## **Overview: CORRESP Procedure**

The CORRESP procedure performs simple correspondence analysis and multiple correspondence analysis (MCA). You can use correspondence analysis to find a low-dimensional graphical representation of the rows and columns of a crosstabulation or contingency table. Each row and column is represented by a point in a plot determined from the cell frequencies. PROC CORRESP can also compute coordinates for supplementary rows and columns.

PROC CORRESP can read two kinds of input: raw categorical responses on two or more classification variables or a two-way contingency table. The correspondence analysis plot is displayed with ODS Graphics. For more information about ODS Graphics, see the section "ODS Graphics" on page 2038.

## **Background**

Correspondence analysis is a popular data analysis method in France and Japan. In France, correspondence analysis was developed under the influence of Jean-Paul Benzécri; in Japan, it was developed under Chikio Hayashi. The name *correspondence analysis* is a translation of the French *analyse des correspondances*. The technique apparently has many independent beginnings (for example, Richardson and Kuder 1933; Hirshfield 1935; Horst 1935; Fisher 1940; Guttman 1941; Burt 1950; Hayashi 1950). It has had many other names, including optimal scaling, reciprocal averaging, optimal scoring, and appropriate scoring in the United States; quantification method in Japan; homogeneity analysis in the Netherlands; dual scaling in Canada; and scalogram analysis in Israel.

Correspondence analysis is described in more detail in French in Benzécri (1973) and Lebart, Morineau, and Tabard (1977). In Japanese, the subject is described in Komazawa (1982); Nishisato (1982); Kobayashi (1981). In English, correspondence analysis is described in Lebart, Morineau, and Warwick (1984); Greenacre (1984); Nishisato (1980); Tenenhaus and Young (1985); Gifi (1990); Greenacre and Hastie (1987), and many other sources. Hoffman and Franke (1986) offer a short, introductory treatment that uses examples from the field of market research.

## **Getting Started: CORRESP Procedure**

Data are available containing the numbers of Ph.D.'s awarded in the United States during the years 1973 through 1978 (U.S. Bureau of the Census 1979). The table has six rows, one for each of six academic disciplines, and six columns for the six years.

The following DATA step reads the complete table into a SAS data set, and PROC CORRESP displays correspondence analysis results including the inertia decomposition and coordinates:

```
title "Number of Ph.D.'s Awarded from 1973 to 1978";
data PhD;
   input Science $ 1-19 y1973-y1978;
   label y1973 = '1973'
         y1974 = '1974'
         y1975 = '1975'
         y1976 = '1976'
         y1977 = '1977'
         y1978 = '1978';

         0.00356 383.856 100.00
  Total
Degrees of Freedom = 25
```

The concept of *inertia* in correspondence analysis is analogous to the concept of variance in principal component analysis, and it is proportional to the chi-square information.

The total chi-square statistic in Figure 32.1, which is a measure of the association between the rows and columns in the full five dimensions of the (centered) table, is 383.856. The maximum number of dimensions (or axes) is the minimum of the number of rows and columns, minus one. More than 96% of the total chi-square and inertia is explained by the first dimension, indicating that the association between the row and column categories is essentially one-dimensional. The plot in Figure 32.2 shows how the number of doctorates in the different disciplines changes over time. The plot shows that the number of doctorates in the behavioral sciences is associated with later years, and the number of doctorates in mathematics and engineering is associated with earlier years. This is consistent with the data that show that the number of doctorates in the behavioral sciences is increasing, the number of doctorates in every other discipline is decreasing, and the rate of decrease is greatest for mathematics and engineering.

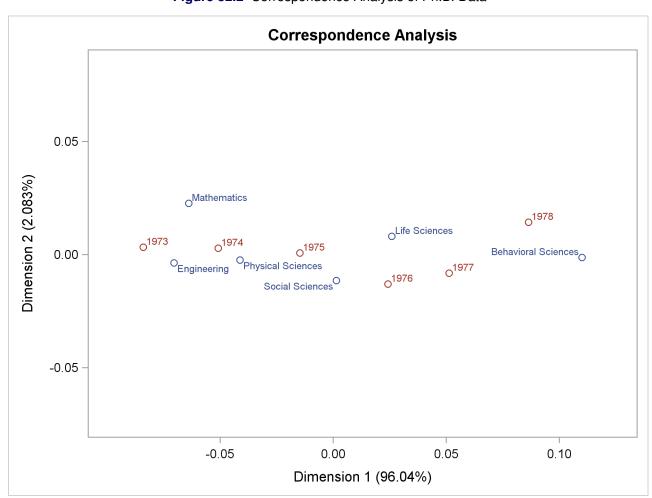

Figure 32.2 Correspondence Analysis of Ph.D. Data

## **Syntax: CORRESP Procedure**

The following statements are available in the CORRESP procedure.

```
PROC CORRESP < options > ;

TABLES < row-variables, > column-variables ;

VAR variables ;

BY variables ;

ID variable ;

SUPPLEMENTARY variables ;

WEIGHT variable ;
```

There are two separate forms of input to PROC CORRESP. One form is specified in the TABLES statement, the other in the VAR statement. You must specify either the TABLES or the VAR statement, but not both, each time you run PROC CORRESP.

Specify the TABLES statement if you are using raw, categorical data, the levels of which define the rows and columns of a table.

Specify the VAR statement if your data are already in tabular form. PROC CORRESP is generally more efficient with VAR statement input than with TABLES statement input.

The other statements are optional. All of the statements are explained, in alphabetical order, following the PROC CORRESP statement. All of the options in PROC CORRESP can be abbreviated to their first three letters, except for the OUTF= option. This is a special feature of PROC CORRESP and is not generally true of SAS/STAT procedures.

#### **PROC CORRESP Statement**

```
PROC CORRESP < options > ;
```

The PROC CORRESP statement invokes the CORRESP procedure. Table 32.1 summarizes the options available in the PROC CORRESP statement. These options are described following the table.

Table 32.1 Summary of PROC CORRESP Statement Options

| Option         | Description                                 |
|----------------|---|
| Data Set Optio | ns  |
| DATA=          | Specifies input SAS data set                |
| OUTC=          | Specifies output coordinate SAS data set    |
| OUTF=          | Specifies output frequency SAS data set     |
| Row and Colui  | mn Coordinates                              |
| DIMENS=        | Specifies the number of dimensions or axes  |
| MCA            | Performs multiple correspondence analysis   |
| PROFILE=       | Standardizes the row and column coordinates |
| Table Construc | ction                                       |
| BINARY         | Specifies binary table                      |

Table 32.1 continued

| Option           | Description   |
|------------------|---|
| CROSS=           | Specifies cross levels of TABLES variables            |
| FREQOUT          | Specifies input data in PROC FREQ output              |
| MISSING          | Includes observations with missing values             |
| Control Displaye | ed Output   |
| ALL              | Displays all output                                   |
| BENZECRI         | Displays inertias adjusted by Benzécri's method       |
| CELLCHI2         | Displays cell contributions to chi-square             |
| CP               | Displays column profile matrix                        |
| <b>DEVIATION</b> | Displays observed minus expected values               |
| <b>EXPECTED</b>  | Displays chi-square expected values                   |
| <b>GREENACRE</b> | Displays inertias adjusted by Greenacre's method      |
| NOCOLUMN=        | Suppresses the display of column coordinates          |
| NOPRINT          | Suppresses the display of all output                  |
| NOROW=           | Suppresses the display of row coordinates             |
| OBSERVED         | Displays contingency table of observed frequencies    |
| PLOTS=           | Specifies ODS Graphics details                        |
| PRINT=           | Displays percentages or frequencies                   |
| RP               | Displays row profile matrix                           |
| SHORT            | Suppresses all point and coordinate statistics        |
| UNADJUSTED       | Displays unadjusted inertias                          |
| Other Options    |   |
| COLUMN=          | Specifies esoteric column coordinate standardizations |
| MININERTIA=      | Specifies minimum inertia                             |
| NVARS=           | Specifies number of classification variables          |
| ROW=             | Specifies esoteric row coordinate standardizations    |
| SINGULAR=        | Specifies effective zero                              |
| SOURCE           | Includes level source in the OUTC= data set           |

The display options control the amount of displayed output. The CELLCHI2, EXPECTED, and DEVI-ATION options display additional chi-square information. See the "Details: CORRESP Procedure" section for more information. The unit of the matrices displayed by the CELLCHI2, CP, DEVIATION, EXPECTED, OBSERVED, and RP options depends on the value of the PRINT= option. The table construction options control the construction of the contingency table; these options are valid only when you also specify a TABLES statement.

You can specify the following options in the PROC CORRESP statement. They are given in alphabetical order.

#### **ALL**

is equivalent to specifying the OBSERVED, RP, CP, CELLCHI2, EXPECTED, and DEVIATION options. Specifying the ALL option does not affect the PRINT= option. Therefore, only frequencies (not percentages) for these options are displayed unless you specify otherwise with the PRINT= option.

#### **BENZECRI**

#### **BEN**

displays adjusted inertias when performing multiple correspondence analysis. By default, unadjusted inertias, the usual inertias from multiple correspondence analysis, are displayed. However, adjusted inertias that use a method proposed by Benzécri (1979) and described by Greenacre (1984, p. 145) can be displayed by specifying the BENZECRI option. Specify the UNADJUSTED option to output the usual table of unadjusted inertias as well. See the section "MCA Adjusted Inertias" on page 2031 for more information.

#### **BINARY**

enables you to create binary tables easily. When you specify the BINARY option, specify only column variables in the TABLES statement. Each input data set observation forms a single row in the constructed table.

#### **CELLCHI2**

#### **CEL**

displays the contribution to the total chi-square test statistic for each cell. See also the descriptions of the DEVIATION, EXPECTED, and OBSERVED options.

#### COLUMN=B | BD | DB | DBD | DBD1/2 | DBID1/2

#### COL=B | BD | DB | DBD | DBD1/2 | DBID1/2

provides other standardizations of the column coordinates. The COLUMN= option is rarely needed. Typically, you should use the PROFILE= option instead (see the section "The PROFILE=, ROW=, and COLUMN= Options" on page 2028). By default, COLUMN=DBD.

#### CP

displays the column profile matrix. Column profiles contain the observed conditional probabilities of row membership given column membership. See also the RP option.

#### CROSS=BOTH | COLUMN | NONE | ROW

#### CRO=BOT | COL | NON | ROW

specifies the method of crossing (factorially combining) the levels of the TABLES variables. The default is CROSS=NONE.

**NONE** causes each level of every row variable to become a row label and each level of

every column variable to become a column label.

**ROW** causes each combination of levels for all row variables to become a row label,

whereas each level of every column variable becomes a column label.

**COLUMN** causes each combination of levels for all column variables to become a column

label, whereas each level of every row variable becomes a row label.

**BOTH** causes each combination of levels for all row variables to become a row label and

each combination of levels for all column variables to become a column label.

The section "TABLES Statement" on page 2008 provides a more detailed description of this option.

#### DATA=SAS-data-set

specifies the SAS data set to be used by PROC CORRESP. If you do not specify the DATA= option, PROC CORRESP uses the most recently created SAS data set.

#### **DEVIATION**

#### **DEV**

displays the matrix of deviations between the observed frequency matrix and the product of its row marginals and column marginals divided by its grand frequency. For ordinary two-way contingency tables, these are the observed minus expected frequencies under the hypothesis of row and column independence and are components of the chi-square test statistic. See also the CELLCHI2, EXPECTED, and OBSERVED options.

