## Overview: FREQ Procedure

The FREQ procedure produces one-way to  $n$ -way frequency and contingency (crosstabulation) tables. For two-way tables, PROC FREQ computes tests and measures of association. For  $n$ -way tables, PROC FREQ provides stratified analysis by computing statistics across, as well as within, strata.

For one-way frequency tables, PROC FREQ computes goodness-of-fit tests for equal proportions or specified null proportions. For one-way tables, PROC FREQ also provides confidence limits and tests for binomial proportions, including tests for noninferiority and equivalence.

For contingency tables, PROC FREQ can compute various statistics to examine the relationships between two classification variables. For some pairs of variables, you might want to examine the existence or strength of any association between the variables. To determine if an association exists, chi-square tests are computed. To estimate the strength of an association, PROC FREQ computes measures of association that tend to be close to zero when there is no association and close to the maximum (or minimum) value when there is perfect association. The statistics for contingency tables include the following:

- chi-square tests and measures
- measures of association
- risks (binomial proportions) and risk differences for  $2 \times 2$  tables
- odds ratios and relative risks for  $2 \times 2$  tables
- tests for trend
- tests and measures of agreement
- Cochran-Mantel-Haenszel statistics

PROC FREQ computes asymptotic standard errors, confidence intervals, and tests for measures of association and measures of agreement. Exact  $p$ -values and confidence intervals are available for many test statistics and measures. PROC FREQ also performs analyses that adjust for any stratification variables by computing statistics across, as well as within, strata for  $n$ -way tables. These statistics include Cochran-Mantel-Haenszel statistics and measures of agreement.

In choosing measures of association to use in analyzing a two-way table, you should consider the study design (which indicates whether the row and column variables are dependent or independent), the measurement scale of the variables (nominal, ordinal, or interval), the type of association that each measure is designed to detect, and any assumptions required for valid interpretation of a measure. You should exercise care in selecting measures that are appropriate for your data.

Similar comments apply to the choice and interpretation of test statistics. For example, the Mantel-Haenszel chi-square statistic requires an ordinal scale for both variables and is designed to detect a linear association. The Pearson chi-square, on the other hand, is appropriate for all variables and can detect any kind of association, but it is less powerful for detecting a linear association because its power is dispersed over a greater number of degrees of freedom (except for  $2 \times 2$  tables).

For more information about selecting the appropriate statistical analyses, see Agresti (2007) or Stokes, Davis, and Koch (2000).

Several SAS procedures produce frequency counts; only PROC FREQ computes chi-square tests for one-way to  $n$ -way tables and measures of association and agreement for contingency tables. Other procedures to consider for counting include the TABULATE and UNIVARIATE procedures. When you want to produce contingency tables and tests of association for sample survey data, use PROC SURVEYFREQ. See Chapter 14, [“Introduction to Survey Procedures,”](#) for more information. When you want to fit models to categorical data, use a procedure such as CATMOD, GENMOD, GLIMMIX, LOGISTIC, PROBIT, or SURVEYLOGISTIC. See Chapter 8, [“Introduction to Categorical Data Analysis Procedures,”](#) for more information.

PROC FREQ uses the Output Delivery System (ODS), a SAS subsystem that provides capabilities for displaying and controlling the output from SAS procedures. ODS enables you to convert any of the output from PROC FREQ into a SAS data set. See the section [“ODS Table Names”](#) on page 2331 for more information.

PROC FREQ now uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, [“Statistical Graphics Using ODS.”](#) For specific information about the statistical graphics available with the FREQ procedure, see the **PLOTS** option in the **TABLES** statement and the section [“ODS Graphics”](#) on page 2334.

## Getting Started: FREQ Procedure

### Frequency Tables and Statistics

The FREQ procedure provides easy access to statistics for testing for association in a crosstabulation table.

In this example, high school students applied for courses in a summer enrichment program; these courses included journalism, art history, statistics, graphic arts, and computer programming. The students accepted were randomly assigned to classes with and without internships in local companies. Table 35.1 contains counts of the students who enrolled in the summer program by gender and whether they were assigned an internship slot.

**Table 35.1** Summer Enrichment Data

Gender	Internship	Enrollment		
		Yes	No	Total
boys	yes	35	29	64
boys	no	14	27	41
girls	yes	32	10	42
girls	no	53	23	76

The SAS data set SummerSchool is created by inputting the summer enrichment data as cell count data, or providing the frequency count for each combination of variable values. The following DATA step statements create the SAS data set SummerSchool:

```
data SummerSchool;
    input Gender $ Internship $ Enrollment $ Count @@;
    datalines;
boys yes yes 35    boys yes no 29
boys no yes 14    boys no no 27
girls yes yes 32    girls yes no 10
girls no yes 53    girls no no 23
;
```

The variable Gender takes the values ‘boys’ or ‘girls,’ the variable Internship takes the values ‘yes’ and ‘no,’ and the variable Enrollment takes the values ‘yes’ and ‘no.’ The variable Count contains the number of students that correspond to each combination of data values. The double at sign ( @@ ) indicates that more than one observation is included on a single data line. In this DATA step, two observations are included on each line.

Researchers are interested in whether there is an association between internship status and summer program enrollment. The Pearson chi-square statistic is an appropriate statistic to assess the association in the corresponding  $2 \times 2$  table. The following PROC FREQ statements specify this analysis.

You specify the table for which you want to compute statistics with the TABLES statement. You specify the statistics you want to compute with options after a slash (/) in the TABLES statement.

```
proc freq data=SummerSchool order=data;
  tables Internship*Enrollment / chisq;
  weight Count;
run;
```

The ORDER= option controls the order in which variable values are displayed in the rows and columns of the table. By default, the values are arranged according to the alphanumeric order of their unformatted values. If you specify ORDER=DATA, the data are displayed in the same order as they occur in the input data set. Here, because 'yes' appears before 'no' in the data, 'yes' appears first in any table. Other options for controlling order include ORDER=FORMATTED, which orders according to the formatted values, and ORDER=FREQUENCY, which orders by descending frequency count.

In the TABLES statement, Internship\*Enrollment specifies a table where the rows are internship status and the columns are program enrollment. The CHISQ option requests chi-square statistics for assessing association between these two variables. Because the input data are in cell count form, the WEIGHT statement is required. The WEIGHT statement names the variable Count, which provides the frequency of each combination of data values.

Figure 35.1 presents the crosstabulation of Internship and Enrollment. In each cell, the values printed under the cell count are the table percentage, row percentage, and column percentage, respectively. For example, in the first cell, 63.21 percent of the students offered courses with internships accepted them and 36.79 percent did not.

**Figure 35.1** Crosstabulation Table

The FREQ Procedure				
Table of Internship by Enrollment				
Internship	Enrollment			
Frequency				
Percent				
Row Pct				
Col Pct	yes	no	Total	
-----+-----+-----+				
yes	67	39	106	
	30.04	17.49	47.53	
	63.21	36.79		
	50.00	43.82		
-----+-----+-----+				
no	67	50	117	
	30.04	22.42	52.47	
	57.26	42.74		
	50.00	56.18		
-----+-----+-----+				
Total	134	89	223	
	60.09	39.91	100.00	

Figure 35.2 displays the statistics produced by the CHISQ option. The Pearson chi-square statistic is labeled 'Chi-Square' and has a value of 0.8189 with 1 degree of freedom. The associated  $p$ -value is 0.3655, which means that there is no significant evidence of an association between internship status and program enrollment. The other chi-square statistics have similar values and are asymptotically equivalent. The other statistics (phi coefficient, contingency coefficient, and Cramer's  $V$ ) are measures of association derived from the Pearson chi-square. For Fisher's exact test, the two-sided  $p$ -value is 0.4122, which also shows no association between internship status and program enrollment.

**Figure 35.2** Statistics Produced with the CHISQ Option

Statistic	DF	Value	Prob
Chi-Square	1	0.8189	0.3655
Likelihood Ratio Chi-Square	1	0.8202	0.3651
Continuity Adj. Chi-Square	1	0.5899	0.4425
Mantel-Haenszel Chi-Square	1	0.8153	0.3666
Phi Coefficient		0.0606	
Contingency Coefficient		0.0605	
Cramer's V		0.0606	
Fisher's Exact Test			
Cell (1,1) Frequency (F)		67	
Left-sided Pr <= F		0.8513	
Right-sided Pr >= F		0.2213	
Table Probability (P)		0.0726	
Two-sided Pr <= P		0.4122	

The analysis, so far, has ignored gender. However, it might be of interest to ask whether program enrollment is associated with internship status after adjusting for gender. You can address this question by doing an analysis of a set of tables (in this case, by analyzing the set consisting of one for boys and one for girls). The Cochran-Mantel-Haenszel (CMH) statistic is appropriate for this situation: it addresses whether rows and columns are associated after controlling for the stratification variable. In this case, you would be stratifying by gender.

The PROC FREQ statements for this analysis are very similar to those for the first analysis, except that there is a third variable, Gender, in the TABLES statement. When you cross more than two variables, the two rightmost variables construct the rows and columns of the table, respectively, and the leftmost variables determine the stratification.

The following PROC FREQ statements also request frequency plots for the crosstabulation tables. PROC FREQ produces these plots by using ODS Graphics to create graphs as part of the procedure output. Before requesting graphs, you must enable ODS Graphics with the ODS GRAPHICS ON statement.

```
ods graphics on;
proc freq data=SummerSchool;
  tables Gender*Internship*Enrollment /
         chisq cmh plots(only)=freqplot;
  weight Count;
run;
ods graphics off;
```

This execution of PROC FREQ first produces two individual crosstabulation tables of Internship by Enrollment: one for boys and one for girls. Frequency plots and chi-square statistics are produced for each individual table. [Figure 35.3](#), [Figure 35.4](#), and [Figure 35.5](#) show the results for boys. Note that the chi-square statistic for boys is significant at the  $\alpha = 0.05$  level of significance. Boys offered a course with an internship are more likely to enroll than boys who are not.

[Figure 35.4](#) displays the frequency plot of Internship by Enrollment for boys. By default, the frequency plot is displayed as a bar chart with vertical grouping by the row variable Internship. You can use PLOTS= options to request a dot plot instead of a bar chart or to change the orientation of the bars from vertical to horizontal. You can also use PLOTS= options to specify other two-way layouts such as stacked or horizontal grouping.

[Figure 35.6](#), [Figure 35.7](#), and [Figure 35.8](#) display the crosstabulation table, frequency plot, and chi-square statistics for girls. You can see that there is no evidence of association between internship offers and program enrollment for girls.

**Figure 35.3** Crosstabulation Table for Boys

The FREQ Procedure

Figure 35.7 Frequency Plot for Girls

**Figure 35.8** Chi-Square Statistics for Girls

Statistic	DF	Value	Prob
Chi-Square	1	0.5593	0.4546
Likelihood Ratio Chi-Square	1	0.5681	0.4510
Continuity Adj. Chi-Square	1	0.2848	0.5936
Mantel-Haenszel Chi-Square	1	0.5545	0.4565
Phi Coefficient		0.0688	
Contingency Coefficient		0.0687	
Cramer's V		0.0688	
Fisher's Exact Test			
Cell (1,1) Frequency (F)		23	
Left-sided Pr <= F		0.8317	
Right-sided Pr >= F		0.2994	
Table Probability (P)		0.1311	
Two-sided Pr <= P		0.5245	

These individual table results demonstrate the occasional problems with combining information into one table and not accounting for information in other variables such as Gender. [Figure 35.9](#) contains the CMH results. There are three summary (CMH) statistics; which one you use depends on whether your rows and/or columns have an order in  $r \times c$  tables. However, in the case of  $2 \times 2$  tables, ordering does not matter and all three statistics take the same value. The CMH statistic follows the chi-square distribution under the hypothesis of no association, and here, it takes the value 4.0186 with 1 degree of freedom. The associated  $p$ -value is 0.0450, which indicates a significant association at the  $\alpha = 0.05$  level.

Thus, when you adjust for the effect of gender in these data, there is an association between internship and program enrollment. But, if you ignore gender, no association is found. Note that the CMH option also produces other statistics, including estimates and confidence limits for relative risk and odds ratios for  $2 \times 2$  tables and the Breslow-Day Test. These results are not displayed here.

**Figure 35.9** Test for the Hypothesis of No Association

Cochran-Mantel-Haenszel Statistics (Based on Table Scores)				
Statistic	Alternative Hypothesis	DF	Value	Prob
1	Nonzero Correlation	1	4.0186	0.0450
2	Row Mean Scores Differ	1	4.0186	0.0450
3	General Association	1	4.0186	0.0450

## Agreement Study

Medical researchers are interested in evaluating the efficacy of a new treatment for a skin condition. Dermatologists from participating clinics were trained to conduct the study and to evaluate the condition. After the training, two dermatologists examined patients with the skin condition from a pilot study and rated the same patients. The possible evaluations are terrible, poor, marginal, and clear. Table 35.2 contains the data.

**Table 35.2** Skin Condition Data

Dermatologist 1	Dermatologist 2			
	Terrible	Poor	Marginal	Clear
Terrible	10	4	1	0
Poor	5	10	12	2
Marginal	2	4	12	5
Clear	0	2	6	13

The following DATA step statements create the SAS dataset SkinCondition. The dermatologists' evaluations of the patients are contained in the variables Derm1 and Derm2; the variable Count is the number of patients given a particular pair of ratings.

```
data SkinCondition;
    input Derm1 $ Derm2 $ Count;
    datalines;
    terrible terrible 10
    terrible      poor  4
    terrible marginal  1
    terrible      clear  0
    poor      terrible  5
    poor          poor 10
    poor      marginal 12
    poor          clear  2
    marginal terrible  2
    marginal      poor  4
    marginal marginal 12
    marginal      clear  5
    clear      terrible  0
    clear          poor  2
    clear      marginal  6
    clear          clear 13
    ;
```

The following PROC FREQ statements request an agreement analysis of the skin condition data. In order to evaluate the agreement of the diagnoses (a possible contribution to measurement error in the study), the *kappa coefficient* is computed. The AGREE option in the TABLES statement requests the kappa coefficient, together with its standard error and confidence limits. The KAPPA option in the TEST statement requests a test for the null hypothesis that kappa equals zero, or that the agreement is purely by chance.

```
proc freq data=SkinCondition order=data;
  tables Derm1*Derm2 / agree noprint;
  test kappa;
  weight Count;
run;
```

Figure 35.10 shows the results. The kappa coefficient has the value 0.3449, which indicates slight agreement between the dermatologists, and the hypothesis test confirms that you can reject the null hypothesis of no agreement. This conclusion is further supported by the confidence interval of (0.2030, 0.4868), which suggests that the true kappa is greater than zero. The AGREE option also produces Bowker's test for symmetry and the weighted kappa coefficient, but that output is not shown here.

**Figure 35.10** Agreement Study

The FREQ Procedure	
Statistics for Table of Derm1 by Derm2	
Simple Kappa Coefficient	
Kappa	0.3449
ASE	0.0724
95% Lower Conf Limit	0.2030
95% Upper Conf Limit	0.4868
Test of H0: Kappa = 0	
ASE under H0	0.0612
Z	5.6366
One-sided Pr > Z	<.0001
Two-sided Pr >  Z	<.0001

## Syntax: FREQ Procedure

The following statements are available in PROC FREQ:

```
PROC FREQ < options > ;
  BY variables ;
  EXACT statistic-options < / computation-options > ;
  OUTPUT < OUT=SAS-data-set > options ;
  TABLES requests < / options > ;
  TEST options ;
  WEIGHT variable < / option > ;
```

The PROC FREQ statement is the only required statement for the FREQ procedure. If you specify the following statements, PROC FREQ produces a one-way frequency table for each variable in the most recently created data set.

```
proc freq;
run;
```

The rest of this section gives detailed syntax information for the BY, EXACT, OUTPUT, TABLES, TEST, and WEIGHT statements in alphabetical order after the description of the PROC FREQ statement. Table 35.3 summarizes the basic function of each PROC FREQ statement.

**Table 35.3** Summary of PROC FREQ Statements

Statement	Description
BY	Provides separate analyses for each BY group
EXACT	Requests exact tests
OUTPUT	Requests an output data set
TABLES	Specifies tables and requests analyses
TEST	Requests tests for measures of association and agreement
WEIGHT	Identifies a weight variable

## PROC FREQ Statement

**PROC FREQ** <options> ;

The PROC FREQ statement invokes the procedure and optionally identifies the input data set. By default, the procedure uses the most recently created SAS data set.

Table 35.4 lists the options available in the PROC FREQ statement. Descriptions follow in alphabetical order.

**Table 35.4** PROC FREQ Statement Options

Option	Description
COMPRESS	Begins the next one-way table on the current page
DATA=	Names the input data set
FORMCHAR=	Specifies the outline and cell divider characters for crosstabulation tables
NLEVELS	Displays the number of levels for all TABLES variables
NOPRINT	Suppresses all displayed output
ORDER=	Specifies the order for reporting variable values
PAGE	Displays one table per page

You can specify the following options in the PROC FREQ statement.

### COMPRESS

begins display of the next one-way frequency table on the same page as the preceding one-way table if there is enough space to begin the table. By default, the next one-way table begins on the current page only if the entire table fits on that page. The COMPRESS option is not valid with the PAGE option.

### DATA=SAS-data-set

names the SAS data set to be analyzed by PROC FREQ. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

**FORMCHAR(1,2,7)=*'formchar-string'***

defines the characters to be used for constructing the outlines and dividers for the cells of crosstabulation table displays. The *formchar-string* should be three characters long. The characters are used to draw the vertical separators (1), the horizontal separators (2), and the vertical-horizontal intersections (7). If you do not specify the FORMCHAR= option, PROC FREQ uses FORMCHAR(1,2,7)='| - +' by default. Table 35.5 summarizes the formatting characters used by PROC FREQ.

**Table 35.5** Formatting Characters Used by PROC FREQ

Position	Default	Used to Draw
1		Vertical separators
2	-	Horizontal separators
7	+	Intersections of vertical and horizontal separators

The FORMCHAR= option can specify 20 different SAS formatting characters used to display output; however, PROC FREQ uses only the first, second, and seventh formatting characters. Therefore, the proper specification for PROC FREQ is FORMCHAR(1,2,7)= *'formchar-string'*.

Specifying all blanks for *formchar-string* produces crosstabulation tables with no outlines or dividers—for example, FORMCHAR(1,2,7)=' '. You can use any character in *formchar-string*, including hexadecimal characters. If you use hexadecimal characters, you must put an *x* after the closing quote. For information about which hexadecimal codes to use for which characters, see the documentation for your hardware.

See the CALENDAR, PLOT, and TABULATE procedures in the *Base SAS Procedures Guide* for more information about form characters.

**NLEVELS**

displays the “Number of Variable Levels” table, which provides the number of levels for each variable named in the TABLES statements. See the section “[Number of Variable Levels Table](#)” on page 2322 for details. PROC FREQ determines the variable levels from the formatted variable values, as described in the section “[Grouping with Formats](#)” on page 2260.

**NOPRINT**

suppresses the display of all output. You can use the NOPRINT option when you only want to create an output data set. See the section “[Output Data Sets](#)” on page 2320 for information about the output data sets produced by PROC FREQ. Note that the NOPRINT option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, “[Using the Output Delivery System](#).”

**NOTE:** A NOPRINT option is also available in the TABLES statement. It suppresses display of the crosstabulation tables but allows display of the requested statistics.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the order of the variable levels in the frequency and crosstabulation tables, which you request in the TABLES statement.

The ORDER= option can take the following values:

Value of ORDER=	Levels Ordered By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=INTERNAL. The FORMATTED and INTERNAL orders are machine-dependent. The ORDER= option does not apply to missing values, which are always ordered first.

For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

## PAGE

displays only one table per page. Otherwise, PROC FREQ displays multiple tables per page as space permits. The PAGE option is not valid with the [COMPRESS](#) option.

## BY Statement

### BY variables ;

You can specify a BY statement with PROC FREQ to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the FREQ procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

## EXACT Statement

**EXACT** *statistic-options* < / *computation-options* > ;

The EXACT statement requests exact tests or confidence limits for the specified statistics. Optionally, PROC FREQ computes Monte Carlo estimates of the exact  $p$ -values. The *statistic-options* specify the statistics to provide exact tests or confidence limits for. The *computation-options* specify options for the computation of exact statistics. See the section “Exact Statistics” on page 2314 for details.

**NOTE:** PROC FREQ computes exact tests with fast and efficient algorithms that are superior to direct enumeration. Exact tests are appropriate when a data set is small, sparse, skewed, or heavily tied. For some large problems, computation of exact tests might require a considerable amount of time and memory. Consider using asymptotic tests for such problems. Alternatively, when asymptotic methods might not be sufficient for such large problems, consider using Monte Carlo estimation of exact  $p$ -values. See the section “Computational Resources” on page 2317 for more information.

### Statistic-Options

The *statistic-options* specify the statistics to provide exact tests or confidence limits for.

For one-way tables, exact  $p$ -values are available for the binomial proportion tests and the chi-square goodness-of-fit test. Exact confidence limits are available for the binomial proportion.

For two-way tables, exact  $p$ -values are available for the following tests: Pearson chi-square test, likelihood-ratio chi-square test, Mantel-Haenszel chi-square test, Fisher’s exact test, Jonckheere-Terpstra test, and Cochran-Armitage test for trend. Exact  $p$ -values are also available for tests of the following statistics: Pearson correlation coefficient, Spearman correlation coefficient, Kendall’s tau- $b$ , Stuart’s tau- $c$ , Somers’  $D(C|R)$ , Somers’  $D(R|C)$ , simple kappa coefficient, and weighted kappa coefficient.

For  $2 \times 2$  tables, PROC FREQ provides exact confidence limits for the odds ratio, exact unconditional confidence limits for the proportion difference, and McNemar’s exact test. For stratified  $2 \times 2$  tables, PROC FREQ provides Zelen’s exact test for equal odds ratios, exact confidence limits for the common odds ratio, and an exact test for the common odds ratio.

Table 35.6 lists the available *statistic-options* and the exact statistics computed. Most of the option names are identical to the corresponding option names in the TABLES and OUTPUT statements. You can request exact computations for groups of statistics by using options that are identical to the following TABLES statement options: CHISQ, MEASURES, and AGREE. For example, when you specify the CHISQ option in the EXACT statement, PROC FREQ computes exact  $p$ -values for the Pearson chi-square, likelihood-ratio chi-square, and Mantel-Haenszel chi-square tests. You can request exact computations for an individual statistic by specifying the corresponding *statistic-option* from the list in Table 35.6.

**Table 35.6** EXACT Statement *Statistic-Options*

<i>Statistic-Option</i>	<b>Exact Statistics Computed</b>
AGREE	McNemar's test (for $2 \times 2$ tables), simple kappa coefficient test, weighted kappa coefficient test
BINOMIAL	Binomial proportion tests for one-way tables
CHISQ	Chi-square goodness-of-fit test for one-way tables; Pearson chi-square, likelihood-ratio chi-square, and Mantel-Haenszel chi-square tests for two-way tables
COMOR	Confidence limits for the common odds ratio and common odds ratio test (for $h \times 2 \times 2$ tables)
EQOR   ZELEN	Zelen's test for equal odds ratios (for $h \times 2 \times 2$ tables)
FISHER	Fisher's exact test
JT	Jonckheere-Terpstra test
KAPPA	Test for the simple kappa coefficient
KENTB	Test for Kendall's tau- <i>b</i>
LRCHI	Likelihood-ratio chi-square test
MCNEM	McNemar's test (for $2 \times 2$ tables)
MEASURES	Tests for the Pearson correlation and Spearman correlation, confidence limits for the odds ratio (for $2 \times 2$ tables)
MHCHI	Mantel-Haenszel chi-square test
OR	Confidence limits for the odds ratio (for $2 \times 2$ tables)
PCHI	Pearson chi-square test
PCORR	Test for the Pearson correlation coefficient
RISKDIFF	Confidence limits for the proportion differences (for $2 \times 2$ tables)
RISKDIFF1	Confidence limits for the column 1 proportion difference
RISKDIFF2	Confidence limits for the column 2 proportion difference
SCORR	Test for the Spearman correlation coefficient
SMDCR	Test for Somers' $D(C R)$
SMDRC	Test for Somers' $D(R C)$
STUTC	Test for Stuart's tau- <i>c</i>
TREND	Cochran-Armitage test for trend
WTKAP	Test for the weighted kappa coefficient

### Using TABLES Statement Options with the EXACT Statement

If you use only one TABLES statement, you do not need to specify the same options in both the TABLES and EXACT statements; when you specify a *statistic-option* in the EXACT statement, PROC FREQ automatically invokes the corresponding TABLES statement option. However, when you use multiple TABLES statements and want exact computations, you must specify options in the TABLES statements to request the desired statistics. PROC FREQ then performs exact computations for all statistics that you also specify in the EXACT statement.

The **TABLES** statement group option **CHISQ** includes tests that correspond to the following EXACT statement individual *statistic-options*: LRCHI, MHCHI, and PCHI. The **MEASURES** option in the TABLES statement includes statistics that correspond to the following EXACT statement *statistic-options*: KENTB, OR, PCORR, SCORR, SMDCR, SMDRC, and STUTC. The **AGREE** option in the TABLES statement produces analyses that correspond to the KAPPA, MCNEM, and WTKAP *statistic-options* in the EXACT statement. The **CMH** option in the TABLES statement produces analyses that correspond to the COMOR and EQOR (ZELEN) *statistic-options* in the EXACT statement.

## Computation-Options

The *computation-options* specify options for computation of exact statistics. You can specify the following *computation-options* in the EXACT statement after a slash (/).

### **ALPHA=** $\alpha$

specifies the level of the confidence limits for Monte Carlo *p*-value estimates. The value of  $\alpha$  must be between 0 and 1, and the default is 0.01. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=.01 produces 99% confidence limits for the Monte Carlo estimates.

The ALPHA= option invokes the **MC** option.

### **MAXTIME=***value*

specifies the maximum clock time (in seconds) that PROC FREQ can use to compute an exact *p*-value. If the procedure does not complete the computation within the specified time, the computation terminates. The value of MAXTIME= must be a positive number. The MAXTIME= option is valid for Monte Carlo estimation of exact *p*-values, as well as for direct exact *p*-value computation. See the section “[Computational Resources](#)” on page 2317 for more information.

### **MC**

requests Monte Carlo estimation of exact *p*-values instead of direct exact *p*-value computation. Monte Carlo estimation can be useful for large problems that require a considerable amount of time and memory for exact computations but for which asymptotic approximations might not be sufficient. See the section “[Monte Carlo Estimation](#)” on page 2317 for more information.

The MC option is available for all EXACT *statistic-options* except the BINOMIAL option and the following options that apply only to  $2 \times 2$  or  $h \times 2 \times 2$  tables: COMOR, EQOR, MCNEM, RISKDIFF, and OR. PROC FREQ computes only exact tests or confidence limits for these statistics.

The ALPHA=, N=, and SEED= options also invoke the MC option.

### **N=***n*

specifies the number of samples for Monte Carlo estimation. The value of *n* must be a positive integer, and the default is 10,000. Larger values of *n* produce more precise estimates of exact *p*-values. Because larger values of *n* generate more samples, the computation time increases.

The N= option invokes the **MC** option.

**POINT**

requests exact point probabilities for the test statistics.

The POINT option is available for all the EXACT statement *statistic-options* except the OR and RISKDIFF options, which provide exact confidence limits. The POINT option is not available with the MC option.

**SEED=number**

specifies the initial seed for random number generation for Monte Carlo estimation. The value of the SEED= option must be an integer. If you do not specify the SEED= option or if the SEED= value is negative or zero, PROC FREQ uses the time of day from the computer's clock to obtain the initial seed.

The SEED= option invokes the MC option.

---

## OUTPUT Statement

**OUTPUT** < OUT= SAS-data-set > options ;

The OUTPUT statement creates a SAS data set that contains statistics computed by PROC FREQ. You specify which statistics to store in the output data set with the OUTPUT statement *options*. The output data set contains one observation for each two-way table or stratum, and one observation for summary statistics across all strata. For more information about the contents of the output data set, see the section “[Contents of the OUTPUT Statement Output Data Set](#)” on page 2321.

Only one OUTPUT statement is allowed for each execution of PROC FREQ. You must specify a **TABLES** statement with the OUTPUT statement. If you use multiple TABLES statements, the contents of the OUTPUT data set correspond to the last TABLES statement. If you use multiple table requests in a TABLES statement, the contents of the OUTPUT data set correspond to the last table request.

Note that you can use the Output Delivery System (ODS) to create a SAS data set from any piece of PROC FREQ output. For more information, see the section “[ODS Table Names](#)” on page 2331.

Also note that the output data set created by the OUTPUT statement is not the same as the output data set created by the OUT= option in the TABLES statement. The OUTPUT statement creates a data set that contains statistics (such as the Pearson chi-square and its *p*-value), and the OUT= option in the TABLES statement creates a data set that contains frequency table counts and percentages. See the section “[Output Data Sets](#)” on page 2320 for more information.

You can specify the following options in an OUTPUT statement:

**OUT=SAS-data-set**

names the output data set. If you omit the OUT= option, the data set is named DATA $n$ , where  $n$  is the smallest integer that makes the name unique.

*options*

specify the statistics you want in the output data set. [Table 35.7](#) lists the available options, together with the TABLES statement options needed to produce the statistics. You can output groups of statistics by using group options identical to those available in the **TABLES** statement,

which include the [AGREE](#), [ALL](#), [CHISQ](#), [CMH](#), and [MEASURES](#) options. Or you can request statistics individually.

When you specify an option in the OUTPUT statement, the output data set contains all statistics from that analysis—the estimate or test statistic plus any associated standard error, confidence limits, *p*-values, and degrees of freedom. See the section “[Contents of the OUTPUT Statement Output Data Set](#)” on page 2321 for details.

If you want to store a statistic in the output data set, you must also request computation of that statistic with the appropriate [TABLES](#) or [EXACT](#) statement option. For example, you cannot specify the option PCHI (Pearson chi-square) in the OUTPUT statement without also specifying a TABLES or EXACT statement option to compute the Pearson chi-square test. The TABLES statement option [ALL](#) or [CHISQ](#) requests the Pearson chi-square test. If you have only one TABLES statement, the EXACT statement option CHISQ or PCHI also requests the Pearson chi-square test. [Table 35.7](#) lists the TABLES statement options required to produce the OUTPUT data set statistics. Note that the [ALL](#) option in the [TABLES](#) statement invokes the [CHISQ](#), [MEASURES](#), and [CMH](#) options.

**Table 35.7** OUTPUT Statement Options

Option	Output Data Set Statistics	Required TABLES Statement Option
AGREE	McNemar’s test, Bowker’s test, simple and weighted kappas; for multiple strata, overall simple and weighted kappas, tests for equal kappas, and Cochran’s <i>Q</i>	<a href="#">AGREE</a>
AJCHI	Continuity-adjusted chi-square ( $2 \times 2$ tables)	<a href="#">CHISQ</a>
ALL	CHISQ, MEASURES, and CMH statistics; N	<a href="#">ALL</a>
BDCHI	Breslow-Day test ( $h \times 2 \times 2$ tables)	<a href="#">CMH</a> , <a href="#">CMH1</a> , or <a href="#">CMH2</a>
BINOMIAL	Binomial statistics for one-way tables	<a href="#">BINOMIAL</a>
CHISQ	For one-way tables, goodness-of-fit test; for two-way tables, Pearson, likelihood-ratio, continuity-adjusted, and Mantel-Haenszel chi-squares, Fisher’s exact test ( $2 \times 2$ tables), phi and contingency coefficients, Cramer’s <i>V</i>	<a href="#">CHISQ</a>
CMH	Cochran-Mantel-Haenszel (CMH) correlation, row mean scores (ANOVA), and general association statistics; for $2 \times 2$ tables, logit and Mantel-Haenszel adjusted odds ratios and relative risks, Breslow-Day test	<a href="#">CMH</a>
CMH1	CMH output, except row mean scores (ANOVA) and general association statistics	<a href="#">CMH</a> or <a href="#">CMH1</a>
CMH2	CMH output, except general association statistic	<a href="#">CMH</a> or <a href="#">CMH2</a>
CMHCOR	CMH correlation statistic	<a href="#">CMH</a> , <a href="#">CMH1</a> , or <a href="#">CMH2</a>
CMHGA	CMH general association statistic	<a href="#">CMH</a>
CMHRMS	CMH row mean scores (ANOVA) statistic	<a href="#">CMH</a> or <a href="#">CMH2</a>
COCHQ	Cochran’s <i>Q</i> ( $h \times 2 \times 2$ tables)	<a href="#">AGREE</a>
CONTGY	Contingency coefficient	<a href="#">CHISQ</a>
CRAMV	Cramer’s <i>V</i>	<a href="#">CHISQ</a>
EQKAP	Test for equal simple kappas	<a href="#">AGREE</a>
EQOR   ZELEN	Zelen’s test for equal odds ratios ( $h \times 2 \times 2$ tables)	<a href="#">CMH</a> and <a href="#">EXACT EQOR</a>

Table 35.7 continued

Option	Output Data Set Statistics	Required TABLES Statement Option
EQWKP	Test for equal weighted kappas	AGREE
FISHER	Fisher's exact test	CHISQ or FISHER <sup>1</sup>
GAILSIMON	Gail-Simon test	GAILSIMON
GAMMA	Gamma	MEASURES
JT	Jonckheere-Terpstra test	JT
KAPPA	Simple kappa coefficient	AGREE
KENTB	Kendall's tau- <i>b</i>	MEASURES
LAMCR	Lambda asymmetric ( <i>C</i>   <i>R</i> )	MEASURES
LAMDAS	Lambda symmetric	MEASURES
LAMRC	Lambda asymmetric ( <i>R</i>   <i>C</i> )	MEASURES
LGOR	Adjusted logit odds ratio ( $h \times 2 \times 2$ tables)	CMH, CMH1, or CMH2
LGRRC1	Adjusted column 1 logit relative risk	CMH, CMH1, or CMH2
LGRRC2	Adjusted column 2 logit relative risk	CMH, CMH1, or CMH2
LRCHI	Likelihood-ratio chi-square	CHISQ
MCNEM	McNemar's test ( $2 \times 2$ tables)	AGREE
MEASURES	Gamma, Kendall's tau- <i>b</i> , Stuart's tau- <i>c</i> ,  Somers' $D(C R)$ and $D(R C)$ , Pearson and Spearman correlations, lambda asymmetric ( <i>C</i>   <i>R</i> ) and ( <i>R</i>   <i>C</i> ), lambda symmetric, uncertainty coefficients ( <i>C</i>   <i>R</i> ) and ( <i>R</i>   <i>C</i> ), symmetric uncertainty coefficient; odds ratio and relative risks ( $2 \times 2$ tables)	MEASURES
MHCHI	Mantel-Haenszel chi-square	CHISQ
MHOR   COMOR	Adjusted Mantel-Haenszel odds ratio ( $h \times 2 \times 2$ tables)	CMH, CMH1, or CMH2
MHRRC1	Adjusted column 1 Mantel-Haenszel relative risk	CMH, CMH1, or CMH2
MHRRC2	Adjusted column 2 Mantel-Haenszel relative risk	CMH, CMH1, or CMH2
N	Number of nonmissing observations	
NMISS	Number of missing observations	
OR	Odds ratio ( $2 \times 2$ tables)	MEASURES or RELRISK
PCHI	Chi-square goodness-of-fit test for one-way tables, Pearson chi-square for two-way tables	CHISQ
PCORR	Pearson correlation coefficient	MEASURES
PHI	Phi coefficient	CHISQ
PLCORR	Polychoric correlation coefficient	PLCORR
RDIF1	Column 1 risk difference (row 1 - row 2)	RISKDIFF
RDIF2	Column 2 risk difference (row 1 - row 2)	RISKDIFF
RELRISK	Odds ratio and relative risks ( $2 \times 2$ tables)	MEASURES or RELRISK
RISKDIFF	Risks and risk differences ( $2 \times 2$ tables)	RISKDIFF
RISKDIFF1	Column 1 risks and risk difference	RISKDIFF

<sup>1</sup>CHISQ computes Fisher's exact test for  $2 \times 2$  tables. Use the FISHER option to compute Fisher's exact test for general  $r \times c$  tables.

Table 35.7 continued

Option	Output Data Set Statistics	Required TABLES Statement Option
RISKDIFF2	Column 2 risks and risk difference	RISKDIFF
RRC1	Column 1 relative risk	MEASURES or RELRISK

URC	Uncertainty coefficient ( $R C$ )	MEASURES
WTKAP	Weighted kappa coefficient	AGREE

## TABLES Statement

**TABLES** *requests* </ options> ;

The TABLES statement requests one-way to  $n$ -way frequency and crosstabulation tables and statistics for those tables.

If you omit the TABLES statement, PROC FREQ generates one-way frequency tables for all data set variables that are not listed in the other statements.

The following argument is required in the TABLES statement.

### *requests*

specify the frequency and crosstabulation tables to produce. A request is composed of one variable name or several variable names separated by asterisks. To request a one-way frequency table, use a single variable. To request a two-way crosstabulation table, use an asterisk between two variables. To request a multiway table (an  $n$ -way table, where  $n > 2$ ), separate the desired variables with asterisks. The unique values of these variables form the rows, columns, and strata of the table. You can include up to 50 variables in a single multiway table request.

For two-way to multiway tables, the values of the last variable form the crosstabulation table columns, while the values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one stratum. PROC FREQ produces a separate crosstabulation table for each stratum. For example, a specification of A\*B\*C\*D in

a TABLES statement produces  $k$  tables, where  $k$  is the number of different combinations of values for A and B. Each table lists the values for C down the side and the values for D across the top.

You can use multiple TABLES statements in the PROC FREQ step. PROC FREQ builds all the table requests in one pass of the data, so that there is essentially no loss of efficiency. You can also specify any number of table requests in a single TABLES statement. To specify multiple table requests quickly, use a grouping syntax by placing parentheses around several variables and joining other variables or variable combinations. For example, the statements shown in Table 35.8 illustrate grouping syntax.

**Table 35.8** Grouping Syntax

Request	Equivalent to
tables A*(B C);	tables A*B A*C;
tables (A B)*(C D);	tables A*C B*C A*D B*D;
tables (A B C)*D;	tables A*D B*D C*D;
tables A – – C;	tables A B C;
tables (A – – C)*D;	tables A*D B*D C*D;

The TABLES statement variables are one or more variables from the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. PROC FREQ uses the formatted values of the TABLES variable to determine the categorical variable levels. So if you assign a format to a variable with a FORMAT statement, PROC FREQ formats the values before dividing observations into the levels of a frequency or crosstabulation table. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

If you use PROC FORMAT to create a user-written format that combines missing and non-missing values into one category, PROC FREQ treats the entire category of formatted values as missing. See the discussion in the section “[Grouping with Formats](#)” on page 2260 for more information.

The frequency or crosstabulation table lists the values of both character and numeric variables in ascending order based on internal (unformatted) variable values unless you change the order with the **ORDER=** option. To list the values in ascending order by formatted value, use **ORDER=FORMATTED** in the PROC FREQ statement.

## Without Options

If you request a one-way frequency table for a variable without specifying options, PROC FREQ produces frequencies, cumulative frequencies, percentages of the total frequency, and cumulative percentages for each value of the variable. If you request a two-way or an  $n$ -way crosstabulation table without specifying options, PROC FREQ produces crosstabulation tables that include cell frequencies, cell percentages of the total frequency, cell percentages of row frequencies, and cell percentages of column frequencies. The procedure excludes observations with missing values from the table but displays the total frequency of missing observations below each table.

## Options

Table 35.9 lists the options available in the TABLES statement. Descriptions follow in alphabetical order.

**Table 35.9** TABLES Statement Options

Option	Description
<b>Control Statistical Analysis</b>	
AGREE	Requests tests and measures of classification agreement
ALL	Requests tests and measures of association produced by CHISQ, MEASURES, and CMH
ALPHA=	Sets the confidence level for confidence limits
BDT	Requests Tarone's adjustment for the Breslow-Day test
BINOMIAL	Requests binomial proportion, confidence limits, and tests for one-way tables
BINOMIALC	Requests BINOMIAL statistics with a continuity correction
CHISQ	Requests chi-square tests and measures based on chi-square
CL	Requests confidence limits for the MEASURES statistics
CMH	Requests all Cochran-Mantel-Haenszel statistics
CMH1	Requests CMH correlation statistic, adjusted odds ratios, and adjusted relative risks
CMH2	Requests CMH correlation and row mean scores (ANOVA) statistics, adjusted odds ratios, and adjusted relative risks
CONVERGE=	Specifies convergence criterion for polychoric correlation
FISHER	Requests Fisher's exact test for tables larger than $2 \times 2$
GAILSIMON	Requests Gail-Simon test for qualitative interactions
JT	Requests Jonckheere-Terpstra test
MAXITER=	Specifies maximum number of iterations for polychoric correlation
MEASURES	Requests measures of association
MISSING	Treats missing values as nonmissing
PLCORR	Requests polychoric correlation
REL RISK	Requests relative risk measures for $2 \times 2$ tables
RISKDIFF	Requests risks and risk differences for $2 \times 2$ tables
RISKDIFFC	Requests RISKDIFF statistics with a continuity correction
SCORES=	Specifies the type of row and column scores
TESTF=	Specifies expected frequencies for one-way chi-square test
TESTP=	Specifies expected proportions for one-way chi-square test
TREND	Requests Cochran-Armitage test for trend
<b>Control Additional Table Information</b>	
CELLCHI2	Displays cell contributions to the Pearson chi-square statistic
CUMCOL	Displays cumulative column percentages
DEVIATION	Displays deviations of cell frequencies from expected values
EXPECTED	Displays expected cell frequencies
MISSPRINT	Displays missing value frequencies
SPARSE	Includes all possible combinations of variable levels in LIST and OUT=

Table 35.9 *continued*

Option	Description
TOTPCT	Displays percentages of total frequency for $n$ -way tables ( $n > 2$ )
CONTENTS=	Specifies the contents label for crosstabulation tables
CROSSLIST	Displays crosstabulation tables in ODS column format
FORMAT=	Formats the frequencies in crosstabulation tables
LIST	Displays two-way to $n$ -way tables in list format
NOCOL	Suppresses display of column percentages
NOCUM	Suppresses display of cumulative frequencies and percentages
NOFREQ	Suppresses display of frequencies
NOPERCENT	Suppresses display of percentages
NOPRINT	Suppresses display of crosstabulation tables but displays statistics
NOROW	Suppresses display of row percentages
NOSPARE	Suppresses zero frequency levels in CROSSLIST, LIST and OUT=
NOWARN	Suppresses log warning message for the chi-square test
PRINTKWT	Displays kappa coefficient weights
SCOROUT	Displays row and column scores
<b>Produce Statistical Graphics</b>	
PLOTS=	Requests plots from ODS Graphics
<b>Create an Output Data Set</b>	
OUT=	Names an output data set to contain frequency counts
OUTCUM	Includes cumulative frequencies and percentages in the output data set for one-way tables
OUTEXPECT	Includes expected frequencies in the output data set
OUTPCT	Includes row, column, and two-way table percentages in the output data set

You can specify the following options in a TABLES statement.

