observed information matrix rather than the expected information matrix (these are generally not the same). The standard error estimates for the parameter estimates are taken as the square roots of the corresponding diagonal elements of V .

If convergence of the maximum likelihood estimates is attained, a Type III chi-square test statistic is computed for each effect, testing whether there is any contribution from any of the levels of the effect. This statistic is computed as a quadratic form in the appropriate parameter estimates by using the corresponding submatrix of the asymptotic covariance matrix estimate. See Chapter 42, “[The GLM Procedure](#),” and Chapter 15, “[The Four Types of Estimable Functions](#),” for more information about Type III estimable functions.

The asymptotic covariance matrix is computed as the inverse of the observed information matrix. Note that if the NOINT option is specified and classification variables are used, the first classification variable contains a contribution from an intercept term. The results are displayed in an ODS table named “Type3Analysis”.

Chi-square tests for individual parameters are Wald tests based on the observed information matrix and the parameter estimates. If an effect has a single degree of freedom in the parameter estimates table, the chi-square test for this parameter is equivalent to the Type III test for this effect.

Prior to SAS 8.2, a multiple-degrees-of-freedom statistic was computed for each effect to test for contribution from any level of the effect. In general, the Type III test statistic in a main-effect-only model (no interaction terms) will be equal to the previously computed effect statistic, unless there are collinearities among the effects. If there are collinearities, the Type III statistic will adjust for them, and the value of the Type III statistic and the number of degrees of freedom might not be equal to those of the previous effect statistic.

The theory behind these tests assumes large samples. If the samples are not large, it might be better to base the tests on log-likelihood ratios. These changes in log likelihood can be obtained by fitting the model twice, once with all the parameters of interest and once leaving out the parameters to be tested. See Cox and Oakes (1984) for a discussion of the merits of some possible test methods.

If some of the independent variables are perfectly correlated with the response pattern, then the theoretical parameter estimates can be infinite. Although fitted probabilities of 0 and 1 are not especially pathological, infinite parameter estimates are required to yield these probabilities. Due to the finite precision of computer arithmetic, the actual parameter estimates are not infinite. Indeed, since the tails of the distributions allowed in the PROBIT procedure become small rapidly, an argument to the cumulative distribution function of around 20 becomes effectively infinite. In the case of such parameter estimates, the standard error estimates and the corresponding chi-square tests are not trustworthy.

Distributions

The distributions, $F(x)$, allowed in the PROBIT procedure are specified with the DISTRIBUTION= option in the MODEL statement. The cumulative distribution functions for the available distributions are

Cumulative Distribution Function	Distribution
$\int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{z^2}{2}\right) dz$	Normal
$\frac{1}{1+e^{-x}}$	Logistic
$1 - e^{-e^x}$	Extreme value or Gompertz

The variances of these three distributions are not all equal to 1, and their means are not all equal to zero. Their means and variances are shown in the following table, where γ is the Euler constant.

Distribution	Mean	Variance
Normal	0	1
Logistic	0	$\pi^2/3$
Extreme value or Gompertz	$-\gamma$	$\pi^2/6$

When comparing parameter estimates by using different distributions, you need to take into account the different scalings and, for the extreme value (or Gompertz) distribution, a possible shift in location. For example, if the fitted probabilities are in the neighborhood of 0.1 to 0.9, then the parameter estimates from the logistic model should be about $\pi/\sqrt{3}$ larger than the estimates from the probit model.

INEST= SAS-data-set

The INEST= data set names a SAS data set that specifies initial estimates for all the parameters in the model.

The INEST= data set must contain the intercept variables (named Intercept for binary response model and Intercept, Intercept2, Intercept3, and so forth, for multinomial response models) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in a BY group, the first one read is used for that BY group.

If the INEST= data set also contains the _TYPE_ variable, only observations with the _TYPE_ value “PARMS” are used as starting values. Combining the INEST= data set and the option MAXIT= in the MODEL statement, partial scoring can be done, such as predicting on a validation data set by using the model built from a training data set.

You can specify starting values for the iterative algorithm in the INEST= data set. This data set overwrites the INITIAL= option in the MODEL statement, which is a little difficult to use for models with multilevel interaction effects. The INEST= data set has the same structure as the “OUTEST= SAS-data-set” on page 6411, but it is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization.

Model Specification

For a two-level response, the probability that the lesser response occurs is modeled by the probit equation as

$$p = C + (1 - C)F(\mathbf{x}'\mathbf{b})$$

The probability of the other (complementary) event is $1 - p$.

For a multilevel response with outcomes labeled l_i for $i = 1, 2, \dots, k$, the probability, p_j , of observing level l_j is as follows:

$$\begin{aligned}
p_1 &= C + (1 - C)F(\mathbf{x}'\mathbf{b}) \\
p_2 &= (1 - C)(F(a_2 + \mathbf{x}'\mathbf{b}) - F(\mathbf{x}'\mathbf{b})) \\
&\vdots \\
p_j &= (1 - C)(F(a_j + \mathbf{x}'\mathbf{b}) - F(a_{j-1} + \mathbf{x}'\mathbf{b})) \\
&\vdots \\
p_k &= (1 - C)(1 - F(a_{k-1} + \mathbf{x}'\mathbf{b}))
\end{aligned}$$

Thus, for a k -level response, there are $k - 2$ additional parameters, a_2, a_3, \dots, a_{k-1} , estimated. These parameters are denoted by `Interceptj`, $j = 2, 3, \dots, k - 1$, in the output.

An intercept parameter is always added to the set of independent variables as the first term in the model unless the `NOINT` option is specified in the `MODEL` statement. If a classification variable taking on k levels is used as one of the independent variables, a set of k indicator variables is generated to model the effect of this variable. Because of the presence of the intercept term, there are at most $k - 1$ degrees of freedom for this effect in the model.

Lack-of-Fit Tests

Two goodness-of-fit tests can be requested from the PROBIT procedure: a Pearson's chi-square test and a log-likelihood ratio chi-square test.

To compute the test statistics, you can use the `AGGREGATE` or `AGGREGATE=` option grouping the observations into subpopulations. If neither `AGGREGATE` nor `AGGREGATE=` is specified, `PROC PROBIT` assumes that each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the *events/trials* syntax.

If the Pearson's goodness-of-fit chi-square test is requested and the p -value for the test is too small, variances and covariances are adjusted by a heterogeneity factor (the goodness-of-fit chi-square divided by its degrees of freedom) and a critical value from the t distribution is used to compute the fiducial limits. The Pearson's chi-square test statistic is computed as

$$\chi_P^2 = \sum_{i=1}^m \sum_{j=1}^k \frac{(r_{ij} - n_i \hat{p}_{ij})^2}{n_i \hat{p}_{ij}}$$

where the sum on i is over grouping, the sum on j is over levels of response, r_{ij} is the frequency of response level j for the i th grouping, n_i is the total frequency for the i th grouping, and \hat{p}_{ij} is the fitted probability for the j th level at the i th grouping.

The likelihood ratio chi-square test statistic is computed as

$$\chi_D^2 = 2 \sum_{i=1}^m \sum_{j=1}^k r_{ij} \ln \left(\frac{r_{ij}}{n_i \hat{p}_{ij}} \right)$$

This quantity is sometimes called the deviance. If the modeled probabilities fit the data, these statistics should be approximately distributed as chi-square with degrees of freedom equal to $(k - 1) \times m - q$, where k is the number of levels of the multinomial or binomial response, m is the number of sets of independent variable values (covariate patterns), and q is the number of parameters fit in the model.

In order for the Pearson's statistic and the deviance to be distributed as chi-square, there must be sufficient replication within the groupings. When this is not true, the data are sparse, and the p -values for these statistics are not valid and should be ignored. Similarly, these statistics, divided by their degrees of freedom, cannot serve as indicators of overdispersion. A large difference between the Pearson's statistic and the deviance provides some evidence that the data are too sparse to use either statistic.

Rescaling the Covariance Matrix

One way of correcting overdispersion is to multiply the covariance matrix by a dispersion parameter. You can supply the value of the dispersion parameter directly, or you can estimate the dispersion parameter based on either the Pearson's chi-square statistic or the deviance for the fitted model.

The Pearson's chi-square statistic χ_P^2 and the deviance χ_D^2 are defined in the section “[Lack-of-Fit Tests](#)” on page 6408. If the SCALE= option is specified in the MODEL statement, the dispersion parameter is estimated by

$$\hat{\sigma}^2 = \begin{cases} \chi_P^2 / (m(k - 1) - q) & \text{SCALE=PEARSON} \\ \chi_D^2 / (m(k - 1) - q) & \text{SCALE=DEVIANCE} \\ (\text{constant})^2 & \text{SCALE=constant} \end{cases}$$

In order for the Pearson's statistic and the deviance to be distributed as chi-square, there must be sufficient replication within the subpopulations. When this is not true, the data are sparse, and the p -values for these statistics are not valid and should be ignored. Similarly, these statistics, divided by their degrees of freedom, cannot serve as indicators of overdispersion. A large difference between the Pearson's statistic and the deviance provides some evidence that the data are too sparse to use either statistic.

You can use the AGGREGATE (or AGGREGATE=) option to define the subpopulation profiles. If you do not specify this option, each observation is regarded as coming from a separate subpopulation. For *events/trials* syntax, each observation represents n Bernoulli trials, where n is the value of the *trials* variable; for *single-trial* syntax, each observation represents a single trial. Without the AGGREGATE (or AGGREGATE=) option, the Pearson's chi-square statistic and the deviance are calculated only for *events/trials* syntax.

Note that the parameter estimates are not changed by this method. However, their standard errors are adjusted for overdispersion, affecting their significance tests.

Tolerance Distribution

For a single independent variable, such as a dosage level, the models for the probabilities can be justified on the basis of a population with mean μ and scale parameter σ of tolerances for the subjects. Then, given a dose x , the probability, P , of observing a response in a particular subject is the probability that the subject's tolerance is less than the dose or

$$P = F\left(\frac{x - \mu}{\sigma}\right)$$

Thus, in this case, the intercept parameter, b_0 , and the regression parameter, b_1 , are related to μ and σ by

$$b_0 = -\frac{\mu}{\sigma}, \quad b_1 = \frac{1}{\sigma}$$

NOTE: The parameter σ is not equal to the standard deviation of the population of tolerances for the logistic and extreme value distributions.

Inverse Confidence Limits

In bioassay problems, estimates of the values of the independent variables that yield a desired response are often needed. For instance, the value yielding a 50% response rate (called the ED50 or LD50) is often used. The INVERSECL option requests that confidence limits be computed for the value of the independent variable that yields a specified response. These limits are computed only for the first continuous variable effect in the model. The other variables are set either at their mean values if they are continuous or at the reference (last) level if they are discrete variables. For a discussion of inverse confidence limits, see Hubert, Bohidar, and Peace (1988).

For the PROBIT procedure, the response variable is a probability. An estimate of the first continuous variable value needed to achieve a response of p is given by

$$\hat{x}_1 = \frac{1}{b_1} (F^{-1}(p) - \mathbf{x}^{*'} \mathbf{b}^*)$$

where F is the cumulative distribution function used to model the probability, \mathbf{x}^* is the vector of independent variables excluding the first one, which can be specified by the XDATA= option described in the section “[XDATA= SAS-data-set](#)” on page 6411, \mathbf{b}^* is the vector of parameter estimates excluding the first one, and b_1 is the estimated regression coefficient for the independent variable of interest. This estimate assumes that there is no natural response rate ($C = 0$). When C is nonzero, the quantiles and confidence limits for the independent variable correspond to the adjusted probability $C + (1 - C)p$, rather than to p . As a result, an estimate of the value yielding response rate p is associated with the $(p - C)/(1 - C)$ quantile. For example, if $C = 0.1$ then an estimate of the LD50 is found corresponding to the 0.44 quantile. This value can be thought of as yielding 50% of the variable’s effect, but a 44% response rate. For both binary and ordinal models, the INVERSECL option provides estimates of the value of x_1 , which yields $\Pr(\text{first response level}) = p$, for various values of p .

This estimator is given as a ratio of random variables, such as $r = a/b$. Confidence limits for this ratio can be computed by using Fieller’s theorem. A brief description of this theorem follows. See Finney (1971) for a more complete description of Fieller’s theorem.

If the random variables a and b are thought to be distributed as jointly normal, then for any fixed value r the following probability statement holds if z is an $\alpha/2$ quantile from the standard normal distribution and \mathbf{V} is the variance-covariance matrix of a and b :

$$\Pr((a - rb)^2 > z^2(V_{aa} - 2rV_{ab} + r^2V_{bb})) = \alpha$$

Usually the inequality can be solved for r to yield a confidence interval. The PROBIT procedure uses a value of 1.96 for z , corresponding to an α value of 0.05, unless the goodness-of-fit p -value is less than the specified value of the HPROB= option. When this happens, the covariance matrix is scaled by the heterogeneity factor, and a t distribution quantile is used for z .

It is possible for the roots of the equation for r to be imaginary or for the confidence interval to be all points outside of an interval. In these cases, the limits are set to missing by the PROBIT procedure.

Although the normal and logistic distribution give comparable fitted values of p if the empirically observed proportions are not too extreme, they can give appreciably different values when extrapolated into the tails. Correspondingly, the estimates of the confidence limits and dose values can be different for the two distributions even when they agree quite well in the body of the data. Extrapolation outside of the range of the actual data is often sensitive to model assumptions, and caution is advised if extrapolation is necessary.

OUTEST= SAS-data-set

The OUTEST= data set contains parameter estimates and the log likelihood for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different models used by the PROBIT procedure. If you specify the COVOUT option, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates.

The OUTEST= data set contains each variable used as a dependent or independent variable in any MODEL statement. One observation consists of parameter values for the model with the dependent variable having the value -1. If you specify the COVOUT option, there are additional observations containing the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

<code>_MODEL_</code>	a character variable containing the label of the MODEL statement, if present, or blank otherwise
<code>_NAME_</code>	a character variable containing the name of the dependent variable for the parameter estimates observations or the name of the row for the covariance matrix estimates
<code>_TYPE_</code>	a character variable containing the type of the observation, either PARMS for parameter estimates or COV for covariance estimates
<code>_DIST_</code>	a character variable containing the name of the distribution modeled
<code>_LNLIKE_</code>	a numeric variable containing the last computed value of the log likelihood
<code>_C_</code>	a numeric variable containing the estimated threshold parameter
<code>INTERCEPT</code>	a numeric variable containing the intercept parameter estimates and covariances

Any BY variables specified are also added to the OUTEST= data set.

XDATA= SAS-data-set

The XDATA= data set is used for specifying values for the effects in the MODEL statement when predicted values and/or fiducial limits for a single continuous variable (dose variable) are required. It is also used for plots specified by the CDFPLOT, IPPLOT, LPREDPLOT, and PREDPLOT statement.

The XDATA= data names a SAS data set that contains user input values for all the independent variables in the MODEL statement and the variables in the CLASS statement. The XDATA= data set has the same structure as the DATA= data set but is not required to have all the variables or observations that appear in the DATA= data set.

The XDATA= data set must contain all the independent variables in the MODEL statement and variables in the CLASS statement. Even though variables in the CLASS statement are not used in the MODEL statement, valid values are required for these variables in the XDATA= data set. Missing values are not allowed. For independent variables in the MODEL statement, although the dose variable's value is not used in the computing of predicted values and/or fiducial limits for the dose variable, missing values are not allowed in the XDATA= data set for any of the independent variables. Missing values are allowed for the dependent variables and other variables if they are included in the XDATA= data set and not listed in the CLASS statement.

If BY processing is used, the XDATA= data set should also include the BY variables, and there must be at least one valid observation for each BY group. If there is more than one valid observation in one BY group, the last one read is used for that BY group.

If there is no XDATA= data set in the PROC PROBIT statement, by default, the PROBIT procedure will use overall mean for effects containing continuous variable (or variables) and the highest level of a single classification variable as reference level. The rules are summarized as follows:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

Traditional High-Resolution Graphics

This section provides examples of using syntax available with the traditional high-resolution plots. A more modern alternative is to use ODS Graphics. See the section “[ODS Graphics](#)” on page 6415 for details.

There are four plot statements that you can use to request traditional high-resolution plots: CDFPLOT, IPPPLOT, LPREDPLOT, and PREDPPLOT. Some of these statements apply only to either the binomial model or the multinomial model. [Table 75.39](#) shows the availability of these statements for different models.

Table 75.39 Plot Statement Availability

Statement	Binomial	Multinomial
CDFPLOT	No	Yes
IPPPLOT	Yes	No
LPREDPLOT	Yes	Yes
PREDPPLOT	Yes	Yes

The following example uses the data set study in the section “[Estimating the Natural Response Threshold Parameter](#)” on page 6347 to illustrate how to create high-resolution plots for the binomial model:

```
proc probit data=study log10 optc;
  model respond/number=dose;
  predpplot var=dose cfit=blue; inset;
  lpredplot var=dose cfit=blue; inset;
  ippplot   var=dose cfit=blue; inset/pos=se;
run;
```

All plot statements must follow the MODEL statement. The VAR= option specifies a continuous independent variable (dose variable) against which the predicted probability or the linear predictor is plotted. The INSET statement requests the inset box with summary information. See the section “[INSET Statement](#)” on page 6369 for more details.

The PREDPLOT statement creates a plot that shows the relationship between dosage level, observed response proportions, and estimated probability values. See the section “[PREDPLOT Statement](#)” on page 6395 for more details. The IPPLOT statement creates a similar plot. See the section “[IPPLOT Statement](#)” on page 6371 for details about this plot. The LPREDPLOT statement creates a linear predictor plot, which is described in the section “[LPREDPLOT Statement](#)” on page 6379.

The following example uses the data set multi from [Example 75.2](#) to illustrate how to create high-resolution plots for the multinomial model:

```
proc probit data=multi order=data;
  class prep symptoms;
  model symptoms=prep ldose;
  cdfplot var=ldose level=("None" "Mild" "Severe")
          cfit=blue cframe=ligr noconf;
  lpredplot var=ldose level=("None" "Mild" "Severe")
           cfit=blue cframe=ligr;
  predpplot var=ldose level=("None" "Mild" "Severe")
           cfit=blue cframe=ligr;
  weight n;
run;
```

The CDFPLOT statement creates a plot that shows the relationship between the cumulative response probabilities and the dose levels. The multinomial model plots are similar to those with the binomial model.

Displayed Output

If you request the iteration history (ITPRINT), PROC PROBIT displays the following:

- the current value of the log likelihood
- the ridging parameter for the modified Newton-Raphson optimization process
- the current estimate of the parameters
- the current estimate of the parameter C for a natural (threshold) model
- the values of the gradient and the Hessian on the last iteration

If you include classification variables, PROC PROBIT displays the following:

- the numbers of levels for each classification variable
- the (ordered) values of the levels
- the number of observations used

After the model is fit, PROC PROBIT displays the following:

- the name of the input data set
- the name of the dependent variables
- the number of observations used
- the number of events and the number of trials
- the final value of the log-likelihood function
- the parameter estimates
- the standard error estimates of the parameter estimates
- approximate chi-square test statistics for the test

If you specify the COVB or CORRB options, PROC PROBIT displays the following:

- the estimated covariance matrix for the parameter estimates
- the estimated correlation matrix for the parameter estimates

If you specify the LACKFIT option, PROC PROBIT displays the following:

- a count of the number of levels of the response and the number of distinct sets of independent variables
- a goodness-of-fit test based on the Pearson's chi-square
- a goodness-of-fit test based on the likelihood-ratio chi-square

If you specify only one independent variable, the normal distribution is used to model the probabilities, and the response is binary, then PROC PROBIT displays the following:

- the mean MU of the stimulus tolerance
- the scale parameter SIGMA of the stimulus tolerance
- the covariance matrix for MU, SIGMA, and the natural response parameter C

If you specify the INVERSECL options, PROC PROBIT also displays the following:

- the estimated dose along with the 95% fiducial limits for probability levels 0.01 to 0.10, 0.15 to 0.85 by 0.05, and 0.90 to 0.99

ODS Table Names

PROC PROBIT assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 75.40 ODS Tables Produced by PROC PROBIT

ODS Table Name	Description	Statement	Option
ClassLevels	Classification variable levels	CLASS	Default
ConvergenceStatus	Convergence status	MODEL	Default
CorrB	Parameter estimate correlation matrix	MODEL	CORRB
CovB	Parameter estimate covariance matrix	MODEL	COVB
CovTolerance	Covariance matrix for location and scale	MODEL	Default
GoodnessOfFit	Goodness-of-fit tests	MODEL	LACKFIT
Heterogeneity	Heterogeneity correction	MODEL	LACKFIT
IterHistory	Iteration history	MODEL	ITPRINT
LagrangeStatistics	Lagrange statistics	MODEL	NOINT
LastGrad	Last evaluation of the gradient	MODEL	ITPRINT
LastHess	Last evaluation of the Hessian	MODEL	ITPRINT
LogProbitAnalysis	Probit analysis for log dose	MODEL	INVERSECL
ModelInfo	Model information	MODEL	Default
MuSigma	Location and scale	MODEL	Default
NObs	Observations summary	PROC	Default
ParameterEstimates	Parameter estimates	MODEL	Default
ParmInfo	Parameter indices	MODEL	Default
ProbitAnalysis	Probit analysis for linear dose	MODEL	INVERSECL
ResponseLevels	Response-covariate profile	MODEL	LACKFIT
ResponseProfiles	Counts for ordinal data	MODEL	Default
Type3Analysis	Type III tests	MODEL	Default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

These ODS graphs are controlled by the **PLOTS=** option in the PROC PROBIT statement. You can specify more than one graph request with the **PLOTS=** option. [Table 75.41](#) summarizes these requests.

Table 75.41 Options for Plots

Option	Plot
ALL	All appropriate plots
CDFPLOT	Estimated cumulative probability
IPPPLOT	Inverse predicted probability
LPREDPLOT	Linear predictor
NONE	No plot
PREDPPLOT	Predicted probability

The following subsections provide information about these graphs.

ODS Graph Names

PROC PROBIT assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 75.42.

Table 75.42 Graphs Produced by PROC PROBIT

ODS Graph Name	Plot Description	Statement	PLOTS= Option
CDFPlot	Estimated cumulative probability	PROC	CDFPLOT
IPPPlot	Inverse predicted probability	PROC	IPPPLOT
LPredPlot	Linear predictor	PROC	LPREDPLOT
PredPPlot	Predicted probability	PROC	PREDPPLOT

CDF Plot

For a multinomial model, the predicted cumulative distribution function is defined as

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}})$$

where $j = 1, \dots, k$ are the indexes of the k levels of the multinomial response variable, F is the CDF of the distribution used to model the cumulative probabilities, $\hat{\mathbf{b}}$ is the vector of estimated parameters, \mathbf{x} is the covariate vector, \hat{a}_j are estimated ordinal intercepts with $\hat{a}_1 = 0$, and C is the threshold parameter, either known or estimated from the model. Let x_1 be the covariate corresponding to the dose variable and \mathbf{x}_{-1} be the vector of the rest of the covariates. Let the corresponding estimated parameters be \hat{b}_1 and $\hat{\mathbf{b}}_{-1}$. Then

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + x_1\hat{b}_1 + \mathbf{x}'_{-1}\hat{\mathbf{b}}_{-1})$$

To plot \hat{F}_j as a function of x_1 , \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

The LEVEL= suboption specifies the levels of the multinomial response variable for which the CDF curves are requested. There are $k - 1$ curves for a k -level multinomial response variable (for the highest level, it is the constant line 1). You can specify any of them to be plotted by the LEVEL= suboption. See the plot in [Output 75.2.6](#) for an example.

Inverse Predicted Probability Plot

For the binomial model, the response variable is a probability. An estimate of the dose level \hat{x}_1 needed for a response of p is given by

$$\hat{x}_1 = (F^{-1}(p) - \mathbf{x}'_{-1}\hat{\mathbf{b}}_{-1})/\hat{b}_1$$

where F is the cumulative distribution function used to model the probability, \mathbf{x}_{-1} is the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ is the vector of the estimated parameters corresponding to \mathbf{x}_{-1} , and \hat{b}_1 is the estimated parameter for the dose variable of interest.

To plot \hat{x}_1 as a function of p , \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

[Output 75.4.12](#) in [Example 75.4](#) shows an inverse predicted probability plot.

Linear Predictor Plot

For both binomial models and multinomial models, the linear predictor $\mathbf{x}'\mathbf{b}$ can be plotted against the first single continuous variable (dose variable) in the MODEL statement.

Let x_1 be the covariate of the dose variable, \mathbf{x}_{-1} be the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ be the vector of estimated parameters corresponding to \mathbf{x}_{-1} , and \hat{b}_1 be the estimated parameter for the dose variable of interest.

To plot $\hat{\mathbf{x}}'\mathbf{b}$ as a function of x_1 , \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

For the multinomial model, you can use the LEVEL= suboption to specify the levels for which the linear predictor lines are plotted.

The confidence limits for the predicted values are only available for the binomial model. [Output 75.4.13](#) in [Example 75.4](#) shows a linear predictor plot for a binomial model.

Predicted Probability Plot

The predicted probability is

$$\hat{p} = C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}})$$

for the binomial model and

$$\begin{aligned}\hat{p}_1 &= C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}}) \\ \hat{p}_j &= (1 - C)(F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}}) - F(\hat{a}_{j-1} + \mathbf{x}'\hat{\mathbf{b}})), \quad j = 2, \dots, k - 1 \\ \hat{p}_k &= (1 - C)(1 - F(\hat{a}_{k-1} + \mathbf{x}'\hat{\mathbf{b}}))\end{aligned}$$

for the multinomial model with k response levels, where F is the cumulative distribution function used to model the probability, \mathbf{x}' is the vector of the covariates, \hat{a}_j are the estimated ordinal intercepts with $\hat{a}_1 = 0$, C is the threshold parameter, either known or estimated from the model, and $\hat{\mathbf{b}}'$ is the vector of estimated parameters.

To plot \hat{p} (or \hat{p}_j) as a function of a continuous variable x_1 , the remaining covariates \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

For the multinomial model, you can use the LEVEL= suboption to specify the levels for which the linear predictor lines are plotted.

Confidence limits are plotted only for the binomial model. [Output 75.1.7](#) in [Example 75.1](#) shows a predicted probability plot for a binomial model; and [Output 75.2.3](#) in [Example 75.2](#) shows a predicted probability plot for a multinomial model.

Examples: PROBIT Procedure

Example 75.1: Dosage Levels

In this example, Dose is a variable representing the level of a stimulus, N represents the number of subjects tested at each level of the stimulus, and Response is the number of subjects responding to that level of the stimulus. Both probit and logit response models are fit to the data. The LOG10 option in the PROC PROBIT statement requests that the log base 10 of Dose is used as the independent variable. Specifically, for a given level of Dose, the probability p of a positive response is modeled as

$$p = \Pr(\text{Response}) = F(b_0 + b_1 \times \log_{10}(\text{Dose}))$$

The probabilities are estimated first by using the normal distribution function (the default) and then by using the logistic distribution function. Note that, in this model specification, the natural rate is assumed to be zero.

The LACKFIT option specifies lack-of-fit tests and the INVERSECL option specifies inverse confidence limits.

In the DATA step that reads the data, a number of observations are generated that have a missing value for the response. Although the PROBIT procedure does not use the observations with the missing values to fit the model, it does give predicted values for all nonmissing sets of independent variables. These data points fill in the plot of fitted and observed values in the logistic model displayed in [Output 75.1.7](#). The plot, requested with the PLOT=PREDPLOT option, displays the estimated logistic cumulative distribution function and the observed response rates.

The following statements produce [Output 75.1.1](#):

```
data a;
    infile cards eof=eof;

Estimated Covariance Matrix for Tolerance Parameters		
	MU	SIGMA
MU	0.002418	-0.000409
SIGMA	-0.000409	0.004072

The p -values in the goodness-of-fit table of 0.6009 for the Pearson's chi-square and 0.4616 for the likelihood ratio chi-square indicate an adequate fit for the model fit with the normal distribution.

Tolerance distribution parameter estimates for the normal distribution indicate a mean tolerance for the population of 0.5303.

Output 75.1.2 displays probit analysis with the logarithm of dose levels. The LD50 (ED50 for log dose) is 0.5303, the dose corresponding to a probability of 0.5. This is the same as the mean tolerance for the normal distribution.

Output 75.1.2 Probit Analysis with Normal Distribution

The PLOT=PREDPLOT option together with the ODS GRAPHICS statement creates the plot of observed and fitted probabilities in [Output 75.1.7](#). The dashed line represent pointwise confidence bands for the probabilities.

Output 75.1.7 Plot of Observed and Fitted Probabilities

Example 75.2: Multilevel Response

In this example, two preparations, a standard preparation and a test preparation, are each given at several dose levels to groups of insects. The symptoms are recorded for each insect within each group, and two multilevel probit models are fit. Because the natural sort order of the three levels is not the same as the response order, the ORDER=DATA option is specified in the PROC PROBIT statement to get the desired order. The following statements fit two models:

```
data multi;
  input Prep $ Dose Symptoms $ N;
  LDose=log10(Dose);
  if Prep='test' then PrepDose=LDose;
  else PrepDose=0;
  datalines;
stand    10      None      33
stand    10      Mild       7
stand    10      Severe     10
stand    20      None      17
stand    20      Mild      13
stand    20      Severe     17
stand    30      None      14

  weight N;
run;
```

Results of these two models are shown in [Output 75.2.1](#) and [Output 75.2.2](#). The first model allows for nonparallelism between the dose response curves for the two preparations by inclusion of an interaction between Prep and LDose. The interaction term is labeled PrepDose in the “Analysis of Parameter Estimates” table. The results of this first model indicate that the parameter for the interaction term is not significant, having a Wald chi-square of 0.73. Also, since the first model is a generalization of the second, a likelihood ratio test statistic for this same parameter can be obtained by multiplying the difference in log likelihoods between the two models by 2. The value obtained, $2 \times (-345.94 - (-346.31))$, is 0.73. This is in close agreement with the Wald chi-square from the first model. The lack-of-fit test statistics for the two models do not indicate a problem with either fit.

Output 75.2.1 Multilevel Response: Nonparallel Analysis

The negative coefficient associated with LDose indicates that the probability of having no symptoms (Symptoms='None') or no or mild symptoms (Symptoms='None' or Symptoms='Mild') decreases as LDose increases; that is, the probability of a severe symptom increases with LDose. This association is apparent for both treatment groups.

The negative coefficient associated with the standard treatment group (Prep = stand) indicates that the standard treatment is associated with more severe symptoms across all Ldose values.

The following statements use the PLOTS= option to create the plot shown in [Output 75.2.3](#) and [Output 75.2.4](#). [Output 75.2.3](#) is the plot of the probabilities of the response taking on individual levels as a function of LDose. Since there are two covariates, LDose and Prep, the value of the classification variable Prep is fixed at the highest level, test. Instead of individual response level probabilities, the CDFPLOT option creates the plot of the cumulative response probabilities with confidence limits shown in [Output 75.2.4](#).

```
proc probit data=multi order=data
    plots=(predpplot(level=("None" "Mild" "Severe"))
           cdfplot(level=("None" "Mild" "Severe")));

Output 75.2.5 Plot of Predicted Probabilities for the Standard Preparation Group**Output 75.2.6** Plot of Predicted Cumulative Probabilities for the Standard Preparation Group

Example 75.3: Logistic Regression

In this example, a series of people are asked whether or not they would subscribe to a new newspaper. For each person, the variables `sex` (Female, Male), `age`, and `subs` (1=yes,0=no) are recorded. The PROBIT procedure is used to fit a logistic regression model to the probability of a positive response (subscribing) as a function of the variables `sex` and `age`. Specifically, the probability of subscribing is modeled as

$$p = \Pr(\text{subs} = 1) = F(b_0 + b_1 \times \text{sex} + b_2 \times \text{age})$$

where F is the cumulative logistic distribution function.

By default, the PROBIT procedure models the probability of the lower response level for binary data. One way to model $\Pr(\text{subs} = 1)$ is to format the response variable so that the formatted value corresponding to `subs=1` is the lower level. The following statements format the values of `subs` as 1 = 'accept' and 0 = 'reject', so that PROBIT models $\Pr(\text{accept}) = \Pr(\text{subs} = 1)$. They produce [Output 75.3.1](#).

```
data news;
  input sex $ age subs @@;
  datalines;

Output 75.3.1 continued

Analysis of Maximum Likelihood Parameter Estimates								
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr >	ChiSq
Intercept	1	-5.7620	2.7635	-11.1783	-0.3458	4.35		0.0371
sex Female	1	-2.4224	0.9559	-4.2959	-0.5489	6.42		0.0113
sex Male	0	0.0000
age	1	0.1649	0.0652	0.0371	0.2927	6.40		0.0114

Output 75.3.1 shows that there appears to be an effect due to both the variables `sex` and `age`. The positive coefficient for `age` indicates that older people are more likely to subscribe than younger people. The negative coefficient for `sex` indicates that females are less likely to subscribe than males.

Example 75.4: An Epidemiology Study

The data in this example, which are from an epidemiology study, consist of five variables: the number, `r`, of individuals surviving after an epidemic, out of `n` treated, for combinations of medicine dosage (`dose`), treatment (`treat` = A, B), and sex (`sex` = 0(Female), 1(Male)).

To see whether the two treatments have different effects on male and female individual survival rates, the interaction term between the two variables `treat` and `sex` is included in the model.

The following invocation of PROC PROBIT fits the binary probit model to the grouped data:

```
data epidemic;
  input treat$ dose n r sex @@;
  label dose = Dose;
  datalines;
A 2.17 142 142 0 A .57 132 47 1
A 1.68 128 105 1 A 1.08 126 100 0
A 1.79 125 118 0 B 1.66 117 115 1

treatBsex1	treat*sex	B	1

Output 75.4.3 displays background information about the model fit. Included are the name of the input data set, the response variables used, the numbers of observations, events, and trials, the type of distribution, and the final value of the log-likelihood function.

Output 75.4.3 Model Information

The Probit Procedure	
Model Information	
Data Set	WORK.EPIDEMIC
Events Variable	r
Trials Variable	n
Number of Observations	10
Number of Events	1011
Number of Trials	1204
Name of Distribution	Normal
Log Likelihood	-387.2467391

Output 75.4.4 displays the table of goodness-of-fit tests requested with the LACKFIT option in the PROC PROBIT statement. Two goodness-of-fit statistics, the Pearson's chi-square statistic and the likelihood ratio chi-square statistic, are computed. The grouping method for computing these statistics can be specified by the AGGREGATE= option. The details can be found in the AGGREGATE= option, and an example can be found in the second part of this example. By default, the PROBIT procedure uses the covariates in the MODEL statement to do grouping. Observations with the same values of the covariates in the MODEL statement are grouped into cells and the two statistics are computed according to these cells. The total number of cells and the number of levels for the response variable are reported next in the "Response-Covariate Profile."

In this example, neither the Pearson's chi-square nor the log-likelihood ratio chi-square tests are significant at the 0.1 level, which is the default test level used by the PROBIT procedure. That means that the model, which includes the interaction of treat and sex, is suitable for this epidemiology data set. (Further investigation shows that models without the interaction of treat and sex are not acceptable by either test.)

Output 75.4.4 Goodness-of-Fit Tests and Response-Covariate Profile

Goodness-of-Fit Tests				
Statistic	Value	DF	Value/DF	Pr > ChiSq
Pearson Chi-Square	4.9317	4	1.2329	0.2944
L.R. Chi-Square	5.7079	4	1.4270	0.2220
Response-Covariate Profile				
Response Levels		2		
Number of Covariate Values		10		

Output 75.4.5 displays the Type III test results for all effects specified in the MODEL statement, which include the degrees of freedom for the effect, the Wald Chi-Square test statistic, and the *p*-value.

Output 75.4.5 Type III Tests

Type III Analysis of Effects			
Effect	DF	Wald	Pr > ChiSq
		Chi-Square	
dose	1	42.1691	<.0001
treat	1	16.1421	<.0001
sex	1	1.7710	0.1833
treat*sex	1	13.9343	0.0002

Output 75.4.6 displays the table of parameter estimates for the model. The PROBIT procedure displays information for all the parameters of an effect. Degenerate parameters are indicated by 0 degree of freedom. Confidence intervals are computed for all parameters with nonzero degrees of freedom, including the natural threshold C if the OPTC option is specified in the PROC PROBIT statement. The confidence level can be specified by the ALPHA= option in the MODEL statement. The default confidence level is 95%.

Output 75.4.6 Analysis of Parameter Estimates

Analysis of Maximum Likelihood Parameter Estimates							
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	-0.8871	0.3632	-1.5991	-0.1752	5.96	0.0146

If the XDATA= option is used to input a data set for the independent variables in the MODEL statement, the PROBIT procedure uses these values for the independent variables other than the single continuous variable. Missing values are not permitted in the XDATA= data set for the independent variables, although the value for the single continuous variable is not used in the computing of the fiducial limits. A suitable valid value should be given. In the data set xval created by the SAS statements on page 6436, dose = 2.

Only one observation from the XDATA= data set is used to produce a probit analysis table for a combination of classification variable levels. If more than one observation is present in the XDATA= data set, only the last observation is used.

See the section “XDATA= SAS-data-set” on page 6411 for the default values for those effects other than the single continuous variable, for which the fiducial limits are computed.

In this example, there are two classification variables, treat and sex. Fiducial limits for the dose variable are computed for the highest level of the classification variables, treat = B and sex = 1, which is the default specification. Since these are the default values, you would get the same values and fiducial limits if you did not specify the XDATA= option in this example. The confidence level for the fiducial limits can be specified by the ALPHA= option in the MODEL statement. The default level is 95%.

If a LOG10 or LOG option is used in the PROC PROBIT statement, the values and the fiducial limits are computed for both the single continuous variable and its logarithm.

Output 75.4.10 displays the OUTEST= data set. All parameters for an effect are included. The name of a parameter is generated by combining the variable names and levels in the effect. The maximum length of a parameter name is 32.

Output 75.4.10 Outest Data Set for Epidemiology Study

The plots in the following three outputs, [Output 75.4.11](#), [Output 75.4.12](#), and [Output 75.4.13](#), are generated by the PLOTS= option. The first plot, specified with the PREDPPLOT option, is the plot of the predicted probability against the first single continuous variable dose in the MODEL statement. You can specify values of other independent variables in the MODEL statement by using an XDATA= data set or by using the default values.

The second plot, specified with the IPPPLOT option, is the inverse of the predicted probability plot with the fiducial limits. It should be pointed out that the fiducial limits are *not* just the inverse of the confidence limits in the predicted probability plot; see the section “[Inverse Confidence Limits](#)” on page 6410 for the computation of these limits. The third plot, specified with the LPREDPLOT option, is the plot of the linear predictor $\mathbf{x}'\boldsymbol{\beta}$ against the first single continuous variable with the Wald confidence intervals.

Output 75.4.11 Predicted Probability Plot

Output 75.4.12 Inverse Predicted Probability Plot

Output 75.4.13 Linear Predictor Plot

When you combine the INEST= data set and the MAXIT= option in the MODEL statement, the PROBIT procedure can do prediction, if the parameterizations for the models used for the training data and the validation data are exactly the same. The following SAS statements show an example:

```
data validate;
  input treat $ dose sex n r group @@;
  datalines;
B 2.0 0 44 43 1 B 2.0 1 54 52 2
B 1.5 1 36 32 3 B 1.5 0 45 40 4
A 2.0 0 66 64 5 A 2.0 1 89 89 6
A 1.5 1 45 39 7 A 1.5 0 66 60 8
B 2.0 0 44 44 1 B 2.0 1 54 54 2
B 1.5 1 36 30 3 B 1.5 0 45 41 4
A 2.0 0 66 65 5 A 2.0 1 89 88 6
A 1.5 1 45 38 7 A 1.5 0 66 59 8
;

proc probit optc data=validate inest=out1;
  class treat sex;
  model r/n = dose treat sex sex*treat / maxit = 0;
  output out = out3 p =p;
run;

proc probit optc lackfit data=validate inest=out1;
  class treat sex;
  model r/n = dose treat sex sex*treat / aggregate = group;
  output out = out4 p =p;
run;
```

After the first invocation of PROC PROBIT, you have the estimated parameters and their covariance matrix in the data set OUTEST = Out1, and the fitted probabilities for the training data set epidemic in the data set OUTPUT = Out2. See [Output 75.4.10](#) for the data set Out1 and [Output 75.4.14](#) for the data set Out2.

The validation data are collected in data set validate. The second invocation of PROC PROBIT simply passes the estimated parameters from the training data set epidemic to the validation data set validate for prediction. The predicted probabilities are stored in the data set OUTPUT = Out3 (see [Output 75.4.15](#)). The third invocation of PROC PROBIT passes the estimated parameters as initial values for a new fit of the validation data set with the same model. Predicted probabilities are stored in the data set OUTPUT = Out4 (see [Output 75.4.16](#)). Goodness-of-fit tests are computed based on the cells grouped by the AGGREGATE= group variable. Results are shown in [Output 75.4.17](#).

Example 75.5: Model Postfitting Analysis

Recall the previous example of an epidemic study, in which the `treat*sex` interaction is statistically significant. Suppose you want to know whether such an effect is the same at different levels of the two categorical variables.

The following SAS statements fit a probit model and use the `SLICE` statement to request analysis of the two-way interaction term `treat*sex`:

```
proc probit data=epidemic;
  class treat sex;
  model r/n = dose treat sex treat*sex;
  slice treat*sex / diff;
  effectplot;
run;
```

Output 75.5.1 displays the test results for the interaction effect. As you can see, the difference between the two treatments is not significant among females.

Output 75.5.1 Tests Conditional on treat*sex

The Probit Procedure			
Chi-Square Test for treat*sex Least Squares Means Slice			
Slice	Num DF	Chi-Square	Pr > ChiSq
treat A	1	18.52	<.0001
Chi-Square Test for treat*sex Least Squares Means Slice			
Slice	Num DF	Chi-Square	Pr > ChiSq
treat B	1	2.65	0.1035
Chi-Square Test for treat*sex Least Squares Means Slice			
Slice	Num DF	Chi-Square	Pr > ChiSq
sex 0	1	0.00	0.9579
Chi-Square Test for treat*sex Least Squares Means Slice			
Slice	Num DF	Chi-Square	Pr > ChiSq
sex 1	1	47.43	<.0001

The DIFF option computes effect differences between groups within the same slice. Results are displayed in [Output 75.5.2](#).

Output 75.5.2 Effect Differences Conditional on treat*sex

Simple Differences of treat*sex Least Squares Means						
Slice	sex	_sex	Estimate	Standard Error	z Value	Pr > z
treat A	0	1	0.5957	0.1384	4.30	<.0001

Output 75.5.2 *continued*

Simple Differences of treat*sex Least Squares Means						
Slice	sex	_sex	Estimate	Standard Error	z Value	Pr > z
treat B	0	1	-0.2956	0.1816	-1.63	0.1035
Simple Differences of treat*sex Least Squares Means						
Slice	treat	_treat	Estimate	Standard Error	z Value	Pr > z
sex 0	A	B	-0.00899	0.1702	-0.05	0.9579
Simple Differences of treat*sex Least Squares Means						
Slice	treat	_treat	Estimate	Standard Error	z Value	Pr > z
sex 1	A	B	-0.9003	0.1307	-6.89	<.0001

The EFFECTPLOT statement produces a predicted probability plot for dose by the four groups that are formed by the treat*sex interaction. The plot is displayed in [Output 75.5.3](#). The two overlapping curves represent the two treatment groups for females, suggesting no treatment effect. It appears that males tend to respond to the two treatments differently: those on treatment B have a better survival rate, and those on treatment A have a worse chance of survival.

Output 75.5.3 Predicted Probability versus Dose Level by treat*sex

Overview: QUANTLIFE Procedure

The QUANTLIFE procedure performs quantile regression analysis for survival data, where observations are not always directly observed.

Quantile regression (Koenker and Bassett 1978) is a type of regression analysis that explores how the conditional quantile of a response variable depends on its covariates. By estimating a set of conditional quantiles, you can gain more insight about the conditional distribution of the response given its covariates.

Quantile regression provides a flexible way to capture heterogeneous effects in the sense that the tails and the central location of the conditional distributions can vary differently with the covariates. Thus, quantile regression offers a powerful tool in survival analysis, where the lifetimes are skewed, and extreme survival times can be of special interest (Koenker and Geling 2001; Huang 2010).

When the observations are fully observed, you can use the QUANTREG procedure to fit a standard quantile regression model. See Chapter 77, “The QUANTREG Procedure,” for an introduction to the basic concepts of quantile regression analysis.

However, lifetime data often contain incomplete observations because of censoring (Klein and Moeschberger 2003; Hosmer, Lemeshow, and May 2008). When censoring occurs, the usual standard quantile regression approach can lead to biased estimates. Thus, special approaches have been developed that account for censoring and provide valid estimates. Portnoy (2003) proposed a method to estimate conditional quantile functions by generalizing the idea of the Kaplan-Meier estimator of the survival function. Peng and Huang (2008) developed a different quantile regression approach that is motivated by the Nelson-Aalen estimator of the cumulative hazard function. Both methods can be implemented with linear programming algorithms and both are available in the QUANTLIFE procedure. Like the standard quantile regression method for uncensored data, these two methods are distribution-free and apply to heteroscedastic data.

Features

The QUANTLIFE procedure provides the following features:

- quantile regression methods for censored data that are based on generalizations of the Kaplan-Meier and the Nelson-Aalen estimator
- the interior point algorithm for parameter estimation, which uses parallel computing when multiple processors are available
- hypothesis tests for the regression parameter
- semiparametric quantile regression that uses spline effects
- survival plots, conditional quantile plots, and quantile process plots

Quantile Regression

Suppose a data set contains observations (Y_i, x_i) , where Y_i is a dependent variable of interest (such as the survival time or some monotone transformation of the survival time) and x_i is a $p \times 1$ vector of covariates.

You can use regression analysis to explore the relationship between a response Y_i and its predictor x_i . Classical linear regression estimates the conditional mean function $E(Y_i|x_i)$ with a linear predictor $x_i'\beta$; a linear quantile regression estimates the τ th conditional quantile function $Q_\tau(Y_i|x_i)$ with a different linear predictor $x_i'\beta(\tau)$, where the quantile level τ ranges between 0 and 1. For example, $x_i'\beta(0.95)$ is the linear predictor for the 0.95th quantile (commonly referred to as the 95th percentile).

The quantile regression coefficient $\beta(\tau)$ can be estimated by minimizing the following objective function over b :

$$r(b) = \sum_{i=1}^n \rho_{\tau}(Y_i - x_i' b),$$

The loss function $\rho_{\tau}(u)$ is defined as $u(\tau - I(u < 0))$, in contrast to the square loss function for classical linear regression.

When $\tau = 0.5$, the coefficient $\beta(0.5)$ minimizes the sum of absolute residuals, which corresponds to median regression (or L_1 regression).

The following set of regression quantiles is referred to as the *quantile process*, and it completely describes the conditional distribution of Y_i given the predictor x_i :

$$\{\beta(\tau) : \tau \in (0, 1)\}$$

When all the observations are observed, you can use the QUANTREG procedure to estimate the quantile function $Q(\tau|X = x)$ and draw statistical inference about the regression parameters $\beta(\tau)$. See Chapter 77, “The QUANTREG Procedure,” for details.

However, when the observations are incomplete, as is the case with censored data in survival analysis, the classical quantile regression method is not appropriate. The QUANTLIFE procedure implements appropriate quantile regression methods to model the relationship between the response Y_i and the predictor x_i .

Getting Started: QUANTLIFE Procedure

This example uses the human immunodeficiency virus (HIV) study data from Hosmer and Lemeshow (1999) to illustrate the basic features of PROC QUANTLIFE.

In this study, subjects were followed after a confirmed diagnosis of HIV. The primary goal was to evaluate the effect of various factors on the survival time. Two covariates for each subject were collected: age and history of prior intravenous drug use.

The following DATA step creates the data set HIV, which contains the variable Time (the follow-up time in days), the variable Status (with value 0 if Time was censored and 1 otherwise), the variable Drug (with value 1 for prior intravenous drug use and 0 otherwise), and the variable Age (the patient’s age in years at the beginning of the follow-up).

```
data HIV;
  input Time Age Drug Status;
  datalines;
    5      46      0      1
    6      35      1      0
    8      30      1      1
    3      30      1      1
    22     36      0      1
    1      32      1      0

    ... more lines ...

    1      34      1      1
;
```

You can use PROC QUANTLIFE to explore the relationship between the survival time and the two covariates at different quantiles.

Suppose you are interested in the median survivors and in the longer and shorter survivors. The following statements fit a linear model for the 25th, 50th, and 75th percentiles:

```
ods graphics on;
proc quantlife data=hiv log plots=quantplot seed=1268;
  class Drug;
  model Time*Status(0) = Drug Age / quantile=(0.25 0.5 0.75);
  Drug_Effect: test Drug;
run;
```

The LOG option fits a quantile regression model for the log of Time, as is done by an accelerated failure time (AFT) model in standard survival analysis. The SEED= option is specified to maintain reproducibility of the resampling method that is used for statistical inference.

The MODEL statement specifies the response variable, Time, and the censoring variable, Censor. The value that indicates censoring is enclosed in parentheses. The values of Time are considered to be censored if the value of Censor is 0; otherwise, they are considered to be event times. The QUANTILE= option requests a fit of the conditional quantile function $Q(\tau|X = x)$ at the quantile levels 0.25, 0.5, and 0.75.

The TEST statement requests a test for the hypothesis that there is no Drug effect at each of the quantile levels.

Figure 76.1 displays basic model information. For example, you can see from Figure 76.1 that the response is log(Time), and the censoring rate is 20%.

Figure 76.1 Model Fitting Information

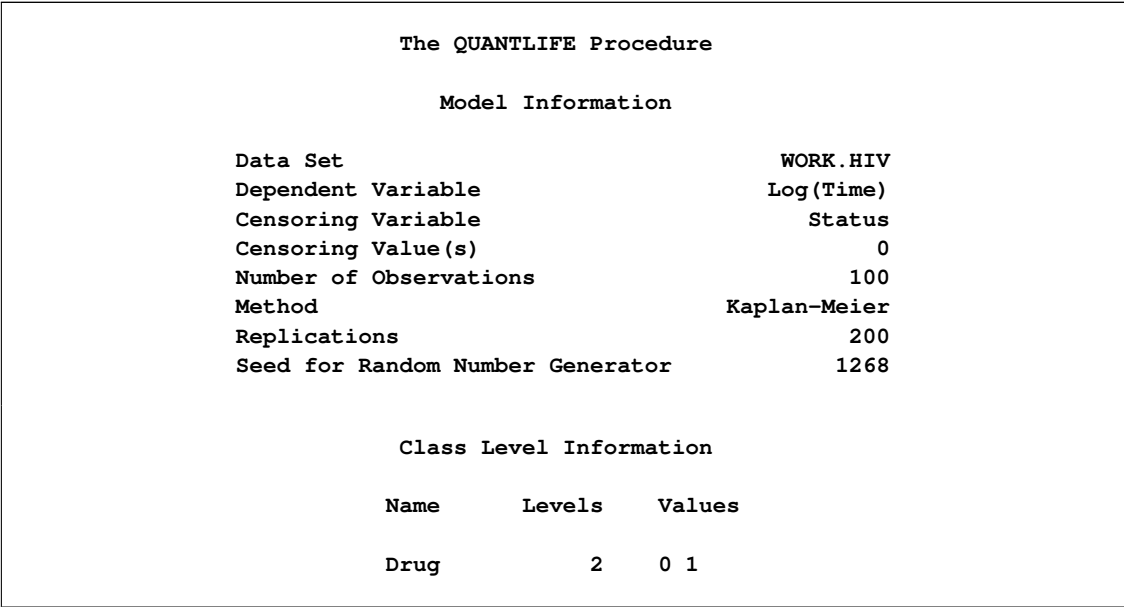

Figure 76.1 *continued*

Summary of the Number of Event and Censored Values			
Total	Event	Censored	Percent Censored
100	80	20	20.00

Figure 76.2 displays the parameter estimates, which are computed using the default Kaplan-Meier-type estimator. See the section “[Kaplan-Meier-Type Estimator for Censored Quantile Regression](#)” on page 6468 for details. In addition, Figure 76.2 displays standard errors, 95% confidence limits, t values, and p -values that are computed by the default resampling method, exponentially weighted resampling. See the section “[Exponentially Weighted Method](#)” on page 6470.

A different quantile regression model is fitted for each quantile, and the first column (Quantile) in Figure 76.2 identifies the model for the parameter estimates. Age has a negative effect on survival time. You can use the parameter estimates to predict the survival time at the quantiles of interests. For example, the 75th percentile survival time for a person with no previous IV drug use at age 45 is

$$\exp(5.3351 + 1.1451 - 0.0941 \times 36) = 9.4 \text{ years}$$

	Drug 1	0	0	0	0	0	.	.
	Age	1	-0.1059	0.0194	-0.1439	-0.0679	-5.46	<.0001
0.7500	Intercept	1	5.3351	0.9091	3.5532	7.1170	5.87	<.0001
	Drug 0	1	1.1451	0.2625	0.6307	1.6596	4.36	<.0001
	Drug 1	0	0	0	0	0	.	.
	Age	1	-0.0941	0.0223	-0.1378	-0.0505	-4.23	<.0001

The PLOTS=QUANTPLOT option in the PROC QUANTLIFE statement requests the quantile process plots, which are shown in Figure 76.3. The quantile process plot is a scatter plot of an estimated regression. Figure 76.3 shows that the estimated coefficients for the two covariates does not change much across quantiles.

Figure 76.3 Estimated Parameters

The tests that are requested by the TEST statement are shown in Figure 76.4.

Figure 76.4 Tests of Significance

Test Drug_Effect Results				
Quantile	DF	Chi-Square	Pr > ChiSq	
0.2500	1	4.67	0.0307	
0.5000	1	9.70	0.0018	
0.7500	1	19.03	<.0001	

The tests indicate that the coefficient of Drug is significantly different from 0 at the 25th, 50th, and 75th percentiles.

Syntax: QUANTLIFE Procedure

The following statements are available in the QUANTLIFE procedure:

```

PROC QUANTLIFE < options > ;
  BASELINE < options > ;
  BY variables ;
  CLASS variables ;
  EFFECT name = effect-type ( variables < / options > ) ;
  MODEL response < * censor(list) > = < effects > < / options > ;
  OUTPUT < OUT=SAS-data-set> < keyword=name ... keyword=name > ;
  TEST effects < / options > ;
  WEIGHT variable ;

```

The PROC QUANTLIFE and MODEL statements are required. The PROC QUANTLIFE statement invokes the procedure. The CLASS statement specifies which explanatory variables are treated as categorical. The MODEL statement specifies the variables to be used in the regression. You can specify main effects and interaction terms in the MODEL statement, as you can in the GLM procedure (Chapter 42, “[The GLM Procedure](#).”) The OUTPUT statement creates an output data set to contain predicted values, residuals, and estimated standard errors. The TEST statement requests linear tests for the model parameters. The WEIGHT statement identifies a variable in the input data set whose values are used to weight the observations. In one invocation of PROC QUANTLIFE, multiple OUTPUT and TEST statements are allowed.

The rest of this section provides detailed syntax information for each statement, beginning with the PROC QUANTLIFE statement. The remaining statements are covered in alphabetical order.

PROC QUANTLIFE Statement

```
PROC QUANTLIFE < options > ;
```

The PROC QUANTLIFE statement invokes the QUANTLIFE procedure. [Table 76.1](#) summarizes the options available in this statement.

Table 76.1 Options Available in the PROC QUANTLIFE Statement

Option	Description
Data Set Options	
DATA=	Specifies the input SAS data set
OUTBOOTEST=	Creates an output SAS data set for parameter estimates from resampled data sets
Basic Options	
ALPHA=	Specifies the confidence level
CI=	Specifies a resampling method for computing confidence interval and test statistics
LOG	Requests log transformation of the response
METHOD=	Specifies a method to fit quantile regression
NAMELEN=	Specifies the length of effect names
NREP=	Specifies the number of replications
SEED=	Specifies the seed for the random number generator

Table 76.1 *continued*

Option	Description
PLOTS=	Specifies the plots to be produced with ODS graphics
Computational Options	
GRIDSIZE=	Specifies a step size for the grid for computing regression quantiles
INITTAU=	Specifies the first quantile level for computing regression quantiles
KAPPA=	Specifies the step-length parameter for the interior point algorithm
MAXIT=	Specifies the maximum number of iterations for the interior point algorithm
TOLERANCE=	Specifies the convergence criterion of the interior point algorithm

You can specify the following *options* in the PROC QUANTLIFE statement.

ALPHA=*value*

specifies the confidence level for the regression parameters. The *value* must be between 0 and 1. The default is ALPHA=0.05, which corresponds to a 95% confidence interval.

CI= EW | PW | NONE

specifies the method used to compute confidence intervals for regression parameters. In addition to confidence intervals, the QUANTLIFE procedure also computes standard errors, *t* values, and *p*-values for regression parameters. You can suppress these computations by specifying CI=NONE. The QUANTLIFE procedure provides two resampling methods for computing confidence intervals, the exponentially weighted (EW) method and the pairwise (PW) resampling method. See the section “[Confidence Interval](#)” on page 6470 methods for details. The default is CI=EW, which requests the exponentially weighted method.

DATA=*SAS-data-set*

specifies the input SAS data set that the QUANTLIFE procedure uses. By default, the most recently created SAS data set is used.

GRIDSIZE=*value*

specifies the step size for computing regression quantiles. The *value* must be between 0 and 1. See the section “[Details: QUANTLIFE Procedure](#)” on page 6468 for details.

INITTAU=*value*

specifies the first quantile level for computing regression quantiles. The *value* must be between 0 and 1. See the section “[Details: QUANTLIFE Procedure](#)” on page 6468 for details.

KAPPA=*value*

specifies the step-length parameter for the interior point algorithm. The *value* must be between 0 and 1. The interior point method used by the QUANTLIFE is identical to the interior point method used by the QUANTREG procedure. See the section Chapter 77.13, “[Interior Point Algorithm](#),” for details. The default is KAPPA=0.99995.

LOG

requests that a log transformation of the response variable be performed before the model is fitted.

MAXIT=*n*

specifies the maximum number of iterations for the interior point algorithm. The default is MAXIT=1000.

METHOD= KM | NA

specifies the method used to estimate the regression parameters. KM specifies the Kaplan-Meier-type method (see the section “[Kaplan-Meier-Type Estimator for Censored Quantile Regression](#)” on page 6468) and NA specifies the Nelson-Aalen-type method (see the section “[Nelson-Aalen-Type Estimator for Censored Quantile Regression](#)” on page 6469). The default is METHOD=KM.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default is NAMELEN=20.

NREP=*n*

specifies the number of replications to draw in the resampling method. The default is NREP=200.

OUTBOOTEST=SAS-data-set

creates a data set to contain the parameter estimates from the resampled data sets.

See the section “[OUTBOOTEST= Output Data Set](#)” on page 6471 for a detailed description of the contents of the OUTBOOTEST= data set.

PLOTS =(plot-request < ...plot-request >)

requests various plots.

When you specify one *plot-request*, you can omit the parentheses around the plot request.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc quantlife plots=survival;
  model y=x1;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

You can specify one or more of the following *plot-requests*:

ALL

creates all appropriate plots.

NONE

suppresses all the plots in the procedure. Specifying this option is equivalent to disabling ODS Graphics for the entire procedure.

QUANTILE

plots the estimated quantile function for each combination of covariate values in the COVARIATES= data set specified in the BASELINE statement. If the COVARIATES= data set is not specified, the estimated quantile function is plotted for the reference set of covariate values that consists of reference levels for the CLASS variables and average values for the continuous variables. When the estimated quantile function is not monotonic, the quantile function (Chernozhukov, Fernandez-Val, and Galichon 2009) is rearranged to make it monotonic and then plotted.

QUANTPLOT < / UNPACK >

plots the regression quantile process. The estimated coefficient of each specified covariate effect is plotted as a function of the quantile level. You can use the UNPACK option to create individual process plots.

SURVIVAL

plots the estimated survival function for each combination of covariate values in the COVARIATES= data set specified in the BASELINE statement. If the COVARIATES= data set is not specified, the estimated survival function is plotted for the reference set of covariate values that consists of reference levels for the CLASS variables and average values for the continuous variables.

SEED=number

specifies a positive integer to start the pseudorandom number generator. The default is a value that is generated from reading the time of day from the computer's clock. However, to duplicate the results under identical situations, you must specify the same seed in subsequent runs of the QUANTLIFE procedure. The seed information is displayed in the "Model Information" table.

TOLERANCE=value

specifies the tolerance for the convergence criterion of the interior point algorithm. Both the QUANTLIFE procedure and the QUANTREG procedure use the duality gap as the convergence criterion. See Chapter 77.13, "[Interior Point Algorithm](#)," for details. The default is TOLERANCE=1E-8.

BASELINE Statement

```
BASELINE < OUT=SAS-data-set> < COVARIATES=SAS-data-set> < keyword=name ... keyword=name>
;
```

The BASELINE statement creates an output data set to contain the survival function estimates or the conditional quantile function estimates for every set of covariates (x) in the COVARIATES= data set. If the COVARIATES= data set is not specified, PROC QUANTLIFE uses a reference set of covariates that consists of the reference levels for the CLASS variables and the average values for the continuous variables.

The following options are available in the BASELINE statement.

OUT=SAS-data-set

names the output data set. If you omit the OUT= option, the data set is created and given a default name by using the DATA n convention. See the section "[OUT= Output Data Set in the BASELINE Statement](#)" on page 6471 for more information.

COVARIATES=SAS-data-set

names the SAS data set that contains the sets of explanatory variable values for which the quantities of interest are estimated. All variables in the COVARIATES= data set are copied to the OUT= data set. Thus, the variables in the COVARIATES= data set can be used to identify the covariate sets in the OUT= data set.

keyword =name

specifies the statistics to be included in the OUT= data set and assigns names to the variables that contain these statistics. Specify a *keyword* for each desired statistic, an equal sign, and the name of the variable for the statistic.

You can specify the following *keywords*:

SURVIVAL

specifies the estimated survival function.

QUANTILE

specifies the estimated quantile function.

TAU

specifies the quantile level, which is the complement of the survival function.

BY Statement

BY variables ;

You can specify a BY statement with PROC QUANTLIFE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the QUANTLIFE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / **TRUNCATE** > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*.

You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables.

EFFECT Statement

EFFECT *name=effect-type* (*variables* < / *options* >) ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.
MULTIMEMBER MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 76.2 summarizes the *options* available in the EFFECT statement.

Table 76.2 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect
Lag Effects Options	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Multimember Effects Options	
NOEFFECT	Specifies that observations with all missing levels for the multi-member variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

MODEL Statement

MODEL *response* < * *censor(list)* > = < *effects* > < / *options* > ;

The MODEL statement identifies the response variable, the optional censoring variable, and the explanatory effects, including covariates, main effects, interactions, and nested effects; see the section “Specification of Effects” on page 3324 of Chapter 42, “The GLM Procedure,” for more information. In the MODEL

statement, the response variable precedes the equal sign. This name can optionally be followed by an asterisk, the name of the censoring variable, and a list of censoring values (separated by blanks or commas if you list more than one value) enclosed in parentheses. If the censoring variable takes on one of these values, the corresponding failure time is considered to be censored. Following the equal sign are the explanatory effects (sometimes called independent variables or covariates) for the model.

The censoring variable must be numeric.

Options

You can specify the following *options* after a slash (/).

NOINT

specifies no intercept regression.

QUANTILE=*number-list* | PROCESS

specifies the quantile levels of interest for quantile regression analysis. You can specify any number of quantile levels in the interval (0, 1). You can also compute the entire quantile process by specifying the PROCESS option.

If you do not specify the QUANTILE= option, the QUANTLIFE procedure fits a median regression, which corresponds to QUANTILE=0.5.

OUTPUT Statement

OUTPUT < **OUT**=*SAS-data-set* > *keyword=name* < . . . *keyword=name* > ;

The OUTPUT statement creates a SAS data set to contain statistics that are calculated after fitting models for all quantiles specified by the QUANTILE= option in the MODEL statement. At least one specification of the form *keyword=name* is required.

All variables in the original data set are included in the new data set, along with the variables that are created. These new variables contain fitted values and estimated quantiles. If you want to create a permanent SAS data set, you must specify a two-level name (see the section “SAS Files” in *SAS Language Reference: Concepts* for more information about permanent SAS data sets).

The following specifications can appear in the OUTPUT statement:

OUT=*SAS-data-set* specifies the new data set. By default, the procedure uses the *DATAn* convention to name the new data set. See the section “[OUT= Output Data Set in the OUTPUT Statement](#)” on page 6471 for more information.

keyword=name specifies the statistics to include in the output data set and gives names to the new variables. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable to contain the statistic.

You can specify the following *keywords*, which represent the indicated statistics:

PREDICTED P	specifies a variable to contain the predicted response.
RESIDUAL RES	specifies a variable to contain the residuals, $y_i - x_i' \hat{\beta}(\tau)$.
SAMPLEWEIGHT SW	specifies variables for sample weights from the bootstrap samples. For the i th sample, a column that contains the weights that are used for that sample is added. The name of this column is formed by appending an index i to the name that you specify. If you do not specify a name, then the default prefix is <i>sw</i> .
STDP	specifies a variable to contain the estimates of the standard errors of the estimated response.

TEST Statement

< label: > TEST effects < / options > ;

In quantile regression analysis, you might be interested in testing whether a covariate effect is statistically significant for a given quantile. You can use the TEST statement to obtain a test for the canonical linear hypothesis concerning the parameters of the tested *effects*,

$$\beta_j = 0, \quad j = i_1, \dots, i_q$$

where q is the total number of parameters of the tested effects. The tested *effects* can be any set of effects in the MODEL statement.

You can include multiple TEST statements, provided that they appear after the MODEL statement. The optional *label*, which must be a valid SAS name, is used to identify output from the corresponding TEST statement. See the section “[Testing Effects of Covariates](#)” on page 6470 for more information about these tests.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement specifies a weight variable in the input data set.

To request weighted quantile regression, place the weights in a variable and specify the name in the WEIGHT statement. The values of the WEIGHT variable can be nonintegral and are not truncated. Observations with nonpositive or missing values for the weight variable do not contribute to the fit of the model. See the section Chapter 77.13, “[Details: QUANTREG Procedure](#),” for more information about weighted quantile regression.

Details: QUANTLIFE Procedure

Notation for Censored Quantile Regression

Let T be a dependent variable, such as a survival time, and let x be a $p \times 1$ covariate vector. Quantile regression methods focus on modeling the conditional quantile function, $Q_\tau(T|x)$, which is defined as

$$Q_\tau(T|x) = \inf\{t : P(T \leq t|x) = \tau\}, 0 < \tau < 1$$

For example, $Q_{0.5}(T|x)$ is the conditional median quantile, and $Q_{0.95}(T|x)$ is the conditional quantile function that corresponds to the 95th percentile.

A linear quantile regression model for $Q_\tau(T|x)$ has the form $x'\beta(\tau)$. One of the advantages of quantile regression analysis is that the covariate effect $\beta(\tau)$ can change with τ . Unlike ordinary least squares regression, which estimates the conditional expectation function $E(T|x)$, quantile regression offers the flexibility to model the entire conditional distribution.

Given observations $(T_i, x_i), i = 1, \dots, n$, standard quantile regression estimates the regression coefficients $\beta(\tau)$ by minimizing the following objective function over b :

$$r(b) = \sum_{i=1}^n \rho_\tau(T_i - x_i' b)$$

where $\rho_\tau(u) = u(\tau - I(u < 0))$.

However, in many applications, the responses T_i are subject to censoring. For example, in a biomedical study, censoring occurs when patients withdraw from the study or die from a cause that is unrelated to the disease being studied.

Let C_i denote the censoring variable. In the case of right-censoring, the triples (x_i, Y_i, Δ_i) are observed, where $Y_i = \min(T_i, C_i)$ and $\Delta_i = I(T_i \leq C_i)$ are the observed response variable and the censoring indicator, respectively. Standard quantile regression leads to a biased estimator of the regression parameters $\beta(\tau)$.

The following sections describe two methods for estimating the quantile coefficient $\beta(\tau)$ in the presence of right-censoring.

Kaplan-Meier-Type Estimator for Censored Quantile Regression

Portnoy (2003) proposes the use of weighted quantile regression to sequentially estimate $\beta(\tau_k)$ along the equally spaced grid $0 < \tau_1 < \dots < \tau_M < 1$. You can request this method by specifying the METHOD=KM option in the PROC QUANTLIFE statement. The grid points $0 < \tau_1 < \dots < \tau_M < 1$ are equally spaced with τ_1 specified by the INITTAU= option and the step between adjacent grid points specified by the GRIDSIZE=option.

This method uses a weight function $w_i(\tau)$ for each censored observation. The weight function is constructed as follows: Let $\hat{\tau}_i$ be the first grid point at which $x_i'\hat{\beta}(\tau_i) \geq C_i$ and $x_i'\hat{\beta}(\tau_{i+1}) < C_i$; otherwise let $\hat{\tau}_i = 1$. When computing the τ th quantile, assign weight $w_i(\tau) = \frac{\tau - \hat{\tau}_i}{1 - \hat{\tau}_i}$ to the censored observation Y_i if $\tau > \hat{\tau}_i$; otherwise assign $w_i(\tau) = 1$. The algorithm for computing $\hat{\beta}(\tau_k), k = 1, \dots, M$ is as follows:

1. Compute $\hat{\beta}(\tau_1)$ by using the standard quantile regression method.
2. For $k = 2, \dots, M$, obtain $\hat{\beta}(\tau_k)$ sequentially by minimizing the following weighted quantile regression objective function:

$$r_w(b) = \sum_{\Delta_i=1} \rho_{\tau_k}(Y_i - x_i' b) + \sum_{\Delta_i=0} \{w_i(\tau_k) \rho_{\tau_k}(Y_i - x_i' b) + (1 - w_i(\tau_k)) \rho_{\tau_k}(Y^* - x_i' b)\}$$

where $w_i(\tau_k)$ is the weight for the right-censored observation Y_i at computing $\hat{\beta}(\tau_k)$, and the complementary weight $1 - w_i(\tau_k)$ are for Y^* , a large constant that is greater than all $x_i' \hat{\beta}(\tau)$.

The weighted quantile regression method is similar to Efron's redistribution-of-mass idea (Efron 1967) for the Kaplan-Meier estimator.

Note that if all observations are uncensored, $\hat{\beta}(\tau_k)$ is the same as the standard quantile regression estimator.

Nelson-Aalen-Type Estimator for Censored Quantile Regression

Peng and Huang (2008) propose a method for censored quantile regression that is based on the Nelson-Aalen estimator of the cumulative hazard function. Let $F_i(t|x) = P(T_i \leq t|x_i)$, $\Lambda(t|x_i) = -\log(1 - F_i(t|x_i))$, and $N_i(t) = I\{\{T_i \leq t\} \text{ and } \{\Delta_i = 1\}\}$. Then the following equation is a martingale process that is associated with the counting process $N_i(t)$ (Fleming and Harrington 1991):

$$M_i(t) = N_i(t) - \Lambda(t \wedge Y_i | x)$$

Based on the martingale process, Peng and Huang (2008) derive the following estimating equation:

$$n^{-1/2} \sum_{i=1}^n x_i [N_i(\exp(x_i' \beta(\tau))) - \int_0^\tau I(Y_i \geq \exp(x_i' \beta(u))) dH(u)] = 0$$

where $H(u) = -\log(1 - u)$ and $u \in [0, 1)$. By approximating the integral in the estimating equation on a grid $0 = \tau_0 < \tau_1 < \dots < \tau_M < 1$, the regression quantiles $\beta(\tau_k)$, $k = 1, \dots, M$, can be estimated sequentially by solving the following linear programming problem:

$$\min \{\alpha(\tau_k)' u + (\Delta - \alpha(\tau_k))' v \mid z = Xb + u - v, u \geq 0, v \geq 0\}$$

where

$$\alpha(\tau_k) = \sum_{j=1}^{k-1} I(Y_i \geq \exp(x_i' \hat{\beta}(\tau_j))) H((u_{j+1}) - H(u_j))$$

See Koenker (2008) for details. You can request this method by specifying the METHOD=NA option. The grid points $0 = \tau_0 < \tau_1 < \dots < \tau_M < 1$ are equally spaced with τ_1 specified by the INITAU=option and the grid step between two adjacent grid points specified by the GRIDSIZE=option.

Confidence Interval

Direct computation of the covariance of the parameter estimators involves a complicated density estimation. Instead, the QUANTLIFE procedure computes confidence intervals for the quantile regression parameters $\beta(\tau)$ by using resampling methods. The QUANTLIFE procedure implements two different methods, the exponentially weighted method and the pairwise resampling method.

Exponentially Weighted Method

This method samples weights $w_i, i = 1, \dots, n$, from a standard exponential distribution with mean 1 and variance 1. Then it computes the censored quantile regression estimators $\hat{\beta}(\tau)$ based on the observed data (x_i, Y_i, Δ_i) with the weights w_i . These steps are repeated B times (where B is the value of the NREP= option in the PROC QUANTLIFE statement). The confidence intervals can be obtained from these B estimates. You can specify this method with the CI=EW option in the PROC QUANTLIFE statement.

Pairwise Method

This method samples (x_i, Y_i, Δ_i) with replacement and computes the quantile regression estimators $\hat{\beta}(\tau)$ based on the resampled data. These steps are repeated B times (where B is the value of the NREP= option in the PROC QUANTLIFE statement). The confidence intervals can be obtained from these B estimates. You can specify this method with the CI=PW option in the PROC QUANTLIFE statement.

Testing Effects of Covariates

Consider the linear model

$$y_i = \mathbf{x}'_{1i}\boldsymbol{\beta}_1 + \mathbf{x}'_{2i}\boldsymbol{\beta}_2 + \epsilon_i$$

where $\boldsymbol{\beta}_1$ and $\boldsymbol{\beta}_2$ are p -dimensional and q -dimensional parameters, respectively, and $\epsilon_i, i = 1, \dots, n$, are errors. Denote $\mathbf{x}'_i = (\mathbf{x}'_{1i}, \mathbf{x}'_{2i})$, and let $\hat{\boldsymbol{\beta}}_1(\tau)$ and $\hat{\boldsymbol{\beta}}_2(\tau)$ be the parameter estimates for $\boldsymbol{\beta}_1$ and $\boldsymbol{\beta}_2$, respectively, at the τ th quantile.

The QUANTLIFE procedure implements the Wald test for the hypothesis:

$$H_0 : \beta_2(\tau) = 0$$

The Wald test statistic, which is based on the estimated coefficients $\hat{\boldsymbol{\beta}}_2$ from the unrestricted fitted model, is given by

$$T_W(\tau) = \hat{\boldsymbol{\beta}}_2'(\tau) \hat{\Sigma}(\tau)^{-1} \hat{\boldsymbol{\beta}}_2(\tau)$$

where $\hat{\Sigma}(\tau)$ is an estimator of the covariance of $\hat{\boldsymbol{\beta}}_2(\tau)$, which is obtained by using resampling methods.

Output Data Sets

OUTBOOTEST= Output Data Set

The OUTBOOTEST= data set contains parameter estimates for the specified model from resampled data sets. A set of observations is created for each quantile level and for each resampled data set.

If the QUANTLIFE procedure does not produce valid solutions, the parameter estimates are set to missing in the OUTBOOTEST= data set.

If created, this data set contains all variables that are specified in the MODEL statement. Each observation contains parameter estimates for a specified quantile level.

The following variables are also included in the data set:

- any specified BY variables
- `_STATUS_`, a character variable of length 12 that contains the status of the model fit: either NORMAL, NOUNIQUE, or NOVALID
- Intercept, a numeric variable that contains the intercept parameter estimates
- `_TAU_`, a numeric variable that contains the specified quantile levels

For continuous explanatory variables, the names of the parameters are the same as they are for the corresponding variables. For CLASS variables, the parameter names are obtained by concatenating the corresponding CLASS variable name with the CLASS category. For interaction and nested effects, the parameter names are created by concatenating the names of each component effect.

OUT= Output Data Set in the OUTPUT Statement

The OUT= data set that is specified in the OUTPUT statement contains all the variables in the input data set, along with statistics you request by specifying *keyword=name* options. The additional variables are calculated for each observation in the input data set.

OUT= Output Data Set in the BASELINE Statement

The OUT= data set that is specified in the BASELINE statement contains all the variables in the COVARIATES= data set, along with statistics you request by specifying *keyword=name* options.

ODS Table Names

Table 76.3 lists the names that the QUANTLIFE procedure assigns to each table it creates. You can specify these names when you use the Output Delivery System (ODS) to select tables and create output data sets.

Table 76.3 ODS Tables Produced in PROCQUANTLIFE

ODS Table Name	Description	Statement	Option
ClassLevels	Classification variable levels	CLASS	Default
ModelInfo	Model information	MODEL	Default
NObs	Number of observations	PROC	Default
ParameterEstimates	Parameter estimates	MODEL	Default
CensoredSummary	Summary of event and censored observations	PROC	Dfault
Tests	Results for tests	TEST	Default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The QUANTLIFE procedure assigns a name to each graph it creates. You can use these names to refer to the graphs when you use ODS. The names along with the required statements and options are listed in [Table 76.4](#).

Table 76.4 Graphs Produced by PROC QUANTLIFE

ODS Graph Name	Plot Description	PLOTS= Option
QuantilePlot	Quantile function plot	QUANTILE
QuantPanel	Panel of quantile plots with confidence limits	QUANTPLOT
QuantPlot	Scatter plot for regression quantiles with confidence limits	QUANTPLOT / UNPACK
SurvivalPlot	Survivor function plot	SURVIVAL

Examples: QUANTLIFE Procedure

Example 76.1: Primary Biliary Cirrhosis Study

This example illustrates how to detect varying covariate effects on survival time with quantile regression analysis. Consider a study of primary biliary cirrhosis, a rare but fatal chronic liver disease discussed by Fleming and Harrington (1991). Researchers followed 418 patients with this disease, of whom 161 died during the study.

The data set contains the following variables:

- Time, follow-up time, in years
- Status, event indicator with value 1 for death time and value 0 for censored time
- Age, age in years from birth to study registration
- Albumin, serum albumin level, in gm/dl
- Bilirubin, serum bilirubin level, in mg/dl
- Edema, edema presence
- Protime, prothrombin time, in seconds

The following statements create the data set PBC that is used in this example:

```
data pbc;
  input Time Status Age Albumin Bilirubin Edema Protime @@;
  label Time="Follow-up Time in Days";
  logAlbumin  = log(Albumin);
  logBilirubin = log(Bilirubin);
  logProtime  = log(Protime);
  datalines;
400 1 58.7652 2.60 14.5 1.0 12.2 4500 0 56.4463 4.14 1.1 0.0 10.6

;
```

The next statements fit a linear model for the log of survival time of the PBC patients with the covariates logBilirubin, logProtime, logAlbumin, Age, and Edema.

```
ods graphics on;
proc quantlife data=pbcr log method=na plot=(quantplot survival) seed=1268;
    model Time*Status(0)=logBilirubin logProtime logAlbumin Age Edema
        /quantile=(.1 .2 .3 .4 .5 .6 .75);
run;
```

You use the QUANTILE= option to specify a set of quantiles of interest for comparing quantile-specific covariate effects. The METHOD= option specifies the Nelson-Aalen method for estimating the regression parameters.

The QUANTLIFE procedure provides resampling methods for computing confidence limits for the parameters; see the section “Confidence Interval” on page 6470 for details. By default, the repetition number is 200. You can request a different number of repetitions with the NREP= option. You can also use the SEED= option to specify the seed for generating random numbers so that you can later reproduce the results.

Figure 76.1.1 displays model information and information about censoring in the data. Out of 418 observations, 257 are censored.

Output 76.1.1 Model Information

For comparison, the following statements use the LIFEREG procedure to fit a Weibull distribution to the data. The LIFEREG procedure fits an accelerated failure time model, which assumes that the effect of independent variables is multiplicative on the event time.

```
proc lifereg data=pbcr;
  model Time*Status(0)=logBilirubin logProtime logAlbumin Age Edema;
run;
```

Figure 76.1.3 provides the parameter estimates that are computed by PROC LIFEREG.

Output 76.1.3 Parameter Estimates From PROC LIFEREG

The LIFEREG Procedure							
Analysis of Maximum Likelihood Parameter Estimates							
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	12.2155	1.4539	9.3658	15.0651	70.59	<.0001
logBilirubin	1	-0.5770	0.0556	-0.6861	-0.4680	107.55	<.0001
logProtime	1	-1.7565	0.5248	-2.7850	-0.7280	11.20	0.0008

Edema	1	-0.6303	0.1805	-0.9842	-0.2764	12.19	0.0005
Scale	1	0.6807	0.0430	0.6014	0.7704		
Weibull Shape	1	1.4691	0.0928	1.2980	1.6628		

The p -value for logProtime is very small. For this same variable, the p -values that result from the quantile regression analysis are 0.3148 for the 0.5th quantile and 0.4338 for the 0.75th quantile, and the p -values are much smaller for the lower quantiles. Apparently, the effect of this covariate depends on which side of the response distribution is being modeled.

The PLOT=QUANTPLOT option in the PROC QUANTLIFE statement requests the quantile process plots in Figure 76.1.4 and Figure 76.1.5. These displays plot the estimated regression parameter against the quantile level. You can use these plots to compare quantile-specific covariate effects. If the curve is not constant, it can indicate heterogeneity in the data. The interpretation of the regression coefficients at a given quantile is similar to classical regression analysis. That is, the coefficient from a given covariate indicates the effect on log(Time) of a unit change in that covariate, assuming that the other covariates are fixed.

Output 76.1.4 Quantile Processes with 95% Confidence Bands

Output 76.1.5 Quantile Processes with 95% Confidence Bands

In the first panel, you can see that the effect of `logProtime` has a negative effect over the lower quantiles, which diminishes in magnitude at the median and upper quantiles. This insight would be missed with the accelerated failure model.

Example 76.2: Drug Abuse Study

This example reproduces analysis done by Portnoy (2003), which demonstrates how to use quantile regression to analyze survival times. The example uses drug abuse data provided by Hosmer and Lemeshow (1999). The goal of this study is to compare treatment effects on reducing drug abuse.

The data set contains the following variables:

- Time, time to return to drug use in days
- Status, event indicator with value 1 for return to drug use and value 0 for censored time
- Age, age in years at enrollment
- Treatment, with value 1 for six-month treatment and value 0 for three-month treatment
- Beck, Beck Depression Inventory score at admission to the program
- IV3, indicator of the recent IV drug use
- NDT, number of prior drug treatments.
- RACE, race indicator with value 1 for white and value 0 for nonwhite
- SITE, treatment sites (A and B)
- LOT, length (days) of treatment.

The following statements create the data set:

```
data uis;
  input  ID Age Becktot Hercoc Ivhx Ndrugtx Race Treat Site Lot Time
  Censor;
  Iv3 = (Ivhx = 3);
  Nd1 = 1 / ((Ndrugtx+1) / 10);
  Nd2 = (1 / ((Ndrugtx+1) / 10)) * log((Ndrugtx+1) / 10);
  if (Treat = 1) then Frac = Lot / 180;
  else Frac = Lot / 90;
  datalines;
    1 39 9.0000 4 3 1 0 1 0 123 188 1
    2 33 34.0000 4 2 8 0 1 0 25 26 1
    3 33 10.0000 2 3 3 0 1 0 7 207 1
    4 32 20.0000 4 3 1 0 0 0 66 144 1

    ... more lines ...

    626 28 10.0 4 2 3 0 1 1 21 35 1
    627 35 17.0 1 3 2 0 0 1 184 379 1
    628 46 31.5 1 3 15 1 1 1 9 377 1
;
```

The following statements replicate the analysis of Portnoy (2003):

```
ods graphics on;
proc quantlife data=uis log seed=999 plots=(quantplot survival);
  class Race Site Treat;
  model Time*Censor(0)=Nd1 Nd2 Iv3 Becktota
        Treat Frac Race Age|Site
        / quantile=0.05 to 0.85 by 0.05 ;
  baseline out=Predsurvf survival=surv quantile=Time;

run;
```

Figure 76.2.1 displays the model information. Out of 628 subjects, 53 contain missing values and are not included in the analysis. The censoring rate is 20.87%.

Output 76.2.1 Model Information

The QUANTLIFE Procedure

Figure 76.2.2, Figure 76.2.3, and Figure 76.2.4 display regression quantile process plots for each covariate.

Output 76.2.2 Quantile Processes with 95% Confidence Bands**Output 76.2.3** Quantile Processes with 95% Confidence Bands

Output 76.2.4 Quantile Processes with 95% Confidence Bands

You can see the varying effects for Nd and Frac, while the treatment effect is fairly constant. See Portnoy (2003) for more details about the covariate effects that can be discovered with quantile regression.

In survival analysis, a plot of the estimated survival function is often of interest. There is a one-to-one relationship between the quantile function and the survival function. When you specify the PLOTS= SURVIVAL option, the QUANTLIFE procedure estimates the survival function by fitting a quantile regression model for a grid of equally spaced quantile levels. You can specify the grid points with the INITTAU=option and the step between adjacent grid points with the GRIDSIZE=option. See the section “[Kaplan-Meier-Type Estimator for Censored Quantile Regression](#)” on page 6468 for more information.

Figure 76.4 shows the estimated survival function at the reference set of covariate values that consist of reference levels for the CLASS variables and average values for the continuous variables. You can output the predicted survival function by specifying the SURVIVAL= option in the BASELINE statement.

Output 76.2.5 Survival Function

Overview: QUANTREG Procedure

The QUANTREG procedure models the effects of covariates on the conditional quantiles of a response variable by means of quantile regression.

Ordinary least squares (OLS) regression models the relationship between one or more covariates X and the *conditional mean* of the response variable Y given $X = x$. Quantile regression, which was introduced by Koenker and Bassett (1978), extends the regression model to *conditional quantiles* of the response variable, such as the median or the 90th percentile. Quantile regression is particularly useful when the rate of change in the conditional quantile, expressed by the regression coefficients, depends on the quantile.

Figure 77.1 Trout Density in Streams

Figure 77.1 illustrates an ecological study in which it is revealing to model upper conditional quantiles. The points represent measurements of trout density and stream width-to-depth ratio taken at 13 streams over seven years.

As analyzed by Dunham, Cade, and Terrell (2002), in addition to the ratio, trout density depends on a number of unmeasured limiting factors related to the integrity of stream habitat. The interaction of these factors results in unequal variances for the conditional distributions of density given the ratio. When the ratio is the “active” limiting effect, changes in the upper conditional percentiles of density provide a better estimate of this effect than changes in the conditional mean.

The red and green curves represent the conditional 90th and 50th percentiles of density as determined with the QUANTREG procedure. The analysis was done by using a simple linear regression model for the logarithm of density. (The curves in Figure 77.1 were obtained by transforming the fitted lines back to the

original scale. For more details, see the section “[Analysis of Fish-Habitat Relationships](#)” on page 6490.) The slope parameter for the 90th percentile has an estimated value of -0.0215 and is significant with a p -value less than 0.01. On the other hand, the slope parameter for the 50th percentile is not significantly different from zero. Similarly, the slope parameter for the mean, obtained with OLS regression, is not significantly different from zero.

Figure 77.2 Quantiles for Body Mass Index

Quantile regression is especially useful with data that are heterogeneous in the sense that the tails and the central location of the conditional distributions vary differently with the covariates. An even more pronounced example of heterogeneity is shown in [Figure 77.2](#), which plots the body mass index of 8,250 men versus their age.

Here, both upper (overweight) and lower (underweight) conditional quantiles are important because they provide the basis for developing growth charts and establishing health standards. The curves in [Figure 77.2](#) were determined with the QUANTREG procedure by using polynomial quantile regression; details are provided in the section “[Growth Charts for Body Mass Index](#)” on page 6495. Clearly, the rate of change with age (as expressed by the regression coefficients), particularly for ages less than 20, is different for each conditional quantile.

Heterogeneous data occur in many fields, including biomedicine, econometrics, survival analysis, and ecology. Quantile regression, which includes median regression as a special case, provides a complete picture of the covariate effect when a set of percentiles is modeled, and so it offers the capability to capture important features of the data that might be missed by models that average over the conditional distribution.

Because it makes no distributional assumption about the error term in the model, quantile regression offers considerable model robustness. The assumption of normality, which is often made with OLS regression

in order to compute conditional quantiles as offsets from the mean, forces a common set of regression coefficients for all the quantiles. Obviously, quantiles with common slopes would be inappropriate in the preceding examples.

Quantile regression is also flexible in the sense that it does not involve a link function that relates the variance and the mean of the response variable. Generalized linear models, which you can fit with the GENMOD procedure, require both a link function and a distributional assumption such as the normal or Poisson distribution. The goal of generalized linear models is inference about the regression parameters in the linear predictor for the mean of the population. In contrast, the goal of quantile regression is inference on regression coefficients for the conditional quantiles of a response variable that is usually assumed to be continuous.

Quantile regression also offers a degree of data robustness. Unlike OLS regression, it is robust to extreme points in the response direction (outliers). However, it is not robust to extreme points in the covariate space (leverage points). When both types of robustness are of concern, you should consider using the ROBUSTREG procedure (Chapter 80, “[The ROBUSTREG Procedure](#).”)

Also, unlike OLS regression, quantile regression is equivariant to monotone transformations of the response variable. For instance, as illustrated in the trout example, the logarithm of the 90th conditional percentile of trout density is the 90th conditional percentile of the logarithm of density.

Note that quantile regression cannot be carried out simply by segmenting the unconditional distribution of the response variable and then obtaining least squares fits for the subsets. This approach leads to disastrous results when, for example, the data include outliers. In contrast, quantile regression uses *all* of the data for fitting quantiles, even the extreme quantiles.

Features

The main features of the QUANTREG procedure are as follows:

- offers simplex, interior point, and smoothing algorithms for estimation
- provides sparsity, rank, and resampling methods for confidence intervals
- provides asymptotic and bootstrap methods for covariance and correlation matrices of the estimated parameters
- provides the Wald, likelihood ratio, and rank tests for the regression parameter estimates and the Wald test for heteroscedasticity
- provides outlier and leverage-point diagnostics
- enables parallel computing when multiple processors are available
- provides row-wise or column-wise output data sets with multiple quantiles
- provides regression quantile spline fits
- produces fit plots, diagnostic plots, and quantile process plots by using ODS Graphics

The next section provides notation and a formal definition for quantile regression.

