### Overview: GLMPOWER Procedure

Power and sample size analysis optimizes the resource usage and design of a study, improving chances of conclusive results with maximum efficiency. The GLMPOWER procedure performs prospective power and sample size analysis for linear models, with a variety of goals:

- determining the sample size required to get a significant result with adequate probability (power)
- characterizing the power of a study to detect a meaningful effect
- conducting what-if analyses to assess sensitivity of the power or required sample size to other factors

Here *prospective* indicates that the analysis pertains to planning for a future study. This is in contrast to *retrospective* analysis for a past study, which is not supported by this procedure.

The statistical analyses that are covered include Type III tests and contrasts of fixed effects in univariate linear models, optionally with covariates. The covariates can be continuous or categorical. Tests and contrasts involving random effects are not supported. For power and sample size analyses in a variety of other statistical situations, see Chapter 67, “[The POWER Procedure](#).”

Input for PROC GLMPOWER includes the components considered in study planning:

- design (including subject profiles and their allocation weights)
- statistical model
- contrasts of class effects
- significance level (alpha)
- surmised response means for subject profiles (often called “cell means”)
- surmised variability
- power
- sample size

In order to identify power or sample size as the result parameter, you designate it by a missing value in the input. The procedure calculates this result value over one or more scenarios of input values for all other components.

You specify the design and the cell means by using an *exemplary data set*, a data set of artificial values constructed to represent the intended sampling design and the surmised response means in the underlying population. You specify the model and contrasts by using [MODEL](#) and [CONTRAST](#) statements similar to those in the GLM, ANOVA, and MIXED procedures. You specify the remaining parameters with the [POWER](#) statement, which is similar to analysis statements in the POWER procedure.

In addition to tabular results, PROC GLMPOWER produces graphs. You can produce the most common types of plots easily with default settings and use a variety of options for more customized graphics. For example, you can control the choice of axis variables, axis ranges, number of plotted points, mapping of graphical features (such as color, line style, symbol, and panel) to analysis parameters, and legend appearance.

The GLMPOWER procedure is one of several tools available in SAS/STAT software for power and sample size analysis. PROC POWER covers a variety of other analyses such as *t* tests, equivalence

tests, confidence intervals, binomial proportions, multiple regression, one-way ANOVA, survival analysis, logistic regression, and the Wilcoxon rank-sum test. The Power and Sample Size application provides a user interface and implements many of the analyses supported in the procedures. See Chapter 67, “[The POWER Procedure](#),” and Chapter 68, “[The Power and Sample Size Application](#),” for details.

The following sections of this chapter describe how to use PROC GLMPOWER and discuss the underlying statistical methodology. The section “[Getting Started: GLMPOWER Procedure](#)” on page 2641 introduces PROC GLMPOWER with examples of power computation for a two-way analysis of variance. The section “[Syntax: GLMPOWER Procedure](#)” on page 2647 describes the syntax of the procedure. The section “[Details: GLMPOWER Procedure](#)” on page 2658 summarizes the methods employed by PROC GLMPOWER and provides details on several special topics. The section “[Examples: GLMPOWER Procedure](#)” on page 2664 illustrates the use of the GLMPOWER procedure with several applications.

For an overview of methodology and SAS tools for power and sample size analysis, see Chapter 19, “[Introduction to Power and Sample Size Analysis](#).” For more discussion and examples for linear models, see Casteloe and O’Brien (2001), O’Brien and Shieh (1992), Muller et al. (1992), and O’Brien and Muller (1993). For additional discussion of general power and sample size concepts, see O’Brien and Casteloe (2007), Casteloe (2000), Muller and Benignus (1992), and Lenth (2001).

---

## Getting Started: GLMPOWER Procedure

---

### Simple Two-Way ANOVA

---

This example demonstrates how to use PROC GLMPOWER to compute and plot power for each effect test in a two-way analysis of variance (ANOVA).

Suppose you are planning an experiment to study the effect of light exposure at three levels on the growth of two varieties of flowers. The planned data analysis is a two-way ANOVA with flower height (measured at two weeks) as the response and a model consisting of the effects of light exposure, flower variety, and their interaction. You want to calculate the power of each effect test for a balanced design with a total of 60 specimens (10 for each combination of exposure and variety) with  $\alpha = 0.05$  for each test.

As a first step, create an *exemplary data set* describing your conjectures about the underlying population means. You believe that the mean flower height for each combination of variety and exposure level (that is, for each design profile, or for each *cell* in the design) roughly follows [Table 41.1](#).

**Table 41.1** Mean Flower Height (in cm) by Variety and Exposure

Variety	Exposure		
	1	2	3
1	14	16	21
2	10	15	16

The following statements create a data set named Exemplary containing these cell means.

```
data Exemplary;
  do Variety = 1 to 2;
    do Exposure = 1 to 3;
      input Height @@;
      output;
    end;
  end;
  datalines;
    14 16 21
    10 15 16
  ;
run;
```

You also conjecture that the error standard deviation is about 5 cm.

Use the **DATA=** option in the **PROC GLMPOWER** statement to specify Exemplary as the exemplary data set. Identify the classification variables (Variety and Exposure) by using the **CLASS** statement. Specify the model by using the **MODEL** statement. Use the **POWER** statement to specify power as the result parameter and provide values for the other analysis parameters, error standard deviation and total sample size. The following SAS statements perform the power analysis:

```
proc glmpower data=Exemplary;
  class Variety Exposure;
  model Height = Variety | Exposure;
  power
    stddev = 5
    ntotal = 60
    power = .;
run;
```

The **MODEL** statement defines the full model including both main effects and the interaction. The **POWER=** option in the **POWER** statement identifies power as the result parameter with a missing value (**POWER=.**). The **STDDEV=** option specifies an error standard deviation of 5, and the **NTOTAL=** option specifies a total sample size of 60. The default value for the **ALPHA=** option sets the significance level to  $\alpha = 0.05$ .

Figure 41.1 shows the output.

**Figure 41.1** Sample Size Analysis for Two-Way ANOVA

The GLMPower Procedure			
Fixed Scenario Elements			
Dependent Variable		Height	
Error Standard Deviation		5	
Total Sample Size		60	
Alpha		0.05	
Error Degrees of Freedom		54	
Computed Power			
Index	Source	Test DF	Power
1	Variety	1	0.718
2	Exposure	2	0.957
3	Variety*Exposure	2	0.191

The power is about 0.72 for the test of the Variety effect. In other words, there is a probability of 0.72 that the test of the Variety effect will produce a significant result (given the assumptions for the means and error standard deviation). The power is 0.96 for the test of the Exposure effect and 0.19 for the interaction test.

Now, suppose you want to account for some of your uncertainty in conjecturing the true error standard deviation by evaluating the power at reasonable low and high values, 4 and 6.5. You also want to plot power for sample sizes between 30 and 90. The following statements perform the analysis:

```
proc glmpower data=Exemplary;
  class Variety Exposure;
  model Height = Variety | Exposure;
  power
    stddev = 4 6.5
    ntotal = 60
    power = .;
  plot x=n min=30 max=90;
run;
```

The **PLOT** statement with the **X=N** option requests a plot with sample size on the X axis. (The result parameter—in this case, power—is always plotted on the other axis.) The **MIN=** and **MAX=** options in the **PLOT** statement specify the sample size range.

Figure 41.2 shows the output, and Figure 41.3 shows the plot.

**Figure 41.2** Sample Size Analysis for Two-Way ANOVA with Input Ranges

The GLMPOWER Procedure				
Fixed Scenario Elements				
Dependent Variable			Height	
Total Sample Size			60	
Alpha			0.05	
Error Degrees of Freedom			54	
Computed Power				
Index	Source	Std Dev	Test DF	Power
1	Variety	4.0	1	0.887
2	Variety	6.5	1	0.496
3	Exposure	4.0	2	0.996
4	Exposure	6.5	2	0.793
5	Variety*Exposure	4.0	2	0.280
6	Variety*Exposure	6.5	2	0.130

