# **Overview: GLMSELECT Procedure**

The GLMSELECT procedure performs effect selection in the framework of general linear models. A variety of model selection methods are available, including the LASSO method of Tibshirani (1996) and the related LAR method of Efron et al. (2004). The procedure offers extensive capabilities for customizing the selection with a wide variety of selection and stopping criteria, from traditional and computationally efficient significance-level-based criteria to more computationally intensive validation-based criteria. The procedure also provides graphical summaries of the selection search.

The GLMSELECT procedure compares most closely to REG and GLM. The REG procedure supports a variety of model-selection methods but does not support a CLASS statement. The GLM procedure supports a CLASS statement but does not include effect selection methods. The GLMSELECT procedure fills this gap. GLMSELECT focuses on the standard independently and identically distributed general linear model for univariate responses and offers great flexibility for and insight into the model selection algorithm. GLM-SELECT provides results (displayed tables, output data sets, and macro variables) that make it easy to take the selected model and explore it in more detail in a subsequent procedure such as REG or GLM.

# **Features**

The main features of the GLMSELECT procedure are as follows:

# Model Specification

- supports different parameterizations for classification effects
- supports any degree of interaction (crossed effects) and nested effects
- supports hierarchy among effects
- supports partitioning of data into training, validation, and testing roles
- supports constructed effects including spline and multimember effects

#### • Selection Control

- provides multiple effect selection methods
- enables selection from a very large number of effects (tens of thousands)
- offers selection of individual levels of classification effects
- provides effect selection based on a variety of selection criteria
- provides stopping rules based on a variety of model evaluation criteria
- provides leave-one-out and k-fold cross validation
- supports data resampling and model averaging

# • Display and Output

- produces graphical representation of selection process
- produces output data sets containing predicted values and residuals
- produces an output data set containing the design matrix
- produces macro variables containing selected models
- supports parallel processing of BY groups
- supports multiple SCORE statements

The GLMSELECT procedure supports the following effect selection methods. These methods are explained in detail in the section "Model-Selection Methods" on page 3559.

FORWARD Forward selection. This method starts with no effects in the model and adds effects.

BACKWARD Backward elimination. This method starts with all effects in the model and deletes ef-

fects.

STEPWISE Stepwise regression. This is similar to the FORWARD method except that effects already

in the model do not necessarily stay there.

LAR Least angle regression. This method, like forward selection, starts with no effects in

the model and adds effects. The parameter estimates at any step are "shrunk" when

compared to the corresponding least squares estimates.

LASSO This method adds and deletes parameters based on a version of ordinary least squares

where the sum of the absolute regression coefficients is constrained.

Hybrid versions of LAR and LASSO are also supported. They use LAR or LASSO to select the model, but then estimate the regression coefficients by ordinary weighted least squares.

The GLMSELECT procedure is intended primarily as a model selection procedure and does not include regression diagnostics or other postselection facilities such as hypothesis testing, testing of contrasts, and LS-means analyses. The intention is that you use PROC GLMSELECT to select a model or a set of candidate models. Further investigation of these models can be done by using these models in existing regression procedures.

# **Getting Started: GLMSELECT Procedure**

The following data set contains salary and performance information for Major League Baseball players who played at least one game in both the 1986 and 1987 seasons, excluding pitchers. The salaries (*Sports Illustrated*, April 20, 1987) are for the 1987 season and the performance measures are from 1986 (Collier Books, *The 1987 Baseball Encyclopedia Update*).

```

Suppose you want to investigate whether you can model the players' salaries for the 1987 season based on performance measures for the previous season. The aim is to obtain a parsimonious model that does not overfit this particular data, making it useful for prediction. This example shows how you can use PROC GLMSELECT as a starting point for such an analysis. Since the variation of salaries is much greater for the higher salaries, it is appropriate to apply a log transformation to the salaries before doing the model selection.

The following code selects a model with the default settings:

```
ods graphics on;
proc glmselect data=baseball plots=all;
   class league division;
   model logSalary = nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB league division nOuts nAssts nError
                   / details=all stats=all;
run;
ods graphics off;
```

PROC GLMSELECT performs effect selection where effects can contain classification variables that you specify in a CLASS statement. The "Class Level Information" table shown in Figure 45.1 lists the levels of the classification variables division and league.

Figure 45.1 Class Level Information

```
The GLMSELECT Procedure
         Class Level Information
Class
                        Values
              Levels
league
                   2
                        American National
division
                   2
                        East West
```

When you specify effects that contain classification variables, the number of parameters is usually larger than the number of effects. The "Dimensions" table in Figure 45.2 shows the number of effects and the number of parameters considered.

Figure 45.2 Dimensions

```
Dimensions
Number of Effects
                        19

The GLMSELECT Pro	ocedure	
Data Set	WORK.BASEBALL	
Dependent Variable	logSalary	
Selection Method	Stepwise	
Select Criterion	SBC	
Stop Criterion	SBC	
Effect Hierarchy Enforced	None	

You find details of the default search settings in the "Model Information" table shown in Figure 45.3. The default selection method is a variant of the traditional stepwise selection where the decisions about what effects to add or drop at any step and when to terminate the selection are both based on the Schwarz Bayesian information criterion (SBC). The effect in the current model whose removal yields the maximal decrease in the SBC statistic is dropped provided this lowers the SBC value. Once no decrease in the SBC value can be obtained by dropping an effect in the model, the effect whose addition to the model yields the lowest SBC statistic is added and the whole process is repeated. The method terminates when dropping or adding any effect increases the SBC statistic.

Figure 45.4 Candidates for Entry at Step Two

Best	10	Entry Ca	Candidates
Rank		Effect	SBC
1		nHits	-252.5794
2		nAtBat	-241.5789
3		nRuns	-240.1010
4		nRBI	-232.2880
5		nBB	-223.3741
6		nHome	-208.0565
7		nOuts	-205.8107
8		division	on -194.4688
9		crBB	-191.5141
10		nAssts	-190.9425

The DETAILS=ALL option requests details of each step of the selection process. The "Best 10 Entry Candidates" table at each step shows the candidates for inclusion or removal at that step ranked from best to worst in terms of the selection criterion, which in this example is the SBC statistic. By default only the 10 best candidates are shown. Figure 45.4 shows the candidate table at step two.

To help in the interpretation of the selection process, you can use graphics supported by PROC GLMSE-LECT. ODS Graphics must be enabled before requesting plots. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." With ODS Graphics enabled, the PLOTS=ALL option together with the DETAILS=STEPS option in the MODEL statement produces a needle plot view of the "Candidates" tables. The plot corresponding to the "Candidates" table at step two is shown in Figure 45.5. You can see that adding the effect 'nHits' yields the smallest SBC value, and so this effect is added at step two.

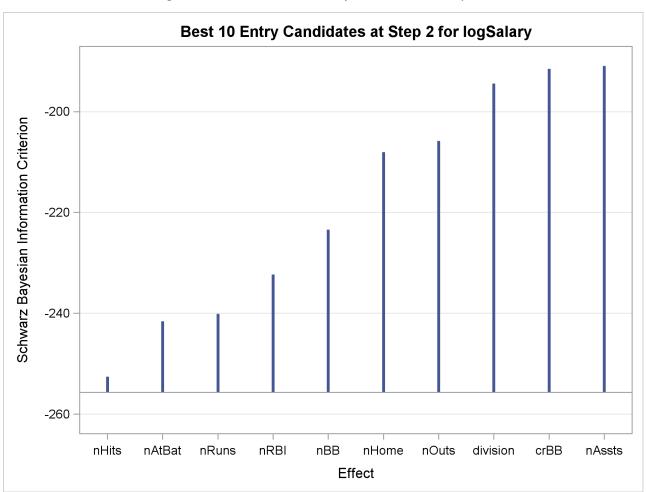

Figure 45.5 Needle Plot of Entry Candidates at Step Two

The "Stepwise Selection Summary" table in Figure 45.6 shows the effect that was added or dropped at each step of the selection process together with fit statistics for the model at each step. The STATS=ALL option in the MODEL statement requests that all the available fit statistics are displayed. See the section "Criteria Used in Model Selection Methods" on page 3568 for descriptions and formulas. The criterion panel in Figure 45.7 provides a graphical view of the progression of these fit criteria as the selection process evolves. Note that none of these criteria has a local optimum before step five.

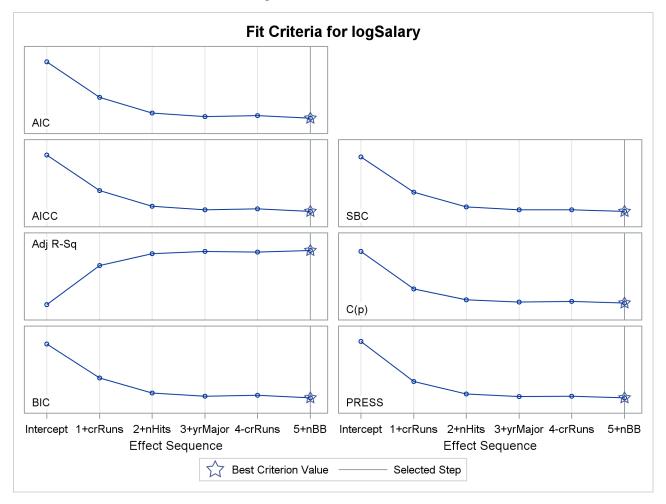

Figure 45.7 Criterion Panel

The stop reason and stop details tables in Figure 45.8 gives details of why the selection process terminated. This table shows that at step five the best add candidate, 'division', and the best drop candidate, 'nBB', yield models with SBC values of -268.6094 and -262.8353, respectively. Both of these values are larger than the current SBC value of -269.7804, and so the selection process stops at the model at step five.

Selection stopped at a local minimum of the SBC criterion. Stop Details Candidate Candidate Compare SBC For **Effect** SBC Entry division -268.6094 -269.7804 -262.8353 -269.7804 Removal nBB

Figure 45.8 Stopping Details

The coefficient panel in Figure 45.9 enables you to visualize the selection process. In this plot, standardized coefficients of all the effects selected at some step of the stepwise method are plotted as a function of the step number. This enables you to assess the relative importance of the effects selected at any step of the selection process as well as providing information as to when effects entered the model. The lower plot in the panel shows how the criterion used to choose the selected model changes as effects enter or leave the model.

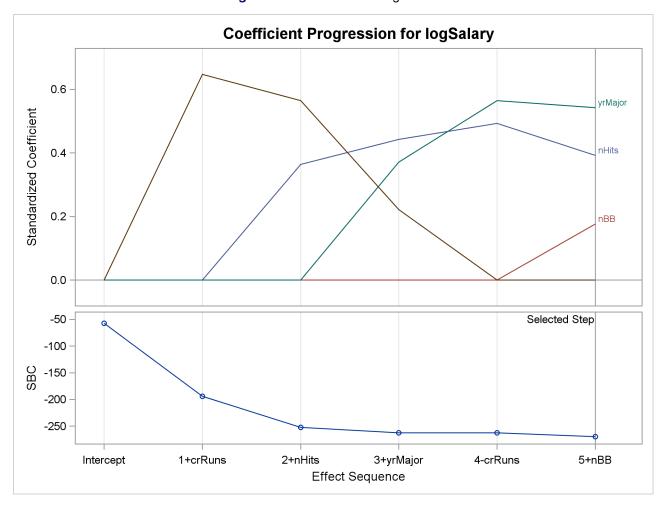

Figure 45.9 Coefficient Progression

The selected effects, analysis of variance, fit statistics, and parameter estimates tables shown in Figure 45.10 give details of the selected model.

PROC GLMSELECT provides you with the flexibility to use several selection methods and many fit criteria for selecting effects that enter or leave the model. You can also specify criteria to determine when to stop the selection process and to choose among the models at each step of the selection process. You can find continued exploration of the baseball data that uses a variety of these methods in Example 45.1.

# **Syntax: GLMSELECT Procedure**

The following statements are available in the GLMSELECT procedure:

```
PROC GLMSELECT < options > ;
   BY variables;
   CLASS variable < (v-options) > < variable < (v-options . . .) >> < / v-options > < options > ;
   CODE < options > ;
   EFFECT name = effect-type (variables < / options >);
   FREQ variable;
   MODEL variable = < effects > </ options > ;
   MODELAVERAGE < options>;
   OUTPUT < OUT=SAS-data-set> < keyword< =name>> < ... keyword< =name>> ;
   PARTITION < options > ;
   PERFORMANCE < options > ;
   SCORE < DATA=SAS-data-set> < OUT=SAS-data-set> ;
   STORE < OUT = > item-store-name < / LABEL = 'label' > ;
   WEIGHT variable:
```

All statements other than the MODEL statement are optional and multiple SCORE statements can be used. CLASS and EFFECT statements, if present, must precede the MODEL statement.

The STORE and CODE statements are also used by many other procedures. A summary description of functionality and syntax for these statements is also shown after the PROC GLMSELECT statement in alphabetical order, but you can find full documentation about them in the section "STORE Statement" on page 501 of Chapter 19, "Shared Concepts and Topics."

# **PROC GLMSELECT Statement**

```
PROC GLMSELECT < options > ;
```

The PROC GLMSELECT statement invokes the GLMSELECT procedure. Table 45.1 summarizes the options available in the PROC GLMSELECT statement.

<b>Table 45.1</b>	PROC GLMSELECT	Statement Options

Option	Description
<b>Data Set Options</b>	
DATA=	Names a data set to use for the regression
MAXMACRO=	Sets the maximum number of macro variables produced
TESTDATA=	Names a data set that contains test data
VALDATA=	Names a data set that contains validation data

Table 45.1 continued

Option	Description
ODS Graphics Options PLOTS=	Produces ODS graphical displays
Other Options	
OUTDESIGN=	Requests a data set that contains the design matrix
NAMELEN=	Sets the length of effect names in tables and output data sets
NOPRINT	Suppresses displayed output including plots
SEED=	Sets the seed used for pseudo-random number generation

Following are explanations of the options that you can specify in the PROC GLMSELECT statement (in alphabetical order).

#### **DATA**=*SAS*-data-set

names the SAS data set to be used by PROC GLMSELECT. If the DATA= option is not specified, PROC GLMSELECT uses the most recently created SAS data set. If the named data set contains a variable named \_ROLE\_, then this variable is used to assign observations for training, validation, and testing roles. See the section "Using Validation and Test Data" on page 3577 for details on using the \_ROLE\_ variable.

# MAXMACRO=n

specifies the maximum number of macro variables with selected effects to create. By default, MAX-MACRO=100. PROC GLMSELECT saves the list of selected effects in a macro variable, &\_GLSIND. Say your input effect list consists of x1-x10. Then &\_GLSIND would be set to x1 x3 x4 x10 if, for example, the first, third, fourth, and tenth effects were selected for the model. This list can be used, for example, in the model statement of a subsequent procedure. If you specify the OUTDESIGN= option in the PROC GLMSELECT statement, then PROC GLMSELECT saves the list of columns in the design matrix in a macro variable named &\_GLSMOD.

With BY processing, one macro variable is created for each BY group, and the macro variables are indexed by the BY group number. The MAXMACRO= option can be used to either limit or increase the number of these macro variables when you are processing data sets with many BY groups.

With no BY processing, PROC GLMSELECT creates the following:

_GLSIND	selected effects
_GLSIND1	selected effects
_GLSMOD	design matrix columns
_GLSMOD1	design matrix columns
_GLSNUMBYS	number of BY groups
GLSNUMMACROBYS	number of GLSINDi macro variables actually made

With BY processing, PROC GLMSELECT creates the following:

_GLSIND	selected effects for BY group 1
_GLSIND1	selected effects for BY group 1
_GLSIND2	selected effects for BY group 2
_GLSIND <i>m</i>	selected effects for BY group <i>m</i> , where a number is substituted for <i>m</i>
_GLSMOD	design matrix columns for BY group 1
_GLSMOD1	design matrix columns for BY group 1
_ _GLSMOD2	design matrix columns for BY group 2
_GLSMOD <i>m</i>	design matrix columns for BY group $m$ , where a number is substituted for $m$

\_GLSNUMBYS n, the number of BY groups

\_GLSNUMMACROBYS the number m of \_GLSINDi macro variables actually

made. This value can be less than GLSNUMBYS = n, and it is less than or equal to the MAXMACRO= value.

See the section "Macro Variables Containing Selected Models" on page 3572 for further details.

#### **NOPRINT**

suppresses all displayed output including plots.

#### NAMELEN=n

specifies the length of effect names in tables and output data sets to be n characters long, where n is a value between 20 and 200 characters. The default length is 20 characters.

# OUTDESIGN < (options) >< =SAS-data-set >

creates a data set that contains the design matrix. By default, the GLMSELECT procedure includes in the OUTDESIGN data set the X matrix corresponding to the parameters in the selected model. Two schemes for naming the columns of the design matrix are available. In the first scheme, names of the parameters are constructed from the parameter labels that appear in the ParameterEstimates table. This naming scheme is the default when you do not request BY processing and is not available when you do use BY processing. In the second scheme, the design matrix column names consist of a prefix followed by an index. The default naming prefix is X.

You can specify the following options in parentheses to control the contents of the OUTDESIGN data set:

# **ADDINPUTVARS**

requests that all variables in the input data set be included in the OUTDESIGN= data set.

# **FULLMODEL**

specifies that parameters corresponding to all the effects specified in the MODEL statement be included in the OUTDESIGN= data set. By default, only parameters corresponding to the selected model are included.

#### **NAMES**

produces a table associating columns in the OUTDESIGN data set with the labels of the parameters they represent.

# PREFIX<=prefix>

requests that the design matrix column names consist of a prefix followed by an index. The default naming prefix is \_X. You can optionally specify a different prefix.

# **PARMLABELSTYLE**=options

specifies how parameter names and labels are constructed for nested and crossed effects.

The following options are available:

# INTERLACED < (SEPARATOR=quoted string) >

forms parameter names and labels by positioning levels of classification variables and constructed effects adjacent to the associated variable or constructed effect name and using " \* " as the delimiter for both crossed and nested effects. This style of naming parameters and labels is used in the TRANSREG procedure. You can request truncation of the classification variable names used in forming the parameter names and labels by using the CPREFIX= and LPREFIX= options in the CLASS statement. You can use the SEPARATOR= suboption to change the delimiter between the crossed variables in the effect. PARMLABELSTYLE=INTERLACED is not supported if you specify the SPLIT option in an EFFECT statement or a CLASS statement. The following are examples of the parameter labels in this style (Age is a continuous variable, Gender and City are classification variables):

```
Age
Gender male * City Beijing
City London * Age
```

#### **SEPARATE**

specifies that in forming parameter names and labels, the effect name appears before the levels associated with the classification variables and constructed effects in the effect. You can control the length of the effect name by using the NAMELEN= option in the PROC GLMSELECT statement. In forming parameter labels, the first level that is displayed is positioned so that it starts at the same offset in every parameter label—this enables you to easily distinguish the effect name from the levels when the parameter labels are displayed in a column in the "Parameter Estimates" table. This style of labeling is used in the GLM procedure and is the default if you do not specify the PARMLABELSTYLE option. The following are examples of the parameter labels in this style (Age is a continuous variable, Gender and City are classification variables):

```
Age
Gender*City male Beijing
Age*City London
```

# **SEPARATECOMPACT**

requests the same parameter naming and labeling scheme as PARMLABELSTYLE=SEPARATE except that the first level in the parameter label is separated from the effect name by a single blank. This style of labeling is used in the PLS procedure. The following are examples of the parameter labels in this style (Age is a continuous variable, Gender and City are classification variables):

```
Age
Gender*City male Beijing
Age*City London
```

```
PLOTS < (global-plot-options) > < = plot-request < (options) > >
```

PLOTS < (global-plot-options) > < = (plot-request < (options) > < ... plot-request < (options) > >) > controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=all
plots=coefficients(unpack)
plots(unpack)=(criteria candidates)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc glmselect plots=all;
   model y = x1-x100;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 600 in Chapter 21, "Statistical Graphics Using ODS."

# **Global Plot Options**

The *global-options* apply to all plots generated by the GLMSELECT procedure, unless it is altered by a specific-plot-option.

#### **ENDSTEP**=n

specifies that the step ranges shown on the horizontal axes of plots terminates at specified step. By default, the step range shown terminates at the final step of the selection process. If you specify the ENDSTEP= option as both a global plot option and a specific plot option, then the ENDSTEP= value on the specific plot is used.

# LOGP | LOGPVALUE

displays the natural logarithm of the entry and removal significance levels when the SE-LECT=SL option is specified.

#### **MAXSTEPLABEL**=*n*

specifies the maximum number of characters beyond which labels of effects on plots are truncated.

#### MAXPARMLABEL= n

specifies the maximum number of characters beyond which parameter labels on plots are truncated.

#### STARTSTEP=n

specifies that the step ranges shown on the horizontal axes of plots start at the specified step. By default, the step range shown starts at the initial step of the selection process. If you specify the STARTSTEP= option both as a global plot option and a specific plot option, then the STARTSTEP= value on the specific plot is used.

# STEPAXIS=EFFECT | NORMB | NUMBER

specifies the horizontal axis to be used on the plots, where this axis represents the sequence of entering or departing effects.

#### STEPAXIS=EFFECT

requests that each step be labeled by a prefix followed by the name of the effect that enters or leaves at that step. The prefix consists of the step number followed by a "+" sign or a "-" sign depending on whether the effect enters or leaves at that step.

# STEPAXIS=NORMB

is valid only with LAR and LASSO selection methods and requests that the horizontal axis value at step i be the L1 norm of the parameters at step i, normalized by the L1 norm of the parameters at the final step.

# STEPAXIS=NUMBER

requests that each step be labeled by the step number.

# **UNPACK**

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACK to get each plot individually. You can also specify UNPACK as a suboption with CRITERIA and COEFFICIENTS.

# **Specific Plot Options**

The following listing describes the specific plots and their options.

#### **ALL**

requests that all default plots be produced. Note that candidate plots are produced only if you specify DETAILS=STEPS or DETAILS=ALL in the MODEL statement.

# ASE | ASEPLOT < (aseplot-option) >

plots the progression of the average square error on the training data, and the test and validation data whenever these data are provided with the TESTDATA= and VALDATA= options or are produced by using a PARTITION statement. The following *aseplot-option* option is available:

# STEPAXIS=EFFECT | NORMB | NUMBER

specifies the horizontal axis to be used.

# CANDIDATES | CANDIDATESPLOT < (candidatesplot-options) >

produces a needle plot of the SELECT= criterion values for the candidates for entry or removal at each step of the selection process, ordered from best to worst. Candidates plots are not available if you specify SELECTION=NONE, SELECTION=LAR, or SELECTION=LASSO in the MODEL statement, or if you have not specified DETAILS=ALL or DETAILS=STEPS in the MODEL statement. The following *candidatesplot-options* are available:

# LOGP | LOGPVALUE

displays the natural logarithm of the entry and removal significance levels when the SE-LECT=SL option is specified.

# SHOW=number

specifies the maximum number of candidates displayed at each step. The default is SHOW=10.

# COEFFICIENTS | COEFFICIENTPANEL < (coefficientPanel-options) >

plots a panel of two plots. The upper plot shows the progression of the parameter values as the selection process proceeds. The lower plot shows the progression of the CHOOSE= criterion. If no CHOOSE= criterion is in effect, then the AICC criterion is displayed. The following *coefficientPanel-options* are available:

# LABELGAP=percentage

specifies the percentage of the vertical axis range that forms the minimum gap between successive parameter labels at the final step of the coefficient progression plot. If the values of more than one parameter at the final step are closer than this gap, then the labels on all but one of these parameters is suppressed. The default value is LABELGAP=5. Planned enhancements to the automatic label collision avoidance algorithm will obviate the need for this option in future releases of the GLMSELECT procedure.

# LOGP | LOGPVALUE

displays the natural logarithm of the entry and removal significance levels when the SE-LECT=SL option is specified.

# STEPAXIS=EFFECT | NORMB | NUMBER

specifies the horizontal axis to be used.

# **UNPACK | UNPACKPANEL**

displays the coefficient progression and the CHOOSE= criterion progression in separate plots.

# CRITERIA | CRITERIONPANEL < (criterionPanel-options) >

plots a panel of model fit criteria. The criteria that are displayed are ADJRSQ, AIC, AICC, and SBC, as well as any other criteria that are named in the CHOOSE=, SELECT=, STOP=, or STATS= option in the MODEL statement. The following *criterionPanel-options* are available:

# STEPAXIS=EFFECT | NORMB | NUMBER

specifies the horizontal axis to be used.

#### **UNPACK | UNPACKPANEL**

displays each criterion progression on a separate plot.

# **EFFECTSELECTPCT** <(effectSelectPct-options)>

requests a bar chart whose bars correspond to effects that are selected in at least one sample when you use the MODELAVERAGE statement. The length of a bar corresponds to the percentage of samples where the selected model contains the effect the bar represents. The EFFECTSELECT-PCT option is ignored if you do not specify a MODELAVERAGE statement. The following <code>effectSelectPct-options</code> are available:

# MINPCT=percent

specifies that effects that appear in fewer than the specified percentage of the sample selected models not be included in the plot. By default, effects that are shown in the EffectS-electPct table are displayed.