#### AGREE <(WT=FC)>

requests tests and measures of classification agreement for square tables. The AGREE option provides McNemar's test for  $2 \times 2$  tables and Bowker's test of symmetry for square tables with more than two response categories. The AGREE option also produces the simple kappa coefficient, the weighted kappa coefficient, their asymptotic standard errors, and their confidence limits. When there are multiple strata, the AGREE option provides overall simple and weighted kappas as well as tests for equal kappas among strata. When there are multiple strata and two response categories, PROC FREQ computes Cochran's  $Q$  test. See the section "Tests and Measures of Agreement" on page 2299 for details about these statistics.

If you specify the WT=FC option in parentheses following the AGREE option, PROC FREQ uses Fleiss-Cohen weights to compute the weighted kappa coefficient. By default, PROC FREQ uses Cicchetti-Allison weights. See the section "Weighted Kappa Coefficient" on page 2301 for details. You can specify the PRINTKWT option to display the kappa coefficient weights.

AGREE statistics are computed only for square tables, where the number of rows equals the number of columns. If your table is not square due to observations with zero weights, you can specify the **ZEROS** option in the **WEIGHT** statement to include these observations. For more details, see the section “[Tables with Zero Rows and Columns](#)” on page 2304.

You can use the **TEST** statement to request asymptotic tests for the simple and weighted kappa coefficients. You can request exact  $p$ -values for the simple and weighted kappa coefficient tests, as well as for McNemar’s test, by specifying the corresponding options in the **EXACT** statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

## **ALL**

requests all of the tests and measures that are computed by the **CHISQ**, **MEASURES**, and **CMH** options. The number of CMH statistics computed can be controlled by the **CMH1** and **CMH2** options.

## **ALPHA= $\alpha$**

specifies the level of confidence limits. The value of  $\alpha$  must be between 0 and 1, and the default is 0.05. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of **ALPHA=0.05** produces 95% confidence limits.

**ALPHA=** applies to confidence limits requested by **TABLES** statement options. There is a separate **ALPHA=** option in the **EXACT** statement that sets the level of confidence limits for Monte Carlo estimates of exact  $p$ -values, which are requested in the **EXACT** statement.

## **BDT**

requests Tarone’s adjustment in the Breslow-Day test for homogeneity of odds ratios. (You must specify the **CMH** option to compute the Breslow-Day test.) See the section “[Breslow-Day Test for Homogeneity of the Odds Ratios](#)” on page 2310 for more information.

## **BINOMIAL < (binomial-options) >**

requests the binomial proportion for one-way tables. When you specify the **BINOMIAL** option, PROC FREQ also provides the asymptotic standard error, asymptotic (Wald) and exact (Clopper-Pearson) confidence limits, and the asymptotic equality test for the binomial proportion by default.

You can specify *binomial-options* inside the parentheses following the **BINOMIAL** option. The **LEVEL=** binomial-option identifies the variable level for which to compute the proportion. If you do not specify **LEVEL=**, PROC FREQ computes the proportion for the first level that appears in the output. The **P=** binomial-option specifies the null proportion for the binomial tests. If you do not specify **P=**, PROC FREQ uses **P=0.5** by default.

You can also specify *binomial-options* to request confidence limits and tests of noninferiority, superiority, and equivalence for the binomial proportion. [Table 35.10](#) summarizes the *binomial-options*.

Available confidence limits for the binomial proportion include Agresti-Coull, exact (Clopper-Pearson), Jeffreys, Wald, and Wilson (score) confidence limits. You can specify more than one type of binomial confidence limits in the same analysis. If you do not specify any confidence limit requests with *binomial-options*, PROC FREQ computes Wald asymptotic confidence limits and exact (Clopper-Pearson) confidence limits by default. The **ALPHA=** option determines the confidence level, and the default of **ALPHA=0.05** produces 95% confidence limits for the binomial proportion.

To request exact tests for the binomial proportion, specify the **BINOMIAL** option in the **EXACT** statement. PROC FREQ then computes exact  $p$ -values for all binomial tests that you request with *binomial-options*, which can include tests of noninferiority, superiority, and equivalence, as well as the test of equality.

See the section “[Binomial Proportion](#)” on page 2280 for details.

**Table 35.10** BINOMIAL Options

Task	<i>Binomial-Option</i>
Specify the variable level	LEVEL=
Specify the null proportion	P=
Request a continuity correction	CORRECT
Request confidence limits	AGRESTICOULL   AC ALL EXACT   CLOPPERPEARSON JEFFREYS   J WILSON   W WALD
Request tests	EQUIV   EQUIVALENCE NONINF   NONINFERIORITY SUP   SUPERIORITY
Specify the test margin	MARGIN=
Specify the test variance	VAR=SAMPLE   NULL

You can specify the following *binomial-options* inside parentheses following the **BINOMIAL** option.

#### **AGRESTICOULL | AC**

requests Agresti-Coull confidence limits for the binomial proportion. See the section “[Agresti-Coull Confidence Limits](#)” on page 2280 for details.

#### **ALL**

requests all available types of confidence limits for the binomial proportion. These include the following: Agresti-Coull, exact (Clopper-Pearson), Jeffreys, Wald, and Wilson (score) confidence limits.

#### **CORRECT**

includes a continuity correction in the asymptotic Wald confidence limits and tests. The **CORRECT** binomial-option has the same effect as the **BINOMIALC** option.

#### **EQUIV | EQUIVALENCE**

requests a test of equivalence for the binomial proportion. See the section “[Equivalence Test](#)” on page 2285 for details. You can specify the equivalence test margins, the null proportion, and the variance type with the **MARGIN=**, **P=**, and **VAR=** binomial-options, respectively.

**EXACT****CLOPPERPEARSON**

requests exact (Clopper-Pearson) confidence limits for the binomial proportion. See the section “[Exact \(Clopper-Pearson\) Confidence Limits](#)” on page 2281 for details. If you do not request any binomial confidence limits by specifying binomial-options, PROC FREQ produces Wald and exact (Clopper-Pearson) confidence limits by default.

**JEFFREYS | J**

requests Jeffreys confidence limits for the binomial proportion. See the section “[Jeffreys Confidence Limits](#)” on page 2281 for details.

**LEVEL=***level-number* | ‘*level-value*’

specifies the variable level for the binomial proportion. By default, PROC FREQ computes the proportion of observations for the first variable level that appears in the output. To request a different level, use **LEVEL=***level-number* or **LEVEL=**‘*level-value*’, where *level-number* is the variable level’s number or order in the output, and *level-value* is the formatted value of the variable level. The value of *level-number* must be a positive integer. You must enclose *level-value* in single quotes.

**MARGIN=***value* | (*lower,upper*)

specifies the margin for the noninferiority, superiority, and equivalence tests, which you request with the **NONINF**, **SUP**, and **EQUIV** binomial-options, respectively. If you do not specify **MARGIN=**, PROC FREQ uses a margin of 0.2 by default.

For noninferiority and superiority tests, specify a single *value* for the **MARGIN=** option. The **MARGIN=** *value* must be a positive number. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC FREQ converts that number to a proportion. The procedure treats the value 1 as 1%.

For noninferiority and superiority tests, the test limits must be between 0 and 1. The limits are determined by the null proportion value (which you can specify with the **P=** binomial-option) and by the margin value. The noninferiority limit equals the null proportion minus the margin. By default, the null proportion equals 0.5 and the margin equals 0.2, which gives a noninferiority limit of 0.3. The superiority limit equals the null proportion plus the margin, which is 0.7 by default.

For an equivalence test, you can specify a single **MARGIN=** *value*, or you can specify both *lower* and *upper* values. If you specify a single **MARGIN=** *value*, it must be a positive number, as described previously. If you specify a single **MARGIN=** *value* for an equivalence test, PROC FREQ uses  $-value$  as the lower margin and *value* as the upper margin for the test. If you specify both *lower* and *upper* values for an equivalence test, you can specify them in proportion form as numbers between  $-1$  or  $1$ . Or you can specify them in percentage form as numbers between  $-100$  and  $100$ , and PROC FREQ converts the numbers to proportions. The value of *lower* must be less than the value of *upper*.

The equivalence limits must be between 0 and 1. The equivalence limits are determined by the null proportion value (which you can specify with the **P=** binomial-option) and by the margin values. The lower equivalence limit equals the null proportion plus the

lower margin. By default, the null proportion equals 0.5 and the lower margin equals  $-0.2$ , which gives a lower equivalence limit of 0.3. The upper equivalence limit equals the null proportion plus the upper margin, which is 0.7 by default.

See the sections “[Noninferiority Test](#)” on page 2283 and “[Equivalence Test](#)” on page 2285 for details.

#### **NONINF | NONINFERIORITY**

requests a test of noninferiority for the binomial proportion. See the section “[Noninferiority Test](#)” on page 2283 for details. You can specify the noninferiority test margin, the null proportion, and the variance type with the **MARGIN=**, **P=**, and **VAR=** binomial-options, respectively.

#### **P=value**

specifies the null hypothesis proportion for the binomial tests. If you omit the **P=** option, PROC FREQ uses 0.5 as the null proportion. The null proportion *value* must be a positive number. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC FREQ converts that number to a proportion. The procedure treats the value 1 as 1%.

#### **SUP | SUPERIORITY**

requests a test of superiority for the binomial proportion. See the section “[Superiority Test](#)” on page 2284 for details. You can specify the superiority test margin, the null proportion, and the variance type with the **MARGIN=**, **P=**, and **VAR=** binomial-options, respectively.

#### **VAR=SAMPLE | NULL**

specifies the type of variance estimate to use for the tests of noninferiority, superiority, and equivalence. The default is **VAR=SAMPLE**, which estimates the variance from the sample proportion. **VAR=NULL** uses the null proportion to compute the variance. See the sections “[Noninferiority Test](#)” on page 2283 and “[Equivalence Test](#)” on page 2285 for details.

#### **WALD**

requests Wald confidence limits for the binomial proportion. See the section “[Wald Confidence Limits](#)” on page 2280 for details. If you do not request any binomial confidence limits by specifying binomial-options, PROC FREQ produces Wald and exact (Clopper-Pearson) confidence limits by default.

#### **WILSON | W**

#### **SCORE**

requests Wilson confidence limits for the binomial proportion. These are also known as *score* confidence limits. See the section “[Wilson \(Score\) Confidence Limits](#)” on page 2281 for details.

#### **BINOMIALC <(binomial-options)>**

requests the **BINOMIAL** option statistics for one-way tables, and includes a continuity correction in the asymptotic Wald confidence limits and tests. The **BINOMIAL** option statistics include the binomial proportion, its asymptotic standard error, asymptotic (Wald) and exact

(Clopper-Pearson) confidence limits, and the asymptotic equality test for the binomial proportion by default. The *binomial-options* available with the BINOMIALC option are the same as those available with BINOMIAL. See the description of the [BINOMIAL](#) option for details.

### CELLCHI2

displays each crosstabulation table cell's contribution to the total Pearson chi-square statistic. The cell contribution is computed as

$$\frac{(\text{frequency} - \text{expected})^2}{\text{expected}}$$

where *frequency* is the table cell frequency or count and *expected* is the expected cell frequency, which is computed under the null hypothesis that the row and column variables are independent. See the section "[Pearson Chi-Square Test for Two-Way Tables](#)" on page 2267 for details.

The CELLCHI2 option has no effect for one-way tables or for tables that are displayed with the LIST option.

### CHISQ < ( option ) >

requests chi-square tests of homogeneity or independence and measures of association based on the chi-square statistic. The tests include the Pearson chi-square, likelihood-ratio chi-square, and Mantel-Haenszel chi-square. The measures include the phi coefficient, the contingency coefficient, and Cramer's *V*. For  $2 \times 2$  tables, the CHISQ option also provides Fisher's exact test and the continuity-adjusted chi-square. See the section "[Chi-Square Tests and Statistics](#)" on page 2265 for details.

For one-way tables, the CHISQ option provides a chi-square goodness-of-fit test for equal proportions. If you specify the null hypothesis proportions with the [TESTP=](#) option, PROC FREQ computes a chi-square goodness-of-fit test for the specified proportions. If you specify null hypothesis frequencies with the [TESTF=](#) option, PROC FREQ computes a chi-square goodness-of-fit test for the specified frequencies. See the section "[Chi-Square Test for One-Way Tables](#)" on page 2266 for more information.

To request Fisher's exact test for tables larger than  $2 \times 2$ , use the FISHER option in the [EXACT](#) statement. Exact tests are also available for other CHISQ statistics, including the Pearson, likelihood-ratio, and Mantel-Haenszel chi-square, and the chi-square goodness-of-fit test for one-way tables. You can use the EXACT statement to request these tests. See the section "[Exact Statistics](#)" on page 2314 for details.

You can specify the following option in parentheses following the CHISQ option:

**WARN=** *value*

**WARN=** ( *values* )

controls the warning message about the validity of the asymptotic Pearson chi-square test. By default, PROC FREQ displays a warning when more than 20% of the table cells have expected frequencies that are less than 5. If you specify the NOPRINT option in the PROC FREQ statement, this warning is included in the log; otherwise, the warning is displayed as a footnote in the chi-square table. You can use the WARN= option to suppress the warning and to include a warning indicator in the output data set.

The `WARN=` option can take one or more of the following values. If you specify more than one value, enclose the values in parentheses following `WARN=`. For example, `warn = (output noprint)`.

Value of <code>WARN=</code>	Description
<code>OUTPUT</code>	Adds a warning indicator variable to the output data set
<code>NOLOG</code>	Suppresses the chi-square warning message in the log
<code>NOPRINT</code>	Suppresses the chi-square warning message in the display
<code>NONE</code>	Suppresses the chi-square warning message entirely

If you specify the `WARN=OUTPUT` option, the chi-square ODS output data set contains a variable named `Warning` that equals 1 for the Pearson chi-square when more than 20% of the table cells have expected frequencies that are less than 5 and equals 0 otherwise. If you specify `WARN=OUTPUT` and also specify the `CHISQ` option in the `OUTPUT` statement, then the statistics output data set contains a variable named `WARN_PCHI` that indicates the warning.

The `WARN=NOLOG` option has the same effect as the `NOWARN` option in the `TABLES` statement.

## CL

requests confidence limits for the [MEASURES](#) statistics. If you omit the `MEASURES` option, the `CL` option invokes `MEASURES`. You can set the level of the confidence limits by using the `ALPHA=` option. The default of `ALPHA=0.5` produces 95% confidence limits. See the sections “[Measures of Association](#)” on page 2270 and “[Confidence Limits](#)” on page 2271 for more information.

## CMH < ( *cmh-options* ) >

requests Cochran-Mantel-Haenszel statistics, which test for association between the row and column variables after adjusting for the remaining variables in a multiway table. The Cochran-Mantel-Haenszel statistics include the nonzero correlation statistic, the row mean scores (ANOVA) statistic, and the general association statistic. In addition, for  $2 \times 2$  tables, the `CMH` option provides the adjusted Mantel-Haenszel and logit estimates of the odds ratio and relative risks, together with their confidence limits. For stratified  $2 \times 2$  tables, the `CMH` option provides the Breslow-Day test for homogeneity of odds ratios. (To request Tarone’s adjustment for the Breslow-Day test, specify the `BDT` *cmh-option*.) See the section “[Cochran-Mantel-Haenszel Statistics](#)” on page 2304 for details.

You can use the `CMH1` or `CMH2` option to control the number of `CMH` statistics that `PROC FREQ` computes.

For stratified  $2 \times 2$  tables, you can request Zelen’s exact test for equal odds ratios by specifying the `EQOR` option in the `EXACT` statement. See the section “[Zelen’s Exact Test for Equal Odds Ratios](#)” on page 2311 for details. You can request exact confidence limits for the common odds ratio by specifying the `COMOR` option in the `EXACT` statement. This option also provides a common odds ratio test. See the section “[Exact Confidence Limits for the Common Odds Ratio](#)” on page 2311 for details.

You can specify the following *cmh-options* in parentheses following the CMH option. These *cmh-options*, which apply to stratified  $2 \times 2$  tables, are also available with the **CMH1** or **CMH2** option.

#### **BDT**

requests Tarone's adjustment in the Breslow-Day test for homogeneity of odds ratios. See the section "[Breslow-Day Test for Homogeneity of the Odds Ratios](#)" on page 2310 for details. The BDT *cmh-option* has the same effect as the **BDT** option in the TABLES statement.

#### **GAILSIMON | GS < COLUMN=1 | 2 >**

requests the Gail-Simon test for qualitative interaction, which applies to stratified  $2 \times 2$  tables. See the section "[Gail-Simon Test for Qualitative Interactions](#)" on page 2313 for details.

The COLUMN= option specifies the column of the risk differences to use in computing the Gail-Simon test. By default, PROC FREQ uses column 1 risk differences. If you specify COLUMN=2, PROC FREQ uses column 2 risk differences.

The GAILSIMON *cmh-option* has the same effect as the **GAILSIMON** option in the TABLES statement.

#### **MANTELFLEISS | MF**

requests the Mantel-Fleiss criterion for the Mantel-Haenszel statistic for stratified  $2 \times 2$  tables. See the section "[Mantel-Fleiss Criterion](#)" on page 2307 for details.

#### **CMH1 < ( cmh-options ) >**

requests the Cochran-Mantel-Haenszel correlation statistic. This option does not provide the CMH row mean scores (ANOVA) statistic or the general association statistic, which are provided by the **CMH** option. For tables larger than  $2 \times 2$ , the CMH1 option requires less memory than the CMH option, which can require an enormous amount of memory for large tables.

For  $2 \times 2$  tables, the CMH1 option also provides the adjusted Mantel-Haenszel and logit estimates of the odds ratio and relative risks, together with their confidence limits. For stratified  $2 \times 2$  tables, the CMH1 option provides the Breslow-Day test for homogeneity of odds ratios.

The *cmh-options* available with the CMH1 option are the same as those available with the CMH option. See the description of the **CMH** option for details.

#### **CMH2 < ( cmh-options ) >**

requests the Cochran-Mantel-Haenszel correlation statistic and the row mean scores (ANOVA) statistic. This option does not provide the CMH general association statistic, which is provided by the **CMH** option. For tables larger than  $2 \times 2$ , the CMH2 option requires less memory than the CMH option, which can require an enormous amount of memory for large tables.

For  $2 \times 2$  tables, the CMH1 option also provides the adjusted Mantel-Haenszel and logit estimates of the odds ratio and relative risks, together with their confidence limits. For stratified  $2 \times 2$  tables, the CMH1 option provides the Breslow-Day test for homogeneity of odds ratios.

The *cmh-options* available with the CMH2 option are the same as those available with the CMH option. See the description of the [CMH](#) option for details.

#### **CONTENTS=***'string'*

specifies the label to use for crosstabulation tables in the contents file, the Results window, and the trace record. For information about output presentation, see the *SAS Output Delivery System: User's Guide*.

If you omit the CONTENTS= option, the contents label for crosstabulation tables is “Cross-Tabular Freq Table” by default.

Note that contents labels for all crosstabulation tables that are produced by a single TABLES statement use the same text. To specify different contents labels for different crosstabulation tables, request the tables in separate TABLES statements and use the CONTENTS= option in each TABLES statement.

To remove the crosstabulation table entry from the contents file, you can specify a null label with CONTENTS= ''.

The CONTENTS= option affects only contents labels for crosstabulation tables. It does not affect contents labels for other PROC FREQ tables.

To specify the contents label for any PROC FREQ table, you can use PROC TEMPLATE to create a customized table definition. The CONTENTS\_LABEL attribute in the DEFINE TABLE statement of PROC TEMPLATE specifies the contents label for the table. See the chapter “The TEMPLATE Procedure” in the *SAS Output Delivery System: User's Guide* for more information.

#### **CONVERGE=***value*

specifies the convergence criterion for computing the polychoric correlation, which you request with the [PLCORR](#) option. The CONVERGE= *value* must be a positive number. By default CONVERGE=0.0001. Iterative computation of the polychoric correlation stops when the convergence measure falls below the value of CONVERGE= or when the number of iterations exceeds the value specified in the [MAXITER=](#) option, whichever happens first. See the section “[Polychoric Correlation](#)” on page 2277 for details.

#### **CROSSLIST**

displays crosstabulation tables in ODS column format instead of the default crosstabulation cell format. In a CROSSLIST table display, the rows correspond to the crosstabulation table cells, and the columns correspond to descriptive statistics such as Frequency and Percent. The CROSSLIST table displays the same information as the default crosstabulation table, but uses an ODS column format instead of the table cell format. See the section “[Multiway Tables](#)” on page 2324 for details about the contents of the CROSSLIST table.

You can control the contents of a CROSSLIST table with the same options available for the default crosstabulation table. These include the [NOFREQ](#), [NOPERCENT](#), [NOROW](#), and [NOCOL](#) options. You can request additional information in a CROSSLIST table with the [CELLCHI2](#), [DEVIATION](#), [EXPECTED](#), [MISSPRINT](#), and [TOTPCT](#) options.

The [FORMAT=](#) option and the [CUMCOL](#) option have no effect for CROSSLIST tables. You cannot specify both the [LIST](#) option and the CROSSLIST option in the same TABLES statement.

You can use the [NOSPARSE](#) option to suppress display of variable levels with zero frequency in CROSSTAB tables. By default for CROSSTAB tables, PROC FREQ displays all levels of the column variable within each level of the row variable, including any column variable levels with zero frequency for that row. And for multiway tables displayed with the CROSSTAB option, the procedure displays all levels of the row variable for each stratum of the table by default, including any row variable levels with zero frequency for the stratum.

#### **CUMCOL**

displays the cumulative column percentages in the cells of the crosstabulation table. The CUMCOL option does not apply to crosstabulation tables produced with the [LIST](#) or [CROSSTAB](#) option.

#### **DEVIATION**

displays the deviation of the frequency from the expected frequency for each cell of the crosstabulation table. See the section “[Pearson Chi-Square Test for Two-Way Tables](#)” on page 2267 for details. The DEVIATION option does not apply to crosstabulation tables produced with the [LIST](#) option.

#### **EXPECTED**

displays the expected cell frequencies under the hypothesis of independence (or homogeneity) for crosstabulation tables. See the section “[Pearson Chi-Square Test for Two-Way Tables](#)” on page 2267 for details. The EXPECTED option does not apply to tables produced with the [LIST](#) option.

#### **FISHER | EXACT**

requests Fisher’s exact test for tables that are larger than  $2 \times 2$ . (For  $2 \times 2$  tables, the CHISQ option provides Fisher’s exact test.) This test is also known as the Freeman-Halton test. See the sections “[Fisher’s Exact Test](#)” on page 2268 and “[Exact Statistics](#)” on page 2314 for more information.

If you omit the [CHISQ](#) option in the TABLES statement, the FISHER option invokes CHISQ. You can also request Fisher’s exact test by specifying the FISHER option in the [EXACT](#) statement.

**NOTE:** PROC FREQ computes exact tests with fast and efficient algorithms that are superior to direct enumeration. Exact tests are appropriate when a data set is small, sparse, skewed, or heavily tied. For some large problems, computation of exact tests might require a considerable amount of time and memory. Consider using asymptotic tests for such problems. Alternatively, when asymptotic methods might not be sufficient for such large problems, consider using Monte Carlo estimation of exact  $p$ -values. See the section “[Computational Resources](#)” on page 2317 for more information.

#### **FORMAT=***format-name*

specifies a format for the following crosstabulation table cell values: frequency, expected frequency, and deviation. PROC FREQ also uses the specified format to display the row and column total frequencies and the overall total frequency in crosstabulation tables.

You can specify any standard SAS numeric format or a numeric format defined with the FORMAT procedure. The format length must not exceed 24. If you omit the FORMAT= option, by default PROC FREQ uses the BEST6. format to display frequencies less than 1E6, and the BEST7. format otherwise.

The `FORMAT=` option applies only to crosstabulation tables displayed in the default format. It does not apply to crosstabulation tables produced with the [LIST](#) or [CROSSLIST](#) option.

To change display formats in any `FREQ` table, you can use `PROC TEMPLATE`. See the chapter “The `TEMPLATE` Procedure” in the *SAS Output Delivery System: User’s Guide* for more information.

#### **GAILSIMON | GS < COLUMN = 1 | 2 >**

requests the Gail-Simon test for qualitative interaction, which applies to stratified  $2 \times 2$  tables. See the section “[Gail-Simon Test for Qualitative Interactions](#)” on page 2313 for details.

The `COLUMN=` option specifies the column of the risk differences to use in computing the Gail-Simon test. By default, `PROC FREQ` uses column 1 risk differences. If you specify `COLUMN=2`, `PROC FREQ` uses column 2 risk differences.

#### **JT**

requests the Jonckheere-Terpstra test. See the section “[Jonckheere-Terpstra Test](#)” on page 2297 for details.

#### **LIST**

displays two-way to  $n$ -way crosstabulation tables in a list format instead of the default crosstabulation cell format. The `LIST` option displays the entire multiway table in one table, instead of displaying a separate two-way table for each stratum. See the section “[Multiway Tables](#)” on page 2324 for details.

The `LIST` option is not available when you also specify statistical options. You must use the standard crosstabulation table display or the [CROSSLIST](#) display when you request statistical tests or measures.

#### **MAXITER=number**

specifies the maximum number of iterations for computing the polychoric correlation, which you request with the [PLCORR](#) option. The value of the `MAXITER=` option must be a positive integer. By default `MAXITER=20`. Iterative computation of the polychoric correlation stops when the number of iterations exceeds the `MAXITER=` value or when the convergence measures falls below the value of the [CONVERGE=](#) option, whichever happens first. See the section “[Polychoric Correlation](#)” on page 2277 for details.

#### **MEASURES**

requests several measures of association and their asymptotic standard errors. The `MEASURES` option provides the following statistics: gamma, Kendall’s tau- $b$ , Stuart’s tau- $c$ , Somers’  $D(C|R)$ , Somers’  $D(R|C)$ , the Pearson and Spearman correlation coefficients, lambda (symmetric and asymmetric), and uncertainty coefficients (symmetric and asymmetric). To request confidence limits for these measures of association, you can specify the [CL](#) option.

For  $2 \times 2$  tables, the `MEASURES` option also provides the odds ratio, column 1 relative risk, column 2 relative risk, and the corresponding confidence limits. Alternatively, you can obtain the odds ratio and relative risks, without the other measures of association, by specifying the [RELRISK](#) option.

See the section “[Measures of Association](#)” on page 2270 for details.

You can use the **TEST** statement to request asymptotic tests for the following measures of association: gamma, Kendall's tau-*b*, Stuart's tau-*c*, Somers'  $D(C|R)$ , Somers'  $D(R|C)$ , and the Pearson and Spearman correlation coefficients. You can use the **EXACT** statement to request exact confidence limits for the odds ratio and exact tests for the following measures of association: Kendall's tau-*b*, Stuart's tau-*c*, Somers'  $D(C|R)$  and  $D(R|C)$ , and the Pearson and Spearman correlation coefficients. See the section “[Exact Statistics](#)” on page 2314 for more information.

### **MISSING**

treats missing values as a valid nonmissing level for all TABLES variables. The MISSING option displays the missing levels in frequency and crosstabulation tables and includes them in all calculations of percentages, tests, and measures.

By default, if you do not specify the MISSING or **MISSPRINT** option, an observation is excluded from a table if it has a missing value for any of the variables in the TABLES request. When PROC FREQ excludes observations with missing values, it displays the total frequency of missing observations below the table. See the section “[Missing Values](#)” on page 2261 for more information.

### **MISSPRINT**

displays missing value frequencies in frequency and crosstabulation tables but does not include the missing value frequencies in any computations of percentages, tests, or measures.

By default, if you do not specify the **MISSING** or **MISSPRINT** option, an observation is excluded from a table if it has a missing value for any of the variables in the TABLES request. When PROC FREQ excludes observations with missing values, it displays the total frequency of missing observations below the table. See the section “[Missing Values](#)” on page 2261 for more information.

### **NOCOL**

suppresses the display of column percentages in crosstabulation table cells.

### **NOCUM**

suppresses the display of cumulative frequencies and percentages in one-way frequency tables. The NOCUM option also suppresses the display of cumulative frequencies and percentages in crosstabulation tables in list format, which you request with the **LIST** option.

### **NOFREQ**

suppresses the display of cell frequencies in crosstabulation tables. The NOFREQ option also suppresses row total frequencies. This option has no effect for one-way tables or for crosstabulation tables in list format, which you request with the **LIST** option.

### **NOPERCENT**

suppresses the display of overall percentages in crosstabulation tables. These percentages include the cell percentages of the total (two-way) table frequency, as well as the row and column percentages of the total table frequency. To suppress the display of cell percentages of row or column totals, use the **NOROW** or **NOCOL** option, respectively.

For one-way frequency tables and crosstabulation tables in list format, the NOPERCENT option suppresses the display of percentages and cumulative percentages.

**NOPRINT**

suppresses the display of frequency and crosstabulation tables but displays all requested tests and statistics. To suppress the display of all output, including tests and statistics, use the [NOPRINT](#) option in the PROC FREQ statement.

**NOROW**

suppresses the display of row percentages in crosstabulation table cells.

**NOSPARSE**

suppresses the display of cells with a zero frequency count in [LIST](#) output and omits them from the [OUT=](#) data set. The NOSPARSE option applies when you specify the [ZEROS](#) option in the [WEIGHT](#) statement to include observations with zero weights. By default, the ZEROS option invokes the [SPARSE](#) option, which displays table cells with a zero frequency count in the LIST output and includes them in the [OUT=](#) data set. See the description of the [ZEROS](#) option for more information.

The NOSPARSE option also suppresses the display of variable levels with zero frequency in [CROSSLIST](#) tables. By default for CROSSLIST tables, PROC FREQ displays all levels of the column variable within each level of the row variable, including any column variable levels with zero frequency for that row. For multiway tables displayed with the CROSSLIST option, the procedure displays all levels of the row variable for each stratum of the table by default, including any row variable levels with zero frequency for the stratum.

**NOWARN**

suppresses the log warning message about the validity of the asymptotic Pearson chi-square test. By default, PROC FREQ provides a warning about the validity of the asymptotic Pearson chi-square test when more than 20 cells have expected frequencies that are less than 5. This warning message appears in the log if you specify the NOPRINT option in the PROC FREQ statement,

The NOWARN option is equivalent to the [CHISQ\(WARN=NOLOG\)](#) option. You can also use the [CHISQ\(WARN=\)](#) option to suppress the warning message in the display and to request a warning variable in the chi-square ODS output data set or in the OUTPUT data set.

**OUT=SAS-data-set**

names an output data set that contains frequency or crosstabulation table counts and percentages. If more than one table request appears in the TABLES statement, the contents of the [OUT=](#) data set correspond to the last table request in the TABLES statement. The [OUT=](#) data set variable COUNT contains the frequencies and the variable PERCENT contains the percentages. See the section “[Output Data Sets](#)” on page 2320 for details. You can specify the following options to include additional information in the [OUT=](#) data set: [OUTCUM](#), [OUTEXPECT](#), and [OUTPCT](#).

**OUTCUM**

includes cumulative frequencies and cumulative percentages in the [OUT=](#) data set for one-way tables. The variable CUM\_FREQ contains the cumulative frequencies, and the variable CUM\_PCT contains the cumulative percentages. See the section “[Output Data Sets](#)” on page 2320 for details. The OUTCUM option has no effect for two-way or multiway tables.

**OUTEXPECT**

includes expected cell frequencies in the **OUT=** data set for crosstabulation tables. The variable **EXPECTED** contains the expected cell frequencies. See the section “[Output Data Sets](#)” on page 2320 for details. The **EXPECTED** option has no effect for one-way tables.

**OUTPCT**

includes the following additional variables in the **OUT=** data set for crosstabulation tables:

<b>PCT_COL</b>	percentage of column frequency
<b>PCT_ROW</b>	percentage of row frequency
<b>PCT_TABL</b>	percentage of stratum (two-way table) frequency, for $n$ -way tables where $n > 2$

See the section “[Output Data Sets](#)” on page 2320 for details. The **OUTPCT** option has no effect for one-way tables.

**PLCORR**

requests the polychoric correlation coefficient. For  $2 \times 2$  tables, this statistic is more commonly known as the tetrachoric correlation coefficient, and it is labeled as such in the displayed output. See the section “[Polychoric Correlation](#)” on page 2277 for details. Also see the descriptions of the **CONVERGE=** and **MAXITER=** options, which you can specify to control the iterative computation of the polychoric correlation coefficient.

If you omit the **MEASURES** option, the **PLCORR** option invokes **MEASURES**.

**PLOTS** < (*global-plot-options*) > < = *plot-request* < (*plot-options*) > >

**PLOTS** < (*global-plot-options*) >

< = (*plot-request* < (*plot-options*) > < ... *plot-request* < (*plot-options*) > > ) >

controls the plots that are produced through ODS Graphics. *Plot-requests* identify the plots, and *plot-options* control the appearance and content of the plots. You can specify *plot-options* in parentheses following a *plot-request*. A *global-plot-option* applies to all plots for which it is available, unless it is altered by a specific *plot-option*. You can specify *global-plot-options* in parentheses following the **PLOTS** option.

When you specify only one *plot-request*, you can omit the parentheses around the request. For example:

```
plots=all
plots=freqplot
plots=(freqplot oddsratioplot)
plots(only)=(cumfreqplot deviationplot)
```

For information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” You must enable ODS Graphics before requesting plots, as shown in the following example:

```
ods graphics on;
proc freq;
  tables treatment*response / chisq plots=freqplot;
  weight wt;
run;
ods graphics off;
```

The PLOTS= option has no effect when you specify the **NOPRINT** option in the PROC FREQ statement.

If you have enabled ODS Graphics but do not specify the PLOTS= option, then PROC FREQ produces all plots that are associated with the analyses that you request in the TABLES statement.

Table 35.11 lists the available *plot-requests*, together with their *plot-options* and required TABLES statement options.

**Table 35.11** PLOTS= Options

<i>Plot-Request</i>	<i>Plot-Options</i>	<b>Required TABLES Statement Option</b>
CUMFREQPLOT	ORIENT= SCALE= TYPE=	One-way table request
DEVIATIONPLOT	NOSTAT ORIENT= TYPE=	CHISQ (one-way table)
FREQPLOT	ORIENT= SCALE= TYPE=	Any table request
FREQPLOT	NPANELPOS= TWOWAY=	Two-way or multiway table
KAPPAPLOT	NPANELPOS= ORDER= RANGE= STATS	AGREE ( $h \times r \times r$ table)
ODDSRATIOPLOT	EXACT* LOGBASE= NPANELPOS= ORDER= RANGE= STATS	MEASURES or RELRISK ( $h \times 2 \times 2$ table)
RELRISKPLOT	LOGBASE= NPANELPOS= ORDER= RANGE= STATS	MEASURES or RELRISK ( $h \times 2 \times 2$ table)
RISKDIFFPLOT	EXACT* NPANELPOS= ORDER= RANGE= STATS	RISKDIFF ( $h \times 2 \times 2$ table)

\* Also requires EXACT statement

**Table 35.11** *continued*

<i>Plot-Request</i>	<i>Plot-Options</i>	<b>Required TABLES Statement Option</b>
WTKAPPAPLOT	NPANELPOS= ORDER= RANGE= STATS	AGREE ( $h \times r \times r$ table, $r > 2$ )

***Global-Plot-Options***

A *global-plot-option* applies to all plots for which the option is available, unless it is altered by a specific *plot-option*. You can specify *global-plot-options* in parentheses following the PLOTS option.

The following specific *plot-options* are available as *global-plot-options*: COLUMN=, EXACT, LOGBASE=, NPANELPOS=, ORDER=, ORIENT=, RANGE=, SCALE=, STATS, and TYPE=. These *plot-options* are described in the section “Plot-Options.” Additionally, you can specify the following *global-plot-option* in parentheses following the PLOTS option:

**ONLY**

suppresses the default plots and requests only the plots that are specified as *plot-requests*.

***Plot-Requests***

The following *plot-requests* are available with the PLOTS= option:

**ALL**

requests all plots that are associated with the specified analyses. This is the default if you do not specify the PLOTS(ONLY) option.

**CUMFREQPLOT < ( *plot-options* ) >**

requests a plot of cumulative frequencies. Cumulative frequency plots are available for one-way frequency tables. The following *plot-options* are available for CUMFREQPLOT: ORIENT=, SCALE=, and TYPE=.

**DEVIATIONPLOT < ( *plot-options* ) >**

requests a plot of relative deviations from expected frequencies. Deviation plots are available for one-way frequency tables. To produce a deviation plot, you must also specify the CHISQ option in the TABLES statement. The following *plot-options* are available for DEVIATIONPLOT: NOSTAT, ORIENT= and TYPE=.

**FREQPLOT < ( *plot-options* ) >**

requests a frequency plot. Frequency plots are available for frequency and crosstabulation tables. For multiway tables, PROC FREQ provides a two-way frequency plot for each stratum.

The following *plot-options* are available for FREQPLOT for all tables: ORIENT=, SCALE=, and TYPE=. Additionally, the TWOWAY= and NPANELPOS= *plot-options* are available for two-way and multiway tables. You can use the TWOWAY= *plot-option* to specify the layout of a two-way frequency plot. The NPANELPOS= *plot-option* is not available with the TWOWAY=STACKED layout.

**KAPPAPLOT** < ( *plot-options* ) >

requests a plot of kappa statistics and confidence limits. Kappa plots are available for multiway square tables. To produce a kappa plot, you must also specify the AGREE option in the TABLES statement. The following *plot-options* are available for KAPPAPLOT: NPANELPOS=, ORDER=, RANGE=, and STATS.

**NONE**

suppresses all plots.

**ODDSRATIOPLOT** < ( *plot-options* ) >

requests a plot of odds ratios with confidence limits. Odds ratio plots are available for multiway  $2 \times 2$  tables. To produce an odds ratio plot, you must also specify the MEASURES or RELRISK option in the TABLES statement. The following *plot-options* are available for ODDSRATIOPLOT: EXACT, LOGBASE=, NPANELPOS=, ORDER=, RANGE=, and STATS. If you request a plot of exact confidence limits by specifying the EXACT *plot-option*, you must also request computation of exact confidence limits by specifying the **EXACT** statement.

**RELRISKPLOT** < ( *plot-options* ) >

requests a plot of relative risks with confidence limits. Relative risk plots are available for multiway  $2 \times 2$  tables. To produce a relative risk plot, you must also specify the MEASURES or RELRISK option in the TABLES statement. The following *plot-options* are available for RELRISKPLOT: COLUMN=, LOGBASE=, NPANELPOS=, ORDER=, RANGE=, and STATS.

**RISKDIFFPLOT** < ( *plot-options* ) >

requests a plot of risk (proportion) differences with confidence limits. Risk difference plots are available for multiway  $2 \times 2$  tables. To produce a risk difference plot, you must also specify the RISKDIFF option in the TABLES statement. The following *plot-options* are available for RISKDIFF: COLUMN=, EXACT, NPANELPOS=, ORDER=, RANGE=, and STATS. If you request a plot of exact confidence limits by specifying the EXACT *plot-option*, you must also request computation of exact confidence limits by specifying the **EXACT** statement.

**WTKAPPAPLOT** < ( *plot-options* ) >

requests a plot of weighted kappa statistics with confidence limits. Weighted kappa plots are available for multiway square tables. To produce a weighted kappa plot, you must also specify the AGREE option in the TABLES statement. Note that simple kappa and weighted kappa statistics are the same for  $2 \times 2$  tables; therefore, the procedure does not present weighted kappa statistics for  $2 \times 2$  tables. The following *plot-options* are available for WTKAPPAPLOT: NPANELPOS=, ORDER=, RANGE=, and STATS.

**Plot-Options**

You can specify the following *plot-options* in parentheses after a *plot-request*:

**COLUMN=1 | 2**

specifies the risk column for the relative risk plot (RELRIKSPLOT) and the risk difference plot (RISKDIFFPLOT). If you specify the COLUMN=1 *plot-option*, then the plot displays the column 1 risk differences or the column 1 relative risks. Similarly, COLUMN=2 displays the column 2 risk differences or relative risks. The default is COLUMN=1.

**EXACT**

requests exact confidence limits instead of asymptotic confidence limits in the odds ratio plot (ODDSRATIOPLOT) and the risk difference plot (RISKDIFFPLOT). If you specify the EXACT *plot-option*, you must also request computation of the exact confidence limits by specifying the EXACT statement.

**LOGBASE=2 | E | 10**

applies to the odds ratio plot (ODDSRATIOPLOT) and the relative risk plot (RELRIKSPLOT). The LOGBASE= *plot-option* displays the odds ratio or relative risk axis on the specified log scale.

**NOSTAT**

applies to the deviation plot (DEVIATIONPLOT). The NOSTAT *plot-option* suppresses the chi-square *p*-value that is displayed by default in the deviation plot.