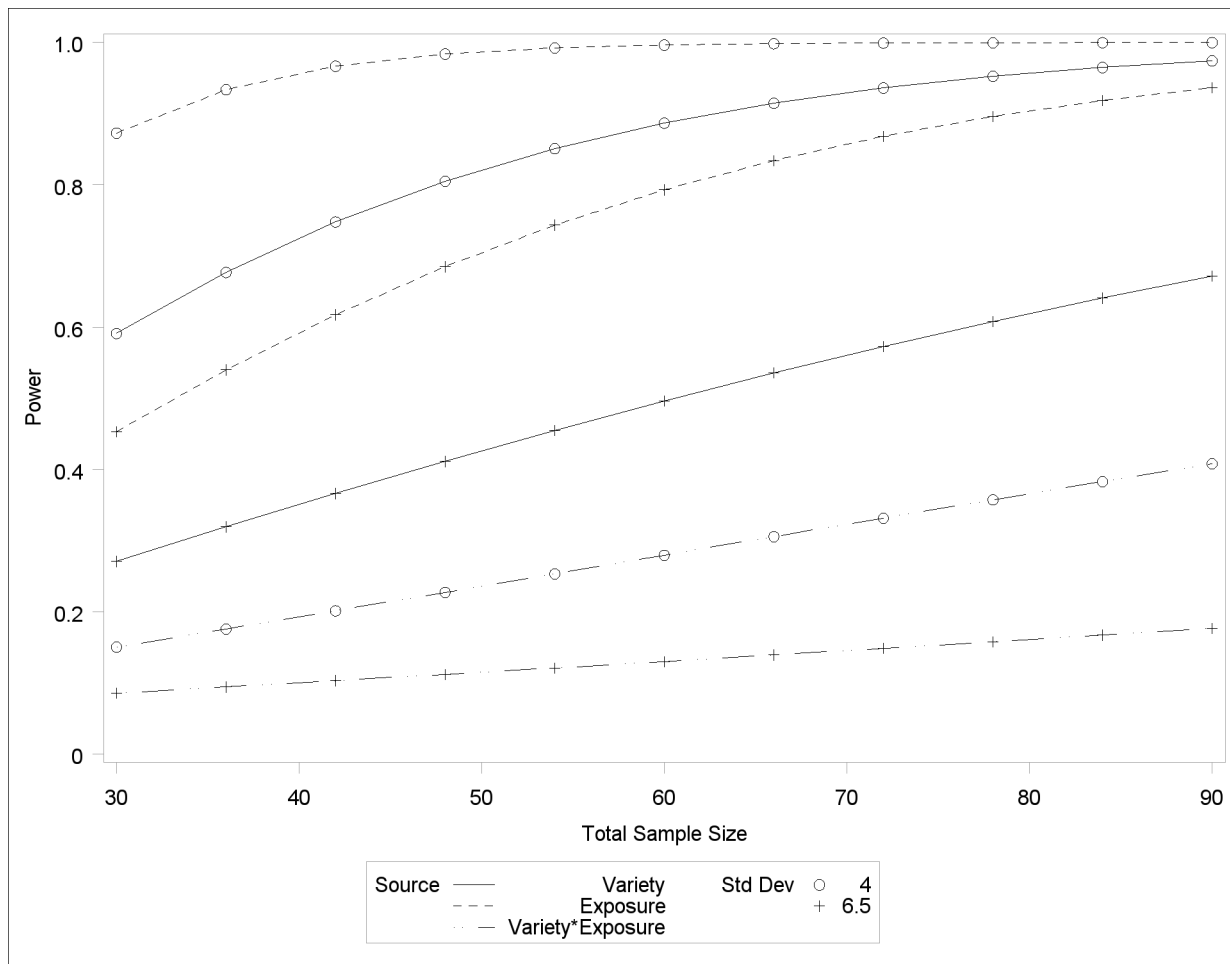

**Figure 41.3** Plot of Power versus Sample Size for Two-Way ANOVA with Input Ranges

Figure 41.2 reveals that the power ranges from about 0.130 to 0.996 for the different effect tests and scenarios for standard deviation, with a sample size of 60. In Figure 41.3, the line style identifies the effect test, and the plotting symbol identifies the standard deviation. The locations of the plotting symbols identify actual computed powers; the curves are linear interpolations of these points. Note that the computed points in the plot occur at sample size multiples of 6, because there are 6 cells in the design (and by default, sample sizes are rounded to produce integer cell sizes).

## Incorporating Contrasts, Unbalanced Designs, and Multiple Means Scenarios

Suppose you want to compute power for the two-way ANOVA described in the section “[Simple Two-Way ANOVA](#)” on page 2641, but you want to additionally perform the following tasks:

- try an unbalanced sample size allocation with respect to Exposure, using twice as many samples for levels 2 and 3 as for level 1

- consider an additional, less optimistic scenario for the cell means, shown in [Table 41.2](#)
- test a contrast of Exposure comparing levels 1 and 3

**Table 41.2** Additional Cell Means Scenario

Variety	Exposure		
	1	2	3
1	15	16	20
2	11	14	15

To specify the unbalanced design and the additional cell means scenario, you can add two new variables to the exemplary data set (Weight for the sample size weights, and HeightNew for the new cell means scenario). Change the name of the original cell means scenario to HeightOrig. The following statements define the exemplary data set:

```
data Exemplary;
  input Variety $ Exposure $ HeightOrig HeightNew Weight;
  datalines;
    1 1 14 15 1
    1 2 16 16 2
    1 3 21 20 2
    2 1 10 11 1
    2 2 15 14 2
    2 3 16 15 2
  ;
run;
```

In PROC GLMPOWER, specify the name of the weight variable by using the [WEIGHT](#) statement, and specify the name of the cell means variables as dependent variables in the [MODEL](#) statement. Use the [CONTRAST](#) statement to specify the contrast as you would in PROC GLM. The following statements perform the sample size analysis.

```
proc glmpower data=Exemplary;
  class Variety Exposure;
  model HeightOrig HeightNew = Variety | Exposure;
  weight Weight;
  contrast 'Exposure=1 vs Exposure=3' Exposure 1 0 -1;
  power
    stddev = 5
    ntotal = 60
    power = .;
run;
```

[Figure 41.4](#) shows the output.

**Figure 41.4** Sample Size Analysis for More Complex Two-Way ANOVA

The GLMPOWER Procedure						
Fixed Scenario Elements						
	Weight Variable		Weight			
	Error Standard Deviation		5			
	Total Sample Size		60			
	Alpha		0.05			
	Error Degrees of Freedom		54			
Computed Power						
Index	Dependent	Type	Source	Test DF	Power	
1	HeightOrig	Effect	Variety	1	0.672	
2	HeightOrig	Effect	Exposure	2	0.911	
3	HeightOrig	Effect	Variety*Exposure	2	0.217	
4	HeightOrig	Contrast	Exposure=1 vs Exposure=3	1	0.951	
5	HeightNew	Effect	Variety	1	0.754	
6	HeightNew	Effect	Exposure	2	0.633	
7	HeightNew	Effect	Variety*Exposure	2	0.137	
8	HeightNew	Contrast	Exposure=1 vs Exposure=3	1	0.705	

The power of the contrast of Exposure levels 1 and 3 is about 0.95 for the original cell means scenario (HeightOrig) and only 0.71 for the new one (HeightNew). The power is higher for the test of Variety, but lower for the tests of Exposure and of Variety\*Exposure for the new cell means scenario compared to the original one. Note also for the HeightOrig scenario that the power for the unbalanced design (Figure 41.4) compared to the balanced design (Figure 41.1) is slightly lower for the tests of Variety and Exposure, but slightly higher for the test of Variety\*Exposure.

## Syntax: GLMPOWER Procedure

The following statements are available in PROC GLMPOWER:

```

PROC GLMPOWER < options > ;
  BY variables ;
  CLASS variables ;
  CONTRAST 'label' effect values < ... effect values > < / options > ;
  MODEL dependents = independents ;
  PLOT < plot-options > < / graph-options > ;
  POWER < options > ;
  WEIGHT variable ;

```

The **PROC GLMPOWER** statement, the **MODEL** statement, and the **POWER** statement are required. If your model contains classification effects, the classification variables must be listed in

a **CLASS** statement, and the **CLASS** statement must appear before the **MODEL** statement. In addition, **CONTRAST** and **POWER** statements must appear after the **MODEL** statement. **PLOT** statements must appear after the **POWER** statement that defines the analysis for the plot.

You can use multiple **CONTRAST**, **POWER**, and **PLOT** statements. Each **CONTRAST** statement defines a separate contrast. Each **POWER** statement produces a separate analysis and uses the information contained in the **CLASS**, **MODEL**, **WEIGHT**, and all **CONTRAST** statements. Each **PLOT** statement refers to the previous **POWER** statement and generates a separate graph (or set of graphs).

Table 41.3 summarizes the basic functions of each statement in PROC GLMPOWER. The syntax of each statement in Table 41.3 is described in the following pages.

**Table 41.3** Statements in the GLMPOWER Procedure

Statement	Description
<b>PROC GLMPOWER</b>	invokes procedure and specifies exemplary data set
<b>BY</b>	specifies variables to define subgroups for the analysis
<b>CLASS</b>	declares classification variables
<b>CONTRAST</b>	defines linear tests of model parameters
<b>MODEL</b>	defines model and specifies dependent variable(s) used for cell means scenarios
<b>PLOT</b>	displays graphs for preceding <b>POWER</b> statement
<b>POWER</b>	identifies parameter to solve for and provides one or more scenarios for values of other analysis parameters
<b>WEIGHT</b>	specifies variable for allocating sample sizes to different subject profiles

## PROC GLMPOWER Statement

**PROC GLMPOWER** < options> ;

The **PROC GLMPOWER** statement invokes the GLMPOWER procedure. You can specify the following options.

**DATA=SAS-data-set**

names a SAS data set to be used as the exemplary data set, which is an artificial data set constructed to represent the intended sampling design and the conjectured response means for the underlying population.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sorting order for the levels of all classification variables (specified in the [CLASS](#) statement). This order determines which parameters in the model correspond to each level in the data; so the [ORDER=](#) option might be useful when you use [CONTRAST](#) statements. Note that the [ORDER=](#) option applies to the levels for all classification variables. The exception is the default [ORDER=FORMATTED](#) for numeric variables for which you have supplied no explicit format. In this case, the levels are ordered by their internal values.

The following table shows how PROC GLMPower interprets values of the [ORDER=](#) option.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, [ORDER=FORMATTED](#). For FORMATTED and INTERNAL, the sort order is machine dependent. For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of [BY](#)-group processing in *SAS Language Reference: Concepts*.

**PLOTONLY**

specifies that only graphical results from the [PLOT](#) statement be produced.

---

## BY Statement

**BY variables ;**

You can specify a [BY](#) statement with PROC GLMPower to obtain separate analyses for observations in groups defined by the [BY](#) variables. When a [BY](#) statement appears, the procedure expects the exemplary data set to be sorted in order of the [BY](#) variables.

If your exemplary data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar [BY](#) statement.
- Specify the option NOTSORTED or DESCENDING in the [BY](#) statement for the GLMPower procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the [BY](#) variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the **BY** variables by using the DATASETS procedure (in Base SAS software).

Because sorting the data changes the order in which PROC GLMPOWER reads observations, the sorting order for the levels of the classification variables might be affected if you have also specified **ORDER=DATA** in the **PROC GLMPOWER** statement. This, in turn, affects specifications in **CONTRAST** statements.

For more information about the **BY** statement, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variables* ;

The **CLASS** statement names the classification variables to be used in the analysis. Classification variables can be either character or numeric.

---

## CONTRAST Statement

**CONTRAST** *'label' effect values < ... effect values> </ options>* ;

The **CONTRAST** statement enables you to define custom hypothesis tests by specifying an **L** vector or matrix for testing the hypothesis  $\mathbf{L}\boldsymbol{\beta} = 0$ . Thus, to use this feature you must be familiar with the details of the model parameterization used in PROC GLM. For more information, see the section “[Parameterization of PROC GLM Models](#)” on page 2489 of Chapter 39, “[The GLM Procedure](#).” All of the elements of the **L** vector can be given, or if only certain portions of the **L** vector are given, the remaining elements are constructed by PROC GLMPOWER from the context (in a manner similar to rule 4 discussed in the section “[Construction of Least Squares Means](#)” on page 2526 of Chapter 39, “[The GLM Procedure](#)”).

There is no limit to the number of **CONTRAST** statements you can specify. Each sample size analysis includes tests for all **CONTRAST** statements.

In the **CONTRAST** statement,

<i>label</i>	identifies the contrast on the output. A label is required for every contrast specified. Labels must be enclosed in quotes.
<i>effect</i>	identifies an effect that appears in the <b>MODEL</b> statement, or the INTERCEPT effect. You do not need to include all effects that are in the <b>MODEL</b> statement.
<i>values</i>	are constants that are elements of the <b>L</b> vector associated with the effect.

