Software

The procedures and applications in SAS/STAT software were implemented by the following members of the development staff. Program development includes design, programming, debugging, support, and documentation. In the following list, the names of the developers who currently provide primary support are listed first; other developers and previous developers are also listed.

ACECLUS	Warren F. Kuhfeld, Ann Kuo, Warren S. Sarle, Donna Lucas Watts
ANOVA	Randall D. Tobias, Yang C. Yuan
BOXPLOT	Bucky Ransdell, Robert N. Rodriguez
CALIS	Yiu-Fai Yung
CANCORR	Warren F. Kuhfeld, Ann Kuo, Warren S. Sarle, Donna Lucas Watts
CANDISC	Warren F. Kuhfeld, Warren S. Sarle, Yang C. Yuan
CATMOD	Robert E. Derr, John P. Sall, Donna Lucas Watts
CLUSTER	Bart Killam, Warren S. Sarle
CORRESP	Warren F. Kuhfeld
DISCRIM	Warren F. Kuhfeld, Warren S. Sarle, Yang C. Yuan
DISTANCE	Warren F. Kuhfeld, Ann Kuo
FACTOR	Yiu-Fai Yung, John P. Sall, Warren S. Sarle
FASTCLUS	Bart Killam, Warren S. Sarle, Donna Lucas Watts

FMM	John Castelloe, Oliver Schabenberger
FREQ	Donna Lucas Watts, John P. Sall
GAM	Weijie Cai, Robert Cohen, Randall D. Tobias
GENMOD	Gordon Johnston
GLIMMIX	Min Zhu, Oliver Schabenberger
GLM	Randall D. Tobias, James H. Goodnight, John P. Sall, Warren S. Sarle, Yang C. Yuan
GLMMOD	Randall D. Tobias
GLMPOWER	John Castelloe, Mike Cybrynski
GLMSELECT	Robert Cohen
HPMIXED	Tianlin Wang
INBREED	Wendy Czika, Anthony Baiching An
KDE	Bucky Ransdell, Russell D. Wolfinger
KRIGE2D	Alexander Kolovos, Bart Killam
LATTICE	Randall D. Tobias, Oliver Schabenberger, Russell D. Wolfinger
LIFEREG	Gordon Johnston
LIFETEST	Ying So
LOESS	Robert Cohen
LOGISTIC	Robert E. Derr, Ying So
MCMC	Fang Chen
MDS	Warren S. Sarle, Warren F. Kuhfeld
MI	Yang C. Yuan
MIANALYZE	Yang C. Yuan
MIXED	Tianlin Wang, Oliver Schabenberger, Russell D. Wolfinger
MODECLUS	Warren F. Kuhfeld, Ann Kuo, Warren S. Sarle
MULTTEST	Robert E. Derr, Russell D. Wolfinger
NESTED	Randall D. Tobias, Leigh A. Ihnen
NLIN	Biruk Gebremariam, Don Erdman, James H. Goodnight, Leigh A. Ihnen, Oliver Schabenberger,
NLMIXED	Randall D. Tobias, Oliver Schabenberger, Russell D. Wolfinger
NPAR1WAY	Donna Lucas Watts, Jane Evans, John P. Sall
ORTHOREG	Randall D. Tobias, John P. Sall
PHREG	Ying So
PLAN	Pushpal K Mukhopadhyay, Leigh A. Ihnen, Randall D. Tobias
PLM	Weijie Cai, Robert E. Derr, Oliver Schabenberger
PLS	Randall D. Tobias
POWER	John Castelloe, Mike Cybrynski
Power and Sample Size Application	Wayne Watson
PRINCOMP	Warren F. Kuhfeld, Ann Kuo, Warren S. Sarle
PRINQUAL	Warren F. Kuhfeld
PROBIT	Gordon Johnston
PSS	Wayne Watson
QUANTREG	Guixian Lin
REG	Robert Cohen, Leigh A. Ihnen, John P. Sall
ROBUSTREG	Yonggang Yao

RSREG	Robert E. Derr, John P. Sall, Randall D. Tobias
SCORE	Ann Kuo, Donna Lucas Watts
SEQDESIGN	Yang C. Yuan
SEQTEST	Yang C. Yuan
SIM2D	Alexander Kolovos, Bart Killam
SIMNORMAL	Bart Killam
STDIZE	Amy Shi, Warren F. Kuhfeld, Ann Kuo
STEPDISC	Warren F. Kuhfeld, Warren S. Sarle, Yang C. Yuan
SURVEYFREQ	Donna Lucas Watts
SURVEYLOGISTIC	Anthony Baiching An, Pushpal K Mukhopadhyay
SURVEYMEANS	Anthony Baiching An
SURVEYPHREG	Pushpal K Mukhopadhyay
SURVEYREG	Anthony Baiching An, Pushpal K Mukhopadhyay
SURVEYSELECT	Donna Lucas Watts
TPSPLINE	Weijie Cai, Randall D. Tobias
TRANSREG	Warren F. Kuhfeld
TREE	Bucky Ransdell, Warren S. Sarle
TTEST	John Castelloe, James H. Goodnight, Padraic Neville, Warren S. Sarle
VARCLUS	Warren S. Sarle
VARCOMP	Tianlin Wang, James H. Goodnight, Oliver Schabenberger, Randall D. Tobias, Russell D. Wolfinger
VARIOGRAM	Alexander Kolovos, Bart Killam
Probability Routines	Georges Guirguis
Numerical and Graphical Routines	Anthony Baiching An, Fang Chen, Robert Cohen, Mike Cybrynski, Robert E. Derr, Jane Evans, Georges Guirguis, Warren F. Kuhfeld, Warren S. Sarle, Oliver Schabenberger, Randall D. Tobias, Donna Lucas Watts, Yang C. Yuan, Leigh A. Ihnen, Richard D. Langston, Katherine Ng, John P. Sall, Tianlin Wang

The following people contribute to SAS/STAT software with their leadership and support: Robert Cohen, Robert E. Derr, Warren F. Kuhfeld, Robert N. Rodriguez, Maura E. Stokes, and Randall D. Tobias.

Testing

Shu An, Jack J. Berry, Ming-Chun Chang, Bruce Elsheimer, Betsy Enstrom, Gregory D. Goodwin, Gerardo I. Hurtado, Cheryl LeSaint, Yu Liang, Fouad G. Younan, Wei Zhang

Technical Support

Rob Agnelli, Phil Gibbs, Duane Hayes, Elizabeth S. Edwards, Kathleen Kiernan, Paul T. Savarese, David Schlotzhauer, Jill Tao

Acknowledgments

Many people make significant and continuing contributions to the development of SAS software products. The following are some of the people who have contributed significant amounts of their time to help us make improvements to SAS/STAT software. This includes research and consulting, testing, and reviewing documentation. We are grateful for the involvement of these members of the statistical community and the many others who are not mentioned here for their feedback, suggestions, and consulting.

Alan Agresti, University of Florida; Paul Allison, University of Pennsylvania; Douglas Bates, University of Wisconsin; John Barnard Jr., Cleveland Clinic Foundation; David Binder, David Binder Research; Suzette Blanchard, Frontier Science Technology Research Foundation; Mary Butler Moore, formerly of University of Florida at Gainesville; Wilbert P. Byrd, Clemson University; Vincent Carey, Harvard University; Sally Carson, RAND; Love Casanova, CSC-FSG; Helene Cavior, Abacus Concepts; Rao Chaganty, Old Dominion University; George Chao, DuPont Merek Pharmaceutical Company; Colin Chen, Fannie Mae; Daniel M. Chilko, West Virginia University; Marc Cohen, Fair Isaac Corporation; Jan de Leeuw, University of California, Los Angeles; Dave DeLong, Duke University; Alex Dmitrienko, Eli Lilly; Sandra Donaghy, North Carolina State University; David B. Duncan, Johns Hopkins University; Paul Eilers, Leiden University; Scott Emerson, University of Washington; Michael Farrell, Oak Ridge National Laboratory; Stewart Fossceco, SLF Consulting; Michael Friendly, York University; Rudolf J. Freund, Texas A&M University; Wayne Fuller, Iowa State University; Andrzej Galecki, University of Michigan; A. Proctor, North Carolina State University; Bahjat Qaqish, University of North Carolina at Chapel Hill; Dana Quade, University of North Carolina at Chapel Hill; Bill Raynor, Kimberly Clark; Georgia Roberts, Statistics Canada; James Roger, GlaxoSmithKline; Peter Rousseeuw, University of Antwerp; Donald Rubin, Harvard University; Joseph L. Schafer, Pennsylvania State University; Robert Schechter, AstraZeneca; Shayle Searle, Cornell University; Pat Hermes Smith, formerly of Ciba-Geigy; Roger Smith, formerly of USDA; Phil Spector, University of California, Berkeley; Michael Speed, Texas A&M University at College Station; William Stanish, Statistical Insight; Rodney Strand, Orion Enterprises, LLC; Walter Stroup, University of Nebraska; Robert Teichman, ICI Americas Inc.; Terry M. Therneau, Mayo Clinic; Edward Vonesh, Northwestern University; Grace Wahba, University of Wisconsin at Madison; Glenn Ware, University of Georgia; Peter H. Westfall, Texas Tech University; Edward W. Whitehorne, CI Partners, LLC; William Wigton, USDA; William Wilson, University of North Florida; Philip Whittall, Unilever (retired); Dong Xiang; Victor Yohai, University of Buenos Aires; Forrest W. Young (deceased), formerly of University of North Carolina at Chapel Hill; Ruben Zamar, University of British Columbia; Scott Zeger, Johns Hopkins University

The final responsibility for the SAS System lies with SAS alone. We hope that you will always let us know your opinions about the SAS System and its documentation. It is through your participation that SAS software is continuously improved.

Please see Feedback at `http://www.sas.com/statistics/` for your comments.

Chapter 1

What's New in SAS/STAT 9.3

Contents

Overview

SAS/STAT 9.3 includes one new procedure and many enhancements.

New Experimental FMM Procedure

The experimental FMM procedure fits statistical models to data where the distribution of the response is a finite mixture of univariate distributions. These models are useful for applications such as estimating multimodal or heavy-tailed densities, fitting zero-inflated or hurdle models to count data with excess zeros, modeling overdispersed data, and fitting regression models with complex error distributions.

PROC FMM fits finite mixtures of regression models or finite mixtures of generalized linear models in which the regression structure and the covariates can be the same across components or different. Maximum likelihood and Bayesian methods are available with the FMM procedure.

Highlights of Enhancements

The following are the highlights of the enhancements in SAS/STAT 9.3:

- The EFFECT statement is now production. This statement is available in the HPMIXED, GLIMMIX, GLMSELECT, LOGISTIC, ORTHOREG, PHREG, PLS, QUANTREG, ROBUSTREG, SURVEYLOGISTIC, and SURVEYREG procedures.
- The MCMC procedure now supports the RANDOM statement.
- The METHOD=FIML option in the CALIS procedure is now production. This option specifies the full information maximum likelihood method. Instead of deleting observations with missing values, the full information maximum likelihood method uses all available information from all observations.
- The SURVEYPHREG procedure is now production.
- The HPMIXED procedure now provides a REPEATED statement and additional covariance structures.
- The MI procedure offers fully conditional specification methods for multiple imputation.

More information about the changes and enhancements follows. Details can be found in the documentation for the individual procedures in the *SAS/STAT 9.3 User's Guide*.

Highlights of Enhancements in SAS/STAT 9.22

Some users might be unfamiliar with updates made in SAS/STAT 9.22. The following are some of the major enhancements that were introduced in SAS/STAT 9.22:

- The experimental SURVEYPHREG procedure performs regression analysis based on the Cox proportional hazards model for sample survey data. The procedure provides design-based variance estimates, confidence intervals, and hypothesis tests concerning the parameters and model effects.
- The PLM procedure takes model results that are stored from SAS/STAT linear modeling procedures and performs additional postfitting inferences without your having to repeat your original analysis. The PLM procedure can perform tasks such as testing hypotheses, computing confidence intervals, producing prediction plots, and scoring new data sets by using familiar statements such as the ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements.
- The EFFECT statement is now available in the GLIMMIX, GLMSELECT, HPMIXED, ORTHOREG, PHREG, PLS, QUANTREG, ROBUSTREG, SURVEYLOGISTIC, and SURVEYREG procedures. This statement enables you to construct a much richer family of linear models than you can traditionally define with the CLASS statement. Effect types include splines for semiparametric modeling, multimember effects for situations in which measurements can belong to more than one class, lag effects, and polynomials.
- Exact Poisson regression is now available with the GENMOD procedure.
- The MCMC procedure can create samples from the posterior predictive distribution.
- The zero-inflated negative binomial model is now available with the GENMOD procedure.
- The HPMIXED procedure is now production.
- The CALIS procedure has been completely revised and includes enhancements that were formerly available in the experimental TCALIS procedure.

ODS Graphics Changes

Producing graphs with ODS Graphics no longer requires a SAS/GRAPH® license. In addition, the family of statistical graphics procedures (SGPANEL, SGPLOT, SGRENDER, and SGSCATTER) has moved from SAS/GRAPH to Base SAS® license.

The MAXPOINTS= option has been added to the ANOVA, CLUSTER, GLM, LOGISTIC, MIXED, QUANTREG, and VARCLUS procedures. This option specifies a limit for the number of points that can be displayed on certain plots, and these plots are not created when this limit is exceeded. Note that the REG procedure already provided this option.

The frequency plots and cumulative frequency plots of PROC FREQ and the weighted frequency plot of PROC SURVEYFREQ are no longer produced automatically when ODS Graphics is enabled. You can request these graphs with the PLOTS= option.

In SAS 9.3, the default destination in the SAS windowing environment is HTML; in addition, ODS Graphics is enabled by default in the SAS windowing environment. These new defaults have several advantages. Graphs are integrated with tables, and all output is displayed in the same HTML file using a new style. This new style, HTMLBLUE, is an all-color style, which is designed to integrate tables and modern statistical graphics. You can view and modify the default settings by selecting **Tools ► Options ► Preference** from the menu at the top of the main SAS window. Then click the **Results** Tab.

Enhancements

CALIS Procedure

The following features are now production:

- METHOD=FIML option
- mean structure analysis with the COSAN model
- extended PATH modeling language that supports the specification of variances or covariances as paths
- unnamed free parameter specification in all model types
- improved RAM model specification

In addition, PROC CALIS now provides detailed analysis of the missing patterns with the FIML estimation method. With the COVPATTERN= and MEANPATTERN= options, you can specify various standard mean and covariance patterns by using keywords. PROC CALIS then generates the required covariance and mean structures automatically.

CLUSTER Procedure

The CLUSTER procedure now produces a dendrogram by default when ODS Graphics is enabled. The MAXCLUS= option enables you to right-truncate the CCC, PSF, and PST2 plots to improve readability. The MAXPOINTS= option enables you to suppress the dendrogram when there is a large number of clusters.

EFFECT Statement

The EFFECT statement is now production. This statement is available in the HPMIXED, GLIMMIX, GLMSELECT, LOGISTIC, ORTHOREG, PHREG, PLS, QUANTREG, ROBUSTREG, SURVEYLOGISTIC, and SURVEYREG procedures.

The NATURALCUBIC option specifies a natural cubic spline basis for the spline expansion.

EFFECTPLOT Statement

The CLUSTER option modifies the box plot display by displaying a plot for each level of the SLICEBY= classification variable.

FREQ Procedure

The FREQ procedure now produces agreement plots when the AGREE option is specified and ODS Graphics is enabled. It also offers a number of alternative confidence limits for the proportion difference, and it provides exact unconditional confidence limits for the proportion difference that are based on the Farrington-Manning score statistic.

GENMOD Procedure

The EXACTMAX option in the MODEL statement limits the number of response values for exact Poisson regression.

GLIMMIX Procedure

The EFFECT statement is now production.

GLMPOWER Procedure

The GLMPOWER procedure now produces its graphs with ODS Graphics.

GLMSELECT Procedure

The GLMSELECT procedure now provides a STORE statement which enables you to save the context and results of the statistical analysis for further processing with the PLM procedure.

The MODELAVERAGE statement, which specifies model selection on resampled subsets of the input data, is now production.

The EFFECT statement is now production.

HPMIXED Procedure

The HPMIXED procedure now provides the REPEATED statement, which defines the repeated effect and the residual covariance structure in the mixed model. The AR(1), CS, CSH, UC, UCH, and UN covariance structures are now available with the TYPE= option in the RANDOM statement.

The EFFECT statement is now production.

LIFETEST Procedure

The X axis tick marks are now aligned with the at-risk values in the survival plot.

The survival plot template is available in the SAS sample library in macro form, which makes it easier to modify.

LOGISTIC Procedure

You can now request that standardized residuals be saved in the output data set. In addition, the STDRES suboption of the INFLUENCE option in the MODEL statement includes standardized residuals and likelihood residuals in the resulting display. The FITSTAT option in the SCORE statement produces the AIC, SBC, RSq, AUC, and Brier score fit statistics. Additionally, the ODDSRATIO statement and the CLDISPLAY= suboption of the CLODDS option control the appearance of the confidence limit error bars.

The EFFECT statement is now production.

MCMC Procedure

The new RANDOM statement simplifies the construction of hierarchical random-effects models and significantly reduces simulation time while improving convergence, especially in models with a large number of subjects or clusters. This statement defines random effects that can enter the model in a linear or nonlinear fashion and supports univariate and multivariate prior distributions.

In addition to the default Metropolis-based algorithms, PROC MCMC now takes advantages of certain forms of conjugacy in the model in order to sample directly from the target conditional distributions. In

many situations, the conjugate sampler increases sampling efficiency and provides a substantial reduction in computing time.

The MCMC procedure now supports multivariate distributions including the Dirichlet, inverse Wishart, multivariate normal, and multinomial distributions.

MI Procedure

The experimental FCS statement specifies a multivariate imputation by fully conditional specification (FCS) methods. For data with an arbitrary missing data pattern, these methods enable you to impute missing values for all variables, assuming that a joint distribution for these variables exists. The FCS method requires fewer iterations than the MCMC method.

MULTTEST Procedure

The STOUFFER option in the PROC statement produces adjusted p-values by using the Stouffer-Liptak combination method.

NLIN Procedure

The NLIN procedure provides several experimental features for diagnosing your nonlinear model fit, including the PLOTS, NLINMEASURES, and BIAS options in the PROC NLIN statement, in addition to producing observation-wise statistics in the OUTPUT data set. The PLOTS option enables you to plot the fitted model, fit diagnostics, tangential and Jacobian leverage, and local influence. The NLINMEASURES displays global measures of nonlinearity, and the BIAS option computes Box's bias statistics for the parameter estimates. Finally, you can add the leverage, local influence, and residual diagnostics in the output data set that is produced with the OUTPUT statement.

ORTHOREG Procedure

The EFFECT statement is now production.

PHREG Procedure

The PHREG procedure now fits frailty models with the addition of the RANDOM statement. You often use frailty models when you analyze clustered data and want to account for the within-cluster correlation with

random effects. In addition, the NLOPTIONS statement is available with PROC PHREG, and the Zellner g-prior is now available for the piecewise exponential model.

The EFFECT statement is production.

PLS Procedure

The EFFECT statement is now production.

POWER Procedure

Graphs are now produced with ODS Graphics.

QUANTREG Procedure

The new QINTERACT option in the TEST statement enables you to test whether any difference exists among the coefficients across quantiles if several quantiles are specified in the MODEL statement.

The RANKSCORE option in the TEST statement now supports the tau score function, which is appropriate for non-iid error models.

The EFFECT statement is now production.

ROBUSTREG Procedure

The new MCDINFO suboption of the LEVERAGE option in the MODEL statement displays detailed information about the MCD covariance estimate, including the low-dimensional structure, the breakdown value, the MCD center, and the MCD covariance.

The EFFECT statement is now production.

SURVEYFREQ Procedure

You can now produce Rao-Scott chi-square tests with second-order corrections.

SURVEYLOGISTIC Procedure

Replication variance estimation is now available for domain analysis.

The EFFECT statement is now production.

SURVEYMEANS Procedure

Variance estimation based on replication methods is now available for quantiles.

SURVEYPHREG Procedure

The SURVEYPHREG procedure is now production. Also, the addition of programming statements enables you to include time-dependent covariates in the model.

SURVEYREG Procedure

The SURVEYREG procedure now provides replication variance estimation for domain analysis.

The EFFECT statement is now production.

SURVEYSELECT Procedure

Instead of specifying the total sample size to allocate among the strata, you can specify the desired margin of error for estimating the overall mean from the stratified sample.

VARCLUS Procedure

The VARCLUS procedure now produces a dendrogram by default when ODS Graphics is enabled. The MAXPOINTS= option enables you to suppress the dendrogram when there is a large number of clusters.

What's Changed

What follows are changes in software behavior from SAS/STAT 9.22 to SAS/STAT 9.3. Several of these changes are related to ODS Graphics. A few procedures have adopted the MAXPOINTS= option as a way to avoid producing plots when the number of points exceeds a specified limit. The default limit is 5,000 points.

ANOVA Procedure

Box plots, which are created with the MEANS statement or for one-way ANOVA when ODS Graphics is enabled, are not produced when the number of outlier points exceeds the limit, which is controlled by the MAXPOINTS= option.

CLUSTER Procedure

The CLUSTER procedure now produces a dendrogram by default when ODS Graphics is enabled.

FREQ Procedure

Frequency plots and cumulative frequency plots are no longer produced by default when ODS Graphics is enabled. You can request these plots with the PLOTS=FREQPLOT and PLOTS=CUMFREQPLOT options in the TABLES statement.

GLM Procedure

The fit plot, box plot, interaction plot, ANCOVA plot, and contour fit plot are not produced when the number of points exceeds the limit, which is contolled by the MAXPOINTS= option. This limit also applies to diagnostic plots and residual plots.

LOGISTIC Procedure

Plots associated with the INFLUENCE or IPLOTS= options in the MODEL statement are not produced when the number of points exceeds the limit, which is controlled by the MAXPOINTS= option.

If the ODDSRATIO statement or CLODDS= option is specified, the default "Odds Ratio" table is no longer produced, and only the requested results are displayed.

MCMC Procedure

PROC MCMC no longer produces the tuning, burn-in, and sampling history tables by default. To produce this information, specify the MCHISTORY= option in the PROC MCMC statement.

The scaled inverse chi-square distribution is parameterized in terms of $scale^2$, as opposed to *scale* in the previous release.

MIXED Procedure

Plots associated with the INFLUENCE, RESIDUAL, and VCIRY options are not produced when the number of points exceeds the limit, which is controlled by the MAXPOINTS= option.

QUANTREG Procedure

The fit plot is not produced when the number of points exceeds the limit, which is controlled by the MAXPOINTS= option.

The rank score test has changed.

SURVEYFREQ Procedure

The weighted frequency plot is no longer produced by default when ODS Graphics is enabled. You can request this display with the PLOTS=WTFREQPLOT option in the TABLES statement.

VARCLUS Procedure

The VARCLUS procedure now produces a dendrogram by default when ODS Graphics is enabled.

Chapter 2

Introduction

Contents

Overview of SAS/STAT Software

SAS/STAT software provides comprehensive statistical tools for a wide range of statistical analyses, including analysis of variance, categorical data analysis, cluster analysis, multiple imputation, multivariate analysis, nonparametric analysis, power and sample size computations, psychometric analysis, regression, survey data analysis, and survival analysis. A few examples include nonlinear mixed models, generalized linear models, correspondence analysis, and robust regression. The software is constantly being updated to reflect new methodology.

In addition to over sixty procedures for statistical analysis, SAS/STAT software also includes the Market Research Application (MRA), a point-and-click interface to commonly used techniques in market research. The Analyst Application provides convenient access to some of the more commonly used statistical analyses in SAS/STAT software including analysis of variance, regression, logistic regression, mixed models, survival analysis, and some multivariate techniques. Also, the Power and Sample Size Application (PSS) is an interface to power and sample size computations. The Analyst Application and MRA are documented separately.

Experimental Software

Experimental software is sometimes included as part of a production-release product. It is provided to (sometimes targeted) customers in order to obtain feedback. All experimental uses are marked Experimental in this document. Whenever an experimental procedure, statement, or option is used, a message is printed to the SAS log to indicate that it is experimental.

The design and syntax of experimental software might change before any production release. Experimental software has been tested prior to release, but it has not necessarily been tested to production-quality standards, and so should be used with care.

About This Book

Since SAS/STAT software is a part of the SAS System, this book assumes that you are familiar with Base SAS software and with the books *SAS Language Reference: Concepts* and the *Base SAS Procedures Guide*. It also assumes that you are familiar with basic SAS System concepts such as creating SAS data sets with the DATA step and manipulating SAS data sets with the procedures in Base SAS software (for example, the PRINT and SORT procedures).

Chapter Organization

This book is organized as follows.

Chapter 1, "What's New in SAS/STAT 9.3," provides information about the changes and enhancements to SAS/STAT software in SAS 9.3.

Chapter 2, this chapter, provides an overview of SAS/STAT software and summarizes related information, products, and services. The remaining introductory chapters (Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," through Chapter 17, "Introduction to Structural Equation Modeling with Latent Variables,") provide an introduction to the broad areas covered by SAS/STAT software.

Chapter 18, "Introduction to Power and Sample Size Analysis," provides documentation for the Power and Sample Size Application (PSS).

Chapter 19, "Shared Concepts and Topics," provides information about topics that are common to multiple procedures. Topics include parameterization of model effects, the EFFECT statement, and the NLOPTIONS statement. Starting in SAS/STAT 9.22, this chapter also documents the following statements that are used for postfitting analysis and are common across many modeling procedures: EFFECTPLOT, ESTIMATE, LSMEANS, LSMESTIMATE, SLICE, STORE, and TEST.

Chapter 20, "Using the Output Delivery System," explains the fundamentals of using the Output Delivery System (ODS) to manage your SAS output.

Chapter 21, "Statistical Graphics Using ODS," describes the extension to ODS that enables many statistical procedures to create statistical graphics as easily as they create tables.

Subsequent chapters describe the SAS procedures that make up SAS/STAT software. These chapters appear in alphabetical order by procedure name and are organized as follows:

- The "Overview" section provides a brief description of the analysis provided by the procedure.
- The "Getting Started" section provides a quick introduction to the procedure through a simple example.
- The "Syntax" section describes the SAS statements and options that control the procedure.
- The "Details" section discusses methodology and miscellaneous details, such as ODS tables and ODS graphics.
- The "Examples" section contains examples that use the procedure.
- The "References" section contains references for the methodology and for examples of the procedure.

Following the chapters on the SAS/STAT procedures, Chapter A, "Special SAS Data Sets," documents the special SAS data sets that are associated with SAS/STAT procedures.

Typographical Conventions

This book uses several type styles for presenting information. The following list explains the meaning of the typographical conventions used in this book:

roman	is the standard type style used for most text.
UPPERCASE ROMAN	is used for SAS statements, options, and other SAS language elements when they appear in the text. However, you can enter these elements in your own SAS programs in lowercase, uppercase, or a mixture of the two.
UPPERCASE BOLD	is used in the "Syntax" sections' initial lists of SAS statements and options.
oblique	is used for user-supplied values for options in the syntax definitions. In the text, these values are written in *italic*.

VariableName	is used for the names of variables and data sets when they appear in the text.
bold	is used to refer to matrices and vectors.
italic	is used for terms that are defined in the text, for emphasis, and for references to publications.
`monospace`	is used for example code. In most cases, this book uses lowercase type for SAS code.

Options Used in Examples

Output of Examples

Most of the output shown in this book is produced with the following SAS System options:

```
options linesize=80 pagesize=500 nonumber nodate;
```

The HTMLBLUE style is used to create the HTML output and graphs that appear in the online documentation. A style template controls stylistic elements such as colors, fonts, and presentation attributes. The style template is specified in the ODS HTML statement as follows:

```
ods html style=HTMLBlue;
```

See Chapter 21, "Statistical Graphics Using ODS," for more information about styles.

If you run the examples, you might get slightly different output. This is a function of the SAS System options used and the precision used by your computer for floating-point calculations.

Where to Turn for More Information

This section describes other sources of information about SAS/STAT software.

Accessing the SAS/STAT Sample Library

The SAS/STAT sample library includes many examples that illustrate the use of SAS/STAT software, including the examples used in this documentation. To access these sample programs from the SAS windowing environment, select **Help** from the main menu and then select **Getting Started with SAS Software**. On the **Contents** tab, expand the **Learning to Use SAS**, **Sample SAS Programs**, and **SAS/STAT** items. Then click **Samples**.

Sashelp Data Sets

SAS provides over 200 data sets in the Sashelp library. These data sets are available for you to use for examples and for testing code. For example, the following step uses the Sashelp.Class data set:

```
proc reg data=sashelp.class;
   model weight = height;
run; quit;
```

You do not need to provide a DATA step to use Sashelp data sets.

The following steps list all of the data sets that are available in Sashelp:

```
ods listing close;
proc contents data=sashelp._all_;
   ods output members=m;
run;
ods listing;

proc print;
   where memtype = 'DATA';
run;
```

The results of these steps (over 200 data set names) are not displayed.

The following steps provide detailed information about the Sashelp data sets:

```
proc contents data=sashelp._all_;
run;
```

The results of this step (hundreds of pages of PROC CONTENTS information) are not displayed. See Chapter B, "Sashelp Data Sets," for more information about Sashelp data sets.

Online Documentation

This documentation is available online with the SAS System. To access SAS/STAT documentation from the SAS windowing environment, select **Help** from the main menu and then select **SAS Help and Documentation**. (Alternatively, you can type **help STAT** in the command line.) On the **Contents** tab, expand the **SAS Products**, **SAS/STAT**, and **SAS/STAT User's Guide** items. Then expand chapters and click on sections. You can search the documentation by using the **Search** tab.

You can also access the documentation by going to `http://support.sas.com/documentation`.

SAS Technical Support Services

As with all SAS products, the SAS Technical Support staff is available to respond to problems and answer technical questions regarding the use of SAS/STAT software. Go to `http://support.sas.com/techsup` for more information.

Related SAS Software

Many features not found in SAS/STAT software are available in other parts of the SAS System. If you do not find something you need in SAS/STAT software, try looking for the feature in the following SAS software products.

SAS/IML Software

SAS/IML software gives you access to a powerful and flexible programming language (Interactive Matrix Language) in a dynamic, interactive environment. The fundamental object of the language is a data matrix. You can use SAS/IML software interactively (at the statement level) to see results immediately, or you can store statements in a module and execute them later. The programming is dynamic because necessary activities such as memory allocation and dimensioning of matrices are done automatically. SAS/IML software is of interest to users of SAS/STAT software because it enables you to program your methods in the SAS System.

Base SAS Software

The features provided by SAS/STAT software are in addition to the features provided by Base SAS software. Many data management and reporting capabilities you will need are part of Base SAS software. Refer to *SAS Language Reference: Concepts*, *SAS Language Reference: Dictionary*, and the *Base SAS Procedures Guide* for documentation of Base SAS software.

ODS Graphics

Base SAS software provides the following:

- The SG family of procedures provides a simple syntax for creating stand-alone statistical graphics. These procedures include SGPLOT, SGSCATTER, and SGPANEL, which provide a simple and con-

venient syntax for producing many types of displays. They are particularly convenient for exploring and presenting data. See the *SAS ODS Graphics: Procedures Guide* for more information.

- The GTL (Graph Template Language) and the SGRENDER procedure provide a powerful syntax for creating customized graphs. See the *SAS Graph Template Language: User's Guide* and the *SAS Graph Template Language: Reference* for more information. You can also use the GTL to modify the SAS templates that are provided for use with SAS/STAT procedures. See Chapter 22, "ODS Graphics Template Modification," for more information about template modification.
- The ODS Graphics Editor enables you to make immediate changes to ODS Graphics by using a point-and-click interface. See the *SAS ODS Graphics Editor: User's Guide* for more information.

See Chapter 21, "Statistical Graphics Using ODS," for more information about ODS Graphics.

SAS DATA Step

The DATA step is your primary tool for reading and processing data in the SAS System. The DATA step provides a powerful general purpose programming language that enables you to perform all kinds of data processing tasks. The DATA step is documented in *SAS Language Reference: Concepts*.

Base SAS Procedures

Base SAS software includes many useful SAS procedures. Base SAS procedures are documented in the *Base SAS Procedures Guide*. The following is a list of Base SAS procedures you might find useful:

CORR	computes correlations.
RANK	computes rankings or order statistics.
STANDARD	standardizes variables to a fixed mean and variance.
MEANS	computes descriptive statistics and summarizes or collapses data over cross sections.
TABULATE	prints descriptive statistics in tabular format.
UNIVARIATE	computes descriptive statistics.

SAS/ETS Software

SAS/ETS software provides SAS procedures for econometrics and time series analysis. It includes capabilities for forecasting, systems modeling and simulation, seasonal adjustment, and financial analysis and reporting. In addition, SAS/ETS software includes an interactive time series forecasting system.

SAS/GRAPH Software

SAS/GRAPH software includes procedures that create two- and three-dimensional plots and charts.

SAS/INSIGHT Software

SAS/INSIGHT software is a highly interactive tool for data analysis. You can explore data through a variety of interactive graphs including bar charts, scatter plots, box plots, and three-dimensional rotating plots. You can examine distributions and perform parametric and nonparametric regression, analyze general linear models and generalized linear models, examine correlation matrices, and perform principal component analyses. Any changes you make to your data show immediately in all graphs and analyses. You can also configure SAS/INSIGHT software to produce graphs and analyses tailored to the way you work.

SAS/INSIGHT software might be of interest to users of SAS/STAT software for interactive graphical viewing of data, editing data, exploratory data analysis, and checking distributional assumptions.

SAS/OR Software

SAS/OR software provides SAS procedures for operations research and project planning and includes a point-and-click interface to project management. Its capabilities include the following:

- solving transportation problems
- linear, integer, and mixed-integer programming
- nonlinear programming
- scheduling projects
- plotting Gantt charts
- drawing network diagrams
- solving optimal assignment problems
- network flow programming

SAS/OR software might be of interest to users of SAS/STAT software for its mathematical programming features. In particular, the NLP procedure in SAS/OR software solves nonlinear programming problems, and it can be used for constrained and unconstrained maximization of user-defined likelihood functions.

SAS/QC Software

SAS/QC software provides a variety of procedures for statistical quality control and quality improvement. SAS/QC software includes procedures for the following:

- Shewhart control charts
- cumulative sum control charts
- moving average control charts
- process capability analysis
- Ishikawa diagrams
- Pareto charts
- experimental design

SAS/QC software also includes the ADX interface for experimental design.

SAS/IML Studio

Many users of SAS/STAT software will be interested in SAS/IML Studio, which is new in SAS 9.2 software. Formerly known as SAS Stat Studio, SAS/IML Studio is a tool for data exploration and analysis; it provides a highly flexible programming environment in which you can run SAS/STAT or SAS/IML analyses and display the results with dynamically linked graphics and data tables. You can also move seamlessly between interactive analysis and programatically driven analysis. SAS/IML Studio is intended for data analysts who write SAS programs to solve statistical problems but need more versatility for data exploration and model building.

The programming language in SAS/IML Studio, which is called *IMLPlus*, is an enhanced version of the SAS/IML programming language. IMLPlus extends SAS/IML by providing features such as the ability to create and manipulate dynamically linked graphs and the ability to call SAS procedures.

SAS/IML Studio also includes an interface to the R language. The IMLPlus language provides functions that transfer data between SAS data sets and R data frames, and between SAS/IML matrices and R matrices.

SAS/IML Studio runs on a PC in the Microsoft Windows operating environment. For more information about SAS/IML Studio, see the *SAS/IML Studio User's Guide* and *SAS/IML Studio for SAS/STAT Users*.

Chapter 3

Introduction to Statistical Modeling with SAS/STAT Software

Contents

Overview: Statistical Modeling

There are more than 70 procedures in SAS/STAT software, and the majority of them are dedicated to solving problems in statistical modeling. The goal of this chapter is to provide a roadmap to statistical models and to modeling tasks, enabling you to make informed choices about the appropriate modeling context and tool. This chapter also introduces important terminology, notation, and concepts used throughout this documentation. Subsequent introductory chapters discuss model families and related procedures.

It is difficult to capture the complexity of statistical models in a simple scheme, so the classification used here is necessarily incomplete. It is most practical to classify models in terms of simple criteria, such as the presence of random effects, the presence of nonlinearity, characteristics of the data, and so on. That is the approach used here. After a brief introduction to statistical modeling in general terms, the chapter describes a number of model classifications and relates them to modeling tools in SAS/STAT software.

Statistical Models

Deterministic and Stochastic Models

Purely mathematical models, in which the relationships between inputs and outputs are captured entirely in deterministic fashion, can be important theoretical tools but are impractical for describing observational, experimental, or survey data. For such phenomena, researchers usually allow the model to draw on stochastic as well as deterministic elements. When the uncertainty of realizations leads to the inclusion of random components, the resulting models are called *stochastic* models. A *statistical* model, finally, is a stochastic model that contains *parameters*, which are unknown constants that need to be estimated based on assumptions about the model and the observed data.

There are many reasons why statistical models are preferred over deterministic models. For example:

- Randomness is often introduced into a system in order to achieve a certain balance or representativeness. For example, random assignment of treatments to experimental units allows unbiased inferences about treatment effects. As another example, selecting individuals for a survey sample by random mechanisms ensures a representative sample.
- Even if a deterministic model can be formulated for the phenomenon under study, a stochastic model can provide a more parsimonious and more easily comprehended description. For example, it is possible in principle to capture the result of a coin toss with a deterministic model, taking into account the properties of the coin, the method of tossing, conditions of the medium through which the coin travels and of the surface on which it lands, and so on. A very complex model is required to describe the simple outcome—heads or tails. Alternatively, you can describe the outcome quite simply as the result of a stochastic process, a Bernoulli variable that results in heads with a certain probability.
- It is often sufficient to describe the average behavior of a process, rather than each particular realization. For example, a regression model might be developed to relate plant growth to nutrient availability. The explicit aim of the model might be to describe how the average growth changes with

nutrient availability, not to predict the growth of an individual plant. The support for the notion of averaging in a model lies in the nature of expected values, describing typical behavior in the presence of randomness. This, in turn, requires that the model contain stochastic components.

The defining characteristic of statistical models is their dependence on parameters and the incorporation of stochastic terms. The properties of the model and the properties of quantities derived from it must be studied in a long-run, average sense through expectations, variances, and covariances. The fact that the parameters of the model must be estimated from the data introduces a stochastic element in applying a statistical model: because the model is not deterministic but includes randomness, parameters and related quantities derived from the model are likewise random. The properties of parameter estimators can often be described only in an asymptotic sense, imagining that some aspect of the data increases without bound (for example, the number of observations or the number of groups).

The process of estimating the parameters in a statistical model based on your data is called *fitting* the model. For many classes of statistical models there are a number of procedures in SAS/STAT software that can perform the fitting. In many cases, different procedures solve identical estimation problems—that is, their parameter estimates are identical. In some cases, the same model parameters are estimated by different statistical principles, such as least squares versus maximum likelihood estimation. Parameter estimates obtained by different methods typically have different statistical properties—distribution, variance, bias, and so on. The choice between competing estimation principles is often made on the basis of properties of the estimators. Distinguishing properties might include (but are not necessarily limited to) computational ease, interprative ease, bias, variance, mean squared error, and consistency.

Model-Based and Design-Based Randomness

A statistical model is a description of the data-generating mechanism, not a description of the specific data to which it is applied. The aim of a model is to capture those aspects of a phenomenon that are relevant to inquiry and to explain how the data could have come about as a realization of a random experiment. These relevant aspects might include the genesis of the randomness and the stochastic effects in the phenomenon under study. Different schools of thought can lead to different model formulations, different analytic strategies, and different results. Coarsely, you can distinguish between a viewpoint of *innate* randomness and one of *induced* randomness. This distinction leads to model-based and design-based inference approaches.

In a design-based inference framework, the random variation in the observed data is induced by random *selection* or random *assignment*. Consider the case of a survey sample from a finite population of size N; suppose that $\mathcal{F}_N = \{y_i : i \in U_N\}$ denotes the finite set of possible values and U_N is the index set $U_N = \{1, 2, \ldots, N\}$. Then a sample S, a subset of U_N, is selected by probability rules. The realization of the random experiment is the selection of a particular set S; the associated values selected from $\mathcal{F}_N$ are considered fixed. If properties of a design-based sampling estimator are evaluated, such as bias, variance, and mean squared error, they are evaluated with respect to the distribution induced by the sampling mechanism.

Design-based approaches also play an important role in the analysis of data from controlled experiments by randomization tests. Suppose that k treatments are to be assigned to kr homogeneous experimental units. If you form k sets of r units with equal probability, and you assign the jth treatment to the tth set, a completely randomized experimental design (CRD) results. A design-based view treats the potential response of a particular treatment for a particular experimental unit as a constant. The stochastic nature of the error-control design is induced by randomly selecting one of the potential responses.

Statistical models are often used in the design-based framework. In a survey sample the model is used to motivate the choice of the finite population parameters and their sample-based estimators. In an experimental design, an assumption of additivity of the contributions from treatments, experimental units, observational errors, and experimental errors leads to a linear statistical model. The approach to statistical inference where statistical models are used to construct estimators and their properties are evaluated with respect to the distribution induced by the sample selection mechanism is known as *model-assisted inference* (Särndal, Swensson, and Wretman 1992).

In a purely model-based framework, the only source of random variation for inference comes from the unknown variation in the responses. Finite population values are thought of as a realization of a superpopulation model that describes random variables $Y_1, Y_2, \cdots$. The observed values $y_1, y_2, \cdots$ are realizations of these random variables. A model-based framework does not imply that there is only one source of random variation in the data. For example, mixed models might contain random terms that represent selection of effects from hierarchical (super-) populations at different granularity. The analysis takes into account the hierarchical structure of the random variation, but it continues to be model based.

A design-based approach is implicit in SAS/STAT procedures whose name commences with SURVEY, such as the SURVEYFREQ, SURVEYMEANS, SURVEYREG, and SURVEYLOGISTIC procedures. Inferential approaches are model based in other SAS/STAT procedures. For more information about analyzing survey data with SAS/STAT software, see Chapter 14, "Introduction to Survey Procedures."

Model Specification

If the model is accepted as a description of the data-generating mechanism, then its parameters are estimated using the data at hand. Once the parameter estimates are available, you can apply the model to answer questions of interest about the study population. In other words, the model becomes the lens through which you view the problem itself, in order to ask and answer questions of interest. For example, you might use the estimated model to derive new predictions or forecasts, to test hypotheses, to derive confidence intervals, and so on.

Obviously, the model must be "correct" to the extent that it sufficiently describes the data-generating mechanism. Model selection, diagnosis, and discrimination are important steps in the model-building process. This is typically an iterative process, starting with an initial model and refining it. The first important step is thus to formulate your knowledge about the data-generating process and to express the real observed phenomenon in terms of a statistical model. A statistical model describes the distributional properties of one or more variables, the *response* variables. The extent of the required distributional specification depends on the model, estimation technique, and inferential goals. This description often takes the simple form of a model with additive error structure:

$$\text{response} = \text{mean} + \text{error}$$

In mathematical notation this simple model equation becomes

$$Y = f(x_1, \cdots, x_k; \beta_1, \cdots, \beta_p) + \epsilon$$

In this equation Y is the *response* variable, often also called the *dependent* variable or the *outcome* variable. The terms $x_1, \cdots, x_k$ denote the values of k regressor variables, often termed the *covariates* or the "independent" variables. The terms $\beta_1, \cdots, \beta_p$ denote parameters of the model, unknown constants that are to

be estimated. The term ϵ denotes the random disturbance of the model; it is also called the residual term or the error term of the model.

In this simple model formulation, stochastic properties are usually associated only with the ϵ term. The covariates $x_1, \cdots, x_k$ are usually known values, not subject to random variation. Even if the covariates are measured with error, so that their values are in principle random, they are considered fixed in most models fit by SAS/STAT software. In other words, stochastic properties under the model are derived conditional on the xs. If ϵ is the only stochastic term in the model, and if the errors have a mean of zero, then the function $f(\cdot)$ is the *mean function* of the statistical model. More formally,

$$\mathrm{E}[Y] = f(x_1, \cdots, x_k; \beta_1, \cdots, \beta_p)$$

where $\mathrm{E}[\cdot]$ denotes the expectation operator.

In many applications, a simple model formulation is inadequate. It might be necessary to specify not only the stochastic properties of a single error term, but also how model errors associated with different observations relate to each other. A simple additive error model is typically inappropriate to describe the data-generating mechanism if the errors do not have zero mean or if the variance of observations depends on their means. For example, if Y is a Bernoulli random variable that takes on the values 0 and 1 only, a regression model with additive error is not meaningful. Models for such data require more elaborate formulations involving probability distributions.

Classes of Statistical Models

Linear and Nonlinear Models

A statistical estimation problem is nonlinear if the estimating equations—the equations whose solution yields the parameter estimates—depend on the parameters in a nonlinear fashion. Such estimation problems typically have no closed-form solution and must be solved by iterative, numerical techniques.

Nonlinearity in the mean function is often used to distinguish between linear and nonlinear models. A model has a nonlinear mean function if the derivative of the mean function with respect to the parameters depends on at least one other parameter. Consider, for example, the following models that relate a response variable Y to a single regressor variable x:

$$\mathrm{E}[Y|x] = \beta_0 + \beta_1 x$$
$$\mathrm{E}[Y|x] = \beta_0 + \beta_1 x + \beta_2 x^2$$
$$\mathrm{E}[Y|x] = \beta + x/\alpha$$

In these expressions, $\mathrm{E}[Y|x]$ denotes the expected value of the response variable Y at the fixed value of x. (The conditioning on x simply indicates that the predictor variables are assumed to be non-random. Conditioning is often omitted for brevity in this and subsequent chapters.)

The first model in the previous list is a simple linear regression (SLR) model. It is linear in the parameters β_0 and β_1 since the model derivatives do not depend on unknowns:

$$\frac{\partial}{\beta_0}(\beta_0 + \beta_1 x) = 1$$
$$\frac{\partial}{\beta_1}(\beta_0 + \beta_1 x) = x$$

The model is also linear in its relationship with x (a straight line). The second model is also linear in the parameters, since

$$\frac{\partial}{\beta_0}\left(\beta_0 + \beta_1 x + \beta_2 x^2\right) = 1$$
$$\frac{\partial}{\beta_1}\left(\beta_0 + \beta_1 x + \beta_2 x^2\right) = x$$
$$\frac{\partial}{\beta_2}\left(\beta_0 + \beta_1 x + \beta_2 x^2\right) = x^2$$

However, this second model is *curvilinear*, since it exhibits a curved relationship when plotted against x. The third model, finally, is a nonlinear model since

$$\frac{\partial}{\beta}(\beta + x/\alpha) = 1$$
$$\frac{\partial}{\alpha}(\beta + x/\alpha) = -\frac{x}{\alpha^2}$$

The second of these derivatives depends on a parameter α. A model is nonlinear if it is not linear in at least one parameter. Only the third model is a nonlinear model. A graph of $\mathrm{E}[Y]$ versus the regressor variable thus does not indicate whether a model is nonlinear. A curvilinear relationship in this graph can be achieved by a model that is linear in the parameters.

Nonlinear mean functions lead to nonlinear estimation. It is important to note, however, that nonlinear estimation arises also because of the estimation principle or because the model structure contains nonlinearity in other parts, such as the covariance structure. For example, fitting a simple linear regression model by minimizing the sum of the absolute residuals leads to a nonlinear estimation problem despite the fact that the mean function is linear.

Regression Models and Models with Classification Effects

A linear regression model in the broad sense has the form

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where $\mathbf{Y}$ is the vector of response values, $\mathbf{X}$ is the matrix of regressor effects, $\boldsymbol{\beta}$ is the vector of regression parameters, and $\boldsymbol{\epsilon}$ is the vector of errors or residuals. A regression model in the narrow sense—as compared

to a classification model—is a linear model in which all regressor effects are continuous variables. In other words, each effect in the model contributes a single column to the **X** matrix and a single parameter to the overall model. For example, a regression of subjects' weight (Y) on the regressors age (x_1) and body mass index (bmi, x_2) is a regression model in this narrow sense. In symbolic notation you can write this regression model as

$$\text{weight} = \text{age} + \text{bmi} + \text{error}$$

This symbolic notation expands into the statistical model

$$Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \epsilon_i$$

Single parameters are used to model the effects of age (β_1) and bmi (β_2), respectively.

A classification effect, on the other hand, is associated with possibly more than one column of the **X** matrix. Classification with respect to a variable is the process by which each observation is associated with one of k levels; the process of determining these k levels is referred to as *levelization* of the variable. Classification variables are used in models to identify experimental conditions, group membership, treatments, and so on. The actual values of the classification variable are not important, and the variable can be a numeric or a character variable. What is important is the association of discrete values or levels of the classification variable with groups of observations. For example, in the previous illustration, if the regression also takes into account the subjects' gender, this can be incorporated in the model with a two-level classification variable. Suppose that the values of the gender variable are coded as "F" and "M," respectively. In symbolic notation the model

$$\text{weight} = \text{age} + \text{bmi} + \text{gender} + \text{error}$$

expands into the statistical model

$$Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \tau_1 I(\text{gender} = \text{"F"}) + \tau_2 I(\text{gender} = \text{"M"}) + \epsilon_i$$

where $I(\text{gender} = \text{"F"})$ is the indicator function that returns 1 if the value of the gender variable is "F" and 0 otherwise. Parameters τ_1 and τ_2 are associated with the gender classification effect. This form of parameterizing the gender effect in the model is only one of several different methods of incorporating the levels of a classification variable in the model. This form, the so-called singular parameterization, is the most general approach, and it is used in the GLM, MIXED, and GLIMMIX procedures. Alternatively, classification effects with various forms of nonsingular parameterizations are available in such procedures as GENMOD and LOGISTIC. See the documentation for the individual SAS/STAT procedures on their respective facilities for parameterizing classification variables and the section "Parameterization of Model Effects" on page 397 in Chapter 19, "Shared Concepts and Topics," for general details.

Models that contain only classification effects are often identified with *analysis of variance* (ANOVA) models, because ANOVA methods are frequently used in their analysis. This is particularly true for experimental data where the model effects comprise effects of the treatment and error-control design. However, classification effects appear more widely than in models to which analysis of variance methods are applied. For example, many mixed models, where parameters are estimated by restricted maximum likelihood, consist entirely of classification effects but do not permit the sum of squares decomposition typical for ANOVA techniques.

Many models contain both continuous and classification effects. For example, a continuous-by-class effect consists of at least one continuous variable and at least one classification variable. Such effects are convenient, for example, to vary slopes in a regression model by the levels of a classification variable. Also, recent enhancements to linear modeling syntax in some SAS/STAT procedures (including GLIMMIX and GLMSELECT) enable you to construct sets of columns in $\mathbf{X}$ matrices from a single continuous variable. An example is modeling with splines where the values of a continuous variable x are expanded into a spline basis that occupies multiple columns in the $\mathbf{X}$ matrix. For purposes of the analysis you can treat these columns as a single unit or as individual, unrelated columns. For more details, see the section "EFFECT Statement" on page 406 in Chapter 19, "Shared Concepts and Topics."

Univariate and Multivariate Models

A multivariate statistical model is a model in which multiple response variables are modeled jointly. Suppose, for example, that your data consist of heights (h_i) and weights (w_i) of children, collected over several years (t_i). The following separate regressions represent two univariate models:

$$w_i = \beta_{w0} + \beta_{w1} t_i + \epsilon_{wi}$$
$$h_i = \beta_{h0} + \beta_{h1} t_i + \epsilon_{hi}$$

In the univariate setting, no information about the children's heights "flows" to the model about their weights and vice versa. In a multivariate setting, the heights and weights would be modeled jointly. For example:

$$\begin{aligned} \mathbf{Y}_i = \begin{bmatrix} w_i \\ h_i \end{bmatrix} &= \mathbf{X}\boldsymbol{\beta} + \begin{bmatrix} \epsilon_{wi} \\ \epsilon_{hi} \end{bmatrix} \\ &= \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}_i \\ \boldsymbol{\epsilon}_i &\sim \left(\mathbf{0}, \begin{bmatrix} \sigma_1^2 & \sigma_{12} \\ \sigma_{12} & \sigma_2^2 \end{bmatrix} \right) \end{aligned}$$

The vectors $\mathbf{Y}_i$ and $\boldsymbol{\epsilon}_i$ collect the responses and errors for the two observation that belong to the same subject. The errors from the same child now have the correlation

$$\text{Corr}[\epsilon_{wi}, \epsilon_{hi}] = \frac{\sigma_{12}}{\sqrt{\sigma_1^2 \sigma_2^2}}$$

and it is through this correlation that information about heights "flows" to the weights and vice versa. This simple example shows only one approach to modeling multivariate data, through the use of covariance structures. Other techniques involve seemingly unrelated regressions, systems of linear equations, and so on.

Multivariate data can be coarsely classified into three types. The response vectors of *homogeneous multivariate data* consist of observations of the same attribute. Such data are common in repeated measures experiments and longitudinal studies, where the same attribute is measured repeatedly over time. Homogeneous multivariate data also arise in spatial statistics where a set of geostatistical data is the incomplete observation of a single realization of a random experiment that generates a two-dimensional surface. One hundred measurements of soil electrical conductivity collected in a forest stand compose a single observation of a 100-dimensional homogeneous multivariate vector. *Heterogeneous multivariate* observations arise when the responses that are modeled jointly refer to different attributes, such as in the previous example of children's weights and heights. There are two important subtypes of heterogeneous multivariate data. In

homocatanomic multivariate data the observations come from the same distributional family. For example, the weights and heights might both be assumed to be normally distributed. With *heterocatanomic multivariate data* the observations can come from different distributional families. The following are examples of heterocatanomic multivariate data:

- For each patient you observe blood pressure (a continuous outcome), the number of prior episodes of an illness (a count variable), and whether the patient has a history of diabetes in the family (a binary outcome). A multivariate model that models the three attributes jointly might assume a lognormal distribution for the blood pressure measurements, a Poisson distribution for the count variable and a Bernoulli distribution for the family history.
- In a study of HIV/AIDS survival, you model jointly a patients CD4 cell count over time—itself a homogeneous multivariate outcome—and the survival of the patient (event-time data).

Fixed, Random, and Mixed Models

Each term in a statistical model represents either a *fixed effect* or a *random effect*. Models in which all effects are fixed are called fixed-effects models. Similarly, models in which all effects are random—apart from possibly an overall intercept term—are called random-effects models. Mixed models, then, are those models that have fixed-effects and random-effects terms. In matrix notation, the linear fixed, linear random, and linear mixed model are represented by the following model equations, respectively:

$$\begin{aligned}
\mathbf{Y} &= \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon} \\
\mathbf{Y} &= \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon} \\
\mathbf{Y} &= \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}
\end{aligned}$$

In these expressions, $\mathbf{X}$ and $\mathbf{Z}$ are design or regressor matrices associated with the fixed and random effects, respectively. The vector $\boldsymbol{\beta}$ is a vector of fixed-effects parameters, and the vector $\boldsymbol{\gamma}$ represents the random effects. The mixed modeling procedures in SAS/STAT software assume that the random effects $\boldsymbol{\gamma}$ follow a normal distribution with variance-covariance matrix $\mathbf{G}$ and, in most cases, that the random effects have mean zero.

Random effects are often associated with classification effects, but this is not necessary. As an example of random regression effects, you might want to model the slopes in a growth model as consisting of two components: an overall (fixed-effects) slope that represents the slope of the average individual, and individual-specific random deviations from the overall slope. The $\mathbf{X}$ and $\mathbf{Z}$ matrix would then have column entries for the regressor variable associated with the slope. You are modeling fixed and randomly varying regression coefficients.

Having random effects in your model has a number of important consequences:

- Some observations are no longer uncorrelated but instead have a covariance that depends on the variance of the random effects.
- You can and should distinguish between the inference spaces; inferences can be drawn in a broad, intermediate, and narrow inference space. In the narrow inference space, conclusions are drawn about the particular values of the random effects selected in the study. The broad inference space applies if inferences are drawn with respect to all possible levels of the random effects. The intermediate

inference space can be applied for effects consisting of more than one random term, when inferences are broad with respect to some factors and narrow with respect to others. In fixed-effects models, there is no corresponding concept to the broad and intermediate inference spaces.

- Depending on the structure of $\mathbf{G}$ and $\text{Var}[\boldsymbol{\epsilon}]$ and also subject to the balance in your data, there might be no closed-form solution for the parameter estimates. Although the model is linear in $\boldsymbol{\beta}$, iterative estimation methods might be required to estimate all parameters of the model.
- Certain concepts, such as least squares means and Type III estimable functions, are meaningful only for fixed effects.
- By using random effects, you are modeling variation through variance. Variation in data simply implies that things are not equal. Variance, on the other hand, describes a feature of a random variable. Random effects in your model are random variables: they model variation through variance.

It is important to properly determine the nature of the model effects as fixed or random. An effect is either fixed or random by its very nature; it is improper to consider it fixed in one analysis and random in another depending on what type of results you want to produce. If, for example, a treatment effect is random and you are interested in comparing treatment means, and only the levels selected in the study are of interest, then it is not appropriate to model the treatment effect as fixed so that you can draw on least squares mean analysis. The appropriate strategy is to model the treatment effect as random and to compare the solutions for the treatment effects in the narrow inference space.

In determining whether an effect is fixed or random, it is helpful to inquire about the *genesis* of the effect. If the levels of an effect are randomly sampled, then the effect is a random effect. The following are examples:

- In a large clinical trial, drugs A, B, and C are applied to patients in various clinical centers. If the clinical centers are selected at random from a population of possible clinics, their effect on the response is modeled with a random effect.
- In repeated measures experiments with people or animals as subjects, subjects are declared to be random because they are selected from the larger population to which you want to generalize.
- Fertilizers could be applied at a number of levels. Three levels are randomly selected for an experiment to represent the population of possible levels. The fertilizer effects are random effects.

Quite often it is not possible to select effects at random, or it is not known how the values in the data became part of the study. For example, suppose you are presented with a data set consisting of student scores in three school districts, with four to ten schools in each district and two to three classrooms in each school. How do you decide which effects are fixed and which are random? As another example, in an agricultural experiment conducted in successive years at two locations, how do you decide whether location and year effects are fixed or random? In these situations, the fixed or random nature of the effect might be debatable, bearing out the adage that "one modeler's fixed effect is another modeler's random effect." However, this fact does not constitute license to treat as random those effects that are clearly fixed, or vice versa.

When an effect cannot be randomized or it is not known whether its levels have been randomly selected, it can be a random effect if its impact on the outcome variable is of a stochastic nature—that is, if it is the realization of a random process. Again, this line of thinking relates to the genesis of the effect. A random year, location, or school district effect is a placeholder for different environments that cannot be selected at random but whose effects are the cumulative result of many individual random processes. Note that this

argument does not imply that effects are random because the experimenter does not know much about them. The key notion is that effects represent something, whether or not that something is known to the modeler. Broadening the inference space beyond the observed levels is thus possible, although you might not be able to articulate what the realizations of the random effects represent.

A consequence of having random effects in your model is that some observations are no longer uncorrelated but instead have a covariance that depends on the variance of the random effect. In fact, in some modeling applications random effects might be used not only to model heterogeneity in the parameters of a model, but also to induce correlations among observations. The typical assumption about random effects in SAS/STAT software is that the effects are normally distributed.

For more information about mixed modeling tools in SAS/STAT software, see Chapter 6, "Introduction to Mixed Modeling Procedures."

Generalized Linear Models

A class of models that has gained increasing importance in the past several decades is the class of generalized linear models. The theory of generalized linear models originated with Nelder and Wedderburn (1972) and Wedderburn (1974), and was subsequently made popular in the monograph by McCullagh and Nelder (1989). This class of models extends the theory and methods of linear models to data with nonnormal responses. Before this theory was developed, modeling of nonnormal data typically relied on transformations of the data, and the transformations were chosen to improve symmetry, homogeneity of variance, or normality. Such transformations have to be performed with care because they also have implications for the error structure of the model, Also, back-transforming estimates or predicted values can introduce bias.

Generalized linear models also apply a transformation, known as the *link function*, but it is applied to a deterministic component, the mean of the data. Furthermore, generalized linear model take the distribution of the data into account, rather than assuming that a transformation of the data leads to normally distributed data to which standard linear modeling techniques can be applied.

To put this generalization in place requires a slightly more sophisticated model setup than that required for linear models for normal data:

- The *systematic* component is a linear predictor similar to that in linear models, $\eta = \mathbf{x}'\boldsymbol{\beta}$. The linear predictor is a linear function in the parameters. In contrast to the linear model, η does not represent the mean function of the data.
- The *link function* $g(\cdot)$ relates the linear predictor to the mean, $g(\mu) = \eta$. The link function is a monotonic, invertible function. The mean can thus be expressed as the inversely linked linear predictor, $\mu = g^{-1}(\eta)$. For example, a common link function for binary and binomial data is the logit link, $g(t) = \log\{t/(1-t)\}$. The mean function of a generalized linear model with logit link and a single regressor can thus be written as

$$\log\left\{\frac{\mu}{1-\mu}\right\} = \beta_0 + \beta_1 x$$

$$\mu = \frac{1}{1+\exp\{-\beta_0 - \beta_1 x\}}$$

  This is known as a logistic regression model.

- The *random component* of a generalized linear model is the distribution of the data, assumed to be a member of the exponential family of distributions. Discrete members of this family include the Bernoulli (binary), binomial, Poisson, geometric, and negative binomial (for a given value of the scale parameter) distribution. Continuous members include the normal (Gaussian), beta, gamma, inverse gaussian, and exponential distribution.

The standard linear model with normally distributed error is a special case of a generalized linear model; the link function is the identity function and the distribution is normal.

Latent Variable Models

Latent variable modeling involves variables that are not observed directly in your research. It has a relatively long history, dating back from the measure of general intelligence by common factor analysis (Spearman 1904) to the emergence of modern-day structural equation modeling (Jöreskog 1973; Keesling, 1972; Wiley, 1973).

Latent variables are involved in almost all kinds of regression models. In a broad sense, all additive error terms in regression models are latent variables simply because they are not measured in research. Hereafter, however, a narrower sense of latent variables is used when referring to latent variable models. Latent variables are *systematic* unmeasured variables that are also referred to as *factors*. For example, in the following diagram a simple relation between Emotional Intelligence and Career Achievement is shown:

In the diagram, both Emotional Intelligence and Career Achievement are treated as latent factors. They are hypothetical constructs in your model. You hypothesize that Emotional Intelligence is a "causal factor" or predictor of Career Achievement. The symbol β represents the regression coefficient or the effect of Emotional Intelligence on Career Achievement. However, the "causal relationship" or prediction is not perfect. There is an error term δ, which accounts for the unsystematic part of the prediction. You can represent the preceding diagram by using the following linear equation:

$$\mathrm{CA} = \beta \mathrm{EI} + \delta$$

where CA represents Career Achievement and EI represents Emotional Intelligence. The means of the latent factors in the linear model are arbitrary, and so they are assumed to be zero. The error variable δ also has a zero mean with an unknown variance. This equation represents the so-called "structural model," where the "true" relationships among latent factors are theorized.

In order to model this theoretical model with latent factors, some observed variables must somehow relate to these factors. This calls for the measurement models for latent factors. For example, Emotional Intelligence could be measured by some established tests. In these tests, individuals are asked to respond to certain special situations that involve stressful decision making, personal confrontations, and so on. Their responses to these situations are then rated by experts or a standardized scoring system. Suppose there are three such tests and the test scores are labeled as X1, X2 and X3, respectively. The measurement model for the latent

factor Emotional Intelligence is specified as follows:

$$\begin{aligned} \text{X1} &= a_1\text{EI} + e_1 \\ \text{X2} &= a_2\text{EI} + e_2 \\ \text{X3} &= a_3\text{EI} + e_3 \end{aligned}$$

where a_1, a_2, and a_3 are regression coefficients and e_1, e_2, and e_3 are measurement errors. Measurement errors are assumed to be independent of the latent factors EI and CA. In the measurement model, X1, X2, and X3 are called the indicators of the latent variable EI. These observed variables are assumed to be centered in the model, and therefore no intercept terms are needed. Each of the indicators is a scaled measurement of the latent factor EI plus a unique error term.

Similarly, you need to have a measurement model for the latent factor CA. Suppose that there are four observed indicators Y1, Y2, Y3, and Y4 (for example, Job Status) for this latent factor. The measurement model for CA is specified as follows:

$$\begin{aligned} \text{Y1} &= a_4\text{CA} + e_4 \\ \text{Y2} &= a_5\text{CA} + e_5 \\ \text{Y3} &= a_6\text{CA} + e_6 \\ \text{Y4} &= a_7\text{CA} + e_7 \end{aligned}$$

where a_4, a_5, a_6, and a_7 are regression coefficients and e_4, e_5, e_6, and e_7 are error terms. Again, the error terms are assumed to be independent of the latent variables EI and CA, and Y1, Y2, Y3, and Y4 are centered in the equations.

Given the data for the measured variables, you analyze the structural and measurement models simultaneously by the structural equation modeling techniques. In other words, estimation of β, a_1–a_7, and other parameters in the model are carried out simultaneously in the modeling.

Modeling involving the use of latent factors is quite common in social and behavioral sciences, personality assessment, and marketing research. Hypothetical constructs, although not observable, are very important in building theories in these areas.

Another use of latent factors in modeling is to "purify" the predictors in regression analysis. A common assumption in linear regression models is that predictors are measured without errors. That is, in the following linear equation x is assumed to have been measured without errors:

$$y = \alpha + \beta x + \epsilon$$

However, if x has been contaminated with measurement errors that cannot be ignored, the estimate of β might be biased severely so that the true relationship between x and y would be masked.

A measurement model for x provides a solution to such a problem. Let F_x be a "purified" version of x. That is, F_x is the "true" measure of x without measurement errors, as described in the following equation:

$$x = F_x + \delta$$

where δ represents a random measurement error term. Now, the linear relationship of interest is specified in the following new linear regression equation:

$$y = \alpha + \beta F_x + \epsilon$$

In this equation, F_x, which is now free from measurement errors, replaces x in the original equation. With measurement errors taken into account in the simultaneous fitting of the measurement and the new regression equations, estimation of β is unbiased; hence it reflects the true relationship much better.

Certainly, introducing latent factors in models is not a "free lunch." You must pay attention to the identification issues induced by the latent variable methodology. That is, in order to estimate the parameters in structural equation models with latent variables, you must set some identification constraints in these models. There are some established rules or conventions that would lead to proper model identification and estimation. See Chapter 17, "Introduction to Structural Equation Modeling with Latent Variables," for examples and general details.

In addition, because of the nature of latent variables, estimation in structural equation modeling with latent variables does not follow the same form as that of linear regression analysis. Instead of defining the estimators in terms of the data matrices, most estimation methods in structural equation modeling use the fitting of the first- and second- order moments. Hence, estimation principles described in the section "Classical Estimation Principles" on page 38 do not apply to structural equation modeling. However, you can see the section "Estimation Criteria" on page 1246 in Chapter 26, "The CALIS Procedure," for details about estimation in structural equation modeling with latent variables.

Bayesian Models

Statistical models based on the classical (or *frequentist*) paradigm treat the parameters of the model as fixed, unknown constants. They are not random variables, and the notion of probability is derived in an objective sense as a limiting relative frequency. The Bayesian paradigm takes a different approach. Model parameters are random variables, and the probability of an event is defined in a subjective sense as the degree to which you believe that the event is true. This fundamental difference in philosophy leads to profound differences in the statistical content of estimation and inference. In the frequentist framework, you use the data to best estimate the unknown value of a parameter; you are trying to pinpoint a value in the parameter space as well as possible. In the Bayesian framework, you use the data to update your beliefs about the *behavior* of the parameter to assess its distributional properties as well as possible.

Suppose you are interested in estimating θ from data $\mathbf{Y} = [Y_1, \cdots, Y_n]$ by using a statistical model described by a density $p(\mathbf{y}|\theta)$. Bayesian philosophy states that θ cannot be determined exactly, and uncertainty about the parameter is expressed through probability statements and distributions. You can say, for example, that θ follows a normal distribution with mean 0 and variance 1, if you believe that this distribution best describes the uncertainty associated with the parameter.

The following steps describe the essential elements of Bayesian inference:

1. A probability distribution for θ is formulated as $\pi(\theta)$, which is known as the *prior* distribution, or just the prior. The prior distribution expresses your beliefs, for example, on the mean, the spread, the skewness, and so forth, about the parameter prior to examining the data.
2. Given the observed data $\mathbf{Y}$, you choose a statistical model $p(\mathbf{y}|\theta)$ to describe the distribution of $\mathbf{Y}$ given θ.
3. You update your beliefs about θ by combining information from the prior distribution and the data through the calculation of the *posterior* distribution, $p(\theta|\mathbf{y})$.

The third step is carried out by using Bayes' theorem, from which this branch of statistical philosophy derives its name. The theorem enables you to combine the prior distribution and the model in the following way:

$$p(\theta|\mathbf{y}) = \frac{p(\theta, \mathbf{y})}{p(\mathbf{y})} = \frac{p(\mathbf{y}|\theta)\pi(\theta)}{p(\mathbf{y})} = \frac{p(\mathbf{y}|\theta)\pi(\theta)}{\int p(\mathbf{y}|\theta)\pi(\theta)d\theta}$$

The quantity $p(\mathbf{y}) = \int p(\mathbf{y}|\theta)\pi(\theta)\, d\theta$ is the normalizing constant of the posterior distribution. It is also the marginal distribution of $\mathbf{Y}$, and it is sometimes called the marginal distribution of the data.

The likelihood function of θ is any function proportional to $p(\mathbf{y}|\theta)$—that is, $L(\theta) \propto p(\mathbf{y}|\theta)$. Another way of writing Bayes' theorem is

$$p(\theta|\mathbf{y}) = \frac{L(\theta)\pi(\theta)}{\int L(\theta)\pi(\theta)\, d\theta}$$

The marginal distribution $p(\mathbf{y})$ is an integral; therefore, provided that it is finite, the particular value of the integral does not yield any additional information about the posterior distribution. Hence, $p(\theta|\mathbf{y})$ can be written up to an arbitrary constant, presented here in proportional form, as

$$p(\theta|\mathbf{y}) \propto L(\theta)\pi(\theta)$$

Bayes' theorem instructs you how to update existing knowledge with new information. You start from a prior belief $\pi(\theta)$, and, after learning information from data $\mathbf{y}$, you change or update the belief on θ and obtain $p(\theta|\mathbf{y})$. These are the essential elements of the Bayesian approach to data analysis.

In theory, Bayesian methods offer a very simple alternative to statistical inference—all inferences follow from the posterior distribution $p(\theta|\mathbf{y})$. However, in practice, only the most elementary problems enable you to obtain the posterior distribution analytically. Most Bayesian analyses require sophisticated computations, including the use of simulation methods. You generate samples from the posterior distribution and use these samples to estimate the quantities of interest.

Both Bayesian and classical analysis methods have their advantages and disadvantages. Your choice of method might depend on the goals of your data analysis. If prior information is available, such as in the form of expert opinion or historical knowledge, and you want to incorporate this information into the analysis, then you might consider Bayesian methods. In addition, if you want to communicate your findings in terms of probability notions that can be more easily understood by nonstatisticians, Bayesian methods might be appropriate. The Bayesian paradigm can provide a framework for answering specific scientific questions that a single point estimate cannot sufficiently address. On the other hand, if you are interested in estimating parameters and in formulating inferences based on the properties of the parameter estimators, then there is no need to use Bayesian analysis. When the sample size is large, Bayesian inference often provides results for parametric models that are very similar to the results produced by classical, frequentist methods.

For more information, see Chapter 7, "Introduction to Bayesian Analysis Procedures."

Classical Estimation Principles

An estimation principle captures the set of rules and procedures by which parameter estimates are derived. When an estimation principle "meets" a statistical model, the result is an *estimation problem*, the solution of which are the parameter estimates. For example, if you apply the estimation principle of least squares to the SLR model $Y_i = \beta_0 + \beta_1 x_i + \epsilon_i$, the estimation problem is to find those values $\widehat{\beta}_0$ and $\widehat{\beta}_1$ that minimize

$$\sum_{i=1}^{n} (y_i - \beta_0 - \beta_1 x_i)^2$$

The solutions are the least squares estimators.

The two most important classes of estimation principles in statistical modeling are the least squares principle and the likelihood principle. All principles have in common that they provide a metric by which you measure the distance between the data and the model. They differ in the nature of the metric; least squares relies on a geometric measure of distance, while likelihood inference is based on a distance that measures plausability.

Least Squares

The idea of the ordinary least squares (OLS) principle is to choose parameter estimates that minimize the squared distance between the data and the model. In terms of the general, additive model,

$$Y_i = f(x_{i1}, \cdots, x_{ik}; \beta_1, \cdots, \beta_p) + \epsilon_i$$

the OLS principle minimizes

$$\text{SSE} = \sum_{i=1}^{n} \left(y_i - f(x_{i1}, \cdots, x_{ik}; \beta_1, \cdots, \beta_p)\right)^2$$

The least squares principle is sometimes called "nonparametric" in the sense that it does not require the distributional specification of the response or the error term, but it might be better termed "distributionally agnostic." In an additive-error model it is only required that the model errors have zero mean. For example, the specification

$$\begin{aligned} Y_i &= \beta_0 + \beta_1 x_i + \epsilon_i \\ \text{E}[\epsilon_i] &= 0 \end{aligned}$$

is sufficient to derive ordinary least squares (OLS) estimators for β_0 and β_1 and to study a number of their properties. It is easy to show that the OLS estimators in this SLR model are

$$\begin{aligned} \widehat{\beta}_1 &= \left(\sum_{i=1}^{n} (Y_i - \overline{Y}) \sum_{i=1}^{n} (x_i - \overline{x})\right) \Big/ \sum_{i=1}^{n} (x_i - \overline{x})^2 \\ \widehat{\beta}_0 &= \overline{Y} - \widehat{\beta}_1 \overline{x} \end{aligned}$$

Based on the assumption of a zero mean of the model errors, you can show that these estimators are unbiased, $\text{E}[\widehat{\beta}_1] = \beta_1, \text{E}[\widehat{\beta}_0] = \beta_0$. However, without further assumptions about the distribution of the ϵ_i, you cannot

derive the variability of the least squares estimators or perform statistical inferences such as hypothesis tests or confidence intervals. In addition, depending on the distribution of the ϵ_i, other forms of least squares estimation can be more efficient than OLS estimation.

The conditions for which ordinary least squares estimation is efficient are zero mean, homoscedastic, uncorrelated model errors. Mathematically,

$$\begin{aligned} \mathrm{E}[\epsilon_i] &= 0 \\ \mathrm{Var}[\epsilon_i] &= \sigma^2 \\ \mathrm{Cov}[\epsilon_i, \epsilon_j] &= 0 \text{ if } i \neq j \end{aligned}$$

The second and third assumption are met if the errors have an *iid* distribution—that is, if they are independent and identically distributed. Note, however, that the notion of stochastic independence is stronger than that of absence of correlation. Only if the data are normally distributed does the latter implies the former.

The various other forms of the least squares principle are motivated by different extensions of these assumptions in order to find more efficient estimators.

Weighted Least Squares

The objective function in weighted least squares (WLS) estimation is

$$\mathrm{SSE}_w = \sum_{i=1}^{n} w_i \left(Y_i - f(x_{i1}, \cdots, x_{ik}; \beta_1, \cdots, \beta_p)\right)^2$$

where w_i is a weight associated with the ith observation. A situation where WLS estimation is appropriate is when the errors are uncorrelated but not homoscedastic. If the weights for the observations are proportional to the reciprocals of the error variances, $\mathrm{Var}[\epsilon_i] = \sigma^2/w_i$, then the weighted least squares estimates are best linear unbiased estimators (BLUE). Suppose that the weights w_i are collected in the diagonal matrix $\mathbf{W}$ and that the mean function has the form of a linear model. The weighted sum of squares criterion then can be written as

$$\mathrm{SSE}_w = (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})' \mathbf{W} (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})$$

which gives rise to the weighted normal equations

$$(\mathbf{X}'\mathbf{W}\mathbf{X})\boldsymbol{\beta} = \mathbf{X}'\mathbf{W}\mathbf{Y}$$

The resulting WLS estimator of $\boldsymbol{\beta}$ is

$$\widehat{\boldsymbol{\beta}}_w = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-} \mathbf{X}'\mathbf{W}\mathbf{Y}$$

Iteratively Reweighted Least Squares

If the weights in a least squares problem depend on the parameters, then a change in the parameters also changes the weight structure of the model. Iteratively reweighted least squares (IRLS) estimation is an iterative technique that solves a series of weighted least squares problems, where the weights are recomputed between iterations. IRLS estimation can be used, for example, to derive maximum likelihood estimates in generalized linear models.

Generalized Least Squares

The previously discussed least squares methods have in common that the observations are assumed to be uncorrelated—that is, $\text{Cov}[\epsilon_i, \epsilon_j] = 0$, whenever $i \neq j$. The weighted least squares estimation problem is a special case of a more general least squares problem, where the model errors have a general convariance matrix, $\text{Var}[\boldsymbol{\epsilon}] = \boldsymbol{\Sigma}$. Suppose again that the mean function is linear, so that the model becomes

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon} \qquad \boldsymbol{\epsilon} \sim (\mathbf{0}, \boldsymbol{\Sigma})$$

The generalized least squares (GLS) principle is to minimize the generalized error sum of squares

$$\text{SSE}_g = (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})' \boldsymbol{\Sigma}^{-1} (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})$$

This leads to the generalized normal equations

$$(\mathbf{X}'\boldsymbol{\Sigma}^{-1}\mathbf{X})\boldsymbol{\beta} = \mathbf{X}'\boldsymbol{\Sigma}^{-1}\mathbf{Y}$$

and the GLS estimator

$$\widehat{\boldsymbol{\beta}}_g = \left(\mathbf{X}'\boldsymbol{\Sigma}^{-1}\mathbf{X}\right)^{-} \mathbf{X}'\boldsymbol{\Sigma}^{-1}\mathbf{Y}$$

Obviously, WLS estimation is a special case of GLS estimation, where $\boldsymbol{\Sigma} = \sigma^2\mathbf{W}^{-1}$—that is, the model is

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon} \qquad \boldsymbol{\epsilon} \sim \left(\mathbf{0}, \sigma^2\mathbf{W}^{-1}\right)$$

Likelihood

There are several forms of likelihood estimation and a large number of offshoot principles derived from it, such as pseudo-likelihood, quasi-likelihood, composite likelihood, etc. The basic likelihood principle is *maximum likelihood*, which asks to estimate the model parameters by those quantities that maximize the likelihood function of the data. The likelihood function is the joint distribution of the data, but in contrast to a probability mass or density function, it is thought of as a function of the parameters, given the data. The heuristic appeal of the maximum likelihood estimates (MLE) is that these are the values that make the observed data "most likely." Especially for discrete response data, the value of the likelihood function is the ordinate of a probability mass function, even if the likelihood is not a probability function. Since a statistical model is thought of as a representation of the data-generating mechanism, what could be more preferable as parameter estimates than those values that make it most likely that the data at hand will be observed?

Maximum likelihood estimates, if they exist, have appealing statistical properties. Under fairly mild conditions, they are best-asymptotic-normal (BAN) estimates—that is, their asymptotic distribution is normal, and no other estimator has a smaller asymptotic variance. However, their statistical behavior in finite samples is often difficult to establish, and you have to appeal to the asymptotic results that hold as the sample size tends to infinity. For example, maximum likelihood estimates are often biased estimates and the bias disappears as the sample size grows. A famous example is random sampling from a normal distribution. The corresponding statistical model is

$$Y_i = \mu + \epsilon_i$$
$$\epsilon_i \sim iid\ N(0, \sigma^2)$$

where the symbol $\sim$ is read as "is distributed as" and *iid* is read as "independent and identically distributed." Under the normality assumption, the density function of y_i is

$$f(y_i; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left\{-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\right\}$$

and the likelihood for a random sample of size n is

$$L(\mu, \sigma^2; \mathbf{y}) = \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left\{-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\right\}$$

Maximizing the likelihood function $L(\mu, \sigma^2; \mathbf{y})$ is equivalent to maximizing the log-likelihood function $\log L = l(\mu, \sigma^2; \mathbf{y})$,

$$\begin{aligned} l(\mu, \sigma^2; \mathbf{y}) &= \sum_{i=1}^{n} -\frac{1}{2}\left(\log\{2\pi\} + \frac{(y_i - \mu)^2}{\sigma^2} + \log\{\sigma^2\}\right) \\ &= -\frac{1}{2}\left(n\log\{2\pi\} + n\log\{\sigma^2\} + \sum_{i=1}^{n}(y_i - \mu)^2/\sigma^2\right) \end{aligned}$$

The maximum likelihood estimators of μ and σ^2 are thus

$$\widehat{\mu} = \frac{1}{n}\sum_{i=1}^{n} Y_i = \overline{Y} \qquad \widehat{\sigma}^2 = \frac{1}{n}\sum_{i=1}^{n}(Y_i - \widehat{\mu})^2$$

The MLE of the mean μ is the sample mean, and it is an unbiased estimator of μ. However, the MLE of the variance σ^2 is not an unbiased estimator. It has bias

$$\mathrm{E}\left[\widehat{\sigma}^2 - \sigma^2\right] = -\frac{1}{n}\sigma^2$$

As the sample size n increases, the bias vanishes.

For certain classes of models, special forms of likelihood estimation have been developed to maintain the appeal of likelihood-based statistical inference and to address specific properties that are believed to be shortcomings:

- The bias in maximum likelihood parameter estimators of variances and covariances has led to the development of restricted (or residual) maximum likelihood (REML) estimators that play an important role in mixed models.
- Quasi-likelihood methods do not require that the joint distribution of the data be specified. These methods derive estimators based on only the first two moments (mean and variance) of the joint distributions and play an important role in the analysis of correlated data.
- The idea of composite likelihood is applied in situations where the likelihood of the vector of responses is intractable but the likelihood of components or functions of the full-data likelihood are tractable. For example, instead of the likelihood of $\mathbf{Y}$, you might consider the likelihood of pairwise differences $Y_i - Y_j$.

- The pseudo-likelihood concept is also applied when the likelihood function is intractable, but the likelihood of a related, simpler model is available. An important difference between quasi-likelihood and pseudo-likelihood techniques is that the latter make distributional assumptions to obtain a likelihood function in the pseudo-model. Quasi-likelihood methods do not specify the distributional family.
- The penalized likelihood principle is applied when additional constraints and conditions need to be imposed on the parameter estimates or the resulting model fit. For example, you might augment the likelihood with conditions that govern the smoothness of the predictions or that prevent overfitting of the model.

Least Squares or Likelihood

For many statistical modeling problems, you have a choice between a least squares principle and the maximum likelihood principle. Table 3.1 compares these two basic principles.

Table 3.1 Least Squares and Maximum Likelihood

Criterion	Least Squares	Maximum Likelihood
Requires specification of joint distribution of data	No, but in order to perform confirmatory inference (tests, confidence intervals), a distributional assumption is needed, or an appeal to asymptotics.	Yes, no progress can be made with the genuine likelihood principle without knowing the distribution of the data.
All parameters of the model are estimated	No. In the additive-error type models, least squares provides estimates of only the parameters in the mean function. The residual variance, for example, must be estimated by some other method—typically by using the mean squared error of the model.	Yes
Estimates always exist	Yes, but they might not be unique, such as when the $\mathbf{X}$ matrix is singular.	No, maximum likelihood estimates do not exist for all estimation problems.
Estimators are biased	Unbiased, provided that the model is correct—that is, the errors have zero mean.	Often biased, but asymptotically unbiased
Estimators are consistent	Not necessarily, but often true. Sometimes estimators are consistent even in a misspecified model, such as when misspecification is in the covariance structure.	Almost always
Estimators are best linear unbiased estimates (BLUE)	Typically, if the least squares assumptions are met.	Not necessarily: estimators are often nonlinear in the data and are often biased.
Asymptotically most efficient	Not necessarily	Typically
Easy to compute	Yes	No

Inference Principles for Survey Data

Design-based and model-assisted statistial inference for survey data requires that the randomness due to the selection mechanism be taken into account. This can require special estimation principles and techniques.

The SURVEYMEANS, SURVEYFREQ, SURVEYREG, and SURVEYLOGISTIC procedures support design-based and/or model-assisted inference for sample surveys. Suppose π_i is the selection probability for unit i in sample S. The inverse of the inclusion probability is known as sampling weight and is denoted by w_i. Briefly, the idea is to apply a relationship that exists in the population to the sample and to take into account the sampling weights. For example, to estimate the finite population total $T_N = \sum_{i \in U_N} y_i$ based on the sample S, you can accumulate the sampled values while properly weighting: $\widehat{T}_\pi = \sum_{i \in S} w_i y_i$. It is easy to verify that $\widehat{T}_\pi$ is design-unbiased in the sense that $\mathrm{E}[\widehat{T}_\pi | \mathcal{F}_N] = T_N$ (see Cochran 1997).

When a statistical model is present, similar ideas apply. For example, if β_{N0} and β_{N1} are finite population quantities for a simple linear regression working model that minimize the sum of squares

$$\sum_{i \in U_N} (y_i - \beta_{0N} - \beta_{1N} x_i)^2$$

in the population, then the sample-based estimators $\widehat{\beta}_{0S}$ and $\widehat{\beta}_{1S}$ are obtained by minimizing the weighted sum of squares

$$\sum_{i \in S} w_i (y_i - \hat{\beta}_{0S} - \hat{\beta}_{1S} x_i)^2$$

in the sample, taking into account the inclusion probabilities.

In model-assisted inference, weighted least squares or pseudo-maximum likelihood estimators are commonly used to solve such estimation problems. Maximum pseudo-likelihood or weighted maximum likelihood estimators for survey data maximize a sample-based estimator of the population likelihood. Assume a working model with uncorrelated responses such that the finite population log-likelihood is

$$\sum_{i \in U_N} l(\theta_{1N}, \ldots, \theta_{pN}; y_i),$$

where $\theta_{1N}, \ldots, \theta_{pN}$ are finite population quantities. For independent sampling, one possible sample-based estimator of the population log likelihood is

$$\sum_{i \in S} w_i l(\theta_{1N}, \ldots, \theta_{pN}; y_i)$$

Sample-based estimators $\widehat{\theta}_{1S}, \ldots, \widehat{\theta}_{pS}$ are obtained by maximizing this expression.

Design-based and model-based statistical analysis might employ the same statistical model (for example, a linear regression) and the same estimation principle (for example, weighted least squares), and arrive at the same estimates. The design-based estimation of the precision of the estimators differs from the model-based estimation, however. For complex surveys, design-based variance estimates are in general different from their model-based counterpart. The SAS/STAT procedures for survey data (SURVEYMEANS, SURVEYFREQ, SURVEYREG, and SURVEYLOGISTIC procedures) compute design-based variance estimates for complex survey data. See the section "Variance Estimation" on page 253, in Chapter 14, "Introduction to Survey Procedures," for details about design-based variance estimation.

Statistical Background

Hypothesis Testing and Power

In statistical hypothesis testing, you typically express the belief that some effect exists in a population by specifying an alternative hypothesis H_1. You state a null hypothesis H_0 as the assertion that the effect does *not* exist and attempt to gather evidence to reject H_0 in favor of H_1. Evidence is gathered in the form of sample data, and a statistical test is used to assess H_0. If H_0 is rejected but there really is *no* effect, this is called a *Type I error*. The probability of a Type I error is usually designated "alpha" or α, and statistical tests are designed to ensure that α is suitably small (for example, less than 0.05).

If there is an effect in the population but H_0 is *not* rejected in the statistical test, then a *Type II error* has been committed. The probability of a Type II error is usually designated "beta" or β. The probability $1 - \beta$ of avoiding a Type II error—that is, correctly rejecting H_0 and achieving statistical significance, is called the *power* of the test.

An important goal in study planning is to ensure an acceptably high level of power. Sample size plays a prominent role in power computations because the focus is often on determining a sufficient sample size to achieve a certain power, or assessing the power for a range of different sample sizes.

There are several tools available in SAS/STAT software for power and sample size analysis. PROC POWER covers a variety of analyses such as t tests, equivalence tests, confidence intervals, binomial proportions, multiple regression, one-way ANOVA, survival analysis, logistic regression, and the Wilcoxon rank-sum test. PROC GLMPOWER supports more complex linear models. The Power and Sample Size application provides a user interface and implements many of the analyses supported in the procedures.

Important Linear Algebra Concepts

A *matrix* $\mathbf{A}$ is a rectangular array of numbers. The *order* of a matrix with n rows and k columns is $(n \times k)$. The element in row i, column j of $\mathbf{A}$ is denoted as a_{ij}, and the notation $\left[a_{ij}\right]$ is sometimes used to refer to the two-dimensional row-column array

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1k} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2k} \\ a_{31} & a_{32} & a_{33} & \cdots & a_{3k} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & a_{nk} \end{bmatrix} = \left[a_{ij}\right]$$

A *vector* is a one-dimensional array of numbers. A *column vector* has a single column ($k = 1$). A *row vector* has a single row ($n = 1$). A *scalar* is a matrix of order (1×1)—that is, a single number. A *square* matrix has the same row and column order, $n = k$. A *diagonal* matrix is a square matrix where all off-diagonal elements are zero, $a_{ij} = 0$ if $i \neq j$. The *identity* matrix $\mathbf{I}$ is a diagonal matrix with $a_{ii} = 1$ for all

i. The *unit vector* $\mathbf{1}$ is a vector where all elements are 1. The *unit matrix* $\mathbf{J}$ is a matrix of all 1s. Similarly, the elements of the null vector and the null matrix are all 0.

Basic matrix operations are as follows:

Addition — If $\mathbf{A}$ and $\mathbf{B}$ are of the same order, then $\mathbf{A} + \mathbf{B}$ is the matrix of elementwise sums,

$$\mathbf{A} + \mathbf{B} = \left[a_{ij} + b_{ij}\right]$$

Subtraction — If $\mathbf{A}$ and $\mathbf{B}$ are of the same order, then $\mathbf{A} - \mathbf{B}$ is the matrix of elementwise differences,

$$\mathbf{A} - \mathbf{B} = \left[a_{ij} - b_{ij}\right]$$

Dot product — The dot product of two n-vectors $\mathbf{a}$ and $\mathbf{b}$ is the sum of their elementwise products,

$$\mathbf{a} \cdot \mathbf{b} = \sum_{i=1}^{n} a_i b_i$$

The dot product is also known as the *inner product* of $\mathbf{a}$ and $\mathbf{b}$. Two vectors are said to be *orthogonal* if their dot product is zero.

Multiplication — Matrices $\mathbf{A}$ and $\mathbf{B}$ are said to be conformable for $\mathbf{AB}$ multiplication if the number of columns in $\mathbf{A}$ equals the number of rows in $\mathbf{B}$. Suppose that $\mathbf{A}$ is of order $(n \times k)$ and that $\mathbf{B}$ is of order $(k \times p)$. The product $\mathbf{AB}$ is then defined as the $(n \times p)$ matrix of the dot products of the ith row of $\mathbf{A}$ and the jth column of $\mathbf{B}$,

$$\mathbf{AB} = \left[\mathbf{a_i} \cdot \mathbf{b_j}\right]_{n \times p}$$

Transposition — The transpose of the $(n \times k)$ matrix $\mathbf{A}$ is denoted as $\mathbf{A}'$ or $\mathbf{A}^T$ or $\mathbf{A}^{\mathrm{T}}$ and is obtained by interchanging the rows and columns,

$$\mathbf{A}' = \begin{bmatrix} a_{11} & a_{21} & a_{31} & \cdots & a_{n1} \\ a_{12} & a_{22} & a_{23} & \cdots & a_{n2} \\ a_{13} & a_{23} & a_{33} & \cdots & a_{n3} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{1k} & a_{2k} & a_{3k} & \cdots & a_{nk} \end{bmatrix} = \left[a_{ji}\right]$$

A *symmetric* matrix is equal to its transpose, $\mathbf{A} = \mathbf{A}'$. The inner product of two $(n \times 1)$ column vectors $\mathbf{a}$ and $\mathbf{b}$ is $\mathbf{a} \cdot \mathbf{b} = \mathbf{a}'\mathbf{b}$.

Matrix Inversion

Regular Inverses

The right inverse of a matrix $\mathbf{A}$ is the matrix that yields the identity when $\mathbf{A}$ is postmultiplied by it. Similarly, the left inverse of $\mathbf{A}$ yields the identity if $\mathbf{A}$ is premultiplied by it. $\mathbf{A}$ is said to be invertible and $\mathbf{B}$ is said to be the inverse of $\mathbf{A}$, if $\mathbf{B}$ is its right and left inverse, $\mathbf{BA} = \mathbf{AB} = \mathbf{I}$. This requires $\mathbf{A}$ to be square and

nonsingular. The inverse of a matrix $\mathbf{A}$ is commonly denoted as $\mathbf{A}^{-1}$. The following results are useful in manipulating inverse matrices (assuming both $\mathbf{A}$ and $\mathbf{C}$ are invertible):

$$\begin{aligned}
\mathbf{A}\mathbf{A}^{-1} &= \mathbf{A}^{-1}\mathbf{A} = \mathbf{I} \\
\left(\mathbf{A}'\right)^{-1} &= \left(\mathbf{A}^{-1}\right)' \\
\left(\mathbf{A}^{-1}\right)^{-1} &= \mathbf{A} \\
(\mathbf{AC})^{-1} &= \mathbf{C}^{-1}\mathbf{A}^{-1} \\
\text{rank}(\mathbf{A}) &= \text{rank}\left(\mathbf{A}^{-1}\right)
\end{aligned}$$

If $\mathbf{D}$ is a diagonal matrix with nonzero entries on the diagonal—that is, $\mathbf{D} = \text{diag}\,(d_1, \cdots, d_n)$—then $\mathbf{D}^{-1} = \text{diag}\,(1/d_1, \cdots, 1/d_n)$. If $\mathbf{D}$ is a block-diagonal matrix whose blocks are invertible, then

$$\mathbf{D} = \begin{bmatrix} \mathbf{D}_1 & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{D}_2 & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{D}_3 & \cdots & \mathbf{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{D}_n \end{bmatrix} \qquad \mathbf{D}^{-1} = \begin{bmatrix} \mathbf{D}_1^{-1} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{D}_2^{-1} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{D}_3^{-1} & \cdots & \mathbf{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{D}_n^{-1} \end{bmatrix}$$

In statistical applications the following two results are particularly important, because they can significantly reduce the computational burden in working with inverse matrices.

Partitioned Matrix Suppose $\mathbf{A}$ is a nonsingular matrix that is partitioned as

$$\mathbf{A} = \begin{bmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{bmatrix}$$

Then, provided that all the inverses exist, the inverse of $\mathbf{A}$ is given by

$$\mathbf{A}^{-1} = \begin{bmatrix} \mathbf{B}_{11} & \mathbf{B}_{12} \\ \mathbf{B}_{21} & \mathbf{B}_{22} \end{bmatrix}$$

where $\mathbf{B}_{11} = \left(\mathbf{A}_{11} - \mathbf{A}_{12}\mathbf{A}_{22}^{-1}\mathbf{A}_{21}\right)^{-1}$, $\mathbf{B}_{12} = -\mathbf{B}_{11}\mathbf{A}_{12}\mathbf{A}_{22}^{-1}$, $\mathbf{B}_{21} = -\mathbf{A}_{22}^{-1}\mathbf{A}_{21}\mathbf{B}_{11}$, and $\mathbf{B}_{22} = \left(\mathbf{A}_{22} - \mathbf{A}_{21}\mathbf{A}_{11}^{-1}\mathbf{A}_{12}\right)^{-1}$.

Patterned Sum Suppose $\mathbf{R}$ is $(n \times n)$ nonsingular, $\mathbf{G}$ is $(k \times k)$ nonsingular, and $\mathbf{B}$ and $\mathbf{C}$ are $(n \times k)$ and $(k \times n)$ matrices, respectively. Then the inverse of $\mathbf{R} + \mathbf{BGC}$ is given by

$$(\mathbf{R} + \mathbf{BGC})^{-1} = \mathbf{R}^{-1} - \mathbf{R}^{-1}\mathbf{B}\left(\mathbf{G}^{-1} + \mathbf{C}\mathbf{R}^{-1}\mathbf{B}\right)^{-1}\mathbf{C}\mathbf{R}^{-1}$$

This formula is particularly useful if $k << n$ and $\mathbf{R}$ has a simple form that is easy to invert. This case arises, for example, in mixed models where $\mathbf{R}$ might be a diagonal or block-diagonal matrix, and $\mathbf{B} = \mathbf{C}'$.

Another situation where this formula plays a critical role is in the computation of regression diagnostics, such as in determining the effect of removing an observation from the analysis. Suppose that $\mathbf{A} = \mathbf{X}'\mathbf{X}$ represents the crossproduct matrix in the linear model $\text{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$. If $\mathbf{x}_i'$ is the ith row of the $\mathbf{X}$ matrix, then $(\mathbf{X}'\mathbf{X} - \mathbf{x}_i\mathbf{x}_i')$ is the crossproduct matrix in the same model with the ith observation removed. Identifying $\mathbf{B} = -\mathbf{x}_i$,

$\mathbf{C} = \mathbf{x}_i'$, and $\mathbf{G} = \mathbf{I}$ in the preceding inversion formula, you can obtain the expression for the inverse of the crossproduct matrix:

$$\left(\mathbf{X}'\mathbf{X} - \mathbf{x}_i\mathbf{x}_i'\right)^{-1} = \mathbf{X}'\mathbf{X} + \frac{\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{x}_i\mathbf{x}_i'\left(\mathbf{X}'\mathbf{X}\right)^{-1}}{1 - \mathbf{x}_i'\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{x}_i}$$

This expression for the inverse of the reduced data crossproduct matrix enables you to compute "leave-one-out" deletion diagnostics in linear models without refitting the model.

Generalized Inverse Matrices

If $\mathbf{A}$ is rectangular (not square) or singular, then it is not invertible and the matrix $\mathbf{A}^{-1}$ does not exist. Suppose you want to find a solution to simultaneous linear equations of the form

$$\mathbf{A}\mathbf{b} = \mathbf{c}$$

If $\mathbf{A}$ is square and nonsingular, then the unique solution is $\mathbf{b} = \mathbf{A}^{-1}\mathbf{c}$. In statistical applications, the case where $\mathbf{A}$ is $(n \times k)$ rectangular is less important than the case where $\mathbf{A}$ is a $(k \times k)$ square matrix of rank less than k. For example, the normal equations in ordinary least squares (OLS) estimation in the model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$ are

$$\left(\mathbf{X}'\mathbf{X}\right)\boldsymbol{\beta} = \mathbf{X}'\mathbf{Y}$$

A *generalized inverse* matrix is a matrix $\mathbf{A}^-$ such that $\mathbf{A}^-\mathbf{c}$ is a solution to the linear system. In the OLS example, a solution can be found as $\left(\mathbf{X}'\mathbf{X}\right)^-\mathbf{X}'\mathbf{Y}$, where $\left(\mathbf{X}'\mathbf{X}\right)^-$ is a generalized inverse of $\mathbf{X}'\mathbf{X}$.

The following four conditions are often associated with generalized inverses. For the square or rectangular matrix $\mathbf{A}$ there exist matrices $\mathbf{G}$ that satisfy

(i)	$\mathbf{AGA}$	$=$	$\mathbf{A}$
(ii)	$\mathbf{GAG}$	$=$	$\mathbf{G}$
(iii)	$(\mathbf{AG})'$	$=$	$\mathbf{AG}$
(iv)	$(\mathbf{GA})'$	$=$	$\mathbf{GA}$

The matrix $\mathbf{G}$ that satisfies all four conditions is unique and is called the Moore-Penrose inverse, after the first published work on generalized inverses by Moore (1920) and the subsequent definition by Penrose (1955). Only the first condition is required, however, to provide a solution to the linear system above.

Pringle and Rayner (1971) introduced a numbering system to distinguish between different types of generalized inverses. A matrix that satisfies only condition (i) is a g_1-inverse. The g_2-inverse satistifes conditions (i) and (ii). It is also called a *reflexive* generalized inverse. Matrices satisfying conditions (i)–(iii) or conditions (i), (ii), and (iv) are g_3-inverses. Note that a matrix that satisfies the first three conditions is a right generalized inverse, and a matrix that satisfies conditions (i), (ii), and (iv) is a left generalized inverse. For example, if $\mathbf{B}$ is $(n \times k)$ of rank k, then $\left(\mathbf{B}'\mathbf{B}\right)^{-1}\mathbf{B}'$ is a left generalized inverse of $\mathbf{B}$. The notation g_4-inverse for the Moore-Penrose inverse, satisfying conditions (i)–(iv), is often used by extension, but note that Pringle and Rayner (1971) do not use it; rather, they call such a matrix "the" generalized inverse.

If the $(n \times k)$ matrix $\mathbf{X}$ is rank-deficient—that is, $\text{rank}(\mathbf{X}) < \min\{n, k\}$—then the system of equations

$$\left(\mathbf{X}'\mathbf{X}\right)\boldsymbol{\beta} = \mathbf{X}'\mathbf{Y}$$

does not have a unique solution. A particular solution depends on the choice of the generalized inverse. However, some aspects of the statistical inference are invariant to the choice of the generalized inverse. If $\mathbf{G}$ is a generalized inverse of $\mathbf{X}'\mathbf{X}$, then $\mathbf{XGX}'$ is invariant to the choice of $\mathbf{G}$. This result comes into play, for example, when you are computing predictions in an OLS model with a rank-deficient $\mathbf{X}$ matrix, since it implies that the predicted values

$$\mathbf{X}\widehat{\boldsymbol{\beta}} = \mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{y}$$

are invariant to the choice of $\left(\mathbf{X}'\mathbf{X}\right)^{-}$.

Matrix Differentiation

Taking the derivative of expressions involving matrices is a frequent task in statistical estimation. Objective functions that are to be minimized or maximized are usually written in terms of model matrices and/or vectors whose elements depend on the unknowns of the estimation problem. Suppose that $\mathbf{A}$ and $\mathbf{B}$ are real matrices whose elements depend on the scalar quantities β and θ—that is, $\mathbf{A} = \left[a_{ij}(\beta,\theta)\right]$, and similarly for $\mathbf{B}$.

The following are useful results in finding the derivative of elements of a matrix and of functions involving a matrix. For more in-depth discussion of matrix differentiation and matrix calculus, see, for example, Magnus and Neudecker (1999) and Harville (1997).

The derivative of $\mathbf{A}$ with respect to β is denoted $\dot{\mathbf{A}}_\beta$ and is the matrix of the first derivatives of the elements of $\mathbf{A}$:

$$\dot{\mathbf{A}}_\beta = \frac{\partial}{\partial\beta}\mathbf{A} = \left[\frac{\partial a_{ij}(\beta,\theta)}{\partial\beta}\right]$$

Similarly, the second derivative of $\mathbf{A}$ with respect to β and θ is the matrix of the second derivatives

$$\ddot{\mathbf{A}}_{\beta\theta} = \frac{\partial^2}{\partial\beta\,\partial\theta}\mathbf{A} = \left[\frac{\partial^2 a_{ij}(\beta,\theta)}{\partial\beta\,\partial\theta}\right]$$

The following are some basic results involving sums, products, and traces of matrices:

$$\frac{\partial}{\partial\beta}c_1\mathbf{A} = c_1\dot{\mathbf{A}}_\beta$$

$$\frac{\partial}{\partial\beta}(\mathbf{A}+\mathbf{B}) = \dot{\mathbf{A}}_\beta + \dot{\mathbf{B}}_\beta$$

$$\frac{\partial}{\partial\beta}(c_1\mathbf{A}+c_2\mathbf{B}) = c_1\dot{\mathbf{A}}_\beta + c_2\dot{\mathbf{B}}_\beta$$

$$\frac{\partial}{\partial\beta}\mathbf{AB} = \mathbf{A}\dot{\mathbf{B}}_\beta + \dot{\mathbf{A}}_\beta\mathbf{B}$$

$$\frac{\partial}{\partial\beta}\text{trace}(\mathbf{A}) = \text{trace}\left(\dot{\mathbf{A}}_\beta\right)$$

$$\frac{\partial}{\partial\beta}\text{trace}(\mathbf{AB}) = \text{trace}\left(\mathbf{A}\dot{\mathbf{B}}_\beta\right) + \text{trace}\left(\dot{\mathbf{A}}_\beta\mathbf{B}\right)$$

The next set of results is useful in finding the derivative of elements of $\mathbf{A}$ and of functions of $\mathbf{A}$, if $\mathbf{A}$ is a nonsingular matrix:

$$\frac{\partial}{\partial\beta}\mathbf{x}'\mathbf{A}^{-1}\mathbf{x} = -\mathbf{x}'\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1}\mathbf{x}$$

$$\frac{\partial}{\partial\beta}\mathbf{A}^{-1} = -\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1}$$

$$\frac{\partial}{\partial\beta}|\mathbf{A}| = |\mathbf{A}|\,\text{trace}\left(\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\right)$$

$$\frac{\partial}{\partial\beta}\log\{|\mathbf{A}|\} = \frac{1}{|\mathbf{A}|}\frac{\partial}{\partial\beta}\mathbf{A} = \text{trace}\left(\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\right)$$

$$\frac{\partial^2}{\partial\beta\partial\theta}\mathbf{A}^{-1} = -\mathbf{A}^{-1}\ddot{\mathbf{A}}_{\beta\theta}\mathbf{A}^{-1} + \mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1}\dot{\mathbf{A}}_\theta\mathbf{A}^{-1} + \mathbf{A}^{-1}\dot{\mathbf{A}}_\theta\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1}$$

$$\frac{\partial^2}{\partial\beta\partial\theta}\log\{|\mathbf{A}|\} = \text{trace}\left(\mathbf{A}^{-1}\ddot{\mathbf{A}}_{\beta\theta}\right) - \text{trace}\left(\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1}\dot{\mathbf{A}}_\theta\right)$$

Now suppose that $\mathbf{a}$ and $\mathbf{b}$ are column vectors that depend on β and/or θ and that $\mathbf{x}$ is a vector of constants. The following results are useful for manipulating derivatives of linear and quadratic forms:

$$\frac{\partial}{\partial\mathbf{x}}\mathbf{a}'\mathbf{x} = \mathbf{a}$$

$$\frac{\partial}{\partial\mathbf{x}'}\mathbf{B}\mathbf{x} = \mathbf{B}$$

$$\frac{\partial}{\partial\mathbf{x}}\mathbf{x}'\mathbf{B}\mathbf{x} = \left(\mathbf{B} + \mathbf{B}'\right)\mathbf{x}$$

$$\frac{\partial^2}{\partial\mathbf{x}\partial\mathbf{x}'}\mathbf{x}'\mathbf{B}\mathbf{x} = \mathbf{B} + \mathbf{B}'$$

Matrix Decompositions

To decompose a matrix is to express it as a function—typically a product—of other matrices that have particular properties such as orthogonality, diagonality, triangularity. For example, the Cholesky decomposition of a symmetric positive definite matrix $\mathbf{A}$ is $\mathbf{C}\mathbf{C}' = \mathbf{A}$, where $\mathbf{C}$ is a lower-triangular matrix. The spectral decomposition of a symmetric matrix is $\mathbf{A} = \mathbf{P}\mathbf{D}\mathbf{P}'$, where $\mathbf{D}$ is a diagonal matrix and $\mathbf{P}$ is an orthogonal matrix.

Matrix decomposition play an important role in statistical theory as well as in statistical computations. Calculations in terms of decompositions can have greater numerical stability. Decompositions are often necessary to extract information about matrices, such as matrix rank, eigenvalues, or eigenvectors. Decompositions are also used to form special transformations of matrices, such as to form a "square-root" matrix. This section briefly mentions several decompositions that are particularly prevalent and important.

LDU, LU, and Cholesky Decomposition

Every square matrix $\mathbf{A}$, whether it is positive definite or not, can be expressed in the form $\mathbf{A} = \mathbf{L}\mathbf{D}\mathbf{U}$, where $\mathbf{L}$ is a unit lower-triangular matrix, $\mathbf{D}$ is a diagonal matrix, and $\mathbf{U}$ is a unit upper-triangular matrix.

(The diagonal elements of a unit triangular matrix are 1.) Because of the arrangement of the matrices, the decomposition is called the LDU decomposition. Since you can absorb the diagonal matrix into the triangular matrices, the decomposition

$$\mathbf{A} = \mathbf{L}\mathbf{D}^{1/2}\mathbf{D}^{1/2}\mathbf{U} = \mathbf{L}^*\mathbf{U}^*$$

is also referred to as the LU decomposition of $\mathbf{A}$.

If the matrix $\mathbf{A}$ is positive definite, then the diagonal elements of $\mathbf{D}$ are positive and the LDU decomposition is unique. Furthermore, we can add more specificity to this result in that for a symmetric, positive definite matrix, there is a unique decomposition $\mathbf{A} = \mathbf{U}'\mathbf{D}\mathbf{U}$, where $\mathbf{U}$ is unit upper-triangular and $\mathbf{D}$ is diagonal with positive elements. Absorbing the square root of $\mathbf{D}$ into $\mathbf{U}$, $\mathbf{C} = \mathbf{D}^{1/2}\mathbf{U}$, the decomposition is known as the *Cholesky* decomposition of a positive-definite matrix:

$$\mathbf{B} = \mathbf{U}'\mathbf{D}^{1/2}\,\mathbf{D}^{1/2}\mathbf{U} = \mathbf{C}'\mathbf{C}$$

where $\mathbf{C}$ is upper triangular.

If $\mathbf{B}$ is $(n \times n)$ symmetric nonnegative definite of rank k, then we can extend the Cholesky decomposition as follows. Let $\mathbf{C}^*$ denote the lower-triangular matrix such that

$$\mathbf{C}^* = \begin{bmatrix} \mathbf{C}_{k\times k} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

Then $\mathbf{B} = \mathbf{C}\mathbf{C}'$.

Spectral Decomposition

Suppose that $\mathbf{A}$ is an $(n \times n)$ symmetric matrix. Then there exists an orthogonal matrix $\mathbf{Q}$ and a diagonal matrix $\mathbf{D}$ such that $\mathbf{A} = \mathbf{Q}\mathbf{D}\mathbf{Q}'$. Of particular importance is the case where the orthogonal matrix is also orthonormal—that is, its column vectors have unit norm. Denote this orthonormal matrix as $\mathbf{P}$. Then the corresponding diagonal matrix—$\mathbf{\Lambda} = \text{diag}(\lambda_i, \cdots, \lambda_n)$, say—contains the eigenvalues of $\mathbf{A}$. The spectral decomposition of $\mathbf{A}$ can be written as

$$\mathbf{A} = \mathbf{P}\mathbf{\Lambda}\mathbf{P}' = \sum_{i=1}^{n} \lambda_i \mathbf{p}_i \mathbf{p}_i'$$

where $\mathbf{p}_i$ denotes the ith column vector of $\mathbf{P}$. The right-side expression decomposes $\mathbf{A}$ into a sum of rank-1 matrices, and the weight of each contribution is equal to the eigenvalue associated with the ith eigenvector. The sum furthermore emphasizes that the rank of $\mathbf{A}$ is equal to the number of nonzero eigenvalues.

Harville (1997, p. 538) refers to the spectral decomposition of $\mathbf{A}$ as the decomposition that takes the previous sum one step further and accumulates contributions associated with the distinct eigenvalues. If $\lambda_i^*, \cdots, \lambda_k^*$ are the distinct eigenvalues and $\mathbf{E}_j = \sum \mathbf{p}_i \mathbf{p}_i'$, where the sum is taken over the set of columns for which $\lambda_i = \lambda_j^*$, then

$$\mathbf{A} = \sum_{i=1}^{k} \lambda_j^* \mathbf{E}_j$$

You can employ the spectral decomposition of a nonnegative definite symmetric matrix to form a "square-root" matrix of $\mathbf{A}$. Suppose that $\mathbf{\Lambda}^{1/2}$ is the diagonal matrix containing the square roots of the λ_i. Then $\mathbf{B} = \mathbf{P}\mathbf{\Lambda}^{1/2}\mathbf{P}'$ is a square-root matrix of $\mathbf{A}$ in the sense that $\mathbf{BB} = \mathbf{A}$, because

$$\mathbf{BB} = \mathbf{P}\mathbf{\Lambda}^{1/2}\mathbf{P}'\mathbf{P}\mathbf{\Lambda}^{1/2}\mathbf{P}' = \mathbf{P}\mathbf{\Lambda}^{1/2}\mathbf{\Lambda}^{1/2}\mathbf{P}' = \mathbf{P}\mathbf{\Lambda}\mathbf{P}'$$

Generating the Moore-Penrose inverse of a matrix based on the spectral decomposition is also simple. Denote as $\mathbf{\Delta}$ the diagonal matrix with typical element

$$\delta_i = \begin{cases} 1/\lambda_i & \lambda_i \neq 0 \\ 0 & \lambda_i = 0 \end{cases}$$

Then the matrix $\mathbf{P}\mathbf{\Delta}\mathbf{P}' = \sum \delta_i \mathbf{p}_i \mathbf{p}_i'$ is the Moore-Penrose (g_4-generalized) inverse of $\mathbf{A}$.

Singular-Value Decomposition

The singular-value decomposition is related to the spectral decomposition of a matrix, but it is more general. The singular-value decomposition can be applied to any matrix. Let $\mathbf{B}$ be an $(n \times p)$ matrix of rank k. Then there exist orthogonal matrices P and Q of order $(n \times n)$ and $(p \times p)$, respectively, and a diagonal matrix $\mathbf{D}$ such that

$$\mathbf{P}'\mathbf{B}\mathbf{Q} = \mathbf{D} = \begin{bmatrix} \mathbf{D}_1 & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

where $\mathbf{D}_1$ is a diagonal matrix of order k. The diagonal elements of $\mathbf{D}_1$ are strictly positive. As with the spectral decomposition, this result can be written as a decomposition of $\mathbf{B}$ into a weighted sum of rank-1 matrices

$$\mathbf{B} = -\mathbf{P}\mathbf{D}\mathbf{Q}' = \sum_{i=1}^{n} d_i \mathbf{p}_i \mathbf{q}_i'$$

The scalars $d_1, \cdots, d_k$ are called the *singular values* of the matrix $\mathbf{B}$. They are the positive square roots of the nonzero eigenvalues of the matrix $\mathbf{B}'\mathbf{B}$. If the singular-value decomposition is applied to a symmetric, nonnegative definite matrix $\mathbf{A}$, then the singular values $d_1, \cdots, d_n$ are the nonzero eigenvalues of $\mathbf{A}$ and the singular-value decomposition is the same as the spectral decomposition.

As with the spectral decomposition, you can use the results of the singular-value decomposition to generate the Moore-Penrose inverse of a matrix. If $\mathbf{B}$ is $(n \times p)$ with singular-value decomposition $\mathbf{P}\mathbf{D}\mathbf{Q}'$, and if $\mathbf{\Delta}$ is a diagonal matrix with typical element

$$\delta_i = \begin{cases} 1/d_i & |d_i| \neq 0 \\ 0 & d_i = 0 \end{cases}$$

then $\mathbf{Q}\mathbf{\Delta}\mathbf{P}'$ is the g_4-generalized inverse of $\mathbf{B}$.

Expectations of Random Variables and Vectors

If Y is a discrete random variable with mass function $p(y)$ and support (possible values) $y_1, y_2, \cdots$, then the expectation (expected value) of Y is defined as

$$\mathrm{E}[Y] = \sum_{j=1}^{\infty} y_j \; p(y_j)$$

provided that $\sum |y_j| p(y_j) < \infty$, otherwise the sum in the definition is not well-defined. The expected value of a function $h(y)$ is similarly defined: provided that $\sum |h(y_j)| p(y_j) < \infty$,

$$\mathrm{E}[h(Y)] = \sum_{j=1}^{\infty} h(y_j)\, p(y_j)$$

For continuous random variables, similar definitions apply, but summation is replaced by integration over the support of the random variable. If X is a continuous random variable with density function $f(x)$, and $\int |x| f(x) dx < \infty$, then the expectation of X is defined as

$$\mathrm{E}[X] = \int_{-\infty}^{\infty} x f(x)\, dx$$

The expected value of a random variable is also called its *mean* or its first moment. A particularly important function of a random variable is $h(Y) = (Y - \mathrm{E}[Y])^2$. The expectation of $h(Y)$ is called the *variance* of Y or the second central moment of Y. When you study the properties of multiple random variables, then you might be interested in aspects of their joint distribution. The covariance between random variables Y and X is defined as the expected value of the function $(Y - \mathrm{E}[Y])(X - \mathrm{E}[X])$, where the expectation is taken under the bivariate joint distribution of Y and X:

$$\mathrm{Cov}[Y, X] = \mathrm{E}[(Y - \mathrm{E}[Y])(X - \mathrm{E}[X])] = \mathrm{E}[YX] - \mathrm{E}[Y]\mathrm{E}[X] = \int\int x\, y f(x, y)\; dxdy - \mathrm{E}[Y]\mathrm{E}[X]$$

The *covariance* between a random variable and itself is the variance, $\mathrm{Cov}[Y, Y] = \mathrm{Var}[Y]$.

In statistical applications and formulas, random variables are often collected into vectors. For example, a random sample of size n from the distribution of Y generates a random vector of order $(n \times 1)$,

$$\mathbf{Y} = \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_n \end{bmatrix}$$

The expected value of the $(n \times 1)$ random vector $\mathbf{Y}$ is the vector of the means of the elements of $\mathbf{Y}$:

$$\mathbf{E}[\mathbf{Y}] = [\mathrm{E}[Y_i]] = \begin{bmatrix} \mathrm{E}[Y_1] \\ \mathrm{E}[Y_2] \\ \vdots \\ \mathrm{E}[Y_n] \end{bmatrix}$$

It is often useful to directly apply rules about working with means, variances, and covariances of random vectors. To develop these rules, suppose that $\mathbf{Y}$ and $\mathbf{U}$ denote two random vectors with typical elements $Y_1, \cdots, Y_n$ and $U_1, \cdots, U_k$. Further suppose that $\mathbf{A}$ and $\mathbf{B}$ are constant (nonstochastic) matrices, that $\mathbf{a}$ is a constant vector, and that the c_i are scalar constants.

The following rules enable you to derive the mean of a linear function of a random vector:

$$\begin{aligned} \mathrm{E}[\mathbf{A}] &= \mathbf{A} \\ \mathrm{E}[\mathbf{Y} + \mathbf{a}] &= \mathrm{E}[\mathbf{Y}] \\ \mathrm{E}[\mathbf{AY} + \mathbf{a}] &= \mathbf{A}\mathrm{E}[\mathbf{Y}] + \mathbf{a} \\ \mathrm{E}[\mathbf{Y} + \mathbf{U}] &= \mathrm{E}[\mathbf{Y}] + \mathrm{E}[\mathbf{U}] \end{aligned}$$

The *covariance matrix* of $\mathbf{Y}$ and $\mathbf{U}$ is the $(n \times k)$ matrix whose typical element in row i, column j is the covariance between Y_i and U_j. The covariance matrix between two random vectors is frequently denoted with the Cov "operator."

$$\begin{aligned}
\text{Cov}[\mathbf{Y}, \mathbf{U}] &= \left[\text{Cov}[Y_i, U_j]\right] \\
&= \text{E}\left[(\mathbf{Y} - \text{E}[\mathbf{Y}])\,(\mathbf{U} - \text{E}[\mathbf{U}])'\right] = \text{E}\left[\mathbf{Y}\mathbf{U}'\right] - \text{E}[\mathbf{Y}]\text{E}[\mathbf{U}]' \\
&= \begin{bmatrix}
\text{Cov}[Y_1, U_1] & \text{Cov}[Y_1, U_2] & \text{Cov}[Y_1, U_3] & \cdots & \text{Cov}[Y_1, U_k] \\
\text{Cov}[Y_2, U_1] & \text{Cov}[Y_2, U_2] & \text{Cov}[Y_2, U_3] & \cdots & \text{Cov}[Y_2, U_k] \\
\text{Cov}[Y_3, U_1] & \text{Cov}[Y_3, U_2] & \text{Cov}[Y_3, U_3] & \cdots & \text{Cov}[Y_3, U_k] \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\text{Cov}[Y_n, U_1] & \text{Cov}[Y_n, U_2] & \text{Cov}[Y_n, U_3] & \cdots & \text{Cov}[Y_n, U_k]
\end{bmatrix}
\end{aligned}$$

The *variance matrix* of a random vector $\mathbf{Y}$ is the covariance matrix between $\mathbf{Y}$ and itself. The variance matrix is frequently denoted with the Var "operator."

$$\begin{aligned}
\text{Var}[\mathbf{Y}] &= \text{Cov}[\mathbf{Y}, \mathbf{Y}] = \left[\text{Cov}[Y_i, Y_j]\right] \\
&= \text{E}\left[(\mathbf{Y} - \text{E}[\mathbf{Y}])\,(\mathbf{Y} - \text{E}[\mathbf{Y}])'\right] = \text{E}\left[\mathbf{Y}\mathbf{Y}'\right] - \text{E}[\mathbf{Y}]\text{E}[\mathbf{Y}]' \\
&= \begin{bmatrix}
\text{Cov}[Y_1, Y_1] & \text{Cov}[Y_1, Y_2] & \text{Cov}[Y_1, Y_3] & \cdots & \text{Cov}[Y_1, Y_n] \\
\text{Cov}[Y_2, Y_1] & \text{Cov}[Y_2, Y_2] & \text{Cov}[Y_2, Y_3] & \cdots & \text{Cov}[Y_2, Y_n] \\
\text{Cov}[Y_3, Y_1] & \text{Cov}[Y_3, Y_2] & \text{Cov}[Y_3, Y_3] & \cdots & \text{Cov}[Y_3, Y_n] \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\text{Cov}[Y_n, Y_1] & \text{Cov}[Y_n, Y_2] & \text{Cov}[Y_n, Y_3] & \cdots & \text{Cov}[Y_n, Y_n]
\end{bmatrix} \\
&= \begin{bmatrix}
\text{Var}[Y_1] & \text{Cov}[Y_1, Y_2] & \text{Cov}[Y_1, Y_3] & \cdots & \text{Cov}[Y_1, Y_n] \\
\text{Cov}[Y_2, Y_1] & \text{Var}[Y_2] & \text{Cov}[Y_2, Y_3] & \cdots & \text{Cov}[Y_2, Y_n] \\
\text{Cov}[Y_3, Y_1] & \text{Cov}[Y_3, Y_2] & \text{Var}[Y_3] & \cdots & \text{Cov}[Y_3, Y_n] \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\text{Cov}[Y_n, Y_1] & \text{Cov}[Y_n, Y_2] & \text{Cov}[Y_n, Y_3] & \cdots & \text{Var}[Y_n]
\end{bmatrix}
\end{aligned}$$

Because the variance matrix contains variances on the diagonal and covariances in the off-diagonal positions, it is also referred to as the *variance-covariance matrix* of the random vector $\mathbf{Y}$.

If the elements of the covariance matrix $\text{Cov}[\mathbf{Y}, \mathbf{U}]$ are zero, the random vectors are uncorrelated. If $\mathbf{Y}$ and $\mathbf{U}$ are normally distributed, then a zero covariance matrix implies that the vectors are stochastically independent. If the off-diagonal elements of the variance matrix $\text{Var}[\mathbf{Y}]$ are zero, the elements of the random vector $\mathbf{Y}$ are uncorrelated. If $\mathbf{Y}$ is normally distributed, then a diagonal variance matrix implies that its elements are stochastically independent.

Suppose that $\mathbf{A}$ and $\mathbf{B}$ are constant (nonstochastic) matrices and that c_i denotes a scalar constant. The following results are useful in manipulating covariance matrices:

$$\begin{aligned}
\text{Cov}[\mathbf{AY}, \mathbf{U}] &= \mathbf{A}\text{Cov}[\mathbf{Y}, \mathbf{U}] \\
\text{Cov}[\mathbf{Y}, \mathbf{BU}] &= \text{Cov}[\mathbf{Y}, \mathbf{U}]\mathbf{B}' \\
\text{Cov}[\mathbf{AY}, \mathbf{BU}] &= \mathbf{A}\text{Cov}[\mathbf{Y}, \mathbf{U}]\mathbf{B}' \\
\text{Cov}[c_1\mathbf{Y}_1 + c_2\mathbf{U}_1, c_3\mathbf{Y}_2 + c_4\mathbf{U}_2] &= c_1c_3\text{Cov}[\mathbf{Y}_1, \mathbf{Y}_2] + c_1c_4\text{Cov}[\mathbf{Y}_1, \mathbf{U}_2] \\
&\quad + c_2c_3\text{Cov}[\mathbf{U}_1, \mathbf{Y}_2] + c_2c_4\text{Cov}[\mathbf{U}_1, \mathbf{U}_2]
\end{aligned}$$

Since $\text{Cov}[\mathbf{Y}, \mathbf{Y}] = \text{Var}[\mathbf{Y}]$, these results can be applied to produce the following results, useful in manipulating variances of random vectors:

$$\begin{aligned}
\text{Var}[\mathbf{A}] &= \mathbf{0} \\
\text{Var}[\mathbf{AY}] &= \mathbf{A}\text{Var}[\mathbf{Y}]\mathbf{A}' \\
\text{Var}[\mathbf{Y} + \mathbf{x}] &= \text{Var}[\mathbf{Y}] \\
\text{Var}[\mathbf{x}'\mathbf{Y}] &= \mathbf{x}'\text{Var}[\mathbf{Y}]\mathbf{x} \\
\text{Var}[c_1\mathbf{Y}] &= c_1^2\text{Var}[\mathbf{Y}] \\
\text{Var}[c_1\mathbf{Y} + c_2\mathbf{U}] &= c_1^2\text{Var}[\mathbf{Y}] + c_2^2\text{Var}[\mathbf{U}] + 2c_1c_2\text{Cov}[\mathbf{Y}, \mathbf{U}]
\end{aligned}$$

Another area where expectation rules are helpful is quadratic forms in random variables. These forms arise particularly in the study of linear statistical models and in linear statistical inference. Linear inference is statistical inference about linear function of random variables, even if those random variables are defined through nonlinear models. For example, the parameter estimator $\widehat{\boldsymbol{\theta}}$ might be derived in a nonlinear model, but this does not prevent statistical questions from being raised that can be expressed through linear functions of $\boldsymbol{\theta}$; for example,

$$H_0: \begin{cases} \theta_1 - 2\theta_2 = 0 \\ \theta_2 - \theta_3 = 0 \end{cases}$$

if $\mathbf{A}$ is a matrix of constants and $\mathbf{Y}$ is a random vector, then

$$\text{E}[\mathbf{Y}'\mathbf{AY}] = \text{trace}(\mathbf{A}\text{Var}[\mathbf{Y}]) + \text{E}[\mathbf{Y}]'\mathbf{A}\text{E}[\mathbf{Y}]$$

Mean Squared Error

The mean squared error is arguably the most important criterion used to evaluate the performance of a predictor or an estimator. (The subtle distinction between predictors and estimators is that random variables are predicted and constants are estimated.) The mean squared error is also useful to relay the concepts of bias, precision, and accuracy in statistical estimation. In order to examine a mean squared error, you need a target of estimation or prediction, and a predictor or estimator that is a function of the data. Suppose that the target, whether a constant or a random variable, is denoted as U. The mean squared error of the estimator or predictor $T(\mathbf{Y})$ for U is

$$\text{MSE}\left[T(\mathbf{Y}); U\right] = \text{E}\left[(T(\mathbf{Y}) - U)^2\right]$$

The reason for using a squared difference to measure the "loss" between $T(\mathbf{Y})$ and U is mostly convenience; properties of squared differences involving random variables are more easily examined than, say, absolute differences. The reason for taking an expectation is to remove the randomness of the squared difference by averaging over the distribution of the data.

Consider first the case where the target U is a constant—say, the parameter β—and denote the mean of the estimator $T(\mathbf{Y})$ as μ_T. The mean squared error can then be decomposed as

$$\begin{aligned}\text{MSE}[T(\mathbf{Y});\beta] &= \text{E}\left[(T(\mathbf{Y})-\beta)^2\right] \\ &= \text{E}\left[(T(\mathbf{Y})-\mu_T)^2\right] - \text{E}\left[(\beta-\mu_T)^2\right] \\ &= \text{Var}[T(\mathbf{Y})] + (\beta-\mu_T)^2\end{aligned}$$

The mean squared error thus comprises the variance of the estimator and the squared bias. The two components can be associated with an estimator's precision (small variance) and its accuracy (small bias).

If $T(\mathbf{Y})$ is an unbiased estimator of β—that is, if $\text{E}[T(\mathbf{Y})] = \beta$—then the mean squared error is simply the variance of the estimator. By choosing an estimator that has minimum variance, you also choose an estimator that has minimum mean squared error among all unbiased estimators. However, as you can see from the previous expression, bias is also an "average" property; it is defined as an expectation. It is quite possible to find estimators in some statistical modeling problems that have smaller mean squared error than a minimum variance unbiased estimator; these are estimators that permit a certain amount of bias but improve on the variance. For example, in models where regressors are highly collinear, the ordinary least squares estimator continues to be unbiased. However, the presence of collinearity can induce poor precision and lead to an erratic estimator. Ridge regression stabilizes the regression estimates in this situation, and the coefficient estimates are somewhat biased, but the bias is more than offset by the gains in precision.

When the target U is a random variable, you need to carefully define what an unbiased prediction means. If the statistic and the target have the same expectation, $\text{E}[U] = \text{E}[T(\mathbf{Y})]$, then

$$\text{MSE}\left[T(\mathbf{Y});U\right] = \text{Var}[T(\mathbf{Y})] + \text{Var}[U] - 2\text{Cov}[T(\mathbf{Y}),U]$$

In many instances the target U is a new observation that was not part of the analysis. If the data are uncorrelated, then it is reasonable to assume in that instance that the new observation is also not correlated with the data. The mean squared error then reduces to the sum of the two variances. For example, in a linear regression model where U is a new observation Y_0 and $T(\mathbf{Y})$ is the regression estimator

$$\widehat{Y}_0 = \mathbf{x}_0'\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{Y}$$

with variance $\text{Var}[Y_0] = \sigma^2\mathbf{x}_0'\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{x}_0$, the mean squared prediction error for Y_0 is

$$\text{MSE}\left[\widehat{Y};Y_0\right] = \sigma^2\left(\mathbf{x}_0'\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{x}_0 + 1\right)$$

and the mean squared prediction error for predicting the mean $\text{E}[Y_0]$ is

$$\text{MSE}\left[\widehat{Y};\text{E}[Y_0]\right] = \sigma^2\mathbf{x}_0'\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{x}_0$$

Linear Model Theory

This section presents some basic statistical concepts and results for the linear model with homoscedastic, uncorrelated errors in which the parameters are estimated by ordinary least squares. The model can be written as

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon} \qquad \boldsymbol{\epsilon} \sim (0, \sigma^2\mathbf{I})$$

where $\mathbf{Y}$ is an $(n \times 1)$ vector and $\mathbf{X}$ is an $(n \times k)$ matrix of known constants. The model equation implies the following expected values:

$$\mathrm{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$$

$$\mathrm{Var}[\mathbf{Y}] = \sigma^2\mathbf{I} \Leftrightarrow \mathrm{Cov}[Y_i, Y_j] = \begin{cases} \sigma^2 & i = j \\ 0 & \text{otherwise} \end{cases}$$

Finding the Least Squares Estimators

Finding the least squares estimator of $\boldsymbol{\beta}$ can be motivated as a calculus problem or by considering the geometry of least squares. The former approach simply states that the OLS estimator is the vector $\widehat{\boldsymbol{\beta}}$ that minimizes the objective function

$$\mathrm{SSE} = (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})$$

Applying the differentiation rules from the section "Matrix Differentiation" on page 48 leads to

$$\begin{aligned} \frac{\partial}{\partial\boldsymbol{\beta}}\mathrm{SSE} &= \frac{\partial}{\partial\boldsymbol{\beta}}(\mathbf{Y}'\mathbf{Y} - 2\mathbf{Y}'\mathbf{X}\boldsymbol{\beta} + \boldsymbol{\beta}'\mathbf{X}'\mathbf{X}\boldsymbol{\beta}) \\ &= \mathbf{0} - 2\mathbf{X}'\mathbf{Y} + 2\mathbf{X}'\mathbf{X}\boldsymbol{\beta} \\ \frac{\partial^2}{\partial\boldsymbol{\beta}\partial\boldsymbol{\beta}}\mathrm{SSE} &= \mathbf{X}'\mathbf{X} \end{aligned}$$

Consequently, the solution to the *normal equations*, $\mathbf{X}'\mathbf{X}\boldsymbol{\beta} = \mathbf{X}'\mathbf{Y}$, solves $\frac{\partial}{\partial\boldsymbol{\beta}}\mathrm{SSE} = 0$, and the fact that the second derivative is nonnegative definite guarantees that this solution minimizes SSE. The geometric argument to motivate ordinary least squares estimation is as follows. Assume that $\mathbf{X}$ is of rank k. For any value of $\boldsymbol{\beta}$, such as $\tilde{\boldsymbol{\beta}}$, the following identity holds:

$$\mathbf{Y} = \mathbf{X}\tilde{\boldsymbol{\beta}} + \left(\mathbf{Y} - \mathbf{X}\tilde{\boldsymbol{\beta}}\right)$$

The vector $\mathbf{X}\tilde{\boldsymbol{\beta}}$ is a point in a k-dimensional subspace of R^n, and the residual $(\mathbf{Y} - \mathbf{X}\tilde{\boldsymbol{\beta}})$ is a point in an $(n-k)$-dimensional subspace. The OLS estimator is the value $\widehat{\boldsymbol{\beta}}$ that minimizes the distance of $\mathbf{X}\tilde{\boldsymbol{\beta}}$ from $\mathbf{Y}$, implying that $\mathbf{X}\widehat{\boldsymbol{\beta}}$ and $(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}})$ are orthogonal to each other; that is,

$(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}})'\mathbf{X}\widehat{\boldsymbol{\beta}} = \mathbf{0}$. This in turn implies that $\widehat{\boldsymbol{\beta}}$ satisfies the normal equations, since

$$\widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y} = \widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{X}\widehat{\boldsymbol{\beta}} \Leftrightarrow \mathbf{X}'\mathbf{X}\widehat{\boldsymbol{\beta}} = \mathbf{X}'\mathbf{Y}$$

Full-Rank Case

If $\mathbf{X}$ is of full column rank, the OLS estimator is unique and given by

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{Y}$$

The OLS estimator is an unbiased estimator of $\boldsymbol{\beta}$—that is,

$$\begin{aligned}\mathrm{E}[\widehat{\boldsymbol{\beta}}] &= \mathrm{E}\left[\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{Y}\right] \\ &= \left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathrm{E}[\mathbf{Y}] = \left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{X}\boldsymbol{\beta} = \boldsymbol{\beta}\end{aligned}$$

Note that this result holds if $\mathrm{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$; in other words, the condition that the model errors have mean zero is sufficient for the OLS estimator to be unbiased. If the errors are homoscedastic and uncorrelated, the OLS estimator is indeed the *best* linear unbiased estimator (BLUE) of $\boldsymbol{\beta}$—that is, no other estimator that is a linear function of $\mathbf{Y}$ has a smaller mean squared error. The fact that the estimator is unbiased implies that no other linear estimator has a smaller variance. If, furthermore, the model errors are normally distributed, then the OLS estimator has minimum variance among all unbiased estimators of $\boldsymbol{\beta}$, whether they are linear or not. Such an estimator is called a *uniformly minimum variance unbiased estimator*, or UMVUE.

Rank-Deficient Case

In the case of a rank-deficient $\mathbf{X}$ matrix, a generalized inverse is used to solve the normal equations:

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{Y}$$

Although a g_1-inverse is sufficient to solve a linear system, computational expedience and interpretation of the results often dictate the use of a generalized inverse with reflexive properties (that is, a g_2-inverse; see the section "Generalized Inverse Matrices" on page 47 for details). Suppose, for example, that the $\mathbf{X}$ matrix is partitioned as $\mathbf{X} = [\mathbf{X}_1\ \mathbf{X}_2]$, where $\mathbf{X}_1$ is of full column rank and each column in $\mathbf{X}_2$ is a linear combination of the columns of $\mathbf{X}_1$. The matrix

$$\mathbf{G}_1 = \begin{bmatrix} \left(\mathbf{X}_1'\mathbf{X}_1\right)^{-1} & \left(\mathbf{X}_1'\mathbf{X}_1\right)^{-1}\mathbf{X}_1'\mathbf{X}_2 \\ -\mathbf{X}_2'\mathbf{X}_1\left(\mathbf{X}_1'\mathbf{X}_1\right)^{-1} & \mathbf{0} \end{bmatrix}$$

is a g_1-inverse of $\mathbf{X}'\mathbf{X}$ and

$$\mathbf{G}_2 = \begin{bmatrix} \left(\mathbf{X}_1'\mathbf{X}_1\right)^{-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

is a g_2-inverse. If the least squares solution is computed with the g_1-inverse, then computing the variance of the estimator requires additional matrix operations and storage. On the other hand, the variance of the solution that uses a g_2-inverse is proportional to G_2.

$$\begin{aligned}\mathrm{Var}\left[\mathbf{G}_1\mathbf{X}'\mathbf{Y}\right] &= \sigma^2\mathbf{G}_1\mathbf{X}'\mathbf{X}\mathbf{G}_1 \\ \mathrm{Var}\left[\mathbf{G}_2\mathbf{X}'\mathbf{Y}\right] &= \sigma^2\mathbf{G}_2\mathbf{X}'\mathbf{X}\mathbf{G}_2 = \sigma^2\mathbf{G}_2\end{aligned}$$

If a generalized inverse $\mathbf{G}$ of $\mathbf{X}'\mathbf{X}$ is used to solve the normal equations, then the resulting solution is a biased estimator of $\boldsymbol{\beta}$ (unless $\mathbf{X}'\mathbf{X}$ is of full rank, in which case the generalized inverse is "the" inverse), since $\mathrm{E}\left[\widehat{\boldsymbol{\beta}}\right] = \mathbf{G}\mathbf{X}'\mathbf{X}\boldsymbol{\beta}$, which is not in general equal to $\boldsymbol{\beta}$.

If you think of estimation as "estimation without bias," then $\widehat{\boldsymbol{\beta}}$ is the estimator of something, namely $\mathbf{GX}\boldsymbol{\beta}$. Since this is not a quantity of interest and since it is not unique—it depends on your choice of $\mathbf{G}$—Searle (1971, p. 169) cautions that in the less-than-full-rank case, $\widehat{\boldsymbol{\beta}}$ is a solution to the normal equations and "nothing more."

Analysis of Variance

The identity

$$\mathbf{Y} = \mathbf{X}\tilde{\boldsymbol{\beta}} + \left(\mathbf{Y} - \mathbf{X}\tilde{\boldsymbol{\beta}}\right)$$

holds for all vectors $\tilde{\boldsymbol{\beta}}$, but only for the least squares solution is the residual $(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}})$ orthogonal to the predicted value $\mathbf{X}\widehat{\boldsymbol{\beta}}$. Because of this orthogonality, the additive identity holds not only for the vectors themselves, but also for their lengths (Pythagorean theorem):

$$||\mathbf{Y}||^2 = ||\mathbf{X}\widehat{\boldsymbol{\beta}}||^2 + ||(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}})||^2$$

Note that $\mathbf{X}\widehat{\boldsymbol{\beta}} = \mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{Y} = \mathbf{HY}$ and note that $\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}} = (\mathbf{I} - \mathbf{H})\mathbf{Y} = \mathbf{MY}$. The matrices $\mathbf{H}$ and $\mathbf{M} = \mathbf{I} - \mathbf{H}$ play an important role in the theory of linear models and in statistical computations. Both are *projection* matrices—that is, they are symmetric and idempotent. (An idempotent matrix $\mathbf{A}$ is a square matrix that satisfies $\mathbf{AA} = \mathbf{A}$. The eigenvalues of an idempotent matrix take on the values 1 and 0 only.) The matrix $\mathbf{H}$ projects onto the subspace of R^n that is spanned by the columns of $\mathbf{X}$. The matrix $\mathbf{M}$ projects onto the orthogonal complement of that space. Because of these properties you have $\mathbf{H}' = \mathbf{H}$, $\mathbf{HH} = \mathbf{H}$, $\mathbf{M}' = \mathbf{M}$, $\mathbf{MM} = \mathbf{M}$, $\mathbf{HM} = \mathbf{0}$.

The Pythagorean relationship now can be written in terms of $\mathbf{H}$ and $\mathbf{M}$ as follows:

$$||\mathbf{Y}||^2 = \mathbf{Y}'\mathbf{Y} = ||\mathbf{HY}||^2 + ||\mathbf{MY}||^2 = \mathbf{Y}'\mathbf{H}'\mathbf{HY} + \mathbf{Y}'\mathbf{M}'\mathbf{MY} = \mathbf{Y}'\mathbf{HY} + \mathbf{Y}'\mathbf{MY}$$

If $\mathbf{X}'\mathbf{X}$ is deficient in rank and a generalized inverse is used to solve the normal equations, then you work instead with the projection matrices $\mathbf{H} = \mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'$. Note that if $\mathbf{G}$ is a generalized inverse of $\mathbf{X}'\mathbf{X}$, then $\mathbf{XGX}'$, and hence also $\mathbf{H}$ and $\mathbf{M}$, are invariant to the choice of $\mathbf{G}$.

The matrix $\mathbf{H}$ is sometimes referred to as the "hat" matrix because when you premultiply the vector of observations with $\mathbf{H}$, you produce the fitted values, which are commonly denoted by placing a "hat" over the $\mathbf{Y}$ vector, $\widehat{\mathbf{Y}} = \mathbf{HY}$.

The term $\mathbf{Y}'\mathbf{Y}$ is the uncorrected total sum of squares (SST) of the linear model, $\mathbf{Y}'\mathbf{MY}$ is the error (residual) sum of squares (SSR), and $\mathbf{Y}'\mathbf{HY}$ is the uncorrected model sum of squares. This leads to the analysis of variance table shown in Table 3.2.

Table 3.2 Analysis of Variance with Uncorrected Sums of Squares

Source	df	Sum of Squares
Model	rank($\mathbf{X}$)	SSM $= \mathbf{Y}'\mathbf{HY} = \widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y}$
Residual	$n -$ rank($\mathbf{X}$)	SSR $= \mathbf{Y}'\mathbf{MY} = \mathbf{Y}'\mathbf{Y} - \widehat{\boldsymbol{\beta}}\mathbf{X}'\mathbf{Y} = \sum_{i=1}^{n}\left(Y_i - \widehat{Y}_i\right)^2$
Uncorr. Total	n	SST $= \mathbf{Y}'\mathbf{Y} = \sum_{i=1}^{n} Y_i^2$

When the model contains an intercept term, then the analysis of variance is usually corrected for the mean, as shown in Table 3.3.

Table 3.3 Analysis of Variance with Corrected Sums of Squares

Source	df	Sum of Squares
Model	$\text{rank}(\mathbf{X}) - 1$	$\text{SSM}_c = \widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y} - n\overline{Y}^2 = \sum_{i=1}^{n}\left(\widehat{Y}_i - \overline{Y}_i\right)^2$
Residual	$n - \text{rank}(\mathbf{X})$	$\text{SSR} = \mathbf{Y}'\mathbf{M}\mathbf{Y} = \mathbf{Y}'\mathbf{Y} - \widehat{\boldsymbol{\beta}}\mathbf{X}'\mathbf{Y} = \sum_{i=1}^{n}\left(Y_i - \widehat{Y}_i\right)^2$
Corrected Total	$n - 1$	$\text{SST}_c = \mathbf{Y}'\mathbf{Y} - n\overline{Y}^2 = \sum_{i=1}^{n}\left(Y_i - \overline{Y}\right)^2$

The *coefficient of determination*, also called the R-square statistic, measures the proportion of the total variation explained by the linear model. In models with intercept, it is defined as the ratio

$$R^2 = 1 - \frac{\text{SSR}}{\text{SST}_c} = 1 - \frac{\sum_{i=1}^{n}\left(Y_i - \widehat{Y}_i\right)^2}{\sum_{i=1}^{n}\left(Y_i - \overline{Y}\right)^2}$$

In models without intercept, the R-square statistic is a ratio of the uncorrected sums of squares

$$R^2 = 1 - \frac{\text{SSR}}{\text{SST}} = 1 - \frac{\sum_{i=1}^{n}\left(Y_i - \widehat{Y}_i\right)^2}{\sum_{i=1}^{n} Y_i^2}$$

Estimating the Error Variance

The least squares principle does not provide for a parameter estimator for σ^2. The usual approach is to use a method-of-moments estimator that is based on the sum of squared residuals. If the model is correct, then the mean square for error, defined to be SSR divided by its degrees of freedom,

$$\begin{aligned}\widehat{\sigma}^2 &= \frac{1}{n - \text{rank}(\mathbf{X})}\left(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}}\right)'\left(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}}\right) \\ &= \text{SSR}/(n - \text{rank}(\mathbf{X}))\end{aligned}$$

is an unbiased estimator of σ^2.

Maximum Likelihood Estimation

To estimate the parameters in a linear model with mean function $\text{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$ by maximum likelihood, you need to specify the distribution of the response vector $\mathbf{Y}$. In the linear model with a continuous response variable, it is commonly assumed that the response is normally distributed. In that case, the estimation problem is completely defined by specifying the mean and variance of $\mathbf{Y}$ in addition to the normality assumption. The model can be written as $\mathbf{Y} \sim N(\mathbf{X}\boldsymbol{\beta}, \sigma^2\mathbf{I})$, where the notation $N(\mathbf{a}, \mathbf{V})$ indicates a multivariate normal distribution with mean vector $\mathbf{a}$ and variance matrix $\mathbf{V}$. The log likelihood for $\mathbf{Y}$ then can be written as

$$l(\boldsymbol{\beta}, \sigma^2; \mathbf{y}) = -\frac{n}{2}\log\{2\pi\} - \frac{n}{2}\log\{\sigma^2\} - \frac{1}{2\sigma^2}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})$$

This function is maximized in $\boldsymbol{\beta}$ when the sum of squares $(\mathbf{y}-\mathbf{X}\boldsymbol{\beta})'(\mathbf{y}-\mathbf{X}\boldsymbol{\beta})$ is minimized. The maximum likelihood estimator of $\boldsymbol{\beta}$ is thus identical to the ordinary least squares estimator. To maximize $l(\boldsymbol{\beta},\sigma^2;\mathbf{y})$ with respect to σ^2, note that

$$\frac{\partial l(\boldsymbol{\beta},\sigma^2;\mathbf{y})}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{1}{2\sigma^4}(\mathbf{y}-\mathbf{X}\boldsymbol{\beta})'(\mathbf{y}-\mathbf{X}\boldsymbol{\beta})$$

Hence the MLE of σ^2 is the estimator

$$\begin{aligned}\widehat{\sigma}^2_M &= \frac{1}{n}\left(\mathbf{Y}-\mathbf{X}\widehat{\boldsymbol{\beta}}\right)'\left(\mathbf{Y}-\mathbf{X}\widehat{\boldsymbol{\beta}}\right)\\ &= \mathrm{SSR}/n\end{aligned}$$

This is a biased estimator of σ^2, with a bias that decreases with n.

Estimable Functions

A function $\mathbf{L}\boldsymbol{\beta}$ is said to be estimable if there exists a linear combination of the expected value of $\mathbf{Y}$, such as $\mathbf{K}\mathrm{E}[\mathbf{Y}]$, that equals $\mathbf{L}\boldsymbol{\beta}$. Since $\mathrm{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$, the definition of estimability implies that $\mathbf{L}\boldsymbol{\beta}$ is estimable if there is a matrix $\mathbf{K}$ such that $\mathbf{L} = \mathbf{KX}$. Another way of looking at this result is that the rows of $\mathbf{X}$ form a generating set from which all estimable functions can be constructed.

The concept of estimability of functions is important in the theory and application of linear models because hypotheses of interest are often expressed as linear combinations of the parameter estimates (for example, hypotheses of equality between parameters, $\beta_1 = \beta_2 \Leftrightarrow \beta_1 - \beta_2 = 0$). Since estimability is not related to the particular value of the parameter estimate, but to the row space of $\mathbf{X}$, you can test only hypotheses that consist of estimable functions. Further, because estimability is not related to the value of $\boldsymbol{\beta}$ (Searle 1971, p. 181), the choice of the generalized inverse in a situation with rank-deficient $\mathbf{X}'\mathbf{X}$ matrix is immaterial, since

$$\mathbf{L}\widehat{\boldsymbol{\beta}} = \mathbf{KX}\widehat{\boldsymbol{\beta}} = \mathbf{KX}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{Y}$$

where $\mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}$ is invariant to the choice of generalized inverse.

$\mathbf{L}\boldsymbol{\beta}$ is estimable if and only if $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}(\mathbf{X}'\mathbf{X}) = \mathbf{L}$ (see, for example, Searle 1971, p. 185). If $\mathbf{X}$ is of full rank, then the *Hermite* matrix $(\mathbf{X}'\mathbf{X})^{-}(\mathbf{X}'\mathbf{X})$ is the identity, which implies that all linear functions are estimable in the full-rank case.

See Chapter 15, "The Four Types of Estimable Functions," for many details about the various forms of estimable functions in SAS/STAT.

Test of Hypotheses

Consider a general linear hypothesis of the form $H:\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$, where $\mathbf{L}$ is a $(k \times p)$ matrix. It is assumed that $\mathbf{d}$ is such that this hypothesis is linearly consistent—that is, that there exists *some* $\boldsymbol{\beta}$ for which $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$. This is always the case if $\mathbf{d}$ is in the column space of $\mathbf{L}$, if $\mathbf{L}$ has full row rank, or if $\mathbf{d} = \mathbf{0}$; the latter is the most common case. Since many linear models have a rank-deficient $\mathbf{X}$ matrix, the question arises whether the hypothesis is testable. The idea of testability of a hypothesis is—not surprisingly—connected to the concept of estimability as introduced previously. The hypothesis $H:\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ is testable if it consists of estimable functions.

There are two important approaches to testing hypotheses in statistical applications—the reduction principle and the linear inference approach. The reduction principle states that the validity of the hypothesis can be inferred by comparing a suitably chosen summary statistic between the model at hand and a reduced model in which the constraint $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ is imposed. The linear inference approach relies on the fact that $\widehat{\boldsymbol{\beta}}$ is an estimator of $\boldsymbol{\beta}$ and its stochastic properties are known, at least approximately. A test statistic can then be formed using $\widehat{\boldsymbol{\beta}}$, and its behavior under the restriction $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ can be ascertained.

The two principles lead to identical results in certain—for example, least squares estimation in the classical linear model. In more complex situations the two approaches lead to similar but not identical results. This is the case, for example, when weights or unequal variances are involved, or when $\widehat{\boldsymbol{\beta}}$ is a nonlinear estimator.

Reduction Tests

The two main reduction principles are the sum of squares reduction test and the likelihood ratio test. The test statistic in the former is proportional to the difference of the residual sum of squares between the reduced model and the full model. The test statistic in the likelihood ratio test is proportional to the difference of the log likelihoods between the full and reduced models. To fix these ideas, suppose that you are fitting the model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$, where $\boldsymbol{\epsilon} \sim N(\mathbf{0}, \sigma^2\mathbf{I})$. Suppose that SSR denotes the residual sum of squares in this model and that SSR_H is the residual sum of squares in the model for which $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ holds. Then under the hypothesis the ratio

$$(\text{SSR}_H - \text{SSR})/\sigma^2$$

follows a chi-square distribution with degrees of freedom equal to the rank of $\mathbf{L}$. Maybe surprisingly, the residual sum of squares in the full model is distributed independently of this quantity, so that under the hypothesis,

$$F = \frac{(\text{SSR}_H - \text{SSR})/\text{rank}(\mathbf{L})}{\text{SSR}/(n - \text{rank}(\mathbf{X}))}$$

follows an F distribution with $\text{rank}(\mathbf{L})$ numerator and $n - \text{rank}(\mathbf{X})$ denominator degrees of freedom. Note that the quantity in the denominator of the F statistic is a particular estimator of σ^2—namely, the unbiased moment-based estimator that is customarily associated with least squares estimation. It is also the restricted maximum likelihood estimator of σ^2 if $\mathbf{Y}$ is normally distributed.

In the case of the likelihood ratio test, suppose that $l(\widehat{\boldsymbol{\beta}}, \widehat{\sigma}^2; \mathbf{y})$ denotes the log likelihood evaluated at the ML estimators. Also suppose that $l(\widehat{\boldsymbol{\beta}}_H, \widehat{\sigma}^2_H; \mathbf{y})$ denotes the log likelihood in the model for which $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ holds. Then under the hypothesis the statistic

$$\lambda = 2\left(l(\widehat{\boldsymbol{\beta}}, \widehat{\sigma}^2; \mathbf{y}) - l(\widehat{\boldsymbol{\beta}}_H, \widehat{\sigma}^2_H; \mathbf{y})\right)$$

follows approximately a chi-square distribution with degrees of freedom equal to the rank of $\mathbf{L}$. In the case of a normally distributed response, the log-likelihood function can be profiled with respect to $\boldsymbol{\beta}$. The resulting profile log likelihood is

$$l(\widehat{\sigma}^2; \mathbf{y}) = -\frac{n}{2}\log\{2\pi\} - \frac{n}{2}\left(\log\{\widehat{\sigma}^2\}\right)$$

and the likelihood ratio test statistic becomes

$$\lambda = n\left(\log\left\{\widehat{\sigma}^2_H\right\} - \log\left\{\widehat{\sigma}^2\right\}\right) = n\left(\log\left\{\text{SSR}_H\right\} - \log\left\{\text{SSR}\right\}\right) = n\left(\log\left\{\text{SSR}_H/\text{SSR}\right\}\right)$$

The preceding expressions show that, in the case of normally distributed data, both reduction principles lead to simple functions of the residual sums of squares in two models. As Pawitan (2001, p. 151) puts it, there is, however, an important difference not in the computations but in the statistical content. The least squares principle, where sum of squares reduction tests are widely used, does not require a distributional specification. Assumptions about the distribution of the data are added to provide a framework for confirmatory inferences, such as the testing of hypotheses. This framework stems directly from the assumption about the data's distribution, or from the sampling distribution of the least squares estimators. The likelihood principle, on the other hand, requires a distributional specification at the outset. Inference about the parameters is implicit in the model; it is the result of further *computations* following the estimation of the parameters. In the least squares framework, inference about the parameters is the result of further *assumptions*.

Linear Inference

The principle of linear inference is to formulate a test statistic for $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ that builds on the linearity of the hypothesis about $\boldsymbol{\beta}$. For many models that have linear components, the estimator $\mathbf{L}\widehat{\boldsymbol{\beta}}$ is also linear in $\mathbf{Y}$. It is then simple to establish the distributional properties of $\mathbf{L}\widehat{\boldsymbol{\beta}}$ based on the distributional assumptions about $\mathbf{Y}$ or based on large-sample arguments. For example, $\widehat{\boldsymbol{\beta}}$ might be a nonlinear estimator, but it is known to asymptotically follow a normal distribution; this is the case in many nonlinear and generalized linear models.

If the sampling distribution or the asymptotic distribution of $\widehat{\boldsymbol{\beta}}$ is normal, then one can easily derive quadratic forms with known distributional properties. For example, if the random vector $\mathbf{U}$ is distributed as $N(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, then $\mathbf{U}'\mathbf{A}\mathbf{U}$ follows a chi-square distribution with rank($\mathbf{A}$) degrees of freedom and noncentrality parameter $1/2\boldsymbol{\mu}'\mathbf{A}\boldsymbol{\mu}$, provided that $\mathbf{A}\boldsymbol{\Sigma}\mathbf{A}\boldsymbol{\Sigma} = \mathbf{A}\boldsymbol{\Sigma}$.

In the classical linear model, suppose that $\mathbf{X}$ is deficient in rank and that $\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{Y}$ is a solution to the normal equations. Then, if the errors are normally distributed,

$$\widehat{\boldsymbol{\beta}} \sim N\left(\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{X}\boldsymbol{\beta}, \sigma^2\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-}\right)$$

Because $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ is testable, $\mathbf{L}\boldsymbol{\beta}$ is estimable, and thus $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X} = \mathbf{L}$, as established in the previous section. Hence,

$$\mathbf{L}\widehat{\boldsymbol{\beta}} \sim N\left(\mathbf{L}\boldsymbol{\beta}, \sigma^2\mathbf{L}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{L}'\right)$$

The conditions for a chi-square distribution of the quadratic form

$$(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})'\left(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'\right)^{-}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})$$

are thus met, provided that

$$(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-}\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-}\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}' = (\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-}\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'$$

This condition is obviously met if $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'$ is of full rank. The condition is also met if $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'^{-}$ is a reflexive inverse (a g_2-inverse) of $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}$.

The test statistic to test the linear hypothesis $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ is thus

$$F = \frac{(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})'\left(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'\right)^{-}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})/\text{rank}(\mathbf{L})}{SSR/(n - \text{rank}(\mathbf{X}))}$$

and it follows an F distribution with rank($\mathbf{L}$) numerator and $n - \text{rank}(\mathbf{X})$ denominator degrees of freedom under the hypothesis.

This test statistic looks very similar to the F statistic for the sum of squares reduction test. This is no accident. If the model is linear and parameters are estimated by ordinary least squares, then you can show that the quadratic form $(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})' \left(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'\right)^{-} (\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})$ equals the differences in the residual sum of squares, $\text{SSR}_H - \text{SSR}$, where SSR_H is obtained as the residual sum of squares from OLS estimation in a model that satisfies $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$. However, this correspondence between the two test formulations does not apply when a different estimation principle is used. For example, assume that $\boldsymbol{\epsilon} \sim N(\mathbf{0}, \mathbf{V})$ and that $\boldsymbol{\beta}$ is estimated by generalized least squares:

$$\widehat{\boldsymbol{\beta}}_g = \left(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}\right)^{-} \mathbf{X}'\mathbf{V}^{-1}\mathbf{Y}$$

The construction of $\mathbf{L}$ matrices associated with hypotheses in SAS/STAT software is frequently based on the properties of the $\mathbf{X}$ matrix, not of $\mathbf{X}'\mathbf{V}^{-}\mathbf{X}$. In other words, the construction of the $\mathbf{L}$ matrix is governed only by the design. A sum of squares reduction test for $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ that uses the generalized residual sum of squares $(\mathbf{Y} - \widehat{\boldsymbol{\beta}}_g)'\mathbf{V}^{-1}(\mathbf{Y} - \widehat{\boldsymbol{\beta}}_g)$ is not identical to a linear hypothesis test with the statistic

$$F^* = \frac{\widehat{\boldsymbol{\beta}}_g'\mathbf{L}' \left(\mathbf{L}\left(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}\right)^{-}\mathbf{L}'\right)^{-} \mathbf{L}\widehat{\boldsymbol{\beta}}_g}{\text{rank}(\mathbf{L})}$$

Furthermore, $\mathbf{V}$ is usually unknown and must be estimated as well. The estimate for $\mathbf{V}$ depends on the model, and imposing a constraint on the model would change the estimate. The asymptotic distribution of the statistic F^* is a chi-square distribution. However, in practical applications the F distribution with rank($\mathbf{L}$) numerator and ν denominator degrees of freedom is often used because it provides a better approximation to the sampling distribution of F^* in finite samples. The computation of the denominator degrees of freedom ν, however, is a matter of considerable discussion. A number of methods have been proposed and are implemented in various forms in SAS/STAT (see, for example, the degrees-of-freedom methods in the MIXED and GLIMMIX procedures).

Residual Analysis

The model errors $\boldsymbol{\epsilon} = \mathbf{Y} - \mathbf{X}\boldsymbol{\beta}$ are unobservable. Yet important features of the statistical model are connected to them, such as the distribution of the data, the correlation among observations, and the constancy of variance. It is customary to diagnose and investigate features of the model errors through the fitted residuals $\widehat{\boldsymbol{\epsilon}} = \mathbf{Y} - \widehat{\mathbf{Y}} = \mathbf{Y} - \mathbf{H}\mathbf{Y} = \mathbf{M}\mathbf{Y}$. These residuals are projections of the data onto the null space of $\mathbf{X}$ and are also referred to as the "raw" residuals to contrast them with other forms of residuals that are transformations of $\widehat{\boldsymbol{\epsilon}}$. For the classical linear model, the statistical properties of $\widehat{\boldsymbol{\epsilon}}$ are affected by the features of that projection and can be summarized as follows:

$$\begin{aligned} \text{E}[\widehat{\boldsymbol{\epsilon}}] &= \mathbf{0} \\ \text{Var}[\widehat{\boldsymbol{\epsilon}}] &= \sigma^2\mathbf{M} \\ \text{rank}(\mathbf{M}) &= n - \text{rank}(\mathbf{X}) \end{aligned}$$

Furthermore, if $\boldsymbol{\epsilon} \sim N(\mathbf{0}, \sigma^2\mathbf{I})$, then $\widehat{\boldsymbol{\epsilon}} \sim N(\mathbf{0}, \sigma^2\mathbf{M})$.

Because $\mathbf{M} = \mathbf{I} - \mathbf{H}$, and the "hat" matrix $\mathbf{H}$ satisfies $\partial\widehat{\mathbf{Y}}/\partial\mathbf{Y}$, the hat matrix is also the leverage matrix of the model. If h_{ii} denotes the ith diagonal element of $\mathbf{H}$ (the leverage of observation i), then the leverages

are bounded in a model with intercept, $1/n \leq h_{ii} \leq 1$. Consequently, the variance of a raw residual is less than that of an observation: $\text{Var}[\widehat{\epsilon}_i] = \sigma^2(1 - h_{ii}) < \sigma^2$. In applications where the variability of the data is estimated from fitted residuals, the estimate is invariably biased low. An example is the computation of an empirical semivariogram based on fitted (detrended) residuals.

More important, the diagonal entries of $\mathbf{H}$ are not necessarily identical; the residuals are heteroscedastic. The "hat" matrix is also not a diagonal matrix; the residuals are correlated. In summary, the only property that the fitted residuals $\widehat{\boldsymbol{\epsilon}}$ share with the model errors is a zero mean. It is thus commonplace to use transformations of the fitted residuals for diagnostic purposes.

Raw and Studentized Residuals

A *standardized* residual is a raw residual that is divided by its standard deviation:

$$\widehat{\epsilon}_i^* = \frac{Y_i - \widehat{Y}_i}{\sqrt{\text{Var}[Y_i - \widehat{Y}_i]}} = \frac{\widehat{\epsilon}_i}{\sqrt{\sigma^2(1 - h_{ii})}}$$

Because σ^2 is unknown, residual standardization is usually not practical. A *studentized* residual is a raw residual that is divided by its estimated standard deviation. If the estimate of the standard deviation is based on the same data that were used in fitting the model, the residual is also called an *internally studentized* residual:

$$\widehat{\epsilon}_{is} = \frac{Y_i - \widehat{Y}_i}{\sqrt{\widehat{\text{Var}}[Y_i - \widehat{Y}_i]}} = \frac{\widehat{\epsilon}_i}{\sqrt{\widehat{\sigma}^2(1 - h_{ii})}}$$

If the estimate of the residual's variance does not involve the ith observation, it is called an *externally studentized* residual. Suppose that $\widehat{\sigma}^2_{-i}$ denotes the estimate of the residual variance obtained without the ith observation; then the externally studentized residual is

$$\widehat{\epsilon}_{ir} = \frac{\widehat{\epsilon}_i}{\sqrt{\widehat{\sigma}^2_{-i}(1 - h_{ii})}}$$

Scaled Residuals

A scaled residual is simply a raw residual divided by a scalar quantity that is not an estimate of the variance of the residual. For example, residuals divided by the standard deviation of the response variable are scaled and referred to as Pearson or Pearson-type residuals:

$$\widehat{\epsilon}_{ic} = \frac{Y_i - \widehat{Y}_i}{\sqrt{\widehat{\text{Var}}[Y_i]}}$$

In generalized linear models, where the variance of an observation is a function of the mean μ and possibly of an extra scale parameter, $\text{Var}[Y] = a(\mu)\phi$, the Pearson residual is

$$\widehat{\epsilon}_{iP} = \frac{Y_i - \widehat{\mu}_i}{\sqrt{a(\widehat{\mu})}}$$

because the sum of the squared Pearson residuals equals the Pearson X^2 statistic:

$$X^2 = \sum_{i=1}^{n} \widehat{\epsilon}_{iP}^2$$

When the scale parameter ϕ participates in the scaling, the residual is also referred to as a Pearson-type residual:

$$\widehat{\epsilon}_{iP} = \frac{Y_i - \widehat{\mu}_i}{\sqrt{a(\widehat{\mu})\phi}}$$

Other Residuals

You might encounter other residuals in SAS/STAT software. A "leave-one-out" residual is the difference between the observed value and the residual obtained from fitting a model in which the observation in question did not participate. If $\widehat{Y}_i$ is the predicted value of the ith observation and $\widehat{Y}_{i,-i}$ is the predicted value if Y_i is removed from the analysis, then the "leave-one-out" residual is

$$\widehat{\epsilon}_{i,-i} = Y_i - \widehat{Y}_{i,-i}$$

Since the sum of the squared "leave-one-out" residuals is the PRESS statistic (prediction sum of squares; Allen 1974), $\widehat{\epsilon}_{i,-i}$ is also called the PRESS residual. The concept of the PRESS residual can be generalized if the deletion residual can be based on the removal of sets of observations. In the classical linear model, the PRESS residual for case deletion has a particularly simple form:

$$\widehat{\epsilon}_{i,-i} = Y_i - \widehat{Y}_{i,-i} = \frac{\widehat{\epsilon}_i}{1 - h_{ii}}$$

That is, the PRESS residual is simply a scaled form of the raw residual, where the scaling factor is a function of the leverage of the observation.

When data are correlated, $\mathrm{Var}[\mathbf{Y}] = \mathbf{V}$, you can scale the vector of residuals rather than scale each residual separately. This takes the covariances among the observations into account. This form of scaling is accomplished by forming the Cholesky root $\mathbf{C}'\mathbf{C} = \mathbf{V}$, where $\mathbf{C}'$ is a lower-triangular matrix. Then $\mathbf{C}'^{-1}\mathbf{Y}$ is a vector of uncorrelated variables with unit variance. The Cholesky residuals in the model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$ are

$$\widehat{\boldsymbol{\epsilon}}_C = \mathbf{C}'^{-1}\left(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}}\right)$$

In generalized linear models, the fit of a model can be measured by the scaled deviance statistic D^*. It measures the difference between the log likelihood under the model and the maximum log likelihood that is achievable. In models with a scale parameter ϕ, the deviance is $D = \phi \times D^* = \sum_{i=1}^{n} d_i$. The deviance residuals are the signed square roots of the contributions to the deviance statistic:

$$\widehat{\epsilon}_{id} = \mathrm{sign}\{y_i - \widehat{\mu}_i\}\sqrt{d_i}$$

Sweep Operator

The sweep operator (Goodnight 1979) is closely related to Gauss-Jordan elimination and the Forward Doolittle procedure. The fact that a sweep operation can produce a generalized inverse by in-place mapping

with minimal storage and that its application invariably leads to some form of matrix inversion is important, but this observation does not do justice to the pervasive relevance of sweeping to statistical computing. In this section the sweep operator is discussed as a conceptual tool for further insight into linear model operations. Consider the nonnegative definite, symmetric, partitioned matrix

$$\mathbf{A} = \begin{bmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{12}' & \mathbf{A}_{22} \end{bmatrix}$$

Sweeping a matrix consists of performing a series of row operations akin to Gauss-Jordan elimination. Basic row operations are the multiplication of a row by a constant and the addition of a multiple of one row to another. The sweep operator restricts row operations to pivots on the diagonal elements of a matrix; further details about the elementary operations can be found in Goodnight (1979). The process of sweeping the matrix $\mathbf{A}$ on its leading partition is denoted as $\text{Sweep}(\mathbf{A}, \mathbf{A}_{11})$ and leads to

$$\text{Sweep}(\mathbf{A}, \mathbf{A}_{11}) = \begin{bmatrix} \mathbf{A}_{11}^{-} & \mathbf{A}_{11}^{-}\mathbf{A}_{12} \\ -\mathbf{A}_{12}'\mathbf{A}_{11}^{-} & \mathbf{A}_{22} - \mathbf{A}_{12}'\mathbf{A}_{11}^{-}\mathbf{A}_{12} \end{bmatrix}$$

If the kth row and column are set to zero when the pivot is zero (or in practice, less than some singularity tolerance), the generalized inverse in the leading position of the swept matrix is a reflexive, g_2-inverse. Suppose that the crossproduct matrix of the linear model is augmented with a "Y-border" as follows:

$$\mathbf{C} = \begin{bmatrix} \mathbf{X}'\mathbf{X} & \mathbf{X}'\mathbf{Y} \\ \mathbf{Y}'\mathbf{X} & \mathbf{Y}'\mathbf{Y} \end{bmatrix}$$

Then the result of sweeping on the rows of $\mathbf{X}$ is

$$\begin{aligned} \text{Sweep}(\mathbf{C}, \mathbf{X}) &= \begin{bmatrix} (\mathbf{X}'\mathbf{X})^{-} & (\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{Y} \\ -\mathbf{Y}'\mathbf{X}(\mathbf{X}'\mathbf{X})^{-} & \mathbf{Y}'\mathbf{Y} - \mathbf{Y}'\mathbf{X}(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{Y} \end{bmatrix} \\ &= \begin{bmatrix} (\mathbf{X}'\mathbf{X})^{-} & \widehat{\boldsymbol{\beta}} \\ -\widehat{\boldsymbol{\beta}} & \mathbf{Y}'\mathbf{M}\mathbf{Y} \end{bmatrix} = \begin{bmatrix} (\mathbf{X}'\mathbf{X})^{-} & \widehat{\boldsymbol{\beta}} \\ -\widehat{\boldsymbol{\beta}} & \text{SSR} \end{bmatrix} \end{aligned}$$

The "Y-border" has been transformed into the least squares solution and the residual sum of squares.

Partial sweeps are common in model selection. Suppose that the $\mathbf{X}$ matrix is partitioned as $[\mathbf{X}_1\ \mathbf{X}_2]$, and consider the augmented crossproduct matrix

$$\mathbf{C} = \begin{bmatrix} \mathbf{X}_1'\mathbf{X}_1 & \mathbf{X}_1'\mathbf{X}_2 & \mathbf{X}_1'\mathbf{Y} \\ \mathbf{X}_2'\mathbf{X}_1 & \mathbf{X}_2'\mathbf{X}_2 & \mathbf{X}_2'\mathbf{Y} \\ \mathbf{Y}'\mathbf{X}_1 & \mathbf{Y}'\mathbf{X}_2 & \mathbf{Y}'\mathbf{Y} \end{bmatrix}$$

Sweeping on the $\mathbf{X}_1$ partition yields

$$\text{Sweep}(\mathbf{C}, \mathbf{X}_1) = \begin{bmatrix} (\mathbf{X}_1'\mathbf{X}_1)^{-} & (\mathbf{X}_1'\mathbf{X}_1)^{-}\mathbf{X}_1'\mathbf{X}_2 & (\mathbf{X}_1'\mathbf{X}_1)^{-}\mathbf{X}_1'\mathbf{Y} \\ -\mathbf{X}_2'\mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-} & \mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2 & \mathbf{X}_2'\mathbf{M}_1\mathbf{Y} \\ \mathbf{Y}'\mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-} & \mathbf{Y}'\mathbf{M}_1\mathbf{X}_2 & \mathbf{Y}'\mathbf{M}_1\mathbf{Y} \end{bmatrix}$$

where $\mathbf{M}_1 = \mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-}\mathbf{X}_1'$. The entries in the first row of this partition are the generalized inverse of $\mathbf{X}'\mathbf{X}$, the coefficients for regressing $\mathbf{X}_2$ on $\mathbf{X}_1$, and the coefficients for regressing $\mathbf{Y}$ on $\mathbf{X}_1$. The diagonal entries $\mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2$ and $\mathbf{Y}'\mathbf{M}_1\mathbf{Y}$ are the sum of squares and crossproduct matrices for regressing $\mathbf{X}_2$ on $\mathbf{X}_1$ and for regressing $\mathbf{Y}$ on $\mathbf{X}_1$, respectively. As you continue to sweep the matrix, the last cell in the partition contains the residual sum of square of a model in which $\mathbf{Y}$ is regressed on all columns swept up to that point.

The sweep operator is not only useful to conceptualize the computation of least squares solutions, Type I and Type II sums of squares, and generalized inverses. It can also be used to obtain other statistical information. For example, adding the logarithms of the pivots of the rows that are swept yields the log determinant of the matrix.

Chapter 4

Introduction to Regression Procedures

Contents

Overview: Regression Procedures

This chapter provides an overview of procedures in SAS/STAT software that perform regression analysis. The REG procedure provides the most extensive analysis capabilities for linear regression models involving

individual numeric independent variables. Many other procedures can fit such models, but they are designed for more general models, such as robust regression, generalized linear regression, nonlinear regression, nonparametric regression, regression modeling of survey data, regression modeling of survival data, and regression modeling of transformed variables.

The aim of this chapter is to provide a brief road map and delineation of the various SAS/STAT procedures that can fit regression models. Some of the procedures that fall into this category are the CATMOD, GAM, GENMOD, GLIMMIX, GLM, LIFEREG, LOESS, LOGISTIC, MIXED, NLIN, NLMIXED, ORTHOREG, PHREG, PLS, PROBIT, REG, ROBUSTREG, RSREG, SURVEYLOGISTIC, SURVEYPHREG, SURVEYREG, and TRANSREG procedures.

This chapter also briefly mentions several procedures in SAS/ETS software.

Introduction

Recall from Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," that the general regression problem is to model the mean of a random vector $\mathbf{Y}$ as a function of a parameters and covariates in a statistical model. The many forms of regression models have their origin in the characteristics of the response variable (discrete or continuous, normal or nonnormal distributed), assumptions about the form of the model (linear, nonlinear, or generalized linear), assumptions about the data-generating mechanism (survey, observational, or experimental data), and estimation principles. The following procedures, listed in alphabetical order, perform at least one type of regression analysis.

CATMOD analyzes data that can be represented by a contingency table. PROC CATMOD fits linear models to functions of response frequencies, and it can be used for linear and logistic regression. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 29, "The CATMOD Procedure," for more information.

GAM fits generalized additive models. The models fitted with the GAM procedure are nonparameteric in that the usual assumption of a linear predictor is relaxed. The name stems from the fact that the models consist of additive, smooth functions in the regression variables. The GAM procedure can fit additive models to nonnormal data. See Chapter 38, "The GAM Procedure," for more information.

GENMOD fits generalized linear models. PROC GENMOD is especially suited for responses with discrete outcomes, and it performs logistic regression and Poisson regression in addition to fitting generalized estimating equations for repeated measures data. Bayesian analysis capabilities for generalized linear models are also available with the GENMOD procedure. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 39, "The GENMOD Procedure," for more information.

GLIMMIX fits generalized linear mixed models by likelihood-based methods. In addition to many other analyses, PROC GLIMMIX can perform simple, multiple, polynomial, and weighted regression. The GLIMMIX procedure can also fit linear mixed models and models without random effects. See Chapter 40, "The GLIMMIX Procedure," for more information.

GLM uses the method of least squares to fit general linear models. In addition to many other analyses, PROC GLM can perform simple, multiple, polynomial, and weighted regres-

	sion. PROC GLM has many of the same input/output capabilities as PROC REG, but it does not provide as many diagnostic tools or allow interactive changes in the model or data. See Chapter 5, "Introduction to Analysis of Variance Procedures," and Chapter 41, "The GLM Procedure," for more information.
LIFEREG	fits parametric models to failure-time data that might be right-censored. These types of models are commonly used in survival analysis. See Chapter 14, "Introduction to Survey Procedures," and Chapter 50, "The LIFEREG Procedure," for more information.
LOESS	fits nonparametric models by using a local regression method. PROC LOESS is suitable for modeling regression surfaces where the underlying parametric form is unknown and where robustness in the presence of outliers is required. See Chapter 52, "The LOESS Procedure," for more information.
LOGISTIC	fits logistic models for binomial and ordinal outcomes. PROC LOGISTIC provides a wide variety of model-building methods and computes numerous regression diagnostics. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 53, "The LOGISTIC Procedure," for more information.
MIXED	fits linear mixed models by likelihood-based techniques. In addition to many other analyses, PROC MIXED can fit models without random effects; hence, the procedure can perform simple, multiple, polynomial, and weighted regression. See Chapter 58, "The MIXED Procedure," for more information.
NLIN	fits general nonlinear regression models by the method of nonlinear least squares. Several different iterative methods are available. See Chapter 62, "The NLIN Procedure," for more information.
NLMIXED	fits general nonlinear mixed regression models by the method of maximum likelihood. With the NLMIXED procedure you can specify a custom objective function for parameter estimation and fit models with or without random effects. See Chapter 63, "The NLMIXED Procedure," for more information.
ORTHOREG	performs regression by using the Gentleman-Givens computational method. For ill-conditioned data, PROC ORTHOREG can produce more accurate parameter estimates than other procedures such as PROC GLM and PROC REG. See Chapter 65, "The ORTHOREG Procedure," for more information.
PHREG	fits Cox proportional hazards regression models to survival data. See Chapter 66, "The PHREG Procedure," for more information.
PLS	performs partial least squares regression, principal components regression, and reduced rank regression, with cross validation for the number of components. See Chapter 69, "The PLS Procedure," for more information.
PROBIT	performs probit regression in addition to logistic regression and ordinal logistic regression. The PROBIT procedure is useful when the dependent variable is either dichotomous or polychotomous and the independent variables are continuous. See Chapter 74, "The PROBIT Procedure," for more information.
QUANTREG	models the effects of covariates on the conditional quantiles of a response variable by means of quantile regression. See Chapter 75, "The QUANTREG Procedure," for more information.
REG	performs linear regression with many diagnostic capabilities, selects models by using one of nine methods, produces scatter plots of raw data and statistics, highlights scatter plots

to identify particular observations, and allows interactive changes in both the regression model and the data that are used to fit the model. See Chapter 76, "The REG Procedure," for more information.

ROBUSTREG performs robust regression by using Huber M estimation and high breakdown value estimation. PROC ROBUSTREG is suitable for detecting outliers and providing resistant (stable) results in the presence of outliers. See Chapter 77, "The ROBUSTREG Procedure," for more information.

RSREG builds quadratic response-surface regression models. PROC RSREG analyzes the fitted response surface to determine the factor levels of optimum response and performs a ridge analysis to search for the region of optimum response. See Chapter 78, "The RSREG Procedure," for more information.

SURVEYLOGISTIC fits logistic models for binary and ordinal outcomes to survey data by maximum likelihood. See Chapter 87, "The SURVEYLOGISTIC Procedure," for more information.

SURVEYPHREG fits proportional hazards models for survey data by maximizing a partial pseudo-likelihood function that incorporates the sampling weights. The procedure provides design-based variance estimates, confidence intervals, and tests for the estimated proportional hazards regression coefficients. See Chapter 89, "The SURVEYPHREG Procedure," for more information.

SURVEYREG fits linear regression models to survey data by generalized least squares by using elementwise regresssion. See Chapter 90, "The SURVEYREG Procedure," for more information.

TRANSREG fits univariate and multivariate linear models, optionally with spline and other nonlinear transformations. Models include ordinary regression and ANOVA, multiple and multivariate regression, metric and nonmetric conjoint analysis, metric and nonmetric vector and ideal point preference mapping, redundancy analysis, canonical correlation, and response surface regression. See Chapter 93, "The TRANSREG Procedure," for more information.

Several SAS/ETS procedures also perform regression. The following procedures are documented in the *SAS/ETS User's Guide*.

AUTOREG implements regression models that use time series data where the errors are autocorrelated. See Chapter 8, "The AUTOREG Procedure" (*SAS/ETS User's Guide*), for more details.

COUNTREG analyzes regression models in which the dependent variable takes nonnegative integer or count values. See Chapter 11, "The COUNTREG Procedure" (*SAS/ETS User's Guide*), for more details.

MODEL handles nonlinear simultaneous systems of equations, such as econometric models. See Chapter 19, "The MODEL Procedure" (*SAS/ETS User's Guide*), for more details.

PANEL analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. See Chapter 20, "The PANEL Procedure" (*SAS/ETS User's Guide*), for more details.

PDLREG performs regression analysis with polynomial distributed lags. See Chapter 21, "The PDLREG Procedure" (*SAS/ETS User's Guide*), for more details.

SYSLIN handles linear simultaneous systems of equations, such as econometric models. See Chapter 29, "The SYSLIN Procedure" (*SAS/ETS User's Guide*), for more details.

Introductory Example: Linear Regression

Regression analysis is the analysis of the relationship between a response or outcome variable and another set of variables. The relationship is expressed through a statistical model equation that predicts a *response variable* (also called a *dependent variable* or *criterion*) from a function of *regressor variables* (also called *independent variables, predictors, explanatory variables, factors,* or *carriers*) and *parameters*. In a linear regression model the predictor function is linear in the parameters (but not necessarily linear in the regressor variables). The parameters are estimated so that a measure of fit is optimized. For example, the equation for the ith observation might be

$$Y_i = \beta_0 + \beta_1 x_i + \epsilon_i$$

where Y_i is the response variable, x_i is a regressor variable, β_0 and β_1 are unknown parameters to be estimated, and ϵ_i is an error term. This model is termed the simple linear regression (SLR) model, because it is linear in β_0 and β_1 and contains only a single regressor variable.

Suppose you are using regression analysis to relate a child's weight to a child's height. One application of a regression model with the response variable Weight is to predict a child's weight for a known height. Suppose you collect data by measuring heights and weights of 19 randomly selected schoolchildren. A simple linear regression model with the response variable weight and the regressor variable height can be written as

$$\text{Weight}_i = \beta_0 + \beta_1 \, \text{Height}_i + \epsilon_i$$

where

Weight_i	is the response variable for the ith child
Height_i	is the regressor variable for the ith child
β_0, β_1	are the unknown regression parameters
ϵ_i	is the unobservable random error associated with the ith observation

The data set sashelp.class, which is available in the Sashelp library, identifies the children and their observed heights (variable Height) and weights (variable Weight). The following statements perform the regression analysis:

```
ods graphics on;
proc reg data=sashelp.class;
   model Weight = Height;
run;
```

Figure 4.1 displays the default tabular output of the REG procedure for this model. Nineteen observations are read from the data set and all observations are used in the analysis. The estimates of the two regression parameters are $\widehat{\beta_0} = -143.02692$ and $\widehat{\beta_1} = 3.89903$. These estimates are obtained by the least squares

principle. See the sections "Classical Estimation Principles" and "Linear Model Theory" in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," for details about the principle of least squares estimation and its role in linear model analysis. For a general discussion of the theory of least squares estimation of linear models and its application to regression and analysis of variance, refer to one of the applied regression texts, including Draper and Smith (1981), Daniel and Wood (1980), Johnston (1972), and Weisberg (1985).

Figure 4.1 Regression for Weight and Height Data

The REG Procedure
Model: MODEL1
Dependent Variable: Weight

Number of Observations Read 19
Number of Observations Used 19

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	7193.24912	7193.24912	57.08	<.0001
Error	17	2142.48772	126.02869		
Corrected Total	18	9335.73684			

Root MSE	11.22625	R-Square	0.7705
Dependent Mean	100.02632	Adj R-Sq	0.7570
Coeff Var	11.22330		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-143.02692	32.27459	-4.43	0.0004
Height	1	3.89903	0.51609	7.55	<.0001

Based on the least squares estimates shown in Figure 4.1, the fitted regression line relating height to weight is described by the equation

$$\widehat{\text{Weight}} = -143.02692 + 3.89903 \times \text{Height}$$

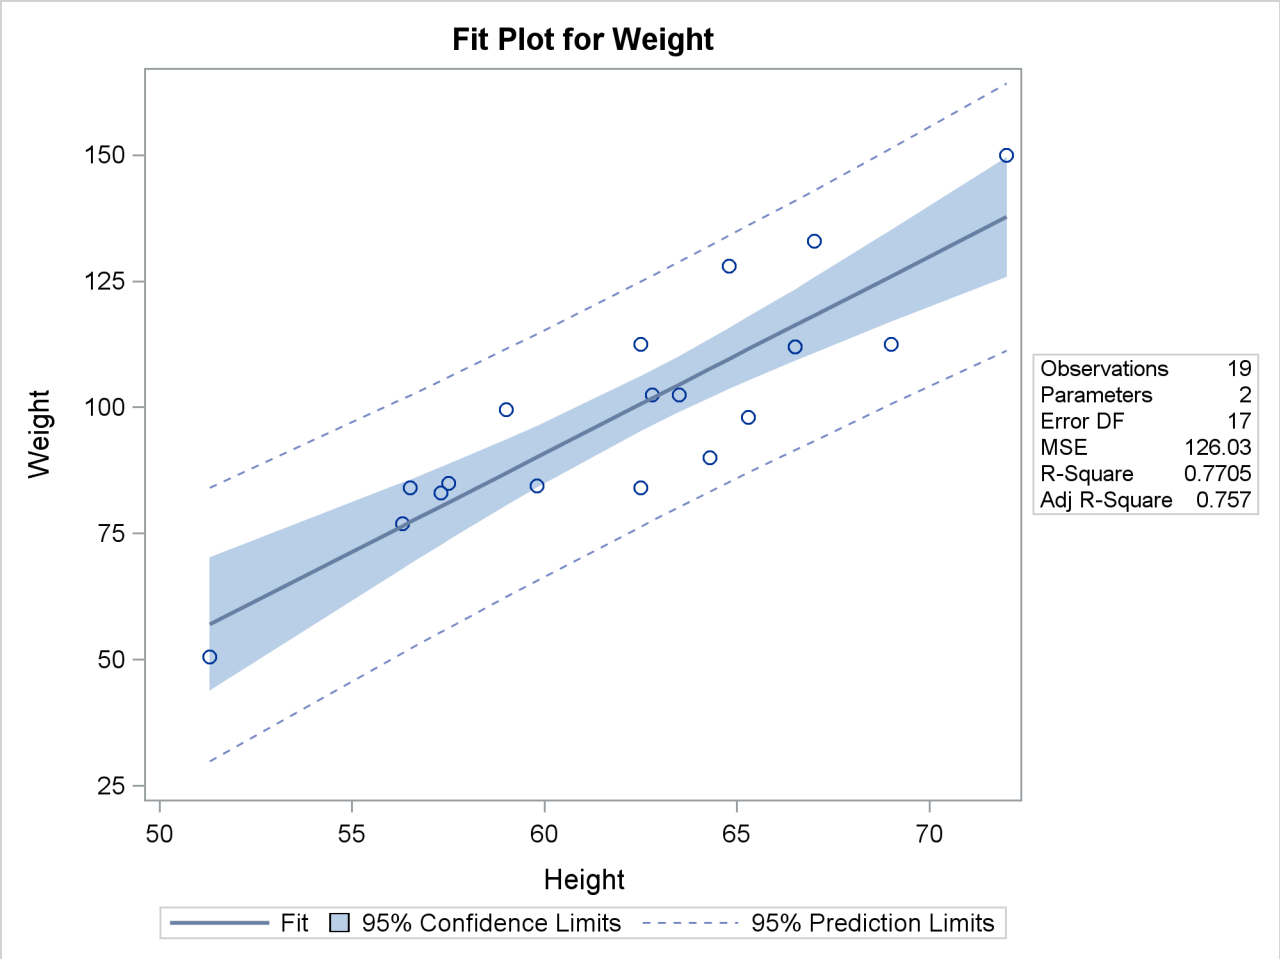
The "hat" notation is used to emphasize that $\widehat{\text{Weight}}$ is not one of the original observations but a value predicted under the regression model that has been fit to the data. At the least squares solution the residual sum of squares

$$\text{SSE} = \sum_{i=1}^{19} (\text{Weight}_i - \beta_0 - \beta_1 \text{Height}_i)^2$$

is minimized and the achieved criterion value is displayed in the analysis of variance table as the error sum of squares (2142.48772).

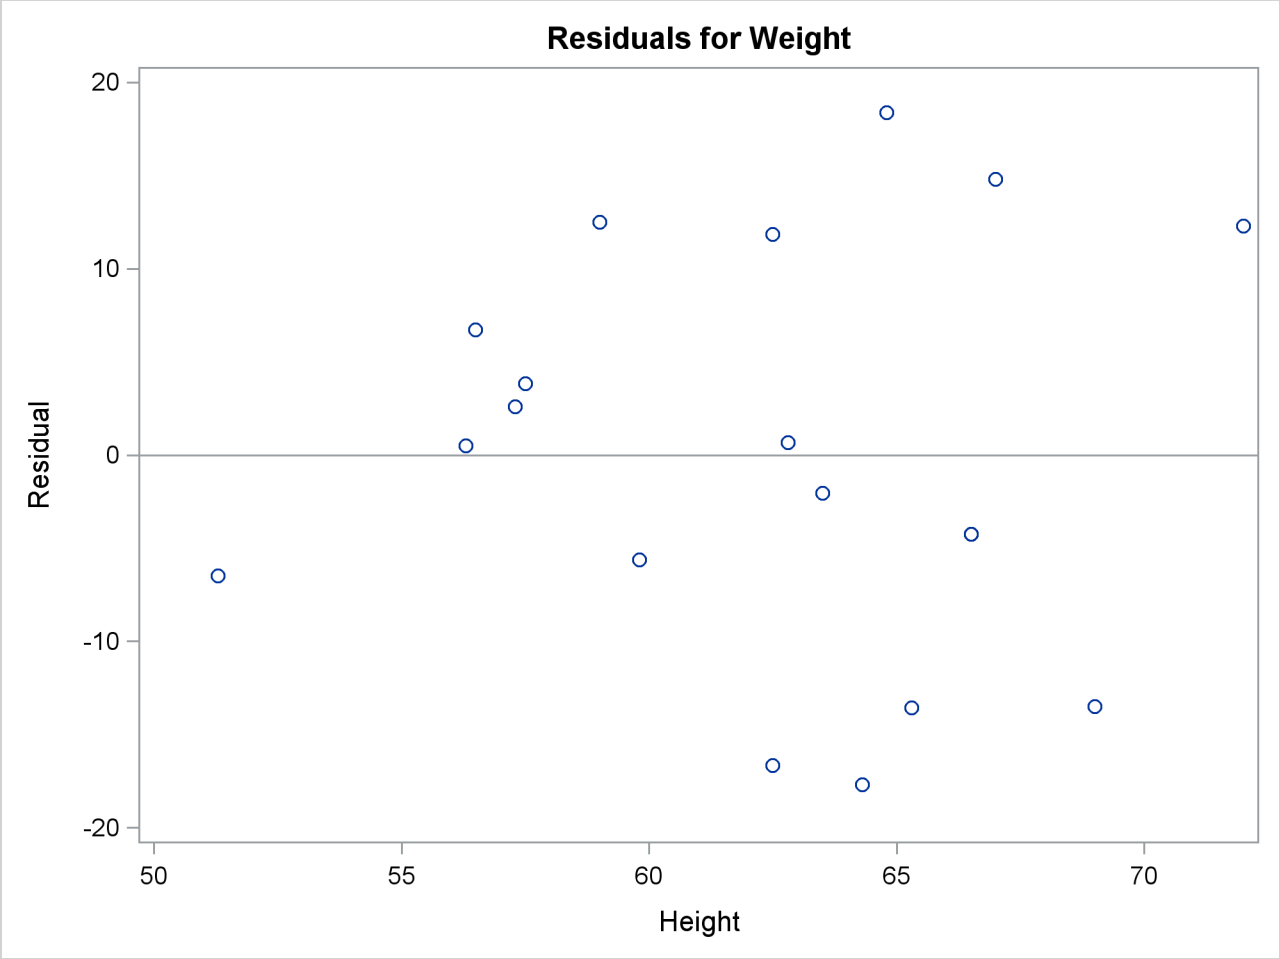
Figure 4.2 displays the fit plot produced by ODS Graphics. The fit plot shows the positive slope of the fitted line. The average weight of a child changes by $\widehat{\beta}_1 = 3.89903$ units for each unit change in height. The 95% confidence limits in the fit plot are pointwise limits that cover the mean weight for a particular height with probability 0.95. The prediction limits, which are wider than the confidence limits, show the pointwise limits that cover a new observation for a given height with probability 0.95.

Figure 4.2 Fit Plot for Regression of Weight on Height



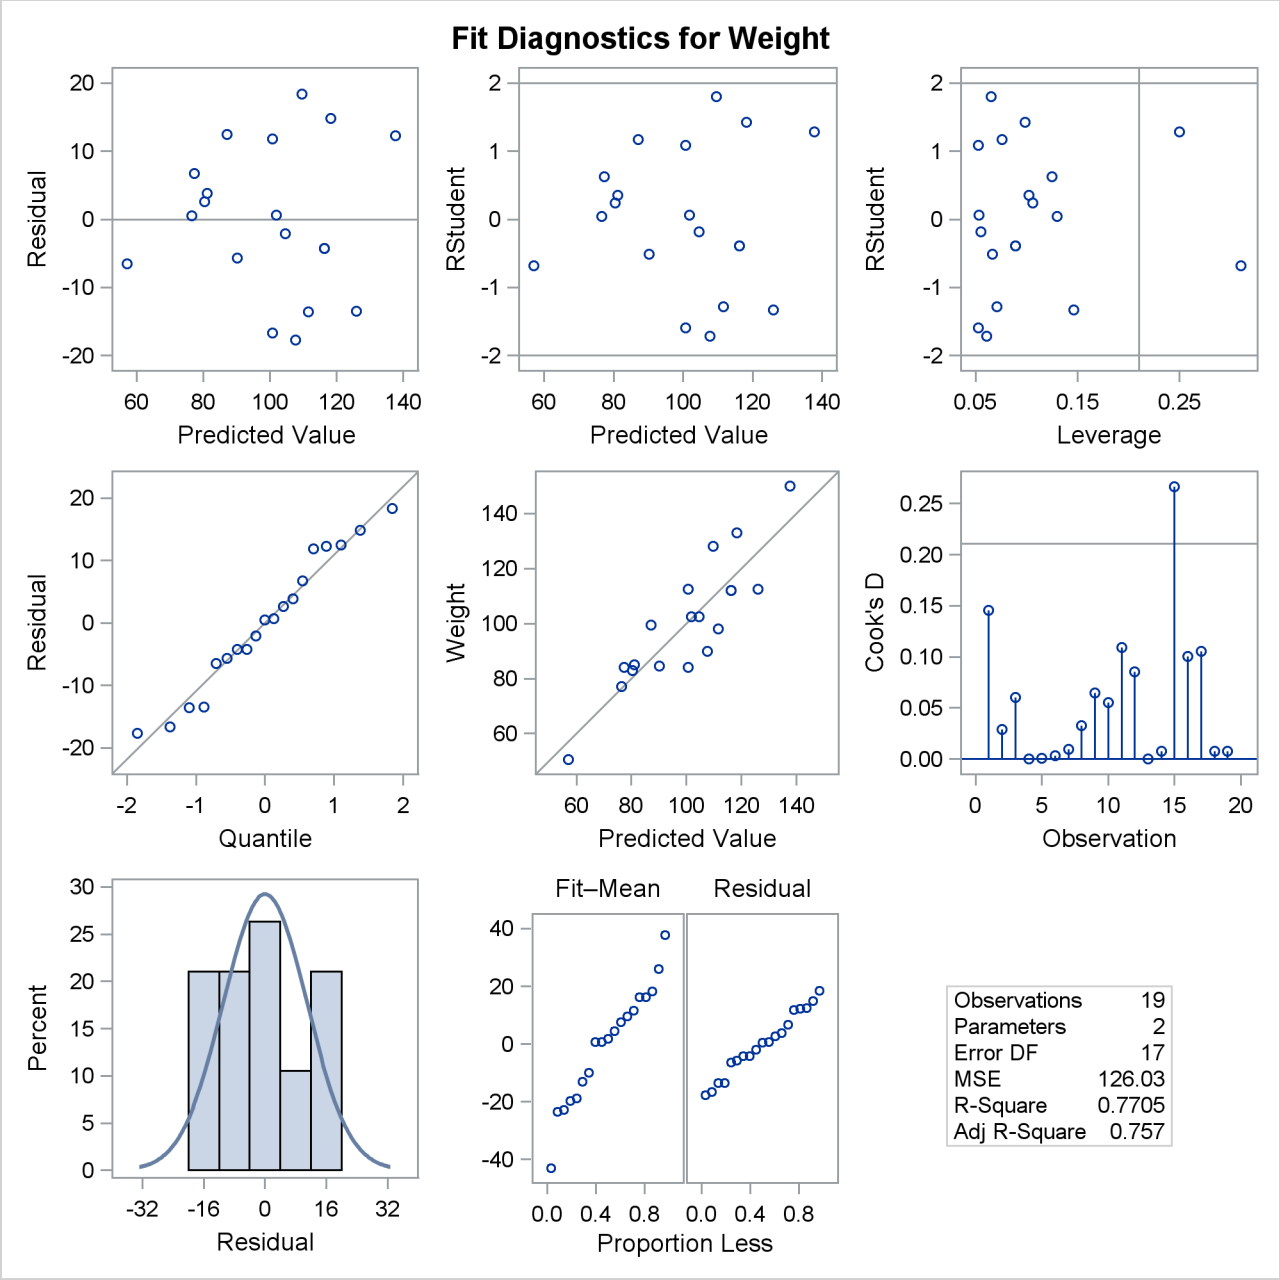
Regression is often used in an exploratory fashion to look for empirical relationships, such as the relationship between Height and Weight. In this example, Height is not the cause of Weight. You would need a controlled experiment to confirm the relationship scientifically. See the section "Comments on Interpreting Regression Statistics" on page 99 for more information. A separate question from a possible cause-and-effect relationship between the two variables involved in this regression is whether the simple linear regression model adequately describes the relationship in these data. If the usual assumptions about the model errors ϵ_i are met in the SLR model, then the errors should have zero mean and equal variance and be uncorrelated. Because the children were randomly selected, the observations from different children are not correlated. If the mean function of the model is correctly specified, the fitted residuals $\text{Weight}_i - \widehat{\text{Weight}}_i$ should scatter about the zero reference line without discernible structure. The residual plot in Figure 4.3 confirms this behavior.