Quantile Regression

Quantile regression generalizes the concept of a univariate quantile to a conditional quantile given one or more covariates. Recall that a student's score on a test is at the τ quantile if his or her score is better than that of $100\tau\%$ of the students who took the test. The score is also said to be at the 100τ percentile.

For a random variable Y with probability distribution function

$$F(y) = \text{Prob}(Y \leq y)$$

the τ quantile of Y is defined as the inverse function

$$Q(\tau) = \inf \{y : F(y) \geq \tau\}$$

where $0 < \tau < 1$. In particular, the median is $Q(1/2)$.

For a random sample $\{y_1, \dots, y_n\}$ of Y , it is well known that the sample median minimizes the sum of absolute deviations

$$\text{median} = \arg \min_{\xi \in \mathbf{R}} \sum_{i=1}^n |y_i - \xi|$$

Likewise, the general τ sample quantile $\xi(\tau)$, which is the analog of $Q(\tau)$, is formulated as the minimizer

$$\xi(\tau) = \arg \min_{\xi \in \mathbf{R}} \sum_{i=1}^n \rho_\tau(y_i - \xi)$$

where $\rho_\tau(z) = z(\tau - I(z < 0))$, $0 < \tau < 1$, and where $I(\cdot)$ denotes the indicator function. The loss function ρ_τ assigns a weight of τ to positive residuals $y_i - \xi$ and a weight of $1 - \tau$ to negative residuals.

Using this loss function, the linear conditional quantile function extends the τ sample quantile $\xi(\tau)$ to the regression setting in the same way that the linear conditional mean function extends the sample mean. Recall that OLS regression estimates the linear conditional mean function $E(Y|X = x) = \mathbf{x}'\boldsymbol{\beta}$ by solving for

$$\hat{\boldsymbol{\beta}} = \arg \min_{\boldsymbol{\beta} \in \mathbf{R}^p} \sum_{i=1}^n (y_i - \mathbf{x}_i' \boldsymbol{\beta})^2$$

The estimated parameter $\hat{\boldsymbol{\beta}}$ minimizes the sum of squared residuals in the same way that the sample mean $\hat{\mu}$ minimizes the sum of squares:

$$\hat{\mu} = \arg \min_{\mu \in \mathbf{R}} \sum_{i=1}^n (y_i - \mu)^2$$

Likewise, quantile regression estimates the linear conditional quantile function, $Q(\tau|X = x) = \mathbf{x}'\boldsymbol{\beta}(\tau)$, by solving

$$\hat{\boldsymbol{\beta}}(\tau) = \arg \min_{\boldsymbol{\beta} \in \mathbf{R}^p} \sum_{i=1}^n \rho_{\tau}(y_i - \mathbf{x}_i' \boldsymbol{\beta})$$

for $\tau \in (0, 1)$. The quantity $\hat{\boldsymbol{\beta}}(\tau)$ is called the τ *regression quantile*. The case $\tau = 0.5$, which minimizes the sum of absolute residuals, corresponds to median regression, which is also known as L_1 regression.

The set of regression quantiles

$$\{\boldsymbol{\beta}(\tau) : \tau \in (0, 1)\}$$

is referred to as the *quantile process*.

The QUANTREG procedure computes the quantile function $Q(\tau|X = x)$ and conducts statistical inference on the estimated parameters $\hat{\boldsymbol{\beta}}(\tau)$.

Getting Started: QUANTREG Procedure

The following examples demonstrate how you can use the QUANTREG procedure to fit linear models for selected quantiles or for the entire quantile process. The first example explains the use of the procedure in the fish-habitat example, and the second example explains the use of the procedure to construct growth charts for body mass index.

Analysis of Fish-Habitat Relationships

Quantile regression is used extensively in ecological studies (Cade and Noon 2003). Recently, Dunham, Cade, and Terrell (2002) applied quantile regression to analyze fish-habitat relationships for Lahontan cut-throat trout in 13 streams of the eastern Lahontan basin, which covers most of northern Nevada and parts of southern Oregon. The density of trout (number of trout per meter) was measured by sampling stream sites from 1993 to 1999. The width-to-depth ratio of the stream site was determined as a measure of stream habitat.

The goal of this study was to explore the relationship between the conditional quantiles of trout density and the width-to-depth ratio. The scatter plot of the data in [Figure 77.1](#) indicates a nonlinear relationship, and so it is reasonable to fit regression models for the conditional quantiles of the log of density. Since regression quantiles are equivariant under any monotonic (linear or nonlinear) transformation (Koenker and Hallock 2001), the exponential transformation converts the conditional quantiles to the original density scale.

The data set trout, which follows, includes the average numbers of Lahontan cutthroat trout per meter of stream (Density), the logarithm of Density (LnDensity), and the width-to-depth ratios (WDRatio) for 71 samples.

;
```

The following statements use the QUANTREG procedure to fit a simple linear model for the 50th and 90th percentiles of LnDensity:

```
ods graphics on;

proc quantreg data=trout alpha=0.1 ci=resampling;
  model LnDensity = WDRatio / quantile=0.5 0.9
                                CovB seed=1268;
  test WDRatio / wald lr;
run;
```

The MODEL statement specifies a simple linear regression model with LnDensity as the response variable Y and WDRatio as the covariate X . The QUANTILE= option requests that the regression quantile function $Q(\tau|X = x) = x'\beta(\tau)$ be estimated by solving

$$\hat{\beta}(\tau) = \arg \min_{\beta \in \mathbb{R}^2} \sum_{i=1}^n \rho_{\tau}(y_i - x_i' \beta)$$

where $\tau = (0.5, 0.9)$.

By default, the regression coefficients $\hat{\beta}(\tau)$ are estimated with the simplex algorithm, which is explained in the section “[Simplex Algorithm](#)” on page 6516. The ALPHA= option requests 90% confidence limits for the regression parameters, and the option CI=RESAMPLING specifies that the intervals are to be computed with the MCMB resampling method of He and Hu (2002). By specifying the CI=RESAMPLING option, the QUANTREG procedure also computes standard errors, t values, and p -values of regression parameters with the MCMB resampling method. The SEED= option specifies a seed for the resampling method. The COVB option requests covariance matrices for the estimated regression coefficients, and the TEST statement requests tests for the hypothesis that the slope parameter (the coefficient of WDRatio) is zero.

[Figure 77.3](#) displays model information and summary statistics for the variables in the model. The summary statistics include the median and the standardized median absolute deviation (MAD), which are robust measures of univariate location and scale, respectively. See Huber (1981, p. 108) for more details about the standardized MAD.

Figure 77.3 Model Fitting Information and Summary Statistics

The QUANTREG Procedure

WDRatio	1	-0.0136	0.0123	-0.0341	0.0068	-1.11	0.2705

Figure 77.5 Parameter Estimates at QUANTILE=0.9

Parameter Estimates							
Parameter	DF	Estimate	Standard Error	90% Confidence Limits		t Value	Pr > t
Intercept	1	0.0576	0.2606	-0.3769	0.4921	0.22	0.8257
WDRatio	1	-0.0215	0.0075	-0.0340	-0.0091	-2.88	0.0053

The 90th percentile of trout density can be predicted from the width-to-depth ratio as follows:

$$y_{90} = \exp(0.0576 - 0.0215x)$$

This is the upper dashed curve plotted in Figure 77.1. The lower dashed curve for the median can be obtained in a similar fashion.

The covariance matrices for the estimated parameters are shown in Figure 77.6. The resampling method used for the confidence intervals is used to compute these matrices.

Figure 77.6 Covariance Matrices of the Estimated Parameters

Estimated Covariance Matrix for Quantile = 0.5		
	Intercept	WDRatio
Intercept	0.156191	-.004653
WDRatio	-.004653	0.000151

0.9	Wald	8.3031	1	8.30	0.0040
0.9	Likelihood Ratio	9.0529	1	9.05	0.0026

In many quantile regression problems it is useful to examine how the estimated regression parameters for each covariate change as a function of τ in the interval $(0, 1)$. The following statements use the QUANTREG procedure to request the estimated quantile processes $\hat{\beta}(\tau)$ for the slope and intercept parameters:

```
proc quantreg data=trout alpha=0.1 ci=resampling;
  model LnDensity = WDRatio / quantile=process seed=1268
    plot=quantplot;
run;
```

The QUANTILE=PROCESS option requests an estimate of the quantile process for each regression parameter. The options ALPHA=0.1 and CI=RESAMPLING specify that 90% confidence bands for the quantile processes are to be computed with the resampling method.

Figure 77.8 displays a portion of the objective function table for the entire quantile process. The objective function is evaluated at 77 values of τ in the interval $(0, 1)$. The table also provides predicted values of the

conditional quantile function $Q(\tau)$ at the mean for WDRatio, which can be used to estimate the conditional density function.

The PLOT=QUANTPLOT option in the MODEL statement, together with ODS Graphics, requests a plot of the estimated quantile processes. The left side of Figure 77.10 displays the process for the intercept, and the right side displays the process for the coefficient of WDRatio.

The process plot for WDRatio shows that the slope parameter changes from positive to negative as the quantile increases, and it changes sign with a sharp drop at the 40th percentile. The 90% confidence bands show that the relationship between LnDensity and WDRatio (expressed by the slope) is not significant below

the 78th percentile. This situation can also be seen in [Figure 77.9](#), which shows that 0 falls between the lower and upper confidence limits of the slope parameter for quantiles below 0.78. Since the confidence intervals for the extreme quantiles are not stable due to insufficient data, the confidence band is not displayed outside the interval (0.05, 0.95).

Figure 77.10 Quantile Processes for Intercept and Slope

Growth Charts for Body Mass Index

Body mass index (BMI) is defined as the ratio of weight (kg) to squared height (m^2) and is a widely used measure for categorizing individuals as overweight or underweight. The percentiles of BMI for specified ages are of particular interest. As age increases, these percentiles provide growth patterns of BMI not only for the majority of the population, but also for underweight or overweight extremes of the population. In addition, the percentiles of BMI for a specified age provide a reference for individuals at that age with respect to the population.

Smooth quantile curves have been widely used for reference charts in medical diagnosis to identify unusual subjects, whose measurements lie in the tails of the reference distribution. This example explains how to use the QUANTREG procedure to create growth charts for BMI.

A SAS data set named `bmimen` was created by merging and cleaning the 1999–2000 and 2001–2002 survey results for men published by the National Center for Health Statistics. This data set contains the variables Weight (kg), Height (m), BMI (kg/m^2), Age (year), and SeQN (respondent sequence number) for 8,250 men. More details can be found in [Chen \(2005\)](#).

The data set used in this example is a subset of the original data set of [Chen \(2005\)](#). It contains the two variables BMI and Age with 3264 observations.

```
data bmimen;
  input BMI Age @@;
  SqrtAge = sqrt(Age);
  InveAge = 1/Age;
```

```

LogBMI = log(BMI);
datalines;

;

```

The logarithm of BMI is used as the response (although this does not improve the quantile regression fit, it helps with statistical inference.) A preliminary median regression is fitted with a parametric model, which involves six powers of Age.

The following statements invoke the QUANTREG procedure:

```

proc quantreg data=bmimen algorithm=interior(tolerance=1e-5) ci=resampling;
  model logbmi = inveage sqrtage age sqrtage*age
               age*age age*age*age
               / diagnostics cutoff=4.5 quantile=.5 seed=1268;
  id age bmi;
  test_age_cubic: test age*age*age / wald lr rankscore(tau);
run;

```

The MODEL statement provides the model, and the option QUANTILE=0.5 requests median regression, which computes $\hat{\beta}(\frac{1}{2})$ by using the interior point algorithm as requested with the ALGORITHM= option. See the section “[Interior Point Algorithm](#)” on page 6517 for details about this algorithm.

Figure 77.11 displays the estimated parameters, standard errors, 95% confidence intervals, t values, and p -values that are computed by the resampling method as requested by the CI= option. All of the parameters are considered significant since the p -values are smaller than 0.001.

Figure 77.11 Parameter Estimates with Median Regression: Men

The QUANTREG Procedure							
Parameter Estimates							
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		t Value	Pr > t
Intercept	1	7.8909	0.8168	6.2895	9.4924	9.66	<.0001

Age	1	1.9759	0.2537	1.4785	2.4733	7.79	<.0001
SqrtAge*Age	1	-0.3347	0.0424	-0.4179	-0.2515	-7.89	<.0001
Age*Age	1	0.0227	0.0029	0.0170	0.0284	7.77	<.0001
Age*Age*Age	1	-0.0000	0.0000	-0.0001	-0.0000	-7.40	<.0001

The TEST statement requests Wald, likelihood ratio, and rank tests for the significance of the cubic term in Age. The test results, shown in Figure 77.12, indicate that this term is significant. Higher-order terms are not significant.

Figure 77.12 Test of Significance for Cubic Term

Test test_age_cubic Results				
Test	Test Statistic	DF	Chi- Square	Pr > ChiSq
Wald	54.7417	1	54.74	<.0001
Likelihood Ratio	56.9473	1	56.95	<.0001
Rank_Tau	42.5731	1	42.57	<.0001

Median regression and, more generally, quantile regression are robust to extremes of the response variable. The DIAGNOSTICS option in the MODEL statement requests a diagnostic table of outliers, shown in Figure 77.13, which uses a cutoff value specified with the CUTOFF= option. The variables specified in the ID statement are included in the table.

With CUTOFF=4.5, 14 men are identified as outliers. All of these men have large positive standardized residuals, which indicates that they are overweight for their age. The cutoff value 4.5 is ad hoc; it corresponds to a probability less than $0.5E-5$ if normality is assumed, but the standardized residuals for median regression usually do not meet this assumption.

In order to construct the chart shown in Figure 77.2, the same model used for median regression is used for other quantiles. Note that the QUANTREG procedure can compute fitted values for multiple quantiles.

Figure 77.13 Diagnostics with Median Regression

Diagnostics				
Obs	Age	BMI	Standardized Residual	Outlier
1337	8.900000	36.500000	5.3575	*

1505	9.900000	35.500000	4.8862	*
1764	14.900000	46.800000	5.6403	*
1838	16.200000	50.400000	5.9138	*
1845	16.300000	42.600000	4.6683	*
1870	16.700000	42.600000	4.5930	*
1957	18.100000	49.900000	5.5053	*
2002	18.700000	52.700000	5.8106	*
2016	18.900000	48.400000	5.1603	*
2264	32.000000	55.600000	5.3085	*
2291	35.000000	60.900000	5.9406	*
2732	66.000000	14.900000	-4.7849	*

The following statements request fitted values for 10 quantile levels ranging from 0.03 to 0.97:

```
proc quantreg data=bmimen algorithm=interior(tolerance=1e-5) ci=none;
  model logbmi = invage sqrtage age sqrtage*age
               age*age age*age*age
               / quantile=0.03,0.05,0.1,0.25,0.5,0.75,
               0.85,0.90,0.95,0.97;
  output out=outp pred=p/columnwise;
run;

data outbmi;
  set outp;
  pbmi = exp(p);
run;

proc sgplot data=outbmi;
  title 'BMI Percentiles for Men: 2-80 Years Old';
  yaxis label='BMI (kg/m**2)' min=10 max=45 values=(10 15 20 25 30 35 40 45);
  xaxis label='Age (Years)' min=2 max=80 values=(2 10 20 30 40 50 60 70 80);

  scatter x=age y=bmi /markerattrs=(size=1);
  series x=age y=pbmi/group=QUANTILE;
run;
```

The fitted values are stored in the OUTPUT data set outp. The COLUMNWISE option arranges these fitted values for all quantiles in the single variable p by groups of the quantiles. After the exponential transformation, the fitted BMI values together with the original BMI values are plotted against age to create the display shown in [Figure 77.2](#).

The fitted quantile curves reveal important information. During the quick growth period (ages 2 to 20), the dispersion of BMI increases dramatically; it becomes stable during middle age, and then it contracts after age 60. This pattern suggests that effective population weight control should start in childhood.

Compared to the 97th percentile in reference growth charts published by CDC in 2000 (Kuczmarski, Ogden, and Guo 2002), the 97th percentile for 10-year-old boys in [Figure 77.2](#) is 6.4 BMI units higher (an increase of 27%). This can be interpreted as a warning of overweight or obesity. See Chen (2005) for a detailed analysis.

  WEIGHT variable ;

```

The PROC QUANTREG statement invokes the QUANTREG procedure. The CLASS statement specifies which explanatory variables are treated as categorical. The ID statement names variables to identify observations in the outlier diagnostics tables. The MODEL statement is required and specifies the variables used in the regression. Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure (Chapter 42, “[The GLM Procedure](#).”) The OUTPUT statement creates an output data set containing predicted values, residuals, and estimated standard errors. The PERFORMANCE statement tunes the performance of PROC QUANTREG by using single or multiple processors available in the hardware. The TEST statement requests linear tests for the model parameters. The WEIGHT statement identifies a variable in the input data set whose values are used to weight the observations. In one invocation of PROC QUANTREG, multiple OUTPUT and TEST statements are allowed.

The [EFFECT](#) and [ESTIMATE](#) statements are also available in other procedures. Summary descriptions of functionality and syntax for these statements are provided in this chapter, and you can find full documentation about them in Chapter 19, “[Shared Concepts and Topics](#).”

PROC QUANTREG Statement

```

PROC QUANTREG < options > ;

```

The PROC QUANTREG statement invokes the QUANTREG procedure. [Table 77.1](#) summarizes the options available in the PROC QUANTREG statement.

Table 77.1 PROC QUANTREG Statement Options

Option	Description
ALGORITHM=	Specifies an algorithm to estimate the regression parameters
CI=	Specifies a method to compute confidence intervals
DATA=	Specifies the input SAS data set
INEST=	Specifies an input SAS data set that contains initial estimates
NAMELEN=	Specifies the length of effect names
ORDER=	Specifies the order in which to sort classification variables

Table 77.1 *continued*

Option	Description
OUTEST=	Specifies an output SAS data set containing the parameter estimates
PLOT	Specifies options that control details of the plots

You can specify the following options in the PROC QUANTREG statement.

ALGORITHM=*algorithm* < (*suboptions*) >

specifies an algorithm to estimate the regression parameters. Three algorithms are available: simplex (SIMPLEX), interior point (INTERIOR), and smoothing (SMOOTH).

The default algorithm depends on the number of the observations (n) and the number of the covariates (p) in the model estimation. See Table 77.2 for the relevant defaults.

Table 77.2 The Default Estimation Algorithm

	$p \leq 100$	$p > 100$
$n \leq 5000$	Simplex	Smoothing
$n > 5000$	Interior point	Smoothing

Table 77.3 summarizes the options available for each of these methods.

Table 77.3 Options for Estimation Algorithms

ALGORITHM= Value	Algorithm	Suboptions
SIMPLEX	Simplex	MAXSTATIONARY=
INTERIOR	Interior point	KAPPA= MAXIT= TOLERANCE=
SMOOTH	Smoothing	RRATIO=

With ALGORITHM=SIMPLEX you can specify the following *suboption*:

- MAXSTATIONARY= m specifies that if the objective function has not improved for m consecutive iterations, the algorithm terminates. By default, $m = 1000$.

With ALGORITHM=INTERIOR you can specify the following *suboptions*:

- KAPPA=*value* specifies the step length parameter for the interior point algorithm. This parameter should be between 0 and 1. The larger the parameter, the faster the algorithm. However, numeric instability can occur as the parameter approaches 1. By default, KAPPA=0.99995. See the section “[Interior Point Algorithm](#)” on page 6517 for details.
- MAXIT= m sets the maximum number of iterations for the interior point algorithm. By default, $m = 1000$.
- TOLERANCE=*value* specifies the tolerance for the convergence criterion of the interior point algorithm. The default *value* is 1E–8. The QUANTREG procedure uses the duality gap as the convergence criterion. See the section “[Interior Point Algorithm](#)” on page 6517 for details.

With the interior point algorithm, you can use the PERFORMANCE statement to enable parallel computing when multiple processors are available in the hardware.

With ALGORITHM=SMOOTH you can specify the following *suboption*:

- **RRATIO=***value* specifies the reduction ratio for the smoothing algorithm. This ratio is used for reducing the threshold of the smoothing algorithm. The *value* should be between 0 and 1. In theory, the smaller the reduction ration, the faster the smoothing algorithm. However, the optimal ratio is quite data dependent in practice. See the section “[Smoothing Algorithm](#)” on page 6520 for details.

ALPHA=*value*

sets the confidence level for the confidence intervals for regression parameters. The *value* must be between 0 and 1. The default is ALPHA=0.05, corresponding to a 0.95 confidence interval.

CI=NONE | RANK | SPARSITY<(BF | HS)></IID> | RESAMPLING<(NREP=*n*)>

specifies a method to compute confidence intervals for regression parameters. When you specify CI=SPARSITY or CI=RESAMPLING, the QUANTREG procedure also computes standard errors, *t* values, and *p*-values for regression parameters.

The following table summarizes these methods.

Table 77.4 Options for Confidence Intervals

Value of CI=	Method	Additional Options
NONE	No confidence intervals computed	
RANK	By inverting rank-score tests	
SPARSITY	By estimating sparsity function	HS BF IID
RESAMPLING	By resampling	NREP

By default, when there are fewer than 5,000 observations, fewer than 20 variables in the data set, and the algorithm is simplex, the QUANTREG procedure computes confidence intervals by using the inverting rank-score test method; otherwise, the resampling method is used.

By default, confidence intervals are not computed for the quantile process, which is estimated when you specify the QUANTILE=PROCESS option in the MODEL statement. Confidence intervals for the quantile process are computed with the sparsity or resampling methods when you specify CI=SPARSITY or CI=RESAMPLING, respectively. The rank method for confidence intervals is not available with quantile processes because it is computationally prohibitive.

With the SPARSITY option, there are two suboptions for estimating the sparsity function. If you specify the IID suboption, the sparsity function is estimated by assuming that the errors in the linear model are independent and identically distributed (iid). By default, the sparsity function is estimated by assuming that the conditional quantile function is locally linear. See the section “[Sparsity](#)” on page 6523 for details. With both methods two bandwidth selection methods are available. You can specify the Bofinger method with the BF suboption or the Hall-Sheather method with the HS suboption. By default, the Hall-Sheather method is used.

With the RESAMPLING option, you can specify the number of repeats with the NREP=*n* suboption. By default, NREP=200. The value of *n* must be greater than 50.

DATA=SAS-data-set

specifies the input SAS data set used by the QUANTREG procedure. By default, the most recently created SAS data set is used.

INEST=SAS-data-set

specifies an input SAS data set that contains initial estimates for all the parameters in the model. The interior point algorithm and the smoothing algorithm use these estimates as a start. See the section “[INEST= Data Set](#)” on page 6529 for a detailed description of the contents of the INEST= data set.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the classification variables (which are specified in the [CLASS](#) statement). This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

OUTEST=SAS-data-set

specifies an output SAS data set containing the parameter estimates for all quantiles. See the section “[OUTEST= Data Set](#)” on page 6529 for a detailed description of the contents of the OUTEST= data set.

PLOT | PLOTS<(global-plot-options)> <=plot-request>**PLOT | PLOTS<(global-plot-options)> <=(plot-request < ... plot-request >)>**

specifies options that control details of the plots. These plots fall into two categories, diagnostic plots and fit plots. If you do not specify the PLOTS= option, PROC QUANTREG produces the quantile fit plot by default when a single continuous variable is specified in the model. You can use the PLOTS= option in the PROC QUANTREG statement to request various diagnostic plots. In addition

to these two categories of plots, you can use the **PLOT=** option in the MODEL statement to request the quantile process plot for any effects specified in the model.

When you specify one *plot-request*, you can omit the parentheses around the plot request. Here are some examples:

```
plots=ddplot
plots=(ddplot rdplot)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc quantreg plots=fitplot;
  model y=x1;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The *global-plot-options* apply to all plots generated by the QUANTREG procedure. The following global plot option is available:

MAXPOINTS=NONE | *number*

specifies that plots with elements that require processing more than *number* points be suppressed. The default is MAXPOINTS=5000. This cutoff is ignored if you specify MAXPOINTS=NONE.

ONLY

suppresses the default quantile fit plot. Only plots specifically requested are displayed.

You can specify more than one plot request within the parentheses after PLOTS=. For a single plot request, you can omit the parentheses. The following plot requests are available.

ALL

creates all appropriate plots.

DDPLOT<(LABEL=ALL | LEVERAGE | NONE | OUTLIER)>

creates a plot of robust distance against Mahalanobis distance. See the section “[Leverage Point and Outlier Detection](#)” on page 6528 for details about robust distance. The LABEL= option specifies how the points on this plot are to be labeled, as summarized by the following table.

Table 77.5 Options for Label

Value of LABEL=	Label Method
ALL	Label all points
LEVERAGE	Label leverage points
NONE	No labels
OUTLIERS	Label outliers

By default, the QUANTREG procedure labels both outliers and leverage points.

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

FITPLOT<(NOLIMITS | SHOWLIMITS | NODATA)>

creates a plot of fitted conditional quantiles against the single continuous variable that is specified in the model. This plot is produced only when the response is modeled as a function of a single continuous variable. Multiple lines or curves are drawn on this plot if you specify several quantiles with the QUANTILE= option in the MODEL statement. By default, confidence limits are added to the plot when a single quantile is requested, and the confidence limits are not shown on the plot when multiple quantiles are requested. The NOLIMITS option suppresses these limits. The SHOWLIMITS option adds these limits when multiple quantiles are requested. The NODATA option suppresses the observed data, which are superimposed on the plot by default.

HISTOGRAM

creates a histogram for the standardized residuals based on the quantile regression estimates. The histogram is superimposed with a normal density curve and a kernel density curve.

NONE

suppresses all plots.

QQPLOT

creates the normal quantile-quantile plot for the standardized residuals based on the quantile regression estimates.

RDPlot<(LABEL=ALL | LEVERAGE | NONE | OUTLIER)>

creates the plot of standardized residual against robust distance. See the section “[Leverage Point and Outlier Detection](#)” on page 6528 for details about robust distance. The LABEL= option specifies a label method for points on this plot. These label methods are described in [Table 77.5](#).

By default, the QUANTREG procedure labels both outliers and leverage points.

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

PP

requests preprocessing to speed up the interior point algorithm or the smoothing algorithm. The preprocessing uses a subsampling algorithm to reduce the original problem to a smaller one iteratively. It assumes that the data set is evenly distributed. Preprocessing should be used only for very large data sets, such as data sets with more than 100,000 observations. See Portnoy and Koenker (1997) for details.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC QUANTREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input

data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the QUANTREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / **TRUNCATE** > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC QUANTREG statement. You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

EFFECT Statement

EFFECT *name=effect-type (variables < / options>)* ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.
MULTIMEMBER MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 77.6 summarizes the *options* available in the EFFECT statement.

Table 77.6 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect
Lag Effects Options	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Multimember Effects Options	
NOEFFECT	Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects

Table 77.6 *continued*

Option	Description
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
    <,...<'label'> estimate-specification <(divisor=n)>>
    </ options> ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form $L\beta$. You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 77.7 summarizes the options available in the ESTIMATE statement.

Table 77.7 ESTIMATE Statement Options

Option	Description
Construction and Computation of Estimable Functions	
DIVISOR=	Specifies a list of values to divide the coefficients
NOFILL	Suppresses the automatic fill-in of coefficients for higher-order effects
SINGULAR=	Tunes the estimability checking difference

Table 77.7 continued

Option	Description
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple comparison adjustment of estimates
ALPHA= α	Determines the confidence level $(1 - \alpha)$
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiplicity-corrected p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits
CORR	Displays the correlation matrix of estimates
COV	Displays the covariance matrix of estimates
E	Prints the L matrix
JOINT	Produces a joint F or chi-square test for the estimable functions
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the ESTIMATE statement, see the section “[ESTIMATE Statement](#)” on page 437 in Chapter 19, “[Shared Concepts and Topics](#).”

ID Statement

ID *variables* ;

When the diagnostics table is requested with the DIAGNOSTICS option in the MODEL statement, the variables listed in the ID statement are displayed in addition to the observation number. These values are useful for identifying observations. If the ID statement is omitted, only the observation number is displayed.

MODEL Statement

< label: > MODEL *response* = *< effects >* *< / options >* ;

Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure (Chapter 42, “[The GLM Procedure](#).”) Classification variables in the MODEL statement must be specified in the CLASS statement.

The optional *label*, which must be a valid SAS name, is used to label output from the matching MODEL statement.

Options

Table 77.8 summarizes the options available in the MODEL statement.

Table 77.8 MODEL Statement Options

Option	Description
CORRB	Produces the estimated correlation matrix
COVB	Produces the estimated covariance matrix
CUTOFF=	Specifies the multiplier of the cutoff value for outlier detection
DIAGNOSTICS	Requests the outlier diagnostics
ITPRINT	Displays the iteration history
LEVERAGE	Requests an analysis of leverage points
NODIAG	Suppresses the computation for outlier diagnostics
NOINT	Specifies no-intercept regression
NOSUMMARY	Suppresses the computation for summary statistics
PLOT=	Requests plots
QUANTILE=	Specifies the quantile levels
SCALE=	Specifies the scale value used to compute the standardized residuals
SEED=	Specifies the seed for the random number generator
SINGULAR=	Specifies the tolerance for testing singularity

You can specify the following options for the model fit.

CORRB

produces the estimated correlation matrix of the parameter estimates. When the resampling method is used to compute the confidence intervals, the QUANTREG procedure computes the bootstrap correlation. When the sparsity method is used to compute the confidence intervals, the procedure computes the asymptotic correlation based on an estimator of the sparsity function. The rank method for confidence intervals does not provide a correlation estimate.

COVB

produces the estimated covariance matrix of the parameter estimates. When the resampling method is used to compute the confidence intervals, the QUANTREG procedure computes the bootstrap covariance. When the sparsity method is used to compute the confidence intervals, the procedure computes the asymptotic covariance based on an estimator of the sparsity function. The rank method for confidence intervals does not provide a covariance estimate.

CUTOFF=*value*

specifies the multiplier of the cutoff value for outlier detection. The default *value* is 3.

DIAGNOSTICS<(ALL)>

requests the outlier diagnostics. By default, only observations identified as outliers or leverage points are displayed. To request that all observations be displayed, specify the ALL option.

ITPRINT

displays the iteration history of the interior point algorithm or the smoothing algorithm.

LEVERAGE<(CUTOFF=value | CUTOFFALPHA=value | H=n)>

requests an analysis of leverage points for the continuous covariates. The results are added to the diagnostics table, which you can request with the **DIAGNOSTICS** option in the **MODEL** statement. You can specify the cutoff value for leverage-point detection with the **CUTOFF=** option. The default cutoff value is $\sqrt{\chi^2_{p;1-\alpha}}$, where α can be specified with the **CUTOFFALPHA=** option. By default, $\alpha = 0.025$. You can use the **H=** option to specify the number of points to be minimized for the MCD algorithm used for the leverage-point analysis. By default, $H = [(3n + p + 1)/4]$, where n is the number of observations and p is the number of independent variables. The **LEVERAGE** option is ignored if the model includes classification variables as covariates.

NODIAG

suppresses the computation for outlier diagnostics. If you specify the **NODIAG** option, the diagnostics summary table will not be provided.

NOINT

specifies no intercept regression.

NOSUMMARY

suppresses the computation for summary statistics. If you specify the **NOSUMMARY** option, the summary statistics table will not be provided.

PLOT=plot-option**PLOTS=(plot-options)**

You can use the **PLOTS=** option in the **MODEL** statement together with **ODS Graphics** to request the quantile process plot in addition to all plots available with the **PLOT=** option in the **PROC QUANTREG** statement. The plot options in the **PROC QUANTREG** statement overwrite the plot options in the **MODEL** statement if you specify the same options in both statements.

You can specify the following plot option only in the **MODEL** statement:

QUANTPLOT<(EFFECTS) </ <NOLIMITS> <EXTENDCI> <UNPACK> <OLS> > >

plots the regression quantile process. The estimated coefficient of each specified covariate effect is plotted as a function of the quantile. If you do not specify a covariate effect, quantile processes are plotted for all covariate effects in the **MODEL** statement. You can use the **NOLIMITS** option to suppress confidence bands for the quantile processes. By default, confidence bands are plotted, and process plots are displayed in panels, each of which can hold up to four plots. By default, the confidence limits are plotted for quantiles in the range between 0.05 and 0.95. You can use the **EXTENDCI** option to plot the confidence limits even for quantiles outside this range. You can use the **UNPACK** option to create individual process plots. For an individual process plot, you can superimpose the ordinary least squares estimate and its confidence limits by specifying the **OLS** option. The confidence level of the ordinary least squares estimate is specified with the **ALPHA=** option in the **PROC QUANTREG** statement.

Again, **ODS Graphics** must be enabled before requesting plots.

For more information about enabling and disabling **ODS Graphics**, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

QUANTILE=*number-list* | **PROCESS**

specifies the quantile levels for the quantile regression. You can specify any number of quantile levels in (0, 1). You can also compute the entire quantile process by specifying the PROCESS option. Only the simplex algorithm is available for computing the quantile process.

If you do not specify the QUANTILE= option, the QUANTREG procedure fits a median regression, which corresponds to QUANTILE=0.5.

SCALE=*number*

specifies the scale value used to compute the standardized residuals. By default, the scale is computed as the corrected median of absolute residuals. See the section “[Leverage Point and Outlier Detection](#)” on page 6528 for details.

SEED=*number*

specifies the seed for the random number generator used to compute the MCMB confidence intervals. This seed is also used to randomly select the subgroups for preprocessing when you specify the PP option in the PROC QUANTREG statement. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock.

By default or if you specify zero, the QUANTREG procedure generates a seed between one and one billion.

SINGULAR=*value*

sets the tolerance for testing singularity of the information matrix and the crossproducts matrix for the initial least squares estimates. Roughly, the test requires that a pivot be at least this value times the original diagonal value. By default, SINGULAR=1E-12.

OUTPUT Statement

OUTPUT < **OUT=***SAS-data-set* > *keyword=name* < ... *keyword=name* > < / **COLUMNWISE** > ;

The OUTPUT statement creates a SAS data set containing statistics calculated after fitting models for all specified quantiles with the QUANTILE= option in the MODEL statement. At least one specification of the form *keyword=name* is required.

All variables in the original data set are included in the new data set, along with the variables created as options to the OUTPUT statement. These new variables contain fitted values and estimated quantiles. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

If you specify multiple quantiles in the MODEL statement, the COLUMNWISE option arranges the created OUTPUT data set in column-wise form. This arrangement repeats the input data for each quantile. By default, the OUTPUT data set is created in row-wise form. For each appropriate keyword specified in the OUTPUT statement, one variable for each specified quantile is generated. These variables appear in the sorted order of the specified quantiles.

The following specifications can appear in the OUTPUT statement:

<code>OUT=SAS-data-set</code>	specifies the new data set. By default, the procedure uses the <code>DATAn</code> convention to name the new data set.
<code>keyword=name</code>	specifies the statistics to include in the output data set and gives names to the new variables. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

LEVERAGE	specifies a variable to indicate leverage points. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the MODEL statement. See the section “ Leverage Point and Outlier Detection ” on page 6528 for how to define LEVERAGE.
MAHADIST MD	specifies a variable to contain the Mahalanobis distance. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the MODEL statement.
OUTLIER	specifies a variable to indicate outliers. See the section “ Leverage Point and Outlier Detection ” on page 6528 for how to define OUTLIER.
PREDICTED P	specifies a variable to contain the estimated response.
QUANTILE Q	specifies a variable to contain the quantile for which the quantile regression is fitted. If you specify the COLUMNWISE option, this variable is created by default. If multiple quantiles are specified in the MODEL statement and the COLUMNWISE option is not specified, this variable is not created.
RESIDUAL RES	specifies a variable to contain the residuals (unstandardized) $y_i - \mathbf{x}_i' \hat{\boldsymbol{\beta}}$
ROBDIST RD	specifies a variable to contain the robust MCD distance. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the MODEL statement.
SPLINE SP	specifies a variable to contain the estimated spline effect, which includes all spline effects in the model and their interactions.
SRESIDUAL SR	specifies a variable to contain the standardized residuals $\frac{y_i - \mathbf{x}_i' \hat{\boldsymbol{\beta}}}{\hat{\sigma}}$ <p>See the section “Leverage Point and Outlier Detection” on page 6528 for how to compute σ.</p>
STDP	specifies a variable to contain the estimates of the standard errors of the estimated response.

PERFORMANCE Statement

The PERFORMANCE statement is used to change default options that affect the performance of PROC QUANTREG and to request tables that show the performance options in effect and timing details.

PERFORMANCE < options > ;

The following options are available:

CPUCOUNT=1-1024

CPUCOUNT=ACTUAL

specifies the number of processors to use in the computation of the interior point algorithm. CPU-COUNT=ACTUAL sets CPUCOUNT to be the number of physical processors available. Note that this can be less than the physical number of CPUs if the SAS process has been restricted by system administration tools. Setting CPUCOUNT= to a number greater than the actual number of available CPUs might result in reduced performance. This option overrides the SAS system option CPU-COUNT=. If CPUCOUNT=1, then **NOTHREADS** is in effect, and PROC QUANTREG uses singly threaded code.

DETAILS

requests the “PerfSettings” table that shows the performance settings in effect and the “Timing” table that provides a broad timing breakdown of the PROC QUANTREG step.

THREADS

enables multithreaded computation for the interior point algorithm. This option overrides the SAS system option **THREADS** | **NOTHREADS**. If you do not specify the **ALGORITHM=INTERIOR** option, then PROC QUANTREG ignores this option and uses singly threaded code.

NOTHREADS

disables multithreaded computation for the interior point algorithm. This option overrides the SAS system option **THREADS** | **NOTHREADS**.

TEST Statement

< label: > **TEST** effects < / options > ;

In quantile regression analysis, you might be interested in testing whether a covariate effect is statistically significant for a given quantile. In other situations, you might be interested in testing whether the coefficients of a covariate are the same across a set of quantiles. You can use the TEST Statement to perform these tests.

Testing Effects of Covariates

You can use TEST statement to obtain a test for the canonical linear hypothesis concerning the parameters of the tested effects

$$\beta_j = 0, \quad j = i_1, \dots, i_q$$

where q is the total number of parameters of the tested effects. The tested *effects* can be any set of effects in the MODEL statement. Three types of tests (Wald, likelihood ratio, and rank methods) are available for testing effects of covariates by the following *options* in the TEST statement after a slash (/):

WALD

requests Wald tests.

LR

requests likelihood ratio tests.

RANKSCORE <(NORMAL | WILCOXON | SIGN | TAU)>

requests rank tests. The NORMAL, WILCOXON, and SIGN functions are implemented and suitable for iid error models, and the TAU score function is implemented and appropriate for non-iid error models. By default, the TAU score function is used. See Koenker (2005) for more information about the score functions.

Testing for Heteroscedasticity

You can test whether there is any difference among the estimated coefficients across quantiles if several quantiles are specified in the MODEL statement. The test for such heteroscedasticity can be requested by the option QINTERACT after a slash (/) in the TEST statement. See [Example 77.5](#).

You can submit multiple TEST statements, provided that they appear after the MODEL statement. The optional *label*, which must be a valid SAS name, is used to identify output from the corresponding TEST statement. See the section “[Linear Test](#)” on page 6526 for details about these tests.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement specifies a weight variable in the input data set.

To request weighted quantile regression, place the weights in a variable and specify the name in the WEIGHT statement. The values of the WEIGHT variable can be nonintegral and are not truncated. Observations with nonpositive or missing values for the weight variable do not contribute to the fit of the model. See the section “[Details: QUANTREG Procedure](#)” on page 6514 for more information about weighted quantile regression.

Details: QUANTREG Procedure

Quantile Regression as an Optimization Problem

The model for linear quantile regression is

$$\mathbf{y} = \mathbf{A}'\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, \dots, y_n)'$ is the $(n \times 1)$ vector of responses, $\mathbf{A}' = (\mathbf{x}_1, \dots, \mathbf{x}_n)'$ is the $(n \times p)$ regressor matrix, $\boldsymbol{\beta} = (\beta_1, \dots, \beta_p)'$ is the $(p \times 1)$ vector of unknown parameters, and $\boldsymbol{\epsilon} = (\epsilon_1, \dots, \epsilon_n)'$ is the $(n \times 1)$ vector of unknown errors.

L_1 regression, also known as median regression, is a natural extension of the sample median when the response is conditioned on the covariates. In L_1 regression, the least absolute residuals estimate $\hat{\beta}_{LAR}$, referred to as the L_1 -norm estimate, is obtained as the solution of the minimization problem

$$\min_{\beta \in \mathbf{R}^p} \sum_{i=1}^n |y_i - \mathbf{x}_i' \beta|$$

More generally, for quantile regression Koenker and Bassett (1978) defined the τ regression quantile, $0 < \tau < 1$, as any solution to the minimization problem

$$\min_{\beta \in \mathbf{R}^p} \left[\sum_{i \in \{i: y_i \geq \mathbf{x}_i' \beta\}} \tau |y_i - \mathbf{x}_i' \beta| + \sum_{i \in \{i: y_i < \mathbf{x}_i' \beta\}} (1 - \tau) |y_i - \mathbf{x}_i' \beta| \right]$$

The solution is denoted as $\hat{\beta}(\tau)$, and the L_1 -norm estimate corresponds to $\hat{\beta}(1/2)$. The τ regression quantile is an extension of the τ sample quantile $\hat{\xi}(\tau)$, which can be formulated as the solution of

$$\min_{\xi \in \mathbf{R}} \left[\sum_{i \in \{i: y_i \geq \xi\}} \tau |y_i - \xi| + \sum_{i \in \{i: y_i < \xi\}} (1 - \tau) |y_i - \xi| \right]$$

If you specify weights $w_i, i = 1, \dots, n$, with the WEIGHT statement, weighted quantile regression is carried out by solving

$$\min_{\beta_w \in \mathbf{R}^p} \left[\sum_{i \in \{i: y_i \geq \mathbf{x}_i' \beta_w\}} w_i \tau |y_i - \mathbf{x}_i' \beta_w| + \sum_{i \in \{i: y_i < \mathbf{x}_i' \beta_w\}} w_i (1 - \tau) |y_i - \mathbf{x}_i' \beta_w| \right]$$

Weighted regression quantiles β_w can be used for L-estimation; see Koenker and Zhao (1994).

Optimization Algorithms

The optimization problem for median regression has been formulated and solved as a linear programming (LP) problem since the 1950s. Variations of the simplex algorithm, especially the method of Barrodale and Roberts (1973), have been widely used to solve this problem. The simplex algorithm is computationally demanding in large statistical applications, and in theory the number of iterations can increase exponentially with the sample size. This algorithm is often useful with data containing no more than tens of thousands of observations.

Several alternatives have been developed to handle L_1 regression for larger data sets. The interior point approach of Karmarkar (1984) solves a sequence of quadratic problems in which the relevant interior of the constraint set is approximated by an ellipsoid. The worst-case performance of the interior point algorithm has been proved to be better than that of the simplex algorithm. More important, experience has shown that the interior point algorithm is advantageous for larger problems.

Like L_1 regression, general quantile regression fits nicely into the standard primal-dual formulations of linear programming.

In addition to the interior point method, various heuristic approaches are available for computing L_1 -type solutions. Among these, the finite smoothing algorithm of Madsen and Nielsen (1993) is the most useful. It approximates the L_1 -type objective function with a smoothing function, so that the Newton-Raphson algorithm can be used iteratively to obtain a solution after a finite number of iterations. The smoothing algorithm extends naturally to general quantile regression.

The QUANTREG procedure implements the simplex, interior point, and smoothing algorithms. The remainder of this section describes these algorithms in more detail.

Simplex Algorithm

Let $\mu = [y - \mathbf{A}'\beta]_+$, $\nu = [\mathbf{A}'\beta - y]_+$, $\phi = [\beta]_+$, and $\varphi = [-\beta]_+$, where $[z]_+$ is the nonnegative part of z .

Let $D_{LAR}(\beta) = \sum_{i=1}^n |y_i - \mathbf{x}'_i \beta|$. For the L_1 problem, the simplex approach solves $\min_{\beta} D_{LAR}(\beta)$ by reformulating it as the constrained minimization problem

$$\min_{\beta} \{ \mathbf{e}'\mu + \mathbf{e}'\nu \mid y = \mathbf{A}'\beta + \mu - \nu, \{\mu, \nu\} \in \mathbf{R}_+^n \}$$

where \mathbf{e} denotes an $(n \times 1)$ vector of ones.

Let $\mathbf{B} = [\mathbf{A}' \quad -\mathbf{A}' \quad \mathbf{I} \quad -\mathbf{I}]$, $\theta = (\phi' \quad \varphi' \quad \mu' \quad \nu')'$, and $\mathbf{d} = (\mathbf{0}' \quad \mathbf{0}' \quad \mathbf{e}' \quad \mathbf{e}')$, where $\mathbf{0}' = (0 \ 0 \ \dots \ 0)_p$. The reformulation presents a standard LP problem:

$$\begin{aligned} (P) \quad & \min_{\theta} \mathbf{d}'\theta \\ \text{subject to} \quad & \mathbf{B}\theta = \mathbf{y} \\ & \theta \geq 0 \end{aligned}$$

This problem has the dual formulation

$$\begin{aligned} (D) \quad & \max_z \mathbf{y}'\mathbf{z} \\ \text{subject to} \quad & \mathbf{B}'\mathbf{z} \leq \mathbf{d} \end{aligned}$$

which can be simplified as

$$\max_z \mathbf{y}'\mathbf{z}; \quad \text{subject to } \mathbf{A}\mathbf{z} = \mathbf{0}, \mathbf{z} \in [-1, 1]^n$$

By setting $\eta = \frac{1}{2} + \frac{1}{2}\mathbf{e}$, $\mathbf{b} = \frac{1}{2}\mathbf{A}\mathbf{e}$, the problem becomes

$$\max_{\eta} \mathbf{y}'\eta; \quad \text{subject to } \mathbf{A}\eta = \mathbf{b}, \eta \in [0, 1]^n$$

For quantile regression, the minimization problem is $\min_{\beta} \sum \rho_{\tau}(y_i - \mathbf{x}'_i \beta)$, and a similar set of steps leads to the dual formulation

$$\max_z \mathbf{y}'\mathbf{z}; \quad \text{subject to } \mathbf{A}\mathbf{z} = (1 - \tau)\mathbf{A}\mathbf{e}, \mathbf{z} \in [0, 1]^n$$

The QUANTREG procedure solves this LP problem by using the simplex algorithm of Barrodale and Roberts (1973). This algorithm solves the primary LP problem (P) by two stages, which exploit the special structure of the coefficient matrix \mathbf{B} . The first stage picks the columns in \mathbf{A}' or $-\mathbf{A}'$ as pivotal columns. The

second stage interchanges the columns in \mathbf{I} or $-\mathbf{I}$ as basis or nonbasis columns, respectively. The algorithm obtains an optimal solution by executing these two stages interactively. Moreover, because of the special structure of \mathbf{B} , only the main data matrix \mathbf{A} is stored in the current memory.

Although this special version of the simplex algorithm was introduced for median regression, it extends naturally to quantile regression for any given quantile and even to the entire quantile process (Koenker and d'Orey 1994). It greatly reduces the computing time required by the general simplex algorithm, and it is suitable for data sets with fewer than 5,000 observations and 50 variables.

Interior Point Algorithm

There are many variations of interior point algorithms. The QUANTREG procedure uses the primal-dual predictor-corrector algorithm implemented by Lustig, Marsten, and Shanno (1992). The text by Roos, Terlaky, and Vial (1997) provides more information about this particular algorithm. The following brief introduction of this algorithm uses the notation in the first reference.

To be consistent with the conventional LP setting, let $\mathbf{c} = -\mathbf{y}$, $\mathbf{b} = (1 - \tau)\mathbf{A}\mathbf{e}$, and let \mathbf{u} be the general upper bound. The linear program to be solved is

$$\begin{array}{ll} \min \{ \mathbf{c}'\mathbf{z} \} \\ \text{subject to} & \mathbf{A}\mathbf{z} = \mathbf{b} \\ & \mathbf{0} \leq \mathbf{z} \leq \mathbf{u} \end{array}$$

To simplify the computation, this is treated as the *primal* problem. The problem has n variables. The index i denotes a variable number, and k denotes an iteration number. If k is used as a subscript or superscript, it denotes “of iteration k .”

Let \mathbf{v} be the primal slack so that $\mathbf{z} + \mathbf{v} = \mathbf{u}$. Associate dual variables \mathbf{w} with these constraints. The interior point algorithm solves the system of equations to satisfy the Karush-Kuhn-Tucker (KKT) conditions for optimality:

$$\begin{aligned} \mathbf{A}\mathbf{z} &= \mathbf{b} \\ \mathbf{z} + \mathbf{v} &= \mathbf{u} \\ \mathbf{A}'\mathbf{t} + \mathbf{s} - \mathbf{w} &= \mathbf{c} \\ \mathbf{Z}\mathbf{S}\mathbf{e} &= \mathbf{0} \\ \mathbf{V}\mathbf{W}\mathbf{e} &= \mathbf{0} \\ \mathbf{z}, \mathbf{s}, \mathbf{v}, \mathbf{w} &\geq \mathbf{0} \\ \text{where} \\ \mathbf{W} &= \text{diag}(\mathbf{w}) \text{ (that is, } W_{i,j} = w_i \text{ if } i = j, W_{i,j} = 0 \text{ otherwise)} \\ \mathbf{V} &= \text{diag}(\mathbf{v}), \mathbf{Z} = \text{diag}(\mathbf{z}), \mathbf{S} = \text{diag}(\mathbf{s}) \end{aligned}$$

These are the conditions for feasibility, with the addition of *complementarity* conditions $\mathbf{Z}\mathbf{S}\mathbf{e} = \mathbf{0}$ and $\mathbf{V}\mathbf{W}\mathbf{e} = \mathbf{0}$. $\mathbf{c}'\mathbf{z} = \mathbf{b}'\mathbf{t} - \mathbf{u}'\mathbf{w}$ must occur at the optimum. Complementarity forces the optimal objectives of the primal and dual to be equal, $\mathbf{c}'\mathbf{z}_{opt} = \mathbf{b}'\mathbf{t}_{opt} - \mathbf{u}'\mathbf{w}_{opt}$, as

$$\begin{aligned}
0 &= \mathbf{v}'_{opt} \mathbf{w}_{opt} = (\mathbf{u} - \mathbf{z}_{opt})' \mathbf{w}_{opt} = \mathbf{u}' \mathbf{w}_{opt} - \mathbf{z}'_{opt} \mathbf{w}_{opt} \\
0 &= \mathbf{z}'_{opt} \mathbf{s}_{opt} = \mathbf{s}'_{opt} \mathbf{z}_{opt} = (\mathbf{c} - \mathbf{A}' \mathbf{t}_{opt} + \mathbf{w}_{opt})' \mathbf{z}_{opt} \\
&= \mathbf{c}' \mathbf{z}_{opt} - \mathbf{t}'_{opt} (\mathbf{A} \mathbf{z}_{opt}) + \mathbf{w}'_{opt} \mathbf{z}_{opt} = \mathbf{c}' \mathbf{z}_{opt} - \mathbf{b}' \mathbf{t}_{opt} + \mathbf{u}' \mathbf{w}_{opt}
\end{aligned}$$

Therefore

$$0 = \mathbf{c}' \mathbf{z}_{opt} - \mathbf{b}' \mathbf{t}_{opt} + \mathbf{u}' \mathbf{w}_{opt}$$

The *duality gap*, $\mathbf{c}' \mathbf{z} - \mathbf{b}' \mathbf{t} + \mathbf{u}' \mathbf{w}$, is used to measure the convergence of the algorithm. You can specify a tolerance for this convergence criterion with the TOLERANCE= option in the PROC QUANTREG statement.

Before the optimum is reached, it is possible for a solution $(\mathbf{z}, \mathbf{t}, \mathbf{s}, \mathbf{v}, \mathbf{w})$ to violate the KKT conditions in one of several ways:

- Primal bound constraints can be broken, $\delta_b = \mathbf{u} - \mathbf{z} - \mathbf{v} \neq \mathbf{0}$.
- Primal constraints can be broken, $\delta_c = \mathbf{b} - \mathbf{A} \mathbf{z} \neq \mathbf{0}$.
- Dual constraints can be broken, $\delta_d \mathbf{s} = \mathbf{c} - \mathbf{A}' \mathbf{t} - \mathbf{s} + \mathbf{w} \neq \mathbf{0}$.
- Complementarity conditions are unsatisfied, $\mathbf{z}' \mathbf{s} \neq 0$ and $\mathbf{v}' \mathbf{w} \neq 0$.

The interior point algorithm works by using Newton's method to find a direction $(\Delta \mathbf{z}^k, \Delta \mathbf{t}^k, \Delta \mathbf{s}^k, \Delta \mathbf{v}^k, \Delta \mathbf{w}^k)$ to move from the current solution $(\mathbf{z}^k, \mathbf{t}^k, \mathbf{s}^k, \mathbf{v}^k, \mathbf{w}^k)$ toward a better solution:

$$(\mathbf{z}^{k+1}, \mathbf{t}^{k+1}, \mathbf{s}^{k+1}, \mathbf{v}^{k+1}, \mathbf{w}^{k+1}) = (\mathbf{z}^k, \mathbf{t}^k, \mathbf{s}^k, \mathbf{v}^k, \mathbf{w}^k) + \kappa (\Delta \mathbf{z}^k, \Delta \mathbf{t}^k, \Delta \mathbf{s}^k, \Delta \mathbf{v}^k, \Delta \mathbf{w}^k)$$

κ is the *step length* and is assigned a value as large as possible, but not so large that a \mathbf{z}_i^{k+1} or \mathbf{s}_i^{k+1} is "too close" to zero. You can control the step length with the KAPPA= option in the PROC QUANTREG statement.

The QUANTREG procedure implements a predictor-corrector variant of the primal-dual interior point algorithm. First, Newton's method is used to find a direction $(\Delta \mathbf{z}_{aff}^k, \Delta \mathbf{t}_{aff}^k, \Delta \mathbf{s}_{aff}^k, \Delta \mathbf{v}_{aff}^k, \Delta \mathbf{w}_{aff}^k)$ in which to move. This is known as the *affine* step.

In iteration k , the *affine* step system that must be solved is

$$\begin{aligned}
\Delta \mathbf{z}_{aff} + \Delta \mathbf{v}_{aff} &= \delta_b \\
\mathbf{A} \Delta \mathbf{z}_{aff} &= \delta_c \\
\mathbf{A}' \Delta \mathbf{t}_{aff} + \Delta \mathbf{s}_{aff} - \Delta \mathbf{w}_{aff} &= \delta_d \\
\mathbf{S} \Delta \mathbf{z}_{aff} + \mathbf{Z} \Delta \mathbf{s}_{aff} &= -\mathbf{Z} \mathbf{S} \mathbf{e} \\
\mathbf{V} \Delta \mathbf{w}_{aff} + \mathbf{W} \Delta \mathbf{z}_{aff} &= -\mathbf{V} \mathbf{W} \mathbf{e}
\end{aligned}$$

Therefore, the computations involved in solving the affine step are

$$\begin{aligned}
\Theta &= \mathbf{SZ}^{-1} + \mathbf{WV}^{-1} \\
\rho &= \Theta^{-1}(\delta_d + (\mathbf{S} - \mathbf{W})\mathbf{e} - \mathbf{V}^{-1}\mathbf{W}\delta_b) \\
\Delta t_{\text{aff}} &= (\mathbf{A}\Theta^{-1}\mathbf{A}')^{-1}(\delta_c + \mathbf{A}\rho) \\
\Delta z_{\text{aff}} &= \Theta^{-1}\mathbf{A}'\Delta t_{\text{aff}} - \rho \\
\Delta v_{\text{aff}} &= \delta_b - \Delta z_{\text{aff}} \\
\Delta w_{\text{aff}} &= -\mathbf{W}\mathbf{e} - \mathbf{V}^{-1}\mathbf{W}\Delta z_{\text{aff}} \\
\Delta s_{\text{aff}} &= -\mathbf{S}\mathbf{e} - \mathbf{Z}^{-1}\mathbf{S}\Delta z_{\text{aff}} \\
(\mathbf{z}_{\text{aff}}, \mathbf{t}_{\text{aff}}, \mathbf{s}_{\text{aff}}, \mathbf{v}_{\text{aff}}, \mathbf{w}_{\text{aff}}) &= (\mathbf{z}, \mathbf{t}, \mathbf{s}, \mathbf{v}, \mathbf{w}) + \kappa(\Delta z_{\text{aff}}, \Delta t_{\text{aff}}, \Delta s_{\text{aff}}, \Delta v_{\text{aff}}, \Delta w_{\text{aff}})
\end{aligned}$$

where κ is the *step length* as before.

The success of the affine step is gauged by calculating the complementarity of $\mathbf{z}'\mathbf{s}$ and $\mathbf{v}'\mathbf{w}$ at $(\mathbf{z}_{\text{aff}}^k, \mathbf{t}_{\text{aff}}^k, \mathbf{s}_{\text{aff}}^k, \mathbf{v}_{\text{aff}}^k, \mathbf{w}_{\text{aff}}^k)$ and comparing it with the complementarity at the starting point $(\mathbf{z}^k, \mathbf{t}^k, \mathbf{s}^k, \mathbf{v}^k, \mathbf{w}^k)$. If the affine step was successful in reducing the complementarity by a substantial amount, the need for centering is not great, and a value close to zero is assigned to σ in a second linear system (see following), which is used to determine a centering vector. If, however, the affine step was unsuccessful, then centering is deemed beneficial, and a value close to 1.0 is assigned to σ . In other words, the value of σ is adaptively altered depending on progress made toward the optimum.

The following linear system is solved to determine a centering vector $(\Delta z_c, \Delta t_c, \Delta s_c, \Delta v_c, \Delta w_c)$ from $(\mathbf{z}_{\text{aff}}, \mathbf{t}_{\text{aff}}, \mathbf{s}_{\text{aff}}, \mathbf{v}_{\text{aff}}, \mathbf{w}_{\text{aff}})$:

$$\begin{aligned}
\Delta z_c + \Delta v_c &= 0 \\
\mathbf{A}\Delta z_c &= 0 \\
\mathbf{A}'\Delta t_c + \Delta s_c - \Delta w_c &= 0 \\
\mathbf{S}\Delta z_c + \mathbf{Z}\Delta s_c &= -\mathbf{Z}_{\text{aff}}\mathbf{S}_{\text{aff}}\mathbf{e} + \sigma\mu\mathbf{e} \\
\mathbf{V}\Delta w_c + \mathbf{W}\Delta v_c &= -\mathbf{V}_{\text{aff}}\mathbf{W}_{\text{aff}}\mathbf{e} + \sigma\mu\mathbf{e}
\end{aligned}$$

where $\zeta_{\text{start}} = \mathbf{z}'\mathbf{s} + \mathbf{v}'\mathbf{w}$, complementarity at the start of the iteration
 $\zeta_{\text{aff}} = \mathbf{z}'_{\text{aff}}\mathbf{s}_{\text{aff}} + \mathbf{v}'_{\text{aff}}\mathbf{w}_{\text{aff}}$, the affine complementarity
 $\mu = \zeta_{\text{aff}}/2n$, the average complementarity
 $\sigma = (\zeta_{\text{aff}}/\zeta_{\text{start}})^3$

Therefore, the computations involved in solving the centering step are

$$\begin{aligned}
\rho &= \Theta^{-1}(\sigma\mu(\mathbf{Z}^{-1} - \mathbf{V}^{-1})\mathbf{e} - \mathbf{Z}^{-1}\mathbf{Z}_{\text{aff}}\mathbf{S}_{\text{aff}}\mathbf{e} + \mathbf{V}^{-1}\mathbf{V}_{\text{aff}}\mathbf{W}_{\text{aff}}\mathbf{e}) \\
\Delta t_c &= (\mathbf{A}\Theta^{-1}\mathbf{A}')^{-1}\mathbf{A}\rho \\
\Delta z_c &= \Theta^{-1}\mathbf{A}'\Delta t_c - \rho \\
\Delta v_c &= -\Delta z_c \\
\Delta w_c &= \sigma\mu\mathbf{V}^{-1}\mathbf{e} - \mathbf{V}^{-1}\mathbf{V}_{\text{aff}}\mathbf{W}_{\text{aff}}\mathbf{e} - \mathbf{V}^{-1}\mathbf{W}_{\text{aff}}\Delta v_c \\
\Delta s_c &= \sigma\mu\mathbf{Z}^{-1}\mathbf{e} - \mathbf{Z}^{-1}\mathbf{Z}_{\text{aff}}\mathbf{S}_{\text{aff}}\mathbf{e} - \mathbf{Z}^{-1}\mathbf{S}_{\text{aff}}\Delta z_c
\end{aligned}$$

Then

$$\begin{aligned}(\Delta z, \Delta t, \Delta s, \Delta v, \Delta w) &= (\Delta z_{aff}, \Delta t_{aff}, \Delta s_{aff}, \Delta v_{aff}, \Delta w_{aff}) + (\Delta z_c, \Delta t_c, \Delta s_c, \Delta v_c, \Delta w_c) \\(z^{k+1}, t^{k+1}, s^{k+1}, v^{k+1}, w^{k+1}) &= (z^k, t^k, s^k, v^k, w^k) + \kappa(\Delta z, \Delta t, \Delta s, \Delta v, \Delta w)\end{aligned}$$

where, as before, κ is the *step length* assigned a value as large as possible, but not so large that a z_i^{k+1} , s_i^{k+1} , v_i^{k+1} , or w_i^{k+1} is “too close” to zero.

Although the predictor-corrector variant entails solving two linear systems instead of one, fewer iterations are usually required to reach the optimum. The additional overhead of the second linear system is small because the matrix $(\mathbf{A}\Theta^{-1}\mathbf{A}')$ has already been factorized in order to solve the first linear system.

You can specify the starting point with the INEST= option in the PROC statement. By default, the starting point is set to be the least squares estimate.

Smoothing Algorithm

To minimize the sum of the absolute residuals $D_{LAR}(\boldsymbol{\beta})$, the smoothing algorithm approximates the non-differentiable function D_{LAR} by the following smooth function, which is referred to as the Huber function:

$$D_\gamma(\boldsymbol{\beta}) = \sum_{i=1}^n H_\gamma(r_i(\boldsymbol{\beta}))$$

where

$$H_\gamma(t) = \begin{cases} t^2/(2\gamma) & \text{if } |t| \leq \gamma \\ |t| - \gamma/2 & \text{if } |t| > \gamma \end{cases}$$

Here $r_i(\boldsymbol{\beta}) = y_i - \mathbf{x}_i'\boldsymbol{\beta}$, and the *threshold* γ is a positive real number. The function D_γ is continuously differentiable and a minimizer β_γ of D_γ is close to a minimizer $\hat{\boldsymbol{\beta}}_{LAR}$ of $D_{LAR}(\boldsymbol{\beta})$ when γ is close to zero.

The advantage of the smoothing algorithm as described in Madsen and Nielsen (1993) is that the L_1 solution $\hat{\boldsymbol{\beta}}_{LAR}$ can be detected when $\gamma > 0$ is small. In other words, it is not necessary to let γ converge to zero in order to find a minimizer of $D_{LAR}(\boldsymbol{\beta})$. The algorithm terminates before going through the entire sequence of values of γ that are generated by the algorithm. Convergence is indicated by no change of the status of residuals $r_i(\boldsymbol{\beta})$ as γ goes through this sequence.

The smoothing algorithm extends naturally from L_1 regression to general quantile regression; see Chen (2007). The function

$$D_{\rho_\tau}(\boldsymbol{\beta}) = \sum_{i=1}^n \rho_\tau(y_i - \mathbf{x}_i'\boldsymbol{\beta})$$

can be approximated by the smooth function

$$D_{\gamma,\tau}(\boldsymbol{\beta}) = \sum_{i=1}^n H_{\gamma,\tau}(r_i(\boldsymbol{\beta}))$$

where

$$H_{\gamma,\tau}(t) = \begin{cases} t(\tau - 1) - \frac{1}{2}(\tau - 1)^2\gamma & \text{if } t \leq (\tau - 1)\gamma \\ \frac{t^2}{2\gamma} & \text{if } (\tau - 1)\gamma \leq t \leq \tau\gamma \\ t\tau - \frac{1}{2}\tau^2\gamma & \text{if } t \geq \tau\gamma \end{cases}$$

The function $H_{\gamma,\tau}$ is determined by whether $r_i(\boldsymbol{\beta}) \leq (\tau - 1)\gamma$, $r_i(\boldsymbol{\beta}) \geq \tau\gamma$, or $(\tau - 1)\gamma \leq r_i(\boldsymbol{\beta}) \leq \tau\gamma$. These inequalities divide \mathbf{R}^p into subregions separated by the parallel hyperplanes $r_i(\boldsymbol{\beta}) = (\tau - 1)\gamma$ and $r_i(\boldsymbol{\beta}) = \tau\gamma$. The set of all such hyperplanes is denoted by $B_{\gamma,\tau}$:

$$B_{\gamma,\tau} = \{\boldsymbol{\beta} \in \mathbf{R}^p \mid \exists i : r_i(\boldsymbol{\beta}) = (\tau - 1)\gamma \text{ or } r_i(\boldsymbol{\beta}) = \tau\gamma\}$$

Define the sign vector $s_\gamma(\boldsymbol{\beta}) = (s_1(\boldsymbol{\beta}), \dots, s_n(\boldsymbol{\beta}))'$ as

$$s_i = s_i(\boldsymbol{\beta}) = \begin{cases} -1 & \text{if } r_i(\boldsymbol{\beta}) \leq (\tau - 1)\gamma \\ 0 & \text{if } (\tau - 1)\gamma \leq r_i(\boldsymbol{\beta}) \leq \tau\gamma \\ 1 & \text{if } r_i(\boldsymbol{\beta}) \geq \tau\gamma \end{cases}$$

and introduce

$$w_i = w_i(\boldsymbol{\beta}) = 1 - s_i^2(\boldsymbol{\beta})$$

Therefore,

$$\begin{aligned} H_{\gamma,\tau}(r_i(\boldsymbol{\beta})) &= \frac{1}{2\gamma} w_i r_i^2(\boldsymbol{\beta}) \\ &+ s_i \left[\frac{1}{2} r_i(\boldsymbol{\beta}) + \frac{1}{4} (1 - 2\tau)\gamma + s_i (r_i(\boldsymbol{\beta}) (\tau - \frac{1}{2}) - \frac{1}{4} (1 - 2\tau + 2\tau^2)\gamma) \right] \end{aligned}$$

yielding

$$D_{\gamma,\tau}(\boldsymbol{\beta}) = \frac{1}{2\gamma} \mathbf{r}' \mathbf{W}_{\gamma,\tau} \mathbf{r} + \mathbf{v}'(s) \mathbf{r} + c(s)$$

where $\mathbf{W}_{\gamma,\tau}$ is the diagonal $n \times n$ matrix with diagonal elements $w_i(\boldsymbol{\beta})$, $\mathbf{v}'(s) = (s_1((2\tau - 1)s_1 + 1)/2, \dots, s_n((2\tau - 1)s_n + 1)/2)$, $c(s) = \sum [\frac{1}{4}(1 - 2\tau)\gamma s_i - \frac{1}{4}s_i^2(1 - 2\tau + 2\tau^2)\gamma]$, and $r(\boldsymbol{\beta}) = (r_1(\boldsymbol{\beta}), \dots, r_n(\boldsymbol{\beta}))'$.

The gradient of $D_{\gamma,\tau}$ is given by

$$D_{\gamma,\tau}^{(1)}(\boldsymbol{\beta}) = -\mathbf{A} \left[\frac{1}{\gamma} \mathbf{W}_{\gamma,\tau}(\boldsymbol{\beta}) \mathbf{r}(\boldsymbol{\beta}) + \mathbf{v}(s) \right]$$

and for $\boldsymbol{\beta} \in \mathbf{R}^p \setminus B_{\gamma,\tau}$ the Hessian exists and is given by

$$D_{\gamma,\tau}^{(2)}(\boldsymbol{\beta}) = \frac{1}{\gamma} \mathbf{A} \mathbf{W}_{\gamma,\tau}(\boldsymbol{\beta}) \mathbf{A}'$$

The gradient is a continuous function in \mathbf{R}^p , whereas the Hessian is piecewise constant.

Following Madsen and Nielsen (1993), the vector \mathbf{s} is referred to as a γ -feasible sign vector if there exists $\boldsymbol{\beta} \in \mathbf{R}^p \setminus B_{\gamma, \tau}$ with $\mathbf{s}_\gamma(\boldsymbol{\beta}) = \mathbf{s}$. If \mathbf{s} is γ -feasible, then Q_s is defined as the quadratic function $Q_s(\boldsymbol{\alpha})$ that is derived from $D_{\gamma, \tau}(\boldsymbol{\beta})$ by substituting \mathbf{s} for \mathbf{s}_γ . Thus, for any $\boldsymbol{\beta}$ with $\mathbf{s}_\gamma = \mathbf{s}$,

$$Q_s(\boldsymbol{\alpha}) = \frac{1}{2}(\boldsymbol{\alpha} - \boldsymbol{\beta})' D_{\gamma, \tau}^{(2)}(\boldsymbol{\beta})(\boldsymbol{\alpha} - \boldsymbol{\beta}) + D_{\gamma, \tau}^{(1)}(\boldsymbol{\beta})(\boldsymbol{\alpha} - \boldsymbol{\beta}) + D_{\gamma, \tau}(\boldsymbol{\beta})$$

In the domain $C_s = \{\boldsymbol{\alpha} | \mathbf{s}_\gamma(\boldsymbol{\alpha}) = \mathbf{s}\}$

$$D_{\gamma, \tau}(\boldsymbol{\alpha}) = Q_s(\boldsymbol{\alpha})$$

For each $\gamma > 0$ and $\theta \in \mathbf{R}^p$, there can be one or several corresponding quadratics Q_s . If $\theta \notin B_{\gamma, \tau}$ then Q_s is characterized by θ and γ , but for $\theta \in B_{\gamma, \tau}$ the quadratic is not unique. Therefore, a *reference*

$$(\gamma, \theta, \mathbf{s})$$

determines the quadratic.

Again following Madsen and Nielsen (1993), let

$(\gamma, \theta, \mathbf{s})$ be a *feasible reference* if \mathbf{s} is a γ -feasible sign vector with $\theta \in C_s$, and

$(\gamma, \theta, \mathbf{s})$ be a *solution reference* if it is feasible and θ minimizes $D_{\gamma, \tau}$.

The smoothing algorithm for minimizing D_{ρ_τ} is based on minimizing $D_{\gamma, \tau}$ for a set of decreasing γ . For each new value of γ , information from the previous solution is used. Finally, when γ is small enough, a solution can be found by the modified Newton-Raphson algorithm as stated by Madsen and Nielsen (1993):

find an initial solution reference $(\gamma, \boldsymbol{\beta}_\gamma, \mathbf{s})$

repeat

decrease γ

find a solution reference $(\gamma, \boldsymbol{\beta}_\gamma, \mathbf{s})$

until $\gamma = 0$

$\boldsymbol{\beta}_0$ is the solution.

By default, the initial solution reference is found by letting $\boldsymbol{\beta}_\gamma$ be the least squares solution. Alternatively, you can specify the initial solution reference with the INEST= option in the PROC QUANTREG statement. Then γ and \mathbf{s} are chosen according to these initial values.

There are several approaches for determining a decreasing sequence of values of γ . The QUANTREG procedure uses a strategy by Madsen and Nielsen (1993). The computation involved is not significant comparing with the Newton-Raphson step. You can control the ratio of consecutive decreasing values of γ with the RRATIO= suboption of the ALGORITHM= option in the PROC QUANTREG statement. By default,

$$\text{RRATIO} = \begin{cases} 0.1 & \text{if } n \geq 10000 \text{ and } p \leq 20 \\ 0.9 & \text{if } \frac{p}{n} \geq 0.1 \text{ or } \{n \leq 5000 \text{ and } p \geq 300\} \\ 0.5 & \text{otherwise} \end{cases}$$

For the L_1 and quantile regression, it turns out that the smoothing algorithm is very efficient and competitive, especially for a *fat* data set—namely, when $\frac{p}{n} > 0.05$ and $\mathbf{A}\mathbf{A}'$ is dense. See Chen (2007) for a complete smoothing algorithm and details.

Confidence Interval

The QUANTREG procedure provides three methods to compute confidence intervals for the regression quantile parameter $\beta(\tau)$: sparsity, rank, and resampling. The sparsity method is the most direct and the fastest, but it involves estimation of the sparsity function, which is not robust for data that are not independently and identically distributed. To deal with this problem, the QUANTREG procedure computes a Huber sandwich estimate by using a local estimate of the sparsity function. The rank method, which computes confidence intervals by inverting the rank score test, does not suffer from this problem, but it uses the simplex algorithm and is computationally expensive with large data sets. The resampling method, which uses the bootstrap approach, addresses these problems, but at a computation cost.

Based on these properties, the QUANTREG uses a combination of the resampling and rank methods as the default. For data sets with more than either 5,000 observations or 20 variables, the QUANTREG procedure uses the MCMC resampling method; otherwise it uses the rank method. You can request a particular method by using the CI= option in the PROC QUANTREG statement.

Sparsity

Consider the linear model

$$y_i = \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i$$

and assume that $\{\epsilon_i\}$, $i = 1, \dots, n$, are iid with a distribution F and a density $f = F'$, where $f(F^{-1}(\tau)) > 0$ in a neighborhood of τ . Under some mild conditions

$$\sqrt{n}(\hat{\boldsymbol{\beta}}(\tau) - \boldsymbol{\beta}(\tau)) \rightarrow N(0, \omega^2(\tau, F)\boldsymbol{\Omega}^{-1})$$

where $\omega^2(\tau, F) = \tau(1-\tau)/f^2(F^{-1}(\tau))$ and $\boldsymbol{\Omega} = \lim_{n \rightarrow \infty} n^{-1} \sum \mathbf{x}_i \mathbf{x}_i'$. See Koenker and Bassett (1982b).

This asymptotic distribution for the regression quantile $\hat{\boldsymbol{\beta}}(\tau)$ can be used to construct confidence intervals. However, the reciprocal of the density function

$$s(\tau) = [f(F^{-1}(\tau))]^{-1}$$

which is called the *sparsity function*, must first be estimated.

Since

$$s(t) = \frac{d}{dt} F^{-1}(t)$$

$s(t)$ can be estimated by the difference quotient of the empirical quantile function—that is,

$$\hat{s}_n(t) = [\hat{F}_n^{-1}(t + h_n) - \hat{F}_n^{-1}(t - h_n)]/2h_n$$

where \hat{F}_n is an estimate of F^{-1} and h_n is a bandwidth that tends to zero as $n \rightarrow \infty$.

The QUANTREG procedure provides two bandwidth methods. The Bofinger bandwidth

$$h_n = n^{-1/5} \left(\frac{4.5s^2(t)}{(s^{(2)}(t))^2} \right)^{1/5}$$

is an optimizer of mean squared error for standard density estimation, and the Hall-Sheather bandwidth

$$h_n = n^{-1/3} z_\alpha^{2/3} \left(\frac{1.5s(t)}{s^{(2)}(t)} \right)^{1/3}$$

is based on Edgeworth expansions for studentized quantiles, where $s^{(2)}(t)$ is the second derivative of $s(t)$ and z_α satisfies $\Phi(z_\alpha) = 1 - \alpha/2$ for the construction of $1 - \alpha$ confidence intervals. The quantity

$$\frac{s(t)}{s^{(2)}(t)} = \frac{f^2}{2(f^{(1)}/f)^2 + [(f^{(1)}/f)^2 - f^{(2)}/f]}$$

is not sensitive to f and can be estimated by assuming f is Gaussian.

\hat{F}^{-1} can be estimated by the empirical quantile function of the residuals from the quantile regression fit,

$$\hat{F}^{-1}(t) = r_{(i)}, \text{ for } t \in [(i-1)/n, i/n),$$

or the empirical quantile function of regression proposed by Bassett and Koenker (1982),

$$\hat{F}^{-1}(t) = \bar{\mathbf{x}}' \hat{\boldsymbol{\beta}}(t)$$

The QUANTREG procedure interpolates the first empirical quantile function and gets the piecewise linear version

$$\hat{F}^{-1}(t) = \begin{cases} r_{(1)} & \text{if } t \in [0, 1/2n) \\ \lambda r_{(i+1)} + (1-\lambda)r_{(i)} & \text{if } t \in [(2j-1)/2n, (2i+1)/2n) \\ r_{(n)} & \text{if } t \in [(2n-1)/2n, 1] \end{cases}$$

\hat{F}^{-1} is set to a constant if $t \pm h_n$ falls outside $[0, 1]$.

This estimator of the sparsity function is sensitive to the iid assumption. Alternately, Koenker and Machado (1999) considered the non-iid case. By assuming local linearity of the conditional quantile function $Q(\tau|x)$ in x , they proposed a local estimator of the density function by using the difference quotient. A Huber sandwich estimate of the covariance and standard error is computed and used to construct the confidence intervals. One difficulty with this method is the selection of the bandwidth when using the difference quotient. With a small sample size, either the Bofinger or the Hall-Sheather bandwidth tends to be too large to assure local linearity of the conditional quantile function. The QUANTREG procedure uses a heuristic bandwidth selection in these cases.

By default, the QUANTREG procedure computes non-iid confidence intervals. You can request iid confidence intervals with the IID option in the PROC statement.

Inversion of Rank Tests

The classical theory of rank tests can be extended to test the hypothesis $H_0: \beta_2 = \eta$ in the linear regression model $\mathbf{y} = \mathbf{X}_1\beta_1 + \mathbf{X}_2\beta_2 + \boldsymbol{\epsilon}$. Here $(\mathbf{X}_1, \mathbf{X}_2) = \mathbf{A}'$. See Gutenbrunner and Jureckova (1992) for more details. By inverting this test, confidence intervals can be computed for the regression quantiles that correspond to β_2 .

The rank score function $\hat{a}_n(t) = (\hat{a}_{n1}(t), \dots, \hat{a}_{nn}(t))$ can be obtained by solving the dual problem

$$\max_a \{(\mathbf{y} - \mathbf{X}_2\eta)'a | \mathbf{X}_1'a = (1-t)\mathbf{X}_1'e, a \in [0, 1]^n\}$$

For a fixed quantile τ , integrating $\hat{a}_{ni}(t)$ with respect to the τ -quantile score function

$$\varphi_\tau(t) = \tau - I(t < \tau)$$

yields the τ -quantile scores

$$\hat{b}_{ni} = - \int_0^1 \varphi_\tau(t) d\hat{a}_{ni}(t) = \hat{a}_{ni}(\tau) - (1 - \tau)$$

Under the null hypothesis $H_0: \beta_2 = \eta$

$$S_n(\eta) = n^{-1/2} \mathbf{X}_2' \hat{b}_n(\eta) \rightarrow N(0, \tau(1 - \tau) \mathbf{\Omega}_n)$$

for large n , where $\mathbf{\Omega}_n = n^{-1} \mathbf{X}_2' (\mathbf{I} - \mathbf{X}_1 (\mathbf{X}_1' \mathbf{X}_1)^{-1} \mathbf{X}_1') \mathbf{X}_2$.

Let

$$T_n(\eta) = \frac{1}{\sqrt{\tau(1 - \tau)}} S_n(\eta) \mathbf{\Omega}_n^{-1/2}$$

Then $T_n(\hat{\beta}_2(\tau)) = 0$ from the constraint $\mathbf{A}\hat{\mathbf{a}} = (1 - \tau)\mathbf{A}\mathbf{e}$ in the full model. In order to obtain confidence intervals for β_2 , a critical value can be specified for T_n . The dual vector $\hat{a}_n(\eta)$ is a piecewise constant in η , and η can be altered without compromising the optimality of $\hat{a}_n(\eta)$ as long as the signs of the residuals in the primal quantile regression problem do not change. When η gets to such a boundary, the solution does change, but can be restored by taking one simplex pivot. The process can continue in this way until $T_n(\eta)$ exceeds the specified critical value. Since $T_n(\eta)$ is piecewise constant, interpolation can be used to obtain the desired level of confidence interval; see Koenker and d'Orey (1994).

Resampling

The bootstrap can be implemented to compute confidence intervals for regression quantile estimates. As in other regression applications, both the residual bootstrap and the xy -pair bootstrap can be used. The former assumes iid random errors and resamples from the residuals, while the later resamples xy pairs and accommodates some forms of heteroscedasticity. Koenker (1994) considered a more interesting resampling mechanism, resampling directly from the full regression quantile process, which he called the Heqf bootstrap.

In contrast with these bootstrap methods, Parzen, Wei, and Ying (1994) observed that

$$S(\boldsymbol{\beta}) = n^{-1/2} \sum_{i=1}^n \mathbf{x}_i (\tau - I(y_i \leq \mathbf{x}_i' \boldsymbol{\beta}))$$

which is the estimating equation for the τ regression quantile, is a pivotal quantity for the τ quantile regression parameter β_τ . In other words, the distribution of $\mathbf{S}(\boldsymbol{\beta})$ can be generated exactly by a random vector \mathbf{U} , which is a weighted sum of independent, re-centered Bernoulli variables. They further showed that for large n , the distribution of $\hat{\boldsymbol{\beta}}(\tau) - \boldsymbol{\beta}_\tau$ can be approximated by the conditional distribution of $\hat{\boldsymbol{\beta}}_U - \hat{\boldsymbol{\beta}}_n(\tau)$, where $\hat{\boldsymbol{\beta}}_U$ solves an augmented quantile regression problem with $n + 1$ observations with $\mathbf{x}_{n+1} = -n^{-1/2} \mathbf{u} / \tau$ and y_{n+1} sufficiently large for a given realization of \mathbf{u} . By exploiting the asymptotically pivot role of the quantile regression “gradient condition,” this approach also achieves some robustness to certain heteroscedasticity.

Although the bootstrap method by Parzen, Wei, and Ying (1994) is much simpler, it is too time-consuming for relatively large data sets, especially for high-dimensional data sets. The QUANTREG procedure implements a new, general resampling method developed by He and Hu (2002), which is referred to as the

Markov chain marginal bootstrap (MCMB). For quantile regression, the MCMB method has the advantage that it solves p one-dimensional equations instead of p -dimensional equations, as do the previous bootstrap methods. This greatly improves the feasibility of the resampling method in computing confidence intervals for regression quantiles.

Covariance-Correlation

You can specify the COVB and CORRB options in the MODEL statement to request covariance and correlation matrices for the estimated parameters.

The QUANTREG procedure provides two methods for computing the covariance and correlation matrices of the estimated parameters: an asymptotic method and a bootstrap method. Bootstrap covariance and correlation matrices are computed when resampling confidence intervals are computed. Asymptotic covariance and correlation matrices are computed when asymptotic confidence intervals are computed. The rank method for confidence intervals does not provide a covariance-correlation estimate.

Asymptotic Covariance-Correlation

This method corresponds to the sparsity method for the confidence intervals. For the sparsity function in the computation of the asymptotic covariance and correlation, the QUANTREG procedure provides both iid and non-iid estimates. By default, the QUANTREG procedure computes non-iid estimates.

Bootstrap Covariance-Correlation

This method corresponds to the resampling method for the confidence intervals. The Markov chain marginal bootstrap (MCMB) method is used.

Linear Test

Consider the linear model

$$y_i = \mathbf{x}'_{1i}\boldsymbol{\beta}_1 + \mathbf{x}'_{2i}\boldsymbol{\beta}_2 + \epsilon_i$$

where $\boldsymbol{\beta}_1$ and $\boldsymbol{\beta}_2$ are p - and q -dimensional unknown parameters, and $\{\epsilon_i\}$, $i = 1, \dots, n$, are errors with unknown density function f_i . Let $\mathbf{x}'_i = (\mathbf{x}'_{1i}, \mathbf{x}'_{2i})$; $\hat{\boldsymbol{\beta}}_1(\tau)$ and $\hat{\boldsymbol{\beta}}_2(\tau)$ be the parameter estimates for $\boldsymbol{\beta}_1$ and $\boldsymbol{\beta}_2$ respectively at the τ quantile. The covariance matrix $\boldsymbol{\Omega}$ for the parameter estimates is partitioned correspondingly as $\boldsymbol{\Omega}_{ij}$ with $i = 1, 2$; $j = 1, 2$; and $\boldsymbol{\Omega}^{22} = (\boldsymbol{\Omega}_{22} - \boldsymbol{\Omega}_{21}\boldsymbol{\Omega}_{11}^{-1}\boldsymbol{\Omega}_{12})^{-1}$.

Testing Effects of Covariates

Three tests are available in the QUANTREG procedure for the linear null hypothesis $H_0 : \boldsymbol{\beta}_2 = 0$ at the τ quantile.

The Wald test statistic, which is based on the estimated coefficients for the unrestricted model, is given by

$$T_W(\tau) = \hat{\boldsymbol{\beta}}'_2(\tau) \hat{\boldsymbol{\Sigma}}(\tau)^{-1} \hat{\boldsymbol{\beta}}_2(\tau)$$

where $\hat{\boldsymbol{\Sigma}}(\tau)$ is an estimator of the covariance of $\hat{\boldsymbol{\beta}}_2(\tau)$. The QUANTREG procedure provides two estimators for the covariance, as described in the previous section. The estimator based on the asymptotic covariance is

$$\hat{\Sigma}(\tau) = \frac{1}{n} \hat{\omega}(\tau)^2 \Omega^{22}$$

where $\hat{\omega}(\tau) = \sqrt{\tau(1-\tau)}\hat{s}(\tau)$ and $\hat{s}(\tau)$ is the estimated sparsity function. The estimator based on the bootstrap covariance is the empirical covariance of the MCMB samples.

The likelihood ratio test is based on the difference between the objective function values in the restricted and unrestricted models. Let $D_0(\tau) = \sum \rho_\tau(y_i - \mathbf{x}_i \hat{\beta}(\tau))$ and $D_1(\tau) = \sum \rho_\tau(y_i - \mathbf{x}_{1i} \hat{\beta}_1(\tau))$, and set

$$T_{LR}(\tau) = 2(\tau(1-\tau)\hat{s}(\tau))^{-1}(D_1(\tau) - D_0(\tau))$$

where $\hat{s}(\tau)$ is the estimated sparsity function.

The rank test statistic is given by

$$T_R(\tau) = \mathbf{S}_n' \mathbf{M}_n^{-1} \mathbf{S}_n / A^2(\varphi)$$

where

$$\mathbf{S}_n = n^{-1/2}(\mathbf{X}_2 - \hat{\mathbf{X}}_2)' \hat{\mathbf{b}}_n$$

$$\Psi = \text{diag}(f_i(Q_{y_i}(\tau | \mathbf{x}_{1i}, \mathbf{x}_{2i})))$$

$$\hat{\mathbf{X}}_2 = \mathbf{X}_1(\mathbf{X}_1' \Psi \mathbf{X}_1)^{-1} \mathbf{X}_1' \mathbf{X}_2$$

$$\mathbf{M}_n = (\mathbf{X}_2 - \hat{\mathbf{X}}_2)(\mathbf{X}_2 - \hat{\mathbf{X}}_2)' / n$$

$$\hat{\mathbf{b}}_{ni} = \int_0^1 \hat{\mathbf{a}}_{ni}(t) d\varphi(t)$$

$$\hat{\mathbf{a}}(t) = \max_{\mathbf{a}} \{\mathbf{y}' \mathbf{a} | \mathbf{X}_1' \mathbf{a} = (1-t)\mathbf{X}_1' \mathbf{e}, \mathbf{a} \in [0, 1]^n\}$$

$$A^2(\varphi) = \int_0^1 (\varphi(t) - \bar{\varphi}(t))^2 dt$$

$$\bar{\varphi}(t) = \int_0^1 \varphi(t) dt$$

and $\varphi(t)$ is a score function.

The following score functions are available in the QUANTREG procedure:

Wilcoxon scores: $\phi(t) = t - 1/2$

Normal scores: $\phi(t) = \Phi^{-1}(t)$, where Φ is the normal distribution function

Sign scores: $\phi(t) = 1/2 \text{ sign}(t - 1/2)$

Tau scores: $\phi_\tau(t) = \tau - I(t < \tau)$.

The rank test statistic $T_R(\tau)$, unlike Wald tests or likelihood ratio tests, requires no estimation of the nuisance parameter f_i under iid error models (Gutenbrunner et al. 1993).

Koenker and Machado (1999) prove that the three test statistics ($T_W(\tau)$, $T_{LR}(\tau)$, and $T_R(\tau)$) are asymptotically equivalent and that their distributions converge to χ_q^2 under the null hypothesis, where q is the dimension of β_2 .

Testing for Heteroscedasticity

After you obtain the parameter estimates for several quantiles specified in the MODEL statement, you can test whether there are significant difference for the estimates for the same covariates across the quantiles. For example, if you want to test whether the parameters β_2 are the same across quantiles, the null hypothesis H_0 can be written as: $\beta_2(\tau_1) = \dots = \beta_2(\tau_k)$, where $\tau_j, j = 1, \dots, k$, are the quantiles specified in the MODEL statement. See Koenker and Bassett (1982a) for details.

Leverage Point and Outlier Detection

The QUANTREG procedure uses robust multivariate location and scale estimates for leverage-point detection.

Mahalanobis distance is defined as

$$\text{MD}(\mathbf{x}_i) = [(\mathbf{x}_i - \bar{\mathbf{x}})' \bar{\mathbf{C}}(\mathbf{A})^{-1} (\mathbf{x}_i - \bar{\mathbf{x}})]^{1/2}$$

where $\bar{\mathbf{x}} = \frac{1}{n} \sum_{i=1}^n \mathbf{x}_i$ and $\bar{\mathbf{C}}(\mathbf{A}) = \frac{1}{n-1} \sum_{i=1}^n (\mathbf{x}_i - \bar{\mathbf{x}})' (\mathbf{x}_i - \bar{\mathbf{x}})$ are the empirical multivariate location and scale. Here, $\mathbf{x}_i = (\mathbf{x}_{i1}, \dots, \mathbf{x}_{i(p-1)})'$ does not include the intercept variable. The relationship between the Mahalanobis distance $\text{MD}(\mathbf{x}_i)$ and the matrix $\mathbf{H} = (h_{ij}) = \mathbf{A}'(\mathbf{A}\mathbf{A}')^{-1}\mathbf{A}$ is

$$h_{ii} = \frac{1}{n-1} \text{MD}_i^2 + \frac{1}{n}$$

Robust distance is defined as

$$\text{RD}(\mathbf{x}_i) = [(\mathbf{x}_i - \mathbf{T}(\mathbf{A}))' \mathbf{C}(\mathbf{A})^{-1} (\mathbf{x}_i - \mathbf{T}(\mathbf{A}))]^{1/2}$$

where $\mathbf{T}(\mathbf{A})$ and $\mathbf{C}(\mathbf{A})$ are robust multivariate location and scale estimates computed with the minimum covariance determinant (MCD) method of Rousseeuw and Van Driessen (1999).

These distances are used to detect leverage points. You can use the DIAGNOSTICS and LEVERAGE options in the MODEL statement to request leverage-point and outlier diagnostics. Two new variables, Leverage and Outlier, are created and saved in an output data set specified in the OUTPUT statement.

Let $C(p) = \sqrt{\chi_{p;1-\alpha}^2}$ be the cutoff value. The variable LEVERAGE is defined as

$$\text{LEVERAGE} = \begin{cases} 0 & \text{if } \text{RD}(\mathbf{x}_i) \leq C(p) \\ 1 & \text{otherwise} \end{cases}$$

You can specify a cutoff value with the LEVERAGE option in the MODEL statement.

Residuals $r_i, i = 1, \dots, n$, based on quantile regression estimates are used to detect vertical outliers. The variable OUTLIER is defined as

$$\text{OUTLIER} = \begin{cases} 0 & \text{if } |r_i| \leq k\sigma \\ 1 & \text{otherwise} \end{cases}$$

You can specify the multiplier k of the cutoff value with the CUTOFF= option in the MODEL statement. You can specify the scale σ with the SCALE= option in the MODEL statement. By default, $k = 3$ and the scale σ is computed as the corrected median of the absolute residuals $\sigma = \text{median}\{|r_i|/\beta_0, i = 1, \dots, n\}$, where $\beta_0 = \Phi^{-1}(0.75)$ is an adjustment constant for consistency with the normal distribution.

An ODS table called DIAGNOSTICS contains these two variables.

INEST= Data Set

The INEST= data set specifies initial estimates for all the parameters in the model. The INEST= data set must contain the intercept variable (named Intercept) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in one BY group, the first one read is used for that BY group.

If the INEST= data set also contains the `_TYPE_` variable, only observations with the `_TYPE_` value 'PARMS' are used as starting values.

You can specify starting values for the interior point algorithm or the smoothing algorithm in the INEST= data set. The INEST= data set has the same structure as the OUTEST= data set but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization. If you specify more than one quantile in the MODEL statement, the same initial values are used for all quantiles.

OUTEST= Data Set

The OUTEST= data set contains parameter estimates for the specified model with all quantiles. A set of observations is created for each quantile specified. You can also specify a label in the MODEL statement to distinguish between the estimates for different models used by the QUANTREG procedure.

Note that, if the QUANTREG procedure does not produce valid solutions, the parameter estimates are set to missing in the OUTEST data set.

If created, this data set contains all variables specified in the MODEL statement and the BY statement. Each observation consists of parameter values for a specified quantile with the dependent variable having the value -1.

The following variables are also added to the data set:

<code>_MODEL_</code>	a character variable of length 8 containing the label of the MODEL statement, if present. Otherwise, the variable's value is blank.
<code>_ALGORITHM_</code>	a character variable of length 8 containing the name of the algorithm used for computing the parameter estimates, either SIMPLEX, INTERIOR, or SMOOTH
<code>_TYPE_</code>	a character variable of length 8 containing the type of the observation. it is fixed as PARMS to indicate that the observation includes parameter estimates.
<code>_STATUS_</code>	a character variable of length 12 containing the status of model fitting, either NORMAL, NOUNIQUE, or NOVALID
Intercept	a numeric variable containing the intercept parameter estimates
<code>_QUANTILE_</code>	a numeric variable containing the specified quantile levels

Any BY variables specified are also added to the OUTEST= data set.

Computational Resources

The various algorithms need different amounts of memory for working space. Let p be the number of parameters estimated and n be the number of observations used in the model estimation.

For the simplex algorithm, the minimum working space (in bytes) needed is

$$2np + 6n + 10p$$

for the interior point algorithm,

$$np + p^2 + 13n + 4p$$

and for the smoothing algorithm,

$$np + p^2 + 6n + 4p$$

For the last two algorithms, if you want to use preprocessing, an extra amount

$$np + 6n + 2p$$

is needed.

If sufficient space is available, the input data set is kept in memory; otherwise, the input data set is reread as necessary, and the execution time of the procedure increases substantially.

ODS Table Names

The QUANTREG procedure assigns a name to each table it creates. You can specify these names when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 77.9 ODS Tables Produced in PROC QUANTREG

ODS Table Name	Description	Statement	Option
ClassLevels	Classification variable levels	CLASS	default
CorrB	Parameter estimate correlation matrix	MODEL	CORRB
CovB	Parameter estimate covariance matrix	MODEL	COVB
Diagnostics	Outlier diagnostics	MODEL	DIAGNOSTICS
DiagSummary	Summary of the outlier diagnostics	MODEL	DIAGNOSTICS

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

For a single quantile, two plots are particularly useful in revealing outliers and leverage points. The first is a scatter plot of the standardized residuals for the specified quantile against the robust distances. The second is a scatter plot of the robust distances against the classical Mahalanobis distances. You can request these two plots by using the PLOT=RDPLOT and PLOT=DDPLOT options.

You can also request a normal quantile-quantile plot and a histogram of the standardized residuals for the specified quantile with the PLOT=QQPLOT and PLOT=HISTOGRAM options, respectively.

You can request a plot of fitted conditional quantiles by the single continuous variable specified in the model with the PLOT=FITPLOT option.

All these plots can be requested by specifying corresponding plot options in either the PROC QUANTREG statement or the MODEL statement. If you specify same plot options in both statements, options in the PROC QUANTREG statement override options in the MODEL statement.

You can specify the PLOT=QUANTPLOT option in only the MODEL statement to request a quantile process plot with confidence bands.

The plot options in the PROC QUANTREG statement and the MODEL statement are summarized in [Table 77.10](#). See the [PLOT=](#) option in the PROC QUANTREG statement and the [PLOT=](#) option in the MODEL statement for details.

Table 77.10 Options for Plots

Keyword	Plot
ALL	All appropriate plots
DDPLOT	Robust distance vs. Mahalanobis distance
FITPLOT	Conditional quantile fit vs. independent variable
HISTOGRAM	Histogram of standardized robust residuals
NONE	No plot
QUANTPLOT	Scatter plot of regression quantile
QQPLOT	Q-Q plot of standardized robust residuals
RDPLOT	Standardized robust residual vs. robust distance

The following subsections provide information about these graphs.

ODS Graph Names

The QUANTREG procedure assigns a name to each graph it creates. You can use these names to reference the graphs when using ODS. The names along with the required statements and options are listed in Table 77.11.

Table 77.11 Graphs Produced by PROC QUANTREG

ODS Graph Name	Plot Description	Statement	Option
DDPlot	Robust distance versus Mahalanobis distance	PROC MODEL	DDPLOT
FitPlot	Quantile fit versus independent variable	PROC MODEL	FITPLOT
Histogram	Histogram of standardized robust residuals	PROC MODEL	HISTOGRAM
QQPlot	Q-Q plot of standardized robust residuals	PROC MODEL	QQPLOT
QuantPanel	Panel of quantile plots with confidence limits	MODEL	QUANTPLOT
QuantPlot	Scatter plot for regression quantiles with confidence limits	MODEL	QUANTPLOT UNPACK
RDPlot	Standardized robust residual versus robust distance	PROC MODEL	RDPLOT

Fit Plot

When the model has a single independent continuous variable (with or without the intercept), the QUANTREG procedure automatically creates a plot of fitted conditional quantiles against this independent variable for one or more quantiles specified in the MODEL statement.

The following example reuses the trout data set in the section “[Analysis of Fish-Habitat Relationships](#)” on page 6490 to show the fit plot for one or several quantiles.