You can specify the following option in the **CONTRAST** statement after a slash (/):

**SINGULAR=***number*

tunes the estimability checking. If  $\text{ABS}(\mathbf{L} - \mathbf{LH}) > C \times \text{number}$  for any row in the contrast, then  $\mathbf{L}$  is declared nonestimable.  $\mathbf{H}$  is the  $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$  matrix, and  $C$  is  $\text{ABS}(\mathbf{L})$  except for rows where  $\mathbf{L}$  is zero, and then it is 1. The default value for the **SINGULAR=** option is  $10^{-4}$ . Values for the **SINGULAR=** option must be between 0 and 1.

The **CONTRAST** statement enables you to perform custom hypothesis tests. If the hypothesis is estimable, then the sum of squares due to it,  $\text{SS}(H_0: \mathbf{L}\boldsymbol{\beta} = 0)$ , is computed as

$$(\mathbf{Lb})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{Lb})$$

where  $\mathbf{b} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}$  is the estimated solution vector.

The degrees of freedom associated with the hypothesis are equal to the row rank of  $\mathbf{L}$ . The sum of squares computed in this situation is equivalent to the sum of squares computed using an  $\mathbf{L}$  matrix with any row deleted that is a linear combination of previous rows.

Multiple-degrees-of-freedom hypotheses can be specified by separating the rows of the  $\mathbf{L}$  matrix with commas.

---

## MODEL Statement

**MODEL** *dependents = independents ;*

The **MODEL** statement serves two basic purposes:

- The *dependents* specify scenarios for the cell means.
- The *independents* specify the independent effects.

The *independents* can involve classification variables, continuous variables, or both. You can include main effects and interactions by using the effects notation of PROC GLM; see the section “[Specification of Effects](#)” on page 2486 in Chapter 39, “[The GLM Procedure](#)” for further details. For any model effect involving classification variables (interactions as well as main effects), the number of levels cannot exceed 32,767. If no independent effects are specified, only an intercept term is fit. The **MODEL** statement must appear before the **POWER** statement if the **EFFECTS** option is used in the **POWER** statement.

You can account for covariates in the model by using the **NCOVARIATES=** option and either the **CORRXY=** or **PROPVARREDUCTION=** option in the **POWER** statement.

Each dependent variable refers to a set of surmised cell means in the exemplary data set (named by the **DATA=** option in the **PROC GLMPOWER** statement). These cell means are response means for all of the subject profiles. Multiple dependent variables correspond to multiple scenarios for these cell means. All models are univariate; the GLMPOWER procedure currently does not support multivariate analyses.

The **MODEL** statement is required. You can specify only one **MODEL** statement.

## PLOT Statement

**PLOT** < *plot-options* > < / *graph-options* > ;

The **PLOT** statement produces a graph or set of graphs for the sample size analysis defined by the previous **POWER** statement. The *plot-options* define the plot characteristics, and the *graph-options* are like those in SAS/GRAPH software.

### Options

You can specify the following *plot-options* in the **PLOT** statement.

#### **INTERPOL=JOIN | NONE**

specifies the type of curve to draw through the computed points. The **INTERPOL=JOIN** option connects computed points with straight lines. The **INTERPOL=NONE** option leaves computed points unconnected.

#### **KEY=BYCURVE** < ( *bycurve-options* ) >

#### **KEY=BYFEATURE** < ( *byfeature-options* ) >

#### **KEY=ONCURVES**

specifies the style of key (or “legend”) for the plot. The default is **KEY=BYFEATURE**, which specifies a key with a column of entries for each plot feature (line style, color, and/or symbol). Each entry shows the mapping between a value of the feature and the value(s) of the analysis parameter(s) linked to that feature. The **KEY=BYCURVE** option specifies a key with each row identifying a distinct curve in the plot. The **KEY=ONCURVES** option places a curve-specific label adjacent to each curve.

You can specify the following *byfeature-options* in parentheses after the **KEY=BYCURVE** option.

#### **NUMBERS=OFF | ON**

specifies how the key should identify curves. If **NUMBERS=OFF**, then the key includes symbol, color, and line style samples to identify the curves. If **NUMBERS=ON**, then the key includes numbers matching numeric labels placed adjacent to the curves. The default is **NUMBERS=ON**.

#### **POS=BOTTOM | INSET**

specifies the position of the key. The **POS=BOTTOM** option places the key below the X axis. The **POS=INSET** option places the key inside the plotting region and attempts to choose the least crowded corner. The default is **POS=BOTTOM**.

You can specify the following *byfeature-options* in parentheses after **KEY=BYFEATURE** option.

#### **POS=BOTTOM | INSET**

specifies the position of the key. The **POS=BOTTOM** option places the key below the X axis. The **POS=INSET** option places the key inside the plotting region and attempts to choose the least crowded corner. The default is **POS=BOTTOM**.

**MARKERS=ANALYSIS | COMPUTED | NICE | NONE**

specifies the locations for plotting symbols.

The **MARKERS=ANALYSIS** option places plotting symbols at locations corresponding to the values of the relevant input parameter from the **POWER** statement preceding the **PLOT** statement.

The **MARKERS=COMPUTED** option (the default) places plotting symbols at the locations of actual computed points from the sample size analysis.

The **MARKERS=NICE** option places plotting symbols at tick mark locations (corresponding to the argument axis).

The **MARKERS=NONE** option disables plotting symbols.

**MAX=number | DATAMAX**

specifies the maximum of the range of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). The default is **DATAMAX**, which specifies the maximum value that occurs for this parameter in the **POWER** statement that precedes the **PLOT** statement.

**MIN=number | DATAMIN**

specifies the minimum of the range of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). The default is **DATAMIN**, which specifies the minimum value that occurs for this parameter in the **POWER** statement that precedes the **PLOT** statement.

**NPOINTS=number****NPTS=number**

specifies the number of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). You cannot use the **NPOINTS=** and **STEP=** options simultaneously. The default value for typical situations is 20.

**STEP=number**

specifies the increment between values of the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). You cannot use the **STEP=** and **NPOINTS=** options simultaneously. By default, the **NPOINTS=** option is used instead of the **STEP=** option.

**VARY ( feature <BY parameter-list> <, ..., feature <BY parameter-list> > )**

specifies how plot features should be linked to varying analysis parameters. Available *features* are **COLOR**, **LINESTYLE**, **PANEL**, and **SYMBOL**. A “panel” refers to a separate plot with a heading identifying the subset of values represented in the plot.

The *parameter-list* is a list of one or more names separated by spaces. Each name must match the name of an analysis option used in the **POWER** statement preceding the **PLOT** statement, *or* one of the following keywords: **SOURCE** (for the tests) and **DEPENDENT** (for the cell means scenarios). Also, the name must be the *primary* name for the analysis option—that is, the one listed first in the syntax description.

If you omit the < **BY parameter-list** > portion for a feature, then one or more multivalued parameters from the analysis will be automatically selected for you.

**X=N | POWER**

specifies a plot with the requested type of parameter on the X axis and the parameter being solved for on the Y axis. When **X=N**, sample size is assigned to the X axis. When **X=POWER**, power is assigned to the X axis. You cannot use the **X=** and **Y=** options simultaneously. The default is **X=POWER**, unless the result parameter is power, in which case the default is **X=N**.

**XOPTS= ( *x-options* )**

specifies plot characteristics pertaining to the X axis.

You can specify the following *x-options* in parentheses.

**CROSSREF=NO | YES**

specifies whether the reference lines defined by the **REF=** *x-option* should be crossed with a reference line on the Y axis that indicates the solution point on the curve.

**REF=number-list**

specifies locations for reference lines extending from the X axis across the entire plotting region. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 2658 for information about specifying the *number-list*.

**Y=N | POWER**

specifies a plot with the requested type of parameter on the Y axis and the parameter being solved for on the X axis. When **Y=N**, sample size is assigned to the Y axis. When **Y=POWER**, power is assigned to the Y axis. You cannot use the **Y=** and **X=** options simultaneously. By default, the **X=** option is used instead of the **Y=** option.

**YOPTS= ( *y-options* )**

specifies plot characteristics pertaining to the Y axis.

You can specify the following *y-options* in parentheses.

**CROSSREF=NO | YES**

specifies whether the reference lines defined by the **REF=** *y-option* should be crossed with a reference line on the X axis that indicates the solution point on the curve.

**REF=number-list**

specifies locations for reference lines extending from the Y axis across the entire plotting region. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 2658 for information about specifying the *number-list*.

You can specify the following *graph-options* in the **PLOT** statement after a slash (/).

**DESCRIPTION='string'**

specifies a descriptive string of up to 40 characters that appears in the “Description” field of the graphics catalog. The description does not appear on the plots. By default, PROC GLMPOWER assigns a description either of the form “Y versus X” (for a single-panel plot) or of the form “Y versus X (S),” where Y is the parameter on the Y axis, X is the parameter on the X axis, and S is a description of the subset represented on the current panel of a multipanel plot.

**NAME=***'string'*

specifies a name of up to eight characters for the catalog entry for the plot. The default name is PLOT $n$ , where  $n$  is the number of the plot statement within the current invocation of PROC GLMPOWER. If the name duplicates the name of an existing entry, SAS/GRAPH software adds a number to the duplicate name to create a unique entry—for example, PLOT11 and PLOT12 for the second and third panels of a multipanel plot generated in the first **PLOT** statement in an invocation of PROC GLMPOWER.

## POWER Statement

**POWER** <options> ;

The **POWER** statement performs power and sample size analyses for the Type III test of each effect in the model defined by the **MODEL** statements and for the contrasts defined by all **CONTRAST** statements. The **MODEL** statement must appear before the **POWER** statement if the **EFFECTS** option is used in the **POWER** statement.

## Summary of Options

Table 41.4 summarizes categories of options available in the **POWER** statement.

**Table 41.4** Summary of Options in the POWER Statement

Task	Options
Specify effects	<b>EFFECTS=</b>
Specify significance level	<b>ALPHA=</b>
Specify covariates	<b>CORRXY=</b> <b>NCOVARIATES=</b> <b>PROPVARREDUCTION=</b>
Specify error standard deviation	<b>STDDEV=</b>
Specify sample size	<b>NTOTAL=</b>
Specify power	<b>POWER=</b>
Control sample size rounding	<b>NFRACTIONAL</b>
Control ordering in output	<b>OUTPUTORDER=</b> <b>DEPENDENT</b>

Table 41.5 summarizes the valid result parameters.

**Table 41.5** Summary of Result Parameters in the POWER Statement

Solve for	Syntax
Power	<b>POWER = .</b>
Sample size	<b>NTOTAL = .</b>

## Dictionary of Options

### **ALPHA=***number-list*

specifies the level of significance of each test. The default is 0.05, corresponding to the usual  $0.05 \times 100\% = 5\%$  level of significance. Note that this is a test-wise significance level with the same value for all tests, not incorporating any corrections for multiple testing. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 2658 for information about specifying the *number-list*.

