Overview: SCORE Procedure

The SCORE procedure multiplies values from two SAS data sets, one containing coefficients (for example, factor-scoring coefficients or regression coefficients) and the other containing raw data to be scored using the coefficients from the first data set. The result of this multiplication is a SAS data set containing linear combinations of the coefficients and the raw data values.

Many statistical procedures output coefficients that PROC SCORE can apply to raw data to produce scores. The new score variable is formed as a linear combination of raw data and scoring coefficients. For each observation in the raw data set, PROC SCORE multiplies the value of a variable in the raw data set by the matching scoring coefficient from the data set of scoring coefficients. This

multiplication process is repeated for each variable in the VAR statement. The resulting products are then summed to produce the value of the new score variable. This entire process is repeated for each observation in the raw data set. In other words, PROC SCORE cross multiplies part of one data set with another.

Raw Data Set

The raw data set can contain the original data used to calculate the scoring coefficients, or it can contain an entirely different data set. The raw data set must contain all the variables needed to produce scores. In addition, the scoring coefficients and the variables in the raw data set that are used in scoring must have the same names. See the section “[Getting Started: SCORE Procedure](#)” on page 5756 for more information.

Scoring Coefficients Data Set

The data set containing scoring coefficients must contain two special variables: the `_TYPE_` variable and the `_NAME_` or `_MODEL_` variable.

- The `_TYPE_` variable identifies the observations that contain scoring coefficients.
- The `_NAME_` or `_MODEL_` variable provides a SAS name for the new score variable.

PROC SCORE first looks for a `_NAME_` variable in the SCORE= input data set. If there is such a variable, the variable’s value is what SCORE uses to name the new score variable. If the SCORE= data set does not have a `_NAME_` variable, then PROC SCORE looks for a `_MODEL_` variable.

For example, PROC FACTOR produces an output data set that contains factor-scoring coefficients. In this output data set, the scoring coefficients are identified by `_TYPE_='SCORE'`. For `_TYPE_='SCORE'`, the `_NAME_` variable has values of 'Factor1', 'Factor2', and so forth. PROC SCORE gives the new score variables the names Factor1, Factor2, and so forth.

As another example, the REG procedure produces an output data set that contains parameter estimates. In this output data set, the parameter estimates are identified by `_TYPE_='PARMS'`. The `_MODEL_` variable contains the label used in the MODEL statement in PROC REG, or it uses `MODEL n` if no label is specified. This label is the name PROC SCORE gives to the new score variable.

Standardization of Raw Data

PROC SCORE automatically standardizes or centers the DATA= variables for you, based on information from the original variables and analysis from the SCORE= data set.

If the SCORE= scoring coefficients data set contains observations with `_TYPE_='MEAN'` and `_TYPE_='STD'`, then PROC SCORE standardizes the raw data before scoring. For example, this type of SCORE= data set can come from PROC PRINCOMP without the COV option.

If the SCORE= scoring coefficients data set contains observations with `_TYPE_='MEAN'` but `_TYPE_='STD'` is absent, then PROC SCORE centers the raw data (the means are subtracted) before scoring. For example, this type of SCORE= data set can come from PROC PRINCOMP with the COV option.

If the SCORE= scoring coefficients data set does not contain observations with `_TYPE_='MEAN'` and `_TYPE_='STD'`, or if you use the NOSTD option, then PROC SCORE does not center or standardize the raw data.

If the SCORE= scoring coefficients are obtained from observations with `_TYPE_='USCORE'`, then PROC SCORE “standardizes” the raw data by using the uncorrected standard deviations identified by `_TYPE_='USTD'`, and the means are not subtracted from the raw data. For example, this type of SCORE= data set can come from PROC PRINCOMP with the NOINT option. For more information about `_TYPE_='USCORE'` scoring coefficients in `TYPE=UCORR` or `TYPE=UCOV` output data sets, see Appendix A, “[Special SAS Data Sets](#).”