Figure 4.3 Residual Plot for Regression of Weight on Height



An even more detailed look at the model-data agreement is gained with the panel of regression diagnostics in Figure 4.4. The graph in the upper left panel repeats the raw residual plot in Figure 4.3. The plot of the RSTUDENT residuals shows externally studentized residuals that take into account heterogeneity in the variability of the residuals. RSTUDENT residuals that exceed the threshold values of ± 2 often indicate outlying observations. The residual-by-leverage plot shows that two observations have high leverage—that is, they are unusual in their height values relative to the other children. The normal-probability Q-Q plot in the second row of the panel shows that the normality assumption for the residuals is reasonable. The plot of the Cook's D statistic shows that observation 15 exceeds the threshold value; this indicates that the observation for this child is influential on the regression parameter estimates.

Figure 4.4 Panel of Regression Diagnostics



For detailed information about the interpretation of regression diagnostics and about ODS statistical graphics with the REG procedure, see Chapter 76, "The REG Procedure."

SAS/STAT regression procedures produce the following information for a typical regression analysis:

- parameter estimates derived by using the least squares criterion
- estimates of the variance of the error term
- estimates of the variance or standard deviation of the sampling distribution of the parameter estimates

- tests of hypotheses about the parameters

SAS/STAT regression procedures can produce many other specialized diagnostic statistics, including the following:

- collinearity diagnostics to measure how strongly regressors are related to other regressors and how this affects the stability and variance of the estimates (REG)
- influence diagnostics to measure how each individual observation contributes to determining the parameter estimates, the SSE, and the fitted values (LOGISTIC, MIXED, REG, RSREG)
- lack-of-fit diagnostics that measure the lack of fit of the regression model by comparing the error variance estimate to another pure error variance that is not dependent on the form of the model (CATMOD, PROBIT, RSREG)
- diagnostic scatter plots that check the fit of the model and highlighted scatter plots that identify particular observations or groups of observations (REG)
- predicted and residual values, and confidence intervals for the mean and for an individual value (GLM, LOGISTIC, REG)
- time series diagnostics for equally spaced time series data that measure how much errors might be related across neighboring observations. These diagnostics can also measure functional goodness of fit for data that are sorted by regressor or response variables (REG, SAS/ETS procedures).

Many SAS/STAT procedures produce general and specialized statistical graphics through ODS Graphics to diagnose the fit of the model and the model-data agreement, and to highlight observations that are influential on the analysis. Figure 4.2 and Figure 4.3, for example, are two of the ODS statistical graphs produced by the REG procedure by default for the simple linear regression model. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." For specific information about the ODS statistical graphs available with a SAS/STAT procedure, see the PLOTS option in the "Syntax" section for the PROC statement and the "ODS Table Names" section in the "Details" section of the individual procedure documentation.

Linear Regression: The REG Procedure

The REG procedure is a general-purpose procedure for linear regression that does the following:

- handles multiple regression models
- provides nine model-selection methods
- allows interactive changes both in the model and in the data used to fit the model
- allows linear equality restrictions on parameters
- tests linear hypotheses and multivariate hypotheses

- produces collinearity diagnostics, influence diagnostics, and partial regression leverage plots
- saves estimates, predicted values, residuals, confidence limits, and other diagnostic statistics in output SAS data sets
- generates plots of data and of various statistics
- "paints" or highlights scatter plots to identify particular observations or groups of observations
- uses, optionally, correlations or crossproducts for input

Model-Selection Methods in Linear Regression Models

An important step in building statistical models is to determine which effects and variables affect the response variable and to form a model that fits the data well without incurring the negative effects of overfitting the model. Models that are overfit—that is, contain too many regressor variables and unimportant regressor variables—have a tendency to be too closely molded to a a particular set of data, have unstable regression coefficients, and possibly have poor predictive precision. In situations where many potential regressor variables are available for inclusion in a regression model, guided, numerical variable-selection methods offer one approach to model building.

The model-selection techniques for linear regression models implemented in the REG procedure are as follows:

NONE — specifies that no selection be made. This method is the default and uses the full model given in the MODEL statement to fit the linear regression.

FORWARD — specifies that variables be selected based on a forward-selection algorithm. This method starts with no variables in the model and adds variables one by one to the model. At each step, the variable added is the one that most improves the fit of the model. You can also specify groups of variables to treat as a unit during the selection process. An option enables you to specify the criterion for inclusion.

BACKWARD — specifies that variables be selected based on a backward-elimination algorithm. This method starts with a full model and eliminates variables one by one from the model. At each step, the variable with the smallest contribution to the model is deleted. You can also specify groups of variables to treat as a unit during the selection process. An option enables you to specify the criterion for exclusion.

STEPWISE — specifies that variables be selected for the model based on a stepwise-regression algorithm, which combines forward-selection and backward-elimination steps. This method is a modification of the forward-selection method in that variables already in the model do not necessarily stay there. You can also specify groups of variables to treat as a unit during the selection process. Again, options enable you to specify criteria for entry into the model and for remaining in the model.

MAXR — specifies that model formation be based on the maximum R^2 improvement. This method tries to find the best one-variable model, the best two-variable model, and so on. The MAXR method differs from the STEPWISE method in that many more models are evaluated. The MAXR method considers all possible variable exchanges before making any

exchange. The STEPWISE method might remove the "worst" variable without considering what the "best" remaining variable might accomplish, whereas MAXR would consider what the "best" remaining variable might accomplish. Consequently, model building based on the maximum R^2 improvement typically takes much longer to run than stepwise model building.

MINR — specifies that model formation be based on the minimum R^2 improvement. This method closely resembles MAXR, but the switch chosen is the one that produces the smallest increase in R^2.

RSQUARE — finds a specified number of models having the highest R^2 in each of a range of model sizes.

CP — finds a specified number of models with the lowest C_p within a range of model sizes.

ADJRSQ — finds a specified number of models having the highest adjusted R^2 within a range of model sizes.

The GLMSELECT procedure has been specifically designed for the purpose of model building in linear models. In addition to having a wider array of selection methods and criteria compared to the REG procedure, the GLMSELECT procedure also supports classification variables. See Chapter 44, "The GLMSELECT Procedure," for more information.

Regression with the REG and GLM Procedures

In terms of the assumptions about the basic model and the estimation principles, the REG and GLM procedures are very closely related. Both procedures estimate parameters by ordinary or weighted least squares and assume homoscedastic, uncorrelated model errors with zero mean. An assumption of normality of the model errors is not necessary for parameter estimation, but it is implied in confirmatory inference based on the parameter estimates—that is, the computation of tests, p-values, and confidence and prediction intervals.

The GLM procedure supports a CLASS statement for the levelization of classification variables; see the section "Parameterization of Model Effects" on page 397 in Chapter 19, "Shared Concepts and Topics," on the parameterization of classification variables in statistical models. Classification variables are accommodated in the REG procedure by the inclusion of the necessary dummy regressor variables.

Most of the statistics based on predicted and residual values that are available in PROC REG are also available in PROC GLM. However, PROC GLM does not produce collinearity diagnostics, influence diagnostics, or scatter plots. In addition, PROC GLM allows only one model and fits the full model.

Both procedures are interactive, in that they do not stop after processing a RUN statement. The procedures accept statements until a QUIT statement is submitted.

Response Surface Regression: The RSREG Procedure

The RSREG procedure fits a quadratic response-surface model, which is useful in searching for factor values that optimize a response. The following features in PROC RSREG make it preferable to other regression procedures for analyzing response surfaces:

- automatic generation of quadratic effects
- a lack-of-fit test
- solutions for critical values of the surface
- eigenvalues of the associated quadratic form
- a ridge analysis to search for the direction of optimum response

Partial Least Squares Regression: The PLS Procedure

The PLS procedure fits models by using any of a number of linear predictive methods, including *partial least squares* (PLS). Ordinary least squares regression, as implemented in the GLM or REG procedure, has the single goal of minimizing sample response prediction error by seeking linear functions of the predictors that explain as much variation in each response as possible. The techniques implemented in the PLS procedure have the additional goal of accounting for variation in the predictors under the assumption that directions in the predictor space that are well sampled should provide better prediction for *new* observations when the predictors are highly correlated. All of the techniques implemented in the PLS procedure work by extracting successive linear combinations of the predictors, called *factors* (also called *components* or *latent vectors*), which optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, the method of partial least squares balances the two objectives, seeking factors that explain both response and predictor variation.

Generalized Linear Regression

As outlined in the section "Generalized Linear Models" on page 33 of Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," the class of generalized linear model generalizes the linear regression model in two ways:

- by allowing the data to come from a distribution that is a member of the exponential family of distributions
- by introducing a link function $g(\cdot)$ that provides a mapping between the linear predictor $\eta = \mathbf{x}'\boldsymbol{\beta}$ and the mean of the data, $g(\mathrm{E}[Y]) = \eta$. The link function is monotonic, so that $\mathrm{E}[Y] = g^{-1}(\eta)$ and $g^{-1}(\cdot)$ is called the inverse link function.

One of the most commonly used generalized linear regression models is the logistic model for binary or binomial data. Suppose that Y denotes a binary outcome variable that takes on the values 1 and 0 with probabilities π and $1 - \pi$, respectively. The probability π is also referred to as the "success probability," supposing that the coding $Y = 1$ corresponds to a success in a Bernoulli experiment. The success probability is also the mean of Y, and one of the aims of logistic regression analysis is to study how regressor variables affect the outcome probabilities or functions thereof, such as odds ratios.

The logistic regression model for π is defined by a linear predictor $\eta = \mathbf{x}'\boldsymbol{\beta}$ and the logit link function:

$$\text{logit}\{\Pr(Y = 0)\} = \log\left\{\frac{\pi}{1-\pi}\right\} = \mathbf{x}'\boldsymbol{\beta}$$

The inversely linked linear predictor function in this model is

$$\Pr(Y = 0) = \frac{1}{1 + \exp\{-\eta\}}$$

An extension of the dichotomous logistic regression model is models for multinomial (polychotomous) data. Two classes of models for multinomial data can be fit with procedures in SAS/STAT software: models for ordinal data that rely on cumulative link functions and models for nominal (unordered) outcomes that rely on generalized logits. The next section briefly discusses SAS/STAT procedures for logistic regression. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," for more information about the comparison of the procedures mentioned there with respect to analysis of categorical responses.

Logistic Regression

The SAS/STAT procedures CATMOD, GENMOD, GLIMMIX, LOGISTIC, and PROBIT can fit generalized linear models for binary, binomial, and multinomial outcomes.

CATMOD provides maximum likelihood estimation for logistic regression, including the analysis of logits for dichotomous outcomes and the analysis of generalized logits for polychotomous outcomes. The CATMOD procedure can analyze data represented by a contingency table.

GENMOD is a general modeling procedure for generalized linear models. It estimates parameters by maximum likelihood. Like the LOGISTIC procedure, it uses CLASS and MODEL statements in SAS/STAT procedures to form the statistical model and can fit models to binary and ordinal outcomes. The GENMOD procedure does not fit generalized logit models for nominal outcomes. However, the procedure also provides the capability of solving generalized estimating equations (GEE) to model correlated data and can perform a Bayesian analysis.

GLIMMIX is a general modeling procedure for generalized linear mixed models. If the model does not contain random effects, the GLIMMIX procedure fits generalized linear models by the method of maximum likelihood. In the class of logistic regression models, the procedure can fit models to binary, binomial, ordinal, and nominal outcomes.

LOGISTIC is specifically designed for logistic regression and estimates parameters by maximum likelihood. The procedure fits the usual logistic regression model for binary data as well as models with cumulative link function for ordinal data (such as the proportional odds model) and the generalized logit model for nominal data. The LOGISTIC procedure offers a number of variable selection methods and can perform conditional and exact conditional logistic regression analysis.

PROBIT calculates maximum likelihood estimates of regression parameters and the natural (or threshold) response rate for quantal response data from biological assays or other discrete event data. This includes probit, logit, ordinal logistic, and extreme value (or gompit) regression models.

SURVEYLOGISTIC is designed for logistic regression and estimates parameters by maximum likelihood. The procedure incorporates complex survey sample designs, including designs with stratification, clustering, and unequal weighting.

Other Generalized Linear Models

When a generalized linear model is formed with distributions other than the binary, binomial, or multinomial, you can use the GENMOD and GLIMMIX procedures for parameter estimation and inference.

Both procedures can accommodate correlated observations, but they use different techniques to accomplish this goal. The GENMOD procedure can fit correlated data models via generalized estimating equations that rely on a first- and second-moment specification for the response data and a working correlation assumption. With the GLIMMIX procedure, you can model correlations between the observations by (1) specifying random effects in the conditional distribution that induce a marginal correlation structure or (2) direct modeling of the marginal dependence. The GLIMMIX procedure employs likelihood-based techniques in parameter estimation.

The GENMOD procedure supports a Bayesian analysis through its BAYES statement.

With the GLIMMIX procedure you can vary the distribution or link function on an observation-by-observation basis.

To fit a generalized linear model with a distribution that is not available in the GENMOD or GLIMMIX procedure, you can use the NLMIXED procedure and code the log-likelihood function of an observation with SAS programming statements.

Regression for Ill-Conditioned Data: The ORTHOREG Procedure

The ORTHOREG procedure performs linear least squares regression by using the Gentleman-Givens computational method, and it can produce more accurate parameter estimates for ill-conditioned data. PROC GLM and PROC REG produce very accurate estimates for most problems. However, if you have very ill-conditioned data, consider using the ORTHOREG procedure. The collinearity diagnostics in PROC REG can help you to determine whether PROC ORTHOREG would be useful.

Quantile Regression: The QUANTREG Procedure

The QUANTREG procedure models the effects of covariates on the conditional quantiles of a response variable by means of quantile regression.

Ordinary least squares regression models the relationship between one or more covariates X and the conditional mean of the response variable $\mathrm{E}[Y|X = x]$. Quantile regression extends the regression model to conditional quantiles of the response variable, such as the 90th percentile. Quantile regression is particularly useful when the rate of change in the conditional quantile, expressed by the regression coefficients, depends

on the quantile. An advantage of quantile regression over least squares regression is its flexibility for modeling data with heterogeneous conditional distributions. Data of this type occur in many fields, including biomedicine, econometrics, and ecology.

Features that you will find in the QUANTREG procedure include the following:

- simplex, interior point, and smoothing algorithms for estimation
- sparsity, rank, and resampling methods for confidence intervals
- asymptotic and bootstrap methods to estimate covariance and correlation matrices of the parameter estimates
- Wald and likelihood ratio tests for the regression parameter estimates
- regression quantile spline fits

Nonlinear Regression

Recall from Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," that a nonlinear regression model is a statistical model in which the mean function depends on the model parameters in a nonlinear function. The SAS/STAT procedures that can fit general, nonlinear models are the NLIN and NLMIXED procedures. The procedures have the following in common:

- Nonlinear models are fit by iterative methods.
- You must provide an expression for the model through programming statements.
- Analytic derivatives of the objective function with respect to the parameters are calculated automatically.
- A grid search is available to select the best starting values for the parameters from a set of starting points that you provide.

The following items reflect some important differences between the NLIN and NLMIXED procedures:

- Parameters are estimated by nonlinear least squares with the NLIN procedure and by maximum likelihood with the NLMIXED procedure.
- The NLMIXED procedure enables you to construct nonlinear models that contain normally distributed random effects.
- The NLIN procedure requires that you declare all model parameters in the PARAMETERS statement and assign starting values. The NLMIXED procedure determines the parameters in your model based on the PARAMETER statement and the other modeling statements. It is not necessary to supply starting values for all parameters in the NLMIXED procedure, but it is highly recommended.
- The residual variance is not a parameter in models fit with the NLIN procedure, but it is in models fit with the NLMIXED procedure.

- The default iterative optimization method in the NLIN procedure is the Gauss-Newton method; the default method in the NLMIXED procedure is the quasi-Newton method. Other optimization techniques are available in both procedures.

Nonlinear models are fit with iterative techniques that begin from starting values and attempt to iteratively improve on the estimates by updating the estimates. There is no guarantee that the solution achieved when the iterative algorithm converges will correspond to a global optimum.

Nonparametric Regression

Regression models that suppose a parametric form express the mean of an observation as a function of regressor variables $x_1, \cdots, x_k$ and parameters $\beta_1, \cdots, \beta_p$:

$$\mathrm{E}[Y] = f(x_1, \cdots, x_k; \beta_1, \cdots, \beta_p)$$

Nonparametric regression techniques not only relax the assumption of linearity in the regression parameters, but they also do not require that you specify a precise functional form for the relationship between response and regressor variables. Consider a regression problem where the relationship between response Y and regressor X is to be modeled. It is assumed that $\mathrm{E}[Y_i] = g(x_i) + \epsilon_i$, where $g(\cdot)$ is an unspecified regression function. Two primary approaches in nonparametric regression modeling are as follows:

- approximate $g(x_i)$ locally by a parametric function constructed from information in a local neighborhood of x_i
- approximate the unknown function $g(x_i)$ by a smooth, flexible function and determine the necessary smoothness and continuity properties from the data

The SAS/STAT procedures LOESS, GAM, and TPSPLINE fit nonparametric regression models by one of these methods.

Local Regression: The LOESS Procedure

The LOESS procedure implements a local regression approach for estimating regression surfaces pioneered by Cleveland, Devlin, and Grosse (1988). No assumptions about the parametric form of the entire regression surface are made with the LOESS procedure. Only a parametric form of the local approximation is specified by the user. Furthermore, the LOESS procedure is suitable when there are outliers in the data and a robust fitting method is necessary.

Smooth Function Approximation: The TPSPLINE Procedure

The TPSPLINE procedure decomposes the regressor contributions to the mean function into parametric components and into smooth functional components. Suppose that the regressor variables are collected into the vector $\mathbf{x}$ and that this vector is partitioned as $\mathbf{x} = [\mathbf{x}_1' \ \mathbf{x}_2']'$. The relationship between Y and $\mathbf{x}_2$ is linear

(parametric) and the relationship between Y and $\mathbf{x}_1$ is nonparametric. The TPSPLINE procedure fits models of the form

$$\mathrm{E}[Y] = g(\mathbf{x}_1) + \mathbf{x}_2'\boldsymbol{\beta}$$

The function $g(\cdot)$ can be represented as a sequence of spline basis functions.

The parameters are estimated by a penalized least squares method. The penalty is applied to the usual least squares criterion to obtain a regression estimate that fits the data well and to prevent the fit from attempting to interpolate the data (fit the data too closely).

Generalized Additive Models: The GAM Procedure

Generalized additive models are nonparametric models in which one or more regressor variables are present and can make different smooth contributions to the mean function. For example, if $\mathbf{x}_i = [x_{i1}, x_{i2}, \cdots, x_{ik}]$ is a vector of k regressor for the ith observation, then an additive model represents the mean function as

$$\mathrm{E}[Y] = f_0 + f_1(x_{i1}) + f_2(x_{i2}) + \cdots + f_3(x_{i3})$$

The individual functions f_j can have a parametric or nonparametric form. If all f_j are parametric, the GAM procedure fits a fully parametric model. If some f_j are nonparametric, the GAM procedure fits a semiparametric model. Otherwise, the models are fully nonparametric.

The generalization of additive models is akin to the generalization for linear models: nonnormal data are accommodated by explicitly modeling the distribution of the data as a member of the exponential family and by applying a monotonic link function that provides a mapping between the predictor and the mean of the data.

Robust Regression: The ROBUSTREG Procedure

The ROBUSTREG procedure implements algorithms to detect outliers and provide resistant (stable) results in the presence of outliers. The ROBUSTREG procedure provides four such methods: M estimation, LTS estimation, S estimation, and MM estimation.

- M estimation was introduced by Huber (1973), and it is the simplest approach both computationally and theoretically. Although it is not robust with respect to leverage points, it is still used extensively in analyzing data for which it can be assumed that the contamination is mainly in the response direction.
- Least trimmed squares (LTS) estimation is a high breakdown value method introduced by Rousseeuw (1984). The breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness.
- S estimation is a high breakdown value method introduced by Rousseeuw and Yohai (1984). With the same breakdown value, it has a higher statistical efficiency than LTS estimation.
- MM estimation, introduced by Yohai (1987), combines high breakdown value estimation and M estimation. It has both the high breakdown property and a higher statistical efficiency than S estimation.

For diagnostic purposes, the ROBUSTREG procedure also implements robust leverage-point detection based on the robust Mahalanobis distance. The robust distance is computed by using a generalized minimum covariance determinant (MCD) algorithm.

Regression with Transformations: The TRANSREG Procedure

The TRANSREG procedure can fit many standard linear models. In addition, PROC TRANSREG can find nonlinear transformations of the data and fit a linear model to the transformed variables. This is in contrast to PROC REG and PROC GLM, which fit linear models to data, or PROC NLIN, which fits nonlinear models to data. The TRANSREG procedure fits many types of linear models, including the following:

- ordinary regression and ANOVA
- metric and nonmetric conjoint analysis
- metric and nonmetric vector and ideal point preference mapping
- simple, multiple, and multivariate regression with variable transformations
- redundancy analysis with variable transformations
- canonical correlation analysis with variable transformations
- response surface regression with variable transformations

Interactive Features in the CATMOD, GLM, and REG Procedures

The CATMOD, GLM, and REG procedures do not stop after processing a RUN statement. More statements can be submitted as a continuation of the previous statements. Many new features in these procedures are useful to request after you have reviewed the results from previous statements. The procedures stop if a DATA step or another procedure is requested or if a QUIT statement is submitted.

Statistical Background in Linear Regression

The remainder of this chapter outlines the way in which many SAS/STAT regression procedures calculate various regression quantities. The discussion focuses on the linear regression models. General statistical background about linear statistical models can be found in the section "Linear Model Theory" of Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software."

Exceptions and further details are documented with individual procedures.

Linear Regression Models

In matrix notation, a linear model is written as

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where $\mathbf{X}$ is the $(n \times k)$ design matrix (rows are observations and columns are the regressors), $\boldsymbol{\beta}$ is the $(k \times 1)$ vector of unknown parameters, and $\boldsymbol{\epsilon}$ is the $(n \times 1)$ vector of unobservable model errors. The first column of $\mathbf{X}$ is usually a vector of 1s and is used to estimate the intercept term.

The statistical theory of linear models is based on strict classical assumptions. Ideally, the response is measured with all the factors controlled in an experimentally determined environment. If you cannot control the factors experimentally, some tests must be interpreted as being conditional on the observed values of the regressors.

Other assumptions are as follows:

- The form of the model is correct (all important explanatory variables have been included). This assumption is reflected mathematically in the assumption of a zero mean of the model errors, $\mathrm{E}[\boldsymbol{\epsilon}] = \mathbf{0}$.
- Regressor variables are measured without error.
- The expected value of the errors is zero.
- The variance of the error (and thus the dependent variable) for the ith observation is σ^2/w_i, where w_i is a known weight factor. Usually, $w_i = 1$ for all i and thus σ^2 is the common, constant variance.
- The errors are uncorrelated across observations.

When hypotheses are tested, or when confidence and prediction intervals are computed, an additional assumption is made that the errors are normally distributed.

Parameter Estimates and Associated Statistics

The Least Squares Estimators

Least squares estimators of the regression parameters are found by solving the normal equations

$$\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)\boldsymbol{\beta} = \mathbf{X}'\mathbf{W}\mathbf{Y}$$

for the vector $\boldsymbol{\beta}$, where $\mathbf{W}$ is a diagonal matrix with the observed weights on the diagonal. The resulting estimator of the parameter vector is

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{W}\mathbf{Y}$$

This is an unbiased estimator, since

$$\begin{aligned}\mathrm{E}\left[\widehat{\boldsymbol{\beta}}\right] &= \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{W}\mathrm{E}[\mathbf{Y}] \\ &= \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{W}\mathbf{X}\boldsymbol{\beta} = \boldsymbol{\beta}\end{aligned}$$

Notice that the only assumption necessary in order for the least squares estimators to be unbiased is that of a zero mean of the model errors. If the estimator is evaluated at the observed data, it is referred to Subidxleast squaresestimate (Introduction to Regression)as the least squares estimate,

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{W}\mathbf{y}$$

If the standard classical assumptions are met, the least squares estimators of the regression parameters are the best linear unbiased estimators (BLUE). In other words, the estimators have minimum variance in the class of estimators that are unbiased and that are linear functions of the responses. If the additional assumption of normally distributed errors is satisfied, then the following are true:

- The statistics that are computed have the proper sampling distributions for hypothesis testing.
- Parameter estimators are normally distributed.
- Various sums of squares are distributed proportional to chi-square, at least under proper hypotheses.
- Ratios of estimators to standard errors follow the Student's t distribution under certain hypotheses.
- Appropriate ratios of sums of squares follow an F distribution for certain hypotheses.

When regression analysis is used to model data that do not meet the assumptions, the results should be interpreted in a cautious, exploratory fashion. The significance probabilities under these circumstances are unreliable.

Box (1966) and Mosteller and Tukey (1977, Chapters 12 and 13) discuss the problems that are encountered with regression data, especially when the data are not under experimental control.

Estimating the Precision

Assume for the present that $\mathbf{X}'\mathbf{W}\mathbf{X}$ has full column rank k (this assumption is relaxed later). The variance of the error terms, $\mathrm{Var}[\epsilon_i] = \sigma^2$, is then estimated by the mean square error

$$s^2 = \mathrm{MSE} = \frac{\mathrm{SSE}}{n-k} = \frac{1}{n-k}\sum_{i=1}^{n} w_i\left(y_i - \mathbf{x}_i'\boldsymbol{\beta}\right)^2$$

where $\mathbf{x}_i'$ is the ith row of the design matrix $\mathbf{X}$. The residual variance estimate is also unbiased: $\mathrm{E}[s^2] = \sigma^2$.

The covariance matrix of the least squares estimators is

$$\mathrm{Var}\left[\widehat{\boldsymbol{\beta}}\right] = \sigma^2\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}$$

An estimate of the covariance matrix is obtained by replacing σ^2 with its estimate, s^2 in the preceding formula. This estimate is often referred to as COVB in SAS/STAT modeling procedures:

$$\mathrm{COVB} = \widehat{\mathrm{Var}}\left[\widehat{\boldsymbol{\beta}}\right] = s^2\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}$$

The correlation matrix of the estimates, often referred to as CORRB, is derived by scaling the covariance matrix: Let $\mathbf{S} = \text{diag}\left(\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\right)^{-\frac{1}{2}}$. Then the correlation matrix of the estimates is

$$\text{CORRB} = \mathbf{S}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{S}$$

The estimated standard error of the ith parameter estimator is obtained as the square root of the ith diagonal element of the COVB matrix. Formally,

$$\text{STDERR}\left(\widehat{\boldsymbol{\beta}}_i\right) = \sqrt{\left[s^2(\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}\right]_{ii}}$$

The ratio

$$t = \frac{\widehat{\boldsymbol{\beta}}_i}{\text{STDERR}\left(\widehat{\boldsymbol{\beta}}_i\right)}$$

follows a Student's t distribution with $(n-k)$ degrees of freedom under the hypothesis that β_i is zero and provided that the model errors are normally distributed.

Regression procedures display the t ratio and the significance probability, which is the probability under the hypothesis $H\colon \beta_i = 0$ of a larger absolute t value than was actually obtained. When the probability is less than some small level, the event is considered so unlikely that the hypothesis is rejected.

Type I SS and Type II SS measure the contribution of a variable to the reduction in SSE. Type I SS measure the reduction in SSE as that variable is entered into the model in sequence. Type II SS are the increment in SSE that results from removing the variable from the full model. Type II SS are equivalent to the Type III and Type IV SS reported in the GLM procedure. If Type II SS are used in the numerator of an F test, the test is equivalent to the t test for the hypothesis that the parameter is zero. In polynomial models, Type I SS measure the contribution of each polynomial term after it is orthogonalized to the previous terms in the model. The four types of SS are described in Chapter 15, "The Four Types of Estimable Functions."

Coefficient of Determination

The coefficient of determination in a regression model, also known as the R-square statistic (R^2), measures the proportion of variability in the response that is explained by the regressor variables. In a linear regression model with intercept, R^2 is defined as

$$R^2 = 1 - \frac{\text{SSE}}{\text{SST}}$$

where SSE is the residual (error) sum of squares and SST is the total sum of squares corrected for the mean. The adjusted R^2 statistic is an alternative to R^2 that takes into account the number of parameters in the model. This statistic is calculated as

$$\text{ADJRSQ} = 1 - \frac{n-i}{n-p}\left(1 - R^2\right)$$

where n is the number of observations used to fit the model, p is the number of parameters in the model (including the intercept), and i is 1 if the model includes an intercept term, and 0 otherwise.

R^2 statistics also play an important indirect role in regression calculations. For example, the proportion of variability explained by regressing all other variables in a model on a particular regressor can provide insights into the interrelationship among the regressors.

Tolerances and variance inflation factors measure the strength of interrelationships among the regressor variables in the model. If all variables are orthogonal to each other, both tolerance and variance inflation are 1. If a variable is very closely related to other variables, the tolerance approaches 0 and the variance inflation gets very large. Tolerance (TOL) is 1 minus the R^2 that results from the regression of the other variables in the model on that regressor. Variance inflation (VIF) is the diagonal of $(\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}$, if $(\mathbf{X}'\mathbf{W}\mathbf{X})$ is scaled to correlation form. The statistics are related as

$$\text{VIF} = \frac{1}{\text{TOL}}$$

Explicit and Implicit Intercepts

A linear model contains an *explicit* intercept if the $\mathbf{X}$ matrix contains a column whose nonzero values do not vary, typically a column of ones. Many SAS/STAT procedures automatically add this column of ones as the first column in the $\mathbf{X}$ matrix. Procedures that support a NOINT option in the MODEL statement provide the capability to suppress the automatic addition of the intercept column.

In general, models without intercept should be the exception, especially if your model does not contain classification variables. An overall intercept is provided in many models to adjust for the grand total or overall mean in your data. A simple linear regression without intercept, such as

$$\text{E}[Y_i] = \beta_1 x_i + \epsilon_i$$

assumes that Y has mean zero if X takes on the value zero. This might not be a reasonable assumption.

If you explicitly suppress the intercept in a statistical model, the calculation and interpretation of your results can change. For example, the exclusion of the intercept in the following PROC REG statements leads to a different calculation of the R-square statistic. It also affects the calculation of the sum of squares in the analysis of variance for the model. For example, the model and error sum of squares add up to the uncorrected total sum of squares in the absence of an intercept.

```
proc reg;
   model y = x / noint;
quit;
```

Many statistical models contain an *implicit* intercept. This occurs when a linear function of one or more columns in the $\mathbf{X}$ matrix produces a column of constant, nonzero values. For example, the presence of a CLASS variable in the GLM parameterization always implies an intercept in the model. If a model contains an implicit intercept, adding an intercept to the model does not alter the quality of the model fit, but it changes the interpretation (and number) of the parameter estimates.

The way in which the implicit intercept is detected and accounted for in the analysis depends on the procedure. For example, the following statements in the GLM procedure lead to an implied intercept:

```
proc glm;
   class a;
   model y = a / solution noint;
```

```
run;
```

Whereas the analysis of variance table uses the uncorrected total sum of squares (due to the NOINT option), the implied intercept does not lead to a redefinition or recalculation of the R-square statistic (compared to the model without the NOINT option). Also, because the intercept is implied by the presence of the CLASS variable a in the model, the same error sum of squares results whether the NOINT option is specified or not.

A different approach is taken, for example, by the TRANSREG procedure. The ZERO=NONE option in the CLASS parameterization of the following statements leads to an implicit intercept model:

```
proc transreg;
   model ide(y) = class(a / zero=none) / ss2;
run;
```

The analysis of variance table or the regression fit statistics are not affected in the TRANSREG procedure. Only the interpretation of the parameter estimates changes because of the way in which the intercept is accounted for in the model.

Implied intercepts not only occur when classification effects are present in the model. They also occur with B-splines and other sets of constructed columns.

Models Not of Full Rank

If the $\mathbf{X}$ matrix is not of full rank, then a generalized inverse can be used to solve the normal equations to minimize the SSE:

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{W}\mathbf{y}$$

However, these estimates are not unique since there are an infinite number of solutions corresponding to different generalized inverses. PROC REG and other regression procedures choose a nonzero solution for all variables that are linearly independent of previous variables and a zero solution for other variables. This corresponds to using a generalized inverse in the normal equations, and the expected values of the estimates are the Hermite normal form of $\mathbf{X}'\mathbf{W}\mathbf{X}$ multiplied by the true parameters:

$$\mathrm{E}\left[\widehat{\boldsymbol{\beta}}\right] = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)\boldsymbol{\beta}$$

Degrees of freedom for the estimates that correspond to singularities are not counted (reported as zero). The hypotheses that are not testable have t tests displayed as missing. The message that the model is not of full rank includes a display of the relations that exist in the matrix.

See the sections "Generalized Inverse Matrices" and "Linear Model Theory" in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," on the nature and construction of generalized inverses and their importance for statistical inference in linear models.

Predicted and Residual Values

After the model has been fit, predicted and residual values are usually calculated, graphed, and output. The predicted values are calculated from the estimated regression equation; the raw residuals are calculated as

the observed minus the predicted value. Often other forms of residuals are used for model diagnostics, such as studentized or cumulative residuals. Some procedures can calculate standard errors of residuals, predicted mean values, and individual predicted values.

Consider the ith observation where $\mathbf{x}_i'$ is the row of regressors, $\widehat{\boldsymbol{\beta}}$ is the vector of parameter estimates, and s^2 is the estimate of the residual variance (the mean squared error). The *leverage* value of the ith observation is defined as

$$h_i = w_i \mathbf{x}_i' (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \mathbf{x}_i$$

where $\mathbf{X}$ is the design matrix for the observed data, $\mathbf{x}_i'$ is an arbitrary regressor vector (possibly but not necessarily a row of $\mathbf{X}$), $\mathbf{W}$ is a diagonal matrix with the observed weights on the diagonal, and w_i is the weight corresponding to $\mathbf{x}_i'$.

Then the predicted mean and the standard error of the predicted mean are

$$\begin{aligned} \widehat{y}_i &= \mathbf{x}_i' \widehat{\boldsymbol{\beta}} \\ \text{STDERR}(\widehat{y}_i) &= \sqrt{s^2 h_i / w_i} \end{aligned}$$

The standard error of the individual (future) predicted value y_i is

$$\text{STDERR}(y_i) = \sqrt{s^2 (1 + h_i)/w_i}$$

If the predictor vector $\mathbf{x}_i$ corresponds to an observation in the analysis data, then the raw residual for that observation and the standard error of the raw residual are defined as

$$\begin{aligned} \text{RESID}_i &= y_i - \mathbf{x}_i' \widehat{\boldsymbol{\beta}} \\ \text{STDERR}(\text{RESID}_i) &= \sqrt{s^2 (1 - h_i)/w_i} \end{aligned}$$

The *studentized residual* is the ratio of the raw residual and its estimated standard error. Symbolically,

$$\text{STUDENT}_i = \frac{\text{RESID}_i}{\text{STDERR}(\text{RESID}_i)}$$

There are two kinds of intervals involving predicted values that are associated with a measure of confidence: the *confidence* interval for the mean value of the response and the *prediction* (or *forecasting*) interval for an individual observation. As discussed in the section "Mean Squared Error" in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," both intervals are based on the mean squared error of predicting a target based on the result of the model fit. The difference in the expressions for the confidence interval and the prediction interval comes about because the target of estimation is a constant in the case of the confidence interval (the mean of an observation) and the target is a random variable in the case of the prediction interval (a new observation).

For example, you can construct a confidence interval for the ith observation that contains the true mean value of the response with probability $1 - \alpha$. The upper and lower limits of the confidence interval for the mean value are

$$\begin{aligned} \text{LowerM} &= \mathbf{x}_i' \widehat{\boldsymbol{\beta}} - t_{\alpha/2,\nu} \sqrt{s^2 h_i / w_i} \\ \text{UpperM} &= \mathbf{x}_i' \widehat{\boldsymbol{\beta}} + t_{\alpha/2,\nu} \sqrt{s^2 h_i / w_i} \end{aligned}$$

where $t_{\alpha/2,\nu}$ is the tabulated t quantile with degrees of freedom equal to the degrees of freedom for the mean squared error, $\nu = n - \text{rank}(\mathbf{X})$.

The limits for the prediction interval for an individual response are

$$\text{LowerI} = \mathbf{x}_i'\widehat{\boldsymbol{\beta}} - t_{\alpha/2,\nu}\sqrt{s^2(1+h_i)/w_i}$$
$$\text{UpperI} = \mathbf{x}_i'\widehat{\boldsymbol{\beta}} + t_{\alpha/2,\nu}\sqrt{s^2(1+h_i)/w_i}$$

Influential observations are those that, according to various criteria, appear to have a large influence on the analysis. One measure of influence, Cook's D, measures the change to the estimates that results from deleting an observation:

$$\text{COOKD}_i = \frac{1}{k}\text{STUDENT}_i^2\left(\frac{\text{STDERR}(\widehat{y}_i)}{\text{STDERR}(\text{RESID}_i)}\right)^2$$

where k is the number of parameters in the model (including the intercept). For more information, see Cook (1977, 1979).

The *predicted residual* for observation i is defined as the residual for the ith observation that results from dropping the ith observation from the parameter estimates. The sum of squares of predicted residual errors is called the *PRESS statistic*:

$$\text{PRESID}_i = \frac{\text{RESID}_i}{1-h_i}$$
$$\text{PRESS} = \sum_{i=1}^{n} w_i \text{PRESID}_i^2$$

Testing Linear Hypotheses

Testing of linear hypothesis based on estimable functions is discussed in the section "Test of Hypotheses" on page 60 in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," and the construction of special sets of estimable functions corresponding to Type I–Type IV hypotheses is discussed in Chapter 15, "The Four Types of Estimable Functions." In linear regression models, testing of general linear hypotheses follows along the same lines. Test statistics are usually formed based on sums of squares associated with the hypothesis in question. Furthermore, when $\mathbf{X}$ is of full rank—as is the case in many regression models—the consistency of the linear hypothesis is guaranteed.

Recall from Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," that the general form of a linear hypothesis for the parameters is $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$, where $\mathbf{L}$ is $(q \times k)$, $\boldsymbol{\beta}$ is $(k \times 1)$, and $\mathbf{d}$ is $(q \times 1)$. To test this hypothesis, the linear function is taken with respect to the parameter estimates: $\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d}$. This linear function in $\widehat{\boldsymbol{\beta}}$ has variance

$$\text{Var}\left[\mathbf{L}\widehat{\boldsymbol{\beta}}\right] = \mathbf{L}\text{Var}[\widehat{\boldsymbol{\beta}}]\mathbf{L}' = \sigma^2\mathbf{L}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\mathbf{L}'$$

The *sum of squares due to the hypothesis* is a simple quadratic form:

$$\text{SS}(H) = \text{SS}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d}) = \left(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d}\right)'\left(\mathbf{L}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\mathbf{L}'\right)^{-1}\left(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d}\right)$$

If this hypothesis is testable, then $\mathrm{SS}(H)$ can be used in the numerator of an F statistic:

$$F = \frac{\mathrm{SS}(H)/q}{s^2} = \frac{\mathrm{SS}(\mathbf{Lb}-\mathbf{d})/q}{s^2}$$

If $\widehat{\boldsymbol{\beta}}$ is normally distributed, which follows as a consequence of normally distributed model errors, then this statistic follows an F distribution with q numerator degrees of freedom and $n - \mathrm{rank}(\mathbf{X})$ denominator degrees of freedom. Note that it was assumed in this derivation that $\mathbf{L}$ is of full row rank q.

Multivariate Tests

Multivariate hypotheses involve several dependent variables in the form

$$H\colon \mathbf{L}\boldsymbol{\beta}\mathbf{M} = \mathbf{d}$$

where $\mathbf{L}$ is a linear function on the regressor side, $\boldsymbol{\beta}$ is a matrix of parameters, $\mathbf{M}$ is a linear function on the dependent side, and $\mathbf{d}$ is a matrix of constants. The special case (handled by PROC REG) in which the constants are the same for each dependent variable is expressed as

$$(\mathbf{L}\boldsymbol{\beta} - \mathbf{cj})\mathbf{M} = \mathbf{0}$$

where $\mathbf{c}$ is a column vector of constants and $\mathbf{j}$ is a row vector of 1s. The special case in which the constants are 0 is then

$$\mathbf{L}\boldsymbol{\beta}\mathbf{M} = \mathbf{0}$$

These multivariate tests are covered in detail in Morrison (1976), Timm (1975), Mardia, Kent, and Bibby (1979), Bock (1975), and other works cited in Chapter 9, "Introduction to Multivariate Procedures."

Notice that in contrast to the tests discussed in the preceding section, $\boldsymbol{\beta}$ here is a matrix of parameter estimates. Suppose that the matrix of estimates is denoted as $\mathbf{B}$. To test the multivariate hypothesis, construct two matrices, $\mathbf{H}$ and $\mathbf{E}$, that correspond to the numerator and denominator of a univariate F test:

$$\begin{aligned}\mathbf{H} &= \mathbf{M}'(\mathbf{LB}-\mathbf{cj})'(\mathbf{L}(\mathbf{X}'\mathbf{WX})^{-}\mathbf{L}')^{-1}(\mathbf{LB}-\mathbf{cj})\mathbf{M}\\ \mathbf{E} &= \mathbf{M}'\left(\mathbf{Y}'\mathbf{WY} - \mathbf{B}'(\mathbf{X}'\mathbf{WX})\mathbf{B}\right)\mathbf{M}\end{aligned}$$

Four test statistics, based on the eigenvalues of $\mathbf{E}^{-1}\mathbf{H}$ or $(\mathbf{E}+\mathbf{H})^{-1}\mathbf{H}$, are formed. Let λ_i be the ordered eigenvalues of $\mathbf{E}^{-1}\mathbf{H}$ (if the inverse exists), and let ξ_i be the ordered eigenvalues of $(\mathbf{E}+\mathbf{H})^{-1}\mathbf{H}$. It happens that $\xi_i = \lambda_i/(1+\lambda_i)$ and $\lambda_i = \xi_i/(1-\xi_i)$, and it turns out that $\rho_i = \sqrt{\xi_i}$ is the ith canonical correlation.

Let p be the rank of $(\mathbf{H}+\mathbf{E})$, which is less than or equal to the number of columns of $\mathbf{M}$. Let q be the rank of $\mathbf{L}(\mathbf{X}'\mathbf{WX})^{-}\mathbf{L}'$. Let v be the error degrees of freedom and $s = \min(p,q)$. Let $m = (|p-q|-1)/2$, and let $n = (v-p-1)/2$. Then the following statistics test the multivariate hypothesis in various ways, and their p-values can be approximated by F distributions. Note that in the special case that the rank of $\mathbf{H}$ is 1, all of these F statistics will be the same and the corresponding p-values will in fact be exact, since in this case the hypothesis is really univariate.

Wilks' Lambda

If

$$\Lambda = \frac{\det(\mathbf{E})}{\det(\mathbf{H}+\mathbf{E})} = \prod_{i=1}^{n} \frac{1}{1+\lambda_i} = \prod_{i=1}^{n}(1-\xi_i)$$

then

$$F = \frac{1-\Lambda^{1/t}}{\Lambda^{1/t}} \cdot \frac{rt-2u}{pq}$$

is approximately F distributed, where

$$\begin{aligned} r &= v - \frac{p-q+1}{2} \\ u &= \frac{pq-2}{4} \\ t &= \begin{cases} \sqrt{\frac{p^2q^2-4}{p^2+q^2-5}} & \text{if} p^2+q^2-5>0 \\ 1 & \text{otherwise} \end{cases} \end{aligned}$$

The degrees of freedom are pq and $rt-2u$. The distribution is exact if $\min(p,q) \leq 2$. (See Rao 1973, p. 556.)

Pillai's Trace

If

$$\mathbf{V} = \text{trace}\left(\mathbf{H}(\mathbf{H}+\mathbf{E})^{-1}\right) = \sum_{i=1}^{n} \frac{\lambda_i}{1+\lambda_i} = \sum_{i=1}^{n} \xi_i$$

then

$$F = \frac{2n+s+1}{2m+s+1} \cdot \frac{\mathbf{V}}{s-\mathbf{V}}$$

is approximately F distributed with $s(2m+s+1)$ and $s(2n+s+1)$ degrees of freedom.

Hotelling-Lawley Trace

If

$$U = \text{trace}\left(\mathbf{E}^{-1}\mathbf{H}\right) = \sum_{i=1}^{n} \lambda_i = \sum_{i=1}^{n} \frac{\xi_i}{1-\xi_i}$$

then for $n > 0$

$$F = (U/c)((4+(pq+2)/(b-1))/(pq))$$

is approximately F distributed with pq and $4 + (pq + 2)/(b - 1)$ degrees of freedom, where $b = (p + 2n)(q + 2n)/(2(2n + 1)(n - 1))$ and $c = (2 + (pq + 2)/(b - 1))/(2n)$; while for $n \leq 0$

$$F = \frac{2(sn + 1)\mathbf{U}}{s^2(2m + s + 1)}$$

is approximately F with $s(2m + s + 1)$ and $2(sn + 1)$ degrees of freedom.

Roy's Maximum Root

If $\Theta = \lambda_1$, then

$$F = \Theta\frac{v - r + q}{r}$$

where $r = \max(p, q)$ is an upper bound on F that yields a lower bound on the significance level. Degrees of freedom are r for the numerator and $v - r + q$ for the denominator.

Tables of critical values for these statistics are found in Pillai (1960).

Exact Multivariate Tests

Beginning with SAS 9, if you specify the MSTAT=EXACT option in the appropriate statement, p-values for three of the four tests are computed exactly (Wilks' lambda, the Hotelling-Lawley trace, and Roy's greatest root), and the p-values for the fourth (Pillai's trace) are based on an F approximation that is more accurate (but occasionally slightly more liberal) than the default. The exact p-values for Roy's greatest root benefit the most, since in this case the F approximation provides only a lower bound for the p-value. If you use the F-based p-value for this test in the usual way, declaring a test significant if $p < 0.05$, then your decisions might be very liberal. For example, instead of the nominal 5% Type I error rate, such a procedure can easily have an actual Type I error rate in excess of 30%. By contrast, basing such a procedure on the exact p-values will result in the appropriate 5% Type I error rate, under the usual regression assumptions.

The MSTAT=EXACT option is supported in the ANOVA, CANCORR, CANDISC, GLM, and REG procedures.

The exact p-values are based on the following sources:

- **Wilks' lambda:** Lee (1972), Davis (1979)
- **Pillai's trace:** Muller (1998)
- **Hotelling-Lawley trace:** Davis (1970), Davis (1980)
- **Roy's greatest root:** Davis (1972), Pillai and Flury (1984)

Note that, although the MSTAT=EXACT p-value for Pillai's trace is still approximate, it has "substantially greater accuracy" than the default approximation (Muller 1998).

Since most of the MSTAT=EXACT p-values are not based on the F distribution, the columns in the multivariate tests table corresponding to this approximation—in particular, the F value and the numerator and

denominator degrees of freedom—are no longer displayed, and the column containing the p-values is labeled "P Value" instead of "Pr > F." Suppose, for example, you use the following PROC ANOVA statements to perform a multivariate analysis of an archaeological data set:

```
data Skulls;
   input Loc $20. Basal Occ Max;
   datalines;
Minas Graes, Brazil  2.068 2.070 1.580
Minas Graes, Brazil  2.068 2.074 1.602
Minas Graes, Brazil  2.090 2.090 1.613
Minas Graes, Brazil  2.097 2.093 1.613
Minas Graes, Brazil  2.117 2.125 1.663
Minas Graes, Brazil  2.140 2.146 1.681
Matto Grosso, Brazil 2.045 2.054 1.580
Matto Grosso, Brazil 2.076 2.088 1.602
Matto Grosso, Brazil 2.090 2.093 1.643
Matto Grosso, Brazil 2.111 2.114 1.643
Santa Cruz, Bolivia  2.093 2.098 1.653
Santa Cruz, Bolivia  2.100 2.106 1.623
Santa Cruz, Bolivia  2.104 2.101 1.653
;

proc anova data=Skulls;
   class Loc;
   model Basal Occ Max = Loc / nouni;
   manova h=Loc;
   ods select MultStat;
run;
```

The default multivariate tests, based on the F approximations, are shown in Figure 4.5.

Figure 4.5 Default Multivariate Tests

The ANOVA Procedure
Multivariate Analysis of Variance

MANOVA Test Criteria and F Approximations for
the Hypothesis of No Overall Loc Effect
H = Anova SSCP Matrix for Loc
E = Error SSCP Matrix

S=2 M=0 N=3

Statistic	Value	F Value	Num DF	Den DF	Pr > F
Wilks' Lambda	0.60143661	0.77	6	16	0.6032
Pillai's Trace	0.44702843	0.86	6	18	0.5397
Hotelling-Lawley Trace	0.58210348	0.75	6	9.0909	0.6272
Roy's Greatest Root	0.35530890	1.07	3	9	0.4109

NOTE: F Statistic for Roy's Greatest Root is an upper bound.
NOTE: F Statistic for Wilks' Lambda is exact.

If you specify MSTAT=EXACT in the MANOVA statement, as in the following statements, then the dis-

played output is the much simpler table shown in Figure 4.6.

```
proc anova data=Skulls;
   class Loc;
   model Basal Occ Max = Loc / nouni;
   manova h=Loc / mstat=exact;
   ods select MultStat;
run;
```

Figure 4.6 Multivariate Tests with MSTAT=EXACT

The ANOVA Procedure
Multivariate Analysis of Variance

MANOVA Tests for the Hypothesis of No Overall Loc Effect
H = Anova SSCP Matrix for Loc
E = Error SSCP Matrix

S=2 M=0 N=3

Statistic	Value	P-Value
Wilks' Lambda	0.60143661	0.6032
Pillai's Trace	0.44702843	0.5521
Hotelling-Lawley Trace	0.58210348	0.6337
Roy's Greatest Root	0.35530890	0.7641

Notice that the p-value for Roy's greatest root is substantially larger in the new table, and correspondingly more in line with the p-values for the other tests.

If you reference the underlying ODS output object for the table of multivariate statistics, it is important to note that its structure does not depend on the value of the MSTAT= specification. In particular, it always contains columns corresponding to both the default MSTAT=FAPPROX and the MSTAT=EXACT tests. Moreover, since the MSTAT=FAPPROX tests are relatively cheap to compute, the columns corresponding to them are always filled in, even though they are not displayed when you specify MSTAT=EXACT. On the other hand, for MSTAT=FAPPROX (which is the default), the column of exact p-values contains missing values, and is not displayed.

Comments on Interpreting Regression Statistics

In most applications, regression models are merely useful approximations. Reality is often so complicated that you cannot know what the true model is. You might have to choose a model more on the basis of what variables can be measured and what kinds of models can be estimated than on a rigorous theory that explains how the universe really works. However, even in cases where theory is lacking, a regression model can be an excellent predictor of the response if the model is carefully formulated from a large sample. The interpretation of statistics such as parameter estimates might nevertheless be highly problematic.

Statisticians usually use the word "prediction" in a technical sense. *Prediction* in this sense does not refer to "predicting the future" (statisticians call that *forecasting*) but rather to guessing the response from the

values of the regressors in an observation taken under the same circumstances as the sample from which the regression equation was estimated. If you developed a regression model for predicting consumer preferences in 1977, it might not give very good predictions in 2007 no matter how well it did in 1977. If it is the future you want to predict, your model must include whatever relevant factors might change over time. If the process you are studying does in fact change over time, you must take observations at several, perhaps many, different times. Analysis of such data is the province of SAS/STAT procedures such as MIXED and GLIMMIX and SAS/ETS procedures such as AUTOREG and STATESPACE. See Chapter 40, "The GLIMMIX Procedure," and Chapter 58, "The MIXED Procedure," for more information about modeling serial correlation in longitudinal, repeated measures, or time series data with SAS/STAT mixed modeling procedures. See the *SAS/ETS User's Guide* for more information about the AUTOREG and STATESPACE procedures.

The comments in the rest of this section are directed toward linear least squares regression. For more detailed discussions of the interpretation of regression statistics, see Darlington (1968), Mosteller and Tukey (1977), Weisberg (1985), and Younger (1979).

Interpreting Parameter Estimates from a Controlled Experiment

Parameter estimates are easiest to interpret in a controlled experiment in which the regressors are manipulated independently of each other. In a well-designed experiment, such as a randomized factorial design with replications in each cell, you can use lack-of-fit tests and estimates of the standard error of prediction to determine whether the model describes the experimental process with adequate precision. If so, a regression coefficient estimates the amount by which the mean response changes when the regressor is changed by one unit while all the other regressors are unchanged. However, if the model involves interactions or polynomial terms, it might not be possible to interpret individual regression coefficients. For example, if the equation includes both linear and quadratic terms for a given variable, you cannot physically change the value of the linear term without also changing the value of the quadratic term. Sometimes it might be possible to recode the regressors, such as by using orthogonal polynomials, to simplify the interpretation.

If the nonstatistical aspects of the experiment are also treated with sufficient care (such as the use of placebos and double blinds), then you can state conclusions in causal terms; that is, this change in a regressor causes that change in the response. Causality can never be inferred from statistical results alone or from an observational study.

If the model you fit is not the true model, then the parameter estimates can depend strongly on the particular values of the regressors used in the experiment. For example, if the response is actually a quadratic function of a regressor but you fit a linear function, the estimated slope can be a large negative value if you use only small values of the regressor, a large positive value if you use only large values of the regressor, or near zero if you use both large and small regressor values. When you report the results of an experiment, it is important to include the values of the regressors. It is also important to avoid extrapolating the regression equation outside the range of regressors in the sample.

Interpreting Parameter Estimates from an Observational Study

In an observational study, parameter estimates can be interpreted as the expected difference in response of two observations that differ by one unit on the regressor in question and that have the same values for all other regressors. You cannot make inferences about "changes" in an observational study since you have not

actually changed anything. It might not be possible even in principle to change one regressor independently of all the others. Neither can you draw conclusions about causality without experimental manipulation.

If you conduct an observational study and you do not know the true form of the model, interpretation of parameter estimates becomes even more convoluted. A coefficient must then be interpreted as an average over the sampled population of expected differences in response of observations that differ by one unit on only one regressor. The considerations that are discussed under controlled experiments for which the true model is not known also apply.

Comparing Parameter Estimates

Two coefficients in the same model can be directly compared only if the regressors are measured in the same units. You can make any coefficient large or small just by changing the units. If you convert a regressor from feet to miles, the parameter estimate is multiplied by 5280.

Sometimes standardized regression coefficients are used to compare the effects of regressors measured in different units. Standardized estimates are defined as the estimates that result when all variables are standardized to a mean of 0 and a variance of 1. Standardized estimates are computed by multiplying the original estimates by the sample standard deviation of the regressor variable and dividing by the sample standard deviation of the dependent variable.

Standardizing the variables effectively makes the standard deviation the unit of measurement. This makes sense only if the standard deviation is a meaningful quantity, which usually is the case only if the observations are sampled from a well-defined population. In a controlled experiment, the standard deviation of a regressor depends on the values of the regressor selected by the experimenter. Thus, you can make a standardized regression coefficient large by using a large range of values for the regressor.

In some applications you might be able to compare regression coefficients in terms of the practical range of variation of a regressor. Suppose that each independent variable in an industrial process can be set to values only within a certain range. You can rescale the variables so that the smallest possible value is zero and the largest possible value is one. Then the unit of measurement for each regressor is the maximum possible range of the regressor, and the parameter estimates are comparable in that sense. Another possibility is to scale the regressors in terms of the cost of setting a regressor to a particular value, so comparisons can be made in monetary terms.

Correlated Regressors

In an experiment, you can often select values for the regressors such that the regressors are orthogonal (not correlated with each other). Orthogonal designs have enormous advantages in interpretation. With orthogonal regressors, the parameter estimate for a given regressor does not depend on which other regressors are included in the model, although other statistics such as standard errors and p-values might change.

If the regressors are correlated, it becomes difficult to disentangle the effects of one regressor from another, and the parameter estimates can be highly dependent on which regressors are used in the model. Two correlated regressors might be nonsignificant when tested separately but highly significant when considered together. If two regressors have a correlation of 1.0, it is impossible to separate their effects.

It might be possible to recode correlated regressors to make interpretation easier. For example, if X and Y are highly correlated, they could be replaced in a linear regression by $X + Y$ and $X - Y$ without changing the fit of the model or statistics for other regressors.

Errors in the Regressors

If there is error in the measurements of the regressors, the parameter estimates must be interpreted with respect to the measured values of the regressors, not the true values. A regressor might be statistically nonsignificant when measured with error even though it would have been highly significant if measured accurately.

Probability Values (*p*-Values)

Probability values (p-values) do not necessarily measure the importance of a regressor. An important regressor can have a large (nonsignificant) p-value if the sample is small, if the regressor is measured over a narrow range, if there are large measurement errors, or if another closely related regressor is included in the equation. An unimportant regressor can have a very small p-value in a large sample. Computing a confidence interval for a parameter estimate gives you more useful information than just looking at the p-value, but confidence intervals do not solve problems of measurement errors in the regressors or highly correlated regressors.

Interpreting R^2

R^2 is usually defined as the proportion of variance of the response that is predictable from (can be explained by) the regressor variables. It might be easier to interpret $\sqrt{1 - R^2}$, which is approximately the factor by which the standard error of prediction is reduced by the introduction of the regressor variables.

R^2 is easiest to interpret when the observations, including the values of both the regressors and response, are randomly sampled from a well-defined population. Nonrandom sampling can greatly distort R^2. For example, excessively large values of R^2 can be obtained by omitting from the sample observations with regressor values near the mean.

In a controlled experiment, R^2 depends on the values chosen for the regressors. A wide range of regressor values generally yields a larger R^2 than a narrow range. In comparing the results of two experiments on the same variables but with different ranges for the regressors, you should look at the standard error of prediction (root mean square error) rather than R^2.

Whether a given R^2 value is considered to be large or small depends on the context of the particular study. A social scientist might consider an R^2 of 0.30 to be large, while a physicist might consider 0.98 to be small.

You can always get an R^2 arbitrarily close to 1.0 by including a large number of completely unrelated regressors in the equation. If the number of regressors is close to the sample size, R^2 is very biased. In such cases, the adjusted R^2 and related statistics discussed by Darlington (1968) are less misleading.

If you fit many different models and choose the model with the largest R^2, all the statistics are biased and the p-values for the parameter estimates are not valid. Caution must be taken with the interpretation of R^2 for models with no intercept term. As a general rule, no-intercept models should be fit only when theoretical

justification exists and the data appear to fit a no-intercept framework. The R^2 in those cases is measuring something different (see Kvalseth 1985).

Incorrect Data Values

All regression statistics can be seriously distorted by a single incorrect data value. A decimal point in the wrong place can completely change the parameter estimates, R^2, and other statistics. It is important to check your data for outliers and influential observations. Residual and influence diagnostics are particularly useful in this regard.

When a data point is declared as influential or as outlying as measured by a particular model diagnostic, this does not imply that the case should be excluded from the analysis. The label "outlier" does not have a negative connotation. It means that a data point is unusual with respect to the model at hand. If your data follow a strong curved trend and you fit a linear regression, then many data points might be labeled as outliers not because they are "bad" or incorrect data values, but because your model is not appropriate.

Chapter 5

Introduction to Analysis of Variance Procedures

Contents

Overview: Analysis of Variance Procedures

The statistical term "analyis of variance" is used in a variety of circumstances in statistical theory and applications. In the *narrowest* sense, and the original sense of the phrase, it signifies a decomposition of a variance into contributing components. This was the sense used by R. A. Fisher when he defined the term to mean the expression of genetic variance as a sum of variance components due to environment, heredity, and so forth:

$$\sigma^2 = \sigma_1^2 + \sigma_2^2 + \cdots + \sigma_p^2$$

In this sense of the term, the SAS/STAT procedures that fit variance component models, such as the GLIMMIX, HPMIXED, MIXED, NESTED, and VARCOMP procedures, are "true" analysis of variance procedures.

Analysis of variance methodology in a slightly broader sense—and the sense most frequently understood today—applies the idea of an additive decomposition of variance to an additive decomposition of *sums of squares*, whose expected values are functionally related to components of variation. A collection of sums

of squares that measure and can be used for inference about meaningful features of a model is called a *sum of squares analysis of variance*, whether or not such a collection is an additive decomposition. In a linear model, the decomposition of sums of squares can be expressed in terms of projections onto orthogonal subspaces spanned by the columns of the design matrix **X**. This is the general approach followed in the section "Analysis of Variance" on page 58 in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software." Depending on the statistical question at hand, the projections can be formulated based on estimable functions, with different types of estimable functions giving rise to different types of sums of squares. Note that not all sum of squares analyses necessarily correspond to additive decompositions. For example, the Type III sums of squares often test hypotheses about the model that are more meaningful than those corresponding to the Type I sums of squares. But while the Type I sums of squares additively decompose the sum of squares due to all model contributions, the Type III sums of squares do not necessarily add up to any useful quantity. The four types of estimable functions in SAS/STAT software, their interpretation, and their construction are discussed in Chapter 15, "The Four Types of Estimable Functions." The application of sum of squares analyses is not necessarily limited to models with classification effects (factors). The methodology also applies to linear regression models that contain only continuous regressor variables.

An even broader sense of the term "analysis of variance" pertains to statistical models that contain classification effects (factors), and in particular, to models that contain *only* classification effects. Any statistical approach that measures features of such a model and can be used for inference is called a *general analysis of variance*. Thus the procedures for general analysis of variance in SAS/STAT are considered to be those that can fit statistical models containing factors, whether the data are experimental or observational. Some procedures for general analysis of variance have a statistical estimation principle that gives rise to a sum of squares analysis as discussed previously; others express a factor's contribution to the model fit in some other form. Note that this view of analysis of variance includes, for example, maximum likelihood estimation in generalized linear models with the GENMOD procedure, restricted maximum likelihood estimation in linear mixed models with the MIXED procedure, the estimation of variance components with the VARCOMP procedure, the comparison of means of groups with the TTEST procedure, and the nonparametric analysis of rank scores with the NPAR1WAY procedure, and so on.

In summary, analysis of variance in the contemporary sense of statistical modeling and analysis is more aptly described as *analysis of variation*, the study of the influences on the variation of a phenomenon. This can take, for example, the following forms:

- an analysis of variance table based on sums of squares followed by more specific inquiries into the relationship among factors and their levels
- a deviance decomposition in a generalized linear model
- a series of Type III tests followed by comparisons of least squares means in a mixed model

Procedures That Perform Sum of Squares Analysis of Variance

The flagship procedure in SAS/STAT software for linear modeling with sum of squares analysis techniques is the GLM procedure. It handles most standard analysis of variance problems. The following list provides descriptions of PROC GLM and other procedures that are used for more specialized situations:

ANOVA	performs analysis of variance, multivariate analysis of variance, and repeated measures analysis of variance for *balanced* designs. PROC ANOVA also performs multiple comparison tests on arithmetic means.
GLM	performs analysis of variance, regression, analysis of covariance, repeated measures analysis, and multivariate analysis of variance. PROC GLM produces several diagnostic measures, performs tests for random effects, provides contrasts and estimates for customized hypothesis tests, provides tests for means adjusted for covariates, and performs multiple-comparison tests on both arithmetic and adjusted means.
LATTICE	computes the analysis of variance and analysis of simple covariance for data from an experiment with a lattice design. PROC LATTICE analyzes balanced square lattices, partially balanced square lattices, and some rectangular lattices.
MIXED	performs mixed model analysis of variance and repeated measures analysis of variance via covariance structure modeling. When you choose one of the method-of-moment estimation techniques, the MIXED procedure produces an analysis of variance table with sums of squares, mean squares, and expected mean squares. PROC MIXED constructs statistical tests and intervals, enables customized contrasts and estimates, and computes empirical Bayes predictions.
NESTED	performs analysis of variance and analysis of covariance for purely nested random models.
ORTHOREG	performs regression by using the Gentleman-Givens computational method. For ill-conditioned data, PROC ORTHOREG can produce more accurate parameter estimates than other procedures, such as PROC GLM. See Chapter 65, "The ORTHOREG Procedure," for more information.
VARCOMP	estimates variance components for random or mixed models. If you choose the METHOD=TYPE1 or METHOD=GRR option, the VARCOMP procedure produces an analysis of variance table with sums of squares that correspond to the random effects in your models.
TRANSREG	fits univariate and multivariate linear models, optionally with spline and other nonlinear transformations. Models include ordinary regression and ANOVA, multiple and multivariate regression, metric and nonmetric conjoint analysis, metric and nonmetric vector and ideal point preference mapping, redundancy analysis, canonical correlation, and response surface regression. See Chapter 93, "The TRANSREG Procedure," for more information.

Procedures That Perform General Analysis of Variance

Many procedures in SAS/STAT enable you to incorporate classification effects into your model and to perform statistical inferences for experimental factors and their interactions. These procedures do not necessarily rely on sums of squares decompositions to perform these inferences. Examples of such procedures are the CATMOD, GENMOD, GLIMMIX, LOGISTIC, NPAR1WAY, and TTEST procedures. In fact, any one of the more than two dozen SAS/STAT modeling procedures that include a CLASS statement can be said to perform analysis of variance in this general sense. For more information about individual procedures, refer to their corresponding chapters in this documentation.

The following section discusses procedures in SAS/STAT that compute analysis of variance in models with classification factors in the narrow sense—that is, they produce analysis of variance tables and form F tests based on sums of squares, mean squares, and expected mean squares.

The subsequent sections discuss procedures that perform statistical inference in models with classification effects in the broader sense.

The following section also presents an overview of some of the fundamental features of analysis of variance. Subsequent sections describe how this analysis is performed with procedures in SAS/STAT software. For more detail, see the chapters for the individual procedures. Additional sources are described in the section "References" on page 116.

Statistical Details for Analysis of Variance

From Sums of Squares to Linear Hypotheses

Analysis of variance (ANOVA) is a technique for analyzing data in which one or more *response* (or *dependent* or simply Y) variables are measured under various conditions identified by one or more classification variables. The combinations of levels for the classification variables form the cells of the design for the data. This design can be the result of a controlled experiment or the result of an observational study in which you observe factors and factor level combinations in an uncontrolled environment. For example, an experiment might measure weight change (the dependent variable) for men and women who participated in three different weight-loss programs. The six cells of the design are formed by the six combinations of gender (men, women) and program (A, B, C).

In an analysis of variance, the variation in the response is separated into variation attributable to differences between the classification variables and variation attributable to random error. An analysis of variance constructs tests to determine the significance of the classification effects. A typical goal in such an analysis is to compare means of the response variable for various combinations of the classification variables.

The least squares principle is central to computing sums of squares in analysis of variance models. Suppose that you are fitting the linear model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$ and that the error terms satisfy the usual assumptions (uncorrelated, zero mean, homogeneous variance). Further, suppose that $\mathbf{X}$ is partitioned according to several model effects, $\mathbf{X} = [\mathbf{X}_1\ \mathbf{X}_2 \cdots \mathbf{X}_k]$. If $\widehat{\boldsymbol{\beta}}$ denotes the ordinary least squares solution for this model, then the sum of squares attributable to the overall model can be written as

$$\text{SSM} = \widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y} = \mathbf{Y}'\mathbf{H}\mathbf{Y}$$

where $\mathbf{H}$ is the "hat" matrix $\mathbf{H} = \mathbf{X}(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'$. (This model sum of squares is not yet corrected for the presence of an explicit or implied intercept. This adjustment would consist of subtracting $n\overline{Y}^2$ from SSM.) Because of the properties of the hat matrix $\mathbf{H}$, you can write $\mathbf{X}' = \mathbf{X}'\mathbf{H}$ and $\mathbf{H}\mathbf{X} = \mathbf{X}$. The (uncorrected) model sum of squares thus can also be written as

$$\text{SSM} = \widehat{\boldsymbol{\beta}}'(\mathbf{X}'\mathbf{X})\widehat{\boldsymbol{\beta}}$$

This step is significant, because it demonstrates that sums of squares can be identified with quadratic functions in the least squares coefficients. The generalization of this idea is to do the following:

- consider hypotheses of interest in an analysis of variance model
- express the hypotheses in terms of linear estimable functions of the parameters
- compute the sums of squares associated with the estimable function
- construct statistical tests based on the sums of squares

Decomposing a model sum of squares into sequential, additive components, testing the significance of experimental factors, comparing factor levels, and performing other statistical inferences fall within this generalization. Suppose that $\mathbf{L}\boldsymbol{\beta}$ is an estimable function (see the section "Estimable Functions" on page 60 in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," and Chapter 15, "The Four Types of Estimable Functions," for details). The sum of squares associated with the hypothesis $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ is

$$\mathrm{SS}(H) = \mathrm{SS}(\mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = \widehat{\boldsymbol{\beta}}'\mathbf{L}'\left(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'\right)^{-1}\mathbf{L}\widehat{\boldsymbol{\beta}}$$

One application would be to form sums of squares associated with the different components of $\mathbf{X}$. For example, you can form a matrix $\mathbf{L}_2$ matrix such that $\mathbf{L}_2\boldsymbol{\beta} = \mathbf{0}$ tests the effect of adding the columns for $\mathbf{X}_2$ to an empty model or to test the effect of adding $\mathbf{X}_2$ to a model that already contains $\mathbf{X}_1$.

These sums of squares can also be expressed as the difference between two residual sums of squares, since $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ can be thought of as a (linear) restriction on the parameter estimates in the model:

$$\mathrm{SS}(H) = \mathrm{SSR}(\text{constrained model}) - \mathrm{SSR}(\text{full model})$$

If, in addition to the usual assumptions mentioned previously, the model errors are assumed to be normally distributed, then $\mathrm{SS}(H)$ follows a distribution that is proportional to a chi-square distribution. This fact, and the independence of $\mathrm{SS}(H)$ from the residual sum of squares, enables you to construct F tests based on sums of squares in least squares models.

The extension of sum of squares analysis of variance to general analysis of variance for classification effects depends on the fact that the distributional properties of quadratic forms in normal random variables are well understood. It is not necessary to first formulate a sum of squares to arrive at an exact or even approximate F test. The generalization of the expression for $\mathrm{SS}(H)$ is to form test statistics based on quadratic forms

$$\widehat{\boldsymbol{\beta}}'\mathbf{L}'\,\mathrm{Var}\left[\mathbf{L}\widehat{\boldsymbol{\beta}}\right]^{-1}\mathbf{L}\widehat{\boldsymbol{\beta}}$$

that follow a chi-square distribution if $\widehat{\boldsymbol{\beta}}$ is normally distributed.

Tests of Effects Based on Expected Mean Squares

Statistical tests in analysis of variance models can be constructed by comparing independent mean squares. To test a particular null hypothesis, you compute the ratio of two mean squares that have the same expected

value under that hypothesis; if the ratio is much larger than 1, then that constitutes significant evidence against the null. In particular, in an analysis of variance model with fixed effects only, the expected value of each mean square has two components: quadratic functions of fixed parameters and random variation. For example, for a fixed effect called A, the expected value of its mean square is

$$\mathrm{E}[\mathrm{MS(A)}] = \mathrm{Q}(\boldsymbol{\beta}) + \sigma^2$$

where σ^2 is the common variance of the ϵ_i.

Under the null hypothesis of no A effect, the fixed portion $\mathrm{Q}(\boldsymbol{\beta})$ of the expected mean square is zero. This mean square is then compared to another mean square—say, MS(E)—that is independent of the first and has the expected value σ^2. The ratio of the two mean squares

$$F = \frac{\mathrm{MS(A)}}{\mathrm{MS(E)}}$$

has an F distribution under the null hypothesis.

When the null hypothesis is false, the numerator term has a larger expected value, but the expected value of the denominator remains the same. Thus, large F values lead to rejection of the null hypothesis. The probability of getting an F value at least as large as the one observed given that the null hypothesis is true is called the *significance probability value* (or the *p*-value). A *p*-value of less than 0.05, for example, indicates that data with *no* A effect will yield F values as large as the one observed less than 5% of the time. This is usually considered moderate evidence that there *is* a real A effect. Smaller *p*-values constitute even stronger evidence. Larger *p*-values indicate that the effect of interest is less than random noise. In this case, you can conclude either that there is no effect at all or that you do not have enough data to detect the differences being tested.

The actual pattern in expected mean squares of terms related to fixed quantities ($\mathrm{Q}(\boldsymbol{\beta})$) and functions of variance components depends on which terms in your model are fixed effects and which terms are random effects. This has bearing on how F statistics can be constructed. In some instances, exact tests are not available, such as when a linear combination of expected mean squares is necessary to form a proper denominator for an F test and a Satterthwaite approximation is used to determine the degrees of freedom of the approximation. The GLM and MIXED procedures can generate tables of expected mean squares and compute degrees of freedom by Satterthwaite's method. The MIXED and GLIMMIX procedures can apply Satterthwaite approximations and other degrees-of-freedom computations more widely than in analysis of variance models. See the section "Fixed, Random, and Mixed Models" on page 31 in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," for a discussion of fixed versus random effects in statistical models.

Analysis of Variance for Fixed-Effect Models

PROC GLM for General Linear Models

The GLM procedure is the flagship tool for classical analysis of variance in SAS/STAT software. It performs analysis of variance by using least squares regression to fit general linear models. Among the statistical

methods available in PROC GLM are regression, analysis of variance, analysis of covariance, multivariate analysis of variance, repeated measures analysis, and partial correlation analysis.

While PROC GLM can handle most common analysis of variance problems, other procedures are more efficient or have more features than PROC GLM for certain specialized analyses, or they can handle specialized models that PROC GLM cannot. Much of the rest of this chapter is concerned with comparing PROC GLM to other procedures.

PROC ANOVA for Balanced Designs

When you design an experiment, you choose how many experimental units to assign to each combination of levels (or cells) in the classification. In order to achieve good statistical properties and simplify the computations, you typically attempt to assign the same number of units to every cell in the design. Such designs are called *balanced designs*.

In SAS/STAT software, you can use the ANOVA procedure to perform analysis of variance for balanced data. The ANOVA procedure performs computations for analysis of variance that assume the balanced nature of the data. These computations are simpler and more efficient than the corresponding general computations performed by PROC GLM. Note that PROC ANOVA can be applied to certain designs that are not balanced in the strict sense of equal numbers of observations for all cells. These additional designs include all one-way models, regardless of how unbalanced the cell counts are, as well as Latin squares, which do not have data in all cells. In general, however, the ANOVA procedure is recommended only for balanced data. **If you use ANOVA to analyze a design that is not balanced, you must assume responsibility for the validity of the output.** You are responsible for recognizing incorrect results, which might include negative values reported for the sums of squares. If you are not certain that your data fit into a balanced design, then you probably need the framework of general linear models in the GLM procedure.

Comparing Group Means

The F test for a classification factor that has more than two levels tells you whether the level effects are significantly different from each other, but it does not tell you which levels differ from which other levels.

If the level comparisons are expressed through differences of the arithmetic cell means, you can use the MEANS statement in the GLM and ANOVA procedure for comparison. If arithmetic means are not appropriate for comparison, for example, because your data are unbalanced or means need to be adjusted for other model effects, then you can use the LSMEANS statement in the GLIMMIX, GLM, and MIXED procedures for level comparisons.

If you have specific comparisons in mind, you can use the CONTRAST statement in these procedures to make these comparisons. However, if you make many comparisons that use some given significance level (0.05, for example), you are more likely to make a type 1 error (incorrectly rejecting a hypothesis that the means are equal) simply because you have more chances to make the error.

Multiple-comparison methods give you more detailed information about the differences among the means and enable you to control error rates for a multitude of comparisons. A variety of multiple-comparison

methods are available with the MEANS statement in both the ANOVA and GLM procedures, as well as the LSMEANS statement in the GLIMMIX, GLM, and MIXED procedures. These are described in detail in the section "Multiple Comparisons" on page 3234 in Chapter 41, "The GLM Procedure," and in Chapter 40, "The GLIMMIX Procedure," and Chapter 58, "The MIXED Procedure."

PROC TTEST for Comparing Two Groups

If you want to perform an analysis of variance and have only one classification variable with two levels, you can use PROC TTEST. In this special case, the results generated by PROC TTEST are equivalent to the results generated by PROC ANOVA or PROC GLM.

You can use PROC TTEST with balanced or unbalanced groups. In addition to the test assuming equal variances, PROC TTEST also performs a Satterthwaite test assuming unequal variances.

The TTEST procedure also performs equivalence tests, computes confidence limits, and supports both normal and lognormal data. If you have an AB/BA crossover design with no carryover effects, then you can use the TTEST procedure to analyze the treatment and period effects.

The PROC NPAR1WAY procedure performs nonparametric analogues to t tests. See Chapter 16, "Introduction to Nonparametric Analysis," for an overview and Chapter 64, "The NPAR1WAY Procedure," for details on PROC NPAR1WAY.

Analysis of Variance for Categorical Data and Generalized Linear Models

A *categorical variable* is defined as one that can assume only a limited number of values. For example, a person's gender is a categorical variable that can assume one of two values. Variables with levels that simply name a group are said to be measured on a *nominal scale*. Categorical variables can also be measured using an *ordinal scale*, which means that the levels of the variable are ordered in some way. For example, responses to an opinion poll are usually measured on an ordinal scale, with levels ranging from "strongly disagree" to "no opinion" to "strongly agree."

For two categorical variables, one measured on an ordinal scale and one measured on a nominal scale, you can assign scores to the levels of the ordinal variable and test whether the mean scores for the different levels of the nominal variable are significantly different. This process is analogous to performing an analysis of variance on continuous data, which can be performed by PROC CATMOD. If there are n nominal variables, rather than 1, then PROC CATMOD can perform an n-way analysis of variance of the mean scores.

For two categorical variables measured on a nominal scale, you can test whether the distribution of the first variable is significantly different for the levels of the second variable. This process is an analysis of variance of proportions, rather than means, and can be performed by PROC CATMOD. The corresponding n-way analysis of variance can also be performed by PROC CATMOD.

See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 29, "The CATMOD Procedure," for more information.

The GENMOD procedure uses maximum likelihood estimation to fit generalized linear models. This family includes models for categorical data such as logistic, probit, and complementary log-log regression for binomial data and Poisson regression for count data, as well as continuous models such as ordinary linear regression, gamma, and inverse gaussian regression models. PROC GENMOD performs analysis of variance through likelihood ratio and Wald tests of fixed effects in generalized linear models, and provides contrasts and estimates for customized hypothesis tests. It performs analysis of repeated measures data with generalized estimating equation (GEE) methods.

See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 39, "The GENMOD Procedure," for more information.

Nonparametric Analysis of Variance

Analysis of variance is sensitive to the distribution of the error term. If the error term is not normally distributed, the statistics based on normality can be misleading. The traditional test statistics are called *parametric tests* because they depend on the specification of a certain probability distribution except for a set of free parameters. Parametric tests are said to depend on distributional assumptions. Nonparametric methods perform the tests without making any strict distributional assumptions. Even if the data are distributed normally, nonparametric methods are often almost as powerful as parametric methods.

Most nonparametric methods are based on taking the ranks of a variable and analyzing these ranks (or transformations of them) instead of the original values. The NPAR1WAY procedure performs a nonparametric one-way analysis of variance. Other nonparametric tests can be performed by taking ranks of the data (using the RANK procedure) and using a regular parametric procedure (such as GLM or ANOVA) to perform the analysis. Some of these techniques are outlined in the description of PROC RANK in *SAS Language Reference: Concepts* and in Conover and Iman (1981).

Constructing Analysis of Variance Designs

Analysis of variance is most often used for data from designed experiments. You can use the PLAN procedure to construct designs for many experiments. For example, PROC PLAN constructs designs for completely randomized experiments, randomized blocks, Latin squares, factorial experiments, certain balanced incomplete block designs, and balanced crossover designs.

Randomization, or randomly assigning experimental units to cells in a design and to treatments within a cell, is another important aspect of experimental design. For either a new or an existing design, you can use PROC PLAN to randomize the experimental plan.

Additional features for design of experiments are available in SAS/QC software. The FACTEX and OPTEX procedures can construct a wide variety of designs, including factorials, fractional factorials, and D-optimal

or A-optimal designs. These procedures, as well as the ADX Interface, provide features for randomizing and replicating designs; saving the design in an output data set; and interactively changing the design by changing its size, use of blocking, or the search strategies used. For more information, see the *SAS/QC User's Guide*.

References

Analysis of variance was pioneered by R. A. Fisher (1925). For a general introduction to analysis of variance, see an intermediate statistical methods textbook such as Steel and Torrie (1980), Snedecor and Cochran (1980), Milliken and Johnson (1984), Mendenhall (1968), John (1971), Ott (1977), or Kirk (1968). A classic source is Scheffé (1959). Freund, Littell, and Spector (1991) bring together a treatment of these statistical methods and SAS/STAT software procedures. Schlotzhauer and Littell (1997) cover how to perform *t* tests and one-way analysis of variance with SAS/STAT procedures. Texts on linear models include Searle (1971), Graybill (1976), and Hocking (1984). Kennedy and Gentle (1980) survey the computing aspects. Other references include the following:

Chapter 6

Introduction to Mixed Modeling Procedures

Contents

Overview: Mixed Modeling Procedures

A mixed model is a model that contains fixed and random effects. Since all statistical models contain some stochastic component and many models contain a residual error term, the preceding sentence deserves some clarification. The classical linear model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$ contains the parameters $\boldsymbol{\beta}$ and the random vector $\boldsymbol{\epsilon}$. The vector $\boldsymbol{\beta}$ is a vector of fixed-effects parameters; its elements are unknown constants to be estimated from the data. A mixed model in the narrow sense also contains random effects, which are unobservable random variables. If the vector of random effects is denoted by $\boldsymbol{\gamma}$, then a linear mixed model can be written as

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

In a broader sense, mixed modeling and mixed model software is applied to special cases and generalizations of this model. For example, a purely random effects model, $\mathbf{Y} = \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$, or a correlated-error model, $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$, is subsumed by mixed modeling methodology.

Over the last few decades virtually every form of classical statistical model has been enhanced to accommodate random effects. The linear model has been extended to the linear mixed model, generalized linear models have been extended to generalized linear mixed models, and so on. In parallel with this trend, SAS/STAT software offers a number of classical and contemporary mixed modeling tools. The aim of this chapter is to provide a brief introduction and comparison of the procedures for mixed model analysis (in the broad sense) in SAS/STAT software. The theory and application of mixed models are discussed at length in many monographs, including Milliken and Johnson (1992), Diggle, Liang, and Zeger (1994), Davidian and Giltinan (1995), Verbeke and Molenberghs (1997, 2000), Vonesh and Chinchilli (1997), Demidenko (2004), Molenberghs and Verbeke (2005), and Littell et al. (2006).

The following procedures in SAS/STAT software can perform mixed and random effects analysis to various degrees:

GLM — is primarily a tool for fitting linear models by least squares. The GLM procedure has some capabilities for including random effects in a statistical model and for performing statistical tests in mixed models. Repeated measures analysis is also possible with the GLM procedure, assuming unstructured covariance modeling. Estimation methods for covariance parameters in PROC GLM are based on the method of moments, and a portion of its output applies only to the fixed-effects model.

GLIMMIX — fits generalized linear mixed models by likelihood-based techniques. As in the MIXED procedure, covariance structures are modeled parametrically. The GLIMMIX procedure also has built-in capabilities for mixed model smoothing and joint modeling of heterocatanomic multivariate data.

HPMIXED — fits linear mixed models by sparse-matrix techniques. The HPMIXED procedure is designed to handle large mixed model problems, such as the solution of mixed model equations with thousands of fixed-effects parameters and random-effects solutions.

LATTICE — computes the analysis of variance and analysis of simple covariance for data from an experiment with a lattice design. PROC LATTICE analyzes balanced square lattices, partially balanced square lattices, and some rectangular lattices. Analyses performed with the LATTICE procedure can also be performed as mixed models for complete or incomplete block designs with the MIXED procedure.

MIXED — performs mixed model analysis and repeated measures analysis by way of structured covariance models. The MIXED procedure estimates parameters by likelihood or moment-based techniques. You can compute mixed model diagnostics and influence analysis for observations and groups of observations. The default fitting method maximizes the restricted likelihood of the data under the assumption that the data are normally distributed and any missing data are missing at random. This general framework accommodates many common correlated-data methods, including variance component models and repeated measures analyses.

NESTED — performs analysis of variance and analysis of covariance for purely nested random-effects models. Because of its customized algorithms, PROC NESTED can be useful for large data sets with nested random effects.

NLMIXED — fits mixed models in which the fixed or random effects enter nonlinearly. The NLMIXED procedure requires that you specify components of your mixed model via programming statements. Some built-in distributions enable you to easily specify the conditional distribution of the data, given the random effects.

VARCOMP — estimates variance components for random or mixed models.

The focus in the remainder of this chapter is on procedures designed for random effects and mixed model analysis: the GLIMMIX, HPMIXED, MIXED, NESTED, NLMIXED, and VARCOMP procedures. The important distinction between fixed and random effects in statistical models is addressed in the section "Fixed, Random, and Mixed Models" on page 31, in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software."

Types of Mixed Models

Linear, Generalized Linear, and Nonlinear Mixed Models

The linear model shown at the beginning of this chapter was incomplete because the distributional properties of the random variables and their relationship were not specified. In this section the specification of the models is completed and the three model classes, linear mixed models (LMM), generalized linear mixed models (GLMM), and nonlinear mixed models (NLMM), are delineated.

Linear Mixed Model

It is a defining characteristic of the class of linear mixed models (LMM), the class of generalized linear mixed models (GLMM), and the class of nonlinear mixed models (NLMM) that the random effects are normally distributed. In the linear mixed model, this also applies to the error term; furthermore, the errors and random effects are uncorrelated. The standard linear mixed model (LMM) is thus represented by the following assumptions:

$$\begin{aligned} \mathbf{Y} &= \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon} \\ \boldsymbol{\gamma} &\sim N(\mathbf{0}, \mathbf{G}) \\ \boldsymbol{\epsilon} &\sim N(\mathbf{0}, \mathbf{R}) \\ \mathrm{Cov}[\boldsymbol{\gamma}, \boldsymbol{\epsilon}] &= \mathbf{0} \end{aligned}$$

The matrices $\mathbf{G}$ and $\mathbf{R}$ are covariance matrices for the random effects and the random errors, respectively. A *G-side* random effect in a linear mixed model is an element of $\boldsymbol{\gamma}$, and its variance is expressed through an element in $\mathbf{G}$. An *R-side* random variable is an element of $\boldsymbol{\epsilon}$, and its variance is an element of $\mathbf{R}$. The GLIMMIX, HPMIXED, and MIXED procedures express the $\mathbf{G}$ and $\mathbf{R}$ matrices in parametric form—that is, you structure the covariance matrix, and its elements are expressed as functions of some parameters, known as the *covariance parameters* of the mixed models. The NLMIXED procedure also parameterizes the covariance structure, but you accomplish this with programming statements rather than with predefined syntax.

Since the right side of the model equation contains multiple random variables, the stochastic properties of $\mathbf{Y}$ can be examined by conditioning on the random effects, or through the marginal distribution. Because of the linearity of the G-side random effects and the normality of the random variables, the conditional and the

marginal distribution of the data are also normal with the following mean and variance matrices:

$$\begin{aligned}\mathbf{Y}|\boldsymbol{\gamma} &\sim N(\mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma}, \mathbf{R}) \\ \mathbf{Y} &\sim N(\mathbf{X}\boldsymbol{\beta}, \mathbf{V}) \\ \mathbf{V} &= \mathbf{Z}\mathbf{G}\mathbf{Z}' + \mathbf{R}\end{aligned}$$

Parameter estimation in linear mixed models is based on likelihood or method-of-moment techniques. The default estimation method in PROC MIXED, and the only method available in PROC HPMIXED, is restricted (residual) maximum likelihood, a form of likelihood estimation that accounts for the parameters in the fixed-effects structure of the model to reduce the bias in the covariance parameter estimates. Moment-based estimation of the covariance parameters is available in the MIXED procedure through the METHOD= option in the PROC MIXED statement. The moment-based estimators are associated with sums of squares, expected mean squares (EMS), and the solution of EMS equations.

Parameter estimation by likelihood-based techniques in linear mixed models maximizes the marginal (restricted) log likelihood of the data—that is, the log likelihood is formed from $\mathbf{Y} \sim N(\mathbf{X}\boldsymbol{\beta}, \mathbf{V})$. This is a model for $\mathbf{Y}$ with mean $\mathbf{X}\boldsymbol{\beta}$ and covariance matrix $\mathbf{V}$, a correlated-error model. Such *marginal models* arise, for example, in the analysis of time series data, repeated measures, or spatial data, and are naturally subsumed into the linear mixed model family. Furthermore, some mixed models have an equivalent formulation as a correlated-error model, when both give rise to the same marginal mean and covariance matrix. For example, a mixed model with a single variance component is identical to a correlated-error model with compound-symmetric covariance structure, provided that the common correlation is positive.

Generalized Linear Mixed Model

In a generalized linear mixed model (GLMM) the G-side random effects are part of the linear predictor, $\boldsymbol{\eta} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma}$, and the predictor is related nonlinearly to the conditional mean of the data

$$\mathrm{E}[\mathbf{Y}|\boldsymbol{\gamma}] = g^{-1}(\boldsymbol{\eta}) = g^{-1}(\mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma})$$

where $g^{-1}(\cdot)$ is the inverse link funtion. The conditional distribution of the data, given the random effects, is a member of the exponential family of distributions, such as the binary, binomial, Poisson, gamma, beta, or chi-square distribution. Because the normal distribution is also a member of the exponential family, the class of the linear mixed models is a subset of the generalized linear mixed models. In order to completely specify a GLMM, you need to do the following:

1. Formulate the linear predictor, including fixed and random effects.
2. Choose a link function.
3. Choose the distribution of the response, conditional on the random effects, from the exponential family.

As an example, suppose that s pairs of twins are randomly selected in a matched-pair design. One of the twins in each pair receives a treatment and the outcome variable is some binary measure. This is a study with s clusters (subjects) and each cluster is of size 2. If Y_{ij} denotes the binary response of twin $j = 1, 2$ in cluster i, then a linear predictor for this experiment could be

$$\eta_{ij} = \beta_0 + \tau x_{ij} + \gamma_i$$

where x_{ij} denotes a regressor variable that takes on the value 1 for the treated observation in each pair, and 0 otherwise. The γ_i are pair-specific random effects that model heterogeneity across sets of twins and that induce a correlation between the members of each pair. By virtue of random sampling the sets of twins, it is reasonable to assume that the γ_i are independent and have equal variance. This leads to a diagonal **G** matrix,

$$\text{Var}[\boldsymbol{\gamma}] = \text{Var}\begin{bmatrix} \gamma_1 \\ \gamma_2 \\ \gamma_3 \\ \vdots \\ \gamma_s \end{bmatrix} = \begin{bmatrix} \sigma^2_\gamma & 0 & 0 & \cdots & 0 \\ 0 & \sigma^2_\gamma & 0 & \cdots & 0 \\ 0 & 0 & \sigma^2_\gamma & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & \sigma^2_\gamma \end{bmatrix}$$

A common link function for binary data is the logit link, which leads in the second step of model formulation to

$$\begin{aligned} \text{E}\left[Y_{ij}|\gamma_i\right] = \mu_{ij}|\gamma_i &= \frac{1}{1+\exp\{-\eta_{ij}\}} \\ \text{logit}\left\{\frac{\mu_{ij}|\gamma_i}{1-\mu_{ij}|\gamma_i}\right\} &= \eta_{ij} \end{aligned}$$

The final step, choosing a distribution from the exponential family, is automatic in this example; only the binary distribution comes into play to model the distribution of $Y_{ij}|\gamma_i$.

As for the linear mixed model, there is a marginal model in the case of a generalized linear mixed model that results from integrating the joint distribution over the random effects. This marginal distribution is elusive for many GLMMs, and parameter estimation proceeds by either approximating the model or by approximating the marginal integral. Details of these approaches are described in the section "Generalized Linear Mixed Models Theory" on page 2943, in Chapter 40, "The GLIMMIX Procedure."

A marginal model, one that models correlation through the **R** matrix and does not involve G-side random effects, can also be formulated in the GLMM family; such models are the extension of the correlated-error models in the linear mixed model family. Because nonnormal distributions in the exponential family exhibit a functional mean-variance relationship, fully parametric estimation is not possible in such models. Instead, estimating equations are formed based on first-moment (mean) and second-moment (covariance) assumptions for the marginal data. The approaches for modeling correlated nonnormal data via generalized estimating equations (GEE) fall into this category (see, for example, Liang and Zeger 1986; Zeger and Liang 1986).

Nonlinear Mixed Model

In a nonlinear mixed model (NLMM), the fixed and/or random effects enter the conditional mean function nonlinearly. If the mean function is a general, nonlinear function, then it is customary to assume that the conditional distribution is normal, such as in modeling growth curves or pharmacokinetic response. This is not a requirement, however.

An example of a nonlinear mixed model is the following logistic growth curve model for the jth observation of the ith subject (cluster):

$$f(\boldsymbol{\beta}, \boldsymbol{\gamma}_i, x_{ij}) = \frac{\beta_1 + \gamma_{i1}}{1 + \exp[-(x_{ij} - \beta_2)/(\beta_3 + \gamma_{i2})]}$$

$$Y_{ij} = f(\boldsymbol{\beta}, \boldsymbol{\gamma}_i, x_{ij}) + \epsilon_{ij}$$

$$\begin{bmatrix} \gamma_{i1} \\ \gamma_{i2} \end{bmatrix} \sim N\left(\begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} \sigma_1^2 & \sigma_{12} \\ \sigma_{21} & \sigma_2^2 \end{bmatrix} \right)$$

$$Y_{ij} | \gamma_{i1}, \gamma_{i2} \sim N(0, \sigma_\epsilon^2)$$

The inclusion of R-side covariance structures in GLMM and NLMM models is not as straightforward as in linear mixed models for the following reasons:

- The normality of the conditional distribution in the LMM enables straightforward modeling of the covariance structure because the mean structure and covariance structure are not functionally related.
- The linearity of the random effects in the LMM leads to a marginal distribution that incorporates the **R** matrix in a natural and meaningful way.

To incorporate R-side covariance structures when random effects enter nonlinearly or when the data are not normally distributed requires estimation approaches that rely on linearizations of the mixed model. Among such estimation methods are the pseudo-likelihood methods that are available with the GLIMMIX procedure. Generalized estimating equations also solve this marginal estimation problem for nonnormal data; these are available with the GENMOD procedure.

Models for Clustered and Hierarchical Data

Mixed models are often applied in situations where data are clustered, grouped, or otherwise hierarchically organized. For example, observations might be collected by randomly selecting schools in a school district, then randomly selecting classrooms within schools, followed by selecting students within the classroom. A longitudinal study might randomly select individuals and take repeatedly measurements on them. In the first example, a school is a cluster of observations, which consists of smaller clusters (classrooms) and so on. In the longitudinal example the observations for a particular individual form a cluster. Mixed models are popular analysis tools for hierarchically organized data for the following reasons:

- The selection of groups is often performed randomly, so that the associated effects are random effects.
- The data from different clusters are independent by virtue of the random selection or by assumption.
- The observations from the same cluster are often correlated, such as the repeated observations in a repeated measures or longitudinal study.

- It is often believed that there is heterogeneity in model parameters across subjects; for example, slopes and intercepts might differ across individuals in a longitudinal growth study. This heterogeneity, if due to stochastic sources, can be modeled with random effects.

A linear mixed models with clustered, hierarchical structure can be written as a special case of the general linear mixed model by introducing appropriate subscripts. For example, a mixed model with one type of clustering and s clusters can be written as

$$\mathbf{Y}_i = \mathbf{X}_i\boldsymbol{\beta} + \mathbf{Z}_i\boldsymbol{\gamma}_i + \boldsymbol{\epsilon}_i \quad i = 1, \cdots, s$$

In SAS/STAT software, the clusters are referred to as *subjects*, and the effects that define clusters in your data can be specified with the SUBJECT= option in the GLIMMIX, HPMIXED, MIXED, and NLMIXED procedures. The vector $\mathbf{Y}_i$ collects the n_i observations for the ith subject. In certain disciplines, the organization of a hierarchical model is viewed in a *bottom-up* form, where the measured observations represent the first level, these are collected into units at the second level, and so forth. In the school data example, the bottom-up approach considers a student's score as the level-1 observation, the classroom as the level-2 unit, and the school district as the level-3 unit (if these were also selected from a population of districts).

The following points are noteworthy about mixed models with SUBJECT= specification:

- A SUBJECT= option is available in the RANDOM statements of the GLIMMIX, HPMIXED, MIXED, and NLMIXED procedures and in the REPEATED statement of the MIXED and HPMIXED procedures.
- A SUBJECT= specification is required in the NLMIXED and HPMIXED procedures. It is not required with any other mixed modeling procedure in SAS/STAT software.
- Specifying models with subjects is usually more computationally efficient in the MIXED and GLIMMIX procedures, especially if the SUBJECT= effects are identical or contained within each other. The computational efficiency of the HPMIXED procedure is not dependent on SUBJECT= effects in the manner in which the MIXED and GLIMMIX procedures are affected.
- There is no limit to the number of SUBJECT= effects with the MIXED, HPMIXED, and GLIMMIX procedures—that is, you can achieve an arbitrary depth of the nesting.

Models with Subjects and Groups

The concept of a subject as a unit of clustering observations in a mixed model has been described in the preceding section. This concept is important for mixed modeling with the GLIMMIX, HPMIXED, MIXED, and NLMIXED procedures. Observations from two subjects are considered uncorrelated in the analysis. Observations from the same subject are potentially correlated, depending on your specification of the covariance structure. Random effects at the subject level always lead to correlation in the marginal distribution of the observations that belong to the subject.

The GLIMMIX, HPMIXED, and MIXED procedures also support the notion of a GROUP= effect in the specification of the covariance structure. Like a subject effect, a G-side group effect identifies independent

random effects. In addition to a subject effect, the group effect assumes that the realizations of the random effects correspond to draws from different distributions; in other words, each level of the group effect is associated with a different set of covariance parameters. For example, the following statements in any of these procedures fit a random coefficient model with fixed intercept and slope and subject-specific random intercept and slope:

```
class id;
model y = x;
random intercept x / subject=id;
```

The interpretation of the RANDOM statement is that for each ID an independent draw is made from a bivariate normal distribution with zero mean and a diagonal covariance matrix. In the following statements (in any of these procedures) these independent draws come from different bivariate normal distributions depending on the value of the grp variable.

```
class id grp;
model y = x;
random intercept x / subject=id group=grp;
```

Adding GROUP= effects in your model increases the flexibility to model heterogeneity in the covariance parameters, but it can add numerical complexity to the estimation process.

Linear Mixed Models

You can fit linear mixed models in SAS/STAT software with the GLM, GLIMMIX, HPMIXED, LATTICE, MIXED, NESTED, and VARCOMP procedures.

The procedure specifically designed for statistical estimation in linear mixed models is the MIXED procedure. To fit the linear mixed model

$$\begin{aligned} \mathbf{Y} &= \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon} \\ \boldsymbol{\gamma} &\sim N(\mathbf{0}, \mathbf{G}) \\ \boldsymbol{\epsilon} &\sim N(\mathbf{0}, \mathbf{R}) \\ \text{Cov}[\boldsymbol{\gamma}, \boldsymbol{\epsilon}] &= \mathbf{0} \end{aligned}$$

with the MIXED procedure, you specify the fixed-effects design matrix $\mathbf{X}$ in the MODEL statement, the random-effects design matrix $\mathbf{Z}$ in the RANDOM statement, the covariance matrix of the random effects $\mathbf{G}$ with options (SUBJECT=, GROUP=, TYPE=) in the RANDOM statement, and the $\mathbf{R}$ matrix in the REPEATED statement.

By default, covariance parameters are estimated by restricted (residual) maximum likelihood. In supported models, the METHOD=TYPE1, METHOD=TYPE2, and METHOD=TYPE3 options lead to method-of-moment-based estimators and analysis of variance. The MIXED procedure provides an extensive list of diagnostics for mixed models, from various residual graphics to observationwise and groupwise influence diagnostics.

The NESTED procdedure performs an analysis of variance in nested random effects models. The VARCOMP procedure can be used to estimate variance components associated with random effects in random

and mixed models. The LATTICE procedure computes analysis of variance for balanced and partially balanced square lattices. You can fit the random and mixed models supported by these procedures with the MIXED procedure as well. Some specific analyses, such as the analysis of Gauge R & R studies in the VARCOMP procedure (Burdick, Borror, and Montgomery 2005), are unique to the specialized procedures.

The GLIMMIX procedure can fit most of the models that you can fit with the MIXED procedure, but it does not offer method-of-moment-based estimation and analysis of variance in the narrow sense. Also, PROC GLIMMIX does not support the same array of covariance structures as the MIXED procedure and does not support a sampling-based Bayesian analysis. An in-depth comparison of the GLIMMIX and MIXED procedures can be found in the section "Comparing the GLIMMIX and MIXED Procedures" on page 2992, in Chapter 40, "The GLIMMIX Procedure."

Comparing the MIXED and GLM Procedures

Random- and mixed-effects models can also be fitted with the GLM procedure, but the philosophy is different from that of PROC MIXED and other dedicated mixed modeling procedures. The following lists important differences between the GLM and MIXED procedures in fitting random and mixed models:

- The default estimation method for covariance parameters in the MIXED procedure is restricted maximum likelihood. Covariance parameters are estimated by the method of moments by solving expressions for expected mean squares.
- In the GLM procedure, fixed and random effects are listed in the MODEL statement. Only fixed effects are listed in the MODEL statement of the MIXED procedure. In the GLM procedure, random effects must be repeated in the RANDOM statement.
- You can request tests for model effects by adding the TEST option in the RANDOM statement of the GLM procedure. PROC GLM then constructs exact tests for random effects if possible and constructs approximate tests if exact tests are not possible. For details on how the GLM procedure constructs tests for random effects, see the section "Computation of Expected Mean Squares for Random Effects" on page 3262, in Chapter 41, "The GLM Procedure." Tests for fixed effects are constructed by the MIXED procedure as Wald-type F tests, and the degrees of freedom for these tests can be determined by a variety of methods.
- Some of the output of the GLM procedure applies only to the fixed effects part of the model, whether a RANDOM statement is specified or not.
- Variance components are independent in the GLM procedure and covariance matrices are generally unstructured. The default covariance structure for variance components in the MIXED procedure is also a variance component structure, but the procedure offers a large number of parametric structures to model covariation among random effects and observations.

Comparing the MIXED and HPMIXED Procedures

The HPMIXED procedure is designed to solve large mixed model problems by using sparse matrix techniques. The largeness of a mixed model can take many forms: a large number of observations, large number of columns in the $\mathbf{X}$ matrix, a large number of random effects, or a large number of covariance parameters. The province of the HPMIXED procedure is parameter estimation, inference, and prediction in mixed models with large $\mathbf{X}$ and/or $\mathbf{Z}$ matrices, many observations, but relatively few covariance parameters.

The models that you can fit with the HPMIXED procedure are a subset of the models available with the MIXED procedure. The HPMIXED procedure supports only a limited number of types of covariance structure in the RANDOM and REPEATED statements in order to balance performance and generality.

To some extent, the generality of the MIXED procedure precludes it from serving as a high-performance computing tool for all the model-data scenarios that the procedure can potentially estimate parameters for. For example, although efficient sparse algorithms are available to estimate variance components in large mixed models, the computational configuration changes profoundly when, for example, standard error adjustments and degrees of freedom by the Kenward-Roger method are requested.

Generalized Linear Mixed Models

Generalized linear mixed models can be fit with the GLIMMIX and NLMIXED procedures in SAS/STAT software. The GLIMMIX procedure is specifically designed to fit this class of models and offers syntax very similar to the syntax of other linear modeling procedures, such as the MIXED procedure. Consider a generalized linear model with linear predictor and link function

$$\mathrm{E}[\mathbf{Y}|\boldsymbol{\gamma}] = g^{-1}(\boldsymbol{\eta}) = g^{-1}(\mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma})$$

and distribution in the exponential family. The fixed-effects design matrix $\mathbf{X}$ is specified in the MODEL statement of the GLIMMIX procedure, and the random-effects design matrix $\mathbf{Z}$ is specified in the RANDOM statement, along with the covariance matrix of the random effects and the covariance matrix of R-side random variables. The link function and (conditional) distribution are determined by defaults or through options in the MODEL statement.

The GLIMMIX procedure can fit heterocatanomic multivariate data—that is, data that stem from different distributions. For example, one measurement taken on a patient might be a continuous, normally distributed outcome, whereas another measurement might be a binary indicator of medical history. The GLIMMIX procedure also provides capabilities for mixed model smoothing and mixed model splines.

The GLIMMIX procedure offers an extensive array of postprocessing features to produce output statistics and to perform linear inference. The ESTIMATE and LSMESTIMATE statements support multiplicity-adjusted p-values for the protection of the familywise Type-I error rate. The LSMEANS statement supports the slicing of interactions, simple effect differences, and ODS statistical graphs for group comparisons.

The default estimation technique in the GLIMMIX procedure depends on the class of models fit. For linear mixed models, the default technique is restricted maximum likelihood, as in the MIXED procedure. For

generalized linear mixed models, the estimation is based on linearization methods (pseudo-likelihood) or on integral approximation by adaptive quadrature or Laplace methods.

The NLMIXED procedure facilitates the fitting of generalized linear mixed models through several built-in distributions from the exponential family (binary, binomial, gamma, negative binomial, and Poisson). You have to code the linear predictor and link function with SAS programming statements and assign starting values to all parameters, including the covariance parameters. Although you are not required to specify starting values with the NLMIXED procedure (because the procedure assigns a default value of 1.0 to every parameter not explictly given a starting value), it is highly recommended that you specify good starting values. The default estimation technique of the NLMIXED procedure, an adaptive Gauss-Hermite quadrature, is also available in the GLIMMIX procedure through the METHOD=QUAD option in the PROC GLIMMIX statement. The Laplace approximation that is available in the NLMIXED procedure by setting QPOINTS=1 is available in the GLIMMIX procedure through the METHOD=LAPLACE option.

Comparing the GENMOD and GLIMMIX Procedures

The GENMOD and GLIMMIX procedures can fit generalized linear models and estimate the parameters by maximum likelihood. For multinomial data, the GENMOD procedure fits cumulative link models for ordinal data. The GLIMMIX procedure fits these models and generalized logit models for nominal data.

When data are correlated, you can use the REPEATED statement in the GENMOD procedure to fit marginal models via generalized estimating equations. A working covariance structure is assumed, and the standard errors of the parameter estimates are computed according to an empirical ("sandwich") estimator that is robust to the misspecification of the covariance structure. Marginal generalized linear models for correlated data can also be fit with the GLIMMIX procedure by specifying the random effects as R-side effects. The empirical covariance estimators are available through the EMPIRICAL= option in the PROC GLIMMIX statement. The essential difference between the estimation approaches taken by the GLIMMIX procedure and generalized estimating equations is that the latter approach estimates the covariance parameters by the method of moments, whereas the GLIMMIX procedure uses likelihood-based techniques.

The GENMOD procedure supports nonsingular parameterizations of classification variables through its CLASS statement. The GLIMMIX procedure supports only the standard, GLM-type singular parameterization of CLASS variables. For the differences between these parameterizations, see the section "Parameterization of Model Effects" on page 397, in Chapter 19, "Shared Concepts and Topics."

Nonlinear Mixed Models: The NLMIXED Procedure

PROC NLMIXED handles models in which the fixed or random effects enter nonlinearly. It requires that you specify a conditional distribution of the data given the random effects, with available distributions including the normal, binomial, and Poisson. You can alternatively code your own distribution with SAS programming statements. Under a normality assumption for the random effects, PROC NLMIXED performs maximum likelihood estimation via adaptive Gaussian quadrature and a dual quasi-Newton optimization algorithm. Besides standard maximum likelihood results, you can obtain empirical Bayes predictions of the random

effects and estimates of arbitrary functions of the parameters with delta-method standard errors. PROC NLMIXED has a wide variety of applications; two of the most common applications are nonlinear growth curves and overdispersed binomial data.

Chapter 7

Introduction to Bayesian Analysis Procedures

Contents

Overview

SAS/STAT software provides Bayesian capabilities in four procedures: GENMOD, LIFEREG, MCMC, and PHREG. The GENMOD, LIFEREG, and PHREG procedures provide Bayesian analysis in addition to the standard frequentist analyses they have always performed. Thus, these procedures provide convenient access to Bayesian modeling and inference for generalized linear models, accelerated life failure models, Cox regression models, and piecewise constant baseline hazard models (also known as piecewise exponential models). The MCMC procedure is a general procedure that fits Bayesian models with arbitrary priors and likelihood functions.

This chapter provides an overview of Bayesian statistics; describes specific sampling algorithms used in these four procedures; and discusses posterior inference and convergence diagnostics computations. Sources that provide in-depth treatment of Bayesian statistics can be found at the end of this chapter, in the section "A Bayesian Reading List" on page 161. Additional chapters contain syntax, details, and examples for the individual procedures GENMOD (see Chapter 39, "The GENMOD Procedure"), LIFEREG (see Chapter 50, "The LIFEREG Procedure"), MCMC (see Chapter 54, "The MCMC Procedure"), and PHREG (see Chapter 66, "The PHREG Procedure").

Introduction

The most frequently used statistical methods are known as *frequentist* (or *classical*) methods. These methods assume that unknown parameters are fixed constants, and they define probability by using limiting relative frequencies. It follows from these assumptions that probabilities are objective and that you cannot make probabilistic statements about parameters because they are fixed. Bayesian methods offer an alternative approach; they treat parameters as random variables and define probability as "degrees of belief" (that is, the probability of an event is the degree to which you believe the event is true). It follows from these postulates that probabilities are subjective and that you can make probability statements about parameters. The term "Bayesian" comes from the prevalent usage of Bayes' theorem, which was named after the Reverend Thomas Bayes, an eighteenth century Presbyterian minister. Bayes was interested in solving the question of inverse probability: after observing a collection of events, what is the probability of one event?

Suppose you are interested in estimating θ from data $\mathbf{y} = \{y_1, \ldots, y_n\}$ by using a statistical model described by a density $p(\mathbf{y}|\theta)$. Bayesian philosophy states that θ cannot be determined exactly, and uncertainty about the parameter is expressed through probability statements and distributions. You can say that θ follows a normal distribution with mean 0 and variance 1, if it is believed that this distribution best describes the uncertainty associated with the parameter. The following steps describe the essential elements of Bayesian inference:

1. A probability distribution for θ is formulated as $\pi(\theta)$, which is known as the *prior* distribution, or just the prior. The prior distribution expresses your beliefs (for example, on the mean, the spread, the skewness, and so forth) about the parameter before you examine the data.
2. Given the observed data $\mathbf{y}$, you choose a statistical model $p(\mathbf{y}|\theta)$ to describe the distribution of $\mathbf{y}$ given θ.
3. You update your beliefs about θ by combining information from the prior distribution and the data through the calculation of the *posterior* distribution, $p(\theta|\mathbf{y})$.

The third step is carried out by using Bayes' theorem, which enables you to combine the prior distribution and the model in the following way:

$$p(\theta|\mathbf{y}) = \frac{p(\theta, \mathbf{y})}{p(\mathbf{y})} = \frac{p(\mathbf{y}|\theta)\pi(\theta)}{p(\mathbf{y})} = \frac{p(\mathbf{y}|\theta)\pi(\theta)}{\int p(\mathbf{y}|\theta)\pi(\theta)d\theta}$$

The quantity

$$p(\mathbf{y}) = \int p(\mathbf{y}|\theta)\pi(\theta)d\theta$$

is the normalizing constant of the posterior distribution. This quantity $p(\mathbf{y})$ is also the marginal distribution of $\mathbf{y}$, and it is sometimes called the marginal distribution of the data. The likelihood function of θ is any function proportional to $p(\mathbf{y}|\theta)$; that is, $L(\theta) \propto p(\mathbf{y}|\theta)$. Another way of writing Bayes' theorem is as follows:

$$p(\theta|\mathbf{y}) = \frac{L(\theta)\pi(\theta)}{\int L(\theta)\pi(\theta)d\theta}$$

The marginal distribution $p(\mathbf{y})$ is an integral. As long as the integral is finite, the particular value of the integral does not provide any additional information about the posterior distribution. Hence, $p(\theta|\mathbf{y})$ can be written up to an arbitrary constant, presented here in proportional form as:

$$p(\theta|\mathbf{y}) \propto L(\theta)\pi(\theta)$$

Simply put, Bayes' theorem tells you how to update existing knowledge with new information. You begin with a prior belief $\pi(\theta)$, and after learning information from data $\mathbf{y}$, you change or update your belief about θ and obtain $p(\theta|\mathbf{y})$. These are the essential elements of the Bayesian approach to data analysis.

In theory, Bayesian methods offer simple alternatives to statistical inference—all inferences follow from the posterior distribution $p(\theta|\mathbf{y})$. In practice, however, you can obtain the posterior distribution with straightforward analytical solutions only in the most rudimentary problems. Most Bayesian analyses require sophisticated computations, including the use of simulation methods. You generate samples from the posterior distribution and use these samples to estimate the quantities of interest. PROC MCMC uses a self-tuning Metropolis algorithm (see the section "Metropolis and Metropolis-Hastings Algorithms" on page 141). The GENMOD, LIFEREG, and PHREG procedures use the Gibbs sampler (see the section "Gibbs Sampler" on page 142). An important aspect of any analysis is assessing the convergence of the Markov chains. Inferences based on nonconverged Markov chains can be both inaccurate and misleading.

Both Bayesian and classical methods have their advantages and disadvantages. From a practical point of view, your choice of method depends on what you want to accomplish with your data analysis. If you have prior information (either expert opinion or historical knowledge) that you want to incorporate into the analysis, then you should consider Bayesian methods. In addition, if you want to communicate your findings in terms of probability notions that can be more easily understood by nonstatisticians, Bayesian methods might be appropriate. The Bayesian paradigm can often provide a framework for answering specific scientific questions that a single point estimate cannot sufficiently address. Alternatively, if you are interested only in estimating parameters based on the likelihood, then numerical optimization methods, such as the Newton-Raphson method, can give you very precise estimates and there is no need to use a Bayesian analysis. For further discussions of the relative advantages and disadvantages of Bayesian analysis, see the section "Bayesian Analysis: Advantages and Disadvantages" on page 138.

Background in Bayesian Statistics

Prior Distributions

A prior distribution of a parameter is the probability distribution that represents your uncertainty about the parameter before the current data are examined. Multiplying the prior distribution and the likelihood function together leads to the posterior distribution of the parameter. You use the posterior distribution to carry out all inferences. You cannot carry out any Bayesian inference or perform any modeling without using a prior distribution.

Objective Priors versus Subjective Priors

Bayesian probability measures the degree of belief that you have in a random event. By this definition, probability is highly subjective. It follows that all priors are *subjective priors*. Not everyone agrees with this notion of subjectivity when it comes to specifying prior distributions. There has long been a desire to obtain results that are objectively valid. Within the Bayesian paradigm, this can be somewhat achieved by using prior distributions that are "objective" (that is, that have a minimal impact on the posterior distribution). Such distributions are called *objective* or *noninformative* priors (see the next section). However, while noninformative priors are very popular in some applications, they are not always easy to construct. See DeGroot and Schervish (2002, Section 1.2) and Press (2003, Section 2.2) for more information about interpretations of probability. See Berger (2006) and Goldstein (2006) for discussions about objective Bayesian versus subjective Bayesian analysis.

Noninformative Priors

Roughly speaking, a prior distribution is noninformative if the prior is "flat" relative to the likelihood function. Thus, a prior $\pi(\theta)$ is noninformative if it has minimal impact on the posterior distribution of θ. Other names for the noninformative prior are *vague*, *diffuse*, and *flat* prior. Many statisticians favor noninformative priors because they appear to be more objective. However, it is unrealistic to expect that noninformative priors represent total ignorance about the parameter of interest. In some cases, noninformative priors can lead to *improper posteriors* (nonintegrable posterior density). You cannot make inferences with improper posterior distributions. In addition, noninformative priors are often not invariant under transformation; that is, a prior might be noninformative in one parameterization but not necessarily noninformative if a transformation is applied.

See Box and Tiao (1973) for a more formal development of noninformative priors. See Kass and Wasserman (1996) for techniques for deriving noninformative priors.

Improper Priors

A prior $\pi(\theta)$ is said to be improper if

$$\int \pi(\theta) d\theta = \infty$$

For example, a uniform prior distribution on the real line, $\pi(\theta) \propto 1$, for $-\infty < \theta < \infty$, is an improper prior. Improper priors are often used in Bayesian inference since they usually yield noninformative priors and proper posterior distributions. Improper prior distributions can lead to posterior impropriety (improper posterior distribution). To determine whether a posterior distribution is proper, you need to make sure that the normalizing constant $\int p(\mathbf{y}|\theta)p(\theta)d\theta$ is finite for all $\mathbf{y}$. If an improper prior distribution leads to an improper posterior distribution, inference based on the improper posterior distribution is invalid.

The GENMOD, LIFEREG, and PHREG procedures allow the use of improper priors—that is, the flat prior on the real line—for regression coefficients. These improper priors do not lead to any improper posterior distributions in the models that these procedures fit. PROC MCMC allows the use of any prior, as long as the distribution is programmable using DATA step functions. However, the procedure does not verify whether the posterior distribution is integrable. You must ensure this yourself.

Informative Priors

An informative prior is a prior that is not dominated by the likelihood and that has an impact on the posterior distribution. If a prior distribution dominates the likelihood, it is clearly an informative prior. These types of distributions must be specified with care in actual practice. On the other hand, the proper use of prior distributions illustrates the power of the Bayesian method: information gathered from the previous study, past experience, or expert opinion can be combined with current information in a natural way. See the "Examples" sections of the GENMOD and PHREG procedure chapters for instructions about constructing informative prior distributions.

Conjugate Priors

A prior is said to be a conjugate prior for a family of distributions if the prior and posterior distributions are from the same family, which means that the form of the posterior has the same distributional form as the prior distribution. For example, if the likelihood is binomial, $y \sim \text{Bin}(n, \theta)$, a conjugate prior on θ is the beta distribution; it follows that the posterior distribution of θ is also a beta distribution. Other commonly used conjugate prior/likelihood combinations include the normal/normal, gamma/Poisson, gamma/gamma, and gamma/beta cases. The development of conjugate priors was partially driven by a desire for computational convenience—conjugacy provides a practical way to obtain the posterior distributions. The Bayesian procedures do not use conjugacy in posterior sampling.

Jeffreys' Prior

A very useful prior is Jeffreys' prior (Jeffreys 1961). It satisfies the local uniformity property: a prior that does not change much over the region in which the likelihood is significant and does not assume large values outside that range. It is based on the Fisher information matrix. Jeffreys' prior is defined as

$$\pi(\theta) \propto |I(\theta)|^{1/2}$$

where | | denotes the determinant and $I(\theta)$ is the Fisher information matrix based on the likelihood function $p(\mathbf{y}|\theta)$:

$$I(\theta) = -E\left[\frac{\partial^2 \log p(\mathbf{y}|\theta)}{\partial \theta^2}\right]$$

Jeffreys' prior is locally uniform and hence noninformative. It provides an automated scheme for finding a noninformative prior for any parametric model $p(\mathbf{y}|\theta)$. Another appealing property of Jeffreys' prior is that it is invariant with respect to one-to-one transformations. The invariance property means that if you have a locally uniform prior on θ and $\phi(\theta)$ is a one-to-one function of θ, then $p(\phi(\theta)) = \pi(\theta) \cdot |\phi'(\theta)|^{-1}$ is a locally uniform prior for $\phi(\theta)$. This invariance principle carries through to multidimensional parameters as well. While Jeffreys' prior provides a general recipe for obtaining noninformative priors, it has some shortcomings: the prior is improper for many models, and it can lead to improper posterior in some cases; and the prior can be cumbersome to use in high dimensions. PROC GENMOD calculates Jeffreys' prior automatically for any generalized linear model. You can set it as your prior density for the coefficient parameters, and it does not lead to improper posteriors. You can construct Jeffreys' prior for a variety of statistical models in the MCMC procedure. See the section "Example 54.4: Logistic Regression Model with Jeffreys' Prior" on page 4408 for an example. PROC MCMC does not guarantee that the corresponding posterior distribution is proper, and you need to exercise extra caution in this case.

Bayesian Inference

Bayesian inference about θ is primarily based on the posterior distribution of θ. There are various ways in which you can summarize this distribution. For example, you can report your findings through point estimates. You can also use the posterior distribution to construct hypothesis tests or probability statements.

Point Estimation and Estimation Error

Classical methods often report the maximum likelihood estimator (MLE) or the method of moments estimator (MOME) of a parameter. In contrast, Bayesian approaches often use the posterior mean. The definition of the posterior mean is given by

$$E(\theta|\mathbf{y}) = \int \theta \; p(\theta|\mathbf{y}) \, d\theta$$

Other commonly used posterior estimators include the posterior median, defined as

$$\theta\colon P(\theta \geq \text{median}|\mathbf{y}) = P(\text{median} \leq \theta|\mathbf{y}) = \frac{1}{2}$$

and the posterior mode, defined as the value of θ that maximizes $p(\theta|\mathbf{y})$.

The variance of the posterior density (simply referred to as the *posterior variance*) describes the uncertainty in the parameter, which is a random variable in the Bayesian paradigm. A Bayesian analysis typically uses the posterior variance, or the posterior standard deviation, to characterize the dispersion of the parameter. In multidimensional models, covariance or correlation matrices are used.

If you know the distributional form of the posterior density of interest, you can report the exact posterior point estimates. When models become too difficult to analyze analytically, you have to use simulation algorithms, such as the Markov chain Monte Carlo (MCMC) method to obtain posterior estimates (see the section "Markov Chain Monte Carlo Method" on page 139). All of the Bayesian procedures rely on MCMC to obtain all posterior estimates. Using only a finite number of samples, simulations introduce an additional level of uncertainty to the accuracy of the estimates. *Monte Carlo standard error (MCSE)*, which is the standard error of the posterior mean estimate, measures the simulation accuracy. See the section "Standard Error of the Mean Estimate" on page 159 for more information.

The posterior standard deviation and the MCSE are two completely different concepts: the posterior standard deviation describes the uncertainty in the parameter, while the MCSE describes only the uncertainty in the parameter estimate as a result of MCMC simulation. The posterior standard deviation is a function of the sample size in the data set, and the MCSE is a function of the number of iterations in the simulation.

Hypothesis Testing

Suppose you have the following null and alternative hypotheses: H_0 is $\theta \in \Theta_0$ and H_1 is $\theta \in \Theta_0^c$, where Θ_0 is a subset of the parameter space and Θ_0^c is its complement. Using the posterior distribution $\pi(\theta|\mathbf{y})$, you can compute the posterior probabilities $P(\theta \in \Theta_0|\mathbf{y})$ and $P(\theta \in \Theta_0^c|\mathbf{y})$, or the probabilities that H_0 and H_1 are true, respectively. One way to perform a Bayesian hypothesis test is to accept the null hypothesis if $P(\theta \in \Theta_0|\mathbf{y}) \geq P(\theta \in \Theta_0^c|\mathbf{y})$ and vice versa, or to accept the null hypothesis if $P(\theta \in \Theta_0|\mathbf{y})$ is greater than a predefined threshold, such as 0.75, to guard against falsely accepted null distribution.

It is more difficult to carry out a point null hypothesis test in a Bayesian analysis. A point null hypothesis is a test of $H_0\colon \theta = \theta_0$ versus $H_1\colon \theta \neq \theta_0$. If the prior distribution $\pi(\theta)$ is a continuous density, then the posterior probability of the null hypothesis being true is 0, and there is no point in carrying out the test. One alternative is to restate the null to be a small interval hypothesis: $\theta \in \Theta_0 = (\theta_0 - a, \theta_0 + a)$, where a is a very small constant. The Bayesian paradigm can deal with an interval hypothesis more easily. Another approach is to give a mixture prior distribution to θ with a positive probability of p_0 on θ_0 and the density $(1 - p_0)\pi(\theta)$ on $\theta \neq \theta_0$. This prior ensures a nonzero posterior probability on θ_0, and you can then make realistic probabilistic comparisons. For more detailed treatment of Bayesian hypothesis testing, see Berger (1985).

Interval Estimation

The Bayesian set estimates are called *credible sets*, which is also known as *credible intervals*. This is analogous to the concept of confidence intervals used in classical statistics. Given a posterior distribution $p(\theta|\mathbf{y})$, A is a credible set for θ if

$$P(\theta \in A|\mathbf{y}) = \int_A p(\theta|\mathbf{y})d\theta$$

For example, you can construct a 95% credible set for θ by finding an interval, A, over which $\int_A p(\theta|\mathbf{y}) = 0.95$.

You can construct credible sets that have equal tails. A $100(1-\alpha)\%$ equal-tail interval corresponds to the $100(\alpha/2)$th and $100(1-\alpha/2)$th percentiles of the posterior distribution. Some statisticians prefer this interval because it is invariant under transformations. Another frequently used Bayesian credible set is called the *highest posterior density* (HPD) interval.

A $100(1-\alpha)\%$ HPD interval is a region that satisfies the following two conditions:

1. The posterior probability of that region is $100(1-\alpha)\%$.
2. The minimum density of any point within that region is equal to or larger than the density of any point outside that region.

The HPD is an interval in which most of the distribution lies. Some statisticians prefer this interval because it is the smallest interval.

One major distinction between Bayesian and classical sets is their interpretation. The Bayesian probability reflects a person's subjective beliefs. Following this approach, a statistician can make the claim that θ is inside a credible interval with measurable probability. This property is appealing because it enables you to make a direct probability statement about parameters. Many people find this concept to be a more natural way of understanding a probability interval, which is also easier to explain to nonstatisticians. A confidence interval, on the other hand, enables you to make a claim that the interval covers the true parameter. The interpretation reflects the uncertainty in the sampling procedure; a confidence interval of $100(1-\alpha)\%$ asserts that, in the long run, $100(1-\alpha)\%$ of the realized confidence intervals cover the true parameter.

Bayesian Analysis: Advantages and Disadvantages

Bayesian methods and classical methods both have advantages and disadvantages, and there are some similarities. When the sample size is large, Bayesian inference often provides results for parametric models that are very similar to the results produced by frequentist methods. Some advantages to using Bayesian analysis include the following:

- It provides a natural and principled way of combining prior information with data, within a solid decision theoretical framework. You can incorporate past information about a parameter and form a

prior distribution for future analysis. When new observations become available, the previous posterior distribution can be used as a prior. All inferences logically follow from Bayes' theorem.

- It provides inferences that are conditional on the data and are exact, without reliance on asymptotic approximation. Small sample inference proceeds in the same manner as if one had a large sample. Bayesian analysis also can estimate any functions of parameters directly, without using the "plug-in" method (a way to estimate functionals by plugging the estimated parameters in the functionals).
- It obeys the likelihood principle. If two distinct sampling designs yield proportional likelihood functions for θ, then all inferences about θ should be identical from these two designs. Classical inference does not in general obey the likelihood principle.
- It provides interpretable answers, such as "the true parameter θ has a probability of 0.95 of falling in a 95% credible interval."
- It provides a convenient setting for a wide range of models, such as hierarchical models and missing data problems. MCMC, along with other numerical methods, makes computations tractable for virtually all parametric models.

There are also disadvantages to using Bayesian analysis:

- It does not tell you how to select a prior. There is no correct way to choose a prior. Bayesian inferences require skills to translate subjective prior beliefs into a mathematically formulated prior. If you do not proceed with caution, you can generate misleading results.
- It can produce posterior distributions that are heavily influenced by the priors. From a practical point of view, it might sometimes be difficult to convince subject matter experts who do not agree with the validity of the chosen prior.
- It often comes with a high computational cost, especially in models with a large number of parameters. In addition, simulations provide slightly different answers unless the same random seed is used. Note that slight variations in simulation results do not contradict the early claim that Bayesian inferences are exact. The posterior distribution of a parameter is exact, given the likelihood function and the priors, while simulation-based estimates of posterior quantities can vary due to the random number generator used in the procedures.

For more in-depth treatments of the pros and cons of Bayesian analysis, see Berger (1985, Sections 4.1 and 4.12), Berger and Wolpert (1988), Bernardo and Smith (1994, with a new edition coming out), Carlin and Louis (2000, Section 1.4), Robert (2001, Chapter 11), and Wasserman (2004, Section 11.9).

The following sections provide detailed information about the Bayesian methods provided in SAS.

Markov Chain Monte Carlo Method

The Markov chain Monte Carlo (MCMC) method is a general simulation method for sampling from posterior distributions and computing posterior quantities of interest. MCMC methods sample successively from

a target distribution. Each sample depends on the previous one, hence the notion of the Markov chain. A Markov chain is a sequence of random variables, $\theta^1, \theta^2, \cdots$, for which the random variable θ^t depends on all previous θs only through its immediate predecessor θ^{t-1}. You can think of a Markov chain applied to sampling as a mechanism that traverses randomly through a target distribution without having any memory of where it has been. Where it moves next is entirely dependent on where it is now.

Monte Carlo, as in Monte Carlo integration, is mainly used to approximate an expectation by using the Markov chain samples. In the simplest version

$$\int_S g(\theta)p(\theta)d\theta \cong \frac{1}{n}\sum_{t=1}^{n} g(\theta^t)$$

where $g(\cdot)$ is a function of interest and θ^t are samples from $p(\theta)$ on its support S. This approximates the expected value of $g(\theta)$. The earliest reference to MCMC simulation occurs in the physics literature. Metropolis and Ulam (1949) and Metropolis et al. (1953) describe what is known as the Metropolis algorithm (see the section "Metropolis and Metropolis-Hastings Algorithms" on page 141). The algorithm can be used to generate sequences of samples from the joint distribution of multiple variables, and it is the foundation of MCMC. Hastings (1970) generalized their work, resulting in the Metropolis-Hastings algorithm.

Geman and Geman (1984) analyzed image data by using what is now called Gibbs sampling (see the section "Gibbs Sampler" on page 142). These MCMC methods first appeared in the mainstream statistical literature in Tanner and Wong (1987).

The Markov chain method has been quite successful in modern Bayesian computing. Only in the simplest Bayesian models can you recognize the analytical forms of the posterior distributions and summarize inferences directly. In moderately complex models, posterior densities are too difficult to work with directly. With the MCMC method, it is possible to generate samples from an arbitrary posterior density $p(\theta|\mathbf{y})$ and to use these samples to approximate expectations of quantities of interest. Several other aspects of the Markov chain method also contributed to its success. Most importantly, if the simulation algorithm is implemented correctly, the Markov chain is guaranteed to converge to the target distribution $p(\theta|\mathbf{y})$ under rather broad conditions, regardless of where the chain was initialized. In other words, a Markov chain is able to improve its approximation to the true distribution at each step in the simulation. Furthermore, if the chain is run for a very long time (often required), you can recover $p(\theta|\mathbf{y})$ to any precision. Also, the simulation algorithm is easily extensible to models with a large number of parameters or high complexity, although the "curse of dimensionality" often causes problems in practice.

Properties of Markov chains are discussed in Feller (1968), Breiman (1968), and Meyn and Tweedie (1993). Ross (1997) and Karlin and Taylor (1975) give a non-measure-theoretic treatment of stochastic processes, including Markov chains. For conditions that govern Markov chain convergence and rates of convergence, see Amit (1991), Applegate, Kannan, and Polson (1990), Chan (1993), Geman and Geman (1984), Liu, Wong, and Kong (1991a, b), Rosenthal (1991a, b), Tierney (1994), and Schervish and Carlin (1992). Besag (1974) describes conditions under which a set of conditional distributions gives a unique joint distribution. Tanner (1993), Gilks, Richardson, and Spiegelhalter (1996), Chen, Shao, and Ibrahim (2000), Liu (2001), Gelman et al. (2004), Robert and Casella (2004), and Congdon (2001, 2003, 2005) provide both theoretical and applied treatments of MCMC methods. You can also see the section "A Bayesian Reading List" on page 161 for a list of books with varying levels of difficulty of treatment of the subject and its application to Bayesian statistics.

Metropolis and Metropolis-Hastings Algorithms

The Metropolis algorithm is named after its inventor, the American physicist and computer scientist Nicholas C. Metropolis. The algorithm is simple but practical, and it can be used to obtain random samples from any arbitrarily complicated target distribution of any dimension that is known up to a normalizing constant.

Suppose you want to obtain T samples from a univariate distribution with probability density function $f(\theta|\mathbf{y})$. Suppose θ^t is the tth sample from f. To use the Metropolis algorithm, you need to have an initial value θ^0 and a symmetric *proposal* density $q(\theta^{t+1}|\theta^t)$. For the $(t+1)$th iteration, the algorithm generates a sample from $q(\cdot|\cdot)$ based on the current sample θ^t, and it makes a decision to either accept or reject the new sample. If the new sample is accepted, the algorithm repeats itself by starting at the new sample. If the new sample is rejected, the algorithm starts at the current point and repeats. The algorithm is self-repeating, so it can be carried out as long as required. In practice, you have to decide the total number of samples needed in advance and stop the sampler after that many iterations have been completed.

Suppose $q(\theta_{\text{new}}|\theta^t)$ is a symmetric distribution. The proposal distribution should be an easy distribution from which to sample, and it must be such that $q(\theta_{\text{new}}|\theta^t) = q(\theta^t|\theta_{\text{new}})$, meaning that the likelihood of jumping to θ_{new} from θ^t is the same as the likelihood of jumping back to θ^t from θ_{new}. The most common choice of the proposal distribution is the normal distribution $N(\theta^t, \sigma)$ with a fixed σ. The Metropolis algorithm can be summarized as follows:

1. Set $t = 0$. Choose a starting point θ^0. This can be an arbitrary point as long as $f(\theta^0|\mathbf{y}) > 0$.
2. Generate a new sample, θ_{new}, by using the proposal distribution $q(\cdot|\theta^t)$.
3. Calculate the following quantity:

$$r = \min\left\{\frac{f(\theta_{\text{new}}|\mathbf{y})}{f(\theta^t|\mathbf{y})}, 1\right\}$$

4. Sample u from the uniform distribution $U(0,1)$.
5. Set $\theta^{t+1} = \theta_{\text{new}}$ if $u < r$; otherwise set $\theta^{t+1} = \theta^t$.
6. Set $t = t + 1$. If $t < T$, the number of desired samples, return to step 2. Otherwise, stop.

Note that the number of iteration keeps increasing regardless of whether a proposed sample is accepted.

This algorithm defines a chain of random variates whose distribution will converge to the desired distribution $f(\theta|\mathbf{y})$, and so from some point forward, the chain of samples is a sample from the distribution of interest. In Markov chain terminology, this distribution is called the *stationary distribution* of the chain, and in Bayesian statistics, it is the posterior distribution of the model parameters. The reason that the Metropolis algorithm works is beyond the scope of this documentation, but you can find more detailed descriptions and proofs in many standard textbooks, including Roberts (1996) and Liu (2001). The random-walk Metropolis algorithm is used in the MCMC procedure.

You are not limited to a symmetric random-walk proposal distribution in establishing a valid sampling algorithm. A more general form, the Metropolis-Hastings (MH) algorithm, was proposed by Hastings (1970).

The MH algorithm uses an asymmetric proposal distribution: $q(\theta_{\text{new}}|\theta^t) \neq q(\theta^t|\theta_{\text{new}})$. The difference in its implementation comes in calculating the ratio of densities:

$$r = \min\left\{\frac{f(\theta_{\text{new}}|\mathbf{y})q(\theta^t|\theta_{\text{new}})}{f(\theta^t|\mathbf{y})q(\theta_{\text{new}}|\theta^t)}, 1\right\}$$

Other steps remain the same.

The extension of the Metropolis algorithm to a higher-dimensional $\boldsymbol{\theta}$ is straightforward. Suppose $\boldsymbol{\theta} = (\theta_1, \theta_2, \cdots, \theta_k)'$ is the parameter vector. To start the Metropolis algorithm, select an initial value for each θ_k and use a multivariate version of proposal distribution $q(\cdot|\cdot)$, such as a multivariate normal distribution, to select a k-dimensional new parameter. Other steps remain the same as those previously described, and this Markov chain eventually converges to the target distribution of $f(\boldsymbol{\theta}|\mathbf{y})$. Chib and Greenberg (1995) provide a useful tutorial on the algorithm.

Gibbs Sampler

The Gibbs sampler, named by Geman and Geman (1984) after the American physicist Josiah W. Gibbs, is a special case of the "Metropolis and Metropolis-Hastings Algorithms" on page 141 in which the proposal distributions exactly match the posterior conditional distributions and proposals are accepted 100% of the time. Gibbs sampling requires you to decompose the joint posterior distribution into full conditional distributions for each parameter in the model and then sample from them. The sampler can be efficient when the parameters are not highly dependent on each other and the full conditional distributions are easy to sample from. Some researchers favor this algorithm because it does not require an instrumental proposal distribution as Metropolis methods do. However, while deriving the conditional distributions can be relatively easy, it is not always possible to find an efficient way to sample from these conditional distributions.

Suppose $\boldsymbol{\theta} = (\theta_1, \ldots, \theta_k)'$ is the parameter vector, $p(\mathbf{y}|\boldsymbol{\theta})$ is the likelihood, and $\pi(\boldsymbol{\theta})$ is the prior distribution. The full posterior conditional distribution of $\pi(\theta_i|\theta_j, i \neq j, \mathbf{y})$ is proportional to the joint posterior density; that is,

$$\pi(\theta_i|\theta_j, i \neq j, \mathbf{y}) \propto p(\mathbf{y}|\boldsymbol{\theta})\pi(\boldsymbol{\theta})$$

For instance, the one-dimensional conditional distribution of θ_1 given $\theta_j = \theta_j^*, 2 \leq j \leq k$, is computed as the following:

$$\pi(\theta_1|\theta_j = \theta_j^*, 2 \leq j \leq k, \mathbf{y}) = p(\mathbf{y}|(\boldsymbol{\theta} = (\theta_1, \theta_2^*, \ldots, \theta_k^*)')\pi(\boldsymbol{\theta} = (\theta_1, \theta_2^*, \ldots, \theta_k^*)')$$

The Gibbs sampler works as follows:

1. Set $t = 0$, and choose an arbitrary initial value of $\boldsymbol{\theta}^{(0)} = \{\theta_1^{(0)}, \ldots, \theta_k^{(0)}\}$.
2. Generate each component of $\boldsymbol{\theta}$ as follows:

- draw $\theta_1^{(t+1)}$ from $\pi(\theta_1|\theta_2^{(t)}, \ldots, \theta_k^{(t)}, \mathbf{y})$
- draw $\theta_2^{(t+1)}$ from $\pi(\theta_2|\theta_1^{(t+1)}, \theta_3^{(t)}, \ldots, \theta_k^{(t)}, \mathbf{y})$
- ...
- draw $\theta_k^{(t+1)}$ from $\pi(\theta_k|\theta_1^{(t+1)}, \ldots, \theta_{k-1}^{(t+1)}, \mathbf{y})$

3. Set $t = t + 1$. If $t < T$, the number of desired samples, return to step 2. Otherwise, stop.

The name "Gibbs" was introduced by Geman and Geman (1984). Gelfand et al. (1990) first used Gibbs sampling to solve problems in Bayesian inference. See Casella and George (1992) for a tutorial on the sampler. The GENMOD, LIFEREG, and PHREG procedures update parameters using the Gibbs sampler.

Adaptive Rejection Sampling Algorithm

The GENMOD, LIFEREG, and PHREG procedures use the adaptive rejection sampling (ARS) algorithm to sample parameters sequentially from their univariate full conditional distributions. The ARS algorithm is a rejection algorithm that was originally proposed by Gilks and Wild (1992). Given a log-concave density (the log of the density is concave), you can construct an envelope to the density by using linear segments. You then use the linear segment envelope as a proposal density (it becomes a piecewise exponential density on the original scale and is easy to generate samplers from) in the rejection sampling. The log-concavity condition is met in some of the models fit by the procedures. For example, the posterior densities for the regression parameters in the generalized linear models are log-concave under flat priors. When this condition fails, the ARS algorithm calls for an additional Metropolis-Hastings step (Gilks, Best, and Tan 1995), and the modified algorithm becomes the adaptive rejection metropolis sampling (ARMS) algorithm. The GENMOD, LIFEREG, and PHREG procedures can recognize whether a model is log-concave and select the appropriate sampler for the problem at hand.

The GENMOD, LIFEREG, and PHREG procedures implement the ARMS algorithm based on code kindly provided by Walter R. Gilks, University of Leeds (Gilks 2003), to obtain posterior samples. For a detailed description and explanation of the algorithm, see Gilks and Wild (1992) and Gilks, Best, and Tan (1995).

Independence Sampler

Another type of Metropolis algorithm is the "independence" sampler. It is called the independence sampler because the proposal distribution in the algorithm does not depend on the current point as it does with the random-walk Metropolis algorithm. For this sampler to work well, you want to have a proposal distribution that mimics the target distribution and have the acceptance rate be as high as possible.

1. Set $t = 0$. Choose a starting point θ^0. This can be an arbitrary point as long as $f(\theta^0|\mathbf{y}) > 0$.
2. Generate a new sample, θ_{new}, by using the proposal distribution $q(\cdot)$. The proposal distribution does not depend on the current value of θ^t.
3. Calculate the following quantity:

$$r = \min\left\{\frac{f(\theta_{\text{new}}|\mathbf{y})/q(\theta_{\text{new}})}{f(\theta^t|\mathbf{y})/q(\theta^t)}, 1\right\}$$

4. Sample u from the uniform distribution $U(0, 1)$.
5. Set $\theta^{t+1} = \theta_{\text{new}}$ if $u < r$; otherwise set $\theta^{t+1} = \theta^t$.
6. Set $t = t + 1$. If $t < T$, the number of desired samples, return to step 2. Otherwise, stop.

A good proposal density should have thicker tails than those of the target distribution. This requirement sometimes can be difficult to satisfy especially in cases where you do not know what the target posterior distributions are like. In addition, this sampler does not produce independent samples as the name seems to imply, and sample chains from independence samplers can get stuck in the tails of the posterior distribution if the proposal distribution is not chosen carefully. The MCMC procedure uses the independence sampler.

Gamerman Algorithm

The Gamerman algorithm, named after the inventor Dani Gamerman is a special case of the "Metropolis and Metropolis-Hastings Algorithms" on page 141 in which the proposal distribution is derived from one iteration of the iterative weighted least squares (IWLS) algorithm. As the name suggests, a weighted least squares algorithm is carried out inside an iteration loop. For each iteration, a set of weights for the observations is used in the least squares fit. The weights are constructed by applying a weight function to the current residuals. The proposal distribution uses the current iteration's values of the parameters to form the proposal distribution from which to generate a proposed random value (Gamerman 1997).

The multivariate sampling algorithm is simple but practical, and can be used to obtain random samples from the posterior distribution of the regression parameters in a generalized linear model (GLM). See "Generalized Linear Regression" on page 81 for further details on generalized linear regression models. See McCullagh and Nelder (1989) for a discussion of transformed observations and diagonal matrix of weights pertaining to IWLS.

The GENMOD procedure uses the Gamerman algorithm to sample parameters from their multivariate posterior conditional distributions. For a detailed description and explanation of the algorithm, see Gamerman (1997).

Burn-in, Thinning, and Markov Chain Samples

Burn-in refers to the practice of discarding an initial portion of a Markov chain sample so that the effect of initial values on the posterior inference is minimized. For example, suppose the target distribution is $N(0, 1)$ and the Markov chain was started at the value 10^6. The chain might quickly travel to regions around 0 in a few iterations. However, including samples around the value 10^6 in the posterior mean calculation can produce substantial bias in the mean estimate. In theory, if the Markov chain is run for an infinite amount of time, the effect of the initial values decreases to zero. In practice, you do not have the luxury of infinite samples. In practice, you assume that after t iterations, the chain has reached its target distribution and you can throw away the early portion and use the good samples for posterior inference. The value of t is the burn-in number.

With some models you might experience poor mixing (or slow convergence) of the Markov chain. This can happen, for example, when parameters are highly correlated with each other. Poor mixing means that the Markov chain slowly traverses the parameter space (see the section "Visual Analysis via Trace Plots"

on page 145 for examples of poorly mixed chains) and the chain has high dependence. High sample autocorrelation can result in biased Monte Carlo standard errors. A common strategy is to *thin* the Markov chain in order to reduce sample autocorrelations. You thin a chain by keeping every kth simulated draw from each sequence. You can safely use a thinned Markov chain for posterior inference as long as the chain converges. It is important to note that thinning a Markov chain can be wasteful because you are throwing away a $\frac{k-1}{k}$ fraction of all the posterior samples generated. MacEachern and Berliner (1994) show that you always get more precise posterior estimates if the entire Markov chain is used. However, other factors, such as computer storage or plotting time, might prevent you from keeping all samples.

To use the GENMOD, LIFEREG, MCMC, and PHREG procedures, you need to determine the total number of samples to keep ahead of time. This number is not obvious and often depends on the type of inference you want to make. Mean estimates do not require nearly as many samples as small-tail percentile estimates. In most applications, you might find that keeping a few thousand iterations is sufficient for reasonably accurate posterior inference. In all four procedures, the relationship between the number of iterations requested, the number of iterations kept, and the amount of thinning is as follows:

$$\text{kept} = \left[\frac{\text{requested}}{\text{thinning}} \right]$$

where [ ] is the rounding operator.

Assessing Markov Chain Convergence

Simulation-based Bayesian inference requires using simulated draws to summarize the posterior distribution or calculate any relevant quantities of interest. You need to treat the simulation draws with care. There are usually two issues. First, you have to decide whether the Markov chain has reached its stationary, or the desired posterior, distribution. Second, you have to determine the number of iterations to keep after the Markov chain has reached stationarity. Convergence diagnostics help to resolve these issues. Note that many diagnostic tools are designed to verify a necessary but not sufficient condition for convergence. There are no conclusive tests that can tell you when the Markov chain has converged to its stationary distribution. You should proceed with caution. Also, note that you should check the convergence of *all* parameters, and not just those of interest, before proceeding to make any inference. With some models, certain parameters can appear to have very good convergence behavior, but that could be misleading due to the slow convergence of other parameters. If some of the parameters have bad mixing, you cannot get accurate posterior inference for parameters that appear to have good mixing. See Cowles and Carlin (1996) and Brooks and Roberts (1998) for discussions about convergence diagnostics.

Visual Analysis via Trace Plots

Trace plots of samples versus the simulation index can be very useful in assessing convergence. The trace tells you if the chain has not yet converged to its stationary distribution—that is, if it needs a longer burn-in period. A trace can also tell you whether the chain is mixing well. A chain might have reached stationarity if the distribution of points is not changing as the chain progresses. The aspects of stationarity that are most

recognizable from a trace plot are a relatively constant mean and variance. A chain that mixes well traverses its posterior space rapidly, and it can jump from one remote region of the posterior to another in relatively few steps. Figure 7.1 through Figure 7.4 display some typical features that you might see in trace plots. The traces are for a parameter called γ.

Figure 7.1 Essentially Perfect Trace for γ

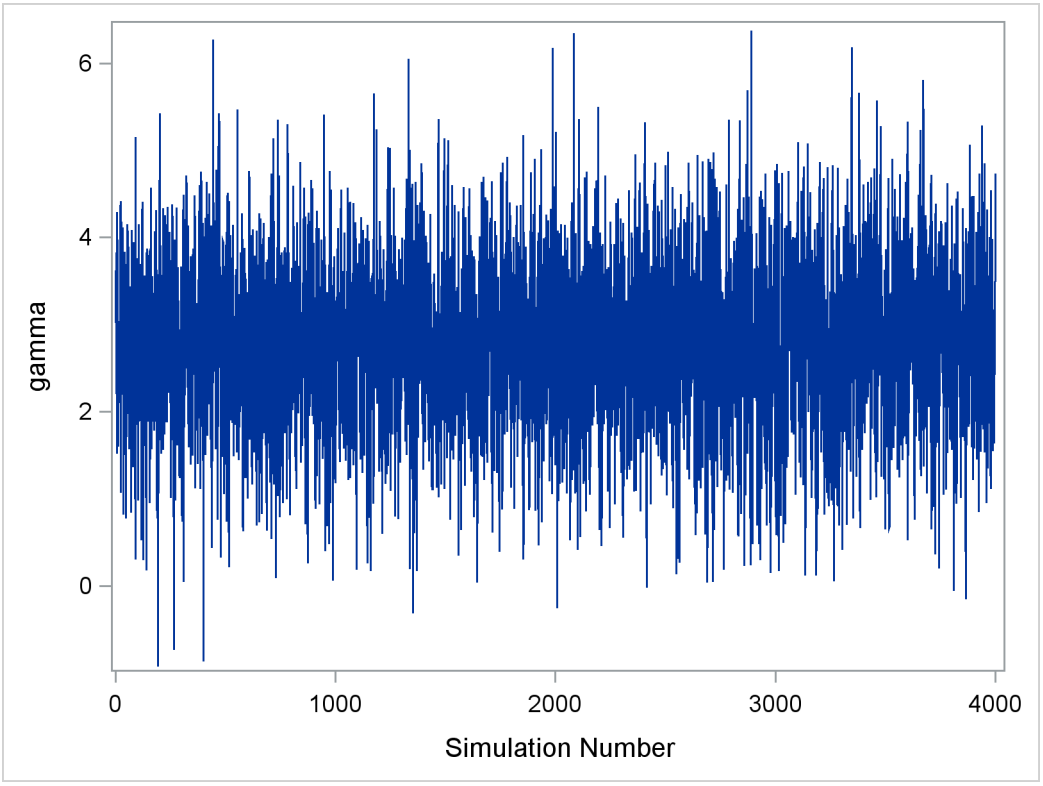

Figure 7.1 displays a "perfect" trace plot. Note that the center of the chain appears to be around the value 3, with very small fluctuations. This indicates that the chain could have reached the right distribution. The chain is mixing well; it is exploring the distribution by traversing to areas where its density is very low. You can conclude that the mixing is quite good here.

Figure 7.2 Nonconvergence of γ

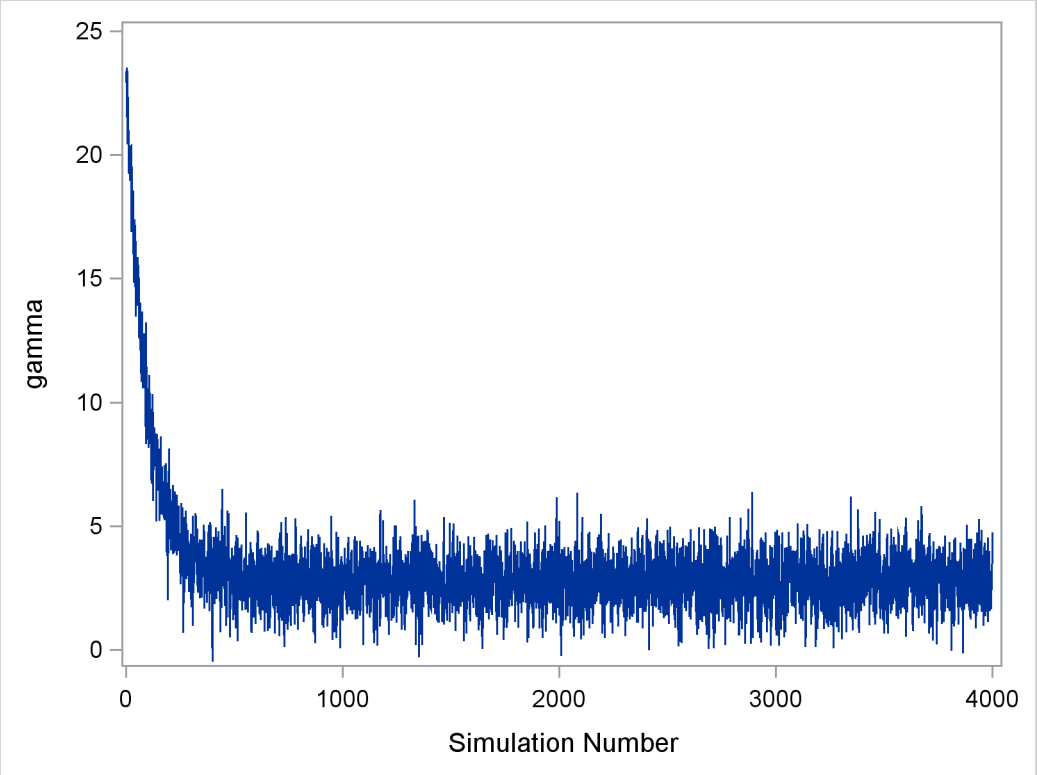

Figure 7.2 displays a trace plot for a chain that starts at a very remote initial value and makes its way to the targeting distribution. The first few hundred observations should be discarded. This chain appears to be mixing very well locally. It travels relatively quickly to the target distribution, reaching it in a few hundred iterations. If you have a chain that looks like this, you would want to increase the burn-in sample size. If you need to use this sample to make inferences, you would want to use only the samples toward the end of the chain.

Figure 7.3 Marginal Mixing for γ

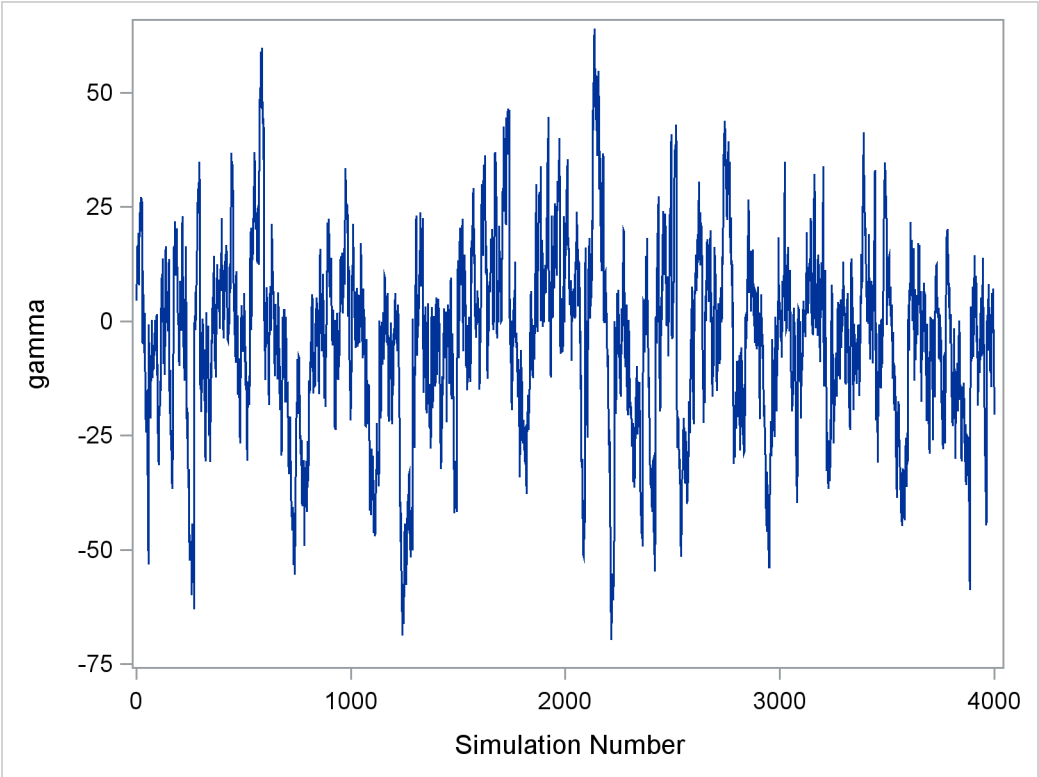

Figure 7.3 demonstrates marginal mixing. The chain is taking only small steps and does not traverse its distribution quickly. This type of trace plot is typically associated with high autocorrelation among the samples. To obtain a few thousand independent samples, you need to run the chain for much longer.

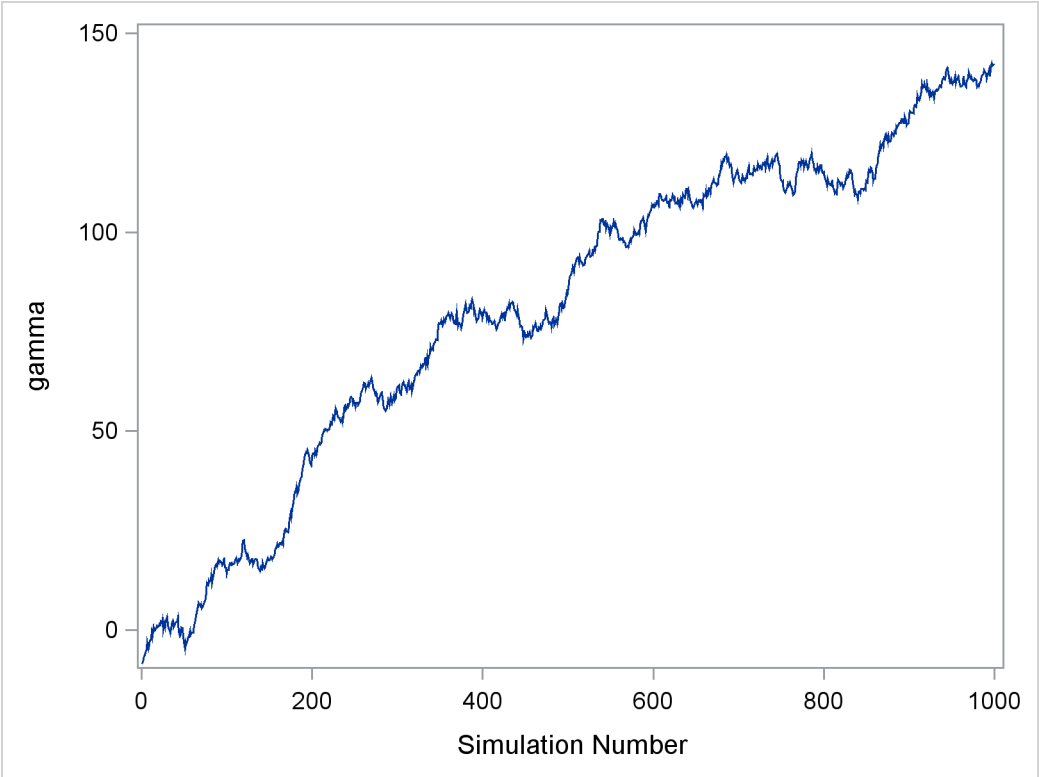
Figure 7.4 Bad Mixing, Nonconvergence of γ



The trace plot shown in Figure 7.4 depicts a chain with serious problems. It is mixing very slowly, and it offers no evidence of convergence. You would want to try to improve the mixing of this chain. For example, you might consider reparameterizing your model on the log scale. Run the Markov chain for a long time to see where it goes. This type of chain is entirely unsuitable for making parameter inferences.

Statistical Diagnostic Tests

The Bayesian procedures include several statistical diagnostic tests that can help you assess Markov chain convergence. For a detailed description of each of the diagnostic tests, see the following subsections. Table 7.1 provides a summary of the diagnostic tests and their interpretations.

Table 7.1 Convergence Diagnostic Tests Available in the Bayesian Procedures

Name	Description	Interpretation of the Test
Gelman-Rubin	Uses parallel chains with dispersed initial values to test whether they all converge to the same target distribution. Failure could indicate the presence of a multi-mode posterior distribution (different chains converge to different local modes) or the need to run a longer chain (burn-in is yet to be completed).	One-sided test based on a variance ratio test statistic. Large $\widehat{R}_c$ values indicate rejection.

Table 7.1 (continued)

Name	Description	Interpretation of the test
Geweke	Tests whether the mean estimates have converged by comparing means from the early and latter part of the Markov chain.	Two-sided test based on a z-score statistic. Large absolute z values indicate rejection.
Heidelberger-Welch (stationarity test)	Tests whether the Markov chain is a covariance (or weakly) stationary process. Failure could indicate that a longer Markov chain is needed.	One-sided test based on a Cramer–von Mises statistic. Small p-values indicate rejection.
Heidelberger-Welch (half-width test)	Reports whether the sample size is adequate to meet the required accuracy for the mean estimate. Failure could indicate that a longer Markov chain is needed.	If a relative half-width statistic is greater than a predetermined accuracy measure, this indicates rejection.
Raftery-Lewis	Evaluates the accuracy of the estimated (desired) percentiles by reporting the number of samples needed to reach the desired accuracy of the percentiles. Failure could indicate that a longer Markov chain is needed.	If the total samples needed are fewer than the Markov chain sample, this indicates rejection.
autocorrelation	Measures dependency among Markov chain samples.	High correlations between long lags indicate poor mixing.
effective sample size	Relates to autocorrelation; measures mixing of the Markov chain.	Large discrepancy between the effective sample size and the simulation sample size indicates poor mixing.

Gelman and Rubin Diagnostics

Gelman and Rubin diagnostics (Gelman and Rubin 1992; Brooks and Gelman 1997) are based on analyzing multiple simulated MCMC chains by comparing the variances within each chain and the variance between chains. Large deviation between these two variances indicates nonconvergence.

Define $\{\theta^t\}$, where $t = 1, \ldots, n$, to be the collection of a single Markov chain output. The parameter θ^t is the tth sample of the Markov chain. For notational simplicity, θ is assumed to be single dimensional in this section.

Suppose you have M parallel MCMC chains that were initialized from various parts of the target distribution. Each chain is of length n (after discarding the burn-in). For each θ^t, the simulations are labeled as θ^t_m, where $t = 1, \ldots, n$ and $m = 1, \ldots, M$. The between-chain variance B and the within-chain variance W are calculated as

$$
\begin{aligned}
B &= \frac{n}{M-1}\sum_{m=1}^{M}(\bar{\theta}_{m}^{\cdot}-\bar{\theta}_{\cdot}^{\cdot})^2, \quad \text{where } \bar{\theta}_{m}^{\cdot}=\frac{1}{n}\sum_{t=1}^{n}\theta_{m}^{t}, \quad \bar{\theta}_{\cdot}^{\cdot}=\frac{1}{M}\sum_{m=1}^{M}\bar{\theta}_{m}^{\cdot} \\
W &= \frac{1}{M}\sum_{m=1}^{M}s_{m}^{2}, \quad \text{where } s_{m}^{2}=\frac{1}{n-1}\sum_{t=1}^{n}(\theta_{m}^{t}-\bar{\theta}_{m}^{\cdot})^2
\end{aligned}
$$

The posterior marginal variance, $\text{var}(\theta|\mathbf{y})$, is a weighted average of W and B. The estimate of the variance is

$$
\widehat{V}=\frac{n-1}{n}W+\frac{M+1}{nM}B
$$

If all M chains have reached the target distribution, this posterior variance estimate should be very close to the within-chain variance W. Therefore, you would expect to see the ratio $\widehat{V}/W$ be close to 1. The square root of this ratio is referred to as the *potential scale reduction factor* (PSRF). A large PSRF indicates that the between-chain variance is substantially greater than the within-chain variance, so that longer simulation is needed. If the PSRF is close to 1, you can conclude that each of the M chains has stabilized, and they are likely to have reached the target distribution.

A refined version of PSRF is calculated, as suggested by Brooks and Gelman (1997), as

$$
\widehat{\mathrm{R}}_{c}=\sqrt{\frac{\hat{d}+3}{\hat{d}+1}\cdot\frac{\widehat{V}}{W}}=\sqrt{\frac{\hat{d}+3}{\hat{d}+1}\left(\frac{n-1}{n}+\frac{M+1}{nM}\frac{B}{W}\right)}
$$

where

$$
\hat{d}=\frac{2\widehat{V}^2}{\widehat{\text{Var}}(\widehat{V})}
$$

and

$$
\begin{aligned}
\widehat{\text{Var}}(\widehat{V}) &= \left(\frac{n-1}{n}\right)^2\frac{1}{M}\widehat{\text{Var}}(s_{m}^{2})+\left(\frac{M+1}{nM}\right)^2\frac{2}{M-1}B^2 \\
&\quad +2\frac{(M+1)(n-1)}{n^2M}\frac{n}{M}\left(\widehat{\text{cov}}(s_{m}^{2},(\bar{\theta}_{m}^{\cdot})^2)-2\bar{\theta}_{\cdot}^{\cdot}\widehat{\text{cov}}(s_{m}^{2},\bar{\theta}_{m}^{\cdot})\right)
\end{aligned}
$$

All the Bayesian procedures also produce an upper $100(1-\alpha/2)\%$ confidence limit of $\widehat{\mathrm{R}}_{c}$. Gelman and Rubin (1992) showed that the ratio B/W in $\widehat{\mathrm{R}}_{c}$ has an F distribution with degrees of freedom $M-1$

and $2W^2 M/\widehat{\text{Var}}(s_m^2)$. Because you are concerned only if the scale is large, not small, only the upper $100(1-\alpha/2)\%$ confidence limit is reported. This is written as

$$\sqrt{\left(\frac{n-1}{n}+\frac{M+1}{nM}\cdot F_{1-\alpha/2}\left(M-1,\frac{2W^2}{\widehat{\text{Var}}(s_m^2)/M}\right)\right)\cdot\frac{\hat{d}+3}{\hat{d}+1}}$$

In the Bayesian procedures, you can specify the number of chains that you want to run. Typically three chains are sufficient. The first chain is used for posterior inference, such as mean and standard deviation; the other $M-1$ chains are used for computing the diagnostics and are discarded afterward. This test can be computationally costly, because it prolongs the simulation M-fold.

It is best to choose different initial values for all M chains. The initial values should be as dispersed from each other as possible so that the Markov chains can fully explore different parts of the distribution before they converge to the target. Similar initial values can be risky because all of the chains can get stuck in a local maximum; that is something this convergence test cannot detect. If you do not supply initial values for all the different chains, the procedures generate them for you.

Geweke Diagnostics

The Geweke test (Geweke 1992) compares values in the early part of the Markov chain to those in the latter part of the chain in order to detect failure of convergence. The statistic is constructed as follows. Two subsequences of the Markov chain $\{\theta^t\}$ are taken out, with $\{\theta_1^t : t = 1,\ldots,n_1\}$ and $\{\theta_2^t : t = n_a,\ldots,n\}$, where $1 < n_1 < n_a < n$. Let $n_2 = n - n_a + 1$, and define

$$\bar{\theta}_1 = \frac{1}{n_1}\sum_{t=1}^{n_1}\theta^t \quad \text{and} \quad \bar{\theta}_2 = \frac{1}{n_2}\sum_{t=n_a}^{n}\theta^t$$

Let $\hat{s}_1(0)$ and $\hat{s}_2(0)$ denote consistent spectral density estimates at zero frequency (see the subsection "Spectral Density Estimate at Zero Frequency" on page 153 for estimation details) for the two MCMC chains, respectively. If the ratios n_1/n and n_2/n are fixed, $(n_1+n_2)/n < 1$, and the chain is stationary, then the following statistic converges to a standard normal distribution as $n \to \infty$:

$$Z_n = \frac{\bar{\theta}_1 - \bar{\theta}_2}{\sqrt{\frac{\hat{s}_1(0)}{n_1}+\frac{\hat{s}_2(0)}{n_2}}}$$

This is a two-sided test, and large absolute z-scores indicate rejection.

Spectral Density Estimate at Zero Frequency

For one sequence of the Markov chain $\{\theta_t\}$, the relationship between the h-lag covariance sequence of a time series and the spectral density, f, is

$$s_h = \frac{1}{2\pi}\int_{-\pi}^{\pi} \exp(\mathrm{i}\omega h) f(\omega) d\omega$$

where i indicates that ωh is the complex argument. Inverting this Fourier integral,

$$f(\omega) = \sum_{h=-\infty}^{\infty} s_h \exp(-\mathrm{i}\omega h) = s_0 \left(1 + 2\sum_{h=1}^{\infty} \rho_h \cos(\omega h)\right)$$

It follows that

$$f(0) = \sigma^2 \left(1 + 2\sum_{h=1}^{\infty} \rho_h\right)$$

which gives an autocorrelation adjusted estimate of the variance. In this equation, σ^2 is the naive variance estimate of the sequence $\{\theta_t\}$ and ρ_h is the lag h autocorrelation. Due to obvious computational difficulties, such as calculation of autocorrelation at infinity, you cannot effectively estimate $f(0)$ by using the preceding formula. The usual route is to first obtain the *periodogram* $p(\omega)$ of the sequence, and then estimate $f(0)$ by smoothing the estimated periodogram. The periodogram is defined to be

$$p(\omega) = \frac{1}{n}\left[\left(\sum_{t=1}^{n} \theta_t \sin(\omega t)\right)^2 + \left(\sum_{t=1}^{n} \theta_t \cos(\omega t)\right)^2\right]$$

The procedures use the following way to estimate $\hat{f}(0)$ from p (Heidelberger and Welch 1981). In $p(\omega)$, let $\omega = \omega_k = 2\pi k/n$ and $k = 1, \ldots, [\frac{n}{2}]$.[1] A smooth spectral density in the domain of $(0, \pi]$ is obtained by fitting a gamma model with the log link function, using $p(\omega_k)$ as response and $x_1(\omega_k) = \sqrt{3}(4\omega_k/(2\pi) - 1)$ as the only regressor. The predicted value $\hat{f}(0)$ is given by

$$\hat{f}(0) = \exp(\hat{\beta}_0 - \sqrt{3}\hat{\beta}_1)$$

where $\hat{\beta}_0$ and $\hat{\beta}_1$ are the estimates of the intercept and slope parameters, respectively.

[1] This is equivalent to the fast Fourier transformation of the original time series θ_t.

Heidelberger and Welch Diagnostics

The Heidelberger and Welch test (Heidelberger and Welch 1981, 1983) consists of two parts: a stationary portion test and a half-width test. The stationarity test assesses the stationarity of a Markov chain by testing the hypothesis that the chain comes from a covariance stationary process. The half-width test checks whether the Markov chain sample size is adequate to estimate the mean values accurately.

Given $\{\theta^t\}$, set $S_0 = 0$, $S_n = \sum_{t=1}^{n} \theta^t$, and $\bar{\theta} = (1/n) \sum_{t=1}^{n} \theta^t$. You can construct the following sequence with s coordinates on values from $\frac{1}{n}, \frac{2}{n}, \cdots, 1$:

$$B_n(s) = (S_{[ns]} - [ns]\bar{\theta})/(n\,\hat{p}(0))^{1/2}$$

where [ ] is the rounding operator, and $\hat{p}(0)$ is an estimate of the spectral density at zero frequency that uses the second half of the sequence (see the section "Spectral Density Estimate at Zero Frequency" on page 153 for estimation details). For large n, B_n converges in distribution to a Brownian bridge (Billingsley 1986). So you can construct a test statistic by using B_n. The statistic used in these procedures is the Cramer–von Mises statistic[2]; that is $\int_0^1 B_n(s)^2 ds = CVM(B_n)$. As $n \to \infty$, the statistic converges in distribution to a standard Cramer–von Mises distribution. The integral $\int_0^1 B_n(s)^2 ds$ is numerically approximated using Simpson's rule.

Let $y_i = B_n(s)^2$, where $s = 0, \frac{1}{n}, \cdots, \frac{n-1}{n}, 1$, and $i = ns = 0, 1, \cdots, n$. If n is even, let $m = n/2$; otherwise, let $m = (n-1)/2$. The Simpson's approximation to the integral is

$$\int_0^1 B_n(s)^2 ds \approx \frac{1}{3n}\left[y_0 + 4(y_1 + \cdots + y_{2m-1}) + 2(y_2 + \cdots + y_{2m-2}) + y_{2m}\right]$$

Note that Simpson's rule requires an even number of intervals. When n is odd, y_n is set to be 0 and the value does not contribute to the approximation.

This test can be performed repeatedly on the same chain, and it helps you identify a time t when the chain has reached stationarity. The whole chain, $\{\theta^t\}$, is first used to construct the Cramer–von Mises statistic. If it passes the test, you can conclude that the entire chain is stationary. If it fails the test, you drop the initial 10% of the chain and redo the test by using the remaining 90%. This process is repeated until either a time t is selected or it reaches a point where there are not enough data remaining to construct a confidence interval (the cutoff proportion is set to be 50%).

The part of the chain that is deemed stationary is put through a half-width test, which reports whether the sample size is adequate to meet certain accuracy requirements for the mean estimates. Running the simulation less than this length of time would not meet the requirement, while running it longer would not provide any additional information that is needed. The statistic calculated here is the *relative half-width* (RHW) of the confidence interval. The RHW for a confidence interval of level $1-\alpha$ is

$$\text{RHW} = \frac{z_{(1-\alpha/2)} \cdot (\hat{s}_n/n)^{1/2}}{\hat{\theta}}$$

[2] The von Mises distribution was first introduced by von Mises (1918). The density function is $p(\theta|\mu\kappa) \sim M(\mu,\kappa) = [2\pi I_0(\kappa)]^{-1} \exp(\kappa\cos(\theta-\mu))$ $(0 \le \theta \le 2\pi)$, where the function $I_0(\kappa)$ is the modified Bessel function of the first kind and order zero, defined by $I_0(\kappa) = (2\pi)^{-1} \int_0^{2\pi} \exp(\kappa\cos(\theta-\mu))d\theta$.

where $z_{(1-\alpha/2)}$ is the z-score of the $100(1-\alpha/2)$th percentile (for example, $z_{(1-\alpha/2)} = 1.96$ if $\alpha = 0.05$), $\hat{s}_n$ is the variance of the chain estimated using the spectral density method (see explanation in the section "Spectral Density Estimate at Zero Frequency" on page 153), n is the length, and $\hat{\theta}$ is the estimated mean. The RHW quantifies accuracy of the $1-\alpha$ level confidence interval of the mean estimate by measuring the ratio between the sample standard error of the mean and the mean itself. In other words, you can stop the Markov chain if the variability of the mean stabilizes with respect to the mean. An implicit assumption is that large means are often accompanied by large variances. If this assumption is not met, then this test can produce false rejections (such as a small mean around 0 and large standard deviation) or false acceptance (such as a very large mean with relative small variance). As with any other convergence diagnostics, you might want to exercise caution in interpreting the results.

The stationarity test is one-sided; rejection occurs when the p-value is greater than $1-\alpha$. To perform the half-width test, you need to select an α level (the default of which is 0.05) and a predetermined tolerance value ϵ (the default of which is 0.1). If the calculated RHW is greater than ϵ, you conclude that there are not enough data to accurately estimate the mean with $1-\alpha$ confidence under tolerance of ϵ.

Raftery and Lewis Diagnostics

If your interest lies in posterior percentiles, you want a diagnostic test that evaluates the accuracy of the estimated percentiles. The Raftery-Lewis test (Raftery and Lewis 1992, 1996) is designed for this purpose. Notation and deductions here closely resemble those in Raftery and Lewis (1996).

Suppose you are interested in a quantity θ_q such that $P(\theta \leq \theta_q|\mathbf{y}) = q$, where q can be an arbitrary cumulative probability, such as 0.025. This θ_q can be empirically estimated by finding the $[n \cdot 100 \cdot q]$th number of the sorted $\{\theta^t\}$. Let $\hat{\theta}_q$ denote the estimand, which corresponds to an estimated probability $P(\theta \leq \hat{\theta}_q) = \hat{P}_q$. Because the simulated posterior distribution converges to the true distribution as the simulation sample size grows, $\hat{\theta}_q$ can achieve any degree of accuracy if the simulator is run for a very long time. However, running too long a simulation can be wasteful. Alternatively, you can use coverage probability to measure accuracy and stop the chain when a certain accuracy is reached.

A stopping criterion is reached when the estimated probability is within $\pm r$ of the true cumulative probability q, with probability s, such as $P(\hat{P}_q \in (q-r, q+r)) = s$. For example, suppose you want the coverage probability s to be 0.95 and the amount of tolerance r to be 0.005. This corresponds to requiring that the estimate of the cumulative distribution function of the 2.5th percentile be estimated to within ± 0.5 percentage points with probability 0.95.

The Raftery-Lewis diagnostics test finds the number of iterations, M, that need to be discarded (burn-ins) and the number of iterations needed, N, to achieve a desired precision. Given a predefined cumulative probability q, these procedures first find $\hat{\theta}_q$, and then they construct a binary $0-1$ process $\{Z_t\}$ by setting $Z_t = 1$ if $\theta^t \leq \hat{\theta}_q$ and 0 otherwise for all t. The sequence $\{Z_t\}$ is itself not a Markov chain, but you can construct a subsequence of $\{Z_t\}$ that is approximately Markovian if it is sufficiently k-thinned. When k becomes reasonably large, $\{Z_t^{(k)}\}$ starts to behave like a Markov chain.

Next, the procedures find this thinning parameter k. The number k is estimated by comparing the Bayesian information criterion (BIC) between two Markov models: a first-order and a second-order Markov model. A jth-order Markov model is one in which the current value of $\{Z_t^{(k)}\}$ depends on the previous j values. For example, in a second-order Markov model,

$$p\left(Z_t^{(k)} = z_t | Z_{t-1}^{(k)} = z_{t-1}, Z_{t-2}^{(k)} = z_{t-2}, \cdots, Z_0^{(k)} = z_0\right)$$
$$= \quad p\left(Z_t^{(k)} = z_t | Z_{t-1}^{(k)} = z_{t-1}, Z_{t-2}^{(k)} = z_{t-2}\right)$$

where $z_i = \{0, 1\}, i = 0, \cdots, t$. Given $\{Z_t^{(k)}\}$, you can construct two transition count matrices for a second-order Markov model:

	$z_t = 0$		$z_t = 1$	
	$z_{t-1} = 0$	$z_{t-1} = 1$	$z_{t-1} = 0$	$z_{t-1} = 1$
$z_{t-2} = 0$	w_{000}	w_{010}	w_{001}	w_{011}
$z_{t-2} = 1$	w_{100}	w_{110}	w_{101}	w_{111}

For each k, the procedures calculate the BIC that compares the two Markov models. The BIC is based on a likelihood ratio test statistic that is defined as

$$G_k^2 = 2\sum_{i=0}^{1}\sum_{j=0}^{1}\sum_{l=0}^{1} w_{ijl} \log \frac{w_{ijl}}{\hat{w}_{ijl}}$$

where $\hat{w}_{ijl}$ is the expected cell count of w_{ijl} under the null model, the first-order Markov model, where the assumption $(Z_t^{(k)} \perp Z_{t-2}^{(k)}) | Z_{t-1}^{(k)}$ holds. The formula for the expected cell count is

$$\hat{w}_{ijl} = \frac{\sum_i w_{ijl} \cdot \sum_l w_{ijl}}{\sum_i \sum_l w_{ijl}}$$

The BIC is $G_k^2 - 2\log(n_k - 2)$, where n_k is the k-thinned sample size (every kth sample starting with the first), with the last two data points discarded due to the construction of the second-order Markov model. The thinning parameter k is the smallest k for which the BIC is negative. When k is found, you can estimate a transition probability matrix between state 0 and state 1 for $\{Z_t^{(k)}\}$:

$$Q = \begin{pmatrix} 1-\alpha & \alpha \\ \beta & 1-\beta \end{pmatrix}$$

Because $\{Z_t^{(k)}\}$ is a Markov chain, its equilibrium distribution exists and is estimated by

$$\pi = (\pi_0, \pi_1) = \frac{(\beta, \alpha)}{\alpha + \beta}$$

where $\pi_0 = P(\theta \leq \theta_q|\mathbf{y})$ and $\pi_1 = 1 - \pi_0$. The goal is to find an iteration number m such that after m steps, the estimated transition probability $P(Z_m^{(k)} = i|Z_0^{(k)} = j)$ is within ϵ of equilibrium π_i for $i, j = 0, 1$. Let $e_0 = (1, 0)$ and $e_1 = 1 - e_0$. The estimated transition probability after step m is

$$P(Z_m^{(k)} = i|Z_0^{(k)} = j) = e_j \left[\begin{pmatrix} \pi_0 & \pi_1 \\ \pi_0 & \pi_1 \end{pmatrix} + \frac{(1-\alpha-\beta)^m}{\alpha+\beta} \begin{pmatrix} \alpha & -\alpha \\ -\beta & \beta \end{pmatrix} \right] e_j^\top$$

which holds when

$$m = \frac{\log\left(\frac{(\alpha+\beta)\epsilon}{\max(\alpha,\beta)}\right)}{\log(1-\alpha-\beta)}$$

assuming $1 - \alpha - \beta > 0$.

Therefore, by time m, $\{Z_t^{(k)}\}$ is sufficiently close to its equilibrium distribution, and you know that a total size of $M = mk$ should be discarded as the burn-in.

Next, the procedures estimate N, the number of simulations needed to achieve desired accuracy on percentile estimation. The estimate of $P(\theta \leq \theta_q|\mathbf{y})$ is $\bar{Z}_n^{(k)} = \frac{1}{n}\sum_{t=1}^{n} Z_t^{(k)}$. For large n, $\bar{Z}_n^{(k)}$ is normally distributed with mean q, the true cumulative probability, and variance

$$\frac{1}{n}\frac{(2-\alpha-\beta)\alpha\beta}{(\alpha+\beta)^3}$$

$P(q - r \leq \bar{Z}_n^{(k)} \leq q + r) = s$ is satisfied if

$$n = \frac{(2-\alpha-\beta)\alpha\beta}{(\alpha+\beta)^3} \left\{ \frac{\Phi^{-1}\left(\frac{s+1}{2}\right)}{r} \right\}^2$$

Therefore, $N = nk$.

By using similar reasoning, the procedures first calculate the minimal number of iterations needed to achieve the desired accuracy, assuming the samples are independent:

$$N_{min} = \left\{ \Phi^{-1}\left(\frac{s+1}{2}\right) \right\}^2 \frac{q(1-q)}{r^2}$$

If $\{\theta^t\}$ does not have that required sample size, the Raftery-Lewis test is not carried out. If you still want to carry out the test, increase the number of Markov chain iterations.

The ratio N/N_{min} is sometimes referred to as the *dependence factor*. It measures deviation from posterior sample independence: the closer it is to 1, the less correlated are the samples. There are a few things to keep in mind when you use this test. This diagnostic tool is specifically designed for the percentile of interest and does not provide information about convergence of the chain as a whole (Brooks and Roberts 1999). In addition, the test can be very sensitive to small changes. Both N and N_{min} are inversely proportional to r^2, so you can expect to see large variations in these numbers with small changes to input variables, such as the desired coverage probability or the cumulative probability of interest. Last, the time until convergence for a parameter can differ substantially for different cumulative probabilities.

Autocorrelations

The sample autocorrelation of lag h is defined in terms of the sample autocovariance function:

$$\hat{\rho}(h) = \frac{\hat{\gamma}(h)}{\hat{\gamma}(0)}, \quad |h| < n$$

The sample autocovariance function of lag h (of $\left\{\theta_i^t\right\}$) is defined by

$$\hat{\gamma}(h) = \frac{1}{n-h}\sum_{t=1}^{n-h}\left(\theta_i^{t+h} - \bar{\theta}_i\right)\left(\theta_i^t - \bar{\theta}_i\right), \quad 0 \le h < n$$

Effective Sample Size

You can use autocorrelation and trace plots to examine the mixing of a Markov chain. A closely related measure of mixing is the effective sample size (ESS) (Kass et al. 1998).

ESS is defined as follows:

$$\text{ESS} = \frac{n}{\tau} = \frac{n}{1 + 2\sum_{k=1}^{\infty}\rho_k(\theta)}$$

where n is the total sample size and $\rho_k(\theta)$ is the autocorrelation of lag k for θ. The quantity τ is referred to as the autocorrelation time. To estimate τ, the Bayesian procedures first find a cutoff point k after which the autocorrelations are very close to zero, and then sum all the ρ_k up to that point. The cutoff point k is such that $\rho_k < 0.05$ or $\rho_k < 2s_k$, where s_k is the estimated standard deviation:

$$s_k = 2\sqrt{\left(\frac{1}{n}\left(1 + 2\sum_{j=1}^{k-1}\rho_k^2(\theta)\right)\right)}$$

ESS and τ are inversely proportional to each other, and low ESS or high τ indicates bad mixing of the Markov chain.

Summary Statistics

Let $\boldsymbol{\theta}$ be a p-dimensional parameter vector of interest: $\boldsymbol{\theta} = \{\theta_1, \ldots, \theta_p\}$. For each $i \in \{1, \ldots, p\}$, there are n observations: $\theta_i = \{\theta_i^t,\ t = 1, \ldots, n\}$.

Mean

The posterior mean is calculated by using the following formula:

$$E(\theta_i|\mathbf{y}) \approx \bar{\theta}_i = \frac{1}{n}\sum_{t=1}^{n}\theta_i^t, \text{ for } i = 1, \ldots, n$$

Standard Deviation

Sample standard deviation (expressed in variance term) is calculated by using the following formula:

$$\mathrm{Var}(\theta_i|\mathbf{y}) \approx s_i^2 = \frac{1}{n-1}\sum_{t=1}^{n}\left(\theta_i^t - \bar{\theta}_i\right)^2$$

Standard Error of the Mean Estimate

Suppose you have n iid samples, the mean estimate is $\bar{\theta}_i$, and the sample standard deviation is s_i. The standard error of the estimate is $\hat{\sigma}_i/\sqrt{n}$. However, positive autocorrelation (see the section "Autocorrelations" on page 158 for a definition) in the MCMC samples makes this an underestimate. To take account of the autocorrelation, the Bayesian procedures correct the standard error by using effective sample size (see the section "Effective Sample Size" on page 158).

Given an effective sample size of m, the standard error for $\bar{\theta}_i$ is $\hat{\sigma}_i/\sqrt{m}$. The procedures use the following formula (expressed in variance term):

$$\widehat{\mathrm{Var}}(\bar{\theta}_i) = \frac{1 + 2\sum_{k=1}^{\infty}\rho_k(\theta_i)}{n} \cdot \frac{\sum_{t=1}^{n}\left(\theta_i^t - \bar{\theta}_i\right)^2}{(n-1)}$$

The standard error of the mean is also known as the Monte Carlo standard error (MCSE). The MCSE provides a measurement of the accuracy of the posterior estimates, and small values do not necessarily indicate that you have recovered the true posterior mean.

Percentiles

Sample percentiles are calculated using Definition 5 (see Chapter 4, "The UNIVARIATE Procedure" (*Base SAS Procedures Guide: Statistical Procedures*),).

Correlation

Correlation between θ_i and θ_j is calculated as

$$r_{ij} = \frac{\sum_{t=1}^{n}\left(\theta_i^t - \bar{\theta}_i\right)\left(\theta_j^t - \bar{\theta}_j\right)}{\sqrt{\sum_t \left(\theta_i^t - \bar{\theta}_i\right)^2 \sum_t \left(\theta_j^t - \bar{\theta}_j\right)^2}}$$

Covariance

Covariance θ_i and θ_j is calculated as

$$s_{ij} = \sum_{t=1}^{n}\left(\theta_i^t - \bar{\theta}_i\right)\left(\theta_j^t - \bar{\theta}_j\right)/(n-1)$$

Equal-Tail Credible Interval

Let $\pi\left(\theta_i|\mathbf{y}\right)$ denote the marginal posterior cumulative distribution function of θ_i. A $100\left(1-\alpha\right)\%$ Bayesian equal-tail credible interval for θ_i is $\left(\theta_i^{\alpha/2}, \theta_i^{1-\alpha/2}\right)$, where $\pi\left(\theta_i^{\alpha/2}|\mathbf{y}\right) = \frac{\alpha}{2}$, and $\pi\left(\theta_i^{1-\alpha/2}|\mathbf{y}\right) = 1 - \frac{\alpha}{2}$. The interval is obtained using the empirical $\frac{\alpha}{2}$th and $(1-\frac{\alpha}{2})$th percentiles of $\left\{\theta_i^t\right\}$.

Highest Posterior Density (HPD) Interval

For a definition of an HPD interval, see the section "Interval Estimation" on page 138. The procedures use the Chen-Shao algorithm (Chen and Shao 1999; Chen, Shao, and Ibrahim 2000) to estimate an empirical HPD interval of θ_i:

1. Sort $\left\{\theta_i^t\right\}$ to obtain the ordered values:
$$\theta_{i(1)} \leq \theta_{i(2)} \leq \cdots \leq \theta_{i(n)}$$
2. Compute the $100\left(1-\alpha\right)\%$ credible intervals:
$$R_j\left(n\right) = \left(\theta_{i(j)}, \theta_{i(j+[(1-\alpha)n])}\right)$$
for $j = 1, 2, \ldots, n - [(1-\alpha)\,n]$.
3. The $100\left(1-\alpha\right)\%$ HPD interval, denoted by $R_{j*}\left(n\right)$, is the one with the smallest interval width among all credible intervals.

Deviance Information Criterion (DIC)

The deviance information criterion (DIC) (Spiegelhalter et al. 2002) is a model assessment tool, and it is a Bayesian alternative to Akaike's information criterion (AIC) and the Bayesian information criterion (BIC, also known as the Schwarz criterion). The DIC uses the posterior densities, which means that it takes the prior information into account. The criterion can be applied to nonnested models and models that have non-iid data. Calculation of the DIC in MCMC is trivial—it does not require maximization over the parameter space, like the AIC and BIC. A smaller DIC indicates a better fit to the data set.

Letting $\boldsymbol{\theta}$ be the parameters of the model, the deviance information formula is

$$\text{DIC} = \overline{D(\boldsymbol{\theta})} + p_D = D(\overline{\boldsymbol{\theta}}) + 2p_D$$

where

$D(\boldsymbol{\theta}) = 2\left(\log(f(\mathbf{y})) - \log(p(\mathbf{y}|\boldsymbol{\theta}))\right)$: deviance

where

$p(\mathbf{y}|\boldsymbol{\theta})$: likelihood function with the normalizing constants.

$f(\mathbf{y})$: a standardizing term that is a function of the data alone. This term is constant with respect to the parameter and is irrelevant when you compare different models that have the same likelihood function. Since the term cancels out in DIC comparisons, its calculation is often omitted.

NOTE: You can think of the deviance as the difference in twice the log likelihood between the saturated, $f(\mathbf{y})$, and fitted, $p(\mathbf{y}|\boldsymbol{\theta})$, models.

$\overline{\boldsymbol{\theta}}$: posterior mean, approximated by $\frac{1}{n}\sum_{t=1}^{n}\boldsymbol{\theta}^t$

$\overline{D(\boldsymbol{\theta})}$: posterior mean of the deviance, approximated by $\frac{1}{n}\sum_{t=1}^{n}D(\boldsymbol{\theta}^t)$. The expected deviation measures how well the model fits the data.

$D(\overline{\boldsymbol{\theta}})$: deviance evaluated at $\bar{\boldsymbol{\theta}}$, equal to $-2\log(p(\mathbf{y}|\bar{\boldsymbol{\theta}}))$. It is the deviance evaluated at your "best" posterior estimate.

p_D: effective number of parameters. It is the difference between the measure of fit and the deviance at the estimates: $\overline{D(\boldsymbol{\theta})} - D(\overline{\boldsymbol{\theta}})$. This term describes the complexity of the model, and it serves as a penalization term that corrects deviance's propensity toward models with more parameters.

A Bayesian Reading List

This section lists a number of Bayesian textbooks of varying difficulty degrees and a few tutorial/review papers.

Textbooks

Introductory Books

Berry, D. A. (1996), *Statistics: A Bayesian Perspective*, London: Duxbury Press.

Bolstad, W. M. (2007), *Introduction to Bayesian Statistics*, 2nd ed. New York: John Wiley & Sons.

DeGroot, M. H. and Schervish, M. J. (2002), *Probability and Statistics*, Reading, MA: Addison Wesley.

Gamerman, D. and Lopes, H. F. (2006), *Markov Chain Monte Carlo: Stochastic Simulation for Bayesian Inference,* 2nd ed. London: Chapman & Hall/CRC.

Ghosh, J. K., Delampady, M., and Samanta, T. (2006), *An Introduction to Bayesian Analysis,* New York: Springer-Verlag.

Lee, P. M. (2004), *Bayesian Statistics: An Introduction,* 3rd ed. London: Arnold.

Sivia, D. S. (1996), *Data Analysis: A Bayesian Tutorial,* Oxford: Oxford University Press.

Intermediate-Level Books

Chapter 8

Introduction to Categorical Data Analysis Procedures

Contents

Overview: Categorical Data Analysis Procedures

There are two approaches to performing categorical data analyses. The first computes statistics based on tables defined by *categorical variables* (variables that assume only a limited number of discrete values), performs hypothesis tests about the association between these variables, and requires the assumption of a randomized process; following Stokes, Davis, and Koch (2000), call these methods *randomization procedures*. The other approach investigates the association by modeling a categorical response variable, regardless of whether the explanatory variables are continuous or categorical; call these methods *modeling procedures*. Several procedures in SAS/STAT software can be used for the analysis of categorical data.

The randomization procedures are:

FREQ builds frequency tables or contingency tables and can produce numerous statistics. For one-way frequency tables, it can perform tests for equal proportions, specified proportions, or the binomial proportion. For contingency tables, it can compute various tests and measures of association and agreement including chi-square statistics, odds ratios, correlation statistics, Fisher's exact test for any size two-way table, kappa, and trend tests. In addition, it performs stratified analysis, computing Cochran-Mantel-Haenszel

statistics and estimates of the common relative risk. Exact p-values and confidence intervals are available for various test statistics and measures. See Chapter 36, "The FREQ Procedure," for more information.

SURVEYFREQ incorporates complex sample designs to analyze one-way, two-way, and multiway crosstabulation tables. Estimates population totals and proportions and performs tests of goodness-of-fit and independence. See Chapter 14, "Introduction to Survey Procedures," and Chapter 86, "The SURVEYFREQ Procedure," for more information.

The modeling procedures, which require a categorical response variable, are:

CATMOD fits linear models to functions of categorical data, facilitating such analyses as regression, analysis of variance, linear modeling, log-linear modeling, logistic regression, and repeated measures analysis. Maximum likelihood estimation is used for the analysis of logits and generalized logits, and weighted least squares analysis is used for fitting models to other response functions. Iterative proportional fitting (IPF), which avoids the need for parameter estimation, is available for fitting hierarchical log-linear models when there is a single population. See Chapter 29, "The CATMOD Procedure," for more information.

GENMOD fits generalized linear models with maximum-likelihood methods. This family includes logistic, probit, and complementary log-log regression models for binomial data, Poisson and negative binomial regression models for count data, and multinomial models for ordinal response data. It performs likelihood ratio and Wald tests for Type I, Type III, and user-defined contrasts. It analyzes repeated measures data with generalized estimating equation (GEE) methods. Bayesian analysis capabilities for generalized linear models are also available. See Chapter 39, "The GENMOD Procedure," for more information.

GLIMMIX fits generalized linear mixed models with maximum-likelihood methods. If the model does not contain random effects, the GLIMMIX procedure fits generalized linear models by the method of maximum likelihood. This family includes logistic, probit, and complementary log-log regression models for binomial data, Poisson and negative binomial regression models for count data, and multinomial models for ordinal response data. See Chapter 40, "The GLIMMIX Procedure," for more information.

LOGISTIC fits linear logistic regression models for discrete response data with maximum-likelihood methods. It provides four variable selection methods, computes regression diagnostics, and compares and outputs receiver operating characteristic curves. It can also perform stratified conditional logistic regression analysis for binary response data and exact conditional regression analysis for binary and nominal response data. The logit link function in the logistic regression models can be replaced by the probit function or the complementary log-log function. See Chapter 53, "The LOGISTIC Procedure," for more information.

PROBIT fits models with probit, logit, or complementary log-log links for quantal assay or other discrete event data. It is mainly designed for dose-response analysis with a natural response rate. It computes the fiducial limits for the dose variable and provides various graphical displays for the analysis. See Chapter 74, "The PROBIT Procedure," for more information.

SURVEYLOGISTIC fits logistic models for binary and ordinal outcomes to survey data by maximum likelihood, incorporating complex survey sample designs. See Chapter 87, "The SURVEYLOGISTIC Procedure," for more information.

Also see Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," and Chapter 4, "Introduction to Regression Procedures," for more information about all the modeling and regression procedures.

Other procedures that can be used for categorical data analysis and modeling are:

CORRESP performs simple and multiple correspondence analyses, using a contingency table, Burt table, binary table, or raw categorical data as input. See Chapter 9, "Introduction to Multivariate Procedures," and Chapter 31, "The CORRESP Procedure," for more information.

PRINQUAL performs a principal component analysis of qualitative and/or quantitative data, and multidimensional preference analysis. See Chapter 9, "Introduction to Multivariate Procedures," and Chapter 73, "The PRINQUAL Procedure," for more information.

TRANSREG fits univariate and multivariate linear models, optionally with spline and other nonlinear transformations. Models include ordinary regression and ANOVA, multiple and multivariate regression, metric and nonmetric conjoint analysis, metric and nonmetric vector and ideal point preference mapping, redundancy analysis, canonical correlation, and response surface regression. See Chapter 4, "Introduction to Regression Procedures," and Chapter 93, "The TRANSREG Procedure," for more information.

Introduction

A *categorical variable* is a variable that assumes only a limited number of discrete values. The measurement scale for a categorical variable is unrestricted. It can be *nominal*, which means that the observed levels are not ordered. It can be *ordinal*, which means that the observed levels are ordered in some way. Or it can be *interval*, which means that the observed levels are ordered and numeric and that any interval of one unit on the scale of measurement represents the same amount, regardless of its location on the scale. One example of a categorical variable is litter size; another is the number of times a subject has been married. A variable that lies on a nominal scale is sometimes called a *qualitative* or *classification variable*.

Categorical data result from observations on multiple subjects where one or more categorical variables are observed for each subject. If there is only one categorical variable, then the data are generally represented by a *frequency table*, which lists each observed value of the variable and its frequency of occurrence.

If there are two or more categorical variables, then a subject's *profile* is defined as the subject's observed values for each of the variables. Such categorical data can be represented by a frequency table that lists each observed profile and its frequency of occurrence.

If there are exactly two categorical variables, then the data are often represented by a two-dimensional *contingency table*, which has one row for each level of variable 1 and one column for each level of variable 2. The intersections of rows and columns, called *cells*, correspond to variable profiles, and each cell contains the frequency of occurrence of the corresponding profile.

