Expression Engine Language

DataFlux Data Management Platform is a powerful suite of data cleansing and data integration software applications. You can use the Data Job Expression node to run a scripting language to process your data sets in ways that are not built into the DataFlux Data Management Studio. The Expression Engine Language (EEL) provides many statements, functions, and variables for manipulating data in DataFlux Data Management Studio and SAS Event Stream Processing Engine.

⚠️ **Caution:** It is recommended that you have some programming experience before using the EEL.

Multiple macro files are supported along with the concept of user- and system-level macros, in a specific order.

System macros are defined in the dfexec_home location and displayed through the user interface, but they cannot be added or edited. User settings are stored in the %apdata% location. You can view, add, or edit through the user interface. Changes to the system-level macro cause an override where the new value is written to the user location. To promote this change, you must update the system location outside of DataFlux Data Management Studio. New system macros and macro files must be created outside the software.

Load order is important because technical support can use load order to force a macro to be a specific value. In the following, the base directory is defined by dfexec_home. In a typical installation, this is the root directory where DataFlux Data Management Studio is installed.

Command line declarations override environment variables which in turn override macro variable values declared in any of the system or user configuration files. Refer to the *DataFlux Data Management Studio Online Help* for more information on using macro variables. The results from the Expression node are determined by the code in the Expression Properties dialog.

This reference guide will guide you through solutions to address some common EEL tasks. Most examples use the Expression node in the Data Job Editor. All of the examples in this guide also apply to other nodes where EEL is used in DataFlux Data Management Studio.

**Overview of the Expression Engine Language**

Operations in the EEL are processed in symbols. Symbols are similar to variables; they are either fields passed from the node above or are variables declared in the code. EEL code consists of declarations, statements, and labels.
Declarations

Declarations establish the existence of variables in memory. Declared variables are available only after their declaration, so it is better to make all declarations at the beginning of a code segment. Place declarations in the code outside of programmatic constructs, so declaring a variable in a for loop is illegal.

Statements

Statements are either assignments (for example: x=y) or keywords (for example: goto) followed by parameters. Statements can be located anywhere in a code segment.

Labels

Labels are named locations in a code segment and can be located anywhere in the code segment. Reserved keywords cannot be used for label names, see Reserved Words.

Pieces of Expression code do not need to be separated by anything, but it is best to use white space and new-line characters for readability. Code might include comments. Comments are text within a code segment that are not executed. Comments can be either C-style (starts with /* and ends with */) or C++ style (starts with // and continues to the end of a line).

Assume that there are two symbols (output fields from the previous step) named "x" and "y." Following is an example of Expression code:

```
  // Declaration of integer z
  integer z
  // Assignment statement
  z=x+y
```

This example creates another symbol/field, "z" and sets the value of z to x + y, making z ready for the next step.

A segment of Expression code can also be a straight expression. In the context of the Expression main code area, if a straight expression value is false, then the row is not sent to output. For example, assume the same fields from the previous example, "x" and "y". Consider the following straight expression in the Expression code area:

```
  x<=y
```

EEL in the Expression code area executes on each record of your data set. Only records where the value of x is less than or equal to y are output to the next node. If you have more than one function in the main code area, the last function to execute determines the overall expression value. For example, if the last function returns a true value, then the entire expression returns true.
The following example includes several of the concepts discussed above:

```plaintext
// declarations
integer x; /*semicolon is safely ignored, and can use C-style comments*/
real y

// statements
x=10 y=12.4 /* more than one statement can be on a line */
```

**Declaration of Symbols**

Declarations have the following syntax:

```plaintext
["static"] ["private" | "public"] ["hidden" | "visible"] type[(*size)]
["array"] identifier
```

where type is:

"integer" | "string" | "real" | "boolean" | "date"

and identifier is a non-keyword word starting with an alphabetic character followed by characters, digits, underscores, or any string delimited by back quotes (`). Refer to [Reserved Words](#) for a list of reserved keywords.

ℹ️ **Note:** Size is applicable to the string type only.

ℹ️ **Note:** The global symbol type is deprecated but is equivalent to static public.

Additional information about declaring symbols:

- The default symbol type is public.
- Private symbols are visible only within the code block in which they are declared.
- Static symbols are public by default. You can also declare a static symbol as private.
- String symbols can be declared with a size. If you assign a value to a string symbol, it is truncated to this size. If you do not specify a size, 255 is used by default.

ℹ️ **Note:** The maximum size is 2GB. However, this applies only to fields within the Expression node. If the symbol is available in the output, it is truncated to 32k when the Expression node passes the value on to the next node. For example, if you define a string of length 45k, you can work with it inside the expression node. However, it is truncated to 32k on output.

- The keyword, bytes, qualifies a string size in bytes. See the previous note for additional details.
Symbols can be declared anywhere in code except within programmatic constructs, such as loops. It is good practice to declare symbols at the beginning of the code block.

In DataFlux Data Management Studio - Data Job Editor, all symbols declared in code are available in the output unless they are declared private or hidden.

Before code is executed, symbols are reset to null. If the symbols are declared static or have been declared in the pre-processing step, they retain their value from the previous execution.

The static keyword can be used when declaring symbols. It specifies that the value of the symbol value is not reset between calls to the expression (between rows read in Data Job Editor). This replaces the global keyword. The pre-processing expression defaults all symbols to static public whether they are declared static or not.

Hidden and visible keywords can be used when declaring symbols. The default is visible if none is specified. Hidden symbols are not output from the expression step in Data Jobs. Note that this differs from public and private. Private variables are not output either, but they are not visible outside the expression block. Hidden variables are visible outside the expression block but are not output.

To declare a variable with spaces or other special characters in the name, write your variable name between back quotes (`). For example:

```java
string `my var`
`my var`="Hello"
```

Note: It is the grave accent character (´), also known as the back quote, that is employed, and not the apostrophe (') or quotation marks ("). The grave accent is found above the tab key on standard keyboards.

Here are some sample declarations:

```java
// a 30-character string available
// only to the code block
private string(30) name

// a 30-byte string
string(30 bytes) name

// a 255 character public string
string address

// a global real number
global real number

// a public date field. Use back quotes if symbols include spaces
date `birth date`
```
Public or global symbols declared in one area are available to other areas as follows:

- Symbols declared in Pre-Processing are available to any block.
- Symbols declared in Expression are available to Expression and Post-Processing.
- Symbols declared in Post-Processing are only available to Post-Processing.
- Automatic symbols, which are symbols from the previous step, are available to any of the three blocks.

**Statements**

Statements have the following syntax:

```
statement:
| "goto" label
| identifier "=" expression
| "return" expression
| "if" expression ["then"] statement ["else" statement]
| "for" identifier ["="] expression ["to"] expression ["step" expression] statement
| "begin" statement [statement...] "end"
| ["call"] function
| "while" expression statement

label: identifier ":;

expression:
described later

function: identifier "(" parameter [,parameter...] ")"
```

Statements can optionally be separated by a semicolon or new-line character. To group more than one statement together (for example, in a for loop), use begin/end.

**Goto and Label**

**Syntax:** goto label

**Syntax:** label: identifier ":;

A goto statement jumps code control to a label statement. A label can occur anywhere in the same code block. For example:

```
integer x
x=0
// label statement called start
start:
x=x+1
if x < 10 goto start
```
Assignment

Assigns the value of an expression to a symbol as follows:

- Only read-write symbols can be assigned a value.
- In Data Jobs, all symbols are read-write.
- A symbol assigned an expression of a different type receives the converted (or coerced) value of that expression. For example, if you assign a number to a string-type symbol, the symbol contains a string representation of that number.
- If the expression cannot be converted into the type of symbol, the symbol’s value is null. For example, if you assign a non-date string to a string symbol.

```
integer num
string str
date dt
boolean b
real r

// assign 1 to num
num=1
// assign Jan 28 '03 to the date symbol
dt=#01/28/03#
// sets boolean to true
b=true
// also sets boolean to true
b='yes'
// sets real to 30.12 (converting from string)
r="30.12"
// sets string to the string representation of the date
str=dt
// sets num to the rounded value of r
num=r
```

Arrays

In the EEL, you can create arrays of primitive types such as integers, strings, reals, dates, and Booleans. It is not possible to create arrays of objects such as dbCursor, dbconnection, regex, and file.

The syntax to create arrays of primitive types is as follows:

```
string array string_list
integer array integer_list
date array date_list
Boolean array boolean_list
real array real_list
```
There are three supported functions on arrays: **dim**, **set**, and **get**.

For more information on arrays, see Arrays.

**Return**

**Syntax:** "return" expression

The return statement exits the code block immediately, returning a value.

- In the Data Jobs, the return type is converted to Boolean.
- If a false value is returned from Expression, the record is not included in the output.

The following is an example of a return statement:

```plaintext
// only include rows where ID >= 200
if id < 200
    return false
```

**If/Else**

**Syntax:** "if" expression ["then"] statement ["else" statement]

The if/else statement branches to one or more statements, depending on the expression.

- Use this to execute code conditionally.
- If you need to execute more than one statement in a branch, use begin/end.
- The then keyword is optional.
- If you nest if/else statements, the else statement corresponds to the closest if statement (see the previous example). It is better to use begin/end statements if you do this, as it makes the code more readable.

In the following example, you can change the value of Age to see different outcomes:

```plaintext
string(20) person
integer x
integer y
integer age
Age=10

if Age < 20 then
    person="child"
else
    person="adult"

if Age==10
    begin
        x=50
        y=20
    end
```
// nested if/else
if Age <= 60   
  if Age < 40
    call print("Under 40")
  // this else corresponds to the inner if statement
  else
    call print("Age 40 to 60")
  // this else corresponds to the outer if statement
else
  call print("Over 60")

For

The for loop executes one or more statements multiple times.

- For loops are based on a symbol which is set to some value at the start of the loop, and changes with each iteration of the loop.
- A for loop has a start value, an end value, and an optional step value.
- The start, end, and step value can be any expression.
- The expressions are only evaluated before the loop begins.
- If the step value is not specified, it defaults to 1.
- If you are starting at a high number and ending at a lower number, you must use a negative step.
- If you need to execute more than one statement in the loop, use begin/end.

For example:

    integer i
    for i = 1 to 10 step 2
      call print('Value of i is ' & i)

    integer x
    integer y
    x=10 y=20

    for i = x to y
      call print('Value of i is ' & i)
    for i = y to x step -1
      begin
        call print('Value of i is ' & i)
        x=i /*does not affect the loop since start/end/step expressions are only evaluated before loop*/
      end
While

Syntax: "while" expression statement

The while loop allows you to execute the same code multiple times; a condition remains true.

For example:

```plaintext
integer i
i=1000
// keep looping while the value of i is > 10
while i > 10
    i=i/2

// you can use begin/end to enclose more than one statement
while i < 1000
    begin
        i=i*2
        call print('Value if i is ' & i)
    end
```

Begin/End

Syntax: "begin" statement [statement...] "end"

The begin/end statement groups multiple statements together. If you need to execute multiple statements in a for or while loop or in an if/then/else statement, you must use begin/end. These can be nested as well.

Call

Syntax: ["call"] function

This statement calls a function and discards the return value.

Expressions

- An expression can include operators in combination with numbers, strings, functions, functions which use other functions.
- An expression always has a resulting value.
- The resulting value can be one of the following: string, integer, real, date, and Boolean.
- The resulting value can also be null (a special type of value).

This section covers different types of expressions.
Operators

The following table lists operators in order of precedence:

<table>
<thead>
<tr>
<th>Operators</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(, )</td>
<td>parentheses (can be nested to any depth)</td>
</tr>
<tr>
<td>*</td>
<td>multiply</td>
</tr>
<tr>
<td>/</td>
<td>divide</td>
</tr>
<tr>
<td>%</td>
<td>modulo</td>
</tr>
<tr>
<td>+</td>
<td>add</td>
</tr>
<tr>
<td>-</td>
<td>subtract</td>
</tr>
<tr>
<td>&amp;</td>
<td>string concatenation</td>
</tr>
<tr>
<td>!=</td>
<td>not equal (&quot;!=&quot; and &quot;:&lt;&gt;&quot; are the same)</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>not equal</td>
</tr>
<tr>
<td>==</td>
<td>comparison operator (= is an assignment and should not be used for comparisons)</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
</tr>
<tr>
<td>&lt;</td>
<td>less than</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
</tr>
<tr>
<td>and</td>
<td>Boolean and</td>
</tr>
<tr>
<td>or</td>
<td>Boolean or</td>
</tr>
</tbody>
</table>

Modulo Operator

The modulo operator is represented by the % symbol. The result of the expression a%d ("a modulo d") returns a value r, for example:

\[ a = qd + r \text{ and } 0 \leq r < |d|, \text{ where } |d| \text{ denotes the absolute value of } d \]

If either a or d are not integers, they are rounded down to the nearest integer before the modulo calculation is performed.

For positive values of a and d, it can be the remainder on division of a by d. For example:

<table>
<thead>
<tr>
<th>a</th>
<th>d</th>
<th>a%d (r)</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>11</td>
<td>-3</td>
<td>2</td>
</tr>
<tr>
<td>-11</td>
<td>3</td>
<td>-2</td>
</tr>
<tr>
<td>9.4</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>9.6</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>10</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>9.4</td>
<td>3.2</td>
<td>0</td>
</tr>
<tr>
<td>9.6</td>
<td>3.2</td>
<td>0</td>
</tr>
<tr>
<td>10</td>
<td>3.2</td>
<td>1</td>
</tr>
<tr>
<td>-10.2</td>
<td>3.2</td>
<td>-2</td>
</tr>
</tbody>
</table>
Comparison Operator

Do not confuse the comparison operator (==) with the assignment operator (=). For example:

```plaintext
// correct statements to compare the value of x and y
if x==y then statement1
else statement2

// Assigning a value
x=y
```

String Expressions

A string expression is a string of undeclared length. Strings can be concatenated using an ampersand (&) or operated upon with built-in functions. For information about defining the length of a string, see Declaration of Symbols. For example:

```plaintext
string str
// simple string
str="Hello"
// concatenate two strings
str="Hello" & " There"
```

Note: Setting a string variable to a string expression results in a truncated string if the variable was declared with a shorter length than the expression.

When a string value is used in a Boolean expression, the value will be evaluated and the following values will be considered true, (upper/lower/mixed): true, t; yes, y; or 1. The following values will be considered false (also upper/lower/mixed): false, no, n, or 0.

For more about string expressions, see Strings.

Integer and Real Expressions

Integer and real expressions result in an integer or real value, respectively.

For example:

```plaintext
integer x
real r

// order of precedence starts with parentheses,
// then multiplication, then addition
x=1+(2+3)*4

// string is converted to value 10
x=5 + "10"
r=3.14

// x will now be 3
x=r
```
Date Expressions

- A date value is stored as a real value with the whole portion representing number of days since January 1, 1900, and the fraction representing the fraction of a day.

- If years are specified as two digits, then the years between 51 and 99 are assumed to be in 1900. Other years are assumed to be in 2000.

- A date constant is denoted with a number sign (#).

- If a whole number is added to a date, the resulting date is advanced by the specified number of days.

- To make changes to the locale setting in Microsoft Windows, refer to the locale() function topic in this reference guide.

For example:

```plaintext
date date_value1
date data_value2
date_value1 = todate("01/02/03")
date_value2 = #01-02-03#
```

🔍 **Note:** The actual results depend on your Windows system settings.

For more on date expressions, see Dates and Times.

Boolean Expressions

- A Boolean expression can either be true or false.

- Results of comparisons are always Boolean.

- Using AND or OR in an expression also results in a Boolean value.

For example:

```plaintext
boolean a
boolean b
boolean c

a=true
b=false
// c is true
c=a or b
// c is false
c=a and b
// c is true
c=10<20
// c is false
c=10==20
// c is true
c=10!=20
// c is true
c='yes'
// c is false
c='no'
```
Null Propagation

If any part of a mathematical expression has a null value, the entire expression is usually null.

The following table shows how nulls are propagated:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>null == value</td>
<td>null (applies to all comparison operators)</td>
</tr>
<tr>
<td>null &amp; string</td>
<td>string</td>
</tr>
<tr>
<td>null &amp; null</td>
<td>null</td>
</tr>
<tr>
<td>number + null</td>
<td>null (applies to all arithmetic operations)</td>
</tr>
<tr>
<td>null + null</td>
<td>null (applies to all arithmetic operations)</td>
</tr>
<tr>
<td>null AND null</td>
<td>null</td>
</tr>
<tr>
<td>null AND true</td>
<td>null</td>
</tr>
<tr>
<td>null AND false</td>
<td>false</td>
</tr>
<tr>
<td>null OR null</td>
<td>null</td>
</tr>
<tr>
<td>null OR true</td>
<td>true</td>
</tr>
<tr>
<td>null OR false</td>
<td>false</td>
</tr>
<tr>
<td>not null</td>
<td>null</td>
</tr>
<tr>
<td>if null</td>
<td>statement following if is not executed</td>
</tr>
<tr>
<td>for loop</td>
<td>runtime error if any of the terms are null</td>
</tr>
<tr>
<td>while null</td>
<td>statement following while is not executed</td>
</tr>
</tbody>
</table>

For example:

```java
integer x
integer y
integer z
boolean b
string s
x=10
y=null // z has a value of null
z=x + y // b is true
b=true or null // b is null
b=false or null // use isnull function to determine if null
if isnull(b)
  call print("B is null")
// s is "str"
s="str" & null
```

Coercion

If a part of an expression is not the type expected in that context, it is converted into the correct type.

- A type can be coerced into other types.
- If a value cannot be coerced, it results in null.
To explicitly coerce one type to another type, use one of the following functions: `toboolean`, `todate`, `tointeger`, `toreal`, or `tostring`. These functions are helpful when there is a need to force a comparison of different types. For example, to compare a string variable called 'xyz' with a number '123.456', the number is converted to a string before the comparison is completed using the following example:

```
toreal(xyz) > 123.456
```

The following table shows the rules for coercion:

<table>
<thead>
<tr>
<th>Coercion Type</th>
<th>To String</th>
<th>To Integer</th>
<th>To Real</th>
<th>To Date</th>
<th>To Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>from String</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>from Integer</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>from Real</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>from Date</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>from Boolean</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>no</td>
<td>no</td>
</tr>
</tbody>
</table>

The following table shows special considerations for coercion:

<table>
<thead>
<tr>
<th>Coercion Type</th>
<th>Resulting Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>date to string</td>
<td>A default date format is used: YYYY/MM/DD hh:mm:ss. Use the <code>formatdate</code> function for a more flexible conversion.</td>
</tr>
<tr>
<td>date to number</td>
<td>The number represents days since 12/30/1899. Hours, minutes, seconds, and milliseconds are converted to a fraction, where 1 hour = 1/24 units, 1 minute = 1/(24*60) units, and so on.</td>
</tr>
<tr>
<td>string to date</td>
<td>Most date formats are recognized and intelligently converted. See the Date Expressions section for more information.</td>
</tr>
<tr>
<td>string to Boolean</td>
<td>The values yes, no, true, false, y, n, t, and f are recognized.</td>
</tr>
<tr>
<td>integer to real to Boolean</td>
<td>Any non-zero value is true. Zero is false.</td>
</tr>
</tbody>
</table>

### Functions

- A function can be part of an expression.
- If you need to call a function but do not want the return value, use `call`.
- Each function has a specific return type and parameter type.
- If the parameters provided to the function are not the correct type, they are sometimes coerced.
- A function sometimes requires a parameter to be a specific type. If you pass a parameter of the wrong type, it is not coerced and you get an error.
- Functions normally propagate null (there might be exceptions).
- Some functions might modify the value of their parameters if they are documented to do so.
- Some functions might accept a variable number of parameters.
For example:

```plaintext
string str
integer x
str="Hello there"
// calls the upper function
if upper(str)=='HELLO THERE'
  // calls the print function
call print("yes")

// x is set to 7 (position of word 'there')
x=instr(str,"there",1)
```

**Global Functions**

You can register global functions (or user-defined functions, known as UDF’s) that can be reused from any expression in the system (including data and process flow nodes, business rules, and more). To do this, create one text file (or more) in the installation under etc/udf. Each file might contain one or more function definitions. Each definition is enclosed in a function/end function block. The return type for each function can be integer, real, date, string, or Boolean. To get to function parameters, use the `parameter()` and `parametercount()` functions as well as individual functions for the types (parameterboolean, parameterdate, parameterinteger, parameterreal, or parameterstring).

The following functions are applicable when registering the global functions mentioned earlier. Each global function accepts an integer as a parameter to indicate which parameter is desired. Each function returns the type specified and converts the parameter to that type, if it is not already the type specified.

- `parameterboolean`
- `parameterdate`
- `parameterinteger`
- `parameterreal`
- `parameterstring`

**Example**

```plaintext
function example_udf return string
  // this function is declared to return a string
  // retrieve the number of parameters passed
  print("You passed " & parametercount() & " parameters")
  integer x
  for x = 1 to parametercount()
  begin
    print("Parameter " & x & " type is " & parametertype(x) & " value is " & parameter(x))
    if(parametertype(x)=="integer")
      print("Integer: " & parameterinteger(x))
```

else if parametertype(x)=="real"
    print("Real: " & parameterreal(x))
end
return "string val"
end function

Objects

The EEL supports a number of objects. Generally, an object is a type of code in which not only the data type of a data structure is defined, but also the types of operations that can be applied to the data structure. In particular, the EEL supports objects for:

- **Blue Fusion**: Expressions and Functions
- **Databases**: Database connectivity (dbconnect object)
- **Files**: Text file reading and writing (file object)
- **Regular Expressions**: Regular expression searches (regex object)
Expression Engine Language Functions

The following is a list of DataFlux Expression Engine Language (EEL) functions. Click a function to view syntax, descriptions, and other useful information.

- **Array Functions**
- **Blue Fusion Functions**
- **Boolean Functions**
- **Database Functions**
- **Data Input Functions**
- **Date and Time Functions**
- **Execution Functions**
- **File Functions**
- **Information/Conversion Functions**
- **Logging Functions**
- **Macro Variable Functions**
- **Mathematical Functions**
- **Node Functions**
- **Regular Expression Functions**
- **Search Functions**
- **String Functions**

 pena: There is a new keyword, bytes, for string size. The 255 in the declaration string(255) refers to characters, while in string(255 bytes) the number refers to 255 bytes. Specifically, string(255 bytes) is used for multi-byte languages. For more information, see Declaration of Symbols.

- **Experimental Functions**
Array Functions

In the DataFlux Expression Engine Language (EEL), it is possible to create arrays of simple types such as string, integer, date, Boolean, and real. Currently there are three functions that apply to array types: set, get, and dim.

- dim
- get
- set

**dim Function**

The dim function creates, resizes, or determines the size of an array. If a parameter is specified, the array is resized/created. The new size is returned.

**Category:** Array

**Syntax**

arrayName[dim[(newsize)]

**Arguments**

arrayName

is the name of the array that you declared earlier in the process

newsize

[optional] is the numeric size (dimension) of the array, this can be specified as a numeric constant, field name, or expression

returns

an integer representing the current size of the array

**Details**

The dim function is used to size and resize the array. It creates, resizes, or determines the size of the array. If a parameter is specified, the array is created or resized. The supported array types include:

- String
- Integer
- Date
- Boolean
- Real
Examples

The following statements illustrate the dim function:

```csharp
// declare the string array
string array string_list
// Set the dimension of the String_List array to a size of 5
rc = string_list.dim(5) // outputs 5
// <omitted code to perform some actions on the array>
// Re-size the array size to 10
rc = string_list.dim(10) // outputs 10
// Query the current size
rc = string_list.dim() // outputs 10
```

get Function

The get function retrieves the value of the specified item within an array. The returned value is the value of the array.

Category: Array

Syntax

```csharp
<array name>.get(n)
```

Arguments

array name

is the name of the array that you declared earlier in the process

n

is the index of the array element for which the content is retrieved; this can be specified as a numeric constant, field name, or expression

returns

a string with the content of the specified array element that was retrieved

Details

The get function returns the value of a particular element in the array.

Examples

The following statements illustrate the get function:

Example 1

```csharp
// Declare the string array "string_list" and Integer "i"
string array string_list
integer i
```
/ Set the dimension of string_list array to 5 and initialize the counter
(i) to 1
string_list.dim(5)
i=1

// Set and print each entry in the array, incrementing the counter by 1
while(i<=5)
begin
    string_list.set(i,"Hello")
    print(string_list.get(i))
    i=i+1
end

Example 2

string array string_list
integer i

// set the dimension
string_list.dim(5)
i=1

// set and print each entry in the array
while(i<=5)
begin
    string_list.set(i,"Hello")
    print(string_list.get(i))
    i=i+1
end

// resize the array to 10
string_list.dim(10)
while(i<=10)
begin
    string_list.set(i,"Goodbye")
    print(string_list.get(i))
    i=i+1
end

set Function

The set function sets values for items within an array. The returned value is the
value of the array.

Category: Array

Syntax

<array name>.set(n,"string")

Arguments

array name

    is the name of the array that you declared earlier in the process
n

is the number of the dimension you are setting the value for; this can be specified as a numeric constant, field name, or expression

string

is the value you want to place into the array element; this can be specified as a string constant, field name, or expression

returns

Boolean [true = success; false = error]

Details

The set function sets the value of an entry in the array.

Examples

The following statements illustrate the set function:

Example 1

```java
//Declare the string array "string_list"
// Set the dimension of string_list array to 5
string array string_list
string_list.dim(5)

// Set the first string element in the array to "Hello"
string_list.set(1,"Hello")
```

Example 2

```java
string array string_list
string_list.dim(5)
// sets the first string element in the array to hello
string_list.set(1,"hello")
```

Blue Fusion Functions

DataFlux Expression Engine Language (EEL) supports the Blue Fusion object. You can use Blue Fusion to perform the listed functions (object methods) from within the EEL node. Some of the advantages of using Blue Fusion functions within the EEL include dynamically changing match definitions, reading match definitions from another column, or setting different definitions.

The Blue Fusion functions supported within the Expression node are:

- `bluefusion.case`
- `bluefusion.extract`
- `bluefusion.gender`
- `bluefusion.getlasterror`
- `bluefusion.identify`
- `bluefusion Initialize`
- `bluefusion.loadqkb`
- `bluefusion.matchcode`
- `bluefusion.matchscore`
- `bluefusion.parse`
- `bluefusion.pattern`
- `bluefusion.standardize`
- `bluefusion.token`
- `bluefusion.tokenvalue`
- `bluefusion.value`

**bluefusion.case Function**

The `bluefusion.case` function applies casing rules (upper, lower, or proper) to a string. Optionally applies context-specific casing logic using a case definition in the Quality Knowledge Base (QKB).

**Category:** Blue Fusion

**Syntax**

`bluefusion.case (<case_def>, casing_type, input, result)`

**Arguments**

- `case_def`
  
  [optional] a string representing the name of a case definition in the QKB

- `casing_type`
  
  integer numeric constant that specifies the type of casing that is applied, [1 = uppercase, 2 = lowercase, 3 = propercase]

- `input`
  
  a string representing the input value or input field name
result

   a string representing the output field name

returns

   Boolean [1 = success, 0 = error]

Details

The bluefusion.case function applies casing rules to an input string and outputs the result to a field.

The function is a member of the bluefusion class. A bluefusion object can be declared as a variable and must then be initialized using a call to the function bluefusion_initialize.

You can specify one of three casing types: upper, lower, or propercase. When uppercase or lowercase is specified, the function applies Unicode uppercase or lower case mappings to the characters in the input string. When propercasing is specified, the function applies uppercase mappings to the first letter in each word and lowercase mappings to the remaining letters.