```
ods graphics on;

proc quantreg data=trout ci=resampling;
  model LnDensity = WDRatio / quantile=0.9 seed=1268;
run;

proc quantreg data=trout ci=resampling;
  model LnDensity = WDRatio / quantile=0.5 0.75 0.9 seed=1268;
run;
```

For a single quantile, the confidence limits for the fitted conditional quantiles are also plotted if you specify the CI=RESAMPLING or CI=SPARSITY option. (See [Figure 77.14](#).) For multiple quantiles, confidence limits are not plotted by default. (See [Figure 77.15](#).) You can add the confidence limits on the plot by specifying the option PLOT=FITPLOT(SHOWLIMITS).

The QUANTREG procedure also provides fit plots for quantile regression splines and polynomials if they are based on a single continuous variable. See [Example 77.4](#) and [Example 77.5](#) for some examples.

Figure 77.15 Fit Plot for Multiple Quantiles

Quantile Process Plot

A quantile process plot is a scatter plot of an estimated regression parameter against quantile. You can request this plot with the `PLOT=QUANTPLOT` option in the `MODEL` statement when multiple regression quantiles or the entire quantile process is computed. Quantile process plots are often used to check model variations at different quantiles, which is usually called model heterogeneity.

By default, panels are used to hold multiple process plots (up to four in each panel). You can use the `UNPACK` option to request individual process plots. [Figure 77.10](#) in the section “[Analysis of Fish-Habitat Relationships](#)” on page 6490 shows a panel with two quantile process plots. [Output 77.2.9](#) in [Example 77.2](#) shows a single quantile process plot. [Example 77.3](#) demonstrates more quantile process plots and their usage.

Distance-Distance Plot

The distance-distance plot (DDPLOT) is mainly used for leverage-point diagnostics. It is a scatter plot of the robust distances against the classical Mahalanobis distances for the continuous independent variables. See the section “[Leverage Point and Outlier Detection](#)” on page 6528 for details about the robust distance. If there is a classification variable specified in the model, this plot is not created.

You can use the `PLOT=DDPLOT` option to request this plot. The following statements use the growth data set in [Example 77.2](#) to create a single plot, shown in [Output 77.2.4](#) in [Example 77.2](#):

```
ods graphics on;

proc quantreg data=growth ci=resampling plot=ddplot;
  model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2
           llntr2 gedy2 ly2 gcony2 lblakp2 pol2 ttrad2
           / quantile=.5 diagnostics leverage(cutoff=8) seed=1268;
  id Country;
run;
```

The reference lines represent the cutoff values. The diagonal line is also drawn to show the distribution of the distances. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the `LABEL=` option as described in [Table 77.5](#).

Residual-Distance Plot

The residual-distance plot (RDPLLOT) is used for both outlier and leverage-point diagnostics. It is a scatter plot of the standardized residuals against the robust distances. See the section “[Leverage Point and Outlier Detection](#)” on page 6528 for details about the robust distance. If a classification variable is specified in the model, this plot is not created.

You can use the `PLOT=RDPLLOT` option to request this plot. The following statements use the growth data set in [Example 77.2](#) to create a single plot, shown in [Output 77.2.3](#) in [Example 77.2](#):

```
ods graphics on;

proc quantreg data=growth ci=resampling plot=rdplot;
  model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2
           llntr2 gedy2 ly2 gcony2 lblakp2 pol2 ttrad2
           / quantile=.5 diagnostics leverage(cutoff=8) seed=1268;
  id Country;
run;
```

The reference lines represent the cutoff values. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the LABEL= option as described in [Table 77.5](#).

If you specify ID variables in the ID statement, instead of observation numbers, the values of the first ID variable are used as labels.

Histogram and Q-Q Plot

PROC QUANTREG produces a histogram and a Q-Q plot for the standardized residuals. The histogram is superimposed with a normal density curve and a kernel density curve. Using the growth data set in [Example 77.2](#), the following statements create the plot shown in [Output 77.2.5](#) in [Example 77.2](#):

```
ods graphics on;

proc quantreg data=growth ci=resampling plot=histogram;
  model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2
          lintr2 gedy2 ly2 gcony2 lblakp2 pol2 ttrad2
          / quantile=.5 diagnostics leverage(cutoff=8) seed=1268;
  id Country;
run;
```

Examples: QUANTREG Procedure

Example 77.1: Comparison of Algorithms

This example illustrates and compares the three algorithms for regression estimation available in the QUANTREG procedure. The simplex algorithm is the default because of its stability. Although this algorithm is slower than the interior point and smoothing algorithms for large data sets, the difference is not as significant for data sets with fewer than 5,000 observations and 50 variables. The simplex algorithm can also compute the entire quantile process, which is shown in [Example 77.2](#).

The following statements generate 1,000 random observations. The first 950 observations are from a linear model, and the last 50 observations are significantly biased in the y-direction. In other words, 5% of the observations are contaminated with outliers.

```
data a (drop=i);
  do i=1 to 1000;
    x1=rannor(1234);
    x2=rannor(1234);
    e=rannor(1234);
    if i > 950 then y=100 + 10*e;
    else y=10 + 5*x1 + 3*x2 + 0.5 * e;
    output;
  end;
run;
```

The following statements invoke the QUANTREG procedure to fit a median regression model with the default simplex algorithm. They produce the results in [Output 77.1.1](#) through [Output 77.1.3](#).

```
proc quantreg data=a;
  model y = x1 x2;
run;
```

[Output 77.1.1](#) displays model information and summary statistics for variables in the model. It indicates that the simplex algorithm is used to compute the optimal solution and the rank method is used to compute confidence intervals of the parameters.

By default, the QUANTREG procedure fits a median regression model. This is indicated by the quantile value 0.5 in [Output 77.1.2](#), which also displays the objective function value and the predicted value of the response at the means of the covariates.

[Output 77.1.3](#) displays parameter estimates and confidence limits. These estimates are reasonable, which indicates that median regression is robust to the 50 outliers.

Output 77.1.1 Model Fit Information and Summary Statistics with Simplex Algorithm

BMI Percentiles for Men: 2-80 Years Old						
The QUANTREG Procedure						
Model Information

x1	-0.6546	0.0230	0.7099	0.0222	0.9933	1.0085
x2	-0.7891	-0.0747	0.6839	-0.0401	1.0394	1.0857
y	6.1045	10.6936	14.9569	14.4864	20.4087	6.5696

Output 77.1.2 Quantile and Objective Function with Simplex Algorithm

Quantile and Objective Function	
Quantile	0.5
Objective Function	2441.1927
Predicted Value at Mean	10.0259

Output 77.1.3 Parameter Estimates with Simplex Algorithm

Parameter Estimates				
Parameter	DF	Estimate	95% Confidence Limits	
Intercept	1	10.0364	9.9959	10.0756
x1	1	5.0106	4.9602	5.0388
x2	1	3.0294	2.9944	3.0630

The following statements refit the model by using the interior point algorithm:

```
proc quantreg algorithm=interior(tolerance=1e-6)
    ci=none data=a;
    model y = x1 x2 / itprint nosummary;
run;
```

The TOLERANCE= option specifies the stopping criterion for convergence of the interior point algorithm, which is controlled by the duality gap. Although the default criterion is 1E-8, the value 1E-6 is often sufficient. The ITPRINT option requests the iteration history for the algorithm. The option CI=NONE suppresses the computation of confidence limits, and the option NOSUMMARY suppresses the table of summary statistics.

Output 77.1.4 displays model fit information.

0.0000846	36	14	2517	2621	2441.1927
1E-12	37	14	2517	2621	2441.1927

Output 77.1.9 displays the parameter estimates obtained with the smoothing algorithm, which are identical to those obtained with the simplex and interior point algorithms. All three algorithms should have the same parameter estimates unless the problem does not have a unique solution.

Output 77.1.9 Parameter Estimates with Smoothing Algorithm

Parameter Estimates		
Parameter	DF	Estimate
Intercept	1	10.0364
x1	1	5.0106
x2	1	3.0294

The interior point algorithm and the smoothing algorithm offer better performance than the simplex algorithm for large data sets. See Chen (2004) for more details on choosing an appropriate algorithm on the basis of data set size. All three algorithms should have the same parameter estimates, unless the optimization problem has multiple solutions.

Example 77.2: Quantile Regression for Econometric Growth Data

This example uses a SAS data set named *Growth*, which contains economic growth rates for countries during two time periods, 1965–1975 and 1975–1985. The data come from a study by Barro and Lee (1994) and have also been analyzed by Koenker and Machado (1999).

There are 161 observations and 15 variables in the data set. The variables, which are listed in the following table, include the national growth rates (GDP) for the two periods, 13 covariates, and a name variable (Country) for identifying the countries in one of the two periods.

Variable	Description
Country	Country's name and period
GDP	Annual change per capita GDP
lgdp2	Initial per capita GDP
mse2	Male secondary education
fse2	Female secondary education
fhe2	Female higher education
mhe2	Male higher education
lexp2	Life expectancy
lintr2	Human capital
gedy2	Education/GDP
ly2	Investment/GDP
gcony2	Public consumption/GDP
lblakp2	Black market premium
pol2	Political instability
ttrad2	Growth rate terms trade

The goal is to study the effect of the covariates on GDP. The following statements request median regression for a preliminary exploration. They produce the results in [Output 77.2.1](#) through [Output 77.2.6](#).

The QUANTREG procedure employs the default simplex algorithm to estimate the parameters. The MCMB resampling method is used to compute confidence limits.

[Output 77.2.1](#) displays model information and summary statistics for the variables in the model. Six summary statistics are computed, including the median and the median absolute deviation (MAD), which are robust measures of univariate location and scale, respectively. For the variable lintr2 (Human Capital), both the mean and standard deviation are much larger than the corresponding robust measures, median and MAD. This indicates that this variable might have outliers.

Diagnostics for the median regression fit are displayed in [Output 77.2.3](#) and [Output 77.2.4](#), which are requested with the PLOTS= option. [Output 77.2.3](#) plots the standardized residuals from median regression against the robust MCD distance. This display is used to diagnose both vertical outliers and horizontal leverage points. [Output 77.2.4](#) plots the robust MCD distance against the Mahalanobis distance. This display is used to diagnose leverage points.

The cutoff value 8 specified with the LEVERAGE option is close to the maximum of the Mahalanobis distance. Eighteen points are diagnosed as high leverage points, and almost all are countries with high human capital, which is the major contributor to the high leverage as observed from the summary statistics. Four points are diagnosed as outliers by using the default cutoff value of 3. However, these are not extreme outliers.

A histogram of the standardized residuals and two fitted density curves are displayed in [Output 77.2.5](#). This shows that median regression fits the data well.

Output 77.2.3 Residual-Robust Distance Plot**Output 77.2.4** Robust Distance-Mahalanobis Distance Plot

Output 77.2.5 Histogram for Residuals

Tests of significance for the initial per-capita GDP (LGDP2) are shown in [Output 77.2.6](#).

Output 77.2.6 Tests for Regression Coefficient

Test test_lgdp2 Results				
Test	Test Statistic	DF	Chi- Square	Pr > ChiSq
Wald	43.2684	1	43.27	<.0001
Likelihood Ratio	36.3047	1	36.30	<.0001

The QUANTREG procedure computes entire quantile processes for covariates when you specify QUANTILE=PROCESS in the MODEL statement, as follows:

```
proc quantreg data=growth ci=resampling;
  model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2 llntr2
    gedy2 ly2 gcony2 lblackp2 pol2 ttrad2
    / quantile=process plot=quantplot seed=1268;
run;
```

Confidence limits for quantile processes can be computed with the sparsity or resampling methods, but not the rank method, because the computation would be prohibitively expensive.

A total of 14 quantile process plots are produced. [Output 77.2.7](#) and [Output 77.2.8](#) display two panels of eight selected process plots. The 95% confidence bands are shaded.

Output 77.2.7 Quantile Processes with 95% Confidence Bands

Output 77.2.8 Quantile Processes with 95% Confidence Bands

As pointed out by Koenker and Machado (1999), previous studies of the Barro growth data have focused on the effect of the initial per-capita GDP on the growth of this variable (annual change per-capita GDP). A single process plot for this effect can be requested with the following statements:

```
proc quantreg data=growth ci=resampling;
  model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2 lintr2
           gedy2 ly2 gcony2 lblakp2 pol2 ttrad2
           / quantile=process plot=quantplot(lgdp2) seed=1268;
run;
```

The plot is shown in [Output 77.2.9](#).

Output 77.2.9 Quantile Process Plot for LGDP2

The confidence bands here are computed with the MCMB resampling method, unlike in Koenker and Machado (1999), where the rank method was used to compute confidence limits for a few selected points. [Output 77.2.9](#) suggests that the effect of the initial level of GDP is relatively constant over the entire distribution, with a slightly stronger effect in the upper tail.

The effects of other covariates are quite varied. An interesting covariate is public consumption/GDP (gcony2) (first plot in second panel), which has a constant effect over the upper half of the distribution and a larger effect in the lower tail. For an analysis of the effects of the other covariates, see Koenker and Machado (1999).

Example 77.3: Quantile Regression Analysis of Birth-Weight Data

This example is patterned after a quantile regression analysis of covariates associated with birth weight that was carried out by Koenker and Hallock (2001). Their study used a subset of the June 1997 Detailed Natality Data published by the National Center for Health Statistics and demonstrated that conditional quantile functions provide more complete information about the covariate effects than ordinary least squares regression.

This example is based on Koenker and Hallock (2001); Abreveya (2001); it uses data for live, singleton births to mothers in the United States who were recorded as black or white, and who were between the ages

of 18 and 45. For convenience, this example uses 50,000 observations, which were randomly selected from the qualified observations. Observations with missing data for any of the variables were deleted.

The following table describes the variables in the data.

Variable	Description
Weight	Infant's birth weight
Black	Indicator of black mother
Married	Indicator of married mother
Boy	Indicator of boy
Visit	Prenatal visit: 0 = no visit, 1 = visit in second trimester, 2 = visit in last trimester, 3 = visit in first trimester
Ed	Mother's education level: 0 = high school, 1 = some college, 2 = college, 3 = less than high school
Smoke	Indicator of smoking mother
CigsPer	Number of cigarettes smoked per day
Mom_Age	Mother's age
M_WtGain	Mother's weight gain during pregnancy

There are four levels of education of the mother. By default, the QUANTREG procedure treats the highest level (3 - less than high school) as a reference level. The regression coefficients of other levels measure the effect relative to this level. Likewise, there are four levels of prenatal medical care of the mother, and a first visit in the first trimester serves as the reference level. These two variables are treated as classification variables in the model.

The following statements fit a regression model for 19 quantiles of birth weight, which are evenly spaced in the interval (0, 1). The model includes linear and quadratic effects for the age of the mother and for weight gain during pregnancy.

```
ods graphics on;

proc quantreg ci=sparsity/iid algorithm=interior(tolerance=5.e-4)
    data=sashelp.bweight;
    class visit ed;
    model weight = black married boy visit ed smoke
                  cigsper mom_age mom_age*mom_age
                  m_wtgain m_wtgain*m_wtgain /
                  quantile= 0.05 to 0.95 by 0.05
                  plot=quantplot;
run;
```

Output 77.3.1 displays the model information and summary statistics for the variables in the model.

Among the 11 independent variables, Black, Married, Boy, and Smoke are binary variables. For these variables, the mean represents the proportion in the category. The two continuous variables, Mom_Age and M_WtGain, are centered at their medians, which are 27 and 30, respectively.

The quantile plots for the intercept and the other 15 factors with nonzero degree of freedom are shown in the following four panels. In each plot, the regression coefficient at a given quantile indicates the effect on birth weight of a unit change in that factor, assuming that the other factors are fixed. The bands represent 95% confidence intervals.

Although the data set used here is a subset of the Natality data set, the results are quite similar to those of Koenker and Hallock (2001) for the full data set.

In [Output 77.3.2](#), the first plot is for the intercept. As explained by Koenker and Hallock (2001), the intercept “may be interpreted as the estimated conditional quantile function of the birth-weight distribution of a girl born to an unmarried, white mother with less than a high school education, who is 27 years old and had a weight gain of 30 pounds, didn’t smoke, and had her first prenatal visit in the first trimester of the pregnancy.”

The second plot shows that infants born to black mothers weigh less than infants born to white mothers, especially in the lower tail of the birth-weight distribution. The third plot shows that marital status has a large positive effect on birth weight, especially in the lower tail. The fourth plot shows that boys weigh more than girls for any chosen quantile; this difference is smaller in the lower quantiles of the distribution.

In [Output 77.3.3](#), the first three plots deal with prenatal care. Compared with babies born to mothers who had a prenatal visit in the first trimester, babies born to mothers who received no prenatal care weigh less, especially in the lower quantiles of the birth-weight distributions. As noted by Koenker and Hallock (2001), “babies born to mothers who delayed prenatal visits until the second or third trimester have substantially *higher* birthweights in the lower tail than mothers who had a prenatal visit in the first trimester. This might be interpreted as the self-selection effect of mothers confident about favorable outcomes.”

The fourth plot in [Output 77.3.3](#) and the first two plots in [Output 77.3.4](#) are for variables related to education. Education beyond high school is associated with a positive effect on birth weight. The effect of high school education is uniformly around 15 grams across the entire birth-weight distribution (this is a pure location shift effect), while the effect of some college and college education is more positive in the lower quantiles than the upper quantiles.

The remaining two plots in [Output 77.3.4](#) show that smoking is associated with a large negative effect on birth weight.

The linear and quadratic effects for the two continuous variables are shown in [Output 77.3.5](#). Both of these variables are centered at their median. At the lower quantiles, the quadratic effect of the mother’s age is more concave. The optimal age at the first quantile is about 33, and the optimal age at the third quantile is about 38. The effect of the mother’s weight gain is clearly positive, as indicated by the narrow confidence bands for both linear and quadratic coefficients.

See Koenker and Hallock (2001) for more details about the covariate effects discovered with quantile regression.

Example 77.4: Nonparametric Quantile Regression for Ozone Levels

Tracing seasonal trends in the level of tropospheric ozone is essential for predicting high-level periods, observing long-term trends, and discovering potential changes in pollution. Traditional methods for modeling seasonal effects are based on the conditional mean of ozone concentration; however, the upper conditional quantiles are more critical from a public health perspective. In this example, the QUANTREG procedure fits conditional quantile curves for seasonal effects by using nonparametric quantile regression with cubic B-splines.

The data used here are from Chock, Winkler, and Chen (2000), who studied the association between daily mortality and ambient air pollutant concentrations in Pittsburgh, Pennsylvania. The data set ozone contains the following two variables: Ozone (daily-maximum one-hour ozone concentration (ppm)) and Days (index of 1,095 days (3 years)).

```
data ozone;
  days = _n_;
  input ozone @@;
  datalines;

0.0220 0.0210 0.0210 0.0130 0.0130 0.0130 0.0330 0.0330 0.0330 0.0325
0.0320 0.0320 0.0320 0.0120 0.0200 0.0200 0.0200 0.0320 0.0320 0.0250
0.0180 0.0180 0.0270 0.0270 0.0290
;
```

Output 77.4.1, which displays the time series plot of ozone concentration for the three years, shows a clear seasonal pattern.

In this example, cubic B-splines are used to fit the seasonal effect. These splines are generated with 11 knots, which split the 3 years into 12 seasons. The following statements create the spline basis and fit multiple quantile regression spline curves:

```
ods graphics on;

proc quantreg data=ozone algorithm=smooth ci=none plot=fitplot(nodata);
  effect sp = spline( days / knotmethod = list
    (90 182 272 365 455 547 637 730 820 912 1002) );
  model ozone = sp / quantile = 0.5 0.75 0.90 0.95 seed=1268;
run;
```

Output 77.4.1 Time Series of Ozone Levels in Pittsburgh, Pennsylvania

The **EFFECT** statement creates spline bases for the variable **Days**. The **KNOTMETHOD=LIST** option provides all internal knots for these bases. Cubic spline bases are generated by default. These bases are treated as components of the spline effect *sp*, which is used in the **MODEL** statement. Spline fits for four quantiles are requested with the **QUANTILE=** option.

When ODS Graphics is enabled, the **QUANTREG** procedure automatically generates a fit plot, which includes all fitted curves.

Output 77.4.2 displays these curves obtained with the **QUANTREG** procedure. The curves show that peak ozone levels occur in the summer. For the three years (1989–1991), the median curve (labeled 50%) does not cross the 0.08 ppm line, which is the 1997 EPA 8-hour standard. The median curve and the 75% curve show a drop for the ozone concentration levels in 1990. However, with the 90% and 95% curves, peak ozone levels tend to increase. This indicates that there might have been more days with low ozone concentration in 1990, but the top 10% and 5% tend to have higher ozone concentration levels.

Output 77.4.2 Quantiles of Ozone Levels in Pittsburgh, Pennsylvania

The quantile curves also show that high ozone concentration in 1989 had a longer duration than in 1990 and 1991. This is indicated by the wider spread of the quantile curves in 1989.

Example 77.5: Quantile Polynomial Regression for Salary Data

This example uses the data set from a university union survey of salaries of professors in 1991. The survey covered departments in U.S. colleges and universities that list programs in statistics. The goal here is to examine the relationship between faculty salaries and years of service.

The data include salaries and years of service for 459 professors. The scatter plot in [Output 77.5.1](#) shows that the relationship is not linear, and a quadratic or cubic regression curve is appropriate. [Output 77.5.1](#) shows a cubic curve.

The curve in [Output 77.5.1](#) does not adequately describe the conditional salary distributions and how they change with length of service. [Output 77.5.2](#) shows the 25th, 50th, and 75th percentiles for each number of years, which gives a better picture of the conditional distributions.

```
data salary;
  input Salaries Years @@;
  label Salaries='Salaries (1000s of dollars)';

;
```

Output 77.5.1 Salary with Years as Professor: Cubic Fit

Output 77.5.2 Salary with Years as Professor: Sample Quantiles

These descriptive percentiles do not clearly show trends with length of service. The following statements use the QUANTREG procedure to obtain a smooth version by using polynomial quantile regression. The results are shown in [Output 77.5.3](#) and [Output 77.5.5](#).

```
ods graphics on;

proc quantreg data=salary ci=sparsity;
  model salaries = years years*years years*years*years
    /quantile=0.25 0.5 0.75
    plot=fitplot(showlimits);

  test years/QINTERACT;

run;
```

[Output 77.5.3](#) displays the regression coefficients for the three quantiles, from which you can see that there is a difference among the estimated parameters of the variable *years* across the three quantiles. To test whether the difference is significant, you can specify the option QINTERACT in the TEST statement. [Output 77.5.4](#) indicates that the difference is not significant with the *p*-value greater than 0.05.

Output 77.5.3 Regression Coefficients

Overview: QUANTSELECT Procedure

Quantile regression, which was introduced by Koenker and Bassett (1978), is a modern method that models the effects of covariates on the conditional quantiles of a response variable. The QUANTSELECT procedure performs effect selection in the framework of quantile regression. A variety of effect selection methods are available, including greedy methods and penalty methods. The QUANTSELECT procedure offers extensive capabilities for customizing the effect selection processes with a variety of candidate selecting, effect-selection stopping, and final-model choosing criteria. PROC QUANTSELECT also provides graphical summaries for the effect selection processes.

The QUANTSELECT procedure compares most closely to the GLMSELECT and QUANTREG procedures. PROC GLMSELECT performs effect selection in the framework of general linear models. PROC QUANTREG supports a variety of estimation and inference methods for quantile regression but does not directly provide effect selection facilities. The QUANTSELECT procedure, as a counterpart of PROC GLMSELECT for quantile regression, fills this gap.

The QUANTSELECT procedure focuses on linear quantile models for univariate responses and offers great flexibility for and insight into the effect selection algorithm. The QUANTSELECT procedure inherits most of its syntax from PROC GLMSELECT and PROC QUANTREG. The QUANTSELECT procedure provides results that are similar to those of PROC GLMSELECT and PROC QUANTREG. These results (displayed tables, output data sets, and macro variables) make it easy to explore the selected models in PROC QUANTREG.

Features

The main features of the QUANTSELECT procedure are as follows:

- supports the following model specifications:
 - interaction (crossed) effects and nested effects
 - constructed effects such as regression splines
 - hierarchy among effects
 - partitioning of data into training, validation, and testing roles
- provides the following selection controls:
 - multiple methods for effect selection
 - selection for quantile process and single quantile levels
 - selection of individual or grouped effects
 - selection based on a variety of selection criteria
 - stopping rules based on a variety of model evaluation criteria
- produces the following display and output:
 - graphical representation of the selection process
 - output data sets that contain predicted values and residuals
 - an output data set that contains the design matrix
 - macro variables that contain selected effects

The QUANTSELECT procedure supports the following effect selection methods. These methods are explained in detail in the section “[Effect Selection Methods](#)” on page 6597.

- Forward selection starts with no effects or with forced-in effects in the model and adds more effects.
- Backward elimination starts with all effects in the model and deletes effects.
- Stepwise regression is similar to the forward selection method except that effects already in the model do not necessarily stay there.
- LASSO regression adds and deletes effects based on a constrained version of estimated check risk where the L1-norm of regression coefficients is penalized (Tibshirani 1996; Belloni and Chernozhukov 2011). Adaptive LASSO (Zou 2006; Wu and Liu 2009) is implemented as a special case of LASSO methods where the L1-norm of certain weighted regression coefficients is penalized. See the discussion in the section “[LASSO Method \(LASSO\)](#)” on page 6598 for additional details. The QUANTSELECT procedure uses LASSO methods only to determine the adding and dropping covariate effects at a step; a post-penalized model that is associated with the step is refitted without penalty, and the selection criteria and the parameter estimates are from the post-penalized model.

The QUANTSELECT procedure is intended primarily as an effect selection procedure and does not include regression diagnostics and hypothesis testing. The intention is that you use the QUANTSELECT procedure to select a model or a set of models, where each model contains a set of selected effects, and then you can further investigate these models by using PROC QUANTREG or other analytic tools.

Getting Started: QUANTSELECT Procedure

This example demonstrates how you can use the QUANTSELECT procedure to select covariate effects for quantile regression. The data set under investigation contains salary and performance information for Major League Baseball (MLB) players, excluding pitchers, who played at least one game in both the 1986 and 1987 seasons. The salaries (Time Inc. 1987) are for the 1987 season, and the performance measures are from 1986 (Reichler 1987).

```
data baseball;
  length team $ 12;
  input name $ 1-18 nAtBat nHits nHome nRuns nRBI nBB
        yrMajor crAtBat crHits crHome crRuns crRbi crBB

                   American West KansasCity CF 408 4 3 1000
;

```

Suppose you want to investigate how the MLB players' salaries for the 1987 season depend on performance measures for the players' previous season and MLB careers. As a starting point for such an analysis, you can use the following statements to obtain a parsimonious conditional median model at $\tau = 0.5$:

```

proc quantselect data=baseball;
  class Div;
  model Salary = nAtBat nHits nHome nRuns nRBI nBB yrMajor crAtBat
                crHits crHome crRuns crRbi crBB nAssts nError nOuts
                Div
    / selection=lasso(adaptive stop=aic choose=sbc sh=7);
run;

```

The `SELECTION=LASSO(ADAPTIVE)` option in the `MODEL` statement specifies the adaptive LASSO method (Zou 2006), which controls the effect selection process. The `STOP=AIC` option specifies that Akaike's information criterion (AIC) be used to determine the stopping condition. The `CHOOSE=SBC` option specifies that the Schwarz Bayesian information criterion (SBC) be used to determine the final selected model. The `SH=` option specifies the number of stop horizons, which requests that the selection process be stopped whenever the `STOP=` criterion values at step $s + 1, \dots, s + SH$ are worse than those for step s for some $s \in \{0, 1, \dots\}$.

Figure 78.1 shows the "Model Information" table, which indicates the effect selection settings. You can see that the default quantile type is single level, so this effect selection is effective only for $\tau = 0.5$.

Figure 78.1 Model Information

The QUANTSELECT Procedure		
Model Information		
Data Set	WORK.BASEBALL	
Dependent Variable	Salary	
Selection Method	Adaptive LASSO	
Quantile Type	Single Level	
Stop Criterion	AIC	
Choose Criterion	SBC	

Figure 78.2 summarizes the effect selection process, which starts with an intercept-only model at step 0. At step 1, the effect that corresponds to the career runs is added to the model that reduced the AIC value from 2691.6511 to 2510.7297. You can see that step 10 has the minimum AIC and that step 7 has the minimum SBC. Common sense also tells you that the SBC favors a smaller model than the AIC.

Figure 78.2 Selection Summary

The QUANTSELECT Procedure				
Quantile = 0.5

16	nAssts	17	2449.9731	2510.6997
* Optimal Value Of Criterion				

Figure 78.3 shows that the selection process stopped at a local minimum of the STOP= criterion, which is step 10. According to the SH=7 option, the effect selection process is stopped at step 10 because all the AIC values for step 11 through step 17 are no less than the AIC at step 10. Step 17 is ignored in the selection summary table because it is the last step.

Figure 78.3 Stop Reason

```
Selection stopped at a local minimum of the AIC criterion.
```

Figure 78.4 shows how the final selected model is determined. CHOOSE=SBC is specified in this example, so the model at step 7 is chosen as the final selected model.

Figure 78.4 Selection Reason

```
The model at step 7 is selected where SBC is 2473.62.
```

Figure 78.5 shows the final selected effects and Figure 78.6 shows the parameter estimates for the final selected model.

Figure 78.5 Selected Effects

Quantile regression can fit a conditional quantile model at any quantile level $\tau \in (0, 1)$, so it can describe the entire distribution of a response variable conditional on covariate effects. To further investigate the effects that might affect the MLB players' salaries, you can also conduct effect selection at $\tau = 0.1$ and $\tau = 0.9$, which correspond to low-end salaries and high-end salaries respectively. The following statements use the same selection settings that are used in the previous program:

```
proc quantselect data=baseball;
  class Div;
  model Salary = nAtBat nHits nHome nRuns nRBI nBB yrMajor crAtBat
                 crHits crHome crRuns crRbi crBB nAssts nError nOuts
                 Div
    / quantiles=0.1 0.9 selection=lasso(adaptive stop=aic choose=sbc sh=7);
run;
```

Figure 78.7 shows the effect selection summary with $\tau = 0.1$.

To visually illustrate how the model evolves through the selection process, the QUANTSELECT procedure provides the coefficient plot, the average check loss plot, and several criterion plots in either packed or unpacked forms. You can request these plots by using the **PLOTS=** option. The following statements request all the plots for the baseball data at $\tau = 0.1$; they also use the **STOP=AIC** criterion, the **CHOOSE=SBC** criterion, and the **SH=7** option:

```

ods graphics on;
proc quantselect data=baseball plot=all;
  class Div;
  model Salary = nAtBat nHits nHome nRuns nRBI nBB yrMajor crAtBat
                crHits crHome crRuns crRbi crBB nAssts nError nOuts
                Div
                / quantiles=0.1 selection=lasso(adaptive stop=aic choose=sbc sh=7);
run;

```

Figure 78.11 shows the progression of the parameter estimates as the selection process proceeds.

Figure 78.11 Coefficient Panel: $\tau = 0.1$

Figure 78.12 shows the progression of the average check losses as the selection process proceeds.

Figure 78.12 Average Check Loss Plot: $\tau = 0.1$

Figure 78.13 shows the progression of four effect selection criteria as the selection process proceeds.

Figure 78.13 Criterion Panel: $\tau = 0.1$

Syntax: QUANTSELECT Procedure

The following statements are available in PROC QUANTSELECT:

```

PROC QUANTSELECT < options > ;
    BY variables ;
    CLASS variable < (v-options) > < variable < (v-options ...) > > < / v-options > < options > ;
    EFFECT name = effect-type (variables < / options > ) ;
    MODEL variable = < effects > < / options > ;
    OUTPUT < OUT=SAS-data-set > < keyword < =name > > < ... keyword < =name > > ;
    PARTITION < options > ;
    WEIGHT variable ;

```

The PROC QUANTSELECT statement invokes the procedure. All statements other than the **MODEL** statement are optional. **CLASS** and **EFFECT** statements, if present, must precede the **MODEL** statement.

PROC QUANTSELECT Statement

```

PROC QUANTSELECT < options > ;

```

Table 78.1 lists the *options* available in the PROC QUANTSELECT statement.

Table 78.1 PROC QUANTSELECT Statement Options

<i>option</i>	Description
Data Set Options	
DATA=	Names a data set to use for the regression
MAXMACRO=	Sets the maximum number of macro variables to produce
TESTDATA=	Names a data set that contains test data
VALDATA=	Names a data set that contains validation data
ODS Graphics Options	
PLOTS=	Produces ODS Graphics displays
Other Options	
OUTDESIGN=	Names a data set that contains the design matrix
NOPRINT	Suppresses displayed output (including plots)
SEED=	Sets the seed used for pseudorandom number generation

You can specify the following *options* (shown in alphabetical order) in the PROC QUANTSELECT statement.

DATA=SAS-data-set

names the SAS data set to be used by PROC QUANTSELECT. If the DATA= option is not specified, PROC QUANTSELECT uses the most recently created SAS data set. If the data set contains a variable named `_ROLE_`, then this variable is used to assign observations for training, validation, and testing roles. See the section “[Using Validation and Test Data](#)” on page 6602 for more information about using the `_ROLE_` variable.

MAXMACRO=*n*

specifies the maximum number of macro variables with selected effects to create. By default, MAXMACRO=100.

PROC QUANTSELECT saves the list of selected effects in a macro variable, `&_QRSIND`. For example, suppose your input effect list consists of `x1–x10`. Then `&_QRSIND` would be set to `x1 x3 x4 x10` if the first, third, fourth, and tenth effects were selected for the model. This list can be used in the MODEL statement of a subsequent procedure.

If you specify the OUTDESIGN= option in the PROC QUANTSELECT statement, then PROC QUANTSELECT saves the list of columns in the design matrix in a macro variable named `&_QRSMOD`.

With multiple quantile levels and BY processing, one macro variable is created for each combination of quantile level and BY group, and the macro variables are indexed by the BY-group number and the quantile level index. You can use the MAXMACRO= option to either limit or increase the number of these macro variables when you are processing data sets with many combinations of quantile level and BY group.

With a single quantile level and no BY-group processing, PROC QUANTSELECT creates the macro variables shown in [Table 78.2](#).

Table 78.2 Macro Variables Created for a Single Quantile Level and No BY Processing

Macro Variable Name	Contains
<code>_QRSIND</code>	Selected effects
<code>_QRSIND1</code>	Selected effects
<code>_QRSINDT1</code>	Selected effects
<code>_QRSIND1T1</code>	Selected effects
<code>_QRSMOD</code>	Selected design matrix columns
<code>_QRSMOD1</code>	Selected design matrix columns
<code>_QRSMODT1</code>	Selected design matrix columns
<code>_QRSMOD1T1</code>	Selected design matrix columns

With multiple quantile levels and BY-group processing, PROC QUANTSELECT creates the macro variables shown in [Table 78.3](#).

Table 78.3 Macro Variables Created for a Multiple Quantile Levels and BY-Group Processing

Macro Variable Name	Contains
_QRSIND	Selected effects for quantile 1 and BY group 1
_QRSINDT1	Selected effects for quantile 1 and BY group 1
_QRSINDT2	Selected effects for quantile 2 and BY group 1
.	
.	
.	
_QRSIND1	Selected effects for quantile 1 and BY group 1
_QRSIND1T1	Selected effects for quantile 1 and BY group 1
_QRSIND1T2	Selected effects for quantile 2 and BY group 1
.	
.	
.	
_QRSIND2	Selected effects for quantile 1 and BY group 2
_QRSIND2T1	Selected effects for quantile 1 and BY group 2
_QRSIND2T2	Selected effects for quantile 2 and BY group 2
.	
.	
.	
_QRSIND mTn	Selected effects for quantile n and BY group m

If you specify the OUTDESIGN= option, PROC QUANTSELECT also creates the macro variables shown in Table 78.4.

Table 78.4 Macro Variables Created When the OUTDESIGN= Option Is Specified

Macro Variable Name	Contains
_QRSMOD	Selected design matrix columns for BY group 1
_QRSMOD1	Selected design matrix columns for BY group 1
_QRSMOD2	Selected design matrix columns for BY group 2
.	
.	
.	
_QRSMOD mTn	Selected design matrix columns for quantile n and BY group m

The macros variables in [Table 78.5](#) show the number of quantiles and BY groups:

Table 78.5 Macro Variables Showing the Number of Quantiles and BY Groups

Macro Variable Name	Contains
_QRSNUMBYS	The number of BY groups
_QRSNUMTAUS	The number of quantiles
_QRSBY1NUMTAUS	The number of _QRS1INDj macro variables actually made
_QRSBY2NUMTAUS	The number of _QRS2INDj macro variables actually made
.	
.	
.	
_QRSNUMBYTAUS	The number of _QRSiINDj macro variables actually made. This value can be less than $_QRSNUMBYS \times _QRSNUMTAUS$, and it is less than or equal to $MAXMACRO=n$.

See the section “[Macro Variables That Contain Selected Models](#)” on page 6600 for more information.

NOPRINT

suppresses all displayed output (including plots).

OUTDESIGN< (*options*)= >< SAS-data-set >

creates a data set that contains the design matrix. By default, the QUANTSELECT procedure includes in the OUTDESIGN data set the **X** matrix that corresponds to all the effects in the selected models. Two schemes for naming the columns of the design matrix are available:

- In the first scheme, names of the parameters are constructed from the parameter labels that appear in the parameter estimates table. This naming scheme is the default when you do not request BY processing; it is not available when you do use BY processing.
- In the second scheme, the design matrix column names consist of a prefix followed by an index. The default name prefix is **_X**. This scheme is used when you specify the **PREFIX=** option or a BY statement; otherwise the first scheme is used.

You can specify the following *options* in parentheses to control the contents of the OUTDESIGN= data set:

ADDINPUTVARS

includes all the input data set variables in the OUTDESIGN= data set.

ADDVALDATA

includes all the VALDATA= data set variables in the OUTDESIGN= data set. This option is ignored if the VALDATA= data set is not specified.

ADDTESTDATA

includes all the TESTDATA= data set variables in the OUTDESIGN= data set. This option is ignored if TESTDATA= data set is not specified.

FULLMODEL

includes in the OUTDESIGN= data set parameters that correspond to all effects that are specified in the MODEL statement. By default, only parameters that correspond to the selected model are included.

NAMES

produces a table that associates columns in the OUTDESIGN= data set with the labels of the parameters they represent.

PREFIX*<=prefix>*

creates the design matrix column names from a prefix followed by an index. The default *prefix* is *_X*.

PLOTS *<(global-plot-options)> <= plot-request <(options)>>*

PLOTS *<(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>)>*

controls the plots that are produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses around it. Here are some examples:

```
plots=all
plots=coefficients(unpack)
plots(unpack)=(coef acl crit)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc quantselect plots=all;
  class temp sex / split;
  model depVar = sex sex*temp;
run;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

You can specify the following *global-plot-options*, which apply to all plots generated by the QUANTSELECT procedure, unless they are altered by specific plot *options*.

ENDSTEP*=n*

specifies that the step ranges shown on the horizontal axes of plots terminate at the specified step. By default, the step range shown terminates at the final step of the selection process. If you specify the ENDSTEP= option as both a *global-plot-option* and as an *option* for a specific *plot-request*, then PROC QUANTSELECT uses the ENDSTEP=*n option* for the specific *plot-request*.

LOGP | LOGPVALUE

displays the natural logarithm of the entry and removal significance levels when the [SELECT=SL](#) option is specified in the MODEL statement.

MAXSTEPLABEL*=n*

specifies the maximum number of characters beyond which labels of effects on plots are truncated. The default is MAXSTEPLABEL=256.

MAXPARMLABEL=*n*

specifies the maximum number of characters beyond which parameter labels on plots are truncated. The default is MAXPARMLABEL=256.

STARTSTEP=*n*

specifies that the step ranges shown on the horizontal axes of plots start at the specified step. By default, the step range shown starts at the initial step of the selection process. If you specify the STATSTEP= option as both a *global-plot-option* and as an *option* for a specific *plot-request*, then PROC QUANTSELECT uses the STARTSTEP=*n* option for the specific *plot-request*. The default is STARTSTEP=0.

STEPAXIS=EFFECT | NORMB | NUMBER

specifies the method for labeling the horizontal plot axis. This axis represents the sequence of entering or departing effects. The default is STEPAXIS=EFFECT.

STEPAXIS=EFFECT

labels each step by a prefix followed by the name of the effect that enters or leaves at that step. The prefix consists of the step number followed by a “+” sign or a “-” sign, depending on whether the effect enters or leaves at that step.

STEPAXIS=NORMB

labels the horizontal axis value at step *i* with the penalty on the parameter estimates at step *i*, normalized by the penalty on the parameter estimates at the final step. This option is valid only with regularization selection methods.

STEPAXIS=NUMBER

labels each step with the step number.

UNPACK

displays each graph separately. (By default, some graphs can appear together in a single panel.) You can also specify UNPACK as a suboption with CRITERIA and COEFFICIENTS options for specific *plot-requests*.

The following list describes the specific *plot-requests* and their *options*.

ALL

displays all appropriate graphs.

ACL | ACLPLOT < (*acplot-option*) >

plots the progression of the average check losses on the training data, and on the test and validation data when these data are provided with the TESTDATA= or VALDATA= options or are produced by using a PARTITION statement. When the PROC QUANTSELECT procedure is applied on multiple quantile levels, the ACL option and its suboptions apply to the ACL plots for each of the quantile levels.

You can specify the following *acplot-option*:

STEPAXIS=EFFECT | NORMB | NUMBER

specifies the method for labeling the horizontal plot axis. See the STEPAXIS= option in the *global-plot-options* for more information.

COEF | COEFFICIENTS | COEFFICIENTPANEL <(coefficient-panel-options)>

displays a panel of two plots for each quantile level. The upper plot shows the progression of the parameter values as the selection process proceeds. The lower plot shows the progression of the **CHOOSE=** criterion. If no **CHOOSE=** criterion is in effect, then the AICC criterion is displayed. You can specify the following *coefficient-panel-options*:

LABELGAP=percentage

specifies the percentage of the vertical axis range that forms the minimum gap between successive parameter labels at the final step of the coefficient progression plot. If the values of more than one parameter at the final step are closer than this gap, then the labels on all but one of these parameters are suppressed. The default is **LABELGAP=5**.

LOGP | LOGPVALUE

displays the natural logarithm of the entry and removal significance levels when the **SELECT=SL** option is specified in the **MODEL** statement.

STEPAXIS=EFFECT | NORMB | NUMBER

specifies the horizontal axis to be used. See the **STEPAXIS=** option in the *global-options* for more information.

UNPACK | UNPACKPANEL

displays the coefficient progression and the **CHOOSE=** criterion progression in separate plots.

CRIT | CRITERIA | CRITERIONPANEL <(criterion-panel-options)>

plots a panel of model fit criteria. If multiple quantile levels apply, the **CRITERIA** option plots a panel of model fit criteria for each quantile level. The criteria that are displayed are AIC, AICC, and SBC, in addition to any other criteria that are named in the **CHOOSE=**, **SELECT=**, **STOP=**, and **STATS=** options in the **MODEL** statement. You can specify the following *criterion-panel-options*:

STEPAXIS=EFFECT | NORMB | NUMBER

specifies the horizontal axis to be used. See the **STEPAXIS=** option in the *global-options* for more information.

UNPACK | UNPACKPANEL

displays each criterion progression on a separate plot.

NONE

suppresses all plots.

SEED=number

specifies an integer that is used to start the pseudorandom number generator for random partitioning of data for training, testing, and validation. If you do not specify a seed or if you specify a value less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

TESTDATA=SAS-data-set

names a SAS data set that contains test data. This data set must contain all the effects that are specified in the **MODEL** statement. Furthermore, when you also specify a **BY** statement and the **TESTDATA=** data set contains any of the **BY** variables, then the **TESTDATA=** data set must also contain all the

BY variables sorted in the order of the BY variables. In this case, only the test data for a specific BY group are used with the corresponding BY group in the analysis data. If the TESTDATA= data set contains none of the BY variables, then the entire TESTDATA= data set is used with each BY group of the analysis data.

If you specify both a TESTDATA= data set and the **PARTITION** statement, then the testing observations from the DATA= data set are merged with the TESTDATA= data set for testing purposes.

VALDATA=SAS-data-set

names a SAS data set that contains validation data. This data set must contain all the effects that are specified in the **MODEL** statement. Furthermore, when a BY statement is used and the VALDATA= data set contains any of the BY variables, then the VALDATA= data set must also contain all the BY variables sorted in the order of the BY variables. In this case, only the validation data for a specific BY group are used with the corresponding BY group in the analysis data. If the VALDATA= data set contains none of the BY variables, then the entire VALDATA= data set is used with each BY group of the analysis data.

If you specify both a VALDATA= data set and the **PARTITION** statement, then the validation observations from the DATA= data set are merged with the VALDATA= data set for validation purposes.

BY Statement

BY variables ;

You can specify a BY statement with PROC QUANTSELECT to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the QUANTSELECT procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable* < (*v-options*) > < *variable* < (*v-options* ...) > > < / *v-options* > < *options* > ;

The CLASS statement names the classification variables to be used in the analysis. The CLASS statement must precede the MODEL statement.

Table 78.6 summarizes the *options* and *v-options* available in the CLASS statement.

Table 78.6 CLASS Statement Options

<i>option or v-option</i>	Description
DELIMITER=	Specifies the delimiter
DESCENDING	Reverses the sort order
MISSING	Allows for missing values
ORDER=	Specifies the sort order
PARAM=	Specifies the parameterization method
REF=	Specifies the reference level
SHOW	Requests a table for each CLASS variable
SPLIT	Splits CLASS variables into independent effects

You can specify the following *options* after a slash (/):

DELIMITER='c'

specifies the delimiter character, 'c', to be used between levels of classification variables when parameter names and lists of class level values are built. The default delimiter is a space. This option is useful if the levels of a classification variable contain embedded blanks.

SHOW | SHOWCODING

requests a table that shows the coding used for each classification variable.

You can specify various *v-options* for each variable by enclosing them in parentheses after the variable name; these are called individual *v-options*. You can also specify global *v-options* by placing them after a slash (/) at the end of the CLASS statement. Global *v-options* are applied to all the variables specified in the CLASS statement. If you specify more than one CLASS statement, the global *v-options* specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *v-options* override the global *v-options*.

You can specify the following *v-options*:

DESCENDING

DESC

reverses the sort order of the classification variable.

MISSING

allows missing values, such as ' .' for a numeric variable or a blank for a character variable, as valid values for the CLASS variable.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of classification variables. If ORDER=FORMATTED for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values. The following table shows how PROC QUANTSELECT interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent.

For more information about sort order, see the chapter on the SORT procedure in the Bookrefprocguide and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

PARAM=keyword

specifies the parameterization method for the classification variable or variables. Design matrix columns are created from CLASS variables according to the following coding schemes. The default is PARAM=GLM. If PARAM=ORTHOPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used. See the section “CLASS Variable Parameterization and the SPLIT Option” on page 3570 in Chapter 45, “The GLMSELECT Procedure,” for more information.

EFFECT	specifies effect coding.
GLM	specifies less-than-full-rank coding. This option can be used only as a global <i>v-option</i> (after the slash in the CLASS statement).
ORDINAL THERMOMETER	specifies the cumulative parameterization for an ordinal CLASS variable.
POLYNOMIAL POLY	specifies polynomial coding.
REFERENCE REF	specifies reference-cell coding.
ORTHEFFECT	orthogonalizes PARAM=EFFECT.
ORTHORDINAL ORTHOTHERM	orthogonalizes PARAM=ORDINAL.
ORTHOPOLY	orthogonalizes PARAM=POLYNOMIAL.
ORTHREF	orthogonalizes PARAM=REFERENCE.

The EFFECT, POLYNOMIAL, REFERENCE, and ORDINAL coding schemes and their orthogonal parameterizations are full rank. The REF= option in the CLASS statement determines the reference level for the EFFECT and REFERENCE schemes and their orthogonal parameterizations.

REF=*'level'* | **FIRST** | **LAST**

specifies the reference level for PARAM=EFFECT, PARAM=REFERENCE, and their orthogonalizations. For an individual (but not a global) REF= *v-option*, you can specify the *level* of the variable to use as the reference level. For a global or individual REF= *v-option*, you can specify REF=FIRST (which designates the first-ordered level as reference) or REF=LAST (which designates the last-ordered level as reference). The default is REF=LAST.

SPLIT

enables the columns of the design matrix that correspond to any effect that contains a split classification variable to be selected to enter or leave a model independently of the other design columns of that effect. For example, suppose a variable named temp has three levels with values 'hot', 'warm', and 'cold', and a variable named sex has two levels with values 'M' and 'F'. The following statements include SPLIT as a global *v-option*:

```
proc quantselect;
  class temp sex / split;
  model depVar = sex sex*temp;
run;
```

Because both the classification variables are split, the two effects named in the **MODEL** statement are split into eight effects. The effect 'sex' is split into two effects labeled 'sex_M' and 'sex_F'. The effect 'sex*temp' is split into six effects labeled 'sex_M*temp_hot', 'sex_F*temp_hot', 'sex_M*temp_warm', 'sex_F*temp_warm', 'sex_M*temp_cold', and 'sex_F*temp_cold'. The previous PROC QUANTSELECT statements are equivalent to the following statements for the split version of the DATA= data set:

```
proc quantselect;
  model depVar =  sex_M sex_F sex_M*temp_hot  sex_F*temp_hot
                  sex_M*temp_warm sex_F*temp_warm
                  sex_M*temp_cold sex_F*temp_cold;
run;
```

You can specify the SPLIT option for individual classification variables. For example, consider the following PROC QUANTSELECT statements:

```
proc quantselect;
  class temp(split) sex;
  model depVar = sex sex*temp;
run;
```

In this case, the effect 'sex' is not split, and the effect 'sex*temp' is split into three effects labeled 'sex*temp_hot', 'sex*temp_warm', and 'sex*temp_cold'. Furthermore each of these three split effects now has two parameters that correspond to the two levels of 'sex, ' and the previous PROC QUANTSELECT statements are equivalent to the following statements for the split version of the DATA= data set:

```
proc quantselect;
  class sex;
  model depVar = sex sex*temp_hot sex*temp_warm sex*temp_cold;
run;
```

EFFECT Statement

EFFECT *name=effect-type (variables < / options>)* ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.
MULTIMEMBER MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 78.7 summarizes the *options* available in the EFFECT statement.

Table 78.7 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect
Lag Effects Options	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Multimember Effects Options	
NOEFFECT	Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects

Table 78.7 continued

Option	Description
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “[EFFECT Statement](#)” on page 393 in Chapter 19, “[Shared Concepts and Topics](#).”

MODEL Statement

MODEL *dependent* = < *effects* > / < *options* > ;

The MODEL statement names the dependent variable and the covariate effects, including covariates, main effects, constructed effects, interactions, and nested effects; see the section “[Specification of Effects](#)” on page 3324 in Chapter 42, “[The GLM Procedure](#),” for more information. If you omit the explanatory effects, PROC QUANTSELECT fits an intercept-only model.

After the keyword MODEL, specify the dependent (response) variable, followed by an equal sign, followed by the explanatory effects.

Table 78.8 summarizes the *options* available in the MODEL statement.

Table 78.8 MODEL Statement Options

Option	Description
DETAILS=	Specifies the level of effect selection detail to display
HIERARCHY=	Specifies hierarchy of effects to impose
NOINT	Specifies models without an explicit intercept
QUANTILES=	Specifies quantile levels to be applied
SELECTION=	Specifies effect selection method
STATS=	Specifies additional statistics to be displayed
TEST=	Specifies the test type for computing significance levels

The following list provides details about the *options* that you can specify in the MODEL statement after a slash (/):

DETAILS=ALL | SUMMARY

specifies the level of effect selection detail that is displayed. The DETAILS=SUMMARY option produces only the selection summary table. The DETAILS=ALL option produces the following:

- entry and removal statistics for each variable that is selected in the model building process
- average check loss and parameter estimates
- entry and removal statistics for the top five candidates for inclusion or exclusion at each step
- a selection summary table

The default is DETAILS=SUMMARY.

HIERARCHY=keyword**HIER=keyword**

specifies whether and how the model hierarchy requirement is applied. This option also controls whether a single effect or multiple effects are allowed to enter or leave the model in one step. You can specify that only CLASS effects, or both CLASS and continuous effects, be subject to the hierarchy requirement. This option is ignored unless you also specify one of the following options: [SELECTION=FORWARD](#), [SELECTION=BACKWARD](#), or [SELECTION=STEPWISE](#).

Model hierarchy refers to the requirement that for any term to be in the model, all model effects contained in the term must be present in the model. For example, in order for the interaction A*B to enter the model, the main effects A and B must be in the model. Likewise, neither effect A nor effect B can leave the model while the interaction A*B is in the model.

You can specify the following *keywords*:

NONE

specifies that model hierarchy not be maintained. Any single effect can enter or leave the model at any given step of the selection process.

SINGLE

specifies that only one effect enter or leave the model at one time, subject to the model hierarchy requirement. For example, suppose that the model contains the main effects A and B and the interaction A*B. In the first step of the selection process, either A or B can enter the model. In the second step, the other main effect can enter the model. The interaction effect can enter the model only when both main effects have already entered. Also, before A or B can be removed from the model, the A*B interaction must first be removed. All effects (CLASS and interval) are subject to the hierarchy requirement.

SINGLECLASS

is the same as HIERARCHY=SINGLE except that only CLASS effects are subject to the hierarchy requirement.

The default is HIERARCHY=NONE.

NOINT

suppresses the intercept term that is otherwise included in the model.

QUANTILES=< *number-list* | **PROCESS** <(*option*)>>

QUANTILE=< *number-list* | **PROCESS** <(*option*)>>

specifies the quantile levels for the quantile regression. You can specify any number of quantile levels in (0, 1). If you do not specify this option, the QUANTSELECT procedure performs median regression effect selection that corresponds to QUANTILES=0.5.

If you specify the QUANTILES=PROCESS option, the QUANTSELECT procedure performs effect selection for quantile process regression. The QUANTILES=PROCESS option cannot be used with LASSO selection methods. You can specify the following *option* in parentheses after QUANTILES=PROCESS.

NTAU=*n* | **ALL**

specifies how many quantile levels that you expect to cover for the quantile process. If you specify NTAU=ALL, the QUANTSELECT procedure performs effect selection for accurate quantile process regression. If you specify NTAU=*n*, the QUANTSELECT procedure performs effect selection for approximate quantile process regression. The approximate quantile process is computed at *n* equally spaced quantile levels: $\{\frac{1}{n+1}, \dots, \frac{n}{n+1}\}$.

SELECTION=*method* <(*method-options*)>

specifies the *method* used to select the model, optionally followed by parentheses that enclose *method-options* that apply to the specified method. The default is SELECTION=STEPWISE.

You can specify the following *methods*, which are explained in detail in the section “[Effect Selection Methods](#)” on page 6597.

NONE	specifies full model fitting without effect selection.
FORWARD	specifies forward selection. This method starts with no effects in the model and adds effects.
BACKWARD	specifies backward elimination. This method starts with all effects in the model and deletes effects.
STEPWISE	specifies stepwise regression. This is similar to the FORWARD method except that effects already in the model do not necessarily stay there.
LASSO	specifies a method that adds and deletes parameters based on a version of estimated check risk where the weighted L1-norm of certain weighted regression coefficients is penalized. For more information, see the section “ LASSO Method (LASSO) ” on page 6598. If the model contains CLASS variables or constructed effects, these CLASS variables or constructed effects are split into separate covariates.

[Table 78.9](#) lists the applicable *method-options* for each *method*.

Table 78.9 Applicable *method-options* for Each *method*

<i>method-option</i>	FORWARD	BACKWARD	STEPWISE	LASSO
ADAPTIVE				X
CHOOSE=	X	X	X	X
INCLUDE=	X	X	X	X
MAXSTEP=	X	X	X	X
SELECT=	X	X	X	
SLENTY=	X		X	
SLSTAY=		X	X	
STOP=	X	X	X	X
STOPHORIZON=	X	X	X	X

You can specify the following *method-option* in parentheses after the *method*. As described in [Table 78.9](#), not all *method-options* apply to every SELECTION= method.

ADAPTIVE**ADAPT**

specifies the adaptive LASSO selection method. The ADAPTIVE option can be used only with the SELECTION=LASSO option.

CHOOSE=criterion

chooses from the list of models (with one model at each step of the selection process) the model that yields the best value of the specified *criterion* as the final selected model. If the optimal value of the specified *criterion* occurs for more than one model, then the model with the smallest number of parameters is chosen. If you do not specify the CHOOSE= option, then the model selected is the model at the final step in the selection process for the SELECT=SL criterion, or the STOP= option is applied as the CHOOSE= option for all the other cases.

You can specify the following values for *criterion* in the CHOOSE= option. See the section “[Criteria Used in Model Selection Methods](#)” on page 6598 for more information about these criteria.

ADJR1	chooses the model with the largest adjusted quantile regression R statistic.
AIC	chooses the model with the smallest Akaike’s information criterion.
AICC	chooses the model with the smallest corrected Akaike’s information criterion.
SBC	chooses the model with the smallest Schwarz Bayesian information criterion.
VALIDATE	chooses the model with the smallest average check loss for the validation data. You can specify CHOOSE=VALIDATE only if you have specified a VALDATA= data set in the PROC QUANTSELECT statement or if you have reserved part of the input data for validation by using either a PARTITION statement or a _ROLE_ variable in the input data.

INCLUDE=n

forces the first *n* effects listed in the MODEL statement to be included in all models. The selection methods are performed on the other effects in the MODEL statement. The INCLUDE= option is available only with SELECTION=FORWARD, SELECTION=STEPWISE, and SELECTION=BACKWARD.

MAXSTEP=*n*

specifies the maximum number of selection steps. The default value of *n* is the number of effects in the MODEL statement when SELECTION=FORWARD or SELECTION=BACKWARD and is three times the number of effects when SELECTION=STEPWISE or SELECTION=LASSO.

SELECT=*criterion*

specifies the criterion that PROC QUANTSELECT uses to determine the order in which effects enter or leave at each step of the specified selection method. This option is not valid when SELECTION=LASSO. You can specify the following values for *criterion*: ADJR1, AIC, AICC, SBC, SL, and VALIDATE. See the section “Criteria Used in Model Selection Methods” on page 6598 for more information about these criteria.

When SELECT=SL, the effect selection depends on the selection method and is described in the relevant subsection of the section “Effect Selection Methods” on page 6597. Otherwise, the effect that is selected to enter or leave at a step of the selection process is the effect whose addition to or removal from the current model produces the maximum improvement in the specified criterion.

If validation data exist, the default is SELECT=VALIDATE; otherwise, the default is SELECT=SBC.

SLENTRY=*value***SLE=*value***

specifies the significance level for entry, used when the STOP=SL or SELECT=SL option is in effect. The defaults are 0.50 when SELECTION=FORWARD and 0.15 when SELECTION=STEPWISE.

SLSTAY=*value***SLS=*value***

specifies the significance level for staying in the model, used when the STOP=SL or SELECT=SL option is in effect. The defaults are 0.10 when SELECTION=BACKWARD and 0.15 when SELECTION=STEPWISE.

STOP=*criterion*

specifies the *criterion* for stopping the selection process. If the maximum number of steps is specified in the MAXSTEP= option and the *criterion* does not stop the selection process before the maximum number of steps for the selection method, then the selection process terminates at the maximum number of steps.

You can specify the following values for *criterion*. See the section “Criteria Used in Model Selection Methods” on page 6598 for more detailed descriptions of these criteria.

NONE	enables the model selection process to go through all possible steps.
ADJR1	stops selection at the step where the next SH= steps (or all remaining steps) would yield models with smaller values of the adjusted quantile regression R (ADJR1) statistic.
AIC	stops selection at the step where the next SH= steps (or all remaining steps) would yield models with larger values of Akaike's information criterion.

AICC	stops selection at the step where the next SH= steps (or all remaining steps) would yield models with larger values of the corrected Akaike's information criterion.
SBC	stops selection at the step where the next SH= steps (or all remaining steps) would yield models with larger values of the Schwarz Bayesian information criterion.
VALIDATE	stops selection at the step where the next SH= steps (or all remaining steps) would yield models with larger values of the average check loss for the validation data. You can specify STOP=VALIDATE only if you have specified a VALIDATA= data set in the PROC QUANTSELECT statement or if you have reserved part of the input data for validation by using either a PARTITION statement or a _ROLE_ variable in the input data.

The default value of this option depends on other options as follows:

- If you specify SELECT=SL and you also specify the SLE= *method-option* or the SLS= *method-option*, the STOP option is ignored.
- If do not specify both SELECT=SL and one or both of the SLE= or SLS= *method-options* and validation data exist, the default is STOP=VALIDATE.
- If do not specify both SELECT=SL and one or both of the SLE= or SLS= *method-options* and validation data do not exist, the default is one of the following:
 - When you specify SELECTION=LASSO, the default is STOP=SBC.
 - When you specify SELECTION=NONE, FORWARD, BACKWARD, or STEPWISE, the default is the criterion specified in the SELECT= *method-option*.

STOPHORIZON=*n*

SH=*n*

looks ahead for the specified number of steps to decide whether an extremum of the stop criterion is achieved. This option applies only to the STOP= criterion. The default is STOPHORIZON=1.

For example, suppose that the stop criterion values at steps 1 through 5 are 4, 3, 5, 6, and 2, respectively. If you specify STOPHORIZON=1, then the selection process terminates after looking at the model at step 3, and the final selected model is the model at step 2. If you specify STOPHORIZON=2, the selection process stops after looking at the model at step 4, and the final selected model is the model at step 2. However, if you specify STOPHORIZON=3 or higher, then the local minimum in the stop value sequence at step 2 cannot stop the selection process because a lower value is achieved at step 5, which is within 3 steps beyond this local minimum step.

STAT=*name* | (*names*)

STATS=*name* | (*names*)

specifies which model fit statistics to display in the selection summary table. To specify multiple model fit statistics, specify a list of *names* in parentheses. If you omit this option, the default set of statistics that are displayed in these tables includes all the criteria that are specified in any of the **CHOOSE=**, **SELECT=**, and **STOP=** *method-options*.

You can specify the following values for *name*:

ADJR1	displays the adjusted quantile regression R statistic.
AIC	displays the Akaike's information criterion.
AICC	displays the corrected Akaike's information criterion.
ACL	displays the average check losses for the training, test, and validation data. The ACL statistics for the test and validation data are reported only if you have specified the TESTDATA= option or the VALDATA= option in the PROC QUANTSELECT statement or if you have reserved part of the input data for testing or validation by using either a PARTITION statement or a _ROLE_ variable in the input data.
R1	displays the quantile regression R statistic.
SBC	displays the Schwarz Bayesian information criterion.

The statistics ADJR1, AIC, AICC, and SBC can be computed with little computation cost. However, computing ACL for test and validation data when these are not used in any of the **CHOOSE=**, **SELECT=**, and **STOP=** *method-options* can hurt performance.

TEST=*name*

specifies the test type for computing significance levels.

You can specify the following values for *name*:

LR1	specifies the likelihood ratio test Type I. The LR1 test score is defined as
------------	--

$$\frac{2(D_1(\tau) - D_2(\tau))}{\tau(1 - \tau)\hat{s}}$$

where $D_1(\tau) = \sum \rho_\tau(y_i - \mathbf{x}_i \hat{\boldsymbol{\beta}}_1(\tau))$ is the sum of check losses for the reduced model, $D_2(\tau) = \sum \rho_\tau(y_i - \mathbf{x}_i \hat{\boldsymbol{\beta}}(\tau))$ is the sum of check losses for the extended model, and \hat{s} is the estimated sparsity function. For more information about the sparsity function, see the section “**Sparsity**” on page 6523 of Chapter 77, “**The QUANTREG Procedure**.”

LR2	specifies the likelihood ratio test Type II. The LR2 test score is defined as
------------	---

$$\frac{2D_2(\tau) (\log(D_1(\tau)) - \log(D_2(\tau)))}{\tau(1 - \tau)\hat{s}}$$

where \hat{s} is computed on the reduced model for testing the entry effect and on the extended model for testing the removal effect.

OUTPUT Statement

OUTPUT < **OUT**=SAS-data-set> < keyword < =name> > ...< keyword < =name> > ;

The OUTPUT statement creates a new SAS data set that saves diagnostic measures that are calculated for the selected model. If you do not specify a *keyword*, then the only diagnostic included is the predicted response.

All the variables in the original data set are included in the new data set, along with variables that are created by the *keyword* options in the OUTPUT statement. These new variables contain the values of a variety of statistics and diagnostic measures that are calculated for each observation in the data set.

The OUTPUT data set is created in row-wise form, and the variable `_QUANTILE_` is optional. For each appropriate keyword specified in the OUTPUT statement, one variable for each specified quantile level is generated. These variables appear in the sorted order of the specified quantile levels.

If you specify a BY statement, then a variable `_BY_` that indexes the BY groups is included. For each observation, the value of `_BY_` is the index of the BY group to which this observation belongs. This variable is useful for matching BY groups with macro variables that PROC QUANTSELECT creates. See the section “[Macro Variables That Contain Selected Models](#)” on page 6600 for more information.

If you have partitioned the input data with a **PARTITION** statement, then a character variable `_ROLE_` is included in the output data set. The following table shows the value of `_ROLE_` for each observation:

<code>_ROLE_</code> Value	Observation Role
TEST	Testing
TRAIN	Training
VALIDATE	Validation

If you want to create a permanent SAS data set, you must specify a two-level name. For more information about permanent SAS data sets, see the discussion in *SAS Language Reference: Concepts*.

You can specify the following arguments in the OUTPUT statement:

keyword < =name>

specifies the statistics to include in the output data set and optionally names the new variables that contain the statistics. Specify one of the following *keywords* for each desired statistic, followed optionally by an equal sign, and the *name* of a variable to contain the statistic. If you specify *keyword*=*name*, the new variable that contains the requested statistic has the specified name. If you omit the optional =*name* after a *keyword*, then the new variable name is formed by using a prefix of one or more characters that identify the statistic, followed by an underscore (_), followed by the dependent variable name.

PREDICTED | **PRED** | **P** includes predicted values in the output data set. The prefix for the default name is p.

RESIDUAL | **RESID** | **R** includes residuals, calculated as ACTUAL – PREDICTED, in the output data set. The prefix for the default name is r.

OUT=SAS-data-set

names the output data set. By default, PROC QUANTSELECT uses the *DATA*n** convention to name the new data set.

PARTITION Statement

PARTITION < option > ;

The PARTITION statement specifies how observations in the input data set are logically partitioned into disjoint subsets for model training, validation, and testing. Either you can designate a variable in the input data set and a set of formatted values of that variable to determine the role of each observation, or you can specify proportions to use for random assignment of observations for each role.

An alternative to using a PARTITION statement is to provide a variable named `_ROLE_` in the input data set to define roles of observations in the input data. If you specify a PARTITION statement, then any `_ROLE_` variable in the input data set is ignored. If you do not use a PARTITION statement and the input data do not contain a variable named `_ROLE_`, then all observations in the input data set are assigned to model training.

You can specify either (but not both) of the following *options*:

ROLEVAR=*variable* (< **TEST=***value*> < **TRAIN=***value*> < **VALIDATE=***value*>)

ROLE=*variable* (< **TEST=***value*> < **TRAIN=***value*> < **VALIDATE=***value*>)

names the variable in the input data set whose values are used to assign roles to each observation. The **TEST=**, **TRAIN=**, and **VALIDATE=** suboptions specify the formatted values of this variable that are used to assign observations roles. If you do not specify the **TRAIN=** suboption, then all observations whose role is not determined by the **TEST=** or **VALIDATE=** suboptions are assigned to training. If you specify a **TESTDATA=** data set in the PROC QUANTSELECT statement, then you cannot also specify the **TEST=** suboption in the PARTITION statement. If you specify a **VALDATA=** data set in the PROC QUANTSELECT statement, then you cannot also specify the **VALIDATE=** suboption in the PARTITION statement.

FRACTION(< **TEST=***fraction*> < **VALIDATE=***fraction*>)

requests that specified proportions of the observations in the input data set be randomly assigned training and validation roles. You specify the proportions for testing and validation by using the **TEST=** and **VALIDATE=** suboptions. If you specify both the **TEST=** and the **VALIDATE=** suboptions, then the sum of the specified fractions must be less than 1 and the remaining fraction of the observations are assigned to the training role. If you specify a **TESTDATA=** data set in the PROC QUANTSELECT statement, then you cannot also specify the **TEST=** suboption in the PARTITION statement. If you specify a **VALDATA=** data set in the PROC QUANTSELECT statement, then you cannot also specify the **VALIDATE=** suboption in the PARTITION statement.

WEIGHT Statement

WEIGHT *variable* ;

A WEIGHT statement names a variable in the input data set with values that are relative weights for a weighted quantile regression fit.

Values of the weight variable must be nonnegative. If an observation's weight is 0, the observation is deleted from the analysis. If a weight is negative or missing, it is set to 0, and the observation is excluded from the analysis.

Details: QUANTSELECT Procedure

Effect Selection Methods

The effect selection methods implemented in PROC QUANTSELECT are specified with the **SELECTION=** option in the **MODEL** statement.

Full Model Fitted (NONE)

The complete model specified in the **MODEL** statement is used to fit the model, and no effect selection is done. You request this method by specifying **SELECTION=NONE** in the **MODEL** statement.

Forward Selection (FORWARD)

The forward selection technique begins with just the forced-in covariates and then sequentially adds the effect that most improves the fit. The process terminates when no significant improvement can be obtained by adding any effect. You request this method by specifying **SELECTION=FORWARD** in the **MODEL** statement.

If you specify the **SELECT=SL method-option**, you can use the **TEST= method-option** to specify a test statistic for gauging improvement in fit. For example, if **TEST=LR1**, at each step the effect that yields the most significant likelihood ratio statistic is added and the process continues until all effects that are not in the model have LR1 statistics that are not significant at the entry significance level (which is specified in the **SLE=** option). Because effects can contribute different degrees of freedom to the model, it is necessary to compare the *p*-values that correspond to these statistics.

Backward Elimination (BACKWARD)

The backward elimination technique starts from the full model, which includes all independent effects. Then effects are deleted one by one until a stopping condition is satisfied. At each step, the effect that shows the smallest contribution to the model is deleted. You request this method by specifying **SELECTION=BACKWARD** in the **MODEL** statement.

Suppose you specify the **SELECT=SL method-option** and the **TEST=LR1 method-option** to gauge improvement in quantile regression fit. At any step, the predictor that produces the least significant LR1 statistic is dropped and the process continues until all effects that remain in the model have LR1 statistics that are significant at the stay significance level (which is specified in the **SLS=** option).

Stepwise Selection (STEPWISE)

The stepwise method is a modification of the forward selection technique in which effects already in the model do not necessarily stay there. You request this method by specifying **SELECTION=STEPWISE** in the **MODEL** statement.

In the implementation of the stepwise selection method, the same entry and removal approaches for the forward selection and backward elimination methods are used to assess contributions of effects as they are added to or removed from a model. Suppose you specify `SELECT=SL`. If, at a step of the stepwise method, any effect in the model is not significant at the level specified by the `SLSTAY= method-option`, then the least significant of these effects is removed from the model and the algorithm proceeds to the next step. This ensures that no effect can be added to a model while some effect currently in the model is not deemed significant. Only after all necessary deletions have been accomplished can another effect be added to the model. In this case, the effect whose addition yields the most significant statistic value is added to the model and the algorithm proceeds to the next step. The stepwise process ends when none of the effects outside the model is significant at the level specified by the `SLENTY= method-option` and every effect in the model is significant at the level specified by the `SLSTAY= method-option`. In some cases, neither of these two conditions for stopping is met and the sequence of models cycles. In this case, the stepwise method terminates at the end of the second cycle.

Just as with forward selection and backward elimination, you can use the `SELECT= method-option` to change the criterion used to assess effect contributions. You can also use the `STOP= method-option` to specify a stopping criterion and use the `CHOOSE= method-option` to specify a criterion used to select among the sequence of models produced.

LASSO Method (LASSO)

The standard LASSO method uses a standardized design matrix that orthogonalizes selectable covariates against forced-in covariates, and then scales the orthogonalized selectable covariates so that they all have the same sum of squares. See the information about the standard parameter estimate in the section “[Parameter Estimates](#)” on page 6606 for more information about design matrix orthogonalization. The LASSO method initializes all the selectable coefficients into 0 at step 0. The predictor that reduces the average check loss the fastest relative to the L1-norm of the selectable coefficient increment is determined, and a step is taken in the direction of this predictor.

The difference between adaptive LASSO and standard LASSO methods is in the prescaling of the selectable coefficients. After orthogonalization against forced-in covariates, the adaptive LASSO method first fits a full model without penalty, and then scales the orthogonalized selectable covariates with the corresponding coefficients from the full model. This adaptive scaling can be equivalently substituted by using a weighted L1-norm penalty, where the weights are the reciprocals of the corresponding coefficients from the full model.

The length of this step determines the coefficient of this predictor and is chosen when some residual changes its sign or some predictor that is not used in the model can reduce the average check loss more efficiently. This process continues until all predictors are in the model.

As with other selection methods, the issue of when to stop the selection process is crucial. You can use the `CHOOSE= method-option` to specify a criterion for choosing among the models at each step. You can also use the `STOP= method-option` to specify a stopping criterion. See the section “[Criteria Used in Model Selection Methods](#)” on page 6598 for more information and [Table 78.10](#) for the formulas for evaluating these criteria.

Criteria Used in Model Selection Methods

PROC QUANTSELECT supports a variety of fit statistics that you can specify as criteria for the `CHOOSE=`, `SELECT=`, and `STOP= method-options` in the `MODEL` statement.

Single Quantile Effect Section

The following fit statistics are available for single quantile effect selection:

AIC	applies the Akaike's information criterion (Akaike 1981; Darlington 1968; Judge et al. 1985).
AICC	applies the corrected Akaike's information criterion (Hurvich and Tsai 1989).
SBC	applies the Schwarz Bayesian information criterion (Schwarz 1978; Judge et al. 1985).
SL<(LR1 LR2)>	specifies the significance level of a statistic used to assess an effect's contribution to the fit when it is added to or removed from a model. LR1 specifies likelihood ratio Type I, and LR2 specifies the likelihood ratio Type II. By default, the LR1 statistic is applied.
ADJR1	applies the adjusted quantile regression R statistic.
VALIDATE	applies the average check loss for the validation data.

Table 78.10 provides formulas and definitions for these fit statistics.

Table 78.10 Formulas and Definitions for Model Fit Summary Statistics for Single Quantile Effect Section

Statistic	Definition or Formula
n	Number of observations
p	Number of parameters including the intercept
$r_i(\tau)$	Residual for the i th observation; $r_i(\tau) = y_i - \mathbf{x}_i\boldsymbol{\beta}(\tau)$
$D(\tau)$	Total sum of check losses; $D(\tau) = \sum_{i=1}^n \rho_{\tau}(r_i)$
$D_0(\tau)$	Total sum of check losses for intercept-only model if intercept is a forced-in effect, otherwise for empty-model.
$ACL(\tau)$	Average check loss; $ACL(\tau) = \frac{D(\tau)}{n}$
$R1(\tau)$	Counterpart of linear regression R-square for quantile regression; $1 - \frac{D(\tau)}{D_0(\tau)}$
$ADJR1(\tau)$	Adjusted R1; $(\tau) = 1 - \frac{(n-1)D(\tau)}{(n-p)D_0(\tau)}$
$AIC(\tau)$	$2n \ln(ACL(\tau)) + 2p$
$AICC(\tau)$	$2n \ln(ACL(\tau)) + \frac{2pn}{n-p-1}$
$SBC(\tau)$	$2n \ln(ACL(\tau)) + p \ln(n)$

Quantile Process Effect Section

The following statistics are available for quantile process effect selection:

AIC	specifies Akaike's information criterion (Akaike 1981; Darlington 1968; Judge et al. 1985).
AICC	specifies the corrected Akaike's information criterion (Hurvich and Tsai 1989).
SBC	specifies Schwarz Bayesian information criterion (Schwarz 1978; Judge et al. 1985).
ADJR1	specifies the adjusted quantile regression R statistic.

VALIDATE specifies average check loss for the validation data.

Table 78.11 provides formulas and definitions for the fit statistics.

Table 78.11 Formulas and Definitions for Model Fit Summary Statistics for Quantile Process Effect Section

Statistic	Definition or Formula
D	Integral of total sum of check losses; $D = \int_0^1 D(\tau) d\tau$
D_0	Integral of total sum of check losses for intercept-only model or empty-model if the NOINT option is used; $D_0 = \int_0^1 D_0(\tau) d\tau$
ACL	Integral of average check loss; $ACL = \frac{D}{n}$
R1	$1 - \frac{D}{D_0}$
ADJR1	Adjusted R1; $1 - \frac{(n-1)D}{(n-p)D_0}$
AIC	$\int_0^1 AIC(\tau) d\tau$
AICC	$\int_0^1 AICC(\tau) d\tau$
SBC	$\int_0^1 SBC(\tau) d\tau$

Macro Variables That Contain Selected Models

PROC QUANTSELECT saves the list of selected effects in a macro variable so that you can use other SAS procedures to perform post-selection analyses. This list does not explicitly include the intercept so that you can use it in the **MODEL** statement of other SAS/STAT regression procedures.

Table 78.12 describes the macro variables that PROC QUANTSELECT creates. When multiple quantile levels or BY processing are used, one macro variable, indexed by the quantile level order and the BY group number, is created for each quantile level and BY group combination.

Table 78.12 Macro Variables Created for Subsequent Processing

Macro Variable	Description
Single Quantile Level and No BY processing	
_QRSIND	Selected model
Multiple Quantile Levels and No BY Processing	
_QRSNUMTAUS	Number of quantile levels
_QRSINDT1	Selected model for the first quantile level
_QRSINDT2	Selected model for the second quantile level
...	
Single Quantile Level and BY Processing	
_QRSNUMBYS	Number of BY groups
_QRSIND1	Selected model for BY group 1
_QRSIND2	Selected model for BY group 2
...	
Multiple Quantile Levels and BY Processing	
_QRSNUMTAUS	Number of quantile levels
_QRSNUMBYS	Number of BY groups
_QRSIND1T1	Selected model for the first quantile level and BY group 1
_QRSIND1T2	Selected model for the second quantile level and BY group 1
...	
_QRSIND2T1	Selected model for the first quantile level and BY group 2
_QRSIND2T2	Selected model for the second quantile level and BY group 2
...	

The macro variables _QRSIND, _QRSINDT1, _QRSIND1, and _QRSIND1T1 are all synonyms. If you do not specify multiple quantile levels or BY processing, the macro variables _QRSNUMTAUS and _QRSNUMBYS are both set to 1.

PROC QUANTSELECT creates two output data set variables, _BY_ and _QUANTILE_, to aid in associating macro variables with output data set observations when multiple quantile levels or BY processing are used. The values of these two variables are integers that match the i,j components of the macro variable names _QRSIND i T j .

Using Validation and Test Data

When you have sufficient data, you can subdivide your data into three parts: training, validation, and test data. During the selection process, models are fit on the training data, and the prediction error for the models so obtained is found by using the validation data. This prediction error on the validation data can be used to decide when to terminate the selection process or to decide which effects to include as the selection process proceeds. Finally, after a selected model has been obtained, the test set can be used to assess how the selected model generalizes on data that played no role in selecting the model.

In some cases you might want to use only training and test data. For example, you might decide to use an information criterion to decide which effects to include and when to terminate the selection process. In this case no validation data are required, but test data can still be useful in assessing the predictive performance of the selected model. In other cases you might decide to use validation data during the selection process but forgo assessing the selected model on test data. Hastie, Tibshirani, and Friedman (2001) note that it is difficult to give a general rule for how many observations you should assign to each role. They note that a typical split might be 50% for training and 25% each for validation and testing.

PROC QUANTSELECT provides several methods for partitioning data into training, validation, and test data. You can provide data for each role in separate data sets that you specify with the **DATA=**, **TESTDATA=**, and **VALDATA=** options in the PROC QUANTSELECT procedure. An alternative method is to use a **PARTITION** statement to logically subdivide the **DATA=** data set into separate roles. You can name the fractions of the data that you want to reserve as test data and validation data. The following statements randomly subdivide the **inData** data set to use 25% of the data for validation and 25% for testing, leaving 50% of the data for training:

```
proc quantselect data=inData;
  partition fraction(test=0.25 validate=0.25);
  ...
run;
```

If you need to exercise more control over the partitioning of the input data set, you can name a variable in the input data set and a formatted value of that variable to correspond to each role. The following statements assign roles to observations in the **inData** data set based on the value of the variable named **group** in that data set:

```
proc quantselect data=inData;
  partition roleVar=group(test='group 1' train='group 2');
  ...
run;
```

Observations whose value of the variable **group** is 'group 1' are assigned for testing, and those whose value is 'group 2' are assigned to training. All other observations are ignored.

You can also combine the use of the **PARTITION** statement with named data sets for specifying data roles. For example, the following statements reserve 40% of the **inData** data set for validation, leaving the remaining 60% for training:

```
proc quantselect data=inData testData=inTest;
  partition fraction(validate=0.4);
  ...
run;
```

Data for testing are supplied in the `inTest` data set. Because a `TESTDATA=` data set is specified, additional observations for testing cannot be reserved by specifying a `PARTITION` statement.