**NPANELPOS=*n***

applies to the following plots: FREQPLOT (for two-way and multiway tables), KAPPAPLOT, ODDSRATIOPLOT, RELRIKSPLOT, RISKDIFFPLOT, and WTKAPPAPLOT.

The NPANELPOS= *plot-option* divides the plot into multiple panels that display at most  $|n|$  statistics per panel. If *n* is positive, the number of statistics per panel is balanced; but if *n* is negative, the number of statistics per panel is not balanced. By default,  $n = 0$  and all statistics are displayed in a single plot. For example, suppose you want to display 21 odds ratios. Then NPANELPOS=20 displays two panels, the first with 11 odds ratios and the second with 10; NPANELPOS=-20 displays 20 odds ratios in the first panel but only one in the second.

For two-way frequency plots, NPANELPOS= divides the plot into multiple panels that display at most  $|n|$  levels of the row variable per panel. The NPANELPOS= *plot-option* applies to two-way plots that are displayed with grouped layout, which you specify with the TWOWAY=GROUPVERTICAL or TWOWAY=GROUPHORIZONTAL *plot-option*. The NPANELPOS= *plot-option* does not apply to the TWOWAY=STACKED layout.

**ORDER=ASCENDING | DESCENDING**

displays the statistics in sorted order. By default, the statistics are displayed in the order in which the corresponding strata appear in the multiway table display. The ORDER= *plot-option* applies to the following plots: KAPPAPLOT, ODDSRATIOPLOT, RELRIKSPLOT, RISKDIFFPLOT, and WTKAPPAPLOT.

**ORIENT=HORIZONTAL | VERTICAL**

controls the orientation of the plot. The **ORIENT=** *plot-option* applies to the following plots: CUMFREQPLOT, DEVIATIONPLOT, and FREQPLOT.

**ORIENT=HORIZONTAL** places the variable levels on the Y axis and the frequencies, percentages, or statistic-values on the X axis. **ORIENT=VERTICAL** places the variable levels on the X axis. The default orientation is **ORIENT=VERTICAL** for bar charts (**TYPE=BAR**) and **ORIENT=HORIZONTAL** for dot plots (**TYPE=DOT**).

**RANGE= ( < min> < ,max> ) | CLIP**

specifies the range of values to display. The **RANGE=** *plot-option* applies to the following plots: KAPPAPLOT, ODDSRATIO PLOT, RELRISK PLOT, RISKDIFF PLOT, and WTKAPPAPLOT. If you specify **RANGE=CLIP**, the confidence limits are clipped and the display range is determined by the minimum and maximum values of the estimates. By default, the display range includes all confidence limits.

**SCALE=FREQ | LOG | PERCENT | SQRT**

specifies the scale of the frequencies to display. The **SCALE=** *plot-option* applies to the frequency plot (FREQPLOT) and the cumulative frequency plot (CUMFREQPLOT).

The default is **SCALE=FREQ**, which displays unscaled frequencies. **SCALE=LOG** displays log (base 10) frequencies. **SCALE=PERCENT** displays percentages (relative frequencies). **SCALE=SQRT** displays square roots of the frequencies, which produces a plot known as a *rootogram*.

**STATS**

displays the values of the statistics and their confidence limits on the right side of the plot. If you do not request the **STATS** *plot-option*, the statistic values are not displayed. The **STATS** *plot-option* applies to the following plots: KAPPAPLOT, ODDSRATIO PLOT, RELRISK PLOT, RISKDIFF PLOT, and WTKAPPAPLOT.

**TWOWAY=GROUPVERTICAL | GROUPTHORIZONTAL | STACKED**

specifies the layout for a two-way frequency plot (FREQPLOT). The **TWOWAY=** *plot-option* applies to frequency plots for two-way and multiway table requests; PROC FREQ produces a two-way frequency plot for each stratum of a multiway table request.

**TWOWAY=GROUPVERTICAL** produces a grouped plot with a vertical common baseline. The plot is grouped by the row variable, which is the first variable that you specify in a two-way table request. **TWOWAY=GROUPTHORIZONTAL** produces a grouped plot with a horizontal common baseline.

**TWOWAY=STACKED** produces stacked frequency plots for two-way tables. In a stacked bar chart, the bars correspond to the column variable values, and the row frequencies are stacked within each column. In a stacked dot plot, the dotted lines correspond to the columns, and the row frequencies within columns are plotted as data dots on the same column line.

The default two-way layout is **TWOWAY=GROUPVERTICAL**. The **ORIENT=**, **SCALE=**, and **TYPE=** *plot-options* are available for each **TWOWAY=** layout.

**TYPE=BARCHART | DOTPLOT**

specifies the plot type for frequency (FREQPLOT), cumulative frequency (CUMFREQPLOT), and deviation plots (DEVIATIONPLOT). TYPE=BARCHART produces a bar chart, and TYPE=DOTPLOT produces a dot plot. The default is TYPE=BARCHART.

**PRINTKWT**

displays the weights that PROC FREQ uses to compute the weighted kappa coefficient. You must also specify the [AGREE](#) option to request the weighted kappa coefficient. You can specify (WT=FC) with the AGREE option to request Fleiss-Cohen weights. By default, PROC FREQ uses Cicchetti-Allison weights to compute the weighted kappa coefficient. See the section “[Weighted Kappa Coefficient](#)” on page 2301 for details.

**RELRISK**

requests relative risk measures and their confidence limits for  $2 \times 2$  tables. These measures include the odds ratio and the column 1 and 2 relative risks. See the section “[Odds Ratio and Relative Risks for 2 x 2 Tables](#)” on page 2294 for details.

You can also obtain the RELRISK measures by specifying the [MEASURES](#) option, which produces other measures of association in addition to the relative risks.

You can request exact confidence limits for the odds ratio by specifying the OR option in the EXACT statement.

**RISKDIFF <(riskdiff-options)>**

requests risks, or binomial proportions, for  $2 \times 2$  tables. For column 1 and column 2, PROC FREQ computes the row 1 risk, row 2 risk, total risk, and risk difference (row 1 – row 2), together with their asymptotic standard errors and asymptotic (Wald) confidence limits. PROC FREQ also provides exact (Clopper-Pearson) confidence limits for the row 1, row 2, and total risks. The [ALPHA=](#) option determines the confidence level, and the default of ALPHA=0.05 produces 95% confidence limits. See the section “[Risks and Risk Differences](#)” on page 2287 for details.

You can specify *riskdiff-options* inside the parentheses following the RISKDIFF option to request tests of noninferiority, superiority, and equivalence for the risk difference. Available test methods include Farrington-Manning, Hauck-Anderson, and Newcombe score (Wilson), in addition to the Wald test. [Table 35.12](#) summarizes the *riskdiff-options*.

You can request exact unconditional confidence limits for the risk difference by specifying the RISKDIFF option in the [EXACT](#) statement. See the section “[Exact Unconditional Confidence Limits for the Risk Difference](#)” on page 2293 for more information.

**Table 35.12** RISKDIFF (Proportion Difference) Options

Task	<i>Riskdiff-Option</i>
Specify the column	COLUMN=1   2
Request a continuity correction	CORRECT
Request tests	EQUAL EQUIV   EQUIVALENCE NONINF   NONINFERIORITY SUP   SUPERIORITY
Specify the test method	METHOD=
Specify the test margin	MARGIN=
Specify the test variance	VAR=SAMPLE   NULL

You can specify the following *riskdiff-options* inside parentheses following the RISKDIFF option.

**COLUMN=1 | 2 | BOTH**

specifies the table column for which to compute the risk difference tests of noninferiority, superiority, or equivalence, which you request with the **NONINF**, **SUP**, and **EQUIV** riskdiff-options, respectively. You can specify COLUMN=1, COLUMN=2, or COLUMN=BOTH. If you do not specify the COLUMN= option, PROC FREQ computes the risk difference tests for column 1. The COLUMN= option has no effect on the table of risk estimates and confidence limits or on the equality test; PROC FREQ computes these statistics for both column 1 and column 2.

**CORRECT**

includes a continuity correction in the asymptotic Wald confidence limits and tests. The CORRECT riskdiff-option also includes a continuity correction in the Newcombe score confidence limits, which you request with the **METHOD=SCORE** riskdiff-option. **METHOD=HA** and **METHOD=FM** do not use continuity corrections. The CORRECT riskdiff-option has the same effect as the **RISKDIFFC** option.

**EQUAL**

requests a test of the null hypothesis that the risk difference equals zero. PROC FREQ provides an asymptotic Wald test of equality. See the section “Equality Test” on page 2289 for details. You can specify the test variance type with the **VAR=** riskdiff-option.

**EQUIV | EQUIVALENCE**

requests a test of equivalence for the risk difference. See the section “Equivalence Tests” on page 2292 for details. You can specify the equivalence test margins with the **MARGIN=** riskdiff-option and the test method with the **METHOD=** riskdiff-option. PROC FREQ uses **METHOD=WALD** by default.

**MARGIN=value | (lower,upper)**

specifies the margin for the noninferiority, superiority, and equivalence tests, which you request with the **NONINF**, **SUP**, and **EQUIV** riskdiff-options, respectively. If you do not specify MARGIN=, PROC FREQ uses a margin of 0.2 by default.

For noninferiority and superiority tests, specify a single *value* for the `MARGIN=` riskdiff-option. The `MARGIN= value` must be a positive number. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC FREQ converts that number to a proportion. The procedure treats the value 1 as 1%.

For an equivalence test, you can specify a single `MARGIN= value`, or you can specify both *lower* and *upper* values. If you specify a single `MARGIN= value`, it must be a positive number, as described previously. If you specify a single `MARGIN= value` for an equivalence test, PROC FREQ uses  $-value$  as the lower margin and *value* as the upper margin for the test. If you specify both *lower* and *upper* values for an equivalence test, you can specify them in proportion form as numbers between  $-1$  or  $1$ . Or you can specify them in percentage form as numbers between  $-100$  and  $100$ , and PROC FREQ converts the numbers to proportions. The value of *lower* must be less than the value of *upper*.

#### **METHOD=method**

specifies the method for the noninferiority, superiority, and equivalence tests, which you request with the `NONINF`, `SUP`, and `EQUIV` riskdiff-options, respectively. The following methods are available:

FM	Farrington-Manning
HA	Hauck-Anderson
SCORE   NEWCOMBE   WILSON	Newcombe score (Wilson)
WALD	Wald

The default is `METHOD=WALD`. See the section “[Noninferiority Test](#)” on page 2289 for descriptions of these methods.

For `METHOD=SCORE` and `METHOD=WALD`, you can request a continuity correction with the `CORRECT` riskdiff-option. For `METHOD=WALD`, you can specify the variance type with the `VAR=` riskdiff-option.

#### **NONINF | NONINFERIORITY**

requests a test of noninferiority for the risk difference. See the section “[Noninferiority Test](#)” on page 2289 for details. You can specify the test margin with the `MARGIN=` riskdiff-option and the test method with the `METHOD=` riskdiff-option. PROC FREQ uses `METHOD=WALD` by default.

#### **SUP | SUPERIORITY**

requests a test of superiority for the binomial proportion. See the section “[Superiority Test](#)” on page 2292 for details. You can specify the test margin with the `MARGIN=` riskdiff-option and the test method with the `METHOD=` riskdiff-option. PROC FREQ uses `METHOD=WALD` by default.

#### **VAR=SAMPLE | NULL**

specifies the type of variance estimate to use for the Wald tests of noninferiority, superiority, equivalence, and equality. The default is `VAR=SAMPLE`, which estimates the variance from the sample proportions. `VAR=NULL` uses the null hypothesis values to compute the variance. See the sections “[Equality Test](#)” on page 2289 and “[Noninferiority Test](#)” on page 2289 for details.

**RISKDIFFC** <(*riskdiff-options*)>

requests the **RISKDIFF** option statistics for  $2 \times 2$  tables and includes a continuity correction in the asymptotic Wald confidence limits and tests.

The **RISKDIFF** option statistics include risks, or binomial proportions, for  $2 \times 2$  tables. For column 1 and column 2, PROC FREQ computes the row 1 risk, row 2 risk, total risk, and risk difference (row 1 – row 2), together with their asymptotic standard errors and asymptotic (Wald) confidence limits. PROC FREQ also provides exact (Clopper-Pearson) confidence limits for the row 1, row 2, and total risks. See the section “[Risks and Risk Differences](#)” on page 2287 for details.

You can request additional tests and statistics for the risk difference by specifying *riskdiff-options* in parentheses after **RISKDIFFC**. The *riskdiff-options* are the same as those available with **RISKDIFF**. See the description of the **RISKDIFF** option for details.

You can request exact unconditional confidence limits for the risk difference by specifying the **RISKDIFF** option in the **EXACT** statement. See the section “[Exact Unconditional Confidence Limits for the Risk Difference](#)” on page 2293 for more information.

**SCORES=***type*

specifies the type of row and column scores that PROC FREQ uses to compute the following statistics: Mantel-Haenszel chi-square, Pearson correlation, Cochran-Armitage test for trend, weighted kappa coefficient, and Cochran-Mantel-Haenszel statistics. The value of *type* can be one of the following:

- MODRIDIT
- RANK
- RIDIT
- TABLE

See the section “[Scores](#)” on page 2265 for descriptions of these score types.

If you do not specify the **SCORES=** option, PROC FREQ uses **SCORES=TABLE** by default. For character variables, the row and column **TABLE** scores are the row and column numbers. That is, the **TABLE** score is 1 for row 1, 2 for row 2, and so on. For numeric variables, the row and column **TABLE** scores equal the variable values. See the section “[Scores](#)” on page 2265 for details. Using **MODRIDIT**, **RANK**, or **RIDIT** scores yields nonparametric analyses.

You can use the **SCOROUT** option to display the row and column scores.

**SCOROUT**

displays the row and column scores that PROC FREQ uses to compute score-based tests and statistics. You can specify the score type with the **SCORES=** option. See the section “[Scores](#)” on page 2265 for details.

The scores are computed and displayed only when PROC FREQ computes statistics for two-way tables. You can use ODS to store the scores in an output data set. See the section “[ODS Table Names](#)” on page 2331 for more information.

**SPARSE**

reports all possible combinations of the variable values for an  $n$ -way table when  $n > 1$ , even if a combination does not occur in the data. The SPARSE option applies only to crosstabulation tables displayed in LIST format and to the OUT= output data set. If you do not use the LIST or OUT= option, the SPARSE option has no effect.

When you specify the SPARSE and LIST options, PROC FREQ displays all combinations of variable values in the table listing, including those with a frequency count of zero. By default, without the SPARSE option, PROC FREQ does not display zero-frequency levels in LIST output. When you use the SPARSE and OUT= options, PROC FREQ includes empty crosstabulation table cells in the output data set. By default, PROC FREQ does not include zero-frequency table cells in the output data set.

See the section “[Missing Values](#)” on page 2261 for more information.

**TESTF=(values)**

specifies the null hypothesis frequencies for a one-way chi-square goodness-of-fit test, which you request with the CHISQ option. See the section “[Chi-Square Test for One-Way Tables](#)” on page 2266 for details.

You can separate the TESTF= *values* with blanks or commas. The number of *values* must equal the number of variable levels in the one-way table. The sum of the *values* must equal the total frequency for the one-way table. List the *values* in the order in which the corresponding variable levels appear in the output. If you omit the CHISQ option, the TESTF= option invokes CHISQ.

**TESTP=(values)**

specifies the null hypothesis proportions for a one-way chi-square goodness-of-fit test, which you request with the CHISQ option. See the section “[Chi-Square Test for One-Way Tables](#)” on page 2266 for details.

You can separate the TESTP= *values* with blanks or commas. The number of *values* must equal the number of variable levels in the one-way table. List the *values* in the order in which the corresponding variable levels appear in the output. You can specify *values* in probability form as numbers between 0 and 1, where the proportions sum to 1. Or you can specify *values* in percentage form as numbers between 0 and 100, where the percentages sum to 100. If you omit the CHISQ option, the TESTP= option invokes CHISQ.

**TOTPCT**

displays the percentage of the total multiway table frequency in crosstabulation tables for  $n$ -way tables, where  $n > 2$ . By default, PROC FREQ displays the percentage of the individual two-way table frequency but does not display the percentage of the total frequency for multiway crosstabulation tables. See the section “[Multiway Tables](#)” on page 2324 for more information.

The percentage of total multiway table frequency is displayed by default when you specify the LIST option. It is also provided by default in the PERCENT variable in the OUT= output data set.

**TREND**

requests the Cochran-Armitage test for trend. The table must be  $2 \times C$  or  $R \times 2$  to compute the trend test. See the section “[Cochran-Armitage Test for Trend](#)” on page 2296 for details.

## TEST Statement

### TEST options ;

The TEST statement requests asymptotic tests for measures of association and measures of agreement. You must use a **TABLES** statement with the TEST statement.

#### options

specify the statistics for which to provide asymptotic tests. [Table 35.13](#) lists the available statistics, which include measures of association and agreement. The option names are identical to those in the **TABLES** and **OUTPUT** statements. You can request all tests for groups of statistics by using group options **MEASURES** or **AGREE**. Or you can request tests individually by using the options shown in [Table 35.13](#).

For each measure of association or agreement that you specify, PROC FREQ provides an asymptotic test that the measure equals zero. PROC FREQ displays the asymptotic standard error under the null hypothesis, the test statistic, and the  $p$ -values. Additionally, PROC FREQ reports the confidence limits for the measure. The **ALPHA=** option in the **TABLES** statement determines the confidence level, which by default equals 0.05 and provides 95% confidence limits. See the sections “[Asymptotic Tests](#)” on page 2271 and “[Confidence Limits](#)” on page 2271 for details. Also see the section “[Statistical Computations](#)” on page 2264 for information about individual measures.

You can request exact tests for selected measures of association and agreement by using the **EXACT** statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

If you use only one **TABLES** statement, you do not need to specify the same options in both the **TABLES** and **TEST** statements; when you specify an option in the **TEST** statement, PROC FREQ automatically invokes the corresponding **TABLES** statement option. However, when you use the **TEST** statement with multiple **TABLES** statements, you must specify options in the **TABLES** statements to request the desired statistics. PROC FREQ then provides asymptotic tests for those statistics that you also specify in the **TEST** statement.

**Table 35.13** TEST Statement Options

Option	Asymptotic Tests Computed	Required TABLES Statement Option
AGREE	simple and weighted kappa coefficients	AGREE
GAMMA	gamma	ALL or MEASURES
KAPPA	simple kappa coefficient	AGREE
KENTB	Kendall's tau- $b$	ALL or MEASURES
MEASURES	gamma, Kendall's tau- $b$ , Stuart's tau- $c$ , Somers' $D(C R)$ , Somers' $D(R C)$ , Pearson and Spearman correlations	ALL or MEASURES
PCORR	Pearson correlation coefficient	ALL or MEASURES
SCORR	Spearman correlation coefficient	ALL or MEASURES
SMDCR	Somers' $D(C R)$	ALL or MEASURES
SMDRC	Somers' $D(R C)$	ALL or MEASURES
STUTC	Stuart's tau- $c$	ALL or MEASURES
WTKAP	weighted kappa coefficient	AGREE

---

## WEIGHT Statement

**WEIGHT** *variable* *</option>* ;

The WEIGHT statement names a numeric variable that provides a weight for each observation in the input data set. The WEIGHT statement is most commonly used to input cell count data. See the section “[Inputting Frequency Counts](#)” on page 2259 for more information. If you use a WEIGHT statement, PROC FREQ assumes that an observation represents  $n$  observations, where  $n$  is the value of *variable*. The value of the WEIGHT *variable* is not required to be an integer.

If the value of the WEIGHT *variable* is missing, PROC FREQ does not use that observation in the analysis. If the value of the WEIGHT *variable* is zero, PROC FREQ ignores the observation unless you specify the ZEROS option, which includes observations with zero weights. If you do not specify a WEIGHT statement, each observation has a default weight of 1. The sum of the WEIGHT *variable* values represents the total number of observations.

If any value of the WEIGHT *variable* is negative, PROC FREQ displays the frequencies computed from the weighted values but does not compute percentages and statistics. If you create an output data set by using the [OUT=](#) option in the TABLES statement, PROC FREQ assigns missing values to the PERCENT variable. PROC FREQ also assigns missing values to the variables that the OUTEXPECT and OUTPCT options provide. If any value of the WEIGHT *variable* is negative, you cannot create an output data set by using the [OUTPUT](#) statement because statistics are not computed when there are negative weights.

You can specify the following option in the WEIGHT statement:

### ZEROS

includes observations with zero weight values. By default, PROC FREQ ignores observations with zero weights.

If you specify the ZEROS option, frequency and crosstabulation tables display any levels corresponding to observations with zero weights. Without the ZEROS option, PROC FREQ does not process observations with zero weights, and so does not display levels that contain only observations with zero weights.

With the ZEROS option, PROC FREQ includes levels with zero weights in the chi-square goodness-of-fit test for one-way tables. Also, PROC FREQ includes any levels with zero weights in binomial computations for one-way tables. This makes it possible to compute binomial tests and estimates when the specified level contains no observations with positive weights.

For two-way tables, the ZEROS option enables computation of kappa statistics when there are levels that contain no observations with positive weight. For more information, see the section “[Tables with Zero Rows and Columns](#)” on page 2304.

Note that even with the ZEROS option, PROC FREQ does not compute the [CHISQ](#) or [MEASURES](#) statistics for two-way tables when the table has a zero row or zero column because most of these statistics are undefined in this case.

The ZEROS option invokes the [SPARSE](#) option in the TABLES statement, which includes

table cells with a zero frequency count in the **LIST** output and in the **OUT=** data set. By default, without the **SPARSE** option, PROC FREQ does not include zero frequency cells in the **LIST** output or in the **OUT=** data set. If you specify the **ZEROS** option in the **WEIGHT** statement but do not want the **SPARSE** option, you can specify the **NOSPARSE** option in the **TABLES** statement.

---

## Details: FREQ Procedure

---

### Inputting Frequency Counts

---

PROC FREQ can use either raw data or cell count data to produce frequency and crosstabulation tables. *Raw data*, also known as case-record data, report the data as one record for each subject or sample member. *Cell count data* report the data as a table, listing all possible combinations of data values along with the frequency counts. This way of presenting data often appears in published results.

The following DATA step statements store raw data in a SAS data set:

```
data Raw;
  input Subject $ R C @@;
  datalines;
01 1 1 02 1 1 03 1 1 04 1 1 05 1 1
06 1 2 07 1 2 08 1 2 09 2 1 10 2 1
11 2 1 12 2 1 13 2 2 14 2 2 14 2 2
;
```

You can store the same data as cell counts by using the following DATA step statements:

```
data CellCounts;
  input R C Count @@;
  datalines;
1 1 5 1 2 3
2 1 4 2 2 3
;
```

The variable **R** contains the values for the rows, and the variable **C** contains the values for the columns. The variable **Count** contains the cell count for each row and column combination.

Both the **Raw** data set and the **CellCounts** data set produce identical frequency counts, two-way tables, and statistics. When using the **CellCounts** data set, you must include a **WEIGHT** statement to specify that the variable **Count** contains cell counts. For example, the following PROC FREQ statements create a two-way crosstabulation table by using the **CellCounts** data set:

```
proc freq data=CellCounts;
  tables R*C;
  weight Count;
run;
```

## Grouping with Formats

PROC FREQ groups a variable's values according to its formatted values. If you assign a format to a variable with a FORMAT statement, PROC FREQ formats the variable values before dividing observations into the levels of a frequency or crosstabulation table.

For example, suppose that variable X has the values 1.1, 1.4, 1.7, 2.1, and 2.3. Each of these values appears as a level in the frequency table. If you decide to round each value to a single digit, include the following statement in the PROC FREQ step:

```
format X 1.;
```

Now the table lists the frequency count for formatted level 1 as two and for formatted level 2 as three.

PROC FREQ treats formatted character variables in the same way. The formatted values are used to group the observations into the levels of a frequency table or crosstabulation table. PROC FREQ uses the entire value of a character format to classify an observation.

You can also use the FORMAT statement to assign formats that were created with the FORMAT procedure to the variables. User-written formats determine the number of levels for a variable and provide labels for a table. If you use the same data with different formats, then you can produce frequency counts and statistics for different classifications of the variable values.

When you use PROC FORMAT to create a user-written format that combines missing and nonmissing values into one category, PROC FREQ treats the entire category of formatted values as missing. For example, a questionnaire codes 1 as yes, 2 as no, and 8 as a no answer. The following PROC FORMAT statements create a user-written format:

```
proc format;
  value Questfmt 1   ='Yes'
                2   ='No'
                8,. ='Missing';
run;
```

When you use a FORMAT statement to assign Questfmt. to a variable, the variable's frequency table no longer includes a frequency count for the response of 8. You must use the MISSING or MISSPRINT option in the TABLES statement to list the frequency for no answer. The frequency count for this level includes observations with either a value of 8 or a missing value (.).

The frequency or crosstabulation table lists the values of both character and numeric variables in ascending order based on internal (unformatted) variable values unless you change the order with the ORDER= option. To list the values in ascending order by formatted values, use ORDER=FORMATTED in the PROC FREQ statement.

For more information about the FORMAT statement, see *SAS Language Reference: Concepts*.

## Missing Values

When the value of the WEIGHT variable is missing, PROC FREQ does not include that observation in the analysis.

PROC FREQ treats missing BY variable values like any other BY variable value. The missing values form a separate BY group.

If an observation has a missing value for a variable in a TABLES request, by default PROC FREQ does not include that observation in the frequency or crosstabulation table. Also by default, PROC FREQ does not include observations with missing values in the computation of percentages and statistics. The procedure displays the number of missing observations below each table.

PROC FREQ also reports the number of missing values in output data sets. The TABLES statement OUT= data set includes an observation that contains the missing value frequency. The NMISS option in the OUTPUT statement provides an output data set variable that contains the missing value frequency.

The following options change the way in which PROC FREQ handles missing values of TABLES variables:

- MISSPRINT** displays missing value frequencies in frequency or crosstabulation tables but does not include them in computations of percentages or statistics.
- MISSING** treats missing values as a valid nonmissing level for all TABLES variables. Displays missing levels in frequency and crosstabulation tables and includes them in computations of percentages and statistics.

This example shows the three ways that PROC FREQ can handle missing values of TABLES variables. The following DATA step statements create a data set with a missing value for the variable A:

```
data one;
  input A Freq;
  datalines;
1 2
2 2
. 2
;
```

The following PROC FREQ statements request a one-way frequency table for the variable A. The first request does not specify a missing value option. The second request specifies the MISSPRINT option in the TABLES statement. The third request specifies the MISSING option in the TABLES statement.

```
proc freq data=one;
  tables A;
  weight Freq;
  title 'Default';
run;
```

```

proc freq data=one;
  tables A / missprint;
  weight Freq;
  title 'MISSPRINT Option';
run;
proc freq data=one;
  tables A / missing;
  weight Freq;
  title 'MISSING Option';
run;

```

Figure 35.11 displays the frequency tables produced by this example. The first table shows PROC FREQ's default behavior for handling missing values. The observation with a missing value of the TABLES variable A is not included in the table, and the frequency of missing values is displayed below the table. The second table, for which the MISSPRINT option is specified, displays the missing observation but does not include its frequency when computing the total frequency and percentages. The third table shows that PROC FREQ treats the missing level as a valid nonmissing level when the MISSING option is specified. The table displays the missing level, and PROC FREQ includes this level when computing frequencies and percentages.

**Figure 35.11** Missing Values in Frequency Tables

Default				
The FREQ Procedure				
A	Frequency	Percent	Cumulative Frequency	Cumulative Percent
1	2	50.00	2	50.00
2	2	50.00	4	100.00
Frequency Missing = 2				
MISSPRINT Option				
The FREQ Procedure				
A	Frequency	Percent	Cumulative Frequency	Cumulative Percent
.	2	.	.	.
1	2	50.00	2	50.00
2	2	50.00	4	100.00
Frequency Missing = 2				
MISSING Option				
The FREQ Procedure				
A	Frequency	Percent	Cumulative Frequency	Cumulative Percent
.	2	33.33	2	33.33
1	2	33.33	4	66.67
2	2	33.33	6	100.00

When a combination of variable values for a two-way table is missing, PROC FREQ assigns zero to the frequency count for the table cell. By default, PROC FREQ does not display missing combinations in LIST format. Also, PROC FREQ does not include missing combinations in the OUT= output data set by default. To include missing combinations, you can specify the SPARSE option with the LIST or OUT= option in the TABLES statement.

---

## In-Database Computation

The FREQ procedure can use in-database computation to construct frequency and crosstabulation tables when the **DATA=** input data set is stored as a table in a supported database management system (DBMS). Supported databases include Teradata, DB2 under UNIX, and Oracle. In-database computation can provide the advantages of faster processing and reduced data transfer between the database and SAS software. For information about in-database computation, see the section “In-Database Procedures” in *SAS/ACCESS 9.2 for Relational Databases: Reference*.

PROC FREQ performs in-database computation by using SQL implicit pass-through. The procedure generates SQL queries that are based on the tables that you request in the **TABLES** statement. The database executes these SQL queries to construct initial summary tables, which are then transmitted to PROC FREQ. The procedure uses this summary information to perform the remaining analyses and tasks in the usual way (out of the database). So instead of transferring the entire data set over the network between the database and SAS software, the in-database method transfers only the summary tables. This can substantially reduce processing time when the dimensions of the summary tables (in terms of rows and columns) are much smaller than the dimensions of the entire database table (in terms of individual observations). Additionally, in-database summarization uses efficient parallel processing, which can also provide performance advantages.

In-database computation is controlled by the **SQLGENERATION** option, which you can specify in either a **LIBNAME** statement or an **OPTIONS** statement. See the section “In-Database Procedures” in *SAS/ACCESS 9.2 for Relational Databases: Reference* for details about the **SQLGENERATION** option and other options that affect in-database computation. By default, PROC FREQ uses in-database computation when possible. There are no FREQ procedure options that control in-database computation.

PROC FREQ uses formatted values to group observations into the levels of frequency and crosstabulation tables. See the section “**Grouping with Formats**” on page 2260 for more information. If formats are available in the database, then in-database summarization uses the formats. If formats are not available in the database, then in-database summarization is based on the raw data values, and PROC FREQ performs the final, formatted classification (out of the database). For more information, see the section “Deploying and Using SAS Formats in Teradata” in *SAS/ACCESS 9.2 for Relational Databases: Reference*.

The order of observations is not inherently defined for DBMS tables. The following options relate to the order of observations and therefore should not be specified for PROC FREQ in-database computation:

- If you specify the **FIRSTOBS=** or **OBS=** data set option, PROC FREQ does not perform in-database computation.

- If you specify the NOTSORTED option in the BY statement, PROC FREQ in-database computation ignores it and uses the default ASCENDING order for BY variables.
- If you specify the ORDER=DATA option for input data in a DBMS table, PROC FREQ computation might produce different results for separate runs of the same analysis. In addition to determining the order of variable levels in crosstabulation table displays, the ORDER= option can also affect the values of many of the test statistics and measures that PROC FREQ computes.

---

## Statistical Computations

### Definitions and Notation

A two-way table represents the crosstabulation of row variable  $X$  and column variable  $Y$ . Let the table row values or levels be denoted by  $X_i$ ,  $i = 1, 2, \dots, R$ , and the column values by  $Y_j$ ,  $j = 1, 2, \dots, C$ . Let  $n_{ij}$  denote the frequency of the table cell in the  $i$ th row and  $j$ th column and define the following notation:

$$n_{i\cdot} = \sum_j n_{ij} \quad (\text{row totals})$$

$$n_{\cdot j} = \sum_i n_{ij} \quad (\text{column totals})$$

$$n = \sum_i \sum_j n_{ij} \quad (\text{overall total})$$

$$p_{ij} = n_{ij}/n \quad (\text{cell percentages})$$

$$p_{i\cdot} = n_{i\cdot}/n \quad (\text{row percentages of total})$$

$$p_{\cdot j} = n_{\cdot j}/n \quad (\text{column percentages of total})$$

$$R_i = \text{score for row } i$$

$$C_j = \text{score for column } j$$

$$\bar{R} = \sum_i n_{i\cdot} R_i / n \quad (\text{average row score})$$

$$\bar{C} = \sum_j n_{\cdot j} C_j / n \quad (\text{average column score})$$

$$A_{ij} = \sum_{k>i} \sum_{l>j} n_{kl} + \sum_{k<i} \sum_{l<j} n_{kl}$$

$$D_{ij} = \sum_{k>i} \sum_{l<j} n_{kl} + \sum_{k<i} \sum_{l>j} n_{kl}$$

$$P = \sum_i \sum_j n_{ij} A_{ij} \quad (\text{twice the number of concordances})$$

$$Q = \sum_i \sum_j n_{ij} D_{ij} \quad (\text{twice the number of discordances})$$

## Scores

PROC FREQ uses scores of the variable values to compute the Mantel-Haenszel chi-square, Pearson correlation, Cochran-Armitage test for trend, weighted kappa coefficient, and Cochran-Mantel-Haenszel statistics. The SCORES= option in the TABLES statement specifies the score type that PROC FREQ uses. The available score types are TABLE, RANK, RIDIT, and MODRIDIT scores. The default score type is TABLE. Using MODRIDIT, RANK, or RIDIT scores yields nonparametric analyses.

For numeric variables, table scores are the values of the row and column levels. If the row or column variable is formatted, then the table score is the internal numeric value corresponding to that level. If two or more numeric values are classified into the same formatted level, then the internal numeric value for that level is the smallest of these values. For character variables, table scores are defined as the row numbers and column numbers (that is, 1 for the first row, 2 for the second row, and so on).

Rank scores, which you request with the SCORES=RANK option, are defined as

$$R1_i = \sum_{k < i} n_{k.} + (n_{i.} + 1)/2 \quad i = 1, 2, \dots, R$$

$$C1_j = \sum_{l < j} n_{.l} + (n_{.j} + 1)/2 \quad j = 1, 2, \dots, C$$

where  $R1_i$  is the rank score of row  $i$ , and  $C1_j$  is the rank score of column  $j$ . Note that rank scores yield midranks for tied values.

Ridit scores, which you request with the SCORES=RIDIT option, are defined as rank scores standardized by the sample size (Bross 1958, Mack and Skillings 1980). Ridit scores are derived from the rank scores as

$$R2_i = R1_i/n \quad i = 1, 2, \dots, R$$

$$C2_j = C1_j/n \quad j = 1, 2, \dots, C$$

Modified ridit scores (SCORES=MODRIDIT) represent the expected values of the order statistics of the uniform distribution on (0,1) (van Elteren 1960, Lehmann 1975). Modified ridit scores are derived from rank scores as

$$R3_i = R1_i/(n + 1) \quad i = 1, 2, \dots, R$$

$$C3_j = C1_j/(n + 1) \quad j = 1, 2, \dots, C$$

## Chi-Square Tests and Statistics

The CHISQ option provides chi-square tests of homogeneity or independence and measures of association based on the chi-square statistic. When you specify the CHISQ option in the TABLES statement, PROC FREQ computes the following chi-square tests for each two-way table: the Pearson chi-square, likelihood-ratio chi-square, and Mantel-Haenszel chi-square. PROC FREQ provides the following measures of association based on the Pearson chi-square statistic: the phi coefficient, contingency coefficient, and Cramer's  $V$ . For  $2 \times 2$  tables, the CHISQ option also provides Fisher's exact test and the continuity-adjusted chi-square. You can request Fisher's exact test for general  $R \times C$  tables by specifying the FISHER option in the TABLES or EXACT statement.

For one-way frequency tables, the CHISQ option provides a chi-square goodness-of-fit test. The other chi-square tests and statistics described in this section are computed only for two-way tables.

All of the two-way test statistics described in this section test the null hypothesis of no association between the row variable and the column variable. When the sample size  $n$  is large, these test statistics have an asymptotic chi-square distribution when the null hypothesis is true. When the sample size is not large, exact tests might be useful. PROC FREQ provides exact tests for the Pearson chi-square, the likelihood-ratio chi-square, and the Mantel-Haenszel chi-square (in addition to Fisher's exact test). PROC FREQ also provides an exact chi-square goodness-of-fit test for one-way tables. You can request these exact tests by specifying the corresponding options in the EXACT statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

Note that the Mantel-Haenszel chi-square statistic is appropriate only when both variables lie on an ordinal scale. The other chi-square tests and statistics in this section are appropriate for either nominal or ordinal variables. The following sections give the formulas that PROC FREQ uses to compute the chi-square tests and statistics. See Agresti (2007), Stokes, Davis, and Koch (2000), and the other references cited for each statistic for more information.

### **Chi-Square Test for One-Way Tables**

For one-way frequency tables, the CHISQ option in the TABLES statement provides a chi-square goodness-of-fit test. Let  $C$  denote the number of classes, or levels, in the one-way table. Let  $f_i$  denote the frequency of class  $i$  (or the number of observations in class  $i$ ) for  $i = 1, 2, \dots, C$ . Then PROC FREQ computes the one-way chi-square statistic as

$$Q_P = \sum_{i=1}^C \frac{(f_i - e_i)^2}{e_i}$$

where  $e_i$  is the expected frequency for class  $i$  under the null hypothesis.

In the test for equal proportions, which is the default for the CHISQ option, the null hypothesis specifies equal proportions of the total sample size for each class. Under this null hypothesis, the expected frequency for each class equals the total sample size divided by the number of classes,

$$e_i = n/C \quad \text{for } i = 1, 2, \dots, C$$

In the test for specified frequencies, which PROC FREQ computes when you input null hypothesis frequencies by using the TESTF= option, the expected frequencies are the TESTF= values that you specify. In the test for specified proportions, which PROC FREQ computes when you input null hypothesis proportions by using the TESTP= option, the expected frequencies are determined from the specified TESTP= proportions  $p_i$  as

$$e_i = p_i \times n \quad \text{for } i = 1, 2, \dots, C$$

Under the null hypothesis (of equal proportions, specified frequencies, or specified proportions),  $Q_P$  has an asymptotic chi-square distribution with  $C - 1$  degrees of freedom.

In addition to the asymptotic test, you can request an exact one-way chi-square test by specifying the CHISQ option in the EXACT statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

### **Pearson Chi-Square Test for Two-Way Tables**

The Pearson chi-square for two-way tables involves the differences between the observed and expected frequencies, where the expected frequencies are computed under the null hypothesis of independence. The Pearson chi-square statistic is computed as

$$Q_P = \sum_i \sum_j \frac{(n_{ij} - e_{ij})^2}{e_{ij}}$$

where  $n_{ij}$  is the observed frequency in table cell  $(i, j)$  and  $e_{ij}$  is the expected frequency for table cell  $(i, j)$ . The expected frequency is computed under the null hypothesis that the row and column variables are independent,

$$e_{ij} = \frac{n_{i \cdot} \cdot n_{\cdot j}}{n}$$

When the row and column variables are independent,  $Q_P$  has an asymptotic chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom. For large values of  $Q_P$ , this test rejects the null hypothesis in favor of the alternative hypothesis of general association.

In addition to the asymptotic test, you can request an exact Pearson chi-square test by specifying the PCHI or CHISQ option in the EXACT statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

For  $2 \times 2$  tables, the Pearson chi-square is also appropriate for testing the equality of two binomial proportions. For  $R \times 2$  and  $2 \times C$  tables, the Pearson chi-square tests the homogeneity of proportions. See Fienberg (1980) for details.

### **Likelihood-Ratio Chi-Square Test**

The likelihood-ratio chi-square involves the ratios between the observed and expected frequencies. The likelihood-ratio chi-square statistic is computed as

$$G^2 = 2 \sum_i \sum_j n_{ij} \ln \left( \frac{n_{ij}}{e_{ij}} \right)$$

where  $n_{ij}$  is the observed frequency in table cell  $(i, j)$  and  $e_{ij}$  is the expected frequency for table cell  $(i, j)$ .

When the row and column variables are independent,  $G^2$  has an asymptotic chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom.

In addition to the asymptotic test, you can request an exact likelihood-ratio chi-square test by specifying the LRCHI or CHISQ option in the EXACT statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

### **Continuity-Adjusted Chi-Square Test**

The continuity-adjusted chi-square for  $2 \times 2$  tables is similar to the Pearson chi-square, but it is adjusted for the continuity of the chi-square distribution. The continuity-adjusted chi-square is most

useful for small sample sizes. The use of the continuity adjustment is somewhat controversial; this chi-square test is more conservative (and more like Fisher's exact test) when the sample size is small. As the sample size increases, the continuity-adjusted chi-square becomes more like the Pearson chi-square.

The continuity-adjusted chi-square statistic is computed as

$$Q_C = \sum_i \sum_j \frac{(\max(0, |n_{ij} - e_{ij}| - 0.5))^2}{e_{ij}}$$

Under the null hypothesis of independence,  $Q_C$  has an asymptotic chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom.

### **Mantel-Haenszel Chi-Square Test**

The Mantel-Haenszel chi-square statistic tests the alternative hypothesis that there is a linear association between the row variable and the column variable. Both variables must lie on an ordinal scale. The Mantel-Haenszel chi-square statistic is computed as

$$Q_{MH} = (n - 1)r^2$$

where  $r^2$  is the Pearson correlation between the row variable and the column variable. For a description of the Pearson correlation, see the “[Pearson Correlation Coefficient](#)” on page 2274. The Pearson correlation and thus the Mantel-Haenszel chi-square statistic use the scores that you specify in the SCORES= option in the TABLES statement. See Mantel and Haenszel (1959) and Landis, Heyman, and Koch (1978) for more information.

Under the null hypothesis of no association,  $Q_{MH}$  has an asymptotic chi-square distribution with one degree of freedom.

In addition to the asymptotic test, you can request an exact Mantel-Haenszel chi-square test by specifying the MHCHI or CHISQ option in the EXACT statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

### **Fisher's Exact Test**

Fisher's exact test is another test of association between the row and column variables. This test assumes that the row and column totals are fixed, and then uses the hypergeometric distribution to compute probabilities of possible tables conditional on the observed row and column totals. Fisher's exact test does not depend on any large-sample distribution assumptions, and so it is appropriate even for small sample sizes and for sparse tables.