The caller can optionally invoke the use of a case definition. A case definition is an object in the QKB that contains context-specific casing logic. For example, a case definition implemented for the purpose of propercasing name data can be used to convert the string "Mcdonald" to "McDonald". Refer to the QKB documentation for information about what case definitions are available in your QKB. If you do not want to use a case definition, you can omit the case definition parameter by entering a blank string for the case definition parameter. In this case, generic Unicode case mappings are applied to the input string as described earlier.

🔍 Note: If you want to use a case definition, you must call bluefusion.loadqkb before calling bluefusion.case. The function bluefusion.loadqkb loads the contents of a QKB into memory and links that QKB with the bluefusion object. This enables bluefusion.case to access the case definition you specify.

Examples

The following statements illustrate the bluefusion.case function:

```plaintext
bluefusion bf
string output
bf = bluefusion_initialize()
bf.case('', 1, "ronald mcdonald", output) // outputs "RONALD MCDONALD"
bf.case('', 3, "ronald mcdonald", output) // outputs "Ronald Mcdonald"
bf.loadqkb("ENUSA")
bf.case("Proper (Name)", 3, "ronald mcdonald", output) // outputs "Ronald McDonald"
```
bluefusion.extract Function

The extract Blue Fusion function extracts attributes from a string.

Category: Blue Fusion

Syntax

bluefusion.extract(string, string)

Arguments

string

a string that represents the attribute that needs to be extracted

returns

a value, token, or tokenvalue from the extract function

Details

The bluefusion.extract function will extract attributes from a string into tokens. The first parameter is the name of the QKB extraction definition. The second is the string where the attributes are extracted. This function returns a number of tokens that were created. It returns 0 if it fails.

Example

The following statements illustrate the bluefusion.extract function:

```c
bluefusion bf
string output
integer o
integer i

/* Initialize BF */
bf = bluefusion_initialize()
bf.loadqkb("EN")

/* Extract using the "Product Attributes" Extraction definition (using 
QKB PD 2012A) */
o = bf.extract("Product Attributes", "DOOR RANCHERO WOOD 16X8 WHT")

/* print all of the tokens we got */
print (o & " tokens filled")
for i = 1 to o
begin
    bf.token(i, output)
    print ("token #" & i & " = " & output)
    bf.value(i, output)
    print ("value #" & i & " = " & output)
end
/* to get a token's value by its name... */
bf.tokenvalue("Colors", output)
print ("Colors = " & output)
```
bluefusion.gender Function

The bluefusion.gender function determines the gender of an individual's name using a gender analysis definition in the QKB.

Category: Blue Fusion

Syntax

bluefusion.gender(gender_def, input, result)

Arguments

gender_def
    a string representing the name of a gender analysis definition in the QKB

input
    a string representing the input value or input field name

result
    a string representing the output field name

returns
    Boolean [1 = success, 0 = error]

Details

The bluefusion.gender function analyzes a string representing an individual's name and determines the gender of the name.

The function is a member of the bluefusion class. A bluefusion object can be declared as a variable and must then be initialized using a call to the function bluefusion_initialize. The member function bluefusion.loadqkb must then be called to load the contents of a QKB into memory and link that QKB with the bluefusion object. The bluefusion object then retains information about the QKB and the QKB locale setting.

When calling bluefusion.gender, you must specify the name of a gender analysis definition. A gender analysis definition is an object in the QKB that contains reference data and logic used to determine the gender of the input name string. See your QKB documentation for information about which gender analysis definitions are available in your QKB.

Examples

The following statements illustrate the bluefusion.gender function:

```cpp
bluefusion bf
string output
bf = bluefusion_initialize()
```
bf.loadqkb("ENUSA")
bf.gender("Name", "John Smith", output)  // outputs "M"
bf.gender("Name", "Jane Smith", output)  // outputs "F"
bf.gender("Name", "J. Smith", output)  // outputs "U" (unknown)

**bluefusion.getlasterror Function**

The bluefusion.getlasterror function returns a string describing the most recent error encountered by a bluefusion object.

**Category:** Blue Fusion

**Syntax**

bluefusion.getlasterror()

**Arguments**

returns

a string containing an error message

**Details**

The bluefusion.getlasterror function is a member of the bluefusion class. It returns an error message describing the most recent error encountered by a bluefusion object. The error might have occurred during invocation of any other bluefusion member function.

A best practice for programmers is to check the result code for each bluefusion call. If a result code indicates failure, use bluefusion.getlasterror to retrieve the associated error message.

**Examples**

The following statements illustrate the bluefusion.getlasterror function:

```plaintext
bluefusion bf
integer rc
string errmsg
bf = bluefusion_initialize()
rc = bf.loadqkb("XXXXX")
// an invalid locale name -- this will cause an error
if (rc == 0) then
    errmsg = bf.getlasterror()
// returns an error message
```
bluefusion.identify Function

The bluefusion.identify function identifies the context of a string using an identification analysis definition in the QKB.

**Category:** Blue Fusion

**Syntax**

bluefusion.identify(ident_def, input, result)

**Arguments**

- **ident_def**
  A string representing the name of an identification analysis definition in the QKB

- **input**
  A string representing the input value or input field name

- **result**
  A string representing the output field name

**returns**

Boolean [1 = success, 0 = error]

**Details**

The bluefusion.identify function analyzes a string and determines the context of the string. The context refers to a logical type of data, such as name, address, or phone.

The function is a member of the bluefusion class. A bluefusion object can be declared as a variable and must then be initialized using a call to the function bluefusion_initialize. The member function bluefusion.loadqkb must then be called to load the contents of a QKB into memory and link that QKB with the bluefusion object. The bluefusion object then retains information about the QKB and the QKB locale setting.

When calling bluefusion.identify, you must specify the name of an identification analysis definition. An identification analysis definition is an object in the QKB that contains reference data and logic used to identify the context of the input string. Refer to your QKB documentation for information about which identification analysis definitions are available in your QKB.

🔍 **Note:** For each identification analysis definition, there is a small set of possible contexts that might be output. Refer to the description of an identification analysis definition in the QKB documentation to see which contexts that definition is able to identify.
Examples
The following statements illustrate the bluefusion.identify function:

```plaintext
bluefusion bf
string output
bf = bluefusion_initialize()
bf.loadqkb("ENUSA")
bf.identify("Individual/Organization", "John Smith", output)
// outputs "INDIVIDUAL"

bf.identify("Individual/Organization", "DataFlux Corp", output)
// outputs "ORGANIZATION"
```

bluefusion_initialize Function
The bluefusion_initialize function instantiates and initializes a bluefusion object.

**Category:** Blue Fusion

**Syntax**
```
bluefusion_initialize()
```

**Arguments**
returns

an initialized instance of a Blue Fusion object

**Details**
The bluefusion_initialize instantiates and initializes a bluefusion object. The object can then be used to invoke bluefusion class functions.

**Examples**
The following statements illustrate the bluefusion_initialize function:

```plaintext
bluefusion bf
bf = bluefusion_initialize()
```

bluefusion.loadqkb Function
The bluefusion.loadqkb function loads definitions from a QKB into memory and links those definitions with the bluefusion object.

**Category:** Blue Fusion

**Syntax**
```
bluefusion.loadqkb(locale)
```
**Arguments**

locale

a five-character locale code name representing a locale supported by the QKB

returns

Boolean [1 = success, 0 = error]

**Details**

The function `bluefusion.loadqkb` is a member of the `bluefusion` class. A `bluefusion` object can be declared as a variable and must then be initialized through a call to the function `bluefusion.initialize`. The function `bluefusion.loadqkb` can be called after the initialization.

The `bluefusion.loadqkb` function loads definitions from a QKB into memory and links those definitions with the `bluefusion` object. A definition is a callable object that uses context-sensitive logic and reference data to perform analysis and transformation of strings. Definitions are used as parameters in other `bluefusion` functions.

When calling `bluefusion.loadqkb` you must specify a locale code. This locale code is a five-character string representing the ISO codes for the locale’s language and country. Refer to your QKB documentation for a list of codes for locales that are supported in your QKB.

🔍 **Note:** Only one locale code can be specified in each call to `bluefusion.loadqkb`. Only definitions associated with that locale are loaded into memory. This means that support for only one locale at a time can be loaded for use by a `bluefusion` object. Therefore, in order to make use of QKB definitions for more than one locale, you must either use multiple instances of the `bluefusion` class or call `bluefusion.loadqkb` multiple times for the same instance, specifying a different locale with each call.

**Examples**

The following statements illustrate the `bluefusion.loadqkb` function:

```c
bluefusion bf_en
// we instantiate two bluefusion objects
bluefusion bf_fr
string output_en
string output_fr
bf_en = bluefusion_initialize()
bf_fr = bluefusion_initialize()

bf_en.loadqkb("ENUSA"
// loads QKB support for locale English, US

bf_fr.loadqkb("FRFRA")
// loads QKB support for locale French, France
```
bf_en.gender("Name", "Jean LaFleur", output_en)
// output is 'U'

bf_fr.gender("Name", "Jean LaFleur", output_fr)
// output is 'M'

**bluefusion.matchcode Function**

The bluefusion.matchcode function generates a match code for a string using a match definition in the QKB.

**Category:** Blue Fusion

**Syntax**

bluefusion.matchcode(match_def, sensitivity, input, result)

**Arguments**

- **match_def**
  
a string representing the name of a match definition in the QKB

- **sensitivity**
  
integer numeric constant that specifies the sensitivity level to be used when generating the match code [possible values are 50–95]

- **input**
  
a string representing the input value or input field name

- **result**
  
a string representing the output field name

**returns**

Boolean [1 = success, 0 = error]

**Details**

The bluefusion.matchcode function generates a match code for an input string and outputs the match code to a field. The match code is a fuzzy representation of the input string. It can be used to do a fuzzy comparison of the input string to another string.

The function is a member of the bluefusion class. A bluefusion object can be declared as a variable and must then be initialized through a call to the function bluefusion_initialize. The member function bluefusion.loadqkb must then be called to load the contents of a Quality Knowledge Base (QKB) into memory and link that QKB with the bluefusion object. The bluefusion object then retains information about the QKB and the QKB locale setting.
When calling `bluefusion.matchcode` you must specify the name of a match definition. A match definition is an object in the QKB that contains context-specific reference data and logic used to generate a match code for the input string. Refer to your QKB documentation for information about which match definitions are available in your QKB.

You must also specify a level of sensitivity. The sensitivity indicates the level of fuzziness that is used when generating the match code. A higher sensitivity means that the match code is less fuzzy (yielding fewer false positives and more false negatives in comparisons), while a lower sensitivity means that the match code is more fuzzy (yielding fewer false negatives and more false positives in comparisons). The valid range for the sensitivity parameter is 50–95.

**Examples**

The following statements illustrate the `bluefusion.matchcode` function:

```plaintext
code
bluefusion bf
string output
bf = bluefusion_initialize()
bf.loadqkb("ENUSA")
bf.matchcode("Name", 85, "John Smith", output)
// Outputs match code "4B~2$$$$$$$$C@P$$$$$$"

bf.matchcode("Name", 85, "Johnny Smith", output)
// Outputs match code "4B~2$$$$$$$$C@P$$$$$$"
```

**bluefusion.matchscore Function**

The `bluefusion.matchscore` function takes two input strings along with the name of the match definition and outputs the sensitivity for the match strings.

**Category:** Blue Fusion

**Syntax**

`bluefusion.matchscore(definition_name, input1, input2, use_wildcards);`

**Arguments**

`definition_name`

- the name of the match definition to use

`input1`

- the first input string to check
input2

the second input string to check

use_wildcards

true if wildcards in generated match codes should be considered for the purpose of scoring

**Details**

The bluefusion.matchscore function determines the highest sensitivity value where two input strings generate the same match code.

**Examples**

The following statements illustrate the bluefusion.matchscore function:

```plaintext
bluefusion b;
b = bluefusion_initialize();
b.loadqkb("ENUSA");

integer x;
x = b.matchscore("Name", "John Jones", "John J. Jones", false);
```

**bluefusion.parse Function**

The bluefusion.parse function parses a string.

**Category:** Blue Fusion

**Syntax**

bluefusion.parse(string, string)

**Arguments**

string

a string that represents the string that needs to be separated into words; this can be specified as fixed string, field name, or expression

returns

a value, token, or tokenvalue from the parse function

**Details**

The bluefusion.parse function parses the input string into tokens. The first parameter is the name of the QKB parse definition. The second parameter is the string from which the tokens are parsed. This returns the number of tokens created. It returns 0 if it fails.
Example

The following statements illustrate the bluefusion.parse function:

```plaintext
/* Parse (using QKB CI 2013A) */
o = bf.parse("Name", "Mr. John Q Public Sr")

/* print all of the tokens available */
print (o & " tokens filled")
for i = 1 to o
begin
    bf.token(i, output)
    print ("token #" & i & " = " & output)
    bf.value(i, output)
    print ("value #" & i & " = " & output)
end

/* Get a token value by the name. */
bf.tokenvalue("Given Name", output)
print ("Given Name= " & output)
```

bluefusion.pattern Function

The bluefusion.pattern function generates a pattern for a string using a pattern analysis definition in the QKB.

Category: Blue Fusion

Syntax

bluefusion.pattern(pattern_def, input, result)

Arguments

pattern_def

  a string representing the name of a match definition in the QKB

input

  a string representing the input value or input field name

result

  a string representing the output field name

returns

  Boolean [1 = success, 0 = error]

Details

The bluefusion.pattern function generates a pattern for the input string and outputs the pattern to a field. The pattern is a simple representation of the characters in the input string. Such patterns can be used to perform pattern frequency analysis for a set of text strings.
The function is a member of the bluefusion class. A bluefusion object can be declared as a variable and must then be initialized through a call to the function bluefusion_initialize. The member function bluefusion.loadqkb must then be called to load the contents of a QKB into memory and link that QKB with the bluefusion object. The bluefusion object then retains information about the QKB and the QKB locale setting.

When calling bluefusion.pattern you must specify the name of a pattern analysis definition. A pattern analysis definition is an object in the QKB that contains logic used to generate a pattern for the input string. Refer to your QKB documentation for information about which pattern analysis definitions are available in your QKB.

**Examples**

The following statements illustrate the bluefusion.pattern function:

```plaintext
bluefusion bf
string output
bf = bluefusion_initialize()
bf.loadqkb("ENUSA")
bf.pattern("Character", "abc123", output)
// Outputs "aaa999"
```

### bluefusion.standardize Function

The bluefusion.standardize function generates a standard for a string using a standardization definition in the QKB.

**Category:** Blue Fusion

**Syntax**

```
bluefusion.standardize(stand_def, input, result)
```

**Arguments**

- **stand_def**
  - a string representing the name of a standardization definition in the QKB
- **input**
  - a string representing the input value or input field name
- **result**
  - a string representing the output field name

**returns**

Boolean [1 = success, 0 = error]
Details

The bluefusion.standardize function generates a normalized standard for an input string and outputs the standard to a field.

The function is a member of the bluefusion class. A bluefusion object can be declared as a variable and must then be initialized through a call to the function bluefusion_initialize. The member function bluefusion.loadqkb must then be called to load the contents of a QKB into memory and link that QKB with the bluefusion object. The bluefusion object then retains information about the QKB and the QKB locale setting.

When calling bluefusion.standardize, you must specify the name of a standardization definition. A standardization definition is an object in the QKB that contains context-specific reference data and logic used to generate a standard for the input string. Refer to your QKB documentation for information about which standardization definitions are available in your QKB.

Examples

The following statements illustrate the bluefusion.standardize function:

```java
bluefusion bf
string output
bf = bluefusion_initialize()
bf.loadqkb("ENUSA")
bf.standardize("Name", "mcdonald, mister ronald", output)
// Outputs "Mr Ronald McDonald"
```

**bluefusion.token Function**

The bluefusion.token function is used to get a token name for the index from a parse or extract function.

**Category:** Blue Fusion

**Syntax**

bluefusion.token(integer, string)

**Arguments**

**integer**

- an integer that represents a specific ASCII character; this can be specified as a numeric constant, a field name, or an expression

**string**

- a string that represents the string that needs to be parsed or extracted; this can be specified as fixed string, field name, or expression
returns

a token from the parse or extract function

**Details**

The bluefusion.token function is used to retrieve an extraction or parse token name for the index. This function will follow a parse or extract function.

**Examples**

**Example 1**

The following statements illustrate the bluefusion.token function following the bluefusion.extract function:

```plaintext
bluefusion bf
string output
integer o
integer i

/* Initialize BF */
bf = bluefusion_initialize()
bf.loadqkb("EN")

/* Extract using the "Product Attributes" Extraction definition (using QKB PD 2012A) */
o = bf.extract("Product Attributes", "DOOR RANCHERO WOOD 16X8 WHT")

/* print all of the tokens we got */
print (o & " tokens filled")
for i = 1 to o
begin
    bf.token(i, output)
    print ("token #" & i & " = " & output)
    bf.value(i, output)
    print ("value #" & i & " = " & output)
end
/* to get a token's value by its name... */
bf.tokenvalue("Colors", output)
print ("Colors = " & output)
```

**Example 2**

The following statements illustrate the bluefusion.token function following the bluefusion.parse function:

```plaintext
/* Parse (using QKB CI 2013A) */
o = bf.parse("Name", "Mr. John Q Public Sr")

/* print all of the tokens available */
print (o & " tokens filled")
for i = 1 to o
begin
    bf.token(i, output)
    print ("token #" & i & " = " & output)
    bf.value(i, output)
    print ("value #" & i & " = " & output)
end
```
/* Get a token value by the name. */
bf.tokenvalue("Given Name", output)
print ("Given Name= " & output)

**bluefusion.tokenvalue** Function

The bluefusion.tokenvalue function is used to get an attribute from the last parse or extract function.

**Category:** Blue Fusion

**Syntax**

```
bluefusion.tokenvalue(string, string)
```

**Arguments**

- **string**
  
  a string that represents the string that needs to be parsed or extracted; this can be specified as fixed string, field name, or expression

- **returns**
  
  a token value from the parse or extract function

**Details**

The bluefusion.tokenvalue function is used to retrieve an extraction or parse result value. The first parameter is the token name. It returns the attribute stored in that token in the second parameter. It returns true on success and false on failure (for example, if the token was not found). This function will follow a parse or extract function.

**Examples**

**Example 1**

The following statements illustrate the bluefusion.tokenvalue function following the bluefusion.extract function:

```c
bluefusion bf
string output
integer o
integer i

/* Initialize BF */
bf = bluefusion.initialize()
bf.loadqkb("EN")

/* Extract using the "Product Attributes" Extraction definition (using QKB PD 2012A) */
o = bf.extract("Product Attributes", "DOOR RANCHERO WOOD 16X8 WHT")

/* print all of the tokens we got */
```
print (o & " tokens filled")
for i = 1 to o
begin
  bf.token(i, output)
  print ("token #" & i & " = " & output)
  bf.value(i, output)
  print ("value #" & i & " = " & output)
end
/* to get a token's value by its name... */
bf.tokenvalue("Colors", output)
print ("Colors = " & output)

Example 2
The following statements illustrate the bluefusion.tokenvalue function following the bluefusion.parse function:

/* Parse (using QKB CI 2013A) */
o = bf.parse("Name", "Mr. John Q Public Sr")

/* print all of the tokens available */
print (o & " tokens filled")
for i = 1 to o
begin
  bf.token(i, output)
  print ("token #" & i & " = " & output)
  bf.value(i, output)
  print ("value #" & i & " = " & output)
end

/* Get a token value by the name. */
bf.tokenvalue("Given Name", output)
print ("Given Name= " & output)

bluefusion.value Function
The bluefusion.value function is used to retrieve the value from the last parse or extract function.

Category: Blue Fusion

Syntax
bluefusion.value(integer, string)

Arguments

integer

an integer that represents a specific ASCII character; this can be specified as a numeric constant, a field name, or an expression

string

a string that represents the string that needs to be extracted or parsed; this can be specified as fixed string, field name, or expression
returns

an integer that represents the number of words found

Details

The bluefusion.value function is used to retrieve an extraction or parse result. The first parameter is the index of a token. The second parameter receives the attribute that is stored in the token. The function returns true if it is able to get the token value. It returns false if it fails. This function follows a parse or extract function.

Examples

Example 1

The following statements illustrate the bluefusion.value function following the bluefusion.extract function:

```plaintext
bluefusion bf
string output
integer o
integer i
/* Initialize BF */
bf = bluefusion_initialize()
bf.loadqkb("EN")
/* Extract using the "Product Attributes" Extraction definition (using QKB PD 2012A) */
o = bf.extract("Product Attributes", "DOOR RANCHERO WOOD 16X8 WHT")
/* print all of the tokens we got */
print (o & " tokens filled")
for i = 1 to o
begin
   bf.token(i, output)
   print ("token #" & i & " = " & output)
   bf.value(i, output)
   print ("value #" & i & " = " & output)
end
/* to get a token's value by its name... */
bf.tokenvalue("Colors", output)
print ("Colors = " & output)
```

Example 2

The following statements illustrate the bluefusion.value function following the bluefusion.parse function:

```plaintext
/* Parse (using QKB CI 2013A) */
o = bf.parse("Name", "Mr. John Q Public Sr")
/* print all of the tokens available */
print (o & " tokens filled")
for i = 1 to o
begin
   bf.token(i, output)
   print ("token #" & i & " = " & output)
   bf.value(i, output)
```

print ("value #" & i & ") = " & output)
end

/* Get a token value by the name. */
bf.tokenvalue("Given Name", output)
print ("Given Name= " & output)

Boolean Functions

Boolean is a basic data type representing a true or false value.

Boolean variables can be declared in the following formats:

```plaintext
boolean b
b=true //sets boolean b to true
b='yes' //also sets boolean b to true
b=0 //sets boolean b to false
```

This data type is used when comparisons are made. Using AND or OR in an expression also results in a Boolean value.

Database Functions

To work with databases, use the DBConnect object in DataFlux Expression Engine Language (EEL). You can connect to data sources using built-in functions that are associated with the dbconnect object. You can also return a list of data sources, and evaluate data input from parent nodes.

- `dbconnect`
- `dbdatasources`

Overview of the dbconnect Object

The dbconnect object allows you to use the EEL to connect directly to a relational database system and execute commands on that system as part of your expression code. There are three objects associated with this functionality:

**dbconnection**

- a connection to the database

**dbstatement**

- a prepared statement

**dbcursor**

- a cursor for reading a result set

Releasing Objects

When objects are set to null, they are released. Depending on whether objects are defined as static or nonstatic, see Declaration of Symbols for additional details. When
symbols are automatically reset to null, you need to use the release() methods to explicitly release database objects.

**Global Functions**

**dbconnect([connect_string])**

Connects to a database, returns a dbconnection object.

**dbdatasources()**

Returns a list of data sources as a dbcursor. The data source includes:

**NAME**

a string containing the name of the data source

**DESCRIPTION**

a string containing the driver (shown in the ODBC Administrator and DataFlux Connection Administrator)

**TYPE**

an integer containing the subsystem type of the connection [1 = ODBC; 2 = DataFlux TKTS]

**HAS_CREDENTIALS**

a Boolean representing if the Save Connection exists

**USER_DESCRIPTION**

a string containing the user-defined description of the data source (defined in the ODBC Administrator and DataFlux Connection Administrator)

**Example**

```javascript
// list all data sources
dbcursor db_curs
db_curs = dbdatasources()
ncols = db_curs.columns()

while db_curs.next()
begin
for i_col=0 to ncols-1
begin
  colname = db_curs.columnname(i_col)
  coltype = db_curs.columnType(i_col)
  collength = db_curs.columnlength(i_col)
  colvalue = db_curs.valuestring(i_col)
  pushrow()
end
end

db_curs.release()
```
**DBConnection Object Methods**

**execute([sql_string])**

Executes an SQL statement and returns the number of rows affected

**tableinfo([table],[schema])**

Gets a list of fields for a table; the second parameter is optional

**tablelist()**

Gets a list of tables

**prepare([sql_string])**

Prepares a statement and returns a dbstatement object

**select([sql_string])**

Runs SQL and returns a dbcursor object

**begintransaction()**

Starts a transaction

**endtransaction([commit])**

Ends a transaction. If commit is true, the transaction is committed, otherwise it is rolled back

**release()**

Releases the connection explicitly

**DBStatement Object Methods**

**setparaminfo([param_index],[string_type],[size])**

Sets information for a parameter. String_type can be string, integer, real, dates, or Boolean. If string_type is string, size is the string length

**setparameter([param_index],[value])**

Sets the value of a parameter

**execute()**

Executes the statement and returns the number of rows affected

**select()**

Executes the statement and returns the results as a dbcursor
release()
    Explicitly releases the statement

**DBCursor Object Methods**

next()
    Retrieves the next record

release()
    Explicitly releases the cursor

columns()
    Returns the number of columns

columnname([index])
    Returns the name of the specified column (0-based index)

columntype([index])
    Returns the type of the specified column (0-based index)

columnlength([index])
    Returns the length of the specified column (0-based index)

valuestring([index])
    Returns the value of the specified column as a string (0-based index)

valuereal([index])
    Returns the value of the specified column as a real (0-based index)

valueinteger([index])
    Returns the value of the specified column as an integer (0-based index)

**Getting Table List from Database**

The following code lets you get a list of tables in a particular database.

```c
//Expression
string DSN
DSN="DataFlux Sample"
string connectStr
//Preparing the connection string
connectStr = "DSN=" & DSN

DBConnection dbConn
dbConn = dbConnect( connectStr )
```
string tablename
string datapath
string tcatalog
string tabletype

DBCursor cursTables

//Retrieve table information in a cursor
cursTables = dbConn.tablelist();

//Iterate through the cursor
while( cursTables.next() )
begin
    datapath = cursTables.valuestring(0); tcatalog =
    cursTables.valuestring(1); tablename = cursTables.valuestring(2);
    tabletype = cursTables.valuestring(3)
    pushrow()
end

cursTables.release();

**dbconnect Function**

The `dbconnect` function connects to a data source name (DSN) and returns a DBConnection object.

**Category:** Database

**Syntax**

dbconnect([connect_string])

**Arguments**

connect_string

    is the database connection information

**Details**

This function is used to connect to a database. The function returns a DBConnection object.

The connect string needs the data source name and, optionally, the data source type. If the data source type is not specified, it defaults to ODBC. Examples of connect strings:

"DSN=DataFlux Sample"
"DSN=DataFlux Sample;DFXTYPE=ODBC"
"DSN=Localized DSN for Federation Server data;DFXTYPE=TKTS"

📚 **Note:** Saved Connections can also be used as parameters to this function.
Examples

The following statements illustrate the dbconnect function:

```c
// Declare a dbconnection variable to contain the connection
// information
dbconnection my_database

// Use the dbconnect function to set a connection to the DataFlux Sample database
my_database = dbconnect("DSN=DataFlux Sample")
```

**dbdatasources Function**

The dbdatasources function returns a list of data sources as a dbcursor.

**Category:** Database

**Syntax**

```c
object/array = dbdatasources()
```

**Examples**

The following statements illustrate the dbdatasources function:

```c
// Declare a DBCursor variable
DBCursor cursDS

// Retrieve datasource information in a cursor
cursDS = dbdatasources()
```

**Data Input Functions**

DataFlux Expression Engine Language (EEL) provides built-in functions that allow you to evaluate data coming in from a parent node, as well as set the value of a field, and determine the type of field and the maximum length.

- `fieldcount`
- `fieldname`
- `fieldtype`
- `fieldvalue`
- `readrow`
- `rowestimate`
- `seteof`
- `setfieldvalue`

The fieldcount, fieldname, and fieldvalue functions allow you to dynamically access values from the parent node without knowing the names of the incoming fields.
fieldcount Function

The fieldcount function is a way of dynamically accessing values from the parent node without knowing the names of the incoming fields. Returns the number of incoming fields.