If there are more than two categorical variables, then the data can be represented by a *multidimensional contingency table*. There are two commonly used methods for displaying such tables, and both require that the variables be divided into two sets.

- In the first method, one set contains a row variable and a column variable for a two-dimensional contingency table, and the second set contains all of the other variables. The variables in the second set are used to form a set of profiles. Thus, the data are represented as a series of two-dimensional contingency tables, one for each profile. This is the data representation used by PROC FREQ. For example, if you request tables for RACE*SEX*AGE*INCOME, the FREQ procedure represents the data as a series of contingency tables: the row variable is AGE, the column variable is INCOME, and the combinations of levels of RACE and SEX form a set of profiles.
- In the second method, one set contains the independent variables, and the other set contains the dependent variables. Profiles based on the independent variables are called *population profiles*, whereas those based on the dependent variables are called *response profiles*. A two-dimensional contingency table is then formed, with one row for each population profile and one column for each response profile. Since any subject can have only one population profile and one response profile, the contingency table is uniquely defined. This is the data representation used by the modeling procedures.

NOTE: Modeling procedures for categorical data analysis only require that the response variable be categorical—the explanatory variables are allowed to be continuous or categorical. However, note that PROC CATMOD was designed to handle contingency table data, and it does not efficiently handle continuous covariates.

Sampling Frameworks and Distribution Assumptions

This section discusses the sampling frameworks and distribution assumptions for the modeling and randomization procedures.

Simple Random Sampling: One Population

Suppose you take a simple random sample of 100 people and ask each person the following question, "Of the three colors red, blue, and green, which is your favorite?" You then tabulate the results in a frequency table as shown in Table 8.1.

Table 8.1 One-Way Frequency Table

	Favorite Color			
	Red	**Blue**	**Green**	**Total**
Frequency	52	31	17	100
Proportion	0.52	0.31	0.17	1.00

In the population you are sampling, you assume there is an unknown probability that a population member, selected at random, would choose any given color. In order to estimate that probability, you use the sample proportion

$$p_j = \frac{n_j}{n}$$

where n_j is the frequency of the jth response and n is the total frequency.

Because of the random variation inherent in any random sample, the frequencies have a probability distribution representing their relative frequency of occurrence in a hypothetical series of samples. For a simple random sample, the distribution of frequencies for a frequency table with three levels is as follows. The probability that the first frequency is n_1, the second frequency is n_2, and the third is $n_3 = n - n_1 - n_2$, is given by

$$\Pr(n_1, n_2, n_3) = \frac{n!}{n_1! n_2! n_3!} \pi_1^{n_1} \pi_2^{n_2} \pi_3^{n_3}$$

where π_j is the true probability of observing the jth response level in the population.

This distribution, called the *multinomial distribution*, can be generalized to any number of response levels. The special case of two response levels is called the *binomial distribution*.

Simple random sampling is the type of sampling required by the (non-survey) modeling procedures when there is one population. The modeling procedures use the multinomial distribution to estimate a probability vector and its covariance matrix. If the sample size is sufficiently large, then the probability vector is approximately normally distributed as a result of central limit theory. This result is used to compute appropriate test statistics for the specified statistical model.

Stratified Simple Random Sampling: Multiple Populations

Suppose you take two simple random samples, 50 men and 50 women, and ask the same question as before. You are now sampling two different populations that may have different response probabilities. The data can be tabulated as shown in Table 8.2.

Table 8.2 Two-Way Contingency Table: Sex by Color

	Favorite Color			
Sex	**Red**	**Blue**	**Green**	**Total**
Male	30	10	10	50
Female	20	10	20	50
Total	50	20	30	100

Note that the row marginal totals (50, 50) of the contingency table are fixed by the sampling design, but the column marginal totals (50, 20, 30) are random. There are six probabilities of interest for this table, and they are estimated by the sample proportions

$$p_{ij} = \frac{n_{ij}}{n_i}$$

where n_{ij} denotes the frequency for the ith population and the jth response and n_i is the total frequency for the ith population. For this contingency table, the sample proportions are shown in Table 8.3.

Table 8.3 Table of Sample Proportions by Sex

	Favorite Color			
Sex	**Red**	**Blue**	**Green**	**Total**
Male	0.60	0.20	0.20	1.00
Female	0.40	0.20	0.40	1.00

The probability distribution of the six frequencies is the *product multinomial distribution*

$$\Pr(n_{11}, n_{12}, n_{13}, n_{21}, n_{22}, n_{23}) = \frac{n_1! n_2! \pi_{11}^{n_{11}} \pi_{12}^{n_{12}} \pi_{13}^{n_{13}} \pi_{21}^{n_{21}} \pi_{22}^{n_{22}} \pi_{23}^{n_{23}}}{n_{11}! n_{12}! n_{13}! n_{21}! n_{22}! n_{23}!}$$

where π_{ij} is the true probability of observing the jth response level in the ith population. The product multinomial distribution is simply the product of two or more individual multinomial distributions since the populations are independent. This distribution can be generalized to any number of populations and response levels.

Stratified simple random sampling is the type of sampling required by the modeling procedures when there is more than one population. The product multinomial distribution is used to estimate a probability vector and its covariance matrix. If the sample sizes are sufficiently large, then the probability vector is approximately normally distributed as a result of central limit theory, and this result is used to compute appropriate test statistics for the specified statistical model. The statistics are known as Wald statistics, and they are approximately distributed as chi-square when the null hypothesis is true.

Observational Data: Analyzing the Entire Population

Sometimes the observed data do not come from a random sample but instead represent a complete set of observations on some population. For example, suppose a class of 100 students is classified according to sex and favorite color. The results are shown in Table 8.4.

In this case, you could argue that all of the frequencies are fixed since the entire population is observed; therefore, there is no sampling error. On the other hand, you could hypothesize that the observed table has only fixed marginals and that the cell frequencies represent one realization of a conceptual process of assigning color preferences to individuals. The assignment process is open to hypothesis, which means that you can hypothesize restrictions on the joint probabilities.

Table 8.4 Two-Way Contingency Table: Sex by Color

	Favorite Color			
Sex	**Red**	**Blue**	**Green**	**Total**
Male	16	21	20	57
Female	12	20	11	43
Total	28	41	31	100

The usual hypothesis (sometimes called *randomness*) is that the distribution of the column variable (Favorite Color) does not depend on the row variable (Sex). This implies that, for each row of the table, the assignment process corresponds to a simple random sample (without replacement) from the finite population represented by the column marginal totals (or by the column marginal subtotals that remain after sampling other rows). The hypothesis of randomness implies that the probability distribution on the frequencies in the table is the *hypergeometric distribution*.

If the same row and column variables are observed for each of several populations, then the probability distribution of all the frequencies can be called the *multiple hypergeometric distribution.* Each population is called a *stratum*, and an analysis that draws information from each stratum and then summarizes across them is called a *stratified analysis* (or a *blocked analysis* or a *matched analysis*). PROC FREQ does such a stratified analysis, computing test statistics and measures of association.

In general, the populations are formed on the basis of cross-classifications of independent variables. Stratified analysis is a method of adjusting for the effect of these variables without being forced to estimate parameters for them. Note that PROC LOGISTIC can perform analyses on stratified tables as well, using the usual modeling procedure assumptions, by using conditional or exact conditional logistic regression.

The multiple hypergeometric distribution is the one used by PROC FREQ for the computation of Cochran-Mantel-Haenszel statistics. These statistics are in the class of *randomization model test statistics*, which require minimal assumptions for their validity. PROC FREQ uses the multiple hypergeometric distribution to compute the mean and the covariance matrix of a function vector in order to measure the deviation between the observed and expected frequencies with respect to a particular type of alternative hypothesis. If the cell frequencies are sufficiently large, then the function vector is approximately normally distributed as a result of central limit theory, and PROC FREQ uses this result to compute a quadratic form that has a chi-square distribution when the null hypothesis is true.

Randomized Experiments

Consider a *randomized experiment* in which patients are assigned to one of two treatment groups according to a randomization process that allocates 50 patients to each group. After a specified period of time, each patient's status (cured or uncured) is recorded. Suppose the data shown in Table 8.5 give the results of the experiment. The null hypothesis is that the two treatments are equally effective. Under this hypothesis, treatment is a randomly assigned label that has no effect on the cure rate of the patients. But this implies that each row of the table represents a simple random sample from the finite population whose cure rate is described by the column marginal totals. Therefore, the column marginals (58, 42) are fixed under the hypothesis. Since the row marginals (50, 50) are fixed by the allocation process, the hypergeometric distribution is induced on the cell frequencies. Randomized experiments can also be specified in a stratified framework, and Cochran-Mantel-Haenszel statistics can be computed relative to the corresponding multiple hypergeometric distribution.

Table 8.5 Two-Way Contingency Table: Treatment by Status

	Status		
Treatment	**Cured**	**Uncured**	**Total**
1	36	14	50
2	22	28	50
Total	58	42	100

Relaxation of Sampling Assumptions

As indicated previously, the modeling procedures assume that the data are from a stratified simple random sample, so they use the product multinomial distribution. If the data are not from such a sample, then in many cases it is still possible to use a modeling procedure by arguing that each row of the contingency table *does* represent a simple random sample from some hypothetical population. The extent to which the inferences are generalizable depends on the extent to which the hypothetical population is perceived to resemble the target population.

Similarly, the Cochran-Mantel-Haenszel statistics use the multiple hypergeometric distribution, which requires fixed row and column marginal totals in each contingency table. If the sampling process does not yield a table with fixed margins, then it is usually possible to fix the margins through conditioning arguments similar to the ones used by Fisher when he developed the Exact Test for 2×2 tables. In other words, if you want fixed marginal totals, you can generally make your analysis conditional on those observed totals.

For more information on sampling models for categorical data, see Bishop, Fienberg, and Holland (1975, Chapter 13) and Agresti (2002, Chapter 1.2).

Comparison of PROC FREQ and the Modeling Procedures

PROC FREQ is used primarily to investigate the relationship between two variables; any confounding variables are taken into account by stratification rather than by parameter estimation. Modeling procedures are used to investigate the relationship among many variables, all of which are integrated into a parametric model.

When a modeling procedure estimates the covariance matrix of the frequencies, it assumes that the frequencies were obtained by a stratified simple random-sampling procedure. However, some modeling procedures can handle different sampling methods. PROC CATMOD can analyze input data that consists of a function vector and a covariance matrix, so you can estimate the covariance matrix of the frequencies in the appropriate manner before modeling the data. PROC SURVEYLOGISTIC can analyze data from a completely different, but known, sampling scheme.

For the FREQ procedure, Fisher's Exact Test and Cochran-Mantel-Haenszel (CMH) statistics are based on the hypergeometric distribution, which corresponds to fixed marginal totals. However, by conditioning arguments, these tests are generally applicable to a wide range of sampling procedures. Similarly, the Pearson and likelihood-ratio chi-square statistics can be derived under a variety of sampling situations.

PROC FREQ can do some traditional nonparametric analysis (such as the Kruskal-Wallis test and Spearman's correlation) since it can generate rank scores internally. Fisher's Exact Test and the CMH statistics are also inherently nonparametric. However, the main vehicle for nonparametric analyses in the SAS System is the NPAR1WAY procedure.

A large sample size is required for the validity of the chi-square distributions, the standard errors, and the covariance matrices for PROC FREQ and the modeling procedures. If sample size is a problem, then PROC FREQ has the advantage with its CMH statistics because it does not use any degrees of freedom to estimate

parameters for confounding variables. In addition, PROC FREQ can compute exact p-values for any two-way table, provided that the sample size is sufficiently small in relation to the size of the table. It can also produce exact p-values for many tests, including the test of binomial proportions, the Cochran-Armitage test for trend, and the Jonckheere-Terpstra test for ordered differences among classes. PROC LOGISTIC can perform exact conditional logistic regression and Firth's penalized-likelihood regression to compensate for small sample sizes.

See the procedure chapters for more information. In addition, some well-known texts that deal with analyzing categorical data are listed in the "References" section of this chapter.

Comparison of Modeling Procedures

The CATMOD, GENMOD, GLIMMIX, LOGISTIC, PROBIT, and SURVEYLOGISTIC procedures can all be used for statistical modeling of categorical data.

The CATMOD procedure treats all explanatory (independent) variables as classification variables by default, and you specify continuous covariates in the DIRECT statement. The other procedures treat covariates as continuous by default, and you specify the classification variables in the CLASS statement.

The CATMOD procedure provides weighted least squares estimation of many response functions, such as means, cumulative logits, and proportions, and you can also compute and analyze other response functions that can be formed from the proportions corresponding to the rows of a contingency table. In addition, a user can input and analyze a set of response functions and user-supplied covariance matrix with weighted least squares. PROC CATMOD also provides maximum likelihood estimation for binary and polytomous logistic regression.

The GENMOD procedure is also a general statistical modeling tool which fits generalized linear models to data; it fits several useful models to categorical data including logistic regression, the proportional odds model, and Poisson and negative binomial regression for count data. The GENMOD procedure also provides a facility for fitting generalized estimating equations to correlated response data that are categorical, such as repeated dichotomous outcomes. The GENMOD procedure fits models using maximum likelihood estimation. PROC GENMOD can perform Type I and Type III tests, and it provides predicted values and residuals. Bayesian analysis capabilities for generalized linear models are also available.

The GLIMMIX procedure fits many of the same models as the GENMOD procedure but also allows the inclusion of random effects. The GLIMMIX procedure fits models using maximum likelihood estimation.

The LOGISTIC procedure is specifically designed for logistic regression. It performs the usual logistic regression analysis for dichotomous outcomes and it fits the proportional odds model and the generalized logit model for ordinal and nominal outcomes, respectively, by the method of maximum likelihood. This procedure has capabilities for a variety of model-building techniques, including stepwise, forward, and backward selection. It computes predicted values, the receiver operating characteristics (ROC) curve and the area beneath the curve, and a number of regression diagnostics. It can create output data sets containing these values and other statistics. PROC LOGISTIC can perform a conditional logistic regression analysis (matched-set and case-controlled) for binary response data. For small data sets, PROC LOGISTIC can perform exact conditional logistic regression. Firth's bias-reducing penalized-likelihood method can also be used in place of conditional and exact conditional logistic regression.

The PROBIT procedure is designed for quantal assay or other discrete event data. In additional to performing the logistic regression analysis, it can estimate the threshold response rate. PROC PROBIT can also estimate the values of independent variables that yield a desired response.

The SURVEYLOGISTIC procedure performs logistic regression for binary, ordinal, and nominal responses under a specified complex sampling scheme, instead of the usual stratified simple random sampling.

Stokes, Davis, and Koch (2000) provide substantial discussion of these procedures, particularly the use of the FREQ, LOGISTIC, GENMOD, and CATMOD procedures for statistical modeling.

Logistic Regression

Dichotomous Response

You have many choices of performing logistic regression in the SAS System. The CATMOD, GENMOD, GLIMMIX, LOGISTIC, PROBIT, and SURVEYLOGISTIC procedures fit the usual logistic regression model.

PROC CATMOD might not be efficient when there are continuous independent variables with large numbers of different values. For a continuous variable with a very limited number of values, PROC CATMOD might still be useful.

PROC GLIMMIX enables you to specify random effects in the models; in particular, you can fit a random-intercept logistic regression model.

PROC LOGISTIC provides the capability of model-building and performs conditional and exact conditional logistic regression. It can also use Firth's bias-reducing penalized likelihood method.

PROC PROBIT enables you to estimate the natural response rate and compute fiducial limits for the dose variable.

The LOGISTIC, GENMOD, GLIMMIX, PROBIT, and SURVEYLOGISTIC procedures can analyze summarized data by enabling you to input the numbers of events and trials; the ratio of events to trials must be between 0 and 1.

Ordinal Response

PROC LOGISTIC fits the proportional odds model to the ordinal response data by default, PROC PROBIT fits this model if you specify the logistic distribution, and PROC GENMOD and PROC GLIMMIX fit this model if you specify the CLOGIT link and the multinomial distribution. PROC CATMOD fits the cumulative logit or adjacent-category logit response functions.

Nominal Response

When the response variable is nominal, there is no concept of ordering of the response values. Response functions called *generalized logits* can be fit by the CATMOD, GLIMMIX, and LOGISTIC procedures. PROC CATMOD fits this model by default; PROC GLIMMIX and PROC LOGISTIC require you to specify the GLOGIT link.

Numerical Differences

Differences in the way the models are parameterized and fit might result in different parameter estimates if you perform logistic regression in each of these procedures.

- Parameter estimates from the procedures can differ in sign depending on the ordering of response levels, which you can change if you want.
- The parameter estimates associated with a categorical independent variable might differ among the procedures, since the estimates depend on the coding of the indicator variables in the design matrix. By default, the design matrix column produced by PROC CATMOD and PROC LOGISTIC for a binary independent variable is coded using the values 1 and -1 (deviation from the mean coding, which is a full-rank parameterization). The same column produced by the CLASS statement of PROC GENMOD, PROC GLIMMIX, and PROC PROBIT is coded using 1 and 0 (GLM coding, which is less-than-full-rank parameterization). As a result, the parameter estimate printed by PROC LOGISTIC is one-half of the estimate produced by PROC GENMOD. Both PROC GENMOD and PROC LOGISTIC allow you to select either a full-rank parameterization or the less-than-full-rank parameterization. The GLIMMIX and PROBIT procedures allow only the less-than-full-rank parameterization for the CLASS variables. The CATMOD procedure allows only full-rank parameterizations. See the "Details" sections in the chapters on the CATMOD, GENMOD, GLIMMIX, LOGISTIC, and PROBIT procedures for more information on the generation of the design matrices used by these procedures. See Chapter 19, "Shared Concepts and Topics," for a general discussion of the various parameterizations.
- The maximum-likelihood algorithm used differs among the procedures. PROC LOGISTIC uses the Fisher's scoring method by default, while PROC PROBIT, PROC GENMOD, PROC GLIMMIX, and PROC CATMOD use the Newton-Raphson method. The parameter estimates should be the same for all three procedures, and the standard errors should be the same for the logistic model. For the normal and extreme-value (Gompertz) distributions in PROC PROBIT, which correspond to the probit and cloglog links, respectively, in PROC GENMOD and PROC LOGISTIC, the standard errors might differ. In general, tests computed using the standard errors from the Newton-Raphson method are more conservative.
- The LOGISTIC, GENMOD, GLIMMIX, and PROBIT procedures can fit a cumulative regression model for ordinal response data by using maximum-likelihood estimation. PROC LOGISTIC and PROC GENMOD use a different parameterization from that of PROC PROBIT, which results in different intercept parameters. Estimates of the slope parameters, however, should be the same for both procedures. The estimated standard errors of the slope estimates are slightly different between the procedures because of the different computational algorithms used as default.

Chapter 9

Introduction to Multivariate Procedures

Contents

Overview: Multivariate Procedures

The procedures discussed in this chapter investigate relationships among variables without designating some as independent and others as dependent. Principal component analysis and common factor analysis examine relationships within a single set of variables, whereas canonical correlation looks at the relationship between two sets of variables. The following is a brief description of SAS/STAT multivariate procedures:

CORRESP performs simple and multiple correspondence analyses, with a contingency table, Burt table, binary table, or raw categorical data as input. Correspondence analysis is a weighted form of principal component analysis that is appropriate for frequency data. The results are displayed in plots and tables and are also available in output data sets.

PRINCOMP performs a principal component analysis and outputs standardized or unstandardized principal component scores. The results are displayed in plots and tables and are also available in output data sets.

PRINQUAL performs a principal component analysis of qualitative data and multidimensional preference analysis. The results are displayed in plots and are also available in output data sets.

FACTOR performs principal component and common factor analyses with rotations and outputs component scores or estimates of common factor scores. The results are displayed in plots and tables and are also available in output data sets.

CANCORR performs a canonical correlation analysis and outputs canonical variable scores. The results are displayed in tables and are also available in output data sets for plotting.

Many other SAS/STAT procedures can also analyze multivariate data—for example, the CATMOD, GLM, REG, CALIS, and TRANSREG procedures as well as the procedures for clustering and discriminant analysis.

The purpose of *principal component analysis* (Rao 1964) is to derive a small number of linear combinations (principal components) of a set of variables that retain as much of the information in the original variables as possible. Often a small number of principal components can be used in place of the original variables for plotting, regression, clustering, and so on. Principal component analysis can also be viewed as an attempt to uncover approximate linear dependencies among variables.

The purpose of *common factor analysis* (Mulaik 1972) is to explain the correlations or covariances among a set of variables in terms of a limited number of unobservable, latent variables. The latent variables are not generally computable as linear combinations of the original variables. In common factor analysis, it is assumed that the variables are linearly related if not for uncorrelated random error or *unique variation* in each variable; both the linear relations and the amount of unique variation can be estimated.

Principal component and common factor analysis are often followed by rotation of the components or factors. *Rotation* is the application of a nonsingular linear transformation to components or common factors to aid interpretation.

The purpose of *canonical correlation analysis* (Mardia, Kent, and Bibby 1979) is to explain or summarize the relationship between two sets of variables by finding a small number of linear combinations from each set of variables that have the highest possible between-set correlations. Plots of the canonical variables can be useful in examining multivariate dependencies. If one of the two sets of variables consists of dummy variables generated from a classification variable, the canonical correlation is equivalent to canonical discriminant analysis (see Chapter 28, "The CANDISC Procedure"). If both sets of variables are dummy variables, canonical correlation is equivalent to simple correspondence analysis.

The purpose of *correspondence analysis* (Lebart, Morineau, and Warwick 1984; Greenacre 1984; Nishisato 1980) is to summarize the associations between a set of categorical variables in a small number of dimensions. Correspondence analysis computes scores on each dimension for each row and column category in a contingency table. Plots of these scores show the relationships among the categories.

The PRINQUAL procedure obtains linear and nonlinear transformations of variables by using the method of alternating least squares (Young 1981) to optimize properties of the transformed variables' covariance or correlation matrix. PROC PRINQUAL nonlinearly transforms variables, improving their fit to a principal component model. The name, PRINQUAL, for principal components of qualitative data, comes from the special case analysis of fitting a principal component model to nominal and ordinal scale of measurement variables (Young, Takane, and de Leeuw 1978). However, PROC PRINQUAL also has facilities for smoothly transforming continuous variables. All of PROC PRINQUAL's transformations are also available in the TRANSREG procedure, which fits regression models with nonlinear transformations. PROC PRINQUAL can also perform metric and nonmetric multidimensional preference (MDPREF) analyses (Carroll 1972) and produce plots of the results.

Comparison of the PRINCOMP and FACTOR Procedures

Although PROC FACTOR can be used for common factor analysis, the default method is principal components. PROC FACTOR produces the same results as PROC PRINCOMP except that scoring coefficients from PROC FACTOR are normalized to give principal component scores with unit variance, whereas PROC PRINCOMP by default produces principal component scores with variance equal to the corresponding eigenvalue. PROC PRINCOMP can also compute scores standardized to unit variance. Both procedures produce graphical results through ODS Graphics.

PROC PRINCOMP has the following advantages over PROC FACTOR:

- PROC PRINCOMP is slightly faster if a small number of components is requested.
- PROC PRINCOMP can analyze somewhat larger problems in a fixed amount of memory.
- PROC PRINCOMP can output scores from an analysis of a partial correlation or covariance matrix.
- PROC PRINCOMP is simpler to use.

PROC FACTOR has the following advantages over PROC PRINCOMP for principal component analysis:

- PROC FACTOR produces more output.
- PROC FACTOR does rotations.

If you want to perform a common factor analysis, you must use PROC FACTOR instead of PROC PRINCOMP. Principal component analysis should never be used if a common factor solution is desired (Dziuban and Harris 1973; Lee and Comrey 1979).

Comparison of the PRINCOMP and PRINQUAL Procedures

The PRINCOMP procedure performs principal component analysis. The PRINQUAL procedure finds linear and nonlinear transformations of variables to optimize properties of the transformed variables' covariance or correlation matrix. One property is the sum of the first n eigenvalues, which is a measure of the fit of a principal component model with n components. Use PROC PRINQUAL to find nonlinear transformations of your variables or to perform a multidimensional preference analysis. Use PROC PRINCOMP to fit a principal component model to your data or to PROC PRINQUAL's output data set. PROC PRINCOMP produces a report of the principal component analysis, a number of graphical displays, and output data sets. PROC PRINQUAL produces only a few graphs and an output data set.

Comparison of the PRINCOMP and CORRESP Procedures

As summarized previously, PROC PRINCOMP performs a principal component analysis of interval-scaled data. PROC CORRESP performs correspondence analysis, which is a weighted form of principal component analysis that is appropriate for frequency data. If your data are categorical, use PROC CORRESP instead of PROC PRINCOMP. Both procedures produce graphical displays of the results with ODS Graphics. The plots produced by PROC CORRESP graphically show relationships among the categories of the categorical variables.

Comparison of the PRINQUAL and CORRESP Procedures

Both PROC PRINQUAL and PROC CORRESP can be used to summarize associations among variables measured on a nominal scale. PROC PRINQUAL searches for a single nonlinear transformation of the original scoring of each nominal variable that optimizes some aspect of the covariance matrix of the transformed variables. For example, PROC PRINQUAL could be used to find scorings that maximize the fit of a principal component model with one component. PROC CORRESP uses the crosstabulations of nominal variables, not covariances, and produces multiple scores for each category of each nominal variable. The main conceptual difference between PROC PRINQUAL and PROC CORRESP is that PROC PRINQUAL assumes that the categories of a nominal variable correspond to values of a single underlying interval variable, whereas PROC CORRESP assumes that there are multiple underlying interval variables and therefore uses different category scores for each dimension of the correspondence analysis. Scores from PROC CORRESP on the first dimension match the single set of PROC PRINQUAL scores (with appropriate standardizations for both analyses).

Comparison of the TRANSREG and PRINQUAL Procedures

Both the TRANSREG and PRINQUAL procedures are data transformation procedures that have many of the same transformations. These procedures can either directly perform the specified transformation (such as taking the logarithm of the variable) or search for an optimal transformation (such as a spline with a specified number of knots). Both procedures can use an iterative, alternating least squares analysis. Both procedures create an output data set that can be used as input to other procedures. PROC PRINQUAL displays relatively little output, whereas PROC TRANSREG displays many results. PROC TRANSREG has two sets of variables, usually dependent and independent, and it fits linear models such as ordinary regression and ANOVA, multiple and multivariate regression, metric and nonmetric conjoint analysis, metric and nonmetric vector and ideal point preference mapping, redundancy analysis, canonical correlation, and response surface regression. In contrast, PROC PRINQUAL has one set of variables, fits a principal component model or multidimensional preference analysis, and can also optimize other properties of a correlation or covariance matrix. PROC TRANSREG performs hypothesis testing and can be used to code experimental

designs prior to their use in other analyses. PROC TRANSREG can also perform Box-Cox transformations and fit models with smoothing spline and penalized B-spline transformations.

See Chapter 4, "Introduction to Regression Procedures," for comparisons of the TRANSREG and REG procedures.

Chapter 10

Introduction to Discriminant Procedures

Contents

Overview: Discriminant Procedures

The SAS procedures for discriminant analysis fit data with one classification variable and several quantitative variables. The purpose of discriminant analysis can be to find one or more of the following:

- a mathematical rule, or *discriminant function*, for guessing to which class an observation belongs, based on knowledge of the quantitative variables only
- a set of linear combinations of the quantitative variables that best reveals the differences among the classes
- a subset of the quantitative variables that best reveals the differences among the classes

The SAS discriminant procedures are as follows:

DISCRIM computes various discriminant functions for classifying observations. Linear or quadratic discriminant functions can be used for data with approximately multivariate normal within-class distributions. Nonparametric methods can be used without making any assumptions about these distributions.

CANDISC performs a canonical analysis to find linear combinations of the quantitative variables that best summarize the differences among the classes.

STEPDISC uses forward selection, backward elimination, or stepwise selection to try to find a subset of quantitative variables that best reveals differences among the classes.

Background: Discriminant Procedures

The term *discriminant analysis* (Fisher 1936; Cooley and Lohnes 1971; Tatsuoka 1971; Kshirsagar 1972; Lachenbruch 1975, 1979; Gnanadesikan 1977; Klecka 1980; Hand 1981, 1982; Silverman 1986) refers to several different types of analyses. Classificatory discriminant analysis is used to classify observations into two or more known groups on the basis of one or more quantitative variables. Classification can be done by either a parametric method or a nonparametric method in the DISCRIM procedure. A parametric method is appropriate only for approximately normal within-class distributions. The method generates either a linear discriminant function (the within-class covariance matrices are assumed to be equal) or a quadratic discriminant function (the within-class covariance matrices are assumed to be unequal).

When the distribution within each group is not assumed to have any specific distribution or is assumed to have a distribution different from the multivariate normal distribution, nonparametric methods can be used to derive classification criteria. These methods include the kernel method and nearest-neighbor methods. The kernel method uses uniform, normal, Epanechnikov, biweight, or triweight kernels in estimating the group-specific density at each observation. The within-group covariance matrices or the pooled covariance matrix can be used to scale the data.

The performance of a discriminant function can be evaluated by estimating error rates (probabilities of misclassification). Error count estimates and posterior probability error rate estimates can be evaluated with PROC DISCRIM. When the input data set is an ordinary SAS data set, the error rates can also be estimated by cross validation.

In multivariate statistical applications, the data collected are largely from distributions different from the normal distribution. Various forms of nonnormality can arise, such as qualitative variables or variables with underlying continuous but nonnormal distributions. If the multivariate normality assumption is violated, the use of parametric discriminant analysis might not be appropriate. When a parametric classification criterion (linear or quadratic discriminant function) is derived from a nonnormal population, the resulting error rate estimates might be biased.

If your quantitative variables are not normally distributed, or if you want to classify observations on the basis of categorical variables, you should consider using the CATMOD or LOGISTIC procedure to fit a categorical linear model with the classification variable as the dependent variable. Press and Wilson (1978) compare logistic regression and parametric discriminant analysis and conclude that logistic regression is preferable to parametric discriminant analysis in cases for which the variables do not have multivariate normal distributions within classes. However, if you do have normal within-class distributions, logistic regression is less efficient than parametric discriminant analysis. Efron (1975) shows that with two normal populations having a common covariance matrix, logistic regression is between one-half and two-thirds as effective as the linear discriminant function in achieving asymptotically the same error rate.

Do not confuse discriminant analysis with cluster analysis. All varieties of discriminant analysis require prior knowledge of the classes, usually in the form of a sample from each class. In cluster analysis, the data do not include information about class membership; the purpose is to construct a classification. See Chapter 11, "Introduction to Clustering Procedures."

Canonical discriminant analysis is a dimension-reduction technique related to principal components and canonical correlation, and it can be performed by both the CANDISC and DISCRIM procedures. A discriminant criterion is always derived in PROC DISCRIM. If you want canonical discriminant analysis without the use of a discriminant criterion, you should use PROC CANDISC. Stepwise discriminant analysis is a variable-selection technique implemented by the STEPDISC procedure. After selecting a subset of variables with PROC STEPDISC, use any of the other discriminant procedures to obtain more detailed analyses. PROC CANDISC and PROC STEPDISC perform hypothesis tests that require the within-class distributions to be approximately normal, but these procedures can be used descriptively with nonnormal data.

Another alternative to discriminant analysis is to perform a series of univariate one-way ANOVAs. All three discriminant procedures provide summaries of the univariate ANOVAs. The advantage of the multivariate approach is that two or more classes that overlap considerably when each variable is viewed separately might be more distinct when examined from a multivariate point of view.

Example: Contrasting Univariate and Multivariate Analyses

Consider an artificial data set with two classes of observations indicated by 'H' and 'O'. The following statements generate and plot the data:

```
data random;
   drop n;

   Group = 'H';
   do n = 1 to 20;
      x = 4.5 + 2 * normal(57391);
      y = x + .5 + normal(57391);
      output;
   end;

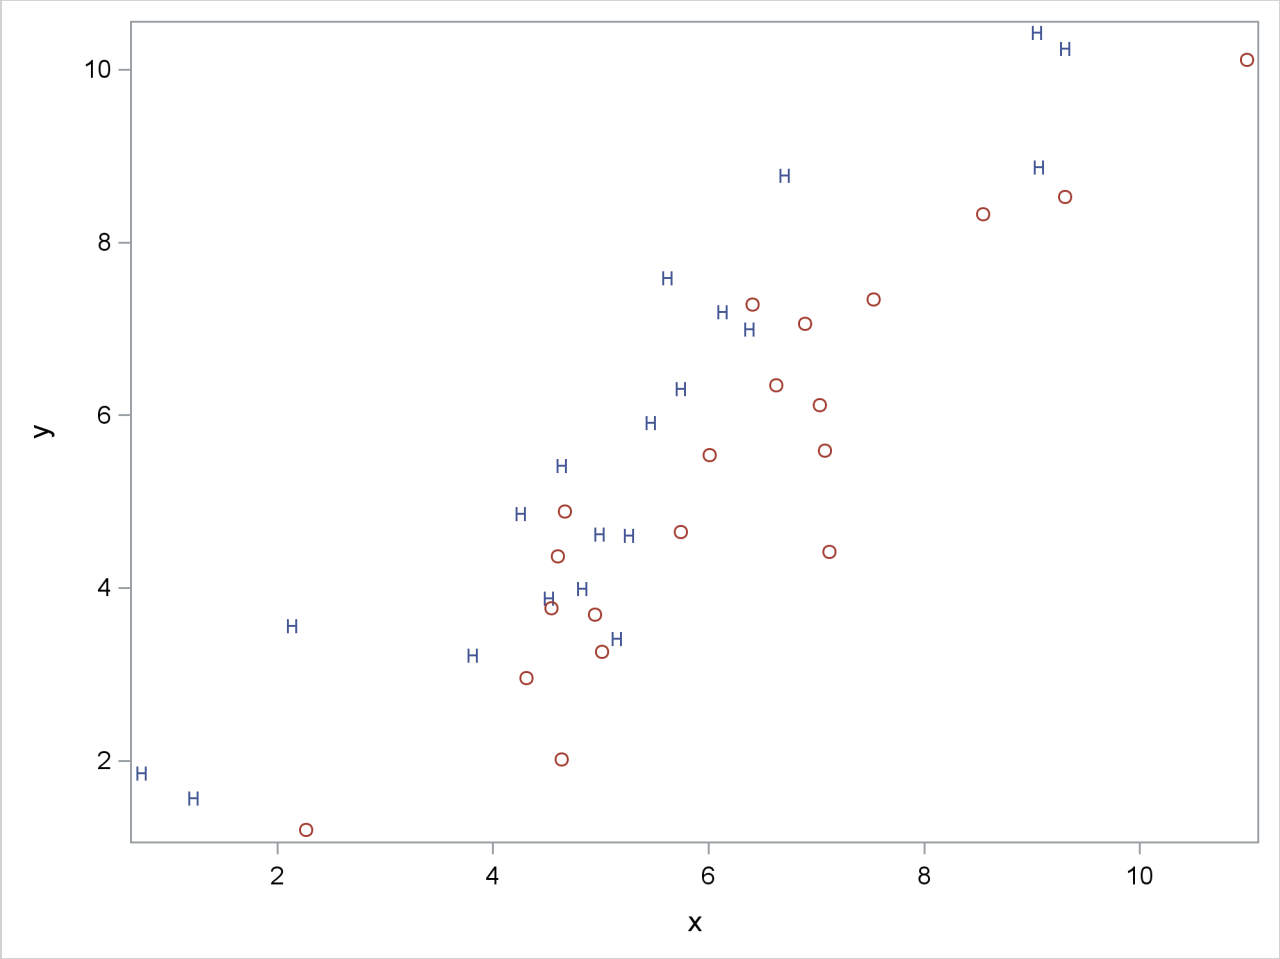
   Group = 'O';
   do n = 1 to 20;
      x = 6.25 + 2 * normal(57391);
      y = x - 1 + normal(57391);
      output;
   end;

run;

proc sgplot noautolegend;
   scatter y=y x=x / markerchar=group group=group;
run;
```

The plot is shown in Figure 10.1.

Figure 10.1 Groups for Contrasting Univariate and Multivariate Analyses



The following statements perform a canonical discriminant analysis and display the results in Figure 10.2:

```
proc candisc anova;
   class Group;
   var x y;
run;
```

Figure 10.2 Contrasting Univariate and Multivariate Analyses

The CANDISC Procedure

Pooled Within-Class Standardized Canonical Coefficients

Variable	Can1
x	-2.592150014
y	2.474116072

Raw Canonical Coefficients

Variable	Can1
x	-1.205756217
y	1.010412967

Class Means on Canonical Variables

Group	Can1
H	0.7277811475
O	-.7277811475

The univariate R squares are very small, 0.0503 for x and 0.0037 for y, and neither variable shows a significant difference between the classes at the 0.10 level.

The multivariate test for differences between the classes is significant at the 0.0003 level. Thus, the multivariate analysis has found a highly significant difference, whereas the univariate analyses failed to achieve even the 0.10 level. The raw canonical coefficients for the first canonical variable, Can1, show that the classes differ most widely on the linear combination -1.205756217 x + 1.010412967 y or approximately y - 1.2 x. The R square between Can1 and the class variable is 0.357963 as given by the squared canonical correlation, which is much higher than either univariate R square.

In this example, the variables are highly correlated within classes. If the within-class correlation were smaller, there would be greater agreement between the univariate and multivariate analyses.

Chapter 11

Introduction to Clustering Procedures

Contents

Overview: Clustering Procedures

You can use SAS clustering procedures to cluster the observations or the variables in a SAS data set. Both hierarchical and disjoint clusters can be obtained. Only numeric variables can be analyzed directly by the procedures, although the DISTANCE procedure can compute a distance matrix that uses character or numeric variables.

The purpose of cluster analysis is to place objects into groups, or clusters, suggested by the data, not defined a priori, such that objects in a given cluster tend to be similar to each other in some sense, and objects in different clusters tend to be dissimilar. You can also use cluster analysis to summarize data rather than to find "natural" or "real" clusters; this use of clustering is sometimes called *dissection* (Everitt 1980).

Any generalization about cluster analysis must be vague because a vast number of clustering methods have been developed in several different fields, with different definitions of clusters and similarity among objects. The variety of clustering techniques is reflected by the variety of terms used for cluster analysis: botryology, classification, clumping, competitive learning, morphometrics, nosography, nosology, numerical taxonomy, partitioning, Q-analysis, systematics, taximetrics, taxonorics, typology, unsupervised pattern recognition, vector quantization, and winner-take-all learning. Good (1977) has also suggested aciniformics and agminatics.

Several types of clusters are possible:

- Disjoint clusters place each object in one and only one cluster.
- Hierarchical clusters are organized so that one cluster can be entirely contained within another cluster, but no other kind of overlap between clusters is allowed.
- Overlapping clusters can be constrained to limit the number of objects that belong simultaneously to two clusters, or they can be unconstrained, allowing any degree of overlap in cluster membership.
- Fuzzy clusters are defined by a probability or grade of membership of each object in each cluster. Fuzzy clusters can be disjoint, hierarchical, or overlapping.

The data representations of objects to be clustered also take many forms. The most common are as follows:

- a square distance or similarity matrix, in which both rows and columns correspond to the objects to be clustered. A correlation matrix is an example of a similarity matrix.
- a coordinate matrix, in which the rows are observations and the columns are variables, as in the usual SAS multivariate data set. The observations, the variables, or both can be clustered.

The SAS procedures for clustering are oriented toward disjoint or hierarchical clusters from coordinate data, distance data, or a correlation or covariance matrix. The following procedures are used for clustering:

CLUSTER	performs hierarchical clustering of observations by using eleven agglomerative methods applied to coordinate data or distance data and draws tree diagrams, which are also called *dendrograms* or *phenograms*.
FASTCLUS	finds disjoint clusters of observations by using a *k*-means method applied to coordinate data. PROC FASTCLUS is especially suitable for large data sets.
MODECLUS	finds disjoint clusters of observations with coordinate or distance data by using nonparametric density estimation. It can also perform approximate nonparametric significance tests for the number of clusters.
VARCLUS	performs both hierarchical and disjoint clustering of variables by using oblique multiple-group component analysis and draws tree diagrams, which are also called *dendrograms* or *phenograms*.
TREE	draws tree diagrams, also called *dendrograms* or *phenograms*, by using output from the CLUSTER or VARCLUS procedure. PROC TREE can also create a data set indicating cluster membership at any specified level of the cluster tree.

The following procedures are useful for processing data prior to the actual cluster analysis:

ACECLUS	attempts to estimate the pooled within-cluster covariance matrix from coordinate data without knowledge of the number or the membership of the clusters (Art, Gnanadesikan, and Kettenring 1982). PROC ACECLUS outputs a data set containing canonical variable scores to be used in the cluster analysis proper.

DISTANCE computes various measures of distance, dissimilarity, or similarity between the observations (rows) of a SAS data set. PROC DISTANCE also provides various nonparametric and parametric methods for standardizing variables. Different variables can be standardized with different methods.

PRINCOMP performs a principal component analysis and outputs principal component scores.

STDIZE standardizes variables by using any of a variety of location and scale measures, including mean and standard deviation, minimum and range, median and absolute deviation from the median, various M-estimators and A-estimators, and some scale estimators designed specifically for cluster analysis.

Massart and Kaufman (1983) is the best elementary introduction to cluster analysis. Other important texts are Anderberg (1973), Sneath and Sokal (1973), Duran and Odell (1974), Hartigan (1975) Titterington, Smith, and Makov (1985), McLachlan and Basford (1988), and Kaufman and Rousseeuw (1990). Hartigan (1975) and Spath (1980) give numerous FORTRAN programs for clustering. Any prospective user of cluster analysis should study the Monte Carlo results of Milligan (1980), Milligan and Cooper (1985), and Cooper and Milligan (1988). Important references on the statistical aspects of clustering include MacQueen (1967), Wolfe (1970), Scott and Symons (1971), Hartigan (1977, 1978, 1981, 1985a), Symons (1981), Everitt (1981) Sarle (1983), Bock (1985), and Thode, Mendell, and Finch (1988). Bayesian methods have important advantages over maximum likelihood; see Binder (1978, 1981), Banfield and Raftery (1993), and Bensmail et al. (1997). For fuzzy clustering, see Bezdek (1981) and Bezdek and Pal (1992). The signal-processing perspective is provided by Gersho and Gray (1992). See Blashfield and Aldenderfer (1978) for a discussion of the fragmented state of the literature on cluster analysis.

Clustering Variables

Factor rotation is often used to cluster variables, but the resulting clusters are fuzzy. It is preferable to use PROC VARCLUS if you want hard (nonfuzzy), disjoint clusters. Factor rotation is better if you want to be able to find overlapping clusters. It is often a good idea to try both PROC VARCLUS and PROC FACTOR with an oblique rotation, compare the amount of variance explained by each, and see how fuzzy the factor loadings are and whether there seem to be overlapping clusters.

You can use PROC VARCLUS to harden a fuzzy factor rotation; use PROC FACTOR to create an output data set containing scoring coefficients and initialize PROC VARCLUS with this data set as follows:

```
proc factor rotate=promax score outstat=fact;
run;

proc varclus initial=input proportion=0;
run;
```

You can use any rotation method instead of the PROMAX method. The SCORE and OUTSTAT= options are necessary in the PROC FACTOR statement. PROC VARCLUS reads the correlation matrix from the data set created by PROC FACTOR. The INITIAL=INPUT option tells PROC VARCLUS to read initial scoring coefficients from the data set. The option PROPORTION=0 keeps PROC VARCLUS from splitting any of the clusters.

Clustering Observations

PROC CLUSTER is easier to use than PROC FASTCLUS because one run produces results from one cluster up to as many as you like. You must run PROC FASTCLUS once for each number of clusters.

The time required by PROC FASTCLUS is roughly proportional to the number of observations, whereas the time required by PROC CLUSTER with most methods varies with the square or cube of the number of observations. Therefore, you can use PROC FASTCLUS with much larger data sets than PROC CLUSTER.

If you want to hierarchically cluster a data set that is too large to use with PROC CLUSTER directly, you can have PROC FASTCLUS produce, for example, 50 clusters, and let PROC CLUSTER analyze these 50 clusters instead of the entire data set. The MEAN= data set produced by PROC FASTCLUS contains two special variables:

- The variable _FREQ_ gives the number of observations in the cluster.
- The variable _RMSSTD_ gives the root mean square across variables of the cluster standard deviations.

These variables are automatically used by PROC CLUSTER to give the correct results when clustering clusters. For example, you could specify Ward's minimum variance method Ward (1963):

```
proc fastclus maxclusters=50 mean=temp;
   var x y z;
run;

ods graphics on;
proc cluster method=ward outtree=tree;
   var x y z;
run;
```

Or you could specify Wong's hybrid method (Wong 1982):

```
proc fastclus maxclusters=50 mean=temp;
   var x y z;
run;

ods graphics on;
proc cluster method=density hybrid outtree=tree;
   var x y z;
run;
```

More detailed examples are given in Chapter 30, "The CLUSTER Procedure."

Characteristics of Methods for Clustering Observations

Many simulation studies comparing various methods of cluster analysis have been performed. In these studies, artificial data sets containing known clusters are produced using pseudo-random-number generators. The data sets are analyzed by a variety of clustering methods, and the degree to which each clustering method recovers the known cluster structure is evaluated. See Milligan (1981) for a review of such studies. In most of these studies, the clustering method with the best overall performance has been either average linkage or Ward's minimum variance method. The method with the poorest overall performance has almost invariably been single linkage. However, in many respects, the results of simulation studies are inconsistent and confusing.

When you attempt to evaluate clustering methods, it is essential to realize that most methods are biased toward finding clusters possessing certain characteristics related to size (number of members), shape, or dispersion. Methods based on the least squares criterion (Sarle 1982), such as *k*-means and Ward's minimum variance method, tend to find clusters with roughly the same number of observations in each cluster. Average linkage is somewhat biased toward finding clusters of equal variance. Many clustering methods tend to produce compact, roughly hyperspherical clusters and are incapable of detecting clusters with highly elongated or irregular shapes. The methods with the least bias are those based on nonparametric density estimation such as single linkage and density linkage.

Most simulation studies have generated compact (often multivariate normal) clusters of roughly equal size or dispersion. Such studies naturally favor average linkage and Ward's method over most other hierarchical methods, especially single linkage. It would be easy, however, to design a study that uses elongated or irregular clusters in which single linkage would perform much better than average linkage or Ward's method (see some of the following examples). Even studies that compare clustering methods that use "realistic" data might unfairly favor particular methods. For example, in all the data sets used by Mezzich and Solomon (1980), the clusters established by field experts are of equal size. When interpreting simulation or other comparative studies, you must, therefore, decide whether the artificially generated clusters in the study resemble the clusters you suspect might exist in your data in terms of size, shape, and dispersion. If, like many people doing exploratory cluster analysis, you have no idea what kinds of clusters to expect, you should include at least one of the relatively unbiased methods, such as density linkage, in your analysis.

The rest of this section consists of a series of examples that illustrate the performance of various clustering methods under various conditions. The first, and simplest, example shows a case of well-separated clusters. The other examples show cases of poorly separated clusters, clusters of unequal size, parallel elongated clusters, and nonconvex clusters.

Well-Separated Clusters

If the population clusters are sufficiently well separated, almost any clustering method performs well, as demonstrated in the following example, which uses single linkage. In this and subsequent examples, the output from the clustering procedures is not shown, but cluster membership is displayed in scatter plots. The SAS autocall macro MODSTYLE is specified to change the default marker symbols for the plot. For more information about autocall libraries, see *SAS Macro Language: Reference*. The following SAS statements produce Figure 11.1:

```
data compact;
   keep x y;
   n=50; scale=1;
   mx=0; my=0; link generate;
   mx=8; my=0; link generate;
   mx=4; my=8; link generate;
   stop;
generate:
   do i=1 to n;
      x=rannor(1)*scale+mx;
      y=rannor(1)*scale+my;
      output;
   end;
   return;
run;

proc cluster data=compact outtree=tree method=single noprint;
run;

proc tree noprint out=out n=3;
   copy x y;
run;

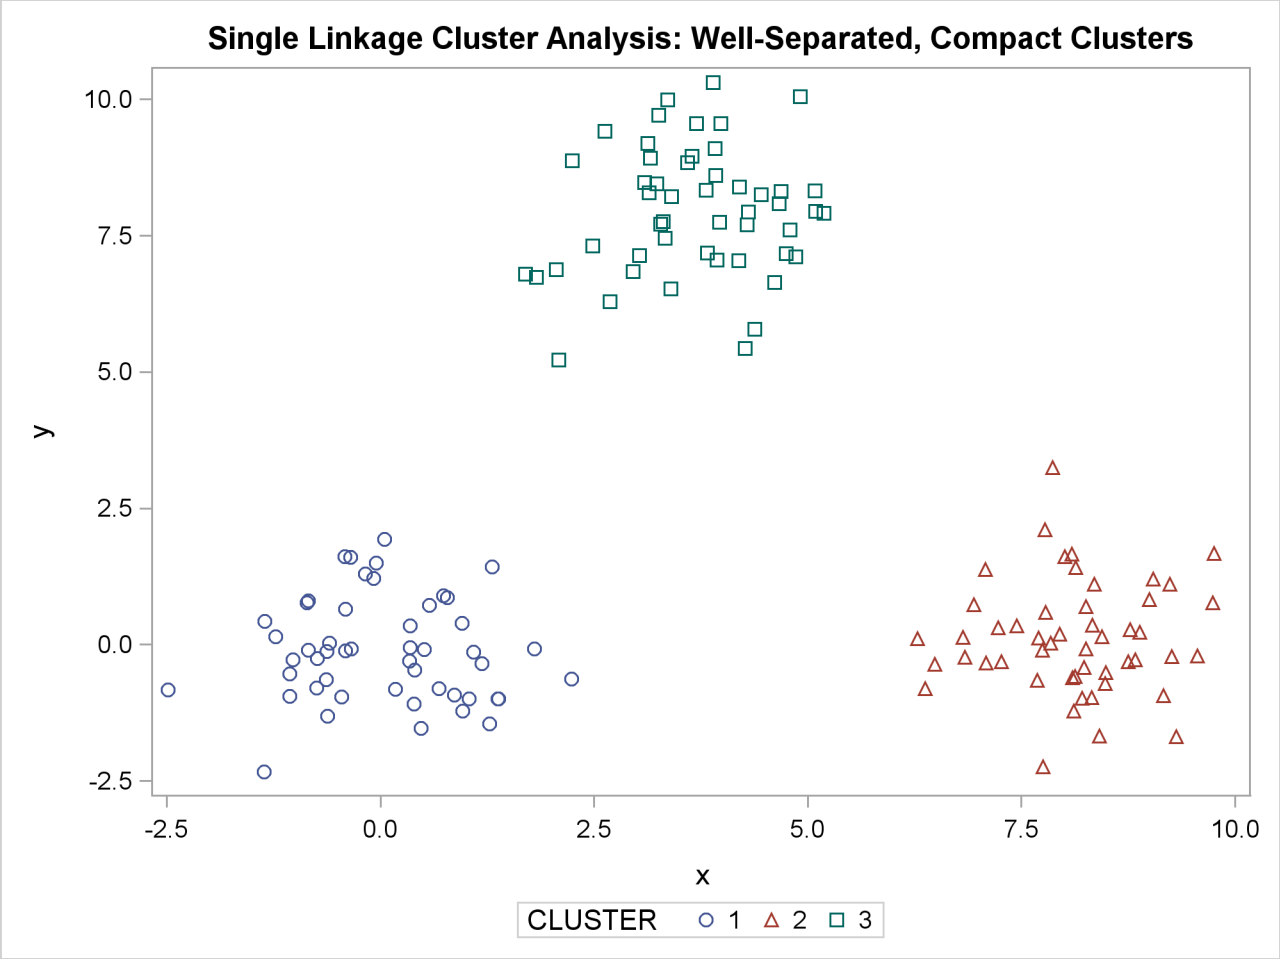
   title 'Single Linkage Cluster Analysis: '
         'Well-Separated, Compact Clusters';
run;
```

Figure 11.1 Well-Separated, Compact Clusters: PROC CLUSTER METHOD=SINGLE



Poorly Separated Clusters

To see how various clustering methods differ, you must examine a more difficult problem than that of the previous example.

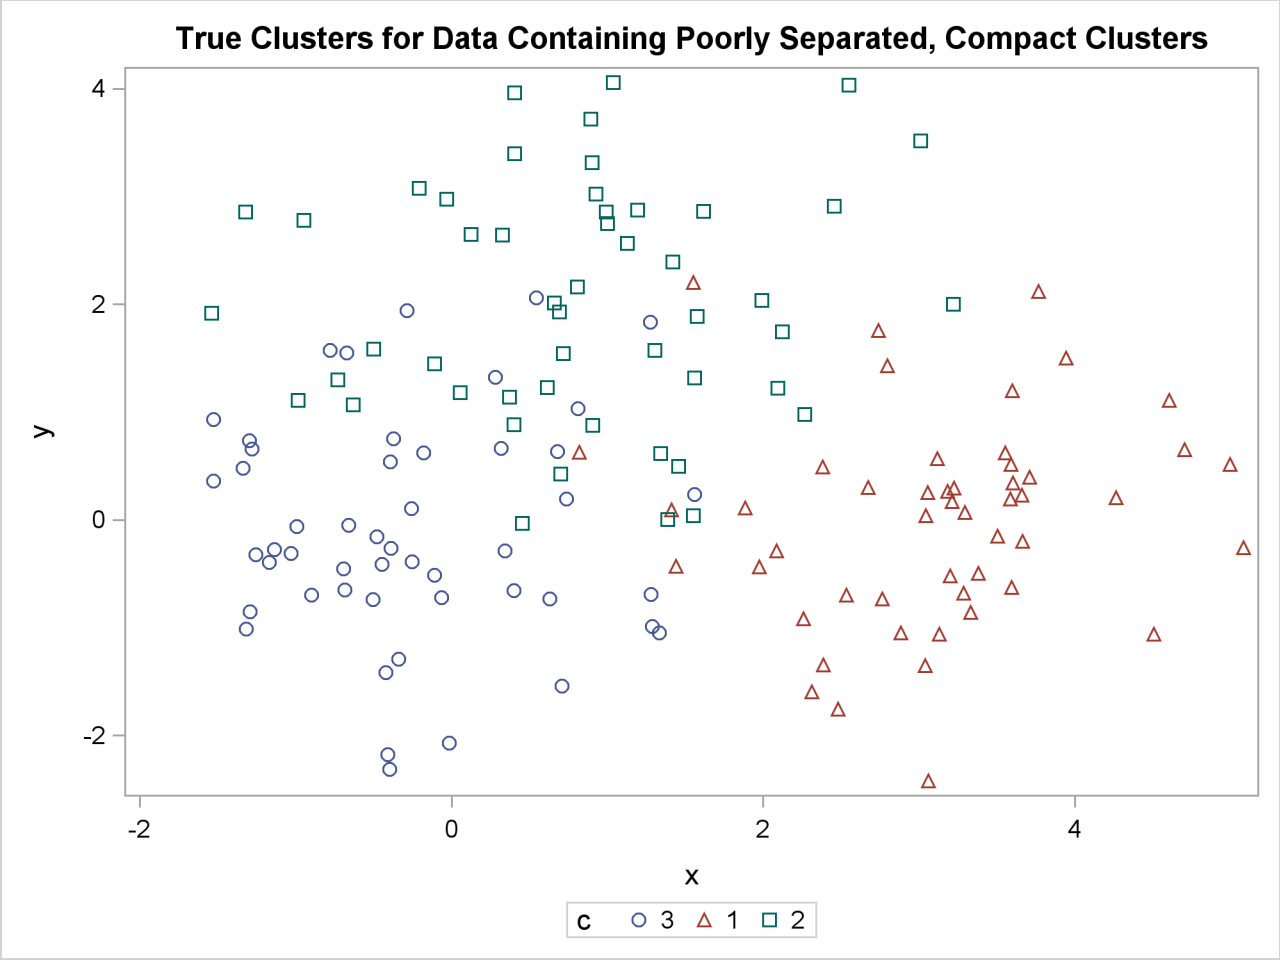
The following data set is similar to the first except that the three clusters are much closer together. This example demonstrates the use of PROC FASTCLUS and five hierarchical methods available in PROC CLUSTER. To help you compare methods, this example plots true, generated clusters. Also included is a bubble plot of the density estimates obtained in conjunction with two-stage density linkage in PROC CLUSTER.

The following SAS statements produce Figure 11.2:

```
data closer;
   keep x y c;
   n=50; scale=1;
   mx=0; my=0; c=3; link generate;
   mx=3; my=0; c=1; link generate;
   mx=1; my=2; c=2; link generate;
   stop;
generate:
   do i=1 to n;
      x=rannor(9)*scale+mx;
      y=rannor(9)*scale+my;
      output;
   end;
   return;
run;

title 'True Clusters for Data Containing Poorly Separated, Compact Clusters';
proc sgplot;
   scatter y=y x=x / group=c ;
run;
```

Figure 11.2 Poorly Separated, Compact Clusters: Plot of True Clusters



The following statements use the FASTCLUS procedure to find three clusters and then use the SGPLOT procedure to plot the clusters. The following statements produce Figure 11.3:

```
proc fastclus data=closer out=out maxc=3 noprint;
   var x y;

         'Poorly Separated, Compact Clusters';
run;

proc sgplot;
   scatter y=y x=x / group=cluster;
run;
```

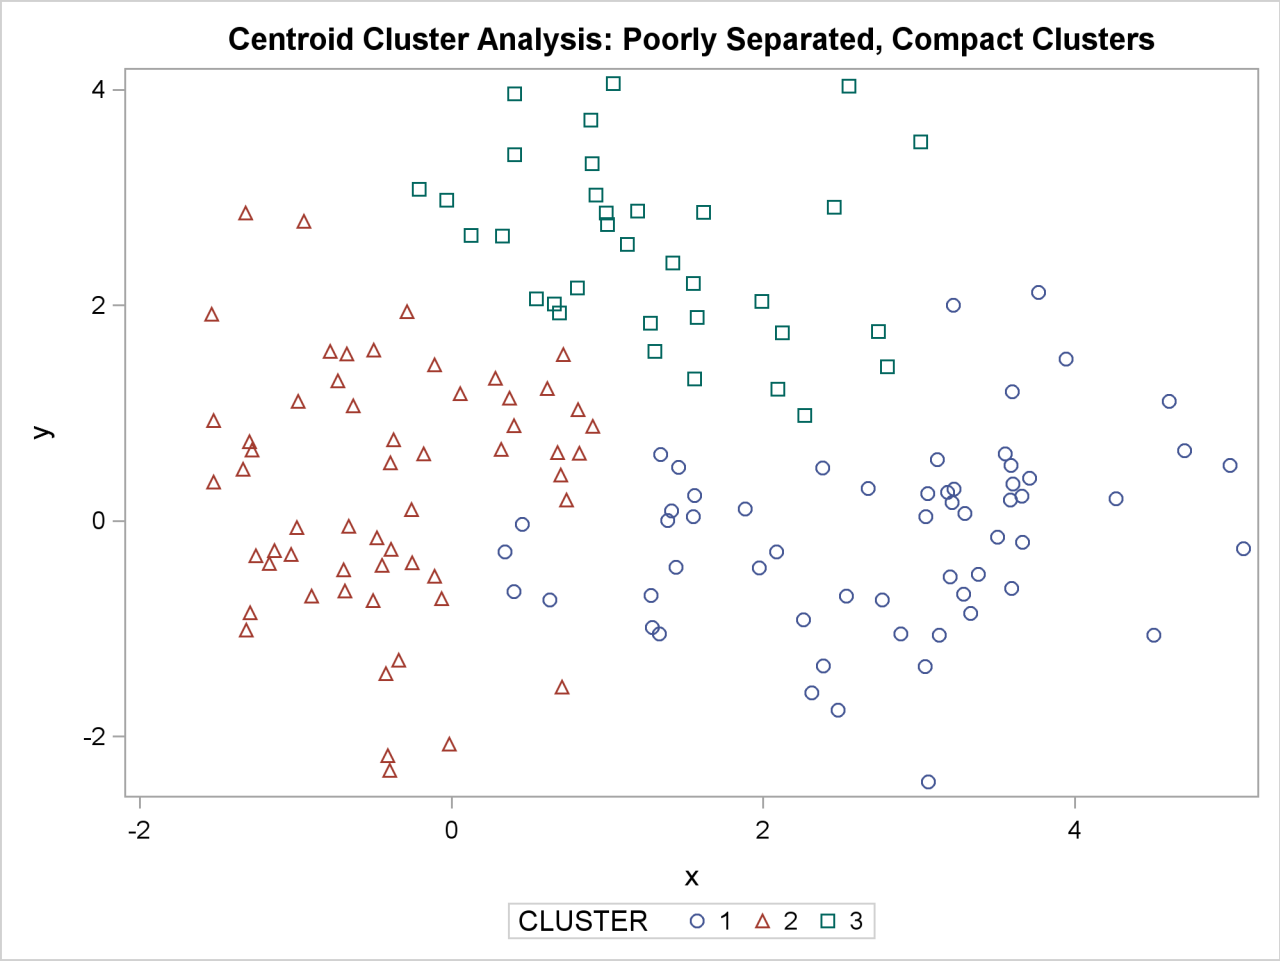
Figure 11.6 Poorly Separated, Compact Clusters: PROC CLUSTER METHOD=CENTROID



The following SAS statements produce Figure 11.7 and Figure 11.8:

```
proc cluster data=closer outtree=tree method=twostage k=10 noprint;
   var x y;
run;

proc tree noprint out=out n=3;
   copy x y _dens_;
   title 'Two-Stage Density Linkage Cluster Analysis: '
         'Poorly Separated, Compact Clusters';
run;

proc sgplot;
   scatter y=y x=x / group=cluster;
run;

proc sgplot;
   bubble y=y x=x size=_dens_ / nofill lineattrs=graphdatadefault;
   title 'Estimated Densities for Data Containing Poorly Separated, '
         'Compact Clusters';
run;
```

Figure 11.7 Poorly Separated, Compact Clusters: PROC CLUSTER METHOD=TWOSTAGE

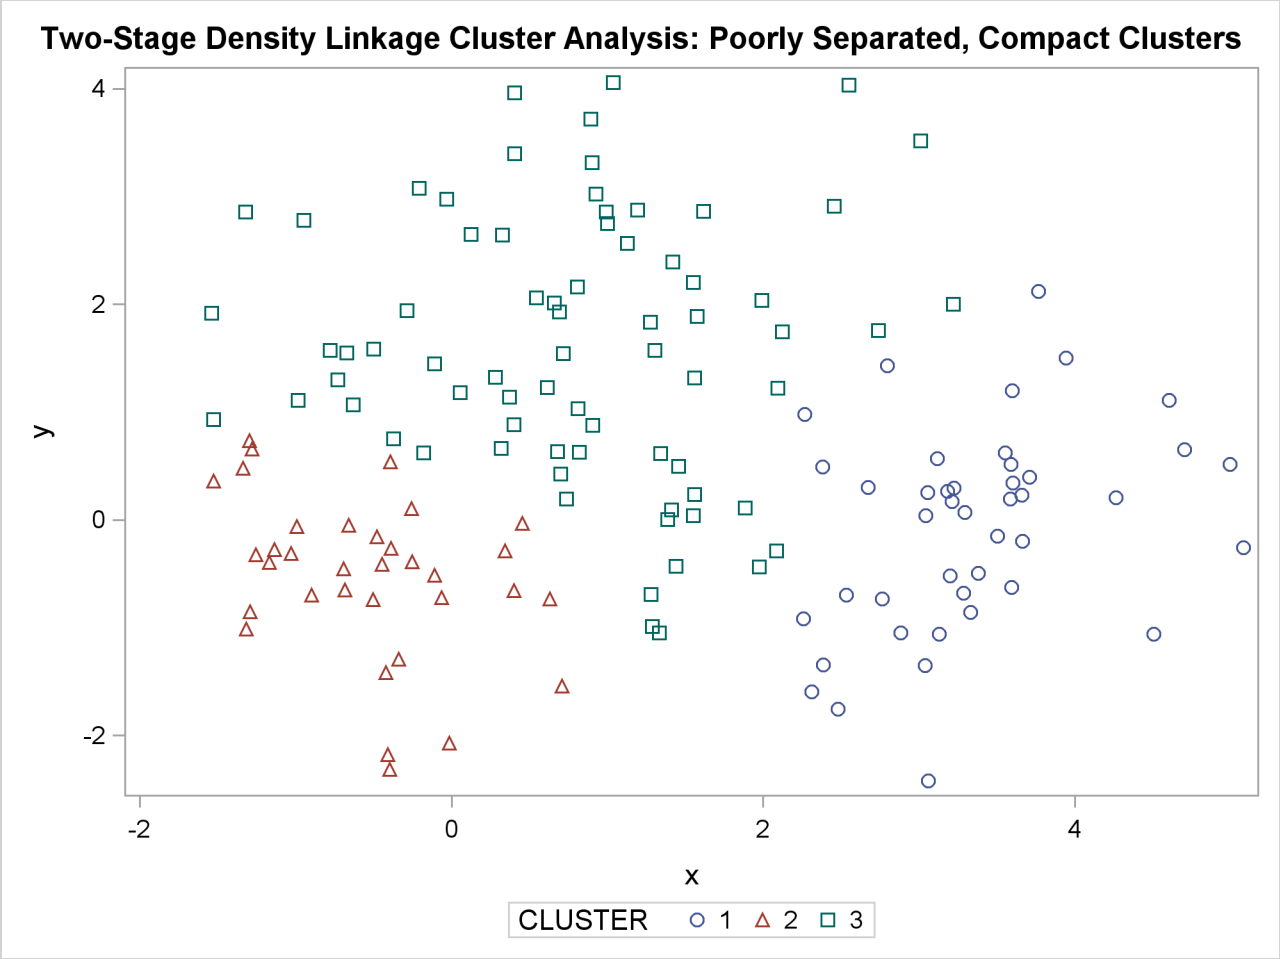


Figure 11.8 Poorly Separated, Compact Clusters: PROC CLUSTER METHOD=TWOSTAGE

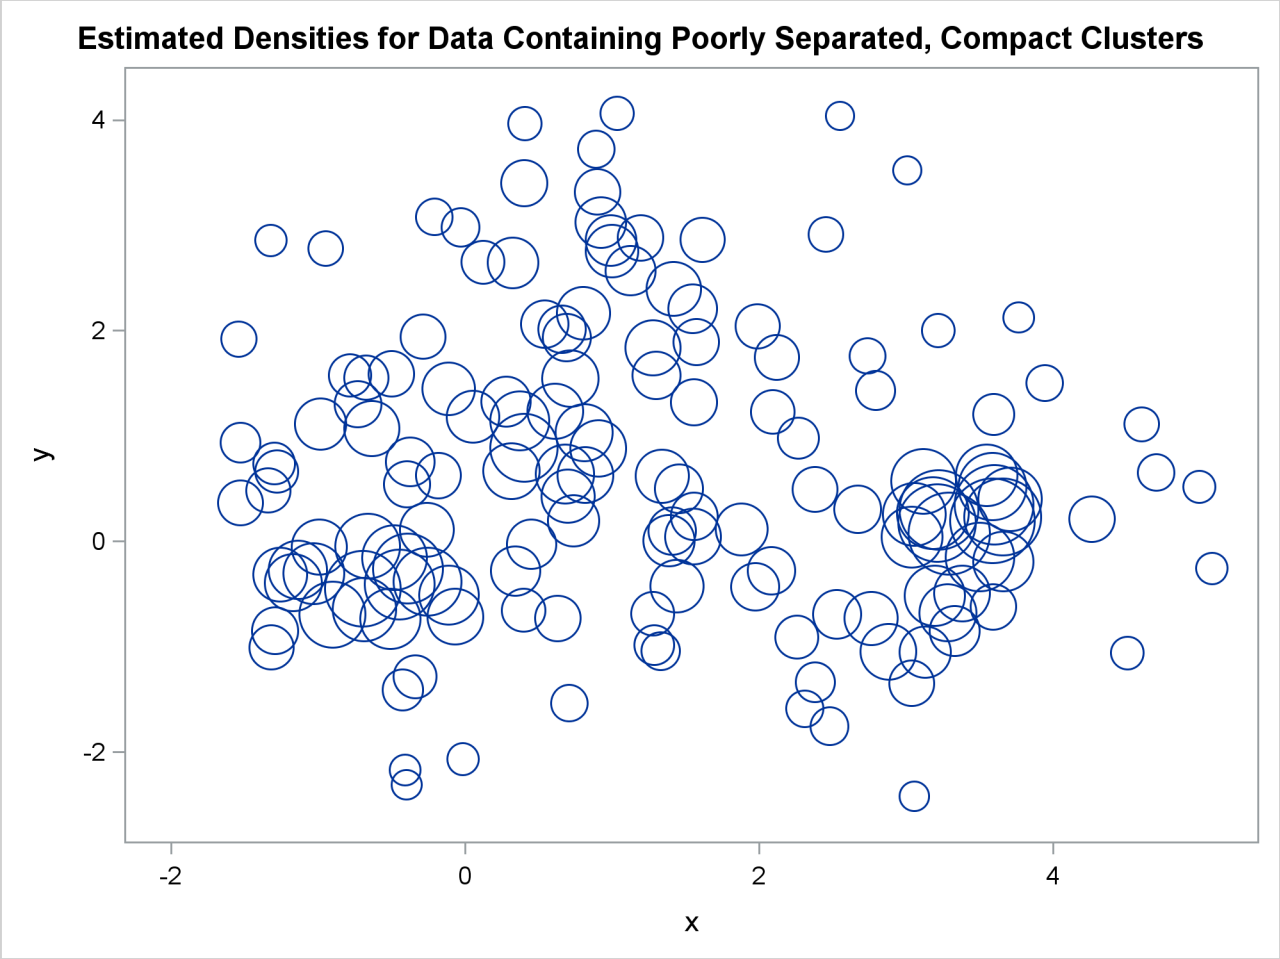


In two-stage density linkage, each cluster is a region surrounding a local maximum of the estimated probability density function. If you think of the estimated density function as a landscape with mountains and valleys, each mountain is a cluster, and the boundaries between clusters are placed near the bottoms of the valleys.

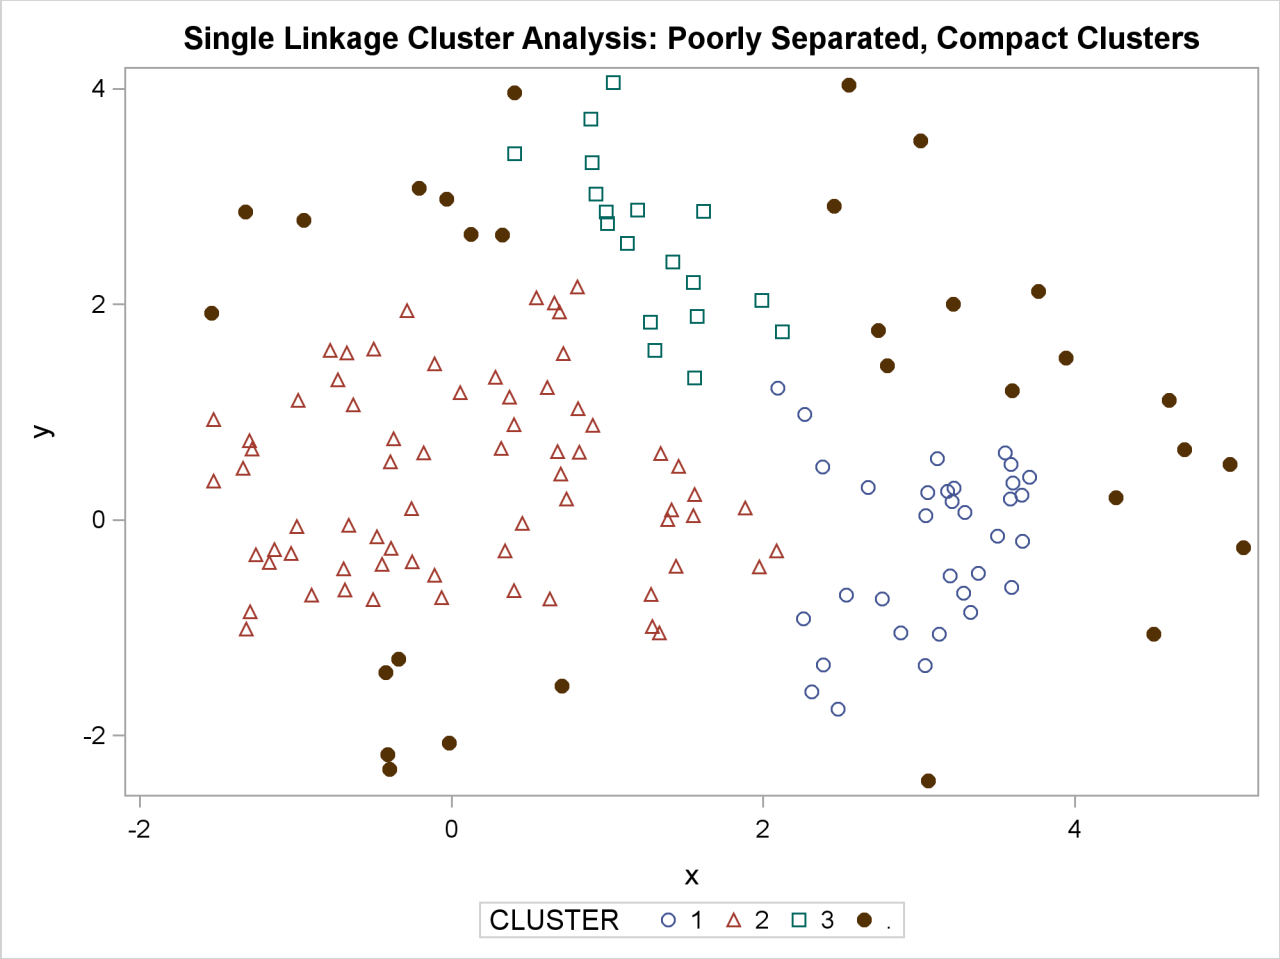
The following SAS statements produce Figure 11.9:

```
proc cluster data=closer outtree=tree method=single noprint;
   var x y;
run;

proc tree data=tree noprint out=out n=3 dock=5;
   copy x y;
   title 'Single Linkage Cluster Analysis: '
         'Poorly Separated, Compact Clusters';
run;

proc sgplot;
   scatter y=y x=x / group=cluster;
run;
```

Figure 11.9 Poorly Separated, Compact Clusters: PROC CLUSTER METHOD=SINGLE



The two least squares methods, PROC FASTCLUS and Ward's, yield the most uniform cluster sizes and the best recovery of the true clusters. This result is expected since these two methods are biased toward recovering compact clusters of equal size. With average linkage, the lower-left cluster is too large; with the centroid method, the lower-right cluster is too large; and with two-stage density linkage, the top cluster is too large. The single linkage analysis resembles average linkage except for the large number of outliers resulting from the DOCK= option in the PROC TREE statement; the outliers are plotted as filled circles (missing values).

Multinormal Clusters of Unequal Size and Dispersion

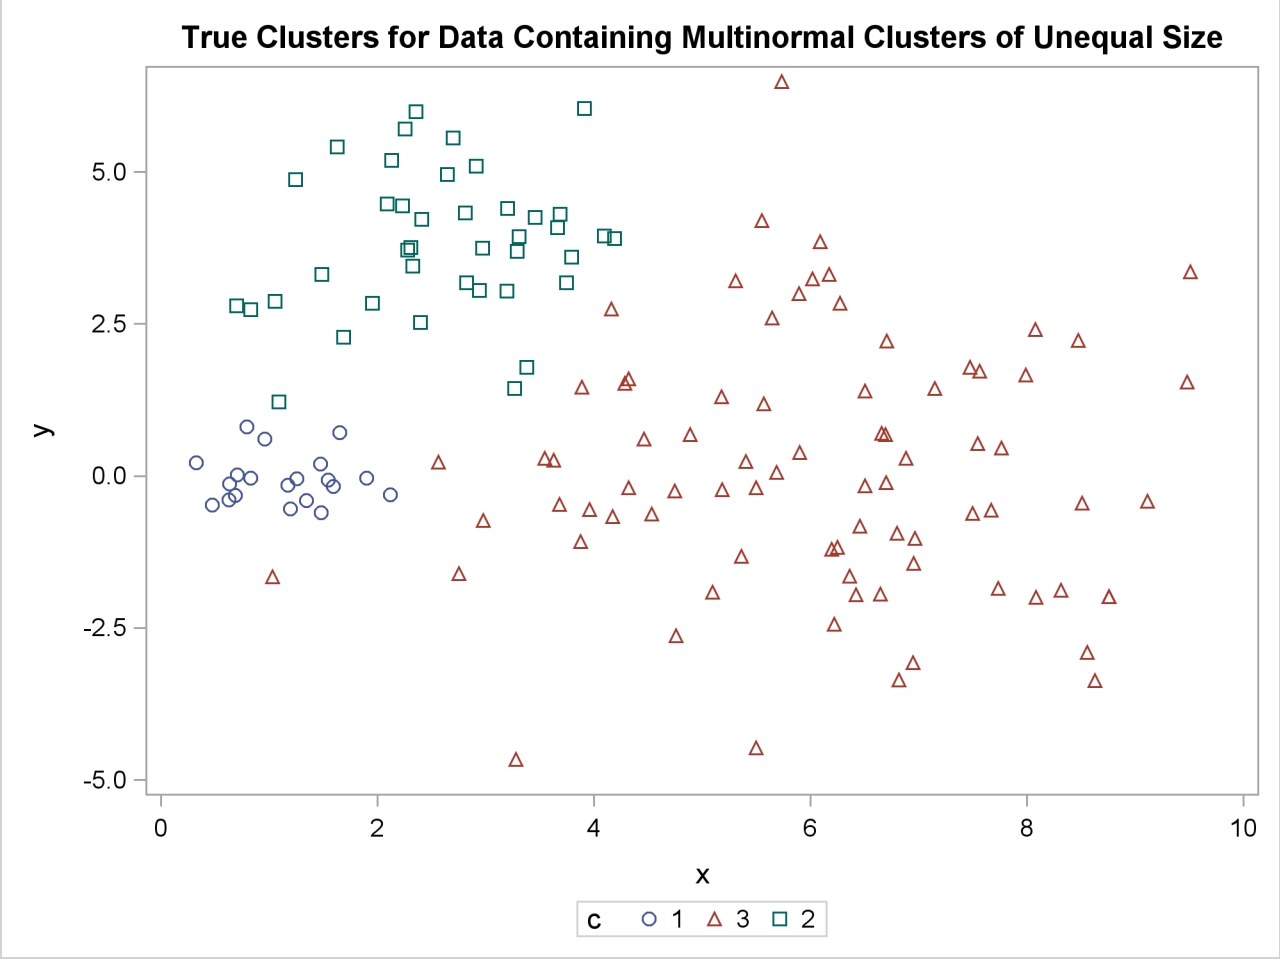
In this example, there are three multinormal clusters that differ in size and dispersion. PROC FASTCLUS and five of the hierarchical methods available in PROC CLUSTER are used. To help you compare methods, the true, generated clusters are plotted.

The following SAS statements produce Figure 11.10:

```
data unequal;
   keep x y c;
   mx=1; my=0; n=20; scale=.5; c=1; link generate;
   mx=6; my=0; n=80; scale=2.; c=3; link generate;
   mx=3; my=4; n=40; scale=1.; c=2; link generate;
   stop;
generate:
   do i=1 to n;
      x=rannor(1)*scale+mx;
      y=rannor(1)*scale+my;
      output;
   end;
   return;
run;

title 'True Clusters for Data Containing Multinormal Clusters of Unequal Size';
proc sgplot;
   scatter y=y x=x / group=c;
run;
```

Figure 11.10 Generated Clusters of Unequal Size



The following statements use the FASTCLUS procedure to find three clusters and then use the SGPLOT procedure to plot the clusters. The following statements produce Figure 11.11:

```
proc fastclus data=unequal out=out maxc=3 noprint;
   var x y;
   title 'FASTCLUS Analysis: Compact Clusters of Unequal Size';
run;

proc sgplot;

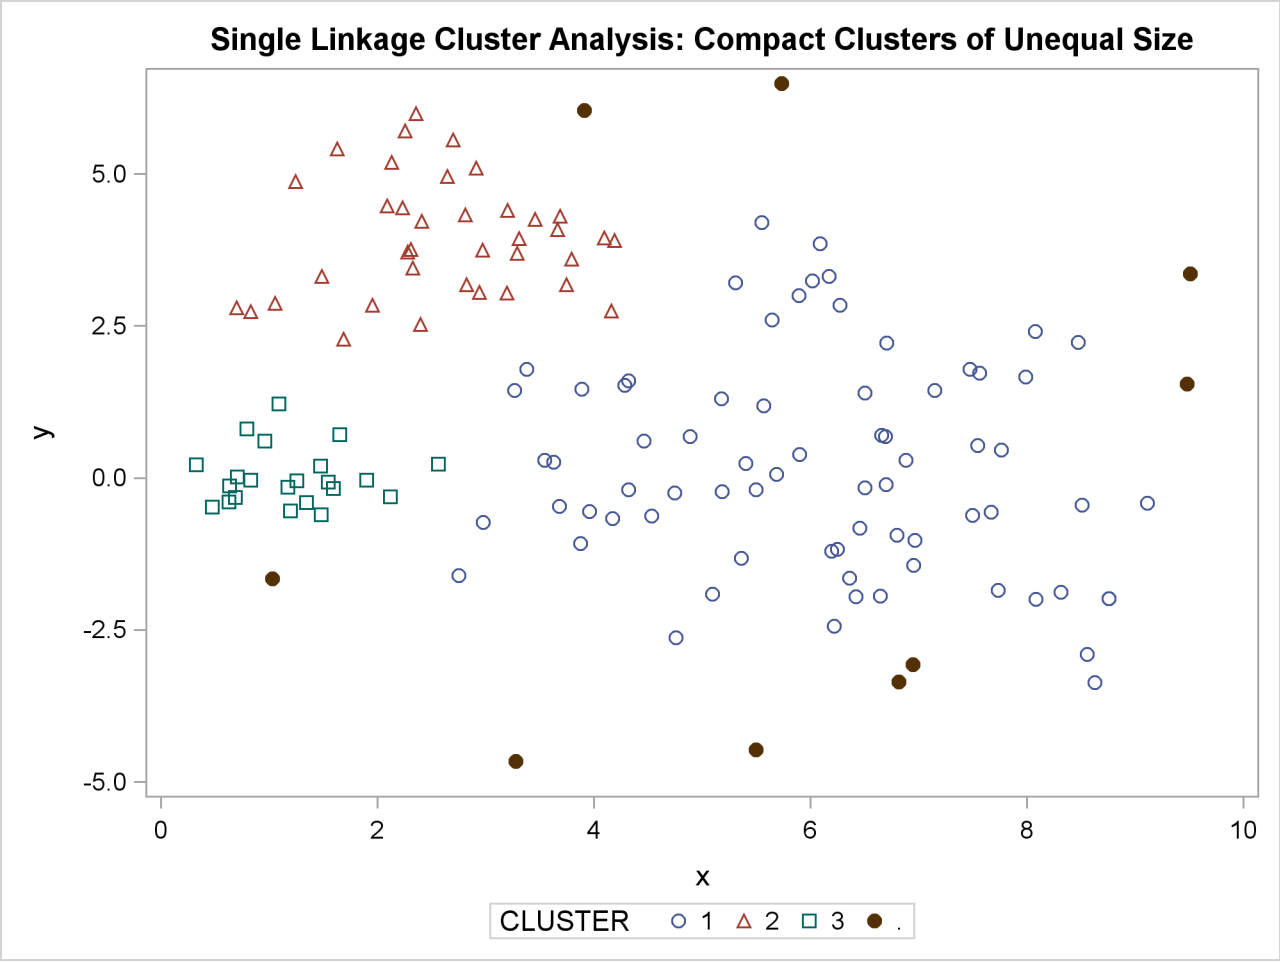
The following SAS statements produce Figure 11.17:

```
proc cluster data=unequal outtree=tree method=single noprint;
   var x y;
run;

proc tree data=tree noprint out=out n=3 dock=5;
   copy x y;
   title 'Single Linkage Cluster Analysis: '
         'Compact Clusters of Unequal Size';
run;

proc sgplot;
   scatter y=y x=x / group=cluster;
run;
```

Figure 11.17 Compact Clusters of Unequal Size: PROC CLUSTER METHOD=SINGLE



In the PROC FASTCLUS analysis, the smallest cluster, in the bottom-left portion of the plot, has stolen members from the other two clusters, and the upper-left cluster has also acquired some observations that rightfully belong to the larger, lower-right cluster. With Ward's method, the upper-left cluster is separated correctly, but the lower-left cluster has taken a large bite out of the lower-right cluster. For both of these

methods, the clustering errors are in accord with the biases of the methods to produce clusters of equal size. In the average linkage analysis, both the upper-left and lower-left clusters have encroached on the lower-right cluster, thereby making the variances more nearly equal than in the true clusters. The centroid method, which lacks the size and dispersion biases of the previous methods, obtains an essentially correct partition.

Two-stage density linkage does almost as well, even though the compact shapes of these clusters favor the traditional methods. Single linkage also produces excellent results.

Elongated Multinormal Clusters

In this example, the data are sampled from two highly elongated multinormal distributions with equal covariance matrices. The following SAS statements produce Figure 11.18:

```
data elongate;
   keep x y;
   ma=8; mb=0; link generate;
   ma=6; mb=8; link generate;
   stop;
generate:
   do i=1 to 50;
      a=rannor(7)*6+ma;
      b=rannor(7)+mb;
      x=a-b;
      y=a+b;
      output;
   end;
   return;
run;

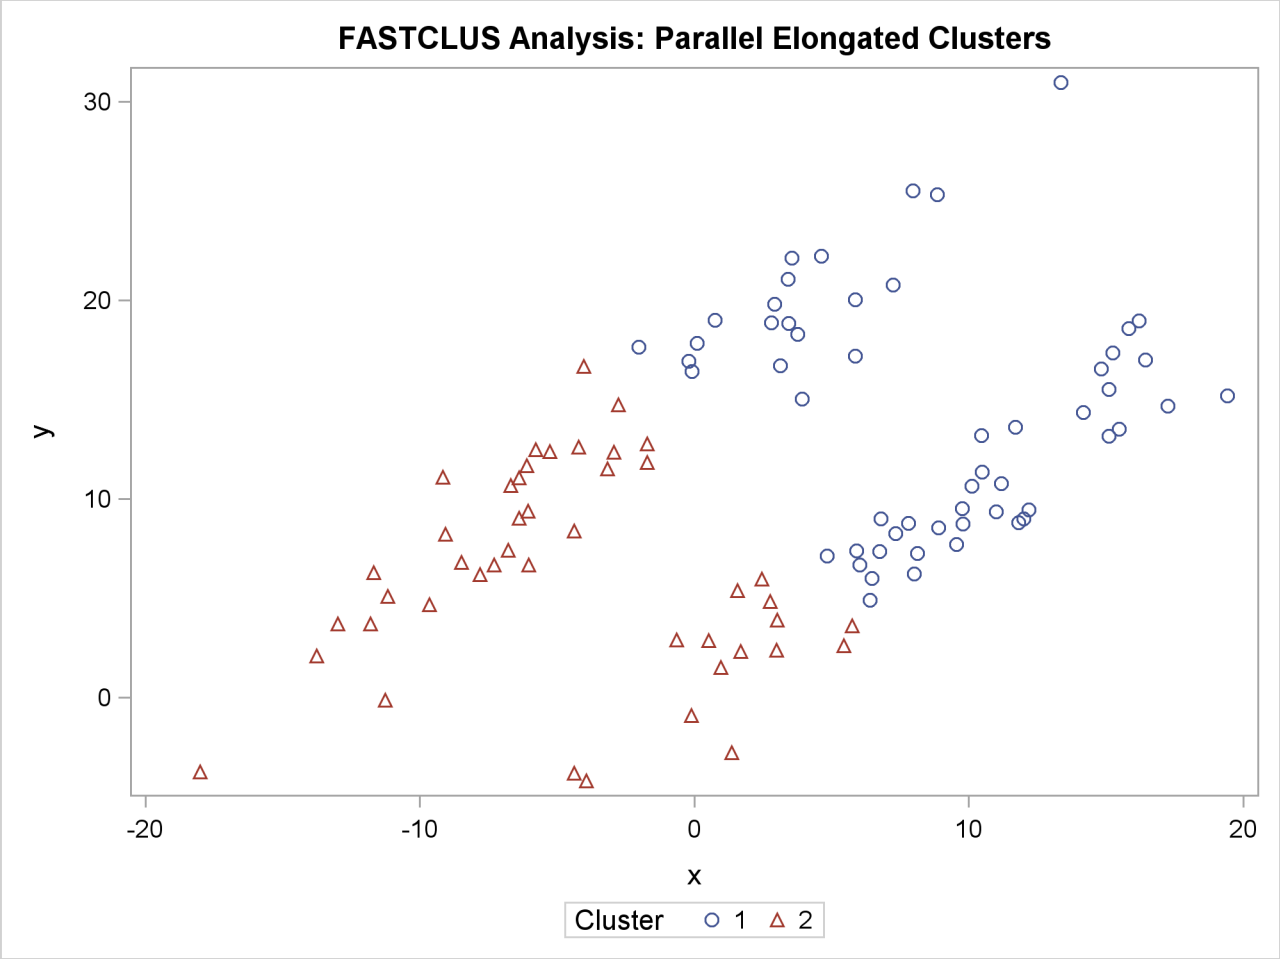
proc fastclus data=elongate out=out maxc=2 noprint;
run;

%modstyle(name=ClusterStyle2,parent=Statistical,type=CLM,
markers=Circle Triangle circlefilled);
ods listing style=ClusterStyle2;

proc sgplot;
   scatter y=y x=x / group=cluster;
   title 'FASTCLUS Analysis: Parallel Elongated Clusters';
run;
```

Notice that PROC FASTCLUS found two clusters, as requested by the MAXC= option. However, it attempted to form spherical clusters, which are obviously inappropriate for these data.

Figure 11.18 Parallel Elongated Clusters: PROC FASTCLUS



The following SAS statements produce Figure 11.19:

```
proc cluster data=elongate outtree=tree method=average noprint;
run;

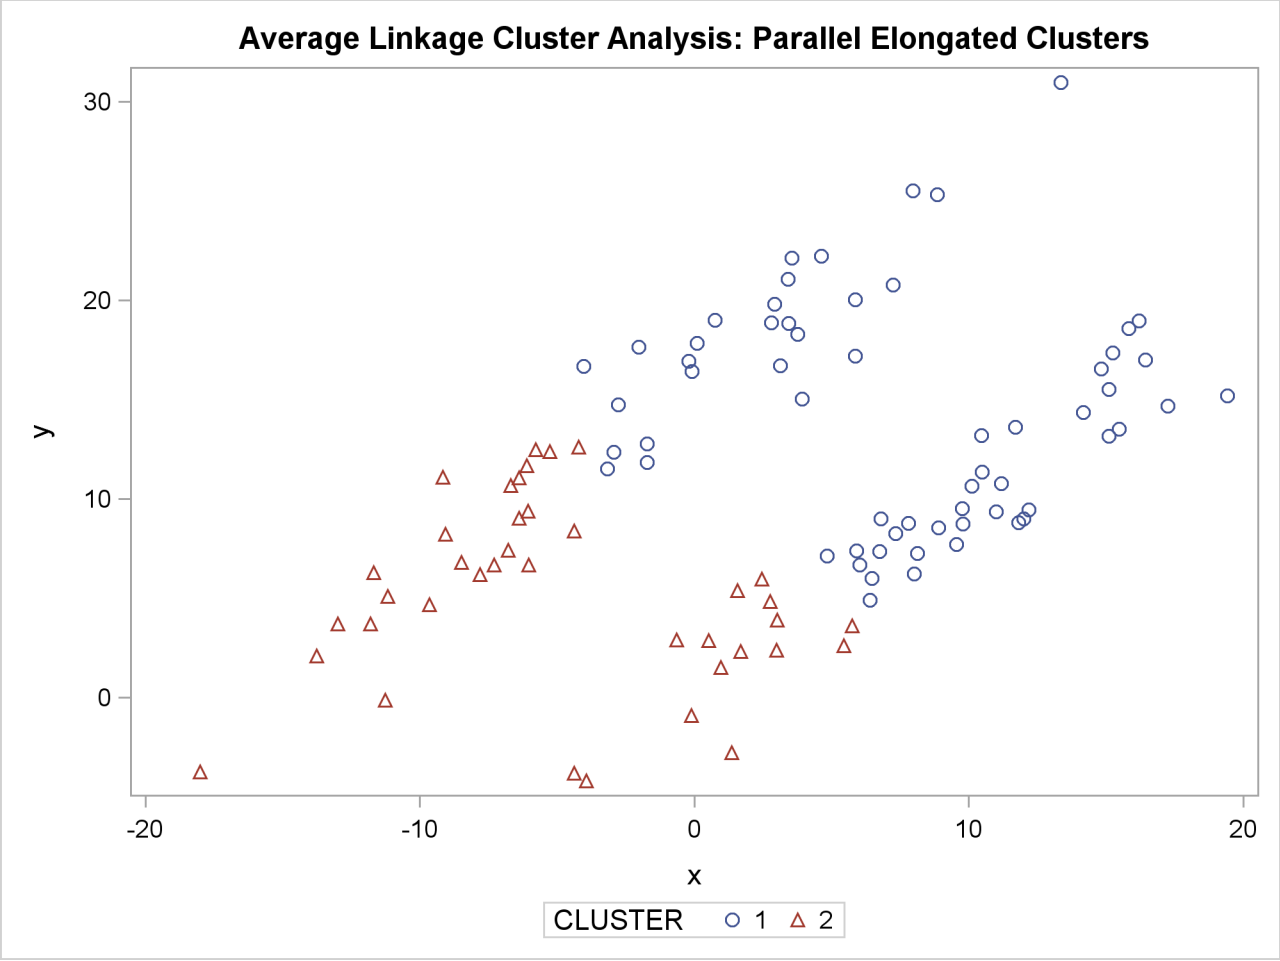
   copy x y;
run;

proc sgplot;
   scatter y=y x=x / group=cluster;
   title 'Average Linkage Cluster Analysis: '
         'Parallel Elongated Clusters';
run;
```

Figure 11.19 Parallel Elongated Clusters: PROC CLUSTER METHOD=AVERAGE



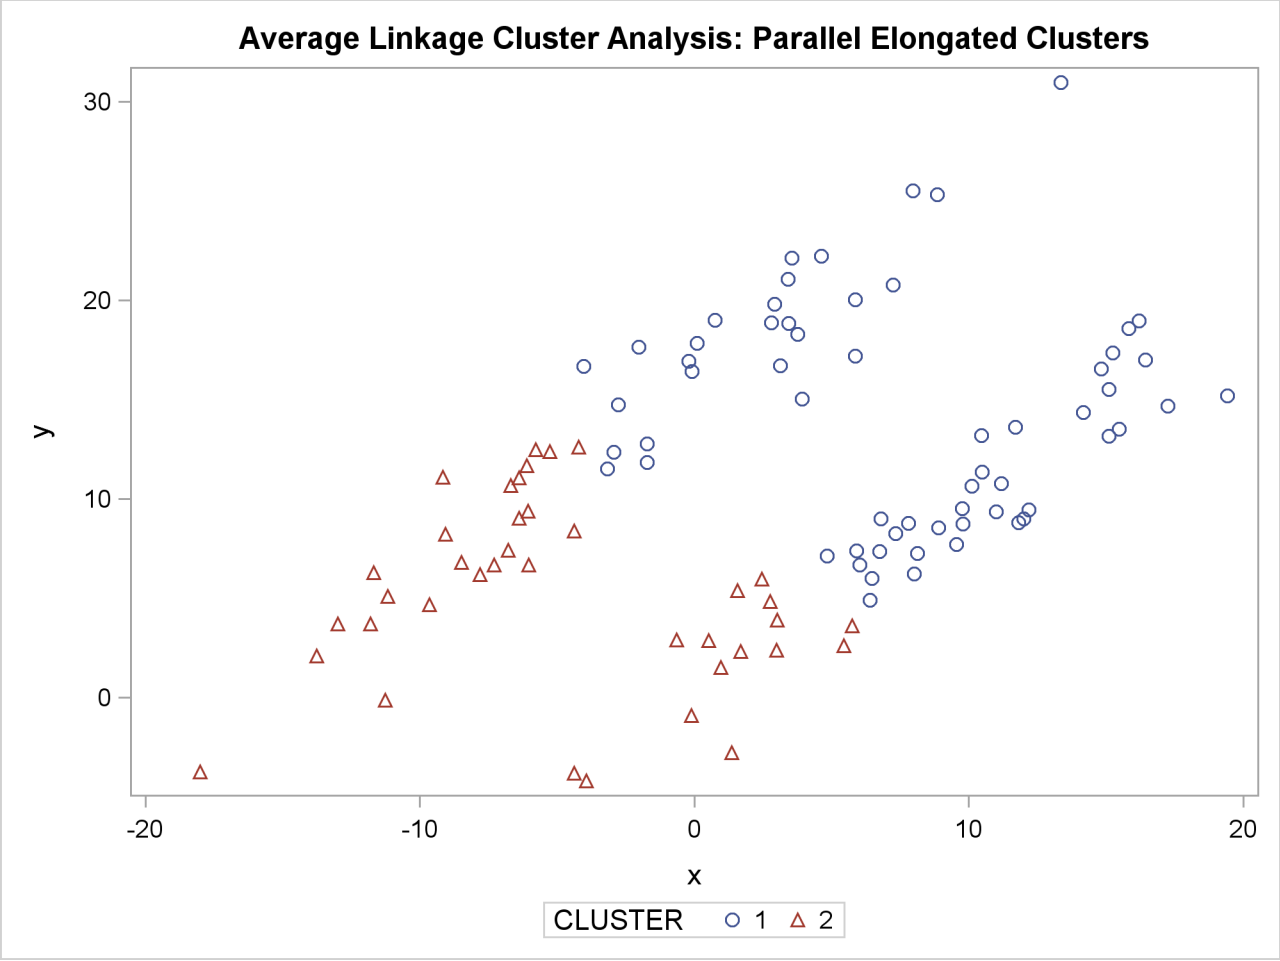
The following SAS statements produce Figure 11.20:

```
proc cluster data=elongate outtree=tree method=twostage k=10 noprint;
run;

proc tree noprint out=out n=2;
   copy x y;
run;

proc sgplot;
   scatter y=y x=x / group=cluster;
   title 'Two-Stage Density Linkage Cluster Analysis: '
         'Parallel Elongated Clusters';
run;
```

Figure 11.20 Parallel Elongated Clusters: PROC CLUSTER METHOD=TWOSTAGE



PROC FASTCLUS and average linkage fail miserably. Ward's method and the centroid method (not shown) produce almost the same results. Two-stage density linkage, however, recovers the correct clusters. Single linkage (not shown) finds the same clusters as two-stage density linkage except for some outliers.

In this example, the population clusters have equal covariance matrices. If the within-cluster covariances are known, the data can be transformed to make the clusters spherical so that any of the clustering methods can find the correct clusters. But when you are doing a cluster analysis, you do not know what the true clusters are, so you cannot calculate the within-cluster covariance matrix. Nevertheless, it is sometimes possible to estimate the within-cluster covariance matrix without knowing the cluster membership or even the number of clusters, using an approach invented by Art, Gnanadesikan, and Kettenring (1982). A method for obtaining such an estimate is available in the ACECLUS procedure.

In the following analysis, PROC ACECLUS transforms the variables X and Y into the canonical variables Can1 and Can2. The latter are plotted and then used in a cluster analysis by Ward's method. The clusters are then plotted with the original variables X and Y.

The following SAS statements produce Figure 11.21 and Figure 11.22:

```
proc aceclus data=elongate out=ace p=.1;
   var x y;
   title 'ACECLUS Analysis: Parallel Elongated Clusters';
run;

proc sgplot;
   scatter y=can2 x=can1;
   title 'Data Containing Parallel Elongated Clusters';
   title2 'After Transformation by PROC ACECLUS';
run;
```

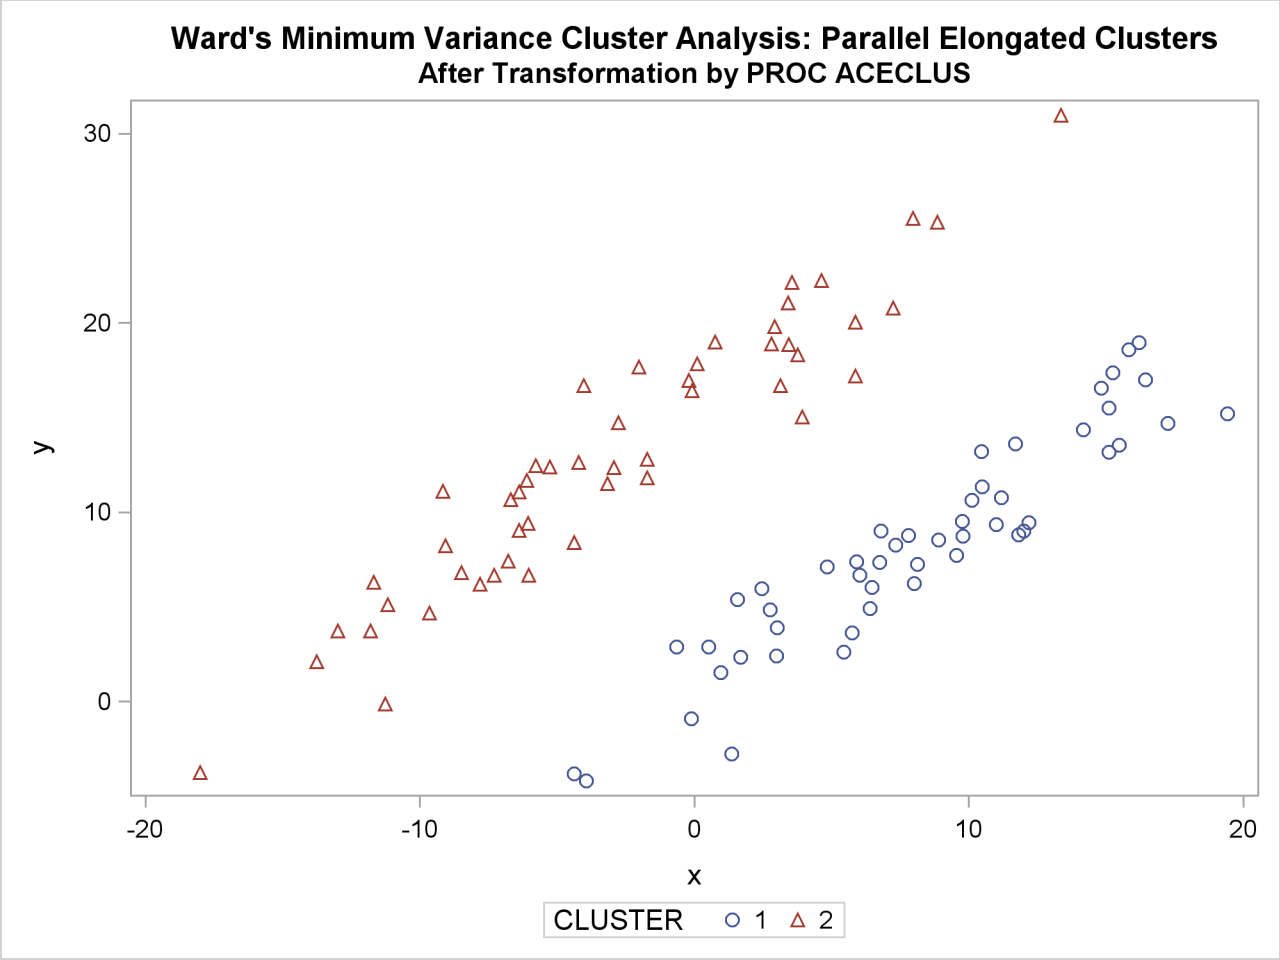
Figure 11.23 Transformed Data Containing Parallel Elongated Clusters: PROC CLUSTER METHOD=WARD



Nonconvex Clusters

If the population clusters have very different covariance matrices, using PROC ACECLUS is of no avail. Although methods exist for estimating multinormal clusters with unequal covariance matrices (Wolfe 1970; Symons 1981; Everitt and Hand 1981; Titterington, Smith, and Makov 1985; McLachlan and Basford 1988), these methods tend to have serious problems with initialization and might converge to degenerate solutions. For unequal covariance matrices or radically nonnormal distributions, the best approach to cluster analysis is through nonparametric density estimation, as in density linkage. The next example illustrates population clusters with nonconvex density contours. The following SAS statements produce Figure 11.24:

```
data noncon;
   keep x y;
   do i=1 to 100;
      a=i*.0628319;
      x=cos(a)+(i>50)+rannor(7)*.1;
      y=sin(a)+(i>50)*.3+rannor(7)*.1;
      output;
   end;
run;

proc fastclus data=noncon out=out maxc=2 noprint;
run;

proc sgplot;

   scatter y=y x=x / group=cluster;
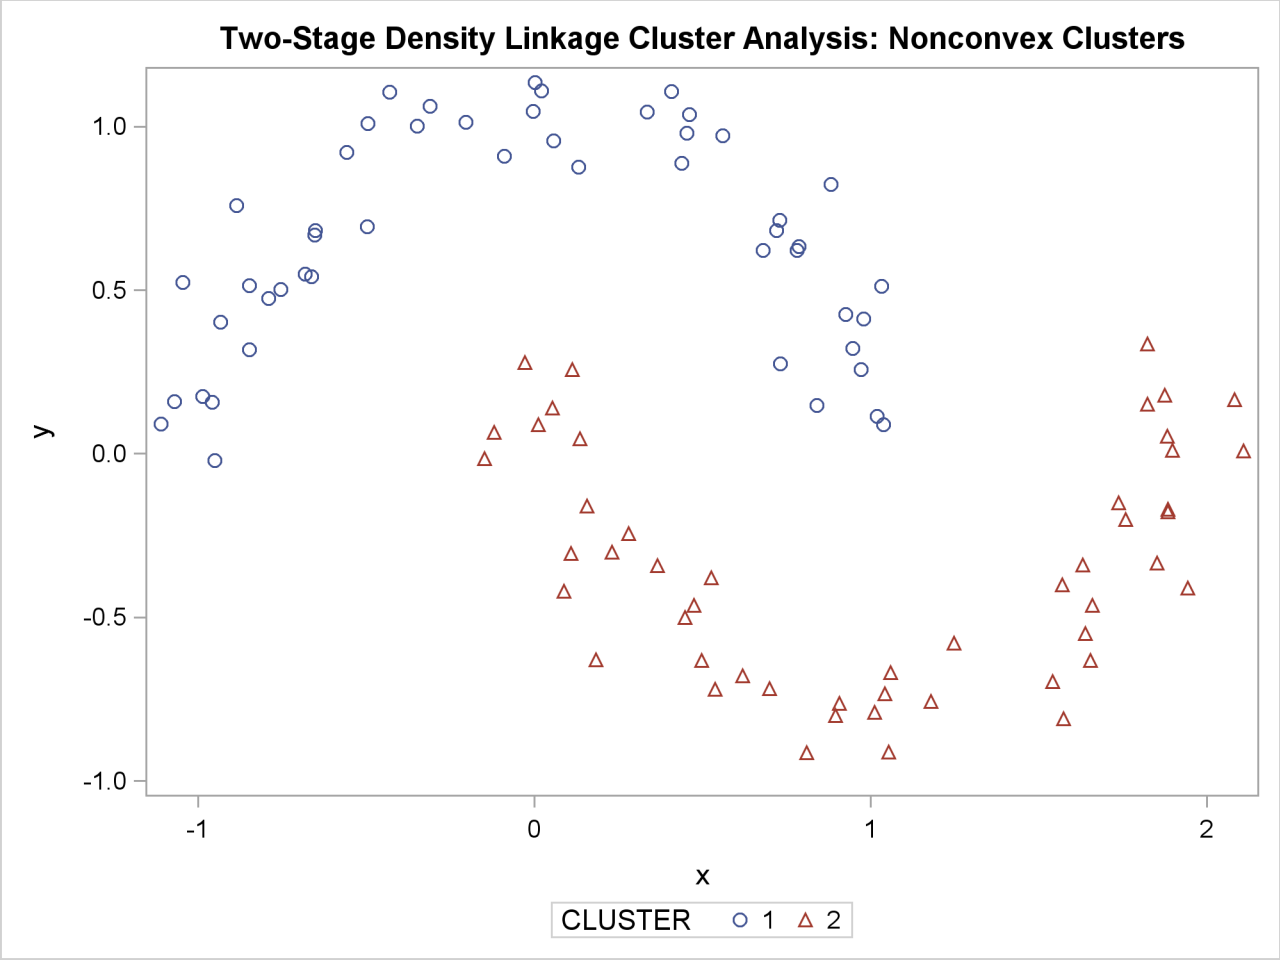
   title 'Two-Stage Density Linkage Cluster Analysis: Nonconvex Clusters';
run;
```

Figure 11.26 Nonconvex Clusters: PROC CLUSTER METHOD=TWOSTAGE



Ward's method and average linkage (not shown) do better than PROC FASTCLUS but not as well as the centroid method. Two-stage density linkage recovers the correct clusters, as does single linkage (not shown).

The preceding examples are intended merely to illustrate some of the properties of clustering methods in common use. If you intend to perform a cluster analysis, you should consult more systematic and rigorous studies of the properties of clustering methods, such as Milligan (1980).

The Number of Clusters

There are no completely satisfactory methods that can be used for determining the number of population clusters for any type of cluster analysis (Everitt 1979; Hartigan 1985a; Bock 1985).

If your purpose in clustering is dissection—that is, to summarize the data without trying to uncover real clusters—it might suffice to look at R square for each variable and pooled over all variables. Plots of R square against the number of clusters are useful.

It is always a good idea to look at your data graphically. If you have only two or three variables, use PROC SGPLOT to make scatter plots identifying the clusters. With more variables, use PROC CANDISC to compute canonical variables for plotting.

Ordinary significance tests, such as analysis of variance F tests, are not valid for testing differences between clusters. Since clustering methods attempt to maximize the separation between clusters, the assumptions of the usual significance tests, parametric or nonparametric, are drastically violated. For example, if you take a sample of 100 observations from a single univariate normal distribution, have PROC FASTCLUS divide it into two clusters, and run a t test between the clusters, you usually obtain a p-value of less than 0.0001. For the same reason, methods that purport to test for clusters against the null hypothesis that objects are assigned randomly to clusters (such as McClain and Rao 1975 and Klastorin 1983) are useless.

Most valid tests for clusters either have intractable sampling distributions or involve null hypotheses for which rejection is uninformative. For clustering methods based on distance matrices, a popular null hypothesis is that all permutations of the values in the distance matrix are equally likely (Ling 1973; Hubert 1974). Using this null hypothesis, you can do a permutation test or a rank test. The trouble with the permutation hypothesis is that, with any real data, the null hypothesis is implausible even if the data do not contain clusters. Rejecting the null hypothesis does not provide any useful information (Hubert and Baker 1977).

Another common null hypothesis is that the data are a random sample from a multivariate normal distribution (Wolfe 1970, 1978; Duda and Hart 1973; Lee 1979). The multivariate normal null hypothesis arises naturally in normal mixture models (Titterington, Smith, and Makov 1985; McLachlan and Basford 1988). Unfortunately, the likelihood ratio test statistic does not have the usual asymptotic χ^2 distribution because the regularity conditions do not hold. Approximations to the asymptotic distribution of the likelihood ratio have been suggested Wolfe (1978), but the adequacy of these approximations is debatable (Everitt 1981; Thode, Mendell, and Finch 1988). For small samples, bootstrapping seems preferable (McLachlan and Basford 1988). Bayesian inference provides a promising alternative to likelihood ratio tests for the number of mixture components for both normal mixtures and other types of distributions (Binder 1978, 1981; Banfield and Raftery 1993; Bensmail et al. 1997).

The multivariate normal null hypothesis is better than the permutation null hypothesis, but it is not satisfactory because there is typically a high probability of rejection if the data are sampled from a distribution with lower kurtosis than a normal distribution, such as a uniform distribution. The tables in Englemann and Hartigan (1969), for example, generally lead to rejection of the null hypothesis when the data are sampled from a uniform distribution. Hawkins, Muller, and ten Krooden (1982, pp. 337–340) discuss a highly conservative Bonferroni method for the use of hypothesis testing. The conservativeness of this approach might compensate to some extent for the liberalness exhibited by tests based on normal distributions when the population is uniform.

Perhaps a better null hypothesis is that the data are sampled from a uniform distribution (Hartigan 1978; Arnold 1979; Sarle 1983) The uniform null hypothesis leads to conservative error rates when the data are sampled from a strongly unimodal distribution such as the normal. However, in two or more dimensions and depending on the test statistic, the results can be very sensitive to the shape of the region of support of the uniform distribution. Sarle (1983) suggests using a hyperbox with sides proportional in length to the singular values of the centered coordinate matrix.

Given that the uniform distribution provides an appropriate null hypothesis, there are still serious difficulties in obtaining sampling distributions. Some asymptotic results are available (Hartigan 1978, 1985a; Pollard 1981; Bock 1985) for the within-cluster sum of squares, the criterion that PROC FASTCLUS and Ward's minimum variance method attempt to optimize. No distributional theory for finite sample sizes has yet appeared. Currently, the only practical way to obtain sampling distributions for realistic sample sizes is by computer simulation.

Arnold (1979) used simulation to derive tables of the distribution of a criterion based on the determinant of the within-cluster sum of squares matrix $|\mathbf{W}|$. Both normal and uniform null distributions were used. Having obtained clusters with either PROC FASTCLUS or PROC CLUSTER, you can compute Arnold's criterion with the ANOVA or CANDISC procedure. Arnold's tables provide a conservative test because PROC FASTCLUS and PROC CLUSTER attempt to minimize the trace of $\mathbf{W}$ rather than the determinant. Marriott (1971, 1975) also provides useful information about $|\mathbf{W}|$ as a criterion for the number of clusters.

Sarle (1983) used extensive simulations to develop the cubic clustering criterion (CCC), which can be used for crude hypothesis testing and estimating the number of population clusters. The CCC is based on the assumption that a uniform distribution on a hyperrectangle will be divided into clusters shaped roughly like hypercubes. In large samples that can be divided into the appropriate number of hypercubes, this assumption gives very accurate results. In other cases the approximation is generally conservative. For details about the interpretation of the CCC, consult Sarle (1983).

Milligan and Cooper (1985) and Cooper and Milligan (1988) compared 30 methods of estimating the number of population clusters by using four hierarchical clustering methods. The three criteria that performed best in these simulation studies with a high degree of error in the data were a pseudo F statistic developed by Calinski and Harabasz (1974), a statistic referred to as $J_e(2)/J_e(1)$ by Duda and Hart (1973) that can be transformed into a pseudo t^2 statistic, and the cubic clustering criterion. The pseudo F statistic and the CCC are displayed by PROC FASTCLUS; these two statistics and the pseudo t^2 statistic, which can be applied only to hierarchical methods, are displayed by PROC CLUSTER. It might be advisable to look for consensus among the three statistics—that is, local peaks of the CCC and pseudo F statistic combined with a small value of the pseudo t^2 statistic and a larger pseudo t^2 for the next cluster fusion. It must be emphasized that these criteria are appropriate only for compact or slightly elongated clusters, preferably clusters that are roughly multivariate normal.

Recent research has tended to deemphasize mixture models in favor of nonparametric models in which clusters correspond to modes in the probability density function. Hartigan and Hartigan (1985) and Hartigan (1985b) developed a test of unimodality versus bimodality in the univariate case.

Nonparametric tests for the number of clusters can also be based on nonparametric density estimates. This approach requires much weaker assumptions than mixture models, namely, that the observations are sampled independently and that the distribution can be estimated nonparametrically. Silverman (1986) describes a bootstrap test for the number of modes using a Gaussian kernel density estimate, but problems have been reported with this method under the uniform null distribution. Further developments in nonparametric methods are given by Müller and Sawitzki (1991), Minnotte (1992), and Polonik (1993). All of these methods suffer from heavy computational requirements.

One useful descriptive approach to the number-of-clusters problem is provided by Wong and Schaack (1982) based on a *k*th-nearest-neighbor density estimate. The *k*th-nearest-neighbor clustering method developed by Wong and Lane (1983) is applied with varying values of *k*. Each value of *k* yields an estimate of the number of modal clusters. If the estimated number of modal clusters is constant for a wide range of *k* values, there is strong evidence of at least that many modes in the population. A plot of the estimated number of modes against *k* can be highly informative. Attempts to derive a formal hypothesis test from this diagnostic plot have met with difficulties, but a simulation approach similar to Silverman (1986) does seem to work Girman (1994). The simulation, of course, requires considerable computer time.

PROC MODECLUS uses a less expensive approximate nonparametric test for the number of clusters. This test sacrifices statistical efficiency for computational efficiency. The method for conducting significance tests is described in the chapter on the MODECLUS procedure. This method has the following useful features:

- No distributional assumptions are required.
- The choice of smoothing parameter is not critical since you can try any number of different values.
- The data can be coordinates or distances.
- Time and space requirements for the significance tests are no worse than those for obtaining the clusters.
- The power is high enough to be useful for practical purposes.

The method for computing the *p*-values is based on a series of plausible approximations. There are as yet no rigorous proofs that the method is infallible. Neither are there any asymptotic results. However, simulations for sample sizes ranging from 20 to 2000 indicate that the *p*-values are almost always conservative. The only case discovered so far in which the *p*-values are liberal is a uniform distribution in one dimension for which the simulated error rates exceed the nominal significance level only slightly for a limited range of sample sizes.

Introduction to Scoring, Standardization, and Ranking Procedures

Contents

Overview: Scoring, Standardization, and Ranking Procedures

Several SAS/STAT procedures are utilities that produce an output data set with new variables that are transformations of data in the input data set. SAS/STAT software includes four of these procedures. The RANK procedure produces rank scores across observations, the SCORE procedure constructs functions across the variables, and the STANDARD and STDIZE procedures transform each variable individually.

RANK	ranks the observations of each numeric variable and outputs ranks or rank scores. For a complete discussion of the RANK procedure, see the *Base SAS Procedures Guide: Statistical Procedures*.
SCORE	constructs new variables that are linear combinations of old variables according to a scoring data set. This procedure is used with the FACTOR procedure and other procedures that output scoring coefficients.
STANDARD	standardizes variables to a given mean and standard deviation. For a complete discussion of PROC STANDARD, see the *Base SAS Procedures Guide: Statistical Procedures*.
STDIZE	standardizes variables by subtracting a location measure and dividing by a scale measure. A variety of location and scale measures are provided. Such measures include the mean, median, Huber's estimate, Tukey's biweight estimate, and Andrew's wave estimate.

Chapter 13

Introduction to Survival Analysis Procedures

Contents

Overview

Data that measure lifetime or the length of time until the occurrence of an event are called *lifetime, failure time,* or *survival* data. For example, variables of interest might be the lifetime of diesel engines, the length of time a person stay on a job, or the survival time for heart transplant patients. Such data have special considerations that must be incorporated into any analysis.

Survival data consist of a response (event time, failure time, or survival time) variable that measures the duration of time until a specified event occurs and possibly a set of independent variables thought to be associated with the failure time variable. These independent variables (concomitant variables, covariates, or prognostic factors) can be either discrete, such as sex or race, or continuous, such as age or temperature. The system that gives rise to the event of interest can be biological (as for most medical data) or physical (as for engineering data). The purpose of survival analysis is to model the underlying distribution of the failure time variable and to assess the dependence of the failure time variable on the independent variables.

An intrinsic characteristic of survival data is the possibility for censoring of observations (that is, the actual time until the event is not observed). Such censoring can arise from withdrawal from the experiment or termination of the experiment. Because the response is usually a duration, some of the possible events may not yet have occurred when the period for data collection has terminated. For example, clinical trials are conducted over a finite period of time with staggered entry of patients. That is, patients enter a clinical trial over time, and thus the length of follow-up varies by individuals; consequently, the time to the event may not be ascertained on all patients in the study. Additionally, some of the responses may be lost to follow-up (for example, a participant may move or refuse to continue to participate) before termination

of data collection. In either case, only a lower bound on the failure time of the censored observations is known. These observations are said to be *right censored*. Thus, an additional variable is incorporated into the analysis to indicate which failure times are observed event times and which are censored times. More generally, the failure time might only be known to be smaller than a given value (*left censored*) or known to be within a given interval (*interval censored*). There are numerous possible censoring schemes that arise in survival analysis. The monograph by Maddala (1983) discusses several related types of censoring situations, and the text by Kalbfleisch and Prentice (1980) also discusses several censoring schemes. Data with censored observations cannot be analyzed by ignoring the censored observations because, among other considerations, the longer-lived individuals are generally more likely to be right censored. The method of analysis must take the censoring into account and correctly use the censored observations as well as the uncensored observations.

Another characteristic of survival data is that the response cannot be negative. This suggests that a transformation of the survival time such as a log transformation might be necessary or that specialized methods might be more appropriate than those that assume a normal distribution for the error term. It is especially important to check any underlying assumptions as a part of the analysis because some of the models used are very sensitive to these assumptions.

Survival Analysis Procedures

There are four SAS procedures for analyzing survival data:

- The LIFEREG procedure is a parametric regression procedure for modeling the distribution of survival time with a set of concomitant variables.
- The LIFETEST procedure is a nonparametric procedure for estimating the survivor function, comparing the underlying survival curves of two or more samples, and testing the association of survival time with other variables.
- The PHREG procedure is a semiparametric procedure that fits the Cox proportional hazards model and its extensions.
- The SURVEYPHREG procedure is a Cox modeling procedure similar to PROC PHREG, appropriate for data collected from a survey sample.

The LIFEREG Procedure

The LIFEREG procedure fits parametric accelerated failure time models to survival data that may be left, right, or interval censored. The parametric model is of the form

$$y = \mathbf{x}'\boldsymbol{\beta} + \sigma\epsilon$$

where y is usually the log of the failure time variable, $\mathbf{x}$ is a vector of covariate values, $\boldsymbol{\beta}$ is a vector of unknown regression parameters, σ is an unknown scale parameter, and ϵ is an error term. The baseline distribution of the error term can be specified as one of several possible distributions including (but not limited

to) the log normal, log logistic, and Weibull distributions. Several texts that discuss these parametric models are Kalbfleisch and Prentice (1980), Lawless (1982), Nelson (1990), and Meeker and Escobar (1998). For more information about PROC LIFEREG, see Chapter 50, "The LIFEREG Procedure."

The LIFETEST Procedure

The LIFETEST procedure computes nonparametric estimates of the survival distribution function. You can request either the product-limit (Kaplan and Meier 1958) or the life-table (actuarial) estimate of the distribution. The texts by Cox and Oakes (1984) and Kalbfleisch and Prentice (1980) provide good discussions of the product-limit estimator, and the texts by Lee (1992) and Elandt-Johnson and Johnson (1980) include detailed discussions of the life-table estimator. PROC LIFETEST computes nonparametric tests to compare the survival curves of two or more groups. The procedure also computes rank tests of association of the survival time variable with other concomitant variables as given in Kalbfleisch and Prentice (1980, Chapter 6). For more information about PROC LIFETEST, see Chapter 51, "The LIFETEST Procedure."

The PHREG Procedure

The PHREG procedure fits the proportional hazards model of Cox (1972, 1975) to survival data that might be right censored. The Cox model is a semiparametric model in which the hazard function of the survival time is given by

$$\lambda(t;\mathbf{x}) = \lambda_0(t)e^{\boldsymbol{\beta}'\mathbf{x}(t)}$$

where $\lambda_0(t)$ is an unspecified baseline hazard function, $\mathbf{x}(t)$ is a vector of covariate values (possibly time-dependent), and $\boldsymbol{\beta}$ is a vector of unknown regression parameters. The model is referred to as a semiparametric model because part of the model involves the unspecified baseline function over time (which has an infinite dimension) and the other part involves a finite number of regression parameters. Several texts that discuss the Cox regression models are Collett (1994), Cox and Oakes (1984), Kalbfleisch and Prentice (1980), and Lawless (1982). Extensions of the Cox model are discussed in Therneau and Grambsch (2000), Andersen et al. (1992), and Fleming and Harrington (1991). For more information about PROC PHREG, see Chapter 66, "The PHREG Procedure."

The SURVEYPHREG Procedure

The SURVEYPHREG procedure fits the Cox proportional hazards model for sample survey data. The procedure is similar to the PHREG procedure, except that it incorporates complex sample design information in the analysis. The proportional hazards regression coefficients are estimated by maximizing a partial pseudo-log-likelihood function that incorporates the sampling weights. PROC SURVEYPHREG provides design-based variance estimates, confidence intervals, and tests for the estimated regression coefficients. For more information about PROC SURVEYPHREG, see Chapter 89, "The SURVEYPHREG Procedure."

Survival Analysis with SAS/STAT Procedures

The typical goal in survival analysis is to characterize the distribution of the survival time for a given population, to compare the survival distributions among different groups, or to study the relationship between the survival time and some concomitant variables.

A first step in the analysis of a set of survival data is to use PROC LIFETEST to compute and plot the estimate of the distribution of the survival time. In many applications, there are often several survival curves to compare. For example, you want to compare the survival experiences of patients who receive different treatments for their disease. The association between covariates and the survival time variable can be investigated by computing estimates of the survival distribution function within strata defined by the covariates. In particular, if the proportional hazards model is appropriate, the estimates of the log(-log(SURVIVAL)) plotted against the log(TIME) variable should give approximately parallel lines, where SURVIVAL is the survival distribution estimate and TIME is the failure time variable. Additionally, these lines should be approximately straight if the Weibull model is appropriate.

Statistics that test for association between failure time and covariates can be used to select covariates for further investigation. The LIFETEST procedure computes linear rank statistics using either Wilcoxon or log-rank scores. These statistics and their estimated covariance matrix can be used with the REG procedure with the option METHOD=RSQUARE to find the subset of variables that produce the largest joint test statistic for association. An illustration of this methodology is given in Example 51.1 of Chapter 51, "The LIFETEST Procedure."

Another approach to examining the relationship between the concomitant variables and survival time is through a regression model in which the survival time has a distribution that depends on the concomitant variables. The regression coefficients can be interpreted as describing the direction and strength of the relationship of each explanatory variable on the effect of the survival time.

In many biological systems, the Cox model might be a reasonable description of the relationship between the distribution of the survival time and the prognostic factors. You use PROC PHREG to fit the Cox regression model. The regression coefficient is interpreted as the increase of the log-hazard ratio resulting in the increase of one unit in the covariate. However, the underlying hazard function is left unspecified and, as in any other model, the results can be misleading if the proportional hazards assumptions do not hold.

Accelerated failure time models are popular for survival data of physical systems. In many cases, the underlying survival distribution is known empirically. You use PROC LIFEREG to fit these parametric models. Also, PROC LIFEREG can accommodate data with left-censored or interval-censored observations, which are not allowed in PROC PHREG.

A common technique for checking the validity of a regression model is to embed it in a larger model and use the likelihood ratio test to check whether the reduction to the actual model is valid. Other techniques include examining the residuals. Both PROC LIFEREG and PROC PHREG produce predicted values, residuals, and other computed values that can be used to assess the model adequacy.

Bayesian Survival Analysis with SAS/STAT Procedures

Bayesian analysis of survival models can be requested in the LIFEREG and PHREG procedures. In addition to the Cox model, PROC PHREG also allow you to fit a piecewise exponential model. In Bayesian analysis, the model parameters are treated as random variables, and inference about parameters is based on the posterior distribution of the parameters. A posterior distribution is a weighted likelihood function of the data with a prior distribution of the parameters using the Bayes theorem. The prior distribution enables you to incorporate into the analysis knowledge or experience of the likely range of values of the parameters of interest. You can specify normal or uniform prior distributions for the model regression coefficients in both LIFEREG and PHREG procedures. In addition, you can specify a gamma or improper prior distribution for the scale or variance parameter in PROC LIFEREG. For the piecewise exponential model in PROC PHREG, you can specify normal or uniform prior distributions for the log-hazard parameters; alternatively, you can specify gamma or improper prior distributions for the hazards parameters. If you have no prior knowledge of the parameter values, you can use a noninformative prior distribution, and the results of a Bayesian analysis will be very similar to a classical analysis based on maximum likelihood.

A closed form of the posterior distribution is often not feasible, and a Markov chain Monte Carlo method by Gibbs sampling is used to simulate samples from the posterior distribution. You can perform inference by using the simulated samples, for example, to estimate the probability that a function of the parameters of interest lies within a specified range of values.

See Chapter 7, "Introduction to Bayesian Analysis Procedures," for an introduction to the basic concepts of Bayesian statistics. Also see "Bayesian Analysis: Advantages and Disadvantages" on page 138 for a discussion of the advantages and disadvantages of Bayesian analysis. See Ibrahim, Chen, and Sinha (2001), Gelman et al. (2004), and Gilks, Richardson, and Spiegelhalter (1996) for more information about Bayesian analysis, including guidance about choosing prior distributions.

Chapter 14

Introduction to Survey Sampling and Analysis Procedures

Contents

Overview: Survey Sampling and Analysis Procedures

This chapter introduces the SAS/STAT procedures for survey sampling and describes how you can use these procedures to analyze survey data.

Researchers often use sample survey methodology to obtain information about a large population by selecting and measuring a sample from that population. Due to variability among items, researchers apply scientific probability-based designs to select the sample. This reduces the risk of a distorted view of the population and enables statistically valid inferences to be made from the sample. See Lohr (2010), Kalton (1983), Cochran (1977), and Kish (1965) for more information about statistical sampling and analysis of complex survey data. To select probability-based random samples from a study population, you can use the SURVEYSELECT procedure, which provides a variety of methods for probability sampling. To analyze sample survey data, you can use the SURVEYMEANS, SURVEYFREQ, SURVEYREG, SURVEYLOGISTIC, and SURVEYPHREG procedures, which incorporate the sample design into the analyses.

Many SAS/STAT procedures, such as the MEANS, FREQ, GLM, LOGISTIC, and PHREG procedures, can compute sample means, produce crosstabulation tables, and estimate regression relationships. However, in

most of these procedures, statistical inference is based on the assumption that the sample is drawn from an infinite population by simple random sampling. If the sample is in fact selected from a finite population by using a complex survey design, these procedures generally do not calculate the estimates and their variances according to the design actually used. Using analyses that are not appropriate for your sample design can lead to incorrect statistical inferences.

The SURVEYMEANS, SURVEYFREQ, SURVEYREG, SURVEYLOGISTIC, and SURVEYPHREG procedures properly analyze complex survey data by taking into account the sample design. These procedures can be used for multistage or single-stage designs, with or without stratification, and with or without unequal weighting. The survey analysis procedures provide a choice of variance estimation methods, which include Taylor series linearization, balanced repeated replication (BRR), and the jackknife.

Table 14.1 briefly describes the SAS/STAT sampling and analysis procedures.

Table 14.1 Survey Sampling and Analysis Procedures in SAS/STAT Software

PROC SURVEYSELECT	
Selection Methods	Simple random sampling (without replacement) Unrestricted random sampling (with replacement) Systematic Sequential Probability proportional to size (PPS) sampling, with and without replacement PPS systematic PPS for two units per stratum PPS sequential with minimum replacement
Allocation Methods	Proportional Optimal Neyman
Sampling Tools	Cluster sampling Replicated sampling Serpentine sorting
PROC SURVEYMEANS	
Statistics	Estimates of population means and totals Estimates of population proportions Estimates of population quantiles Ratio estimates Standard errors Confidence limits Hypothesis tests Domain analysis

Analyses	Proportional hazards regression model fitting Breslow and Efron likelihoods Regression coefficients Covariance matrices Confidence limits Hypothesis tests Hazard ratios Contrasts Predicted values and standard errors Martingale, Schoenfeld, score, and deviance residuals Domain analysis

The Survey Procedures

The SURVEYSELECT procedure provides methods for probability sample selection. The SURVEYMEANS, SURVEYFREQ, SURVEYREG, SURVEYLOGISTIC, and SURVEYPHREG procedures provide statistical analyses for sample survey data. The following sections contain brief descriptions of these procedures. See the chapters on these procedures for more detailed information.

PROC SURVEYSELECT

The SURVEYSELECT procedure provides a variety of methods for selecting probability-based random samples. The procedure can select a simple random sample or can sample according to a complex multistage sample design that includes stratification, clustering, and unequal probabilities of selection. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population.

PROC SURVEYSELECT provides methods for both equal probability sampling and probability proportional to size (PPS) sampling. In PPS sampling, a unit's selection probability is proportional to its size measure. PPS sampling is often used in cluster sampling, where you select clusters (groups of sampling units) of varying size in the first stage of selection. Available PPS methods include without replacement, with replacement, systematic, and sequential with minimum replacement. The procedure can apply these methods for stratified and replicated sample designs.

For stratified sampling, PROC SURVEYSELECT provides survey design methods to allocate the total sample size among the strata. Available allocation methods include proportional, Neyman, and optimal allo-

cation. Optimal allocation maximizes the estimation precision within the available resources, taking into account stratum sizes, costs, and variances.

See Chapter 91, "The SURVEYSELECT Procedure," for more information.

PROC SURVEYMEANS

The SURVEYMEANS procedure produces estimates of population means and totals from sample survey data. The procedure also computes estimates of proportions for categorical variables, estimates of quantiles for continuous variables, and ratio estimates of means and proportions. For all of these statistics, PROC SURVEYMEANS provides standard errors, confidence limits, and *t* tests.

PROC SURVEYMEANS provides domain analysis, which computes estimates for domains (subpopulations), in addition to analysis for the entire study population. Formation of subpopulations can be unrelated to the sample design, and so the domain sample sizes can actually be random variables. Domain analysis takes this variability into account by using the entire sample to estimate the variance of domain estimates. Domain analysis is also known as subgroup analysis, subpopulation analysis, and subdomain analysis.

See Chapter 88, "The SURVEYMEANS Procedure," for more information.

PROC SURVEYFREQ

The SURVEYFREQ procedure produces one-way to *n*-way frequency and crosstabulation tables from sample survey data. These tables include estimates of population totals, population proportions (overall proportions, and also row and column proportions), and corresponding standard errors. Confidence limits, coefficients of variation, and design effects are also available. The procedure provides a variety of options to customize the table display.

For one-way frequency tables, PROC SURVEYFREQ provides Rao-Scott chi-square goodness-of-fit tests, which are adjusted for the sample design. You can test a null hypothesis of equal proportions for a one-way frequency table, or you can input custom null hypothesis proportions for the test. For two-way frequency tables, PROC SURVEYFREQ provides design-adjusted tests of independence, or no association, between the row and column variables. These tests include the Rao-Scott chi-square test, the Rao-Scott likelihood ratio test, the Wald chi-square test, and the Wald log-linear chi-square test.

For 2×2 tables, PROC SURVEYFREQ computes estimates and confidence limits for risks (or row proportions), the risk difference, the odds ratio, and relative risks.

PROC SURVEYFREQ uses ODS Graphics to create graphs as part of its output. Available statistical graphics include weighted frequency plots and odds ratio plots.

See Chapter 86, "The SURVEYFREQ Procedure," for more information.

PROC SURVEYREG

The SURVEYREG procedure performs regression analysis for sample survey data. The procedure fits linear models and computes regression coefficients and their variance-covariance matrix. The procedure enables you to specify classification effects by using the same syntax as in the GLM procedure.

PROC SURVEYREG provides hypothesis tests for the model effects. The procedure also provides custom hypothesis tests for linear combinations of the regression parameters. The procedure computes confidence limits for the parameter estimates, and also for any specified linear functions of the regression parameters. The procedure can produce an output data set that contains the predicted values from the linear regression, their standard errors and confidence limits, and the residuals.

PROC SURVEYREG also performs regression analysis for domains (subpopulations).

See Chapter 90, "The SURVEYREG Procedure," for more information.

PROC SURVEYLOGISTIC

The SURVEYLOGISTIC procedure provides logistic regression analysis for sample survey data. Logistic regression analysis investigates the relationship between discrete responses and a set of explanatory variables. PROC SURVEYLOGISTIC fits linear logistic regression models for discrete response survey data by the method of maximum likelihood and incorporates the sample design into the analysis. The SURVEYLOGISTIC procedure enables you to specify categorical classification variables (also known as CLASS variables) as explanatory variables in the model by using the same syntax for main effects and interactions as in the GLM and LOGISTIC procedures.

The following link functions are available for regression in PROC SURVEYLOGISTIC: the cumulative logit function (CLOGIT), the generalized logit function (GLOGIT), the probit function (PROBIT), and the complementary log-log function (CLOGLOG). The procedure performs maximum likelihood estimation of the regression coefficients with either the Fisher scoring algorithm or the Newton-Raphson algorithm.

PROC SURVEYLOGISTIC also performs logistic regression analysis for domains (subpopulations).

See Chapter 87, "The SURVEYLOGISTIC Procedure," for more information.

PROC SURVEYPHREG

The SURVEYPHREG procedure performs regression analysis based on the Cox proportional hazards model for sample survey data. Cox's semiparametric model is widely used in the analysis of survival data to estimate hazard rates when explanatory variables are available. The regression coefficients are estimated by maximizing a psuedo-partial-likelihood function that incorporates the sampling weights. The procedure

provides design-based variance estimates, confidence intervals, and tests for the estimated regression coefficients.

PROC SURVEYPHREG provides hypothesis tests for the model effects. The procedure also provides custom hypothesis tests for linear combinations of the regression parameters. The procedure computes hazard ratios and their confidence limits. The procedure can produce several observation-level output statistics, such as predicted values and their standard errors, martingale residuals, Schoenfeld residuals, score residuals, and deviance residuals.

PROC SURVEYPHREG also performs proportional hazards regressions for domains (subpopulations).

See Chapter 89, "The SURVEYPHREG Procedure," for more information.

Survey Design Specification

Survey sampling is the process of selecting a probability-based sample from a finite population according to a sample design. You then collect data from these selected units and use them to estimate characteristics of the entire population.

A *sample design* encompasses the rules and operations by which you select sampling units from the population and the computation of sample statistics, which are estimates of the population values of interest. The objective of your survey often determines appropriate sample designs and valid data collection methodology. A complex sample design can include stratification, clustering, multiple stages of selection, and unequal weighting. The survey procedures can be used for single-stage designs or for multistage designs, with or without stratification, and with or without unequal weighting.

To analyze your survey data with the SURVEYMEANS, SURVEYFREQ, SURVEYREG, SURVEYLOGISTIC, and SURVEYPHREG procedures, you need to specify sample design information for the procedures. This information can include design strata, clusters, and sampling weights. All the survey analysis procedures use the same syntax for specifying sample design information. You provide sample design information with the STRATA, CLUSTER, and WEIGHT statements, and with the RATE= or TOTAL= option in the PROC statement.

If you provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a STRATA or CLUSTER statement. Otherwise, you should specify STRATA and CLUSTER statements whenever your design includes stratification and clustering.

When there are clusters (PSUs) in the sample design, the procedures estimate variance by using the PSUs, as described in the section "Variance Estimation" on page 253. For a multistage sample design, the procedures use only the first stage of the sample design for variance estimation. Therefore, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

The following sections provide brief descriptions of basic sample design concepts and terminology used in the survey procedures. See Lohr (2010), Kalton (1983), Cochran (1977), and Kish (1965) for more detailed information.

Population

Population refers to the target population, which is the group of units (individuals or elements) of interest for study. Often, the primary objective is to estimate certain characteristics of this population, which are called *population values*. A *sampling unit* is an individual or element in the target population. A *sample* is a subset of the population that is selected for the study.

Before you use the survey procedures, you should have a well-defined target population, sampling units, and an appropriate sample design.

In order to select a sample according to your sample design, you need to have a list of sampling units in the population. This is called a *sampling frame*. PROC SURVEYSELECT uses probability-based selection methods to select a sample from a sampling frame.

Stratification

Stratified sampling involves selecting samples independently within strata, which are nonoverlapping subgroups of the survey population. Stratification controls the distribution of the sample size in the strata. It is widely used to meet a variety of survey objectives. For example, with stratification you can ensure adequate sample sizes for subgroups of interest, including small subgroups, or you can use stratification to improve the precision of overall estimates. To improve precision, units within strata should be as homogeneous as possible for the characteristics of interest.

Clustering

Cluster sampling involves selecting clusters, which are groups of sampling units. For example, clusters might be schools, hospitals, or geographical areas, and sampling units might be students, patients, or citizens. Cluster sampling can provide efficiency in frame construction and other survey operations. However, it can also result in a loss in precision of your estimates, compared to a nonclustered sample of the same size. To minimize this effect, units within clusters should be as heterogeneous as possible for the characteristics of interest.

Multistage Sampling

In *multistage sampling*, you select an initial (first-stage) sample that is based on groups of elements in the population, which are called *primary sampling units* (*PSUs*).

Then you create a second-stage sample by drawing a subsample from each selected PSU in the first-stage sample. By repeating this operation, you can select a higher-stage sample. If you include all the elements from the selected primary sampling units, then the two-stage sample is a cluster sample.

Sampling Weights

Sampling weights, which are also known as *survey weights*, are positive values associated with the units in your sample. Ideally, the weight of a sampling unit should be the "frequency" that the sampling unit represents in the target population.

Often, sampling weights are the reciprocals of the selection probabilities for the sampling units. When you use PROC SURVEYSELECT, the procedure generates the sampling weight component for each stage of the design, and you can multiply these sampling weight components to obtain the final sampling weights. Sometimes, sampling weights also include nonresponse adjustments, postsampling stratification, or regression adjustments by using supplemental information.

When the sampling units have unequal weights, you must provide the weights to the survey analysis procedures. If you do not specify sampling weights, the procedures use equal weights in the analyses.

Population Totals and Sampling Rates

If you use Taylor series variance estimation, the survey procedures include a finite population correction factor in the analysis if you input either the sampling rate or the population total.

The sampling rate is the ratio of the sample size (the number of sampling units in the sample) n to the population size (the total number of sampling units in the target population) N, $f = n/N$. This ratio is also called the *sampling fraction*. If you select a sample without replacement, the extra efficiency compared to selecting a sample with replacement can be measured by the *finite population correction* (*fpc*) factor, $(1 - f)$.

To include a finite population correction factor in your analysis, you can input either the sampling rate or the population total. Otherwise, the procedures do not use the *fpc* in computing variance estimates. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for details.

As discussed in the section "Variance Estimation" on page 253, for a multistage sample design, the procedures use only the first stage of the sample design for variance estimation. Therefore, if you are specifying the sampling rate, you should input the *first-stage sampling rate*, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the target population.

If you use BRR or jackknife variance estimate, the procedures do not include a finite population correction in the analysis, and you do not need to input the sampling rate or the population total.

Variance Estimation

The survey analysis procedures provide a choice of variance estimation methods for complex survey designs. In addition to the Taylor series linearization method, the procedures offer two replication-based (resampling) methods—balanced repeated replication (BRR) and the delete-1 jackknife. These variance estimation methods usually give similar, satisfactory results (Lohr 2010; Särndal, Swensson, and Wretman 1992; Wolter 2007). The choice of a variance estimation method can depend on the sample design used, the sample design information available, the parameters to be estimated, and computational issues. See Lohr (2010) for more details.

The Taylor series linearization method is appropriate for all designs where the first-stage sample is selected with replacement, or where the first-stage sampling fraction is small, as it often is in practice. The Taylor

series method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Fuller 1975; Woodruff 1971). When there are clusters (PSUs) in the sample design, the procedures estimate the variance from the variation among the PSUs. When the design is stratified, the procedures pool stratum variance estimates to compute the overall variance estimate.

For a multistage sample design, the Taylor series method uses only the first stage of the sample design. Therefore, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

Replication methods for variance estimation draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. Commonly used resampling schemes include *balanced repeated replication* (BRR) and the *jackknife*. The parameter of interest is estimated from each replicate, and the variability among the replicate estimates is used to estimate the overall variance of the parameter estimate.

The BRR variance estimation method requires a stratified sample design with two PSUs in each stratum. Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights for the remaining PSUs. The adjusted weights are called *replicate weights*. The survey procedures also provide Fay's method, which is a modification of the BRR method.

The jackknife method deletes one PSU at a time from the full sample to create replicates, and modifies the original weights to obtain replicate weights. The total number of replicates equals the number of PSUs. If the sample design is stratified, each stratum must contain at least two PSUs, and the jackknife is applied separately within each stratum.

Instead of having the survey procedures generate replicate weights for the analysis, you can directly input your own replicate weights. This can be useful if you need to do multiple analyses with the same set of replicate weights, or if you have access to replicate weights without complete design information.

See the chapters on the survey procedures for complete details. For more information about variance estimation for sample survey data, see Lohr (2010); Wolter (2007); Särndal, Swensson, and Wretman (1992); Lee, Forthoffer, and Lorimor (1989); Cochran (1977); Kish (1965); and Hansen, Hurwitz, and Madow (1953).

Example: Survey Sampling and Analysis Procedures

This section demonstrates how you can use the survey procedures to select a probability-based sample and then analyze the survey data to make inferences about the population. The analyses include descriptive statistics and regression analysis. This example is a survey of income and expenditures for a group of households in North Carolina and South Carolina. The goals of the survey are as follows:

- Estimate total income and total living expenses
- Estimate the median income and the median living expenses
- Investigate the linear relationship between income and living expenses

Sample Selection

To select a sample with PROC SURVEYSELECT, you input a SAS data set that contains the sampling frame (the list of units from which the sample is to be selected). You also specify the selection method, the desired sample size or sampling rate, and other selection parameters. PROC SURVEYSELECT selects the sample and produces an output data set that contains the selected units, their selection probabilities, and their sampling weights. See Chapter 91, "The SURVEYSELECT Procedure," for more information about PROC SURVEYSELECT.

In this example, the sample design is a stratified sample design, with households as the sampling units and selection by simple random sampling. The SAS data set HHFrame contains the sampling frame, which is the list of households in the survey population. The sampling frame is stratified by the variables State and Region. Within strata, households are selected by simple random sampling. The following PROC SURVEYSELECT statements select a probability sample of households according to this sample design:

```
proc surveyselect data=HHFrame out=HHSample
                  method=srs n=(3, 5, 3, 6, 2);
   strata State Region;
run;
```

The STRATA statement names the stratification variables State and Region. In the PROC SURVEYSELECT statement, the DATA= option names the SAS data set HHFrame as the input data set (or sampling frame) from which to select the sample. The OUT= option stores the sample in the SAS data set named HHSample. The METHOD=SRS option specifies simple random sampling as the sample selection method. The N= option specifies the stratum sample sizes.

The SURVEYSELECT procedure then selects a stratified random sample of households and produces the output data set HHSample, which contains the selected households together with their selection probabilities and sampling weights. The data set HHSample also contains the sampling unit identification variable Id and the stratification variables State and Region from the input data set HHFrame.

Survey Data Analysis

You can use the SURVEYMEANS and SURVEYREG procedures to estimate population values and perform regression analyses for survey data. The following example briefly shows the capabilities of these procedures. See Chapter 88, "The SURVEYMEANS Procedure," and Chapter 90, "The SURVEYREG Procedure," for more information.

The following PROC SURVEYMEANS statements estimate the total income and living expenses for the survey population based on the data from the stratified sample design:

```
proc surveymeans data=HHSample sum median;
   var Income Expense;
   strata State Region;
   weight Weight;
run;
```

The PROC SURVEYMEANS statement invokes the procedure, and the DATA= option names the SAS data set HHSample as the input data set to be analyzed. The keywords SUM and MEDIAN request estimates of population totals and medians.

The VAR statement specifies the two analysis variables Income and Expense. The STRATA statement names the stratification variables State and Region. The WEIGHT statement specifies the sampling weight variable Weight.

You can use PROC SURVEYREG to perform regression analysis for survey data. Suppose that, in order to explore the relationship between household income and living expenses in the survey population, you choose the following linear model:

$$\text{Expense} = \alpha + \beta * \text{Income} + \text{error}$$

The following PROC SURVEYREG statements fit this linear model for the survey population based on the data from the stratified sample design:

```
proc surveyreg data=HHSample;
   strata State Region ;
   model  Expense = Income;
   weight Weight;
run;
```

The STRATA statement names the stratification variables State and Region. The MODEL statement specifies the model, with Expense as the dependent variable and Income as the independent variable. The WEIGHT statement specifies the sampling weight variable Weight.

Chapter 15

The Four Types of Estimable Functions

Contents

Overview

Many regression and analysis of variance procedures in SAS/STAT label tests for various effects in the model as Type I, Type II, Type III, or Type IV. These four types of hypotheses might not always be sufficient for a statistician to perform all desired inferences, but they should suffice for the vast majority of analyses. This chapter explains the hypotheses involved in each of the four test types. For additional discussion, see Freund, Littell, and Spector (1991) or Milliken and Johnson (1984).

The primary context of the discussion is testing linear hypotheses in least squares regression and analysis of variance, such as with PROC GLM. In this context, tests correspond to hypotheses about linear functions of the true parameters and are evaluated using sums of squares of the estimated parameters. Thus, there will be frequent references to Type I, II, III, and IV (estimable) functions and corresponding Type I, II, III, and IV sums of squares, or simply SS.

Estimability

Given a response or dependent variable $\mathbf{Y}$, predictors or independent variables $\mathbf{X}$, and a linear expectation model $\mathrm{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$ relating the two, a primary analytical goal is to estimate or test for the significance of

certain linear combinations of the elements of $\boldsymbol{\beta}$. For least squares regression and analysis of variance, this is accomplished by computing linear combinations of the observed **Y**s. An unbiased linear estimate of a specific linear function of the individual βs, say $\mathbf{L}\boldsymbol{\beta}$, is a linear combination of the **Y**s that has an expected value of $\mathbf{L}\boldsymbol{\beta}$. Hence, the following definition:

> A linear combination of the parameters $\mathbf{L}\boldsymbol{\beta}$ is estimable if and only if a linear combination of the **Y**s exists that has expected value $\mathbf{L}\boldsymbol{\beta}$.

Any linear combination of the **Y**s, for instance **KY**, will have expectation $\mathrm{E}[KY] = \mathbf{KX}\boldsymbol{\beta}$. Thus, the expected value of any linear combination of the **Y**s is equal to that same linear combination of the rows of **X** multiplied by $\boldsymbol{\beta}$. Therefore,

> $\mathbf{L}\boldsymbol{\beta}$ is estimable if and only if there is a linear combination of the rows of **X** that is equal to **L**—that is, if and only if there is a **K** such that $\mathbf{L} = \mathbf{KX}$.

Thus, the rows of **X** form a generating set from which any estimable **L** can be constructed. Since the row space of **X** is the same as the row space of $\mathbf{X}'\mathbf{X}$, the rows of $\mathbf{X}'\mathbf{X}$ also form a generating set from which all estimable **L**s can be constructed. Similarly, the rows of $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$ also form a generating set for **L**.

Therefore, if **L** can be written as a linear combination of the rows of **X**, $\mathbf{X}'\mathbf{X}$, or $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$, then $\mathbf{L}\boldsymbol{\beta}$ is estimable.

In the context of least squares regression and analysis of variance, an estimable linear function $\mathbf{L}\boldsymbol{\beta}$ can be estimated by $\mathbf{L}\widehat{\boldsymbol{\beta}}$, where $\widehat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{Y}$. From the general theory of linear models, the unbiased estimator $\mathbf{L}\widehat{\boldsymbol{\beta}}$ is, in fact, the *best* linear unbiased estimator of $\mathbf{L}\boldsymbol{\beta}$, in the sense of having minimum variance as well as maximum likelihood when the residuals are normal. To test the hypothesis that $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$, compute the sum of squares

$$\mathrm{SS}(H_0\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = (\mathbf{L}\widehat{\boldsymbol{\beta}})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-1}\mathbf{L}\widehat{\boldsymbol{\beta}}$$

and form an F test with the appropriate error term. Note that in contexts more general than least squares regression (for example, generalized and/or mixed linear models), linear hypotheses are often tested by analogous sums of squares of the estimated linear parameters $(\mathbf{L}\widehat{\boldsymbol{\beta}})'(\mathrm{Var}[\mathbf{L}\widehat{\boldsymbol{\beta}}])^{-1}\mathbf{L}\widehat{\boldsymbol{\beta}}$.

General Form of an Estimable Function

This section demonstrates a shorthand technique for displaying the generating set for any estimable **L**. Suppose

$$\mathbf{X} = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad \boldsymbol{\beta} = \begin{bmatrix} \mu \\ A_1 \\ A_2 \\ A_3 \end{bmatrix}$$

$\mathbf{X}$ is a generating set for $\mathbf{L}$, but so is the smaller set

$$\mathbf{X}^* = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{bmatrix}$$

$\mathbf{X}^*$ is formed from $\mathbf{X}$ by deleting duplicate rows.

Since all estimable $\mathbf{L}$s must be linear functions of the rows of $\mathbf{X}^*$ for $\mathbf{L}\boldsymbol{\beta}$ to be estimable, an $\mathbf{L}$ for a single-degree-of-freedom estimate can be represented symbolically as

$$L1 \times (1\ 1\ 0\ 0) + L2 \times (1\ 0\ 1\ 0) + L3 \times (1\ 0\ 0\ 1)$$

or

$$\mathbf{L} = (L1 + L2 + L3,\ L1,\ L2,\ L3)$$

For this example, $\mathbf{L}\boldsymbol{\beta}$ is estimable if and only if the first element of $\mathbf{L}$ is equal to the sum of the other elements of $\mathbf{L}$ or if

$$\mathbf{L}\boldsymbol{\beta} = (L1 + L2 + L3) \times \mu + L1 \times A_1 + L2 \times A_2 + L3 \times A_3$$

is estimable for any values of $L1$, $L2$, and $L3$.

If other generating sets for $\mathbf{L}$ are represented symbolically, the symbolic notation looks different. However, the inherent nature of the rules is the same. For example, if row operations are performed on $\mathbf{X}^*$ to produce an identity matrix in the first 3×3 submatrix of the resulting matrix

$$\mathbf{X}^{**} = \begin{bmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & -1 \end{bmatrix}$$

then $\mathbf{X}^{**}$ is also a generating set for $\mathbf{L}$. An estimable $\mathbf{L}$ generated from $\mathbf{X}^{**}$ can be represented symbolically as

$$\mathbf{L} = (L1,\ L2,\ L3,\ L1 - L2 - L3)$$

Note that, again, the first element of $\mathbf{L}$ is equal to the sum of the other elements.

With multiple generating sets available, the question arises as to which one is the best to represent $\mathbf{L}$ symbolically. Clearly, a generating set containing a minimum of rows (of full row rank) and a maximum of zero elements is desirable.

The generalized g_2-inverse $(\mathbf{X}'\mathbf{X})^-$ of $\mathbf{X}'\mathbf{X}$ computed by the modified sweep operation (Goodnight 1979) has the property that $(\mathbf{X}'\mathbf{X})^-\mathbf{X}'\mathbf{X}$ usually contains numerous zeros. For this reason, in PROC GLM the nonzero rows of $(\mathbf{X}'\mathbf{X})^-\mathbf{X}'\mathbf{X}$ are used to represent $\mathbf{L}$ symbolically.

If the generating set represented symbolically is of full row rank, the number of symbols $(L1, L2, \ldots)$ represents the maximum rank of any testable hypothesis (in other words, the maximum number of linearly independent rows for any $\mathbf{L}$ matrix that can be constructed). By letting each symbol in turn take on the value of 1 while the others are set to 0, the original generating set can be reconstructed.

Introduction to Reduction Notation

Reduction notation can be used to represent differences in sums of squares (SS) for two models. The notation $R(\mu, A, B, C)$ denotes the complete main-effects model for effects A, B, and C. The notation

$$R(A \mid \mu, B, C)$$

denotes the difference between the model SS for the complete main-effects model containing A, B, and C and the model SS for the reduced model containing only B and C.

In other words, this notation represents the differences in model SS produced by

```
proc glm;
   class a b c;
   model y = a b c;
run;
```

and

```
proc glm;
   class b c;
   model y = b c;
run;
```

As another example, consider a regression equation with four independent variables. The notation $R(\beta_3, \beta_4 \mid \beta_1, \beta_2)$ denotes the differences in model SS between

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_4 x_4 + \epsilon$$

and

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \epsilon$$

This is the difference in the model SS for the models produced, respectively, by

```
model y = x1 x2 x3 x4;
```

and

```
model y = x1 x2;
```

The following examples demonstrate the ability to manipulate the symbolic representation of a generating set. Note that any operations performed on the symbolic notation have corresponding row operations that are performed on the generating set itself.

Examples

A One-Way Classification Model

For the model

$$Y = \mu + A_i + \epsilon \qquad i = 1, 2, 3$$

the general form of estimable functions $\mathbf{L}\boldsymbol{\beta}$ is (from the previous example)

$$\mathbf{L}\boldsymbol{\beta} = L1 \times \mu + L2 \times A_1 + L3 \times A_2 + (L1 - L2 - L3) \times A_3$$

Thus,

$$\mathbf{L} = (L1, L2, L3, L1 - L2 - L3)$$

Tests involving only the parameters A_1, A_2, and A_3 must have an $\mathbf{L}$ of the form

$$\mathbf{L} = (0, L2, L3, -L2 - L3)$$

Since this $\mathbf{L}$ for the A parameters involves only two symbols, hypotheses with at most two degrees of freedom can be constructed. For example, letting $(L2, L3)$ be $(1, 0)$ and $(0, 1)$, respectively, yields

$$\mathbf{L} = \begin{bmatrix} 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & -1 \end{bmatrix}$$

The preceding $\mathbf{L}$ can be used to test the hypothesis that $A_1 = A_2 = A_3$. For this example, any $\mathbf{L}$ with two linearly independent rows with column 1 equal to zero produces the same sum of squares. For example, a joint test for linear and quadratic effects of A

$$\mathbf{L} = \begin{bmatrix} 0 & 1 & 0 & -1 \\ 0 & 1 & -2 & 1 \end{bmatrix}$$

gives the same SS. In fact, for any $\mathbf{L}$ of full row rank and any nonsingular matrix $\mathbf{K}$ of conformable dimensions,

$$\text{SS}(H_0\colon \mathbf{L}\boldsymbol{\beta} = 0) = \text{SS}(H_0\colon \mathbf{KL}\boldsymbol{\beta} = 0)$$

A Three-Factor Main-Effects Model

Consider a three-factor main-effects model involving the CLASS variables A, B, and C, as shown in Table 15.1.

Table 15.1 Three-Factor Main-Effects Model

Obs	A	B	C
1	1	2	1
2	1	1	2
3	2	1	3
4	2	2	2
5	2	2	2

The general form of an estimable function is shown in Table 15.2.

Table 15.2 General Form of an Estimable Function for Three-Factor Main-Effects Model

Parameter	Coefficient
μ (Intercept)	$L1$
$A1$	$L2$
$A2$	$L1 - L2$
$B1$	$L4$
$B2$	$L1 - L4$
$C1$	$L6$
$C2$	$L1 + L2 - L4 - 2 \times L6$
$C3$	$-L2 + L4 + L6$

Since only four symbols ($L1$, $L2$, $L4$, and $L6$) are involved, any testable hypothesis will have at most four degrees of freedom. If you form an $\mathbf{L}$ matrix with four linearly independent rows according to the preceding rules, then testing $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ is equivalent to testing that E[$\mathbf{Y}$] is uniformly 0. Symbolically,

$$\text{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = 0) = R(\mu, A, B, C)$$

In a main-effects model, the usual hypothesis of interest for a main effect is the equality of all the parameters. In this example, it is not possible to unambiguously test such a hypothesis because of confounding: any test for the equality of the parameters for any one of A, B, or C will necessarily involve the parameters for the other two effects. One way to proceed is to construct a maximum rank hypothesis (MRH) involving only the parameters of the main effect in question. This can be done using the general form of estimable functions. Note the following:

- To get an MRH involving only the parameters of A, the coefficients of $\mathbf{L}$ associated with μ, $B1$, $B2$, $C1$, $C2$, and $C3$ must be equated to zero. Starting at the top of the general form, let $L1 = 0$, then $L4 = 0$, then $L6 = 0$. If $C2$ and $C3$ are not to be involved, then $L2$ must also be zero. Thus, $A1 - A2$ is not estimable; that is, the MRH involving only the A parameters has zero rank and $R(A \mid \mu, B, C) = 0$.
- To obtain the MRH involving only the B parameters, let $L1 = L2 = L6 = 0$. But then to remove $C2$ and $C3$ from the comparison, $L4$ must also be set to 0. Thus, $B1 - B2$ is not estimable and $R(B \mid \mu, A, C) = 0$.
- To obtain the MRH involving only the C parameters, let $L1 = L2 = L4 = 0$. Thus, the MRH involving only C parameters is

  $$C1 - 2 \times C2 + C3 = K \qquad \text{(for any } K\text{)}$$

  or any multiple of the left-hand side equal to K. Furthermore,

  $$\text{SS}(H_0\colon\ C1 - 2 \times C2 + C3 = 0) = R(C \mid \mu, A, B)$$

A Multiple Regression Model

Suppose

$$\text{E}[Y] = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3$$

where the $\mathbf{X}'\mathbf{X}$ matrix has full rank. The general form of estimable functions is as shown in Table 15.3.

Table 15.3 General Form of Estimable Functions for a Multiple Regression Model When $\mathbf{X}'\mathbf{X}$ Matrix Is of Full Rank

Parameter	Coefficient
β_0	$L1$
β_1	$L2$
β_2	$L3$
β_3	$L4$

For example, to test the hypothesis that $\beta_2 = 0$, let $L1 = L2 = L4 = 0$ and let $L3 = 1$. Then $\text{SS}(\mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = R(\beta_2 \mid \beta_0, \beta_1, \beta_3)$. In this full-rank case, all parameters, as well as any linear combination of parameters, are estimable.

Suppose, however, that $X3 = 2x_1 + 3x_2$. The general form of estimable functions is shown in Table 15.4.

Table 15.4 General Form of Estimable Functions for a Multiple Regression Model When $\mathbf{X}'\mathbf{X}$ Matrix Is Not of Full Rank

Parameter	Coefficient
β_0	$L1$
β_1	$L2$
β_2	$L3$
β_3	$2 \times L2 + 3 \times L3$

For this example, it is possible to test $H_0: \beta_0 = 0$. However, β_1, β_2, and β_3 are not jointly estimable; that is,

$$\begin{aligned} R(\beta_1 \mid \beta_0, \beta_2, \beta_3) &= 0 \\ R(\beta_2 \mid \beta_0, \beta_1, \beta_3) &= 0 \\ R(\beta_3 \mid \beta_0, \beta_1, \beta_2) &= 0 \end{aligned}$$

Estimable Functions

Type I SS and Estimable Functions

In PROC GLM, the Type I SS and the associated hypotheses they test are byproducts of the modified sweep operator used to compute a generalized g_2-inverse of $\mathbf{X}'\mathbf{X}$ and a solution to the normal equations. For the model $\text{E}[Y] = x_1\beta_1 + x_2\beta_2 + x_3\beta_3$, the Type I SS for each effect are as follows:

Effect	Type I SS
x_1	$R(\beta_1)$
x_2	$R(\beta_2 \mid \beta_1)$
x_3	$R(\beta_3 \mid \beta_1, \beta_2)$

Note that some other SAS/STAT procedures compute Type I hypotheses by sweeping $\mathbf{X}'\mathbf{X}$ (for example, PROC MIXED and PROC GLIMMIX), but their test statistics are not necessarily equivalent to the results of using those procedures to fit models that contain successively more effects.

The Type I SS are model-order dependent; each effect is adjusted only for the preceding effects in the model.

There are numerous ways to obtain a Type I hypothesis matrix $\mathbf{L}$ for each effect. One way is to form the $\mathbf{X}'\mathbf{X}$ matrix and then reduce $\mathbf{X}'\mathbf{X}$ to an upper triangular matrix by row operations, skipping over any rows with a zero diagonal. The nonzero rows of the resulting matrix associated with x_1 provide an $\mathbf{L}$ such that

$$\text{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = R(\beta_1)$$

The nonzero rows of the resulting matrix associated with x_2 provide an $\mathbf{L}$ such that

$$\text{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = R(\beta_2 \mid \beta_1)$$

The last set of nonzero rows (associated with x_3) provide an $\mathbf{L}$ such that

$$\text{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = R(\beta_3 \mid \beta_1, \beta_2)$$

Another more formalized representation of Type I generating sets for x_1, x_2, and x_3, respectively, is

$$\begin{array}{lcccccc}
\mathbf{G}_1 & = & (& \mathbf{X}_1'\mathbf{X}_1 & \mid & \mathbf{X}_1'\mathbf{X}_2 & \mid & \mathbf{X}_1'\mathbf{X}_3 &) \\
\mathbf{G}_2 & = & (& 0 & \mid & \mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2 & \mid & \mathbf{X}_2'\mathbf{M}_1\mathbf{X}_3 &) \\
\mathbf{G}_3 & = & (& 0 & \mid & 0 & \mid & \mathbf{X}_3'\mathbf{M}_2\mathbf{X}_3 &)
\end{array}$$

where

$$\mathbf{M}_1 = \mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^-\mathbf{X}_1'$$

and

$$\mathbf{M}_2 = \mathbf{M}_1 - \mathbf{M}_1\mathbf{X}_2(\mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2)^-\mathbf{X}_2'\mathbf{M}_1$$

Using the Type I generating set $\mathbf{G}_2$ (for example), if an $\mathbf{L}$ is formed from linear combinations of the rows of $\mathbf{G}_2$ such that $\mathbf{L}$ is of full row rank and of the same row rank as $\mathbf{G}_2$, then $\text{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = R(\beta_2 \mid \beta_1)$.

In the GLM procedure, the Type I estimable functions displayed symbolically when the E1 option is requested are

$$\begin{aligned}
\mathbf{G}_1^* &= (\mathbf{X}_1'\mathbf{X}_1)^-\mathbf{G}_1 \\
\mathbf{G}_2^* &= (\mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2)^-\mathbf{G}_2 \\
\mathbf{G}_3^* &= (\mathbf{X}_3'\mathbf{M}_2\mathbf{X}_3)^-\mathbf{G}_3
\end{aligned}$$

As can be seen from the nature of the generating sets $\mathbf{G}_1$, $\mathbf{G}_2$, and $\mathbf{G}_3$, only the Type I estimable functions for β_3 are guaranteed not to involve the β_1 and β_2 parameters. The Type I hypothesis for β_2 can (and often does) involve β_3 parameters, and likewise the Type I hypothesis for β_1 often involves β_2 and β_3 parameters.

There are, however, a number of models for which the Type I hypotheses are considered appropriate. These are as follows:

- balanced ANOVA models specified in proper sequence (that is, interactions do not precede main effects in the MODEL statement and so forth)
- purely nested models (specified in the proper sequence)
- polynomial regression models (in the proper sequence)

Type II SS and Estimable Functions

For main-effects models and regression models, the general form of estimable functions can be manipulated to provide tests of hypotheses involving only the parameters of the effect in question. The same result can also be obtained by entering each effect in turn as the last effect in the model and obtaining the Type I SS for that effect. These are the *Type II SS*. Using a modified reversible sweep operator, it is possible to obtain the Type II SS without actually refitting the model.

Thus, the **Type II SS correspond to the R notation in which each effect is adjusted for all other appropriate effects**. For a regression model such as

$$\mathrm{E}[Y] = x_1\beta_1 + x_2\beta_2 + x_3\beta_3$$

the Type II SS correspond to

Effect	Type II SS
x_1	$R(\beta_1 \mid \beta_2, \beta_3)$
x_2	$R(\beta_2 \mid \beta_1, \beta_3)$
x_3	$R(\beta_3 \mid \beta_1, \beta_2)$

For a main-effects model (A, B, and C as classification variables), the Type II SS correspond to

Effect	Type II SS
A	$R(A \mid B, C)$
B	$R(B \mid A, C)$
C	$R(C \mid A, B)$

As the discussion in the section "A Three-Factor Main-Effects Model" on page 263 indicates, for regression and main-effects models the Type II SS provide an MRH for each effect that does not involve the parameters of the other effects.

In order to see what effects are appropriate to adjust for in computing Type II estimable functions, note that for models involving interactions and nested effects, in the absence of a priori parametric restrictions, it is not possible to obtain a test of a hypothesis for a main effect free of parameters of higher-level interactions effects with which the main effect is involved. It is reasonable to assume, then, that any test of a hypothesis concerning an effect should involve the parameters of that effect and only those other parameters with which that effect is involved. The concept of effect containment helps to define this involvement.

Contained Effect

Given two effects $F1$ and $F2$, $F1$ is said to be *contained in* $F2$ provided that the following two conditions are met:

- Both effects involve the same continuous variables (if any).
- $F2$ has more CLASS variables than $F1$ does, and if $F1$ has CLASS variables, they all appear in $F2$.

Note that the intercept effect μ is contained in all pure CLASS effects, but it is not contained in any effect involving a continuous variable. No effect is contained by μ.

Type II, Type III, and Type IV estimable functions rely on this definition, and they all have one thing in common: the estimable functions involving an effect $F1$ also involve the parameters of all effects that contain $F1$, and they do not involve the parameters of effects that do not contain $F1$ (other than $F1$).

Hypothesis Matrix for Type II Estimable Functions

The Type II estimable functions for an effect $F1$ have an $\mathbf{L}$ (before reduction to full row rank) of the following form:

- All columns of $\mathbf{L}$ associated with effects not containing $F1$ (except $F1$) are zero.
- The submatrix of $\mathbf{L}$ associated with effect $F1$ is $(\mathbf{X}_1'\mathbf{M}\mathbf{X}_1)^-(\mathbf{X}_1'\mathbf{M}\mathbf{X}_1)$.
- Each of the remaining submatrices of $\mathbf{L}$ associated with an effect $F2$ that contains $F1$ is $(\mathbf{X}_1'\mathbf{M}\mathbf{X}_1)^-(\mathbf{X}_1'\mathbf{M}\mathbf{X}_2)$.

In these submatrices,

$$\begin{aligned}
\mathbf{X}_0 &= \text{the columns of } \mathbf{X} \text{ whose associated effects do not contain } F1 \\
\mathbf{X}_1 &= \text{the columns of } \mathbf{X} \text{ associated with } F1 \\
\mathbf{X}_2 &= \text{the columns of } \mathbf{X} \text{ associated with an } F2 \text{ effect that contains } F1 \\
\mathbf{M} &= \mathbf{I} - \mathbf{X}_0(\mathbf{X}_0'\mathbf{X}_0)^-\mathbf{X}_0'
\end{aligned}$$

For the model

```
class A B;
model Y = A B A*B;
```

the Type II SS correspond to

$$R(A \mid \mu, B), \quad R(B \mid \mu, A), \quad R(A * B \mid \mu, A, B)$$

for effects A, B, and $A * B$, respectively. For the model

```
class A B C;
model Y =  A B(A) C(A B);
```

the Type II SS correspond to

$$R(A \mid \mu), \quad R(B(A) \mid \mu, A), \quad R(C(AB) \mid \mu, A, B(A))$$

for effects A, $B(A)$ and $C(A\,B)$, respectively. For the model

```
model Y = x x*x;
```

the Type II SS correspond to

$$R(X \mid \mu, X * X) \text{ and } R(X * X \mid \mu, X)$$

for x and $x * x$, respectively.

Note that, as in the situation for Type I tests, PROC MIXED and PROC GLIMMIX compute Type I hypotheses by sweeping $\mathbf{X}'\mathbf{X}$, but their test statistics are not necessarily equivalent to the results of sequentially fitting with those procedures models that contain successively more effects; while PROC TRANSREG computes tests labeled as being Type II by leaving out each effect in turn, but the specific linear hypotheses associated with these tests might not be precisely the same as the ones derived from successively sweeping $\mathbf{X}'\mathbf{X}$.

Example of Type II Estimable Functions

For a 2×2 factorial with w observations per cell, the general form of estimable functions is shown in Table 15.5. Any nonzero values for $L2$, $L4$, and $L6$ can be used to construct $\mathbf{L}$ vectors for computing the Type II SS for A, B, and $A * B$, respectively.

Table 15.5 General Form of Estimable Functions for 2×2 Factorial

Effect	Coefficient
μ	$L1$
$A1$	$L2$
$A2$	$L1 - L2$
$B1$	$L4$
$B2$	$L1 - L4$
$AB11$	$L6$
$AB12$	$L2 - L6$
$AB21$	$L4 - L6$
$AB22$	$L1 - L2 - L4 + L6$

For a balanced 2×2 factorial with the same number of observations in every cell, the Type II estimable functions are shown in Table 15.6.

Table 15.6 Type II Estimable Functions for Balanced 2×2 Factorial

	Coefficients for Effect		
Effect	A	B	$A * B$
μ	0	0	0
$A1$	$L2$	0	0
$A2$	$-L2$	0	0
$B1$	0	$L4$	0
$B2$	0	$-L4$	0
$AB11$	$0.5 * L2$	$0.5 * L4$	$L6$
$AB12$	$0.5 * L2$	$-0.5 * L4$	$-L6$
$AB21$	$-0.5 * L2$	$0.5 * L4$	$-L6$
$AB22$	$-0.5 * L2$	$-0.5 * L4$	$L6$

Now consider an unbalanced 2×2 factorial with two observations in every cell except the $AB22$ cell, which contains only one observation. The general form of estimable functions is the same as if it were balanced, since the same effects are still estimable. However, the Type II estimable functions for A and B are not the same as they were for the balanced design. The Type II estimable functions for this unbalanced 2×2 factorial are shown in Table 15.7.

Table 15.7 Type II Estimable Functions for Unbalanced 2×2 Factorial

	Coefficients for Effect		
Effect	A	B	$A * B$
μ	0	0	0
$A1$	$L2$	0	0
$A2$	$-L2$	0	0
$B1$	0	$L4$	0
$B2$	0	$-L4$	0
$AB11$	$0.6 * L2$	$0.6 * L4$	$L6$
$AB12$	$0.4 * L2$	$-0.6 * L4$	$-L6$
$AB21$	$-0.6 * L2$	$0.4 * L4$	$-L6$
$AB22$	$-0.4 * L2$	$-0.4 * L4$	$L6$

By comparing the hypothesis being tested in the balanced case to the hypothesis being tested in the unbalanced case for effects A and B, you can note that the Type II hypotheses for A and B are dependent on the cell frequencies in the design. For unbalanced designs in which the cell frequencies are not proportional to the background population, the Type II hypotheses for effects that are contained in other effects are of questionable value.

However, if an effect is not contained in any other effect, the Type II hypothesis for that effect is an MRH that does not involve any parameters except those associated with the effect in question.

Thus, Type II SS are appropriate for the following models:

- any balanced model
- any main-effects model
- any pure regression model
- an effect not contained in any other effect (regardless of the model)

In addition to the preceding models, Type II SS are generally accepted by most statisticians for purely nested models.

Type III and IV SS and Estimable Functions

When an effect is contained in another effect, the Type II hypotheses for that effect are dependent on the cell frequencies. The philosophy behind both the Type III and Type IV hypotheses is that the hypotheses tested for any given effect should be the same for all designs with the same general form of estimable functions.

To demonstrate this concept, recall the hypotheses being tested by the Type II SS in the balanced 2×2 factorial shown in Table 15.6. Those hypotheses are precisely the ones that the Type III and Type IV hypotheses employ for all 2×2 factorials that have at least one observation per cell. The Type III and Type IV hypotheses for a design without missing cells usually differ from the hypothesis employed for the same design with missing cells since the general form of estimable functions usually differs.

Many SAS/STAT procedures can perform tests of Type III hypotheses, but only PROC GLM offers Type IV tests as well.

Type III Estimable Functions

Type III hypotheses are constructed by working directly with the general form of estimable functions. The following steps are used to construct a hypothesis for an effect $F1$:

1. For every effect in the model except $F1$ and those effects that contain $F1$, equate the coefficients in the general form of estimable functions to zero.

   If $F1$ is not contained in any other effect, this step defines the Type III hypothesis (as well as the Type II and Type IV hypotheses). If $F1$ is contained in other effects, go on to step 2. (See the section "Type II SS and Estimable Functions" on page 267 for a definition of when effect $F1$ is contained in another effect.)

2. If necessary, equate new symbols to compound expressions in the $F1$ block in order to obtain the simplest form for the $F1$ coefficients.

3. Equate all symbolic coefficients outside the $F1$ block to a linear function of the symbols in the $F1$ block in order to make the $F1$ hypothesis orthogonal to hypotheses associated with effects that contain $F1$.

By once again observing the Type II hypotheses being tested in the balanced 2×2 factorial, it is possible to verify that the A and $A * B$ hypotheses are orthogonal and also that the B and $A * B$ hypotheses are orthogonal. This principle of orthogonality between an effect and any effect that contains it holds for all balanced designs. Thus, construction of Type III hypotheses for any design is a logical extension of a process that is used for balanced designs.

The Type III hypotheses are precisely the hypotheses being tested by programs that reparameterize using the usual assumptions (for example, constraining all parameters for an effect to sum to zero). When no missing cells exist in a factorial model, Type III SS coincide with Yates' weighted squares-of-means technique. When cells are missing in factorial models, the Type III SS coincide with those discussed in Harvey (1960) and Henderson (1953).

The following discussion illustrates the construction of Type III estimable functions for a 2×2 factorial with no missing cells.

To obtain the $A * B$ interaction hypothesis, start with the general form and equate the coefficients for effects μ, A, and B to zero, as shown in Table 15.8.

Table 15.8 Type III Hypothesis for $A * B$ Interaction

Effect	General Form	$L1 = L2 = L4 = 0$
μ	$L1$	0
$A1$	$L2$	0
$A2$	$L1 - L2$	0
$B1$	$L4$	0
$B2$	$L1 - L4$	0
$AB11$	$L6$	$L6$
$AB12$	$L2 - L6$	$-L6$
$AB21$	$L4 - L6$	$-L6$
$AB22$	$L1 - L2 - L4 + L6$	$L6$

The last column in Table 15.8 represents the form of the MRH for $A * B$.

To obtain the Type III hypothesis for A, first start with the general form and equate the coefficients for effects μ and B to zero (let $L1 = L4 = 0$). Next let $L6 = K \times L2$, and find the value of K that makes the A hypothesis orthogonal to the A*B hypothesis. In this case, $K = 0.5$. Each of these steps is shown in Table 15.9.

In Table 15.9, the fourth column (under $L6 = K \times L2$) represents the form of all estimable functions not involving μ, $B1$, or $B2$. The prime difference between the Type II and Type III hypotheses for A is the way K is determined. Type II chooses K as a function of the cell frequencies, whereas Type III chooses K such that the estimable functions for A are orthogonal to the estimable functions for $A * B$.

Table 15.9 Type III Hypothesis for A

Effect	General Form	$L1 = L4 = 0$	$L6 = K \times L2$	$K = 0.5$
μ	$L1$	0	0	0
$A1$	$L2$	$L2$	$L2$	$L2$
$A2$	$L1 - L2$	$-L2$	$-L2$	$-L2$
$B1$	$L4$	0	0	0
$B2$	$L1 - L4$	0	0	0
$AB11$	$L6$	$L6$	$K * L2$	$0.5 * L2$
$AB12$	$L2 - L6$	$L2 - L6$	$(1 - K) * L2$	$0.5 * L2$
$AB21$	$L4 - L6$	$-L6$	$-K * L2$	$-0.5 * L2$
$AB22$	$L1 - L2 - L4 + L6$	$-L2 + L6$	$-(1 - K) * L2$	$-0.5 * L2$

An example of Type III estimable functions in a 3×3 factorial with unequal cell frequencies and missing diagonals is given in Table 15.10 (N_1 through N_6 represent the nonzero cell frequencies).

Table 15.10 3×3 Factorial Design with Unequal Cell Frequencies and Missing Diagonals

		B		
		1	2	3
A	1		N_1	N_2
	2	N_3		N_4
	3	N_5	N_6	

For any nonzero values of N_1 through N_6, the Type III estimable functions for each effect are shown in Table 15.11.

Table 15.11 Type III Estimable Functions for 3×3 Factorial Design with Unequal Cell Frequencies and Missing Diagonals

Effect	A	B	$A * B$
μ	0	0	0
$A1$	$L2$	0	0
$A2$	$L3$	0	0
$A3$	$-L2 - L3$	0	0
$B1$	0	$L5$	0
$B2$	0	$L6$	0
$B3$	0	$-L5 - L6$	0
$AB12$	$0.667 * L2 + 0.333 * L3$	$0.333 * L5 + 0.667 * L6$	$L8$
$AB13$	$0.333 * L2 - 0.333 * L3$	$-0.333 * L5 - 0.667 * L6$	$-L8$
$AB21$	$0.333 * L2 + 0.667 * L3$	$0.667 * L5 + 0.333 * L6$	$-L8$
$AB23$	$-0.333 * L2 + 0.333 * L3$	$-0.667 * L5 - 0.333 * L6$	$L8$
$AB31$	$-0.333 * L2 - 0.667 * L3$	$0.333 * L5 - 0.333 * L6$	$L8$
$AB32$	$-0.667 * L2 - 0.333 * L3$	$-0.333 * L5 + 0.333 * L6$	$-L8$

Type IV Estimable Functions

By once again looking at the Type II hypotheses being tested in the balanced 2×2 factorial (see Table 15.6), you can see another characteristic of the hypotheses employed for balanced designs: the coefficients of lower-order effects are averaged across each higher-level effect involving the same subscripts. For example, in the A hypothesis, the coefficients of $AB11$ and $AB12$ are equal to one-half the coefficient of $A1$, and the coefficients of $AB21$ and $AB22$ are equal to one-half the coefficient of $A2$. With this in mind, the basic concept used to construct Type IV hypotheses is that the coefficients of any effect, say $F1$, are distributed equitably across higher-level effects that contain $F1$. When missing cells occur, this same general philosophy is adhered to, but care must be taken in the way the distributive concept is applied.

Construction of Type IV hypotheses begins as does the construction of the Type III hypotheses. That is, for an effect $F1$, equate to zero all coefficients in the general form that do not belong to $F1$ or to any other effect containing $F1$. If $F1$ is not contained in any other effect, then the Type IV hypothesis (and Type II and III) has been found. If $F1$ is contained in other effects, then simplify, if necessary, the coefficients associated with $F1$ so that they are all free coefficients or functions of other free coefficients in the $F1$ block.

To illustrate the method of resolving the free coefficients outside the $F1$ block, suppose that you are interested in the estimable functions for an effect A and that A is contained in AB, AC, and ABC. (In other words, the main effects in the model are A, B, and C.)

With missing cells, the coefficients of intermediate effects (here they are AB and AC) do not always have an equal distribution of the lower-order coefficients, so the coefficients of the highest-order effects are determined first (here it is ABC). Once the highest-order coefficients are determined, the coefficients of intermediate effects are automatically determined.

The following process is performed for each free coefficient of A in turn. The resulting symbolic vectors are then added together to give the Type IV estimable functions for A.

1. Select a free coefficient of A, and set all other free coefficients of A to zero.
2. If any of the levels of A have zero as a coefficient, equate all of the coefficients of higher-level effects involving that level of A to zero. This step alone usually resolves most of the free coefficients remaining.
3. Check to see if any higher-level coefficients are now zero when the coefficient of the associated level of A is not zero. If this situation occurs, the Type IV estimable functions for A are not unique.
4. For each level of A in turn, if the A coefficient for that level is nonzero, count the number of times that level occurs in the higher-level effect. Then equate each of the higher-level coefficients to the coefficient of that level of A divided by the count.

An example of a 3×3 factorial with four missing cells (N_1 through N_5 represent positive cell frequencies) is shown in Table 15.12.

Table 15.12 3×3 Factorial Design with Four Missing Cells

		B		
		1	2	3
A	1	N_1	N_2	
	2	N_3	N_4	
	3			N_5

The Type IV estimable functions are shown in Table 15.13.

Table 15.13 Type IV Estimable Functions for 3×3 Factorial Design with Four Missing Cells

Effect	A	B	$A * B$
μ	0	0	0
$A1$	$-L3$	0	0
$A2$	$L3$	0	0
$A3$	0	0	0
$B1$	0	$L5$	0
$B2$	0	$-L5$	0
$B3$	0	0	0
$AB11$	$-0.5 * L3$	$0.5 * L5$	$L8$
$AB12$	$-0.5 * L3$	$-0.5 * L5$	$-L8$
$AB21$	$0.5 * L3$	$0.5 * L5$	$-L8$
$AB22$	$0.5 * L3$	$-0.5 * L5$	$L8$
$AB33$	0	0	0

A Comparison of Type III and Type IV Hypotheses

For the vast majority of designs, Type III and Type IV hypotheses for a given effect are the same. Specifically, they are the same for any effect $F1$ that is not contained in other effects for any design (with or without missing cells). For factorial designs with no missing cells, the Type III and Type IV hypotheses coincide for all effects. When there are missing cells, the hypotheses can differ. By using the GLM procedure, you can study the differences in the hypotheses and then decide on the appropriateness of the hypotheses for a particular model.

The Type III hypotheses for three-factor and higher completely nested designs with unequal Ns in the lowest level differ from the Type II hypotheses; however, the Type IV hypotheses do correspond to the Type II hypotheses in this case.

When missing cells occur in a design, the Type IV hypotheses might not be unique. If this occurs in PROC GLM, you are notified, and you might need to consider defining your own specific comparisons.

Chapter 16

Introduction to Nonparametric Analysis

Contents

Overview: Nonparametric Analysis

In statistical inference, or hypothesis testing, the traditional tests are called *parametric tests* because they depend on the specification of a probability distribution (such as the normal) except for a set of free parameters. Parametric tests are said to depend on distributional assumptions. *Nonparametric tests*, on the other hand, do not require any strict distributional assumptions. Even if the data are distributed normally, nonparametric methods are often almost as powerful as parametric methods.

Many nonparametric methods analyze the ranks of a variable rather than the original values. Procedures such as PROC NPAR1WAY calculate the ranks for you and then perform appropriate nonparametric tests. However, there are some situations in which you use a procedure such as PROC RANK to calculate ranks and then use another procedure to perform the appropriate test. See the section "Obtaining Ranks" on page 283 for details.

Although the NPAR1WAY procedure is specifically targeted for nonparametric analysis, many other procedures also perform nonparametric analyses. Some general references on nonparametrics include Hollander and Wolfe (1999), Conover (1999), Gibbons and Chakraborti (1992), Hettmansperger (1984), Randles and Wolfe (1979), and Lehmann (1975).

Testing for Normality

Many parametric tests assume an underlying normal distribution for the population. If your data do not meet this assumption, you might prefer to use a nonparametric analysis.

Base SAS software provides several tests for normality in the UNIVARIATE procedure. Depending on your sample size, PROC UNIVARIATE performs the Kolmogorov-Smirnov, Shapiro-Wilk, Anderson-Darling, and Cramér-von Mises tests. For more information, see the chapter "The UNIVARIATE Procedure" in the *Base SAS Procedures Guide*.

Comparing Distributions

To test the hypothesis that two or more groups of observations have identical distributions, use the NPAR1WAY procedure, which provides empirical distribution function (EDF) statistics. The procedure calculates the Kolmogorov-Smirnov test, the Cramér-von Mises test, and, when the data are classified into only two samples, the Kuiper test. Exact *p*-values are available for the two-sample Kolmogorov-Smirnov test. To obtain these tests, use the EDF option in the PROC NPAR1WAY statement. See Chapter 64, "The NPAR1WAY Procedure," for details.

One-Sample Tests

Base SAS software provides two one-sample tests in the UNIVARIATE procedure: a sign test and the Wilcoxon signed rank test. Both tests are designed for situations where you want to make an inference about the location (median) of a population. For example, suppose you want to test whether the median resting pulse rate of marathon runners differs from a specified value.

By default, both of these tests examine the hypothesis that the median of the population from which the sample is drawn is equal to a specified value, which is zero by default. The Wilcoxon signed rank test requires that the distribution be symmetric; the sign test does not require this assumption. These tests can also be used for the case of two related samples; see the section "Comparing Two Independent Samples" on page 279 for more information.

These two tests are automatically provided by the UNIVARIATE procedure. For details, formulas, and examples, see the chapter "The UNIVARIATE Procedure" in the *Base SAS Procedures Guide*.

Two-Sample Tests

This section describes tests appropriate for two independent samples (for example, two groups of subjects given different treatments) and for two related samples (for example, before-and-after measurements on a single group of subjects). Related samples are also referred to as paired samples or matched pairs.

Comparing Two Independent Samples

SAS/STAT software provides several nonparametric tests for location and scale differences for two independent samples.

When you perform these tests, your data should consist of a random sample of observations from two different populations. Your goal is to compare either the location parameters (medians) or the scale parameters of the two populations. For example, suppose your data consist of the number of days in the hospital for two groups of patients: those who received a standard surgical procedure and those who received a new, experimental surgical procedure. These patients are a random sample from the population of patients who have received the two types of surgery. Your goal is to decide whether the median hospital stays differ for the two populations.

Tests in the NPAR1WAY Procedure

The NPAR1WAY procedure provides the following location tests: Wilcoxon rank sum test (Mann-Whitney U test), median test, Savage test, and Van der Waerden (normal scores) test. Note that the Wilcoxon rank sum test can also be obtained from the FREQ procedure. PROC NPAR1WAY provides Hodges-Lehmann estimation of the location shift between two samples, including asymptotic (Moses) and exact confidence limits.

In addition, PROC NPAR1WAY produces the following tests for scale differences: Siegel-Tukey test, Ansari-Bradley test, Klotz test, and Mood test. PROC NPAR1WAY also provides the Conover test, which can be used to test for differences in both location and scale.

Additionally, PROC NPAR1WAY provides tests that use the input data observations as scores, enabling you to produce a wide variety of tests. You can construct any scores for your data with the DATA step, and then PROC NPAR1WAY computes the corresponding linear rank test. You can directly analyze the raw data this way, producing the permutation test known as Pitman's test.

When data are sparse, skewed, or heavily tied, the usual asymptotic tests might not be appropriate. In these situations, exact tests might be suitable for analyzing your data. The NPAR1WAY procedure can produce exact *p*-values for all of the two-sample tests for location and scale differences.

See Chapter 64, "The NPAR1WAY Procedure," for details, formulas, and examples of these tests.

Tests in the FREQ Procedure

The FREQ procedure provides nonparametric tests that compare the location of two groups and that test for independence between two variables.

The situation in which you want to compare the location of two groups of observations corresponds to a table with two rows. In this case, the asymptotic Wilcoxon rank sum test can be obtained by using SCORES=RANK in the TABLES statement and by looking at either of the following:

- the Mantel-Haenszel statistic in the list of tests for no association. This is labeled as "Mantel Haenszel Chi-Square," and PROC FREQ displays the statistic, the degrees of freedom, and the p-value. To obtain this statistic, specify the CHISQ option in the TABLES statement.
- the CMH statistic 2 in the section on Cochran-Mantel-Haenszel statistics. PROC FREQ displays the statistic, the degrees of freedom, and the p-value. To obtain this statistic, specify the CMH2 option in the TABLES statement.

When you test for independence, the question being answered is whether the two variables of interest are related in some way. For example, you might want to know if student scores on a standard test are related to whether students attended a public or private school. One way to think of this situation is to consider the data as a two-way table; the hypothesis of interest is whether the rows and columns are independent. In the preceding example, the groups of students would form the two rows, and the scores would form the columns. The special case of a two-category response (Pass/Fail) leads to a 2×2 table; the case of more than two categories for the response (A/B/C/D/F) leads to a $2 \times c$ table, where c is the number of response categories.

For testing whether two variables are independent, PROC FREQ provides Fisher's exact test. For a 2×2 table, PROC FREQ automatically provides Fisher's exact test when you specify the CHISQ option in the TABLES statement. For a $2 \times c$ table, use the FISHER option in the EXACT statement to obtain the test.

See Chapter 36, "The FREQ Procedure," for details, formulas, and examples of these tests.

Comparing Two Related Samples

SAS/STAT software provides the following nonparametric tests for comparing the locations of two related samples:

- Wilcoxon signed rank test
- sign test
- McNemar's test

The first two tests are available in the UNIVARIATE procedure, and the last test is available in the FREQ procedure. When you perform these tests, your data should consist of pairs of measurements for a random sample from a single population. For example, suppose your data consist of SAT scores for students before

and after attending a course on how to prepare for the SAT. The pairs of measurements are the scores before and after the course, and the students should be a random sample of students who attended the course. Your goal in analysis is to decide whether the median change in scores is significantly different from zero.

Tests in the UNIVARIATE Procedure

By default, PROC UNIVARIATE performs a Wilcoxon signed rank test and a sign test. To use these tests on two related samples, perform the following steps:

1. In the DATA step, create a new variable that contains the differences between the two related variables.
2. Run PROC UNIVARIATE, using the new variable in the VAR statement.

See the chapter "The UNIVARIATE Procedure" in the *Base SAS Procedures Guide* for details and examples of these tests.

Tests in the FREQ Procedure

The FREQ procedure can be used to obtain McNemar's test, which is simply another special case of a Cochran-Mantel-Haenszel statistic (and also of the sign test). The AGREE option in the TABLES statement produces this test for 2×2 tables, and exact p-values are also available for this test. See Chapter 36, "The FREQ Procedure," for more information.

Tests for *k* Samples

Comparing *k* Independent Samples

One goal in comparing k independent samples is to determine whether the location parameters (medians) of the populations are different. Another goal is to determine whether the scale parameters for the populations are different. For example, suppose new employees are randomly assigned to one of three training programs. At the end of the program, the employees are given a standard test that provides a rating score of their job ability. The goal of analysis is to compare the median scores for the three groups and decide whether the differences are real or due to chance alone.

To compare k independent samples, either the NPAR1WAY or the FREQ procedure provides a Kruskal-Wallis test. PROC NPAR1WAY also provides the Savage, median, and Van der Waerden (normal scores) tests. In addition, PROC NPAR1WAY produces the following tests for scale differences: Siegel-Tukey test, Ansari-Bradley test, Klotz test, and Mood test. PROC NPAR1WAY also provides the Conover test, which can be used to test for differences in both location and scale. Note that you can obtain exact p-values for all of these tests.

Additionally, you can specify the SCORES=DATA option to use the input data observations as scores. This enables you to produce a very wide variety of tests. You can construct any scores for your data with the DATA step, and then PROC NPAR1WAY computes the corresponding linear rank and one-way ANOVA tests. You can also analyze the raw data with the SCORES=DATA option; for two-sample data, this permutation test is known as Pitman's test.

See Chapter 64, "The NPAR1WAY Procedure," for details, formulas, and examples.

To produce a Kruskal-Wallis test in the FREQ procedure, use SCORES=RANK and the CMH2 option in the TABLES statement. Then, look at the second Cochran-Mantel-Haenszel statistic (labeled "Row Mean Scores Differ") to obtain the Kruskal-Wallis test. The FREQ procedure also provides the Jonckheere-Terpstra test, which is more powerful than the Kruskal-Wallis test for comparing k samples against ordered alternatives. The exact test is also available. In addition, you can obtain a ridit analysis, developed by Bross (1958), by specifying SCORES=RIDIT or SCORES=MODRIDIT in the TABLES statement in the FREQ procedure. See Chapter 36, "The FREQ Procedure," for more information.

Comparing *k* Dependent Samples

Friedman's test enables you to compare the locations of three or more dependent samples. You can obtain Friedman's chi-square with the FREQ procedure by using the CMH2 option and SCORES=RANK and by looking at the second CMH statistic in the output. For an example, see Chapter 36, "The FREQ Procedure." This chapter also contains formulas and other details about the CMH statistics. For a discussion of how to use the RANK and GLM procedures to obtain Friedman's test, see Ipe (1987).

Measures of Correlation and Associated Tests

The CORR procedure in Base SAS software provides several nonparametric measures of association and associated tests. It computes Spearman's rank-order correlation, Kendall's tau-b, and Hoeffding's measure of dependence, and it provides tests for each of these statistics. PROC CORR also computes Spearman's partial rank-order correlation and Kendall's partial tau-b. Finally, PROC CORR computes Cronbach's coefficient alpha for raw and standardized variables. This statistic can be used to estimate the reliability coefficient. For a general discussion of correlations, formulas, interpretation, and examples, see the chapter "The CORR Procedure" in the *Base SAS Procedures Guide*.

The FREQ procedure also provides some nonparametric measures of association: gamma, Kendall's tau-b, Stuart's tau-c, Somers' D, and the Spearman rank correlation. The output includes the measure, the asymptotic standard error, confidence limits, and the asymptotic test that the measure equals zero. Exact tests are also available for some of these measures. For more information, see Chapter 36, "The FREQ Procedure."

Obtaining Ranks

The primary procedure for obtaining ranks is the RANK procedure in Base SAS software. Note that the PRINQUAL and TRANSREG procedures also provide rank transformations. With all three of these procedures, you can create an output data set and use it as input to another SAS/STAT procedure or to the IML procedure. For more information, see the chapter "The RANK Procedure" in the *Base SAS Procedures Guide*. Also see Chapter 73, "The PRINQUAL Procedure," and Chapter 93, "The TRANSREG Procedure."

In addition, you can specify SCORES=RANK in the TABLES statement in the FREQ procedure. PROC FREQ then uses ranks to perform the analyses requested and generates nonparametric analyses.

For more discussion of the rank transform, see Iman and Conover (1979); Conover and Iman (1981); Hora and Conover (1984); Iman, Hora, and Conover (1984); Hora and Iman (1988); and Iman (1988).

Kernel Density Estimation

The KDE procedure performs either univariate or bivariate kernel density estimation. Statistical *density estimation* involves approximating a hypothesized probability density function from observed data. *Kernel density estimation* is a nonparametric technique for density estimation in which a known density function (the kernel) is averaged across the observed data points to create a smooth approximation.

PROC KDE uses a Gaussian density as the kernel, and its assumed variance determines the smoothness of the resulting estimate. PROC KDE outputs the kernel density estimate to a SAS data set, which you can then use with other procedures for plotting or analysis. PROC KDE also computes a variety of common statistics, including estimates of the percentiles of the hypothesized probability density function.

For more information, see Chapter 47, "The KDE Procedure."

Introduction to Structural Equation Modeling with Latent Variables

Contents

Overview of Structural Equation Modeling with Latent Variables

Structural equation modeling includes analysis of covariance structures and mean structures, fitting systems of linear structural equations, factor analysis, and path analysis. In terms of the mathematical and statistical techniques involved, these various types of analyses are more or less interchangeable because the underlying methodology is based on analyzing the mean and covariance structures. However, the different analysis types emphasize different aspects of the analysis.

The analysis of covariance structures refers to the formulation of a model for the observed variances and covariances among a set of variables. The model expresses the variances and covariances as functions of some basic parameters. Similarly, the analysis of mean structures refers to the formulation of a model for the observed means. The model expresses the means as functions of some basic parameters. Usually, the covariance structures are of primary interest. However, sometimes the mean structures are analyzed simultaneously with the covariance structures in a model.

Corresponding to this kind of abstract formulation of mean and covariance structure analysis, PROC CALIS offers you two matrix-based modeling languages for specifying your model:

- MSTRUCT: a matrix-based model specification language that enables you to directly specify the parameters in the covariance and mean model matrices
- COSAN: a general matrix-based model specification language that enables you to specify a very wide class of mean and covariance structure models in terms of matrix expressions

Instead of focusing directly on the mean and covariance structures, other generic types of structural equation modeling emphasize more about the functional relationships among variables. Mean and covariance structures are still the means of these analyses, but they are usually implied from the structural relationships, rather than being directly specified as in the COSAN or MSTRUCT modeling languages.

In linear structural equations, the model is formulated as a system of equations that relates several random variables with assumptions about the variances and covariances of the random variables. The variables involved in the system of linear structural equations could be observed (manifest) or latent. Causal relationships between variables are hypothesized in the model.

When all observed variables in the model are hypothesized as indicator measures of underlying latent factors and the main interest is about studying the structural relations among the latent factors, it is a modeling scenario for factor-analysis or LISREL (Keesling 1972; Wiley 1973; Jöreskog 1973). PROC CALIS provides you two modeling languages that are closely related to this type of modeling scenario:

- FACTOR: a non-matrix-based model specification language that supports both exploratory and confirmatory factor analysis, including orthogonal and oblique factor rotations
- LISMOD: a matrix-based model specification language that enables you to specify the parameters in the LISREL model matrices

When causal relationships among observed and latent variables are freely hypothesized so that the observed variables are not limited to the roles of being measured indicators of latent factors, it is a modeling scenario for general path modeling (path analysis). In general path modeling, the model is formulated as a path diagram, in which arrows that connect variables represent variances, covariances, and path coefficients (effects). Depending on the way you represent the path diagram, you can use any of the following three different modeling languages in PROC CALIS:

- PATH: a non-matrix-based language that enables you to specify path-like relationships among variables
- RAM: a matrix-based language that enables you to specify the paths, variances, and covariance parameters in terms of the RAM model matrices (McArdle and McDonald 1984)
- LINEQS: an equation-based language that uses linear equations to specify functional or path relationships among variables (for example, the EQS model by Bentler 1995)

Although various types of analyses are put into distinct classes (with distinct modeling languages), with careful parameterization and model specification, it is possible to apply any of these modeling languages to the same analysis. For example, you can use the PATH modeling language to specify a confirmatory factor-analysis model, or you can use the LISMOD modeling language to specify a general path model. However, for some situations some modeling languages are easier to use than others. See the section "Which Modeling

Language?" on page 1012 of Chapter 26, "The CALIS Procedure," for a detailed discussion of the modeling languages supported in PROC CALIS.

Loehlin (1987) provides an excellent introduction to latent variable models by using path diagrams and structural equations. A more advanced treatment of structural equation models with latent variables is given by Bollen (1989). Fuller (1987) provides a highly technical statistical treatment of measurement-error models.

This chapter illustrates applications of PROC CALIS, describes some of the main modeling features of PROC CALIS, and compares the CALIS procedure with the FACTOR and the SYSLIN procedures.

Testing Covariance Patterns

The most basic use of PROC CALIS is testing covariance patterns. Consider a repeated-measures experiment where individuals are tested for their motor skills at three different time points. No treatments are introduced between these tests. The three test scores are denoted as X_1, X_2, and X_3, respectively. These test scores are likely correlated because the same set of individuals has been used. More specifically, the researcher wants to test the following pattern of the population covariance matrix Σ:

$$\Sigma = \begin{pmatrix} \phi & \theta & \theta \\ \theta & \phi & \theta \\ \theta & \theta & \phi \end{pmatrix}$$

Because there are no treatments between the tests, this pattern assumes that the distribution of motor skills stays more or less the same over time, as represented by the same ϕ for the diagonal elements of Σ. The covariances between the test scores for motor skills also stay the same, as represented by the same θ for all the off-diagonal elements of Σ.

Suppose you summarize your data in a covariance matrix, which is stored in the following SAS data set:

```
data motor(type=cov);
   input _type_ $ _name_ $ x1 x2 x3;
   datalines;
COV     x1      3.566   1.342   1.114
COV     x2      1.342   4.012   1.056
COV     x3      1.114   1.056   3.776
N        .         36      36      36
;
```

The diagonal elements are somewhat close to each other but are not the same. The off-diagonal elements are also very close to each other but are not the same. Could these observed differences be due to chance? Given the sample covariance matrix, can you test the hypothesized patterned covariance matrix in the population?

Setting up this patterned covariance model in PROC CALIS is straightforward with the MSTRUCT modeling language:

```
proc calis data=motor;
   mstruct var  = x1-x3;
   matrix _cov_ = phi
                  theta phi
                  theta theta phi;
run;
```

In the VAR= option in the MSTRUCT statement, you specify that x1–x3 are the variables in the covariance matrix. Next, you specify the elements of the patterned covariance matrix in the MATRIX statement with the _COV_ keyword. Because the covariance matrix is symmetric, you need to specify only the lower triangular elements in the MATRIX statement. You use phi for the parameters of all diagonal elements and theta for the parameters of all off-diagonal elements. Matrix elements with the same parameter name are implicitly constrained to be equal. Hence, this is the patterned covariance matrix that you want to test. Some output results from PROC CALIS are shown in Figure 17.1.

Figure 17.1 Fit Summary

Fit Summary

Chi-Square	0.3656
Chi-Square DF	4
Pr > Chi-Square	0.9852

MSTRUCT _COV_ Matrix: Estimate/StdErr/t-value

	x1	x2	x3
x1	3.7847	1.1707	1.1707
	0.5701	0.5099	0.5099
	6.6383	2.2960	2.2960
	[phi]	[theta]	[theta]
x2	1.1707	3.7847	1.1707
	0.5099	0.5701	0.5099
	2.2960	6.6383	2.2960
	[theta]	[phi]	[theta]
x3	1.1707	1.1707	3.7847
	0.5099	0.5099	0.5701
	2.2960	2.2960	6.6383
	[theta]	[theta]	[phi]

First, PROC CALIS shows that the chi-square test for the model fit is 0.3656 (df=4, p=0.9852). Because the chi-square test is not significant, it supports the hypothesized patterned covariance model. Next, PROC CALIS shows the estimates in the covariance matrix under the hypothesized model. The estimates for the diagonal elements are all 3.7847, and the estimates for off-diagonal elements are all 1.1707. Estimates of standard errors and t values for these covariance and variance parameters are also shown.

The MSTRUCT modeling language in PROC CALIS enables you to test various kinds of covariance and mean patterns, including matrices with fixed or constrained values. For example, consider a population covariance model in which correlations among the motor test scores are hypothesized to be zero. In other words, the covariance pattern is:

$$\Sigma = \begin{pmatrix} \phi_1 & 0 & 0 \\ 0 & \phi_2 & 0 \\ 0 & 0 & \phi_3 \end{pmatrix}$$

Essentially, this diagonally-patterned covariance model means that the data are randomly and independently generated for x1–x3 under the multivariate normal distribution. Only the variances of the variables are parameters in the model, and the variables are not correlated at all.

You can use the MSTRUCT modeling language of PROC CALIS to fit this diagonally-patterned covariance matrix to the data for motor skills, as shown in the following statements:

```
proc calis data=motor;
   mstruct var  = x1-x3;
   matrix _cov_ = phi1
                  0.   phi2
                  0.     0.    phi3;
run;
```

Some of the output is shown in Figure 17.2.

Figure 17.2 Fit Summary: Testing Uncorrelatedness

Fit Summary

Chi-Square	9.2939
Chi-Square DF	3
Pr > Chi-Square	0.0256

MSTRUCT _COV_ Matrix: Estimate/StdErr/t-value

	x1	x2	x3
x1	3.5660 0.8524 4.1833 [phi1]	0	0
x2	0	4.0120 0.9591 4.1833 [phi2]	0
x3	0	0	3.7760 0.9026 4.1833 [phi3]

PROC CALIS shows that the chi-square test for the model fit is 9.2939 (df=3, p=0.0256). Because the chi-square test is significant, it does not support the patterned covariance model that postulates zero correlations among the variables. This conclusion is consistent with what is already known—the motor test scores should be somewhat correlated because they are measurements over time for the same group of individuals.

The output also shows the estimates of variances under the model. Each diagonal element of the covariance matrix has a distinct estimate because different parameters have been hypothesized under the patterned covariance model.

Testing Built-In Covariance Patterns in PROC CALIS

Some covariance patterns are well-known in multivariate statistics. For example, testing the diagonal pattern for a covariance matrix in the preceding section is a test of uncorrelatedness between the observed variables. Under the multivariate normal assumption, this test is also a test of independence between the observed variables. This test of independence is routinely applied in maximum likelihood factor analysis for testing the zero common factor hypothesis for the observed variables. For testing such a well-known covariance pattern, PROC CALIS provides an efficient way of specifying a model. With the COVPATTERN= option, you can invoke the built-in covariance patterns in PROC CALIS without the MSTRUCT model specifications, which could become laborious when the number of variables are large.

For example, to test the diagonal pattern (uncorrelatedness) of the motor skills, you can simply use the following specification:

```
proc calis data=motor covpattern=uncorr;
run;
```

The COVPATTERN=UNCORR option in the PROC CALIS statement invokes the diagonally patterned covariance matrix for the motor skills. PROC CALIS then generates the appropriate free parameters for this built-in covariance pattern. As a result, the MATRIX statement is not needed for specifying the free parameters, as it is if you use explicit MSTRUCT model specifications. Some of the output for using the COVPATTERN= option is shown in Figure 17.3.

Figure 17.3 Fit Summary: Testing Uncorrelatedness with the COVPATTERN= Option

Fit Summary

Chi-Square	8.8071
Chi-Square DF	3
Pr > Chi-Square	0.0320

Figure 17.3 *continued*

MSTRUCT _COV_ Matrix: Estimate/StdErr/t-value

	x1	x2	x3
x1	3.5660 0.8524 4.1833 [_varparm_1]	0	0
x2	0	4.0120 0.9591 4.1833 [_varparm_2]	0
x3	0	0	3.7760 0.9026 4.1833 [_varparm_3]

In the second table of Figure 17.3, the estimates of variances and their standard errors are the same as those shown in Figure 17.2. The only difference is that the parameter names (for example, _varparm_1) for the variances in Figure 17.3 are generated by PROC CALIS, instead of being specified as those in Figure 17.2.

However, the current chi-square test for the model fit is 8.8071 (df=3, p=0.0320), which is different from that in Figure 17.2 for testing the same covariance pattern. The reason is that the chi-square correction due to Bartlett (1950) has been applied automatically to the current built-in covariance pattern testing. Theoretically, this corrected chi-square value is more accurate. Therefore, in addition to its efficiency in specification, the built-in covariance pattern with the COVPATTERN= option offers an extra advantage in the automatic chi-square correction.

The COVPATTERN= option supports many other built-in covariance patterns. For details, see the COVPATTERN= option. See also the MEANPATTERN= option for testing built-in mean patterns.

Direct and Implied Covariance Patterns

You have seen how you can use PROC CALIS to test covariance patterns directly. Basically, you can specify the parameters in the covariance and mean matrices directly by using the MSTRUCT modeling language, which is invoked by the MSTRUCT statement. You can also use the COVPATTERN= option to test some built-in covariance patterns in PROC CALIS. To handle more complicated covariance and mean structures that are products of several model matrices, you can use the COSAN modeling language. The COSAN modeling language is too powerful to consider in this introductory chapter, but see the COSAN statement and the section "The COSAN Model" on page 1193 of Chapter 26, "The CALIS Procedure."

This section considers the fitting of patterned covariances matrix directly by using the MSTRUCT and the MATRIX statements or by the COVPATTERN= option. However, in most applications of structural equation modeling, the covariance patterns are not specified directly but are implied from the linear structural relationships among variables. The next few sections show how you can use other modeling languages in PROC CALIS to specify structural equation models with implied mean and covariance structures.

Regression with Measurement Errors

In this section, you start with a linear regression model and learn how the regression equation can be specified in PROC CALIS. The regression model is then extended to include measurement errors in the predictors and in the outcome variables. Problems with model identification are introduced.

Simple Linear Regression

Consider fitting a linear equation to two observed variables, Y and X. Simple linear regression uses the following model form:

$$Y = \alpha + \beta X + E_Y$$

The model makes the following assumption:

$$\mathrm{Cov}(X, E_Y) = 0$$

The parameters α and β are the intercept and regression coefficient, respectively, and E_Y is an error term. If the values of X are fixed, the values of E_Y are assumed to be independent and identically distributed realizations of a normally distributed random variable with mean zero and variance $\mathrm{Var}(E_Y)$. If X is a random variable, X and E_Y are assumed to have a bivariate normal distribution with zero correlation and variances $\mathrm{Var}(X)$ and $\mathrm{Var}(E_Y)$, respectively. Under either set of assumptions, the usual formulas hold for the estimates of the intercept and regression coefficient and their standard errors. (See Chapter 4, "Introduction to Regression Procedures.")

In the REG procedure, you can fit a simple linear regression model with a MODEL statement that lists only the names of the manifest variables, as shown in the following statements:

```
proc reg;
   model Y = X;
run;
```

You can also fit this model with PROC CALIS, but the syntax is different. You can specify the simple linear regression model in PROC CALIS by using the LINEQS modeling language, as shown in the following statements:

```
proc calis;
   lineqs
      Y = beta * X + Ey;
run;
```

LINEQS stands for "LINear EQuationS." You invoke the LINEQS modeling language by using the LINEQS statement in PROC CALIS. In the LINEQS statement, you specify the linear equations of your model. The LINEQS statement syntax is similar to the mathematical equation that you would write for the model. An obvious difference between the LINEQS and the PROC REG model specification is that in LINEQS you can name the parameter involved (for example, beta) and you also specify the error term explicitly. The additional syntax required by the LINEQS statement seems to make the model specification more time-consuming and cumbersome. However, this inconvenience is minor and is offset by the modeling flexibility

of the LINEQS modeling language (and of PROC CALIS, generally). As you proceed to more examples in this chapter, you will find the benefits of specifying parameter names for more complicated models with constraints. You will also find that specifying parameter names for unconstrained parameters is optional. Using parameter names in the current example is for the ease of reference in the current discussion.

You might wonder whether an intercept term is missing in the LINEQS statement and where you should put the intercept term if you want to specify it. The intercept term, which is considered as a mean structure parameter in the context of structural equation modeling, is usually omitted when statistical inferences can be drawn from analyzing the covariance structures alone. However, this does not mean that the regression equation has a default fixed-zero intercept in the LINEQS specification. Rather, it means only that the mean structures are saturated and are not estimated in the covariance structure model. Therefore, in the preceding LINEQS specification, the intercept term α is implicitly assumed in the model. It is not of primary interest and is not estimated.

However, if you want to estimate the intercept, you can specify it in the LINEQS equations, as shown in the following specification:

```
proc calis;
   lineqs
      Y = alpha * Intercept + beta * X + Ey;
run;
```

In this LINEQS statement, alpha represents the intercept parameter α and intercept represents an internal "variable" that has a fixed value of 1 for each observation. With this specification, an estimate of α is displayed in the PROC CALIS output results. However, estimation results for other parameters are the same as those from the specification without the intercept term. For this reason the intercept term is not specified in the examples of this section.

Errors-in-Variables Regression

For ordinary unconstrained regression models, there is no reason to use PROC CALIS instead of PROC REG. But suppose that the predictor variable X is a random variable that is contaminated by errors (especially measurement errors), and you want to estimate the linear relationship between the true, error-free scores. The following model takes this kind of measurement errors into account:

$$\begin{aligned} Y &= \alpha + \beta F_X + E_Y \\ X &= F_X + E_X \end{aligned}$$

The model assumes the following:

$$\mathrm{Cov}(F_X, E_Y) = \mathrm{Cov}(F_X, E_X) = \mathrm{Cov}(E_X, E_Y) = 0$$

There are two equations in the model. The first one is the so-called structural model, which describes the relationships between Y and the true score predictor F_X. This equation is your main interest. However, F_X is a latent variable that has not been observed. Instead, what you have observed for this predictor is X, which is the contaminated version of F_X with measurement error or other errors, denoted by E_X, added. This measurement process is described in the second equation, or the so-called measurement model. By

analyzing the structural and measurement models (or the two linear equations) simultaneously, you want to estimate the true score effect β.

The assumption that the error terms E_X and E_Y and the latent variable F_X are jointly uncorrelated is of critical importance in the model. This assumption must be justified on substantive grounds such as the physical properties of the measurement process. If this assumption is violated, the estimators might be severely biased and inconsistent.

You can express the current errors-in-variables model by the LINEQS modeling language as shown in the following statements:

```
proc calis;
   lineqs
      Y = beta * Fx + Ey,
      X = 1.   * Fx + Ex;
run;
```

In this specification, you need to specify only the equations involved without specifying the assumptions about the correlations among Fx, Ey, and Ex. In the LINEQS modeling language, you should always name latent factors with the 'F' or 'f' prefix (for example, Fx) and error terms with the 'E' or 'e' prefix (for example, Ey and Ex). Given this LINEQS notation, latent factors and error terms, by default, are uncorrelated in the model.

Consider an example of an errors-in-variables regression model. Fuller (1987, pp. 18–19) analyzes a data set from Voss (1969) that involves corn yields (Y) and available soil nitrogen (X) for which there is a prior estimate of the measurement error for soil nitrogen Var(E_X) of 57. The scientific question is: how does nitrogen affect corn yields? The linear prediction of corn yields by nitrogen should be based on a measure of nitrogen that is not contaminated with measurement error. Hence, the errors-in-variables model is applied. F_X in the model represents the "true" nitrogen measure, X represents the observed measure of nitrogen, which has a true score component F_X and an error component E_X. Given that the measurement error for soil nitrogen Var(E_X) is 57, you can specify the errors-in-variables regression model with the following statements in PROC CALIS:

```
data corn(type=cov);
   input _type_ $ _name_ $ y x;
   datalines;
cov    y    87.6727    .
cov    x    104.8818   304.8545
mean   .    97.4545    70.6364
n      .    11         11
;

proc calis data=corn;
   lineqs
      Y  = beta * Fx + Ey,
      X  = 1.   * Fx + Ex;
   variance
      Ex = 57.;
run;
```

In the VARIANCE statement, the variance of Ex (measurement error for X) is given as the constant value 57. PROC CALIS produces the estimates shown in Figure 17.4.

Figure 17.4 Errors-in-Variables Model for Corn Data

Linear Equations

y	=	0.4232*Fx	+	1.0000 Ey	
Std Err		0.1658 beta			
t Value		2.5520			
x	=	1.0000 Fx	+	1.0000 Ex	

Estimates for Variances of Exogenous Variables

Variable Type	Variable	Parameter	Estimate	Standard Error	t Value
Error	Ex		57.00000		
Latent	Fx	_Add1	247.85450	136.33508	1.81798
Error	Ey	_Add2	43.29105	23.92488	1.80946

In Figure 17.4, the estimate of beta is 0.4232 with a standard error estimate of 0.1658. The t value is 2.552. It is significant at the 0.05 α-level when compared to the critical value of the standard normal variate (that is, the z table). Also shown in Figure 17.4 are the estimated variances of Fx, Ey, and their estimated standard errors. The names of these parameters have the prefix '_Add'. They are added by PROC CALIS as default parameters. By employing some conventional rules for setting default parameters, PROC CALIS makes your model specification much easier and concise. For example, you do not need to specify each error variance parameter manually if it is not constrained in the model. However, you can specify these parameters explicitly if you desire. Note that in Figure 17.4, the variance of Ex is shown to be 57 without a standard error estimate because it is a fixed constant in the model.

What if you did not model the measurement error in the predictor X? That is, what is the estimate of beta if you use ordinary regression of Y on X, as described by the equation in the section "Simple Linear Regression" on page 292? You can specify such a linear regression model easily by the LINEQS modeling language. Here, you specify this linear regression model as a special case of the errors-in-variables model. That is, you constrain the variance of measurement error E_x to 0 in the preceding LINEQS model specification to form the linear regression model, as shown in the following statements:

```
proc calis data=corn;
   lineqs
      Y  = beta * Fx + Ey,
      X  = 1. *   Fx + Ex;
   variance
      Ex = 0.;
run;
```

Fixing the variance of Ex to zero forces the equality of X and F_X in the measurement model so that this "new" errors-in-variables model is in fact an ordinary regression model. PROC CALIS produces the estimation results in Figure 17.5.

Figure 17.5 Ordinary Regression Model for Corn Data: Zero Measurement Error in X

Linear Equations

```
y       =    0.3440*Fx   +  1.0000 Ey
Std Err      0.1301 beta
t Value      2.6447
x       =    1.0000 Fx   +  1.0000 Ex
```

Estimates for Variances of Exogenous Variables

Variable Type	Variable	Parameter	Estimate	Standard Error	t Value
Error	Ex		0		
Latent	Fx	_Add1	304.85450	136.33508	2.23607
Error	Ey	_Add2	51.58928	23.07143	2.23607

The estimate of beta is now 0.3440, which is an underestimate of the effect of nitrogen on corn yields given the presence of nonzero measurement error in X, where the estimate of beta is 0.4232.

Regression with Measurement Errors in X and Y

What if there are also measurement errors in the outcome variable Y? How can you write such an extended model? The following model would take measurement errors in both X and Y into account:

$$\begin{aligned} F_Y &= \alpha + \beta F_X + D_{Fy} \\ Y &= F_Y + E_Y \\ X &= F_X + E_X \end{aligned}$$

with the following assumption:

$$\begin{aligned} \mathrm{Cov}(F_X, D_{Fy}) &= \mathrm{Cov}(F_X, E_Y) = \mathrm{Cov}(F_X, E_X) = \mathrm{Cov}(F_Y, E_Y) \\ &= \mathrm{Cov}(F_Y, E_X) = \mathrm{Cov}(E_X, E_Y) = \mathrm{Cov}(E_X, D_{Fy}) \\ &= \mathrm{Cov}(E_Y, D_{Fy}) = 0 \end{aligned}$$

Again, the first equation, expressing the relationship between two latent true-score variables, defines the structural or causal model. The next two equations express the observed variables in terms of a true score plus error; these two equations define the measurement model. This is essentially the same form as the so-called LISREL model (Keesling 1972; Wiley 1973; Jöreskog 1973), which has been popularized by the LISREL program (Jöreskog and Sörbom 1988). Typically, there are several X and Y variables in a LISREL model. For the moment, however, the focus is on the current regression form in which there is only a single predictor and a single outcome variable. The LISREL model is considered in the section "Fitting LISREL Models by the LISMOD Modeling Language" on page 347.

With the intercept term left out for modeling, you can use the following statements for fitting the regression model with measurement errors in both X and Y:

```
proc calis data=corn;
   lineqs
      Fy  = beta * Fx + DFy,
      Y   = 1.   * Fy + Ey,
      X   = 1.   * Fx + Ex;
run;
```

Again, you do not need to specify the zero-correlation assumptions in the LINEQS model because they are set by default given the latent factors and errors in the LINEQS modeling language. When you run this model, PROC CALIS issues the following warning:

```
WARNING: Estimation problem not identified: More parameters to
         estimate ( 5 ) than the total number of mean and
         covariance elements ( 3 ).
```

The five parameters in the model include beta and the variances for the exogenous variables: Fx, DFy, Ey, and Ex. These variance parameters are treated as free parameters by default in PROC CALIS. You have five parameters to estimate, but the information for estimating these five parameters comes from the three unique elements in the sample covariance matrix for X and Y. Hence, your model is in the so-called underidentification situation. Model identification is discussed in more detail in the section "Model Identification" on page 299.

To make the current model identified, you can put constraints on some parameters. This reduces the number of independent parameters to estimate in the model. In the errors-in-variables model for the corn data, the variance of Ex (measurement error for X) is given as the constant value 57, which was obtained from a previous study. This could still be applied in the current model with measurement errors in both X and Y. In addition, if you are willing to accept the assumption that the structural equation model is (almost) deterministic, then the variance of Dfy could be set to 0. With these two parameter constraints, the current model is just-identified. That is, you can now estimate three free parameters from three distinct covariance elements in the data. The following statements show the LINEQS model specification for this just-identified model:

```
proc calis data=corn;
   lineqs
      Fy  = beta * Fx + Dfy,
      Y   = 1.   * Fy + Ey,
      X   = 1.   * Fx + Ex;
   variance
      Ex  = 57.,
      Dfy = 0.;
run;
```

Figure 17.6 shows the estimation results.

Figure 17.6 Regression Model With Measurement Errors in X and Y for Corn Data

Error         Ey          _Add2           43.29105       23.92488       1.80946
```

In Figure 17.6, the estimate of beta is 0.4232, which is basically the same as the estimate for beta in the errors-in-variables model shown in Figure 17.4. The estimated variances for Fx and Ey match for the two models too. In fact, it is not difficult to show mathematically that the current constrained model with measurements errors in both Y and X is equivalent to the errors-in-variables model for the corn data. The numerical results merely confirm this fact.