You can use PROC SCORE to score the data that were also used to generate the scoring coefficients, although more typically, scoring results are directly obtained from the OUT= data set in a procedure that computes scoring coefficients. When scoring new data, it is important to realize that PROC SCORE assumes that the new data have approximately the same scales as the original data. For example, if you specify the COV option with PROC PRINCOMP for the original analysis, the scoring coefficients in the PROC PRINCOMP OUTSTAT= data set are not appropriate for standardized data. With the COV option, PROC PRINCOMP will not output `_TYPE_='STD'` observations to the OUTSTAT= data set, and PROC SCORE will only subtract the means of the original (not new) variables from the new variables before multiplying. Without the COV option in PROC PRINCOMP, both the original variable means and standard deviations will be in the OUTSTAT= data set, and PROC SCORE will subtract the original variable means from the new variables and divide them by the original variable standard deviations before multiplying.

In general, procedures that output scoring coefficients in their OUTSTAT= data sets provide the necessary information for PROC SCORE to determine the appropriate standardization. However, if you use PROC SCORE with a scoring coefficients data set that you constructed without `_TYPE_='MEAN'` and `_TYPE_='STD'` observations, you might have to do the relevant centering or standardization of the new data first. If you do this, you must use the means and standard deviations of the original variables—that is, the variables that were used to generate the coefficients—not the means and standard deviations of the variables to be scored.

See the section “[Getting Started: SCORE Procedure](#)” on page 5756 for further illustration.

Getting Started: SCORE Procedure

The SCORE procedure multiplies the values from two SAS data sets and creates a new data set to contain the results of the multiplication. The variables in the new data set are linear combinations of the variables in the two input data sets. Typically, one of these data sets contains raw data that you want to score, and the other data set contains scoring coefficients.

The following example demonstrates how to use the SCORE procedure to multiply values from two SAS data sets, one containing factor-scoring coefficients and the other containing raw data to be scored using the scoring coefficients.

Suppose you are interested in the performance of three different types of schools: private schools, state-run urban schools, and state-run rural schools. You want to compare the schools' performances as measured by student grades on standard tests in English, mathematics, and biology. You administer these tests and record the scores for each of the three types of schools.

The following DATA step creates the SAS data set Schools. The data are provided by Chaseling (1996).

```
data Schools;
    input Type $ English Math Biology @@;
    datalines;
p 52 55 45 p 42 49 40 p 63 64 54
p 47 50 51 p 64 69 47 p 63 67 54
p 59 63 42 p 56 61 41 p 41 44 72

... more lines ...

r 50 47 49 r 55 48 46 r 38 36 51
;
```

The data set Schools contains the character variable Type, which represents the type of school. Valid values are p (private schools), r (state-run rural schools), and u (state-run urban schools).

The three numeric variables in the data set are English, Math, and Biology, which represent the student scores for English, mathematics, and biology, respectively. The double trailing at sign (@@) in the INPUT statement specifies that observations are input from each line until all values are read.

The following statements invoke the FACTOR procedure to compute the data set of factor scoring coefficients. The statements perform a principal components factor analysis that uses all three numeric variables in the SAS data set Schools. The OUTSTAT= option requests that PROC FACTOR output the factor scores to the data set Scores. The NOPRINT option suppresses display of the output.

```
proc factor data=Schools score outstat=Scores noprint;
    var english math biology;
run;

proc score data=schools score=Scores out=New;
    var english math biology;
    id type;
run;
```

The SCORE procedure is then invoked using Schools as the raw data set to be scored and Scores as the scoring data set. The OUT= option creates the SAS data set New to contain the linear combinations.

The VAR statement specifies that the variables English, Math, and Biology are used in computing scores. The ID statement copies the variable Type from the Schools data set to the output data set New.

The following statements print the SAS output data set Scores, the first two observations from the original data set Schools, and the first two observations of the resulting data set New.

```

title 'OUTSTAT= Data Set from PROC FACTOR';
proc print data=Scores;
run;

title 'First Two Observations of the DATA= Data Set from PROC SCORE';
proc print data=Schools(obs=2);
run;

title 'First Two Observations of the OUT= Data Set from PROC SCORE';
proc print data=New(obs=2);
run;

```

Figure 76.1 displays the output data set Scores produced by the FACTOR procedure. The last observation (number 11) contains the scoring coefficients (_TYPE_='SCORE'). Only one factor has been retained.