**2 × 2 Tables** For 2 × 2 tables, PROC FREQ gives the following information for Fisher's exact test: table probability, two-sided  $p$ -value, left-sided  $p$ -value, and right-sided  $p$ -value. The table probability equals the hypergeometric probability of the observed table, and is in fact the value of the test statistic for Fisher's exact test.

Where  $p$  is the hypergeometric probability of a specific table with the observed row and column totals, Fisher's exact  $p$ -values are computed by summing probabilities  $p$  over defined sets of tables,

$$PROB = \sum_A p$$

The two-sided  $p$ -value is the sum of all possible table probabilities (conditional on the observed row and column totals) that are less than or equal to the observed table probability. For the two-sided  $p$ -value, the set  $A$  includes all possible tables with hypergeometric probabilities less than or equal to the probability of the observed table. A small two-sided  $p$ -value supports the alternative hypothesis of association between the row and column variables.

For  $2 \times 2$  tables, one-sided  $p$ -values for Fisher's exact test are defined in terms of the frequency of the cell in the first row and first column of the table, the (1,1) cell. Denoting the observed (1,1) cell frequency by  $n_{11}$ , the left-sided  $p$ -value for Fisher's exact test is the probability that the (1,1) cell frequency is less than or equal to  $n_{11}$ . For the left-sided  $p$ -value, the set  $A$  includes those tables with a (1,1) cell frequency less than or equal to  $n_{11}$ . A small left-sided  $p$ -value supports the alternative hypothesis that the probability of an observation being in the first cell is actually less than expected under the null hypothesis of independent row and column variables.

Similarly, for a right-sided alternative hypothesis,  $A$  is the set of tables where the frequency of the (1,1) cell is greater than or equal to that in the observed table. A small right-sided  $p$ -value supports the alternative that the probability of the first cell is actually greater than that expected under the null hypothesis.

Because the (1,1) cell frequency completely determines the  $2 \times 2$  table when the marginal row and column sums are fixed, these one-sided alternatives can be stated equivalently in terms of other cell probabilities or ratios of cell probabilities. The left-sided alternative is equivalent to an odds ratio less than 1, where the odds ratio equals  $(n_{11}n_{22}/n_{12}n_{21})$ . Additionally, the left-sided alternative is equivalent to the column 1 risk for row 1 being less than the column 1 risk for row 2,  $p_{1|1} < p_{1|2}$ . Similarly, the right-sided alternative is equivalent to the column 1 risk for row 1 being greater than the column 1 risk for row 2,  $p_{1|1} > p_{1|2}$ . See Agresti (2007) for details.

**$R \times C$  Tables** Fisher's exact test was extended to general  $R \times C$  tables by Freeman and Halton (1951), and this test is also known as the Freeman-Halton test. For  $R \times C$  tables, the two-sided  $p$ -value definition is the same as for  $2 \times 2$  tables. The set  $A$  contains all tables with  $p$  less than or equal to the probability of the observed table. A small  $p$ -value supports the alternative hypothesis of association between the row and column variables. For  $R \times C$  tables, Fisher's exact test is inherently two-sided. The alternative hypothesis is defined only in terms of general, and not linear, association. Therefore, Fisher's exact test does not have right-sided or left-sided  $p$ -values for general  $R \times C$  tables.

For  $R \times C$  tables, PROC FREQ computes Fisher's exact test by using the network algorithm of Mehta and Patel (1983), which provides a faster and more efficient solution than direct enumeration. See the section "Exact Statistics" on page 2314 for more details.

### Phi Coefficient

The phi coefficient is a measure of association derived from the Pearson chi-square. The range of the phi coefficient is  $-1 \leq \phi \leq 1$  for  $2 \times 2$  tables. For tables larger than  $2 \times 2$ , the range is

$0 \leq \phi \leq \min(\sqrt{R-1}, \sqrt{C-1})$  (Liebetrau 1983). The phi coefficient is computed as

$$\phi = (n_{11}n_{22} - n_{12}n_{21}) / \sqrt{n_{1.}n_{2.}n_{.1}n_{.2}} \quad \text{for } 2 \times 2 \text{ tables}$$

$$\phi = \sqrt{Q_P/n} \quad \text{otherwise}$$

See Fleiss, Levin, and Paik (2003, pp. 98–99) for more information.

### Contingency Coefficient

The contingency coefficient is a measure of association derived from the Pearson chi-square. The range of the contingency coefficient is  $0 \leq P \leq \sqrt{(m-1)/m}$ , where  $m = \min(R, C)$  (Liebetrau 1983). The contingency coefficient is computed as

$$P = \sqrt{Q_P / (Q_P + n)}$$

See Kendall and Stuart (1979, pp. 587–588) for more information.

### Cramer's V

Cramer's  $V$  is a measure of association derived from the Pearson chi-square. It is designed so that the attainable upper bound is always 1. The range of Cramer's  $V$  is  $-1 \leq V \leq 1$  for  $2 \times 2$  tables; for tables larger than  $2 \times 2$ , the range is  $0 \leq V \leq 1$ . Cramer's  $V$  is computed as

$$V = \phi \quad \text{for } 2 \times 2 \text{ tables}$$

$$V = \sqrt{\frac{Q_P/n}{\min(R-1, C-1)}} \quad \text{otherwise}$$

See Kendall and Stuart (1979, p. 588) for more information.

## Measures of Association

When you specify the MEASURES option in the TABLES statement, PROC FREQ computes several statistics that describe the association between the row and column variables of the contingency table. The following are measures of ordinal association that consider whether the column variable  $Y$  tends to increase as the row variable  $X$  increases: gamma, Kendall's tau- $b$ , Stuart's tau- $c$ , and Somers'  $D$ . These measures are appropriate for ordinal variables, and they classify pairs of observations as *concordant* or *discordant*. A pair is concordant if the observation with the larger value of  $X$  also has the larger value of  $Y$ . A pair is discordant if the observation with the larger value of  $X$  has the smaller value of  $Y$ . See Agresti (2007) and the other references cited for the individual measures of association.

The Pearson correlation coefficient and the Spearman rank correlation coefficient are also appropriate for ordinal variables. The Pearson correlation describes the strength of the linear association between the row and column variables, and it is computed by using the row and column scores specified by the SCORES= option in the TABLES statement. The Spearman correlation is computed with rank scores. The polychoric correlation (requested by the PLCORR option) also requires ordinal variables and assumes that the variables have an underlying bivariate normal distribution. The following

measures of association do not require ordinal variables and are appropriate for nominal variables: lambda asymmetric, lambda symmetric, and the uncertainty coefficients.

PROC FREQ computes estimates of the measures according to the formulas given in the following sections. For each measure, PROC FREQ computes an asymptotic standard error (ASE), which is the square root of the asymptotic variance denoted by *var* in the following sections.

### Confidence Limits

If you specify the CL option in the TABLES statement, PROC FREQ computes asymptotic confidence limits for all MEASURES statistics. The confidence coefficient is determined according to the value of the ALPHA= option, which, by default, equals 0.05 and produces 95% confidence limits.

The confidence limits are computed as

$$est \pm (z_{\alpha/2} \times ASE)$$

where *est* is the estimate of the measure,  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the standard normal distribution, and ASE is the asymptotic standard error of the estimate.

### Asymptotic Tests

For each measure that you specify in the TEST statement, PROC FREQ computes an asymptotic test of the null hypothesis that the measure equals zero. Asymptotic tests are available for the following measures of association: gamma, Kendall's tau-*b*, Stuart's tau-*c*, Somers'  $D(C|R)$ , Somers'  $D(R|C)$ , the Pearson correlation coefficient, and the Spearman rank correlation coefficient. To compute an asymptotic test, PROC FREQ uses a standardized test statistic *z*, which has an asymptotic standard normal distribution under the null hypothesis. The test statistic is computed as

$$z = est / \sqrt{\text{var}_0(est)}$$

where *est* is the estimate of the measure and  $\text{var}_0(est)$  is the variance of the estimate under the null hypothesis. Formulas for  $\text{var}_0(est)$  for the individual measures of association are given in the following sections.

Note that the ratio of *est* to  $\sqrt{\text{var}_0(est)}$  is the same for the following measures: gamma, Kendall's tau-*b*, Stuart's tau-*c*, Somers'  $D(C|R)$ , and Somers'  $D(R|C)$ . Therefore, the tests for these measures are identical. For example, the *p*-values for the test of  $H_0$ : gamma = 0 equal the *p*-values for the test of  $H_0$ : tau-*b* = 0.

PROC FREQ computes one-sided and two-sided *p*-values for each of these tests. When the test statistic *z* is greater than its null hypothesis expected value of zero, PROC FREQ displays the right-sided *p*-value, which is the probability of a larger value of the statistic occurring under the null hypothesis. A small right-sided *p*-value supports the alternative hypothesis that the true value of the measure is greater than zero. When the test statistic is less than or equal to zero, PROC FREQ displays the left-sided *p*-value, which is the probability of a smaller value of the statistic occurring under the null hypothesis. A small left-sided *p*-value supports the alternative hypothesis that the true value of the measure is less than zero. The one-sided *p*-value  $P_1$  can be expressed as

$$P_1 = \begin{cases} \text{Prob}(Z > z) & \text{if } z > 0 \\ \text{Prob}(Z < z) & \text{if } z \leq 0 \end{cases}$$

where  $Z$  has a standard normal distribution. The two-sided  $p$ -value  $P_2$  is computed as

$$P_2 = \text{Prob}(|Z| > |z|)$$

### Exact Tests

Exact tests are available for the following measures of association: Kendall's tau- $b$ , Stuart's tau- $c$ , Somers'  $D(C|R)$  and  $(R|C)$ , the Pearson correlation coefficient, and the Spearman rank correlation coefficient. If you request an exact test for a measure of association in the **EXACT** statement, PROC FREQ computes the exact test of the hypothesis that the measure equals zero. See the section "Exact Statistics" on page 2314 for details.

### Gamma

The gamma ( $\Gamma$ ) statistic is based only on the number of concordant and discordant pairs of observations. It ignores tied pairs (that is, pairs of observations that have equal values of  $X$  or equal values of  $Y$ ). Gamma is appropriate only when both variables lie on an ordinal scale. The range of gamma is  $-1 \leq \Gamma \leq 1$ . If the row and column variables are independent, then gamma tends to be close to zero. Gamma is estimated by

$$G = (P - Q) / (P + Q)$$

and the asymptotic variance is

$$\text{var}(G) = \frac{16}{(P + Q)^4} \sum_i \sum_j n_{ij} (QA_{ij} - PD_{ij})^2$$

For  $2 \times 2$  tables, gamma is equivalent to Yule's  $Q$ . See Goodman and Kruskal (1979) and Agresti (2002) for more information.

The variance under the null hypothesis that gamma equals zero is computed as

$$\text{var}_0(G) = \frac{4}{(P + Q)^2} \left( \sum_i \sum_j n_{ij} (A_{ij} - D_{ij})^2 - (P - Q)^2/n \right)$$

See Brown and Benedetti (1977) for details.

### Kendall's Tau- $b$

Kendall's tau- $b$  ( $\tau_b$ ) is similar to gamma except that tau- $b$  uses a correction for ties. Tau- $b$  is appropriate only when both variables lie on an ordinal scale. The range of tau- $b$  is  $-1 \leq \tau_b \leq 1$ . Kendall's tau- $b$  is estimated by

$$t_b = (P - Q) / \sqrt{w_r w_c}$$

and the asymptotic variance is

$$\text{var}(t_b) = \frac{1}{w^4} \left( \sum_i \sum_j n_{ij} (2wd_{ij} + t_b v_{ij})^2 - n^3 t_b^2 (w_r + w_c)^2 \right)$$

where

$$\begin{aligned} w &= \sqrt{w_r w_c} \\ w_r &= n^2 - \sum_i n_{i.}^2 \\ w_c &= n^2 - \sum_j n_{.j}^2 \\ d_{ij} &= A_{ij} - D_{ij} \\ v_{ij} &= n_{i.} w_c + n_{.j} w_r \end{aligned}$$

See Kendall (1955) for more information.

The variance under the null hypothesis that tau-*b* equals zero is computed as

$$\text{var}_0(t_b) = \frac{4}{w_r w_c} \left( \sum_i \sum_j n_{ij} (A_{ij} - D_{ij})^2 - (P - Q)^2 / n \right)$$

See Brown and Benedetti (1977) for details.

PROC FREQ also provides an exact test for the Kendall's tau-*b*. You can request this test by specifying the KENTB option in the EXACT statement. See the section “Exact Statistics” on page 2314 for more information.

### Stuart's Tau-*c*

Stuart's tau-*c* ( $\tau_c$ ) makes an adjustment for table size in addition to a correction for ties. Tau-*c* is appropriate only when both variables lie on an ordinal scale. The range of tau-*c* is  $-1 \leq \tau_c \leq 1$ . Stuart's tau-*c* is estimated by

$$t_c = m(P - Q) / n^2(m - 1)$$

and the asymptotic variance is

$$\text{var}(t_c) = \frac{4m^2}{(m - 1)^2 n^4} \left( \sum_i \sum_j n_{ij} d_{ij}^2 - (P - Q)^2 / n \right)$$

where  $m = \min(R, C)$  and  $d_{ij} = A_{ij} - D_{ij}$ . The variance under the null hypothesis that tau-*c* equals zero is the same as the asymptotic variance *var*,

$$\text{var}_0(t_c) = \text{var}(t_c)$$

See Brown and Benedetti (1977) for details.

PROC FREQ also provides an exact test for the Stuart's tau-*c*. You can request this test by specifying the STUTC option in the EXACT statement. See the section “Exact Statistics” on page 2314 for more information.

**Somers' D**

Somers'  $D(C|R)$  and Somers'  $D(R|C)$  are asymmetric modifications of tau- $b$ .  $C|R$  indicates that the row variable  $X$  is regarded as the independent variable and the column variable  $Y$  is regarded as dependent. Similarly,  $R|C$  indicates that the column variable  $Y$  is regarded as the independent variable and the row variable  $X$  is regarded as dependent. Somers'  $D$  differs from tau- $b$  in that it uses a correction only for pairs that are tied on the independent variable. Somers'  $D$  is appropriate only when both variables lie on an ordinal scale. The range of Somers'  $D$  is  $-1 \leq D \leq 1$ . Somers'  $D(C|R)$  is computed as

$$D(C|R) = (P - Q) / w_r$$

and its asymptotic variance is

$$\text{var}(D(C|R)) = \frac{4}{w_r^4} \sum_i \sum_j n_{ij} (w_r d_{ij} - (P - Q)(n - n_{i.}))^2$$

where  $d_{ij} = A_{ij} - D_{ij}$  and

$$w_r = n^2 - \sum_i n_{i.}^2$$

See Somers (1962), Goodman and Kruskal (1979), and Liebetrau (1983) for more information.

The variance under the null hypothesis that  $D(C|R)$  equals zero is computed as

$$\text{var}_0(D(C|R)) = \frac{4}{w_r^2} \left( \sum_i \sum_j n_{ij} (A_{ij} - D_{ij})^2 - (P - Q)^2 / n \right)$$

See Brown and Benedetti (1977) for details.

Formulas for Somers'  $D(R|C)$  are obtained by interchanging the indices.

PROC FREQ also provides exact tests for Somers'  $D(C|R)$  and  $(R|C)$ . You can request these tests by specifying the SMDCR and SMDCR options in the **EXACT** statement. See the section "[Exact Statistics](#)" on page 2314 for more information.

**Pearson Correlation Coefficient**

The Pearson correlation coefficient ( $\rho$ ) is computed by using the scores specified in the SCORES= option. This measure is appropriate only when both variables lie on an ordinal scale. The range of the Pearson correlation is  $-1 \leq \rho \leq 1$ . The Pearson correlation coefficient is estimated by

$$r = v/w = ss_{rc} / \sqrt{ss_r ss_c}$$

and its asymptotic variance is

$$\text{var}(r) = \frac{1}{w^4} \sum_i \sum_j n_{ij} \left( w(R_i - \bar{R})(C_j - \bar{C}) - \frac{b_{ij}v}{2w} \right)^2$$

where  $R_i$  and  $C_j$  are the row and column scores and

$$ss_r = \sum_i \sum_j n_{ij} (R_i - \bar{R})^2$$

$$ss_c = \sum_i \sum_j n_{ij} (C_j - \bar{C})^2$$

$$ss_{rc} = \sum_i \sum_j n_{ij} (R_i - \bar{R})(C_j - \bar{C})$$

$$b_{ij} = (R_i - \bar{R})^2 ss_c + (C_j - \bar{C})^2 ss_r$$

$$v = ss_{rc}$$

$$w = \sqrt{ss_r ss_c}$$

See Snedecor and Cochran (1989) for more information.

The SCORES= option in the TABLES statement determines the type of row and column scores used to compute the Pearson correlation (and other score-based statistics). The default is SCORES=TABLE. See the section “[Scores](#)” on page 2265 for details about the available score types and how they are computed.

The variance under the null hypothesis that the correlation equals zero is computed as

$$\text{var}_0(r) = \left( \sum_i \sum_j n_{ij} (R_i - \bar{R})^2 (C_j - \bar{C})^2 - ss_{rc}^2 / n \right) / ss_r ss_c$$

Note that this expression for the variance is derived for multinomial sampling in a contingency table framework, and it differs from the form obtained under the assumption that both variables are continuous and normally distributed. See Brown and Benedetti (1977) for details.

PROC FREQ also provides an exact test for the Pearson correlation coefficient. You can request this test by specifying the PCORR option in the [EXACT](#) statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

### **[Spearman Rank Correlation Coefficient](#)**

The Spearman correlation coefficient ( $\rho_s$ ) is computed by using rank scores, which are defined in the section “[Scores](#)” on page 2265. This measure is appropriate only when both variables lie on an ordinal scale. The range of the Spearman correlation is  $-1 \leq \rho_s \leq 1$ . The Spearman correlation coefficient is estimated by

$$r_s = v / w$$

and its asymptotic variance is

$$\text{var}(r_s) = \frac{1}{n^2 w^4} \sum_i \sum_j n_{ij} (z_{ij} - \bar{z})^2$$

where  $R1_i$  and  $C1_j$  are the row and column rank scores and

$$v = \sum_i \sum_j n_{ij} R(i) C(j)$$

$$w = \frac{1}{12} \sqrt{FG}$$

$$F = n^3 - \sum_i n_{i.}^3$$

$$G = n^3 - \sum_j n_{.j}^3$$

$$R(i) = R1_i - n/2$$

$$C(j) = C1_j - n/2$$

$$\bar{z} = \frac{1}{n} \sum_i \sum_j n_{ij} z_{ij}$$

$$z_{ij} = w v_{ij} - v w_{ij}$$

$$v_{ij} = n \left( R(i) C(j) + \frac{1}{2} \sum_l n_{il} C(l) + \frac{1}{2} \sum_k n_{kj} R(k) + \right. \\ \left. \sum_l \sum_{k>i} n_{kl} C(l) + \sum_k \sum_{l>j} n_{kl} R(k) \right)$$

$$w_{ij} = \frac{-n}{96w} (F n_{.j}^2 + G n_{i.}^2)$$

See Snedecor and Cochran (1989) for more information.

The variance under the null hypothesis that the correlation equals zero is computed as

$$\text{var}_0(r_s) = \frac{1}{n^2 w^2} \sum_i \sum_j n_{ij} (v_{ij} - \bar{v})^2$$

where

$$\bar{v} = \sum_i \sum_j n_{ij} v_{ij} / n$$

Note that the asymptotic variance is derived for multinomial sampling in a contingency table framework, and it differs from the form obtained under the assumption that both variables are continuous and normally distributed. See Brown and Benedetti (1977) for details.

PROC FREQ also provides an exact test for the Spearman correlation coefficient. You can request this test by specifying the SCORR option in the **EXACT** statement. See the section “Exact Statistics” on page 2314 for more information.

### Polychoric Correlation

When you specify the PLCORR option in the TABLES statement, PROC FREQ computes the polychoric correlation. This measure of association is based on the assumption that the ordered, categorical variables of the frequency table have an underlying bivariate normal distribution. For  $2 \times 2$  tables, the polychoric correlation is also known as the tetrachoric correlation. See Drasgow (1986) for an overview of polychoric correlation. The polychoric correlation coefficient is the maximum likelihood estimate of the product-moment correlation between the normal variables, estimating thresholds from the observed table frequencies. The range of the polychoric correlation is from  $-1$  to  $1$ . Olsson (1979) gives the likelihood equations and an asymptotic covariance matrix for the estimates.

To estimate the polychoric correlation, PROC FREQ iteratively solves the likelihood equations by a Newton-Raphson algorithm that uses the Pearson correlation coefficient as the initial approximation. Iteration stops when the convergence measure falls below the convergence criterion or when the maximum number of iterations is reached, whichever occurs first. The CONVERGE= option sets the convergence criterion, and the default value is  $0.0001$ . The MAXITER= option sets the maximum number of iterations, and the default value is  $20$ .

### Lambda (Asymmetric)

Asymmetric lambda,  $\lambda(C|R)$ , is interpreted as the probable improvement in predicting the column variable  $Y$  given knowledge of the row variable  $X$ . The range of asymmetric lambda is  $0 \leq \lambda(C|R) \leq 1$ . Asymmetric lambda ( $C|R$ ) is computed as

$$\lambda(C|R) = \frac{\sum_i r_i - r}{n - r}$$

and its asymptotic variance is

$$\text{var}(\lambda(C|R)) = \frac{n - \sum_i r_i}{(n - r)^3} \left( \sum_i r_i + r - 2 \sum_i (r_i | l_i = l) \right)$$

where

$$r_i = \max_j(n_{ij})$$

$$r = \max_j(n_{.j})$$

$$c_j = \max_i(n_{ij})$$

$$c = \max_i(n_{i.})$$

The values of  $l_i$  and  $l$  are determined as follows. Denote by  $l_i$  the unique value of  $j$  such that  $r_i = n_{ij}$ , and let  $l$  be the unique value of  $j$  such that  $r = n_{.j}$ . Because of the uniqueness assumptions, ties in the frequencies or in the marginal totals must be broken in an arbitrary but consistent manner. In case of ties,  $l$  is defined as the smallest value of  $j$  such that  $r = n_{.j}$ .

For those columns containing a cell  $(i, j)$  for which  $n_{ij} = r_i = c_j$ ,  $cs_j$  records the row in which  $c_j$  is assumed to occur. Initially  $cs_j$  is set equal to  $-1$  for all  $j$ . Beginning with  $i = 1$ , if there is at least one value  $j$  such that  $n_{ij} = r_i = c_j$ , and if  $cs_j = -1$ , then  $l_i$  is defined to be the smallest such value of  $j$ , and  $cs_j$  is set equal to  $i$ . Otherwise, if  $n_{il} = r_i$ , then  $l_i$  is defined to be equal to  $l$ . If neither condition is true, then  $l_i$  is taken to be the smallest value of  $j$  such that  $n_{ij} = r_i$ .

The formulas for lambda asymmetric ( $R|C$ ) can be obtained by interchanging the indices.

See Goodman and Kruskal (1979) for more information.

### **Lambda (Symmetric)**

The nondirectional lambda is the average of the two asymmetric lambdas,  $\lambda(C|R)$  and  $\lambda(R|C)$ . Its range is  $0 \leq \lambda \leq 1$ . Lambda symmetric is computed as

$$\lambda = \frac{\sum_i r_i + \sum_j c_j - r - c}{2n - r - c} = \frac{w - v}{w}$$

and its asymptotic variance is computed as

$$\text{var}(\lambda) = \frac{1}{w^4} \left( wvy - 2w^2 \left( n - \sum_i \sum_j (n_{ij} | j = l_i, i = k_j) \right) - 2v^2(n - n_{kl}) \right)$$

where

$$r_i = \max_j(n_{ij})$$

$$r = \max_j(n_{.j})$$

$$c_j = \max_i(n_{ij})$$

$$c = \max_i(n_{i.})$$

$$w = 2n - r - c$$

$$v = 2n - \sum_i r_i - \sum_j c_j$$

$$x = \sum_i (r_i | l_i = l) + \sum_j (c_j | k_j = k) + r_k + c_l$$

$$y = 8n - w - v - 2x$$

The definitions of  $l_i$  and  $l$  are given in the previous section. The values  $k_j$  and  $k$  are defined in a similar way for lambda asymmetric ( $R|C$ ).

See Goodman and Kruskal (1979) for more information.

### Uncertainty Coefficients (Asymmetric)

The uncertainty coefficient  $U(C|R)$  measures the proportion of uncertainty (entropy) in the column variable  $Y$  that is explained by the row variable  $X$ . Its range is  $0 \leq U(C|R) \leq 1$ . The uncertainty coefficient is computed as

$$U(C|R) = (H(X) + H(Y) - H(XY)) / H(Y) = v/w$$

and its asymptotic variance is

$$\text{var}(U(C|R)) = \frac{1}{n^2 w^4} \sum_i \sum_j n_{ij} \left( H(Y) \ln \left( \frac{n_{ij}}{n_{i\cdot}} \right) + (H(X) - H(XY)) \ln \left( \frac{n_{\cdot j}}{n} \right) \right)^2$$

where

$$v = H(X) + H(Y) - H(XY)$$

$$w = H(Y)$$

$$H(X) = - \sum_i \left( \frac{n_{i\cdot}}{n} \right) \ln \left( \frac{n_{i\cdot}}{n} \right)$$

$$H(Y) = - \sum_j \left( \frac{n_{\cdot j}}{n} \right) \ln \left( \frac{n_{\cdot j}}{n} \right)$$

$$H(XY) = - \sum_i \sum_j \left( \frac{n_{ij}}{n} \right) \ln \left( \frac{n_{ij}}{n} \right)$$

The formulas for the uncertainty coefficient  $U(R|C)$  can be obtained by interchanging the indices.

See Theil (1972, pp. 115–120) and Goodman and Kruskal (1979) for more information.

### Uncertainty Coefficient (Symmetric)

The uncertainty coefficient  $U$  is the symmetric version of the two asymmetric uncertainty coefficients. Its range is  $0 \leq U \leq 1$ . The uncertainty coefficient is computed as

$$U = 2 (H(X) + H(Y) - H(XY)) / (H(X) + H(Y))$$

and its asymptotic variance is

$$\text{var}(U) = 4 \sum_i \sum_j \frac{n_{ij} \left( H(XY) \ln \left( \frac{n_{i\cdot} n_{\cdot j}}{n^2} \right) - (H(X) + H(Y)) \ln \left( \frac{n_{ij}}{n} \right) \right)^2}{n^2 (H(X) + H(Y))^4}$$

where  $H(X)$ ,  $H(Y)$ , and  $H(XY)$  are defined in the previous section. See Goodman and Kruskal (1979) for more information.

## Binomial Proportion

If you specify the BINOMIAL option in the TABLES statement, PROC FREQ computes the binomial proportion for one-way tables. By default, this is the proportion of observations in the first variable level that appears in the output. (You can use the LEVEL= option to specify a different level for the proportion.) The binomial proportion is computed as

$$\hat{p} = n_1 / n$$

where  $n_1$  is the frequency of the first (or designated) level and  $n$  is the total frequency of the one-way table. The standard error of the binomial proportion is computed as

$$se(\hat{p}) = \sqrt{\hat{p}(1 - \hat{p}) / n}$$

### Confidence Limits

By default, PROC FREQ provides asymptotic and exact (Clopper-Pearson) confidence limits for the binomial proportion. If you do not specify any confidence limit requests with *binomial-options*, PROC FREQ computes the standard Wald asymptotic confidence limits. You can also request Agresti-Coull, Jeffreys, and Wilson (score) confidence limits for the binomial proportion. See Brown, Cai, and DasGupta (2001), Agresti and Coull (1998), and Newcombe (1998) for details about these binomial confidence limits, including comparisons of their performance.

**Wald Confidence Limits** The standard Wald asymptotic confidence limits are based on the normal approximation to the binomial distribution. PROC FREQ computes the Wald confidence limits for the binomial proportion as

$$\hat{p} \pm (z_{\alpha/2} \times se(\hat{p}))$$

where  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the standard normal distribution. The confidence level  $\alpha$  is determined by the ALPHA= option, which, by default, equals 0.05 and produces 95% confidence limits.

If you specify the CORRECT binomial-option or the BINOMIALC option, PROC FREQ includes a continuity correction of  $1/2n$  in the Wald asymptotic confidence limits. The purpose of this correction is to adjust for the difference between the normal approximation and the binomial distribution, which is a discrete distribution. See Fleiss, Levin, and Paik (2003) for more information. With the continuity correction, the asymptotic confidence limits for the binomial proportion are computed as

$$\hat{p} \pm (z_{\alpha/2} \times se(\hat{p}) + (1/2n))$$

**Agresti-Coull Confidence Limits** If you specify the AGRESTICOULL binomial-option, PROC FREQ computes Agresti-Coull confidence limits for the binomial proportion as

$$\tilde{p} \pm (z_{\alpha/2} \times \sqrt{\tilde{p}(1 - \tilde{p}) / \tilde{n}})$$

where

$$\begin{aligned}\tilde{n}_1 &= n_1 + (z_{\alpha/2})/2 \\ \tilde{n} &= n + z_{\alpha/2}^2 \\ \tilde{p} &= \tilde{n}_1 / \tilde{n}\end{aligned}$$

The Agresti-Coull confidence interval has the same basic form as the standard Wald interval but uses  $\tilde{p}$  in place of  $\hat{p}$ . For  $\alpha = 0.05$ , the value of  $z_{\alpha/2}$  is close to 2, and this interval is the “add 2 successes and 2 failures” adjusted Wald interval in Agresti and Coull (1998).

**Jeffreys Confidence Limits** If you specify the JEFFREYS binomial-option, PROC FREQ computes the Jeffreys confidence limits for the binomial proportion as

$$\left( \beta(\alpha/2, n_1 + 1/2, n - n_1 + 1/2), \beta(1 - \alpha/2, n_1 + 1/2, n - n_1 + 1/2) \right)$$

where  $\beta(\alpha, b, c)$  is the  $\alpha$ th percentile of the beta distribution with shape parameters  $b$  and  $c$ . The lower confidence limit is set to 0 when  $n_1 = 0$ , and the upper confidence limit is set to 1 when  $n_1 = n$ . This is an equal-tailed interval based on the noninformative Jeffreys prior for a binomial proportion. See Brown, Cai, and DasGupta (2001) for details. See Berger (1985) for information about using beta priors for inference on the binomial proportion.

**Wilson (Score) Confidence Limits** If you specify the WILSON binomial-option, PROC FREQ computes Wilson confidence limits for the binomial proportion. These are also known as score confidence limits and are attributed to Wilson (1927). The confidence limits are based on inverting the normal test that uses the null proportion in the variance (the score test). Wilson confidence limits are the roots of

$$|p - \hat{p}| = z_{\alpha/2} \sqrt{p(1 - p)/n}$$

and are computed as

$$\left( \hat{p} + z_{\alpha/2}^2/2n \pm z_{\alpha/2} \sqrt{\left( \hat{p}(1 - \hat{p}) + z_{\alpha/2}^2/4n \right) / n} \right) / \left( 1 + z_{\alpha/2}^2/n \right)$$

The Wilson interval has been shown to have better performance than the Wald interval and the exact (Clopper-Pearson) interval. See Agresti and Coull (1998), Brown, Cai, and DasGupta (2001), and Newcombe (1998) for more information.

**Exact (Clopper-Pearson) Confidence Limits** The exact or Clopper-Pearson confidence limits for the binomial proportion are constructed by inverting the equal-tailed test based on the binomial distribution. This method is attributed to Clopper and Pearson (1934). The exact confidence limits  $p_L$  and  $p_U$  satisfy the following equations, for  $n_1 = 1, 2, \dots, n - 1$ :

$$\sum_{x=n_1}^n \binom{n}{x} p_L^x (1 - p_L)^{n-x} = \alpha/2$$

$$\sum_{x=0}^{n_1} \binom{n}{x} p_U^x (1 - p_U)^{n-x} = \alpha/2$$

The lower confidence limit equals 0 when  $n_1 = 0$ , and the upper confidence limit equals 1 when  $n_1 = n$ .

PROC FREQ computes the exact (Clopper-Pearson) confidence limits by using the  $F$  distribution as

$$p_L = \left( 1 + \frac{n - n_1 + 1}{n_1 F(1 - \alpha/2, 2n_1, 2(n - n_1 + 1))} \right)^{-1}$$

$$p_U = \left( 1 + \frac{n - n_1}{(n_1 + 1) F(\alpha/2, 2(n_1 + 1), 2(n - n_1))} \right)^{-1}$$

where  $F(\alpha, b, c)$  is the  $\alpha$ th percentile of the  $F$  distribution with  $b$  and  $c$  degrees of freedom. See Leemis and Trivedi (1996) for a derivation of this expression. Also see Collett (1991) for more information about exact binomial confidence limits.

Because this is a discrete problem, the confidence coefficient (or coverage probability) of the exact (Clopper-Pearson) interval is not exactly  $(1 - \alpha)$  but is at least  $(1 - \alpha)$ . Thus, this confidence interval is conservative. Unless the sample size is large, the actual coverage probability can be much larger than the target value. See Agresti and Coull (1998), Brown, Cai, and DasGupta (2001), and Leemis and Trivedi (1996) for more information about the performance of these confidence limits.

### Tests

The BINOMIAL option provides an asymptotic equality test for the binomial proportion by default. You can also specify *binomial-options* to request tests of noninferiority, superiority, and equivalence for the binomial proportion. If you specify the BINOMIAL option in the EXACT statement, PROC FREQ also computes exact  $p$ -values for the tests that you request with the *binomial-options*.

**Equality Test** PROC FREQ computes an asymptotic test of the hypothesis that the binomial proportion equals  $p_0$ , where you can specify the value of  $p_0$  with the  $P=$  binomial-option. If you do not specify a null value with  $P=$ , PROC FREQ uses  $p_0 = 0.5$  by default. The binomial test statistic is computed as

$$z = (\hat{p} - p_0)/se$$

By default, the standard error is based on the null hypothesis proportion as

$$se = \sqrt{p_0(1 - p_0)/n}$$

If you specify the VAR=SAMPLE binomial-option, the standard error is computed from the sample proportion as

$$se = \sqrt{\hat{p}(1 - \hat{p})/n}$$

If you specify the CORRECT binomial-option or the BINOMIALC option, PROC FREQ includes a continuity correction in the asymptotic test statistic, towards adjusting for the difference between the normal approximation and the discrete binomial distribution. See Fleiss, Levin, and Paik (2003) for details. The continuity correction of  $(1/2n)$  is subtracted from the numerator of the test statistic if  $(\hat{p} - p_0)$  is positive; otherwise, the continuity correction is added to the numerator.

PROC FREQ computes one-sided and two-sided  $p$ -values for this test. When the test statistic  $z$  is greater than zero (its expected value under the null hypothesis), PROC FREQ computes the

right-sided  $p$ -value, which is the probability of a larger value of the statistic occurring under the null hypothesis. A small right-sided  $p$ -value supports the alternative hypothesis that the true value of the proportion is greater than  $p_0$ . When the test statistic is less than or equal to zero, PROC FREQ computes the left-sided  $p$ -value, which is the probability of a smaller value of the statistic occurring under the null hypothesis. A small left-sided  $p$ -value supports the alternative hypothesis that the true value of the proportion is less than  $p_0$ . The one-sided  $p$ -value  $P_1$  can be expressed as

$$P_1 = \begin{cases} \text{Prob}(Z > z) & \text{if } z > 0 \\ \text{Prob}(Z < z) & \text{if } z \leq 0 \end{cases}$$

where  $Z$  has a standard normal distribution. The two-sided  $p$ -value is computed as  $P_2 = 2 \times P_1$ .

If you specify the BINOMIAL option in the EXACT statement, PROC FREQ also computes an exact test of the null hypothesis  $H_0: p = p_0$ . To compute the exact test, PROC FREQ uses the binomial probability function,

$$\text{Prob}(X = x \mid p_0) = \binom{n}{x} p_0^x (1 - p_0)^{(n-x)} \quad \text{for } x = 0, 1, 2, \dots, n$$

where the variable  $X$  has a binomial distribution with parameters  $n$  and  $p_0$ . To compute the left-sided  $p$ -value,  $\text{Prob}(X \leq n_1)$ , PROC FREQ sums the binomial probabilities over  $x$  from zero to  $n_1$ . To compute the right-sided  $p$ -value,  $\text{Prob}(X \geq n_1)$ , PROC FREQ sums the binomial probabilities over  $x$  from  $n_1$  to  $n$ . The exact one-sided  $p$ -value is the minimum of the left-sided and right-sided  $p$ -values,

$$P_1 = \min ( \text{Prob}(X \leq n_1 \mid p_0), \text{Prob}(X \geq n_1 \mid p_0) )$$

and the exact two-sided  $p$ -value is computed as  $P_2 = 2 \times P_1$ .

**Noninferiority Test** If you specify the NONINF binomial-option, PROC FREQ provides a noninferiority test for the binomial proportion. The null hypothesis for the noninferiority test is

$$H_0: p - p_0 \leq -\delta$$

versus the alternative

$$H_a: p - p_0 > -\delta$$

where  $\delta$  is the noninferiority margin and  $p_0$  is the null proportion. Rejection of the null hypothesis indicates that the binomial proportion is not inferior to the null value. See Chow, Shao, and Wang (2003) for more information.

You can specify the value of  $\delta$  with the MARGIN= binomial-option, and you can specify  $p_0$  with the P= binomial-option. By default,  $\delta = 0.2$  and  $p_0 = 0.5$ .

PROC FREQ provides an asymptotic Wald test for noninferiority. The test statistic is computed as

$$z = (\hat{p} - p_0^*) / se$$

where  $p_0^*$  is the noninferiority limit,

$$p_0^* = p_0 - \delta$$

By default, the standard error is computed from the sample proportion as

$$se = \sqrt{\hat{p}(1 - \hat{p})/n}$$

If you specify the VAR=NULL binomial-option, the standard error is based on the noninferiority limit (determined by the null proportion and the margin) as

$$se = \sqrt{p_0^*(1 - p_0^*)/n}$$

If you specify the CORRECT binomial-option or the BINOMIALC option, PROC FREQ includes a continuity correction in the asymptotic test statistic  $z$ . The continuity correction of  $(1/2n)$  is subtracted from the numerator of the test statistic if  $(\hat{p} - p_0^*)$  is positive; otherwise, the continuity correction is added to the numerator.

The  $p$ -value for the noninferiority test is

$$P_z = \text{Prob}(Z > z)$$

where  $Z$  has a standard normal distribution.

As part of the noninferiority analysis, PROC FREQ provides asymptotic Wald confidence limits for the binomial proportion. These confidence limits are computed as described in the section “[Wald Confidence Limits](#)” on page 2280 but use the same standard error (VAR=NULL or VAR=SAMPLE) as the noninferiority test statistic  $z$ . The confidence coefficient is  $100(1 - 2\alpha)\%$  (Schuirmann 1999). By default, if you do not specify the ALPHA= option, the noninferiority confidence limits are 90% confidence limits. You can compare the confidence limits to the noninferiority limit,  $p_0^* = p_0 - \delta$ .

If you specify the BINOMIAL option in the EXACT statement, PROC FREQ provides an exact noninferiority test for the binomial proportion. The exact  $p$ -value is computed by using the binomial probability function with parameters  $p_0^*$  and  $n$ ,

$$P_x = \sum_{k=n_1}^{k=n} \binom{n}{k} (p_0^*)^k (1 - p_0^*)^{(n-k)}$$

See Chow, Shao, Wang (2003, p. 116) for details. If you request exact binomial statistics, PROC FREQ also includes exact (Clopper-Pearson) confidence limits for the binomial proportion in the equivalence analysis display. See the section “[Exact \(Clopper-Pearson\) Confidence Limits](#)” on page 2281 for details.

**Superiority Test** If you specify the SUP binomial-option, PROC FREQ provides a superiority test for the binomial proportion. The null hypothesis for the superiority test is

$$H_0: p - p_0 \leq \delta$$

versus the alternative

$$H_a: p - p_0 > \delta$$

where  $\delta$  is the superiority margin and  $p_0$  is the null proportion. Rejection of the null hypothesis indicates that the binomial proportion is superior to the null value. You can specify the value of  $\delta$  with

the MARGIN= binomial-option, and you can specify the value of  $p_0$  with the P= binomial-option. By default,  $\delta = 0.2$  and  $p_0 = 0.5$ .

The superiority analysis is identical to the noninferiority analysis but uses a positive value of the margin  $\delta$  in the null hypothesis. The superiority limit equals  $p_0 + \delta$ . The superiority computations follow those in the section “[Noninferiority Test](#)” on page 2283 but replace  $-\delta$  with  $\delta$ . See Chow, Shao, and Wang (2003) for more information.

**Equivalence Test** If you specify the EQUIV binomial-option, PROC FREQ provides an equivalence test for the binomial proportion. The null hypothesis for the equivalence test is

$$H_0: p - p_0 \leq \delta_L \quad \text{or} \quad p - p_0 \geq \delta_U$$

versus the alternative

$$H_a: \delta_L < p - p_0 < \delta_U$$

where  $\delta_L$  is the lower margin,  $\delta_U$  is the upper margin, and  $p_0$  is the null proportion. Rejection of the null hypothesis indicates that the binomial proportion is equivalent to the null value. See Chow, Shao, and Wang (2003) for more information.

You can specify the value of the margins  $\delta_L$  and  $\delta_U$  with the MARGIN= binomial-option. If you do not specify MARGIN=, PROC FREQ uses lower and upper margins of  $-0.2$  and  $0.2$  by default. If you specify a single margin value  $\delta$ , PROC FREQ uses lower and upper margins of  $-\delta$  and  $\delta$ . You can specify the null proportion  $p_0$  with the P= binomial-option. By default,  $p_0 = 0.5$ .

PROC FREQ computes two one-sided tests (TOST) for equivalence analysis (Schuirmann 1987). The TOST approach includes a right-sided test for the lower margin and a left-sided test for the upper margin. The overall  $p$ -value is taken to be the larger of the two  $p$ -values from the lower and upper tests.