It is important to emphasize that the equivalence shown here is not a general statement about the current model with measurement errors in X and Y and the errors-in-variables model. Essentially, the equivalence of the two models as applied to the corn data is due to those constraints imposed on the measurement error variances for DFy and Ex. The more important implication from these two analyses is that for the model with measurement errors in both X and Y, you need to set more parameter constraints to make the model identified. Some constraints might be substantively meaningful, while others might need strong or risky assumptions.

For example, setting the variance of Ex to 57 is substantively meaningful because it is based on a prior study. However, setting the variance of Dfy to 0 implies the acceptance of the deterministic structural model, which could be a rather risky assumption in most practical situations. It turns out that using these two constraints together for the model identification of the regression with measurement errors in both X and Y does not give you more substantively important information than what the errors-in-variables model has already given you (compare Figure 17.6 with Figure 17.4). Therefore, the set of identification constraints you use might be important in at least two aspects. First, it might lead to an identified model if you set them properly. Second, given that the model is identified, the meaningfulness of your model depends on how reasonable your identification constraints are.

The two identification constraints set on the regression model with measurement errors in both X and Y make the model identified. But they do not lead to model estimates that are more informative than that of the errors-in-variables regression. Some other sets of identification constraints, if available, might have been more informative. For example, if there were a prior study about the measurement error variance of corn yields (Y), a fixed constant for the variance of Ey could have been set, instead of the unrealistic zero

variance constraint of Dfy. This way the estimation results of the regression model with measurement errors in both X and Y would offer you something different from the errors-in-variables regression.

Setting identification constraints could be based on convention or other arguments. See the section "Illustration of Model Identification: Spleen Data" on page 300 for an example where model identification is attained by setting constant error variances for X and Y in the model. For the corn data, you have seen that fixing the error variance of the predictor variable led to model identification of the errors-in-variables model. In this case, prior knowledge about the measurement error variance is necessary. This necessity is partly due to the fact that each latent true score variable has only one observed variable as its indicator measure. When you have more measurement indicators for the same latent factor, fixing the measurement error variances to constants for model identification would not be necessary. This is the modeling scenario assumed by the LISREL model (see the section "Fitting LISREL Models by the LISMOD Modeling Language" on page 347), of which the confirmatory factor model is a special case. The confirmatory factor model is described and illustrated in the section "The FACTOR and RAM Modeling Languages" on page 322.

Model Identification

As discussed in the preceding section, if you try to fit the errors-in-variables model with measurement errors in both X and Y without applying certain constraints, the model is not identified and you cannot obtain unique estimates of the parameters. For example, the errors-in-variables model with measurement errors in both X and Y has five parameters (one coefficient β and four variances). The covariance matrix of the observed variables Y and X has only three elements that are free to vary, since $\mathrm{Cov}(Y,X)=\mathrm{Cov}(X,Y)$. Therefore, the covariance structure can be expressed as three equations in five unknown parameters. Since there are fewer equations than unknowns, there are many different sets of values for the parameters that provide a solution for the equations. Such a model is said to be underidentified.

If the number of parameters equals the number of free elements in the covariance matrix, then there might exist a unique set of parameter estimates that exactly reproduce the observed covariance matrix. In this case, the model is said to be just-identified or saturated.

If the number of parameters is less than the number of free elements in the covariance matrix, there might exist no set of parameter estimates that reproduces the observed covariance matrix exactly. In this case, the model is said to be overidentified. Various statistical criteria, such as maximum likelihood, can be used to choose parameter estimates that approximately reproduce the observed covariance matrix. If you use ML, FIML, GLS, or WLS estimation, PROC CALIS can perform a statistical test of the goodness of fit of the model under the certain statistical assumptions.

If the model is just-identified or overidentified, it is said to be identified. If you use ML, FIML, GLS, or WLS estimation for an identified model, PROC CALIS can compute approximate standard errors for the parameter estimates. For underidentified models, PROC CALIS obtains approximate standard errors by imposing additional constraints resulting from the use of a generalized inverse of the Hessian matrix.

You cannot guarantee that a model is identified simply by counting the parameters. For example, for any latent variable, you must specify a numeric value for the variance, or for some covariance involving the variable, or for a coefficient of an indicator variable. Otherwise, the scale of the latent variable is indeterminate, and the model is underidentified regardless of the number of parameters and the size of the covariance

matrix. As another example, an exploratory factor analysis with two or more common factors is always underidentified because you can rotate the common factors without affecting the fit of the model.

PROC CALIS can usually detect an underidentified model by computing the approximate covariance matrix of the parameter estimates and checking whether any estimate is linearly related to other estimates (Bollen 1989, pp. 248–250), in which case PROC CALIS displays equations showing the linear relationships among the estimates. Another way to obtain empirical evidence regarding the identification of a model is to run the analysis several times with different initial estimates to see whether the same final estimates are obtained. Bollen (1989) provides detailed discussions of conditions for identification in a variety of models.

Illustration of Model Identification: Spleen Data

When your model involves measurement errors in variables and you need to use latent true scores in the regression or structural equation, you might encounter some model identification problems in estimation if you do not put certain identification constraints in the model. An example is shown in the section "Regression with Measurement Errors in X and Y" on page 296 for the corn data. You "solved" the problem by assuming a deterministic model with perfect prediction in the structural model. However, this assumption could be very risky and does not lead to estimation results that are substantively different from the model with measurement error only in X.

This section shows how you can apply another set of constraints to make the measurement model with errors in both X and Y identified without assuming the deterministic structural model. First, the identification problem is illustrated here again in light of the PROC CALIS diagnostics.

The following example is inspired by Fuller (1987, pp. 40–41). The hypothetical data are counts of two types of cells in spleen samples: cells that form rosettes and nucleated cells. It is reasonable to assume that counts have a Poisson distribution; hence, the square roots of the counts should have a constant error variance of 0.25. You can use PROC CALIS to fit this regression model with measurement errors in X and Y to the data. (See the section "Regression with Measurement Errors in X and Y" on page 296 for model definitions.) However, before fitting this target model, it is illustrative to see what would happen if you do not assume the constant error variance.

The following statements show the LINEQS specification of an errors-in-variables regression model for the square roots of the counts without constraints on the parameters:

```
data spleen;
   input rosette nucleate;
   sqrtrose=sqrt(rosette);
   sqrtnucl=sqrt(nucleate);
   datalines;
4 62
5 87
5 117
6 142
8 212
9 120
12 254
13 179
```

```
15 125
19 182
28 301
51 357
;

proc calis data=spleen;
   lineqs factrose = beta * factnucl + disturb,
          sqrtrose =        factrose + err_rose,
          sqrtnucl =        factnucl + err_nucl;
   variance
          factnucl = v_factnucl,
          disturb  = v_disturb,
          err_rose = v_rose,
          err_nucl = v_nucl;
run;
```

This model is underidentified. You have five parameters to estimate in the model, but the number of distinct covariance elements is only three.

In the LINEQS statement, you specify the structural equation and then two measurement equations. In the structural equation, the variables factrose and factnucl are latent true scores for the corresponding measurements in sqrtrose and sqrtnucl, respectively. The structural equation represents the true variable relationship of interest. You name the regression coefficient parameter as beta and the error term as disturb in the structural model. (For structural equations, you can use names with prefix 'D' or 'd' to denote error terms.) The variance of factnucl and the variance of disturb are also parameters in the model. You name these variance parameters as v_factnucl and v_disturb in the VARIANCE statement. Therefore, you have three parameters in the structural equation.

In the measurement equations, the observed variables sqrtrose and sqrtnucl are specified as the sums of their corresponding true latent scores and error terms, respectively. The error variances are also parameters in the model. You name them as v_rose and v_nucl in the VARIANCE statement. Now, together with the three parameters in the structural equation, you have a total of five parameters in your model.

All variance specifications in the VARIANCE statement are actually optional in PROC CALIS. They are free parameters by default. In this example, it is useful to name these parameters so that explicit references to these parameters can be made in the following discussion.

PROC CALIS displays the following warning when you fit this underidentified model:

```
WARNING: Estimation problem not identified: More parameters to
         estimate ( 5 ) than the total number of mean and
         covariance elements ( 3 ).
```

In this warning, the three covariance elements refer to the sample variances of sqrtrose and sqrtnucl and their covariance. PROC CALIS diagnoses the parameter indeterminacy as follows:

```
   NOTE: Covariance matrix for the estimates is not full rank.
   NOTE: The variance of some parameter estimates is zero or
         some parameter estimates are linearly related to other
         parameter estimates as shown in the following equations:

v_rose       =      -0.147856   +       0.447307   *   v_disturb

v_nucl       =    -110.923690   -       0.374367   *   beta       +
                    10.353896   *   v_factnucl     +   1.536613   *   v_disturb
```

With the warning and the notes, you are now certain that the model is underidentified and you cannot interpret your parameter estimates meaningfully.

Now, to make the model identified, you set the error variances to 0.25 in the VARIANCE statement, as shown in the following specification:

```
proc calis data=spleen residual;
   lineqs factrose = beta * factnucl + disturb,
          sqrtrose =        factrose + err_rose,
          sqrtnucl =        factnucl + err_nucl;
   variance
          factnucl = v_factnucl,
          disturb  = v_disturb,
          err_rose = 0.25,
          err_nucl = 0.25;
run;
```

In the specification, you use the RESIDUAL option in the PROC CALIS statement to request the residual analysis. An annotated fit summary is shown in Figure 17.7.

Figure 17.7 Spleen Data: Annotated Fit Summary for the Just-Identified Model

```
                          Fit Summary

                Chi-Square              0.0000
                Chi-Square DF                0
                Pr > Chi-Square              .
```

You notice that the model fit chi-square is 0 and the corresponding degrees of freedom is also 0. This indicates that your model is "just" identified, or your model is saturated—you have three distinct elements in the sample covariance matrix for the estimation of three parameters in the model. In the PROC CALIS results, you no longer see the warning message about underidentification or any notes about linear dependence in parameters.

For just-identified or saturated models like the current case, you expect to get zero residuals in the covariance matrix, as shown in Figure 17.8:

Figure 17.8 Spleen Data: Residuals for the Just-identified Model

Raw Residual Matrix

	sqrtrose	sqrtnucl
sqrtrose	0.00000	0.00000
sqrtnucl	0.00000	0.00000

Residuals are the differences between the fitted covariance matrix and the sample covariance matrix. When the residuals are all zero, the fitted covariance matrix matches the sample covariance matrix perfectly (the parameter estimates reproduce the sample covariance matrix exactly).

You can now interpret the estimation results of this just-identified model, as shown in Figure 17.9:

Figure 17.9 Spleen Data: Parameter Estimated for the Just-Identified Model

Linear Equations

```
factrose =    0.3907*factnucl +  1.0000 disturb
Std Err       0.0771 beta
t Value       5.0692
sqrtrose =    1.0000 factrose +  1.0000 err_rose
sqrtnucl =    1.0000 factnucl +  1.0000 err_nucl
```

Estimates for Variances of Exogenous Variables

Variable Type	Variable	Parameter	Estimate	Standard Error	t Value
Latent	factnucl	v_factnucl	10.50458	4.58577	2.29069
Disturbance	disturb	v_disturb	0.38153	0.28556	1.33607
Error	err_rose		0.25000		
	err_nucl		0.25000		

Notice that because the error variance parameters for variables err_rose and err_nucl are fixed constants in the model, there are no standard error estimates for them in Figure 17.9. For the current application, the estimation results of the just-identified model are those you would interpret and report. However, to completely illustrate model identification, an additional constraint is imposed to show an overidentified model. In the section "Regression with Measurement Errors in X and Y" on page 296, you impose a zero-variance constraint on the disturbance variable Dfy for the model identification. Would this constraint be necessary here for the spleen data too? The answer is no because with the two constraints on the variances of err_rose and err_nucl, the model has already been meaningfully specified and identified. Adding more constraints such as a zero variance for disturb would make the model overidentified unnecessarily. The following statements show the specification of such an overidentified model for the spleen data:

```
proc calis data=spleen residual;
   lineqs factrose = beta * factnucl + disturb,
          sqrtrose =        factrose + err_rose,
          sqrtnucl =        factnucl + err_nucl;
   variance
          factnucl = v_factnucl,
          disturb  = 0.,
          err_rose = 0.25,
          err_nucl = 0.25;
run;
```

An annotated fit summary table for the overidentified model is shown in Figure 17.10.

Figure 17.10 Spleen Data: Annotated Fit Summary for the Overidentified Model

Fit Summary

Chi-Square	5.2522
Chi-Square DF	1
Pr > Chi-Square	0.0219
Standardized RMSR (SRMSR)	0.0745
Adjusted GFI (AGFI)	0.1821
RMSEA Estimate	0.6217
Bentler Comparative Fit Index	0.6535

The chi-square is 5.2522 (df=1, p=0.0219). Overall, the model does not provide a good fit. The sample size is so small that the p-value of the chi-square test should not be taken to be accurate, but to get a small p-value with such a small sample indicates that it is possible that the model is seriously deficient.

This same conclusion can be drawn by looking at other fit indices in the table. In Figure 17.10, several fit indices are computed for the model. For example, the standardized root mean square residual (SRMSR) is 0.0745 and the adjusted goodness of fit (AGFI) is 0.1821. By conventions, a good model should have an SRMSR smaller than 0.05 and an AGFI larger than 0.90. The root mean square error of approximation (RMSEA) (Steiger and Lind 1980) is 0.6217, but an RMSEA below 0.05 is recommended for a good model fit (Browne and Cudeck 1993). The comparative fit index (CFI) is 0.6535, which is also low as compared to the acceptable level at 0.90.

When you fit an overidentified model, usually you do not find estimates that match the sample covariance matrix exactly. The discrepancies between the fitted covariance matrix and the sample covariance matrix are shown as residuals in the covariance matrix, as shown in Figure 17.11.

Figure 17.11 Spleen Data: Residuals for the Overidentified Model

Raw Residual Matrix

	sqrtrose	sqrtnucl
sqrtrose	0.28345	-0.11434
sqrtnucl	-0.11434	0.04613

As you can see in Figure 17.11, the residuals are nonzero. This indicates that the parameter estimates do not reproduce the sample covariance matrix exactly. For overidentified models, nonzero residuals would be the norm rather than exception, but the general goal is to find the "best" set of estimates so that the residuals are as small as possible.

The parameter estimates are shown in Figure 17.12.

Figure 17.12 Spleen Data: Parameter Estimated for the Overidentified Model

```
                          Linear Equations

              factrose =    0.4034*factnucl +  1.0000 disturb
              Std Err       0.0508 beta
              t Value       7.9439
              sqrtrose =    1.0000 factrose +  1.0000 err_rose
              sqrtnucl =    1.0000 factnucl +  1.0000 err_nucl

              Estimates for Variances of Exogenous Variables

Variable                                                    Standard
Type          Variable    Parameter       Estimate          Error       t Value

Latent        factnucl    v_factnucl      10.45846        4.56608       2.29047
Disturbance   disturb                            0
Error         err_rose                     0.25000
              err_nucl                     0.25000
```

The estimate of beta in this model is 0.4034. Given that the model fit is bad and the zero variance for the error term disturb is unreasonable, beta could have been overestimated in the current overidentified model, as compared with the just-identified model, where the estimate of beta is only 0.3907. In summary, both the fit summary and the estimation results indicate that the zero variance for disturb in the overidentified model for the spleen data has been imposed unreasonably.

The purpose of the current illustration is not that you should not consider an overidentified model for your data in general. Quite the opposite, in practical structural equation modeling it is usually the overidentified models that are of the paramount interest. You can test or gauge the model fit of overidentified models. Good overidentified models enable you to establish scientific theories that are precise and general. However, most fit indices are not meaningful when applied to just-identified saturated models. Also, even though you always get zero residuals for just-identified saturated models, those models usually are not precise enough to be a scientific theory.

The overidentified model for the spleen data highlights the importance of setting meaningful identification constraints. Whether your resulting model is just-identified or overidentified, it is recommended that you do the following:

- Give priorities to those identification constraints that are derived from prior studies, substantive grounds, or mathematical basis.
- Avoid making unnecessary identification constraints that might bias your model estimation.

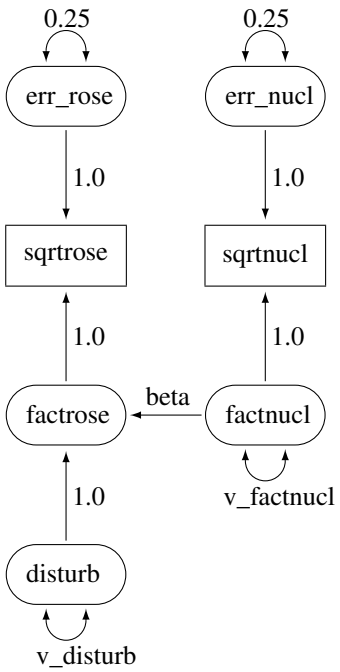
Path Diagrams and Path Analysis

Sections "Errors-in-Variables Regression" on page 293, "Regression with Measurement Errors in X and Y" on page 296, and "Illustration of Model Identification: Spleen Data" on page 300 show how you can specify models by means of equations in the LINEQS modeling language. This section shows you how to specify models that are represented by path diagrams. The PATH modeling language of PROC CALIS is the main tool for this purpose.

Complicated models are often easier to understand when they are expressed as path diagrams. One advantage of path diagrams over equations is that variances and covariances can be shown directly in the path diagram. Loehlin (1987) provides a detailed discussion of path diagrams. Another advantage is that the path diagram can be transcribed easily into the PATH modeling language supported by PROC CALIS.

A path diagram for the spleen data is shown in Figure 17.13. It explicitly shows all latent variables (including error terms) and variances of exogenous variables.

Figure 17.13 Path Diagram: Spleen Data



The path diagram shown in Figure 17.13 is essentially a graphical representation of the same just-identified model for the spleen data that is described in the section "Illustration of Model Identification: Spleen Data" on page 300. In path diagrams, it is customary to write the names of manifest or observed variables in rectangles and the names of latent variables in ovals. For example, sqrtrose and sqrtnucl are observed variables in the path diagram, while all others are latent variables.

The effects (the regression coefficients) in each equation are indicated by drawing arrows from the predictor variables to the outcome variable. For example, the path from factnucl to factrose is labeled with the

regression coefficient beta in the path diagram shown in Figure 17.13. Other paths are labeled with fixed coefficients (or effects) of 1.

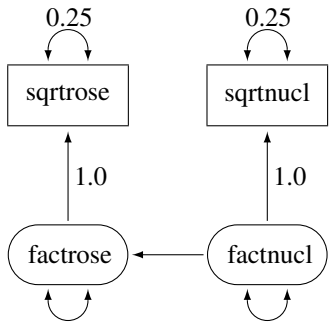
Variances of exogenous variables are drawn as double-headed arrows in Figure 17.13. For example, the variance of disturb is shown as a double-headed arrow pointing to the variable itself and is named v_disturb. Variances of the err_nucl and err_rose are also drawn as double-headed arrows but are labeled with fixed constants 0.25.

The path diagram shown in Figure 17.13 matches the features in the LINEQS model closely. For example, the error terms are depicted explicitly and their paths (regression coefficients) that connect to the associated endogenous variables are marked with fixed constants 1, reflecting the same specification in the equations of the LINEQS model. However, you can simplify the path diagram by using McArdle's RAM (reticular action model) notation (McArdle and McDonald 1984), as described in the following section.

A Simplified Path Diagram for the Spleen Data

The main simplification in the path diagram is to drop all the error terms in the model. Instead, error variances are treated as residual (or partial) variances for the endogenous variables in the model or path diagram. Hence, in the path diagrams for RAM models, error variances are also represented by double-headed arrows directly attached to the endogenous variables, which is the same way you represent variances for the exogenous variables. The RAM model convention leads to a simplified representation of the path diagram for the spleen data, as shown in Figure 17.14.

Figure 17.14 Simplified Path Diagram: Spleen



Another simplification done in Figure 17.14 is the omission of the parameter labeling in the path diagram. This simplification is not a part of the RAM notation. It is just a convention in PROC CALIS that you can omit the unconstrained parameter names without affecting the meaning of the model. Hence, the parameter names beta, v_disturb, and v_factnucl are no longer necessary in the simplified path diagram Figure 17.14. As you can see, this convention makes the task of model specification considerably simpler and easier.

The following statements show the specification of the simplified path diagram in Figure 17.14:

```
proc calis data=spleen;
   path
      sqrtrose <--- factrose   = 1.0,
      sqrtnucl <--- factnucl   = 1.0,
      factrose <--- factnucl   ;
   pvar
      sqrtrose = 0.25,      /* error variance for sqrtrose */
      sqrtnucl = 0.25,      /* error variance for sqrtnucl */
      factrose,             /* disturbance/error variance for factrose */
      factnucl;             /* variance of factnucl */
run;
```

The PATH statement invokes the PATH modeling language of PROC CALIS. In the PATH modeling language, each entry of specification corresponds to either a single- or double- headed arrow specification in the path diagram shown in Figure 17.14, as explained in the following:

- The PATH statement enables you to specify each of the single-headed arrows (paths) as path entries, which are separated by commas. You have three single-headed arrows in the path diagram and therefore you have three path entries in the PATH statement. The path entries "sqrtrose <--- factrose" and "sqrtnucl <--- factnucl" are followed by the constant 1, indicating fixed path coefficients. The path "factrose <--- factnucl" is also specified, but without giving a fixed value or a parameter name. By default, this path entry is associated with a free parameter for the effect or path coefficient.
- The PVAR statement enables you to specify each of the double-headed arrows with both heads pointing to the ***same*** variable, exogenous or endogenous. This type of arrows represents variances or error variances. You have four such double-headed arrows in the path diagram, and therefore there are four corresponding entries under the PVAR statement. Two of them are assigned with fixed constants (0.25), and the remaining two (error variance of factrose and variance of factnucl) are free variance parameters.
- The PCOV statement enables you to specify each of the double-headed arrows with its heads pointing to ***different*** variables, exogenous or endogenous. This type of arrows represents covariances between variables or their error terms. You do not have this type of double-headed arrows in the current path diagram, and therefore you do not need a PCOV statement for the corresponding model specification.

The estimation results are shown in Figure 17.15. Essentially, these are exactly the same estimation results as those that result from the LINEQS modeling language for the just-identified model in section "Illustration of Model Identification: Spleen Data" on page 300.

Figure 17.15 Spleen Data: RAM Model

PATH List

Path			Parameter	Estimate	Standard Error	t Value
sqrtrose	<---	factrose		1.00000		
sqrtnucl	<---	factnucl		1.00000		
factrose	<---	factnucl	_Parm1	0.39074	0.07708	5.06920

Figure 17.15 *continued*

Variance Parameters

Variance Type	Variable	Parameter	Estimate	Standard Error	t Value
Error	sqrtrose		0.25000		
	sqrtnucl		0.25000		
	factrose	_Parm2	0.38153	0.28556	1.33607
Exogenous	factnucl	_Parm3	10.50458	4.58577	2.29069

Notice in Figure 17.15 that the path coefficient for path "factrose <--- factnucl" is given a parameter name _Parm1, which is generated automatically by PROC CALIS. This is the same beta parameter of the LINEQS model in the section "Illustration of Model Identification: Spleen Data" on page 300. Also, the variance parameters _Parm2 and _Parm3 in Figure 17.15 are the same v_disturb and v_factnucl parameters, respectively, in the preceding LINEQS model.

In PROC CALIS, using parameter names to specify free parameters is optional. Parameter names are generated for free parameters by default. Or, if you choose parameter names for your own convenience, you can do so without changing the model specification. For example, you can specify the preceding PATH model equivalently by adding the desired parameter names, as shown in the following statements:

```
proc calis data=spleen;
   path
      sqrtrose <--- factrose   = 1.0,
      sqrtnucl <--- factnucl   = 1.0,
      factrose <--- factnucl   = beta;
   pvar
      sqrtrose = 0.25,       /* error variance for sqrtrose */
      sqrtnucl = 0.25,       /* error variance for sqrtnucl */
      factrose = v_disturb,  /* disturbance/error variance for factrose */
      factnucl = v_factnucl; /* variance of factnucl */
run;
```

A path diagram provides you an easy and conceptual way to represent your model, while the PATH modeling language in PROC CALIS offers you an easy way to input your path diagram in a non-graphical fashion. This is especially useful for models with more complicated path structures. See the section "A Combined Measurement-Structural Model" on page 330 for a more elaborated example of the PATH model application.

The next section provides examples of the PATH model applied to classical test theory.

Some Measurement Models

In the section "Regression with Measurement Errors in X and Y" on page 296, outcome variables and predictor variables are assumed to have been measured with errors. In order to study the true relationships among the true scores variables, models for measurement errors are also incorporated into the estimation. The context of applications is that of regression or econometric analysis.

In the social and behavioral sciences, the same kind of model is developed in the context of test theory or item construction for measuring cognitive abilities, personality traits, or other latent variables. This kind of modeling is better-known as measurement models or confirmatory factor analysis (these two terms are interchangeable) in the psychometric field. Usually, applications in the social and behavioral sciences involve a much larger number of observed variables. This section considers some of these measurement or confirmatory factor-analytic models. For illustration purposes, only a handful of variables are used in the examples. Applications that use the PATH modeling language in PROC CALIS are described.

H4: Full Measurement Model for Lord Data

Psychometric test theory involves many kinds of models that relate scores on psychological and educational tests to latent variables that represent intelligence or various underlying abilities. The following example uses data on four vocabulary tests from Lord (1957). Tests W and X have 15 items each and are administered with very liberal time limits. Tests Y and Z have 75 items and are administered under time pressure. The covariance matrix is read by the following DATA step:

```
data lord(type=cov);
   input _type_ $ _name_ $ W X Y Z;
   datalines;
n    . 649       .       .       .
cov W 86.3979    .       .       .
cov X 57.7751 86.2632    .       .
cov Y 56.8651 59.3177 97.2850    .
cov Z 58.8986 59.6683 73.8201 97.8192
;
```

The psychometric model of interest states that W and X are determined by a single common factor F_1, and Y and Z are determined by a single common factor F_2. The two common factors are expected to have a positive correlation, and it is desired to estimate this correlation. It is convenient to assume that the common factors have unit variance, so their correlation will be equal to their covariance. The error terms for all the manifest variables are assumed to be uncorrelated with each other and with the common factors. The model equations are

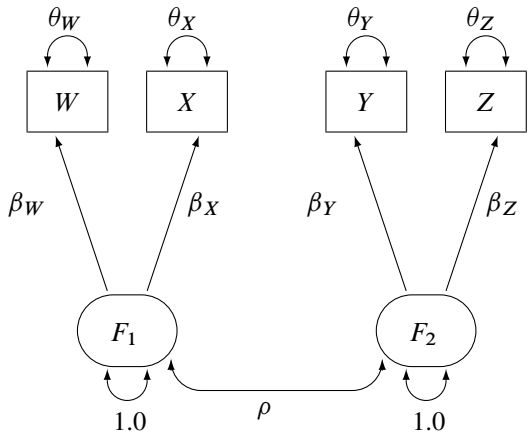
$$
\begin{aligned}
W &= \beta_W F_1 + E_W \\
X &= \beta_X F_1 + E_X \\
Y &= \beta_Y F_2 + E_Y \\
Z &= \beta_Z F_2 + E_Z
\end{aligned}
$$

with the following assumptions:

$$\begin{aligned}
\text{Var}(F_1) &= \text{Var}(F_2) = 1 \\
\text{Cov}(F_1, F_2) &= \rho \\
\text{Cov}(E_W, E_X) &= \text{Cov}(E_W, E_Y) = \text{Cov}(E_W, E_Z) = \text{Cov}(E_X, E_Y) \\
&= \text{Cov}(E_X, E_Z) = \text{Cov}(E_Y, E_Z) = \text{Cov}(E_W, F_1) \\
&= \text{Cov}(E_W, F_2) = \text{Cov}(E_X, F_1) = \text{Cov}(E_X, F_2) \\
&= \text{Cov}(E_Y, F_1) = \text{Cov}(E_Y, F_2) = \text{Cov}(E_Z, F_1) \\
&= \text{Cov}(E_Z, F_2) = 0
\end{aligned}$$

The corresponding path diagram is shown in Figure 17.16.

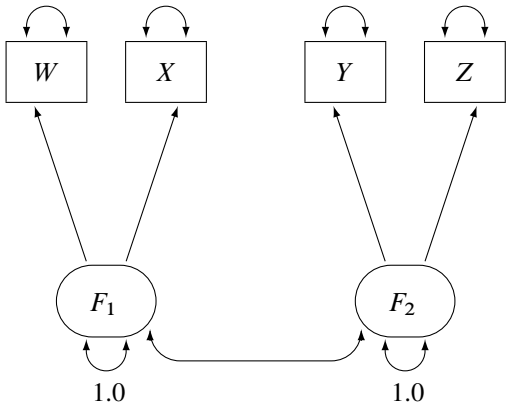
Figure 17.16 Path Diagram: Lord Data



In Figure 17.16, error terms are not explicitly represented, but error variances for the observed variables are represented by double-headed arrows that point to the variables. The error variance parameters in the model are labeled with θ_W, θ_X, θ_Y, and θ_Z, respectively, for the four observed variables. In the terminology of confirmatory factor analysis, these four variables are called indicators of the corresponding latent factors F_1 and F_2.

Figure 17.16 represents the model equations clearly. It includes all the variables and the parameters in the diagram. However, sometimes researchers represent the same model with a simplified path diagram in which unconstrained parameters are not labeled, as shown in Figure 17.17.

Figure 17.17 Simplified Path Diagram: Lord Data



This simplified representation is also compatible with the PATH modeling language of PROC CALIS. In fact, this might be an easier starting point for modelers. With the following rules, the conversion from the path diagram to the PATH model specification is very straightforward:

- Each single-headed arrow in the path diagram is specified in the PATH statement.
- Each double-headed arrow that points to a single variable is specified in the PVAR statement.
- Each double-headed arrow that points to two distinct variables is specified in the PCOV statement.

Hence, you can convert the simplified path diagram in Figure 17.17 easily to the following PATH model specification:

```
proc calis data=lord;
   path
      W <--- F1,
      X <--- F1,
      Y <--- F2,
      Z <--- F2;
   pvar
      F1 = 1.0,
      F2 = 1.0,
      W X Y Z;
   pcov
      F1 F2;
run;
```

In this specification, you do not need to specify the parameter names. However, you do need to specify fixed values specified in the path diagram. For example, the variances of F1 and F2 are both fixed at 1 in the PVAR statement.

These fixed variances are applied solely for the purpose of model identification. Because F1 and F2 are latent variables and their scales are arbitrary, fixing their scales are necessary for model identification. Beyond

these two identification constraints, none of the parameters in the model is constrained. Therefore, this is referred to as the "full" measurement model for the Lord data.

An annotated fit summary is displayed in Figure 17.18.

Figure 17.18 Fit Summary, H4: Full Model With Two Factors for Lord Data

Fit Summary

Chi-Square	0.7030
Chi-Square DF	1
Pr > Chi-Square	0.4018
Standardized RMSR (SRMSR)	0.0030
Adjusted GFI (AGFI)	0.9946
RMSEA Estimate	0.0000
Bentler Comparative Fit Index	1.0000

The chi-square value is 0.7030 (df=1, p=0.4018). This indicates that you cannot reject the hypothesized model. The standardized root mean square error (SRMSR) is 0.003, which is much smaller than the conventional 0.05 value for accepting good model fit. Similarly, the RMSEA value is virtually zero, indicating an excellent fit. The adjusted GFI (AGFI) and Bentler comparative fit index are close to 1, which also indicate an excellent model fit.

The estimation results are displayed in Figure 17.19.

Figure 17.19 Estimation Results, H4: Full Model With Two Factors for Lord Data

PATH List

--------Path--------			Parameter	Estimate	Standard Error	t Value
W	<---	F1	_Parm1	7.50066	0.32339	23.19390
X	<---	F1	_Parm2	7.70266	0.32063	24.02354
Y	<---	F2	_Parm3	8.50947	0.32694	26.02730
Z	<---	F2	_Parm4	8.67505	0.32560	26.64301

Exogenous	F1		1.00000		
	F2		1.00000		
Error	W	_Parm5	30.13796	2.47037	12.19979
	X	_Parm6	26.93217	2.43065	11.08021
	Y	_Parm7	24.87396	2.35986	10.54044
	Z	_Parm8	22.56264	2.35028	9.60000

Figure 17.19 *continued*

Covariances Among Exogenous Variables

Var1	Var2	Parameter	Estimate	Standard Error	t Value
F1	F2	_Parm9	0.89855	0.01865	48.17998

All estimates are shown with estimates of standard errors in Figure 17.19. They are all statistically significant, supporting nontrivial relationships between the observed variables and the latent factors. Notice that each free parameter in the model has been named automatically in the output. For example, the path coefficient from F1 to W is named _Parm1.

Two results in Figure 17.19 are particularly interesting. First, in the table for estimates of the path coefficients, _Parm1 and _Parm2 values form one cluster, while _Parm3 and _Parm4 values from another cluster. This seems to indicate that the effects from F1 on the indicators W and X could have been the same in the population and the effects from F2 on the indicators Y and Z could also have been the same in the population. Another interesting result is the estimate for the correlation between F1 and F2 (both were set to have variance 1). The correlation estimate (_Parm9 in the Figure 17.19) is 0.8986. It is so close to 1 that you wonder whether F1 and F2 could have been the same factor in the population. These estimation results can be used to motivate additional analyses for testing the suggested constrained models against new data sets. However, for illustration purposes, the same data set is used to demonstrate the additional model fitting in the subsequent sections.

In an analysis of these data by Jöreskog and Sörbom (1979, pp. 54–56) (see also Loehlin 1987, pp. 84–87), four hypotheses are considered:

H_1: One-factor model with parallel tests
$\rho = 1$
$\beta_W = \beta_X$ and $\mathrm{Var}(E_W) = \mathrm{Var}(E_X)$
$\beta_Y = \beta_Z$ and $\mathrm{Var}(E_Y) = \mathrm{Var}(E_Z)$

H_2: Two-factor model with parallel tests
$\beta_W = \beta_X$ and $\mathrm{Var}(E_W) = \mathrm{Var}(E_X)$
$\beta_Y = \beta_Z$ and $\mathrm{Var}(E_Y) = \mathrm{Var}(E_Z)$

H_3: Congeneric model: One factor without assuming parallel tests
$\rho = 1$

H_4: Full model: Two factors without assuming parallel tests

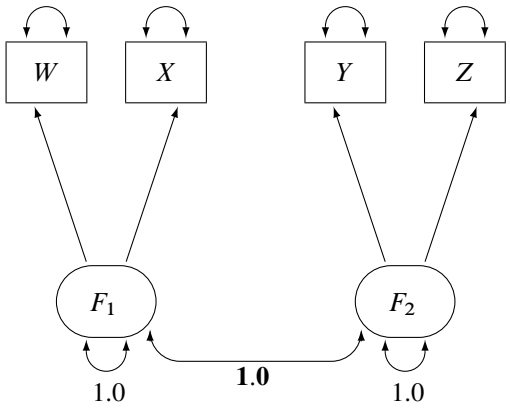
These hypotheses are ordered such that the latter models are less constrained. The hypothesis H_4 is the full model that has been considered in this section. The hypothesis H_3 specifies that there is really just one common factor instead of two; in the terminology of test theory, W, X, Y, and Z are said to be congeneric. Setting the correlation ρ between F1 and F2 to 1 makes the two factors indistinguishable. The hypothesis

H_2 specifies that W and X have the same true scores and have equal error variance; such tests are said to be parallel. The hypothesis H_2 also requires Y and Z to be parallel. Because ρ is not constrained to 1 in H_2, two factors are assumed for this model. The hypothesis H_1 says that W and X are parallel tests, Y and Z are parallel tests, and all four tests are congeneric (with ρ also set to 1).

H3: Congeneric (One-Factor) Model for Lord Data

The path diagram for this congeneric (one-factor) model is shown in Figure 17.20.

Figure 17.20 H3: Congeneric (One-Factor) Model for Lord Data



The only difference between the current path diagram in Figure 17.20 for the congeneric (one-factor) model and the preceding path diagram in Figure 17.17 for the full (two-factor) model is that the double-headed path that connects F1 and F2 is fixed to 1 in the current path diagram. Accordingly, you need to modify only slightly the preceding PROC CALIS specification to form the new model specification, as shown in the following statements:

```
proc calis data=lord;
   path
      W <--- F1,
      X <--- F1,
      Y <--- F2,
      Z <--- F2;
   pvar
      F1 = 1.0,
      F2 = 1.0,
      W X Y Z;
   pcov
      F1 F2 = 1.0;
run;
```

This specification sets the covariance between F1 and F2 to 1.0 in the PCOV statement. An annotated fit summary is displayed in Figure 17.21.

Figure 17.21 Fit Summary, H3: Congeneric (One-Factor) Model for Lord Data

Fit Summary

Chi-Square	36.2095
Chi-Square DF	2
Pr > Chi-Square	<.0001
Standardized RMSR (SRMSR)	0.0277
Adjusted GFI (AGFI)	0.8570
RMSEA Estimate	0.1625
Bentler Comparative Fit Index	0.9766

The chi-square value is 36.2095 ($df = 2$, $p < 0.0001$). This indicates that you can reject the hypothesized model at the 0.01 α-level. The standardized root mean square error (SRMSR) is 0.0277, which indicates a good fit. Bentler's comparative fit index is 0.9766, which is also a good model fit. However, the adjusted GFI (AGFI) is 0.8570, which is not very impressive. Also, the RMSEA value is 0.1625, which is too large to be an acceptable model. Therefore, the congeneric model might not be the one you want to use.

The estimation results are displayed in Figure 17.22. Because the model does not fit well, the corresponding estimation results are not interpreted.

Figure 17.22 Estimation Results, H3: Congeneric (One-Factor) Model for Lord Data

PATH List

Path			Parameter	Estimate	Standard Error	t Value
W	<---	F1	_Parm1	7.10470	0.32177	22.08012
X	<---	F1	_Parm2	7.26908	0.31826	22.83973
Y	<---	F2	_Parm3	8.37344	0.32542	25.73143
Z	<---	F2	_Parm4	8.51060	0.32409	26.26002

Variance Parameters

Variance Type	Variable	Parameter	Estimate	Standard Error	t Value
Exogenous	F1		1.00000		
	F2		1.00000		
Error	W	_Parm5	35.92111	2.41467	14.87619
	X	_Parm6	33.42373	2.31037	14.46684
	Y	_Parm7	27.17043	2.24621	12.09613
	Z	_Parm8	25.38887	2.20837	11.49664

Figure 17.22 *continued*

Covariances Among Exogenous Variables

Var1	Var2	Estimate	Standard Error	t Value
F1	F2	1.00000		

Perhaps a more natural way to specify the model under hypothesis H_3 is to use only one factor in the PATH model, as shown in the following statements:

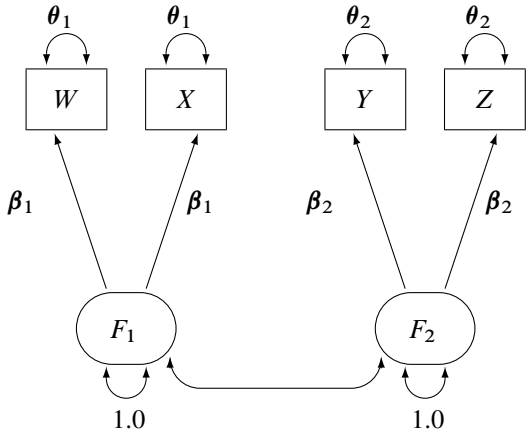
```
proc calis data=lord;
   path
      W <--- F1,
      X <--- F1,
      Y <--- F1,
      Z <--- F1;
   pvar
      F1 = 1.0,
      W X Y Z;
run;
```

This produces essentially the same results as the specification with two factors that have perfect correlation.

H2: Two-Factor Model with Parallel Tests for Lord Data

The path diagram for the two-factor model with parallel tests is shown in Figure 17.23.

Figure 17.23 H2: Two-Factor Model with Parallel Tests for Lord Data



The hypothesis H_2 requires that variables or tests under each factor are "interchangeable." In terms of the measurement model, several pairs of parameters must be constrained to have equal estimates. That is, under the parallel-test model W and X should have the same effect or path coefficient β_1 from their common factor

F1, and they should also have the same measurement error variance θ_1. Similarly, Y and Z should have the same effect or path coefficient β_2 from their common factor F2, and they should also have the same measurement error variance θ_2. These constraints are labeled in Figure 17.23.

You can impose each of these equality constraints by giving the same name for the parameters involved in the PATH model specification. The following statements specify the path diagram in Figure 17.23:

```
proc calis data=lord;
   path
      W <--- F1   = beta1,
      X <--- F1   = beta1,
      Y <--- F2   = beta2,
      Z <--- F2   = beta2;
   pvar
      F1  = 1.0,
      F2  = 1.0,
      W X = 2 * theta1,
      Y Z = 2 * theta2;
   pcov
      F1 F2;
run;
```

Note that the specification **2*theta1** in the PVAR statement means that theta1 is specified twice for the error variances of the two variables W and X. Similarly for the specification **2*theta2**. An annotated fit summary is displayed in Figure 17.24.

Figure 17.24 Fit Summary, H2: Two-Factor Model with Parallel Tests for Lord Data

Fit Summary

Chi-Square	1.9335
Chi-Square DF	5
Pr > Chi-Square	0.8583
Standardized RMSR (SRMSR)	0.0076
Adjusted GFI (AGFI)	0.9970
RMSEA Estimate	0.0000
Bentler Comparative Fit Index	1.0000

The chi-square value is 1.9335 (df=5, p=0.8583). This indicates that you cannot reject the hypothesized model H2. The standardized root mean square error (SRMSR) is 0.0076, which indicates a very good fit. Bentler's comparative fit index is 1.0000. The adjusted GFI (AGFI) is 0.9970, and the RMSEA is close to zero. All results indicate that this is a good model for the data.

The estimation results are displayed in Figure 17.25.

Figure 17.25 Estimation Results, H2: Two-Factor Model with Parallel Tests for Lord Data

PATH List

Path			Parameter	Estimate	Standard Error	t Value
W	<---	F1	beta1	7.60099	0.26844	28.31580
X	<---	F1	beta1	7.60099	0.26844	28.31580
Y	<---	F2	beta2	8.59186	0.27967	30.72146
Z	<---	F2	beta2	8.59186	0.27967	30.72146

Variance Parameters

Variance Type	Variable	Parameter	Estimate	Standard Error	t Value
Exogenous	F1		1.00000		
	F2		1.00000		
Error	W	theta1	28.55545	1.58641	18.00000
	X	theta1	28.55545	1.58641	18.00000
	Y	theta2	23.73200	1.31844	18.00000
	Z	theta2	23.73200	1.31844	18.00000

Covariances Among Exogenous Variables

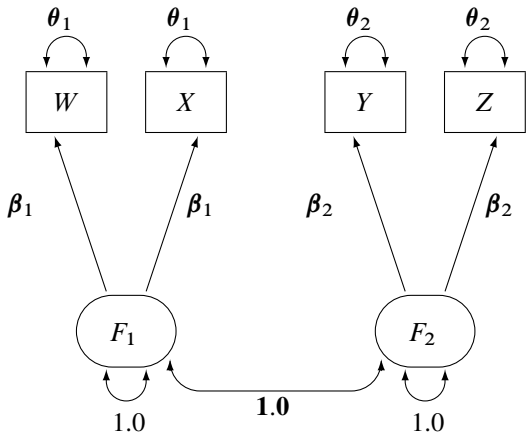
Var1	Var2	Parameter	Estimate	Standard Error	t Value
F1	F2	_Parm1	0.89864	0.01865	48.18011

Notice that because you explicitly specify the parameter names for the path coefficients (that is, beta1 and beta2), they are used in the output shown in Figure 17.25. The correlation between F1 and F2 is 0.8987, which is a very high correlation that suggests F1 and F2 might have been the same factor in the population. The next section sets this value to one so that the current model becomes a one-factor model with parallel tests.

H1: One-Factor Model with Parallel Tests for Lord Data

The path diagram for the one-factor model with parallel tests is shown in Figure 17.26.

Figure 17.26 H1: One-Factor Model with Parallel Tests for Lord Data



The hypothesis H_1 differs from H_2 in that F1 and F2 have a perfect correlation in H_1. This is indicated by the fixed value 1.0 for the double-headed path that connects F1 and F2 in Figure 17.26. Again, you need only minimal modification of the preceding specification for H_2 to specify the path diagram in Figure 17.26, as shown in the following statements:

```
proc calis data=lord;
   path
      W <--- F1   = beta1,
      X <--- F1   = beta1,
      Y <--- F2   = beta2,
      Z <--- F2   = beta2;
   pvar
      F1  = 1.0,
      F2  = 1.0,
      W X = 2 * theta1,
      Y Z = 2 * theta2;
   pcov
      F1 F2 = 1.0;
run;
```

The only modification of the preceding specification is in the PCOV statement, where you put a constant 1 for the covariance between F1 and F2. An annotated fit summary is displayed in Figure 17.27.

Figure 17.27 Fit Summary, H1: One-Factor Model with Parallel Tests for Lord Data

Fit Summary

Chi-Square	37.3337
Chi-Square DF	6
Pr > Chi-Square	<.0001
Standardized RMSR (SRMSR)	0.0286
Adjusted GFI (AGFI)	0.9509
RMSEA Estimate	0.0898
Bentler Comparative Fit Index	0.9785

The chi-square value is 37.3337 (df=6, p<0.0001). This indicates that you can reject the hypothesized model H1 at the 0.01 α-level. The standardized root mean square error (SRMSR) is 0.0286, the adjusted GFI (AGFI) is 0.9509, and Bentler's comparative fit index is 0.9785. All these indicate good model fit. However, the RMSEA is 0.0898, which does not support an acceptable model for the data.

The estimation results are displayed in Figure 17.28.

Figure 17.28 Estimation Results, H1: One-Factor Model with Parallel Tests for Lord Data

PATH List

--------Path--------			Parameter	Estimate	Standard Error	t Value
W	<---	F1	beta1	7.18623	0.26598	27.01802
X	<---	F1	beta1	7.18623	0.26598	27.01802
Y	<---	F2	beta2	8.44198	0.28000	30.14943
Z	<---	F2	beta2	8.44198	0.28000	30.14943

Variance Parameters

Variance Type	Variable	Parameter	Estimate	Standard Error	t Value
Exogenous	F1		1.00000		
	F2		1.00000		
Error	W	theta1	34.68865	1.64634	21.07010
	X	theta1	34.68865	1.64634	21.07010
	Y	theta2	26.28513	1.39955	18.78119
	Z	theta2	26.28513	1.39955	18.78119

Covariances Among Exogenous Variables

Var1	Var2	Estimate	Standard Error	t Value
F1	F2	1.00000		

The goodness-of-fit tests for the four hypotheses are summarized in the following table.

Hypothesis	Number of Parameters	χ^2	Degrees of Freedom	p-value	$\hat{\rho}$
H_1	4	37.33	6	< .0001	1.0
H_2	5	1.93	5	0.8583	0.8986
H_3	8	36.21	2	< .0001	1.0
H_4	9	0.70	1	0.4018	0.8986

Recall that the estimates of ρ for H_2 and H_4 are almost identical, about 0.90, indicating that the speeded and unspeeded tests are measuring almost the same latent variable. However, when ρ was set to 1 in H_1 and H_3 (both one-factor models), both hypotheses were rejected. Hypotheses H_2 and H_4 (both two-factor models) seem to be consistent with the data. Since H_2 is obtained by adding four constraints (for the requirement of parallel tests) to H_4 (the full model), you can test H_2 versus H_4 by computing the differences of the chi-square statistics and their degrees of freedom, yielding a chi-square of 1.23 with four degrees of freedom, which is obviously not significant. In a sense, the chi-square difference test means that representing the data by H_2 would not be significantly worse than representing the data by H_4. In addition, because H_2 offers a more precise description of the data (with the assumption of parallel tests) than H_4, it should be chosen because of its simplicity. In conclusion, the two-factor model with parallel tests provides the best explanation of the data.

The FACTOR and RAM Modeling Languages

In the section "Some Measurement Models" on page 309, you use the path diagram to represent the measurement models for data with cognitive tests and then you use the PATH modeling language to specify the model in PROC CALIS. You could have used other types of modeling languages for specifying the same model. In this section, the FACTOR and the RAM modeling languages are illustrated.

Specifying the Full Measurement Model (H4) by the FACTOR Modeling Language: Lord Data

The measurement models described in the section "Some Measurement Models" on page 309 are also known as confirmatory factor models. PROC CALIS has a specific modeling language, called FACTOR, for confirmatory factor models. You can use this modeling language for both exploratory and confirmatory factor analysis.

For example, the full measurement model H4 in the section "H4: Full Measurement Model for Lord Data" on page 310 can be specified equivalently by the FACTOR modeling language with the following statements:

```
proc calis data=lord;
   factor
      F1  --->  W  X,
      F2  --->  Y  Z;
   pvar
      F1 = 1.0,
      F2 = 1.0,
      W X Y Z;
   cov
      F1 F2;
run;
```

In the specification, you use the FACTOR statement to invoke the FACTOR modeling language. In the FACTOR statement, you specify the paths from the latent factors to the measurement indicators. For example, F1 has two paths to its indicators, W and X. Similarly, F2 has two paths to its indicators, Y and Z. Next, you use the PVAR statement to specify the variances, which is exactly the same way you use the PATH model specification in the section "H4: Full Measurement Model for Lord Data" on page 310. Lastly, you use the COV statement to specify the covariance among the factors, much like you use the PCOV statement to specify the same covariance in the PATH model specification.

Given the same confirmatory factor model, there is a major difference between the paths specified by the PATH statement and the paths specified by the FACTOR statement. In the FACTOR statement, each path must start with a latent factor followed by a right arrow and the variable list. In the PATH statement, each path can start or end with an observed or latent variable, and the direction of the arrow can be left or right.

The fit summary table for the FACTOR model is shown in Figure 17.29:

Figure 17.29 Fit Summary of the Full Confirmatory Factor Model for Lord Data

Fit Summary

Chi-Square	0.7030
Chi-Square DF	1
Pr > Chi-Square	0.4018
Standardized RMSR (SRMSR)	0.0030
Adjusted GFI (AGFI)	0.9946
RMSEA Estimate	0.0000
Bentler Comparative Fit Index	1.0000

This is exactly the same fit summary as shown in Figure 17.18, which is for the PATH model specification. Therefore, this confirms that the same model is being fit by the FACTOR model specification.

The estimation results are shown in Figure 17.30.

Figure 17.30 Estimation Results of Full Confirmatory Factor Model for Lord Data

Factor Loading Matrix: Estimate/StdErr/t-value

	F1	F2
W	7.5007 0.3234 23.1939 [_Parm1]	0
X	7.7027 0.3206 24.0235 [_Parm2]	0
Y	0	8.5095 0.3269 26.0273 [_Parm3]
Z	0	8.6751 0.3256 26.6430 [_Parm4]

Factor Covariance Matrix: Estimate/StdErr/t-value

	F1	F2
F1	1.0000	0.8986 0.0186 48.1800 [_Parm9]
F2	0.8986 0.0186 48.1800 [_Parm9]	1.0000

Error Variances

Variable	Parameter	Estimate	Standard Error	t Value
W	_Parm5	30.13796	2.47037	12.19979
X	_Parm6	26.93217	2.43065	11.08021
Y	_Parm7	24.87396	2.35986	10.54044
Z	_Parm8	22.56264	2.35028	9.60000

Again, these are the same estimates as those shown in Figure 17.19, which is for the PATH model specification. The FACTOR results displayed in Figure 17.30 are arranged differently though. No paths are shown there. The relationships between the latent factors and its indicators are shown in matrix form. The factor variance and covariances are also shown in matrix form.

Specifying the Parallel Tests Model (H2) by the FACTOR Modeling Language: Lord Data

In the section "H2: Two-Factor Model with Parallel Tests for Lord Data" on page 317, you fit a two-factor model with parallel tests for the Lord data by the PATH modeling language in PROC CALIS. Some paths and error variance are constrained under the PATH model. You can also specify this parallel tests model by the FACTOR modeling language, as shown in the following statements:

```
proc calis data=lord;
   factor
      F1  --->  W  X    = 2 * beta1,
      F2  --->  Y  Z    = 2 * beta2;
   pvar
      F1  = 1.0,
      F2  = 1.0,
      W X = 2 * theta1,
      Y Z = 2 * theta2;
   cov
      F1 F2;
run;
```

In this specification, you specify some parameters explicitly. You apply the parameter beta1 to the loadings of both W and X on F1. This means that F1 has the same amount of effect on W and X. Similarly, you apply the parameter beta2 to the loadings of Y and Z on F2. The constraints on the error variances for W, X, Y, and Z in this FACTOR model specification are done in the same way as in the PATH model specification in the section "H2: Two-Factor Model with Parallel Tests for Lord Data" on page 317.

The fit summary table for this parallel tests model is shown in Figure 17.31.

Figure 17.31 Fit Summary of the Confirmatory Factor Model with Parallel Tests for Lord Data

Fit Summary

Chi-Square	1.9335
Chi-Square DF	5
Pr > Chi-Square	0.8583
Standardized RMSR (SRMSR)	0.0076
Adjusted GFI (AGFI)	0.9970
RMSEA Estimate	0.0000
Bentler Comparative Fit Index	1.0000

All the fit indices shown in Figure 17.31 for the FACTOR model match the corresponding PATH model results displayed in Figure 17.24. All the estimation results in Figure 17.32 for the FACTOR model are the same as those for the corresponding PATH model in Figure 17.25.

Figure 17.32 Estimation Results of the Confirmatory Factor Model with Parallel Tests for Lord Data

Factor Loading Matrix: Estimate/StdErr/t-value

	F1	F2
W	7.6010 0.2684 28.3158 [beta1]	0
X	7.6010 0.2684 28.3158 [beta1]	0
Y	0	8.5919 0.2797 30.7215 [beta2]
Z	0	8.5919 0.2797 30.7215 [beta2]

Factor Covariance Matrix: Estimate/StdErr/t-value

	F1	F2
F1	1.0000	0.8986 0.0187 48.1801 [_Parm1]
F2	0.8986 0.0187 48.1801 [_Parm1]	1.0000

Error Variances

Variable	Parameter	Estimate	Standard Error	t Value
W	theta1	28.55545	1.58641	18.00000
X	theta1	28.55545	1.58641	18.00000
Y	theta2	23.73200	1.31844	18.00000
Z	theta2	23.73200	1.31844	18.00000

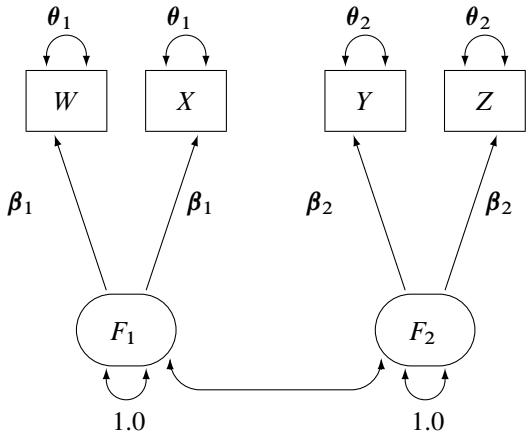
Specifying the Parallel Tests Model (H2) by the RAM Modeling Language: Lord Data

In the preceding section, you use the FACTOR modeling language of PROC CALIS to specify the parallel tests model. This model has also been specified by the PATH modeling language in the section "H2: Two-Factor Model with Parallel Tests for Lord Data" on page 317. The two specifications are equivalent; they lead to the same model fitting and estimation results. The main reason for providing two different types of modeling languages in PROC CALIS is that different researchers come from different fields of applications. Some researchers might be more comfortable with the confirmatory factor tradition, and some might equate structural equation models with path diagrams for variables.

PROC CALIS has still another modeling language that is closely related to the path diagram representation: the RAM model specification. In this section, the parallel tests model (H2) described in "H2: Two-Factor Model with Parallel Tests for Lord Data" on page 317 is used to illustrate the RAM model specification in PROC CALIS.

The path diagram for this model is reproduced in Figure 17.33.

Figure 17.33 H2: Two-Factor Model with Parallel Tests for Lord Data



The path diagram in Figure 17.33 can be readily transcribed into the RAM model specification by following these simple rules:

- Each single- or double- headed path corresponds to an entry in the RAM model specification.
- The single-headed paths are specified with the _A_ path type or matrix keyword.
- The double-headed paths are specified with the _P_ path type or matrix keyword.

At this point, you do not need to define the RAM model matrices _A_ and _P_, as long as you recognize that they are used as keywords to distinguish different path types. There are 11 single- or double- headed paths in Figure 17.33, and therefore you expect to specify these 11 elements in the RAM model, as shown in the following statements:

```
proc calis data=lord;
   ram var = W X Y Z F1 F2, /* W=1, X=2, Y=3, Z=4, F1=5, F2=6*/
       _A_   1  5  beta1,
       _A_   2  5  beta1,
       _A_   3  6  beta2,
       _A_   4  6  beta2,
       _P_   5  5  1.0,
       _P_   6  6  1.0,
       _P_   1  1  theta1,
       _P_   2  2  theta1,
       _P_   3  3  theta2,
       _P_   4  4  theta2,
       _P_   5  6  ;
run;
```

In this specification, the RAM statement invokes the RAM modeling language. The first option is the VAR= option where you specify the variables, observed and latent, in the model. The order in the VAR= variable list represents the order of these variables in the RAM model matrices. For this example, W is 1, X is 2, and so on. Next, you specify 11 RAM entries for the 11 path elements in the path diagram shown in Figure 17.33.

The first four entries are for the single-headed paths. They all begin with the _A_ keyword. In each of these _A_ entries, you specify the variable number of the outcome variable (being pointed at), and then the variable number of the predictor variable. At the end of the entry, you can specify a parameter name, a fixed value, an initial value, or nothing. In this example, all the _A_ entries are specified with parameter names. The first two paths are constrained because they use the same parameter name beta1. The next two paths are constrained because they use the same parameter name beta2.

The rest of the RAM entries in the example are of the _P_ type, which is for the specification of variances or covariances in the RAM model (the double-headed arrows in the path diagram). The _P_ entry with [5,5] is for the variance of the fifth variable, F1, on the VAR= list. This variance is fixed at 1.0 in the model, and so is the variance of the sixth variable, F2, in the next _P_ entry.

The next four _P_ entries are for the specification of error variances of the observed variables W, X, Y, and Z. You use the desired parameter names for constraining these parameters, as required in the parallel test model.

The last _P_ entry in the RAM statement is for the covariance between the fifth variable (F1) and the sixth variable (F2). You specify neither a parameter name nor a fixed value at the end of this entry. By default, this empty parameter specification is treated as a free parameter in the model. A parameter name for this entry is generated by PROC CALIS.

The fit summary for this RAM model is shown in Figure 17.34, and the estimation results are shown in Figure 17.35.

Figure 17.34 Fit Summary of RAM Model with Parallel Tests for Lord Data

Fit Summary

Chi-Square	1.9335
Chi-Square DF	5
Pr > Chi-Square	0.8583
Standardized RMSR (SRMSR)	0.0076
Adjusted GFI (AGFI)	0.9970
RMSEA Estimate	0.0000
Bentler Comparative Fit Index	1.0000

Figure 17.35 Estimation Results of RAM Model with Parallel Tests for Lord Data

RAM Pattern and Estimates

Matrix	--Row--		-Column-		Parameter	Estimate	Standard Error	t Value
_A_ (1)	W	1	F1	5	beta1	7.60099	0.26844	28.31580
	X	2	F1	5	beta1	7.60099	0.26844	28.31580
	Y	3	F2	6	beta2	8.59186	0.27967	30.72146
	Z	4	F2	6	beta2	8.59186	0.27967	30.72146
_P_ (2)	F1	5	F1	5		1.00000		
	F2	6	F2	6		1.00000		
	W	1	W	1	theta1	28.55545	1.58641	18.00000
	X	2	X	2	theta1	28.55545	1.58641	18.00000
	Y	3	Y	3	theta2	23.73200	1.31844	18.00000
	Z	4	Z	4	theta2	23.73200	1.31844	18.00000
	F1	5	F2	6	_Parm1	0.89864	0.01865	48.18011

Again, the model fit and the estimation results match those from the PATH model specification in Figure 17.24 and Figure 17.25, and those from the FACTOR model specification in Figure 17.31 and Figure 17.32.

A Combined Measurement-Structural Model

To illustrate a more complex model, this example uses some well-known data from Haller and Butterworth (1960). Various models and analyses of these data are given by Duncan, Haller, and Portes (1968), Jöreskog and Sörbom (1988), and Loehlin (1987).

The study concerns the career aspirations of high school students and how these aspirations are affected by close friends. The data are collected from 442 seventeen-year-old boys in Michigan. There are 329 boys in the sample who named another boy in the sample as a best friend. The data from these 329 boys paired with the data from their best friends are analyzed.

The method of data collection introduces two statistical problems. First, restricting the analysis to boys whose best friends are in the original sample causes the reduced sample to be biased. Second, since the data from a given boy might appear in two or more observations, the observations are not independent. Therefore, any statistical conclusions should be considered tentative. It is difficult to accurately assess the effects of the dependence of the observations on the analysis, but it could be argued on intuitive grounds that since each observation has data from two boys and since it seems likely that many of the boys appear in the data set at least twice, the effective sample size might be as small as half of the reported 329 observations.

The correlation matrix, taken from Jöreskog and Sörbom (1988), is shown in the following DATA step:

```

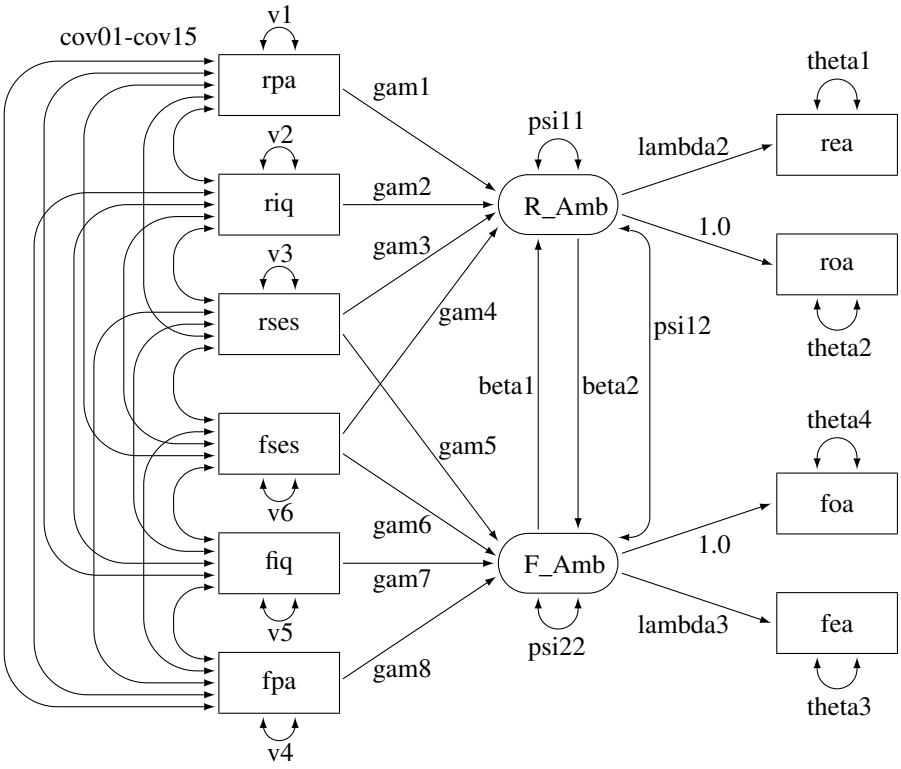
Career Aspiration: Analysis 1

The model analyzed by Jöreskog and Sörbom (1988) is displayed in the path diagram in Figure 17.36.

Figure 17.36 Path Diagram: Career Aspiration – Jöreskog and Sörbom (1988)



Two latent variables, R_Amb and F_Amb, represent the respondent's level of ambition and his best friend's level of ambition, respectively. The model states that the respondent's ambition (R_Amb) is determined by his intelligence (riq) and socioeconomic status (rses), his perception of his parents' aspiration for him (rpa), and his friend's socioeconomic status (fses) and ambition (F_Amb). It is assumed that his friend's intelligence (fiq) and parental aspiration (fpa) affect the respondent's ambition only indirectly through the friend's ambition (F_Amb). Ambition is indicated by the manifest variables of occupational (roa) and educational aspiration (rea), which are assumed to have uncorrelated residuals. The path coefficient from ambition to occupational aspiration is set to 1.0 to determine the scale of the ambition latent variable.

The path diagram shown in Figure 17.36 appears to be very complicated. Sometimes when researchers draw their path diagram with a lot of variables, they omit the covariances among exogenous variables for overall clarity. For example, the double-headed paths that represent cov01–cov15 in Figure 17.36 can be omitted. In addition, unconstrained variance and error variance parameters in the path diagram could be omitted without losing the pertinent information in the path diagram. For example, variance parameters v1–v6 and error variance parameters theta1–theta4 in Figure 17.36 detract from the main focus on the functional relationships of the model.

These omissions in the path diagram are in fact inconsequential when you transcribe them into the PATH model in PROC CALIS. The reason is that PROC CALIS employs several useful default parameterization rules that make the model specification process much easier and more intuitive. Here are the sets of default covariance structure parameters in the PATH modeling language:

- variances for all exogenous (observed or latent) variables
- error variances of all endogenous (observed or latent) variables
- covariances among all exogenous (observed or latent, excluding error) variables

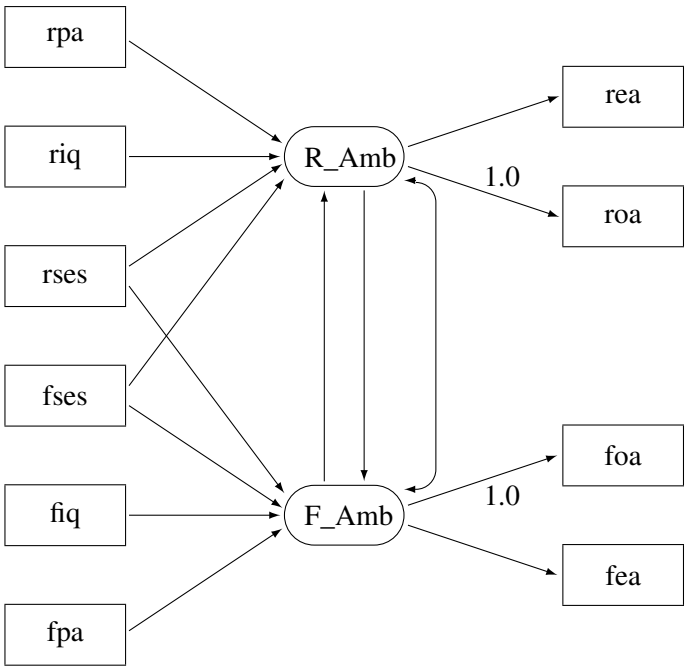
For example, these rules for setting default covariance structure parameters mean that the following sets of parameters in Figure 17.36 are optional in the path diagram representation and in the corresponding PATH model specification:

- v1–v6
- theta1–theta4, psi11, and psi22
- cov01–cov15

Note that the double-headed path labeled with psi12, which is a covariance parameter among error terms for R_Amb and F_Amb, is not a default parameter. As a result, it must be represented in the path diagram and in the PATH model specification.

Another simplification is to omit the unconstrained parameter names in the path diagram. In the PATH model specification, an "unnamed" parameter is a free parameter by default—there is no need to give unique names to denote free parameters. With all the mentioned simplifications, you can depict your path diagram simply as the one in Figure 17.37.

Figure 17.37 Simplified Path Diagram for Career Aspiration : Analysis 1



The simplified path diagram in Figure 17.37 is readily transcribed into the PATH model as shown in the following statements:

```
proc calis data=aspire nobs=329;
   path
      /* structural model of influences */
      R_Amb <--- rpa     ,
      R_Amb <--- riq     ,
      R_Amb <--- rses    ,
      R_Amb <--- fses    ,
      F_Amb <--- rses    ,
      F_Amb <--- fses    ,
      F_Amb <--- fiq     ,
      F_Amb <--- fpa     ,
      R_Amb <--- F_Amb   ,
      F_Amb <--- R_Amb   ,

      /* measurement model for aspiration */
      rea <---  R_Amb      ,
      roa <---  R_Amb  = 1.,
      foa <---  F_Amb  = 1.,
      fea <---  F_Amb    ;
   pcov
      R_Amb  F_Amb;
run;
```

Again, because you have 15 paths (single- or double- headed) in the path diagram, you expect that there are 15 entries in the PATH and the PCOV statements. Essentially, in this PATH model specification you specify all the functional relationships (single-headed arrows) in the path diagram and the covariance of error terms (double-headed arrows) for R_Amb and F_Amb.

Since this TYPE=CORR data set does not contain an observation with _TYPE_=N giving the sample size, it is necessary to specify the NOBS= option in the PROC CALIS statement.

The fit summary is displayed in Figure 17.38, and the estimation results are displayed in Figure 17.39.

Figure 17.38 Career Aspiration Data: Fit Summary for Analysis 1

Fit Summary

Chi-Square	26.6972
Chi-Square DF	15
Pr > Chi-Square	0.0313
Standardized RMSR (SRMSR)	0.0202
Adjusted GFI (AGFI)	0.9428
RMSEA Estimate	0.0488
Akaike Information Criterion	106.6972
Schwarz Bayesian Criterion	258.5395
Bentler Comparative Fit Index	0.9859

The model fit chi-square value is 26.6972 (df=15, p=0.0313). From the hypothesis testing point of view, this result says that this is an extreme sample given the model is true; therefore, the model should be rejected. But in social and behavioral sciences, you rarely abandon a model purely on the ground of chi-square significance test. The main reason is that you might only need to find a model that is approximately true, but the hypothesis testing framework is for testing exact model representation in the population. To determine whether a model is good or bad, you usually consult other fit indices. Several fit indices are shown in Figure 17.38.

The standardized RMSR is 0.0202. The RMSEA value is 0.0488. Both of these indices are smaller than 0.05, which indicate good model fit by convention. The adjusted GFI is 0.9428, and the comparative fit index is 0.9859. Again, values greater than 0.9 for these indices indicate good model fit by convention. Therefore, you can conclude that this is a good model for the data. Akaike's information criterion (AIC) and the Schwarz Bayesian criterion are also shown. You cannot interpret these values directly, but they are useful for model comparison given the same data, as shown in later sections.

fpa	rses	_Add21	0.09310	0.05545	1.67885
fpa	fiq	_Add22	0.20870	0.05641	3.70000
fses	riq	_Add23	0.18610	0.05616	3.31352
fses	rpa	_Add24	0.01860	0.05523	0.33680
fses	rses	_Add25	0.27070	0.05720	4.73226
fses	fiq	_Add26	0.29500	0.05757	5.12435
fses	fpa	_Add27	-0.04380	0.05527	-0.79249

In Figure 17.39, some of the paths do not show significance. That is, fses does not seem to be a good indicator of a respondent's ambition R_Amb and rses does not seem to be a good indicator of a friend's ambition F_Amb. The t values are 1.445 and 1.195, respectively, which are much smaller than the nominal 1.96 value at the 0.05 α-level of significance. Other paths are either significant or marginally significant.

You should be very cautious about interpreting the current analysis results for two reasons. First, as mentioned previously the data consist of dependent observations, and it was not certain how the issue could have been addressed beyond setting the sample size to half of the actual size. Second, structural equation modeling methodology is mainly applicable when you analyze covariance structures. When you input a correlation matrix for analysis, there is no guarantee that the statistical tests and standard error estimates are applicable. You should view the interpretations made here just as an exercise of applying structural equation modeling.

In Output 17.39, all parameter names are generated by PROC CALIS. Alternatively, you can also name these parameters in your PATH model specification. The following shows a PATH model specification that corresponds to the complete path diagram shown in Figure 17.36:

```
proc calis data=aspire nobs=329;
   path
      /* structural model of influences */
      rpa    --->  R_Amb   =  gam1,
      riq    --->  R_Amb   =  gam2,
      rses   --->  R_Amb   =  gam3,
      fses   --->  R_Amb   =  gam4,
      rses   --->  F_Amb   =  gam5,
      fses   --->  F_Amb   =  gam6,
      fiq    --->  F_Amb   =  gam7,
      fpa    --->  F_Amb   =  gam8,
      F_Amb  --->  R_Amb   = beta1,
      R_Amb  --->  F_Amb   = beta2,

      /* measurement model for aspiration */
      R_Amb  --->  rea     = lambda2,
      R_Amb  --->  roa     = 1.,
      F_Amb  --->  foa     = 1.,
      F_Amb  --->  fea     = lambda3;
   pvar
      R_Amb = psi11,
      F_Amb = psi22,
      rpa riq rses fpa fiq fses = v1-v6,
      rea roa fea foa = theta1-theta4;
   pcov
      R_Amb F_Amb = psi12,
      rpa riq rses fpa fiq fses = cov01-cov15;
run;
```

In this specification, the names of the parameters correspond to those used by Jöreskog and Sörbom (1988). Compared with the simplified version of the same model specification, you name 27 more parameters in the current specification. You have to be careful with this many parameters. If you inadvertently repeat the use of some parameter names, you will have unexpected constraints in the model.

The results from this analysis are displayed in Figure 17.40.

Figure 17.40 Career Aspiration Data: Estimation Results with Designated Parameter Names (Analysis 1)

riq	fpa	cov05	0.10210	0.05550	1.83955
rses	fpa	cov06	0.09310	0.05545	1.67885
rpa	fiq	cov07	0.07820	0.05538	1.41195
riq	fiq	cov08	0.33550	0.05824	5.76060
rses	fiq	cov09	0.23020	0.05666	4.06284
fpa	fiq	cov10	0.20870	0.05641	3.70000
rpa	fses	cov11	0.01860	0.05523	0.33680
riq	fses	cov12	0.18610	0.05616	3.31352
rses	fses	cov13	0.27070	0.05720	4.73226
fpa	fses	cov14	-0.04380	0.05527	-0.79249
fiq	fses	cov15	0.29500	0.05757	5.12435

These are the same results as displayed in Figure 17.39 for the simplified PATH model specification. The only differences are the arrangement of estimation results and the naming of the parameters.

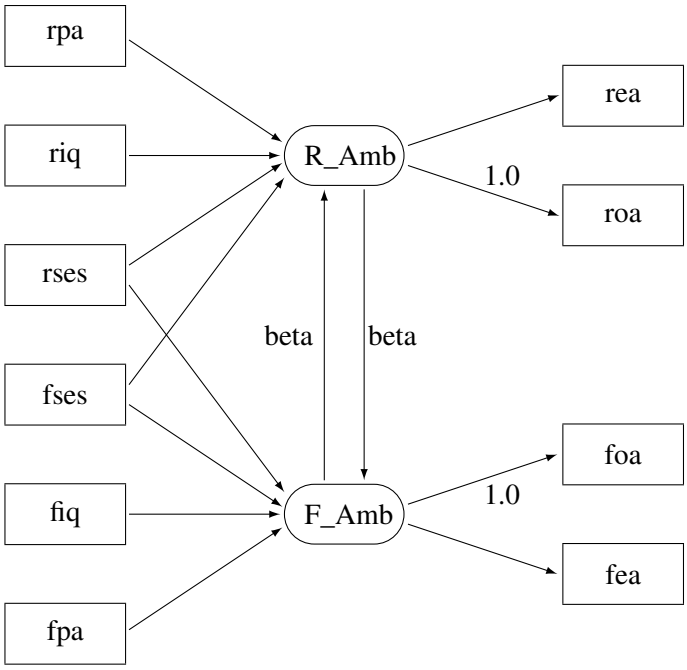
Career Aspiration: Analysis 2

Jöreskog and Sörbom (1988) present more detailed results from a second analysis in which two constraints are imposed:

- The coefficients that connect the latent ambition variables are equal.
- The covariance of the disturbances of the ambition variables is zero.

Applying these constraints to Figure 17.37, you get the path diagram displayed in Figure 17.41.

Figure 17.41 Path Diagram for Career Aspiration : Analysis 2



In Figure 17.41, the double-headed path that connected R_Amb and F_Amb no longer exists. Also, the single-headed paths between R_Amb and F_Amb are both labeled with beta, indicating the required constrained effects in the model. The path diagram in Figure 17.41 is transcribed into the PATH model in the following statements:

```
proc calis data=aspire nobs=329;
   path
      /* structural model of influences */
      rpa    ---> R_Amb         ,
      riq    ---> R_Amb         ,
      rses   ---> R_Amb         ,
      fses   ---> R_Amb         ,
      rses   ---> F_Amb         ,
      fses   ---> F_Amb         ,
      fiq    ---> F_Amb         ,
      fpa    ---> F_Amb         ,
      F_Amb  ---> R_Amb   = beta,
      R_Amb  ---> F_Amb   = beta,

      /* measurement model for aspiration */
      R_Amb  ---> rea         ,
      R_Amb  ---> roa     = 1.,
      F_Amb  ---> foa     = 1.,
      F_Amb  ---> fea     ;
run;
```

The only differences between the current specification and the preceding specification for Analysis 1 are the labeling of two paths with the same parameter beta and the deletion of PCOV statement where the covariance of R_Amb and F_Amb was specified in Analysis 1. The fit summary of the current model is displayed in Figure 17.42, and the estimation results are displayed in Figure 17.43.

Figure 17.42 Career Aspiration Data: Fit Summary for Analysis 2

Fit Summary

Chi-Square	26.8987
Chi-Square DF	17
Pr > Chi-Square	0.0596
Standardized RMSR (SRMSR)	0.0203
Adjusted GFI (AGFI)	0.9492
RMSEA Estimate	0.0421
Akaike Information Criterion	102.8987
Schwarz Bayesian Criterion	247.1489
Bentler Comparative Fit Index	0.9880

The model fit chi-square value is 26.8987 (df=17, p=0.0596). The standardized RMSR and the RMSEA are both less than 0.05, while the adjusted GFI and comparative fit index are both bigger than 0.9. All these indicate a good model fit, but how does this model (Analysis 2) compare with that in Analysis 1?

The difference between the chi-square values for Analyses 1 and 2 is $26.8987 - 26.6972 = 0.2015$ with two degrees of freedom, which is far from significant. This indicates that the restricted model (Analysis 2) fits as well as the unrestricted model (Analysis 1). The AIC is 102.8987, and the SBC is 247.149. Both of these values are smaller than that of Analysis 1 (106.697 for AIC and 258.540 for SBC), and hence they indicate that the current model is a better one.

fses	fiq	_Add26	0.29500	0.05757	5.12435
fses	fpa	_Add27	-0.04380	0.05527	-0.79249

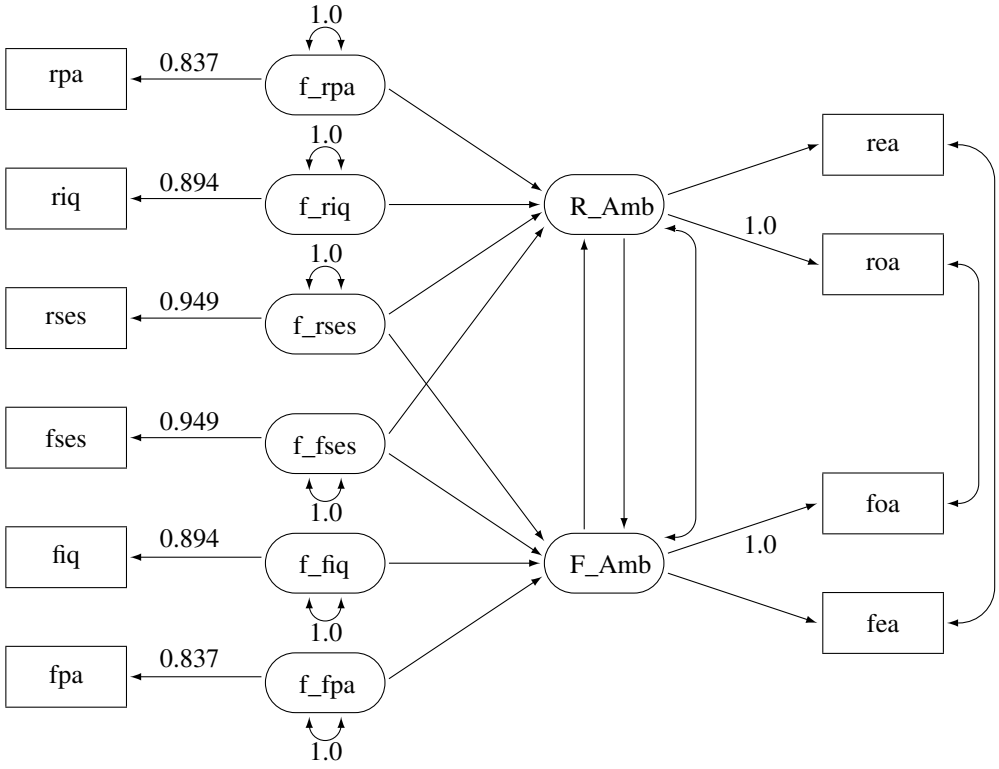
Like Analysis 1, the same two paths in the current analysis are not significant. That is, fses does not seem to be a good indicator of a respondent's ambition R_Amb, and rses does not seem to be a good indicator of a friend's ambition F_Amb. The t values are 1.862 and 1.768, respectively.

Career Aspiration: Analysis 3

Loehlin (1987) points out that the models considered are unrealistic in at least two respects. First, the variables of parental aspiration, intelligence, and socioeconomic status are assumed to be measured without error. Loehlin adds uncorrelated measurement errors to the model and assumes, for illustrative purposes, that the reliabilities of these variables are known to be 0.7, 0.8, and 0.9, respectively. In practice, these reliabilities would need to be obtained from a separate study of the same or a very similar population. If these constraints are omitted, the model is not identified. However, constraining parameters to a constant

in an analysis of a correlation matrix might make the chi-square goodness-of-fit test inaccurate, so there is more reason to be skeptical of the p-values. Second, the error terms for the respondent's aspiration are assumed to be uncorrelated with the corresponding terms for his friend. Loehlin introduces a correlation between the two educational aspiration error terms and between the two occupational aspiration error terms. These additions produce the path diagram for Loehlin's model shown in Figure 17.44.

Figure 17.44 Path Diagram for Career Aspiration: Analysis 3



In Figure 17.44, the observed variables rpa, riq, rses, fses, fiq, and fpa are all measured with measurement errors. Their true scores counterparts f_rpa, f_riq, f_rses, f_fses, f_fiq, and f_fpa are latent variables in the model. Path coefficients from these latent variables to the observed variables are fixed coefficients, indicating the square roots of the theoretical reliabilities in the model. These latent variables, rather than the observed counterparts, serve as predictors of the ambition factors R_Amb and F_Amb in the current model (Analysis 3). The error terms for these two latent factors are correlated, as indicated by a double-headed path (arrow) that connects the two factors. Correlated errors for the occupational aspiration variables (roa and foa) and the educational aspiration variables (rea and fea) are also shown in Figure 17.44. Again, these correlated errors are represented by two double-headed paths (arrows) in the path diagram.

You use the following statements to specify the path model for Analysis 3:

```
proc calis data=aspire nobs=329;
   path
      /* measurement model for intelligence and environment */
      rpa     <---  f_rpa    = 0.837,
      riq     <---  f_riq    = 0.894,
      rses    <---  f_rses   = 0.949,
      fses    <---  f_fses   = 0.949,
      fiq     <---  f_fiq    = 0.894,
      fpa     <---  f_fpa    = 0.837,

      /* structural model of influences */
      f_rpa   --->  R_Amb,
      f_riq   --->  R_Amb,
      f_rses  --->  R_Amb,
      f_fses  --->  R_Amb,
      f_rses  --->  F_Amb,
      f_fses  --->  F_Amb,
      f_fiq   --->  F_Amb,
      f_fpa   --->  F_Amb,
      F_Amb   --->  R_Amb,
      R_Amb   --->  F_Amb,

      /* measurement model for aspiration */
      R_Amb   --->  rea        ,
      R_Amb   --->  roa    = 1.,
      F_Amb   --->  foa    = 1.,
      F_Amb   --->  fea    ;
   pvar
      f_rpa f_riq f_rses f_fses f_fiq f_fpa = 6 * 1.0;
   pcov
      R_Amb F_Amb  ,
      rea  fea     ,
      roa  foa     ;
run;
```

In this specification, the measurement model for the six intelligence and environment variables are added. They are the first six paths in the PATH statement. Fixed constants are set for these path coefficients so as to make the measurement model identified and to set the required reliabilities of these measurement indicators. The structural model of influences and the measurement model for aspiration are the same as specified in Analysis 1. (See the section "Career Aspiration: Analysis 1" on page 331.) All the correlated errors are specified in the PCOV statement.

The fit summary of the current model is displayed in Figure 17.45.

Figure 17.45 Career Aspiration Data: Fit Summary for Analysis 3

Fit Summary

Chi-Square	12.0132
Chi-Square DF	13
Pr > Chi-Square	0.5266
Standardized RMSR (SRMSR)	0.0149
Adjusted GFI (AGFI)	0.9692
RMSEA Estimate	0.0000
Akaike Information Criterion	96.0132
Schwarz Bayesian Criterion	255.4476
Bentler Comparative Fit Index	1.0000

Since the p-value for the chi-square test is 0.5266, this model clearly cannot be rejected. Both the standardized RMSR and the RMSEA are very small, and both the adjusted GFI and the comparative fit index are high. All these point to an excellent model fit. However, Schwarz's Bayesian criterion for this model (SBC = 255.4476) is somewhat larger than for Jöreskog and Sörbom (1988) Analysis 2 in Figure 17.42 (SBC = 247.1489), suggesting that a more parsimonious model would be desirable.

The estimation results are displayed in Figure 17.46.

Figure 17.46 Career Aspiration Data: Estimation Results for Analysis 3

Like Analyses 1 and 2, two paths that concern the validity of the indicators in the current analysis do not show significance. That is, f_fses does not seem to be a good indicator of a respondent's ambition R_Amb, and f_rses does not seem to be a good indicator of a friend's ambition F_Amb. The t values are 1.588 and 1.212, respectively. In addition, in the current model (Analysis 3), the structural relationships between the ambition factors do not show significance. The t value for the path from the friend's ambition factor F_Amb on the respondent's ambition factor R_Amb is only 1.044, while the t value for the path from the respondent's ambition factor R_Amb on the friend's ambition factor F_Amb is only 1.079. These cast doubts on the validity of the structural model and perhaps even the entire model.

Fitting LISREL Models by the LISMOD Modeling Language

The model described in the section "Career Aspiration: Analysis 3" on page 342 provides a good example of the LISREL model. In PROC CALIS, the LISREL model specifications are supported by a matrix-based language called LISMOD (LISREL model). In this section, the path diagram in Figure 17.44 is specified by the LISMOD modeling language of PROC CALIS. See the section "Career Aspiration: Analysis 3" on page 342 for detailed descriptions of the model.

In order to understand the LISMOD modeling language of PROC CALIS, some basic understanding of the LISREL model is necessary. In a LISREL model, variables are classified into four distinct classes:

- ξ is a vector of exogenous (independent) latent variables in the model. They are specified in XI= variable list in the LISMOD statement.
- η is a vector of endogenous (dependent) latent variables in the model. They are specified in ETA= variable list in the LISMOD statement.
- x is a vector of observed indicator variables for ξ in the model. They are specified in XVAR= variable list in the LISMOD statement.
- y is a vector of observed indicator variables for η in the model. They are specified in YVAR= variable list in the LISMOD statement.

For detailed descriptions of the LISMOD modeling language, see the LISMOD statement and the section "The LISMOD Model and Submodels" on page 1212. To successfully set up a LISMOD model in PROC CALIS, you first need to recognize these classes of variables in your model. For the path diagram in Figure 17.44, it is not difficult to see the following:

- ξ is the vector of the intelligence and environmental factors: f_rpa, f_riq, f_rses, f_fses, f_fiq, and f_fpa. These variables are exogenous because no single-headed arrows point to them.
- η is the vector of the ambition factors: R_Amb, and F_Amb. They are endogenous because each of them has at least one single-headed arrow pointing to it.
- x is the vector of the observed indicator variables for the intelligence and environmental factors ξ. These indicators are rpa, riq, rses, fses, fiq, and fpa.

- y is the vector of observed indicator variables for the ambition factors η. These indicators are rea, roa, foa, and fea.

In LISMOD, you do not need to define error terms explicitly as latent variables. The parameters in LISMOD are defined as entries in various model matrices. The following statements specify the LISMOD model for the diagram in Figure 17.44:

```
proc calis data=aspire nobs=329;
   lismod
      xi   = f_rpa f_riq f_rses f_fses f_fiq f_fpa,
      eta  = R_Amb F_Amb,
      xvar = rpa riq rses fses fiq fpa,
      yvar = rea roa foa fea;

   /* measurement model for aspiration */
   matrix _lambday_ [1,1], [2,1] = 1.0, [3,2] = 1.0, [4,2];
   matrix _thetay_  [4,1], [3,2];

   /* measurement model for intelligence and environment */
   matrix _lambdax_ [1,1] = 0.837 0.894 0.949 0.949 0.894 0.837;

   /* structural model of influences */
   matrix _beta_ [2,1],[1,2];
   matrix _gamma_ [1,1 to 4], [2,3 to 6];

   /* Covariances among Eta-variables */
   matrix _psi_ [2,1];

   /* Fixed variances for Xi-variables */
   matrix _phi_ [1,1] = 6 * 1.0;
run;
```

The LISMOD statement invokes the LISMOD modeling language of PROC CALIS. In the LISMOD statement, you list the four classes of variables in the model in the XI=, ETA=, XVAR=, and YVAR= variable lists, respectively. After you define the four classes of variables, you use several MATRIX statements to specify the model matrices and the parameters in the model.

Basically, there are three model components in the LISMOD specification: two measurement models and one structural model. The first measurement model specifies the functional relationships between observed variables y (YVAR= variables) and the endogenous (dependent) latent factors η (ETA= variables). The second measurement model specifies the functional relationships between observed variables x and (XVAR= variables) and the exogenous (independent) latent factors ξ (XI= variables). The structural model specifies the relationships between the endogenous and exogenous latent variables η and ξ. To facilitate the discussion of these model components and the corresponding LISMOD model specification, some initial model output from PROC CALIS are shown.

The Measurement Model for y

The first component of the LISMOD specification is the measurement model for y, as shown in the following equation:

$$y = \mathbf{\Lambda_y}\eta + \epsilon$$

In the context of covariance structure analysis, without loss of generality, it is assumed that y and η are centered so that there is no intercept term in the equation. This equation essentially states that y is a function of the true scores vector η plus the error term ϵ, which is independent of η. The model matrices involved in this measurement model are $\mathbf{\Lambda_y}$ (effects of η on y) and $\mathbf{\Theta_y}$, which is the covariance matrix of ϵ.

For the career aspiration data, you specify the following two MATRIX statements for this measurement model:

```
matrix _lambday_ [1,1], [2,1] = 1.0, [3,2] = 1.0, [4,2];
matrix _thetay_  [4,1], [3,2];
```

The first matrix statement is for matrix $\mathbf{\Lambda_y}$. You specify four parameters in this matrix. The [1,1] and [4,2] elements are free parameters, and the [2,1] and [3,2] elements have fixed values of 1. You do not specify other elements in this matrix. By default, unspecified elements in the $\mathbf{\Lambda_y}$ matrix are fixed zeros. You can check your initial model specification of this matrix, as shown in the Figure 17.47.

Figure 17.47 Career Aspiration Analysis 3: Initial Measurement Model for y

Initial _LAMBDAY_ Matrix

	R_Amb	F_Amb
rea	.	0
	[_Parm01]	
roa	1.0000	0
foa	0	1.0000
fea	0	.
		[_Parm02]

Figure 17.47 *continued*

Initial _THETAY_ Matrix

	rea	roa	foa	fea
rea	. [_Add07]	0	0	. [_Parm13]
roa	0	. [_Add08]	. [_Parm14]	0
foa	0	. [_Parm14]	. [_Add09]	0
fea	. [_Parm13]	0	0	. [_Add10]

NOTE: Parameters with prefix '_Add' are added by PROC CALIS.

In Figure 17.47, the initial _LAMBDAY_ matrix is a 4×2 matrix. The _LAMBDAY_ matrix contains information about the relationships between the row indicator variables y (YVAR= variables) and the column factors η (ETA= variables). As specified in the MATRIX statement for _LAMBDAY_, the [1,1] and [4,2] are free parameters named _Parm01 and _Parm02, respectively. These parameter names are generated by PROC CALIS. Fixed values 1.0 appear in the [2,1] and [3,2] elements. These fixed values are used to identify the scales of the latent variables R_Amb and F_Amb.

The _THETAY_ matrix in Figure 17.47 is the covariance matrix among the error terms for the y-variables (YVAR= variables). This is a 4×4 matrix for the four measured indicators. As specified in the MATRIX statement for _THETAY_, the [4,1] and [3,2] elements are free parameters named _Parm13 and _Parm14, respectively. Because _THETAY_ is a symmetric matrix, elements [1,4] and [2,3] are also implicitly specified as parameters in this model matrix.

As shown in Figure 17.47, PROC CALIS adds four default free parameters to the _THETAY_ matrix. On the diagonal of the _THETAY_ matrix, parameters _Add07, _Add08, _Add09, and _Add10 are added as default free parameters by PROC CALIS automatically. In general, error variances are default free parameters in PROC CALIS. You do not have to specify them but you can specify them if you want to, especially when you need to set fixed values or other constraints on them.

The Measurement Model for x

The second component of the LISMOD specification is the measurement model for x, as shown in the following equation:

$$x = \mathbf{\Lambda_x}\xi + \delta$$

The measurement model for x is similar to that for y. Assuming that x and ξ are centered, this equation states that x is a function of the true scores vector ξ plus the error term δ, which is independent of ξ. The model matrices involved in this measurement model are $\mathbf{\Lambda_x}$ (effects of ξ on x) and $\mathbf{\Theta_x}$, which is the covariance matrix of δ.

For the career aspiration data, you specify the following MATRIX statement for this measurement model:

```
matrix _lambdax_ [1,1] = 0.837 0.894 0.949 0.949 0.894 0.837;
```

Figure 17.48 shows the output related to the specification of the measurement model for x.

Figure 17.48 Career Aspiration Analysis 3: Initial Measurement Model for x

Initial _LAMBDAX_ Matrix

	f_rpa	f_riq	f_rses	f_fses	f_fiq	f_fpa
rpa	0.8370	0	0	0	0	0
riq	0	0.8940	0	0	0	0
rses	0	0	0.9490	0	0	0
fses	0	0	0	0.9490	0	0
fiq	0	0	0	0	0.8940	0
fpa	0	0	0	0	0	0.8370

Initial _THETAX_ Matrix

	rpa	riq	rses	fses	fiq	fpa
rpa	. [_Add01]	0	0	0	0	0
riq	0	. [_Add02]	0	0	0	0
rses	0	0	. [_Add03]	0	0	0
fses	0	0	0	. [_Add04]	0	0
fiq	0	0	0	0	. [_Add05]	0
fpa	0	0	0	0	0	. [_Add06]

NOTE: Parameters with prefix '_Add' are added by PROC CALIS.

In Figure 17.48, the initial _LAMBDAX_ matrix is a 6×6 matrix. The _LAMBDAX_ matrix contains information about the relationships between the row indicator variables x (XVAR= variables) and the column factors ξ (XI= variables). As specified in the MATRIX statement for _LAMBDAX_, the diagonal elements are filled with the fixed values provided. The [1,1] specification in the MATRIX statement for _LAMBDAX_ provides the starting element for the subsequent parameter list to fill in. In this case, the list contains six fixed values, and PROC CALIS proceeds from [1,1] to [2,2], [3,3] and so on until the entire list of parameters is consumed. This kind of notation is a shortcut of the following equivalent specification:

```
matrix _lambdax_ [1,1]=0.837, [2,2]=0.894, [3,3]=0.949,
                 [4,4]=0.949, [5,5]=0.894, [6,6]=0.837;
```

PROC CALIS provides many different kinds of shortcuts in specifying matrix elements. See the MATRIX statement of Chapter 26, "The CALIS Procedure," for details.

At the bottom of Figure 17.48, the initial _THETAX_ matrix is shown. Even though you did not specify any elements of this matrix in any MATRIX statements, the diagonal elements of this matrix are set as default parameters by PROC CALIS. Default parameters added by PROC CALIS are all denoted by names with the prefix '_Add'.

The Structural Model

The last component of the LISMOD specification is the structural model that describes the relationship between η and ξ, as shown in the following equation:

$$\eta = \boldsymbol{\beta}\eta + \boldsymbol{\Gamma}\xi + \zeta$$

In this equation, η is endogenous (dependent) and ξ is exogenous (independent). Variables in η can have effects among themselves. Their effects are specified in the $\boldsymbol{\beta}$ matrix. The effects of ξ on η are specified in the $\boldsymbol{\Gamma}$ matrix. Finally, the error term for the structural relationships is denoted by ζ, which is independent of ξ.

There are four model matrices assumed in the structural model. $\boldsymbol{\beta}$ and $\boldsymbol{\Gamma}$ are matrices for the effects of variables. In addition, matrix $\boldsymbol{\Psi}$ denotes the covariance matrix for the error term ζ, and matrix $\boldsymbol{\Phi}$ denotes the covariance matrix of ξ.

For the career aspiration data, you use the following MATRIX statements for the structural model:

```
matrix _beta_ [2,1],[1,2];
matrix _gamma_ [1,1 to 4], [2,3 to 6];
matrix _psi_ [2,1];
matrix _phi_ [1,1] = 6 * 1.0;
```

In Figure 17.49, initial _BETA_ and _GAMMA_ matrices are shown.

Figure 17.49 Career Aspiration Analysis 3: Initial Structural Equations

Initial _BETA_ Matrix

	R_Amb	F_Amb
R_Amb	0	. [_Parm12]
F_Amb	. [_Parm11]	0

Initial _GAMMA_ Matrix

	f_rpa	f_riq	f_rses	f_fses	f_fiq	f_fpa
R_Amb	. [_Parm03]	. [_Parm04]	. [_Parm05]	. [_Parm06]	0	0
F_Amb	0	0	. [_Parm07]	. [_Parm08]	. [_Parm09]	. [_Parm10]

In Figure 17.49, the _BETA_ matrix contains information about the relationships among the η-variables (ETA= variables). Both the row and column variables of the _BETA_ matrix refer to the list of η-variables. The row variables receive effects from the column variables. You specify two parameters in the _BETA_ matrix: element [2,1] is the effect of R_Amb on F_Amb, and element [2,1] is the effect of F_Amb on R_Amb. Other effects are fixed zeros in this matrix.

The _GAMMA_ matrix contains information about the relationships between the η-variables (ETA= variables) and the ξ-variables (XI= variables). The row variables are the η-variables, which receive effects from the column ξ-variables. You specify eight free parameters in this matrix. These eight parameters represent the eight path coefficients from ξ (the intelligence and environment factors) to the η variables (the ambition factors), as shown in the path diagram in Figure 17.44. A shortcut in the MATRIX statement syntax for the _GAMMA_ matrix has been used. That is, `[1, 1 to 4]` means the [1,1], [1,2], [1,3], and [1,4] elements, and `[2, 3 to 6]` means the [2,3], [2,4], [2,5], and [2,6] elements. All these elements are free parameters in the model and free parameter names are generated for these elements.

Figure 17.50 shows the initial _PSI_ and _PHI_ matrices.

NOTE: Parameters with prefix '_Add' are added by PROC CALIS.

The _PSI_ matrix contains information about the covariances of error terms for the η-variables, which are endogenous in the structural model. There are two η-variables in the model—the two ambition factors R_Amb and F_Amb. You specify the [2,1] element as a free parameter in the MATRIX statement for _PSI_. This means that the error covariance between R_Amb and F_Amb is a free parameter to estimate in the model. In Figure 17.50, both [2,1] and [1,2] elements are named as _Parm15 because _PSI_ is a symmetric matrix. Again, the diagonal elements of this covariance matrix, which are for the error variances of the ambition factors, are default free parameters in PROC CALIS. These parameters are named with the prefix _Add.

Finally, the _PHI_ matrix contains information about the covariances among the exogenous latent factors in the structural model. For the _PHI_ matrix, you fix all the diagonal elements to 1 in the MATRIX statement for _PHI_. This makes the latent variable scales identified. These fixed values are echoed in the output of the initial _PHI_ matrix shown in Figure 17.50. In addition, all covariances among latent exogenous variables are set to be free parameters by default.

Fit Summary of the LISMOD Model for Career Aspiration Analysis 3

Figure 17.51 shows the fit summary of the LISMOD model. All these fit index values match those from using the PATH model specification of the same model, as shown in Figure 17.45. Therefore, you are confident that the current LISMOD model specification is equivalent to the PATH model specification shown in the section "Career Aspiration: Analysis 3" on page 342.

Figure 17.51 Career Aspiration Analysis 3: Fit Summary of the LISMOD Model

Fit Summary

Chi-Square	12.0132
Chi-Square DF	13
Pr > Chi-Square	0.5266
Standardized RMSR (SRMSR)	0.0149
Adjusted GFI (AGFI)	0.9692
RMSEA Estimate	0.0000
Akaike Information Criterion	96.0132
Schwarz Bayesian Criterion	255.4476
Bentler Comparative Fit Index	1.0000

Estimation results are shown in Figure 17.52, Figure 17.53, and Figure 17.54, respectively for the measurement model for y, measurement model for x, and the structural model. These are the same estimation results as those from the equivalent PATH model specification in Figure 17.46. However, estimates in the LISMOD model are now arranged in the matrix form, with standard error estimates and t values shown.

Some Important PROC CALIS Features

In this section, some of the main features of PROC CALIS are introduced. Emphasis is placed on showing how these features are useful in practical structural equation modeling.

Modeling Languages for Specifying Models

PROC CALIS provides several modeling languages to specify a model. Different modeling languages in PROC CALIS are signified by the main model specification statement used. In this chapter, you have seen examples of the FACTOR, LINEQS, LISMOD, MSTRUCT, PATH, and RAM modeling languages. Depending on your modeling philosophy and the type of the model, you can choose a modeling language that is most suitable for your application. For example, models specified using structural equations can be transcribed directly into the LINEQS statement. Models that are hypothesized using path diagrams can be

described easily in the PATH or RAM statement. First-order confirmatory or exploratory factor models are most conveniently specified by using the FACTOR and MATRIX statements. Traditional LISREL models are supported through the LISMOD and MATRIX statements. Finally, patterned covariance and mean models can be specified directly by the MSTRUCT and MATRIX statements, or by the COVPATTERN= and MEANPATTERN= options.

For most applications in structural equation modeling, the PATH and LINEQS statements are the easiest to use. For testing the built-in covariance and mean patterns of PROC CALIS, the use of the COVPATTERN= and the MEANPATTERN= options are the most efficient. In other cases, the FACTOR, LISMOD, MSTRUCT, or RAM statement might be more suitable. For very general matrix model specifications, you can use the COSAN modeling language. See the COSAN statement and the section "The COSAN Model" on page 1193 of Chapter 26, "The CALIS Procedure," for details about the COSAN modeling language. See also the section "Which Modeling Language?" on page 1012 in Chapter 26, "The CALIS Procedure," for a more detailed discussion about the use of different modeling languages.

Estimation Methods

The CALIS procedure provides six methods of estimation specified by the METHOD= option:

DWLS	diagonally weighted least squares
FIML	full-information maximum likelihood
GLS	normal theory generalized least squares
ML	maximum likelihood for multivariate normal distributions
ULS	unweighted least squares
WLS	weighted least squares for arbitrary distributions

Each estimation method is based on finding parameter estimates that minimize a discrepancy (badness-of-fit) function, which measures the difference between the observed sample covariance matrix and the fitted (predicted) covariance matrix, given the model and the parameter estimates. The difference between the observed sample mean vector and the fitted (predicted) mean vector is also taken into account when the mean structures are modeled. See the section "Estimation Criteria" on page 1246 in Chapter 26, "The CALIS Procedure," for formulas, or refer to Loehlin (1987, pp. 54–62) and Bollen (1989, pp. 104–123) for further discussion.

The default estimation is METHOD=ML, which is the most popular method for applications. The option METHOD=GLS usually produces very similar results to those produced by METHOD=ML. If your data contain random missing values and it is important to use the information from those incomplete observations, you might want to use the FIML method, which provides a sound treatment of missing values in data. METHOD=ML and METHOD=FIML are essentially the same method when you do not have missing values (see Example 26.15 of Chapter 26, "The CALIS Procedure,"). Asymptotically, ML and GLS are the same. Both methods assume a multivariate normal distribution in the population. The WLS method with the default weight matrix is equivalent to the asymptotically distribution free (ADF) method, which yields asymptotically normal estimates regardless of the distribution in the population. When the multivariate normal assumption is in doubt, especially if the variables have high kurtosis, you should seriously consider the WLS method. When a correlation matrix is analyzed, only WLS can produce correct standard error estimates. However, in order to use the WLS method with the expected statistical properties, the sample size must be large. Several thousand might be a minimum requirement.

The ULS and DWLS methods yield reasonable estimates under less restrictive assumptions. You can apply these methods to normal or nonnormal situations or to covariance or correlation matrices. The drawback is that the statistical qualities of the estimates seem to be unknown. For this reason, PROC CALIS does not provide standard errors or test statistics with these two methods.

You cannot use METHOD=ML or METHOD=GLS if the observed covariance matrix is singular. You can either remove variables involved in the linear dependencies or use less restrictive estimation methods such as ULS. Specifying METHOD=ML assumes that the predicted covariance matrix is nonsingular. If ML fails because of a singular predicted covariance matrix, you need to examine whether the model specification leads to the singularity. If so, modify the model specification to eliminate the problem. If not, you probably need to use other estimation methods.

You should remove outliers and try to transform variables that are skewed or heavy-tailed. This applies to all estimation methods, since all the estimation methods depend on the sample covariance matrix, and the sample covariance matrix is a poor estimator for distributions with high kurtosis (Bollen 1989, pp. 415–418; Huber 1981; Hampel et al. 1986). PROC CALIS displays estimates of univariate and multivariate kurtosis (Bollen 1989, pp. 418–425) if you specify the KURTOSIS option in the PROC CALIS statement.

See the section "Estimation Methods" on page 361 for the general use of these methods. See the section "Estimation Criteria" on page 1246 of Chapter 26, "The CALIS Procedure," for details about these estimation criteria.

Statistical Inference

When you specify the ML, FIML, GLS, or WLS estimation with appropriate models, PROC CALIS can compute the following:

- a chi-square goodness-of-fit test of the specified model versus the alternative that the data are from a population with unconstrained covariance matrix (Loehlin 1987, pp. 62–64; Bollen 1989, pp. 110, 115, 263–269)
- approximate standard errors of the parameter estimates (Bollen 1989, pp. 109, 114, 286), displayed with the STDERR option
- various modification indices, requested via the MODIFICATION or MOD option, that give the approximate change in the chi-square statistic that would result from removing constraints on the parameters or constraining additional parameters to zero (Bollen 1989, pp. 293–303)

If you have two models such that one model results from imposing constraints on the parameters of the other, you can test the constrained model against the more general model by fitting both models with PROC CALIS. If the constrained model is correct, the difference between the chi-square goodness of fit statistics for the two models has an approximate chi-square distribution with degrees of freedom equal to the difference between the degrees of freedom for the two models (Loehlin 1987, pp. 62–67; Bollen 1989, pp. 291–292).

All of the test statistics and standard errors computed under ML and GLS depend on the assumption of multivariate normality. Normality is a much more important requirement for data with random independent variables than it is for fixed independent variables. If the independent variables are random, distributions with high kurtosis tend to give liberal tests and excessively small standard errors, while low kurtosis tends to produce the opposite effects (Bollen 1989, pp. 266–267, 415–432).

All test statistics and standard errors computed by PROC CALIS are based on asymptotic theory and should not be trusted in small samples. There are no firm guidelines on how large a sample must be for the asymptotic theory to apply with reasonable accuracy. Some simulation studies have indicated that problems are likely to occur with sample sizes less than 100 (Loehlin 1987, pp. 60–61; Bollen 1989, pp. 267–268). Extrapolating from experience with multiple regression would suggest that the sample size should be at least 5 to 20 times the number of parameters to be estimated in order to get reliable and interpretable results. The WLS method might even require that the sample size be over several thousand.

The asymptotic theory requires the parameter estimates to be in the interior of the parameter space. If you do an analysis with inequality constraints and one or more constraints are active at the solution (for example, if you constrain a variance to be nonnegative and the estimate turns out to be zero), the chi-square test and standard errors might not provide good approximations to the actual sampling distributions.

For modeling correlation structures, the only theoretically correct method is the WLS method with the default ASYCOV=CORR option. For other methods, standard error estimates for modeling correlation structures might be inaccurate even for sample sizes as large as 400. The chi-square statistic is generally the same regardless of which matrix is analyzed, provided that the model involves no scale-dependent constraints. However, if the purpose is to obtain reasonable parameter estimates for the correlation structures only, then you might also find other estimation methods useful.

If you fit a model to a correlation matrix and the model constrains one or more elements of the predicted matrix to equal 1.0, the degrees of freedom of the chi-square statistic must be reduced by the number of such constraints. PROC CALIS attempts to determine which diagonal elements of the predicted correlation matrix are constrained to a constant, but it might fail to detect such constraints in complicated models, particularly when programming statements are used. If this happens, you should add parameters to the model to release the constraints on the diagonal elements.

Multiple-Group Analysis

PROC CALIS supports multiple-group multiple-model analysis. You can fit the same covariance (and mean) structure model to several independent groups (data sets). Or, you can fit several different but constrained models to the independent groups (data sets). In PROC CALIS, you can use the GROUP statements to define several independent groups and the MODEL statements to define several different models. For example, the following statements show a multiple-group analysis by PROC CALIS:

```
proc calis;
   group 1 / data=set1;
   group 2 / data=set2;
   group 3 / data=set3;
   model 1 / group=1,2;
      path
         y <--- x   = beta ,
         x <--- z   = gamma;
   model 2 / group=3;
      path
         y <--- x   = beta,
         x <--- z   = alpha;
run;
```

In this specification, you conduct a three-group analysis. You define two PATH models. You fit Model 1 to Groups 1 and 2 and Model 2 to Group 3. The two models are constrained for the y<---x path because they use the same path coefficient parameter beta. Other parameters in the models are not constrained.

To facilitate model specification by model referencing, you can use the REFMODEL statement to specify models based on model referencing. For example, the previous example can be specified equivalently as the following statements:

```
proc calis;
   group 1 / data=set1;
   group 2 / data=set2;
   group 3 / data=set3;
   model 1 / group=1,2;
      path
         y <--- x   = beta ,
         x <--- z   = gamma;
   model 2 / group=3;
      refmodel 1;
      renameparm gamma=alpha;
run;
```

The current specification differs from the preceding specification in the definition of Model 2. In the current specification, Model 2 is making reference to Model 1. Basically, this means that the *explicit* specification in Model 1 is transferred to Model 2. However, the RENAMEPARM statement requests a name change for gamma, which becomes a new parameter named alpha in Model 2. Hence, Model 2 and Model 1 are not the same. They are constrained by the same path coefficient beta for the y<---x path, but they have different path coefficients for the x<---z path.

Model referencing by the REFMODEL statement offers you an efficient and concise way to define models based on the similarities and differences between models. The advantages become more obvious when you have several large models in multiple-group analysis and each model differs just a little bit from each other.

Goodness-of-Fit Statistics

In addition to the chi-square test, there are many other statistics for assessing the goodness of fit of the predicted correlation or covariance matrix to the observed matrix.

Akaike's information criterion (AIC, Akaike 1987) and Schwarz's Bayesian criterion (SBC, Schwarz 1978) are useful for comparing models with different numbers of parameters—the model with the smallest value of AIC or SBC is considered best. Based on both theoretical considerations and various simulation studies, SBC seems to work better, since AIC tends to select models with too many parameters when the sample size is large.

There are many descriptive measures of goodness of fit that are scaled to range approximately from zero to one: the goodness-of-fit index (GFI) and GFI adjusted for degrees of freedom (AGFI) (Jöreskog and Sörbom 1988), centrality (McDonald 1989), and the parsimonious fit index (James, Mulaik, and Brett 1982). Bentler and Bonett (1980) and Bollen (1986) have proposed measures for comparing the goodness of fit of one model with another in a descriptive rather than inferential sense.

The root mean squared error approximation (RMSEA) proposed by Steiger and Lind (1980) does not assume a true model being fitted to the data. It measures the discrepancy between the fitted model and the covariance matrix in the population. For samples, RMSEA and confidence intervals can be estimated. Statistical tests for determining whether the population RMSEAs fall below certain specified values are available (Browne and Cudeck 1993). In the same vein, Browne and Cudeck (1993) propose the expected cross validation index (ECVI), which measures how good a model is for predicting future sample covariances. Point estimate and confidence intervals for ECVI are also developed.

None of these measures of goodness of fit are related to the goodness of prediction of the structural equations. Goodness of fit is assessed by comparing the observed correlation or covariance and mean matrices with the matrices computed from the model and parameter estimates. Goodness of prediction is assessed by comparing the actual values of the endogenous variables with their predicted values, usually in terms of root mean squared error or proportion of variance accounted for (R square). For latent endogenous variables, root mean squared error and R square can be estimated from the fitted model.

Customizable Fit Summary Table

Because there are so many fit indices that PROC CALIS can display and researchers prefer certain sets of fit indices, PROC CALIS enables you to customize the set of fit indices to display. For example, you can use the following statement to limit the set of fit indices to display:

```
fitindex on(only) = [chisq SRMSR RMSEA AIC];
```

With this statement, only the model-fit chi-square, standardized root mean square residual, root mean square error of approximation, and Akaiki's information criterion are displayed in your output. You can also save all your fit index values in an output data file by adding the OUTFIT= option in the FITINDEX statement. This output data file contains all available fit index values even if you have limited the set of fit indices to display in the listing output.

Standardized Solution

In many applications in social and behavioral sciences, measurement scales of variables are arbitrary. Although it should not be viewed as a universal solution, some researchers resort to the standardized solution for interpreting estimation results. PROC CALIS computes the standardized solutions for all models (except for COSAN) automatically. Standard error estimates are also produced for standardized solutions so that you can examine the statistical significance of the standardized estimates too.

However, equality or linear constraints on parameters are almost always set on the unstandardized variables. These parameter constraints are not preserved when the estimation solution is standardized. This would add difficulties in interpreting standardized estimates when your model is defined meaningfully with constraints on the unstandardized variables.

A general recommendation is to make sure your variables are measured on "comparable" scales (it does not necessarily mean that they are mean- and variance-standardized) for the analysis. But what makes different kinds of variables "comparable" is an ongoing philosophical issue.

Some researchers might totally abandon the concept of standardized solutions in structural equation modeling. If you prefer to turn off the standardized solutions in PROC CALIS, you can use the NOSTAND option in the PROC CALIS statement.

Testing Parametric Functions

Oftentimes, researchers might have a priori hypotheses about the parameters in their models. After knowing the model fit is satisfactory, they want to test those hypotheses under the model. PROC CALIS provides two statements for testing these kinds of hypotheses. The TESTFUNC statement enables you to test each parametric function separately, and the SIMTESTS statement enables you to test parametric functions jointly (and separately). For example, assuming that effect1, effect2, effect3, and effect4 are parameters in your model, the following SIMTESTS statement tests the joint hypothesis test1, which consists of two component hypotheses diff_effect and sum_effect:

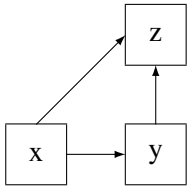
```
SIMTESTS  test1 = (diff_effect sum_ffect);
diff_effect = effect1 - effect2;
sum_effect  = effect3 + effect4;
```

To make test1 well-defined, each of the component hypotheses diff_effect and sum_effect is assumed to be defined as a parametric function by some SAS programming statements. In the specification, diff_effect represents the difference between effect1 and effect2, and sum_effect represents the sum of effect3 and effect4. Hence, the component hypotheses being tested are:

$$H_1: \quad \text{diff\_effect} = \text{effect1} - \text{effect2} = 0$$
$$H_2: \quad \text{sum\_effect} = \text{effect3} + \text{effect4} = 0$$

Effect Analysis

In structural equation modeling, effects from one variable to other variables can be direct or indirect. For example, in the following path diagram x has a direct effect on z in addition to an indirect effect on z via y:



However, y has only a direct effect (but no indirect effect) on z. In cases like this, researchers are interested in computing the total, direct, and indirect effects from x and y to z. You can use the EFFPART option in the PROC CALIS statement to request this kind of effect partitioning in your model. Total, direct, and indirect effects are displayed, together with their standard error estimates. If your output contains standardized results (default), the standardized total, direct, and indirect effects and their standard error estimates are also displayed. With the EFFPART option, effects analysis is applied to all variables (excluding error terms) in your model.

In large models with many variables, researchers might want to analyze the effects only for a handful of variables. In this regard, PROC CALIS provides you a way to do a customized version of effect analysis. For example, the following EFFPART statement requests the effect partitioning of x1 and x2 on y1 and y2, even though there might be many more variables in the model:

```
effpart   x1 x2 ---> y1 y2;
```

See the EFFPART statement of Chapter 26, "The CALIS Procedure," for details.

Model Modifications

When you fit a model and the model fit is not satisfactory, you might want to know what you could do to improve the model. The LM (Lagrange multiplier) tests in PROC CALIS can help you improve the model fit by testing the potential free parameters in the model. To request the LM tests, you can use the MODIFICATION option in the PROC CALIS statement.

The LM test results contain lists of parameters, organized according to their types. In each list, the potential parameter with the greatest model improvement is shown first. Adding these new parameters improves the model fit approximately by the amount of the corresponding LM statistic.

Sometimes, researchers might have a target set of parameters they want to test in the LM tests. PROC CALIS offers a flexible way that you can customize the set the parameters for the LM tests. See the LMTESTS statement for details.

In addition, the Wald statistics produced by PROC CALIS suggest whether any parameters in your model can be dropped (or fixed to zero) without significantly affecting the model fit. You can request the Wald statistics with the MODIFICATION option in the PROC CALIS statement.

Optimization Methods

PROC CALIS uses a variety of nonlinear optimization algorithms for computing parameter estimates. These algorithms are very complicated and do not always work for every data set. PROC CALIS generally informs you when the computations fail, usually by displaying an error message about the iteration limit being exceeded. When this happens, you might be able to correct the problem simply by increasing the iteration limit (MAXITER= and MAXFUNC=). However, it is often more effective to change the optimization method (OMETHOD=) or initial values. For more details, see the section "Use of Optimization Techniques" on page 1283 in Chapter 26, "The CALIS Procedure," and refer to Bollen (1989, pp. 254–256).

PROC CALIS might sometimes converge to a local optimum rather than the global optimum. To gain some protection against local optima, you can run the analysis several times with different initial estimates. The RANDOM= option in the PROC CALIS statement is useful for generating a variety of initial estimates.

Other Commonly Used Options

Other commonly used options in the PROC CALIS statement include the following:

- INMODEL= to input model specification from a data set, usually created by the OUTMODEL= option
- MEANSTR to analyze the mean structures
- NOBS to specify the number of observations
- NOPARMNAME to suppress the printing of parameter names
- NOSE to suppress the display of approximate standard errors
- OUTMODEL= to output model specification and estimation results to an external file for later use (for example, fitting the same model to other data sets)
- RESIDUAL to display residual correlations or covariances

Comparison of the CALIS and FACTOR Procedures for Exploratory Factor Analysis

Both the CALIS and the FACTOR procedures can fit exploratory factor models. However, there are several notable differences:

- By default, PROC FACTOR analyzes the correlation matrix, while PROC CALIS analyzes the covariance matrix.

- PROC FACTOR and PROC CALIS use different parameterizations in the initial factor solution. PROC CALIS uses a lower triangle pattern on the factor loading matrix (a confirmatory factor pattern) in the initial unrotated solution, while PROC FACTOR use certain matrix constraints in the initial unrotated solution. All other things being equal, PROC CALIS and PROC FACTOR might give the same solution after the same factor rotation.
- Because of the way it parameterizes, PROC FACTOR is usually more efficient computationally. PROC CALIS uses a more general algorithm that might not be computationally optimal for exploratory factor analysis.

Comparison of the CALIS and SYSLIN Procedures

The SYSLIN procedure in SAS/ETS software can fit certain kinds of path models and linear structural equation models. PROC CALIS differs from PROC SYSLIN in that PROC CALIS is more general in the use of latent variables in the models. Latent variables are unobserved, hypothetical variables, as distinct from manifest variables, which are the observed data. PROC SYSLIN allows at most one latent variable, the error term, in each equation. PROC CALIS allows several latent variables to appear in an equation—in fact, all the variables in an equation can be latent as long as there are other equations that relate the latent variables to manifest variables.

Both the CALIS and SYSLIN procedures enable you to specify a model as a system of linear equations. When there are several equations, a given variable might be a dependent variable in one equation and an independent variable in other equations. Therefore, additional terminology is needed to describe unambiguously the roles of variables in the system. Variables with values that are determined jointly and simultaneously by the system of equations are called *endogenous variables*. Variables with values that are determined outside the system—that is, in a manner separate from the process described by the system of equations—are called exogenous variables. The purpose of the system of equations is to explain the variation of each endogenous variable in terms of exogenous variables or other endogenous variables or both. Refer to Loehlin (1987, p. 4) for further discussion of endogenous and exogenous variables. In the econometric literature, error and disturbance terms are usually distinguished from exogenous variables, but in systems with more than one latent variable in an equation, the distinction is not always clear.

In PROC SYSLIN, endogenous variables are identified by the ENDOGENOUS statement. In PROC CALIS, endogenous variables are identified by the procedure automatically after you specify the model. With different modeling languages, the identification of endogenous variables by PROC CALIS is done by different sets of rules. For example, when you specify structural equations by using the LINEQS modeling language in PROC CALIS, endogenous variables are assumed to be those that appear on the left-hand sides of the equations; a given variable can appear on the left-hand side of at most one equation. When you specify your model by using the PATH modeling language in PROC CALIS, endogenous variables are those variables pointed to by arrows at least once in the path specifications.

PROC SYSLIN provides many methods of estimation, some of which are applicable only in special cases. For example, ordinary least squares estimates are suitable in certain kinds of systems but might be statistically biased and inconsistent in other kinds. PROC CALIS provides three major methods of estimation that can be used with most models. Both the CALIS and SYSLIN procedures can do maximum likelihood estimation, which PROC CALIS calls ML and PROC SYSLIN calls FIML. PROC SYSLIN can be much faster

than PROC CALIS in those special cases for which it provides computationally efficient estimation methods. However, PROC CALIS has a variety of sophisticated algorithms for maximum likelihood estimation that might be much faster than FIML in PROC SYSLIN.

PROC CALIS can impose a wider variety of constraints on the parameters, including nonlinear constraints, than can PROC SYSLIN. For example, PROC CALIS can constrain error variances or covariances to equal specified constants, or it can constrain two error variances to have a specified ratio.

Chapter 18

Introduction to Power and Sample Size Analysis

Contents

Overview

Power and sample size analysis optimizes the resource usage and design of a study, improving chances of conclusive results with maximum efficiency. The standard statistical testing paradigm implicitly assumes that Type I errors (mistakenly concluding significance when there is no true effect) are more costly than Type II errors (missing a truly significant result). This may be appropriate for your situation, or the relative costs of the two types of error may be reversed. For example, in screening experiments for drug development, it is often less damaging to carry a few false positives forward for follow-up testing than to miss potential leads. Power and sample size analysis can help you achieve your desired balance between Type I and Type II errors. With optimal designs and sample sizes, you can improve your chances of detecting effects that might otherwise have been ignored, save money and time, and perhaps minimize risks to subjects.

Relevant tools in SAS/STAT software for power and sample size analysis include the following:

- the GLMPOWER procedure
- the POWER procedure
- the Power and Sample Size application
- the %POWTABLE macro
- various procedures, statements, and functions in Base SAS and SAS/STAT for developing customized formulas and simulations

These tools, discussed in detail in the section "SAS/STAT Tools for Power and Sample Size Analysis" on page 379, deal exclusively with *prospective* analysis—that is, planning for a future study. This is in contrast to *retrospective* analysis for a past study, which is not supported by the main tools. Although retrospective analysis is more convenient to perform, it is often uninformative or misleading, especially when power is computed directly based on observed data.

The goals of prospective power and sample size analysis include the following:

- determining the sample size required to get a significant result with adequate probability (power)
- characterizing the power of a study to detect a meaningful effect
- computing the probability of achieving the desired precision of a confidence interval, or the sample size required to ensure this probability
- conducting what-if analyses to assess how sensitive the power or required sample size is to other factors

The phrase *power analysis* is used for the remainder of this document as a shorthand to represent any or all of these goals. For more information about the GLMPOWER procedure, see Chapter 43, "The GLMPOWER Procedure." For more information about the POWER procedure, see Chapter 70, "The POWER Procedure." For more information about the Power and Sample Size application, see Chapter 71, "The Power and Sample Size Application."

Coverage of Statistical Analyses

The GLMPOWER procedure covers power analysis for Type III tests and contrasts of fixed effects in univariate linear models, optionally with covariates. The covariates can be continuous or categorical. Tests and contrasts involving random effects are not supported.

The POWER procedure covers power analysis for the following:

- t tests, equivalence tests, and confidence intervals for means
- tests, equivalence tests, and confidence intervals for binomial proportions

- multiple regression
- tests of correlation and partial correlation
- one-way analysis of variance
- rank tests for comparing two survival curves
- logistic regression with binary response
- Wilcoxon Mann-Whitney rank-sum test

The Power and Sample Size application covers a large subset of the analyses in the GLMPOWER and POWER procedures.

Statistical Background

Hypothesis Testing, Power, and Confidence Interval Precision

Standard Hypothesis Tests

In statistical hypothesis testing, you typically express the belief that some effect exists in a population by specifying an alternative hypothesis H_1. You state a null hypothesis H_0 as the assertion that the effect does *not* exist and attempt to gather evidence to reject H_0 in favor of H_1. Evidence is gathered in the form of sample data, and a statistical test is used to assess H_0. If H_0 is rejected but there really is *no* effect, this is called a *Type I error*. The probability of a Type I error is usually designated "alpha" or α, and statistical tests are designed to ensure that α is suitably small (for example, less than 0.05).

If there is an effect in the population but H_0 is *not* rejected in the statistical test, then a *Type II error* has been committed. The probability of a Type II error is usually designated "beta" or β. The probability $1 - \beta$ of avoiding a Type II error (that is, correctly rejecting H_0 and achieving statistical significance) is called the *power* of the test.

Most, but not all, of the power analyses in the GLMPOWER and POWER procedures are based on such standard hypothesis tests.

Equivalence and Noninferiority

Whereas the standard two-sided hypothesis test for a parameter μ (such as a mean difference) aims to demonstrate that it is significantly different than a null value μ_0:

$$H_0{:}\mu = \mu_0$$
$$H_1{:}\mu \neq \mu_0$$

an equivalence test instead aims to demonstrate that it is *significantly similar* to some value, expressed in terms of a range θ_L, θ_U around that value:

$$H_0{:}\mu < \theta_L \quad \text{or} \quad \mu > \theta_U$$
$$H_1{:}\theta_L \leq \mu \leq \theta_U$$

Whereas the standard one-sided hypothesis test for μ (say, the upper one-sided test) aims to demonstrate that it is significantly greater than μ_0:

$$H_0{:}\mu \leq \mu_0$$
$$H_1{:}\mu > \mu_0$$

a corresponding noninferiority test aims to demonstrate that it is *not significantly less* than μ_0, expressed in terms of a margin $\delta > 0$:

$$H_0{:}\mu \leq \mu_0 - \delta$$
$$H_1{:}\mu > \mu_0 - \delta$$

Corresponding forms of these hypotheses with the inequalities reversed apply to lower one-sided noninferiority tests (sometimes called *nonsuperiority* tests).

The POWER procedure performs power analyses for equivalence tests for one-sample, paired, and two-sample tests of normal and lognormal mean differences and ratios. It also supports noninferiority tests for a variety of analyses of means, proportions, and correlation, both directly (with a MARGIN= option representing δ) and indirectly (with an option for a custom null value representing the sum or difference of μ_0 and δ).

Confidence Interval Precision

An analysis of confidence interval precision is analogous to a traditional power analysis, with *CI Half-Width* taking the place of effect size and *Prob(Width)* taking the place of power. The *CI Half-Width* is the margin of error associated with the confidence interval, the distance between the point estimate and an endpoint. The *Prob(Width)* is the probability of obtaining a confidence interval with *at most* a target half-width.

The POWER procedure performs confidence interval precision analyses for *t*-based confidence intervals for one-sample, paired, and two-sample designs, and for several varieties of confidence intervals for a binomial proportion.

Computing Power and Sample Size

For some statistical models and tests, power analysis calculations are exact—that is, they are based on a mathematically accurate formula that expresses power in terms of the other components. Such formulas typically involve either enumeration or noncentral versions of the distribution of the test statistic.

When a power computation is based on a noncentral t, F, or chi-square distribution, the noncentrality parameter generally has the same form as the test statistic, with the conjectured population parameters in place of their corresponding estimators.

For example, the test statistic for a two-sample t test is computed as follows:

$$t = N^{\frac{1}{2}}(w_1 w_2)^{\frac{1}{2}}\left(\frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{s_p}\right)$$

where N is the total sample size, w_1 and w_2 are the group allocation weights, $\bar{x}_1$ and $\bar{x}_2$ are the sample means, μ_0 is the null mean difference, and s_p is the pooled standard deviation. Under the null hypothesis, the statistic $F = t^2$ is distributed as $F(1, N-2)$. In general, F has a noncentral F distribution $F(1, N-2, \delta^2)$ where

$$\delta = N^{\frac{1}{2}}(w_1 w_2)^{\frac{1}{2}}\left(\frac{\mu_{\text{diff}} - \mu_0}{\sigma}\right)$$

and μ_{diff} and σ are the (unknown) true mean difference and common group standard deviation, respectively. Note that the square-root noncentrality δ is exactly the same as the t statistic except that the estimators of mean difference and standard deviation are replaced by their correponding true population values.

The power for the two-sided two-sample t test with significance level α is computed as

$$P\left(F \geq F_{1-\alpha}(1, N-2)\right)$$

where F is distributed as $F(1, N-2, \delta^2)$ and $F_{1-\alpha}(1, N-2)$ is the $100(1-\alpha)\%$ quantile of the central F distribution with 1 and $N-2$ degrees of freedom. See the section "Customized Power Formulas (DATA Step)" on page 388 for an example of the implementation of this formula in the DATA step.

In the absence of exact mathematical results, approximate formulas can sometimes be used. When neither exact power computations nor reasonable approximations are possible, simulation provides an increasingly viable alternative. You specify values for model parameters and use them to randomly generate a large number of hypothetical data sets. Applying the statistical test to each data set, you estimate power with the percentage of times the null hypothesis is rejected. While the simulation approach is computationally intensive, faster computing makes this less of an issue. A simulation-based power analysis is always a valid option, and, with a large number of data set replications, it can often be more accurate than approximations. See the section "Empirical Power Simulation (DATA Step, SAS/STAT Software)" on page 389 for an example of an empirical power simulation.

Sample size is usually computed by iterative numerical methods because it often cannot be expressed in closed form as a function of the other parameters. Sample size tends to appear in both a noncentrality parameter and a degrees of freedom term for the critical value.

Power and Study Planning

Power analysis is most effective when performed at the study planning stage, and as such it encourages early collaboration between researcher and statistician. It also focuses attention on effect sizes and variability in the underlying scientific process, concepts that both researcher and statistician should consider carefully at this stage.

There are many factors involved in a power analysis, such as the research objective, design, data analysis method, power, sample size, Type I error, variability, and effect size. By performing a power analysis, you can learn about the relationships between these factors, optimizing those that are under your control and exploring the implications of those that are fixed or unknown.

Components of Study Planning

Even when the research questions and study design seem straightforward, the ensuing power analysis can seem technically daunting. It is often helpful to break the process down into five components:

- **Study Design**: What is the structure of the planned design? This must be clearly and completely specified. What groups and treatments ("cells" and "factors" of the design) are going to be assessed, and what will be the relative sizes of those cells? How is each case going to be studied—that is, what is the primary outcome measure ("dependent variable")? Will covariates be measured and included in the statistical model?
- **Scenario Model**: What are your beliefs about patterns in the data? Imagine that you had unlimited time and resources to execute the study design, so that you could gather an "infinite data set." Characterize that infinite data set as best you can using a mathematical model, realizing that it will be a simplification of reality. Alternatively, as is common with complex linear models, you may decide to construct an "exemplary" data set that mimics the infinite data set. However you do this, your scenario model should capture the key features of the study design and the main relationships among the primary outcome variables and study factors.
- **Effects and Variability**: What exactly are the "signals and noises" in the patterns you suspect? Set specific values for the parameters of your scenario model, keeping at most one unspecified. It is often enlightening to consider a variety of realistic possibilities for the key values by performing a sensitivity analysis, to explore the consequences of competing views on what the infinite data set might look like.
- **Statistical Method**: How will you cast your model in statistical terms and conduct the eventual data analysis? Define the statistical models and procedures that will be used to embody the study design and estimate and/or test the effects central to the research question. What significance levels will be used? Will one- or two-sided tests be used?
- **Aim of Assessment**: Finally, what needs to be determined in the power analysis? Most often you want to examine the statistical powers obtained across the various scenarios for the effects, variability, alternative varieties of the statistical procedures to be used, and the feasible total sample sizes. Sometimes the goal is to find sample size values that provide given levels of power, say 85%, 90%, or 95%.

Effect Size

There is some confusion in practice about how to postulate the effect size. One alternative is to specify the effect size that represents minimal clinical significance; then the result of the power analysis reveals the chances of detecting a minimally meaningful effect size. Often this minimal effect size is so small that it requires excessive resources to detect. Another alternative is to make an educated guess of the true underlying effect size. Then the power analysis determines the chance of detecting the effect size that is believed to be true. The choice is ultimately determined by the research goals. Finally, you can specify a

collection of possible values, perhaps spanning the range between minimally meaningful effects and larger surmised effects.

You can arrive at values for required quantities in a power analysis, such as effect sizes and measures of variability, in many different ways. For example, you can use pilot data, results of previous studies reported in literature, educated guesses derived from theory, or educated guesses derived from partial data (a small sample or even just quantiles).

Uncertainty and Sensitivity Analysis

Uncertainty is a fact of life in any power analysis, because at least some of the numbers used are best guesses of unknown values. The result of a power calculation, whether it be achieved power or required sample size or something else, serves only as a point estimate, conditional on the conjectured values of the other components. It is not feasible in general to quantify the variability involved in using educated guesses or undocumented results to specify these components. If observed data are used, relevant adjustments for variability in the data tend to be problematic in the sense of producing confidence intervals for power that are too wide for practical use. But there is a useful way for you to characterize the uncertainty in your power analysis, and also discover the extent to which statistical power is affected by each component. You can posit a reasonable range for each input component, vary each one within its range, and observe the variety of results in the form of tables or graphs.

SAS/STAT Tools for Power and Sample Size Analysis

This section demonstrates how you can use the different SAS power analysis tools mentioned in the section "Overview" on page 373 to generate graphs, tables, and narratives; implement your own power formulas; and simulate empirical power.

Suppose you want to compute the power of a two-sample *t* test. You conjecture that the mean difference is between 5 and 6 and that the common group standard deviation is between 12 and 18. You plan to use a significance level between 0.05 and 0.1 and a sample size between 100 and 200. The following SAS statements use the POWER procedure to compute the power for these scenarios:

```
proc power;
   twosamplemeans test=diff
      meandiff = 5 6
      stddev = 12 18
      alpha = 0.05 0.1
      ntotal = 100 200
      power = .;
run;
```

Figure 18.1 shows the results. Depending on the plausibility of the various combinations of input parameter values, the power ranges between 0.379 and 0.970.

Figure 18.1 PROC POWER Tabular Output

The POWER Procedure
Two-Sample t Test for Mean Difference

Computed Power

Index	Alpha	Mean Diff	Std Dev	N Total	Power
1	0.05	5	12	100	0.541
2	0.05	5	12	200	0.834
3	0.05	5	18	100	0.280
4	0.05	5	18	200	0.498
5	0.05	6	12	100	0.697
6	0.05	6	12	200	0.940
7	0.05	6	18	100	0.379
8	0.05	6	18	200	0.650
9	0.10	5	12	100	0.664
10	0.10	5	12	200	0.902
11	0.10	5	18	100	0.397
12	0.10	5	18	200	0.623
13	0.10	6	12	100	0.799
14	0.10	6	12	200	0.970
15	0.10	6	18	100	0.505
16	0.10	6	18	200	0.759

The following seven sections illustrate additional ways of displaying these results using the different SAS tools.

Basic Graphs (POWER, GLMPOWER, Power and Sample Size Application)

If you include a PLOT statement, the GLMPOWER and POWER procedures produce standard power curves, which represent any multivalued input parameters with varying line styles, symbols, colors, and/or panels. The Power and Sample Size application also has an option to produce power curves. If ODS Graphics is enabled, then graphs are created using ODS Graphics; otherwise, traditional graphs are produced.

To display default power curves for the preceding PROC POWER call, add the PLOT statement with no arguments as follows:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power plotonly;
   twosamplemeans test=diff
      meandiff = 5 6
      stddev = 12 18
      alpha = 0.05 0.1
      ntotal = 100 200
      power = .;
   plot;
run;

ods graphics off;
```

The ODS GRAPHICS ON statement enables ODS Graphics. The ODS LISTING STYLE=HTMLBLUECML statement specifies the HTMLBLUECML style, which is suitable for use with PROC POWER because it allows both marker symbols and line styles to vary.

Figure 18.2 shows the results. Note that the line style varies by the significance level α, the symbol varies by the mean difference, and the panel varies by standard deviation.

Figure 18.2 PROC POWER Default Graphical Output

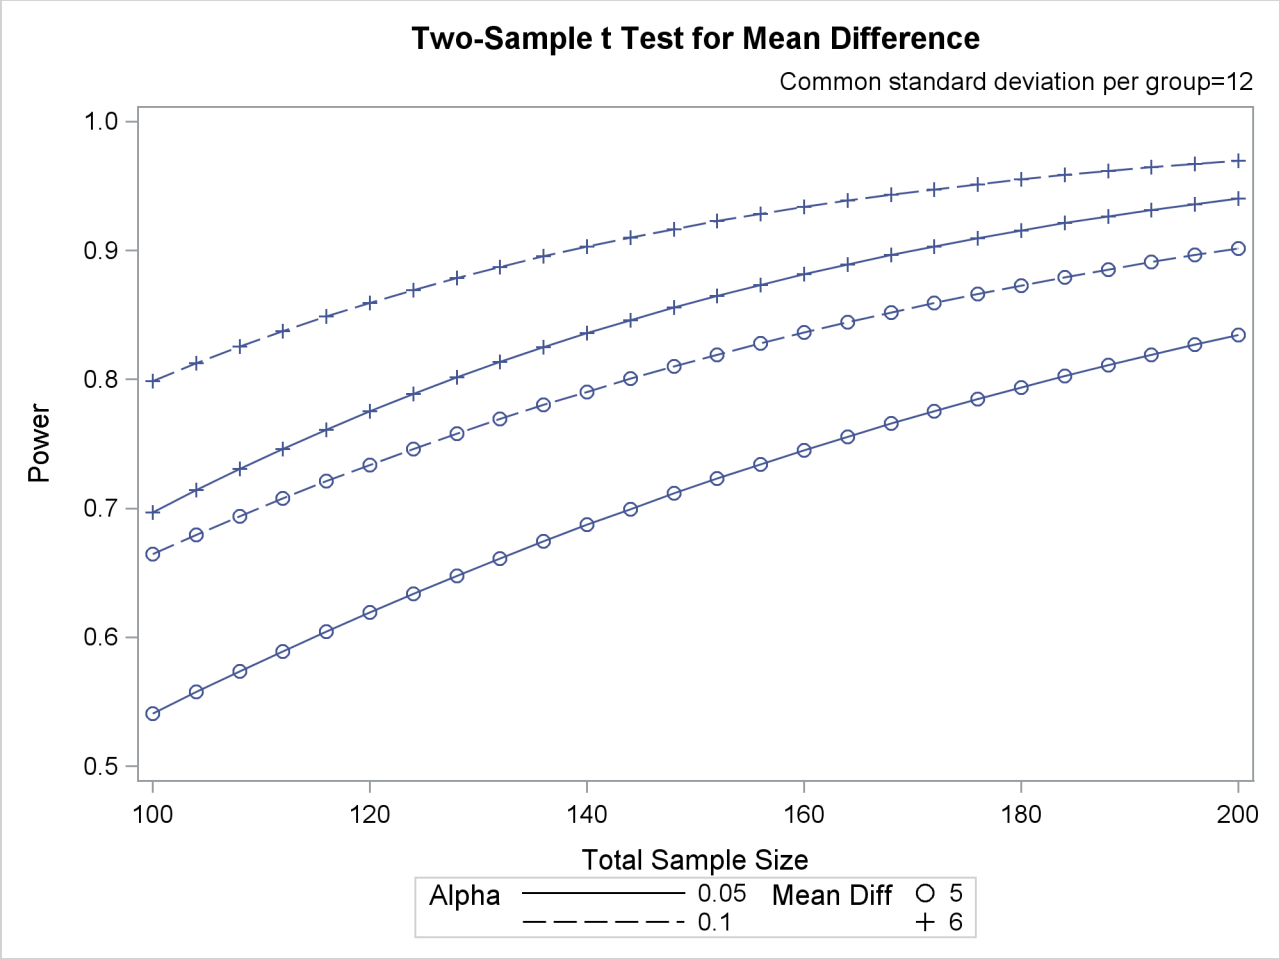

Figure 18.2 *continued*

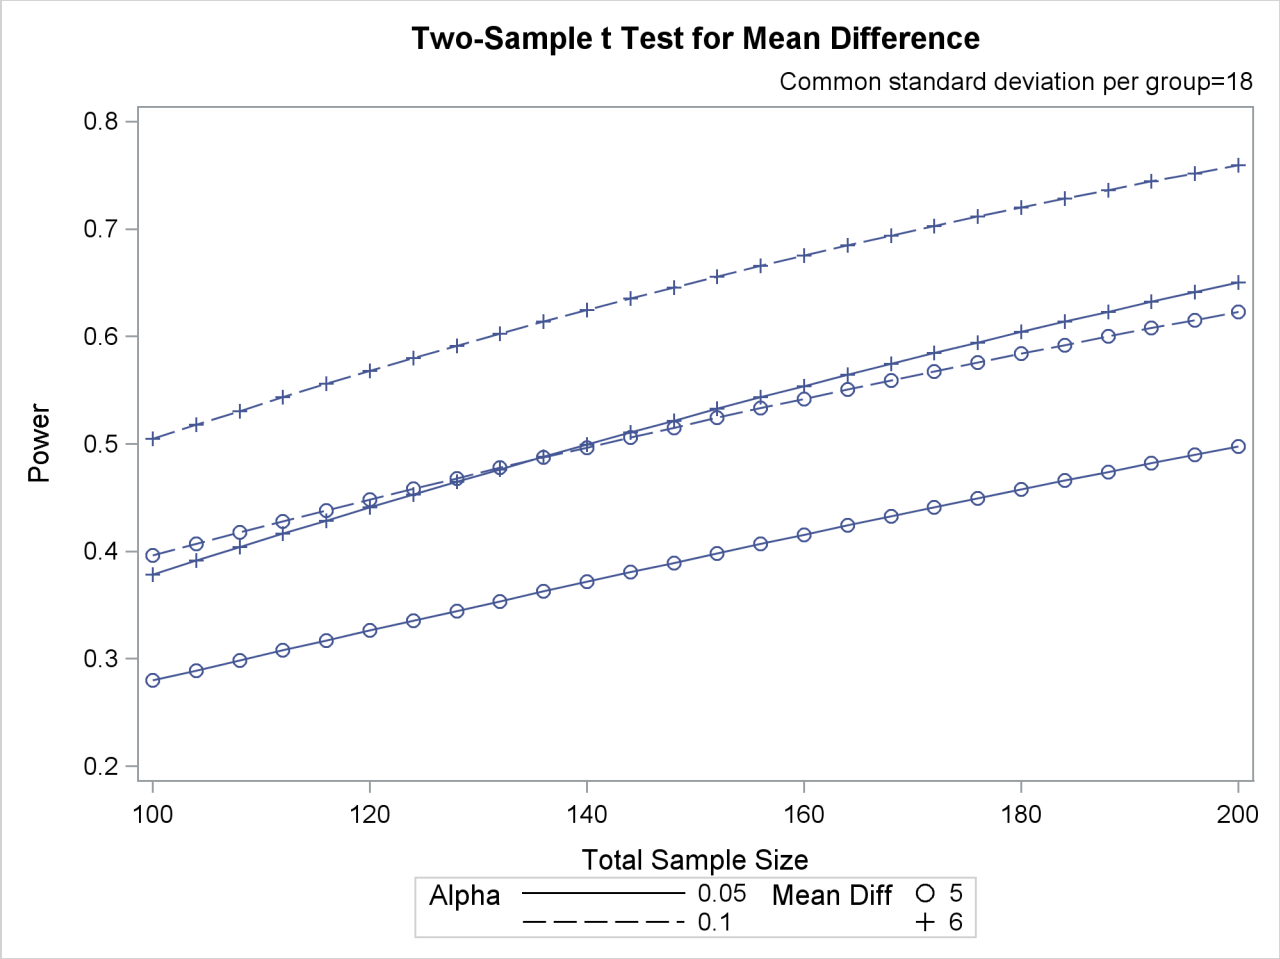


Highly Customized Graphs (POWER, GLMPOWER)

Example 70.8 of Chapter 70, "The POWER Procedure," demonstrates various ways you can modify and enhance plots created in the GLMPOWER or POWER procedures:

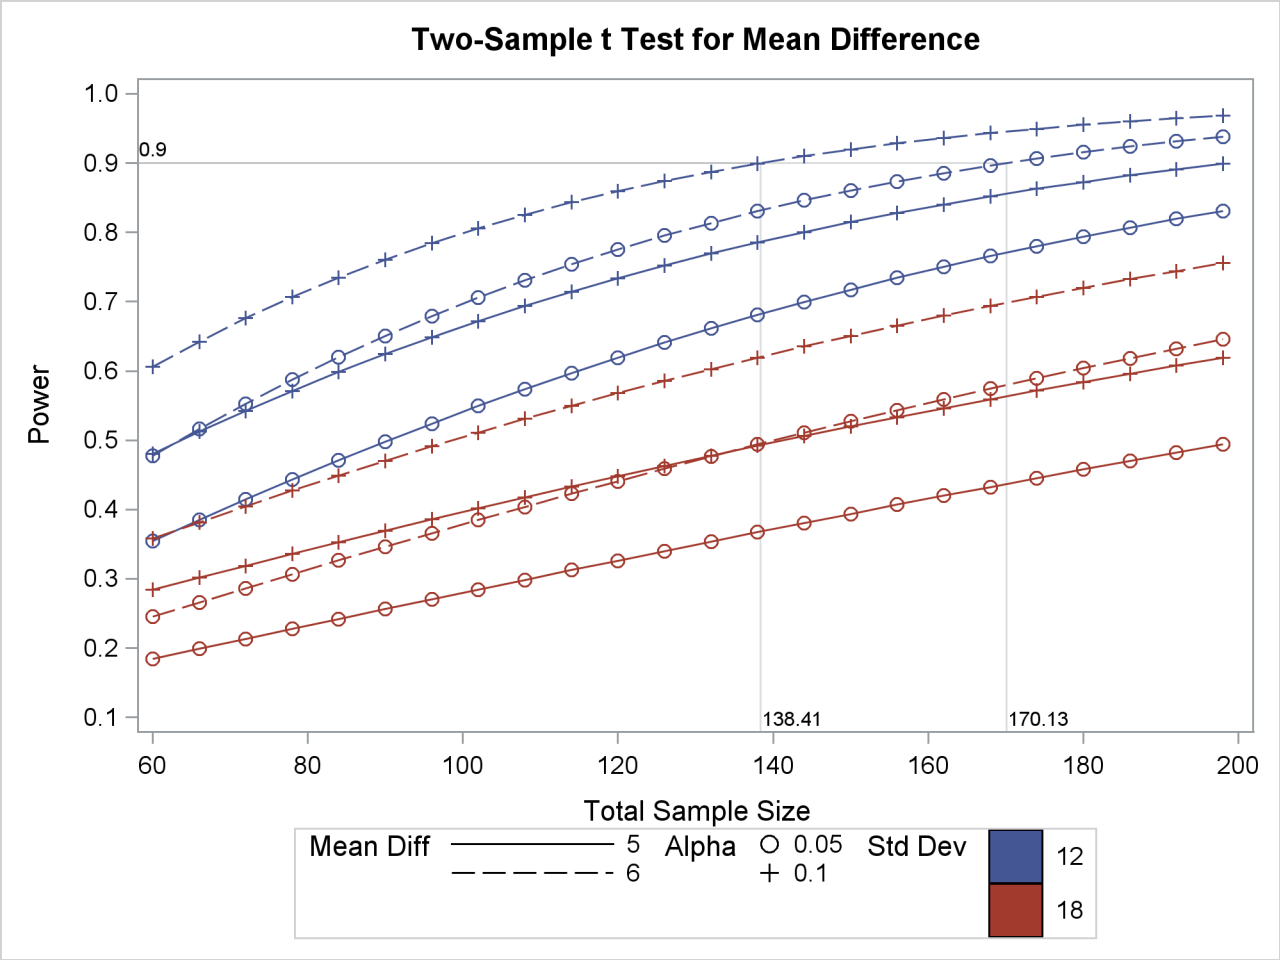
- assigning analysis parameters to axes
- fine-tuning a sample size axis
- adding reference lines
- linking plot features to analysis parameters
- choosing key (legend) styles
- modifying symbol locations

For example, replace the default PLOT statement with the following statement to modify the graphical results in Figure 18.2 to lower the minimum sample size to 60, show a reference line at power=0.9 with corresponding sample size values, distinguish standard deviation by color instead of panel, and swap the roles of α and mean difference:

```
plot
   min=60
   yopts=(ref=0.9 crossref=yes)
   vary(color by stddev, linestyle by meandiff, symbol by alpha);
```

Figure 18.3 shows the results. The plot reveals that only the scenarios with the largest mean difference and smallest standard deviation achieve a power of at least 0.9 for this sample size range.

Figure 18.3 PROC POWER Customized Graphical Output



Formatted Tables (%POWTABLE Macro)

The %POWTABLE macro renders the output of the POWER and GLMPOWER procedures in rectangular form, and it optionally produces simplified results using weighted means across chosen variables. PROC REPORT and the Output Delivery System (ODS) are used to generate the tables. Base SAS and SAS/STAT 9.1 or higher versions are required.

You can run the %POWTABLE macro for the output in Figure 18.1 to display the results in a form more suitable for quickly discerning relationships among parameters. First use the ODS OUTPUT statement to assign the "Output" table produced by the POWER procedure to a data set as follows:

```
ods output output=powdata;
```

Next, specify the same PROC POWER statements that generate Figure 18.1. Finally, use the %POWTABLE macro to assign analysis parameters to table dimensions. To create a table of computed power values with mean difference assigned to rows, sample size and α assigned to columns, and standard deviation assigned to "panels" (rendered by default as rows separated by blank lines), specify the following statements:

```
%powtable ( Data = powdata,
            Entries = power,
            Rows = meandiff,
            Cols = ntotal alpha,
            Panels = stddev )
```

Figure 18.4 shows the results.

Figure 18.4 %POWTABLE Macro Output

The POWTABLE Macro

Entries are Power

		N Total			
		100		200	
Std Dev	Mean Diff	Alpha 0.05	Alpha 0.10	Alpha 0.05	Alpha 0.10
12	5	0.541	0.664	0.834	0.902
	6	0.697	0.799	0.940	0.970
18	5	0.280	0.397	0.498	0.623
	6	0.379	0.505	0.650	0.759

Narratives and Graphical User Interface (Power and Sample Size Application)

The Power and Sample Size application produces narratives for the results. Narratives are descriptions of the input parameters and a statement about the computed power or sample size.

For example, the Power and Sample Size application creates the following narrative for the scenario corresponding to the first row in Figure 18.1:

"For a two-sample pooled t test of a normal mean difference with a two-sided significance level of 0.05, assuming a common standard deviation of 12, a total sample size of 100 assuming a balanced design has a power of 0.541 to detect a mean difference of 5."

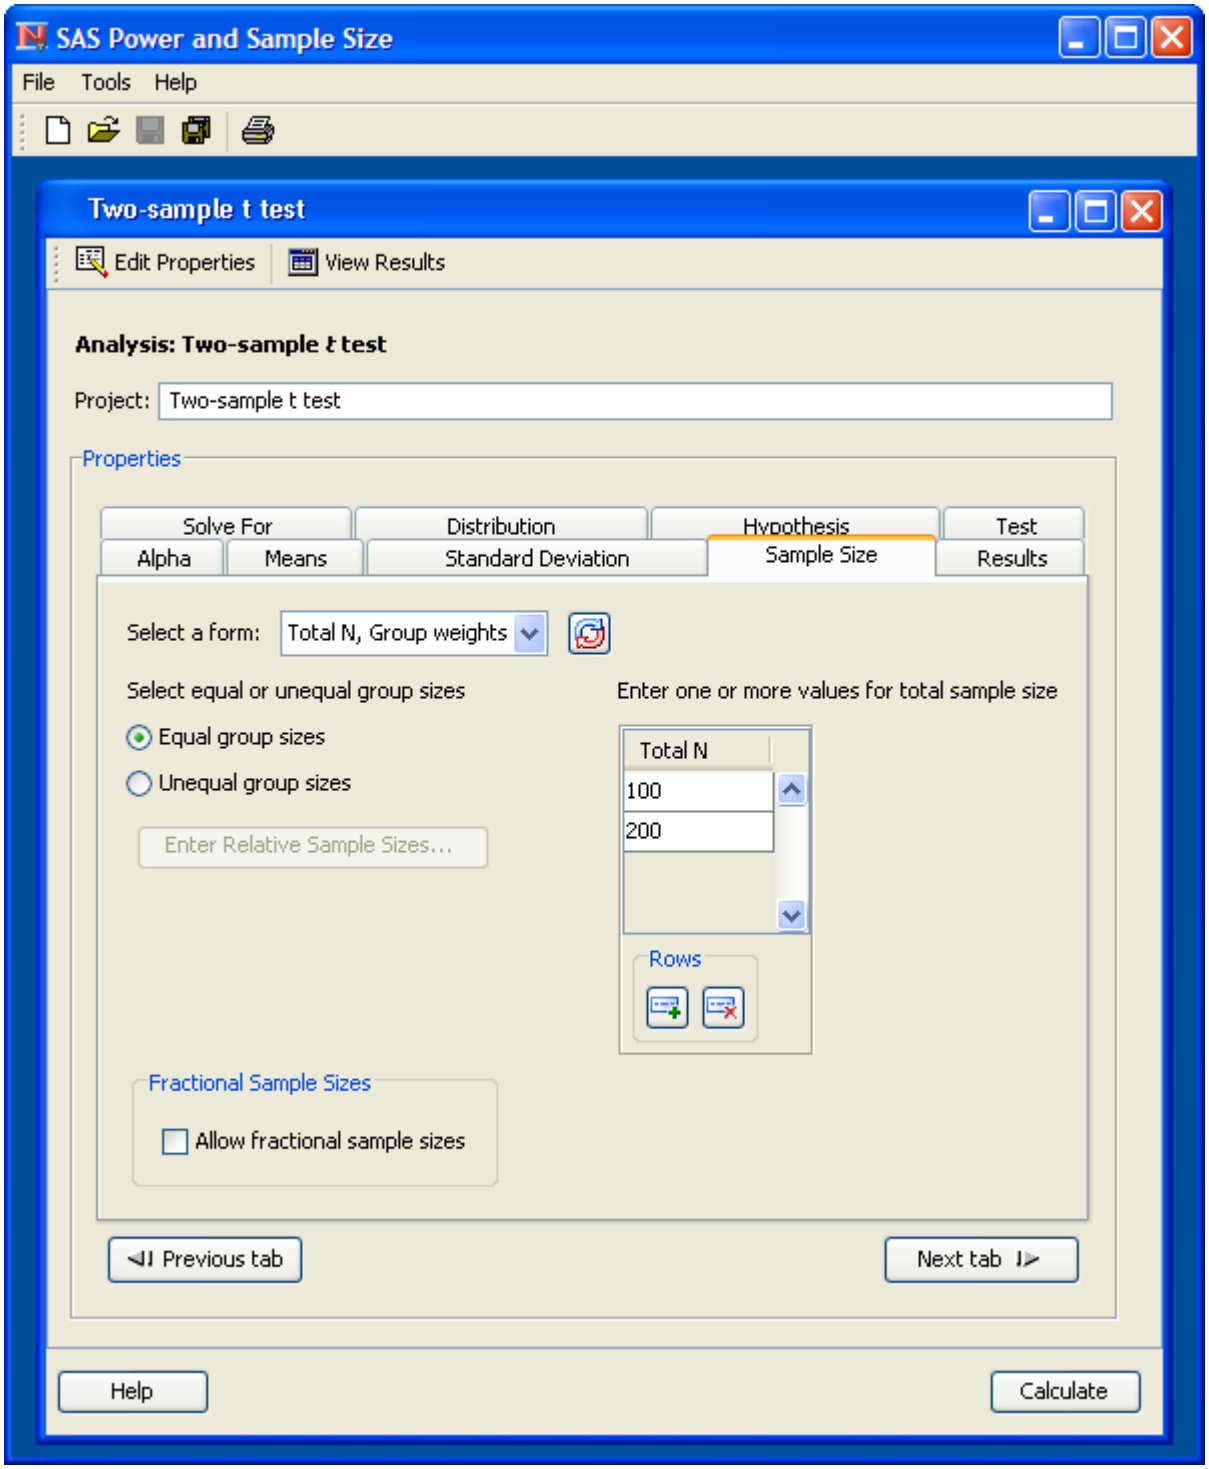
The Power and Sample Size application also provides multiple input parameter options, stores the results in a project format, displays power curves, and shows the SAS log and SAS code. You can access each project to review the results or to edit your input parameters and produce another analysis.

Where appropriate, several alternate ways of entering values for certain parameters are offered. For example, in the two-sample *t* test analysis, sample sizes can be entered in any of several parameterizations:

- total sample size in a balanced design
- sample size per group in a balanced design
- total sample size and group allocation weights
- groupwise sample sizes

See Figure 18.5 for an illustration of the application, showing the sample size input page for a two-sample *t* test.

Figure 18.5 Power and Sample Size Application



Customized Power Formulas (DATA Step)

If you want to perform a power compuation for an analysis that is not currently supported directly in SAS/STAT tools, and you have a power formula, then you can program the formula in the DATA step.

For purposes of illustration, here is the power formula in the section "Computing Power and Sample Size" on page 376 implemented in the DATA step to compute power for the *t* test example:

```
data tpow;
   do meandiff = 5, 6;
      do stddev = 12, 18;
         do alpha = 0.05, 0.1;
            do ntotal = 100, 200;
               ncp = ntotal * 0.5 * 0.5 * meandiff**2 / stddev**2;
               critval = finv(1-alpha, 1, ntotal-2, 0);
               power = sdf('f', critval, 1, ntotal-2, ncp);
               output;
            end;
         end;
      end;
   end;
run;

proc print data=tpow;
run;
```

The output is shown in Figure 18.6.

Figure 18.6 Customized Power Formula (DATA Step)

Obs	meandiff	stddev	alpha	ntotal	ncp	critval	power
1	5	12	0.05	100	4.3403	3.93811	0.54102
2	5	12	0.05	200	8.6806	3.88885	0.83447
3	5	12	0.10	100	4.3403	2.75743	0.66434
4	5	12	0.10	200	8.6806	2.73104	0.90171
5	5	18	0.05	100	1.9290	3.93811	0.27981
6	5	18	0.05	200	3.8580	3.88885	0.49793
7	5	18	0.10	100	1.9290	2.75743	0.39654
8	5	18	0.10	200	3.8580	2.73104	0.62287
9	6	12	0.05	100	6.2500	3.93811	0.69689
10	6	12	0.05	200	12.5000	3.88885	0.94043
11	6	12	0.10	100	6.2500	2.75743	0.79895
12	6	12	0.10	200	12.5000	2.73104	0.96985
13	6	18	0.05	100	2.7778	3.93811	0.37857
14	6	18	0.05	200	5.5556	3.88885	0.65012
15	6	18	0.10	100	2.7778	2.75743	0.50459
16	6	18	0.10	200	5.5556	2.73104	0.75935

Empirical Power Simulation (DATA Step, SAS/STAT Software)

You can obtain a highly accurate power estimate by simulating the power empirically. You need to use this approach for analyses that are not supported directly in SAS/STAT tools and for which you lack a power formula. But the simulation approach is also a viable alternative to existing power approximations. A high number of simulations will yield a more accurate estimate than a non-exact power approximation.

Although exact power computations for the two-sample *t* test are supported in several of the SAS/STAT tools, suppose for purposes of illustration that you want to simulate power for the continuing *t* test example. This section describes how you can use the DATA step and SAS/STAT software to do this.

The simulation involves generating a large number of data sets according to the distributions defined by the power analysis input parameters, computing the relevant *p*-value for each data set, and then estimating the power as the proportion of times that the *p*-value is significant.

The following statements compute a power estimate along with a 95% confidence interval for power for the first scenario in the two-sample *t* test example, with 10,000 simulations:

```
%let meandiff =     5;
%let stddev   =    12;
%let alpha    =  0.05;
%let ntotal   =   100;
%let nsim     = 10000;

data simdata;
   call streaminit(123);
   do isim = 1 to &nsim;
      do i = 1 to floor(&ntotal/2);
         group = 1;
         y = rand('normal', 0        , &stddev);
         output;
         group = 2;
         y = rand('normal', &meandiff, &stddev);
         output;
      end;
   end;
run;

ods listing close;
proc ttest data=simdata;
   ods output ttests=tests;
   by isim;
   class group;
   var y;
run;
ods listing;

data tests;
   set tests;
   where method="Pooled";
   issig = probt < &alpha;
run;
```

```
proc freq data=tests;
   ods select binomialprop;
   tables issig / binomial(level='1');
run;
```

First the DATA step is used to randomly generate *nsim*=10,000 data sets based on the *meandiff*, *stddev*, and *ntotal* parameters and the normal distribution, consistent with the assumptions underlying the two-sample *t* test. These data sets are contained in a large SAS data set called simdata indexed by the variable isim.

The CALL STREAMINIT(123) statement initializes the random number generator with a specific sequence and ensures repeatable results for purposes of this example. (**NOTE:** Skip this step when you are performing actual power simulations.)

The TTEST procedure is run using isim as a BY variable, with the ODS LISTING CLOSE statement to suppress output. The ODS OUTPUT statement saves the "TTests" table to a data set called tests. The *p*-values are contained in a column called probt.

The subsequent DATA step defines a variable called issig to flag the significant *p*-values.

Finally, the FREQ procedure computes the empirical power estimate as the estimate of $P(\text{issig} = 1)$ and provides approximate and exact confidence intervals for this estimate.

Figure 18.7 shows the results. The estimated power is 0.5388 with 95% confidence interval (0.5290, 0.5486). Note that the exact power of 0.541 shown in the first row in Figure 18.1 is contained within this tight confidence interval.

Figure 18.7 Simulated Power (DATA Step, SAS/STAT Software)

```
                The FREQ Procedure

              Binomial Proportion
                 for issig = 1
--------------------------------
Proportion                0.5388
ASE                       0.0050
95% Lower Conf Limit      0.5290
95% Upper Conf Limit      0.5486

Exact Conf Limits
95% Lower Conf Limit      0.5290
95% Upper Conf Limit      0.5486
```

Chapter 19

Shared Concepts and Topics

Contents

This chapter introduces a number of concepts that are common to two or more SAS/STAT procedures. Most sections display a listing of the procedures for which the shared topic is relevant.

Levelization of Classification Variables

A classification variable is a variable that enters the statistical analysis or model not through its values, but through its levels. The process of associating values of a variable with levels is termed *levelization*.

This section covers in particular procedures that support a CLASS statement for specifying classification variables. Some of the concepts discussed also apply to procedures that use different syntax to request levelization of variables (for example, the CLASS() transformation in the TRANSREG procedure).

During the process of levelization, observations that share the same value are assigned to the same level. The manner in which values are grouped can be affected by the inclusion of formats. The sort order of the levels can be determined with the ORDER= option in the procedure statement. With the GENMOD, GLMSELECT, and LOGISTIC procedures, you can also control the sorting order separately for each variable in the CLASS statement.

Consider the data on nine observations in Table 19.1. The variable A is integer valued, and the variable X is a continuous variable with a missing value for the fourth observations. The fourth and fifth columns of Table 19.1 apply two different formats to the variable X.

Table 19.1 Example Data for Levelization

Obs	A	x	FORMAT x 3.0	FORMAT x 3.1
1	2	1.09	1	1.1
2	2	1.13	1	1.1
3	2	1.27	1	1.3
4	3	.	.	.
5	3	2.26	2	2.3
6	3	2.48	2	2.5
7	4	3.34	3	3.3
8	4	3.34	3	3.3
9	4	3.14	3	3.1

By default, levelization of the variables groups observations by the formatted value of the variable, except for numerical variables for which no explicit format is provided. Numerical variables for which no explicit format is provided are sorted by their internal value. The levelization of the four columns in table Table 19.1 leads to the level assignment in Table 19.2.

Table 19.2 Values and Levels

	A		X		FORMAT x 3.0		FORMAT x 3.1	
Obs	Value	Level	Value	Level	Value	Level	Value	Level
1	2	1	1.09	1	1	1	1.1	1
2	2	1	1.13	2	1	1	1.1	1
3	2	1	1.27	3	1	1	1.3	2
4	3	2	.	.	.	.	.	.
5	3	2	2.26	4	2	2	2.3	3
6	3	2	2.48	5	2	2	2.5	4
7	4	3	3.34	7	3	3	3.3	6
8	4	3	3.34	7	3	3	3.3	6
9	4	3	3.14	6	3	3	3.1	5

The ORDER= option in the PROC statement specifies the sorting order for the levels of CLASS variables. When ORDER=FORMATTED (which is the default) is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values. To order numeric class levels with no explicit format by their BEST12. formatted values, you can specify the BEST12. format explicitly for the CLASS variables.

The following table shows how values of the ORDER= option are interpreted.

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

For FORMATTED and INTERNAL values, the sort order is machine dependent. For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

The GLMSELECT, LOGISTIC, and GENMOD procedures support a MISSING option in the CLASS statement. When this option is in effect, missing values ('.' for a numeric variable and blanks for a character variable) are included in the levelization and are assigned a level. Table 19.3 displays the results of levelizing the values in Table 19.1 when the MISSING option is in effect.

Table 19.3 Values and Levels with MISSING Option

	A		X		FORMAT x 3.0		FORMAT x 3.1	
Obs	Value	Level	Value	Level	Value	Level	Value	Level
1	2	1	1.09	2	1	2	1.1	2
2	2	1	1.13	3	1	2	1.1	2
3	2	1	1.27	4	1	2	1.3	3
4	3	2	.	1	.	1	.	1
5	3	2	2.26	5	2	3	2.3	4
6	3	2	2.48	6	2	3	2.5	5
7	4	3	3.34	8	3	4	3.3	7
8	4	3	3.34	8	3	4	3.3	7
9	4	3	3.14	7	3	4	3.1	6

When the MISSING option is not specified, or for procedures whose CLASS statement does not support this option, it is important to understand the implications of missing values for your statistical analysis. When a SAS/STAT procedure levelizes the CLASS variables, an observation for which a CLASS variable has a missing value is excluded from the analysis. This is true regardless of whether the variable is used to form the statistical model. Consider, for example, the case where some observations contain missing values for variable A but the records for these observations are otherwise complete with respect to all other variables in the statistical models. The analysis results from the following statements do not include any observations for which variable A contains missing values, even though A is not specified in the MODEL statement:

```
class A B;
model y = B x B*x;
```

Many statistical procedures print a "Number of Observations" table that shows the number of observations read from the data set and the number of observations used in the analysis. Pay careful attention to this table—especially when your data set contains missing values—to ensure that no observations are unintentionally excluded from the analysis.

Parameterization of Model Effects

The general form of a linear regression model is defined in Chapter 3, "Regression Models and Models with Classification Effects" as

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

This section describes how matrices of regressor effects such as $\mathbf{X}$ are constructed in SAS/STAT software. These constructions (*parameterization* rules) apply to regression models, models with classification effects, generalized linear models, and mixed models. The simplest and most general parameterization rules are the ones used in the GLM procedure, and they are discussed first. Several procedures also support alternate parameterizations of classification variables, including the CATMOD, GENMOD, GLMSELECT, LOGISTIC, PHREG, SURVEYLOGISTIC, and SURVEYPHREG procedures. These are discussed after the GLM parameterization of classification variables and model effects.

All modeling procedures that have a CLASS statement support classification variables and effects, and those procedures that additionally support the supplemental parameterizations have a PARAM= option in the CLASS statement.

GLM Parameterization of Classification Variables and Effects

This section applies to the following procedures:
GAM, GENMOD, GLIMMIX, GLM, GLMPOWER, GLMSELECT, LIFEREG, LOGISTIC, MI, MIXED, MULLTEST, ORTHOREG, PHREG, PLS, QUANTREG, ROBUSTREG, SURVEYLOGISTIC, and SURVEYPHREG.

Intercept

By default, SAS/STAT linear models automatically include a column of 1s in $\mathbf{X}$ which corresponds to an intercept parameter. In many procedures you can use the NOINT option in the MODEL statement to suppress this intercept. For example, the NOINT option is useful when the MODEL statement contains a classification effect and you want the parameter estimates to be in terms of the mean response for each level of that effect.

Regression Effects

Numeric variables or polynomial terms that involve them can be included in the model as regression effects (covariates). The actual values of such terms are included as columns of the relevant model matrices. You can use the bar operator with a regression effect to generate polynomial effects. For example, X|X|X expands to X X*X X*X*X, which is a cubic model.

Main Effects

If a classification variable has m levels, the GLM parameterization generates m columns for its main effect in the model matrix. Each column is an indicator variable for a given level. The order of the columns is the sort order of the values of their levels and frequently can be controlled with the ORDER= option in the procedure or CLASS statement.

Table 19.4 is an example where β_0 denotes the intercept and A and B are classification variables with two and three levels, respectively.

Table 19.4 Example of Main Effects

Data		**I**	A		B		
A	B	β_0	A1	A2	B1	B2	B3
1	1	1	1	0	1	0	0
1	2	1	1	0	0	1	0
1	3	1	1	0	0	0	1
2	1	1	0	1	1	0	0
2	2	1	0	1	0	1	0
2	3	1	0	1	0	0	1

Typically, there are more columns for these effects than there are degrees of freedom to estimate them. In other words, the GLM parameterization of main effects is *singular*.

Interaction Effects

Often a model includes interaction (crossed) effects to account for how the effect of a variable changes with the values of other variables. With an interaction, the terms are first reordered to correspond to the order of the variables in the CLASS statement. Thus, B*A becomes A*B if A precedes B in the CLASS statement. Then, the GLM parameterization generates columns for all combinations of levels that occur in the data. The order of the columns is such that the rightmost variables in the interaction change faster than the leftmost variables (Table 19.5). In the MIXED and GLIMMIX procedures, which support both fixed- and random-effects models, empty columns (that is, columns that would contain all 0s) are not generated for fixed effects, but they are generated for random effects.

Table 19.5 Example of Interaction Effects

Data		I	A		B			A*B					
A	B	β_0	A1	A2	B1	B2	B3	A1B1	A1B2	A1B3	A2B1	A2B2	A2B3
1	1	1	1	0	1	0	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	1	0	0	0
2	1	1	0	1	1	0	0	0	0	0	1	0	0
2	2	1	0	1	0	1	0	0	0	0	0	1	0
2	3	1	0	1	0	0	1	0	0	0	0	0	1

In the preceding matrix, main-effects columns are not linearly independent of crossed-effects columns; in fact, the column space for the crossed effects contains the space of the main effect.