### **CORRXY=***number-list*

specifies the multiple correlation ( $\rho$ ) between all covariates and the response. The error standard deviation given by the **STDDEV=** option is consequently reduced by multiplying it by a factor of  $(1 - \rho^2)^{\frac{1}{2}}$ , provided that the number of covariates (as determined by the **NCOVARIATES=** option) is greater than zero. You cannot use the **CORRXY=** and the **PROPVARREDUCTION=** options simultaneously. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 2658 for information about specifying the *number-list*.

### **DEPENDENT**

specifies the location of the Dependent column in the output when the **OUTPUTORDER=REVERSE** option or **OUTPUTORDER=SYNTAX** option is used, according to its relative position in the **POWER** statement.

### **EFFECTS** <= <( **effect** ... **effect** ) >>

specifies the model effects to include in the power analysis. By default, or if the **EFFECTS** keyword is specified without the equal sign (=), all model effects are included. Specify **EFFECTS=()** to exclude all model effect tests from the power analysis. You can include main effects and interactions by using the effects notation of PROC GLM; see the section “[Specification of Effects](#)” on page 2486 in Chapter 39, “[The GLM Procedure](#)” for further details. The **MODEL** statement must appear before the **POWER** statement if the **EFFECTS** option is used.

### **NCOVARIATES=***number-list*

### **NCOVARIATE=***number-list*

### **NCOV=***number-list*

### **NCOV=***number-list*

specifies the number of additional degrees of freedom to accommodate covariate effects—both class and continuous—not listed in the **MODEL** statement. The error degrees of freedom are consequently reduced by the value of the **NCOVARIATES=** option, and the error standard deviation (whose unadjusted value is provided with the **STDDEV=** option) is reduced according to the value of the **CORRXY=** or **PROPVARREDUCTION=** option. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 2658 for information about specifying the *number-list*.

### **NFRACTIONAL**

### **NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 2659 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

**NTOTAL=number-list**

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). Values for the sample size must be no smaller than the model degrees of freedom (counting the covariates). See the section “[Specifying Value Lists in the POWER Statement](#)” on page 2658 for information about specifying the *number-list*.

**OUTPUTORDER=INTERNAL | REVERSE | SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **DEPENDENT**
- **EFFECTS=**
- weight variable (from the **WEIGHT** statement)
- **ALPHA=**
- **NCOVARIATES=**
- **CORRXY=**
- **PROPVARREDUCTION=**
- **STDDEV=**
- **NTOTAL=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **POWER** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **POWER** statement.

**POWER=number-list**

specifies the desired power of each test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability (for example, 0.9) rather than a percentage. Note that this is a test-wise power with the same value for all tests, without any correction for multiple testing. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 2658 for information about specifying the *number-list*.

**PROPVARREDUCTION=number-list****PVRED=number-list**

specifies the proportional reduction ( $r$ ) in total  $R^2$  incurred by the covariates—in other words, the amount of additional variation explained by the covariates. The error standard deviation given by the **STDDEV=** option is consequently reduced by multiplying it by a factor of  $(1 - r)^{\frac{1}{2}}$ , provided that the number of covariates (as determined by the **NCOVARIATES=** option) is greater than zero. You cannot use the **PROPVARREDUCTION=** and the **CORRXY=** options simultaneously. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 2658 for information about specifying the *number-list*.

**STDDEV=number-list**

specifies the error standard deviation, or root MSE. If covariates are specified using the

**NCOVARIATES=** option, then the **STDDEV=** option denotes the error standard deviation before accounting for these covariates. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 2658 for information about specifying the *number-list*.

## Restrictions on Option Combinations

For the relationship between covariates and response, specify either the multiple correlation (by using the **CORRXY=** option) or the proportional reduction in total  $R^2$  (by using the **PROPVARREDUCTION=** option).

---

## WEIGHT Statement

**WEIGHT** *variable* ;

The **WEIGHT** statement names a variable that provides a profile weight (“cell weight”) for each observation in the exemplary data set specified by the **DATA=** option in the **PROC GLMPOWER** statement.

If the **WEIGHT** statement is not used, then a balanced design is assumed with default cell weights of 1.

---

## Details: GLMPOWER Procedure

---

### Specifying Value Lists in the POWER Statement

To specify one or more scenarios for an analysis parameter (or set of parameters) in the **POWER** statement, you provide a list of values for the option that corresponds to the parameter(s). To identify the parameter you want to solve for, you place a missing value in the appropriate list.

Scenarios for scalar-valued parameters, such as power, are represented by a *number-list*.

### Number-Lists

A *number-list* can be one of two things: a series of one or more numbers expressed in the form of one or more DOLISTs, or a missing value indicator ( . ).

The DOLIST format is the same as in the DATA step. For example, you can specify four scenarios (30, 50, 70, and 100) for a total sample size in either of the following ways:

```
NTOTAL = 30 50 70 100
NTOTAL = 30 to 70 by 20 100
```

A missing value identifies a parameter as the result parameter; it is valid only with options representing parameters you can solve for in a given analysis. For example, you can request a solution for `NTOTAL`:

```
NTOTAL = .
```

---

## Sample Size Adjustment Options

By default, PROC GLMPOWER rounds sample sizes conservatively (down in the input, up in the output) so that all total sizes *and* sample sizes for individual design profiles are integers. This is generally considered conservative because it selects the closest realistic design providing *at most* the power of the (possibly fractional) input or mathematically optimized design. In addition, all design profile sizes are adjusted to be multiples of their corresponding weights. If a design profile is present more than once in the exemplary data set, then the weights for that design profile are summed. For example, if a particular design profile is present twice in the exemplary data set with weight values 2 and 6, then all sample sizes for this design profile become multiples of  $2 + 6 = 8$ .

With the `NFRACTIONAL` option, sample size input is not rounded, and sample size output is reported in two versions, a raw “fractional” version and a “ceiling” version rounded up to the nearest integer.

Whenever an input sample size is adjusted, both the original (“nominal”) and adjusted (“actual”) sample sizes are reported. Whenever computed output sample sizes are adjusted, both the original input (“nominal”) power and the achieved (“actual”) power at the adjusted sample size are reported.

---

## Error and Information Output

The Error column in the main output table explains reasons for missing results and flags numerical results that are bounds rather than exact answers.

The Info column provides further information about Error entries, warnings about any boundary conditions detected, and notes about any adjustments to input. Note that the Info column is hidden by default in the main output. You can view it by using the ODS OUTPUT statement to save the output as a data set and the PRINT procedure. For example, the following SAS statements print both the Error and Info columns for a power computation in a one-way ANOVA:

```
data MyExemp;
  input A $ Y1 Y2;
  datalines;
    1   10 11
    2   12 11
    3   15 11
  ;
run;
```

```

proc glmpower data=MyExemp;
  class A;
  model Y1 Y2 = A;
  power
    stddev = 2
    ntotal = 3 10
    power = .;
  ods output output=Power;
run;

proc print noobs data=Power;
  var NominalNTotal NTotal Dependent Power Error Info;
run;

```

The output is shown in [Figure 41.5](#).

**Figure 41.5** Error and Information Columns

Nominal NTotal	NTotal	Dependent	Power	Error	Info
3	3	Y1	.	Invalid input	Error DF=0
10	9	Y1	0.557		Input N adjusted
3	3	Y2	.	Invalid input	Error DF=0 / No effect
10	9	Y2	0.050		Input N adjusted / No effect

The sample size of 3 specified with the **NTOTAL=** option causes an “Invalid input” message in the Error column and an “Error DF=0” message in the Info column, because a sample size of 3 is so small that there are no degrees of freedom left for the error term. The sample size of 10 causes an “Input N adjusted” message in the Info column, because it is rounded down to 9 to produce integer group sizes of 3 per cell. The cell means scenario represented by the dependent variable Y2 causes a “No effect” message to appear in the Info column, because the means in this scenario are all equal.

## Displayed Output

If you use the **PLOTONLY** option in the **PROC GLMPOWER** statement, the procedure displays only graphical output. Otherwise, the displayed output of the GLMPOWER procedure includes the following:

- the “Fixed Scenario Elements” table, which shows all applicable single-valued analysis parameters, in the following order: the dependent variable representing the cell means, the source of the test, the weight variable, parameters input explicitly, parameters supplied with defaults, and ancillary results

- an output table showing the following when applicable (in order): the index of the scenario, the dependent variable representing the cell means, the type of the test, the source of the test, all multivalued input, ancillary results, the primary computed result, and error descriptions
- plots (if requested)

The exception to these ordering conventions is that the **DEPENDENT** and **EFFECTS** options may be used along with the **OUTPUTORDER=SYNTAX** or **OUTPUTORDER=REVERSE** option in the **POWER** statement to specify the relative location of the output for dependent variable and type and source of test.

Ancillary results include the following:

- Actual Power, the achieved power, if it differs from the input (Nominal) power value
- fractional sample size, if the **NFRACTIONAL** option is used in the **POWER** statement

If sample size is the result parameter and the **NFRACTIONAL** option is used in the **POWER** statement, then both “Fractional” and “Ceiling” sample size results are displayed. Fractional sample sizes correspond to the “Nominal” values of power. Ceiling sample sizes are simply the fractional sample sizes rounded up to the nearest integer; they correspond to “Actual” values of power.

The noncentrality parameter is computed and stored in a hidden column called Noncentrality in the “Output” table.

## ODS Table Names

PROC GLMPOWER assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 41.6](#). For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 41.6** ODS Tables Produced by PROC GLMPOWER

ODS Table Name	Description	Statement
FixedElements	factoid with single-valued analysis parameters	default
Output	all input and computed analysis parameters, error messages, and information messages for each scenario	default
PlotContent	data contained in plots, including analysis parameters and indices identifying plot features. ( <b>NOTE:</b> This table is saved as a data set and not displayed in PROC GLMPOWER output.)	<b>PLOT</b>

The ODS pathnames are created as follows:

- Glmpower.Power<  $n$  >.FixedElements
- Glmpower.Power<  $n$  >.Output
- Glmpower.Power<  $n$  >.PlotContent
- Glmpower.Power<  $n$  >.Plot<  $m$  >

where

- the Plot<  $m$  > objects are the graphs.
- the <  $n$  > indexing the [POWER](#) statement is used only if there is more than one instance.
- the <  $n$  > indexing the plots increases with every panel in every plot statement, resetting to 1 only at new analysis statements.

---

## Computational Methods and Formulas

This section describes the approaches used in PROC GLMPOWER to compute power and sample size.