Figure 76.1 Listing of the Data Set Created by PROC FACTOR

Figure 76.2 First Two Observations of the Schools Data Set

First Two Observations of the DATA= Data Set from PROC SCORE				
Obs	Type	English	Math	Biology
1	p	52	55	45
2	p	42	49	40

Figure 76.3 lists the first two observations of the output data set New created by PROC SCORE.

Figure 76.3 Listing of the New Data Set

First Two Observations of the OUT= Data Set from PROC SCORE		
Obs	Type	Factor1
1	p	-0.17604
2	p	-0.80294

The score variable Factor1 in the New data set is named according to the value of the `_NAME_` variable in the Scores data set. The values of the variable Factor1 are computed as follows: the DATA= data set variables are standardized using the same means and standard deviations that PROC FACTOR used when extracting the factors because the Scores data set contains observations with `_TYPE_='MEAN'` and `_TYPE_='STD'`.

Note that in order to correctly use standardized scoring coefficients created by other procedures such as PROC FACTOR in this example, the data to be scored must be standardized in the same way that the data were standardized when the scoring coefficients were computed. Otherwise, the resulting scores might be incorrect. PROC SCORE does this automatically if the SCORE= data set is the original OUTSTAT= data set output from the procedure creating the scoring coefficients.

These standardized variables are then multiplied by their respective standardized scoring coefficients from the data set Scores. These products are summed over all three variables, and the sum is the value of the new variable Factor1. The first two values of the scored variable Factor1 are obtained as follows:

$$\left(\frac{(52 - 55.525)}{12.949} \times 0.390 \right) + \left(\frac{(55 - 52.325)}{12.356} \times 0.378 \right) + \left(\frac{(45 - 50.350)}{12.239} \times 0.347 \right) = -0.17604$$