When your model contains many interaction effects, you might be able to code them more parsimoniously by using the bar operator (|). The bar operator generates all possible interaction effects. For example, A|B|C expands to A B A*B C A*C B*C A*B*C. To eliminate higher-order interaction effects, use the at sign (@) in conjunction with the bar operator. For instance, A|B|C|D@2 expands to A B A*B C A*C B*C D A*D B*D C*D.

Nested Effects

Nested effects are generated in the same manner as crossed effects. Hence, the design columns generated by the following two statements are the same (but the ordering of the columns is different):

```
model Y=A B(A);

model Y=A A*B;
```

The nesting operator in SAS/STAT software is more of a notational convenience than an operation distinct from crossing. Nested effects are typically characterized by the property that the nested variables never appear as main effects. The order of the variables within nesting parentheses is made to correspond to the order of these variables in the CLASS statement. The order of the columns is such that variables outside the parentheses index faster than those inside the parentheses, and the rightmost nested variables index faster than the leftmost variables (Table 19.6).

Table 19.6 Example of Nested Effects

Data		I	A		B(A)					
A	B	β_0	A1	A2	B1A1	B2A1	B3A1	B1A2	B2A2	B3A2
1	1	1	1	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	0
2	1	1	0	1	0	0	0	1	0	0
2	2	1	0	1	0	0	0	0	1	0
2	3	1	0	1	0	0	0	0	0	1

Continuous-Nesting-Class Effects

When a continuous variable nests or crosses with a classification variable, the design columns are constructed by multiplying the continuous values into the design columns for the classification effect (Table 19.7).

Table 19.7 Example of Continuous-Nesting-Class Effects

Data		**I**	A		X(A)	
X	A	β_0	A1	A2	X(A1)	X(A2)
21	1	1	1	0	21	0
24	1	1	1	0	24	0
22	1	1	1	0	22	0
28	2	1	0	1	0	28
19	2	1	0	1	0	19
23	2	1	0	1	0	23

This model estimates a separate intercept and a separate slope for X within each level of A.

Continuous-by-Class Effects

Continuous-by-class effects generate the same design columns as continuous-nesting-class effects. Table 19.8 shows the construction of the X*A effect. The two columns for this effect are the same as the columns for the X(A) effect in Table 19.7.

Table 19.8 Example of Continuous-by-Class Effects

Data		**I**	**X**	A		X*A	
X	A	β_0	X	A1	A2	X*A1	X*A2
21	1	1	21	1	0	21	0
24	1	1	24	1	0	24	0
22	1	1	22	1	0	22	0
28	2	1	28	0	1	0	28
19	2	1	19	0	1	0	19
23	2	1	23	0	1	0	23

You can use continuous-by-class effects together with pure continuous effects to test for homogeneity of slopes.

General Effects

An example that combines all the effects is X1*X2*A*B*C(D E). The continuous list comes first, followed by the crossed list, followed by the nested list in parentheses. You should be aware of the sequencing of parameters when you use statements that depend on the ordering of parameters. Such statements include CONTRAST and ESTIMATE statements, which are used in a number of procedures to estimate and test functions of the parameters.

Effects might be renamed by the procedure to correspond to ordering rules. For example, B*A(E D) might be renamed A*B(D E) to satisfy the following:

- Classification variables that occur outside parentheses (crossed effects) are sorted in the order in which they appear in the CLASS statement.
- Variables within parentheses (nested effects) are sorted in the order in which they appear in the CLASS statement.

The sequencing of the parameters generated by an effect can be described by which variables have their levels indexed faster:

- Variables in the crossed list index faster than variables in the nested list.
- Within a crossed or nested list, variables to the right index faster than variables to the left.

For example, suppose a model includes four effects—A, B, C, and D—each having two levels, 1 and 2. If the CLASS statement is

```
class A B C D;
```

then the order of the parameters for the effect B*A(C D), which is renamed A*B(C D), is

$$
\begin{array}{llll}
A_1B_1C_1D_1 \rightarrow & A_1B_2C_1D_1 \rightarrow & A_2B_1C_1D_1 \rightarrow & A_2B_2C_1D_1 \rightarrow \\
A_1B_1C_1D_2 \rightarrow & A_1B_2C_1D_2 \rightarrow & A_2B_1C_1D_2 \rightarrow & A_2B_2C_1D_2 \rightarrow \\
A_1B_1C_2D_1 \rightarrow & A_1B_2C_2D_1 \rightarrow & A_2B_1C_2D_1 \rightarrow & A_2B_2C_2D_1 \rightarrow \\
A_1B_1C_2D_2 \rightarrow & A_1B_2C_2D_2 \rightarrow & A_2B_1C_2D_2 \rightarrow & A_2B_2C_2D_2
\end{array}
$$

Note that first the crossed effects B and A are sorted in the order in which they appear in the CLASS statement so that A precedes B in the parameter list. Then, for each combination of the nested effects in turn, combinations of A and B appear. The B effect changes fastest because it is rightmost in the cross list. Then A changes next fastest, and D changes next fastest. The C effect changes most slowly because it is leftmost in the nested list.

Other Parameterizations

This section applies to the following procedures:
CATMOD, GENMOD, GLMSELECT, LOGISTIC, PHREG, and SURVEYPHREG.

Some SAS/STAT procedures, including GENMOD, GLMSELECT, and LOGISTIC, support nonsingular parameterizations for classification effects. A variety of these nonsingular parameterizations are available. In most of these procedures you use the PARAM= option in the CLASS statement to specify the parameterization.

Consider a model with one CLASS variable A that has four levels, 1, 2, 5, and 7. Details of the possible choices for the PARAM= option follow.

EFFECT

Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of −1. For example, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

Effect Coding

	Design Matrix		
A	**A1**	**A2**	**A5**
1	1	0	0
2	0	1	0
5	0	0	1
7	−1	−1	−1

Parameter estimates of CLASS main effects that use the effect coding scheme estimate the difference in the effect of each nonreference level compared to the average effect over all four levels.

The EFFECT parameterization is the default parameterization in the CATMOD procedure. See the section "Generation of the Design Matrix" on page 1747, in Chapter 29, "The CATMOD Procedure," for further details about parameterization of model effects with the CATMOD procedure.

GLM

As in the GLM procedure, four columns are created to indicate group membership. The design matrix columns for A are as follows.

GLM Coding				
	Design Matrix			
A	**A1**	**A2**	**A5**	**A7**
1	1	0	0	0
2	0	1	0	0
5	0	0	1	0
7	0	0	0	1

Parameter estimates of CLASS main effects that use the GLM coding scheme estimate the difference in the effects of each level compared to the last level. See the previous section for details about the GLM parameterization of model effects.

ORDINAL

THERMOMETER

Three columns are created to indicate group membership of the higher levels of the effect. For the first level of the effect (which for A is 1), all three dummy variables have a value of 0. The design matrix columns for A are as follows.

Ordinal Coding			
	Design Matrix		
A	**A2**	**A5**	**A7**
1	0	0	0
2	1	0	0
5	1	1	0
7	1	1	1

The first level of the effect is a control or baseline level. Parameter estimates of CLASS main effects, using the ORDINAL coding scheme, estimate the differences between effects of successive levels. When the parameters have the same sign, the effect is monotonic across the levels.

POLYNOMIAL

POLY

Three columns are created. The first represents the linear term (x), the second represents the quadratic term $\left(x^2\right)$, and the third represents the cubic term $\left(x^3\right)$, where x is the level value. If the CLASS levels are not numeric, they are translated into 1, 2, 3, ... according to their sorting order. The design matrix columns for A are as follows.

Polynomial Coding			
	Design Matrix		
A	APOLY1	APOLY2	APOLY3
1	1	1	1
2	2	4	8
5	5	25	125
7	7	49	343

REFERENCE

REF

Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of 0. For example, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

Reference Coding			
	Design Matrix		
A	A1	A2	A5
1	1	0	0
2	0	1	0
5	0	0	1
7	0	0	0

Parameter estimates of CLASS main effects that use the reference coding scheme estimate the difference in the effect of each nonreference level compared to the effect of the reference level.

The REFERENCE parameterization is also available through the MODEL statement in the CATMOD procedure. See the section "Generation of the Design Matrix" on page 1747, in Chapter 29, "The CATMOD Procedure," for further details about parameterization of model effects with the CATMOD procedure.

ORTHEFFECT

The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=EFFECT. The design matrix columns for A are as follows.

Orthogonal Effect Coding			
	Design Matrix		
A	AOEFF1	AOEFF2	AOEFF3
1	1.41421	−0.81650	−0.57735
2	0	1.63299	−0.57735
5	0	0	1.73205
7	−1.41421	−0.81649	−0.57735

ORTHORDINAL

ORTHOTHERM

The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=ORDINAL. The design matrix columns for A are as follows.

Orthogonal Ordinal Coding			
	Design Matrix		
A	**AOORD1**	**AOORD2**	**AOORD3**
1	−1.73205	0	0
2	0.57735	−1.63299	0
5	0.57735	0.81650	−1.41421
7	0.57735	0.81650	1.41421

ORTHPOLY

The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=POLY. The design matrix columns for A are as follows.

Orthogonal Polynomial Coding			
	Design Matrix		
A	**AOPOLY1**	**AOPOLY2**	**AOPOLY5**
1	−1.15311	0.90712	−0.92058
2	−0.73380	−0.54041	1.47292
5	0.52414	−1.37034	−0.92058
7	1.36277	1.00363	0.36823

ORTHREF

The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=REFERENCE. The design matrix columns for A are as follows.

Orthogonal Reference Coding			
	Design Matrix		
A	**AOREF1**	**AOREF2**	**AOREF3**
1	1.73205	0	0
2	−0.57735	1.63299	0
5	−0.57735	−0.81650	1.41421
7	−0.57735	−0.81650	−1.41421

EFFECT Statement

This section applies to the following procedures:
GLIMMIX, GLMSELECT, HPMIXED, LOGISTIC, ORTHOREG, PHREG, PLS, QUANTREG, ROBUSTREG, SURVEYLOGISTIC, and SURVEYREG.

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 397. For example, the terms A, B, x, A*x, A*B, and sub in the following statements define fixed, random, and subject effects of the usual type in a mixed model:

```
proc glimmix;
   class A B sub;
   model y = A B x A*x;
   random A*B / subject=sub;
run;
```

A constructed effect, on the other hand, is assigned through the EFFECT statement. For example, in the following program, the EFFECT statement defines a constructed effect named spl:

```
proc glimmix;
   class A B SUB;
   effect spl = spline(x);
   model y = A B A*spl;
   random A*B / subject=sub;
run;
```

The columns of spl are formed from the data set variable x as a cubic B-spline basis with three equally spaced interior knots.

Each constructed effect corresponds to a collection of columns that are referred to by using the name you supply. You can specify multiple EFFECT statements, and all EFFECT statements must precede the MODEL statement.

The general syntax for the EFFECT statement with *effect-specification* is

EFFECT *effect-name* = *effect-type* (*var-list* < / *effect-options* >) ;

The name of the effect is specified after the EFFECT keyword. This name can appear in only one EFFECT statement and cannot be the name of a variable in the input data set. The *effect-type* is specified after an equal sign, followed by a list of variables within parentheses which are used in constructing the effect. *Effect-options* that are specific to an *effect-type* can be specified after a slash (/) following the variable list. The following *effect-types* are available and are discussed in the following sections:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period. **Note:** The LAG *effect-type* is experimental in this release.
MULTIMEMBER | MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL | POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 19.9 summarizes important options for each type of EFFECT statement.

Table 19.9 Important EFFECT Statement Options

Option	Description
Options for Collection Effects	
DETAILS	Displays the constituents of the collection effect
Options for Lag Effects	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Options for Multimember Effects	
NOEFFECT	Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects
Options for Polynomial Effects	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial

Table 19.9 *continued*

Option	Description
Options for Spline Effects	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

Collection Effects

EFFECT *name*=**COLLECTION (***var-list* < / **DETAILS** >**) ;**

You use a collection effect to define a set of variables that are treated as a single effect with multiple degrees of freedom. The variables in *var-list* can be continuous or classification variables. The columns in the design matrix that are contributed by a collection effect are the design columns of its constituent variables in the order in which they appear in the definition of the collection effect. If you specify the DETAILS option, then a table that shows the constituents of the collection effect is displayed.

Lag Effects (Experimental)

EFFECT *name*=**LAG (***variable* / *lag-options***) ;**

A lag effect is a classification effect for the CLASS variable that is given after the keyword LAG. A lag effect is used to represent the effect of a previous value of the lagged variable when there is some inherent ordering of the observations of this variable. A typical example where lag effects are useful is a study in which different subjects are given sequences of treatments and you want to investigate whether the treatment in the previous period is important in understanding the outcome in the current period. You can do this by including a lagged treatment effect in your model.

The precise definition of a LAG effect depends on a subdivision of the data into disjoint subsets, often referred to as "subjects," and an ordering into units called "periods" of the observations within a subject. For an observation that belongs to a given subject and at a given period, the design matrix columns of the lagged variable are the usual design matrix columns of that variable except for the observation at the preceding period for that subject. Observations at the initial period do not have a preceding value, and so the design matrix columns of the lag effect for these observations are set to zero. You can also define lag effects where the number of periods that are lagged is greater than one. If the number of periods that are lagged is n, then the design matrix columns of observations in periods less than or equal to n are set to zero. The design matrix columns that correspond to a subject at period p, where $p > n$, are the usual design matrix columns of the lagged variable for that subject at period $p - n$.

A convenient way to represent the organization of observations into subjects and periods is to form the lag design matrix. The rows and columns of this matrix correspond to the subjects and periods respectively. The lag design matrix entry is the treatment for the corresponding subject and period. In a valid lag design there is at most one observation for a given period and subject. For example, the following set of treatments by subject and period form a valid lag design:

Subject	Period	Treatment
Sheila	1	B
Joey	1	A
Athena	1	A
Gelindo	1	A
Sheila	2	C
Joey	2	A
Athena	2	.
Gelindo	2	B
Sheila	3	B
Joey	3	C
Athena	3	A
Gelindo	3	B

The associated lag design matrix is

	--Period---		
Subject	1	2	3
Athena	A		A
Gelindo	A	B	B
Joey	A	A	C
Sheila	B	C	B

Note that the subject Athena did not receive a treatment at period 2, and so the corresponding entry in the lag design matrix is missing. You can define a lag effect for this lag design with the following statements:

```
CLASS treatment;
EFFECT Lag = LAG( treatment / WITHIN=subject PERIOD=period);
```

When GLM coding is used for the CLASS variable treatment, the design matrix columns Lag_A, Lag_B, and Lag_C for the constructed effect Lag are as follows:

Subject	period	treatment	Lag_A	Lag_B	Lag_C
Athena	1	A	0	0	0
Athena	2		1	0	0
Athena	3	A	.	.	.
Gelindo	1	A	0	0	0
Gelindo	2	B	1	0	0
Gelindo	3	B	0	1	0
Joey	1	A	0	0	0
Joey	2	A	1	0	0
Joey	3	C	1	0	0
Sheila	1	B	0	0	0
Sheila	2	C	0	1	0
Sheila	3	B	0	0	1

The design matrix columns for each subject at period 1 are all zero because there are no lagged observations for period 1. You can also see that the design matrix columns at period 3 for subject Athena are missing because Athena did not receive a treatment at period 2. Nevertheless, the design matrix columns for Athena at period 2 are nonmissing and correspond to the treatment "A" that she received in period 1.

The following *lag-options* are required:

PERIOD=*variable*

specifies the period variable of the LAG design. The number of periods is the number of unique formatted values of the PERIOD= variable, and the ordering of the period is formed by sorting these formatted values in ascending order. You must specify a PERIOD= variable.

WITHIN=(*variables)*

WITHIN=*variable*

specifies a variable (or a list of variables within parentheses) that defines the subject grouping of the lag design. If there is only one WITHIN= *variable*, then the parentheses are not required. Each *subject* is defined by the unique set of formatted values of the *variables* in the WITHIN= list. The subjects are sorted in ascending lexicographic order. You must specify a WITHIN= variable.

You can also specify the following *lag-options*:

DESIGNROLE=*variable*

specifies a numeric variable that is used to subset observations into a fitting group in which the value of the DESIGNROLE= variable is nonzero and a second group in which the value of the specified *variable* is zero. The observations in the fitting group are used to form the LAG design matrix that is used in fitting the model. The LAG design that corresponds to the non-fitting group is used when scoring observations in the input data set that do not belong to the fitting group. This option is useful when you want to obtain predicted values in an output data set for observations that are not used in fitting the model. If you do not specify a DESIGNROLE= *variable*, then all observations are assigned to the fitting group.

DETAILS
requests a table that shows the lag design matrix of the lag effect.

NLAG= *n*
specifies the number of lags. By default NLAG=1.

Multimember Effects

EFFECT *name*=**MULTIMEMBER (***var-list* < / *mm-options* >**) ;**

EFFECT *name*=**MM (***var-list* < / *mm-options* >**) ;**

A multimember effect is formed from one or more classification variables in such a way that each observation can be associated with one or more levels of the union of the levels of the classification variables. In other words, a multimember effect is a classification-type effect with possibly more than one nonzero column entry for each observation. Multimember effects are useful, for example, in modeling the following:

- nurses' effects on patient recovery in hospitals
- teachers' effects on student scores
- lineage effects in genetic studies. See Example 40.16 in Chapter 40, "The GLIMMIX Procedure," for an application with random multimember effects in a genetic diallel experiment.

The levels of a multimember effect consist of the union of formatted values of the variables that define this effect. Each such level contributes one column to the design matrix. For each observation, the value that corresponds to each level of the multimember effect in the design matrix is the number of times that this level occurs for the observation.

For example, the following data provide teacher information and end-of-year test scores for students after two semesters:

Student	Score	Teacher1	Teacher2
Mary	87	Tobias	Cohen
Tom	89	Rodriguez	Tobias
Fred	82	Cohen	Cohen
Jane	88	Tobias	.
Jack	99	.	.

For example, Mary had different teachers in the two semesters, Fred had the same teacher in both semesters, and Jane received instruction only in the first semester.

You can model the effect of the teachers on student performance by using a multimember effect specified as follows:

```
CLASS teacher1 teacher2;
EFFECT teacher = MM(teacher1 teacher2);
```

The levels of the teacher effect are Cohen, Rodriguez, and Tobias, and the associated design matrix columns are as follows:

Student	Cohen	Rodriguez	Tobias
Mary	1	0	1
Tom	0	1	1
Fred	2	0	0
Jane	0	0	1
Jack	.	.	.

You can specify the following *mm-options* after a slash (/):

DETAILS
requests a table that shows the levels of the multimember effect.

NOEFFECT
specifies that, for observations with all missing levels of the multimember variables, the values in the corresponding design matrix columns be set to zero. If, in the preceding example, the teacher effect is defined by

```
EFFECT teacher = MM(teacher1 teacher2 / noeffect);
```

then the associated design matrix columns values for Jack are all zero. This enables you to include Jack in the analysis even though there is no effect of teachers on his performance.

A situation where it is important to designate observations as having no effect due to a classification variable is the analysis of crossover designs, where lagged treatment levels are used to model the carryover effects of treatments between periods. Since there is no carryover effect for the first period, the treatment lag effect in a crossover design can be modeled with a multimember effect that consists of a single classification variable and the NOEFFECT option, as in the following statements:

```
CLASS Treatment lagTreatment;
EFFECT Carryover = MM(lagTreatment / noeffect);
```

The lagTreatment variable contains a missing value for the first period. Otherwise, it contains the value of the treatment variable for the preceding period.

STDIZE
specifies that for each observation, the entries in the design matrix that corresponds to the multimember effect be scaled to have a sum of one.

WEIGHT=*wght-list*
specifies numeric variables used to weigh the contributions of each of the classification effects that define the constructed multimember effect. The number of variables in *wght-list* must match the number of classification variables that define the effect.

Polynomial Effects

EFFECT *name*=**POLYNOMIAL (***var-list* < / *polynomial-options* >**) ;**

EFFECT *name*=**POLY (***var-list* < / *polynomial-options* >**) ;**

The variables in *var-list* must be numeric. A design matrix column is generated for each term of the specified polynomial. By default, each of these terms is treated as a separate effect for the purpose of model building. For example, the statements

```
proc glmselect;
   effect MyPoly = polynomial(x1-x3/degree=2);
   model y = MyPoly;
run;
```

yield the identical analysis to the statements

```
proc glmselect;
   model y = x1 x2 x3 x1*x1 x1*x2 x1*x3 x2*x2 x2*x3 x3*x3;
run;
```

You can specify the following *polynomial-options* after a slash (/):

DEGREE=*n*
specifies the degree of the polynomial. The degree must be a positive integer. The degree is typically a small integer, such as 1, 2, or 3. The default is DEGREE=1.

DETAILS
requests a table that shows the details of the specified polynomial, including the number of terms generated. If you also specify the STANDARDIZE option, then a table that shows the standardization details is also produced.

LABELSTYLE=(*style-opts***)**
LABELSTYLE=*style-opt*
specifies how the terms in the polynomial are labeled. By default, powers are shown with ^ as the exponentiation operator and ∗ as the multiplication operator. For example, a polynomial term such as $x_1^3 x_2 x_3^2$ is labeled x1^3*x2*x3^2. You can change the style of the label by using the following *style-opts* within parentheses. If you specify a single *style-opt*, then you can omit the enclosing parentheses.

EXPAND
specifies that each variable with an exponent greater than 1 be written as products of that variable. For example, the term $x_1^3 x_2 x_3^2$ receives the label x1*x1*x1*x2*x3*x3.

EXPONENT < =*quoted string* **>**
specifies that each variable with an exponent greater than 1 be written using exponential notation. By default, the symbol ^ is used as the exponentiation operator. If you supply the optional quoted string after an equal sign, then that string is used as the exponentiation operator. For example, if you specify

```
LABELSTYLE=(EXPONENT="**")
```

then the term $x_1^3 x_2 x_3^2$ receives the label x1**3*x2*x3**2.

INCLUDENAME

specifies that the name of the effect followed by an underscore be used as a prefix for term labels. For example, the following statement generates terms with labels MyPoly_x1 and MyPoly_x1^2:

```
EFFECT MyPoly=POLYNOMIAL(x1/degree=2 labelstyle=INCLUDENAME)
```

The INCLUDENAME option is ignored if you also specify the NOSEPARATE option in the EFFECT=POLYNOMIAL statement.

PRODUCTSYMBOL=NONE | *quoted string*

specifies that the supplied string be used as the product symbol. For example, the following statement generates terms with labels x1, x2, and x1 x2:

```
EFFECT MyPoly=POLYNOMIAL(x1 x2 / degree=2 mdegree=1
                                 labelstyle=(PRODUCTSYMBOL=" "))
```

If you specify PRODUCTSYMBOL=NONE, then the labels are formed by juxtaposing the constituent variable names.

MDEGREE=*n*

specifies the maximum degree of any variable in a term of the polynomial. This degree must be a positive integer. The default is the degree of the specified polynomial. For example, the following statement generates the terms x_1, x_2, x_1^2, x_1x_2, x_2^2,$x_1^2x_2$, $x_1x_2^2$ and $x_1^2x_2^2$:

```
EFFECT MyPoly=POLYNOMIAL(x1 x2/degree=4 MDEGREE=2);
```

NOSEPARATE

specifies that the polynomial be treated as a single effect with multiple degrees of freedom. The effect name that you specify is used as the constructed effect name, and the labels of the terms are used as labels of the corresponding parameters.

STANDARDIZE < (*centerscale-opts***) > < = *standardize-opt* >**

specifies that the variables that define the polynomial be standardized. By default, the standardized variables receive prefix "s_" in the variable names.

You can use the following *centerscale-opts* to specify how the center and scale are estimated:

METHOD=MOMENTS

specifies that the center be estimated by the variable mean and the scale be estimated by the standard deviation. If a weight variable is specified using a WEIGHT statement, the observations with invalid weights are ignored when forming the mean and standard deviation, but the weights are otherwise not used. Only observations that are used in performing the analysis are used for the standardization.

METHOD=RANGE

specifies that the center be estimated by the midpoint of the variable range and the scale be estimated as half the variable range. Any observation that has a missing value for any regressor used in the model is ignored when computing the range of variables in a polynomial effect. Observations with valid regressor values but missing or invalid values of frequency variables, weight variables, or dependent variables are used in computing variable ranges. The default (if you do not specify the METHOD= suboption) is METHOD=RANGE.

METHOD=WMOMENTS

is the same as METHOD=MOMENTS except that weighted means and weighted standard deviations are used.

Let

$$
\begin{aligned}
n &= \text{number of observations used in the analysis} \\
w &= \text{weight variable} \\
f &= \text{frequency variable} \\
x &= \text{variable to be standardized} \\
x_{(n)} &= \mathrm{Max}_{i=1}^{n}(x_i) \\
x_{(1)} &= \mathrm{Min}_{i=1}^{n}(x_i) \\
F &= \text{sum of frequencies} \\
&= \Sigma_{i=1}^{n} f_i \\
WF &= \text{sum of weighted frequencies} \\
&= \Sigma_{i=1}^{n} w_i f_i
\end{aligned}
$$

Table 19.10 shows how the center and scale are computed for each of the supported methods.

Table 19.10 Center and Scale Estimates by Method

Method	Center	Scale
Range	$(x_{(n)} + x_{(1)})/2$	$(x_{(n)} - x_{(1)})/2$
Moments	$\bar{x} = \Sigma_{i=1}^{n} f_i x_i / F$	$\sqrt{\Sigma_{i=1}^{n} f_i (x_i - \bar{x})^2/(F-1)}$
WMoments	$\bar{x}_w = \Sigma_{i=1}^{n} w_i f_i x_i / WF$	$\sqrt{\Sigma_{i=1}^{n} w_i f_i (x_i - \bar{x}_w)^2/(F-1)}$

PREFIX=NONE | *quoted-string*

specifies the prefix that is appended to standardized variables when forming the term labels. If you omit this option, the default prefix is "s_". If you specify PREFIX=NONE, then standardized variables are not prefixed.

You can control whether the standardization is to center, scale, or both center and scale by specifying a *standardize-opt*:

CENTER
specifies that variables be centered but not scaled. For a variable x,

$$\text{s\_x} = x - \text{center}$$

CENTERSCALE
specifies that variables be centered and scaled. This is the default if you do not specify a *standardization-opt*. For a variable x,

$$\text{s\_x} = \frac{x - \text{center}}{\text{scale}}$$

NONE
specifies that no standardization be performed.

SCALE
specifies that variables be scaled but not centered. For a variable x,

$$\text{s\_x} = \frac{x}{\text{scale}}$$

Spline Effects

This section discusses the construction of spline effects through the EFFECT statement. You can also include spline effects in statistical models by other means. The TRANSREG procedure has dedicated facilities for including regression splines in your model and controlling the construction of the splines. For example, you can use the TRANSREG procedure to fit a spline function but restrict the function to be always increasing or decreasing (monotone). See the section "Using Splines and Knots" on page 7845 in Chapter 93, "The TRANSREG Procedure," for more information about using splines with the TRANSREG procedure. The GAM and TPSPLINE procedures also can model the effects of regressor variables in terms of smooth functions that are generated from spline bases. For more information see Chapter 38, "The GAM Procedure," and Chapter 92, "The TPSPLINE Procedure."

A spline effect expands variables into spline bases whose form depends on the options that you specify. You can find details about regression splines and spline bases in the section "Splines and Spline Bases" on page 420. You request a spline effect with the syntax

EFFECT *name*=**SPLINE (***var-list* < / *spline-options* >**) ;**

The variables in *var-list* must be numeric. Design matrix columns are generated separately for each of these variables, and the set of columns is collectively referred to with the specified name. By default, the spline basis that is generated for each variable is a cubic B-spline basis with three equally spaced knots positioned between the minimum and maximum values of that variable. This yields by default seven design matrix columns for each of the variables in the SPLINE effect.

You can specify the following *spline-options* after a slash (*/*):

BASIS=BSPLINE
specifies a B-spline basis for the spline expansion. For splines of degree d defined with n knots, this basis consists of $n + d + 1$ columns. In order to completely specify the B-spline basis, d left-side boundary knots and $\max\{d, 1\}$ right-side boundary knots are also required. See the suboptions KNOTMETHOD=, DATABOUNDARY, KNOTMIN=, and KNOTMAX= for details about how to specify the positions of both the internal and boundary knots. This is the default if you do not specify the BASIS= suboption.

BASIS=TPF(*options*)
specifies a truncated power function basis for the spline expansion. For splines of degree d defined with n knots for a variable x, this basis consists of an intercept, polynomials x, x^2,..., x^d and one truncated power function for each of the n knots. Unlike the B-spline basis, no boundary knots are required. See the suboption KNOTMETHOD= for details about how you can specify the position of the internal knots.

You can modify the number of columns when you request BASIS=TPF with the following *options*:

NOINT
excludes the intercept column.

NOPOWERS
excludes the intercept and polynomial columns.

DATABOUNDARY
specifies that the extremes of the data be used as boundary knots when building a B-spline basis.

DEGREE=*n*
specifies the degree of the spline transformation. The degree must be a nonnegative integer. The degree is typically a small integer, such as 0, 1, 2, or 3. The default is DEGREE=3.

DETAILS
requests tables that show the knot locations and the knots associated with each spline basis function.

KNOTMAX=*value*
specifies that, for each variable in the EFFECT statement, the right-side boundary knots be equally spaced starting at the maximum of the variable and ending at the specified value. This option is ignored for variables whose maximum value is greater than the specified value or if the DATABOUNDARY option is also specified.

KNOTMETHOD=*knot-method*<(*knot-options*)>
specifies how to construct the knots for spline effects. You can choose from the following *knot-methods* and affect the knot construction further with the method-specific *knot-options*:

EQUAL<(*n*)>
specifies that n equally spaced knots be positioned between the extremes of the data. The default is $n = 3$. For a B-spline basis, any needed boundary knots continue to be equally spaced unless the DATABOUNDARY option has also been specified. KNOTMETHOD=EQUAL is the default if no *knot-method* is specified.

LIST(*number-list***)**
specifies the list of internal knots to be used in forming the spline basis columns. For a B-spline basis, the data extremes are used as boundary knots.

LISTWITHBOUNDARY(*number-list***)**
specifies the list of all knots that are used in forming the spline basis columns. When you use a truncated power function basis, this list is interpreted as the list of internal knots. When you use a B-spline basis of degree d, then the first d entries are used as left-side boundary knots and the last MAX(d, 1) entries in the list are used as right-side boundary knots.

MULTISCALE< (*multiscale-options***) >**
specifies that multiple B-spline bases be generated, corresponding to sets with an increasing number of internal knots. As you increase the number of internal knots, the spline basis you generate is able to approximate features of the data at finer scales. So, by generating bases at multiple scales, you facilitate the modeling of both coarse- and fine-grained features of the data. For scale i, the spline basis corresponds to 2^i equally spaced internal knots. By default, the bases for scales 0–7 are generated. For each scale, a separate spline effect is generated. The name of the constructed spline effect at scale i is formed by appending _Si to the effect name that you specify in the EFFECT statement. If you specify multiple variables in the EFFECT statement, then spline bases are generated separately for each variable at each scale and the name of the corresponding effect is obtained by appending the variable name followed by _Si to the name in the EFFECT statement. For example, the following statement generates effects named spl_x1_S0, spl_x1_S1, spl_x1_S2, . . ., spl_x1_S7 and spl_x2_S1, spl_x2_S2, . . ., spl_x2_S7:

```
EFFECT spl = spline(x1 x2 / knotmethod=multiscale);
```

The MULTISCALE option is ignored if you specify the BASIS=TPF *spline-option*. The MULTISCALE option is not available for spline effects that are specified in the RANDOM statement of the GLIMMIX procedure.

You can control which scales are included with the following *multiscale-options*:

STARTSCALE=*n*
specifies the start scale, where n is a positive integer. The default is STARTSCALE=0.

ENDSCALE=*n*
specifies the end scale, where n is a positive integer. The default is ENDSCALE=7.

PERCENTILES(*n***)**
requests that internal knots be placed at n equally spaced percentiles of the variable or variables named in the EFFECT statement. For example, the following statement positions internal knots at the deciles of the variable x. For a B-spline basis, the extremes of the data are used as boundary knots:

```
EFFECT spl = spline(x / knotmethod=percentiles(9));
```

RANGEFRACTIONS(*fraction-list***)**
requests that internal knots be placed at each fraction of the ranges of the variables in the EFFECT statement. For example, if variable x1 ranges between 1 and 3, and variable x2 ranges

between 0 and 20, then the following EFFECT statement uses internal knots 1.2, 2, and 2.5 for variable x1 and internal knots 2, 10, and 15 for variable x2:

```
EFFECT spl = spline(x1 x2 / knotmethod=rangefractions(.1 .5 .75));
```

For a B-spline basis, the data extremes are used as boundary knots.

KNOTMIN=*value*

specifies that for each variable in the EFFECT statement, the left-side boundary knots be equally spaced starting at the specified value and ending at the minimum of the variable. This option is ignored for variables whose minimum value is less than the specified value or if the DATABOUNDARY option is also specified.

NATURALCUBIC

specifies a natural cubic spline basis for the spline expansion. Natural cubic splines, also known as restricted cubic splines, are cubic splines that are constrained to be linear beyond the extreme knots. The natural cubic spline basis that is produced by the EFFECT statement is obtained by starting from the unrestricted truncated power function cubic spline basis that is defined with n distinct knots and imposes the linearity constraints beyond the extreme knots. This basis consists of an intercept, the polynomial x, and $n-2$ functions that are all linear beyond the largest knot. The ith function, $i = 1, 2, \ldots, n-2$, is zero to the left of the ith knot, which is called the "break knot." See the section "Splines and Spline Bases" on page 420 for details of this basis. You can use the NOINT and NOPOWERS suboptions of the BASIS=TPF option to supress the intercept and polynomial x when forming the columns of the natural cubic spline basis. When you specify the NATURALCUBIC option, the options BASIS=BSPLINE, DATABOUNDARY, DEGREE=, and KNOTMETHOD=MULTISCALE are not applicable.

SEPARATE

specifies that when multiple variables are specified in the EFFECT statement, the spline basis for each variable be treated as a separate effect. The names of these separated effects are formed by appending an underscore followed by the name of the variable to the name that you specify in the EFFECT statement. For example, the effect names generated with the following statement are spl_x1 and spl_x2:

```
EFFECT spl = spline(x1 x2 / separate);
```

In procedures that support variable selection, such as the GLMSELECT procedure, these two effects can enter or leave the model independently during the selection process. Separated effects are not supported in the RANDOM statement of the GLIMMIX procedure.

SPLIT

specifies that each individual column in the design matrix that corresponds to the spline effect be treated as a separate effect that can enter or leave the model independently. Names for these split effects are generated by appending the variable name and an index for each column to the name that you specify in the EFFECT statement. For example, the effects generated for the spline effect in the following statement are spl_x1:1, spl_x1:2, ..., spl_x1:7 and spl_x2:1, spl_x2:2, ..., spl_x2:7:

```
EFFECT spl = spline(x1 x2 / split);
```

The SPLIT option is not supported in the GLIMMIX procedure.

Splines and Spline Bases

This section provides details about the construction of spline bases with the EFFECT statement. A spline function is a piecewise polynomial function in which the individual polynomials have the same degree and connect smoothly at join points whose abscissa values, referred to as knots, are prespecified. You can use spline functions to fit curves to a wide variety of data.

A spline of degree 0 is a step function with steps located at the knots. A spline of degree 1 is a piecewise linear function where the lines connect at the knots. A spline of degree 2 is a piecewise quadratic curve whose values and slopes coincide at the knots. A spline of degree 3 is a piecewise cubic curve whose values, slopes, and curvature coincide at the knots. Visually, a cubic spline is a smooth curve, and it is the most commonly used spline when a smooth fit is desired. Note that when no knots are used, splines of degree d are simply polynomials of degree d.

More formally, suppose you specify knots $k_1 < k_2 < k_3 < \cdots < k_n$. Then a spline of degree $d \geq 0$ is a function $S(x)$ with $d-1$ continuous derivatives such that

$$S(x) = \begin{cases} P_0(x) & x < k_1 \\ P_i(x) & k_i \leq x < k_{i+1};\ i = 1, 2, \ldots, n-1 \\ P_n(x) & x \geq k_n \end{cases}$$

where each $P_i(x)$ is a polynomial of degree d. The requirement that $S(x)$ has $d-1$ continuous derivatives is satisfied by requiring that the function values and all derivatives up to order $d-1$ of the adjacent polynomials at each knot match.

A counting argument yields the number of parameters that define a spline with n knots. There are $n+1$ polynomials of degree d, giving $(n+1)(d+1)$ coefficients. However, there are d restrictions at each of the n knots, so the number of free parameters is $(n+1)(d+1) - nd = n+d+1$. In mathematical terminology this says that the dimension of the vector space of splines of degree d on n distinct knots is $n+d+1$. If you have $n+d+1$ basis vectors, then you can fit a curve to your data by regressing your dependent variable by using this basis for the corresponding design matrix columns. In this context, such a spline is known as a regression spline. The EFFECT statement provides a simple mechanism for obtaining such a basis.

If you remove the restriction that the knots of a spline must be distinct and allow repeated knots, then you can obtain functions with less smoothness and even discontinuities at the repeated knot location. For a spline of degree d and a repeated knot with multiplicity $m \leq d$, the piecewise polynomials that join such a knot are required to have only $d-m$ matching derivatives. Note that this increases the number of free parameters by $m-1$ but also decreases the number of distinct knots by $m-1$. Hence the dimension of the vector space of splines of degree d with n knots is still $n+d+1$, provided that any repeated knot has a multiplicity less than or equal to d.

The EFFECT statement provides support for the commonly used *truncated power function* basis and *B-spline* basis. With exact arithmetic and by using the complete basis, you obtain the same fit with either of these bases. The following sections provide details about constructing spline bases for the space of splines of degree d with n knots that satisfies $k_1 \leq k_2 \leq k_3 < \cdots \leq k_n$.

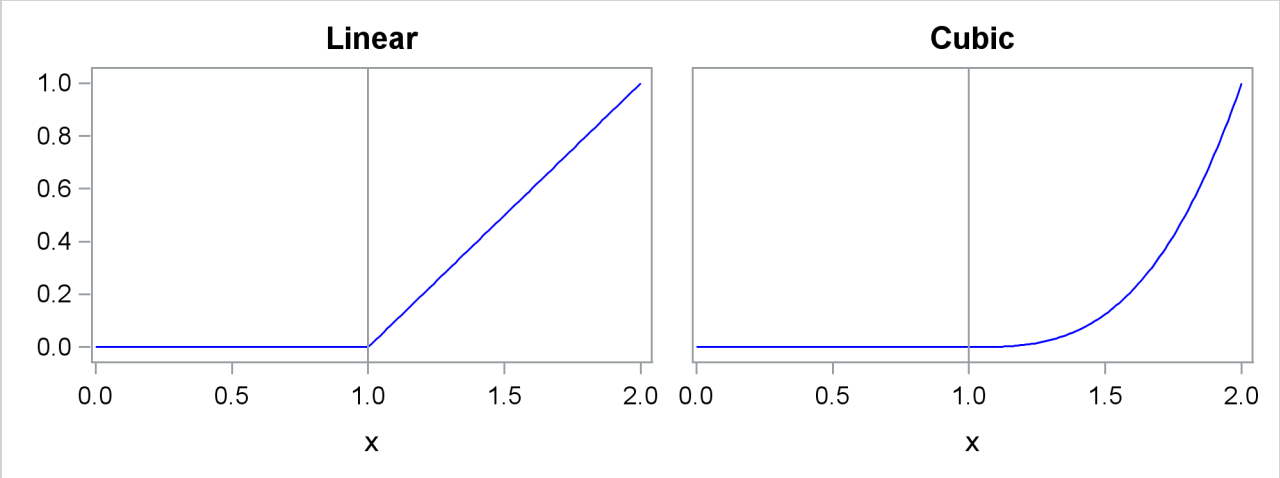
Truncated Power Function Basis

A truncated power function for a knot k_i is a function defined by

$$t_i(x) = \begin{cases} 0 & x < k_i \\ (x - k_i)^d & x \geq k_i \end{cases}$$

Figure 19.1 shows such functions for $d = 1$ and $d = 3$ with a knot at $x = 1$.

Figure 19.1 Truncated Power Functions with Knot at $x = 1$



The name is derived from the fact that these functions are shifted power functions that get truncated to zero to the left of the knot. These functions are piecewise polynomial functions with two pieces whose function values and derivatives of all orders up to $d - 1$ are zero at the defining knot. Hence these functions are splines of degree d. It is easy to see that these n functions are linearly independent. However, they do not form a basis, because such a basis requires $n + d + 1$ functions. The usual way to add $d + 1$ additional basis functions is to use the polynomials $1, x, x^2, \ldots, x^d$. These $d + 1$ functions together with the n truncated power functions $t_i(x), i = 1, 2, \ldots, n$ form the truncated power basis.

Note that each time a knot is repeated, the associated exponent used in the corresponding basis function is reduced by 1. For example, for splines of degree d with three repeated knots $k_i = k_{i+1} = k_{i+2}$ the corresponding basis functions are $t_i(x) = (x - k_i)_+^d$, $t_{i+1}(x) = (x - k_i)_+^{d-1}$, and $t_{i+2}(x) = (x - k_i)_+^{d-2}$. Provided that the multiplicity of each repeated knot is less than or equal to the degree, this construction continues to yield a basis for the associated space of splines.

The main advantage of the truncated power function basis is the simplicity of its construction and the ease of interpreting the parameters in a model that corresponds to these basis functions. However, there are two weaknesses when you use this basis for regression. These functions grow rapidly without bound as x increases, resulting in numerical precision problems when the x data span a wide range. Furthermore, many or even all of these basis functions can be nonzero when evaluated at some x value, resulting in a design matrix with few zeros that precludes the use of sparse matrix technology to speed up computation. This weakness can be addressed by using a B-spline basis.

B-Spline Basis

A B-spline basis can be built by starting with a set of Haar basis functions, which are functions that are 1 between adjacent knots and 0 elsewhere, and then applying a simple linear recursion relationship d times, yielding the $n + d + 1$ needed basis functions. For the purpose of building the B-spline basis, the n prespecified knots are referred to as internal knots. This construction requires d additional knots, known as boundary knots, to be positioned to the left of the internal knots, and MAX$(d, 1)$ boundary knots to be positioned to the right of the internal knots. The actual values of these boundary knots can be arbitrary. The EFFECT statement provides several methods for placing the needed boundary knots, including the common method of using repeated values of the data extremes as the boundary knots. The boundary knot placement affects the precise form of the basis functions that are generated, but it does not affect the following two desirable properties:

1. The B-spline basis functions are nonzero over an interval that spans at most $d + 2$ knots. This yields design matrix columns each of whose rows contain at most $d + 2$ adjacent nonzero entries.
2. The computation of the basis functions at any x value is numerically stable and does not require evaluating powers of this value.

The following figures show the B-spline bases defined on $[0, 1]$ with four equally spaced internal knots at 0.2, 0.4, 0.6, and 0.8.

Figure 19.2 shows a linear B-spline basis. Note that this basis consists of six functions each of which is nonzero over an interval that spans at most three knots.

Figure 19.2 Linear B-Spline Basis with Four Equally Spaced Interior Knots

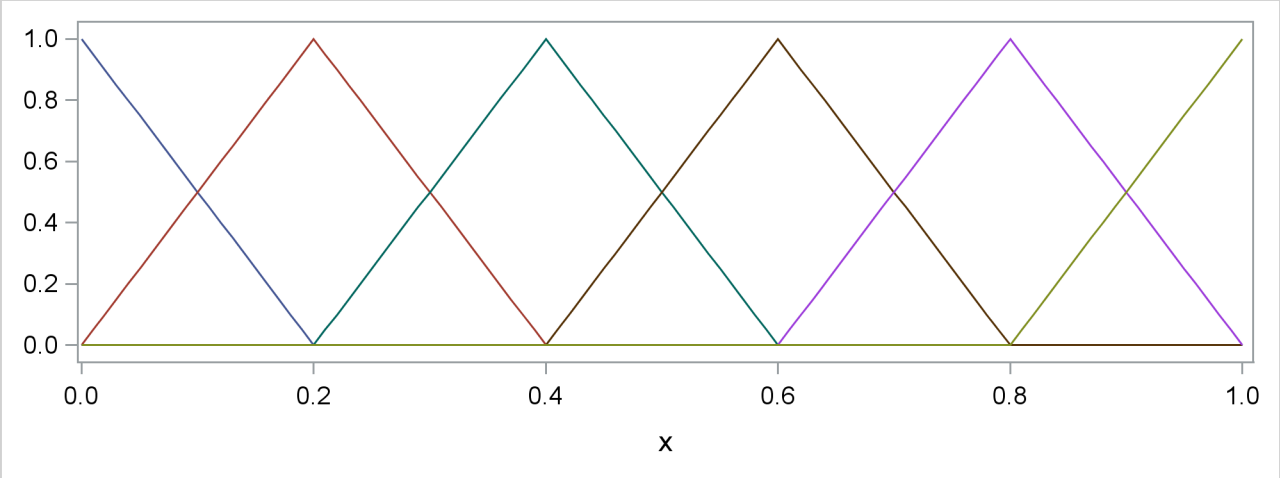


Figure 19.3 shows a cubic B-spline basis where the needed boundary knots are positioned at $x = 0$ and $x = 1$. Note that this basis consists of eight functions, each of which is nonzero over an interval spanning at most five knots.

Figure 19.3 Cubic B-Spline Basis with Four Equally Spaced Interior Knots

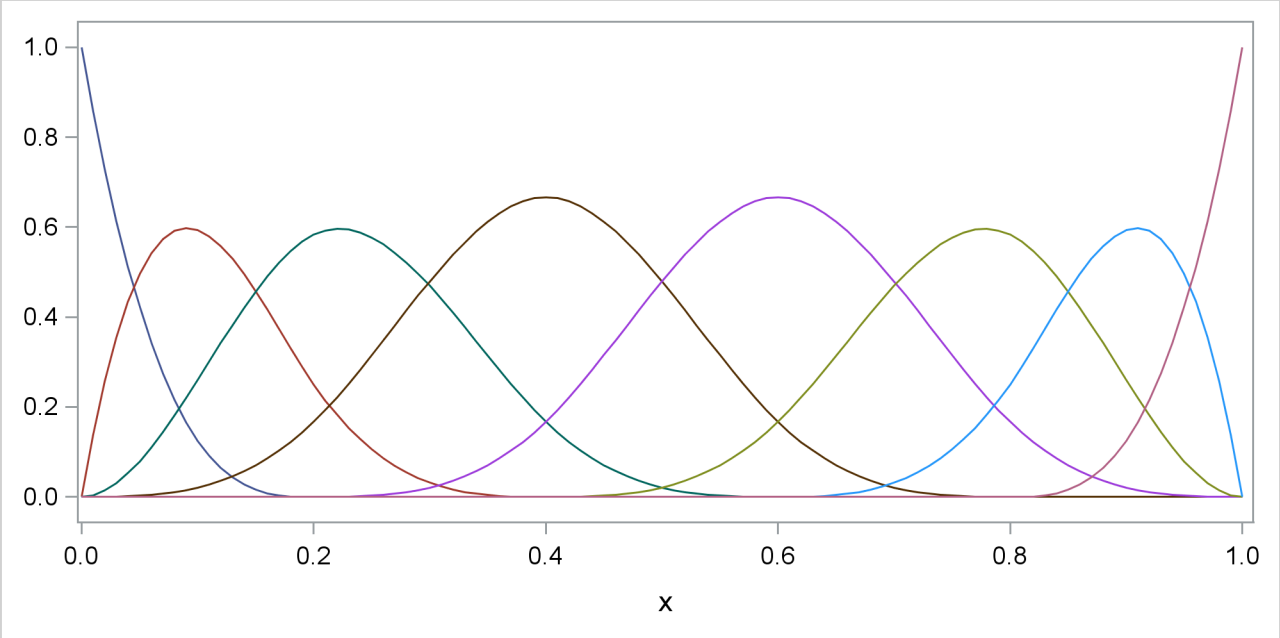

Figure 19.4 shows a different cubic B-spline basis where the needed left-side boundary knots are positioned at −0.6, −0.4, −0.2, and 0. The right-side boundary knots are positioned at 1, 1.2, 1.4, and 1.6. Note that, as in the basis shown in Figure 19.3, this basis consists of eight functions, each of which is nonzero over an interval spanning at most five knots. The different positioning of the boundary knots has merely changed the shape of the individual basis functions.

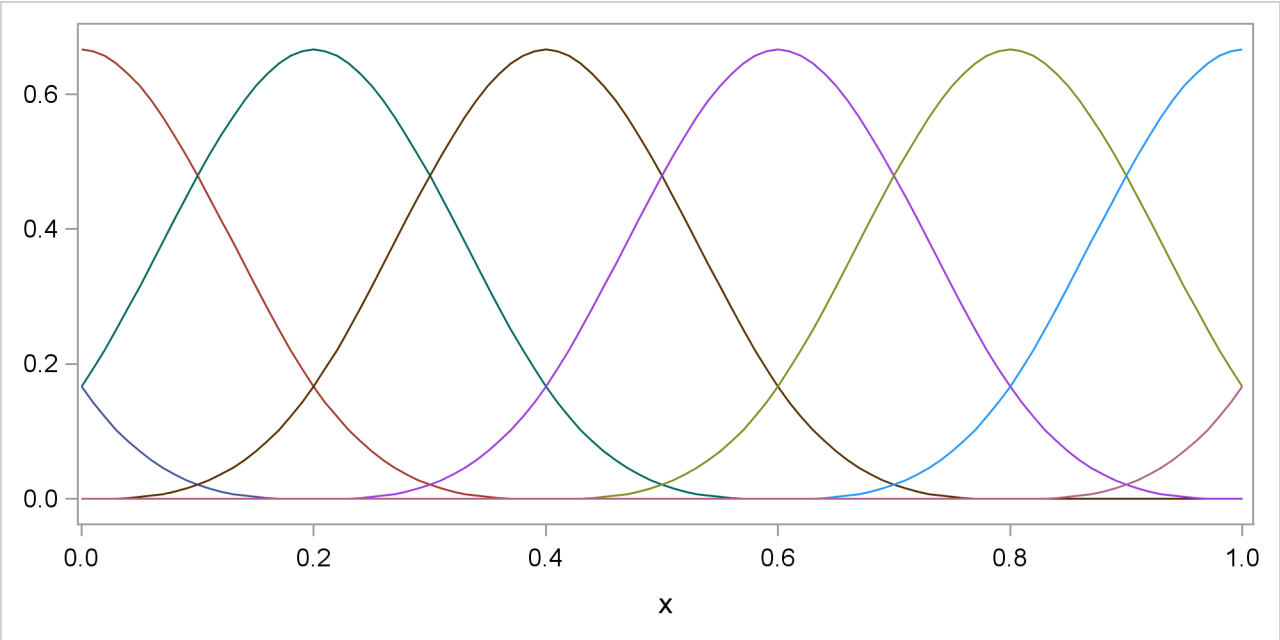
Figure 19.4 Cubic B-Spline Basis with Equally Spaced Boundary and Interior Knots

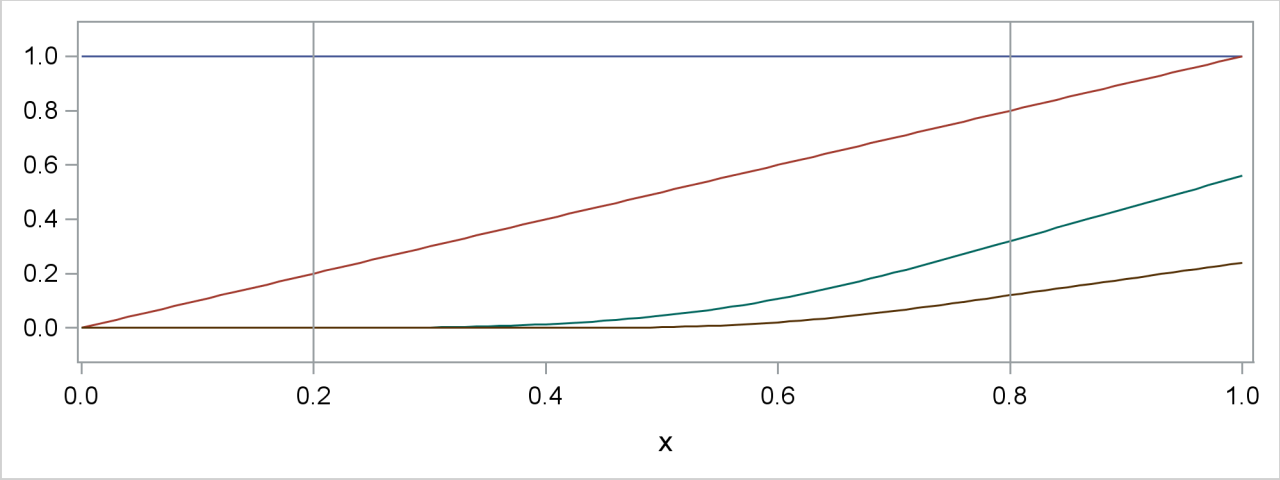


You can find details about this construction in Hastie, Tibshirani, and Friedman (2001).

Natural Cubic Spline Basis

Natural cubic splines are cubic splines with the additional restriction that the splines are required to be linear beyond the extreme knots. Some authors use the terminology "restricted cubic splines" in preference to the terminology "natural cubic splines." The space of unrestricted cubic splines on n knots has dimension $n + 4$. Imposing the restrictions that the cubic polynomials beyond the first and last knot reduce to linear polynomials reduces the number of degrees of freedom by 4, and so a basis for the natural cubic splines consists of n functions. Starting from the truncated power function basis for the unrestricted cubic splines, you can obtain a reduced basis by imposing linearity constraints. You can find details about this construction in Hastie, Tibshirani, and Friedman (2001). Figure 19.5 shows this natural cubic spline basis defined on $[0, 1]$ with four equally spaced internal knots at 0.2, 0.4, 0.6, and 0.8. Note that this basis consists of four basis functions that are all linear beyond the extreme knots at 0.2 and 0.8.

Figure 19.5 Natural Cubic Spline Basis with Four Equally Spaced Knots



EFFECTPLOT Statement

This statement applies to the following procedures:
GENMOD, LOGISTIC, ORTHOREG, and PLM.

The EFFECTPLOT statement produces a display (*effect plot*) of a complex fitted model and provides options for changing and enhancing the displays. One simple effect plot is the display for a linear regression of the response Y on a single predictor X: the regression line is drawn with the predicted response on the Y axis and the covariate on the X axis. The regression line can be enhanced by displaying the observations and adding confidence and prediction limits. When your model is more complicated—with more continuous and categorical covariates, nestings and interactions, and link functions—the effect plots display the behavior of some covariates over their ranges while fixing other covariates at some fixed values; this can enable easier interpretation and explanation of the resulting model.

By default, a single plot is produced based on the type of response variable and the number of continuous and classification covariates in the model. You can also specify options to do the following:

- select the variables to display on the plots
- produce multiple plots based on the following: the levels of classification covariates; the minimum, maximum, mean or middle (midrange) value of continuous covariates; and specified values of the covariates
- specify different fixed values for continuous and classification covariates that are not displayed on the plot
- panel and unpanel plots
- select variables to slice or group by
- display (or remove from display) observations and confidence limits

Syntax: EFFECTPLOT Statement

EFFECTPLOT < *plot-type*< *(plot-definition-options)* > >< / *options* > **;**

The available *plot-types* and their *plot-definition-options* are described in Table 19.11. Table 19.13 lists the *options* that can be specified after a slash (*/*) for any *plot-type*, and Table 19.14 lists additional *options* that enhance specific *plot-types*. Full descriptions of the *plot-definition-options* and the other *options* are provided in the section "Dictionary of Options" on page 427.

Table 19.11 *Plot-Types* and *Plot-Definition-Options*

Plot-Type and Description	Plot-Definition-Options
BOX Displays a box plot of continuous response data at each level of a CLASS effect, with predicted values superimposed and connected by a line. This is an alternative to the INTERACTION *plot-type*.	PLOTBY= variable or CLASS effect X= CLASS variable or effect
CONTOUR Displays a contour plot of predicted values against two continuous covariates.	PLOTBY= variable or CLASS effect X= continuous variable Y= continuous variable
FIT Displays a curve of predicted values versus a continuous variable.	PLOTBY= variable or CLASS effect X= continuous variable
INTERACTION Displays a plot of predicted values (possibly with error bars) versus the levels of a CLASS effect. The predicted values are connected with lines and can be grouped by the levels of another CLASS effect.	PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= CLASS variable or effect
SLICEFIT Displays a curve of predicted values versus a continuous variable grouped by the levels of a CLASS effect.	PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= continuous variable

By default, a single plot is produced based on the type of response variable and the number of continuous and classification covariates in the model as shown in Table 19.12. If you have a polytomous response model, then the response variable is treated as the grouping classification variable in this table. If your model does not fit into Table 19.12, then a default plot is not produced; however, specifying the *plot-type* argument displays a plot with the extra continuous covariates fixed at their mean values and the extra classification covariates fixed at their reference levels.

Table 19.12 Default *Plot-Types*

Number of Covariates		Type of Response Variable	
Classification	**Continuous**	**Continuous or Binary**	**Polytomous**
1	0	INTERACTION	INTERACTION with groups
2	0	INTERACTION with groups	None
0	1	FIT	SLICEFIT
0	2	CONTOUR	None
1	1	SLICEFIT	None

Table 19.13 and Table 19.14 list the *options* that can be specified after a slash (/) to enhance the effect plots.

Table 19.13 Available *Options* for All *Plot-Types*

AT<*args*>	ATLEN=	ATORDER=	ILINK	INDIVIDUAL*
LINK	MOFF	NCOLS=*	NOOBS*	NROWS=*
OBS<(*options*)>	PLOTBYLEN=	PREDLABEL=	UNPACK	

* Not available for the BOX *plot-type*

NOTE: If your model contains an offset variable and the MOFF option is not specified or not valid, then the predicted values are computed only at the observations. In this case, the FIT and SLICEFIT *plot-types* display scatter plots of the predicted values, the CONTOUR *plot-type* displays the residuals against two continuous covariates but with no fitted surface, the INTERACTION *plot-type* does not connect the predicted values with lines, and the BOX *plot-type* is unchanged.

Table 19.14 Additional *Options* for Each *Plot-Type*

	POLYBAR	YRANGE=		
SLICEFIT	ALPHA=	CLI	CLM	EXTEND=
	GRIDSIZE=	LIMITS	YRANGE=	

Dictionary of Options

This section describes the EFFECTPLOT *options* in alphabetical order.

ALPHA=*value*

specifies the significance level, $0 \leq value \leq 1$, for producing $100(1 - value/2)\%$ prediction and confidence limits. By default, *value*=0.05.

AT < *contopt* **> <** *classopt* **> <** *variable1*=*varopt* **<** *variable2*=*varopt*... **> >**

where *contopt*= **MEAN** | **MIN** | **MAX** | **MIDRANGE**

classopt= **ALL** | **REF**

varopt= *contopts* | *number-list* | *classopts* | *'class-level'...'class-level'*

specifies values at which to fix continuous and class variables when they are not used in X=, Y=, SLICEBY=, or PLOTBY= effects. The *contopt* keyword fixes continuous variables at their mean, minimum, maximum, or midrange= $\frac{1}{2}$(minimum + maximum); the default is to use the mean. The *classopt* keyword either fixes a CLASS variable at its reference (last) level or indicates that all levels of the CLASS variable should be processed; the default is to use the reference level. The *varopt* values

enable you to specify *contopt* and *classopt* keywords, or to specify lists of numbers or class levels. You can specify a CLASS variable only once in the AT specification, but you can specify a continuous variable multiple times; for example, the following syntax is valid when X is a continuous variable:

```
effectplot / at(x=min max x=0 to 2 by 1 x=2 5 7);
```

Duplicate AT values are suppressed, so the last X=2 value is ignored.

You can also specify *plug-in values* for CLASS variable levels when computing the predicted values $\boldsymbol{x}'\boldsymbol{\beta}$. For example, suppose a CLASS variable A with two levels={0,1} is in the model. Then instead of using the coding for A in the $\boldsymbol{x}$ vector by specifying **AT(A=all)**, **AT(A=ref)** or **AT(A='0' '1')**, you can specify a numeric list to plug in. For example, if the proportion of A's that equal 0 in the data set is 0.3, then you can input the proportions for all levels of the variable by specifying **AT(A=0.3 0.7)**. Under GLM coding, A=0 is coded as "1 0" and A=1 is coded as "0 1", so the plug-in specification replaces both of these codings with "0.3 0.7". Under REFERENCE coding A=0 is coded as "1" and A=1 is coded as "0", so this specification replaces both of these codings with "0.3" followed by "0.7"; however, if another variable is nested within A, then only "0.3" is used. To plug in values, you must specify a multiple of the number of parameters used for the CLASS variable or, if a variable is nested within the CLASS variable, a multiple of the number of levels of the CLASS variable.

The plug-in values are distributed through the rest of the model effects in the following fashion. If a variable is nested within a plug-in variable, then its coding is multiplied by the plug-in value for the level it is nested in. If a variable interacts with a plug-in variable, its coding is multiplied by the appropriate plug-in value for the level it is interacting with. Lag, multimember, polynomial, and spline constructed effects are affected only by interactions and nestings. If the plug-in variable is part of a collection effect, then its values are replaced by the plug-in values; collection effects are also affected by interactions and nestings.

The AT levels are used for computing the predicted values. If the OBS option is also specified, then all observations are still displayed on all of the plots. For example, if you specify the options **AT(A='1') OBS**, then the fitted values are computed with A=1, but all of the observations are displayed with their predicted values computed at their observed level of A. If you want to display only a subset of the observations based on the levels of a CLASS variable, then you must specify either the PLOTBY= option or the OBS(BYAT) option.

ATLEN=*n*

specifies the maximum length ($1 \le n \le 256$) of the levels of the AT variables that are displayed in footnotes and headers. By default, up to 256 characters of the CLASS levels are displayed, and the continuous AT levels are displayed with a BEST format that has a width greater than or equal to 5, which distinguishes each level. **CAUTION:** If the levels of your AT variables are not unique when the first *n* characters are displayed, then the levels are combined in the plots but not in the underlying computations. Also, at most *n* characters for continuous AT variables are displayed.

ATORDER=ASCENDING | DESCENDING

uses the AT values for continuous variables in ascending or descending order as specified. By default, values are used in the order of their first appearance in the AT option.

CLI

displays normal (Wald) prediction limits. This option is available only for normal distributions with identity links. If your model is from a Bayesian analysis, then sampling-based intervals are computed; see the section "Analysis Based on Posterior Estimates" on page 5645 in Chapter 68, "The PLM Procedure," for more information.

CLM

displays confidence limits. These are computed as the normal (Wald) confidence limits for the linear predictor, and if the ILINK option is specified, the limits are also back-transformed by the inverse link function. If your model is from a Bayesian analysis, then sampling-based intervals are computed; see the section "Analysis Based on Posterior Estimates" on page 5645 in Chapter 68, "The PLM Procedure," for more information.

CLUSTER

modifies the BOX *plot-type* by displaying a box plot for each level of the SLICEBY= classification variable.

EXTEND=DATA | *value*

extends continuous covariate axes by $value \times \frac{1}{2} range$ in both directions, where *range* is the range of the X axis. Specifying the DATA keyword displays curves to the range of the data within the appropriate SLICEBY=, PLOTBY=, and AT level. For the CONTOUR *plot-type*, *value*=0.05 by default; other *plot-types* set the default value to 0. When constructed effects are present, only the EXTEND=DATA option is available.

GRIDSIZE=*n*

specifies the resolution of curves by computing the predicted values at n equally spaced x-values and specifies the resolution of surfaces by computing the predicted values on an $n \times n$ grid of points. Default values are n=200 for curves and bands, n=50 for surfaces, and n=2 for lines. If results of a Bayesian or bootstrap analysis are being displayed, then the defaults are n=500000/B, where B is the number of samples, the upper limit is equal to the usual defaults, and the lower limit equal to 20.

ILINK

displays the fit on the scale of the inverse link function. In particular, the results are displayed on the probability scale for logistic regression. By default, a procedure displays the fit on either the link or inverse link scale.

INDIVIDUAL

displays individual probabilities for polytomous response models with cumulative links on the scale of the inverse link function. This option is not available when the LINK option is specified, and confidence limits are not available with this option.

LIMITS

invokes the CLI and CLM options.

LINK

displays the fit on the scale of the link function; that is, the linear predictor. Note that probabilities or observed proportions near 0 and 1 are transformed to ± 20. By default, a procedure displays the fit on either the link or inverse link scale.

MOFF

moves the offset for a Poisson regression model to the response side of the equation. If the ILINK option is also in effect, then the rate is displayed on the Y axis, while the LINK option displays the log of the rate on the Y axis. Without this option, the predicted values are computed and displayed only for the observations.

NCOLS=*n*

specifies the maximum number of columns in a paneled plot. This option is not available with the BOX *plot-type*.

The default choice of NROWS= and NCOLS= is based on the number of PLOTBY= and AT levels. If there is only one plot being displayed in a panel, then NROWS=1 and NCOLS=1 and the plots are produced as if you specified only the UNPACK option. If only two plots are displayed in a panel, then NROWS=1 and NCOLS=2. For all other cases, a 2x2, 2x3, or 3x3 panel is chosen based on how much of the last panel is used, with ties going to the larger panels. For example, if 14 plots are being created, then this requires either four 2x2 panels with 50% of the last panel filled, three 2x3 panels with 33% of the last panel filled, or two 3x3 panels with 55% of the last panel filled; in this case, the 3x3 panels are chosen.

If you specify both of the NROWS= and NCOLS= options, then those are the values used. However, if you only specify one of the options but have fewer plots, then the panel size is reduced; for example, if you specify NROWS=6 but only have four plots, then a plot with four rows and one column is produced.

NOCLI

suppresses the prediction limits.

NOCLM

suppresses the confidence limits.

NOLIMITS

invokes the NOCLI and NOCLM options.

NOOBS

suppresses the display of observations and overrides the specification of the OBS= option.

NROWS=*n*

specifies the maximum number of rows in a paneled plot. This option is not available with the BOX *plot-type*. See the NCOLS= option for more details.

OBS< (*options***) >**

displays observations on the effect plots. An input data set is required; hence the OBS option is not available with PROC PLM. The OBS option is overridden by the NOOBS option. When the ILINK option is specified with binary response variables, then either the observed proportions or a coded value of the response is displayed. For polytomous response variables, the observed values are overlaid onto the fitted curves unless the LOCATION= option is specified. Whether observations are displayed by default or not depends upon the procedure. If the PLOTBY= option is specified, then the observations displayed on each plot are from the corresponding PLOTBY= level for classification effects; for continuous effects, all observations are displayed on every plot.

The following *options* are available:

BYAT subsets the observations by AT level and by the PLOTBY= level. If you specify the PLOTBY= option without specifying this option, the observations are displayed on the plots that correspond to their PLOTBY= level without regard to any classification variables specified in the AT option. However, for FIT *plot-types* a distance can be computed and displayed (see the DISTANCE option for more information). This option is ignored when there are no AT variables.

CDISPLAY=NONE | OUTLINE | GRADIENT | OUTLINEGRADIENT controls the display of observations on contour plots. The keyword OUTLINE displays the observations as circles, GRADIENT displays gradient-colored dots, OUTLINEGRADIENT displays gradient-filled-circles, and NONE suppresses the display of the observations. The default is CDISPLAY=OUTLINEGRADIENT.

CGRADIENT=RESIDUAL | DEPENDENT specifies what the gradient-shading of the observed values on the CONTOUR *plot-type* represents. The RESIDUAL keyword shades the observations by the raw residual value and displays the fitted surface as a line contour plot. The DEPENDENT keyword shades the observations by the response variable value and displays the fitted surface as a contour shaded on the same scale. The default is CGRADIENT=DEPENDENT.

DEPTH=*depth* specifies the number of overlapping observations that can be distinguished by adjusting their transparency; you can specify $1 \leq depth \leq 100$. By default, DEPTH=1. The DEPTH= option is available with FIT, SLICEFIT, and INTERACTION *plot-types*.

DISTANCE displays observations on FIT *plot-types* with a color-gradient that indicates how far the observation is from the AT and PLOTBY= level. This option is ignored unless an AT or PLOTBY= option is specified.

The distance is computed as the square root of the following number: for each continuous AT and PLOTBY= variable, add the square of the difference from the observed value divided by the range of the variable; for each CLASS AT and PLOTBY= variable, add 1 if the CLASS levels are different. Thus the largest possible distance is the square root of the number of AT and PLOTBY= variables. Observations at zero distance are displayed with the darkest color, and the color fades as the distance increases.

Note that the UNPACKed panels compute the maximum distance within each panel and hence do not use the same gradient across all panels. Also, the PANELS *panel-type* computes the maximum distance within each PLOTBY= level, so a different gradient is used for each PLOTBY= level. All other *panel-types* compute the maximum distance across all observations and therefore use the same gradient on every plot.

FITATCLASS computes fitted values only for class levels that are observed in the data set. This option is ignored when the GLM parameterization is used.

FRINGE displays observations in a fringe (rug) plot at the bottom of the plot. This option is available only with FIT and SLICEFIT *plot-types*.

JITTER<(*options***)>** shifts (*jitters*) the observations. By default, the jittering in the X direction is achieved by adding a random number that is generated according to a normal distribution with mean=0 and standard deviation= $jitter/2$ and truncating at $\pm jitter$, where *jitter*=0.01 times the range of the X axis; the jittering in the Y direction is performed independently

but in the same fashion. The JITTER option is not available with the BOX *plot-type*. The following *options* are available:

FACTOR=*factor* sets the jitter to *factor* times the range of the axis, and jitters in both the X and Y directions. You can specify $0 \leq factor \leq 1$.

SEED=*seed* specifies an integer to use as the initial seed for the random number generator. If you do not specify a seed, or if you specify a value less than or equal to zero, then the time of day from the computer clock is used to generate an initial seed.

X=*x-jitter* sets the jitter to *x-jitter* for the X direction; the jitter in the Y direction is assumed to be 0 unless the Y= option is also specified. You can specify $x\text{-}jitter \geq 0$. The X= option is not available for the INTERACTION *plot-type*. This option is ignored if the FACTOR= option is also specified.

Y=*y-jitter* sets the jitter to *y-jitter* for the Y direction; the jitter in the X direction is assumed to be 0 unless the X= option is also specified. You can specify $y\text{-}jitter \geq 0$. This option is ignored if the FACTOR= option is also specified.

LABEL<=OBS> labels markers with their observation number.

LOCATION=*location* specifies where the observed values for polytomous response models are displayed when the SLICEBY= variable is the response. This option is available only with the SLICEFIT and INTERACTION *plot-types*. The observations are always displayed at their appropriate X-axis value, but their Y-axis location can depend on the specification of the YRANGE= option or on the minimum and maximum computed predicted values in addition to the specified *location*. The following *locations* are available:

BOTTOM<=*factor*> displays the first response level at the minimum predicted value, and displays succeeding response levels above the first level at $factor \times range$ intervals, where *range* is the range of the predicted values. You can specify $0 \leq factor \leq 1$, but the largest usable value, which corresponds to LOCATION=SPREAD, is $factor = \frac{1}{k}$, where $k + 1$ is the number of response levels that are displayed. By default, $factor = 0.03$.

CURVE displays the observations for polytomous response models at their predicted values. For displays on the LINK scale, the reference level is displayed at the maximum value. This method is the default.

FIRST displays the observations for a response level at the first displayed predicted value for that response level.

MAX displays the observations for a response level at the maximum displayed predicted value for that response level.

MIDDLE displays the observations for a response level at the middle of the displayed predicted values for that response level.

MIN displays the observations for a response level at the minimum displayed predicted value for that response level.

SPREAD displays the observations with the response levels evenly spread across the Y axis.

TOP<=*factor*> displays the last response level at the maximum predicted value, and displays preceding response levels below the last level at *factor*×*range* intervals, where *range* is the range of the predicted values. You can specify $0 \leq factor \leq 1$, but the largest usable value, which corresponds to LOCATION=SPREAD, is $factor = \frac{1}{k}$, where $k+1$ is the number of response levels that are displayed. By default, $factor = 0.03$.

PLOTBY<*(panel-type)*>=*effect*<=*numeric-list*>
specifies a variable or CLASS effect at whose levels the predicted values are computed and the plots are displayed. You can specify the response variable as the *effect* for polytomous response models. The *panel-type* argument specifies the method in which the plots are grouped for the display. The following *panel-types* are available.

COLUMNS specifies that the columns within each panel correspond to different levels of the PLOTBY= effect and hence the rows correspond to different AT levels.

PACK specifies that plots be displayed in the panels as they are produced with no control over the placement of the PLOTBY= and AT levels.

PANELS | LEVELS specifies that each level of the PLOTBY= effect begin a new panel of plots and the AT levels define the plots within the panels.

ROWS specifies that the rows within each panel correspond to different levels of the PLOTBY= effect and hence the columns correspond to different AT levels.

This option is ignored with the BOX *plot-type*; box plots are always displayed in an unpacked fashion, grouped by the PLOTBY= and AT levels. If you specify a continuous variable as the *effect*, then you can either specify a *numeric-list* of values at which to display that variable or, by default, five equally spaced values from the minimum variable value to its maximum are displayed.

The default *panel-type* is based on the number of PLOTBY= and AT levels as shown in the following table.

Number of PLOTBY Levels	Number of AT Levels	Resulting *panel-type*
1	1	(UNPACK)
>1	1	PACK
1	>1	PACK
2	>1	ROWS
3	>1	COLUMNS
>3	>1	PANELS

The default dimensions of the panels are also based on the number of PLOTBY= and AT levels; see the NCOLS= option for details.

Specification of the *panel-type* is honored except in the following cases. If you specify a *panel-type* but produce only one plot, specify the NROWS=1 and NCOLS=1 options, or specify the UNPACK option, then the plots are produced as if you specified only the UNPACK option. If you specify the PANELS *panel-type* with only one AT level, then the plots are produced with the UNPACK option.

However, if you specify the PANELS *panel-type* but the PLOTBY= effect has only one level, then the *panel-type* is changed to PACK.

PLOTBYLEN=*n*

specifies the maximum length ($1 \leq n \leq 256$) of the levels of the PLOTBY= variables, which are displayed in footnotes and headers. By default, up to 256 characters of the CLASS levels are displayed. **CAUTION:** If the levels of your PLOTBY= variables are not unique when the first *n* characters are displayed, then the levels are combined in the plots but not in the underlying computations.

POLYBAR

displays polytomous response data as a stacked histogram with bar heights defined by the individual predicted value. Your response variable must be the *effect* specified in the SLICEBY= option. If you specify the INDIVIDUAL option, then the histogram bars are displayed in a side-by-side fashion. If you specify the CLM option, then error bars are displayed on the side-by-side histogram bars.

PREDLABEL=*'label'*

specifies a label to be displayed on the Y axis. The default Y axis label is determined by your model. For the CONTOUR *plot-type*, this option changes the title to "*label* for Y."

SHOWCLEGEND

displays the gradient-legend for the CONTOUR *plot-type*. This option has no effect when the OBS(CGRADIENT=RESIDUAL) option is also specified.

SLICEBY=NONE | *effect*< *=numeric-list*>

displays the fitted values at the different levels of the specified variable or CLASS effect. You can specify the response variable as the *effect* for polytomous response models. Use this option to modify SLICEFIT, INTERACTION, and BOX *plot-types*. If you specify a continuous variable as the *effect*, then you can either specify a *numeric-list* of values at which to display that variable or, by default, five equally spaced values from the minimum variable value to its maximum are displayed. The NONE keyword is available for preventing the INTERACTION *plot-type* from slicing by a second class covariate. Note that the SLICEBY=NONE option is not available for the SLICEFIT *plot-type*, since that is the same as the FIT *plot-type*. The BOX *plot-type* accepts only classification effects.

SMOOTH

overlays a loess smooth on the FIT *plot-type* for models that have only one continuous predictor. This option is not available for binary or polytomous response models.

UNPACK

suppresses paneling. By default, multiple plots can appear in some output *panels*. Specify UNPACK to display each plot separately.

X=*effect*

specifies values to display on the X axis. For BOX and INTERACTION *plot-types*, *effect* can be a CLASS effect in the MODEL statement. For FIT, SLICEFIT, and CONTOUR *plot-types*, *effect* can be any continuous variable in the model.

Y=*args*

specifies values to display on the Y axis for the CONTOUR *plot-type*. The Y= argument can be any continuous variable in the model.

YRANGE=CLIP | (< *min* **><** *,max* **>)**

displays the predicted values on the Y axis in the range [*min*,*max*]. The YRANGE=CLIP option has the same effect as specifying the minimum predicted value as *min* and the maximum predicted value as *max*. The axis might extend beyond your specified values. By default, when the Y axis displays predicted probabilities, the entire Y axis, [0,1], is displayed. This option is useful if your predicted probabilities are all contained in some subset of this range. This option is not available with the CONTOUR *plot-type*.

ODS Graphics: EFFECTPLOT Statement

To produce the EFFECTPLOT displays, ODS Graphics must be enabled. For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." The available graph names are provided in Table 19.15.

Table 19.15 Graphs Produced by the EFFECTPLOT Statement

ODS Graph Name	Plot Description
BoxFitPlot	A box plot of the responses at each level of one classification effect, overlaid with a plot of the predicted values
ContourFitPlot	A contour plot of the fitted surface against two continuous covariates
ContourFitPanel	A panel of ContourFitPlots
FitPlot	A curve of the predicted values plotted against one continuous covariate
FitPanel	A panel of FitPlots
InteractionPlot	A plot of the predicted values (connected by a line) against one classification effect, possibly for each level of a second classification effect
InteractionPanel	A panel of InteractionPlots
SliceFitPlot	A curve of the predicted values against one continuous covariate for each level of a second classification covariate
SliceFitPanel	A panel of SliceFitPlots

Examples: EFFECTPLOT Statement

Example 19.1: A Saddle Surface

Myers (1976) analyzes an experiment reported by Frankel (1961) which is aimed at maximizing the yield of mercaptobenzothiazole (MBT) by varying processing time and temperature. Myers uses a two-factor model in which the estimated surface does not have a unique optimum. The objective is to find the settings of time and temperature in the processing of a chemical that maximize the yield. The following statements create the data set d:

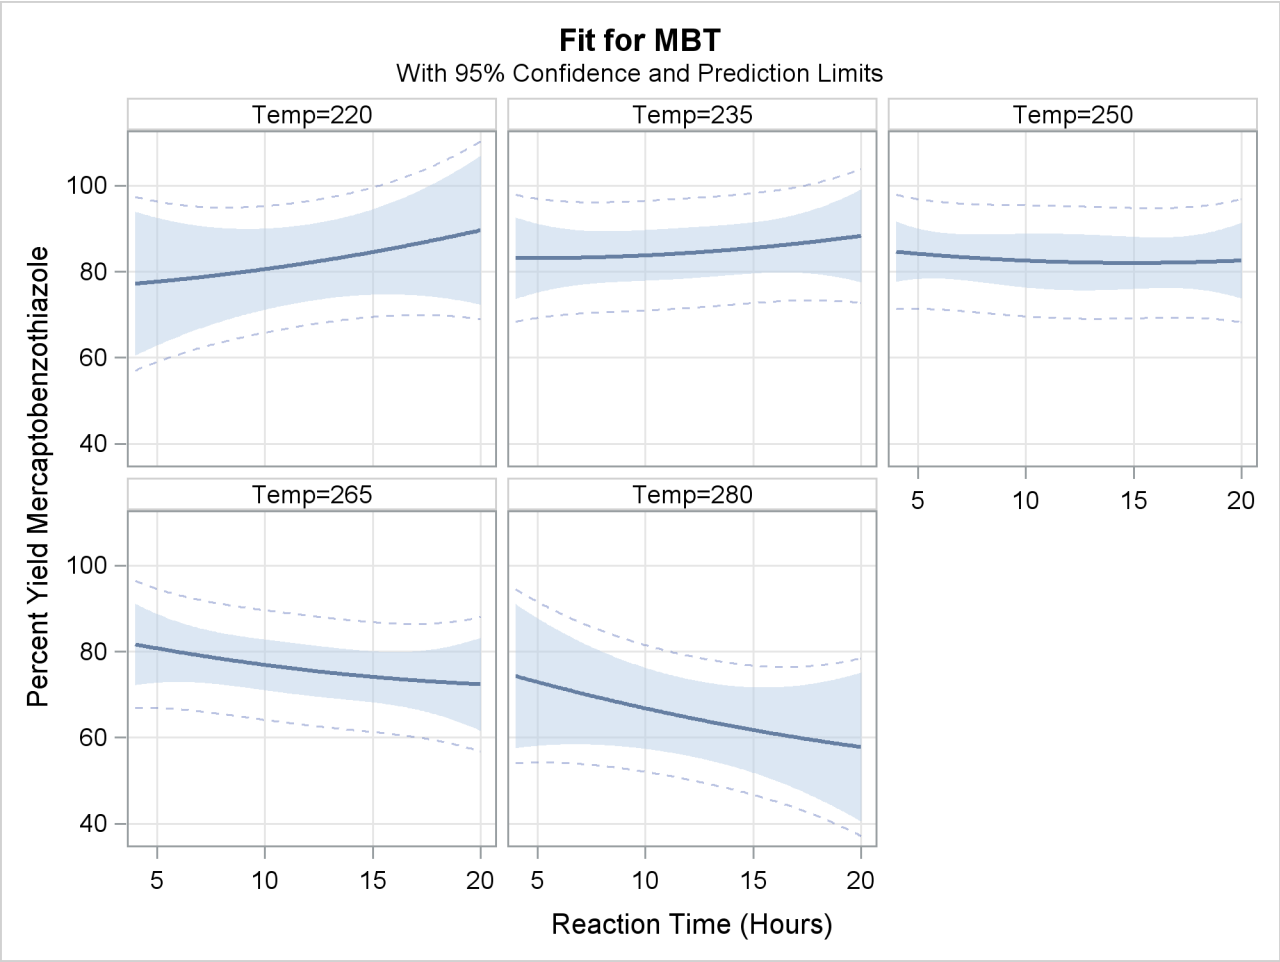
```
data d;
   input Time Temp MBT @@;
   label Time = "Reaction Time (Hours)"
         Temp = "Temperature (Degrees Centigrade)"
         MBT  = "Percent Yield Mercaptobenzothiazole";
   datalines;
 4.0  250  83.8    20.0  250  81.7    12.0  250  82.4
12.0  250  82.9    12.0  220  84.7    12.0  280  57.9
12.0  250  81.2     6.3  229  81.3     6.3  271  83.1
17.7  229  85.3    17.7  271  72.7     4.0  250  82.0
;
```

In the following statements, the ORTHOREG procedure fits a response surface regression model to the data and uses the EFFECTPLOT statement to create a slice of the response surface. The FIT *plot-type* requests plots of the predicted yield against the Time variable, and the PLOTBY= option specifies that the Temp variable is fixed at five equally spaced values so that five fitted regression curves are displayed in Output 19.1.1.

```
ods graphics on;
proc orthoreg data=d;
   model MBT=Time|Time|Temp|Temp@2;
   effectplot fit(x=time plotby=temp);
run;
ods graphics off;
```

The displays in Output 19.1.1 show that the slope of the surface changes as the temperature increases.

Output 19.1.1 Panel of Fit Plots

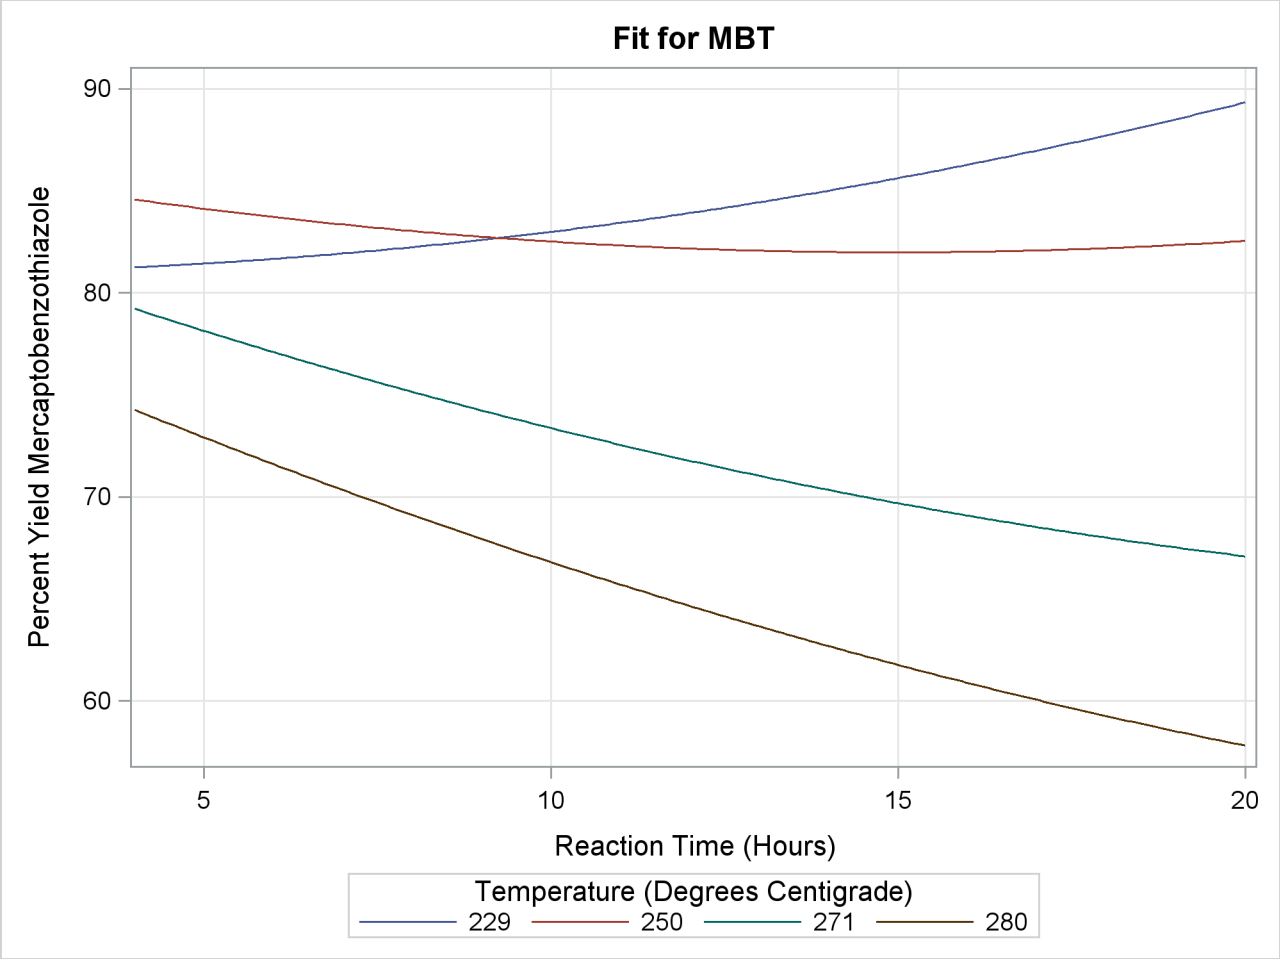


It might be more informative to see these results in one graphic, so the following statements specify the SLICEFIT *plot-type* to overlay plots of the predicted yield versus time, fixed at several values of temperature. In this case, the SLICEBY= option is specified to explicitly use the same four temperatures as used in the experiment.

```
ods graphics on;
proc orthoreg data=d;
   model MBT=Time|Time|Temp|Temp@2;
   effectplot slicefit(x=time sliceby=temp=229 250 271 280);
run;
ods graphics off;
```

Output 19.1.2 shows that you should choose either low temperatures and long times to optimize the yield, or maybe high temperatures and short times.

Output 19.1.2 Fit Plot Grouped (Sliced) by Temp

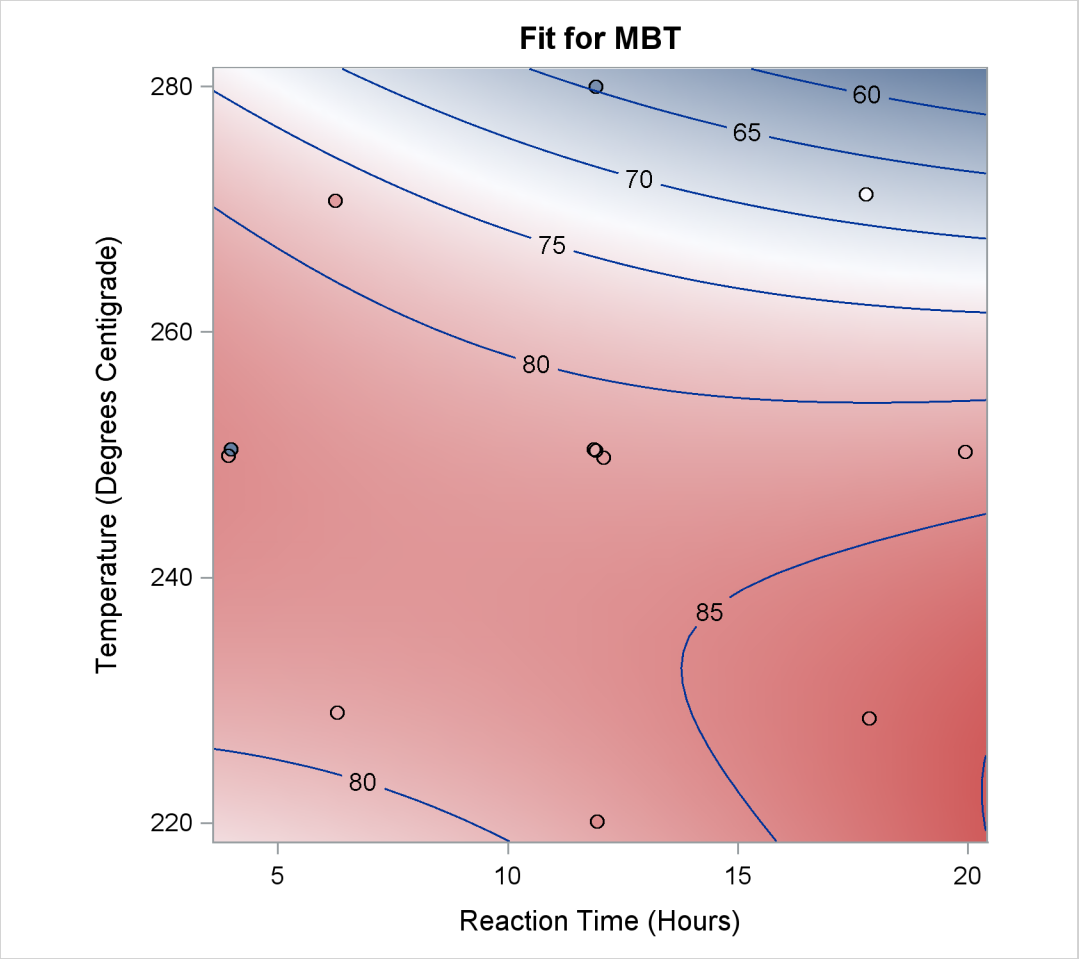


Another plot might explain the reason for this more clearly. The following statements produces the default EFFECTPLOT statement display, enhanced by the OBS(JITTER) option to jitter the observations so that you can see the replicated points.

```
ods graphics on;
proc orthoreg data=d;
   model MBT=Time|Time|Temp|Temp@2;
   effectplot / obs(jitter);
run;
ods graphics off;
```

Output 19.1.3 shows the reason for the changing slopes is that the surface is at a saddle point. This surface does not have an optimum point.

Output 19.1.3 Contour Fit Plot with Jittered Observations



Example 19.2: Unbalanced Two-Way ANOVA

This example uses data from Kutner (1974, p. 98) to illustrate a two-way analysis of variance. The original data source is Afifi and Azen (1972, p. 166). The following statements create the data set a:

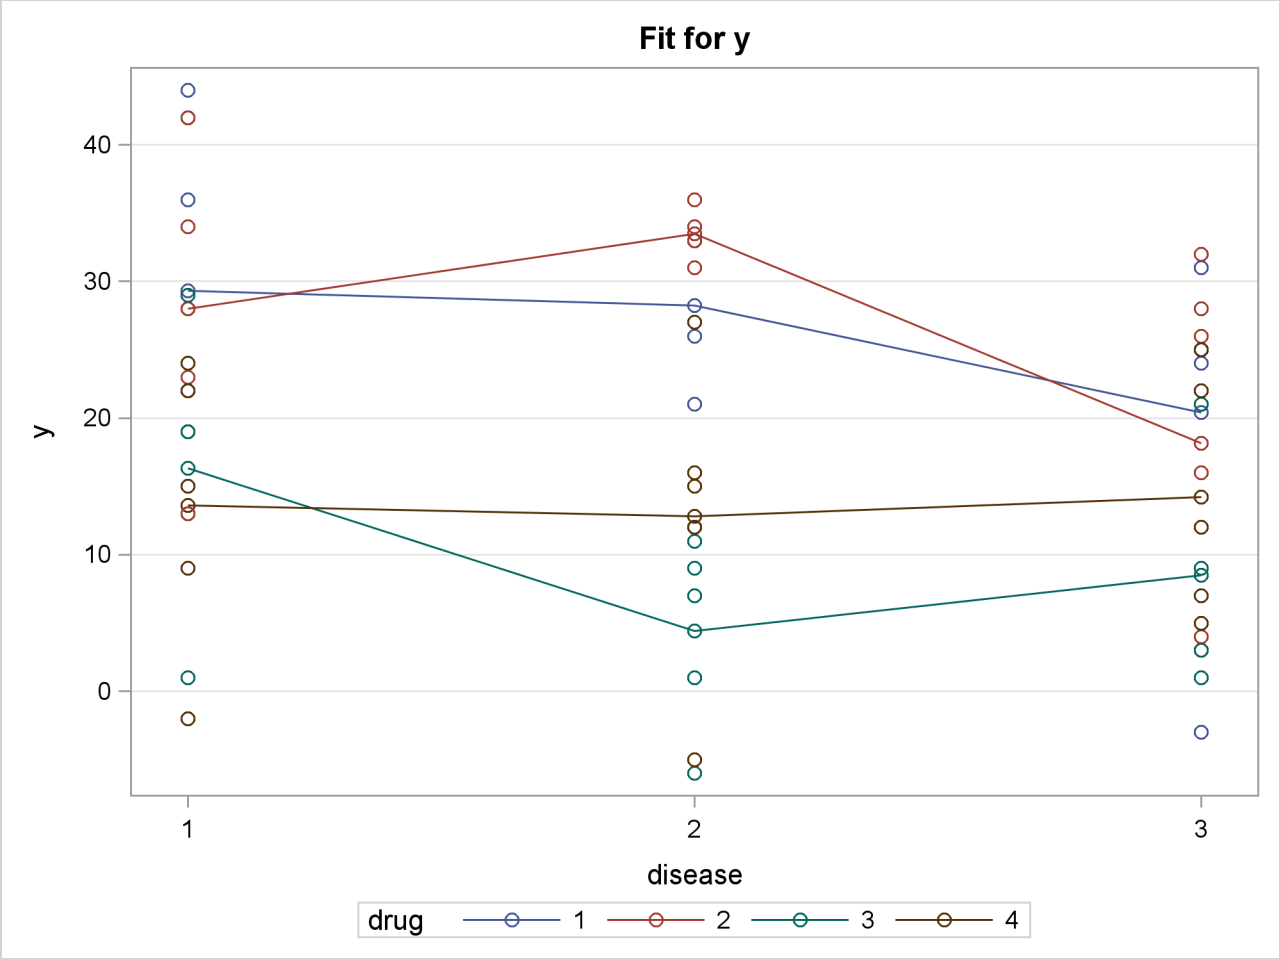
```
data a;
   input drug disease @;
   do i=1 to 6;
      input y @;
      output;
   end;
   datalines;
1 1 42 44 36 13 19 22
1 2 33  . 26  . 33 21
1 3 31 -3  . 25 25 24
2 1 28  . 23 34 42 13
2 2  . 34 33 31  . 36
2 3  3 26 28 32  4 16
3 1  .  .  1 29  . 19
3 2  . 11  9  7  1 -6
3 3 21  1  .  9  3  .
4 1 24  .  9 22 -2 15
4 2 27 12 12 -5 16 15
4 3 22  7 25  5 12  .
;
```

In the following statements, PROC GENMOD fits two classification variables and their interaction to Y. The first EFFECTPLOT statement displays the default graphic, which plots the predicted values against Disease for each of the three Drug levels. The OBS option also displays the observations on the plot. The second EFFECTPLOT statement modifies the default to plot the predicted values against Drug for each of the three Disease levels. The CLM option is specified to produce 95% confidence bars for the means.

```
ods graphics on;
proc genmod data=a;
   class drug disease;
   model y=disease drug disease*drug / d=n;
   effectplot / obs;
   effectplot interaction(sliceby=disease) / clm;
run;
ods graphics off;
```

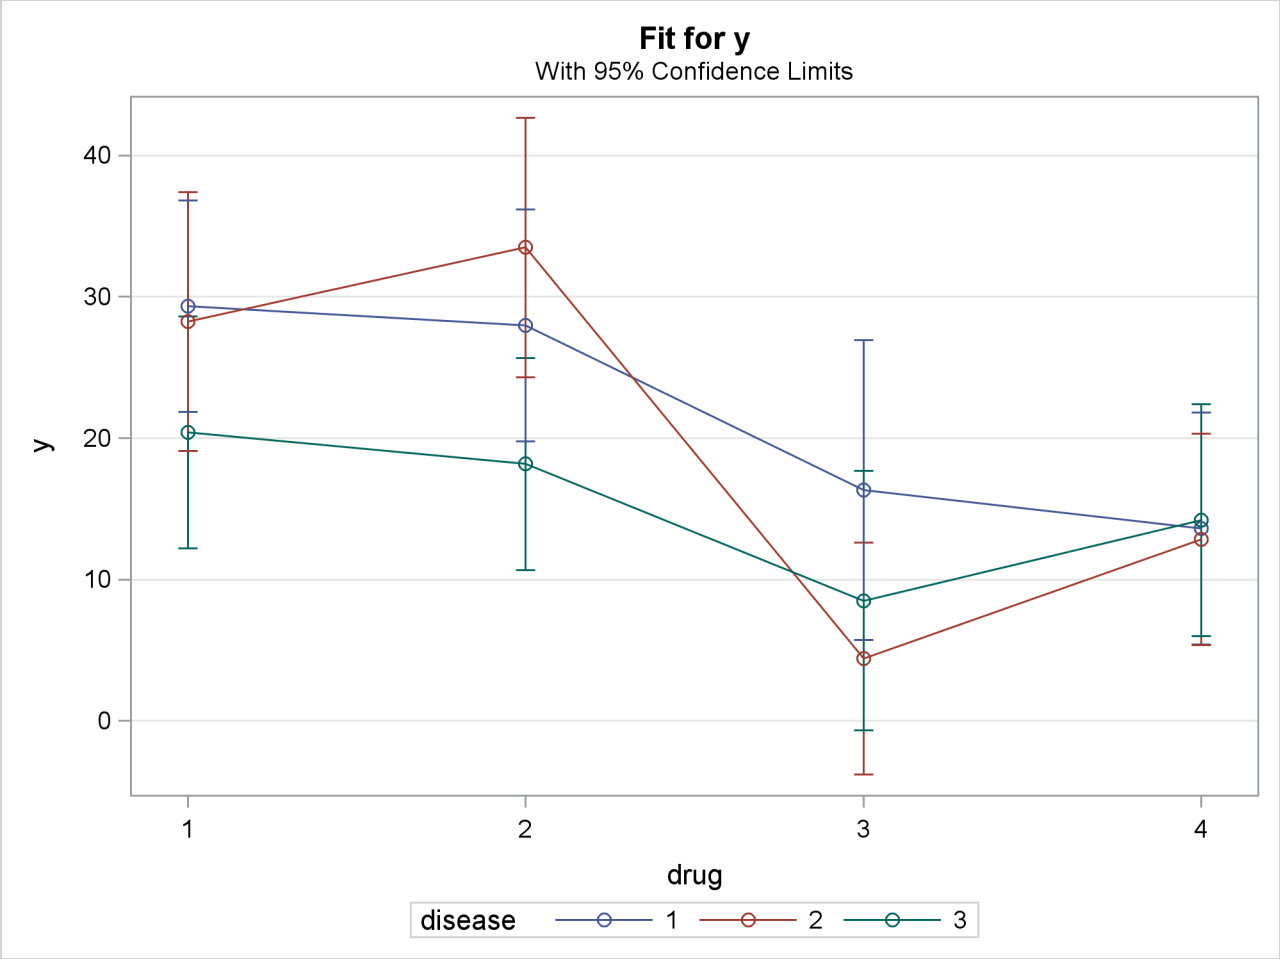
In Output 19.2.1, the default interaction plot is produced, and the observations are also displayed. From this plot, you can compare the performance of the drugs for a given disease . The predicted values are connected with a line to provide something for your eye to follow—obviously a line has no intrinsic meaning in this graphic. Drugs 3 and 4 are consistently outperformed by the first two drugs.

Output 19.2.1 Interaction Plot: Default with Observations



By default, the first classification variable is displayed on the X axis and the second classification variable is used for grouping. Specifying the SLICEBY=DISEASE option in the second EFFECTPLOT statement reverses this, displays the classification variable with the most levels on the X axis, and slices by fewer levels, resulting in a more readable display. Output 19.2.2 shows how well a given drug performs on each disease.

Output 19.2.2 Interaction Plot with Specified SLICEBY= Effect

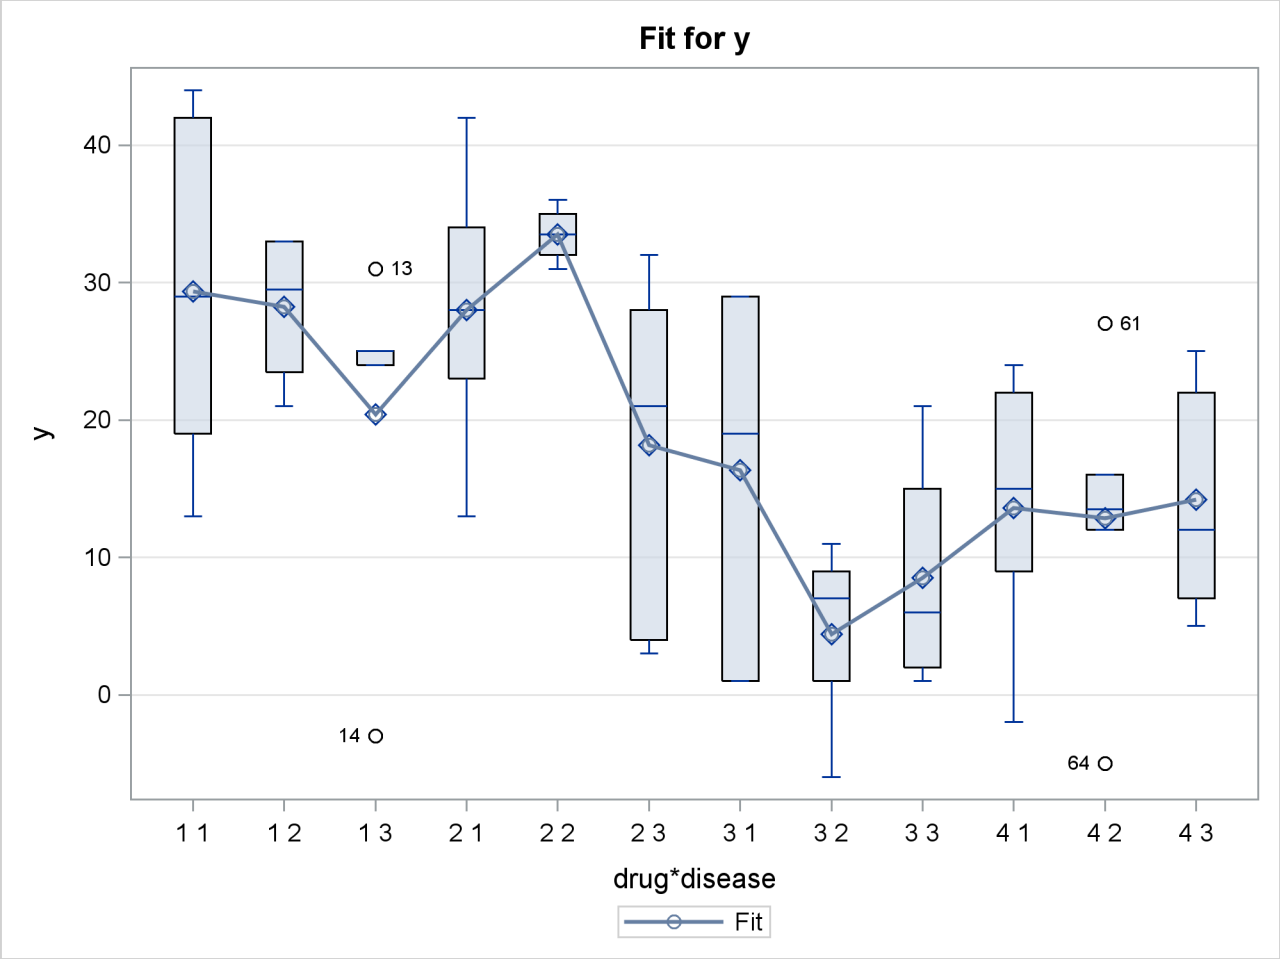


In the following statements, the BOX *plot-type* is requested to display box plots of the predictions by each drug and disease combination. The second EFFECTPLOT statement displays the same information by using an INTERACTION *plot-type* and specifies the OBS option to display the individual observations. The third EFFECTPLOT statement creates an interaction plot of predictions versus drug for each of the Disease levels, and displays them in a panel.

```
ods graphics on;
proc genmod data=a;
   class drug disease;
   model y=drug disease drug*disease / d=n;
   effectplot box;
   effectplot interaction(x=drug*disease) / obs;
   effectplot interaction(plotby=disease);
run;
ods graphics off;
```

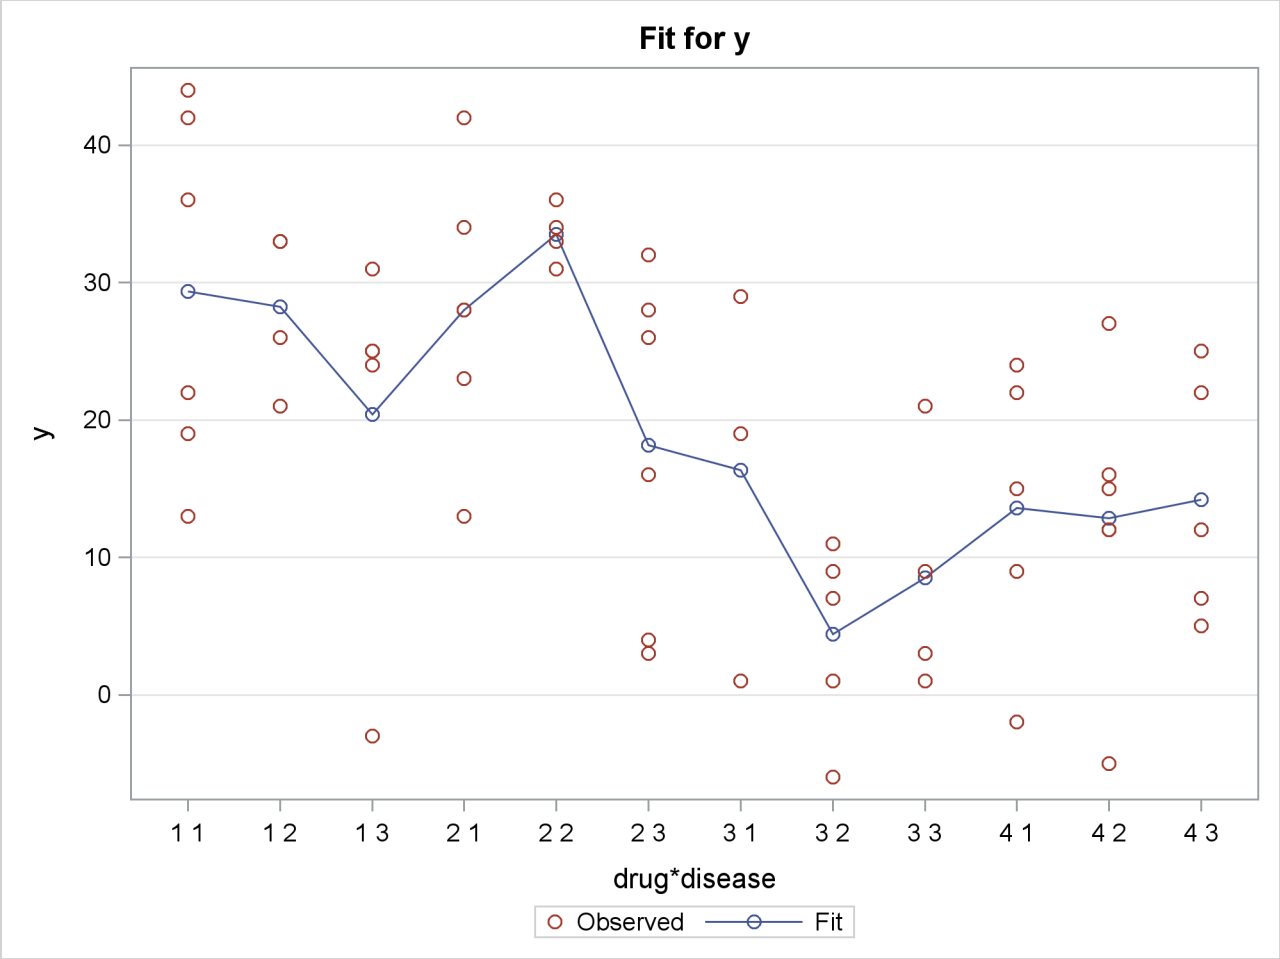
In the box plot in Output 19.2.3, the predicted values are displayed as circles; they coincide with the mean of the data at each level which are displayed as diamonds. The predicted values are again connected by lines. It is difficult to make any conclusions from this graphic.

Output 19.2.3 Box Fit Plot



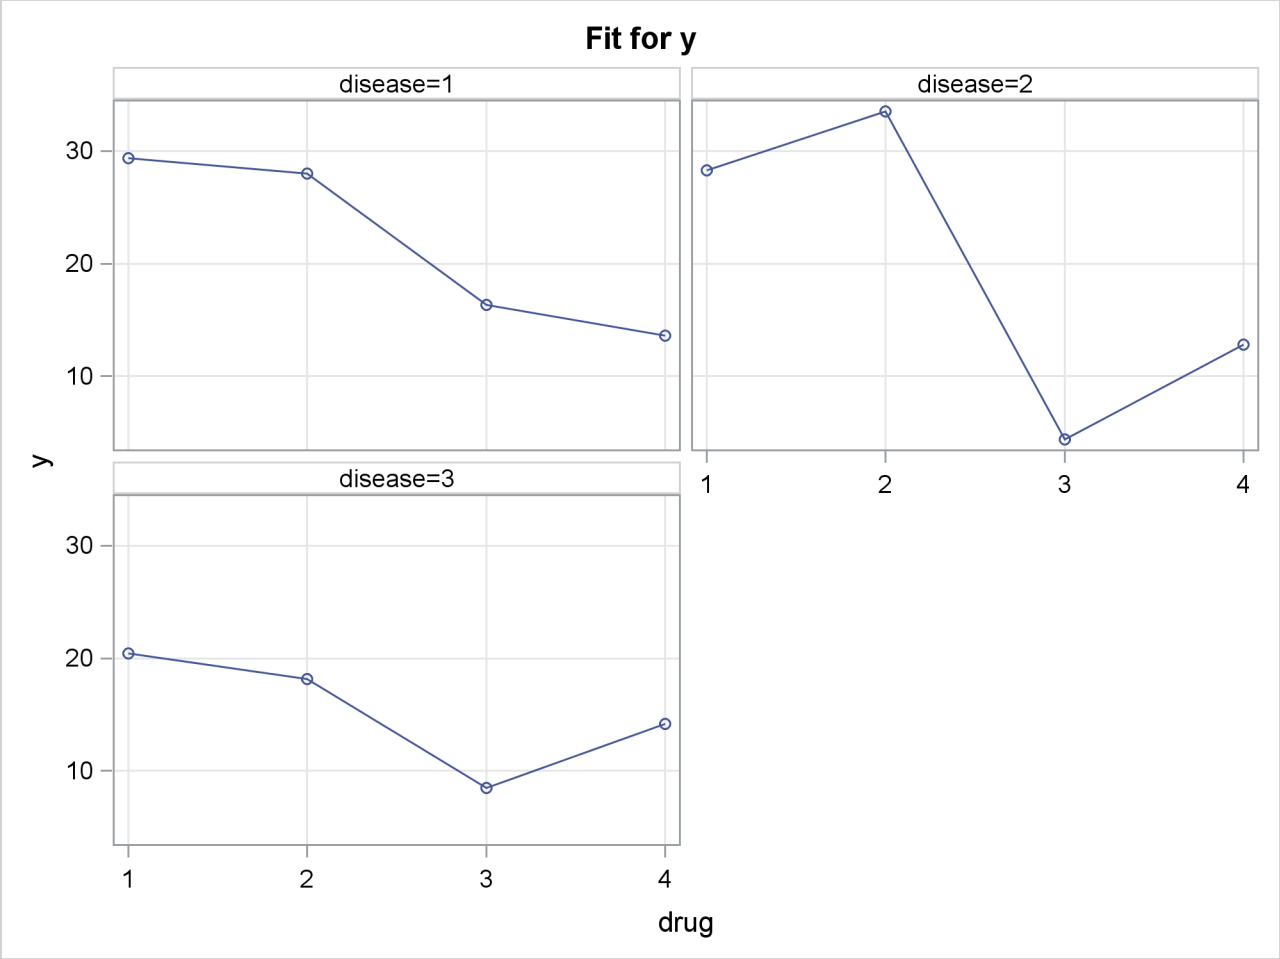
Output 19.2.4 shows the interaction plot at every combination of Drug and Disease. This plot is identical to the preceding box plot, except the boxes are replaced by the actual observations. Again, it is difficult to see any pattern in the plot.

Output 19.2.4 Interaction Plot with Specified X= Effect



Output 19.2.5 groups the observations by Disease, and for each disease displays the effectiveness of the four drugs in a panel of plots.

Output 19.2.5 Interaction Plot with Specified PLOTBY= Effect



Example 19.3: Logistic Regression

Consider a study of the analgesic effects of treatments on elderly patients with neuralgia. Two test treatments and a placebo are compared. The response variable is whether the patient reported pain or not. Researchers recorded the age and gender of 60 patients and the duration of complaint before the treatment began. The following DATA step creates the data set Neuralgia:

```
Data Neuralgia;
   input Treatment $ Sex $ Age Duration Pain $ @@;
   datalines;
P  F  68   1  No   B  M  74  16  No  P  F  67  30  No
P  M  66  26  Yes  B  F  67  28  No  B  F  77  16  No
A  F  71  12  No   B  F  72  50  No  B  F  76   9  Yes
A  M  71  17  Yes  A  F  63  27  No  A  F  69  18  Yes
B  F  66  12  No   A  M  62  42  No  P  F  64   1  Yes
A  F  64  17  No   P  M  74   4  No  A  F  72  25  No
P  M  70   1  Yes  B  M  66  19  No  B  M  59  29  No
A  F  64  30  No   A  M  70  28  No  A  M  69   1  No
B  F  78   1  No   P  M  83   1  Yes B  F  69  42  No
B  M  75  30  Yes  P  M  77  29  Yes P  F  79  20  Yes
A  M  70  12  No   A  F  69  12  No  B  F  65  14  No
B  M  70   1  No   B  M  67  23  No  A  M  76  25  Yes
P  M  78  12  Yes  B  M  77   1  Yes B  F  69  24  No
P  M  66   4  Yes  P  F  65  29  No  P  M  60  26  Yes
A  M  78  15  Yes  B  M  75  21  Yes A  F  67  11  No
P  F  72  27  No   P  F  70  13  Yes A  M  75   6  Yes
B  F  65   7  No   P  F  68  27  Yes P  M  68  11  Yes
P  M  67  17  Yes  B  M  70  22  No  A  M  65  15  No
P  F  67   1  Yes  A  M  67  10  No  P  F  72  11  Yes
A  F  74   1  No   B  M  80  21  Yes A  F  69   3  No
;
```

The Neuralgia data set contains five variables. The Pain variable is the response. A specification of Pain=Yes indicates that the patient felt pain, and Pain=No indicates that the patient did not feel pain. The variable Treatment is a categorical variable with three levels: A and B represent the two test treatments, and P represents the placebo treatment. The gender of the patients is given by the categorical variable Sex. The variable Age is the age of the patients, in years, when treatment began. The duration of complaint, in months, before the treatment began is given by the variable Duration.

In the following statements, a complex model that includes classification and continuous covariates and an interaction term is fit to the Neuralgia data. When you try to create a default effect plot from this model, computations stop because the best type of plot cannot easily be determined.

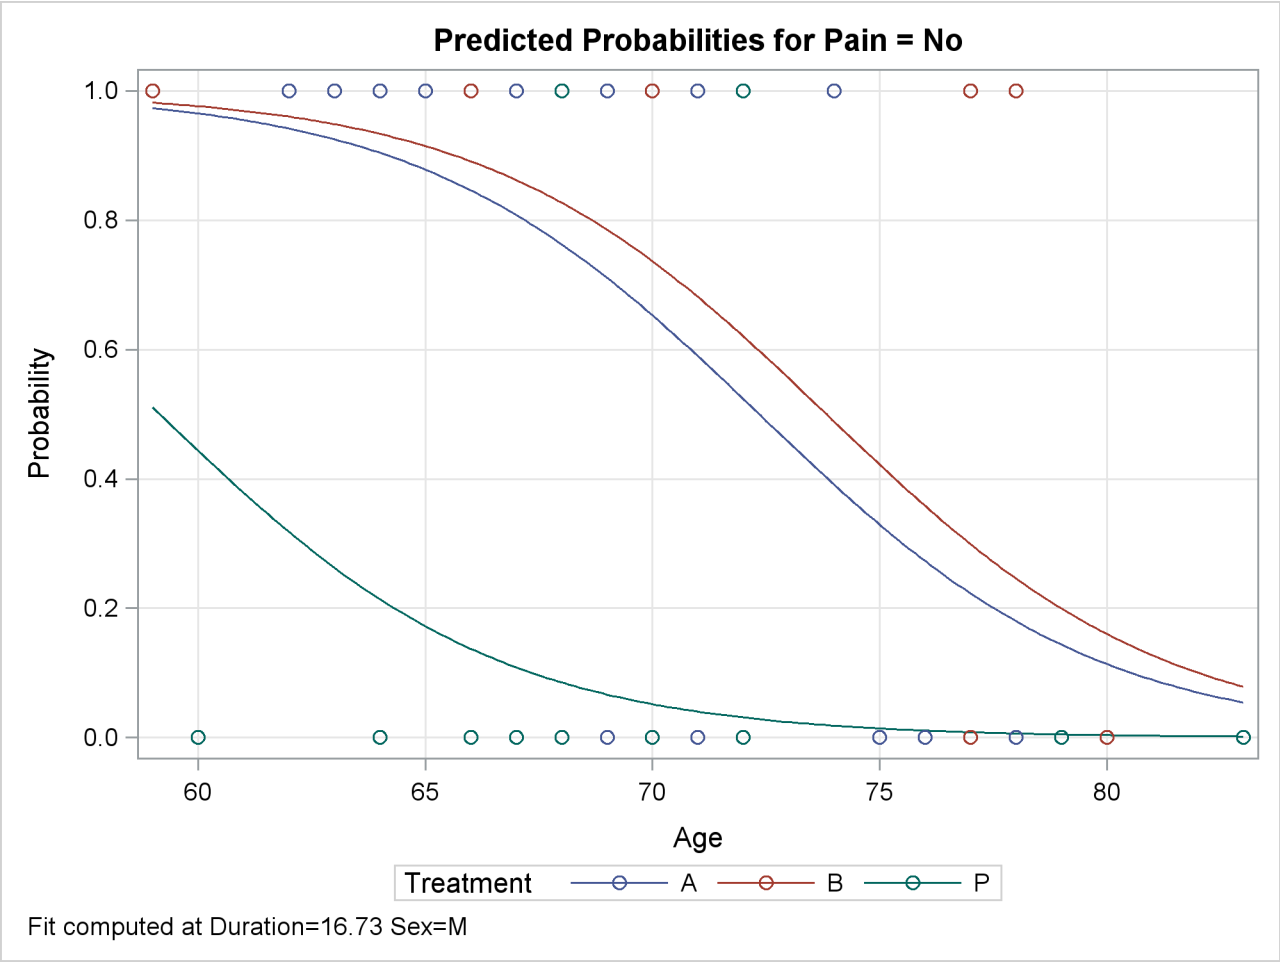
```
ods graphics on;
proc logistic data=Neuralgia;
   class Treatment Sex / param=ref;
   model Pain= Treatment|Sex Age Duration;
   effectplot;
run;
ods graphics off;
```

To produce an effect plot for this model, you need to first choose the type of plot to be created. In this case, since there are both classification and continuous covariates on the model, a SLICEFIT *plot-type* displays the first continuous covariate (Age) on the X axis and displays fit curves that correspond to each level of the first classification covariate (Treatment). The following statements produce Output 19.3.1.

```
ods graphics on;
proc logistic data=Neuralgia;
   class Treatment Sex / param=ref;
   model Pain= Treatment|Sex Age Duration;
   effectplot slicefit;
run;
ods graphics off;
```

By default, effect plots from PROC LOGISTIC are displayed on the probability scale. The predicted values are computed at the mean of the Duration variable, 16.73, and at the reference level of the Sex variable, M. Observations are also displayed on the sliced-fit plot in Output 19.3.1. While the display of binary responses can give you a feel for the spread of the data, it does not enable you to evaluate the fit of the model.

Output 19.3.1 Default Fit Plot Sliced by Treatment

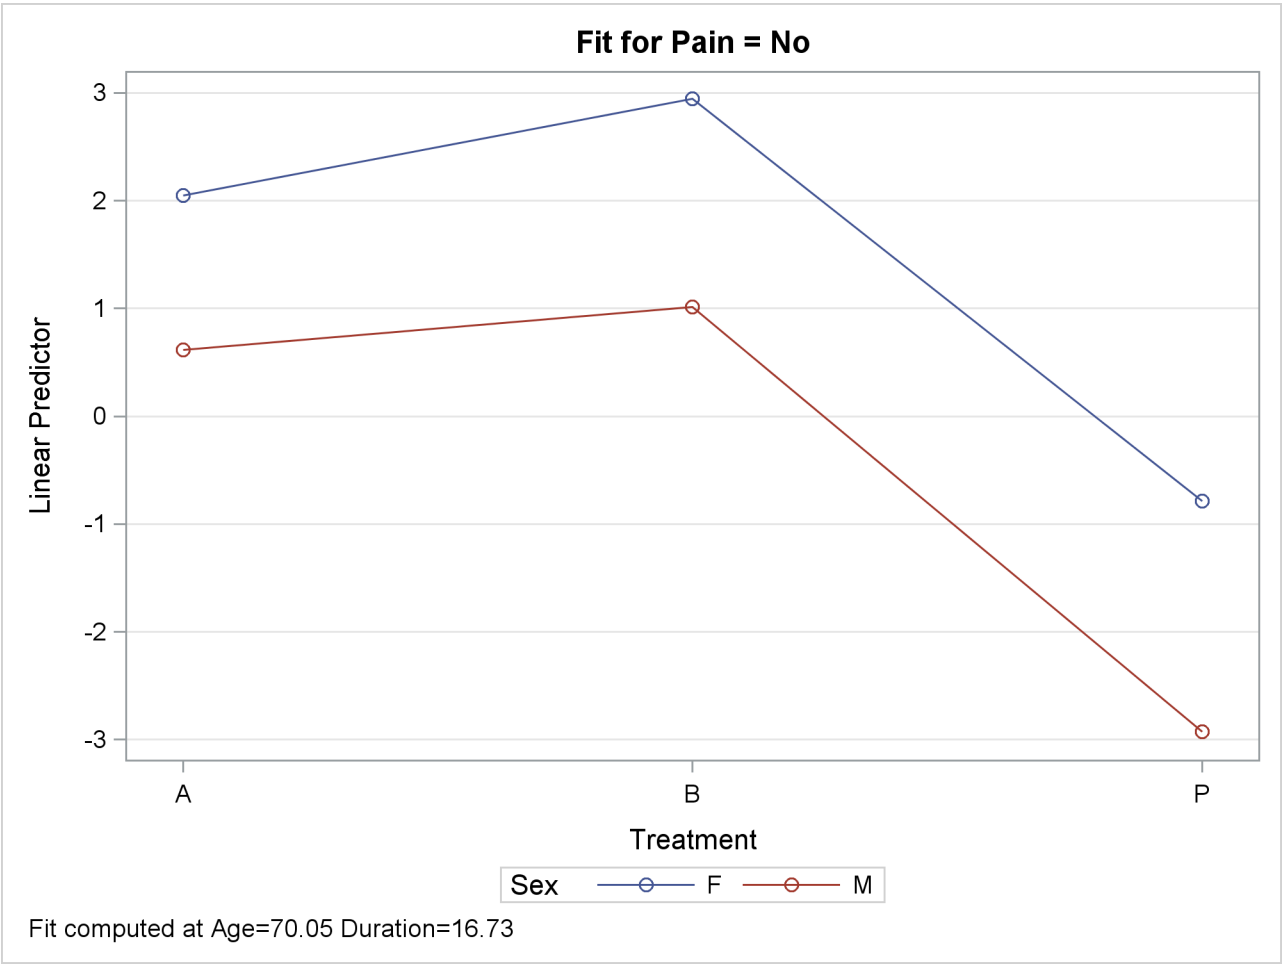


In the following statements, an INTERACTION *plot-type* is specified for the Treatment variable, with the Sex effect chosen for grouping the fits. The Age and Duration variables are set to their mean values for computing the predicted values. The NOOBS option suppresses the display of the binary observations on this plot. The LINK option is specified to display the fit on the LOGIT scale; if there is no interaction between Treatment and Sex, then the resulting curves shown in Output 19.3.2 will have similar slopes across the treatments.

```
ods graphics on;
proc logistic data=Neuralgia;
   class Treatment Sex / param=ref;
   model Pain= Treatment|Sex Age Duration;
   effectplot interaction(x=Treatment sliceby=Sex) / noobs link;
run;
ods graphics off;
```

In Output 19.3.2, the slopes of the lines seem "parallel" across the treatments, corroborating the nonsignificance of the interaction terms.

Output 19.3.2 Interaction Plot of an Interaction Effect

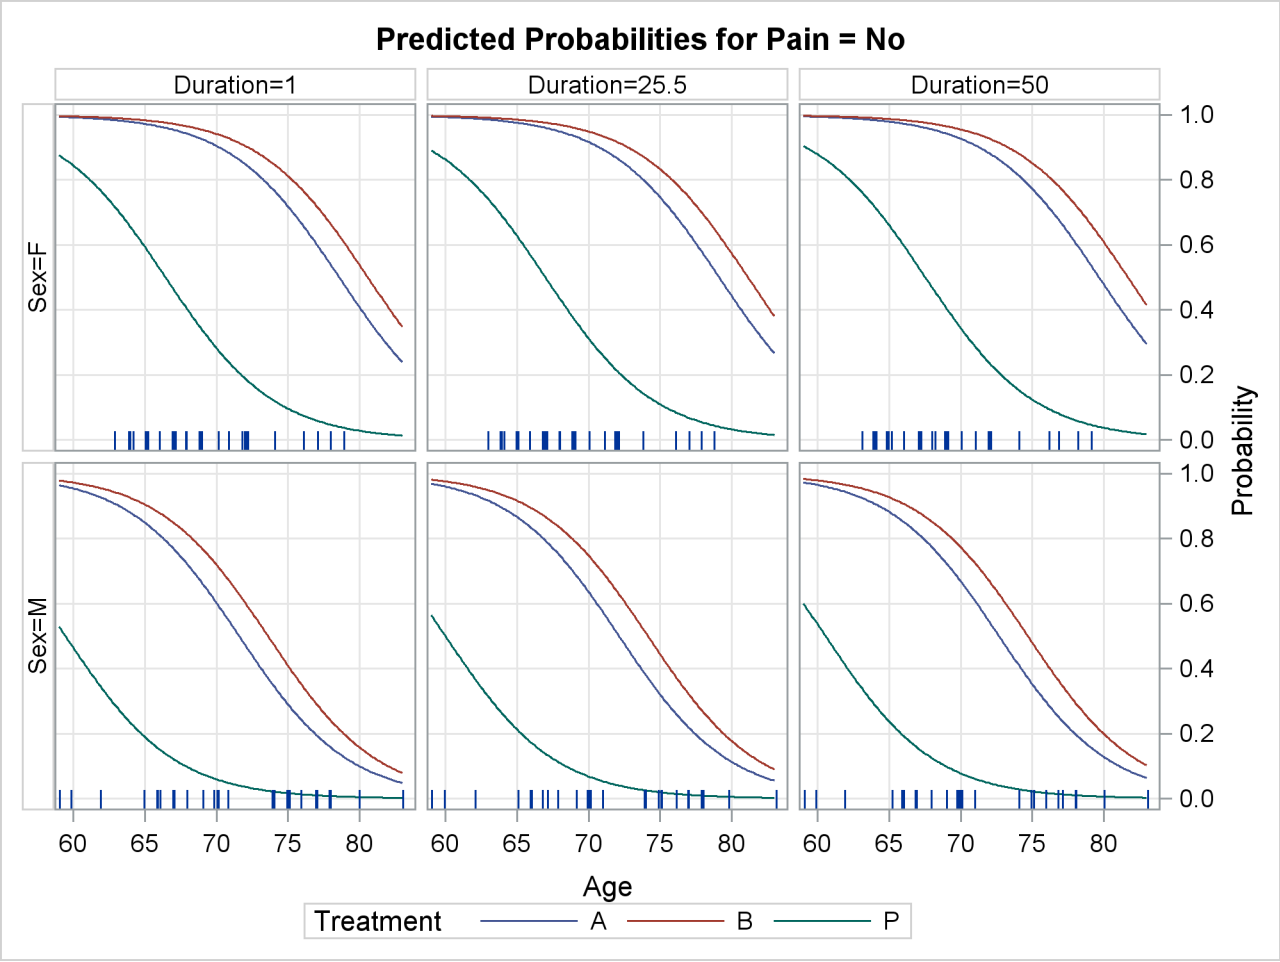


In the following statements, the interaction effect is removed, and the Duration variable is investigated further. The PLOTBY(ROWS)= option displays the Sex levels in the rows of a panel of plots, and the AT option computes the fits for several values of the Duration main effect in the columns of the panel. The OBS(FRINGE) option moves the observations to a fringe (rug) plot at the bottom of the plot, the observations are subsetted and displayed according to the value of the PLOTBY= variable, and the JITTER option makes overlaid fringes more visible. A STORE statement is also specified to save the model information for a later display. These statements produce Output 19.3.3.

```
ods graphics on;
proc logistic data=Neuralgia;
   class Treatment Sex / param=ref;
   model Pain= Treatment Sex Age Duration;
   effectplot slicefit(sliceby=Treatment plotby(rows)=Sex)
      / at(Duration=min midrange max) obs(fringe jitter);
   store logimodel;
run;
ods graphics off;
```

The predicted probability curves in Output 19.3.3 look very similar across the different values of the Duration variable, which agrees with the nonsignificance of Duration in this model. The fringe plot displays only female patients in the SEX=F row of the panel and displays only male patients in the SEX=M row, because the PLOTBY=SEX option subsets the observations.

Output 19.3.3 Sliced-Fit Plot with AT Option

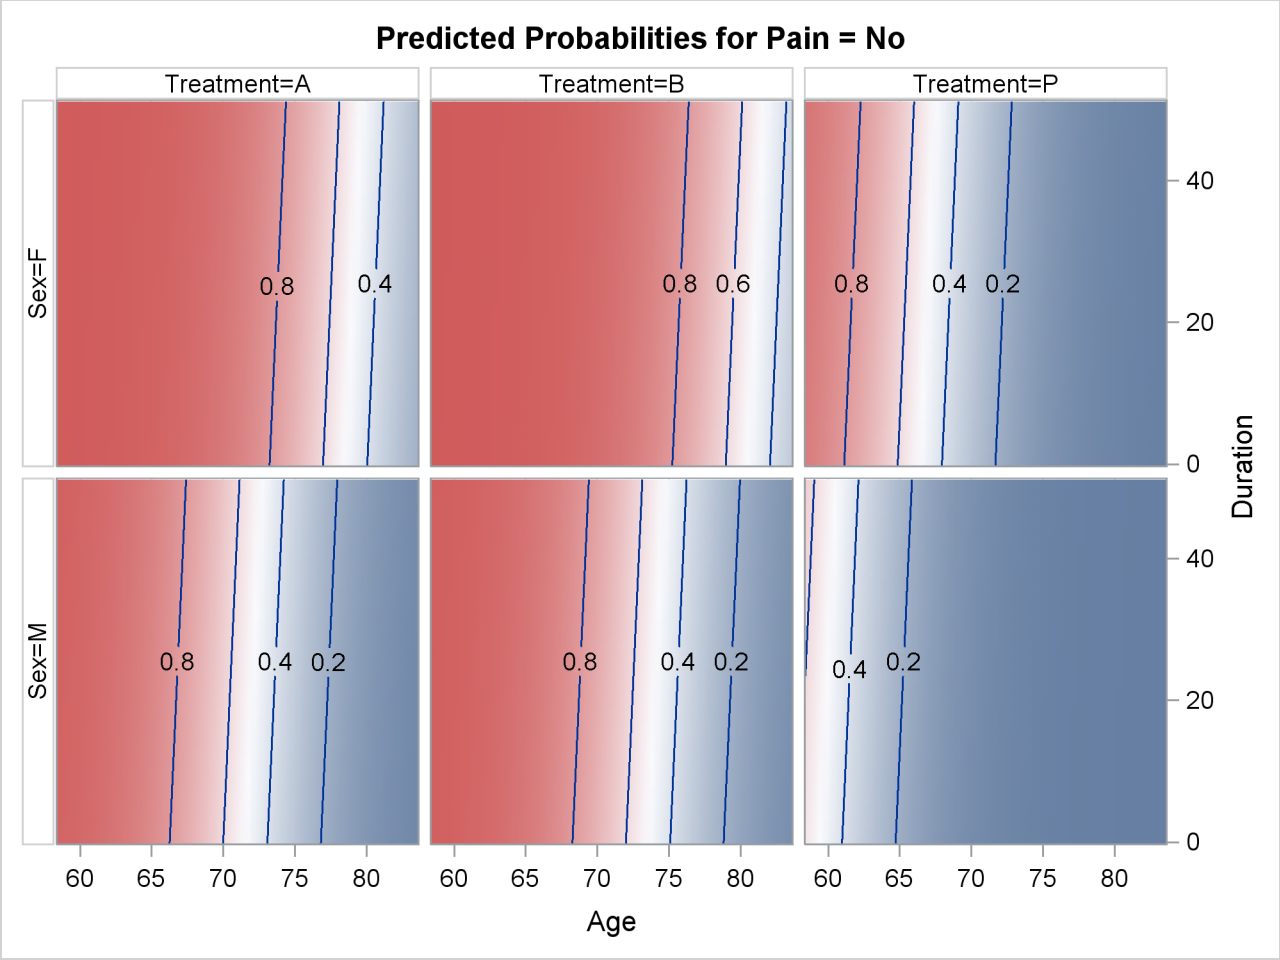


The following statements use the stored model and the PLM procedure to display a panel of contour plots:

```
ods graphics on;
proc plm source=logimodel;
   effectplot contour(plotby=Treatment) / at(Sex=all);
run;
ods graphics off;
```

Output 19.3.4 again confirms that Duration is not significant.

Output 19.3.4 Contour Fit Panel



ESTIMATE Statement

This statement documentation applies to the following procedures:
LOGISTIC, ORTHOREG, PHREG, PLM, SURVEYLOGISTIC, SURVEYPHREG, and SURVEYREG.
The ESTIMATE statement in the GENMOD, GLIMMIX, GLM, and MIXED procedures are documented in the respective procedure chapters.

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form $\mathbf{L}\boldsymbol{\beta}$. You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Syntax: ESTIMATE Statement

ESTIMATE < *'label'* > *estimate-specification* < **(***divisor***=***n***)** >
< **,** < *'label'* > *estimate-specification* < **(***divisor***=***n***)** > > < *, . . .* >
< */ options* > **;**

The basic element of the ESTIMATE statement is the *estimate-specification*, which consists of model effects and their coefficients. A *estimate-specification* takes the general form

effect name < *effect values . . .* >

The following variables can appear in the ESTIMATE statement:

label is an optional label that identifies the particular row of the estimate in the output.

effect identifies an effect that appears in the MODEL statement. The keyword INTERCEPT can be used as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.

values are constants that are elements of the **L** matrix and are associated with the fixed and random effects. There are two basic methods of specifying the entries of the **L** matrix. The traditional representation—also known as the positional syntax—relies on entering coefficients in the position they assume in the **L** matrix. For example, in the following statements the elements of **L** that are associated with the b main effect receive a 1 in the first position and a −1 in the second position:

```
class a b;
model y = a b a*b;
estimate 'B at A2' b 1 -1  a*b 0  0  1 -1;
```

The elements that are associated with the interaction receive a 1 in the third position and a −1 in the fourth position. In order to specify coefficients correctly for the interaction

term, you need to know how the levels of a and b vary in the interaction, which is governed by the order of the variables in the CLASS statement. The nonpositional syntax is designed to make it easier to enter coefficients for interactions and is necessary to enter coefficients for effects that are constructed with the EFFECT statement. In square brackets you enter the coefficient followed by the associated levels of the CLASS variables. If B has two levels and A has three levels, the previous ESTIMATE statement, by using nonpositional syntax for the interaction term, becomes the following statement:

```
estimate 'B at A2' b 1 -1 a*b [1, 2 1] [-1, 2 2];
```

The previous statement assigns value 1 to the interaction where A is at level 2 and B is at level 1, and it assigns −1 to the interaction where both classification variables are at level 2. The comma that separates the entry for the **L** matrix from the level indicators is optional. Further details about the nonpositional contrast syntax and its use with constructed effects can be found in the section "Positional and Nonpositional Syntax for Coefficients in Linear Functions" on page 462.

Based on the *estimate-specifications* in your ESTIMATE statement, the procedure constructs the matrix **L** to test the hypothesis $H: \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$. The procedure supports nonpositional syntax for the coefficients of model effects in the ESTIMATE statement. For details see the section "Positional and Nonpositional Syntax for Coefficients in Linear Functions" on page 462.

The procedure then produces for each row **l** of **L** an approximate *t* test of the hypothesis $H: \mathbf{l}\boldsymbol{\beta} = 0$. You can also obtain multiplicity-adjusted *p*-values and confidence limits for multirow estimates with the ADJUST= option.

Note that multirow estimates are permitted. Unlike releases prior to SAS 9.22, you do not need to specify a '*label*' for every row of the estimate; the procedure constructs a default label if a label is not specified.

If the procedure finds the estimate to be nonestimable, then it displays "Non-est" for the estimate entry.

Table 19.16 summarizes important options in the ESTIMATE statement. All ESTIMATE options are subsequently discussed in alphabetical order.

Table 19.16 Important ESTIMATE Statement Options

Option	Description
Construction and Computation of Estimable Functions	
DIVISOR=	Specifies a list of values to divide the coefficients
NOFILL	Suppresses the automatic fill-in of coefficients for higher-order effects
SINGULAR=	Tunes the estimability checking difference

Table 19.16 *continued*

Option	Description
Degrees of Freedom and *p*-values	
ADJUST=	Determines the method for multiple comparison adjustment of estimates
ALPHA=α	Determines the confidence level ($1-\alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiplicity-corrected *p*-values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits
CORR	Displays the correlation matrix of estimates
COV	Displays the covariance matrix of estimates
E	Prints the **L** matrix
JOINT	Produces a joint F or chi-square test for the estimable functions
PLOTS=	Requests ODS statistical graphics if the analysis is sampling-based
SEED=	Specifies the seed for computations that depend on random numbers
Generalized Linear Modeling	
CATEGORY=	Specifies how to construct estimable functions with multinomial data
EXP	Exponentiates and displays estimates
ILINK	Computes and displays estimates and standard errors on the inverse linked scale

You can specify the following options in the ESTIMATE statement after a slash (/).

ADJDFE=SOURCE

ADJDFE=ROW

specifies how denominator degrees of freedom are determined when *p*-values and confidence limits are adjusted for multiple comparisons with the ADJUST= option. When you do not specify the ADJDFE= option, or when you specify ADJDFE=SOURCE, the denominator degrees of freedom for multiplicity-adjusted results are the denominator degrees of freedom for the final effect that is listed in the ESTIMATE statement from the "Type III" table.

The ADJDFE=ROW setting is useful if you want multiplicity adjustments to take into account that denominator degrees of freedom are not constant across estimates. For example, this can be the case when the denominator degrees of freedom are computed by the Satterthwaite method or according to Kenward and Roger (1997).

The ADJDFE= option has an effect only in mixed models that use these degree-of-freedom methods. It is not supported by the procedures that perform chi-square-based inference (LOGISTIC, PHREG, and SURVEYLOGISTIC).

ADJUST=BON

ADJUST=SCHEFFE

ADJUST=SIDAK

ADJUST=SIMULATE< (*simoptions*) >

ADJUST=T

requests a multiple comparison adjustment for the *p*-values and confidence limits for the estimates. The adjusted quantities are produced in addition to the unadjusted quantities. Adjusted confidence limits are produced if the CL or ALPHA= option is in effect. For a description of the adjustments, see Chapter 41, "The GLM Procedure," and Chapter 60, "The MULTTEST Procedure," and the documentation for the ADJUST= option in the LSMEANS statement.

If the STEPDOWN option is in effect, the *p*-values are further adjusted in a step-down fashion.

ALPHA=*number*

requests that a *t* type confidence interval be constructed with confidence level $1 - number$. The value of *number* must be between 0 and 1; the default is 0.05. If the "Estimates" table shows infinite degrees of freedom, then the confidence interval is a *z* type interval.

CATEGORY=*category-options*

specifies how to construct estimates and multiplicity corrections for models with multinomial data (ordinal or nominal). This option is also important for constructing sets of estimable functions for *F* or chi-square tests with the JOINT option.

The *category-options* are used to indicate how response variable levels are treated in constructing the estimable functions. Possible values for the *category-options* are the following:

JOINT

computes the estimable functions for every nonredundant category and treats them as a set. For example, a three-row ESTIMATE statement in a model with three response categories leads to six estimable functions.

SEPARATE

computes the estimable functions for every nonredundant category in turn. For example, a three-row ESTIMATE statement in a model with three response categories leads to two sets of three estimable functions.

quoted-value-list

computes the estimable functions only for the list of values given. The list must consist of formatted values of the response categories.

Consider the following ESTIMATE statements in the LOGISTIC procedure for an ordinal model with response categories 'vg', 'g', 'm', 'b', and 'vb'. Because there are five response categories, there are four nonredundant categories for the cumulative link model.

```
proc logistic data=icecream;
   class brand / param=glm;
   model taste(order=data) = brand / link=logit;
   freq count;

   estimate brand 1 -1,
            intercept 1 brand  0 1 / category='m','vg';

   estimate intercept 1 brand 1    / category=joint
                                     adjust=simulate(seed=1);

   estimate brand 1 -1,
            brand 1 1 -2           / category=separate
                                     adjust=bon;
run;
```

The first ESTIMATE statement requests a two-row estimable function. The result is produced for two of the four nonredundant response categories. The second ESTIMATE statement produces four *t* tests, one for each nonredundant category. The multiplicity adjustment with *p*-value computation by simulation treats the four estimable functions as a unit for family-wise Type I error protection. The third ESTIMATE statement computes a two-row estimable function and reports its results separately for all nonredundant categories. The Bonferroni adjustment in this statement applies to a family of two tests that correspond to the two-row estimable function. Four Bonferroni adjustments for sets of size two are performed.

The CATEGORY= option is supported only by the procedures that support generalized linear modeling (LOGISTIC and SURVEYLOGISTIC) and by PROC PLM when it is used to perform statistical analyses on item stores created by these procedures.

CHISQ

requests that chi-square tests be performed in addition to *F* tests, when you request an *F* test with the JOINT option. This option has no effect in procedures that produce chi-square statistics by default.

CL

requests that *t* type confidence limits be constructed. If the procedure shows the degrees of freedom in the "Estimates" table as infinite, then the confidence limits are *z* intervals. The confidence level is 0.95 by default, and you can change the confidence level with the ALPHA= option. The confidence intervals are adjusted for multiplicity when you specify the ADJUST= option. However, if a step-down *p*-value adjustment is requested with the STEPDOWN option, only the *p*-values are adjusted for multiplicity.

CORR

displays the estimated correlation matrix of the linear combination of the parameter estimates.

COV

displays the estimated covariance matrix of the linear combination of the parameter estimates.

DF=*number*

specifies the degrees of freedom for the *t* test and confidence limits. This option is not supported by the procedures that perform chi-square-based inference (LOGISTIC, PHREG, and SUVEYLOGISTIC).

DIVISOR=*value-list*

specifies a list of values by which to divide the coefficients so that fractional coefficients can be entered as integer numerators. If you do not specify *value-list*, a default value of 1.0 is assumed. Missing values in the *value-list* are converted to 1.0.

If the number of elements in *value-list* exceeds the number of rows of the estimate, the extra values are ignored. If the number of elements in *value-list* is less than the number of rows of the estimate, the last value in *value-list* is copied forward.

If you specify a row-specific divisor as part of the specification of the estimate row, this value multiplies the corresponding divisor that is implied by the *value-list*. For example, the following statement divides the coefficients in the first row by 8, and the coefficients in the third and fourth row by 3:

```
estimate 'One vs. two'   A 2 -2  (divisor=2),
         'One vs. three' A 1  0 -1         ,
         'One vs. four'  A 3  0  0 -3      ,
         'One vs. five'  A 1  0  0  0  -1  / divisor=4,.,3;
```

Coefficients in the second row are not altered.

E

requests that the **L** matrix coefficients be displayed.

EXP

requests exponentiation of the estimate. When you model data with the logit, cumulative logit, or generalized logit link functions, and the estimate represents a log odds ratio or log cumulative odds ratio, the EXP option produces an odds ratio. In proportional hazards model, this option produces estimates of hazard ratios. If you specify the CL or ALPHA= option, the (adjusted) confidence bounds are also exponentiated.

The EXP option is supported only by PROC PHREG, PROC SURVEYPHREG, the procedures that support generalized linear modeling (LOGISTIC and SURVEYLOGISTIC), and by PROC PLM when it is used to perform statistical analyses on item stores created by these procedures.

ILINK

requests that the estimate and its standard error also be reported on the scale of the mean (the inverse linked scale). The computation of the inverse linked estimate depends on the estimation mode. For example, if the analysis is based on a posterior sample when a BAYES statement is present, the inversely linked estimate is the average of the inversely linked values across the sample of posterior parameter estimates. If the analysis is not based on a sample of parameter estimates, the procedure computes the value on the mean scale by applying the inverse link to the estimate. The interpretation of this quantity depends on the *effect values* specified in your ESTIMATE statement and on the link function. For example, in a model for binary data with logit link the following statements compute

$$\frac{1}{1+\exp\{-(\alpha_1-\alpha_2)\}}$$

where α_1 and α_2 are the fixed-effects solutions that are associated with the first two levels of the classification effect A:

```
class A;
model y = A / dist=binary link=logit;
estimate 'A one vs. two' A 1 -1 / ilink;
```

This quantity is not the difference of the probabilities that are associated with the two levels,

$$\pi_1 - \pi_2 = \frac{1}{1+\exp\{-\beta_0 - \alpha_1\}} - \frac{1}{1+\exp\{-\beta_0 - \alpha_2\}}$$

The standard error of the inversely linked estimate is based on the delta method. If you also specify the CL option, the procedure computes confidence limits for the estimate on the mean scale. In multinomial models for nominal data, the limits are obtained by the delta method. In other models they are obtained from the inverse link transformation of the confidence limits for the estimate. The ILINK option is specific to an ESTIMATE statement.

The ILINK option is supported only by the procedures that support generalized linear modeling (LOGISTIC and SURVEYLOGISTIC) and by PROC PLM when it is used to perform statistical analyses on item stores created by these procedures.

JOINT< (*joint-test-options*) >
requests that a joint F or chi-square test be produced for the rows of the estimate. The JOINT option in the ESTIMATE statement essentially replaces the CONTRAST statement.

When the LOWERTAILED or the UPPERTAILED options are in effect, or if the BOUNDS option described below is in effect, the JOINT option produces the chi-bar-square statistic according to Silvapulle and Sen (2004). This statistic uses a simulation-based approach to compute p-values in situations where the alternative hypotheses of the estimable functions are not simple two-sided hypotheses. See the section "Joint Hypothesis Tests with Complex Alternatives, the Chi-Bar-Square Statistic" on page 465 for more information about this test statistic.

You can specify the following *joint-test-options* in parentheses:

ACC=γ
specifies the accuracy radius for determining the necessary sample size in the simulation-based approach of Silvapulle and Sen (2004) for tests with order restrictions. The value of γ must be strictly between 0 and 1; the default value is 0.005.

EPS=ϵ
specifies the accuracy confidence level for determining the necessary sample size in the simulation-based approach of Silvapulle and Sen (2004) for tests with order restrictions. The value of ϵ must be strictly between 0 and 1; the default value is 0.01.

LABEL='*label*'
assigns an identifying label to the joint test. If you do not specify a label, the first non-default label for the ESTIMATE rows is used to label the joint test.

NOEST

ONLY

performs only the F or chi-square test and suppresses other results from the ESTIMATE statement. This option is useful for emulating the CONTRAST statement that is available in other procedures.

NSAMP=*n*

specifies the number of samples for the simulation-based method of Silvapulle and Sen (2004). If n is not specified, it is constructed from the values of the ALPHA=α, the ACC=γ, and the EPS=ϵ options. With the default values for γ, ϵ, and α (0.005, 0.01, and 0.05, respectively), NSAMP=12,604 by default.

CHISQ

adds a chi-square test if the procedure produces an F test by default.

BOUNDS=*value-list*

specifies boundary values for the estimable linear function. The null value of the hypothesis is always zero. If you specify a positive boundary value z, the hypotheses are $H: \theta = 0$, $H_a: \theta > 0$ with the added constraint that $\theta < z$. The same is true for negative boundary values. The alternative hypothesis is then $H_a: \theta < 0$ subject to the constraint $\theta > -|z|$. If you specify a missing value, the hypothesis is assumed to be two-sided. The BOUNDS option enables you to specify sets of one- and two-sided joint hypotheses. If all values in *value-list* are set to missing, the procedure performs a simulation-based p-value calculation for a two-sided test.

LOWER

LOWERTAILED

requests that the p-value for the t test be based only on values that are less than the test statistic. A two-tailed test is the default. A lower-tailed confidence limit is also produced if you specify the CL or ALPHA= option.

Note that for ADJUST=SCHEFFE the one-sided adjusted confidence intervals and one-sided adjusted p-values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the F distribution.

If you request a joint test with the JOINT option, then a one-sided left-tailed order restriction is applied to all estimable functions, and the corresponding chi-bar-square statistic of Silvapulle and Sen (2004) is computed in addition to the two-sided, standard, F or chi-square statistic. See the JOINT option for how to control the computation of the simulation-based chi-bar-square statistic.

NOFILL

suppresses the automatic fill-in of coefficients of higher-order effects.

PLOTS=*plot-options*

produces ODS statistical graphics of the distribution of estimable functions if the procedure performs the analysis in a sampling-based mode. For example, this is the case when procedures support a BAYES statement and perform a Bayesian analysis. The estimable functions are then computed for each of the posterior parameter estimates, and the "Estimates" table reports simple descriptive statistics for the evaluated functions. The PLOTS= option enables you in this situation to visualize the distribution of the estimable function. The following *plot-options* are available:

ALL

produces all possible plots with their default settings.

BOXPLOT< (*boxplot-options***) >**

produces box plots of the distribution of the estimable function across the posterior sample. A separate box is generated for each estimable function, and all boxes appear on a single graph by default. You can affect the appearance of the box plot graph with the following options:

ORIENTATION=VERTICAL | HORIZONTAL

ORIENT=VERT | HORIZ specifies the orientation of the boxes. The default is vertical orientation of the box plots.

NPANELPOS=*number* specifies how to break the series of box plots across multiple panels. If the NPANELPOS option is not specified, or if *number* equals zero, then all box plots are displayed in a single graph; this is the default. If a negative number is specified, then exactly up to |*number*| of box plots are displayed per panel. If *number* is positive, then the number of boxes per panel is balanced to achieve small variation in the number of box plots per graph.

DISTPLOT< (*distplot-options***) >**

DIST< (*distplot-options***) >**

generates panels of histograms with a kernel density overlaid. A separate plot in each panel contains the results for each estimable function. You can specify the following *distplot-options* in parentheses:

BOX | NOBOX controls the display of a horizontal box plot of the estimable function's distribution across the posterior sample below the graph. The BOX option is enabled by default.

HIST | NOHIST controls the display of the histogram of the estimable function's distribution across the posterior sample. The HIST option is enabled by default.

NORMAL | NONORMAL controls the display of a normal density estimate on the graph. The NONORMAL option is enabled by default.

KERNEL | NOKERNEL controls the display of a kernel density estimate on the graph. The KERNEL option is enabled by default.

NROWS=*number* specifies the highest number of rows in a panel. The default is 3.

NCOLS=*number* specifies the highest number of columns in a panel. The default is 3.

UNPACK unpacks the panel into separate graphics.

NONE

does not produce any plots.

SEED=*number*

specifies the seed for the sampling-based components of the computations for the ESTIMATE statement (for example, chi-bar-square statistics and simulated *p*-values). *number* specifies an integer that is used to start the pseudo-random number generator for the simulation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock. There could be multiple ESTIMATE statements with SEED= specifications and there could be other statements that can supply a random number seed. Since the procedure has only one random number stream, the initial seed is shown in the SAS log.

SINGULAR=*number*

tunes the estimability checking. If **v** is a vector, define ABS(**v**) to be the largest absolute value of the elements of **v**. If ABS($\mathbf{L} - \mathbf{LT}$) is greater than *c*number* for any row of **L** in the contrast, then $\mathbf{L}\boldsymbol{\beta}$ is declared nonestimable. Here, **T** is the Hermite form matrix $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$, and *c* is ABS(**L**), except when it equals 0, and then *c* is 1. The value for *number* must be between 0 and 1; the default is 1E−4.

STEPDOWN< *(step-down-options)* >

requests that multiplicity adjustments for the *p*-values of estimates be further adjusted in a step-down fashion. Step-down methods increase the power of multiple testing procedures by taking advantage of the fact that a *p*-value is never declared significant unless all smaller *p*-values are also declared significant. The STEPDOWN adjustment combined with ADJUST=BON corresponds to the methods of Holm (1979) and "Method 2" of Shaffer (1986); this is the default. Using step-down-adjusted *p*-values combined with ADJUST=SIMULATE corresponds to the method of Westfall (1997).

If the ESTIMATE statement is applied with a STEPDOWN option in a mixed model where the degrees-of-freedom method is that of Kenward and Roger (1997) or of Satterthwaite, then step-down-adjusted *p*-values are produced only if the ADJDFE=ROW option is in effect.

Also, the STEPDOWN option affects only *p*-values, not confidence limits. For ADJUST=SIMULATE, the generalized least squares hybrid approach of Westfall (1997) is used to increase Monte Carlo accuracy. You can specify the following *step-down-options* in parentheses after the STEPDOWN option:

MAXTIME=*n*

specifies the time (in seconds) to be spent computing the maximal logically consistent sequential subsets of equality hypotheses for TYPE=LOGICAL. The default is MAXTIME=60. If the MAXTIME value is exceeded, the adjusted tests are not computed. When this occurs, you can try increasing the MAXTIME value. However, note that there are common multiple comparisons problems for which this computation requires a huge amount of time—for example, all pairwise comparisons between more than 10 groups. In such cases, try to use TYPE=FREE (the default) or TYPE=LOGICAL(*n*) for small *n*.

ORDER=PVALUE

ORDER=ROWS

specifies the order in which the step-down tests to be performed. ORDER=PVALUE is the default, with estimates being declared significant only if all estimates with smaller (unadjusted) *p*-values are significant. If you specify ORDER=ROWS, then significances are evaluated in the order in which they are specified in the syntax.

REPORT

specifies that a report on the step-down adjustment be displayed, including a listing of the sequential subsets (Westfall 1997) and, for ADJUST=SIMULATE, the step-down simulation results.

TYPE=LOGICAL<(*n*)>

TYPE=FREE

specifies how step-down adjustment are made. If you specify TYPE=LOGICAL, the step-down adjustments are computed by using maximal logically consistent sequential subsets of equality hypotheses (Shaffer 1986, Westfall 1997). Alternatively, for TYPE=FREE, sequential subsets are computed ignoring logical constraints. The TYPE=FREE results are more conservative than those for TYPE=LOGICAL, but they can be much more efficient to produce for many estimates. For example, it is not feasible to take logical constraints between all pairwise comparisons of more than about 10 groups. For this reason, TYPE=FREE is the default.

However, you can reduce the computational complexity of taking logical constraints into account by limiting the depth of the search tree used to compute them, specifying the optional depth parameter as a number n in parentheses after TYPE=LOGICAL. As with TYPE=FREE, results for TYPE=LOGICAL(n) are conservative relative to the true TYPE=LOGICAL results. But even for TYPE=LOGICAL(0) they can be appreciably less conservative than TYPE=FREE, and they are computationally feasible for much larger numbers of estimates. If you do not specify n or if $n = -1$, the full search tree is used.

TESTVALUE=*value-list*

TESTMEAN=*value-list*

specifies the value under the null hypothesis for testing the estimable functions in the ESTIMATE statement. The rules for specifying the *value-list* are very similar to those for specifying the divisor list in the DIVISOR= option. If no TESTVALUE= is specified, all tests are performed as $H: \mathbf{L}\boldsymbol{\beta} = 0$. Missing values in the *value-list* also are translated to zeros. If you specify fewer values than rows in the ESTIMATE statement, the last value in *value-list* is carried forward.

The TESTVALUE= option affects only p-values from individual, joint, and multiplicity-adjusted tests. It does not affect confidence intervals.

The TESTVALUE option is not available for the multinomial distribution, and the values are ignored when you perform a sampling-based (Bayesian) analysis.

UPPER

UPPERTAILED

requests that the p-value for the t test be based only on values that are greater than the test statistic. A two-tailed test is the default. An upper-tailed confidence limit is also produced if you specify the CL or ALPHA= option.

Note that for ADJUST=SCHEFFE the one-sided adjusted confidence intervals and one-sided adjusted p-values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the F distribution.

If you request a joint test with the JOINT option, then a one-sided right-tailed order restriction is applied to all estimable functions, and the corresponding chi-bar-square statistic of Silvapulle and Sen (2004) is computed in addition to the two-sided, standard, F or chi-square statistic. See the JOINT option for how to control the computation of the simulation-based chi-bar-square statistic.

Positional and Nonpositional Syntax for Coefficients in Linear Functions

When you define custom linear hypotheses with the ESTIMATE statement, the procedure sets up an **L** vector or matrix that conforms to the model effect solutions. (Note that the following remarks also apply to the LSMESTIMATE statement, where you specify coefficients of the matrix **K** which is then converted into a coefficient matrix that conforms to the model effects solutions.)

There are two methods for specifying the entries in a coefficient matrix (hereafter simply referred to as the **L** matrix); they are called the positional and nonpositional methods. In the positional form, which is the traditional method, you provide a list of values that occupy the elements of the **L** matrix that is associated with the effect in question in the order in which the values are listed. For traditional model effects that consist of continuous and classification variables, the positional syntax is simpler in some cases (main effects) and more cumbersome in others (interactions). When you work with effects that are constructed through the EFFECT statement, the nonpositional syntax is essential.

For example, consider the following two-way model with interactions where factors A and B have three and two levels, respectively:

```
proc logistic;
   class a b;
   model y = a b a*b;
run;
```

To test the difference of the B levels at the second level of A with an ESTIMATE statement (a slice), you need to assign coefficients 1 and -1 to the levels of B and to the levels of the interaction where A is at the second level. Two examples of equivalent ESTIMATE statements that use positional and nonpositional syntax are as follows:

```
estimate 'B at A2' b 1 -1 a*b 0  0  1 -1      ;
estimate 'B at A2' b 1 -1 a*b [1 2 1] [-1 2 2];
```

Because A precedes B in the CLASS statement, the levels of the interaction are formed as $\alpha_1\beta_1, \alpha_1\beta_2, \alpha_2\beta_1, \alpha_2\beta_2, \cdots$. If B precedes A in the CLASS statement, you need to modify the coefficients accordingly:

```
proc logistic;
   class b a;
   model y = a b a*b;
   estimate 'B at A2' b 1 -1 a*b 0  1  0  0 -1     ;
   estimate 'B at A2' b 1 -1 a*b [1  1 2] [-1  2 2];
   estimate 'B at A2' b 1 -1 a*b [1, 1 2] [-1, 2 2];
run;
```

You can optionally separate the **L** value entry from the level indicators with a comma, as in the last ESTIMATE statement.

The general syntax for defining coefficients with the nonpositional syntax is as follows:

effect-name [*multiplier* <,> *level-values*] . . . <[*multiplier* <,> *level-values*]>

The first entry in square brackets is the multiplier that is applied to the elements of **L** for the effect after the *level-values* have been resolved and any necessary action that forms **L** has been taken.

The *level-values* are organized in a specific form:

- The number of entries should equal the number of terms that are needed to construct the effect. For effects that do not contain any constructed effects, this number is simply the number of terms in the name of the effect.
- Values of continuous variables that are needed for the construction of the **L** matrix precede the level indicators of CLASS variables.
- If the effect involves constructed effects, then you need to provide as many continuous and classification variables as are needed for the effect formation. For example, if a collection effect is defined as

```
class c;
effect v = collection(x1 x2 c);
```

  then a proper nonpositional syntax would be

```
v [0.5,  0.2 0.3 3]
```

- If an effect contains both regular terms (old-style effects) and constructed effects, then the order of the coefficients is as follows: continuous values for old-style effects, class levels for classification variables in old-style effects, continuous values for constructed effects, and finally class levels that are needed for constructed effects. Assume that C has four levels so that effect v contributes six elements to the **L** matrix. When the procedure resolves this syntax, the values 0.2 and 0.3 are assigned to the positions for x1 and x2 and a 1 is associated with the third level of C. The resulting vector is then multiplied by 0.5 to produce

$$[0.1 \quad 0.15 \quad 0 \quad 0 \quad 0.5 \quad 0]$$

Note that you enter the **levels** of the classification variables in the square brackets, not their formatted values. The ordering of the levels of classification variables can be gleaned from the "Class Level Information" table.

To specify values for continuous variables, simply give their value as one of the terms in the effect. The nonpositional syntax in the following ESTIMATE statement is read as "1 times the value 0.4 in the column that is associated with level 2 of A"

```
proc phreg;
   class a / param=glm;
   model y = a a*x / s;
   lsmeans a / e at x=0.4;
   estimate 'A2 at x=0.4' intercept 1 a 0 1 a*x [1,0.4 2] / e;
run;
```

Because the value before the comma serves as a multiplier, the same estimable function could also be constructed with the following statements:

```
estimate 'A2 at x=0.4' intercept 1 a 0 1 a*x [ 4,  0.1 2];
estimate 'A2 at x=0.4' intercept 1 a 0 1 a*x [ 2,  0.2 2];
estimate 'A2 at x=0.4' intercept 1 a 0 1 a*x [-1, -0.4 2];
```

Note that continuous variables that are needed to construct an effect are always listed before any CLASS variables.

When you work with constructed effects, the nonpositional syntax works in the same way. For example, the following model contains a classification effect and a B-spline. The first two ESTIMATE statements produce predicted values for level 1 of C when the continuous variable x takes on the values 20 and 10, respectively.

```
proc orthoreg;
   class c;
   effect spl = spline(x / knotmethod=equal(5));
   model y = c spl;
   estimate 'C = 1 @ x=20' intercept 1 c 1 spl [1,20],
            'C = 1 @ x=10' intercept 1 c 1 spl [1,10];
   estimate 'Difference'   spl [1,20] [-1,10];
run;
```

In this example, the ORTHOREG procedure computes the spline coefficients for the first ESTIMATE statement based on $x = 20$, and similarly in the second statement for $x = 10$. The third ESTIMATE statement computes the difference of the predicted values. Because the spline effect does not interact with the classification variable, this difference does not depend on the level of C. If such an interaction is present, you can estimate the difference in predicted values for a given level of C by using the nonpositional syntax. Because the effect C*spl contains both old-style terms (C) and a constructed effect, you specify the values for the old-style terms before assigning values to constructed effects.

```
proc orthoreg;
   class c;
   effect spl = spline(x / knotmethod=equal(5));
   model y = spl*c;
   estimate 'C2 = 1, x=20' intercept 1 c*spl [1,1 20];
   estimate 'C2 = 2, x=20' intercept 1 c*spl [1,2 20];
   estimate 'C diff at x=20' c*spl [1,1 20] [-1,2 20];
run;
```

It is recommended that you add the E option to the ESTIMATE or LSMESTIMATE statement to verify that the **L** matrix is formed according to your expectations.

In any row of an ESTIMATE statement you can choose positional and nonpositional syntax separately for each effect. However, you cannot mix the two forms of syntax for coefficients of a single effect. For example, the following statement is not proper because both forms of syntax are used for the interaction effect:

```
estimate 'A1B1 - A1B2' b 1 -1  a*b 0 1  [-1, 1 2];
```

Joint Hypothesis Tests with Complex Alternatives, the Chi-Bar-Square Statistic

Silvapulle and Sen (2004) propose a test statistic for testing hypotheses where the null or the alternative hypothesis or both involve inequalities. You can test special cases of these hypotheses with the JOINT option in the ESTIMATE and the LSMESTIMATE statement. Consider the k estimable functions $\mathbf{L}\boldsymbol{\beta}$ and the hypotheses $H_0\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ and $H_a\colon \mathbf{L}\boldsymbol{\beta} \geq \mathbf{0}$. The alternative hypothesis defines a convex cone $\mathcal{C}$ at the origin. Suppose that under the null hypothesis $\mathbf{L}\widehat{\boldsymbol{\beta}}$ follows a multivariate normal distribution with mean $\mathbf{0}$ and variance $\mathbf{V}$. The restricted alternative prevents you from using the usual F or chi-square test machinery, since the distribution of the test statistic under the alternative might not follow the usual rules. Silvapulle and Sen (2004) coined a statistic that takes into account the projection of the observed estimate onto the convex cone formed by the alternative parameter space. This test statistic is called the chi-bar-square statistic, and p-values are obtained by simulation; see, in particular, Chapter 3.4 in Silvapulle and Sen (2004).

Briefly, let $\mathbf{U}$ be a multivariate normal random variable with mean $\mathbf{0}$ and variance matrix $\mathbf{V}$. The chi-bar-square statistic is the random variable

$$\begin{aligned} \overline{\chi}^2 &= \mathbf{U}'\mathbf{V}^{-1}\mathbf{U} - Q \\ Q &= \min_{\boldsymbol{\theta}\in C}(\mathbf{U}-\boldsymbol{\theta})'\mathbf{V}^{-1}(\mathbf{U}-\boldsymbol{\theta}) \end{aligned}$$

and it can be motivated by a geometric argument. The quadratic form in Q is the $\mathbf{V}$-projection of $\mathbf{U}$ onto the cone $\mathcal{C}$. Suppose that this projected point is $\tilde{\mathbf{U}}$. If $\mathbf{U} \in \mathcal{C}$, then $Q = 0$ and $\tilde{\mathbf{U}} = \mathbf{U}$. If $\mathbf{U}$ is completely outside of the cone $\mathcal{C}$, then $\tilde{\mathbf{U}}$ is a point on the surface of the cone. Similarly, $\mathbf{U}'\mathbf{V}^{-1}\mathbf{U}$ is the length of the segment from the origin to $\mathbf{U}$ in the $\mathbf{V}$-space with norm $||x|| = (\mathbf{x}'\mathbf{V}^{-1}\mathbf{x})^{1/2}$. If you apply the Pythagorean theorem, you can see that the chi-bar-square statistic measures the length of the segment from the origin to the projected point $\tilde{\mathbf{U}}$ in $\mathcal{C}$.

To calculate p-values for chi-bar-square statistics, a simulation-based approach is taken. Consider again the set of k estimable functions $\mathbf{L}\boldsymbol{\beta}$ with estimate $\mathbf{L}\widehat{\boldsymbol{\beta}} = \mathbf{U}$ and variance $\mathbf{L}\mathrm{Var}[\hat{\boldsymbol{\beta}}]\mathbf{L}' = \mathbf{V}$.

First, the observed value of the statistic is computed as

$$\overline{\chi}^2_{obs} = \mathbf{U}'\mathbf{V}^{-1}\mathbf{U} - Q$$

Then, n independent random samples $\mathbf{Z}_1, \cdots, \mathbf{Z}_n$ are drawn from an $N(\mathbf{0}, \mathbf{V})$ distribution and the following chi-bar-statistics are computed for the sample:

$$\begin{aligned} \overline{\chi}^2_1 &= \mathbf{Z}_1'\mathbf{V}^{-1}\mathbf{Z}_1 - \min_{\boldsymbol{\theta}\in C}(\mathbf{Z}_1-\boldsymbol{\theta})'\mathbf{V}^{-1}(\mathbf{Z}_1-\boldsymbol{\theta}) \\ &\vdots \\ \overline{\chi}^2_n &= \mathbf{Z}_n'\mathbf{V}^{-1}\mathbf{Z}_n - \min_{\boldsymbol{\theta}\in C}(\mathbf{Z}_n-\boldsymbol{\theta})'\mathbf{V}^{-1}(\mathbf{Z}_n-\boldsymbol{\theta}) \end{aligned}$$

The p-value is estimated by the fraction of simulated statistics that are greater than or equal to the observed value $\overline{\chi}^2_{obs}$.

Notice that unless **U** is interior to the cone $\mathcal{C}$, finding the value of Q requires the solution to a quadratic optimization problem. When k is large, or when many simulations are requested, the computation of p-values for chi-bar-square statistics might require considerable computing time.

ODS Table Names: ESTIMATE Statement

Each table created by the ESTIMATE statement has a name associated with it, and you can use this name to refer to the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 19.17. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 19.17 ODS Tables Produced by the ESTIMATE statement

Table Name	Description	Required Option
Coef	**L** matrix coefficients	E
Estimates	ESTIMATE statement results	Default
Contrasts	Joint test results	JOINT

ODS Graphics: ESTIMATE Statement

This section describes the use of ODS Graphics for creating statistical graphs of the distribution of estimable functions with the ESTIMATE statement. The plots can be produced only in association with the PHREG procedure, which can perform Bayesian analysis. The plots are available via these procedures directly, and also via PROC PLM when it is run using an item store that was created by these procedures.

To request these graphs you must do the following:

- ensure that ODS Graphics is enabled
- use a BAYES statement with PROC PHREG, or use PROC PLM to perform statistical analysis on an item store that was saved from a Bayesian analysis
- request plots with the PLOTS= option in the ESTIMATE statement

For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." The available graphs are summarized in Table 19.18.

Table 19.18 Graphs Produced by the ESTIMATE statement

ODS Graph Name	Plot Description	Required Option
BoxPlot	Displays box plots of estimable functions across a posterior sample.	PLOTS=BOXPLOT

Table 19.18 *continued*

ODS Graph Name	Plot Description	Required Option
DistPanel	Displays panels of histograms with kernel density curves overlaid. Each plot contains the results for the posterior sample of each estimable function.	PLOTS=DISTPLOT
DistPlot	Displays a histogram with a kernel density curve overlaid. The plot contains the results for the posterior sample of the estimable function.	PLOTS=DISTPLOT(UNPACK)

For details about the *plot-options* of the ESTIMATE statement, see the PLOTS= option in the section "ESTIMATE Statement" on page 451.

LSMEANS Statement

This statement documentation applies to the following procedures:
GENMOD, LOGISTIC, ORTHOREG, PHREG, PLM, SURVEYLOGISTIC, SURVEYPHREG, and SURVEYREG.
The GLIMMIX, GLM, and MIXED procedures also support LSMEANS statements. The relevant statement documentation for these procedures can be found in the specific procedure chapter.

The LSMEANS statement computes least squares means (LS-means) of fixed effects. In the GLM, MIXED, and GLIMMIX procedures, LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Thus it is important not to interpret the name with a strict association with least squares estimation. Least squares is the predominant estimation technique for the type of models in which LS-means were first applied. Their interpretation and importance reaches beyond the least squares principle, however. A more appropriate approach to LS-means views them as linear combinations of the parameter estimates that are constructed in such a way that they correspond to average predicted values in a population where the levels of classification variables are balanced.

This contemporary—and historically correct—interpretation of the concept of least squares means underlines their importance in all classes of models where predicted values are reasonably formed as linear combinations of the parameter estimates. LS-means distinguish themselves from general estimable functions in that they take the structure for the model and data into account through the structure of the $\mathbf{X}$ and $\mathbf{X}'\mathbf{X}$ matrix in your model. For example, in a generalized linear model the structure of the $\mathbf{X}$ matrix informs the analysis about the possible levels of classification variables and predictions on the linear (the linked) scale are computed as $\mathbf{x}'\boldsymbol{\beta}$. LS-means are thus meaningful quantities in such models when the linear estimable

function that corresponds to an averaged prediction is constructed on the linked scale. For example, in a binomial model with logit link, the least squares means are predicted population margins of the logits. You can then transform the least squares means to the data scale with the ILINK option, and you can display differences of least squares means in terms of odds ratios with the ODDSRATIO option. The underlying principle—unless you perform a Bayesian analysis—is to construct the estimates or their differences on the linked scale and to apply appropriate transformations in a second step.

Least squares means computations are also supported for multinomial models.

LS-means are computed as $\mathbf{L}\boldsymbol{\beta}$ where the $\mathbf{L}$ matrix that is constructed to compute the predicted values is the same as the $\mathbf{L}$ matrix that is formed in PROC GLM.

Each LS-mean is computed as $\mathbf{L}\widehat{\boldsymbol{\beta}}$, where $\mathbf{L}$ is the coefficient matrix that is associated with the least squares mean and $\widehat{\boldsymbol{\beta}}$ is the estimate of the fixed-effects parameter vector. The approximate standard error for the LS-mean is computed as the square root of $\mathbf{L}\widehat{\mathrm{Var}}[\widehat{\boldsymbol{\beta}}]\mathbf{L}'$. The approximate variance matrix of the fixed-effects estimates depends on the estimation method.

Syntax: LSMEANS Statement

LSMEANS < *model-effects* > < / *options* > **;**

LS-means can be computed for any effect in the statistical model that involves only CLASS variables. You can specify multiple effects in one LSMEANS statement or in multiple LSMEANS statements, and all LSMEANS statements must appear after the MODEL statement. If you do not specify *model-effects*, the options in the LSMEANS statement are applied to all suitable model effects.

As in the ESTIMATE statement, the $\mathbf{L}$ matrix is tested for estimability; if this test fails, the procedure displays "Non-est" for the LS-means entries. Note that linear functions of LS-means, such as differences, can be estimable, even if the means themselves are not estimable. Estimability checks for differences are thus applied separately from checks for the means.

Assuming the LS-mean is estimable, the procedure constructs an approximate t test to test the null hypothesis that the associated population quantity equals zero.

Table 19.19 summarizes important options in the LSMEANS statement. All LSMEANS options are subsequently discussed in alphabetical order.

Table 19.19 Important LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies the covariate value in computing LS-means
BYLEVEL	Computes separate margins
DIFF	Requests differences of LS-means
OM=	Specifies the weighting scheme for LS-means computation as determined by the input data set
SINGULAR=	Tunes estimability checking

Table 19.19 *continued*

Option	Description
Degrees of Freedom and *p*-values	
ADJUST=	Determines the method for multiple comparison adjustment of LS-means differences
ALPHA=α	Determines the confidence level ($1-\alpha$)
STEPDOWN	Adjusts multiple comparison *p*-values further in a step-down fashion
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the **L** matrix
LINES	Produces a "Lines" display for pairwise LS-means differences
MEANS	Prints the LS-means
PLOTS=	Requests ODS statistical graphics of means and mean comparisons
SEED=	Specifies the seed for computations that depend on random numbers
Generalized Linear Modeling	
EXP	Exponentiates and displays estimates of LS-means or LS-means differences
ILINK	Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale
ODDSRATIO	Reports (simple) differences of least squares means in terms of odds ratios if permitted by the link function

You can specify the following options in the LSMEANS statement after a slash (/):

ADJDFE=ROW

ADJDFE=SOURCE

specifies how denominator degrees of freedom are determined when *p*-values and confidence limits are adjusted for multiple comparisons with the ADJUST= option. When you do not specify the ADJDFE= option or when you specify ADJDFE=SOURCE, the denominator degrees of freedom for multiplicity-adjusted results are the denominator degrees of freedom for the LS-mean effect in the "Type III Tests of Fixed Effects" table. When you specify ADJDFE=ROW, the denominator degrees of freedom for multiplicity-adjusted results correspond to the degrees of freedom that are displayed in the DF column of the "Differences of Least Squares Means" table.

The ADJDFE=ROW setting is particularly useful if you want multiplicity adjustments to take into account that denominator degrees of freedom are not constant across LS-mean differences.

In one-way models with heterogeneous variance, combining certain ADJUST= options with the ADJDFE=ROW option corresponds to particular methods of performing multiplicity adjustments in the presence of heteroscedasticity. For example, the following statements fit a heteroscedastic one-way

model and perform Dunnett's T3 method (Dunnett 1980), which is based on the studentized maximum modulus (ADJUST=SMM):

```
proc glimmix;
   class A;
   model y = A / ddfm=satterth;
   random _residual_ / group=A;
   lsmeans A / adjust=smm adjdfe=row;
run;
```

If you combine the ADJDFE=ROW option with ADJUST=SIDAK, the multiplicity adjustment corresponds to the T2 method of Tamhane (1979), and ADJUST=TUKEY corresponds to the method of Games-Howell (Games and Howell 1976). Note that ADJUST=TUKEY gives the exact results for the case of fractional degrees of freedom in the one-way model, but it does not take into account that the degrees of freedom are subject to variability. A more conservative method, such as ADJUST=SMM, might protect the overall error rate better.

Unless the ADJUST= option is specified in the LSMEANS statement, the ADJDFE= option has no effect. The option is not supported by the procedures that perform chi-square-based inference (GENMOD, LOGISTIC, PHREG, and SURVEYLOGISTIC).

ADJUST=BON

ADJUST=DUNNETT

ADJUST=NELSON

ADJUST=SCHEFFE

ADJUST=SIDAK

ADJUST=SIMULATE< (*simoptions***) >**

ADJUST=SMM | GT2

ADJUST=TUKEY

requests a multiple comparison adjustment for the *p*-values and confidence limits for the differences of LS-means. The adjusted quantities are produced in addition to the unadjusted quantities. By default, the procedure performs all pairwise differences. If you specify ADJUST=DUNNETT, the procedure analyzes all differences with a control level. If you specify ADJUST=NELSON, ANOM differences are taken. The ADJUST= option implies the DIFF option.

The BON (Bonferroni) and SIDAK adjustments involve correction factors described in Chapter 41, "The GLM Procedure," and Chapter 60, "The MULTTEST Procedure"; also see Westfall and Young (1993) and Westfall et al. (1999). When you specify ADJUST=TUKEY and your data are unbalanced, the procedure uses the approximation described in Kramer (1956) and identifies the adjustment as "Tukey-Kramer" in the results. Similarly, when you specify ADJUST=DUNNETT or ADJUST=NELSON and the LS-means are correlated, the procedure uses the factor-analytic covariance approximation described in Hsu (1992) and identifies the adjustment in the results as "Dunnett-Hsu" or "Nelson-Hsu," respectively. The approximation derives an approximate "effective sample sizes" for which exact critical values are computed. Computing the exact adjusted *p*-values and critical values for unbalanced designs can be computationally intensive, in particular for ADJUST=NELSON. A simulation-based approach, as specified by the ADJUST=SIM option, while nondeterministic, can provide inferences that are sufficiently accurate in much less time. The preceding references also describe the SCHEFFE and SMM adjustments.

Nelson's adjustment applies only to the analysis of means (Ott 1967; Nelson 1982, 1991, 1993), where LS-means are compared against an average LS-mean. It does not apply to all pairwise differences of least squares means. See the DIFF=ANOM option for more details regarding the analysis of means with the procedure.

The SIMULATE adjustment computes adjusted p-values and confidence limits from the simulated distribution of the maximum or maximum absolute value of a multivariate t random vector. All covariance parameters, except the residual scale parameter, are fixed at their estimated values throughout the simulation, potentially resulting in some underdispersion. The simulation estimates q, the true $(1-\alpha)$th quantile, where $1-\alpha$ is the confidence coefficient. The default α is 0.05, and you can change this value with the ALPHA= option in the LSMEANS statement.

The number of samples is set so that the tail area for the simulated q is within γ of $1-\alpha$ with $100(1-\epsilon)\%$ confidence. In equation form,

$$\Pr(|F(\widehat{q}) - (1-\alpha)| \leq \gamma) = 1 - \epsilon$$

where $\hat{q}$ is the simulated q and F is the true distribution function of the maximum; see Edwards and Berry (1987) for details. By default, $\gamma = 0.005$ and $\epsilon = 0.01$, placing the tail area of $\hat{q}$ within 0.005 of 0.95 with 99% confidence. You can specify the following *simoptions* in parentheses after the ADJUST=SIMULATE option:

ACC=*value* specifies the target accuracy radius γ of a $100(1-\epsilon)\%$ confidence interval for the true probability content of the estimated $(1-\alpha)$th quantile. The default value is ACC=0.005.

EPS=*value* specifies the value ϵ for a $100\times(1-\epsilon)\%$ confidence interval for the true probability content of the estimated $(1-\alpha)$th quantile. The default value for the accuracy confidence is 99%, which corresponds to EPS=0.01.

NSAMP=*n* specifies the sample size for the simulation. By default, n is set based on the values of the target accuracy radius γ and accuracy confidence $100\times(1-\epsilon)\%$ for an interval for the true probability content of the estimated $(1-\alpha)$th quantile. With the default values for γ, ϵ, and α (0.005, 0.01, and 0.05, respectively), NSAMP=12,604 by default.

SEED=*number* specifies an integer that is used to start the pseudo-random number generator for the simulation. If you do not specify a seed, or specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer's clock.

THREADS specifies that the computational work for the simulation be divided into parallel threads, where the number of threads is the value of the SAS system option CPUCOUNT=. For large simulations (as specified directly using the NSAMP= *simoption* or indirectly using the ACC= or EPS= *simoptions*), parallel processing can markedly speed up the computation of adjusted p-values and confidence intervals. However, because the parallel processing has different pseudo-random number streams, the precise results are different from the default ones, which are computed in sequence rather than in parallel. This option overrides the SAS system option THREADS | NOTHREADS.

NOTHREADS specifies that the computational work for the simulation be performed in sequence rather than in parallel. NOTHREADS is the default. This option overrides the SAS system option THREADS | NOTHREADS.

If the STEPDOWN option is in effect, the p-values are further adjusted in a step-down fashion. For certain options and data, this adjustment is exact under an *iid* $N(0, \sigma^2)$ model for the dependent variable, in particular for the following:

- for ADJUST=DUNNETT when the means are uncorrelated
- for ADJUST=TUKEY with STEPDOWN(TYPE=LOGICAL) when the means are balanced and uncorrelated.

The first case is a consequence of the nature of the successive step-down hypotheses for comparisons with a control; the second uses an extension of the maximum studentized range distribution appropriate for partition hypotheses (Royen 1989). Finally, for STEPDOWN(TYPE=FREE), ADJUST=TUKEY employs the Royen (1989) extension in such a way that the resulting p-values are conservative.

ALPHA=*number*

requests that a t type confidence interval be constructed for each of the LS-means with confidence level $1 - number$. The value of *number* must be between 0 and 1; the default is 0.05.

AT *variable*=*value*

AT (*variable-list***)=(***value-list***)**

AT MEANS

modifies the values of the covariates that are used in computing LS-means. By default, all covariate effects are set equal to their mean values for computation of standard LS-means. The AT option enables you to assign arbitrary values to the covariates. Additional columns in the output table indicate the values of the covariates.

If there is an effect that contains two or more covariates, the AT option sets the effect equal to the product of the individual means rather than the mean of the product (as with standard LS-means calculations). The AT MEANS option sets covariates equal to their mean values (as with standard LS-means) and incorporates this adjustment to crossproducts of covariates.

As an example, consider the following statements:

```
class A;
model Y = A x1 x2 x1*x2;
lsmeans A;
lsmeans A / at means;
lsmeans A / at x1=1.2;
lsmeans A / at (x1 x2)=(1.2 0.3);
```

For the first two LSMEANS statements, the LS-means coefficient for x1 is $\overline{x}_1$ (the mean of x1) and for x2 is $\overline{x}_2$ (the mean of x2). However, for the first LSMEANS statement, the coefficient for x1*x2 is $\overline{x_1 x_2}$, but for the second LSMEANS statement, the coefficient is $\overline{x}_1 \times \overline{x}_2$. The third LSMEANS statement sets the coefficient for x1 equal to 1.2 and leaves it at $\overline{x}_2$ for x2, and the final LSMEANS statement sets these values to 1.2 and 0.3, respectively.

Even if you specify a WEIGHT variable, the unweighted covariate means are used for the covariate coefficients if there is no AT specification. If you specify the AT option, WEIGHT or FREQ variables are taken into account as follows. The weighted covariate means are then used for the covariate coefficients for which no explicit AT values are given, or if you specify AT MEANS. Observations that do not contribute to the analysis because of a missing dependent variable are included in computing the covariate means. Use the E option in conjunction with the AT option to check that the modified LS-means coefficients are the ones you want.

The AT option is disabled if you specify the BYLEVEL option.

BYLEVEL

requests that separate margins be computed for each level of the LSMEANS effect.

The standard LS-means have equal coefficients across classification effects. The BYLEVEL option changes these coefficients to be proportional to the observed margins. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins observed in the input data set. In this case, the resulting LS-means are actually equal to raw means for fixed-effects models and certain balanced random-effects models, but their estimated standard errors account for the covariance structure that you have specified. If a WEIGHT statement is specified, the procedure uses weighted margins to construct the LS-means coefficients.

If the AT option is specified, the BYLEVEL option disables it.

CL

requests that *t* type confidence limits be constructed for each of the LS-means. The confidence level is 0.95 by default; this can be changed with the ALPHA= option. If you specify an ADJUST= option, then the confidence limits are adjusted for multiplicity. But if you also specify STEPDOWN, then only *p*-values are step-down adjusted, not the confidence limits.

CORR

displays the estimated correlation matrix of the least squares means as part of the "Least Squares Means" table.

COV

displays the estimated covariance matrix of the least squares means as part of the "Least Squares Means" table.

DF=*number*

specifies the degrees of freedom for the *t* test and confidence limits. The default is the denominator degrees of freedom taken from the "Type III Tests" table that corresponds to the LS-means effect. The option is not supported by the procedures that perform chi-square-based inference (GENMOD, LOGISTIC, PHREG and SURVEYLOGISTIC).

DIFF<=*difftype***>**

PDIFF<=*difftype***>**

requests that differences of the LS-means be displayed. You can use one of the following optional *difftype* values to specify which differences to produce:

ALL requests all pairwise differences; this is the default.

ANOM requests differences between each LS-mean and the average LS-mean, as in the *analysis of means* (Ott 1967). The average is computed as a weighted mean of the LS-means, the weights being inversely proportional to the diagonal entries of the $\mathbf{L}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{L}'$ matrix. If LS-means are nonestimable, this design-based weighted mean is replaced with an equally weighted mean. Note that the ANOM procedure in SAS/QC software implements both tables and graphics for the analysis of means with a variety of response types. For one-way designs and normal data with identity link, the DIFF=ANOM computations are equivalent to the results of PROC ANOM. If the LS-means being compared are uncorrelated, exact adjusted *p*-values and critical values for confidence limits can be computed in the analysis of means; see Nelson (1982, 1991, 1993) and Guirguis and Tobias (2004) in addition to the documentation for the ADJUST=NELSON option.

CONTROL requests differences with a control, which, by default, is the first valid level of each of the specified LSMEANS effects. For example, suppose the effects A and B are classification variables, both of them have two levels 1 and 2, and the A=1, B=1 cell is missing. Unless the procedure supports a MISSING option in the CLASS statement and the option is in effect, the following LSMEANS statement uses the level (1,2) of A*B as the control:

```
lsmeans A*B / diff=control;
```

Nevertheless, you can still specify a valid level as the control—for example, (2,1) of A*B. To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the CONTROL keyword. For example, if the effects A, B, and C are classification variables, each having two levels, 1 and 2, the following LSMEANS statement specifies the (1,2) level of A*B and the (2,1) level of B*C as controls:

```
lsmeans A*B B*C / diff=control('1' '2' '2' '1');
```

For multiple effects, the results depend upon the order of the list, and so you should check the output to make sure that the controls are correct.

Two-tailed tests and confidence limits are associated with the CONTROL *difftype*. For one-tailed results, use either the CONTROLL or CONTROLU *difftype*.

CONTROLL tests whether the noncontrol levels are significantly smaller than the control; the upper confidence limits for the control minus the noncontrol levels are considered to be infinity and are displayed as missing.

CONTROLU tests whether the noncontrol levels are significantly larger than the control; the upper confidence limits for the noncontrol levels minus the control are considered to be infinity and are displayed as missing.

If you want to perform multiple comparison adjustments on the differences of LS-means, you must specify the ADJUST= option.

The differences of the LS-means are displayed in a table titled "Differences of Least Squares Means."

E

requests that the **L** matrix coefficients for the LSMEANS effects be displayed.

EXP

requests exponentiation of the LS-means or LS-mean differences. When you model data with the logit, cumulative logit, or generalized logit link functions, and the estimate represents a log odds ratio or log cumulative odds ratio, the EXP option produces an odds ratio. In proportional hazards model, the exponentiation of the LS-mean differences produces estimates of hazard ratios. If you specify the CL or ALPHA= option, the (adjusted) confidence bounds are also exponentiated.

The EXP option is supported only by PROC PHREG, PROC SURVEYPHREG, the procedures that support generalized linear modeling (GENMOD, LOGISTIC, and SURVEYLOGISTIC), and PROC PLM when it is used to perform statistical analyses on item stores that are created by these procedures.

ILINK

requests that estimates and their standard errors in the "Least Squares Means" table also be reported on the scale of the mean (the inverse linked scale). This enables you to obtain estimates of predicted probabilities and their standard errors in logistic models, for example. The option is specific to an LSMEANS statement. If you also specify the CL option, the procedure computes confidence intervals for the predicted means by applying the inverse link transform to the confidence limits on the linked (linear) scale. Standard errors on the inverse linked scale are computed by the delta method.

The ILINK option is supported only by the procedures that support generalized linear modeling (GENMOD, LOGISTIC and SURVEYLOGISTIC) and by PROC PLM when it is used to perform statistical analyses on item stores that are created by these procedures.

LINES

presents results of comparisons between all pairs of least squares means by listing the means in descending order and indicating nonsignificant subsets by line segments beside the corresponding LS-means. When all differences have the same variance, these comparison lines are guaranteed to accurately reflect the inferences that are based on the corresponding tests, which are made by comparing the respective p-values to the value of the ALPHA= option (0.05 by default). However, equal variances might not be the case for differences between LS-means. If the variances are not all the same, then the comparison lines might be conservative, in the sense that if you base your inferences on the lines alone, you will detect fewer significant differences than the tests indicate. If there are any such differences, the procedure lists the pairs of means that are inferred to be significantly different by the tests but not by the comparison lines. However, even though the variances in many cases are unequal, they are similar enough that the comparison lines accurately reflect the test inferences.

MEANS | NOMEANS

determines whether to print the least squares means themselves. For most procedure, MEANS is the default behavior. For example, the NOMEANS option is the default for the PHREG procedure. You can then use the MEANS option to produce the table of least squares means, if desired.

ODDSRATIO

OR

requests that LS-mean differences (DIFF, ADJUST= options) are also reported in terms of odds ratios. The ODDSRATIO option is ignored unless you use either the logit, cumulative logit, or generalized logit link function. If you specify the CL or ALPHA= option, confidence intervals for the odds ratios are also computed. These intervals are adjusted for multiplicity when you specify the ADJUST= option.

The ODDSRATIO option is supported only by the procedures that support generalized linear modeling (GENMOD, LOGISTIC and SURVEYLOGISTIC) and by PROC PLM when it is used to perform statistical analyses on item stores created by these procedures.

OBSMARGINS<=*OM-data-set***>**

OM<=*OM-data-set***>**

specifies a potentially different weighting scheme for the computation of LS-means coefficients. The standard LS-means have equal coefficients across classification effects; however, the OM option changes these coefficients to be proportional to those found in the *OM-data-set*. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins that are observed in *OM-data-set*.

By default, *OM-data-set* is the same as the analysis data set. You can optionally specify another data set that describes the population for which you want to make inferences. This data set must contain all model variables except for the dependent variable (which is ignored if it is present). In addition, the levels of all CLASS variables must be the same as those that occur in the analysis data set. If a level of a classification effect in the original data set is not present in the *OM-data-set*, the LS-means for that level are undefined. The corresponding rows of the LSMeans table are displayed as missing. Specifying an *OM-data-set* enables you to construct arbitrarily weighted LS-means.

In computing the observed margins, the procedure uses all observations for which there are no missing or invalid independent variables, including those for which there are missing dependent variables. Also, if you use a WEIGHT statement, the procedure computes weighted margins to construct the LS-means coefficients. If your data are balanced, the LS-means are unchanged by the OM option.

The BYLEVEL option modifies the observed-margins LS-means. Instead of computing the margins across all of the *OM-data-set*, the procedure computes separate margins for each level of the LSMEANS effect in question. In this case the resulting LS-means are actually equal to raw means for fixed-effects models and certain balanced random-effects models, but their estimated standard errors account for the covariance structure that you have specified.

You can use the E option in conjunction with either the OM or BYLEVEL option to verify that the modified LS-means coefficients are the ones you want. It is possible that the modified LS-means are not estimable when the standard ones are estimable, or vice versa.

PDIFF

is the same as the DIFF option.

PLOT | PLOTS<=*plot-request***<(***options***)>>**

PLOT | PLOTS<=(*plot-request***<(***options***)> <...** *plot-request***<(***options***)> >)>**

requests that graphics related to least squares means be produced via ODS Graphics, provided that ODS Graphics is enabled and the *plot-request* does not conflict with other options in the LSMEANS statement. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS."

The available options and suboptions are as follows:

ALL

requests that the default plots that correspond to this LSMEANS statement be produced. The default plot depends on the options in the statement.

ANOMPLOT

ANOM

requests an analysis-of-means display in which least squares means are compared to an average least squares mean. Least squares mean ANOM plots are produced only for those model effects that are listed in LSMEANS statements and have options that do not contradict with the display. For example, the following statements produce analysis-of-mean plots for effects A and C:

```
lsmeans A / diff=anom plot=anom;
lsmeans B / diff      plot=anom;
lsmeans C /           plot=anom;
```

The DIFF option in the second LSMEANS statement implies all pairwise differences.

BOXPLOT< *boxplot-options* **>**

produces box plots of the distribution of the least squares mean or least squares mean differences across a posterior sample. For example, this plot is available in procedures that support a Bayesian analysis through the BAYES statement.

A separate box is generated for each estimable function, and all boxes appear on a single graph by default. You can affect the appearance of the box plot graph with the following options:

ORIENTATION=VERTICAL | HORIZONTAL

ORIENT=VERT | HORIZ specifies the orientation of the boxes. The default is vertical orientation of the box plots.

NPANELPOS=*number* specifies how to break the series of box plots across multiple panels. If the NPANELPOS option is not specified, or if *number* equals zero, then all box plots are displayed in a single graph; this is the default. If a negative number is specified, then exactly up to |*number*| of box plots are displayed per panel. If *number* is positive, then the number of boxes per panel is balanced to achieve small variation in the number of box plots per graph.

CONTROLPLOT

CONTROL

requests a display in which least squares means are visually compared against a reference level. These plots are produced only for statements with options that are compatible with control differences. For example, the following statements produce control plots for effects A and C:

```
lsmeans A / diff=control('1') plot=control;
lsmeans B / diff              plot=control;
lsmeans C                     plot=control;
```

The DIFF option in the second LSMEANS statement implies all pairwise differences.

DIFFPLOT< (*diffplot-options***) >**

DIFFOGRAM< (*diffplot-options***) >**

DIFF< (*diffplot-options***) >**

requests a display of all pairwise least squares mean differences and their significance. The display is also known as a "mean-mean scatter plot" when it is based on arithmetic means

(Hsu 1996 and Hsu and Peruggia 1994). For each comparison a line segment, centered at the LS-means in the pair, is drawn. The length of the segment corresponds to the projected width of a confidence interval for the least squares mean difference. Segments that fail to cross the 45-degree reference line correspond to significant least squares mean differences.

LS-mean difference plots are produced only for statements with options that are compatible with the display. For example, the following statements request differences against a control level for the A effect, all pairwise differences for the B effect, and the least squares means for the C effect:

```
lsmeans A / diff=control('1') plot=diff;
lsmeans B / diff              plot=diff;
lsmeans C                     plot=diff;
```

The DIFF= type in the first statement is incompatible with a display of all pairwise differences.

You can specify the following *diffplot-options*:

ABS determines the positioning of the line segments in the plot. This is the default *diffplot-options*. When the ABS option is in effect, all line segments are shown on the same side of the reference line.

NOABS determines the positioning of the line segments in the plot. The NOABS option separates comparisons according to the sign of the difference.