When you use a `PARTITION` statement, the output data set that is created by an `OUTPUT` statement contains a character variable `_ROLE_` whose values 'TRAIN', 'TEST', and 'VALIDATE' indicate the role of each observation. `_ROLE_` is blank for observations that were not assigned to any of these three roles. When the input data set specified in the `DATA=` option in the `PROC QUANTSELECT` statement contains an `_ROLE_` variable, no `PARTITION` statement is used, and the `TESTDATA=` and `VALDATA=` options are not specified, then the `_ROLE_` variable is used to define the roles of each observation. This is useful when you want to rerun `PROC QUANTSELECT` but use the same data partitioning as you used in a previous `PROC QUANTSELECT` step. For example, the following statements use the same data for testing and training in both `PROC QUANTSELECT` steps:

```
proc quantselect data=inData;
  partition fraction(test=0.5);
  model y=x1-x10 / selection=forward;
  output out=outDataForward;
run;

proc quantselect data=outDataForward;
  model y=x1-x10 / selection=backward;
run;
```

When you have reserved observations for training, validation, and testing, a model that is fit on the training data is scored on the validation and test data, and the average check loss, denoted by ACL, is computed separately for each of these subsets. The ACL for each data role is the sum of check losses for observations in that role divided by the number of observations in that role.

Using the Validation ACL as the STOP= Criterion

If you have provided observations for validation, then you can use the `STOP=VALIDATE` *method-option* to specify the validation ACL as the `STOP=` criterion in the `SELECTION=` option in the `MODEL` statement. At step k of the selection process, the best candidate effect to enter or leave the current model is determined. The “best candidate” means the effect that gives the best value of the `SELECT=` criterion that does not need to be based on the validation data. The validation ACL for the model with this candidate effect added is computed. If this validation ACL is greater than the validation ACL for the model at step k , then the selection process terminates at step k .

Using the Validation ACL as the CHOOSE= Criterion

When you specify the `CHOOSE=VALIDATE` *method-option* in the `SELECTION=` option in the `MODEL` statement, the validation ACL is computed for the models at each step of the selection process. The model that yields the smallest validation ACL and contains the fewest effects is selected.

Using the Validation ACL as the SELECT= Criterion

You request the validation ACL as the selection criterion by specifying the `SELECT=VALIDATE` *method-option* in the `SELECTION=` option in the `MODEL` statement. At step k of the selection process, the validation ACL is computed for each model where a candidate for entry is added or candidate for removal is dropped. The selected candidate for entry or removal is the one that yields a model with the minimal validation ACL.

Displayed Output

The following sections describe the output that is displayed by PROC QUANTSELECT. The output is organized into various tables, which are discussed in the order of appearance. The contents of a table might change depending on the options you specify.

Model Information

The “Model Information” table displays basic information about the data sets and the settings used to control effect selection. These settings include the following:

- the selection method
- the criteria used to select effects, stop the selection, and choose the selected model
- the effect hierarchy enforced

The ODS name of the “Model Information” table is ModelInfo.

Number of Observations

The “Number of Observations” table displays the number of observations read from the input data set and the number of observations used in the analysis. If you use a **PARTITION** statement, the table also displays the number of observations used for each data role. If you specify **TESTDATA=** or **VALDATA=** data sets in the PROC QUANTSELECT statement, then “Number of Observations” tables are also produced for these data sets. The ODS name of the “Number of Observations” table is NObs.

Class Level Information

The “Class Level Information” table lists the levels of every variable specified in the **CLASS** statement. The ODS name of the “Class Level Information” table is ClassLevelInfo.

Class Level Coding

The “Class Level Coding” table shows the coding used for every variable specified in the **CLASS** statement. The ODS name of the “Class Level Coding” table is ClassLevelCoding.

Candidates

The “Candidates” table displays the effect name and value of the criterion used to select entering or departing effects at each step of the selection process. The effects are displayed in sorted order from best to worst of the selection criterion. You request this table with the **DETAILS=** option in the **MODEL** statement. The ODS name of the “Candidates” table is either EntryCandidates for addition candidates or RemovalCandidates for removal candidates.

Selection Summary

The “Selection Summary” table displays details about the sequence of steps of the selection process. For each step, the effect that entered or dropped out is displayed along with the statistics used to select the effect, stop the selection, and choose the selected model. You can request that additional statistics be displayed with the **STATS=** option in the **MODEL** statement. For all criteria that you can use for effect selection, the steps at which the optimal values of these criteria occur are also indicated. The ODS name of the “Selection Summary” table is SelectionSummary.

Stop Reason

The “Stop Reason” table displays the reason why the selection stopped. [Table 78.13](#) shows the possible stop reasons.

Table 78.13 Reasons for Stopping

Stop Reason	Description
1	The selected model is a perfect fit.
2	The specified maximum number of steps has been reached.
3	The specified maximum number of effects are in the model.
4	The specified minimum number of effects are in the model.
5	The stopping criterion found a local optimum.
6	No suitable add or drop candidate is available.
7	All effects are in the model.
8	All effects have been dropped.
9	The sequence of effect additions and removals is cycling.
10	Adding or dropping any effect does not improve the SELECT= criterion.
11	No effect is significant at the specified significance level for entry or significance level for staying levels.
12	All remaining effects are required.

The ODS name of the “Stop Reason” table is StopReason.

Selection Reason

The “Selection Reason” table displays how the final selected model is determined. [Table 78.14](#) shows the possible selection reasons:

Table 78.14 Selection Reasons

Selection Reason	Description
1	The last valid model that occurs in the selection process is the final model.
2	The first model with the minimum CHOOSE= criterion value in the selection process is the final model.

The ODS name of the “Selection Reason” table is SelectionReason.

Selected Effects

The “Selected Effects” table displays a string that contains the list of effects in the selected model. The ODS name of the “Selected Effects” table is SelectedEffects.

Parameter Estimates

The “Parameter Estimates” table displays the parameters in the selected model and their estimates. The following information is displayed for each parameter in the selected model:

- the parameter label that includes the effect name and level information for effects that contain classification variables
- the degrees of freedom (DF) for the parameter. There is one degree of freedom unless the model is not full rank.
- the parameter estimate
- the standard parameter estimate, which is computed on a standardized design matrix. Let $\mathbf{X} = (\mathbf{X}_1, \mathbf{X}_2)$ denote the original design matrix, where \mathbf{X}_1 is the submatrix for all the forced-in effects, and \mathbf{X}_2 is the submatrix for the rest of the effects that are subject to selection. Let

$$\mathbf{X}_2^* = [\mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-1}\mathbf{X}_1']\mathbf{X}_2 \text{ and } \mathbf{X}_2^{**} = (s_Y \sqrt{n - p_1})^{-1} [\text{diag}(\mathbf{X}_2^{*'}\mathbf{X}_2^*)]^{-\frac{1}{2}} \mathbf{X}_2^*$$

where p_1 is the rank of \mathbf{X}_1 and $s_Y = \sqrt{\frac{\mathbf{Y}^{*'}\mathbf{Y}^*}{n - p_1}}$ with $\mathbf{Y}^* = [\mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-1}\mathbf{X}_1']\mathbf{Y}$.

Then standard parameter estimates are defined as $(\mathbf{0}, \boldsymbol{\beta}_2^{**})$, where $(\boldsymbol{\beta}_1, \boldsymbol{\beta}_2^{**})$ are the parameter estimates computed on the standardized design matrix $(\mathbf{X}_1, \mathbf{X}_2^{**})$.

You can also use the DETAILS= option in the MODEL statement to request “Parameter Estimates” tables for the models at each step of the selection process. The ODS name of the “Parameter Estimates” table is “ParameterEstimates.”

ODS Table Names

PROC QUANTSELECT assigns a name to each table it creates. You can use these names to refer to the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 78.15.

For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 78.15 ODS Tables Produced by PROC QUANTSELECT

ODS Table Name	Description	Statement	Option
BSplineDetails	B-spline basis details	EFFECT	DETAILS
EntryCandidates	Entry effect ranking	MODEL	DETAILS=
RemovalCandidates	Removal effect ranking	MODEL	DETAILS=

Table 78.15 *continued*

ODS Table Name	Description	Statement	Option
ClassLevelCoding	Classification variable coding	CLASS	SHOWCODING
ClassLevelInfo	Classification variable levels	CLASS	Default
CollectionLevelInfo	Levels of collection effects	EFFECT	DETAILS
MMLevelInfo	Levels of multimember effects	EFFECT	DETAILS
ModelInfo	Model information	MODEL	Default
NObs	Number of observations	MODEL	Default
ParameterNames	Labels for column names in the design matrix	PROC	OUTDESIGN(names)
ParameterEstimates	Selected model parameter estimates	MODEL	Default
PolynomialDetails	Polynomial details	EFFECT	DETAILS
PolynomialScaling	Polynomial scaling	EFFECT	DETAILS
SelectedEffects	List of selected effects	MODEL	Default
SelectionSummary	Selection summary	MODEL	Default
StopDetails	Stopping criterion details	MODEL	Default
StopReason	Reason why selection stopped	MODEL	Default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

PROC QUANTSELECT assigns a name to each graph it creates using ODS. You can use these names to refer to the graphs when using ODS. The names are listed in [Table 78.16](#).

Table 78.16 ODS Graphics Produced by PROC QUANTSELECT

ODS Graph Name	Plot Description	PLOTS Option
ACLPlot	Average check loss by step	ACL
AICCPLOT	Corrected Akaike’s information criterion by step	CRITERIA(UNPACK)
AICPlot	Akaike’s information criterion by step	CRITERIA(UNPACK)
AdjR1Plot	Adjusted quantile regression R by step	CRITERIA(UNPACK)

Example: QUANTSELECT Procedure

Example 78.1: Simulated Data Example

This simulation study exemplifies the unity of motive and effect for the PROC QUANTSELECT procedure. The following statements generate a data set that is based on a naive instrumental model (Chernozhukov and Hansen 2008):

```
%let seed=321;
%let p=20;
%let n=3000;

data analysisData;
  array x{&p} x1-x&p;
  do i=1 to &n;
    U = ranuni(&seed);
    x1 = ranuni(&seed);
    x2 = ranexp(&seed);
    x3 = abs(rannor(&seed));
    y = x1*(U-0.1) + x2*(U*U-0.25) + x3*(exp(U)-exp(0.9));
    do j=4 to &p;
      x{j} = ranuni(&seed);
    end;
    output;
  end;
run;
```

Variable U of the data set indicates the true quantile level of the response y conditional on $\mathbf{x} = (x_1, \dots, x_p)$.

Let $Q_y(\tau|\mathbf{x}) = \mathbf{x}\boldsymbol{\beta}(\tau)$ denote the underlying quantile regression model, where $\boldsymbol{\beta}(\tau) = (\beta_1(\tau), \dots, \beta_p(\tau))'$. Then, the true parameter functions are

$$\begin{aligned}
 \beta_1(\tau) &= \tau - 0.1 \\
 \beta_2(\tau) &= \tau^2 - 0.25 \\
 \beta_3(\tau) &= \exp(\tau) - \exp(0.9) \\
 \beta_4(\tau) &= \dots = \beta_p(\tau) = 0
 \end{aligned}$$

It is easy to see that, at $\tau = 0.1$, only $\beta_2(0.1) = -0.24$ and $\beta_3(0.1) = \exp(0.1) - \exp(0.9) \approx -1.354432$ are nonzero parameters. Therefore, an effective effect selection method should select x_2 and x_3 and drop all the other effects in this data set at $\tau = 0.1$. By the same rationale, x_1 and x_3 should be selected at $\tau = 0.5$ with $\beta_1(0.5) = 0.4$ and $\beta_3(0.5) \approx -0.810882$, and x_1 and x_2 should be selected at $\tau = 0.9$ with $\beta_1(0.9) = 0.8$ and $\beta_2(0.9) = 0.56$.

The following statements use PROC QUANTSELECT with the adaptive LASSO method:

```
proc quantselect data=analysisData;
  model y= x1-x&p / quantile=0.1 0.5 0.9
    selection=lasso(adaptive);
run;
```

The selected effects and the relevant estimates are shown in [Output 78.1.1](#) for $\tau = 0.1$, [Output 78.1.2](#) for $\tau = 0.5$, and [Output 78.1.3](#) for $\tau = 0.9$. You can see that the adaptive LASSO method correctly selects active effects for all three quantile levels.

Output 78.1.1 Parameter Estimates at $\tau = 0.1$

The QUANTSELECT Procedure			
Quantile = 0.1			
Selected Effects: Intercept x2 x3			
Parameter Estimates			
Parameter	DF	Estimate	Standardized Estimate
Intercept	1	0.011793	0
x2	1	-0.228709	-0.218287
x3	1	-1.379907	-0.784520

Output 78.1.2 Parameter Estimates at $\tau = 0.5$

The QUANTSELECT Procedure			
Quantile = 0.5			
Selected Effects: Intercept x1 x3			
Parameter Estimates			
Parameter	DF	Estimate	Standardized Estimate
Intercept	1	0.011778	0
x1	1	0.425843	0.118792
x3	1	-0.863316	-0.490822

Output 78.1.3 Parameter Estimates at $\tau = 0.9$

The QUANTSELECT Procedure			
Quantile = 0.9			
Selected Effects: Intercept x1 x2			
Parameter Estimates			
Parameter	DF	Estimate	Standardized Estimate
Intercept	1	-0.007738	0
x1	1	0.782942	0.218407
x2	1	0.576445	0.550177

The QUANTSELECT procedure can perform effect selection not only at a single quantile level but also for the entire quantile process. You can specify the QUANTILE=PROCESS option to do effect selection for the entire quantile process. With the QUANTILE=PROCESS option specified, the ParameterEstimates table produced by the QUANTSELECT procedure actually shows the mean prediction model of y conditional on x . In this simulation study, the true mean model is

$$E(y|x) = x\beta$$

where

$$\begin{aligned}\beta_1 &= E(U) - 0.1 = 0.4 \\ \beta_2 &= E(U^2) - 0.25 \approx 0.083333 \\ \beta_3 &= E(\exp(U)) - \exp(0.9) \approx -0.741321 \\ \beta_4 &= \dots = \beta_p = 0\end{aligned}$$

The following statements perform effect selection for the quantile process with the forward selection method.

```
proc quantselect data=analysisData;
  model y= x1-x&p / quantile=process(ntau=all)
    selection=forward;
run;
```

Output 78.1.4 shows that, by default, the SELECT= and STOP= options are both set to SBC. The selected effects and the relevant estimates for the conditional mean model are shown in Output 78.1.5.

Output 78.1.4 Model Information

The QUANTSELECT Procedure	
Model Information	
Data Set	WORK.ANALYSISDATA
Dependent Variable	y
Selection Method	Forward
Quantile Type	Process
Select Criterion	SBC
Stop Criterion	SBC
Choose Criterion	SBC

Output 78.1.5 Parameter Estimates

Parameter Estimates			
Parameter	DF	Estimate	Standardized Estimate
Intercept	1	0.007833	0
x1	1	0.418825	0.116834
x2	1	0.094791	0.090472
x3	1	-0.785686	-0.446687

Linear regression is the most popular method for estimating conditional means. The following statements show how to select effects with the GLMSELECT procedure, and [Output 78.1.6](#) shows the resulting selected effects and their estimates. You can see that the mean estimates from the QUANTSELECT procedure are similar to those from the GLMSELECT procedure. However, quantile regression can provide detailed distribution information, which is not available from linear regression.

```
proc glmselect data=analysisData;
  model y= x1-x3 / selection=forward(select=sbc stop=sbc choose=sbc);
run;
```

Output 78.1.6 Parameter Estimates

The GLMSELECT Procedure				
Selected Model				
Parameter Estimates				
Parameter	DF	Estimate	Standard Error	t Value
Intercept	1	-0.010143	0.043129	-0.24
x1	1	0.434553	0.057385	7.57
x2	1	0.114183	0.016771	6.81
x3	1	-0.797194	0.028156	-28.31

Overview: REG Procedure

The REG procedure is one of many regression procedures in the SAS System. It is a general-purpose procedure for regression, while other SAS regression procedures provide more specialized applications.

Other SAS/STAT procedures that perform at least one type of regression analysis are the CATMOD, GENMOD, GLM, LOGISTIC, MIXED, NLIN, ORTHOREG, PROBIT, RSREG, and TRANSREG procedures. SAS/ETS procedures are specialized for applications in time series or simultaneous systems. These other SAS/STAT regression procedures are summarized in Chapter 4, “[Introduction to Regression Procedures](#),” which also contains an overview of regression techniques and defines many of the statistics computed by PROC REG and other regression procedures.

PROC REG provides the following capabilities:

- multiple **MODEL** statements

- nine model-selection methods
- interactive changes both in the model and the data used to fit the model
- linear equality restrictions on parameters
- tests of linear hypotheses and multivariate hypotheses
- collinearity diagnostics
- predicted values, residuals, studentized residuals, confidence limits, and influence statistics
- correlation or crossproduct input
- requested statistics available for output through output data sets
- ODS Graphics. For more information, see the section “[ODS Graphics](#)” on page 6745.

Nine model-selection methods are available in PROC REG. In the simplest method, PROC REG fits the complete model that you specify. The other eight methods involve various ways of including or excluding variables from the model. You specify these methods with the [SELECTION=](#) option in the [MODEL](#) statement.

The methods are identified in the following list and are explained in detail in the section “[Model-Selection Methods](#)” on page 6701.

NONE	no model selection. This is the default. The complete model specified in the MODEL statement is fit to the data.
FORWARD	forward selection. This method starts with no variables in the model and adds variables.
BACKWARD	backward elimination. This method starts with all variables in the model and deletes variables.
STEPWISE	stepwise regression. This is similar to the FORWARD method except that variables already in the model do not necessarily stay there.
MAXR	forward selection to fit the best one-variable model, the best two-variable model, and so on. Variables are switched so that R square is maximized.
MINR	similar to the MAXR method, except that variables are switched so that the increase in R square from adding a variable to the model is minimized.
RSQUARE	finds a specified number of models with the highest R square in a range of model sizes.
ADJRSQ	finds a specified number of models with the highest adjusted R square in a range of model sizes.
CP	finds a specified number of models with the lowest C_p in a range of model sizes.

Getting Started: REG Procedure

Simple Linear Regression

Suppose that a response variable Y can be predicted by a linear function of a regressor variable X . You can estimate β_0 , the intercept, and β_1 , the slope, in

$$Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$$

for the observations $i = 1, 2, \dots, n$. Fitting this model with the REG procedure requires only the following MODEL statement, where y is the outcome variable and x is the regressor variable.

```
proc reg;
    model y=x;
run;
```

For example, you might use regression analysis to find out how well you can predict a child's weight if you know that child's height. The `Class` data set used in this example is available in the `Sashelp` library.

The equation of interest is

$$\text{Weight} = \beta_0 + \beta_1 \text{Height} + \epsilon$$

The variable `Weight` is the response or dependent variable in this equation, and β_0 and β_1 are the unknown parameters to be estimated. The variable `Height` is the regressor or independent variable, and ϵ is the unknown error. The following commands invoke the REG procedure and fit this model to the data.

```
ods graphics on;

proc reg data=sashelp.class;
    model Weight = Height;
run;

ods graphics off;
```

Figure 79.1 includes some information concerning model fit.

The F statistic for the overall model is highly significant ($F = 57.076$, $p < 0.0001$), indicating that the model explains a significant portion of the variation in the data.

The degrees of freedom can be used in checking accuracy of the data and model. The model degrees of freedom are one less than the number of parameters to be estimated. This model estimates two parameters, β_0 and β_1 ; thus, the degrees of freedom should be $2 - 1 = 1$. The corrected total degrees of freedom are always one less than the total number of observations in the data set, in this case $19 - 1 = 18$.

Several simple statistics follow the ANOVA table. The Root MSE is an estimate of the standard deviation of the error term. The coefficient of variation, or Coeff Var, is a unitless expression of the variation in the data. The R-square and Adj R-square are two statistics used in assessing the fit of the model; values close to 1 indicate a better fit. The R-square of 0.77 indicates that Height accounts for 77% of the variation in Weight.

Figure 79.1 ANOVA Table

The REG Procedure					
Model: MODEL1					
Dependent Variable: Weight					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	7193.24912	7193.24912	57.08	<.0001
Error	17	2142.48772	126.02869		
Corrected Total	18	9335.73684			
Root MSE		11.22625	R-Square	0.7705	
Dependent Mean		100.02632	Adj R-Sq	0.7570	
Coeff Var		11.22330			

The “Parameter Estimates” table in [Figure 79.2](#) contains the estimates of β_0 and β_1 . The table also contains the t statistics and the corresponding p -values for testing whether each parameter is significantly different from zero. The p -values ($t = -4.43$, $p = 0.0004$ and $t = 7.55$, $p < 0.0001$) indicate that the intercept and Height parameter estimates, respectively, are highly significant.

From the parameter estimates, the fitted model is

$$\text{Weight} = -143.0 + 3.9 \times \text{Height}$$

Figure 79.2 Parameter Estimates

Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	-143.02692	32.27459	-4.43	0.0004
Height	1	3.89903	0.51609	7.55	<.0001

If ODS Graphics is enabled, then PROC REG produces a variety of plots. [Figure 79.3](#) shows a plot of the residuals versus the regressor and [Figure 79.4](#) shows a panel of diagnostic plots.

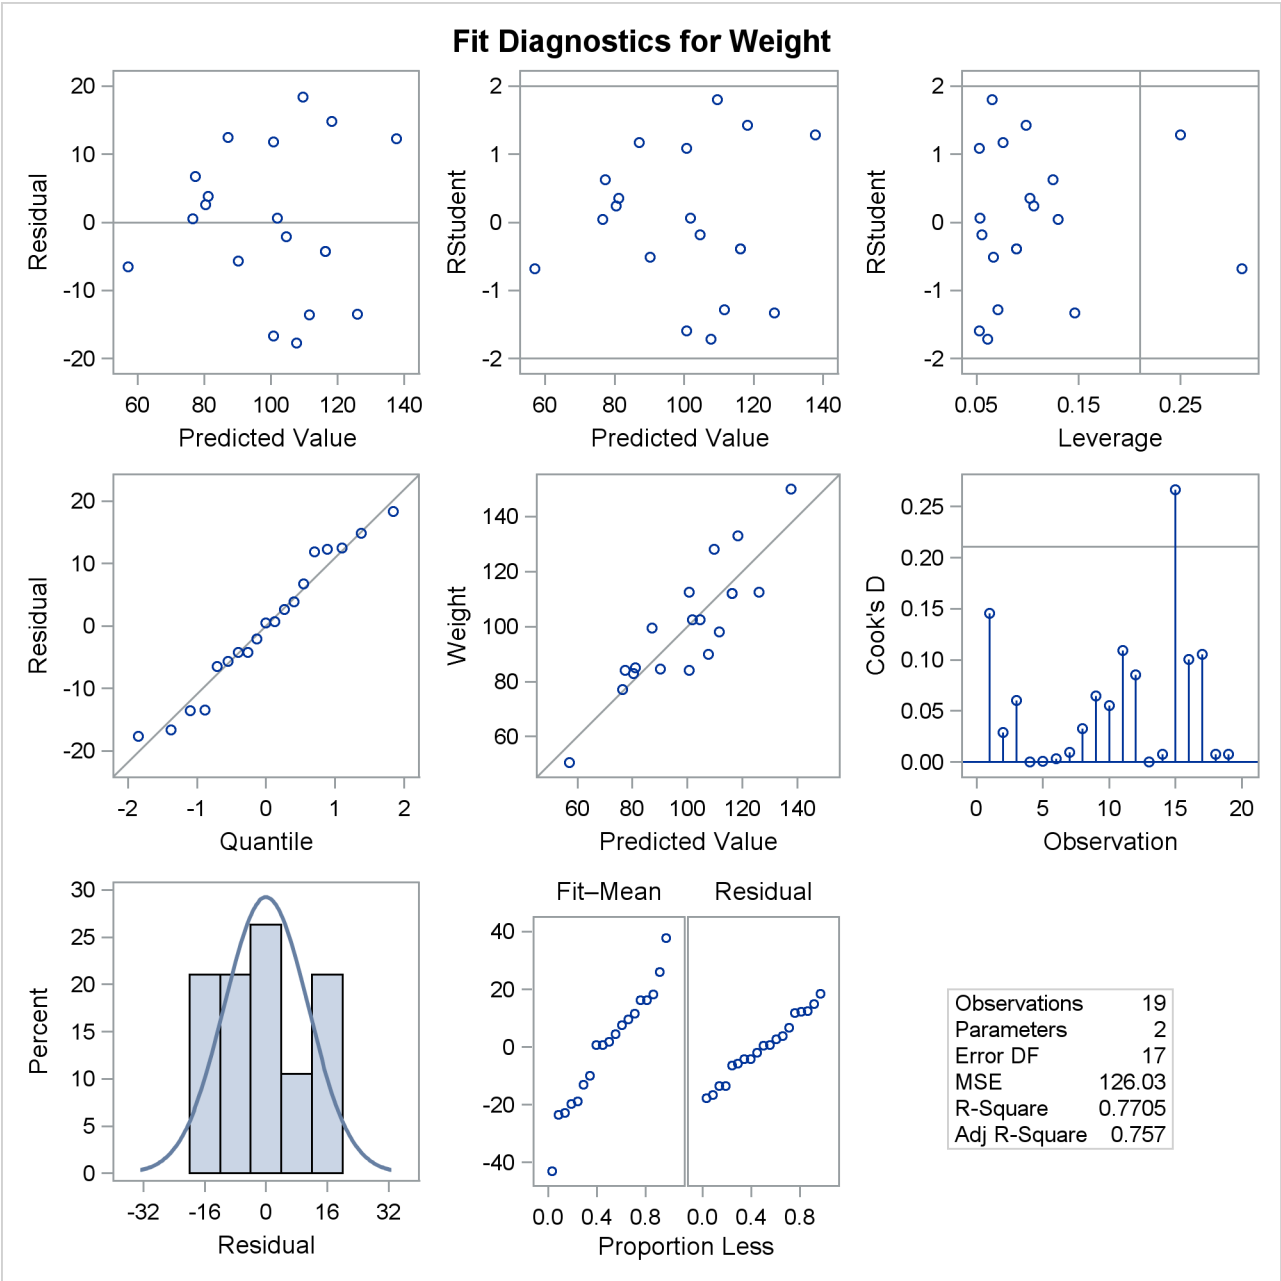

Figure 79.3 Residuals vs. Regressor

Figure 79.4 Fit Diagnostics

A trend in the residuals would indicate nonconstant variance in the data. The plot of residuals by predicted values in the upper-left corner of the diagnostics panel in Figure 79.4 might indicate a slight trend in the residuals; they appear to increase slightly as the predicted values increase. A fan-shaped trend might indicate the need for a variance-stabilizing transformation. A curved trend (such as a semicircle) might indicate the need for a quadratic term in the model. Since these residuals have no apparent trend, the analysis is considered to be acceptable.

Polynomial Regression

Consider a response variable Y that can be predicted by a polynomial function of a regressor variable X . You can estimate β_0 , the intercept; β_1 , the slope due to X ; and β_2 , the slope due to X^2 , in

$$Y_i = \beta_0 + \beta_1 X_i + \beta_2 X_i^2 + \epsilon_i$$

for the observations $i = 1, 2, \dots, n$.

Consider the following example on population growth trends. The population of the United States from 1790 to 2000 is fit to linear and quadratic functions of time. Note that the quadratic term, `YearSq`, is created in the `DATA` step; this is done since polynomial effects such as `Year*Year` cannot be specified in the `MODEL` statement in `PROC REG`. The data are as follows:

```
data USPopulation;
  input Population @@;
  retain Year 1780;
  Year      = Year+10;
  YearSq    = Year*Year;
  Population = Population/1000;
  datalines;
3929 5308 7239 9638 12866 17069 23191 31443 39818 50155
62947 75994 91972 105710 122775 131669 151325 179323 203211
226542 248710 281422
;

ods graphics on;

proc reg data=USPopulation plots=ResidualByPredicted;
  var YearSq;
  model Population=Year / r clm cli;
run;
```

The `DATA` option ensures that the procedure uses the intended data set. Any variable that you might add to the model but that is not included in the first `MODEL` statement must appear in the `VAR` statement.

The “Analysis of Variance” and “Parameter Estimates” tables are displayed in [Figure 79.5](#).

Figure 79.5 ANOVA Table and Parameter Estimates

The REG Procedure					
Model: MODEL1					
Dependent Variable: Population					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	146869	146869	228.92	<.0001
Error	20	12832	641.58160		
Corrected Total	21	159700			
	Root MSE	25.32946	R-Square	0.9197	
	Dependent Mean	94.64800	Adj R-Sq	0.9156	
	Coeff Var	26.76175			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	-2345.85498	161.39279	-14.54	<.0001
Year	1	1.28786	0.08512	15.13	<.0001

The Model F statistic is significant ($F = 228.92$, $p < 0.0001$), indicating that the model accounts for a significant portion of variation in the data. The R-square indicates that the model accounts for 92% of the variation in population growth. The fitted equation for this model is

$$\text{Population} = -2345.85 + 1.29 \times \text{Year}$$

In the MODEL statement, three options are specified: R requests a residual analysis to be performed, CLI requests 95% confidence limits for an individual value, and CLM requests these limits for the expected value of the dependent variable. You can request specific $100(1 - \alpha)\%$ limits with the ALPHA= option in the PROC REG or MODEL statement.

Figure 79.6 shows the “Output Statistics” table. The residual, its standard error, and the studentized residuals are displayed for each observation. The studentized residual is the residual divided by its standard error. The magnitude of each studentized residual is shown in a print plot. Studentized residuals follow a t distribution and can be used to identify outlying or extreme observations. Asterisks (*) extending beyond the dashed lines indicate that the residual is more than three standard errors from zero. Many observations having absolute studentized residuals greater than two might indicate an inadequate model. Cook’s D is a measure of the change in the predicted values upon deletion of that observation from the data set; hence, it measures the influence of the observation on the estimated regression coefficients.

Figure 79.6 Output Statistics

Figure 79.7 shows the residual statistics table. A fairly close agreement between the PRESS statistic (see Table 79.9) and the Sum of Squared Residuals indicates that the MSE is a reasonable measure of the predictive accuracy of the fitted model (Neter, Wasserman, and Kutner 1990).

Figure 79.7 Residual Statistics

Sum of Residuals	0
Sum of Squared Residuals	12832
Predicted Residual SS (PRESS)	16662

Graphical representations are very helpful in interpreting the information in the “Output Statistics” table. When ODS Graphics is enabled, the REG procedure produces a default set of diagnostic plots that are appropriate for the requested analysis.

Figure 79.8 displays a panel of diagnostics plots. These diagnostics indicate an inadequate model:

- The plots of residual and studentized residual versus predicted value show a clear quadratic pattern.
- The plot of studentized residual versus leverage seems to indicate that there are two outlying data points. However, the plot of Cook’s D distance versus observation number reveals that these two points are just the data points for the endpoint years 1790 and 2000. These points show up as apparent outliers because the departure of the linear model from the underlying quadratic behavior in the data shows up most strongly at these endpoints.
- The normal quantile plot of the residuals and the residual histogram are not consistent with the assumption of Gaussian errors. This occurs as the residuals themselves still contain the quadratic behavior that is not captured by the linear model.
- The plot of the dependent variable versus the predicted value exhibits a quadratic form around the 45-degree line that represents a perfect fit.
- The “Residual-Fit” (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals shows that the spread in the residuals is no greater than the spread in the centered fit. For inappropriate models, the spread of the residuals in such a plot is often greater than the spread of the centered fit. In this case, the RF plot shows that the linear model does indeed capture the increasing trend in the data, and hence accounts for much of the variation in the response.

Figure 79.8 Diagnostics Panel

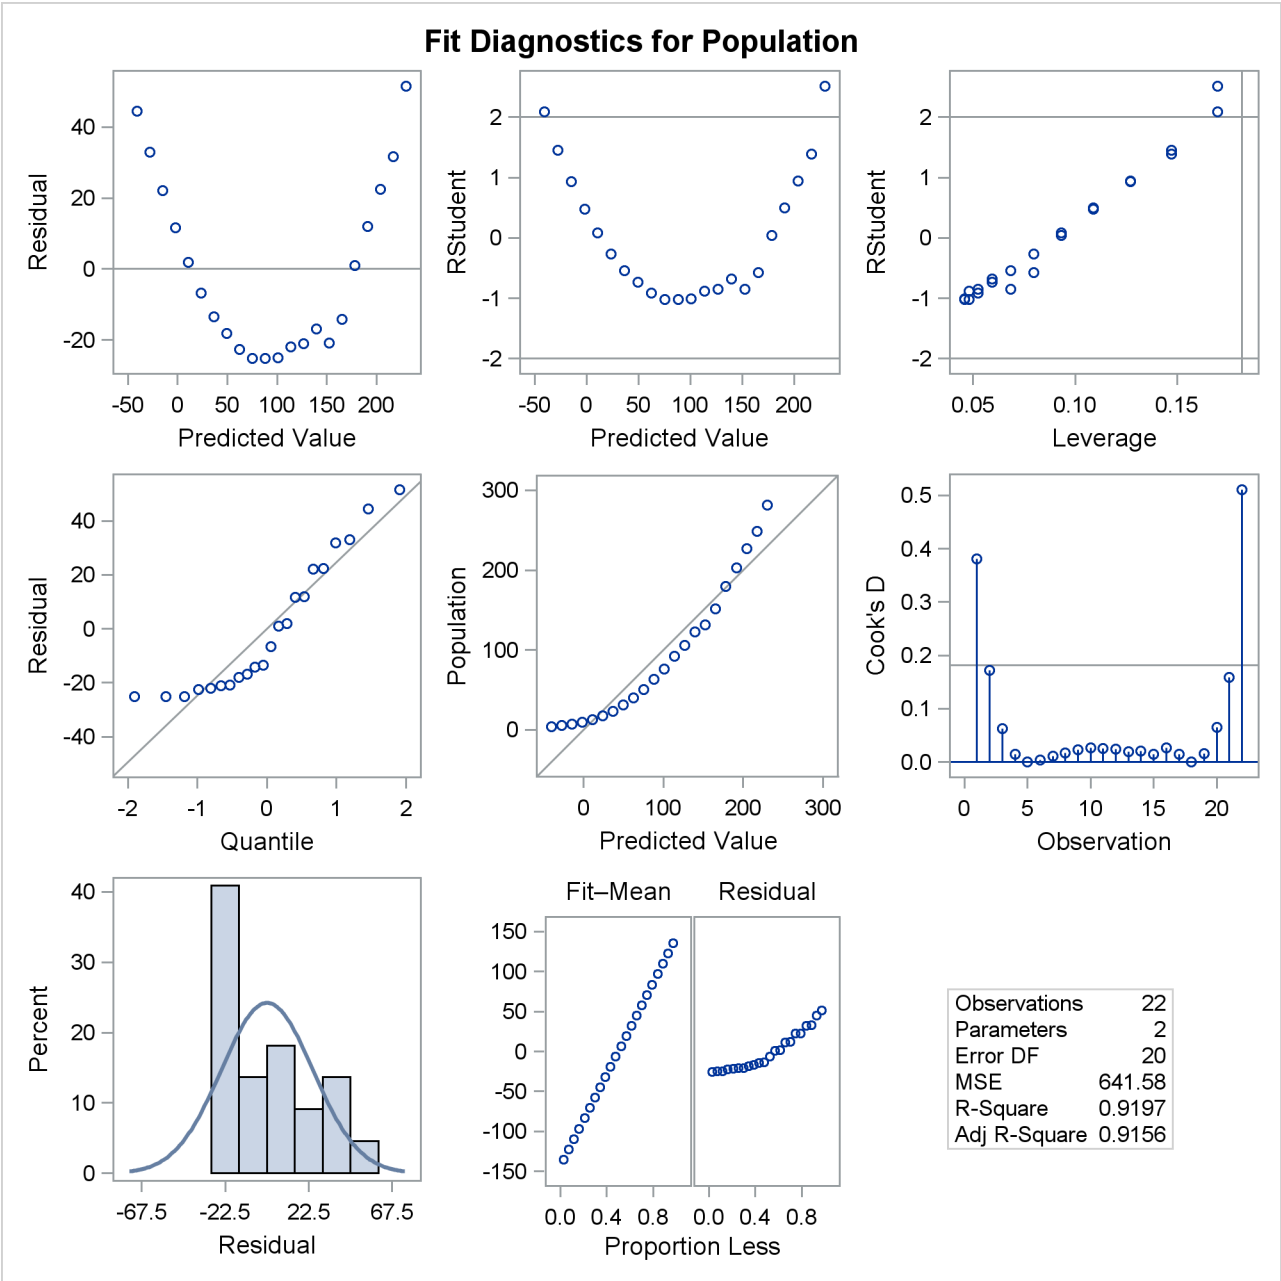

Figure 79.9 shows a plot of residuals versus Year. Again you can see the quadratic pattern that strongly indicates that a quadratic term should be added to the model.

Figure 79.9 Residual Plot

Figure 79.10 shows the “FitPlot” consisting of a scatter plot of the data overlaid with the regression line, and 95% confidence and prediction limits. Note that this plot also indicates that the model fails to capture the quadratic nature of the data. This plot is produced for models containing a single regressor. You can use the ALPHA= option in the model statement to change the significance level of the confidence band and prediction limits.

Figure 79.10 Fit Plot

These default plots provide strong evidence that the `Yearsq` needs to be added to the model. You can use the interactive feature of PROC REG to do this by specifying the following statements:

```
add YearSq;
print;
run;
```

The ADD statement requests that `YearSq` be added to the model, and the PRINT command causes the model to be refit and displays the ANOVA and parameter estimates for the new model. The print statement also produces updated ODS graphical displays.

Figure 79.11 displays the ANOVA table and parameter estimates for the new model.

Figure 79.11 ANOVA Table and Parameter Estimates

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	159529	79765	8864.19	<.0001
Error	19	170.97193	8.99852		
Corrected Total	21	159700			
	Root MSE	2.99975	R-Square	0.9989	
	Dependent Mean	94.64800	Adj R-Sq	0.9988	
	Coeff Var	3.16938			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	21631	639.50181	33.82	<.0001
Year	1	-24.04581	0.67547	-35.60	<.0001
YearSq	1	0.00668	0.00017820	37.51	<.0001

The overall F statistic is still significant ($F = 8864.19$, $p < 0.0001$). The R-square has increased from 0.9197 to 0.9989, indicating that the model now accounts for 99.9% of the variation in Population. All effects are significant with $p < 0.0001$ for each effect in the model.

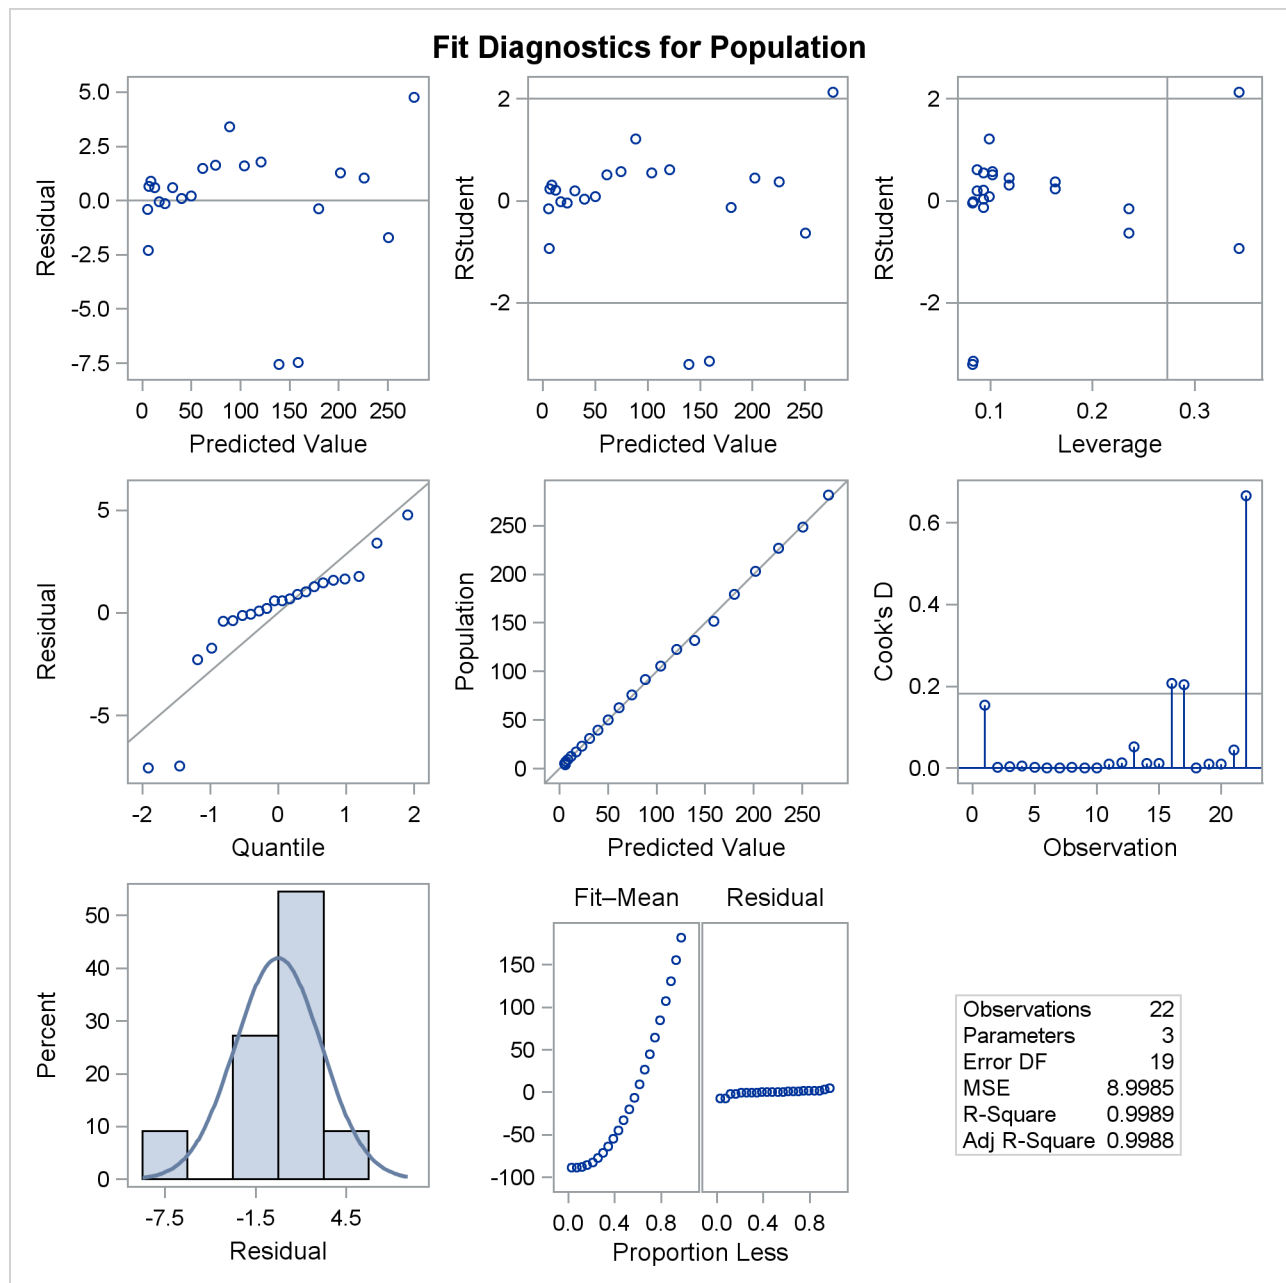

The fitted equation is now

$$\text{Population} = 21631 - 24.046 \times \text{Year} + 0.0067 \times \text{Yearsq}$$

Figure 79.12 show the panel of diagnostics for this quadratic polynomial model. These diagnostics indicate that this model is considerably more successful than the corresponding linear model:

- The plots of residuals and studentized residuals versus predicted values exhibit no obvious patterns.
- The points on the plot of the dependent variable versus the predicted values lie along a 45-degree line, indicating that the model successfully predicts the behavior of the dependent variable.
- The plot of studentized residual versus leverage shows that the years 1790 and 2000 are leverage points with 2000 showing up as an outlier. This is confirmed by the plot of Cook's D distance versus observation number. This suggests that while the quadratic model fits the current data well, the model might not be quite so successful over a wider range of data. You might want to investigate whether the population trend over the last couple of decades is growing slightly faster than quadratically.

Figure 79.12 Diagnostics Panel

When a model contains more than one regressor, PROC REG does not produce a fit plot. However, when all the regressors in the model are functions of a single variable, it is appropriate to plot predictions and residuals as a function of that variable. You request such plots by using the PLOTS=PREDICTIONS option in the PROC REG statement, as the following code illustrates:

```
proc reg data=USPopulation plots=predictions(X=Year);
  model Population=Year Yearsq;
quit;

ods graphics off;
```

Figure 79.13 shows the data, predictions, and residuals by Year. These plots confirm that the quadratic polynomial model successfully model the growth in U.S. population between the years 1780 and 2000.

Figure 79.13 Predictions and Residuals by Year

To complete an analysis of these data, you might want to examine influence statistics and, since the data are essentially time series data, examine the Durbin-Watson statistic.

Using PROC REG Interactively

The REG procedure can be used interactively. After you specify a model with a MODEL statement and run PROC REG with a RUN statement, a variety of statements can be executed without reinvoking PROC REG.

The section “[Interactive Analysis](#)” on page 6697 describes which statements can be used interactively. These interactive statements can be executed singly or in groups by following the single statement or group of statements with a RUN statement. Note that the MODEL statement can be repeated. This is an important difference from the GLM procedure, which supports only one MODEL statement.

If you use PROC REG interactively, you can end the REG procedure with a DATA step, another PROC step, an ENDSAS statement, or a QUIT statement. The syntax of the QUIT statement is

```
quit;
```

When you are using PROC REG interactively, additional RUN statements do not end PROC REG but tell the procedure to execute additional statements.

When a BY statement is used with PROC REG, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure.

When you use PROC REG interactively, you can fit a model, perform diagnostics, and then refit the model and perform diagnostics on the refitted model. Most of the interactive statements implicitly refit the model; for example, if you use the ADD statement to add a variable to the model, the regression equation is automatically recomputed. The two exceptions to this automatic recomputing are the PAINT and REWEIGHT statements. These two statements do not cause the model to be refitted. To refit the model, you can follow these statements either with a REFIT statement, which causes the model to be explicitly recomputed, or with another interactive statement that causes the model to be implicitly recomputed.

Syntax: REG Procedure

The following statements are available in the REG procedure:

```

PROC REG < options > ;
    < label: > MODEL dependents = < regressors > < / options > ;
    BY variables ;
    FREQ variable ;
    ID variables ;
    VAR variables ;
    WEIGHT variable ;
    ADD variables ;
    CODE < options > ;
    DELETE variables ;
    < label: > MTEST < equation, ..., equation > < / options > ;
    OUTPUT < OUT=SAS-data-set > < keyword=names > < ... keyword=names > ;
    PAINT < condition | ALLOBS > < / options > | < STATUS | UNDO > ;
    PLOT < yvariable* xvariable > < =symbol > < ... yvariable* xvariable > < =symbol > < / options > ;
    PRINT < options > < ANOVA > < MODELDATA > ;
    REFIT ;
    RESTRICT equation, ..., equation ;
    REWEIGHT < condition | ALLOBS > < / options > | < STATUS | UNDO > ;
    STORE < options > ;
    < label: > TEST equation, < , ..., equation > < / option > ;

```

Although there are numerous statements and options available in PROC REG, many analyses use only a few of them. Often you can find the features you need by looking at an example or by scanning this section.

In the preceding list, brackets denote optional specifications, and vertical bars denote a choice of one of the specifications separated by the vertical bars. In all cases, *label* is optional.

The **PROC REG** statement is required. To fit a model to the data, you must specify the **MODEL** statement. If you want to use only the options available in the **PROC REG** statement, you do not need a **MODEL** statement, but you must use a **VAR** statement. (See the example in the section “OUTSSCP= Data Sets” on page 6696.) Several **MODEL** statements can be used. In addition, several **MTEST**, **OUTPUT**, **PAINT**, **PLOT**, **PRINT**, **RESTRICT**, and **TEST** statements can follow each **MODEL** statement.

The **ADD**, **DELETE**, and **REWEIGHT** statements are used interactively to change the regression model and the data used in fitting the model. The **ADD**, **DELETE**, **MTEST**, **OUTPUT**, **PLOT**, **PRINT**, **RESTRICT**, and **TEST** statements implicitly refit the model; changes made to the model are reflected in the results from these statements. The **REFIT** statement is used to refit the model explicitly and is most helpful when it follows **PAINT** and **REWEIGHT** statements, which do not refit the model.

The **BY**, **FREQ**, **ID**, **VAR**, and **WEIGHT** statements are optionally specified once for the entire PROC step, and they must appear before the first RUN statement.

When a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as an input data set to **PROC REG**, statements and options that require the original data are not available. Specifically, the **OUTPUT**, **PAINT**, **PLOT**, and **REWEIGHT** statements and the **MODEL** and **PRINT** statement options P, R, CLM, CLI, DW, DWPROB, INFLUENCE, PARTIAL, and PARTIALDATA are disabled.

You can specify the following statements with the REG procedure in addition to the **PROC REG** statement:

ADD	adds independent variables to the regression model.
BY	specifies variables to define subgroups for the analysis.
CODE	requests that the procedure write SAS DATA step code to a file or catalog entry for computing predicted values according to the fitted model.
DELETE	deletes independent variables from the regression model.
FREQ	specifies a frequency variable.
ID	names a variable to identify observations in the tables.
MODEL	specifies the dependent and independent variables in the regression model, requests a model selection method, displays predicted values, and provides details on the estimates (according to which options are selected).
MTEST	performs multivariate tests across multiple dependent variables.
OUTPUT	creates an output data set and names the variables to contain predicted values, residuals, and other diagnostic statistics.
PAINT	paints points in scatter plots.
PLOT	generates scatter plots.
PRINT	displays information about the model and can reset options.
REFIT	refits the model.
RESTRICT	places linear equality restrictions on the parameter estimates.
REWEIGHT	excludes specific observations from analysis or changes the weights of observations used.
STORE	requests that the procedure save the estimated parameters of the fitted model.
TEST	performs an F test on linear functions of the parameters.
VAR	lists variables for which crossproducts are to be computed, variables that can be interactively added to the model, or variables to be used in scatter plots.
WEIGHT	declares a variable to weight observations.

The **CODE** and **STORE** statements are also used by many other procedures. A summary description of functionality and syntax for these statements is also shown after the **PROC REG** statement in alphabetical order, but you can find full documentation about them in the section “**STORE Statement**” on page 501 of Chapter 19, “**Shared Concepts and Topics**.”

PROC REG Statement

PROC REG <options> ;

The PROC REG statement invokes the REG procedure. The PROC REG statement is required. If you want to fit a model to the data, you must also use a **MODEL** statement. If you want to use only the PROC REG options, you do not need a **MODEL** statement, but you must use a **VAR** statement. If you do not use a **MODEL** statement, then the COVOUT and OUTEST= options are not available.

Table 79.1 summarizes the options available in the PROC REG statement. Note that any option specified in the PROC REG statement applies to all **MODEL** statements.

Table 79.1 PROC REG Statement Options

Option	Description
Data Set Options	
DATA=	Names a data set to use for the regression
OUTEST=	Outputs a data set that contains parameter estimates and other model fit summary statistics
OUTSSCP=	Outputs a data set that contains sums of squares and crossproducts
COVOUT	Outputs the covariance matrix for parameter estimates to the OUTEST= data set
EDF	Outputs the number of regressors, the error degrees of freedom, and the model R square to the OUTEST= data set
OUTSEB	Outputs standard errors of the parameter estimates to the OUTEST= data set
OUTSTB	Outputs standardized parameter estimates to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
OUTVIF	Outputs the variance inflation factors to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
PCOMIT=	Performs incomplete principal component analysis and outputs estimates to the OUTEST= data set
PRESS	Outputs the PRESS statistic to the OUTEST= data set
RIDGE=	Performs ridge regression analysis and outputs estimates to the OUTEST= data set
RSQUARE	Same effect as the EDF option
TABLEOUT	Outputs standard errors, confidence limits, and associated test statistics of the parameter estimates to the OUTEST= data set
ODS Graphics Options	
PLOTS=	Produces ODS graphical displays
Traditional Graphics Options	
ANNOTATE=	Specifies an annotation data set
GOUT=	Specifies the graphics catalog in which graphics output is saved
Display Options	
CORR	Displays correlation matrix for variables listed in MODEL and VAR statements

Table 79.1 *continued*

Option	Description
SIMPLE	Displays simple statistics for each variable listed in MODEL and VAR statements
USSCP	Displays uncorrected sums of squares and crossproducts matrix
ALL	Displays all statistics (CORR , SIMPLE , and USSCP)
NOPRINT	Suppresses output
LINEPRINTER	Creates printer plots
Other Options	
ALPHA=	Sets significance value for confidence and prediction intervals and tests
SINGULAR=	Sets criterion for checking for singularity

Following are explanations of the options that you can specify in the **PROC REG** statement (in alphabetical order).

Note that any option specified in the **PROC REG** statement applies to all **MODEL** statements.

ALL

requests the display of many tables. Using the **ALL** option in the **PROC REG** statement is equivalent to specifying **ALL** in every **MODEL** statement. The **ALL** option also implies the **CORR**, **SIMPLE**, and **USSCP** options.

ALPHA=number

sets the significance level used for the construction of confidence intervals. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the **PROC REG** option **TABLEOUT**; the **MODEL** options **CLB**, **CLI**, and **CLM**; the **OUTPUT** statement keywords **LCL**, **LCLM**, **UCL**, and **UCLM**; the **PLOT** statement keywords **LCL.**, **LCLM.**, **UCL.**, and **UCLM.**; and the **PLOT** statement options **CONF** and **PRED**.

ANNOTATE=SAS-data-set

ANNO=SAS-data-set

specifies an input data set containing annotate variables, as described in *SAS/GRAPH: Reference*. You can use this data set to add features to the traditional graphics that you request with the **PLOT** statement. Features provided in this data set are applied to all plots produced in the current run of **PROC REG**. To add features to individual plots, use the **ANNOTATE=** option in the **PLOT** statement. This option cannot be used if the **LINEPRINTER** option is specified.

CORR

displays the correlation matrix for all variables listed in the **MODEL** or **VAR** statement.

COVOUT

outputs the covariance matrices for the parameter estimates to the **OUTEST=** data set. This option is valid only if the **OUTEST=** option is also specified. See the section “**OUTEST= Data Set**” on page 6690.

DATA=SAS-data-set

names the SAS data set to be used by PROC REG. The data set can be an ordinary SAS data set or a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set. If one of these special TYPE= data sets is used, the [OUTPUT](#), [PAINT](#), [PLOT](#), and [REWEIGHT](#) statements, ODS Graphics, and some options in the [MODEL](#) and [PRINT](#) statements are not available. See Appendix A, “[Special SAS Data Sets](#),” for more information about TYPE= data sets. If the DATA= option is not specified, PROC REG uses the most recently created SAS data set.

EDF

outputs the number of regressors in the model excluding and including the intercept, the error degrees of freedom, and the model R square to the OUTEST= data set.

GOUT=graphics-catalog

specifies the graphics catalog in which traditional graphics output is saved. The default *graphics-catalog* is WORK.GSEG. The GOUT= option cannot be used if the [LINEPRINTER](#) option is specified.

LINEPRINTER | LP

creates printer plots. If you do not specify this option, requested plots are created on a high-resolution graphics device. See the [PLOTS=](#) option for information about using ODS graphics to create modern statistical graphics.

NOPRINT

suppresses the normal display of results. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

OUTEST=SAS-data-set

requests that parameter estimates and optional model fit summary statistics be output to this data set. See the section “[OUTEST= Data Set](#)” on page 6690 for details. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

OUTSEB

outputs the standard errors of the parameter estimates to the OUTEST= data set. The value SEB for the variable _TYPE_ identifies the standard errors. If the RIDGE= or PCOMIT= option is specified, additional observations are included and identified by the values RIDGESEB and IPCSEB, respectively, for the variable _TYPE_. The standard errors for ridge regression estimates and IPC estimates are limited in their usefulness because these estimates are biased. This option is available for all model selection methods except RSQUARE, ADJRSQ, and CP.

OUTSSCP=SAS-data-set

requests that the sums of squares and crossproducts matrix be output to this TYPE=SSCP data set. See the section “[OUTSSCP= Data Sets](#)” on page 6696 for details. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

OUTSTB

outputs the standardized parameter estimates as well as the usual estimates to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The values RIDGESTB and IPCSTB for the variable _TYPE_ identify ridge regression estimates and IPC estimates, respectively.

OUTVIF

outputs the variance inflation factors (VIF) to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The factors are the diagonal elements of the inverse of the correlation matrix of regressors as adjusted by ridge regression or IPC analysis. These observations are identified in the output data set by the values RIDGEVIF and IPCVIF for the variable `_TYPE_`.

PCOMIT=*list*

requests an incomplete principal component (IPC) analysis for each value *m* in the list. The procedure computes parameter estimates by using all but the last *m* principal components. Each value of *m* produces a set of IPC estimates, which are output to the OUTEST= data set. The values of *m* are saved by the variable `_PCOMIT_`, and the value of the variable `_TYPE_` is set to IPC to identify the estimates. Only nonnegative integers can be specified with the PCOMIT= option.

If you specify the PCOMIT= option, [RESTRICT](#) statements are ignored.

PLOTS <(global-plot-options)> <= plot-request <(options)>>

PLOTS <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots          = none
plots          = diagnostics(unpack)
plots          = (all fit(stats)=none)
plots(label)   = (rstudentbyleverage cooks)
plots(only)    = (diagnostics(stats=all) fit(nocli stats=(aic sbc))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc reg;
  model y = x1-x10;
run;

proc reg plots=diagnostics(stats=(default aic sbc));
  model y = x1-x10;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC REG produces a default set of plots. [Table 79.2](#) lists the default set of plots produced.

Table 79.2 Default Graphs Produced

Plot	Conditional On
DiagnosticsPanel	Unconditional
ResidualPlot	Unconditional
FitPlot	Model with one regressor (excluding intercept)
PartialPlot	PARTIAL option specified in MODEL statement
RidgePanel	RIDGE= option specified in PROC REG or MODEL statement

For models with multiple dependent variables, separate plots are produced for each dependent variable. For jobs with more than one **MODEL** statement, plots are produced for each model statement.

The *global-options* apply to all plots generated by the REG procedure, unless it is altered by a *specific-plot-option*. The following global plot options are available:

LABEL

specifies that the LABEL option be applied to each plot that supports a LABEL option. See the descriptions of the specific plots for details.

MAXPOINTS=NONE | *max* < *heat-max* >

suppresses most plots that require processing more than *max* points. When the number of points exceeds *max* but does not exceed *heat-max* divided by the number of independent variables, heat maps are displayed instead of scatter plots for the fit and residual plots. All other plots are suppressed when the number of points exceeds *max*. The default is MAXPOINTS=5000 150000. These cutoffs are ignored if you specify MAXPOINTS=NONE.

NOTE: Heat maps are experimental in this release.

MODELLABEL

requests that the model label be displayed in the upper-left corner of all plots. This option is useful when you use more than one **MODEL** statement.

ONLY

suppress the default plots. Only plots specifically requested are displayed.

STATS=ALL | **DEFAULT** | **NONE** | (*plot-statistics*)

requests statistics that are included on the fit plot and diagnostics panel. [Table 79.3](#) lists the statistics that you can request. STATS=ALL requests all these statistics; STATS=NONE suppresses them.

Table 79.3 Statistics Available on Plots

Keyword	Default	Description
ADJRSQ	x	adjusted R-square
AIC		Akaike's information criterion
BIC		Sawa's Bayesian information criterion
CP		Mallows' C_p statistic
COEFFVAR		coefficient of variation
DEPMEAN		mean of dependent

Table 79.3 *continued*

Keyword	Default	Description
DEFAULT		all default statistics
EDF	x	error degrees of freedom
GMSEP		estimated MSE of prediction, assuming multivariate normality
JP		final prediction error
MSE	x	mean squared error
NOBS	x	number of observations used
NPARM	x	number of parameters in the model (including the intercept)
PC		Amemiya's prediction criterion
RSQUARE	x	R-square
SBC		SBC statistic
SP		SP statistic
SSE		error sum of squares

You request statistics in addition to the default set by including the keyword **DEFAULT** in the *plot-statistics* list.

UNPACK

suppresses paneling.

USEALL

specifies that predicted values at data points with missing dependent variable(s) be included on appropriate plots. By default, only points used in constructing the SSCP matrix appear on plots.

The following specific plots are available:

ADJRSQ <(adjrsq-options)>

displays the adjusted R-square values for the models examined when you request variable selection with the **SELECTION=** option in the **MODEL** statement.

The following *adjrsq-options* are available for models where you request the **RSQUARE**, **ADJRSQ**, or **CP** selection method:

LABEL

requests that the model number corresponding to the one displayed in the “Subset Selection Summary” table be used to label the model with the largest adjusted R-square statistic at each value of the number of parameters.

LABELVARS

requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the largest adjusted R-square statistic at each value of the number of parameters.

AIC <(aic-options)>

displays Akaike's information criterion (AIC) for the models examined when you request variable selection with the SELECTION= option in the [MODEL](#) statement.

The following *aic-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL

requests that the model number corresponding to the one displayed in the "Subset Selection Summary" table be used to label the model with the smallest AIC statistic at each value of the number of parameters.

LABELVARS

requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the smallest AIC statistic at each value of the number of parameters.

ALL

produces all appropriate plots.

BIC <(bic-options)>

displays Sawa's Bayesian information criterion (BIC) for the models examined when you request variable selection with the SELECTION= option in the [MODEL](#) statement.

The following *bic-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL

requests that the model number corresponding to the one displayed in the "Subset Selection Summary" table be used to label the model with the smallest BIC statistic at each value of the number of parameters.

LABELVARS

requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the smallest BIC statistic at each value of the number of parameters.

COOKSD <(LABEL)>

plots Cook's D statistic by observation number. Observations whose Cook's D statistic lies above the horizontal reference line at value $4/n$, where n is the number of observations used, are deemed to be influential (Rawlings, Pantula, and Dickey 1998). If you specify the LABEL option, then points deemed as influential are labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables in one or more ID statements, then the first ID variable you specify is used for the labeling.

CP <(cp-options)>

displays Mallows' C_p statistic for the models examined when you request variable selection with the SELECTION= option in the [MODEL](#) statement. For models where you request the RSQUARE, ADJRSQ, or CP selection, reference lines corresponding to the equations $C_p = p$ and $C_p = 2p - p_{full}$, where p_{full} is the number of parameters in the full model (excluding the intercept) and p is the number of parameters in the subset model (including the intercept), are displayed on the plot of C_p versus p . For the purpose of parameter estimation, Hocking (1976)

suggests selecting a model where $C_p \leq 2p - p_{full}$. For the purpose of prediction, Hocking suggests the criterion $C_p \leq p$. Mallows (1973) suggests that all subset models with C_p small and near p be considered for further study.

The following *cp-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL

requests that the model number corresponding to the one displayed in the “Subset Selection Summary” table be used to label the model with the smallest C_p statistic at each value of the number of parameters.

LABELVARS

requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the smallest C_p statistic at each value of the number of parameters.

CRITERIA | CRITERIONPANEL <(criteria-options)>

produces a panel of fit criteria for the models examined when you request variable selection with the SELECTION= option in the **MODEL** statement. The fit criteria displayed are R-square, adjusted R-square, Mallows’ C_p , Akaike’s information criterion (AIC), Sawa’s Bayesian information criterion (BIC), and Schwarz’s Bayesian information criterion (SBC). For SELECTION=RSQUARE, SELECTION=ADJRSQ, or SELECTION=CP, scatter plots of these statistics versus the number of parameters (including the intercept) are displayed. For other selection methods, line plots of these statistics as function of the selection step number are displayed.

The following *criteria-options* are available:

LABEL

requests that the model number corresponding to the one displayed in the “Subset Selection Summary” table be used to label the best model at each value of the number of parameters. This option applies only to the RSQUARE, ADJRSQ, and CP selection methods.

LABELVARS

requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the best model at each value of the number of parameters. Since these labels are typically long, LABELVARS is supported only when the panel is unpacked. This option applies only to the RSQUARE, ADJRSQ, and CP selection methods.

UNPACK

suppresses paneling. Separate plots are produced for each of the six fit statistics. For models where you request the RSQUARE, ADJRSQ, or CP selection, two reference lines corresponding to the equations $C_p = p$ and $C_p = 2p - p_{full}$, where p_{full} is the number of parameters in the full model (excluding the intercept) and p is the number of parameters in the subset model (including the intercept), are displayed on the plot of C_p versus p . For the purpose of parameter estimation, Hocking (1976) suggests selecting a model where $C_p \leq 2p - p_{full}$. For the purpose of prediction, Hocking suggests the criterion $C_p \leq p$. Mallows (1973) suggests that all subset models with C_p small and near p be considered for further study.

DFBETAS <(DFBETAS-options)>

produces panels of DFBETAS by observation number for the regressors in the model. Note that each panel contains at most six plots, and multiple panels are used in the case where there are more than six regressors (including the intercept) in the model. Observations whose DFBETAS' statistics for a regressor are greater in magnitude than $2/\sqrt{n}$, where n is the number of observations used, are deemed to be influential for that regressor (Rawlings, Pantula, and Dickey 1998).

The following *DFBETAS-options* are available:

COMMONAXES

specifies that the same DFBETAS axis be used in all panels when multiple panels are needed. By default, the DFBETAS axis is chosen independently for each panel. If you also specify the UNPACK option, then the same DFBETAS axis is used for each regressor.

LABEL

specifies that observations whose magnitude are greater than $2/\sqrt{n}$ be labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables on one or more ID statements, then the first ID variable you specify is used for the labeling.

UNPACK

suppresses paneling. The DFBETAS statistics for each regressor are displayed on separate plots.

DFFITS <(LABEL)>

plots the DFFITS statistic by observation number. Observations whose DFFITS' statistic is greater in magnitude than $2\sqrt{p/n}$, where n is the number of observations used and p is the number of regressors, are deemed to be influential (Rawlings, Pantula, and Dickey 1998). If you specify the LABEL option, then these influential observations are labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables in one or more ID statements, then the first ID variable you specify is used for the labeling.

DIAGNOSTICS <(diagnostics-options)>

produces a summary panel of fit diagnostics:

- residuals versus the predicted values
- studentized residuals versus the predicted values
- studentized residuals versus the leverage
- normal quantile plot of the residuals
- dependent variable values versus the predicted values
- Cook's D versus observation number
- histogram of the residuals
- "Residual-Fit" (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals
- box plot of the residuals if you specify the STATS=NONE suboption

You can specify the following *diagnostics-options*:

STATS=stats-options

determines which model fit statistics are included in the panel. See the global STATS= suboption for details. The PLOTS= suboption of the DIAGNOSTICSPANEL option overrides the global PLOTS= suboption.

UNPACK

produces the eight plots in the panel as individual plots. Note that you can also request individual plots in the panel by name without having to unpack the panel.

FITPLOT | FIT <(fit-options)>

produces a scatter plot of the data overlaid with the regression line, confidence band, and prediction band for models that depend on at most one regressor excluding the intercept. When the number of points exceeds the MAXPOINTS=*max* value, a heat map is displayed instead of a scatter plot. By default, heat maps are not displayed if the number of observations times the number of independent variables is greater than 150,000. See the MAXPOINTS= option.

You can specify the following *fit-options*:

NOCLI

suppresses the prediction limits.

NOCLM

suppresses the confidence limits.

NOLIMITS

suppresses the confidence and prediction limits.

STATS=stats-options

determines which model fit statistics are included in the panel. See the global STATS= suboption for details. The PLOTS= suboption of the FITPLOT option overrides the global PLOTS= suboption.

OBSERVEDBYPREDICTED <(LABEL)>

plots dependent variable values by the predicted values. If you specify the LABEL option, then points deemed as outliers or influential (see the RSTUDENTBYLEVERAGE option for details) are labeled.

NONE

suppresses all plots.

PARTIAL <(UNPACK)>

produces panels of partial regression plots for each regressor with at most six regressors per panel. If you specify the UNPACK option, then all partial plot panels are unpacked.

PREDICTIONS (X=numeric-variable <prediction-options>)

produces a panel of two plots whose horizontal axis is the variable you specify in the required X= suboption. The upper plot in the panel is a scatter plot of the residuals. The lower plot shows the data overlaid with the regression line, confidence band, and prediction band. This plot is appropriate for models where all regressors are known to be functions of the single variable that you specify in the X= suboption.

You can specify the following *prediction-options*:

NOCLI

suppresses the prediction limits.

NOCLM

suppresses the confidence limits

NOLIMITS

suppresses the confidence and prediction limits

SMOOTH

requests a nonparametric smoothing of the residuals as a function of the variable you specify in the X= suboption. This nonparametric fit is a loess fit that uses local linear polynomials, linear interpolation, and a smoothing parameter that is selected to yield a local minimum of the corrected Akaike's information criterion (AICC). See Chapter 53, “[The LOESS Procedure](#),” for details. The SMOOTH option is not supported when a [FREQ](#) statement is used.

UNPACK

suppresses paneling.

QQPLOT | QQ

produces a normal quantile plot of the residuals.

RESIDUALBOXPLOT | BOXPLOT <(LABEL)>

produces a box plot consisting of the residuals. If you specify label option, points deemed far-outliers are labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables in one or more ID statements, then the first ID variable you specify is used for the labeling.

RESIDUALBYPREDICTED <(LABEL)>

plots residuals by predicted values. If you specify the LABEL option, then points deemed as outliers or influential (see the RSTUDENTBYLEVERAGE option for details) are labeled.

RESIDUALS <(residual-options)>

produces panels of the residuals versus the regressors in the model. Each panel contains at most six plots, and multiple panels are used when the model contains more than six regressors (including the intercept). When the number of points exceeds the MAXPOINTS=*max* value, a heat map is displayed instead of a scatter plot. By default, heat maps are not displayed if the number of observations times the number of independent variables is greater than 150,000. See the [MAXPOINTS=](#) option. You can specify the following *residual-options*:

SMOOTH

requests a nonparametric smoothing of the residuals for each regressor. Each nonparametric fit is a loess fit that uses local linear polynomials, linear interpolation, and a smoothing parameter that is selected to yield a local minimum of the corrected Akaike's information criterion (AICC). See Chapter 53, “[The LOESS Procedure](#),” for details. The SMOOTH option is not supported when a [FREQ](#) statement is used.

UNPACK

suppresses paneling.

RESIDUALHISTOGRAM

produces a histogram of the residuals.

RFPLOT | RF

produces a “Residual-Fit” (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals. This plot “shows how much variation in the data is explained by the fit and how much remains in the residuals” (Cleveland 1993).

RIDGE | RIDGEPANEL | RIDGEPLOT <(ridge-options)>

creates panels of VIF values and standardized ridge estimates by ridge values for each coefficient. The VIF values for each coefficient are connected by lines and are displayed in the upper plot in each panel. The points corresponding to the standardized estimates of each coefficient are connected by lines and are displayed in the lower plot in each panel. By default, at most 10 coefficients are represented in a panel and multiple panels are produced for models with more than 10 regressors. For ridge estimates to be computed and plotted, the OUTEST= option must be specified in the [PROC REG](#) statement, and the RIDGE= list must be specified in either the [PROC REG](#) or the [MODEL](#) statement. (See [Example 79.5](#).)

The following *ridge-options* are available:

COMMONAXES

specifies that the same VIF axis and the same standardized estimate axis are used in all panels when multiple panels are needed. By default, these axes are chosen independently for the regressors shown in each panel.

RIDGEAXIS=LINEAR | LOG

specifies the axis type used to display the ridge parameters. The default is RIDGEAXIS=LINEAR. Note that the point with the ridge parameter equal to zero is not displayed if you specify RIDGEAXIS=LOG.

UNPACK

suppresses paneling. The traces of the VIF statistics and standardized estimates are shown in separate plots.

VARSPERPLOT=ALL**VARSPERPLOT=number**

specifies the maximum number of regressors displayed in each panel or in each plot if you additionally specify the UNPACK option. If you specify VARSPERPLOT=ALL, then the VIF values and ridge traces for all regressors are displayed in a single panel.

VIFAXIS=LINEAR | LOG

specifies the axis type used to display the VIF statistics. The default is VIFAXIS=LINEAR.

RSQUARE <(rsquare-options)>

displays the R-square values for the models examined when you request variable selection with the SELECTION= option in the [MODEL](#) statement.

The following *rsquare-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL

requests that the model number corresponding to the one displayed in the “Subset Selection Summary” table be used to label the model with the largest R-square statistic at each value of the number of parameters.

LABELVARS

requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the largest R-square statistic at each value of the number of parameters.

RSTUDENTBYLEVERAGE <(LABEL)>

plots studentized residuals by leverage. Observations whose studentized residuals lie outside the band between the reference lines $RSTUDENT = \pm 2$ are deemed outliers. Observations whose leverage values are greater than the vertical reference $LEVERAGE = 2p/n$, where p is the number of parameters including the intercept and n is the number of observations used, are deemed influential (Rawlings, Pantula, and Dickey 1998). If you specify the LABEL option, then points deemed as outliers or influential are labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables in one or more ID statements, then the first ID variable you specify is used for the labeling.

RSTUDENTBYPREDICTED <(LABEL)>

plots studentized residuals by predicted values. If you specify the LABEL option, then points deemed as outliers or influential (see the RSTUDENTBYLEVERAGE option for details) are labeled.

SBC <(sbc-options)>

displays Schwarz’s Bayesian information criterion (SBC) for the models examined when you request variable selection with the SELECTION= option in the **MODEL** statement.

The following *sbc-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL

requests that the model number corresponding to the one displayed in the “Subset Selection Summary” table be used to label the model with the smallest SBC statistic at each value of the number of parameters.

LABELVARS

requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the smallest SBC statistic at each value of the number of parameters.

PRESS

outputs the PRESS statistic to the OUTEST= data set. The values of this statistic are saved in the variable `_PRESS_`. This option is available for all model selection methods except RSQUARE, ADJRSQ, and CP.

RIDGE=*list*

requests a ridge regression analysis and specifies the values of the ridge constant k (see the section “Computations for Ridge Regression and IPC Analysis” on page 6739). Each value of k produces

a set of ridge regression estimates that are placed in the OUTEST= data set. The values of k are saved by the variable `_RIDGE_`, and the value of the variable `_TYPE_` is set to RIDGE to identify the estimates.

Only nonnegative numbers can be specified with the RIDGE= option. [Example 79.5](#) illustrates this option.

If ODS Graphics is enabled (see the section “[ODS Graphics](#)” on page 6745), then ridge regression plots are automatically produced. These plots consist of panels containing ridge traces for the regressors, with at most eight ridge traces per panel.

If you specify the RIDGE= option, [RESTRICT](#) statements are ignored.

RSQUARE

has the same effect as the [EDF](#) option.

SIMPLE

displays the sum, mean, variance, standard deviation, and uncorrected sum of squares for each variable used in PROC REG.

SINGULAR= n

tunes the mechanism used to check for singularities. The default value is machine dependent but is approximately $1\text{E-}7$ on most machines. This option is rarely needed.

Singularity checking is described in the section “[Computational Methods](#)” on page 6740.

TABLEOUT

outputs the standard errors and $100(1 - \alpha)\%$ confidence limits for the parameter estimates, the t statistics for testing if the estimates are zero, and the associated p -values to the OUTEST= data set. The `_TYPE_` variable values STDERR, LnB, UnB, T, and PVALUE, where $n = 100(1 - \alpha)$, identify these rows in the OUTEST= data set. The α level can be set with the ALPHA= option in the [PROC REG](#) or [MODEL](#) statement. The OUTEST= option must be specified in the [PROC REG](#) statement for this option to take effect.

USSCP

displays the uncorrected sums-of-squares and crossproducts matrix for all variables used in the procedure.

ADD Statement

ADD *variables* ;

The ADD statement adds independent variables to the regression model. Only variables used in the [VAR](#) statement or used in [MODEL](#) statements before the first RUN statement can be added to the model. You can use the ADD statement interactively to add variables to the model or to include a variable that was previously deleted with a [DELETE](#) statement. Each use of the ADD statement modifies the [MODEL](#) label.

See the section “[Interactive Analysis](#)” on page 6697 for an example.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC REG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the REG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

When a BY statement is used with PROC REG, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure. A BY statement that appears after the first RUN statement is ignored.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CODE Statement

CODE < *options* > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 79.4 summarizes the *options* available in the CODE statement.

Table 79.4 CODE Statement Options

Option	Description
CATALOG=	Names the catalog entry where the generated code is saved
DUMMIES	Retains the dummy variables in the data set
ERROR	Computes the error function
FILE=	Names the file where the generated code is saved
FORMAT=	Specifies the numeric format for the regression coefficients
GROUP=	Specifies the group identifier for array names and statement labels
IMPUTE	Imputes predicted values for observations with missing or invalid covariates

Table 79.4 *continued*

Option	Description
LINESIZE=	Specifies the line size of the generated code
LOOKUP=	Specifies the algorithm for looking up CLASS levels
RESIDUAL	Computes residuals

For details about the syntax of the CODE statement, see the section “[CODE Statement](#)” on page 390 in Chapter 19, “[Shared Concepts and Topics](#).”

DELETE Statement

DELETE *variables* ;

The DELETE statement deletes independent variables from the regression model. The DELETE statement performs the opposite function of the [ADD](#) statement and is used in a similar manner. Each use of the DELETE statement modifies the [MODEL](#) label.

For an example of how the [ADD](#) statement is used (and how the DELETE statement can be used), see the section “[Interactive Analysis](#)” on page 6697.

FREQ Statement

FREQ *variable* ;

When a FREQ statement appears, each observation in the input data set is assumed to represent n observations, where n is the value of the FREQ variable. The analysis produced when you use a FREQ statement is the same as an analysis produced by using a data set that contains n observations in place of each observation in the input data set. When the procedure determines degrees of freedom for significance tests, the total number of observations is considered to be equal to the sum of the values of the FREQ variable.

If the value of the FREQ variable is missing or is less than 1, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

The FREQ statement must appear before the first RUN statement, or it is ignored.

ID Statement

ID *variables* ;

When one of the [MODEL](#) statement options CLI, CLM, P, R, and INFLUENCE is requested, the variables listed in the ID statement are displayed beside each observation. These variables can be used to identify each observation. If the ID statement is omitted, the observation number is used to identify the observations.

Although there are no restrictions on the length of ID variables, PROC REG might truncate ID values to 16 characters for display purposes.

MODEL Statement

<label> MODEL dependents = <regressors> </options> ;

After the keyword **MODEL**, the dependent (response) variables are specified, followed by an equal sign and the regressor variables. Variables specified in the **MODEL** statement must be numeric variables in the data set being analyzed. For example, if you want to specify a quadratic term for variable **X1** in the model, you cannot use **X1*X1** in the **MODEL** statement but must create a new variable (for example, **X1SQUARE=X1*X1**) in a **DATA** step and use this new variable in the **MODEL** statement. The label in the **MODEL** statement is optional.

Table 79.5 summarizes the options available in the **MODEL** statement. Equations for the statistics available are given in the section “**Model Fit and Diagnostic Statistics**” on page 6715.

Table 79.5 MODEL Statement Options

Option	Description
Model Selection and Details of Selection	
SELECTION=	Specifies model selection method
BEST=	Specifies maximum number of subset models displayed or output to the OUTEST= data set
DETAILS	Produces summary statistics at each step
DETAILS=	Specifies the display details for FORWARD , BACKWARD , and STEPWISE methods
GROUPNAMES=	Provides names for groups of variables
INCLUDE=	Includes first <i>n</i> variables in the model
MAXSTEP=	Specifies maximum number of steps that might be performed
NOINT	Fits a model without the intercept term
PCOMIT=	Performs incomplete principal component analysis and outputs estimates to the OUTEST= data set
RIDGE=	Performs ridge regression analysis and outputs estimates to the OUTEST= data set
SLE=	Sets criterion for entry into model
SLS=	Sets criterion for staying in model
START=	Specifies number of variables in model to begin the comparing and switching process
STOP=	Stops selection criterion
Statistics	
ADJRSQ	Computes adjusted R square
AIC	Computes Akaike's information criterion
B	Computes parameter estimates for each model
BIC	Computes Sawa's Bayesian information criterion
CP	Computes Mallows' C_p statistic
GMSEP	Computes estimated MSE of prediction assuming multivariate normality
JP	Computes J_p , the final prediction error
MSE	Computes MSE for each model
PC	Computes Amemiya's prediction criterion

Table 79.5 *continued*

Option	Description
RMSE	Displays root MSE for each model
SBC	Computes the SBC statistic
SP	Computes S_p statistic for each model
SSE	Computes error sum of squares for each model
Data Set Options	
EDF	Outputs the number of regressors, the error degrees of freedom, and the model R square to the OUTEST= data set
OUTSEB	Outputs standard errors of the parameter estimates to the OUTEST= data set
OUTSTB	Outputs standardized parameter estimates to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
OUTVIF	Outputs the variance inflation factors to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
PRESS	Outputs the PRESS statistic to the OUTEST= data set
RSQUARE	Has same effect as the EDF option
Regression Calculations	
I	Displays inverse of sums of squares and crossproducts
XPX	Displays sums-of-squares and crossproducts matrix
Details on Estimates	
ACOV	Displays heteroscedasticity-consistent covariance matrix of estimates and heteroscedasticity-consistent standard errors
ACOVMETHOD=	Specifies method for computing the asymptotic heteroscedasticity-consistent covariance matrix
COLLIN	Produces collinearity analysis
COLLINOINT	Produces collinearity analysis with intercept adjusted out
CORRB	Displays correlation matrix of estimates
COVB	Displays covariance matrix of estimates
HCC	Displays heteroscedasticity-consistent standard errors
HCCMETHOD=	Specifies method for computing the asymptotic heteroscedasticity-consistent covariance matrix
LACKFIT	Performs lack-of-fit test
PARTIALR2	Displays squared semipartial correlation coefficients computed using Type I sums of squares
PCORR1	Displays squared partial correlation coefficients computed using Type I sums of squares
PCORR2	Displays squared partial correlation coefficients computed using Type II sums of squares
SCORR1	Displays squared semipartial correlation coefficients computed using Type I sums of squares
SCORR2	Displays squared semipartial correlation coefficients computed using Type II sums of squares
SEQB	Displays a sequence of parameter estimates during selection process

Table 79.5 *continued*

Option	Description
SPEC	Tests that first and second moments of model are correctly specified
SS1	Displays the sequential sums of squares
SS2	Displays the partial sums of squares
STB	Displays standardized parameter estimates
TOL	Displays tolerance values for parameter estimates
WHITE	Displays heteroscedasticity-consistent standard errors
VIF	Computes variance-inflation factors
Predicted and Residual Values	
CLB	Computes $100(1 - \alpha)\%$ confidence limits for the parameter estimates
CLI	Computes $100(1 - \alpha)\%$ confidence limits for an individual predicted value
CLM	Computes $100(1 - \alpha)\%$ confidence limits for the expected value of the dependent variable
DW	Computes a Durbin-Watson statistic
DWPROB	Computes a Durbin-Watson statistic and p -value
INFLUENCE	Computes influence statistics
P	Computes predicted values
PARTIAL	Displays partial regression plots for each regressor
PARTIALDATA	Displays partial regression data
R	Produces analysis of residuals
Display Options and Other Options	
ALL	Requests the following options: ACOV, CLB, CLI, CLM, CORRB, COVB, HCC, I, P, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, XPX
ALPHA=	Sets significance value for confidence and prediction intervals and tests
NOPRINT	Suppresses display of results
SIGMA=	Specifies the true standard deviation of error term for computing CP and BIC
SINGULAR=	Sets criterion for checking for singularity

You can specify the following options in the **MODEL** statement after a slash (/).

ACOV

displays the estimated asymptotic covariance matrix of the estimates under the hypothesis of heteroscedasticity and heteroscedasticity-consistent standard errors of parameter estimates. See the **HCCMETHOD=** option and the **HCC** option and the section “Testing for Heteroscedasticity” on page 6732 for more information.

ACOVMETHOD=0,1,2, or 3

See the [HCCMETHOD=](#) option.

ADJRSQ

computes R square adjusted for degrees of freedom for each model selected (Darlington 1968; Judge et al. 1980).

AIC

outputs Akaike's information criterion for each model selected (Akaike 1969; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the AIC statistic is also added to the SubsetSelSummary table.

ALL

requests all these options: ACOV, CLB, CLI, CLM, CORRB, COVB, HCC, I, P, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, and XPX.

ALPHA=number

sets the significance level used for the construction of confidence intervals for the current [MODEL](#) statement. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the [MODEL](#) options CLB, CLI, and CLM; the [OUTPUT](#) statement keywords LCL, LCLM, UCL, and UCLM; the [PLOT](#) statement keywords LCL., LCLM., UCL., and UCLM.; and the [PLOT](#) statement options CONF and PRED. If you specify this option in the [MODEL](#) statement, it takes precedence over the [ALPHA=](#) option in the [PROC REG](#) statement.

B

is used with the RSQUARE, ADJRSQ, and CP model-selection methods to compute estimated regression coefficients for each model selected.

BEST=n

is used with the RSQUARE, ADJRSQ, and CP model-selection methods. If SELECTION=CP or SELECTION=ADJRSQ is specified, the BEST= option specifies the maximum number of subset models to be displayed or output to the OUTEST= data set. For SELECTION=RSQUARE, the BEST= option requests the maximum number of subset models for each size.

If the BEST= option is used without the [B](#) option (displaying estimated regression coefficients), the variables in each MODEL are listed in order of inclusion instead of the order in which they appear in the [MODEL](#) statement.

If the BEST= option is omitted and the number of regressors is less than 11, all possible subsets are evaluated. If the BEST= option is omitted and the number of regressors is greater than 10, the number of subsets selected is, at most, equal to the number of regressors. A small value of the BEST= option greatly reduces the CPU time required for large problems.

BIC

outputs Sawa's Bayesian information criterion for each model selected (Sawa 1978; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the BIC statistic is also added to the SubsetSelSummary table.

CLB

requests the $100(1 - \alpha)\%$ upper and lower confidence limits for the parameter estimates. By default, the 95% limits are computed; the [ALPHA=](#) option in the [PROC REG](#) or [MODEL](#) statement can be

used to change the α level. If any of the **MODEL** statement options **ACOV**, **HCC**, or **WHITE** are in effect, then the **CLB** option also produces heteroscedasticity-consistent $100(1 - \alpha)\%$ upper and lower confidence limits for the parameter estimates.

CLI

requests the $100(1 - \alpha)\%$ upper and lower confidence limits for an individual predicted value. By default, the 95% limits are computed; the **ALPHA=** option in the **PROC REG** or **MODEL** statement can be used to change the α level. The confidence limits reflect variation in the error, as well as variation in the parameter estimates. See the section “[Predicted and Residual Values](#)” on page 6708 and Chapter 4, “[Introduction to Regression Procedures](#),” for more information.

CLM

displays the $100(1 - \alpha)\%$ upper and lower confidence limits for the expected value of the dependent variable (mean) for each observation. By default, the 95% limits are computed; the **ALPHA=** in the **PROC REG** or **MODEL** statement can be used to change the α level. This is not a prediction interval (see the **CLI** option) because it takes into account only the variation in the parameter estimates, not the variation in the error term. See the section “[Predicted and Residual Values](#)” on page 6708 and Chapter 4, “[Introduction to Regression Procedures](#),” for more information.

COLLIN

requests a detailed analysis of collinearity among the regressors. This includes eigenvalues, condition indices, and decomposition of the variances of the estimates with respect to each eigenvalue. See the section “[Collinearity Diagnostics](#)” on page 6713.

COLLINOINT

requests the same analysis as the **COLLIN** option with the intercept variable adjusted out rather than included in the diagnostics. See the section “[Collinearity Diagnostics](#)” on page 6713.

CORRB

displays the correlation matrix of the estimates. This is the $(\mathbf{X}'\mathbf{X})^{-1}$ matrix scaled to unit diagonals.

COVB

displays the estimated covariance matrix of the estimates. This matrix is $(\mathbf{X}'\mathbf{X})^{-1}s^2$, where s^2 is the estimated mean squared error.

CP

outputs Mallows' C_p statistic for each model selected (Mallows 1973; Hocking 1976) to the **OUTEST=** data set. See the section “[Criteria Used in Model-Selection Methods](#)” on page 6704 for a discussion of the use of C_p . If **SELECTION=ADJR SQ**, **SELECTION=RSQUARE**, or **SELECTION=CP** is specified, then the C_p statistic is also added to the **SubsetSelSummary** table.

DETAILS

DETAILS=name

specifies the level of detail produced when the **BACKWARD**, **FORWARD**, or **STEPWISE** method is used, where *name* can be **ALL**, **STEPS**, or **SUMMARY**. The **DETAILS** or **DETAILS=ALL** option produces entry and removal statistics for each variable in the model building process, ANOVA and parameter estimates at each step, and a selection summary table. The option **DETAILS=STEPS** provides the step information and summary table. The option **DETAILS=SUMMARY** produces only the summary table. The default if the **DETAILS** option is omitted is **DETAILS=STEPS**.

DW

calculates a Durbin-Watson statistic to test whether or not the errors have first-order autocorrelation. (This test is appropriate only for time series data.) Note that your data should be sorted by the date/time ID variable before you use this option. The sample autocorrelation of the residuals is also produced. See the section “[Autocorrelation in Time Series Data](#)” on page 6738.

DWPROB

calculates a Durbin-Watson statistic and a p -value to test whether or not the errors have first-order autocorrelation. Note that it is not necessary to specify the DW option if the DWPROB option is specified. (This test is appropriate only for time series data.) Note that your data should be sorted by the date/time ID variable before you use this option. The sample autocorrelation of the residuals is also produced. See the section “[Autocorrelation in Time Series Data](#)” on page 6738.

EDF

outputs the number of regressors in the model excluding and including the intercept, the error degrees of freedom, and the model R square to the OUTEST= data set.

GMSEP

outputs the estimated mean square error of prediction assuming that both independent and dependent variables are multivariate normal (Stein 1960; Darlington 1968) to the OUTEST= data set. (Note that Hocking’s formula (1976, eq. 4.20) contains a misprint: “ $n - 1$ ” should read “ $n - 2$.”) If SELECTION=ADJR SQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the GMSEP statistic is also added to the SubsetSelSummary table.