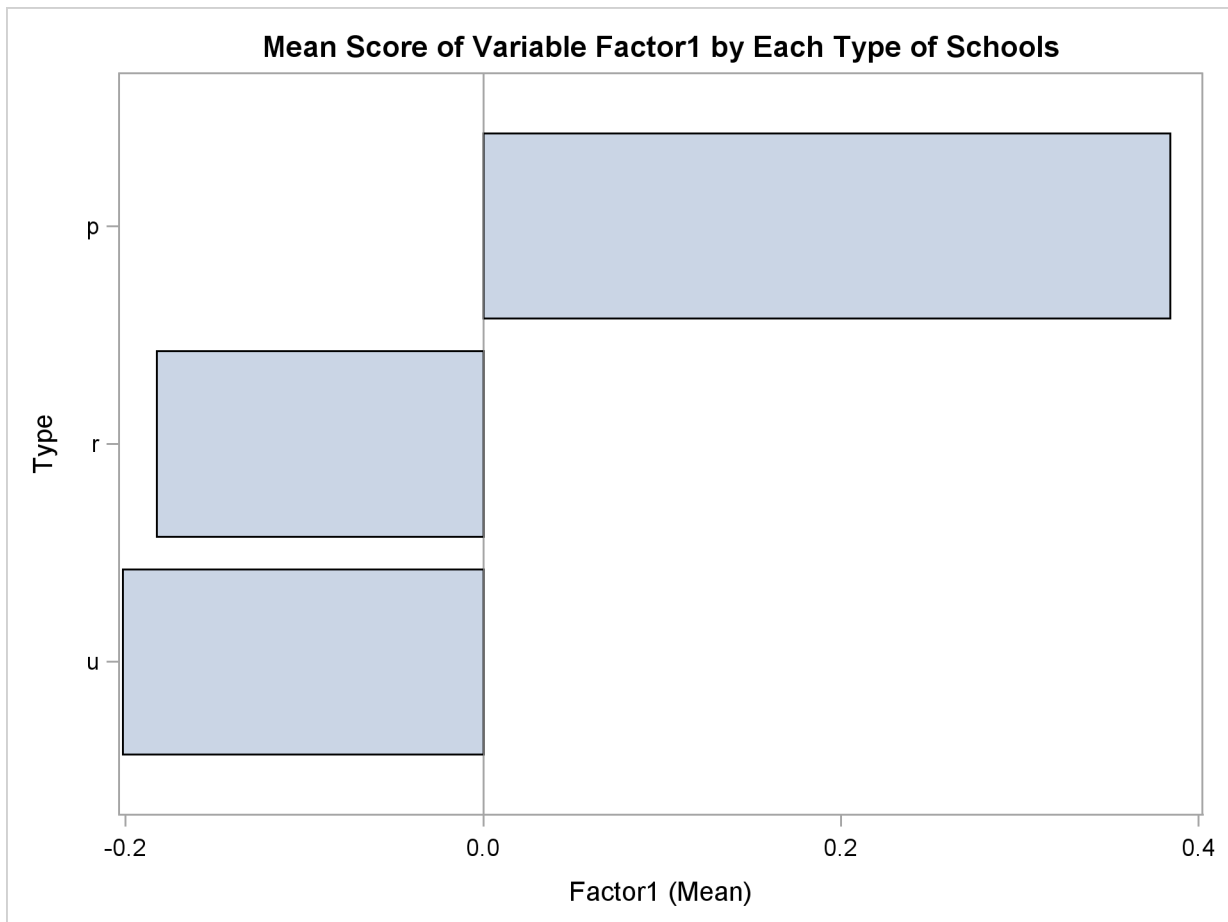

$$\left(\frac{(42 - 55.525)}{12.949} \times 0.390 \right) + \left(\frac{(49 - 52.325)}{12.356} \times 0.378 \right) + \left(\frac{(40 - 50.350)}{12.239} \times 0.347 \right) = -0.80294$$

The following statements request that the SGPLOT procedure produce a horizontal bar chart of the variable Type. The length of each bar represents the mean of the variable Factor1.

```
title 'Mean Score of Variable Factor1 by Each Type of Schools';
proc sgplot data=New;
  hbar type / stat = mean response=Factor1;
run;
```

Figure 76.4 displays the mean score of the variable Factor1 for each of the three school types. For private schools (Type=p), the average value of the variable Factor1 is 0.384, while for state-run schools the average values are much lower. The state-run urban schools (Type=u) have the lowest mean value of -0.202 , and the state-run rural schools (Type=r) have a mean value of -0.183 .

Figure 76.4 Bar Chart of School Type

Syntax: SCORE Procedure

The following statements are available in the SCORE procedure:

```
PROC SCORE DATA=SAS-data-set< options > ;
    BY variables ;
    ID variables ;
    VAR variables ;
```

The only required statement is the PROC SCORE statement. The BY, ID, and VAR statements are described following the PROC SCORE statement.

PROC SCORE Statement

```
PROC SCORE DATA= SAS-data-set < options > ;
```

You can specify the following options in the PROC SCORE statement.

DATA=SAS-data-set

names the input SAS data set containing the raw data to score. This option is required.

NOSTD

suppresses centering and scaling of the raw data. Ordinarily, if PROC SCORE finds `_TYPE_='MEAN'`, `_TYPE_='USCORE'`, `_TYPE_='USTD'`, or `_TYPE_='STD'` observations in the SCORE= data set, the procedure uses these to standardize the raw data before scoring.

OUT=SAS-data-set

specifies the name of the SAS data set created by PROC SCORE. If you want to create a permanent SAS data set, you must specify a two-level name. See *SAS Language Reference: Concepts* for more information about permanent SAS data sets. If the OUT= option is omitted, PROC SCORE still creates an output data set and automatically names it according to the DATAn convention, as if you omitted a data set name in a DATA statement.

PREDICT

specifies that PROC SCORE should treat coefficients of -1 in the SCORE= data set as 0. In regression applications, the dependent variable is coded with a coefficient of -1 . Applied directly to regression results, PROC SCORE produces negative residuals (see the description of the RESIDUAL option, which follows); the PREDICT option produces predicted values instead.

RESIDUAL

reverses the sign of each score. Applied directly to regression results, PROC SCORE produces negative residuals (PREDICT–ACTUAL); the RESIDUAL option produces positive residuals (ACTUAL–PREDICT) instead.

SCORE=SAS-data-set

names the data set containing the scoring coefficients. If you omit the SCORE= option, the most recently created SAS data set is used. This data set must have two special variables: `_TYPE_` and either `_NAME_` or `_MODEL_`.