CENTER marks the center point for each comparison. This point corresponds to the intersection of two least squares means.

NOLINES suppresses the display of the line segments that represent the confidence bounds for the differences of the least squares means. The NOLINES option implies the CENTER option. The default is to draw line segments in the upper portion of the plot area without marking the center point.

DISTPLOT< *distplot-options* **>**

DIST< *distplot-options* **>**

generates panels of histograms with a kernel density overlaid if the analysis has access to a set of posterior parameter estimates. For example, this plot is available in procedures that support a Bayesian analysis through the BAYES statement. A separate plot in each panel contains the results for each least squares mean or least squares mean differences. You can sepcify the following *distplot-options* in parentheses:

BOX | NOBOX controls the display of a horizontal box plot of the estimable function's distribution across the posterior sample below the graph. The BOX option is enabled by default.

HIST | NOHIST controls the display of the histogram of the estimable function's distribution across the posterior sample. The HIST option is enabled by default.

NORMAL | NONORMAL controls the display of a normal density estimate on the graph. The NONORMAL option is enabled by default.

KERNEL | NOKERNEL controls the display of a kernel density estimate on the graph. The KERNEL option is enabled by default.

NROWS=*number* specifies the highest number of rows in a panel. The default is 3.

NCOLS=*number* specifies the highest number of columns in a panel. The default is 3.

UNPACK unpacks the panel into separate graphics.

MEANPLOT<(*meanplot-options***)>**
requests displays of the least squares means.

The following *meanplot-options* control the display of the least squares means.

ASCENDING
displays the least squares means in ascending order. This option has no effect if means are displayed in separate plots.

CL
displays upper and lower confidence limits for the least squares means. By default, 95% limits are drawn. You can change the confidence level with the ALPHA= option. Confidence limits are drawn by default if the CL option is specified in the LSMEANS statement.

CLBAND
displays confidence limits as bands. This option implies the JOIN option.

DESCENDING
displays the least squares means in descending order. This option has no effect if means are displayed in separate plots.

ILINK
requests that means (and confidence limits) be displayed on the inverse linked scale.

JOIN
CONNECT
connects the least squares means with lines. This option is implied by the CLBAND option. If the effect contains nested variables and a SLICEBY= effect contains classification variables that appear as crossed effects, this option is ignored.

SLICEBY=*fixed-effect*
specifies an effect by which to group the means in a single plot. For example, the following statement requests a plot in which the levels of A are placed on the horizontal axis and the means that belong to the same level of B are joined by lines:

```
lsmeans A*B / plot=meanplot(sliceby=b join);
```

Unless the LS-mean effect contains at least two classification variables, the SLICEBY= option has no effect. The *fixed-effect* does not have to be an effect in your MODEL statement, but it must consist entirely of classification variables and it must be contained in the LS-mean effect.

PLOTBY=*fixed-effect*

specifies an effect by which to break interaction plots into separate displays. For example, the following statement requests for each level of C one plot of the A*B cell means that are associated with that level of C:

```
lsmeans A*B*C / plot=meanplot(sliceby=b plotby=c clband);
```

In each plot, levels of A are displayed on the horizontal axis, and confidence bands are drawn around the means that share the same level of B.

The PLOTBY= option has no effect unless the LS-mean effect contains at least three classification variables. The *fixed-effect* does not have to be an effect in the MODEL statement, but it must consist entirely of classification variables and it must be contained in the LS-mean effect.

NONE

requests that no plots be produced.

When LS-mean calculations are adjusted for multiplicity by using the ADJUST= option, the plots are adjusted accordingly.

SEED=*number*

specifies the seed for the sampling-based components of the computations for the LSMEANS statement (for example, chi-bar-square statistics and simulated *p*-values). *number* specifies an integer that is used to start the pseudo-random-number generator for the simulation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock. Note that there could be multiple LSMEANS statements with SEED= specifications and there could be other statements that can supply a random number seed. Since the procedure has only one random number stream, the initial seed is shown in the SAS log.

SINGULAR=*number*

tunes the estimability checking. If $\mathbf{v}$ is a vector, define ABS($\mathbf{v}$) to be the largest absolute value of the elements of $\mathbf{v}$. If ABS($\mathbf{K}' - \mathbf{K}'\mathbf{T}$) is greater than c*$number$ for any row of $\mathbf{K}'$ in the contrast, then $\mathbf{K}'\boldsymbol{\beta}$ is declared nonestimable. Here, $\mathbf{T}$ is the Hermite form matrix $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$, and c is ABS($\mathbf{K}'$), except when it equals 0, and then c is 1. The value for *number* must be between 0 and 1; the default is 1E−4.

STEPDOWN<(*step-down-options***)>**

requests that multiple comparison adjustments for the *p*-values of LS-mean differences be further adjusted in a step-down fashion. Step-down methods increase the power of multiple comparisons by taking advantage of the fact that a *p*-value is never declared significant unless all smaller *p*-values are also declared significant. The STEPDOWN adjustment combined with ADJUST=BON corresponds to the methods of Holm (1979) "Method 2" of Schaffer (1986); this is the default. Using step-down-adjusted *p*-values combined with ADJUST=SIMULATE corresponds to the method of Westfall (1997).

If the denominator degrees of freedom are computed by the Kenward-Roger (Kenward and Roger 1997) or Satterthwaite method in a mixed model, then step-down-adjusted *p*-values are produced only if the ADJDFE=ROW option is in effect.

Also, STEPDOWN affects only *p*-values, not confidence limits. For ADJUST=SIMULATE, the generalized least squares hybrid approach of Westfall (1997) is used to increase Monte Carlo accuracy.

You can specify the following *step-down-options* in parentheses:

MAXTIME=*n*

specifies the time (in seconds) to be spent computing the maximal logically consistent sequential subsets of equality hypotheses for TYPE=LOGICAL. The default is MAXTIME=60. If the MAXTIME value is exceeded, the adjusted tests are not computed. When this occurs, you can try increasing the MAXTIME value. However, note that there are common multiple comparisons problems for which this computation requires a huge amount of time—for example, all pairwise comparisons between more than 10 groups. In such cases, try to use TYPE=FREE (the default) or TYPE=LOGICAL(n) for small n.

REPORT

specifies that a report on the step-down adjustment be displayed, including a listing of the sequential subsets (Westfall 1997) and, for ADJUST=SIMULATE, the step-down simulation results.

TYPE=LOGICAL<(*n***)>**

TYPE=FREE

specifies how step-down adjustment are made. If you specify TYPE=LOGICAL, the step-down adjustments are computed by using maximal logically consistent sequential subsets of equality hypotheses (Shaffer 1986, Westfall 1997). Alternatively, for TYPE=FREE, sequential subsets are computed ignoring logical constraints. The TYPE=FREE results are more conservative than those for TYPE=LOGICAL, but they can be much more efficient to produce for many comparisons. For example, it is not feasible to take logical constraints between all pairwise comparisons of more than 10 groups. For this reason, TYPE=FREE is the default.

However, you can reduce the computational complexity of taking logical constraints into account by limiting the depth of the search tree used to compute them, specifying the optional depth parameter as a number n in parentheses after TYPE=LOGICAL. As with TYPE=FREE, results for TYPE=LOGICAL(n) are conservative relative to the true TYPE=LOGICAL results. But even for TYPE=LOGICAL(0) they can be appreciably less conservative than TYPE=FREE, and they are computationally feasible for much larger numbers of comparisons. If you do not specify n or if $n = -1$, the full search tree is used.

ODS Table Names: LSMEANS Statement

Each table created by the LSMEANS statement has a name associated with it, and you can use this name to refer to the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 19.20. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 19.20 ODS Tables Produced by the LSMEANS statement

Table Name	Description	Required Option
Coef	**L** matrix coefficients	E
Diffs	Differences of LS-means	DIFF or ADJUST= or STEPDOWN

Table 19.20 *continued*

Table Name	Description	Required Option
LSMeans	LS-means	Default
LSMLines	Lines display for LS-means	LINES

ODS Graphics: LSMEANS Statement

This section describes the use of ODS Graphics for creating graphics that are related to LS-means in procedures that support the common LSMEANS or SLICE statement. There are two groups of available plots: those that can be produced by all procedures that support these two statements, and those that can be produced only in association with the two procedures that can perform Bayesian analysis (PROC GENMOD and PROC PHREG). Plots that are associated with the Bayesian analysis are available via these procedures directly, and also by using PROC PLM with an item store that was created by these procedures.

Plots in the first group depict the LS-means and their differences; when LS-mean comparisons are adjusted for multiplicity by using the ADJUST= option, the plots are adjusted accordingly. To request plots in this group, ODS Graphics must be enabled and you must request plots with the appropriate PLOTS= option in the LSMEANS or SLICE statement. Plots in the second group depict the posterior sample distribution of LS-means and their differences. To request plots in this group, you must also use a BAYES statement with PROC GENMOD or PROC PHREG, or use PROC PLM to perform statistical analysis on an item store that was saved from a Bayesian analysis.

For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." The available graphs are summarized in Table 19.21 and Table 19.22.

Table 19.21 Graphs Produced by All Procedures That Support the Common LSMEANS or SLICE Statement

ODS Graph Name	Plot Description	Required Option
AnomPlot	Requests an analysis of means display in which least squares means are compared to an average least squares mean.	PLOTS=ANOM
ControlPlot	Requests a display in which least squares means are compared to a reference level.	PLOTS=CONTROL
DiffPlot	Displays all pairwise least squares mean differences and their significance. This plot is also known as a "mean-mean scatter plot" when based on arithmetic means.	PLOTS=DIFF
MeanPlot	Displays least squares means.	PLOTS=MEANPLOT

Table 19.22 Graphs Produced by Procedures That Support the LSMEANS or SLICE Statement and Bayesian Analysis

ODS Graph Name	Plot Description	Required Option
BoxPlot	Displays box plots of LS-means or LS-mean differences across a posterior sample.	PLOTS=BOXPLOT
DistPanel	Displays panels of histograms with kernel density curves overlaid. Each plot contains the results for the posterior sample of each LS-mean or LS-mean difference.	PLOTS=DISTPLOT
DistPlot	Displays a histogram with a kernel density curve overlaid. The plot contains the results for the posterior sample of the LS-mean or LS-mean difference.	PLOTS=DISTPLOT(UNPACK)

You can supply the same *plot-options* to the SLICE statement to produce these graphs. For details about the *plot-options* of the LSMEANS or SLICE statement, see the PLOTS= option in the section "LSMEANS Statement" on page 467. For more details about the DIFFPLOT in particular, see the section "Graphics for LS-Mean Comparisons" on page 3012 in Chapter 40, "The GLIMMIX Procedure."

LSMESTIMATE Statement

This statement documentation applies to the following procedures:
GENMOD, LOGISTIC, MIXED, ORTHOREG, PHREG, PLM, SURVEYLOGISTIC, SURVEYPHREG, and SURVEYREG. The LSMESTIMATE statement in the GLIMMIX procedure is documented in Chapter 40, "The GLIMMIX Procedure."

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means. In contrast to the LSMEANS statement, the LSMESTIMATE statement does not produce the least squares means or their differences; instead, you can estimate any linear function of the least squares means (including the means themselves or their differences). In contrast to the linear functions that are constructed with the ESTIMATE statement, you do not specify coefficients for the individual parameter estimates. Instead, with the LSMESTIMATE statement you specify coefficients for the least squares means; these are then converted for you into estimable functions for the parameter estimates.

The LSMESTIMATE statement thus combines important and convenient features of the LSMEANS and the ESTIMATE statement. As with the LSMEANS statement, the following conditions are true:

- You need to specify only a single effect; the mapping into linear estimable functions in terms of the parameter estimates is performed by the procedure.
- You can use the AT=, BYLEVEL, and OBSMARGINS options to affect the computation of the underlying least squares means.

As with the ESTIMATE statement you can do the following:

- specify multiple-row linear combinations.
- perform multiplicity corrections to control the familywise Type I error probability with the ADJUST= option.
- construct general linear functions of the least squares means.
- perform joint F or chi-square tests with or without order restrictions through the JOINT option.
- rely on positional or nonpositional syntax to specify coefficients for linear functions. For details about using nonpositional syntax, see the section "Positional and Nonpositional Syntax for Coefficients in Linear Functions" on page 462.

The computation of an LSMESTIMATE involves two coefficient matrices. Suppose that there are n_l levels for a valid least squares means effect (an effect that is part of your model and consists of classification variables only). Then the LS-means are formed as $\mathbf{L}_1\widehat{\boldsymbol{\beta}}$, where $\mathbf{L}_1$ is a $(n_l \times p)$ coefficient matrix. The $(k \times n_l)$ coefficient matrix $\mathbf{K}$ is formed from the *values* that you supply in the k rows of the LSMESTIMATE statement. The least squares means estimates then represent the $(k \times 1)$ vector

$$\mathbf{K}\mathbf{L}_1\boldsymbol{\beta} = \mathbf{L}\boldsymbol{\beta}$$

Because the analytic features and capabilities of the LSMESTIMATE statement are an amalgam of the LSMEANS and the ESTIMATE statement, the syntax of the statement follows the same pattern.

Syntax: LSMESTIMATE Statement

LSMESTIMATE *model-effect* < *'label'* > *values* < *divisor*=*n* >
< , < *'label'* > *values* < *divisor*=*n* > > < , . . . >
< / *options* > ;

In contrast to a multirow estimate in the ESTIMATE statement, you specify only a single effect in the LSMESTIMATE statement. The row labels are optional and follow the *model-effect* specification. For example, the following statements fit a split-split-plot design and compare the average of the third and fourth LS-mean of the whole-plot factor A to the first LS-mean of the factor:

```
proc glimmix;
   class a b block;
   model y = a b a*b /  s;
   random int a / sub=block;
   lsmestimate A 'a1 vs avg(a3,a4)' 2 0 -1 -1 divisor=2;
run;
```

The order in which coefficients are assigned to the least squares means corresponds to the order in which they are displayed in the "Least Squares Means" table. You can use the ELSM option to see how coefficients are matched to levels of the fixed effect.

The optional *divisor*=*n* specification enables you to assign a separate divisor to each row of the LSMESTIMATE. You can also assign divisor values through the DIVISOR= option. See the description of the DIVISOR= option that follows for the interaction between the two ways of specifying divisors.

Table 19.23 summarizes important options in the LSMESTIMATE statement. All LSMESTIMATE options are subsequently discussed in alphabetical order.

Table 19.23 Important LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
BYLEVEL	Computes separate margins
DIVISOR=	Specifies a list of values to divide the coefficients
OM=	Specifies the weighting scheme for LS-means computation as determined by a data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and *p*-values	
ADJUST=	Determines the method for multiple comparison adjustment of LS-means differences
ALPHA=α	Determines the confidence level ($1-\alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiple comparison *p*-values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference

Table 19.23 *continued*

Option	Description
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the **L** matrix
ELSM	Prints the **K** matrix
JOINT	Produces a joint F or chi-square test for the LS-means and LS-means differences
PLOTS=	Requests ODS statistical graphics of means and mean comparisons
SEED=	Specifies the seed for computations that depend on random numbers
Generalized Linear Modeling	
CATEGORY=	Specifies how to construct estimable functions with multinomial data
EXP	Exponentiates and displays LS-means estimates
ILINK	Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale

You can specify the following options in the LSMESTIMATE statement after a slash (/):

ADJDFE=SOURCE

ADJDFE=ROW

specifies how denominator degrees of freedom are determined when p-values and confidence limits are adjusted for multiple comparisons with the ADJUST= option. When you do not specify the ADJDFE= option or when you specify ADJDFE=SOURCE, the denominator degrees of freedom for multiplicity-adjusted results are the denominator degrees of freedom for the LS-mean effect in the "Type III Tests of Fixed Effects" table.

The ADJDFE=ROW setting is useful if you want multiplicity adjustments to take into account that denominator degrees of freedom are not constant across estimates. For example, this can be the case when the denominator degrees of freedom are computed by the Satterthwaite or Kenward-Roger method (Kenward and Roger 1997) in a mixed model.

The ADJDFE= option is not supported by the procedures that perform chi-square-based inference (GENMOD, LOGISTIC, PHREG and SURVEYLOGISTIC).

ADJUST=BON

ADJUST=SCHEFFE

ADJUST=SIDAK

ADJUST=SIMULATE< (*simoptions***) >**

ADJUST=T

requests a multiple comparison adjustment for the *p*-values and confidence limits for the LS-mean estimates. The adjusted quantities are produced in addition to the unadjusted *p*-values and confidence limits. Adjusted confidence limits are produced if the CL or ALPHA= option is in effect. For a description of the adjustments, see Chapter 41, "The GLM Procedure," and Chapter 60, "The MULTTEST Procedure," in addition to the documentation for the ADJUST= option in the LSMEANS statement.

Not all adjustment methods of the LSMEANS statement are available for the LSMESTIMATE statement. Multiplicity adjustments in the LSMEANS statement are designed specifically for differences of least squares means.

If you specify the STEPDOWN option, the *p*-values are further adjusted in a step-down fashion.

ALPHA=*number*

requests that a *t* type confidence interval be constructed for each of the LS-means with confidence level $1 - number$. The value of *number* must be between 0 and 1; the default is 0.05.

AT *variable***=***value*

AT (*variable-list***)=(***value-list***)**

AT MEANS

modifies the values of the covariates used in computing LS-means. See the AT option in the LSMEANS statement for details.

BYLEVEL

requests that the procedure compute separate margins for each level of the LSMEANS effect.

The standard LS-means have equal coefficients across classification effects. The BYLEVEL option changes these coefficients to be proportional to the observed margins. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins observed in the input data set. In this case, the resulting LS-means are actually equal to raw means for fixed-effects models and certain balanced random-effects models, but their estimated standard errors account for the covariance structure that you have specified. If a WEIGHT statement is specified, the procedure uses weighted margins to construct the LS-means coefficients.

If the AT option is specified, the BYLEVEL option disables it.

CATEGORY=*category-options*

specifies how to construct estimates and multiplicity corrections for models with multinomial data (ordinal or nominal). This option is also important for constructing sets of estimable functions for *F* tests with the JOINT option.

The *category-options* indicate how response variable levels are treated in constructing the estimable functions. Possible value for the *category-options* are the following:

JOINT
computes the estimable functions for every nonredundant category and treats them as a set. For example, a three-row LSMESTIMATE statement in a model with three response categories leads to six estimable functions.

SEPARATE
computes the estimable functions for every nonredundant category in turn. For example, a three-row LSMESTIMATE statement in a model with three response categories leads to two sets of three estimable functions.

quoted-value-list
computes the estimable functions only for the list of values given. The list must consist of formatted values of the response categories.

For further details about using the CATEGORY= option in models for multinomial data, see the documentation for the CATEGORY= option in the ESTIMATE statement.

The CATEGORY= option is supported only by the procedures that support generalized linear modeling (GENMOD, LOGISTIC, and SURVEYLOGISTIC) and by PROC PLM when it is used to perform statistical analyses on item stores that were created by these procedures.

CHISQ
requests that chi-square tests be performed in addition to F tests, when you request an F test with the JOINT option. This option has no effect in procedures that produce chi-square statistics by default.

CL
requests that t type confidence limits be constructed for each of the LS-means. The confidence level is 0.95 by default; this can be changed with the ALPHA= option. If you specify an ADJUST= option, then the confidence limits are adjusted for multiplicity. But if you also specify STEPDOWN, then only p-values are step-down adjusted, not the confidence limits.

CORR
displays the estimated correlation matrix of the linear combination of the least squares means.

COV
displays the estimated covariance matrix of the linear combination of the least squares means.

DF=*number*
specifies the degrees of freedom for the tests and confidence limits. The option is not supported by the procedures that perform chi-square-based inference (GENMOD, LOGISTIC, PHREG, and SURVEYLOGISTIC).

DIVISOR=*value-list*
specifies a list of values by which to divide the coefficients so that fractional coefficients can be entered as integer numerators. If you do not specify *value-list*, a default value of 1.0 is assumed. Missing values in the *value-list* are converted to 1.0.

If the number of elements in *value-list* exceeds the number of rows of the estimate, the extra values are ignored. If the number of elements in *value-list* is less than the number of rows of the estimate, the last value in *value-list* is carried forward.

If you specify a row-specific divisor as part of the specification of the estimate row, this value multiplies the corresponding value in the *value-list*. For example, the following statement divides the coefficients in the first row by 8, and the coefficients in the third and fourth row by 3:

```
lsmestimate A 'One vs. two'   8 -8   divisor=2,
              'One vs. three' 1  0 -1         ,
              'One vs. four'  3  0  0 -3      ,
              'One vs. five'  3  0  0  0  -3  / divisor=4,.,3;
```

Coefficients in the second row are not altered.

E

requests that the **L** coefficients of the estimable function be displayed. These are the coefficients that apply to the fixed-effect parameter estimates. The E option displays the coefficients that you would need to enter in an equivalent ESTIMATE statement.

ELSM

requests that the **K** matrix coefficients be displayed. These are the coefficients that apply to the LS-means. This option is useful to ensure that you assigned the coefficients correctly to the LS-means.

EXP

requests exponentiation of the least squares means estimate. When you model data with the logit link function and the estimate represents a log odds ratio, the EXP option produces an odds ratio. If you specify the CL or ALPHA= option, the (adjusted) confidence limits for the estimate are also exponentiated.

The EXP option is supported only by PROC PHREG, PROC SURVEYPHREG, the procedures that support generalized linear modeling (GENMOD, LOGISTIC, and SURVEYLOGISTIC), and by PROC PLM when it is used to perform statistical analyses on item stores that were created by these procedures.

ILINK

requests that the estimate and its standard error also be reported on the scale of the mean (the inverse linked scale). The computation of the inverse linked estimate depends on the estimation mode. For example, if the analysis is based on a posterior sample when a BAYES statement is present, the inversely linked estimate is the average of the inversely linked values across the sample of posterior parameter estimates. If the analysis is not based on a sample of parameter estimates, the procedure computes the value on the mean scale by applying the inverse link to the estimate.

The interpretation of the inversely linked quantity depends on the coefficients that are specified in your LSMESTIMATE statement and the link function. For example, in a model for binary data with logit link the following LSMESTIMATE statement computes

$$q = \frac{1}{1 + \exp\{-(\tau_1 - \tau_2)\}}$$

where τ_1 and τ_2 are the least squares means that are associated with the first two levels of the classification effect A:

```
proc logistic;
   class A / param=glm;
   model y = A / dist=binary link=logit;
   lsmestimate A 1 -1 / ilink;
run;
```

The quantity q is not the difference of the probabilities associated with the two levels,

$$\pi_1 - \pi_2 = \frac{1}{1+\exp\{-\tau_1\}} - \frac{1}{1+\exp\{-\tau_2\}}$$

The standard error of the inversely linked estimate is based on the delta method. If you also specify the CL or ALPHA= option, the procedure computes confidence intervals for the inversely linked estimate. These intervals are obtained by applying the inverse link to the confidence intervals on the linked scale.

The ILINK option is supported only by the procedures that support generalized linear modeling (GENMOD, LOGISTIC, and SURVEYLOGISTIC) and by PROC PLM when it is used to perform statistical analyses on item stores that were created by these procedures.

JOINT< (*joint-test-options*) >
requests that a joint F or chi-square test be produced for the rows of the estimate. For more information about the simulation-based p-value calculation, see the section "Joint Hypothesis Tests with Complex Alternatives, the Chi-Bar-Square Statistic" on page 465. You can specify the following *joint-test-options* in parentheses:

ACC=γ
specifies the accuracy radius for determining the necessary sample size in the simulation-based approach of Silvapulle and Sen (2004) for tests with order restrictions. The value of γ must be strictly between 0 and 1; the default value is 0.005.

EPS=ϵ
specifies the accuracy confidence level for determining the necessary sample size in the simulation-based approach of Silvapulle and Sen (2004) for F tests with order restrictions. The value of ϵ must be strictly between 0 and 1; the default value is 0.01.

LABEL='*label*'
assigns an identifying label to the joint test. If you do not specify a label, the first non-default label for the ESTIMATE rows is used to label the joint test.

NOEST
ONLY
performs only the joint test and suppresses other results from the ESTIMATE statement. This option is useful for emulating the CONTRAST statement that is available in other procedures.

NSAMP=*n*
specifies the number of samples for the simulation-based method of Silvapulle and Sen (2004). If n is not specified, it is constructed from the values of the ALPHA=α, the ACC=γ, and the EPS=ϵ options. With the default values for γ, ϵ, and α (0.005, 0.01, and 0.05, respectively), NSAMP=12,604 by default.

CHISQ

adds a chi-square test if the procedure produces an F test by default.

BOUNDS=*value-list*

specifies boundary values for the estimable linear function. The null value of the hypothesis is always zero. If you specify a positive boundary value z, the hypotheses are $H: \theta = 0$, $H_a: \theta > 0$ with the added constraint that $\theta < z$. The same is true for negative boundary values. The alternative hypothesis is then $H_a: \theta < 0$ subject to the constraint $\theta > -|z|$. If you specify a missing value, the hypothesis is assumed to be two-sided. The BOUNDS option enables you to specify sets of one- and two-sided joint hypotheses. If all values in *value-list* are set to missing, the procedure performs a simulation-based p-value calculation for a two-sided test.

LOWER

LOWERTAILED

requests that the p-value for the t test be based only on values that are less than the test statistic. A two-tailed test is the default. A lower-tailed confidence limit is also produced if you specify the CL or ALPHA= option.

Note that for ADJUST=SCHEFFE the one-sided adjusted confidence intervals and one-sided adjusted p-values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the F distribution.

If you request an F test with the JOINT option, then a one-sided left-tailed order restriction is applied to all estimable functions, and the corresponding chi-bar-square statistic of Silvapulle and Sen (2004) is computed in addition to the two-sided, standard, F or chi-square statistic. See the JOINT option for how to control the computation of the simulation-based chi-bar-square statistic.

OBSMARGINS< =*OM-data-set* **>**

OM< =*OM-data-set* **>**

specifies a potentially different weighting scheme for the computation of LS-means coefficients. The standard LS-means have equal coefficients across classification effects; however, the OM option changes these coefficients to be proportional to those found in the *OM-data-set*. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins observed in *OM-data-set*. See the OBSMARGINS option in the LSMEANS statement for further details.

PLOTS=*plot-options*

produces ODS statistical graphics of the distribution of estimable functions if the procedure performs the analysis in a sampling-based mode. For example, this is the case when procedures support a BAYES statement and perform a Bayesian analysis. The estimable functions are then computed for each of the posterior parameter estimates, and the "Least Squares Means Estimates" table reports simple descriptive statistics for the evaluated functions. In this situation, the PLOTS= option enables you to visualize the distribution of the estimable function. The following *plot-options* are available:

ALL

produces all possible plots with their default settings.

BOXPLOT< (*boxplot-options***) >**

produces box plots of the distribution of the estimable function across the posterior sample.

A separate box plot is generated for each estimable function and all box plots appear on a single graph by default. You can affect the appearance of the box plot graph with the following options:

ORIENTATION=VERTICAL | HORIZONTAL

ORIENT=VERT | HORIZ specifies the orientation of the boxes. The default is vertical orientation of the box plots.

NPANELPOS=*number* specifies how to break the series of box plots across multiple panels. If the NPANELPOS option is not specified, or if *number* equals zero, then all box plots are displayed in a single graph; this is the default. If a negative number is specified, then exactly up to |*number*| of box plots are displayed per panel. If *number* is positive, then the number of boxes per panel is balanced to achieve small variation in the number of box plots per graph.

DISTPLOT< (*distplot-options***) >**

DIST< (*distplot-options***) >**

generates panels of histograms with a kernel density overlaid. A separate plot in each panel contains the results for each estimable function. You can specify the following *distplot-options* in parentheses:

BOX | NOBOX controls the display of a horizontal box plot below the histogram. The BOX option is enabled by default.

HIST | NOHIST controls the display of the histogram of the estimable function's distribution across the posterior sample. The HIST option is enabled by default.

NORMAL | NONORMAL controls the display of a normal density estimate on the graph. The NONORMAL option is enabled by default.

KERNEL | NOKERNEL controls the display of a kernel density estimate on the graph. The KERNEL option is enabled by default.

NROWS=*number* specifies the highest number of rows in a panel. The default is 3.

NCOLS=*number* specifies the highest number of columns in a panel. The default is 3.

UNPACK unpacks the panel into separate graphics.

NONE

does not produce any plots.

SEED=*number*

specifies the seed for the sampling-based components of the computations for the LSMESTIMATE statement (for example, chi-bar-square statistics and simulated *p*-values). *number* specifies an integer that is used to start the pseudo-random-number generator for the simulation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock. Note that there could be multiple LSMESTIMATE statements with SEED= specifications and there could be other statements that can supply a random number seed. Since the procedure has only one random number stream, the initial seed is shown in the SAS log.

SINGULAR=*number*

tunes the estimability checking as documented for the SINGULAR= option in the ESTIMATE statement.

STEPDOWN<(*step-down-options***)>**

requests that multiplicity adjustments for the p-values of estimable functions be further adjusted in a step-down fashion. Step-down methods increase the power of multiple testing procedures by taking advantage of the fact that a p-value is never declared significant unless all smaller p-values are also declared significant. The STEPDOWN adjustment combined with ADJUST=BON corresponds to the methods of Holm (1979) and "Method 2" of Shaffer (1986); this is the default. Using step-down-adjusted p-values combined with ADJUST=SIMULATE corresponds to the method of Westfall (1997).

If the ESTIMATE statement is applied with a STEPDOWN option in a mixed model where the degrees-of-freedom method is that of Kenward and Roger (1997) or of Satterthwaite, then step-down-adjusted p-values are produced only if the ADJDFE=ROW option is in effect.

Also, the STEPDOWN option affects only p-values, not confidence limits. For ADJUST=SIMULATE, the generalized least squares hybrid approach of Westfall (1997) is used to increase Monte Carlo accuracy.

You can specify the following *step-down-options* in parentheses:

MAXTIME=*n*

specifies the time (in seconds) to be spent computing the maximal logically consistent sequential subsets of equality hypotheses for TYPE=LOGICAL. The default is MAXTIME=60. If the MAXTIME value is exceeded, the adjusted tests are not computed. When this occurs, you can try increasing the MAXTIME value. However, note that there are common multiple comparisons problems for which this computation requires a huge amount of time—for example, all pairwise comparisons between more than 10 groups. In such cases, try to use TYPE=FREE (the default) or TYPE=LOGICAL(n) for small n.

ORDER=PVALUE

ORDER=ROWS

specifies the order in which the step-down tests are performed. ORDER=PVALUE is the default, with LS-mean estimates being declared significant only if all LS-mean estimates with smaller (unadjusted) p-values are significant. If you specify ORDER=ROWS, then significances are evaluated in the order in which they are specified.

REPORT

specifies that a report on the step-down adjustment be displayed, including a listing of the sequential subsets (Westfall 1997) and, for ADJUST=SIMULATE, the step-down simulation results.

TYPE=LOGICAL<(*n***)>**

TYPE=FREE

specifies how step-down adjustment are made. If you specify TYPE=LOGICAL, the step-down adjustments are computed by using maximal logically consistent sequential subsets of equality hypotheses (Shaffer 1986, Westfall 1997). Alternatively, for TYPE=FREE, sequential subsets are computed ignoring logical constraints. The TYPE=FREE results are more conservative than

those for TYPE=LOGICAL, but they can be much more efficient to produce for many estimates. For example, it is not feasible to take logical constraints between all pairwise comparisons of more than about 10 groups. For this reason, TYPE=FREE is the default.

However, you can reduce the computational complexity of taking logical constraints into account by limiting the depth of the search tree used to compute them, specifying the optional depth parameter as a number n in parentheses after TYPE=LOGICAL. As with TYPE=FREE, results for TYPE=LOGICAL(n) are conservative relative to the true TYPE=LOGICAL results. But even for TYPE=LOGICAL(0), they can be appreciably less conservative than TYPE=FREE, and they are computationally feasible for much larger numbers of estimates. If you do not specify n or if $n = -1$, the full search tree is used.

TESTVALUE=*value-list*

TESTMEAN=*value-list*

specifies the value under the null hypothesis for testing the estimable functions in the LSMESTIMATE statement. The rules for specifying the *value-list* are very similar to those for specifying the divisor list in the DIVISOR= option. If no TESTVALUE= is specified, all tests are performed as $H: \mathbf{L}\boldsymbol{\beta} = 0$. Missing values in the *value-list* also are translated to zeros. If you specify fewer values than rows in the LSMESTIMATE statement, the last value in *value-list* is carried forward.

The TESTVALUE= option affects only p-values from individual, joint, and multiplicity-adjusted tests. It does not affect confidence intervals.

The TESTVALUE option is not available for the multinomial distribution, and the values are ignored when you perform a sampling-based (Bayesian) analysis.

UPPER

UPPERTAILED

requests that the p-value for the t test be based only on values that are greater than the test statistic. A two-tailed test is the default. An upper-tailed confidence limit is also produced if you specify the CL or ALPHA= option.

Note that for ADJUST=SCHEFFE the one-sided adjusted confidence intervals and one-sided adjusted p-values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the F distribution.

If you request a joint test with the JOINT option, then a one-sided right-tailed order restriction is applied to all estimable functions, and the corresponding chi-bar-square statistic of Silvapulle and Sen (2004) is computed in addition to the two-sided, standard, F or chi-square statistic. See the JOINT option for how to control the computation of the simulation-based chi-bar-square statistic.

ODS Table Names: LSMESTIMATE Statement

Each table created by the LSMESTIMATE statement has a name associated with it, and you can use this name to refer to the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 19.24. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 19.24 ODS Tables Produced by the LSMESTIMATE statement

Table Name	Description	Required Option
Coef	**L** matrix coefficients or **K** matrix coefficients	E or ELSM
LSMEstimates	Estimates among LS-means	Default
Contrasts	Joint test results for LS-means estimates	JOINT

ODS Graphics: LSMESTIMATE Statement

This section describes the use of ODS for creating statistical graphs of the distribution of LS-means and LS-mean differences with the LSMESTIMATE statement. The plots can be produced only in association with the two procedures that can perform Bayesian analysis (PROC GENMOD and PROC PHREG). The plots are available via these procedures directly, and also via PROC PLM when run using an item store that was created by these procedures. To request these graphs, you must do the following:

- ensure that ODS Graphics is enabled
- use a BAYES statement with PROC GENMOD or PROC PHREG, or use PROC PLM to perform statistical analysis on an item store that was saved from a Bayesian analysis
- request plots with the PLOTS= option in the LSMESTIMATE statement

For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." The available graphs are summarized in Table 19.25.

Table 19.25 Graphs Produced by the LSMESTIMATE statement

ODS Graph Name	Plot Description	Required Option
BoxPlot	Displays box plots of LS-means or LS-mean differences across a posterior sample.	PLOTS=BOXPLOT
DistPanel	Displays panels of histograms with kernel density curves overlaid. Each plot contains the results for the posterior sample of each LS-mean or LS-mean difference.	PLOTS=DISTPLOT
DistPlot	Displays a histogram with a kernel density curve overlaid. The plot contains the results for the posterior sample of the LS-mean or LS-mean difference.	PLOTS=DISTPLOT(UNPACK)

For details about the *plot-options* of the LSMESTIMATE statement, see the PLOTS= option in the section "LSMESTIMATE Statement" on page 483.

NLOPTIONS Statement

This section applies to the following procedures:
CALIS, GLIMMIX, HPMIXED, PHREG, SURVEYPHREG, and VARIOGRAM. See the individual procedure chapters for deviations from the common syntax and defaults shown here.

Syntax: NLOPTIONS Statement

The NLOPTIONS statement provides you with syntax to control aspects of the nonlinear optimizations in the CALIS, GLIMMIX, HPMIXED, PHREG, SURVEYPHREG, and VARIOGRAM procedures.

NLOPTIONS < *options* > **;**

The nonlinear optimization options are described in alphabetical order after Table 19.26, which summarizes the options by category. The notation used in describing the options is generic in the sense that $\boldsymbol{\psi}$ denotes the $p \times 1$ vector of parameters for the optimization and ψ_i is its ith element. The objective function being minimized, its $p \times 1$ gradient vector, and its $p \times p$ Hessian matrix are denoted as $f(\boldsymbol{\psi})$, $\mathbf{g}(\boldsymbol{\psi})$, and $\mathbf{H}(\boldsymbol{\psi})$, respectively. The gradient with respect to the ith parameter is denoted as $g_i(\boldsymbol{\psi})$. Superscripts in parentheses denote the iteration count; for example, $f(\boldsymbol{\psi})^{(k)}$ is the value of the objective function at iteration k. In the mixed model procedures, the parameter vector $\boldsymbol{\psi}$ might consist of fixed effects only, covariance parameters only, or fixed effects and covariance parameters. In the CALIS procedure, $\boldsymbol{\psi}$ consists of all independent parameters that are defined in the models and in the PARAMETERS statement.

Table 19.26 Options to Control Aspects of the Optimization

Option	Description
Optimization	
HESCAL=	Determines the type of Hessian scaling
INHESSIAN=	Specifies the start for approximated Hessian
LINESEARCH=	Specifies the line-search method
LSPRECISION=	Specifies the line-search precision
RESTART=	Specifies the iteration number for update restart
TECHNIQUE=	Determines the minimization technique
UPDATE=	Determines the update technique
Termination Criteria	
ABSCONV=	Tunes an absolute function convergence criterion
ABSFCONV=	Tunes an absolute function difference convergence criterion
ABSGCONV=	Tunes the absolute gradient convergence criterion
ABSXCONV=	Tunes the absolute parameter convergence criterion
FCONV=	Tunes the relative function convergence criterion
FCONV2=	Tunes another relative function convergence criterion
FSIZE=	Specifies the value used in the FCONV and GCONV criteria

Table 19.26 *continued*

Option	Description
GCONV=	Tunes the relative gradient convergence criterion
GCONV2=	Tunes another relative gradient convergence criterion
MAXFUNC=	Specifies the maximum number of function calls
MAXITER=	Specifies the maximum number of iterations
MAXTIME=	Specifies the upper limit for seconds of CPU time
MINITER=	Specifies the minimum number of iterations
XCONV=	Specifies the relative parameter convergence criterion
XSIZE=	Specifies the value used in the XCONV criterion
Step Length	
DAMPSTEP=	Dampens steps in a line search
INSTEP=	Specifies the initial trust region radius
MAXSTEP=	Specifies the maximum trust region radius
Printed Output	
PALL	Displays (almost) all printed output
PHISTORY	Displays optimization history
NOPRINT	Suppresses all printed output
Covariance Matrix Tolerances	
ASINGULAR=	Specifies the absolute singularity for inertia
MSINGULAR=	Specifies the relative M singularity for inertia
VSINGULAR=	Specifies the relative V singularity for inertia
Constraint Specifications	
LCEPSILON=	Specifies the range for active constraints
LCDEACT=	Specifies the LM tolerance for deactivating
LCSINGULAR=	Specifies the tolerance for dependent constraints
Remote Monitoring	
SOCKET=	Specifies the fileref for remote monitoring

ABSCONV=*r*

ABSTOL=*r*

specifies an absolute function convergence criterion: for minimization, termination requires $f(\psi^{(k)}) \leq r$. The default value of r is the negative square root of the largest double-precision value, which serves only as a protection against overflows.

ABSFCONV=*r* **<** *n* **>**

ABSFTOL=*r* **<** *n* **>**

specifies an absolute function difference convergence criterion:

- For all techniques except NMSIMP (specified by the TECHNIQUE= option), termination requires a small change of the function value in successive iterations,

$$|f(\boldsymbol{\psi}^{(k-1)}) - f(\boldsymbol{\psi}^{(k)})| \leq r$$

- The same formula is used for the NMSIMP technique, but $\boldsymbol{\psi}(k)$ is defined as the vertex with the lowest function value, and $\boldsymbol{\psi}^{(k-1)}$ is defined as the vertex with the highest function value in the simplex.

The default value is $r = 0$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSGCONV=*r* **<** *n* **>**

ABSGTOL=*r* **<** *n* **>**

specifies an absolute gradient convergence criterion:

- For all techniques except NMSIMP (specified by the TECHNIQUE= option), termination requires the maximum absolute gradient element to be small:

$$\max_j |g_j(\boldsymbol{\psi}^{(k)})| \leq r$$

- This criterion is not used by the NMSIMP technique.

The default value is r =1E−5. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSXCONV=*r* **<** *n* **>**

ABSXTOL=*r* **<** *n* **>**

specifies an absolute parameter convergence criterion:

- For all techniques except NMSIMP, termination requires a small Euclidean distance between successive parameter vectors,

$$\| \boldsymbol{\psi}^{(k)} - \boldsymbol{\psi}^{(k-1)} \|_2 \leq r$$

- For the NMSIMP technique, termination requires either a small length $\alpha^{(k)}$ of the vertices of a restart simplex,

$$\alpha^{(k)} \leq r$$

or a small simplex size,

$$\delta^{(k)} \leq r$$

where the simplex size $\delta^{(k)}$ is defined as the L1 distance from the simplex vertex $\boldsymbol{\xi}^{(k)}$ with the smallest function value to the other p simplex points $\boldsymbol{\psi}_l^{(k)} \neq \boldsymbol{\xi}^{(k)}$:

$$\delta^{(k)} = \sum_{\boldsymbol{\psi}_l \neq y} \parallel \boldsymbol{\psi}_l^{(k)} - \boldsymbol{\xi}^{(k)} \parallel_1$$

The default is r =1E−8 for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

ASINGULAR=*r*

ASING=*r*

specifies an absolute singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is the square root of the smallest positive double-precision value.

DAMPSTEP<=*r***>**

specifies that the initial step length value $\alpha^{(0)}$ for each line search (used by the QUANEW, CONGRA, or NEWRAP technique) cannot be larger than r times the step length value used in the former iteration. If the DAMPSTEP option is specified but r is not specified, the default is $r = 2$. The DAMPSTEP= option can prevent the line-search algorithm from repeatedly stepping into regions where some objective functions are difficult to compute or where they could lead to floating-point overflows during the computation of objective functions and their derivatives. The DAMPSTEP= option can save time-consuming function calls during the line searches of objective functions that result in very small steps.

FCONV=*r***<** *n* **>**

FTOL=*r***<** *n* **>**

specifies a relative function convergence criterion:

- For all techniques except NMSIMP, termination requires a small relative change of the function value in successive iterations,

$$\frac{|f(\boldsymbol{\psi}^{(k)}) - f(\boldsymbol{\psi}^{(k-1)})|}{\max(|f(\boldsymbol{\psi}^{(k-1)})|, \text{FSIZE})} \leq r$$

  where FSIZE is defined by the FSIZE= option.

- The same formula is used for the NMSIMP technique, but $\boldsymbol{\psi}^{(k)}$ is defined as the vertex with the lowest function value and $\boldsymbol{\psi}^{(k-1)}$ is defined as the vertex with the highest function value in the simplex.

The default is $r = 10^{-\text{FDIGITS}}$, where FDIGITS is by default $-\log_{10}\{\epsilon\}$ and ϵ is the machine precision. Some procedures, such as the GLIMMIX procedure, enable you to change the value with the FDIGITS= option in the PROC statement. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

FCONV2=*r*< *n*>

FTOL2=*r*< *n*>

specifies a second function convergence criterion:

- For all techniques except NMSIMP, termination requires a small predicted reduction,

  $$df^{(k)} \approx f(\boldsymbol{\psi}^{(k)}) - f(\boldsymbol{\psi}^{(k)} + \mathbf{s}^{(k)})$$

  of the objective function. The predicted reduction

  $$\begin{aligned} df^{(k)} &= -\mathbf{g}^{(k)'}\mathbf{s}^{(k)} - \frac{1}{2}\mathbf{s}^{(k)'}\mathbf{H}^{(k)}\mathbf{s}^{(k)} \\ &= -\frac{1}{2}\mathbf{s}^{(k)'}\mathbf{g}^{(k)} \leq r \end{aligned}$$

  is computed by approximating the objective function f by the first two terms of the Taylor series and substituting the Newton step,

  $$\mathbf{s}^{(k)} = -[\mathbf{H}^{(k)}]^{-1}\mathbf{g}^{(k)}$$

- For the NMSIMP technique, termination requires a small standard deviation of the function values of the $p+1$ simplex vertices $\boldsymbol{\psi}_l^{(k)}$, $l = 0, \ldots, p$,

  $$\sqrt{\frac{1}{n+1}\sum_l \left[f(\boldsymbol{\psi}_l^{(k)}) - \overline{f}(\boldsymbol{\psi}^{(k)})\right]^2} \leq r$$

  where $\overline{f}(\boldsymbol{\psi}^{(k)}) = \frac{1}{p+1}\sum_l f(\boldsymbol{\psi}_l^{(k)})$. If there are p_{act} boundary constraints active at $\boldsymbol{\psi}^{(k)}$, the mean and standard deviation are computed only for the $n+1-p_{act}$ unconstrained vertices.

The default value is r =1E−6 for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

FSIZE=*r*

specifies the FSIZE parameter of the relative function and relative gradient termination criteria. The default value is $r = 0$. For more details, see the FCONV= and GCONV= options.

GCONV=*r*< *n*>

GTOL=*r*< *n*>

specifies a relative gradient convergence criterion:

- For all techniques except CONGRA and NMSIMP, termination requires that the normalized predicted function reduction be small,

  $$\frac{\mathbf{g}(\boldsymbol{\psi}^{(k)})'[\mathbf{H}^{(k)}]^{-1}\mathbf{g}(\boldsymbol{\psi}^{(k)})}{\max(|f(\boldsymbol{\psi}^{(k)})|, \mathrm{FSIZE})} \leq r$$

  where FSIZE is defined by the FSIZE= option. For the CONGRA technique (where a reliable Hessian estimate $\mathbf{H}$ is not available), the following criterion is used:

  $$\frac{\| \mathbf{g}(\boldsymbol{\psi}^{(k)}) \|_2^2 \quad \| \mathbf{s}(\boldsymbol{\psi}^{(k)}) \|_2}{\| \mathbf{g}(\boldsymbol{\psi}^{(k)}) - \mathbf{g}(\boldsymbol{\psi}^{(k-1)}) \|_2 \max(|f(\boldsymbol{\psi}^{(k)})|, \mathrm{FSIZE})} \leq r$$

- This criterion is not used by the NMSIMP technique.

The default value is $r = 1E{-}8$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

GCONV2=*r*<*n*>

GTOL2=*r*<*n*>

specifies another relative gradient convergence criterion:

- For least squares problems and the TRUREG, LEVMAR, NRRIDG, and NEWRAP techniques, the following criterion of Browne (1982) is used:

$$\max_j \frac{|\mathbf{g}_j(\boldsymbol{\psi}^{(k)})|}{\sqrt{f(\boldsymbol{\psi}^{(k)})\mathbf{H}^{(k)}_{j,j}}} \leq r$$

- This criterion is not used by the other techniques.

The default value is $r = 0$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

HESCAL=0 | 1 | 2 | 3

HS=0 | 1 | 2 | 3

specifies the scaling version of the Hessian (or crossproduct Jacobian) matrix used in NRRIDG, TRUREG, LEVMAR, NEWRAP, or DBLDOG optimization.

If HS is not equal to 0, the first iteration and each restart iteration set the diagonal scaling matrix $D^{(0)} = \text{diag}(d_i^{(0)})$:

$$d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)}$$

where $H_{i,i}^{(0)}$ are the diagonal elements of the Hessian (or crossproduct Jacobian). In every other iteration, the diagonal scaling matrix $D^{(0)} = \text{diag}(d_i^{(0)})$ is updated depending on the HS option:

HS=0 specifies that no scaling be done.

HS=1 specifies the Moré (1978) scaling update:

$$d_i^{(k+1)} = \max\left[d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}\right]$$

HS=2 specifies the Dennis, Gay, and Welsch (1981) scaling update:

$$d_i^{(k+1)} = \max\left[0.6 * d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}\right]$$

HS=3 specifies that d_i be reset in each iteration:

$$d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}$$

In each scaling update, ϵ is the relative machine precision. The default value is HS=0. Scaling of the Hessian can be time-consuming in the case where general linear constraints are active.

INHESSIAN<=*r*>

INHESS<=*r*>

specifies how the initial estimate of the approximate Hessian is defined for the quasi-Newton techniques QUANEW and DBLDOG. There are two alternatives:

- If you do not use the *r* specification, the initial estimate of the approximate Hessian is set to the Hessian at $\psi^{(0)}$.
- If you do use the *r* specification, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix $r\mathbf{I}$.

By default (if you do not specify the option INHESSIAN=*r*), the initial estimate of the approximate Hessian is set to the multiple of the identity matrix $r\mathbf{I}$, where the scalar r is computed from the magnitude of the initial gradient.

INSTEP=*r*

SALPHA=*r*

RADIUS=*r*

reduces the length of the first trial step during the line search of the first iterations. For highly nonlinear objective functions, such as the EXP function, the default initial radius of the trust-region algorithm TRUREG or DBLDOG or the default step length of the line-search algorithms can result in arithmetic overflows. If this occurs, you should specify decreasing values of $0 < r < 1$ such as INSTEP=1E−1, INSTEP=1E−2, INSTEP=1E−4, and so on, until the iteration starts successfully.

- For trust-region algorithms (TRUREG or DBLDOG), the INSTEP= option specifies a factor $r > 0$ for the initial radius $\Delta^{(0)}$ of the trust region. The default initial trust-region radius is the length of the scaled gradient. This step corresponds to the default radius factor of $r = 1$.
- For line-search algorithms (NEWRAP, CONGRA, or QUANEW), the INSTEP= option specifies an upper bound for the initial step length for the line search during the first five iterations. The default initial step length is $r = 1$.
- For the Nelder-Mead simplex algorithm, by using TECH=NMSIMP, the INSTEP=*r* option defines the size of the start simplex.

LCDEACT=*r*

LCD=*r*

specifies a threshold r for the Lagrange multiplier that determines whether an active inequality constraint remains active or can be deactivated. For maximization, r must be greater than zero; for minimization, r must be smaller than zero. An active inequality constraint can be deactivated only if its Lagrange multiplier is less than the threshold value. The default value is

$$r = \pm \min(0.01, \max(0.1 \times \text{ABSGCONV}, 0.001 \times \text{gmax}^{(k)}))$$

where "+" is for maximization, "–" is for minimization, ABSGCONV is the value of the absolute gradient criterion, and $\text{gmax}^{(k)}$ is the maximum absolute element of the gradient or the projected gradient.

LCEPSILON=*r*

LCEPS=*r*

LCE=*r*

specifies the range r for active and violated boundary constraints, where $r \geq 0$. If the point $\boldsymbol{\psi}^{(k)}$ satisfies the following condition, the constraint i is recognized as an active constraint:

$$|\sum_{j=1}^{k} a_{ij}\psi_j^{(k)} - b_i| \leq r \times (|b_i| + 1)$$

Otherwise, the constraint i is either an inactive inequality or a violated inequality or equality constraint. The default value is r =1E−8. During the optimization process, the introduction of rounding errors can force the optimization to increase the value of r by a factor of 10^k for some $k > 0$. If this happens, it is indicated by a message displayed in the log.

LCSINGULAR=*r*

LCSING=*r*

LCS=*r*

specifies a criterion r, where $r \geq 0$, that is used in the update of the QR decomposition and that determines whether an active constraint is linearly dependent on a set of other active constraints. The default value is r =1E−8. The larger r becomes, the more the active constraints are recognized as being linearly dependent. If the value of r is larger than 0.1, it is reset to 0.1.

LINESEARCH=*i*

LIS=*i*

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques. See Fletcher (1987) for an introduction to line-search techniques. The value of i can be $1, \ldots, 8$ as follows. The default is LIS=2.

LIS=1 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is similar to one used by the Harwell subroutine library.

LIS=2 specifies a line-search method that needs more function than gradient calls for quadratic and cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option. This is the default.

LIS=3 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.

LIS=4 specifies a line-search method that needs the same number of function and gradient calls for stepwise extrapolation and cubic interpolation.

LIS=5 specifies a line-search method that is a modified version of LIS=4.

LIS=6 specifies a golden-section line search (Polak 1971), which uses only function values for linear approximation.

LIS=7 specifies a bisection line search (Polak 1971), which uses only function values for linear approximation.

LIS=8 specifies the Armijo line-search technique (Polak 1971), which uses only function values for linear approximation.

LSPRECISION=*r*

LSP=*r*

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3. Usually an imprecise line search is inexpensive and successful. For more difficult optimization problems, a more precise and expensive line search might be necessary (Fletcher 1987). The LIS=2 line-search method (which is the default for the NEWRAP, QUANEW, and CONGRA techniques) and the LIS=3 line-search method approach exact line search for small LSPRECISION= values. If you have numerical problems, try to decrease the LSPRECISION= value to obtain a more precise line search. The default values are shown in Table 19.27.

Table 19.27 Default Values for Line-Search Precision

TECH=	UPDATE=	LSP Default
QUANEW	DBFGS, BFGS	$r = 0.4$
QUANEW	DDFP, DFP	$r = 0.06$
CONGRA	All	$r = 0.1$
NEWRAP	No update	$r = 0.9$

For more details, see Fletcher (1987).

MAXFUNC=*i*

MAXFU=*i*

specifies the maximum number i of function calls in the optimization process. The default values are as follows:

- 125 for the TRUREG, NRRIDG, NEWRAP, and LEVMAR techniques
- 500 for the QUANEW and DBLDOG techniques
- 1000 for the CONGRA technique
- 3000 for the NMSIMP technique

Optimization can terminate only after completing a full iteration. Therefore, the number of function calls that are actually performed can exceed the number that is specified by the MAXFUNC= option.

MAXITER=*i*

MAXIT=*i*

specifies the maximum number i of iterations in the optimization process. The default values are as follows:

- 50 for the TRUREG, NRRIDG, NEWRAP, and LEVMAR techniques
- 200 for the QUANEW and DBLDOG techniques
- 400 for the CONGRA technique
- 1000 for the NMSIMP technique

These default values are also valid when i is specified as a missing value.

MAXSTEP=*r*<*n*>

specifies an upper bound for the step length of the line-search algorithms during the first n iterations. By default, r is the largest double-precision value and n is the largest integer available. Setting this option can improve the speed of convergence for the CONGRA, QUANEW, and NEWRAP techniques.

MAXTIME=*r*

specifies an upper limit of r seconds of CPU time for the optimization process. The default value is the largest floating-point double representation of your computer. The time specified by the MAXTIME= option is checked only once at the end of each iteration. Therefore, the actual running time can be much longer than that specified by the MAXTIME= option. The actual running time includes the rest of the time needed to finish the iteration and the time needed to generate the output of the results.

MINITER=*i*

MINIT=*i*

specifies the minimum number of iterations. The default value is 0. If you request more iterations than are actually needed for convergence to a stationary point, the optimization algorithms can behave strangely. For example, the effect of rounding errors can prevent the algorithm from continuing for the required number of iterations.

MSINGULAR=*r*

MSING=*r*

specifies a relative singularity criterion r, where $R > 0$, for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is 1E−12.

NOPRINT

suppresses output that is related to optimization, such as the iteration history. This option, along with all NLOPTIONS statement options for displayed output, are ignored by the GLIMMIX and HPMIXED procedures.

PALL

displays all optional output for optimization. This option is supported only by the CALIS and SURVEYPHREG procedures.

PHISTORY

PHIST

displays the optimization history. The PHISTORY option is implied if the PALL option is specified. The PHISTORY option is supported only by the CALIS and SURVEYPHREG procedures.

RESTART=*i*

REST=*i*

specifies that the QUANEW or CONGRA technique is restarted with a steepest search direction after at most i iterations, where $i > 0$. Default values are as follows:

- When TECHNIQUE=CONGRA and UPDATE=PB, restart is performed automatically; so i is not used.

- When TECHNIQUE=CONGRA and UPDATE≠PB, $i = \min(10p, 80)$, where p is the number of parameters.
- When TECHNIQUE=QUANEW, i is the largest integer available.

SINGULAR=*r*

SING=*r*

specifies the singularity criterion r, $r0 \leq r \leq 1$, that is used for the inversion of the Hessian matrix. The default value is 1E−8.

SOCKET=*fileref*

specifies the fileref that contains the information needed for remote monitoring.

TECHNIQUE=*value*

TECH=*value*

OMETHOD=*value*

OM=*value*

specifies the optimization technique. You can find additional information about choosing an optimization technique in the section "Choosing an Optimization Algorithm" on page 508. Valid values for the TECHNIQUE= option are as follows:

- CONGRA
  performs a conjugate-gradient optimization, which can be more precisely specified with the UPDATE= option and modified with the LINESEARCH= option. When you specify this option, UPDATE=PB by default.
- DBLDOG
  performs a version of double-dogleg optimization, which can be more precisely specified with the UPDATE= option. When you specify this option, UPDATE=DBFGS by default.
- LEVMAR
  performs a highly stable, but for large problems memory- and time-consuming, Levenberg-Marquardt optimization technique, a slightly improved variant of the Moré (1978) implementation. You can also specify this technique with the alias LM or MARQUARDT. In the CALIS procedure, this is the default optimization technique if there are fewer than 40 parameters to estimate. The GLIMMIX and HPMIXED procedures do not support this optimization technique.
- NMSIMP
  performs a Nelder-Mead simplex optimization. The CALIS procedure does not support this optimization technique.
- NONE
  does not perform any optimization. This option can be used for the following:
  - to perform a grid search without optimization
  - to compute estimates and predictions that cannot be obtained efficiently with any of the optimization techniques
  - to obtain inferences for known values of the covariance parameters
- NEWRAP
  performs a Newton-Raphson optimization that combines a line-search algorithm with ridging. The line-search algorithm LIS=2 is the default method.

- NRRIDG
  performs a Newton-Raphson optimization with ridging. This is the default optimization technique in the SURVEYPHREG procedure.
- QUANEW
  performs a quasi-Newton optimization, which can be defined more precisely with the UPDATE= option and modified with the LINESEARCH= option.
- TRUREG
  performs a trust-region optimization.

UPDATE=*method*

UPD=*method*

specifies the update method for the quasi-Newton, double-dogleg, or conjugate-gradient optimization technique. Not every update method can be used with each optimizer.

The following are the valid methods for the UPDATE= option:

- BFGS
  performs the original Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the inverse Hessian matrix.
- DBFGS
  performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default update method.
- DDFP
  performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- DFP
  performs the original DFP update of the inverse Hessian matrix.
- PB
  performs the automatic restart update method of Powell (1977) and Beale (1972).
- FR
  performs the Fletcher-Reeves update (Fletcher 1987).
- PR
  performs the Polak-Ribiere update (Fletcher 1987).
- CD
  performs a conjugate-descent update of Fletcher (1987).

VERSION=1 | 2

VS=1 | 2

specifies the version of the quasi-Newton optimization technique with nonlinear constraints.

VS=1 specifies the update of the μ vector as in Powell (1978a, 1978b) (update like VF02AD).

VS=2 specifies the update of the μ vector as in Powell (1982a, 1982b) (update like VMCWD).

The default is VERSION=2.

VSINGULAR=*r*

VSING=*r*

specifies a relative singularity criterion r, where $r > 0$, for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is $r = 1\text{E}{-8}$.

XCONV=*r*< *n*>

XTOL=*r*< *n*>

specifies the relative parameter convergence criterion:

- For all techniques except NMSIMP, termination requires a small relative parameter change in subsequent iterations:

$$\frac{\max_j |\psi_j^{(k)} - \psi_j^{(k-1)}|}{\max(|\psi_j^{(k)}|, |\psi_j^{(k-1)}|, \text{XSIZE})} \leq r$$

- For the NMSIMP technique, the same formula is used, but $\psi_j^{(k)}$ is defined as the vertex with the lowest function value and $\psi_j^{(k-1)}$ is defined as the vertex with the highest function value in the simplex.

The default value is $r = 1\text{E}{-8}$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

XSIZE=*r*

specifies the XSIZE parameter r of the relative parameter termination criterion, where $r \geq 0$. The default value is $r = 0$. For more details, see the XCONV= option.

Choosing an Optimization Algorithm

First- or Second-Order Algorithms

The factors that go into choosing a particular optimization technique for a particular problem are complex. Trial and error can be involved.

For many optimization problems, computing the gradient takes more computer time than computing the function value. Computing the Hessian sometimes takes *much* more computer time and memory than computing the gradient, especially when there are many decision variables. Unfortunately, optimization techniques that do not use some kind of Hessian approximation usually require many more iterations than techniques that do use a Hessian matrix, and, as a result, the total run time of these techniques is often longer. Techniques that do not use the Hessian also tend to be less reliable. For example, they can terminate more easily at stationary points than at global optima.

Table 19.28 shows which derivatives are required for each optimization technique.

Table 19.28 Derivatives Required

Algorithm	First-Order	Second-Order
LEVMAR	x	x
TRUREG	x	x
NEWRAP	x	x
NRRIDG	x	x
QUANEW	x	-
DBLDOG	x	-
CONGRA	x	-
NMSIMP	-	-

The second-derivative methods TRUREG, NEWRAP, and NRRIDG are best for small problems where the Hessian matrix is not expensive to compute. Sometimes the NRRIDG algorithm can be faster than the TRUREG algorithm, but TRUREG can be more stable. The NRRIDG algorithm requires only one matrix with $p(p+1)/2$ double words; TRUREG and NEWRAP require two such matrices. Here, p denotes the number of parameters in the optimization.

The first-derivative methods QUANEW and DBLDOG are best for medium-sized problems where the objective function and the gradient are much faster to evaluate than the Hessian. In general, the QUANEW and DBLDOG algorithms require more iterations than TRUREG, NRRIDG, and NEWRAP, but each iteration can be much faster. The QUANEW and DBLDOG algorithms require only the gradient to update an approximate Hessian, and they require slightly less memory than TRUREG or NEWRAP (essentially one matrix with $p(p+1)/2$ double words).

The first-derivative method CONGRA is best for large problems where the objective function and the gradient can be computed much faster than the Hessian and where too much memory is required to store the (approximate) Hessian. In general, the CONGRA algorithm requires more iterations than QUANEW or DBLDOG, but each iteration can be much faster. Because CONGRA requires only a factor of p double-word memory, many large applications can be solved only by CONGRA.

The no-derivative method NMSIMP is best for small problems where derivatives are not continuous or are very difficult to compute.

Each optimization method uses one or more convergence criteria that determine when it has converged. An algorithm is considered to have converged when any one of the convergence criteria is satisfied. For example, under the default settings, the QUANEW algorithm will converge if ABSGCONV <1E−5, FCONV $< 10^{-FDIGITS}$, or GCONV <1E−8.

Algorithm Descriptions

Trust Region Optimization (TRUREG)

The trust region method uses the gradient $\mathbf{g}(\boldsymbol{\psi}^{(k)})$ and the Hessian matrix $\mathbf{H}(\boldsymbol{\psi}^{(k)})$; thus, it requires that the objective function $f(\boldsymbol{\psi})$ have continuous first- and second-order derivatives inside the feasible region.

The trust region method iteratively optimizes a quadratic approximation to the nonlinear objective function within a hyperelliptic trust region with radius Δ that constrains the step size that corresponds to the quality of the quadratic approximation. The trust region method is implemented based on Dennis, Gay, and Welsch (1981), Gay (1983), and Moré and Sorensen (1983).

The trust region method performs well for small- to medium-sized problems, and it does not need many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

Newton-Raphson Optimization with Line Search (NEWRAP)

The NEWRAP technique uses the gradient $\mathbf{g}(\boldsymbol{\psi}^{(k)})$ and the Hessian matrix $\mathbf{H}(\boldsymbol{\psi}^{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region. If second-order derivatives are computed efficiently and precisely, the NEWRAP method can perform well for medium-sized to large problems, and it does not need many function, gradient, and Hessian calls.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. Otherwise, a combination of ridging and line search is performed to compute successful steps. If the Hessian is not positive definite, a multiple of the identity matrix is added to the Hessian matrix to make it positive definite (Eskow and Schnabel 1991).

In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation (LIS=2).

Newton-Raphson Ridge Optimization (NRRIDG)

The NRRIDG technique uses the gradient $\mathbf{g}(\boldsymbol{\psi}^{(k)})$ and the Hessian matrix $\mathbf{H}(\boldsymbol{\psi}^{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. If at least one of these two conditions is not satisfied, a multiple of the identity matrix is added to the Hessian matrix.

The NRRIDG method performs well for small- to medium-sized problems, and it does not require many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

Because the NRRIDG technique uses an orthogonal decomposition of the approximate Hessian, each iteration of NRRIDG can be slower than that of the NEWRAP technique, which works with a Cholesky decomposition. Usually, however, NRRIDG requires fewer iterations than NEWRAP.

Quasi-Newton Optimization (QUANEW)

The (dual) quasi-Newton method uses the gradient $\mathbf{g}(\boldsymbol{\psi}^{(k)})$, and it does not need to compute second-order derivatives because they are approximated. It works well for medium-sized to moderately large optimization problems, where the objective function and the gradient are much faster to compute than the Hessian. However, in general, it requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which compute second-order derivatives. QUANEW is the default optimization algorithm because it provides an appropriate balance between the speed and stability required for most nonlinear mixed model applications.

The QUANEW technique is one of the following, depending upon the value of the UPDATE= option:

- the original quasi-Newton algorithm, which updates an approximation of the inverse Hessian
- the dual quasi-Newton algorithm, which updates the Cholesky factor of an approximate Hessian (this is the default)

You can specify four update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- BFGS performs the original BFGS update of the inverse Hessian matrix.
- DFP performs the original DFP update of the inverse Hessian matrix.

In each iteration, a line search is performed along the search direction to find an approximate optimum. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α that satisfies the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit of the step size. Violating the left-side Goldstein condition can affect the positive definiteness of the quasi-Newton update. In that case, either the update is skipped or the iterations are restarted with an identity matrix, resulting in the steepest descent or ascent search direction. You can specify line-search algorithms other than the default with the LIS= option.

The QUANEW algorithm uses its own line-search technique. Of the options and parameters that control the line search for other algorithms, only the INSTEP= option applies here. In several applications, large steps in the first iterations are troublesome. You can use the INSTEP= option to impose an upper bound for the step size α during the first five iterations. You can also use the INHESSIAN= option to specify a different starting approximation for the Hessian. If you specify only the INHESSIAN option, the Cholesky factor of a (possibly ridged) finite-difference approximation of the Hessian is used to initialize the quasi-Newton update process.

Double-Dogleg Optimization (DBLDOG)

The double-dogleg optimization method combines the ideas of the quasi-Newton and trust region methods. In each iteration, the double-dogleg algorithm computes the step $\mathbf{s}^{(k)}$ as the linear combination of the steepest descent or ascent search direction $\mathbf{s}_1^{(k)}$ and a quasi-Newton search direction $\mathbf{s}_2^{(k)}$,

$$\mathbf{s}^{(k)} = \alpha_1 \mathbf{s}_1^{(k)} + \alpha_2 \mathbf{s}_2^{(k)}$$

The step is requested to remain within a prespecified trust region radius; see Fletcher (1987, p. 107). Thus, the DBLDOG subroutine uses the dual quasi-Newton update but does not perform a line search. You can specify two update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno update of the Cholesky factor of the Hessian matrix. This is the default.

- DDFP performs the dual Davidon, Fletcher, and Powell update of the Cholesky factor of the Hessian matrix.

The double-dogleg optimization technique works well for medium-sized to moderately large optimization problems, where the objective function and the gradient are much faster to compute than the Hessian. The implementation is based on Dennis and Mei (1979) and Gay (1983), but it is extended for dealing with boundary and linear constraints. The DBLDOG technique generally requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which require second-order derivatives; however, each of the DBLDOG iterations is computationally cheap. Furthermore, the DBLDOG technique requires only gradient calls for the update of the Cholesky factor of an approximate Hessian.

Conjugate Gradient Optimization (CONGRA)

Second-order derivatives are not required by the CONGRA algorithm and are not even approximated. The CONGRA algorithm can be expensive in function and gradient calls, but it requires only $O(p)$ memory for unconstrained optimization. In general, many iterations are required to obtain a precise solution, but each of the CONGRA iterations is computationally cheap. You can specify four different update formulas for generating the conjugate directions by using the UPDATE= option:

- PB performs the automatic restart update method of Powell (1977) and Beale (1972). This is the default.
- FR performs the Fletcher-Reeves update (Fletcher 1987).
- PR performs the Polak-Ribiere update (Fletcher 1987).
- CD performs a conjugate-descent update of Fletcher (1987).

The default often behaves best for typical examples, whereas UPDATE=CD can perform poorly.

The CONGRA subroutine should be used for optimization problems with large p. For the unconstrained or boundary-constrained case, CONGRA requires only $O(p)$ bytes of working memory, whereas all other optimization methods require order $O(p^2)$ bytes of working memory. During p successive iterations, uninterrupted by restarts or changes in the working set, the conjugate gradient algorithm computes a cycle of p conjugate search directions. In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α that satisfies the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit for the step size. Other line-search algorithms can be specified with the LIS= option.

Nelder-Mead Simplex Optimization (NMSIMP)

The Nelder-Mead simplex method does not use any derivatives and does not assume that the objective function has continuous derivatives. The objective function itself needs to be continuous. This technique is quite expensive in the number of function calls, and it might be unable to generate precise results for $p \gg 40$.

The original Nelder-Mead simplex algorithm is implemented and extended to boundary constraints. This algorithm does not compute the objective for infeasible points, but it changes the shape of the simplex adapting to the nonlinearities of the objective function, which contributes to an increased speed of convergence. It uses a special termination criterion.

SLICE Statement

This statement applies to the following procedures:
GENMOD, GLIMMIX, LOGISTIC, MIXED, ORTHOREG, PHREG, PLM, SURVEYLOGISTIC, SURVEYPHREG, and SURVEYREG.

The SLICE statement is similar to the LSMEANS statement. You use it to perform inferences on model effects that consist entirely of classification variables. With the SLICE statement, these effects must be higher-order effects of at least two classification variables. The effect is then partitioned into subsets that correspond to variables used in forming the effect. You can use the same options as you use for the LSMEANS statement to perform an analysis for the partitions. This analysis is also known as an analysis of simple effects (Winer 1971).

By default, the interaction effect is partitioned by all main effects. For example, the following statements produce simple-effect differences among the A levels for each level of B and simple-effect differences among the B levels for each level of A:

```
class a b;
model y = a b a*b;
slice a*b / diff nof;
```

For example, if the *model-effect* is a three-way interaction effect, the default output includes comparisons of the two-way interaction means.

Suppose, for example, that the interaction effect A*B is significant in your analysis and that you want to test the effect of A for each level of B. The appropriate statement is

```
slice A*B / sliceBy = B;
```

This produces an F test for each level of B that compares the equality of the levels of A.

For example, assume that in a balanced design factors A and B have $a = 4$ and $b = 3$ levels, respectively. Consider the following statements:

```
class a b;
model y = a b a*b;
slice a*b / sliceby=a diff;
```

The SLICE statement produces four F tests, one per level of A. The first of these tests is constructed by extracting the three rows that correspond to the first level of A from the coefficient matrix for the A*B interaction. Call this matrix $\mathbf{L}_{a1}$ and its rows $\mathbf{l}_{a1}^{(1)}$, $\mathbf{l}_{a1}^{(2)}$, and $\mathbf{l}_{a1}^{(3)}$. The slice tests the two-degrees-of-freedom hypothesis

$$H: \begin{cases} \left(\mathbf{l}_{a1}^{(1)} - \mathbf{l}_{a1}^{(2)}\right)\boldsymbol{\beta} = 0 \\ \left(\mathbf{l}_{a1}^{(1)} - \mathbf{l}_{a1}^{(3)}\right)\boldsymbol{\beta} = 0 \end{cases}$$

In a balanced design, where μ_{ij} denotes the mean response if A is at level i and B is at level j, this hypothesis is equivalent to $H: \mu_{11} = \mu_{12} = \mu_{13}$. The DIFF option considers the three rows of $\mathbf{L}_{a1}$ in turn and performs tests of the difference between pairs of rows. By default, all pairwise differences within the subset of $\mathbf{L}$ are considered; in the example this corresponds to tests of the form

$$H: \left(\mathbf{l}_{a1}^{(1)} - \mathbf{l}_{a1}^{(2)}\right)\boldsymbol{\beta} = 0$$
$$H: \left(\mathbf{l}_{a1}^{(1)} - \mathbf{l}_{a1}^{(3)}\right)\boldsymbol{\beta} = 0$$
$$H: \left(\mathbf{l}_{a1}^{(2)} - \mathbf{l}_{a1}^{(3)}\right)\boldsymbol{\beta} = 0$$

In the example, with $a = 4$ and $b = 3$, this produces four sets of least squares means differences. Within each set, factor A is held fixed at a particular level and each set consists of three comparisons.

Syntax: SLICE Statement

SLICE *model-effect* < / *options* > **;**

You can specify all options of the LSMEANS statement in the SLICE statement. The philosophy of the SLICE statement is to apply the analysis according to the options to the subsets of the $\mathbf{L}$ matrix that correspond to chosen partitions.

The following behavior differences between the SLICE and the LSMEANS statement are noteworthy:

- The specification of the *model-effect* is optional in the LSMEANS statement and required in the SLICE statement.
- Only a single SLICE *model-effect* can be specified before the option slash (/). However, you can specify multiple partitioning rules with the SLICEBY option.
- The MEANS option is the default for most procedures in the LSMEANS statement. For the SLICE statement, the default is the NOMEANS option.

Also, the three generalized linear modeling options: EXP, ILINK, and ODDSRATIO in the SLICE statement are additionally supported by PROC GLIMMIX and by PROC PLM when it is used to perform statistical analyses on item stores that were created by PROC GLIMMIX.

In addition to the options in the LSMEANS statement, you can specify the following options in the SLICE statement after the slash (/):

SLICEBY < **=** > *slice-specification*

SIMPLE < **=** > *slice-specification*

SLICEBY(*slice-specification* < **,** *slice-specification* < **, . . .** > **>)**

SIMPLE(*slice-specification* < **,** *slice-specification* < **, . . .** > **>)**

determines how to construct the partition of the least squares means for the *model-effect*. A *slice-specification* consists of an effect name followed by an optional list of formatted values. For example, the following statements creates partitions of the A*B interaction effect for all levels of variable A:

```
class a b;
model y = a b a*b;
slice a*b / sliceby=a;
```

The following statements produces two partitions of the interaction:

```
class a b;
model y = a b a*b;
slice a*b / sliceby(b='2' a='1') diff;
```

In the first partition the variable B takes on formatted value '2'. In the second partition the variable A takes on the formatted value '1'.

NOF

suppresses the *F* test for testing the mutual equality of the estimable functions in the partition.

ODS Table Names: SLICE Statement

Each table created by the SLICE statement has a name associated with it, and you can use this name to refer to the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 19.29. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 19.29 ODS Tables Produced by the SLICE statement

Table Name	Description	Required Option
Coef	**L** matrix coefficients	E
Slices	LS-means slices	MEANS
SliceDiffs	Simple differences of LS-means slices	DIFF or ADJUST= or STEPDOWN or NOF
SliceLines	Lines display for LS-means slices	LINES
SliceTests	Tests for LS-means slices	Default

STORE Statement

This statement applies to the following procedures:
GENMOD, GLIMMIX, GLM, LOGISTIC, MIXED, ORTHOREG, PHREG, SURVEYLOGISTIC, SURVEYPHREG, and SURVEYREG.

The STORE statement requests that the procedure save the context and results of the statistical analysis into an item store. An item store is a binary file format that cannot be modified by the user. The contents of the item store can be processed with the PLM procedure. One example of item store technology is to perform a time-consuming analysis and to store its results by using the STORE statement. At a later time you can then perform specific statistical analysis tasks based on the saved results of the previous analysis, without having to fit the model again. The following statements show an example in which a mixed model is fit with the MIXED procedure and the postprocessing analysis is performed with the PLM procedure:

```
proc mixed data=MyBigDataSet;
   class Env A B sub;
   model y = A B x / ddfm=KenwardRoger;
   random int A*B / sub=Env;
   repeated / subject=Env*A*B type=AR(1);
   store sasuser.mixed;
run;

proc plm source=sasuser.mixed;
   show cov Parms;
   lsmeans A B / diff;
   score data=NewData out=ScoreResults;
run;
```

The STORE statement in the PROC MIXED step requests that the MIXED procedure save those results that are needed to perform statistical tasks with the PLM procedure. For example, the MIXED procedure saves the necessary pieces of information that relate to the Kenward-Roger degree-of-freedom method. The results from the LSMEANS statement in the PROC PLM step thus apply this technique for calculating denominator degrees of freedom. The SHOW statement in the PLM procedure reveals the contents of the item store in terms of ODS tables, and the SCORE statement computes predicted values in a new data set. For more information about postprocessing tasks based on item stores, see the documentation for the PLM procedure.

Syntax: STORE Statement

STORE < **OUT=** >*item-store-name* < / **LABEL=***'label'* > **;**

The *item-store-name* is a usual one- or two-level SAS name, like the names that are used for SAS data sets. If you specify a one-level name, then the item store resides in the WORK library and is deleted at the end of the SAS session. Since item stores usually are used to perform postprocessing tasks, typical usage specifies a two-level name of the form *libname.membername*.

If an item store by the same name as specified in the STORE statement already exists, the existing store is replaced.

You can add a custom label with the LABEL= option in the STORE statement after the slash (/). When the PLM procedure processes an item store, the label appears in the PROC PLM output along with other identifying information.

TEST Statement

This statement documentation applies to the following procedures:
ORTHOREG, PLM, SURVEYPHREG, and SURVEYREG.

The TEST statement enables you to perform *F* tests for model effects that test Type I, II, or Type III hypotheses. See Chapter 15, "The Four Types of Estimable Functions," for details about the construction of Type I, II, and III estimable functions.

Syntax: TEST Statement

TEST < *model-effects* > < / *options* > **;**

Table 19.30 summarizes options in the TEST statement.

Table 19.30 TEST Statement Options

Option	Description
CHISQ	Requests chi-square tests
DDF=	Specifies denominator degrees of freedom for fixed effects
E	Requests Type I, Type II, and Type III coefficients
E1	Requests Type I coefficients
E2	Requests Type II coefficients
E3	Requests Type III coefficients
HTYPE=	Indicates the type of hypothesis test to perform
INTERCEPT	Adds a row that corresponds to the overall intercept

You can specify the following options in the TEST statement after the slash (/):

CHISQ
requests that chi-square tests be performed for the relevant effects in addition to the *F* tests. Type III tests are the default; you can produce the Type I and Type II tests by using the HTYPE= option. This option has no effect when the procedure produces chi-square statistics by default.

DDF=*value-list*

DF=*value-list*

specifies the denominator degrees of freedom for the fixed effects. The *value-list* specification is a list of numbers or missing values (.) separated by commas. The order of degrees of freedom should match the order of the fixed effects that are specified in the TEST statement; otherwise it should match the order in which the effects appear in the "Type III Tests of Fixed Effects" table. If you want to retain the default degrees of freedom for a particular effect, use a missing value for its location in the list. In the following example, the first TEST statement assigns 3 denominator degrees of freedom to A and 4.7 to A*B, while those for B remain the same, and the second TEST statement assigns 5 denominator degrees of freedom to A and uses the default degrees of freedom for B.

```
model Y = A B A*B;
test  / ddf=3,.,4.7;
test  B A / ddf=.,5;
```

E

requests that Type I, Type II, and Type III **L** matrix coefficients be displayed for all relevant effects.

E1 | EI

requests that Type I **L** matrix coefficients be displayed for all relevant effects.

E2 | EII

requests that Type II **L** matrix coefficients be displayed for all relevant effects.

E3 | EIII

requests that Type III **L** matrix coefficients be displayed for all relevant effects.

HTYPE=*value-list*

indicates the type of hypothesis test to perform on the fixed effects. Valid entries for values in the *value-list* are 1, 2, and 3, which correspond to Type I, Type II, and Type III tests, respectively. The default value is 3.

INTERCEPT

INT

adds a row to the tables for Type I, II, and III tests that correspond to the overall intercept.

ODS Table Names: TEST Statement

Each table created by the TEST statement has a name associated with it, and you can use this name to refer to the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 19.31. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 19.31 ODS Tables Produced by the TEST statement

Table Name	Description	Required Option
Coef	**L** matrix coefficients	E
Tests1	Type I tests of fixed effects	HTYPE=1
Tests2	Type II tests of fixed effects	HTYPE=2
Tests3	Type III tests of fixed effects	Default

Programming Statements

This section applies to the following procedures:
CALIS, GLIMMIX, MCMC, NLIN, NLMIXED, PHREG, and SURVEYPHREG.

The majority of the SAS/STAT modeling procedures can take advantage of the fact that the statistical model can easily be translated into programming syntax (statements and options). However, several procedures require additional flexibility in specifying models—for example, when the model contains general nonlinear functions, when it is necessary to specify complicated restrictions, or when user-supplied expressions need to be evaluated. Procedures that are listed at the beginning of the section support—in addition to the usual procedure statements and options—programming statements that can be used in the SAS DATA step.

The following are valid statements:

ABORT;
CALL *name* < **(** *expression* < *, expression . . .* > **)** >**;**
DELETE;
DO < *variable* **=** *expression*
< **TO** *expression* > < **BY** *expression* >
< *, expression* < **TO** *expression* > < **BY** *expression* > . . . >
>
< **WHILE** *expression* > < **UNTIL** *expression* >**;**
END;
GOTO *statement-label*;
IF *expression*;
IF *expression* **THEN** *program-statement*;
ELSE *program-statement*;
variable **=** *expression*;
variable **+** *expression*;
LINK *statement-label*;
PUT < *variable* > < **=** > < *...* >**;**
RETURN;
SELECT < **(** *expression* **)** >**;**
STOP;
SUBSTR(*variable, index, length* **) =** *expression*;
WHEN (*expression***)** *program-statement*;
OTHERWISE *program-statement*;

For the most part, these programming statements work the same as they do in the SAS DATA step, as documented in *SAS Language Reference: Concepts*. However, there are several differences:

- The ABORT statement does not allow any arguments.
- The DO statement does not allow a character index variable. Thus

```
do i = 1,2,3;
```

  is supported, whereas the following statement is not supported:

```
do i = 'A','B','C';
```

- Not all procedures support LAG functionality. For example, the GLIMMIX procedure does not support lags.
- The PUT statement, used mostly for program debugging, supports only some of the features of the DATA step PUT statement, and it has some features that are not available with the DATA step PUT statement:
  - The PUT statement does not support line pointers, factored lists, iteration factors, overprinting, _INFILE_, the colon (:) format modifier, or "$".

  - The PUT statement does support expressions, but the expression must be enclosed in parentheses. For example, the following statement displays the square root of x:

```
put (sqrt(x));
```

  - The PUT statement supports the item _PDV_ to display a formatted listing of all variables in the program. For example:

```
put _pdv_;
```

- The WHEN and OTHERWISE statements enable you to specify more than one target statement. That is, DO/END groups are not necessary for multiple-statement WHENs. For example, the following syntax is valid:

```
select;
   when (exp1) stmt1;
               stmt2;
   when (exp2) stmt3;
               stmt4;
end;
```

- The LINK statement is used in a program to jump immediately to the label *statement_label* and to continue program execution at that point. It is not used to specify a link function in a generalized linear model.

Please consult the individual chapters for other, procedure-specific differences between programming statements and the SAS DATA step and for procedure-specific details, limitations, and rules.

When coding your programming statements, avoid defining variables that begin with an underscore (_), because they might conflict with internal variables that are created by procedures that support programming statements.

Chapter 20

Using the Output Delivery System

Contents

Overview: Using the Output Delivery System

Most SAS procedures use the Output Delivery System (ODS) to manage their output. ODS enables you to do the following:

- display your output in hypertext markup language (HTML), rich text format (RTF), portable document format (PDF), PostScript, SAS listing, or other formats
- create SAS data sets directly from tables or plots
- select or exclude individual pieces of output
- customize the layout, format, headers, and style of your output
- produce graphs with ODS Graphics (see Chapter 21, "Statistical Graphics Using ODS")

This chapter discusses some typical applications of ODS with SAS software. For complete documentation about the Output Delivery System, see the *SAS Output Delivery System: User's Guide*.

New Output Defaults in SAS 9.3

In SAS 9.3, output in the SAS windowing environment is created by default in HTML. In addition, ODS Graphics is enabled by default. The following sections explain the advantages of these new defaults and how to change the defaults to match those of previous releases:

- HTML output in the SAS windowing environment (the SAS 9.3 default)
- LISTING output in the SAS windowing environment (the default prior to SAS 9.3)

HTML output with ODS Graphics enabled is the default in the SAS windowing environment for Microsoft Windows and UNIX. LISTING output with ODS Graphics disabled is the default when you run SAS in batch mode or on the mainframe in SAS 9.3. LISTING output with ODS Graphics disabled is the default in all environments in previous SAS releases. Your actual defaults might be different due to your registry, system option, or configuration file settings.

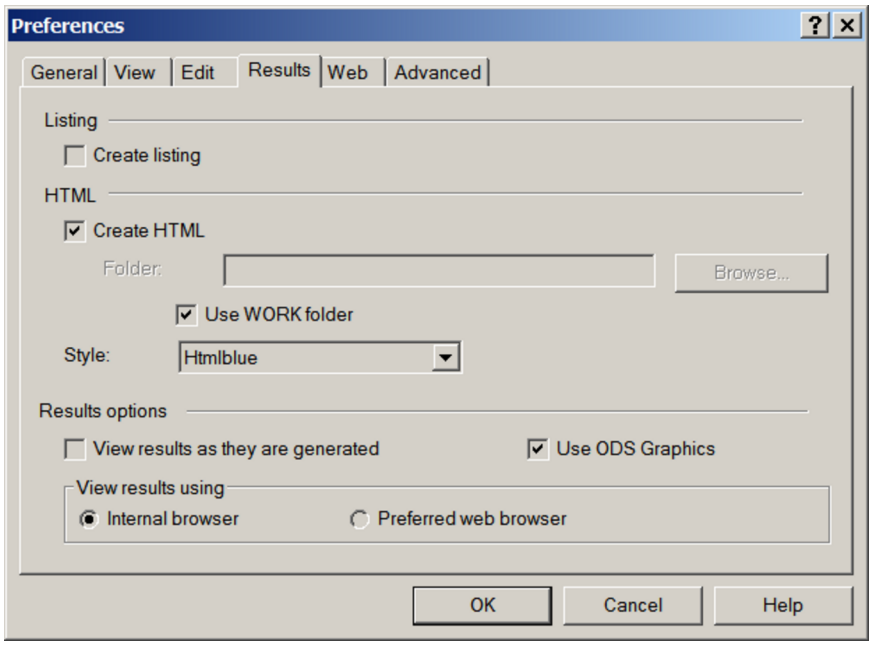
HTML Output in the SAS Windowing Environment

In SAS 9.3, the default destination in the SAS windowing environment is HTML and ODS Graphics is enabled by default.[1] These new defaults have several advantages. Graphs are integrated with tables, and all output is displayed in the same HTML file. The HTML destination uses a new style, HTMLBLUE, which is an all-color style, that is designed to integrate tables and modern statistical graphics.

[1] HTML output with ODS Graphics enabled is the default in the SAS windowing environment for Microsoft Windows and UNIX, but not on the mainframe.

You can view and modify the default settings by selecting **Tools ► Options ► Preferences** from the menu at the top of the main SAS window. Then click the **Results** tab. You can remember this sequence using the mnemonic TOPR (pronounced "topper"). See Figure 20.1.

Figure 20.1 SAS Results Tab with the New Default Settings



The default settings are as follows:

- HTML output is created when **Create HTML** is selected, and all output is viewed in the Results Viewer window.
- ODS Graphics is enabled when **Use ODS Graphics** is selected.
- The default style, HTMLBLUE, is selected from the **Style** list.
- Results are viewed in an internal SAS browser when **Internal browser** is selected.
- Graph image files are saved in the Work folder (not in your current folder) when **Use WORK folder** is selected.
- LISTING output is not created when the **Create listing** box is cleared.

In many cases, graphs are an integral part of a data analysis. However, when you run large computational programs (such as when you use procedures with many BY groups), you might not want to create graphs. In those cases, you should disable ODS Graphics, which will improve the performance of your program. You can disable and re-enable ODS Graphics in your SAS programs with the ODS GRAPHICS OFF and ODS GRAPHICS ON statements. You can also change the ODS Graphics default in the **Results** tab.

In the SAS windowing environment, the current folder is displayed in the status line at the bottom of the main SAS window. When **Use WORK folder** is cleared, graph image files are saved in the current folder and are available after your SAS session ends. They can accumulate with time and take up a great deal of space. When **Use WORK folder** is selected, graph image files are stored in the Work folder and are not available after your SAS session ends.

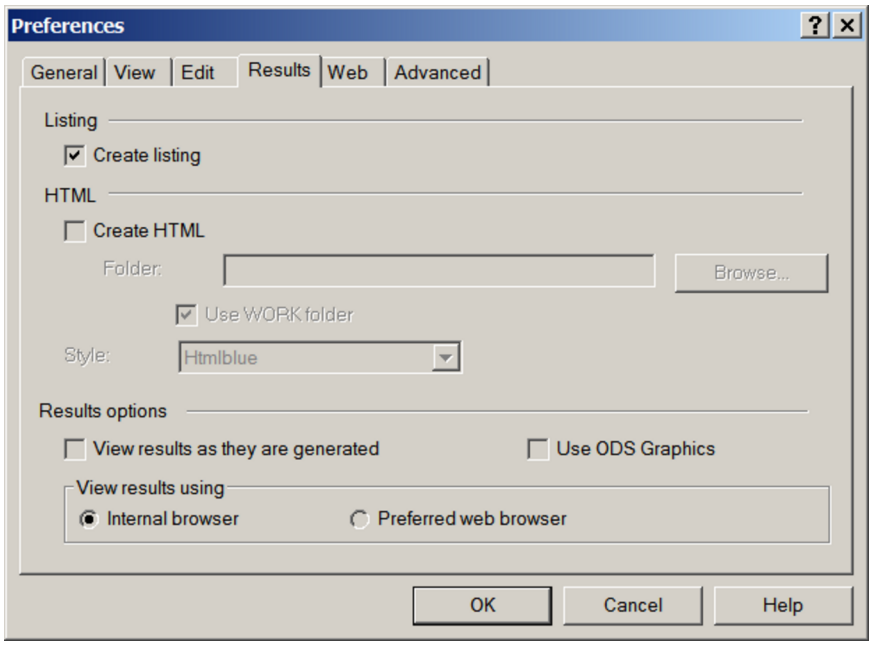
LISTING Output in the SAS Windowing Environment

Prior to SAS 9.3, SAS output in the SAS windowing environment was created by default in the LISTING destination. In the LISTING destination, tables are displayed in monospace, and graphs are not integrated with tables.

You can create LISTING output by selecting **Tools ► Options ► Preferences** from the menu at the top of the main SAS window. Then click the **Results** tab. Select **Create listing**, and clear **Create HTML**. See Figure 20.2. Tabular results are viewed in the Output window. Graphical results are viewed by selecting graphs in the Results window.

Prior to SAS 9.3, ODS Graphics was disabled by default. You can enable or disable ODS Graphics by default by using the **Use ODS Graphics** check box, and you can use the ODS GRAPHICS ON and ODS GRAPHICS OFF statements to enable and disable ODS Graphics in your SAS programs.

Figure 20.2 SAS Results Tab with the Old Default Settings



Assumptions about ODS Defaults in this Chapter

Default settings such as destinations and whether ODS Graphics is enabled vary depending on your operating system, registry settings, configuration file settings, system options, and whether you are using the SAS windowing environment or batch mode. For this reason, this chapter makes no assumptions about these defaults. Instead, all destinations are explicitly closed before some steps without assuming which destination (usually LISTING or HTML) is open, destinations are explicitly opened when needed, and ODS Graphics is explicitly enabled and disabled as needed. In some examples, when all destinations are closed, the LISTING destination is opened at the end of the step so that some destination is available for subsequent output. If you know the defaults for your environment, you do not need to use many of the ODS statements that are used in this chapter.

The HTMLBLUE Style

In SAS 9.3, in the SAS windowing environment, the default ODS style for HTML output is the HTMLBLUE style. However, if you use the ODS HTML statement in batch mode, the default style is still DEFAULT. You can see examples of the HTMLBLUE style in this chapter in Output 20.1.1, Output 20.8.2, and Output 20.8.3. The HTMLBLUE style inherits most of its attributes from the STATISTICAL style, but it has a brighter appearance and color coordination between the tables and graphs. In the HTMLBLUE style, the dominant color is blue; in the DEFAULT style, the dominant color is gray. See Chapter 21, "Statistical Graphics Using ODS," for a comparison of the HTMLBLUE style and other styles.

Default Open Destination

By default, either the LISTING or the HTML destination is open. You can change the default destination three ways, which are described in the next three subsections. The fourth subsection of this section explains how to use ODS statements to open and close destinations.

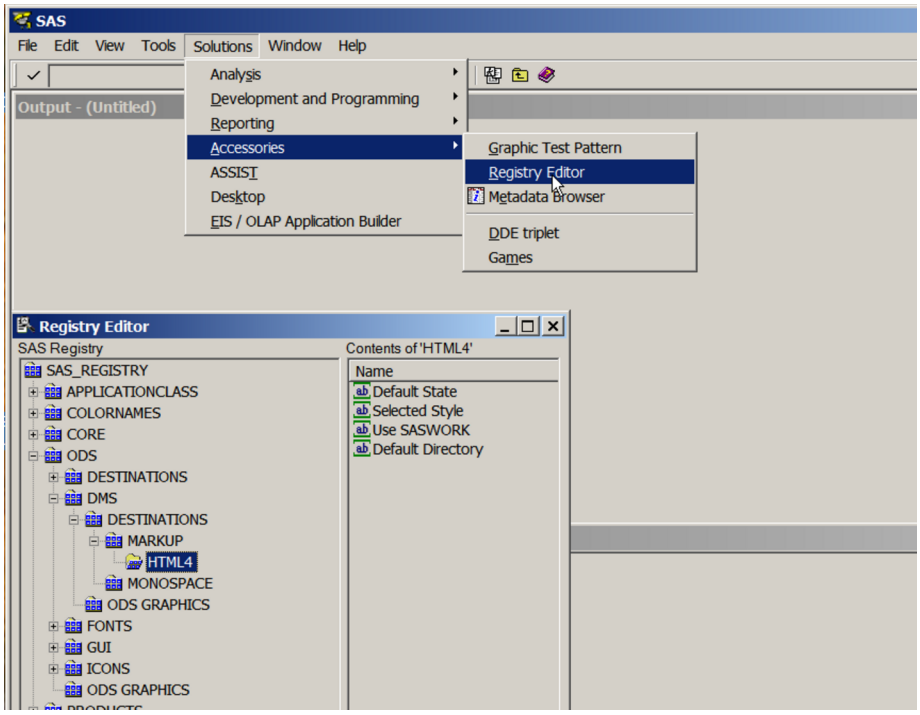
Setting the Default Destination in the Results Tab

You can change the default destination in the SAS windowing environment by selecting **Tools ► Options ► Preferences** from the menu at the top of the main SAS window. Then select the **Results** tab. See sections "HTML Output in the SAS Windowing Environment" on page 526 and "LISTING Output in the SAS Windowing Environment" on page 528. Changing defaults in the SAS windowing environment affects only the SAS windowing environment; it does not affect batch jobs.

Setting the Default Destination in the SAS Registry

You can change the default destination by editing the SAS registry (see Figure 20.3) or by changing system options in your SAS configuration file.

Figure 20.3 SAS Registry Window



Registry customization is generally performed by more advanced users who have experience and knowledge about the SAS System and their operating environment. Incorrect registry entries can corrupt your SAS registry. For more information about SAS configuration files and the SAS registry, see the *SAS Companion* for your operating system.

Setting the Default Destination in SAS System Options

The ODSDEST system option controls the default destination. This option is specified only at SAS start-up time. Other relevant system options that correspond to entries in the **Results** tab in Figure 20.1 include ODSGRAPHICS (which specifies whether ODS Graphics is enabled by default) and ODSSTYLE (which specifies the default style for the HTML destination in the SAS windowing environment). See the *SAS System Options: Reference* for more information.

Setting the Destination in ODS Statements

You can use ODS destination statements to explicitly set destinations. These statements are described in this chapter and in detail in the *SAS Output Delivery System: User's Guide*. When you open a new destination, you should close all other open destinations unless you really need multiple destinations to be open. When multiple destinations are open, each piece of output is created multiple times, once per destination. Closing unneeded destinations increases efficiency.

You can create HTML output in any environment by using the ODS HTML statement as in the following example:

```
ods _all_ close;
ods html file='MyFile.html';

proc reg data=sashelp.class;
   model height=weight;
run; quit;

ods html close;
ods listing;
```

The first statement closes all open destinations. The second statement opens the HTML destination and specifies the HTML output file *MyFile.html*. The last two statements close the HTML destination and open the LISTING destination for subsequent output.

You can create LISTING output in any environment by using the ODS LISTING statement as in the following example:

```
ods _all_ close;
ods listing;

proc reg data=sashelp.class;
   model height=weight;
run; quit;
```

The first statement closes all open destinations. The second statement opens the LISTING destination which sends output to the SAS listing. In this example, the LISTING destination is not closed so that subsequent steps can append more information to the listing.

If the LISTING destination is open, then you can simultaneously create LISTING and HTML output as follows:

```
* The ODS LISTING destination is not closed,
  which is not recommended for efficiency reasons;

ods html file='Reg.htm';

proc reg data=sashelp.class;
   model height=weight;
run; quit;

ods html close;
```

Sometimes you see ODS Graphics notes or warnings multiple times when multiple destinations are open. The messages appear once for each affected graph for each destination.

Output Objects and ODS Destinations

All SAS procedures produce *output objects* that ODS delivers to various *ODS destinations*, according to the default specifications for the procedure or according to your own specifications. Typically, you see

the output objects displayed as tables, data sets, or graphs. Underlying all output (for example, a table of parameter estimates) are two component parts:

- the data component, which consists of the results computed by a SAS procedure
- the template, which contains the instructions for formatting and displaying the results

Each output object has an associated template, provided by the SAS System, that defines its presentation format. You can use the TEMPLATE procedure to view or alter these templates or to create new templates by changing the headers, formats, column order, and so on. For more information, see the chapter titled "The Template Procedure" in the *SAS Output Delivery System: User's Guide*.

You define the form that the output should take by specifying an ODS destination. Some supported destinations are as follows:

- LISTING, the standard SAS monospace listing
- HTML, for viewing in a browser
- RTF, for inclusion in Microsoft Word
- PDF, PostScript, and PCL, for high-fidelity printers
- OUTPUT, for saving results to SAS data sets
- DOCUMENT, for saving, modifying, and replaying your output

You can open multiple ODS destinations at the same time so that a single procedure step can produce output for multiple destinations. If you do not supply any ODS statements, ODS delivers all output to the default destination (which is usually LISTING or HTML). See the section "New Output Defaults in SAS 9.3" on page 526 for more information about default destinations. You can specify an output style for each ODS destination. The style controls the foreground, background, colors, lines, fonts, and so on.

The following statements provide an example of temporarily closing all open destinations for PROC REG and then opening the LISTING destination for PROC PRINT. The REG procedure makes an output data set, Parms, from the parameter estimates table from PROC REG. Closing unneeded open destinations is not required, but it is done in many examples in this chapter for efficiency. Closing the superfluous destinations suppresses the generation of output that is not needed or used. This is particularly beneficial with graphics. This example uses the Sashelp.Class data set, one of the sample data sets in the Sashelp library that are automatically available for your use. The following statements produce Figure 20.4:

```
title 'Getting Started with ODS';

ods _all_ close;

proc reg data=sashelp.class;
   model height=weight;
   ods output ParameterEstimates=parms;
run; quit;

ods listing;

proc print noobs data=parms;
run;
```

The ODS OUTPUT statement contains a table name, an equal sign, and the name of the output SAS data set to create. You can use the ODS TRACE statement to find the table names. The ODS TRACE statement is described in the section "Paths and Selection" on page 534. Also see Example 20.4 for more information.

Figure 20.4 PROC REG Parameter Estimates Table

Getting Started with ODS

Model	Dependent	Variable	DF	Estimate	StdErr	tValue	Probt
MODEL1	Height	Intercept	1	42.57014	2.67989	15.89	<.0001
MODEL1	Height	Weight	1	0.19761	0.02616	7.55	<.0001

You could accomplish the same thing using ODS SELECT statements as follows:

```
ods select none;

proc reg data=sashelp.class;
   model height=weight;
   ods output ParameterEstimates=parms;
run; quit;

ods select all;

proc print noobs data=parms;
run;
```

You can specify ODS EXCLUDE ALL instead of ODS SELECT NONE and ODS EXCLUDE NONE instead of ODS SELECT ALL. These statements remain in effect until a new ODS SELECT or ODS EXCLUDE statement changes the selection list.

The ODS Statement

You use the ODS statement to provide instructions to ODS. You can use the ODS statement to specify options for different destinations, specify the output style, and select and exclude output. Here are some examples:

```
/* open the HTML destination with the HTMLBlue style */
ods html style=HTMLBlue;

/* select only the parameter estimates table */
ods select ParameterEstimates;

/* output the parameter estimates table to a SAS data set*/
ods output ParameterEstimates=Parms;

/* exclude the number of observations, ANOVA, and fit statistics tables */
ods exclude NObs ANOVA FitStatistics;
```

Paths and Selection

Each output from a SAS procedure has an associated name and label. Each name is part of a name path, and each label is part of a label path. For example, PROC GLM has a table called **ErrorSSCP**, and the name path (fully qualified name) is **GLM.Repeated.MANOVA.Model.Error.ErrorSSCP**. Each level in the name path corresponds to a part of the PROC GLM hierarchy of output. Tables and graphs also have labels and label paths. For example, the PROC GLM **ErrorSSCP** table is labeled **'SSCP Matrix'**, and the label path is **'The GLM Procedure'.'Repeated Measures Analysis'.'MANOVA'.'Model'.'Error'.'SSCP Matrix'**.

In order to select, exclude, or modify a table, you must first know its name (or label). You can obtain the table names in several ways:

- You can obtain table names from the individual procedure documentation chapter or from the individual procedure section of the SAS online Help system. See the section "ODS Table Names" within the "Details" section of the procedure documentation chapter.
- You can use the SAS Results window to view the names of the tables that are created in your SAS session (see the section "The SAS Results Window" on page 538 for more information).
- You can use the ODS TRACE statement to find the names of the tables that are created in your SAS session. The ODS TRACE statement writes identifying information to the SAS log or listing for each generated output table.

If you are working interactively with reasonably small data sets, then the ODS TRACE statement is usually the most convenient way to find the names. Specify the ODS TRACE ON statement prior to the procedure statements that create the output for which you want information. For example, the following statements write the trace record for the specific tables created in the REG procedure step:

```
ods trace on;
ods graphics on;
proc reg data=sashelp.class;
   model weight=height;
   model age=height;
run; quit;
ods trace off;
```

By default, the trace output is written to the SAS log. Some of the output from the previous step is as follows:

```
Output Added:
-------------
Name:        NObs
Label:       Number of Observations
Template:    Stat.Reg.NObs
Path:        Reg.MODEL1.Fit.Weight.NObs
-------------
```

```
Output Added:
-------------
Name:       ANOVA
Label:      Analysis of Variance
Template:   Stat.REG.ANOVA
Path:       Reg.MODEL1.Fit.Weight.ANOVA
-------------

Output Added:
-------------
Name:       FitStatistics
Label:      Fit Statistics
Template:   Stat.REG.FitStatistics
Path:       Reg.MODEL1.Fit.Weight.FitStatistics
-------------

Output Added:
-------------
Name:       ParameterEstimates
Label:      Parameter Estimates
Template:   Stat.REG.ParameterEstimates
Path:       Reg.MODEL1.Fit.Weight.ParameterEstimates
-------------

Output Added:
-------------
Name:       DiagnosticsPanel
Label:      Fit Diagnostics
Template:   Stat.REG.Graphics.DiagnosticsPanel
Path:       Reg.MODEL1.ObswiseStats.Weight.DiagnosticPlots.DiagnosticsPanel
-------------

Output Added:
-------------
Name:       ResidualPlot
Label:      Height
Template:   Stat.REG.Graphics.ResidualPlot
Path:       Reg.MODEL1.ObswiseStats.Weight.ResidualPlots.ResidualPlot
-------------

Output Added:
-------------
Name:       FitPlot
Label:      Fit Plot
Template:   Stat.REG.Graphics.Fit
Path:       Reg.MODEL1.ObswiseStats.Weight.FitPlot
-------------

Output Added:
-------------
Name:       NObs
Label:      Number of Observations
Template:   Stat.Reg.NObs
Path:       Reg.MODEL2.Fit.Age.NObs
-------------
```

```
.
.
.

Output Added:
-------------
Name:        FitPlot
Label:       Fit Plot
Template:    Stat.REG.Graphics.Fit
Path:        Reg.MODEL2.ObswiseStats.Age.FitPlot
-------------
```

Alternatively, you can specify the LISTING option (**ods trace on / listing;**), which writes the trace record, interleaved with the procedure output, to the LISTING destination (if it is open).

The trace record contains the name of each created table and its associated label, template, and fully qualified name path. The label provides a description of the table. The fully qualified name path shows the output hierarchy for the table. (An example of the hierarchy is shown in Figure 20.5. The SAS Results window displays the labels, rather than the names of objects, but the hierarchy is the same for both names and labels.) The hierarchy has a level for the REG procedure, a level for the model (MODEL1 or MODEL2), a level for the fit results, a level for the dependent variable (Weight or Age), and a level for the table name (**NObs**, **ANOVA**, **FitStatistics**, **ParameterEstimates**).

When you work with ODS objects, you can often omit levels and instead use a partially qualified name path. A partially qualified name path consists of any part of the fully qualified name path that begins immediately after a period and continues to the end of the fully qualified name path. For example, the table **Reg.Model1.Fit.Weight.ParameterEstimates** can be referenced in any of the following ways:

ParameterEstimates	name
Weight.ParameterEstimates	partially qualified name path
Fit.Weight.ParameterEstimates	partially qualified name path
Model1.Fit.Weight.ParameterEstimates	partially qualified name path
Reg.Model1.Fit.Weight.ParameterEstimates	fully qualified name path

When a procedure creates multiple tables that have the same name, as shown in the preceding trace output, you have several selection options for referring to a table. You can specify the name, a fully qualified name path, or a partially qualified name path in ODS statements such as ODS SELECT, ODS EXCLUDE, or ODS OUTPUT. You can also specify a WHERE clause. For example, you can specify any of the following statements (in addition to other possibilities) to display both tables of parameter estimates:

```
ods select ParameterEstimates;

ods select Weight.ParameterEstimates Age.ParameterEstimates;

ods select Reg.Model1.Fit.Weight.ParameterEstimates
           Reg.Model2.Fit.Age.ParameterEstimates;

ods select where = (_path_ ? 'Parameter');
```

The first ODS SELECT statement specifies the single name, which is shared by both tables. The second statement specifies a partially qualified name path for both tables. The third statement specifies the fully

qualified name path for each table. The fourth statement selects every object (table or graph) that contains the string **'Parameter'** anywhere in its path.

In the first three statements, selection is case insensitive. Any combination of uppercase and lowercase letters works. This is not true in the fourth statement, which uses an ordinary SAS comparison of character strings. For case insensitivity in WHERE clause selection, use the LOWCASE function as in the following example:

```
ods select where = (lowcase(_path_) ? 'parameter');
```

You can also select objects based on a WHERE clause and the label path. The following statements turn on the trace record, display a label path in addition to the name path, and select all tables that have the string **'var'** in the label:

```
ods trace on / label;
ods select where = (lowcase(_label_) ? 'var');
```

A subset of the trace record for PROC REG with this ODS SELECT list, showing just the name path and label path, is as follows:

```
Path:       Reg.MODEL1.Fit.Weight.ANOVA
Label Path: 'The Reg Procedure'.'MODEL1'.'Fit'.Weight.'Analysis of Variance'
Path:       Reg.MODEL2.Fit.Age.ANOVA
Label Path: 'The Reg Procedure'.'MODEL2'.'Fit'.Age.'Analysis of Variance'
```

The ODS SELECT statement selects the ANOVA tables, because they have the string **'Analysis of Variance'** (which when lowercased contains **'var'**) in their labels. WHERE clause selection is also useful for selecting all of the objects within a group or level of the path hierarchy (the group **'MODEL2'** or **'Fit'**). You can specify any part of the name path or label path—for example, **'.Age.'** matches the variable Age and ignores any **'Age'** that might be in the middle of a word, **'2.F'** matches Model 2 fit tables and any other table that has the string **'2.F'** in its path, and so on.

ODS records the specified table names in its internal selection or exclusion list, and then it processes the output it receives. ODS maintains an overall selection or exclusion list that pertains to all ODS destinations, and it maintains a separate selection or exclusion list for each ODS destination. The list for a specific destination provides the primary filtering step. The restrictions that you specify in the overall list are added to the destination-specific lists.

Suppose, for example, that your LISTING exclusion list (that is, the list of tables you want to exclude from the LISTING destination) contains the **FitStatistics** table, which you specify with the following statement:

```
ods listing exclude FitStatistics;
```

Suppose also that your overall selection list (that is, the list of tables you want to select for all destinations) contains the tables **ParameterEstimates** and **FitStatistics**, which you specify with the following statement:

```
ods select ParameterEstimates FitStatistics;
```

ODS then sends only the **ParameterEstimates** and **FitStatistics** tables to all open destinations except the LISTING destination. It sends only the **ParameterEstimates** table to the LISTING destination because the table **FitStatistics** is excluded from that destination.

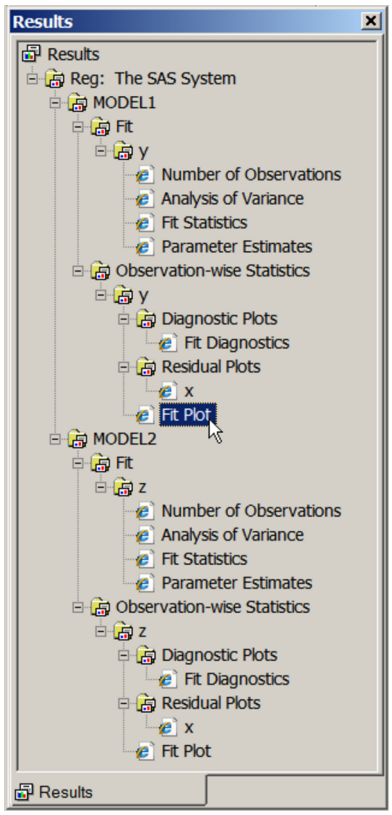
RUN-Group Processing

Some SAS procedures, such as PROC REG and PROC GLM, support RUN-group processing, which means that a RUN statement does not end the procedure. A QUIT statement explicitly ends such procedures. If you omit the QUIT statement, a PROC or a DATA statement implicitly ends such procedures. When you use ODS with procedures that support RUN-group processing, it is good programming practice to specify a QUIT statement at the end of the procedure. This causes ODS to clear the selection or exclusion list, and you are less likely to encounter unexpected results.

The SAS Results Window

The SAS Results window contains a running record of the output from your SAS session. In the SAS windowing environment, select **View ► Results** to open the Results window. Figure 20.5 displays the Results window from the PROC REG step shown previously.

Figure 20.5 The Results Window from the SAS Explorer



When you click the output names in the Results window, you link directly to the output in the Output Results window (for the HTML destination) or the Output window or graph viewer window (for the LISTING destination). The Results window contains an entry for each level of the label path and for each table and graph. You can also use the Results window to determine the names of the templates associated with each table or graph. Right-click the name, and then select **Properties**. You can see all of the templates from the Results window by selecting **View ► Templates ► Sashelp.Tmplmst**. Then click a product such as **Stat**, a procedure such as **REG**, and a template such as **ParameterEstimates**.

The ODS PATH Statement

The ODS PATH statement controls where ODS stores new templates that you create and where ODS finds the templates that your programs use.[2] Compiled templates are stored in a template store, which is a type of item store. (An item store is a special type of SAS file.)

By default, the templates that you write are stored in Sasuser.Templat, and the templates that the SAS System provides are stored in Sashelp.Tmplmst. Templates are found in Sashelp.Tmplmst unless you compile and store them in Sasuser.Templat.

You can see the list of active template stores by submitting the following statement:

```
ods path show;
```

By default, the results are as follows:

```
Current ODS PATH list is:

1. SASUSER.TEMPLAT(UPDATE)
2. SASHELP.TMPLMST(READ)
```

See the section "Controlling Output Appearance with Templates" on page 539 for more information about the template search path and template stores.

Controlling Output Appearance with Templates

A template is a description of how output should appear when it is formatted. Templates describe several characteristics of the output, including headers, column ordering, style information, justification, and formats. Each table in the output has a template, and all SAS templates are stored in the Sashelp library. You can find the template associated with a particular output table or column by using the ODS TRACE statement or the SAS Results window. You can create or modify a template with the TEMPLATE procedure. For example, you can specify different column headings or different orders of columns in a table.

There are a number of different types of templates including column and table templates, graphical templates, and style templates. A column or table template applies to the specific columns or tables that refer

[2] Other types of paths include the name path and label path, which are discussed in the section "Paths and Selection" on page 534.

to the template. Graphical templates are discussed in more detail in Chapter 21, "Statistical Graphics Using ODS." A style template applies to an entire SAS program, including all tables and graphs, and can be specified with the STYLE= option in a valid ODS destination, such as HTML, RTF, or PDF. You can specify a style as follows:

```
ods html style=HTMLBlue;
```

A style template controls stylistic elements such as colors, fonts, and presentation attributes. You can change the style to give your output different looks and color schemes. You can also refer to style information in table templates for individual headers and data cells. You can modify all types of templates with PROC TEMPLATE. For information about creating your own styles, see the *SAS Output Delivery System: User's Guide*.

You can display the contents of a template by running PROC TEMPLATE with a SOURCE statement and a template name, as in the following example:

```
proc template;
   source Stat.REG.ANOVA;
   source Stat.GLM.OverallANOVA;
run;
```

In many cases, a template definition is based at least in part on another template. When you see the PARENT=*template* option in a template definition, you need to look at the specified template to learn more about the rest of the template definition. To illustrate, consider the following PROC GLM step:

```
proc glm data=sashelp.class;
   model height=weight;
run; quit;
```

The ANOVA table from this step is displayed in Figure 20.6.

Figure 20.6 PROC GLM ANOVA Table with the Default Template

Getting Started with ODS

The GLM Procedure

Dependent Variable: Height

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	364.5762619	364.5762619	57.08	<.0001
Error	17	108.5879486	6.3875264		
Corrected Total	18	473.1642105			

The sums of squares and mean squares are presented with eight decimal places. You can change the templates to change the formats of those columns to use fewer decimal places. First, you can use the ODS TRACE statement when you run PROC GLM to determine the name of the template:

```
ods trace output;
proc glm data=sashelp.class;
   model height=weight;
run; quit;
ods trace off;
```

The trace output results include the following:

```
Output Added:
-------------
Name:        OverallANOVA
Label:       Overall ANOVA
Template:    stat.GLM.OverallANOVA
Path:        GLM.ANOVA.Height.OverallANOVA
-------------
```

From this, you can see that the template for the overall ANOVA table is **stat.GLM.OverallANOVA**. You can submit the following statements to see the overall ANOVA table template:

```
proc template;
   source stat.glm.overallanova;
run;
```

The results are as follows:

```
define table Stat.GLM.Overallanova;
   notes "Over-all ANOVA";
   top_space = 1;
   parent = Stat.GLM.ANOVA;
   double_space;
end;
```

The results show that this template inherits its definition from a parent template named **Stat.GLM.ANOVA**. Submit the following statements to see the parent template:

```
proc template;
   source stat.glm.anova;
run;
```

Some of the results are as follows:

```
define SS;
   parent = Stat.GLM.SS;
end;

define MS;
   parent = Stat.GLM.MS;
end;
```

These columns inherit their definitions from the parent columns named **Stat.GLM.SS** and **Stat.GLM.MS**. This is all of the information that you need to redefine these columns, but you can run PROC TEMPLATE again as follows to see more information about how these templates are defined:

```
proc template;
   source Stat.GLM.SS;
   source Stat.GLM.MS;
run;
```

The results are as follows:

```
define column Stat.GLM.Ss;
   notes "Parent for GLM ANOVA Sums of Squares columns";
   parent = Common.ANOVA.SS;
end;
define column Stat.GLM.Ms;
   notes "Parent for GLM ANOVA Mean Squares columns";
   parent = Common.ANOVA.MS;
end;
```

These columns inherit their definitions from the columns named **Common.ANOVA.SS** and **Common.ANOVA.MS**. You can run PROC TEMPLATE as follows to see their definitions:

```
proc template;
   source Common.ANOVA.SS;
   source Common.ANOVA.MS;
run;
```

The results are as follows:

```
define column Common.ANOVA.Ss;
   notes "Default ANOVA Sum of squares column";
   header = "Sum of Squares";
   translate _val_=._ into "";
end;
define column Common.ANOVA.Ms;
   notes "Default ANOVA Mean square column";
   header = "Mean Square";
   translate _val_=._ into "";
end;
```

You can redefine **Common.ANOVA.SS** and **Common.ANOVA.MS** to change all **SS** and **MS** columns in ANOVA tables. This would be the most general redefinition. More specifically, you can redefine **Stat.GLM.SS** and **Stat.GLM.MS** to change **SS** and **MS** columns in ANOVA tables produced by PROC GLM. Finally, and most specifically, you can change the **SS** and **MS** columns in just the overall ANOVA table template.

In this example, the **Stat.GLM.SS** and **Stat.GLM.MS** columns are redefined as follows, so that results are displayed with fewer decimal places:

```
proc template;
   edit Stat.GLM.SS;
      choose_format=max format_width=8;
   end;
   edit Stat.GLM.MS;
      choose_format=max format_width=8;
   end;
run;
```

The CHOOSE_FORMAT=MAX option along with the FORMAT_WIDTH=8 option chooses the format for each column based on the maximum value in that column and an overall width of eight. You are editing and not replacing the definition, so the column header and other information in the definition is not lost. The following step uses the new templates:

```
proc glm data=sashelp.class;
   model height=weight;
run; quit;
```

The new ANOVA results, using the edited templates, are shown in Figure 20.7. You can see that the original results in Figure 20.6 have eight decimal places, whereas the new results in Figure 20.7 have only five decimal places and an overall format width of eight.

Figure 20.7 PROC GLM ANOVA Table after Template Customization

Getting Started with ODS

The GLM Procedure

Dependent Variable: Height

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	364.5763	364.5763	57.08	<.0001
Error	17	108.5879	6.3875		
Corrected Total	18	473.1642			

The preceding PROC TEMPLATE step produces the following notes:

```
NOTE: Overwriting existing template/link: Stat.GLM.Ss
NOTE: COLUMN 'Stat.GLM.Ss' has been saved to: SASUSER.TEMPLAT
NOTE: Overwriting existing template/link: Stat.GLM.Ms
NOTE: COLUMN 'Stat.GLM.Ms' has been saved to: SASUSER.TEMPLAT
```

When you run PROC TEMPLATE to modify or edit a template, the template is stored by default in your Sasuser library. You can then modify the template search path with the ODS PATH statement—for example, so you can access these new templates in a later SAS session. This enables you to create a new default set of templates to modify the display format for all of your SAS output. You can specify the SHOW option in the ODS PATH statement to determine the current template search path. The following statements illustrate the template search path:

```
ods path show;
libname mytpls '.';
ods path (prepend) mytpls.template(update);
ods path show;

proc template;
   edit Stat.GLM.SS;
      choose_format=max format_width=8;
   end;
   edit Stat.GLM.MS;
      choose_format=max format_width=8;
   end;
run;
```

The results of the first statement are as follows:

```
Current ODS PATH list is:

1. SASUSER.TEMPLAT(UPDATE)
2. SASHELP.TMPLMST(READ)
```

This shows that the Sasuser.Templat template store is open for storing new templates and retrieving templates for use. After that, the Sashelp.Tmplmst template store is used, but it is open only for read access. You cannot modify templates in Sashelp. The LIBNAME and second ODS PATH statements add a template store to the front of this list in the current directory. The final ODS PATH SHOW statement shows the new template search path, which is as follows:

```
Current ODS PATH list is:

1. MYTPLS.TEMPLATE(UPDATE)
2. SASUSER.TEMPLAT(UPDATE)
3. SASHELP.TMPLMST(READ)
```

The PROC TEMPLATE step produces the following notes, which show that the templates are now stored in MYTPLS.TEMPLATE:

```
NOTE: Overwriting existing template/link: Stat.GLM.Ss
NOTE: COLUMN 'Stat.GLM.Ss' has been saved to: MYTPLS.TEMPLATE
NOTE: Overwriting existing template/link: Stat.GLM.Ms
NOTE: COLUMN 'Stat.GLM.Ms' has been saved to: MYTPLS.TEMPLATE
```

In all cases, the original template definitions in Sashelp.Tmplmst are not changed. You can delete your custom template and restore the default template as follows:

```
proc template;
   delete Stat.GLM.SS;
   delete Stat.GLM.MS;
run;
```

It is good practice to delete any template redefinitions that you do not want to be permanent, because otherwise they persist beyond the duration of your SAS session.

ODS and the NOPRINT Option

Many SAS procedures support a NOPRINT option that you can use when you want to create an output data set without displaying any output. You use an option (such as the OUTEST= option or an OUTPUT statement with an OUT= option) in addition to the procedure's NOPRINT option to create a data set and suppress displayed output.

You can also use the ODS OUTPUT statement to create output data sets. However, if you specify the NOPRINT option, the procedure might not send any output to ODS. In most procedures that support a NOPRINT option, NOPRINT means no ODS. (However, there are a few procedures that for historical reasons still might produce some output even when NOPRINT is specified.) When you want to create output data sets through the ODS OUTPUT statement and you want to suppress the display of all output, specify the following statement instead of using the NOPRINT option:

```
ods select none;
```

Alternatively, you can close the active ODS destinations like this:

```
ods _all_ close;
```

ODS statements do not instruct a procedure to generate output. Instead, they specify how ODS should manage output after it is created. You must ensure that the proper procedure options are in effect, or the output is not generated. For example, the following statements do not create the requested data set Parms because the SOLUTION option is not specified in the MODEL statement:

```
proc glm data=sashelp.class;
   ods output ParameterEstimates=Parms;
   class sex;
   model height=sex;
run; quit;
```

Since PROC GLM did not create the table, ODS cannot make the output data set. When you execute these statements, the following message is displayed in the log:

```
WARNING: Output 'ParameterEstimates' was not created.
```

The following step creates the output data set:

```
proc glm data=sashelp.class;
   ods output ParameterEstimates=Parms;
   class sex;
   model height=sex / solution;
run; quit;
```

Examples: Using the Output Delivery System

This section provides examples of creating HTML output, selecting and excluding output, tracing ODS output, using the Results window, creating ODS output data sets, modifying templates, creating hyperlinks, and using ODS Graphics.

Example 20.1: Creating HTML Output with ODS

This example demonstrates how you can use the ODS HTML statement to display your output in HTML. The following statements create the data set Scores, which contains the golf scores of boys and girls in a physical education class:

```
title 'Comparing Group Means';

data Scores;
   input Gender $ Score @@;
   datalines;
f 75  f 76  f 80  f 77  f 80  f 77  f 73
m 82  m 80  m 85  m 85  m 78  m 87  m 82
;
```

The TTEST procedure is used to compare the scores. The ODS HTML statement specifies the name of the file to contain the HTML output. The following statements create the HTML file *ttest.htm*:

```
ods html body='ttest.htm' style=HTMLBlue;

proc ttest;
   class Gender;
   var Score;
run;

ods html close;
```

In many cases, the LISTING destination is open by default. See the section "New Output Defaults in SAS 9.3" on page 526 for more information about default destinations. When the LISTING destination is open, the LISTING destination receives all output generated during your SAS session. In this example, the ODS HTML statement also opens the HTML destination, and both destinations receive the generated output. If you are in the SAS windowing environment and are using the internal browser, you do not need to close the HTML destination before viewing your output. However, when you write to an HTML file, you must specify the following statement before you can view your output in an external browser:

```
ods html close;
```

If you do not close the HTML destination, your HTML file might contain no output or incomplete output, or you might experience other unexpected results.

The following statements use ODS to display the output in HTML with a table of contents:

```
ods _all_ close;
ods html body='ttest.htm' contents='ttestc.htm' frame='ttestf.htm'
         style=HTMLBlue;
ods graphics on;

proc ttest;
   class Gender;
   var Score;
run;

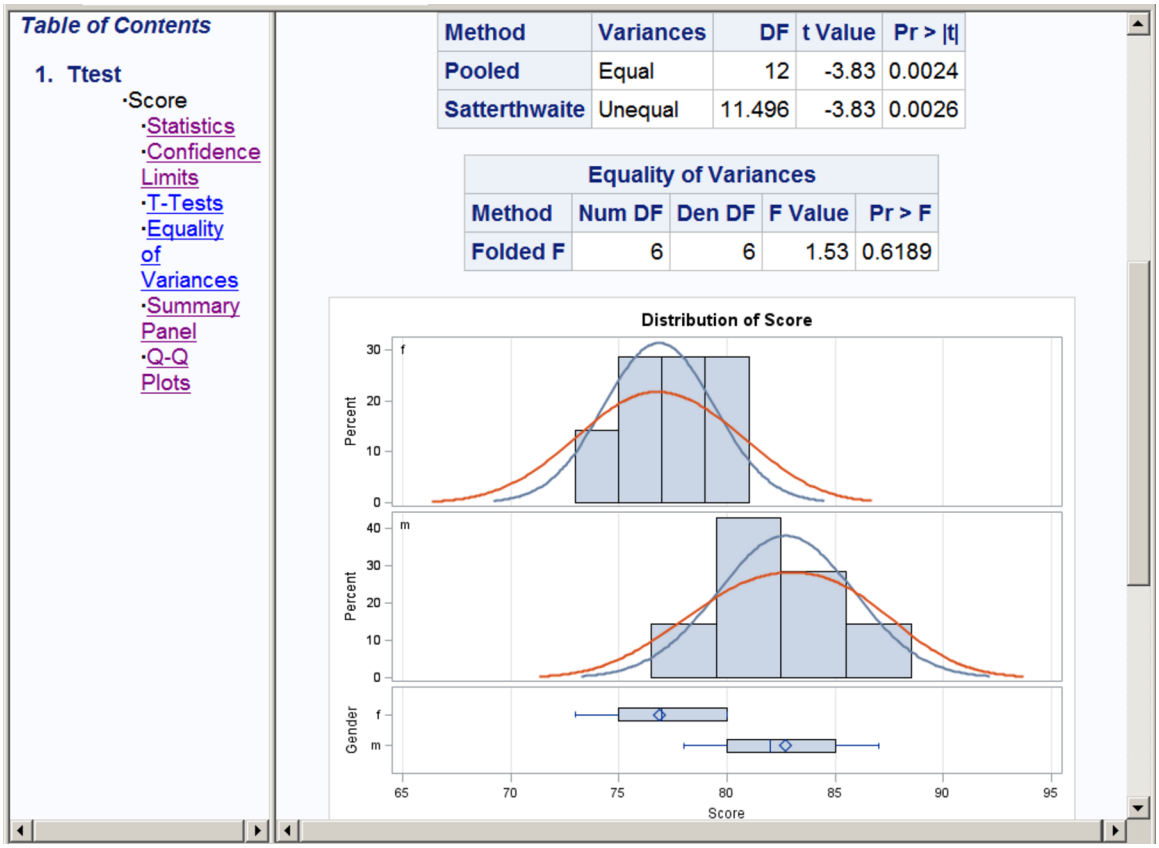
ods html close;
ods listing;
```

The ODS _ALL_ CLOSE statement closes all open destinations. The ODS HTML statement specifies three files and the HTMLBLUE style of output. The BODY= option specifies the file that contains the SAS output. The CONTENTS= option specifies the file that contains the table of contents. The FRAME= option specifies the file that displays both the table of contents and the output. You can open the FRAME= file (*ttestf.htm*) in your browser to view the table of contents together with the generated output (see Output 20.1.1). By default, the HTML files are generated in your current working directory. You can instead specify a path, such as `frame='html/ttestf.htm'`, to store a file in a subdirectory.

If you specify the ODS HTML statement with only the BODY= argument, no table of contents is created. The table of contents contains the descriptive label for each output table produced in the PROC TTEST step. You can select any label in the table of contents, and the corresponding output is displayed on the right side of the browser window.

The ODS GRAPHICS ON statement enables ODS Graphics, which creates the graph displayed in Output 20.1.1. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS."

Output 20.1.1 HTML Output with a Table of Contents and a Frame



Example 20.2: Selecting ODS Tables for Display

You can use the ODS SELECT statement to deliver only a subset of the tables or graphs to ODS destinations. The following statements create an input SAS data set and use PROC GLM to perform an analysis of an unbalanced two-way experimental design:

```
title 'Unbalanced Two-way Design';
data twoway;
   input Treatment Block y @@;
   datalines;
1 1 17   1 1 28   1 1 19   1 1 21   1 1 19   1 2 43
1 2 30   1 2 39   1 2 44   1 2 44   1 3 16
2 1 21   2 1 21   2 1 24   2 1 25   2 2 39   2 2 45
2 2 42   2 2 47   2 3 19   2 3 22   2 3 16
3 1 22   3 1 30   3 1 33   3 1 31   3 2 46   3 3 26
3 3 31   3 3 26   3 3 33   3 3 29   3 3 25
;

proc glm data=twoway;
   class Treatment Block;
   model y = Treatment | Block;
   means Treatment;
```

```
    lsmeans Treatment;
    ods select ModelANOVA Means;
    ods trace on;
    ods show;
run;
```

The ODS SELECT statement selects only two tables (**ModelANOVA** and **Means**) for display in the ODS destinations. In this example, no ODS destinations are explicitly opened. Therefore, only the default destination (usually LISTING or HTML) receives the procedure output. See the section "New Output Defaults in SAS 9.3" on page 526 for more information about default destinations. The ODS SHOW statement displays the current overall selection list in the SAS log. The ODS SHOW statement is not required; it is used here simply to show the effects of the ODS SELECT statement. The results of the ODS SHOW statement are as follows:

```
Current OVERALL select list is:
1. ModelANOVA
2. Means
```

The ODS TRACE statement writes the trace record of the ODS output objects to the SAS log. The trace record is as follows:

```
Output Added:
-------------
Name:        ModelANOVA
Label:       Type I Model ANOVA
Template:    stat.GLM.Tests
Path:        GLM.ANOVA.y.ModelANOVA
-------------

Output Added:
-------------
Name:        ModelANOVA
Label:       Type III Model ANOVA
Template:    stat.GLM.Tests
Path:        GLM.ANOVA.y.ModelANOVA
-------------

Output Added:
-------------
Name:        Means
Label:       Means
Template:    stat.GLM.Means
Path:        GLM.Means.Treatment.Means
-------------
```

There are two tables with the name **ModelANOVA**. One contains the "Type I Model ANOVA" table, and the other contains the "Type III Model ANOVA" table. If you want to select only one of them, you can specify either of the labels in the ODS SELECT statement instead of the name. You specify one of the following:

```
    ods select 'Type I Model ANOVA' Means;
    ods select 'Type III Model ANOVA' Means;
```

In the following statements, the ODS SHOW statement writes the current overall selection list to the SAS log, the QUIT statement ends the PROC GLM step, and the second ODS SHOW statement writes the selection list to the log after PROC GLM terminates:

```
ods show;
quit;
ods show;
```

The results of these statements are as follows:

```
ods show;

 Current OVERALL select list is:
 1. ModelANOVA
 2. Means

quit;
ods show;

 Current OVERALL select list is: ALL
```

PROC GLM supports interactive RUN-group processing. Before the QUIT statement is executed, PROC GLM is active and the ODS selection list remains at its previous setting. The list includes only the two tables, **ModelANOVA** and **Means**. After the QUIT statement, when PROC GLM is no longer active, the selection list is reset to ALL. The displayed output, shown in Output 20.2.1, consists of the three selected tables (two **ModelANOVA** tables and the **Means** table). The LS-means results are not displayed even though an LSMEANS statement was specified. This is because the LS-means table, named **LSMeans**, is not specified in the ODS SELECT statement. Other tables are suppressed as well.

Output 20.2.1 Selected Tables from PROC GLM

Unbalanced Two-way Design

The GLM Procedure

Dependent Variable: y

```

For more information about ODS exclusion and selection lists, see the section "The ODS Statement" on page 533.

Example 20.3: Excluding ODS Tables from Display

The following example demonstrates how you can use the ODS EXCLUDE statement to exclude particular tables from ODS destinations. This example also creates a SAS data set from the excluded table and uses it to create a specialized plot.

The data are from Hemmerle and Hartley (1973). The response variable consists of measurements from an oven experiment, and the model contains a fixed effect a and random effects b and a*b. The following statements create the input SAS data set:

```
title 'Oven Measurements';

data hh;
   input a b y @@;
   datalines;
1 1 237   1 1 254    1 1 246
1 2 178   1 2 179
2 1 208   2 1 178    2 1 187
2 2 146   2 2 145    2 2 141
3 1 186   3 1 183
3 2 142   3 2 125    3 2 136
;
```

The following ODS statements are submitted before the analysis, which will be done with the MIXED procedure:

```
ods _all_ close;
ods html body='mixed.htm' contents='mixedc.htm' frame='mixedf.htm'
         style=HTMLBlue;
ods exclude ParmSearch(persist);
ods show;
```

The ODS HTML statement specifies the filenames to contain the output generated from the statements that follow. The ODS EXCLUDE statement excludes the table **ParmSearch** from display. Although the table

is excluded from the displayed output, the information contained in the **ParmSearch** table is graphically summarized in a later step.

The PERSIST option in the ODS EXCLUDE statement excludes the table for the entire SAS session or until you execute an ODS SELECT statement or an ODS EXCLUDE NONE statement. If you omit the PERSIST option, the exclusion list is cleared when the procedure terminates. The resulting exclusion list is displayed next:

```
Current OVERALL exclude list is:
1. ParmSearch(PERSIST)
```

The MIXED procedure is run to fit the model:

```
proc mixed data=hh;
   class a b;
   model y = a;
   random b a*b;
   parms (17 to 20 by 0.1) (.3 to .4 by .005) (1.0);
   ods output ParmSearch=parms;
run;

ods show;
```

All output from PROC MIXED, except the **ParmSearch** table, is delivered to the HTML destination. The ODS OUTPUT statement outputs the table **ParmSearch** to a SAS data set called Parms.

The ODS SHOW statement again displays the overall current exclusion list after PROC MIXED has terminated. The results of the ODS SHOW statement are displayed next:

```
Current OVERALL exclude list is:
1. ParmSearch(PERSIST)
```

The **ParmSearch** table is saved in the Parms data set (as specified in the ODS OUTPUT statement). The following steps plot the surface of the residual log likelihood as a function of the covariance parameters and produce Output 20.3.1:

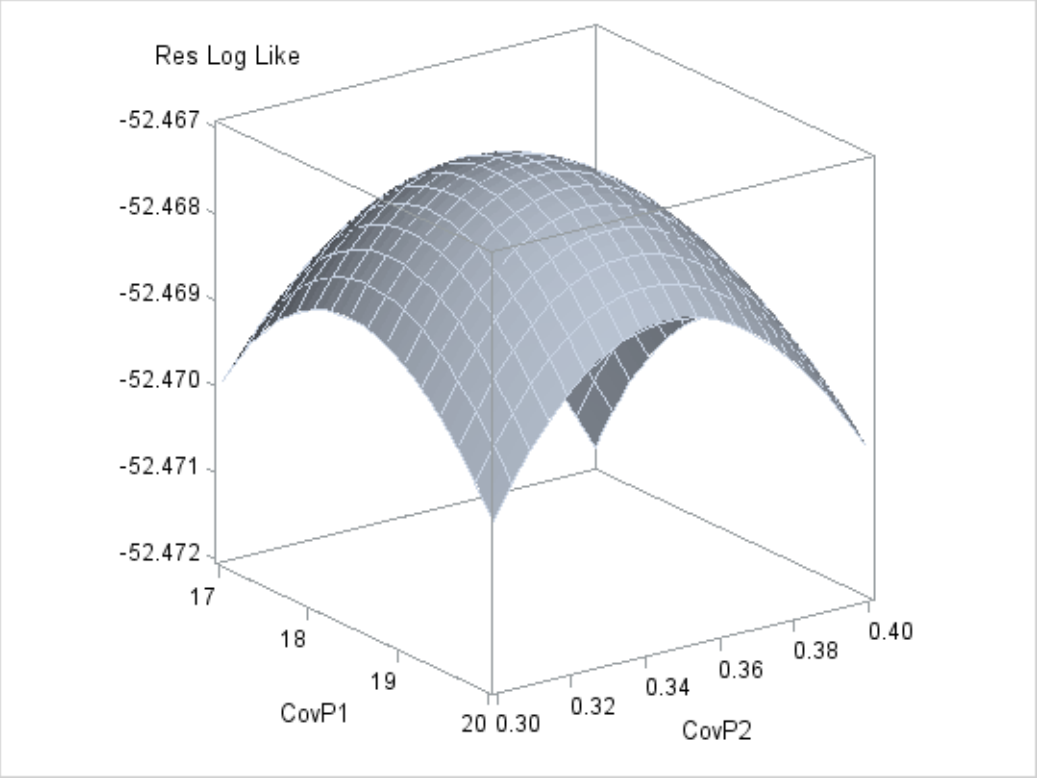
```
proc template;
   define statgraph surface;
      begingraph;
         layout overlay3d;
            surfaceplotparm x=CovP1 y=CovP2 z=ResLogLike;
         endlayout;
      endgraph;
   end;
run;

proc sgrender data=parms template=surface;
run;

ods html close;
```

PROC TEMPLATE is used to create a template for displaying the data as a three-dimensional surface plot. The plot is displayed with the ODS Graphics procedure SGRENDER. For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS."

Output 20.3.1 HTML Output from PROC MIXED



Example 20.4: Creating an Output Data Set from an ODS Table

In this example, the GENMOD procedure is used to perform Poisson regression, and part of the resulting procedure output is written to a SAS data set with the ODS OUTPUT statement. Insurance claims data are classified by two factors: age group (with two levels) and car type (with three levels). The following statements create the data set Insure:

```
title 'Insurance Claims';

data Insure;
   input n c Car $ Age;
   ln = log(n);
   datalines;
 500   42  Small  1
1200   37  Medium 1
 100    1  Large  1
 400  101  Small  2
 500   73  Medium 2
 300   14  Large  2
;
```

The variable n represents the number of insurance policyholders, and the variable c represents the number of insurance claims. The variable Car represents the type of car involved (classified into three groups), and the variable Age is the age of a policyholder (classified into two groups).

You can use PROC GENMOD to perform a Poisson regression analysis of these data with a log link function. Assume that the number-of-claims variable, c, has a Poisson probability distribution and the log of its mean, μ_i, is related to the factors Car and Age.

The following statements obtain the names of the tables produced by this PROC GENMOD run. The ODS TRACE statement lists the trace record. If you already know the names, such as by looking them up in the procedure documentation, you do not have to run this step. The following step displays the trace information:

```
ods trace on;

proc genmod data=insure;
   class car age;
   model c = car age / dist=poisson link=log offset=ln obstats;
run;

ods trace off;
```

The trace record from the SAS log is displayed next:

```
Output Added:
-------------
Name:        ModelInfo
Label:       Model Information
Template:    Stat.Genmod.ModelInfo
Path:        Genmod.ModelInfo
-------------

Output Added:
-------------
Name:        NObs
Label:       Number of observations summary
Template:    Stat.Genmod.NObs
Path:        Genmod.NObs
-------------

Output Added:
-------------
Name:        ClassLevels
Label:       Class Level Information
Template:    Stat.Genmod.Classlevels
Path:        Genmod.ClassLevels
-------------
```

```
Output Added:
-------------
Name:       ParmInfo
Label:      Parameter Information
Template:   Stat.Genmod.Parminfo
Path:       Genmod.ParmInfo
-------------

Output Added:
-------------
Name:       ModelFit
Label:      Criteria For Assessing Goodness Of Fit
Template:   stat.genmod.ModelFit

Name:       ObStats
Label:      Observation Statistics
Template:   Stat.Genmod.Obstats
Path:       Genmod.ObStats
-------------
```

In the following step, no output is displayed because the ODS SELECT NONE statement is included. The ODS OUTPUT statement writes the ODS table **ObStats** to a SAS data set named myObStats. All of the usual data set options, such as the KEEP= or RENAME= option, can be used in the ODS OUTPUT statement. Thus, to create the myObStats data set so that it contains only certain columns from the **ObStats** table, you can use the data set options as follows:

```
ods select none;
proc genmod data=insure;
   class car age;
   model c = car age / dist=poisson link=log offset=ln obstats;
   ods output ObStats=myObStats(keep=car age pred
                                rename=(pred=PredictedValue));
run;
```

The KEEP= data set option in the ODS OUTPUT statement specifies that only the variables Car, Age, and Pred are written to the data set. The RENAME= data set option changes the name of variable Pred to PredictedValue. The following statements sort the output data set myObStats, select all output, and produce Output 20.4.1:

```
proc sort data=myObStats;
   by descending PredictedValue;
run;

ods select all;
proc print data=myObStats noobs;
   title2 'Values of Car, Age, and the Predicted Values';
run;
```

The ODS SELECT NONE statement remains in effect until it is explicitly canceled (for example, with the ODS SELECT ALL statement).

Output 20.4.1 The ObStats Table Created as a SAS Data Set

Insurance Claims
Values of Car, Age, and the Predicted Values

Car	Age	Predicted Value
Small	2	107.2011
Medium	2	67.025444
Medium	1	42.974556
Small	1	35.798902
Large	2	13.773459
Large	1	1.2265414

Example 20.5: Creating an Output Data Set: Subsetting the Data

This example demonstrates how you can create an output data set with the ODS OUTPUT statement and also use data set selection keywords to limit the output that ODS writes to a SAS data set. The data set, called Color, contains the eye color and hair color of children from two different regions of Europe. The data are recorded as cell counts, where the variable Count contains the number of children who exhibit each of the 15 combinations of eye and hair color. The following statements create the SAS data set:

```
title 'Hair Color of European Children';

data Color;
   input Region Eyes $ Hair $ Count @@;
   label Eyes  ='Eye Color'
         Hair  ='Hair Color'
         Region='Geographic Region';
   datalines;
```

```
1 blue  fair   23  1 blue  red     7  1 blue  medium 24
1 blue  dark   11  1 green fair   19  1 green red     7
1 green medium 18  1 green dark   14  1 brown fair   34
1 brown red     5  1 brown medium 41  1 brown dark   40
1 brown black   3  2 blue  fair   46  2 blue  red    21
2 blue  medium 44  2 blue  dark   40  2 blue  black   6
2 green fair   50  2 green red    31  2 green medium 37
2 green dark   23  2 brown fair   56  2 brown red    42
2 brown medium 53  2 brown dark   54  2 brown black  13
;
```

The following statements exclude all output and sort the observations in the Color data set by the Region variable:

```
ods select none;

proc sort data=Color;
   by Region;
run;
```

The following ODS OUTPUT statement creates the **ChiSq** table as a SAS data set named myStats:

```
ods output ChiSq=myStats(drop=Table
                         where=(Statistic =: 'Chi' or
                                Statistic =: 'Like'));
```

You specify the table name in the ODS OUTPUT statement.[3] The DROP= data set option excludes variables from the new data set. The WHERE= data set option selects observations for output to the new data set myStats—specifically, those that begin with **'Chi'** or **'Like'**.

The following statements create Output 20.5.1:

```
proc freq data=Color order=data;
   weight Count;
   tables Eyes*Hair / testp=(30 12 30 25 3);
   by Region;
run;

ods select all;
proc print data=myStats noobs;
run;
```

The FREQ procedure is used to create and analyze a crosstabulation table from the two categorical variables Eyes and Hair, for each value of the variable Region.

[3] You can obtain the names of the tables created by any procedure in the individual procedure documentation chapter or from the individual procedure section of the SAS online Help system. (See the "ODS Table Names" section in the "Details" section of the documentation.) You can also determine the names of tables with the ODS TRACE statement (see Example 20.4 and Example 20.2).

Output 20.5.1 Output Data Set from PROC FREQ and ODS

Hair Color of European Children

Region	Statistic	DF	Value	Prob
1	Chi-Square	8	12.6331	0.1251
1	Likelihood Ratio Chi-Square	8	14.1503	0.0779
2	Chi-Square	8	18.2839	0.0192
2	Likelihood Ratio Chi-Square	8	23.3021	0.0030

Example 20.6: RUN-Group Processing

Some SAS procedures, such as PROC REG and PROC GLM, permit you to submit statements, followed by a RUN statement, followed by more statements and more RUN statements. Each group of statements, followed by a RUN statement, is called a RUN group. These procedures can produce several blocks of output for each of several RUN groups. The procedure stays active until a QUIT statement, a DATA statement, another PROC statement, or the end of the SAS session is encountered. However, ODS settings are cleared by default at RUN-group boundaries. In the following analysis, PROC REG is used to compute the covariance matrix of the estimates for two different models, and the covariance matrices are saved in a single SAS data set. The PERSIST= option in the ODS OUTPUT statement is required to make this happen. The PERSIST= option maintains ODS settings across RUN statements for procedures that support RUN-group processing.

Consider the following population growth trends. The population of the United States from 1790 to 1970 is fit to linear and quadratic functions of time. The quadratic term, YearSq, is created in the DATA step; this is necessary since polynomial effects such as Year*Year cannot be specified in the MODEL statement in PROC REG. The data are as follows:

```
title1 'US Population Study';
title2 'Concatenating Two Tables into One Data Set';

data USPopulation;
   input Population @@;
   retain Year 1780;
   Year=Year+10;
   YearSq=Year*Year;
   Population=Population/1000;
   datalines;
3929 5308 7239 9638 12866 17069 23191 31443 39818 50155
62947 75994 91972 105710 122775 131669 151325 179323 203211
;
```

In the following statements, PROC REG is used, and the ODS OUTPUT statement with the PERSIST= option creates a data set with the **CovB** table (the covariance matrix of the estimates):

```
proc reg data=USPopulation;
   ods output covb(persist=run)=Bmatrix;
   var YearSq;
   model Population = Year / covb;
run;
```

The MODEL statement defines the regression model, and the COVB matrix is requested. The RUN statement executes PROC REG and the model is fit, producing a covariance matrix of the estimates with two rows and two columns. The results are displayed in Output 20.6.1 and Output 20.6.2.

Output 20.6.1 Regression Results for the Model Population

US Population Study
Concatenating Two Tables into One Data Set

The REG Procedure
Model: MODEL1
Dependent Variable: Population

Number of Observations Read 19
Number of Observations Used 19

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	66336	66336	201.87	<.0001
Error	17	5586.29253	328.60544		
Corrected Total	18	71923			

Root MSE	18.12748	R-Square	0.9223
Dependent Mean	69.76747	Adj R-Sq	0.9178
Coeff Var	25.98271		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-1958.36630	142.80455	-13.71	<.0001
Year	1	1.07879	0.07593	14.21	<.0001

Output 20.6.2 CovB Matrix for the Model Population

Covariance of Estimates

Variable	Intercept	Year
Intercept	20393.138485	-10.83821461
Year	-10.83821461	0.0057650078

In the next step, the YearSq variable is added to the model and the model is fit again, producing a covariance matrix of the estimates with three rows and three columns:

```
add YearSq;
print;
run; quit;
```

The new COVB matrix is displayed in Output 20.6.3.

Output 20.6.3 CovB Matrix for the Model Population

US Population Study
Concatenating Two Tables into One Data Set

The REG Procedure
Model: MODEL1.1
Dependent Variable: Population

Covariance of Estimates

Variable	Intercept	Year	YearSq
Intercept	711450.62602	−757.2493826	0.2013282694
Year	−757.2493826	0.8061328943	−0.000214361
YearSq	0.2013282694	−0.000214361	5.7010894E−8

The PERSIST=RUN option maintains the ODS selection list across RUN statements for procedures that support RUN-group processing. If the PERSIST=RUN option is omitted, the selection list is cleared when the RUN statement is encountered and only the first COVB matrix is selected. Because the PERSIST=RUN option is specified, the selection list remains in effect throughout the PROC REG step. This ensures that each of the COVB matrices is selected and output. The following statements display the ODS OUTPUT SAS data set and create Output 20.6.4:

```
proc print;
run;
```

Output 20.6.4 Results of the ODS OUTPUT Statement: Specifying the PERSIST Option

US Population Study
Concatenating Two Tables into One Data Set

Obs	_Run_	Model	Dependent	Variable	Intercept	Year	YearSq
1	1	MODEL1	Population	Intercept	20393.138485	−10.83821461	.
2	1	MODEL1	Population	Year	−10.83821461	0.0057650078	.
3	2	MODEL1.1	Population	Intercept	711450.62602	−757.2493826	0.2013282694
4	2	MODEL1.1	Population	Year	−757.2493826	0.8061328943	−0.000214361
5	2	MODEL1.1	Population	YearSq	0.2013282694	−0.000214361	5.7010894E−8

Even though the two COVB matrices do not have the same rows or columns, ODS automatically combines the two tables into one data set.

Example 20.7: ODS Output Data Sets and Using PROC TEMPLATE to Customize Output

You can use ODS statements, the DATA step, and PROC TEMPLATE to modify the appearance of your displayed tables or to display results in forms that are not directly produced by any procedure. The following example, similar to that given in Olinger and Tobias (1998), runs an analysis with PROC GLM. This example has several parts. It creates output data sets with the ODS OUTPUT statement, combines and manipulates those data sets, displays the results by using a standard SAS template, modifies a template by using PROC TEMPLATE, and displays the output data sets by using the modified template. Each step works toward the final goal of taking multiple tables and creating a custom display of those tables in a way that cannot be done directly by PROC GLM.

The following statements create a SAS data set named Histamine that contains the experimental data:

```
title1 'Histamine Study';

data Histamine;
   input Drug $12. Depleted $ hist0 hist1 hist3 hist5;
   logHist0 = log(hist0); logHist1 = log(Hist1);
   logHist3 = log(hist3); logHist5 = log(Hist5);
   datalines;
Morphine      N  .04  .20  .10  .08
Morphine      N  .02  .06  .02  .02
Morphine      N  .07 1.40  .48  .24
Morphine      N  .17  .57  .35  .24
Morphine      Y  .10  .09  .13  .14
Morphine      Y  .07  .07  .06  .07
Morphine      Y  .05  .07  .06  .07
Trimethaphan  N  .03  .62  .31  .22
Trimethaphan  N  .03 1.05  .73  .60
Trimethaphan  N  .07  .83 1.07  .80
Trimethaphan  N  .09 3.13 2.06 1.23
Trimethaphan  Y  .10  .09  .09  .08
Trimethaphan  Y  .08  .09  .09  .10
Trimethaphan  Y  .13  .10  .12  .12
Trimethaphan  Y  .06  .05  .05  .05
;
```

The data set comes from a preclinical drug experiment (Cole and Grizzle 1966). In order to study the effect of two different drugs on histamine levels in the blood, researchers administer the drugs to 13 animals and measure the levels of histamine in the animals' blood after 0, 1, 3, and 5 minutes. The response variable is the logarithm of the histamine level.

In the analysis that follows, PROC GLM is used to perform a repeated measures analysis, naming the drug and depletion status as between-subject factors in the MODEL statement and naming post-administration measurement time as the within-subject factor. For more information about this study and its analysis, see Example 41.7 in Chapter 41, "The GLM Procedure."

The following PROC GLM statements begin the analysis:

```
ods graphics off;
ods trace output;

proc glm data=Histamine;
   class Drug Depleted;
   model LogHist0--LogHist5 = Drug Depleted Drug*Depleted / nouni;
   repeated Time 4 (0 1 3 5) polynomial / summary printe;
run; quit;
```

The portion of the trace output that contains the fully qualified name paths is shown next:

```
Path:       GLM.Data.ClassLevels
Path:       GLM.Data.NObs
Path:       GLM.Repeated.RepeatedLevelInfo
Path:       GLM.Repeated.PartialCorr
Path:       GLM.Repeated.MANOVA.Model.Error.ErrorSSCP
Path:       GLM.Repeated.MANOVA.Model.Error.PartialCorr
Path:       GLM.Repeated.MANOVA.Model.Error.Sphericity
Path:       GLM.Repeated.MANOVA.Model.Time.MultStat
Path:       GLM.Repeated.MANOVA.Model.Time_Drug.MultStat
Path:       GLM.Repeated.MANOVA.Model.Time_Depleted.MultStat
Path:       GLM.Repeated.MANOVA.Model.Time_Drug_Depleted.MultStat
Path:       GLM.Repeated.BetweenSubjects.ModelANOVA
Path:       GLM.Repeated.WithinSubject.ModelANOVA
Path:       GLM.Repeated.WithinSubject.Epsilons
Path:       GLM.Repeated.Summary.Time_1.ModelANOVA
Path:       GLM.Repeated.Summary.Time_2.ModelANOVA
Path:       GLM.Repeated.Summary.Time_3.ModelANOVA
```

The goal here is to output the within-subjects multivariate statistics and the between-subjects ANOVA table to SAS data sets for use in subsequent steps. The following statements run the analysis and save the desired results to output data sets:

```
ods select none;

proc glm data=Histamine;
   class Drug Depleted;
   model LogHist0--LogHist5 = Drug Depleted Drug*Depleted / nouni;
   repeated Time 4 (0 1 3 5) polynomial / summary printe;
   ods output MultStat                    = HistWithin
              BetweenSubjects.ModelANOVA = HistBetween;
run; quit;

ods select all;
```

No output is displayed due to the ODS SELECT statements. The ODS OUTPUT statement creates two SAS data sets, named HistWithin and HistBetween, from the two ODS tables. This analysis creates the following tables:

```
Path:       GLM.Repeated.MANOVA.Model.Time.MultStat
Path:       GLM.Repeated.MANOVA.Model.Time_Drug.MultStat
Path:       GLM.Repeated.MANOVA.Model.Time_Depleted.MultStat
Path:       GLM.Repeated.MANOVA.Model.Time_Drug_Depleted.MultStat
Path:       GLM.Repeated.BetweenSubjects.ModelANOVA
```

Here is the full trace output for the model ANOVA table:

```
Output Added:
-------------
Name:        ModelANOVA
Label:       Type III Model ANOVA
Template:    stat.GLM.Tests
Path:        GLM.Repeated.BetweenSubjects.ModelANOVA
-------------
```

All of the multivariate test results are routed to the HistWithin data set because all multivariate test tables are named **MultStat**, even though they occur in different directories in the output directory hierarchy. Only the between-subject ANOVA table appears in the HistBetween data set, even though there are also other tables named **ModelANOVA**. ODS selects just the one specific table for the HistBetween data set because of the partial name path (**BetweenSubjects.ModelANOVA**) in the second specification. For more information about names and qualified path names, see the discussion in the section "The ODS Statement" on page 533.

The following statements show the names and the variable labels for the two data sets and produce Output 20.7.1:

```
proc contents data=HistBetween varnum;
   ods select position;
run;

proc contents data=HistWithin varnum;
   ods select position;
run;
```

Output 20.7.1 Variable Names and Labels for the Two Data Sets

The following statements create a new data set that contains the two data sets created in the preceding PROC GLM step and display the results in Output 20.7.2:

```
title2 'The Combined Data Set';

data temp1;
   set HistBetween HistWithin;
run;

proc print label;
run;
```

Output 20.7.2 Listing of the Combined Data Set: Histamine Study

The next steps are designed to produce a more parsimonious display of the most important information in Output 20.7.2. The next step creates a data set named HistTests. Only the observations from the input data sets that are needed for interpretation are included. The variable Hypothesis in the HistWithin data set is renamed Source, and the NumDF variable is renamed DF. The renamed variables correspond to the variable names found in the HistBetween data set. These names are chosen since the template for the **ModelANOVA** table is used in subsequent steps. An explicit length for the new variable Source is provided since the input variables, Hypothesis and Source, have different lengths. The following statements produce Output 20.7.3:

```
data HistTests;
   length Source $ 20;
   set HistBetween(where =(Source    ^= 'Error'))
       HistWithin (rename=(Hypothesis =  Source NumDF=DF)
                   where =(Statistic  = 'Hotelling-Lawley Trace'));
run;

proc print label;
   title2 'Listing of the Combined Data Set';
run;
```

The amount of information contained in the HistTests data set is appropriate for interpreting the analysis; however, there is still extra information, and the information of interest is not being displayed in a compact or useful form. This data set consists of multiple tables, an ANOVA table with between-subjects information, and multivariate statistics tables with the variables renamed to match the names in the ANOVA table. This form was chosen so that the data set could be displayed using PROC GLM's ANOVA template. A template specifies how the data set should be displayed and which columns should be displayed. The output from the ODS TRACE statements shows that the template associated with PROC GLM's ANOVA table is named **`Stat.GLM.Tests`**. You can use the **`Stat.GLM.Tests`** template to display the SAS data set HistTests, as follows:

```
title2 'Listing of the Selections, Using a Standard Template';
proc sgrender data=histtests template=Stat.GLM.Tests;
run;
```

The SGRENDER procedure displays the DATA= data set with the specified TEMPLATE= template. (You can use PROC SGRENDER to display both graphs and tables.) The results are displayed in Output 20.7.4.

Output 20.7.4 Listing of the Data Set Using a Standard PROC GLM ANOVA Template

Histamine Study
Listing of the Selections, Using a Standard Template

Source	DF	SS	Mean Square	F Value	Pr > F
Drug	1	5.99336	5.99336	2.71	0.1281
Depleted	1	15.44841	15.44841	6.98	0.0229
Drug*Depleted	1	4.69088	4.69088	2.12	0.1734
Time	3	.	.	24.03	0.0001
Time_Drug	3	.	.	5.78	0.0175
Time_Depleted	3	.	.	21.31	0.0002
Time_Drug_Depleted	3	.	.	12.48	0.0015

Alternatively, you could display the results by using a DATA step as follows:

```
title2 'Listing of the Selections, Using a Standard Template';

data _null_;
   set histtests;
   file print ods=(template='Stat.GLM.Tests');
   put _ods_;
run;
```

The next steps create a final display of these results, this time by using a custom template. This example shows you how to use PROC TEMPLATE to do the following:

- redefine the format for the SS and Mean Square columns
- include the table title and footnote in the body of the table
- translate the missing values for SS and Mean Square in the rows that correspond to multivariate tests to asterisks
- add a footnote to a table
- add a column that depicts the level of significance of each effect

The following statements create a custom template:

```
proc template;
   define table CombinedTests;
      parent=Stat.GLM.Tests;

      header '#Histamine Study##';
      footer '#* - Test computed using Hotelling-Lawley trace';

      column Source DF SS MS FValue ProbF Star;

      define Source; width=20; end;
      define DF; format=bestd3.; end;
      define SS;
         parent=Stat.GLM.SS
         choose_format=max format_width=7;
         translate _val_ = . into '  *';
      end;
      define MS;
         parent=Stat.GLM.MS
         choose_format=max format_width=7;
         translate _val_ = . into '  *';
      end;
      define Star;
         compute as ProbF;
         translate _val_ <= 0.001 into 'xxx',
                   _val_ <= 0.01  into 'xx',
                   _val_ <= 0.05  into 'x',
                   _val_ >  0.05  into '';
         pre_space=1 width=3 just=l;
      end;
   end;
run;
```

The CHOOSE_FORMAT=MAX option along with FORMAT_WIDTH=7 chooses the format for each column based on the maximum value and an overall width of 7. Alternatively, you could have specified a format directly by specifying, for example, FORMAT=7.2 or FORMAT=D8.3. The TRANSLATE statements provide values to display in place of the original values. The first two TRANSLATE statements display missing values as an asterisk with leading blanks added to ensure alignment with the decimal place. The third TRANSLATE statement displays *p*-values greater than 0.05 as a blank, values greater than 0.01 but less than or equal to 0.05 as a single `'x'`, and so on. The ProbF column is printed twice—once in the usual way as a numeric column with a PVALUE format and once with a column of blanks or x's. For detailed information about PROC TEMPLATE, see the section "The Template Procedure" in the *SAS Output Delivery System: User's Guide*. The following statements use the customized template to display the HistTests data set:

```
title2 'Listing of the Selections, Using a Customized Template';

proc sgrender data=HistTests template=CombinedTests;
run;
```

The results are displayed in Output 20.7.5.

Output 20.7.5 Display of the Data Sets Using a Customized Template: Histamine Study

Histamine Study

* - Test computed using Hotelling-Lawley trace

These next steps display the same table, but this time changing the background color for the entire row to highlight effects with p-values less than 0.001 and also those with p-values less than 0.01. The table is displayed three times. Output 20.7.6 displays the results by using bold green and yellow backgrounds and a bold font. Output 20.7.7 displays the results by using subtler cyan and yellow backgrounds and a bold font. Output 20.7.8 displays the results by using very subtle cyan and gray backgrounds and a normal font. This control is provided by the CELLSTYLE statement in PROC TEMPLATE. You can do many things with the CELLSTYLE statement to enhance your output. Several more are shown in other examples in this chapter. These next steps create the custom template with varying colors and fonts and display the results by using PROC SGRENDER:

```
%macro hilight(c1,c2);
   proc template;
        define table CombinedTests;
           parent=Stat.GLM.Tests;

           header '#Histamine Study##';
           footer '#* - Test computed using Hotelling-Lawley trace';

           column Source DF SS MS FValue ProbF;

           cellstyle probf <= 0.001 as {background=&c1},
                     probf <= 0.01  as {background=&c2};

           define DF; format=bestd3.; end;
           define SS;
              parent=Stat.GLM.SS
              choose_format=max format_width=7;
              translate _val_ = . into '  *';
           end;
```

```
            define MS;
               parent=Stat.GLM.MS
               choose_format=max format_width=7;
               translate _val_ = . into '  *';
            end;
         end;
   run;

   proc sgrender data=HistTests template=CombinedTests;
   run;
%mend;

title2;
ods _all_ close;
ods html style=HTMLBlue;

* - Test computed using Hotelling-Lawley trace

All colors are specified in values of the form CX*rrggbb*, where the last six characters specify RGB (red, green, blue) values on the hexadecimal scale of 00 to FF (or 0 to 255 base 10). You can run the following step to see the correspondence between the integer and HEX formatting of values in the range 0 to 255:

```
data _null_;
   do color = 0 to 255;
      put color 3. +1 color hex2.;
   end;
run;
```

The results of this step are not shown. Hexadecimal values 0 through F represent the numbers 0 to 15. A hex value xy can be converted to an integer as follows: $16x + y$. For example, BC is $16 \times 11 + 12 = 188$. Common colors are CXFF0000 (red), CX00FF00 (green), CX0000FF (blue), CXFFFF00 (yellow, a mix of red and green), CXFF00FF (magenta, a mix of red and blue), CX00FFFF (cyan, a mix of green and blue), CXFFFFFF (white, a mix of red, green, and blue), CX000000 (black, no color), CXDDDDDD (very light gray), CX222222 (very dark gray), and so on. Colors become lighter as the RGB values increase and darker as they decrease. For example, cyan (CX00FFFF) can be lightened by increasing the red component from 00 to FF until eventually it becomes indistinguishable from white. It can be darkened by jointly decreasing the green and blue values until it becomes indistinguishable from black.

The three CELLSTYLE statements that set the colors after the macro variables are substituted are as follows:

```
cellstyle probf <= 0.001 as {background=CX22FF22 fontweight=bold},
          probf <= 0.01  as {background=CXFFFF22 fontweight=bold};
cellstyle probf <= 0.001 as {background=CXAAFFFF fontweight=bold},
          probf <= 0.01  as {background=CXFFFFDD fontweight=bold};
cellstyle probf <= 0.001 as {background=CXEEFAFA},
          probf <= 0.01  as {background=CXEEEEEE};
```

The first color, CX22FF22, for the smallest p-values in the first table is a bold green color. The first table uses almost pure green and pure yellow, but a little red and blue are added to slightly lighten the colors. The second table uses a cyan and yellow that are very light due to the addition of AA (170) red and DD (221) blue, respectively. The third table uses a cyan that is not much different from light gray, and a light gray that is not much different from white.

Example 20.8: HTML Output with Hyperlinks between Tables

This example demonstrates how you can use ODS to provide links between different parts of your HTML procedure output. This example creates a table where each row contains a link to another table with more information about that row.

Suppose that you are analyzing a 4×4 factorial experiment for an industrial process, testing for differences in the number of defective products that are manufactured by different machines and use different sources of raw material. The data set Experiment is created as follows:

```
title 'Product Defects Experiment';

data Experiment;
   do Supplier = 'A', 'B', 'C', 'D';
      do Machine = 1 to 4;
         do rep = 1 to 5;
            input Defects @@;
            output;
         end;
      end;
   end;
   datalines;
 2  6  3  3  6  8  6  6  4  4  4  2  4  0  4  5  5  7  8  5
13 12 12 11 12 16 15 14 14 13 11 10 12 12 10 13 13 14 15 12
 2  6  3  6  6  6  4  4  6  6  0  3  2  0  2  4  6  7  6  4
20 19 18 21 22 22 24 23 20 20 17 19 18 16 17 23 20 20 22 21
;
```

Suppose that you are interested in fitting a model to determine the effect that the supplier of raw material and machine type have on the number of defects in the products. If the F test for a factor is significant, you might want to follow up with a multiple-comparison test for the levels of that factor. The tables of interest are the model ANOVA and the multiple-comparison output. Since this is a balanced experiment, the ANOVA procedure computes the appropriate analysis. The following statements produce these tables and Figure 20.8.1:

```
ods _all_ close;
ods html body='anovab.htm' style=HTMLBlue anchor='anova1';
ods trace output;

proc anova data=Experiment;
   ods select ModelANOVA MCLines;
   class Supplier Machine;
   model Defects = Supplier Machine;
   means Supplier Machine / tukey;
run; quit;

ods html close;
ods listing;
```

All destinations are first closed to avoid generating the output multiple times. ODS writes the HTML output to the file *anovab.htm*. The ANCHOR= option specifies *anova1* as the root name for the HTML anchor

tags. This means that within the HTML document, the URL for the first table will be *anova1*, the URL for the second table will be *anova2*, and so on.

Output 20.8.1 ANOVA and Multiple-Comparison Results: Histamine Study

Product Defects Experiment

The ANOVA Procedure

Dependent Variable: Defects

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Supplier	3	3441.638	1147.213	580.72	<.0001
Machine	3	163.137	54.379	27.53	<.0001

Product Defects Experiment

The ANOVA Procedure

Tukey's Studentized Range (HSD) Test for Defects

Means with the same letter are not significantly different.

Tukey Grouping	Mean	N	Supplier
A	20.1000	20	D
B	12.7000	20	B
C	4.6000	20	A
C			
C	4.1500	20	C

Product Defects Experiment

The ANOVA Procedure

Tukey's Studentized Range (HSD) Test for Defects

Means with the same letter are not significantly different.

Tukey Grouping	Mean	N	Machine
A	11.7500	20	2
A			
A	11.5000	20	4
B	10.1500	20	1
C	8.1500	20	3

The ODS trace output (not shown) shows that PROC ANOVA uses the **Stat.GLM.Tests** template to format the ANOVA table. The following statements demonstrate how you can link a row of the ANOVA table to the corresponding multiple-comparison table by modifying the table template, using the original values and the URLs for the second and third tables (*anova2* and *anova3*):

```
proc template;
   edit Stat.GLM.Tests;
      edit Source;
         cellstyle _val_ = 'Supplier' as {url="#ANOVA2"},
                   _val_ = 'Machine'  as {url="#ANOVA3"};
      end;
   end;
run;
```

This template uses the CELLSTYLE statement to alter the values in the **Source** column (**'Supplier'** and **'Machine'**) of the ANOVA tests table. The values of **'Supplier'** and **'Machine'** are displayed as hyperlinks in the HTML, and clicking them takes you to the links *anova2* and *anova3*, which are the multiple-comparison tables.

You can find the value to use in the URL by viewing the HTML source file, *anovab.htm*. You can either open the HTML file in a text editor or view it in a browser window and select **View ► Source**. Search for **'<a name='** to find the URL names. The first table is *anova1*, the second is *anova2*, the third is *anova3*, and so on. If the ANCHOR= option had not been used in the ODS HTML statement, the names would have been *IDX*, *IDX1*, *IDX2*, and so on. If you do not use the ODS SELECT statement or if you do anything to change the tables that are produced, the names will be different. The statements create the *Supplier* label as a link that enables you to open the table of means from the "Tukey's Studentized Range Test for Defects" associated with the Supplier variable. Similarly, *Machine* provides a link to the table of means from the "Tukey's Studentized Range Test for Defects" associated with the Machine variable.

Next, the analysis is run again, this time using the modified template. The following statements produce the results:

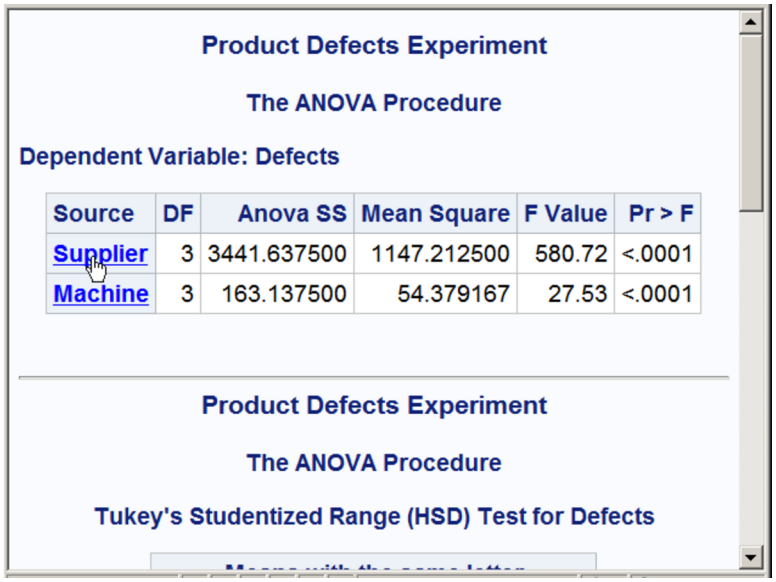
```
ods _all_ close;
ods html body='anovab.htm' style=HTMLBlue anchor='anova1';

proc anova data=Experiment;
   ods select ModelANOVA MCLines;
   class Supplier Machine;
   model Defects = Supplier Machine;
   means Supplier Machine / tukey;
run; quit;

ods html close;
ods listing;
```

The ANOVA table is displayed in Output 20.8.2.

Output 20.8.2 HTML Output from PROC ANOVA: Linked Output



Product Defects Experiment

The ANOVA Procedure

Dependent Variable: Defects

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Supplier	3	3441.637500	1147.212500	580.72	<.0001
Machine	3	163.137500	54.379167	27.53	<.0001

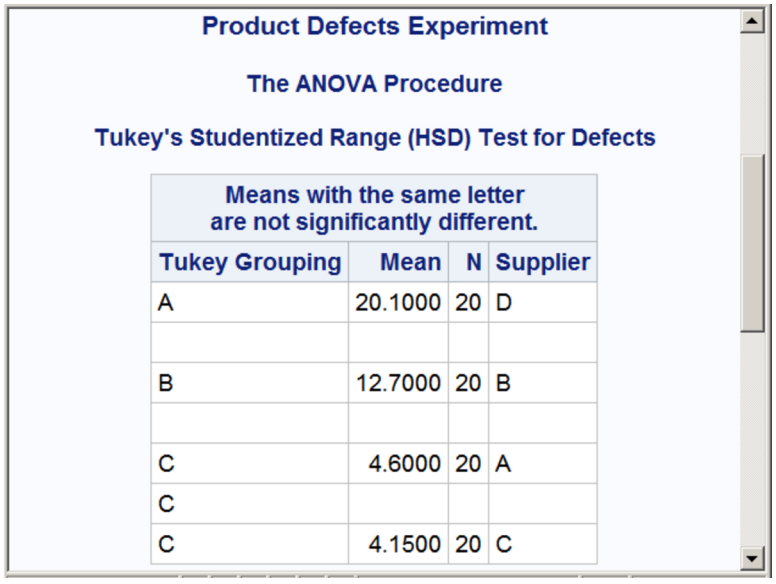
Product Defects Experiment

The ANOVA Procedure

Tukey's Studentized Range (HSD) Test for Defects

The underlined text displayed in Output 20.8.2 shows the links, *Supplier* and *Machine*, that you created with the modified template. When you click a link, the appropriate multiple-comparison table opens in your browser. Output 20.8.3 shows the table from the *Supplier* link.

Output 20.8.3 Linked Output: Multiple-Comparison Table from PROC ANOVA



Product Defects Experiment

The ANOVA Procedure

Tukey's Studentized Range (HSD) Test for Defects

Means with the same letter are not significantly different.

Tukey Grouping	Mean	N	Supplier
A	20.1000	20	D
B	12.7000	20	B
C	4.6000	20	A
C			
C	4.1500	20	C

When you run the PROC TEMPLATE step shown previously, the following note is printed in the SAS log:

```
NOTE: TABLE 'Stat.GLM.Tests' has been saved to: SASUSER.TEMPLAT
```

You can see that there are now two versions of the template by running the following statements:

```
proc template;
   list Stat.GLM.Tests;
run;
```

These statements produce Output 20.8.4.

Output 20.8.4 Templates

```
                          Product Defects Experiment

                      Listing of: MYTPLS.TEMPLATE
                      Path Filter is: Stat.GLM.Tests
                      Sort by: PATH/ASCENDING

                      Obs    Path                Type
                      -------------------------------
                       1     Stat.GLM.Tests      Table

                      Listing of: SASHELP.TMPLMST
                      Path Filter is: Stat.GLM.Tests
                      Sort by: PATH/ASCENDING

                      Obs    Path                Type
                      -------------------------------
                       1     Stat.GLM.Tests      Table
```

You can delete your custom template and restore the default template as follows:

```
proc template;
   delete Stat.GLM.Tests;
run;
```

The following note is printed in the SAS log:

```
NOTE: 'Stat.GLM.Tests' has been deleted from: SASUSER.TEMPLAT
```

Example 20.9: HTML Output with Graphics and Hyperlinks

This example demonstrates how you can use ODS to create links between each bar in a bar chart (Output 20.9.1) and other parts of the analysis (Output 20.9.2). The data in this example are selected from a larger experiment on the use of drugs in the treatment of leprosy (Snedecor and Cochran 1967, p. 422). Variables in the study are as follows:

Drug	two antibiotics (‘a’ and ‘d’) and a control (‘f’)
PreTreatment	a pretreatment score of leprosy bacilli
PostTreatment	a posttreatment score of leprosy bacilli

The data set is created as follows:

```
title 'Treatment of Leprosy';

data drugtest;
   input Drug $ PreTreatment PostTreatment @@;
   datalines;
a 11  6  a  8  0  a  5  2  a 14  8  a 19 11
a  6  4  a 10 13  a  6  1  a 11  8  a  3  0
d  6  0  d  6  2  d  7  3  d  8  1  d 18 18
d  8  4  d 19 14  d  8  9  d  5  1  d 15  9
f 16 13  f 13 10  f 11 18  f  9  5  f 21 23
f 16 12  f 12  5  f 12 16  f  7  1  f 12 20
;
```

The following statement opens the HTML destination:

```
ods _all_ close;
ods html body='glmb.htm' contents='glmc.htm' frame='glmf.htm'
         style=HTMLBlue;
```

The ODS HTML statement specifies the body filename, generates a table of contents for the output, and generates a frame to contain the body and table of contents. The following statements perform the analysis:

```
proc glm data=drugtest;
   class drug;
   model PostTreatment = drug | PreTreatment / solution;
   lsmeans drug / stderr pdiff;
   ods output LSMeans=lsmeans;
run; quit;
```

The ODS OUTPUT statement writes the table of LS-means to the data set named lsmeans. PROC GLM performs an analysis of covariance and computes LS-means for the variable Drug.

The following steps demonstrate how you can create links to connect the results of different analyses. In this example, the table of LS-means is graphically summarized in a horizontal bar chart. Each bar is linked to a plot that displays the relationship between the PostTreatment response variable and the PreTreatment variable for the drug that corresponds to the bar.

NOTE: PROC GLM can use ODS Graphics to create LS-means graphs that are different from the one constructed here. You do not have to run the following steps to get PROC GLM's standard LS-means plots.

The following DATA step creates a new variable named DrugClick that matches each drug value with an HTML file:

```
data lsmeans;
   set lsmeans;
   if drug='a' then DrugClick='drug1.htm';
   if drug='d' then DrugClick='drug2.htm';
   if drug='f' then DrugClick='drug3.htm';
run;
```

The variable DrugClick is used in the chart. The variable provides the connection information for linking the two parts of the analysis together. The files referred to in these statements are created in a later step. The

following statements create the chart:

```
ods graphics / imagemap=yes height=2in width=6.4in;

proc sgplot data=lsmeans;
   title 'Chart of LS-Means for Drug Type';
   hbar drug / response=lsmean stat=mean
               url=drugclick;
   footnote j=l 'Click on the bar to see a plot of PostTreatment '
                'versus PreTreatment for the corresponding drug.';
   format lsmean 6.3;
run;

ods graphics off;
footnote;
ods html close;
```

The chart is created with the ODS Graphics procedure SGPLOT. For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." The ODS GRAPHICS statement is not required before you run SG procedures. However, in this case, it is necessary to specify IMAGEMAP=YES so that the URL= option works properly. The size of the graph is also specified with the HEIGHT= and WIDTH= options. PROC SGPLOT is used, and the HBAR statement requests a horizontal bar chart for the variable Drug. The lengths of the bars represent the values of the LSMean variable. The URL= option specifies the variable DrugClick as the HTML linking variable. The FOOTNOTE statement provides text that indicates how to use the links in the graph.

The following statements provide the second analysis. The three files referred to by the DrugClick variable are created as follows:

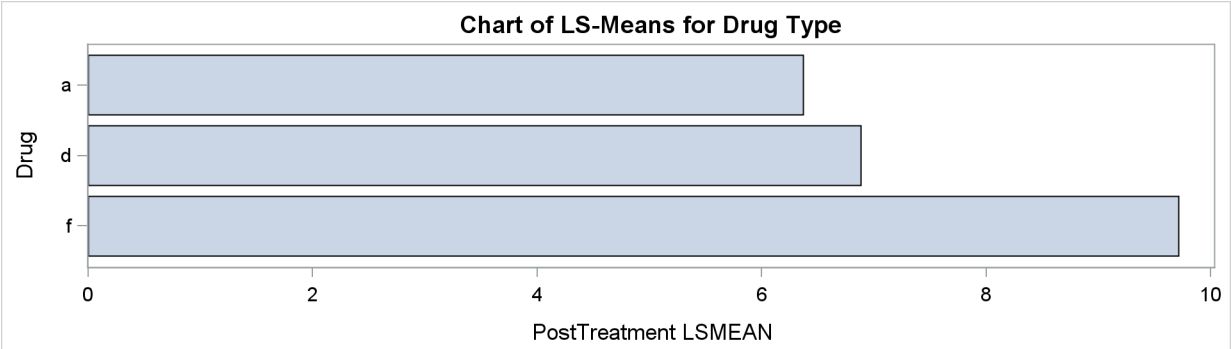
```
ods html body='drug1.htm' newfile=page style=HTMLBlue;

proc sgplot data=drugtest;
   title 'Plot of PostTreatment versus PreTreatment';
   scatter y=PostTreatment x=PreTreatment;
   by drug notsorted;
run;
ods html close;
```

The NEWFILE= option in the ODS HTML statement creates a new HTML file for each page of output. (Page breaks occur only when a procedure explicitly starts a new page.) The NEWFILE= option also increments the filename numeric suffix for each new HTML file created, with the first filename corresponding to that given in the BODY= option, *drug1.htm*.

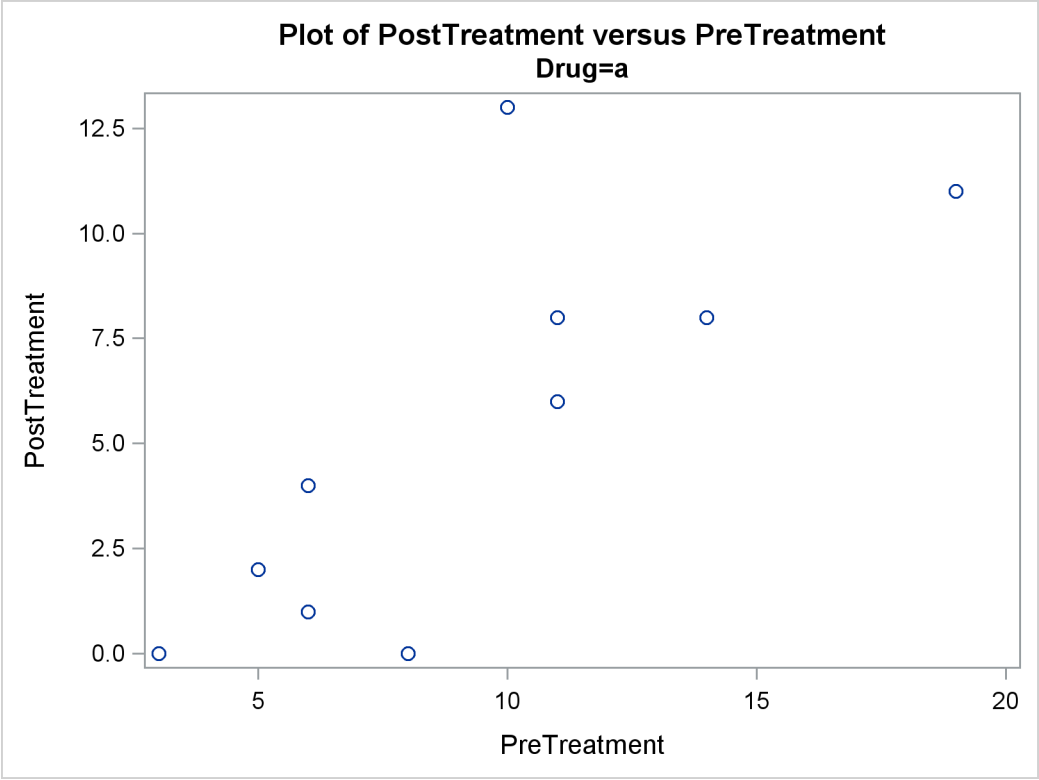
PROC SGPLOT is used, producing a plot of the variable PostTreatment versus the variable PreTreatment for each value of the Drug variable. Three plots are created, and each plot is contained in a separate HTML file. The files are named *drug1.htm*, *drug2.htm*, and *drug3.htm*. The filenames match those filenames specified as values of the DrugClick variable. By default, the HTML files are generated in your current working directory. You can instead specify a path, such as **frame='html/drug2.htm'**, to put a file in a subdirectory. The chart in Output 20.9.1 displays the difference in LS-means for each drug type. When you click on a bar that represents a value of the variable Drug, the browser opens the plot of PostTreatment versus PostTreatment variables that corresponds to that value of the variable Drug. Output 20.9.2 displays the plots for each drug type.

Output 20.9.1 Bar Chart of LS-Means by Drug Type with Links to Plots

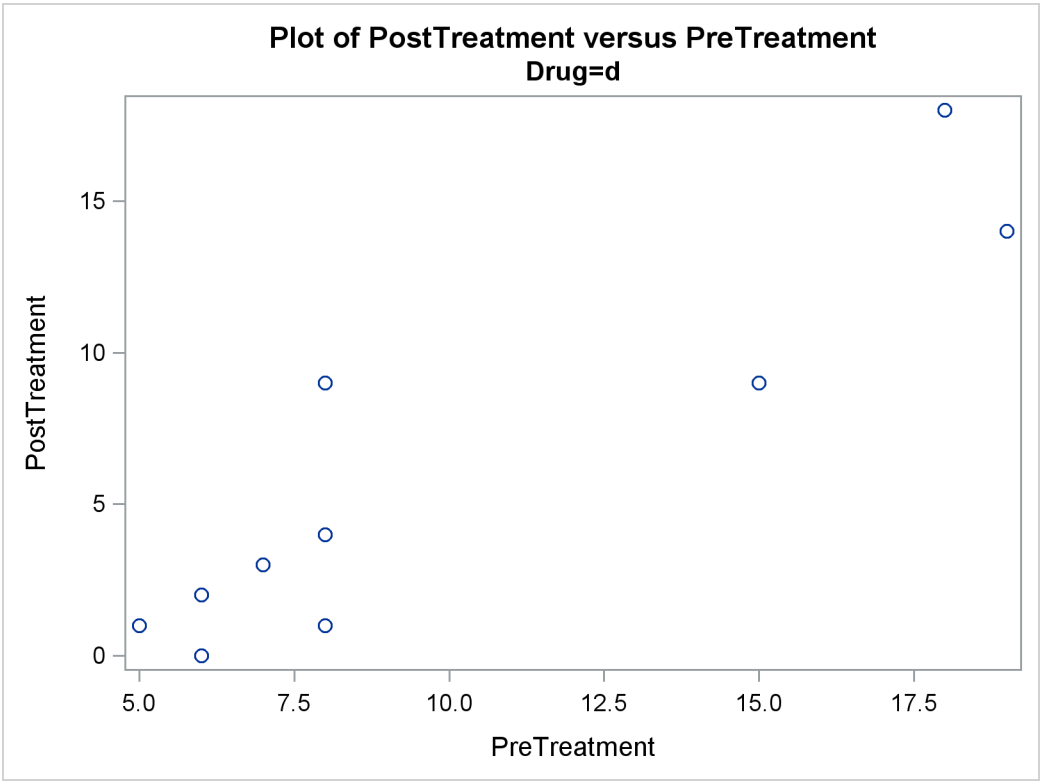


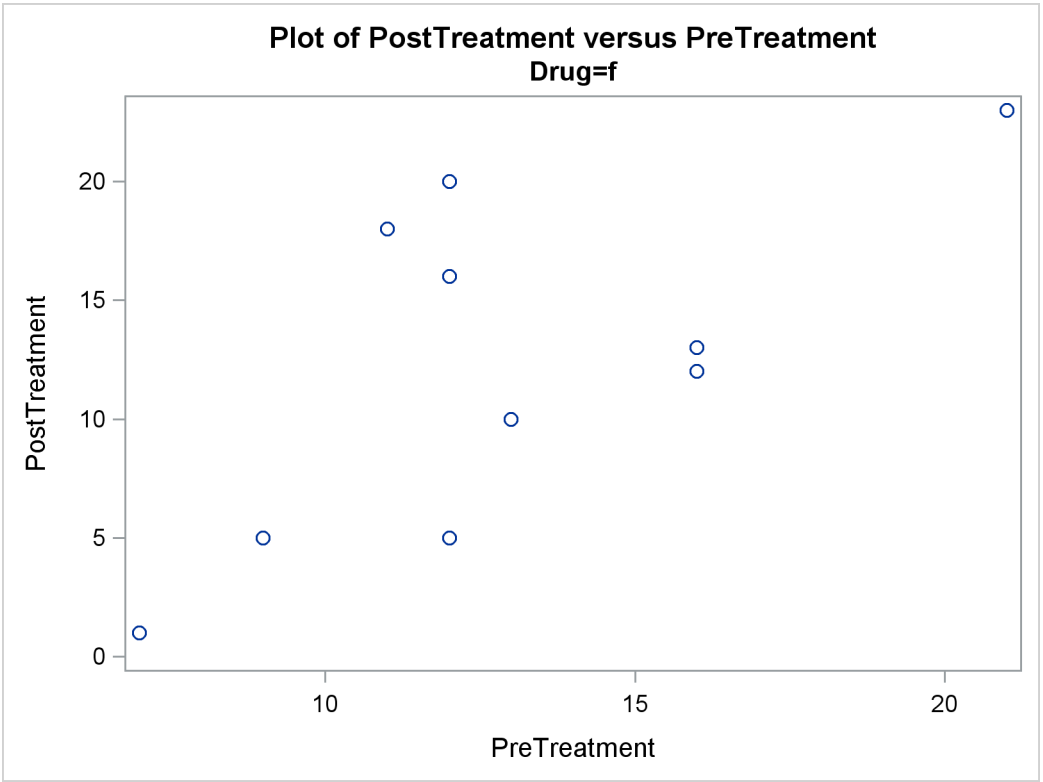
Click on the bar to see a plot of PostTreatment versus PreTreatment for the corresponding drug.

Output 20.9.2 Plots by Drug Type



Output 20.9.2 *continued*





Example 20.10: Correlation and Covariance Matrices

This example demonstrates how you can use ODS to set the background color of individual cells in a table. The color is set to reflect the magnitude of the value in the cell. You can use color to call attention to larger values and to see the pattern in the data in a way that is hard to visualize just by looking at the numbers. This is illustrated with correlation and covariance matrices. The data for this first part of this example are ratings of automobiles. The following statements create the data set:

```
title 'Rating of Automobiles';

data cars;
   input Origin $ 1-8 Make $ 10-19 Model $ 21-36
         (MPG Reliability Acceleration Braking Handling Ride
          Visibility Comfort Quiet Cargo) (1.);
   datalines;
GMC      Buick      Century         3334444544
GMC      Buick      Electra         2434453555

   ... more lines ...

GMC      Pontiac    Sunbird         3134533234
;
```

The following steps edit the template that PROC CORR uses to display the correlation matrix. The CELLSTYLE statement sets the background color to light gray for correlations equal to 1 or –1. Values less than –0.75 or greater than 0.75 are set to red. Values less than –0.50 or greater than 0.50 are set to blue. Values less than –0.25 or greater than 0.25 are set to cyan. Values in the range –0.25 to 0.25 are set to white. PROC CORR is then run using the custom template. Finally, the default template is restored. The following statements produce Output 20.10.1:

```
proc template;
   edit Base.Corr.StackedMatrix;
      column (RowName RowLabel) (Matrix) * (Matrix2);
      edit matrix;
         cellstyle _val_  = -1.00 as {backgroundcolor=CXEEEEEE},
                   _val_ <= -0.75 as {backgroundcolor=red},
                   _val_ <= -0.50 as {backgroundcolor=blue},
                   _val_ <= -0.25 as {backgroundcolor=cyan},
                   _val_ <=  0.25 as {backgroundcolor=white},
                   _val_ <=  0.50 as {backgroundcolor=cyan},
                   _val_ <=  0.75 as {backgroundcolor=blue},
                   _val_ <   1.00 as {backgroundcolor=red},
                   _val_  =  1.00 as {backgroundcolor=CXEEEEEE};
      end;
   end;
run;

ods _all_ close;
ods html body='corr.html' style=HTMLBlue;
```

```
proc corr data=cars noprob;
   ods select PearsonCorr;
run;

ods html close;
ods listing;

proc template;
   delete Base.Corr.StackedMatrix;
run;
```

Output 20.10.1 Correlation Matrix from PROC CORR

Rating of Automobiles

Quiet	-0.49128	0.45302	0.00934	0.00164	-0.02418	0.48498	-0.18347	0.44917	1.00000	0.33846
Cargo	-0.03075	0.35261	-0.12112	0.20880	-0.14274	0.39108	0.35585	0.53836	0.33846	1.00000

The preceding statements used a small number of discrete colors to show the range of values. In contrast, the following statements use a color gradient. The SAS autocall macro **Paint** is available for generating the CELLSTYLE colors list with a list of interpolated colors. If your site has installed the autocall libraries supplied by the SAS System and uses the standard configuration of software supplied by the SAS System, you need to ensure that the SAS System option MAUTOSOURCE is in effect before you begin using autocall macros. The macros do not have to be included (for example, with a %INCLUDE statement). They can be called directly once they are properly installed. For more information about autocall libraries, see *SAS Macro Language: Reference*.

Usually, you can use the **Paint** macro by specifying a list of values and a list of colors. Here is an example for values that range from 0 to 10:

```
%paint(values=0 to 10 by 0.5,
       colors=white cyan blue magenta red)

proc print data=colors;
run;
```

The **Paint** macro prints the following information to the SAS log:

```
Legend:
       0 = White
     2.5 = Cyan
       5 = Blue
     7.5 = Magenta
      10 = Red
```

A value of 0 maps to white, a value of 2.5 maps to cyan, values in the range 0 to 2.5 map to colors in the range from white to cyan, and so on. The **Paint** macro for this step creates an output data set, Colors, which is shown in Output 20.10.2.

Output 20.10.2 Color Interpolation

Rating of Automobiles

Obs	Start	_RGB_
1	0.0	CXFFFFFF
2	0.5	CXCBFFFF
3	1.0	CX97FFFF
4	1.5	CX63FFFF
5	2.0	CX2FFFFF
6	2.5	CX05FFFF
7	3.0	CX00D1FF
8	3.5	CX009CFF
9	4.0	CX0068FF
10	4.5	CX0034FF
11	5.0	CX0000FF
12	5.5	CX3400FF
13	6.0	CX6800FF
14	6.5	CX9C00FF
15	7.0	CXD100FF
16	7.5	CXFA00FF
17	8.0	CXFF00D1
18	8.5	CXFF009C
19	9.0	CXFF0068
20	9.5	CXFF0034
21	10.0	CXFF0000

This shows the color interpolation for a series of points. You could use a smaller BY value in the **Paint** macro to get more points along the color gradient. However, a few dozen colors are usually sufficient for most purposes.

The following steps use the **Paint** macro to create a color gradient for a correlation matrix, edit the template, display the results, and restore the default template:

```
%paint(values=-1 to 1 by 0.05, macro=setstyle,
       colors=CXEEEEEE red magenta blue cyan white
              cyan blue magenta red CXEEEEEE
              -1 -0.99 -0.75 -0.5 -0.25 0 0.25 0.5 0.75 0.99 1)
```

```
proc template;
   edit Base.Corr.StackedMatrix;
      column (RowName RowLabel) (Matrix) * (Matrix2);
      edit matrix;
         %setstyle(backgroundcolor)
      end;
   end;
run;

ods _all_ close;
ods html body='corr.html' style=HTMLBlue;
proc corr data=cars noprob;
   ods select PearsonCorr;
run;
ods html close;
ods listing;

proc template;
   delete Base.Corr.StackedMatrix;
run;
```

The VALUES= option creates a range of values from –1 to 1 with an increment of 0.05. The **Paint** macro generates a CELLSTYLE **_val_ <=** *value* **as {backgroundcolor=** *color***},** line for each value in the list. Specifically, it generates a macro named SETSTYLE (from the MACRO= option) that contains the entire CELLSTYLE statement for use in PROC TEMPLATE. The argument to the macro is the option that you want to set. In this case, it is the background color. You could specify **foreground** instead to set the color of the numbers themselves. The first part of the generated statement is as follows:

```
cellstyle _val_<=-1 as {backgroundcolor=CXEFEEEE},
          _val_<=-0.95 as {backgroundcolor=CXFF0020},
          _val_<=-0.9 as {backgroundcolor=CXFF0062},
          _val_<=-0.85 as {backgroundcolor=CXFF008D},
          _val_<=-0.8 as {backgroundcolor=CXFF00CF},
```

The color mapping for a correlation matrix can be a bit more involved than it is for most tables. This is because you might want the maximum correlations, 1 and –1, to be displayed using colors outside the gradient that is used for other values. Usually, you specify the color list, and the **Paint** macro maps the first color to the minimum value, the last color to the maximum value, and colors in between using equal increments and values based on the minimum and maximum. Alternatively, you can provide these values, as shown in this example. The legend, displayed in the SAS log, is as follows for the **Paint** macro step:

```
Legend:
      -1 = CXEEEEEE
   -0.99 = Red
   -0.75 = Magenta
    -0.5 = Blue
   -0.25 = Cyan
       0 = White
    0.25 = Cyan
     0.5 = Blue
    0.75 = Magenta
    0.99 = Red
       1 = CXEEEEEE
```

Values in the range –0.99 to 0.99 follow the interpolation red to magenta to blue to cyan to white to cyan to blue to magenta to red. Of course, the actual correlations for these data do not span this entire range, so a pure red background does not appear in the matrix. Correlations of 1 and –1 are displayed as light gray. The resulting correlation matrix is displayed in Output 20.10.3. Notice that there are now a number of shades of colors, particularly shades of blues, not just a few discrete colors. The largest values are displayed in shades of purple and magenta.

Output 20.10.3 Correlation Matrix from PROC CORR with a Color Gradient

Rating of Automobiles

The CORR Procedure

Pearson Correlation Coefficients, N = 50

Next, the same technique is used to display the covariance and correlation matrices of a heteroscedastic autoregressive model. The data are based on the famous growth measurement data of Pothoff and Roy (1964), but are modified here to illustrate the technique of painting the entries of a matrix. The data consist of four repeated growth measurements of 11 girls and 16 boys. The measurements from two adjacent children in the original data were combined and rearranged here to emulate a repeated measures sequence with eight observations. The following statements create the data set:

```
title 'Analysis of Repeated Growth Measures';

data pr;
   input Person Gender $ y1 y2 y3 y4 y5 y6 y7 y8;
   array y{8};
   do time=5,7,8,4,3,2,1;
      Response = y{time};
      Age      = time+7;
      output;
   end;
   datalines;

;
```

The following statements create a macro that sets colors for the covariance matrix (SETSTYLE1), create a macro that sets colors for the correlation matrix (SETSTYLE2), edit the templates, run the analysis with PROC GLIMMIX, and restore the default templates:

```
* You need to run the analysis once to know that 20 is a good maximum;
%paint(values=0 to 20 by 0.25,
       colors=cyan blue magenta red, macro=setstyle1)

%paint(values=0 to 1 by 0.05,
       colors=cyan blue magenta red, macro=setstyle2)

proc template;
   edit Stat.Glimmix.V;
      column Subject Index Row Col;
      edit Col;
         %setstyle1(backgroundcolor)
      end;
   end;
   edit Stat.Glimmix.VCorr;
      column Subject Index Row Col;
      edit Col;
         %setstyle2(backgroundcolor)
      end;
   end;
run;

ods _all_ close;
ods html body='ar1.html' style=HTMLBlue;
proc glimmix data=pr;
   class person gender time;
   model response = gender age gender*age;
   random _residual_ / sub=person type=arh(1) v residual vcorr;
   ods select v vcorr;
run;
ods html close;
ods listing;

proc template;
   delete Stat.Glimmix.V;
   delete Stat.Glimmix.VCorr;
run;
```

The results are displayed in Output 20.10.4 and Output 20.10.5. Both the covariance and correlation matrices have a structure that is more obvious when colors are added to the display. In particular, the colors clearly show the banded structure of the correlation matrix.