For the lower margin, the asymptotic Wald test statistic is computed as

$$z_L = (\hat{p} - p_L^*) / se$$

where the lower equivalence limit is

$$p_L^* = p_0 + \delta_L$$

By default, the standard error is computed from the sample proportion as

$$se = \sqrt{\hat{p}(1 - \hat{p})/n}$$

If you specify the VAR=NULL binomial-option, the standard error is based on the lower equivalence limit (determined by the null proportion and the lower margin) as

$$se = \sqrt{p_L^*(1 - p_L^*)/n}$$

If you specify the CORRECT binomial-option or the BINOMIALC option, PROC FREQ includes a continuity correction in the asymptotic test statistic  $z_L$ . The continuity correction of  $(1/2n)$  is

subtracted from the numerator of the test statistic ( $\hat{p} - p_L^*$ ) if the numerator is positive; otherwise, the continuity correction is added to the numerator.

The  $p$ -value for the lower margin test is

$$P_{z,L} = \text{Prob}(Z > z_L)$$

The asymptotic test for the upper margin is computed similarly. The Wald test statistic is

$$z_U = (\hat{p} - p_U^*) / se$$

where the upper equivalence limit is

$$p_U^* = p_0 + \delta_U$$

By default, the standard error is computed from the sample proportion. If you specify the VAR=NULL binomial-option, the standard error is based on the upper equivalence limit as

$$se = \sqrt{p_U^*(1 - p_U^*)/n}$$

If you specify the CORRECT binomial-option or the BINOMIALC option, PROC FREQ includes a continuity correction of  $(1/2n)$  in the asymptotic test statistic  $z_U$ .

The  $p$ -value for the upper margin test is

$$P_{z,U} = \text{Prob}(Z < z_U)$$

Based on the two one-sided tests (TOST), the overall  $p$ -value for the test of equivalence equals the larger  $p$ -value from the lower and upper margin tests, which can be expressed as

$$P_z = \max(P_{z,L}, P_{z,U})$$

As part of the equivalence analysis, PROC FREQ provides asymptotic Wald confidence limits for the binomial proportion. These confidence limits are computed as described in the section “[Wald Confidence Limits](#)” on page 2280, but use the same standard error (VAR=NULL or VAR=SAMPLE) as the equivalence test statistics and have a confidence coefficient of  $100(1 - 2\alpha)\%$  (Schuirmann 1999). By default, if you do not specify the ALPHA= option, the equivalence confidence limits are 90% limits. If you specify VAR=NULL, separate standard errors are computed for the lower and upper margin tests, each based on the null proportion and the corresponding (lower or upper) margin. The confidence limits are computed by using the maximum of these two standard errors. You can compare the confidence limits to the equivalence limits,  $(p_0 + \delta_L, p_0 + \delta_U)$ .

If you specify the BINOMIAL option in the EXACT statement, PROC FREQ also provides an exact equivalence test by using two one-sided exact tests (TOST). The procedure computes lower and upper margin exact tests by using the binomial probability function as described in the section “[Noninferiority Test](#)” on page 2283. The overall exact  $p$ -value for the equivalence test is taken to be the larger  $p$ -value from the lower and upper margin exact tests. If you request exact statistics, PROC FREQ also includes exact (Clopper-Pearson) confidence limits in the equivalence analysis display. The confidence coefficient is  $100(1 - 2\alpha)\%$  (Schuirmann 1999). See the section “[Exact \(Clopper-Pearson\) Confidence Limits](#)” on page 2281 for details.

## Risks and Risk Differences

The RISKDIFF option in the TABLES statement provides estimates of risks (or binomial proportions) and risk differences for  $2 \times 2$  tables. This analysis might be appropriate when comparing the proportion of some characteristic for two groups, where row 1 and row 2 correspond to the two groups, and the columns correspond to two possible characteristics or outcomes. For example, the row variable might be a treatment or dose, and the column variable might be the response. See Collett (1991), Fleiss, Levin, and Paik (2003), and Stokes, Davis, and Koch (2000) for more information.

Let the frequencies of the  $2 \times 2$  table be represented as follows.

	Column 1	Column 2	Total
Row 1	$n_{11}$	$n_{12}$	$n_{1\cdot}$
Row 2	$n_{21}$	$n_{22}$	$n_{2\cdot}$
Total	$n_{\cdot 1}$	$n_{\cdot 2}$	$n$

For column 1 and column 2, PROC FREQ provides estimates of the row 1 risk (or proportion), the row 2 risk, the overall risk and the risk difference. The risk difference is defined as the row 1 risk minus the row 2 risk. The risks are binomial proportions of their rows (row 1, row 2, or overall), and the computation of their standard errors and confidence limits follow the binomial proportion computations, which are described in the section “[Binomial Proportion](#)” on page 2280.

The column 1 risk for row 1 is the proportion of row 1 observations classified in column 1,

$$p_1 = n_{11} / n_{1\cdot}$$

This estimates the conditional probability of the column 1 response, given the first level of the row variable.

The column 1 risk for row 2 is the proportion of row 2 observations classified in column 1,

$$p_2 = n_{21} / n_{2\cdot}$$

and the overall column 1 risk is the proportion of all observations classified in column 1,

$$p = n_{\cdot 1} / n$$

The column 1 risk difference compares the risks for the two rows, and it is computed as the column 1 risk for row 1 minus the column 1 risk for row 2,

$$d = p_1 - p_2$$

The risks and risk difference are defined similarly for column 2.

The standard error of the column 1 risk for row  $i$  is computed as

$$se(p_i) = \sqrt{p_i (1 - p_i) / n_{i\cdot}}$$

The standard error of the overall column 1 risk is computed as

$$se(p) = \sqrt{p (1 - p) / n}$$

If the two rows represent independent binomial samples, the standard error for the column 1 risk difference is computed as

$$se(d) = \sqrt{var(p_1) + var(p_2)}$$

The standard errors are computed in a similar manner for the column 2 risks and risk difference.

### Confidence Limits

By default, the RISKDIFF option provides standard Wald asymptotic confidence limits for the risks (row 1, row 2, and overall) and the risk difference. The risks are equivalent to binomial proportions of their corresponding rows, and the computations follow the methods in the section “[Wald Confidence Limits](#)” on page 2280.

The standard Wald asymptotic confidence limits are based on the normal approximation to the binomial distribution. PROC FREQ computes the Wald confidence limits for the risks and risk differences as

$$est \pm (z_{\alpha/2} \times se(est))$$

where  $est$  is the estimate,  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the standard normal distribution, and  $se(est)$  is the standard error of the estimate. The confidence level  $\alpha$  is determined from the value of the ALPHA= option, which, by default, equals 0.05 and produces 95% confidence limits.

If you specify the CORRECT *riskdiff-option* or the RISKDIFFC option, PROC FREQ includes continuity corrections in the Wald asymptotic confidence limits for the risks and risk differences. The purpose of a continuity correction is to adjust for the difference between the normal approximation and the binomial distribution, which is discrete. See Fleiss, Levin, and Paik (2003) for more information. With the continuity correction, the asymptotic confidence limits are computed as

$$est \pm (z_{\alpha/2} \times se(est) + cc)$$

where  $cc$  is the continuity correction. For the row 1 risk,  $cc = (1/2n_1)$ ; for the row 2 risk,  $cc = (1/2n_2)$ ; for the overall risk,  $cc = (1/2n)$ ; and for the risk difference,  $cc = ((1/n_1 + 1/n_2)/2)$ . The column 1 and column 2 risks use the same continuity corrections.

PROC FREQ also computes exact (Clopper-Pearson) confidence limits for the column 1, column 2, and overall risks. These confidence limits are constructed by inverting the equal-tailed test based on the binomial distribution. PROC FREQ uses the  $F$  distribution to compute the Clopper-Pearson confidence limits. See the section “[Exact \(Clopper-Pearson\) Confidence Limits](#)” on page 2281 for details.

PROC FREQ does not provide exact confidence limits for the risk difference by default. If you specify the RISKDIFF option in the EXACT statement, PROC FREQ provides exact unconditional confidence limits for the risk difference, which are described in the section “[Exact Unconditional Confidence Limits for the Risk Difference](#)” on page 2293. Note that the conditional exact approach, which is the basis for other exact tests provided by PROC FREQ such as Fisher’s exact test, does not apply to the risk difference due to nuisance parameters. See Agresti (1992) for more information.

### Tests

You can specify *riskdiff-options* to request tests of the risk (or proportion) difference. You can request tests of equality, noninferiority, superiority, and equivalence for the risk difference. The test of equality is a standard Wald asymptotic test, available with or without a continuity correction. For noninferiority, superiority, and equivalence tests of the risk difference, the following test methods are provided: Wald (with and without continuity correction), Hauck-Anderson, Farrington-Manning, and Newcombe score (with and without continuity correction). You can specify the test method with the METHOD= *riskdiff-option*. By default, PROC FREQ uses METHOD=WALD.

**Equality Test** If you specify the EQUAL riskdiff-option, PROC FREQ computes a test of equality, or a test of the null hypothesis that the risk difference equals zero. For the column 1 (or 2) risk difference, this test can be expressed as  $H_0: d = 0$  versus the alternative  $H_a: d \neq 0$ , where  $d = p_1 - p_2$  denotes the column 1 (or 2) risk difference. PROC FREQ computes a standard Wald asymptotic test, and the test statistic is

$$z = \hat{d} / \text{se}(\hat{d})$$

By default, the standard error is computed from the sample proportions as

$$\text{se}(\hat{d}) = \sqrt{\hat{p}_1(1 - \hat{p}_1)/n_{1\cdot} + \hat{p}_2(1 - \hat{p}_2)/n_{2\cdot}}$$

If you specify the VAR=NULL riskdiff-option, the standard error is based on the null hypothesis that the row 1 and row 2 risks are equal,

$$\text{se}(\hat{d}) = \sqrt{\hat{p}(1 - \hat{p}) \times (1/n_{1\cdot} + 1/n_{2\cdot})}$$

where  $\hat{p} = n_{\cdot 1}/n$  estimates the overall column 1 risk.

If you specify the CORRECT riskdiff-option or the RISKDIFFC option, PROC FREQ includes a continuity correction in the asymptotic test statistic. If  $\hat{d} > 0$ , the continuity correction is subtracted from  $\hat{d}$  in the numerator of the test statistic; otherwise, the continuity correction is added to the numerator. The value of the continuity correction is  $(1/n_{1\cdot} + 1/n_{2\cdot})/2$ .

PROC FREQ computes one-sided and two-sided  $p$ -values for this test. When the test statistic  $z$  is greater than 0, PROC FREQ displays the right-sided  $p$ -value, which is the probability of a larger value occurring under the null hypothesis. The one-sided  $p$ -value can be expressed as

$$P_1 = \begin{cases} \text{Prob}(Z > z) & \text{if } z > 0 \\ \text{Prob}(Z < z) & \text{if } z \leq 0 \end{cases}$$

where  $Z$  has a standard normal distribution. The two-sided  $p$ -value is computed as  $P_2 = 2 \times P_1$ .

**Noninferiority Test** If you specify the NONINF riskdiff-option, PROC FREQ provides a noninferiority test for the risk difference, or the difference between two proportions. The null hypothesis for the noninferiority test is

$$H_0: p_1 - p_2 \leq -\delta$$

versus the alternative

$$H_a: p_1 - p_2 > -\delta$$

where  $\delta$  is the noninferiority margin. Rejection of the null hypothesis indicates that the row 1 risk is not inferior to the row 2 risk. See Chow, Shao, and Wang (2003) for more information.

You can specify the value of  $\delta$  with the MARGIN= riskdiff-option. By default,  $\delta = 0.2$ . You can specify the test method with the METHOD= riskdiff-option. The following methods are available for the risk difference noninferiority analysis: Wald (with and without continuity correction), Hauck-Anderson, Farrington-Manning, and Newcombe score (with and without continuity correction). The Wald, Hauck-Anderson, and Farrington-Manning methods provide tests and corresponding test-based

confidence limits; the Newcombe score method provides only confidence limits. If you do not specify METHOD=, PROC FREQ uses the Wald test by default.

The confidence coefficient for the test-based confidence limits is  $100(1 - 2\alpha)\%$  (Schuirmann 1999). By default, if you do not specify the ALPHA= option, these are 90% confidence limits. You can compare the confidence limits to the noninferiority limit,  $-\delta$ .

The following sections describe the noninferiority analysis methods for the risk difference.

### **Wald Test**

If you specify the METHOD=WALD riskdiff-option, PROC FREQ provides an asymptotic Wald test of noninferiority for the risk difference. This is also the default method. The Wald test statistic is computed as

$$z = (\hat{d} + \delta) / \text{se}(\hat{d})$$

where  $(\hat{d} = \hat{p}_1 - \hat{p}_2)$  estimates the risk difference and  $\delta$  is the noninferiority margin.

By default, the standard error for the Wald test is computed from the sample proportions as

$$\text{se}(\hat{d}) = \sqrt{\hat{p}_1(1 - \hat{p}_1)/n_1. + \hat{p}_2(1 - \hat{p}_2)/n_2.}$$

If you specify the VAR=NULL riskdiff-option, the standard error is based on the null hypothesis that the risk difference equals  $-\delta$  (Dunnett and Gent 1977). The standard error is computed as

$$\text{se}(\hat{d}) = \sqrt{\tilde{p}(1 - \tilde{p})/n_2. + (\tilde{p} - \delta)(1 - \tilde{p} + \delta)/n_1.}$$

where

$$\tilde{p} = (n_{11} + n_{21} + \delta n_{1.})/n$$

If you specify the CORRECT riskdiff-option or the RISKDIFFC option, a continuity correction is included in the test statistic. The continuity correction is subtracted from the numerator of the test statistic if the numerator is greater than zero; otherwise, the continuity correction is added to the numerator. The value of the continuity correction is  $(1/n_1. + 1/n_2.)/2$ .

The  $p$ -value for the Wald noninferiority test is  $P_z = \text{Prob}(Z > z)$ , where  $Z$  has a standard normal distribution.

### **Hauck-Anderson Test**

If you specify the METHOD=HA riskdiff-option, PROC FREQ provides the Hauck-Anderson test for noninferiority. The Hauck-Anderson test statistic is computed as

$$z = (\hat{d} + \delta \pm cc) / s(\hat{d})$$

where  $\hat{d} = \hat{p}_1 - \hat{p}_2$  and the standard error is computed from the sample proportions as

$$\text{se}(\hat{d}) = \sqrt{\hat{p}_1(1 - \hat{p}_1)/(n_1. - 1) + \hat{p}_2(1 - \hat{p}_2)/(n_2. - 1)}$$

The Hauck-Anderson continuity correction  $cc$  is computed as

$$cc = 1 / (2 \min(n_{1.}, n_{2.}))$$

The  $p$ -value for the Hauck-Anderson noninferiority test is  $P_z = \text{Prob}(Z > z)$ , where  $Z$  has a standard normal distribution. See Hauck and Anderson (1986) and Schuirmann (1999) for more information.

### **Farrington-Manning Test**

If you specify the METHOD=FM riskdiff-option, PROC FREQ provides the Farrington-Manning test of noninferiority for the risk difference. The Farrington-Manning test statistic is computed as

$$z = (\hat{d} + \delta) / \text{se}(\hat{d})$$

where  $\hat{d} = \hat{p}_1 - \hat{p}_2$  and

$$\text{se}(\hat{d}) = \sqrt{\tilde{p}_1(1 - \tilde{p}_1)/n_1 + \tilde{p}_2(1 - \tilde{p}_2)/n_2},$$

where  $\tilde{p}_1$  and  $\tilde{p}_2$  are the maximum likelihood estimators of  $p_1$  and  $p_2$  under the null hypothesis that the risk difference equals  $-\delta$ . The  $p$ -value for the Farrington-Manning noninferiority test is then  $P_z = \text{Prob}(Z > z)$ , where  $Z$  has a standard normal distribution.

From Farrington and Manning (1990), the solution to the maximum likelihood equation is

$$\tilde{p}_1 = 2u \cos(w) - b/3a \quad \text{and} \quad \tilde{p}_2 = \tilde{p}_1 + \delta$$

where

$$\begin{aligned} w &= (\pi + \cos^{-1}(v/u^3))/3 \\ v &= b^3/(3a)^3 - bc/6a^2 + d/2a \\ u &= \text{sign}(v)\sqrt{b^2/(3a)^2 - c/3a} \\ a &= 1 + \theta \\ b &= -(1 + \theta + \hat{p}_1 + \theta\hat{p}_2 - \delta(\theta + 2)) \\ c &= \delta^2 - \delta(2\hat{p}_1 + \theta + 1) + \hat{p}_1 + \theta\hat{p}_2 \\ d &= \hat{p}_1\delta(1 - \delta) \\ \theta &= n_2/n_1. \end{aligned}$$

### **Newcombe Score Confidence Limits**

If you specify the METHOD=SCORE riskdiff-option, PROC FREQ provides the Newcombe hybrid score (or Wilson) confidence limits for the risk difference. The confidence coefficient for the confidence limits is  $100(1 - 2\alpha)\%$  (Schuirmann 1999). By default, if you do not specify the ALPHA= option, these are 90% confidence limits. You can compare the confidence limits to the noninferiority limit,  $-\delta$ .

The Newcombe score confidence limits for the risk difference are constructed from the Wilson score confidence limits for each of the two individual proportions. The confidence limits for the individual proportions are used in the standard error terms of the Wald confidence limits for the proportion difference. See Newcombe (1998) and Barker et al. (2001) for more information.

Wilson score confidence limits for  $p_1$  and  $p_2$  are the roots of

$$|p_i - \hat{p}_i| = z_\alpha \sqrt{p_i(1 - p_i)/n_i}.$$

for  $i = 1, 2$ . The confidence limits are computed as

$$\left( \hat{p}_i + z_{\alpha}^2/2n_{i\cdot} \pm z_{\alpha} \sqrt{(\hat{p}_i(1 - \hat{p}_i) + z_{\alpha}^2/4n_{i\cdot})/n_{i\cdot}} \right) / (1 + z_{\alpha}^2/n_{i\cdot})$$

See the section “**Wilson (Score) Confidence Limits**” on page 2281 for details.

Denote the lower and upper Wilson score confidence limits for  $p_1$  as  $L_1$  and  $U_1$ , and denote the lower and upper confidence limits for  $p_2$  as  $L_2$  and  $U_2$ . The Newcombe score confidence limits for the proportion difference ( $d = p_1 - p_2$ ) are computed as

$$d_L = (\hat{p}_1 - \hat{p}_2) - z_{\alpha} \sqrt{L_1(1 - L_1)/n_{1\cdot} + U_2(1 - U_2)/n_{2\cdot}}$$

$$d_U = (\hat{p}_1 - \hat{p}_2) + z_{\alpha} \sqrt{U_1(1 - U_1)/n_{1\cdot} + L_2(1 - L_2)/n_{2\cdot}}$$

If you specify the CORRECT riskdiff-option, PROC FREQ provides continuity-corrected Newcombe score confidence limits. By including a continuity correction of  $1/2n_{i\cdot}$ , the Wilson score confidence limits for the individual proportions are the roots of

$$|p_i - \hat{p}_i| - 1/2n_{i\cdot} = z_{\alpha} \sqrt{p_i(1 - p_i)/n_{i\cdot}}$$

These confidence limits for the individual proportions are then used in the standard error terms of the Wald confidence limits for the proportion difference to compute  $d_L$  and  $d_U$ .

**Superiority Test** If you specify the SUP riskdiff-option, PROC FREQ provides a superiority test for the risk difference. The null hypothesis is

$$H_0: p_1 - p_2 \leq \delta$$

versus the alternative

$$H_a: p_1 - p_2 > \delta$$

where  $\delta$  is the superiority margin. Rejection of the null hypothesis indicates that the row 1 proportion is superior to the row 2 proportion. You can specify the value of  $\delta$  with the MARGIN= riskdiff-option. By default,  $\delta = 0.2$ .

The superiority analysis is identical to the noninferiority analysis but uses a positive value of the margin  $\delta$  in the null hypothesis. The superiority computations follow those in the section “**Noninferiority Test**” on page 2289 by replacing  $-\delta$  by  $\delta$ . See Chow, Shao, and Wang (2003) for more information.

**Equivalence Tests** If you specify the EQUIV riskdiff-option, PROC FREQ provides an equivalence test for the risk difference, or the difference between two proportions. The null hypothesis for the equivalence test is

$$H_0: p_1 - p_2 \leq -\delta_L \quad \text{or} \quad p_1 - p_2 \geq \delta_U$$

versus the alternative

$$H_a: \delta_L < p_1 - p_2 < \delta_U$$

where  $\delta_L$  is the lower margin and  $\delta_U$  is the upper margin. Rejection of the null hypothesis indicates that the two binomial proportions are equivalent. See Chow, Shao, and Wang (2003) for more information.

You can specify the value of the margins  $\delta_L$  and  $\delta_U$  with the `MARGIN=` riskdiff-option. If you do not specify `MARGIN=`, PROC FREQ uses lower and upper margins of  $-0.2$  and  $0.2$  by default. If you specify a single margin value  $\delta$ , PROC FREQ uses lower and upper margins of  $-\delta$  and  $\delta$ . You can specify the test method with the `METHOD=` riskdiff-option. The following methods are available for the risk difference equivalence analysis: Wald (with and without continuity correction), Hauck-Anderson, Farrington-Manning, and Newcombe's score (with and without continuity correction). The Wald, Hauck-Anderson, and Farrington-Manning methods provide tests and corresponding test-based confidence limits; the Newcombe score method provides only confidence limits. If you do not specify `METHOD=`, PROC FREQ uses the Wald test by default.

PROC FREQ computes two one-sided tests (TOST) for equivalence analysis (Schuirmann 1987). The TOST approach includes a right-sided test for the lower margin  $\delta_L$  and a left-sided test for the upper margin  $\delta_U$ . The overall  $p$ -value is taken to be the larger of the two  $p$ -values from the lower and upper tests.

The section “[Noninferiority Test](#)” on page 2289 gives details about the Wald, Hauck-Anderson, Farrington-Manning and Newcombe score methods for the risk difference. The lower margin equivalence test statistic takes the same form as the noninferiority test statistic but uses the lower margin value  $\delta_L$  in place of  $-\delta$ . The upper margin equivalence test statistic take the same form as the noninferiority test statistic but uses the upper margin value  $\delta_U$  in place of  $-\delta$ .

The test-based confidence limits for the risk difference are computed according to the equivalence test method that you select. If you specify `METHOD=WALD` with `VAR=NULL`, or `METHOD=FM`, separate standard errors are computed for the lower and upper margin tests. In this case, the test-based confidence limits are computed by using the maximum of these two standard errors. The confidence limits have a confidence coefficient of  $100(1 - 2\alpha)\%$  (Schuirmann 1999). By default, if you do not specify the `ALPHA=` option, these are 90% confidence limits. You can compare the confidence limits to the equivalence limits,  $(\delta_L, \delta_U)$ .

### **Exact Unconditional Confidence Limits for the Risk Difference**

If you specify the `RISKDIFF` option in the `EXACT` statement, PROC FREQ provides exact unconditional confidence limits for the risk difference. Unconditional computations differ from the exact conditional approach that PROC FREQ uses for other exact statistics such as Fisher's exact test. (See the section “[Exact Statistics](#)” on page 2314 for more information.) Exact conditional inference does not apply to the risk difference due to nuisance parameters. See Agresti (1992) for details. The unconditional approach eliminates nuisance parameters by maximizing the  $p$ -value over all possible values of the nuisance parameters (Santner and Snell 1980).

Denote the proportion difference by  $d = p_1 - p_2$ . For a  $2 \times 2$  table with row totals  $n_1$  and  $n_2$ , the joint probability function can be expressed in terms of the table cell frequencies and the parameters  $d$  and  $p_2$ ,

$$f(n_{11}, n_{21}; n_1, n_2, d, p_2) = \binom{n_1}{n_{11}} (d + p_2)^{n_{11}} (1 - d - p_2)^{n_1 - n_{11}} \times \binom{n_2}{n_{21}} p_2^{n_{21}} (1 - p_2)^{n_2 - n_{21}}$$

When constructing confidence limits for the proportion difference, the parameter of interest is  $d$  and  $p_2$  is a nuisance parameter.

Denote the observed value of the proportion difference by  $d_0 = \hat{p}_1 - \hat{p}_2$ . The  $100(1 - \alpha/2)\%$  confidence limits for  $d$  are computed as

$$\begin{aligned} d_L &= \sup (d_* : P_U(d_*) > \alpha/2) \\ d_U &= \inf (d_* : P_L(d_*) > \alpha/2) \end{aligned}$$

where

$$\begin{aligned} P_U(d_*) &= \sup_{p_2} \left( \sum_{A, D(a) \geq d_0} f(n_{11}, n_{21}; n_1, n_2, d_*, p_2) \right) \\ P_L(d_*) &= \sup_{p_2} \left( \sum_{A, D(a) \leq d_0} f(n_{11}, n_{21}; n_1, n_2, d_*, p_2) \right) \end{aligned}$$

The set  $A$  includes all  $2 \times 2$  tables with row sums equal to  $n_1$  and  $n_2$ , and  $D(a)$  denotes the value of the proportion difference ( $p_1 - p_2$ ) for table  $a$  in  $A$ . To compute  $P_U(d_*)$ , the sum includes probabilities of those tables for which ( $D(a) \geq d_0$ ), where  $d_0$  is the observed value of the proportion difference. For a fixed value of  $d_*$ ,  $P_U(d_*)$  is taken to be the maximum sum over all possible values of  $p_2$ . See Santner and Snell (1980) and Agresti and Min (2001) for details.

This method of eliminating the nuisance parameter is considered to be a conservative approach (Agresti and Min 2001). Additionally, the confidence limits are conservative for small samples because this is a discrete problem; the confidence coefficient is not exactly  $(1 - \alpha)$  but is at least  $(1 - \alpha)$ . See Agresti (1992) for more information.

## Odds Ratio and Relative Risks for 2 x 2 Tables

### ***Odds Ratio (Case-Control Studies)***

The odds ratio is a useful measure of association for a variety of study designs. For a retrospective design called a *case-control study*, the odds ratio can be used to estimate the relative risk when the probability of positive response is small (Agresti 2002). In a case-control study, two independent samples are identified based on a binary (yes-no) response variable, and the conditional distribution of a binary explanatory variable is examined, within fixed levels of the response variable. See Stokes, Davis, and Koch (2000) and Agresti (2007).

The odds of a positive response (column 1) in row 1 is  $n_{11}/n_{12}$ . Similarly, the odds of a positive response in row 2 is  $n_{21}/n_{22}$ . The odds ratio is formed as the ratio of the row 1 odds to the row 2 odds. The odds ratio for a  $2 \times 2$  table is defined as

$$OR = \frac{n_{11}/n_{12}}{n_{21}/n_{22}} = \frac{n_{11} n_{22}}{n_{12} n_{21}}$$

The odds ratio can be any nonnegative number. When the row and column variables are independent, the true value of the odds ratio equals 1. An odds ratio greater than 1 indicates that the odds of a

positive response are higher in row 1 than in row 2. Values less than 1 indicate the odds of positive response are higher in row 2. The strength of association increases with the deviation from 1.

The transformation  $G = (OR - 1)/(OR + 1)$  transforms the odds ratio to the range  $(-1, 1)$  with  $G = 0$  when  $OR = 1$ ;  $G = -1$  when  $OR = 0$ ; and  $G$  approaches 1 as  $OR$  approaches infinity.  $G$  is the gamma statistic, which PROC FREQ computes when you specify the MEASURES option.

The asymptotic  $100(1 - \alpha)\%$  confidence limits for the odds ratio are

$$(OR \times \exp(-z\sqrt{v}), OR \times \exp(z\sqrt{v}))$$

where

$$v = \text{var}(\ln OR) = \frac{1}{n_{11}} + \frac{1}{n_{12}} + \frac{1}{n_{21}} + \frac{1}{n_{22}}$$

and  $z$  is the  $100(1 - \alpha/2)$ th percentile of the standard normal distribution. If any of the four cell frequencies are zero, the estimates are not computed.

When you specify the OR option in the EXACT statement, PROC FREQ computes exact confidence limits for the odds ratio. Because this is a discrete problem, the confidence coefficient for the exact confidence interval is not exactly  $(1 - \alpha)$  but is at least  $(1 - \alpha)$ . Thus, these confidence limits are conservative. See Agresti (1992) for more information.

PROC FREQ computes exact confidence limits for the odds ratio by using an algorithm based on Thomas (1971). See also Gart (1971). The following two equations are solved iteratively to determine the lower and upper confidence limits,  $\phi_1$  and  $\phi_2$ :

$$\begin{aligned} \sum_{i=n_{11}}^{n_{1\cdot}} \binom{n_{1\cdot}}{i} \binom{n_{2\cdot}}{n_{1\cdot}-i} \phi_1^i / \sum_{i=0}^{n_{1\cdot}} \binom{n_{1\cdot}}{i} \binom{n_{2\cdot}}{n_{1\cdot}-i} \phi_1^i &= \alpha/2 \\ \sum_{i=0}^{n_{11}} \binom{n_{1\cdot}}{i} \binom{n_{2\cdot}}{n_{1\cdot}-i} \phi_2^i / \sum_{i=0}^{n_{1\cdot}} \binom{n_{1\cdot}}{i} \binom{n_{2\cdot}}{n_{1\cdot}-i} \phi_2^i &= \alpha/2 \end{aligned}$$

When the odds ratio equals zero, which occurs when either  $n_{11} = 0$  or  $n_{22} = 0$ , PROC FREQ sets the lower exact confidence limit to zero and determines the upper limit with level  $\alpha$ . Similarly, when the odds ratio equals infinity, which occurs when either  $n_{12} = 0$  or  $n_{21} = 0$ , PROC FREQ sets the upper exact confidence limit to infinity and determines the lower limit with level  $\alpha$ .

### Relative Risks (Cohort Studies)

These measures of relative risk are useful in *cohort* (prospective) study designs, where two samples are identified based on the presence or absence of an explanatory factor. The two samples are observed in future time for the binary (yes-no) response variable under study. Relative risk measures are also useful in cross-sectional studies, where two variables are observed simultaneously. See Stokes, Davis, and Koch (2000) and Agresti (2007) for more information.

The column 1 relative risk is the ratio of the column 1 risk for row 1 to row 2. The column 1 risk for row 1 is the proportion of the row 1 observations classified in column 1,

$$p_{1|1} = n_{11} / n_{1\cdot}$$

Similarly, the column 1 risk for row 2 is

$$p_{1|2} = n_{21} / n_2.$$

The column 1 relative risk is then computed as

$$RR_1 = p_{1|1} / p_{1|2}$$

A relative risk greater than 1 indicates that the probability of positive response is greater in row 1 than in row 2. Similarly, a relative risk less than 1 indicates that the probability of positive response is less in row 1 than in row 2. The strength of association increases with the deviation from 1.

Asymptotic  $100(1 - \alpha)\%$  confidence limits for the column 1 relative risk are computed as

$$(RR_1 \times \exp(-z\sqrt{v}), RR_1 \times \exp(z\sqrt{v}))$$

where

$$v = \text{var}(\ln RR_1) = ((1 - p_{1|1})/n_{11}) + ((1 - p_{1|2})/n_{21})$$

and  $z$  is the  $100(1 - \alpha/2)\text{th}$  percentile of the standard normal distribution. If either  $n_{11}$  or  $n_{21}$  is zero, the estimates are not computed.

PROC FREQ computes the column 2 relative risks in the same way.

### Cochran-Armitage Test for Trend

The TREND option in the TABLES statement provides the Cochran-Armitage test for trend, which tests for trend in binomial proportions across levels of a single factor or covariate. This test is appropriate for a two-way table where one variable has two levels and the other variable is ordinal. The two-level variable represents the response, and the other variable represents an explanatory variable with ordered levels. When the two-way has two columns and  $R$  rows, PROC FREQ tests for trend across the  $R$  levels of the row variable, and the binomial proportion is computed as the proportion of observations in the first column. When the table has two rows and  $C$  columns, PROC FREQ tests for trend across the  $C$  levels of the column variable, and the binomial proportion is computed as the proportion of observations in the first row.

The trend test is based on the regression coefficient for the weighted linear regression of the binomial proportions on the scores of the explanatory variable levels. See Margolin (1988) and Agresti (2002) for details. If the table has two columns and  $R$  rows, the trend test statistic is computed as

$$T = \sum_{i=1}^R n_{i1} (R_i - \bar{R}) / \sqrt{p_{\cdot 1} (1 - p_{\cdot 1}) s^2}$$

where  $R_i$  is the score of row  $i$ ,  $\bar{R}$  is the average row score, and

$$s^2 = \sum_{i=1}^R n_{i\cdot} (R_i - \bar{R})^2$$

The SCORES= option in the TABLES statement determines the type of row scores used in computing the trend test (and other score-based statistics). The default is SCORES=TABLE. See the section

“Scores” on page 2265 for details. For character variables, the table scores for the row variable are the row numbers (for example, 1 for the first row, 2 for the second row, and so on). For numeric variables, the table score for each row is the numeric value of the row level. When you perform the trend test, the explanatory variable might be numeric (for example, dose of a test substance), and the variable values might be appropriate scores. If the explanatory variable has ordinal levels that are not numeric, you can assign meaningful scores to the variable levels. Sometimes equidistant scores, such as the table scores for a character variable, might be appropriate. For more information on choosing scores for the trend test, see Margolin (1988).

The null hypothesis for the Cochran-Armitage test is no trend, which means that the binomial proportion  $p_{i1} = n_{i1}/n_i$  is the same for all levels of the explanatory variable. Under the null hypothesis, the trend statistic has an asymptotic standard normal distribution.

PROC FREQ computes one-sided and two-sided  $p$ -values for the trend test. When the test statistic is greater than its null hypothesis expected value of zero, PROC FREQ displays the right-sided  $p$ -value, which is the probability of a larger value of the statistic occurring under the null hypothesis. A small right-sided  $p$ -value supports the alternative hypothesis of increasing trend in proportions from row 1 to row  $R$ . When the test statistic is less than or equal to zero, PROC FREQ displays the left-sided  $p$ -value. A small left-sided  $p$ -value supports the alternative of decreasing trend.

The one-sided  $p$ -value for the trend test is computed as

$$P_1 = \begin{cases} \text{Prob}(Z > T) & \text{if } T > 0 \\ \text{Prob}(Z < T) & \text{if } T \leq 0 \end{cases}$$

where  $Z$  has a standard normal distribution. The two-sided  $p$ -value is computed as

$$P_2 = \text{Prob}(|Z| > |T|)$$

PROC FREQ also provides exact  $p$ -values for the Cochran-Armitage trend test. You can request the exact test by specifying the TREND option in the EXACT statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

## Jonckheere-Terpstra Test

The JT option in the TABLES statement provides the Jonckheere-Terpstra test, which is a nonparametric test for ordered differences among classes. It tests the null hypothesis that the distribution of the response variable does not differ among classes. It is designed to detect alternatives of ordered class differences, which can be expressed as  $\tau_1 \leq \tau_2 \leq \dots \leq \tau_R$  (or  $\tau_1 \geq \tau_2 \geq \dots \geq \tau_R$ ), with at least one of the inequalities being strict, where  $\tau_i$  denotes the effect of class  $i$ . For such ordered alternatives, the Jonckheere-Terpstra test can be preferable to tests of more general class difference alternatives, such as the Kruskal-Wallis test (produced by the WILCOXON option in the NPAR1WAY procedure). See Pirie (1983) and Hollander and Wolfe (1999) for more information about the Jonckheere-Terpstra test.

The Jonckheere-Terpstra test is appropriate for a two-way table in which an ordinal column variable represents the response. The row variable, which can be nominal or ordinal, represents the classification variable. The levels of the row variable should be ordered according to the ordering you want the test to detect. The order of variable levels is determined by the ORDER= option in the PROC

FREQ statement. The default is ORDER=INTERNAL, which orders by unformatted values. If you specify ORDER=DATA, PROC FREQ orders values according to their order in the input data set. For more information about how to order variable levels, see the [ORDER=](#) option.

The Jonckheere-Terpstra test statistic is computed by first forming  $R(R - 1)/2$  Mann-Whitney counts  $M_{i,i'}$ , where  $i < i'$ , for pairs of rows in the contingency table,

$$M_{i,i'} = \{ \text{number of times } X_{i,j} < X_{i',j'}, \quad j = 1, \dots, n_i; \quad j' = 1, \dots, n_{i'} \} \\ + \frac{1}{2} \{ \text{number of times } X_{i,j} = X_{i',j'}, \quad j = 1, \dots, n_i; \quad j' = 1, \dots, n_{i'} \}$$

where  $X_{i,j}$  is response  $j$  in row  $i$ . The Jonckheere-Terpstra test statistic is computed as

$$J = \sum_{1 \leq i < i' \leq R} M_{i,i'}$$

This test rejects the null hypothesis of no difference among classes for large values of  $J$ . Asymptotic  $p$ -values for the Jonckheere-Terpstra test are obtained by using the normal approximation for the distribution of the standardized test statistic. The standardized test statistic is computed as

$$J^* = (J - E_0(J)) / \sqrt{\text{var}_0(J)}$$

where  $E_0(J)$  and  $\text{var}_0(J)$  are the expected value and variance of the test statistic under the null hypothesis,

$$E_0(J) = \left( n^2 - \sum_i n_{i.}^2 \right) / 4$$

$$\text{var}_0(J) = A/72 + B/(36n(n-1)(n-2)) + C/(8n(n-1))$$

where

$$A = n(n-1)(2n+5) - \sum_i n_{i.}(n_{i.}-1)(2n_{i.}+5) - \sum_j n_{.j}(n_{.j}-1)(2n_{.j}+5)$$

$$B = \left( \sum_i n_{i.}(n_{i.}-1)(n_{i.}-2) \right) \left( \sum_j n_{.j}(n_{.j}-1)(n_{.j}-2) \right)$$

$$C = \left( \sum_i n_{i.}(n_{i.}-1) \right) \left( \sum_j n_{.j}(n_{.j}-1) \right)$$

PROC FREQ computes one-sided and two-sided  $p$ -values for the Jonckheere-Terpstra test. When the standardized test statistic is greater than its null hypothesis expected value of zero, PROC FREQ displays the right-sided  $p$ -value, which is the probability of a larger value of the statistic occurring under the null hypothesis. A small right-sided  $p$ -value supports the alternative hypothesis of increasing order from row 1 to row  $R$ . When the standardized test statistic is less than or equal to zero, PROC FREQ displays the left-sided  $p$ -value. A small left-sided  $p$ -value supports the alternative of decreasing order from row 1 to row  $R$ .

The one-sided  $p$ -value for the Jonckheere-Terpstra test,  $P_1$ , is computed as

$$P_1 = \begin{cases} \text{Prob}(Z > J^*) & \text{if } J^* > 0 \\ \text{Prob}(Z < J^*) & \text{if } J^* \leq 0 \end{cases}$$

where  $Z$  has a standard normal distribution. The two-sided  $p$ -value,  $P_2$ , is computed as

$$P_2 = \text{Prob}(|Z| > |J^*|)$$

PROC FREQ also provides exact  $p$ -values for the Jonckheere-Terpstra test. You can request the exact test by specifying the JT option in the EXACT statement. See the section “Exact Statistics” on page 2314 for more information.

## Tests and Measures of Agreement

When you specify the AGREE option in the TABLES statement, PROC FREQ computes tests and measures of agreement for square tables (that is, for tables where the number of rows equals the number of columns). For two-way tables, these tests and measures include McNemar’s test for  $2 \times 2$  tables, Bowker’s test of symmetry, the simple kappa coefficient, and the weighted kappa coefficient. For multiple strata ( $n$ -way tables, where  $n > 2$ ), PROC FREQ also computes the overall simple kappa coefficient and the overall weighted kappa coefficient, as well as tests for equal kappas (simple and weighted) among strata. Cochran’s  $Q$  is computed for multiway tables when each variable has two levels, that is, for  $h \times 2 \times 2$  tables.

PROC FREQ computes the kappa coefficients (simple and weighted), their asymptotic standard errors, and their confidence limits when you specify the AGREE option in the TABLES statement. If you also specify the KAPPA option in the TEST statement, then PROC FREQ computes the asymptotic test of the hypothesis that simple kappa equals zero. Similarly, if you specify the WTKAP option in the TEST statement, PROC FREQ computes the asymptotic test for weighted kappa.

In addition to the asymptotic tests described in this section, PROC FREQ provides exact  $p$ -values for McNemar’s test, the simple kappa coefficient test, and the weighted kappa coefficient test. You can request these exact tests by specifying the corresponding options in the EXACT statement. See the section “Exact Statistics” on page 2314 for more information.

The following sections provide the formulas that PROC FREQ uses to compute the AGREE statistics. For information about the use and interpretation of these statistics, see Agresti (2002), Agresti (2007), Fleiss, Levin, and Paik (2003), and the other references cited for each statistic.

### McNemar’s Test

PROC FREQ computes McNemar’s test for  $2 \times 2$  tables when you specify the AGREE option. McNemar’s test is appropriate when you are analyzing data from matched pairs of subjects with a dichotomous (yes-no) response. It tests the null hypothesis of marginal homogeneity, or  $p_{1\cdot} = p_{\cdot 1}$ . McNemar’s test is computed as

$$Q_M = (n_{12} - n_{21})^2 / (n_{12} + n_{21})$$

Under the null hypothesis,  $Q_M$  has an asymptotic chi-square distribution with one degree of freedom. See McNemar (1947), as well as the general references cited in the preceding section. In addition to the asymptotic test, PROC FREQ also computes the exact  $p$ -value for McNemar's test when you specify the MCNEM option in the EXACT statement.

### **Bowker's Test of Symmetry**

For Bowker's test of symmetry, the null hypothesis is that the cell proportions are symmetric, or that  $p_{ij} = p_{ji}$  for all pairs of table cells. For  $2 \times 2$  tables, Bowker's test is identical to McNemar's test, and so PROC FREQ provides Bowker's test for square tables larger than  $2 \times 2$ .