**Category:** Data Input

**Syntax**

`fieldcount()`

**Arguments**

- **Returns**
  - an integer, representing the number of incoming fields from the parent node

**Details**

Provides a way of dynamically accessing values from the parent node without knowing the names of the incoming fields. The function returns the number of incoming fields.

**Examples**

The following statements illustrate the fieldcount function:

```plaintext
// Declare a hidden integer for the for loop, initializing it to 0
hidden integer i
i = 0

// Increment through the data once for each column of data in the input data
for i = 1 to FieldCount()
```

fieldname Function

The fieldname function returns the name of a specific field output from the parent node.

**Category:** Data Input

**Syntax**

`fieldname(index)`

**Arguments**

- **index**
  - is the index into the incoming fields
returns a string, representing the name of a specific field output from the parent node

**Examples**

The following statements illustrate the fieldname function:

**Example 1**

```// Declare a string variable to contain the field name String Field3

// Use the Fieldname function to get the third field in the incoming data Field3 = Fieldname(3)
```

**Example 2**

```// Declare a hidden integer for the for loop, initializing it to 0 hidden integer i
i = 0

// Declare a string variable to contain the column names string column_name

// Create a table with a row for each column in the input data source for i = 1 to fieldcount()
begin
    column_name = fieldname(i)
pushrow()
end```

**fieldtype Function**

The fieldtype function returns the field type of a field output from the parent node. If the second parameter is supplied, it is set to the length in chars if the field type is string.

**Category:** Data Input

**Syntax**

`fieldtype(index [, length])`

**Arguments**

`index`

is the index into the incoming fields from the parent node. The second parameter is optional and set to the maximum string length in characters if the field type is a string

`length`

[optional] an integer that contains the length of the field if the field is of type string
returns

a string representing the data type of the specified field

Details

The fieldtype function determines the type and, optionally, the maximum length in characters (for string fields) based upon its index in the list of fields coming from the parent node. It returns a string representation of the field type (for example, integer or date).

Examples

The following statements illustrate the fieldtype function:

```plaintext
// Declare a hidden integer for the for loop, initializing it to 0
hidden integer i
i = 0

// Increment through the data a number of times equal to the number
// of fields in the data
for i = 1 to FieldCount()

// Check the type of each field in the data and take some action
if FieldType(i) == 'Date' then
```

fieldvalue Function

The fieldvalue function returns the value of a specified field as a string.

Category: Data Input

Syntax

string fieldvalue(integer)

Arguments

integer

is the index into the incoming fields

Examples

The following statements illustrate the fieldvalue function:

Example 1

```plaintext
// Declare a string variable to contain the third field value
String Value_Field3

// Use the Fieldvalue function to get the
// value in the third field of the
// incoming data
Value_Field3=Fieldvalue(3)
```
**Example 2**

```java
// Declare a hidden integer for the for loop, initializing it to 0
hidden integer i
i = 0

// Checks each field to see if the field is a name field and the value is numeric
for i = 1 to fieldcount()
begin
    if instr(lower(FieldName(i)),'name') then
        if isnumber(FieldValue(i)) then
            return true
        end
    end
```

**readrow Function**

The `readrow` function is a Data Job-only function. It reads the next row of data from the step above and fills the variables that represent the incoming step's data with the new values. It returns false if there are no more rows to read.

**Category:** Data Input

**Syntax**

```java
readrow()
```

**Arguments**

returns

a Boolean representing whether there are still values in the incoming step's data

[true = there are still rows in parent node; false = no more rows to read]

**Details**

📌 **Note:** The `readrow` function has no effect when called from a pre- or post-expression. When called from a pre-group or post-group expression, it can cause undesirable results.

**Examples**

The following statements illustrate the `readrow` function:

Assume that this step is below a step with a name field and the step outputs four rows, "John", "Paul", "George", and "Igor":

```java
// Declare a string to contain the "old" or "previous" value
string oldname

// Set the value of OLDNAME to whatever is in NAME
oldname = name

// Name has the value "John", oldname also contains "John"
```
// Use the READROW function to read in the next record
readrow()

    // OLDNAME is still "John", but NAME is now "Paul"

rowestimate Function

The rowestimate function sets the estimated total number of rows to be reported by this step.

Category: Data Input

Syntax

rowestimate(integer)

Arguments

integer

an integer, containing an estimate for the total numbers of rows that will be output from the step

returns

Boolean [true = success; false = error]

Details

The rowestimate function is employed by Data Jobs to estimate the number of records that will be output from the step.

Examples

The following statements illustrate the rowestimate function:

    // Declare a hidden integer for the number of output rows
    hidden integer nrows

    // Set the number of rows for the function
    nrows=100

    // This function estimates and sets the # of records that this step will report
    rowestimate(nrows)
**seteof Function**

The `seteof` function sets status to end of file (EOF), preventing further rows from being read in the step. If the parameter is true, the pushed rows are still returned.

**Category:** Data Input

**Syntax**

`seteof([return_pushrow])`

**Arguments**

`return_pushrow`

Boolean value; to specify whether pushed rows are still returned

**Details**

When `seteof()` is called, the node does not read any more rows from the parent node. If Generate rows when no parent is specified is checked, the node stops generating rows. Furthermore, if any rows have been pushed using `pushrow()`, they are discarded, and further calls to `pushrow()` have no effect. The exception to this is if `seteof(true)` is called. In this case, any pushed rows (whether pushed before or after the call to `seteof()`) are still returned to the node below. Notably, if further `pushrow()` calls occur after `seteof(true)` is called, these rows are returned as well. Also note that after `seteof()` is called, the post-group expression and the post-expression are still executed.

**Examples**

The following statements illustrate the `seteof` function:

```
seteof()
```

**setfieldvalue Function**

The `setfieldvalue` function sets the value of a field based on its index in the list of fields coming from the parent node. This is useful for enumerating through the fields and setting values.

**Category:** Data Input

**Syntax**

`setfieldvalue(integer,any)`
Arguments

integer

is the index into the incoming fields

any

is the value you want to set the field to

Details

The setfieldvalue function sets the value of a field based upon its index in the list of fields coming from the parent node. This is useful for enumerating through the fields and setting values.

Examples

The following statements illustrate the setfieldvalue function:

```eel
// Declare a hidden integer for the for loop, initializing it to 0, and a hidden date field
hidden integer i
i = 0
hidden date Date_Field

// Checks each field to see if it is a date field
for i = 1 to FieldCount()
if FieldType(i) == 'Date' then
begin
    Date_Field= FieldValue(i)
// If the date is in the future, then use SETFIELDVALUE to set the value to null
    if Date_Field > today()
    SetFieldValue(i,null)
end
```

Date and Time Functions

Dates, along with integers, reals, Booleans, and strings, are considered basic data types in DataFlux Expression Engine Language (EEL). Similar to other basic data types, EEL provides functions to perform operations on dates.

- `determine_type`
- `formatdate`
- `today`
- `todayGMT`
**determine_type Function**

The `determine_type` function returns the type of data that the input string represents.

**Category:** Date

**Syntax**

determine_type

**Arguments**

returns

string, integer, Boolean, date, or real

**Details**

This function is used to analyze a string to determine if it is one of the following options: string, integer, Boolean, date, or real.

**Examples**

The following statements illustrate the `determine_type` function:

**Example 1**

```plaintext
1000
```

**Results:** integer

**Example 2**

```plaintext
1000.5
```

**Results:** real

**formatdate Function**

The `formatdate` function returns a date formatted as a string.

**Category:** Date and Time

**Syntax**

formatdate(datevar,format)

**Arguments**

datevar

a date that needs to be formatted; this can be specified as field name
format

  a string that represents the format that needs to be applied; this can be specified as fixed string, field name, or expression

returns

  a string with the date formatted as a string

**Formats**

The format parameter can include any string, but the following strings are replaced with the specified values:

- YYYY: four-digit year
- YY: two-digit year
- MMMM: full month in proper case
- MMM: abbreviated three-letter month
- MM: two-digit month
- DD: two-digit day
- hh: hour
- mm: minute
- ss: second
- ms: millisecond

💡 **Note:** The format parameters are case sensitive.

**Details**

The formatdate function dates should be in the format specified by ISO 8601 (YYYY-MM-DD hh:mm:ss:ms) to avoid ambiguity. Remember that date types must start with and end with the # sign (for example, #12-February-2010#).

**Examples**

The following statements illustrate the formatdate function:

**Example 1**

```java
// Declare a date variable and initialize it to a value
date dateval
dateval = #2010-02-12#
// Declare the formatted date variable
string fmtdate
fmtdate = formatdate(dteval, "MM/DD/YY")
```

**Results:** 02/12/10
Example 2

// Declare a date variable and initialize
// it to a value
date dateval
dateval = #2010-02-12#
// Declare the formatted date variable
string fmtdate
fmtdate = formatdate(dateval, "DD MMM YYYY")

Results: February 12, 2010 12 Feb 2010

Example 3

// Declare a date variable and initialize
// it to a value
date dateval
dateval = #2010-02-12#
// Declare the formatted date variable
string fmtdate
fmtdate = formatdate(dateval, "MMMM DD, YYYY")

Results: February 12, 2010

Example 4

day_string=formatdate('date','DD');
month_string=formatdate('date','MM');
year_string=formatdate('date','YYYY');

int_number='date';
date_string=formatdate(int_number,"MMMM DD,YYYY");

df_date='date';

Results:

today Function

The today function returns the current data and time. This function is based on the local time zone.

Category: Date and Time

Syntax

today()
**Arguments**

returns

a date that represents the current date and time value

**Details**

The today function returns the current date and time value. For example, at 4:00 pm on February 12, 2010, the function would return the value "02/12/10 4:00:00 PM". Although it is represented as a character string, the actual value is a date value. For more information, see [Date Expressions](#).

Prior to using this function, you must first declare a date variable to contain the date/time value.

**Examples**

The following statements illustrate the today function:

```plaintext
// declare the date variable to contain the date and time
date currentdate

// Use the TODAY function to populate the date variable with the current
date and time
currentdate = today()
```

**todayGMT Function**

The todayGMT function returns the current date and time. This function is based on Greenwich Mean Time (GMT).

**Category:** Date and Time

**Syntax**

todayGMT()

**Arguments**

returns

a date and time combination that represents the current GMT date and time value

**Details**

The todayGMT function returns the current GMT date and time value. For example, at 4:00 pm on February 12, 2010, the function would return the value "02/12/10 4:00:00 PM". Although it is represented as a character string, the actual value is a date value. For more information see [Date Expressions](#).

Prior to using this function, you must first declare a date variable to contain the date/time value.
Examples
The following statements illustrate the todayGMT function:

```java
// declare the date variable to contain the date and time
date currentdate
// Use the TODAY function to populate the date variable with the current
date and time
currentdate = todayGMT()
```

Execution Functions
The following functions are available for the DataFlux Expression Engine Language (EEL).

- `pushrow`
- `setoutputslot`
- `sleep`

pushrow Function
The pushrow function pushes the current values of all symbols (this includes both field values for the current row and defined symbols in the code) to a stack.

Category: Execution

Syntax
```java
pushrow()
```

Arguments
returns
Boolean (true = success; false = error)

Details
The pushrow function pushes the current values of all symbols (this includes both field values for the current row and defined symbols in the code) to a stack. When the next row is requested, it is given from the top of the stack instead of being read from the step above. When a row is given from the stack, it is not to be processed through the expression again. When the stack is empty, the rows are read from above as usual. This function always returns true.

Examples
The following statements illustrate the pushrow function:

```java
string name
integer age
date Birthday
```
name="Mary"
age=28
Birthday=#21/03/1979#
pushrow()

name="Joe"
age=30
Birthday=#21/03/1977#
pushrow()

### sleep Function

Use the sleep function to set a sleep time at the specified number of milliseconds and runs the interrupt handler.

**Category:** Execution

**Syntax**

sleep(integer duration)

**Arguments**

duration

- an integer representing the number of seconds to pause

**Returns**

Boolean value [true = successful; false = unsuccessful]

**Details**

The sleep function causes the job to pause for the specified number of seconds.

**Examples**

The following statements illustrate the sleep function:

```plaintext
sleep(5)
```

**Results:** The job sleeps for 5 seconds

### External File Functions

Use the external file object to work with files in the DataFlux Expression Engine Language (EEL). Read and write operations are supported in the file object and there are additional functions for manipulating and working with files.

- close
- copyfile
Overview of the File Object

The file object can be used to open, read, and write files. A file is opened using the file object. For example:

```python
File f
f.open("c:\filename.txt","r")
```

In this example, the open() function opens filename.txt. The mode for opening the file is read. Other modes are "a" (append to end of file) and "w" (write). A combination of these switches can be used.

Executing Programs and File Commands

To execute programs, use the execute() function:

```python
execute(string)
```

For example, the following code changes the default permissions of a text file created by the Data Job Editor.

To execute the command in Microsoft Windows, enter:

```python
execute("/bin/chmod", "777", "file.txt")
```

Or, to execute from the UNIX shell, enter:

```python
execute("/bin/sh", "-c", "chmod 777 file.txt")
```
Running a Batch File by Using Execute Function

To invoke the MS-DOS command prompt, call the cmd.exe file. For example:

```//Expression
execute("cmd.exe", "/q", "/c", C:\BatchJobs.bat");
```

The following parameters can be declared:

- `/q` - Turns echo off
- `/c` - Executes the specified command for the MS-DOS prompt and then closes the prompt

**Note:** The expression engine handles the backslash character differently; it does not need to be escaped.

For example:

"C:\\Program Files\\DataFlux" should now be entered as "C:\Program Files\DataFlux"

**close Function**

The close function closes an open file.

**Category:** External file

**Syntax**

```fileobject.close(<filename>)
```

**Arguments**

`filename`

[optional] a string representing the name of the file to be closed; this can be specified as a fixed string, field name, or expression

**returns**

Boolean [1 = success, 0 = error]

**Details**

The close method closes the file that is provided in the filename parameter. If the filename parameter is blank, the currently open file (which was opened by using a fileobject.open call) will be closed.
Examples
The following statements illustrate the close function:

```plaintext
file myfile
if ( myfile.open("data.txt") ) then ...
rc = myfile.close()
```

copyfile Function
The copyfile function copies a file.

Category: External file

Syntax
`copyfile(source_file, target_file)`

Arguments
```
source_file
    a string representing the name of the file to be copied; this can be specified as a fixed string, field name, or expression
target_file
    a string representing the name of the file to be written; this can be specified as a fixed string, field name, or expression
```

returns
```
Boolean [true = success, false = error]
```

Details
The copyfile function copies a file. If the target file exists, the copyfile function will overwrite the target file.

Examples
The following statements illustrate the copyfile function:

```
string source_file
string target_file
boolean rc_ok

source_file="C:\mydata.txt"
target_file="C:\mydata_copy.txt"

rc_ok = copyfile(source_file, target_file)
```
**deletefile Function**

The deletefile function deletes the specified file.

**Category:** External file

**Syntax**

deletefile(filename)

**Arguments**

filename

a string representing the name of the file to be deleted; this can be specified as a fixed string, field name, or expression

**Returns**

Boolean [true = success, false = error]

**Details**

The deletefile function deletes a file from disk. If the file did not exist then the return code will be set to false.

**Examples**

The following statements illustrate the deletefile function:

```plaintext
string filename
boolean rc_ok

filename="C:\mydata_copy.txt"

rc_ok = deletefile(filename)
```

**execute Function**

The execute function runs the specified program.

**Category:** External file

**Syntax**

execute(filename<option1, option2,..., <option N>)

**Arguments**

filename

a string representing the file (or command) to be executed; this can be specified as a fixed string, field name, or expression
option1…N

[optional] a string representing options that are passed to the file (command) that is going to be executed; this can be specified as a fixed string, field name, or expression

returns

an integer, which is the existing status of the program that was executed. If an error occurs, such as the program not found then -1 is returned

**Details**

The execute function invokes a file (or operating system command).

🔍 **Note:** Use single quotation marks for any parameter with embedded spaces. For example:

```
Execute('cmd.exe','/C','"C:\Program Files (x86)\DataFlux\DMStudio\studio25\bin\dmpexec.cmd"','-j','"C:\Repository24\batch_jobs\my data job.ddf"','-l','"C:\temp\log my data job.log"')
```

**Examples**

The following statements illustrate the `execute` function:

```plaintext
integer rc

// Windows example
rc = execute("cmd.exe", "/Q", "/C", "C:\mybatchjob.bat")
// /Q turns echo off
// /C executes the command specified by filename and then closes the prompt

// Unix example
rc = execute("/bin/sh", "-c", "chmod 777 file.txt")
```

**filedate Function**

The filedate function checks the creation or modification date of a file.

**Category:** External file

**Syntax**

`filedate(filename<datetype>)`

**Arguments**

`filename`

a string representing the name of the file for which the creation or modification date needs to be retrieved; this can be specified as a fixed string, field name, or expression
datetype

[optional] a Boolean that specifies whether the creation date or the modification date needs to be returned; this can be specified as a fixed string, field name, or expression [true = modification date, false = creation date] returns a date

Details

The filedate function returns either the creation date or the most recent modification date of a file. If the file does not exist a (null) value is returned. If the parameter datetype is omitted the function behaves like the value would have been specified as false.

Examples

The following statements illustrate the filedate function:

```plaintext
string filename
date creation_date
date modification_date

filename="C:\mydata.txt"

modification_date = filedate(filename, true)
creation_date = filedate(filename, false)
```

fileexists Function

The fileexists function checks whether a specified file exists.

Category: External file

Syntax

fileexists(filename)

Arguments

filename

a string representing the name of the file for which the existence is to be checked; this can be specified as a fixed string, field name, or expression

returns

Boolean [true = success, false = error]

Details

The fileexists function returns true if the file exists.
Examples

The following statements illustrate the fileexists function:

```plaintext
string filename
boolean rc_ok
filename = "C:\doesexist.txt"
rc_ok = fileexists(filename) // outputs "true" if file exists
```

movefile Function

The movefile function moves or renames a specified file.

Category: External file

Syntax

movefile(old_file_name, new_file_name)

Arguments

old_file_name

- a string representing the name of the file to be moved; this can be specified as a fixed string, field name, or expression

new_file_name

- a string representing the name (including location) where the file will be moved; this can be specified as a fixed string, field name, or expression

returns

Boolean (true = success, false = error)

Details

The movefile function moves a file. The directory structure must already be in place for the function to move the file to its new location. If the target file already exists, the file will not be moved and false will be returned.

Examples

The following statements illustrate the movefile function:

```plaintext
string old_file_name
string new_file_name
boolean rc_ok

old_file_name = "C:\mydata_copy.txt"
new_file_name = "C:\TEMP\mydata_copy.txt"
rc_ok = movefile(old_file_name, new_file_name)
```
**open Function**

The open function opens a specified file.

**Category:** External file

**Syntax**

```
fileobject.open(filename<openmode>)
```

**Arguments**

- **filename**
  
  a string representing the name of the file to be opened. If the file does not exist, it will be created. This parameter can be specified as a fixed string, field name, or expression

- **openmode**
  
  [optional] a string representing the openmode to be used. This can be specified as a fixed string, field name, or expression [a = append, r = read, w = write, rw = read and write]

**returns**

a Boolean [1 = success, 0 = error]

**Details**

The open method opens the file that is provided in the filename parameter. If the file does not exist and an openmode is specified containing either an "a" or "w" then the file will be created. If the openmode is not specified a value of false will be returned.

When openmode is "a", the writebytes and writeline methods write at the end of the file, unless seekbegin, seekcurrent, or seekend methods are used to adjust the position in the file. In that case the information is written at the current position in the file.

If an openmode of "w" is used, the writebytes and writeline methods write at the current position in the file and potentially overwrite existing information in the file.

**Examples**

The following statements illustrate the open function:

```
file myfile
if ( myfile.open("data.txt") ) then ...
```
**position Function**

The position function returns the current position of the cursor in a file, which is the number of bytes from the beginning of the file.

**Category:** External file

**Syntax**

```plaintext
fileobject.position()
```

**Arguments**

returns

an integer representing the current position (offset) from the beginning of the file

**Details**

The position method returns the current position of the cursor in a file. Combined with the seekend() method, it can be used to determine the size of a file.

**Examples**

The following statements illustrate the position function:

```plaintext
file f
integer byte_size

f.open("C:\filename.txt", "r")
f.seekend(0) // position cursor at end of file

// or if you want to test return codes for the method calls
// boolean rc_ok
// rc_ok = f.open("C:\filename.txt", "r")
// rc_ok = f.seekend(0) // position cursor at end of file

// The integer variable byte_size will have
// the size of the file in bytes
byte_size = f.position()

f.close()
```

**readbytes Function**

The readbytes function reads a certain number of bytes from a file.

**Category:** External file

**Syntax**

```plaintext
fileobject.readbytes(number_of_bytes, buffer)
```
Arguments

number_of_bytes

an integer specifying the number of bytes that need to be read from the file. This parameter can be specified as a number, field name, or expression

buffer

a string that will contain the bytes that were read. This parameter can be specified as a fixed string, field name, or expression

returns

Boolean [1 = success, 0 = error]

Details

The readbytes method reads the specified number of bytes from a file starting at the current position of the file pointer. The file pointer will be positioned after the last byte read. If the buffer is too small only the first bytes from the file are put into the buffer. It returns true on success otherwise false is returned.

This method is normally used to read binary files. The various format functions can be used to convert the binary information that was read.

Note that this method also reads EOL characters. When reading a windows text file like this:

```
C:\filename.txt
abc
def
```

A readbytes(7, buffer) statement causes the field buffer to contain the following value "abc\n de", which consists of all the information from the first line (3 bytes), followed by a CR and a LF character (2 bytes) which is represented by "\n", followed by the first 2 bytes from the second line. To read text files, use the readline() method.

Examples

The following statements illustrate the readbytes function:

```
string input
file f

f.open("C:\filename.txt", "r")
f.readbytes(7, input)

// or if you want to test return codes for the method calls
// boolean rc_ok
// rc_ok = f.open("C:\filename.txt", "r")
// rc_ok = f.readbytes(7, input)
```
**readline Function**

The readline function reads the next line from an open file.

**Category:** External file

**Syntax**

fileobject.readline()

**Arguments**

returns

- a string containing the line that was read from the file

**Details**

The readline method reads the next line of data from an open file. A maximum of 1024 bytes are read. The text is returned. Null is returned if there was a condition such as end of file.

**Examples**

The following statements illustrate the readline function:

```java
file f
string input
f.open("C:\filename.txt", "r")
input=f.readline()
f.close()
```

**seekbegin Function**

The seekbegin function sets the file pointer to a position starting at the beginning of the file. Returns true on success, false otherwise. The parameter specifies the position.

**Category:** External file

**Syntax**

fileobject.seekbegin(position)

**Arguments**

position

- an integer specifying the number of bytes that need to be moved forward from the beginning of the file. Specifying a 0 means the start of the file. This parameter can be specified as a number, field name, or expression
returns

Boolean (1 = success, 0 = error)

Details

The seekbegin method moves the file pointer to the specified location in the file, where 0 indicates the start of the file. It returns true on success; otherwise, false is returned. Specifying 1 means that reading starts after the first position in the file.

Examples

The following statements illustrate the seekbegin function:

```plaintext
file f
string input
f.open("C:\filename.txt", "r")
input = f.readline()
// return the pointer to the beginning of the file
// and read the first line again
f.seekbegin(0)
f.readline()
f.close()
```

seekcurrent Function

The seekcurrent function sets the file pointer to a position in the file relative to the current position in the file.

Category: External file

Syntax

fileobject.seekcurrent(position)

Arguments

position

an integer specifying the number of bytes that need to be moved from the current position in the file. Positive values specify the number of bytes to move forward, negative values specify the number of bytes to move backward. This parameter can be specified as a number, field name, or expression

returns

Boolean (1 = success, 0 = error)
**Details**

The `seekcurrent` method moves the file pointer from the current position in the file. This method is useful when reading binary files that contain offsets to indicate where related information can be found in the file.

**Examples**

The following statements illustrate the `seekcurrent` function:

```c
file f
string input

f.open("C:\filename.txt", "r")

input = f.readline()

// The file contains 3 bytes per record followed by a CR and LF character
// So move the pointer 3+2=5 positions back to read the beginning of
// the first line and read it again.

f.seekcurrent(-5)

f.readline()

f.close()
```

**seekend Function**

The `seekend` function sets the file pointer to a position in the file counted from the end of the file.

**Category:** External file

**Syntax**

```c
fileobject.seekend(position)
```

**Arguments**

`position`

an integer specifying the number of bytes that need to be back from the end of the file. Specifying a 0 means the end of the file. This parameter can be specified as a number, field name, or expression

**Returns**

Boolean (1 = success, 0 = error)

**Details**

The `seekend` method moves the file pointer backwards the number of bytes that were specified, where 0 indicates the end of the file. It returns true on success otherwise false is returned.

You can use this method when writing information at the end of the file.
You can also use this method in combination with the position() method to determine the size of a file.

**Examples**

The following statements illustrate the seekend function:

```plaintext
file f
f.open("C:\filename.txt", "rw")

// write information to the end of the file
f.seekend(0)
f.writeline("This is the end ")
f.close()
```

**writebytes Function**

The writebytes function writes a certain number of bytes to a file.

**Category:** External file

**Syntax**

fileobject.writebytes(number_of_bytes, buffer)

**Arguments**

- **number_of_bytes**
  - an integer specifying the number of bytes that will be written to the file. This parameter can be specified as a number, field name, or expression

- **buffer**
  - a string that contains the bytes that need to be written. This parameter can be specified as a fixed string, field name, or expression

**returns**

- an integer representing the number of bytes written

**Details**

The writebytes method writes the specified number of bytes to a file starting at the current position in the file. This method will overwrite data that exists at the current position in the file. If the current position in the file plus the number of bytes to be written is larger than the current file size, then the file size will be increased.

When buffer is larger than number_of_bytes specified, then only the first number_of_bytes from buffer will be written. The file needs to be opened in write or append mode for this method to work. The method returns the actual number of bytes written.
This method is normally used to write binary files. To write text files, the `writeline()` method can be used.

**Examples**

The following statements illustrate the `writebytes` function:

```plaintext
string input
file f

string = "this is longer than it needs to be"
f.open("C:\filename.txt", "rw")
// This will write to the beginning of the file
// Only the first 10 bytes from the string will be written
// If the file was smaller than 10 bytes it will be automatically
// appended
f.writebytes(10, input)

f.close()
```

**writeline Function**

Use the `writeline` function to write a line to a file.

**Category:** External file

**Syntax**

```
fileobject.writeline(string)
```

**Arguments**

- `string`  
  a string specifying the information that needs to be written to the file. This parameter can be specified as a fixed string, field name, or expression

**returns**

- a Boolean [1 = success, 0 = error]

**Details**

The `writeline()` method writes the string at the current position in the file. This method overwrites data that exists at the current position in the file. If the current position in the file plus the length of the string is larger than the current file size, then the file size is increased.

The file needs to be opened in write or append mode for this method to work.
Examples
The following statements illustrate the writeline function:

```java
file f
f.open("C:\filename.txt", "a")
f.writeline("This text will be appended to the file")
f.seekbegin(0)
f.writeline("Using seekbegin(0) and Append will still cause the info to be written at the start of the file")
f.close()
```

Information and Conversion Functions
The following information and conversion functions are available for the DataFlux Expression Engine Language (EEL).

- `isalpha`
- `isblank`
- `isnull`
- `isnumber`
- `locale`
- `tobool`
- `typeof`

**isalpha Function**
The isalpha function returns true if the expression is a string made up entirely of alphabetic characters.

**Category:** Information and Conversion Functions

**Syntax**
`isalpha (in_string)`

**Arguments**
`string`

- a string of characters to be searched for any alphabetic characters

**Returns**

Boolean value; true if the "in_string" contains only alpha characters; false otherwise
Details

The isalpha function returns true if "in_string" is determined to be a string containing only alpha characters.

Examples

The following statements illustrate the isalpha function:

Example 1