GROUPNAMES=*'name1' 'name2' ...*

provides names for variable groups. This option is available only in the BACKWARD, FORWARD, and STEPWISE methods. The group name can be up to 32 characters. Subsets of independent variables listed in the [MODEL](#) statement can be designated as variable groups. This is done by enclosing the appropriate variables in braces. Variables in the same group are entered into or removed from the regression model at the same time. However, if the tolerance of any variable (see the [TOL](#) option on page 6659) in a group is less than the setting of the [SINGULAR=](#) option, then the variable is not entered into the model with the rest of its group. If the GROUPNAMES= option is not used, then the names GROUP1, GROUP2, ..., GROUP n are assigned to groups encountered in the [MODEL](#) statement. Variables not enclosed by braces are used as groups of a single variable.

For example:

```
model y={x1 x2} x3 / selection=stepwise
      groupnames='x1 x2' 'x3';
```

Another example:

```
model y={ht wgt age} bodyfat / selection=forward
      groupnames='htwgtage' 'bodyfat';
```

HCC

requests heteroscedasticity-consistent standard errors of the parameter estimates. You can use the [HCCMETHOD=](#) option to specify the method used to compute the heteroscedasticity-consistent covariance matrix.

HCCMETHOD=0,1,2, or 3

specifies the method used to obtain a heteroscedasticity-consistent covariance matrix for use with the **ACOV**, **HCC**, or **WHITE** option in the **MODEL** statement and for heteroscedasticity-consistent tests with the **TEST** statement. The default is **HCCMETHOD=0**. See the section “[Testing for Heteroscedasticity](#)” on page 6732 for details.

I

displays the $(\mathbf{X}'\mathbf{X})^{-1}$ matrix. The inverse of the crossproducts matrix is bordered by the parameter estimates and SSE matrices.

INCLUDE=*n*

forces the first *n* independent variables listed in the **MODEL** statement to be included in all models. The selection methods are performed on the other variables in the **MODEL** statement. The **INCLUDE=** option is not available with **SELECTION=NONE**.

INFLUENCE

requests a detailed analysis of the influence of each observation on the estimates and the predicted values. See the section “[Influence Statistics](#)” on page 6717 for details.

JP

outputs J_p , the estimated mean square error of prediction for each model selected assuming that the values of the regressors are fixed and that the model is correct to the **OUTEST=** data set. The J_p statistic is also called the final prediction error (FPE) by Akaike (Nicholson 1948; Lord 1950; Mallows 1967; Darlington 1968; Rothman 1968; Akaike 1969; Hocking 1976; Judge et al. 1980) If **SELECTION=ADJR SQ**, **SELECTION=RSQUARE**, or **SELECTION=CP** is specified, then the J_p statistic is also added to the SubsetSelSummary table.

LACKFIT

performs a lack-of-fit test. See the section “[Testing for Lack of Fit](#)” on page 6733 for more information. See Draper and Smith (1981) for a discussion of lack-of-fit tests.

MSE

computes the mean square error for each model selected (Darlington 1968).

MAXSTEP=*n*

specifies the maximum number of steps that are done when **SELECTION=FORWARD**, **SELECTION=BACKWARD**, or **SELECTION=STEPWISE** is used. The default value is the number of independent variables in the model for the **FORWARD** and **BACKWARD** methods and three times this number for the stepwise method.

NOINT

suppresses the intercept term that is otherwise included in the model.

NOPRINT

suppresses the normal display of regression results. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

OUTSEB

outputs the standard errors of the parameter estimates to the OUTEST= data set. The value SEB for the variable `_TYPE_` identifies the standard errors. If the RIDGE= or PCOMIT= option is specified, additional observations are included and identified by the values RIDGESEB and IPCSEB, respectively, for the variable `_TYPE_`. The standard errors for ridge regression estimates and incomplete principal components (IPC) estimates are limited in their usefulness because these estimates are biased. This option is available for all model-selection methods except RSQUARE, ADJRSQ, and CP.

OUTSTB

outputs the standardized parameter estimates as well as the usual estimates to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The values RIDGESTB and IPCSTB for the variable `_TYPE_` identify ridge regression estimates and IPC estimates, respectively.

OUTVIF

outputs the variance inflation factors (VIF) to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The factors are the diagonal elements of the inverse of the correlation matrix of regressors as adjusted by ridge regression or IPC analysis. These observations are identified in the output data set by the values RIDGEVIF and IPCVIF for the variable `_TYPE_`.

P

calculates predicted values from the input data and the estimated model. The display includes the observation number, the ID variable (if one is specified), the actual and predicted values, and the residual. If the CLI, CLM, or R option is specified, the P option is unnecessary. See the section “[Predicted and Residual Values](#)” on page 6708 for more information.

PARTIAL

requests partial regression leverage plots for each regressor. You can use the [PARTIALDATA](#) option to obtain a tabular display of the partial regression leverage data. If ODS Graphics is enabled (see the section “[ODS Graphics](#)” on page 6745), then these partial plots are produced in panels with up to six plots per panel. See the section “[Influence Statistics](#)” on page 6717 for more information.

PARTIALDATA

requests partial regression leverage data for each regressor. You can request partial regression leverage plots of these data with the [PARTIAL](#) option. See the section “[Influence Statistics](#)” on page 6717 for more information.

PARTIALR2 < (< TESTS > < SEQTESTS >) >

See the [SCORR1](#) option.

PC

outputs Amemiya’s prediction criterion for each model selected (Amemiya 1976; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the PC statistic is also added to the SubsetSelSummary table.

PCOMIT=/*list*

requests an IPC analysis for each value *m* in the list. The procedure computes parameter estimates by using all but the last *m* principal components. Each value of *m* produces a set of IPC estimates, which is output to the OUTEST= data set. The values of *m* are saved by the variable `_PCOMIT_`, and the value of the variable `_TYPE_` is set to IPC to identify the estimates. Only nonnegative integers can be specified with the PCOMIT= option.

If you specify the PCOMIT= option, **RESTRICT** statements are ignored. The PCOMIT= option is ignored if you use the SELECTION= option in the **MODEL** statement.

PCORR1

displays the squared partial correlation coefficients computed using Type I sum of squares (SS). This is calculated as $SS/(SS+SSE)$, where SSE is the error sum of squares.

PCORR2

displays the squared partial correlation coefficients computed using Type II sums of squares. These are calculated the same way as with the PCORR1 option, except that Type II SS are used instead of Type I SS.

PRESS

outputs the PRESS statistic to the OUTEST= data set. The values of this statistic are saved in the variable `_PRESS_`. This option is available for all model-selection methods except RSQUARE, ADJRSQ, and CP.

R

requests an analysis of the residuals. The results include everything requested by the **P** option plus the standard errors of the mean predicted and residual values, the studentized residual, and Cook's *D* statistic to measure the influence of each observation on the parameter estimates. See the section “[Predicted and Residual Values](#)” on page 6708 for more information.

RIDGE=*list*

requests a ridge regression analysis and specifies the values of the ridge constant *k* (see the section “[Computations for Ridge Regression and IPC Analysis](#)” on page 6739). Each value of *k* produces a set of ridge regression estimates that are placed in the OUTEST= data set. The values of *k* are saved by the variable `_RIDGE_`, and the value of the variable `_TYPE_` is set to RIDGE to identify the estimates.

Only nonnegative numbers can be specified with the RIDGE= option. [Example 79.5](#) illustrates this option.

If you specify the RIDGE= option, **RESTRICT** statements are ignored. The RIDGE= option is ignored if you use the SELECTION= option in the **MODEL** statement.

RMSE

displays the root mean square error for each model selected.

RSQUARE

has the same effect as the **EDF** option.

SBC

outputs the SBC statistic for each model selected (Schwarz 1978; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the SBC statistic is also added to the SubsetSelSummary table.

SCORR1 <(< TESTS> <SEQTESTS>) >

displays the squared semipartial correlation coefficients computed using Type I sums of squares. This is calculated as SS/SST , where SST is the corrected total SS. If the **NOINT** option is used, the uncorrected total SS is used in the denominator. The optional arguments TESTS and SEQTESTS request are sequentially added to a model. The *F*-test values are computed as the Type I sum of squares

for the variable in question divided by a mean square error. If you specify the TESTS option, the denominator MSE is the residual mean square for the full model specified in the MODEL statement. If you specify the SEQTESTS option, the denominator MSE is the residual mean square for the model containing all the independent variables that have been added to the model up to and including the variable in question. The TESTS and SEQTESTS options are not supported if you specify model selection methods or the RIDGE or PCOMIT options. Note that the [PARTIALR2](#) option is a synonym for the SCORR1 option.

SCORR2 <(TESTS)>

displays the squared semipartial correlation coefficients computed using Type II sums of squares. These are calculated the same way as with the SCORR1 option, except that Type II SS are used instead of Type I SS. The optional TEST argument requests F tests and p -values as variables are sequentially added to a model. The F -test values are computed as the Type II sum of squares for the variable in question divided by the residual mean square for the full model specified in the [MODEL](#) statement. The TESTS option is not supported if you specify model selection methods or the RIDGE or PCOMIT options.

SELECTION=*name*

specifies the method used to select the model, where *name* can be FORWARD (or F), BACKWARD (or B), STEPWISE, MAXR, MINR, RSQUARE, ADJRSQ, CP, or NONE (use the full model). The default method is NONE. See the section “[Model-Selection Methods](#)” on page 6701 for a description of each method.

SEQB

produces a sequence of parameter estimates as each variable is entered into the model. This is displayed as a matrix where each row is a set of parameter estimates.

SIGMA=*n*

specifies the true standard deviation of the error term to be used in computing the [CP](#) and [BIC](#) statistics. If the SIGMA= option is not specified, an estimate from the full model is used. This option is available in the RSQUARE, ADJRSQ, and CP model-selection methods only.

SINGULAR=*n*

tunes the mechanism used to check for singularities. If you specify this option in the [MODEL](#) statement, it takes precedence over the SINGULAR= option in the [PROC REG](#) statement. The default value is machine dependent but is approximately $1\text{E-}7$ on most machines. This option is rarely needed. Singularity checking is described in the section “[Computational Methods](#)” on page 6740.

SLENTY=*value*

SLE=*value*

specifies the significance level for entry into the model used in the FORWARD and STEPWISE methods. The defaults are 0.50 for FORWARD and 0.15 for STEPWISE.

SLSTAY=*value*

SLS=*value*

specifies the significance level for staying in the model for the BACKWARD and STEPWISE methods. The defaults are 0.10 for BACKWARD and 0.15 for STEPWISE.

SP

outputs the S_p statistic for each model selected (Hocking 1976) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the SP statistic is also added to the SubsetSelSummary table.

SPEC

performs a test that the first and second moments of the model are correctly specified. See the section “Testing for Heteroscedasticity” on page 6732 for more information.

SS1

displays the sequential sums of squares (Type I SS) along with the parameter estimates for each term in the model. See Chapter 15, “The Four Types of Estimable Functions,” for more information about the different types of sums of squares.

SS2

displays the partial sums of squares (Type II SS) along with the parameter estimates for each term in the model. See the [SS1](#) option also.

SSE

computes the error sum of squares for each model selected.

START=s

is used to begin the comparing-and-switching process in the MAXR, MINR, and STEPWISE methods for a model containing the first s independent variables in the [MODEL](#) statement, where s is the START value. For these methods, the default is START=0.

For the RSQUARE, ADJRSQ, and CP methods, START= s specifies the smallest number of regressors to be reported in a subset model. For these methods, the default is START=1.

The START= option cannot be used with model-selection methods other than the six described here.

STB

produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor.

STOP=s

causes PROC REG to stop when it has found the “best” s -variable model, where s is the STOP value. For the RSQUARE, ADJRSQ, and CP methods, STOP= s specifies the largest number of regressors to be reported in a subset model. For the MAXR and MINR methods, STOP= s specifies the largest number of regressors to be included in the model.

The default setting for the STOP= option is the number of variables in the [MODEL](#) statement. This option can be used only with the MAXR, MINR, RSQUARE, ADJRSQ, and CP methods.

TOL

produces tolerance values for the estimates. Tolerance for a variable is defined as $1 - R^2$, where R square is obtained from the regression of the variable on all other regressors in the model. See the section “Collinearity Diagnostics” on page 6713 for more details.

VIF

produces variance inflation factors with the parameter estimates. Variance inflation is the reciprocal of tolerance. See the section “[Collinearity Diagnostics](#)” on page 6713 for more detail.

WHITE

See the [HCC](#) option.

XPX

displays the $X'X$ crossproducts matrix for the model. The crossproducts matrix is bordered by the $X'Y$ and $Y'Y$ matrices.

MTEST Statement

`<label> MTEST <equation <, ..., equation>> </options>;`

where each *equation* is a linear function composed of coefficients and variable names. The *label* is optional.

The MTEST statement is used to test hypotheses in multivariate regression models where there are several dependent variables fit to the same regressors. If no equations or options are specified, the MTEST statement tests the hypothesis that all estimated parameters except the intercept are zero.

The hypotheses that can be tested with the MTEST statement are of the form

$$(\mathbf{L}\boldsymbol{\beta} - \mathbf{c})\mathbf{M} = 0$$

where \mathbf{L} is a linear function on the regressor side, $\boldsymbol{\beta}$ is a matrix of parameters, \mathbf{c} is a column vector of constants, \mathbf{j} is a row vector of ones, and \mathbf{M} is a linear function on the dependent side. The special case where the constants are zero is

$$\mathbf{L}\boldsymbol{\beta}\mathbf{M} = 0$$

See the section “[Multivariate Tests](#)” on page 6734 for more details.

Each linear function extends across either the regressor variables or the dependent variables. If the equation is across the dependent variables, then the constant term, if specified, must be zero. The equations for the regressor variables form the \mathbf{L} matrix and \mathbf{c} vector in the preceding formula; the equations for dependent variables form the \mathbf{M} matrix. If no equations for the dependent variables are given, PROC REG uses an identity matrix for \mathbf{M} , testing the same hypothesis across all dependent variables. If no equations for the regressor variables are given, PROC REG forms a linear function corresponding to a test that all the nonintercept parameters are zero.

As an example, consider the following statements:

```
model y1 y2 y3=x1 x2 x3;
mtest x1,x2;
mtest y1-y2, y2 -y3, x1;
mtest y1-y2;
```

The first MTEST statement tests the hypothesis that the X1 and X2 parameters are zero for Y1, Y2, and Y3. In addition, the second MTEST statement tests the hypothesis that the X1 parameter is the same for all three dependent variables. For the same model, the third MTEST statement tests the hypothesis that all parameters except the intercept are the same for dependent variables Y1 and Y2.

You can specify the following options in the MTEST statement:

CANPRINT

displays the canonical correlations for the hypothesis combinations and the dependent variable combinations. If you specify

```
mtest / canprint;
```

the canonical correlations between the regressors and the dependent variables are displayed.

DETAILS

displays the **M** matrix and various intermediate calculations.

MSTAT=FAPPROX

MSTAT=EXACT

specifies the method of evaluating the multivariate test statistics. The default is MSTAT=FAPPROX, which specifies that the multivariate tests are evaluated by using the usual approximations based on the *F* distribution, as discussed in the “Multivariate Tests” section in Chapter 4, “[Introduction to Regression Procedures](#).” Alternatively, you can specify MSTAT=EXACT to compute exact *p*-values for three of the four tests (Wilks’ lambda, the Hotelling-Lawley trace, and Roy’s greatest root) and an improved *F* approximation for the fourth (Pillai’s trace). While MSTAT=EXACT provides better control of the significance probability for the tests, especially for Roy’s greatest root, computations for the exact *p*-values can be appreciably more demanding, and are in fact infeasible for large problems (many dependent variables). Thus, although MSTAT=EXACT is more accurate for most data, it is not the default method.

PRINT

displays the **H** and **E** matrices.

OUTPUT Statement

```
OUTPUT < OUT=SAS-data-set > < keyword=names > < ... keyword=names >;
```

The OUTPUT statement creates a new SAS data set that saves diagnostic measures calculated after fitting the model. The OUTPUT statement refers to the most recent [MODEL](#) statement. At least one *keyword=names* specification is required.

All the variables in the original data set are included in the new data set, along with variables created in the OUTPUT statement. These new variables contain the values of a variety of statistics and diagnostic measures that are calculated for each observation in the data set. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

The OUTPUT statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set for PROC REG. See the section “[Input Data Sets](#)” on page 6686 for more details.

The statistics created in the OUTPUT statement are described in this section. More details are given in the section “[Predicted and Residual Values](#)” on page 6708 and the section “[Influence Statistics](#)” on page 6717. Also see Chapter 4, “[Introduction to Regression Procedures](#),” for definitions of the statistics available from the REG procedure.

You can specify the following options in the OUTPUT statement:

OUT=SAS data set

gives the name of the new data set. By default, the procedure uses the `DATA n` convention to name the new data set.

keyword=names

specifies the statistics to include in the output data set and names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable or variables to contain the statistic.

In the output data set, the first variable listed after a keyword in the OUTPUT statement contains that statistic for the first dependent variable listed in the `MODEL` statement; the second variable contains the statistic for the second dependent variable in the `MODEL` statement, and so on. The list of variables following the equal sign can be shorter than the list of dependent variables in the `MODEL` statement. In this case, the procedure creates the new names in order of the dependent variables in the `MODEL` statement.

For example, the following SAS statements create an output data set named `b`:

```
proc reg data=a;
  model y z=x1 x2;
  output out=b
    p=yhat zhat
    r=yresid zresid;
run;
```

In addition to the variables in the input data set, `b` contains the following variables:

- `yhat`, with values that are predicted values of the dependent variable `y`
- `zhat`, with values that are predicted values of the dependent variable `z`
- `yresid`, with values that are the residual values of `y`
- `zresid`, with values that are the residual values of `z`

You can specify the following keywords in the OUTPUT statement. See the section “[Model Fit and Diagnostic Statistics](#)” on page 6715 for computational formulas.

Table 79.6 Keywords for OUTPUT Statement

Keyword	Description
COOKD=names	Cook’s D influence statistic
COVRATIO=names	standard influence of observation on covariance of betas, as discussed in the section “ Influence Statistics ” on page 6717
DFFITS=names	standard influence of observation on predicted value
H=names	leverage, $\mathbf{x}_i (\mathbf{X}'\mathbf{X})^{-1} \mathbf{x}_i'$

Table 79.6 *continued*

Keyword	Description
LCL= <i>names</i>	lower bound of a $100(1 - \alpha)\%$ confidence interval for an individual prediction. This includes the variance of the error, as well as the variance of the parameter estimates.
LCLM= <i>names</i>	lower bound of a $100(1 - \alpha)\%$ confidence interval for the expected value (mean) of the dependent variable
PREDICTED P= <i>names</i>	predicted values
PRESS= <i>names</i>	<i>i</i> th residual divided by $(1 - h)$, where <i>h</i> is the leverage, and where the model has been refit without the <i>i</i> th observation
RESIDUAL R= <i>names</i>	residuals, calculated as ACTUAL minus PREDICTED
RSTUDENT= <i>names</i>	a studentized residual with the current observation deleted
STDI= <i>names</i>	standard error of the individual predicted value
STDP= <i>names</i>	standard error of the mean predicted value
STDR= <i>names</i>	standard error of the residual
STUDENT= <i>names</i>	studentized residuals, which are the residuals divided by their standard errors
UCL= <i>names</i>	upper bound of a $100(1 - \alpha)\%$ confidence interval for an individual prediction
UCLM= <i>names</i>	upper bound of a $100(1 - \alpha)\%$ confidence interval for the expected value (mean) of the dependent variable

PAINT Statement

PAINT < *condition* | **ALLOBS** > < / *options* > ;

PAINT < **STATUS** | **UNDO** > ;

The PAINT statement is used with line printer plots. See the **PLOTS=** option for information about using ODS graphics to create modern statistical graphics.

The PAINT statement selects observations to be *painted* or highlighted in a scatter plot on line printer output; the PAINT statement is ignored if the LINEPRINTER option is not specified in the **PROC REG** statement.

All observations that satisfy *condition* are painted using some specific symbol. The PAINT statement does not generate a scatter plot and must be followed by a **PLOT** statement, which does generate a scatter plot. Several PAINT statements can be used before a **PLOT** statement, and all prior PAINT statement requests are applied to all later **PLOT** statements.

The PAINT statement lists the observation numbers of the observations selected, the total number of observations selected, and the plotting symbol used to paint the points.

On a plot, paint symbols take precedence over all other symbols. If any position contains more than one painted point, the paint symbol for the observation plotted last is used.

The PAINT statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set for PROC REG. Also, the PAINT statement cannot be used for models with more than

one dependent variable. Note that the syntax for the PAINT statement is the same as the syntax for the REWEIGHT statement.

Specifying Condition

Condition is used to select observations to be painted. The syntax of *condition* is

variable compare value

or

variable compare value *logical* *variable compare value*

where

variable is one of the following:

- a variable name in the input data set
- OBS., which is the observation number
- *keyword.*, where *keyword* is a keyword for a statistic requested in the OUTPUT statement

compare is an operator that compares *variable* to *value*. *Compare* can be any one of the following: <, <=, >, >=, =, ^ =. The operators LT, LE, GT, GE, EQ, and NE, respectively, can be used instead of the preceding symbols. See the “Expressions” section in *SAS Language Reference: Concepts* for more information about comparison operators.

value gives an unformatted value of *variable*. Observations are selected to be painted if they satisfy the condition created by *variable compare value*. *Value* can be a number or a character string. If *value* is a character string, it must be eight characters or less and must be enclosed in quotes. In addition, *value* is case-sensitive. In other words, the statements

```
paint name='henry';
```

and

```
paint name='Henry';
```

are not the same.

logical is one of two logical operators. Either AND or OR can be used. To specify AND, use AND or the symbol &. To specify OR, use OR or the symbol |.

Here are some examples of the *variable compare value* form:

```
paint name='Henry';
paint residual.>=20;
paint obs.=99;
```

Here are some examples of the *variable compare value* *logical* *variable compare value* form:

```

paint name='Henry'|name='Mary';
paint residual.>=20 or residual.<=10;
paint obs.>=11 and residual.<=20;

```

Using ALLOBS

Instead of specifying *condition*, the ALLOBS option can be used to select all observations. This is most useful when you want to unpaint all observations. For example,

```

paint allobs / reset;

```

resets the symbols for all observations.

Options in the PAINT Statement

The following options can be used when either a condition is specified, the ALLOBS option is specified, or nothing is specified before the slash. If only an option is listed, the option applies to the observations selected in the previous PAINT statement, *not* to the observations selected by reapplying the condition from the previous PAINT statement. For example, in the statements

```

paint r.>0 / symbol='a';
reweight r.>0;
refit;
paint / symbol='b';

```

the second PAINT statement paints only those observations selected in the first PAINT statement. No additional observations are painted even if, after refitting the model, there are new observations that meet the condition in the first PAINT statement.

NOTE: Options are not available when either the UNDO or STATUS option is used.

You can specify the following options after a slash (/).

NOLIST

suppresses the display of the selected observation numbers. If the NOLIST option is not specified, a list of observations selected is written to the log. The list includes the observation numbers and painting symbol used to paint the points. The total number of observations selected to be painted is also shown.

RESET

changes the painting symbol to the current default symbol, effectively unpainting the observations selected. If you set the default symbol by using the SYMBOL= option in the [PLOT](#) statement, the RESET option in the PAINT statement changes the painting symbol to the symbol you specified. Otherwise, the default symbol of '1' is used.

SYMBOL='character'

specifies a painting symbol. If the SYMBOL= option is omitted, the painting symbol is either the one used in the most recent PAINT statement or, if there are no previous PAINT statements, the symbol '@'. For example,

```
paint / symbol='#';
```

changes the painting symbol for the observations selected by the most recent PAINT statement to '#'. As another example,

```
paint temp lt 22 / symbol='c';
```

changes the painting symbol to 'c' for all observations with TEMP<22. In general, the numbers 1, 2, ..., 9 and the asterisk are not recommended as painting symbols. These symbols are used as default symbols in the PLOT statement, where they represent the number of replicates at a point. If SYMBOL="" is used, no painting is done in the current plot. If SYMBOL=' ' is used, observations are painted with a blank and are no longer seen on the plot.

STATUS and UNDO

Instead of specifying *condition* or the ALLOBS option, you can use the STATUS or UNDO option as follows:

STATUS

lists (in the log) the observation number and plotting symbol of all currently painted observations.

UNDO

undoes changes made by the most recent PAINT statement. Observations might be, but are not necessarily, unpainted. For example:

```
paint obs. <=10 / symbol='a';
...other interactive statements
paint obs.=1 / symbol='b';
...other interactive statements
paint undo;
```

The last PAINT statement changes the plotting symbol used for observation 1 back to 'a'. If the statement

```
paint / reset;
```

is used instead, observation 1 is unpainted.

PLOT Statement

```
PLOT <yvariable* xvariable> <=symbol> <...yvariable* xvariable> <=symbol> </options>;
```

The PLOT statement is used with line printer and traditional graphics. See the PLOTS= option for information about using ODS graphics to create modern statistical graphics.

The PLOT statement in PROC REG displays scatter plots with *yvariable* on the vertical axis and *xvariable* on the horizontal axis. Line printer plots are generated if the LINEPRINTER option is specified in the PROC

REG statement; otherwise, the traditional graphics are created. Points in line printer plots can be marked with *symbols*, while global graphics statements such as GOPTIONS and SYMBOL are used to enhance the traditional graphics. Note that the plots you request by using the PLOT statement are independent of the ODS graphical displays (see the section “ODS Graphics” on page 6745) that are available in PROC REG.

As with most other interactive statements, the PLOT statement implicitly refits the model. For example, if a PLOT statement is preceded by a REWEIGHT statement, the model is recomputed, and the plot reflects the new model.

If there are multiple MODEL statements preceding a PLOT statement, then the PLOT statement refers to the latest MODEL statement.

The PLOT statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as input to PROC REG.

You can specify several PLOT statements for each MODEL statement, and you can specify more than one plot in each PLOT statement.

Specifying Yvariables, Xvariables, and Symbol

More than one *yvariable***xvariable* pair can be specified to request multiple plots. The *yvariables* and *xvariables* can be as follows:

- any variables specified in the VAR or MODEL statement before the first RUN statement
- *keyword.*, where *keyword* is a regression diagnostic statistic available in the OUTPUT statement (see Table 79.7). For example,

```
plot predicted.*residual.;
```

generates one plot of the predicted values by the residuals for each dependent variable in the MODEL statement. These statistics can also be plotted against any of the variables in the VAR or MODEL statements.

- the keyword OBS. (the observation number), which can be plotted against any of the preceding variables
- the keyword NPP. or NQQ., which can be used with any of the preceding variables to construct normal P-P or Q-Q plots, respectively (see the section “Construction of Q-Q and P-P Plots” on page 6739 for more information)
- keywords for model fit summary statistics available in the OUTEST= data set with _TYPE_= PARMS (see Table 79.7). A SELECTION= method (other than NONE) must be requested in the MODEL statement for these variables to be plotted. If one member of a *yvariable***xvariable* pair is from the OUTEST= data set, the other member must also be from the OUTEST= data set.

The OUTPUT statement and the OUTEST= option are not required when their keywords are specified in the PLOT statement.

The *yvariable* and *xvariable* specifications can be replaced by a set of variables and statistics enclosed in parentheses. When this occurs, all possible combinations of *yvariable* and *xvariable* are generated. For example, the following two statements are equivalent:

```
plot (y1 y2)*(x1 x2);
plot y1*x1 y1*x2 y2*x1 y2*x2;
```

The statement

```
plot;
```

is equivalent to respecifying the most recent PLOT statement without any options. However, the line printer options COLLECT, HPLOTS=, SYMBOL=, and VPLOTS=, described in the section “[Line Printer Plots](#)” on page 6675, apply across PLOT statements and remain in effect if they have been previously specified.

Options used for the traditional graphics are described in the following section; see “[Line Printer Plots](#)” on page 6675 for more information.

Traditional Graphics

The display of traditional graphics is described in the following paragraphs, the options are summarized in [Table 79.7](#) and described in the section “[Dictionary of PLOT Statement Options](#)” on page 6671.

Several line printer statements and options are not supported for the traditional graphics. In particular the PAINT statement is disabled, as are the PLOT statement options CLEAR, COLLECT, HPLOTS=, NOCOLLECT, SYMBOL=, and VPLOTS=. To display more than one plot per page or to collect plots from multiple PLOT statements, use the PROC GREPLAY statement (see *SAS/GRAPH: Reference*). Also note that traditional graphics options are not recognized for line printer plots.

The fitted model equation and a label are displayed in the top margin of the plot; this display can be suppressed with the NOMODEL option. If the label is requested but cannot fit on one line, it is not displayed. The equation and label are displayed on one line when possible; if more lines are required, the label is displayed in the first line with the model equation in successive lines. If displaying the entire equation causes the plot to be unacceptably small, the equation is truncated. [Table 79.8](#) lists options to control the display of the equation.

Four statistics are displayed by default in the right margin: the number of observations, R square, the adjusted R square, and the root mean square error. The display of these statistics can be suppressed with the NOSTAT option. You can specify other options to request the display of various statistics in the right margin; see [Table 79.8](#).

A default reference line at zero is displayed if residuals are plotted. If the dependent variable is plotted against the independent variable in a simple linear regression model, the fitted regression line is displayed by default. Default reference lines can be suppressed with the NOLINE option; the lines are not displayed if the OVERLAY option is specified.

Specialized plots are requested with special options. For each coefficient, the RIDGEPLOT option plots the ridge estimates against the ridge values k ; see the description of the RIDGEPLOT option in the section “[Dictionary of PLOT Statement Options](#)” on page 6671 for more details. The CONF option plots $100(1 - \alpha)\%$ confidence intervals for the mean while the PRED option plots $100(1 - \alpha)\%$ prediction intervals; see the description of these options in the section “[Dictionary of PLOT Statement Options](#)” on page 6671 for more details.

If a SELECTION= method is requested, the fitted model equation and the statistics displayed in the margin correspond to the selected model. For the ADJR SQ and CP methods, the selected model is treated as a submodel of the full model. If a CP.*NP. plot is requested, the CHOCKING= and CMALLOWS= options display model selection reference lines; see the descriptions of these options in the section “[Dictionary of PLOT Statement Options](#)” on page 6671 for more details.

PLOT Statement variable Keywords

The following table lists the keywords available as PLOT statement *xvariables* and *yvariables*. All keywords have a trailing dot; for example, “*COOKD.*” requests Cook’s *D* statistic. Neither the **OUTPUT** statement nor the **OUTEST=** option needs to be specified.

Table 79.7 Keywords for PLOT Statement *xvariables*

Keyword	Description
Diagnostic Statistics	
COOKD.	Cook’s <i>D</i> influence statistics
COVRATIO.	standard influence of observation on covariance of betas
DFFITS.	standard influence of observation on predicted value
H.	leverage
LCL.	lower bound of $100(1 - \alpha)\%$ confidence interval for individual prediction
LCLM.	lower bound of $100(1 - \alpha)\%$ confidence interval for the mean of the dependent variable
PREDICTED.	predicted values
PRED. P.	
PRESS.	residuals from refitting the model with current observation deleted
RESIDUAL. R.	residuals
RSTUDENT.	studentized residuals with the current observation deleted
STDI.	standard error of the individual predicted value
STDP.	standard error of the mean predicted value
STDR.	standard error of the residual
STUDENT.	residuals divided by their standard errors
UCL.	upper bound of $100(1 - \alpha)\%$ confidence interval for individual prediction
UCLM.	upper bound of $100(1 - \alpha)\%$ confidence interval for the mean of the dependent variables
Other Keywords Used with Diagnostic Statistics	
NPP.	normal probability-probability plot
NQQ.	normal quantile-quantile plot
OBS.	observation number (cannot plot against OUTEST= statistics)
Model Fit Summary Statistics	
ADJRSQ.	adjusted R-square
AIC.	Akaike’s information criterion
BIC.	Sawa’s Bayesian information criterion
CP.	Mallows’ C_p statistic
EDF.	error degrees of freedom
GMSEP.	estimated MSE of prediction, assuming multivariate normality
IN.	number of regressors in the model not including the intercept
JP.	final prediction error
MSE.	mean squared error
NP.	number of parameters in the model (including the intercept)
PC.	Amemiya’s prediction criterion
RMSE.	root MSE

Table 79.7 *continued*

Keyword	Description
RSQ.	R-square
SBC.	SBC statistic
SP.	SP statistic
SSE.	error sum of squares

Summary of PLOT Statement Graphics Options

Table 79.8 summarizes the *options* available in the PLOT statement. These *options* are available unless the LINEPRINTER option is specified in the PROC REG statement. For complete descriptions, see the section “Dictionary of PLOT Statement Options” on page 6671.

Table 79.8 Traditional Graphics Options

Option	Description
General Graphics Options	
ANNOTATE=	Specifies the annotate data set
<i>SAS-data-set</i>	
CHOCKING= <i>color</i>	Requests a reference line for C_p model selection criteria
CMALLOWS= <i>color</i>	Requests a reference line for the C_p model selection criterion
CONF	Requests plots of $100(1 - \alpha)\%$ confidence intervals for the mean
DESCRIPTION=	Specifies a description for graphics catalog member
<i>'string'</i>	
NAME= <i>'string'</i>	Names the plot in the graphics catalog
OVERLAY	Overlays plots from the same model
PRED	Requests plots of $100(1 - \alpha)\%$ prediction intervals for individual responses
RIDGEPLOT	Requests the ridge trace for ridge regression
Axis and Legend Options	
LEGEND= <i>LEGENDn</i>	Specifies LEGEND statement to be used
NOLEGEND	Suppresses display of the legend
HAXIS= <i>values</i>	Specifies tick mark values for horizontal axis
VAXIS= <i>values</i>	Specifies tick mark values for vertical axis
Reference Line Options	
HREF= <i>values</i>	Specifies reference lines perpendicular to horizontal axis
LHREF= <i>linetype</i>	Specifies line style for HREF= lines
LLINE= <i>linetype</i>	Specifies line style for lines displayed by default
LVREF= <i>linetype</i>	Specifies line style for VREF= lines
NOLINE	Suppresses display of any default reference line
VREF= <i>values</i>	Specifies reference lines perpendicular to vertical axis
Color Options	
CAXIS= <i>color</i>	Specifies color for axis line and tick marks
CFRAME= <i>color</i>	Specifies color for frame
CHREF= <i>color</i>	Specifies color for HREF= lines
CLINE= <i>color</i>	Specifies color for lines displayed by default
CTEXT= <i>color</i>	Specifies color for text

Table 79.8 *continued*

Option	Description
CVREF= <i>color</i>	Specifies color for VREF= lines
Options for Displaying the Fitted Model Equation	
MODELFONT= <i>font</i>	Specifies font of model equation and model label
MODELHT= <i>value</i>	Specifies text height of model equation and model label
MODELLAB= <i>'label'</i>	Specifies model label
NOMODEL	Suppresses display of the fitted model and the label
Options for Displaying Statistics in the Plot Margin	
AIC	Displays Akaike's information criterion
BIC	Displays Sawa's Bayesian information criterion
CP	Displays Mallows' C_p statistic
EDF	Displays the error degrees of freedom
GMSEP	Displays the estimated MSE of prediction assuming multivariate normality
IN	Displays the number of regressors in the model not including the intercept
JP	Displays the J_p statistic
MSE	Displays the mean squared error
NOSTAT	Suppresses display of the default statistics: the number of observations, R-square, adjusted R-square, and root mean square error
NP	Displays the number of parameters in the model including the intercept, if any
PC	Displays the PC statistic
SBC	Displays the SBC statistic
SP	Displays the S_p statistic
SSE	Displays the error sum of squares
STATFONT= <i>font</i>	Specifies font of text displayed in the margin
STATHT= <i>value</i>	Specifies height of text displayed in the margin

Dictionary of PLOT Statement Options

The following entries describe the PLOT statement *options* in detail. Note that these *options* are available unless you specify the LINEPRINTER option in the PROC REG statement.

AIC

displays Akaike's information criterion in the plot margin.

ANNOTATE=SAS-data-set**ANNO=SAS-data-set**

specifies an input data set that contains appropriate variables for annotation. This applies only to displays created with the current PLOT statement. See *SAS/GRAPH: Reference* for more information.

BIC

displays Sawa's Bayesian information criterion in the plot margin.

CAXIS=*color*

CAXES=*color*

CA=*color*

specifies the color for the axes, frame, and tick marks.

CFRAME=*color*

CFR=*color*

specifies the color for filling the area enclosed by the axes and the frame.

CHOCKING=*color*

requests reference lines corresponding to the equations $C_p = p$ and $C_p = 2p - p_{full}$, where p_{full} is the number of parameters in the full model (excluding the intercept) and p is the number of parameters in the subset model (including the intercept). The *color* must be specified; the $C_p = p$ line is solid and the $C_p = 2p - p_{full}$ line is dashed. Only PLOT statements of the form PLOT CP.*NP. produce these lines.

For the purpose of parameter estimation, Hocking (1976) suggests selecting a model where $C_p \leq 2p - p_{full}$. For the purpose of prediction, Hocking suggests the criterion $C_p \leq p$. You can request the single reference line $C_p = p$ with the CMALLOWS= option. If, for example, you specify both CHOCKING=RED and CMALLOWS=BLUE, then the $C_p = 2p - p_{full}$ line is red and the $C_p = p$ line is blue.

CHREF=*color*

CH=*color*

specifies the color for lines requested with the HREF= option.

CLINE=*color*

CL=*color*

specifies the color for lines displayed by default. See the [NOLINE](#) option for details.

CMALLOWS=*color*

requests a $C_p = p$ reference line, where p is the number of parameters (including the intercept) in the subset model. The *color* must be specified; the line is solid. Only PLOT statements of the form PLOT CP.*NP. produce this line.

Mallows (1973) suggests that all subset models with C_p small and near p be considered for further study. See the [CHOCKING=](#) option for related model-selection criteria.

CONF

is a keyword used as a shorthand option to request plots that include $(100 - \alpha)\%$ confidence intervals for the mean response. The ALPHA= option in the [PROC REG](#) or [MODEL](#) statement selects the significance level α , which is 0.05 by default. The CONF option is valid for simple regression models only, and is ignored for plots where confidence intervals are inappropriate. The CONF option replaces the CONF95 option; however, the CONF95 option is still supported when the ALPHA= option is not specified. The OVERLAY option is ignored when the CONF option is specified.

CP

displays Mallows' C_p statistic in the plot margin.

CTEXT=*color*

CT=*color*

specifies the color for text including tick mark labels, axis labels, the fitted model label and equation, the statistics displayed in the margin, and legends.

CVREF=*color*

CV=*color*

specifies the color for lines requested with the VREF= option.

DESCRIPTION=*'string'*

DESC=*'string'*

specifies a descriptive string, up to 40 characters, that appears in the description field of the PROC GREPLAY master menu.

EDF

displays the error degrees of freedom in the plot margin.

GMSEP

displays the estimated mean square error of prediction in the plot margin. Note that the estimate is calculated under the assumption that both independent and dependent variables have a multivariate normal distribution.

HAXIS=*values*

HA=*values*

specifies tick mark values for the horizontal axis.

HREF=*values*

specifies where reference lines perpendicular to the horizontal axis are to appear.

IN

displays the number of regressors in the model (not including the intercept) in the plot margin.

JP

displays the J_p statistic in the plot margin.

LEGEND=**LEGEND***n*

specifies the **LEGEND***n* statement to be used. The **LEGEND***n* statement is a global graphics statement; see *SAS/GRAPH: Reference* for more information.

LHREF=*linetype*

LH=*linetype*

specifies the line style for lines requested with the HREF= option. The default *linetype* is 2. Note that LHREF=1 requests a solid line. See *SAS/GRAPH: Reference* for a table of available line types.

LLINE=*linetype*

LL=*linetype*

specifies the line style for reference lines displayed by default; see the **NOLINE** option for details. The default *linetype* is 2. Note that LLINE=1 requests a solid line.

LVREF=*linetype*

LV=*linetype*

specifies the line style for lines requested with the VREF= option. The default *linetype* is 2. Note that LVREF=1 requests a solid line.

MODELFONT=*font*

specifies the font used for displaying the fitted model label and the fitted model equation. See *SAS/GRAPH: Reference* for tables of software fonts.

MODELHT=*height*

specifies the text height for the fitted model label and the fitted model equation.

MODELLAB='*label*'

specifies the label to be displayed with the fitted model equation. By default, no label is displayed. If the label does not fit on one line, it is not displayed. See the section “[Traditional Graphics](#)” on page 6668 for more information.

MSE

displays the mean squared error in the plot margin.

NAME='*string*'

specifies a descriptive string, up to eight characters, that appears in the name field of the PROC GREPLAY master menu. The default *string* is REG.

NOLEGEND

suppresses the display of the legend.

NOLINE

suppresses the display of default reference lines. A default reference line at zero is displayed if residuals are plotted. If the dependent variable is plotted against the independent variable in a simple regression model, then the fitted regression line is displayed by default. Default reference lines are not displayed if the OVERLAY option is specified.

NOMODEL

suppresses the display of the fitted model equation.

NOSTAT

suppresses the display of statistics in the plot margin. By default, the number of observations, R-square, adjusted R-square, and root MSE are displayed.

NP

displays the number of regressors in the model including the intercept, if any, in the plot margin.

OVERLAY

overlays all plots specified in the PLOT statement from the same model on one set of axes. The variables for the first plot label the axes. The procedure automatically scales the axes to fit all of the variables unless the HAXIS= or VAXIS= option is used. Default reference lines are not displayed. A default legend is produced; the LEGEND= option can be used to customize the legend.

PC

displays the PC statistic in the plot margin.

PRED

is a keyword used as a shorthand option to request plots that include $(100 - \alpha)\%$ prediction intervals for individual responses. The ALPHA= option in the **PROC REG** or **MODEL** statement selects the significance level α , which is 0.05 by default. The PRED option is valid for simple regression models only, and is ignored for plots where prediction intervals are inappropriate. The PRED option replaces the PRED95 option; however, the PRED95 option is still supported when the ALPHA= option is not specified. The OVERLAY option is ignored when the PRED option is specified.

RIDGEPLOT

creates overlaid plots of ridge estimates against ridge values for each coefficient. The points corresponding to the estimates of each coefficient in the plot are connected by lines. For ridge estimates to be computed and plotted, the OUTEST= option must be specified in the **PROC REG** statement, and the RIDGE=list must be specified in either the **PROC REG** or **MODEL** statement.

SBC

displays the SBC statistic in the plot margin.

SP

displays the S_p statistic in the plot margin.

SSE

displays the error sum of squares in the plot margin.

STATFONT=font

specifies the font used for displaying the statistics that appear in the plot margin. See *SAS/GRAPH: Reference* for tables of software fonts.

STATHT=height

specifies the text height of the statistics that appear in the plot margin.

USEALL

specifies that predicted values at data points with missing dependent variable(s) be included on appropriate plots. By default, only points used in constructing the SSCP matrix appear on plots.

VAXIS=values**VA=values**

specifies tick mark values for the vertical axis.

VREF=values

specifies where reference lines perpendicular to the vertical axis are to appear.

Line Printer Plots

Line printer plots are requested with the LINEPRINTER option in the **PROC REG** statement. Points in line printer plots can be marked with *symbols*, which can be specified as a single character enclosed in quotes or the name of any variable in the input data set.

If a character variable is used for the symbol, the first (leftmost) nonblank character in the formatted value of the variable is used as the plotting symbol. If a character in quotes is specified, that character becomes

the plotting symbol. If a character is used as the plotting symbol, and if there are different plotting symbols needed at the same point, the symbol '?' is used at that point.

If an unformatted numeric variable is used for the symbol, the symbols '1', '2', ..., '9' are used for variable values 1, 2, ..., 9. For noninteger values, only the integer portion is used as the plotting symbol. For values of 10 or greater, the symbol '*' is used. For negative values, a '?' is used. If a numeric variable is used, and if there is more than one plotting symbol needed at the same point, the sum of the variable values is used at that point. If the sum exceeds 9, the symbol '*' is used.

If a symbol is not specified, the number of replicates at the point is displayed. The symbol '*' is used if there are 10 or more replicates.

If the LINEPRINTER option is used, you can specify the following options in the PLOT statement after a slash (/):

CLEAR

clears any collected scatter plots before plotting begins but does not turn off the COLLECT option. Use this option when you want to begin a new collection with the plots in the current PLOT statement. For more information about collecting plots, see the [COLLECT](#) and [NOCOLLECT](#) options in this section.

COLLECT

specifies that plots begin to be collected from one PLOT statement to the next and that subsequent plots show an overlay of all collected plots. This option enables you to overlay plots before and after changes to the model or to the data used to fit the model. Plots collected before changes are unaffected by the changes and can be overlaid on later plots. You can request more than one plot with this option, and you do not need to request the same number of plots in subsequent PLOT statements. If you specify an unequal number of plots, plots in corresponding positions are overlaid. For example, the statements

```
plot residual.*predicted. y*x / collect;
run;
```

produce two plots. If these statements are then followed by

```
plot residual.*x;
run;
```

two plots are again produced. The first plot shows residual against X values overlaid on residual against predicted values. The second plot is the same as that produced by the first PLOT statement.

Axes are scaled for the first plot or plots collected. The axes are not rescaled as more plots are collected.

Once specified, the COLLECT option remains in effect until the [NOCOLLECT](#) option is specified.

HPLOTS=number

sets the number of scatter plots that can be displayed across the page. The procedure begins with one plot per page. The value of the HPLOTS= option remains in effect until you change it in a later PLOT statement. See the [VPLOTS=](#) option for an example.

NOCOLLECT

specifies that the collection of scatter plots ends after adding the plots in the current PLOT statement. PROC REG starts with the NOCOLLECT option in effect. After you specify the NOCOLLECT option, any following PLOT statement produces a new plot that contains only the plots requested by that PLOT statement.

For more information, see the [COLLECT](#) option.

OVERLAY

enables requested scatter plots to be superimposed. The axes are scaled so that points on all plots are shown. If the HPLOTS= or VPLOTS= option is set to more than one, the overlaid plot occupies the first position on the page. The OVERLAY option is similar to the COLLECT option in that both options produce superimposed plots. However, OVERLAY superimposes only the plots in the associated PLOT statement; COLLECT superimposes plots across PLOT statements. The OVERLAY option can be used when the COLLECT option is in effect.

SYMBOL='character'

changes the default plotting symbol used for all scatter plots produced in the current and in subsequent PLOT statements. Both SYMBOL="" and SYMBOL=' ' are allowed.

If the SYMBOL= option has not been specified, the default symbol is '1' for positions with one observation, '2' for positions with two observations, and so on. For positions with more than 9 observations, '*' is used. The SYMBOL= option (or a plotting symbol) is needed to avoid any confusion caused by this default convention. Specifying a particular symbol is especially important when either the OVERLAY or COLLECT option is being used.

If you specify the SYMBOL= option and use a number for *character*, that number is used for all points in the plot. For example, the statement

```
plot y*x / symbol='1';
```

produces a plot with the symbol '1' used for all points.

If you specify a plotting symbol and the SYMBOL= option, the plotting symbol overrides the SYMBOL= option. For example, in the statements

```
plot y*x y*v='.' / symbol='*';
```

the symbol used for the plot of Y against X is '*', and a '.' is used for the plot of Y against V.

If a paint symbol is defined with a [PAINT](#) statement, the paint symbol takes precedence over both the SYMBOL= option and the default plotting symbol for the PLOT statement.

VPLOTS=number

sets the number of scatter plots that can be displayed down the page. The procedure begins with one plot per page. The value of the VPLOTS= option remains in effect until you change it in a later PLOT statement.

For example, to specify a total of six plots per page, with two rows of three plots, use the HPLOTS= and VPLOTS= options as follows:

```
plot y1*x1 y1*x2 y1*x3 y2*x1 y2*x2 y2*x3 /
      hplots=3 vplots=2;
run;
```

PRINT Statement

PRINT <options> <ANOVA> <MODELDATA> ;

The PRINT statement enables you to interactively display the results of **MODEL** statement options, produce an ANOVA table, display the data for variables used in the current model, or redisplay the options specified in a **MODEL** or a previous PRINT statement. In addition, like most other interactive statements in PROC REG, the PRINT statement implicitly refits the model; thus, effects of **REWEIGHT** statements are seen in the resulting tables. If ODS Graphics is enabled (see the section “**ODS Graphics**” on page 6745), the PRINT statement also requests the use of the ODS graphical displays associated with the current model.

The following specifications can appear in the PRINT statement:

options

interactively displays the results of **MODEL** statement options, where *options* is one or more of the following: ACOV, ALL, CLI, CLM, COLLIN, COLLINOINT, CORRB, COVB, DW, I, INFLUENCE, P, PARTIAL, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, or XPX. See the section “**MODEL Statement**” on page 6649 for a description of these options.

ANOVA

produces the ANOVA table associated with the current model. This is either the model specified in the last **MODEL** statement or the model that incorporates changes made by **ADD**, **DELETE**, or **REWEIGHT** statements after the last **MODEL** statement.

MODELDATA

displays the data for variables used in the current model.

Use the statement

```
print;
```

to reprint options in the most recently specified PRINT or **MODEL** statement.

Options that require original data values, such as R or INFLUENCE, cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set to PROC REG. See the section “**Input Data Sets**” on page 6686 for more detail.

REFIT Statement

REFIT ;

The REFIT statement causes the current model and corresponding statistics to be recomputed immediately. No output is generated by this statement. The REFIT statement is needed after one or more **REWEIGHT**

statements to cause them to take effect before subsequent **PAINT** or **REWEIGHT** statements. This is sometimes necessary when you are using statistical conditions in **REWEIGHT** statements. For example, consider the following statements:

```
paint student.>2;
plot student.*p.;
reweight student.>2;
refit;
paint student.>2;
plot student.*p.;
```

The second **PAINT** statement paints any additional observations that meet the condition after deleting observations and refitting the model. The **REFIT** statement is used because the **REWEIGHT** statement does not cause the model to be recomputed. In this particular example, the same effect could be achieved by replacing the **REFIT** statement with a **PLOT** statement.

Most interactive statements can be used to implicitly refit the model; any plots or statistics produced by these statements reflect changes made to the model and changes made to the data used to compute the model. The two exceptions are the **PAINT** and **REWEIGHT** statements, which do not cause the model to be recomputed.

RESTRICT Statement

RESTRICT *equation* <, ..., *equation* > ;

A **RESTRICT** statement is used to place restrictions on the parameter estimates in the **MODEL** preceding it. More than one **RESTRICT** statement can follow each **MODEL** statement. Each **RESTRICT** statement replaces any previous **RESTRICT** statement. To lift all restrictions on a model, submit a new **MODEL** statement. If there are several restrictions, separate them with commas. The statement

```
restrict equation1=equation2=equation3;
```

is equivalent to imposing the two restrictions

```
restrict equation1=equation2;
restrict equation2=equation3;
```

Each restriction is written as a linear equation and can be written as

equation

or

equation = *equation*

The form of each *equation* is

$$c_1 \times \text{variable}_1 \pm c_2 \times \text{variable}_2 \pm \cdots \pm c_n \times \text{variable}_n$$

where the c_j 's are constants and the *variable_j*'s are any regressor variables.

When no equal sign appears, the linear combination is set equal to zero. Each variable name mentioned must be a variable in the **MODEL** statement to which the **RESTRICT** statement refers. The keyword **INTERCEPT** can also be used as a variable name, and it refers to the intercept parameter in the regression model.

Note that the parameters associated with the variables are restricted, not the variables themselves. Restrictions should be consistent and not redundant.

Examples of valid **RESTRICT** statements include the following:

```
restrict x1;
restrict a+b=1;
restrict a=b=c;
restrict a=b, b=c;
restrict 2*f=g+h, intercept+f=0;
restrict f=g=h=intercept;
```

The third and fourth statements in this list produce identical restrictions. You cannot specify

```
restrict f-g=0,
           f-intercept=0,
           g-intercept=1;
```

because the three restrictions are not consistent. If these restrictions are included in a **RESTRICT** statement, one of the restrict parameters is set to zero and has zero degrees of freedom, indicating that PROC REG is unable to apply a restriction.

The restrictions usually operate even if the model is not of full rank. Check to ensure that $DF = -1$ for each restriction. In addition, the model DF should decrease by 1 for each restriction.

The parameter estimates are those that minimize the quadratic criterion (SSE) subject to the restrictions. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as zero.

The method used for restricting the parameter estimates is to introduce a Lagrangian parameter for each restriction (Pringle and Rayner 1971). The estimates of these parameters are displayed with test statistics. Note that the t statistic reported for the Lagrangian parameters does not follow a Student's t distribution, but its square follows a beta distribution (LaMotte 1994). The p -value for these parameters is computed using the beta distribution.

The Lagrangian parameter γ measures the sensitivity of the SSE to the restriction constant. If the restriction constant is changed by a small amount ϵ , the SSE is changed by $2\gamma\epsilon$. The t ratio tests the significance of the restrictions. If γ is zero, the restricted estimates are the same as the unrestricted estimates, and a change in the restriction constant in either direction increases the SSE.

RESTRICT statements are ignored if the **PCOMIT=** or **RIDGE=** option is specified in the **PROC REG** statement.

REWEIGHT Statement

```
REWEIGHT <condition | ALLOBS> </options>;
REWEIGHT <STATUS | UNDO>;
```

The REWEIGHT statement interactively changes the weights of observations that are used in computing the regression equation. The REWEIGHT statement can change observation weights, or set them to zero, which causes selected observations to be excluded from the analysis. When a REWEIGHT statement sets observation weights to zero, the observations are not deleted from the data set. More than one REWEIGHT statement can be used. The requests from all REWEIGHT statements are applied to the subsequent statements. Each use of the REWEIGHT statement modifies the MODEL label.

The model and corresponding statistics are not recomputed after a REWEIGHT statement. For example, consider the following statements:

```
reweight r.>0;
reweight r.>0;
```

The second REWEIGHT statement does not exclude any additional observations since the model is not recomputed after the first REWEIGHT statement. Either use a [REFIT](#) statement to explicitly refit the model, or implicitly refit the model by following the REWEIGHT statement with any other interactive statement except a [PAINT](#) statement or another REWEIGHT statement.

The REWEIGHT statement cannot be used if a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as an input data set to PROC REG. Note that the syntax used in the REWEIGHT statement is the same as the syntax in the [PAINT](#) statement.

The syntax of the REWEIGHT statement is described in the following sections.

For detailed examples of using this statement, see the section “[Reweighting Observations in an Analysis](#)” on page 6726.

Specifying Condition

Condition is used to find observations to be reweighted. The syntax of *condition* is

variable compare value

or

variable compare value *logical* *variable compare value*

where

variable is one of the following:

- a variable name in the input data set
- OBS., which is the observation number
- *keyword.*, where *keyword* is a keyword for a statistic requested in the [OUTPUT](#) statement. The keyword specification is applied to all dependent variables in the model.

compare is an operator that compares *variable* to *value*. *Compare* can be any one of the following: <, <=, >, >=, =, ^ =. The operators LT, LE, GT, GE, EQ, and NE, respectively, can be used instead of the preceding symbols. See the “Expressions” chapter in *SAS Language Reference: Concepts* for more information about comparison operators.

value gives an unformatted value of *variable*. Observations are selected to be reweighted if they satisfy the condition created by *variable compare value*. *Value* can be a number or a character string. If *value* is a character string, it must be eight characters or less and must be enclosed in quotes. In addition, *value* is case-sensitive. In other words, the following two statements are not the same:

```
reweight name='steve';
```

```
reweight name='Steve';
```

logical is one of two logical operators. Either AND or OR can be used. To specify AND, use AND or the symbol &. To specify OR, use OR or the symbol |.

Here are some examples of the *variable compare value* form:

```
reweight obs. le 10;
reweight temp=55;
reweight type='new';
```

Here are some example of the *variable compare value logical variable compare value* form:

```
reweight obs.<=10 and residual.<2;
reweight student.<-2 or student.>2;
reweight name='Mary' | name='Susan';
```

Using ALLOBS

Instead of specifying *condition*, you can use the ALLOBS option to select all observations. This is most useful when you want to restore the original weights of all observations. For example,

```
reweight allobs / reset;
```

resets weights for all observations and uses all observations in the subsequent analysis. Note that

```
reweight allobs;
```

specifies that all observations be excluded from analysis. Consequently, using ALLOBS is useful only if you also use one of the options discussed in the following section.

Options in the REWEIGHT Statement

The following options can be used when either a condition, ALLOBS, or nothing is specified before the slash. If only an option is listed, the option applies to the observations selected in the previous REWEIGHT statement, not to the observations selected by reapplying the condition from the previous REWEIGHT statement. For example, consider the following statements:

```
reweight r.>0 / weight=0.1;
refit;
reweight;
```

The second **REWEIGHT** statement excludes from the analysis only those observations selected in the first **REWEIGHT** statement. No additional observations are excluded even if there are new observations that meet the condition in the first **REWEIGHT** statement.

NOTE: Options are not available when either the **UNDO** or **STATUS** option is used.

NOLIST

suppresses the display of the selected observation numbers. If you omit the **NOLIST** option, a list of observations selected is written to the log.

RESET

resets the observation weights to their original values as defined by the **WEIGHT** statement or to **WEIGHT=1** if no **WEIGHT** statement is specified. For example,

```
reweight / reset;
```

resets observation weights to the original weights in the data set. If previous **REWEIGHT** statements have been submitted, this **REWEIGHT** statement applies only to the observations selected by the previous **REWEIGHT** statement. Note that, although the **RESET** option does reset observation weights to their original values, it does not cause the model and corresponding statistics to be recomputed.

WEIGHT=value

changes observation weights to the specified nonnegative real number. If you omit the **WEIGHT=** option, the observation weights are set to zero, and observations are excluded from the analysis. For example:

```
reweight name='Alan';
...other interactive statements
reweight / weight=0.5;
```

The first **REWEIGHT** statement changes weights to zero for all observations with **name='Alan'**, effectively deleting these observations. The subsequent analysis does not include these observations. The second **REWEIGHT** statement applies only to those observations selected by the previous **REWEIGHT** statement, and it changes the weights to 0.5 for all the observations with **NAME='Alan'**. Thus, the next analysis includes all original observations; however, those observations with **NAME='Alan'** have their weights set to 0.5.

STATUS and UNDO

If you omit *condition* and the **ALLOBS** options, you can specify one of the following options.

STATUS

writes to the log the observation's number and the weight of all reweighted observations. If an observation's weight has been set to zero, it is reported as deleted. However, the observation is not deleted from the data set, only from the analysis.

UNDO

undoes the changes made by the most recent **REWEIGHT** statement. Weights might be, but are not necessarily, reset. For example, consider the following statements:

```

reweight student.>2 / weight=0.1;
reweight;
reweight undo;

```

The first **REWEIGHT** statement sets the weights of observations that satisfy the condition to 0.1. The second **REWEIGHT** statement sets the weights of the same observations to zero. The third **REWEIGHT** statement undoes the second, changing the weights back to 0.1.

STORE Statement

STORE < **OUT=** > *item-store-name* < / **LABEL=** 'label' > ;

The **STORE** statement requests that the procedure save the estimated parameters of the fitted model. The resulting item store is a binary file format that cannot be modified. The contents of the item store can be processed with the **PLM** procedure.

For details about the syntax of the **STORE** statement, see the section “**STORE Statement**” on page 501 of Chapter 19, “**Shared Concepts and Topics**.”

NOTE: The information stored by the **STORE** statement in **PROC REG** is a subset of what is usually stored by other procedures that implement this statement. In particular, **PROC REG** stores only the estimated parameters of the model, so that you can later use the **CODE** statement in **PROC PLM** to write SAS DATA step code for prediction to a file or catalog entry. With only this subset of information, many other postprocessing features of **PROC PLM** are not available for item stores that are created by **PROC REG**.

TEST Statement

< *label* : > **TEST** *equation*, < , . . . , *equation* > < / *option* > ;

The **TEST** statement tests hypotheses about the parameters estimated in the preceding **MODEL** statement. It has the same syntax as the **RESTRICT** statement except that it supports an option. Each equation specifies a linear hypothesis to be tested. The rows of the hypothesis are separated by commas.

Variable names must correspond to regressors, and each variable name represents the coefficient of the corresponding variable in the model. An optional label is useful to identify each test with a name. The keyword **INTERCEPT** can be used instead of a variable name to refer to the model’s intercept.

The **REG** procedure performs an *F* test for the joint hypotheses specified in a single **TEST** statement. More than one **TEST** statement can accompany a **MODEL** statement. The numerator is the usual quadratic form of the estimates; the denominator is the mean squared error. If hypotheses can be represented by

$$\mathbf{L}\boldsymbol{\beta} = \mathbf{c}$$

then the numerator of the *F* test is

$$\mathbf{Q} = (\mathbf{L}\mathbf{b} - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}\mathbf{b} - \mathbf{c})$$

divided by degrees of freedom, where **b** is the estimate of β . For example:

```
model y=a1 a2 b1 b2;
applus: test a1+a2=1;
b1:      test b1=0, b2=0;
b2:      test b1, b2;
```

The last two statements are equivalent; since no constant is specified, zero is assumed.

Note that, when the **ACOV**, **HCC**, or **WHITE** option is specified in the **MODEL** statement, tests are recomputed using the heteroscedasticity-consistent covariance matrix specified with the **HCCMETHOD=** option in the **MODEL** statement (see the section “Testing for Heteroscedasticity” on page 6732).

One option can be specified in the **TEST** statement after a slash (/):

PRINT

displays intermediate calculations. This includes $L(X'X)^{-1}L'$ bordered by $Lb - c$, and $(L(X'X)^{-1}L')^{-1}$ bordered by $(L(X'X)^{-1}L')^{-1}(Lb - c)$.

VAR Statement

VAR *variables* ;

The **VAR** statement is used to include numeric variables in the crossproducts matrix that are not specified in the first **MODEL** statement.

Variables not listed in **MODEL** statements before the first **RUN** statement must be listed in the **VAR** statement if you want the ability to add them interactively to the model with an **ADD** statement, to include them in a new **MODEL** statement, or to plot them in a scatter plot with the **PLOT** statement.

In addition, if you want to use options in the **PROC REG** statement and do not want to fit a model to the data (with a **MODEL** statement), you must use a **VAR** statement.

WEIGHT Statement

WEIGHT *variable* ;

A **WEIGHT** statement names a variable in the input data set with values that are relative weights for a weighted least squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, then the weighted estimates are the best linear unbiased estimates (BLUE).

Values of the weight variable must be nonnegative. If an observation's weight is zero, the observation is deleted from the analysis. If a weight is negative or missing, it is set to zero, and the observation is excluded from the analysis. A more complete description of the **WEIGHT** statement can be found in Chapter 42, “The GLM Procedure.”

Observation weights can be changed interactively with the **REWEIGHT** statement.

Details: REG Procedure

Missing Values

PROC REG constructs only one crossproducts matrix for the variables in all regressions. If any variable needed for any regression is missing, the observation is excluded from all estimates. If you include variables with missing values in the **VAR** statement, the corresponding observations are excluded from all analyses, even if you never include the variables in a model. PROC REG assumes that you might want to include these variables after the first RUN statement and deletes observations with missing values.

Input Data Sets

PROC REG does not compute new regressors. For example, if you want a quadratic term in your model, you should create a new variable when you prepare the input data. For example, the statement

```
model y=x1 x1*x1;
```

is not valid. Note that this **MODEL** statement is valid in the GLM procedure.

The input data set for most applications of PROC REG contains standard rectangular data, but special **TYPE=**CORR, **TYPE=**COV, and **TYPE=**SSCP data sets can also be used. **TYPE=**CORR and **TYPE=**COV data sets created by the CORR procedure contain means and standard deviations. In addition, **TYPE=**CORR data sets contain correlations and **TYPE=**COV data sets contain covariances. **TYPE=**SSCP data sets created in previous runs of PROC REG that used the **OUTSSCP=** option contain the sums of squares and crossproducts of the variables.

See Appendix A, “[Special SAS Data Sets](#),” and the “SAS Files” section in *SAS Language Reference: Concepts* for more information about special SAS data sets.

These summary files save CPU time. It takes nk^2 operations (where n = number of observations and k = number of variables) to calculate crossproducts; the regressions are of the order k^3 . When n is in the thousands and k is less than 10, you can save 99% of the CPU time by reusing the SSCP matrix rather than recomputing it.

When you want to use a special SAS data set as input, PROC REG must determine the **TYPE** for the data set. PROC CORR and PROC REG automatically set the type for their output data sets. However, if you create the data set by some other means (such as a DATA step), you must specify its type with the **TYPE=** data set option. If the **TYPE** for the data set is not specified when the data set is created, you can specify **TYPE=** as a data set option in the **DATA=** option in the **PROC REG** statement. For example:

```
proc reg data=a(type=corr);
```

When a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used with PROC REG, statements and options that require the original data values have no effect. The **OUTPUT**, **PAINT**, **PLOT**, and **REWEIGHT** statements and the **MODEL** and **PRINT** statement options **P**, **R**, **CLM**, **CLI**, **DW**, **INFLUENCE**, and **PAR-TIAL** are disabled since the original observations needed to calculate predicted and residual values are not present.

Example Using TYPE=CORR Data Set

The following statements use PROC CORR to produce an input data set for PROC REG. The fitness data for this analysis can be found in [Example 79.2](#).

```
proc corr data=fitness outp=r noprint;
  var Oxygen RunTime Age Weight RunPulse MaxPulse RestPulse;
run;
proc print data=r;
run;
proc reg data=r;
  model Oxygen=RunTime Age Weight;
run;
```

Since the OUTP= data set from PROC CORR is automatically set to TYPE=CORR, the TYPE= data set option is not required in this example. The data set containing the correlation matrix is displayed by the PRINT procedure as shown in [Figure 79.14](#). [Figure 79.15](#) shows results from the regression that uses the TYPE=CORR data as an input data set.

Age	1	-0.17388	0.09955	-1.75	0.0921
Weight	1	-0.05444	0.06181	-0.88	0.3862

The following example uses the saved crossproducts matrix:

```
proc reg data=fitness outsscp=sscp noprint;
  model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse;
run;
proc print data=sscp;
run;
proc reg data=sscp;
  model Oxygen=RunTime Age Weight;
run;
```

First, all variables are used to fit the data and create the SSCP data set. [Figure 79.16](#) shows the PROC PRINT display of the SSCP data set. The SSCP data set is then used as the input data set for PROC REG, and a reduced model is fit to the data.

Weight	1	-0.05444	0.06181	-0.88	0.3862

In the preceding example, the TYPE= data set option is not required since PROC REG sets the OUTSSCP= data set to TYPE=SSCP.

Output Data Sets

OUTEST= Data Set

The OUTEST= specification produces a TYPE=EST output SAS data set containing estimates and optional statistics from the regression models. For each BY group on each dependent variable occurring in each **MODEL** statement, PROC REG outputs an observation to the OUTEST= data set. The variables output to the data set are as follows:

- the BY variables, if any
- **_MODEL_**, a character variable containing the label of the corresponding **MODEL** statement, or **MODEL n** if no label is specified, where n is 1 for the first **MODEL** statement, 2 for the second model statement, and so on
- **_TYPE_**, a character variable with the value 'PARMS' for every observation

- `_DEPVAR_`, the name of the dependent variable
- `_RMSE_`, the root mean squared error or the estimate of the standard deviation of the error term
- Intercept, the estimated intercept, unless the NOINT option is specified
- all the variables listed in any **MODEL** or **VAR** statement. Values of these variables are the estimated regression coefficients for the model. A variable that does not appear in the model corresponding to a given observation has a missing value in that observation. The dependent variable in each model is given a value of -1 .

If you specify the COVOUT option, the covariance matrix of the estimates is output after the estimates; the `_TYPE_` variable is set to the value 'COV' and the names of the rows are identified by the character variable, `_NAME_`.

If you specify the TABLEOUT option, the following statistics listed by `_TYPE_` are added after the estimates:

- STDERR, the standard error of the estimate
- T, the t statistic for testing if the estimate is zero
- PVALUE, the associated p -value
- LnB , the $100(1-\alpha)$ lower confidence limit for the estimate, where n is the nearest integer to $100(1-\alpha)$ and α defaults to 0.05 or is set by using the ALPHA= option in the **PROC REG** or **MODEL** statement
- UnB , the $100(1-\alpha)$ upper confidence limit for the estimate

Specifying the option ADJRSQ, AIC, BIC, CP, EDF, GMSEP, JP, MSE, PC, RSQUARE, SBC, SP, or SSE in the **PROC REG** or **MODEL** statement automatically outputs these statistics and the model R^2 for each model selected, regardless of the model selection method. Additional variables, in order of occurrence, are as follows:

- `_IN_`, the number of regressors in the model not including the intercept
- `_P_`, the number of parameters in the model including the intercept, if any
- `_EDF_`, the error degrees of freedom
- `_SSE_`, the error sum of squares, if the SSE option is specified
- `_MSE_`, the mean squared error, if the MSE option is specified
- `_RSQ_`, the R square statistic
- `_ADJRSQ_`, the adjusted R square, if the ADJRSQ option is specified
- `_CP_`, the C_p statistic, if the CP option is specified
- `_SP_`, the S_p statistic, if the SP option is specified
- `_JP_`, the J_p statistic, if the JP option is specified

- `_PC_`, the PC statistic, if the PC option is specified
- `_GMSEP_`, the GMSEP statistic, if the GMSEP option is specified
- `_AIC_`, the AIC statistic, if the AIC option is specified
- `_BIC_`, the BIC statistic, if the BIC option is specified
- `_SBC_`, the SBC statistic, if the SBC option is specified

The following statements produce and display the OUTEST= data set. This example uses the population data given in the section “[Polynomial Regression](#)” on page 6620. [Figure 79.18](#) through [Figure 79.20](#) show the regression equations and the resulting OUTEST= data set.

```
proc reg data=USPopulation outest=est;
  m1: model Population=Year;
  m2: model Population=Year YearSq;
run;
proc print data=est;
run;
```

1	m1	PARMS	Population	25.3295	-2345.85	1.2879	-1	.
2	m2	PARMS	Population	2.9998	21630.89	-24.0458	-1	.006684346

The following modification of the previous example uses the TABLEOUT and ALPHA= options to obtain additional information in the OUTEST= data set:

```
proc reg data=USPopulation outest=est tableout alpha=0.1;
  m1: model Population=Year/noprint;
  m2: model Population=Year YearSq/noprint;
run;
proc print data=est;
run;
```

Notice that the TABLEOUT option causes standard errors, *t* statistics, *p*-values, and confidence limits for the estimates to be added to the OUTEST= data set. Also note that the ALPHA= option is used to set the confidence level at 90%. The OUTEST= data set is shown in [Figure 79.21](#).

Figure 79.21 The OUTEST= Data Set When TABLEOUT Is Specified

Obs	_MODEL_	_TYPE_	_DEPVAR_	_RMSE_	Intercept	Year	Population	YearSq

11	m2	L90B	Population	2.9998	20525.11	-25.2138	.	0.0064
12	m2	U90B	Population	2.9998	22736.68	-22.8778	.	0.0070

A slightly different OUTEST= data set is created when you use the RSQUARE selection method. The following statements request only the “best” model for each subset size but ask for a variety of model selection statistics, as well as the estimated regression coefficients. An OUTEST= data set is created and displayed. See [Figure 79.22](#) and [Figure 79.23](#) for the results.

```
proc reg data=fitness outest=est;
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
    / selection=rsquare mse jp gmsep cp aic bic sbc b best=1;
run;
proc print data=est;
run;
```

OUTSSCP= Data Sets

The OUTSSCP= option produces a TYPE=SSCP output SAS data set containing sums of squares and crossproducts. A special row (observation) and column (variable) of the matrix called Intercept contain the number of observations and sums. Observations are identified by the character variable _NAME_. The data set contains all variables used in **MODEL** statements. You can specify additional variables that you want included in the crossproducts matrix with a **VAR** statement.

The SSCP data set is used when a large number of observations are explored in many different runs. The SSCP data set can be saved and used for subsequent runs, which are much less expensive since PROC REG never reads the original data again. If you run PROC REG once to create only a SSCP data set, you should list all the variables that you might need in a **VAR** statement or include all the variables that you might need in a **MODEL** statement.

The following statements use the fitness data from [Example 79.2](#) to produce an output data set with the OUTSSCP= option. The resulting output is shown in [Figure 79.24](#).

```
proc reg data=fitness outsscp=sscp;
    var Oxygen RunTime Age Weight RestPulse RunPulse MaxPulse;
run;
proc print data=sscp;
run;
```

Since a model is not fit to the data and since the only request is to create the SSCP data set, a **MODEL** statement is not required in this example. However, since the **MODEL** statement is not used, the **VAR** statement is required.

Interactive Analysis

PROC REG enables you to change interactively both the model and the data used to compute the model, and to produce and highlight scatter plots. See the section “[Using PROC REG Interactively](#)” on page 6630 for an overview of interactive analysis that uses PROC REG. The following statements can be used interactively (without reinvoking PROC REG): **ADD**, **DELETE**, **MODEL**, **MTEST**, **OUTPUT**, **PAINT**, **PLOT**, **PRINT**, **REFIT**, **RESTRICT**, **REWEIGHT**, and **TEST**. All interactive features are disabled if there is a **BY** statement.

The **ADD**, **DELETE**, and **REWEIGHT** statements can be used to modify the current **MODEL**. Every use of an **ADD**, **DELETE**, or **REWEIGHT** statement causes the model label to be modified by attaching an additional number to it. This number is the cumulative total of the number of **ADD**, **DELETE**, or **REWEIGHT** statements following the current **MODEL** statement.

A more detailed explanation of changing the data used to compute the model is given in the section “[Reweightings Observations in an Analysis](#)” on page 6726.

The following statements illustrate the usefulness of the interactive features. First, the full regression model is fit to the `SasHELP.Class` data, and [Figure 79.25](#) is produced.

```
ods graphics on;

proc reg data=sashelp.Class plots(modelLabel only)=ResidualByPredicted;
    model Weight=Age Height;
run;
```

Figure 79.25 Interactive Analysis: Full Model

The REG Procedure					
Model: MODEL1					
Dependent Variable: Weight					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	7215.63710	3607.81855	27.23	<.0001

	Root MSE	11.51114	R-Square	0.7729	
	Dependent Mean	100.02632	Adj R-Sq	0.7445	
	Coeff Var	11.50811			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	-141.22376	33.38309	-4.23	0.0006
Age	1	1.27839	3.11010	0.41	0.6865
Height	1	3.59703	0.90546	3.97	0.0011

Next, the regression model is reduced by the following statements, and [Figure 79.26](#) is produced.

```
delete age;
print;
run;
```

Figure 79.26 Interactive Analysis: Reduced Model

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	7193.24912	7193.24912	57.08	<.0001
Error	17	2142.48772	126.02869		
Corrected Total	18	9335.73684			
Root MSE		11.22625	R-Square	0.7705	
Dependent Mean		100.02632	Adj R-Sq	0.7570	
Coeff Var		11.22330			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	-143.02692	32.27459	-4.43	0.0004
Height	1	3.89903	0.51609	7.55	<.0001

Note that the MODEL label has been changed from MODEL1 to MODEL1.1, since the original MODEL has been changed by the delete statement.

When ODS Graphics is enabled, updated plots are produced whenever a **PRINT** statement is used. The option

```
plots(modelLabel only)=ResidualByPredicted
```

in the PROC REG statement specifies that the only plot produced is a scatter plot of residuals by predicted values. The MODEL LABEL option specifies that the current model label is added to the plot.

The following statements generate a scatter plot of the residuals against the predicted values from the full model. [Figure 79.27](#) is produced, and the scatter plot shows a possible outlier.

```
add age;
print;
run;
```

Figure 79.27 Interactive Analysis: Scatter Plot

The following statements delete the observation with the largest residual, refit the regression model, and produce a scatter plot of residuals against predicted values for the refitted model. [Figure 79.28](#) shows the new scatter plot.

```

reweight r.>20;
print;
run;

ods graphics off;

```

Figure 79.28 Interactive Analysis: Scatter Plot

Model-Selection Methods

The nine methods of model selection implemented in PROC REG are specified with the **SELECTION=** option in the **MODEL** statement. Each method is discussed in this section.

Full Model Fitted (NONE)

This method is the default and provides no model selection capability. The complete model specified in the **MODEL** statement is used to fit the model. For many regression analyses, this might be the only method you need.

Forward Selection (FORWARD)

The forward-selection technique begins with no variables in the model. For each of the independent variables, the FORWARD method calculates F statistics that reflect the variable's contribution to the model if it is included. The p -values for these F statistics are compared to the **SLENTY=** value that is specified in the **MODEL** statement (or to 0.50 if the **SLENTY=** option is omitted). If no F statistic has a significance level

greater than the `SLENTRY=` value, the FORWARD selection stops. Otherwise, the FORWARD method adds the variable that has the largest F statistic to the model. The FORWARD method then calculates F statistics again for the variables still remaining outside the model, and the evaluation process is repeated. Thus, variables are added one by one to the model until no remaining variable produces a significant F statistic. Once a variable is in the model, it stays.

Backward Elimination (BACKWARD)

The backward elimination technique begins by calculating F statistics for a model which includes all of the independent variables. Then the variables are deleted from the model one by one until all the variables remaining in the model produce F statistics significant at the `SLSTAY=` level specified in the `MODEL` statement (or at the 0.10 level if the `SLSTAY=` option is omitted). At each step, the variable showing the smallest contribution to the model is deleted.

Stepwise (STEPWISE)

The stepwise method is a modification of the forward-selection technique and differs in that variables already in the model do not necessarily stay there. As in the forward-selection method, variables are added one by one to the model, and the F statistic for a variable to be added must be significant at the `SLENTRY=` level. After a variable is added, however, the stepwise method looks at all the variables already included in the model and deletes any variable that does not produce an F statistic significant at the `SLSTAY=` level. Only after this check is made and the necessary deletions are accomplished can another variable be added to the model. The stepwise process ends when none of the variables outside the model has an F statistic significant at the `SLENTRY=` level and every variable in the model is significant at the `SLSTAY=` level, or when the variable to be added to the model is the one just deleted from it.

Maximum R^2 Improvement (MAXR)

The maximum R square improvement technique does not settle on a single model. Instead, it tries to find the “best” one-variable model, the “best” two-variable model, and so forth, although it is not guaranteed to find the model with the largest R square for each size.

The MAXR method begins by finding the one-variable model producing the highest R square. Then another variable, the one that yields the greatest increase in R square, is added. Once the two-variable model is obtained, each of the variables in the model is compared to each variable not in the model. For each comparison, the MAXR method determines if removing one variable and replacing it with the other variable increases R square. After comparing all possible switches, the MAXR method makes the switch that produces the largest increase in R square. Comparisons begin again, and the process continues until the MAXR method finds that no switch could increase R square. Thus, the two-variable model achieved is considered the “best” two-variable model the technique can find. Another variable is then added to the model, and the comparing-and-switching process is repeated to find the “best” three-variable model, and so forth.

The difference between the STEPWISE method and the MAXR method is that all switches are evaluated before any switch is made in the MAXR method. In the STEPWISE method, the “worst” variable might be removed without considering what adding the “best” remaining variable might accomplish. The MAXR method might require much more computer time than the STEPWISE method.

Minimum R^2 (MINR) Improvement

The MINR method closely resembles the MAXR method, but the switch chosen is the one that produces the smallest increase in R square. For a given number of variables in the model, the MAXR and MINR methods usually produce the same “best” model, but the MINR method considers more models of each size.

R^2 Selection (RSQUARE)

The RSQUARE method finds subsets of independent variables that best predict a dependent variable by linear regression in the given sample. You can specify the largest and smallest number of independent variables to appear in a subset and the number of subsets of each size to be selected. The RSQUARE method can efficiently perform all possible subset regressions and display the models in decreasing order of R square magnitude within each subset size. Other statistics are available for comparing subsets of different sizes. These statistics, as well as estimated regression coefficients, can be displayed or output to a SAS data set.

The subset models selected by the RSQUARE method are optimal in terms of R square for the given sample, but they are not necessarily optimal for the population from which the sample is drawn or for any other sample for which you might want to make predictions. If a subset model is selected on the basis of a large R square value or any other criterion commonly used for model selection, then all regression statistics computed for that model under the assumption that the model is given a priori, including all statistics computed by PROC REG, are biased.

While the RSQUARE method is a useful tool for exploratory model building, no statistical method can be relied on to identify the “true” model. Effective model building requires substantive theory to suggest relevant predictors and plausible functional forms for the model.

The RSQUARE method differs from the other selection methods in that RSQUARE always identifies the model with the largest R square for each number of variables considered. The other selection methods are not guaranteed to find the model with the largest R square. The RSQUARE method requires much more computer time than the other selection methods, so a different selection method such as the STEPWISE method is a good choice when there are many independent variables to consider.

Adjusted R^2 Selection (ADJRSQ)

This method is similar to the RSQUARE method, except that the adjusted R square statistic is used as the criterion for selecting models, and the method finds the models with the highest adjusted R square within the range of sizes.

Mallows' C_p Selection (CP)

This method is similar to the ADJRSQ method, except that Mallows' C_p statistic is used as the criterion for model selection. Models are listed in ascending order of C_p .

Additional Information about Model-Selection Methods

If the RSQUARE or STEPWISE procedure (as documented in *SAS User's Guide: Statistics, Version 5 Edition*) is requested, PROC REG with the appropriate model-selection method is actually used.

Reviews of model-selection methods by Hocking (1976) and Judge et al. (1980) describe these and other variable-selection methods.

Criteria Used in Model-Selection Methods

When many significance tests are performed, each at a level of, for example, 5%, the overall probability of rejecting at least one true null hypothesis is much larger than 5%. If you want to guard against including any variables that do not contribute to the predictive power of the model in the population, you should specify a very small SLE= significance level for the FORWARD and STEPWISE methods and a very small SLS= significance level for the BACKWARD and STEPWISE methods.

In most applications, many of the variables considered have some predictive power, however small. If you want to choose the model that provides the best prediction computed using the sample estimates, you need only to guard against estimating more parameters than can be reliably estimated with the given sample size, so you should use a moderate significance level, perhaps in the range of 10% to 25%.

In addition to R square, the C_p statistic is displayed for each model generated in the model-selection methods. The C_p statistic is proposed by Mallows (1973) as a criterion for selecting a model. It is a measure of total squared error defined as

$$C_p = \frac{SSE_p}{s^2} - (N - 2p)$$

where s^2 is the MSE for the full model, and SSE_p is the sum-of-squares error for a model with p parameters including the intercept, if any. If C_p is plotted against p , Mallows recommends the model where C_p first approaches p . When the right model is chosen, the parameter estimates are unbiased, and this is reflected in C_p near p . For further discussion, see Daniel and Wood (1980).

The adjusted R square statistic is an alternative to R square that is adjusted for the number of parameters in the model. The adjusted R square statistic is calculated as

$$ADJRSQ = 1 - \frac{(n - i)(1 - R^2)}{n - p}$$

where n is the number of observations used in fitting the model, and i is an indicator variable that is 1 if the model includes an intercept, and 0 otherwise.

Limitations in Model-Selection Methods

The use of model-selection methods can be time-consuming in some cases because there is no built-in limit on the number of independent variables, and the calculations for a large number of independent variables can be lengthy. The recommended limit on the number of independent variables for the MINR method is $20 + i$, where i is the value of the INCLUDE= option.

For the RSQUARE, ADJRSQ, or CP method, with a large value of the BEST= option, adding one more variable to the list from which regressors are selected might significantly increase the CPU time. Also, the time required for the analysis is highly dependent on the data and on the values of the BEST=, START=, and STOP= options.

Parameter Estimates and Associated Statistics

The following example uses the fitness data from [Example 79.2](#). [Figure 79.30](#) shows the parameter estimates and the tables from the SS1, SS2, STB, CLB, COVB, and CORRB options:

```
proc reg data=fitness;
  model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse
    / ss1 ss2 stb clb covb corrb;
run;
```

The procedure first displays an analysis of variance table ([Figure 79.29](#)). The F statistic for the overall model is significant, indicating that the model explains a significant portion of the variation in the data.

Figure 79.29 ANOVA Table

The REG Procedure					
Model: MODEL1					
Dependent Variable: Oxygen					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	6	722.54361	120.42393	22.43	<.0001
Error	24	128.83794	5.36825		
Corrected Total	30	851.38154			
Root MSE		2.31695	R-Square	0.8487	
Dependent Mean		47.37581	Adj R-Sq	0.8108	
Coeff Var		4.89057			

The procedure next displays parameter estimates and some associated statistics ([Figure 79.30](#)). First, the estimates are shown, followed by their standard errors. The next two columns of the table contain the t statistics and the corresponding probabilities for testing the null hypothesis that the parameter is not significantly different from zero. These probabilities are usually referred to as p -values. For example, the Intercept term in the model is estimated to be 102.9 and is significantly different from zero. The next two columns of the table are the result of requesting the SS1 and SS2 options, and they show sequential and partial sums of squares (SS) associated with each variable. The standardized estimates (produced by the STB option) are the parameter estimates that result when all variables are standardized to a mean of 0 and a variance of 1. These estimates are computed by multiplying the original estimates by the standard deviation of the regressor (independent) variable and then dividing by the standard deviation of the dependent variable. The CLB option adds the upper and lower 95% confidence limits for the parameter estimates; the α level can be changed by specifying the ALPHA= option in the [PROC REG](#) or [MODEL](#) statement.

Figure 79.30 SS1, SS2, STB, CLB, COVB, and CORRB Options: Parameter Estimates

Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Type I SS

For further discussion of the parameters and statistics, see the section “[Displayed Output](#)” on page 6740, and Chapter 4, “[Introduction to Regression Procedures](#).”

Predicted and Residual Values

The display of the predicted values and residuals is controlled by the P, R, CLM, and CLI options in the **MODEL** statement. The P option causes PROC REG to display the observation number, the ID value (if an ID statement is used), the actual value, the predicted value, and the residual. The R, CLI, and CLM options also produce the items under the P option. Thus, P is unnecessary if you use one of the other options.

The R option requests more detail, especially about the residuals. The standard errors of the mean predicted value and the residual are displayed. The studentized residual, which is the residual divided by its standard error, is both displayed and plotted. A measure of influence, Cook's *D*, is displayed. Cook's *D* measures the change to the estimates that results from deleting each observation (Cook 1977, 1979). This statistic is very similar to DFFITS.

The CLM option requests that PROC REG display the $100(1 - \alpha)\%$ lower and upper confidence limits for the mean predicted values. This accounts for the variation due to estimating the parameters only. If you want a $100(1 - \alpha)\%$ confidence interval for observed values, then you can use the CLI option, which adds in the variability of the error term. The α level can be specified with the ALPHA= option in the **PROC REG** or **MODEL** statement.

You can use these statistics in **PLOT** and **PAINT** statements. This is useful in performing a variety of regression diagnostics. For definitions of the statistics produced by these options, see Chapter 4, “[Introduction to Regression Procedures](#).”

The following statements use the U.S. population data found in the section “[Polynomial Regression](#)” on page 6620. The results are shown in [Figure 79.32](#) and [Figure 79.33](#).

After producing the usual analysis of variance and parameter estimates tables (Figure 79.32), the procedure displays the results of requesting the options for predicted and residual values (Figure 79.33). For each observation, the requested information is shown. Note that the ID variable is used to identify each observation. Also note that, for observations with missing dependent variables, the predicted value, standard error of the predicted value, and confidence intervals for the predicted value are still available.

The columnar print plot of studentized residuals and Cook's D statistics are displayed as a result of requesting the R option. In the plot of studentized residuals, the large number of observations with absolute values greater than two indicates an inadequate model. You can use ODS Graphics to obtain plots of studentized residuals by predicted values or leverage; see Example 79.1 for a similar example.

Models of Less Than Full Rank

If the model is not full rank, there are an infinite number of least squares solutions for the estimates. PROC REG chooses a nonzero solution for all variables that are linearly independent of previous variables and a zero solution for other variables. This solution corresponds to using a generalized inverse in the normal equations, and the expected values of the estimates are the Hermite normal form of \mathbf{X} multiplied by the true parameters:

$$E(\mathbf{b}) = (\mathbf{X}'\mathbf{X})^-(\mathbf{X}'\mathbf{X})\boldsymbol{\beta}$$

Degrees of freedom for the zeroed estimates are reported as zero. The hypotheses that are not testable have t tests reported as missing. The message that the model is not full rank includes a display of the relations that exist in the matrix.

The following statements use the fitness data from [Example 79.2](#). The variable $\text{Dif} = \text{RunPulse} - \text{RestPulse}$ is created. When this variable is included in the model along with RunPulse and RestPulse , there is a linear dependency (or exact collinearity) between the independent variables. [Figure 79.34](#) shows how this problem is diagnosed.

```
data fit2;
    set fitness;
    Dif=RunPulse-RestPulse;
run;
proc reg data=fit2;
    model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse Dif;
run;
```

Dif	0	0	.	.	.

PROC REG produces a message informing you that the model is less than full rank. Parameters with DF=0 are not estimated, and parameters with DF=B are biased. In addition, the form of the linear dependency among the regressors is displayed.

Collinearity Diagnostics

When a regressor is nearly a linear combination of other regressors in the model, the affected estimates are unstable and have high standard errors. This problem is called *collinearity* or *multicollinearity*. It is a good idea to find out which variables are nearly collinear with which other variables. The approach in PROC REG follows that of Belsley, Kuh, and Welsch (1980). PROC REG provides several methods for detecting collinearity with the COLLIN, COLLINOINT, TOL, and VIF options.

The COLLIN option in the **MODEL** statement requests that a collinearity analysis be performed. First, $X'X$ is scaled to have 1s on the diagonal. If you specify the COLLINOINT option, the intercept variable is adjusted out first. Then the eigenvalues and eigenvectors are extracted. The analysis in PROC REG is reported with eigenvalues of $X'X$ rather than singular values of X . The eigenvalues of $X'X$ are the squares of the singular values of X .

The condition indices are the square roots of the ratio of the largest eigenvalue to each individual eigenvalue. The largest condition index is the condition number of the scaled X matrix. Belsley, Kuh, and Welsch (1980) suggest that, when this number is around 10, weak dependencies might be starting to affect the regression estimates. When this number is larger than 100, the estimates might have a fair amount of numerical error (although the statistical standard error almost always is much greater than the numerical error).

For each variable, PROC REG produces the proportion of the variance of the estimate accounted for by each principal component. A collinearity problem occurs when a component associated with a high condition index contributes strongly (variance proportion greater than about 0.5) to the variance of two or more variables.