### Contrasts in Fixed-Effect Univariate Models

The univariate linear model has the form

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where  $\mathbf{y}$  is the  $N \times 1$  vector of responses,  $\mathbf{X}$  is the  $N \times p$  design matrix,  $\boldsymbol{\beta}$  is the  $p \times 1$  vector of model parameters corresponding to the columns of  $\mathbf{X}$ , and  $\boldsymbol{\epsilon}$  is an  $N \times 1$  vector of errors with

$$\epsilon_1, \dots, \epsilon_N \sim N(0, \sigma^2) \quad (\text{i.i.d.})$$

In PROC GLMPOWER, the model parameters  $\boldsymbol{\beta}$  are not specified directly, but rather indirectly as  $\mathbf{y}^*$ , which represents either conjectured response means or typical response values for each design profile. The  $\mathbf{y}^*$  values are manifested as the dependent variable in the [MODEL](#) statement. The vector  $\boldsymbol{\beta}$  is obtained from  $\mathbf{y}^*$  according to the least squares equation,

$$\boldsymbol{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}^*$$

Note that, in general, there is not a 1-to-1 mapping between  $\mathbf{y}^*$  and  $\boldsymbol{\beta}$ . Many different scenarios for  $\mathbf{y}^*$  might lead to the same  $\boldsymbol{\beta}$ . If you specify  $\mathbf{y}^*$  with the intention of representing cell means, keep in mind that PROC GLMPOWER allows scenarios that are *not* valid cell means according to the model specified in the [MODEL](#) statement. For example, if  $\mathbf{y}^*$  exhibits an interaction effect but the corresponding interaction term is left out of the model, then the cell means ( $\mathbf{X}\boldsymbol{\beta}$ ) derived from

$\beta$  differ from  $\mathbf{y}^*$ . In particular, the cell means thus derived are the projection of  $\mathbf{y}^*$  onto the model space.

It is convenient in power analysis to parameterize the design matrix  $\mathbf{X}$  in three parts,  $\{\ddot{\mathbf{X}}, \mathbf{w}, N\}$ , defined as follows:

1. The  $q \times p$  essence design matrix  $\ddot{\mathbf{X}}$  is the collection of unique rows of  $\mathbf{X}$ . Its rows are sometimes referred to as “design profiles.” Here,  $q \leq N$  is defined simply as the number of unique rows of  $\mathbf{X}$ .
2. The  $q \times 1$  weight vector  $\mathbf{w}$  reveals the relative proportions of design profiles. Row  $i$  of  $\ddot{\mathbf{X}}$  is to be included in the design  $w_i$  times for every  $w_j$  times row  $j$  is included. The weights are assumed to be standardized (that is, sum up to 1).
3. The total sample size is  $N$ . This is the number of rows in  $\mathbf{X}$ . If you gather  $Nw_i = n_i$  copies of the  $i$ th row of  $\ddot{\mathbf{X}}$ , for  $i = 1, \dots, q$ , then you end up with  $\mathbf{X}$ .

It is useful to express the crossproduct matrix  $\mathbf{X}'\mathbf{X}$  in terms of these three parts,

$$\mathbf{X}'\mathbf{X} = N\ddot{\mathbf{X}}'\text{diag}(\mathbf{w})\ddot{\mathbf{X}}$$

since this factors out the portion ( $N$ ) depending on sample size and the portion ( $\ddot{\mathbf{X}}'\text{diag}(\mathbf{w})\ddot{\mathbf{X}}$ ) depending only on the design structure.

A general linear hypothesis for the univariate model has the form

$$H_0: \mathbf{L}\beta = \theta_0$$

$$H_A: \mathbf{L}\beta \neq \theta_0$$

where  $\mathbf{L}$  is an  $r_L \times p$  contrast matrix (assumed to be full rank) and  $\theta_0$  is the null value (usually just a vector of zeros). Note that effect tests are just contrasts that use special forms of  $\mathbf{L}$ . Thus, this scheme covers both effect tests and custom contrasts.

The test statistic is

$$F = \frac{\left( \frac{SS_H}{r_L} \right)}{\hat{\sigma}^2}$$

where

$$SS_H = \frac{1}{N} (\mathbf{L}\hat{\beta} - \theta_0)' (\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1} (\mathbf{L}\hat{\beta} - \theta_0)$$

$$\hat{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}$$

$$\hat{\sigma}^2 = \frac{1}{DF_E} (\mathbf{y} - \mathbf{X}\hat{\beta})' (\mathbf{y} - \mathbf{X}\hat{\beta})$$

where  $DF_E = N - \text{rank}(\mathbf{X})$ . Note that  $DF_E = N - p$  if  $\mathbf{X}$  has full rank.

Under  $H_0$ ,  $F \sim F(r_L, DF_E)$ . Under  $H_A$ ,  $F$  is distributed as  $F(r_L, DF_E, \lambda)$  with noncentrality

$$\lambda = N (\mathbf{L}\beta - \theta_0)' \left( \mathbf{L} (\ddot{\mathbf{X}}'\text{diag}(\mathbf{w})\ddot{\mathbf{X}})^{-1} \mathbf{L}' \right)^{-1} (\mathbf{L}\beta - \theta_0) \sigma^{-2}$$

Muller and Peterson (1984) give the exact power of the test as

$$\text{power} = P(F(r_L, DF_E, \lambda) \geq F_{1-\alpha}(r_L, DF_E))$$

Sample size is computed by inverting the power equation.

See Muller et al. (1992) and O'Brien and Shieh (1992) for additional discussion.

## Adjustments for Covariates

If you specify covariates in the model (whether continuous or categorical), then two adjustments are made in order to compute approximate power in the presence of the covariates. Let  $n_v$  denote the number of covariates (counting dummy variables for categorical covariates individually). In other words,  $n_v$  is the total degrees of freedom used by the covariates. The adjustments are as follows:

1. The error degrees of freedom decrease by  $n_v$ .
2. The error standard deviation  $\sigma$  shrinks by a factor of  $(1 - \rho^2)^{\frac{1}{2}}$  (if the **CORRXY=** option to specify the correlation  $\rho$  between covariates and response) or  $(1 - r)^{\frac{1}{2}}$  (if the **PROPVARREDUCTION=** option is used to specify the proportional reduction in total  $R^2$  incurred by the covariates). Let  $\sigma^*$  represent the updated value of  $\sigma$ .

As a result of these changes, the power is computed as

$$\text{power} = P(F(r_L, DF_E - n_v, \lambda^*) \geq F_{1-\alpha}(r_L, N - r_x - n_v))$$

where  $\lambda^*$  is calculated using  $\sigma^*$  rather than  $\sigma$ :

$$\lambda^* = N (\mathbf{L}\boldsymbol{\beta} - \boldsymbol{\theta}_0)' \left( \mathbf{L} \left( \ddot{\mathbf{X}}' \text{diag}(\mathbf{w}) \ddot{\mathbf{X}} \right)^{-1} \mathbf{L}' \right)^{-1} (\mathbf{L}\boldsymbol{\beta} - \boldsymbol{\theta}_0) (\sigma^*)^{-2}$$

---

## Examples: GLMPOWER Procedure

---

### Example 41.1: One-Way ANOVA

This example deals with the same situation as in [Example 67.1](#) in Chapter 67, “The POWER Procedure.”

Hocking (1985, p. 109) describes a study of the effectiveness of electrolytes in reducing lactic acid buildup for long-distance runners. You are planning a similar study in which you will allocate five different fluids to runners on a 10-mile course and measure lactic acid buildup immediately after the race. The fluids consist of water and two commercial electrolyte drinks, EZDure and LactoZap, each prepared at two concentrations, low (EZD1 and LZ1) and high (EZD2 and LZ2).

You conjecture that the standard deviation of lactic acid measurements given any particular fluid is about 3.75, and that the expected lactic acid values will correspond roughly to [Table 41.7](#). You are least familiar with the LZ1 drink and hence decide to consider a range of reasonable values for that mean.

**Table 41.7** Mean Lactic Acid Buildup by Fluid

Water	EZD1	EZD2	LZ1	LZ2
35.6	33.7	30.2	29 or 28	25.9

You are interested in four different comparisons, shown in [Table 41.8](#) with appropriate contrast coefficients.

**Table 41.8** Planned Comparisons

Comparison	Contrast Coefficients				
	Water	EZD1	EZD2	LZ1	LZ2
Water versus electrolytes	4	-1	-1	-1	-1
EZD versus LZ	0	1	1	-1	-1
EZD1 versus EZD2	0	1	-1	0	0
LZ1 versus LZ2	0	0	0	1	-1

For each of these contrasts you want to determine the sample size required to achieve a power of 0.9 for detecting an effect with magnitude in accord with [Table 41.7](#). You are not yet attempting to choose a single sample size for the study, but rather checking the range of sample sizes needed for individual contrasts. You plan to test each contrast at  $\alpha = 0.025$ . In the interests of reducing costs, you will provide twice as many runners with water as with any of the electrolytes; that is, you will use a sample size weighting scheme of 2:1:1:1:1.

Before calling PROC GLMPOWER, you need to create the *exemplary data set* to specify means and weights for the design profiles:

```
data Fluids;
  input Fluid $ LacticAcid1 LacticAcid2 CellWgt;
  datalines;
    Water      35.6      35.6      2
    EZD1       33.7      33.7      1
    EZD2       30.2      30.2      1
    LZ1        29       28       1
    LZ2        25.9     25.9      1
  ;
run;
```

The variable LacticAcid1 represents the cell means scenario with the larger LZ1 mean (29), and LacticAcid2 represents the scenario with the smaller LZ1 mean (28). The variable CellWgt contains the sample size allocation weights.

Use the **DATA=** option in the **PROC GLMPOWER** statement to specify Fluids as the exemplary data set. The following statements perform the sample size analysis:

```

proc glmpower data=Fluids;
  class Fluid;
  model LacticAcid1 LacticAcid2 = Fluid;
  weight CellWgt;
  contrast "Water vs. others" Fluid  -1 -1 -1 -1 4;
  contrast "EZD vs. LZ"          Fluid  1  1 -1 -1 0;
  contrast "EZD1 vs. EZD2"       Fluid  1 -1  0  0 0;
  contrast "LZ1 vs. LZ2"         Fluid  0  0  1 -1 0;
  power
    stddev = 3.75
    alpha  = 0.025
    ntotal = .
    power  = 0.9;
run;

```

The **CLASS** statement identifies Fluid as a classification variable. The **MODEL** statement specifies the model and the two cell means scenarios LacticAcid1 and LacticAcid2. The **WEIGHT** statement identifies CellWgt as the weight variable. The **CONTRAST** statement specifies the contrasts. Since PROC GLMPOWER by default processes class levels in order of formatted values, the contrast coefficients correspond to the following order: EZD1, EZD2, LZ1, LZ2, Water. (**NOTE:** You could use the **ORDER=DATA** option in the **PROC GLMPOWER** statement to achieve the same ordering as in Table 41.8 instead.) The **POWER** statement specifies total sample size as the result parameter and provides values for the other analysis parameters (error standard deviation, alpha, and power).