Output 20.10.4 Heteroscedastic AR(1) Covariance Matrix

Analysis of Repeated Growth Measures

The GLIMMIX Procedure

Estimated V Matrix for Person 1

4	4.5756	5.1220	7.2885	9.2159	5.0318	2.9836	1.9530
5	2.4983	2.7966	3.9795	5.0318	5.5959	3.3181	2.1720
6	1.4814	1.6582	2.3596	2.9836	3.3181	4.0075	2.6232
7	0.9697	1.0855	1.5446	1.9530	2.1720	2.6232	3.4976

Output 20.10.5 Heteroscedastic AR(1) Correlation Matrix

Estimated V Correlation Matrix for Person 1

Row	Col1	Col2	Col3	Col4	Col5	Col6	Col7
1	1.0000	0.7007	0.4910	0.3440	0.2410	0.1689	0.1183
2	0.7007	1.0000	0.7007	0.4910	0.3440	0.2410	0.1689
3	0.4910	0.7007	1.0000	0.7007	0.4910	0.3440	0.2410
4	0.3440	0.4910	0.7007	1.0000	0.7007	0.4910	0.3440
5	0.2410	0.3440	0.4910	0.7007	1.0000	0.7007	0.4910
6	0.1689	0.2410	0.3440	0.4910	0.7007	1.0000	0.7007
7	0.1183	0.1689	0.2410	0.3440	0.4910	0.7007	1.0000

Alternatively, you could just use the **Paint** macro to do the color interpolation and use its output data set to create other types of style effects. The following statements show one way to set the font to bold and set the foreground color based on the values of the covariances:

```
%let inc = 0.25;

%paint(values=0 to 20 by &inc, colors=blue magenta red)

data cntlin;
   set colors;
   fmtname = 'paintfmt';
   label = _rgb_;
   end = start + &inc;
   keep start end label fmtname;
run;
```

```
proc format cntlin=cntlin;
run;

proc template;
   edit Stat.Glimmix.V;
      column Subject Index Row Col;
      edit Col;
         style = {foreground=paintfmt8. font_weight=bold};
      end;
   end;
run;

ods _all_ close;
ods html body='ar1.html' style=HTMLBlue;
proc glimmix data=pr;
   class person gender time;
   model response = gender age gender*age;
   random _residual_ / sub=person type=arh(1) v residual;
   ods select v;
run;
ods html close;
ods listing;

proc template;
   delete Stat.Glimmix.V;
run;
```

The **Paint** macro creates the SAS data set Colors with the result of the interpolation. This data set can be processed to create a format. The DATA step creates a range of values from Start to End and assigns a color to Label based on the color computed by the **Paint** macro. This data set is input to PROC FORMAT to create the format PAINTFMT. PROC TEMPLATE uses this format to set the color of the values in the table. The cell value is evaluated using the specified FOREGROUND= format for every cell in the table, and the appropriate color is assigned. PROC GLIMMIX does the analysis, and the results are displayed in Output 20.10.6.

Output 20.10.6 Heteroscedastic AR(1) Covariance Matrix

Analysis of Repeated Growth Measures

The GLIMMIX Procedure

Estimated V Matrix for Person 1

Row	Col1	Col2	Col3	Col4	Col5	Col6	Col7
1	19.1973	10.5505	7.3707	4.5756	2.4983	1.4814	0.9697
2	10.5505	11.8104	8.2508	5.1220	2.7966	1.6582	1.0855
3	7.3707	8.2508	11.7407	7.2885	3.9795	2.3596	1.5446
4	4.5756	5.1220	7.2885	9.2159	5.0318	2.9836	1.9530
5	2.4983	2.7966	3.9795	5.0318	5.5959	3.3181	2.1720
6	1.4814	1.6582	2.3596	2.9836	3.3181	4.0075	2.6232
7	0.9697	1.0855	1.5446	1.9530	2.1720	2.6232	3.4976

Many other effects could be achieved by using this approach and different options in the STYLE= specification.

Chapter 21

Statistical Graphics Using ODS

Contents

Introduction

Effective graphics are indispensable for modern statistical analysis. They reveal patterns, differences, and uncertainty that are not readily apparent in tabular output. Graphics provoke questions that stimulate deeper investigation, and they add visual clarity and rich content to reports and presentations.

In earlier SAS releases, creating graphs with statistical procedures typically required additional programming steps such as creating output data sets with the values to plot, modifying these data sets with a DATA step program, and using traditional SAS/GRAPH procedures to produce the plots.

ODS Graphics eliminates the need for additional programming. ODS Graphics is an extension of ODS (the Output Delivery System). ODS manages procedure output and lets you display it in a variety of destinations, such as HTML and RTF. With ODS Graphics, statistical procedures produce graphs as automatically as they produce tables, and graphs are integrated with tables in the ODS output. ODS Graphics is available in procedures in SAS/STAT, Base SAS, SAS/ETS, SAS/QC, and other products (see the section "Procedures That Support ODS Graphics" on page 621). Note that ODS Graphics is automatically provided with Base SAS software.

ODS Graphics might or might not be enabled by default depending on your operating system, whether you are in the SAS windowing environment, your registry, system options, and configuration file settings. For more information about default settings and enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612.

You can enable ODS Graphics with the following statement:

```
ods graphics on;
```

When ODS Graphics is enabled, procedures that support ODS Graphics create appropriate graphs, either by default or when you specify procedure options for requesting specific graphs. These options are documented in the "Syntax" section of each procedure chapter, and the "Details" section of each chapter provides an "ODS Graphics" subsection that lists the graphs that are available. Once ODS Graphics is enabled, it stays enabled for the duration of your SAS session unless you disable it.

You can disable ODS Graphics with the following statement:

```
ods graphics off;
```

You might consider disabling ODS Graphics if your goal is solely to produce computational results. Often though, you can enable ODS Graphics and then leave it enabled. Throughout this chapter, ODS Graphics is enabled only once per section.

Chapter Reading Guide

This chapter provides a basic introduction to ODS Graphics along with more detailed information. The following list provides a guide to reading this chapter:

- If you want to see a few of the many graphs that are produced by statistical procedures by using ODS Graphics, see the section "Getting Started with ODS Statistical Graphics" on page 594.
- If you are using ODS Graphics for the first time, read the section "A Primer on ODS Statistical Graphics" on page 611, which provides the minimum information that you need to get started.
- If you need to create plots of raw data or your own customized plots of statistical results, see the section "Statistical Graphics Procedures" on page 691, which describes SAS procedures that use ODS Graphics.
- If you need information about specialized topics such as accessing your graphs, making changes to your graphs, and working with ODS styles, see the detailed discussions starting with the section "Syntax" on page 622 and including the section "Examples of ODS Statistical Graphics" on page 701.

If you are unfamiliar with ODS, see Chapter 20, "Using the Output Delivery System." For complete documentation about the Output Delivery System, see the *SAS Output Delivery System: User's Guide*. For an introduction to graph template modification, see Chapter 22, "ODS Graphics Template Modification." For an introduction to ODS Graphics, ODS styles, the graph template language, the style template language, the statistical graphics procedures, and graph template modification, see Kuhfeld (2010). For complete documentation about ODS graph templates, see the *SAS Graph Template Language: User's Guide* and the *SAS Graph Template Language: Reference*. For complete documentation about the ODS Graphics Editor, see the *SAS ODS Graphics Editor: User's Guide*. Also see the *SAS ODS Graphics: Procedures Guide* for information about the statistical graphics procedures.

Assumptions about ODS Defaults in This Chapter

Default settings such as destinations and whether or not ODS Graphics is enabled vary depending on your operating system, registry settings, configuration file settings, system options, and whether you are using the SAS windowing environment or batch mode. For this reason, this chapter makes no assumptions about these defaults. Instead, all destinations are often explicitly closed without assuming which destination (usually LISTING or HTML) is open, destinations are explicitly opened when needed, and ODS Graphics is explicitly enabled and disabled as needed. In some examples, when all destinations are closed, the LISTING destination is opened at the end of the step so that some destination is available for subsequent output. If you know the defaults for your environment, you do not need to use many of the ODS statements that are used in this chapter.

Getting Started with ODS Statistical Graphics

This section provides examples that illustrate the most basic uses of ODS Graphics with a few of the many plots that are produced by statistical procedures.

Default Plots for Simple Linear Regression with PROC REG

This example is based on the section "Getting Started: REG Procedure" on page 6342 of Chapter 76, "The REG Procedure." The Class data set used in this example is available in the Sashelp library. The following statements use PROC REG to fit a simple linear regression model in which Weight is the response variable and Height is the independent variable:

```
ods graphics on;

proc reg data=sashelp.class;
   model Weight = Height;
run; quit;
```

The ODS GRAPHICS ON statement requests ODS Graphics in addition to the usual tabular output. The statement ODS GRAPHICS OFF is not used here, but it can be specified to disable ODS Graphics.

The graphical output consists of a fit diagnostics panel, a residual plot, and a fit plot. These plots are integrated with the tabular output and are shown in Figure 21.1, Figure 21.2, and Figure 21.3, respectively. The results are displayed in the HTMLBLUE style.

Figure 21.1 Fit Diagnostics Panel

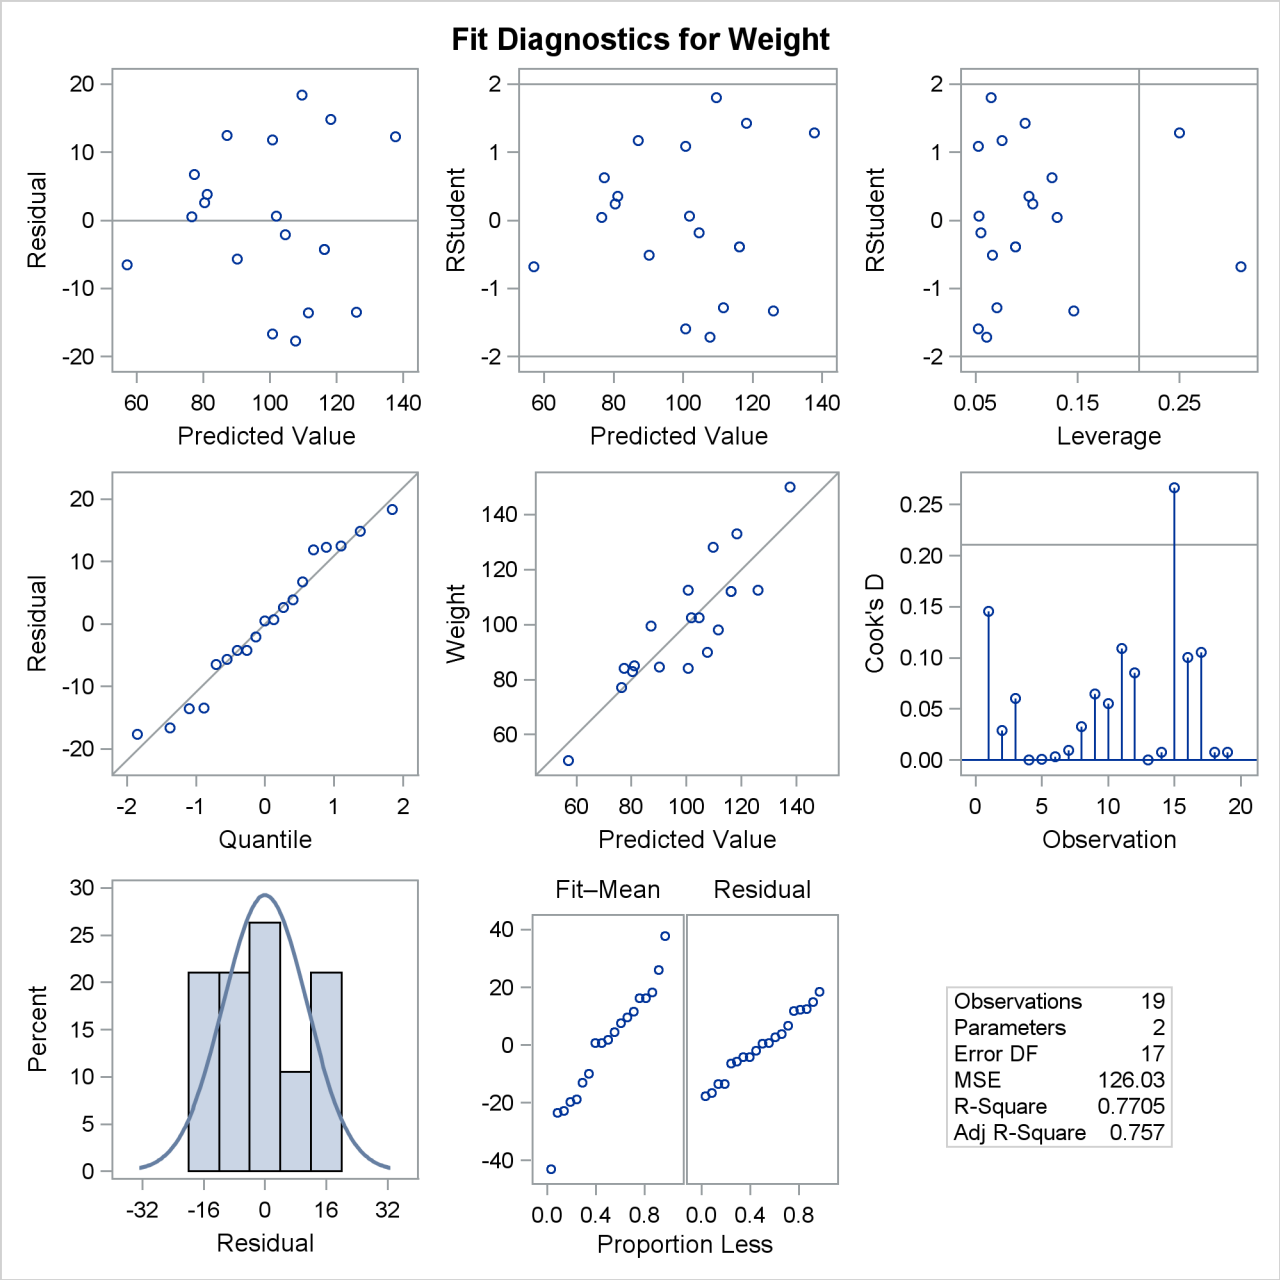

Figure 21.2 Residual Plot

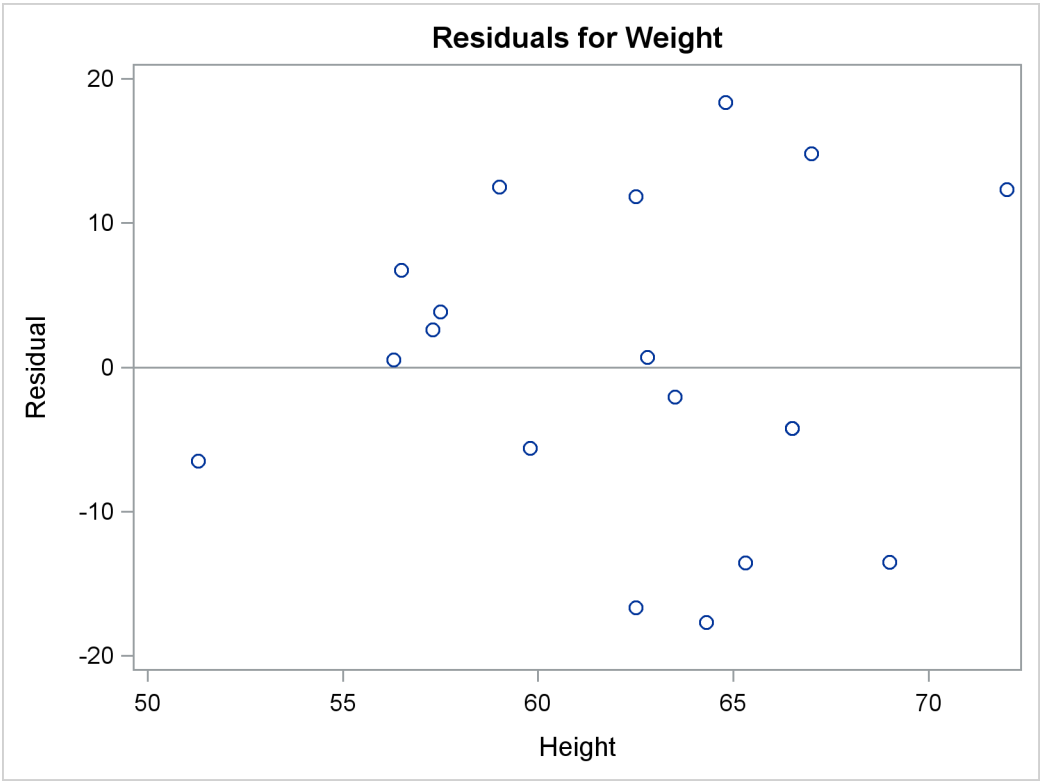

Figure 21.3 Fit Plot

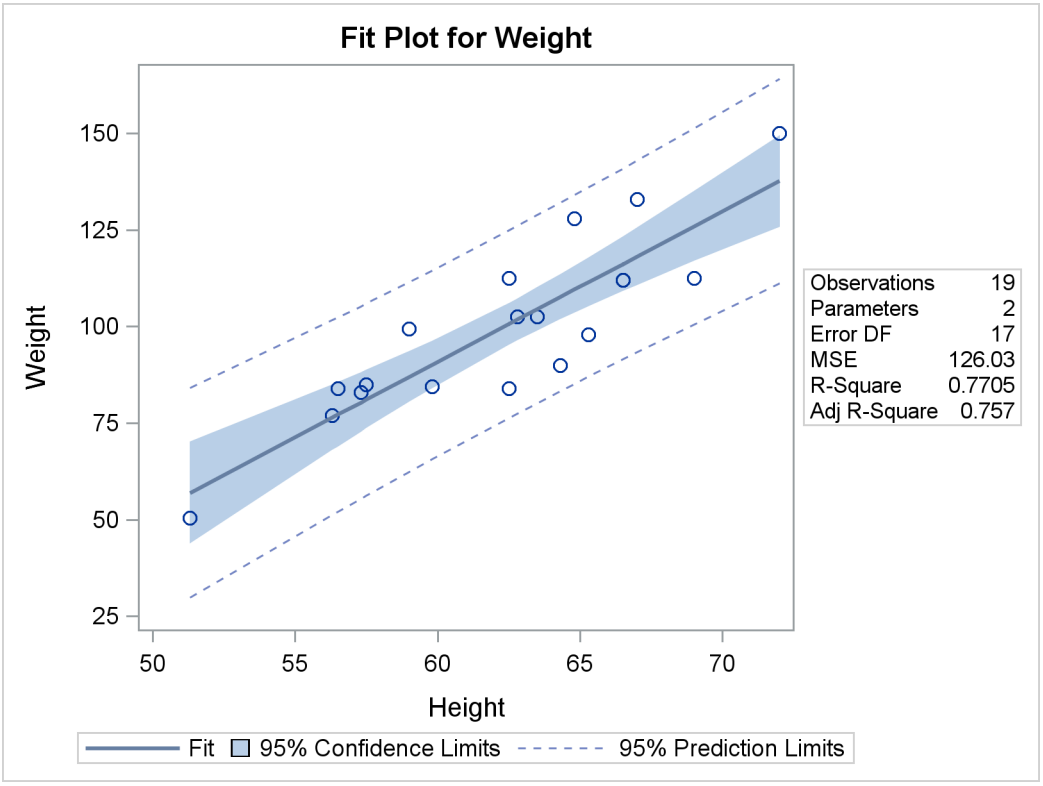


ODS styles control the colors and general appearance of all graphs and tables, and the SAS System provides several styles that are recommended for use with statistical graphics. The default style that you see when you run SAS depends on the ODS destination, system options, and SAS registry settings. For more information about styles, see the section "Graph Styles" on page 613 and the section "Styles" on page 648.

Survival Estimate Plot with PROC LIFETEST

This example is taken from Example 51.2 of Chapter 51, "The LIFETEST Procedure." It shows how to construct a product-limit survival estimate plot. Both the ODS GRAPHICS statement and procedure options are used to request the plot. This examples uses the bone marrow transplant data set, which is available from the Sashelp library. The data set contains disease-free times for three risk categories.

The following statements use PROC LIFETEST to compute the product-limit estimate of the survivor function for each risk category:

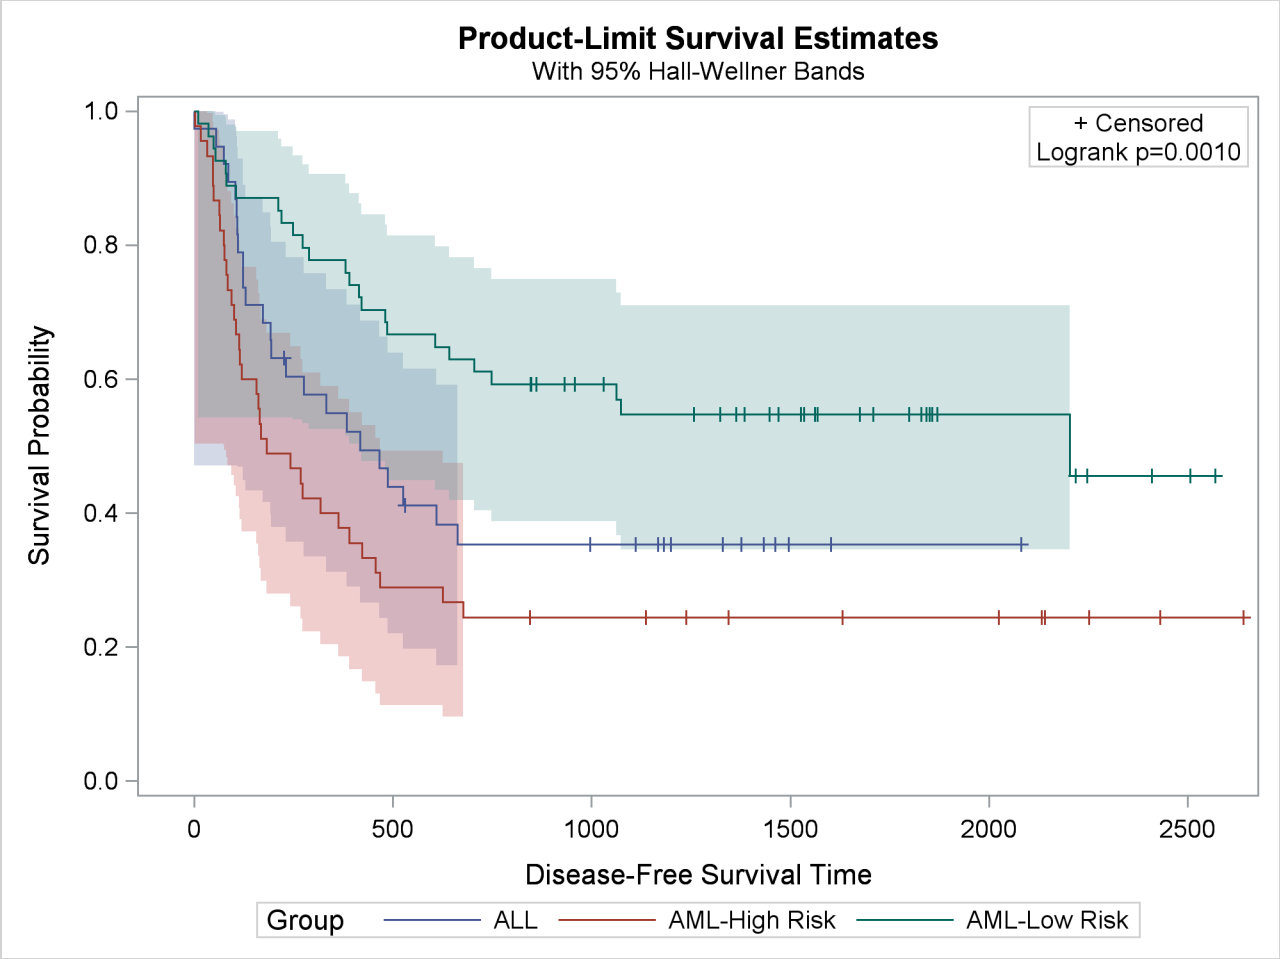
```
ods graphics on;

proc lifetest data=sashelp.BMT plots=survival(cb=hw test);
   time T * Status(0);
   strata Group / test=logrank;
run;
```

The ODS GRAPHICS ON statement enables ODS Graphics, and the PLOTS=SURVIVAL option requests a plot of the estimated survival curves. The CB=HW suboption requests Hall-Wellner confidence bands, and the TEST suboption displays the *p*-value for the log-rank test in a plot inset.

Figure 21.4 displays the plot; note that tabular output is not shown. Patients in the AML-Low Risk group are disease-free longer than those in the ALL group, who in turn fare better than those in the AML-High Risk group.

Figure 21.4 Survival Plot



Contour and Surface Plots with PROC KDE

This example is taken from the section "Getting Started: KDE Procedure" on page 3632 in Chapter 47, "The KDE Procedure." Here, in addition to the ODS GRAPHICS statement, procedure options are used to request plots. The following statements simulate 1,000 observations from a bivariate normal density with means (0,0), variances (10,10), and covariance 9:

```
data bivnormal;
   do i = 1 to 1000;
      z1 = rannor(104);
      z2 = rannor(104);
      z3 = rannor(104);
      x  = 3*z1+z2;
      y  = 3*z1+z3;
      output;
   end;
run;
```

The following statements request a bivariate kernel density estimate for the variables x and y:

```
ods graphics on;

proc kde data=bivnormal;
   bivar x y / plots=contour surface;
run;
```

The PLOTS= option requests a contour plot and a surface plot of the estimate (displayed in Figure 21.5 and Figure 21.6, respectively). For more information about the graphs available in PROC KDE, see the section "ODS Graphics" on page 3651 of Chapter 47, "The KDE Procedure."

Figure 21.5 Contour Plot of Estimated Density

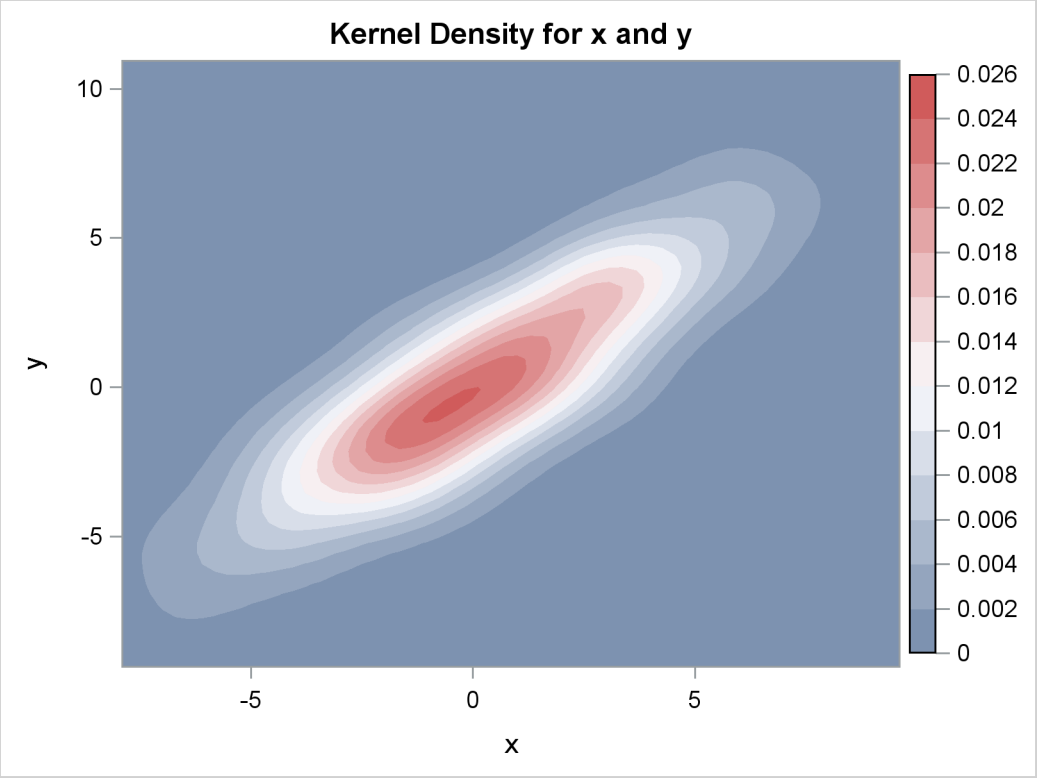


Figure 21.6 Surface Plot of Estimated Density

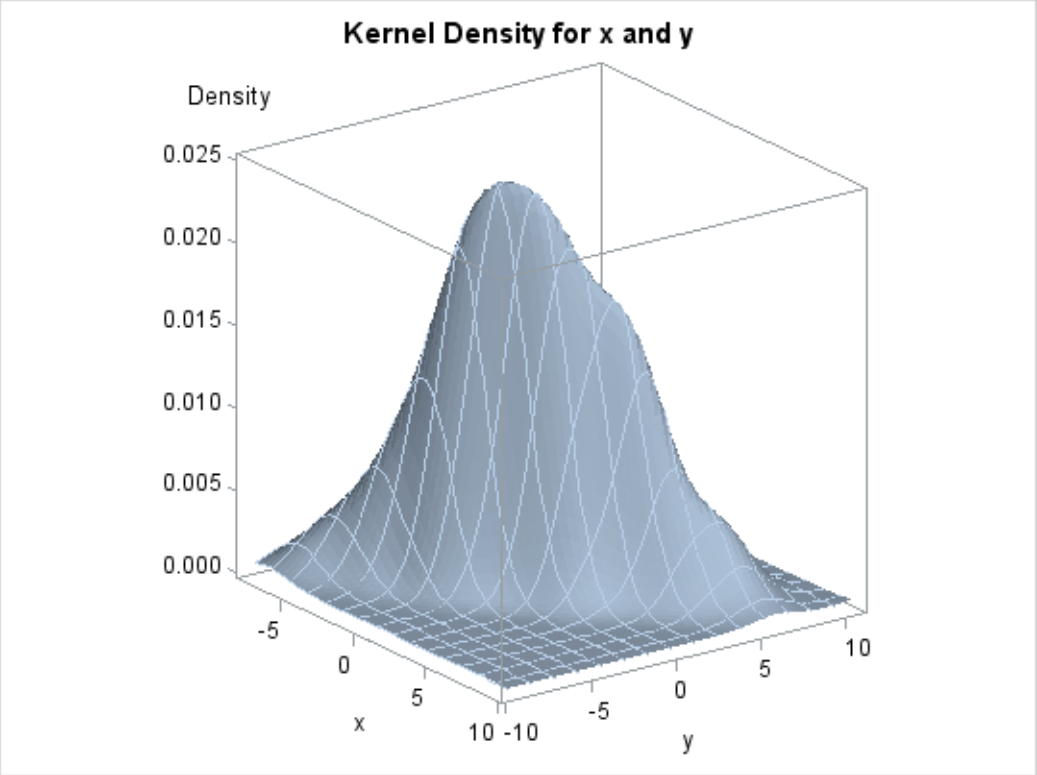

Contour Plots with PROC KRIGE2D

This example is taken from Example 48.2 of Chapter 48, "The KRIGE2D Procedure." The coal seam thickness data set is available from the Sashelp library. The following statements create a SAS data set that contains a copy of these data along with some artificially added missing data:

```
data thick;
   set sashelp.thick;
   if _n_ in (41, 42, 73) then thick = .;
run;
```

The following statements run PROC KRIGE2D:

```
ods graphics on;

proc krige2d data=thick outest=predictions
             plots=(observ(showmissing)
                    pred(fill=pred line=pred obs=linegrad)
                    pred(fill=se line=se obs=linegrad));
   coordinates xc=East yc=North;
   predict var=Thick r=60;
   model scale=7.2881 range=30.6239 form=gauss;
   grid x=0 to 100 by 2.5 y=0 to 100 by 2.5;
run;
```

The PLOTS=OBSERV(SHOWMISSING) option produces a scatter plot of the data along with the locations of any missing data. The PLOTS=PRED option produces maps of the kriging predictions and standard errors. Two instances of the PLOTS=PRED option are specified with suboptions that customize the plots. The results are shown in Figure 21.7.

Figure 21.7 Spatial Distribution

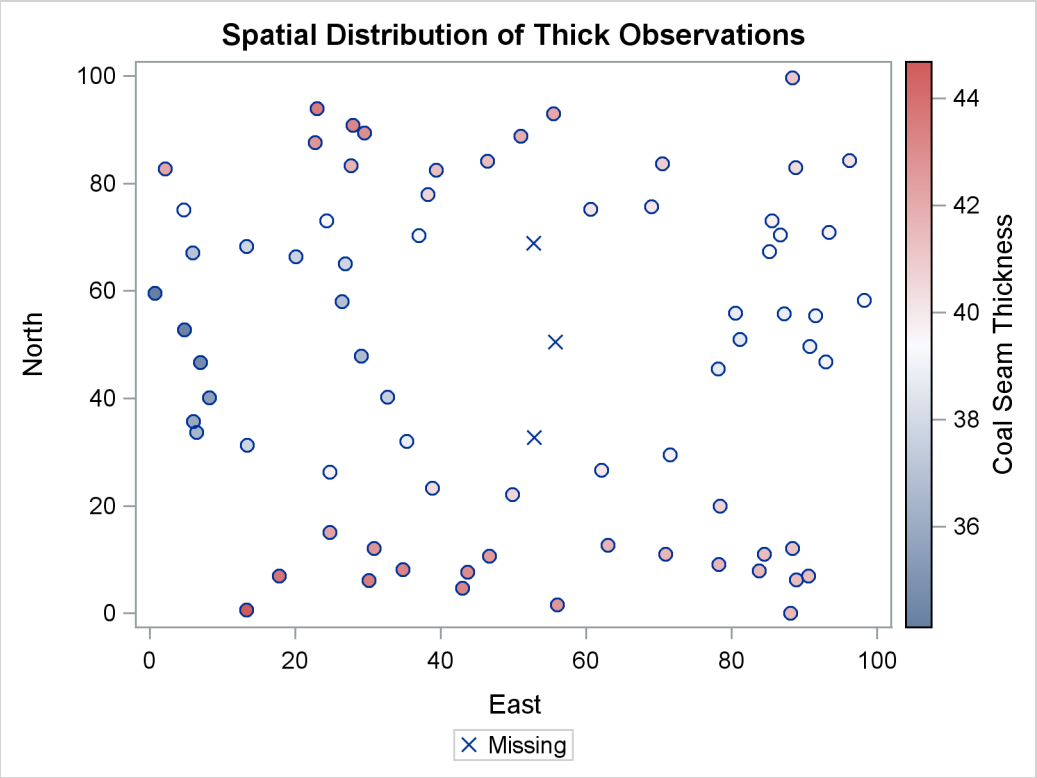

Figure 21.7 *continued*

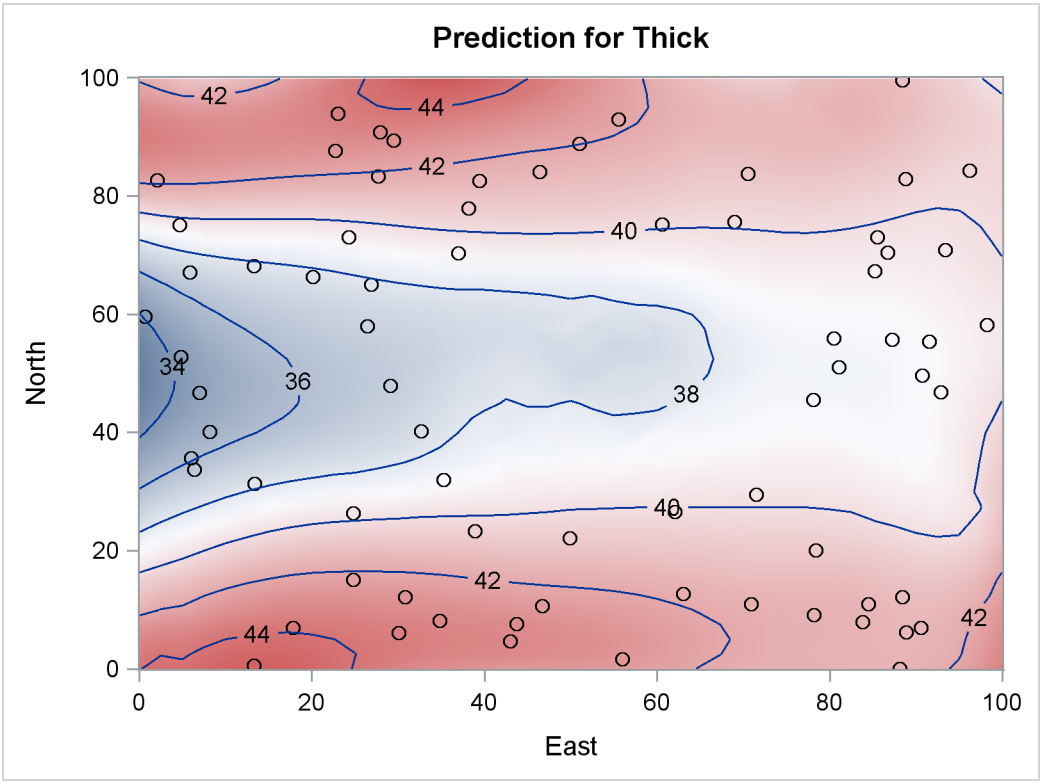
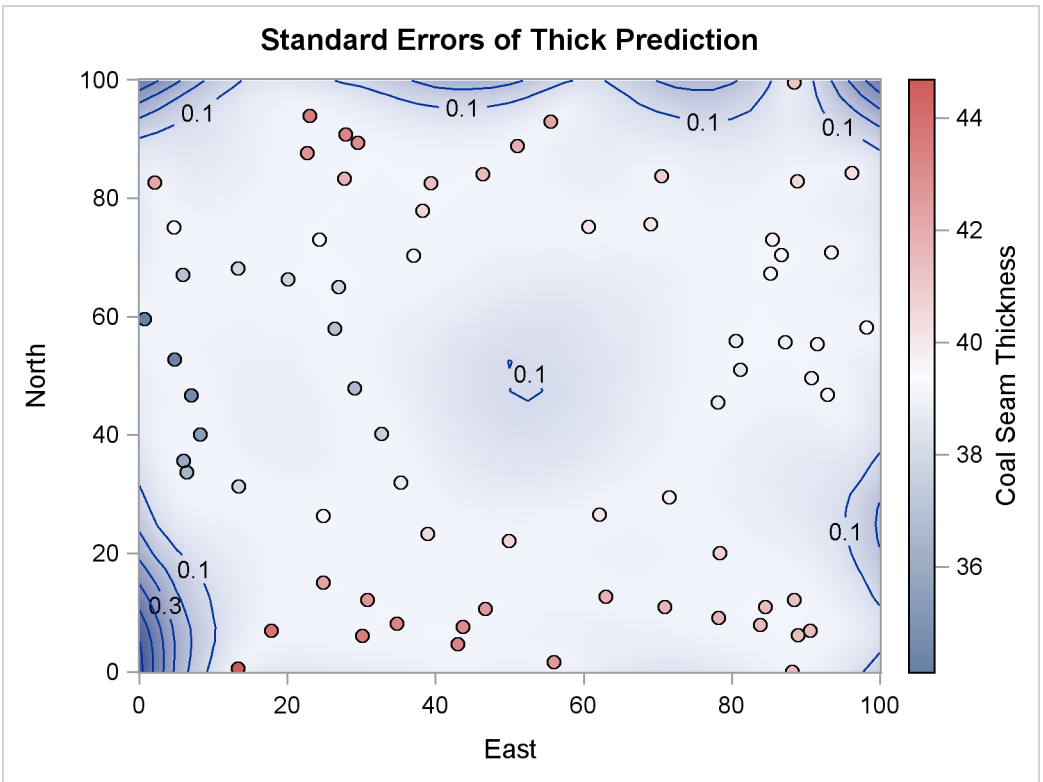




Partial Least Squares Plots with PROC PLS

This example is taken from the section "Getting Started: PLS Procedure" on page 5677 of Chapter 69, "The PLS Procedure." The following statements create a SAS data set that contains measurements of biological activity in the Baltic Sea:

```
data Sample;
   input obsnam $ v1-v27 ls ha dt @@;
   datalines;
EM1   2766 2610 3306 3630 3600 3438 3213 3051 2907 2844 2796
      2787 2760 2754 2670 2520 2310 2100 1917 1755 1602 1467
      1353 1260 1167 1101 1017         3.0110  0.0000   0.00

   ... more lines ...

;
```

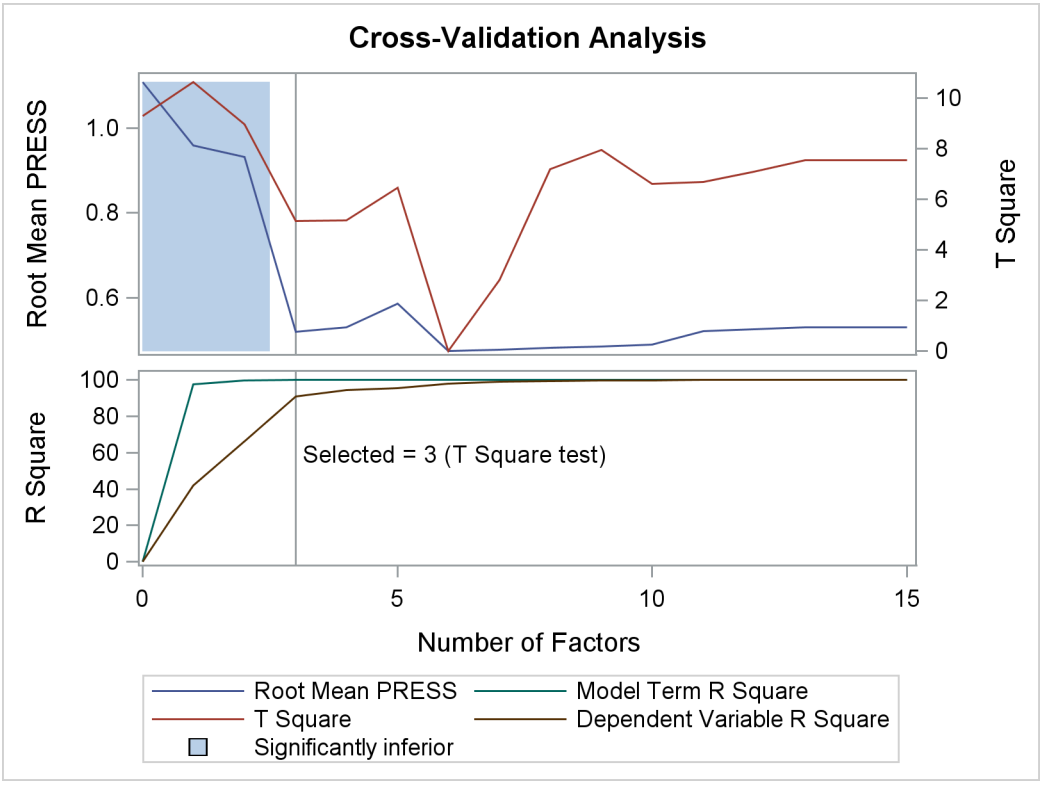
The following statements run PROC PLS:

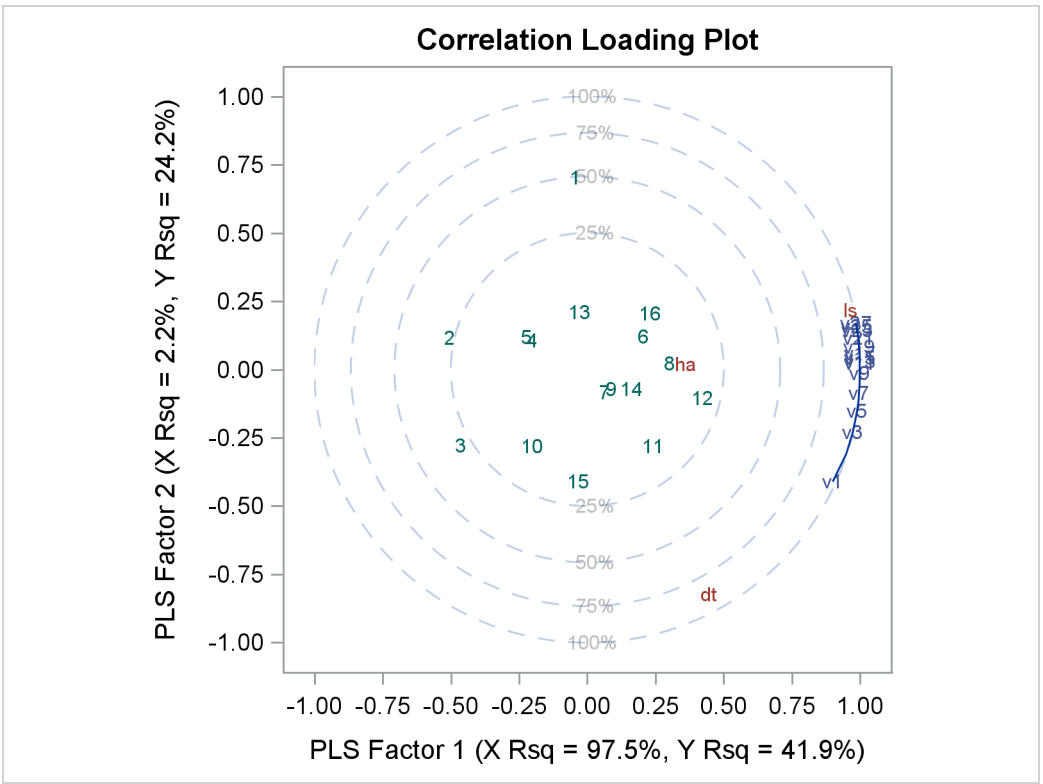
```
ods graphics on;

proc pls data=sample cv=split cvtest(seed=104);
   model ls ha dt = v1-v27;
run;
```

By default, the procedure produces a plot for the cross validation analysis and a correlation loading plot (see Figure 21.8).

Figure 21.8 Partial Least Squares





Box-Cox Transformation Plot with PROC TRANSREG

This example is taken from Example 93.2 of Chapter 93, "The TRANSREG Procedure." The following statements create a SAS data set that contains failure times for yarn:

```
proc format;
   value a -1 =   8 0 =   9 1 =  10;
   value l -1 = 250 0 = 300 1 = 350;
   value o -1 =  40 0 =  45 1 =  50;
run;

data yarn;
   input Fail Amplitude Length Load @@;
   format amplitude a. length l. load o.;
   label fail = 'Time in Cycles until Failure';
   datalines;
 674 -1 -1 -1    370 -1 -1  0    292 -1 -1  1    338  0 -1 -1

   ... more lines ...

;
```

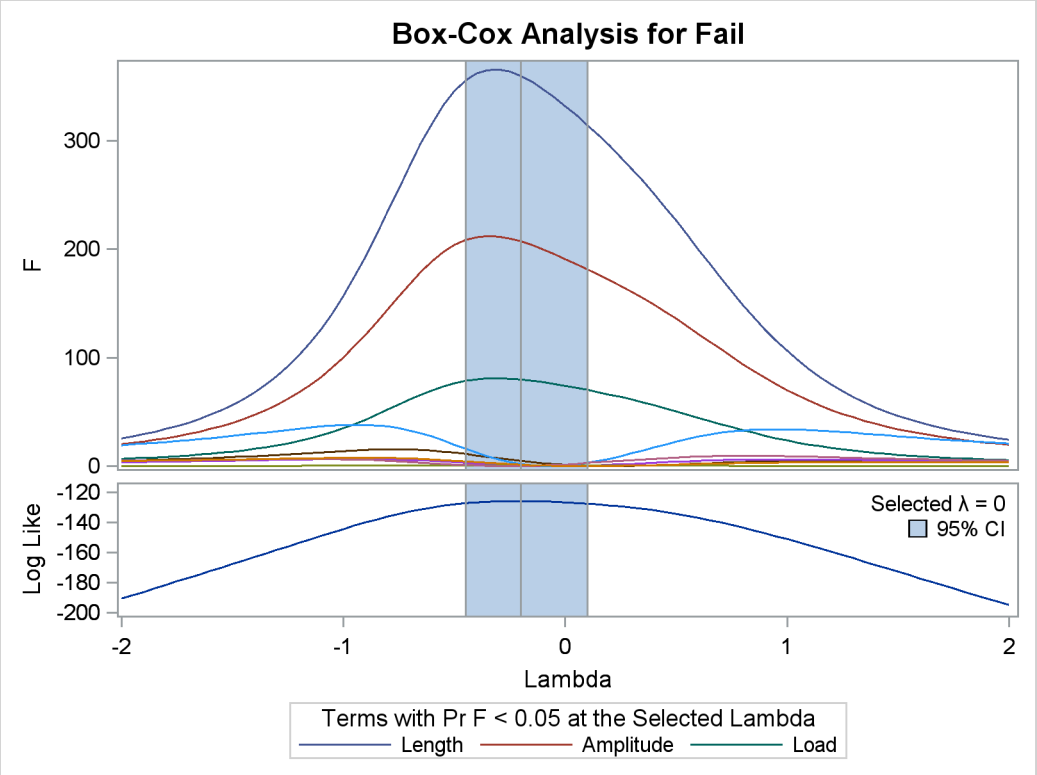
The following statements run PROC TRANSREG:

```
ods graphics on;

proc transreg data=yarn;
   model BoxCox(fail / convenient lambda=-2 to 2 by 0.05) =
         qpoint(length amplitude load);
run;
```

The log-likelihood plot in Figure 21.9 suggests a Box-Cox transformation with $\lambda = 0$.

Figure 21.9 Box-Cox "Significant Effects"



LS-Means Diffogram with PROC GLIMMIX

This example is taken from the section "Graphics for LS-Mean Comparisons" on page 3012 of Chapter 40, "The GLIMMIX Procedure." The following statements create a SAS data set that contains measurements from an experiment that investigates how snapdragons grow in various soils:

```
data plants;
   input Type $ @;
   do Block = 1 to 3;
      input StemLength @;
      output;
   end;
   datalines;
Clarion   32.7 32.3 31.5

   ... more lines ...

;
```

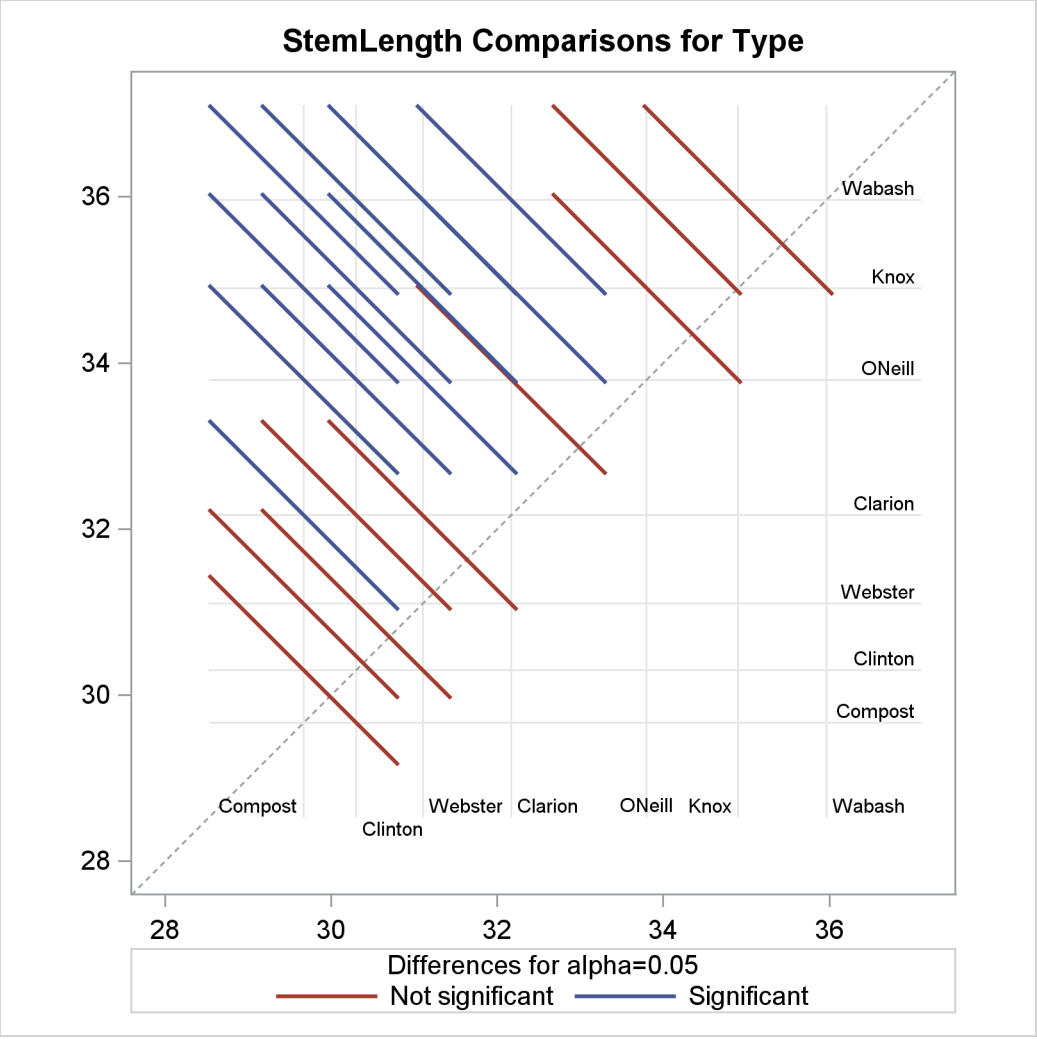
The following statements run PROC GLIMMIX:

```
ods graphics on;

proc glimmix data=plants order=data plots=diffogram;
   class Block Type;
   model StemLength = Block Type;
   lsmeans Type;
run;
```

The PLOTS=DIFFOGRAM option produces a diffogram, shown in Figure 21.10, that displays all of the pairwise least squares mean differences and indicates which are significant.

Figure 21.10 LS-Means Diffogram



Principal Component Analysis Plots with PROC PRINCOMP

This example is taken from Example 72.3 of Chapter 72, "The PRINCOMP Procedure." The following statements create a SAS data set that contains ratings of job performance of police officers:

```
options validvarname=any;

data Jobratings;
   input ('Communication Skills'n
          'Problem Solving'n
          'Learning Ability'n
          'Judgment Under Pressure'n
          'Observational Skills'n
          'Willingness to Confront Problems'n
          'Interest in People'n
          'Interpersonal Sensitivity'n
          'Desire for Self-Improvement'n
          'Appearance'n
          'Dependability'n
          'Physical Ability'n
          'Integrity'n
          'Overall Rating'n) (1.);
   datalines;
26838853879867

   ... more lines ...

;
```

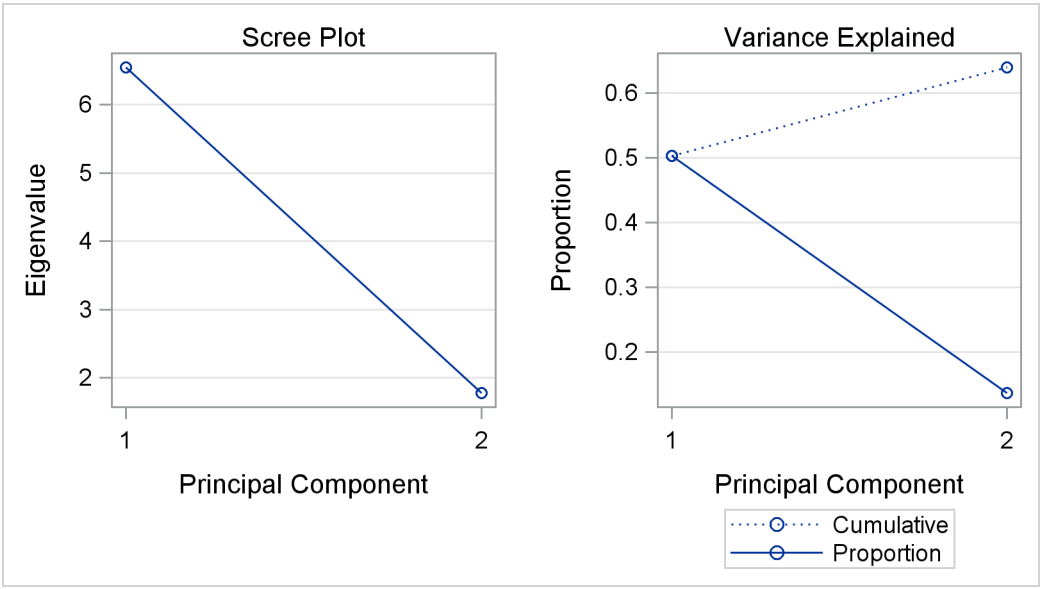
The following statements run PROC PRINCOMP:

```
ods graphics on;

proc princomp data=Jobratings(drop='Overall Rating'n) n=2
              plots=(Matrix PatternProfile);
run;
```

The plots are requested by the PLOTS=(MATRIX PATTERNPROFILE) option. The results, shown in Figure 21.11, contain the default scree and variance-explained plots, along with a scatter plot matrix of component scores and a pattern profile plot.

Figure 21.11 Principal Component Analysis



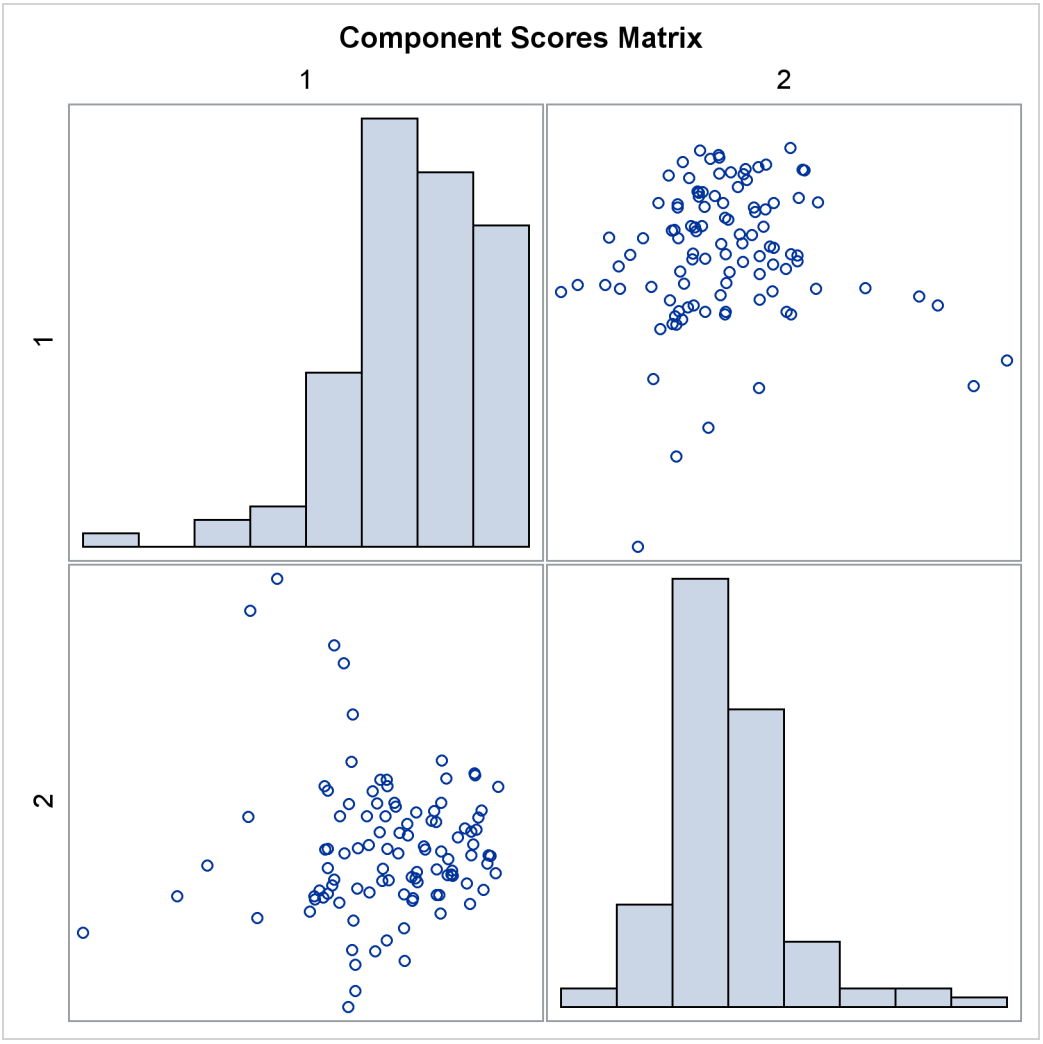


Figure 21.11 *continued*

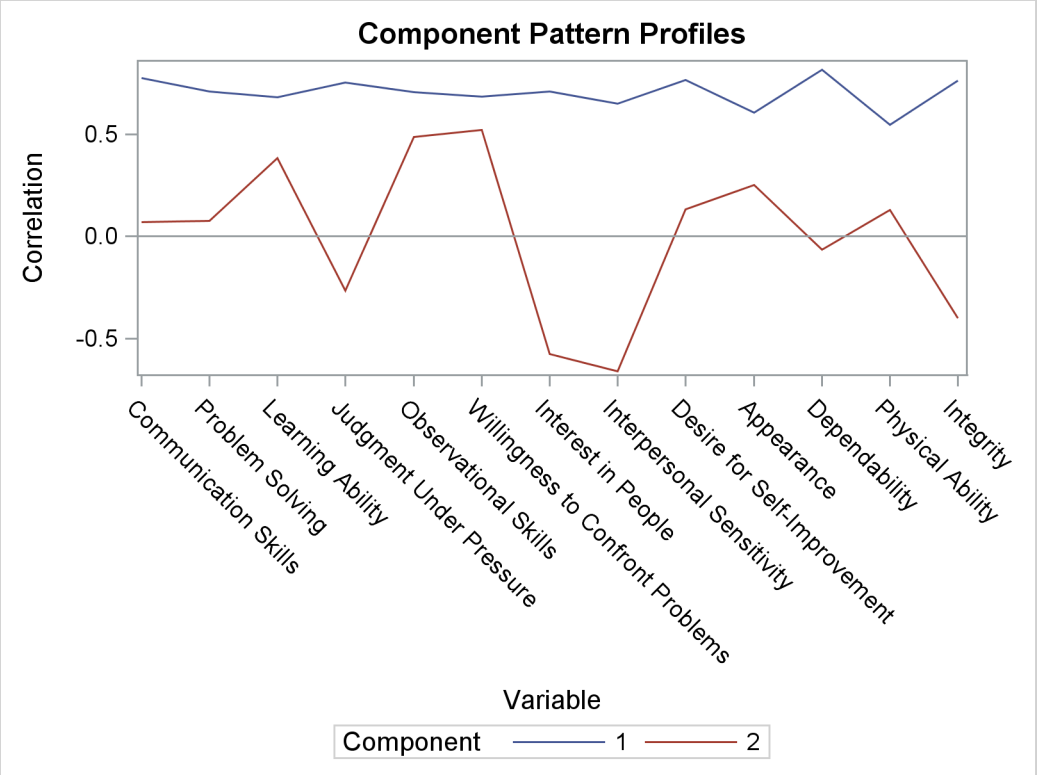


Grouped Scatter Plot with PROC SGPLOT

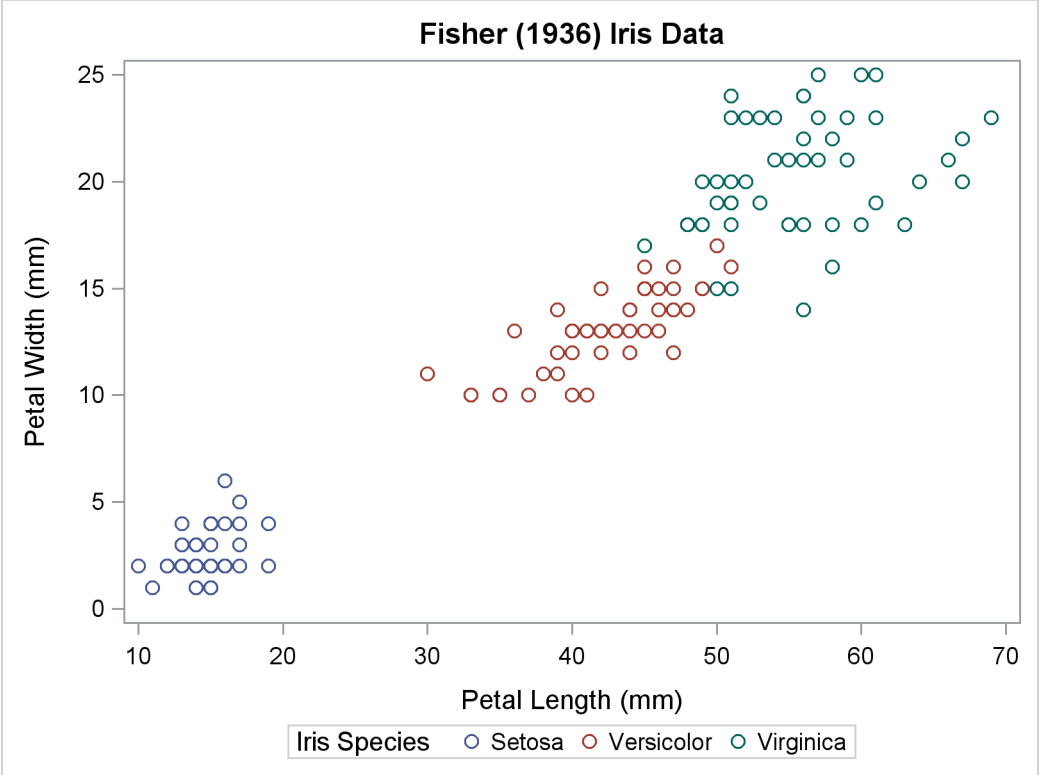
This example is taken from Example 32.1 of Chapter 32, "The DISCRIM Procedure." It uses the Fisher iris data set, which is available from the Sashelp library.

The following statements run PROC SGPLOT to make a scatter plot, grouped by iris species:

```
proc sgplot data=sashelp.iris;
   title 'Fisher (1936) Iris Data';
   scatter x=petallength y=petalwidth / group=species;
run;
```

The results are shown in Figure 21.12.

Figure 21.12 Iris Data



See the section "Statistical Graphics Procedures" on page 691 and the *SAS ODS Graphics: Procedures Guide* for more information about PROC SGPLOT (statistical graphics plot) and other SG procedures. You do not need to enable ODS Graphics in order to use SG procedures (because making plots with ODS Graphics is their sole function).

A Primer on ODS Statistical Graphics

You can enable ODS Graphics by specifying the following statement:

```
ods graphics on;
```

ODS Graphics remains enabled for all procedure steps until you disable it with the following statement:

```
ods graphics off;
```

Once ODS Graphics is enabled, creating graphical output with procedures is as simple as creating tabular output. For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612. See the section "Syntax" on page 622 for details about the more commonly used ODS GRAPHICS statement options.

You can control your output in the following ways:

- ODS destination statements (such as ODS HTML or ODS RTF) specify where you want your graphs displayed. See Figure 21.20 for an example of HTML output. See the section "ODS Destination Statements" on page 625 for a list of the supported destinations. See the section "Syntax" on page 622 for details about the more commonly used ODS destination statement options.
- ODS SELECT and ODS EXCLUDE statements select and exclude graphs from your output. See the section "Selecting and Excluding Graphs" on page 633 for an example of how to select graphs.
- ODS OUTPUT statements create SAS data sets from the data object used to make the plot. See the section "Specifying an ODS Destination for Graphics" on page 628 for an example.
- Procedure options specify which graphs to create. For each procedure, these options are described in the "Syntax" section of the procedure chapter. Typically, you use the PLOTS= option to control all graphs. The available graphs are listed in the "ODS Graphics" section, which is found in the "Details" section of each procedure chapter. Many graphs are produced by default.
- ODS styles control the general appearance and consistency of all graphs and tables. See the sections "Graph Styles" on page 613 and "Styles" on page 648 for more information about styles.
- ODS templates modify the layout and details of each graph. See the section "Graph Templates" on page 716 in Chapter 22, "ODS Graphics Template Modification," for more information about templates.

  NOTE: A default template is provided by SAS for each graph, so you do not need to know anything about templates to create statistical graphics.

You can also access individual graphs, control the resolution and size of graphs, and modify your graphs (as explained in the sections beginning with "Selecting and Viewing Graphs" on page 628). Alternatively, you can use special statistical graphics procedures to create custom graphs directly (see the section "Statistical Graphics Procedures" on page 691).

Enabling and Disabling ODS Graphics

You can enable ODS Graphics by specifying the following statement:

```
ods graphics on;
```

ODS Graphics remains enabled for all procedure steps until you disable it with the following statement:

```
ods graphics off;
```

ODS Graphics might or might not be enabled by default. This depends on a number of factors. ODS Graphics is typically enabled by default in the SAS windowing environment; ODS Graphics is typically disabled by default when you invoke SAS in other ways. However, these defaults can be changed in a number of ways. You can enable or disable ODS Graphics by default in an *autoexec.sas* file, a configuration file such as *SASV9.CFG*, or in the SAS registry. You can change the default in the SAS windowing environment by

selecting **Tools ► Options ► Preferences** from the menu at the top of the main SAS window. Then on the **Results** tab, select the **Use ODS Graphics** check box to enable ODS Graphics by default or clear the check box to disable ODS Graphics by default. You can also change the default output destination (HTML or LISTING) on the **Results** tab. See the section "HTML Output in the SAS Windowing Environment" on page 526 for more information about default ODS Graphics settings and default destinations.

When ODS Graphics is enabled, procedures that support ODS Graphics create graphs, either by default or when you specify procedure options for requesting specific graphs. Often, you can leave ODS Graphics enabled for the duration of your SAS session. However, you might consider disabling ODS Graphics if your goal is solely to produce computational results, particularly for large data sets or with many BY groups.

Graph Styles

ODS styles control the overall appearance of graphs and tables. They specify colors, fonts, line styles, symbol markers, and other attributes of graph elements. The following styles (among the many ODS styles) are recommended for statistical work:

- The HTMLBLUE style is a color style that is recommended for use in Web pages or color print media. See Figure 21.20 for an example. The HTMLBLUE style inherits most of its attributes from the STATISTICAL style, which inherits from the DEFAULT style. The HTMLBLUE style has a brighter appearance than its parents with color coordination between the tables and graphs. The dominant color is blue.

  The HTMLBLUE style is one of the default styles for the HTML destination (depending on SAS option and registry settings). It is also the default style in SAS/STAT documentation. It is an all-color style; groups of observations are distinguished by color instead of by line style or symbol changes.[1] Most other styles simultaneously vary colors, line styles, and marker symbols to show group membership. Output created with the HTMLBLUE style does not print well on black-and-white devices. If you need an alternative to the HTMLBLUE style that varies colors, lines, and markers, use the HTMLBLUECML style or some other style.

- The HTMLBLUECML style is a color style that is recommended for use in Web pages or color print media. It inherits most of its attributes from the HTMLBLUE style. See Figure 21.21 for an example. Groups of observations are distinguished by simultaneous color, line style, and symbol changes. If you need an alternative to the HTMLBLUECML style that is all-color, use the HTMLBLUE style instead.

- The DEFAULT style is a color style. See Figure 21.19 for an example. Most other styles inherit some of their elements from this style. The DEFAULT style is one of the default styles for the HTML destination (depending on SAS registry and option settings). Groups of observations are distinguished by simultaneous color, line style, and symbol changes. Output created with the DEFAULT style might not print well on black-and-white devices.

- The STATISTICAL style is a color style. See Figure 21.22 for an example. Output created with the STATISTICAL style might not print well on black-and-white devices. Groups of observations

[1] More precisely, the HTMLBLUE style is an all-color style for the first 12 groups of observations, which are more than are shown in most analyses. Markers and lines change for groups 13–24 and then again for groups 25–36. Figure 21.36 shows how colors, markers, and line styles change in the HTMLBLUE style, and Figure 21.35 shows how these change in most other styles.

are distinguished by simultaneous color, line style, and symbol changes. The STATISTICAL style inherits elements from the DEFAULT style.

- The ANALYSIS style is a color style with a somewhat different appearance from the STATISTICAL style. See Figure 21.23 for an example. Groups of observations are distinguished by simultaneous color, line style, and symbol changes. The ANALYSIS style inherits elements from the DEFAULT style. Output created with the ANALYSIS style might not print well on black-and-white devices.
- The JOURNAL family of styles (JOURNAL, JOURNAL2, and JOURNAL3) consists of black-and-white or gray-scale styles that are recommended for graphs that appear in journals and in other black-and-white publications. See Figure 21.24 for an example of the JOURNAL style, see Figure 21.9 for an example of the JOURNAL2 style, and see Example 21.3 for a comparison of the three styles.
- The RTF style is used to produce graphs to insert into a Microsoft Word document or a Microsoft PowerPoint slide. See Figure 21.26 for an example of the RTF style, which is the default style for the RTF destination. Groups of observations are distinguished by simultaneous color, line style, and symbol changes. The RTF style inherits elements from the DEFAULT style. Output created with the RTF style might not print well on black-and-white devices.
- The LISTING style is similar to the DEFAULT style, but with a lighter background. See Figure 21.25 for an example. It is the default style for the LISTING destination. Groups of observations are distinguished by simultaneous color, line style, and symbol changes. The LISTING style inherits elements from the DEFAULT style. Output created with the LISTING style might not print well on black-and-white devices.

You specify a style with the STYLE= option in the ODS destination statement. For example, the following statement requests RTF output produced with the JOURNAL style:

```
ods rtf style=Journal;
```

The following statement sets the style for the LISTING destination:

```
ods listing style=HTMLBlue;
```

The style specified with the STYLE= option in the ODS LISTING statement applies only to graphs. SAS monospace format is used for tables.

Most color styles (except the HTMLBLUE style) are compromise styles in the sense that some graph elements are intentionally over-distinguished to facilitate black-and-white printing. For example, fit lines that correspond to different classification levels are distinguished by both colors and line patterns. You can use the HTMLBLUE style when you want groups to be distinguished only by color. You can easily modify any style to be an all-color style like HTMLBLUE. For example:

```
proc template;
   define style styles.Default2;
      parent = default;
      style Graph from Graph / attrpriority = "Color";
      end;
   run;
```

The **AttrPriority = "Color"** option makes a style an all-color style.

You can instead use the %MODSTYLE SAS autocall macro (see the sections "Creating an All-Color Style" on page 678 and "Style Template Modification Macro" on page 676) to modify some other style so that it relies only on color for distinguishability. More generally, you can modify the colors, fonts, and other attributes of graph elements in a style by editing the style template. More information is provided in the section "Styles" on page 648, and detailed information is in the *SAS Output Delivery System: User's Guide*.

ODS Destinations

ODS can send your graphs and tables to a number of different destinations including RTF (rich text format), HTML (hypertext markup language), LISTING (the SAS LISTING destination), DOCUMENT (the ODS document), and PDF (portable document format). You use an ODS statement to open a destination, as in the following examples:

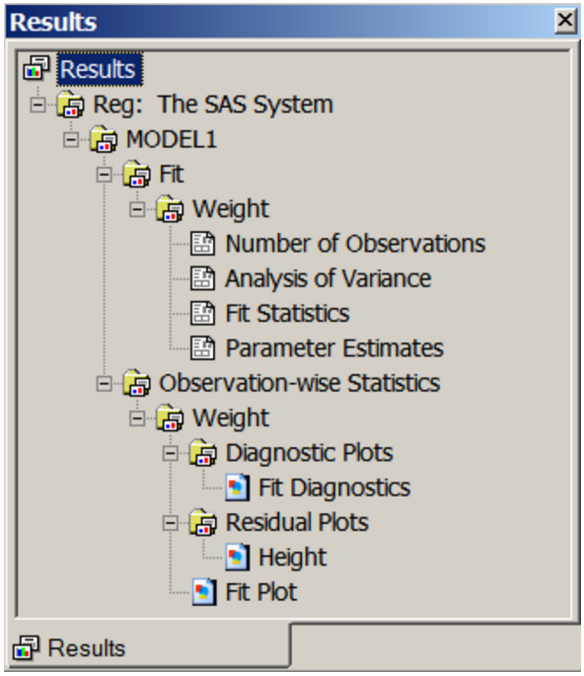
```
ods html body='b.htm';
ods rtf;
ods listing;
ods document name=MyDoc(write);
ods pdf file="contour.pdf";
```

You can close destinations individually or all at once, as in the following examples:

```
ods html close;
ods rtf close;
ods listing close;
ods document close;
ods pdf close;
ods _all_ close;
```

For most ODS destinations (for example, HTML, RTF, and PDF), graphs and tables are integrated in the output, and you view your output with an appropriate viewer, such as a web browser for HTML. However, the LISTING destination is different. If you are using the LISTING destination in the SAS windowing environment, you view your graphs individually by clicking the graph icons in the Results window, shown in Figure 21.13. This action invokes a host-dependent graph viewer (for example, Microsoft Photo Editor on Windows). The graphs produced with ODS Graphics are *not* displayed with traditional graphs in the Graph window.

Figure 21.13 SAS Results Window



If you are using the SAS windowing environment and you prefer to view integrated output, you should use a destination such as HTML or RTF. In many cases, HTML is the default destination in the SAS windowing environment (see the section "HTML Output in the SAS Windowing Environment" on page 526). You can change destinations in the SAS windowing environment by selecting **Tools ► Options ► Preferences** from the menu at the top of the main SAS window and then selecting the **Results** tab.

Instead, you can prevent the Output window from appearing by using ODS statements to close the LISTING destination, as follows:

```
ods listing close;
ods html;
```

A graph is created for every open destination. When you open a new destination, you should close all destinations that you do not need. Closing destinations makes your jobs run faster and with fewer resources, because fewer tables and graphs are produced.

Accessing Individual Graphs

If you are writing a paper or creating a presentation, you need to access your graphs individually. There are various ways to do this, depending on the ODS destination. Three particularly useful methods are as follows:

- If you are viewing RTF output, you can simply copy and paste your graphs from the viewer into a Microsoft Word document or a Microsoft PowerPoint slide.

- If you are viewing HTML output, you can copy and paste your graphs from the viewer, or you can right-click the graph and save it to a file. Copying and pasting from RTF is preferable because the default resolution is higher than with HTML. See the section "Specifying the Size and Resolution of Graphs" on page 617 for details.
- You can save your graphs in image files and then include them into a paper or presentation. For example, you can save your graphs as PNG files and include them into a paper that you are writing with LaTeX or into an HTML document.

You can specify the graphics image format and the filename in the ODS GRAPHICS statement. For example, the following statements, when submitted before a procedure step that produces multiple graphs, save the graphs in PostScript files named *myname.ps*, *myname1.ps*, and so on:

```
ods _all_ close;
ods latex;
ods graphics on / outputfmt=ps imagename='myname';
```

See the section "Image File Types" on page 634 for details about the file types available with various destinations, how they are named, and how they are saved.

If you are using the LISTING destination and the SAS windowing environment, you can also copy from the viewer into a Microsoft Word document or a Microsoft PowerPoint slide.

Specifying the Size and Resolution of Graphs

Two factors to consider when you are creating graphs for a paper or presentation are the size of the graph and its resolution. You can specify the size of a graph in the ODS GRAPHICS statement. The following examples show typical ways to change the size of your graphs:

```
ods graphics on / width=6in;
ods graphics on / height=4in;
ods graphics on / width=4.5in height=3.5in;
```

You can change the resolution with the IMAGE_DPI= option in any ODS destination statement, as in the following example:

```
ods html image_dpi=300;
```

The default resolution of graphs created with the HTML and LISTING destinations is 96 DPI (dots per inch), whereas the default with the RTF destination is 200 DPI. An increase in resolution often improves the quality of the graphs, but it also increases the size of the image file. See the section "Graph Size and Resolution" on page 641 for more information about graph size and resolution.

Modifying Your Graphs

Although ODS Graphics is designed to automate the creation of high-quality statistical graphics, on occasion you might need to modify your graphs. There are two ways you can make modifications, depending on whether the changes you want to make are data-dependent and immediate (for a specific graph you are preparing for a paper or presentation), or whether they are persistent (applied to a graph each time you run the procedure). You can make immediate, ad hoc changes by using the ODS Graphics Editor, which provides a point-and-click interface. You can make persistent changes by modifying the ODS graph template for a particular plot. For an introduction to graph template modification, see Chapter 22, "ODS Graphics Template Modification." A graph template is a program, written in the Graph Template Language (GTL), that specifies the layout and details of a graph.

NOTE: The SAS system provides a template for each graph it creates, so you do not need to know anything about templates to create statistical graphics.

You can use the ODS Graphics Editor to customize titles and labels, annotate data points, add text, and change the properties of graph elements. After you have modified your graph, you can save it as a PNG image file or as an SGE file, which preserves the editing context. You can open SGE files with the ODS Graphics Editor and resume editing.

You can invoke the ODS Graphics Editor in the SAS windowing environment, provided that you have enabled ODS Graphics to create editable graphs. The steps for doing this are described in the section "ODS Graphics Editor" on page 642. Also see *SAS ODS Graphics Editor: User's Guide*.

Figure 21.14 shows the ODS Graphics Editor window for a fit plot created by PROC REG. Figure 21.15 shows modifications made with tools in the ODS Graphics Editor. The title has been changed, and the legend has been repositioned.

Figure 21.14 ODS Graphics Editor Invoked with a Fit Plot

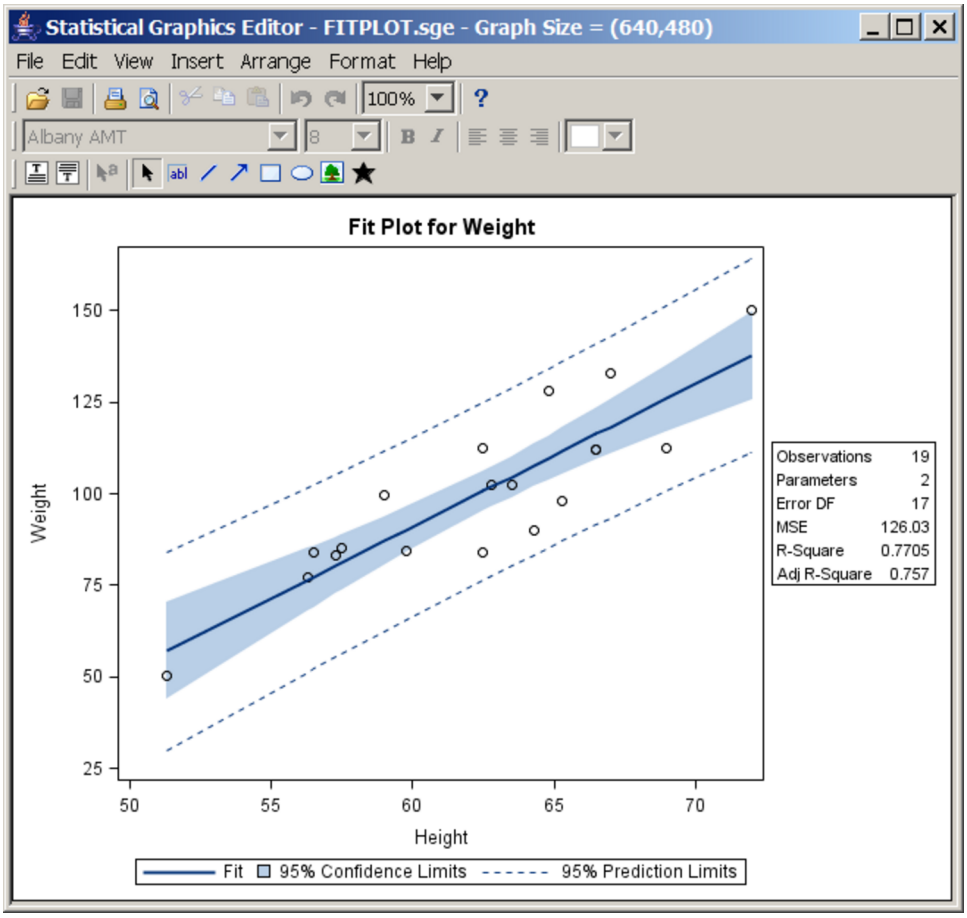


Figure 21.15 Point-and-Click Modifications Made with the ODS Graphics Editor

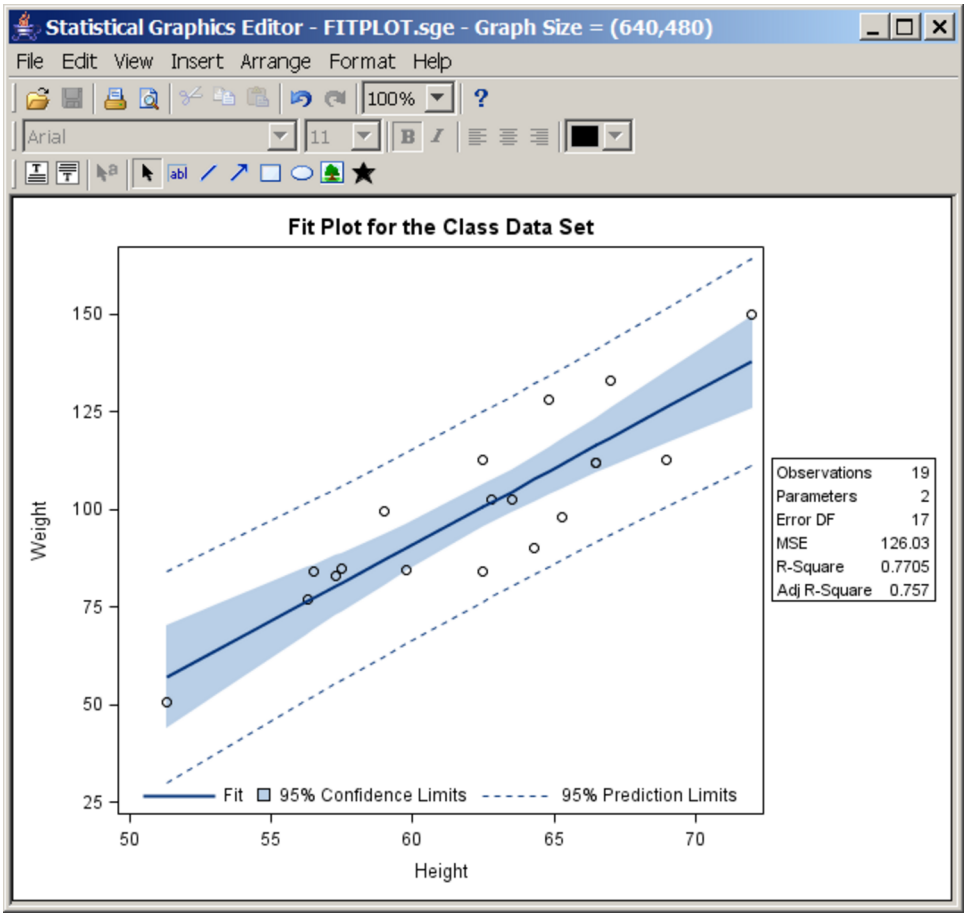

Procedures That Support ODS Graphics

SAS procedures that support ODS Graphics include the following:

SAS/STAT		**SAS/QC**	**SAS/ETS**
ANOVA	NPAR1WAY	ANOM	ARIMA
BOXPLOT	ORTHOREG	CAPABILITY	AUTOREG
CALIS	PHREG	CUSUM	COPULA
CLUSTER	PLM	MACONTROL	ENTROPY
CORRESP	PLS	MVPCHART	ESM
FACTOR	POWER	MVPMODEL	EXPAND
FMM	PRINCOMP	PARETO	MODEL
FREQ	PRINQUAL	RELIABILITY	PANEL
GAM	PROBIT	SHEWHART	SEVERITY
GENMOD	QUANTREG		SIMILARITY
GLIMMIX	REG	**Base SAS**	SYSLIN
GLM	ROBUSTREG	CORR	TIMEID
GLMPOWER	RSREG	FREQ	TIMESERIES
GLMSELECT	SEQDESIGN	UNIVARIATE	UCM
KDE	SEQTEST		VARMAX
KRIGE2D	SIM2D		X12
LIFEREG	SURVEYFREQ	**Other**	
LIFETEST	SURVEYLOGISTIC	HPF	
LOESS	SURVEYPHREG	HPFENGINE	
LOGISTIC	SURVEYREG		
MCMC	TPSPLINE	SAS Risk	
MDS	TRANSREG	Dimensions	
MI	TTEST		
MIXED	VARCLUS		
MULTTEST	VARIOGRAM		
NLIN			

For details about the specific graphs available with a particular procedure, see the PLOTS= option syntax and the "ODS Graphics" section in the corresponding procedure chapter. For the SAS/STAT procedures, the procedure names in the preceding table are links to the "ODS Graphics" section.

Procedures That Support ODS Graphics and Traditional Graphics

A number of procedures that support ODS Graphics produced traditional graphics in previous releases of SAS. These include the UNIVARIATE procedure in Base SAS software; the LIFEREG, LIFETEST, and REG procedures in SAS/STAT software; and the ANOM, CAPABILITY, CUSUM, MACONTROL, PARETO, RELIABILITY, and SHEWHART procedures in SAS/QC software. All of these procedures continue to produce traditional graphics, but in some cases, they do so only when ODS Graphics is not enabled. For more information about the interaction between traditional graphics and ODS graphics in other procedures, see the documentation for that procedure.

Traditional graphs are saved in SAS graphics catalogs and are controlled by the GOPTIONS statement. In contrast, ODS Graphics produces graphs in standard image file formats (not graphics catalogs), and their appearance and layout are controlled by ODS styles and templates.

Syntax

The following sections document some of the most commonly used options in the ODS GRAPHICS statement (section "ODS GRAPHICS Statement" on page 622) and other statements used with ODS Graphics (section "ODS Destination Statements" on page 625). You can find the complete syntax in the *SAS Output Delivery System: User's Guide*. In addition, information about the PLOTS= option is provided in the section "PLOTS= Option" on page 626. Statistical procedures that produce ODS Graphics all have a PLOTS= option that is used to select graphs and control some aspects of the graphs.

ODS GRAPHICS Statement

ODS GRAPHICS < **OFF** | **ON** > < / *options* > **;**

The ODS GRAPHICS statement enables ODS to create graphs. You can enable ODS Graphics by using either of the following equivalent statements:

```
ods graphics on;
ods graphics;
```

You specify one of these statements prior to your procedure invocation, as illustrated in the examples beginning with "Default Plots for Simple Linear Regression with PROC REG" on page 594. Any procedure that supports ODS Graphics then produces graphs, either by default or when you specify procedure options for requesting particular graphs.

To disable ODS Graphics, specify the following statement:

```
ods graphics off;
```

ODS Graphics might or might not be enabled by default depending on your operating system, whether you are in the SAS windowing environment, your registry, system options, and configuration file settings. For more information about default settings and enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612.

The following is a subset of the options, syntax, and capabilities available in the ODS GRAPHICS statement. See the *SAS Output Delivery System: User's Guide* for more information.

ANTIALIAS=ON | OFF

controls the use of antialiasing to smooth the components of a graph. Without antialiasing, pixels are simply set or not set. With antialiasing, pixels at the edge of a line or other object are set to an intermediate color, which makes smoother and more professional looking graphics. Text displayed in a graph is always antialiased. Antialiasing is very time-consuming for larger graphical displays, and its benefits decrease as the number of points increases, so it is turned off by default for plots with many points. If the number of observations in the ODS output object exceeds the ANTIALIASMAX= threshold (10,000 by default), then antialiasing is not used, even if you specify the option ANTIALIAS=ON. The default is ANTIALIAS=ON.

ANTIALIASMAX=*n*

specifies the maximum number of markers or lines to be antialiased before antialiasing is disabled. For example, if there are more than 10,000 point markers and ANTIALIASMAX=10,000 (the default), then no markers are antialiased.

BORDER=ON | OFF

specifies whether to draw the graph with a border. BORDER=ON is the default.

HEIGHT=*dimension*

specifies the height of the graph. The default is HEIGHT=480PX (480 pixels). You can also specify height in inches (for example, HEIGHT=5IN) or centimeters (for example, HEIGHT=12CM).

IMAGEMAP=ON | OFF

controls tooltip generation in the HTML destination. The default is IMAGEMAP=OFF, which means that no tooltips are generated. Tooltips are text boxes that appear in HTML output when you rest your mouse pointer over a part of the plot (see Example 21.1).

IMAGENAME=< *base-file-name* **>**

specifies the base image filename. The default is the name of the output object. You can determine the name of the output object by using the ODS TRACE statement (see the section "Determining Graph Names and Labels" on page 630). The base image name should not include an extension. ODS automatically adds the increment value and the appropriate extension (which is specific to the output destination). See the section "Specifying Base Filenames" on page 637 for an example.

LABELMAX=*n*

specifies the maximum number of labeled areas before labeling is disabled. For example, if LABELMAX=50, and there are more than 50 points with labels, then no points are labeled. The default is LABELMAX=200.

MAXLEGENDAREA=*n*

specifies the maximum percentage of the overall graph area that a legend can occupy. The default is MAXLEGENDAREA=20. Larger legends are dropped from the display.

OUTPUTFMT=< *image-file-type* **| STATIC >**

specifies the image format for graphs. The OUTPUTFMT= option was previously named the IMAGEFMT= option. By default, OUTPUTFMT=STATIC and ODS dynamically uses the best quality static image format for the active output destination. The available image formats include: BMP (Microsoft Windows device-independent bitmap), DIB (Microsoft Windows device-independent bitmap), EMF (Microsoft NT enhanced metafile), EPSI (Adobe encapsulated PostScript interchange), GIF (graphic interchange format), JFIF (JPEG file interchange format), JPEG (Joint Photographic Experts Group), PBM (portable bitmap), PCD (Photo CD), PCL (Printer Command Language), PDF

(portable document format), PICT (the QuickDraw picture format), PNG (Portable Network Graphics), PS (PostScript image file format), SVG (Scalable Vector Graphics), TIFF (Tagged Image File Format), WMF (Microsoft Windows Metafile format), XBM (X Bitmap), and XPM (X-Windows Pixelmap). If the specified image format is not valid for the active output destination, the device is automatically remapped to the default image format.

RESET< *=option* **>**
resets one or more ODS GRAPHICS options to their default settings. The RESET and RESET=ALL options are equivalent. If you want to reset more than one option, but not all of the options, then you must specify RESET= separately for each option you reset (for example, **`ods graphics on / reset=antialias reset=index;`**). The RESET= options include the following:

ALL
resets all of the resettable options to their defaults.

ANTIALIAS
resets the ANTIALIAS= option to its default.

ANTIALIASMAX
resets the ANTIALIASMAX= option to its default.

BORDER
resets the BORDER= option to its default.

INDEX
resets the index counter that is appended to static image files.

HEIGHT
resets the HEIGHT= option to its default.

IMAGEMAP
resets the IMAGEMAP= option to its default.

LABELMAX
resets the LABELMAX= option to its default.

SCALE
resets the SCALE= option to its default.

TIPMAX
resets the TIPMAX= option to its default.

WIDTH
resets the WIDTH= option to its default.

SCALE=ON | OFF
specifies whether the fonts and symbol markers are scaled proportionally with the size of the graph. The default is SCALE=ON. For examples, see Figure 21.52 and Figure 21.53.

SCALEMARKERS=ON | OFF
specifies whether markers are scaled in nested layouts. The default is SCALE=ON.

TIPMAX=*n*

specifies the maximum number of distinct tooltips permitted before tooltips are disabled. Tooltips are text boxes that appear when you rest your mouse pointer over a part of the plot. For example, if TIPMAX=400, and there are more than 400 points in a scatter plot, then no tooltips appear. The default is TIPMAX=500.

WIDTH=*dimension*

specifies the width of the graph. The default is WIDTH=640PX (640 pixels). You can also specify widths in inches (for example, WIDTH=5in) or centimeters (for example, WIDTH=12cm).

ODS Destination Statements

ODS has a number of statements that control the destination of ODS output. The ODS destination statements that are most commonly used with ODS Graphics are: ODS DOCUMENT, ODS HTML, ODS LATEX, ODS LISTING, ODS PCL, ODS PDF, ODS PS, and ODS RTF. Specifying a statement opens a destination, unless the CLOSE option is specified. Each of the following statements opens an ODS destination:

```
ods html;
ods rtf;
ods html image_dpi=300;
ods listing style=HTMLBlue;
```

Each of the following statements closes an ODS destination:

```
ods html close;
ods rtf close;
ods listing close;
```

The following statement closes all open destinations:

```
ods _all_ close;
```

The following two options are commonly used in ODS destination statements to control aspects of ODS Graphics:

IMAGE_DPI=*dpi*

specifies the dots per inch (DPI), which is the image resolution for graphical output. The default varies depending on the destination. For example, the default is 96 for HTML and 200 for RTF.

STYLE=*style-name*

specifies the output style. Commonly used styles include HTMLBLUE, HTMLBLUECML, DEFAULT, LISTING, STATISTICAL, JOURNAL, JOURNAL2, JOURNAL3, RTF, and ANALYSIS.

Other options provide you with ways to control the files that are created. For example, the following statement opens the HTML destination:

```
ods html body='b.html' contents='c.html' frame='a.html';
```

This statement also writes the body of the output to the file *b.html*, the table of contents to the file *c.html*, and an overall frame that contains both the contents and the output to the file *a.html*. Alternatively, you can specify FILE= instead of BODY=.

If you are using a destination for which individual graphs are created (for example, LISTING or HTML), you can use the GPATH= option to specify the directory where your graphics files are saved, as in the following example:

```
ods html gpath="C:\figures";
```

See the sections "Image File Types" on page 634, "Saving Graphics Image Files" on page 638, "LISTING Destination" on page 639, "HTML Destination" on page 639, and "LATEX Destination" on page 639 for more information about individual image files and options specified in the ODS Destination statements. For complete details about the ODS destination statements, see the *SAS Output Delivery System: User's Guide*.

PLOTS= Option

Each statistical procedure that supports ODS Graphics has a PLOTS= option that is used to select graphs and specify some options. The syntax of the PLOTS= option is as follows:

PLOTS <(*global-plot-options*)> <= *plot-request* <*(options)*>>
PLOTS <(*global-plot-options*)> <= (*plot-request* <*(options)*> <... *plot-request* <*(options)*>>)>

The PLOTS= option has a common overall syntax for all statistical procedures, but the specific global plot options, plot requests, and plot options vary across procedures. This section discusses only a few of the options available in the PLOTS= option. For more information about the PLOTS= option, see the "Syntax" section for each procedure that produces ODS Graphics. There are only a limited number of things that you can control with the PLOTS= option. Most graphical details are controlled either by graph templates (see the section "Graph Templates" on page 716 in Chapter 22, "ODS Graphics Template Modification,") or by styles (see the section "Styles" on page 648).

The PLOTS= option usually appears in the PROC statement. However, for some procedures, certain analyses and hence certain plots can appear only if an additional statement is specified. These procedures often have a PLOTS= option in that other statement. For example, the PHREG procedure has a PLOTS= option in the BAYES statement, which is used to perform a Bayesian analysis. See the "Syntax" section of each procedure chapter for more information. The following examples illustrate the syntax of the PLOTS= option:

```
plots=all
plots=none
plots=residuals
plots=residuals(smooth)
plots=(trace autocorr)
plots(unpack)
plots(unpack)=diagnostics
plots=diagnostics(unpack)
plots(only)=freqplot
plots=(scree(unpack) loadings(plotref) preloadings(flip))
plots(unpack maxparmlabel=0 stepaxis=number)=coefficients
plots(sigonly)=(rawprob adjusted(unpack))
```

Also see the "Getting Started" sections "Survival Estimate Plot with PROC LIFETEST" on page 597, "Contour and Surface Plots with PROC KDE" on page 598, "Contour Plots with PROC KRIGE2D" on page 600, "LS-Means Diffogram with PROC GLIMMIX" on page 606, and "Principal Component Analysis Plots with PROC PRINCOMP" on page 608 for examples of the PLOTS= option.

The simplest PLOTS= specifications are of the form PLOTS=*plot-request* or PLOTS=(*plot-requests*). When there is more than one plot request, the plot-request list must appear in parentheses. Each plot request either requests a plot (for example, RESIDUALS) or provides you with a place to specify plot-specific options (for example, DIAGNOSTICS(UNPACK)). Some simple and typical plot requests are explained next:

- PLOTS=ALL requests all plots that are relevant to the analysis. This does not mean that all plots that the procedure can produce are produced. Plots that are produced for one set of options might not appear with PLOTS=ALL and a different set of options. In some cases, certain plots are not produced unless certain options or statements outside the PLOTS= option are specified.
- PLOTS=NONE disables ODS Graphics for just that step. You can use this option instead of specifying ODS GRAPHICS OFF before a procedure step and ODS GRAPHICS ON after the step when you want to suppress graphics for only that step.
- PLOTS=RESIDUALS requests a plot of residuals in a modeling procedure such as PROC REG.
- PLOTS=RESIDUALS(SMOOTH) requests the residuals plot along with a smooth fit function.
- PLOTS=(TRACE AUTOCORR) requests trace and autocorrelation plots in procedures with Bayesian analysis options.

Global plot options appear in parentheses after the option name and before the equal sign. These options affect many or all of the plots. The UNPACK option is a commonly used global plot option. It specifies that plots that are normally produced with multiple plots per panel (or "packed") should be unpacked and appear in multiple panels with one plot in each panel. The specification PLOTS(UNPACK)=(*plot-requests*) unpacks all paneled plots. The UNPACK option is also used as an option in a plot request when you want to unpack only certain panels. For example, the option PLOTS=(DIAGNOSTICS(UNPACK) PARTIAL PREDICTIONS) unpacks only the diagnostics panel. In some cases, unpacked plots contain additional information that is not found in the smaller packed versions. The UNPACK option is not available for all plot requests; it is available only with plots that have multiple panels by default.

Another commonly used global plot option is the ONLY option. Many procedures produce default plots, and additional plots can be requested in the PLOTS= option. Specifying PLOTS=(*plot-requests*) while omitting the default plots does not prevent the default plots from being produced. The ONLY option is used when you want to see only the plots specifically listed in the plot-request list. Procedures that produce no default plots typically do not provide an ONLY option. You can use ODS SELECT and ODS EXCLUDE (see the section "Selecting and Excluding Graphs" on page 633) to select and exclude graphs, but in some situations the ONLY option is more convenient. It is typically more efficient to select plots by using the PLOTS(ONLY)= option, because the procedure does not do extra work to generate a plot that is excluded by the PLOTS(ONLY)= option. In contrast, ODS SELECT and ODS EXCLUDE have their effect after the procedure has done the work to generate the plot.

Selecting and Viewing Graphs

This section describes techniques for selecting and viewing your graphs. Topics include:

- specifying an ODS destination for graphics
- viewing your graphs in the SAS windowing environment
- referring to graphs by name when using ODS
- selecting and excluding graphs from your output

Specifying an ODS Destination for Graphics

If you do not specify an ODS destination, then either the LISTING or the HTML destination is used by default. Here is an example of how you can explicitly specify the HTML destination:

```
ods graphics on;
ods html;

proc reg data=sashelp.class;
   model Weight = Height;
run; quit;

ods html close;
```

This ODS HTML statement creates an HTML file with a default name. See the section "Specifying a File for ODS Output" on page 629 to see how to specify a filename. Other destinations are specified in a similar way. For example, you can specify an RTF destination with the following statements:

```
ods graphics on;
ods rtf;

. . .

ods rtf close;
```

The destinations that ODS supports for graphics are as follows:

Destination	Destination Family
DOCUMENT	
HTML	MARKUP
LATEX	MARKUP
LISTING	
PCL	PRINTER
PDF	PRINTER
PS	PRINTER
RTF	

You can close all open destinations if you are interested only in displaying your output in a nondefault destination. For example, if you want to see your output only in the RTF destination, you can specify the following statements:

```
ods graphics on;
ods _all_ close;
ods rtf;

. . .

ods rtf close;
ods listing;
```

Closing unneeded destinations makes your jobs run faster and creates fewer files. More generally, it makes your jobs consume fewer resources, because a graph is otherwise created for every open destination. The last statement opens the LISTING destination after you are finished using the RTF destination.

You can also use the ODS OUTPUT destination to create an output data set from the data object used to make a plot. Here is an example:

```
ods graphics on;

proc reg data=sashelp.class;
   ods output fitplot=myfitplot;
   model Weight = Height;
run; quit;
```

Specifying a File for ODS Output

You can specify a filename for your output with the FILE= option in the ODS destination statement, as in the following example:

```
ods html file="test.htm";
```

The output is written to the file *test.htm*, which is saved in the SAS current folder. At start-up, the SAS current folder is the same directory in which you started your SAS session. If you are using the SAS windowing environment, then the current folder is displayed in the status line at the bottom of the main SAS

window. If you do not specify a filename for your output, then the SAS System provides a default filename, which depends on the ODS destination. This file is saved in the SAS current folder. You can always check the SAS log to verify the name of the file in which your output is saved. For example, suppose you specify the following statement:

```
ods html;
```

Then the following message is displayed in the SAS log:

```
NOTE: Writing HTML Body file: sashtml.htm
```

The default filenames for each destination are specified in the SAS Registry. For example, Figure 21.54 shows that the default filename in the SAS Registry for the RTF destination is *sasrtf.rtf*. For more information, see the *SAS Companion* for your operating system.

Viewing Your Graphs in the SAS Windowing Environment

The mechanism for viewing graphs created with ODS can vary depending on your operating system, which viewers are installed on your computer, and the ODS destination you have selected. If you do not specify an ODS destination, then the default destination is either HTML or LISTING.

If you are using the SAS windowing environment and the HTML destination, then the results are displayed by default in the SAS Results Viewer unless you chose to use an external browser. To use an external viewer, select **Tools ► Options ► Preferences** from the menu at the top of the main SAS window. Then select the **Results** and **Web** tabs to make your selection.

If you are using the LATEX or the PS destinations, you must use a PostScript viewer, such as GSview. For information about the windowing environment in a different operating system, see the *SAS Companion* for that operating system.

If you do not want to view the results as they are being generated, then select **Tools ► Options ► Preferences** from the menu at the top of the main SAS window. Then on the **Results** tab, clear the **View results as they are generated** checkbox.

If you are using the SAS windowing environment and the LISTING destination, go to the Results window and find the icon for the corresponding graph. You can double-click the graph icon to display the graph in the default viewer that is configured on your computer for the corresponding image file type (see Figure 21.13).

Determining Graph Names and Labels

Procedures assign a name to each graph they create with ODS Graphics. This enables you to refer to ODS graphs in the same way that you refer to ODS tables (see the section "The ODS Statement" on page 533 in Chapter 20, "Using the Output Delivery System,"). You can determine the names of graphs in several ways:

- You can look up graph names in the "ODS Graphics" section of chapters for procedures that use ODS Graphics. For example, see the section "ODS Graphics" on page 6472 in Chapter 76, "The REG Procedure."
- You can use the Results window to view the names of ODS graphs created in your SAS session. See the section "The SAS Results Window" on page 538 in Chapter 20, "Using the Output Delivery System," for more information.
- You can use the ODS TRACE ON statement to list the names of graphs created by your SAS session. This statement adds identifying information in the SAS log (or optionally in the SAS LISTING) for each graph that is produced. See the section "The ODS Statement" on page 533 in Chapter 20, "Using the Output Delivery System," for more information.

The graph name is not the same as the name of the image file that contains the graph (see the section "Naming Graphics Image Files" on page 636).

This example revisits the analysis described in the section "Contour and Surface Plots with PROC KDE" on page 598. To determine which output objects are created by ODS, you specify the ODS TRACE ON statement prior to the procedure statements as follows:

```
ods graphics on;
ods trace on;

proc kde data=bivnormal;
   bivar x y / plots=contour surface;
run;

ods trace off;
```

The trace record from the SAS log is as follows:

```
Output Added:
-------------
Name:        Inputs
Template:    Stat.KDE.Inputs
Path:        KDE.Bivar1.x_y.Inputs
-------------

Output Added:
-------------
Name:        Controls
Template:    Stat.KDE.Controls
Path:        KDE.Bivar1.x_y.Controls
-------------

Output Added:
-------------
Name:        ContourPlot
Label:       Contour Plot
Template:    Stat.KDE.Graphics.Contour
Path:        KDE.Bivar1.x_y.ContourPlot
-------------
```

```
Output Added:
-------------
Name:        SurfacePlot
Label:       Density Surface
Template:    Stat.KDE.Graphics.Surface
Path:        KDE.Bivar1.x_y.SurfacePlot
-------------
```

By default, PROC KDE creates table objects named **Inputs** and **Controls**, and it creates graph objects named **ContourPlot** and **SurfacePlot**. In addition to the name, the trace record provides the label, template, and path for each output object. Graph templates are distinguished from table templates by a naming convention that uses the procedure name in the second level and **Graphics** in the third level. For example, the fully qualified template name for the surface plot created by PROC KDE is **Stat.KDE.Graphics.SurfacePlot**.

You can specify the LISTING option in the ODS TRACE ON statement to write the trace record to the LISTING destination as follows:

```
ods trace on / listing;
```

Each table and graph has a path (or name path), which was previously shown in the trace output. The path consists of the plot name preceded by the names of one or more output groups. Each table and graph also has a label path, which can be seen by adding the LABEL option to the ODS TRACE ON statement, after a slash, as follows:

```
ods trace on / label;

proc kde data=bivnormal;
   bivar x y / plots=contour surface;
run;

ods trace off;
```

A portion of the trace output is shown next:

```
Path:       KDE.Bivar1.x_y.Inputs
Label Path: 'The KDE Procedure'.'Bivariate Analysis'.'x and y'.'KDE.Bivar1.x_y'

Path:       KDE.Bivar1.x_y.Controls
Label Path: 'The KDE Procedure'.'Bivariate Analysis'.'x and y'.'KDE.Bivar1.x_y'

Path:       KDE.Bivar1.x_y.ContourPlot
Label Path: 'The KDE Procedure'.'Bivariate Analysis'.'x and y'.'Contour Plot'

Path:       KDE.Bivar1.x_y.SurfacePlot
Label Path: 'The KDE Procedure'.'Bivariate Analysis'.'x and y'.'Density Surface'
```

The label path contains the information that you see in the HTML table of contents. Names are fixed, they do not vary, and they are not data- or context-dependent. In contrast, labels often reflect data- or context-dependent information.

Selecting and Excluding Graphs

You can use the ODS SELECT and ODS EXCLUDE statements along with graph and table names to specify which ODS outputs are displayed. See the section "The ODS Statement" on page 533 in Chapter 20, "Using the Output Delivery System," for more information about how to use these statements.

This section shows several examples of selecting and excluding graphs by using the data set and trace output created in the section "Determining Graph Names and Labels" on page 630. The following statements use the ODS SELECT statement to select only two graphs, **ContourPlot** and **SurfacePlot**, for display in the output:

```
proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
   bivar x y / plots=contour surface;
run;
```

Equivalently, the following statements use the ODS EXCLUDE statement to exclude the two tables:

```
proc kde data=bivnormal;
   ods exclude Inputs Controls;
   bivar x y / plots=contour surface;
run;
```

You can select or exclude graphs by using either the name or the label. Labels must be specified in quotes. In the context of this example, the following two statements are equivalent:

```
ods select contourplot;
ods select 'Contour Plot';
```

You can also specify multiple levels of the path, as in the following example:

```
ods select x_y.contourplot;
ods select 'x and y'.'Contour Plot';
ods select 'x and y'.contourplot;
ods select x_y.'Contour Plot';
```

Name and label paths can be mixed, as in the last two statements. All four of the preceding statements select the same plot. Furthermore, selection based directly on the names and labels is case-insensitive. The following statements all select the same plot:

```
ods select x_y.contourplot;
ods select 'x and y'.'Contour Plot';
ods select X_Y.CONTOURPLOT;
ods select 'X AND Y'.'CONTOUR PLOT';
```

It is sometimes useful to specify a WHERE clause in an ODS SELECT or ODS EXCLUDE statement. This enables you to specify expressions based on either the name path or the label path. You can base your selection on two automatic variables _path_ and _label_. The following two statements select every object whose path contains the string 'plot' and every object whose label path contains the string 'plot', respectively, ignoring the case in the name and label:

```
ods select where = (lowcase(_path_)  ? 'plot');
ods select where = (lowcase(_label_) ? 'plot');
```

The question mark operator means that the second expression (the string 'plot') is contained in the first expression (the lowercase version of the name or label). For example, all of the following names match 'plot' in the WHERE clause: plot, SurfacePlot, SURFACEPLOT, FitPlot, pLoTtInG, Splotch, and so on. Since WHERE clause selection is based on SAS string comparisons, selection is case-sensitive. The LOWCASE function is used to ensure a match even when the specified string does not match the case of the actual name or label.

WHERE clauses are particularly useful when you want to select all of the objects in a group. A group is a level of the name path or label path hierarchy before the last level. In the following step, all of the objects whose name path contains 'DiagnosticPlots' are selected:

```
proc reg data=sashelp.class plots(unpack);
   ods select where = (_path_ ? 'DiagnosticPlots');
   model Weight = Height;
run; quit;
```

These are the plots that come from unpacking the PROC REG diagnostics panel of plots. All are in a group named 'DiagnosticPlots'.

Graphics Image Files

Accessing your graphs as individual image files is useful when you want to include them in various types of documents. The default image file type depends on the ODS destination, but there are other supported image file types that you can specify. You can also specify the names for your graphics image files and the directory in which you want to save them. This section describes the image file types supported by ODS Graphics, and it explains how to name and save graphics image files.

Image File Types

If you are using the LISTING, HTML, or LATEX destinations, your graphs are individually produced in a specific image file type, such as PNG (Portable Network Graphics). If you are using a destination in the PRINTER family or the RTF destination, the graphs are contained in the ODS output file and cannot be accessed as individual image files. However, you can open an RTF output file in Microsoft Word and then copy and paste the graphs into another document, such as a Microsoft PowerPoint presentation. This is illustrated in Example 21.2.

Table 21.1 shows the various ODS destinations supported by ODS Graphics, the viewer that is appropriate for displaying graphs in each destination, and the image file types supported for each destination.

Table 21.1 Destinations and Image File Types Supported by ODS Graphics

Destination	Destination Family	Recommended Viewer	Image File Types
DOCUMENT		Not applicable	Not applicable
HTML	MARKUP	Web browser	PNG (default), GIF, JPEG,
LATEX	MARKUP	PostScript or PDF viewer after compiling the LaTeX file	PostScript (default), EPSI, GIF, JPEG, PDF, PNG
LISTING		Default viewer in your system for the specified file type	PNG (default), GIF, BMP, DIB, EMF, EPSI, GIF, JFIF, JPEG, PBM, PS, TIFF, WMF
PCL	PRINTER	Not applicable	Contained in PRN file
PDF	PRINTER	PDF viewer, such as Adobe Reader	Contained in PDF file
PS	PRINTER	PostScript viewer, such as GSview	Contained in PostScript file
RTF		Word processor, such as Microsoft Word	Contained in RTF file

For destinations such as PDF and RTF, you can control the types of the images that are contained in the file even though individual files are not made for each image. The default image file type is PNG, and other image types are available. See the *SAS Output Delivery System: User's Guide* for more information.

Scalable Vector Graphics

Scalable vector graphics output is now supported in ODS Graphics. The output type support varies based on the ODS destination that you use. You can specify the OUTPUTFMT= option in the ODS GRAPHICS statement to specify the output type for any destination. For destinations that generate vector graphics by default, you can get image output by specifying the option OUTPUTFMT=STATIC.

Vector graphics are not supported for all graph types. When vector graphics are requested but not supported, the graph automatically changes to image output. Vector graphics are not supported for the following graph types:

- three-dimensional graph
- contour plots with smooth gradient fills
- graphs with continuous legends
- graphs with data skins
- graphs with rotated annotation images
- graphs with transparency (EMF and PS only)

The LISTING destination can generate all of the supported forms of vector-based output: PDF, PS, EMF, SVG, and PCL. Each graph is generated in a separate file that can be included into a larger report. The default output format is a PNG image.

Like the LISTING destination, the ODS PRINTER destination can generate all of the supported vector output types. The output format depends on the type of printer you select. If you select the PDF, SVG, or PCL5C printers, vector-based output is automatically produced. However, if you select PS or EMF printers, you need to set the OUTPUTFMT= option in the ODS GRAPHICS statement to PS or EMF, respectively, to create vector-based output. By default, the output from this destination is in one file instead of individual files for each graph.

The PDF destination renders PDF vector output by default, except for the exceptions noted. You can specify the OUTPUTFMT=STATIC option in the ODS GRAPHICS statement to produce an embedded image in the PDF file.

The LATEX destination renders PS vector output by default, except for the exceptions noted. You can specify the OUTPUTFMT=STATIC option in the ODS GRAPHICS statement to produce an embedded image in the postscript file.

The RTF destination renders PNG image output by default. Vector-based EMF output is also supported for this destination. You can specify the OUTPUTFMT=EMF option in the ODS GRAPHICS statement to select this output type. If one of the noted exceptions occurs, the output type for that graph changes to a PNG image.

The HTML destination renders PNG image output by default. Vector-based SVG output is also supported for this destination. You can specify the OUTPUTFMT=SVG option in the ODS GRAPHICS statement to select this output type. If one of the noted exceptions occurs, the output type for that graph changes to a PNG image.

In most cases, the file size with vector graphics is much smaller than a comparable static image file. However, in some cases, the vector graphics file size is larger than the image version. This is likely for scatter plots of data sets with a large number of observations.

Naming Graphics Image Files

The following discussion applies to the destinations where ODS graphs are created as individual image files (for example, HTML, LISTING, and LATEX). The names of graphics image files are determined by a base filename, an index counter, and an extension. By default, the base filename is the ODS graph name (see the section "Determining Graph Names and Labels" on page 630). There is an index counter for each base filename. The extension indicates the image file type. The first time a graph object with a given base filename is created, the filename consists only of the base filename and the extension. If a graph with the same base filename is created multiple times, then an index counter is appended to the base filename to avoid overwriting previously created images.

To illustrate, consider the following statements:

```
proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
   bivar x y / plots=contour surface;
run;
```

If you run this step at the beginning of a SAS session, the two graphics image files created are *ContourPlot.png* and *SurfacePlot.png*. If you immediately rerun these statements, then ODS creates the same graphs in different image files named *ContourPlot1.png* and *SurfacePlot1.png*. The next time, the image files are named *ContourPlot2.png* and *SurfacePlot2.png*. The index starts at zero, and one is added each time the same name is used. Note, however, that when the index is at zero, 0 is not added to the filename.

Resetting the Index Counter

You can specify the RESET=INDEX option in the ODS GRAPHICS statement to reset the index counter. This is useful when you need to have predictable names. It is particularly useful when you are running a SAS program multiple times in the same session. The following statement resets the index:

```
ods graphics on / reset=index;
```

The index counter is reinitialized at the beginning of your SAS session or if you specify the RESET=INDEX option in the ODS GRAPHICS statement. Graphics image files with the same name are overwritten.

Specifying Base Filenames

You can specify a base filename for all your graphics image files with the IMAGENAME= option in the ODS GRAPHICS statement as follows:

```
ods graphics on / imagename="MyName";
```

You can also specify the RESET=INDEX option as follows:

```
ods graphics on / reset=index imagename="MyName";
```

The IMAGENAME= option overrides the default base filename. With the preceding statement, the graphics image files are named *MyName*, *MyName1*, *MyName2*, and so on.

Specifying Image File Types

You can specify the image file type for the LISTING, HTML, or LATEX destinations with the OUTPUTFMT= option in the ODS GRAPHICS statement as follows:

```
ods graphics on / outputfmts=gif;
```

For more information, see the section "ODS GRAPHICS Statement" on page 622.

Naming Graphics Image Files with Multiple Destinations

Since the index counter depends only on the base filename, if you specify multiple ODS destinations for your output, then the index counter is increased independently of the destination. For example, the following statements create image files named *ContourPlot.png* and *SurfacePlot.png* that correspond to the LISTING destination, and *ContourPlot1.png* and *SurfacePlot1.png* that correspond to the HTML destination:

```
ods listing;
ods html;
ods graphics on / reset;

proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
   bivar x y / plots=contour surface;
run;

ods _all_ close;
ods listing;
```

When you specify one of the destinations in the PRINTER family or the RTF destination, your ODS graphs are embedded in the document, so the index counter is not affected. For example, the following statements create image files *ContourPlot.png* and *SurfacePlot.png* for the LISTING destinations, but no image files for the RTF destination:

```
ods listing;
ods rtf;
ods graphics on / reset;

proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
   bivar x y / plots=contour surface;
run;

ods _all_ close;
```

Saving Graphics Image Files

Knowing where your graphics image files are saved and how they are named is particularly important if you are running in batch mode, if you have disabled the SAS Results window (see the section "Viewing Your Graphs in the SAS Windowing Environment" on page 630), or if you plan to access the files for inclusion in a paper or presentation. The following discussion assumes you are running SAS under the Windows operating system. If you are running on a different operating system, see the *SAS Companion* for your operating system.

In the SAS windowing environment, the current folder is displayed in the status line at the bottom of the main SAS window. When **Use WORK folder** is cleared in the **Tools ► Options ► Preferences ► Results** tab, graph image files are saved in the current folder and are available after your SAS session ends. They can accumulate with time and take up a great deal of space. When **Use WORK folder** is selected, graph image files are stored in the Work folder and are not available after your SAS session ends.

If you are running your SAS programs in batch mode, the graphs are saved by default in the same directory where you started your SAS session. For example, suppose the SAS current folder is *C:\myfiles*. If ODS Graphics is enabled, then your graphics image files are saved in the directory *C:\myfiles*. Traditional graphics are always saved in a catalog in your Work directory.

With the LISTING, HTML, and LATEX destinations, you can specify a directory for saving your graphics image files. With a destination in the PRINTER family and with the RTF destination, you can specify a directory only for your output file. The remainder of this discussion provides details for each destination type.

LISTING Destination

If you are using the LISTING destination, the individual graphs are created as PNG files by default. You can use the GPATH= option in the ODS LISTING statement to specify the directory where your graphics files are saved. For example, if you want to save your graphics image files in *C:\figures*, then you can specify the following:

```
ods listing gpath="C:\figures";
```

It is important to note that the GPATH= option applies only to ODS Graphics. It does not affect the behavior of graphs created with traditional SAS/GRAPH procedures.

HTML Destination

If you are using the HTML destination, the individual graphs are created as PNG files by default. You can use the PATH= and GPATH= options in the ODS HTML statement to specify the directory where your HTML and graphics files are saved, respectively. This also gives you more control over your graphs. For example, if you want to save your HTML file named *test.htm* in the *C:\myfiles* directory, but you want to save your graphics image files in *C:\myfiles\png*, then you can specify the following:

```
ods html path  = "C:\myfiles"
         gpath = "C:\myfiles\png"
         file  = "test.htm";
```

When you specify the URL= suboption with the GPATH= option, SAS creates relative paths for the links and references to the graphics image files in the HTML file. This is useful for building output files that are easily moved from one location to another. For example, the following statements create a relative path to the *png* directory in all the links and references contained in *test.htm*:

```
ods html path  = "C:\myfiles"
         gpath = "C:\myfiles\png" (url="png/")
         file  = "test.htm";
```

If you do not specify the URL= suboption, SAS creates absolute paths that are hard-coded in the HTML file. These can cause broken links if you move the files. For more information, see the ODS HTML statement in the *SAS Output Delivery System: User's Guide*.

LATEX Destination

LaTeX is a document preparation system for high-quality typesetting. The ODS LATEX statement produces output in the form of a LaTeX source file that is ready to compile in LaTeX. When you request ODS Graphics for a LATEX destination, ODS creates the requested graphs as PostScript files by default, and the LaTeX

source file includes references to these image graphics files. You can compile the LaTeX file, or you can ignore this file and simply access the individual PostScript files to include your graphs in a different LaTeX document, such as a paper that you are writing. You can specify the PATH= and GPATH= options in the ODS LATEX statement, as explained previously for the ODS HTML statement. See Example 21.3 for an illustration. The ODS LATEX statement is an alias for the ODS MARKUP statement with the TAGSET=LATEX option. For more information, see the *SAS Output Delivery System: User's Guide*.

The default image file type for the LATEX destination is PostScript. When you use LaTeX to compile your document, the graphics format for included images is Postscript. However, if you prefer to use pdfLaTeX, you can specify a different format such as JPEG, PDF, or PNG, any of which can be directly included into your pdfLaTeXdocument. To specify one of these formats, you use the OUTPUTFMT= option in the ODS GRAPHICS statement. For more information, see the LaTeX documentation for the `graphicx` package.

Creating Graphs in Multiple Destinations

This section illustrates how to send your output to more than one destination with a single execution of your SAS statements. For example, to create LISTING, HTML, and RTF output, you can specify the ODS LISTING, ODS HTML, and the ODS RTF statements before your procedure statements. The ODS _ALL_ CLOSE statement closes all open destinations before and after the other statements are run.

```
ods _all_ close;
ods listing;
ods html;
ods rtf;

. . .

ods _all_ close;
```

You can also specify multiple instances of the same destination. For example, using the data in the section "Contour and Surface Plots with PROC KDE" on page 598, the following statements save the contour plot to the file *contour.pdf* and the surface plot to the file *surface.pdf*:

```
ods _all_ close;
ods pdf file="contour.pdf";
ods pdf select ContourPlot;
ods pdf(id=srf) file="surface.pdf";
ods pdf(id=srf) select SurfacePlot;
ods graphics on;

proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
   bivar x y / plots=contour surface;
run;

ods _all_ close;
```

The ID= option assigns the name **srf** to the second instance of the PDF destination. Without the ID= option, the second ODS PDF statement closes the destination that was opened by the previous ODS PDF statement,

and it opens a new instance of the PDF destination. In that case, the file *contour.pdf* is not created. For more information, see the ODS PDF statement in the *SAS Output Delivery System: User's Guide*.

Graph Size and Resolution

ODS provides options for specifying the size and resolution of graphs. You can specify the size of a graph in the ODS GRAPHICS statement and the resolution in an ODS destination statement. There are two other ways to change the size of a graph, but they are rarely needed. The three methods are as follows:

- Usually, you specify the WIDTH= or HEIGHT= option (or both) in the ODS GRAPHICS statement to change the size of a graph.
- To modify the size of a particular graph, specify the dimensions with the DESIGNHEIGHT= and DESIGNWIDTH= options in the BEGINGRAPH statement in the template. Some templates contain the specification DESIGNWIDTH=DEFAULTDESIGNHEIGHT, which sets the width of the graph to the default height, or DESIGNHEIGHT=DEFAULTDESIGNWIDTH, which sets the height of the graph to the default width.
- To modify the size of all of your ODS graphs, specify the dimensions with the OUTPUTHEIGHT= and OUTPUTWIDTH= options in the style template.

The following examples show typical ways to change the size of your graphs:

```
ods graphics on / width=6in;
ods graphics on / height=4in;
ods graphics on / width=4.5in height=3.5in;
```

The dimensions of the graph can be specified in pixels (for example, 200PX), inches (for example, 3IN), or centimeters (for example, 8CM). The default dimensions of ODS Graphics are 640 pixels wide and 480 pixels high, and these values determine the default aspect ratio. The actual size of the graph in inches depends on your printer or display device. For example, if the resolution of your printer is 100 dots per inch and you want a graph that is 4 inches wide, you should set the width to 400 pixels.

If you specify only one dimension, the other is determined by the default aspect ratio—that is, height=0.75 $\times$ width. For best results, you should create your graphs by using the exact size that is used to display the graphs in your paper or presentation. In other words, avoid generating them at one size and then expanding or shrinking them for inclusion into the your document.

By default, fonts and symbol markers are automatically scaled with the size of the graph. You can suppress this scaling with the SCALE= option, as in the following example:

```
ods graphics on / scale=off;
```

The default resolution of graphs created with HTML and LISTING is 96 DPI (dots per inch), whereas the default with RTF is 200 DPI. The 200 DPI value is recommended if you are copying and pasting graphs into a Microsoft PowerPoint presentation or a Microsoft Word document. Graphs shown in SAS/STAT documentation are typically generated at 300 DPI for display in PDF and 96 DPI for display in HTML.

You can change the resolution with the IMAGE_DPI= option in any ODS destination statement, as in the following example:

```
ods html image_dpi=300;
```

An increase in resolution often improves the quality of the graphs, but it also greatly increases the size of the image file. Going from 96 DPI to 300 DPI increases the size of the image file by roughly a factor of $(300/96)^2 = 9.77$. Even when you are using a higher DPI for most of your graphs, you should consider using a lower DPI for some, such as contour plots, that create large files even at a lower DPI.

If you increase the resolution, you might need to compensate by reducing the size of the graph, as in the following example:

```
ods graphics on / width=4.5in  height=3.5in;
```

Increasing DPI also increases the amount of memory needed for your program to complete. You can increase the amount of memory available to ODS Graphics with an option when you invoke SAS, as in the following example:

```
-jreoptions '(-Xmx256m)'
```

You can modify the default amount of memory available to ODS Graphics by changing JREOPTIONS in your SAS configuration file to the settings –Xmx*nnn*m –Xms*nnn*m, where *nnn* is the amount of memory in megabytes. An example is –Xmx256m –Xms256m. In either case, the exact syntax varies depending on your operating system and the amount of memory that you can allocate varies from system to system. For more information, see the *SAS Companion* for your operating system.

ODS Graphics Editor

The ODS Graphics Editor is a point-and-click interface that you can use to modify a specific graph created by ODS Graphics. For example, if you need to enhance a graph for a paper or presentation, you can use the ODS Graphics Editor to customize the title, modify the axis labels, annotate particular data points, and change graph element properties such as fonts, colors, and line styles.

This section explains how to enable ODS Graphics to create editable graphs and how to invoke the ODS Graphics Editor. You can use the ODS Graphics Editor in the SAS windowing environment, provided that the LISTING destination is open and that you have first enabled ODS Graphics to create editable graphs. **NOTE:** The LISTING destination is typically open by default. There are three steps you must take to edit a graph:

1 You must first enable the creation of editable graphs in one of three ways:
   - use an ODS statement to temporarily enable this feature
   - use a SAS command to temporarily enable this feature
   - use the SAS Registry Editor to permanently enable this feature

   Creating editable graphs takes additional resources, so you might not want to permanently enable this feature.

2 You submit your SAS code and create editable graphs.

3 You invoke the ODS Graphics Editor and edit the plot.

Step 2 involves submitting SAS code in the usual way, and no special instructions are needed for creating graphs that can be edited. Steps 1 and 3 are explained in more detail in the following sections.

Enabling the Creation of Editable Graphs

Temporarily Enable Creation of Editable Graphs by Using an ODS Statement

You can enable the creation of editable graphs within a SAS session by submitting one of the following statements:

```
ods listing sge=on;
ods html sge=on;
```

You can disable the creation of editable graphs by submitting one of the following statements:

```
ods listing sge=off;
ods html sge=off;
```

Temporarily Enable Creation of Editable Graphs by Using a SAS Command

Alternatively, you can enable the creation of editable graphs for the duration of your SAS session by first selecting the Results window and then entering `sgedit on` on the command line. SAS confirms that the creation of editable graphs is enabled by displaying a message in the bottom left corner of the SAS window. The command must be entered from the Results window. If you enter it from any other window, it is ignored.

Permanently Enable Creation of Editable Graphs across SAS Sessions

You can create a default setting that enables or disables the creation of editable graphs across SAS sessions via the 'ODS Graphics Editor' setting in the SAS Registry. You can change this setting in the SAS windowing environment as follows:

1 Open the Registry Editor by entering **regedit** on the command line.

2 Select **SAS_REGISTRY ► ODS ► GUI ► RESULTS**.

3 In the **Value Data** field, click **ODS Graphics Editor** to open the Edit String Value window, and type **On** to enable the creation of editable graphs or type **Off** to disable it.

4 Click **OK**.

Editing a Graph with the ODS Graphics Editor

The ODS Graphics Editor is illustrated using the following example:

```
data sasuser.growth;
   input country $ GDP LFG EQP NEQ GAP;
   datalines;
Argentin  0.0089 0.0118 0.0214 0.2286 0.6079
Austria   0.0332 0.0014 0.0991 0.1349 0.5809

   ... more lines ...

Zambia   -0.0110 0.0275 0.0702 0.2012 0.8695
Zimbabwe  0.0110 0.0309 0.0843 0.1257 0.8875
;

ods graphics on;
ods html style=Statistical sge=on;

proc robustreg data=sasuser.growth
               plots=(ddplot histogram);
   model GDP  = LFG GAP EQP NEQ / diagnostics leverage;
   output out=robout r=resid sr=stdres;
run;

ods _all_ close;
ods listing;
```

The DATA and the PROC ROBUSTREG steps are submitted to the SAS System, in this case from the SAS windowing environment, as shown in Figure 21.16. Two versions of the graph are created: one in an uneditable PNG file (for example, *DDPlot.png*) and one in an editable SGE file (for example, *DDPlot.sge*). Both are saved in the SAS current folder. You can edit the graph in one of three ways:

- In the Results window, double-click the second graph icon for the graph you want to edit (see Figure 21.16). The second icon corresponds to the SGE file, and the first icon corresponds to the PNG file. Clicking the first graph icon invokes a host-dependent graph viewer (for example, Microsoft Photo Editor on Windows), not the ODS Graphics Editor. **NOTE:** The Editor window might be hidden behind other windows in the SAS windowing environment.
- You can edit the graph by selecting it in the SAS Explorer window. You must first navigate to the SAS current folder and to the SGE files.
- You can open the graph from outside of the SAS System. For example, if you are running the SAS System under the Windows operating system, you can click on the graph's SGE file to open it with the ODS Graphics Editor.

Figure 21.16 Results Window with Icons for Editable Plots

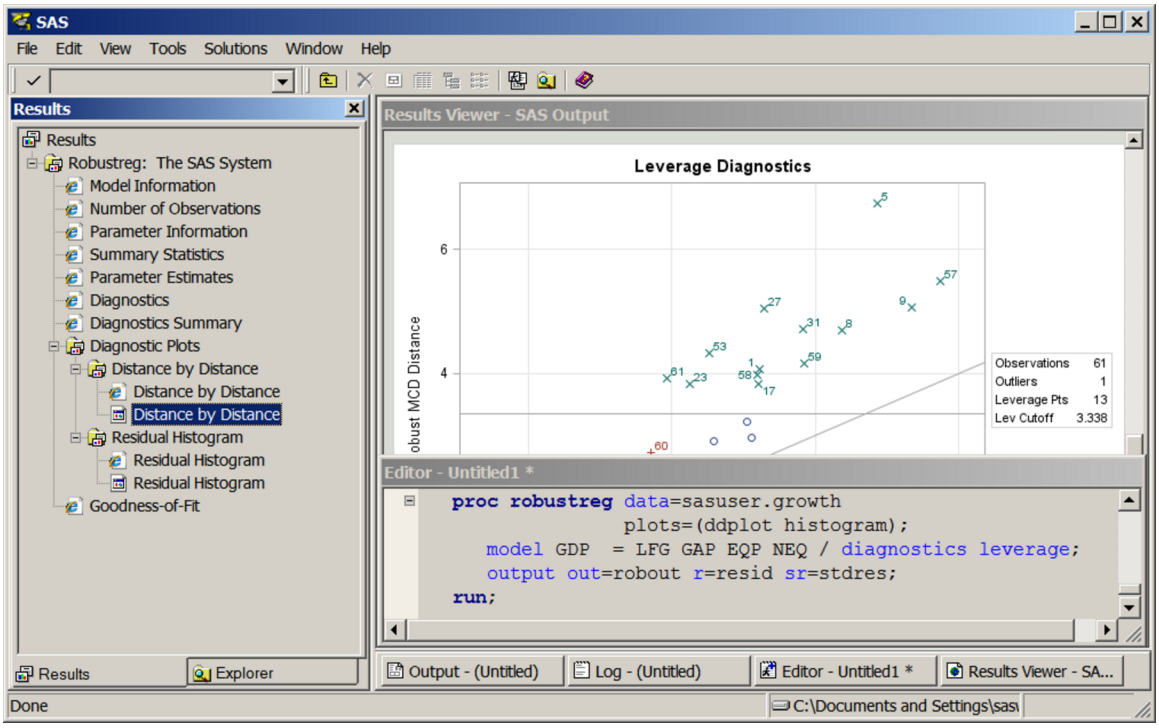

Figure 21.17 shows the ODS Graphics Editor window for the editable diagnostic plot created by PROC ROBUSTREG. In Figure 21.18, various tools in the ODS Graphics Editor are used to modify the title and annotate a particular point. The edited plot can be saved as a PNG file or as an SGE file by selecting **File ► Save As**. After saving the plot, you can edit it again through the SAS Explorer window or by selecting **File ► Open** from the ODS Graphics Editor window. Alternatively, you can reopen the saved plot for editing without first invoking the SAS System. For example, if you are running the SAS System under the Windows operating system, you can click on the plot to open it with the ODS Graphics Editor.

The ODS Graphics Editor does not permit you to make structural changes to a graph (such as moving the positions of data points). The ODS Graphics Editor provides you with a point-and-click way to make one-time changes to a specific graph, whereas the template language (see the section "Graph Templates" on page 716 in Chapter 22, "ODS Graphics Template Modification,") provides you with a programmatic way to make template changes that persist every time you run the procedure. For complete details about the tools available in the ODS Graphics Editor, see *SAS ODS Graphics Editor: User's Guide*.

Figure 21.17 Diagnostic Plot before Editing

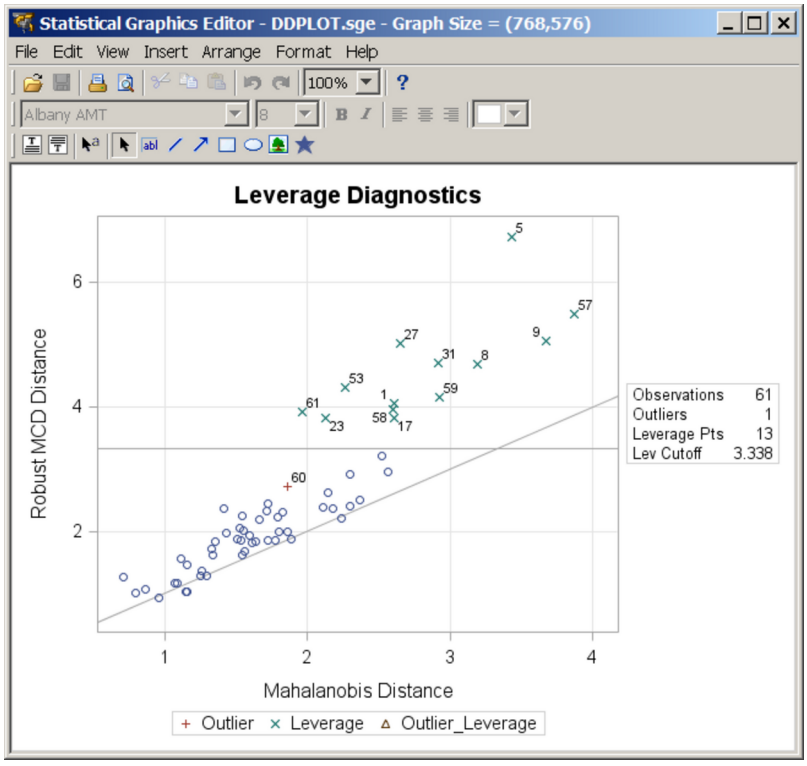

Figure 21.18 Diagnostic Plot after Editing

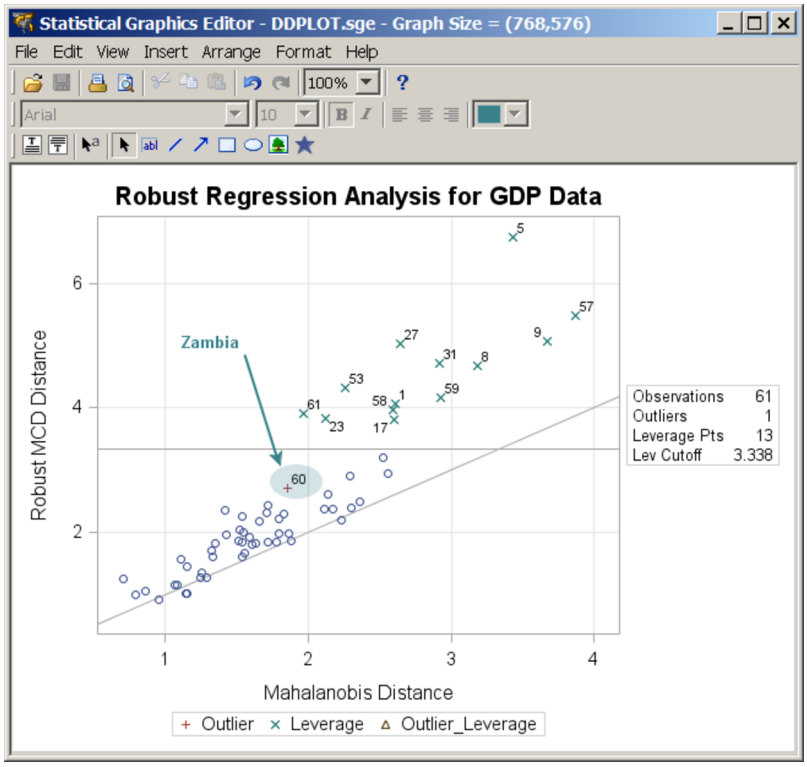

The Default Template Stores and the Template Search Path

Compiled templates are stored in a template store, which is a type of item store. (An item store is a special type of SAS file.) You can see the list of template stores by submitting the following statement:

```
ods path show;
```

The results are as follows:

```
Current ODS PATH list is:

1. SASUSER.TEMPLAT(UPDATE)
2. SASHELP.TMPLMST(READ)
```

These results show that the default template search path consists of Sasuser.Templat followed by Sashelp.Tmplmst. You can add template stores that you create or change the order in which the template stores are searched. This is discussed in detail in the sections "Saving Customized Templates" on page 725, "Using Customized Templates" on page 726, and "Reverting to the Default Templates" on page 727 in Chapter 22, "ODS Graphics Template Modification."

This section discusses the default template stores that you use when you have not modified the template search path with the ODS PATH statement. By default, templates that you write are stored in Sasuser.Templat. If you stored a modified template in Sasuser.Templat, ODS finds and uses your modified template. Otherwise, ODS finds the templates it provides in Sashelp.Tmplmst. You can see a list of all of the templates that you have modified as follows:

```
proc template;
   list / store=sasuser.templat;
run;
```

You can delete any template that you modified (so that ODS finds the default SAS template) by specifying it in a DELETE statement, as in the following statement:

```
proc template;
   delete Stat.REG.Graphics.ResidualPlot;
run;
```

Unless you have administrator privileges, ODS never deletes a template in Sashelp.Tmplmst, so you can safely run the preceding step, even if the template you specify does not exist in Sasuser.Templat. You can run the following step to delete the entire Sasuser.Templat template store of customized templates so that ODS uses only the templates supplied by the SAS System:

```
ods path sashelp.tmplmst(read);
proc datasets library=sasuser nolist;
   delete templat(memtype=itemstor);
run;
ods path sasuser.templat(update) sashelp.tmplmst(read);
```

It is good practice to delete templates that you have customized when you are done with them, so that they are not unexpectedly used later. See the section "Reverting to the Default Templates" on page 727 in Chapter 22, "ODS Graphics Template Modification," for more information.

Styles

ODS styles control the overall appearance of your output. Usually, the only thing you need to do with styles is specify them in an ODS destination statement, as in the following example:

```
ods html body='b.html' style=HTMLBlue;
```

However, you can also modify existing styles and even write your own styles. You can also specify style elements in custom templates that you write, or you can modify which style elements are used in templates supplied by SAS. This section provides an overview of styles and style elements, which are the components of a style. It also describes how to customize a style template and how to specify a default style for your output. Only the most commonly used styles, style elements, and style changes are discussed here. For complete details about styles, see the *SAS Output Delivery System: User's Guide*.

An Overview of Styles

An ODS style template provides formatting information for specific visual aspects of your SAS output (see the section "Style Elements and Attributes" on page 650). The appearance of tables and graphs is coordinated within a particular style. For tables, this information includes a list of fonts and a list of colors. Each font definition specifies a family, size, weight, and style. Colors are associated with common areas of output, including titles, footnotes, BY groups, table headers, and table cells. For graphs, styles also control the appearance of graph elements including lines, markers, fonts and colors. ODS styles also include elements specific to statistical graphics, such as the style of fitted lines, confidence bands, and prediction limits. For more information about styles, see Kuhfeld (2010) and the *SAS Output Delivery System: User's Guide*.

You can specify a style by using the STYLE= option in an ODS destination statement such as HTML, PDF, RTF, or PRINTER. You can also specify a style in the LISTING destination; however, it affects graphs but not tables. Output produced with different styles has the same content, but a different visual appearance. For example, the following statement requests output produced with the JOURNAL style:

```
ods rtf style=Journal;
```

You can use any SAS style or any style that you define yourself. The following statements list the names of all of the styles and then display five of them:

```
proc template;
   list styles;
   source Styles.Default;
   source Styles.Statistical;
   source Styles.Journal;
   source Styles.RTF;
   source Styles.HTMLBlue;
run;
```

The results of this step (not shown) are a list of over fifty styles in the SAS listing and five style templates in the SAS log. Style templates are often hundreds of lines long. See the section "Style Templates and Colors" on page 651 for more information about style templates. Although you can use any style, only a few styles are typically used with ODS Graphics. They are described in Table 21.2.

Table 21.2 Styles

Style	Default in	Description
HTMLBLUE	HTML and SAS/STAT documentation	An all-color style whose dominant colors are shades of blue with sans-serif fonts. See Figure 21.20.
HTMLBLUECML		A color style whose dominant colors are shades of blue with sans-serif fonts. See Figure 21.21.
DEFAULT	HTML	A color style whose dominant colors are gray, blue, and white, with bold sans-serif fonts. See Figure 21.19.
STATISTICAL		A color style whose dominant colors are blue, creamy gray, and white, with sans-serif fonts. See Figure 21.22.
LISTING	LISTING	A color style, similar to DEFAULT but with a white background. See Figure 21.25.
JOURNAL		A black-and-white style with filled areas, with sans-serif fonts. See Figure 21.24.
JOURNAL2		A black-and-white style, similar to JOURNAL but with empty areas. Grouped bar charts use crosshatching to show groups. See Output 21.3.2.
JOURNAL3		A black-and-white style, similar to JOURNAL2 but with a mix of filled areas and crosshatching in grouped bar charts. See Output 21.3.3.
RTF	RTF	A color style whose dominant colors are blue, white, and black, with Times Roman fonts. See Figure 21.26.
ANALYSIS		A color style, similar to STATISTICAL, whose dominant color is tan. See Figure 21.23.

Each ODS destination has its own default style, as shown in Table 21.2. Most output in SAS/STAT documentation uses the HTMLBLUE style. However, throughout this chapter, you can see examples of other styles. For more information about styles, see the *SAS Output Delivery System: User's Guide*.

Style Elements and Attributes

An ODS style template is composed of a set of *style elements*. A style element is a collection of *style attributes* that applies to a particular feature or aspect of the output. A value is specified for each attribute in a style template. For example, **`GraphFit`** is the style element used for fit lines, and its attributes include: **`LineThickness`**, **`LineStyle`**, **`MarkerSize`**, **`MarkerSymbol`**, **`ContrastColor`**, and **`Color`**.

In general, style templates control the overall appearance of ODS tables and graphs. For tables, style templates specify features such as background color, table borders, and color scheme, and they specify the fonts, sizes, and color for the text and values in a table and its headers. For graphs, style templates specify the following features:

- background color
- graph dimensions (height and width)
- borders
- line styles for axes and grid lines
- fonts, sizes, and colors for titles, footnotes, axis labels, axis values, and data labels (see the section "Modifying Graph Fonts in Styles" on page 684 for an illustration)
- marker symbols, colors, and sizes for data points and outliers
- line styles for needles
- line and curve styles for fitted models and predicted values (see the section "Modifying Other Graph Elements in Styles" on page 687 for an illustration)
- line and curve styles for confidence and prediction limits
- fill colors for histogram bars, confidence bands, and confidence ellipses
- colors for box plot features
- colors for surfaces
- color ramps for contour plots

The SAS System supplies a graph template for each graph that is created by statistical procedures. A graph template is a program that specifies the layout and details of a graph. See the section "Graph Templates" on page 716 in Chapter 22, "ODS Graphics Template Modification," for more information about templates. Some template options are specified with a style reference of the form **`style-element`**, or occasionally

style-element:attribute. For example, the symbol, color, and size of markers for basic scatter plots are specified in a template SCATTERPLOT statement as follows:

```
scatterplot x=x y=y / markerattrs=GraphDataDefault;
```

The preceding statement specifies that the appearance for markers is controlled by the **GraphDataDefault** element. Consistent use of this element guarantees a common appearance of markers across all scatter plots, based on the style template that you are using.

In general, ODS Graphics features are determined by style element attributes unless they are overridden by a statement or option in the graph template. For example, suppose that a classification variable is specified with the GROUP= option in a SCATTERPLOT template statement as follows:

```
scatterplot x=X y=Y / group=GroupVar;
```

Then the colors for markers that correspond to the classification levels are assigned by using the style element attributes **GraphData1:ContrastColor** through **GraphData12:ContrastColor**.

Style templates are created and modified with PROC TEMPLATE. For more information, see the *SAS Output Delivery System: User's Guide*. You need to understand the relationships between style elements and graph features if you want to create your own style template or modify a style template. These relationships are explained in the following sections.

Style Templates and Colors

The default style templates that the SAS System provides are stored in the *Styles* directory of Sashelp.Tmplmst. You can display, edit, and save style templates by using the same methods available for modifying graph and table templates, as explained in the section "The Default Template Stores and the Template Search Path" on page 647 and the series of sections beginning with the section "Displaying Templates" on page 722 in Chapter 22, "ODS Graphics Template Modification." In particular, you can display a style template by using one of these methods:

- From the Templates window in the SAS windowing environment, expand the Sashelp.Tmplmst node under **Templates**, and then select **Styles** to display the contents of this folder. To open the Templates window, type **odst** on the command line.
- Use the SOURCE statement in PROC TEMPLATE.

For example, the following statements display the DEFAULT style template in the SAS log:

```
proc template;
   source Styles.Default;
run;
```

Some of the results are as follows:

```
define style Styles.Default;
   . . .
   class GraphColors
      "Abstract colors used in graph styles" /
      . . .
      'gconramp3cend' = cxFF0000
      'gconramp3cneutral' = cxFF00FF
      'gconramp3cstart' = cx0000FF
      . . .
      'gdata12' = cxDDD17E
      'gdata11' = cxB7AEF1
      'gdata10' = cx87C873
      'gdata9' = cxCF974B
      'gdata8' = cxCD7BA1
      'gdata6' = cxBABC5C
      'gdata7' = cx94BDE1
      'gdata4' = cxA9865B
      'gdata5' = cxB689CD
      'gdata3' = cx66A5A0
      'gdata2' = cxDE7E6F
      'gdata1' = cx7C95CA;
   . . .
```

The first part of this list shows that the shading for certain filled plots, such as some contour plots goes from blue (**'gconramp3cstart' = cx0000FF**) to magenta (**'gconramp3cneutral' = cxFF00FF**) to red (**'gconramp3cend' = cxFF0000**). All colors are specified in values of the form CX*rrggbb*, where the last six characters specify RGB (red, green, blue) values on the hexadecimal scale of 00 to FF (or 0 to 255 base 10). The second part of the list (**'gdata1' = cx7C95CA**) shows that the dominant component of the **GraphData1** color is blue because the blue component of the color (CA, which corresponds to 202 base 10) is greater than both the green component (95, which corresponds to 149 base 10) and the red component (7C, which corresponds to 124 base 10).

You can change any part of the style and then submit the style back into the SAS System, after first submitting a PROC TEMPLATE statement. See the sections "Saving Customized Templates" on page 725, "Using Customized Templates" on page 726, and "Reverting to the Default Templates" on page 727 in Chapter 22, "ODS Graphics Template Modification," for more information about modifying, using, and restoring templates. The principles discussed in those sections apply to all templates—table, style, and graph.

Some Common Style Elements

This section explains some common style elements and produces most of the graphs displayed in the section "Style Comparisons" on page 658.

The DEFAULT style is the parent for the styles used for statistical graphics work. You can see all of the elements of the DEFAULT style by running the following step:

```
proc template;
   source styles.default;
run;
```

The source listing of the definition of the DEFAULT style is hundreds of lines long. If you run PROC TEMPLATE with the SOURCE statement for most other styles, you see **`parent = styles.default`** (or in the case of the HTMLBLUE style, you see **`parent = styles.statistical`**, which inherits from the DEFAULT style), and you do not see all of the elements in the style unless you also run the preceding step with a SOURCE statement for all parent styles.

Only a few of the style elements are referenced in the templates that the SAS System provides for statistical procedures. The most commonly used style elements, along with the defaults for the noncolor attributes of the DEFAULT style, are shown next (**`Color`** applies to filled areas, and **`ContrastColor`** applies to markers and lines):

`Graph`	graph size, outer border appearance, and background color
	`Padding = 0`
	`BackgroundColor`
`GraphConfidence`	primary fit confidence interval
	`LineThickness = 1px`
	`LineStyle = 1`
	`MarkerSize = 7px`
	`MarkerSymbol = "triangle"`
	`ContrastColor`
	`Color`
`GraphData1`	attributes related to first grouped data items
	`MarkerSymbol = "circle"`
	`LineStyle = 1`
	`ContrastColor`
	`Color`
`GraphData2`	attributes related to second grouped data items
	`MarkerSymbol = "plus"`
	`LineStyle = 4`
	`ContrastColor`
	`Color`
`GraphData3`	attributes related to third grouped data items
	`MarkerSymbol = "X"`
	`LineStyle = 8`
	`ContrastColor`
	`Color`
`GraphData4`	attributes related to fourth grouped data items
	`MarkerSymbol = "triangle"`
	`LineStyle = 5`
	`ContrastColor`
	`Color`
`GraphData`*n*	attributes related to *n*th grouped data items
	`MarkerSymbol`
	`LineStyle`
	`ContrastColor`
	`Color`

GraphDataDefault	attributes related to data items that are not grouped **EndColor** **NeutralColor** **StartColor** **MarkerSize = 7px** **MarkerSymbol = "circle"** **LineThickness = 1px** **LineStyle = 1** **ContrastColor** **Color**
GraphFit	primary fit line, such as a normal density curve **LineThickness = 2px** **LineStyle = 1** **MarkerSize = 7px** **MarkerSymbol = "circle"** **ContrastColor** **Color**
GraphFit2	secondary fit line, such as a kernel density curve **LineThickness = 2px** **LineStyle = 4** **MarkerSize = 7px** **MarkerSymbol = "X"** **ContrastColor** **Color**
GraphGridLines	horizontal and vertical grid lines drawn at major tick marks **Displayopts = "auto"** **LineThickness = 1px** **LineStyle = 1** **ContrastColor** **Color**
GraphOutlier	outlier data for the graph **LineThickness = 2px** **LineStyle = 42** **MarkerSize = 7px** **MarkerSymbol = "circle"** **ContrastColor** **Color**
GraphPredictionLimits	fills for prediction limits **LineThickness = 1px** **LineStyle = 2** **MarkerSize = 7px** **MarkerSymbol = "chain"** **ContrastColor** **Color**

GraphReference	horizontal and vertical reference lines and drop lines **LineThickness = 1px** **LineStyle = 1** **ContrastColor**
GraphDataText	text font and color for point and line labels **Font = GraphFonts('GraphDataFont')** (where **'GraphDataFont' = ("<sans-serif>, <MTsans-serif>",7pt)**) **Color**
GraphValueText	text font and color for axis tick values and legend values **Font = GraphFonts('GraphValueFont')** (where **'GraphValueFont' = ("<sans-serif>, <MTsans-serif>",9pt)**) **Color**
GraphLabelText	text font and color for axis labels and legend title **Font = GraphFonts('GraphLabelFont')** (where **'GraphLabelFont' = ("<sans-serif>, <MTsans-serif>",10pt,bold)**) **Color**
GraphFootnoteText	text font and color for footnotes **Font = GraphFonts('GraphFootnoteFont')** (where **'GraphFootnoteFont' = ("<sans-serif>, <MTsans-serif>",10pt)**) **Color**
GraphTitleText	text font and color for titles **Font = GraphFonts('GraphTitleFont')** (where **'GraphTitleFont' = ("<sans-serif>, <MTsans-serif>",11pt,bold)**) **Color**
GraphWalls	vertical walls bounded by axes **LineThickness = 1px** **LineStyle = 1** **FrameBorder = on** **ContrastColor** **BackgroundColor** **Color**

You refer to these elements in graph templates as **style-element** or as **style-element:attribute** (for example **GraphDataDefault:ContrastColor**). The default values are not shown for the color attributes since they are typically defined indirectly. For example, **Graph:BackgroundColor** (the color that fills the box outside the graph) is defined elsewhere in the style as **colors('docbg')**. The style also defines **'docbg' = color_list('bgA')** and **'bgA' = cxE0E0E0**. This shows that the background is a shade of gray that is much closer to white (CXFFFFFF) than to black (CX000000). You can see the background color in Figure 21.27. This shade of gray might seem darker (closer to CX000000) than you might expect based on just the RGB values. Your perception of a color change is not a linear function of the change in RGB values.

You can use the following program to see the color and other attributes for a number of style elements:

```
proc format; value vf 5 = 'GraphValueText'; run;

data x1;
   array y[20] y0 - y19;
   do x = 1 to 20; y[x] = x - 0.5; end;
   do x = 0 to 10 by 5; output; end;
   label y0 = 'GraphLabelText' x = 'GraphLabelText';
   format x y0 vf.;
run;

%macro d;
   %do i = 1 %to 12;
      reg y=y%eval(19-&i) x=x / lineattrs=GraphData&i markerattrs=GraphData&i
                                curvelabel="  GraphData&i" curvelabelpos=max;
   %end;
%mend;

%macro l(i, l);
   reg y=y&i x=x / lineattrs=&l markerattrs=&l curvelabel="  &l"
                   curvelabelpos=max;
%mend;

ods listing style=default;

proc sgplot noautolegend data=x1;
   title 'GraphTitleText';
   %d
   %l(19, GraphDataDefault)
   %l( 6, GraphFit)
   %l( 5, GraphFit2)
   %l( 4, GraphPredictionLimits)
   %l( 3, GraphConfidence)
   %l( 2, GraphGridLines)
   %l( 1, GraphOutlier)
   %l( 0, GraphReference)
   xaxis values=(0 5 10);
run;
```

The results in Figure 21.27 display the attributes for a number of the elements of the DEFAULT style.

When there is a group or classification variable, the colors, markers, and lines that distinguish the groups are derived from the **GraphData***n* elements that are defined with the style. In the DEFAULT style, these are elements **GraphData1** through **GraphData12**. There can be any number of groups even though only 12 **GraphData***n* style elements are defined in the DEFAULT style. The following steps create a data set with 40 groups, display one line per group, and produce Figure 21.35:

```
data x2;
   do y = 40 to 1 by -1;
      group = 'Group' || put(41 - y, 2. -L);
      do x = 0 to 10 by 5;
         if x = 10 then do; z = 11; l = group; end;
         else           do; z = .;  l = ' ';   end;
         output;
      end;
   end;
run;

proc sgplot data=x2;
   title 'Colors, Markers, Lines Patterns for Groups';
   series  y=y x=x / group=group markers;
   scatter y=y x=z / group=group markerchar=l;
run;
```

The colors, markers, and line patterns in Figure 21.35 repeat in cycles. The **GraphData1** – **GraphData8** lines in Figure 21.27 exactly match the **Group1** – **Group8** lines in Figure 21.35. After that, there are differences due to the cyclic construction of the grouped style. This is explained next.

The DEFAULT style defines a marker symbol only in **GraphData1** through **GraphData7**. The seven markers are: circle, plus, X, triangle, square, asterisk, and diamond. With the explicit style reference in Figure 21.27, the actual symbol, when no symbol is specified, is the circle. This is what you see for **GraphData8** through **GraphData12**. With the group variable in Figure 21.35, the symbols repeat in cycles. Hence, **Group1**, **Group8**, **Group15**, and so on, are all circles. Similarly, **Group2**, **Group9**, **Group16**, and so on, are all pluses. The DEFAULT style defines 11 different line styles for **GraphData1** through **GraphData11**. You specify line styles by specifying an integer. The default lines styles are: 1, 4, 8, 5, 14, 26, 15, 20, 41, 42, and 2. Hence, **Group1**, **Group12**, **Group23**, and so on, all have the same line style, which is a solid line (line style 1). Similarly, **Group2**, **Group13**, **Group24**, and so on, all have line style 4. There are twelve different colors, so **Group1**, **Group13**, **Group25**, and so on, all have the same colors. Overall, there are $12 \times 11 \times 7 = 924$ color/line/marker combinations that appear before any combination repeats. You can use the %MODSTYLE SAS autocall macro (see the sections "Creating an All-Color Style" on page 678 and "Style Template Modification Macro" on page 676) to conveniently change these style attributes.

The HTMLBLUE style is an all-color style for the first 12 groups of observations. Most analyses have fewer than 12 groups. Markers and lines change for groups 13–24 and then again for groups 25–36. Figure 21.36 shows how colors, markers, and line styles change in the HTMLBLUE style. Figure 21.35 and Figure 21.36 through Figure 21.42 show how these elements change in other styles.

Style Comparisons

In this section, some of the most commonly used styles are compared with a series of figures, most of which were generated in the preceding section. Figure 21.19 through Figure 21.26 show tables and graphs in each of eight styles, for the following analysis:

```
proc reg data=sashelp.class;
   model Weight = Height;
run; quit;
```

Figure 21.27 through Figure 21.34 show some of the more common style elements. Figure 21.35 through Figure 21.42 show how groups of observations are displayed in the graph.

The style comparisons are as follows:

- Figure 21.19, Figure 21.27, and Figure 21.35 show the DEFAULT style.
- Figure 21.20, Figure 21.28, and Figure 21.36 show the HTMLBLUE style.
- Figure 21.21, Figure 21.29, and Figure 21.37 show the HTMLBLUECML style.

Modifying the HTMLBLUE Style

The HTMLBLUE style is an all-color style for the first 12 groups of observations. After each set of 12 groups, the line style and marker change for the next 12 groups. See Figure 21.36. The HTMLBLUECML style is a color style in which groups of observations are distinguished by simultaneous color, line style, and symbol changes. See Figure 21.37. For some graphs, you might want more differentiation than you get in an all-color style like HTMLBLUE but without the overkill differentiation of the HTMLBLUECML style and other styles. This section defines four new styles for this purpose:

HTMLBLUEL – line styles and colors vary together with fixed markers for each set of 11 groups
HTMLBLUEM – markers and colors vary together with fixed line styles for each set of 11 groups
HTMLBLUEFL – line styles and colors vary together with fixed filled markers for each set of 11 groups
HTMLBLUEFM – filled markers and colors vary together with fixed line styles for each set of 5 groups

The following statements show part of the style definition for each of these styles:

```
define style Styles.HTMLBlueL;    parent = styles.htmlbluecml;
   style GraphFit2   from GraphFit2   /                          linestyle = 1;
   style GraphData1  from GraphData1  / markersymbol = "circle" linestyle = 1;
   style GraphData2  from GraphData2  / markersymbol = "circle" linestyle = 4;
   style GraphData3  from GraphData3  / markersymbol = "circle" linestyle = 8;
   style GraphData4  from GraphData4  / markersymbol = "circle" linestyle = 5;
   style GraphData5  from GraphData5  / markersymbol = "circle" linestyle = 14;
   style GraphData6  from GraphData6  / markersymbol = "circle" linestyle = 26;
   style GraphData7  from GraphData7  / markersymbol = "circle" linestyle = 15;
   style GraphData8  from GraphData8  / markersymbol = "circle" linestyle = 20;
   style GraphData9  from GraphData9  / markersymbol = "circle" linestyle = 41;
   style GraphData10 from GraphData10 / markersymbol = "circle" linestyle = 42;
   style GraphData11 from GraphData11 / markersymbol = "circle" linestyle = 2;
   style GraphData12 from GraphData12 / markersymbol = "square" linestyle = 1;
   style GraphData13 from GraphData1  / markersymbol = "square" linestyle = 4;
   style GraphData14 from GraphData2  / markersymbol = "square" linestyle = 8;
   style GraphData15 from GraphData3  / markersymbol = "square" linestyle = 5;
   . . .
end;
define style Styles.HTMLBlueM;    parent = styles.htmlbluecml;
   style GraphFit2   from GraphFit2   /                                  linestyle = 1;
   style GraphData1  from GraphData1  / markersymbol = "circle"          linestyle = 1;
   style GraphData2  from GraphData2  / markersymbol = "square"          linestyle = 1;
   style GraphData3  from GraphData3  / markersymbol = "diamond"         linestyle = 1;
   style GraphData4  from GraphData4  / markersymbol = "asterisk"        linestyle = 1;
   style GraphData5  from GraphData5  / markersymbol = "plus"            linestyle = 1;
   style GraphData6  from GraphData6  / markersymbol = "triangle"        linestyle = 1;
   style GraphData7  from GraphData7  / markersymbol = "circlefilled"    linestyle = 1;
   style GraphData8  from GraphData8  / markersymbol = "starfilled"      linestyle = 1;
   style GraphData9  from GraphData9  / markersymbol = "squarefilled"    linestyle = 1;
   style GraphData10 from GraphData10 / markersymbol = "diamondfilled"   linestyle = 1;
   style GraphData11 from GraphData11 / markersymbol = "trianglefilled" linestyle = 1;
   style GraphData12 from GraphData12 / markersymbol = "circle"          linestyle = 4;
   style GraphData13 from GraphData1  / markersymbol = "square"          linestyle = 4;
   style GraphData14 from GraphData2  / markersymbol = "diamond"         linestyle = 4;
   style GraphData15 from GraphData3  / markersymbol = "asterisk"        linestyle = 4;
   . . .
```

```
end;
define style Styles.HTMLBlueFL;    parent = styles.htmlbluecml;
   style GraphFit2   from GraphFit2   /                                linestyle = 1;
   style GraphData1  from GraphData1  / markersymbol = "circlefilled" linestyle = 1;
   style GraphData2  from GraphData2  / markersymbol = "circlefilled" linestyle = 4;
   style GraphData3  from GraphData3  / markersymbol = "circlefilled" linestyle = 8;
   style GraphData4  from GraphData4  / markersymbol = "circlefilled" linestyle = 5;
   style GraphData5  from GraphData5  / markersymbol = "circlefilled" linestyle = 14;
   style GraphData6  from GraphData6  / markersymbol = "circlefilled" linestyle = 26;
   style GraphData7  from GraphData7  / markersymbol = "circlefilled" linestyle = 15;
   style GraphData8  from GraphData8  / markersymbol = "circlefilled" linestyle = 20;
   style GraphData9  from GraphData9  / markersymbol = "circlefilled" linestyle = 41;
   style GraphData10 from GraphData10 / markersymbol = "circlefilled" linestyle = 42;
   style GraphData11 from GraphData11 / markersymbol = "circlefilled" linestyle = 2;
   style GraphData12 from GraphData12 / markersymbol = "starfilled"   linestyle = 1;
   style GraphData13 from GraphData1  / markersymbol = "starfilled"   linestyle = 4;
   style GraphData14 from GraphData2  / markersymbol = "starfilled"   linestyle = 8;
   style GraphData15 from GraphData3  / markersymbol = "starfilled"   linestyle = 5;
   . . .
end;
define style Styles.HTMLBlueFM;    parent = styles.htmlbluecml;
   style GraphFit2   from GraphFit2   /                                  linestyle = 1;
   style GraphData1  from GraphData1  / markersymbol = "circlefilled"   linestyle = 1;
   style GraphData2  from GraphData2  / markersymbol = "starfilled"     linestyle = 1;
   style GraphData3  from GraphData3  / markersymbol = "squarefilled"   linestyle = 1;
   style GraphData4  from GraphData4  / markersymbol = "diamondfilled"  linestyle = 1;
   style GraphData5  from GraphData5  / markersymbol = "trianglefilled" linestyle = 1;
   style GraphData6  from GraphData6  / markersymbol = "circlefilled"   linestyle = 4;
   style GraphData7  from GraphData7  / markersymbol = "starfilled"     linestyle = 4;
   style GraphData8  from GraphData8  / markersymbol = "squarefilled"   linestyle = 4;
   style GraphData9  from GraphData9  / markersymbol = "diamondfilled"  linestyle = 4;
   style GraphData10 from GraphData10 / markersymbol = "trianglefilled" linestyle = 4;
   style GraphData11 from GraphData11 / markersymbol = "circlefilled"   linestyle = 8;
   style GraphData12 from GraphData12 / markersymbol = "starfilled"     linestyle = 8;
   style GraphData13 from GraphData1  / markersymbol = "squarefilled"   linestyle = 8;
   style GraphData14 from GraphData2  / markersymbol = "diamondfilled"  linestyle = 8;
   style GraphData15 from GraphData3  / markersymbol = "trianglefilled" linestyle = 8;
   . . .
end;
```

New **GraphData***n* style elements are created that inherit colors from the **GraphData1** through **GraphData12** style elements. The line styles and markers are explicitly set in the new style definitions. The **style GraphFit2 from GraphFit2 / linestyle = 1** statement creates a solid second fit line. You can remove that statement if you prefer a dashed second fit line.

The following statements use SAS macros to generate these four new styles:

```
proc template;
   %let m = circle square diamond asterisk plus triangle circlefilled
            starfilled squarefilled diamondfilled trianglefilled;
   %let ls = 1 4 8 5 14 26 15 20 41 42 2;
   %macro makestyle;
      %let l = %eval(%sysfunc(mod(&k,12))+1);
      %let k = %eval(&k+1);
      style GraphData&k from GraphData&l /
            linestyle=%scan(&ls, &j) markersymbol="%scan(&m, &i)";
      %mend;
```

```
define style styles.HTMLBlueL;
   parent=styles.htmlbluecml;
   style GraphFit2 from GraphFit2 / linestyle = 1;
   %macro htmlbluel;
      %let k = 0;
      %do i = 1 %to 11; %do j = 1 %to 11; %makestyle %end; %end;
      %mend;
    %htmlbluel
    end;
define style styles.HTMLBlueM;
   parent=styles.htmlbluecml;
   style GraphFit2 from GraphFit2 / linestyle = 1;
   %macro htmlbluem;
      %let k = 0;
      %do j = 1 %to 11; %do i = 1 %to 11; %makestyle %end; %end;
      %mend;
    %htmlbluem
    end;
%let m = circlefilled starfilled squarefilled diamondfilled trianglefilled;
define style styles.HTMLBlueFL;
   parent=styles.htmlbluecml;
   style GraphFit2 from GraphFit2 / linestyle = 1;
   %macro htmlbluel;
      %let k = 0;
      %do i = 1 %to 5; %do j = 1 %to 11; %makestyle %end; %end;
      %mend;
    %htmlbluel
    end;
define style styles.HTMLBlueFM;
   parent=styles.htmlbluecml;
   style GraphFit2 from GraphFit2 / linestyle = 1;
   %macro htmlbluem;
      %let k = 0;
      %do j = 1 %to 11; %do i = 1 %to 5; %makestyle %end; %end;
      %mend;
    %htmlbluem
    end;
run;
```

The %LET m statement provides the list of markers. The %LET ls statement provides the list of line styles. The MAKESTYLE macro makes the kth style element from the **GraphData**n style element for $n = \text{mod}(k - 1, 12) + 1$. The remaining macros vary markers and line styles in the appropriate order over the elements in each list.

The following step that was used in the section "Style Comparisons" on page 658 is used with the different styles to produce Figure 21.43 through Figure 21.46:

```
proc sgplot data=x2;
   title 'Colors, Markers, Lines Patterns for Groups';
   series  y=y x=x / group=group markers;
   scatter y=y x=z / group=group markerchar=l;
run;
```

Style Template Modification Macro

The **%ModStyle** macro provides easy ways to customize the style elements (**GraphData1**–**GraphData***n*) that control how groups of observations are distinguished. Examples of using the **%ModStyle** macro can be found in the sections "Creating an All-Color Style" on page 678 and "Changing the Default Markers and Lines" on page 680. Also see Kuhfeld (2009) for more information about this macro.

You do not need to include autocall macros (for example, with a **%include** statement). You can call them directly once they are properly installed. If your site has installed the autocall libraries supplied by the SAS System and uses the standard configuration of SAS software, you need to ensure that the SAS system option MAUTOSOURCE is in effect to begin using the autocall macros. For more information about autocall libraries, see the *SAS Macro Language: Reference*. For details about installing autocall macros, consult your host documentation.

The **%ModStyle** macro has the following options:

COLORS=*color-list*

specifies a space-delimited list of colors for markers and lines. If you do not specify this option, then the colors from the parent style are used. You can specify the colors using any SAS color notation such as CX*rrggbb*.

COLORS=GRAYS generates seven distinguishable grayscale colors from blackest to whitest. The colors should be mixed up to be more easily distinguished when you need fewer colors, but you can do that with your own COLORS= list. The HLS (hue/light/saturation) coding generates colors by setting hue and saturation to 0 and incrementing the lightness for each gray. You can also use the keywords BLUES, PURPLES, MAGENTAS, REDS, ORANGES, YELLOWS, GREENS, and CYANS to generate seven colors with a fixed hue and a saturation of AA (hex).

COLORS=SHADES INT generates seven colors as described previously, except that you specify an integer $0 \leq \text{INT} < 360$. See *SAS/GRAPH: Reference*. The available hues include: GRAY, GREY, BLUE=0, PURPLE=30, MAGENTA=60, RED=120, ORANGE=150, YELLOW=180, GREEN=240, and CYAN=300.

DISPLAY=*n*

specifies whether to display the generated template. By default, the template is not displayed. Specify DISPLAY=1 to display the generated template.

FILLCOLORS=*color-list*

specifies a space-delimited list of colors for bands and fills. If you do not specify this option, then the colors from the parent style are used.

Fill colors from the parent style are designed to work well with the colors from the parent style. If you specify a COLORS= list, then you might want to redefine the FILLCOLORS= list as well. You need to have at least as many fill colors as you have colors (any extra fill colors are ignored). Two shortcuts are available: FILLCOLORS=COLORS uses the COLORS= colors for the fills (your confidence bands should have transparency for this to be useful) and FILLCOLORS=LIGHTCOLORS modifies the lightness associated with each color generated by COLORS=SHADES (this is allowed only with COLORS=SHADES).

LINESTYLES=*line-style-list*

specifies a space-delimited list of line styles. The default is:

```
LineStyles=Solid MediumDash MediumDashShortDash LongDash
           DashDashDot LongDashShortDash DashDotDot Dash
           ShortDashDot MediumDashDotDot ShortDash
```

Line style numbers can range from 1 to 46. Some line styles have names associated with them. You can specify either the name or the number for the following number/name pairs: 1 Solid, 2 ShortDash, 4 MediumDash, 5 LongDash, 8 MediumDashShortDash, 14 DashDashDot, 15 DashDotDot, 20 Dash, 26 LongDashShortDash, 34 Dot, 35 ThinDot, 41 ShortDashDot, and 42 MediumDashDotDot.

MARKERS=*marker-list*

specifies a space-delimited list of marker symbols. By default, **Markers=Circle Plus X Triangle Square Asterisk Diamond**. The available marker symbols are listed in *SAS Graph Template Language: Reference*. Two shortcuts are available: MARKERS=FILLED is an alias for the specification **Markers=CircleFilled TriangleFilled SquareFilled DiamondFilled StarFilled HomeDownFilled**, and MARKERS=EMPTY is an alias for the specification **Markers=Circle Triangle Square Diamond Star HomeDown**.

NAME=*style-name*

specifies the name of the new style that you are creating. This name is used when you specify the style in an ODS destination statement (for example, ODS HTML STYLE=*style-name*). The default is NAME=NEWSTYLE.

NUMBEROFGROUPS=*n*

specifies *n*, the number of **GraphData***n* style elements to create. The **GraphData1**–**GraphData***n* style elements contain *n* combinations of colors, markers, and line styles. By default, 32 combinations are created.

PARENT=*style-name*

specifies the parent style. The new style inherits most of its attributes from the parent style. The default is PARENT=DEFAULT (which is one of the default styles for HTML and the parent style for all of the styles that are recommended for statistical graphics). If your goals are to change colors or create an all-color style, you can use any style as the parent style. However, if your goal is to change markers or line styles without creating an all-color style, do not use the HTMLBLUE style as a parent. The HTMLBLUE style is an all-color style that is different from other styles due to its use of the ATTRPRIORITY= style option.

TYPE=*type-specification*

specifies how your new style cycles through colors, markers, and line styles. The default is TYPE=LMbyC.

These first three methods work well with all plots, because cycling line styles and markers together ensures that both scatterplot markers and series plot lines are distinguishable:

CLM

cycles through colors, line styles, and markers simultaneously. The first group uses the first color, line style, and marker; the second group uses the second color, line style, and marker; and so on. This is the method used by the ODS Graphics styles.

LMbyC
fixes line style and marker, cycles through colors, and then moves to the next line style and marker. This is the default and creates a style where the first groups are distinguished entirely by color.

CbyLM
fixes color, cycles through line style and marker, and then moves to the next color. This option uses the smaller of the number of line styles or the number of markers when cycling within a color.

The following two methods might not work well with all plots:

CbyLbyM
fixes color and line style, then cycles through markers, increments line style, and then cycles through markers. After all line styles have been used, then this option moves to the next color and continues.

LbyMbyC
fixes line style and marker, then cycles through colors, increments marker, and then cycles through colors. After all markers have been used, then this option moves to the next line style and continues. This is closest to the legacy SAS/GRAPH method.

Creating an All-Color Style

Many styles are designed to make color plots where lines, functions, and groups of observations can be distinguished even when the plot is sent to a black-and-white printer. Hence, lines differ not only in color but also in pattern. Similarly, markers differ in both color and symbol. This is not true with the HTMLBLUE style, which is an all-color style.

You can easily modify any style to be an all-color style by using the ATTRPRIORITY= option. For example:

```
proc template;
   define style styles.StatColor;
      parent = statistical;
      style Graph from Graph / attrpriority = "Color";
      end;
   run;
```

Alternatively, you can make an all-color style with the %MODSTYLE autocall macro. It creates a new style by modifying a parent style and reordering the colors, line patterns, and marker symbols in the **GraphData***n* style elements (see the section "Some Common Style Elements" on page 652). By default, the macro creates a new style that distinguishes lines and groups only by color. The macro is documented in the section "Style Template Modification Macro" on page 676.

The following example illustrates the default use of the macro and is taken from the section "Fitting a Curve through a Scatter Plot" on page 7764 of Chapter 93, "The TRANSREG Procedure." The data come from an experiment in which nitrogen oxide emissions from a single cylinder engine are measured for various combinations of fuel and equivalence ratio. This gas data set is available from the Sashelp library.

The following statements fit separate curves for each group and produce Figure 21.47 and Figure 21.48:

```
ods listing style=statistical;
ods graphics on;

proc transreg data=sashelp.Gas ss2 plots=transformation lprefix=0;
   model identity(nox) = class(Fuel / zero=none) * pbspline(EqRatio);
run;

%modstyle(parent=statistical, name=StatColor)
ods listing style=StatColor;

proc transreg data=sashelp.Gas ss2 plots=transformation lprefix=0;
   model identity(nox) = class(Fuel / zero=none) * pbspline(EqRatio);
run;
```

The first PROC TRANSREG step uses the STATISTICAL style to create the fit plot in Figure 21.47, which uses different colors, line patterns, and markers for each group. Then the macro creates a new style, called STATCOLOR, that inherits its characteristics from the STATISTICAL style. Only the attributes of the lines and markers are changed. In Figure 21.48, which is created with the modified style, the groups are differentiated only by color. This is the easiest and most common way for you to use this macro. However, you can use it to perform other style modifications as illustrated in the section "Changing the Default Markers and Lines" on page 680. The macro is documented in the section "Style Template Modification Macro" on page 676.

Figure 21.47 Fit Plot with the STATISTICAL Style

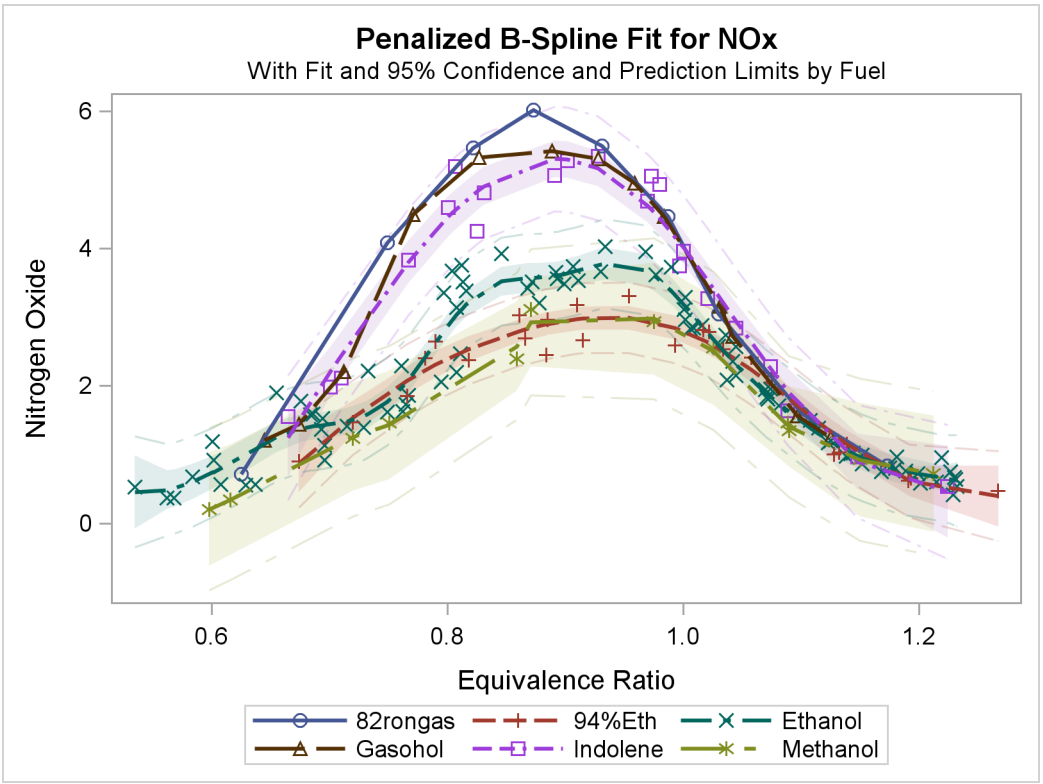

Figure 21.48 Fit Plot with the Modified Style

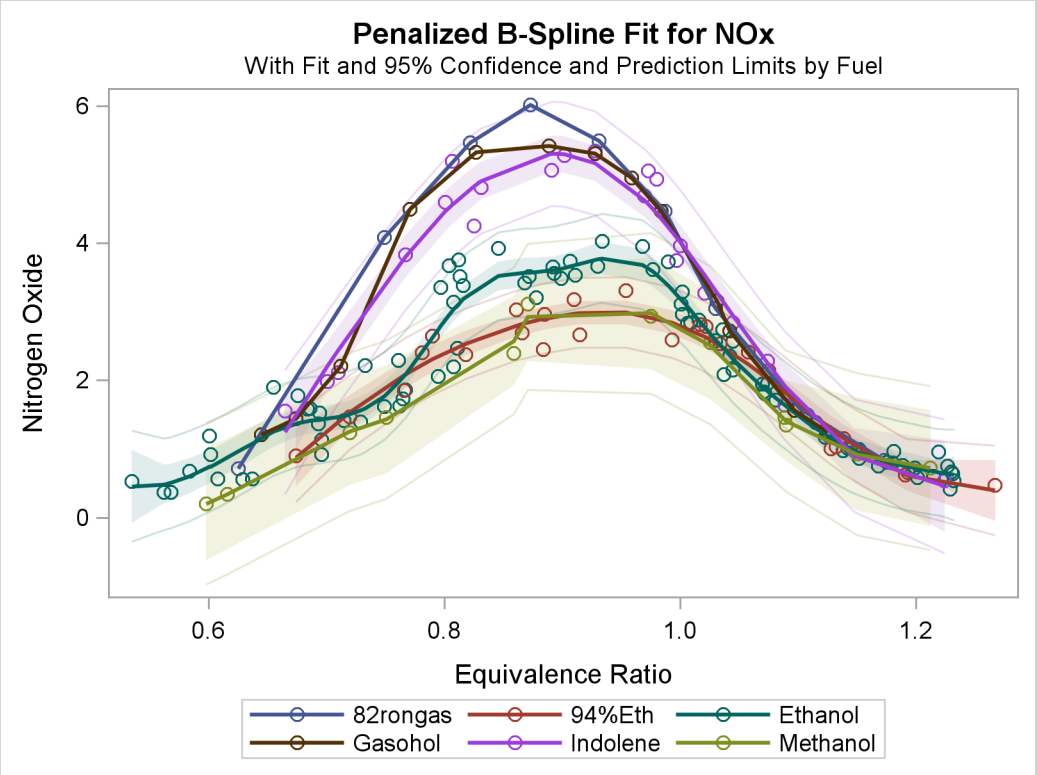


Changing the Default Markers and Lines

The preceding section shows how to use the %MODSTYLE autocall macro to create an all-color style. You can also use the %MODSTYLE macro to change markers and line styles. This example creates a new style called MARKSTYLE that inherits from the STATISTICAL style but uses a different set of markers. The following statements create artificial data, change the marker list, and display the results:

```
data x;
   do g = 1 to 12;
      do x = 1 to 10;
         y = 13 - g + sin(x * 0.1 * g);
         output;
      end;
   end;
run;

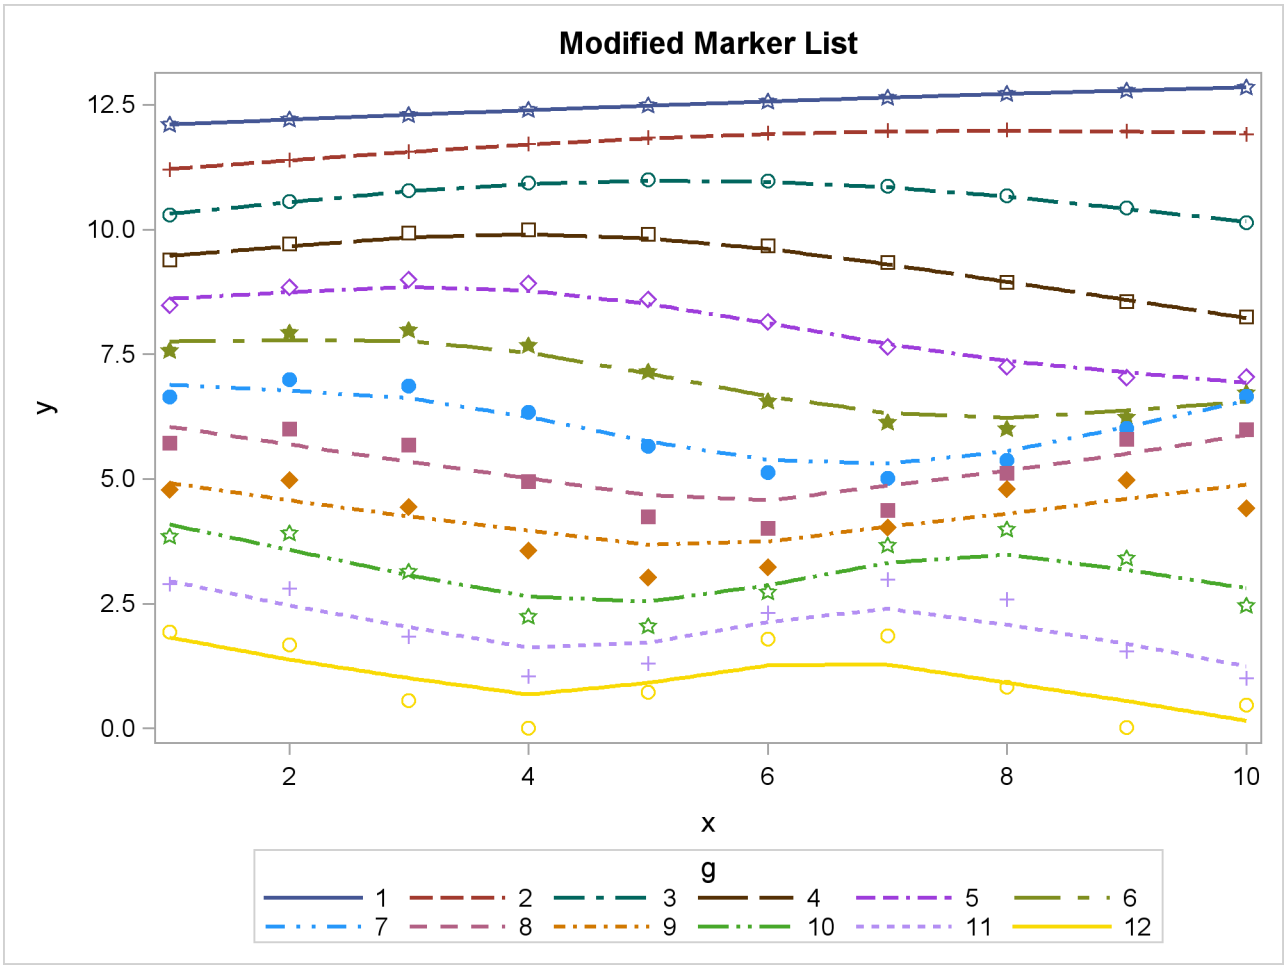
%modstyle(name=markstyle, parent=statistical, type=CLM,
          markers=star plus circle square diamond starfilled
                  circlefilled squarefilled diamondfilled)
```

```
ods listing style=markstyle;

proc sgplot;
   title 'Modified Marker List';
   loess y=y x=x / group=g;
run;
```

The NAME= option specifies the new style name, and the PARENT= option specifies the parent style. The TYPE= option controls the method of cycling through colors, lines, and markers. The default, TYPE=LMbyC, fixes (holds constant) the line styles and markers, while cycling through the color list. This is illustrated in the section "Creating an All-Color Style" on page 678. This example uses TYPE=CLM to cycle through colors, line styles, and markers (holding none of them fixed). Other TYPE= values are described in the section "Style Template Modification Macro" on page 676. The values specified with the TYPE= option are case-sensitive ('by' is lower case and the 'L', 'C', and 'M' are upper case). The new marker list is specified with the MARKERS= option. The results are displayed in Figure 21.49. The marker list is reused in the tenth and subsequent groups since only nine markers are defined.

Figure 21.49 A Modified Style with a New List of Markers



The following statements create a new style called LINESTYLE that inherits from the STATISTICAL style and changes the line list:

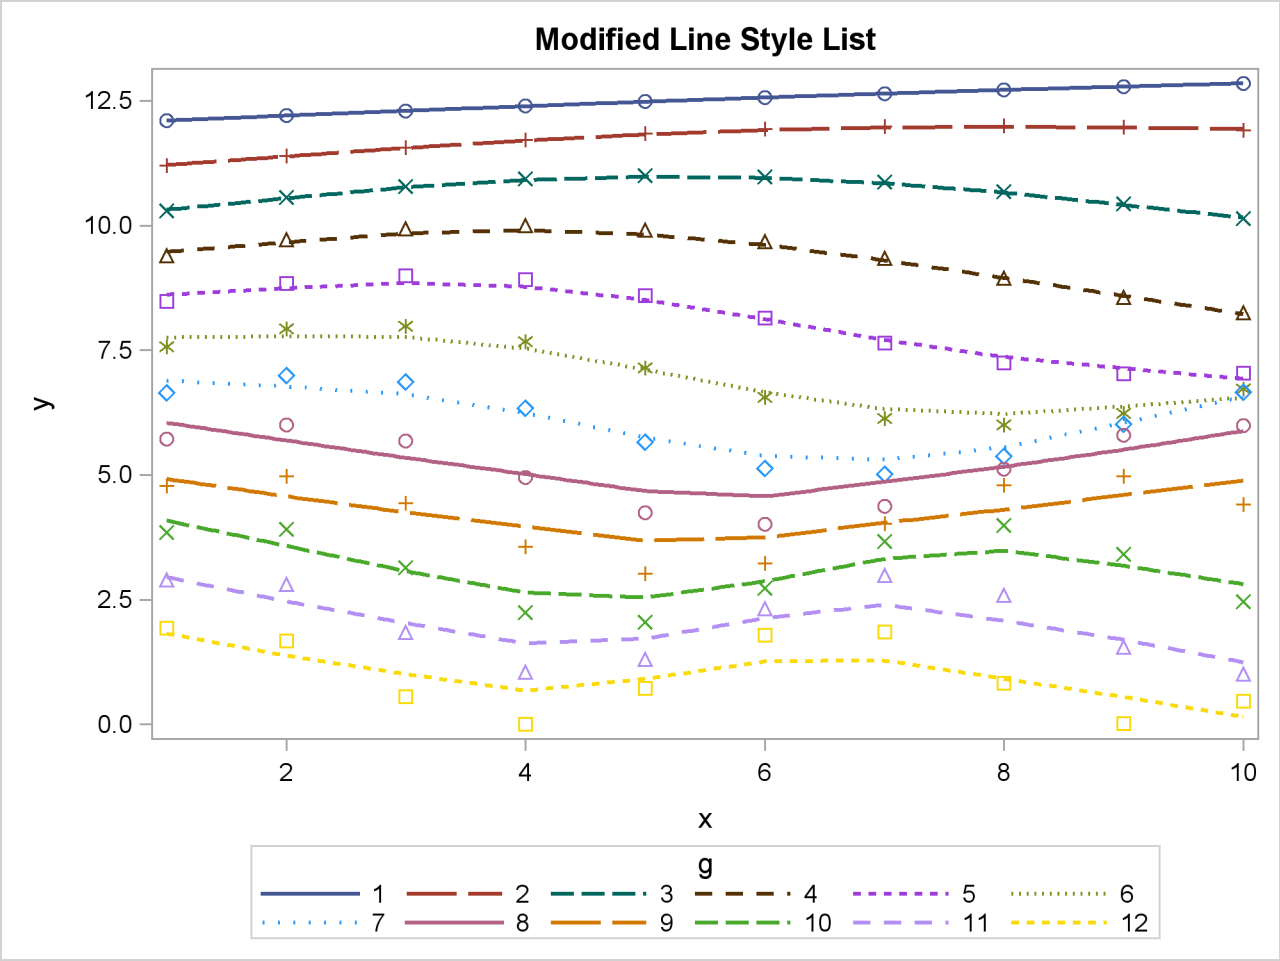
```
%modstyle(name=linestyle, parent=statistical, type=CLM,
          linestyles=Solid LongDash MediumDash Dash ShortDash Dot ThinDot)

ods listing style=linestyle;

proc sgplot;
   title 'Modified Line Style List';
   loess y=y x=x / group=g;
run;
```

The new line list is specified with the LINESTYLES= option. The results are displayed in Figure 21.50. In this example, each of the first seven groups uses a dash pattern that is shorter than the previous group. The line list is reused in the eighth and subsequent groups since only seven line patterns are defined.

Figure 21.50 Modified Style with a New List of Line Styles



You can learn more about style modification by examining the new styles, as in the following example:

```
proc template;
   source styles.markstyle;
   source styles.linestyle;
run;
```

The results show the definitions of **GraphData1** through **GraphData32** that the macro created. An abridged listing of the results follows:

```
define style Styles.Markstyle;
   parent = Styles.statistical;
   . . .
   style GraphData1 /
      markersymbol = "star"
      linestyle = 1
      contrastcolor = ColorStyles('c1')
      color = FillStyles('f1');
   . . .
   style GraphData32 /
      markersymbol = "diamond"
      linestyle = 42
      contrastcolor = ColorStyles('c8')
      color = FillStyles('f8');
end;

define style Styles.Linestyle;
   parent = Styles.statistical;
   . . .
   style GraphData1 /
      markersymbol = "circle"
      linestyle = 1
      contrastcolor = ColorStyles('c1')
      color = FillStyles('f1');
   . . .
   style GraphData32 /
      markersymbol = "triangle"
      linestyle = 20
      contrastcolor = ColorStyles('c8')
      color = FillStyles('f8');
end;
```

You can use the NUMBEROFGROUPS= option in the %MODSTYLE macro to control the number of **GraphData***n* style elements created in the new style.

Modifying Graph Fonts in Styles

You can modify an ODS style to customize the general appearance of plots produced with ODS Graphics, just as you can modify a style to customize the general appearance of ODS tables. This section shows you how to customize fonts used in graphs. The following step displays the HTMLBLUE style and its parent styles, STATISTICAL and DEFAULT:

```
proc template;
   source Styles.HTMLBlue;
   source Styles.Statistical;
   source Styles.Default;
run;
```

If you search for 'font', you find the style elements that control graph fonts:

```
style GraphFonts /
   'GraphDataFont' = ("<sans-serif>, <MTsans-serif>",7pt)
   'GraphUnicodeFont' = ("<MTsans-serif-unicode>",9pt)
   'GraphValueFont' = ("<sans-serif>, <MTsans-serif>",9pt)
   'GraphLabelFont' = ("<sans-serif>, <MTsans-serif>",10pt)
   'GraphFootnoteFont' = ("<sans-serif>, <MTsans-serif>",10pt,italic)
   'GraphTitleFont' = ("<sans-serif>, <MTsans-serif>",11pt,bold)
   'GraphTitle1Font' = ("<sans-serif>, <MTsans-serif>",14pt,bold)
   'GraphAnnoFont' = ("<sans-serif>, <MTsans-serif>",10pt);
```

The font **GraphTitle1Font** is used only in traditional graphics; it is not used with ODS Graphics. The following fonts are the ones typically used for the text in most graphs:

- **GraphDataFont** is the smallest font. It is used for text that needs to be small (labels for points in scatter plots, labels for contours, and so on)
- **GraphValueFont** is the next largest font. It is used for axis value (tick marks) labels and legend entry labels.
- **GraphLabelFont** is the next largest font. It is used for axis labels and legend titles.
- **GraphFootnoteFont** is the next largest font. It is used for all footnotes.
- **GraphTitleFont** is the largest font. It is used for all titles.
- **GraphUnicodeFont** is used for special characters. See the section "Unicode and Special Characters" on page 754.