# ORDER=ASCENDING | DESCENDING | MODEL

specifies the ordering of the effects in the bar chart. ORDER=MODEL specifies that effects appear in the order in which they appear in the MODEL statement. ORDER=ASCENDING | DESCENDING specifies that the effects are shown in ascending or descending order of the number of samples in which the effects appear in the selected model. The default is ORDER=DESCENDING.

#### **NONE**

suppresses all plots.

#### PARMDIST < (parmDist-options) >

produces a panel that shows histograms and box plots of the parameter estimate values across samples when you use a MODELAVERAGE statement. There is a histogram and box plot for each parameter that appears in the AvgParmEst table. The PARMDIST option is ignored if you do not specify a MODELAVERAGE statement. The following *parmDist-options* are available:

#### MINPCT=percent

specifies that distributions be shown only for parameters whose estimates are nonzero in at least the specified percentage of the selected models. By default, distributions are shown for the all parameters that appear in the AvgParmEst table.

# ORDER=ASCENDING | DESCENDING | MODEL

specifies the ordering of the parameters in the panels. ORDER=MODEL specifies that parameters be shown in the order in which the corresponding effects appear in the MODEL statement. ORDER=ASCENDING | DESCENDING specifies that the parameters be shown in an ascending or descending order of the number of samples in which the parameter estimate is nonzero. The default is ORDER=DESCENDING.

# **NOBOXPLOTS**

suppress the box plots.

# **PLOTSPERPANEL**=number

specifies the maximum number of parameter distributions that appear in a panel. If the number of relevant parameters is greater than *number*, then multiple panels are produced. Valid values are 1–16 with 9 as the default.

#### **UNPACK**

specifies that the distribution for each relevant parameter be shown in a separate plot.

# SEED=number

specifies an integer used to start the pseudo-random number generator for resampling the data, random cross validation, and random partitioning of data for training, testing, and validation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer's clock.

#### TESTDATA=SAS-data-set

names a SAS data set containing test data. This data set must contain all the variables specified in the MODEL statement. Furthermore, when a BY statement is used and the TESTDATA=data set contains any of the BY variables, then the TESTDATA= data set must also contain all the BY variables sorted in the order of the BY variables. In this case, only the test data for a specific BY group is used with the corresponding BY group in the analysis data. If the TESTDATA= data set contains none of the BY variables, then the entire TESTDATA = data set is used with each BY group of the analysis data.

If you specify a TESTDATA=data set, then you cannot also reserve observations for testing by using a PARTITION statement.

# VALDATA=SAS-data-set

names a SAS data set containing validation data. This data set must contain all the variables specified in the MODEL statement. Furthermore, when a BY statement is used and the VALDATA=data set contains any of the BY variables, then the VALDATA= data set must also contain all the BY variables sorted in the order of the BY variables. In this case, only the validation data for a specific BY group are used with the corresponding BY group in the analysis data. If the VALDATA= data set contains none of the BY variables, then the entire VALDATA = data set is used with each BY group of the analysis data.

If you specify a VALDATA=data set, then you cannot also reserve observations for validation by using a PARTITION statement.

# **BY Statement**

# BY variables:

You can specify a BY statement with PROC GLMSELECT to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the GLMSELECT procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

• Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in SAS Language Reference: Concepts. For more information about the DATASETS procedure, see the discussion in the Base SAS Procedures Guide.

# **CLASS Statement**

**CLASS** variable < (v-options) > . . . < variable < (v-options) > > < / options > ;

The CLASS statement names the classification variables to be used in the analysis. The CLASS statement must precede the MODEL statement.

Table 45.2 summarizes the options available in the CLASS statement.

**Option Description** Specifies maximum number of CLASS variable name characters CPREFIX= **DELIMITER=** Specifies the delimiter **DESCENDING** Reverses the sort order Labels design variables LPREFIX= **MISSING** Allows for missing values ORDER= Specifies the sort order PARAM= Specifies the parameterization method Specifies the reference level REF= **SHOW** Requests a table for each CLASS variable

Splits CLASS variables into independent effects

Table 45.2 CLASS Statement Options

The following options can be specified after a slash (/):

# **DELIMITER**=quoted character

specifies the delimiter that is used between levels of classification variables in building parameter names and lists of class level values. The default if you do not specify DELIMITER= is a space. This option is useful if the levels of a classification variable contain embedded blanks.

# SHOW | SHOWCODING

**SPLIT** 

requests a table for each classification variable that shows the coding used for that variable.

You can specify various *v-options* for each variable by enclosing them in parentheses after the variable name. You can also specify global *v-options* for the CLASS statement by placing them after a slash (/). Global *v-options* are applied to all the variables specified in the CLASS statement. If you specify more than one CLASS statement, the global *v-options* specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *v-options* override the global *v-options*.

The following *v-options* are available:

#### **CPREFIX**=n

specifies that, at most, the first n characters of a CLASS variable name be used in creating names for the corresponding design variables. The default is  $32 - \min(32, \max(2, f))$ , where f is the formatted length of the CLASS variable. The CPREFIX= applies only when you specify the PARMLABEL-STYLE=INTERLACED option in the PROC GLMSELECT statement.

#### **DESCENDING**

#### **DESC**

reverses the sort order of the classification variable.

#### LPREFIX=n

specifies that, at most, the first n characters of a CLASS variable label be used in creating labels for the corresponding design variables. The default is  $256 - \min(256, \max(2, f))$ , where f is the formatted length of the CLASS variable. The LPREFIX= applies only when you specify the PARM-LABELSTYLE=INTERLACED option in the PROC GLMSELECT statement.

#### **MISSING**

allows missing value ('.' for a numeric variable and blanks for a character variables) as a valid value for the CLASS variable.

# ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option might be useful when you use the CONTRAST or ESTIMATE statement. If ORDER=FORMATTED for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values. Note that this represents a change from previous releases for how class levels are ordered. Before SAS 8, numeric class levels with no explicit format were ordered by their BEST12. formatted values, and in order to revert to the previous ordering you can specify this format explicitly for the affected classification variables. The change was implemented because the former default behavior for ORDER=FORMATTED often resulted in levels not being ordered numerically and usually required the user to intervene with an explicit format or ORDER=INTERNAL to get the more natural ordering. The following table shows how PROC GLMSELECT interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

# **PARAM**=*keyword*

specifies the parameterization method for the classification variable or variables. Design matrix columns are created from CLASS variables according to the following coding schemes. The default is PARAM=GLM. If PARAM=ORTHPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used. See the section "CLASS Variable Parameterization and the SPLIT Option" on page 3570 for further details.

**EFFECT** specifies effect coding.

**GLM** specifies less-than-full-rank, reference-cell coding; this option can be used only

as a global option.

**ORDINAL** 

**THERMOMETER** specifies the cumulative parameterization for an ordinal CLASS variable.

**POLYNOMIAL** 

**POLY** specifies polynomial coding.

REFERENCE

**REF** specifies reference-cell coding.

**ORTHEFFECT** orthogonalizes PARAM=EFFECT.

**ORTHORDINAL** 

**ORTHOTHERM** orthogonalizes PARAM=ORDINAL.

**ORTHPOLY** orthogonalizes PARAM=POLYNOMIAL.

**ORTHREF** orthogonalizes PARAM=REFERENCE.

The EFFECT, POLYNOMIAL, REFERENCE, and ORDINAL schemes and their orthogonal parameterizations are full rank. The REF= option in the CLASS statement determines the reference level for the EFFECT and REFERENCE schemes and their orthogonal parameterizations.

# REF='level' | keyword

specifies the reference level for PARAM=EFFECT, PARAM=REFERENCE, and their orthogonalizations. For an individual (but not a global) variable REF= option, you can specify the *level* of the variable to use as the reference level. For a global or individual variable REF= option, you can use one of the following keywords. The default is REF=LAST.

**FIRST** designates the first-ordered level as reference. **LAST** designates the last-ordered level as reference.

#### **SPLIT**

splits the columns of the design matrix that correspond to any effect that contains a split classification variable so that they can enter or leave a model independently of the other design columns for that effect. For example, suppose a variable named temp has three levels with values 'hot', 'warm', and 'cold', and a variable named sex has two levels with values 'M' and 'F' are used in a PROC GLMSELECT job as follows:

```
proc glmselect;
   class temp sex/split;
   model depVar = sex sex*temp;
run;
```

The two effects named in the MODEL statement are split into eight independent effects. The effect 'sex' is split into two effects labeled 'sex\_M' and 'sex\_F'. The effect 'sex\*temp' is split into six effects labeled 'sex\_M\*temp\_hot', 'sex\_F\*temp\_hot', 'sex\_M\*temp\_warm', 'sex\_F\*temp\_warm', 'sex\_M\*temp\_cold', and 'sex\_F\*temp\_cold'. Thus the previous PROC GLMSELECT step is equivalent to the following step:

The split option can be used on individual classification variables. For example, consider the following PROC GLMSELECT step:

```
proc glmselect;
  class temp(split) sex;
  model depVar = sex sex*temp;
run;
```

In this case the effect 'sex' is not split and the effect 'sex\*temp' is split into three effects labeled 'sex\*temp\_hot', 'sex\*temp\_warm', and 'sex\*temp\_cold'. Furthermore each of these three split effects now has two parameters that correspond to the two levels of 'sex', and the PROC GLMSELECT step is equivalent to the following:

```
proc glmselect;
  class sex;
  model depVar = sex sex*temp_hot sex*temp_warm sex*temp_cold;
run:
```

# **CODE Statement**

# **CODE** < options > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 45.3 summarizes the *options* available in the CODE statement.

Table 45.3 CODE Statement Options

Option	Description
CATALOG=	Names the catalog entry where the generated code is saved
DUMMIES	Retains the dummy variables in the data set
ERROR	Computes the error function
FILE=	Names the file where the generated code is saved
FORMAT=	Specifies the numeric format for the regression coefficients
GROUP=	Specifies the group identifier for array names and statement labels
IMPUTE	Imputes predicted values for observations with missing or invalid
	covariates
LINESIZE=	Specifies the line size of the generated code
LOOKUP=	Specifies the algorithm for looking up CLASS levels
RESIDUAL	Computes residuals

For details about the syntax of the CODE statement, see the section "CODE Statement" on page 390 in Chapter 19, "Shared Concepts and Topics."

# **EFFECT Statement**

# **EFFECT** name=effect-type (variables < / options >);

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 383 in Chapter 19, "Shared Concepts and Topics."

You can specify the following effect-types:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.
MULTIMEMBER   MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL   POLY	is a multivariate polynomial effect in the specified numeric variables.

**SPLINE** is a regression spline effect whose columns are univariate spline expansions

of one or more variables. A spline expansion replaces the original variable

with an expanded or larger set of new variables.

Table 45.4 summarizes the *options* available in the EFFECT statement.

Table 45.4 EFFECT Statement Options

Option	Description		
<b>Collection Effects Opti</b>	Collection Effects Options		
DETAILS	Displays the constituents of the collection effect		
<b>Lag Effects Options</b>			
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned		
DETAILS	Displays the lag design of the lag effect		
NLAG=	Specifies the number of periods in the lag		
PERIOD=	Names the variable that defines the period		
WITHIN=	Names the variable or variables that define the group within which each period is defined		
<b>Multimember Effects</b>	Options		
NOEFFECT WEIGHT=	Specifies that observations with all missing levels for the multi- member variables should have zero values in the corresponding design matrix columns Specifies the weight variable for the contributions of each of the classification effects		
Polynomial Effects Op	tions		
DEGREE=	Specifies the degree of the polynomial		
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial		
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial		
<b>Spline Effects Options</b>			
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion		
DEGREE=	Specifies the degree of the spline transformation		
KNOTMETHOD=	Specifies how to construct the knots for spline effects		

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section "EFFECT Statement" on page 393 in Chapter 19, "Shared Concepts and Topics."

# **FREQ Statement**

# FREQ variable;

The variable specified in the FREQ statement identifies a variable in the input data set containing the frequency of occurrence of each observation. PROC GLMSELECT treats each observation as if it appears n times, where n is the value of the FREQ variable for the observation. If it is not an integer, the frequency value is truncated to an integer. If it is less than 1 or if it is missing, the observation is not used.

# **MODEL Statement**

**MODEL** dependent = < effects > / < options > ;

The MODEL statement names the dependent variable and the explanatory effects, including covariates, main effects, constructed effects, interactions, and nested effects; see the section "Specification of Effects" on page 3324 in Chapter 42, "The GLM Procedure," for more information. If you omit the explanatory effects, the procedure fits an intercept-only model.

After the keyword MODEL, the dependent (response) variable is specified, followed by an equal sign. The explanatory effects follow the equal sign.

Table 45.5 summarizes the options available in the MODEL statement.

Option **Description** CVDETAILS= Requests details when cross validation is used CVMETHOD= Specifies how subsets for cross validation are formed **DETAILS=** Specifies details to be displayed Specifies the hierarchy of effects to impose HIERARCHY= Specifies models without an explicit intercept **NOINT ORDERSELECT** Requests that parameter estimates be displayed in the order in which the parameters first entered the model SELECTION= Specifies the model selection method Specifies additional statistics to be displayed STATS= **SHOWPVALUES** Requests p-values in "ANOVA" and "Parameter Estimates" tables **STB** Adds standardized coefficients to "Parameter Estimates" tables

Table 45.5 MODEL Statement Options

You can specify the following options in the MODEL statement after a slash (/):

# CVDETAILS=ALL CVDETAILS=COEFFS CVDETAILS=CVPRESS

specifies the details produced when cross validation is requested as the CHOOSE=, SELECT=, or STOP= criterion in the MODEL statement. If n-fold cross validation is being used, then the training data are subdivided into n parts, and at each step of the selection process, models are obtained on

each of the *n* subsets of the data obtained by omitting one of these parts. CVDETAILS=COEFFS requests that the parameter estimates obtained for each of these *n* subsets be included in the parameter estimates table. CVDETAILS=CVPRESS requests a table containing the predicted residual sum of squares of each of these models scored on the omitted subset. CVDETAILS=ALL requests both CVDETAILS=COEFFS and CVDETAILS=CVPRESS. If DETAILS=STEPS or DETAILS=ALL has been specified in the MODEL statement, then the requested CVDETAILS are produced for every step of the selection process.

CVMETHOD=BLOCK < (n) > CVMETHOD=RANDOM < (n) > CVMETHOD=SPLIT < (n) > CVMETHOD=INDEX (variable)

specifies how the training data are subdivided into *n* parts when you request *n*-fold cross validation by using any of the CHOOSE=CV, SELECT=CV, and STOP=CV suboptions of the SELECTION= option in the MODEL statement.

- CVMETHOD=BLOCK requests that parts be formed of *n* blocks of consecutive training observations.
- CVMETHOD=SPLIT requests that the *i*th part consist of training observations  $i, i + n, i + 2n, \ldots$
- CVMETHOD=RANDOM assigns each training observation randomly to one of the *n* parts.
- CVMETHOD=INDEX(*variable*) assigns observations to parts based on the formatted value of the named variable. This input data set variable is treated as a classification variable and the number of parts *n* is the number of distinct levels of this variable. By optionally naming this variable in a CLASS statement you can use the CLASS statement options ORDER= and MISS-ING to control how the levelization of this variable is done.

*n* defaults to 5 with CVMETHOD=BLOCK, CVMETHOD=SPLIT, or CVMETHOD=RANDOM. If you do not specify the CVMETHOD= option, then the CVMETHOD defaults to CVMETHOD=RANDOM(5).

#### **DETAILS**=level

# **DETAILS=STEPS** < (step options) >

specifies the level of detail produced, where *level* can be ALL, STEPS, or SUMMARY. The default if the DETAILS= option is omitted is DETAILS=SUMMARY. The DETAILS=ALL option produces the following:

- entry and removal statistics for each variable selected in the model building process
- ANOVA, fit statistics, and parameter estimates
- entry and removal statistics for the top 10 candidates for inclusion or exclusion at each step
- a selection summary table

The DETAILS=SUMMARY option produces only the selection summary table.

The option DETAILS=STEPS <(step options) > provides the step information and the selection summary table. The following options can be specified within parentheses after the DETAILS=STEPS option:

#### ALL

requests ANOVA, fit statistics, parameter estimates, and entry or removal statistics for the top 10 candidates for inclusion or exclusion at each selection step.

#### **ANOVA**

requests ANOVA at each selection step.

# FITSTATISTICS | FITSTATS | FIT

requests fit statistics at each selection step. The default set of statistics includes all of the statistics named in the CHOOSE=, SELECT=, and STOP= suboptions specified in the MODEL statement SELECTION= option, but additional statistics can be requested with the STATS= option in the MODEL statement.

# PARAMETERESTIMATES | PARMEST

requests parameter estimates at each selection step.

# CANDIDATES < (SHOW= ALL | n) >

requests entry or removal statistics for the best *n* candidate effects for inclusion or exclusion at each step. If you specify SHOW=ALL, then all candidates are shown. If SHOW= is not specified. then the best 10 candidates are shown. The entry or removal statistic is the statistic named in the SELECT= option that is specified in the MODEL statement SELECTION= option.

# **HIERARCHY**=keyword

# **HIER**=*keyword*

specifies whether and how the model hierarchy requirement is applied. This option also controls whether a single effect or multiple effects are allowed to enter or leave the model in one step. You can specify that only classification effects, or both classification and continuous effects, be subject to the hierarchy requirement. The HIERARCHY= option is ignored unless you also specify one of the following options: SELECTION=FORWARD, SELECTION=BACKWARD, or SELECTION=STEPWISE.

Model hierarchy refers to the requirement that for any term to be in the model, all model effects contained in the term must be present in the model. For example, in order for the interaction A\*B to enter the model, the main effects A and B must be in the model. Likewise, neither effect A nor effect B can leave the model while the interaction A\*B is in the model.

The keywords you can specify in the HIERARCHY= option are as follows:

# **NONE**

specifies that model hierarchy not be maintained. Any single effect can enter or leave the model at any given step of the selection process.

# **SINGLE**

specifies that only one effect enter or leave the model at one time, subject to the model hierarchy requirement. For example, suppose that the model contains the main effects A and B and the interaction A\*B. In the first step of the selection process, either A or B can enter the model. In the second step, the other main effect can enter the model. The interaction effect can enter the model only when both main effects have already entered. Also, before A or B can be removed from the model, the A\*B interaction must first be removed. All effects (CLASS and interval) are subject to the hierarchy requirement.

# **SINGLECLASS**

is the same as HIERARCHY=SINGLE except that only CLASS effects are subject to the hierarchy requirement.

The default value is HIERARCHY=NONE.

# **NOINT**

suppresses the intercept term that is otherwise included in the model.

no model selection

# **ORDERSELECT**

NONE

specifies that for the selected model, effects be displayed in the order in which they first entered the model. If you do not specify the ORDERSELECT option, then effects in the selected model are displayed in the order in which they appeared in the MODEL statement.

# SELECTION=method < (method options) >

specifies the method used to select the model, optionally followed by parentheses enclosing options applicable to the specified method. The default if the SELECTION= option is omitted is SELECTION=STEPWISE.

The following methods are available and are explained in detail in the section "Model-Selection Methods" on page 3559.

_	
FORWARD	forward selection. This method starts with no effects in the model and adds effects.
BACKWARD	backward elimination. This method starts with all effects in the model and deletes effects.
STEPWISE	stepwise regression. This is similar to the FORWARD method except that effects already in the model do not necessarily stay there.
LAR	least angle regression. This method, like forward selection, starts with no effects in the model and adds effects. The parameter estimates at any step are "shrunk" when compared to the corresponding least squares estimates. If the model contains classification variables, then these classification variables are split. See the SPLIT option in the CLASS statement for details.
LASSO	This method adds and deletes parameters based on a version of ordinary least squares where the sum of the absolute regression coefficients is constrained. If

split. See the SPLIT option in the CLASS statement for details.

the model contains classification variables, then these classification variables are

Table 45.6 lists the applicable suboptions for each of these methods.

Option	FORWARD	BACKWARD	STEPWISE	LAR LASSO
STOP =	Х	X	x	Х
CHOOSE =	X	X	X	X
STEPS =	X	X	X	X
MAXSTEPS =	X	X	X	X
SELECT =	X	X	X	
INCLUDE =	X	X	X	
SLENTRY =	X		X	
SLSTAY =		X	X	
DROP =			X	
ADAPTIVE				X
LSCOEFFS				X

**Table 45.6** Applicable SELECTION= Options by Method

The syntax of the suboptions that you can specify in parentheses after the SELECTION= option method follows. Note that, as described in Table 45.6, not all selection suboptions are applicable to every SELECTION= method.

# ADAPTIVE < (< GAMMA=non-negative number > < INEST=SAS-data-set > ) >

requests that adaptive weights be applied to each of the coefficients in the LAR and LASSO methods. You use the optional INEST= option to name the SAS data set that contains estimates which are used to form the adaptive weights for all the parameters in the model. If you do not specify an INEST= data set, then ordinary least squares estimates of the parameters in the model are used in forming the adaptive weights. You use the GAMMA= option to specify the power transformation that is applied to the parameters in forming the adaptive weights. The default value is GAMMA=1.

# CHOOSE=criterion

specifies the criterion for choosing the model. The specified *criterion* is evaluated at each step of the selection process, and the model that yields the best value of the criterion is chosen. If the optimal value of the criterion occurs for models at more than one step, then the model with the smallest number of parameters is chosen. If you do not specify the CHOOSE= option, then the model at the final step in the selection process is selected.

The criteria that you can specify in the CHOOSE= option are shown in Table 45.7. See the section "Criteria Used in Model Selection Methods" on page 3568 for more detailed descriptions of these criteria.

Criterion	Criterion
ADJRSQ	Adjusted R-square statistic
AIC	Akaike's information criterion
AICC	Corrected Akaike's information criterion
BIC	Sawa Bayesian information criterion
CP	Mallows' C(p) statistic
CV	Predicted residual sum of square with k-fold cross validation
PRESS	Predicted residual sum of squares
SBC	Schwarz Bayesian information criterion
VALIDATE	Average square error for the validation data

**Table 45.7** Criteria for the CHOOSE= Option

For ADJRSQ the chosen value is the largest one; for all other criteria, the smallest value is chosen. You can use the CHOOSE=VALIDATE option only if you have specified a VALDATA= data set in the PROC GLMSELECT statement or if you have reserved part of the input data for validation by using either a PARTITION statement or a \_ROLE\_ variable in the input data.

# **DROP**=*policy*

specifies when effects are eligible to be dropped in the STEPWISE method. Valid values for policy are BEFOREADD and COMPETITIVE.

If you specify DROP=BEFOREADD, then effects currently in the model are examined to see if any meet the requirements to be removed from the model. If so, the effect that gives the best value of the removal criterion is dropped from the model and the stepwise method proceeds to the next step. Only when no effect currently in the model meets the requirement to be removed from the model are any effects added to the model.

DROP=COMPETITIVE can be specified only if the SELECT= criterion is not SL. If you specify DROP=COMPETITIVE, then the SELECT= criterion is evaluated for all models where an effect currently in the model is dropped or an effect not yet in the model is added. The effect whose removal or addition to the model yields the maximum improvement to the SELECT= criterion is dropped or added.

The default if you do not specify DROP= suboption with the STEPWISE method is DROP=BEFOREADD. If SELECT=SL, then this yields the traditional stepwise method as implemented in PROC REG.

# INCLUDE=n

forces the first n effects listed in the MODEL statement to be included in all models. The selection methods are performed on the other effects in the MODEL statement. The INCLUDE= option is available only with SELECTION=FORWARD, SELECTION=STEPWISE, and SELEC-TION=BACKWARD.

#### **LSCOEFFS**

requests a hybrid version of the LAR and LASSO methods, where the sequence of models is determined by the LAR or LASSO algorithm but the coefficients of the parameters for the model at any step are determined by using ordinary least squares.

#### MAXSTEP=n

specifies the maximum number of selection steps that are done. The default value of *n* is the number of effects in the model statement for the FORWARD, BACKWARD, and LAR methods and is three times the number of effects for the STEPWISE and LASSO methods.

# **SELECT**=criterion

specifies the criterion that PROC GLMSELECT uses to determine the order in which effects enter and/or leave at each step of the specified selection method. The SELECT= option is not valid with the LAR and LASSO methods. The criteria that you can specify with the SELECT= option are ADJRSQ, AIC, AICC, BIC, CP, CV, PRESS, RSQUARE, SBC, SL, and VALIDATE. See the section "Criteria Used in Model Selection Methods" on page 3568 for a description of these criteria. The default value of the SELECT= criterion is SELECT=SBC. You can use SELECT=SL to request the traditional approach where effects enter and leave the model based on the significance level. With other SELECT= criteria, the effect that is selected to enter or leave at a step of the selection process is the effect whose addition to or removal from the current model gives the maximum improvement in the specified criterion.

#### SLENTRY=value

#### SLE=value

specifies the significance level for entry, used when the STOP=SL or SELECT=SL option is in effect. The defaults are 0.50 for FORWARD and 0.15 for STEPWISE.