#### **DIMENS**=n

#### DIM=n

specifies the number of dimensions or axes to use. The default is DIMENS=2. The maximum value of the DIMENS= option in an  $(n_r \times n_c)$  table is  $n_r - 1$  or  $n_c - 1$ , whichever is smaller. For example, in a table with 4 rows and 5 columns, the maximum specification is DIMENS=3. If your table has 2 rows or 2 columns, specify DIMENS=1.

#### **EXPECTED**

#### **EXP**

displays the product of the row marginals and the column marginals divided by the grand frequency of the observed frequency table. For ordinary two-way contingency tables, these are the expected frequencies under the hypothesis of row and column independence and are components of the chi-square test statistic. In other situations, this interpretation is not strictly valid. See also the CELLCHI2, DE-VIATION, and OBSERVED options.

#### **FREQOUT**

#### **FRE**

indicates that the PROC CORRESP input data set has the same form as an output data set from the FREQ procedure, even if it was not directly produced by PROC FREQ. The FREQOUT option enables PROC CORRESP to take shortcuts in constructing the contingency table.

When you specify the FREQOUT option, you must also specify a WEIGHT statement. The cell frequencies in a PROC FREQ output data set are contained in a variable called COUNT, so specify COUNT in a WEIGHT statement with PROC CORRESP. The FREQOUT option might produce unexpected results if the DATA= data set is structured incorrectly. Each of the two variable lists specified in the TABLES statement must consist of a single variable, and observations must be grouped by the levels of the row variable and then by the levels of the column variable. It is not required that the observations be sorted by the row variable and column variable, but they must be grouped consistently. There must be as many observations in the input data set (or BY group) as there are cells in the completed contingency table. Zero cells must be specified with zero weights. When you use PROC FREQ to create the PROC CORRESP input data set, you must specify the SPARSE option in the FREQ procedure's TABLES statement so that the zero cells are written to the output data set.

#### **GREENACRE**

#### **GRE**

displays adjusted inertias when you are performing multiple correspondence analysis. By default,

unadjusted inertias, the usual inertias from multiple correspondence analysis, are displayed. However, adjusted inertias that use a method proposed by Greenacre (1984, p. 156) can be displayed by specifying the GREENACRE option. Specify the UNADJUSTED option to output the usual table of unadjusted inertias as well. See the section "MCA Adjusted Inertias" on page 2031 for more information.

#### MCA

requests a multiple correspondence analysis. This option requires that the input table be a Burt table, which is a symmetric matrix of crosstabulations among several categorical variables. If you specify the MCA option and a VAR statement, you must also specify the NVARS= option, which gives the number of categorical variables that were used to create the table. With raw categorical data, if you want results for the individuals as well as the categories, use the BINARY option instead.

#### MININERTIA=n

#### MIN=n

specifies the minimum inertia  $(0 \le n \le 1)$  used to create the "best" tables—the indicator of which points best explain the inertia of each dimension. By default, MININERTIA=0.8. See the section "Algorithm and Notation" on page 2026 for more information.

#### **MISSING**

#### MIS

specifies that observations with missing values for the TABLES statement variables are included in the analysis. Missing values are treated as a distinct level of each categorical variable. By default, observations with missing values are excluded from the analysis.

#### NOCOLUMN <= BOTH | DATA | PRINT >

#### NOC < = BOT | DAT | PRI >

suppresses the display of the column coordinates and statistics and omits them from the output coordinate data set.

**BOTH** suppresses all column information from both the SAS listing and the output data

set. The NOCOLUMN option is equivalent to the option NOCOLUMN=BOTH.

**DATA** suppresses all column information from the output data set.

**PRINT** suppresses all column information from the SAS listing.

#### **NOPRINT**

#### **NOP**

suppresses the display of all output. This option is useful when you need only an output data set. This option disables the Output Delivery System (ODS), including ODS Graphics, for the duration of the PROC. For more information, see Chapter 20, "Using the Output Delivery System."

#### NOROW <= BOTH | DATA | PRINT>

#### NOR < = BOT | DAT | PRI >

suppresses the display of the row coordinates and statistics and omits them from the output coordinate data set.

**BOTH** suppresses all row information from both the SAS listing and the output data set.

The NOROW option is equivalent to the option NOROW=BOTH.

**DATA** suppresses all row information from the output data set. **PRINT** suppresses all row information from the SAS listing.

The NOROW option can be useful when the rows of the contingency table are replications.

#### NVARS=n

#### NVA=n

specifies the number of classification variables that were used to create the Burt table. For example, suppose the Burt table was originally created with the following statement:

```
tables a b c;
```

You must specify NVARS=3 to read the table with a VAR statement.

The NVARS= option is required when you specify both the MCA option and a VAR statement. (See the section "VAR Statement" on page 2008 for an example.)

#### **OBSERVED**

#### **OBS**

displays the contingency table of observed frequencies and its row, column, and grand totals. If you do not specify the OBSERVED or ALL option, the contingency table is not displayed.

#### OUTC=SAS-data-set

#### OUT=SAS-data-set

creates an output coordinate SAS data set to contain the row, column, supplementary observation, and supplementary variable coordinates. This data set also contains the masses, squared cosines, quality of each point's representation in the DIMENS=*n* dimensional display, relative inertias, partial contributions to inertia, and best indicators.

#### **OUTF=**SAS-data-set

creates an output frequency SAS data set to contain the contingency table, row, and column profiles, the expected values, and the observed minus expected values and contributions to the chi-square statistic.

```
PLOTS<(global-plot-options)>>= plot-request < (options)>>
```

```
PLOTS<(global-plot-options) > <= (plot-request < (options) > <... plot-request < (options) > >) > specifies options that control the details of the plots. When you specify only one plot request, you can omit the parentheses around the plot request.
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc corresp;
   tables Marital, Origin;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 600 in Chapter 21, "Statistical Graphics Using ODS."

By default, for simple correspondence analysis, PROC CORRESP prints the configuration of points consisting of the row coordinates and column coordinates. With MCA, only column coordinates are printed. The default plots (y \* x) are Dim2 \* Dim1, Dim3 \* Dim1, Dim3 \* Dim2, and so on. When you specify PLOTS(FLIP), the plots are Dim1 \* Dim2, Dim1 \* Dim3, Dim2 \* Dim3, and so on.

The global plot option is as follows:

#### **FLIP**

FLI

flips or interchanges the X-axis and Y-axis dimensions.

The plot requests include the following:

#### **ALL**

produces all appropriate plots.

#### **NONE**

NON

suppresses all plots.

#### PRINT=BOTH | FREQ | PERCENT

#### PRI=BOT | FRE | PER

affects the OBSERVED, RP, CP, CELLCHI2, EXPECTED, and DEVIATION options. The default is PRINT=FREQ.

- The PRINT=FREQ option displays output in the appropriate raw or natural units. (That is, PROC CORRESP displays raw frequencies for the OBSERVED option, relative frequencies with row marginals of 1.0 for the RP option, and so on.)
- The PRINT=PERCENT option scales results to percentages for the display of the output. (All elements in the OBSERVED matrix sum to 100.0, the row marginals are 100.0 for the RP option, and so on.)
- The PRINT=BOTH option displays both percentages and frequencies.

#### PROFILE=BOTH | COLUMN | NONE | ROW

#### PRO=BOT | COL | NON | ROW

specifies the standardization for the row and column coordinates. The default is PROFILE=BOTH.

| ВОТН | specifies a standard | correspondence | analysis, | which jointly | displays the p | orincipal |
|------|----------------------|----------------|-----------|---------------|----------------|-----------|
|      | 1                    | 1              | ,         | 3             | 1 / 1          | 1         |

row and column coordinates. Row coordinates are computed from the row profile matrix, and column coordinates are computed from the column profile matrix.

**ROW** specifies a correspondence analysis of the row profile matrix. The row coordinates

are weighted centroids of the column coordinates.

**COLUMN** specifies a correspondence analysis of the column profile matrix. The column

coordinates are weighted centroids of the row coordinates.

**NONE** is rarely needed. Row and column coordinates are the generalized singular vectors,

without the customary standardizations.

#### ROW=A | AD | DA | DAD | DAD1/2 | DAID1/2

provides other standardizations of the row coordinates. The ROW= option is rarely needed. Typically, you should use the PROFILE= option instead (see the section "The PROFILE=, ROW=, and COLUMN= Options" on page 2028). By default, ROW=DAD.

#### RP

displays the row profile matrix. Row profiles contain the observed conditional probabilities of column membership given row membership. See also the CP option.

#### SHORT

#### SHO

suppresses the display of all point and coordinate statistics except the coordinates. The following information is suppressed: each point's mass, relative contribution to the total inertia, and quality of representation in the DIMENS=*n* dimensional display; the squared cosines of the angles between each axis and a vector from the origin to the point; the partial contributions of each point to the inertia of each dimension; and the best indicators.

#### SINGULAR=n

#### SIN=n

specifies the largest value that is considered to be within rounding error of zero. The default value is 1E–8. This parameter is used in checking for zero rows and columns, in checking Burt table diagonal sums for equality, in checking denominators before dividing, and so on. Typically, you should not assign a value outside the range 1E–6 to 1E–12.

#### SOURCE

#### SOU

adds the variable \_VAR\_, which contains the name or label of the variable corresponding to the current level, to the OUTC= and OUTF= data sets.

#### **UNADJUSTED**

#### **UNA**

displays unadjusted inertias when performing multiple correspondence analysis. By default, unadjusted inertias, the usual inertias from multiple correspondence analysis, are displayed. However, if adjusted inertias are requested by either the GREENACRE option or the BENZECRI option, then the unadjusted inertia table is not displayed unless the UNADJUSTED option is specified. See the section "MCA Adjusted Inertias" on page 2031 for more information.

#### **BY Statement**

#### BY variables;

You can specify a BY statement with PROC CORRESP to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the CORRESP procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in SAS Language Reference: Concepts. For more information about the DATASETS procedure, see the discussion in the Base SAS Procedures Guide.

#### **ID Statement**

ID variable:

You specify the ID statement only in conjunction with the VAR statement. You cannot specify the ID statement when you use the TABLES statement or the MCA option. When you specify an ID variable, PROC CORRESP labels the rows of the tables with the ID values and places the ID variable in the output data set.

#### **SUPPLEMENTARY Statement**

#### **SUPPLEMENTARY** variables;

SUP variables;

The SUPPLEMENTARY statement specifies variables that are to be represented as points in the joint row and column space but that are not used in determining the locations of the other, active row and column points of the contingency table. Supplementary observations on supplementary variables are ignored in simple correspondence analysis but are needed to compute the squared cosines for multiple correspondence analysis. Variables that are specified in the SUPPLEMENTARY statement must also be specified in the TABLES or VAR statement.

When you specify a VAR statement, each SUPPLEMENTARY variable indicates one supplementary column of the table. Supplementary variables must be numeric with VAR statement input.

When you specify a TABLES statement, each SUPPLEMENTARY variable indicates a set of rows or columns of the table that is supplementary. Supplementary variables can be either character or numeric with TABLES statement input.

#### **TABLES Statement**

**TABLES** < row-variables, > column-variables;

The TABLES statement instructs PROC CORRESP to create a contingency table, Burt table, or binary table from the values of two or more categorical variables. The TABLES statement specifies classification variables that are used to construct the rows and columns of the contingency table. The variables can be either numeric or character. The variable lists in the TABLES statement and the CROSS= option together determine the row and column labels of the contingency table.

You can specify both row variables and column variables separated by a comma, or you can specify only column variables and no comma. If you do not specify row variables (that is, if you list variables but do not use the comma as a delimiter), then you should specify either the MCA or the BINARY option. With the MCA option, PROC CORRESP creates a Burt table, which is a crosstabulation of each variable with itself and every other variable. The Burt table is symmetric. With the BINARY option, PROC CORRESP creates a binary table, which consists of one row for each input data set observation and one column for each category of each TABLES statement variable. If the binary matrix is **Z**, then the Burt table is **Z'Z**. Specifying the BINARY option with the NOROWS option produces the same results as specifying the MCA option (except for the chi-square statistics).

See Figure 32.6 for an example or see the section "The MCA Option" on page 2030 for a detailed description of Burt tables.

You can use the WEIGHT statement with the TABLES statement to read category frequencies. Specify the SUPPLEMENTARY statement to name variables with categories that are supplementary rows or columns. You cannot specify the ID or VAR statement with the TABLES statement. See the section "Using the TABLES Statement" on page 2010 for an example.

#### **VAR Statement**

#### VAR variables;

You should specify the VAR statement when your data are in tabular form. The VAR variables must be numeric. The VAR statement instructs PROC CORRESP to read an existing contingency table, binary indicator matrix, fuzzy-coded indicator matrix, or Burt table, rather than raw data. See the section "Algorithm and Notation" on page 2026 for a description of a binary indicator matrix and a fuzzy-coded indicator matrix.

You can specify the WEIGHT statement with the VAR statement to read category frequencies and designate supplementary rows. Specify the SUPPLEMENTARY statement to name supplementary variables. You cannot specify the TABLES statement with the VAR statement.

#### **WEIGHT Statement**

#### **WEIGHT** variable;

The WEIGHT statement specifies weights for each observation and indicates supplementary observations for simple correspondence analyses with VAR statement input. You can include only one WEIGHT statement, and the weight variable must be numeric.

If you omit the WEIGHT statement, each observation contributes a value of 1 to the frequency count for its category. That is, each observation represents one subject. When you specify a WEIGHT statement, each observation contributes the value of the weighting variable for that observation. For example, a weight of 3 means that the observation represents three subjects. Weight values are not required to be integers.

You can specify the WEIGHT statement with a TABLES statement to indicate category frequencies, as in the following example:

```
proc freq;
   tables a*b / out=outfreq sparse;
run;

proc corresp freqout;
   tables a, b;
   weight count;
run;
```

If you specify a VAR statement, you can specify the WEIGHT statement to indicate supplementary observations and to weight some rows of the table more heavily than others. When the value of the WEIGHT variable is negative, the observation is treated as supplementary, and the absolute value of the weight is used as the weighting value.

You cannot specify a WEIGHT statement with a VAR statement and the MCA option, because the table must be symmetric. Supplementary variables are indicated with the SUPPLEMENTARY statement, so differential weighting of rows is inappropriate.

## **Details: CORRESP Procedure**

## **Input Data Set**

PROC CORRESP can read two kinds of input:

- raw category responses on two or more classification variables with the TABLES statement
- a two-way contingency table with the VAR statement

You can use output from PROC FREQ as input for PROC CORRESP.

The classification variables referred to by the TABLES statement can be either numeric or character variables. Normally, all observations for a given variable that have the same formatted value are placed in the same level, and observations with different values are placed in different levels.

The variables in the VAR statement must be numeric. The values of the observations specify the cell frequencies. These values are not required to be integers, but only those observations with all nonnegative, nonmissing values are used in the correspondence analysis. Observations with one or more negative values are removed from the analysis.

The WEIGHT variable must be numeric. Observations with negative weights are treated as supplementary observations. The absolute values of the weights are used to weight the observations.

## **Using the TABLES Statement**

This section explains some of the choices for the correspondence analysis input data table and illustrates some table-construction capabilities of PROC CORRESP. The SAS data set Neighbor, which follows, will be used throughout this section to illustrate various ways in which PROC CORRESP can read and process data. This data set consists of one observation for each resident in a fictitious neighborhood along with some personal information.

```

                       Tall Brown
          Old
Igor
                       Short
```

This first step creates a simple contingency table or crosstabulation. In the TABLES statement, each variable list consists of a single variable. The following statements produce the table in Figure 32.3.

```
proc corresp data=Neighbor dimens=1 observed short;
   title2 'Simple Crosstabulation';
   ods select observed;
   tables Sex, Age;
run;
```

These statements create a contingency table with two rows (Female and Male) and two columns (Old and Young) and show the neighbors categorized by age and sex. The DIMENS=1 option specifies the number of dimensions in the correspondence analysis. Typically, you do not have to specify this option, because typically your tables will be larger than two by two. The default is DIMENS=2, which is too large for a table with a two-level factor. The OBSERVED option displays the contingency table. The SHORT option limits the displayed output. Because it contains missing values, the observation where Name='Igor' is omitted from the analysis. The table is shown in Figure 32.3.

Figure 32.3 Contingency Table for Sex, Age

|        |            | e Construct<br>tabulation | ion |  |
|--------|------------|---------------------------|-----|--|
| Th     | e CORRESP  | Procedure                 |     |  |
|        | Contingenc | y Table                   |     |  |
|        | Old        | Young                     | Sum |  |
| Female | 2          | 2                         | 4   |  |
| Male   | 4          | 3                         | 7   |  |
| Sum    | 6          | 5                         | 11  |  |

The preceding example showed how to make a two-way contingency table based on the levels of two categorical variables, which, if it were larger, would be a very typical form of data for a correspondence analysis. However, many other types of tables, N, can be used as input to a correspondence analysis, and all tables can be defined based on a binary matrix, Z. The BINARY option enables you to directly compute and display this matrix. The TABLES statement consists of a single list of all the categorical variables. The following statements produce Figure 32.4.

```
proc corresp data=neighbor observed short binary;
  title2 'Binary Coding';
  ods select binary;
  tables Hair Height Sex Age;
run;
```

| 1  | 0     | 0     | 1         | 1                    | 0       | 0      | 1    | 1   | 0     |
| 2  | 0     | 1     | 0         | 0                    | 1       | 1      | 0    | 0   | 1     |
| 3  | 0     | 1     | 0         | 1                    | 0       | 0      | 1    | 1   | 0     |
| 4  | 0     | 0     | 1         | 0                    | 1       | 1      | 0    | 1   | 0     |
| 5  | 0     | 1     | 0         | 1                    | 0       | 1      | 0    | 1   | 0     |
| 6  | 1     | 0     | 0         | 0                    | 1       | 0      | 1    | 0   | 1     |
| 7  | 0     | 1     | 0         | 0                    | 1       | 0      | 1    | 0   | 1     |
| 8  | 1     | 0     | 0         | 1                    | 0       | 0      | 1    | 1   | 0     |
| 9  | 1     | 0     | 0         | 1                    | 0       | 1      | 0    | 0   | 1     |
| 10 | 0     | 1     | 0         | 0                    | 1       | 0      | 1    | 1   | 0     |
| 11 | 0     | 1     | 0         | 0                    | 1       | 0      | 1    | 0   | 1     |

In this case,  $N = \mathbb{Z}$  is directly analyzed. The binary matrix has one row for each individual or case and one column for each category. A binary table constructed from m categorical variables has m partitions. This binary table has four partitions, one for each of the four categorical variables. Each partition has a 1 in each row, and each row contains exactly four 1s since there are four categorical variables. More generally, the binary design matrix has exactly m 1s in each row. The 1s indicate the categories to which the observation applies. For example, the categorical variable Sex, with two levels (Female and Male), is coded using two indicator variables. For the variable Sex, a male would be coded Female=0 and Male=1, and a female would be coded Female=1 and Male=0. This is the same kind of coding that procedures like GLM and TRANSREG use for CLASS variables.

Implicitly, the binary table has an automatic row variable that is equal to the observation number. Alternatively, when there is a row ID variable, as there is in this case, you can use it as a row variable in the TABLES statement, and the resulting ordinary observed frequency table is the binary table. This example uses two variable lists: Name for the row variable, and Hair Height Sex Age for the column variables. Since two lists were provided, the BINARY option was not specified. The following statements produce Figure 32.5.

```
proc corresp data=neighbor observed short;
   title2 'Binary Coding';
   ods select observed;
   tables Name, Hair Height Sex Age;
run;
```

Figure 32.5 Binary Table Using a Row Variable

With the MCA option, the Burt table ( $\mathbf{Z}'\mathbf{Z}$ ) is analyzed. A Burt table is a partitioned symmetric matrix containing all pairs of crosstabulations among a set of categorical variables. Each diagonal partition is a diagonal matrix containing marginal frequencies (a crosstabulation of a variable with itself). Each off-diagonal partition is an ordinary contingency table. The following statements produce Figure 32.6.

```
proc corresp data=neighbor observed short mca;
   title2 'MCA Burt Table';
   ods select burt;
   tables Hair Height Sex Age;
run;
```

Note that there is a single variable list in the TABLES statement, since the row and column variable lists are the same.

| Female | 1     | 2     | 1         | 2         | 2        | 4        | 0    | 2   | 2     |
| Male   | 2     | 4     | 1         | 3         | 4        | 0        | 7    | 4   | 3     |
| Old    | 1     | 3     | 2         | 4         | 2        | 2        | 4    | 6   | 0     |
| Young  | 2     | 3     | 0         | 1         | 4        | 2        | 3    | 0   | 5     |

This Burt table is composed of all pairs of crosstabulations among the variables Hair, Height, Sex, and Age. It is composed of sixteen individual subtables—the number of variables squared. Both the rows and the columns have the same nine categories (in this case Blond, Brown, White, Short, Tall, Female, Male, Old, and Young). Below the diagonal (from left to right, top to bottom) are the following crosstabulations: Height \* Hair, Sex \* Hair, Sex \* Height, Age \* Hair, Age \* Height, and Age \* Sex. Each crosstabulation below the diagonal has a transposed counterpart above the diagonal. The diagonal contains the crosstabulations: Hair \* Hair, Height \* Height, Sex \* Sex, and Age \* Age. The diagonal elements of the diagonal partitions contain marginal frequencies of the off-diagonal partitions. The table Hair \* Height, for example, has three rows for Hair and two columns for Height. The values of the Hair \* Height table, summed across rows, sum to the diagonal values of the Height \* Height table, as displayed in the following results. The following statements produce Figure 32.7.

```
proc corresp data=neighbor observed short dimens=1;
   title2 'Part of the Burt Table';
   ods output observed=o;
   tables Hair Height, Height;
run;

proc print data=o(drop=sum) label noobs;
   where label ne 'Sum';
   label label = '00'x;
run;
```

|    | Tall                   | 0     | 6    |  |

A simple crosstabulation of Hair  $\times$  Height is  $N = \mathbf{Z}_{\text{Hair}}'\mathbf{Z}_{\text{Height}}$ . Tables such as  $(N = \mathbf{Z}_{\text{Hair}}'\mathbf{Z}_{\text{Height},\text{Sex}})$ , made up of several crosstabulations, can also be analyzed in simple correspondence analysis. The following statements produce Figure 32.8.