TYPE=name or 'string'

specifies the observations in the SCORE= data set that contain scoring coefficients. The TYPE= procedure option is unrelated to the data set option that has the same name. PROC SCORE examines the values of the special variable `_TYPE_` in the SCORE= data set. When the value of `_TYPE_` matches `TYPE=name`, the observation in the SCORE= data set is used to score the raw data in the DATA= data set.

If you omit the TYPE= option, scoring coefficients are read from observations with either `_TYPE_='SCORE'` or `_TYPE_='USCORE'`. Because the default for PROC SCORE is `TYPE=SCORE`, you need not specify the TYPE= option for factor scoring or for computing scores from OUTSTAT= data sets from the CANCELL, CANDISC, PRINCOMP, or VARCLUS procedure. When you use regression coefficients from PROC REG, specify `TYPE=PARMS`.

The maximum length of the argument specified in the TYPE= option depends on the length defined by the VALIDVARNAME= SAS system option. For additional information, see *SAS Language Reference: Dictionary*.

Note that the TYPE= option setting is not case sensitive. For example, the two option settings `TYPE='MyScore'` and `TYPE='myscore'` are equivalent.

BY Statement

BY variables ;

You can specify a BY statement with PROC SCORE to obtain separate scoring for observations in groups defined by the BY variables. You can also specify a BY statement to apply separate groups of scoring coefficients to the entire DATA= data set.

If your SCORE= input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for PROC SCORE. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

If the DATA= data set does not contain any of the BY variables, the entire DATA= data set is scored by each BY group of scoring coefficients in the SCORE= data set.

If the DATA= data set contains some but not all of the BY variables, or if some BY variables do not have the same type or length in the DATA= data set as in the SCORE= data set, then PROC SCORE prints an error message and stops.

If all the BY variables appear in the DATA= data set with the same type and length as in the SCORE= data set, then each BY group in the DATA= data set is scored using scoring coefficients from the corresponding BY group in the SCORE= data set. The BY groups in the DATA= data set must be in the same order as in the SCORE= data set. All BY groups in the DATA= data set must also appear in the SCORE= data set. If you do not specify the NOTSORTED option, some BY groups can appear in the SCORE= data set but not in the DATA= data set; such BY groups are not used in computing scores.

ID Statement

ID *variables* ;

The ID statement identifies variables from the DATA= data set to be included in the OUT= data set. If there is no ID statement, all variables from the DATA= data set are included in the OUT= data set. The ID variables can be character or numeric.

VAR Statement

VAR *variables* ;

The VAR statement specifies the variables to be used in computing scores. These variables must be in both the DATA= and SCORE= input data sets and must be numeric. If you do not specify a VAR statement, the procedure uses all numeric variables in the SCORE= data set. You should almost always specify a VAR statement with PROC SCORE because you would rarely use all the numeric variables in your data set to compute scores.

Details: SCORE Procedure

Missing Values

If one of the scoring variables in the DATA= data set has a missing value for an observation, all the scores have missing values for that observation. The exception to this criterion is that if the PREDICT option is specified, the variable with a coefficient of -1 can tolerate a missing value and still produce a prediction score. Also, a variable with a coefficient of 0 can tolerate a missing value.

If a scoring coefficient in the SCORE= data set has a missing value for an observation, the coefficient is not used in creating the new score variable for the observation. In other words, missing values of scoring coefficients are treated as zeros. This treatment affects only the observation in which the missing value occurs.

Regression Parameter Estimates from PROC REG

If the SCORE= data set is an OUTEST= data set produced by PROC REG and if you specify TYPE=PARMS, the interpretation of the new score variables depends on the PROC SCORE options chosen and the variables listed in the VAR statement. If the VAR statement contains only the independent variables used in a model in PROC REG, the new score variables give the predicted values. If the VAR statement contains the dependent variables and the independent variables used in a model in PROC REG, the interpretation of the new score variables depends on the PROC SCORE options chosen. If you omit both the PREDICT and the RESIDUAL options, the new score variables give negative residuals (PREDICT–ACTUAL). If you specify the RESIDUAL option, the new score variables give positive residuals (ACTUAL–PREDICT). If you specify the PREDICT option, the new score variables give predicted values.

Unless you specify the NOINT option for PROC REG, the OUTEST= data set contains the variable Intercept. The SCORE procedure uses the intercept value in computing the scores.