#### SLSTAY=value

# SLS=value

specifies the significance level for staying in the model, used when the STOP=SL or SELECT=SL option is in effect. The defaults are 0.10 for BACKWARD and 0.15 for STEPWISE.

# STEPS=n

specifies the number of selection steps to be done. If the STEPS= option is specified, the STOP= and MAXSTEP= options are ignored.

# STOP=n

# STOP=criterion

specifies when PROC GLMSELECT stops the selection process. If the STEPS= option is specified, then the STOP= option is ignored. If the STOP=option does not cause the selection process to stop before the maximum number of steps for the selection method, then the selection process terminates at the maximum number of steps.

If you do not specify the STOP= option but do specify the SELECT= option, then the criterion named in the SELECT=option is also used as the STOP= criterion. If you do not specify either the STOP= or SELECT= option, then the default is STOP=SBC.

If STOP=n is specified, then PROC GLMSELECT stops selection at the first step for which the selected model has n effects.

The nonnumeric arguments that you can specify in the STOP= option are shown in Table 45.8. See the section "Criteria Used in Model Selection Methods" on page 3568 for more detailed descriptions of these criteria.

Option	Criteria
NONE	
<b>ADJRSQ</b>	Adjusted R-square statistic
AIC	Akaike's information criterion
AICC	Corrected Akaike's information criterion
BIC	Sawa Bayesian information criterion
CP	Mallows' C(p) statistic
CV	Predicted residual sum of square with k-fold cross validation
PRESS	Predicted residual sum of squares
SBC	Schwarz Bayesian information criterion
SL	Significance level
VALIDATE	Average square error for the validation data

**Table 45.8** Nonnumeric Criteria for the STOP= Option

With the SL criterion, selection stops at the step where the significance level for entry of all the effects not yet in the model is greater than the SLE= value for addition steps in the FORWARDS and STEPWISE methods and where the significance level for removal of any effect in the current model is greater than the SLS= value in the BACKWARD and STEPWISE methods. With the ADJRSQ criterion, selection stops at the step where the next step would yield a model with a smaller value of the Adjusted R-square statistic; for all other criteria, selection stops at the step where the next step would yield a model with a larger value of the criteria. You can use the VALIDATE option only if you have specified a VALDATA= data set in the PROC GLMSELECT statement or if you have reserved part of the input data for validation by using either a PARTITION statement or a ROLE variable in the input data.

# STAT|STATS=name

# STATS=(names)

specifies which model fit statistics are displayed in the fit summary table and fit statistics tables. If you omit the STATS= option, the default set of statistics that are displayed in these tables includes all the criteria specified in any of the CHOOSE=, SELECT=, and STOP= options specified in the MODEL statement SELECTION= option.

The statistics that you can specify follow:

ADJRSQ	the adjusted R-square statistic
AIC	Akaike's information criterion
AICC	corrected Akaike's information criterion
ASE	the average square errors for the training, test, and validation data. The ASE statistics for the test and validation data are reported only if you have specified TEST-DATA= and/or VALDATA= in the PROC GLMSELECT statement or if you have reserved part of the input data for testing and/or validation by using either a PAR-TITION statement or a <code>ROLE</code> _ variable in the input data.
BIC	the Sawa Bayesian information criterion
СР	the Mallows' C(p) statistic

<b>FVALUE</b>	the F statistic for entering or departing effects
PRESS	the predicted residual sum of squares statistic
RSQUARE	the R-square statistic
SBC	the Schwarz Bayesian information criterion
SL	the significance level of the $F$ statistic for entering or departing effects

The statistics ADJRSQ, AIC, AICC, FVALUE, RSQUARE, SBC, and SL can be computed with little computation cost. However, computing BIC, CP, CVPRESS, PRESS, and ASE for test and validation data when these are not used in any of the CHOOSE=, SELECT=, and STOP= options specified in the MODEL statement SELECTION= option can hurt performance.

## **SHOWPVALUES**

## **SHOWPVALS**

displays p-values in the "ANOVA" and "Parameter Estimates" tables. These p-values are generally liberal because they are not adjusted for the fact that the terms in the model have been selected.

## STB

produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor.

# **MODELAVERAGE Statement (Experimental)**

# **MODELAVERAGE** < options>;

The experimental MODELAVERAGE statement requests that model selection be repeated on resampled subsets of the input data. An average model is produced by averaging the parameter estimates of the selected models that are obtained for each resampled subset of the input data.

Table 45.9 summarizes the options available in the MODELAVERAGE statement.

**Table 45.9** MODELAVERAGE Statement Options

Option	Description
ALPHA=	Specifies lower and upper quantiles of the sample parameter
DETAILS	Displays model selection details
NSAMPLES=	Specifies the number of samples used for the refit averaging
REFIT	Performs a second round of model averaging
SAMPLING=	Specifies how to generate the samples taken from the training data
SUBSET	Uses only a subset of the selected models in forming the average model
TABLES	Controls the displayed tables

The following *options* are available:

#### $ALPHA=\alpha$

controls which lower and upper quantiles of the sample parameter estimates are displayed. The AL-PHA= option also controls which quantiles of the predicted values are added to the output data set when the LOWER= and UPPER= options are specified in the OUTPUT statement. The lower and upper quantiles used are  $\alpha/2$  and  $1-\alpha/2$ , respectively. The value specified must lie in the interval [0,1]. The default value is ALPHA=0.5.

#### **DETAILS**

requests that model selection details be displayed for each sample of the data. The level of detail shown is controlled by the DETAILS= option in the MODEL statement.

#### NSAMPLES=n

specifies the number of samples to be used. The default value is NSAMPLES=100.

# REFIT < (refit-options) >

requests that a second round of model averaging, referred to as the refit averaging, be performed. Usually, the initial round of model averaging produces a model that contains a large number of effects. You can use the refit option to obtain a more parsimonious model. For each data sample in the refit, a least squares model is fit with no effect selection. The effects that are used in the refit depend on the results of the initial round of model averaging. If you do not specify any *refit-options*, then effects that are selected in at least twenty percent of the samples in the initial round of model averaging are used in the refit model average. The following *refit-options* are available:

### BEST=n

specifies that the *n* most frequently selected effects in the initial round of model averaging be used in the refit averaging.

# MINPCT=percent

specifies that the effects that are selected at least the specified percentage of times in the initial round of model averaging be used in the refit averaging.

### NSAMPLES=n

specifies the number of samples to be used for the refit averaging. The default value is the number of samples used in the initial round of model averaging.

## SAMPLING=SRS | URS < (sampling-options) >

specifies how the samples of the usable observations in the training data are generated. SAMPLING=SRS specifies simple random sampling in which samples are generated by randomly drawing without replacement. SAMPLING=URS specifies unrestricted random sampling in which samples are generated by randomly drawing with replacement. Model averaging with samples drawn without replacement corresponds to the bootstrap methodology. The default is SAMPLING=URS. If you specify a frequency variable by using a FREQ statement, then the *i*th observation is sampled  $f_i$  times, where  $f_i$  is the frequency of the *i*th observation.

You can specify one of the following sampling-options:

## PERCENT=percent

specifies the percentage of the training data that is used in each sample. The default value is 75% for SAMPLING=SRS and 100% for SAMPLING=URS.

#### SIZE=n

specifies the sum of frequencies in each sample.

## **SUBSET**(*subset-options*)

specifies that only a subset of the selected models be used in forming the average model and producing predicted values. The following *subset-options* are available:

# BEST=n

specifies that only the best n models be used, where the model ranking criterion used is the frequency score. See the section "Model Selection Frequencies and Frequency Scores" on page 3577 for the definition of the frequency score. If multiple models with the same frequency score correspond to the nth best model, then all these tied models are used in forming the average model and producing predicted values.

## MINMODELFREQ=freq

specifies that only models that are selected at least freq times be used in forming the average model and producing predicted values.

```
TABLES < (ONLY) > < =table-request < (options) >>
```

```
TABLES < (ONLY) > < = (table-request < (options) > < ... table-request < (options) > >) >
```

controls the displayed output that is produced in the initial round of model averaging. By default, the following tables are produced:

**EFFECTSELECTPCT** displays the percentage of times that effects appear in the selected models.

**MODELSELECTFREQ** displays the frequency with which models are selected.

displays the mean, standard deviation, and quantiles of the parameter estimates of **AVGPARMEST** the parameters that appear in the selected models.

When you specify only one table-request, you can omit the outer parentheses. Here are some examples:

```
tables=none
tables=(all parmest(minpct=10))
tables(only) = effects electpct (order=model minpct=15)
```

The following *table-request* options are available:

## ALL

requests that all model averaging output tables be produced. You can specify other options with ALL; for example, to request all tables and to require that effects are displayed in decreasing order of selection frequency in the EffectSelectPct table, specify TABLES=(ALL EFFECTSE-LECTPCT(ORDER=DESCENDING)).

## **EFFECTSELECTPCT** < (effectSelectPct-options) >

specifies how the effects in the EffectSelectPct table are displayed. The following effectSelectPct-options are available:

#### ALL

specifies that effects that appear in the selected model for any sample be displayed.

# MINPCT=percent

specifies that the effects displayed must appear in the selected model for at least the specified percentage of the samples. By default, this table includes effects that appear in at least twenty percent of the selected models. The MINPCT= option is ignored if you also specify the ALL option as a *effectSelectPct* option.

## ORDER=ASCENDING | DESCENDING | MODEL

specifies the order in which the effects are displayed. ORDER=MODEL specifies that effects be displayed in the order in which they appear in the MODEL statement. ORDER= ASCENDING | DESCENDING specifies that the effects be displayed in ascending or descending order of their selection frequency.

# MODELSELECTFREQ < (modelSelectFreq-options) >

specifies how the models in the ModelSelectFreq table are displayed. The following *modelSelectFreq-options* are available:

## **ALL**

specifies that all selected models be displayed in the ModelSelectFreq table.

#### BEST=n

specifies that only the best n models be displayed, where the model ranking criterion used is the frequency score. See the section "Model Selection Frequencies and Frequency Scores" on page 3577 for the definition of the frequency score. The default value is BEST=20. The BEST= option is ignored if you also specify the ALL option as a *modelSelectFreq-option*.

## **ONLY**

suppresses the default output. If you specify the ONLY option within parentheses after the TABLES option, then only the tables specifically requested are produced.

# **PARMEST** < (parmEst-options) >

specifies how the parameters in the AvgParmEst table are displayed. The following parmEstoptions are available:

## **ALL**

specifies that parameters that are nonzero in the selected model for any sample be displayed.

# MINPCT=percent

specifies that the parameters displayed must have nonzero estimates in the selected model for at least the specified percentage of the samples. By default, this table includes parameters that appear in at least twenty percent of the selected models. The MINPCT= option is ignored if you also specify the ALL option as a parmEst option.

#### **NONZEROPARMS**

specifies that for each parameter, the sample that is used to compute the estimate mean, standard deviation, and quantiles consist of just the nonzero values of that parameter in the selected models. If you do not specify the NONZEROPARMS option, then parameters that do not appear in a selected model are assigned the value zero in that model and these zero values are retained when computing the estimate means, standard deviations, and quantiles.

# ORDER=ASCENDING | DESCENDING | MODEL

specifies the order in which the effects are displayed. ORDER=MODEL specifies that effects are displayed in the order in which they appear in the MODEL statement. ORDER=ASCENDING | DESCENDING specifies that the effects are displayed in ascending or descending order of their selection frequency.

# **OUTPUT Statement**

**OUTPUT** < **OUT=**SAS-data-set> < keyword< =name>> ... < keyword< =name>> ;

The OUTPUT statement creates a new SAS data set that saves diagnostic measures calculated for the selected model. If you do not specify a *keyword*, then the only diagnostic included is the predicted response.

All the variables in the original data set are included in the new data set, along with variables created in the OUTPUT statement. These new variables contain the values of a variety of statistics and diagnostic measures that are calculated for each observation in the data set. If you specify a BY statement, then a variable \_BY\_ that indexes the BY groups is included. For each observation, the value of \_BY\_ is the index of the BY group to which this observation belongs. This variable is useful for matching BY groups with macro variables that PROC GLMSELECT creates. See the section "Macro Variables Containing Selected Models" on page 3572 for details.

If you have requested *n*-fold cross validation by requesting CHOOSE=CV, SELECT=CV, or STOP=CV in the MODEL statement, then a variable \_CVINDEX\_ is included in the output data set. For each observation used for model training the value of \_CVINDEX\_ is *i* if that observation is omitted in forming the *i*th subset of the training data. See the CVMETHOD= for additional details. The value of \_CVINDEX\_ is 0 for all observations in the input data set that are not used for model training.

If you have partitioned the input data with a PARTITION statement, then a character variable <code>\_ROLE\_</code> is included in the output data set. For each observation the value of <code>\_ROLE\_</code> is as follows:

\_ROLE\_ Observation Role

TEST testing
TRAIN training
VALIDATE validation

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see SAS Language Reference: Concepts.

Details on the specifications in the OUTPUT statement follow.

# keyword<=name>

specifies the statistics to include in the output data set and optionally names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), followed optionally by an equal sign, and a variable to contain the statistic.

If you specify *keyword=name*, the new variable that contains the requested statistic has the specified name. If you omit the optional *=name* after a *keyword*, then the new variable name is formed by using a prefix of one or more characters that identify the statistic. For residuals and predicted values, the prefix is followed by an underscore (\_), followed by the dependent variable name.

The keywords allowed and the statistics they represent are as follows:

**PREDICTED** | **PRED** | **P** predicted values. The prefix for the default name is p.

**RESIDUAL | RESID | R** residual, calculated as ACTUAL – PREDICTED. The prefix for the default name is *r*.

When you also use the MODELAVERAGE statement, the following keywords and the statistics that they represent are also available:

**LOWER**  $\alpha/2$  percentile of the sample predicted values. By default,  $\alpha=0.5$ , which yields

the 25th percentile. You can change the value of  $\alpha$  by using the ALPHA= option

in the MODELAVERAGE statement. The default name is LOWER.

**MEDIAN** median of the sample predicted values. The default name is *median*.

**SAMPLEFREQ** | **SF** sample frequencies. For the *i*th sample, a column that contains the frequencies used for that sample is added. The name of this column is formed by appending an

index i to the name that you specify. If you do not specify a name, then the default

prefix is sf.

**SAMPLEPRED** | **SP** sample predictions. For the *i*th sample, a column that contains the predicted

values produced by the model selected for that sample is added. The name of this column is formed by appending an index i to the name that you specify. If you do

not specify a name, then the default prefix is sp.

**STANDARDDEVIATION | STDDEV** standard deviation of the sample predicted values. The default

name is stdDev.

**UPPER**  $1 - \alpha/2$  percentile of the sample predicted values. By default,  $\alpha = 0.5$ , which

yields the 75th percentile. You can change the value of  $\alpha$  by using the ALPHA=

option in the MODELAVERAGE statement. The default name is UPPER.

## OUT=SAS data set

specifies the name of the new data set. By default, the procedure uses the DATA*n* convention to name the new data set.

# **PARTITION Statement**

The PARTITION statement specifies how observations in the input data set are logically partitioned into disjoint subsets for model training, validation, and testing. Either you can designate a variable in the input data set and a set of formatted values of that variable to determine the role of each observation, or you can specify proportions to use for random assignment of observations for each role.

An alternative to using a PARTITION statement is to provide a variable named \_ROLE\_ in the input data set to define roles of observations in the input data. If you specify a PARTITION statement then the \_ROLE\_

variable if present in the input data set is ignored. If you do not use a PARTITION statement and the input data do not contain a variable named \_ROLE\_, then all observations in the input data set are assigned to model training.

The following mutually exclusive options are available:

# ROLEVAR | ROLE=variable(< TEST='value' > < TRAIN='value' > < VALIDATE='value' >)

names the variable in the input data set whose values are used to assign roles to each observation. The formatted values of this variable that are used to assign observations roles are specified in the TEST=, TRAIN=, and VALIDATE= suboptions. If you do not specify the TRAIN= suboption, then all observations whose role is not determined by the TEST= or VALIDATE= suboptions are assigned to training. If you specify a TESTDATA= data set in the PROC GLMSELECT statement, then you cannot also specify the TEST= suboption in the PARTITION statement. If you specify a VALDATA= data set in the PROC GLMSELECT statement, then you cannot also specify the VALIDATE= suboption in the PARTITION statement.

# FRACTION(< TEST=fraction > < VALIDATE=fraction >)

requests that specified proportions of the observations in the input data set be randomly assigned training and validation roles. You specify the proportions for testing and validation by using the TEST= and VALIDATE= suboptions. If you specify both the TEST= and the VALIDATE= suboptions, then the sum of the specified fractions must be less than one and the remaining fraction of the observations are assigned to the training role. If you specify a TESTDATA= data set in the PROC GLMSELECT statement, then you cannot also specify the TEST= suboption in the PARTITION statement. If you specify a VALDATA= data set in the PROC GLMSELECT statement, then you cannot also specify the VALIDATE= suboption in the PARTITION statement.

# PERFORMANCE Statement

#### **PERFORMANCE** < options > :

The PERFORMANCE statement is used to change default options that affect the performance of PROC GLMSELECT and to request tables that show the performance options in effect and timing details.

The following options are available:

# **DETAILS**

requests the PerfSettings table that shows the performance settings in effect and the Timing table that provides a broad timing breakdown of the PROC GLMSELECT step.

#### BUILDSSCP=FULL

#### **BUILDSSCP=INCREMENTAL**

specifies whether the SSCP matrix is built incrementally as the selection process progresses or whether the SCCP matrix for the full model is built at the outset. Building the SSCP matrix incrementally can significantly reduce the memory required and the time taken to perform model selection in cases where the number of parameters in the selected model is much smaller than the number of parameters in the full model, but it can hurt performance in other cases since it requires at least one pass through the model training data at each step. If you use backward selection or no selection, or if the BIC or CP statistics are required in the selection process, then the BUILDSSCP=INCREMENTAL option is ignored. In other cases, BUILDSSCP=INCREMENTAL is used by default if the number

of effects is greater than 100. See the section "Building the SSCP Matrix" on page 3575 for further details.

# **SCORE Statement**

**SCORE** < **DATA**=*SAS*-data-set > < **OUT**=*SAS*-data-set > < keyword< =name >> . . . < keyword< =name >> ;

The SCORE statement creates a new SAS data set containing predicted values and optionally residuals for data in a new data set that you name. If you do not specify a DATA= data set, then the input data are scored. If you have multiple data sets to predict, you can specify multiple SCORE statements. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see SAS Language Reference: Concepts.

When a BY statement is used, the score data set must either contain all the BY variables sorted in the order of the BY variables or contain none of the BY variables. If the score data set contains all of the BY variables, then the model selected for a given BY group is used to score just the matching observations in the score data set. If the score data set contains none of the BY variables, then the entire score data set is scored for each BY group.

All observations in the score data set are retained in the output data set. However, only those observations that contain nonmissing values for all the continuous regressors in the selected model and whose levels of the class variables appearing in effects of the selected model are represented in the corresponding class variable in the procedure's input data set are scored. All the variables in the input data set are included in the output data set, along with variables containing predicted values and optionally residuals.

Details on the specifications in the SCORE statement follow:

# DATA=SAS data set

names the data set to be scored. If you omit this option, then the input data set named in the DATA= option in the PROC GLMSELECT statement is scored.

#### keyword<=name>

specifies the statistics to include in the output data set and optionally names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), followed optionally by an equal sign, and a variable to contain the statistic.

If you specify *keyword=name*, the new variable that contains the requested statistic has the specified name. If you omit the optional *=name* after a *keyword*, then the new variable name is formed by using a prefix of one or more characters that identify the statistic, followed by an underscore (\_), followed by the dependent variable name.

The keywords allowed and the statistics they represent are as follows:

**PREDICTED | PRED | P** predicted values. The prefix for the default name is p.

**RESIDUAL** | **RESID** |  $\mathbf{R}$  residual, calculated as ACTUAL – PREDICTED. The prefix for the default name is r.

#### OUT=SAS data set

gives the name of the new output data set. By default, the procedure uses the DATAn convention to name the new data set.

# **STORE Statement**

STORE < OUT = >item-store-name < / LABEL='label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section "STORE Statement" on page 501 in Chapter 19, "Shared Concepts and Topics."

# **WEIGHT Statement**

# WEIGHT variable;

A WEIGHT statement names a variable in the input data set with values that are relative weights for a weighted least squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, then the weighted estimates are the best linear unbiased estimates (BLUE).

Values of the weight variable must be nonnegative. If an observation's weight is zero, the observation is deleted from the analysis. If a weight is negative or missing, it is set to zero, and the observation is excluded from the analysis. A more complete description of the WEIGHT statement can be found in Chapter 42, "The GLM Procedure."

# **Details: GLMSELECT Procedure**

# **Model-Selection Methods**

The model selection methods implemented in PROC GLMSELECT are specified with the SELECTION= option in the MODEL statement.

# **Full Model Fitted (NONE)**

The complete model specified in the MODEL statement is used to fit the model and no effect selection is done. You request this by specifying SELECTION=NONE in the MODEL statement.

# Forward Selection (FORWARD)

The forward selection technique begins with just the intercept and then sequentially adds the effect that most improves the fit. The process terminates when no significant improvement can be obtained by adding any effect.

In the traditional implementation of forward selection, the statistic used to gauge improvement in fit is an F statistic that reflects an effect's contribution to the model if it is included. At each step, the effect that yields the most significant F statistic is added. Note that because effects can contribute different degrees of freedom to the model, it is necessary to compare the p-values corresponding to these F statistics.

More precisely, if the current model has p parameters excluding the intercept, and if you denote its residual sum of squares by  $RSS_p$  and you add an effect with k degrees of freedom and denote the residual sum of squares of the resulting model by  $RSS_{p+k}$ , then the F statistic for entry with k numerator degrees of freedom and n - (p + k) - 1 denominator degrees of freedom is given by

$$F = \frac{(RSS_p - RSS_{p+k})/k}{RSS_{p+k}/(n - (p+k) - 1)}$$

where n is number of observations used in the analysis.

The process stops when the significance level for adding any effect is greater than some specified entry significance level. A well-known problem with this methodology is that these F statistics do not follow an F distribution (Draper, Guttman, and Kanemasu 1971). Hence these p-values cannot reliably be interpreted as probabilities. Various ways to approximate this distribution are described by Miller (2002). Another issue when you use significance levels of entering effects as a stopping criterion arises because the entry significance level is an a priori specification that does not depend on the data. Thus, the same entry significance level can result in overfitting for some data and underfitting for other data.

One approach to address the critical problem of when to stop the selection process is to assess the quality of the models produced by the forward selection method and choose the model from this sequence that "best" balances goodness of fit against model complexity. PROC GLMSELECT supports several criteria that you can use for this purpose. These criteria fall into two groups—information criteria and criteria based on out-of-sample prediction performance.

You use the CHOOSE= option of forward selection to specify the criterion for selecting one model from the sequence of models produced. If you do not specify a CHOOSE= criterion, then the model at the final step is the selected model.

For example, if you specify

#### selection=forward(select=SL choose=AIC SLE=0.2)

then forward selection terminates at the step where no effect can be added at the 0.2 significance level. However, the selected model is the first one with the minimal value of Akaike's information criterion. Note that in some cases this minimal value might occur at a step much earlier that the final step, while in other cases the AIC criterion might start increasing only if more steps are done (that is, a larger value of SLE is used). If what you are interested in is minimizing AIC, then too many steps are done in the former case and too few in the latter case. To address this issue, PROC GLMSELECT enables you to specify a stopping criterion with the STOP= option. With a stopping criterion specified, forward selection continues until a local extremum of the stopping criterion in the sequence of models generated is reached. You can also specify STOP= number, which causes forward selection to continue until there are the specified number of effects in the model.

For example, if you specify

#### selection=forward(select=SL stop=AIC)

then forward selection terminates at the step where the effect to be added at the next step would produce a model with an AIC statistic larger than the AIC statistic of the current model. Note that in most cases, provided that the entry significance level is large enough that the local extremum of the named criterion occurs before the final step, specifying

#### selection=forward(select=SL choose=CRITERION)

or

#### selection=forward(select=SL stop=CRITERION)

selects the same model, but more steps are done in the former case. In some cases there might be a better local extremum that cannot be reached if you specify the STOP= option but can be found if you use the CHOOSE= option. Also, you can use the CHOOSE= option in preference to the STOP= option if you want examine how the named criterion behaves as you move beyond the step where the first local minimum of this criterion occurs.

Note that you can specify both the CHOOSE= and STOP= options. You might want to consider models generated by forward selection that have at most some fixed number of effects but select from within this set based on a criterion you specify. For example, specifying

## selection=forward(stop=20 choose=ADJRSQ)

requests that forward selection continue until there are 20 effects in the final model and chooses among the sequence of models the one that has the largest value of the adjusted R-square statistic. You can also combine these options to select a model where one of two conditions is met. For example,

### selection=forward(stop=AICC choose=PRESS)

chooses whatever occurs first between a local minimum of the predicted residual sum of squares (PRESS) and a local minimum of corrected Akaike's information criterion (AICC).