```c
// Expression
string letters
letters="lmnop"
string mixed
mixed="1a2b3c"

string alphatype
alphatype=isalpha(letters) // returns true
string mixedtype
mixedtype=isalpha(mixed) // returns false
```

Example 2

```c
string all_Alpha
all_Alpha="abcdefghijklmnopqrstuvwxyz"

string non_Alpha
non_Alpha="%^&*0123456789"

string error_message1
string error_message2
if (NOT isalpha(all_Alpha))
   error_message1 = "all_Alpha string contains alpha numeric characters"
else
   error_message1 = "all_Alpha string contains alpha numeric characters"
if(isalpha(non_Alpha))
   error_message2= "non_Alpha string contains alpha numeric characters"
else
   error_message2= "non_Alpha string does not contain alpha numeric characters"
```

Example 3

```c
string all_Alpha
string error_message
all_Alpha="abcdefghijklmnopqrstuvwxyz"
if (isalpha(all_Alpha))
   begin
      error_message= "alpha strings were identified as alpha"
   end
```
isblank Function

The isblank function checks to see if an argument contains a blank, empty value. When the argument value is blank, the function returns true; otherwise, it returns false.

**Category:** Information and Conversion Functions

**Syntax**

boolean isblank (argvalue)

**Arguments**

argvalue

  string, date, integer, real

returns

  Boolean [true = successful, false = failed]

**Details**

The isblank function takes the following argument types: string, date integer, real.

**Examples**

The following statements illustrate the isblank function:

```plaintext
ingter x
string y
date z
string error_message1
string error_message2
string error_message3

y="Hello"

if(isblank(x) )
  error_message1 = "Integer x is blank"
else
  error_message1= "Integer x is not blank"

if( isblank(y) )
  error_message2 =" String y value is blank"
else
  error_message2 =" String y value is not blank"

if( isblank(z) )
  error_message3 =" Date z value is blank"
else
  error_message3 =" Date z value is not blank"
```
**isnull Function**

The isnull function checks to see if an argument value contains a null value. When the argument value is null, the function returns true; otherwise, it returns false.

**Category:** Information and Conversion Functions

**Syntax**

boolean isnull(argvalue)

**Arguments**

argvalue

  string, date, integer, real

returns

  Boolean [true = successful, false = failed]

**Details**

The isnull function takes the following argument types: string, date integer, real.

⚠️ **Note:** When comparing data variables in the Expression Engine, a null value is always considered to be less than a non-null value. This is different from some DBMSs where null values are not considered to be less than non-null values.

**Examples**

The following statements illustrate the isnull function:

**Example 1**

```plaintext
// Expression
if State <> "NC" OR isnull(State)
    return true
else
    return false
```

**Example 2**

```plaintext
integer x
string y
string error_message1
string error_message2

y="Hello"

if(isnull(x) )
    error_message1 = "Integer x is null"
else
    error_message1= "Integer x is not null"
```
if( isnull(y) )
    error_message2 = "String y value is null"
else
    error_message2 = "String y value is not null"

**isnumber Function**

The isnumber function checks to see if an argument value contains a numerical value. When the argument value is a number, the function returns true; otherwise, it returns false.

**Category:** Information and Conversion Functions

**Syntax**

Boolean isnumber(argvalue)

**Arguments**

argvalue

    string, date, integer, real

returns

    Boolean [true = successful, false = failed]

**Details**

The isnumber function takes the following argument types: string, date integer, real.

**Examples**

The following statements illustrate the isnumber function:

```plaintext
string x
string y
date z
string error_message1
string error_message2
string error_message3

x ="5"
y="Hello"
z="01/01/10"

if(isnumber(x) )
    error_message1 = "String x is a number"
else
    error_message1= "String x is not a number"

if( isnumber(y) )
    error_message2 = " String y value is a number"
else
    error_message2 =" String y value is not a number"
```
if( isnumber(z) )
    error_message3 = "String z value is a number"
else
    error_message3 = "String z value is not a number"

locale Function

The locale function sets the locale; this affects certain operations such as uppercasing and date operations. It will return the previous locale. If no parameter is passed, the current locale is returned. The locale setting is a global setting.

Category: Information

Syntax

string locale()

string locale("locale_string")

Arguments

returns

    string value of the current locale setting

Details

If a parameter is specified, it is set; otherwise, it is retrieved. If setting, the old locale is retrieved.

The following values can be set in the locale() function:

- You can use a two-character abbreviation for the US and UK locales
- A three-character abbreviation can be used for some countries, like GER, FRA, or DEU

Here are some examples:

    my_locale = locale("DEU")
    my_locale = locale("German")
    my_locale = locale("German_Germany")
    my_locale = locale("German_Germany.1252")

The locale() function returns the current setting using Country_Language.codepage notations.

📝 Note: If you use ("iso8601"), the date is set in the ISO8601 format.
Examples

The following statements illustrate the locale function:

```java
string currentSetting
string newSetting

currentSetting = locale();
newSetting = locale("FRA");
```

**tobolean Function**

The toboolean function converts the argument to a Boolean value.

**Category:** Information and Conversion Functions

**Syntax**

Boolean toboolean(value)

**Arguments**

value

is passed in as one of the following: real, integer, string, or date

returns

a Boolean value is returned if value can be converted to a Boolean value

**Examples**

The following statements illustrate the toboolean function:

```java
boolean convertedValue
integer result
result = 1
convertedValue = toboolean(result)
Print (convertedValue)
```

**typeof Function**

The typeof function identifies the data type of the passed in value.

**Category:** Information and Conversion Functions

**Syntax**

string typeof(in_value)
Arguments
returns

string identifier for the value type:

  Boolean values return Boolean
  integer values return integer
  real values return real
  string values return string

Details

The typeof Function identifies the data type of in_value.

Examples

The following statements illustrate the typeof function:

Example 1

// Expression
string hello
hello="hello"

boolean error
error=false

// variable that will contain the type
string type
type=typeof(hello)

// type should be string
if(type<>"string") then
  error=true

Example 2

string content
content = "Today is sunny"

hidden integer one
one =1

hidden real pi
pi=3.1415962

hidden boolean test
test=false

hidden string type

type= typeof(content);
if (type == "string")
    begin
        error_message="The data type for variable 'Content' is string"
    end

type=typeof(one)
if (type == "integer")
    begin
        error_message="The data type for variable 'one' is integer"
    end

type= typeof(pi);
if (type == "real")
    begin
        error_message="The data type for variable 'real' was real"
    end

type= typeof(test);
if (type == "boolean")
    begin
        error_message="The data type for variable 'test' was boolean"
    end

Logging Functions

The following logging functions are available for the DataFlux Expression Engine Language (EEL).

- **logmessage**
- **print**
- **raiseerror**
- **sendnodestatus**

**logmessage Function**

The logmessage function prints a message to the log.

**Category:** Logging

**Syntax**

logMessage(string message)

**Arguments**

message

- a string representing the text of the message to be written to the log

**Returns**

Boolean [true = success, false = error]
Details
The logmessage function is used to send a message to the log file.

Examples
The following statements illustrate the logmessage function:

```
logmessage("This message will go to the log file")
```

print Function
The print function prints the string to the step log. If the second parameter is true, no linefeeds will be appended after the text.

Category: Logging

Syntax
```
print(string[, no linefeed])
```

Arguments
- **string** is the text to be printed; this can be specified as a text constant or a field name
- **no linefeed** [optional] the second Boolean determines whether or not linefeeds will be printed to the log after the text

Returns
- Boolean [true = success; false = error]

Examples
The following statements illustrate the print function:

```
// Declare a string variable to contain the input value
string input

// Set the string variable to a value
// Use the PRINT function to write a note to the log
input='hello'
print('The value of input is ' & input)
```
**raiseerror Function**

The `raiseerror` function prints a message to the run log.

**Category:** Logging

**Syntax**

```plaintext
boolean raiseerror(string usererror)
```

**Arguments**

`usererror`

- is a string that is printed to the jobs output

**Returns**

- Boolean value

**Details**

The `raiseerror` function raises a user-defined error. Users can define a condition and then use `raiseerror` to stop the job and return an error message when the condition occurs. This is useful for evaluating problems unique to an installation. The user can then search for the error message to see if the associated condition was responsible for stopping the job.

**Examples**

The following statements illustrate the `raiseerror` function:

```plaintext
raiseerror("user defined error")
```

**Macro Variable Functions**

Macros (or variables) are used to substitute values in a job. This might be useful if you want to run a job in different modes at different times. For example, you might want to have the job run every week, but read from a different file every time that it runs. In this situation, you would specify the filename with a macro rather than the actual name of the file. Then, set that macro value either on the command line (if running in batch) or by using another method.

- `getvar`
- `setvar`
- `varset`
Using Macro Variables

All of the settings in the DataFlux configuration file are represented by macros in the Data Job Editor. For example, the path to the QKB is represented by the macro BLUEFUSION/QKB. To use a macro in a job, enter it with double percent signs before and after the value. For example:

Old value:

```
C:\myfiles\inputfile01.txt
```

Using macros, you enter instead:

```
%%MYFILE%%
```

You can also use the macro to substitute some part of the parameter; for example, C:\myfiles\%%MYFILE%%. A macro can be used anywhere in a job where text can be entered. If a Data Job step (such as a drop-down list) prevents you from entering a macro, go to the Advanced tab and enter it there. After you enter a macro under the Advanced tab, you get a warning if you try to return to the standard property dialog. Depending on your macro, you might need to avoid the standard property dialog and use the advanced dialog thereafter. If the property value is plain text, you can return to the standard dialog.

You can choose to use variables for data input paths and filenames in the Data Job Expression node. You can declare macro variables by any of these ways:

- entering them in the Macros folder of the Administration riser bar
- editing the macro.cfg file directly
- specifying a file location when you launch a job from the command line

When you add macros using the Administration riser, Data Management Studio directly edits the macro.cfg file. If you edit the macro.cfg file directly, you can also add multiple comments.

Command line declarations override the macro variable values declared in app.cfg. The results from Expression are determined by the code in the Expression Properties dialog.

Specifically, the value of a macro is determined in one of the following ways:

- In the first case, if you are running in batch in Windows, the -VAR or -VARFILE option lets you specify the values of the macros. For example:

```
-VAR "key1=value1,key2=value2"
-VARFILE "C:\mymacros.txt"
```

**Note:** The return code can be checked by creating a batch file, then checking the errorlevel in the batch file by using:

```
IF ERRORLEVEL [return code variable] GOTO
```
If the return code is not set, it returns a 0 on success and 1 on failure. The return code can be set using the \texttt{RETURN\_CODE} macro.

- In the second case, the file contains each macro on its own line, followed by an equal sign and the value.
  - If running in batch on UNIX, all current environment variables are read in as macros.
  - If running Data Jobs in Windows, the values specified in \texttt{Tools > Options > Global} are used.
  - If running the Data Management Server, the values can be passed in the SOAP request packet.
  - If using an embedded job, the containing job can specify the values as parameters.
  - The app.cfg file can be used to store additional values. These values are always read regardless of which mode is used.

### Using \texttt{getvar()} and \texttt{setvar()}

Macro variable values can be read within a single function using the \texttt{%my\_macro%} syntax. If you are using more than one expression in your job, use \texttt{getvar()} to read variables and \texttt{setvar()} to read and modify variables. With \texttt{getvar()} and \texttt{setvar()}, changes to the value persist from one function to the next. Note that changes affect only that session of the Data Job Editor and are not written back to the configuration file.

The following table contains information about predefined macros:

<table>
<thead>
<tr>
<th>Predefined Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_JOBFILENAME</td>
<td>The name of the current job.</td>
</tr>
<tr>
<td>_JOBPATH</td>
<td>The path of the current job.</td>
</tr>
<tr>
<td>_JOBPATHFILENAME</td>
<td>The path and filename to the current job.</td>
</tr>
<tr>
<td>TEMP</td>
<td>The path to the temporary directory.</td>
</tr>
</tbody>
</table>

\textbf{Note:} For \texttt{setvar()}, if you set a macro in an expression step on a page, the new value cannot be reflected in nodes on that page. This is because those nodes have already read the old value of the macro and might have acted upon it (such as opening a file before the macro value was changed). This issue arises only from using \texttt{setvar()}; thus, \texttt{setvar()} is useful only for setting values that are read on following pages or from other expression nodes with \texttt{getvar()}.

### \texttt{getvar} Function

The \texttt{getvar} function returns runtime variables. These are variables that are passed into DataFlux Data Management Studio on the command line using \texttt{-VAR} or \texttt{-VARFILE}.

\textbf{Category:} Macro Variable
Syntax
getvar(string[, string])

Arguments
string

The first parameter is the name of the variable and is not case sensitive. The second parameter is the value that is returned if the variable does not exist.

Details
The getvar function returns variables that are passed into DataFlux Data Management Studio on the command line using -VAR or -VARFILE.

Examples
The following statements illustrate the getvar function:

```java
testInParam=getvar("DF_String_Input")
File f
f.open("%%DataFlowTargets%%DF_String_Input.txt", "w")
f.writeline("DF_String_Input = "&testInParam)
seteof()
f.close()
```

setvar Function
The setvar function sets the Data Job macro variable value, indicated by the first parameter, to the values in the second parameter. Returns true.

Category: Macro Variable

Syntax
setvar(macroname, value)

Arguments
macroname

Sets the macro named in macroname to value. The macroname argument is a string

value

The value argument can be any of the following: real, integer, string, date, or Boolean

returns

Boolean value; true if macro was set to new value
Examples
The following statements illustrate the setvar function:

```plaintext
string macroName

macroName = "myMacro"
newValue = 10

success=setvar(macroName, newValue)
```

**varset Function**
The varset function sets the Data Job macro variable value specified by the first parameter. Returns true.

**Category:** Macro Variable

**Syntax**
varset(macroname, value)

**Arguments**
macroname

Sets the macro named in macroname to value. The macroname argument is a string

value

The value argument can be any of the following: real, integer, string, date, or Boolean

returns

Boolean value; true if macro was set to new value

**Examples**
The following statements illustrate the varset function:

```plaintext
varset("myMacroName", "newValue");
```

**Mathematical Functions**
The following mathematical functions are available for the DataFlux Expression Engine Language (EEL).

- **abs**
- **ceil**
abs Function

The abs function returns the absolute value of a number.

**Category:** Mathematical

**Syntax**

```
abs(argument)
```

**Arguments**

argument

- a real that can be specified as a numeric constant, field name, or expression

**Details**

The abs function returns a nonnegative number that is equal in magnitude to the magnitude of the argument.

**Examples**

The following statements illustrate the abs function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x = abs(3.5)</td>
<td>// outputs 3.5</td>
</tr>
<tr>
<td>x = abs(-7)</td>
<td>// outputs 7</td>
</tr>
<tr>
<td>x = abs(-3*1.5)</td>
<td>// outputs 4.5</td>
</tr>
</tbody>
</table>

ceil Function

The ceil function returns the smallest integer that is greater than or equal to the argument.

**Category:** Mathematical
**Syntax**

ceil(argument)

**Arguments**

argument

a real that can be specified as a numeric constant, field name, or expression

returns

a real that represents the smallest integer that is greater than or equal to the argument

**Details**

The ceil function returns the smallest integer that is greater than or equal to the argument, also called rounding up (ceiling).

**Examples**

The following statements illustrate the ceil function:

```
  x = ceil(3.5)  // outputs 4
  x = ceil(-3.5) // outputs -3
  x = ceil(-3)   // outputs -3
  x = ceil(-3*1.5) // outputs -4
```

**floor Function**

The floor function returns the largest integer that is less than or equal to the argument.

**Category:** Mathematical

**Syntax**

floor(argument)

**Arguments**

argument

a real that can be specified as a numeric constant, field name, or expression
returns

a real that represents the largest integer that is less than or equal to the argument

**Details**

The floor function returns the largest integer that is less than or equal to the argument. This is also called rounding down.

**Examples**

The following statements illustrate the floor function:

```
x = floor(3.5)  // outputs 3
x = floor(-3.5) // outputs -4
x = floor(-3)   // outputs -3
x = floor(-3*1.5) // outputs -5
```

**max Function**

The max function returns the maximum value of a series of values.

**Category:** Mathematical

**Syntax**

`max(argument1 <, argument2,...,argument N>)`

**Arguments**

`argument1`

a real that can be specified as a numeric constant, field name, or expression

`argument2..N`

[optional] a real that can be specified as a numeric constant, field name, or expression

**returns**

a real that represents the maximum value of the series of input values

**Details**

The max function returns the maximum value of a series of values. The function returns null if all values are null.
Examples

The following statements illustrate the max function:

```plaintext
x = max(1, 3, -2)  // outputs 3
x = max(1, null, 3)  // outputs 3
x = max(-3)  // outputs -3
x = max(4, -3*1.5)  // outputs 4
```

min Function

The min function returns the minimum value of a series of values.

Category: Mathematical

Syntax

```
min(argument1 <, argument2, ...,argument N>)
```

Arguments

argument1

a real that can be specified as a numeric constant, field name, or expression

argument2..N

[optional] a real that can be specified as a numeric constant, field name, or expression

returns

a real that represents the minimum value of the series of input values

Details

The min function returns the maximum value of a series of values. The function returns null if all values are null.

Examples

The following statements illustrate the min function:

```plaintext
x = min(1, 3, -2)  // outputs -2
x = min(1, null, 3)  // outputs 1
x = min(-3)  // outputs -3
x = min(4, -3*1.5)  // outputs -4.5
```
**pow Function**

The pow function raises a number to the specified power.

**Category:** Mathematical

**Syntax**

pow(x, y)

**Arguments**

x

a real that can be specified as a numeric constant, field name, or expression

y

a real that can be specified as a numeric constant, field name, or expression

**Returns**

a real that represents x raised to the power y ($x^y$)

**Details**

The pow function raises x to the power y ($x^y$).

**Examples**

The following statements illustrate the pow function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x = pow(5,2)</td>
<td>// outputs 25</td>
</tr>
<tr>
<td>x = pow(5,-2)</td>
<td>// outputs 0.04</td>
</tr>
<tr>
<td>x = pow(16,0.5)</td>
<td>// outputs 4</td>
</tr>
</tbody>
</table>

**round Function**

The round function rounds a number to the nearest number with the specified decimal places.

**Category:** Mathematical

**Syntax**

round(argument <decimals>)
**Arguments**

**argument**

a real that can be specified as a numeric constant, field name, or expression

decimals

[optional] specifies a numeric constant, field name, or expression representing the amount of decimals to provide in the result of the rounding operation

**returns**

a real that represents the argument rounded to the nearest number with the specified decimal places

**Details**

The round function rounds the argument to the nearest number with the specified number of decimals. If no value is provided for decimals, 0 is assumed. A positive value for decimals is used to round to the right of the decimal point. A negative value is used to the left of the decimal point.

**Examples**

The following statements illustrate the round function:

\[
x = \text{round}(1.2345,1) \\
// outputs 1.2
\]

\[
x = \text{round}(1.449,2) \\
// outputs 1.45
\]

\[
x = \text{round}(9.8765,1) \\
// outputs 9.9
\]

\[
x = \text{round}(9.8765) \\
// outputs 10
\]

**Node Functions**

The following node functions are available for the DataFlux Expression Engine Language (EEL).

- `raiseevent`
- `pctcomplete`
- `sendnodestatus`
- `setoutputslot`
- `uniqueid`
**raiseevent Function**

The `raiseevent` function raises the specified event; pass an arbitrary number of key value pairs for event data.

**Category:** Node

**Syntax**

```plaintext
raiseevent(event_name, <key1, value1>, ..., <keyN, valueN>)
```

**Arguments**

- `event_name`  
  a string representing the name of the event to be raised

- `key1...keyN`  
  [optional] a string representing a name of key

- `value1...valueN`  
  [optional] a string representing a value for the associated key

**Returns**

Boolean value; true if the event was successfully raised; false otherwise

**Details**

The `raiseevent` function raises an event. The first parameter is the name of the event to raise. There is another process job node to catch the event. In that node, you can specify the name of the event to catch. Subsequent parameters are event data in the form of key/value. The keys and values are arbitrary, but they must come in pairs. For example, you might have the function with three parameters (name, key, value) or five parameters (name, key, value, key, value) and so on.

**Examples**

The following statements illustrate the `raiseevent` function:

```plaintext
//!event INFO_MISSING  
raiseevent("INFO_MISSING", "FILE", "OK", "FIELDS", "NO DATE")
```

**pctcomplete Function**

The `pctcomplete` function reports to the user interface the estimated percent complete.

**Category:** Node
Syntax
pctcomplete

Arguments
returns
    integer

Details
This function is used to view the estimated percent complete for a process flow or data flow.

sendnodestatus Function
The sendnodestatus function sends a node status.

Category: Node

Syntax
sendnodestatus(status key, statusvalue)

Arguments
status key
    a string representing the name of the status key available value is:
    "_PCT_COMPLETE" //percent complete
    "_OVERALL" //overall status

status value
    a string representing the value of the status key

returns
    Boolean value; true if the sendnodestatus was successful; false otherwise

Details

🎉 Note: The sendnodestatus function is applicable only in a process job.

The sendnodestatus function tells the process job engine of the status of the node. If an expression is going to run for a long time it is a good idea for it to send its status. It takes two parameters, a status key, and a status value.
Available keys are:

```
"__PCT_COMPLETE" // percent complete
"__OVERALL" // overall status (suitable for displaying on the ui with a node)
```

**Examples**

The following statements illustrate the sendnodestatus function:

```
integer i
for i = 1 to 100
begin
  sleep (100)
  sendnodestatus ("__PCT_COMPLETE", i)
end
```

**setoutputslot Function**

The setoutputslot function sets output slot to slot. This will become the output slot when the expression exits.

**Category:** Node

**Syntax**

```
setoutputslot(slot)
```

**Arguments**

`slot`

an integer representing the active output slot when the expression node exits

**Returns**

Boolean [true = success; false = error]

**Details**

📝 **Note:** The setoutputslot function is only applicable in a process job.

The setoutputslot function tells the node (the expression node in which it is running) to exit on the specified slot. In a process job, if you follow a node by two other nodes, you specify a slot for each. For example 0 and 1. If you run setoutputslot(1) it tells the process job to continue with the node that is linked at slot 1. If setoutputslot is not called, it exits on 0 by default.
Examples
The following statements illustrate the setoutputslot function:

```plaintext
if tointeger(counter) <= 5 then setoutputslot(0)
else setoutputslot(1)
```

uniqueid Function
The uniqueid function returns a unique identifier.

**Category:** Date

**Syntax**
uniqueid

**Arguments**
returns
  string

**Details**
This uniqueid function string is used to uniquely identify a row of data on a single machine or multiple machines. It is available for process and data flows.

Regular Expression Functions
The regular expression (regex) object allows you to perform regular expression searches of strings in DataFlux Expression Engine Language.

- `compile`
- `findfirst`
- `findnext`
- `matchlength`
- `matchstart`
- `replace`
- `substringcount`
- `substringlength`
- `substringstart`
**compile Function**

This compile function compiles a valid regular expression using the encoding indicated.

**Category:** Regular Expression

**Syntax**

```
r.compile(regex, encoding)
```

**Arguments**

- `regex` is a Perl-compatible regular expression

- `encoding` is a string that defines the encoding constant shown in the table below. Use a value from the Encoding column (see Encoding). This input is optional. Not including this parameter instructs DataFlux to use the default encoding for the operating system

**Returns**

1 (true) if the regular expression compilation was successful, 0 (false) if regular expression compilation failed. Failure could be due to an incorrectly formatted regular expression or possibly an invalid encoding constant

**Details**

The compile function is used with a regular expression object. You must define a regular expression object first as a variable before you can use compile to use a PERL-compatible regular expression. Regular expressions can be used to do advanced pattern matching (and in some cases pattern replacement). Use the other functions listed below to find patterns in a given string (which can be a variable), determine how long the matching patterns are, and to replace patterns where desired.

For performance reasons, it is best to compile a regular expression in a preprocessing step in the Expression node. This means that the regular expression is compiled just once before data rows are processed by the expression node.

🔍 **Note:** The sample code in this section generally places the `compile()` function on the expression tab with the rest of the expression code for clarity.

In some cases, you might need to have the regular expression compiled before every row is evaluated. For example, you can use a variable to define the regular expression that you want to compile. The variable might come from the data row itself, and you would need to recompile the regular expression for each row to have the pattern searching work correctly.
Take care to design regular expressions that find patterns only for which you want to search. Poorly written regular expression code can require a lot of additional processing that can negatively impact performance.

**Examples**

The following statements illustrate the compile regex function:

```javascript
// You must define a regex object
regex r
// Then compile your regular expression
// This example will match any single digit in an input string
r.compile("[0-9]", "ISO-8859-1")
// Terminate the expression node processing
seteof()
```

### findfirst Function

The findfirst function searches the specified string for a pattern match using an already compiled regular expression.

**Category:** Regular Expression

**Syntax**

```
findfirst(input)
```

**Arguments**

- **input**
  
  is a string value in which you want to search for the pattern defined by your compiled regular expression. This can be an explicit string ("MyValue") or this can be a variable already defined in your expression code or passed to your expression node as a column from a previous node (MyValue or "My Value")

  **Restriction:** Must be non-null and not blank

**returns**

- Boolean: 1 (true) if a pattern match was found, 0 (false) if no pattern match was found

**Details**

The findfirst function indicates if one or more pattern matches were found in the input. This function can be used to enter a logical loop that pulls out a series of
matched patterns from an input string. A false value indicates that no match is found and that processing can continue.

**Examples**

The following statements illustrate the `findfirst` regex function:

```plaintext
Note: This example can be run in a stand-alone expression node if the "Generate rows when no parent is specified" option is selected. If passing data to this node, turn this setting off and remove the `seteof()` function. Unless stated otherwise, all code shown should be typed in the **Expression** tab of the Expression node.

```plaintext
// You must define a regex object
regex r
// Then compile your regular expression. This one will match any single
// uppercase letter
r.compile("[A-Z]")
// If a pattern match is found this will evaluate to 1 (TRUE)
if r.findfirst("Abc")
// Print the output to the statistics file. You must run
// this job for stats to be written. A preview will not generate
// a message in the log.
print("Found match starting at " & r.matchstart() & " length " &
r.matchlength())
// Terminate the expression node processing
seteof()
```

**findnext Function**

This `findnext` function continues searching the string for the next match after using the `findfirst()` function.

**Category:** Regular Expression

**Syntax**

```
r.findnext(input)
```

**Arguments**

input

is a string value in which you want to search for the pattern defined by your compiled regular expression. This can be an explicit string ("MyValue") or this can be a variable already defined in your expression code or passed to your expression node as a column from a previous node (MyValue or "My Value")

**Restriction:** Must be non-null and not blank

returns

Boolean: 1 (true) if a pattern match was found, 0 (false) if no pattern match was found
Details

The `findnext` function indicates that another pattern match has been found after `findfirst()` has been used. Using a "While" statement loop lets you iterate through all potential pattern matches using this function as long as the return value is equal to true.

Examples

The following statements illustrate the `findnext` regex function:

```plaintext
// Define some string variables
string MyString
string MySubString

// Set one to some sample input
MyString = "DwAwTxAxPyLyUzXz"

// You must define a regex object
regex r
// Then compile your regular expression
// This one will match any single uppercase letter
r.compile("[A-Z]"
// Find the first pattern match
if r.findfirst(MyString)
begin
    // Pull the pattern from MyString and place it into MySubString
    MySubString = mid(MyString, r.matchstart(), r.matchlength())
    // Use pushrow to create new rows - this is purely for the sake of
    // clarity in the example
    pushrow()
    // Create a while loop that continues to look for matches
    while r.findnext(MyString)
    begin
        // Pull the pattern from MyString and place it into MySubString
        // again
        MySubString = mid(MyString, r.matchstart(), r.matchlength())
        // Just for display again
        pushrow()
    end
end
// Terminate the expression node processing
seteof(true)
// Prevent the last pushrow() from showing up twice
return false
```

**matchlength Function**

The `matchlength` function returns the length of the last pattern match found.