Output 41.1.1 displays the results.

**Output 41.1.1** Sample Sizes for One-Way ANOVA Contrasts

The GLMPOWER Procedure							
Fixed Scenario Elements							
Weight Variable				CellWgt			
Alpha				0.025			
Error Standard Deviation				3.75			
Nominal Power				0.9			
Computed N Total							
Index	Dependent	Type	Source	Test DF	Error DF	Actual Power	N Total
1	LacticAcid1	Effect	Fluid	4	25	0.958	30
2	LacticAcid1	Contrast	Water vs. others	1	25	0.947	30
3	LacticAcid1	Contrast	EZD vs. LZ	1	55	0.929	60
4	LacticAcid1	Contrast	EZD1 vs. EZD2	1	169	0.901	174
5	LacticAcid1	Contrast	LZ1 vs. LZ2	1	217	0.902	222
6	LacticAcid2	Effect	Fluid	4	25	0.972	30
7	LacticAcid2	Contrast	Water vs. others	1	19	0.901	24
8	LacticAcid2	Contrast	EZD vs. LZ	1	43	0.922	48
9	LacticAcid2	Contrast	EZD1 vs. EZD2	1	169	0.901	174
10	LacticAcid2	Contrast	LZ1 vs. LZ2	1	475	0.902	480

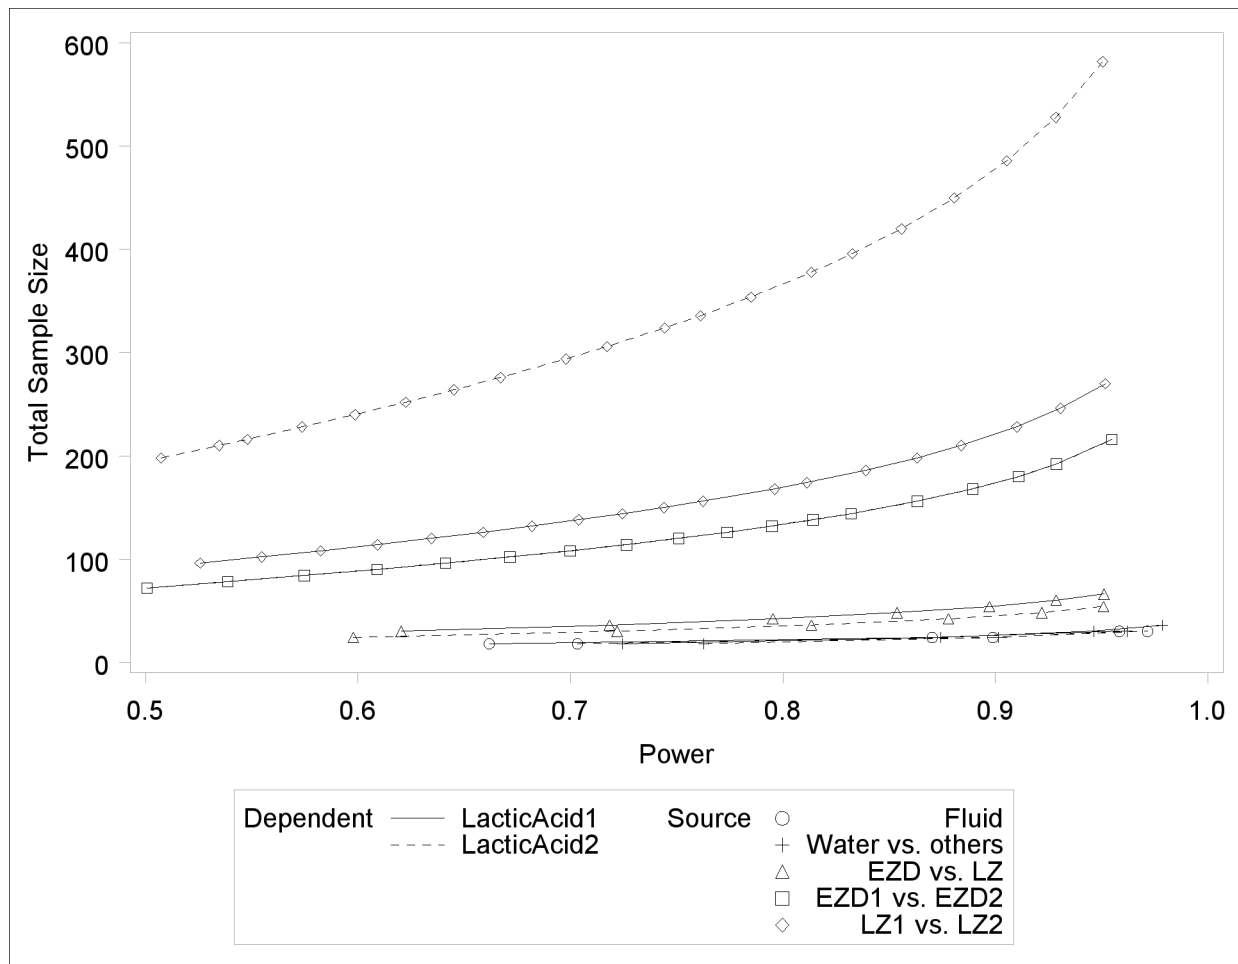

The sample sizes range from 24 for the comparison of water versus electrolytes to 480 for the comparison of LZ1 versus LZ2, both assuming the smaller LZ1 mean. The sample size for the latter comparison is relatively large because the small mean difference of  $28 - 25.9 = 2.1$  is hard to detect. PROC GLMPower also includes the effect test for Fluid. Note that, in this case, it is equivalent to TEST=OVERALL\_F in the ONEWAYANOVA statement of PROC POWER, since there is only one effect in the model.

The Nominal Power of 0.9 in the “Fixed Scenario Elements” table in [Output 41.1.1](#) represents the input target power, and the Actual Power column in the “Computed N Total” table is the power at the sample size (N Total) adjusted to achieve the specified sample weighting. Note that all of the sample sizes are rounded up to multiples of 6 to preserve integer group sizes (since the group weights add up to 6). You can use the NFRACtIONAL option in the POWER statement to compute raw fractional sample sizes.

Suppose you want to plot the required sample size for the range of power values from 0.5 to 0.95. First, define the analysis by specifying the same statements as before, but add the PLOTONLY option to the PROC GLMPower statement to disable the nongraphical results. Next, specify the PLOT statement with X=POWER to request a plot with power on the X axis. (The result parameter—here sample size—is always plotted on the other axis.) Use the MIN= and MAX= options in the PLOT statement to specify the power range. The following statements produce the plot:

```
proc glmpower data=Fluids plotonly;
  class Fluid;
  model LacticAcid1 LacticAcid2 = Fluid;
  weight CellWgt;
  contrast "Water vs. others" Fluid  -1 -1 -1 -1 4;
  contrast "EZD vs. LZ"      Fluid   1  1 -1 -1 0;
  contrast "EZD1 vs. EZD2"   Fluid   1 -1  0  0 0;
  contrast "LZ1 vs. LZ2"     Fluid    0  0  1 -1 0;
  power
    stddev = 3.75
    alpha  = 0.025
    ntotal = .
    power  = 0.9;
  plot x=power min=.5 max=.95;
run;
```

See [Output 41.1.2](#) for the resulting plot.

**Output 41.1.2** Plot of Sample Size versus Power for One-Way ANOVA Contrasts

In [Output 41.1.2](#), the line style identifies the cell means scenario, and the plotting symbol identifies the test. The plotting symbol locations identify actual computed powers; the curves are linear interpolations of these points. The plot shows that the required sample size is highest for the test of LZ1 versus LZ2, which was previously found to require the most resources.

Note that some of the plotted points in [Output 41.1.2](#) are unevenly spaced. This is because the plotted points are the *rounded* sample size results at their corresponding *actual* power levels. The range specified with the [MIN=](#) and [MAX=](#) values in the [PLOT](#) statement corresponds to *nominal* power levels. In some cases, actual power is substantially higher than nominal power. To obtain plots with evenly spaced points (but with *fractional* sample sizes at the computed points), you can use the [NFRACTIONAL](#) option in the [POWER](#) statement preceding the [PLOT](#) statement.