It is important to keep in mind that forward selection bases the decision about what effect to add at any step by considering models that differ by one effect from the current model. This search paradigm cannot guarantee reaching a "best" subset model. Furthermore, the add decision is greedy in the sense that the effect deemed most significant is the effect that is added. However, if your goal is to find a model that is best in terms of some selection criterion other than the significance level of the entering effect, then even this one step choice might not be optimal. For example, the effect you would add to get a model with the smallest value of the PRESS statistic at the next step is not necessarily the same effect that has the most significant entry *F* statistic. PROC GLMSELECT enables you to specify the criterion to optimize at each step by using the SELECT= option. For example,

#### selection=forward(select=CP)

requests that at each step the effect that is added be the one that gives a model with the smallest value of the Mallows' C(p) statistic. Note that in the case where all effects are variables (that is, effects with one degree of freedom and no hierarchy), using ADJRSQ, AIC, AICC, BIC, CP, RSQUARE, or SBC as the selection criterion for forward selection produces the same sequence of additions. However, if the degrees of freedom contributed by different effects are not constant, or if an out-of-sample prediction-based criterion is used, then different sequences of additions might be obtained.

You can use SELECT= together with CHOOSE= and STOP=. If you specify only the SELECT= criterion, then this criterion is also used as the stopping criterion. In the previous example where only the selection criterion is specified, not only do effects enter based on the Mallows' C(p) statistic, but the selection terminates when the C(p) statistic first increases.

You can find discussion and references to studies about criteria for variable selection in Burnham and Anderson (2002), along with some cautions and recommendations.

## **Examples of Forward Selection Specifications**

#### selection=forward

adds effects that at each step give the lowest value of the SBC statistic and stops at the step where adding any effect would increase the SBC statistic.

#### selection=forward(select=SL)

adds effects based on significance level and stops when all candidate effects for entry at a step have a significance level greater than the default entry significance level of 0.15.

#### selection=forward(select=SL stop=validation)

adds effects based on significance level and stops at a step where adding any effect increases the error sum of squares computed on the validation data.

## selection=forward(select=AIC)

adds effects that at each step give the lowest value of the AIC statistic and stops at the step where adding any effect would increase the AIC statistic.

#### selection=forward(select=ADJRSQ stop=SL SLE=0.2)

adds effects that at each step give the largest value of the adjusted R-square statistic and stops at the step where the significance level corresponding to the addition of this effect is greater than 0.2.

# **Backward Elimination (BACKWARD)**

The backward elimination technique starts from the full model including all independent effects. Then effects are deleted one by one until a stopping condition is satisfied. At each step, the effect showing the smallest contribution to the model is deleted. In traditional implementations of backward elimination, the contribution of an effect to the model is assessed by using an F statistic. At any step, the predictor producing the least significant F statistic is dropped and the process continues until all effects remaining in the model have F statistics significant at a stay significance level (SLS).

More precisely, if the current model has p parameters excluding the intercept, and if you denote its residual sum of squares by  $RSS_p$  and you drop an effect with k degrees of freedom and denote the residual sum of squares of the resulting model by  $RSS_{p-k}$ , then the F statistic for removal with k numerator degrees of freedom and n - p - k denominator degrees of freedom is given by

$$F = \frac{(RSS_{p-k} - RSS_p)/k}{RSS_p/(n-p-k)}$$

where n is number of observations used in the analysis.

Just as with forward selection, you can change the criterion used to assess effect contributions with the SELECT= option. You can also specify a stopping criterion with the STOP= option and use a CHOOSE= option to provide a criterion used to select among the sequence of models produced. See the discussion in the section "Forward Selection (FORWARD)" on page 3559 for additional details.

## **Examples of Backward Selection Specifications**

#### selection=backward

removes effects that at each step produce the largest value of the Schwarz Bayesian information criterion (SBC) statistic and stops at the step where removing any effect increases the SBC statistic.

#### selection=backward(stop=press)

removes effects based on the SBC statistic and stops at the step where removing any effect increases the predicted residual sum of squares (PRESS).

#### selection=backward(select=SL)

removes effects based on significance level and stops when all candidate effects for removal at a step have a significance level less than the default stay significance level of 0.15.

## selection=backward(select=SL choose=validate SLS=0.1)

removes effects based on significance level and stops when all effects in the model are significant at the 0.1 level. Finally, from the sequence of models generated, choose the one that gives the smallest average square error when scored on the validation data.

# Stepwise Selection(STEPWISE)

The stepwise method is a modification of the forward selection technique that differs in that effects already in the model do not necessarily stay there.

In the traditional implementation of stepwise selection method, the same entry and removal F statistics for the forward selection and backward elimination methods are used to assess contributions of effects as they are added to or removed from a model. If at a step of the stepwise method, any effect in the model is not significant at the SLSTAY= level, then the least significant of these effects is removed from the model and the algorithm proceeds to the next step. This ensures that no effect can be added to a model while some effect currently in the model is not deemed significant. Only after all necessary deletions have been accomplished can another effect be added to the model. In this case the effect whose addition yields the most significant F value is added to the model and the algorithm proceeds to the next step. The stepwise process ends when none of the effects outside the model has an F statistic significant at the SLENTRY= level and every effect in the model is significant at the SLSTAY= level. In some cases, neither of these two conditions for stopping is met and the sequence of models cycles. In this case, the stepwise method terminates at the end of the second cycle.

Just as with forward selection and backward elimination, you can change the criterion used to assess effect contributions, with the SELECT= option. You can also specify a stopping criterion with the STOP= option and use a CHOOSE= option to provide a criterion used to select among the sequence of models produced. See the discussion in the section "Forward Selection (FORWARD)" on page 3559 for additional details.

For selection criteria other than significance level, PROC GLMSELECT optionally supports a further modification in the stepwise method. In the standard stepwise method, no effect can enter the model if removing any effect currently in the model would yield an improved value of the selection criterion. In the modification, you can use the DROP=COMPETITIVE option to specify that addition and deletion of effects should be treated competitively. The selection criterion is evaluated for all models obtained by deleting an effect from the current model or by adding an effect to this model. The action that most improves the selection criterion is the action taken.

## **Examples of Stepwise Selection Specifications**

#### selection=stepwise

requests stepwise selection based on the SBC criterion. First, if removing any effect yields a model with a lower SBC statistic than the current model, then the effect producing the smallest SBC statistic is removed. When removing any effect increases the SBC statistic, then provided that adding some effect lowers the SBC statistic, the effect producing the model with the lowest SBC is added.

## selection=stepwise(select=SL)

requests the traditional stepwise method. First, if the removal of any effect yields an F statistic that is not significant at the default stay level of 0.15, then the effect whose removal produces the least significant F statistic is removed and the algorithm proceeds to the next step. Otherwise the effect whose addition yields the most significant F statistic is added, provided that it is significant at the default entry level of 0.15.

## selection=stepwise(select=SL stop=SBC)

is the traditional stepwise method, where effects enter and leave based on significance levels, but with the following extra check: If any effect to be added or removed yields a model whose SBC statistic is greater than the SBC statistic of the current model, then the stepwise method terminates at the current model. Note that in this case, the entry and stay significance levels still play a role as they determine whether an effect is deleted from or added to the model. This might result in the selection terminating before a local minimum of the SBC criterion is found.

# selection=stepwise(select=SL SLE=0.1 SLS=0.08 choose=AIC)

selects effects to enter or drop as in the previous example except that the significance level for entry is now 0.1 and the significance level to stay is 0.08. From the sequence of models produced, the selected model is chosen to yield the minimum AIC statistic.

# selection=stepwise(select=AICC drop=COMPETITIVE)

requests stepwise selection based on the AICC criterion with steps treated competitively. At any step, evaluate the AICC statistics corresponding to the removal of any effect in the current model or the addition of any effect to the current model. Choose the addition or removal that produced this minimum value, provided that this minimum is lower than the AICC statistic of the current model.

#### selection=stepwise(select=SBC drop=COMPETITIVE stop=VALIDATE)

requests stepwise selection based on the SBC criterion with steps treated competitively and where stopping is based on the average square error over the validation data. At any step, SBC statistics corresponding to the removal of any effect from the current model or the addition of any effect to the current model are evaluated. The addition or removal that produces the minimum SBC value is made. The average square error on the validation data for the model with this addition or removal is evaluated. If this average square error is greater than the average square error on the validation data prior to this addition or deletion, then the algorithm terminates at this prior model.

# Least Angle Regression (LAR)

Least angle regression was introduced by Efron et al. (2004). Not only does this algorithm provide a selection method in its own right, but with one additional modification it can be used to efficiently produce LASSO solutions. Just like the forward selection method, the LAR algorithm produces a sequence of

The algorithm starts by centering the covariates and response, and scaling the covariates so that they all have the same corrected sum of squares. Initially all coefficients are zero, as is the predicted response. The predictor that is most correlated with the current residual is determined and a step is taken in the direction of this predictor. The length of this step determines the coefficient of this predictor and is chosen so that some other predictor and the current predicted response have the same correlation with the current residual. At this point, the predicted response moves in the direction that is equiangular between these two predictors. Moving in this direction ensures that these two predictors continue to have a common correlation with the current residual. The predicted response moves in this direction until a third predictor has the same correlation with the current residual as the two predictors already in the model. A new direction is determined that is equiangular between these three predictors and the predicted response moves in this direction until a fourth predictor joins the set having the same correlation with the current residual. This process continues until all predictors are in the model.

As with other selection methods, the issue of when to stop the selection process is crucial. You can specify a criterion to use to choose among the models at each step with the CHOOSE= option. You can also specify a stopping criterion with the STOP= option. See the section "Criteria Used in Model Selection Methods" on page 3568 for details and Table 45.10 for the formulas for evaluating these criteria. These formulas use the approximation that at step k of the LAR algorithm, the model has k degrees of freedom. See Efron et al. (2004) for a detailed discussion of this so-called simple approximation.

A modification of LAR selection suggested in Efron et al. (2004) uses the LAR algorithm to select the set of covariates in the model at any step, but uses ordinary least squares regression with just these covariates to obtain the regression coefficients. You can request this hybrid method by specifying the LSCOEFFS suboption of SELECTION=LAR.

# **Lasso Selection (LASSO)**

LASSO (least absolute shrinkage and selection operator) selection arises from a constrained form of ordinary least squares regression where the sum of the absolute values of the regression coefficients is constrained to be smaller than a specified parameter. More precisely let  $\mathbf{X} = (\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_m)$  denote the matrix of covariates and let  $\mathbf{y}$  denote the response, where the  $\mathbf{x}_i$ s have been centered and scaled to have unit standard deviation and mean zero, and  $\mathbf{y}$  has mean zero. Then for a given parameter t, the LASSO regression coefficients  $\boldsymbol{\beta} = (\beta_1, \beta_2, \dots, \beta_m)$  are the solution to the constrained optimization problem

minimize
$$||\mathbf{y} - \mathbf{X}\boldsymbol{\beta}||^2$$
 subject to  $\sum_{j=1}^m |\beta_j| \le t$ 

Provided that the LASSO parameter *t* is small enough, some of the regression coefficients will be exactly zero. Hence, you can view the LASSO as selecting a subset of the regression coefficients for each LASSO parameter. By increasing the LASSO parameter in discrete steps, you obtain a sequence of regression coefficients where the nonzero coefficients at each step correspond to selected parameters.

Early implementations (Tibshirani 1996) of LASSO selection used quadratic programming techniques to solve the constrained least squares problem for each LASSO parameter of interest. Later Osborne, Presnell, and Turlach (2000) developed a "homotopy method" that generates the LASSO solutions for all values of

t. Efron et al. (2004) derived a variant of their algorithm for least angle regression that can be used to obtain a sequence of LASSO solutions from which all other LASSO solutions can be obtained by linear interpolation. This algorithm for SELECTION=LASSO is used in PROC GLMSELECT. It can be viewed as a stepwise procedure with a single addition to or deletion from the set of nonzero regression coefficients at any step.

As with the other selection methods supported by PROC GLMSELECT, you can specify a criterion to choose among the models at each step of the LASSO algorithm with the CHOOSE= option. You can also specify a stopping criterion with the STOP= option. See the discussion in the section "Forward Selection (FORWARD)" on page 3559 for additional details. The model degrees of freedom PROC GLMSELECT uses at any step of the LASSO are simply the number of nonzero regression coefficients in the model at that step. Efron et al. (2004) cite empirical evidence for doing this but do not give any mathematical justification for this choice.

A modification of LASSO selection suggested in Efron et al. (2004) uses the LASSO algorithm to select the set of covariates in the model at any step, but uses ordinary least squares regression with just these covariates to obtain the regression coefficients. You can request this hybrid method by specifying the LSCOEFFS suboption of SELECTION=LASSO.

# **Adaptive Lasso Selection**

Adaptive lasso selection is a modification of lasso selection; in adaptive lasso selection weights are applied to each of the parameters in forming the lasso constraint (Zou 2006). More precisely, suppose that the response y has mean zero and the regressors x are scaled to have mean zero and common standard deviation. Furthermore, suppose that you can find a suitable estimator  $\hat{\beta}$  of the parameters in the true model and you define a weight vector by  $w = 1/|\hat{\boldsymbol{\beta}}|^{\gamma}$ , where  $\gamma \geq 0$ . Then the adaptive lasso regression coefficients  $\boldsymbol{\beta} = (\beta_1, \beta_2, \dots, \beta_m)$  are the solution to the constrained optimization problem

minimize
$$||\mathbf{y} - \mathbf{X}\boldsymbol{\beta}||^2$$
 subject to  $\sum_{j=1}^m |w_j \beta_j| \le t$ 

You can specify  $\hat{\beta}$  by using the INEST=suboption of the SELECTION=LASSO option in the MODEL statement. The INEST= data set has the same structure as the OUTEST= data set that is produced by several SAS/STAT procedures including the REG and LOGISTIC procedures. The INEST= data set must contain all explanatory variables in the MODEL statement. It must also contain an intercept variable named Intercept unless the NOINT option is specified in the MODEL statement. If BY processing is used, the INEST= data set must also include the BY variables, and there must be one observation for each BY group. If the INEST= data set also contains the \_TYPE\_ variable, only observations with \_TYPE\_ value 'PARMS' are used.

If you do not specify an INEST= data set, then PROC GLMSELECT uses the solution to the unconstrained least squares problem as the estimator  $\hat{\beta}$ . This is appropriate unless collinearity is a concern. If the regressors are collinear or nearly collinear, then Zou (2006) suggests using a ridge regression estimate to form the adaptive weights.

# **Model Selection Issues**

Many authors caution against the use of "automatic variable selection" methods and describe pitfalls that plague many such methods. For example, Harrell (2001) states that "stepwise variable selection has been a very popular technique for many years, but if this procedure had just been proposed as a statistical method, it would most likely be rejected because it violates every principle of statistical estimation and hypothesis testing." He lists and discusses several of these issues and cites a variety of studies that highlight these problems. He also notes that many of these issues are not restricted to stepwise selection, but affect forward selection and backward elimination, as well as methods based on all-subset selection.

In their introductory chapter, Burnham and Anderson (2002) discuss many issues involved in model selection. They also strongly warn against "data dredging," which they describe as "the process of analyzing data with few or no a priori questions, by subjectively and iteratively searching the data for patterns and 'significance'." However, Burnham and Anderson also discuss the desirability of finding parsimonious models. They note that using "full models" that contain many insignificant predictors might avoid some of the inferential problems arising in models with automatically selected variables but will lead to overfitting the particular sample data and produce a model that performs poorly in predicting data not used in training the model.

One problem in the traditional implementations of forward, backward, and stepwise selection methods is that they are based on sequential testing with specified entry (SLE) and stay (SLS) significance levels. However, it is known that the "F-to-enter" and "F-to-delete" statistics do not follow an F distribution (Draper, Guttman, and Kanemasu 1971). Hence the SLE and SLS values cannot reliably be viewed as probabilities. One way to address this difficulty is to replace hypothesis testing as a means of selecting a model with information criteria or out-of-sample prediction criteria. While Harrell (2001) points out that information criteria were developed for comparing only prespecified models, Burnham and Anderson (2002) note that AIC criteria have routinely been used for several decades for performing model selection in time series analysis.

Problems also arise when the selected model is interpreted as if it were prespecified. There is a "selection bias" in the parameter estimates that is discussed in detail in Miller (2002). This bias occurs because a parameter is more likely to be selected if it is above its expected value than if it is below its expected value. Furthermore, because multiple comparisons are made in obtaining the selected model, the *p*-values obtained for the selected model are not valid. When a single best model is selected, inference is conditional on that model.

Model averaging approaches provide a way to make more stable inferences based on a set of models. PROC GLMSELECT provides support for model averaging by averaging models that are selected on resampled data. Other approaches for performing model averaging are presented in Burnham and Anderson (2002), and Bayesian approaches are discussed in Raftery, Madigan, and Hoeting (1997).

Despite these difficulties, careful and informed use of variable selection methods still has its place in modern data analysis. For example, Foster and Stine (2004) use a modified version of stepwise selection to build a predictive model for bankruptcy from over 67,000 possible predictors and show that this yields a model whose predictions compare favorably with other recently developed data mining tools. In particular, when the goal is prediction rather than estimation or hypothesis testing, variable selection with careful use of validation to limit both under and over fitting is often a useful starting point of model development.

# **Criteria Used in Model Selection Methods**

PROC GLMSELECT supports a variety of fit statistics that you can specify as criteria for the CHOOSE=, SELECT=, and STOP= options in the MODEL statement. The following statistics are available:

ADJRSQ	adjusted R-square statistic (Darlington 1968; Judge et al. 1985)
AIC	Akaike's information criterion (Darlington 1968; Judge et al. 1985)
AICC	corrected Akaike's information criterion (Hurvich and Tsai 1989)
BIC	Sawa Bayesian information criterion (Sawa 1978; Judge et al. 1985)
CP	Mallows' $C_p$ statistic (Mallows 1973; Hocking 1976)
PRESS	predicted residual sum of squares statistic
SBC	Schwarz Bayesian information criterion (Schwarz 1978; Judge et al. 1985)
SL	significance level of the $F$ statistic used to assess an effect's contribution to the fit when it is added to or removed from a model
VALIDATE	average square error over the validation data

Table 45.10 provides formulas and definitions for the fit statistics.

Table 45.10 Formulas and Definitions for Model Fit Summary Statistics

Statistic	Definition or Formula
n	Number of observations
p	Number of parameters including the intercept
$\hat{\sigma}^2$	Estimate of pure error variance from fitting the full model
SST	Total sum of squares corrected for the mean for the
	dependent variable
SSE	Error sum of squares
ASE	$\frac{\text{SSE}}{n}$
MSE	$\frac{\text{SSE}}{n-p}$
$R^2$	$1 - \frac{\text{SSE}}{\text{SST}}$
ADJRSQ	n-p
AIC	$n \ln \left( \frac{\text{SSE}}{n} \right) + 2p + n + 2$
AICC	$1 + \ln\left(\frac{\text{SSE}}{n}\right) + \frac{2(p+1)}{n-p-2}$
BIC	$n \ln \left( \frac{\text{SSE}}{n} \right) + 2(p+2)q - 2q^2 \text{ where } q = \frac{n\hat{\sigma}^2}{\text{SSE}}$
$\mathrm{CP}\left(C_{p}\right)$	$\frac{\text{SSE}}{\hat{\sigma}^2} + 2p - n$

Table 45.10 continued

Statistic	Definition or Formula
PRESS	$\sum_{i=1}^{n} \frac{r_i^2}{(1 - h_i)^2}$ where $r_i = \text{residual at observation } i \text{ and } h_i = \text{leverage of observation } i = \mathbf{x}_i (\mathbf{X}'\mathbf{X})^{-} \mathbf{x}_i'$
RMSE	$\sqrt{MSE}$
SBC	$n\ln\left(\frac{\text{SSE}}{n}\right) + p\ln(n)$

### Formulas for AIC and AICC

There is some inconsistency in the literature on the precise definitions for the AIC and AICC statistics. The definitions used in PROC GLMSELECT changed between the experimental and the production release of the procedure in SAS 9.2. The definitions now used in PROC GLMSELECT yield the same final models as before, but PROC GLMSELECT makes the connection between the AIC statistic and the AICC statistic more transparent.

In the context of linear regression, several different versions of the formulas for AIC and AICC appear in the statistics literature. However, for a fixed number of observations, these different versions differ by additive and positive multiplicative constants. Because the model selected to yield a minimum of a criterion is not affected if the criterion is changed by additive and positive multiplicative constants, these changes in the formula for AIC and AICC do not affect the selection process.

The following section provides details about these changes. Formulas used in the experimental download release are denoted with a superscript of (d) and n, p and SSE are defined in Table 45.10.

The experimental download release of PROC GLMSELECT used the following formulas for AIC (Darlington 1968; Judge et al. 1985) and AICC (Hurvich, Simonoff, and Tsai 1998):

$$AIC^{(d)} = n\log\left(\frac{SSE}{n}\right) + 2p$$

and

$$AICC^{(d)} = \log\left(\frac{SSE}{n}\right) + 1 + \frac{2(p+1)}{n-p-2}$$

PROC GLMSLECT now uses the definitions of AIC and AICC found in Hurvich and Tsai (1989):

$$AIC = n\log\left(\frac{SSE}{n}\right) + 2p + n + 2$$

and

AICC = AIC + 
$$\frac{2(p+1)(p+2)}{n-p-2}$$

Hurvich and Tsai (1989) show that the formula for AICC can also be written as

AICC = 
$$n\log\left(\frac{\text{SSE}}{n}\right) + \frac{n(n+p)}{n-p-2}$$

The relationships between the alternative forms of the formulas are

$$AIC = AIC^{(d)} + n + 2$$

$$AICC = n AICC^{(d)}$$

# **CLASS Variable Parameterization and the SPLIT Option**

The GLMSELECT procedure supports nonsingular parameterizations for classification effects. A variety of these nonsingular parameterizations are available. You use the PARAM= option in the CLASS statement to specify the parameterization. See the section "Other Parameterizations" on page 387 in Chapter 19, "Shared Concepts and Topics," for details.

PROC GLMSELECT also supports the ability to split classification effects. You can use the SPLIT option in the CLASS statement to request that the columns of the design matrix that correspond to any effect that contains a split classification variable can be selected to enter or leave a model independently of the other design columns of that effect. The following statements illustrate the use of SPLIT option together with other features of the CLASS statement:

```
data codingExample;
   drop i;
   do i=1 to 1000;
      c1 = 1 + mod(i, 6);
             i < 50 then c2 = 'very low';
      else if i < 250 then c2 = 'low';
      else if i < 500 then c2 = 'medium';
      else if i < 800 then c2 = 'high';
                           c2 = 'very high';
      else
      x1 = ranuni(1);
      x2 = ranuni(1);
      y = x1 + 10*(c1=3) +5*(c1=5) +rannor(1);
      output;
   end;
run:
proc glmselect data=codingExample;
   class c1(param=ref split) c2(param=ordinal order=data) /
          delimiter = ',' showcoding;
   model y = c1 c2 x1 x2/orderselect;
run;
```

The "Class Level Information" table shown in Figure 45.11 is produced by default whenever you specify a CLASS statement.

Figure 45.11 Class Level Information

The GLMSELECT Procedure							
	Class Level Information						
Class	Levels	Values					
c1	6 *	1,2,3,4,5,6					
c2	5	very low, low, medium, high, very high					
* Associated Parameters Split							

Note that because the levels of the variable c2 contain embedded blanks, the DELIMITER="," option has been specified. The SHOWCODING option requests the display of the "Class Level Coding" table shown in Figure 45.12. An ordinal parameterization is used for c2 because its levels have a natural order. Furthermore, because these levels appear in their natural order in the data, you can preserve this order by specifying the ORDER=DATA option.

Figure 45.12 Class Level Coding

	Class Le	evel Co	oding			
c1		Desig	yn Vari	iables		
Level	1	2	3	4	5	
1	1	0	0	0	0	
2	0	1	0	0	0	
3	0	0	1	0	0	
4	0	0		1	0	
5	0	0	0	0	1	
6	0	0	0	0	0	

The SPLIT option has been specified for the classification variable c1. This permits the parameters associated with the effect c1 to enter or leave the model individually. The "Parameter Estimates" table in Figure 45.13 shows that for this example the parameters that correspond to only levels 3 and 5 of c1 are in the selected model. Finally, note that the ORDERSELECT option in the MODEL statement specifies that the parameters are displayed in the order in which they first entered the model.

Figure 45.13 Parameter Estimates

		Parameter Estima	tes		
			Standard		
Parameter	DF	Estimate	Error	t Value	
Intercept	1	-0.216680	0.068650	-3.16	
c1_3	1	10.160900	0.087898	115.60	
c1_5	1	5.018015	0.087885	57.10	
<b>x</b> 1	1	1.315468	0.109772	11.98	

# **Macro Variables Containing Selected Models**

Often you might want to perform postselection analysis by using other SAS procedures. To facilitate this, PROC GLMSELECT saves the list of selected effects in a macro variable. This list does not explicitly include the intercept so that you can use it in the MODEL statement of other SAS/STAT regression procedures.

The following table describes the macro variables that PROC GLMSELECT creates. Note that when BY processing is used, one macro variable, indexed by the BY group number, is created for each BY group.