Output Data Set

PROC SCORE produces an output data set but displays no output. The output OUT= data set contains the following variables:

- the ID variables, if any
- all variables from the DATA= data set, if no ID variables are specified
- the BY variables, if any

- the new score variables, named from the `_NAME_` or `_MODEL_` values in the `SCORE=` data set

Computational Resources

Let

- v = number of variables used in computing scores
- s = number of new score variables
- b = maximum number of new score variables in a BY group
- n = original input value

Memory

The array storage required is approximately $8(4v + (3 + v)b + s)$ bytes. When you do not use BY processing, the array storage required is approximately $8(4v + (4 + v)s)$ bytes.

Time

The time required to construct the scoring matrix is roughly proportional to vs , and the time needed to compute the scores is roughly proportional to nvs .

Examples: SCORE Procedure

The following three examples use a subset of the Fitness data set. The complete data set is given in Chapter 73, “[The REG Procedure](#).”

Example 76.1: Factor Scoring Coefficients

This example shows how to use PROC SCORE with factor scoring coefficients. First, the FACTOR procedure produces an output data set containing scoring coefficients in observations identified by `_TYPE_='SCORE'`. These data, together with the original data set `Fitness`, are supplied to PROC SCORE, resulting in a data set containing scores `Factor1` and `Factor2`. The following statements produce [Output 76.1.1](#) through [Output 76.1.3](#):

```

/* This data set contains only the first 12 observations */
/* from the full data set used in the chapter on PROC REG. */

Since the PROC SCORE statement does not contain the NOSTD option, the data in the Fitness data set are standardized before scoring. For each variable specified in the VAR statement, the mean and standard deviation are obtained from the FactOut data set. For each observation in the Fitness data set, the variables are then standardized. For example, for observation 1 in the Fitness data set, the variable Age is standardized to $0.5569 = [(44 - 42.4167)/2.8431]$.

After the data in the Fitness data set are standardized, the standardized values of the variables in the VAR statement are multiplied by the matching coefficients in the FactOut data set, and the resulting products are summed. This sum is output as a value of the new score variable.

Output 76.1.3 displays the FScore data set produced by PROC SCORE. This data set contains the variables Age, Weight, Oxygen, RunTime, RestPulse, and RunPulse from the Fitness data set. It also contains Factor1 and Factor2, the two new score variables.

Output 76.1.3 OUT= Data Set from PROC SCORE Reproduced with PROC PRINT

Example 76.2: Regression Parameter Estimates

In this example, PROC REG computes regression parameter estimates for the Fitness data. (See [Example 76.1](#) to for more information about how to create the Fitness data set.) The parameter estimates are output to a data set and used as scoring coefficients. For the first part of this example, PROC SCORE is used to score the Fitness data, which are the same data used in the regression.

In the second part of this example, PROC SCORE is used to score a new data set, Fitness2. For PROC SCORE, the TYPE= specification is PARMS, and the names of the score variables are found in the variable _MODEL_, which gets its values from the model label. The following code produces [Output 76.2.1](#) through [Output 76.2.3](#):

```
proc reg data=Fitness outest=RegOut;

OxyHat: model Oxygen=Age Weight RunTime RunPulse RestPulse;
  title 'REGRESSION SCORING EXAMPLE';
run;

proc print data=RegOut;
  title2 'OUTEST= Data Set from PROC REG';
run;

proc score data=Fitness score=RegOut out=RScoreP type=parms;
  var Age Weight RunTime RunPulse RestPulse;
run;

proc print data=RScoreP;
  title2 'Predicted Scores for Regression';
run;
```

```

proc score data=Fitness score=RegOut out=RScoreR type=parms;
    var Oxygen Age Weight RunTime RunPulse RestPulse;
run;