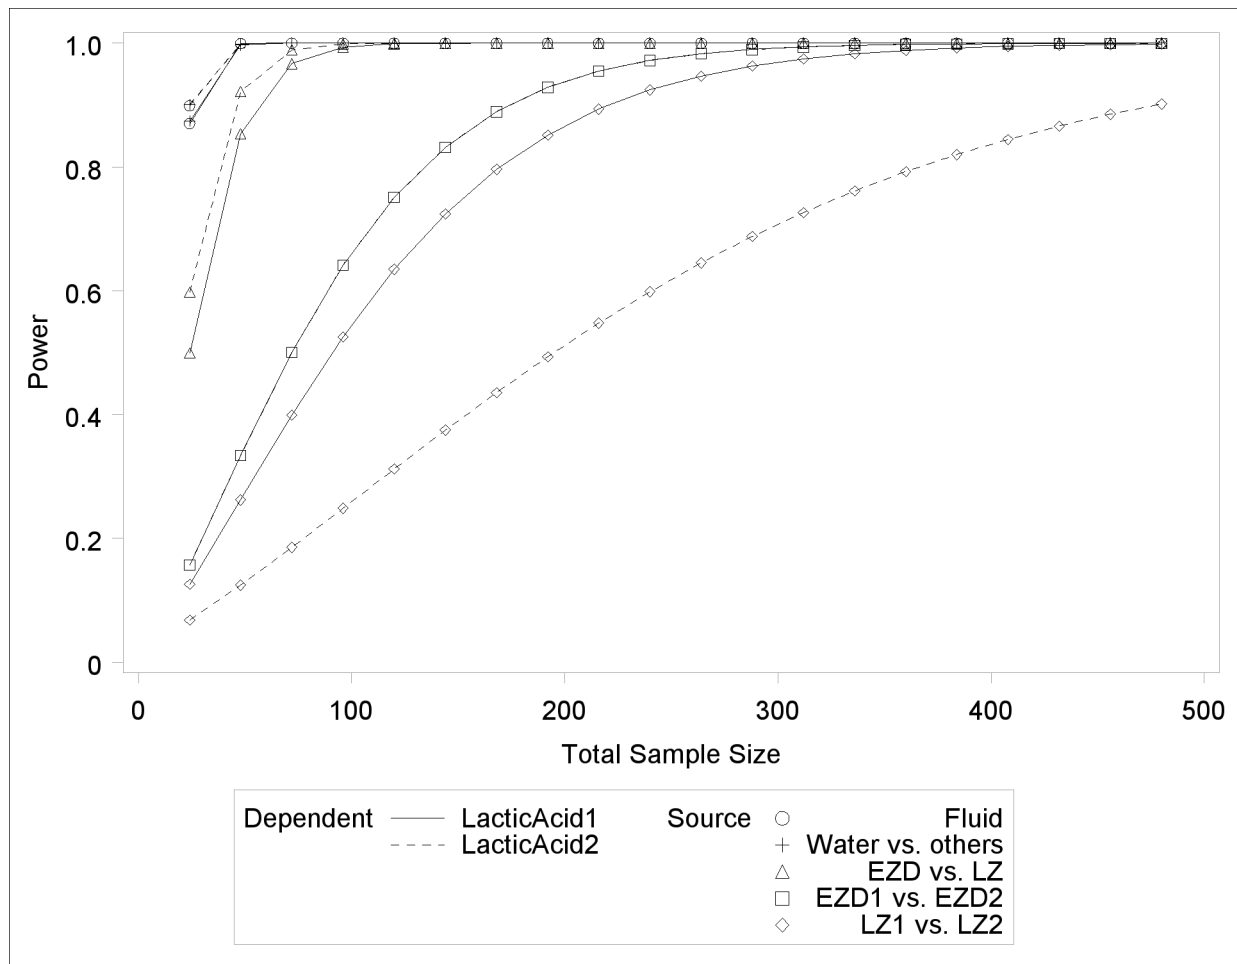

Finally, suppose you want to plot the power for the range of sample sizes you will likely consider for the study (the range of 24 to 480 that achieves 0.9 power for different comparisons). In the [POWER](#) statement, identify power as the result ([POWER=.](#)), and specify any total sample size value (say, [NTOTAL=100](#)). Specify the [PLOT](#) statement with [X=N](#) to request a plot with sample size on the X axis.

The following statements produce the plot:

```
proc glmpower data=Fluids plotonly;
  class Fluid;
  model LacticAcid1 LacticAcid2 = Fluid;
  weight CellWgt;
  contrast "Water vs. others" Fluid  -1 -1 -1 -1 4;
  contrast "EZD vs. LZ"          Fluid  1  1 -1 -1 0;
  contrast "EZD1 vs. EZD2"       Fluid  1 -1  0  0 0;
  contrast "LZ1 vs. LZ2"         Fluid  0  0  1 -1 0;
  power
    stddev = 3.75
    alpha  = 0.025
    ntotal = 24
    power  = .;
  plot x=n min=24 max=480;
run;
```

Note that the value 100 specified with the `NTOTAL=100` option is not used. It is overridden in the plot by the `MIN=` and `MAX=` options in the `PLOT` statement, and the `PLOTONLY` option in the `PROC GLMPower` statement disables nongraphical results. But the `NTOTAL=` option (along with a value) is still needed in the `POWER` statement as a placeholder, to identify the desired parameterization for sample size.

See [Output 41.1.3](#) for the plot.

**Output 41.1.3** Plot of Power versus Sample Size for One-Way ANOVA Contrasts

Although [Output 41.1.2](#) and [Output 41.1.3](#) surface essentially the same computations for practical power ranges, they each provide a different quick visual assessment. [Output 41.1.2](#) reveals the range of required sample sizes for powers of interest, and [Output 41.1.3](#) reveals the range of achieved powers for sample sizes of interest.

## Example 41.2: Two-Way ANOVA with Covariate

Suppose you can enhance the planned study discussed in [Example 41.1](#) in two ways:

- incorporate results from races at two different altitudes (“high” and “low”)
- measure the body mass index of each runner before the race

This is equivalent to adding a second fixed effect and a continuous covariate to your model.

Since lactic acid buildup is more pronounced at higher altitudes, you will include altitude as a factor in the model along with fluid, extending the one-way ANOVA to a two-way ANOVA. In

doing so, you expect to lower the residual standard deviation from about 3.75 to 3.5 (in addition to generalizing the study results). You assume there is negligible interaction between fluid and altitude and plan to use a main-effects-only model. You conjecture that the mean lactic acid buildup follows Table 41.9.

**Table 41.9** Mean Lactic Acid Buildup by Fluid and Altitude

Altitude	Fluid				
	Water	EZD1	EZD2	LZ1	LZ2
High	36.9	35.0	31.5	30	27.1
Low	34.3	32.4	28.9	27	24.7

By including a measurement of body mass index as a covariate in the study, you hope to further reduce the error variability. The extent of this reduction in variability is commonly expressed in two alternative ways: (1) the correlation between the covariates and the response or (2) the proportional reduction in total  $R^2$  incurred by the covariates. You prefer the former and guess that the correlation between body mass index and lactic acid buildup is between 0.2 and 0.3. You specify these estimates with the `NCOVARIATES=` and `CORRXY=` options in the `POWER` statement. The covariate is not included in the `MODEL` statement.

You are interested in the same four fluid comparisons as in Example 41.1, shown in Table 41.8, except this time you want to marginalize over the effect of altitude.

For each of these contrasts, you want to determine the sample size required to achieve a power of 0.9 to detect an effect with magnitude according to Table 41.9. You are not yet attempting to choose a single sample size for the study, but rather checking the range of sample sizes needed by individual contrasts. You plan to test each contrast at  $\alpha = 0.025$ . You will provide twice as many runners with water as with any of the electrolytes, and you predict that you can study approximately two-thirds as many runners at high altitude than at low altitude. The resulting planned sample size weighting scheme is shown in Table 41.10. Since the scheme is only approximate, you use the `NFRACTIONAL` option in the `POWER` statement to disable the rounding of sample sizes up to integers satisfying the weights exactly.

**Table 41.10** Approximate Sample Size Allocation Weights

Altitude	Fluid				
	Water	EZD1	EZD2	LZ1	LZ2
High	4	2	2	2	2
Low	6	3	3	3	3

First, you create the exemplary data set to specify means and weights for the design profiles:

```
data Fluids2;
  input Altitude $ Fluid $ LacticAcid CellWgt;
  datalines;
    High      Water      36.9      4
    High      EZD1       35.0      2
    High      EZD2       31.5      2
    High      LZ1        30        2
    High      LZ2        27.1      2
    Low       Water      34.3      6
    Low       EZD1       32.4      3
    Low       EZD2       28.9      3
    Low       LZ1        27        3
    Low       LZ2        24.7      3
  ;
run;
```

The variables Altitude, Fluid, and LacticAcid specify the factors and cell means in [Table 41.9](#). The variable CellWgt contains the sample size allocation weights in [Table 41.10](#).

Use the **DATA=** option in the **PROC GLMPOWER** statement to specify Fluids2 as the exemplary data set. The following statements perform the sample size analysis:

```
proc glmpower data=Fluids2;
  class Altitude Fluid;
  model LacticAcid = Altitude Fluid;
  weight CellWgt;
  contrast "Water vs. others" Fluid  -1 -1 -1 -1 4;
  contrast "EZD vs. LZ"      Fluid   1  1 -1 -1 0;
  contrast "EZD1 vs. EZD2"   Fluid   1 -1  0  0 0;
  contrast "LZ1 vs. LZ2"     Fluid    0  0  1 -1 0;
  power
    nfractional
    stddev      = 3.5
    ncovariates = 1
    corrxy      = 0.2 0.3 0
    alpha       = 0.025
    ntotal      = .
    power       = 0.9;
run;
```

The **CLASS** statement identifies Altitude and Fluid as classification variables. The **MODEL** statement specifies the model, and the **WEIGHT** statement identifies CellWgt as the weight variable. The **CONTRAST** statement specifies the contrasts in [Table 41.8](#). As in [Example 41.1](#), the order of the contrast coefficients corresponds to the formatted class levels (EZD1, EZD2, LZ1, LZ2, Water). The **POWER** statement specifies total sample size as the result parameter and provides values for the other analysis parameters. The **NCOVARIATES=** option specifies the single covariate (body mass index), and the **CORRXY=** option specifies the two scenarios for its correlation with lactic acid buildup (0.2 and 0.3). [Output 41.2.1](#) displays the results.

Output 41.2.1 Sample Sizes for Two-Way ANOVA Contrasts

The GLMPOWER Procedure	
Fixed Scenario Elements	
Dependent Variable	LacticAcid
Weight Variable	CellWgt
Alpha	0.025
Number of Covariates	1

18	Contrast	LZ1 vs. LZ2	0.0	3.50	1	279	285.363976

Computed Ceiling N Total		
Index	Actual Power	Ceiling N Total
1	0.902	91
2	0.901	86
3	0.903	95
4	0.912	23
5	0.908	22
6	0.919	24
7	0.905	22
8	0.903	21
9	0.910	23
10	0.903	42
11	0.903	40
12	0.906	44
13	0.901	146
14	0.902	139
15	0.901	152
16	0.901	275
17	0.900	260
18	0.901	286