**Category:** Regular Expression
Syntax

r.matchlength()

Arguments

There is no input value. This function operates on the pattern match substring found using findfirst() or findnext().

returns

a positive integer value that represents the number of characters found to be a pattern match of the regular expression. NULL is returned if there is no substring currently under consideration and therefore no length to return.

Details

The matchlength function should be used to determine the length in characters of the currently matched pattern found with findfirst() or findnext(). Used in conjunction with matchstart(), this function can be used to find matching substrings and populate variables in your expression code.

Examples

The following statements illustrate the matchlength regex function:

(Paint) Note: This example can be run in a stand-alone expression node if the "Generate rows when no parent is specified" option is selected. If passing data to this node instead, turn this setting off and remove the seteof() function. Unless stated otherwise, all code shown should be typed in the Expression tab of the Expression node.

// Define some variables
integer i
string MyString

//Supply some values for the variables
i = 0
MyString = "DataFlux"
// Uncomment the line below to see the value of variable i change
//MyString = "Data_Management_Studio"

//You must define a regex object
regex r
//Then compile your regular expression.
// This expression will match as many "word" characters as it can
// (alphanumerics and underscore)
r.compile("\w*")
// If a pattern match is found then set i to show the length of
// the captured substring
if r.findfirst(MyString) then i = r.matchlength()
// Terminate the expression node processing
seteof()
**matchstart Function**

The matchstart function returns the location of the last pattern match found.

**Category:** Regular Expression

**Syntax**

```r.matchstart()```

**Arguments**

`input`

is a string value in which you want to search for the pattern defined by your compiled regular expression

**Restriction:** Must be non-null and not blank

`returns`

an integer value that represents the starting character position of the substring found to be a pattern match of the regular expression. NULL is returned if there is no substring currently under consideration and therefore no length to return

**Details**

The matchstart function returns the position of a substring that has been matched to the regular expression. A logical loop can be used to iterate through all matching substrings and the `matchlength()` function can be used in conjunction with matchstart to pull out matching substrings so that comparisons can be made to other values or to values stored in other variables.

**Examples**

The following statements illustrate the matchstart regex function:

🔍 **Note:** This example can be run in a stand-alone expression node if the "Generate rows when no parent is specified" option is selected. If passing data to this node instead, turn this setting off and remove the `seteof()` function. The `pushrow` statements are also unnecessary if passing data values in to the node as data rows. Unless stated otherwise, all code shown should be typed in the Expression tab of the Expression node.

```// Define some string variables
string MyString
string MySubString
integer StartLocation

// Set one to some sample input
MyString = "00AA111BBB2222CCCC"
// Will hold the starting location of matched patterns
```
StartLocation = 0

// You must define a regex object
regex r
// Then compile your regular expression
// This one will match any single uppercase letter
r.compile("[A-Z]+)
// Find the first pattern match
if r.findfirst(MyString)
begin
    // Pull the pattern from MyString and place it into MySubString
    MySubString = mid(MyString, r.matchstart(), r.matchlength())
    // Use pushrow to create new rows - this is purely for the sake of
    // clarity in the example
    pushrow()
    // Create a while loop that continues to look for matches
    while r.findnext(MyString)
    begin
        // Pull the pattern from MyString and place it into MySubString
        // again
        MySubString = mid(MyString, r.matchstart(), r.matchlength())
        // Set StartLocation to the starting point of each pattern found
        StartLocation = r.matchstart()
        // Just for display again
        pushrow()
    end
end
// Terminate the expression node processing
seteof(true)
// Prevent the last pushrow() from showing up twice
return false

replace Function

The replace function searches for the first string, and replaces it with the second. This differs from the replace() function used outside of the regex object.

Category: Regular Expression

Syntax

r.replace(input, replacement value)

Arguments

input

is a string value in which you want to search for the pattern defined by your compiled regular expression. This can be an explicit string ("MyValue") or this can be a variable already defined in your expression code or passed to your expression node as a column from a previous node (MyValue or "My Value")

Restriction: Must be non-null and not blank

replacement value

is a string value that takes the place of the substring matched by the compiled regular expression
returns

a string value with the replacement made if a replacement could indeed be
made given the regular expression in play and the value supplied for input. If
no replacement could be made, then the original value for input is returned.

Details

This replace regular expression function extends the capabilities of the regex object
from simply finding patterns that match a regular expression to replacing the
matching substring with a new value. For example, if you wanted to match all
substrings that match a pattern of two hyphens with any letter in between (-A-, -B-, etc) and replace
with a single letter (Z for instance), you would compile your
regular expression for finding the hyphen/letter/hyphen pattern, and then use "Z" as
the replacement value of the replace() function passing in a variable or string value
for input.

There are limitations to this functionality. You cannot easily replace the matched
substring with a "captured" part of that substring. In the earlier example, you would
have to parse the matched substring after it was found using findfirst() or findnext()
and create the replacement value based on that operation. But matched patterns
can be of variable length so guessing the position of parts of substrings can be tricky.

Compare this to similar functionality provided with using regular expressions as part
of standardization definitions. In the case of QKB definitions that use regular
expressions, much smarter replacements can be made because the regular
expression engine allows you to use captured substrings in replacement values.

Examples

The following statements illustrate the replace regex function:

💡 Note: This example can be run in a stand-alone expression node if
the "Generate rows when no parent is specified" option is selected. If
passing data to this node, turn this setting off and remove the seteof()
function. Unless stated otherwise, all code shown should be typed in
the Expression tab of the Expression node.

```plaintext
//Define two string variables
string MyString
string MyNewString

// Provide a value for MyString
MyString = "12Flux"

// Defined a regular expression object variable
regex r
// Compile a regular expression that will look for a series of digits
// either 2 or 3 digits long
r. compile("\d{2,3}"")
// Use the replace function to place "Data" in place of the found
// pattern and save that in a new string variable.
// If you change MyString to 1234 or 12345 you can see the
// difference in how the pattern is found
MyNewString = r.replace(MyString,"Data")
```
substringcount Function

The substringcount function returns the number of subpatterns found to have matched the pattern specified by the compiled regular expression. The regular expression has to contain subpatterns that can be pattern matched.

Category: Regular Expression

Syntax

r.substringcount()

Arguments

There is no input value.

returns

a positive integer that specifies the number of substrings found to have matched the regular expression. A "0" is returned if no substrings are found

Details

The substringcount function should be used to find the total number of subpatterns found to have matched the regular expression. Normally simple regular expressions evaluate to "1" but if you design regular expressions using subpatterns then this function will return the number found.

The syntax for using subpatterns is open and closed parentheses. For example:

(Mr|Mrs) Smith

Here the subpattern is the "(Mr|Mrs)" and using this function returns the number "2" for the count of substrings since the entire string is considered the first subpattern, and the part inside the parentheses is the second subpattern.

This function can provide the upper number for a logical loop using the FOR command so your code can iterate through the matched subpatterns for comparison to other values.

Examples

The following statements illustrate the substringcount regex function:

🌈 Note: This example can be run in a stand-alone expression node if the "Generate rows when no parent is specified" option is selected. If passing data to this node, turn this setting off and remove the `seteof()` function. The `pushrow` statements are also unnecessary if passing data values in to the node as data rows. Unless stated otherwise, all code shown should be typed in the Expression tab of the Expression node.
//Define some variables
string MyString
string MyString2
integer i
integer SSC
integer SSS
integer SSL

// Set initial values for variables
i = 0
SSS = 0
SSL = 0
SSC = 0

// Sample input string
MyString = "DataFlux Data Management Studio"

// Define a regular expression object
regex r
// Then compile it - notice the use of ( and )
r. compile("(DataFlux|DF) Data Management (Studio|Platform)")
// Find the first substring
if r.findfirst(MyString)
begin
    // Use the "substring" functions to find the number of substrings
    SSC = r.substringcount()
    // Loop through substrings
    for i = 1 to SSC
    begin
        // Then pull out substrings
        SSS = r.substringstart(i)
        SSL = r.substringlength(i)
        MyString2 = mid(MyString, SSS, SSL)
        // Place the substrings in a data row
        pushrow()
        end
    end
    // Terminate the expression node processing
    seteof(true)
    // Prevent the last pushrow() from showing up twice
    return false
end

substringlength Function

The substringlength function returns the length of the nth captured subpattern. The regular expression must contain subpatterns that can be pattern matched.

Category: Regular Expression

Syntax

r.substringlength(nth)
Arguments

nth

is a positive integer value that specifies the substring whose length you want to be returned

**Restriction:** Must be non-null and not blank

returns

a positive integer value that represents the number of characters found to be a subpattern match of the regular expression. NULL is returned if there is no substring currently under consideration and therefore no length to return.

Details

The substringlength can be used to find the length in characters of the subpattern specified by passing an integer value as input. See the Details for the function `substringcount()` for more information on working with subpatterns.

Most simple regular expressions do not have subpatterns, and this function behaves similarly to `matchlength()`. However if your regular expression does use subpatterns, then this function can be used to find the length of individually captured subpatterns found within the overall matched pattern.

Examples

The following statements illustrate the substringlength regex function:

📚 **Note:** This example can be run in a stand-alone expression node if the "Generate rows when no parent is specified" option is selected. If passing data to this node instead, turn this setting off and remove the `seteof()` function. The `pushrow` statements are also unnecessary if passing data values in to the node as data rows. Unless stated otherwise, all code shown should be typed in the Expression tab of the Expression node.

```plaintext
//Define some variables
string MyString
string MyString2
integer i
integer SSC
integer SSS
integer SSL

// Set initial values for variables
i = 0
SSS = 0
SSL = 0
SSC = 0

// Sample input string
MyString = "DataFlux Data Management Studio"
```
// Define a regular expression object
regex r
// Then compile it - notice the use of ( and )
r.compile("(DataFlux|DF) Data Management (Studio|Platform)")
// Find the first substring
if r.findfirst(MyString)
begin
  // Use the "substring" functions to find the number of substrings
  SSC = r.substringcount()
  // Loop through substrings
  for i = 1 to SSC
    begin
      // Then pull out substrings
      SSS = r.substringstart(i)
      SSL = r.substringlength(i)
      MyString2 = mid(MyString, SSS, SSL)
      // Place the substrings in a data row
      pushrow()
    end
  end
  // Terminate the expression node processing
  seteof(true)
  // Prevent the last pushrow() from showing up twice
  return false
end

**substringstart Function**

The substringstart function returns the start location of the nth captured subpattern. The regular expression has to contain subpatterns that can be pattern matched.

**Category:** Regular Expression

**Syntax**

```plaintext
r.substringstart(nth)
```

**Arguments**

nth

is a positive integer value that specifies the subpattern whose starting location you want to be returned

**Restriction:** Must be non-null and not blank

returns

a positive integer value that represents the starting character location of a matched subpattern. NULL is returned if there is no substring currently under consideration and therefore no length to return

**Details**

The substringstart takes the input integer that you supply and returns a starting location for the subpattern represented by that input integer. Use `substringcount()` to determine the number of subpatterns under consideration. Use `substringlength()`
with this function to pull out the matched subpatterns and use them in evaluation logic of your expression code.

Most simple regular expressions will not have subpatterns and this function will behave similarly to `matchstart()`. However if your regular expression does use subpatterns, then this function can be used to find the starting point of individually captured subpatterns found within the overall matched pattern.

**Examples**

The following statements illustrate the `substringstart regex function`:

```plaintext
Note: This example can be run in a stand-alone expression node if the "Generate rows when no parent is specified" option is selected. If passing data to this node instead, turn this setting off and remove the `seteof()` function. The `pushrow` statements are also unnecessary if passing data values in to the node as data rows. Unless stated otherwise, all code shown should be entered in the Expression tab of the Expression node.

//Define some variables
string MyString
string MyString2
integer i
integer SSC
integer SSS
integer SSL

// Set initial values for variables
i = 0
SSS = 0
SSL = 0
SSC = 0

// Sample input string
MyString = "DataFlux Data Management Studio"

// Define a regular expression object
regex r
// Then compile it - notice the use of ( and )
r. compile("(DataFlux|DF) Data Management (Studio|Platform)"
// Find the first substring
if r.findfirst(MyString)
begin
    // Use the "substring" functions to find the number of substrings
    SSC = r.substringcount()
    // Loop through substrings
    for i = 1 to SSC
    begin
        // Then pull out substrings
        SSS = r.substringstart(i)
        SSL = r.substringlength(i)
        MyString2 = mid(MyString, SSS, SSL)
        // Place the substrings in a data row
        pushrow()
    end
end
// Terminate the expression node processing
seteof(true)
```
// Prevent the last pushrow() from showing up twice
return false

Repository Functions

The following repository function is available for the DataFlux Expression Engine Language (EEL).

- **is_preview_mode**

**is_preview_mode Function**

The is_preview_mode function returns TRUE if the job is executed in preview mode; otherwise, it returns FALSE.

**Category:** Repository

**Syntax**

`is_preview_mode()`

**Details**

Returns TRUE if the job is executed in preview mode.

Search Functions

The following search function is available for the DataFlux Expression Engine Language (EEL).

- **inlist**

**inlist Function**

The inlist function returns true if the target parameter matches any of the value parameters.

**Category:** Search

**Syntax**

`inlist (target_parameter1, value_parameter1, value_parameter2)`

**Arguments**

- **target_parameter**
  
  string, integer or date value; this value will be "searched" value_parameter
value_parameter

string, integer or date value; this value will be searched for among the check_parameter arguments

returns

Boolean [true = successful, false = failed]

Details

The first parameter is compared against each of the value_parameters. True is returned if a match is found.

Examples

The following statements illustrate the inlist function:

```plaintext
string error_message

integer a
a=5
integer b
b=5

if (inlist(a,3,5)<>true)
    error_message="integer 5 not found in argument list of 3,5 "
else
    error_message="integer 5 was found in argument list of 3,5 "

print(error_message,false)
```

String Functions

There are several functions available in DataFlux Expression Engine Language (EEL) that affect the built-in string data type.

- **aparse**
- **asc**
- **chr**
- **compare**
- **edit_distance**
- **has_control_chars**
- **instr**
- **left**
- **len**
- **lower**
- match_string
- mid
- mkdir
- parse
- pattern
- replace
- right
- rmdir
- sort
- sort_words
- todate
- tointeger
- toreal
- tostring
- trim
- upper
- username
- vareval

**aparse Function**

The `aparse` function parses a string into words and returns the number of words found.

**Category:** String

**Syntax**

`aparse(string,delimiter,word_list)`

**Arguments**

`string`

A string that represents the string that needs to be separated into words; this can be specified as fixed string, field name, or expression

**Restriction:** string should not be null, it causes a runtime error
delimiter

A string that contains the character to be used as delimiter when separating the string into words; this can be specified as fixed string, field name, or expression.

**Restriction:** If multiple characters are specified only the last character is used.

word_list

A string array that represents the words that were found during parsing, this is specified as a field name.

returns

An integer that represents the number of words found.

**Details**

The `aparse` function fills the parameter `word_list` with a list of words using the delimiter specified. The function returns the number of words found.

If parameter `string` is empty (""`) a value of 1 is returned and the `word_list` has one element that contains an empty string.

The `parse` function is similar. It returns individual string fields instead of a string array, the string fields must be specified as part of the function invocation. The `aparse` function does not have this restriction and can therefore be used when the maximum number of words is not known in advance.

**Examples**

The following statements illustrate the `aparse` function:

```plaintext
string = "one:two:three"
delimiter = ":"
nwords = aparse(string, delimiter, word_list) // outputs 3
first_word = word_list.get(1) // outputs "one"
last_word = word_list.get(nwords) // outputs "three"
```

**asc Function**

The `asc` function returns the position of a character in the ASCII collating sequence.

**Category:** String

**Syntax**

`asc(string)`
**Arguments**

string

a string that represents the character that needs to be found in the ASCII collating sequence; this can be specified as character constant, field name, or expression

**Restriction:** if multiple characters are specified only the first character is used

returns

an integer that represents the position of a character in the ASCII collating sequence

**Details**

The asc function returns the position of the specified character in the ASCII collating sequence.

See [Appendix A: ASCII Values](#) for a complete list of ASCII values.

**Examples**

The following statements illustrate the asc function:

```asc_value = asc("a") // outputs 97
character_content = chr(97) // outputs the letter "a"
```

The following examples support Unicode codepoints:

😊 **Note:** The following examples use Greek characters but any supported Unicode character set might be used.

```string(l) character
// See http://www.unicode.org/charts/ for a list of Unicode codepoints
character=asc(913) // Greek capital letter Alpha
character=asc(914) // Greek capital letter Beta
```

**chr Function**

The chr function returns an ASCII character for an ASCII code.

**Category:** String

**Syntax**

chr(n)
**Arguments**

n

an integer that represents a specific ASCII character; this can be specified as a numeric constant, a field name, or an expression

returns

a string that represents the n-th character in the ASCII collating sequence

**Details**

The chr function returns n-th character in the ASCII collating sequence.

See [Appendix A: ASCII Values](#) for a complete list of ASCII values.

**Examples**

The following statements illustrate the chr function:

```plaintext
character_content = chr(97) // outputs the letter "a"
ascii_value = asc("a") // outputs 97
```

The following examples support Unicode codepoints:

📝 **Note:** The following examples use Greek characters but any supported Unicode character set can be used.

```plaintext
string input_string // this is a string that could contain greek characters
string(1) character
boolean greek_capital
for i=1 to len(input_string)
begin
    character=mid(input_string,i,1)
    if chr(character)>=913 and chr(character)<=939 then
        greek_capital=true
end
```

**compare Function**

The compare function returns the result of comparing two strings.

**Category:** String

**Syntax**

```plaintext
compare(string1, string2[,modifier])
```
Arguments

string1

a string to be used in the comparison; this can be specified as string constant, field name, or expression

string2

a string to be used in the comparison; this can be specified as string constant, field name, or expression

modifier

[optional] a Boolean string that modifies the action of the compare function; this can be specified as string constant, field name, or expression [true = case insensitive, false = case sensitive]

returns

an integer representing the result of a lexicographical comparison of the two strings:

[-1 = string1 < string 2, 0 = string1 equals string2, 1 = string1 > string2]

Details

The compare function compares two strings lexicographically. If the parameter modifier is omitted, the function behaves like a value of false was specified.

If you just want to check whether two strings are equal, it is more efficient to use the == operator, for example:

if string1 == string2 then match=true

The match_string function can be used to do string comparisons using wildcards.

Examples

The following statements illustrate the compare function:

// hallo comes before hello when alphabetically sorted
rc = compare("hello", "hallo") // outputs 1

// Hello comes before hello when alphabetically sorted
rc = compare("Hello", "hello") // outputs -1

modifier = null
rc = compare("Hello", "hello", modifier) // outputs -1
rc = compare("Hello", "hello", true) // outputs 0
**edit_distance Function**

The edit_distance function returns the number of corrections that would need to be applied to transform one string into the other.

**Category:** String

**Syntax**

\[ \text{edit_distance}(\text{string1}, \text{string2}) \]

**Arguments**

- **string1**
  
a string to be used in the comparison; this can be specified as string constant, field name, or expression

- **string2**
  
a string to be used in the comparison; this can be specified as string constant, field name, or expression

**returns**

an integer representing the number of corrections that would need to be applied to turn string1 into string2

**Details**

The edit_distance function returns the number of corrections that need to be applied to transform string1 into string2.

**Examples**

The following statements illustrate the edit_distance function:

```plaintext
distance = edit_distance("hello", "hllo")  
// outputs 1

distance = edit_distance("hello", "hlelo")  
// outputs 2

distance = edit_distance("hello", "hey")  
// outputs 3
```

**has_control_chars Function**

The has_control_chars function determines if the string contains control characters.

**Category:** String
Syntax

boolean has_control_chars(string targetstring)

Arguments

targetstring

is a string to be search for existence of any ASCII control characters

returns

Boolean [true = successful; false = failed]

Details

The has_control_chars function can be used to identify non-printable ASCII controls characters as found on the ASCII character table.

Note: The only control character the has_control_chars function does not detect is 0 (null character).

See Appendix B: ASCII Control Characters for a list of control characters.

Examples

The following statements illustrate the has_control_chars function:

```java
boolean result_1
string error_message1

string test
test="Contol character: "&chr(13)
result_1=has_control_chars(test)
if(result_1)
  error_message1 = "test string contains control character"
else
  error_message1 = "test string does not contain control character"
```

instr Function

The instr function returns the position of one string within another string.

Category: String

Syntax

instr(source,excerpt<count>)
**Arguments**

source

a string that represents the string of characters to search for in source; this can be specified as string constant, field name, or expression

count

[optional] an integer that specifies the occurrence of excerpt to search for; this can be specified as numeric constant, field name, or expression. For example, a value of 2 indicates to search for the second occurrence of excerpt in source

returns

an integer representing the position at which the excerpt was found

**Details**

The instr function searches source from left to right for the count-th occurrence of excerpt. If the string is not found in source, the function returns a value of 0.

**Examples**

The following statements illustrate the instr function:

```java
source = "This is a simple sentence."
excerpt = "is"

position = instr(source, excerpt, 1) // outputs 3
position = instr(source, excerpt, 2) // outputs 6
```

**left Function**

The left function returns the leftmost characters of a string.

**Category:** String

**Syntax**

`left(source,count)`

**Arguments**

source

a string to be searched; this can be specified as string constant, field name, or expression

count

an integer that specifies how many characters to return; this can be specified as numeric constant, field name, or expression
returns

a string representing the leftmost characters

**Details**

The left function returns the leftmost count characters of source.

When a count of zero or less is specified, an empty string is returned. If source is null, the function returns a null value.

**Examples**

The following statements illustrate the left function:

```sql
source = "abcdefg"
result = left(source, 4) // outputs the string "abcd"
```

**len Function**

The len function returns the length of a string.

**Category:** String

**Syntax**

len(source)

**Arguments**

source

a string for which the length needs to be determined; this can be specified as string constant, field name, or expression

returns

an integer representing the length of the string

**Details**

The len function returns the length of a string.

The length of an empty string ("") is zero. If source is null, the function returns a null value. To remove leading and trailing blanks, use the *trim* function.

**Examples**

The following statements illustrate the len function:

```sql
string(30) source
source = "abcdefg"
length_string = len(source) // outputs 7
```
lower Function

The lower function converts a string to lowercase.

Category: String

Syntax

lower(source)

Arguments

source

a string; this can be specified as string constant, field name, or expression

returns

a string, representing the source string in lowercase

Details

The lower function returns the lowercase of a string. If source is null, the function returns a null value.

Examples

The following statements illustrate the lower function:

source = "MÜNCHEN in Germany"
lowcase_string = lower(source) // outputs "münchen in germany"

match_string Function

The match_string function determines if the first string matches the second string, which can contain wildcards.

Category: String

Syntax

match_string(string1,string2)
**Arguments**

string1

- a string that needs to be searched; this can be specified as string constant, field name, or expression

string2

- a string that represents a search pattern; this can be specified as string constant, field name, or expression

returns

- a Boolean, indicating whether a match has been found [true = match was found; false = no match was found]

**Details**

The match_string function searches string1 using the search pattern specified in string2. If a match was found, true is returned otherwise, false is returned.

Search strings can include wildcards in the leading (*ABC) and trailing (ABC*) position, or a combination of the two (*ABC*). Wildcards within a string are invalid (A*BC).

A question mark can be used as a wildcard but is matched only to a character. For example, AB? will match ABC, not AB.

To execute a search for a character that is used as a wildcard, precede the character with a backslash. This denotes that the character should be used literally and not as a wildcard. Valid search strings include: *BCD*, *B?D*, *BCDE, *BC?E, *BCD?, ABCD*, AB?D*, ?BCD*, *B??*, *B\??* (will match the literal string AB?\E). An invalid example is: AB*DE.

For more complex searches, regular expressions instead of the match_string() function are recommended.

If source is null the function returns a null value.

**Examples**

The following statements illustrate the match_string function:

```java
string1 = "Monday is sunny, Tuesday is rainy & Wednesday is windy"
string2 = "Tuesday is"
match = match_string(string1, string2) // outputs false
string2 = "*Tuesday is*"
match = match_string(string1, string2) // outputs true
```
**mid Function**

The mid function extracts a substring from an argument.

**Category:** String

**Syntax**

mid(source, position<, length>)

**Arguments**

- **source**
  
  a string that needs to be searched; this can be specified as string constant, field name, or expression

- **position**
  
  an integer that represents the beginning character position; this can be specified as a numeric constant, field name, or expression

- **length**
  
  [optional] an integer that represents the length of the substring to extract; this can be specified as a numeric constant, field name, or expression

**Returns**

a string, representing the extracted substring

**Details**

The mid function returns the substring with specified length starting at specified position.

If length is null, zero, or larger than the length of the expression that remains in source after position, the remainder of the expression is returned.

If length is omitted, the remainder of the string will be extracted.

**Examples**

The following statements illustrate the mid function:

```plaintext
source = "06MAY98"
result = mid(source, 3, 3) // outputs "MAY"
result = mid(source, 3) // outputs "MAY98"
```
mkdir Function

The mkdir function creates a directory. If the second parameter is true, the directory will be recursively created.

**Category:** String

**Syntax**

boolean mkdir(string[, boolean])

**Arguments**

boolean

is a Boolean expression that is either true or false

string

is the text string that contains the directory to be created

boolean

[optional] the second Boolean expression creates the directory recursively based on whether or not the expression is true or false

**Examples**

The following statements illustrate the mkdir function:

**Example 1**

```java
// Declare a string variable to contain the path to the directory to be created
dir=

// Declare a Boolean variable for the MKDIR function call
d

// Use the MKDIR function to create the C:\DataQuality\my_data directory
mkdir(dir)
```

**Example 2**

```java
// Declare a string variable to contain the path to the directory to be created
dir=

// Declare Boolean variables for the MKDIR function call and the optional condition
b
d

// Set the condition for Boolean b to "true"
b=true
```
// Use the MKDIR function to create the new directory, recursively based on the value of Boolean b
mkdir(dir,b)

**parse Function**

Parses a string into words and returns the number of words found.

**Category:** String

**Syntax**

parse(string, delimiter, word1 <, word2 , ..., wordN>)

**Arguments**

string

- a string that represents the string that needs to be separated into words; this can be specified as fixed string, field name, or expression

delimiter

- a string that contains the character to be used as delimiter when separating the string into words; this can be specified as fixed string, field name, or expression

word1

- a string that represents the first word found; this is specified as a field name

word2...wordN

- [optional] a string that represents the words found; this is specified as a field name

**returns**

- an integer that represents the number of words found

**Details**

The parse function fills the provided parameters with words using the delimiter specified. The function returns the number of words found.

If string is null,, the function returns null. If string is empty (""") a value of 1 is returned.

The aparse function is similar. The aparse function is more flexible, as you do not have to know, in advance, what the maximum number of words is and can be used to easily determine the last word in a string.
Examples

The following statements illustrate the parse function:

```java
string = "one:two:three"
delimiter = ":"
nwords = parse(string, delimiter, word1, word2) // outputs 3
// word1 will contain the value "one"
// word2 will contain the value "two"
```

**pattern Function**

The pattern function indicates if a string has numbers or uppercase and lowercase characters.

**Category:** String

**Syntax**

`pattern(string)`

**Arguments**

*string*

- a string that represents the string for which the pattern needs to be determined; this can be specified as fixed string, field name, or expression

**returns**

- a string with the pattern found

**Details**

The pattern function replaces each number with a 9, each uppercase character with an "A" and each lowercase character with an "a". Other characters are not replaced.

If string is null, the function returns null. If string is empty (""), an empty value is returned.

**Examples**

The following statements illustrate the pattern function:

```java
source_string = "12/b Abc-Str."
result = pattern(source_string) // outputs "99/a Aaa-Aaa."
```

**replace Function**

The replace function replaces the first occurrence of one string with another string, and returns the string with the replacement made.

**Category:** String
Syntax
replace(source, search, replace<, integer>)

Arguments
source
a string that needs to be searched, this can be specified as string constant, field name, or expression

search
a string that represents the text to be searched for; this can be specified as string constant, field name, or expression

replace
a string that represents the replacement for text that was found; this can be specified as string constant, field name, or expression

count
an integer that represents how many replacements should be made; this can be specified as numeric constant, field name, or expression

returns
a string that represents the string with the replacements made

Details
The replace function replaces the first occurrence of one string with another string, and returns the string with the replacement made. If count is omitted or set to zero, all occurrences will be replaced in the string.

If source is null, the function returns a null value.

Examples
The following statements illustrate the replace function:

```plaintext
source_string = "It's a first! This is the first time I came in first place!"
search = "first"
replace = "second"
count = 2
result = replace(source_string, search, replace, count)
// outputs "It's a second! This is the second time I came in first place!"
```
**right Function**

The right function returns the rightmost characters of a string.

**Category:**

**Syntax**

right(source,count)

**Arguments**

source

a string to be searched; this can be specified as string constant, field name, or expression

count

an integer that specifies how many characters to return; this can be specified as numeric constant, field name, or expression

returns

a string representing the rightmost characters

**Details**

The right function returns the rightmost count characters of source.

When a count of zero or less is specified, an empty string is returned. If source is null, the function returns a null value.

**Examples**

The following statements illustrate the right function:

```plaintext
source = "abcdefg"
result = right(source, 4) // outputs the string "defg"

source = "abcdefg ".
result = right(source, 4) // outputs the string "fg ".
```

**rmdir Function**

The rmdir function deletes a directory if it is empty.

**Category:** String

**Syntax**

boolean rmdir(string)
Arguments

boolean

is a Boolean expression that is either true or false

string

is the text string that contains the directory to be checked and removed if empty

Examples

The following statements illustrate the rmdir function:

```java
// Declare a string variable to contain the path to the directory to be created
string dir
dir="C:\DataQuality\my_data"

// Declare a Boolean variable for the MKDIR function call
boolean d

// Use the MKDIR function to create the C:\DataQuality\my_data directory
d rmdir(dir)
```

sort Function

The sort function returns the string with its characters sorted alphabetically.

Category: String

Syntax

sort(source<,ascending<,remove_duplicates>>)

Arguments

source

a string that needs to be sorted; this can be specified as string constant, field name, or expression

ascending

[optional] a Boolean that represents whether the text should be sorted in ascending order; this can be specified as Boolean constant, field name, or expression

remove_duplicates

[optional] a Boolean that represents whether duplicate characters should be removed; this can be specified as Boolean constant, field name, or expression
returns

a string that represents the sorted string

**Details**

The sort function returns a string with its characters sorted alphabetically. If ascending is true or omitted, the string will be sorted in ascending order. A false value results in a descending sort order. If remove_duplicates is true duplicate characters are being discarded. If remove_duplicates is omitted, duplicates are not discarded.

If source is null, the function returns a null value.

**Examples**

The following statements illustrate the sort function:

```
source_string = "A short Sentence."
ascending = true
remove_duplicates = true
result = sort(source_string, ascending, remove_duplicates)
// outputs "AAScehnorst"
```

**sort_words Function**

The sort_words function returns a string, consisting of the words within the input string sorted alphabetically.

**Category:** String

**Syntax**

`sort_words(source<,ascending<,remove_duplicates>>)`

**Arguments**

source

a string that needs to be sorted; this can be specified as string constant, field name, or expression

ascending

[optional] a Boolean that represents whether the words in the input string should be sorted in ascending order; this can be specified as a Boolean constant, field name, or expression

remove_duplicates

[optional] a Boolean that represents whether duplicate words should be removed; this can be specified as a Boolean constant, field name, or expression
returns
a string that represents the sorted string

**Details**

The `sort_words` function returns a string with its words sorted alphabetically. If ascending is true or omitted, the string is sorted in ascending order. A false value results in a descending sort order. If `remove_duplicates` is true, duplicate words are being discarded. If `remove_duplicates` is omitted, duplicates are not discarded.

cka **Note:** Special characters like ",诞!" are not treated as separation characters.

If source is null, the function returns a null value.

**Examples**

The following statements illustrate the `sort_words` function:

```plaintext
source_string = "It's a first! This is the first time I came in first place!"
ascending = true
remove_duplicates = true
result = sort_words(source_string, ascending, remove_duplicates)
// outputs "I It's This a came first first! in is place! the time"
```

### todate Function

The `todate` function converts the argument to a date value.

cka **Note:** The `todate()` function depends on the default Short Date regional setting on your Microsoft Windows environment. You can change the locale setting on Windows.

**Category:** String

**Syntax**

date todate(any)

**Arguments**

date
contains the date value returned by the function

any
is the value passed into the function for conversion to a date value
Examples

The following statements illustrate the todate function:

```plaintext
// Declare the date variable to contain the date value
date dateval

// Use the TODATE function to populate the date variable
dateval=todate(3750)

// Returns the value:
4/7/10 12:00:00 AM
```

tointeger Function

The tointeger function converts the argument to an integer value.

Category: String

Syntax

```plaintext
integer tointeger(any)
```

Arguments

```plaintext
integer

contains the integer value returned by the function

any

is the value passed into the function for conversion to an integer value
```

Examples

The following statements illustrate the tointeger function:

Example 1

```plaintext
if tointeger(counter)<= 5
  setoutputsot(0)
else
  setoutputsot(1)
```

Example 2

```plaintext
// Declare an integer variable to contain the integer value
integer intval

// Use the TOINTEGER function to populate the integer variable
intval=tointeger(3750.12345)

// Returns the value:
3750
```
**toreal Function**

The toreal function converts the argument to a real value.

**Category:** String

**Syntax**

real toreal(any)

**Arguments**

real

contains the real value returned by the function

any

is the value passed into the function for conversion to a real value

**Examples**

The following statements illustrate the toreal function:

```plaintext
// Declare a real variable to contain the real value
real realval

// Use the TOREAL function to populate the real variable
realval=toreal(3750.12345)

// Returns the value:
3750.12345
```

**tostring Function**

The tostring function converts the argument to a string value.

**Category:** String

**Syntax**

string tostring(any)

**Arguments**

string

contains the string value returned by the function

any

is the value passed into the function for conversion to a string value
**Examples**

The following statements illustrate the tostring function:

```java
// Declare a string variable to contain the string
String stringval

// Use the TOINTEGER function to populate the integer variable
stringval=tostring(3750.12345)

// Returns the string
3750.12345
```

**trim Function**

The trim function removes leading and trailing white space.

**Category:** String

**Syntax**

```
trim(source)
```

**Arguments**

source

a string from which the leading and trailing white space needs to be removed; this can be specified as string constant, field name, or expression

returns

a string representing the string with leading and trailing white space removed

**Details**

The trim function returns the string with leading and trailing white space removed.

If source is null, the function returns a null value. If source is an empty value (""), the function returns an empty value.

**Examples**

The following statements illustrate the trim function:

```java
source = " abcd " // 2 leading and 2 trailing spaces
result = trim(source) // outputs "abcd"
length = len(source) // outputs 8
length = len(result) // outputs 4
```
**upper Function**

The upper function converts a string to uppercase.

**Category:** String

**Syntax**

`upper(source)`

**Arguments**

`source`

- a string; this can be specified as a string constant, field name, or expression

**returns**

- a string representing the source string in uppercase

**Details**

The upper function returns the uppercase of a string. If source is null, the function returns a null value.

**Examples**

The following statements illustrate the upper function:

```java
source = "MÜNCHEN in Germany"
upcase_string = upper(source) // outputs "MÜNCHEN IN GERMANY"
```

**username Function**

The username function returns the operating system username of the logged-in user.

**Category:** String

**Syntax**

`string username()`

**Arguments**

`string`

- contains the string returned by the function
Examples

The following statements illustrate the username function:

```plaintext
// Declare the string value for the function
string user

// Use the USERNAME function to get the OS user name
user = username()
```

vareval Function

The vareval function evaluates and returns the value of a variable with the given name.

**Category:** String

**Syntax**

```plaintext
string vareval(string)
```

**Arguments**

- `string`: the first string contains the string returned by the function
- `string`: the second string is the field name passing into the function for conversion to a string

**Details**

The vareval function evaluates a string as though it were a variable.

🔍 **Note:** Since it has to look up the field name each time it is called, vareval is a slow function and should be used sparingly.

**Examples**

The following statements illustrate the vareval function:

```plaintext
// Declare the string values for the function
string field_number
string field_value
// Declare a hidden integer as a counter
hidden integer n
// Loop through all 5 variables in an input data source
for n=1 to 5
// Output the value in each of the fields field_1 through field_5
begin
    field_number='field_' & n
    field_value=vareval(field_number)
    n=n+1
end
```
// Return false to prevent the last row from showing up twice

return false

## Experimental Functions

The following functions are currently experimental and are not yet fully supported.

We encourage you to experiment with these functions and e-mail any questions, comments, or issues to [experimental@dataflux.com](mailto:experimental@dataflux.com).

</table>

For more information about experimental testing, refer to [What Is Experimental?](#).

**decode Function**

The decode function transcodes the string contents to the specified encoding.

**Syntax**

integer decode(string, string, string)

**encode Function**

The encode function transcodes the source buffer to the string encoding.

**Syntax**

integer encode(string, string, string)

**formatib Function**

The formatib function returns a number formatted in SAS IB. The first parameter is the value to format, the second parameter is the W.D format, and the third parameter is the formatted SAS IB number.

**Syntax**

integer formatib(real, string, string)

**formatpd Function**

The formatpd function returns a number formatted in SAS PD. The first parameter is the value to format, the second parameter is the W.D format, and the third parameter is the formatted SAS PD number.

**Syntax**

integer formatpd(real, string, string)
formatpiccomp Function

The formatpiccomp function returns a number formatted in COMP. The first parameter is the value to format, the second parameter is the PIC format, and the third parameter is the formatted COMP number.

Syntax

integer formatpiccomp(real, string, string)

formatpiccomp3 Function

The formatpiccomp3 function returns a number formatted in COMP-3. The first parameter is the value to format, the second parameter is the PIC format, and the third parameter is the formatted COMP-3 number.

Syntax

integer formatpiccomp3(real, string, string)

formatpiccomp5 Function

The formatpiccomp5 function returns a number formatted in COMP-5. The first parameter is the value to format, the second is the PIC format, and the third parameter is the formatted COMP-5 number.

Syntax

integer formatpiccomp5(real, string, string)

formatpicsigndec Function

The formatpicsigndec function returns a number formatted in COBOL signed decimal. The first parameter is the number to be formatted, the second parameter is the PIC format, and the third parameter is the formatted COBOL Signed Decimal number. The fourth parameter returns true if there is an encoding, false if the default for ASCII. The fifth parameter is true for trailing sign orientation, which is the default.

Syntax

integer formatpicsigndec(real, string, string[, boolean[, boolean]])

formats370fib Function

The formats370fib function returns a number formatted in z/OS integer. The first parameter is the value to be formatted, the second parameter is the W.D format, and the third parameter is the formatted z/OS integer.

Syntax

integer formats370fib(real, string, string)
**formats370fpd Function**

The `formats370fpd` function returns a number formatted in z/OS packed decimal. The first parameter is the value to be formatted, the second is the W.D format, and the third is the formatted z/OS packed decimal.

**Syntax**

```plaintext```
integer formats370fpd(real, string, string)
```

**ib Function**

The `ib` function returns a number from a SAS IB value. The first parameter is the IB value, and the second parameter is the W.D format.

**Syntax**

```plaintext```
real ib(string[, string])
```

**normsinv Function**

The `normsinv` function returns the inverse of the cumulative standardized normal distribution.

**Syntax**

```plaintext```
real normsinv(real)
```

**Arguments**

- `real`
  
  is a real number to be passed to the function

**parameter Function**

The `parameter` function returns the value of a parameter, or null if the parameter does not exist.

**Syntax**

```plaintext```
string parameter(integer)
```

**Arguments**

- `string`
  
  contains the value returned by the function for the specified parameter

- `integer`
  
  is the number of the parameter whose value is to be returned
**Details**

The parameter function returns `<null>` if the parameter does not exist.

**parametercount Function**

The parametercount function returns the number of parameters available.

**Syntax**

```
integer parametercount()
```

**Arguments**

```
integer
```

is the number of the parameters returned by the function

**pd Function**

The pd function returns a number from a SAS PD value. The first string contains the number, and the second string contains the W.D format.

**Syntax**

```
real pd(string[, string])
```

**Arguments**

```
real
```

is the numeric value returned by the function

```
string
```

the first string is the unformatted number; the second (optional) string is the SAS format, specified as W.D (width.decimal)

```
string
```

[optional] the second string is the SAS format, specified as W(idth).D(ecimal)

**Examples**

```
// Declare a STRING variable to contain the packed decimal string
string pdstring
// Declare a REAL variable to contain the real value of the packed decimal
decl pdreal
// Declare a hidden INTEGER value to contain the packed decimal string
integer len
// Use FORMATPD function to create a packed decimal string
len = formatpd (30.56789, "8.2", pdstring);
```
// Format the packed decimal number into a real number of length 8 with 2
decimal places
pdreal = pd(pdstring, "8.2");

Results: This should return with a value of 30.57

**piccomp Function**

The piccomp function returns a number from a COMP value. The first string contains
the number, and the second string contains the PIC format.

**Syntax**

real piccomp(string[, string])

**piccomp3 Function**

The piccomp3 function returns a number from a COMP-3 value. The first string
contains the number, and the second string contains the PIC format.

**Syntax**

real piccomp3(any[, string])

**piccomp5 Function**

The piccomp5 function returns a number from a COMP-5 value. The first string
contains the number, and the second string contains the PIC format.

**Syntax**

real piccomp5(string[, string])

**picsigndec Function**

The picsigndec function returns a number from a COBOL signed decimal value. The
first string is the number, the second string contains the PIC format, the third string
is false if ASCII encoded, and the fourth string is true if using a trailing sign.

**Syntax**

real picsigndec(string[, string[, boolean[, boolean]]])

**s370fib Function**

The s370fib function returns a number from a z/OS integer. The first string is the
number, and the second string is the W.D format.

**Syntax**

real = s370fib(string, format_str)
**Arguments**

`string`

the octet array containing IBM mainframe binary data to convert

`format_str`

the string containing the w.d. format of the data

**s370fpd Function**

The s370fpd function returns a number from a z/OS packed decimal. The first string is the number, and the second string is the W.D format.

**Syntax**

```plaintext
real s370fpd(string[, string])
```
Data Job Expressions Node

The DataFlux Data Management Studio Expressions node is a utility that allows you to create your own nodes using the DataFlux Expression Engine Language (EEL) scripting language.

For information about the Data Job Expressions node, refer to the DataFlux Data Management Studio Online Help.

Frequently Asked Questions

This section introduces frequently asked questions along with exercises. These topics include examples that illustrate specific concepts related to the DataFlux Expression Engine Language (EEL).

- Testing and Evaluating
- Selecting Output Fields
- Sub-Setting
- Initializing and Declaring Variables
- Saving Expressions
- Counting Records
- Debugging and Printing Error Messages

The EEL allows you to format and alter data through built-in functions and external processes. Specifically, you can use the following to structure and manipulate data:

- Creating Groups
- Retrieving and Converting Binary Data
- Supporting COBOL
- Using Array Functions
- Using Blue Fusion Functions
- Using Date and Time Functions
- Using Database Functions
- Using Encode and Decode Functions
- Using File Functions
- Using Integer and Real Functions
- Using Regular Expressions Functions
- Using String Functions
FAQ: Testing and Evaluating

In order to test an expression prior to running a Data Job, you must create sample rows.

**Exercise 1: How do I test an expression without using a table to create rows?**

In the Expression Properties dialog, select **Generate rows when no parent is specified**.

This creates sample empty rows in the **Preview** tab.

🪐 **Note:** If you do not select **Generate rows when no parent is specified**, and you do not have output specified in the post-processing step, no data is output.

**Exercise 2: Is it possible to create test rows with content rather than empty rows?**

This involves creating extra rows with the pushrow() function in the Pre-expression section.

🪐 **Note:** To use the pushrow() function, **Generate rows when no parent is specified** must not be selected.

Consider the code example below:

```java
// Pre-Expression
string name // the name of the person
string address // the address of the person
integer age // the age of the person

// Content for the first row
name="Bob"
address="106 NorthWoods Village Dr"
age=30

// Create an extra row for the
// fields defined above
pushrow()

// The content for the extra row
name="Adam"
address="100 RhineStone Circle"
age=32

// Create an extra row for the
// fields defined above
pushrow()

// The content for extra row
name="Mary"
address="105 Liles Rd"
age=28
```
The pushrow() function creates the rows.

**FAQ: Selecting Output Fields**

Some fields are used for calculation or to contain intermediate values, but are not meaningful in the output. As you test or build scripts, you might need to exclude fields from the output.

**Exercise: How do I exclude some fields in the expression from being listed in the output?**

To accomplish this, use the hidden-keyword before declaring a variable.

Consider the following example:

```java
// Pre-Expression
// This declares a string
// type that will be hidden
hidden string noDisplay

// Expression
// Assigns any value to the string type
noDisplay='Hello World But Hidden'
```

The noDisplay string field is not output to the Preview tab.

To verify this, remove the parameter hidden from the string noDisplay declaration. Observe that noDisplay is output.

**FAQ: Subsetting**

When you work with large record sets in the Data Job Editor, it can be time-consuming to test new jobs. You can shorten this time when you build your expression and test your logic against a subset of large record sets.

**Exercise 1: Apply your expression to a subset of your data by controlling the number of records processed.**

Consider the following example:

```java
// Pre-Expression
// We make this variable hidden so it is not output to the screen
hidden integer count

    count=0
hidden integer subset_num

    subset_num=100
```
// This function estimates and sets the # of records that this step will report
rowestimate(subset_num)

// Expression
if(count==subset_num)
  seteof()
else
  count=count + 1

Keep track of the number of records output with the integer variable count. Once count matches the size of the subset, use the seteof() function to prevent any more rows from being created.

The exact syntax for seteof() function is:

boolean seteof(boolean)

When seteof() is called, the node does not read any more rows from the parent node. If *Generate rows when no parent is specified* is checked, the node stops generating rows. Furthermore, if any rows have been pushed using pushrow(), they are discarded, and further calls to pushrow() have no effect. The exception to this is if seteof(true) is called. In this case, any pushed rows (whether pushed before or after the call to seteof()) are still returned to the node below. Notably, if further pushrow() calls occur after seteof(true) is called, these rows are returned as well. Also note that after seteof() is called, the post-group expression and the post expression are still executed.

The rowestimate() function is employed by Data Jobs to estimate the number of records that will be output from this step.

If you remove the hidden parameter from the integer count declaration, integers 1—100 are output.

Another approach to solving this problem is shown in the following example:

**Exercise 2: Apply your expression to a subset of your code by filtering out rows of data.**

```
// Pre-Expression
integer counter
counter=0
integer subset_num
subset_num=50

// Expression
if counter < subset_num
  begin
    counter=counter + 1
  end
else
  return true
```
By setting the return value to true or false, you can use this approach as a filter to select which rows go to the next step.

(Collision) **Note:** If you always return false, you get no output and your expression enters an infinite loop.

**FAQ: Initializing and Declaring Variables**

As an expression is evaluated, each row updates with the values of the fields in the expression. This may lead to re-initialization of certain variables in the expression. You might want to initialize a variable only once and then use its value for the rest of the expression script.

**Exercise:** How do I initialize a variable just one time and not with each iteration of a loop?

Declare the variable in the pre-expression step, and it is initialized only once before the expression process takes over.

**FAQ: Saving Expressions**

**Exercise:** How do I save my expressions?

You can save an expression without saving the entire Data Job. Click Save. Your expression is saved in an .exp text file format that you can load using Load.

**FAQ: Counting Records**

**Exercise 1:** How do I count the number of records in a table using DataFlux Expression Engine Language (EEL)?

In this example, a connection is made to the Contacts table in the DataFlux sample database, and output to an HTML report. For more information on connecting to a data source and specifying data outputs, refer to the DataFlux Data Management Studio online Help.

Define an integer type in the pre-expression step that contains the count.

```
// Pre-Expression
// Declare and initialize an integer variable for the record count
integer recordCount
recordCount=0

// Expression
// Increment recordCount by one
recordCount=recordCount+1
```
The value of recordCount increases in increments of one until the final count is reached. If you want to increase the count for only those values that do not have a null value, enter the following in the expression:

```eel
// Check if the value is null
if(NOT isnull('address')) then
    recordCount=recordCount+1
```

In this example, the value recordCount is updated after each row iteration.

📍 **Note:** Field names must be enclosed in grave accents (ASCII `&96;) rather than apostrophes (ASCII `&39;).

**Exercise 2: How do I see the final count of the records in a table instead of seeing it get incremented by one on every row?**

Declare a count variable as hidden. In the post-expression step, assign the value of count to another field that you want to display in the output (finalCount). Using `pushrow()`, add an extra row to the output to display finalCount. Add the final row in the post-processing step, so that finalCount is assigned only after all of the rows are processed in the expression step.

Here is the EEL code:

```eel
// Preprocessing
hidden integer count
count=0

// Expression
if(NOT isnull('address')) then
    count=count+1

// Post Processing
// Create a variable that will contain the final value and assign it a value
integer finalCount

finalCount=count

// Add an extra row to the output
pushrow()
```

When you enter this code and then run the code, the last row should display the total number of records in the table that are not null.
Exercise 3: How do I get just one row in the end with the final count instead of browsing through a number of rows until I come to the last one?

A simple way to do this is to return false from the main expression. The only row that is output is the one that was created with pushrow().

Or, you can devise a way to indicate that a row is being pushed. The final row displayed is an extra pushed row on top of the stack of rows that is displayed. Therefore, you can filter all the other rows from your view except the pushed row.

To indicate that a row is pushed on your expression step, select **Pushed status field** and enter a new name for the field.

Once you indicate with a Boolean field whether a row is pushed or not, add another expression step that filters rows that are not pushed:

```plaintext
// Preprocessing
hidden integer count
count=0

// Add a boolean field to indicate
// if the row is pushed
boolean pushed

// Expression
if(NOT isnull(`address`)) then
    count=count+1

// Name the pushed status field "pushed"
if (pushed) then
```

*Displaying the Final Record Count*
```java
return true
else
return false

// Post Processing
integer finalCount
finalCount=count

pushrow()
```

**FAQ: Debugging and Printing Error Messages**

**Exercise: Is there a way to print error messages or to get debugging information?**

You can use the `print()` function that is available to print messages. When previewing output, these messages print to the Log tab.

In a previous example of calculating the number of records in a table, in the end, you can output the final count to the statistics file. In the post-processing section, you would have:

```java
// Post Processing

// Integer to have the final count
integer finalCount

finalCount=count

// Add one extra row for post processing
pushrow()

// Print result to file
print('The final value for count is: '& finalCount)
```

**FAQ: Creating Groups**

Expressions provide the ability to organize content into groups. The DataFlux Expression Engine Language (EEL) has built-in grouping functionality that contains this logic. Once data is grouped, you can use other functions to perform actions on the grouped data.

🌟 **Note:** The use of grouping in EEL is similar to the use of the `Group By` clause in SQL.

**Exercise 1: Can EEL group my data and then count the number of times each different entry occurs?**

Yes. For example, you can count the number of different states that contacts are coming from, using the contacts table from a DataFlux sample database.
Exercise 2: How can I count each state in the input so that "NC", "North Carolina", and "N Carolina" are grouped together?

A convenient way to accomplish this is to add an expression node or a standardization node in the Data Job Editor, where you can standardize all entries prior to grouping.

Building on the previous example, add a Standardization step:

1. In Data Job Editor, click Quality.
2. Double-click the Standardization node.
3. In the Standardization Properties dialog box, select State and specify the State/Province (Abbreviation) definition. This creates a new field called STATE_Stnd.
4. Click Additional Outputs and select all.
5. Click OK.
6. In the Standardization Properties dialog box, click OK.
7. In the Expression Properties dialog box, click Grouping. Make sure that Grouping is now by STATE_Stnd and not STATE.
8. Click OK.

The statecount now increments by each standardized state name rather than by each permutation of state and province names.

Exercise 3: How do I group my data and find averages for each group?

To illustrate how this can be done, use sample data.

Step 1: Connect to a Data Source

1. Connect to the Purchase table in the DataFlux sample database.
2. In the Data Source Properties dialog box, click Add All.
3. Find the Field Name for ITEM AMOUNT. Change the Output Name to ITEM_AMOUNT.

Step 2: Sort the Data

Now that you have connected to the Purchase table, sort on the data field that you use for grouping. In this case, sort by DEPARTMENT.

1. In the Data Job Editor, click Utilities.
2. Double-click Data Sorting. This adds a Data Sorting node.
3. In the Data Sorting Properties dialog box, select DEPARTMENT and set the Sort Order to Ascending.
4. Click OK.
Step 3: Create Groups

To create groups out of the incoming data, add another Expression node to the job after the sorting step.

1. In the Expression Properties dialog box, click **Grouping**. The following three tabs are displayed: Group Fields, Group Pre-Expression, and Group Post-Expression.

2. On the Group Fields tab, select DEPARTMENT.

3. On the Group Pre-Expression tab, declare the following fields, and then click **OK**:

   ```
   // Group Pre-Expression
   // This variable will contain the total
   // sales per department
   real total
   total=0

   // This variable will keep track of the
   // number of records for each department
   integer count
   count=0

   // This variable will contain the
   // running average total
   real average
   average=0
   ```

4. On the Expression tab, update the variables with each upcoming new row, and then click **OK**:

   ```
   // Expression
   // increase the total sales
   total=total+ITEM_AMOUNT

   // increase the number of entries
   count=count+1

   // error checking that the count of entries is not 0
   if count !=0 then
     begin
       average=total/count
       average=round(average,2)
     end
   ```

When you preview the Expression node, you should see the following in the last four columns:

<table>
<thead>
<tr>
<th>Department</th>
<th>Total</th>
<th>Count</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3791.7</td>
<td>1</td>
<td>3791.7</td>
</tr>
<tr>
<td>1</td>
<td>6025.4</td>
<td>2</td>
<td>3012.7</td>
</tr>
<tr>
<td>1</td>
<td>7294.5</td>
<td>3</td>
<td>2431.5</td>
</tr>
<tr>
<td>1</td>
<td>11155.2</td>
<td>4</td>
<td>2788.8</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>
FAQ: Retrieving and Converting Binary Data

DataFlux expressions provide the ability to retrieve data in binary format. This section describes how to retrieve and convert binary data in big-endian or little-endian formats, as well as mainframe and packed data formats.

Big-Endian and Little-Endian Format

Exercise 1: How do I retrieve binary data in either big-endian or little-endian format?

To retrieve binary data, use the ib() function. It also determines the byte order based on your host or native system. The syntax is:

```
real = ib(string, format_str)
```

where:

- **string**: The octet array containing binary data to convert.
- **format_str**: The string containing the format of the data, expressed as w.d. The width (w) must be between 1 and 8, inclusive, with the default being 4. The optional decimal (d) must be between 0 and 10, inclusive.

The w.d formats/informats specify the width of the data in bytes. The optional decimal portion specifies an integer which represents the power of ten by which to divide (when reading) or multiply (when formatting) the data. For example:

```
//Expression
//File handler to open the binary file
file input_file
//The binary value to be retrieved
real value
//The number of bytes that were read
integer bytes_read
//4-byte string buffer
string(4) buffer
input_file.open("C:\binary_file", "r")
//This reads the 4 byte string buffer
bytes_read=input_file.readbytes(4, buffer)
//The width (4) specifies 4 bytes read
//The decimal (0) specifies that the data is not divided by any power of ten
value = ib(buffer, "4.0")
```

Exercise 2: How do I force my system to read big-endian data regardless of its endianness?

To force your system to read big-endian data, use the s370fib() function. The syntax is:

```
real = s370fib(string, format_str)
```

where:

- **string**: The octet array containing IBM mainframe binary data to convert.
- **format_str**: The string containing the w.d format of the data.
Use this function just like the ib() function. This function always reads binary data in big-endian format. The s370fib() function is incorporated for reading IBM mainframe binary data.

**Exercise 3: How do I read little-endian data regardless of the endianness of my system?**

Currently, there are no functions available for this purpose.

**Exercise 4: How do I read IBM mainframe binary data?**

To read IBM mainframe binary data, use the s370fib() function, described in Exercise 2.

**Exercise 5: How do I read binary data on other non-IBM mainframes?**

Currently, there are no functions available for this purpose.

**Exercise 6: Is there support for reading binary packed data on IBM mainframes?**

To read binary packed data on IBM mainframes, use the function s370fpd(). The syntax is:

```python
real = s370fpd(string, format_str)
```

where:

- **string**: The octet array containing IBM mainframe packed decimal data to convert.
- **format_str**: The string containing the w.d format of the data.

This function retrieves IBM mainframe-packed decimal values. The width (w) must be between 1 and 16, inclusive, with the default being 1. The optional decimal (d) must be between 0 and 10, inclusive. This function treats your data in big-endian format.

**Exercise 7: How do I read non-IBM mainframe packed data?**

To read non-IBM mainframe packed data, use the function pd(). The syntax is:

```python
real = pd(string, format_str)
```

where:

- **string**: The octet array containing IBM mainframe binary data to convert.
- **format_str**: The string containing the w.d format of the data.
Converting Binary Data to a Certain Format

Just as it is possible to retrieve data in a special binary format, it is also possible to format data to a special binary format.

Exercise 8: How do I format binary data to the native endianness of my system?

To format binary data, use the formatib() function. The syntax is:

\[
\text{integer} = \text{formatib}(\text{real}, \text{format_str}, \text{string})
\]

where:

- **real**: The numeric to convert to a native endian binary value.
- **format_str**: The string containing the w.d format of the data.
- **string**: The octet array in which to place the formatted native endian binary data.

returns:

- **integer**: The byte length of formatted binary data.

This function produces native endian integer binary values. The width (w) must be between 1 and 8, inclusive, with the default being 4. For example:

```c
//Expression
//The byte size of the buffer that contains the content
real format_size
//The real type number
real number
//The real number that is retrieved
real fib_format
number=10.125
//The buffer that contains the formatted data
string(4) buffer
format_size= formatib(number, "4.3", buffer)
//4.3 is to specify 4 bytes to read the entire data and 3 to multiply it by 1000
//The reason to multiply it by a 1000 is to divide it later by 1000
//To restore it back to a real number
fib_format= ib(buffer, "4.3")
//Verify that the formatting worked
//Fib_format should be 10.125
```

Exercise 9: How do I change to other formats?

To change to other formats, use the following functions:

**Non-IBM mainframe packed data**

\[
\text{integer} = \text{formatpd}(\text{real}, \text{format_str}, \text{string})
\]

where:

- **real**: The numeric to convert to a native-packed decimal value.
• **format**\_**str**: The string containing the w.d format of the data.
• **string**: The octet array in which to place the formatted native-packed decimal data.

  **returns:**

  **integer**: The byte length of formatted packed decimal data.

**IBM mainframe binary data**

  ```
  integer = formats370fib(real, format\_str, string)
  ```

  **where:**

  • **real**: The numeric to convert to an IBM Mainframe binary value.
  • **format**\_**str**: The string containing the w.d format of the data.
  • **string**: The octet array in which to place the formatted IBM mainframe binary data.

  **returns:**

  **integer**: The byte length of formatted binary data

**IBM mainframe packed decimal data**

  ```
  integer = formats370fpd(real, format\_str, string)
  ```

  **where:**

  • **real**: The numeric to convert to an IBM mainframe-packed decimal value.
  • **format**\_**str**: The string containing the w.d format of the data.
  • **string**: The octet array in which to place the formatted IBM mainframe-packed decimal data.

  **returns:**

  **integer**: The byte length of formatted packed decimal data.

**FAQ: Supporting COBOL**

Using expressions, it is possible to read binary data in specified COBOL COMP, COMP-3, and COMP-5 data formats. The following examples demonstrate how to do this.

• [Reading binary data](#)
• [Formatting binary data](#)
Reading

Exercise 1: How do I read native endian binary data for COBOL?

To read native endian binary data, use the piccomp() function. The syntax is:

```c
real piccomp(string, format_str)
```

where:

- **string**: The octet array containing COBOL formatted packed decimal data to convert.

- **format_str**: The string containing the PIC 9 format of the data.

The piccomp() function determines the number of bytes (2, 4, or 8) to consume by comparing the sum of the 9s in the integer and fraction portions to fixed ranges. If the sum is less than 5, then 2 bytes are consumed. If the sum is greater than 4 and less than 10, then 4 bytes are consumed. If the sum is greater than 9 and less than 19, then 8 bytes are consumed. For example:

```c
//Expression
//file handler to open files
File pd
integer rc
string(4) buffer
real comp
if (pd.open("binary_input.out", "r"))
begin
rc = pd.readbytes(4, buffer)
if (4 == rc) then
comp = piccomp(buffer, "S9(8)")
pd.close()
end
```

In the preceding example, because of the format of the string is S9(8), 4 bytes were consumed. Notice that all of the COBOL data functions support a PIC designator of the long form:

```
[S][9+]\[v9+\] (ex: S99999, 99999v99, S999999v99, SV99)
```

Or of the shortened count form:

```
[S][9(count)][v9(count)] (ex: S9(5), 9(5)v99, S9(6)v9(2), sv9(2))
```

Exercise 2: How do I read packed decimal numbers?

To read packed decimal numbers, use the piccomp3() function. The syntax is:

```c
real piccomp3(string, format_str)
```

where:

- **string**: The octet array containing COBOL-formatted packed decimal data to convert.

- **format_str**: The string containing the PIC 9 format of the data.
The piccomp3() function determines the number of bytes to consume by taking the sum of the 9s in the integer and fraction portions and adding 1. If the new value is odd, 1 is added to make it even. The result is then divided by 2. As such, S9(7) would mean there are 4 bytes to consume. The packed data is always in big-endian form.

The piccomp3() function is used the same as the piccomp() function. For an example of the piccomp3() function, see Exercise 1.

**Exercise 3: How do I read signed decimal numbers in COBOL format?**

To read signed decimal numbers, use the picsigndec() function. The syntax is:

```plaintext
real picsigndec(string buffer, string format_str, boolean ebcdic, boolean trailing)
where:

- **string buffer**: The octet array containing a COBOL-formatted signed decimal number to convert.
- **string format_str**: The string containing the PIC 9 format of the data. The default format_str is S9(4).
- **boolean ebcdic**: The Boolean when set to non-zero indicates the string is EBCDIC. The default ebcdic setting is false.
- **boolean trailing**: The Boolean when set to non-zero indicates the sign is trailing. The default trailing setting is true.

The picsigndec() function determines the number of bytes to consume by taking the sum of the 9s in the integer and fraction portions of format_str. For example:

```plaintext
//Expression
//file handler to open files
file pd
integer rc
string(6) buffer
real comp
if (pd.open("binary_input.out", "r"))
begin
rc = pd.readbytes(6, buffer)
if (4 == rc) then
comp = picsigndec(buffer, "S9(4)\V99",1,1)
pd.close()
end
```
Formatting

It is also possible to format data to a specific COBOL format, as demonstrated by the following exercises:

**Exercise 4: How do I format from a real to COBOL format?**

To format from a real to a COBOL format, use the formatpiccomp() function. The syntax is:

```plaintext
integer = formatpiccomp(Real number, string format_str, string result)
```

where:

- **real number**: The numeric to convert to a COBOL native endian binary value.
- **string format_str**: The string containing the PIC 9 format of the data.
- **string result**: The octet array in which to place the COBOL-formatted native endian binary data.

**returns:**

- **integer**: The byte length of formatted binary data.

The formatpiccomp() function does the reverse of piccomp(). As with the picsigndec() function, the formatpicsigndec() function determines the number of bytes to consume by taking the sum of the 9s in the integer and fraction portions. For example:

```plaintext
//Expression
real comp
comp = 10.125
integer rc
rc = formatpiccomp(comp, "s99V999", buffer)
//The string buffer will contain the real value comp formatted to platform COBOL COMP native endian format. ??///
```

**Exercise 5: What is the list of functions available for COBOL formatting?**

The syntax for a COBOL-packed decimal value is:

```plaintext
integer = formatpiccomp3(Real number, string format_str, string result)
```

where:

- **real number**: The numeric to convert to a COBOL packed decimal value.
- **string format_str**: The string containing the PIC 9 format of the data.
- **string result**: The octet array in which to place the COBOL formatted packed decimal data.

**returns:**

- **integer**: The byte length of formatted packed decimal data.
The syntax for a COBOL-signed decimal value is:

```plaintext
integer = formatpicsigndec(real number, string format_str, string buffer, boolean ebcdic, boolean trailing)
```

where:

- **real number**: The numeric to convert to a COBOL-signed decimal value.
- **string format_str**: The string containing the PIC 9 format of the data.
- **string buffer**: The octet array in which to place the COBOL-formatted packed decimal data.
- **boolean ebcdic**: The Boolean when non-zero indicates to format in EBCDIC.
- **boolean trailing**: The Boolean when non-zero indicates to set the sign on the trailing byte.

returns:

- **integer**: The byte length of the formatted signed decimal.

The COBOL-format functions are used the same as the formatpiccomp() function. For an example of the COBOL-format functions, see Exercise 4.

### FAQ: Using Array Functions

This section contains additional information about arrays, including:

- [Creating an Array](#)
- [Retrieving Elements from an Array](#)
- [Changing an Array Size](#)
- [Determining an Array’s Size](#)
- [Finding Common Values Between Columns Using Arrays](#)

#### Creating an Array

**Exercise: How do I create an array and provide values for the items in the array?**

To declare an array, use the reserved key word array.

```plaintext
string array variable_name
integer array variable_name
boolean array variable_name
date array variable_name
real array variable_name
```

For example:

```plaintext
// declare an array of integer types
integer array integer_list
```
// set the size of the array to 5
integer_list.dim(5)

// the index that will go through the array
integer index
index=0

// Set the values of the items inside the
// array to their index number
for index=1 to 5
begin
    integer_list.set(index, index);
end

Retrieving Elements from an Array

Exercise: How do I retrieve elements from an array?

To retrieve elements from an array, use the following example; it builds on the previous example:

integer first
integer last

// Getting the first item from integer array
first=integer_list.get(1);

// Getting the last item from integer array
last=integer_list.get(5)

Changing an Array Size

Exercise: How do I change the size of an array?

To change the size of an array, use the dim() function. For example:

// array is originally initialized to 5
string array string_container
string_container.dim(5)
...
...
// the array is sized now to 10
string_container.dim(10)

Determining an Array's Size

Exercise: How do I determine the size of an array?

To determine the size of an array, use the dim() function. Remember that the dim() function is also used to set the size of an array. If no parameter is specified, the array size does not change.

For example:

// Expression
integer array_size
string array array_lister
...
...
// after performing some operations on the array
// array_size will then contain
// the size of the array
array_size=array_lister.dim()

Finding Common Values Between Columns Using Arrays

Exercise: How do I find out if entries in one column occur in another column regardless of row position and number of times they occur?

One way to address this problem is to create two arrays for storing two columns. Then, check if the values in one array exist in the other array. Find those values that match and store them in a third array for output.

Create a Data Input node as Text File Input, and set the text file to C:\arrayTextDocument.txt in Data Jobs. Begin with the following text in the file:

c:\arrayTextDocument.txt

<table>
<thead>
<tr>
<th>A_ID</th>
<th>B_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
</tr>
</tbody>
</table>

Create an Expression node, and declare the following variables in the pre-expression step:

// Pre-Expression
// This is where we declare and initialize our variables.
hidden string array column_A
hidden string array column_B
hidden string array column

hidden integer column_A_size
column_A_size=1
column_A.dim(column_A_size)

hidden integer column_B_size
column_B_size=1
column_B.dim(column_B_size)

hidden integer commun_size
commun_size=1
commun.dim(commun_size)

All the variables are hidden and are not displayed on the output. All the arrays are defined in the beginning to be of size 1. Later, these arrays will be expanded to accommodate the number of rows that are added.

// Expression

// Name your First_Column field as you need
column_A.set(column_A.size, `A_ID`)
column_A_size=column_A_size+1
column_A.dim(column_A_size)

// Name the Second_Column field as you need
column_B.set(column_B_size, 'B_ID')

column_B_size=column_B_size+1
column_B.dim(column_B_size)

In this step, we retrieve input into the arrays and expand the size of the arrays as necessary. The size of the array might become quite large depending on the size of the column, so it is recommended you use this example with small tables.

// Post Expression
// This is the step where most of the logic will be implemented

// index to iterate through column_A
hidden integer index_column_A

// index to iterate through column_B
hidden integer index_column_B

// index to iterate through commun array
hidden integer index_commun

// index to display the commun values that were found
hidden integer commun_display_index

// string that will contain the items from column A when retrieving
hidden string a

// string that will contain the items from column B when retrieving
hidden string b

// String that will contain the contents of the commun array when retrieving
hidden string commun_content

// This boolean variable
// is to check if a commun entry has already been found. If so, don’t display it again
hidden boolean commun_found

// This is the variable
// that will display the common entries in the end
string commun_display

// Retrieves the entries in column A
for index_column_A=1 to column_A_size Step 1
begin
  a=column_A.get(index_column_A)
  for index_column_B=1 to column_B_size Step 1
  begin
    b=column_B.get(index_column_B)
    // Compare the entries from column A with
    // the entries from column B
    if(compare(a,b)==0)
    begin

}
// Check if this entry was already found once
commun_found=false
for index_commun=1 to commun_size Step 1
  begin
    commun_content=commun.get(index_commun)
    if(compare(commun_content,a)==0) then
      commun_found=true
    end
  end
if(commun_found==false)
  begin
    commun.set(commun_size,a)
    commun_size=commun_size+1
    commun.dim(commun_size)
  end
end
end

// Display the contents of the commun array
// to the screen output
for commun_display_index=1 to commun_size Step 1
  begin
    pushrow()
    commun_display=commun.get(commun_display_index)
  end
end

If you want to see the output limited to the common values, add another Expression
node and the following filtering code:

// Expression
if(isnull(`commun_display`)) then
  return false
else
  return true

FAQ: Using Blue Fusion Functions

Once a Blue Fusion object is defined and initialized, the function methods listed can
be used within the Expression node.

Exercises

The following exercises demonstrate how the Blue Fusion object methods can be
used in the Expression node.

Exercise 1: How do I start a Blue Fusion instance and load a QKB?

To start a Blue Fusion instance and load a QKB, add the following in the Pre-
Processing tab:

// Pre-processing
// defines a bluefusion object called bf
bluefusion bf;
// initializes the bluefusion object bf
bf = bluefusion_initialize()

// loads the English USA Locale
bf.loadqkb("ENUSA");

To load other QKBs, refer to their abbreviation. Go to the DataFlux Data Management Studio Administration riser bar and click Quality Knowledge Base to see which QKBs are available for your system.

**Exercise 2: How do I create match codes?**

To create match codes, after you initialize the Blue Fusion object with a QKB in the **Pre-Processing** tab, enter the following expressions:

```plaintext
// Expression

// define mc as the return string that contains the match code
string mc

// define the return code ret as an integer
integer ret

// define a string to hold any error message that is returned,
string error_message

// generate a match code for the string Washington D.C.,
// using the City definition at a sensitivity of 85, and
// put the result in mc
ret = bf.matchcode("city", 85, "Washington DC", mc);

// if an error occurs, display it; otherwise return a success message
if ret == 0 then
    error_message = bf.getlasterror()
else
    error_message = 'Successful'
```

**Exercise 3: How do I use Blue Fusion standardize?**

To use Blue Fusion standardize, enter the following expressions after you initialize the Blue Fusion object in the **Pre-Processing** tab:

```plaintext
// Expression

// define stdn as the return string that contains the standardization
string stdn

// define the return code ret as an integer
integer ret

// define a string to hold any error message that is returned
string error_message

// standardize the phone number 9195550673,
// and put the result in stdn
ret = bf.standardize("phone", "9195550673", stdn);

// if an error occurs display it; otherwise return a success message,
if ret == 0 then
    error_message = bf.getlasterror()
else
    error_message = 'Successful'
```
Exercise 4: How do I use Blue Fusion identify?

To use Blue Fusion identify, after you initialize the Blue Fusion object in the Pre-Processing tab, enter the following expressions:

```csharp
// Expression
// define iden as the return string that contains the identification string iden
// define the return code ret as an integer integer ret
// define a string to hold any error message that is returned string error_message
// generate an Ind/Org identification for IBM and put the result in iden ret = bf.identify("Individual/Organization", "IBM", iden);
// if an error occurs display it; otherwise return a success message, if ret == 0 then
  error_message = bf.getlasterror()
else
  error_message = 'Successful'
```

Exercise 5: How can I perform gender analysis?

To perform gender analysis, after you initialize the Blue Fusion object in the Pre-Processing tab, enter the following expressions:

```csharp
// Expression
// define gend as the return string that contains the gender string gend
// define the return code ret as an integer integer ret
// define a string to hold any error message that is returned string error_message
// generate a gender identification for Michael Smith, and put the result in gend ret = bf.gender("name","Michael Smith",gend);
// if an error occurs display it; otherwise return a success message, if ret == 0 then
  error_message = bf.getlasterror()
else
  error_message = 'Successful'
```

Exercise 6: How can I do string casing?

To perform string casing after you initialize the Blue Fusion object in the Pre-Processing tab, enter the following expressions:

```csharp
// Expression
// define case as the return string that contains the case string case
```
// define the return code ret as an integer
integer ret

// define a string to hold any error message that is returned
string error_message

// convert the upper case NEW YORK to propercase
ret = bf.case("Proper", 3, "NEW YORK", case);

// if an error occurs display it; otherwise return a success message,
if ret == 0 then
  error_message = bf.getlasterror()
else
  error_message = 'Successful'

Exercise 7: How can I do pattern analysis?

To perform pattern analysis after you initialize the Blue Fusion object in the Pre-Processing tab, enter the following expressions:

//Expression

//define pattern as the return string
string pattern

//define the return code ret as an integer
integer ret

// define a string to hold any error message that is returned
string error_message

// analyze the pattern 919-447-3000 and output the result
// as pattern
ret = bf.pattern("character", "919-447-3000", pattern);

// if an error occurs display it; otherwise return a success message,
if ret == 0 then
  error_message = bf.getlasterror()
else
  error_message = 'Successful'

FAQ: Using Date and Time Functions

In this section, you will find additional information about date and time functions, including:

- Finding Today's Date
- Formatting a Date
- Extracting Parts from a Date
- Adding or Subtracting from a Date
- Comparing Dates
**Finding Today's Date**

**Exercise: How do I find the year, month, and day values for today's date?**

To determine the parts of the current date, use the `today()` function.

```plaintext
date today()
```

The following function returns the current date and time:

```plaintext
// Expression
date localtime
localtime=today()
```

**Formatting a Date**

**Exercise 1: What formats can a date have?**

Dates should be in the format specified by ISO 8601 (YYYY-MM-DD hh:mm:ss) to avoid ambiguity. Remember that date types must start with and end with the # sign. For example:

**Date only:**

```plaintext
// Expression date dt
dt=#2007-01-10#
//Jan 10 2007
```

**Date with time:**

```plaintext
// Expression date dt
dt=#2007-01-10 12:27:00#
//Jan 10 2007 at 12:27:00
```

**Exercise 2: How do I format the date?**

To specify a format for the date in Expression Engine Language (EEL), use the `formatdate()` function:

```plaintext
string formatdate(date, string)
```

The `formatdate()` function returns a date formatted as a string. For example:

```plaintext
// Expression
// all have the same output until formatted explicitly
date dt
dt=#2007-01-13#

string formata
string formatb
string formatc
formata=formatdate(dt, "MMM/DD/YY") // outputs 01/13/07
formatb=formatdate(dt, "DD MMMM YYYY") // outputs 13 January 2007
formatc=formatdate(dt, "MMM DD YYYY") // outputs Jan 13 2007
```
Extracting Parts from a Date

Exercise: How do I get individual components out of a date?

To extract parts of a date, use the `formatdate()` function. For example:

```
// Expression
date dt
dt=#10 January 2003#

string year
string month
string day

// year should be 03
year=formatdate(dt, "YY")
// month should be January
month=formatdate(dt, "MMMM")
// day should be 10
day=formatdate(dt, "DD")
```

Note that if the date format is ambiguous, EEL will parse the date as MDY.

Adding or Subtracting from a Date

Exercise: Can I do arithmetic with dates?

EEL offers the ability to add or subtract days from an existing date. For example:

```
// Expression
date dt // variable that will contain the date
dt=#10 January 2003#
date later
date earlier

// add three days to the original date
later=dt+3
// subtract three days from the original date
earlier=dt-3
```

Comparing Dates

Exercise: How do I check if two dates match and are the same?

To compare dates, use the `formatdate()` function.

Convert the date to a string type using `formatdate()` function and then check for the value of the string. For example:

```
date dt

// the variable that will contain the date
// that we want to compare against
dt=#1/1/2007#

// The string variable that will contain the
dt date in a string format
string dt_string
```
// The variable that will convert the
// incoming date fields to string
dt_string=formatdate(dt, "MM/DD/YY")
string Date_string

// Notice that 'DATE' is the incoming field
// from the data source It is written between '' so
// it does not conflict with the date data type
Date_string=formatdate('DATE', "MM/DD/YY")

// boolean variable to check if the dates matched
boolean date_match

// Initialize the variable to false
date_match=false

if(compare(dt_string, Date_string)==0)then
    date_match=true

FAQ: Using Database Functions

Connecting to a Database

Exercise: How do I connect to a database?

To connect to a database, use the `dbconnect()` function. This function returns a
`dbconnection` object. The syntax is:

    dbconnection test_database

For example:

    // Set connection object to desired data source
    // Saved DataFlux connections can also be used
test_database=dbconnect("DSN=DataFlux Sample")

Listing Data Sources

Exercise 1: How do I return a list of data sources?

To return a list of data sources as a `dbcursor`, use the `dbdatasources()` function.

The following example works with the Contacts table in the DataFlux sample
database. Make sure you have some match codes in that table in a field called
CONTACT_MATCHCODE. In the step before your expression step, use a match code
generation node and have match codes created for some sample names in a text file.
This text file is your job input step. Call this new field "Name_MatchCode." This
example queries the Contacts table in the DataFlux sample database to see if there
are any names that match the names you provided in your text file input.

Pre-processing window

    // Declare Database Connection Object
dbconnection db_obj

    // Declare Database Statement Object
dbstatement db_stmt
// Set connection object to desired data source
// Saved DataFlux connections can also be used
db_obj=dbconnect("DSN=DataFlux Sample")

// Prepare the SQL statement and define parameters
// to be used for the database lookup
db_stmt=db_obj.prepare("Select * from Contacts where Contact = ?")
db_stmt.setparaminfo(0,"string",30)

Expression window

// Declare Database Cursor and define fields returned from table
dbcursor db_curs
string Database_ID
string COMPANY
string CONTACT
string ADDRESS

// Set parameter values and execute the statement
db_stmt.setparameter(0,Name)
db_curs=db_stmt.select()

// Move through the result set adding rows to output
while db_curs.next() begin
    Database_ID=db_curs.valuestring(0)
    COMPANY=db_curs.valuestring(1)
    CONTACT=db_curs.valuestring(2)
    ADDRESS=db_curs.valuestring(3)
    pushrow()
end

db_curs.release()

// Prevent the last row from occurring twice
return false

FAQ: Using Encode and Decode Functions

Exercise 1: How do I transcode a given expression string from its native encoding into the specified encoding?

To transcode an expression, use the encode function and decode function. For example:

//Expression
string expression_string
expression_string="Hello World"
string decode_string
string encode_string
integer decode_return
integer encode_return
decode_return = decode("IBM1047", expression_string, decode_string)
//Decode to IBM1047 EBCDIC
encode_return = encode("IBM1047",decode_string,encode_string)
//Encode string should be "Hello World"

Exercise 2: What are the available encodings?

Refer to Appendix B: Encoding for a list of available encodings.
FAQ: Using File Functions

File Operations

Exercise 1: How do I open a file?

To open a file in Expression Engine Language (EEL), use this expression:

```csharp
// Expression
File f
f.open("C:\filename.txt","r")
```

The second parameter to the file object indicates the mode for opening the file (read, write, or read/write).

Exercise 2: How do I read lines from a file, treating each line as a single row from a data source?

After opening a file, use the following code to read a string line of input:

```csharp
// Pre-Expression
File f
string input
f.open("C:\filename.txt", "rw")

// Expression
input=f.readline()

// Post Expression
f.close()
```

Make sure that you have selected Generate rows when no parent is specified. The file cursor advances one line in the text file for the each row of input from the data source.

Exercise 3: How do I read lines from a text file, and create one output line for each line in the text file?

Write a while loop that iterates through each line in the file with every row. For example, consider the following text files:

```
c:\filename.txt

Name
Jim
Joan
Pat

```

```
c:\filepet.txt

Pet
Fluffy
Fido
Spot
```
Use the following expression:

```java
// Expression
File f
File g
string input
input='hello'
f.open("C:\filename.txt")
g.open("C:\filepet.txt")

while (NOT isnull(input))
begin
    input=f.readline()
    print('The value of input is ' & input)
    input=g.readline()
    print('The value of input is ' & input)
end

seteof()
```

This prints the contents of the two files to the log. If you preview the job, you see null for the input string since, the input string has a null value at the completion of the loop.

A good way to see how this example works in your job is to add an expression step that sets the end of file:

```java
// Expression
seteof()
```

The preview pane shows the value of input as null, but the log pane shows each of the possible values listed in the filename.txt and filepet.txt files.

**Exercise 4: How do I write to a file?**

To write to a file, use the writeline() function in the file object. For example:

```java
// Expression
File f
f.open("C:\filename.txt", "w")
f.writeline("Hello World ")

// Post Expression
f.close()
```

⚠️ **Caution:** This function overwrites the current contents of your text file.

**Exercise 5: How do I move from one position to another in a file?**

To move from one position in a file to another, there are three available functions: seekbegin(), seekcurrent(), and seekend().
The seekbegin() function sets the file pointer to a position starting at the beginning of the file. It returns true on success; otherwise, it returns false. The parameter specifies the position:

```
seekbegin([position])
```

The seekcurrent() function sets the file pointer to a position starting at the current position. It returns true on success; otherwise, it returns false. The parameter specifies the number of bytes from the current position:

```
seekcurrent([position])
```

The seekend() function sets the file pointer to a position starting at the end of the file. It returns true on success; otherwise, it returns false. The parameter specifies the position from the end of the file:

```
seekend([position])
```

All of these functions receive as a parameter the number of bytes to move from the current position in the file. Specify 0 in the seekbegin() or the seekend() functions to go directly to the beginning or the end of the file. For example: In order to append to the end of a file you would select `Generate rows when no parent is specified`, and enter:

```
// Expression
File f
f.open("C:\Text_File\file_content.txt", "rw")
f.seekend(0)
f.writeline("This is the end ")
seteof()
```

This example adds the text "This is the end" to the end of the file. If you move to the beginning of the file, use the writeln() function to overwrite existing content.