Bowker's test of symmetry is computed as

$$Q_B = \sum_{i < j} \sum (n_{ij} - n_{ji})^2 / (n_{ij} + n_{ji})$$

For large samples,  $Q_B$  has an asymptotic chi-square distribution with  $R(R-1)/2$  degrees of freedom under the null hypothesis of symmetry. See Bowker (1948) for details.

### **Simple Kappa Coefficient**

The simple kappa coefficient, introduced by Cohen (1960), is a measure of interrater agreement. PROC FREQ computes the simple kappa coefficient as

$$\hat{\kappa} = (P_o - P_e) / (1 - P_e)$$

where  $P_o = \sum_i p_{ii}$  and  $P_e = \sum_i p_{i\cdot} p_{\cdot i}$ . If the two response variables are viewed as two independent ratings of the  $n$  subjects, the kappa coefficient equals +1 when there is complete agreement of the raters. When the observed agreement exceeds chance agreement, kappa is positive, with its magnitude reflecting the strength of agreement. Although this is unusual in practice, kappa is negative when the observed agreement is less than chance agreement. The minimum value of kappa is between  $-1$  and  $0$ , depending on the marginal proportions.

The asymptotic variance of the simple kappa coefficient is computed as

$$\text{var}(\hat{\kappa}) = (A + B - C) / (1 - P_e)^2 n$$

where

$$A = \sum_i p_{ii} (1 - (p_{i\cdot} + p_{\cdot i})(1 - \hat{\kappa}))^2$$

$$B = (1 - \hat{\kappa})^2 \sum_{i \neq j} \sum p_{ij} (p_{i\cdot} + p_{\cdot j})^2$$

$$C = (\hat{\kappa} - P_e(1 - \hat{\kappa}))^2$$

See Fleiss, Cohen, and Everitt (1969) for details.

PROC FREQ computes confidence limits for the simple kappa coefficient as

$$\hat{\kappa} \pm (z_{\alpha/2} \times \sqrt{\text{var}(\hat{\kappa})})$$

where  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the standard normal distribution. The value of  $\alpha$  is determined by the value of the ALPHA= option, which, by default, equals 0.05 and produces 95% confidence limits.

To compute an asymptotic test for the kappa coefficient, PROC FREQ uses the standardized test statistic  $\hat{\kappa}^*$ , which has an asymptotic standard normal distribution under the null hypothesis that kappa equals zero. The standardized test statistic is computed as

$$\hat{\kappa}^* = \hat{\kappa} / \sqrt{\text{var}_0(\hat{\kappa})}$$

where  $\text{var}_0(\hat{\kappa})$  is the variance of the kappa coefficient under the null hypothesis,

$$\text{var}_0(\hat{\kappa}) = \left( P_e + P_e^2 - \sum_i p_{i \cdot} p_{\cdot i} (p_{i \cdot} + p_{\cdot i}) \right) / (1 - P_e)^2 n$$

See Fleiss, Levin, and Paik (2003) for details.

PROC FREQ also provides an exact test for the simple kappa coefficient. You can request the exact test by specifying the KAPPA or AGREE option in the EXACT statement. See the section “[Exact Statistics](#)” on page 2314 for more information.

### Weighted Kappa Coefficient

The weighted kappa coefficient is a generalization of the simple kappa coefficient that uses weights to quantify the relative difference between categories. For  $2 \times 2$  tables, the weighted kappa coefficient equals the simple kappa coefficient. PROC FREQ displays the weighted kappa coefficient only for tables larger than  $2 \times 2$ . PROC FREQ computes the kappa weights from the column scores, by using either Cicchetti-Allison weights or Fleiss-Cohen weights, both of which are described in the following section. The weights  $w_{ij}$  are constructed so that  $0 \leq w_{ij} < 1$  for all  $i \neq j$ ,  $w_{ii} = 1$  for all  $i$ , and  $w_{ij} = w_{ji}$ . The weighted kappa coefficient is computed as

$$\hat{\kappa}_w = (P_{o(w)} - P_{e(w)}) / (1 - P_{e(w)})$$

where

$$P_{o(w)} = \sum_i \sum_j w_{ij} p_{ij}$$

$$P_{e(w)} = \sum_i \sum_j w_{ij} p_{i \cdot} p_{\cdot j}$$

The asymptotic variance of the weighted kappa coefficient is

$$\text{var}(\hat{\kappa}_w) = \left( \sum_i \sum_j p_{ij} (w_{ij} - (\bar{w}_{i \cdot} + \bar{w}_{\cdot j})/2)(1 - \hat{\kappa}_w)^2 - (\hat{\kappa}_w - P_{e(w)}(1 - \hat{\kappa}_w))^2 \right) / (1 - P_{e(w)})^2 n$$

where

$$\bar{w}_{i\cdot} = \sum_j p_{\cdot j} w_{ij}$$

$$\bar{w}_{\cdot j} = \sum_i p_{i\cdot} w_{ij}$$

See Fleiss, Cohen, and Everitt (1969) for details.

PROC FREQ computes confidence limits for the weighted kappa coefficient as

$$\hat{\kappa}_w \pm (z_{\alpha/2} \times \sqrt{\text{var}(\hat{\kappa}_w)})$$

where  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the standard normal distribution. The value of  $\alpha$  is determined by the value of the ALPHA= option, which, by default, equals 0.05 and produces 95% confidence limits.

To compute an asymptotic test for the weighted kappa coefficient, PROC FREQ uses the standardized test statistic  $\hat{\kappa}_w^*$ , which has an asymptotic standard normal distribution under the null hypothesis that weighted kappa equals zero. The standardized test statistic is computed as

$$\hat{\kappa}_w^* = \hat{\kappa}_w / \sqrt{\text{var}_0(\hat{\kappa}_w)}$$

where  $\text{var}_0(\hat{\kappa}_w)$  is the variance of the weighted kappa coefficient under the null hypothesis,

$$\text{var}_0(\hat{\kappa}_w) = \left( \sum_i \sum_j p_{i\cdot} p_{\cdot j} (w_{ij} - (\bar{w}_{i\cdot} + \bar{w}_{\cdot j}))^2 - P_{e(w)}^2 \right) / (1 - P_{e(w)})^2 n$$

See Fleiss, Levin, and Paik (2003) for details.

PROC FREQ also provides an exact test for the weighted kappa coefficient. You can request the exact test by specifying the WTKAPPA or AGREE option in the EXACT statement. See the section “Exact Statistics” on page 2314 for more information.

**Weights** PROC FREQ computes kappa coefficient weights by using the column scores and one of the two available weight types. The column scores are determined by the SCORES= option in the TABLES statement. The two available types of kappa weights are Cicchetti-Allison and Fleiss-Cohen weights. By default, PROC FREQ uses Cicchetti-Allison weights. If you specify (WT=FC) with the AGREE option, then PROC FREQ uses Fleiss-Cohen weights to compute the weighted kappa coefficient.

PROC FREQ computes Cicchetti-Allison kappa coefficient weights as

$$w_{ij} = 1 - \frac{|C_i - C_j|}{C_C - C_1}$$

where  $C_i$  is the score for column  $i$  and  $C$  is the number of categories or columns. See Cicchetti and Allison (1971) for details.

The SCORES= option in the TABLES statement determines the type of column scores used to compute the kappa weights (and other score-based statistics). The default is SCORES=TABLE. See

the section “**Scores**” on page 2265 for details. For numeric variables, table scores are the values of the variable levels. You can assign numeric values to the levels in a way that reflects their level of similarity. For example, suppose you have four levels and order them according to similarity. If you assign them values of 0, 2, 4, and 10, the Cicchetti-Allison kappa weights take the following values:  $w_{12} = 0.8$ ,  $w_{13} = 0.6$ ,  $w_{14} = 0$ ,  $w_{23} = 0.8$ ,  $w_{24} = 0.2$ , and  $w_{34} = 0.4$ . Note that when there are only two categories (that is,  $C = 2$ ), the weighted kappa coefficient is identical to the simple kappa coefficient.

If you specify (WT=FC) with the AGREE option in the TABLES statement, PROC FREQ computes Fleiss-Cohen kappa coefficient weights as

$$w_{ij} = 1 - \frac{(C_i - C_j)^2}{(C_C - C_1)^2}$$

See Fleiss and Cohen (1973) for details.

For the preceding example, the Fleiss-Cohen kappa weights are:  $w_{12} = 0.96$ ,  $w_{13} = 0.84$ ,  $w_{14} = 0$ ,  $w_{23} = 0.96$ ,  $w_{24} = 0.36$ , and  $w_{34} = 0.64$ .

### Overall Kappa Coefficient

When there are multiple strata, PROC FREQ combines the stratum-level estimates of kappa into an overall estimate of the supposed common value of kappa. Assume there are  $q$  strata, indexed by  $h = 1, 2, \dots, q$ , and let  $\text{var}(\hat{\kappa}_h)$  denote the variance of  $\hat{\kappa}_h$ . The estimate of the overall kappa coefficient is computed as

$$\hat{\kappa}_T = \sum_{h=1}^q \frac{\hat{\kappa}_h}{\text{var}(\hat{\kappa}_h)} / \sum_{h=1}^q \frac{1}{\text{var}(\hat{\kappa}_h)}$$

See Fleiss, Levin, and Paik (2003) for details.

PROC FREQ computes an estimate of the overall weighted kappa in the same way.

### Tests for Equal Kappa Coefficients

When there are multiple strata, the following chi-square statistic tests whether the stratum-level values of kappa are equal:

$$Q_K = \sum_{h=1}^q (\hat{\kappa}_h - \hat{\kappa}_T)^2 / \text{var}(\hat{\kappa}_h)$$

Under the null hypothesis of equal kappas for the  $q$  strata,  $Q_K$  has an asymptotic chi-square distribution with  $q - 1$  degrees of freedom. See Fleiss, Levin, and Paik (2003) for more information. PROC FREQ computes a test for equal weighted kappa coefficients in the same way.

### Cochran's Q Test

Cochran's  $Q$  is computed for multiway tables when each variable has two levels, that is, for  $2 \times 2 \cdots \times 2$  tables. Cochran's  $Q$  statistic is used to test the homogeneity of the one-dimensional

margins. Let  $m$  denote the number of variables and  $N$  denote the total number of subjects. Cochran's  $Q$  statistic is computed as

$$Q_C = m(m-1) \left( \sum_{j=1}^m T_j^2 - T^2 \right) / \left( mT - \sum_{k=1}^N S_k^2 \right)$$

where  $T_j$  is the number of positive responses for variable  $j$ ,  $T$  is the total number of positive responses over all variables, and  $S_k$  is the number of positive responses for subject  $k$ . Under the null hypothesis, Cochran's  $Q$  has an asymptotic chi-square distribution with  $m - 1$  degrees of freedom. See Cochran (1950) for details. When there are only two binary response variables ( $m = 2$ ), Cochran's  $Q$  simplifies to McNemar's test. When there are more than two response categories, you can test for marginal homogeneity by using the repeated measures capabilities of the CATMOD procedure.

### Tables with Zero Rows and Columns

The AGREE statistics are defined only for square tables, where the number of rows equals the number of columns. If the table is not square, PROC FREQ does not compute AGREE statistics. In the kappa statistic framework, where two independent raters assign ratings to each of  $n$  subjects, suppose one of the raters does not use all possible  $r$  rating levels. If the corresponding table has  $r$  rows but only  $r - 1$  columns, then the table is not square and PROC FREQ does not compute AGREE statistics. To create a square table in this situation, use the ZEROS option in the WEIGHT statement, which requests that PROC FREQ include observations with zero weights in the analysis. Include zero-weight observations in the input data set to represent any rating levels that are not used by a rater, so that the input data set has at least one observation for each possible rater and rating combination. The analysis then includes all rating levels, even when all levels are not actually assigned by both raters. The resulting table (of rater 1 by rater 2) is a square table, and AGREE statistics can be computed.

For more information, see the description of the ZEROS option. By default, PROC FREQ does not process observations that have zero weights, because these observations do not contribute to the total frequency count, and because any resulting zero-weight row or column causes many of the tests and measures of association to be undefined. However, kappa statistics are defined for tables with a zero-weight row or column, and the ZEROS option makes it possible to input zero-weight observations and construct the tables needed to compute kappas.

### Cochran-Mantel-Haenszel Statistics

The CMH option in the TABLES statement gives a stratified statistical analysis of the relationship between the row and column variables after controlling for the strata variables in a multiway table. For example, for the table request A\*B\*C\*D, the CMH option provides an analysis of the relationship between C and D, after controlling for A and B. The stratified analysis provides a way to adjust for the possible confounding effects of A and B without being forced to estimate parameters for them.

The CMH analysis produces Cochran-Mantel-Haenszel statistics, which include the correlation statistic, the ANOVA (row mean scores) statistic, and the general association statistic. For  $2 \times 2$  tables, the CMH option also provides Mantel-Haenszel and logit estimates of the common odds ratio and the common relative risks, as well as the Breslow-Day test for homogeneity of the odds ratios.

Exact statistics are also available for stratified  $2 \times 2$  tables. If you specify the EQOR option in the EXACT statement, PROC FREQ provides Zelen's exact test for equal odds ratios. If you specify the COMOR option in the EXACT statement, PROC FREQ provides exact confidence limits for the common odds ratio and an exact test that the common odds ratio equals one.

Let the number of strata be denoted by  $q$ , indexing the strata by  $h = 1, 2, \dots, q$ . Each stratum contains a contingency table with  $X$  representing the row variable and  $Y$  representing the column variable. For table  $h$ , denote the cell frequency in row  $i$  and column  $j$  by  $n_{hij}$ , with corresponding row and column marginal totals denoted by  $n_{hi\cdot}$  and  $n_{h\cdot j}$ , and the overall stratum total by  $n_h$ .

Because the formulas for the Cochran-Mantel-Haenszel statistics are more easily defined in terms of matrices, the following notation is used. Vectors are presumed to be column vectors unless they are transposed ( $'$ ).

$$\begin{aligned} \mathbf{n}'_{hi} &= (n_{hi1}, n_{hi2}, \dots, n_{hiC}) & (1 \times C) \\ \mathbf{n}'_h &= (\mathbf{n}'_{h1}, \mathbf{n}'_{h2}, \dots, \mathbf{n}'_{hR}) & (1 \times RC) \\ p_{hi\cdot} &= n_{hi\cdot} / n_h & (1 \times 1) \\ p_{h\cdot j} &= n_{h\cdot j} / n_h & (1 \times 1) \\ \mathbf{P}'_{h*} &= (p_{h1\cdot}, p_{h2\cdot}, \dots, p_{hR\cdot}) & (1 \times R) \\ \mathbf{P}'_{h\cdot*} &= (p_{h\cdot 1}, p_{h\cdot 2}, \dots, p_{h\cdot C}) & (1 \times C) \end{aligned}$$

Assume that the strata are independent and that the marginal totals of each stratum are fixed. The null hypothesis,  $H_0$ , is that there is no association between  $X$  and  $Y$  in any of the strata. The corresponding model is the multiple hypergeometric; this implies that, under  $H_0$ , the expected value and covariance matrix of the frequencies are, respectively,

$$\begin{aligned} \mathbf{m}_h &= \mathbf{E}[\mathbf{n}_h \mid H_0] = n_h (\mathbf{P}_{h*} \otimes \mathbf{P}_{h\cdot*}) \\ \mathbf{var}[\mathbf{n}_h \mid H_0] &= c \left( (\mathbf{D}_{\mathbf{P}_{h*}} - \mathbf{P}_{h*} \mathbf{P}'_{h*}) \otimes (\mathbf{D}_{\mathbf{P}_{h\cdot*}} - \mathbf{P}_{h\cdot*} \mathbf{P}'_{h\cdot*}) \right) \end{aligned}$$

where

$$c = n_h^2 / (n_h - 1)$$

and where  $\otimes$  denotes Kronecker product multiplication and  $\mathbf{D}_{\mathbf{a}}$  is a diagonal matrix with the elements of  $\mathbf{a}$  on the main diagonal.

The generalized CMH statistic (Landis, Heyman, and Koch 1978) is defined as

$$Q_{CMH} = \mathbf{G}' \mathbf{V}_G^{-1} \mathbf{G}$$

where

$$\begin{aligned} \mathbf{G} &= \sum_h \mathbf{B}_h (\mathbf{n}_h - \mathbf{m}_h) \\ \mathbf{V}_G &= \sum_h \mathbf{B}_h (\mathbf{Var}(\mathbf{n}_h \mid H_0)) \mathbf{B}'_h \end{aligned}$$

and where

$$\mathbf{B}_h = \mathbf{C}_h \otimes \mathbf{R}_h$$

is a matrix of fixed constants based on column scores  $\mathbf{C}_h$  and row scores  $\mathbf{R}_h$ . When the null hypothesis is true, the CMH statistic has an asymptotic chi-square distribution with degrees of freedom equal to the rank of  $\mathbf{B}_h$ . If  $\mathbf{V}_G$  is found to be singular, PROC FREQ prints a message and sets the value of the CMH statistic to missing.

PROC FREQ computes three CMH statistics by using this formula for the generalized CMH statistic, with different row and column score definitions for each statistic. The CMH statistics that PROC FREQ computes are the correlation statistic, the ANOVA (row mean scores) statistic, and the general association statistic. These statistics test the null hypothesis of no association against different alternative hypotheses. The following sections describe the computation of these CMH statistics.

**CAUTION:** The CMH statistics have low power for detecting an association in which the patterns of association for some of the strata are in the opposite direction of the patterns displayed by other strata. Thus, a nonsignificant CMH statistic suggests either that there is no association or that no pattern of association has enough strength or consistency to dominate any other pattern.

### **Correlation Statistic**

The correlation statistic, popularized by Mantel and Haenszel (1959) and Mantel (1963), has one degree of freedom and is known as the Mantel-Haenszel statistic.

The alternative hypothesis for the correlation statistic is that there is a linear association between  $X$  and  $Y$  in at least one stratum. If either  $X$  or  $Y$  does not lie on an ordinal (or interval) scale, then this statistic is not meaningful.

To compute the correlation statistic, PROC FREQ uses the formula for the generalized CMH statistic with the row and column scores determined by the SCORES= option in the TABLES statement. See the section “[Scores](#)” on page 2265 for more information about the available score types. The matrix of row scores  $\mathbf{R}_h$  has dimension  $1 \times R$ , and the matrix of column scores  $\mathbf{C}_h$  has dimension  $1 \times C$ .

When there is only one stratum, this CMH statistic reduces to  $(n - 1)r^2$ , where  $r$  is the Pearson correlation coefficient between  $X$  and  $Y$ . When nonparametric (RANK or RIDIT) scores are specified, the statistic reduces to  $(n - 1)r_s^2$ , where  $r_s$  is the Spearman rank correlation coefficient between  $X$  and  $Y$ . When there is more than one stratum, this CMH statistic becomes a stratum-adjusted correlation statistic.

### **ANOVA (Row Mean Scores) Statistic**

The ANOVA statistic can be used only when the column variable  $Y$  lies on an ordinal (or interval) scale so that the mean score of  $Y$  is meaningful. For the ANOVA statistic, the mean score is computed for each row of the table, and the alternative hypothesis is that, for at least one stratum, the mean scores of the  $R$  rows are unequal. In other words, the statistic is sensitive to location differences among the  $R$  distributions of  $Y$ .

The matrix of column scores  $\mathbf{C}_h$  has dimension  $1 \times C$ , and the column scores are determined by the SCORES= option.

The matrix of row scores  $\mathbf{R}_h$  has dimension  $(R - 1) \times R$  and is created internally by PROC FREQ as

$$\mathbf{R}_h = [\mathbf{I}_{R-1}, -\mathbf{J}_{R-1}]$$

where  $\mathbf{I}_{R-1}$  is an identity matrix of rank  $R - 1$  and  $\mathbf{J}_{R-1}$  is an  $(R - 1) \times 1$  vector of ones. This matrix has the effect of forming  $R - 1$  independent contrasts of the  $R$  mean scores.

When there is only one stratum, this CMH statistic is essentially an analysis of variance (ANOVA) statistic in the sense that it is a function of the variance ratio  $F$  statistic that would be obtained from a one-way ANOVA on the dependent variable  $Y$ . If nonparametric scores are specified in this case, then the ANOVA statistic is a Kruskal-Wallis test.

If there is more than one stratum, then this CMH statistic corresponds to a stratum-adjusted ANOVA or Kruskal-Wallis test. In the special case where there is one subject per row and one subject per column in the contingency table of each stratum, this CMH statistic is identical to Friedman's chi-square. See [Example 35.9](#) for an illustration.

### General Association Statistic

The alternative hypothesis for the general association statistic is that, for at least one stratum, there is some kind of association between  $X$  and  $Y$ . This statistic is always interpretable because it does not require an ordinal scale for either  $X$  or  $Y$ .

For the general association statistic, the matrix  $\mathbf{R}_h$  is the same as the one used for the ANOVA statistic. The matrix  $\mathbf{C}_h$  is defined similarly as

$$\mathbf{C}_h = [\mathbf{I}_{C-1}, -\mathbf{J}_{C-1}]$$

PROC FREQ generates both score matrices internally. When there is only one stratum, then the general association CMH statistic reduces to  $Q_P(n - 1)/n$ , where  $Q_P$  is the Pearson chi-square statistic. When there is more than one stratum, then the CMH statistic becomes a stratum-adjusted Pearson chi-square statistic. Note that a similar adjustment can be made by summing the Pearson chi-squares across the strata. However, the latter statistic requires a large sample size in each stratum to support the resulting chi-square distribution with  $q(R - 1)(C - 1)$  degrees of freedom. The CMH statistic requires only a large overall sample size because it has only  $(R - 1)(C - 1)$  degrees of freedom.

See Cochran (1954); Mantel and Haenszel (1959); Mantel (1963); Birch (1965); and Landis, Heyman, and Koch (1978).

### Mantel-Fleiss Criterion

If you specify the **MF** option in parentheses following the CMH option in the TABLES statement, PROC FREQ computes the Mantel-Fleiss criterion for stratified  $2 \times 2$  tables. The Mantel-Fleiss criterion can be used to assess the validity of the chi-square approximation for the distribution of the Mantel-Haenszel statistic for  $2 \times 2$  tables. See Mantel and Fleiss (1980), Mantel and Haenszel (1959), Stokes, Davis, and Koch (2000), and Dimitrienko et al. (2005) for details.

The Mantel-Fleiss criterion is computed as

$$MF = \min \left( \left[ \sum_h m_{h11} - \sum_h (n_{h11})_L \right], \left[ \sum_h (n_{h11})_U - \sum_h m_{h11} \right] \right)$$

where  $m_{h11}$  is the expected value of  $n_{h11}$  under the hypothesis of no association between the row and column variables in table  $h$ ,  $(n_{h11})_L$  is the minimum possible value of the table cell frequency, and  $(n_{h11})_U$  is the maximum possible value,

$$\begin{aligned} m_{h11} &= n_{h1\cdot} \cdot n_{\cdot 1} / n_h \\ (n_{h11})_L &= \max(0, n_{h1\cdot} - n_{h\cdot 2}) \\ (n_{h11})_U &= \min(n_{h\cdot 1}, n_{h1\cdot}) \end{aligned}$$

The Mantel-Fleiss guideline accepts the validity of the Mantel-Haenszel approximation when the value of the criterion is at least 5. When the criterion is less than 5, PROC FREQ displays a warning.

### **Adjusted Odds Ratio and Relative Risk Estimates**

The CMH option provides adjusted odds ratio and relative risk estimates for stratified  $2 \times 2$  tables. For each of these measures, PROC FREQ computes a Mantel-Haenszel estimate and a logit estimate. These estimates apply to  $n$ -way table requests in the TABLES statement, when the row and column variables both have two levels.

For example, for the table request A\*B\*C\*D, if the row and column variables C and D both have two levels, PROC FREQ provides odds ratio and relative risk estimates, adjusting for the confounding variables A and B.

The choice of an appropriate measure depends on the study design. For case-control (retrospective) studies, the odds ratio is appropriate. For cohort (prospective) or cross-sectional studies, the relative risk is appropriate. See the section “[Odds Ratio and Relative Risks for 2 x 2 Tables](#)” on page 2294 for more information on these measures.

Throughout this section,  $z$  denotes the  $100(1 - \alpha/2)$ th percentile of the standard normal distribution.

**Odds Ratio, Case-Control Studies** PROC FREQ provides Mantel-Haenszel and logit estimates for the common odds ratio for stratified  $2 \times 2$  tables.

The Mantel-Haenszel estimate of the common odds ratio is computed as

$$OR_{MH} = \left( \sum_h n_{h11} n_{h22} / n_h \right) / \left( \sum_h n_{h12} n_{h21} / n_h \right)$$

It is always computed unless the denominator is zero. See Mantel and Haenszel (1959) and Agresti (2002) for details.

To compute confidence limits for the common odds ratio, PROC FREQ uses the Greenland and Robins (1985) variance estimate for  $\ln(OR_{MH})$ . The  $100(1 - \alpha/2)$  confidence limits for the common odds ratio are

$$\left( OR_{MH} \times \exp(-z\hat{\sigma}), OR_{MH} \times \exp(z\hat{\sigma}) \right)$$

where

$$\begin{aligned}\hat{\sigma}^2 &= \widehat{\text{var}}(\ln(OR_{MH})) \\ &= \frac{\sum_h (n_{h11} + n_{h22})(n_{h11} n_{h22})/n_h^2}{2 (\sum_h n_{h11} n_{h22}/n_h)^2} \\ &\quad + \frac{\sum_h [(n_{h11} + n_{h22})(n_{h12} n_{h21}) + (n_{h12} + n_{h21})(n_{h11} n_{h22})]/n_h^2}{2 (\sum_h n_{h11} n_{h22}/n_h) (\sum_h n_{h12} n_{h21}/n_h)} \\ &\quad + \frac{\sum_h (n_{h12} + n_{h21})(n_{h12} n_{h21})/n_h^2}{2 (\sum_h n_{h12} n_{h21}/n_h)^2}\end{aligned}$$

Note that the Mantel-Haenszel odds ratio estimator is less sensitive to small  $n_h$  than the logit estimator.

The adjusted logit estimate of the common odds ratio (Woolf 1955) is computed as

$$OR_L = \exp \left( \sum_h w_h \ln(OR_h) / \sum_h w_h \right)$$

and the corresponding  $100(1 - \alpha)\%$  confidence limits are

$$\left( OR_L \times \exp \left( -z / \sqrt{\sum_h w_h} \right), OR_L \times \exp \left( z / \sqrt{\sum_h w_h} \right) \right)$$

where  $OR_h$  is the odds ratio for stratum  $h$ , and

$$w_h = 1/\text{var}(\ln(OR_h))$$

If any table cell frequency in a stratum  $h$  is zero, PROC FREQ adds 0.5 to each cell of the stratum before computing  $OR_h$  and  $w_h$  (Haldane 1955) for the logit estimate. The procedure prints a warning when this occurs.

**Relative Risks, Cohort Studies** PROC FREQ provides Mantel-Haenszel and logit estimates of the common relative risks for stratified  $2 \times 2$  tables.

The Mantel-Haenszel estimate of the common relative risk for column 1 is computed as

$$RR_{MH} = \left( \sum_h n_{h11} n_{h2\cdot} / n_h \right) / \left( \sum_h n_{h21} n_{h1\cdot} / n_h \right)$$

It is always computed unless the denominator is zero. See Mantel and Haenszel (1959) and Agresti (2002) for more information.

To compute confidence limits for the common relative risk, PROC FREQ uses the Greenland and Robins (1985) variance estimate for  $\log(RR_{MH})$ . The  $100(1-\alpha/2)$  confidence limits for the common relative risk are

$$(RR_{MH} \times \exp(-z\hat{\sigma}), RR_{MH} \times \exp(z\hat{\sigma}))$$

where

$$\hat{\sigma}^2 = \widehat{\text{var}}(\ln(RR_{MH})) = \frac{\sum_h (n_{h1} \cdot n_{h2} \cdot n_{h1} - n_{h11} n_{h21} n_h) / n_h^2}{(\sum_h n_{h11} n_{h2} / n_h) (\sum_h n_{h21} n_{h1} / n_h)}$$

The adjusted logit estimate of the common relative risk for column 1 is computed as

$$RR_L = \exp\left(\sum_h w_h \ln(RR_h) / \sum_h w_h\right)$$

and the corresponding  $100(1-\alpha)\%$  confidence limits are

$$\left( RR_L \times \exp\left(-z / \sqrt{\sum_h w_h}\right), RR_L \times \exp\left(z / \sqrt{\sum_h w_h}\right) \right)$$

where  $RR_h$  is the column 1 relative risk estimate for stratum  $h$  and

$$w_h = 1 / \text{var}(\ln(RR_h))$$

If  $n_{h11}$  or  $n_{h21}$  is zero, then PROC FREQ adds 0.5 to each cell of the stratum before computing  $RR_h$  and  $w_h$  for the logit estimate. The procedure prints a warning when this occurs. See Kleinbaum, Kupper, and Morgenstern (1982, Sections 17.4 and 17.5) for details.

### **Breslow-Day Test for Homogeneity of the Odds Ratios**

When you specify the CMH option, PROC FREQ computes the Breslow-Day test for stratified  $2 \times 2$  tables. It tests the null hypothesis that the odds ratios for the  $q$  strata are equal. When the null hypothesis is true, the statistic has approximately a chi-square distribution with  $q - 1$  degrees of freedom. See Breslow and Day (1980) and Agresti (2007) for more information.

The Breslow-Day statistic is computed as

$$Q_{BD} = \sum_h (n_{h11} - E(n_{h11} | OR_{MH}))^2 / \text{var}(n_{h11} | OR_{MH})$$

where  $E$  and  $\text{var}$  denote expected value and variance, respectively. The summation does not include any table with a zero row or column. If  $OR_{MH}$  equals zero or if it is undefined, then PROC FREQ does not compute the statistic and prints a warning message.

For the Breslow-Day test to be valid, the sample size should be relatively large in each stratum, and at least 80% of the expected cell counts should be greater than 5. Note that this is a stricter sample size requirement than the requirement for the Cochran-Mantel-Haenszel test for  $q \times 2 \times 2$  tables, in that each stratum sample size (not just the overall sample size) must be relatively large. Even when

the Breslow-Day test is valid, it might not be very powerful against certain alternatives, as discussed in Breslow and Day (1980).

If you specify the BDT option, PROC FREQ computes the Breslow-Day test with Tarone's adjustment, which subtracts an adjustment factor from  $Q_{BD}$  to make the resulting statistic asymptotically chi-square. The Breslow-Day-Tarone statistic is computed as

$$Q_{BDT} = Q_{BD} - \left( \sum_h (n_{h11} - E(n_{h11} | OR_{MH})) \right)^2 / \sum_h \text{var}(n_{h11} | OR_{MH})$$

See Tarone (1985), Jones et al. (1989), and Breslow (1996) for more information.

### **Zelen's Exact Test for Equal Odds Ratios**

If you specify the EQOR option in the EXACT statement, PROC FREQ computes Zelen's exact test for equal odds ratios for stratified  $2 \times 2$  tables. Zelen's test is an exact counterpart to the Breslow-Day asymptotic test for equal odds ratios. The reference set for Zelen's test includes all possible  $q \times 2 \times 2$  tables with the same row, column, and stratum totals as the observed multiway table and with the same sum of cell (1, 1) frequencies as the observed table. The test statistic is the probability of the observed  $q \times 2 \times 2$  table conditional on the fixed margins, which is a product of hypergeometric probabilities.

The  $p$ -value for Zelen's test is the sum of all table probabilities that are less than or equal to the observed table probability, where the sum is computed over all tables in the reference set determined by the fixed margins and the observed sum of cell (1, 1) frequencies. This test is similar to Fisher's exact test for two-way tables. See Zelen (1971), Hirji (2006), and Agresti (1992) for more information. PROC FREQ computes Zelen's exact test by using the polynomial multiplication algorithm of Hirji et al. (1996).

### **Exact Confidence Limits for the Common Odds Ratio**

If you specify the COMOR option in the EXACT statement, PROC FREQ computes exact confidence limits for the common odds ratio for stratified  $2 \times 2$  tables. This computation assumes that the odds ratio is constant over all the  $2 \times 2$  tables. Exact confidence limits are constructed from the distribution of  $S = \sum_h n_{h11}$ , conditional on the marginal totals of the  $2 \times 2$  tables.

Because this is a discrete problem, the confidence coefficient for these exact confidence limits is not exactly  $(1 - \alpha)$  but is at least  $(1 - \alpha)$ . Thus, these confidence limits are conservative. See Agresti (1992) for more information.

PROC FREQ computes exact confidence limits for the common odds ratio by using an algorithm based on Vollset, Hirji, and Elashoff (1991). See also Mehta, Patel, and Gray (1985).

Conditional on the marginal totals of  $2 \times 2$  table  $h$ , let the random variable  $S_h$  denote the frequency of table cell (1, 1). Given the row totals  $n_{h1\cdot}$  and  $n_{h2\cdot}$  and column totals  $n_{\cdot 1}$  and  $n_{\cdot 2}$ , the lower and upper bounds for  $S_h$  are  $l_h$  and  $u_h$ ,

$$\begin{aligned} l_h &= \max(0, n_{h1\cdot} - n_{h2\cdot}) \\ u_h &= \min(n_{h1\cdot}, n_{\cdot 1}) \end{aligned}$$

Let  $C_{s_h}$  denote the hypergeometric coefficient,

$$C_{s_h} = \binom{n_{h \cdot 1}}{s_h} \binom{n_{h \cdot 2}}{n_{h1 \cdot} - s_h}$$

and let  $\phi$  denote the common odds ratio. Then the conditional distribution of  $S_h$  is

$$P(S_h = s_h \mid n_{1 \cdot}, n_{\cdot 1}, n_{\cdot 2}) = C_{s_h} \phi^{s_h} / \sum_{x=l_h}^{x=u_h} C_x \phi^x$$

Summing over all the  $2 \times 2$  tables,  $S = \sum_h S_h$ , and the lower and upper bounds of  $S$  are  $l$  and  $u$ ,

$$l = \sum_h l_h \quad \text{and} \quad u = \sum_h u_h$$

The conditional distribution of the sum  $S$  is

$$P(S = s \mid n_{h1 \cdot}, n_{h \cdot 1}, n_{h \cdot 2}; h = 1, \dots, q) = C_s \phi^s / \sum_{x=l}^{x=u} C_x \phi^x$$

where

$$C_s = \sum_{s_1 + \dots + s_q = s} \left( \prod_h C_{s_h} \right)$$

Let  $s_0$  denote the observed sum of cell (1,1) frequencies over the  $q$  tables. The following two equations are solved iteratively for lower and upper confidence limits for the common odds ratio,  $\phi_1$  and  $\phi_2$ :

$$\begin{aligned} \sum_{x=s_0}^{x=u} C_x \phi_1^x / \sum_{x=l}^{x=u} C_x \phi_1^x &= \alpha/2 \\ \sum_{x=l}^{x=s_0} C_x \phi_2^x / \sum_{x=l}^{x=u} C_x \phi_2^x &= \alpha/2 \end{aligned}$$

When the observed sum  $s_0$  equals the lower bound  $l$ , PROC FREQ sets the lower confidence limit to zero and determines the upper limit with level  $\alpha$ . Similarly, when the observed sum  $s_0$  equals the upper bound  $u$ , PROC FREQ sets the upper confidence limit to infinity and determines the lower limit with level  $\alpha$ .

When you specify the COMOR option in the EXACT statement, PROC FREQ also computes the exact test that the common odds ratio equals one. Setting  $\phi = 1$ , the conditional distribution of the sum  $S$  under the null hypothesis becomes

$$P_0(S = s \mid n_{h1 \cdot}, n_{h \cdot 1}, n_{h \cdot 2}; h = 1, \dots, q) = C_s / \sum_{x=l}^{x=u} C_x$$

The point probability for this exact test is the probability of the observed sum  $s_0$  under the null hypothesis, conditional on the marginals of the stratified  $2 \times 2$  tables, and is denoted by  $P_0(s_0)$ . The expected value of  $S$  under the null hypothesis is

$$E_0(S) = \sum_{x=l}^{x=u} x C_x / \sum_{x=l}^{x=u} C_x$$

The one-sided exact  $p$ -value is computed from the conditional distribution as  $P_0(S \geq s_0)$  or  $P_0(S \leq s_0)$ , depending on whether the observed sum  $s_0$  is greater or less than  $E_0(S)$ ,

$$P_1 = P_0(S \geq s_0) = \sum_{x=s_0}^{x=u} C_x / \sum_{x=l}^{x=u} C_x \quad \text{if } s_0 > E_0(S)$$

$$P_1 = P_0(S \leq s_0) = \sum_{x=l}^{x=s_0} C_x / \sum_{x=l}^{x=u} C_x \quad \text{if } s_0 \leq E_0(S)$$

PROC FREQ computes two-sided  $p$ -values for this test according to three different definitions. A two-sided  $p$ -value is computed as twice the one-sided  $p$ -value, setting the result equal to one if it exceeds one,

$$P_2^a = 2 \times P_1$$

Additionally, a two-sided  $p$ -value is computed as the sum of all probabilities less than or equal to the point probability of the observed sum  $s_0$ , summing over all possible values of  $s$ ,  $l \leq s \leq u$ ,

$$P_2^b = \sum_{l \leq s \leq u: P_0(s) \leq P_0(s_0)} P_0(s)$$

Also, a two-sided  $p$ -value is computed as the sum of the one-sided  $p$ -value and the corresponding area in the opposite tail of the distribution, equidistant from the expected value,

$$P_2^c = P_0(|S - E_0(S)| \geq |s_0 - E_0(S)|)$$

## Gail-Simon Test for Qualitative Interactions

The **GAILSIMON** option in the TABLES statement provides the Gail-Simon test for qualitative interaction for stratified  $2 \times 2$  tables. See Gail and Simon (1985), Silvapulle (2001), and Dimitrienko et al. (2005) for details.

The Gail-Simon test is based on the risk differences in stratified  $2 \times 2$  tables, where the risk difference is defined as the row 1 risk (proportion in column 1) minus the row 2 risk. See the section “**Risks and Risk Differences**” on page 2287 for details. By default, the procedure uses column 1 risks to compute the Gail-Simon test. If you specify the **COLUMN=2** option, the procedure uses column 2 risks.

PROC FREQ computes the Gail-Simon test statistics as described in Gail and Simon (1985),

$$Q- = \sum_h (d_h/s_h)^2 I(d_h > 0)$$

$$Q+ = \sum_h (d_h/s_h)^2 I(d_h < 0)$$

$$Q = \min(Q-, Q+)$$

where  $d_h$  is the risk difference in table  $h$ ,  $s_h$  is the standard error of the risk difference, and  $I(d_h > 0)$  equals 1 if  $d_h > 0$  and 0 otherwise. Similarly,  $I(d_h < 0)$  equals 1 if  $d_h < 0$  and 0 otherwise. The  $q \times 2$  tables (strata) are indexed by  $h = 1, 2, \dots, q$ .

The  $p$ -values for the Gail-Simon statistics are computed as

$$p(Q-) = \sum_h (1 - F_h(Q-)) B(h; n = q, p = 0.5)$$

$$p(Q+) = \sum_h (1 - F_h(Q+)) B(h; n = q, p = 0.5)$$

$$p(Q) = \sum_{h=1}^{q-1} (1 - F_h(Q)) B(h; n = (q - 1), p = 0.5)$$

where  $F_h(\cdot)$  is the cumulative chi-square distribution function with  $h$  degrees of freedom and  $B(h; n, p)$  is the binomial probability function with parameters  $n$  and  $p$ . The statistic  $Q$  tests the null hypothesis of no qualitative interaction. The statistic  $Q-$  tests the null hypothesis of positive risk differences. A small  $p$ -value for  $Q-$  indicates negative differences; similarly, a small  $p$ -value for  $Q+$  indicates positive risk differences.

## Exact Statistics

Exact statistics can be useful in situations where the asymptotic assumptions are not met, and so the asymptotic  $p$ -values are not close approximations for the true  $p$ -values. Standard asymptotic methods involve the assumption that the test statistic follows a particular distribution when the sample size is sufficiently large. When the sample size is not large, asymptotic results might not be valid, with the asymptotic  $p$ -values differing perhaps substantially from the exact  $p$ -values. Asymptotic results might also be unreliable when the distribution of the data is sparse, skewed, or heavily tied. See Agresti (2007) and Bishop, Fienberg, and Holland (1975) for more information. Exact computations are based on the statistical theory of exact conditional inference for contingency tables, reviewed by Agresti (1992).

In addition to computation of exact  $p$ -values, PROC FREQ provides the option of estimating exact  $p$ -values by Monte Carlo simulation. This can be useful for problems that are so large that exact computations require a great amount of time and memory, but for which asymptotic approximations might not be sufficient.

Exact statistics are available for many PROC FREQ tests. For one-way tables, PROC FREQ provides exact  $p$ -values for the binomial proportion tests and the chi-square goodness-of-fit test. Exact confidence limits are available for the binomial proportion. For two-way tables, PROC FREQ provides exact  $p$ -values for the following tests: Pearson chi-square test, likelihood-ratio chi-square test, Mantel-Haenszel chi-square test, Fisher's exact test, Jonckheere-Terpstra test, and Cochran-Armitage test for trend. PROC FREQ also computes exact  $p$ -values for tests of the following statistics: Kendall's tau- $b$ , Stuart's tau- $c$ , Somers'  $D(C|R)$ , Somers'  $D(R|C)$ , Pearson correlation coefficient, Spearman correlation coefficient, simple kappa coefficient, and weighted kappa coefficient. For  $2 \times 2$  tables, PROC FREQ provides exact confidence limits for the odds ratio, exact unconditional confidence limits for the proportion difference, and McNemar's exact test. For stratified  $2 \times 2$  tables, PROC FREQ provides Zelen's exact test for equal odds ratios, exact confidence limits for the common odds ratio, and an exact test for the common odds ratio.