The VIF option in the **MODEL** statement provides the variance inflation factors (VIF). These factors measure the inflation in the variances of the parameter estimates due to collinearities that exist among the regressor (independent) variables. There are no formal criteria for deciding if a VIF is large enough to affect the predicted values.

The TOL option requests the tolerance values for the parameter estimates. The tolerance is defined as $1 / \text{VIF}$.

For a complete discussion of the preceding methods, see Belsley, Kuh, and Welsch (1980). For a more detailed explanation of using the methods with PROC REG, see Freund and Littell (1986).

This example uses the COLLIN option on the fitness data found in [Example 79.2](#). The following statements produce [Figure 79.35](#).

```
proc reg data=fitness;
    model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse
        / tol vif collin;
run;
```

Model Fit and Diagnostic Statistics

This section gathers the formulas for the statistics available in the **MODEL**, **PLOT**, and **OUTPUT** statements. The model to be fit is $Y = X\beta + \epsilon$, and the parameter estimate is denoted by $b = (X'X)^{-1}X'Y$. The subscript i denotes values for the i th observation, the parenthetical subscript (i) means that the statistic is computed by using all observations except the i th observation, and the subscript jj indicates the j th diagonal matrix entry. The ALPHA= option in the **PROC REG** or **MODEL** statement is used to set the α value for the t statistics.

Table 79.9 contains the summary statistics for assessing the fit of the model.

Table 79.9 Formulas and Definitions for Model Fit Summary Statistics

Model Option or Statistic	Definition or Formula
n	the number of observations
p	the number of parameters including the intercept
i	1 if there is an intercept, 0 otherwise
$\hat{\sigma}^2$	the estimate of pure error variance from the SIGMA= option or from fitting the full model
SST_0	the uncorrected total sum of squares for the dependent variable

Table 79.9 continued

Model Option or Statistic	Definition or Formula
SST ₁	the total sum of squares corrected for the mean for the dependent variable
SSE	the error sum of squares
MSE	$\frac{SSE}{n - p}$
R ²	$1 - \frac{SSE}{SST_i}$
ADJRSQ	$1 - \frac{(n - i)(1 - R^2)}{n - p}$
AIC	$n \ln \left(\frac{SSE}{n} \right) + 2p$
BIC	$n \ln \left(\frac{SSE}{n} \right) + 2(p + 2)q - 2q^2$ where $q = \frac{n\hat{\sigma}^2}{SSE}$
CP (C _p)	$\frac{SSE}{\hat{\sigma}^2} + 2p - n$
GMSEP	$\frac{MSE(n + 1)(n - 2)}{n(n - p - 1)} = \frac{1}{n} S_p(n + 1)(n - 2)$
JP (J _p)	$\frac{n + p}{n} MSE$
PC	$\frac{n + p}{n - p} (1 - R^2) = J_p \left(\frac{n}{SST_i} \right)$
PRESS	the sum of squares of pred _{r_i} (see Table 79.10)
RMSE	\sqrt{MSE}
SBC	$n \ln \left(\frac{SSE}{n} \right) + p \ln(n)$
SP (S _p)	$\frac{MSE}{n - p - 1}$

Table 79.10 contains the diagnostic statistics and their formulas; these formulas and further information can be found in Chapter 4, “Introduction to Regression Procedures,” and in the section “Influence Statistics” on page 6717. Each statistic is computed for each observation.

Table 79.10 Formulas and Definitions for Diagnostic Statistics

MODEL Option or Statistic	Formula
PRED (\hat{Y}_i)	$\mathbf{X}_i \mathbf{b}$
RES (r_i)	$\mathbf{Y}_i - \hat{\mathbf{Y}}_i$
H (h_i)	$\mathbf{x}_i (\mathbf{X}'\mathbf{X})^{-1} \mathbf{x}_i'$
STDP	$\sqrt{h_i \hat{\sigma}^2}$
STDI	$\sqrt{(1 + h_i) \hat{\sigma}^2}$
STDR	$\sqrt{(1 - h_i) \hat{\sigma}^2}$

Table 79.10 continued

MODEL Option or Statistic	Formula
LCL	$\hat{Y}_i - t_{\frac{\alpha}{2}} \text{STDI}$
LCLM	$\hat{Y}_i - t_{\frac{\alpha}{2}} \text{STDP}$
UCL	$\hat{Y}_i + t_{\frac{\alpha}{2}} \text{STDI}$
UCLM	$\hat{Y}_i + t_{\frac{\alpha}{2}} \text{STDP}$
STUDENT	$\frac{r_i}{\text{STDR}_i}$
RSTUDENT	$\frac{r_i}{\hat{\sigma}_{(i)} \sqrt{1 - h_i}}$
COOKD	$\frac{1}{p} \text{STUDENT}^2 \frac{\text{STDP}^2}{\text{STDR}^2}$
COVRATIO	$\frac{\det(\hat{\sigma}_{(i)}^2 (\mathbf{x}'_{(i)} \mathbf{x}_{(i)})^{-1})}{\det(\hat{\sigma}^2 (\mathbf{X}' \mathbf{X})^{-1})}$
DFFITS	$\frac{(\hat{Y}_i - \hat{Y}_{(i)})}{(\hat{\sigma}_{(i)} \sqrt{h_i})}$
DFBETAS _j	$\frac{\mathbf{b}_j - \mathbf{b}_{(i)j}}{\hat{\sigma}_{(i)} \sqrt{(\mathbf{X}' \mathbf{X})_{jj}}}$
PRESS(pred _{r_i})	$\frac{r_i}{1 - h_i}$

Influence Statistics

This section discusses the INFLUENCE option, which produces several influence statistics, and the PARTIAL option, which produces partial regression leverage plots.

The INFLUENCE Option

The INFLUENCE option (in the **MODEL** statement) requests the statistics proposed by Belsley, Kuh, and Welsch (1980) to measure the influence of each observation on the estimates. Influential observations are those that, according to various criteria, appear to have a large influence on the parameter estimates.

Let $\mathbf{b}(i)$ be the parameter estimates after deleting the i th observation; let $s(i)^2$ be the variance estimate after deleting the i th observation; let $\mathbf{X}(i)$ be the \mathbf{X} matrix without the i th observation; let $\hat{y}(i)$ be the i th value predicted without using the i th observation; let $r_i = y_i - \hat{y}_i$ be the i th residual; and let h_i be the i th diagonal of the projection matrix for the predictor space, also called the *hat matrix*:

$$h_i = \mathbf{x}_i (\mathbf{X}' \mathbf{X})^{-1} \mathbf{x}_i'$$

Belsley, Kuh, and Welsch (1980) propose a cutoff of $2p/n$, where n is the number of observations used to fit the model and p is the number of parameters in the model. Observations with h_i values above this cutoff should be investigated.

For each observation, PROC REG first displays the residual, the studentized residual (RSTUDENT), and the h_i . The studentized residual RSTUDENT differs slightly from STUDENT since the error variance is estimated by $s_{(i)}^2$ without the i th observation, not by s^2 . For example,

$$\text{RSTUDENT} = \frac{r_i}{s_{(i)} \sqrt{(1 - h_i)}}$$

Observations with RSTUDENT larger than 2 in absolute value might need some attention.

The COVRATIO statistic measures the change in the determinant of the covariance matrix of the estimates by deleting the i th observation:

$$\text{COVRATIO} = \frac{\det(s^2(i)(\mathbf{X}'_{(i)}\mathbf{X}_{(i)})^{-1})}{\det(s^2(\mathbf{X}'\mathbf{X})^{-1})}$$

Belsley, Kuh, and Welsch (1980) suggest that observations with

$$|\text{COVRATIO} - 1| \geq \frac{3p}{n}$$

where p is the number of parameters in the model and n is the number of observations used to fit the model, are worth investigation.

The DFFITS statistic is a scaled measure of the change in the predicted value for the i th observation and is calculated by deleting the i th observation. A large value indicates that the observation is very influential in its neighborhood of the \mathbf{X} space.

$$\text{DFFITS} = \frac{\hat{y}_i - \hat{y}_{(i)}}{s_{(i)} \sqrt{h_{(i)}}}$$

Large values of DFFITS indicate influential observations. A general cutoff to consider is 2; a size-adjusted cutoff recommended by Belsley, Kuh, and Welsch (1980) is $2\sqrt{p/n}$, where n and p are as defined previously.

The DFFITS statistic is very similar to Cook's D , defined in the section “[Predicted and Residual Values](#)” on page 6708.

The DFBETAS statistics are the scaled measures of the change in each parameter estimate and are calculated by deleting the i th observation:

$$\text{DFBETAS}_j = \frac{b_j - b_{(i)j}}{s_{(i)} \sqrt{(\mathbf{X}'\mathbf{X})_{jj}}}$$

where $(\mathbf{X}'\mathbf{X})_{jj}$ is the (j, j) element of $(\mathbf{X}'\mathbf{X})^{-1}$.

In general, large values of DFBETAS indicate observations that are influential in estimating a given parameter. Belsley, Kuh, and Welsch (1980) recommend 2 as a general cutoff value to indicate influential observations and $2/\sqrt{n}$ as a size-adjusted cutoff.

The following statements use the population example in the section “Polynomial Regression” on page 6620. See Figure 79.32 for the fitted regression equation. The INFLUENCE option produces the tables shown in Figure 79.36 and Figure 79.37.

```
proc reg data=USPopulation;
  model Population=Year YearSq / influence;
run;
```

Figure 79.37 Residual Statistics

Sum of Residuals	-4.7569E-11
Sum of Squared Residuals	170.97193
Predicted Residual SS (PRESS)	237.71229

In [Figure 79.36](#), observations 16, 17, and 19 exceed the cutoff value of 2 for RSTUDENT. None of the observations exceeds the general cutoff of 2 for DFFITS or the DFBETAS, but observations 16, 17, and 19 exceed at least one of the size-adjusted cutoffs for these statistics. Observations 1 and 19 exceed the cutoff for the hat diagonals, and observations 1, 2, 16, 17, and 18 exceed the cutoffs for COVRATIO. Taken together, these statistics indicate that you should look first at observations 16, 17, and 19 and then perhaps investigate the other observations that exceeded a cutoff.

When ODS Graphics is enabled, you can request influence diagnostic plots by using the PLOTS= option in the PROC REG statement as shown in the following statements:

```
ods graphics on;

proc reg data=USPopulation
    plots(label)=(Cooksd RStudentByLeverage DFFITS DFBETAS);
    id Year;
    model Population=Year YearSq;
run;

ods graphics off;
```

The LABEL suboption specified in the PLOTS(LABEL)= option requests that observations that exceed the relevant cutoffs for the statistics being plotted are labeled. Since Year has been named in an ID statement, the value of Year is used for the labels. The requested plots are shown in [Figure 79.38](#).

Figure 79.38 continued

Figure 79.38 *continued*

Figure 79.38 continued

The PARTIAL and PARTIALDATA Options

The **PARTIAL** option in the **MODEL** statement produces partial regression leverage plots. If ODS Graphics is not enabled, this option requires the use of the **LINEPRINTER** option in the **PROC REG** statement. One plot is created for each regressor in the current full model. For example, plots are produced for regressors included by using **ADD** statements; plots are not produced for interim models in the various model-selection methods but only for the full model. If you use a model-selection method and the final model contains only a subset of the original regressors, the **PARTIAL** option still produces plots for all regressors in the full model. If ODS Graphics is enabled, these plots are produced as high-resolution graphics, in panels with a maximum of six partial regression leverage plots per panel. Multiple panels are displayed for models with more than six regressors.

For a given regressor, the partial regression leverage plot is the plot of the dependent variable and the regressor after they have been made orthogonal to the other regressors in the model. These can be obtained by plotting the residuals for the dependent variable against the residuals for the selected regressor, where the residuals for the dependent variable are calculated with the selected regressor omitted, and the residuals for the selected regressor are calculated from a model where the selected regressor is regressed on the remaining regressors. A line fit to the points has a slope equal to the parameter estimate in the full model.

When ODS Graphics is not enabled, points in the plot are marked by the number of replicates appearing at one position. The symbol '*' is used if there are 10 or more replicates. If an ID statement is specified, the leftmost nonblank character in the value of the ID variable is used as the plotting symbol.

The PARTIALDATA option in the **MODEL** statement produces a table that contains the partial regression data that are displayed in the partial regression leverage plots. You can request partial regression data even if you do not request plots with the PARTIAL option.

The following statements use the fitness data in [Example 79.2](#) with the PARTIAL option and ODS Graphics to produce the partial regression leverage plots. The plots are shown in [Figure 79.39](#).

```
ods graphics on;

proc reg data=fitness;
  model Oxygen=RunTime Weight Age / partial;
run;

ods graphics off;
```

Figure 79.39 Partial Regression Leverage Plots

Reweighting Observations in an Analysis

Reweighting observations is an interactive feature of PROC REG that enables you to change the weights of observations used in computing the regression equation. Observations can also be deleted from the analysis (not from the data set) by changing their weights to zero. In the following statements, the Sashelp.Class data are used to illustrate some of the features of the **REWEIGHT** statement. First, the full model is fit, and the residuals are displayed in Figure 79.40.

```
proc reg data=sashelp.Class;
  model Weight=Age Height / p;
  id Name;
run;
```

Figure 79.40 Full Model for Sashelp.Class Data, Residuals Shown

Sum of Residuals				0
Sum of Squared Residuals				2120.09974
Predicted Residual SS (PRESS)				3272.72186

Upon examining the data and residuals, you realize that observation 17 (Ronald) was mistakenly included in the analysis. Also, you would like to examine the effect of reweighting to 0.5 those observations with residuals that have absolute values greater than or equal to 17. The following statements show how you request this reweighting:

```

reweight obs.=17;
reweight r. le -17 or r. ge 17 / weight=0.5;
print p;
run;

```

At this point, a message appears (in the log) that tells you which observations have been reweighted and what the new weights are. Figure 79.41 is produced.

Sum of Residuals				0	
Sum of Squared Residuals				1500.61194	
Predicted Residual SS (PRESS)				2287.57621	

The first **REWEIGHT** statement excludes observation 17, and the second **REWEIGHT** statement reweights observations 12 and 16 to 0.5. An important feature to note from this example is that the model is not refit until after the **PRINT** statement. **REWEIGHT** statements do not cause the model to be refit. This is so that multiple **REWEIGHT** statements can be applied to a subsequent model.

In this example, since the intent is to reweight observations with large residuals, the observation that was mistakenly included in the analysis should be deleted; then the model should be fit for those remaining observations, and the observations with large residuals should be reweighted. To accomplish this, use the **REFIT** statement. Note that the model label has been changed from MODEL1 to MODEL1.2 since two **REWEIGHT** statements have been used. The following statements produce Figure 79.42:

```
reweight allobs / weight=1.0;
reweight obs.=17;
refit;
reweight r. le -17 or r. ge 17 / weight=.5;
print;
run;
```

Predicted Residual SS (PRESS)				2473.87984	

Notice that this results in a slightly different model than the previous set of statements: only observation 16 is reweighted to 0.5. Also note that the model label is now MODEL1.5 since five **REWEIGHT** statements have been used for this model.

Another important feature of the **REWEIGHT** statement is the ability to nullify the effect of a previous or all **REWEIGHT** statements. First, assume that you have several **REWEIGHT** statements in effect and you want to restore the original weights of all the observations. The following **REWEIGHT** statement accomplishes this and produces Figure 79.43:

```
reweight allobs / reset;
print;
run;
```

The resulting model is identical to the original model specified at the beginning of this section. Notice that the model label is now MODEL1.6. Note that the Weight column does not appear, since all observations have been reweighted to have weight=1.

Now suppose you want only to undo the changes made by the most recent **REWEIGHT** statement. Use **REWEIGHT UNDO** for this. The following statements produce Figure 79.44:

```

reweight r. le -12 or r. ge 12 / weight=.75;
reweight r. le -17 or r. ge 17 / weight=.5;
reweight undo;
print;
run;

```

Sum of Residuals				0	
Sum of Squared Residuals				1694.87114	
Predicted Residual SS (PRESS)				2547.22751	

The resulting model reflects changes made only by the first **REWEIGHT** statement since the third **REWEIGHT** statement negates the effect of the second **REWEIGHT** statement. Observations 1, 3, 9, 10, 12, 16, and 17 have their weights changed to 0.75. Note that the label MODEL1.9 reflects the use of nine **REWEIGHT** statements for the current model.

Now suppose you want to reset the observations selected by the most recent **REWEIGHT** statement to their original weights. Use the **REWEIGHT** statement with the **RESET** option to do this. The following statements produce Figure 79.45:

```

reweight r. le -12 or r. ge 12 / weight=.75;
reweight r. le -17 or r. ge 17 / weight=.5;
reweight / reset;
print;
run;

```

Predicted Residual SS (PRESS)				2959.57279	

Note that observations that meet the condition of the second **REWEIGHT** statement (residuals with an absolute value greater than or equal to 17) now have weights reset to their original value of 1. Observations 1, 3, 9, 10, and 17 have weights of 0.75, but observations 12 and 16 (which meet the condition of the second **REWEIGHT** statement) have their weights reset to 1.

Notice how the last three examples show three ways to change weights back to a previous value. In the first example, **ALLOBS** and the **RESET** option are used to change weights for all observations back to their original values. In the second example, the **UNDO** option is used to negate the effect of a previous **REWEIGHT** statement, thus changing weights for observations selected in the previous **REWEIGHT** statement to the weights specified in still another **REWEIGHT** statement. In the third example, the **RESET** option is used to change weights for observations selected in a previous **REWEIGHT** statement back to their original values.

Finally, note that the label MODEL1.12 indicates that 12 **REWEIGHT** statements have been applied to the original model.

Testing for Heteroscedasticity

The regression model is specified as $y_i = \mathbf{x}_i \boldsymbol{\beta} + \epsilon_i$, where the ϵ_i 's are identically and independently distributed: $E(\epsilon) = 0$ and $E(\epsilon' \epsilon) = \sigma^2 \mathbf{I}$. If the ϵ_i 's are not independent or their variances are not constant, the parameter estimates are unbiased, but the estimate of the covariance matrix is inconsistent.

In the case of heteroscedasticity, if the regression data are from a simple random sample, then White (1980), showed that matrix

$$\text{HC}_0 = (\mathbf{X}'\mathbf{X})^{-1} (\mathbf{X}' \text{diag}(e_i^2) \mathbf{X}) (\mathbf{X}'\mathbf{X})^{-1}$$

where

$$e_i = y_i - \mathbf{x}_i \mathbf{b}$$

is an asymptotically consistent estimate of the covariance matrix. MacKinnon and White (1985) introduced three alternative heteroscedasticity-consistent covariance matrix estimators that are all asymptotically equivalent to the estimator HC_0 but that typically have better small sample behavior. These estimators labeled HC_1 , HC_2 , and HC_3 are defined as follows:

$$\text{HC}_1 = \frac{n}{n-p} \text{HC}_0$$

where n is the number of observations and p is the number of regressors including the intercept.

$$\text{HC}_2 = (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}' \text{diag}\left(\frac{e_i^2}{1-h_{ii}}\right) \mathbf{X} (\mathbf{X}'\mathbf{X})^{-1}$$

where

$$h_{ii} = \mathbf{x}_i (\mathbf{X}'\mathbf{X})^{-1} \mathbf{x}_i'$$

is the leverage of the i th observation.

$$\text{HC}_3 = (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}' \text{diag}\left(\frac{e_i^2}{(1-h_{ii})^2}\right) \mathbf{X} (\mathbf{X}'\mathbf{X})^{-1}$$

Long and Ervin (2000) studied the performance of these estimators and recommend using the HC_3 estimator if the sample size is less than 250.

You can use the `HCCMETHOD=0,1,2, or 3` in the `MODEL` statement to select a heteroscedasticity-consistent covariance matrix estimator, with `HC0` being the default. The `ACOV` option in the `MODEL` statement displays the heteroscedasticity-consistent covariance matrix estimator in effect and adds heteroscedasticity-consistent standard errors, also known as White standard errors, to the parameter estimates table. If you specify the `HCC` or `WHITE` option in the `MODEL` statement, but do not also specify the `ACOV` option, then the heteroscedasticity-consistent standard errors are added to the parameter estimates table but the heteroscedasticity-consistent covariance matrix is not displayed.

The `SPEC` option performs a model specification test. The null hypothesis for this test maintains that the errors are homoscedastic and independent of the regressors and that several technical assumptions about the model specification are valid. For details, see theorem 2 and assumptions 1–7 of White (1980). When the model is correctly specified and the errors are independent of the regressors, the rejection of this null hypothesis is evidence of heteroscedasticity. In implementing this test, an estimator of the average covariance matrix (White 1980, p. 822) is constructed and inverted. The nonsingularity of this matrix is one of the assumptions in the null hypothesis about the model specification. When PROC REG determines this matrix to be numerically singular, a generalized inverse is used and a note to this effect is written to the log. In such cases, care should be taken in interpreting the results of this test.

When you specify the `SPEC`, `ACOV`, `HCC`, or `WHITE` option in the `MODEL` statement, tests listed in the `TEST` statement are performed with both the usual covariance matrix and the heteroscedasticity-consistent covariance matrix requested with the `HCCMETHOD=` option. Tests performed with the consistent covariance matrix are asymptotic. For more information, see White (1980).

Both the `ACOV` and `SPEC` options can be specified in a `MODEL` or `PRINT` statement.

Testing for Lack of Fit

The test for lack of fit compares the variation around the model with “pure” variation within replicated observations. This measures the adequacy of the specified model. In particular, if there are n_i replicated observations Y_{i1}, \dots, Y_{in_i} of the response all at the same values \mathbf{x}_i of the regressors, then you can predict the true response at \mathbf{x}_i either by using the predicted value \hat{Y}_i based on the model or by using the mean \bar{Y}_i of the replicated values. The test for lack of fit decomposes the residual error into a component due to the variation of the replications around their mean value (the “pure” error) and a component due to the variation of the mean values around the model prediction (the “bias” error):

$$\sum_i \sum_{j=1}^{n_i} (Y_{ij} - \hat{Y}_i)^2 = \sum_i \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2 + \sum_i n_i (\bar{Y}_i - \hat{Y}_i)^2$$

If the model is adequate, then both components estimate the nominal level of error; however, if the bias component of error is much larger than the pure error, then this constitutes evidence that there is significant lack of fit.

If some observations in your design are replicated, you can test for lack of fit by specifying the `LACKFIT` option in the `MODEL` statement (see [Example 79.6](#)). Note that, since all other tests use total error rather than pure error, you might want to hand-calculate the tests with respect to pure error if the lack of fit is significant. On the other hand, significant lack of fit indicates that the specified model is inadequate, so if this is a problem you can also try to refine the model.

Multivariate Tests

The MTEST statement described in the section “[MTEST Statement](#)” on page 6660 can test hypotheses involving several dependent variables in the form

$$(\mathbf{L}\boldsymbol{\beta} - \mathbf{c})\mathbf{M} = 0$$

where \mathbf{L} is a linear function on the regressor side, $\boldsymbol{\beta}$ is a matrix of parameters, \mathbf{c} is a column vector of constants, \mathbf{j} is a row vector of ones, and \mathbf{M} is a linear function on the dependent side. The special case where the constants are zero is

$$\mathbf{L}\boldsymbol{\beta}\mathbf{M} = 0$$

To test this hypothesis, PROC REG constructs two matrices called \mathbf{H} and \mathbf{E} that correspond to the numerator and denominator of a univariate F test:

$$\mathbf{H} = \mathbf{M}'(\mathbf{L}\mathbf{B} - \mathbf{c}\mathbf{j})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}\mathbf{B} - \mathbf{c}\mathbf{j})\mathbf{M}$$

$$\mathbf{E} = \mathbf{M}'(\mathbf{Y}'\mathbf{Y} - \mathbf{B}'(\mathbf{X}'\mathbf{X})\mathbf{B})\mathbf{M}$$

These matrices are displayed for each MTEST statement if the PRINT option is specified.

Four test statistics based on the eigenvalues of $\mathbf{E}^{-1}\mathbf{H}$ or $(\mathbf{E} + \mathbf{H})^{-1}\mathbf{H}$ are formed. These are Wilks' lambda, Pillai's trace, the Hotelling-Lawley trace, and Roy's greatest root. These test statistics are discussed in Chapter 4, “[Introduction to Regression Procedures](#).”

The following code creates MANOVA data from Morrison (1976):

```
* Manova Data from Morrison (1976, 190);
data a;
  input sex $ drug $ @;
  do rep=1 to 4;
    input y1 y2 @;
    sexcode=(sex='m')-(sex='f');
    drug1=(drug='a')-(drug='c');
    drug2=(drug='b')-(drug='c');
    sexdrug1=sexcode*drug1;
    sexdrug2=sexcode*drug2;
    output;
  end;
  datalines;
m a 5 6 5 4 9 9 7 6

Roy's Greatest Root	4.57602675	41.18	2	18	<.0001
NOTE: F Statistic for Roy's Greatest Root is an upper bound.					
NOTE: F Statistic for Wilks' Lambda is exact.					

The four multivariate test statistics are all highly significant, giving strong evidence that the coefficients of drug1 and drug2 are not zero for both dependent variables.

Autocorrelation in Time Series Data

When regression is performed on time series data, the errors might not be independent. Often errors are autocorrelated; that is, each error is correlated with the error immediately before it. Autocorrelation is also a symptom of systematic lack of fit. The DW option provides the Durbin-Watson d statistic to test that the autocorrelation is zero:

$$d = \frac{\sum_{i=2}^n (e_i - e_{i-1})^2}{\sum_{i=1}^n e_i^2}$$

The value of d is close to 2 if the errors are uncorrelated. The distribution of d is reported by Durbin and Watson (1951). Tables of the distribution are found in most econometrics textbooks, such as Johnston (1972) and Pindyck and Rubinfeld (1981).

The sample autocorrelation estimate is displayed after the Durbin-Watson statistic. The sample is computed as

$$r = \frac{\sum_{i=2}^n e_i e_{i-1}}{\sum_{i=1}^n e_i^2}$$

This autocorrelation of the residuals might not be a very good estimate of the autocorrelation of the true errors, especially if there are few observations and the independent variables have certain patterns. If there are missing observations in the regression, these measures are computed as though the missing observations did not exist.

Positive autocorrelation of the errors generally tends to make the estimate of the error variance too small, so confidence intervals are too narrow and true null hypotheses are rejected with a higher probability than the stated significance level. Negative autocorrelation of the errors generally tends to make the estimate of the error variance too large, so confidence intervals are too wide and the power of significance tests is reduced. With either positive or negative autocorrelation, least squares parameter estimates are usually not as efficient as generalized least squares parameter estimates. For more details, see Judge et al. (1985, Chapter 8) and the *SAS/ETS User's Guide*.

The following SAS statements request the DWPROB option for the U.S. population data (see [Figure 79.50](#)). If you use the DW option instead of the DWPROB option, then p -values are not produced.

```
proc reg data=USPopulation;
    model Population=Year YearSq / dwProb;
run;
```

Figure 79.50 Regression Using DW Option

The REG Procedure	
Model: MODEL1	
Dependent Variable: Population

Pr > DW	0.9950
Number of Observations	22
1st Order Autocorrelation	0.323

Computations for Ridge Regression and IPC Analysis

In ridge regression analysis, the crossproduct matrix for the independent variables is centered (the NOINT option is ignored if it is specified) and scaled to one on the diagonal elements. The ridge constant k (specified with the RIDGE= option) is then added to each diagonal element of the crossproduct matrix. The ridge regression estimates are the least squares estimates obtained by using the new crossproduct matrix.

Let \mathbf{X} be an $n \times p$ matrix of the independent variables after centering the data, and let \mathbf{Y} be an $n \times 1$ vector corresponding to the dependent variable. Let \mathbf{D} be a $p \times p$ diagonal matrix with diagonal elements as in $\mathbf{X}'\mathbf{X}$. The ridge regression estimate corresponding to the ridge constant k can be computed as

$$\mathbf{D}^{-\frac{1}{2}}(\mathbf{Z}'\mathbf{Z} + k\mathbf{I}_p)^{-1}\mathbf{Z}'\mathbf{Y}$$

where $\mathbf{Z} = \mathbf{X}\mathbf{D}^{-\frac{1}{2}}$ and \mathbf{I}_p is a $p \times p$ identity matrix.

For IPC analysis, the smallest m eigenvalues of $\mathbf{Z}'\mathbf{Z}$ (where m is specified with the PCOMIT= option) are omitted to form the estimates.

For information about ridge regression and IPC standardized parameter estimates, parameter estimate standard errors, and variance inflation factors, see Rawlings, Pantula, and Dickey (1998); Neter, Wasserman, and Kutner (1990); Marquardt and Snee (1975). Unlike Rawlings, Pantula, and Dickey (1998), the REG procedure uses the mean squared errors of the submodels instead of the full model MSE to compute the standard errors of the parameter estimates.

Construction of Q-Q and P-P Plots

If a normal probability-probability or quantile-quantile plot for the variable x is requested, the n nonmissing values of x are first ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

If a Q-Q plot is requested (with a PLOT statement of the form PLOT *yvariable**NQQ.), the i th-ordered value $x_{(i)}$ is represented by a point with y-coordinate $x_{(i)}$ and x-coordinate $\Phi^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $\Phi(\cdot)$ is the standard normal distribution.

If a P-P plot is requested (with a **PLOT** statement of the form **PLOT yvariable*NPP.**), the i th-ordered value $x_{(i)}$ is represented by a point with y-coordinate $\frac{i}{n}$ and x-coordinate $\Phi\left(\frac{x_{(i)}-\mu}{\sigma}\right)$, where μ is the mean of the nonmissing x -values and σ is the standard deviation. If an x -value has multiplicity k (that is, $x_{(i)} = \dots = x_{(i+k-1)}$), then only the point $\left(\Phi\left(\frac{x_{(i)}-\mu}{\sigma}\right), \frac{i+k-1}{n}\right)$ is displayed.

Computational Methods

The REG procedure first composes a crossproducts matrix. The matrix can be calculated from input data, reformed from an input correlation matrix, or read in from an SSCP data set. For each model, the procedure selects the appropriate crossproducts from the main matrix. The normal equations formed from the crossproducts are solved by using a sweep algorithm (Goodnight 1979). The method is accurate for data that are reasonably scaled and not too collinear.

The mechanism that PROC REG uses to check for singularity involves the diagonal (pivot) elements of $X'X$ as it is being swept. If a pivot is less than **SINGULAR*CSS**, then a singularity is declared and the pivot is not swept (where CSS is the corrected sum of squares for the regressor and **SINGULAR** is machine dependent but is approximately $1E-7$ on most machines or reset in the **PROC REG** statement).

The sweep algorithm is also used in many places in the model-selection methods. The **RSQUARE** method uses the leaps-and-bounds algorithm by Furnival and Wilson (1974).

Computer Resources in Regression Analysis

The REG procedure is efficient for ordinary regression; however, requests for optional features can greatly increase the amount of time required.

The major computational expense in the regression analysis is the collection of the crossproducts matrix. For p variables and n observations, the time required is proportional to np^2 . For each model run, PROC REG needs time roughly proportional to k^3 , where k is the number of regressors in the model. Include an additional nk^2 for the **R**, **CLM**, or **CLI** option and another nk^2 for the **INFLUENCE** option.

Most of the memory that PROC REG needs to solve large problems is used for crossproducts matrices. PROC REG requires $4p^2$ bytes for the main crossproducts matrix plus $4k^2$ bytes for the largest model. If several output data sets are requested, memory is also needed for buffers.

See the section “[Input Data Sets](#)” on page 6686 for information about how to use **TYPE=SSCP** data sets to reduce computing time.

Displayed Output

Many of the more specialized tables are described in detail in previous sections. Most of the formulas for the statistics are in Chapter 4, “[Introduction to Regression Procedures](#),” while other formulas can be found in the section “[Model Fit and Diagnostic Statistics](#)” on page 6715 and the section “[Influence Statistics](#)” on page 6717.

The analysis-of-variance table includes the following:

- the Source of the variation, Model for the fitted regression, Error for the residual error, and C Total for the total variation after correcting for the mean. The Uncorrected Total Variation is produced when the NOINT option is used.
- the degrees of freedom (DF) associated with the source
- the Sum of Squares for the term
- the Mean Square, the sum of squares divided by the degrees of freedom
- the F Value for testing the hypothesis that all parameters are zero except for the intercept. This is formed by dividing the mean square for Model by the mean square for Error.
- the Prob>F, the probability of getting a greater F statistic than that observed if the hypothesis is true. This is the significance probability.

Other statistics displayed include the following:

- Root MSE is an estimate of the standard deviation of the error term. It is calculated as the square root of the mean square error.
- Dep Mean is the sample mean of the dependent variable.
- C.V. is the coefficient of variation, computed as 100 times Root MSE divided by Dep Mean. This expresses the variation in unitless values.
- R-square is a measure between 0 and 1 that indicates the portion of the (corrected) total variation that is attributed to the fit rather than left to residual error. It is calculated as SS(Model) divided by SS(Total). It is also called the *coefficient of determination*. It is the square of the multiple correlation—in other words, the square of the correlation between the dependent variable and the predicted values.
- Adj R-square, the adjusted R square, is a version of R square that has been adjusted for degrees of freedom. It is calculated as

$$\bar{R}^2 = 1 - \frac{(n - i)(1 - R^2)}{n - p}$$

where i is equal to 1 if there is an intercept and 0 otherwise, n is the number of observations used to fit the model, and p is the number of parameters in the model.

The parameter estimates and associated statistics are then displayed, and they include the following:

- the Variable used as the regressor, including the name Intercept to represent the estimate of the intercept parameter
- the degrees of freedom (DF) for the variable. There is one degree of freedom unless the model is not full rank.
- the Parameter Estimate

- the Standard Error, the estimate of the standard deviation of the parameter estimate
- T for H0: Parameter=0, the t test that the parameter is zero. This is computed as the Parameter Estimate divided by the Standard Error.
- the Prob > |T|, the probability that a t statistic would obtain a greater absolute value than that observed given that the true parameter is zero. This is the two-tailed significance probability.

If model-selection methods other than NONE, RSQUARE, ADJRSQ, and CP are used, the analysis-of-variance table and the parameter estimates with associated statistics are produced at each step. Also displayed are the following:

- C(p), which is Mallows' C_p statistic
- bounds on the condition number of the correlation matrix for the variables in the model (Berk 1977)

After statistics for the final model are produced, the following is displayed when the method chosen is FORWARD, BACKWARD, or STEPWISE:

- a Summary table listing Step number, Variable Entered or Removed, Partial and Model R-square, and C(p) and F statistics

The RSQUARE method displays its results beginning with the model containing the fewest independent variables and producing the largest R square. Results for other models with the same number of variables are then shown in order of decreasing R square, and so on, for models with larger numbers of variables. The ADJRSQ and CP methods group models of all sizes together and display results beginning with the model having the optimal value of adjusted R square and C_p , respectively.

For each model considered, the RSQUARE, ADJRSQ, and CP methods display the following:

- Number in Model or IN, the number of independent variables used in each model
- R-square or RSQ, the squared multiple correlation coefficient

If the B option is specified, the RSQUARE, ADJRSQ, and CP methods produce the following:

- Parameter Estimates, the estimated regression coefficients

If the B option is not specified, the RSQUARE, ADJRSQ, and CP methods display the following:

- Variables in Model, the names of the independent variables included in the model

ODS Table Names

PROC REG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 79.11 ODS Tables Produced by PROC REG

ODS Table Name	Description	Statement	Option
ACovEst	Consistent covariance of estimates matrix	MODEL	ALL, ACOV
ACovTestANOVA	Test ANOVA using ACOV estimates	TEST	ACOV (MODEL statement)
ANOVA	Model ANOVA table	MODEL	Default
CanCorr	Canonical correlations for hypothesis combinations	MTEST	CANPRINT
CollinDiag	Collinearity Diagnostics table	MODEL	COLLIN
CollinDiagNoInt	Collinearity Diagnostics for no intercept model	MODEL	COLLINOINT
ConditionBounds	Bounds on condition number	MODEL	(SELECTION=BACKWARD FORWARD STEPWISE MAXR MINR) and DETAILS
Corr	Correlation matrix for analysis variables	PROC	ALL, CORR
CorrB	Correlation of estimates	MODEL	CORRB
CovB	Covariance of estimates	MODEL	COVB
CrossProducts	Bordered model $\mathbf{X}'\mathbf{X}$ matrix	MODEL	ALL, XPX
DWStatistic	Durbin-Watson statistic	MODEL	ALL, DW
DependenceEquations	Linear dependence equations	MODEL	Default if needed
Eigenvalues	MTest eigenvalues	MTEST	CANPRINT
Eigenvectors	MTest eigenvectors	MTEST	CANPRINT
EntryStatistics	Entry statistics for selection methods	MODEL	(SELECTION=BACKWARD FORWARD STEPWISE MAXR MINR) and DETAILS
ErrorPlusHypothesis	MTest error plus hypothesis matrix $\mathbf{H}+\mathbf{E}$	MTEST	PRINT
ErrorSSCP	MTest error matrix \mathbf{E}	MTEST	PRINT
FitStatistics	Model fit statistics	MODEL	Default
HypothesisSSCP	MTest hypothesis matrix	MTEST	PRINT
InvMTestCov	$\text{Inv}(\mathbf{L} \text{ Ginv}(\mathbf{X}'\mathbf{X}) \mathbf{L}')$ and $\text{Inv}(\mathbf{Lb}-\mathbf{c})$	MTEST	DETAILS

Table 79.11 continued

ODS Table Name	Description	Statement	Option
InvTestCov	Inv($\mathbf{L} \text{ Ginv}(\mathbf{X}'\mathbf{X}) \mathbf{L}'$) and Inv($\mathbf{Lb-c}$)	TEST	PRINT
InvXPX	Bordered $\mathbf{X}'\mathbf{X}$ inverse matrix	MODEL	I
MTestCov	$\mathbf{L} \text{ Ginv}(\mathbf{X}'\mathbf{X}) \mathbf{L}'$ and $\mathbf{Lb-c}$	MTEST	DETAILS
MTransform	MTest matrix \mathbf{M} , across dependents	MTEST	DETAILS
MultStat	Multivariate test statistics	MTEST	Default
NObs	Number of observations		Default
OutputStatistics	Output statistics table	MODEL	ALL, CLI, CLM, INFLUENCE, P, R
PartialData	Partial regression leverage data	MODEL	PARTIALDATA
ParameterEstimates	Model parameter estimates	MODEL	Default if SELECTION= is not specified
RemovalStatistics	Removal statistics for selection methods	MODEL	(SELECTION=BACKWARD STEPWISE MAXR MINR) and DETAILS
ResidualStatistics	Residual statistics and PRESS statistic	MODEL	ALL, CLI, CLM, INFLUENCE, P, R
SelParmEst	Parameter estimates for selection methods	MODEL	SELECTION=BACKWARD FORWARD STEPWISE MAXR MINR
SelectionSummary	Selection summary for FORWARD, BACKWARD, and STEPWISE methods	MODEL	SELECTION=BACKWARD FORWARD STEPWISE
SeqParmEst	Sequential parameter estimates	MODEL	SEQB
SimpleStatistics	Simple statistics for analysis variables	PROC	ALL, SIMPLE
SpecTest	White's heteroscedasticity test	MODEL	ALL, SPEC
SubsetSelSummary	Selection summary for R-square, Adj-RSq, and Cp methods	MODEL	SELECTION=RSQUARE ADJRSQ CP
TestANOVA	Test ANOVA table	TEST	Default
TestCov	$\mathbf{L} \text{ Ginv}(\mathbf{X}'\mathbf{X}) \mathbf{L}'$ and $\mathbf{Lb-c}$	TEST	PRINT
USSCP	Uncorrected SSCP matrix for analysis variables	PROC	ALL, USSCP

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The following sections describe the ODS graphical displays produced by PROC REG.

Diagnostics Panel

The “Diagnostics Panel” provides a display that you can use to get an overall assessment of your model. See [Figure 79.8](#) for an example.

The panel contains the following plots:

- residuals versus the predicted values
- externally studentized residuals (RSTUDENT) versus the predicted values
- externally studentized residuals versus the leverage
- normal quantile-quantile plot (Q-Q plot) of the residuals
- dependent variable values versus the predicted values
- Cook’s D versus observation number
- histogram of the residuals
- “Residual-Fit” (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals
- box plot of the residuals if you specify the STATS=NONE suboption

Patterns in the plots of residuals or studentized residuals versus the predicted values, or spread of the residuals being greater than the spread of the centered fit in the RF plot, are indications of an inadequate model. Patterns in the spread about the 45-degree reference line in the plot of the dependent variable values versus the predicted values are also indications of an inadequate model.

The Q-Q plot, residual histogram, and box plot of the residuals are useful for diagnosing violations of the normality and homoscedasticity assumptions. If the data in a Q-Q plot come from a normal distribution, the points will cluster tightly around the reference line. A normal density is overlaid on the residual histogram to help in detecting departures from normality.

Following Rawlings, Pantula, and Dickey (1998), reference lines are shown on the relevant plots to identify observations deemed outliers or influential. Observations whose externally studentized residual magnitudes exceed 2 are deemed outliers. Observations whose leverage value exceeds $2p/n$ or whose Cook’s

D value exceeds $4/n$ are deemed influential (p is the number of regressors including the intercept, and n is the number of observations used in the analysis). If you specify the **LABEL** suboption of the **PLOTS=DIAGNOSTICS** option, then the points deemed outliers or influential are labeled on the appropriate plots.

Fit statistics are shown in the lower right of the plot and can be customized or suppressed by using the **STATS=** suboption of the **PLOTS=DIAGNOSTICS** option.

Residuals by Regressor Plots

Panels of plots of the residuals versus each of the regressors in the model are produced by default. Patterns in these plots are indications of an inadequate model. To help in detecting patterns, you can use the **SMOOTH=** suboption of the **PLOTS=RESIDUALS** option to add loess fits to these residual plots. See Figure 79.1.6 for an example.

Fit and Prediction Plots

A fit plot consisting of a scatter plot of the data overlaid with the regression line, as well as confidence and prediction limits, is produced for models depending on a single regressor. Fit statistics are shown to the right of the plot and can be customized or suppressed by using the **STATS=** suboption of the **PLOTS=FIT** option.

When a model contains more than one regressor, a fit plot is not appropriate. However, if all the regressors in the model are transformations of a single variable in the input data set, then you can request a scatter plot of the dependent variable overlaid with a fit line and confidence and prediction limits versus this variable. You can also plot residuals versus this variable. You request these plots, shown in a panel, with the **PLOTS=PREDICTION** option. See Figure 79.13 for an example.

Influence Plots

In addition to the “Cook’s D Plot” and the “RStudent By Leverage Plot,” you can request plots of the **DFBETAS** and **DFFITS** statistics versus observation number by using the **PLOTS=DFBETAS** and **PLOTS=DFFITS** options. You can also obtain partial regression leverage plots by using the **PLOTS=PARTIAL** option. See the section “Influence Statistics” on page 6717 for examples of these plots and details about their interpretation.

Ridge and VIF Plots

When you use ridge regression, you can request plots of the variance inflation factor (VIF) values and standardized ridge estimates by ridge values for each coefficient with the **PLOTS=RIDGE** option. See Example 79.5 for examples.

Variable Selection Plots

When you request variable selection by using the **SELECTION=** option in the **MODEL** statement, you can request plots of fit criteria for the models examined by using the **PLOTS=CRITERIA** option. The fit criteria are displayed versus the step number for the FORWARD, BACKWARD, and STEPWISE selection methods and the step at which the optimal value of each criterion is obtained is indicated using a “Star” marker. For the all-subset-based selection methods (SELECTION=RSQUARE|ADJRSQ|CP), the fit criteria are displayed versus the number of observations in the model.

The criteria are shown in a panel, but you can use the UNPACK suboption of the **PLOTS=CRITERIA** option to obtain separate plots for each criterion. You can also use the LABEL suboption of the **PLOTS=CRITERIA** option to request that optimal models be labeled on the plots. [Example 79.2](#) provides several examples.

Heat Maps (Experimental)

PROC REG can produce either fit and residual scatter plots for smaller data sets or heat maps for larger data sets. The global plot option **MAXPOINTS=max heat-max** controls which of these are produced. When the number of points exceeds the value of *max* but does not exceed the value of *heat-max* divided by the number of independent variables, heat maps are displayed instead of scatter plots for the fit and residual plots. All other graphs are suppressed when the number of points exceeds *max*. The default is MAXPOINTS=5000 150000. These cutoffs are ignored if you specify MAXPOINTS=NONE. The following statements create both scatter plots and heat maps with artificial data:

```
data x;
  do i = 1 to 25000;
    x = 2 * normal(104);
    y = x + sin(x * 2) + 3 * normal(104);
    output;
  end;
run;

ods graphics on;

proc reg data=x plots(maxpoints=30000);
  model y = x;
run; quit;

proc reg data=x;
  model y = x;
run; quit;
```

Scatter plots are displayed in [Output 79.51](#), and heat maps are displayed in [Output 79.52](#).

Figure 79.51 Scatter Plot

Figure 79.51 continued

Figure 79.52 Heat Map

Figure 79.52 continued

The heat maps show more clearly that the sine function is not fit well by the linear fit function.

ODS Graph Names

PROC REG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 79.12.

Table 79.12 ODS Graphical Displays Produced by PROC REG

ODS Graph Name	Plot Description	PLOTS Option
AdjrsqPlot	Adjusted R-square statistic for models examined doing variable selection	ADJRSQ
AICPlot	AIC statistic for models examined doing variable selection	AIC
BICPlot	BIC statistic for models examined doing variable selection	BIC
CooksDPlot	Cook's D statistic versus observation number	COOKSD
CPPlot	C_p statistic for models examined doing variable selection	CP
DFFITSPlot	DFFITS statistics versus observation number	DFFITS
DFBETASPanel	Panel of DFBETAS statistics versus observation number	DFBETAS
DFBETASPlot	DFBETAS statistics versus observation number	DFBETAS(UNPACK)

Examples: REG Procedure

Example 79.1: Modeling Salaries of Major League Baseball Players

This example features the use of ODS Graphics in the process of building models by using the REG procedure and highlights the use of fit and influence diagnostics.

The following data set contains salary and performance information for Major League Baseball players who played at least one game in both the 1986 and 1987 seasons, excluding pitchers. The salaries (*Sports Illustrated*, April 20, 1987) are for the 1987 season and the performance measures are from 1986 (Collier Books, *The 1987 Baseball Encyclopedia Update*).

```
data baseball;
  length name $ 18;
  length team $ 12;
  input name $ 1-18 no_atbat no_hits no_home no_runs no_rbi no_bb yr_major
         cr_atbat cr_hits cr_home cr_runs cr_rbi cr_bb league $
         division $ team $ position $ no_outs no_assts no_error salary;
  logSalary = log10(salary);
  label name="Player's Name"
        no_hits="Hits in 1986"
        no_runs="Runs in 1986"
        no_rbi="RBIs in 1986"
        no_bb="Walks in 1986"
        yr_major="Years in MLB"
        cr_hits="Career Hits"
        salary="1987 Salary in $ Thousands"
        logSalary = "log10(Salary)";
```

;

```

Suppose you want to investigate whether you can model the players' salaries for the 1987 season based on batting statistics for the previous season and lifetime batting performance. Since the variation in salaries is much greater for higher salaries, it is appropriate to apply a log transformation for this analysis. The following statements begin the analysis:

```

ods graphics on;

proc reg data=baseball;
    id name team league;
    model logSalary = no_hits no_runs no_rbi no_bb yr_major cr_hits;
run;

```

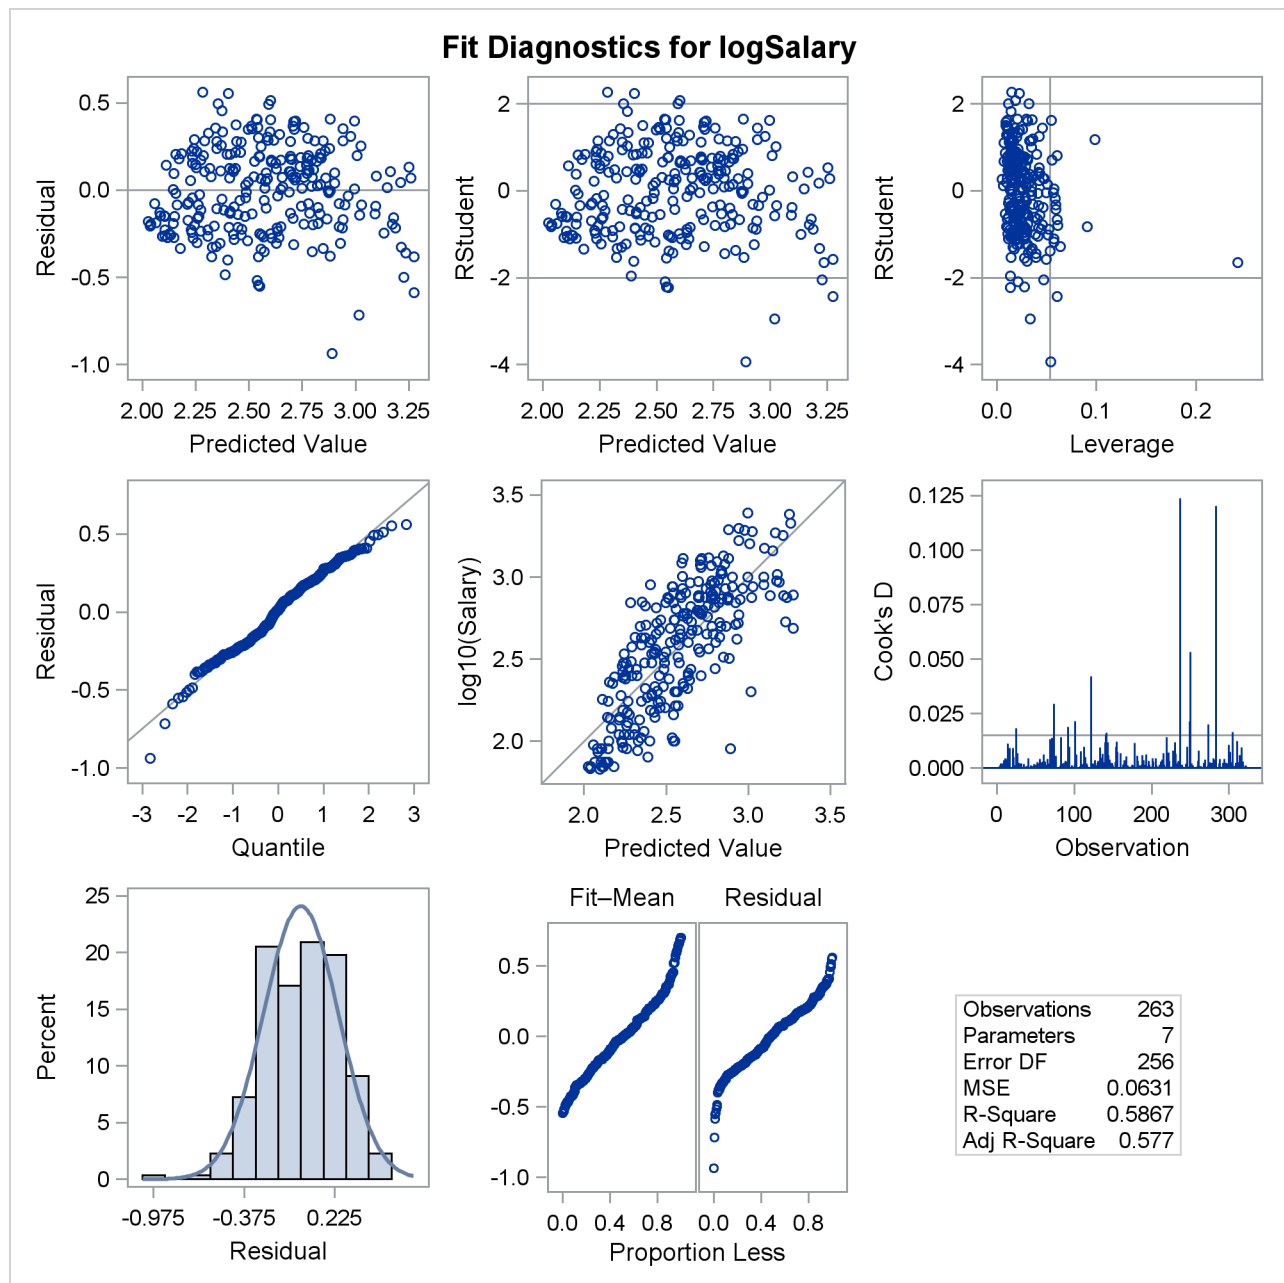

Output 79.1.1 shows the default output produced by PROC REG. The number of observations table shows that 59 observations are excluded because they have missing values for at least one of the variables used in the analysis. The analysis of variance and parameter estimates tables provide details about the fitted model.

Output 79.1.1 Default Output from PROC REG

Before you accept a regression model, it is important to examine influence and fit diagnostics to see whether the model might be unduly influenced by a few observations and whether the data support the assumptions that underlie the linear regression. To facilitate such investigations, you can obtain diagnostic plots by enabling ODS Graphics.

Output 79.1.2 Fit Diagnostics

Output 79.1.2 shows a panel of diagnostic plots. The plot of externally studentized residuals (RStudent) by leverage values reveals that there is one observation with very high leverage that might be overly influencing the fit produced. The plot of Cook's D by observation also indicates two highly influential observations. To investigate further, you can use the PLOTS= option in the PROC REG statement as follows to produce labeled versions of these plots:

```
proc reg data=baseball
  plots(only label)=(RStudentByLeverage CooksD);
  id name team league;
  model logSalary = no_hits no_runs no_rbi no_bb yr_major cr_hits;
run;
```

Output 79.1.3 and Output 79.1.4 reveal that Pete Rose is the highly influential observation. You might obtain a better fit to the remaining data if you omit his statistics when building the model.

Output 79.1.3 Outlier and Leverage Diagnostics

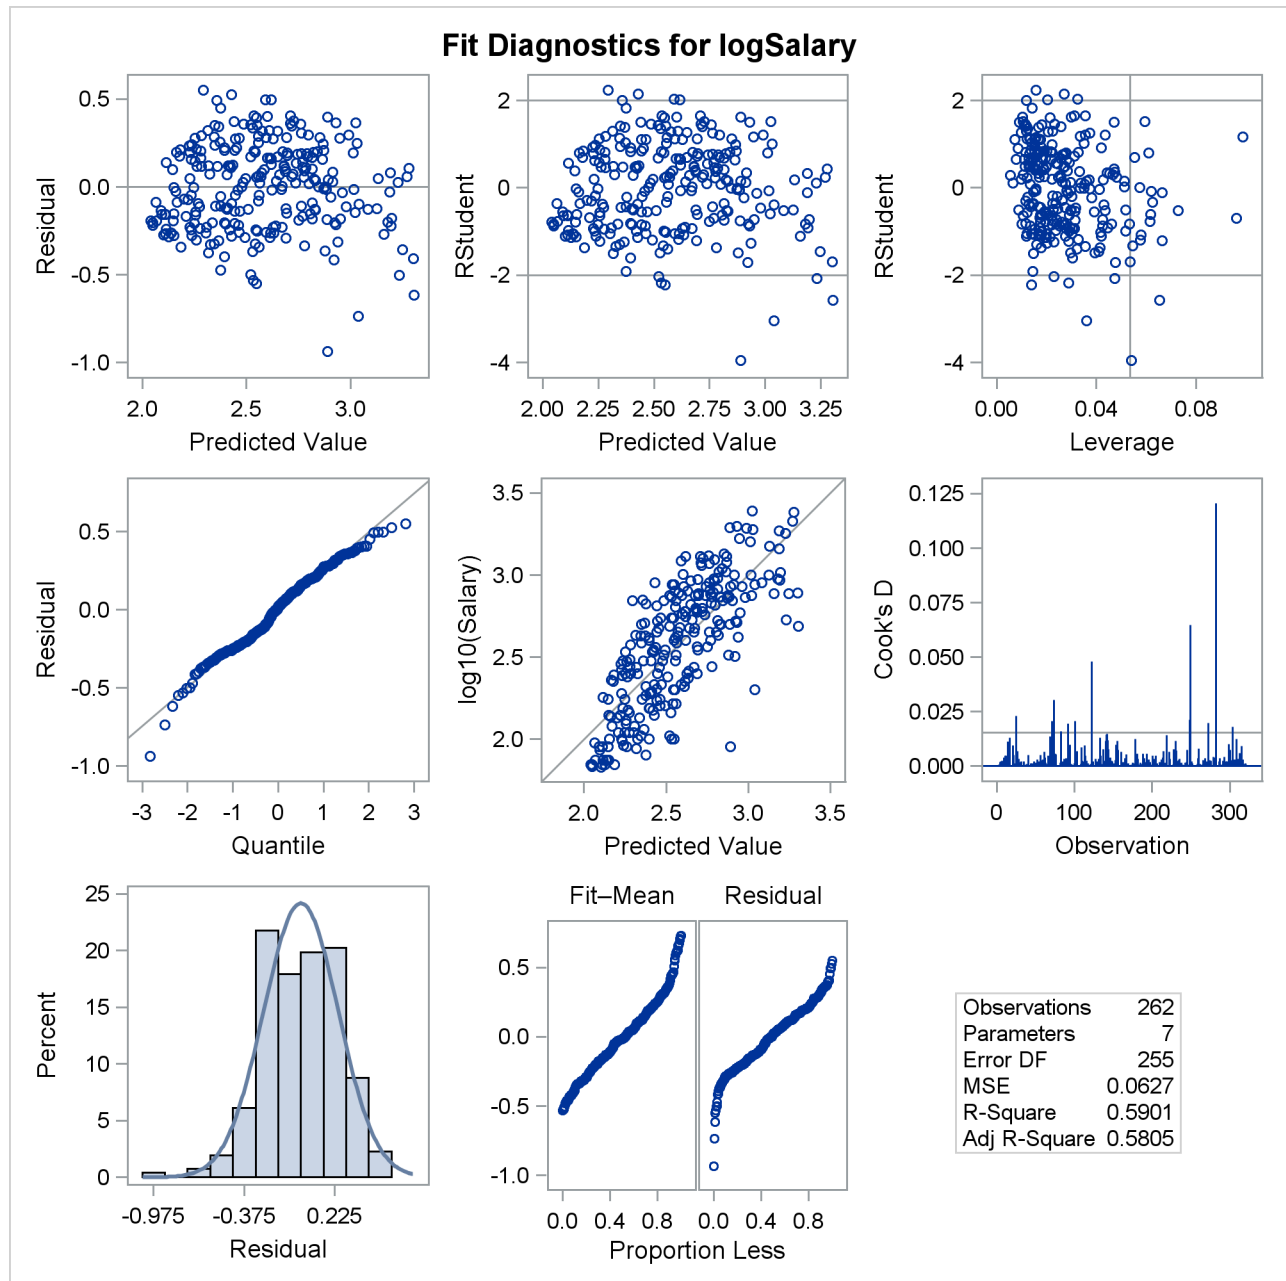

Output 79.1.4 Cook's *D*

The following statements use a WHERE statement to omit Pete Rose's statistics when building the model. An alternative way to do this within PROC REG is to use a [REWEIGHT](#) statement. See "[Reweightings Observations in an Analysis](#)" on page 6726 for details about reweighting.

```
proc reg data=baseball
    plots=(RStudentByLeverage(label) residuals(smooth));
    where name^="Rose, Pete";
    id name team league;
    model logSalary = no_hits no_runs no_rbi no_bb yr_major cr_hits;
run;
```

[Output 79.1.5](#) shows the new fit diagnostics panel. You can see that there are still several influential and outlying observations. One possible reason for observing outliers is that the linear model specified is not appropriate to capture the variation in this data. You can often see evidence of an inappropriate model by observing patterns in plots of residuals.

Output 79.1.5 Fit Diagnostics

Output 79.1.6 shows plots of the residuals by the regressors in the model. When you specify the RESIDUALS(SMOOTH) suboption of the PLOTS option in the **PROC REG** statement, a loess fit is overlaid on each of these plots. You can see the same clear pattern in the residual plots for `yr_major` and `cr_hits`. Players near the start of their careers and players near the end of their careers get paid less than the model predicts.

Output 79.1.6 Residuals by Regressors

You can address this lack of fit by using polynomials of degree 2 for these two variables as shown in the following statements:

```
data baseball;
  set baseball(where=(name^="Rose, Pete"));
  yr_major2 = yr_major*yr_major;
  cr_hits2  = cr_hits*cr_hits;
run;

proc reg data=baseball
  plots=(diagnostics(stats=none) RStudentByLeverage(label)
        CooksD(label) Residuals(smooth)
        DFFITS(label) DFBETAS ObservedByPredicted(label));
  id name team league;
  model logSalary = no_hits no_runs no_rbi no_bb yr_major cr_hits
    yr_major2 cr_hits2;
run;
ods graphics off;
```

Output 79.1.7 shows the analysis of variance and parameter estimates for this model. Note that the R-square value of 0.787 for this model is considerably larger than the R-square value of 0.587 for the initial model shown in Output 79.1.1.

Output 79.1.7 Output from PROC REG

cr_hits	Career Hits	1	0.00073955	0.00011970	6.18	<.0001
yr_major2		1	-0.00625	0.00071687	-8.73	<.0001
cr_hits2		1	-1.44072E-7	4.348471E-8	-3.31	0.0011

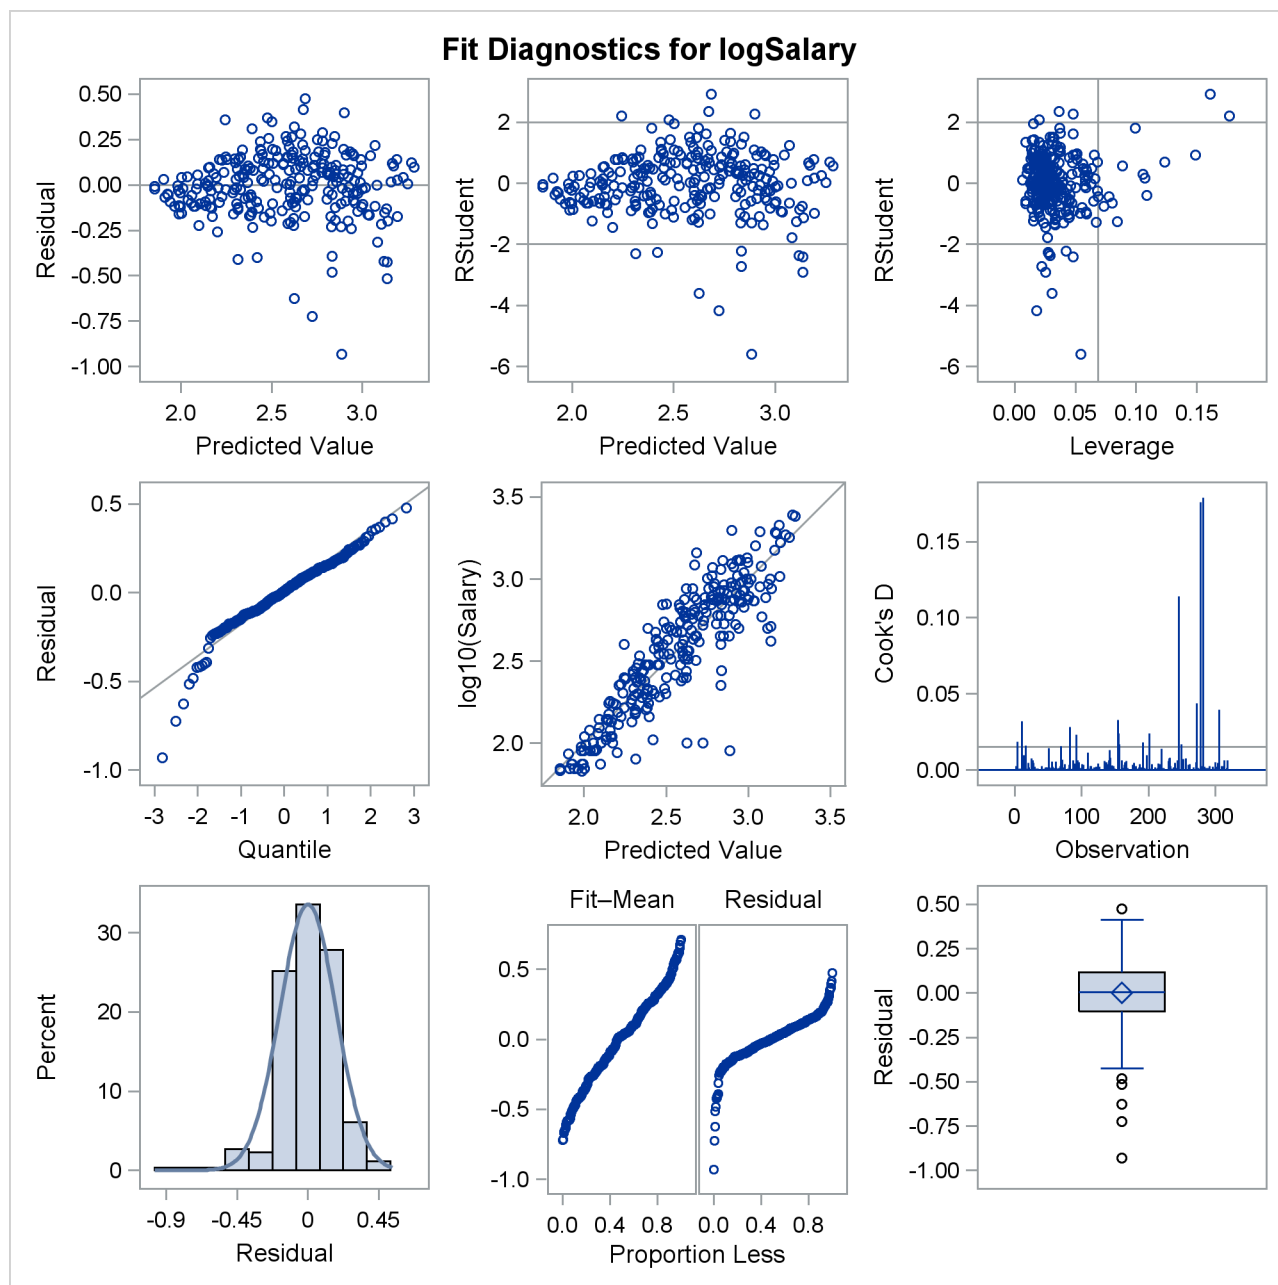

The plots of residuals by regressors in Output 79.1.8 and Output 79.1.9 show that the strong pattern in the plots for cr_majors and cr_hits has been reduced, although there is still some indication of a pattern remaining in these residuals. This suggests that a quadratic function might be insufficient to capture dependence of salary on these regressors.

Output 79.1.8 Residuals by Regressors

Output 79.1.9 Residuals by Regressors

[Output 79.1.10](#) show the diagnostics plots; three of the plots, with points of interest labeled, are shown individually in [Output 79.1.11](#), [Output 79.1.12](#), and [Output 79.1.13](#). The `STATS=NONE` suboption specified in the `PLOTS=DIAGNOSTICS` option replaces the inset of statistics with a box plot of the residuals in the fit diagnostics panel. The observed by predicted value plot reveals a reasonably successful model for explaining the variation in salary for most of the players. However, the model tends to overpredict the salaries of several players near the lower end of the salary range. This bias can also be seen in the distribution of the residuals that you can see in the histogram, Q-Q plot, and box plot in [Output 79.1.10](#).

Output 79.1.10 Fit Diagnostics

Output 79.1.11 Outlier and Leverage Diagnostics

Output 79.1.12 Observed by Predicted Values

Output 79.1.13 Cook's D

The RStudent by leverage plot in [Output 79.1.11](#) and the Cook's D plot in [Output 79.1.13](#) show that there are still a number of influential observations. By specifying the DFFITS and DFBETAS suboptions of the PLOTS= option, you obtain additional influence diagnostics plots shown in [Output 79.1.14](#) and [Output 79.1.15](#). See “[Influence Statistics](#)” on page 6717 for details about the interpretation DFFITS and DFBETAS statistics.

Output 79.1.14 DFFITS

Output 79.1.15 DFBETAS

You can continue this analysis by investigating how the influential observations identified in the various influence plots affect the fit. You can also use PROC ROBUSTREG to obtain a fit that is resistant to the presence of high leverage points and outliers.

Example 79.2: Aerobic Fitness Prediction

Aerobic fitness (measured by the ability to consume oxygen) is fit to some simple exercise tests. The goal is to develop an equation to predict fitness based on the exercise tests rather than on expensive and cumbersome oxygen consumption measurements. Three model-selection methods are used: forward selection, backward selection, and MAXR selection. Here are the data:

```
*-----Data on Physical Fitness-----*
| These measurements were made on men involved in a physical |
| fitness course at N.C.State Univ. The variables are Age      |
| (years), Weight (kg), Oxygen intake rate (ml per kg body    |
| weight per minute), time to run 1.5 miles (minutes), heart  |
| rate while resting, heart rate while running (same time    |
| Oxygen rate measured), and maximum heart rate recorded while|
| running.                                                    |
| ***Certain values of MaxPulse were changed for this analysis.|

The final variable available to add to the model, RestPulse, is not added since it does not meet the 50% (the default value of the SLE option is 0.5 for FORWARD selection) significance-level criterion for entry into the model.

The BACKWARD model-selection method begins with the full model. [Output 79.2.2](#) shows the steps of the BACKWARD method. RestPulse is the first variable deleted, followed by Weight. No other variables are deleted from the model since the variables remaining (Age, RunTime, RunPulse, and MaxPulse) are all significant at the 10% (the default value of the SLS option is 0.1 for the BACKWARD elimination method) significance level.

Note that for all three of these methods, RestPulse contributes least to the model. In the case of forward selection, it is not added to the model. In the case of backward selection, it is the first variable to be removed from the model. In the case of MAXR selection, RestPulse is included only for the full model.

For the STEPWISE, BACKWARD, and FORWARD selection methods, you can control the amount of detail displayed by using the DETAILS option, and you can use ODS Graphics to produce plots that show how selection criteria progress as the selection proceeds. For example, the following statements display only the selection summary table for the FORWARD selection method ([Output 79.2.4](#)) and produce the plots shown in [Output 79.2.5](#) and [Output 79.2.6](#).

```
ods graphics on;

proc reg data=fitness plots=(criteria sbc);
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
    / selection=forward details=summary;
run;
```

Output 79.2.4 Forward Selection Summary

The REG Procedure							
Model: MODEL1							
Dependent Variable: Oxygen							
Summary of Forward Selection							
Step	Variable Entered	Number Vars In	Partial R-Square	Model R-Square	C(p)	F Value	Pr > F
1	RunTime	1	0.7434	0.7434	13.6988	84.01	<.0001

4	MaxPulse	4	0.0257	0.8368	4.8800	4.10	0.0533
5	Weight	5	0.0112	0.8480	5.1063	1.84	0.1871

[Output 79.2.5](#) show how six fit criteria progress as the forward selection proceeds. The step at which each criterion achieves its best value is indicated. For example, the BIC criterion achieves its minimum value for the model at step 4. Note that this does not mean that the model at step 4 achieves the smallest BIC criterion among all possible models that use a subset of the regressors; the model at step 4 yields the smallest BIC statistic among the models at each step of the forward selection. [Output 79.2.6](#) show the progression of the SBC statistic in its own plot. If you want to see six of the selection criteria in individual plots, you can specify the UNPACK suboption of the PLOTS=CRITERIA option in the [PROC REG](#) statement.

Output 79.2.5 Fit Criteria

Output 79.2.6 SBC Criterion

Next, the RSQUARE model-selection method is used to request R square and C_p statistics for all possible combinations of the six independent variables. The following statements produce [Output 79.2.7](#):

```
proc reg data=fitness plots=(criteria(label) cp);
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
    / selection=rsquare cp;
  title 'Physical fitness data: all models';
run;
```

Output 79.2.7 All Models by the RSQUARE Method: PROC REG

The models in [Output 79.2.7](#) are arranged first by the number of variables in the model and then by the magnitude of R square for the model.

Output 79.2.8 shows the panel of fit criteria for the RSQUARE selection method. The best models (based on the R-square statistic) for each subset size are indicated on the plots. The LABEL suboption specifies that these models are labeled by the model number that appears in the summary table shown in Output 79.2.7.

Output 79.2.8 Fit Criteria

Output 79.2.9 shows the plot of the C_p criterion by number of regressors in the model. Useful reference lines suggested by Mallows (1973) and Hocking (1976) are included on the plot. However, because all possible subset models are included on this plot, the better models are all compressed near the bottom of the plot.

Output 79.2.9 C_p Criterion

The following statements use the BEST=20 option in the model statement and SELECTION=CP to restrict attention to the models that yield the 20 smallest values of the C_p statistic:

```
proc reg data=fitness plots(only)=cp(label);
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
    / selection=cp best=20;
run;

ods graphics off;
```

Output 79.2.10 shows the summary table listing the regressors in the 20 models that yield the smallest C_p values, and Output 79.2.11 presents the results graphically. Reference lines $C_p = 2p - p_{full}$ and $C_p = p$ are shown on this plot. See the **PLOTS=CP** option on page 6639 for interpretations of these lines. For the Fitness data, these lines indicate that a six-variable model is a reasonable choice for doing parameter estimation, while a five-variable model might be suitable for doing prediction.

Output 79.2.10 C_p Selection Summary: PROC REG

The REG Procedure				
Model: MODEL1				
Dependent Variable: Oxygen

20	3	13.8974	0.7673	Age RunTime RestPulse

Output 79.2.11 C_p Criterion

Before making a final decision about which model to use, you would want to perform collinearity diagnostics. Note that, since many different models have been fit and the choice of a final model is based on R square, the statistics are biased and the p -values for the parameter estimates are not valid.

Example 79.3: Predicting Weight by Height and Age

In this example, the weights of schoolchildren are modeled as a function of their heights and ages. The example shows the use of a BY statement with `PROC REG`, multiple `MODEL` statements, and the `OUTEST=` and `OUTSSCP=` options, which create data sets. Here are the data:

```
*-----Data on Age, Weight, and Height of Children-----*
| Age (months), height (inches), and weight (pounds) were   |
| recorded for a group of school children.                  |
| From Lewis and Taylor (1967).                             |
*-----*

data hwt;

;
```

Modeling is performed separately for boys and girls. Since the BY statement is used, interactive processing is not possible in this example; no statements can appear after the first RUN statement.

The following statements produce [Output 79.3.1](#) through [Output 79.3.4](#):

```
proc reg outest=est1 outsscp=sscp1 rsquare;
  by sex;
  eq1: model weight=height;
  eq2: model weight=height age;
run;

proc print data=sscp1;
  title2 'SSCP type data set';
run;

proc print data=est1;
  title2 'EST type data set';
run;

For both female and male children, the overall F statistics for both models are significant, indicating that the model explains a significant portion of the variation in the data. For females, the full model is

$$\text{weight} = -150.57 + 3.60 \times \text{height} + 1.91 \times \text{age}$$

and for males, the full model is

$$\text{weight} = -113.71 + 2.68 \times \text{height} + 3.08 \times \text{age}$$

The OUTSSCP= data set is shown in [Output 79.3.5](#). Note how the BY groups are separated. Observations with `_TYPE_='N'` contain the number of observations in the associated BY group. Observations with `_TYPE_='SSCP'` contain the rows of the uncorrected sums of squares and crossproducts matrix. The observations with `_NAME_='Intercept'` contain crossproducts for the intercept.

Output 79.3.5 SSCP Matrix

The OUTEST= data set is displayed in [Output 79.3.6](#); again, the BY groups are separated. The `_MODEL_` column contains the labels for models from the `MODEL` statements. If no labels are specified, the defaults `MODEL1` and `MODEL2` would appear as values for `_MODEL_`. Note that `_TYPE_='PARMS'` for all observations, indicating that all observations contain parameter estimates. The `_DEPVAR_` column displays the dependent variable, and the `_RMSE_` column gives the root mean square error for the associated model. The Intercept column gives the estimate for the intercept for the associated model, and variables with the same name as variables in the original data set (height, age) give parameter estimates for those variables. The dependent variable, weight, is shown with a value of `-1`. The `_IN_` column contains the number of regressors in the model not including the intercept; `_P_` contains the number of parameters in the model; `_EDF_` contains the error degrees of freedom; and `_RSQ_` contains the R square statistic. Finally, note that the `_IN_`, `_P_`, `_EDF_`, and `_RSQ_` columns appear in the OUTEST= data set since the `RSQUARE` option is specified in the `PROC REG` statement.

Example 79.4: Regression with Quantitative and Qualitative Variables

At times it is desirable to have independent variables in the model that are qualitative rather than quantitative. This is easily handled in a regression framework. Regression uses qualitative variables to distinguish between populations. There are two main advantages of fitting both populations in one model. You gain the ability to test for different slopes or intercepts in the populations, and more degrees of freedom are available for the analysis.

Regression with qualitative variables is different from analysis of variance and analysis of covariance. Analysis of variance uses qualitative independent variables only. Analysis of covariance uses quantitative variables in addition to the qualitative variables in order to account for correlation in the data and reduce MSE; however, the quantitative variables are not of primary interest and merely improve the precision of the analysis.

Consider the case where Y_i is the dependent variable, $X1_i$ is a quantitative variable, $X2_i$ is a qualitative variable taking on values 0 or 1, and $X1_i X2_i$ is the interaction. The variable $X2_i$ is called a dummy, binary, or indicator variable. With values 0 or 1, it distinguishes between two populations. The model is of the form

$$Y_i = \beta_0 + \beta_1 X1_i + \beta_2 X2_i + \beta_3 X1_i X2_i + \epsilon_i$$

for the observations $i = 1, 2, \dots, n$. The parameters to be estimated are β_0 , β_1 , β_2 , and β_3 . The number of dummy variables used is one less than the number of qualitative levels. This yields a nonsingular $X'X$ matrix. See Chapter 10 of Neter, Wasserman, and Kutner (1990) for more details.

An example from Neter, Wasserman, and Kutner (1990) follows. An economist is investigating the relationship between the size of an insurance firm and the speed at which it implements new insurance innovations. He believes that the type of firm might affect this relationship and suspects that there might be some interaction between the size and type of firm. The dummy variable in the model enables the two firms to have different intercepts. The interaction term enables the firms to have different slopes as well.

In this study, Y_i is the number of months from the time the first firm implemented the innovation to the time it was implemented by the i th firm. The variable $X1_i$ is the size of the firm, measured in total assets of the firm. The variable $X2_i$ denotes the firm type; it is 0 if the firm is a mutual fund company and 1 if the firm is a stock company. The dummy variable enables each firm type to have a different intercept and slope.

The previous model can be broken down into a model for each firm type by plugging in the values for $X2_i$. If $X2_i = 0$, the model is

$$Y_i = \beta_0 + \beta_1 X1_i + \epsilon_i$$

This is the model for a mutual company. If $X2_i = 1$, the model for a stock firm is

$$Y_i = (\beta_0 + \beta_2) + (\beta_1 + \beta_3)X1_i + \epsilon_i$$

This model has intercept $\beta_0 + \beta_2$ and slope $\beta_1 + \beta_3$.

The data¹ follow. Note that the interaction term is created in the DATA step since polynomial effects such as size*type are not allowed in the **MODEL** statement in the REG procedure.

```

title 'Regression with Quantitative and Qualitative Variables';
data insurance;
  input time size type @@;
  sizetype=size*type;
  datalines;

Coeff Var		17.11450			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	33.83837	2.44065	13.86	<.0001
size	1	-0.10153	0.01305	-7.78	<.0001
type	1	8.13125	3.65405	2.23	0.0408
sizetype	1	-0.00041714	0.01833	-0.02	0.9821

¹From Neter, J., et al., *Applied Linear Statistical Models*, Third Edition, Copyright (c) 1990, Richard D. Irwin. Reprinted with permission of The McGraw-Hill Companies.

The overall F statistic is significant ($F = 45.490$, $p < 0.0001$). The interaction term is not significant ($t = -0.023$, $p = 0.9821$). Hence, this term should be removed and the model refitted, as shown in the following statements:

```
delete sizetype;
print;
run;
```

The **DELETE** statement removes the interaction term (sizetype) from the model. The new ANOVA and parameter estimates tables are shown in [Output 79.4.2](#).

Output 79.4.2 ANOVA Table and Parameter Estimates

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	1504.41333	752.20667	72.50	<.0001
Error	17	176.38667	10.37569		
Corrected Total	19	1680.80000			
Root MSE		3.22113	R-Square	0.8951	
Dependent Mean		19.40000	Adj R-Sq	0.8827	
Coeff Var		16.60377			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	33.87407	1.81386	18.68	<.0001
size	1	-0.10174	0.00889	-11.44	<.0001
type	1	8.05547	1.45911	5.52	<.0001

The overall F statistic is still significant ($F = 72.497$, $p < 0.0001$). The intercept and the coefficients associated with size and type are significantly different from zero ($t = 18.675$, $p < 0.0001$; $t = -11.443$, $p < 0.0001$; $t = 5.521$, $p < 0.0001$, respectively). Notice that the R square did not change with the omission of the interaction term.

The fitted model is

$$\text{time} = 33.87 - 0.102 \times \text{size} + 8.055 \times \text{type}$$

The fitted model for a mutual fund company ($X_{2i} = 0$) is

$$\text{time} = 33.87 - 0.102 \times \text{size}$$

and the fitted model for a stock company ($X_{2i} = 1$) is

$$\text{time} = (33.87 + 8.055) - 0.102 \times \text{size}$$

So the two models have different intercepts but the same slope.

The following statements first use an **OUTPUT** statement to save the residuals and predicted values from the new model in the OUT= data set. Next PROC SGPLOT is used to produce **Output 79.4.3**, which plots residuals versus predicted values. The firm type is used as the plot symbol; this can be useful in determining if the firm types have different residual patterns.

```
output out=out r=r p=p;
run;

proc sgplot data=out;
  scatter x=p y=r / markerchar=type group=type;
run;
```

Output 79.4.3 Plot of Residual vs. Predicted Values

The residuals show no major trend. Neither firm type by itself shows a trend either. This indicates that the model is satisfactory.

The following statements produce the plot of the predicted values versus size that appears in [Output 79.4.4](#), where the firm type is again used as the plotting symbol:

```
proc sgplot data=out;
  scatter x=size y=p / markerchar=type group=type;
run;
```

Output 79.4.4 Plot of Predicted vs. Size

The different intercepts are very evident in this plot.

Example 79.5: Ridge Regression for Acetylene Data

This example uses the acetylene data in Marquardt and Snee (1975) to illustrate the RIDGEPLOT and OUTVIF options. Here are the data:

```
data acetyl;
  input x1-x4 @@;
  x1x2 = x1 * x2;
  x1x1 = x1 * x1;
  label x1 = 'reactor temperature(celsius)'
        x2 = 'h2 to n-heptone ratio'
        x3 = 'contact time(sec)'
        x4 = 'conversion percentage'
        x1x2 = 'temperature-ratio interaction'
        x1x1 = 'squared temperature';
  datalines;
1300 7.5 .012 49 1300 9 .012 50.2 1300 11 .0115 50.5
1300 13.5 .013 48.5 1300 17 .0135 47.5 1300 23 .012 44.5
1200 5.3 .04 28 1200 7.5 .038 31.5 1200 11 .032 34.5
1200 13.5 .026 35 1200 17 .034 38 1200 23 .041 38.5
1100 5.3 .084 15 1100 7.5 .098 17 1100 11 .092 20.5
1100 17 .086 29.5
;

ods graphics on;

proc reg data=acetyl outvif
  outest=b ridge=0 to 0.02 by .002;
  model x4=x1 x2 x3 x1x2 x1x1;
run;
proc print data=b;
run;
```

When ODS Graphics is enabled and you request ridge regression by using the RIDGE= option in the **PROC REG** statement, PROC REG produces a panel showing variance inflation factors (VIF) in the upper plot in the panel and ridge traces in the lower plot. This panel is shown in [Output 79.5.1](#).

Output 79.5.1 Ridge Regression and VIF Traces

The OUTVIF option outputs the variance inflation factors to the OUTEST= data set that is shown in [Output 79.5.2](#).

Output 79.5.2 OUTEST Data Set Showing VIF Values

If you want to obtain separate plots containing the ridge traces and VIF traces, you can specify the UNPACK suboption in the PLOTS=RIDGE option. You can also request that one or both of the VIF axis and ridge parameter axis be displayed on a logarithmic scale. You can see in [Output 79.5.1](#) that the VIF traces for several of the parameters are nearly indistinguishable when displayed on a linear scale. The following code illustrates how you obtain separate VIF and ridge traces with the VIF values displayed on a logarithmic scale. Note that you can obtain plots of VIF values even though you do not specify the OUTVIF option in the PROC REG statement.

```
proc reg data=acetyl plots(only)=ridge(unpack VIFaxis=log)
    outest=b ridge=0 to 0.02 by .002;
    model x4=x1 x2 x3 x1x2 x1x1;
run;

ods graphics off;
```

The requested plots are shown in [Output 79.5.3](#) and [Output 79.5.4](#).

Output 79.5.3 VIF Traces

Output 79.5.4 Ridge Traces

Example 79.6: Chemical Reaction Response

This example shows how you can use lack-of-fit tests with the REG procedure. See the section “[Testing for Lack of Fit](#)” on page 6733 for details about lack-of-fit tests.

In a study of the percentage of raw material that responds in a reaction, researchers identified the following five factors:

- the feed rate of the chemicals (FeedRate), ranging from 10 to 15 liters per minute
- the percentage of the catalyst (Catalyst), ranging from 1% to 2%
- the agitation rate of the reactor (AgitRate), ranging from 100 to 120 revolutions per minute
- the temperature (Temperature), ranging from 140 to 180 degrees Celsius
- the concentration (Concentration), ranging from 3% to 6%

The following data set contains the results of an experiment designed to estimate main effects for all factors:

```

data reaction;
  input FeedRate Catalyst AgitRate Temperature
        Concentration ReactionPercentage;
  datalines;
10.0   1.0  100   140   6.0   37.5
10.0   1.0  120   180   3.0   28.5
10.0   2.0  100   180   3.0   40.4
10.0   2.0  120   140   6.0   48.2
15.0   1.0  100   180   6.0   50.7
15.0   1.0  120   140   3.0   28.9
15.0   2.0  100   140   3.0   43.5
15.0   2.0  120   180   6.0   64.5
12.5   1.5  110   160   4.5   39.0
12.5   1.5  110   160   4.5   40.3
12.5   1.5  110   160   4.5   38.7
12.5   1.5  110   160   4.5   39.7
;

```

The first eight runs of this experiment enable orthogonal estimation of the main effects for all factors. The last four comprise four replicates of the centerpoint.

The following statements fit a linear model. Because this experiment includes replications, you can test for lack of fit by using the LACKFIT option in the **MODEL** statement.

```

proc reg data=reaction;
  model ReactionPercentage=FeedRate Catalyst AgitRate
        Temperature Concentration / lackfit;
run;

```

Output 79.6.1 shows that the lack of fit for the linear model is significant, indicating that a more complex model is required. Models that include interactions should be investigated. In this case, this will require additional experimentation to obtain appropriate data for estimating the effects.

Output 79.6.1 Analysis of Variance

Overview: ROBUSTREG Procedure

The main purpose of robust regression is to detect outliers and provide resistant (stable) results in the presence of outliers. In order to achieve this stability, robust regression limits the influence of outliers. Historically, three classes of problems have been addressed with robust regression techniques:

- problems with outliers in the y -direction (response direction)
- problems with multivariate outliers in the x -space (that is, outliers in the covariate space, which are also referred to as leverage points)
- problems with outliers in both the y -direction and the x -space

Many methods have been developed in response to these problems. However, in statistical applications of outlier detection and robust regression, the methods most commonly used today are Huber M estimation, high breakdown value estimation, and combinations of these two methods. The ROBUSTREG procedure provides four such methods: M estimation, LTS estimation, S estimation, and MM estimation.

- M estimation was introduced by Huber (1973), and it is the simplest approach both computationally and theoretically. Although it is not robust with respect to leverage points, it is still used extensively in data analysis when contamination can be assumed to be mainly in the response direction.
- Least trimmed squares (LTS) estimation is a high breakdown value method introduced by Rousseeuw (1984). The breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness. The performance of this method was improved by the FAST-LTS algorithm of Rousseeuw and Van Driessen (2000).
- S estimation is a high breakdown value method introduced by Rousseeuw and Yohai (1984). With the same breakdown value, it has a higher statistical efficiency than LTS estimation.
- MM estimation, introduced by Yohai (1987), combines high breakdown value estimation and M estimation. It has both the high breakdown property and a higher statistical efficiency than S estimation.

Features

The main features of the ROBUSTREG procedure are as follows:

- offers four estimation methods: M, LTS, S, and MM
- provides 10 weight functions for M estimation
- provides robust R-square and deviance for all estimates
- provides asymptotic covariance and confidence intervals for regression parameter with the M, S, and MM methods

- provides robust Wald and F tests for regression parameters with the M and MM methods
- provides Mahalanobis distance and robust Mahalanobis distance with generalized minimum covariance determinant (MCD) algorithm
- provides outlier and leverage-point diagnostics
- supports parallel computing for S and LTS estimates
- supports constructed effects including spline and multimember effects
- produces fit plots and diagnostic plots by using ODS Graphics

Getting Started: ROBUSTREG Procedure

The following examples demonstrate how you can use the ROBUSTREG procedure to fit a linear regression model and obtain outlier and leverage-point diagnostics.

M Estimation

This example shows how you can use the ROBUSTREG procedure to do M estimation, which is a commonly used method for outlier detection and robust regression when contamination is mainly in the response direction.