proc print data=RScoreR;
    title2 'Negative Residual Scores for Regression';
run;

```

Output 76.2.1 shows the PROC REG output. The column labeled “Parameter Estimates” lists the parameter estimates. These estimates are output to the RegOut data set.

Output 76.2.1 Creating an OUTEST= Data Set with PROC REG

REGRESSION SCORING EXAMPLE					
The REG Procedure					
Model: OxyHat					
Dependent Variable: Oxygen					
Number of Observations Read				12	
Number of Observations Used				12	
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F

Error	6	38.70060	6.45010		
Corrected Total	11	548.32261			
Root MSE		2.53970	R-Square	0.9294	
Dependent Mean		48.38942	Adj R-Sq	0.8706	
Coeff Var		5.24847			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	151.91550	31.04738	4.89	0.0027
Age	1	-0.63045	0.42503	-1.48	0.1885
Weight	1	-0.10586	0.11869	-0.89	0.4068
RunTime	1	-1.75698	0.93844	-1.87	0.1103
RunPulse	1	-0.22891	0.12169	-1.88	0.1090
RestPulse	1	-0.17910	0.13005	-1.38	0.2176

Output 76.2.2 lists the RegOut data set. Note that `_TYPE_='PARMS'` and `_MODEL_='OXYHAT'`, which are from the label in the MODEL statement in PROC REG.

Output 76.2.2 OUTEST= Data Set from PROC REG Reproduced with PROC PRINT

REGRESSION SCORING EXAMPLE						
OUTEST= Data Set from PROC REG						
Obs	_MODEL_	_TYPE_	_DEPVAR_	_RMSE_	Intercept	Age
1	OxyHat	PARMS	Oxygen	2.53970	151.916	-0.63045
Obs	Weight	RunTime	RunPulse	Rest Pulse	Oxygen	
1	-0.10586	-1.75698	-0.22891	-0.17910	-1	

Output 76.2.3 lists the data sets created by PROC SCORE. Since the SCORE= data set does not contain observations with `_TYPE_='MEAN'` or `_TYPE_='STD'`, the data in the Fitness data set are not standardized before scoring. The SCORE= data set contains the variable Intercept, so this intercept value is used in computing the score. To produce the RScoreP data set, the VAR statement in PROC SCORE includes only the independent variables from the model in PROC REG. As a result, the OxyHat variable contains predicted values. To produce the RScoreR data set, the VAR statement in PROC SCORE includes both the dependent variables and the independent variables from the model in PROC REG. As a result, the OxyHat variable contains negative residuals (PREDICT–ACTUAL) as shown in **Output 76.2.4**. If the RESIDUAL option is specified, the variable OxyHat contains positive residuals (ACTUAL–PREDICT). If the PREDICT option is specified, the OxyHat variable contains predicted values.

Output 76.2.3 Predicted Scores from the OUT= Data Set Created by PROC SCORE

REGRESSION SCORING EXAMPLE							
Predicted Scores for Regression

12	45	87.66	37.388	14.03	56	186	37.0080

Output 76.2.4 Residual Scores from the OUT= Data Set Created by PROC SCORE

REGRESSION SCORING EXAMPLE							
Negative Residual Scores for Regression							
Obs	Age	Weight	Oxygen	Run Time	Rest Pulse	Run Pulse	OxyHat
1	44	89.47	44.609	11.37	62	178	-1.73195
2	40	75.07	45.313	10.07	62	185	2.29197
3	44	85.84	54.297	8.65	45	156	1.82407
4	42	68.15	59.571	8.17	40	166	-0.86657
5	38	89.02	49.874	9.22	55	178	1.86460
6	47	77.45	44.811	11.63	58	176	-1.83542
7	40	75.98	45.681	11.95	70	176	-0.84811
8	43	81.19	49.091	10.85	64	162	-0.48897
9	44	81.42	39.442	13.08	63	174	2.01935
10	38	81.87	60.055	8.63	48	170	-3.43787
11	44	73.03	50.541	10.13	45	168	1.58892
12	45	87.66	37.388	14.03	56	186	-0.38002

The second part of this example uses the parameter estimates to score a new data set. The following statements produce [Output 76.2.5](#) and [Output 76.2.6](#):