The following sections summarize the exact computational algorithms, define the exact  $p$ -values that PROC FREQ computes, discuss the computational resource requirements, and describe the Monte Carlo estimation option.

### Computational Algorithms

PROC FREQ computes exact  $p$ -values for general  $R \times C$  tables by using the network algorithm developed by Mehta and Patel (1983). This algorithm provides a substantial advantage over direct enumeration, which can be very time-consuming and feasible only for small problems. See Agresti (1992) for a review of algorithms for computation of exact  $p$ -values, and see Mehta, Patel, and Tsiatis (1984) and Mehta, Patel, and Senchaudhuri (1991) for information about the performance of the network algorithm.

The reference set for a given contingency table is the set of all contingency tables with the observed marginal row and column sums. Corresponding to this reference set, the network algorithm forms a directed acyclic network consisting of nodes in a number of stages. A path through the network corresponds to a distinct table in the reference set. The distances between nodes are defined so that the total distance of a path through the network is the corresponding value of the test statistic. At each node, the algorithm computes the shortest and longest path distances for all the paths that pass through that node. For statistics that can be expressed as a linear combination of cell frequencies multiplied by increasing row and column scores, PROC FREQ computes shortest and longest path distances by using the algorithm of Agresti, Mehta, and Patel (1990). For statistics of other forms, PROC FREQ computes an upper bound for the longest path and a lower bound for the shortest path by following the approach of Valz and Thompson (1994).

The longest and shortest path distances or bounds for a node are compared to the value of the test statistic to determine whether all paths through the node contribute to the  $p$ -value, none of the paths through the node contribute to the  $p$ -value, or neither of these situations occurs. If all paths through the node contribute, the  $p$ -value is incremented accordingly, and these paths are eliminated from further analysis. If no paths contribute, these paths are eliminated from the analysis. Otherwise, the algorithm continues, still processing this node and the associated paths. The algorithm finishes when all nodes have been accounted for.

In applying the network algorithm, PROC FREQ uses full numerical precision to represent all statistics, row and column scores, and other quantities involved in the computations. Although it is possible to use rounding to improve the speed and memory requirements of the algorithm, PROC FREQ does not do this because it can result in reduced accuracy of the  $p$ -values.

For one-way tables, PROC FREQ computes the exact chi-square goodness-of-fit test by the method of Radlow and Alf (1975). PROC FREQ generates all possible one-way tables with the observed total sample size and number of categories. For each possible table, PROC FREQ compares its chi-square value with the value for the observed table. If the table's chi-square value is greater than or equal to the observed chi-square, PROC FREQ increments the exact  $p$ -value by the probability of that table, which is calculated under the null hypothesis by using the multinomial frequency distribution. By default, the null hypothesis states that all categories have equal proportions. If you specify null hypothesis proportions or frequencies by using the TESTP= or TESTF= option in the TABLES statement, then PROC FREQ calculates the exact chi-square test based on that null hypothesis.

Other exact computations are described in sections about the individual statistics. See the section “[Binomial Proportion](#)” on page 2280 for details about how PROC FREQ computes exact confidence limits and tests for the binomial proportion. See the section “[Odds Ratio and Relative Risks for 2 x 2 Tables](#)” on page 2294 for information about computation of exact confidence limits for the odds ratio for  $2 \times 2$  tables. Also, see the sections “[Exact Unconditional Confidence Limits for the Risk Difference](#)” on page 2293, “[Exact Confidence Limits for the Common Odds Ratio](#)” on page 2311, and “[Zelen's Exact Test for Equal Odds Ratios](#)” on page 2311.

### Definition of $p$ -Values

For several tests in PROC FREQ, the test statistic is nonnegative, and large values of the test statistic indicate a departure from the null hypothesis. Such nondirectional tests include the Pearson chi-square, the likelihood-ratio chi-square, the Mantel-Haenszel chi-square, Fisher's exact test for tables larger than  $2 \times 2$ , McNemar's test, and the one-way chi-square goodness-of-fit test. The exact  $p$ -value for a nondirectional test is the sum of probabilities for those tables having a test statistic greater than or equal to the value of the observed test statistic.

There are other tests where it might be appropriate to test against either a one-sided or a two-sided alternative hypothesis. For example, when you test the null hypothesis that the true parameter value equals 0 ( $T = 0$ ), the alternative of interest might be one-sided ( $T \leq 0$ , or  $T \geq 0$ ) or two-sided ( $T \neq 0$ ). Such tests include the Pearson correlation coefficient, Spearman correlation coefficient, Jonckheere-Terpstra test, Cochran-Armitage test for trend, simple kappa coefficient, and weighted kappa coefficient. For these tests, PROC FREQ displays the right-sided  $p$ -value when the observed value of the test statistic is greater than its expected value. The right-sided  $p$ -value is the sum of probabilities for those tables for which the test statistic is greater than or equal to the observed test statistic. Otherwise, when the observed test statistic is less than or equal to the expected value, PROC FREQ displays the left-sided  $p$ -value. The left-sided  $p$ -value is the sum of probabilities for those tables for which the test statistic is less than or equal to the one observed. The one-sided  $p$ -value  $P_1$  can be expressed as

$$P_1 = \begin{cases} \text{Prob( Test Statistic } \geq t ) & \text{if } t > E_0(T) \\ \text{Prob( Test Statistic } \leq t ) & \text{if } t \leq E_0(T) \end{cases}$$

where  $t$  is the observed value of the test statistic and  $E_0(T)$  is the expected value of the test statistic under the null hypothesis. PROC FREQ computes the two-sided  $p$ -value as the sum of the one-sided  $p$ -value and the corresponding area in the opposite tail of the distribution of the statistic, equidistant from the expected value. The two-sided  $p$ -value  $P_2$  can be expressed as

$$P_2 = \text{Prob ( |Test Statistic - } E_0(T) | \geq |t - E_0(T)| )$$

If you specify the POINT option in the EXACT statement, PROC FREQ also displays exact point probabilities for the test statistics. The exact point probability is the exact probability that the test statistic equals the observed value.

### **Computational Resources**

PROC FREQ uses relatively fast and efficient algorithms for exact computations. These recently developed algorithms, together with improvements in computer power, now make it feasible to perform exact computations for data sets where previously only asymptotic methods could be applied. Nevertheless, there are still large problems that might require a prohibitive amount of time and memory for exact computations, depending on the speed and memory available on your computer. For large problems, consider whether exact methods are really needed or whether asymptotic methods might give results quite close to the exact results, while requiring much less computer time and memory. When asymptotic methods might not be sufficient for such large problems, consider using Monte Carlo estimation of exact  $p$ -values, as described in the section “[Monte Carlo Estimation](#)” on page 2317.

A formula does not exist that can predict in advance how much time and memory are needed to compute an exact  $p$ -value for a certain problem. The time and memory required depend on several factors, including which test is being performed, the total sample size, the number of rows and columns, and the specific arrangement of the observations into table cells. Generally, larger problems (in terms of total sample size, number of rows, and number of columns) tend to require more time and memory. Additionally, for a fixed total sample size, time and memory requirements tend to increase as the number of rows and columns increases, because this corresponds to an increase in the number of tables in the reference set. Also for a fixed sample size, time and memory requirements increase as the marginal row and column totals become more homogeneous. See Agresti, Mehta, and Patel (1990) and Gail and Mantel (1977) for more information.

At any time while PROC FREQ is computing exact  $p$ -values, you can terminate the computations by pressing the system interrupt key sequence (see the *SAS Companion* for your system) and choosing to stop computations. After you terminate exact computations, PROC FREQ completes all other remaining tasks. The procedure produces the requested output and reports missing values for any exact  $p$ -values that were not computed by the time of termination.

You can also use the MAXTIME= option in the EXACT statement to limit the amount of time PROC FREQ uses for exact computations. You specify a MAXTIME= value that is the maximum amount of clock time (in seconds) that PROC FREQ can use to compute an exact  $p$ -value. If PROC FREQ does not finish computing an exact  $p$ -value within that time, it terminates the computation and completes all other remaining tasks.

### **Monte Carlo Estimation**

If you specify the option MC in the EXACT statement, PROC FREQ computes Monte Carlo estimates of the exact  $p$ -values instead of directly computing the exact  $p$ -values. Monte Carlo estimation can be useful for large problems that require a great amount of time and memory for exact computations but for which asymptotic approximations might not be sufficient. To describe the precision of each Monte Carlo estimate, PROC FREQ provides the asymptotic standard error and  $100(1 - \alpha)\%$  confidence limits. The confidence level  $\alpha$  is determined by the ALPHA= option in the EXACT statement,

which, by default, equals 0.01 and produces 99% confidence limits. The  $N=n$  option in the EXACT statement specifies the number of samples that PROC FREQ uses for Monte Carlo estimation; the default is 10000 samples. You can specify a larger value for  $n$  to improve the precision of the Monte Carlo estimates. Because larger values of  $n$  generate more samples, the computation time increases. Alternatively, you can specify a smaller value of  $n$  to reduce the computation time.

To compute a Monte Carlo estimate of an exact  $p$ -value, PROC FREQ generates a random sample of tables with the same total sample size, row totals, and column totals as the observed table. PROC FREQ uses the algorithm of Agresti, Wackerly, and Boyett (1979), which generates tables in proportion to their hypergeometric probabilities conditional on the marginal frequencies. For each sample table, PROC FREQ computes the value of the test statistic and compares it to the value for the observed table. When estimating a right-sided  $p$ -value, PROC FREQ counts all sample tables for which the test statistic is greater than or equal to the observed test statistic. Then the  $p$ -value estimate equals the number of these tables divided by the total number of tables sampled.

$$\begin{aligned}\hat{P}_{MC} &= M / N \\ M &= \text{number of samples with (Test Statistic} \geq t) \\ N &= \text{total number of samples} \\ t &= \text{observed Test Statistic}\end{aligned}$$

PROC FREQ computes left-sided and two-sided  $p$ -value estimates in a similar manner. For left-sided  $p$ -values, PROC FREQ evaluates whether the test statistic for each sampled table is less than or equal to the observed test statistic. For two-sided  $p$ -values, PROC FREQ examines the sample test statistics according to the expression for  $P_2$  given in the section “[Definition of  \$p\$ -Values](#)” on page 2316.

The variable  $M$  is a binomially distributed variable with  $N$  trials and success probability  $p$ . It follows that the asymptotic standard error of the Monte Carlo estimate is

$$\text{se}(\hat{P}_{MC}) = \sqrt{\hat{P}_{MC} (1 - \hat{P}_{MC}) / (N - 1)}$$

PROC FREQ constructs asymptotic confidence limits for the  $p$ -values according to

$$\hat{P}_{MC} \pm \left( z_{\alpha/2} \times \text{se}(\hat{P}_{MC}) \right)$$

where  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the standard normal distribution and the confidence level  $\alpha$  is determined by the ALPHA= option in the EXACT statement.

When the Monte Carlo estimate  $\hat{P}_{MC}$  equals 0, PROC FREQ computes the confidence limits for the  $p$ -value as

$$(0, 1 - \alpha^{(1/N)})$$

When the Monte Carlo estimate  $\hat{P}_{MC}$  equals 1, PROC FREQ computes the confidence limits as

$$(\alpha^{(1/N)}, 1)$$

---

## Computational Resources

For each variable in a table request, PROC FREQ stores all of the levels in memory. If all variables are numeric and not formatted, this requires about 84 bytes for each variable level. When there are character variables or formatted numeric variables, the memory that is required depends on the formatted variable lengths, with longer formatted lengths requiring more memory. The number of levels for each variable is limited only by the largest integer that your operating environment can store.

For any single crosstabulation table requested, PROC FREQ builds the entire table in memory, regardless of whether the table has zero cell counts. Thus, if the numeric variables A, B, and C each have 10 levels, PROC FREQ requires 2520 bytes to store the variable levels for the table request A\*B\*C, as follows:

**3 variables \* 10 levels/variable \* 84 bytes/level**

In addition, PROC FREQ requires 8000 bytes to store the table cell frequencies

**1000 cells \* 8 bytes/cell**

even though there might be only 10 observations.

When the variables have many levels or when there are many multiway tables, your computer might not have enough memory to construct the tables. If PROC FREQ runs out of memory while constructing tables, it stops collecting levels for the variable with the most levels and returns the memory that is used by that variable. The procedure then builds the tables that do not contain the disabled variables.

If there is not enough memory for your table request and if increasing the available memory is impractical, you can reduce the number of multiway tables or variable levels. If you are not using the CMH or AGREE option in the TABLES statement to compute statistics across strata, reduce the number of multiway tables by using PROC SORT to sort the data set by one or more of the variables or by using the DATA step to create an index for the variables. Then remove the sorted or indexed variables from the TABLES statement and include a BY statement that uses these variables. You can also reduce memory requirements by using a FORMAT statement in the PROC FREQ step to reduce the number of levels. Additionally, reducing the formatted variable lengths reduces the amount of memory that is needed to store the variable levels. For more information about using formats, see the section [“Grouping with Formats”](#) on page 2260.

---

## Output Data Sets

PROC FREQ produces two types of output data sets that you can use with other statistical and reporting procedures. You can request these data sets as follows:

- Specify the OUT= option in a TABLES statement. This creates an output data set that contains frequency or crosstabulation table counts and percentages
- Specify an OUTPUT statement. This creates an output data set that contains statistics.

PROC FREQ does not display the output data sets. Use PROC PRINT, PROC REPORT, or any other SAS reporting tool to display an output data set.

In addition to these two output data sets, you can create a SAS data set from any piece of PROC FREQ output by using the Output Delivery System. See the section “[ODS Table Names](#)” on page 2331 for more information.

### Contents of the TABLES Statement Output Data Set

The OUT= option in the TABLES statement creates an output data set that contains one observation for each combination of variable values (or table cell) in the last table request. By default, each observation contains the frequency and percentage for the table cell. When the input data set contains missing values, the output data set also contains an observation with the frequency of missing values. The output data set includes the following variables:

- BY variables
- table request variables, such as A, B, C, and D in the table request A\*B\*C\*D
- COUNT, which contains the table cell frequency
- PERCENT, which contains the table cell percentage

If you specify the OUTEXPECT option in the TABLES statement for a two-way or multiway table, the output data set also includes expected frequencies. If you specify the OUTPCT option for a two-way or multiway table, the output data set also includes row, column, and table percentages. The additional variables are as follows:

- EXPECTED, which contains the expected frequency
- PCT\_TABL, which contains the percentage of two-way table frequency, for  $n$ -way tables where  $n > 2$
- PCT\_ROW, which contains the percentage of row frequency
- PCT\_COL, which contains the percentage of column frequency

If you specify the OUTCUM option in the TABLES statement for a one-way table, the output data set also includes cumulative frequencies and cumulative percentages. The additional variables are as follows:

- CUM\_FREQ, which contains the cumulative frequency
- CUM\_PCT, which contains the cumulative percentage

The OUTCUM option has no effect for two-way or multiway tables.

The following PROC FREQ statements create an output data set of frequencies and percentages:

```
proc freq;
  tables A A*B / out=D;
run;
```

The output data set D contains frequencies and percentages for the table of A by B, which is the last table request listed in the TABLES statement. If A has two levels (1 and 2), B has three levels (1, 2, and 3), and no table cell count is zero or missing, then the output data set D includes six observations, one for each combination of A and B levels. The first observation corresponds to A=1 and B=1; the second observation corresponds to A=1 and B=2; and so on. The data set includes the variables COUNT and PERCENT. The value of COUNT is the number of observations with the given combination of A and B levels. The value of PERCENT is the percentage of the total number of observations with that A and B combination.

When PROC FREQ combines different variable values into the same formatted level, the output data set contains the smallest internal value for the formatted level. For example, suppose a variable X has the values 1.1., 1.4, 1.7, 2.1, and 2.3. When you submit the statement

```
format X 1.;
```

in a PROC FREQ step, the formatted levels listed in the frequency table for X are 1 and 2. If you create an output data set with the frequency counts, the internal values of the levels of X are 1.1 and 1.7. To report the internal values of X when you display the output data set, use a format of 3.1 for X.

## Contents of the OUTPUT Statement Output Data Set

The OUTPUT statement creates a SAS data set that contains the statistics that PROC FREQ computes for the last table request. You specify which statistics to store in the output data set. There is an observation with the specified statistics for each stratum or two-way table. If PROC FREQ computes summary statistics for a stratified table, the output data set also contains a summary observation with those statistics.

The OUTPUT data set can include the following variables.

- BY variables
- variables that identify the stratum, such as A and B in the table request A\*B\*C\*D
- variables that contain the specified statistics

The output data set also includes variables with the  $p$ -values and degrees of freedom, asymptotic standard error (ASE), or confidence limits when PROC FREQ computes these values for a specified statistic.

The variable names for the specified statistics in the output data set are the names of the options enclosed in underscores. PROC FREQ forms variable names for the corresponding  $p$ -values, degrees of freedom, or confidence limits by combining the name of the option with the appropriate prefix from the following list:

DF_	degrees of freedom
E_	asymptotic standard error (ASE)
L_	lower confidence limit
U_	upper confidence limit
E0_	ASE under the null hypothesis
Z_	standardized value
P_	$p$ -value
P2_	two-sided $p$ -value
PL_	left-sided $p$ -value
PR_	right-sided $p$ -value
XP_	exact $p$ -value
XP2_	exact two-sided $p$ -value
XPL_	exact left-sided $p$ -value
XPR_	exact right-sided $p$ -value
XPT_	exact point probability
XL_	exact lower confidence limit
XU_	exact upper confidence limit

For example, variable names created for the Pearson chi-square, its degrees of freedom, and its  $p$ -values are \_PCHI\_, DF\_PCHI, and P\_PCHI, respectively.

If the length of the prefix plus the statistic option exceeds eight characters, PROC FREQ truncates the option so that the name of the new variable is eight characters long.

---

## Displayed Output

### Number of Variable Levels Table

If you specify the **NLEVELS** option in the PROC FREQ statement, PROC FREQ displays the “Number of Variable Levels” table. This table provides the number of levels for all variables named in the TABLES statements. PROC FREQ determines the variable levels from the formatted variable values. See “[Grouping with Formats](#)” on page 2260 for details. The “Number of Variable Levels” table contains the following information:

- Variable name
- Levels, which is the total number of levels of the variable

- Number of Nonmissing Levels, if there are missing levels for any of the variables
- Number of Missing Levels, if there are missing levels for any of the variables

## One-Way Frequency Tables

PROC FREQ displays one-way frequency tables for all one-way table requests in the **TABLES** statements, unless you specify the **NOPRINT** option in the PROC statement or the **NOPRINT** option in the TABLES statement. For a one-way table showing the frequency distribution of a single variable, PROC FREQ displays the name of the variable and its values. For each variable value or level, PROC FREQ displays the following information:

- Frequency count, which is the number of observations in the level
- Test Frequency count, if you specify the **CHISQ** and **TESTF=** options to request a chi-square goodness-of-fit test for specified frequencies
- Percent, which is the percentage of the total number of observations. (The **NOPERCENT** option suppresses this information.)
- Test Percent, if you specify the **CHISQ** and **TESTP=** options to request a chi-square goodness-of-fit test for specified percents. (The **NOPERCENT** option suppresses this information.)
- Cumulative Frequency count, which is the sum of the frequency counts for that level and all other levels listed above it in the table. The last cumulative frequency is the total number of nonmissing observations. (The **NOCUM** option suppresses this information.)
- Cumulative Percent, which is the percentage of the total number of observations in that level and in all other levels listed above it in the table. (The **NOCUM** or the **NOPERCENT** option suppresses this information.)

The one-way table also displays the Frequency Missing, which is the number of observations with missing values.

## Statistics for One-Way Frequency Tables

For one-way tables, two statistical options are available in the **TABLES** statement. The **CHISQ** option provides a chi-square goodness-of-fit test, and the **BINOMIAL** option provides binomial proportion statistics and tests. PROC FREQ displays the following information, unless you specify the **NOPRINT** option in the PROC statement:

- If you specify the **CHISQ** option for a one-way table, PROC FREQ provides a chi-square goodness-of-fit test, displaying the Chi-Square statistic, the degrees of freedom (DF), and the probability value ( $Pr > ChiSq$ ). If you specify the **CHISQ** option in the **EXACT** statement, PROC FREQ also displays the exact probability value for this test. If you specify the **POINT** option with the **CHISQ** option in the **EXACT** statement, PROC FREQ displays the exact point probability for the test statistic.

- If you specify the **BINOMIAL** option for a one-way table, PROC FREQ displays the estimate of the binomial Proportion, which is the proportion of observations in the first class listed in the one-way table. PROC FREQ also displays the asymptotic standard error (ASE) and the asymptotic (Wald) and exact (Clopper-Pearson) confidence limits by default. For the binomial proportion test, PROC FREQ displays the asymptotic standard error under the null hypothesis (ASE Under H0), the standardized test statistic (Z), and the one-sided and two-sided probability values.

If you specify the **BINOMIAL** option in the **EXACT** statement, PROC FREQ also displays the exact one-sided and two-sided probability values for this test. If you specify the **POINT** option with the **BINOMIAL** option in the **EXACT** statement, PROC FREQ displays the exact point probability for the test.

- If you request additional binomial confidence limits by specifying *binomial-options*, PROC FREQ provides a table that displays the lower and upper confidence limits for each type that you request. In addition to the Wald and exact (Clopper-Pearson) confidence limits, you can request Agresti-Coull, Jeffreys, and Wilson (score) confidence limits for the binomial proportion.
- If you request a binomial noninferiority or superiority test by specifying the **NONINF** or **SUP** binomial-option, PROC FREQ displays the following information: the binomial Proportion, the test ASE (under H0 or Sample), the test statistic Z, the probability value, the noninferiority or superiority limit, and the test confidence limits. If you specify the **BINOMIAL** option in the **EXACT** statement, PROC FREQ also provides the exact probability value for the test, and exact test confidence limits.
- If you request a binomial equivalence test by specifying the **EQUIV** binomial-option, PROC FREQ displays the binomial Proportion and the test ASE (under H0 or Sample). PROC FREQ displays two one-sided tests (TOST) for equivalence, which include test statistics (Z) and probability values for the Lower and Upper tests, together with the Overall probability value. PROC FREQ also displays the equivalence limits and the test-based confidence limits. If you specify the **BINOMIAL** option in the **EXACT** statement, PROC FREQ provides exact probability values for the TOST and exact test-based confidence limits.

## Multiway Tables

PROC FREQ displays all multiway table requests in the **TABLES** statements, unless you specify the **NOPRINT** option in the PROC statement or the **NOPRINT** option in the **TABLES** statement.

For two-way to multiway crosstabulation tables, the values of the last variable in the table request form the table columns. The values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one stratum.

There are three ways to display multiway tables in PROC FREQ. By default, PROC FREQ displays multiway tables as separate two-way crosstabulation tables for each stratum of the multiway table. Also by default, PROC FREQ displays these two-way crosstabulation tables in table cell format. Alternatively, if you specify the **CROSSLIST** option, PROC FREQ displays the two-way crosstabulation tables in ODS column format. If you specify the **LIST** option, PROC FREQ displays multiway tables in list format, which presents the entire multiway crosstabulation in a single table.

### **Crosstabulation Tables**

By default, PROC FREQ displays two-way crosstabulation tables in table cell format. The row variable values are listed down the side of the table, the column variable values are listed across the top of the table, and each row and column variable level combination forms a table cell.

Each cell of a crosstabulation table can contain the following information:

- Frequency, which is the number of observations in the table cell. (The **NOFREQ** option suppresses this information.)
- Expected frequency under the hypothesis of independence, if you specify the **EXPECTED** option
- Deviation of the cell frequency from the expected value, if you specify the **DEVIATION** option
- Cell Chi-Square, which is the cell's contribution to the total chi-square statistic, if you specify the **CELLCHI2** option
- Tot Pct, which is the cell's percentage of the total multiway table frequency, for  $n$ -way tables when  $n > 2$ , if you specify the **TOTPCT** option
- Percent, which is the cell's percentage of the total (two-way table) frequency. (The **NOPERCENT** option suppresses this information.)
- Row Pct, or the row percentage, which is the cell's percentage of the total frequency for its row. (The **NOROW** option suppresses this information.)
- Col Pct, or column percentage, which is the cell's percentage of the total frequency for its column. (The **NOCOL** option suppresses this information.)
- Cumulative Col%, or cumulative column percentage, if you specify the **CUMCOL** option

The table also displays the Frequency Missing, which is the number of observations with missing values.

### **CROSSLIST Tables**

If you specify the **CROSSLIST** option, PROC FREQ displays two-way crosstabulation tables in ODS column format. The **CROSSLIST** column format is different from the default crosstabulation table cell format, but the **CROSSLIST** table provides the same information (frequencies, percentages, and other statistics) as the default crosstabulation table.

In the **CROSSLIST** table format, the rows of the display correspond to the crosstabulation table cells, and the columns of the display correspond to descriptive statistics such as frequencies and percentages. Each table cell is identified by the values of its **TABLES** row and column variable levels, with all column variable levels listed within each row variable level. The **CROSSLIST** table also provides row totals, column totals, and overall table totals.

For a crosstabulation table in CROSSLIST format, PROC FREQ displays the following information:

- the row variable name and values
- the column variable name and values
- Frequency, which is the number of observations in the table cell. (The **NOFREQ** option suppresses this information.)
- Expected cell frequency under the hypothesis of independence, if you specify the **EXPECTED** option
- Deviation of the cell frequency from the expected value, if you specify the **DEVIATION** option
- Cell Chi-Square, which is the cell's contribution to the total chi-square statistic, if you specify the **CELLCHI2** option
- Total Percent, which is the cell's percentage of the total multiway table frequency, for  $n$ -way tables when  $n > 2$ , if you specify the **TOTPCT** option
- Percent, which is the cell's percentage of the total (two-way table) frequency. (The **NOPERCENT** option suppresses this information.)
- Row Percent, which is the cell's percentage of the total frequency for its row. (The **NOROW** option suppresses this information.)
- Column Percent, the cell's percentage of the total frequency for its column. (The **NOCOL** option suppresses this information.)

The table also displays the Frequency Missing, which is the number of observations with missing values.

### **LIST Tables**

If you specify the **LIST** option in the TABLES statement, PROC FREQ displays multiway tables in a list format rather than as crosstabulation tables. The **LIST** option displays the entire multiway table in one table, instead of displaying a separate two-way table for each stratum. The **LIST** option is not available when you also request statistical options. Unlike the default crosstabulation output, the **LIST** output does not display row percentages, column percentages, and optional information such as expected frequencies and cell chi-squares.

For a multiway table in list format, PROC FREQ displays the following information:

- the variable names and values
- Frequency, which is the number of observations in the level (with the indicated variable values)
- Percent, which is the level's percentage of the total number of observations. (The **NOPERCENT** option suppresses this information.)

- Cumulative Frequency, which is the accumulated frequency of the level and all other levels listed above it in the table. The last cumulative frequency in the table is the total number of nonmissing observations. (The **NOCUM** option suppresses this information.)
- Cumulative Percent, which is the accumulated percentage of the level and all other levels listed above it in the table. (The **NOCUM** or the **NOPERCENT** option suppresses this information.)

The table also displays the Frequency Missing, which is the number of observations with missing values.

## Statistics for Multiway Tables

PROC FREQ computes statistical tests and measures for crosstabulation tables, depending on which statements and options you specify. You can suppress the display of all these results by specifying the NOPRINT option in the PROC statement. With any of the following information, PROC FREQ also displays the Sample Size and the Frequency Missing.

- If you specify the SCOROUT option, PROC FREQ displays the Row Scores and Column Scores that it uses for statistical computations. The Row Scores table displays the row variable values and the Score corresponding to each value. The Column Scores table displays the column variable values and the corresponding Scores. PROC FREQ also identifies the score type used to compute the row and column scores. You can specify the score type with the SCORES= option in the TABLES statement.
- If you specify the CHISQ option, PROC FREQ displays the following statistics for each two-way table: Pearson Chi-Square, Likelihood-Ratio Chi-Square, Continuity-Adjusted Chi-Square (for  $2 \times 2$  tables), Mantel-Haenszel Chi-Square, the Phi Coefficient, the Contingency Coefficient, and Cramer's  $V$ . For each test statistic, PROC FREQ also displays the degrees of freedom (DF) and the probability value (Prob).
- If you specify the CHISQ option for  $2 \times 2$  tables, PROC FREQ also displays Fisher's exact test. The test output includes the cell (1,1) frequency (F), the exact left-sided and right-sided probability values, the table probability (P), and the exact two-sided probability value.
- If you specify the FISHER option in the TABLES statement (or, equivalently, the FISHER option in the EXACT statement), PROC FREQ displays Fisher's exact test for tables larger than  $2 \times 2$ . The test output includes the table probability (P) and the probability value. In addition, PROC FREQ displays the CHISQ output listed earlier, even if you do not also specify the CHISQ option.
- If you specify the PCHI, LRCHI, or MHCHI option in the EXACT statement, PROC FREQ also displays the corresponding exact test: Pearson Chi-Square, Likelihood-Ratio Chi-Square, or Mantel-Haenszel Chi-Square, respectively. The test output includes the test statistic, the degrees of freedom (DF), and the asymptotic and exact probability values. If you also specify the POINT option in the EXACT statement, PROC FREQ displays the point probability for each exact test requested. If you specify the CHISQ option in the EXACT statement, PROC FREQ displays exact probability values for all three of these chi-square tests.

- If you specify the MEASURES option, PROC FREQ displays the following statistics and their asymptotic standard errors (ASE) for each two-way table: Gamma, Kendall's Tau-*b*, Stuart's Tau-*c*, Somers'  $D(C|R)$ , Somers'  $D(R|C)$ , Pearson Correlation, Spearman Correlation, Lambda Asymmetric ( $C|R$ ), Lambda Asymmetric ( $R|C$ ), Lambda Symmetric, Uncertainty Coefficient ( $C|R$ ), Uncertainty Coefficient ( $R|C$ ), and Uncertainty Coefficient Symmetric. If you specify the CL option, PROC FREQ also displays confidence limits for these measures.
- If you specify the PLCORR option, PROC FREQ displays the tetrachoric correlation for  $2 \times 2$  tables or the polychoric correlation for larger tables. In addition, PROC FREQ displays the MEASURES output listed earlier, even if you do not also specify the MEASURES option.
- If you specify the GAMMA, KENTB, STUTC, SMDCR, SMDRC, PCORR, or SCORR option in the TEST statement, PROC FREQ displays asymptotic tests for Gamma, Kendall's Tau-*b*, Stuart's Tau-*c*, Somers'  $D(C|R)$ , Somers'  $D(R|C)$ , the Pearson Correlation, or the Spearman Correlation, respectively. If you specify the MEASURES option in the TEST statement, PROC FREQ displays all these asymptotic tests. The test output includes the statistic, its asymptotic standard error (ASE), Confidence Limits, the ASE under the null hypothesis  $H_0$ , the standardized test statistic ( $Z$ ), and the one-sided and two-sided probability values.
- If you specify the KENTB, STUTC, SMDCR, SMDRC, PCORR, or SCORR option in the EXACT statement, PROC FREQ displays asymptotic and exact tests for the corresponding measure of association: Kendall's Tau-*b*, Stuart's Tau-*c*, Somers'  $D(C|R)$ , Somers'  $D(R|C)$ , the Pearson Correlation, or the Spearman correlation, respectively. The test output includes the correlation, its asymptotic standard error (ASE), Confidence Limits, the ASE under the null hypothesis  $H_0$ , the standardized test statistic ( $Z$ ), and the asymptotic and exact one-sided and two-sided probability values. If you also specify the POINT option in the EXACT statement, PROC FREQ displays the point probability for each exact test requested.
- If you specify the RISKDIFF option for  $2 \times 2$  tables, PROC FREQ displays the Column 1 and Column 2 Risk Estimates. For each column, PROC FREQ displays the Row 1 Risk, Row 2 Risk, Total Risk, and Risk Difference, together with their asymptotic standard errors (ASE) and Asymptotic Confidence Limits. PROC FREQ also displays Exact Confidence Limits for the Row 1 Risk, Row 2 Risk, and Total Risk. If you specify the RISKDIFF option in the EXACT statement, PROC FREQ provides unconditional Exact Confidence Limits for the Risk Difference.
- If you request a noninferiority or superiority test for the proportion difference by specifying the NONINF or SUP riskdiff-option, and if you specify METHOD=HA (Hauck-Anderson), METHOD=FM (Farrington-Manning), or METHOD=WALD (Wald), PROC FREQ displays the following information: the Proportion Difference, the test ASE ( $H_0$ , Sample, Sample H-A, or FM, depending on the method you specify), the test statistic  $Z$ , the probability value, the Noninferiority or Superiority Limit, and the test-based Confidence Limits. If you specify METHOD=SCORE (Newcombe score), PROC FREQ displays the Proportion Difference, the Noninferiority or Superiority Limit, and the score Confidence Limits.
- If you request an equivalence test for the proportion difference by specifying the EQUIV riskdiff-option, and if you specify METHOD=HA (Hauck-Anderson), METHOD=FM (Farrington-Manning), or METHOD=WALD (Wald), PROC FREQ displays the following information: the Proportion Difference and the test ASE ( $H_0$ , Sample, Sample H-A, or FM, depending on the method you specify). PROC FREQ displays a two one-sided test (TOST) for

equivalence, which includes test statistics (Z) and probability values for the Lower and Upper tests, together with the Overall probability value. PROC FREQ also displays the Equivalence Limits and the test-based Confidence Limits. If you specify METHOD=SCORE (Newcombe score), PROC FREQ displays the Proportion Difference, the Equivalence Limits, and the score Confidence Limits.

- If you request an equality test for the proportion difference by specifying the EQUAL riskdiff-option, PROC FREQ displays the following information: the Proportion Difference and the test ASE (H0 or Sample), the test statistic Z, the One-Sided probability value ( $\Pr > Z$  or  $\Pr < Z$ ), and the Two-Sided probability value,  $\Pr > |Z|$ .
- If you specify the MEASURES option or the RELRISK option for  $2 \times 2$  tables, PROC FREQ displays Estimates of the Relative Risk for Case-Control and Cohort studies, together with their Confidence Limits. These measures are also known as the Odds Ratio and the Column 1 and 2 Relative Risks. If you specify the OR option in the EXACT statement, PROC FREQ also displays Exact Confidence Limits for the Odds Ratio.
- If you specify the TREND option, PROC FREQ displays the Cochran-Armitage Trend Test for tables that are  $2 \times C$  or  $R \times 2$ . For this test, PROC FREQ gives the Statistic (Z) and the one-sided and two-sided probability values. If you specify the TREND option in the EXACT statement, PROC FREQ also displays the exact one-sided and two-sided probability values for this test. If you specify the POINT option with the TREND option in the EXACT statement, PROC FREQ displays the exact point probability for the test statistic.
- If you specify the JT option, PROC FREQ displays the Jonckheere-Terpstra Test, showing the Statistic (JT), the standardized test statistic (Z), and the one-sided and two-sided probability values. If you specify the JT option in the EXACT statement, PROC FREQ also displays the exact one-sided and two-sided probability values for this test. If you specify the POINT option with the JT option in the EXACT statement, PROC FREQ displays the exact point probability for the test statistic.
- If you specify the AGREE option and the PRINTKWT option, PROC FREQ displays the Kappa Coefficient Weights for square tables greater than  $2 \times 2$ .
- If you specify the AGREE option, for two-way tables PROC FREQ displays McNemar's Test and the Simple Kappa Coefficient for  $2 \times 2$  tables. For square tables larger than  $2 \times 2$ , PROC FREQ displays Bowker's Test of Symmetry, the Simple Kappa Coefficient, and the Weighted Kappa Coefficient. For McNemar's Test and Bowker's Test of Symmetry, PROC FREQ displays the Statistic (S), the degrees of freedom (DF), and the probability value ( $\Pr > S$ ). If you specify the MCNEM option in the EXACT statement, PROC FREQ also displays the exact probability value for McNemar's test. If you specify the POINT option with the MCNEM option in the EXACT statement, PROC FREQ displays the exact point probability for the test statistic. For the simple and weighted kappa coefficients, PROC FREQ displays the kappa values, asymptotic standard errors (ASE), and Confidence Limits.
- If you specify the KAPPA or WTKAP option in the TEST statement, PROC FREQ displays asymptotic tests for the simple kappa coefficient or the weighted kappa coefficient, respectively. If you specify the AGREE option in the TEST statement, PROC FREQ displays both these asymptotic tests. The test output includes the kappa coefficient, its asymptotic standard error (ASE), Confidence Limits, the ASE under the null hypothesis H0, the standardized test statistic (Z), and the one-sided and two-sided probability values.

- If you specify the KAPPA or WTKAP option in the EXACT statement, PROC FREQ displays asymptotic and exact tests for the simple kappa coefficient or the weighted kappa coefficient, respectively. The test output includes the kappa coefficient, its asymptotic standard error (ASE), Confidence Limits, the ASE under the null hypothesis  $H_0$ , the standardized test statistic (Z), and the asymptotic and exact one-sided and two-sided probability values. If you specify the POINT option in the EXACT statement, PROC FREQ displays the point probability for each exact test requested.
- If you specify the MC option in the EXACT statement, PROC FREQ displays Monte Carlo estimates for all exact  $p$ -values requested by *statistic-options* in the EXACT statement. The Monte Carlo output includes the  $p$ -value Estimate, its Confidence Limits, the Number of Samples used to compute the Monte Carlo estimate, and the Initial Seed for random number generation.
- If you specify the AGREE option, for multiple strata PROC FREQ displays Overall Simple and Weighted Kappa Coefficients, with their asymptotic standard errors (ASE) and Confidence Limits. PROC FREQ also displays Tests for Equal Kappa Coefficients, giving the Chi-Squares, degrees of freedom (DF), and probability values ( $\text{Pr} > \text{ChiSq}$ ) for the Simple Kappa and Weighted Kappa. For multiple strata of  $2 \times 2$  tables, PROC FREQ displays Cochran's  $Q$ , giving the Statistic ( $Q$ ), the degrees of freedom (DF), and the probability value ( $\text{Pr} > Q$ ).
- If you specify the CMH option, PROC FREQ displays Cochran-Mantel-Haenszel Statistics for the following three alternative hypotheses: Nonzero Correlation, Row Mean Scores Differ (ANOVA Statistic), and General Association. For each of these statistics, PROC FREQ gives the degrees of freedom (DF) and the probability value (Prob). If you specify the MANTELLEISS option, PROC FREQ displays the Mantel-Fleiss Criterion for  $2 \times 2$  tables. For  $2 \times 2$  tables, PROC FREQ also displays Estimates of the Common Relative Risk for Case-Control and Cohort studies, together with their confidence limits. These include both Mantel-Haenszel and Logit stratum-adjusted estimates of the common Odds Ratio, Column 1 Relative Risk, and Column 2 Relative Risk. Also for  $2 \times 2$  tables, PROC FREQ displays the Breslow-Day Test for Homogeneity of the Odds Ratios. For this test, PROC FREQ gives the Chi-Square, the degrees of freedom (DF), and the probability value ( $\text{Pr} > \text{ChiSq}$ ).
- If you specify the CMH option in the TABLES statement and also specify the COMOR option in the EXACT statement, PROC FREQ displays exact confidence limits for the Common Odds Ratio for multiple strata of  $2 \times 2$  tables. PROC FREQ also displays the Exact Test of  $H_0$ : Common Odds Ratio = 1. The test output includes the Cell (1,1) Sum (S), Mean of S Under  $H_0$ , One-sided  $\text{Pr} \leq S$ , and Point  $\text{Pr} = S$ . PROC FREQ also provides exact two-sided probability values for the test, computed according to the following three methods:  $2 * \text{One-sided}$ , Sum of probabilities  $\leq \text{Point probability}$ , and  $\text{Pr} \geq |S - \text{Mean}|$ .
- If you specify the CMH option in the TABLES statement and also specify the EQOR option in the EXACT statement, PROC FREQ computes Zelen's exact test for equal odds ratios for  $h \times 2 \times 2$  tables. PROC FREQ displays Zelen's test along with the asymptotic Breslow-Day test produced by the CMH option. PROC FREQ displays the test statistic, Zelen's Exact Test (P), and the probability value, Exact  $\text{Pr} \leq P$ .
- If you specify the GAILSIMON option in the TABLES statement for a multiway  $2 \times 2$  tables, PROC FREQ displays the Gail-Simon test for qualitative interactions. The display include the following statistics and their  $p$ -values: Q+ (Positive Risk Differences), Q- (Negative Risk Differences), and Q (Two-Sided).

## ODS Table Names

PROC FREQ assigns a name to each table that it creates. You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 35.14 lists the ODS table names together with their descriptions and the options required to produce the tables. Note that the ALL option in the TABLES statement invokes the CHISQ, MEASURES, and CMH options.