```
proc corresp data=neighbor observed short dimens=1;
  title2 'Multiple Crosstabulations';
  ods select observed;
  tables Hair, Height Sex;
run;
```

| White |       |             |               |      |     |

The following statements create a table with six rows (Blond\*Short, Blond\*Tall, Brown\*Short, Brown\*Tall, White\*Short, and White\*Tall) and four columns (Female, Male, Old, and Young). The levels of the row variables are crossed by the CROSS=ROW option, forming mutually exclusive categories. Hence each individual fits into exactly one row category, but two column categories. The following statements produce Figure 32.9.

```
proc corresp data=Neighbor cross=row observed short;
   title2 'Multiple Crosstabulations with Crossed Rows';
   ods select observed;
   tables Hair Height, Sex Age;
run;
```

You can enter supplementary variables with TABLES input by including a SUPPLEMENTARY statement. Variables named in the SUPPLEMENTARY statement indicate TABLES variables with categories that are supplementary. In other words, the categories of the variable Age are represented in the row and column space, but they are not used in determining the scores of the categories of the variables Hair, Height, and Sex. The variable used in the SUPPLEMENTARY statement must be listed in the TABLES statement as well. For example, the following statements create a Burt table with seven active rows and columns (Blond, Brown, White, Short, Tall, Female, Male) and two supplementary rows and columns (Old and Young). The following statements produce Figure 32.10.

```
proc corresp data=Neighbor observed short mca;
    title2 'MCA with Supplementary Variables';
    ods select burt supcols;
    tables Hair Height Sex Age;
    supplementary Age;
run;
```

## **Using the VAR Statement**

With VAR statement input, the rows of the contingency table correspond to the observations of the input data set, and the columns correspond to the VAR statement variables. The values of the variables typically contain the table frequencies. The table in Figure 32.3 could be created with VAR statement input by using the following statements:

```
data Ages;
  input Sex $ Old Young;
  datalines;
Female 2 2
Male 4 3
;
proc corresp data=Ages dimens=1 observed short;
  var Old Young;
  id Sex;
run;
```

Only nonnegative values are accepted. Negative values are treated as missing, causing the observation to be excluded from the analysis. The values are not required to be integers. Row labels for the table are specified with an ID variable. Column labels are constructed from the variable name or variable label if one is specified. When you specify multiple correspondence analysis (MCA), the row and column labels are the same and are constructed from the variable names or labels, so you cannot include an ID statement. With MCA, the VAR statement must list the variables in the order in which the rows occur. An example is the table in Figure 32.6, which was created with the following TABLES statement.

```
tables Hair Height Sex Age;
```

```
proc corresp data=table nvars=4 mca;
  var Blond Brown White Short Tall Female Male Old Young;
run;
```

You must specify the NVARS= option in order to specify the number of original categorical variables with the MCA option. The option NVARS=n is needed to find boundaries between the subtables of the Burt table. If f is the sum of all elements in the Burt table  $\mathbf{Z}'\mathbf{Z}$ , then  $f n^{-2}$  is the number of rows in the binary matrix  $\mathbf{Z}$ . The sum of all elements in each diagonal subtable of the Burt table must be  $f n^{-2}$ .

To enter supplementary observations, include a WEIGHT statement with negative weights for those observations. Specify the SUPPLEMENTARY statement to include supplementary variables. You must list supplementary variables in both the VAR and SUPPLEMENTARY statements.

## Missing and Invalid Data

With VAR statement input, observations with missing or negative frequencies are excluded from the analysis. Supplementary variables and supplementary observations with missing or negative frequencies are also excluded. Negative weights are valid with VAR statement input.

With TABLES statement input, observations with negative weights are excluded from the analysis. With this form of input, missing cell frequencies cannot occur. Observations with missing values on the categorical variables are excluded unless you specify the MISSING option. If you specify the MISSING option, ordinary missing values and special missing values are treated as additional levels of a categorical variable. In all cases, if any row or column of the constructed table contains only zeros, that row or column is excluded from the analysis.

Observations with missing weights are excluded from the analysis.

## Coding, Fuzzy Coding, and Doubling

Sometimes, binary data such as Yes/No data are available—for example, 1 means "Yes, I have bought this brand in the last month" and 0 means "No, I have not bought this brand in the last month". The following statements read a data set with Yes/No purchase data for three hypothetical brands.

```
title 'Doubling Yes/No Data';
proc format;
  value yn 0 = 'No ' 1 = 'Yes';
run;

data BrandChoice;
  input a b c;
  label a = 'Brand A' b = 'Brand B' c = 'Brand B';
```

```
format a b c yn.;
   datalines;
0 0 1
1 1 0
0 1 1
0 1 0
1 0 0
```

Data such as these cannot be analyzed directly because the raw data do not consist of partitions, each with one column per level and exactly one 1 in each row. (See the section "Using the TABLES Statement" on page 2010.) The data must be doubled so that both Yes and No are represented by a column in the data matrix. The TRANSREG procedure provides one way of doubling. In the following statements, the DESIGN option specifies that PROC TRANSREG is being used only for coding, not analysis. The option SEPARATORS=': ' specifies that labels for the coded columns are constructed from input variable labels, followed by a colon and space, followed by the formatted value. The variables are designated in the MODEL statement as CLASS variables, and the ZERO=NONE option creates binary variables for all levels. The OUTPUT statement specifies the output data set and drops the \_NAME\_, \_TYPE\_, and Intercept variables. PROC TRANSREG stores a list of coded variable names in a macro variable & TRGIND, which in this case has the value "aNo aYes bNo bYes cNo cYes". This macro variable can be used directly in the VAR statement in PROC CORRESP. The following statements produce Figure 32.12. Only the input table is displayed.

```
proc transreg data=BrandChoice design separators=': ';
   model class(a b c / zero=none);
   output out=Doubled(drop=_: Intercept);
run;
proc print label;
run;
proc corresp data=Doubled norow short;
   var &_trgind;
run;
```

Figure 32.12 Doubling Yes/No Data

|     | Doubling Yes/No Data |                 |                |                 |                |                 |            |            |            |
|-----|----------------------|-----------------|----------------|-----------------|----------------|-----------------|------------|------------|------------|

| 1   | 1                    | 0               | 1              | 0               | 0              | 1               | No         | No         | Yes        |
| 2   | 0                    | 1               | 0              | 1               | 1              | 0               | Yes        | Yes        | No         |
| 3   | 1                    | 0               | 0              | 1               | 0              | 1               | No         | Yes        | Yes        |
| 4   | 1                    | 0               | 0              | 1               | 1              | 0               | No         | Yes        | No         |
| 5   | 0                    | 1               | 1              | 0               | 1              | 0               | Yes        | No         | No         |

A fuzzy-coded indicator also sums to 1.0 across levels of the categorical variable, but it is coded with fractions rather than with 0 and 1. The fractions represent the distribution of the attribute across several levels of the categorical variable.

Ordinal variables, such as survey responses of 1 to 3, can be represented as two fuzzy-coded variables, as shown in Table 32.2.

Table 32.2 Coding an Ordinal Variable

| Ordinal |      |      |
|---------|------|------|
| Values  | Coo  | ling |
| 1       | 0.25 | 0.75 |
| 2       | 0.50 | 0.50 |
| 3       | 0.75 | 0.25 |

The values of the coding sum to one across the two coded variables.

These next steps illustrate the use of binary and fuzzy-coded indicator variables. Fuzzy-coded indicators are used to represent missing data. Note that the missing values in the observation Igor are coded with equal proportions. The following statements produce Figure 32.13.

```
title 'Fuzzy Coding of Missing Values';
proc transreg data=Neighbor design cprefix=0;
   model class(Age Sex Height Hair / zero=none);
   output out=Neighbor2(drop=_: Intercept);
   id Name;
run;
data Neighbor3;
   set Neighbor2;
   if Sex = ' ' then do;
      Female = 0.5;
      Male = 0.5;
   end;
   if Hair = ' ' then do;
      White = 1/3;
      Brown = 1/3;
      Blond = 1/3;
   end;
run;
proc print label noobs data=Neighbor3(drop=age--name);
   format _numeric_ best4.;
run;
```

| Fuzzy Coding of Missing Values |              |               |             |                 |                |               |               |               |

| 0                              | 1            | 1             | 0           | 0               | 1              | 0             | 1             | 0             |
| 1                              | 0            | 0             | 1           | 1               | 0              | 0             | 1             | 0             |
| 1                              | 0            | 1             | 0           | 0               | 1              | 0             | 0             | 1             |
| 1                              | 0            | 1             | 0           | 1               | 0              | 0             | 1             | 0             |
| 0                              | 1            | 0             | 1           | 0               | 1              | 1             | 0             | 0             |
| 0                              | 1            | 0             | 1           | 0               | 1              | 0             | 1             | 0             |
| 1                              | 0            | 0             | 1           | 1               | 0              | 1             | 0             | 0             |
| 0                              | 1            | 1             | 0           | 1               | 0              | 1             | 0             | 0             |
| 1                              | 0            | 0             | 1           | 0               | 1              | 0             | 1             | 0             |
| 0                              | 1            | 0             | 1           | 0               | 1              | 0             | 1             | 0             |
| 1                              | 0            | 0.5           | 0.5         | 1               | 0              | 0.33          | 0.33          | 0.33          |

Figure 32.13 Fuzzy Coding of Missing Values

There is one set of coded variables for each input categorical variable. If observation 12 is excluded, each set is a binary design matrix. Each design matrix has one column for each category and exactly one 1 in each row. Fuzzy coding is shown in the final observation, which corresponds to Igor. The observation for Igor has missing values for the variables Sex and Hair. The design matrix variables are coded with fractions that sum to one within each categorical variable.

An alternative way to represent missing data is to treat missing values as an additional level of the categorical variable. This alternative is available with the MISSING option in the PROC CORRESP statement. This approach yields coordinates for missing responses, allowing the comparison of "missing" along with the other levels of the categorical variables.

Greenacre and Hastie (1987) discuss additional coding schemes, including one for continuous variables. Continuous variables can be coded with PROC TRANSREG by specifying BSPLINE(variables / degree=1) in the MODEL statement.

## **Creating a Data Set Containing the Crosstabulation**

The CORRESP procedure can read or create a contingency or Burt table. PROC CORRESP is generally more efficient with VAR statement input than with TABLES statement input. TABLES statement input requires that the table be created from raw categorical variables, whereas the VAR statement is used to read an existing table. For extremely large problems, if PROC CORRESP runs out of memory, it might be possible to use some other method to create the table and then use VAR statement input with PROC CORRESP.

The following example uses the CORRESP, FREQ, and TRANSPOSE procedures to create rectangular tables from a SAS data set WORK. A that contains the categorical variables V1-V5. The Burt table examples assume that no categorical variable has a value found in any of the other categorical variables (that is, that each row and column label is unique).

You can use PROC CORRESP and the ODS OUTPUT statement as follows to create a rectangular two-way contingency table from two categorical variables:

```
proc corresp data=a observed short;
  ods output Observed=Obs(drop=Sum where=(Label ne 'Sum'));
  tables v1, v2;
run;
```

You can use PROC FREQ and PROC TRANSPOSE to create a rectangular two-way contingency table from two categorical variables, as in the following statements:

```
proc freq data=a;
   tables v1 * v2 / sparse noprint out=freqs;
run;

proc transpose data=freqs out=rfreqs(drop=_:);
   id v2;
   var count;
   by v1;
run;
```

You can use PROC CORRESP and the ODS OUTPUT statement as follows to create a Burt table from five categorical variables:

```
proc corresp data=a observed short mca;
  ods output Burt=Obs;
  tables v1-v5;
run;
```

You can use a DATA step, PROC FREQ, and PROC TRANSPOSE to create a Burt table from five categorical variables, as in the following statements:

```
data b;
   set a;
   array v[5] $ v1-v5;
   do i = 1 to 5;
      row = v[i];
      do j = 1 to 5;
         column = v[j];
         output;
      end;
   end;
   keep row column;
run;
proc freq data=b;
  tables row * column / sparse noprint out=freqs;
run;
proc transpose data=freqs out=rfreqs(drop=_:);
   id column;
   var count;
  by row;
run;
```

## **Output Data Sets**

PROC CORRESP has two output data sets. The OUTC= data set contains coordinates and the results of the correspondence analysis. The OUTF= data set contains frequencies and other cross-tabulation results.

#### The OUTC= Data Set

The OUTC= data set contains two or three character variables and 4n + 4 numeric variables, where n is the number of axes from DIMENS=n (two by default). The OUTC= data set contains one observation for each row, column, supplementary row, and supplementary column point, and one observation for inertias.

The first variable is named \_TYPE\_ and identifies the type of observation. The values of \_TYPE\_ are as follows:

- The 'INERTIA' observation contains the total inertia in the INERTIA variable, and each dimension's inertia in the Contr1–Contrn variables.
- The 'OBS' observations contain the coordinates and statistics for the rows of the table.
- The 'SUPOBS' observations contain the coordinates and statistics for the supplementary rows of the table.
- The 'VAR' observations contain the coordinates and statistics for the columns of the table.
- The 'SUPVAR' observations contain the coordinates and statistics for the supplementary columns of the table.

If you specify the SOURCE option, then the data set also contains a variable \_VAR\_ containing the name or label of the input variable from which that row originates. The name of the next variable is either \_NAME\_ or (if you specify an ID statement) the name of the ID variable.

For observations with a value of 'OBS' or 'SUPOBS' for the \_TYPE\_ variable, the values of the second variable are constructed as follows:

- When you use a VAR statement without an ID statement, the values are 'Row1', 'Row2', and so on.
- When you specify a VAR statement with an ID statement, the values are set equal to the values of the ID variable.
- When you specify a TABLES statement, the \_NAME\_ variable has values formed from the appropriate row variable values.

For observations with a value of 'VAR' or 'SUPVAR' for the \_TYPE\_ variable, the values of the second variable are equal to the names or labels of the VAR (or SUPPLEMENTARY) variables. When you specify a TABLES statement, the values are formed from the appropriate column variable values.

The third and subsequent variables contain the numerical results of the correspondence analysis.

- Quality contains the quality of each point's representation in the DIMENS=*n* dimensional display, which is the sum of squared cosines over the first *n* dimensions.
- Mass contains the masses or marginal sums of the relative frequency matrix.
- Inertia contains each point's relative contribution to the total inertia.

- Dim1–Dim*n* contain the point coordinates.
- Contr1–Contrn contain the partial contributions to inertia.
- SqCos1–SqCos*n* contain the squared cosines.
- Best1-Bestn and Best contain the summaries of the partial contributions to inertia.

#### The OUTF= Data Set

The OUTF= data set contains frequencies and percentages. It is similar to a PROC FREQ output data set. The OUTF= data set begins with a variable called \_TYPE\_, which contains the observation type. If the SOURCE option is specified, the data set contains two variables, \_ROWVAR\_ and \_COLVAR\_, that contain the names or labels of the row and column input variables from which each cell originates. The next two variables are classification variables that contain the row and column levels. If you use TABLES statement input and each variable list consists of a single variable, the names of the first two variables match the names of the input variables; otherwise, these variables are named Row and Column. The next two variables are Count and Percent, which contain frequencies and percentages.

The \_TYPE\_ variable can have the following values:

- 'OBSERVED' observations contain the contingency table.
- 'SUPOBS' observations contain the supplementary rows.
- 'SUPVAR' observations contain the supplementary columns.
- 'EXPECTED' observations contain the product of the row marginals and the column marginals divided by the grand frequency of the observed frequency table. For ordinary two-way contingency tables, these are the expected frequency matrix under the hypothesis of row and column independence.
- 'DEVIATION' observations contain the matrix of deviations between the observed frequency matrix and the product of its row marginals and column marginals divided by its grand frequency. For ordinary two-way contingency tables, these are the observed minus expected frequencies under the hypothesis of row and column independence.
- 'CELLCHI2' observations contain contributions to the total chi-square test statistic.
- 'RP' observations contain the row profiles.
- 'SUPRP' observations contain supplementary row profiles.
- 'CP' observations contain the column profiles.
- 'SUPCP' observations contain supplementary column profiles.

## **Computational Resources**

Let