Macro Variable	Description
No BY processing _GLSIND1	g Selected model
BY processing	
_GLSNUMBYS	Number of BY groups
_GLSIND1	Selected model for BY group 1
_GLSIND2	Selected model for BY group 2

You can use the macro variable \_GLSIND as a synonym for \_GLSIND1. If you do not use BY processing, \_GLSNUMBYS is still defined and has the value 1.

To aid in associating indexed macro variables with the appropriate observations when BY processing is used, PROC GLMSELECT creates a variable \_BY\_ in the output data set specified in an OUTPUT statement (see the section "OUTPUT Statement" on page 3555) that tags observations with an index that matches the index of the appropriate macro variable.

The following statements create a data set with two BY groups and run PROC GLMSELECT to select a model for each BY group.

```
data one(drop=i j);
   array x{5} x1-x5;
   do i=1 to 1000;
      classVar = mod(i, 4) + 1;
      do j=1 to 5;
         x{j} = ranuni(1);
      end;
      if i<400 then do;
         byVar = 'group 1';
               = 3*classVar+7*x2+5*x2*x5+rannor(1);
      end;
      else do;
         byVar = 'group 2';
               = 2*classVar+x5+rannor(1);
         У
      end;
      output;
   end;
run;
```

```
proc glmselect data=one;
   by
         byVar;
   class classVar;
   model y = classVar x1|x2|x3|x4|x5 @2 /
                  selection=stepwise(stop=aicc);
   output out=glmselectOutput;
run;
```

The preceding PROC GLMSELECT step produces three macro variables:

Macro Variable	Value	Description
_GLSNUMBYS	2	Number of BY groups
_GLSIND1	classVar x2 x2*x5	Selected model for the first BY group
_GLSIND2	classVar x5	Selected model for the second BY group

You can now leverage these macro variables and the output data set created by PROC GLMSELECT to perform postselection analyses that match the selected models with the appropriate BY-group observations. For example, the following statements create and run a macro that uses PROC GLM to perform LSMeans analyses.

```
%macro LSMeansAnalysis;
   %do i=1 %to &_GLSNUMBYS;
      title1 "Analysis Using the Selected Model for BY group number &i";
      title2 "Selected Effects: &&_GLSIND&i";
      ods select LSMeans;
      proc glm data=glmselectOutput(where = (_BY_ = &i));
         class classVar;
         model y = &&_GLSIND&i;
         lsmeans classVar;
      run; quit;
   %end;
%mend;
%LSMeansAnalysis;
```

The LSMeans analysis output from PROC GLM is shown in Output 45.14.

Figure 45.14 LS-Means Analyses for Selected Models

```

# Using the STORE Statement

The preceding section shows how you can use macro variables to facilitate performing postselection analysis by using other SAS procedures. An alternative approach is to use the STORE statement to save the results of the PROC GLMSELECT step in an item store. You can then use the PLM procedure to obtain a rich set of postselection analyses. The following statements show how you can use this approach to obtain the same LSMeans analyses as shown in section "Macro Variables Containing Selected Models" on page 3572:

```
proc glmselect data=one;
         byVar;
  by
   class classVar;
  model y = classVar x1|x2|x3|x4|x5 @2 /
                  selection=stepwise(stop=aicc);
   store out=glmselectStore;
run;
proc plm source=glmselectStore;
   lsmeans classVar;
run;
```

The LSMeans analysis output for the first BY group is shown in Figure 45.15.

The PLM Procedure classVar Least Squares Means Standard class Var Estimate Error DF t Value Pr > |t| 0.1050 1 7.8832 393 75.11 < .0001 2 10.9529 0.1043 393 104.99 <.0001 3 13.9412 0.1043 393 133.70 <.0001 16.7929 0.1042 393 161.09 <.0001

# **Building the SSCP Matrix**

Traditional implementations of FORWARD and STEPWISE selection methods start by computing the augmented crossproduct matrix for all the specified effects. This initial crossproduct matrix is updated as effects enter or leave the current model by sweeping the columns corresponding to the parameters of the entering or departing effects. Building the starting crossproduct matrix can be done with a single pass through the data and requires  $O(m^2)$  storage and  $O(nm^2)$  work, where n is the number of observations and m is the number of parameters. If k selection steps are done, then the total work sweeping effects in and out of the model is  $O(km^2)$ . When n >> m, the work required is dominated by the time spent forming the crossproduct matrix. However, when m is large (tens of thousands), just storing the crossproduct matrix becomes intractable even though the number of selected parameters might be small. Note also that when interactions of classification effects are considered, the number of parameters considered can be large, even though the number of effects considered is much smaller.

When the number of selected parameters is smaller than the total number of parameters, it turns out that many of the crossproducts are not needed in the selection process. Let y denote the dependent variable, and suppose at some step of the selection process that X denotes the  $n \times p$  design matrix columns corresponding to the currently selected model. Let  $\mathbf{Z} = \mathbf{z}_1, \mathbf{z}_2, \dots, \mathbf{z}_{m-p}$  denote the design matrix columns corresponding to the m-p effects not yet in the model. Then in order to compute the reduction in the residual sum of squares when  $\mathbf{z}_j$  is added to the model, the only additional crossproducts needed are  $\mathbf{z}'_j y$ ,  $\mathbf{z}'_j \mathbf{X}$ , and  $\mathbf{z}'_j \mathbf{z}_j$ . Note that it is not necessary to compute any of  $\mathbf{z}_{j}'\mathbf{z}_{i}$  with  $i \neq j$  and if  $p \ll m$ , and this yields a substantial saving in both memory required and computational work. Note, however, that this strategy does require a pass through the data at any step where adding an effect to the model is considered.

PROC GLMSELECT supports both of these strategies for building the crossproduct matrix. You can choose which of these strategies to use by specifying the BUILDSSCP=FULL or BUILDSSCP=INCREMENTAL option in the PERFORMANCE statement. If you request BACKWARD selection, then the full SSCP matrix is required. Similarly, if you request the BIC or CP criterion as the SELECT=, CHOOSE=, or STOP= criterion, or if you request the display of one or both of these criteria with the STATS=BIC, STATS=CP, or STATS=ALL option, then the full model needs to be computed. If you do not specify the BUILDSSCP= option, then PROC GLMSELECT switches to the incremental strategy if the number of effects is greater than one hundred. This default strategy is designed to give good performance when the number of selected parameters is less than about 20% of the total number of parameters. Hence if you choose options that you know will cause the selected model to contain a significantly higher percentage of the total number of candidate parameters, then you should consider specifying BUILDSSCP=FULL. Conversely, if you specify fewer than 100 effects in the MODEL statement but many of these effects have a large number of associated parameters, then specifying BUILDSSCP=INCREMENTAL might result in improved performance.

# **Model Averaging**

As discussed in the section "Model Selection Issues" on page 3567, some well-known issues arise in performing model selection for inference and prediction. One approach to address these issues is to use resampled data as a proxy for multiple samples that are drawn from some conceptual probability distribution. A model is selected for each resampled set of data, and a predictive model is built by averaging the predictions of these selected models. You can perform this method of model averaging by using the MODELAVER-AGE statement. Resampling-based methods, in which samples are obtained by drawing with replacement from your data, fall under the umbrella of the widely studied methodology known as the bootstrap (Efron and Tibshirani 1993). For use of the bootstrap in the context of variable selection, see Breiman (1992).

By default, when the average is formed, models that are selected in multiple samples receive more weight than infrequently selected models. Alternatively, you can start by fitting a prespecified set of models on your data, then use information-theoretic approaches to assign a weight to each model in building a weighted average model. You can find a detailed discussion of this methodology in Burnham and Anderson (2002), in addition to some comparisons of this approach with bootstrap-based methods.

In the linear model context, the average prediction that you obtain from a set of models is the same as the prediction that you obtain with the single model whose parameter estimates are the averages of the corresponding estimates of the set of models. Hence, you can regard model averaging as a selection method that selects this average model. To show this, denote by  $\beta^{(i)}$  the parameter estimates for the sample i where  $\beta^{(i)}_j = 0$  if parameter j is not in the selected model for sample i. Then the predicted values  $\hat{y}^{(i)}$  for average model i are given by

$$\hat{y}^{(i)} = \mathbf{X}\boldsymbol{\beta}^{(i)}$$

where X is the design matrix of the data to be scored. Forming averages gives

$$\hat{y}^{(*)} = \frac{1}{N} \sum_{i=1}^{N} \hat{y}^{(i)} = \frac{1}{N} \sum_{i=1}^{N} \mathbf{X} \boldsymbol{\beta}^{(i)} = \mathbf{X} \left( \frac{1}{N} \sum_{i=1}^{N} \boldsymbol{\beta}^{(i)} \right) = \mathbf{X} \boldsymbol{\beta}^{(*)}$$

where for parameter  $j, \beta_j^{(*)} = \frac{1}{N} \sum_{i=1}^N \beta_j^{(i)}$ .

You can see that if a parameter estimate is nonzero for just a few of the sample models, then averaging the estimates for this parameter shrinks this estimate towards zero. It is this shrinkage that ameliorates the bias that a parameter is more likely to be selected if it is above its expected value rather than below it. This reduction in bias often produces improved predictions on new data that you obtain with the average model. However, the average model is not parsimonious since it has nonzero estimates for any parameter that is selected in any sample.

One resampling-based approach for obtaining a parsimonious model is to use the number of times that regressors are selected as an indication of importance and then to fit a new model that uses just the regressors that you deem to be most important. This approach is not without risk. One possible problem is that you

might have several regressors that, for purposes of prediction, can be used as surrogates for one another. In this case it is possible that none of these regressors individually appears in a large enough percentage of the sample models to be deemed important, even though every model contains at least one of them. Despite such potential problems, this strategy is often successful. You can implement this approach by using the REFIT option in the MODELAVERAGE statement. By default, the REFIT option performs a second round of model averaging, where a fixed model that consists of the effects that are selected in a least twenty percent of the samples in the initial round of model averaging is used. The average model is obtained by averaging the ordinary least squares estimates obtained for each sample in the refit. Note that the default selection frequency cutoff of twenty percent is merely a heuristic guideline that often produces reasonable models.

Another approach to obtaining a parsimonious average model is to form the average of just the frequently selected models. You can implement this strategy by using the SUBSET option in the MODELAVERAGE statement. However, in situations where there are many irrelevant regressors, it is often the case that most of the selected models are selected just once. In such situations, having a way to order the models that are selected with the same frequency is desirable. The following section discusses a way to do this.

# **Model Selection Frequencies and Frequency Scores**

The model frequency score orders models by their selection frequency, but also uses effect selection frequencies to order different models that are selected with the same frequency. Let  $\mathbf{x}_i$  denote the *i*th effect and let  $f_i$  denote the selection fraction for this effect.  $f_i$  is computed as the number of samples whose selected model contains effect  $\mathbf{x}_i$  divided by the number of samples. Suppose the *j*th model that consists of the K effects  $\mathbf{x}_{j_1}, \mathbf{x}_{j_2}, \ldots, \mathbf{x}_{j_K}$  is selected  $m_j$  times. Then the model frequency score,  $s_j$ , for this model is computed as the sum of the model selection frequency and the average selection fraction for this model; that is,

$$s_j = m_j + \frac{\sum_{k=1}^K f_{j_k}}{K}$$

When you use the BEST=b suboption of the SUBSET option in the MODELAVERAGE statement, then the average model is formed from the b models with the largest model frequency scores.

# **Using Validation and Test Data**

When you have sufficient data, you can subdivide your data into three parts called the training, validation, and test data. During the selection process, models are fit on the training data, and the prediction error for the models so obtained is found by using the validation data. This prediction error on the validation data can be used to decide when to terminate the selection process or to decide what effects to include as the selection process proceeds. Finally, once a selected model has been obtained, the test set can be used to assess how the selected model generalizes on data that played no role in selecting the model.

In some cases you might want to use only training and test data. For example, you might decide to use an information criterion to decide what effects to include and when to terminate the selection process. In this case no validation data are required, but test data can still be useful in assessing the predictive performance of the selected model. In other cases you might decide to use validation data during the selection process but forgo assessing the selected model on test data. Hastie, Tibshirani, and Friedman (2001) note that it is difficult to give a general rule on how many observations you should assign to each role. They note that a typical split might be 50% for training and 25% each for validation and testing.

PROC GLMSELECT provides several methods for partitioning data into training, validation, and test data. You can provide data for each role in separate data sets that you specify with the DATA=, TESTDATA=, and VALDATA= options in the PROC GLMSELECT procedure. An alternative method is to use a PARTITION statement to logically subdivide the DATA= data set into separate roles. You can name the fractions of the data that you want to reserve as test data and validation data. For example, specifying

```
proc glmselect data=inData;
   partition fraction(test=0.25 validate=0.25);
   ...
run;
```

randomly subdivides the inData data set, reserving 50% for training and 25% each for validation and testing.

In some cases you might need to exercise more control over the partitioning of the input data set. You can do this by naming a variable in the input data set as well as a formatted value of that variable that correspond to each role. For example, specifying

```
proc glmselect data=inData;
   partition roleVar=group(test='group 1' train='group 2')
   ...
run;
```

assigns all roles observations in the inData data set based on the value of the variable named group in that data set. Observations where the value of group is 'group 1' are assigned for testing, and those with value 'group 2' are assigned to training. All other observations are ignored.

You can also combine the use of the PARTITION statement with named data sets for specifying data roles. For example,

```
proc glmselect data=inData testData=inTest;
   partition fraction(validate=0.4);
   ...
run:
```

reserves 40% of the inData data set for validation and uses the remaining 60% for training. Data for testing is supplied in the inTest data set. Note that in this case, because you have supplied a TESTDATA= data set, you cannot reserve additional observations for testing with the PARTITION statement.

When you use a PARTITION statement, the output data set created with an OUTPUT statement contains a character variable \_ROLE\_ whose values 'TRAIN', 'TEST', and 'VALIDATE' indicate the role of each observation. \_ROLE\_ is blank for observations that were not assigned to any of these three roles. When the input data set specified in the DATA= option in the PROC GLMSELECT statement contains an \_ROLE\_ variable and no PARTITION statement is used, and TESTDATA= and VALDATA= are not specified, then the \_ROLE\_ variable is used to define the roles of each observation. This is useful when you want to rerun PROC GLMSELECT but use the same data partitioning as in a previous PROC GLMSELECT step. For example, the following statements use the same data for testing and training in both PROC GLMSELECT steps:

```
proc glmselect data=inData;
  partition fraction(test=0.5);
  model y=x1-x10/selection=forward;
  output out=outDataForward;
run;
```

```
proc glmselect data=outDataForward;
  model y=x1-x10/selection=backward;
run:
```

When you have reserved observations for training, validation, and testing, a model fit on the training data is scored on the validation and test data, and the average squared error, denoted by ASE, is computed separately for each of these subsets. The ASE for each data role is the error sum of squares for observations in that role divided by the number of observations in that role.

# Using the Validation ASE as the STOP= Criterion

If you have provided observations for validation, then you can specify STOP=VALIDATE as a suboption of the SELECTION= option in the MODEL statement. At step k of the selection process, the best candidate effect to enter or leave the current model is determined. Note that here "best candidate" means the effect that gives the best value of the SELECT= criterion that need not be based on the validation data. The validation ASE for the model with this candidate effect added is computed. If this validation ASE is greater than the validation ASE for the model at step k, then the selection process terminates at step k.

# Using the Validation ASE as the CHOOSE= Criterion

When you specify the CHOOSE=VALIDATE suboption of the SELECTION= option in the MODEL statement, the validation ASE is computed for the models at each step of the selection process. The model at the first step yielding the smallest validation ASE is selected.

# Using the Validation ASE as the SELECT= Criterion

You request the validation ASE as the selection criterion by specifying the SELECT=VALIDATE suboption of the SELECTION= option in the MODEL statement. At step k of the selection process, the validation ASE is computed for each model where a candidate for entry is added or candidate for removal is dropped. The selected candidate for entry or removal is the one that yields a model with the minimal validation ASE.

# **Cross Validation**

Deciding when to stop a selection method is a crucial issue in performing effect selection. Predictive performance of candidate models on data not used in fitting the model is one approach supported by PROC GLMSELECT for addressing this problem (see the section "Using Validation and Test Data" on page 3577). However, in some cases, you might not have sufficient data to create a sizable training set and a validation set that represent the predictive population well. In these cases, cross validation is an attractive alternative for estimating prediction error.

In k-fold cross validation, the data are split into k roughly equal-sized parts. One of these parts is held out for validation, and the model is fit on the remaining k-1 parts. This fitted model is used to compute the predicted residual sum of squares on the omitted part, and this process is repeated for each of k parts. The sum of the k predicted residual sum of squares so obtained is the estimate of the prediction error that is denoted by CVPRESS. Note that computing the CVPRESS statistic for k-fold cross validation requires fitting k different models, and so the work and memory requirements increase linearly with the number of cross validation folds.

You can use the CVMETHOD= option in the MODEL statement to specify the method for splitting the data into k parts. CVMETHOD=BLOCK(k) requests that the k parts be made of blocks of floor(n/k) or floor(n/k) + 1 successive observations, where n is the number of observations. CVMETHOD=SPLIT(k)requests that parts consist of observations  $\{1, k + 1, 2k + 1, 3k + 1, ...\}, \{2, k + 2, 2k + 2, 3k + 2, ...\}, ...$  $\{k, 2k, 3k, \ldots\}$ . CVMETHOD=RANDOM(k) partitions the data into random subsets each with roughly floor(n/k) observations. Finally, you can use the formatted value of an input data set variable to define the parts by specifying CVMETHOD=variable. This last partitioning method is useful in cases where you need to exercise extra control over how the data are partitioned by taking into account factors such as important but rare observations that you want to "spread out" across the various parts.

You can request details of the CVPRESS computations by specifying the CVDETAILS= option in the MODEL statement. When you use cross validation, the output data set created with an OUTPUT statement contains an integer-valued variable, \_CVINDEX\_, whose values indicate the subset to which an observation is assigned.

The widely used special case of *n*-fold cross validation when you have *n* observations is known as *leave-one*out cross validation. In this case, each omitted part consists of one observation, and CVPRESS statistic can be efficiently obtained without refitting the model n times. In this case, the CVPRESS statistic is denoted simply by PRESS and is given by

$$PRESS = \sum_{i=1}^{n} \left( \frac{r_i}{1 - h_i} \right)^2$$

where  $r_i$  is the residual and  $h_i$  is the leverage of the *i*th observation. You can request *leave-one-out* cross validation by specifying PRESS instead of CV with the options SELECT=, CHOOSE=, and STOP= in the MODEL statement. For example, if the number of observations in the data set is 100, then the following two PROC GLMSELECT steps are mathematically equivalent, but the second step is computed much more efficiently:

```
proc glmselect;
  model y=x1-x10/selection=forward(stop=CV) cvMethod=split(100);
run;
proc glmselect;
   model y=x1-x10/selection=forward(stop=PRESS);
run;
```

Hastie, Tibshirani, and Friedman (2001) include a discussion about choosing the cross validation fold. They note that as an estimator of true prediction error, cross validation tends to have decreasing bias but increasing variance as the number of folds increases. They recommend five- or tenfold cross validation as a good compromise. By default, PROC GLMSELECT uses CVMETHOD=RANDOM(5) for cross validation.

# Using Cross Validation as the STOP= Criterion

You request cross validation as the stopping criterion by specifying the STOP=CV suboption of the SELEC-TION= option in the MODEL statement. At step k of the selection process, the best candidate effect to enter or leave the current model is determined. Note that here "best candidate" means the effect that gives the best value of the SELECT= criterion that need not be the CV criterion. The CVPRESS score for the model with this candidate effect added or removed is determined. If this CVPRESS score is greater than the CVPRESS score for the model at step k, then the selection process terminates at step k.

# Using Cross Validation as the CHOOSE= Criterion

When you specify the CHOOSE=CV suboption of the SELECTION= option in the MODEL statement, the CVPRESS score is computed for the models at each step of the selection process. The model at the first step yielding the smallest CVPRESS score is selected.

# Using Cross Validation as the SELECT= Criterion

You request cross validation as the selection criterion by specifying the SELECT=CV suboption of the SELECTION= option in the MODEL statement. At step k of the selection process, the CVPRESS score is computed for each model where a candidate for entry is added or a candidate for removal is dropped. The selected candidate for entry or removal is the one that yields a model with the minimal CVPRESS score. Note that at each step of the selection process, this requires forming the CVPRESS statistic for all possible candidate models at the next step. Since forming the CVPRESS statistic for k-fold requires fitting k models, using cross validation as the selection criterion is computationally very demanding compared to using other selection criteria.

# **Displayed Output**

The following sections describe the displayed output produced by PROC GLMSELECT. The output is organized into various tables, which are discussed in the order of appearance. Note that the contents of a table might change depending on the options you specify.

## **Model Information**

The "Model Information" table displays basic information about the data sets and the settings used to control effect selection. These settings include the following:

- the selection method
- the criteria used to select effects, stop the selection, and choose the selected model
- the effect hierarchy enforced

The ODS name of the "Model Information" table is ModelInfo.

# **Performance Settings**

The "Performance Settings" table displays settings that affect performance. These settings include whether threading is enabled and the number of CPUs available as well as the method used to build the crossproduct matrices. This table is displayed only if you specify the DETAILS option in the PERFORMANCE statement. The ODS name of the "Performance Settings" table is PerfSettings.

## **Number of Observations**

The "Number of Observations" table displays the number of observations read from the input data set and the number of observations used in the analysis. If you specify a FREQ statement, the table also displays the sum of frequencies read and used. If you use a PARTITION statement, the table also displays the number

of observations used for each data role. If you specify TESTDATA= or VALDATA= data sets in the PROC GLMSELECT statement, then "Number of Observations" tables are also produced for these data sets. The ODS name of the "Number of Observations" table is NObs.

#### Class Level Information

The "Class Level Information" table lists the levels of every variable specified in the CLASS statement. The ODS name of the "Class Level Information" table is ClassLevelInfo.

# **Class Level Coding**

The "Class Level Coding" table shows the coding used for variables specified in the CLASS statement. The ODS name of the "Class Level Coding" table is ClassLevelCoding.

## **Dimensions**

The "Dimensions" table displays information about the number of effects and the number of parameters from which the selected model is chosen. If you use split classification variables, then this table also includes the number of effects after splitting is taken into account. The ODS name of the "Dimensions" table is Dimensions.

## **Candidates**

The "Candidates" table displays the effect names and values of the criterion used to select entering or departing effects at each step of the selection process. The effects are displayed in sorted order from best to worst of the selection criterion. You request this table with the DETAILS= option in the MODEL statement. The ODS name of the "Candidates" table is Candidates.

# **Selection Summary**

The "Selection Summary" table displays details about the sequence of steps of the selection process. For each step, the effect that was entered or dropped is displayed along with the statistics used to select the effect, stop the selection, and choose the selected model. You can request that additional statistics be displayed with the STATS= option in the MODEL statement. For all criteria that you can use for model selection, the steps at which the optimal values of these criteria occur are also indicated. The ODS name of the "Selection Summary" table is SelectionSummary.

# **Stop Reason**

The "Stop Reason" table displays the reason why the selection stopped. To facilitate programmatic use of this table, an integer code is assigned to each reason and is included if you output this table by using an ODS OUTPUT statement. The reasons and their associated codes follow:

# **Code Stop Reason**

- 1 maximum number of steps done
- 2 specified number of steps done
- 3 specified number of effects in model
- 4 stopping criterion at local optimum
- 5 model is an exact fit
- 6 all entering effects are linearly dependent on those in the model
- 7 all effects are in the model
- 8 all effects have been dropped
- 9 requested full least squares fit completed
- 10 stepwise selection is cycling
- dropping any effect does not improve the selection criterion
- no effects are significant at the specified SLE or SLS levels
- adding or dropping any effect does not improve the selection criterion
- all remaining effects are required

The ODS name of the "Stop Reason" table is StopReason.

# **Stop Details**

The "Stop Details" table compares the optimal value of the stopping criterion at the final model with how it would change if the best candidate effect were to enter or leave the model. The ODS name of the "Stop Details" table is StopDetails.

## **Selected Effects**

The "Selected Effects" table displays a string containing the list of effects in the selected model. The ODS name of the "Selected Effects" table is SelectedEffects.

## **ANOVA**

The "ANOVA" table displays an analysis of variance for the selected model. This table includes the following:

- the Source of the variation, Model for the fitted regression, Error for the residual error, and C Total for the total variation after correcting for the mean. The Uncorrected Total Variation is produced when the NOINT option is used.
- the degrees of freedom (DF) associated with the source
- the Sum of Squares for the term
- the Mean Square, the sum of squares divided by the degrees of freedom
- the F Value for testing the hypothesis that all parameters are zero except for the intercept. This is formed by dividing the mean square for Model by the mean square for Error.

• the Prob>*F*, the probability of getting a greater *F* statistic than that observed if the hypothesis is true. Note that these *p*-values are displayed only if you specify the "SHOWPVALUES" option in the MODEL statement. These *p*-values are generally liberal because they are not adjusted for the fact that the terms in the model have been selected.

You can request "ANOVA" tables for the models at each step of the selection process with the DETAILS= option in the MODEL statement. The ODS name of the "ANOVA" table is ANOVA.

## **Fit Statistics**

The "Fit Statistics" table displays fit statistics for the selected model. The statistics displayed include the following:

- Root MSE, an estimate of the standard deviation of the error term. It is calculated as the square root of the mean square error.
- Dep Mean, the sample mean of the dependent variable
- R-square, a measure between 0 and 1 that indicates the portion of the (corrected) total variation attributed to the fit rather than left to residual error. It is calculated as SS(Model) divided by SS(Total). It is also called the *coefficient of determination*. It is the square of the multiple correlation—in other words, the square of the correlation between the dependent variable and the predicted values.
- Adj R-Sq, the adjusted  $R^2$ , a version of  $R^2$  that has been adjusted for degrees of freedom. It is calculated as

$$\bar{R}^2 = 1 - \frac{(n-i)(1-R^2)}{n-p}$$

where i is equal to 1 if there is an intercept and 0 otherwise, n is the number of observations used to fit the model, and p is the number of parameters in the model.

- fit criteria AIC, AICC, BIC, CP, and PRESS if they are used in the selection process or are requested with the STATS= option. See the section "Criteria Used in Model Selection Methods" on page 3568 for details and Table 45.10 for the formulas for evaluating these criteria.
- the CVPRESS statistic when cross validation is used in the selection process. See the section "Cross Validation" on page 3579 for details.
- the average square errors (ASE) on the training, validation, and test data. See the section "Using Validation and Test Data" on page 3577 for details.

You can request "Fit Statistics" tables for the models at each step of the selection process with the DETAILS= option in the MODEL statement. The ODS name of the "Fit Statistics" table is FitStatistics.

## **Cross Validation Details**

The "Cross Validation Details" table displays the following:

- the fold number
- the number of observations used for fitting

- the number of observations omitted
- the predicted residual sum of squares on the omitted observations

You can request this table with the CVDETAILS= option in the MODEL statement whenever cross validation is used in the selection process. This table is displayed for the selected model, but you can request this table at each step of the selection process by using the DETAILS= option in the MODEL statement. The ODS name of the "Cross Validation Details" table is CVDetails.

#### **Parameter Estimates**

The "Parameter Estimates" table displays the parameters in the selected model and their estimates. The information displayed for each parameter in the selected model includes the following:

- the parameter label that includes the effect name and level information for effects containing classification variables
- the degrees of freedom (DF) for the parameter. There is one degree of freedom unless the model is not full rank.
- the parameter estimate
- the standard error, which is the estimate of the standard deviation of the parameter estimate
- T for H0: Parameter=0, the *t* test that the parameter is zero. This is computed as the parameter estimate divided by the standard error.
- the Prob > |T|, the probability that a *t* statistic would obtain a greater absolute value than that observed given that the true parameter is zero. This is the two-tailed significance probability. Note that these *p*-values are displayed only if you specify the SHOWPVALUES option in the MODEL statement. These *p*-values are generally liberal because they are not adjusted for the fact that the terms in the model have been selected.

If cross validation is used in the selection process, then you can request that estimates of the parameters for each cross validation fold be included in the "Parameter Estimates" table by using the CVDETAILS= option in the MODEL statement. You can request "Parameter Estimates" tables for the models at each step of the selection process with the DETAILS= option in the MODEL statement. The ODS name of the "Parameter Estimates" table is ParameterEstimates.

## **Score Information**

For each SCORE statement, the "Score Information" table displays the names of the score input and output data sets, and the number of observations that were read and successfully scored. The ODS name of the "Score Information" table is ScoreInfo.

## **Timing Breakdown**

The "Timing Breakdown" table displays a broad breakdown of where time was spent in the PROC GLM-SELECT step. This table is displayed only if you specify the DETAILS option in the PERFORMANCE statement. The ODS name of the "Timing Breakdown" table is Timing.

# **ODS Table Names**

PROC GLMSELECT assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 45.11.

For more information about ODS, see Chapter 20, "Using the Output Delivery System."

 Table 45.11
 ODS Tables Produced by PROC GLMSELECT

ODS Table Name	Description	Statement	Option	
ANOVA	Selected model ANOVA table		Default	
		MODEL AVERAGE	Default	
AvgParmEst	Average parameter estimates	MODELAVERAGE

# **ODS Graphics**

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 600 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 599 in Chapter 21, "Statistical Graphics Using ODS."

You must also specify the PLOTS= option in the PROC GLMSELECT statement.

The following sections describe the ODS graphical displays produced by PROC GLMSELECT. The examples use the Baseball data set that is described in the section "Getting Started: GLMSELECT Procedure" on page 3520.

## **ODS Graph Names**

PROC GLMSELECT assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 45.12.

Table 45.12 Graphs Produced by PROC GLMSELECT

ODS Graph Name	Plot Description	PLOTS Option
AdjRSqPlot	Adjusted R-square by step	CRITERIA(UNPACK)
AICCPlot	Corrected Akaike's information criterion by step	CRITERIA(UNPACK)
AICPlot	Akaike's information criterion by step	CRITERIA(UNPACK)
ASEPlot	Average square errors by step	ASE
BICPlot	Sawa's Bayesian information criterion by step	CRITERIA(UNPACK)
CandidatesPlot	SELECT= criterion by effect	CANDIDATES
ChooseCriterionPlot	CHOOSE= criterion by step	COEFFICIENTS(UNPACK)
CoefficientPanel	Coefficients and CHOOSE= criterion by step	COEFFICIENTS
CoefficientPlot	Coefficients by step	COEFFICIENTS(UNPACK)
CPPlot	Mallows' $C_p$ by step	CRITERIA(UNPACK)
CriterionPanel	Fit criteria by step	CRITERIA
CVPRESSPlot	Cross validation predicted RSS by step	CRITERIA(UNPACK)
EffectSelectPctPlot	Resampling effect selection percentages	EFFECTSELECTPCT

<b>ODS Graph Name</b>	Plot Description	PLOTS= Option

PRESSPlot	Predicted RSS by step	CRITERIA(UNPACK)
SBCPlot	Schwarz Bayesian information criterion by step	CRITERIA(UNPACK)
ValidateASEPlot	Average square error on validation data by step	CRITERIA(UNPACK)

Table 45.12 continued

#### **Candidates Plot**

You request the "Candidates Plot" by specifying the PLOTS=CANDIDATES option in the PROC GLMS-ELECT statement and the DETAILS=STEPS option in the MODEL statement. This plot shows the values of selection criterion for the candidate effects for entry or removal, sorted from best to worst from left to right across the plot. The leftmost candidate displayed is the effect selected for entry or removal at that step. You can use this plot to see at what steps the decision about which effect to add or drop is clear-cut. See Figure 45.5 for an example.

#### Coefficient Panel

When you specify the PLOTS=COEFFICIENTS option in the PROC GLMSELECT statement, PROC GLMSELECT produces a panel of two plots showing how the standardized coefficients and the criterion used to choose the final model evolve as the selection progresses. The following statements provide an example:

```
ods graphics on;
proc glmselect data=baseball plots=coefficients;
  class league division;
  model logSalary = nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor|yrMajor crAtBat|crAtBat crHits|crHits
                     crHome|crHome crRuns|crRuns crRbi|crRbi
                     crBB|crBB league division nOuts nAssts nError /
                     selection=forward(stop=AICC CHOOSE=SBC);
run;
```

Figure 45.16 shows the requested graphic. The upper plot in the panel displays the standardized coefficients as a function of the step number. You can request standardized coefficients in the parameter estimates tables by specifying the STB option in the MODEL statement, but this option is not required to produce this plot. To help in tracing the changes in a parameter, the standardized coefficients for each parameter are connected by lines. Coefficients corresponding to effects that are not in the selected model at a step are zero and hence not observable. For example, consider the parameter crAtBat\*crAtBat in Output 45.16. Because crAtBat\*crAtBat enters the model at step 2, the line that represents this parameter starts rising from zero at step 1 when crRuns enters the model. Parameters that are nonzero at the final step of the selection are labeled if their magnitudes are greater than 1% of the range of the magnitudes of all the nonzero parameters at this step. To avoid collision, labels corresponding to parameters with similar values at the final step might get suppressed. You can control when this label collision avoidance occurs by using the LABELGAP= suboption of the PLOTS=COEFFICIENTS option. Planned enhancements to the automatic label collision avoidance algorithm will obviate the need for this option in future releases of the GLMSELECT procedure.

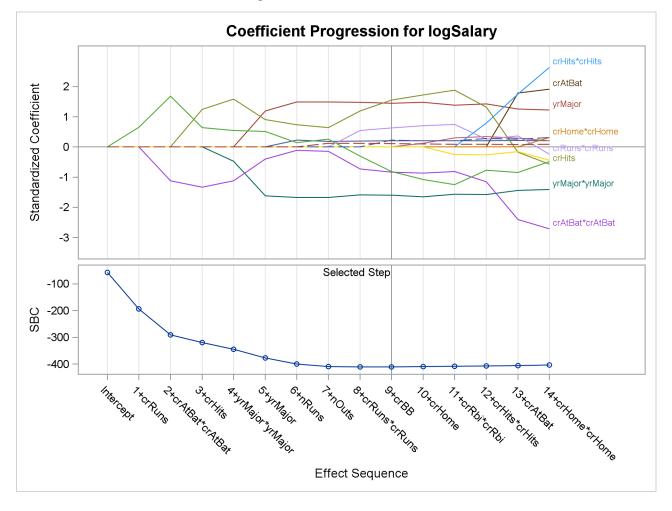

Figure 45.16 Coefficient Panel

The lower plot in the panel shows how the criterion used to choose among the examined models progresses. The selected step occurs at the optimal value of this criterion. In this example, this criterion is the SBC criterion and it achieves its minimal value at step 9 of the forward selection.

In some cases, particularly when the final step contains a large number of parameters, you might be interested in using this plot only to discern if and when the parameters in the model are essential unchanged beyond a certain step. In such cases, you might want to suppress the labeling of the parameters and use a numeric axis on the horizontal axis of the plot. You can do this using the STEPAXIS= and MAXPARMLA-BEL= suboptions of the PLOTS=CRITERIA option. The following statements provide an example:

crBB|crBB league division nOuts nAssts nError / selection=forward(stop=none);

run;

The UNPACK = option requests that the plots of the coefficients and CHOOSE= criterion be shown in separate plots. The STEPAXIS=NUMBER option requests a numeric horizontal axis showing step number, and the MAXPAMLABEL=0 option suppresses the labels for the parameters. The "Coefficient Plot" is shown in Figure 45.17. You can see that the standardized coefficients do not vary greatly after step 16.

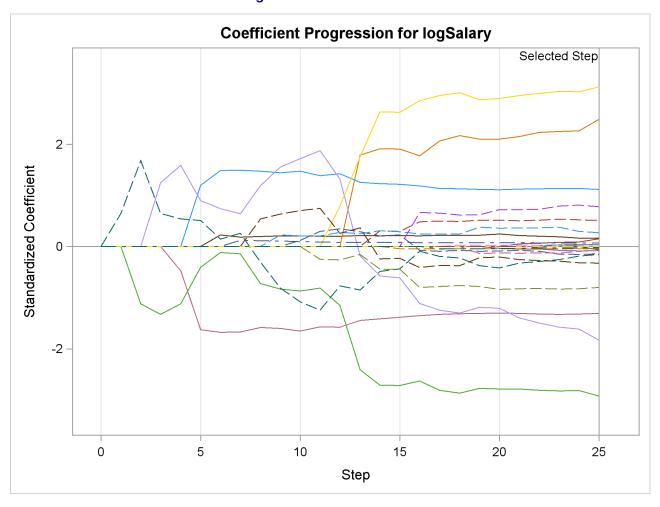

Figure 45.17 Coefficient Plot

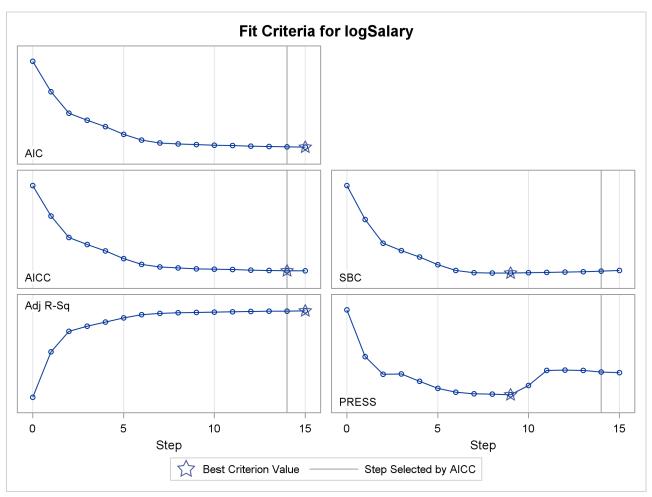

## **Criterion Panel**

You request the criterion panel by specifying the PLOTS=CRITERIA option in the PROC GLMSELECT statement. This panel displays the progression of the ADJRSQ, AIC, AICC, and SBC criteria, as well as any other criteria that are named in the CHOOSE=, SELECT=, STOP=, or STATS= option in the MODEL statement.

The following statements provide an example:

Figure 45.18 shows the requested criterion panel. Note that the PRESS criterion is included in the panel because it is named in the STATS= option in the MODEL statement. The selected step is displayed as a vertical reference line on the plot of each criterion, and the legend indicates which of these criteria is used to make the selection. If the selection terminates for a reason other than optimizing a criterion displayed on this plot, then the legend will not report a reason for the selected step. The optimal value of each criterion is indicated with the "Star" marker. Note that it is possible that a better value of a criterion might have been reached had more steps of the selection process been done.

# **Average Square Error Plot**

You request the average square error plot by specifying the PLOTS=ASE option in the PROC GLMSELECT statement. This plot shows the progression of the average square error (ASE) evaluated separately on the training data, and the test and validation data whenever these data are provided with the TESTDATA= and VALDATA= options or are produced by using a PARTITION statement. You use the plot to detect when overfitting the training data occurs. The ASE decreases monotonically on the training data as parameters are added to a model. However, the average square error on test and validation data typically starts increasing when overfitting occurs. See Output 45.1.9 and Output 45.2.6 for examples.

#### **Examining Specific Step Ranges**

The coefficient panel, criterion panel, and average square error plot display information for all the steps examined in the selection process. In some cases, you might want to focus attention on just a particular step range. For example, it is hard to discern the variation in the criteria displayed in Figure 45.18 near the selected step because the variation in these criteria in the steps close to the selected step is small relative to the variation across all steps. You can request a range of steps to display using the STARTSTEP= and ENDSTEP= suboptions of the PLOTS= option. You can specify these options as both global and specific plot options, with the specific options taking precedence if both are specified. The following statements provide an example:

Figure 45.19 shows the progression of the fit criteria between steps 10 and 16. Note that if the optimal value of a criterion does not occur in this specified step range, then no optimal marker appears for that criterion. The plot of the SBC criterion in Figure 45.19 is one such case.

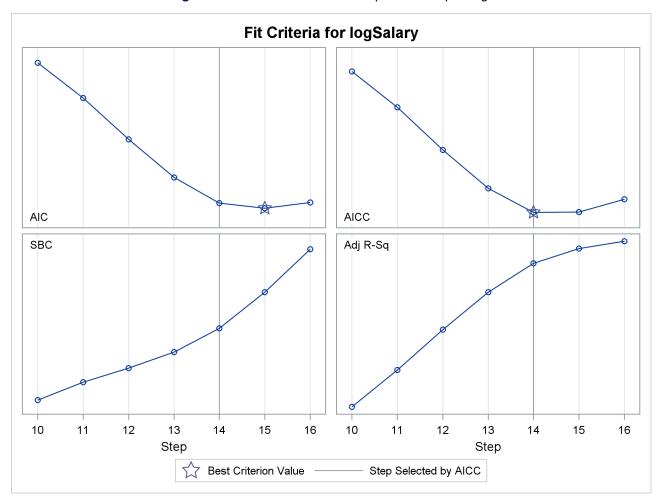

Figure 45.19 Criterion Panel for Specified Step Range

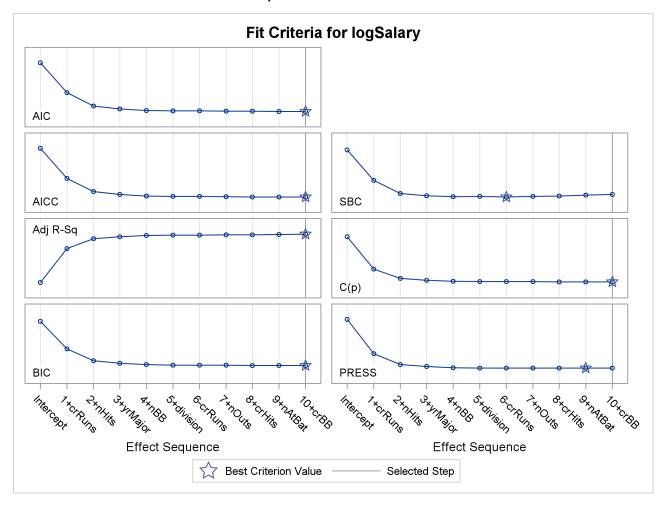

# Examples: GLMSELECT Procedure

# **Example 45.1: Modeling Baseball Salaries Using Performance Statistics**

This example continues the investigation of the baseball data set introduced in the section "Getting Started: GLMSELECT Procedure" on page 3520. In that example, the default stepwise selection method based on the SBC criterion was used to select a model. In this example, model selection that uses other information criteria and out-of-sample prediction criteria is explored.

PROC GLMSELECT provides several selection algorithms that you can customize by specifying criteria for selecting effects, stopping the selection process, and choosing a model from the sequence of models at each step. For more details on the criteria available, see the section "Criteria Used in Model Selection Methods" on page 3568. The SELECT=SL suboption of the SELECTION= option in the MODEL statement in the following code requests the traditional hypothesis test-based stepwise selection approach, where effects in the model that are not significant at the stay significance level (SLS) are candidates for removal and effects not yet in the model whose addition is significant at the entry significance level (SLE) are candidates for addition to the model.

The default SLE and SLS values of 0.15 might not be appropriate for these data. One way to investigate alternative ways to stop the selection process is to assess the sequence of models in terms of model fit statistics. The STATS=ALL option in the MODEL statement requests that all model fit statistics for assessing the sequence of models of the selection process be displayed. To help in the interpretation of the selection process, you can use graphics supported by PROC GLMSELECT. ODS Graphics must be enabled before requesting plots. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." With ODS Graphics enabled, the PLOTS=CRITERIONPANEL option in the PROC GLMSELECT statement produces the criterion panel shown in Output 45.1.1.

Output 45.1.1 Criterion Panel

You can see in Output 45.1.1 that this stepwise selection process would stop at an earlier step if you use the Schwarz Bayesian information criterion (SBC) or predicted residual sum of squares (PRESS) to assess the selected models as stepwise selection progresses. You can use the CHOOSE= suboption of the SE-LECTION= option in the MODEL statement to specify the criterion you want to use to select among the evaluated models. The following statements use the PRESS statistic to choose among the models evaluated during the stepwise selection.

```
proc glmselect data=baseball;
   class league division;
   model logSalary = nAtBat nHits nHome nRuns nRBI nBB
                  yrMajor crAtBat crHits crHome crRuns crRbi
                  crBB league division nOuts nAssts nError
                / selection=stepwise(select=SL choose=PRESS);
run;
```

Note that the selected model is the model at step 9. By default, PROC GLMSELECT displays the selected model, ANOVA and fit statistics, and parameter estimates for the selected model. These are shown in Output 45.1.2.

# Output 45.1.2 Details of Selected Model

#### The GLMSELECT Procedure Selected Model

The selected model, based on PRESS, is the model at Step 9.

Effects: Intercept nAtBat nHits nBB yrMajor crHits division nOuts

#### Analysis of Variance

		Sum of	Mean

division Wes	st 0	0		
nOuts	1	0.000241	0.000134	1.81

Even though the model that is chosen to give the smallest value of the PRESS statistic is the model at step 9, the stepwise selection process continues to the step where the stopping condition based on entry and stay significance levels is met. If you use the PRESS statistic as the stopping criterion, the stepwise selection process stops at step 9. This ability to stop at the first extremum of the criterion you specify can significantly reduce the amount of computation done, especially in the cases where you are selecting from a large number of effects. The following statements request stopping based on the PRESS statistic. The stop reason and stop details tables are shown in Output 45.1.3.

Output 45.1.3 Stopping Based on PRESS Statistic

	The GLMS	ELECT Procedu	re		
Selection	stopped at a loc	al minimum of	the	PRESS criterion.	
	St	op Details			
Candi	date	Candidate		Compare	
For	Effect	PRESS		PRESS

Remov	al nAtBat	88.6866	>	88.5528	

The PLOTS=COEFFICIENTS specification in the PROC GLMSELECT statement requests a plot that enables you to visualize the selection process.

Output 45.1.4 Coefficient Progression Plot

Output 45.1.4 shows the standardized coefficients of all the effects selected at some step of the stepwise method plotted as a function of the step number. This enables you to assess the relative importance of the effects selected at any step of the selection process as well as providing information as to when effects entered the model. The lower plot in the panel shows how the criterion used to choose the selected model changes as effects enter or leave the model.

Model selection is often done in order to obtain a parsimonious model that can be used for prediction on new data. An ever-present danger is that of selecting a model that overfits the "training" data used in the fitting process, yielding a model with poor predictive performance. Using cross validation is one way to assess the predictive performance of the model. Using k-fold cross validation, the training data are subdivided into k parts, and at each step of the selection process, models are obtained on each of the k subsets of the data obtained by omitting one of these parts. The cross validation predicted residual sum of squares, denoted CV PRESS, is obtained by summing the squares of the residuals when each of these submodels is scored on the data omitted in fitting the submodel. Note that the PRESS statistic corresponds to the special case of "leave-one-out" cross validation.

In the preceding example, the PRESS statistic was used to choose among models that were chosen based on entry and stay significance levels. In the following statements, the SELECT=CVPRESS suboption of the SELECTION= option in the MODEL statement requests that the CV PRESS statistic itself be used as the selection criterion. The DROP=COMPETITIVE suboption requests that additions and deletions be considered simultaneously when deciding whether to add or remove an effect. At any step, the CV PRESS statistic for all models obtained by deleting one effect from the model or adding one effect to the model is computed. Among these models, the one yielding the smallest value of the CV PRESS statistic is selected and the process is repeated from this model. The stepwise selection terminates if all additions or deletions increase the CV PRESS statistic. The CVMETHOD=SPLIT(5) option requests five-fold cross validation with the five subsets consisting of observations  $\{1, 6, 11, \ldots\}, \{2, 7, 12, \ldots\}$ , and so on.

The selection summary table is shown in Output 45.1.5. By comparing Output 45.1.5 and Output 45.6 you can see that the sequence of models produced is different from the sequence when the stepwise selection is based on the SBC statistic.

		Stepwise	Selection Summa	ry

Output 45.1.5 Stepwise Selection Based on Cross Validation

If you have sufficient data, another way you can assess the predictive performance of your model is to reserve part of your data for testing your model. You score the model obtained using the training data on the test data and assess the predictive performance on these data that had no role in the selection process. You can also reserve part of your data to validate the model you obtain in the training process. Note that the validation data are not used in obtaining the coefficients of the model, but they are used to decide when to stop the selection process to limit overfitting.

PROC GLMSELECT enables you to partition your data into disjoint subsets for training validation and testing roles. This partitioning can be done by using random proportions of the data, or you can designate a variable in your data set that defines which observations to use for each role. See the section "PARTITION Statement" on page 3556 for more details.

The following statements randomly partition the baseball data set, using 50% for training, 30% for validation, and 20% for testing. The model selected at each step is scored on the validation data, and the average residual sums of squares (ASE) is evaluated. The model yielding the lowest ASE on the validation data is selected. The ASE on the test data is also evaluated, but these data play no role in the selection process. Note that a seed for the pseudo-random number generator is specified in the PROC GLMSELECT statement.