```
data stack;
  input  x1 x2 x3 y exp $ @@;
  datalines;
80 27 89 42 e1 80 27 88 37 e2
75 25 90 37 e3 62 24 87 28 e4
62 22 87 18 e5 62 23 87 18 e6
62 24 93 19 e7 62 24 93 20 e8
58 23 87 15 e9 58 18 80 14 e10
58 18 89 14 e11 58 17 88 13 e12
58 18 82 11 e13 58 19 93 12 e14
50 18 89 8 e15 50 18 86 7 e16
50 19 72 8 e17 50 19 79 8 e18
50 20 80 9 e19 56 20 82 15 e20
70 20 91 15 e21
;
```

The data set `stack` is the well-known stack-loss data set presented by Brownlee (1965). The data describe the operation of a plant for the oxidation of ammonia to nitric acid and consist of 21 four-dimensional observations. The explanatory variables for the response stack-loss (y) are the rate of operation (x_1), the cooling water inlet temperature (x_2), and the acid concentration (x_3).

The following ROBUSTREG statements analyze the data:

```
proc robustreg data=stack;
  model y = x1 x2 x3 / diagnostics leverage;
  id    exp;
  test  x3;
run;
```

By default, the procedure does M estimation with the bisquare weight function, and it uses the median method for estimating the scale parameter. The MODEL statement specifies the covariate effects. The DIAGNOSTICS option requests a table for outlier diagnostics, and the LEVERAGE option adds leverage-point diagnostic results to this table for continuous covariate effects. The ID statement specifies that the variable `exp` is used to identify each observation (experiment) in this table. If the ID statement is omitted, the observation number is used to identify the observations. The TEST statement requests a test of significance for the covariate effects specified. The results of this analysis are displayed in the following figures.

Figure 80.1 Model Fitting Information and Summary Statistics

The ROBUSTREG Procedure						
Model Information						
Data Set	WORK.STACK					
Dependent Variable	Y					
Number of Independent Variables	3					
Number of Observations	21					
Method	M Estimation					
Summary Statistics						
Variable	Q1	Median	Q3	Mean	Standard Deviation	MAD
x1	53.0000	58.0000	62.0000	60.4286	9.1683	5.9304
x2	18.0000	20.0000	24.0000	21.0952	3.1608	2.9652
x3	82.0000	87.0000	89.5000	86.2857	5.3586	4.4478
y	10.0000	15.0000	19.5000	17.5238	10.1716	5.9304

Figure 80.1 displays the model fitting information and summary statistics for the response variable and the continuous covariates. The columns labeled Q1, Median, and Q3 provide the lower quantile, median, and upper quantile, respectively. The column labeled MAD provides a robust estimate of the univariate scale, which is computed as the standardized median absolute deviation (MAD). See Huber (1981, p. 108) for more details about the standardized MAD. The columns labeled Mean and Standard Deviation provide the usual mean and standard deviation. A large difference between the standard deviation and the MAD for a variable indicates some extreme values for this variable. In the stack-loss data, the stack-loss (response `y`) has the biggest difference between the standard deviation and the MAD.

Figure 80.2 Model Parameter Estimates

Parameter Estimates							
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	-42.2854	9.5045	-60.9138	-23.6569	19.79	<.0001
x1	1	0.9276	0.1077	0.7164	1.1387	74.11	<.0001
x2	1	0.6507	0.2940	0.0744	1.2270	4.90	0.0269
x3	1	-0.1123	0.1249	-0.3571	0.1324	0.81	0.3683
Scale	1	2.2819					

Figure 80.2 displays the table of robust parameter estimates, standard errors, and confidence limits. The row labeled Scale provides a point estimate of the scale parameter in the linear regression model, which is obtained by the median method. See the section “M Estimation” on page 6838 for more information about scale estimation methods. For the stack-loss data, M estimation yields the fitted linear model:

$$\hat{y} = -42.2845 + 0.9276x_1 + 0.6507x_2 - 0.1123x_3$$

Figure 80.3 Diagnostics

Diagnostics						
Obs	exp	Mahalanobis Distance	Robust MCD Distance	Leverage	Standardized Robust Residual	Outlier
1	e1	2.2536	5.5284	*	1.0995	
2	e2	2.3247	5.6374	*	-1.1409	
3	e3	1.5937	4.1972	*	1.5604	
4	e4	1.2719	1.5887		3.0381	*
21	e21	2.1768	3.6573	*	-4.5733	*

Figure 80.3 displays outlier and leverage-point diagnostics. Standardized robust residuals are computed based on the estimated parameters. Both the Mahalanobis distance and the robust MCD distance are displayed. Outliers and leverage points, identified with asterisks, are defined by the standardized robust residuals and robust MCD distances that exceed the corresponding cutoff values displayed in the diagnostics summary. Observations 4 and 21 are outliers because their standardized robust residuals exceed the cutoff value in absolute value. The procedure detects four observations with high leverage. Leverage points (points with high leverage) with smaller standardized robust residuals than the cutoff value in absolute value are called good leverage points; others are called bad leverage points. Observation 21 is a bad leverage point.

Two particularly useful plots for revealing outliers and leverage points are a scatter plot of the standardized robust residuals against the robust distances (RDPlot) and a scatter plot of the robust distances against the classical Mahalanobis distances (DDPlot).

For the stack-loss data, the following statements produce the RDPLLOT in Figure 80.4 and the DDPLLOT in Figure 80.5. The histogram and the normal quantile-quantile plots (shown in Figure 80.6 and Figure 80.7, respectively) for the standardized robust residuals are also created with the HISTOGRAM and QQPLOT suboptions of the PLOTS= option.

```
ods graphics on;

proc robustreg data=stack plots=(rdplot ddplot histogram qqplot);
  model y = x1 x2 x3;
run;

ods graphics off;
```

These plots are helpful in identifying outliers in addition to good and bad high leverage points.

These plots are requested when ODS Graphics is enabled by specifying the **PLOTS=** option in the PROC ROBUSTREG statement. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the graphics available in the ROBUSTREG procedure, see the section “ODS Graphics” on page 6865.

Figure 80.4 RDPLLOT for Stackloss Data

Figure 80.5 DDPLLOT for Stackloss Data

Figure 80.6 Histogram

Figure 80.7 Q-Q Plot

Figure 80.8 displays robust versions of goodness-of-fit statistics for the model. You can use the robust information criteria, AICR and BICR, for model selection and comparison. For both AICR and BICR, the lower the value, the more desirable the model.

Figure 80.8 Goodness-of-Fit Statistics

Goodness-of-Fit	
Statistic	Value
R-Square	0.6659
AICR	29.5231
BICR	36.3361
Deviance	125.7905

Figure 80.9 displays the test results requested by the TEST statement. The ROBUSTREG procedure conducts two robust linear tests, the ρ test and the R_n^2 test. See the section “Linear Tests” on page 6844 for information about how the procedure computes test statistics and the correction factor lambda. Due to the large p -values for both tests, you can conclude that the effect x3 is not significant at the 5% level.

Figure 80.9 Test of Significance

Robust Linear Test					
Test	Test Statistic	Lambda	DF	Chi- Square	Pr > ChiSq
Rho	0.9378	0.7977	1	1.18	0.2782
Rn2	0.8092		1	0.81	0.3683

For the bisquare weight function, the default tuning constant, $c = 4.685$, is chosen to yield a 95% asymptotic efficiency of the M estimates with the Gaussian distribution. See the section “[M Estimation](#)” on page 6838 for details. The smaller the constant c , the lower the asymptotic efficiency but the sharper the M estimate as an outlier detector. For the stack-loss data set, you could consider using a sharper outlier detector.

In the following PROC ROBUSTREG step, a smaller constant, $c = 3.5$, is used. This tuning constant corresponds to an efficiency close to 85%. See Chen and Yin (2002) for the relationship between the tuning constant and asymptotic efficiency of M estimates.

```
proc robustreg method=m(wf=bisquare(c=3.5)) data=stack;
  model y = x1 x2 x3 / diagnostics leverage;
  id    exp;
  test  x3;
run;
```

[Figure 80.10](#) displays the table of robust parameter estimates, standard errors, and confidence limits with the constant $c = 3.5$.

The refitted linear model is

$$\hat{y} = -37.1076 + 0.8191x_1 + 0.5173x_2 - 0.0728x_3$$

Figure 80.10 Model Parameter Estimates

The ROBUSTREG Procedure

LTS Estimation

If the data are contaminated in the x -space, M estimation does not do well. The following example shows how you can use LTS estimation to deal with this situation.

```
data hbk;
  input index $ x1 x2 x3 y @@;
  datalines;

;

The data set hbk is an artificial data set generated by Hawkins, Bradu, and Kass (1984). Both ordinary least squares (OLS) estimation and M estimation (not shown here) suggest that observations 11 to 14 are outliers. However, these four observations were generated from the underlying model, whereas observations 1 to 10 were contaminated. The reason that OLS estimation and M estimation do not pick up the contaminated observations is that they cannot distinguish good leverage points (observations 11 to 14) from bad leverage points (observations 1 to 10). In such cases, the LTS method identifies the true outliers.

The following statements invoke the ROBUSTREG procedure with the LTS estimation method:

```
proc robustreg data=hbkc fwls method=lts;
  model y = x1 x2 x3 / diagnostics leverage;
  id index;
run;
```

Figure 80.12 displays the model fitting information and summary statistics for the response variable and independent covariates.

Figure 80.12 Model Fitting Information and Summary Statistics

The ROBUSTREG Procedure						
Model Information						
Data Set	WORK.HBK					
Dependent Variable	Y					
Number of Independent Variables	3					
Number of Observations	75					
Method	LTS Estimation					
Summary Statistics						
Variable	Q1	Median	Q3	Mean	Standard Deviation	MAD
x1	0.8000	1.8000	3.1000	3.2067	3.6526	1.9274
x2	1.0000	2.2000	3.3000	5.5973	8.2391	1.6309
x3	0.9000	2.1000	3.0000	7.2307	11.7403	1.7791
y	-0.5000	0.1000	0.7000	1.2787	3.4928	0.8896

Figure 80.13 displays information about the LTS fit, which includes the breakdown value of the LTS estimate. The breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness. In this example the LTS estimate minimizes the sum of 57 smallest squares of residuals. It can still estimate the true underlying model if the remaining 18 observations are contaminated. This corresponds to the breakdown value around 0.25, which is set as the default.

Figure 80.13 LTS Profile

LTS Profile	
Total Number of Observations	75
Number of Squares Minimized	57
Number of Coefficients	4
Highest Possible Breakdown Value	0.2533

Figure 80.14 displays parameter estimates for covariates and scale. Two robust estimates of the scale parameter are displayed. See the section “[Final Weighted Scale Estimator](#)” on page 6847 for how these estimates are computed. The weighted scale estimator (Wscale) is a more efficient estimator of the scale parameter.

Figure 80.14 LTS Parameter Estimates

LTS Parameter Estimates		
Parameter	DF	Estimate
Intercept	1	-0.3431
x1	1	0.0901
x2	1	0.0703
x3	1	-0.0731
Scale (sLTS)	0	0.7451
Scale (Wscale)	0	0.5749

Figure 80.15 displays outlier and leverage-point diagnostics. The ID variable index is used to identify the observations. If you do not specify this ID variable, the observation number is used to identify the observations. However, the observation number depends on how the data are read. The first 10 observations are identified as outliers, and observations 11 to 14 are identified as good leverage points.

Figure 80.15 Diagnostics

Diagnostics

Syntax: ROBUSTREG Procedure

The following statements are available in the ROBUSTREG procedure:

```

PROC ROBUSTREG < options > ;
  BY variables ;
  CLASS variables ;
  EFFECT name=effect-type(variables < / options > ) ;
  ID variables ;
  MODEL response = < effects > < / options > ;
  OUTPUT < OUT=SAS-data-set > keyword=name < ... keyword=name > ;
  PERFORMANCE < options > ;
  TEST effects ;
  WEIGHT variable ;

```

The PROC ROBUSTREG statement invokes the procedure. The METHOD= option in the PROC ROBUSTREG statement selects one of the four estimation methods, M, LTS, S, and MM. By default, Huber M estimation is used. The MODEL statement is required and specifies the variables used in the regression. Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure (Chapter 42, “The GLM Procedure.”) The CLASS statement specifies which explanatory variables are treated as categorical. The ID statement names variables to identify observations in the outlier diagnostics tables. The WEIGHT statement identifies a variable in the input data set whose values are used to weight the observations. The OUTPUT statement creates an output data set that contains final weights, predicted values, and residuals. The TEST statement requests robust linear tests for the model parameters. The PERFORMANCE statement tunes the performance of the procedure by using single or multiple processors available on the hardware. Multiple OUTPUT and TEST statements are permitted.

PROC ROBUSTREG Statement

```

PROC ROBUSTREG < options > ;

```

The PROC ROBUSTREG statement invokes the ROBUSTREG procedure. Table 80.1 summarizes the options available in the PROC ROBUSTREG statement.

Table 80.1 PROC ROBUSTREG Statement Options

Option	Description
COVOUT	Saves the estimated covariance matrix
DATA=	Specifies the input SAS data set
FWLS	Computes the final weighted least squares estimates
INEST=	Specifies an input SAS data set that contains initial estimates
ITPRINT	Displays the iteration history for the iteratively reweighted least squares algorithm
METHOD=	Specifies the estimation method
NAMELEN=	Specifies the length of effect names
ORDER=	Specifies the order in which to sort classification variables
OUTEST=	Specifies an output SAS data set that contains the parameter estimates

Table 80.1 *continued*

Option	Description
PLOT	Specifies options that control details of the plots
SEED=	Specifies the seed for the random number generator

You can specify the following *options* in the PROC ROBUSTREG statement.

COVOUT

saves the estimated covariance matrix in the OUTEST= data set. This option is not supported for LTS estimation.

DATA=SAS-data-set

specifies the input SAS data set used by PROC ROBUSTREG. By default, the most recently created SAS data set is used.

FWLS

computes the final weighted least squares estimates. These estimates are equivalent to the least squares estimates after the detected outliers are deleted.

INEST=SAS-data-set

specifies an input SAS data set that contains initial estimates for all the parameters in the model. See the section “[INEST= Data Set](#)” on page 6861 for a detailed description of the contents of the INEST= data set.

ITPRINT

displays the iteration history for the iteratively reweighted least squares algorithm used by M and MM estimation. You can also use this option in the MODEL statement.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the classification variables (which are specified in the [CLASS](#) statement). This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

OUTEST=SAS-data-set

specifies an output SAS data set that contains the parameter estimates, and, if the COVOUT option is specified, the estimated covariance matrix. See the section “[OUTEST= Data Set](#)” on page 6862 for a detailed description of the contents of the OUTEST= data set.

PLOT | PLOTS <(global-plot-options)> <=plot-request>

PLOT | PLOTS <(global-plot-options)> <=(plot-request < ...plot-request >)>

specifies options that control details of the plots. If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC ROBUSTREG produces the robust fit plot by default when the model includes a single continuous independent variable.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc robustreg data=stack plots=all;
    model y = x1 x2 x3;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The *global-plot-options* apply to all plots generated by the ROBUSTREG procedure. The following *global-plot-option* is available:

ONLY

suppresses the default robust fit plot. Only plots specifically requested are displayed.

You can specify more than one *plot-request* within the parentheses after PLOTS=. For a single plot request, you can omit the parentheses. The following *plot-requests* are available.

ALL

creates all appropriate plots.

DDPLOT <(LABEL=ALL | LEVERAGE | NONE | OUTLIER)>

creates a plot of robust distance against Mahalanobis distance. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for details about robust distance. The LABEL= option specifies how the points on this plot are to be labeled, as summarized by the following table.

Table 80.2 Options for Label

Value of LABEL=	Label Method
ALL	Label all points
LEVERAGE	Label leverage points
NONE	No labels
OUTLIERS	Label outliers

By default, the ROBUSTREG procedure labels both outliers and leverage points.

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

FITPLOT <(NOLIMITS)>

creates a plot of robust fit against the single independent continuous variable specified in the model. You can request this plot when only a single independent continuous variable is specified in the model. Confidence limits are added on the plot by default. The NOLIMITS option suppresses these limits.

HISTOGRAM

creates a histogram for the standardized robust residuals. The histogram is superimposed with a normal density curve and a kernel density curve.

NONE

suppresses all plots.

QQPLOT

creates the normal quantile-quantile plot for the standardized robust residuals.

RDPLOT <(LABEL=ALL | LEVERAGE | NONE | OUTLIER)>

creates the plot of standardized robust residual against robust distance. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for details about robust distance. The LABEL= option specifies a label method for points on this plot. These label methods are described in [Table 80.2](#).

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

SEED=number

specifies the seed for the random number generator used to randomly select the subgroups and subsets for LTS and S estimation. By default or if you specify zero, the ROBUSTREG procedure generates a random seed.

METHOD=method-type <(options)>

specifies the estimation method and some additional *options* for the estimation method. PROC ROBUSTREG provides four estimation methods: M estimation, LTS estimation, S estimation, and MM estimation. The default method is M estimation.

NOTE: Since the LTS and S methods use subsampling algorithms, these methods are not suitable in an analysis with variables that have only a few unequal values or a few unequal values within one BY group. For example, indicator variables that correspond to a classification variable often fall into this type. The same issue also applies to the initial LTS and S estimates in the MM method. In case of a model that includes classification independent variables or continuous independent variables with a few unequal values, the M method is recommended.

Options with METHOD=M

With METHOD=M *<(options)>*, you can specify the following *options*:

ASYMPCOV=H1 | H2 | H3

specifies the type of asymptotic covariance computed for the M estimate. The three types are described in the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 6843. By default, ASYMPCOV= H1.

CONVERGENCE=*criterion* *<(EPS=value)>*

specifies a convergence criterion for the M estimate. The three criteria listed in the following table are available.

Table 80.3 Options to Specify Convergence Criteria

Type	Option
Coefficient	CONVERGENCE=COEF
Residual	CONVERGENCE=RESID
Weight	CONVERGENCE=WEIGHT

By default, CONVERGENCE=COEF. You can specify the precision of the convergence criterion with the EPS= option. By default, EPS=1E–8.

MAXITER=*n*

sets the maximum number of iterations during the parameter estimation. By default, MAXITER=1000.

SCALE=*scale-type* | *value*

specifies the scale parameter or a method for estimating the scale parameter. These methods and options are summarized in the following table.

Table 80.4 Options to Specify Scale

Scale	Option	Default <i>d</i>
Fixed constant	SCALE= <i>value</i>	
Huber estimate	SCALE=HUBER <i><(D=d)></i>	2.5
Median estimate	SCALE=MED	
Tukey estimate	SCALE=TUKEY <i><(D=d)></i>	2.5

By default, SCALE=MED.

WEIGHTFUNCTION=*function-type*

WF=*function-type*

specifies the weight function used for the M estimate. The ROBUSTREG procedure provides 10 weight functions, which are listed in the following table. You can specify the parameters in these functions with the A=, B=, and C= options. These functions are described in the section “[M Estimation](#)” on page 6838. The default weight function is bisquare.

Table 80.5 Options to Specify Weight Functions

Weight Function	Option	Default <i>a, b, c</i>
Andrews	WF=ANDREWS $\langle (C=c) \rangle$	1.339
Bisquare	WF=BISQUARE $\langle (C=c) \rangle$	4.685
Cauchy	WF=CAUCHY $\langle (C=c) \rangle$	2.385
Fair	WF=FAIR $\langle (C=c) \rangle$	1.4
Hampel	WF=HAMPEL $\langle (\langle A=a \rangle \langle B=b \rangle \langle C=c \rangle) \rangle$	2, 4, 8
Huber	WF=HUBER $\langle (C=c) \rangle$	1.345
Logistic	WF=LOGISTIC $\langle (C=c) \rangle$	1.205
Median	WF=MEDIAN $\langle (C=c) \rangle$	0.01
Talworth	WF=TALWORTH $\langle (C=c) \rangle$	2.795
Welsch	WF=WELSCH $\langle (C=c) \rangle$	2.985

Options with METHOD=LTS

With METHOD=LTS $\langle (options) \rangle$, you can specify the following *options*:

CSTEP=*n*

specifies the number of concentration steps (C-steps) for the LTS estimate. See the section “[LTS Estimate](#)” on page 6845 for information about how the default value is determined.

H=*n*

specifies the quantile for the LTS estimate. See the section “[LTS Estimate](#)” on page 6845 for information about how the default value is determined.

IADJUST=ALL | NONE

requests (IADJUST=ALL) or suppresses (IADJUST=NONE) the intercept adjustment for all estimates in the LTS algorithm. By default, the intercept adjustment is used for data sets with fewer than 10,000 observations. See the section “[Algorithm](#)” on page 6845 for details.

NBEST=*n*

specifies the number of best solutions kept for each subgroup during the computation of the LTS estimate. The default number is 10, which is the maximum number allowed.

NREP=*n*

specifies the number of times to repeat least squares fit in subgroups during the computation of the LTS estimate. See the section “[LTS Estimate](#)” on page 6845 for information about how the default number is determined.

SUBANALYSIS

requests a display of the subgrouping information and parameter estimates within subgroups. This option generates the ODS tables shown in [Table 80.6](#).

Table 80.6 ODS Tables Available with SUBANALYSIS Option

ODS Table Name	Description
BestEstimates	Best final estimates for LTS
BestSubEstimates	Best estimates for each subgroup
CStep	C-step information for LTS
Groups	Grouping information for LTS

SUBGROUPSIZE=*n*

specifies the data set size of the subgroups in the computation of the LTS estimate. The default number is 300.

Options with METHOD=S

With METHOD=S <(options)>, you can specify the following *options*:

ASYMPCOV=H1 | H2 | H3 | H4

specifies the type of asymptotic covariance computed for the S estimate. The four types are described in the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 6849. By default, ASYMPCOV= H4.

CHIF= TUKEY | YOHAI

specifies the χ function for the S estimate. PROC ROBUSTREG provides two χ functions, Tukey’s bisquare function and Yohai’s optimal function, which you can request with CHIF= TUKEY and CHIF= YOHAI, respectively. The default is Tukey’s bisquare function.

EFF= *value*

specifies the efficiency (as a fraction) for the S estimate. The parameter k_0 in the χ function is determined by this efficiency. The default efficiency is determined such that the consistent S estimate has the breakdown value of 25%. This option is overwritten by the K0= option if both of them are used.

K0= *value*

specifies the k_0 parameter in the χ function of the S estimate. For CHIF= TUKEY, the default is 1.548. For CHIF= YOHAI, the default is 0.66. These default values correspond to a 50% breakdown value of the consistent S estimate.

MAXITER=*n*

sets the maximum number of iterations for computing the scale parameter of the S estimate. By default, MAXITER=1000.

NREP=*n*

specifies the number of repeats of subsampling in the computation of the S estimate. See the section “[Algorithm](#)” on page 6848 for information about how the default number of repeats is determined.

NOREFINE

suppresses the refinement for the S estimate. See the section “[Algorithm](#)” on page 6848 for details.

SUBSETSIZE=*n*

specifies the size of the subset for the S estimate. See the section “[Algorithm](#)” on page 6848 for information about how the default value is determined.

TOLERANCE=*value*

specifies the tolerance for the S estimate of the scale. The default value is 0.001.

Options with METHOD=MM

With METHOD=MM <(options)>, you can specify the following *options*:

ASYMPCOV=H1 | H2 | H3 | H4

specifies the type of asymptotic covariance computed for the MM estimate. The four types are described in the section “[Details: ROBUSTREG Procedure](#)” on page 6838. By default, ASYMPCOV=H4.

BIATEST <(ALPHA=*number*)>

requests the bias test for the final MM estimate. See the section “[Bias Test](#)” on page 6852 for details about this test.

CHIF= TUKEY | YOHAI

selects the χ function for the MM estimate. PROC ROBUSTREG provides two χ functions: Tukey’s bisquare function and Yohai’s optimal function, which you can request with CHIF=TUKEY and CHIF=YOHAI, respectively. The default is Tukey’s bisquare function. This χ function is also used by the initial S estimate if you specify the INITEST=S option.

CONVERGENCE=*criterion* <(EPS=*number*)>

specifies a convergence criterion for the MM estimate. The three criteria listed in [Table 80.7](#) are available.

Table 80.7 Options to Specify Convergence Criteria

Type	Option
Coefficient	CONVERGENCE=COEF
Residual	CONVERGENCE=RESID
Weight	CONVERGENCE=WEIGHT

By default, CONVERGENCE=COEF. You can specify the precision of the convergence criterion with the EPS= option. By default, EPS=1E–8.

EFF=value

specifies the efficiency (as a fraction) for the MM estimate. The parameter k_1 in the χ function is determined by this efficiency. The default efficiency is set to 0.85, which corresponds to $k_1 = 3.440$ for CHIF=TUKEY or $k_1 = 0.868$ for CHIF=YOHA1.

INITH=h

specifies the integer h for the initial LTS estimate used by the MM estimator. See the section “[Algorithm](#)” on page 6851 for how to specify h and how the default is determined.

INITEST=LTS | S

specifies the initial estimator for the MM estimator. By default, the LTS estimator with its default settings is used as the initial estimator for the MM estimator.

K0=number

specifies the parameter k_0 in the χ function for the MM estimate. For CHIF=TUKEY, the default is $k_0 = 2.9366$. For CHIF=YOHA1, the default is $k_0 = 0.7405$. These default values correspond to the 25% breakdown value of the MM estimator.

MAXITER=n

sets the maximum number of iterations during the parameter estimation. By default, MAXITER=1000.

BY Statement

BY variables ;

You can specify a BY statement with PROC ROBUSTREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the ROBUSTREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / **TRUNCATE** > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the **MODEL** statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the **ORDER=** option in the **PROC ROBUSTREG** statement. You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

EFFECT Statement

EFFECT *name=effect-type* (*variables* < / *options* >) ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.
MULTIMEMBER MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 80.8 summarizes the *options* available in the EFFECT statement.

Table 80.8 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect
Lag Effects Options	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Multimember Effects Options	
NOEFFECT	Specifies that observations with all missing levels for the multi-member variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

ID Statement

ID *variables* ;

When the diagnostics table is requested with the DIAGNOSTICS option in the MODEL statement, the variables listed in the ID statement are displayed in addition to the observation number. These variables

can be used to identify each observation. If the ID statement is omitted, the observation number is used to identify the observations.

MODEL Statement

< label: > MODEL *response* = **< effects >** **< / options >** ;

Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure (Chapter 42, “The GLM Procedure.”)

The optional *label*, which must be a valid SAS name, is used to label the model in the OUTEST data set.

Table 80.9 summarizes the options available in the MODEL statement.

Table 80.9 MODEL Statement Options

Option	Description
ALPHA=	Specifies the significance level
CORRB	Produces the estimated correlation matrix
COVB	Produces the estimated covariance matrix
CUTOFF=	Specifies the multiplier of the cutoff value for outlier detection
DIAGNOSTICS	Requests the outlier diagnostics
FAILRATIO=	Specifies the failure-ratio threshold
ITPRINT	Displays the iteration history
LEVERAGE	Requests an analysis of leverage points
NOGOODFIT	Suppresses the computation of goodness-of-fit statistics
NOINT	Specifies no-intercept regression
SINGULAR=	Specifies the tolerance for testing singularity

You can specify the following *options* for the model fit.

ALPHA=*value*

specifies the significance level for the confidence intervals for regression parameters. The value must be between 0 and 1. By default, ALPHA=0.05.

CORRB

produces the estimated correlation matrix of the parameter estimates.

COVB

produces the estimated covariance matrix of the parameter estimates.

CUTOFF=*value*

specifies the multiplier of the cutoff value for outlier detection. By default, CUTOFF=3.

DIAGNOSTICS **< (ALL) >**

requests the outlier diagnostics. By default, only observations identified as outliers or leverage points are displayed. Specify the ALL option to display all observations.

FAILRATIO=value

specifies the failure-ratio threshold for the subsampling algorithm of an LTS or S estimate. It also applies to the initial LTS or S step in an MM estimate. The threshold must be between 0 and 1. Its default value is 0.99. See the section “[LTS Estimate](#)” on page 6845 or “[S Estimate](#)” on page 6847 for details.

ITPRINT

displays the iteration history for the iteratively reweighted least squares algorithm used by M and MM estimation. You can also use this option in the PROC ROBUSTREG statement.

LEVERAGE <(leverage-options)>

requests an analysis of leverage points for the covariates. The results are added to the diagnostics table, which you can request with the DIAGNOSTICS option in the MODEL statement.

The following *leverage-options* are available:

CUTOFF=value

specifies the leverage cutoff value for leverage-point detection. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for details. The cutoff value can also be specified with the leverage cutoff α value by using the CUTOFFALPHA= option.

CUTOFFALPHA=value

specifies the leverage cutoff α value for leverage-point detection. The respective leverage cutoff value equals $\sqrt{\chi^2_{p;1-\alpha}}$ (or $\sqrt{\chi^2_{q;1-\alpha}}$ if projection is applied in the generalized MCD algorithm). By default, $\alpha = 0.025$.

H=n**QUANTILE=n**

specifies the quantile to be minimized for the MCD algorithm that is used for the leverage-point analysis. By default, $H = [(3n + p + 1)/4]$, where n is the number of observations and p is the number of independent variables excluding the intercept.

MCDALPHA=value

specifies the MCD cutoff α value for the final MCD reweighting step. The respective MCD cutoff value equals $\sqrt{\chi^2_{p;1-\alpha}}$ (or $\sqrt{\chi^2_{q;1-\alpha}}$ if projection is applied in the generalized MCD algorithm). By default, $\alpha = 0.025$.

MCDCUTOFF=value**MCDCUT=value**

specifies the MCD cutoff value for the final MCD reweighting step. See the section “[Mahalanobis Distance versus Robust Distance](#)” on page 6853 and Rousseeuw and Van Driessen (1999) for details. The cutoff value can also be specified with the MCD cutoff α value by using the MCDALPHA= option.

MCDINFO

requests that detailed information about the MCD covariance estimate be displayed, including the low-dimensional structure, the breakdown value, the MCD center, and the MCD covariance itself. The option outputs the ODS tables of the MCD profile, MCD center, MCD covariance, and MCD correlation.

OPC | OFFPLANEcoef

requests the ODS table of the coefficients for MCD-dropped components, when projection is applied in the generalized MCD algorithm. The OFFPLANEcoef option is ignored for the regular MCD algorithm.

PROJECTIONALPHA=value**PALPHA=value**

specifies the projection cutoff α value to be used to judge whether an observation is on or off the low-dimensional hyperplane identified by the generalized MCD algorithm. The respective projection cutoff value equals $\sqrt{\chi^2_{1;1-\alpha}}$. By default, $\alpha = 0.001$.

PROJECTIONCUTOFF=value**PCUTOFF=value**

specifies the projection cutoff value to be used to judge whether an observation is on or off the low-dimensional hyperplane identified by the projected MCD algorithm. See the section “[Mahalanobis Distance versus Robust Distance](#)” on page 6853 and Rousseeuw and Van Driessen (1999) for details. The projection cutoff value can also be specified with the projection cutoff α value by using the PALPHA= option.

PROJECTIONTOLERANCE=value**PTOL=value**

specifies the projection tolerance value for the low-dimensional structure detection. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for details.

NOGOODFIT

suppresses the computation of goodness-of-fit statistics.

NOINT

specifies no-intercept regression.

SINGULAR=value

specifies the tolerance for testing singularity of the information matrix and the crossproducts matrix for the initial least squares estimates. Roughly, the test requires that a pivot be at least *value* times the original diagonal value. By default, SINGULAR=1E-12.

OUTPUT Statement

OUTPUT < **OUT**=SAS-data-set> *keyword=name* < ... *keyword=name* > ;

The OUTPUT statement creates an output SAS data set that contains statistics calculated after fitting the model. At least one specification of the form *keyword=name* is required.

All variables in the original data set are included in the new data set, along with the variables that are created with *keyword* options in the OUTPUT statement. These new variables contain fitted values and estimated quantiles. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

The following specifications can appear in the OUTPUT statement:

- OUT=SAS-data-set** specifies the new data set. By default, the procedure uses the *DATA**n* convention to name the new data set.
- keyword=name** specifies the statistics to include in the output data set and gives names to the new variables. Specify a keyword for each desired statistic (see the following list), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

- LEVERAGE** specifies a variable to indicate leverage points. To include this variable in the **OUTPUT** data set, you must specify the **LEVERAGE** option in the **MODEL** statement. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for how to define **LEVERAGE**.
- MD** specifies a variable to contain the Mahalanobis distances. See the section “[Robust Distance](#)” on page 6853 for the definition of Mahalanobis distance.
- OUTLIER** specifies a variable to indicate outliers. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for information about how to define **OUTLIER**.
- PMD** specifies a variable to contain the projected Mahalanobis distances. See the section “[Robust Distance](#)” on page 6853 for the definition of projected Mahalanobis distance.
- POD** specifies a variable to contain the projected off-plane distances. See the section “[Robust Distance](#)” on page 6853 for the definition of off-plane distance.
- PRD** specifies a variable to contain the projected robust MCD Mahalanobis distances. See the section “[Robust Distance](#)” on page 6853 for the definition of projected robust distance.
- PREDICTED | P** specifies a variable to contain the estimated responses

$$\hat{y}_i = \mathbf{x}_i' \hat{\boldsymbol{\theta}}$$

- RD** specifies a variable to contain the robust MCD Mahalanobis distances. See the section “[Robust Distance](#)” on page 6853 for the definition of robust distance.
- RESIDUAL | R** specifies a variable to contain the unstandardized residuals

$$y_i - \hat{y}_i \text{ or } y_i - \mathbf{x}_i' \hat{\boldsymbol{\theta}}$$

- SRESIDUAL | SR** specifies a variable to contain the standardized residuals

$$\frac{y_i - \hat{y}_i}{\hat{\sigma}} \text{ or } \frac{y_i - \mathbf{x}_i' \hat{\boldsymbol{\theta}}}{\hat{\sigma}}.$$

By default, the LTS method uses *Wscale* as $\hat{\sigma}$ for computing the standardized residuals.

- STDP** specifies a variable to contain the estimates of the standard errors of the estimated mean responses

$$\sqrt{\mathbf{x}_i' \boldsymbol{\Sigma} \mathbf{x}_i}$$

where $\boldsymbol{\Sigma}$ denotes the covariance matrix of the parameter estimates. You can request the ODS table of this covariance matrix by using the **COVB** option of the **MODEL** statement. The **STDP=** option is applied to **M**, **S**, and **MM** estimation, but not to **LTS** estimation.

STDI specifies a variable to contain the estimates of the standard errors of the individual predicted values

$$\sqrt{\mathbf{x}_i' \boldsymbol{\Sigma} \mathbf{x}_i + \hat{\sigma}^2}.$$

The STDI= option is applied to M, S, and MM estimation, but not to LTS estimation.

WEIGHT specifies a variable to contain the computed final weights.

PERFORMANCE Statement

The PERFORMANCE statement is used to specify options that affect the performance of PROC ROBUSTREG and to request tables that show the performance options in effect and timing details. See Chen (2002) for some empirical results.

PERFORMANCE <options> ;

The following *options* are available:

CPUCOUNT=*n* | ACTUAL

specifies the number of processors to use for forming crossproduct matrices. You can specify any integer in the range 1–1024 for *n*. CPUCOUNT=ACTUAL sets CPUCOUNT to be the number of physical processors available. Note that this can be less than the physical number of CPUs if the SAS process has been restricted by system administration tools. Setting CPUCOUNT= to a number greater than the actual number of available CPUs might result in reduced performance. This option overrides the SAS system option CPUCOUNT=. If CPUCOUNT=1, then NOTHREADS is in effect, and PROC ROBUSTREG uses singly threaded code.

DETAILS

requests the PerfSettings table that shows the performance settings in effect and the “Timing” table that provides a broad timing breakdown of the PROC ROBUSTREG step.

THREADS

enables multithreaded computation. This option overrides the SAS system option NOTHREADS.

NOTHREADS

disables multithreaded computation. This option overrides the SAS system option THREADS.

TEST Statement

<label:> **TEST** effects ;

With M estimation and MM estimation, the TEST statement provides a means of obtaining a test for the canonical linear hypothesis concerning the parameters of the tested effects

$$\theta_j = 0, \quad j = i_1, \dots, i_q$$

where *q* is the total number of parameters of the tested effects.

PROC ROBUSTREG provides two kinds of robust tests: the ρ test and the R_n^2 test. They are described in the section “[Details: ROBUSTREG Procedure](#)” on page 6838. No test is available for LTS and S estimation.

The optional *label*, which must be a valid SAS name, is used to label output from the corresponding TEST statement.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement specifies a weight variable in the input data set.

If you want to use fixed weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. The values of the WEIGHT variable can be nonintegral and are not truncated. Observations with nonpositive or missing values for the weight variable do not contribute to the fit of the model.

Details: ROBUSTREG Procedure

This section describes the statistical and computational aspects of the ROBUSTREG procedure. The following notation is used throughout this section.

Let $\mathbf{X} = (x_{ij})$ denote an $n \times p$ matrix, $\mathbf{y} = (y_1, \dots, y_n)'$ denote a given n -vector of responses, and $\boldsymbol{\theta} = (\theta_1, \dots, \theta_p)'$ denote an unknown p -vector of parameters or coefficients whose components are to be estimated. The matrix \mathbf{X} is called the design matrix. Consider the usual linear model

$$\mathbf{y} = \mathbf{X}\boldsymbol{\theta} + \mathbf{e}$$

where $\mathbf{e} = (e_1, \dots, e_n)'$ is an n -vector of unknown errors. It is assumed that (for a given \mathbf{X}) the components e_i of \mathbf{e} are independent and identically distributed according to a distribution $L(\cdot/\sigma)$, where σ is a scale parameter (usually unknown). Often $L(\cdot) \approx \Phi(\cdot)$, the standard normal distribution function. The vector of residuals for a given value of $\hat{\boldsymbol{\theta}}$ is denoted by $\mathbf{r} = (r_1, \dots, r_n)'$ and the i th row of the matrix \mathbf{X} is denoted by \mathbf{x}_i' .

M Estimation

M estimation in the context of regression was first introduced by Huber (1973) as a result of making the least squares approach robust. Although M estimators are not robust with respect to leverage points, they are popular in applications where leverage points are not an issue.

Instead of minimizing a sum of squares of the residuals, a Huber-type M estimator $\hat{\boldsymbol{\theta}}_M$ of $\boldsymbol{\theta}$ minimizes a sum of less rapidly increasing functions of the residuals:

$$Q(\boldsymbol{\theta}) = \sum_{i=1}^n \rho\left(\frac{r_i}{\sigma}\right)$$

where $\mathbf{r} = \mathbf{y} - \mathbf{X}\boldsymbol{\theta}$. For the ordinary least squares estimation, ρ is the square function, $\rho(z) = z^2$.

If σ is known, then by taking derivatives with respect to $\boldsymbol{\theta}$, $\hat{\boldsymbol{\theta}}_M$ is also a solution of the system of p equations:

$$\sum_{i=1}^n \psi\left(\frac{r_i}{\sigma}\right) x_{ij} = 0, \quad j = 1, \dots, p$$

where $\psi = \frac{\partial \rho}{\partial z}$. If ρ is convex, $\hat{\boldsymbol{\theta}}_M$ is the unique solution.

The ROBUSTREG procedure solves this system by using iteratively reweighted least squares (IRLS). The weight function $w(x)$ is defined as

$$w(z) = \frac{\psi(z)}{z}$$

The ROBUSTREG procedure provides 10 kinds of weight functions through the WEIGHTFUNCTION= option in the MODEL statement. Each weight function corresponds to a ρ function. See the section “[Weight Functions](#)” on page 6840 for a complete discussion. You can specify the scale parameter σ with the SCALE= option in the PROC ROBUSTREG statement.

If σ is unknown, both $\boldsymbol{\theta}$ and σ are estimated by minimizing the function

$$Q(\boldsymbol{\theta}, \sigma) = \sum_{i=1}^n \left[\rho\left(\frac{r_i}{\sigma}\right) + a \right] \sigma, \quad a > 0$$

The algorithm proceeds by alternately improving $\hat{\boldsymbol{\theta}}$ in a location step and $\hat{\sigma}$ in a scale step.

For the scale step, three methods are available to estimate σ , which you can select with the SCALE= option.

1. (SCALE=HUBER <(D=d)>) Compute $\hat{\sigma}$ by the iteration

$$\left(\hat{\sigma}^{(m+1)}\right)^2 = \frac{1}{nh} \sum_{i=1}^n \chi_d\left(\frac{r_i}{\hat{\sigma}^{(m)}}\right) \left(\hat{\sigma}^{(m)}\right)^2$$

where

$$\chi_d(x) = \begin{cases} x^2/2 & \text{if } |x| < d \\ d^2/2 & \text{otherwise} \end{cases}$$

is the Huber function and $h = \frac{n-p}{n} \left(d^2 + (1-d^2)\Phi(d) - 0.5 - d\sqrt{2\pi}e^{-\frac{1}{2}d^2} \right)$ is the Huber constant (Huber 1981, p. 179). You can specify d with the D=d option. By default, D=2.5.

2. (SCALE=TUKEY <(D=d)>) Compute $\hat{\sigma}$ by solving the supplementary equation

$$\frac{1}{n-p} \sum_{i=1}^n \chi_d \left(\frac{r_i}{\sigma} \right) = \beta$$

where

$$\chi_d(x) = \begin{cases} \frac{3x^2}{d^2} - \frac{3x^4}{d^4} + \frac{x^6}{d^6} & \text{if } |x| < d \\ 1 & \text{otherwise} \end{cases}$$

Here $\psi = \frac{1}{6}\chi_1'$ is Tukey's bisquare function, and $\beta = \int \chi_d(s) d\Phi(s)$ is the constant such that the solution $\hat{\sigma}$ is asymptotically consistent when $L(\cdot/\sigma) = \Phi(\cdot)$ (Hampel et al. 1986, p. 149). You can specify d with the D=d option. By default, D=2.5.

3. (SCALE=MED) Compute $\hat{\sigma}$ by the iteration

$$\hat{\sigma}^{(m+1)} = \text{median} \left\{ |y_i - \mathbf{x}_i' \hat{\boldsymbol{\theta}}^{(m)}| / \beta_0, i = 1, \dots, n \right\}$$

where $\beta_0 = \Phi^{-1}(.75)$ is the constant such that the solution $\hat{\sigma}$ is asymptotically consistent when $L(\cdot/\sigma) = \Phi(\cdot)$ (Hampel et al. 1986, p. 312).

SCALE=MED is the default.

Algorithm

The basic algorithm for computing M estimates for regression is iteratively reweighted least squares (IRLS). As the name suggests, a weighted least squares fit is carried out inside an iteration loop. For each iteration, a set of weights for the observations is used in the least squares fit. The weights are constructed by applying a weight function to the current residuals. Initial weights are based on residuals from an initial fit. The ROBUSTREG procedure uses the unweighted least squares fit as a default initial fit. The iteration terminates when a convergence criterion is satisfied. The maximum number of iterations is set to 1,000. You can specify the weight function and the convergence criteria.

Weight Functions

You can specify the weight function for M estimation with the WEIGHTFUNCTION= option. The ROBUSTREG procedure provides 10 weight functions. By default, the procedure uses the bisquare weight function. In most cases, M estimates are more sensitive to the parameters of these weight functions than to the type of the weight function. The median weight function is not stable and is seldom recommended in data analysis; it is included in the procedure for completeness. You can specify the parameters for these weight functions. Except for the Hampel and median weight functions, default values for these parameters are defined such that the corresponding M estimates have 95% asymptotic efficiency in the location model with the Gaussian distribution (Holland and Welsch 1977).

The following list shows the weight functions available. See [Table 80.5](#) for the default values of the constants in these weight functions.

Andrews
$$W(x, c) = \begin{cases} \frac{\sin(x/c)}{x/c} & \text{if } |x| \leq \pi c \\ 0 & \text{otherwise} \end{cases}$$

Bisquare
$$W(x, c) = \begin{cases} (1 - (x/c)^2)^2 & \text{if } |x| < c \\ 0 & \text{otherwise} \end{cases}$$

Cauchy
$$W(x, c) = \frac{1}{1 + (|x|/c)^2}$$

Fair
$$W(x, c) = \frac{1}{(1 + |x|/c)}$$

Hampel
$$W(x, a, b, c) = \begin{cases} 1 & |x| < a \\ \frac{a}{|x|} & a < |x| \leq b \\ \frac{a}{|x|} \frac{c - |x|}{c - b} & b < |x| \leq c \\ 0 & \text{otherwise} \end{cases}$$

Huber
$$W(x, c) = \begin{cases} 1 & \text{if } |x| < c \\ \frac{c}{|x|} & \text{otherwise} \end{cases}$$

Logistic
$$W(x, c) = \frac{\tanh(x/c)}{x/c}$$

Median
$$W(x, c) = \begin{cases} \frac{1}{c} & \text{if } x = 0 \\ \frac{1}{|x|} & \text{otherwise} \end{cases}$$

Talworth
$$W(x, c) = \begin{cases} 1 & \text{if } |x| < c \\ 0 & \text{otherwise} \end{cases}$$

Welsch
$$W(x, c) = \exp\left(-\frac{(x/c)^2}{2}\right)$$

Convergence Criteria

The following convergence criteria are available in PROC ROBUSTREG:

- relative change in the coefficients (CONVERGENCE= COEF)

- relative change in the scaled residuals (CONVERGENCE= RESID)
- relative change in weights (CONVERGENCE= WEIGHT)

You can specify the criteria with the CONVERGENCE= option in the PROC ROBUSTREG statement. The default is CONVERGENCE= COEF.

You can specify the precision of the convergence criterion with the EPS= suboption. The default is EPS=1E–8.

In addition to these convergence criteria, a convergence criterion based on scale-independent measure of the gradient is always checked. See Coleman et al. (1980) for more details. A warning is issued if this criterion is not satisfied.

Asymptotic Covariance and Confidence Intervals

The following three estimators of the asymptotic covariance of the robust estimator are available in PROC ROBUSTREG:

$$H1: K^2 \frac{[1/(n-p)] \sum (\psi(r_i))^2}{[(1/n) \sum (\psi'(r_i))]^2} (\mathbf{X}'\mathbf{X})^{-1}$$

$$H2: K \frac{[1/(n-p)] \sum (\psi(r_i))^2}{[(1/n) \sum (\psi'(r_i))]} \mathbf{W}^{-1}$$

$$H3: K^{-1} \frac{1}{(n-p)} \sum (\psi(r_i))^2 \mathbf{W}^{-1} (\mathbf{X}'\mathbf{X}) \mathbf{W}^{-1}$$

where $K = 1 + \frac{p}{n} \frac{\text{Var}(\psi')}{(E\psi')^2}$ is a correction factor and $W_{jk} = \sum \psi'(r_i) x_{ij} x_{ik}$. See Huber (1981, p. 173) for more details.

You can specify the asymptotic covariance estimate with the option ASYMPCOV= option. The ROBUSTREG procedure uses H1 as the default because of its simplicity and stability. Confidence intervals are computed from the diagonal elements of the estimated asymptotic covariance matrix.

R Square and Deviance

The robust version of R-square is defined as

$$R^2 = \frac{\sum \rho \left(\frac{y_i - \hat{\mu}}{\hat{s}} \right) - \sum \rho \left(\frac{y_i - \mathbf{x}_i' \hat{\boldsymbol{\theta}}}{\hat{s}} \right)}{\sum \rho \left(\frac{y_i - \hat{\mu}}{\hat{s}} \right)}$$

and the robust deviance is defined as the optimal value of the objective function on the σ^2 scale

$$D = 2\hat{s}^2 \sum \rho \left(\frac{y_i - \mathbf{x}_i' \hat{\boldsymbol{\theta}}}{\hat{s}} \right)$$

where $\rho' = \psi$, $\hat{\boldsymbol{\theta}}$ is the M estimator of $\boldsymbol{\theta}$, $\hat{\mu}$ is the M estimator of location, and \hat{s} is the M estimator of the scale parameter in the full model.

Linear Tests

Two tests are available in PROC ROBUSTREG for the canonical linear hypothesis

$$H_0 : \theta_j = 0, \quad j = i_1, \dots, i_q$$

where q is the total number of parameters of the tested effects. The first test is a robust version of the F test, which is referred to as the ρ test. Denote the M estimators in the full and reduced models as $\hat{\theta}(0) \in \Omega_0$ and $\hat{\theta}(1) \in \Omega_1$, respectively. Let

$$\begin{aligned} Q_0 &= Q(\hat{\theta}(0)) = \min\{Q(\theta) | \theta \in \Omega_0\} \\ Q_1 &= Q(\hat{\theta}(1)) = \min\{Q(\theta) | \theta \in \Omega_1\} \end{aligned}$$

with

$$Q = \sum_{i=1}^n \rho\left(\frac{r_i}{\sigma}\right)$$

The robust F test is based on the test statistic

$$S_n^2 = \frac{2}{q}[Q_1 - Q_0]$$

Asymptotically $S_n^2 \sim \lambda \chi_q^2$ under H_0 , where the standardization factor is $\lambda = \int \psi^2(s) d\Phi(s) / \int \psi'(s) d\Phi(s)$ and Φ is the cumulative distribution function of the standard normal distribution. Large values of S_n^2 are significant. This test is a special case of the general τ test of Hampel et al. (1986, Section 7.2).

The second test is a robust version of the Wald test, which is referred to as R_n^2 test. The test uses a test statistic

$$R_n^2 = n(\hat{\theta}_{i_1}, \dots, \hat{\theta}_{i_q}) \mathbf{H}_{22}^{-1} (\hat{\theta}_{i_1}, \dots, \hat{\theta}_{i_q})'$$

where $\frac{1}{n} \mathbf{H}_{22}$ is the $q \times q$ block (corresponding to $\theta_{i_1}, \dots, \theta_{i_q}$) of the asymptotic covariance matrix of the M estimate $\hat{\theta}_M$ of θ in a p -parameter linear model.

Under H_0 , the statistic R_n^2 has an asymptotic χ^2 distribution with q degrees of freedom. Large values of R_n^2 are significant. See Hampel et al. (1986, Chapter 7) for more details.

Model Selection

When M estimation is used, two criteria are available in PROC ROBUSTREG for model selection. The first criterion is a counterpart of the Akaike (1974) information criterion for robust regression (AICR); it is defined as

$$\text{AICR} = 2 \sum_{i=1}^n \rho(r_{i:p}) + \alpha p$$

where $r_{i:p} = (y_i - \mathbf{x}_i' \hat{\theta}) / \hat{\sigma}$, $\hat{\sigma}$ is a robust estimate of σ and $\hat{\theta}$ is the M estimator with p -dimensional design matrix.

As with AIC, α is the weight of the penalty for dimensions. The ROBUSTREG procedure uses $\alpha = 2E\psi^2 / E\psi'$ (Ronchetti 1985) and estimates it by using the final robust residuals.

The second criterion is a robust version of the Schwarz information criteria (BICR); it is defined as

$$\text{BICR} = 2 \sum_{i=1}^n \rho(r_{i:p}) + p \log(n)$$

High-Breakdown-Value Estimation

The *breakdown value* of an estimator is defined as the smallest fraction of contamination that can cause the estimator to take on values that are arbitrarily far from its value on the uncontaminated data. The breakdown value of an estimator can be used as a measure of the robustness of the estimator. Rousseeuw and Leroy (1987) and others introduced the following high-breakdown-value estimators for linear regression.

LTS Estimate

The least trimmed squares (LTS) estimate proposed by Rousseeuw (1984) is defined as the p -vector

$$\hat{\theta}_{LTS} = \arg \min_{\theta} Q_{LTS}(\theta) \text{ with } Q_{LTS}(\theta) = \sum_{i=1}^h r_{(i)}^2$$

where $r_{(1)}^2 \leq r_{(2)}^2 \leq \dots \leq r_{(n)}^2$ are the ordered squared residuals $r_i^2 = (y_i - \mathbf{x}_i' \theta)^2$, $i = 1, \dots, n$, and h is defined in the range $\frac{n}{2} + 1 \leq h \leq \frac{3n+p+1}{4}$.

You can specify the parameter h with the H= option in the PROC ROBUSTREG statement. By default, $h = \lceil \frac{3n+p+1}{4} \rceil$. The breakdown value is $\frac{n-h}{n}$ for the LTS estimate.

The ROBUSTREG procedure computes LTS estimates by using the FAST-LTS algorithm of Rousseeuw and Van Driessen (2000). The estimates are often used to detect outliers in the data, which are then down-weighted in the resulting weighted LS regression.

Algorithm

Least trimmed squares (LTS) regression is based on the subset of h observations (out of a total of n observations) whose least squares fit possesses the smallest sum of squared residuals. The coverage h can be set between $\frac{n}{2}$ and n . The LTS method was proposed by Rousseeuw (1984, p. 876) as a highly robust regression estimator with breakdown value $\frac{n-h}{n}$. The ROBUSTREG procedure uses the FAST-LTS algorithm given by Rousseeuw and Van Driessen (2000). The intercept adjustment technique is also used in this implementation. However, because this adjustment is expensive to compute, it is optional. You can use the IADJUST= option in the PROC ROBUSTREG statement to request or suppress the intercept adjustment. By default, PROC ROBUSTREG does intercept adjustment for data sets with fewer than 10,000 observations. The steps of the algorithm are described briefly as follows. See Rousseeuw and Van Driessen (2000) for details.

1. The default h is $\lceil \frac{3n+p+1}{4} \rceil$, where p is the number of independent variables. You can specify any integer h with $\lceil \frac{n}{2} \rceil + 1 \leq h \leq \lceil \frac{3n+p+1}{4} \rceil$ with the H= option in the MODEL statement. The breakdown value for LTS, $\frac{n-h}{n}$, is reported. The default h is a good compromise between breakdown value and statistical efficiency.
2. If $p = 1$ (single regressor), the procedure uses the exact algorithm of Rousseeuw and Leroy (1987, p. 172).

3. If $p \geq 2$, PROC ROBUSTREG uses the following algorithm. If $n < 2 \text{ } ssubs$, where $ssubs$ is the size of the subgroups (you can specify $ssubs$ by using the SUBGROUPSIZE= option in the PROC ROBUSTREG statement; by default, $ssubs = 300$), PROC ROBUSTREG draws a random p -subset and computes the regression coefficients by using these p points (if the regression is degenerate, another p -subset is drawn). The absolute residuals for all observations in the data set are computed, and the first h points with smallest absolute residuals are selected. From this selected h -subset, PROC ROBUSTREG carries out $nsteps$ C-steps (concentration steps; see Rousseeuw and Van Driessen (2000) for details). You can specify $nsteps$ with the CSTEP= option in the PROC ROBUSTREG statement; by default, $nsteps = 2$. PROC ROBUSTREG redraws p -subsets and repeats the preceding computation $nrep$ times, and then finds the $nbsol$ (at most) solutions with the lowest sums of h squared residuals. You can specify $nrep$ with the NREP= option in the PROC ROBUSTREG statement; by default, $NREP = \min\{500, \binom{n}{p}\}$. For small n and p , all $\binom{n}{p}$ subsets are used and the NREP= option is ignored (Rousseeuw and Hubert 1996). You can specify $nbsol$ with the NBEST= option in the PROC ROBUSTREG statement; by default, $NBEST = 10$. For each of these $nbsol$ best solutions, C-steps are taken until convergence and the best final solution is found.
4. If $n \geq 5ssubs$, construct five disjoint random subgroups with size $ssubs$. If $2ssubs < n < 5ssubs$, the data are split into at most four subgroups with $ssubs$ or more observations in each subgroup, so that each observation belongs to a subgroup and the subgroups have roughly the same size. Let $nsubs$ denote the number of subgroups. Inside each subgroup, PROC ROBUSTREG repeats the step 3 algorithm $nrep / nsubs$ times, keeps the $nbsol$ best solutions, and pools the subgroups, yielding the merged set of size n_{merged} . In the merged set, for each of the $nsubs \times nbsol$ best solutions, $nsteps$ C-steps are carried out by using n_{merged} and $h_{merged} = \lceil n_{merged} \frac{h}{n} \rceil$ and the $nbsol$ best solutions are kept. In the full data set, for each of these $nbsol$ best solutions, C-steps are taken by using n and h until convergence and the best final solution is found.

NOTE: At step 3 in the algorithm, a randomly selected p -subset might be degenerate (that is, its design matrix might be singular). If the total number of p -subsets from any subgroup is more than 4,000 and the ratio of degenerate p -subsets is more than the threshold specified in FAILRATIO= option, the algorithm is terminated with an error message.

R-Square

The robust version of R-square for the LTS estimate is defined as

$$R_{LTS}^2 = 1 - \frac{s_{LTS}^2(\mathbf{X}, \mathbf{y})}{s_{LTS}^2(\mathbf{1}, \mathbf{y})}$$

for models with the intercept term and as

$$R_{LTS}^2 = 1 - \frac{s_{LTS}^2(\mathbf{X}, \mathbf{y})}{s_{LTS}^2(\mathbf{0}, \mathbf{y})}$$

for models without the intercept term, where

$$s_{LTS}(\mathbf{X}, \mathbf{y}) = d_{h,n} \sqrt{\frac{1}{h} \sum_{i=1}^h r_{(i)}^2}$$

Note that s_{LTS} is a preliminary estimate of the parameter σ in the distribution function $L(\cdot/\sigma)$.

Here $d_{h,n}$ is chosen to make s_{LTS} consistent, assuming a Gaussian model. Specifically,

$$\begin{aligned} d_{h,n} &= 1/\sqrt{1 - \frac{2n}{hc_{h,n}}\phi(1/c_{h,n})} \\ c_{h,n} &= 1/\Phi^{-1}\left(\frac{h+n}{2n}\right) \end{aligned}$$

with Φ and ϕ being the distribution function and the density function of the standard normal distribution, respectively.

Final Weighted Scale Estimator

The ROBUSTREG procedure displays two scale estimators, s_{LTS} and Wscale. The estimator Wscale is a more efficient scale estimator based on the preliminary estimate s_{LTS} ; it is defined as

$$\text{Wscale} = \sqrt{\frac{\sum_i w_i r_i^2}{\sum_i w_i - p}}$$

where

$$w_i = \begin{cases} 0 & \text{if } |r_i|/s_{LTS} > k \\ 1 & \text{otherwise} \end{cases}$$

You can specify k with the CUTOFF= option in the MODEL statement. By default, $k = 3$.

S Estimate

The S estimate proposed by Rousseeuw and Yohai (1984) is defined as the p -vector

$$\hat{\theta}_S = \arg \min_{\theta} S(\theta)$$

where the dispersion $S(\theta)$ is the solution of

$$\frac{1}{n-p} \sum_{i=1}^n \chi\left(\frac{y_i - \mathbf{x}_i' \theta}{S}\right) = \beta$$

Here β is set to $\int \chi(s) d\Phi(s)$ such that $\hat{\theta}_S$ and $S(\hat{\theta}_S)$ are asymptotically consistent estimates of θ and σ for the Gaussian regression model. The breakdown value of the S estimate is

$$\frac{\beta}{\max_s \chi(s)}$$

The ROBUSTREG procedure provides two choices for χ : Tukey's bisquare function and Yohai's optimal function.

Tukey's bisquare function, which you can specify with the option CHIF= TUKEY, is

$$\chi_{k_0}(s) = \begin{cases} 3\left(\frac{s}{k_0}\right)^2 - 3\left(\frac{s}{k_0}\right)^4 + \left(\frac{s}{k_0}\right)^6, & \text{if } |s| \leq k_0 \\ 1 & \text{otherwise} \end{cases}$$

The constant k_0 controls the breakdown value and efficiency of the S estimate. If you specify the efficiency by using the EFF= option, you can determine the corresponding k_0 . The default k_0 is 2.9366 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 75.9%.

The Yohai function, which you can specify with the option CHIF=YOHA1, is

$$\chi_{k_0}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_0 \\ k_0^2 [b_0 + b_1(\frac{s}{k_0})^2 + b_2(\frac{s}{k_0})^4 + b_3(\frac{s}{k_0})^6 + b_4(\frac{s}{k_0})^8] & \text{if } 2k_0 < |s| \leq 3k_0 \\ 3.25k_0^2 & \text{if } |s| > 3k_0 \end{cases}$$

where $b_0 = 1.792$, $b_1 = -0.972$, $b_2 = 0.432$, $b_3 = -0.052$, and $b_4 = 0.002$. If you specify the efficiency by using the EFF= option, you can determine the corresponding k_0 . By default, k_0 is set to 0.7405 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 72.7%.

Algorithm

The ROBUSTREG procedure implements the algorithm by Marazzi (1993) for the S estimate, which is a refined version of the algorithm proposed by Ruppert (1992). The refined algorithm is briefly described as follows.

Initialize $iter = 1$.

1. Draw a random q -subset of the total n observations and compute the regression coefficients by using these q observations (if the regression is degenerate, draw another q -subset), where $q \geq p$ can be specified with the SUBSIZE= option. By default, $q = p$.
2. Compute the residuals: $r_i = y_i - \sum_{j=1}^p x_{ij}\theta_j$ for $i = 1, \dots, n$. If $iter = 1$, set $s^* = 2\text{median}\{|r_i|, i = 1, \dots, n\}$; if $s^* = 0$, set $s^* = \min\{|r_i|, i = 1, \dots, n\}$; else while $\sum_{i=1}^n \chi(r_i/s^*) > (n-p)\beta$, set $s^* = 1.5s^*$; go to step 3. If $iter > 1$ and $\sum_{i=1}^n \chi(r_i/s^*) \leq (n-p)\beta$, go to step 3; otherwise, go to step 5.

3. Solve for s the equation

$$\frac{1}{n-p} \sum_{i=1}^n \chi(r_i/s) = \beta$$

using an iterative algorithm.

4. If $iter > 1$ and $s > s^*$, go to step 5. Otherwise, set $s^* = s$ and $\theta^* = \theta$. If $s^* < \text{TOLS}$, return s^* and θ^* ; otherwise, go to step 5.
5. If $iter < \text{NREP}$, set $iter = iter + 1$ and return to step 1; otherwise, return s^* and θ^* .

The ROBUSTREG procedure does the following refinement step by default. You can request that this refinement not be done by using the NOREFINE option in the PROC ROBUSTREG statement.

6. Let $\psi = \chi'$. Using the values s^* and θ^* from the previous steps, compute M estimates θ_M and σ_M of θ and σ with the setup for M estimation that is described in the section “M Estimation” on page 6838. If $\sigma_M > s^*$, give a warning and return s^* and θ^* ; otherwise, return σ_M and θ_M .

You can specify TOLS with the TOLERANCE= option; by default, TOLERANCE=0.001. Alternately, you can specify NREP with the NREP= option. You can also use the options NREP=NREP0 or NREP=NREP1 to determine NREP according to the following table. NREP=NREP0 is set as the default.

Table 80.11 Default NREP

P	NREP0	NREP1
1	150	500
2	300	1000
3	400	1500
4	500	2000
5	600	2500
6	700	3000
7	850	3000
8	1250	3000
9	1500	3000
>9	1500	3000

NOTE: At step 1 in the algorithm, a randomly selected q -subset might be degenerate. If the total number of q -subsets from any subgroup is more than 4,000 and the ratio of degenerate q -subsets is more than the threshold specified in FAILRATIO= option, the algorithm is terminated with an error message.

R-Square and Deviance

The robust version of R-square for the S estimate is defined as

$$R_S^2 = 1 - \frac{(n-p)S_p^2}{(n-1)S_\mu^2}$$

for the model with the intercept term and

$$R_S^2 = 1 - \frac{(n-p)S_p^2}{nS_0^2}$$

for the model without the intercept term, where S_p is the S estimate of the scale in the full model, S_μ is the S estimate of the scale in the regression model with only the intercept term, and S_0 is the S estimate of the scale without any regressor. The deviance D is defined as the optimal value of the objective function on the σ^2 scale:

$$D = S_p^2$$

Asymptotic Covariance and Confidence Intervals

Since the S estimate satisfies the first-order necessary conditions as the M estimate, it has the same asymptotic covariance as that of the M estimate. All three estimators of the asymptotic covariance for the M estimate in the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 6843 can be used for the S estimate. Besides, the weighted covariance estimator H4 described in the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 6852 is also available and is set as the default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.

MM Estimation

MM estimation is a combination of high-breakdown-value estimation and efficient estimation, which was introduced by Yohai (1987). It has the following three steps:

1. Compute an initial (consistent) high-breakdown-value estimate $\hat{\theta}'$. The ROBUSTREG procedure provides two kinds of estimates as the initial estimate: the LTS estimate and the S estimate. By default, the LTS estimate is used because of its speed and high breakdown value. The breakdown value of the final MM estimate is decided by the breakdown value of the initial LTS estimate and the constant k_0 in the χ function. To use the S estimate as the initial estimate, you specify the INITEST=S option in the PROC ROBUSTREG statement. In this case, the breakdown value of the final MM estimate is decided only by the constant k_0 . Instead of computing the LTS estimate or the S estimate as the initial estimate, you can also specify the initial estimate explicitly by using the INEST= option in the PROC ROBUSTREG statement. See the section “[INEST= Data Set](#)” on page 6861 for details.

2. Find $\hat{\sigma}'$ such that

$$\frac{1}{n-p} \sum_{i=1}^n \chi \left(\frac{y_i - \mathbf{x}_i' \hat{\theta}'}{\hat{\sigma}'} \right) = \beta$$

where $\beta = \int \chi(s) d\Phi(s)$.

The ROBUSTREG procedure provides two choices for χ : Tukey's bisquare function and Yohai's optimal function.

Tukey's bisquare function, which you can specify with the option CHIF=DUKEY, is

$$\chi_{k_0}(s) = \begin{cases} 3\left(\frac{s}{k_0}\right)^2 - 3\left(\frac{s}{k_0}\right)^4 + \left(\frac{s}{k_0}\right)^6 & \text{if } |s| \leq k_0 \\ 1 & \text{otherwise} \end{cases}$$

where k_0 can be specified with the K0= option. The default k_0 is 2.9366 such that the asymptotically consistent scale estimate $\hat{\sigma}'$ has the breakdown value of 25%.

Yohai's optimal function, which you can specify with the option CHIF=YOHA1, is

$$\chi_{k_0}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_0 \\ k_0^2 [b_0 + b_1\left(\frac{s}{k_0}\right)^2 + b_2\left(\frac{s}{k_0}\right)^4 + b_3\left(\frac{s}{k_0}\right)^6 + b_4\left(\frac{s}{k_0}\right)^8] & \text{if } 2k_0 < |s| \leq 3k_0 \\ 3.25k_0^2 & \text{if } |s| > 3k_0 \end{cases}$$

where $b_0 = 1.792$, $b_1 = -0.972$, $b_2 = 0.432$, $b_3 = -0.052$, and $b_4 = 0.002$. You can specify k_0 with the K0= option. The default k_0 is 0.7405 such that the asymptotically consistent scale estimate $\hat{\sigma}'$ has the breakdown value of 25%.

3. Find a local minimum $\hat{\theta}_{MM}$ of

$$Q_{MM} = \sum_{i=1}^n \rho \left(\frac{y_i - \mathbf{x}_i' \hat{\theta}}{\hat{\sigma}'} \right)$$

such that $Q_{MM}(\hat{\theta}_{MM}) \leq Q_{MM}(\hat{\theta}')$. The algorithm for M estimation is used here.

The ROBUSTREG procedure provides two choices for ρ : Tukey's bisquare function and Yohai's optimal function.

Tukey's bisquare function, which you can specify with the option CHIF=ITUKEY, is

$$\rho(s) = \chi_{k_1}(s) = \begin{cases} 3\left(\frac{s}{k_1}\right)^2 - 3\left(\frac{s}{k_1}\right)^4 + \left(\frac{s}{k_1}\right)^6 & \text{if } |s| \leq k_1 \\ 1 & \text{otherwise} \end{cases}$$

where k_1 can be specified with the K1= option. The default k_1 is 3.440 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

Yohai's optimal function, which you can specify with the option CHIF=YOHA1, is

$$\rho(s) = \chi_{k_1}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_1 \\ k_1^2[b_0 + b_1\left(\frac{s}{k_1}\right)^2 + b_2\left(\frac{s}{k_1}\right)^4 + b_3\left(\frac{s}{k_1}\right)^6 + b_4\left(\frac{s}{k_1}\right)^8] & \text{if } 2k_1 < |s| \leq 3k_1 \\ 3.25k_1^2 & \text{if } |s| > 3k_1 \end{cases}$$

where k_1 can be specified with the K1= option. The default k_1 is 0.868 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

Algorithm

The initial LTS estimate is computed using the algorithm described in the section "[LTS Estimate](#)" on page 6845. You can control the quantile of the LTS estimate with the option INITH= h , where h is an integer between $\lfloor \frac{n}{2} \rfloor + 1$ and $\lfloor \frac{3n+p+1}{4} \rfloor$. By default, $h = \lfloor \frac{3n+p+1}{4} \rfloor$, which corresponds to a breakdown value of around 25%.

The initial S estimate is computed using the algorithm described in the section "[S Estimate](#)" on page 6847. You can control the breakdown value and efficiency of this initial S estimate by the constant k_0 , which can be specified with the K0 option.

The scale parameter σ is solved by an iterative algorithm

$$(\sigma^{(m+1)})^2 = \frac{1}{(n-p)\beta} \sum_{i=1}^n \chi_{k_0}\left(\frac{r_i}{\sigma^{(m)}}\right) (\sigma^{(m)})^2$$

where $\beta = \int \chi_{k_0}(s) d\Phi(s)$.

Once the scale parameter is computed, the iteratively reweighted least squares (IRLS) algorithm with fixed scale parameter is used to compute the final MM estimate.

Convergence Criteria

In the iterative algorithm for the scale parameter, the relative change of the scale parameter controls the convergence.

In the iteratively reweighted least squares algorithm, the same convergence criteria for the M estimate used before are used here.

Bias Test

Although the final MM estimate inherits the high-breakdown-value property, its bias due to the distortion of the outliers can be high. Yohai, Stahel, and Zamar (1991) introduced a bias test. The ROBUSTREG procedure implements this test when you specify the `BIATEST=` option in the `PROC ROBUSTREG` statement. This test is based on the initial scale estimate $\hat{\sigma}'$ and the final scale estimate $\hat{\sigma}'_1$, which is the solution of

$$\frac{1}{n-p} \sum_{i=1}^n \chi \left(\frac{y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}_{MM}}{\hat{\sigma}'_1} \right) = \beta$$

Let $\psi_{k_0}(z) = \frac{\partial \chi_{k_0}(z)}{\partial z}$ and $\psi_{k_1}(z) = \frac{\partial \chi_{k_1}(z)}{\partial z}$. Compute

$$\begin{aligned} \tilde{r}_i &= (y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}') / \hat{\sigma}' \quad \text{for } i = 1, \dots, n \\ v_0 &= \frac{(1/n) \sum \psi'_{k_0}(\tilde{r}_i)}{(\hat{\sigma}'_1/n) \sum \psi_{k_0}(\tilde{r}_i) \tilde{r}_i} \end{aligned}$$

$$\begin{aligned} p_i^{(0)} &= \frac{\psi_{k_0}(\tilde{r}_i)}{(1/n) \sum \psi'_{k_0}(\tilde{r}_i)} \quad \text{for } i = 1, \dots, n \\ p_i^{(1)} &= \frac{\psi_{k_1}(\tilde{r}_i)}{(1/n) \sum \psi'_{k_1}(\tilde{r}_i)} \quad \text{for } i = 1, \dots, n \\ d^2 &= \frac{1}{n} \sum (p_i^{(1)} - p_i^{(0)})^2 \end{aligned}$$

Let

$$T = \frac{2n(\hat{\sigma}'_1 - \hat{\sigma}')}{v_0 d^2 (\hat{\sigma}')^2}$$

Standard asymptotic theory shows that T approximately follows a χ^2 distribution with p degrees of freedom. If T exceeds the α quantile χ^2_α of the χ^2 distribution with p degrees of freedom, then the ROBUSTREG procedure gives a warning and recommends that you use other methods. Otherwise, the final MM estimate and the initial scale estimate are reported. You can specify α with the `ALPHA=` option following the `BIATEST=` option. By default, `ALPHA=0.99`.

Asymptotic Covariance and Confidence Intervals

Since the MM estimate is computed as a M estimate with a known scale in the last step, the asymptotic covariance for the M estimate can be used here for the asymptotic covariance of the MM estimate. Besides the three estimators H1, H2, and H3 as described in the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 6843, a weighted covariance estimator H4 is available. H4 is calculated as

$$K^2 \frac{[1/(n-p)] \sum (\psi(r_i))^2}{[(1/n) \sum (\psi'(r_i))]^2} \mathbf{W}^{-1}$$

where $K = 1 + \frac{p}{n} \frac{\text{Var}(\psi')}{(E\psi')^2}$ is the correction factor and $W_{jk} = \frac{1}{\bar{w}} \sum w_i x_{ij} x_{ik}$, $\bar{w} = \frac{1}{n} \sum w_i$.

You can specify these estimators with the option `ASYMPCOV= [H1 | H2 | H3 | H4]`. The ROBUSTREG procedure uses H4 as the default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.

R Square and Deviance

The robust version of R-square for the MM estimate is defined as

$$R^2 = \frac{\sum \rho\left(\frac{y_i - \hat{\mu}}{\hat{s}}\right) - \sum \rho\left(\frac{y_i - \mathbf{x}_i' \hat{\boldsymbol{\theta}}}{\hat{s}}\right)}{\sum \rho\left(\frac{y_i - \hat{\mu}}{\hat{s}}\right)}$$

and the robust deviance is defined as the optimal value of the objective function on the σ^2 scale,

$$D = 2\hat{s}^2 \sum \rho\left(\frac{y_i - \mathbf{x}_i' \hat{\boldsymbol{\theta}}}{\hat{s}}\right)$$

where $\rho' = \psi$, $\hat{\boldsymbol{\theta}}$ is the MM estimator of $\boldsymbol{\theta}$, $\hat{\mu}$ is the MM estimator of location, and \hat{s} is the MM estimator of the scale parameter in the full model.

Linear Tests

For MM estimation, the same ρ test and R_n^2 test used for M estimation can be used. See the section “[Linear Tests](#)” on page 6844 for details.

Model Selection

For MM estimation, the same two model selection methods used for M estimation can be used. See the section “[Model Selection](#)” on page 6844 for details.

Robust Distance

The ROBUSTREG procedure uses the robust multivariate location and scatter estimates for leverage-point detection. The procedure computes a robust version of the Mahalanobis distance by using a generalized minimum covariance determinant (MCD) method. The original MCD method was proposed by Rousseeuw (1984).

Algorithm

PROC ROBUSTREG implements a generalized MCD algorithm based on the fast-MCD algorithm formulated by Rousseeuw and Van Driessen (1999), which is similar to the algorithm for least trimmed squares (LTS).

Mahalanobis Distance versus Robust Distance

The canonical Mahalanobis distance is defined as

$$\text{MD}(\mathbf{x}_i) = [(\mathbf{x}_i - \bar{\mathbf{x}})' \bar{\mathbf{C}}(\mathbf{X})^{-1} (\mathbf{x}_i - \bar{\mathbf{x}})]^{1/2}$$

where $\bar{\mathbf{x}} = \frac{1}{n} \sum_{i=1}^n \mathbf{x}_i$ and $\bar{\mathbf{C}}(\mathbf{X}) = \frac{1}{n-1} \sum_{i=1}^n (\mathbf{x}_i - \bar{\mathbf{x}})(\mathbf{x}_i - \bar{\mathbf{x}})'$ are the empirical multivariate location and scatter, respectively. Here $\mathbf{x}_i = (x_{i1}, \dots, x_{ip})'$ excludes the intercept. The relation between the Mahalanobis distance $\text{MD}(\mathbf{x}_i)$ and the hat matrix $\mathbf{H} = (h_{ij}) = \mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'$ is

$$h_{ii} = \frac{1}{n-1} \text{MD}_i^2 + \frac{1}{n}$$

The canonical robust distance is defined as

$$RD(\mathbf{x}_i) = [(\mathbf{x}_i - \mathbf{T}(\mathbf{X}))' \mathbf{C}(\mathbf{X})^{-1} (\mathbf{x}_i - \mathbf{T}(\mathbf{X}))]^{1/2}$$

where $\mathbf{T}(\mathbf{X})$ and $\mathbf{C}(\mathbf{X})$ are the robust multivariate location and scatter, respectively, obtained by MCD.

To achieve robustness, the MCD algorithm estimates the covariance of a multivariate data set mainly through an MCD h -point subset of the data set. This subset has the smallest sample-covariance determinant among all the possible h -subsets. Accordingly, the breakdown value for the MCD algorithm equals $\frac{(n-h)}{n}$. This means the MCD estimate is reliable, even if up to $\frac{100(n-h)}{n}\%$ observations in the data set are contaminated.

Low-Dimensional Structure

It is possible that the original data are in p dimensional space, but the h -point subset that yields the minimum covariance determinant lies in a lower-dimensional hyperplane. Applying the canonical MCD algorithm to such a data set would result in a singular covariance problem (called exact fit in Rousseeuw and Van Driessen (1999)), so that the relevant robust distances cannot be computed. To deal with the singularity problem and provide further leverage point analysis, PROC ROBUSTREG implements a generalized MCD algorithm. See the section “[Generalized MCD Algorithm](#)” on page 6857 for details. The algorithm distinguishes in-(hyper)plane points from off-(hyper)plane points, and performs MCD leverage point analysis in the dimension-reduced space by projecting all points onto the hyperplane.

Low-dimensional structure is often induced by classification covariates. Suppose, in a study with 25 female subjects and 5 male subjects, that *gender* is the only classification effect. If the breakdown setting is larger than $\frac{5}{(25+5)}$, the canonical MCD algorithm fails, and so does the relevant leverage point analysis. In this case, the MCD h -subset would contain only female observations and the constant gender in the h -subset would cause the relevant MCD estimate to be singular. The generalized MCD algorithm solves that problem by identifying all male observations as off-plane leverage points, and then carries out the leverage point analysis with all the other covariates being centered separately for female and male groups against their group means.

In general, low-dimensional structure is not necessarily due to classification covariates. Imagine that 80 children are supposed to play on a straight trail (denoted by $y = x$), but some adventurous children go off the trail. The following statements generate the children data and the relevant scatter plot.

```
data children;
  do i=1 to 80;
    off_trail=ranuni(321)>.9;
    x=rannor(111)*ranuni(321);
    trail_x=(i-40)/80*3;
    trail_y=trail_x;
    if off_trail=1 then y=x-1+rannor(321);
    else y=x;
    output;
  end;
run;

proc sgplot data=children;
  series  x=trail_x y=trail_y/lineattrs=(color="red" pattern=4);
  scatter x=x y=y/group=off_trail;
  ellipse x=x y=y/alpha=.05 lineattrs=(color="green" pattern=34);
run;
```

Figure 80.17 shows the positions of all the 80 children, the trail (as a red dashed line), and a contour curve of regular Mahalanobis distance centered at the mean position (as a green dotted ellipse). In terms of regular Mahalanobis distance, the associated covariance estimate is not singular, but its relevant leverage point analysis completely ignores the trail (which is the entity of the low-dimensional structure). The children outside of the ellipse are defined as leverage points, but the children off the trail would not be viewed as leverage points unless they have large Mahalanobis distances. As mentioned in Rousseeuw and Van Driessen (1999), the canonical MCD method can find the low-dimensional structure, but it does not provide further robust covariance estimation because the MCD covariance estimate is singular. As an improved version of the canonical MCD method, the generalized MCD method can find the trail, identify the children off the trail as off-plane leverage points, and further execute in-plane leverage analysis. The following statements apply the generalized MCD algorithm on the children data set.

```
ods graphics on;
proc robustreg data=children plots=ddplot(label=none);
  model i = x y/leverage(mcdinfo opc);
run;
ods graphics off;
```

Figure 80.17 Scatter Plot for Children Data

Figure 80.18 exactly identifies the equation underlying the trail. The analysis projects off-plane points onto the trail and computes their projected robust distances and projected Mahalanobis distances the same way as is done for the in-plane points.

Figure 80.18 Robust Dependence Equations

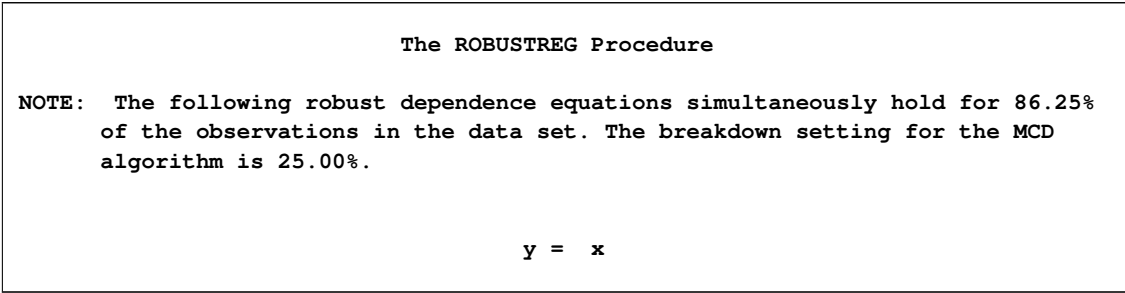

Figure 80.19 shows the relevant distance-distance plot. Robust distance is typically larger than Mahalanobis distance because the sample covariance can be strongly influenced by unusual points that cause the sample covariance to be larger than the MCD covariance.

Figure 80.19 DDPlot for Children Data

NOTE: The PROC ROBUSTREG step in this example is used to obtain the leverage diagnostics; the response is not relevant for this analysis.

Through the off-plane and in-plane symbols and the horizontal cutoff line in Figure 80.19, you can separate all the children into four groups:

- on-trail and close to the MCD center

- on-trail but far away from the MCD center
- off-trail but close to the MCD center
- off-trail and far away from the MCD center

The children in the latter three groups are defined as leverage points in PROC ROBUSTREG.

Generalized MCD Algorithm

The generalized MCD algorithm follows the same resampling strategy as the canonical MCD algorithm by Rousseeuw and Van Driessen (1999) but with modifications in the following aspects.

1. Data are orthonormalized before further processing. The orthonormalized covariates, \mathbf{x}_i^* , are defined by $\mathbf{x}_i^* = (\mathbf{x}_i - \bar{\mathbf{x}})\mathbf{P}\mathbf{\Lambda}^{-1/2}$, where \mathbf{P} and $\mathbf{\Lambda}$ are the eigenvector and eigenvalue matrices of $\bar{\mathbf{C}}(\mathbf{X})$ (that is, $\bar{\mathbf{C}}(\mathbf{X}) = \mathbf{P}\mathbf{\Lambda}\mathbf{P}'$).
2. Let

$$S_h(\mathbf{X}^*) = \frac{1}{h-1} \sum_{j=1}^h (\mathbf{x}_{i_j}^* - \bar{\mathbf{x}}^*)(\mathbf{x}_{i_j}^* - \bar{\mathbf{x}}^*)' = \sum_{j=1}^{p-1} \lambda_j \mathbf{p}_j \mathbf{p}_j'$$

denote the covariance and eigendecomposition for a low-dimensional h -subset $\{\mathbf{x}_{i_1}^*, \dots, \mathbf{x}_{i_h}^*\}$, where $\bar{\mathbf{x}}^* = \frac{1}{h} \sum_{j=1}^h \mathbf{x}_{i_j}^*$ and the eigenvalues satisfy

$$\lambda_1 \geq \dots \geq \lambda_q > 0 = \lambda_{q+1} = \dots = \lambda_p$$

Then, the rank of $S_h(\mathbf{X}^*)$ equals q , and the pseudo-determinant of $S_h(\mathbf{X}^*)$ is defined as $\prod_{j=1}^q \lambda_j$.

In finite precision arithmetic, q is defined as the number of λ 's with $\frac{\lambda_i}{\lambda_1}$ being larger than a certain tolerance value. You can specify this tolerance with the PTOL suboption of the LEVERAGE option.

3. Given $S_h(\mathbf{X}^*)$ and $\bar{\mathbf{x}}^*$ as the covariance and center estimates, the projected Mahalanobis distance for \mathbf{x}_i is defined as

$$\left[\sum_{j=1}^q \frac{((\mathbf{x}_i^* - \bar{\mathbf{x}}^*)\mathbf{p}_j)^2}{\lambda_j} \right]^{1/2}$$

The generalized algorithm also computes off-plane distance for each \mathbf{x}_i as

$$\left[\sum_{j=q+1}^p ((\mathbf{x}_i^* - \bar{\mathbf{x}}^*)\mathbf{p}_j)^2 \right]^{1/2}$$

In finite precision arithmetic, $((\mathbf{x}_i^* - \bar{\mathbf{x}}^*)\mathbf{p}_j)^2$ in the previous off-plane formula are truncated to zero if they satisfy

$$\frac{((\mathbf{x}_i^* - \bar{\mathbf{x}}^*)\mathbf{p}_j)^2}{\lambda_j} \leq \text{cutoff}$$

You can tune this cutoff by using either the PCUTOFF or the PALPHA suboption of the LEVERAGE option. The points with zero off-plane distances are called in-plane points; otherwise, they are called off-plane points. Analogous to ordering all points in terms of their canonical Mahalanobis distances, with the generalized MCD algorithm the points are first sorted by their off-plane distances, and the points with the same off-plane distance values are further sorted by their projected Mahalanobis distances.

4. Instead of comparing the determinants of h -subset covariance matrices, the generalized algorithm compares both the ranks and pseudo-determinants of the h -subset covariance matrices. If the ranks of two matrices are different, the matrix with smaller rank is treated as if its determinant were smaller. If two matrices are of the same rank, they are compared in terms of their pseudo-determinants.
5. Suppose that the $S_h(\mathbf{X}^*)$ of the minimum determinant is singular. Then the relevant low-dimensional structure or hyperplane can be identified by using the eigendecomposition of $S_h(\mathbf{X}^*)$. The eigenvectors that correspond to the nonzero eigenvalues form a basis for the low-dimensional hyperplane. The projected off-plane distance (POD) for \mathbf{x}_i is defined as the off-plane distance associated with the $S_h(\mathbf{X}^*)$. To provide further leverage analysis on the low-dimensional hyperplane, every \mathbf{x}_i^* is transformed into $(\mathbf{x}_i^* \mathbf{p}_1, \dots, \mathbf{x}_i^* \mathbf{p}_q)$, where \mathbf{p}_j are the eigenvectors of the $S_h(\mathbf{X}^*)$. The projected robust distance (PRD) is then computed as the reweighted Mahalanobis distance on all the transformed in-plane points. The off-plane points are assigned zero weights at the reweighting stage, because they are leverage points by definition. The in-plane points are classified into two groups, the normal group and the in-plane leverage group. This classification is made by comparing their projected robust distances with a leverage cutoff value. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for details. This reweighting process mirrors the one proposed by Rousseeuw and Van Driessen (1999). However, the degrees of freedom p for the reweighting critical χ^2 value is replaced by q . You can control the χ^2 critical value with the MCDCUTOFF= or the MCDALPHA= option.

If the data set under investigation has a low-dimensional structure, you can use two ODS objects, DependenceEquations and MCDDependenceEquations, to identify the regressors that are linear combinations of other regressors plus certain constants. The equations in DependenceEquations hold for the entire data set, while the equations in MCDDependenceEquations apply only to the majority of the observations.

By using the OPC suboption of the LEVERAGE option, you can request an ODS table called DroppedComponents. [Figure 80.20](#) shows the DroppedComponents table for the children data example. This table contains a set of coefficient vectors for regressors, which form a basis of the complementary space for the relevant low-dimensional structure.

Figure 80.20 MCD Dropped Components

Coefficients for MCD-Dropped Components	
Parameter	Robust Drop1
x	-1.000
y	1.0000

By using the MCDINFO suboption of the LEVERAGE option, you can request that detailed information about the MCD covariance estimate be displayed in four ODS tables: MCDProfile, MCDCenter, MCD Cov, and MCDCorr. Figure 80.21 shows an example of the MCD information tables for the children data. The number of dimensions in the table MCDProfile equals the number of nonintercept regressors minus the number of design dropped components. The specified value of H is the same as h for the h -subset that you can specify with the QUANTILE= suboption of the LEVERAGE option in the MODEL statement, and the reweighted H is the number of observations that are actually used to compute the MCD center and MCD covariance after the reweighting step of the MCD algorithm.

Figure 80.21 MCD Information

MCD Profile		
Number of Dimensions		2
Number of Robust Dropped Components		1
Number of Observations		80
Number of Off-Plane Observations		11
Specified Value of H		60
Reweighted Value of H		63
Breakdown Value		0.2500

MCD Center		
Parameter Name	Parameter	Center
x	x	0.0307
y	y	0.0307

MCD Covariance		
	x	y
x	0.207713	0.207713
y	0.207713	0.207713

MCD Correlation		
	x	y
x	1	1
y	1	1

Leverage Point and Outlier Detection

The regular variable LEVERAGE is defined as

$$\text{LEVERAGE} = \begin{cases} 0 & \text{if } \text{RD}(\mathbf{x}_i) \leq C(p) \\ 1 & \text{otherwise} \end{cases}$$

where $C(p) = \sqrt{\chi_{p;1-\alpha}^2}$ is the cutoff value. $C(p)$ can be set with the leverage CUTOFF= option, and α can be set with the leverage CUTOFFALPHA= option.

If projected robust distances are computed for a data set that has a low-dimensional structure, the default cutoff value is $C(q) = \sqrt{\chi_{q;1-\alpha}^2}$ where q is the dimensionality of the low-dimensional space. The LEVERAGE is then defined as

$$\text{LEVERAGE} = \begin{cases} 0 & \text{if } \text{POD}(\mathbf{x}_i) = 0 \text{ and } \text{PRD}(\mathbf{x}_i) \leq C(q) \\ 1 & \text{if } \text{POD}(\mathbf{x}_i) = 0 \text{ and } \text{PRD}(\mathbf{x}_i) > C(q) \text{ (called in-plane leverage)} \\ 1 & \text{if } \text{POD}(\mathbf{x}_i) > 0 \text{ (called off-plane leverage)} \end{cases}$$

where POD is the projected off-plane distance and PRD denotes the projected robust distance. You can specify a cutoff value with the CUTOFF or the CUTOFFALPHA suboptions of the LEVERAGE option in the MODEL statement.

Residuals $r_i, i = 1, \dots, n$, based on robust regression estimates are used to detect vertical outliers. The variable OUTLIER is defined as

$$\text{OUTLIER} = \begin{cases} 0 & \text{if } |r_i| \leq k\hat{\sigma} \\ 1 & \text{otherwise} \end{cases}$$

where $\hat{\sigma}$ is the estimated scale in the model and the multiplier k of the cutoff value is specified by the CUTOFF= option in the MODEL statement. By default, $k = 3$.

An ODS table called Diagnostics contains the LEVERAGE and OUTLIER variables.