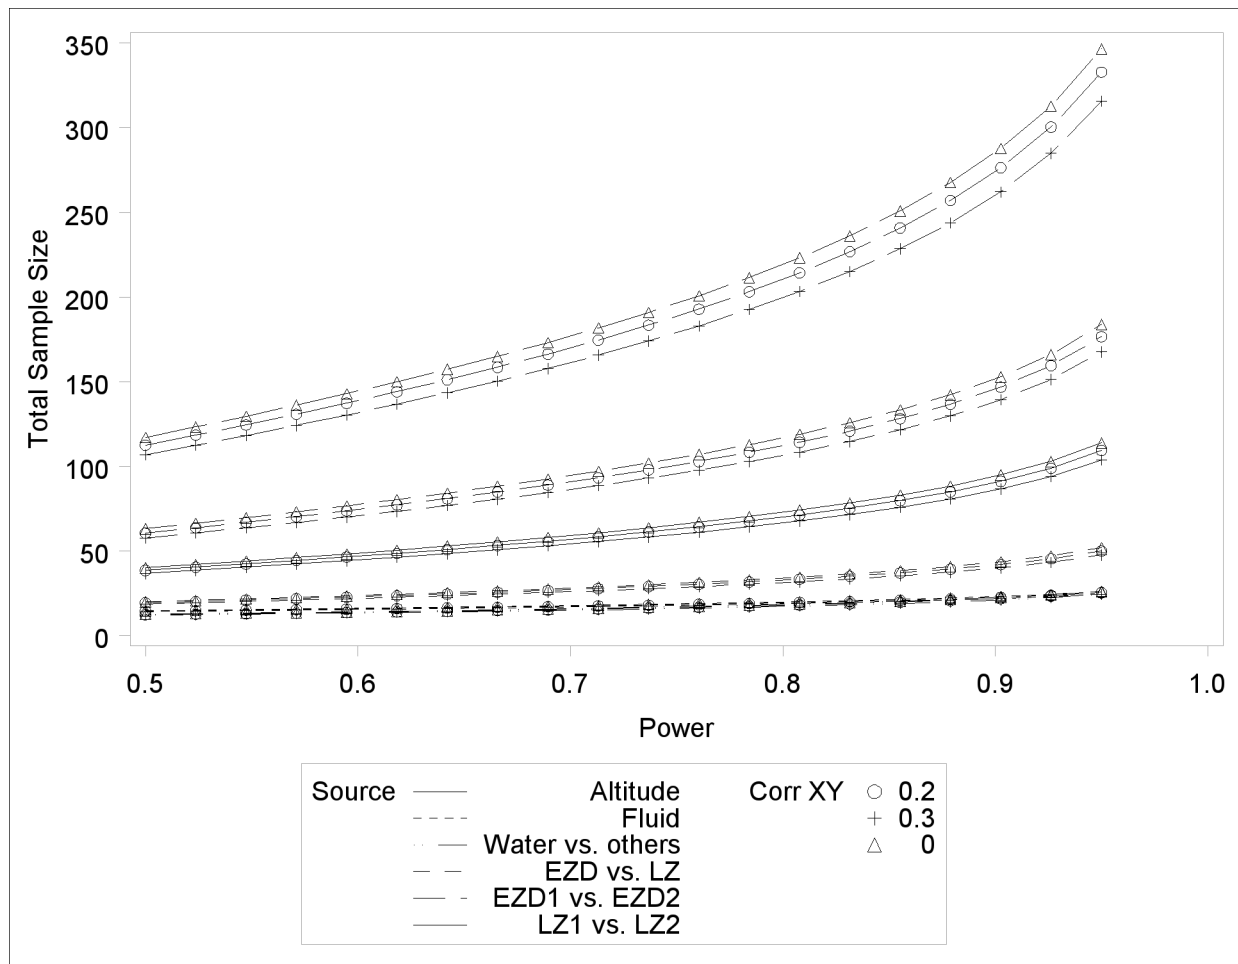

The sample sizes in [Output 41.2.1](#) range from 21 for the comparison of water versus electrolytes (assuming a correlation of 0.3 between body mass and lactic acid buildup) to 275 for the comparison of LZ1 versus LZ2 (assuming a correlation of 0.2). PROC GLMPOWER also includes the effect tests for Altitude and Fluid. Note that the required sample sizes for this study are lower than those for the study in [Example 41.1](#).

Note that the error standard deviation has been reduced from 3.5 to 3.43 (when correlation is 0.2) or 3.34 (when correlation is 0.3) in the approximation of the effect of the body mass index covariate. The error degrees of freedom has also been automatically adjusted, lowered by 1 (the number of covariates).

Suppose you want to plot the required sample size for the range of power values from 0.5 to 0.95. First, define the analysis by specifying the same statements as before, but add the **PLOTONLY** option to the **PROC GLMPower** statement to disable the nongraphical results. Next, specify the **PLOT** statement with **X=POWER** to request a plot with power on the X axis. Sample size is automatically placed on the Y axis. Use the **MIN=** and **MAX=** options in the **PLOT** statement to specify the power range. The following statements produce the plot:

```
proc glmpower data=Fluids2 plotonly;
  class Altitude Fluid;
  model LacticAcid = Altitude Fluid;
  weight CellWgt;
  contrast "Water vs. others" Fluid  -1 -1 -1 -1 4;
  contrast "EZD vs. LZ"      Fluid   1  1 -1 -1 0;
  contrast "EZD1 vs. EZD2"   Fluid   1 -1  0  0 0;
  contrast "LZ1 vs. LZ2"     Fluid   0  0  1 -1 0;
  power
    nfractional
    stddev      = 3.5
    ncovariates = 1
    corrxxy     = 0.2 0.3 0
    alpha       = 0.025
    ntotal      = .
    power       = 0.9;
  plot x=power min=.5 max=.95;
run;
```

See [Output 41.2.2](#) for the resulting plot.

**Output 41.2.2** Plot of Sample Size versus Power for Two-Way ANOVA Contrasts

In [Output 41.1.2](#), the line style identifies the test, and the plotting symbol identifies the scenario for the correlation between covariate and response. The plotting symbol locations identify actual computed powers; the curves are linear interpolations of these points. As in [Example 41.1](#), the required sample size is highest for the test of LZ1 versus LZ2.

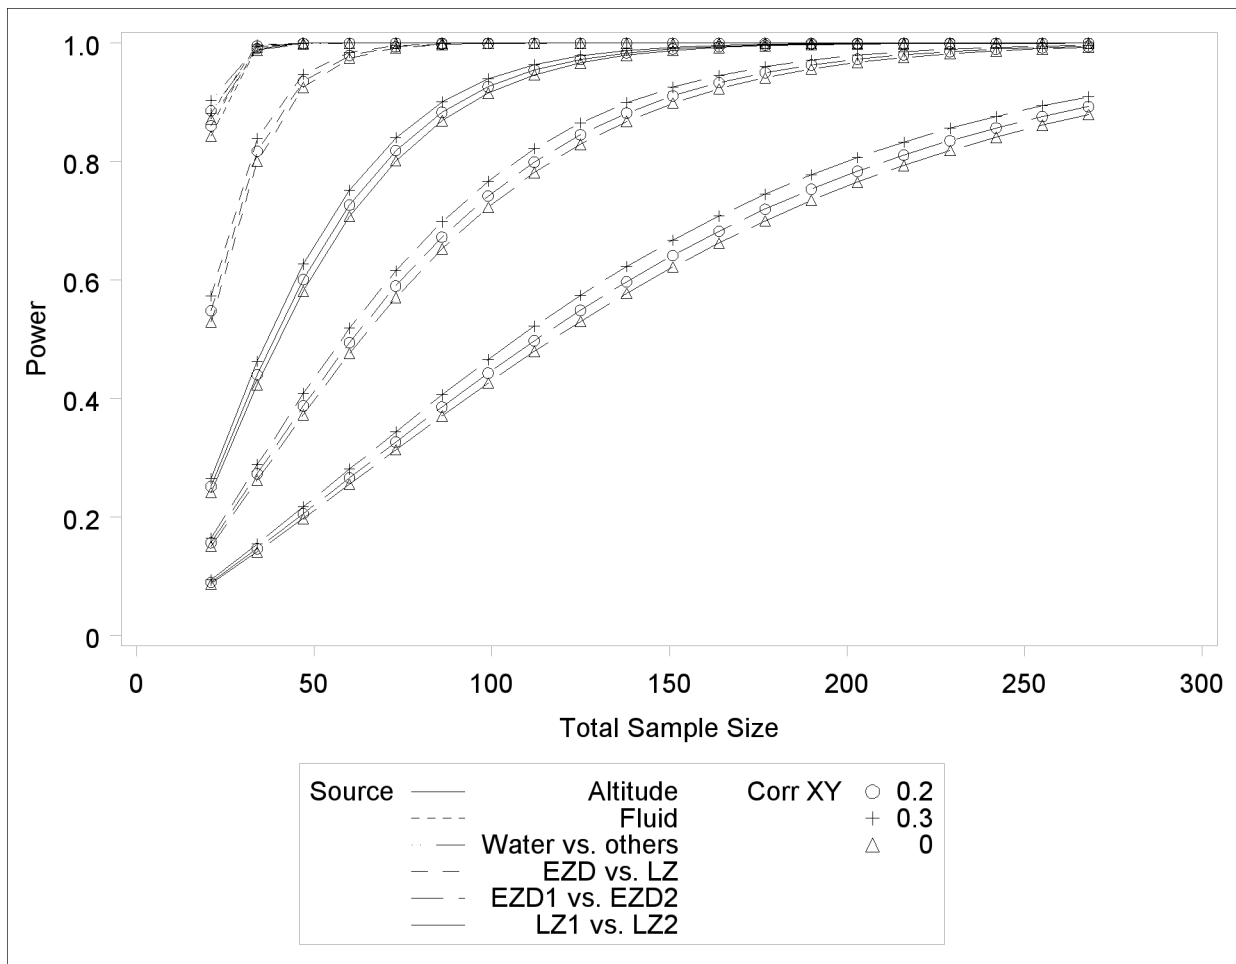

Finally, suppose you want to plot the power for the range of sample sizes you will likely consider for the study (the range of 21 to 275 that achieves 0.9 power for different comparisons). In the **POWER** statement, identify power as the result (**POWER=.**), and specify **NTOTAL=21**. Specify the **PLOT** statement with **X=N** to request a plot with sample size on the X axis.

The following statements produce the plot:

```
proc glmpower data=Fluids2 plotonly;
  class Altitude Fluid;
  model LacticAcid = Altitude Fluid;
  weight CellWgt;
  contrast "Water vs. others" Fluid  -1 -1 -1 -1 4;
  contrast "EZD vs. LZ"          Fluid  1  1 -1 -1 0;
  contrast "EZD1 vs. EZD2"       Fluid  1 -1  0  0 0;
  contrast "LZ1 vs. LZ2"         Fluid  0  0  1 -1 0;
  power
    nfractional
    stddev      = 3.5
    ncovariates = 1
    corrxxy     = 0.2 0.3 0
    alpha       = 0.025
    ntotal      = 21
    power       = .;
  plot x=n min=21 max=275;
run;
```

The `MAX=275` option in the `PLOT` statement sets the maximum sample size value. The `MIN=` option automatically defaults to the value of 21 from the `NTOTAL=` option in the `POWER` statement.

See [Output 41.2.3](#) for the plot.

**Output 41.2.3** Plot of Power versus Sample Size for Two-Way ANOVA Contrasts

Although [Output 41.2.2](#) and [Output 41.2.3](#) surface essentially the same computations for practical power ranges, they each provide a different quick visual assessment. [Output 41.2.2](#) reveals the range of required sample sizes for powers of interest, and [Output 41.2.3](#) reveals the range of powers achieved for sample sizes of interest.