**Table 35.14** ODS Tables Produced by PROC FREQ

ODS Table Name	Description	Statement	Option
BinomialCLs	Binomial confidence limits	TABLES	BINOMIAL(AC   J   W)
BinomialEquiv	Binomial equivalence analysis	TABLES	BINOMIAL(EQUIV)
BinomialEquivLimits	Binomial equivalence limits	TABLES	BINOMIAL(EQUIV)
BinomialEquivTest	Binomial equivalence test	TABLES	BINOMIAL(EQUIV)
BinomialNoninf	Binomial noninferiority test	TABLES	BINOMIAL(NONINF)
BinomialProp	Binomial proportion	TABLES	BINOMIAL
BinomialPropTest	Binomial proportion test	TABLES	BINOMIAL
BinomialSup	Binomial superiority test	TABLES	BINOMIAL(SUP)
BreslowDayTest	Breslow-Day test	TABLES	CMH ( $h \times 2 \times 2$ tables)
CMH	Cochran-Mantel-Haenszel statistics	TABLES	CMH
ChiSq	Chi-square tests	TABLES	CHISQ
CochransQ	Cochran's $Q$	TABLES	AGREE ( $h \times 2 \times 2$ tables)
ColScores	Column scores	TABLES	SCOROUT
CommonOdds-RatioCI	Exact confidence limits for the common odds ratio	EXACT	COMOR ( $h \times 2 \times 2$ tables)
CommonOdds-RatioTest	Common odds ratio exact test	EXACT	COMOR ( $h \times 2 \times 2$ tables)
CommonRelRisks	Common relative risks	TABLES	CMH ( $h \times 2 \times 2$ tables)
CrossList	Crosstabulation table in column format	TABLES	CROSSLIST ( $n$ -way table, $n > 1$ )
CrossTabFreqs	Crosstabulation table	TABLES	( $n$ -way table, $n > 1$ )
EqualKappaTest	Test for equal simple kappas	TABLES	AGREE ( $h \times 2 \times 2$ tables)
EqualKappaTests	Tests for equal kappas	TABLES	AGREE ( $h \times r \times r$ , $r > 2$ )
EqualOddsRatios	Tests for equal odds ratios	EXACT	EQOR ( $h \times 2 \times 2$ tables)
GailSimon	Gail-Simon test	TABLES	GAILSIMON ( $h \times 2 \times 2$ tables)
FishersExact	Fisher's exact test	EXACT or TABLES or TABLES	FISHER FISHER or EXACT CHISQ ( $2 \times 2$ tables)

Table 35.14 continued

ODS Table Name	Description	Statement	Option
FishersExactMC	Monte Carlo estimates for Fisher's exact test	EXACT	FISHER / MC
Gamma	Gamma	TEST	GAMMA
GammaTest	Gamma test	TEST	GAMMA
JTTest	Jonckheere-Terpstra test	TABLES	JT
JTTestMC	Monte Carlo estimates for Jonckheere-Terpstra exact test	EXACT	JT / MC
KappaStatistics	Kappa statistics	TABLES	AGREE, no TEST or EXACT ( $r \times r$ tables, $r > 2$ )
KappaWeights	Kappa weights	TABLES	AGREE and PRINTKWT
List	List format multiway table	TABLES	LIST
LRChiSq	Likelihood-ratio chi-square exact test	EXACT	LRCHI
LRChiSqMC	Monte Carlo exact test for likelihood-ratio chi-square	EXACT	LRCHI / MC
MantelFleiss	Mantel-Fleiss criterion	TABLES	CMH(MF) ( $h \times 2 \times 2$ tables)
McNemarsTest	McNemar's test	TABLES	AGREE ( $2 \times 2$ tables)
Measures	Measures of association	TABLES	MEASURES
MHChiSq	Mantel-Haenszel chi-square exact test	EXACT	MHCHI
MHChiSqMC	Monte Carlo exact test for Mantel-Haenszel chi-square	EXACT	MHCHI / MC
NLevels	Number of variable levels	PROC	NLEVELS

## ODS Graphics

PROC FREQ assigns a name to each graph that it creates with ODS Graphics. You can use these names to refer to the graphs. Table 35.15 lists the names of the graphs that PROC FREQ generates together with their descriptions and the options that are required to produce the graphs.

To request graphics with PROC FREQ, you must first enable ODS Graphics by specifying the ODS GRAPHICS ON statement. See Chapter 21, “Statistical Graphics Using ODS,” for more information. When you have enabled ODS Graphics, you can request specific plots with the PLOTS= option in the TABLES statement. If you do not specify the PLOTS= option but have enabled ODS Graphics, then PROC FREQ produces all plots that are associated with the analyses that you request.

**Table 35.15** ODS Graphics Produced by PROC FREQ

ODS Graph Name	Plot Description	TABLES Statement Option
CumFreqPlot	Cumulative frequency plot	One-way table request
DeviationPlot	Deviation plot	CHISQ and a one-way table request
FreqPlot	Frequency plot	Any table request
KappaPlot	Kappa plot	AGREE ( $h \times r \times r$ table)
ORPlot	Odds ratio plot	MEASURES or RELRISK ( $h \times 2 \times 2$ table)
RelRiskPlot	Relative risk plot	MEASURES or RELRISK ( $h \times 2 \times 2$ table)
RiskDiffPlot	Risk difference plot	RISKDIFF ( $h \times 2 \times 2$ table)
WtKappaPlot	Weighted kappa plot	AGREE ( $h \times r \times r$ table, $r > 2$ )

## Examples: FREQ Procedure

### Example 35.1: Output Data Set of Frequencies

The eye and hair color of children from two different regions of Europe are recorded in the data set Color. Instead of recording one observation per child, the data are recorded as cell counts, where the variable Count contains the number of children exhibiting each of the 15 eye and hair color combinations. The data set does not include missing combinations.

The following DATA step statements create the SAS data set Color:

```
data Color;
  input Region Eyes $ Hair $ Count @@;
  label Eyes  = 'Eye Color'
        Hair   = 'Hair Color'
        Region = 'Geographic Region';
  datalines;
1 blue  fair   23 1 blue  red    7  1 blue  medium 24
1 blue  dark   11 1 green fair   19 1 green red    7
1 green medium 18 1 green dark  14 1 brown fair   34
1 brown red    5 1 brown medium 41 1 brown dark  40
1 brown black  3 2 blue  fair   46 2 blue  red    21
2 blue  medium 44 2 blue  dark   40 2 blue  black   6
2 green fair   50 2 green red    31 2 green medium 37
2 green dark   23 2 brown fair   56 2 brown red    42
2 brown medium 53 2 brown dark   54 2 brown black  13
;
```

The following PROC FREQ statements read the Color data set and create an output data set that contains the frequencies, percentages, and expected cell frequencies of the two-way table of Eyes by Hair. The TABLES statement requests three tables: a frequency table for Eyes, a frequency table for Hair, and a crosstabulation table for Eyes by Hair. The OUT= option creates the FreqCount data set, which contains the crosstabulation table frequencies. The OUTEXPECT option outputs the expected table cell frequencies to FreqCount, and the SPARSE option includes zero cell frequencies in the output data set. The WEIGHT statement specifies that the variable Count contains the observation weights. These statements create [Output 35.1.1](#) through [Output 35.1.3](#).

```
proc freq data=Color;
  tables Eyes Hair Eyes*Hair / out=FreqCount outexpect sparse;
  weight Count;
  title 'Eye and Hair Color of European Children';
run;

proc print data=FreqCount noobs;
  title2 'Output Data Set from PROC FREQ';
run;
```

**Output 35.1.1** displays the two frequency tables produced by PROC FREQ: one showing the distribution of eye color, and one showing the distribution of hair color. By default, PROC FREQ lists the variables values in alphabetical order. The 'Eyes\*Hair' specification produces a crosstabulation table, shown in **Output 35.1.2**, with eye color defining the table rows and hair color defining the table columns. A zero cell frequency for green eyes and black hair indicates that this eye and hair color combination does not occur in the data.

The output data set FreqCount (**Output 35.1.3**) contains frequency counts and percentages for the last table requested in the TABLES statement, Eyes by Hair. Because the SPARSE option is specified, the data set includes the observation with a zero frequency. The variable Expected contains the expected frequencies, as requested by the OUTEXPECT option.

### **Output 35.1.1** Frequency Tables

Eye and Hair Color of European Children				
The FREQ Procedure				
Eye Color				
Eyes	Frequency	Percent	Cumulative Frequency	Cumulative Percent

## Example 35.2: Frequency Dot Plots

This example produces frequency dot plots for the children's eye and hair color data from [Example 35.1](#).

PROC FREQ produces plots by using ODS Graphics to create graphs as part of the procedure output. Frequency plots are available for any frequency or crosstabulation table request. You can display frequency plots as bar charts or dot plots. You can use *plot-options* to specify the orientation (vertical or horizontal), scale, and layout of the plots.

The following PROC FREQ statements request frequency tables and dot plots. The first TABLES statement requests a one-way frequency table of Hair and a crosstabulation table of Eyes by Hair. The PLOTS= option requests frequency plots for the tables, and the TYPE=DOT *plot-option* specifies dot plots. By default, frequency plots are produced as bar charts.

The second TABLES statement requests a crosstabulation table of Region by Hair and a frequency dot plot for this table. The SCALE=PERCENT *plot-option* plots percentages instead of frequency counts. SCALE=LOG and SCALE=SQRT *plot-options* are also available to plot log frequencies and square roots of frequencies, respectively.

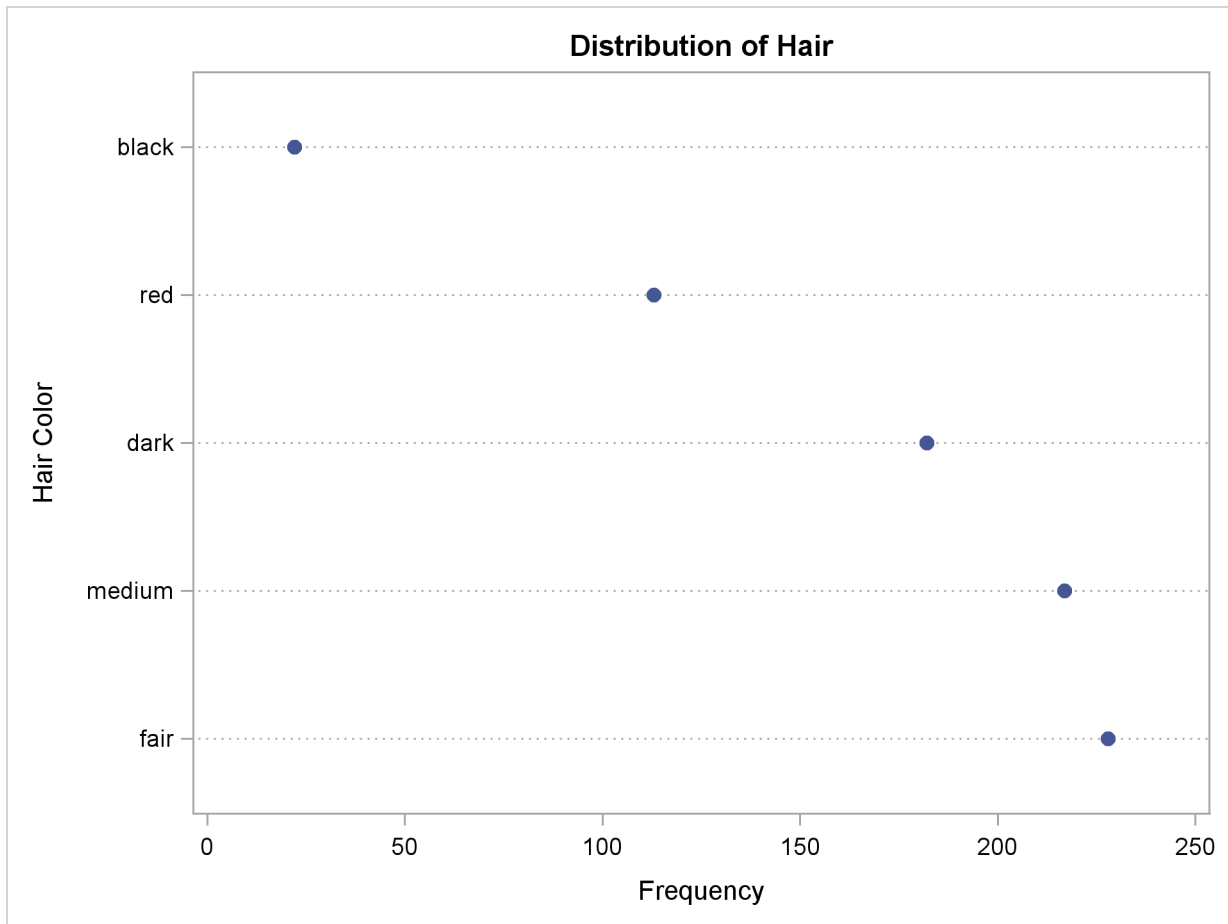

The ORDER=FREQ option in the PROC FREQ statement orders the variable levels by frequency. This order applies to the frequency and crosstabulation table displays and also to the corresponding frequency plots.

Before requesting plots, you must enable ODS Graphics with the ODS GRAPHICS ON statement.

```
ods graphics on;
proc freq data=Color order=freq;
  tables Hair Eyes*Hair / plots=freqplot(type=dot);
  tables Region*Hair / plots=freqplot(type=dot scale=percent);
  weight Count;
  title 'Eye and Hair Color of European Children';
run;
ods graphics off;
```

[Output 35.2.1](#), [Output 35.2.2](#), and [Output 35.2.3](#) display the dot plots produced by PROC FREQ. By default, the orientation of dot plots is horizontal, which places the variable levels on the Y axis. You can specify the ORIENT=VERTICAL *plot-option* to request a vertical orientation. For two-way plots, you can use the TWOWAY= *plot-option* to specify the plot layout. The default layout (shown in [Output 35.2.2](#) and [Output 35.2.3](#)) is GROUPVERTICAL. Two-way layouts STACKED and GROUPTHORIZONTAL are also available.

**Output 35.2.1** One-Way Frequency Dot Plot

Output 35.2.2 Two-Way Frequency Dot Plot

**Output 35.2.3** Two-Way Percent Dot Plot**Example 35.3: Chi-Square Goodness-of-Fit Tests**

This example examines whether the children's hair color (from [Example 35.1](#)) has a specified multinomial distribution for the two geographical regions. The hypothesized distribution of hair color is 30% fair, 12% red, 30% medium, 25% dark, and 3% black.

In order to test the hypothesis for each region, the data are first sorted by Region. Then the FREQ procedure uses a BY statement to produce a separate table for each BY group (Region). The option ORDER=DATA orders the variable values (hair color) in the frequency table by their order in the input data set. The TABLES statement requests a frequency table for hair color, and the option NOCUM suppresses the display of the cumulative frequencies and percentages.

The CHISQ option requests a chi-square goodness-of-fit test for the frequency table of Hair. The TESTP= option specifies the hypothesized (or test) percentages for the chi-square test; the number of percentages listed equals the number of table levels, and the percentages sum to 100%. The TESTP= percentages are listed in the same order as the corresponding variable levels appear in frequency table.

The PLOTS= option requests a deviation plot, which is associated with the CHISQ option and displays the relative deviations from the test frequencies. The TYPE=DOT *plot-option* requests a dot plot instead of the default type, which is a bar chart. The ONLY *global-plot-option* requests that PROC FREQ produce only the deviation plot. By default, PROC FREQ produces all plots associated with the requested analyses. A frequency plot is associated with a one-way table request but is not produced in this example because ONLY is specified with the DEVIATIONPLOT request. Note that ODS Graphics must be enabled before requesting plots. These statements produce [Output 35.3.1](#) through [Output 35.3.4](#).

```
proc sort data=Color;
  by Region;
run;

ods graphics on;
proc freq data=Color order=data;
  tables Hair / nocum chisq testp=(30 12 30 25 3)
    plots(only)=deviationplot(type=dot);
  weight Count;
  by Region;
  title 'Hair Color of European Children';
run;
ods graphics off;
```

**Output 35.3.1** Frequency Table and Chi-Square Test for Region 1

```

Hair Color of European Children

----- Geographic Region=1 -----

The FREQ Procedure

Hair Color

| Hair   | Frequency | Percent | Test<br>Percent |
|--------|-----------|---------|-----------------|
| fair   | 76        | 30.89   | 30.00           |
| red    | 19        | 7.72    | 12.00           |
| medium | 83        | 33.74   | 30.00           |
| dark   | 65        | 26.42   | 25.00           |
| black  | 3         | 1.22    | 3.00            |

----- Geographic Region=1 -----

Chi-Square Test
for Specified Proportions

|            |        |
|------------|--------|
| Chi-Square | 7.7602 |
| DF         | 4      |
| Pr > ChiSq | 0.1008 |

```

Output 35.3.1 shows the frequency table and chi-square test for Region 1. The frequency table lists the variable values (hair color) in the order in which they appear in the data set. The “Test Percent” column lists the hypothesized percentages for the chi-square test. Always check that you have ordered the TESTP= percentages to correctly match the order of the variable levels.

Output 35.3.2 shows the deviation plot for Region 1, which displays the relative deviations from the hypothesized values. The relative deviation for a level is the difference between the observed and hypothesized (test) percentage divided by the test percentage. You can suppress the chi-square  $p$ -value that is displayed by default in the deviation plot by specifying the NOSTATS *plot-option*.

**Output 35.3.2** Deviation Plot for Region 1

Output 35.3.3 and Output 35.3.4 show the results for Region 2. PROC FREQ computes a chi-square statistic for each region. The chi-square statistic is significant at the 0.05 level for Region 2 ( $p=0.0003$ ) but not for Region 1. This indicates a significant departure from the hypothesized percentages in Region 2.

**Output 35.3.3** Frequency Table and Chi-Square Test for Region 2

Hair Color of European Children			
----- Geographic Region=2 -----			
The FREQ Procedure			
Hair Color			
Hair	Frequency	Percent	Test Percent
fair	152	29.46	30.00
red	94	18.22	12.00
medium	134	25.97	30.00
dark	117	22.67	25.00
black	19	3.68	3.00
----- Geographic Region=2 -----			
Chi-Square Test for Specified Proportions			
-----			
Chi-Square	21.3824		
DF	4		
Pr > ChiSq	0.0003		

**Output 35.3.4** Deviation Plot for Region 2

## Example 35.4: Binomial Proportions

In this example, PROC FREQ computes binomial proportions, confidence limits, and tests. The example uses the eye and hair color data from [Example 35.1](#). By default, PROC FREQ computes the binomial proportion as the proportion of observations in the first level of the one-way table. You can designate a different level by using the LEVEL= binomial-option.

The following PROC FREQ statements compute the proportion of children with brown eyes (from the data set in [Example 35.1](#)) and test the null hypothesis that the population proportion equals 50%. These statements also compute an equivalence for the proportion of children with fair hair.

The first TABLES statement requests a one-way frequency table for the variable Eyes. The BINOMIAL option requests the binomial proportion, confidence limits, and test. PROC FREQ computes the proportion with Eyes = 'brown', which is the first level displayed in the table. The AC, WILSON, and EXACT binomial-options request the following confidence limits types: Agresti-Coull, Wilson (score), and exact (Clopper-Pearson). By default, PROC FREQ provides Wald and exact (Clopper-

Pearson) confidence limits for the binomial proportion. The BINOMIAL option also produces an asymptotic Wald test that the proportion equals 0.5. You can specify a different test proportion with the P= binomial-option. The ALPHA=0.1 option specifies that  $\alpha = 10\%$ , which produces 90% confidence limits.

The second TABLES statement requests a one-way frequency table for the variable Hair. The BINOMIAL option requests the proportion for the first level, Hair = 'fair'. The EQUIV binomial-option requests an equivalence test for the binomial proportion. The P=.28 option specifies 0.28 as the null hypothesis proportion, and the MARGIN=.1 option specifies 0.1 as the equivalence test margin.

```
proc freq data=Color order=freq;
  tables Eyes / binomial(ac wilson exact) alpha=.1;
  tables Hair / binomial(equiv p=.28 margin=.1);
  weight Count;
  title 'Hair and Eye Color of European Children';
run;
```

Output 35.4.1 displays the results for eye color, and Output 35.4.2 displays the results for hair color.

**Output 35.4.1** Binomial Proportion for Eye Color

Hair and Eye Color of European Children				
The FREQ Procedure				
Eye Color				
Eyes	Frequency	Percent	Cumulative Frequency	Cumulative Percent
brown	341	44.75	341	44.75
blue	222	29.13	563	73.88
green	199	26.12	762	100.00
Binomial Proportion for Eyes = brown				
Proportion			0.4475	
ASE			0.0180	
Type	90% Confidence Limits			
Wilson			0.4181	0.4773
Agresti-Coull			0.4181	0.4773
Clopper-Pearson (Exact)			0.4174	0.4779
Test of H0: Proportion = 0.5				
ASE under H0			0.0181	
Z			-2.8981	
One-sided Pr < Z			0.0019	
Two-sided Pr >  Z			0.0038	

The frequency table in [Output 35.4.1](#) displays the values of Eyes in order of descending frequency count. PROC FREQ computes the proportion of children in the first level displayed in the frequency table, Eyes = 'brown'. [Output 35.4.1](#) displays the binomial proportion confidence limits and test. The confidence limits are 90% confidence limits. If you do not specify the ALPHA= option, PROC FREQ computes 95% confidence limits by default. Because the value of  $Z$  is less than zero, PROC FREQ displays the a left-sided  $p$ -value (0.0019). This small  $p$ -value supports the alternative hypothesis that the true value of the proportion of children with brown eyes is less than 50%.

[Output 35.4.2](#) displays the equivalence test results produced by the second TABLES statement. The null hypothesis proportion is 0.28 and the equivalence margins are  $-0.1$  and  $0.1$ , which yield equivalence limits of  $0.18$  and  $0.38$ . PROC FREQ provides two one-sided tests (TOST) for equivalence. The small  $p$ -value indicates rejection of the null hypothesis in favor of the alternative that the proportion is equivalent to the null value.

#### Output 35.4.2 Binomial Proportion for Hair Color

Hair Color				
Hair	Frequency	Percent	Cumulative Frequency	Cumulative Percent
-----	-----	-----	-----	-----
fair	228	29.92	228	29.92
medium	217	28.48	445	58.40
dark	182	23.88	627	82.28
red	113	14.83	740	97.11
black	22	2.89	762	100.00

Equivalence Analysis				
H0: P - p0 <= Lower Margin or >= Upper Margin				
Ha: Lower Margin < P - p0 < Upper Margin				
p0 = 0.28    Lower Margin = -0.1    Upper Margin = 0.1				
Proportion		ASE (Sample)		
0.2992		0.0166		
Two One-Sided Tests (TOST)				
Test	Z	P-Value		
Lower Margin	7.1865	Pr > Z	<.0001	
Upper Margin	-4.8701	Pr < Z	<.0001	
Overall			<.0001	
Equivalence Limits		90% Confidence Limits		
0.1800	0.3800	0.2719	0.3265	

### Example 35.5: Analysis of a 2x2 Contingency Table

This example computes chi-square tests and Fisher's exact test to compare the probability of coronary heart disease for two types of diet. It also estimates the relative risks and computes exact confidence limits for the odds ratio.

The data set `FatComp` contains hypothetical data for a case-control study of high fat diet and the risk of coronary heart disease. The data are recorded as cell counts, where the variable `Count` contains the frequencies for each exposure and response combination. The data set is sorted in descending order by the variables `Exposure` and `Response`, so that the first cell of the  $2 \times 2$  table contains the frequency of positive exposure and positive response. The `FORMAT` procedure creates formats to identify the type of exposure and response with character values.

```
proc format;
    value ExpFmt 1='High Cholesterol Diet'
                0='Low Cholesterol Diet';
    value RspFmt 1='Yes'
                0='No';
run;

data FatComp;
    input Exposure Response Count;
    label Response='Heart Disease';
    datalines;
0 0 6
0 1 2
1 0 4
1 1 11
;

proc sort data=FatComp;
    by descending Exposure descending Response;
run;
```

In the following `PROC FREQ` statements, `ORDER=DATA` option orders the contingency table values by their order in the input data set. The `TABLES` statement requests a two-way table of `Exposure` by `Response`. The `CHISQ` option produces several chi-square tests, while the `RELRISK` option produces relative risk measures. The `EXACT` statement requests the exact Pearson chi-square test and exact confidence limits for the odds ratio.

```
proc freq data=FatComp order=data;
    format Exposure ExpFmt. Response RspFmt.;
    tables Exposure*Response / chisq relrisk;
    exact pchi or;
    weight Count;
    title 'Case-Control Study of High Fat/Cholesterol Diet';
run;
```

The contingency table in [Output 35.5.1](#) displays the variable values so that the first table cell contains the frequency for the first cell in the data set (the frequency of positive exposure and positive response).

**Output 35.5.1** Contingency Table

Case-Control Study of High Fat/Cholesterol Diet				
The FREQ Procedure				
Table of Exposure by Response				
Exposure	Response (Heart Disease)			
Frequency				
Percent				
Row Pct				
Col Pct		Yes	No	Total
-----+-----+-----+-----+				
High Cholesterol		11	4	15
Diet		47.83	17.39	65.22
		73.33	26.67	
		84.62	40.00	
-----+-----+-----+-----+				
Low Cholesterol		2	6	8
Diet		8.70	26.09	34.78
		25.00	75.00	
		15.38	60.00	
-----+-----+-----+-----+				
Total		13	10	23
		56.52	43.48	100.00

[Output 35.5.2](#) displays the chi-square statistics. Because the expected counts in some of the table cells are small, PROC FREQ gives a warning that the asymptotic chi-square tests might not be appropriate. In this case, the exact tests are appropriate. The alternative hypothesis for this analysis states that coronary heart disease is more likely to be associated with a high fat diet, so a one-sided test is desired. Fisher's exact right-sided test analyzes whether the probability of heart disease in the high fat group exceeds the probability of heart disease in the low fat group; because this  $p$ -value is small, the alternative hypothesis is supported.

The odds ratio, displayed in [Output 35.5.3](#), provides an estimate of the relative risk when an event is rare. This estimate indicates that the odds of heart disease is 8.25 times higher in the high fat diet group; however, the wide confidence limits indicate that this estimate has low precision.

**Output 35.5.2** Chi-Square Statistics

Statistic	DF	Value	Prob
Chi-Square	1	4.9597	0.0259

## Example 35.6: Output Data Set of Chi-Square Statistics

This example uses the Color data from [Example 35.1](#) to output the Pearson chi-square and the likelihood-ratio chi-square statistics to a SAS data set. The following PROC FREQ statements create a two-way table of eye color versus hair color.

```
proc freq data=Color order=data;
  tables Eyes*Hair / expected cellchi2 norow nocol chisq;
  output out=ChiSqData n nmiss pchi lrchi;
  weight Count;
  title 'Chi-Square Tests for 3 by 5 Table of Eye and Hair Color';
run;

proc print data=ChiSqData noobs;
  title1 'Chi-Square Statistics for Eye and Hair Color';
  title2 'Output Data Set from the FREQ Procedure';
run;
```

The EXPECTED option displays expected cell frequencies in the crosstabulation table, and the CELLCHI2 option displays the cell contribution to the overall chi-square. The NOROW and NOCOL options suppress the display of row and column percents in the crosstabulation table. The CHISQ option produces chi-square tests.

The OUTPUT statement creates the ChiSqData output data set and specifies the statistics to include. The N option requests the number of nonmissing observations, the NMISS option stores the number of missing observations, and the PCHI and LRCHI options request Pearson and likelihood-ratio chi-square statistics, respectively, together with their degrees of freedom and *p*-values.

The preceding statements produce [Output 35.6.1](#) and [Output 35.6.2](#). The contingency table in [Output 35.6.1](#) displays eye and hair color in the order in which they appear in the Color data set. The Pearson chi-square statistic in [Output 35.6.2](#) provides evidence of an association between eye and hair color ( $p=0.0073$ ). The cell chi-square values show that most of the association is due to more green-eyed children with fair or red hair and fewer with dark or black hair. The opposite occurs with the brown-eyed children.

[Output 35.6.3](#) displays the output data set created by the OUTPUT statement. It includes one observation that contains the sample size, the number of missing values, and the chi-square statistics and corresponding degrees of freedom and *p*-values as in [Output 35.6.2](#).

**Output 35.6.1** Contingency Table

Chi-Square Tests for 3 by 5 Table of Eye and Hair Color

## Example 35.7: Cochran-Mantel-Haenszel Statistics

The data set *Migraine* contains hypothetical data for a clinical trial of migraine treatment. Subjects of both genders receive either a new drug therapy or a placebo. Their response to treatment is coded as ‘Better’ or ‘Same’. The data are recorded as cell counts, and the number of subjects for each treatment and response combination is recorded in the variable *Count*.

```
data Migraine;
  input Gender $ Treatment $ Response $ Count @@;
  datalines;
female Active   Better 16   female Active   Same 11
female Placebo  Better  5   female Placebo  Same 20
male   Active   Better 12   male   Active   Same 16
male   Placebo  Better  7   male   Placebo  Same 19
;
```

The following PROC FREQ statements create a multiway table stratified by Gender, where Treatment forms the rows and Response forms the columns. The CMH option produces the Cochran-Mantel-Haenszel statistics. For this stratified  $2 \times 2$  table, estimates of the common relative risk and the Breslow-Day test for homogeneity of the odds ratios are also displayed. The NOPRINT option suppresses the display of the contingency tables. These statements produce [Output 35.7.1](#) through [Output 35.7.3](#).

```
proc freq data=Migraine;
  tables Gender*Treatment*Response / cmh;
  weight Count;
  title 'Clinical Trial for Treatment of Migraine Headaches';
run;
```

**Output 35.7.1** Cochran-Mantel-Haenszel Statistics

Clinical Trial for Treatment of Migraine Headaches				
The FREQ Procedure				
Summary Statistics for Treatment by Response Controlling for Gender				
Cochran-Mantel-Haenszel Statistics (Based on Table Scores)				
Statistic	Alternative Hypothesis	DF	Value	Prob
1	Nonzero Correlation	1	8.3052	0.0040
2	Row Mean Scores Differ	1	8.3052	0.0040
3	General Association	1	8.3052	0.0040

For a stratified  $2 \times 2$  table, the three CMH statistics displayed in [Output 35.7.1](#) test the same hypothesis. The significant  $p$ -value (0.004) indicates that the association between treatment and response remains strong after adjusting for gender.

The CMH option also produces a table of relative risks, as shown in [Output 35.7.2](#). Because this is a prospective study, the relative risk estimate assesses the effectiveness of the new drug; the “Cohort (Col1 Risk)” values are the appropriate estimates for the first column (the risk of improvement). The probability of migraine improvement with the new drug is just over two times the probability of improvement with the placebo.

The large  $p$ -value for the Breslow-Day test (0.2218) in [Output 35.7.3](#) indicates no significant gender difference in the odds ratios.

**Output 35.7.2** CMH Option: Relative Risks

Estimates of the Common Relative Risk (Row1/Row2)				
Type of Study	Method	Value	95% Confidence Limits	
Case-Control (Odds Ratio)	Mantel-Haenszel	3.3132	1.4456	7.5934
	Logit	3.2941	1.4182	7.6515

	Logit	2.1059	1.1951	3.7108
Cohort (Col2 Risk)	Mantel-Haenszel	0.6420	0.4705	0.8761
	Logit	0.6613	0.4852	0.9013

**Output 35.7.3** CMH Option: Breslow-Day Test

Breslow-Day Test for Homogeneity of the Odds Ratios	
Chi-Square	1.4929
DF	1
Pr > ChiSq	0.2218

## Example 35.8: Cochran-Armitage Trend Test

The data set `Pain` contains hypothetical data for a clinical trial of a drug therapy to control pain. The clinical trial investigates whether adverse responses increase with larger drug doses. Subjects receive either a placebo or one of four drug doses. An adverse response is recorded as `Adverse='Yes'`; otherwise, it is recorded as `Adverse='No'`. The number of subjects for each drug dose and response combination is contained in the variable `Count`.

```
data pain;
  input Dose Adverse $ Count @@;
  datalines;
0 No 26    0 Yes  6
1 No 26    1 Yes  7
2 No 23    2 Yes  9
3 No 18    3 Yes 14
4 No  9    4 Yes 23
;
```

The following PROC FREQ statements provide a trend analysis. The TABLES statement requests a table of Adverse by Dose. The MEASURES option produces measures of association, and the CL option produces confidence limits for these measures. The TREND option tests for a trend across the ordinal values of the variable Dose with the Cochran-Armitage test. The EXACT statement produces exact  $p$ -values for this test, and the MAXTIME= option terminates the exact computations if they do not complete within 60 seconds. The TEST statement computes an asymptotic test for Somers'  $D(R|C)$ .

The PLOTS= option requests a frequency plot for the table of Adverse by Dose. By default, PROC FREQ provides a bar chart for the frequency plot. The TWOWAY=STACKED option requests a stacked layout, where the bars correspond to the column variable (Dose) values, and the row variable (Adverse) frequencies are stacked within each bar.

```
ods graphics on;
proc freq data=Pain;
  tables Adverse*Dose / trend measures cl
    plots=freqplot(twoway=stacked);
  test smdrc;
  exact trend / maxtime=60;
  weight Count;
  title 'Clinical Trial for Treatment of Pain';
run;
ods graphics off;
```

Output 35.8.1 through Output 35.8.4 display the results of the analysis. The “Col Pct” values in Output 35.8.1 show the expected increasing trend in the proportion of adverse effects with the increasing dosage (from 18.75% to 71.88%). The corresponding frequency bar chart (Output 35.8.2) also shows this increasing trend.

**Output 35.8.1** Contingency Table

Clinical Trial for Treatment of Pain						
The FREQ Procedure						
Table of Adverse by Dose						
Adverse	Dose					
Frequency						
Percent						
Row Pct						
Col Pct	0	1	2	3	4	Total
-----+-----+-----+-----+-----+-----+-----						
No	26	26	23	18	9	102
	16.15	16.15	14.29	11.18	5.59	63.35
	25.49	25.49	22.55	17.65	8.82	
	81.25	78.79	71.88	56.25	28.13	
-----+-----+-----+-----+-----+-----+-----						
Yes	6	7	9	14	23	59
	3.73	4.35	5.59	8.70	14.29	36.65
	10.17	11.86	15.25	23.73	38.98	
	18.75	21.21	28.13	43.75	71.88	
-----+-----+-----+-----+-----+-----+-----						
Total	32	33	32	32	32	161
	19.88	20.50	19.88	19.88	19.88	100.00

**Output 35.8.2** Stacked Bar Chart of Frequencies

**Output 35.8.3** displays the measures of association produced by the MEASURES option. Somers'  $D(R|C)$  measures the association treating the row variable (Adverse) as the response and the column variable (Dose) as a predictor. Because the asymptotic 95% confidence limits do not contain zero, this indicates a strong positive association. Similarly, the Pearson and Spearman correlation coefficients show evidence of a strong positive association, as hypothesized.

The Cochran-Armitage test (**Output 35.8.4**) supports the trend hypothesis. The small left-sided  $p$ -values for the Cochran-Armitage test indicate that the probability of the Row 1 level (Adverse='No') decreases as Dose increases or, equivalently, that the probability of the Row 2 level (Adverse='Yes') increases as Dose increases. The two-sided  $p$ -value tests against either an increasing or decreasing alternative. This is an appropriate hypothesis when you want to determine whether the drug has progressive effects on the probability of adverse effects but the direction is unknown.

**Output 35.8.3** Measures of Association

## Example 35.9: Friedman's Chi-Square Test

Friedman's test is a nonparametric test for treatment differences in a randomized complete block design. Each block of the design might be a subject or a homogeneous group of subjects. If blocks are groups of subjects, the number of subjects in each block must equal the number of treatments. Treatments are randomly assigned to subjects within each block. If there is one subject per block, then the subjects are repeatedly measured once under each treatment. The order of treatments is randomized for each subject.

In this setting, Friedman's test is identical to the ANOVA (row means scores) CMH statistic when the analysis uses rank scores (SCORES=RANK). The three-way table uses subject (or subject group) as the stratifying variable, treatment as the row variable, and response as the column variable. PROC FREQ handles ties by assigning midranks to tied response values. If there are multiple subjects per treatment in each block, the ANOVA CMH statistic is a generalization of Friedman's test.

The data set Hypnosis contains data from a study investigating whether hypnosis has the same effect on skin potential (measured in millivolts) for four emotions (Lehmann 1975, p. 264). Eight subjects are asked to display fear, joy, sadness, and calmness under hypnosis. The data are recorded as one observation per subject for each emotion.

```
data Hypnosis;
  length Emotion $ 10;
  input Subject Emotion $ SkinResponse @@;
  datalines;
1 fear 23.1 1 joy 22.7 1 sadness 22.5 1 calmness 22.6
2 fear 57.6 2 joy 53.2 2 sadness 53.7 2 calmness 53.1
3 fear 10.5 3 joy 9.7 3 sadness 10.8 3 calmness 8.3
4 fear 23.6 4 joy 19.6 4 sadness 21.1 4 calmness 21.6
5 fear 11.9 5 joy 13.8 5 sadness 13.7 5 calmness 13.3
6 fear 54.6 6 joy 47.1 6 sadness 39.2 6 calmness 37.0
7 fear 21.0 7 joy 13.6 7 sadness 13.7 7 calmness 14.8
8 fear 20.3 8 joy 23.6 8 sadness 16.3 8 calmness 14.8
;
```

In the following PROC FREQ statements, the TABLES statement creates a three-way table stratified by Subject and a two-way table; the variables Emotion and SkinResponse form the rows and columns of each table. The CMH2 option produces the first two Cochran-Mantel-Haenszel statistics, the option SCORES=RANK specifies that rank scores are used to compute these statistics, and the NOPRINT option suppresses the contingency tables. These statements produce [Output 35.9.1](#) and [Output 35.9.2](#).

```
proc freq data=Hypnosis;
  tables Subject*Emotion*SkinResponse /
        cmh2 scores=rank noprint;
run;

proc freq data=Hypnosis;
  tables Emotion*SkinResponse /
        cmh2 scores=rank noprint;
run;
```

Because the CMH statistics in [Output 35.9.1](#) are based on rank scores, the Row Mean Scores Differ statistic is identical to Friedman's chi-square ( $Q = 6.45$ ). The  $p$ -value of 0.0917 indicates that differences in skin potential response for different emotions are significant at the 10% level but not at the 5% level.

When you do not stratify by subject, the Row Mean Scores Differ CMH statistic is identical to a Kruskal-Wallis test and is not significant ( $p=0.9038$  in [Output 35.9.2](#)). Thus, adjusting for subject is critical to reducing the background variation due to subject differences.

#### Output 35.9.1 CMH Statistics: Stratifying by Subject

Clinical Trial for Treatment of Pain				
The FREQ Procedure				
Summary Statistics for Emotion by SkinResponse Controlling for Subject				
Cochran-Mantel-Haenszel Statistics (Based on Rank Scores)				
Statistic	Alternative Hypothesis	DF	Value	Prob
1	Nonzero Correlation	1	0.2400	0.6242
2	Row Mean Scores Differ	3	6.4500	0.0917

#### Output 35.9.2 CMH Statistics: No Stratification

Clinical Trial for Treatment of Pain				
The FREQ Procedure				
Summary Statistics for Emotion by SkinResponse				
Cochran-Mantel-Haenszel Statistics (Based on Rank Scores)				
Statistic	Alternative Hypothesis	DF	Value	Prob
1	Nonzero Correlation	1	0.0001	0.9933
2	Row Mean Scores Differ	3	0.5678	0.9038

### Example 35.10: Cochran's Q Test

When a binary response is measured several times or under different conditions, Cochran's  $Q$  tests that the marginal probability of a positive response is unchanged across the times or conditions. When there are more than two response categories, you can use the CATMOD procedure to fit a repeated-measures model.

The data set `Drugs` contains data for a study of three drugs to treat a chronic disease (Agresti 2002). Forty-six subjects receive drugs A, B, and C. The response to each drug is either favorable ('F') or unfavorable ('U').

```
proc format;
  value $ResponseFmt 'F'='Favorable'
                    'U'='Unfavorable';
run;

data drugs;
  input Drug_A $ Drug_B $ Drug_C $ Count @@;
  datalines;
F F F 6   U F F 2
F F U 16  U F U 4
F U F 2   U U F 6
F U U 4   U U U 6
;
```

The following statements create one-way frequency tables of the responses to each drug. The `AGREE` option produces Cochran's  $Q$  and other measures of agreement for the three-way table. These statements produce [Output 35.10.1](#) through [Output 35.10.5](#).

```
proc freq data=Drugs;
  tables Drug_A Drug_B Drug_C / nocum;
  tables Drug_A*Drug_B*Drug_C / agree noprint;
  format Drug_A Drug_B Drug_C $ResponseFmt.;
  weight Count;
  title 'Study of Three Drug Treatments for a Chronic Disease';
run;
```

The one-way frequency tables in [Output 35.10.1](#) provide the marginal response for each drug. For drugs A and B, 61% of the subjects reported a favorable response while 35% of the subjects reported a favorable response to drug C. [Output 35.10.2](#) and [Output 35.10.3](#) display measures of agreement for the 'Favorable' and 'Unfavorable' levels of drug A, respectively. McNemar's test shows a strong discordance between drugs B and C when the response to drug A is favorable.

#### Output 35.10.1 One-Way Frequency Tables

Study of Three Drug Treatments for a Chronic Disease			
The FREQ Procedure			
Drug_A	Frequency	Percent	
Favorable	28	60.87	
Unfavorable	18	39.13	
Drug_B	Frequency	Percent	
Favorable	28	60.87	
Unfavorable	18	39.13	
Drug_C	Frequency	Percent	
Favorable	16	34.78	
Unfavorable	30	65.22	

**Output 35.10.2** Measures of Agreement for Drug A Favorable

McNemar's Test	
-----	
Statistic (S)	10.8889

## Your Turn

---

We welcome your feedback.

- If you have comments about this book, please send them to **`yourturn@sas.com`**. Include the full title and page numbers (if applicable).
- If you have comments about the software, please send them to **`suggest@sas.com`**.

# SAS® Publishing Delivers!

Whether you are new to the work force or an experienced professional, you need to distinguish yourself in this rapidly changing and competitive job market. SAS® Publishing provides you with a wide range of resources to help you set yourself apart. Visit us online at [support.sas.com/bookstore](http://support.sas.com/bookstore).

## SAS® Press

Need to learn the basics? Struggling with a programming problem? You'll find the expert answers that you need in example-rich books from SAS Press. Written by experienced SAS professionals from around the world, SAS Press books deliver real-world insights on a broad range of topics for all skill levels.

**[support.sas.com/saspress](http://support.sas.com/saspress)**

## SAS® Documentation

To successfully implement applications using SAS software, companies in every industry and on every continent all turn to the one source for accurate, timely, and reliable information: SAS documentation. We currently produce the following types of reference documentation to improve your work experience:

- Online help that is built into the software.
- Tutorials that are integrated into the product.
- Reference documentation delivered in HTML and PDF – **free** on the Web.
- Hard-copy books.