```
proc glmselect data=baseball plots=(CriterionPanel ASE) seed=1;
   partition fraction(validate=0.3 test=0.2);
   class league division;
   model logSalary = nAtBat nHits nHome nRuns nRBI nBB
                  yrMajor crAtBat crHits crHome crRuns crRbi
                  crBB league division nOuts nAssts nError
                / selection=forward(choose=validate stop=10);
run;
```

Output 45.1.6 Number of Observations Table

The GLMSELECT Procedure	
Number of Observations Read	322
Number of Observations Used	263
Number of Observations Used for Training	132
Number of Observations Used for Validation	80
Number of Observations Used for Testing	51

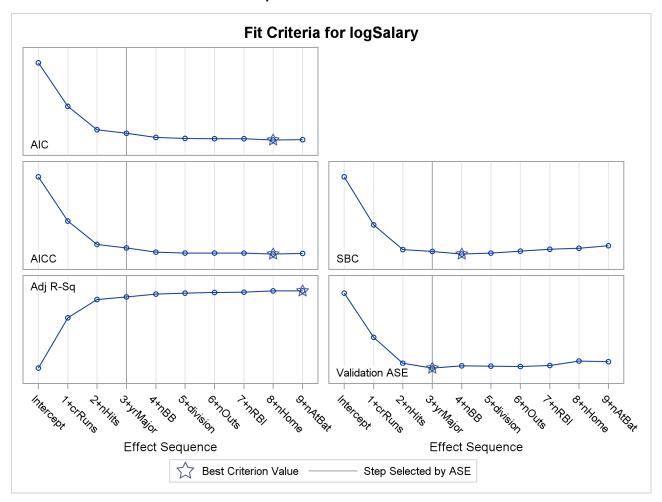

Output 45.1.6 shows the number of observation table. You can see that of the 263 observations that were used in the analysis, 132 (50.2%) observations were used for model training, 80 (30.4%) for model validation, and 51 (19.4%) for model testing.

Output 45.1.7 Selection Summary and Stop Reason

	0 1 2 3 4 5 6	Intercept  crRuns  nHits  yrMajor  nBB  division  nOuts  nRBI  nHome	0.7843 0.4947 0.3248 0.2920* 0.3065 0.3050 0.3028 0.3097 0.3383	0.8818  0.4210 0.4697 0.4614 0.4297 0.4218 0.4186 0.4489	

Output 45.1.7 shows the selection summary table and the stop reason. The forward selection stops at step 9 since the model at this step contains 10 effects, and so it satisfies the stopping criterion requested with the STOP=10 suboption. However, the selected model is the model at step 3, where the validation ASE, the CHOOSE= criterion, achieves its minimum.

Output 45.1.8 Criterion Panel

The criterion panel in Output 45.1.8 shows how the various criteria evolved as the stepwise selection method proceeded. Note that other than the ASE evaluated on the validation data, these criteria are evaluated on the training data.

Output 45.1.9 Average Square Errors by Role

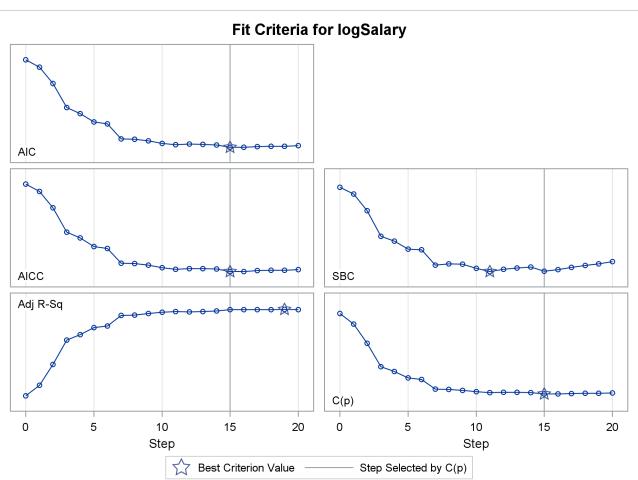

Finally, the ASE plot in Output 45.1.9 shows how the average square error evolves on the training, validation, and test data. Note that while the ASE on the training data continued decreasing as the selection steps proceeded, the ASE on the test and validation data behave more erratically.

LASSO selection, pioneered by Tibshirani (1996), is a constrained least squares method that can be viewed as a stepwise-like method where effects enter and leave the model sequentially. You can find additional details about the LASSO method in the section "Lasso Selection (LASSO)" on page 3565. Note that when classification effects are used with LASSO, the design matrix columns for all effects containing classification variables can enter or leave the model individually. The following statements perform LASSO selection for the baseball data. The LASSO selection summary table is shown in Output 45.1.10.

Output 45.1.10 Selection Summary for LASSO Selection

	mmary	O Selection Su	LAS	
	Number	Effect	Effect

# **Example 45.2: Using Validation and Cross Validation**

This example shows how you can use both test set and cross validation to monitor and control variable selection. It also demonstrates the use of split classification variables.

The following statements produce analysis and test data sets. Note that the same statements are used to generate the observations that are randomly assigned for analysis and test roles in the ratio of approximately two to one.

```
data analysisData testData;
   drop i j c3Num;
   length c3$ 7;
   array x{20} x1-x20;
   do i=1 to 1500;
      do j=1 to 20;
         x{j} = ranuni(1);
      end:
      c1 = 1 + mod(i, 8);
      c2 = ranbin(1, 3, .6);
              i < 50
      if
                       then do; c3 = 'tiny';
                                                 c3Num=1; end;
      else if i < 250 then do; c3 = 'small';
                                                 c3Num=1; end;
      else if i < 600 then do; c3 = 'average'; c3Num=2; end;
      else if i < 1200 then do; c3 = 'big';
                                                 c3Num=3; end;
                                             c3Num=5; end;
      else
                            do; c3 = 'huge';
      y = 10 + x1 + 2*x5 + 3*x10 + 4*x20 + 3*x1*x7 + 8*x6*x7
             + 5*(c1=3)*c3Num + 8*(c1=7) + 5*rannor(1);
      if ranuni(1) < 2/3 then output analysisData;
                         else output testData;
   end;
run;
```

Suppose you suspect that the dependent variable depends on both main effects and two-way interactions. You can use the following statements to select a model:

Note that a TESTDATA= data set is named in the PROC GLMSELECT statement and that a PARTITION statement is used to randomly assign half the observations in the analysis data set for model validation and the rest for model training. You find details about the number of observations used for each role in the number of observations tables shown in Output 45.2.1.

Output 45.2.1 Number of Observations Tables

The GLMSELECT Procedure	
Observation Profile for Analysis Data	
Number of Observations Read	1010
Number of Observations Used	1010
Number of Observations Used for Training	510
Number of Observations Used for Validation	500

The "Class Level Information" and "Dimensions" tables are shown in Output 45.2.2. The "Dimensions" table shows that at each step of the selection process, 278 effects are considered as candidates for entry or removal. Since several of these effects have multilevel classification variables as members, there are 661 parameters.

Output 45.2.2 Class Level Information and Problem Dimensions

	Class Level Information
Class Le	evels Values
c1	8 1 2 3 4 5 6 7 8
c2	4 0 1 2 3
c3	5 tiny small average big huge
	Dimensions
Nu	umber of Effects 278
Nu	umber of Parameters 661

The model statement options request stepwise selection with the default entry and stay significance levels used for both selecting entering and departing effects and stopping the selection method. The CHOOSE=VALIDATE suboption specifies that the selected model is chosen to minimize the predicted residual sum of squares when the models at each step are scored on the observations reserved for validation. The HIERARCHY=SINGLE option specifies that interactions can enter the model only if the corresponding main effects are already in the model, and that main effects cannot be dropped from the model if an interaction with such an effect is in the model. These settings are listed in the model information table shown in Output 45.2.3.

## Output 45.2.3 Model Information

The GLMSELECT Procedure						
Data Set	WORK.ANALYSISDATA					
Test Data Set	WORK.TESTDATA					
Dependent Variable	У					
Selection Method	Stepwise					
Select Criterion	Significance Level					
Stop Criterion	Significance Level					
Choose Criterion	Validation ASE					
Entry Significance Level (SLE)	0.15					
Stay Significance Level (SLS)	0.15					
Effect Hierarchy Enforced	Single					
Random Number Seed	1					

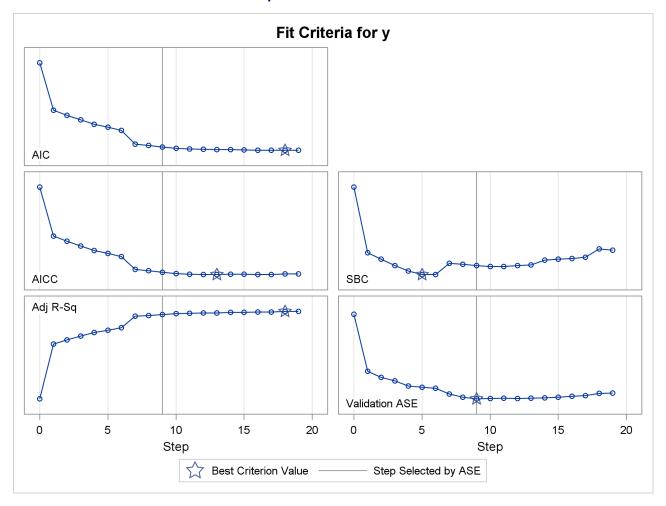

The stop reason and stop details tables are shown in Output 45.2.4. Note that because the STOP= suboption of the SELECTION= option was not explicitly specified, the stopping criterion used is the selection criterion, namely significance level.

Output 45.2.4 Stop Details

ection stopped didate for rem		e candidate for S < 0.15.	entry	nas SLE > U.	is and the
		Stop Detail	s		
Candidate		Candidate		Compare	
For	Effect	Significance		Significand	:e
Entry	x2*x5	0.1742	>	0.1500	(SLE)
Removal	x5*x10	0.0534	<	0.1500	(SLS)

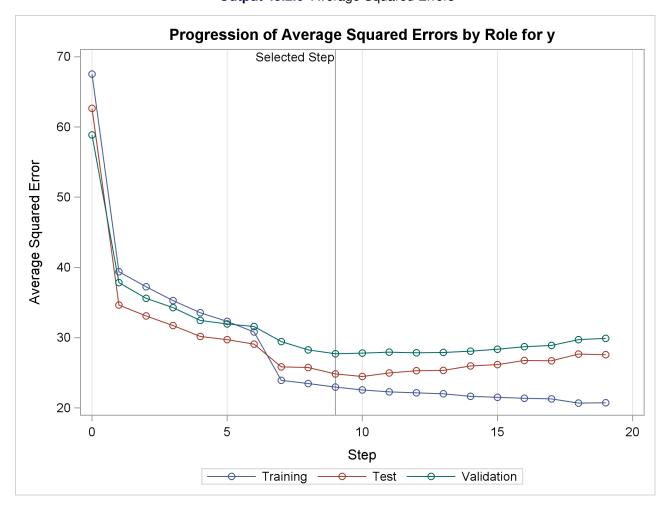

The criterion panel in Output 45.2.5 shows how the various fit criteria evolved as the stepwise selection method proceeded. Note that other than the ASE evaluated on the validation data, these criteria are evaluated on the training data. You see that the minimum of the validation ASE occurs at step 9, and hence the model at this step is selected.

Output 45.2.5 Criterion Panel

Output 45.2.6 shows how the average squared error (ASE) evolved on the training, validation, and test data. Note that while the ASE on the training data decreases monotonically, the errors on both the validation and test data start increasing beyond step 9. This indicates that models after step 9 are beginning to overfit the training data.

Output 45.2.7 shows the selected effects, analysis of variance, and fit statistics tables for the selected model. Output 45.2.8 shows the parameter estimates table.

# Output 45.2.7 Selected Model Details

# The GLMSELECT Procedure Selected Model

The selected model, based on Validation ASE, is the model at Step 9.

Effects: Intercept c1 c3 c1\*c3 x1 x5 x6 x7 x10 x20

The magnitudes of the standardized estimates and the t statistics of the parameters of the effect 'c1' reveal that only levels '3' and '7' of this effect contribute appreciably to the model. This suggests that a more parsimonious model with similar or better predictive power might be obtained if parameters corresponding to the levels of 'c1' are allowed to enter or leave the model independently. You request this with the SPLIT option in the CLASS statement as shown in the following statements:

The "Class Level Information" and "Dimensions" tables are shown in Output 45.2.9. The "Dimensions" table shows that while the model statement specifies 278 effects, after splitting the parameters corresponding to the levels of c1, there are 439 split effects that are considered for entry or removal at each step of the selection process. Note that the total number of parameters considered is not affected by the split option.

The stop reason and stop details tables are shown in Output 45.2.10. Since the validation ASE is specified as the stopping criterion, the selection stops at step 11, where the validation ASE achieves a local minimum and the model at this step is the selected model.

Output 45.2.10 Stop Details

Selection stopped at validation data.	a local mi	nimum of the resid	ual s	um of squares of the
		Stop Details

You find details of the selected model in Output 45.2.11. The list of selected effects confirms that parameters corresponding to levels '3' and '7' only of c1 are in the selected model. Notice that the selected model with classification variable c1 split contains 18 parameters, whereas the selected model without splitting c1 has 45 parameters. Furthermore, by comparing the fit statistics in Output 45.2.7 and Output 45.2.11, you see that this more parsimonious model has smaller prediction errors on both the validation and test data.

Output 45.2.11 Details of the Selected Model

```

Cross validation is often used to assess the predictive performance of a model, especially for when you do not have enough observations for test set validation. See the section "Cross Validation" on page 3579 for further details. The following statements provide an example where cross validation is used as the CHOOSE= criterion.

The CVMETHOD=SPLIT(5) option in the MODEL statement requests five-fold cross validation with the five subsets consisting of observations  $\{1, 6, 11, \ldots\}$ ,  $\{2, 7, 12, \ldots\}$ , and so on. The STATS=PRESS option requests that the leave-one-out cross validation predicted residual sum of squares (PRESS) also be computed and displayed at each step, even though this statistic is not used in the selection process.

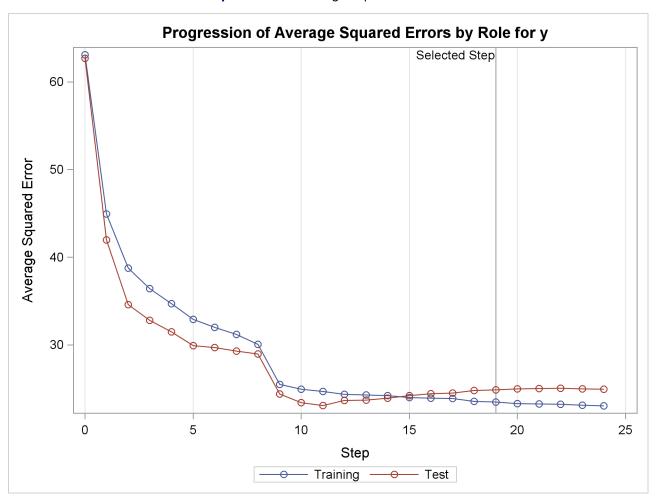

Output 45.2.13 shows how several fit statistics evolved as the selection process progressed. The five-fold CV PRESS statistic achieves its minimum at step 19. Note that this gives a larger model than was selected when the stopping criterion was determined using validation data. Furthermore, you see that the PRESS statistic has not achieved its minimum within 25 steps, so an even larger model would have been selected based on leave-one-out cross validation.

Output 45.2.14 shows how the average squared error compares on the test and training data. Note that the ASE error on the test data achieves a local minimum at step 11 and is already slowly increasing at step 19, which corresponds to the selected model.

The CVDETAILS=ALL option in the MODEL statement requests the "Cross Validation Details" table in Output 45.2.15 and the cross validation parameter estimates that are included in the "Parameter Estimates" table in Output 45.2.16. For each cross validation index, the predicted residual sum of squares on the observations omitted is shown in the "Cross Validation Details" table and the parameter estimates of the corresponding model are included in the "Parameter Estimates" table. By default, these details are shown for the selected model, but you can request this information at every step with the DETAILS= option in the MODEL statement. You use the \_CVINDEX\_ variable in the output data set shown in Output 45.2.17 to find out which observations in the analysis data are omitted for each cross validation fold.

This example demonstrates the usefulness of effect selection when you suspect that interactions of effects are needed to explain the variation in your dependent variable. Ideally, a priori knowledge should be used to decide what interactions to allow, but in some cases this information might not be available. Simply fitting a least squares model allowing all interactions produces a model that overfits your data and generalizes very poorly.

The following statements use forward selection with selection based on the SBC criterion, which is the default selection criterion. At each step, the effect whose addition to the model yields the smallest SBC value is added. The STOP=NONE suboption specifies that this process continue even when the SBC statistic grows whenever an effect is added, and so it terminates at a full least squares model. The BUILDSSCP=FULL option is specified in a PERFORMANCE statement, since building the SSCP matrix incrementally is counterproductive in this case. See the section "BUILDSSCP=FULL" on page 3557 for details. Note that if all you are interested in is a full least squares model, then it is much more efficient to simply specify SE-LECTION=NONE in the MODEL statement. However, in this example the aim is to add effects in roughly increasing order of explanatory power.

The ASE plot shown in Output 45.2.18 clearly demonstrates the danger in overfitting the training data. As more insignificant effects are added to the model, the growth in test set ASE shows how the predictions produced by the resulting models worsen. This decline is particularly rapid in the latter stages of the forward selection, because the use of the SBC criterion results in insignificant effects with lots of parameters being added after insignificant effects with fewer parameters.

Output 45.2.18 Average Squared Error Plot

## **Example 45.3: Scatter Plot Smoothing by Selecting Spline Functions**

This example shows how you can use model selection to perform scatter plot smoothing. It illustrates how you can use the experimental EFFECT statement to generate a large collection of B-spline basis functions from which a subset is selected to fit scatter plot data.

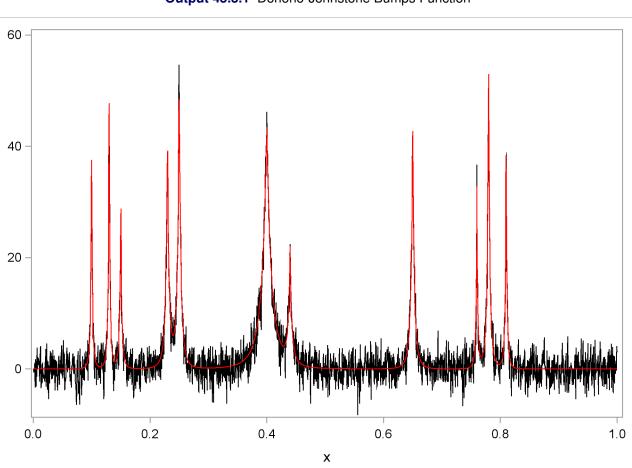

The data for this example come from a set of benchmarks developed by Donoho and Johnstone (1994) that have become popular in the statistics literature. The particular benchmark used is the "Bumps" functions to which random noise has been added to create the test data. The following DATA step, extracted from Sarle (2001), creates the data. The constants are chosen so that the noise-free data have a standard deviation of 7. The standard deviation of the noise is  $\sqrt{5}$ , yielding bumpsNoise with a signal-to-noise ratio of 3.13 (7/ $\sqrt{5}$ ).

```
%let random=12345;
data DoJoBumps;
  keep x bumps bumpsWithNoise;
  pi = arcos(-1);
  do n=1 to 2048;
     x=(2*n-1)/4096;
     link compute;
     bumpsWithNoise=bumps+rannor(&random) *sqrt(5);
      output;
   end;
  stop;
compute:
  array t(11) _temporary_ (.1 .13 .15 .23 .25 .4 .44 .65 .76 .78 .81);
  array b(11) _temporary_ ( 4 5 3 4 5 4.2 2.1 4.3 3.1 5.1 4.2);
  array w(11) _temporary_ (.005 .005 .006 .01 .01 .03 .01 .01 .005 .008 .005);
  bumps=0;
  do i=1 to 11;
     bumps=bumps+b[i] * (1+abs((x-t[i])/w[i])) **-4;
  bumps=bumps*10.528514619;
   return;
run;
```

The following statements use the SGPLOT procedure to produce the plot in Output 45.3.1. The plot shows the bumps function superimposed on the function with added noise.

```
proc sgplot data=DoJoBumps;
   yaxis display=(nolabel);
   series   x=x y=bumpsWithNoise/lineattrs=(color=black);
   series   x=x y=bumps/lineattrs=(color=red);
run;
```

bumps

Output 45.3.1 Donoho-Johnstone Bumps Function

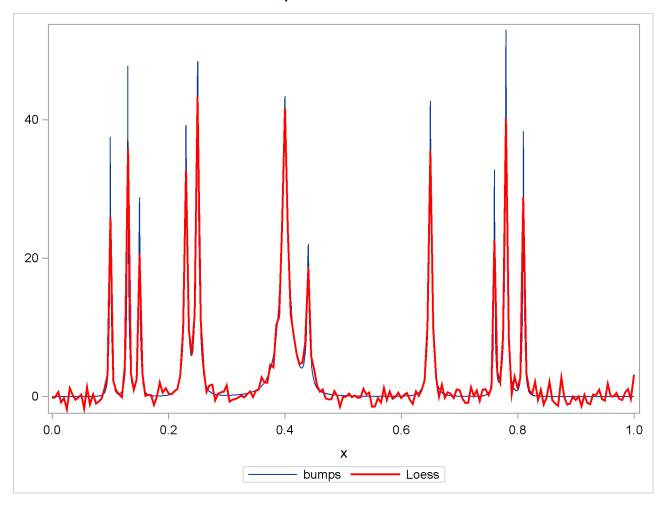

Suppose you want to smooth the noisy data to recover the underlying function. This problem is studied by Sarle (2001), who shows how neural nets can be used to perform the smoothing. The following statements use the LOESS statement in the SGPLOT procedure to show a loess fit superimposed on the noisy data (Output 45.3.2). (See Chapter 53, "The LOESS Procedure," for information about the loess method.)

bumpsWithNoise

```
proc sgplot data=DoJoBumps;
    yaxis display=(nolabel);
    series x=x y=bumps;
    loess x=x y=bumpsWithNoise / lineattrs=(color=red) nomarkers;
run;
```

The algorithm selects a smoothing parameter that is small enough to enable bumps to be resolved. Because there is a single smoothing parameter that controls the number of points for all local fits, the loess method undersmooths the function in the intervals between the bumps.

Output 45.3.2 Loess Fit

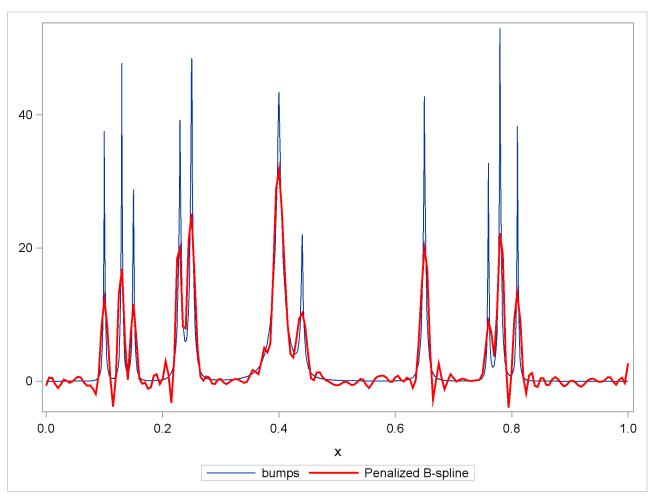

Another approach to doing nonparametric fitting is to approximate the unknown underlying function as a linear combination of a set of basis functions. Once you specify the basis functions, then you can use least squares regression to obtain the coefficients of the linear combination. A problem with this approach is that for most data, you do not know a priori what set of basis functions to use. You need to supply a sufficiently rich set to enable the features in the data to be approximated. However, if you use too rich a set of functions, then this approach yields a fit that undersmooths the data and captures spurious features in the noise.

The penalized B-spline method (Eilers and Marx 1996) uses a basis of B-splines (see the section "EFFECT Statement" on page 393 of Chapter 19, "Shared Concepts and Topics") corresponding to a large number of equally spaced knots as the set of approximating functions. To control the potential overfitting, their algorithm modifies the least squares objective function to include a penalty term that grows with the complexity of the fit.

The following statements use the PBSPLINE statement in the SGPLOT procedure to show a penalized B-spline fit superimposed on the noisy data (Output 45.3.3). See Chapter 97, "The TRANSREG Procedure," for details about the implementation of the penalized B-spline method.

As in the case of loess fitting, you see undersmoothing in the intervals between the bumps because there is only a single smoothing parameter that controls the overall smoothness of the fit.

Output 45.3.3 Penalized B-spline Fit

An alternative to using a smoothness penalty to control the overfitting is to use variable selection to obtain an appropriate subset of the basis functions. In order to be able to represent features in the data that occur at multiple scales, it is useful to select from B-spline functions defined on just a few knots to capture large scale features of the data as well as B-spline functions defined on many knots to capture fine details of the data. The following statements show how you can use PROC GLMSELECT to implement this strategy:

```
proc glmselect data=dojoBumps;
   effect spl = spline(x / knotmethod=multiscale(endscale=8)
                             split details);
   model bumpsWithNoise=spl;
   output out=out1 p=pBumps;
run;
proc sgplot data=out1;
   yaxis display=(nolabel);
   series x=x y=bumps;
   series x=x y=pBumps / lineattrs=(color=red);
run;
```

The KNOTMETHOD=MULTISCALE suboption of the EFFECT spl = SPLINE statement provides a convenient way to generate B-spline basis functions at multiple scales. The ENDSCALE=8 option requests that the finest scale use B-splines defined on 2<sup>8</sup> equally spaced knots in the interval [0, 1]. Because the cubic B-splines are nonzero over five adjacent knots, at the finest scale, the support of each B-spline basis function is an interval of length about 0.02 (5/256), enabling the bumps in the underlying data to be resolved. The default value is ENDSCALE=7. At this scale you will still be able to capture the bumps, but with less sharp resolution. For these data, using a value of ENDSCALE= greater than eight provides unneeded resolution, making it more likely that basis functions that fit spurious features in the noise are selected.

Output 45.3.4 shows the model information table. Since no options are specified in the MODEL statement, PROC GLMSELECT uses the stepwise method with selection and stopping based on the SBC criterion.