```

/* The FITNESS2 data set contains observations 13-16 from */
/* the FITNESS data set used in EXAMPLE 2 in the PROC REG */
/* chapter. */
data Fitness2;
  input Age Weight Oxygen RunTime RestPulse RunPulse;
  datalines;
45 66.45 44.754 11.12 51 176
47 79.15 47.273 10.60 47 162
54 83.12 51.855 10.33 50 166
49 81.42 49.156 8.95 44 180
;

proc print data=Fitness2;
  title 'REGRESSION SCORING EXAMPLE';
  title2 'New Raw Data Set to be Scored';
run;

proc score data=Fitness2 score=RegOut out=NewPred type=parms
  nostd predict;
  var Oxygen Age Weight RunTime RunPulse RestPulse;
run;

proc print data=NewPred;
  title2 'Predicted Scores for Regression';
  title3 'for Additional Data from FITNESS2';
run;

```

[Output 76.2.5](#) lists the Fitness2 data set.

Output 76.2.5 Listing of the Fitness2 Data Set

REGRESSION SCORING EXAMPLE New Raw Data Set to be Scored						
Obs	Age	Weight	Oxygen	Run Time	Rest Pulse	Run Pulse
1	45	66.45	44.754	11.12	51	176
2	47	79.15	47.273	10.60	47	162
3	54	83.12	51.855	10.33	50	166
4	49	81.42	49.156	8.95	44	180

PROC SCORE scores the Fitness2 data set by using the parameter estimates in the RegOut data set. These parameter estimates result from fitting a regression equation to the Fitness data set. The NOSTD option is specified, so the raw data are not standardized before scoring. (However, the NOSTD option is not necessary here. The SCORE= data set does not contain observations with _TYPE_='MEAN' or _TYPE_='STD', so standardization is not performed.) The VAR statement contains the dependent variables and the independent variables used in PROC REG. In addition, the PREDICT option is specified. This combination gives predicted values for the new score variable. The name of the new score variable is OxyHat, from the value of the _MODEL_ variable in the SCORE= data set. [Output 76.2.6](#) shows the data set produced by PROC SCORE.

Output 76.2.6 Predicted Scores from the OUT= Data Set Created by PROC SCORE and Reproduced Using PROC PRINT

REGRESSION SCORING EXAMPLE Predicted Scores for Regression for Additional Data from FITNESS2							
Obs	Age	Weight	Oxygen	Run Time	Rest Pulse	Run Pulse	OxyHat
1	45	66.45	44.754	11.12	51	176	47.5507
2	47	79.15	47.273	10.60	47	162	49.7802
3	54	83.12	51.855	10.33	50	166	43.9682
4	49	81.42	49.156	8.95	44	180	47.5949

Example 76.3: Custom Scoring Coefficients

This example uses a specially created custom scoring data set and produces [Output 76.3.1](#) and [Output 76.3.2](#). The first scoring coefficient creates a variable that is Age—Weight; the second scoring coefficient evaluates the variable RunPulse—RstPulse; and the third scoring coefficient totals all six variables. Since the scoring coefficients data set (data set A) does not contain any observations with `_TYPE_='MEAN'` or `_TYPE_='STD'`, the data in the Fitness data set (see [Example 76.1](#)) are not standardized before scoring.

The following statements produce [Output 76.3.1](#) and [Output 76.3.2](#):

```
data A;
  input _type_ $ _name_ $
        Age Weight RunTime RunPulse RestPulse;
  datalines;
SCORE  AGE_WGT  1 -1  0  0  0
SCORE  RUN_RST  0  0  0  1 -1
SCORE  TOTAL    1  1  1  1  1
;

proc print data=A;
  title 'CONSTRUCTED SCORING EXAMPLE';
  title2 'Scoring Coefficients';
run;

proc score data=Fitness score=A out=B;
  var Age Weight RunTime RunPulse RestPulse;
run;

proc print data=B;
  title2 'Scored Data';
run;
```

Output 76.3.1 Custom Scoring Data Set and Scored Fitness Data: PROC PRINT

CONSTRUCTED SCORING EXAMPLE Scoring Coefficients							
Obs	_type_	_name_	Age	Weight	Run Time	Run Pulse	Rest Pulse

SAS® Documentation

To successfully implement applications using SAS software, companies in every industry and on every continent all turn to the one source for accurate, timely, and reliable information: SAS documentation. We currently produce the following types of reference documentation to improve your work experience:

- Online help that is built into the software.
- Tutorials that are integrated into the product.
- Reference documentation delivered in HTML and PDF – **free** on the Web.
- Hard-copy books.