Close the file with f.close() in the post-processing step:

```
// Post Processing
f.close()
```

**Exercise 6: How do I copy the contents of a file to another file?**

To copy the contents of one file to another, use the Boolean function, copyfile(). This function takes the originating filename as the first parameter and the destination filename as the second parameter. The destination file can be created or amended by this function. For example:

```
// Expression
string names
string pets
names="C:\filename.txt"
pets="C:\filecopy.txt"

copyfile(names, pets)
seteof()
```
**Exercise 7: How do I read or write a certain number of bytes from a text file?**

To read a specified number of bytes from a text file, use the `readbytes()` function:

```plaintext
string input
File a
a.open("C:\filename.txt", "r")
a.readbytes(10, input)
```

To write a specified number of bytes to a text file, use the `writebytes()` function:

```plaintext
string input
input="This string is longer than it needs to be."
File b
b.open("C:\filename.txt", "rw")
b.writebytes(10, input)
```

By overwriting existing data, this expression produces the following:

```
c:\filename.txt
<table>
<thead>
<tr>
<th>This string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Joan</td>
</tr>
<tr>
<td>Pat</td>
</tr>
</tbody>
</table>
```

**Manipulating Files**

**Exercise 1: How do I retrieve information about the file?**

To determine if a file exists, use the `fileexists()` function:

```plaintext
boolean fileexists(string)
```

The `fileexists()` function returns true if the specified file exists. The string parameter is the path to the file.

To find the dates a file was created and modified, use the `filedate()` function:

```plaintext
date filedate (string, boolean)
```

The `filedate()` function returns the date a file was created. If the second parameter is true, it returns the modified date.

For example:

```plaintext
// Expression
boolean file_test
date created
date modified

file_test=fileexists("C:\filename.txt")
created=filedate("C:\filename.txt", false)
modified=filedate("C:\filename.txt", true)

seteof()
```
Note: If the filedate() function returns a null value but the fileexists() function returns true, you most likely entered the file path incorrectly.

To get the size of a file, you can use the open(), seekend(), and position() functions. The size of the file is returned in bytes. For example:

```csharp
// Expression
File f
integer byte_size
f.open("C:\filename.txt", "rw")
f.seekend(0)

// The integer variable byte_size will have
// the size of the file in bytes
byte_size=f.position()
```

Exercise 2: Is it possible to perform operations such as renaming, copying, or deleting a file?

Yes. To delete a file, use the deletefile() function:

```csharp
boolean deletefile(string)
```
This action deletes a file from the disk. The string parameter is the path to the file.

Note: Use care when employing this function. Once you delete a file, it is gone.

To move or rename a file, use the movefile() function:

```csharp
boolean movefile(string, string)
```
For example, the following code moves filename.txt from the root to the Names folder.

```csharp
boolean newLocation
newLocation=movefile("C:\filename.txt","C:\Names\filename.txt")
seteof()
```

Note: The directory structure must already be in place for the function to move the file to its new location.

FAQ: Using Integer and Real Functions

Integers and real types are basic data types in Expression Engine Language (EEL). An integer can be converted to a real type, and a real type value can be converted to an integer.

This section focuses on available functions in EEL that work on integers and real types.
Determining Type

Determine the type of a variable before doing calculations.

Exercise: How do I determine if the variable has a numeric value?

The isnumber() built-in function can be used to determine if a variable has a numeric value. It takes a variable as a parameter and returns true if the expression is a number. For example:

```plaintext
// Expression
string str
string input
input=8 // although a string, input is coerced into an integer

if(isnumber('Input'))
    str="this is a number" // input is a number
else
    str="this is a string"
```

Assigning Values

Exercise: Can integers and real types have negative values?

Yes, integers and real types are not limited to positive values. Add a negative sign in front of the value to make it negative. For example:

```plaintext
// Expression
integer positive
integer negative
positive=1
negative=-1 // negative is equal to -1
```

Casting

The need to coerce from one type to another can happen frequently with integers, real data types, and string types. The user does not have to perform any task; EEL handles the casting automatically.

Exercise 1: Can I assign the value of a real data type to an integer? What about assigning an integer to a real data type?

Yes, integers and real types can be changed from one type to the other. To change the type, assign one type to the other.

Exercise 2: Is it possible to combine integers and real data types with strings?

Yes, a string type can be changed to an integer or a real type. For example:

```plaintext
integer x

// string is converted to value 10
// x will have the value 15
x=5 + "10"
```
**Exercise 3: Is it possible to assign the integer value zero to a Boolean to represent false?**

In EEL, Boolean values can have an integer value of zero, which is interpreted as false. Any non-zero integer value is interpreted as true.

**Range and Precision**

When working with scientific data with either very small or very large values, the range and precision of the integer and real types might be important.

**Exercise: What is the range/precision for real and integer values?**

Integer types are stored as 64-bit signed quantities with a range of $-2 \times 10^{63}$ to $2 \times 10^{63} - 1$.

Real types are stored as high precision values with an approximate precision of 44 digits and a range of $5.0 \times 10^{-324}$ to $1.7 \times 10^{308}$. Real types are based on the IEEE 754 definition.

**List of Operations**

In EEL, the following operations can be performed on real and integer types.

**Exercise: What operations can I do on real and integer types?**

The list of operations for real and integer types includes:

- Multiplication (*)
- Division (/)
- Modulo (%)
- Addition (+)
- Subtraction (–)

Currently, it is not possible to perform trigonometric or logarithmic calculations. You can perform exponential calculations using the pow() function:

```plaintext
real pow(real, real)
```

The pow() function returns a number raised to the power of another number.

```plaintext
// Expression
real exponential

// exponential is 8
exponential = pow(2, 3)
```
Rounding

Integers and real values in EEL can be rounded using the round() function. The second parameter is an integer value that determines how many significant digits to use for the output. A positive value is used to round to the right of the decimal point. A negative value is used to the left of the decimal point.

Exercise: Can integer and real types be rounded?

Yes, by using the round() function. Consider the following code example:

```c
// Expressions
integer integer_value
integer_value=1274
real real_value
real_value=10.126

integer ten
integer hundred
integer thousand

// the value for ten will be 1270
ten=round(integer_value, -1)

// the value for hundred will be 1300
hundred=round(integer_value, -2)

// the value for thousand will be 1000
thousand=round(integer_value, -3)

real real_ten
real real_hundred

// the value for real_ten will be 10.1
real_ten=round(real_value, 1)

// the value for real_hundred will be 10.13
real_hundred=round(real_value, 2)
```

FAQ: Using Regular Expression Functions

Using Regular Expressions

For a regular expression (regex) to work, you must first compile. In the Data Job Editor, this is best done in the pre-processing step. Here are some examples.

Exercise 1: How do I find matches within a string?

To find the first match in the string, use the `findfirst()` function. To find subsequent matches in the string, use `findnext()`. For example:

```c
regex r
r.compile("a.c")
if r.findfirst("abcdef")
    print("Pound match starting at " & r.matchstart() & " length " & r.matchlength())
```
Exercise 2: How do I know if my regex pattern matches part of my input?

To see if your regex pattern finds a match in the input string, follow this example:

```java
regex a
boolean myresult
a.compile("a","ISO-8859-7")
myresult=a.findfirst("abc")
```

Exercise 3: How do I find the regex pattern I want to match?

To find the first instance of the regex pattern that you want to match, follow this example:

```java
integer startingPosition
regex r
r.compile("a.c")
if r.findfirst("abcdef")
    startingPosition=r.matchstart()
```

Exercise 4: How do I replace a string within my regex?

To replace a string, compile the regex and use the replace function as follows:

```java
regex r
r.compile("xyz")
r.replace("abc","def")
```

This exercise replaces "abc" with "def" within the compiled "xyz."

FAQ: Using String Functions

Determining Type

The following exercises demonstrate how to determine the data type of a string.

Exercise 1: How do I determine if an entry is a string?

To determine if the string is a string type, use the typeof() function:

```java
string typeof(any)
```

The typeof() function returns the type of data that the expression converts to. For example:

```
// Expression
string hello
hello="hello"

boolean error
error=false

// variable that will contain the type
string type
type=typeof(hello)
```
// type should be string
if(type<>"string") then
    error=true

**Exercise 2: How do I determine if a string is made up of alphabetic characters?**

To determine if a string is made up entirely of alphabetic character, use the isalpha() function:

```java
boolean isalpha(any)
```

The isalpha() function returns a value of true if the string is made up entirely of alphabetic characters. For example:

```java
// Expression
string letters
letters=\"lmnop\"
string mixed
mixed=\"1a2b3c\"

string alphatype
alphatype=isalpha(letters) // true
string mixedtype
mixedtype=isalpha(mixed) // false
```

**Exercise 3: How can I retrieve all values that are either not equal to X or null values?**

To retrieve the above stated values, use the isnull() function:

```java
boolean isnull(any)
```

For example:

```java
// Expression
if State <> \"NC\" OR isnull(State)
    return true
else
    return false
```

**Extracting Substrings**

**Exercise: How do I get substrings from an existing string?**

To get substrings, there are three available functions: left(), right(), and mid().

To return the leftmost characters of a string, use the left() function:

```java
string left(string, integer)
```

To return the rightmost characters of a string, use the right() function:

```java
string right(string, integer)
```
For example:

```java
// Expression
string greeting
greeting="Hello Josh and John"

string hello
string John
string inbetween

hello=left(greeting, 5) // "Hello"
John=right(greeting, 4) // "John"
inbetween=left(greeting, 10) // "Hello Josh"
inbetween=right(inbetween, 4) // "Josh"
```

Another approach is to use the `mid()` function:

```java
string mid(string, integer p, integer n)
```

The `mid()` function returns a substring starting at position `p` for `n` characters. For example:

```java
string substring
// substring will be the string "Josh"
substring=mid(greeting, 7, 4);
```

### Parsing

**Exercise: How do I parse an existing string into smaller strings?**

To parse a string, use the `aparse()` function:

```java
integer aparse(string, string, array)
```

The `aparse()` function parses a string into a string array. The number of elements in the array is returned. For example:

```java
// Expression
string dataflux
dataflux="Dataflux:dfPower:Architect"

// An array type to contain the parsed words
string array words

// integer to count the number of words
integer count

// count will have a value of 3
count=aparse(dataflux, ":", words)

string first_word
first_word=words.get(1) // First word will be "DataFlux"

string second_word
second_word=words.get(2) // Second word will be "Data Management"
```
string third_word
third_word=words.get(3) // Third Word will be "Studio"

string last_entry // This will have the last entry.
last_entry=words.get(count)

The `aparse()` function is useful if you want to retrieve the last entry after a given separator.

Similar to the `aparse()` function is the `parse()` function. The syntax for the `parse()` function is:

    integer parse(string, string, ...)

The `parse()` function parses a string using another string as a delimiter. The results are stored starting from the third parameter. It returns the total number of parameters.

You would employ the `parse()` function in the following situation:

    // Expression
    integer count
    string first
    string second
    string third

    // first contains "DataFlux"
    // second contains "Data Management"
    // third contains "Studio"
    count=parse("DataFlux:Data Management:Studio", ":", first, second, third);

The main difference between the two functions is that `aparse()` is suited for arrays, while `parse()` is useful for returning individual strings.

**ASCII Conversions**

EEL has the ability to convert characters to their ASCII values, and to convert ASCII values to characters.

**Exercise: Is it possible to convert between ASCII characters and values?**

Yes. To convert between ASCII characters and values, use the `chr()` and `asc()` functions. For example:

    // Expression
    integer ascii_value
    string character_content

    ascii_value=asc("a"); // ascii_value is 97
    character_content=chr(97) // returns the letter "a"

For a complete list of ASCII values, see Appendix A: ASCII Printable Characters.
String Manipulations

Frequently, when working with strings, you might want to perform manipulations such as adjusting the case, removing spaces, concatenating strings, and getting the length of a string. EEL has built-in functions to perform these actions.

Exercise 1: How do I concatenate strings?

To concatenate a string, use the "&" symbol. For example:

```plaintext
// Expression
string Hello
Hello="Hello ">

string World
World=" World"

string Hello_World
Hello_World=Hello & World // outputs "Hello World"
```

Exercise 2: How do I get the length of a string and remove spaces?

To get the length of a string, use the len() function, and then to remove the spaces, use the trim() function.

The len() function returns the length of a string:

```plaintext
integer len(string)
```

The trim() function returns the string with the leading and trailing white-space removed:

```plaintext
string trim(string)
```

For example:

```plaintext
// Expression
string content
content=" Spaces ">

integer content_length

content=trim(content) // Remove spaces

// returns 6
content_length=len(content)
```

Exercise 3: How do I convert a string type to lowercase or uppercase?

To convert a string to lowercase or uppercase, use the lower() and upper() functions.

The lower() function returns the string in lowercase:

```plaintext
string lower(string)
```

The upper() function returns the string in uppercase:

```plaintext
string upper(string)
```
For example:

```java
// Expression
string changeCase
changeCase="MixedCase"
string newCase
newCase=upper(changeCase)
```

### Comparing and Matching

EEL lets you compare strings, find differences between strings, and search for substrings.

**Exercise 1: How do I compare two strings?**

To compare two strings, use an equal comparison (==). For example:

```java
// Expression
string test
boolean match

// initialize
test="Hello"
match=false

// compare string values
if(test=="Hello") then
  match=true
```

To get a more in-depth comparison, consider the `compare()` and `edit_distance()` functions.

The `compare()` function compares two strings:

```java
integer compare(string, string, boolean)
```

It returns:

- \(-1\) if first < second
- 0 if first equals second
- \(1\) if first > second

If the third parameter is true, the comparison is not case sensitive. The comparison between two strings is done lexicographically.

Another similar function is `edit_distance()`:

```java
integer edit_distance(string, string)
```

This function returns the edit distance between two strings. Specifically, this function returns the number of corrections that would need to be applied to turn one string into the other.
The following examples use these functions:

```c
// Expression
integer difference
integer comparison

string hello
hello="hello"

string hey
hey="hey"

// comparison is -1 because hello comes before hey
comparison = compare(hello, hey, true);

// difference is 3 because there are three different letters
difference = edit_distance(hello, hey);
```

**Exercise 2: How do I check if a string matches, or if it is a substring inside another string?**

The following built-in EEL functions handle this situation.

The `instr()` function returns the location of one string within another string, stating the occurrence of the string.

```c
boolean instr(string, string, integer)
```

The `match_string()` function determines if the first string matches the second string, which may contain wildcards.

```c
boolean match_string(string, string)
```

Search strings can include wildcards in the leading (*ABC*) and trailing (*ABC*) position, or a combination of the two (*ABC*). Wildcards within a string are invalid (A*BC). Question marks can be used as a wildcard, but can be matched only to a character. For example, AB? matches ABC, not AB. To execute a search for a character that is used as a wildcard, precede the character with a backslash. This denotes that the character should be used literally and not as a wildcard. Valid search strings include: *BCD*, *B?D*, *BCDE, *BC?E, *BCD?, ABCD*, AB?D*, ?BCD*, *B??*, *B\?\? (will match the literal string AB?\E). An invalid example is: AB*DE. For more complex searches, use regular expressions instead of the `match_string()` function.

Consider the following code example with these functions:

```c
// Expression
string content
content="Monday is sunny, Tuesday is rainy & Wednesday is windy"

string search
search="*Wednesday is windy" // note the * wildcard

integer found_first
integer found_next

boolean match
```
// Check if the search string is in the content
match=match_string(content, search)
if (match) then
    begin
        // Will find the first occurrence of day
        found_first=instr(content, "day", 1)

        // Will find the second occurrence of day
        found_next=instr(content, "day", 2)
    end

Exercise 3: How do I know when the correct Surviving Record is selected as a survivor?

When comparing integers in the Expression Engine, it is important to use the correct variable type. When using the variable type "string", a string value of "5" is actually greater than the string value of "10". If the values need to be compared as integers, the values must be converted into variables of integer type first. To accomplish this conversion use the tointeger() function.

Replacing Strings

The replace() function replaces the first occurrence of one string with another string and returns the string with the replacement made.

    string replace(string, string, string, integer)

If the fourth parameter is omitted or set to 0, all occurrences are replaced in the string. If the fourth parameter is set to another number, that many replacements are made.

Consider the following example:

    // Expression
    string starter
    string replace
    string replaceWith
    string final

    starter="It's a first! This is the first time I came in first place!"
    replace="first"
    replaceWith="second"

    final =replace(starter, replace, replaceWith, 2)
    seteof()

This example produces the following results:

<table>
<thead>
<tr>
<th>starter</th>
<th>replace</th>
<th>replaceWith</th>
<th>final</th>
</tr>
</thead>
<tbody>
<tr>
<td>It's a first! This is the first time I came in first place!</td>
<td>first</td>
<td>second</td>
<td>It's a second! This is the second time I came in first place!</td>
</tr>
</tbody>
</table>
Finding Patterns

It is possible to extract patterns out of strings using EEL. EEL identifies the following as part of a string's pattern:

- 9 = numbers
- a = lowercase letters
- A = uppercase letters

**Exercise: How do I get a string pattern?**

To determine the string pattern, use the `pattern()` function:

```java
string patte
```

The `pattern()` function indicates if a string has numbers or uppercase and lowercase characters. It generates a pattern from the input string. For example:

```java
// Expression
string result;
string pattern_string;
pattern_string="abcdeABCDE98765";

// The result will be aaaaaAAAAA99999
result=pattern(pattern_string);
```

Control Characters

EEL can identify control characters such as a horizontal tab and line feed.

**Exercise: How can I detect control characters in a string?**

To detect control characters, use the `has_control_chars()` function.

```java
boolean has_control_chars(string)
```

The `has_control_chars()` function determines if the string contains control characters. For a list of control characters, see [Appendix A: ASCII Control Characters](#).

Evaluating Strings

EEL allows you to dynamically select the value of a field.

**Exercise: How can I convert field names into values?**

To convert field names into values, use the `vareval()` function.

```java
string vareval(string)
```

The `vareval()` function evaluates a string as though it were a variable.

**Note:** Since it has to look up the field name each time it is called, `vareval()` is a slow function and should be used sparingly.
In the following example, you have incoming data from three fields: field1, field2, and field3, as shown in the following table.

![Table](image)

You can write a for loop that builds the string ("field" & n), and uses the vareval() function to get the value of the field. For example:

```plaintext
// Pre-expression
string field_number
string field_value

// Expression
hidden integer n
for n=1 to 5
begin
    field_number='field_' & n
    field_value=vareval(field_number)
    n=n+1
    pushrow()
end

// this next statement prevents the last row from showing up twice
return false
```
Appendixes

The following topics are available in the Appendix section of this reference guide:

- Appendix A: Reserved Words
- Appendix B: ASCII Values
- Appendix C: Encoding

Appendix A: Reserved Words

The following list of reserved words cannot be used for label names:

- and
- date
- hidden
- pointer
- step
- array
- else
- if
- private
- string
- begin
- end
- integer
- public
- then
- boolean
- for
- not
- real
- to
- bytes
- global
- null
- return
- visible
- call
- goto
- or
- static
- while

Appendix B: ASCII Values

The following tables contain the ASCII printable and control characters that can be represented by decimal values.

ASCII Printable Characters

The following table contains the ASCII printable characters that can be represented by decimal values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Character</th>
<th>Value</th>

</table>
# Appendix C: Encoding

The table below explains the options available with the Encoding drop-down list. In most cases, you will select **Default** from the Encoding drop-down list.

<table>
<thead>
<tr>
<th>Option</th>
<th>Character Set</th>
<th>Encoding Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hp-roman8</td>
<td>Latin</td>
<td>19</td>
<td>An 8-bit Latin character set.</td>
</tr>
<tr>
<td>IBM437</td>
<td>Latin</td>
<td>32</td>
<td>Original character set of the IBM PC. Also known as CP437.</td>
</tr>
<tr>
<td>IBM850</td>
<td>Western Europe</td>
<td>33</td>
<td>A code page used in Western Europe. Also referred to as MS-DOS Code Page 850.</td>
</tr>
<tr>
<td>IBM1047</td>
<td>EBCDIC Latin 1</td>
<td>10</td>
<td>A code page used for Latin 1.</td>
</tr>
<tr>
<td>ISO-8859-1</td>
<td>Latin 1</td>
<td>1</td>
<td>A standard Latin alphabet character set.</td>
</tr>
<tr>
<td>ISO-8859-2</td>
<td>Latin 2</td>
<td>2</td>
<td>An 8-bit character sets for Western alphabetic languages such as Latin, Cyrillic, Arabic, Hebrew, and Greek. Commonly referred to as Latin 2.</td>
</tr>
<tr>
<td>ISO-8859-3</td>
<td>Latin 3</td>
<td>13</td>
<td>An 8-bit character encoding. Formerly used to cover Turkish, Maltese, and Esperanto. Also known as &quot;South European&quot;.</td>
</tr>
<tr>
<td>ISO-8859-4</td>
<td>Latin 4</td>
<td>14</td>
<td>An 8-bit character encoding originally used for Estonian, Latvian, Lithuanian, Greenlandic, and Sami. Also known as &quot;North European&quot;.</td>
</tr>
<tr>
<td>ISO-8859-5</td>
<td>Latin/Cyrillic</td>
<td>3</td>
<td>Cyrillic is an 8-bit character set that can be used for Bulgarian, Belarusian, and Russian.</td>
</tr>
<tr>
<td>ISO-8859-6</td>
<td>Latin/Arabic</td>
<td>9</td>
<td>This is an 8-bit Arabic (limited) character set.</td>
</tr>
<tr>
<td>ISO-8859-7</td>
<td>Latin/Greek</td>
<td>4</td>
<td>An 8-bit character encoding covering the modern Greek language along with mathematical symbols derived from Greek.</td>
</tr>
<tr>
<td>ISO-8859-8</td>
<td>Latin/Hebrew</td>
<td>11</td>
<td>Contains all of the Hebrew letter without Hebrew vowel signs. Commonly known as MIME.</td>
</tr>
<tr>
<td>ISO-8859-9</td>
<td>Turkish</td>
<td>5</td>
<td>This 8-bit character set covers Turkic and Icelandic. Also known as Latin-5.</td>
</tr>
<tr>
<td>ISO-8859-10</td>
<td>Nordic</td>
<td>15</td>
<td>An 8-bit character set designed for Nordic languages. Also known as Latin-6.</td>
</tr>
<tr>
<td>ISO-8859-13</td>
<td>Baltic</td>
<td>16</td>
<td>An 8-bit character set covering Baltic languages. Also known as Latin-7 or &quot;Baltic Rim&quot;.</td>
</tr>
<tr>
<td>ISO-8859-14</td>
<td>Celtic</td>
<td>17</td>
<td>An 8-bit character set covering Celtic languages like Gaelic, Welsh, and Breton. Known as Latin-8 or Celtic.</td>
</tr>
<tr>
<td>Option</td>
<td>Character Set</td>
<td>Encoding Constant</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------</td>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ISO-8859-15</td>
<td>Latin 9</td>
<td>18</td>
<td>An 8-bit character set for English, French, German, Spanish, and Portuguese, as well as other Western European languages.</td>
</tr>
<tr>
<td>KOI8-R</td>
<td>Russian</td>
<td>12</td>
<td>An 8-bit character set covering Russian.</td>
</tr>
<tr>
<td>Shift-JIS</td>
<td>Japanese</td>
<td></td>
<td>Based on character sets for single-byte and double-byte characters. Also known as JIS X 0208.</td>
</tr>
<tr>
<td>TIS-620</td>
<td>Thai</td>
<td>20</td>
<td>A character set used for the Thai language.</td>
</tr>
<tr>
<td>UCS-2BE</td>
<td>Big Endian</td>
<td>7</td>
<td>Means the highest order byte is stored at the highest address. This is similar to UTF-16.</td>
</tr>
<tr>
<td>UCS-2LE</td>
<td>Little Endian</td>
<td>8</td>
<td>Means the lowest order byte of a number is stored in memory at the lowest address. This is similar to UTF-16.</td>
</tr>
<tr>
<td>UTF-8</td>
<td>Unicode</td>
<td></td>
<td>An 8-bit variable length character set for Unicode.</td>
</tr>
<tr>
<td>Windows-874</td>
<td>Windows Thai</td>
<td>21</td>
<td>Microsoft Windows Thai code page character set.</td>
</tr>
<tr>
<td>Windows-1250</td>
<td>Windows Latin 2</td>
<td>22</td>
<td>Windows code page representing Central European languages like Polish, Czech, Slovak, Hungarian, Slovene, Croatian, Romanian, and Albanian. This option can also be used for German.</td>
</tr>
<tr>
<td>Windows-1251</td>
<td></td>
<td>23</td>
<td></td>
</tr>
<tr>
<td>Windows-1252</td>
<td>Windows Latin 1</td>
<td>24</td>
<td>Nearly identical with Windows-1250.</td>
</tr>
<tr>
<td>Windows-1253</td>
<td>Windows Greek</td>
<td>25</td>
<td>A Windows code page used for modern Greek.</td>
</tr>
<tr>
<td>Windows-1254</td>
<td>Windows Turkish</td>
<td>26</td>
<td>Represents the Turkish Windows code page.</td>
</tr>
<tr>
<td>Windows-1255</td>
<td>Windows Hebrew</td>
<td>27</td>
<td>This code page is used to write Hebrew.</td>
</tr>
<tr>
<td>Windows-1256</td>
<td>Windows Arabic</td>
<td>28</td>
<td>This Windows code page is used to write Arabic in Microsoft Windows.</td>
</tr>
<tr>
<td>Windows-1257</td>
<td>Windows Baltic</td>
<td>29</td>
<td>Used to write Estonian, Latvian, and Lithuanian languages in Microsoft Windows.</td>
</tr>
<tr>
<td>Windows-1258</td>
<td>Windows Vietnamese</td>
<td>30</td>
<td>This code page is used to write Vietnamese text.</td>
</tr>
</tbody>
</table>
What Is Experimental?

Experimental software exposes a new product, which has just emerged from in-house (alpha) testing, to a large number of real people, real hardware, and real usage. Experimental testers use a stable version of the pre-release product; it’s usable for your day-to-day activities. In fact, we encourage you to use it that way.

The benefits of testing include:

1. getting a look at the new features before they are generally available
2. making our software better as a result of detecting any issues
3. possibly affecting our future direction of development through your suggestions
Glossary

A

ASCII
this is the acronym for American Standard Code for Information Interchange

C

Comments
text within a code segment that are not executed. Comments can be either C-style (starts with /* and ends with */) or C++ style (starts with // and continues to the end of a line).

E

EEL
this is an acronym used for DataFlux Expression Engine Language

EOF
this is an abbreviation for end of file

I

IEEE 754
this is an abbreviation for the IEEE Standard for Binary Floating-Point Arithmetic. This standard applies to how floating point numbers are represented and the operations related to them.

Q

QKB
this is an acronym for DataFlux Quality Knowledge Base; a QKB is a collection of files and configuration settings that contain all DataFlux data management algorithms. The QKB is directly editable using DataFlux Data Management Studio Customize and DataFlux dfPower Studio.

R

regular expression
this is a mini-language composed of symbols and operators that enables you to express how a computer application should search for a specified pattern in text. A pattern may then be replaced with another pattern, also described using the regular expression language.