Output 45.3.4 Model Settings

The Dimensions table in Output 45.3.7 shows that at each step of the selection process, 548 effects are considered as candidates for entry or removal. Note that although the MODEL statement specifies a single constructed effect spl, the SPLIT suboption causes each of the parameters in this constructed effect to be treated as an individual effect.

Output 45.3.7 Dimensions

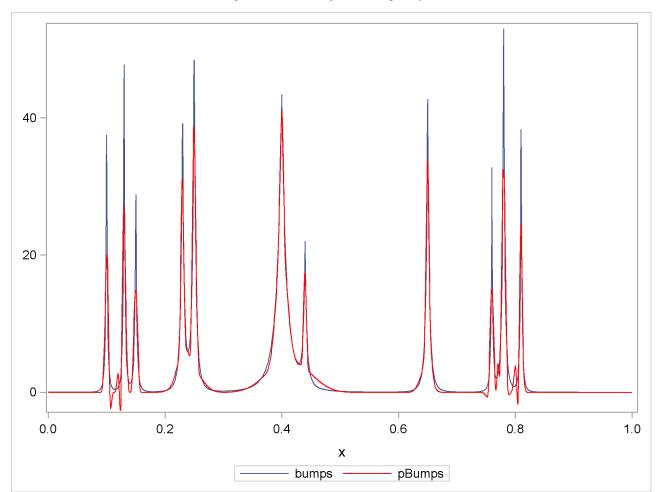

Output 45.3.8 shows the parameter estimates for the selected model. You can see that the selected model contains 31 B-spline basis functions and that all the selected B-spline basis functions are from scales four though eight. For example, the first basis function listed in the parameter estimates table is spl S4:9—the ninth B-spline function at scale 4. You see from Output 45.3.6 that this function is nonzero on the interval (0.29, 0.52).

Output 45.3.8 Parameter Estimates

The OUTPUT statement captures the predicted values in a data set named out1, and Output 45.3.9 shows a fit plot produced by PROC SGPLOT.

Output 45.3.9 Fit by Selecting B-splines

## **Example 45.4: Multimember Effects and the Design Matrix**

This example shows how you can use multimember effects to build predictive models. It also demonstrates several features of the OUTDESIGN= option in the PROC GLMSELECT statement.

The simulated data for this example describe a two-week summer tennis camp. The tennis ability of each camper was assessed and ratings were assigned at the beginning and end of the camp. The camp consisted of supervised group instruction in the mornings with a number of different options in the afternoons. Campers could elect to participate in unsupervised practice and play. Some campers paid for one or more individual lessons from 30 to 90 minutes in length, focusing on forehand and backhand strokes and volleying. The aim of this example is to build a predictive model for the rating improvement of each camper based on the times the camper spent doing each activity and several other variables, including the age, gender, and initial rating of the camper.

The following statements produce the TennisCamp data set:

```
data TennisCamp;
   length forehandCoach $6 backhandCoach $6 volleyCoach $6 gender $1;
   input forehandCoach backhandCoach volleyCoach tLessons tPractice tPlay
         gender inRating nPastCamps age tForehand tBackhand tVolley
         improvement;
   label forehandCoach = "Forehand lesson coach"
         backhandCoach = "Backhand lesson coach"
         volleyCoach = "Volley

```

A multimember effect (see the section "EFFECT Statement" on page 393 of Chapter 19, "Shared Concepts and Topics") is appropriate for modeling the effect of coaches on the campers' improvement, because campers might have worked with multiple coaches. Furthermore, since the time a coach spent with each camper varies, it is appropriate to use these times to weight each coach's contribution in the multimember effect. It is also important not to exclude campers from the analysis if they did not receive any individual instruction. You can accomplish all these goals by using a multimember effect defined as follows:

```
class forehandCoach backhandCoach volleyCoach;
effect coach = MM(forehandCoach backhandCoach volleyCoach/ noeffect
                  weight=(tForehand tBackhand tVolley));
```

Based on similar previous studies, it is known that the time spent practicing should not be included linearly, because there are diminishing returns and perhaps even counterproductive effects beyond about 25 hours. A spline effect with a single knot at 25 provides flexibility in modeling effect of practice time.

The following statements use PROC GLMSELECT to select effects for the model.

Output 45.4.1 shows the class level and MM level information. The levels of the constructed MM effect are the union of the levels of its constituent classification variables. The MM level information is not displayed by default—you request this table by specifying the DETAILS suboption in the relevant EFFECT statement.

Output 45.4.1 Levels of MM EFFECT Coach

	The GLMSELEC	CT Procedure
	Class Level	Information
Class	Levels	Values
forehandCoach backhandCoach volleyCoach gender	5 5 5 2	3
	The GLMSELEC	CT Procedure
Leve	l Details for	r MM Effect coach
Levels	Values	
6	Andy Bruna	a Elaine Greg Mike Tom

Output 45.4.2 shows the parameter estimates for the selected model. You can see that the constructed multimember effect coach and the spline effect practice are both included in the selected model. All coaches provided benefit (all the parameters of the multimember effect coach are positive), with Greg and Mike being the most effective.

Output 45.4.2 Parameter Estimates

Suppose you want to examine regression diagnostics for the selected model. PROC GLMSELECT does not support such diagnostics, so you might want to use the REG procedure to produce these diagnostics. You can overcome the difficulty that PROC REG does not support CLASS and EFFECT statements by using the OUTDESIGN= option in the PROC GLMSELECT statement to obtain the design matrix that you can use as an input data set for further analysis with other SAS procedures.

The following statements use PROC PRINT to produce Output 45.4.3, which shows the first five observations of the design matrix designCamp.

```
proc print data=designCamp(obs=5);
run;
```

Output 45.4.3 First Five Observations of the designCamp Data Set

To facilitate specifying the columns of the design matrix corresponding to the selected model, you can use the macro variable named \_GLSMOD that PROC GLMSELECT creates whenever you specify the OUT-DESIGN= option. The following statements use PROC REG to produce a panel of regression diagnostics corresponding to the model selected by PROC GLMSELECT.

```
ods graphics on;
proc reg data=designCamp;
   model improvement = &_GLSMOD;
quit;
ods graphics off;
```

The regression diagnostics shown in Output 45.4.4 indicate a reasonable model. However, they also reveal the presence of one large outlier and several influential observations that you might want to investigate.

Output 45.4.4 Fit Diagnostics

Sometimes you might want to use subsets of the columns of the design matrix. In such cases, it might be convenient to produce a design matrix with generic names for the columns. You might also want a design matrix containing the columns corresponding to the full model that you specify in the MODEL statement. By default, the design matrix includes only the columns that correspond to effects in the selected model. The following statements show how to do this.

```
proc glmselect data=TennisCamp
     outdesign(fullmodel prefix=parm names)=designCampGeneric;
   class forehandCoach backhandCoach volleyCoach gender;
   effect coach
                  = mm(forehandCoach backhandCoach volleyCoach / noeffect
                         details weight=(tForehand tBackhand tVolley));
   effect practice = spline(tPractice/knotmethod=list(25) details);
   model improvement = coach practice tLessons tPlay age gender
                       inRating nPastCamps;
run;
```

The PREFIX=parm suboption of the OUTDESIGN= option specifies that columns in the design matrix be given the prefix parm with a trailing index. The NAMES suboption requests the table in Output 45.4.5 that associates descriptive labels with the names of columns in the design matrix. Finally, the FULLMODEL suboption specifies that the design matrix include columns corresponding to all effects specified in the MODEL statement.

Output 45.4.5 Descriptive Names of Design Matrix Columns

## **Example 45.5: Model Averaging**

This example shows how you can combine variable selection methods with model averaging to build parsimonious predictive models. This example uses simulated data that consist of observations from the model

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + N(0, \sigma^2)$$

where **X** is drawn from a multivariate normal distribution  $N(0, \mathbf{V})$  with  $V_{i,j} = \rho^{|i-j|}$  where  $0 < \rho < 1$ . This setup has been widely studied in investigations of variable selection methods. For examples, see Breiman (1992); Tibshirani (1996); Zou (2006).

The following statements define a macro that uses the SIMNORMAL procedure to generate the regressors. This macro prepares a TYPE=CORR data set that specifies the desired pairwise correlations. This data set is used as the input data for PROC SIMNORMAL which produces the sampled regressors in an output data set named Regressors.

```
%macro makeRegressorData(nObs=100,nVars=8,rho=0.5,seed=1);
  data varCorr;
     drop i j;
      array x{&nVars};
     length _NAME_ $8 _TYPE_ $8;
     _NAME_ = '';
      TYPE = 'MEAN';
     do j=1 to &nVars; x{j}=0; end;
     output;
      _TYPE_ = 'STD';
```

```
do j=1 to &nVars; x{j}=1;end;
      output;
      _{\text{TYPE}} = 'N';
      do j=1 to &nVars; x\{j\}=10000; end;
      output;
      TYPE = 'CORR';
      do i=1 to &nVars;
         _NAME_="x" || trim(left(i));
         do j= 1 to &nVars;
            x{j}=&rho**(abs(i-j));
         end;
         output;
      end;
   run;
   proc simnormal data=varCorr(type=corr) out=Regressors
               numReal=&nObs seed=&seed;
      var x1-x&nVars;
   run;
%mend;
```

The following statements use the %makeRegressorData macro to generate a sample of 100 observations with 10 regressors, where  $E(\mathbf{X}_i\mathbf{X}_j) = 0.5^{|i-j|}$ , the true coefficients are  $\boldsymbol{\beta}' = (3, 1.5, 0, 0, 2, 0, 0, 0, 0, 0)$ , and  $\sigma = 3$ .

```
%makeRegressorData(nObs=100,nVars=10,rho=0.5);
data simData;
   set regressors;
   yTrue = 3*x1 + 1.5*x2 + 2*x5;
   y = yTrue + 3*rannor(2);
run;
```

The adaptive lasso algorithm (see "Adaptive Lasso Selection" on page 3566) is a modification of the standard lasso algorithm in which weights are applied to each of the parameters in forming the lasso constraint. Zou (2006) shows that the adaptive lasso has theoretical advantages over the standard lasso. Furthermore, simulation studies show that the adaptive lasso tends to perform better than the standard lasso in selecting the correct regressors, particularly in high signal-to-noise ratio cases. The following statements fit an adaptive lasso model to the simData data:

```
proc glmselect data=simData;
  model y=x1-x10/selection=LASSO(adaptive stop=none choose=sbc);
run;
```

The selected model and parameter estimates are shown in Output 45.5.1

Output 45.5.1 Model Selected by Adaptive Lasso

```
The GLMSELECT Procedure
Selected Model

Effects: Intercept x1 x2 x5
```

Output 45.5.1 continued

Param	eter Es	Estimates	
Parameter	DF	Estimate	
Intercept	1	-0.243219	
<b>x1</b>	1	3.246129	
<b>x</b> 2	1	1.310514	
<b>x</b> 5	1	2.132416	

You see that the selected model contains only the relevant regressors x1, x2, and x5. You might want to investigate how frequently the adaptive lasso method selects just the relevant regressors and how stable the corresponding parameter estimates are. In a simulation study, you can do this by drawing new samples and repeating this process many times. What can you do when you only have a single sample of the data available? One approach is to repeatedly draw subsamples from the data that you have, and to fit models for each of these samples. You can then form the average model and use this model for prediction. You can also examine how frequently models are selected, and you can use the frequency of effect selection as a measure of effect importance.

The following statements show how you can use the MODELAVERAGE statement to perform such an analysis:

```
ods graphics on;
proc glmselect data=simData seed=3 plots=(EffectSelectPct ParmDistribution);
   model y=x1-x10/selection=LASSO(adaptive stop=none choose=SBC);
   modelAverage tables=(EffectSelectPct(all) ParmEst(all));
run;
```

The ModelAverageInfo table in Output 45.5.2 shows that the default sampling method is the bootstrap approach of drawing 100 samples with replacement, where the sampling percentage of 100 means that each sample has the same sum of frequencies as the input data. You can use the SAMPLING= and NSAMPLES= options in the MODELAVERAGE statement to modify the sampling method and the number of samples used.

Output 45.5.2 Model Averaging Information

```
The GLMSELECT Procedure

Model Averaging Information

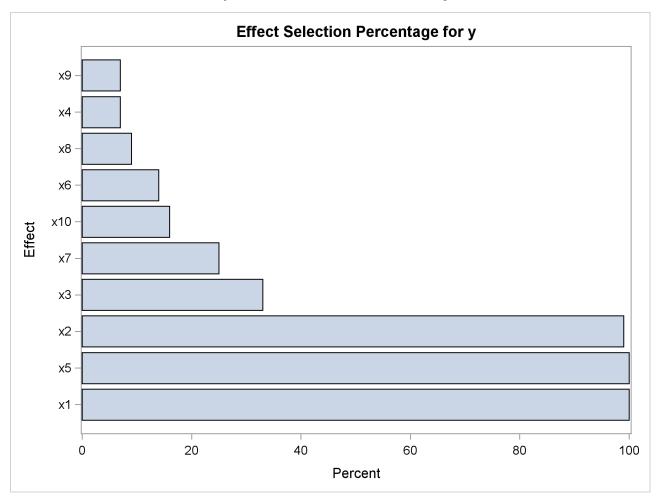

Sampling Method Unrestricted (with replacement)
Sample Percentage 100
Number of Samples 100
```

Output 45.5.3 shows the percentage of samples where each effect is in the selected model. The ALL option of the EFFECTSELECTPCT request in the TABLES= option specifies that effects that appear in any selected model are shown. (By default, the "Effect Selection Percentage" table displays only those effects that are selected at least 20 percent of the time.)

Output 45.5.3 Effect Selection Percentages

Effect Selection Percentage							
Selection							
Effect	Percentage						
<b>x</b> 1	100.0						
<b>x</b> 2	99.00						
<b>x</b> 3	33.00						
×4	7.00						
<b>x</b> 5	100.0						
<b>x</b> 6	14.00						
<b>x</b> 7	25.00						
<b>x</b> 8	9.00						
<b>x</b> 9	7.00						
<b>x10</b>	16.00						

The EFFECTSELECTPCT request in the PLOTS= option in the PROC GLMSELECT statement produces the bar chart shown in Output 45.5.4, which graphically displays the information in the EffectSelectPct table.

Output 45.5.4 Effect Selection Percentages

Output 45.5.5 shows the frequencies with which models get selected. By default, only the "best" 20 models are shown. See the section "Model Selection Frequencies and Frequency Scores" on page 3577 for details about how these models are ordered.

Output 45.5.5 Model Selection Frequency

		Model Se	lection Frequ	ency
		Number		
Times	Selection	of	Frequency	
Selected	Percentage	Effects	Score	Effects in Model
44	44.00	4	45.00	Intercept x1 x2 x5
9	9.00	5	9.86	Intercept x1 x2 x3 x5
8	8.00	6	8.76	Intercept x1 x2 x3 x5 x7
4	4.00	5	4.82	Intercept x1 x2 x5 x8
4	4.00	7	4.67	Intercept x1 x2 x3 x5 x6 x7
3	3.00	5	3.85	Intercept x1 x2 x5 x7
2	2.00	5	2.83	Intercept x1 x2 x5 x10
2	2.00	5	2.81	Intercept x1 x2 x4 x5
2	2.00	6	2.74	Intercept x1 x2 x3 x5 x6
2	2.00	7	2.66	Intercept x1 x2 x3 x5 x6 x10
1	1.00	5	1.83	Intercept x1 x2 x5 x6
1	1.00	4	1.81	Intercept x1 x5 x7
1	1.00	5	1.81	Intercept x1 x2 x5 x9
1	1.00	6	1.75	Intercept x1 x2 x3 x5 x10
1	1.00	6	1.74	Intercept x1 x2 x3 x5 x8
1	1.00	6	1.73	Intercept x1 x2 x5 x6 x7
1	1.00	6	1.72	Intercept x1 x2 x5 x7 x9
1	1.00	6	1.71	Intercept x1 x2 x5 x8 x10
1	1.00	6	1.70	Intercept x1 x2 x4 x5 x10
1	1.00	7	1.68	Intercept x1 x2 x3 x5 x7 x10

You can see that the most frequently selected model is the model that contains just the true underlying regressors. Although this model is selected in 44% of the samples, most of the selected models contain at least one irrelevant regressor. This is not surprising because even though the true model has just a few large effects in this example, the regressors have nontrivial pairwise correlations.

When your goal is simply to obtain a predictive model, then a good strategy is to average the predictions that you get from all the selected models. In the linear model context, this corresponds to using the model whose parameter estimates are the averages of the estimates that you get for each sample, where if a parameter is not in a selected model, the corresponding estimate is defined to be zero. This has the effect of shrinking the estimates of infrequently selected parameters towards zero.

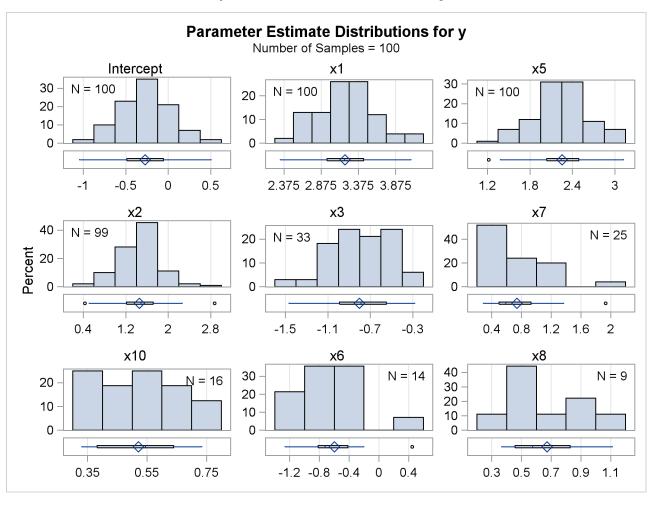

Output 45.5.6 shows the average parameter estimates. The ALL option of the PARMEST request in the TABLES= option specifies that all parameters that are nonzero in any selected model are shown. (By default, the "Average Parameter Estimates" table displays only those parameters that are nonzero in at least 20 percent of the selected models.)

Output 45.5.6 Average Parameter Estimates

<b>x</b> 9		0	0		0

The average estimate for a parameter is computed by dividing the sum of the estimate values for that parameter in each sample by the total number of samples. This corresponds to using zero as the estimate value for the parameter in those samples where the parameter does not appear in the selected model. Similarly, these zero estimates are included in the computation of the estimated standard deviation and quantiles that are displayed in the AvgParmEst table. If you want see the estimates that you get if you do not use zero for nonselected parameters, you can specify the NONZEROPARMS suboption of the PARMEST request in the TABLES=option.

The PARMDISTRIBUTION request in the PLOTS= option in the PROC GLMSELECT statement requests the panel in Output 45.5.7, which shows the distribution of the estimates for each parameter in the average model. For each parameter in the average model, a histogram and box plot of the nonzero values of the estimates are shown. You can use this plot to assess how the selected estimates vary across the samples.

Output 45.5.7 Effect Selection Percentages

You can obtain details about the model selection for each sample by specifying the DETAILS option in the MODELAVERAGE statement. You can use an OUTPUT statement to output the mean predicted value and standard deviation, quantiles of the predicted values, as well as the individual sample frequencies and predicted values for each sample. The following statements show how you do this:

Output 45.5.8 Selection Details for Sample 1

                                                              -1.4887
                                                                       -1.7083
    -7.5840 1.20687 -8.44679 -7.5716
                                      -6.7386 3 1 1 -6.7051
                                                              -9.0558
                                                                       -6.7949
```

By default, the LOWER and UPPER options in the OUTPUT statement produce the lower and upper quartiles of the sample predicted values. You can change the quantiles produced by using the ALPHA= option in the MODELAVERAGE statement. The variables sf1-sf100 contain the sample frequencies used for each sample, and the variables sp1-sp100 hold the corresponding predicted values. Even if you do not specify the DETAILS option in the MODELAVERAGE statement, you can use the sample frequencies in the output data set to reproduce the selection results for any particular sample. For example, the following statements recover the selection for sample 1:

```
proc glmselect data=simOut;
   freq sf1;
   model y=x1-x10/selection=LASSO(adaptive stop=none choose=SBC);
run;
```

The average model is not parsimonious—it includes shrunken estimates of infrequently selected parameters which often correspond to irrelevant regressors. It is tempting to ignore the estimates of infrequently selected parameters by setting their estimate values to zero in the average model. However, this can lead to a poorly performing model. Even though a parameter might occur in only one selected model, it might be a very important term in that model. Ignoring its estimate but including some of the estimates of the other parameters in this model leads to biased predictions. One scenario where this might occur is when the data contains two highly correlated regressors which are both strongly correlated with the response.

You can obtain a parsimonious model by using the frequency of effect selection as a measure of effect importance and refitting a model that contains just the effects that you deem important. In this example, Output 45.5.3 shows that the effects x1, x2, and x5 all get selected at least 99 percent of the time, whereas all other effects get selected less than 34 percent of the time. This large gap suggests that using 35% as the selection cutoff for this data will produce a parsimonious model that retains good predictive performance. You can use the REFIT option to implement this strategy. The REFIT option requests a second round of model averaging, where you use the MINPCT= suboption to specify the minimum percentage of times an effect must be selected in the initial set of samples to be included in the second round of model averaging. The average model is obtained by averaging the ordinary least squares estimates obtained for each sample. The following statements show how you do this:

```
proc glmselect data=simData seed=3 plots=(ParmDistribution);
   model y=x1-x10/selection=LASSO(adaptive stop=none choose=SBC);
   modelAverage refit(minpct=35 nsamples=1000) alpha=0.1;
run;
ods graphics off;
```

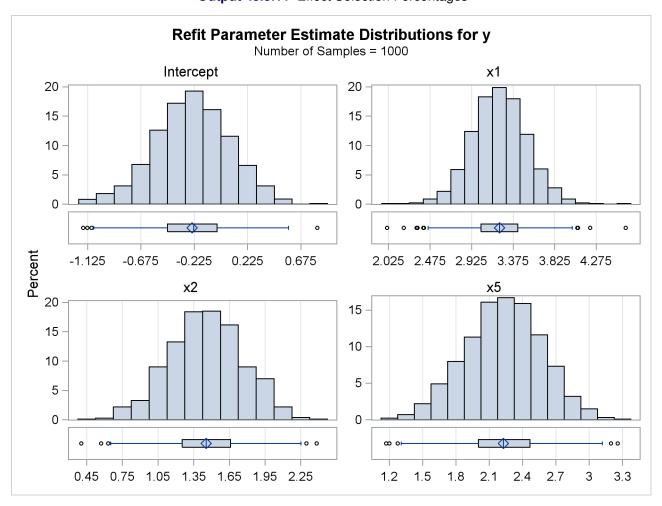

The NSAMPLES=1000 suboption of the REFIT option specifies that 1,000 samples be used in the refit, and the MINPCT=35 suboption specifies the cutoff for inclusion in the refit. The ALPHA=0.1 option specifies that the fifth and 95th percentiles of the estimates be displayed. Output 45.5.10 shows the effects that are used in performing the refit and the resulting average parameter estimates.

Output 45.5.10 Refit Average Parameter Estimates

		The GLMSELECT	Procedure		
	Ref	it Model Aver	aging Results		
	Ef	fects: Interc	ept x1 x2 x5		
	Av	erage Paramet	er Estimates		
Mean StandardEstimate Quantiles					
				<u>z</u>	•
Parameter	Estimate		5%	-	95%
Parameter Intercept		Deviation	5%	Median	
	Estimate	Deviation 0.315207	5%	Median	95% 0.271510
-	Estimate -0.243514	Deviation 0.315207 0.299443	5% -0.762462 2.737843	Median	95% 0.271510 3.708131

Output 45.5.11 displays the distributions of the estimates that are obtained for each parameter in the refit model. Because the distributions are approximately normal and a large number of samples are used, it is reasonable to interpret the range between the fifth and 95th percentiles of each estimate as an approximate 90% confidence interval for that estimate.

Output 45.5.11 Effect Selection Percentages

## **Your Turn**

We welcome your feedback.

- If you have comments about this book, please send them to yourturn@sas.com. Include the full title and page numbers (if applicable).
- If you have comments about the software, please send them to suggest@sas.com.

# **SAS®** Publishing Delivers!

Whether you are new to the work force or an experienced professional, you need to distinguish yourself in this rapidly changing and competitive job market. SAS\* Publishing provides you with a wide range of resources to help you set yourself apart. Visit us online at support.sas.com/bookstore.

#### **SAS®** Press

Need to learn the basics? Struggling with a programming problem? You'll find the expert answers that you need in example-rich books from SAS Press. Written by experienced SAS professionals from around the world, SAS Press books deliver real-world insights on a broad range of topics for all skill levels.

support.sas.com/saspress

#### **SAS®** Documentation

To successfully implement applications using SAS software, companies in every industry and on every continent all turn to the one source for accurate, timely, and reliable information: SAS documentation. We currently produce the following types of reference documentation to improve your work experience:

- Online help that is built into the software.
- Tutorials that are integrated into the product.
- Reference documentation delivered in HTML and PDF free on the Web.
- Hard-copy books.