```
n_r = number of rows in the table n_c = number of columns in the table n = number of observations v = number of VAR statement variables t = number of TABLES statement variables c = \max(n_r, n_c) d = \min(n_r, n_c)
```

For TABLES statement input, more than

$$32(t+1) + 8(\max(2tn,(n_r+3)(n_c+3)))$$

bytes of array space are required.

For VAR statement input, more than

$$16(v+2) + 8(n_r+3)(n_c+3)$$

bytes of array space are required.

#### **Memory**

The computational resources formulas are underestimates of the amounts of memory needed to handle most problems. If you use a utility data set, and if memory could be used with perfect efficiency, then roughly the stated amount of memory would be needed. In reality, most problems require at least two or three times the minimum.

PROC CORRESP tries to store the raw data (TABLES input) and the contingency table in memory. If there is not enough memory, a utility data set is used, potentially resulting in a large increase in execution time.

#### **Time**

The time required to perform the generalized singular value decomposition is roughly proportional to  $2cd^2 + 5d^3$ . Overall computation time increases with table size at a rate roughly proportional to  $(n_r n_c)^{\frac{3}{2}}$ .

## **Algorithm and Notation**

This section is primarily based on the theory of correspondence analysis found in Greenacre (1984). If you are interested in other references, see the section "Background" on page 1996.

Let N be the contingency table formed from those observations and variables that are not supplementary and from those observations that have no missing values and have a positive weight. This table is an  $(n_r \times n_c)$ 

rank q matrix of nonnegative numbers with nonzero row and column sums. If  $\mathbf{Z}_a$  is the binary coding for variable A, and  $\mathbf{Z}_b$  is the binary coding for variable B, then  $\mathbf{N} = \mathbf{Z}_a' \mathbf{Z}_b$  is a contingency table. Similarly, if  $\mathbf{Z}_{b,c}$  contains the binary coding for both variables B and C, then  $\mathbf{N} = \mathbf{Z}_a' \mathbf{Z}_{b,c}$  can also be input to a correspondence analysis. With the BINARY option,  $\mathbf{N} = \mathbf{Z}$ , and the analysis is based on a binary table. In multiple correspondence analysis, the analysis is based on a Burt table,  $\mathbf{Z}'\mathbf{Z}$ .

Let 1 be a vector of 1s of the appropriate order, let I be an identity matrix, and let  $diag(\cdot)$  be a matrix-valued function that creates a diagonal matrix from a vector. Let

$$f = 1'N1$$

$$P = \frac{1}{f}N$$

$$r = P1$$

$$c = P'1$$

$$D_r = diag(r)$$

$$D_c = diag(c)$$

$$R = D_r^{-1}P$$

$$C' = D_c^{-1}P'$$

The scalar f is the sum of all elements in N. The matrix P is a matrix of relative frequencies. The vector  $\mathbf{r}$  contains row marginal proportions or row "masses." The vector  $\mathbf{c}$  contains column marginal proportions or column masses. The matrices  $\mathbf{D_r}$  and  $\mathbf{D_c}$  are diagonal matrices of marginals.

The rows of  $\mathbf{R}$  contain the "row profiles." The elements of each row of  $\mathbf{R}$  sum to one. Each (i, j) element of  $\mathbf{R}$  contains the observed probability of being in column j given membership in row i. Similarly, the columns of  $\mathbf{C}$  contain the column profiles. The coordinates in correspondence analysis are based on the generalized singular value decomposition of  $\mathbf{P}$ ,

$$P = AD_{ii}B'$$

where

$$A'D_{\mathbf{r}}^{-1}A=B'D_{\mathbf{c}}^{-1}B=I$$

In multiple correspondence analysis,

$$P=BD_u^2B^\prime$$

The matrix A, which is the rectangular matrix of left generalized singular vectors, has  $n_r$  rows and q columns; the matrix  $D_u$ , which is a diagonal matrix of singular values, has q rows and columns; and the matrix B, which is the rectangular matrix of right generalized singular vectors, has  $n_c$  rows and q columns. The columns of A and B define the principal axes of the column and row point clouds, respectively.

The generalized singular value decomposition of P - rc', discarding the last singular value (which is zero) and the last left and right singular vectors, is exactly the same as a generalized singular value decomposition of P, discarding the first singular value (which is one), the first left singular vector,  $\mathbf{r}$ , and the first right singular vector,  $\mathbf{c}$ . The first (trivial) column of  $\mathbf{A}$  and  $\mathbf{B}$  and the first singular value in  $\mathbf{D}_{\mathbf{u}}$  are discarded

before any results are displayed. You can obtain the generalized singular value decomposition of P - rc' from the ordinary singular value decomposition of  $D_r^{-1/2}(P - rc')D_c^{-1/2}$ :

$$\begin{split} D_r^{-1/2}(P-rc')D_c^{-1/2} &= UD_uV' = (D_r^{-1/2}A)D_u(D_c^{-1/2}B)' \\ P-rc' &= D_r^{1/2}UD_uV'D_c^{1/2} = (D_r^{1/2}U)D_u(D_c^{1/2}V)' = AD_uB' \end{split}$$

Hence, 
$$A=D_{r}^{1/2}U$$
 and  $B=D_{c}^{1/2}V$  .

The default row coordinates are  $D_r^{-1}AD_u$ , and the default column coordinates are  $D_c^{-1}BD_u$ . Typically the first two columns of  $D_r^{-1}AD_u$  and  $D_c^{-1}BD_u$  are plotted to display graphically associations between the row and column categories. The plot consists of two overlaid plots, one for rows and one for columns. The row points are row profiles, and the column points are column profiles, both rescaled so that distances between profiles can be displayed as ordinary Euclidean distances, then orthogonally rotated to a principal axes orientation. Distances between row points and other row points have meaning, as do distances between column points and other column points. However, distances between column points and row points are not interpretable.

#### The PROFILE=, ROW=, and COLUMN= Options

The PROFILE=, ROW=, and COLUMN= options standardize the coordinates before they are displayed and placed in the output data set. The options PROFILE=BOTH, PROFILE=ROW, and PROFILE=COLUMN provide the standardizations that are typically used in correspondence analysis. There are six choices each for row and column coordinates (see Table 32.3). However, most of the combinations of the ROW= and COLUMN= options are not useful. The ROW= and COLUMN= options are provided for completeness, but they are not intended for general use.

Table 32.3 Coordinates

| ROW=    | Matrix Formula                 |
|---------|--------------------------------|
| A       | A                              |
| AD      | $\mathbf{AD_u}$                |
| DA      | $ m D_r^{-1}A$                 |
| DAD     | $ m D_r^{-1}AD_u$              |
| DAD1/2  | $\mathbf{D_r^{-1}AD_u^{1/2}}$  |
| DAID1/2 | $D_{r}^{-1}A(I+D_{u})^{1/2}$   |
| COLUMN= | Matrix Formula                 |
| В       | В                              |
| BD      | $\mathrm{BD}_{\mathrm{u}}$     |
| DB      | ${ m D_c^{-1}B}$               |
| DBD     | $ m D_c^{-1}BD_u$              |
| DBD1/2  | $ m D_c^{-1}BD_u^{1/2}$        |
|         | ${\rm D_c^{-1}B(I+D_u)^{1/2}}$ |

When PROFILE=ROW (ROW=DAD and COLUMN=DB), the row coordinates  $D_r^{-1}AD_u$  and column coordinates  $D_c^{-1}B$  provide a correspondence analysis based on the row profile matrix. The row profile (conditional probability) matrix is defined as  $R = D_r^{-1}P = D_r^{-1}AD_uB'$ . The elements of each row of R sum to

one. Each (i, j) element of **R** contains the observed probability of being in column j given membership in row i. The "principal" row coordinates  $D_r^{-1}AD_u$  and "standard" column coordinates  $D_c^{-1}B$  provide a decomposition of  $D_r^{-1}AD_uB'D_c^{-1} = D_r^{-1}PD_c^{-1} = RD_c^{-1}$ . Since  $D_r^{-1}AD_u = RD_c^{-1}B$ , the row coordinates are weighted centroids of the column coordinates. Each column point, with coordinates scaled to standard coordinates, defines a vertex in  $(n_c - 1)$ -dimensional space. All of the principal row coordinates are located in the space defined by the standard column coordinates. Distances among row points have meaning, but distances among column points and distances between row and column points are not interpretable.

The option PROFILE=COLUMN can be described as applying the PROFILE=ROW formulas to the transpose of the contingency table. When PROFILE=COLUMN (ROW=DA and COLUMN=DBD), the principal column coordinates  $D_c^{-1}BD_u$  are weighted centroids of the standard row coordinates  $D_r^{-1}A$ . Each row point, with coordinates scaled to standard coordinates, defines a vertex in  $(n_r - 1)$ -dimensional space. All of the principal column coordinates are located in the space defined by the standard row coordinates. Distances among column points have meaning, but distances among row points and distances between row and column points are not interpretable.

The usual sets of coordinates are given by the default PROFILE=BOTH (ROW=DAD and COL-UMN=DBD). All of the summary statistics, such as the squared cosines and contributions to inertia, apply to these two sets of points. One advantage to using these coordinates is that both sets  $(D_r^{-1}AD_u)$  and  $D_c^{-1}BD_u$ ) are postmultiplied by the diagonal matrix  $D_u$ , which has diagonal values that are all less than or equal to one. When  $D_u$  is a part of the definition of only one set of coordinates, that set forms a tight cluster near the centroid, whereas the other set of points is more widely dispersed. Including  $\mathbf{D}_{\mathbf{u}}$  in both sets makes a better graphical display. However, care must be taken in interpreting such a plot. No correct interpretation of distances between row points and column points can be made.

Another property of this choice of coordinates concerns the geometry of distances between points within each set. The default row coordinates can be decomposed into  $D_r^{-1}AD_u = D_r^{-1}AD_uB'D_c^{-1}B =$  $(D_r^{-1}P)(D_c^{-1/2})(D_c^{-1/2}B)$ . The row coordinates are row profiles  $(D_r^{-1}P)$ , rescaled by  $D_c^{-1/2}$  (rescaled so that distances between profiles are transformed from a chi-square metric to a Euclidean metric), then orthogonally rotated (with  $D_c^{-1/2}B$ ) to a principal axes orientation. Similarly, the column coordinates are column profiles rescaled to a Euclidean metric and orthogonally rotated to a principal axes orientation.

The rationale for computing distances between row profiles by using the non-Euclidean chi-square metric is as follows. Each row of the contingency table can be viewed as a realization of a multinomial distribution conditional on its row marginal frequency. The null hypothesis of row and column independence is equivalent to the hypothesis of homogeneity of the row profiles. A significant chi-square statistic is geometrically interpreted as a significant deviation of the row profiles from their centroid, c'. The chi-square metric is the Mahalanobis metric between row profiles based on their estimated covariance matrix under the homogeneity assumption (Greenacre and Hastie 1987). A parallel argument can be made for the column profiles.

When ROW=DAD1/2 and COLUMN=DBD1/2 (Gifi 1990; van der Heijden and de Leeuw 1985), the row coordinates  $D_r^{-1}AD_u^{1/2}$  and column coordinates  $D_c^{-1}BD_u^{1/2}$  are a decomposition of  $D_r^{-1}PD_c^{-1}$ .

In all of the preceding pairs, distances between row and column points are not meaningful. This prompted Carroll, Green, and Schaffer (1986) to propose that row coordinates  $D_r^{-1}A(I + D_u)^{1/2}$  and column coordinates  $D_c^{-1}B(I+D_u)^{1/2}$  be used. These coordinates are (except for a constant scaling) the coordinates dinates from a multiple correspondence analysis of a Burt table created from two categorical variables. This standardization is available with ROW=DAID1/2 and COLUMN=DBID1/2. However, this approach has been criticized on both theoretical and empirical grounds by Greenacre (1989). The Carroll, Green, and Schaffer standardization relies on the assumption that the chi-square metric is an appropriate metric for measuring the distance between the columns of a bivariate indicator matrix. See the section "Using the TABLES Statement" on page 2010 for a description of indicator matrices. Greenacre (1989) showed that this assumption cannot be justified.

#### **The MCA Option**

The MCA option performs a multiple correspondence analysis (MCA). This option requires a Burt table. You can specify the MCA option with a table created from a design matrix with fuzzy coding schemes as long as every row of every partition of the design matrix has the same marginal sum. For example, each row of each partition could contain the probabilities that the observation is a member of each level. Then the Burt table constructed from this matrix no longer contains all integers, and the diagonal partitions are no longer diagonal matrices, but MCA is still valid.

A TABLES statement with a single variable list creates a Burt table. Thus, you can always specify the MCA option with this type of input. If you use the MCA option when reading an existing table with a VAR statement, you must ensure that the table is a Burt table.

If you perform MCA on a table that is not a Burt table, the results of the analysis are invalid. If the table is not symmetric, or if the sums of all elements in each diagonal partition are not equal, PROC CORRESP displays an error message and quits.

A subset of the columns of a Burt table is not necessarily a Burt table, so in MCA it is not appropriate to designate arbitrary columns as supplementary. You can, however, designate all columns from one or more categorical variables as supplementary.

The results of a multiple correspondence analysis of a Burt table Z'Z are the same as the column results from a simple correspondence analysis of the binary (or fuzzy) matrix Z. Multiple correspondence analysis is not a simple correspondence analysis of the Burt table. It is not appropriate to perform a simple correspondence analysis of a Burt table. The MCA option is based on  $P = BD_u^2B'$ , whereas a simple correspondence analysis of the Burt table would be based on  $P = BD_uB'$ .

Since the rows and columns of the Burt table are the same, no row information is displayed or written to the output data sets. The resulting inertias and the default (COLUMN=DBD) column coordinates are the appropriate inertias and coordinates for an MCA. The supplementary column coordinates, cosines, and quality of representation formulas for MCA differ from the simple correspondence analysis formulas because the design matrix column profiles and left singular vectors are not available.

The following statements create a Burt table and perform a multiple correspondence analysis:

```
proc corresp data=Neighbor observed short mca;
  tables Hair Height Sex Age;
run;
```

Both the rows and the columns have the same nine categories (Blond, Brown, White, Short, Tall, Female, Male, Old, and Young).

The usual principal inertias of a Burt table constructed from m categorical variables in MCA are the eigenvalues  $u_k$  from  $\mathbf{D_u^2}$ . The problem with these inertias is that they provide a pessimistic indication of fit. Benzécri (1979) proposed the following inertia adjustment, which is also described by Greenacre (1984, p. 145):

$$\left(\frac{m}{m-1}\right)^2 \times \left(u_k - \frac{1}{m}\right)^2$$
 for  $u_k > \frac{1}{m}$ 

This adjustment computes the percent of adjusted inertia relative to the sum of the adjusted inertias for all inertias greater than  $\frac{1}{m}$ . The Benzécri adjustment is available with the BENZECRI option.

Greenacre (1994, p. 156) argues that the Benzécri adjustment overestimates the quality of fit. Greenacre proposes instead to compute the percentage of adjusted inertia relative to

$$\frac{m}{m-1} \left( \operatorname{trace}(D_u^4) - \frac{n_c - m}{m^2} \right)$$

for all inertias greater than  $\frac{1}{m}$ , where trace  $(D_u^4)$  is the sum of squared inertias. The Greenacre adjustment is available with the GREENACRE option.

Ordinary unadjusted inertias are printed by default with MCA when neither the BENZECRI nor the GREENACRE option is specified. However, the unadjusted inertias are not printed by default when either the BENZECRI or the GREENACRE option is specified. To display both adjusted and unadjusted inertias, specify the UNADJUSTED option in addition to the relevant adjusted inertia option (BENZECRI, GREENACRE, or both).

#### **Supplementary Rows and Columns**

Supplementary rows and columns are represented as points in the joint row and column space, but they are not used in determining the locations of the other active rows and columns of the table. The formulas that are used to compute coordinates for the supplementary rows and columns depend on the PROFILE= option or the ROW= and COLUMN= options. Let  $S_o$  be a matrix with rows that contain the supplementary observations, and let  $S_v$  be a matrix with rows that contain the supplementary variables. Note that  $S_v$  is defined to be the transpose of the supplementary variable partition of the table. Let  $R_s = \operatorname{diag}(S_o 1)^{-1} S_o$  be the supplementary observation profile matrix, and let  $C_s = \operatorname{diag}(S_v 1)^{-1} S_v$  be the supplementary variable profile matrix. Note that the notation  $\operatorname{diag}(\cdot)^{-1}$  means to convert the vector to a diagonal matrix, then invert the diagonal matrix. The coordinates for the supplementary observations and variables are shown in Table 32.4.

| ROW=        | Matrix Formula  |
|-------------|---|
| A           | $\frac{1}{f}$ S <sub>o</sub> D <sub>c</sub> <sup>-1</sup> BD <sub>u</sub> <sup>-1</sup> |
| AD          | $\frac{1}{f}$ S <sub>o</sub> D <sub>c</sub> <sup>-1</sup> B                             |
| DA          | $ m R_sD_c^{-1}BD_u^{-1}$   |
| DAD         | $ m R_sD_c^{-1}B$   |
| DAD1/2      | $\mathrm{R_sD_c^{-1}BD_u^{-1/2}}$   |
| DAID1/2     | $R_s D_c^{-1} B D_u^{-1} (I + D_u)^{1/2}$   |
| COLUMN=     | Matrix Formula  |
| В           | $rac{1}{f}\mathrm{S_{v}D_{r}^{-1}AD_{u}^{-1}}$   |
| BD          | $\frac{1}{f}\mathbf{S_v}\mathbf{D_r^{-1}}\mathbf{A}$                                    |
| DB          | $\mathrm{C_sD_r^{-1}AD_u^{-1}}$   |
| DBD         | $ m C_s D_r^{-1} A$   |
| DBD1/2      | ${ m C_sD_r^{-1}AD_u^{-1/2}}$   |
| DBID1/2     | $C_s D_r^{-1} A D_u^{-1} (I + D_u)^{1/2}$   |
| MCA COLUMN= | Matrix Formula  |
| В           | not allowed   |
| BD          | not allowed   |
| DB          | $\mathrm{C_sD_r^{-1}BD_u^{-2}}$   |
| DBD         | $\mathrm{C_sD_r^{-1}BD_u^{-1}}$   |
| DBD1/2      | ${ m C_sD_r^{-1}BD_u^{-3/2}}$   |
| DBID1/2     | $C_s D_r^{-1} B D_u^{-2} (I + D_u)^{1/2}$   |

**Table 32.4** Coordinates for Supplementary Observations

#### **Statistics That Aid Interpretation**

The partial contributions to inertia, squared cosines, quality of representation, inertia, and mass provide additional information about the coordinates. These statistics are displayed by default. Include the SHORT or NOPRINT option in the PROC CORRESP statement to avoid having these statistics displayed.

These statistics pertain to the default PROFILE=BOTH coordinates, no matter what values you specify for the ROW=, COLUMN=, or PROFILE= option. Let  $sq(\cdot)$  be a matrix-valued function denoting element-wise squaring of the argument matrix. Let t be the total inertia (the sum of the elements in  $D_n^2$ ).

In MCA, let  $D_s$  be the Burt table partition containing the intersection of the supplementary columns and the supplementary rows. The matrix  $D_s$  is a diagonal matrix of marginal frequencies of the supplemental columns of the binary matrix  $\mathbf{Z}$ . Let p be the number of rows in this design matrix. The statistics are defined in Table 32.5.

**Table 32.5** Statistics That Aid Interpretation

| Statistic                                | Matrix Formula  |
|--|---|
| Row partial contributions to inertia     | $\mathrm{D}_{\mathrm{r}}^{-1}\mathrm{sq}(\mathrm{A})$                                   |
| Column partial contributions to inertia  | $D_c^{-1} \mathrm{sq}(B)$   |
| Row squared cosines                      | $\mathrm{diag}(\mathrm{sq}(AD_u)1)^{-1}\mathrm{sq}(AD_u)$                               |
| Column squared cosines                   | $\mathrm{diag}(\mathrm{sq}(BD_u)1)^{-1}\mathrm{sq}(BD_u)$                               |
| Row mass                                 | ${f r}$   |
| Column mass                              | c   |
| Row inertia                              | $rac{1}{t}\mathbf{D}_{\mathbf{r}}^{-1}\mathrm{sq}(\mathbf{A}\mathbf{D}_{\mathbf{u}})1$ |
| Column inertia                           | $rac{1}{t} \mathbf{D_c^{-1}} \mathrm{sq}(\mathbf{BD_u}) 1$                             |
| Supplementary row squared cosines        | $\mathrm{diag}(\mathrm{sq}(R_s-1c')D_c^{-1}1)^{-1}\mathrm{sq}(R_sD_c^{-1}B)$            |
| Supplementary column squared cosines     | $\mathrm{diag}(\mathrm{sq}(C_s-1r')D_r^{-1}1)^{-1}\mathrm{sq}(C_sD_r^{-1}A)$            |
| MCA supplementary column squared cosines | $D_s(\mathit{p}I - D_s)^{-1}\mathrm{sq}(C_sD_r^{-1}BD_u^{-1})$                          |

The quality of representation in the DIMENS=n dimensional display of any point is the sum of its squared cosines over only the n dimensions. Inertia and mass are not defined for supplementary points.

A table that summarizes the partial contributions to inertia table is also computed. The points that best explain the inertia of each dimension and the dimension to which each point contributes the most inertia are indicated. The output data set variable names for this table are Best1-Bestn (where DIMENS=n) and Best. The Best column contains the dimension number of the largest partial contribution to inertia for each point (the index of the maximum value in each row of  $D_r^{-1} \operatorname{sq}(A)$  or  $D_c^{-1} \operatorname{sq}(B)$ ).

For each row, the Best1-Bestn columns contain either the corresponding value of Best, if the point is one of the biggest contributors to the dimension's inertia, or 0 if it is not. Specifically, Best1 contains the value of Best for the point with the largest contribution to dimension one's inertia. A cumulative proportion sum is initialized to this point's partial contribution to the inertia of dimension one. If this sum is less than the value for the MININERTIA= option, then Best1 contains the value of Best for the point with the second-largest contribution to dimension one's inertia. Otherwise, this point's Best1 is 0. This point's partial contribution to inertia is added to the sum. This process continues for the point with the third-largest partial contribution, and so on, until adding a point's contribution to the sum increases the sum beyond the value of the MININERTIA= option. This same algorithm is then used for Best2, and so on.

For example, the following table contains contributions to inertia and the corresponding Best variables. The contribution to inertia variables are proportions that sum to 1 within each column. The first point makes its greatest contribution to the inertia of dimension two, so Best for point one is set to 2, and Best1–Best3 for point one must all be 0 or 2. The second point also makes its greatest contribution to the inertia of dimension two, so Best for point two is set to 2, and Best1–Best3 for point two must all be 0 or 2, and so on.

Assume MININERTIA=0.8, the default. Table 32.6 shows some contributions to inertia. In dimension one, the largest contribution is 0.41302 for the fourth point, so Best1 is set to 1, the value of Best for the fourth point. Because this value is less than 0.8, the second-largest value (0.36456 for point five) is found and its Best1 is set to its Best's value of 1. Because 0.41302 + 0.36456 = 0.77758 is less than 0.8, the third point (0.0882 at point eight) is found and Best1 is set to 3, since the contribution to dimension three for that point is greater than the contribution to dimension one. This increases the sum of the partial contributions to greater than 0.8, so the remaining Best1 values are all 0.

| Contr1  | Contr2  | Contr3  | Best1 | Best2 | Best3 | Best |
|---------|---------|---------|-------|-------|-------|------|
| 0.01593 | 0.32178 | 0.07565 | 0     | 2     | 2     | 2    |
| 0.03014 | 0.24826 | 0.07715 | 0     | 2     | 2     | 2    |

Table 32.6 Best Statistics

## **Displayed Output**

The display options control the amount of displayed output. By default, the following information is displayed:

- an inertia and chi-square decomposition table including the total inertia, the principal inertias of each
  dimension (eigenvalues), the singular values (square roots of the eigenvalues), each dimension's percentage of inertia, a horizontal bar chart of the percentages, and the total chi-square with its degrees
  of freedom and decomposition. The chi-square statistics and degrees of freedom are valid only when
  the constructed table is an ordinary two-way contingency table.
- the coordinates of the rows and columns on the dimensions
- the mass, relative contribution to the total inertia, and quality of representation in the DIMENS=*n* dimensional display of each row and column
- the squared cosines of the angles between each axis and a vector from the origin to the point
- the partial contributions of each point to each dimension's inertia
- the table of indicators of which points best explain the inertia of each dimension

Specific display options and combinations of options display output as follows.

If you specify the OBSERVED or ALL option and you do not specify PRINT=PERCENT, PROC CORRESP displays the following:

- the contingency table, including the row and column marginal frequencies; or with BINARY, the binary table; or the Burt table in MCA
- the supplementary rows
- the supplementary columns

If you specify the OBSERVED or ALL option, with the PRINT=PERCENT or PRINT=BOTH option, PROC CORRESP displays the following:

- the contingency table or Burt table in MCA, scaled to percentages, including the row and column marginal percentages
- the supplementary rows, scaled to percentages
- the supplementary columns, scaled to percentages

If you specify the EXPECTED or ALL option and you do not specify PRINT=PERCENT, PROC CORRESP displays the product of the row marginals and the column marginals divided by the grand frequency of the observed frequency table. For ordinary two-way contingency tables, these are the expected frequencies under the hypothesis of row and column independence.

If you specify the EXPECTED or ALL option with the PRINT=PERCENT or PRINT=BOTH option, PROC CORRESP displays the product of the row marginals and the column marginals divided by the grand frequency of the observed percentages table. For ordinary two-way contingency tables, these are the expected percentages under the hypothesis of row and column independence.

If you specify the DEVIATION or ALL option and you do not specify PRINT=PERCENT, PROC COR-RESP displays the observed minus expected frequencies. For ordinary two-way contingency tables, these are the expected frequencies under the hypothesis of row and column independence.

If you specify the DEVIATION or ALL option with the PRINT=PERCENT or PRINT=BOTH option, PROC CORRESP displays the observed minus expected percentages. For ordinary two-way contingency tables, these are the expected percentages under the hypothesis of row and column independence.

If you specify the CELLCHI2 or ALL option and you do not specify PRINT=PERCENT, PROC CORRESP displays contributions to the total chi-square test statistic, including the row and column marginals. The intersection of the marginals contains the total chi-square statistic.

If you specify the CELLCHI2 or ALL option with the PRINT=PERCENT or the PRINT=BOTH option, PROC CORRESP displays contributions to the total chi-square, scaled to percentages, including the row and column marginals.

If you specify the RP or ALL option and you do not specify PRINT=PERCENT, PROC CORRESP displays the row profiles and the supplementary row profiles.

If you specify the RP or ALL option with the PRINT=PERCENT or the PRINT=BOTH option, PROC CORRESP displays the row profiles (scaled to percentages) and the supplementary row profiles (scaled to percentages).

If you specify the CP or ALL option and you do not specify PRINT=PERCENT, PROC CORRESP displays the column profiles and the supplementary column profiles.

If you specify the CP or ALL option with the PRINT=PERCENT or PRINT=BOTH option, PROC COR-RESP displays the column profiles (scaled to percentages) and the supplementary column profiles (scaled to percentages).

If you do not specify the NOPRINT option, PROC CORRESP displays the inertia and chi-square decomposition table. This includes the nonzero singular values of the contingency table (or, in MCA, the binary matrix **Z** used to create the Burt table), the nonzero principal inertias (or eigenvalues) for each dimension, the total inertia, the total chi-square, the decomposition of chi-square, the chi-square degrees of freedom (appropriate only when the table is an ordinary two-way contingency table), the percentage of the total chi-square and inertia for each dimension, and a bar chart of the percentages.

If you specify the MCA option and you do not specify the NOPRINT option, PROC CORRESP displays the adjusted inertias. This includes the nonzero adjusted inertias, percentages, cumulative percentages, and a bar chart of the percentages.

If you do not specify the NOROW, NOPRINT, or MCA option, PROC CORRESP displays the row coordinates and the supplementary row coordinates (displayed when there are supplementary row points).

If you do not specify the NOROW, NOPRINT, MCA, or SHORT option, PROC CORRESP displays the following:

- the summary statistics for the row points, including the quality of representation of the row points in the *n*-dimensional display, the mass, and the relative contributions to inertia
- the quality of representation of the supplementary row points in the *n*-dimensional display (displayed when there are supplementary row points)
- the partial contributions to inertia for the row points
- the table of indicators of which row points best explain the inertia of each dimension
- the squared cosines for the row points
- the squared cosines for the supplementary row points (displayed when there are supplementary row points)

If you do not specify the NOCOLUMN or NOPRINT option, PROC CORRESP displays the column coordinates and the supplementary column coordinates (displayed when there are supplementary column points).

If you do not specify the NOCOLUMN, NOPRINT, or SHORT option, PROC CORRESP displays the following:

- the summary statistics for the column points, including the quality of representation of the column points in the *n*-dimensional display, the mass, and the relative contributions to inertia for the supplementary column points
- the quality of representation of the supplementary column points in the *n*-dimensional display (displayed when there are supplementary column points)
- the partial contributions to inertia for the column points
- the table of indicators of which column points best explain the inertia of each dimension

- the squared cosines for the column points
- the squared cosines for the supplementary column points

#### **ODS Table Names**

PROC CORRESP assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 32.7 along with the PROC CORRESP statement options needed to produce the table. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 32.7 ODS Tables Produced by PROC CORRESP

| <b>ODS Table Name</b> | Description                     | Option            |  |  |
|-----------------------|---------------------------------|-------------------|--|--|
| AdjInGreenacre        | Greenacre Inertia Adjustment    | GREENACRE         |  |  |
| AdjInBenzecri         | Benzécri Inertia Adjustment     | BENZECRI          |  |  |

Table 32.7 continued

### **ODS Graphics**

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 600 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 599 in Chapter 21, "Statistical Graphics Using ODS."

You can reference every graph produced through ODS Graphics with a name. The names of the graph that PROC CORRESP generates is listed in Table 32.8. It is displayed by default when ODS graphics is enabled.

Table 32.8 Graphs Produced by PROC CORRESP

| ODS Graph Name | Plot Description             |
|----------------|------------------------------|
| ConfigPlot     | Correspondence analysis plot |

## **Examples: CORRESP Procedure**

## **Example 32.1: Simple and Multiple Correspondence Analysis of Automobiles** and Their Owners

In this example, PROC CORRESP creates a contingency table from categorical data and performs a simple correspondence analysis. The data are from a sample of individuals who were asked to provide informa-

<sup>\*</sup>Percentages are displayed when you specify the PRINT=PERCENT or PRINT=BOTH option.

tion about themselves and their automobiles. The questions included origin of the automobile (American, Japanese, European) and family status (single, married, single and living with children, married living with children).

The first steps read the input data and assign formats. PROC CORRESP is used to perform the simple correspondence analysis. The ALL option displays all tables, including the contingency table, chi-square information, profiles, and all results of the correspondence analysis. The OUTC= option creates an output coordinate data set. The TABLES statement specifies the row and column categorical variables. The results are displayed with ODS Graphics.

The following statements produce Output 32.1.1:

```
title1 'Automobile Owners and Auto Attributes';
title2 'Simple Correspondence Analysis';
proc format;
  value Origin 1 = 'American' 2 = 'Japanese' 3 = 'European';

proc corresp all data=Cars outc=Coor;
  tables Marital, Origin;
run;
```

Correspondence analysis locates all the categories in a Euclidean space. The first two dimensions of this space are plotted to examine the associations among the categories. Since the smallest dimension of this table is three, there is no loss of information when only two dimensions are plotted. The plot should be thought of as two different overlaid plots, one for each categorical variable. Distances between points within a variable have meaning, but distances between points from different variables do not.

Output 32.1.1 continued

To interpret the plot, start by interpreting the row points separately from the column points. The European point is near and to the left of the centroid, so it makes a relatively small contribution to the chi-square statistic (because it is near the centroid), it contributes almost nothing to the inertia of dimension one (since its coordinate on dimension one has a small absolute value relative to the other column points), and it makes a relatively large contribution to the inertia of dimension two (since its coordinate on dimension two has a large absolute value relative to the other column points). Its squared cosines for dimension one and two, approximately 0 and 1, respectively, indicate that its position is almost completely determined by its location on dimension two. Its quality of display is 1.0, indicating perfect quality, since the table is two-dimensional after the centering. The American and Japanese points are far from the centroid, and they lie along dimension one. They make relatively large contributions to the chi-square statistic and the inertia of dimension one. The horizontal dimension seems to be largely determined by Japanese versus American automobile ownership.

In the row points, the Married point is near the centroid, and the Single with Kids point has a small coordinate on dimension one that is near zero. The horizontal dimension seems to be largely determined by the Single versus the Married with Kids points. The two interpretations of dimension one show the association with being Married with Kids and owning an American auto, and being single and owning a Japanese auto. The fact that the Married with Kids point is close to the American point and the fact that the Japanese point is near the Single point should be ignored. Distances between row and column points are not defined. The plot shows that more people who are married with kids than you would expect if the rows and columns were independent drive an American auto, and more people who are single than you would expect if the rows and columns were independent drive a Japanese auto.

In the second part of this example, PROC CORRESP creates a Burt table from categorical data and performs a multiple correspondence analysis. The variables used in this example are Origin, Size, Type, Income, Home, Marital, and Sex. MCA specifies multiple correspondence analysis, OBSERVED displays the Burt table, and the OUTC= option creates an output coordinate data set. The TABLES statement with only a single variable list and no comma creates the Burt table.

The following statements produce Output 32.1.2:

```
title2 'Multiple Correspondence Analysis';

* Perform Multiple Correspondence Analysis;
proc corresp mca observed data=Cars outc=Coor;
  tables Origin Size Type Income Home Marital Sex;
run;
```

Output 32.1.2 Multiple Correspondence Analysis

Multiple correspondence analysis locates all the categories in a Euclidean space. The first two dimensions of this space are plotted to examine the associations among the categories. The top-right quadrant of the plot shows that the categories Single, Single with Kids, 1 Income, and Rent are associated. Proceeding clockwise, the categories Sporty, Small, and Japanese are associated. The bottom-left quadrant shows the association between being married, owning your own home, and having two incomes. Having children is associated with owning a large American family auto. Such information could be used in market research to identify target audiences for advertisements.

This interpretation is based on points found in approximately the same direction from the origin and in approximately the same region of the space. Distances between points do not have a straightforward interpretation in multiple correspondence analysis. The geometry of multiple correspondence analysis is not a simple generalization of the geometry of simple correspondence analysis (Greenacre and Hastie 1987; Greenacre 1988).

If you want to perform a multiple correspondence analysis and get scores for the individuals, you can specify the BINARY option to analyze the binary table, as in the following statements. In the interest of space, only the first 10 rows of coordinates are printed in Output 32.1.3.

```
title2 'Binary Table';
* Perform Multiple Correspondence Analysis;
proc corresp data=Cars binary;
  ods select RowCoors;
  tables Origin Size Type Income Home Marital Sex;
run;
```

Output 32.1.3 Correspondence Analysis of a Binary Table

## Example 32.2: Simple Correspondence Analysis of U.S. Population

In this example, PROC CORRESP reads an existing contingency table with supplementary observations and performs a simple correspondence analysis. The data are populations of the 50 U.S. states, grouped into regions, for each of the census years from 1920 to 1970 (U.S. Bureau of the Census 1979). Alaska and Hawaii are treated as supplementary regions, because they were not states during this entire period and are not physically connected to the other 48 states. Consequently, it is reasonable to expect that population changes in these two states operate differently from population changes in the other states. The correspondence analysis is performed giving the supplementary points negative weight, and then the coordinates for the supplementary points are computed in the solution defined by the other points.

The initial DATA step reads the table, provides labels for the years, flags the supplementary rows with negative weights, and specifies absolute weights of 1000 for all observations since the data were originally reported in units of 1000 people.

In the PROC CORRESP statement, PRINT=PERCENT and the display options display the table of cell percentages (OBSERVED), cell contributions to the total chi-square scaled to sum to 100 (CELLCHI2), row profile rows that sum to 100 (RP), and column profile columns that sum to 100 (CP). The SHORT option specifies that the correspondence analysis summary statistics, contributions to inertia, and squared cosines should not be displayed. The option OUTC=COOR creates the output coordinate data set. Since the data are already in table form, a VAR statement is used to read the table. Row labels are specified with the ID statement, and column labels come from the variable labels. The WEIGHT statement flags the supplementary observations and restores the table values to populations.

The following statements produce Output 32.2.1:

```

```

The contingency table shows that the population of all regions increased over this time period. The row profiles show that population increased at a different rate for the different regions. There was a small increase in population in the Midwest, for example, but the population more than quadrupled in the Pacific region over the same period. The column profiles show that in 1920, the U.S. population was concentrated in the NY, NJ, PA, Great Lakes, Midwest, and South Atlantic regions. With time, the population shifted more to the South Atlantic, Mountain, and Pacific regions. This is also clear from the correspondence analysis. The inertia and chi-square decomposition table shows that there are five nontrivial dimensions in the table, but the association between the rows and columns is almost entirely one-dimensional.

**Dimension 1 (98.16%)** 

ODS Graphics is used to plot the results. The data are essentially one-dimensional. For data such as these, it is better to plot the first dimension vertically, as opposed to the default, which is horizontally. The vertical orientation has fewer opportunities for label collisions. Specifying PLOTS(FLIP) on the PROC CORRESP statement switches the vertical and horizontal axes to improve the graphical display.

0.0

Dimension 2 (1.322%)

Row Sup Row Column

The plot shows that the first dimension correctly orders the years. There is nothing in the correspondence analysis that forces this to happen; the analysis has no information about the inherent ordering of the column categories. The ordering of the regions and the ordering of the years reflect the shift over time of the U.S. population from the Northeast quadrant of the country to the South and to the West. The results show that the West and Southeast grew faster than the rest of the contiguous 48 states during this period.

The plot also shows that the growth pattern for Hawaii was similar to the growth pattern for the mountain states and that Alaska's growth was even more extreme than the Pacific states' growth. The row profiles confirm this interpretation.

The Pacific region is farther from the origin than all other active points. The Midwest is the extreme region in the other direction. The table of contributions to the total chi-square shows that 62% of the total chi-square statistic is contributed by the Pacific region, which is followed by the Midwest at over 14%. Similarly the two extreme years, 1920 and 1970, together contribute over 63% to the total chi-square, whereas the years nearer the origin of the plot contribute less.

|  |  |

**OBSERVED** option

PROC CORRESP statement, 2004

OUTC= option

PROC CORRESP statement, 2004

OUTF= option

PROC CORRESP statement, 2004

PLOTS= option

PROC CORRESP statement, 2004

PRINT= option

PROC CORRESP statement, 2005

PROC CORRESP statement, see CORRESP procedure

PROFILE= option

PROC CORRESP statement, 2005

ROW= option

PROC CORRESP statement, 2006

RP option

PROC CORRESP statement, 2006

SHORT option

PROC CORRESP statement, 2006

SINGULAR= option

PROC CORRESP statement, 2006

**SOURCE** option

PROC CORRESP statement, 2006

SUPPLEMENTARY statement

CORRESP procedure, 2007

TABLES statement

CORRESP procedure, 2008

**UNADJUSTED** option

PROC CORRESP statement, 2006

VAR statement

CORRESP procedure, 2008

WEIGHT statement

CORRESP procedure, 2009

## **Your Turn**

We welcome your feedback.

- If you have comments about this book, please send them to yourturn@sas.com. Include the full title and page numbers (if applicable).
- If you have comments about the software, please send them to suggest@sas.com.

# **SAS®** Publishing Delivers!

Whether you are new to the work force or an experienced professional, you need to distinguish yourself in this rapidly changing and competitive job market. SAS\* Publishing provides you with a wide range of resources to help you set yourself apart. Visit us online at support.sas.com/bookstore.

#### **SAS®** Press

Need to learn the basics? Struggling with a programming problem? You'll find the expert answers that you need in example-rich books from SAS Press. Written by experienced SAS professionals from around the world, SAS Press books deliver real-world insights on a broad range of topics for all skill levels.