Implementation of the WEIGHT Statement

You can use the WEIGHT statement to specify a weight variable in the input data set. See the section “WEIGHT Statement” on page 6838 for more information. This section describes how PROC ROBUSTREG implements the WEIGHT statement for each of the estimation methods and for leverage detection.

M Estimation

If you use M estimation with a known scale, instead of minimizing $Q(\boldsymbol{\theta}) = \sum_{i=1}^n \rho(\frac{r_i}{\sigma})$, the weighted M estimation minimizes the weighted Huber-type objective function

$$Q(\boldsymbol{\theta}) = \sum_{i=1}^n v_i \rho\left(\frac{r_i}{\sigma}\right),$$

where v is the weight variable specified by the WEIGHT statement. If you use M estimation with an unknown scale, the weight variable is used in the location steps but not in the scale steps. See the section “[M Estimation](#)” on page 6838 and the SCALE= option for more details. For estimating the covariance of the weighted M estimation, $\psi(r_i)$ and $\psi'(r_i)$ are obtained from the final iteration of the weighted M estimation, and $\mathbf{X}'\mathbf{X}$ and \mathbf{W} are respectively replaced by $\mathbf{X}'\mathbf{V}\mathbf{X}$ and $W_{jk} = \sum v_i \psi'(r_i) x_{ij} x_{ik}$, where \mathbf{V} is a diagonal matrix with its diagonal elements being v_i 's. See the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 6843 for more information. The weight variable does not affect the model degrees of freedom p and the error degrees of freedom $n - p$.

LTS Estimation

LTS estimation ignores the weight variable.

S Estimation

S estimation applies the weight variable only in its M-refinement step. Except for the initial estimates, the M-refinement step of S estimation is the same as the weighted M estimation with unknown scale. If you use the NOREFINE suboption, S estimation ignores the weight variable along with the M-refinement step.

MM Estimation

By default, the initial step of MM estimation is the initial LTS estimation. Unlike the regular LTS estimation, the initial LTS estimation is applied on the weighted data (y_i^*, \mathbf{x}_i^*) 's, where $y_i^* = \sqrt{v_i} y_i$ and $\mathbf{x}_i^* = \sqrt{v_i} \mathbf{x}_i$. After the initial LTS estimation, the weight variable is ignored for the subsequent scale adjustment.

You can use INITEST=S to specify the initial S estimation as the initial step of the MM estimation. Similarly to the regular S estimation, the weight variable is used only in the M-refinement step of the initial S estimation. There is no subsequent scale adjustment step if the initial S estimation is applied.

Except for the initial estimates, the final M estimation of the MM estimation is the same as the weighted M estimation with known scale.

Final Weighted Least Squares Estimation

Final weighted least squares estimation is always applied on the weighted data (y_i^*, \mathbf{x}_i^*) no matter how the weight variable is applied in the preceding estimation. For example, if the option METHOD=LTS is specified along with the option FWLS, although the outliers identified by LTS estimation do not depend on the weight variable, final weighted least squares estimation applies the weight variable on all the points that are not outliers.

Robust Distances and Leverage Detection

Robust distance computation ignores the weight variable. Because leverage detection depends on robust distance, it also ignores the weight variable.

INEST= Data Set

When you use M or MM estimation, you can use the INEST= data set to specify initial estimates for all the parameters in the model. The INEST= option is ignored if you specify LTS or S estimation by using the

METHOD=LTS or METHOD=S option or if you specify the INITEST= option after the METHOD=MM option in the PROC ROBUSTREG statement. The INEST= data set must contain the intercept variable (named Intercept) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in a BY group, the first one read is used for that BY group.

If the INEST= data set also contains the _TYPE_ variable, only observations with _TYPE_ value “PARMS” are used as starting values.

You can specify starting values for the iteratively reweighted least squares algorithm in the INEST= data set. The INEST= data set has the same structure as the OUTEST= data set but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization.

OUTEST= Data Set

The OUTEST= data set contains parameter estimates for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different models used by the ROBUSTREG procedure. If the COVOUT option is specified, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates. If the ROBUSTREG procedure does not converge, the parameter estimates are set to missing in the OUTEST data set.

The OUTEST= data set contains all variables specified in the MODEL statement and the BY statement. One observation consists of parameter values for the model with the dependent variable having the value –1. If the COVOUT option is specified, there are additional observations that contain the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

<code>_MODEL_</code>	is a character variable that contains the label of the MODEL statement, if present. Otherwise, the variable's value is blank.
<code>_NAME_</code>	is a character variable that contains the name of the dependent variable for the parameter estimates or the name of the row for the covariance matrix estimates.
<code>_TYPE_</code>	is a character variable that contains the type of the observation, either PARMS for parameter estimates or COV for covariance estimates.
<code>_METHOD_</code>	is a character variable that contains the type of estimation method: either M estimation, LTS estimation, S estimation, or MM estimation.
<code>_STATUS_</code>	is a character variable that contains the status of model fitting: either Converged, Warning, or Failed.
<code>INTERCEPT</code>	is a numeric variable that contains the intercept parameter estimates and covariances.
<code>_SCALE_</code>	is a numeric variable that contains the scale parameter estimates.

Any BY variables specified are also added to the OUTEST= data set.

Computational Resources

The algorithms for the various estimation methods need a different amount of memory for working space. Let p be the number of parameters estimated and n be the number of observations used in the model estimation.

For M estimation, the minimum working space (in bytes) needed is

$$3n + 2p^2 + 30p$$

If sufficient space is available, the input data set is also kept in memory; otherwise, the input data set is read again for computing the iteratively reweighted least squares estimates and the execution time of the procedure increases substantially. For each reweighted least squares, $O(np^2 + p^3)$ multiplications and additions are required for computing the crossproduct matrix and its inverse. The $O(v)$ notation means that, for large values of the argument, v , $O(v)$ is approximately a constant times v .

Since the iteratively reweighted least squares algorithm converges very quickly (normally within fewer than 20 iterations), the computation of M estimates is fast.

LTS estimation is more expensive in computation. The minimum working space (in bytes) needed is

$$np + 12n + 4p^2 + 60p$$

The memory is mainly used to store the current data used by LTS for modeling. The LTS algorithm uses subsampling and spends much of its computing time on resampling and computing estimates for subsamples. Since it resamples if singularity is detected, it might take more time if the data set has serious singularities.

The MCD algorithm for leverage-point diagnostics is similar to the LTS algorithm.

ODS Table Names

The ROBUSTREG procedure assigns a name to each table it creates. You can specify these names when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 80.12 ODS Tables Produced by PROC ROBUSTREG

ODS Table Name	Description	Statement	Option
BestEstimates	Best final estimates for LTS	PROC	SUBANALYSIS

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If the model includes a single continuous independent variable, a plot of robust fit against this variable (FITPLOT) is provided by default. Two plots are particularly useful in revealing outliers and leverage points. The first is a scatter plot of the standardized robust residuals against the robust distances (RDPLOT). The second is a scatter plot of the robust distances against the classical Mahalanobis distances (DDPLOT). In addition to these two plots, a histogram and a quantile-quantile plot of the standardized robust residuals are also helpful.

PROC ROBUSTREG assigns a name to each graph it creates using ODS. You can use these names to refer to the graphs when using ODS. The names and PLOTS= options are listed in [Table 80.13](#).

Table 80.13 Graphs Produced by PROC ROBUSTREG

ODS Graph Name	Plot Description	Statement	PLOTS= Option
DDPlot	Robust distance versus Mahalanobis distance (or projected robust distance versus Projected Mahalanobis distance)	PROC	DDPLOT
FitPlot	Robust fit versus independent variable	PROC	FITPLOT
Histogram	Histogram of standardized robust residuals	PROC	HISTOGRAM
QQPlot	Q-Q plot of standardized robust residuals	PROC	QQPLOT
RDPlot	Standardized robust residual versus robust distance (or projected robust distance)	PROC	RDPLOT

Fit Plot

When the model has a single independent continuous variable (with or without the intercept), the ROBUSTREG procedure automatically creates a plot of robust fit against this independent variable.

The following simple example shows the fit plot. The data, from Rousseeuw and Leroy (1987, Table 3), include the logarithm of surface temperature and the logarithm of light intensity for 47 stars in the direction of the constellation Cygnus.

```
data star;
  input index x y @@;
  label x = 'Log Temperature'
        y = 'Log Light Intensity';
  datalines;

;
```

The following statements plot the robust fit of the logarithm of light intensity with the MM method against the logarithm of the surface temperature.

```
ods graphics on;

proc robustreg data=star method=mm;
  model y = x;
run;
```

Figure 80.22 shows the fit plot. Confidence limits are added on the plot by default.

Figure 80.22 Robust Fit

You can suppress the confidence limits with the NOLIMITS option, as shown in the following statements:

```
proc robustreg data=star method=mm plot=fitplot(nolimits);
  model y = x;
run;
```

Distance-Distance Plot

The distance-distance plot (DDPLOT) is mainly used for leverage-point diagnostics. It is a scatter plot of the robust distances (or projected robust distances) against the classical Mahalanobis distances (or projected classical Mahalanobis distances) for the independent variables. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for details about the robust distance.

You can use the PLOT=DDPLOT option to request this plot. The following statements use the stack data set in the section “[M Estimation](#)” on page 6811 to create the single plot shown in [Figure 80.5](#).

```
proc robustreg data=stack plot=ddplot;
  model y = x1 x2 x3;
run;
```

The reference lines represent the cutoff values. The diagonal line is also drawn to show the distribution of the distances. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the LABEL= option as described in [Table 80.2](#).

If you specify ID variables in the ID statement, the values of the first ID variable instead of observation numbers are used as labels.

Residual-Distance Plot

The residual-distance plot (RDPLOT) is used for both outlier and leverage-point diagnostics. It is a scatter plot of the standardized robust residuals against the robust distances. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for details about the robust distance.

You can use the PLOT=RDPLOT option to request this plot. The following statements use the stack data set in the section “[M Estimation](#)” on page 6811 to create the plot shown in [Figure 80.4](#).

```
proc robustreg data=stack plot=rdplot;
  model y = x1 x2 x3;
run;
```

The reference lines represent the cutoff values. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the LABEL= option as described in [Table 80.2](#).

If you specify ID variables in the ID statement, the values of the first ID variable instead of observation numbers are used as labels.

Histogram and Q-Q Plot

PROC ROBUSTREG produces a histogram and a Q-Q plot for the standardized robust residuals. The histogram is superimposed with a normal density curve and a kernel density curve. Using the stack data set in the section “[M Estimation](#)” on page 6811, the following statements create the plots in [Figure 80.6](#) and [Figure 80.7](#).

```
proc robustreg data=stack plots=(histogram qqplot);
  model y = x1 x2 x3;
run;
```

Examples: ROBUSTREG Procedure

Example 80.1: Comparison of Robust Estimates

This example contrasts several of the robust methods available in the ROBUSTREG procedure.

The following statements generate 1,000 random observations. The first 900 observations are from a linear model, and the last 100 observations are significantly biased in the y-direction. In other words, 10% of the observations are contaminated with outliers.

```
data a (drop=i);
  do i=1 to 1000;
    x1=rannor(1234);
    x2=rannor(1234);
    e=rannor(1234);
    if i > 900 then y=100 + e;
    else y=10 + 5*x1 + 3*x2 + .5 * e;
    output;
  end;
run;
```

The following statements invoke PROC REG and PROC ROBUSTREG with the data set a.

```
proc reg data=a;
    model y = x1 x2;
run;

proc robustreg data=a method=m;
    model y = x1 x2;
run;

proc robustreg data=a method=mm seed=100;
    model y = x1 x2;
run;

proc robustreg data=a method=s seed=100;
    model y = x1 x2;
run;

proc robustreg data=a method=lts seed=100;
    model y = x1 x2;
run;
```

The tables of parameter estimates generated by using M estimation, MM estimation, S estimation, and LTS estimation in the ROBUSTREG procedure are shown in [Output 80.1.2](#), [Output 80.1.3](#), [Output 80.1.4](#), and [Output 80.1.5](#), respectively. For comparison, the ordinary least squares (OLS) estimates produced by the REG procedure (Chapter 79, “[The REG Procedure](#)”) are shown in [Output 80.1.1](#). The four robust methods, M, MM, S, and LTS, correctly estimate the regression coefficients for the underlying model (10, 5, and 3), but the OLS estimate does not.

Output 80.1.1 OLS Estimates for Data with 10% Contamination

The next statements demonstrate that if the percentage of contamination is increased to 40%, the M method and the MM method with default options fail to estimate the underlying model. [Output 80.1.6](#) and [Output 80.1.7](#) display these estimates. However, by tuning the constant c for the M method and the constants INITH and K0 for the MM method, you can increase the breakdown values of the estimates and capture the right model. [Output 80.1.8](#) and [Output 80.1.9](#) display these estimates. Similarly, you can tune the constant EFF for the S method and the constant H for the LTS method and correctly estimate the underlying model with these methods. Results are not presented.

```

data b (drop=i);

When there are bad leverage points, the M method fails to estimate the underlying model no matter what constant c you use. In this case, other methods (LTS, S, and MM) in PROC ROBUSTREG, which are robust to bad leverage points, correctly estimate the underlying model.

The following statements generate and analyze 1,000 observations with 1% bad high leverage points.

```
data c (drop=i);
  do i=1 to 1000;
    x1=rannor(1234);
    x2=rannor(1234);
    e=rannor(1234);
    if i > 600 then y=100 + e;
    else y=10 + 5*x1 + 3*x2 + .5 * e;
    if i < 11 then x1=200 * rannor(1234);
    if i < 11 then x2=200 * rannor(1234);
    if i < 11 then y= 100*e;
    output;
  end;
run;

proc robustreg data=c method=mm(inith=502 k0=1.8) seed=100;
  model y = x1 x2;
run;

proc robustreg data=c method=s(k0=1.8) seed=100;
  model y = x1 x2;
run;
```

```
proc robustreg data=c method=lts(h=502) seed=100;
  model y = x1 x2;
run;
```

Output 80.1.10 displays the MM estimates with initial LTS estimates, Output 80.1.11 displays the S estimates, and Output 80.1.12 displays the LTS estimates.

Example 80.2: Robust ANOVA

The classical analysis of variance (ANOVA) technique based on least squares assumes that the underlying experimental errors are normally distributed. However, data often contain outliers due to recording or other errors. In other cases, extreme responses occur when control variables in the experiments are set to extremes. It is important to distinguish these extreme points and determine whether they are outliers or important extreme cases. You can use the ROBUSTREG procedure for robust analysis of variance based on M estimation. Typically, there are no high leverage points in a well-designed experiment, so M estimation is appropriate.

The following example shows how to use the ROBUSTREG procedure for robust ANOVA.

An experiment was carried out to study the effects of two successive treatments (T1, T2) on the recovery time of mice with certain diseases. Sixteen mice were randomly assigned into four groups for the four different combinations of the treatments. The recovery times (time) were recorded (in hours) as shown in the following data set recover.

```
data recover;
  input  T1 $ T2 $ time @@;
  datalines;
0 0 20.2  0 0 23.9  0 0 21.9  0 0 42.4
1 0 27.2  1 0 34.0  1 0 27.4  1 0 28.5
0 1 25.9  0 1 34.5  0 1 25.1  0 1 34.2
1 1 35.0  1 1 33.9  1 1 38.3  1 1 39.9
;
```

The following statements invoke the GLM procedure (Chapter 42, “The GLM Procedure”) for a standard ANOVA:

```
proc glm data=recover;
  class T1 T2;
  model time = T1 T2 T1*T2;
run;
```

Output 80.2.1 Overall ANOVA

The GLM Procedure					
Dependent Variable: time					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	3	209.9118750	69.9706250	1.86	0.1905
Error	12	451.9225000	37.6602083		
Corrected Total	15	661.8343750			
	R-Square	Coeff Var	Root MSE	time Mean	
	0.317167	19.94488	6.136791	30.76875	

Output 80.2.2 Model ANOVA

Source	DF	Type I SS	Mean Square	F Value	Pr > F
T1	1	81.4506250	81.4506250	2.16	0.1671
T2	1	106.6056250	106.6056250	2.83	0.1183
T1*T2	1	21.8556250	21.8556250	0.58	0.4609

Output 80.2.1 indicates that the overall model effect is not significant at the 10% level, and Output 80.2.2 indicates that neither treatment is significant at the 10% level.

The following statements invoke the ROBUSTREG procedure with the same model:

```
proc robustreg data=recover;
  class T1 T2;
  model time = T1 T2 T1*T2 / diagnostics;
  T1_T2: test T1*T2;
  output out=robout r=resid sr=stdres;
run;
```

Output 80.2.3 shows some basic information about the model and the response variable time.

Output 80.2.3 Model Fitting Information and Summary Statistics

Example 80.3: Growth Study of De Long and Summers

Robust regression and outlier detection techniques have considerable applications to econometrics. The following example from Zaman, Rousseeuw, and Orhan (2001) shows how these techniques substantially improve the ordinary least squares (OLS) results for the growth study of De Long and Summers.

De Long and Summers (1991) studied the national growth of 61 countries from 1960 to 1985 by using OLS with the following data set growth.

```
data growth;
  input country $ GDP LFG EQP NEQ GAP @@;
  datalines;
Argentina 0.0089 0.0118 0.0214 0.2286 0.6079
Austria 0.0332 0.0014 0.0991 0.1349 0.5809
Belgium 0.0256 0.0061 0.0684 0.1653 0.4109
Bolivia 0.0124 0.0209 0.0167 0.1133 0.8634
Botswana 0.0676 0.0239 0.1310 0.1490 0.9474

... more lines ...

Venezuel 0.0120 0.0378 0.0340 0.0760 0.4974
Zambia -0.0110 0.0275 0.0702 0.2012 0.8695
Zimbabwe 0.0110 0.0309 0.0843 0.1257 0.8875
;
```

The regression equation they used is

$$\text{GDP} = \beta_0 + \beta_1 \text{LFG} + \beta_2 \text{GAP} + \beta_3 \text{EQP} + \beta_4 \text{NEQ} + \epsilon$$

where the response variable is the growth in gross domestic product per worker (GDP) and the regressors are labor force growth (LFG), relative GDP gap (GAP), equipment investment (EQP), and nonequipment investment (NEQ).

The following statements invoke the REG procedure (Chapter 79, “[The REG Procedure](#)”) for the OLS analysis:

```
proc reg data=growth;
  model GDP = LFG GAP EQP NEQ;
run;
```

The OLS analysis shown in [Output 80.3.1](#) indicates that GAP and EQP have a significant influence on GDP at the 5% level.

Output 80.3.1 OLS Estimates

Output 80.3.3 displays the M estimates. Besides GAP and EQP, the robust analysis also indicates that NEQ is significant. This new finding is explained by Output 80.3.4, which shows that Zambia, the 60th country in the data, is an outlier. Output 80.3.4 also identifies leverage points based on the robust MCD distances; however, there are no serious high-leverage points in this data set.

Scale	0	0.0116					

Output 80.3.12 displays the final weighted least squares estimates, which are identical to those reported in Zaman, Rousseeuw, and Orhan (2001).

Example 80.4: Constructed Effects

The algorithms of PROC ROBUSTREG assume that a response variable is linearly dependent on the regressors. However, in practice, a response often depends on some factors in a nonlinear manner. This example demonstrates how a nonlinear response-factor relationship can be modeled by using constructed effects. (See the section “[EFFECT Statement](#)” on page 393 of Chapter 19, “[Shared Concepts and Topics](#),” for details.)

The following data set contains 526 female observations and 474 male observations sampled from 2003 National Health and Nutrition Examination Survey (NHANES). Each observation is composed of three values: BMI (body mass index), Age, and Gender, measured for subjects whose ages are between 20 and 60.

```
data BMI;
  input BMI Age Gender $ @@;

;
```

The goal of this analysis is to evaluate whether the BMI by Age curves are different between women and men at a 5% significance level. In order to provide sufficient flexibility to model the effect of Age on BMI, you can use regression splines that you define with an `EFFECT` statement. In this example, a regression spline of degree 2 with three knots is used for variable Age. The knots are placed at the 25, 50, and 75 percentiles of Age. This analysis assume that there is no interaction between Gender and Age, so that the BMI by Age curves for women and men are the same up to a constant. The following statements produce the BMI by Age scatter plot shown in [Output 80.4.1](#):

```
proc sort data=bmi;
  by age;
run;

ods graphics on;
proc sgplot data=bmi;
  scatter x=age y=bmi/group=gender;
run;
```

Output 80.4.1 Scatter Plot for BMI Data

The observations with large BMI values (for example, BMI > 40) are outliers that can substantially influence an ordinary least squares (OLS) analysis. [Output 80.4.1](#) shows that the distributions of BMI conditional on Age are skewed toward the side of large BMI, and there are more observations with large BMI values (outliers) in the female group. Hence you can expect a significant Gender difference in the BMI by Age OLS regression analysis. This expectation is confirmed by the OLS Gender p -value = 0.0059 in [Output 80.4.2](#), which is produced by the following statements:

```
proc glmselect data=bmi;
  class gender;
  effect Age_Sp=spl(age/degree=2 knotmethod=percentiles(3));
  model bmi = gender age_sp /selection=none showpvalues;
  output out=out_ols P=pred R=res;
run;
```

Output 80.4.2 OLS Estimates

The GLMSELECT Procedure					
Least Squares Model (No Selection)

Age_Sp 4	1	-1.611621	1.123854	-1.43	0.1519
Age_Sp 5	1	-0.484787	1.701281	-0.28	0.7757
Age_Sp 6	0	0	.	.	.

A robust regression method can reduce the outlier influence by automatically assigning smaller or even zero weights to outliers. For the BMI data, a robust regression method is likely to set less weight on observations with large BMI, so more female observations would receive smaller weights than male observations. The following statements invoke PROC ROBUSTREG with the BMI data set:

```
proc robustreg data=bmi method=s seed=100;
  class gender;
  effect Age_Sp=spl(age/degree=2 knotmethod=percentiles(3));
  model bmi = gender age_sp;
  output out=out_s P=pred R=res;
run;
```

Output 80.4.3 shows the parameter estimates and the diagnostics summary produced by PROC ROBUSTREG with the S method. In contrast to OLS, the robust p -value=0.5573 of the Gender coefficient indicates that the Gender effect is not significant. The outlier diagnostics based on the S estimates find 19 outliers that are assigned lower weights by the S method than by the OLS method.

Output 80.4.3 S Estimates and S Diagnostics Summary

To further compare the OLS and S outputs, the following statements plot the BMI predictions in variable Age for both methods in the same graph, which is shown in [Output 80.4.4](#):

```
data out2_s;
  set out_s;
  if gender="F" then label="F, S ";
  if gender="M" then label="M, S ";
run;

data out2_ols;
  merge bmi out_ols;
  if gender='F' then label='F, OLS';
  if gender='M' then label='M, OLS';
  keep pred bmi gender age label;
run;

data out2;
  set out2_ols out2_s;
run;

proc sgplot data=out2;
  series x=age y=pred/group=label;
run;
```

Output 80.4.4 OLS and S Predictions

You can observe the following differences between the OLS and S predictions:

- The OLS prediction is larger
- The OLS curves have a local maximum near Age = 35

Then, a question remains: is the significance of the Gender effect for the OLS regression due solely to the outlying observations? To tentatively answer this question, the following statements drop the observations with the top 10% of BMI values from the original data set and reapply OLS and S methods on the reduced data set:

```
data three;
  set bmi;
  where bmi<38.315;
run;

proc robustreg data=three method=s seed=100;
  class gender;
  effect Age_Sp=spl(age/degree=2 knotmethod=percentiles(3));
  model bmi = gender age_sp;
  output out=out_s P=pred R=res;
run;
```

```

data out2_s;
  set out_s;
  if gender="F" then label="F, S ";
  if gender="M" then label="M, S ";
run;

proc glmselect data=three outdesign=four;
  class gender;
  effect Age_Sp=spl(age/degree=2 knotmethod=percentiles(3));
  model bmi = gender age_sp /selection=none showpvalues;
  output out=out_ols P=pred R=res;
run;

data out2_ols;
  merge three out_ols;
  if gender='F' then label='F, OLS';
  if gender='M' then label='M, OLS';
  keep pred bmi gender age label;
run;

data out2;
  set out2_ols out2_s;
run;

proc sgplot data=out2;
  series x=age y=pred/group=label;
run;
ods graphics off;

```

Output 80.4.5 S Estimates

Output 80.4.7 OLS and S Predictions on the Reduced Data Set

In the reduced data set, 71 female observations and 29 male observations are dropped. [Output 80.4.5](#) and [Output 80.4.6](#) respectively show the refitted S and OLS parameter estimates, and [Output 80.4.7](#) displays the fitted curves on the reduced data set. You can see that Gender is no longer significant for the OLS model, and the OLS turning pattern has also disappeared, but the new S curves do not change much from the previous ones. The OLS BMI by Age curves in [Output 80.4.7](#) are closer to the S curves than to the OLS curves in [Output 80.4.4](#). This suggests that indeed the difference between the OLS and S estimate results are due solely to the influence of the outlying observations.

Example 80.5: Robust Diagnostics

This example models the selling price of a house as a function of several covariates. One of these covariates is a classification variable that indicates whether a house is located on a corner lot (called a corner house in this example). Because corner houses are relatively rare, the inclusion of this classification effect in the model introduces a low-dimensional structure (that is, the majority of the observations are located in a lower dimensional hyperplane defined by being non-corner houses) into the design matrix. As discussed in “Robust Distance” on page 6853, the presence of this low dimensional structure causes difficulties in the traditional computation of robust distances. This example illustrates how you can use the projected robust distance to address those difficulties and to obtain meaningful leverage diagnostics. It also shows how you can use the RDPLOT= and DDLOT= options to illustrate the outlier-leverage relationship.

The following house price data set contains 66 home resale records on seven variables from February 15 to April 30, 1993 (Data and Story Library 2005). The records are randomly selected from the database maintained by the Albuquerque Board of Realtors.

```
data house;
  input price sqft age feats ne cor tax @@;
  label price = "Selling price"
        sqft  = "Square feet of living space"
        age   = "Age of home in year"

To illustrate the dependence detection ability of the generalized MCD algorithm, an extra variable sum is created such that all the observations satisfy $\text{sum} = \text{sqft} + \text{age} + \text{feats} + \text{ne} + \text{cor} + \text{tax}$. Adding sum does not change the rank of the original design matrix, so that sum is expected to be ignored in the model and also in the diagnostics. The next statements apply the MM method and the generalized MCD algorithm to the house price data.

```
ods graphics on;
proc robustreg data=house method=MM plots=all;
  model price = sqft age feats ne cor tax sum /
    leverage(opc mcdinfo) diagnostics;
run;
```

As shown in [Output 80.5.1](#) and [Output 80.5.2](#), PROC ROBUSTREG finds the design dependence equation and forces the parameter estimate of variable sum to be zero.

Output 80.5.1 MM Estimates

The ROBUSTREG Procedure							
Parameter Estimates							
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	46.4062	79.1714	-108.767	201.5792	0.34	0.5578
sqft	1	0.3809	0.0756	0.2327	0.5291	25.37	<.0001
age	1	-2.6067	1.7610	-6.0582	0.8449	2.19	0.1388
feats	1	8.3627	14.7107	-20.4697	37.1951	0.32	0.5697
ne	1	65.0081	40.1329	-13.6508	143.6671	2.62	0.1053

tax	1	0.4699	0.1260	0.2229	0.7170	13.90	0.0002
sum	0	0.0000
Scale	0	157.5593					

Output 80.5.2 Design Dependence Equations

NOTE: The following variables have been ignored in the MCD computation because of linear dependence.

sum = sqft + age + feats + ne + cor + tax

Moreover, PROC ROBUSTREG also identifies a robust dependence equation on cor in [Output 80.5.3](#), which holds for 77.27% of the observations but not for the entire data set.

Output 80.5.3 Robust Dependence Equations

NOTE: The following robust dependence equations simultaneously hold for 77.27% of the observations in the data set. The breakdown setting for the MCD algorithm is 22.73%.

cor = 0

Another way to represent the low-dimensional structure is to specify the coefficients of the MCD-dropped components on the data (see [Output 80.5.4](#)), which form a basis of the complementary space to the relevant low-dimensional hyperplane.

Output 80.5.4 Coefficients for MCD-Dropped Components

Coefficients for MCD-Dropped Components		
Parameter	Design Drop0	Robust Drop1
sqft	0	0
age	0	0
feats	0	0
ne	0	0
cor	0	1.0000
tax	0	0
sum	1.0000	0

By the definitions of projected robust distance and leverage point, an observation is called an off-plane leverage point if at least one of the robust or design dependence equations does not apply to the observation. In this example, the observations with $\text{cor} = 1$ are all off-plane leverage points. [Output 80.5.5](#) lists the leverage points and outliers along with the relevant distance measurements and standardized residuals.

Output 80.5.5 Diagnostics

Diagnostics						
-----Projected Distance-----				Standardized		
Obs	Mahalanobis	Robust	Off-Plane	Leverage	Robust Residual	Outlier
1	3.5567	4.0211	0.0000	*	0.8522	
13	4.0034	5.2310	0.0000	*	0.1411

16	1.0839	1.0905	2.3681	*	0.4148	
18	1.9452	2.4655	2.3681	*	-0.2789	
20	3.6006	4.0771	2.3681	*	-0.0150	
22	3.0210	3.4307	2.3681	*	1.1664	
23	1.5920	1.8197	2.3681	*	0.2422	
24	3.4967	4.5154	0.0000	*	0.6464	
26	3.0420	3.6975	0.0000	*	-1.7068	
29	2.3264	2.9925	2.3681	*	-2.4980	
30	1.2587	1.2714	2.3681	*	-1.2558	
38	2.4064	2.7249	2.3681	*	-1.0620	
42	1.4722	1.4645	2.3681	*	0.2584	
44	2.8491	3.0019	0.0000		4.5665	*
46	3.9725	5.2271	0.0000	*	3.5835	*
47	2.9431	3.3728	2.3681	*	0.1365	
55	2.2325	2.9590	2.3681	*	0.3217	
56	1.7999	1.8119	2.3681	*	0.1715	
65	1.8831	2.1822	2.3681	*	-0.1990	
66	2.2483	2.5673	2.3681	*	0.4134	

From [Output 80.5.6](#) and [Output 80.5.7](#), you can see that there is no apparent corner-related difference for the houses in terms of standardized robust residual and projected MD versus projected RD, although all the corner houses are defined as off-plane leverage points.

Output 80.5.6 Projected RDPLLOT

Output 80.5.7 Projected DDPLLOT

Output 80.5.8 shows more details of the robust diagnostics. The number of dimensions indicates that six regressors are used in the MCD analysis. Since sum is excluded in model fitting, it is ignored in the MCD analysis. The number of robust dropped components equals 1 due to cor. The number of off-plane points implies the 15 corner-house observations. The reweighted value of H is the number of observations that are finally used to estimate the MCD covariance.

You might speculate that the projected MD and projected RD are equal to the regular MD and RD on the same data set without the variable `cor`. In fact, this is not true. (See [Output 80.5.9](#) and [Output 80.5.10](#) for the `RD`PLOT and `DD`PLOT on the data set without `cor`.) When included in the `MODEL`, `cor` is dropped in the distance calculation, but it is still used for the initial orthonormalization step and the h -subset searching. In this example, inclusion of `cor` causes all the other covariates to be centered separately for corner houses and non-corner houses. However, without `cor`, the centering process does not distinguish corner houses from non-corner houses, so that the MCD algorithm can still be influenced by `cor` through the correlation between `cor` and other covariates. The following statements drop the variable `cor` and produce the `RD`PLOT and `DD`PLOT for the reduced model, which are shown in [Output 80.5.9](#) and [Output 80.5.10](#):

```
proc robustreg data=house method=MM plots=all;
  model price = sqft age feats ne tax/leverage(mcdinfo) diagnostics;
run;
ods graphics off;
```

Output 80.5.9 `RD`PLOT for the Reduced Model

Output 80.5.10 DDPLLOT for the Reduced Model

Compared with [Output 80.5.8](#), [Output 80.5.11](#) shows the changes of the MCD information by removing `cor` from the model. You can see that the corner houses are no longer identified as off-plane points and the reweighted value of H is increased from 47 to 52. The breakdown value is intact because it depends only on the specified value of H and the total number of observations.

Output 80.5.11 MCD Information for the Reduced Model

MCD Profile	
Number of Dimensions	5
Number of Robust Dropped Components	0
Number of Observations	66
Number of Off-Plane Observations	0

Overview: RSREG Procedure

The RSREG procedure uses the method of least squares to fit quadratic response surface regression models. Response surface models are a kind of general linear model in which attention focuses on characteristics of the fit response function and in particular, where optimum estimated response values occur.

In addition to fitting a quadratic function, you can use the RSREG procedure to do the following:

- test for lack of fit
- test for the significance of individual factors
- analyze the canonical structure of the estimated response surface
- compute the ridge of optimum response
- predict new values of the response

The RSREG procedure uses ODS Graphics to display the response surfaces, residuals, fit diagnostics, and ridges of optimum response. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).”

Comparison to Other SAS Software

Other SAS/STAT procedures can be used to fit the response surface, but the RSREG procedure is more specialized. PROC RSREG uses a much more compact model syntax than other procedures; for example, the following statements model a three-factor response surface in the REG, GLM, and RSREG procedures:

```
proc reg;
  model y=x1 x1*x1
        x2 x1*x2 x2*x2
        x3 x1*x3 x2*x3 x3*x3;
run;

proc glm;
  model y=x1|x2|x3@2;
run;

proc rsreg;
  model y=x1 x2 x3;
run;
```

Additionally, PROC RSREG includes specialized methodology for analyzing the fitted response surface, such as canonical analysis and optimum response ridges.

Note that the ADX Interface in SAS/QC software provides an *interactive* environment for constructing and analyzing many different kinds of experiments, including response surface experiments. The ADX Interface is the preferred interactive SAS System tool for analyzing experiments, since it includes facilities for checking underlying assumptions and graphically optimizing the response surface; see *Getting Started with the SAS ADX Interface for Design of Experiments* for more information. The RSREG procedure is appropriate for analyzing experiments in a batch environment.

Terminology

Variables are referred to according to the following conventions:

factor variables	independent variables used to construct the quadratic response surface. To estimate the necessary parameters, each variable must have at least three distinct values in the data. Independent variables must be numeric.
response variables	the dependent variables to which the quadratic response surfaces are fit. Dependent variables must be numeric.
covariates	additional independent variables for use in the regression but not in the formation of the quadratic response surface. Covariates must be numeric.
WEIGHT variable	a variable for weighting the observations in the regression. The WEIGHT variable must be numeric.
ID variables	variables not previously described that are transferred to an output data set containing statistics for each observation in the input data set. This data set is created by using the OUT= option in the PROC RSREG statement. ID variables can be either character or numeric.
BY variables	variables for grouping observations. Separate analyses are obtained for each BY group. BY variables can be either character or numeric.

Getting Started: RSREG Procedure

A Response Surface with a Simple Optimum

This example uses the three-factor quadratic model discussed in John (1971). Settings of the temperature, gas–liquid ratio, and packing height are controlled factors in the production of a certain chemical; Schneider and Stockett (1963) performed an experiment in order to determine the values of these three factors that minimize the unpleasant odor of the chemical. The following statements input the SAS data set `smell`; the variable `Odor` is the response, while the variables `T`, `R`, and `H` are the independent factors.

```

title 'Response Surface with a Simple Optimum';
data smell;
  input Odor T R H @@;
  label
    T = "Temperature"
    R = "Gas-Liquid Ratio"
    H = "Packing Height";
  datalines;
66 40 .3 4      39 120 .3 4      43 40 .7 4      49 120 .7 4
58 40 .5 2      17 120 .5 2      -5 40 .5 6      -40 120 .5 6
65 80 .3 2       7 80 .7 2      43 80 .3 6      -22 80 .7 6
-31 80 .5 4     -35 80 .5 4     -26 80 .5 4
;

```

The following statements invoke PROC RSREG on the data set `smell`. Figure 81.1 through Figure 81.3 display the results of the analysis, including a lack-of-fit test requested with the `LACKFIT` option.

```
proc rsreg data=smell;
  model Odor = T R H / lackfit;
run;
```

Figure 81.1 displays the coding coefficients for the transformation of the independent variables to lie between -1 and 1 , simple statistics for the response variable, hypothesis tests for linear, quadratic, and crossproduct terms, and the lack-of-fit test. The hypothesis tests can be used to gain a rough idea of importance of the effects; here the crossproduct terms are not significant. However, the lack of fit for the model is significant, so more complicated modeling or further experimentation with additional variables should be performed before firm conclusions are made concerning the underlying process.

Figure 81.1 Summary Statistics and Analysis of Variance

Response Surface with a Simple Optimum					
The RSREG Procedure					
Coding Coefficients for the Independent Variables					
Factor	Subtracted off		Divided by		
T	80.000000		40.000000		
R	0.500000		0.200000		
H	4.000000		2.000000		
Response Surface for Variable Odor					
Response Mean			15.200000		
Root MSE			22.478508		
R-Square			0.8820		
Coefficient of Variation			147.8849		
Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Linear	3	7143.250000	0.3337	4.71	0.0641
Quadratic	3	11445	0.5346	7.55	0.0264
Crossproduct	3	293.500000	0.0137	0.19	0.8965
Total Model	9	18882	0.8820	4.15	0.0657
Residual	DF	Sum of Squares	Mean Square	F Value	Pr > F
Lack of Fit	3	2485.750000	828.583333	40.75	0.0240
Pure Error	2	40.666667	20.333333		
Total Error	5	2526.416667	505.283333		

Parameter estimates and the factor ANOVA are shown in [Figure 81.2](#). Looking at the parameter estimates, you can see that the crossproduct terms are not significantly different from zero, as noted previously. The Estimate column contains estimates based on the raw data, and the Parameter Estimate from Coded Data column contains estimates based on the coded data. The factor ANOVA table displays tests for all four parameters corresponding to each factor—the parameters corresponding to the linear effect, the quadratic effect, and the effects of the crossproducts with each of the other two factors. The only factor with a significant overall effect is R, indicating that the level of noise left unexplained by the model is still too high to estimate the effects of T and H accurately. This might be due to the lack of fit.

Figure 81.2 Parameter Estimates and Hypothesis Tests

Parameter	DF	Estimate	Standard Error	t Value	Pr > t	Parameter Estimate from Coded Data
Intercept	1	568.958333	134.609816	4.23	0.0083	-30.666667
T	1	-4.102083	1.489024	-2.75	0.0401	-12.125000
R	1	-1345.833333	335.220685	-4.01	0.0102	-17.000000
H	1	-22.166667	29.780489	-0.74	0.4902	-21.375000
T*T	1	0.020052	0.007311	2.74	0.0407	32.083333
R*T	1	1.031250	1.404907	0.73	0.4959	8.250000
R*R	1	1195.833333	292.454665	4.09	0.0095	47.833333
H*T	1	0.018750	0.140491	0.13	0.8990	1.500000
H*R	1	-4.375000	28.098135	-0.16	0.8824	-1.750000
H*H	1	1.520833	2.924547	0.52	0.6252	6.083333

Factor	DF	Sum of Squares	Mean Square	F Value	Pr > F	Label
T	4	5258.016026	1314.504006	2.60	0.1613	Temperature
R	4	11045	2761.150641	5.46	0.0454	Gas-Liquid Ratio
H	4	3813.016026	953.254006	1.89	0.2510	Packing Height

[Figure 81.3](#) displays the canonical analysis and eigenvectors. The canonical analysis indicates that the directions of principal orientation for the predicted response surface are along the axes associated with the three factors, confirming the small interaction effect in the regression ANOVA ([Figure 81.1](#)). The largest eigenvalue (48.8588) corresponds to the eigenvector (0.238091, 0.971116, -0.015690), the largest component of which (0.971116) is associated with R; similarly, the second-largest eigenvalue (31.1035) is associated with T. The third eigenvalue (6.0377), associated with H, is quite a bit smaller than the other two, indicating that the response surface is relatively insensitive to changes in this factor. The coded form of the canonical analysis indicates that the estimated response surface is at a minimum when T and R are both near the middle of their respective ranges (that is, the coded critical values for T and R are both near 0) and H is relatively high; in uncoded terms, the model predicts that the unpleasant odor is minimized when T = 84.876502, R = 0.539915, and H = 7.541050.

Figure 81.3 Canonical Analysis and Eigenvectors

Factor	Critical Value		Label
	Coded	Uncoded	
T	0.121913	84.876502	Temperature
R	0.199575	0.539915	Gas-Liquid Ratio
H	1.770525	7.541050	Packing Height
Predicted value at stationary point: -52.024631			
Eigenvalues	Eigenvectors		
	T	R	H
48.858807	0.238091	0.971116	-0.015690
31.103461	0.970696	-0.237384	0.037399
6.037732	-0.032594	0.024135	0.999177
Stationary point is a minimum.			

To plot the response surface with respect to two of the factor variables, fix H, the least significant factor variable, at its estimated optimum value. The following statements use ODS Graphics to display the surface:

```
ods graphics on;
proc rsreg data=smell
    plots(unpack)=surface(3d at (H=7.541050));
    model Odor = T R H;
    ods select 'T * R = Pred';
run;
ods graphics off;
```

Note that the ODS SELECT statement is specified to select the plot of interest.

Figure 81.4 The Response Surface at the Optimum H

Alternatively, the following statements produce an output data set containing the surface information, which you can then use for plotting surfaces or searching for optima. The first DATA step fixes H, the least significant factor variable, at its estimated optimum value (7.541), and generates a grid of points for T and R. To ensure that the grid data do not affect parameter estimates, the response variable (Odor) is set to missing. (See the section “[Missing Values](#)” on page 6924.) The second DATA step concatenates these grid points to the original data. Then PROC RSREG computes predictions for the combined data. The last DATA step subsets the predicted values over just the grid points, which excludes the predictions at the original data.

```
data grid;
  do;
    Odor = . ;
    H    = 7.541;
    do T = 20 to 140 by 5;
      do R = .1 to .9 by .05;
        output;
      end;
    end;
  end;
run;
data grid;
```

```

    set smell grid;
run;

proc rsreg data=grid out=predict noprint;
    model Odor = T R H / predict;
run;

data grid;
    set predict;
    if H = 7.541;
run;

```

Syntax: RSREG Procedure

The following statements are available in the RSREG procedure.

```

PROC RSREG < options > ;
    MODEL responses = independents < / options > ;
    RIDGE < options > ;
    WEIGHT variable ;
    ID variables ;
    BY variables ;

```

The PROC RSREG and MODEL statements are required.

The BY, ID, MODEL, RIDGE, and WEIGHT statements are described after the PROC RSREG statement, and they can appear in any order.

PROC RSREG Statement

```

PROC RSREG < options > ;

```

The PROC RSREG statement invokes the RSREG procedure. [Table 81.1](#) summarizes the options available in the PROC RSREG statement.

Table 81.1 PROC RSREG Statement Options

Option	Description
DATA=	Names the input SAS data set
NOPRINT	Suppresses the normal display of results
OUT=	Creates the output SAS data set
PLOTS	Controls the plots produced through ODS Graphics

The following list describes these options.

DATA=SAS-data-set

specifies the input SAS data set that contains the data to be analyzed. By default, PROC RSREG uses the most recently created SAS data set.

NOPRINT

suppresses the normal display of results when only the output data set is required.

For more information, see the description of the NOPRINT option in the [MODEL](#) and [RIDGE](#) statements.

Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

OUT=SAS-data-set

creates an output SAS data set that contains statistics for each observation in the input data set. In particular, this data set contains the [BY](#) variables, the [ID](#) variables, the [WEIGHT](#) variable, the variables in the [MODEL](#) statement, and the [output options](#) requested in the [MODEL](#) statement. You must specify [output statistic options](#) in the [MODEL](#) statement; otherwise, the output data set is created but contains no observations. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For more details, see the section “[OUT=SAS-data-set](#)” on page 6928.

PLOTS < (*global-plot-option*) >=*plot-request*< (*options*)>**PLOTS** < (*global-plot-option*) >=(*plot-request*< (*options*)>< . . . *plot-request*< (*options*)> >)

controls the plots produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses from around the *plot-request*. For example:

```
plots = all
plots = (diagnostics ridge surface(unpack))
plots(unpack) = surface(overlaypairs)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc rsreg plots=all;
  model y=x;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

By default, no graphs are created; you must specify the PLOTS= option to make graphs. See [Figure 81.4](#), [Output 81.1.5](#), [Output 81.1.6](#), [Output 81.2.3](#), and [Output 81.2.4](#) for examples of the ODS graphical displays.

The following *global-plot-option* is available.

UNPACKPANELS | UNPACK

suppresses paneling. By default, multiple plots can appear in some output *panels*. Specify the UNPACK option to display each plot separately.

The following *plot-requests* are available.

ALL

produces all appropriate plots. You can specify other options with ALL; for example, to display all plots and unpack the SURFACE contours you can specify `plots=(all surface(unpack))`.

DIAGNOSTICS <(LABEL | UNPACK)>

displays a panel of summary fit diagnostic plots. The plots produced and their usage are discussed in Table 81.2.

Table 81.2 Diagnostic Plots

Diagnostic Plot	Usage
Cook's <i>D</i> statistic versus observation number	Evaluate influence of an observation on the entire parameter estimate vector
Dependent variable values versus predicted values	Evaluate adequacy of fit and detect influential observations
Externally studentized residuals (RStudent) versus leverage	Detect outliers and influential (high-leverage) observations
Externally studentized residuals versus predicted values	Evaluate adequacy of fit and detect outliers
Histogram of residuals	Confirm normality of error terms
Normal quantile plot of residuals	Confirm normality and homogeneity of error terms, and detect outliers
Residuals versus predicted values <i>Residual-fit</i> (RF) spread plot	Evaluate adequacy of fit and detect outliers side-by-side quantile plots of the centered fit and the residuals show “how much variation in the data is explained by the fit and how much remains in the residuals” (Cleveland 1993)

Observations satisfying $RStudent > 2$ or $RStudent < -2$ are called *outliers*, and observations with leverage $> 2p/n$ are called *influential*, where n is the number of observations used in fitting the model and p is the number of parameters used in the model (Rawlings, Pantula, and Dickey 1998). Specifying the LABEL option labels the influential and outlying observations—the label is the first ID variable if the ID statement is specified; otherwise, it is the observation number. Note in the Cook's *D* plot that only observations with *D* exceeding $4/n$ are labeled; these are also called influential observations. The UNPACK option displays each diagnostic plot separately. See Output 81.2.3 for an example of the diagnostics panel.

FIT <(GRIDSIZE=*number*)>

plots the predicted values against a single predictor when you have only one factor or only one covariate in the model. The GRIDSIZE= option specifies the number of points at which the fitted values are computed; by default, GRIDSIZE=200.

NONE

suppresses all plots.

RESIDUALS <(UNPACK | SMOOTH)>

displays plots of residuals against each factor and covariate. The UNPACK option displays each residual plot separately. The SMOOTH option overlays a loess smooth on each residual plot; see Chapter 53, “The LOESS Procedure,” for more information. See [Output 81.1.5](#) for an example of this plot.

RIDGE <(UNPACK)>

displays the maximum and/or minimum ridge plots. This option is available only when a **MAXIMUM** or **MINIMUM** option is specified in the RIDGE statement. The UNPACK option displays the estimated response and factor level ridge plots separately. See [Output 81.1.5](#) for an example of this plot.

SURFACE <(surface-options)>

displays the response surface for each response variable and each pair of factors with all other factors and covariates fixed at their means. By default a panel of contour plots is produced; see [Output 81.1.6](#) for an example of this plot. The following *surface-options* can be specified:

3D

displays three-dimensional surface plots instead of contour plots. See [Figure 81.4](#) for an example of this plot.

AT <keyword><(variable=value-list | keyword <...variable=value-list | keyword>)>

specifies fixed values for factors and covariates. You can specify one or more numbers in the *value-list* or one of the following *keywords*:

MIN	sets the variable to its minimum value.
MEAN	sets the variable to its mean value.
MIDRANGE	sets the variable to the middle value: $\frac{\max + \min}{2}$.
MAX	sets the variable to its maximum value.

Specifying a keyword immediately after AT sets the default value of all variables; for example, **AT MIN** sets all variables not displayed on an axis to their minimum values. By default, continuous variables are set to their means (**AT MEAN**) when they are not used on an axis. For example, if your model contains variables X1, X2, and X3, then specifying **AT (X1=7 9)** produces a contour plot of X2 versus X3 fixing X1 = 7 and then another contour plot with X1 = 9, along with contour plots of X1 versus X2 fixing X3 at its mean, and X1 versus X3 fixing X2 at its mean.

EXTEND=*value*

extends the surface *value*-times the range of each factor in each direction, which enables you to see more of the fitted surface. For example, if factor A has range [0, 10], then specifying **EXTEND=0.1** will compute and display the surface for A in [-1, 11]. You can specify *value* ≥ 0; by default, *value* = 0.1.

FILL=PRED | SE | NONE

produces a filled contour plot for either the predicted values or the standard errors. FILL=SE is the default. If the 3D option is also specified, then the contour plot is projected onto the surface.

GRIDSIZE=*n*

creates an $n \times n$ grid of points at which the estimated values for the surface and standard errors are computed, for $n \geq 1$. By default, $n = 50$.

LINE=<PRED | SE | NONE>

produces a contour line plot for either the predicted values or the standard errors. LINE=PRED is the default. If the 3D option is also specified, then specifying LINE displays a grid on the surface, and the other LINE= specifications are ignored.

NODESIGN

suppresses the display of the design points on the contour surface plots and the overlaid contour-line plots.

OVERLAYPAIRS

produces overlaid contour line plots for all pairs of response variables in addition to the contour surface plots. See Figure 81.6 for an example of this plot.

ROTATE=*angle*

rotates the 3-D surface plots *angle* degrees, $-180 < \text{angle} < 180$. By default, *angle* = 57.

TILT=*angle*

tilts the 3-D surface plots *angle* degrees, $-180 < \text{angle} < 180$. By default, *angle* = 20.

UNPACKPANELS | UNPACK

suppresses paneling, and displays each surface plot separately.

BY Statement

BY variables ;

You can specify a BY statement with PROC RSREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the RSREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

ID Statement

ID *variables* ;

The ID statement names variables that are to be transferred to the data set created by the **OUT=** option in the PROC RSREG statement.

MODEL Statement

MODEL *responses = independents* < / *options* > ;

In the MODEL statement, you specify the response (dependent) variables followed by an equal sign and then the independent variables, some of which can be covariates.

Table 81.3 summarizes the *options* available in the MODEL statement. The *statistic options* specify which statistics are output to the **OUT=** data set. If none of the *statistic options* are selected, the data set is created but contains no observations. The *statistic option* keywords become values of the special variable **_TYPE_** in the output data set.

Table 81.3 MODEL Statement Options

Option	Description
BYOUT	Uses only the first BY group to estimate the model
COVAR=	Declares variables to be simple linear regressors
LACKFIT	Performs a lack-of-fit test
NOCODE	Performs the canonical and ridge analyses using original values
PRESS	Displays the predicted residual sum of squares (PRESS) statistic
Suppress Displayed Output	
NOANOVA	Suppresses the analysis of variance and parameter estimates
NOOPTIMAL	Suppresses the canonical analysis
NOPRINT	Suppresses both the analysis of variance and the canonical analysis
Output Statistics	
ACTUAL	Includes observed response values
PREDICT	Includes values predicted by the model
RESIDUAL	Includes the residuals
L95	Includes the lower bound of a 95% confidence interval for an individual predicted value
U95	Includes the upper bound of a 95% confidence interval for an individual predicted value
L95M	Includes the lower bound of a 95% confidence interval for the expected value of the dependent variable
U95M	Includes the upper bound of a 95% confidence interval for the expected value of the dependent variable
D	Includes Cook's <i>D</i> influence statistic

The following list describes these options in alphabetical order.

ACTUAL

specifies that the observed response values from the input data set be written to the output data set.

BYOUT

uses only the first BY group to estimate the model. Subsequent BY groups have scoring statistics computed in the output data set only. The BYOUT option is used only when a **BY** statement is specified.

COVAR=*n*

declares that the first *n* variables on the right side of the model are simple linear regressors (covariates) and not factors in the quadratic response surface. By default, PROC RSREG forms quadratic and crossproduct effects for all regressor variables in the MODEL statement.

See the section “[Handling Covariates](#)” on page 6926 for more details and [Example 81.2](#) for an example that uses covariates.

D

specifies that Cook’s *D* influence statistic be written to the output data set.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

LACKFIT

performs a lack-of-fit test.

See Draper and Smith (1981) for a discussion of lack-of-fit tests.

L95

specifies that the lower bound of a 95% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

L95M

specifies that the lower bound of a 95% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

NOANOVA

NOAOV

suppresses the display of the analysis of variance and parameter estimates from the model fit.

NOCODE

performs the canonical and ridge analyses with the parameter estimates derived from fitting the response to the original values of the factor variables, rather than their coded values (see the section “[Coding the Factor Variables](#)” on page 6923 for more details). Use this option if the data are already stored in a coded form.

NOOPTIMAL**NOOPT**

suppresses the display of the canonical analysis for the quadratic response surface.

NOPRINT

suppresses the display of both the analysis of variance and the canonical analysis.

PREDICT

specifies that the values predicted by the model be written to the output data set.

PRESS

computes and displays the predicted residual sum of squares (PRESS) statistic for each dependent variable in the model. The PRESS statistic is added to the summary information at the beginning of the analysis of variance, so if the [NOANOVA](#) or [NOPRINT](#) option is specified, then the PRESS option has no effect.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

RESIDUAL

specifies that the residuals, calculated as [ACTUAL](#) – [PREDICTED](#), be written to the output data set.

U95

specifies that the upper bound of a 95% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

U95M

specifies that the upper bound of a 95% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

RIDGE Statement

RIDGE < options > ;

A RIDGE statement computes the ridge of optimum response. The ridge starts at a given point \mathbf{x}_0 , and the point on the ridge at radius r from \mathbf{x}_0 is the collection of factor settings that optimizes the predicted response at this radius. You can think of the ridge as climbing or falling as fast as possible on the surface of predicted response. Thus, the ridge analysis can be used as a tool to help interpret an existing response surface or to indicate the direction in which further experimentation should be performed.

The default starting point, \mathbf{x}_0 , has each coordinate equal to the point midway between the highest and lowest values of the factor in the design. The default radii at which the ridge is computed are 0, 0.1, . . . , 0.9, 1. If the ridge analysis is based on the response surface fit to coded values for the factor variables (see the section “[Coding the Factor Variables](#)” on page 6923 for details), then this results in a ridge that starts at the point with a coded zero value for each coordinate and extends toward, but not beyond, the edge of the range of

experimentation. Alternatively, both the center point of the ridge and the radii at which it is to be computed can be specified.

You can specify the following options in the RIDGE statement:

CENTER=*uncoded-factor-values*

gives the coordinates of the point x_0 from which to begin the ridge. The coordinates should be given in the original (uncoded) factor variable values and should be separated by commas. There must be as many coordinates specified as there are factors in the model, and the order of the coordinates must be the same as that used in the **MODEL** statement. This starting point should be well inside the range of experimentation. The default sets each coordinate equal to the value midway between the highest and lowest values for the associated factor.

MAXIMUM

MAX

computes the ridge of maximum response. Both the **MIN** and **MAX** options can be specified; at least one must be specified.

MINIMUM

MIN

computes the ridge of minimum response. Both the **MIN** and **MAX** options can be specified; at least one must be specified.

NOPRINT

suppresses the display of the ridge analysis when only an output data set is required.

OUTR=*SAS-data-set*

creates an output SAS data set containing the computed optimum ridge.

For details, see the section “**OUTR=SAS-data-set**” on page 6929.

RADIUS=*coded-radii*

gives the distances from the ridge starting point at which to compute the optima. The values in the list represent distances between coded points. The list can take any of the following forms or can be composed of mixtures of them:

m_1, m_2, \dots, m_n specifies several values.

m TO n specifies a sequence where m equals the starting value, n equals the ending value, and the increment equals 1.

m TO n BY i specifies a sequence where m equals the starting value, n equals the ending value, and i equals the increment.

Mixtures of the preceding forms should be separated by commas. The default list runs from 0 to 1 by increments of 0.1. The following are examples of valid lists.

```
radius=0 to 5 by .5;
radius=0, .2, .25, .3, .5 to 1.0 by .1;
```

WEIGHT Statement

WEIGHT *variable* ;

When a WEIGHT statement is specified, a weighted residual sum of squares

$$\sum_i w_i (y_i - \hat{y}_i)^2$$

is minimized, where w_i is the value of the variable specified in the WEIGHT statement, y_i is the observed value of the response variable, and \hat{y}_i is the predicted value of the response variable.

The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than zero. The WEIGHT statement has no effect on degrees of freedom or number of observations. If the weights for the observations are proportional to the reciprocals of the error variances, then the weighted least squares estimates are best linear unbiased estimators (BLUE).

Details: RSREG Procedure

Introduction to Response Surface Experiments

Many industrial experiments are conducted to discover which values of given factor variables optimize a response. If each factor is measured at three or more values, a quadratic response surface can be estimated by least squares regression. The predicted optimal value can be found from the estimated surface if the surface is shaped like a simple hill or valley. If the estimated surface is more complicated, or if the predicted optimum is far from the region of experimentation, then the shape of the surface can be analyzed to indicate the directions in which new experiments should be performed.

Suppose that a response variable y is measured at combinations of values of two factor variables, x_1 and x_2 . The quadratic response surface model for this variable is written as

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_1^2 + \beta_4 x_2^2 + \beta_5 x_1 x_2 + \epsilon$$

The steps in the analysis for such data are as follows:

1. [model fitting and analysis of variance](#), including [lack-of-fit testing](#), to estimate parameters
2. [canonical analysis](#) to investigate the shape of the predicted response surface
3. [ridge analysis](#) to search for the region of optimum response

Model Fitting and Analysis of Variance

The first task in analyzing the response surface is to estimate the parameters of the model by least squares regression and to obtain information about the fit in the form of an analysis of variance. The estimated surface is typically curved: a *hill* with the peak occurring at the unique estimated point of maximum response, a *valley*, or a *saddle surface* with no unique minimum or maximum. Use the results of this phase of the analysis to answer the following questions:

- What is the contribution of each type of effect—linear, quadratic, and crossproduct—to the statistical fit? The ANOVA table with sources labeled “Regression” addresses this question.
- What part of the residual error is due to lack of fit? Does the quadratic response model adequately represent the true response surface? If you specify the **LACKFIT** option in the MODEL statement, then the ANOVA table with sources labeled “Residual” addresses this question. See the section “**Lack-of-Fit Test**” on page 6922 for details.
- What is the contribution of each factor variable to the statistical fit? Can the response be predicted accurately if the variable is removed? The ANOVA table with sources labeled “Factor” addresses this question.
- What are the predicted responses for a grid of factor values? (See the section “**Plotting the Surface**” on page 6924 and the section “**Searching for Multiple Response Conditions**” on page 6924.)

Lack-of-Fit Test

The lack-of-fit test compares the variation around the model with *pure* variation within replicated observations. This measures the adequacy of the quadratic response surface model. In particular, if there are n_i replicated observations Y_{i1}, \dots, Y_{in_i} of the response all at the same values \mathbf{x}_i of the factors, then you can predict the true response at \mathbf{x}_i either by using the predicted value \hat{Y}_i based on the model or by using the mean \bar{Y}_i of the replicated values. The lack-of-fit test decomposes the residual error into a component due to the variation of the replications around their mean value (the *pure* error) and a component due to the variation of the mean values around the model prediction (the *bias* error):

$$\sum_i \sum_{j=1}^{n_i} (Y_{ij} - \hat{Y}_i)^2 = \sum_i \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2 + \sum_i n_i (\bar{Y}_i - \hat{Y}_i)^2$$

If the model is adequate, then both components estimate the nominal level of error; however, if the bias component of error is much larger than the pure error, then this constitutes evidence that there is significant lack of fit.

If some observations in your design are replicated, you can test for lack of fit by specifying the **LACKFIT** option in the MODEL statement. Note that, since all other tests use total error rather than pure error, you might want to hand-calculate the tests with respect to pure error if the lack of fit is significant. On the other hand, significant lack of fit indicates that the quadratic model is inadequate, so if this is a problem you can also try to refine the model, possibly by using PROC GLM for general polynomial modeling; see Chapter 42, “**The GLM Procedure**,” for more information. [Example 81.1](#) illustrates the use of the **LACKFIT** option.

Canonical Analysis

The second task in analyzing the response surface is to examine the overall shape of the curve and determine whether the estimated stationary point is a maximum, a minimum, or a saddle point. The canonical analysis can be used to answer the following questions:

- Is the surface shaped like a hill, a valley, or a saddle, or is it flat?
- If there is a unique optimum combination of factor values, where is it?

- To which factor or factors are the predicted responses most sensitive?

The eigenvalues and eigenvectors in the matrix of second-order parameters characterize the shape of the response surface. The eigenvectors point in the directions of principal orientation for the surface, and the signs and magnitudes of the associated eigenvalues give the shape of the surface in these directions. Positive eigenvalues indicate directions of upward curvature, and negative eigenvalues indicate directions of downward curvature. The larger an eigenvalue is in absolute value, the more pronounced is the curvature of the response surface in the associated direction. Often, all the coefficients of an eigenvector except for one are relatively small, indicating that the vector points roughly along the axis associated with the factor corresponding to the single large coefficient. In this case, the canonical analysis can be used to determine the relative sensitivity of the predicted response surface to variations in that factor. (See the section “[Getting Started: RSREG Procedure](#)” on page 6907 for an example.)

Ridge Analysis

If the estimated surface is found to have a simple optimum well within the range of experimentation, the analysis performed by the preceding two steps might be sufficient. In more complicated situations, further search for the region of optimum response is required. The method of ridge analysis computes the estimated ridge of optimum response for increasing radii from the center of the original design. The ridge analysis answers the following question:

- If there is not a unique optimum of the response surface within the range of experimentation, in which direction should further searching be done in order to locate the optimum?

You can use the [RIDGE](#) statement to compute the ridge of maximum or minimum response.

Coding the Factor Variables

For the results of the canonical and ridge analyses to be interpretable, the values of different factor variables should be comparable. This is because the canonical and ridge analyses of the response surface are not invariant with respect to differences in scale and location of the factor variables. The analysis of variance is not affected by these changes. Although the actual predicted surface does not change, its parameterization does. The usual solution to this problem is to code each factor variable so that its minimum in the experiment is -1 and its maximum is 1 and to carry through the analysis with the coded values instead of the original ones. This practice has the added benefit of making 1 a reasonable boundary radius for the ridge analysis since 1 represents approximately the edge of the experimental region. By default, PROC RSREG computes the linear transformation to perform this coding as the data are initially read in, and the canonical and ridge analyses are performed on the model fit to the coded data. The actual form of the coding operation for each value of a variable is

$$\text{coded value} = (\text{original value} - M)/S$$

where M is the average of the highest and lowest values for the variable in the design and S is half their difference.

Missing Values

If an observation has missing data for any of the variables used by the procedure, then that observation is not used in the estimation process. If one or more response variables are missing, but no factor or covariate variables are missing, then predicted values and confidence limits are computed for the output data set, but the residual and Cook's D statistic are missing.

Plotting the Surface

Specifying the **PLOTS=****SURFACE** option in the PROC RSREG statement displays contour plots for all pairs of factors in the model (see [Example 81.1](#)), while specifying the **PLOTS=****SURFACE(3D)** option displays a three-dimensional surface as shown in [Figure 81.4](#).

You can also generate predicted values for a grid of points with the **PREDICT** option (see the section “[Getting Started: RSREG Procedure](#)” on page 6907 for an example) and then use these values to create a contour plot or a three-dimensional plot of the response surface over a two-dimensional grid. Any two factor variables can be chosen to form the grid for the plot. Several plots can be generated by using different pairs of factor variables.

Searching for Multiple Response Conditions

Suppose you have the following data with two factors and three responses, and you want to find the factor setting that produces responses in a certain region:

```
data a;
  input x1 x2 y1 y2 y3;
  datalines;
-1      -1      1.8 1.940  3.6398
-1       1      2.6 1.843  4.9123
 1      -1      5.4 1.063  6.0128
 1       1      0.7 1.639  2.3629
 0       0      8.5 0.134  9.0910
 0       0      3.0 0.545  3.7349
 0       0      9.8 0.453 10.4412
 0       0      4.1 1.117  5.0042
 0       0      4.8 1.690  6.6245
 0       0      5.9 1.165  6.9420
 0       0      7.3 1.013  8.7442
 0       0      9.3 1.179 10.2762
 1.4142  0      3.9 0.945  5.0245
-1.4142  0      1.7 0.333  2.4041
 0       1.4142  3.0 1.869  5.2695
 0      -1.4142  5.7 0.099  5.4346
;
```

You want to find the values of x_1 and x_2 that maximize y_1 subject to $y_2 < 2$ and $y_3 < y_2 + y_1$. The exact answer is not easy to obtain analytically, but you can obtain a practically feasible solution by checking conditions

across a grid of values in the range of interest. First, append a grid of factor values to the observed data, with missing values for the responses:

```
data b;
  set a end=eof;
  output;
  if eof then do;
    y1=.;
    y2=.;
    y3=.;
    do x1=-2 to 2 by .1;
      do x2=-2 to 2 by .1;
        output;
      end;
    end;
  end;
run;
```

Next, use PROC RSREG to fit a response surface model to the data and to compute predicted values for both the observed data and the grid, putting the predicted values in a data set c:

```
proc rsreg data=b out=c;
  model y1 y2 y3=x1 x2 / predict;
run;
```

Finally, find the subset of predicted values that satisfy the constraints, sort by the unconstrained variable, and display the top five predictions:

```
data d;
  set c;
  if y2<2;
  if y3<y2+y1;

proc sort data=d;
  by descending y1;
run;

data d; set d;
  if (_n_ <= 5);
proc print;
run;
```

The results are displayed in [Figure 81.5](#). They indicate that optimal values of the factors are around 0.3 for x1 and around -0.5 for x2.

Figure 81.5 Top Five Predictions

Obs	x1	x2	_TYPE_	y1	y2	y3
1	0.3	-0.5	PREDICT	6.92570	0.75784	7.60471
2	0.3	-0.6	PREDICT	6.91424	0.74174	7.54194
3	0.3	-0.4	PREDICT	6.91003	0.77870	7.64341
4	0.4	-0.6	PREDICT	6.90769	0.73357	7.51836
5	0.4	-0.5	PREDICT	6.90540	0.75135	7.56883

If you are also interested in simultaneously optimizing y_1 and y_2 , you can specify the following statements to make a visual comparison of the two response surfaces by overlaying their contour plots:

```
ods graphics on;
proc rsreg data=a plots=surface(overlaypairs);
  model y1 y2=x1 x2;
run;
ods graphics off;
```

Figure 81.6 shows that you have to make some compromises in any attempt to maximize both y_1 and y_2 ; however, you might be able to maximize y_1 while minimizing y_2 .

Figure 81.6 Overlaid Line Contours of Predicted Responses

Handling Covariates

Covariate regressors are added to a response surface model because they are believed to account for a sizable yet relatively uninteresting portion of the variation in the data. What the experimenter is really interested in is the response corrected for the effect of the covariates. A common example is the block effect in a block design. In the canonical and ridge analyses of a response surface, which estimate responses at hypothetical

levels of the factor variables, the actual value of the predicted response is computed by using the average values of the covariates. The estimated response values do optimize the estimated surface of the response corrected for covariates, but true prediction of the response requires actual values for the covariates. You can use the **COVAR=** option in the **MODEL** statement to include covariates in the response surface model. [Example 81.2](#) illustrates the use of this option.

Computational Method

Canonical Analysis

For each response variable, the model can be written in the form

$$y_i = \mathbf{x}_i' \mathbf{A} \mathbf{x}_i + \mathbf{b}' \mathbf{x}_i + \mathbf{c}' \mathbf{z}_i + \epsilon_i$$

where

y_i is the i th observation of the response variable.

$\mathbf{x}_i = (x_{i1}, x_{i2}, \dots, x_{ik})'$ are the k factor variables for the i th observation.

$\mathbf{z}_i = (z_{i1}, z_{i2}, \dots, z_{iL})'$ are the L covariates, including the intercept term.

\mathbf{A} is the $k \times k$ symmetrized matrix of quadratic parameters, with diagonal elements equal to the coefficients of the pure quadratic terms in the model and off-diagonal elements equal to half the coefficient of the corresponding crossproduct.

\mathbf{b} is the $k \times 1$ vector of linear parameters.

\mathbf{c} is the $L \times 1$ vector of covariate parameters, one of which is the intercept.

ϵ_i is the error associated with the i th observation. Tests performed by PROC RSREG assume that errors are independently and normally distributed with mean zero and variance σ^2 .

The parameters in \mathbf{A} , \mathbf{b} , and \mathbf{c} are estimated by least squares. To optimize y with respect to \mathbf{x} , take partial derivatives, set them to zero, and solve:

$$\frac{\partial y}{\partial \mathbf{x}} = 2\mathbf{x}' \mathbf{A} + \mathbf{b}' = \mathbf{0} \implies \mathbf{x} = -\frac{1}{2} \mathbf{A}^{-1} \mathbf{b}$$

You can determine if the solution is a maximum or minimum by looking at the eigenvalues of \mathbf{A} :

If the eigenvalues...	then the solution is...
are all negative	a maximum
are all positive	a minimum
have mixed signs	a saddle point
contain zeros	in a flat area

Ridge Analysis

If the largest eigenvalue is positive, its eigenvector gives the direction of steepest ascent from the stationary point; if the largest eigenvalue is negative, its eigenvector gives the direction of steepest descent. The eigenvectors corresponding to small or zero eigenvalues point in directions of relative flatness.

The point on the optimum response ridge at a given radius R from the ridge origin is found by optimizing

$$(\mathbf{x}_0 + \mathbf{d})' \mathbf{A} (\mathbf{x}_0 + \mathbf{d}) + \mathbf{b}' (\mathbf{x}_0 + \mathbf{d})$$

over \mathbf{d} satisfying $\mathbf{d}'\mathbf{d} = R^2$, where \mathbf{x}_0 is the $k \times 1$ vector containing the ridge origin and \mathbf{A} and \mathbf{b} are as previously discussed. By the method of Lagrange multipliers, the optimal \mathbf{d} has the form

$$\mathbf{d} = -(\mathbf{A} - \mu \mathbf{I})^{-1} (\mathbf{A} \mathbf{x}_0 + 0.5 \mathbf{b})$$

where \mathbf{I} is the $k \times k$ identity matrix and μ is chosen so that $\mathbf{d}'\mathbf{d} = R^2$. There can be several values of μ that satisfy this constraint; the correct one depends on which sort of response ridge is of interest. If you are searching for the ridge of maximum response, then the appropriate μ is the unique one that satisfies the constraint and is greater than all the eigenvalues of \mathbf{A} . Similarly, the appropriate μ for the ridge of minimum response satisfies the constraint and is less than all the eigenvalues of \mathbf{A} . (See Myers and Montgomery (1995) for details.)

Output Data Sets

OUT=SAS-data-set

An output data set containing statistics requested with options in the MODEL statement for each observation in the input data set is created whenever the OUT= option is specified in the PROC RSREG statement. The data set contains the following variables:

- the BY variables
- the ID variables
- the WEIGHT variable
- the independent variables in the MODEL statement
- the variable _TYPE_, which identifies the observation type in the output data set. _TYPE_ is a character variable with a length of eight, and it takes on the values 'ACTUAL', 'PREDICT', 'RESIDUAL', 'U95M', 'L95M', 'U95', 'L95', and 'D', corresponding to the options specified.
- the response variables containing special output values identified by the _TYPE_ variable

All confidence limits use the two-tailed Student's t value.

OUTR=SAS-data-set

An output data set containing the optimum response ridge is created when the **OUTR=** option is specified in the **RIDGE** statement. The data set contains the following variables:

- the current values of the **BY** variables
- a character variable **_DEPVAR_** containing the name of the dependent variable
- a character variable **_TYPE_** identifying the type of ridge being computed, **MINIMUM** or **MAXIMUM**. If both **MAXIMUM** and **MINIMUM** are specified, the data set contains observations for the minimum ridge followed by observations for the maximum ridge.
- a numeric variable **_RADIUS_** giving the distance from the ridge starting point
- the values of the model factors at the estimated optimum point at distance **_RADIUS_** from the ridge starting point
- a numeric variable **_PRED_**, which is the estimated expected value of the dependent variable at the optimum
- a numeric variable **_STDERR_**, which is the standard error of the estimated expected value

Displayed Output

All estimates and hypothesis tests assume that the model is correctly specified and the errors are distributed according to classical statistical assumptions.

The output displayed by PROC RSREG includes the following.

Estimation and Analysis of Variance

- The actual form of the coding operation for each value of a variable is

$$\text{coded value} = \frac{1}{S}(\text{original value} - M)$$

where M is the average of the highest and lowest values for the variable in the design and S is half their difference. The Subtracted off column contains the M values for this formula for each factor variable, and S is found in the Divided by column.

- The summary table for the response variable contains the following information.
 - “Response Mean” is the mean of the response variable in the sample. When a **WEIGHT** statement is specified, the mean \bar{y} is calculated by

$$\bar{y} = \frac{\sum_i w_i y_i}{\sum_i w_i}$$

- “Root MSE” estimates the standard deviation of the response variable and is calculated as the square root of the “Total Error” mean square.

- The “R-Square” value is R^2 , or the coefficient of determination. R^2 measures the proportion of the variation in the response that is attributed to the model rather than to random error.
- The “Coefficient of Variation” is 100 times the ratio of the “Root MSE” to the “Response Mean.”
- A table analyzing the significance of the terms of the regression is displayed. Terms are brought into the regression in four steps: (1) the “Intercept” and any covariates in the model, (2) “Linear” terms like X_1 and X_2 , (3) pure “Quadratic” terms like X_1*X_1 or X_2*X_2 , and (4) “Crossproduct” terms like X_1*X_2 . The table displays the following information:
 - the degrees of freedom in the DF column, which should be the same as the number of corresponding parameters unless one or more of the parameters are not estimable
 - Type I Sum of Squares, also called the sequential sums of squares, which measures the reduction in the error sum of squares as sets of terms (Linear, Quadratic, and so forth) are added to the model
 - R-Square, which measures the portion of total R^2 contributed as each set of terms (Linear, Quadratic, and so forth) is added to the model
 - F Value, which tests the null hypothesis that all parameters in the term are zero by using the Total Error mean square as the denominator. This is a test of a Type I hypothesis, containing the usual F test numerator, conditional on the effects of subsequent variables not being in the model.
 - $\text{Pr} > F$, which is the significance value or probability of obtaining at least as great an F ratio given that the null hypothesis is true.
- The Sum of Squares column partitions the “Total Error” into “Lack of Fit” and “Pure Error.” When “Lack of Fit” is significant, there is variation around the model other than random error (such as cubic effects of the factor variables).
 - The “Total Error” Mean Square estimates σ^2 , the variance.
 - F Value tests the null hypothesis that the variation is adequately described by random error.
- A table containing the parameter estimates from the model is displayed.
 - The Estimate column contains the parameter estimates based on the *uncoded* values of the factor variables. If an effect is a linear combination of previous effects, the parameter for the effect is not estimable. When this happens, the degrees of freedom are zero, the parameter estimate is set to zero, and estimates and tests on other parameters are conditional on this parameter being zero.
 - The Standard Error column contains the estimated standard deviations of the parameter estimates based on *uncoded* data.
 - The t Value column contains t values of a test of the null hypothesis that the true parameter is zero when the *uncoded* values of the factor variables are used.
 - The $\text{Pr} > |T|$ column gives the significance value or probability of a greater absolute t ratio given that the true parameter is zero.
 - The Parameter Estimate from Coded Data column contains the parameter estimates based on the *coded* values of the factor variables. These are the estimates used in the subsequent canonical and ridge analyses.

- The sum of squares are partitioned by the factors in the model, and an analysis table is displayed. The test on a factor is a joint test on all the parameters involving that factor. For example, the test for the factor X1 tests the null hypothesis that the true parameters for X1, X1*X1, and X1*X2 are all zero.

Canonical Analysis

- The Critical Value columns contain the values of the factor variables that correspond to the stationary point of the fitted response surface. The critical values can be at a minimum, maximum, or saddle point.
- The eigenvalues and eigenvectors are from the matrix of quadratic parameter estimates based on the coded data. They characterize the shape of the response surface.

Ridge Analysis

- The Coded Radius column contains the distance from the coded version of the associated point to the coded version of the origin of the ridge. The origin is given by the point at radius zero.
- The Estimated Response column contains the estimated value of the response variable at the associated point. The standard error of this estimate is also given. This quantity is useful for assessing the relative credibility of the prediction at a given radius. Typically, this standard error increases rapidly as the ridge moves up to and beyond the design perimeter, reflecting the inherent difficulty of making predictions beyond the range of experimentation.
- The Uncoded Factor Values columns contain the values of the uncoded factor variables that give the optimum response at this radius from the ridge origin.

ODS Table Names

PROC RSREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 81.4](#). For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

Table 81.4 ODS Tables Produced by PROC RSREG

ODS Table Name	Description	Statement
Coding	Coding coefficients for the independent variables	default
ErrorANOVA	Error analysis of variance	default
FactorANOVA	Factor analysis of variance	default
FitStatistics	Overall statistics for fit	default
ModelANOVA	Model analysis of variance	default
ParameterEstimates	Estimated linear parameters	default
Ridge	Ridge analysis for optimum response	RIDGE
Spectral	Spectral analysis	default
StationaryPoint	Stationary point of response surface	default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

PROC RSREG assigns a name to each graph it creates using ODS. The names are listed in [Table 81.5](#). You can use these names to reference the graphs when using ODS. You must also specify the **PLOTS=** option and any other options indicated in [Table 81.5](#).

Table 81.5 Graphs Produced by PROC RSREG

ODS Graph Name	Plot Description	PLOTS= Option
FitPlot	Fit plot for 1 predictor	FIT

Examples: RSREG Procedure

Example 81.1: A Saddle Surface Response Using Ridge Analysis

Myers (1976) analyzes an experiment reported by Frankel (1961) aimed at maximizing the yield of mercaptobenzothiazole (MBT) by varying processing time and temperature. Myers (1976) uses a two-factor model in which the estimated surface does not have a unique optimum. A ridge analysis is used to determine the region in which the optimum lies. The objective is to find the settings of time and temperature in the processing of a chemical that maximize the yield. The following statements produce [Output 81.1.1](#) through [Output 81.1.6](#):

```
data d;
  input Time Temp MBT;
  label Time = "Reaction Time (Hours)"
        Temp = "Temperature (Degrees Centigrade)"
        MBT = "Percent Yield Mercaptobenzothiazole";
  datalines;
    4.0   250   83.8
    20.0  250   81.7
    12.0  250   82.4
    12.0  250   82.9
    12.0  220   84.7
    12.0  280   57.9
    12.0  250   81.2
    6.3   229   81.3
    6.3   271   83.1
    17.7  229   85.3
    17.7  271   72.7
    4.0   250   82.0
  ;

ods graphics on;
proc rsreg data=d plots=(ridge surface);
  model MBT=Time Temp / lackfit;
  ridge max;
run;
ods graphics off;
```

[Output 81.1.1](#) displays the coding coefficients for the transformation of the independent variables to lie between -1 and 1 and some simple statistics for the response variable.

Output 81.1.1 Coding and Response Variable Information

The RSREG Procedure		
Coding Coefficients for the Independent Variables		
Factor	Subtracted off	Divided by
Time	12.000000	8.000000
Temp	250.000000	30.000000
Response Surface for Variable MBT: Percent Yield Mercaptobenzothiazole		
Response Mean		79.916667
Root MSE		4.615964
R-Square		0.8003
Coefficient of Variation		5.7760

Output 81.1.2 shows that the lack of fit for the model is highly significant. Since the quadratic model does not fit the data very well, firm statements about the underlying process should not be based only on the current analysis. Note from the analysis of variance for the model that the test for the time factor is not significant. If further experimentation is undertaken, it might be best to fix Time at a moderate to high value and to concentrate on the effect of temperature. In the actual experiment discussed here, extra runs were made that confirmed the results of the following analysis.

Output 81.1.2 Analyses of Variance

Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Linear	2	313.585803	0.4899	7.36	0.0243
Quadratic	2	146.768144	0.2293	3.44	0.1009
Crossproduct	1	51.840000	0.0810	2.43	0.1698
Total Model	5	512.193947	0.8003	4.81	0.0410
Residual	DF	Sum of Squares	Mean Square	F Value	Pr > F
Lack of Fit	3	124.696053	41.565351	39.63	0.0065
Pure Error	3	3.146667	1.048889		
Total Error	6	127.842720	21.307120		

Output 81.1.2 *continued*

Parameter	DF	Estimate	Standard Error	t Value	Pr > t	Parameter Estimate from Coded Data
Intercept	1	-545.867976	277.145373	-1.97	0.0964	82.173110
Time	1	6.872863	5.004928	1.37	0.2188	-1.014287
Temp	1	4.989743	2.165839	2.30	0.0608	-8.676768
Time*Time	1	0.021631	0.056784	0.38	0.7164	1.384394
Temp*Time	1	-0.030075	0.019281	-1.56	0.1698	-7.218045
Temp*Temp	1	-0.009836	0.004304	-2.29	0.0623	-8.852519

Factor	DF	Sum of Squares	Mean Square	F Value	Pr > F
Time	3	61.290957	20.430319	0.96	0.4704
Temp	3	461.250925	153.750308	7.22	0.0205

Factor	Label
Time	Reaction Time (Hours)
Temp	Temperature (Degrees Centigrade)

The canonical analysis (Output 81.1.3) indicates that the predicted response surface is shaped like a saddle. The eigenvalue of 2.5 shows that the valley orientation of the saddle is less curved than the hill orientation, with an eigenvalue of -9.99. The coefficients of the associated eigenvectors show that the valley is more aligned with Time and the hill with Temp. Because the canonical analysis resulted in a saddle point, the estimated surface does not have a unique optimum.

Output 81.1.3 Canonical Analysis

Factor	Critical Value		Label
	Coded	Uncoded	
Time	-0.441758	8.465935	Reaction Time (Hours)
Temp	-0.309976	240.700718	Temperature (Degrees Centigrade)
Predicted value at stationary point: 83.741940			
Eigenvalues		Eigenvectors	
		Time	Temp
2.528816		0.953223	-0.302267
-9.996940		0.302267	0.953223
Stationary point is a saddle point.			

However, the ridge analysis in [Output 81.1.4](#) and the ridge plot in [Output 81.1.5](#) indicate that maximum yields result from relatively high reaction times and low temperatures. A contour plot of the predicted response surface, shown in [Output 81.1.6](#), confirms this conclusion.

Output 81.1.4 Ridge Analysis

Estimated Ridge of Maximum Response for Variable MBT: Percent Yield Mercaptobenzothiazole

Output 81.1.5 Ridge Plot of Predicted Response Surface

Output 81.1.6 Contour Plot of Predicted Response Surface

Example 81.2: Response Surface Analysis with Covariates

One way of viewing covariates is as extra sources of variation in the dependent variable that can mask the variation due to primary factors. This example demonstrates the use of the **COVAR=** option in PROC RSREG to fit a response surface model to the dependent variables corrected for the covariates.

You have a chemical process with a yield that you hypothesize to be dependent on three factors: reaction time, reaction temperature, and reaction pressure. You perform an experiment to measure this dependence. You are willing to include up to 20 runs in your experiment, but you can perform no more than 8 runs on the same day, so the design for the experiment is composed of three blocks. Additionally, you know that the grade of raw material for the reaction has a significant impact on the yield. You have no control over this, but you keep track of it. The following statements create a SAS data set containing the results of the experiment:

```
data Experiment;
  input Day Grade Time Temp Pressure Yield;
  datalines;
1 67      -1      -1      -1          32.98
1 68      -1       1       1          47.04
1 70       1      -1       1          67.11
```

```

1 66      1      1      -1      26.94
1 74      0      0      0      103.22
1 68      0      0      0      42.94
2 75     -1     -1      1      122.93
2 69     -1      1     -1      62.97
2 70      1     -1     -1      72.96
2 71      1      1      1      94.93
2 72      0      0      0      93.11
2 74      0      0      0      112.97
3 69      1.633  0      0      78.88
3 67     -1.633  0      0      52.53
3 68      0      1.633  0      68.96
3 71      0     -1.633  0      92.56
3 70      0      0      1.633    88.99
3 72      0      0     -1.633   102.50
3 70      0      0      0      82.84
3 72      0      0      0      103.12
;

```

Your first analysis neglects to take the covariates into account. The following statements use PROC RSREG to fit a response surface to the observed yield, but note that Day and Grade are omitted:

```

proc rsreg data=Experiment;
  model Yield = Time Temp Pressure;
run;

```

The ANOVA results shown in [Output 81.2.1](#) indicate that *no* process variable effects are significantly larger than the background noise.

Output 81.2.1 Analysis of Variance Ignoring Covariates

The RSREG Procedure					
Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Linear	3	1880.842426	0.1353	0.67	0.5915
Quadratic	3	2370.438681	0.1706	0.84	0.5023
Crossproduct	3	241.873250	0.0174	0.09	0.9663
Total Model	9	4493.154356	0.3233	0.53	0.8226
Residual	DF	Sum of Squares	Mean Square		
Total Error	10	9405.129724	940.512972		

However, when the yields are adjusted for covariate effects of day and grade of raw material, very strong process variable effects are revealed. The following statements produce the ANOVA results in [Output 81.2.2](#). Note that in order to include the effects of the classification factor Day as covariates, you need to create dummy variables indicating each day separately.

```

data Experiment;
  set Experiment;
  d1 = (Day = 1);
  d2 = (Day = 2);
  d3 = (Day = 3);

ods graphics on;
proc rsreg data=Experiment plots=all;
  model Yield = d1-d3 Grade Time Temp Pressure / covar=4;
run;
ods graphics off;

```

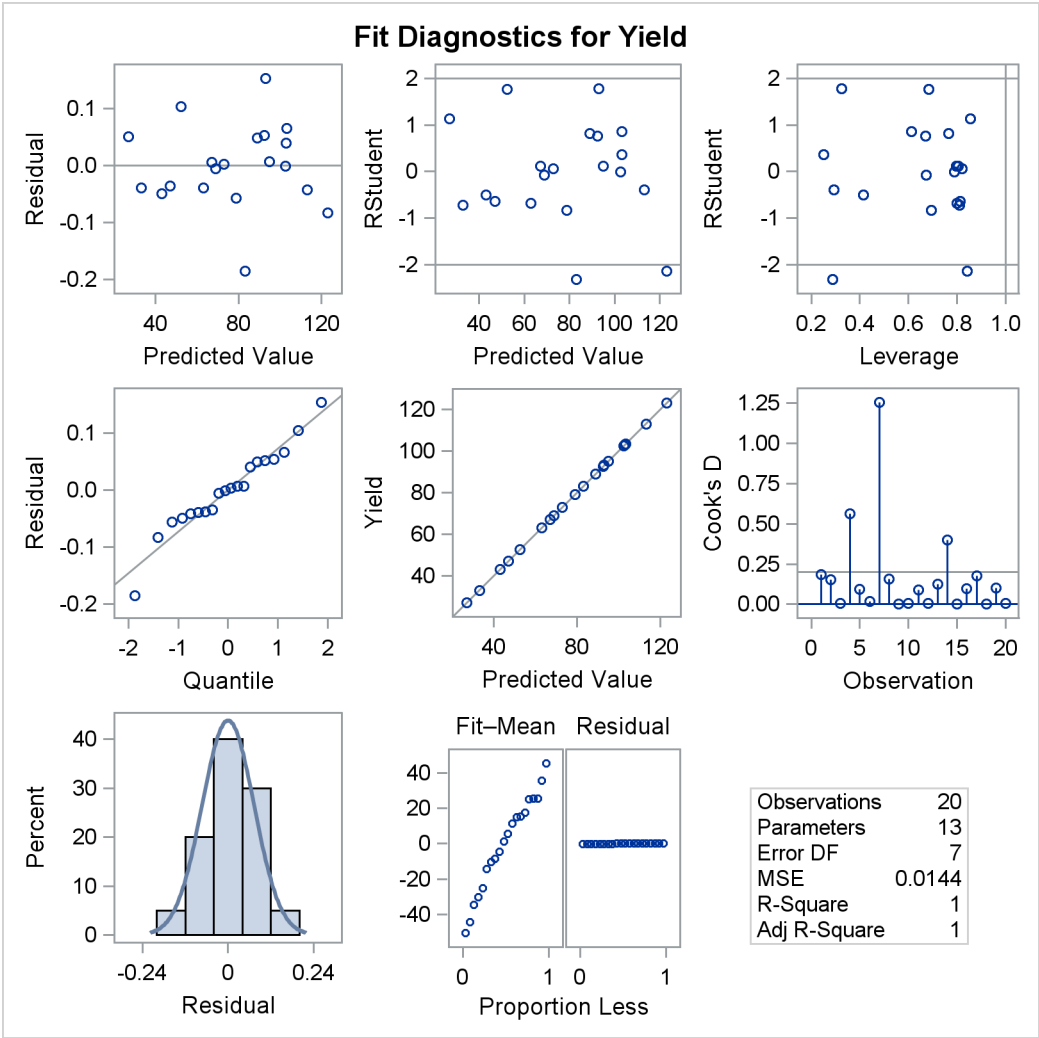

The results show very strong effects due to both the covariates and the process variables.

Output 81.2.2 Analysis of Variance Including Covariates

The RSREG Procedure					
Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Covariates	3	13695	0.9854	316957	<.0001
Linear	3	156.524497	0.0113	3622.53	<.0001
Quadratic	3	22.989775	0.0017	532.06	<.0001
Crossproduct	3	23.403614	0.0017	541.64	<.0001
Total Model	12	13898	1.0000	80413.2	<.0001
Residual	DF	Sum of Squares	Mean Square		
Total Error	7	0.100820	0.014403		

The number of observations in the data set might be too small for the diagnostic plots in [Output 81.2.3](#) to dependably identify problems; however, some outliers are indicated. The residual plots in [Output 81.2.4](#) do not display any obvious structure.

Output 81.2.3 Fit Diagnostics

Output 81.2.4 Residual Plots