The following statements define a style named NEWSTYLE that replaces the graph fonts in the DEFAULT style with italic Times New Roman fonts, which are available with the Windows operating system:

```
proc template;
   define style Styles.NewStyle;
      parent=Styles.Statistical;
      replace GraphFonts  /
         'GraphDataFont'     = ("<MTserif>, Times New Roman",7pt)
         'GraphUnicodeFont'  = ("<MTserif>, Times New Roman",9pt)
         'GraphValueFont'    = ("<MTserif>, Times New Roman",9pt)
         'GraphLabelFont'    = ("<MTserif>, Times New Roman",10pt)
         'GraphFootnoteFont' = ("<MTserif>, Times New Roman",10pt)
         'GraphTitleFont'    = ("<MTserif>, Times New Roman",11pt)
         'GraphTitle1Font'   = ("<MTserif>, Times New Roman",14pt)
         'GraphAnnoFont'     = ("<MTserif>, Times New Roman",10pt);
   end;
run;
```

For more information about the DEFINE, PARENT, and REPLACE statements, see the *SAS Graph Template Language: Reference*.

The "Getting Started" section of Chapter 77, "The ROBUSTREG Procedure," creates the following data set to illustrate the use of the PROC ROBUSTREG for robust regression:

```
data stack;
   input x1 x2 x3 y @@;
   datalines;
80 27 89 42   80 27 88 37   75 25 90 37   62 24 87 28   62 22 87 18
62 23 87 18   62 24 93 19   62 24 93 20   58 23 87 15   58 18 80 14
58 18 89 14   58 17 88 13   58 18 82 11   58 19 93 12   50 18 89  8
50 18 86  7   50 19 72  8   50 19 79  8   50 20 80  9   56 20 82 15
70 20 91 15
;
```

The following statements create a Q-Q plot that uses the HTMLBLUE style (see Figure 21.51) and the NEWSTYLE style (see Figure 21.52):

```
ods listing style=HTMLBlue;
ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;

ods listing close;
ods listing style=NewStyle;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Figure 21.51 Q-Q Plot That Uses the HTMLBLUE Style

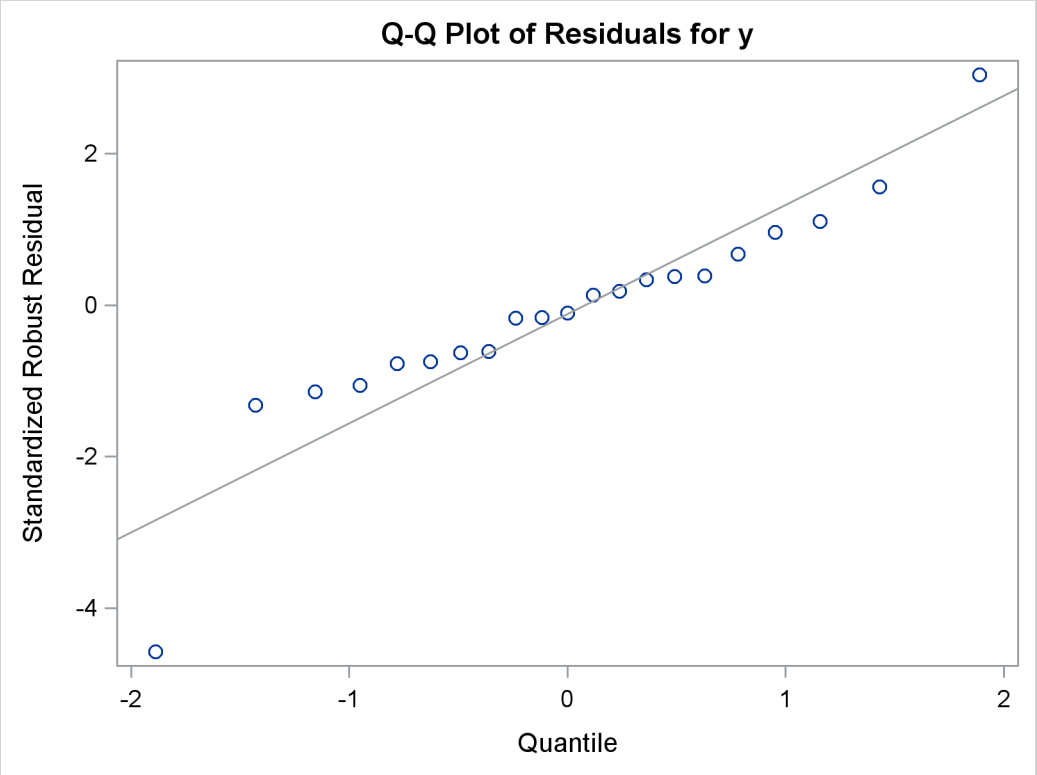


Figure 21.52 Q-Q Plot That Uses the NEWSTYLE Style

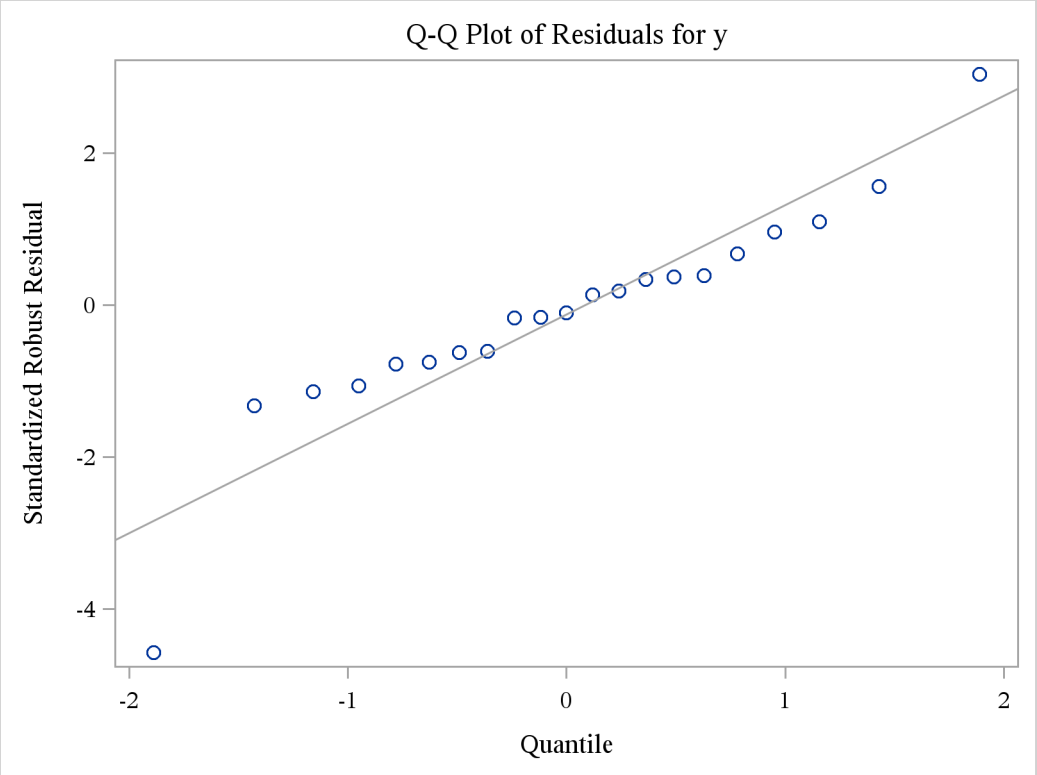


Although this example illustrates the use of a style with graphical output from a particular procedure, a style is applied to *all* of your output (graphs and tables) in the destination for which you specify the style. See the section "Changing the Default Style" on page 689 for information about specifying a default style for all your output.

Modifying Other Graph Elements in Styles

This section illustrates how to modify other style elements for graphics, specifically the style element **GraphReference**, which controls the attributes of reference lines. You can run the following statements to learn more about the **GraphReference** style element:

```
proc template;
   source styles.HTMLBlue;
run;
```

The following are the first two lines of the source listing:

```
define style Styles.HTMLBlue;
   parent = styles.statistical;
```

There is no mention of **GraphReference** in the complete listing of the source because **GraphReference** is inherited from a parent style. Most styles inherit many of their attributes from other styles. To find out more, you must list the parent style, as in the following example:

```
proc template;
   source styles.statistical;
run;
```

Most styles that you typically use with ODS Graphics inherit most of their attributes from only one style, the DEFAULT style. The HTMLBLUE style inherits from the STATISTICAL style, which inherits from the DEFAULT style. A few of the other styles inherit from several parents. You might have to repeat this process multiple times to find the first parent. The following step displays the HTMLBLUE style and its parent styles, STATISTICAL and DEFAULT:

```
proc template;
   source Styles.HTMLBlue;
   source Styles.Statistical;
   source Styles.Default;
run;
```

Styles are listed in the order: style of interest, then its parent, and then its grandparent. If you search the results from the top, you will find the most recent specification of a style element first. The **GraphReference** style element is defined as follows:

```
class GraphReference /
   linethickness = 1px
   linestyle = 1
   contrastcolor = GraphColors('greferencelines');
```

To specify a line thickness of 4 pixels for all reference lines, add the following statement to the definition of the NEWSTYLE style in the section "Modifying Graph Fonts in Styles" on page 684:

```
replace GraphReference / linethickness=4px;
```

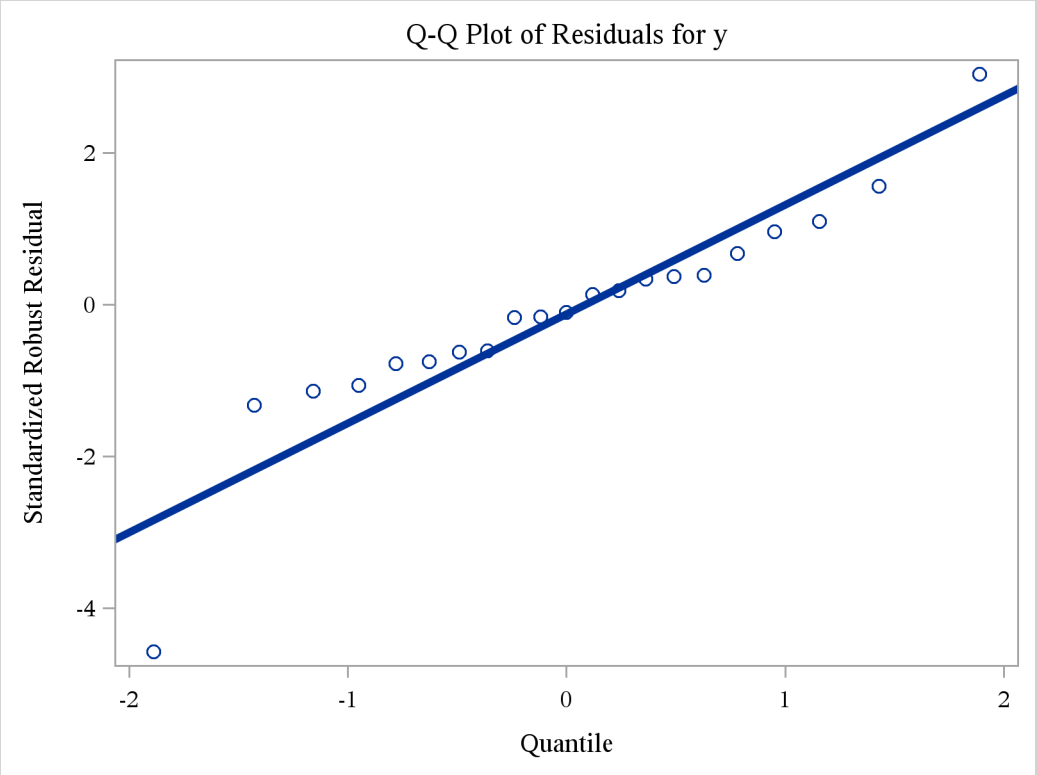
The following statements modify the style and produce the Q-Q plot shown in Figure 21.53:

```
proc template;
   define style Styles.NewStyle;
      parent=Styles.Statistical;
      replace GraphFonts  /
         'GraphDataFont'     = ("<MTserif>, Times New Roman",7pt)
         'GraphUnicodeFont'  = ("<MTserif>, Times New Roman",9pt)
         'GraphValueFont'    = ("<MTserif>, Times New Roman",9pt)
         'GraphLabelFont'    = ("<MTserif>, Times New Roman",10pt)
         'GraphFootnoteFont' = ("<MTserif>, Times New Roman",10pt)
         'GraphTitleFont'    = ("<MTserif>, Times New Roman",11pt)
         'GraphTitle1Font'   = ("<MTserif>, Times New Roman",14pt)
         'GraphAnnoFont'     = ("<MTserif>, Times New Roman",10pt);
      replace GraphReference / linethickness=4px;
   end;
run;

ods listing style=NewStyle;
ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Figure 21.53 Q-Q Plot That Uses the NEWSTYLE Style with a Thicker Line



You can use this approach to modify other attributes of the line, such as **`LineStyle`** and **`ContrastColor`**. These style modifications apply to all graphs that display reference lines, and not just to Q-Q plots produced by PROC ROBUSTREG. You can control the attributes of specific graphs by modifying the graph template, as discussed in the section "Graph Templates" on page 716 in Chapter 22, "ODS Graphics Template Modification." Values specified directly in a graph template override style attributes.

When you are done with the NEWSTYLE style, you do not need to restore the HTMLBLUE style template since you did not modify it. Rather, you inherited from the HTMLBLUE style.

Changing the Default Style

The default style for each ODS destination is specified in the SAS Registry. For example, the default style for the HTML destination is DEFAULT (or HTMLBLUE in the SAS windowing environment) and the default style for the RTF destination is RTF. You can specify a default style for all of your output in a particular ODS destination. This is useful if you want to use a different SAS style, if you have modified one of the styles supplied by the SAS System (see the section "Style Templates and Colors" on page 651), or if you have defined your own style. For example, you can specify the JOURNAL style as the default style for RTF output.

The recommended approach for specifying a default style is as follows. Open the SAS Registry Editor by typing **regedit** on the command line. Expand the node **ODS ► DESTINATIONS** and select a destination

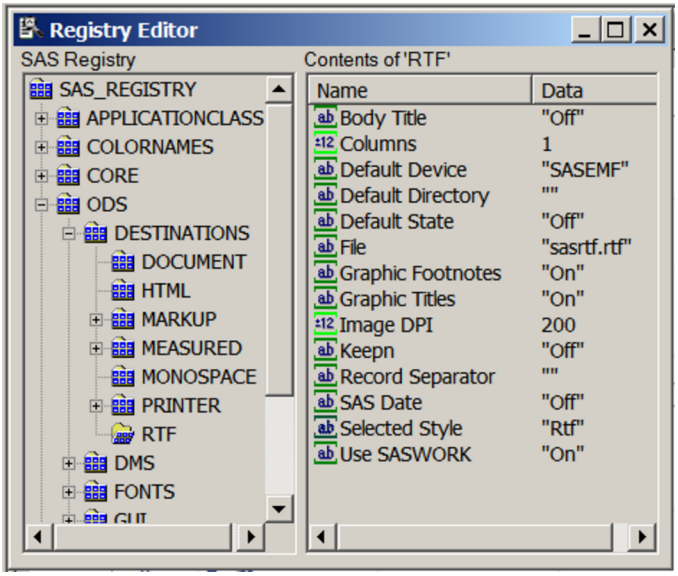
(for example, select **RTF**). Double-click the **Selected Style** item, shown in Figure 21.54, and specify a style. This can be any style supplied by the SAS System or a user-defined style, as long as it can be found with the current template search path (for example, specify **Journal**). You can specify a default style for the other destinations in a similar way.

In a few cases the default style is specified in more than one place. Assume that you are using the SAS windowing environment and Microsoft Windows or UNIX in the following;

- If you expand the node **ODS ► DESTINATIONS ► HTML**, you see that the **Selected Style** is DEFAULT.
- If you expand the node **ODS ► MARKUP ► HTML4**, you see that the **Selected Style** is DEFAULT.
- If you expand the node **ODS ► DMS ► DESTINATIONS ► MARKUP ► HTML4**, you see that the **Selected Style** is HTMLBLUE.

The HTMLBLUE style is the default style for HTML output in the SAS windowing environment, yet the DEFAULT style is the default style for HTML output in other contexts.

Figure 21.54 SAS Registry Editor



ODS searches sequentially through each element of the template search path for the first style template that matches the name of the style specified in the SAS Registry. The first style template found is used. (See the sections "Saving Customized Templates" on page 725, "Using Customized Templates" on page 726, and "Reverting to the Default Templates" on page 727 in Chapter 22, "ODS Graphics Template Modification," for more information about the template search path.) If you are specifying a customized style as your default style, the following are useful suggestions:

- If you save your style in Sasuser.Templat, verify that the name of your default style matches the name of the style specified in the SAS Registry. For example, suppose the RTF style is specified for the RTF destination in the SAS Registry. You can name your style RTF and save it in Sasuser.Templat.

This blocks the RTF style in Sashelp.Tmplmst (provided that you did not alter the default template search path).

- If you save your style in a user-defined template store, verify that this template store is the first in the current template search path. Include the ODS PATH statement in your SAS autoexec file so that it is executed at start-up.

For the HTML destination, an alternative approach for specifying a default style is as follows. From the menu at the top of the main SAS window, select **Tools ► Options ► Preferences**. On the **Results** tab, select the **Create HTML** check box and select a style from the **Style** list.

Statistical Graphics Procedures

Three Base SAS statistical graphics procedures use ODS Graphics and provide a convenient syntax for creating a variety of graphs from raw data or from procedure output.

SGSCATTER	creates single-cell and multi-cell scatter plots and scatter plot matrices with optional fits and ellipses.
SGPLOT	creates single-cell plots with a variety of plot and chart types.
SGPANEL	creates single-page or multi-page panels of plots and charts conditional on classification variables.

You do not need to enable ODS Graphics in order to use these procedures, which are called SG (statistical graphics) procedures. In addition, the Base SAS SGRENDER procedure provides a way to create plots from graph templates that you have modified or written yourself. See the *SAS ODS Graphics: Procedures Guide* and Kuhfeld (2010) for more information about the SG procedures and PROC SGRENDER.

These procedures do much more than make scatter plots. They can produce density plots, dot plots, needle plots, series plots, horizontal and vertical bar charts, histograms, and box plots. They can also compute and display loess fits, polynomial fits, penalized B-spline fits, reference lines, bands, and ellipses. PROC SGRENDER is the most flexible because it uses the Graph Template Language. The syntax for the other SG procedures is much simpler than that of the GTL, and so these procedures are recommended for creating most plots commonly required in statistical work.

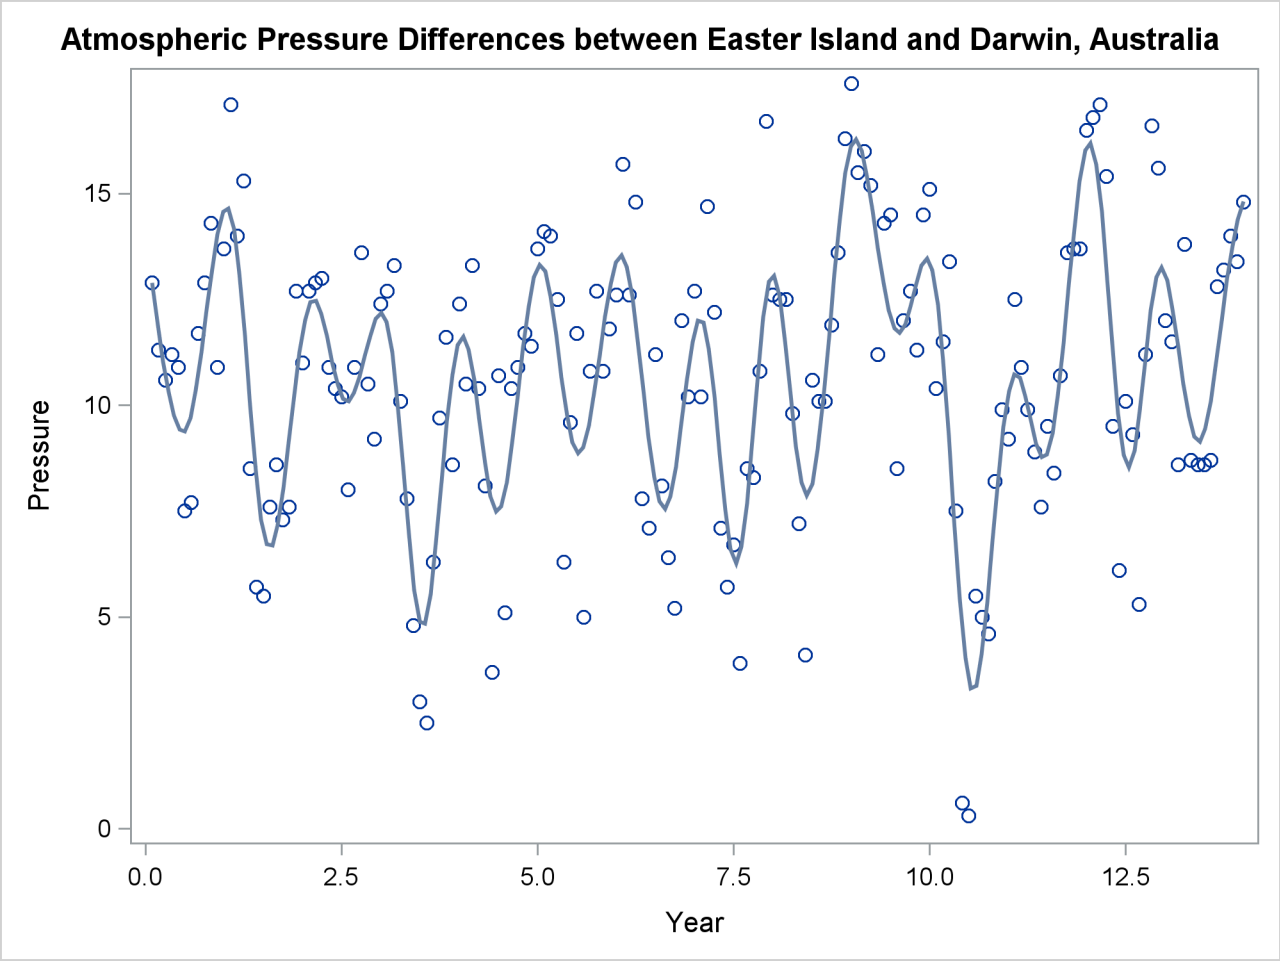
The SGPLOT Procedure

PROC SGPLOT provides a simple way to make a variety of scatter plots. This example is taken from Example 52.4 of Chapter 52, "The LOESS Procedure." The ENSO data set, which contains information about differences in ocean pressure over time, is available from the Sashelp library.

The following statements create a scatter plot of points along with a penalized B-spline fit to the data and produce Figure 21.55:

```
proc sgplot data=sashelp.enso noautolegend;
   title 'Atmospheric Pressure Differences between '
         'Easter Island and Darwin, Australia';
   pbspline y=pressure x=year;
run;
```

Figure 21.55 Penalized B-Spline Fit with PROC SGPLOT



See Chapter 93, "The TRANSREG Procedure," for more information about penalized B-splines. Also see the section "Grouped Scatter Plot with PROC SGPLOT" on page 610 and Figure 21.12 for an example of a scatter plot with groups of observations.

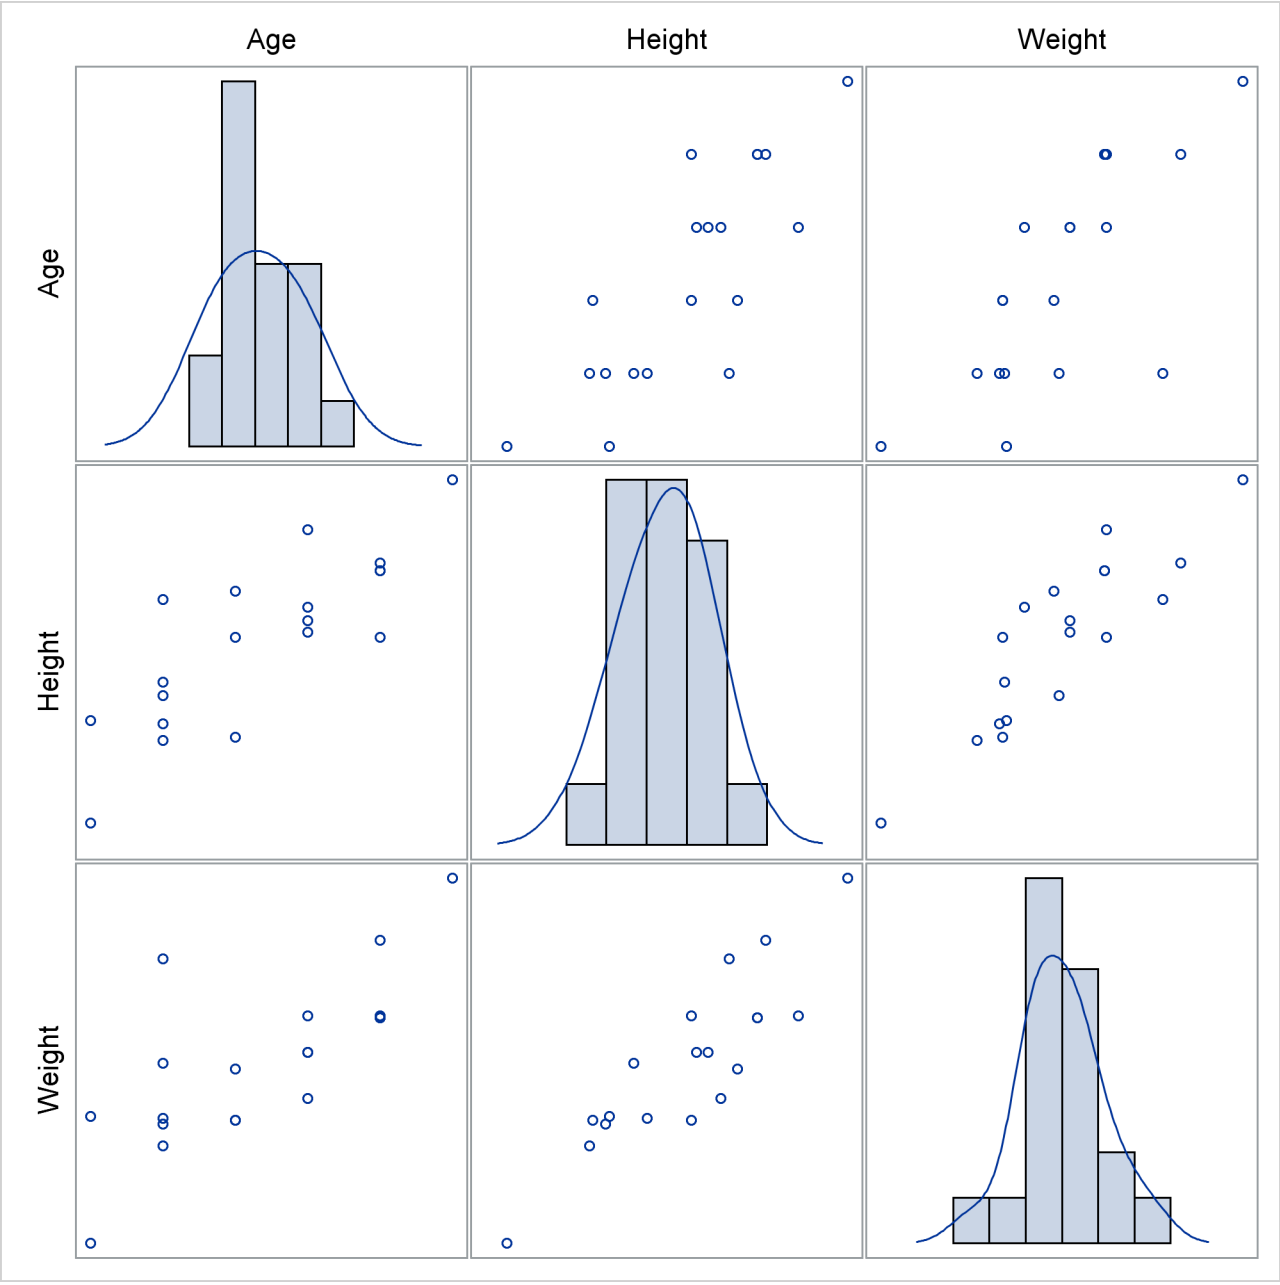
The SGSCATTER Procedure

You can use the SGSCATTER procedure to produce scatter plot matrices. The following step creates a scatter plot matrix from all of the numeric variables in the Class data set (available in the Sashelp library) and produces Figure 21.56:

```
proc sgscatter data=sashelp.class;
   matrix _numeric_ / diagonal=(kernel histogram);
run;
```

The diagonal cells of Figure 21.56 contain a histogram and a kernel density fit. The off-diagonal cells contain all pairs of scatter plots.

Figure 21.56 Scatter Plot Matrix with PROC SGSCATTER



The MATRIX statement creates a symmetric $n \times n$ scatter plot matrix. Other statements are also available. The PLOT statement creates a panel that contains one or more individual scatter plots. The COMPARE statement creates a rectangular $m \times n$ scatter plot matrix. Linear and nonlinear fits can be added, and many graphical features can be requested with options.

The SGPANEL Procedure

The SGPANEL procedure creates paneled plots and charts with one or more classification variables. Classification variables can be designated as row or column variables, or there can be multiple classifications. Graphs are drawn for each combination of the levels of classification variables, showing a subset of the data in each cell.

This example is taken from Example 40.6 of Chapter 40, "The GLIMMIX Procedure." The following statements create the input SAS data sets:

```
data times;
   input time1-time23;
   datalines;
122  150  166  179  219  247  276  296  324  354  380  445
478  508  536  569  599  627  655  668  723  751  781
;

data cows;
   if _n_ = 1 then merge times;
   array t{23} time1 - time23;
   array w{23} weight1 - weight23;
   input cow iron infection weight1-weight23 @@;
   do i=1 to 23;
      weight = w{i};
      tpoint = (t{i}-t{1})/10;
      output;
   end;
   keep cow iron infection tpoint weight;
   datalines;
 1 0 0  4.7    4.905  5.011  5.075  5.136  5.165  5.298  5.323
        5.416  5.438  5.541  5.652  5.687  5.737  5.814  5.799
        5.784  5.844  5.886  5.914  5.979  5.927  5.94

   ... more lines ...

;
```

First, PROC GLIMMIX is run to fit the model, and then the results are prepared for plotting:

```
proc glimmix data=cows;
  t2 = tpoint / 100;
  class cow iron infection;
  model weight = iron infection iron*infection tpoint;
  random t2 / type=rsmooth subject=cow
                  knotmethod=kdtree(bucket=100 knotinfo);
  output out=gmxout pred(blup)=pred;
  nloptions tech=newrap;
run;

data plot;
  set gmxout;
  length Group $ 26;
```

```
      if (iron=0) and (infection=0) then group='Control Group (n=4)';
  else if (iron=1) and (infection=0) then group='Iron - No Infection (n=3)';
  else if (iron=0) and (infection=1) then group='No Iron - Infection (n=9)';
  else group = 'Iron - Infection (n=10)';
run;

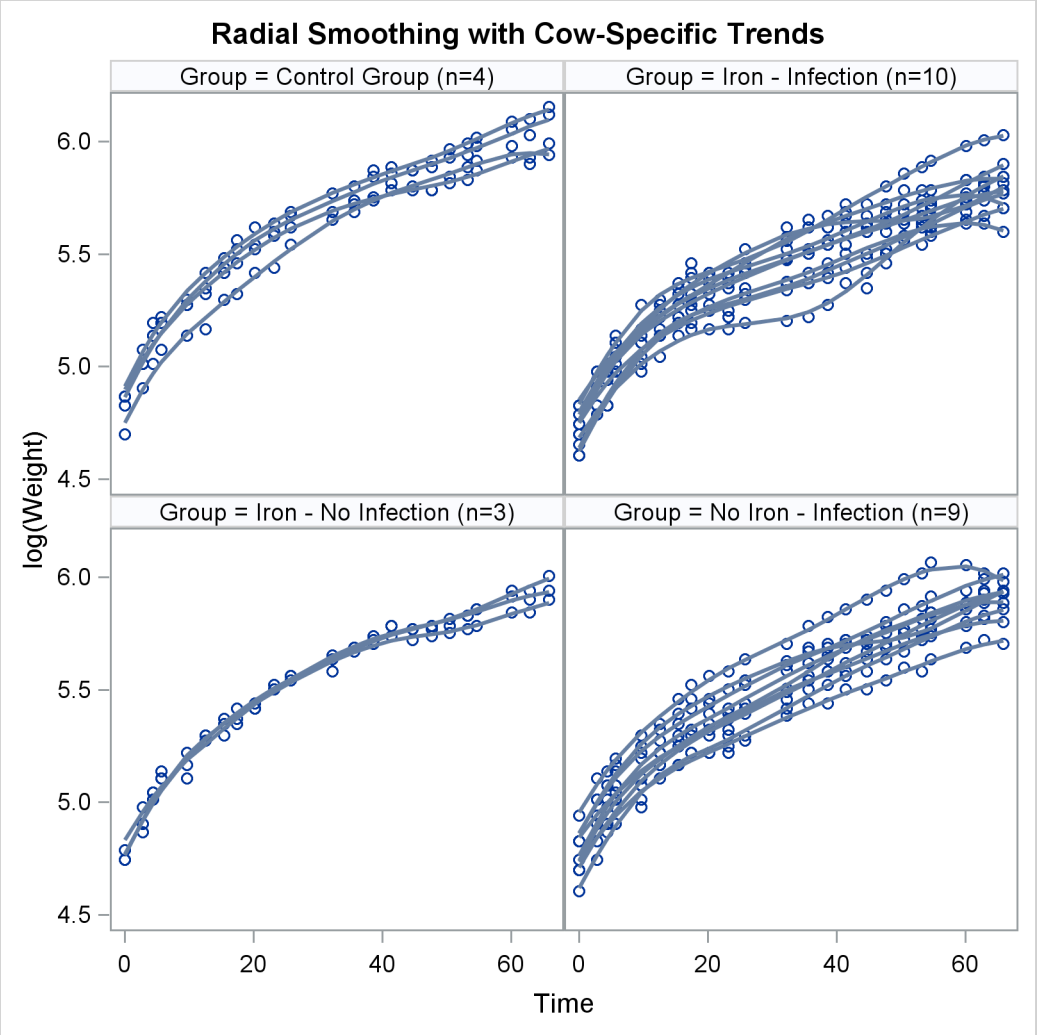
proc sort data=plot; by group cow;
run;
```

The following statements produce graphs of the observed data and fitted profiles in the four groups:

```
proc sgpanel data=plot noautolegend;
  title 'Radial Smoothing with Cow-Specific Trends';
  label tpoint='Time' weight='log(Weight)';
  panelby group / columns=2 rows=2;
  scatter x=tpoint y=weight;
  series  x=tpoint y=pred / group=cow lineattrs=GraphFit;
run;
```

The results are shown in Figure 21.57.

Figure 21.57 Fit Using PROC SGPANEL



The SGRENDER Procedure

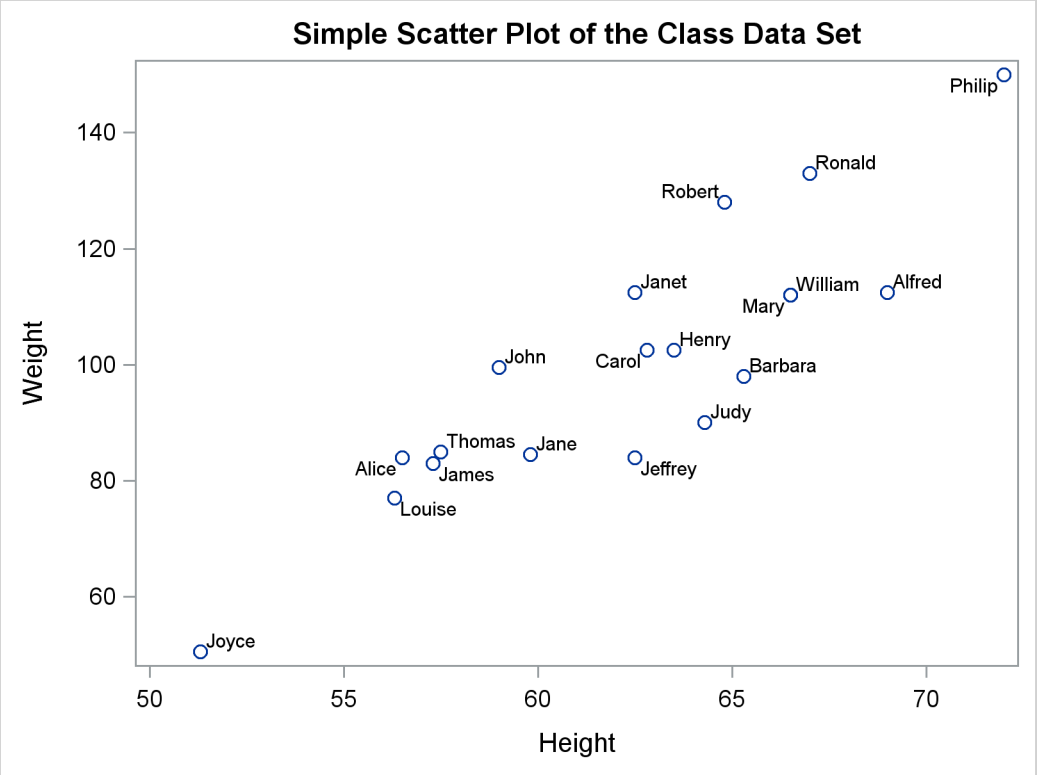
The SGRENDER procedure produces a graph from an input SAS data set and an ODS graph template. With PROC SGRENDER and the Graph Template Language (GTL), you can create highly customized graphs. The following steps create a simple scatter plot of the Class data set (available in the Sashelp library) and produce Figure 21.58:

```
proc template;
   define statgraph Scatter;
      begingraph;
         entrytitle "Simple Scatter Plot of the Class Data Set";
         layout overlay;
            scatterplot y=weight x=height / datalabel=name;
         endlayout;
      endgraph;
   end;
run;

proc sgrender data=sashelp.class template=scatter;
run;
```

The template definition consists of an outer block that begins with a DEFINE statement and ends with an END statement. Inside of that is a BEGINGRAPH/ENDGRAPH block. Inside that block, the ENTRYTITLE statement provides the plot title, and the LAYOUT OVERLAY block contains the statement or statements that define the graph. In this case, there is just a single SCATTERPLOT statement that names the Y-axis (vertical) variable, the X-axis (horizontal) variable, and an optional variable that contains labels for the points. The PROC SGRENDER statement simply specifies the input data set and the template. The real work in using PROC SGRENDER is writing the template.

Figure 21.58 Scatter Plot of Labeled Points with PROC SGRENDER



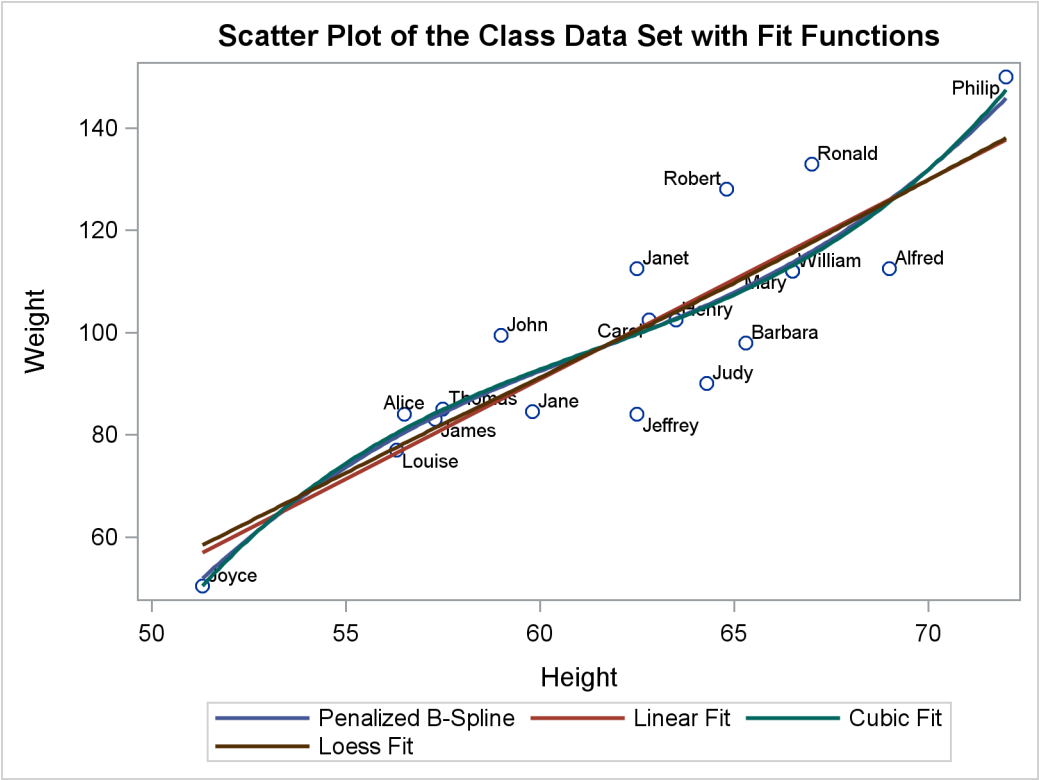
The following steps add a series of fit functions to the scatter plot and create a legend by adding statements to the **Scatter** template:

```
proc template;
   define statgraph Scatter;
      begingraph;
         entrytitle "Scatter Plot of the Class Data Set with Fit Functions";
         layout overlay;
            scatterplot y=weight x=height / datalabel=name;
            pbsplineplot y=weight x=height / name='pbs'
                         legendlabel='Penalized B-Spline'
                         lineattrs=GraphData1;
            regressionplot y=weight x=height / degree=1 name='line'
                         legendlabel='Linear Fit'
                         lineattrs=GraphData2;
            regressionplot y=weight x=height / degree=3 name='cubic'
                         legendlabel='Cubic Fit'
                         lineattrs=GraphData3;
            loessplot y=weight x=height / name='loess'
                         legendlabel='Loess Fit'
                         lineattrs=GraphData4;
            discretelegend 'pbs' 'line' 'cubic' 'loess';
         endlayout;
      endgraph;
   end;
run;
```

```
proc sgrender data=sashelp.class template=scatter;
run;
```

The line attributes for each function are specified with different style elements, **`GraphData1`** through **`GraphData4`**, so that the functions are adequately identified in the legend. The preceding statements create Figure 21.59.

Figure 21.59 Scatter Plot and Fit Functions with PROC SGRENDER



The following statements create a four-panel display of the Class data set and produce Figure 21.60:

```
proc template;
   define statgraph Panel;
      begingraph;
         entrytitle "Paneled Display of the Class Data Set";

         layout lattice / rows=2 columns=2 rowgutter=10 columngutter=10;

            layout overlay;
               scatterplot y=weight x=height;
               pbsplineplot y=weight x=height;
            endlayout;

            layout overlay / xaxisopts=(label='Weight');
               histogram weight;
            endlayout;

            layout overlay / yaxisopts=(label='Height');
               boxplot y=height;
            endlayout;

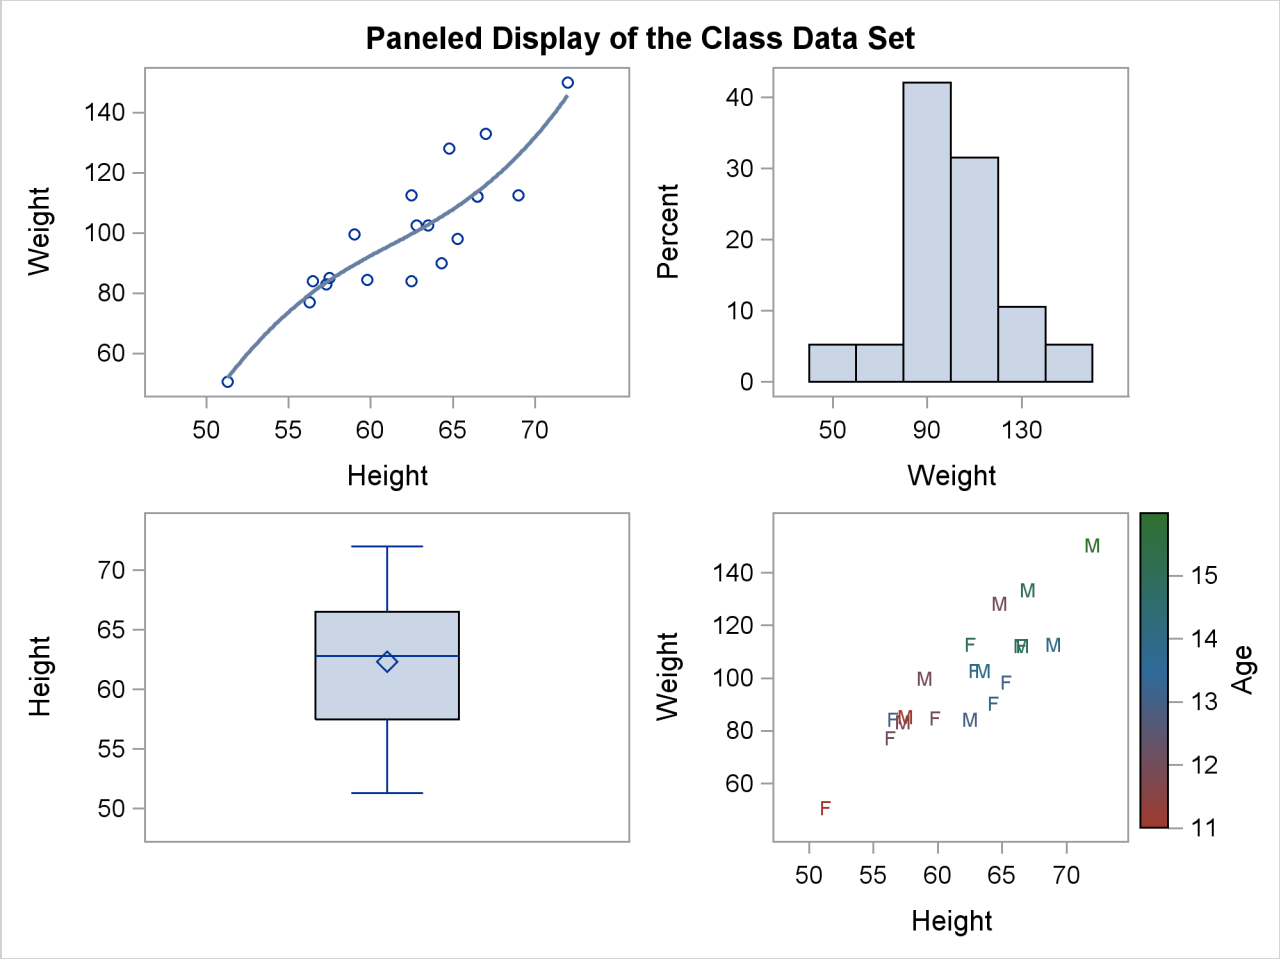
            layout overlay / xaxisopts=(offsetmin=0.1 offsetmax=0.1)
                             yaxisopts=(offsetmin=0.1 offsetmax=0.1);
               scatterplot  y=weight x=height / markercharacter=sex
                  name='color' markercolorgradient=age;
               continuouslegend 'color'/ title='Age';
            endlayout;

         endlayout;
      endgraph;
   end;
run;

proc sgrender data=sashelp.class template=panel;
run;
```

In this template, the outermost layout is a LAYOUT LATTICE. It creates a 2×2 panel of plots with a 10-pixel separation (or gutter) between each plot. Inside the lattice are four LAYOUT OVERLAY blocks—each defining one of the graphs. The first is a simple scatter plot with a nonlinear penalized B-spline fit. The second is a histogram of the dependent variable Weight. The third is a box plot of the independent variable Height. The fourth simultaneously shows height, weight, age, and sex for the students in the class. Each axis has an offset added at both the maximum and minimum. This provides padding between the axes and the data.

Figure 21.60 Multiple Panels Using PROC SGRENDER



Many other types of graphs are available with the SG procedures. However, even the few examples provided here show the power and flexibility available for making professional-quality statistical graphics. See the *SAS Graph Template Language: User's Guide* and the *SAS ODS Graphics: Procedures Guide* for more information.

Examples of ODS Statistical Graphics

Example 21.1: Creating Graphs with Tool Tips in HTML

This example demonstrates how to request graphs in HTML that are enhanced with tooltip displays, which appear when you move a mouse over certain features of the graph. When you specify the HTML destination and the IMAGEMAP=ON option in the ODS GRAPHICS statement, an image map of coordinates for tooltips is generated along with the HTML output file. Individual graphs are saved as PNG files.

Example 58.2 and Example 58.8 of Chapter 58, "The MIXED Procedure," analyze a data set with repeated growth measurements for 27 children. The following step creates the data set:

```
data pr;
   input Person Gender $ y1 y2 y3 y4 @@;
   y=y1; Age=8;  output;
   y=y2; Age=10; output;
   y=y3; Age=12; output;
   y=y4; Age=14; output;
   drop y1-y4;
   datalines;
 1  F  21.0  20.0  21.5  23.0      2  F  21.0  21.5  24.0  25.5

   ... more lines ...

;
```

The following statements fit a mixed model with random intercepts and slopes for each child:

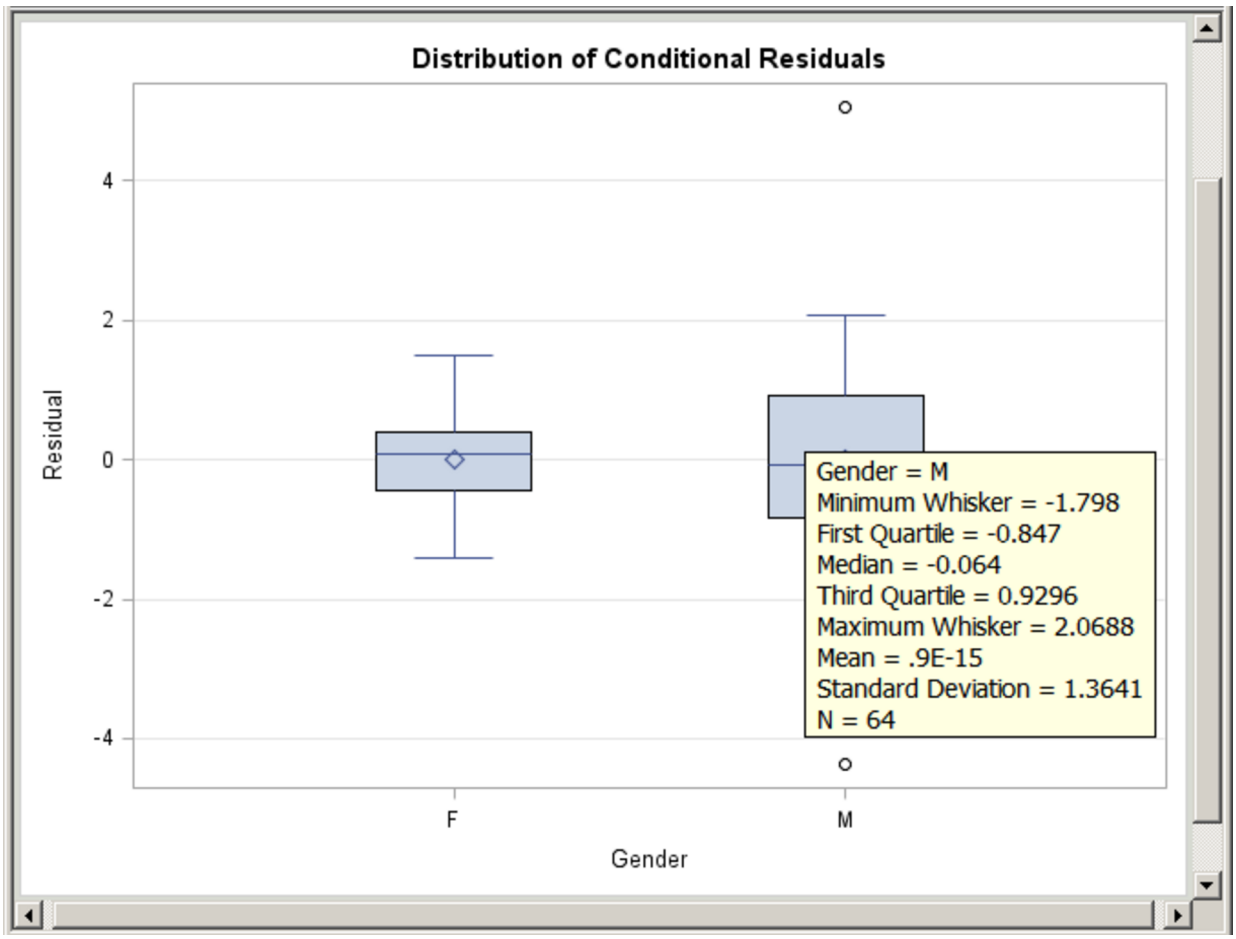
```
ods _all_ close;
ods graphics on / imagemap=on;
ods html body='b.html' style=HTMLBlue;

proc mixed data=pr method=ml plots=boxplot;
   ods select 'Conditional Residuals by Gender';
   class Person Gender;
   model y = Gender Age Gender*Age;
   random intercept Age / type=un subject=Person;
run;

ods html close;
```

The PLOTS=BOXPLOT option in the PROC MIXED statement requests box plots of observed values and residuals for each classification main effect in the model (Gender and Person). Only the by-gender box plots are actually created due to the ODS SELECT statement, which uses the plot label to select the plot. Output 21.1.1 displays the results. Moving the mouse over a box plot displays a tooltip with summary statistics for the class level. Graphics with tooltips are supported for only the HTML destination.

Output 21.1.1 Box Plot with Tool Tips



Example 21.2: Creating Graphs for a Presentation

The RTF destination provides an easy way to create graphs for inclusion into a paper or presentation. You can specify the ODS RTF statement to create a file that is easily imported into a document (such as Microsoft Word or WordPerfect) or a presentation (such as Microsoft PowerPoint).

The following statements request a loess fit and save the output in the file *loess.rtf*:

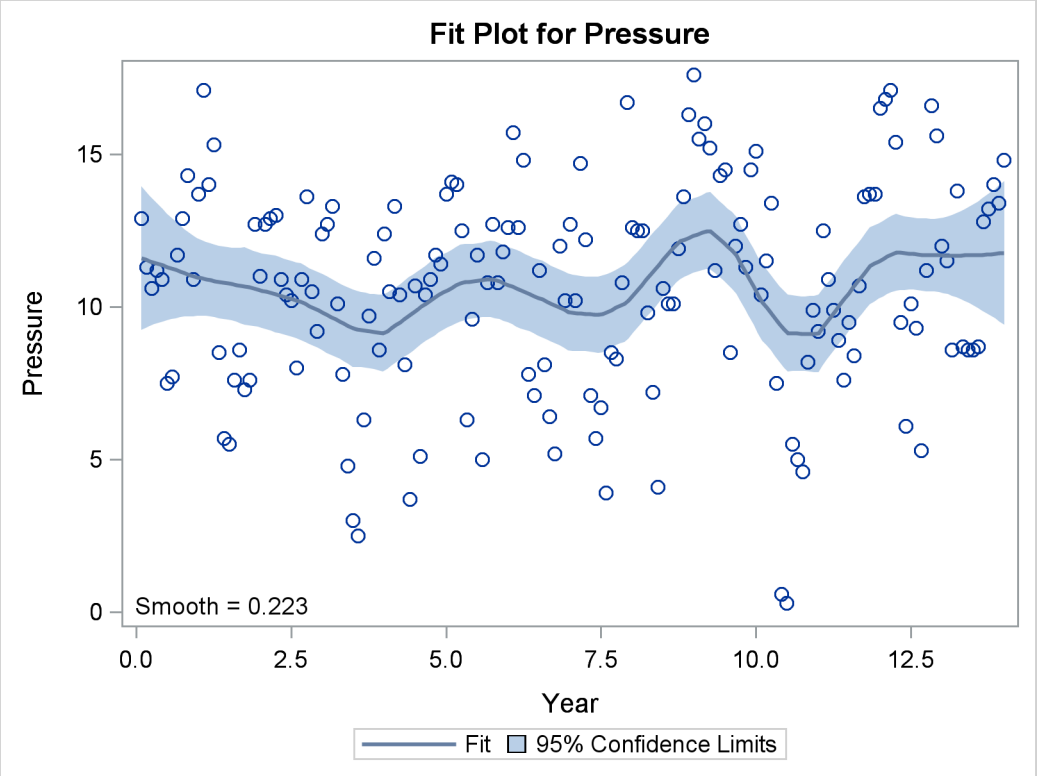
```
ods _all_ close;
ods rtf file="loess.rtf" style=HTMLBlue;
ods graphics on;

proc loess data=sashelp.enso;
   model pressure = year / clm residual;
run;

ods rtf close;
ods listing;
```

The output file includes various tables and the following plots: a plot of the selection criterion versus smoothing parameter, a fit plot with 95% confidence bands, a plot of residual by regressors, and a diagnostics panel. The fit plot is produced with the HTMLBLUE style and is shown in Output 21.2.1.

Output 21.2.1 Loess Fit Plot with the HTMLBLUE Style



If you are running the SAS System in the Microsoft Windows operating system, you can open the RTF file in Microsoft Word and simply copy and paste the graphs into Microsoft PowerPoint. In general, RTF output is convenient for exchange of graphical results between Microsoft Windows applications through the clipboard.

Alternatively, if you use the LISTING or HTML destinations, then your individual graphs are created as PNG files by default. You can insert these files into a Microsoft PowerPoint presentation. See the sections "Naming Graphics Image Files" on page 636 and "Saving Graphics Image Files" on page 638 for information about how the image files are named and saved.

Example 21.3: Creating Graphs in PostScript Files

This example illustrates how to create individual graphs in PostScript files. This is particularly useful when you want to include them in a LaTeX document.

The following statements close all open destinations, open the LATEX destination with the JOURNAL style, and request a grouped bar chart for the Sashelp.Class data set:

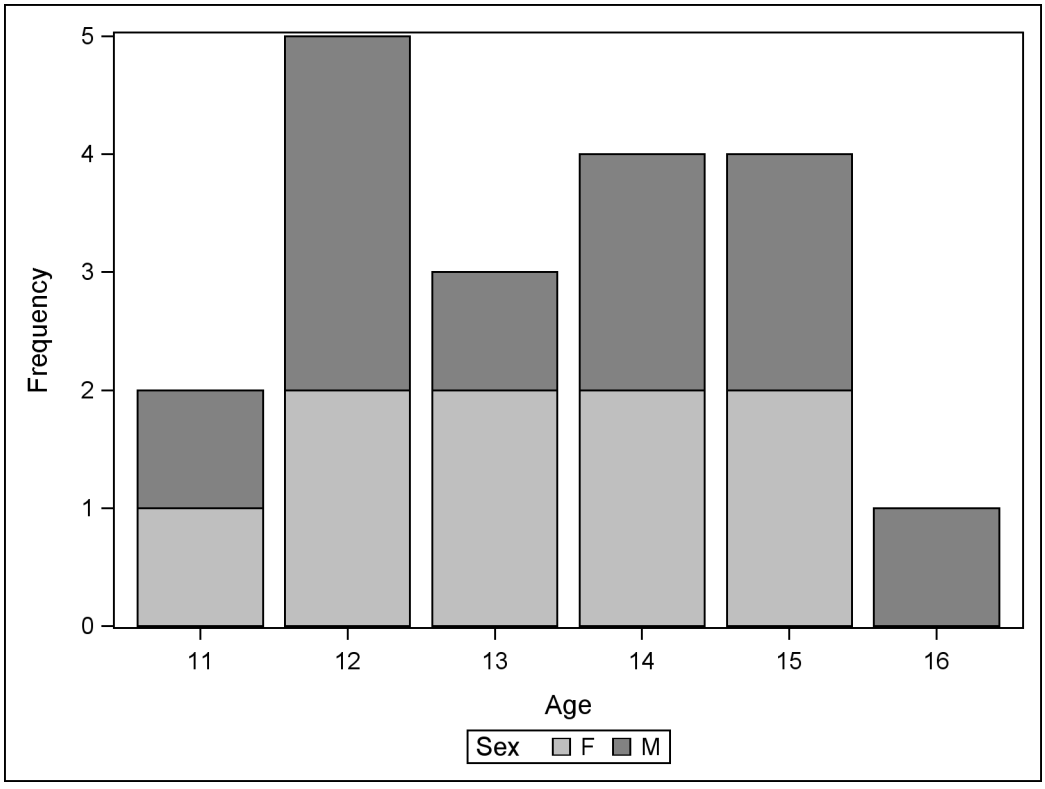
```
ods graphics on / reset=index;
ods _all_ close;
ods latex style=Journal;

proc sgplot data=sashelp.class;
   vbar age / group=sex;
   run;

ods latex close;
ods listing;
```

The JOURNAL style displays gray-scale graphs that are suitable for a journal. When you specify the ODS LATEX destination, ODS creates a PostScript file for each individual graph in addition to a LaTeX source file that includes the tabular output and references to the PostScript files. By default, these files are saved in the SAS current folder. The bar chart shown in Output 21.3.1 is saved by default in a file named *SGPlot.ps*. See the section "Naming Graphics Image Files" on page 636 for details about how graphics image files are named. If both the default destination (LISTING or HTML) and the LATEX destination are open, then two files are created: *SGPlot.png* and *SGPlot1.ps*. If the RESET=INDEX option is not specified in the ODS GRAPHICS statement and you run the step again, the next names are based on an incremented index (*SGPlot2.png* and *SGPlot3.ps*).

Output 21.3.1 Bar Chart Using the JOURNAL Style



You can use the JOURNAL2 style for a different appearance—the bars are not shaded. Crosshatching is used to indicate group membership. The following step produces Output 21.3.2:

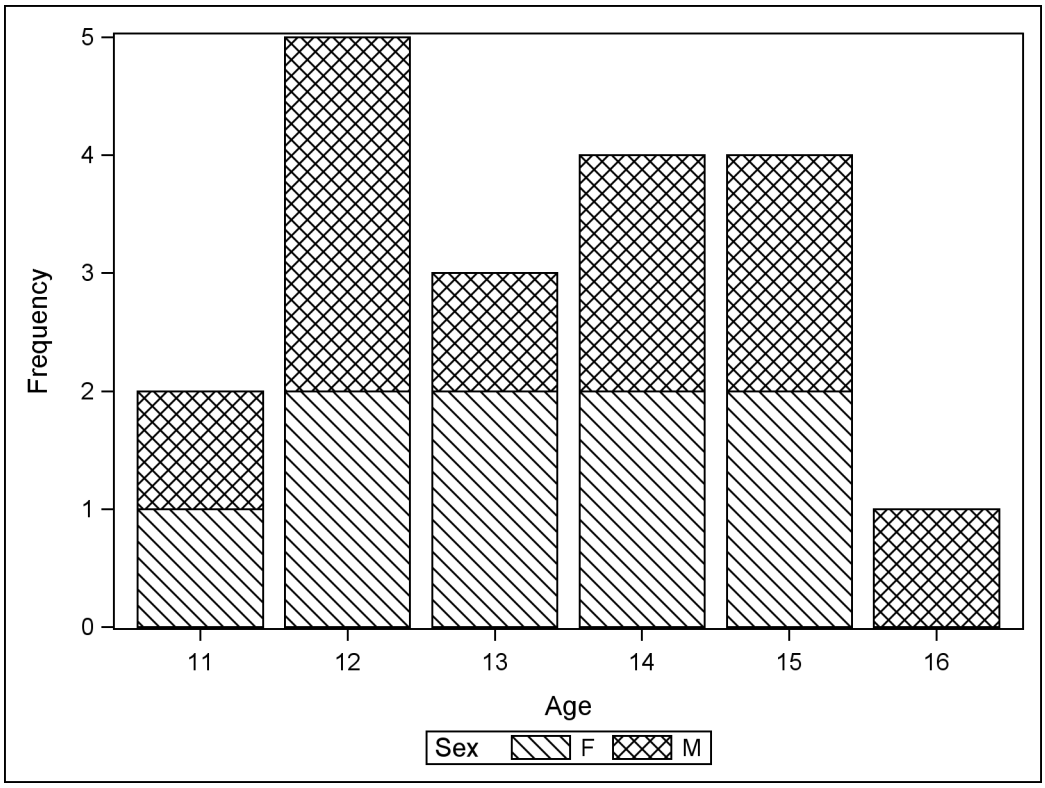
```
ods graphics on / reset=index;
```

```
ods _all_ close;
ods latex style=Journal2;

proc sgplot data=sashelp.class;
   vbar age / group=sex;
   run;

ods latex close;
ods listing;
```

Output 21.3.2 Bar Chart Using the JOURNAL2 Style



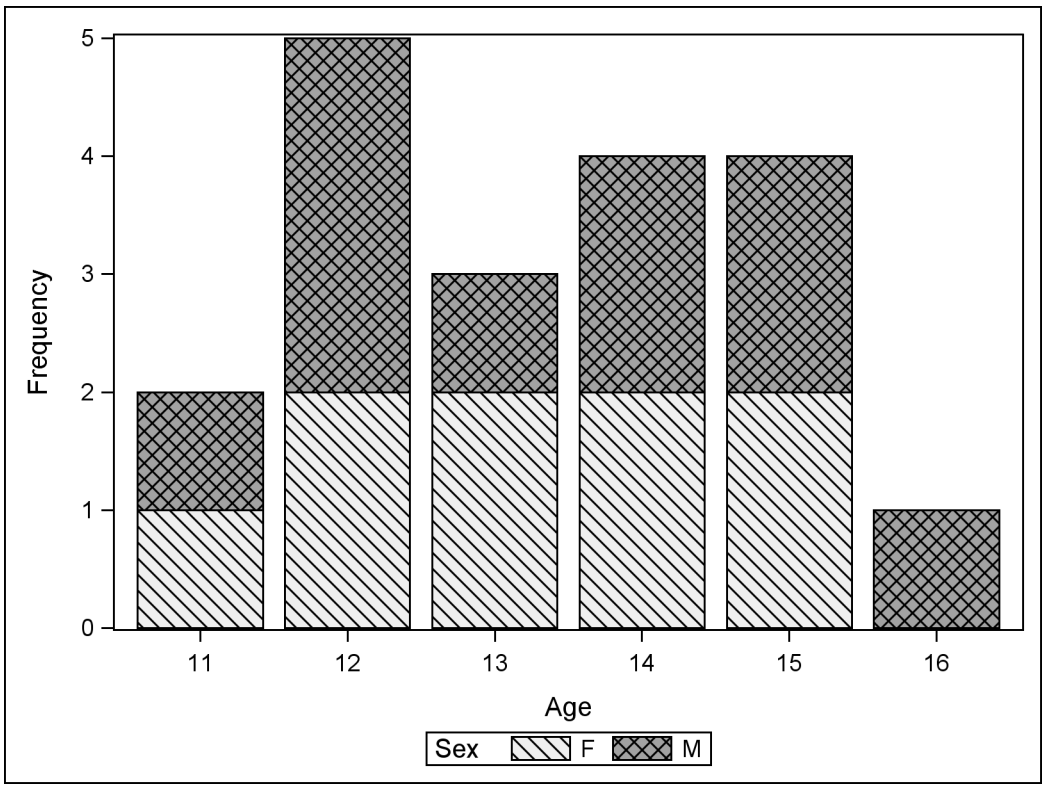
You can use the JOURNAL3 style for a different kind of appearance from the JOURNAL style. A mix of filled areas and crosshatching is used in grouped bar charts. The following step produces Output 21.3.3:

```
ods graphics on / reset=index;
ods _all_ close;
ods latex style=Journal3;

proc sgplot data=sashelp.class;
   vbar age / group=sex;
   run;

ods latex close;
ods listing;
```

Output 21.3.3 Bar Chart Using the JOURNAL3 Style



If you are writing a paper, you can include the graphs in your own LaTeX source file by referencing the names of the individual PostScript graphics files. In this situation, you might not find it necessary to use the LaTeX source file created by the SAS System. Alternatively, you can include PNG files into a LaTeX document, after using some other ODS destination (such as HTML) to create the PNG files.

Example 21.4: Displaying Graphs Using the DOCUMENT Procedure

This example illustrates the use of the ODS DOCUMENT destination and the DOCUMENT procedure to display your ODS graphs. You can use this approach whenever you want to generate and save your output (both tables and graphs) and then display or replay it later, potentially in subsets or more than once. This approach is particularly useful when you want to display your output in multiple ODS destinations, or when you want to use different styles without rerunning your SAS program. This approach is also useful when you want to break your output into separate parts for inclusion into different parts of a document such as a LaTeX file.

Consider again the data set Stack created by the following statements:

```
data stack;
   input x1 x2 x3 y @@;
   datalines;
80 27 89 42   80 27 88 37   75 25 90 37   62 24 87 28   62 22 87 18
62 23 87 18   62 24 93 19   62 24 93 20   58 23 87 15   58 18 80 14
58 18 89 14   58 17 88 13   58 18 82 11   58 19 93 12   50 18 89  8
50 18 86  7   50 19 72  8   50 19 79  8   50 20 80  9   56 20 82 15
70 20 91 15
;
```

The following statements request a Q-Q plot from PROC ROBUSTREG with the Stack data:

```
ods _all_ close;
ods document name=QQDoc(write);

proc robustreg data=stack plots=qqplot;
   model y = x1 x2 x3;
run; quit;

ods document close;
ods listing;
```

The ODS DOCUMENT statement opens an ODS document named **QQDoc**. All of the results—tables, graphs, titles, notes, footnotes, headers—are stored in the ODS document. None of them are displayed since no other destination is open. In order to display the Q-Q plot with PROC DOCUMENT, you first need to determine its name. You can do this by specifying the ODS TRACE ON statement prior to the procedure statements (see the section "Determining Graph Names and Labels" on page 630 for more information). Alternatively, you can type **odsdocuments** (or **odsd** for short) on the command line to open the Documents window, which you can then use to manage your ODS documents.

The following statements specify an HTML destination and display the residual Q-Q plot by using the REPLAY statement in PROC DOCUMENT:

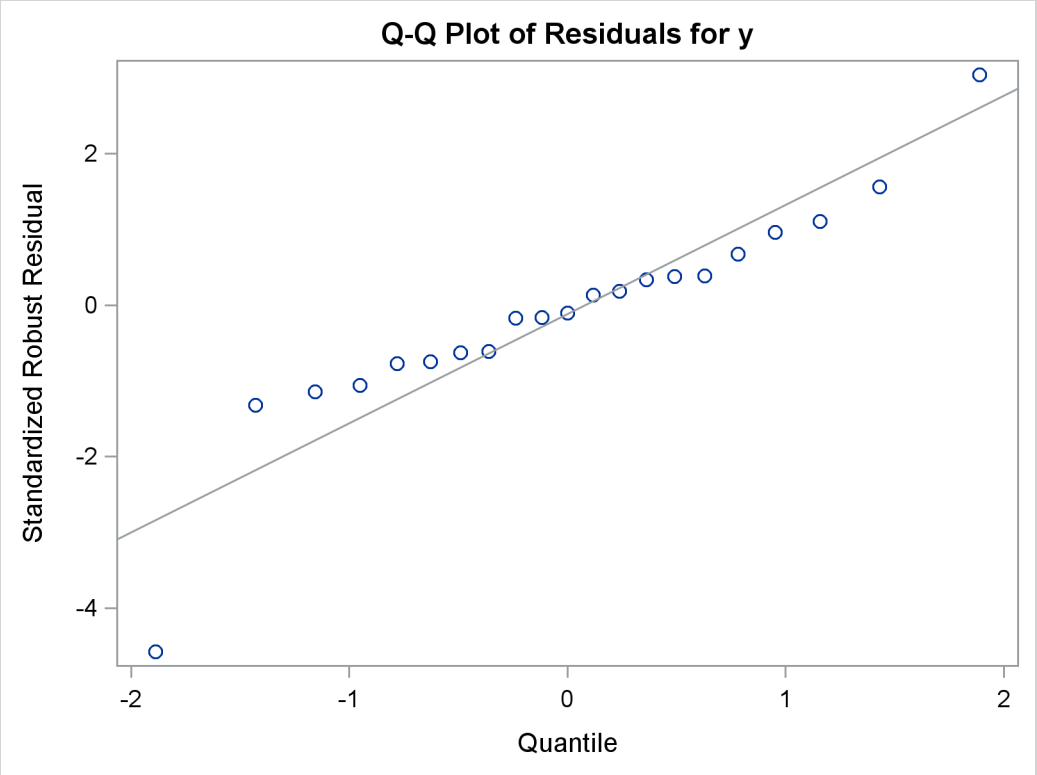
```
ods html body='b.htm';

proc document name=QQDoc;
   ods select QQPlot;
   replay;
run; quit;

ods html close;
```

Subsequent steps can replay one or more objects from the same ODS document. By default, the REPLAY statement attempts to display every output object stored in the ODS document, but here only the Q-Q plot is displayed because it is specified by the ODS SELECT statement. The plot is displayed in Output 21.4.1.

Output 21.4.1 Q-Q Plot Displayed by PROC DOCUMENT



As an alternative to running PROC DOCUMENT with an ODS SELECT statement, you can run PROC DOCUMENT with a *document path* for the Q-Q plot in the REPLAY statement. This approach is preferable when the ODS document contains a large volume of output, so that PROC DOCUMENT does not attempt to process every piece of output stored in the ODS document.

You can determine the ODS document path for the Q-Q plot by specifying the LIST statement with the LEVELS=ALL option in PROC DOCUMENT as follows:

```
proc document name=QQDoc;
   list / levels=all;
run; quit;
```

The contents of the ODS document **QQDoc** are shown in Output 21.4.2.

Output 21.4.2 Contents of the ODS Document `QQDoc`

```
Listing of: \Work.Qqdoc\
Order by: Insertion
Number of levels: All

  Obs    Path                                                                  Type
-------------------------------------------------------------------------------------
       1 \Robustreg#1                                                          Dir
       2 \Robustreg#1\ModelInfo#1                                              Table
       3 \Robustreg#1\NObs#1                                                   Table
       4 \Robustreg#1\ParmInfo#1                                               Table
       5 \Robustreg#1\SummaryStatistics#1                                      Table
       6 \Robustreg#1\ParameterEstimates#1                                     Table
       7 \Robustreg#1\DiagSummary#1                                            Table
       8 \Robustreg#1\DiagnosticPlots#1                                        Dir
       9 \Robustreg#1\DiagnosticPlots#1\QQPlot#1                               Graph
      10 \Robustreg#1\GoodFit#1                                                Table
```

The ODS document path of the `QQPlot` entry in the `QQDoc` ODS document, as shown in Output 21.4.2, is `\Robustreg#1\DiagnosticPlots#1\QQPlot#1`.

You can use this path to display the residual Q-Q plot with PROC DOCUMENT as follows:

```
proc document name=QQDoc;
   replay \Robustreg#1\DiagnosticPlots#1\QQPlot#1;
run; quit;
```

You can also determine the ODS document path from the Results window or the Documents window. Right-click the object icon and select **Properties**.

The SAS/STAT documentation preparation process uses the ODS document. SAS output is saved into an ODS document that is then replayed into sections of the documentation, which is prepared using LaTeX. In general, when you send your output to the DOCUMENT destination, you can use PROC DOCUMENT to rearrange, duplicate, or remove output from the results of a procedure or a database query. For more information, see the ODS DOCUMENT statement in the section "Dictionary of ODS Language Statements" and the chapter "The DOCUMENT Procedure" in the *SAS Output Delivery System: User's Guide*.

Example 21.5: Customizing the Style for Box Plots

This example demonstrates how to modify the style for box plots. This example is taken from Example 21.1. The following step creates the data set:

```
data pr;
   input Person Gender $ y1 y2 y3 y4 @@;
   y=y1; Age=8;  output;
   y=y2; Age=10; output;
   y=y3; Age=12; output;
   y=y4; Age=14; output;
   drop y1-y4;
   datalines;
 1  F  21.0  20.0  21.5  23.0      2  F  21.0  21.5  24.0  25.5

   ... more lines ...

;
```

The following step displays the HTMLBLUE style and its parent styles, STATISTICAL and DEFAULT:

```
proc template;
   source Styles.HTMLBlue;
   source Styles.Statistical;
   source Styles.Default;
run;
```

If you search for 'box', you find the style element that controls some aspects of the box plot:

```
 class GraphBox /
    capstyle = "serif"
    connect = "mean"
    displayopts = "fill caps median mean outliers";
```

You can learn more about the **GraphBox** style element and its attributes in the section on the BOXPLOT statement in the *SAS Graph Template Language: Reference* and in the section on "ODS Style Elements" in the *SAS Output Delivery System: User's Guide*.

The following statements create two new styles by modifying attributes of the **GraphBox** style element. The first style is a sparse style; the box is outlined (not filled), and the median is shown but not the mean. In contrast, the second style produces a filled box, with caps on the whiskers that shows the mean, median, and outliers. In addition, the box is notched.

The following statements create the two styles:

```
proc template;
   define style BoxStyleSparse;
      parent=styles.HTMLBlue;
      style GraphBox / capstyle = "line" displayopts = "median";
   end;
   define style BoxStyleRich;
      parent=styles.HTMLBlue;
      style GraphBox / capstyle = "bracket"
            displayopts = "fill caps median mean outliers notches";
   end;
run;
```

The following steps run PROC MIXED and create box plots that use the two styles:

```
ods graphics on;
ods listing style=boxstylesparse;

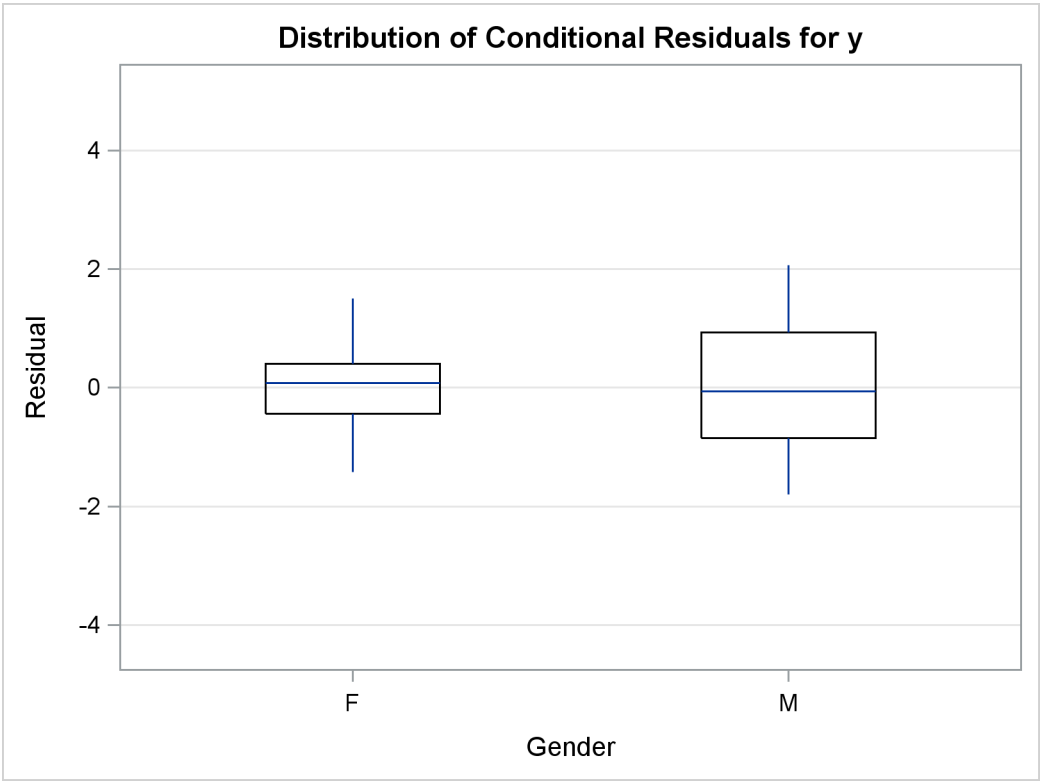
proc mixed data=pr method=ml plots=boxplot;
   ods select 'Conditional Residuals by Gender';
   class Person Gender;
   model y = Gender Age Gender*Age;
   random intercept Age / type=un subject=Person;
run;

ods listing style=boxstylerich;

proc mixed data=pr method=ml plots=boxplot;
   ods select 'Conditional Residuals by Gender';
   class Person Gender;
   model y = Gender Age Gender*Age;
   random intercept Age / type=un subject=Person;
run;
```

The results with the sparse style are displayed in Output 21.5.1, and the results with the richer style are displayed in Output 21.5.2. See Output 21.1.1 in Example 21.1 to see the results of using the HTMLBLUE style.

Output 21.5.1 Box Plot with the Sparse Style



Output 21.5.2 Box Plot with the Richer Style

Chapter 22

ODS Graphics Template Modification

Contents

Graph Templates

This chapter discusses the graph template language and graph template modification in ODS Graphics. Be sure that you are familiar with Chapter 21, "Statistical Graphics Using ODS," before reading this chapter.

Graph templates control the layout and details of graphs produced with ODS Graphics. The SAS System provides a template for every graph produced by statistical procedures. Graph template definitions are written in the Graph Template Language (GTL). This powerful language includes statements for specifying plot layouts (such as lattices or overlays), plot types (such as scatter plots and histograms), and text elements (such as titles, footnotes, and insets). It also provides support for built-in computations (such as histogram binning) and the evaluation of expressions. Options are available for specifying colors, marker symbols, and other attributes of plot features.

Graphs, like all SAS output, are constructed from two underlying components, a data component (or data object) and a template. Procedures supply a table of data values and statistical results to plot. Together, the data object and the template form an output object that ODS displays in one or more output destinations. You can control this display in two ways. You can use the ODS Graphics Editor (discussed in the section "ODS Graphics Editor" on page 642 in Chapter 21, "Statistical Graphics Using ODS,") to modify the output object (but not the underlying data object or template), and you can use the GTL to modify the template. With just a little knowledge of the GTL, you can modify or edit templates, even when you do not understand most of the syntax used in the template definition. See examples starting with Example 22.1.

NOTE: You do not need to know anything about the GTL to create statistical graphics.

This section provides an overview of the Graph Template Language. It also describes how to locate, display, edit, and save templates. A *template definition* is a set of SAS statements that is used together with PROC TEMPLATE to create a compiled template. In addition to graph templates, two other common types of templates are table templates and style templates. A table template describes how to display the output for an output object that is rendered as a table. A style template provides formatting information for visual aspects of your SAS output, including both tables and graphs. In most applications, you do not have to modify the templates that are supplied by SAS. However, when customization is necessary, you can modify the default template with the template language and PROC TEMPLATE.

Compiled templates are stored in a template store, which is a type of item store. (An item store is a special type of SAS file.) The default templates supplied by SAS are stored in the Sashelp.Tmplmst template store. If you are using the SAS windowing environment, an easy way to display, edit, and save your templates is by using the Templates window. For an introduction to the graph template language, see Kuhfeld (2010).

For detailed information about managing templates, see the *SAS Output Delivery System: User's Guide* and the *SAS Graph Template Language: User's Guide*. For details about the syntax of the graph template language, see the *SAS Graph Template Language: Reference*.

The Graph Template Language

Graph template definitions begin with a DEFINE STATGRAPH statement in PROC TEMPLATE, and they end with an END statement. Embedded in every graph template is a BEGINGRAPH/ENDGRAPH block, and embedded in that block are one or more LAYOUT blocks. You can specify the DYNAMIC statement to define dynamic variables (which the procedure uses to pass values to the template definition), the MVAR and NMVAR statements to define macro variables (which you can use to pass values to the template definition), and the NOTES statement to provide descriptive information about the graph. The default templates supplied by SAS for statistical procedures are often lengthy and complex, because they provide ODS Graphics with comprehensive and detailed information about graph construction. Here is one of the simpler graph templates for a statistical procedure:

```
define statgraph Stat.MDS.Graphics.Fit;
   notes "MDS Fit Plot";
   dynamic head;
   begingraph / designwidth=defaultdesignheight;
      entrytitle HEAD;
      layout overlayequated / equatetype=square;
         scatterplot y=FITDATA x=FITDIST / markerattrs=(size=5px);
         lineparm slope=1 x=0 y=0 / extend=true lineattrs=GRAPHREFERENCE;
      endlayout;
   endgraph;
end;
```

This template, supplied for the MDS procedure, creates a scatter plot of two variables, FitData and FitDist, along with a diagonal reference line that passes through the origin. The plot is square and the axes are equated so that a centimeter on one axis represents the same data range as a centimeter on the other axis. The plot title is provided by the evaluation of the dynamic variable Head, which is set by the procedure. It is not unusual for this plot to contain hundreds or even thousands of points, so a five-pixel marker is specified, which is smaller than the seven-pixel marker used by default in most styles.

The statements available in the graph template language can be classified as follows:

- Control statements specify the conditional or iterative flow of control. By default, flow of control is sequential. In other words, each statement is used in the order in which it appears.
- Layout statements specify the arrangement of the components of the graph. Layout statements are arranged in blocks that begin with a LAYOUT statement and end with an ENDLAYOUT statement. The blocks can be nested. Within a layout block, there can be plot, text, and other statements that define one or more graph components. Options provide control for attributes of layouts and components.
- Plot statements specify a number of commonly used displays, including scatter plots, histograms, contour plots, surface plots, and box plots. Plot statements are always provided within a layout block. The plot statements include options to specify the data columns from the data object that is used in the

graph. For example, in the SCATTERPLOT statement, there are mandatory X= and Y= arguments that specify which data columns are used for the X (horizontal) and Y (vertical) axes in the plot. (In the preceding example, FitData and FitDist are the names of columns int the data object that PROC MDS creates for this graph.) There is also a GROUP= option that specifies a data column as an optional classification variable.

- Text statements specify the descriptions that accompany graphs. An entry is any textual description, including titles, footnotes, and legends; it can include symbols to identify graph elements.

The following statements display another of the simpler template definitions—the definition of the scatter plot available in PROC KDE (see Figure 47.6.1 in Chapter 47, "The KDE Procedure,"):

```
proc template;
   define statgraph Stat.KDE.Graphics.ScatterPlot;
      dynamic _TITLE _DEPLABEL _DEPLABEL2;
      BeginGraph;
         EntryTitle _TITLE;
         layout Overlay;
            scatterplot x=X y=Y / markerattrs=GRAPHDATADEFAULT;
         EndLayout;
      EndGraph;
   end;
run;
```

Here, the PROC TEMPLATE and RUN statements have been added to show how you would compile the template if you wanted to modify it. The DEFINE STATGRAPH statement in PROC TEMPLATE begins the graph template definition, and the END statement ends the definition. The DYNAMIC statement defines three dynamic variables that PROC KDE sets at run time. The variable _Title provides the title of the graph. The variables _DepLabel and _DepLabel2 contain the names of the X- and Y-variables, respectively. If you were to modify this template, you could use these dynamic text variables in any text element of the graph definition.

The overall display is specified with the LAYOUT OVERLAY statement inside the BEGINGRAPH/ENDGRAPH block. The title of the graph is specified with the ENTRYTITLE statement. The main plot is a scatter plot specified with the SCATTERPLOT statement. The options in the SCATTERPLOT statement are given after the slash and specify display options such as marker attributes (symbol, color, and size). These attributes can be specified directly, as in the PROC MDS template, or more typically by using indirect references to style attributes, as in the PROC KDE template. The values of these attributes are specified in the definition of the style you are using and are automatically set to different values if you specify a different style. For more information about style references, see the section "Styles" on page 648 in Chapter 21, "Statistical Graphics Using ODS." The ENDLAYOUT statement ends the main layout block. For details about the syntax of the graph template language, see the *SAS Graph Template Language: Reference*.

You can write your own templates and use them to display raw data or output from procedures. For example, consider the iris data from Example 32.1 of Chapter 32, "The DISCRIM Procedure." The iris data set is available from the Sashelp library.

The following statements create a template for a scatter plot of the variables PetalLength and PetalWidth with a legend:

```
proc template;
   define statgraph scatter;
      begingraph;
         entrytitle 'Fisher (1936) Iris Data';
         layout overlayequated / equatetype=fit;
            scatterplot x=petallength y=petalwidth /
                        group=species name='iris';
            layout gridded / autoalign=(topleft);
               discretelegend 'iris' / border=false opaque=false;
            endlayout;
         endlayout;
      endgraph;
   end;
run;
```

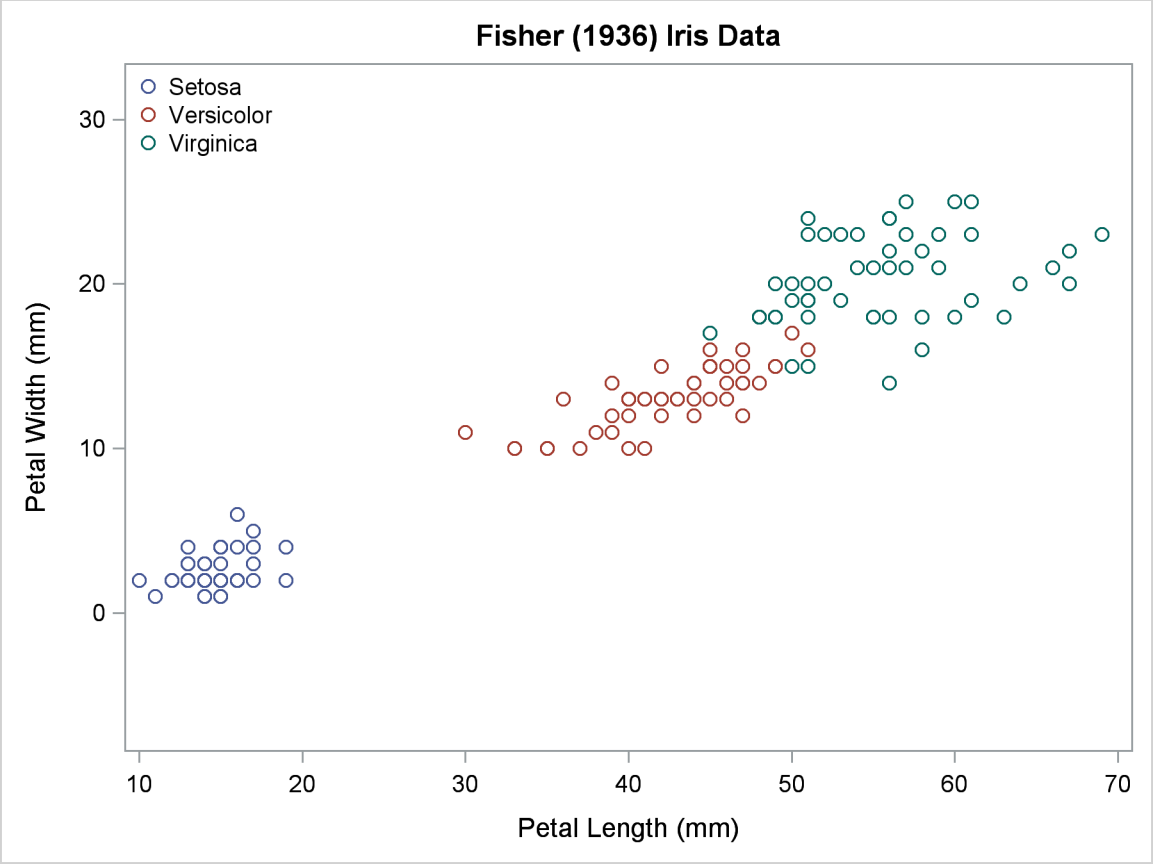
The layout is OVERLAYEQUATED, which equates the axes in the plot. However, unlike the PROC MDS template, which used EQUATETYPE=SQUARE to make a square plot, the EQUATETYPE=FIT option specifies that the lengths of the axes in this plot should fill the entire plotting area. A legend is placed internally in the top-left portion of the plot. There are three groups of observations, indicated by the three species, and each group is plotted with a separate color and symbol that depends on the ODS style. The legend identifies each group. The NAME= option provides the link between the SCATTERPLOT statement and the DISCRETELEGEND statement. An explicit link is needed since some graphical displays are based on multiple plotting statements.

The following step creates the plot by using the SGRENDER procedure, the Sashelp.Iris data set, and the custom template **scatter**:

```
proc sgrender data=sashelp.iris template=scatter;
run;
```

The syntax of PROC SGRENDER is very simple, because all of the graphical options appear in the template. The scatter plot in Figure 22.1 shows the results.

Figure 22.1 Petal Width and Petal Length in Three Iris Species



The intent of this example is to illustrate how you can write a template to create a scatterplot. PROC TEMPLATE and PROC SGRENDER provide you with the power to create highly customized displays. However, usually you can use the SGPLOT, SGSCATTER or SGPANEL procedures instead, which are much simpler to use. These procedures are discussed in the section "Statistical Graphics Procedures" on page 691 in Chapter 21, "Statistical Graphics Using ODS." See the section "Grouped Scatter Plot with PROC SGPLOT" on page 610 and Figure 21.12 in Chapter 21, "Statistical Graphics Using ODS," for an example that plots these data with PROC SGPLOT.

Locating Templates

Before you can customize a graph, you must determine which template is used to create the original graph. You can do this by submitting the ODS TRACE ON statement before the procedure statements that create the graph. The fully qualified template name is displayed in the SAS log. Here is an example:

```
ods trace on;
ods graphics on;

proc reg data=sashelp.class;
   model Weight = Height;
run; quit;
```

The preceding statements create the following trace output, which provides information about both the graphs and tables produced by PROC REG:

```
Output Added:
-------------
Name:        NObs
Label:       Number of Observations
Template:    Stat.Reg.NObs
Path:        Reg.MODEL1.Fit.Weight.NObs
-------------

Output Added:
-------------
Name:        ANOVA
Label:       Analysis of Variance
Template:    Stat.REG.ANOVA
Path:        Reg.MODEL1.Fit.Weight.ANOVA
-------------

Output Added:
-------------
Name:        FitStatistics
Label:       Fit Statistics
Template:    Stat.REG.FitStatistics
Path:        Reg.MODEL1.Fit.Weight.FitStatistics
-------------

Output Added:
-------------
Name:        ParameterEstimates
Label:       Parameter Estimates
Template:    Stat.REG.ParameterEstimates
Path:        Reg.MODEL1.Fit.Weight.ParameterEstimates
-------------

Output Added:
-------------
Name:        DiagnosticsPanel
Label:       Fit Diagnostics
Template:    Stat.REG.Graphics.DiagnosticsPanel
Path:        Reg.MODEL1.ObswiseStats.Weight.DiagnosticPlots.DiagnosticsPanel
-------------

Output Added:
-------------
Name:        ResidualPlot
Label:       Height
Template:    Stat.REG.Graphics.ResidualPlot
Path:        Reg.MODEL1.ObswiseStats.Weight.ResidualPlots.ResidualPlot
-------------
```

```
Output Added:
-------------
Name:        FitPlot
Label:       Fit Plot
Template:    Stat.REG.Graphics.Fit
Path:        Reg.MODEL1.ObswiseStats.Weight.FitPlot
-------------
```

This is also illustrated in Example 22.1 and the section "The ODS Statement" on page 533 in Chapter 20, "Using the Output Delivery System."

Displaying Templates

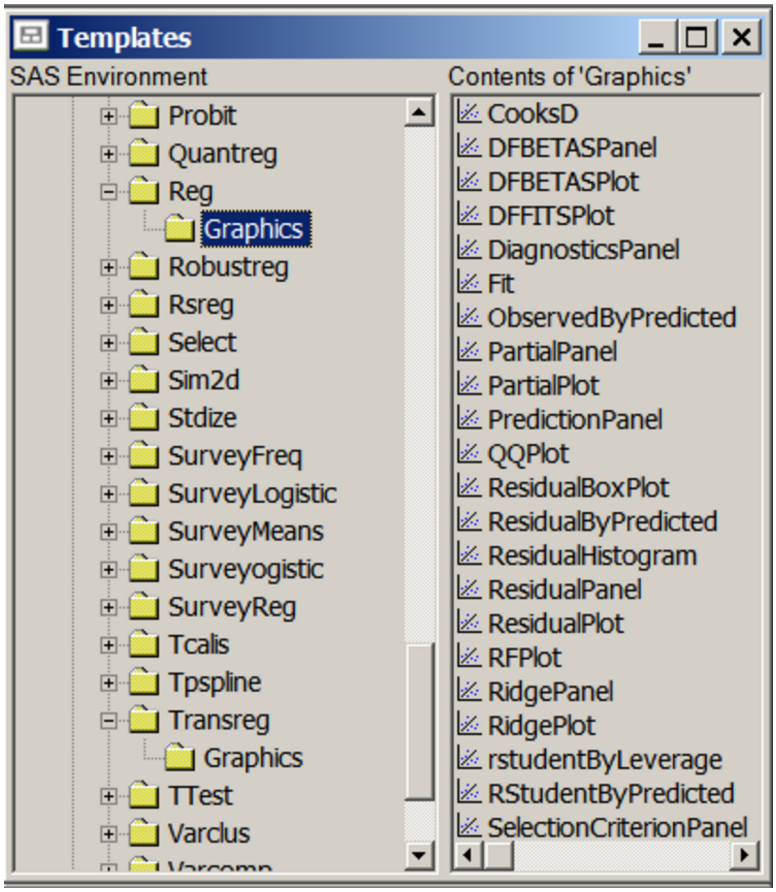
Once you have found the fully qualified name of a template, you can display its definition (source program) by using one of these methods:

- Open the Templates window by issuing the command **odstemplates** (**odst** for short) in the command line of the SAS windowing environment. The template window is shown in Figure 22.2. If you expand the Sashelp.Tmplmst node, you can view all the available templates and double-click any template icon to display its definition. This is illustrated in Example 22.1.
- Use the SOURCE statement in PROC TEMPLATE to display a template definition in the SAS log or write the definition to a file.

For example, the following statements display the template for the PROC REG residual plot:

```
proc template;
   source Stat.REG.Graphics.ResidualPlot;
run;
```

Figure 22.2 Requesting the Templates Window in the Command Line



The template is displayed as follows:

```
define statgraph Stat.Reg.Graphics.ResidualPlot;
   notes "Residual Plot";
   dynamic _XVAR _SHORTXLABEL _TITLE _LOESSLABEL _DEPNAME
           _MODELLABEL _SMOOTH;
   BeginGraph;
      entrytitle halign=left textattrs=GRAPHVALUETEXT
         _MODELLABEL halign=center
         textattrs=GRAPHTITLETEXT _TITLE " for " _DEPNAME;
      entrytitle textattrs=GRAPHVALUETEXT _LOESSLABEL;
      layout overlay / xaxisopts=(shortlabel=_SHORTXLABEL);
         referenceline y=0;
         scatterplot y=RESIDUAL x=_XVAR / primary=true
            rolename=(_tip1=OBSERVATION _id1=ID1 _id2=ID2
            _id3=ID3 _id4=ID4 _id5=ID5) tip=(y x
            _tip1 _id1 _id2 _id3 _id4 _id5);
         if (EXISTS(_SMOOTH))
            loessplot y=_SMOOTH x=_XVAR /
               tiplabel=(y="Smoothed Residual");
         endif;
      endlayout;
   EndGraph;
end;
```

PROC TEMPLATE also tells you where the template is located. In this case, it prints the following note:

```
NOTE: Path 'Stat.Reg.Graphics.ResidualPlot' is in: SASHELP.TMPLMST.
```

The word "Path" in ODS refers to any name or label hierarchy. In the note, the levels of the template name form a path. In the trace output, the levels of the plot name form a different path.

Editing Templates

You can modify the format and appearance of a particular graph by doing the following:

- Modify its template definition (source program).
- Submit the revised template to create a new compiled template.
- Ensure that the ODS search path finds and uses your new template.

Template stores are designated read-only (such as Sashelp.Tmplmst) or updatable (such as Sasuser.Templat).

If you view the templates in an updatable template store from the Templates window, you can select **Open** or **Edit** from the pop-up menu. Either the Template Browser or Template Editor window opens. In the Template Editor window, you can make changes and submit the code directly. For read-only templates or when you select **Open**, the Template Browser window opens and you must copy the definition to an editor window to make changes. Since templates supplied by SAS are in the read-only Sashelp library, an easy way to obtain an editable program file is to use the SOURCE statement with the FILE= option in PROC TEMPLATE to write the template definition to a file as follows:

```
proc template;
   source Stat.REG.Graphics.ResidualPlot / file="residtpl.sas";
run;
```

By default, the file is saved in the SAS current folder. Alternatively, you can omit the slash and the FILE= option and copy and paste the source from the SAS log into an editor. Either way, you must add a PROC TEMPLATE statement before the generated source statements and optionally a RUN statement after the END statement before you submit your modified definition.

Graph definitions are self-contained and do not support inheritance (via the PARENT= option) as do table definitions. Consequently, the EDIT statement in PROC TEMPLATE is not supported for graph definitions.

Here are some important points about what you can and cannot change in a template supplied by SAS while preserving its overall functionality:

- Do not change the template name. A statistical procedure can access only a predefined list of templates. If you change the name, the procedure cannot find your template. You must keep the original name and make sure that it is in a template store that is read before Sashelp.Tmplmst. You control this with the ODS PATH statement (see the section "The Default Template Stores and the Template

Search Path" on page 647 in Chapter 21, "Statistical Graphics Using ODS," the section "Saving Customized Templates" on page 725, and subsequent sections for more information about the template search path and the ODS PATH statement).

- Do not change the names of columns. The underlying data object contains predefined column names that you must use. Be very careful if you change how a column is used in a template. Usually, columns are not interchangeable.
- Do not change the names of DYNAMIC variables. Procedures set values only for a predefined list of dynamic variables. Changing dynamic variable names can lead to runtime errors. Do not add dynamic variables, because the procedure cannot set their values. A few procedures document additional dynamic variables that can be defined in the template if you want to add more information to the output, such additional statistics in an inset table. See the sections "Modifying the Layout and Adding a New Inset Table" on page 778 and "Displaying Survival Summary Statistics" on page 795 for examples.
- Do not change the names of statements (for example, from a SCATTERPLOT to a NEEDLEPLOT or other type of plot).

You can change any of the following:

- You can add macro variables that behave like dynamic variables. They are resolved at the time that the statistical procedure is run, and not at the time that the template is compiled. They are defined with an MVAR or NMVAR statement at the beginning the template. You can set the value of each macro variable with a %LET statement before the statistical procedure is run. See Example 22.6. You can also move a variable from a DYNAMIC statement to an MVAR or NMVAR statement if you want to set it yourself rather than letting the procedure set it.
- You can change the graph size.
- You can change graph titles, footnotes, axis labels, and any other text that appears in the graph.
- You can change which plot features are displayed.
- You can change axis features, such as grid lines, offsets, view ports, tick value formatting, and so on.
- You can change the content and arrangement of insets (small tables of statistics embedded in some graphs).
- You can change the legend location, contents, border, background, title, and so on.

See the *SAS Graph Template Language: Reference* for information about the syntax of the statements in the Graph Template Language.

Saving Customized Templates

After you edit the template definition, you can submit your PROC TEMPLATE statements as you would any other SAS program. If you are using the Template Editor window, select **Submit** from the **Run** menu. See Example 22.1. Alternatively, submit your PROC TEMPLATE statements from the Program Editor. ODS

automatically saves the compiled template in the first template store that it can update, according to the currently defined template search path. If you have not changed the template search path, then the modified template is saved in the Sasuser.Templat template store. You can display the current template search path with the following statement:

```
ods path show;
```

The log messages for the default template search path are as follows:

```
Current ODS PATH list is:

1. SASUSER.TEMPLAT(UPDATE)
2. SASHELP.TMPLMST(READ)
```

If you want to store modified templates in another template store, you can use the ODS PATH statement to add that template store to the front of the list. To use these templates, you must make sure the template search path is set correctly before you attempt to access them in the other SAS sessions. See the section "Using Customized Templates" on page 726.

Using Customized Templates

When you create ODS output (either graphs or tables), ODS searches sequentially through each template store in the template search path for a template that matches the one requested. If you have not changed the default template search path, then ODS searches the Sasuser.Templat store first, then Sashelp.Tmplmst. ODS uses the first template that it finds with the requested name. **NOTE:** Templates with the same name can exist in more than one template store.

The ODS PATH statement specifies the template stores to search, as well as the order in which to search them. You can change the default template search path by using the ODS PATH statement. For example, the following statement sets the template search path so that the template store Work.Mystore is searched first, followed by Sashelp.Tmplmst:

```
ods path work.mystore(update) sashelp.tmplmst(read);
```

The UPDATE option provides update access as well as read access to Work.Mystore. The READ option provides read-only access to Sashelp.Tmplmst. With this path, the template store Sasuser.Templat is no longer searched. You can verify this with the following statement:

```
ods path show;
```

The log messages generated by the preceding statement are as follows:

```
Current ODS PATH list is:

1. WORK.MYSTORE(UPDATE)
2. SASHELP.TMPLMST(READ)
```

For more information, see the *SAS Output Delivery System: User's Guide* and the *SAS Graph Template Language: User's Guide*. Example 22.1 illustrates all the steps of displaying, editing, saving, and using customized templates.

Reverting to the Default Templates

Customized templates are stored in Sasuser.Templat or in some other template store that you create. The templates supplied by SAS are in the read-only template store Sashelp.Tmplmst. If you have modified any of the supplied templates and you want to use the original default templates, you can change your template search path as follows:

```
ods path sashelp.tmplmst(read) sasuser.templat(update);
```

This way the default templates are found first. Alternatively, you can save all of your customized templates in a user-defined template store (for example Work.Mystore). To access these templates, you submit the following statement before running your analysis:

```
ods path mylib.mystore(update) sashelp.tmplmst(read);
```

When you are done, you can reset the default template search path as follows:

```
ods path reset;
```

This restores the template search path to its original state (**sasuser.templat(update) sashelp.tmplmst(read)**). You can also save your customized template as part of your SAS program. You can delete it from the Sasuser.Templat template store when you are done, as in the following statements:

```
proc template;
   delete Stat.REG.Graphics.ResidualPlot;
run;
```

The following note is printed in the SAS log:

```
NOTE: 'Stat.REG.Graphics.ResidualPlot' has been deleted from: SASUSER.TEMPLAT
```

You can run the following step to delete the entire Sasuser.Templat store of customized templates:

```
ods path sashelp.tmplmst(read);
proc datasets library=sasuser nolist;
   delete templat(memtype=itemstor);
run;
ods path sasuser.templat(update) sashelp.tmplmst(read);
```

Graph Template Modification Macro

You can use the **%ModTmplt** autocall macro to insert BY line information, titles, and footnotes in ODS Graphics. You can also use it to remove titles and perform other template modifications. See Kuhfeld (2009) for more information about this macro.

You do not have to include autocall macros (for example, with a **%include** statement). You can call them directly once they are properly installed. If your site has installed the autocall libraries supplied by SAS and uses the standard configuration of SAS supplied software, you need to ensure that the SAS system option MAUTOSOURCE is in effect to begin using the autocall macros. For more information about autocall libraries, see the *SAS Macro Language: Reference*. For details about installing autocall macros, consult your host documentation.

The **%ModTmplt** macro has the following options:

BY=*by-variable-list*
: specifies the list of BY variables. Also see BYLIST=. When graphs are produced (by default or when the STEPS= value contains 'G'), you must specify the BY= option. Otherwise, when you are only modifying the template, you do not need to specify the BY= option.

BYLIST=*by-statement-list*
: specifies the full syntax of the BY statement. You can specify a full BY statement syntax including the DESCENDING or NOTSORTED options. If only BY variables are needed, specify only BY=. If you also need options, then specify the BY variables in the BY= option and the full syntax in the BYLIST= option (for example, specify BY=A B and BYLIST=A DESCENDING B).

DATA=*SAS-data-set*
: specifies the input SAS data set. If you do not specify the DATA= option, the macro uses the most recently created SAS data set.

FILE=*filename*
: specifies the file in which to store the original templates. This is a temporary file. You can specify either a quoted file name or the name from a FILENAME statement that you provide before you call the macro. The default is *"template.txt"*.

OPTIONS=*options*
: specifies one or more of the following options (case is ignored):

  LOG
  : displays a note in the SAS log when each BY group has finished.

  FIRST
  : adds the ENTRYTITLE or ENTRYFOOTNOTE statements as the first titles or footnotes. By default, the statements are added after the last titles or footnotes. Most graph templates provided by SAS do not use footnotes; so this option usually affects only entry titles.

  NOQUOTES
  : specifies that the values of the system titles and footnotes are to be moved to the ENTRYTITLE or ENTRYFOOTNOTE statements without the outer quotation marks. With OP-

TIONS=NOQUOTES, you can specify options in the titles or footnotes in addition to the text. However, you must ensure that you quote the text that provides the actual title or footnote.

The following is an example of an ordinary footnote:

```
footnote "My Footer";
```

With this FOOTNOTE statement and without OPTIONS=NOQUOTES, the macro creates the following ENTRYFOOTNOTE statement:

```
entryfootnote "My Footer";
```

The following footnotes are used with OPTIONS=NOQUOTES:

```
footnote 'halign=left "My Footer"';
footnote2 '"My Second Footer"';
```

With these FOOTNOTE statements and OPTIONS=NOQUOTES, the macro creates the following ENTRYFOOTNOTE statements:

```
entryfootnote halign=left "My Footer";
entryfootnote "My Second Footer";
```

REPLACE

replaces the unconditionally added entry titles and entry footnotes in the templates (those that are not part of IF or ELSE statements) with the system titles and footnotes. The system titles and footnotes are those that are specified in the TITLE or FOOTNOTE statements. You can instead use the TITLES=*SAS-data-set* option to specify titles and footnotes with a data set. If OPTIONS=REPLACE is specified, then OPTIONS=TITLES is ignored.

SOURCE

displays the generated source code. By default, the template source code is not displayed.

TITLES

displays the system titles and footnotes with the graphs. The system titles and footnotes are those that are specified in the TITLE or FOOTNOTE statements. You can instead use the TITLES=*SAS-data-set* option to specify titles and footnotes with a data set. If you also specify OPTIONS=FIRST, the system titles and footnotes are inserted before the previously existing entry titles and entry footnotes in the templates. Otherwise, they are inserted at the end.

You can specify OPTIONS=TITLES or OPTIONS=REPLACE, or insert BY lines, or do both. If you do both, and you do not like where the BY line is inserted relative to your titles and footnotes, just specify OPTIONS=NOQUOTES and _ByLine0 to place the BY line wherever you choose. The following TITLE statements illustrate:

```
title1 '"My First Title"';
title2 '_byline0';
title3 '"My Last Title"';
```

Also, you can embed BY information in a title or a footnote, again with OPTIONS=NOQUOTES. For example:

```
title '"Spline Fit By Sex, " _byline0';
```

When _ByLine0 is specified in any of the titles or footnotes, then the usual BY line is not added.

The following example removes all titles and footnotes:

```
footnote;
title;
%modtmplt(options=replace, template=Stat.Transreg.Graphics, steps=t)
```

STATEMENT=*entry-statement-fragment*

specifies the statement that contains the BY line that gets added to the template along with any statement options. The default is **Statement=EntryFootNote halign=left TextAttrs=GraphValueText**. Other examples include:

```
Statement=EntryTitle
Statement=EntryFootNote halign=left TextAttrs=GraphLabelText
```

STEPS=*steps*

specifies the macro steps to run. Case and white space are ignored. the macro modifies the templates (when 'T' is specified), produces the graphs for each BY group (when 'G' is specified), and deletes the modified templates (when 'D' is specified). The default is STEPS=TGD. You can instead have it perform a subset of these three tasks by specifying a subset of terms in the STEPS= option.

When you use the **%ModTmplt** macro to add BY lines, you usually do not need to delete the templates before you run your procedure again in the normal way. The template modification inserts the BY line through a macro variable and an MVAR statement. When the macro variable _ByLine0 is undefined, the ENTRYTITLE or ENTRYFOOTNOTE statement drops out as if it were not there at all.

STMTOPTS1= *n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**
STMTOPTS2= *n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**
STMTOPTS3= *n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**
STMTOPTS4= *n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**
STMTOPTS5= *n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**
STMTOPTS6= *n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**
STMTOPTS7= *n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**
STMTOPTS8= *n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**
STMTOPTS9= *n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**
STMTOPTS10=*n* **ADD | REPLACE | DELETE | BEFORE | AFTER** *statement-name* **<** *options* **>**

These ten options add or replace options in up to 10 selected statements. The following example illustrates:

```
%modtmplt(template=Stat.glm.graphics.residualhistogram, steps=t,
          stmtopts1=.  add  discretelegend  autoalign=(topleft),
          stmtopts2=1  add  densityplot     legendlabel='Normal Density',
          stmtopts3=2  add  densityplot     legendlabel='Kernel Density',
          stmtopts4=1  add  overlay         yaxisopts=(griddisplay=on)
                            yaxisopts=(label='Normal and Kernel Density'))
```

```
proc glm plots=diagnostics(unpack) data=sashelp.class;
   model weight = height;
run;

%modtmplt(template=Stat.glm.graphics.residualhistogram, steps=d)
```

These options require you to specify a series of values. The first value is the statement number (or missing to modify options on all statements that match the statement name). The second value is: ADD, REPLACE, DELETE, BEFORE, or AFTER. When the second value is ADD or REPLACE, it controls whether you add new options or replace existing options. Alternatively, the second value can be BEFORE or AFTER to add a new statement before or after the named statement. When the value is DELETE, the corresponding statement is deleted. The third value is a statement name. All remaining options are options for the statement named by the third value (with ADD and REPLACE) or for a new statement (with BEFORE and AFTER). In the STMTOPTS1= example, an option is added to all DISCRETELEGEND statements. In the STMTOPTS2= example, an option is added to the first DensityPlot statement. In the STMTOPTS4= example, an option is added to the LAYOUT OVERLAY statement. In most cases, the statement name is the first name that begins the statement. The LAYOUT statement is an exception. In the case of layouts, specify the second name (OVERLAY, GRIDDED, LATTICE, and so on) for the third value. Note that a statement such as `if (expression) EntryTitle...;` is an IF statement not an ENTRYTITLE statement.

If an option is specified multiple times on a GTL statement, the last specification overrides previous specifications. Hence, you do not need to know and respecify all of the options. You can just add an option to the end, and it overrides the previous value. You can use these options only to modify statements that contain a slash, and only to modify the options that come after the slash. Note that in STMTOPTS4=, the YAXISOPTS= option is specified twice. It could have been equivalently specified once as follows:

```
yaxisopts=(griddisplay=on label='Normal and Kernel Density'))
```

The actual specification adds the GRIDDISPLAY=ON to the Y axis options (which by default has only a label specification). The old label is unchanged until the LABEL= option in the second YAXISOPTS= specification overrides it. In other words, YAXISOPTS=(GRIDDISPLAY=ON) augments the old YAXISOPTS= option; it does not replace it.

The following steps delete the legend and instead provide a footnote:

```
%modtmplt(template=Stat.glm.graphics.residualhistogram, steps=t,
          stmtopts1=. delete discretelegend,
          stmtopts2=1 after  begingraph entryfootnote
                      textattrs=GraphLabelText(color=cx445694) 'Normal  '
                      textattrs=GraphLabelText(color=cxA23A2E) 'Kernel')

proc glm plots=diagnostics(unpack) data=sashelp.class;
   model weight = height;
run;

%modtmplt(template=Stat.glm.graphics.residualhistogram, steps=d)
```

TEMPLATE=*SAS-template*
specifies the name of the template to modify. You can specify just the first few levels to modify a series of templates. For example, to modify all of PROC REG's graph templates, specify TEMPLATE=**Stat.Reg.Graphics**. This option is required.

TITLES=*SAS-data-set*
specifies a data set that contains titles or footnotes or both. By default, when the system titles or footnotes are used (when OPTIONS=TITLES or OPTIONS=REPLACE is specified), PROC SQL is used to determine the titles and footnotes. You can instead create this data set yourself so that you can set the graph titles independently from the system titles and footnotes. The data set must contain two variables: Type (Type='T' for titles and Type='F' for footnotes), and Text, which contains the titles and footnotes. Other variables are ignored. Specify the titles and footnotes in the order in which you want them to appear.

TITLEOPTS=*entry-statement-options*
specifies the options for system titles and footnotes. For example, you can specify the HALIGN= and TEXTATTRS= options as in the STATEMENT= option. By default, no title options are used. With OPTIONS=NOQUOTES, you can specify options individually.

Adding a BY Line to Graphs

You can use the **%ModTmplt** macro to display in your graphs BY line information (such as **Sex = 'F'** and **Sex = 'M'** when the statement BY SEX is specified). The **%ModTmplt** macro requires you to construct a SAS macro called **%MyGraph**, which contains the SAS procedure that needs to be run, so that the **%ModTmplt** macro can call it for each BY group. The following example illustrates this usage of the macro:

```
proc sort data=sashelp.class out=class;
   by sex;
run;

%macro mygraph;
proc transreg data=__bydata;
   model identity(weight) = spline(height);
%mend;

%modtmplt(by=sex, data=class, template=Stat.Transreg.Graphics)
```

Notice that the BY and RUN statements are *not* specified in the **%MyGraph** macro. Also notice that you must specify DATA=__BYDATA with the procedure call in the **%MyGraph** macro and specify the real input data set in the DATA= option of the **%ModTmplt** macro.

The **%ModTmplt** macro outputs the specified template or templates to a file, adds an ENTRYFOOTNOTE statement with the BY line information, and then runs the **%MyGraph** macro once for each BY group. In the end, the **%ModTmplt** macro deletes the modified template.

The results of the preceding statements are displayed in Figure 22.3 and Figure 22.4. The BY line is displayed as a left-justified footnote by default. You can change this with the STATEMENT= option (default: **Statement=EntryFootNote Halign=Left TextAttrs=GraphValueText**). For example, you can display the BY line as a centered title by specifying STATEMENT=ENTRYTITLE.

Figure 22.3 The First BY Group

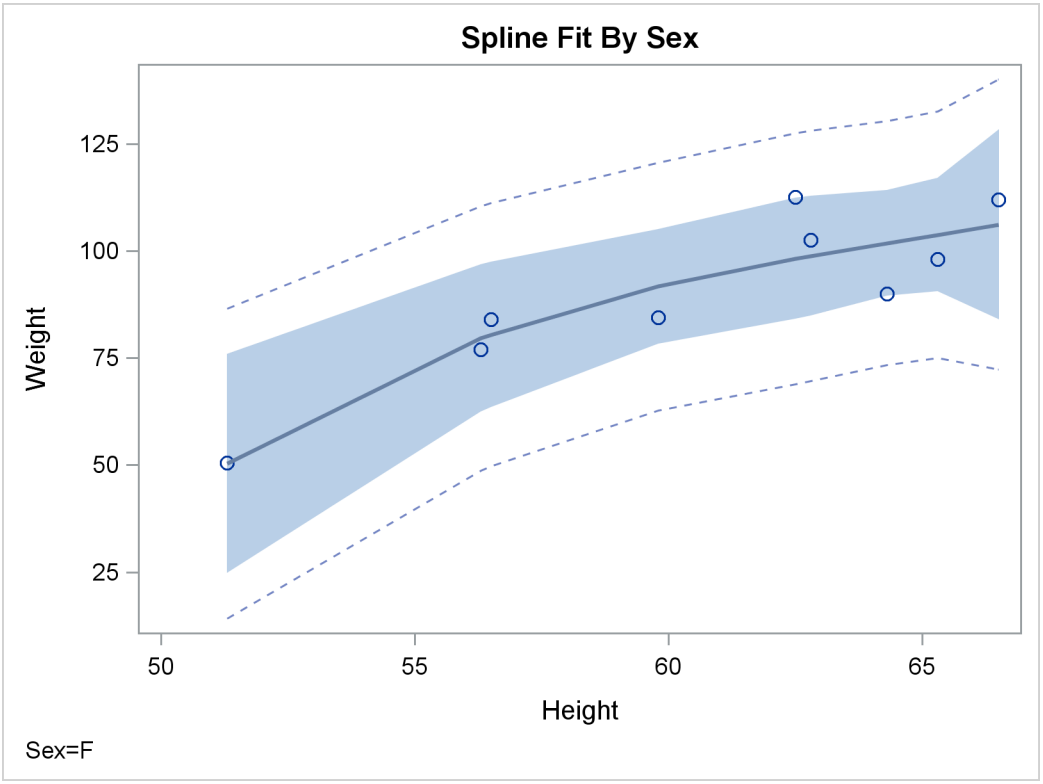


Figure 22.4 The Second BY Group

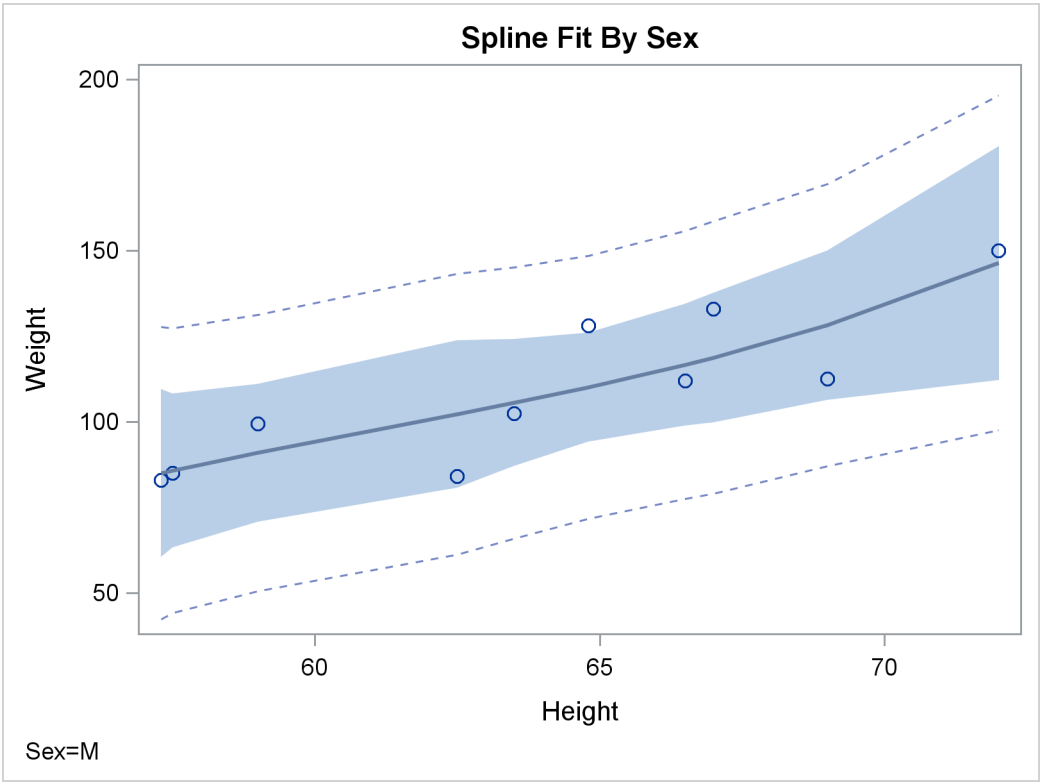


Examples of ODS Graphics Template Modification

Example 22.1: Customizing Graphs Through Template Changes

This example shows how to use PROC TEMPLATE to customize the appearance and content of an ODS graph. It is divided into several parts; each part illustrates a different aspect of the template that you can easily change. You are never required to change a template, but you can if you want to change aspects of the plot.

Modifying Graph Titles and Axis Labels

This section illustrates the discussion in the section "Graph Templates" on page 716 in the context of changing the default title and Y-axis label for a Q-Q plot created with PROC ROBUSTREG. The data set Stack is created by the following statements:

```
data stack;
   input  x1 x2 x3 y @@;
   datalines;
80  27  89  42    80  27  88  37    75  25  90  37

   ... more lines ...

;
```

The following statements request a Q-Q plot for robust residuals created by PROC ROBUSTREG:

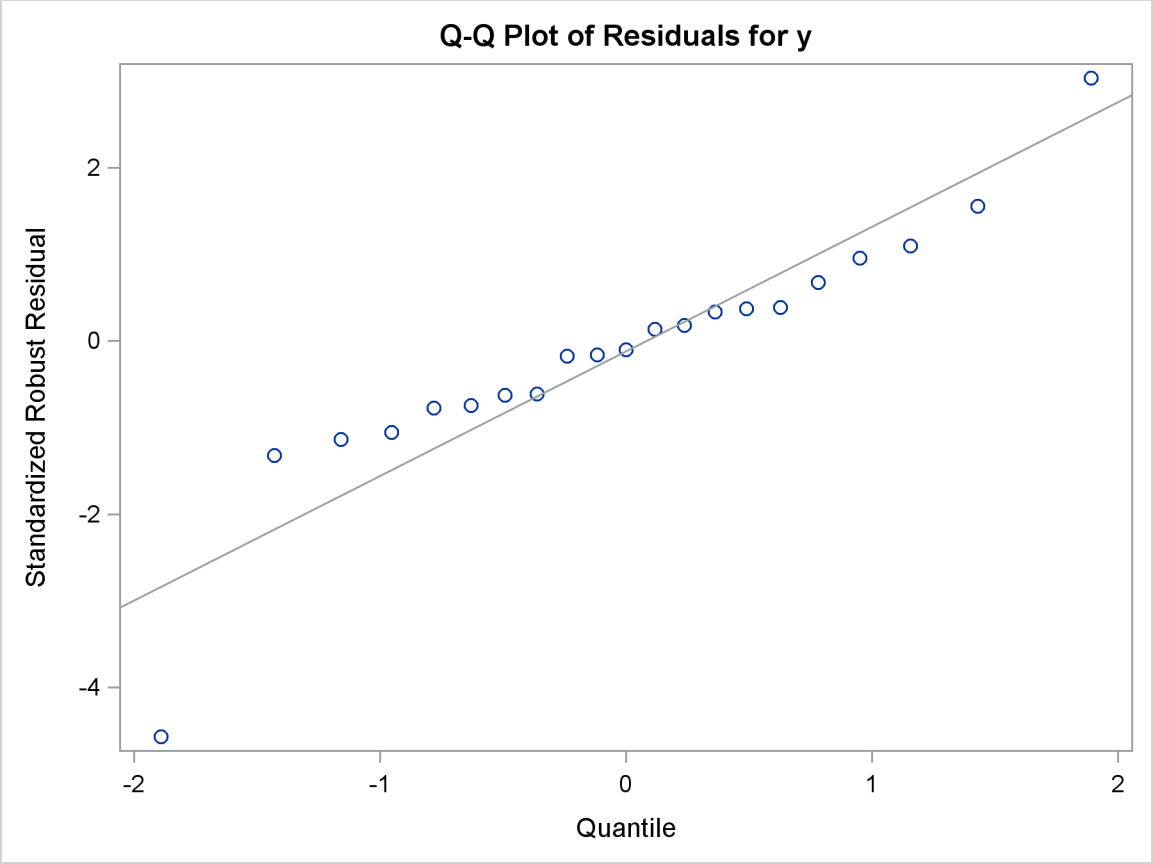
```
ods trace on;
ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;

ods trace off;
```

The Q-Q plot is shown in Output 22.1.1.

Output 22.1.1 Default Q-Q Plot from PROC ROBUSTREG



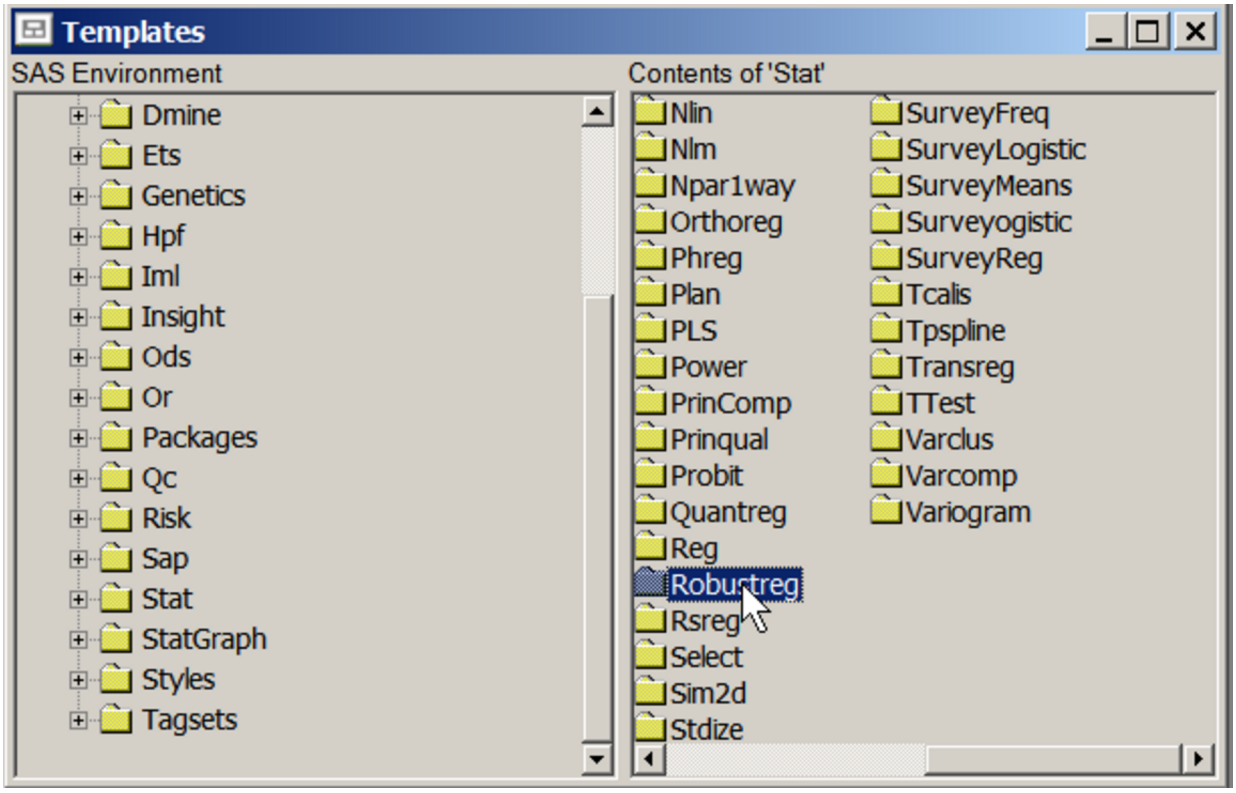
The ODS TRACE ON statement requests a record of all the ODS output objects created by PROC ROBUSTREG. The trace output is as follows:

```
Output Added:
-------------
Name:        QQPlot
Label:       Residual Q-Q Plot
Template:    Stat.Robustreg.Graphics.QQPlot
Path:        Robustreg.DiagnosticPlots.QQPlot
-------------
```

ODS Graphics creates the Q-Q plot from an ODS data object named **QQPlot** and a graph template named **Stat.Robustreg.Graphics.QQPlot**, which is the default template provided by SAS. Default templates supplied by SAS are saved in the Sashelp.Tmplmst template store (see the section "Graph Templates" on page 716).

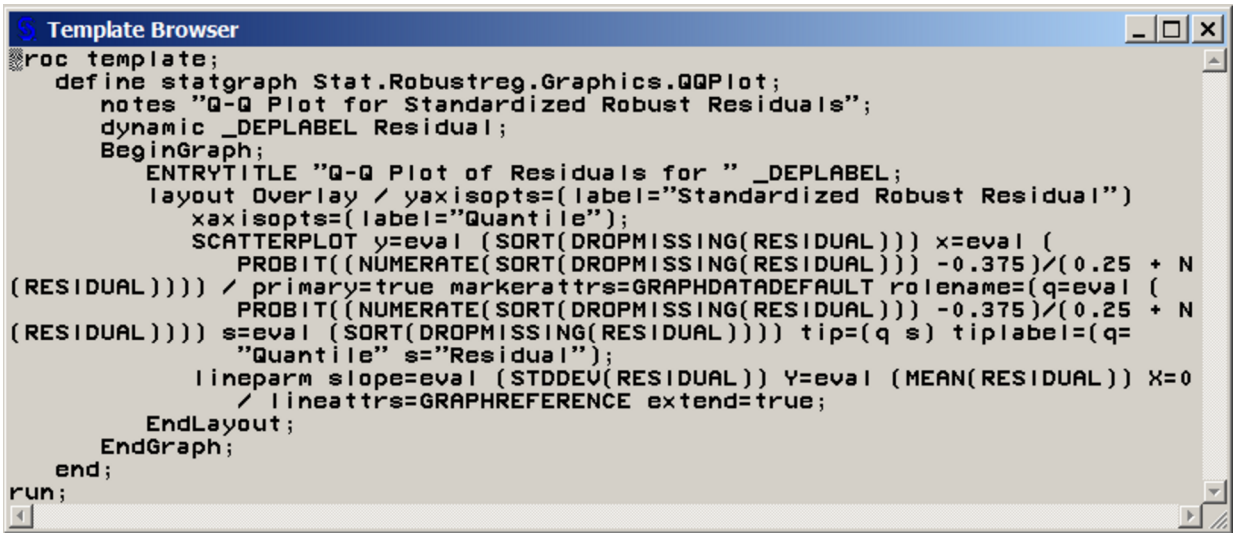
To display the default template definition, open the Templates window by typing **odstemplates** (or **odst** for short) in the command line. Expand Sashelp.Tmplmst and click the **Stat** folder. Output 22.1.2 shows the contents of the **Stat** folder.

Output 22.1.2 The Template Window



Next, open the **Robustreg** folder and then open the **Graphics** folder. Then right-click the `QQPlot` template icon and select **Open**. This opens the Template Browser window shown in Output 22.1.3. You can copy this template to an editor to edit it.

Output 22.1.3 Default Template Definition for Q-Q Plot



Alternatively, you can submit the following statements to display the **QQPlot** template definition in the SAS log:

```
proc template;
   source Stat.Robustreg.Graphics.QQPlot;
run;
```

The SOURCE statement specifies the fully qualified template name. You can copy and paste the template source into the Program Editor and modify it. The template, with a PROC TEMPLATE and RUN statement added, is shown next:

```
proc template;
   define statgraph Stat.Robustreg.Graphics.QQPlot;
      notes "Q-Q Plot for Standardized Robust Residuals";
      dynamic _DEPLABEL Residual;
      BeginGraph;
         ENTRYTITLE "Q-Q Plot of Residuals for " _DEPLABEL;
         layout Overlay / yaxisopts=(label="Standardized Robust Residual")
            xaxisopts=(label="Quantile");
            SCATTERPLOT y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) / primary=true markerattrs=GRAPHDATADEFAULT
               rolename=(q=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) s=eval (SORT(DROPMISSING(RESIDUAL))))
               tip=(q s) tiplabel=(q="Quantile" s="Residual");
            lineparm slope=eval (STDDEV(RESIDUAL)) Y=eval (MEAN(RESIDUAL))
               X=0 / lineattrs=GRAPHREFERENCE extend=true;
         EndLayout;
      EndGraph;
   end;
run;
```

In the template, the default title of the Q-Q plot is specified by the ENTRYTITLE statement. The variable _DepLabel is a dynamic variable that provides the name of the dependent variable in the regression analysis. In this case, the name is y. In this template, the label for the axes are specified by the LABEL= suboption of the YAXISOPTS= option for the LAYOUT OVERLAY statement. In other templates, the axis labels come from the column labels of the X-axis and Y-axis columns of the data object. You can see these labels by specifying ODS OUTPUT with the plot data object and running PROC CONTENTS with the resulting SAS data set.

Suppose you want to change the default title to "Analysis of Residuals", and you want the Y-axis label to display the name of the dependent variable. First, replace the ENTRYTITLE statement with the following statement:

```
entrytitle "Analysis of Residuals";
```

Next, replace the LABEL= suboption with the following:

```
label=("Standardized Robust Residual for " _DEPLABEL)
```

You can use dynamic text variables such as _DepLabel in any text element.

You can then submit the modified template definition as you would any SAS program, for example, by selecting **Submit** from the **Run** menu. After submitting the PROC TEMPLATE statements, you should see the following message in the SAS log:

```
NOTE: STATGRAPH 'Stat.Robustreg.Graphics.QQPlot' has been
  saved to: SASUSER.TEMPLAT
```

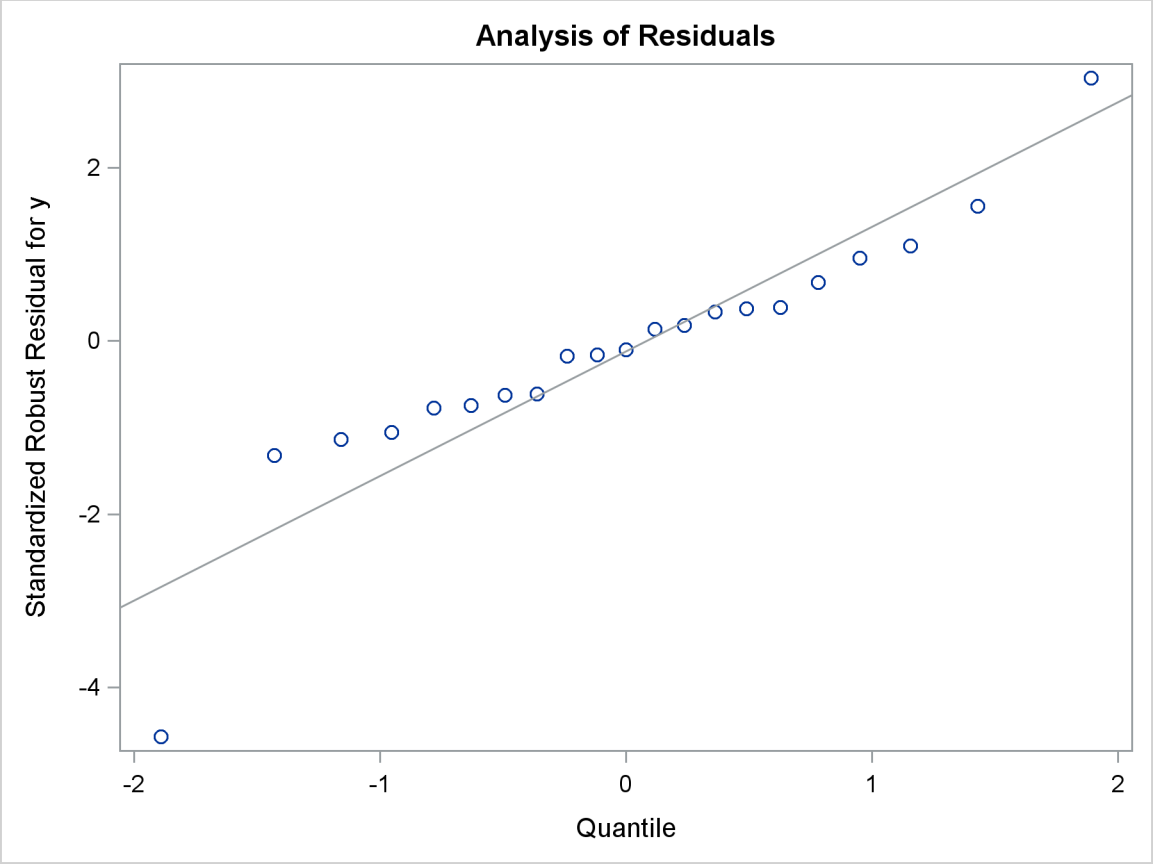
For more information about graph definitions and the graph template language, see the section "Graph Templates" on page 716.

Finally, resubmit the PROC ROBUSTREG statements to display the Q-Q plot created with your modified template. The following statements create Output 22.1.4:

```
proc template;
   define statgraph Stat.Robustreg.Graphics.QQPlot;
      notes "Q-Q Plot for Standardized Robust Residuals";
      dynamic _DEPLABEL Residual;
      BeginGraph;
         entrytitle "Analysis of Residuals";
         layout Overlay /
            yaxisopts=(label=("Standardized Robust Residual for " _DEPLABEL))
            xaxisopts=(label="Quantile");
            SCATTERPLOT y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) / primary=true markerattrs=GRAPHDATADEFAULT
               rolename=(q=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) s=eval (SORT(DROPMISSING(RESIDUAL))))
               tip=(q s) tiplabel=(q="Quantile" s="Residual");
            lineparm slope=eval (STDDEV(RESIDUAL)) Y=eval (MEAN(RESIDUAL))
               X=0 / lineattrs=GRAPHREFERENCE extend=true;
         EndLayout;
      EndGraph;
   end;
run;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Output 22.1.4 Q-Q Plot with Modified Title and Y-Axis Label



If you have not changed the default template search path, the modified template **QQPlot** is used automatically because Sasuser.Templat occurs before Sashelp.Tmplmst in the ODS search path. See the sections "Saving Customized Templates" on page 725, "Using Customized Templates" on page 726, and "Reverting to the Default Templates" on page 727 for more information about the template search path and the ODS PATH statement.

You do not need to rerun the PROC ROBUSTREG analysis after you modify a graph template if you have stored the plot in an ODS document. After you modify your template, you can submit the PROC DOCUMENT statements in Example 21.4 in Chapter 21, "Statistical Graphics Using ODS," to replay the Q-Q plot with the modified template. You can run the following statements to revert to the default template:

```
proc template;
   delete Stat.Robustreg.Graphics.QQPlot;
run;
```

Modifying Colors, Line Styles, and Markers

This section shows you how to customize colors, line attributes, and marker symbol attributes by modifying a graph template. In the **QQPlot** template definition shown in Output 22.1.3, the SCATTERPLOT statement specifies a scatter plot of normal quantiles versus ordered standardized residuals. The attributes of the marker symbol in the scatter plot are specified by: **MarkerAttrs=GraphDataDefault**. This is a reference

to the style element **GraphDataDefault**. See the section "Style Elements and Attributes" on page 650 in Chapter 21, "Statistical Graphics Using ODS," for more information.

The actual value of the marker symbol depends on the style that you are using. In this case, since the HTMLBLUE style is used, the marker symbol is a circle. You can specify a filled circle as the marker symbol by overriding the symbol portion of the style specification as follows: **MarkerAttrs=GraphDataDefault(symbol=CircleFilled)**.

The value of the SYMBOL= option can be any valid marker symbol or a reference to a style attribute of the form **style-element:attribute**. It is recommended that you use style attributes because they are chosen to provide consistency and appropriate emphasis based on display principles for statistical graphics. If you specify values directly in a template, you are overriding the style and you run the risk of creating a graph that is inconsistent with the style definition. For more information about the syntax of the Graph Template Language and style elements for graphics, see the *SAS Graph Template Language: Reference* and the *SAS Output Delivery System: User's Guide*.

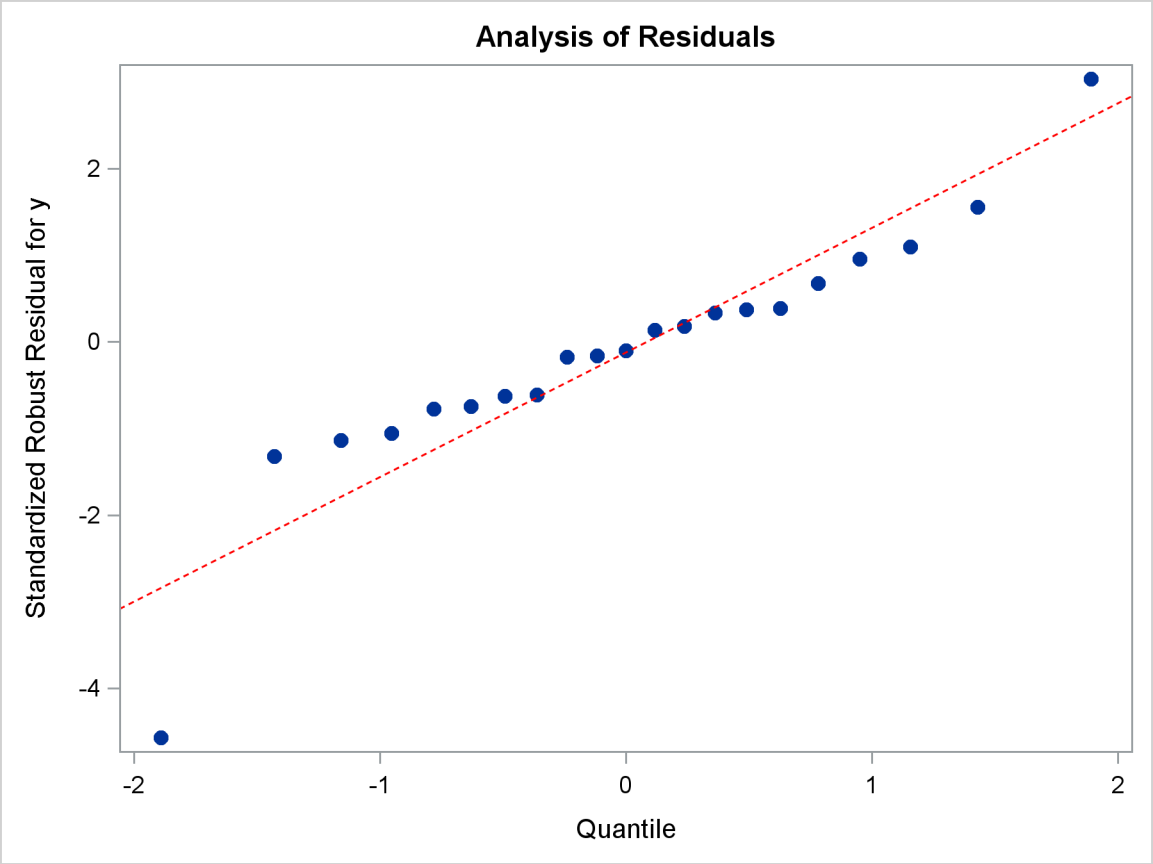
Similarly, you can change the line color and pattern with the LINEATTRS= option in the LINEPARM statement. The LINEPARM statement displays a straight line specified by slope and intercept parameters. The following option changes the color of the line to red and the line pattern to dashed, by overriding those aspects of the style specification: **LineAttrs=GraphReference(color=red pattern=dash)**. To see the results, submit the modified template definition and the PROC ROBUSTREG statements as follows to create Output 22.1.5:

```
proc template;
   define statgraph Stat.Robustreg.Graphics.QQPlot;
      notes "Q-Q Plot for Standardized Robust Residuals";
      dynamic _DEPLABEL Residual;
      BeginGraph;
         entrytitle "Analysis of Residuals";
         layout Overlay /
            yaxisopts=(label=("Standardized Robust Residual for " _DEPLABEL))
            xaxisopts=(label="Quantile");
            SCATTERPLOT y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval(
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) / primary=true
               markerattrs=GraphDataDefault(symbol=CircleFilled)
               rolename=(q=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) s=eval (SORT(DROPMISSING(RESIDUAL))))
               tip=(q s) tiplabel=(q="Quantile" s="Residual");
            lineparm slope=eval (STDDEV(RESIDUAL)) Y=eval (MEAN(RESIDUAL))
               X=0 / lineattrs=GraphReference(color=red pattern=dash)
                     extend=true;
         EndLayout;
      EndGraph;
   end;
run;
```

```
ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Output 22.1.5 Q-Q Plot with Modified Marker Symbols and Line



Alternatively, you can replay the plot with PROC DOCUMENT, as in Example 21.4 in Chapter 21, "Statistical Graphics Using ODS."

Modifying Tick Marks and Grid Lines

This section illustrates how to modify axis tick marks and control grid lines. For example, you can specify the following statement to request tick marks ranging from –4 to 2 in the Y-axis:

```
layout Overlay / yaxisopts=(linearopts=(tickvaluelist=(-4 -3 -2 -1 0 1 2)));
```

The LINEAROPTS= option is used for standard linearly scaled axes (as opposed to log-scaled axes). You use the TICKVALUELIST= to specify the tick marks.

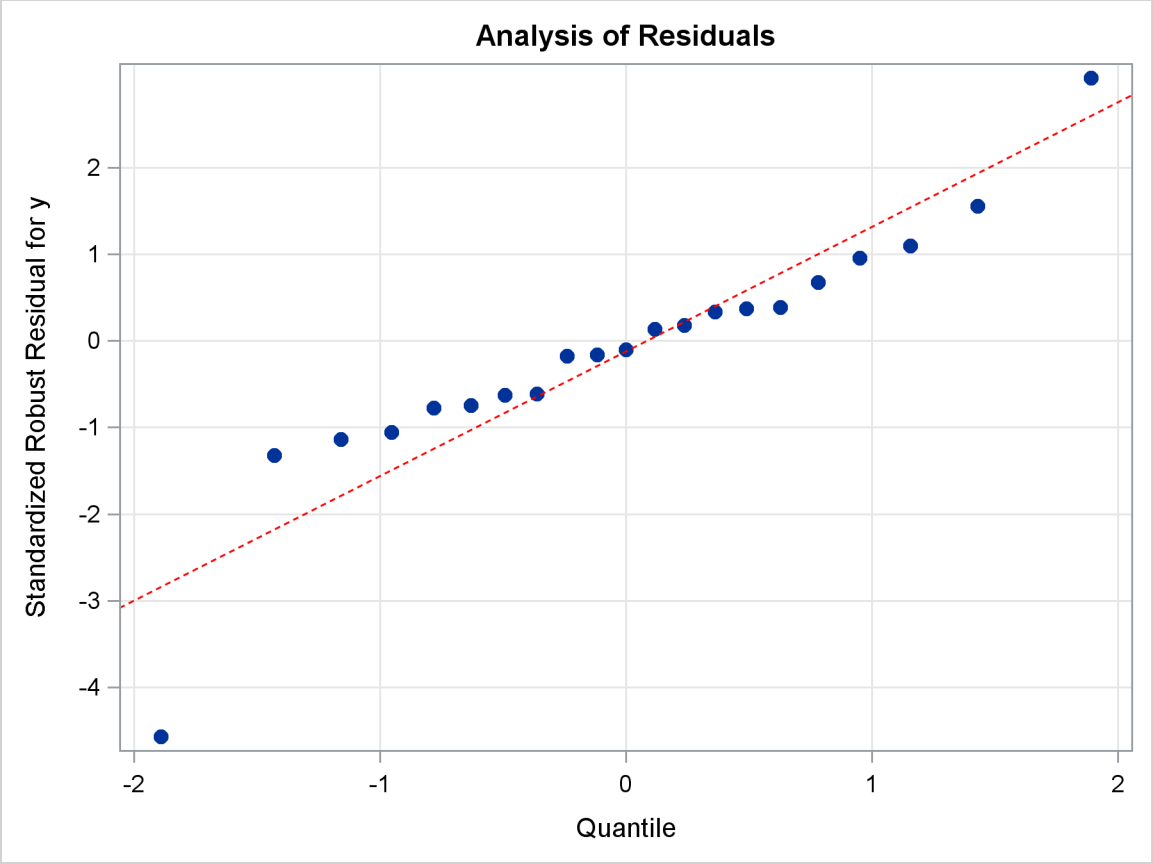
You can control the grid lines by using the GRIDDISPLAY= suboption in the YAXISOPTS= option. Typically, you specify either GRIDDISPLAY=AUTO_OFF (grid lines are not displayed unless the **GraphGridLines** element in the current style contains **DisplayOpts="ON"**) or GRIDDISPLAY=AUTO_ON (grid lines are displayed unless the **GraphGridLines** element in the current style contains **DisplayOpts="OFF"**). Here, the template is modified by specifying GRIDDISPLAY=AUTO_ON for both axes. The following statements produce Output 22.1.6:

```
proc template;
   define statgraph Stat.Robustreg.Graphics.QQPlot;
      notes "Q-Q Plot for Standardized Robust Residuals";
      dynamic _DEPLABEL Residual;
      BeginGraph;
         entrytitle "Analysis of Residuals";
         layout Overlay / yaxisopts=(gridDisplay=Auto_On
            linearopts=(tickvaluelist=(-4 -3 -2 -1 0 1 2))
            label=("Standardized Robust Residual for " _DEPLABEL))
            xaxisopts=(gridDisplay=Auto_On label="Quantile");
            SCATTERPLOT y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval(
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) / primary=true
               markerattrs=GraphDataDefault(symbol=CircleFilled)
               rolename=(q=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) s=eval (SORT(DROPMISSING(RESIDUAL))))
               tip=(q s) tiplabel=(q="Quantile" s="Residual");
            lineparm slope=eval (STDDEV(RESIDUAL)) Y=eval (MEAN(RESIDUAL))
               X=0 / lineattrs=GraphReference(color=red pattern=dash)
                     extend=true;
         EndLayout;
      EndGraph;
   end;
run;

ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Output 22.1.6 Q-Q Plot with Modified Y-Axis Tick Marks and Grids



You can restore the default template by running the following step:

```
proc template;
   delete Stat.Robustreg.Graphics.QQPlot;
run;
```

See the section "Modifying the Style to Show Grid Lines" on page 743 for more information about grid lines.

Modifying the Style to Show Grid Lines

The section "Modifying Tick Marks and Grid Lines" on page 742 explains that grid lines in graphs are controlled both by template options and by the style. Some graphs never display grid lines because they would interfere with the display. Some graphs always display grid lines because they are a critical part of the display. In both cases, grid control is so important that the template writer is not willing to give control to the style. If you want to change the grid display setting for these graphs, you must edit their templates. Most templates, however, let the style control the grid lines. They either do not display grid lines unless the style forces them on, or they display grid lines unless the style forces them off. The HTMLBLUE, STATISTICAL, DEFAULT, and most other styles use the setting `DisplayOpts = "Auto"`. Then templates that specify GRIDDISPLAY=AUTO_OFF (the default) do not display grid lines, and templates that specify GRIDDISPLAY=AUTO_ON do display grid lines. You can easily make a new style with `DisplayOpts`

= "On" or **DisplayOpts = "Off"** if you would prefer to see grid lines more or less often. This example shows how to set **DisplayOpts = "On"**.

First, you need to find the style source for setting grid lines. The following step displays the HTMLBLUE style and its parent styles, STATISTICAL and DEFAULT:

```
proc template;
   source Styles.HTMLBlue;
   source Styles.Statistical;
   source Styles.Default;
run;
```

The advantage of displaying all three styles together is that you can do one search of the results. If grids are defined in the HTMLBLUE style, you will find that first. Otherwise, you will first find the definition in one of the parent styles. An abridged version of the results follows:

```
. . .
class GraphGridLines /
   displayopts = "auto"
   linethickness = 1px
   linestyle = 1
   contrastcolor = GraphColors('ggrid')
   color = GraphColors('ggrid');
. . .
```

You can use this to create a new style that inherits from the HTMLBLUE style, but sets the display options for grids to ON, as in the following example:

```
proc template;
   define style Styles.MyGrids;
      parent=styles.HTMLBlue;
      class GraphGridLines /
         displayopts = "on"
         linethickness = 1px
         linestyle = 1
         contrastcolor = GraphColors('ggrid')
         color = GraphColors('ggrid');
   end;
run;
```

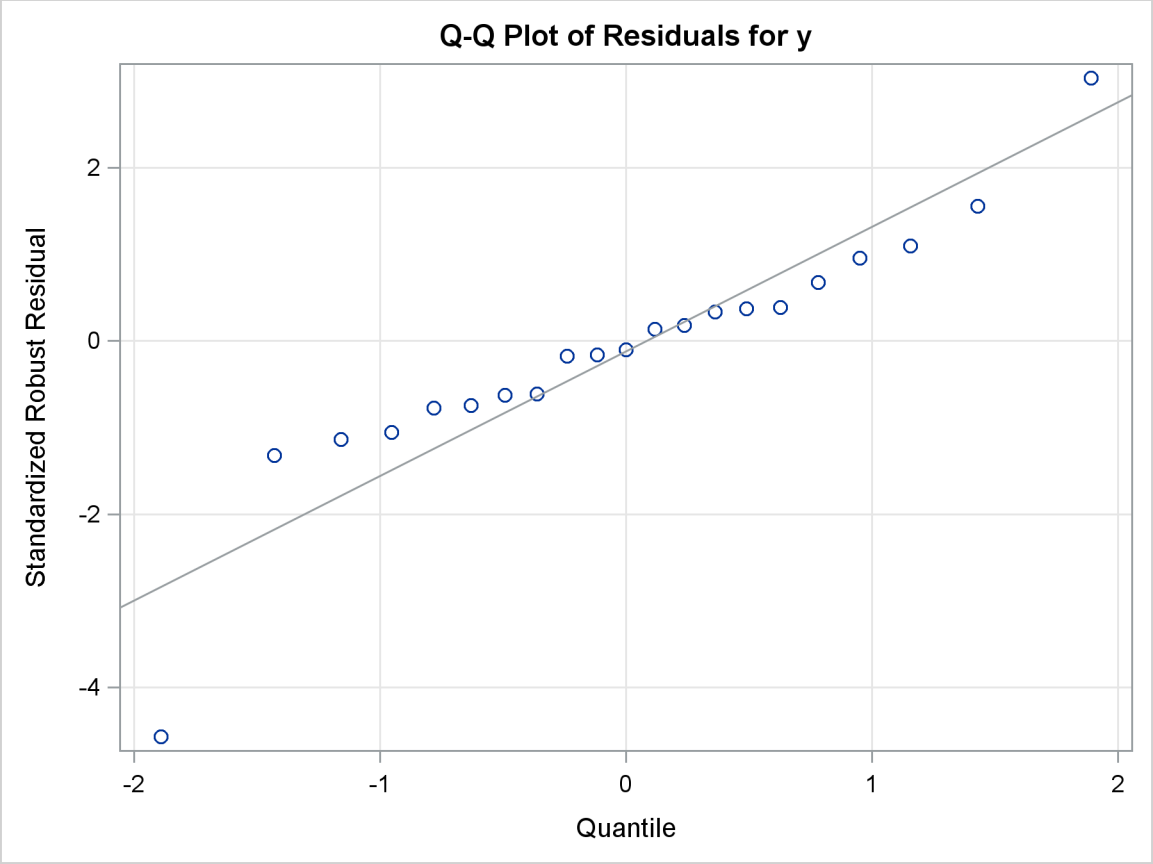
You can use this new style as in the following example:

```
ods graphics on;
ods listing style=mygrids;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

The preceding statements produce Output 22.1.7, which shows the Q-Q plot with grid lines displayed. The default graph template, supplied by SAS, is used because the custom template created in the section "Modifying Tick Marks and Grid Lines" on page 742 is deleted at the end of that section.

Output 22.1.7 A Style that Makes Grid Lines the Typical Default



Example 22.2: Adding Equations and Special Characters to Fit Plots

This example shows how to run the REG and TRANSREG procedures to get fit plots. The R square, mean, and equation for the regression model are output to data sets, and the results are processed and then displayed in subsequent fit plots. This example also illustrates Unicode and how to add special characters to graphs (for example, $\hat{\mu}$ and R^2). The Unicode Consortium http://unicode.org/ provides a list of character codes at http://www.unicode.org/charts/charindex.html.

Simple Linear Regression

The following step runs PROC REG to fit a simple regression model and creates Output 22.2.2 and Output 22.2.1:

```
ods graphics on;
ods trace on;

proc reg data=sashelp.class;
   model weight = height;
run;
```

Output 22.2.1 PROC REG Output

The REG Procedure
Model: MODEL1
Dependent Variable: Weight

Number of Observations Read 19
Number of Observations Used 19

Analysis of Variance

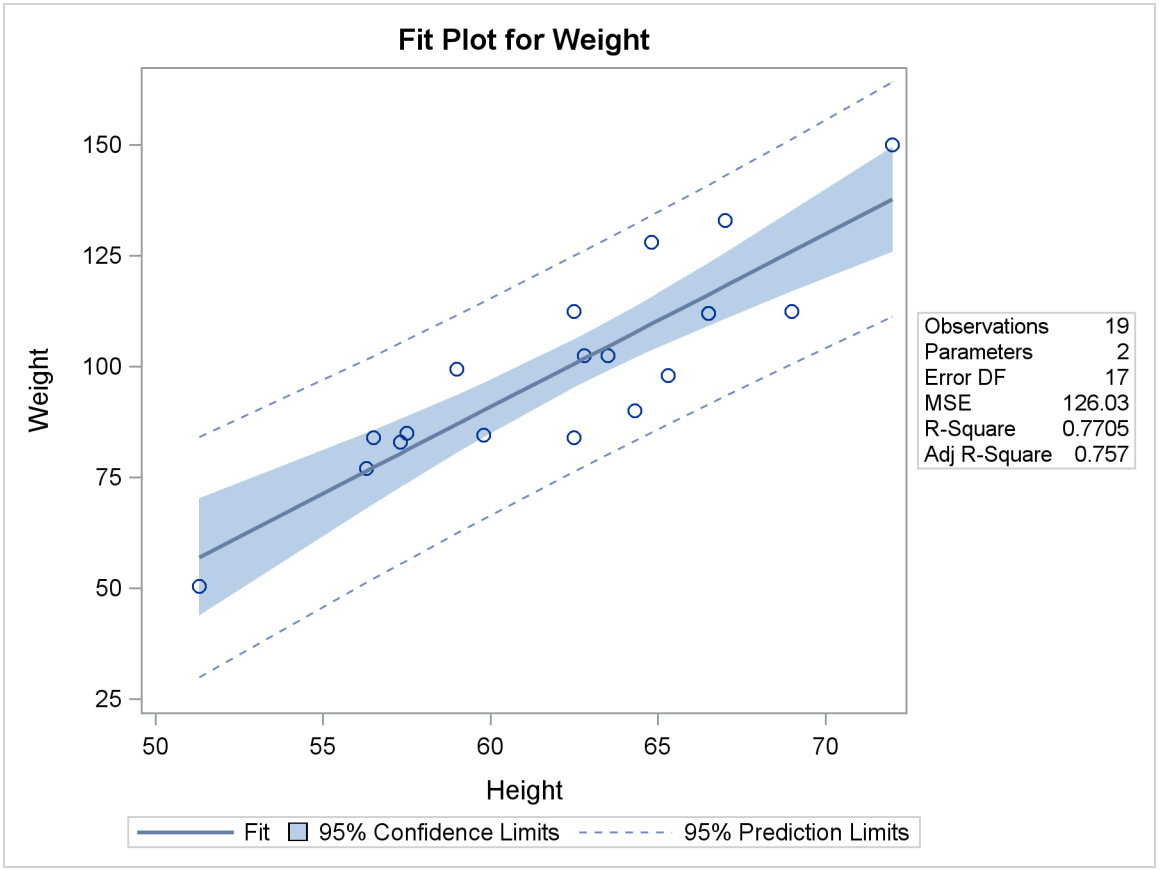
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	7193.24912	7193.24912	57.08	<.0001
Error	17	2142.48772	126.02869		
Corrected Total	18	9335.73684			

Root MSE	11.22625	R-Square	0.7705
Dependent Mean	100.02632	Adj R-Sq	0.7570
Coeff Var	11.22330		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-143.02692	32.27459	-4.43	0.0004
Height	1	3.89903	0.51609	7.55	<.0001

Output 22.2.2 PROC REG Fit Plot



The fit statistics table following the "Analysis of Variance" table displays the R square and the mean. The last table displays the parameter estimates. This information is produced and processed for inclusion in the fit plot as follows:

```
proc reg data=sashelp.class;
   ods output fitstatistics=fs ParameterEstimates=c;
   model weight = height;
run;

data _null_;
   set fs;
   if _n_ = 1 then call symputx('R2'  , put(nvalue2, 4.2)   , 'G');
   if _n_ = 2 then call symputx('mean', put(nvalue1, best6.), 'G');
run;
```

```
data _null_;
   set c;
   length s $ 200;
   retain s ' ';
   if _n_ = 1 then
      s = trim(dependent) || ' = ' ||              /* dependent =             */
          put(estimate, best5. -L);                /* intercept               */
   else if abs(estimate) > 1e-8 then do;           /* skip zero coefficients  */
      s = trim(s) || ' ' ||                        /* string so far           */
          scan('+ -', 1 + (estimate < 0), ' ')     /* + (add) or - (subtract) */
          || ' ' ||
          trim(put(abs(estimate), best5. -L))      /* abs(coefficient)        */
          || ' ' || variable;                      /* variable name           */
   end;                                            /* e for error added next  */
   call symputx('formula', trim(s) || ' + e', 'G');
run;
```

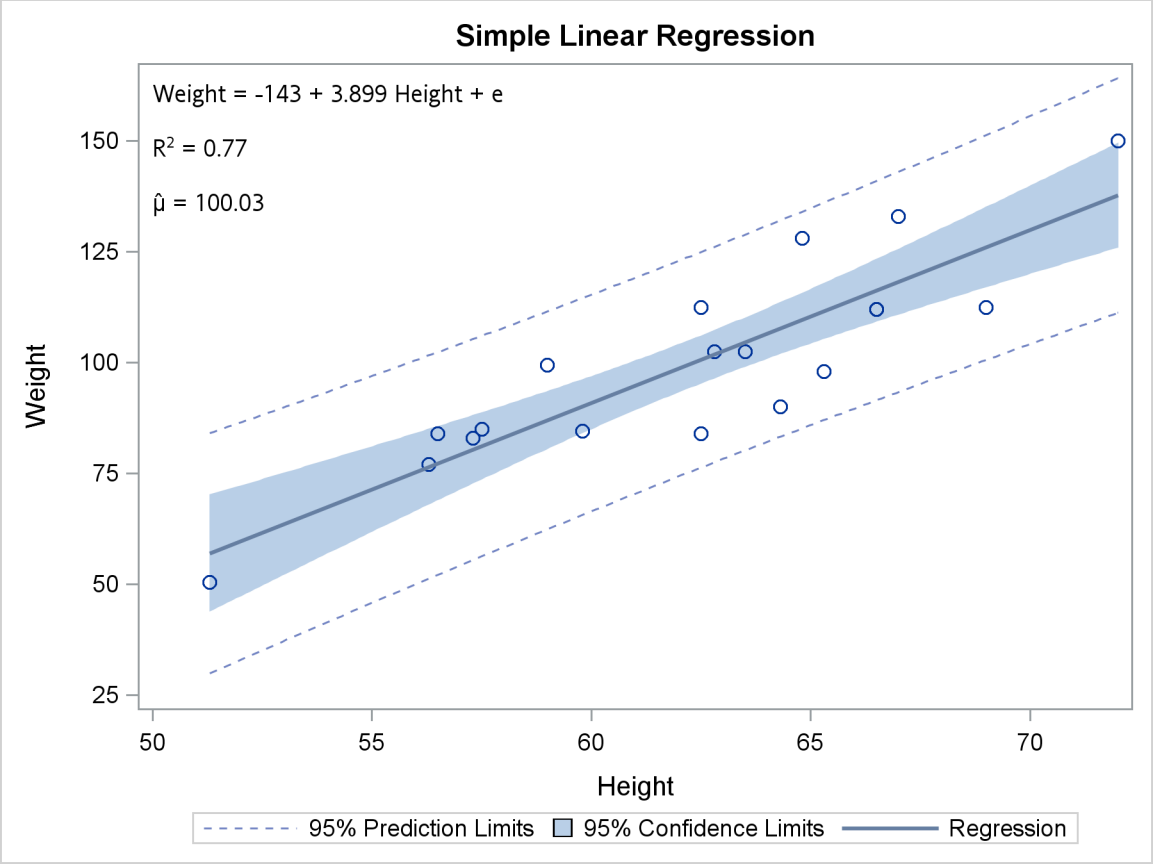
Two SAS data sets are made from the tabular output, and the R square, mean, and equation for the regression model are stored in macro variables. The following step uses PROC SGPLOT with an INSET statement to display the linear fit plot along with the R square, mean, and equation for the regression model:

```
proc sgplot data=sashelp.class;
   title 'Simple Linear Regression';
   inset "&formula"
         "R(*ESC*){sup '2'} = &r2"
         "(*ESC*){unicode mu}(*ESC*){unicode hat} = &mean" / position=topleft;
    reg y=weight x=height / clm cli;
run;
```

The results are displayed in Output 22.2.3.

Each separate string in the INSET statement is displayed in a separate line. The first string is the formula, which is generated in the second DATA step. The next string is the R square, and it consists of an ‘R’, an escaped superscript 2, and the value of R square (which is stored in a macro variable). The string for the mean consists of two Unicode specifications, one for the Greek letter μ, and one to put a hat over it. These special character specifications appear in quotes and are escaped with **(*ESC*)** so that they are processed as special characters rather than as literal text. Typically, you must escape special characters in quotes, and not escape them when they are not in quotes. See the section “Unicode and Special Characters” on page 754 for a list of a few of the more commonly used Unicode characters.

Output 22.2.3 Fit Plot from PROC SGPLOT with Equation



The same information can be added to the graph that PROC REG produces by adding the following statements to the PROC REG template for a fit plot:

```
mvar formula;

layout gridded / autoalign=(topleft topright bottomleft bottomright);
   entry halign=left formula;
   entry halign=left "R"{sup '2'} " = " eval(put(_rsquare, 4.2));
   entry halign=left "(*ESC*){unicode mu}(*ESC*){unicode hat} = "
         eval(put(_depmean, best6.))
         / textattrs=GraphValueText (family=GraphUnicodeText:FontFamily);
   endlayout;
```

The MVAR statement names macro variables whose values are added to the graph. The MVAR statement is added to the PROC REG fit plot template near the top. The LAYOUT GRIDDED block creates a table that consists of the equation, R square, and mean. The LAYOUT GRIDDED block is added to the PROC REG fit plot template inside the LAYOUT OVERLAY. The option **autoalign=(topleft topright bottomleft bottomright)** is used to position the table in a part of the graph that is open, first trying the top left corner.

In this example, in the LAYOUT GRIDDED block, two dynamic variables for R square, and the mean are used instead of the macro variables that were made in previous steps. The origin of the names of the two dynamic variables that are used in this example are revealed in the next step when the source code for the PROC REG fit plot is displayed. The first ENTRY statement creates a text line for the formula and left-

justifies it. The second ENTRY statement creates the R square line. It consists of a literal 'R', a specification for a superscript of 2 ({**sup 2**}), an equal sign surrounded by spaces, and the formatted value of the dynamic variable with the R square. The third ENTRY statement creates the mean line. It consists of two Unicode specifications, one for the Greek letter μ, and one to put a hat over it. These special character specifications appear in quotes (unlike the {**sup 2**}) and are escaped with **(*ESC*)** so that they are processed as special characters rather than as literal text. Typically, you must escape special characters in quotes, and not escape them when they are not in quotes. Note that **sup** along with **sub** (subscript) must not appear in quotes in the GTL, but they can appear in quotes in PROC SGPLOT (as was previously shown). The option **textattrs=GraphValueText (family=GraphUnicodeText:FontFamily)** is specified to ensure that a font that recognizes Unicode characters is used. See the section "Unicode and Special Characters" on page 754 for a list of a few of the more commonly used Unicode characters.

You can use the trace information from the PROC REG step (not shown) and the following step to display the template for the fit plot:

```
proc template;
   source Stat.Reg.Graphics.Fit;
run;
```

Some of the results are as follows:

```
define statgraph Stat.Reg.Graphics.Fit;
   notes "Fit Plot";
   dynamic _DEPLABEL _DEPNAME _MODELLABEL _SHOWSTATS _NSTATSCOLS _SHOWNObs
      _SHOWTOTFREQ _SHOWNParm _SHOWEDF _SHOWMSE _SHOWRSquare _SHOWAdjRSq
      _SHOWSSE _SHOWDepMean _SHOWCV _SHOWAIC _SHOWBIC _SHOWCP _SHOWGMSEP
      _SHOWJP _SHOWPC _SHOWSBC _SHOWSP _NObs _NParm _EDF _MSE _RSquare _AdjRSq
      _SSE _DepMean _CV _AIC _BIC _CP _GMSEP _JP _PC _SBC _SP _PREDLIMITS
      _CONFLIMITS _XVAR _SHOWCLM _SHOWCLI _WEIGHT _SHORTXLABEL _SHORTYLABEL
      _TITLE _TOTFreq;
   BeginGraph;
      entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL halign=center
         textattrs=GRAPHTITLETEXT _TITLE " for " _DEPNAME;
      layout Overlay / yaxisopts=(label=_DEPLABEL shortlabel=_SHORTYLABEL)
         xaxisopts=(shortlabel=_SHORTXLABEL);
               .
               .
               .
               if (_SHOWRSQUARE^=0)
                  entry halign=left "R-Square" / valign=top;
                  entry halign=right eval (PUT(_RSQUARE,BEST6.)) / valign=top;
               endif;
               .
               .
               .
               if (_SHOWDEPMEAN^=0)
                  entry halign=left "Dependent Mean" / valign=top;
                  entry halign=right eval (PUT(_DEPMEAN,BEST6.)) / valign=top;
               endif;
               .
               .
               .
         endif;
      endlayout;
   EndGraph;
end;
```

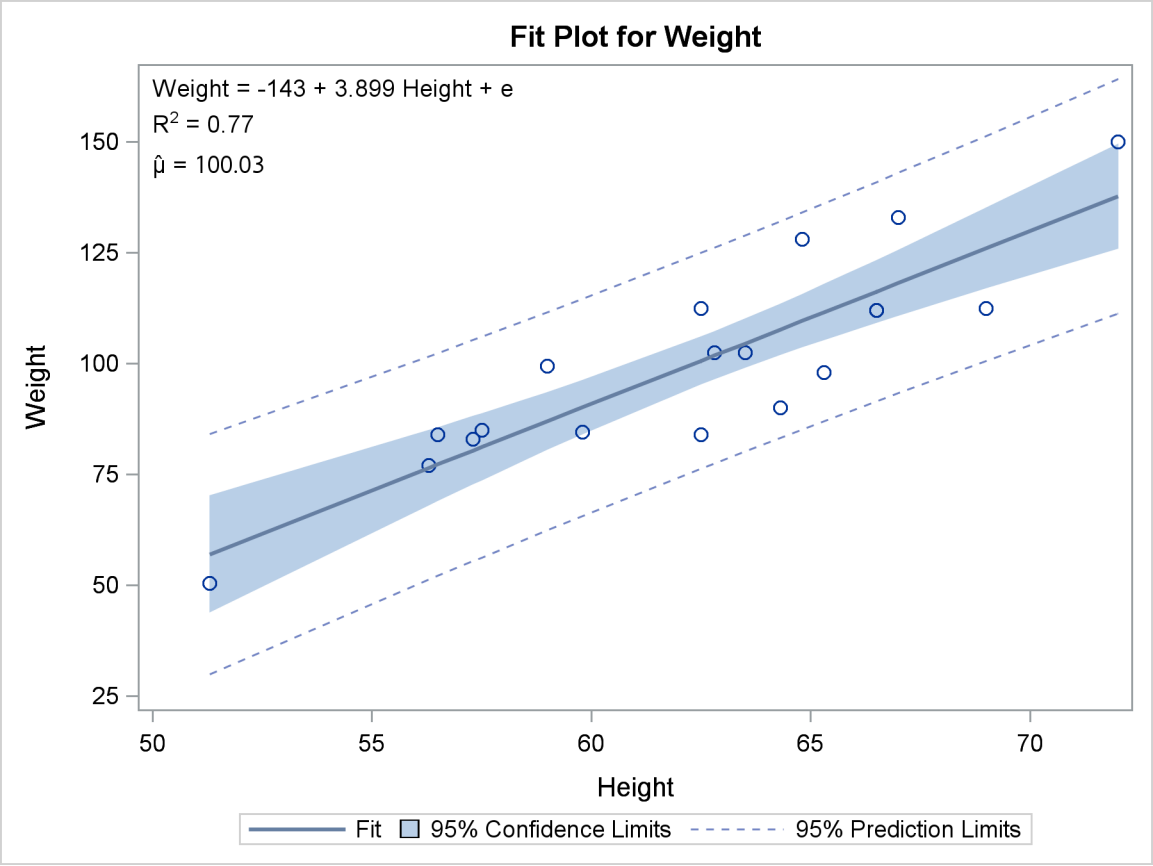
The preceding results show that the dynamic variables _RSquare and _DepMean contain the R square and the mean of the dependent variable. The MVAR statement and the LAYOUT GRIDDED block can be added to the template, and in the interest of maximizing graph size, the table of statistics can be removed, creating the following template:

```
proc template;
   define statgraph Stat.Reg.Graphics.Fit;
      notes "Fit Plot";
      mvar formula;
      dynamic _DEPLABEL _DEPNAME _MODELLABEL _SHOWSTATS _NSTATSCOLS _SHOWNObs
         _SHOWTOTFREQ _SHOWNParm _SHOWEDF _SHOWMSE _SHOWRSquare _SHOWAdjRSq
         _SHOWSSE _SHOWDepMean _SHOWCV _SHOWAIC _SHOWBIC _SHOWCP _SHOWGMSEP
         _SHOWJP _SHOWPC _SHOWSBC _SHOWSP _NObs _NParm _EDF _MSE _RSquare _AdjRSq
         _SSE _DepMean _CV _AIC _BIC _CP _GMSEP _JP _PC _SBC _SP _PREDLIMITS
         _CONFLIMITS _XVAR _SHOWCLM _SHOWCLI _WEIGHT _SHORTXLABEL _SHORTYLABEL
         _TITLE _TOTFreq;
      BeginGraph;
         entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL halign=center
            textattrs=GRAPHTITLETEXT _TITLE " for " _DEPNAME;
         layout Overlay / yaxisopts=(label=_DEPLABEL shortlabel=_SHORTYLABEL)
            xaxisopts=(shortlabel=_SHORTXLABEL);
            if (_SHOWCLM=1)
               BANDPLOT limitupper=UPPERCLMEAN limitlower=LOWERCLMEAN x=_XVAR /
                  fillattrs=GRAPHCONFIDENCE connectorder=axis name="Confidence"
                  LegendLabel=_CONFLIMITS;
            endif;
            layout gridded / autoalign=(topleft topright bottomleft bottomright);
               entry halign=left formula;
               entry halign=left "R"{sup '2'} " = "  eval(put(_rsquare, 4.2));
               entry halign=left "(*ESC*){unicode mu}(*ESC*){unicode hat} = "
                     eval(put(_depmean, best6.))
                     / textattrs=GraphValueText (family=GraphUnicodeText:FontFamily);
               endlayout;
            if (_SHOWCLI=1)
               if (_WEIGHT=1)
                  SCATTERPLOT y=PREDICTEDVALUE x=_XVAR / markerattrs=(size=0)
                     datatransparency=.6 yerrorupper=UPPERCL yerrorlower=LOWERCL
                     name="Prediction" LegendLabel=_PREDLIMITS;
               else
                  BANDPLOT limitupper=UPPERCL limitlower=LOWERCL x=_XVAR / display
                     =(outline) outlineattrs=GRAPHPREDICTIONLIMITS connectorder=
                     axis name="Prediction" LegendLabel=_PREDLIMITS;
               endif;
            endif;
            SCATTERPLOT y=DEPVAR x=_XVAR / markerattrs=GRAPHDATADEFAULT primary=
               true rolename=(_tip1=OBSERVATION _id1=ID1 _id2=ID2 _id3=ID3 _id4=
               ID4 _id5=ID5) tip=(y x _tip1 _id1 _id2 _id3 _id4 _id5);
            SERIESPLOT y=PREDICTEDVALUE x=_XVAR / lineattrs=GRAPHFIT connectorder=
               xaxis name="Fit" LegendLabel="Fit";
            if (_SHOWCLI=1 OR _SHOWCLM=1)
               DISCRETELEGEND "Fit" "Confidence" "Prediction" / across=3 HALIGN=
                  CENTER VALIGN=BOTTOM;
            endif;
         endlayout;
      EndGraph;
   end;
run;
```

The following step uses the modified template to create Output 22.2.4:

```
proc reg data=sashelp.class;
   model weight = height;
run;
```

Output 22.2.4 PROC REG Fit Plot with the Equation



You can restore the default template by running the following step:

```
proc template;
   delete Stat.Reg.Graphics.Fit;
run;
```

Cubic Fit Function

The following steps run PROC TRANSREG to find a cubic fit function and display the equation in a plot generated by PROC SGPLOT:

```
proc transreg data=sashelp.class ss2;
   ods output fitstatistics=fs coef=c;
   model identity(weight) = pspline(height);
run;
```

```
data _null_;
   set fs;
   if _n_ = 1 then call symputx('R2'  , put(value2, 4.2)   , 'G');
   if _n_ = 2 then call symputx('mean', put(value1, best6.), 'G');
run;

data _null_;
   set c end=eof;
   length s $ 200 c $ 1;
   retain s ' ';
   if _n_ = 1 then
      s = scan(dependent, 2, '()') || ' = ' ||    /* dependent =             */
          put(coefficient, best5. -L);            /* intercept               */
   else if abs(coefficient) > 1e-8 then do;       /* skip zero coefficients  */
      s = trim(s) || ' ' ||                       /* string so far           */
          scan('+ -', 1 + (coefficient < 0), ' ') /* + (add) or - (subtract) */
          || ' ' ||
          trim(put(abs(coefficient), best5. -L )) /* abs(coefficient)        */
          || ' ' || scan(variable, 2, '._');      /* variable name           */
      c = scan(variable, 2, '_');                 /* grab power              */
      if c ne '1' then                            /* skip power for linear   */
         s = trim(s) ||                           /* string so far           */
             "(*ESC*){sup '" || c || "'}";        /* add superscript         */
   end;                                           /* e for error added next  */
   if eof then call symputx('formula', trim(s) || ' + e', 'G');
run;

proc sgplot data=sashelp.class;
   title 'Cubic Fit Function';
   inset "&formula"
         "R(*ESC*){sup '2'} = &r2"
         "(*ESC*){unicode mu}(*ESC*){unicode hat} = &mean" / position=topleft;
    reg y=weight x=height / degree=3 cli clm;
run;
```

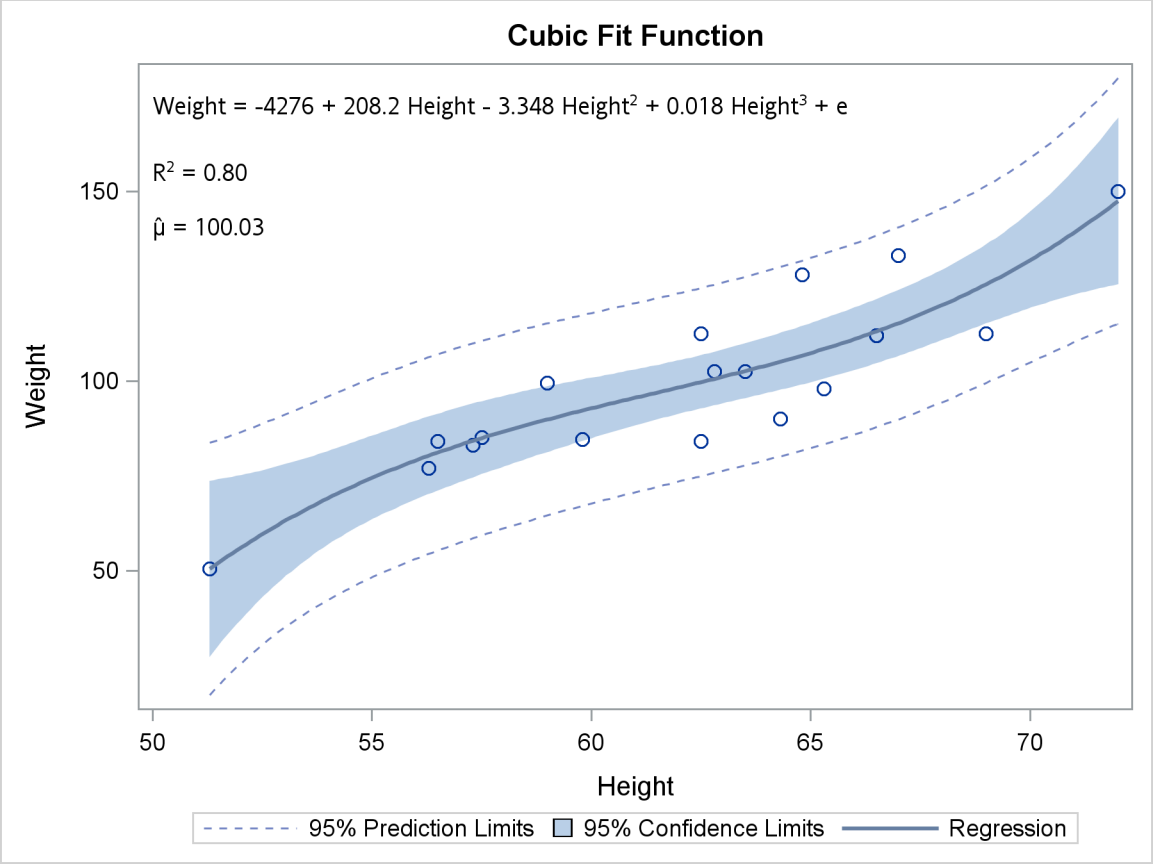
These steps create Output 22.2.5.

The PROC TRANSREG MODEL statement fits a model with an untransformed dependent variable and a cubic polynomial function of the independent variable. By default, PSPLINE fits a cubic polynomial spline with no knots, which is simply a cubic polynomial. The fit statistics and parameter estimates are output to data sets, and their values are stored in macro variables. There are three independent variables plus the intercept. Variable names and exponents are extracted from the TRANSREG parameter names of Pspline.Height_1, Pspline.Height_2, and Pspline.Height_3 by using the SCAN function. Exponents are added by using the specifications `"(*ESC*){sup '2'}"` and `"(*ESC*){sup '3'}"`, which are explained in more detail with the INSET statement.

PROC SGPLOT with an INSET statement makes the plot. Each separate string is displayed in a separate line. The first string is the formula, which is generated in the second DATA step. The next string is the R square: it consists of an 'R', an escaped superscript 2, and the value of R square (which is stored in a macro variable). The string for the mean consists of two Unicode specifications, one for the Greek letter μ, and one to put a hat over it. These special character specifications appear in quotes and are escaped with `(*ESC*)` so that they are processed as special characters rather than as literal text. Typically, you must

escape special characters in quotes, and not escape them when they are not in quotes. See section "Simple Linear Regression" on page 746 for more information about Unicode characters. See the section "Unicode and Special Characters" on page 754 for a list of a few of the more commonly used Unicode characters.

Output 22.2.5 Cubic Fit Function with the Equation



Unicode and Special Characters

The following steps illustrate Unicode specifications for a number of commonly used characters and create Output 22.2.6 and Output 22.2.7, which are charts of Unicode characters:

```
%let l = halign=left;

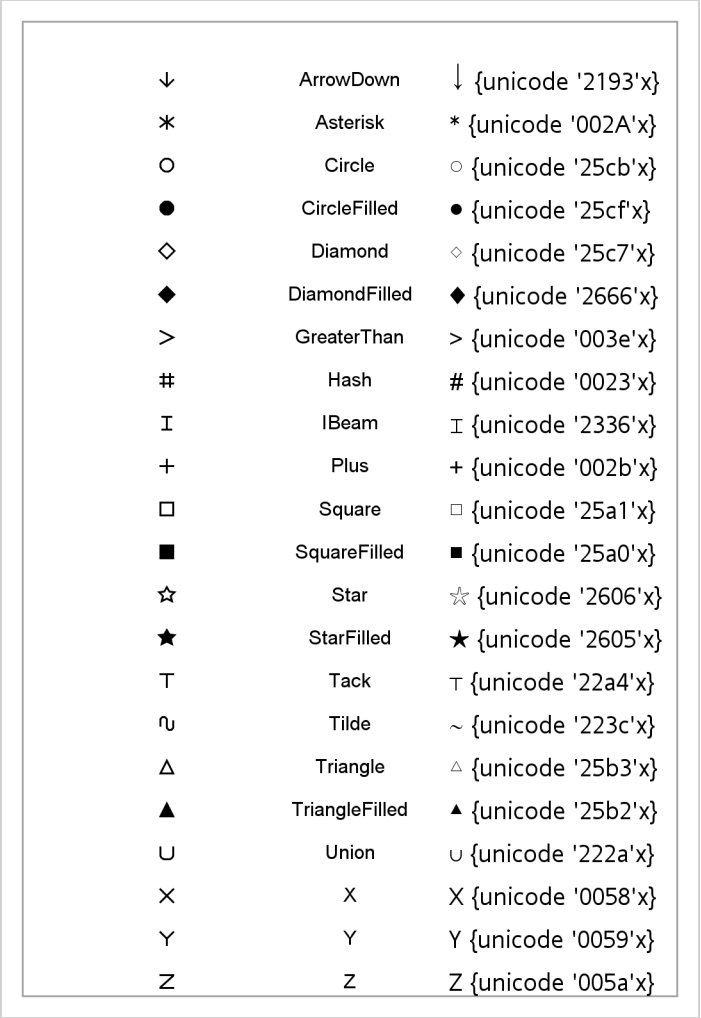
Output 22.2.7 Markers, Marker Names, Unicode Characters, Unicode Specifications



The Unicode Consortium `http://unicode.org/` provides a list of character codes at `http://www.unicode.org/charts/charindex.html`.

The following rules apply to Unicode and special character specifications in ODS graphics:

- Each character can be specified by looking up its code and specifying it as a hexadecimal constant. Example: {**unicode '221e'x**}.
- Lower case Greek letters can be specified by using names instead of hexadecimal constants. Example: {**unicode alpha**}.
- Upper case Greek letters can be specified by using names followed by **_u** instead of a hexadecimal constants. Example: {**unicode alpha_u**}.
- Superscript and subscript have special abbreviations. Examples: {**sup 2**} and {**sub 2**}.
- The **sup** and **sub** specifications must not appear escaped and in quotes in the GTL. They must appear outside of quotes.
- Some characters overprint the character that comes before. Example: **'El nin'** {**tilde**} **'o'**, which is equivalent to **'El nin'** {**unicode '0303'x**} **'o'** creates 'El niño'.
- Specifications inside quotes are escaped. Example: **"(*ESC*)**{**unicode beta**}**"**.
- Specifications outside quotes are not escaped. Example: {**unicode beta**}.

Example 22.3: Customizing Survival Plots

The LIFETEST procedure, like other statistical procedures, provides a PLOTS= option and other options for modifying its output without requiring template changes. See Chapter 51, "The LIFETEST Procedure," for more information. Those options are sufficient for most purposes. This example shows ways that you can change the graph by changing the graph template when those options are not sufficient. The first part of this example shows how to find the name of the template, display the template by using PROC TEMPLATE and the SOURCE statement, and make simple title changes. This approach is sufficient for most simple changes.

As this example progresses, a more aggressive approach to template modification is introduced. The survival plot template in PROC LIFETEST is long, and it has distinct components for different scenarios (single stratum versus multiple strata). The same options are often repeated in multiple statements. The next part of the example rewrites the template using macros and macro variables so that it is more modular and easier to modify. The subsequent parts of this example modify the template in other ways by using the rewritten template as the starting point. If you need to change the survival plot template, you too might find it easier to use this rewritten template as a starting point instead of the template as it is displayed by using PROC TEMPLATE and the SOURCE statement.

This example consists of the following parts:

- **Modifying the plot title:** This part identifies the template, displays it, explains its overall structure, and modifies the titles. See the section "Modifying the Plot Title" on page 761.
- **Modifying the axes:** This part explains the options that control the X and Y axes, and shows how to modify the ticks and axis labels. See the section "Modifying the Axes" on page 765.

- **Creating a template that is easy to modify:** This part shows how you can reorganize and modularize the entire template to make it easy to customize it in various ways. See the section "Creating a Template That is Easy to Modify" on page 768.
- **Modifying the plot title in the revised template:** This part shows how to change the title by using the revised template. See the section "Modifying the Plot Title in the Revised Template" on page 774.
- **Modifying the legend and inset table:** This part removes the small inset table and moves the legend inside the graph. The censoring information above the X axis is moved outside the graph. See the section "Modifying the Legend and Inset Table" on page 775.
- **Modifying the layout and adding a new inset table:** This part moves the event and total information out of the graph and the legend in. It also moves the small inset table. See the section "Modifying the Layout and Adding a New Inset Table" on page 778.
- **Changing line styles:** This part shows how to modify a style template to change line colors and styles. See the section "Changing Line Styles" on page 784.
- **Changing fonts:** This part shows how to change the graph template and the style template to change some of the fonts that are used in the graph. See the section "Changing Fonts" on page 787.
- **Changing how censored data are displayed:** This part shows how to change or remove the plus marks that are used to display censored observations. See the section "Changing How Censored Data Are Displayed" on page 792.
- **Displaying survival summary statistics:** This part adds to the graph a table with event, censoring and survival information. See the section "Displaying Survival Summary Statistics" on page 795.

This example uses the bone marrow transplant data set Sashelp.BMT, which is also used in the section "Survival Estimate Plot with PROC LIFETEST" on page 597 in Chapter 21, "Statistical Graphics Using ODS."

Modifying the Plot Title

This first part of this example changes the default title of the survival plot in PROC LIFETEST from "Product-Limit Survival Estimates" to "Kaplan-Meier Plot" through a template change.

The following statements run PROC LIFETEST to display the survival plot and to determine the template name:

```
proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;

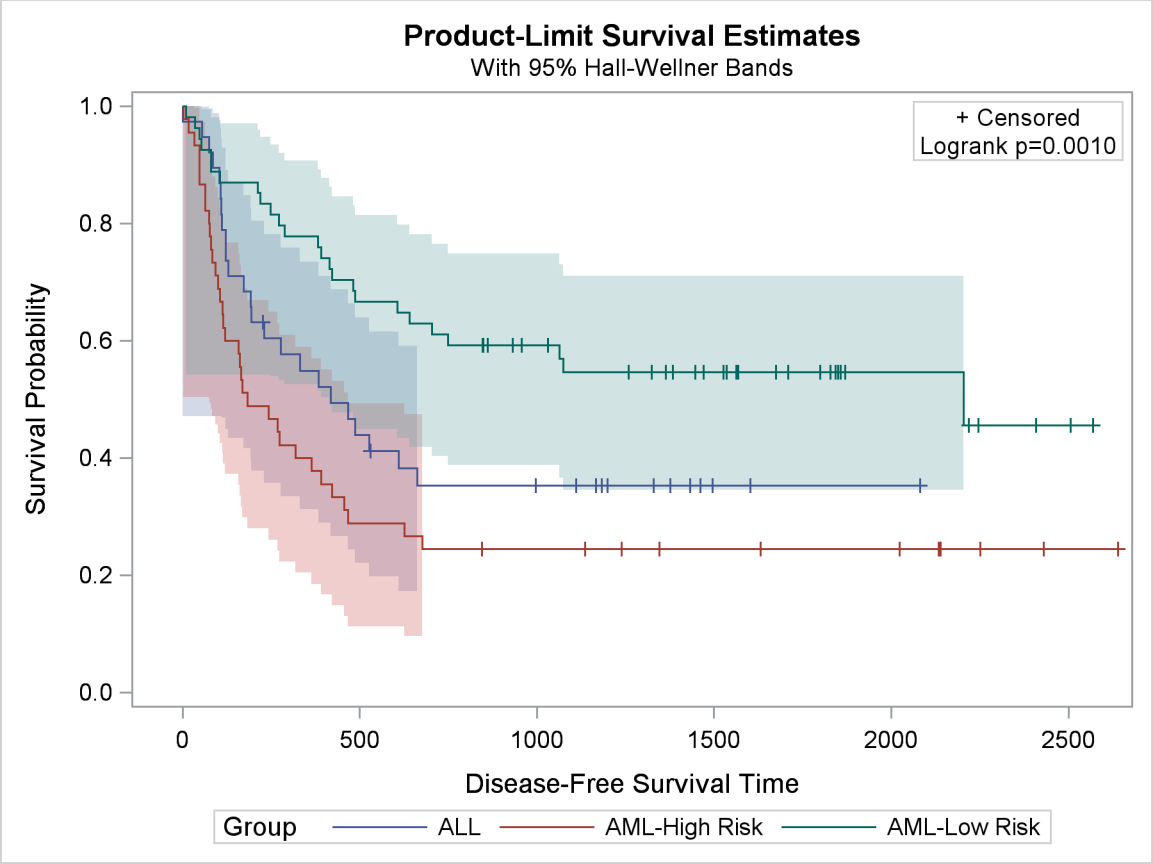
ods graphics on;
ods trace on;

proc lifetest data=sashelp.BMT plots=survival(cb=hw test);
   time T * Status(0);
   strata Group;
run;

ods trace off;
```

The survival plot is displayed in Output 22.3.1. Notice that the Hall-Welner bands by design stop at the last event.

Output 22.3.1 Product Limit Survival Plot



The relevant part of the trace output from the SAS log is as follows:

```
Output Added:
-------------
Name:        SurvivalPlot
Label:       Survival Curves
Template:    Stat.Lifetest.Graphics.ProductLimitSurvival
Path:        Lifetest.SurvivalPlot
-------------
```

The trace output shows that the template name for the survival plot is:

Stat.Lifetest.Graphics.ProductLimitSurvival.

The following statements display the template:

```
proc template;
   source Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

The results, at 158 lines, are lengthy. A partial display of the results is as follows:

```
define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
   dynamic NStrata xName plotAtRisk plotCensored plotCL plotHW plotEP labelCL

            XTICKVALFITPOL)) yaxisopts=(label="Survival Probability" shortlabel
            ="Survival" linearopts=(viewmin=0 viewmax=1 tickvaluelist=(0 .2 .4
            .6 .8 1.0)));
            .
            .
            .
         endlayout;
      endif;
   EndGraph;
end;
```

This template has a two-part structure. The graph is created one way for a single stratum (in the statements that follow **`if (NSTRATA=1)`**); otherwise it is created a different way (in the statements that follow the ELSE near the middle of the template). You can change the title by locating and changing ENTRYTITLE statements, which are the GTL statements that provide graph titles. Change just the entry titles that provide the first title lines. In most templates, all ENTRYTITLE statements are near the top of the template. They are not near the top of this template due to the two-part structure. The following step shows the changes that you could make to change the title (as displayed in Output 22.3.2):

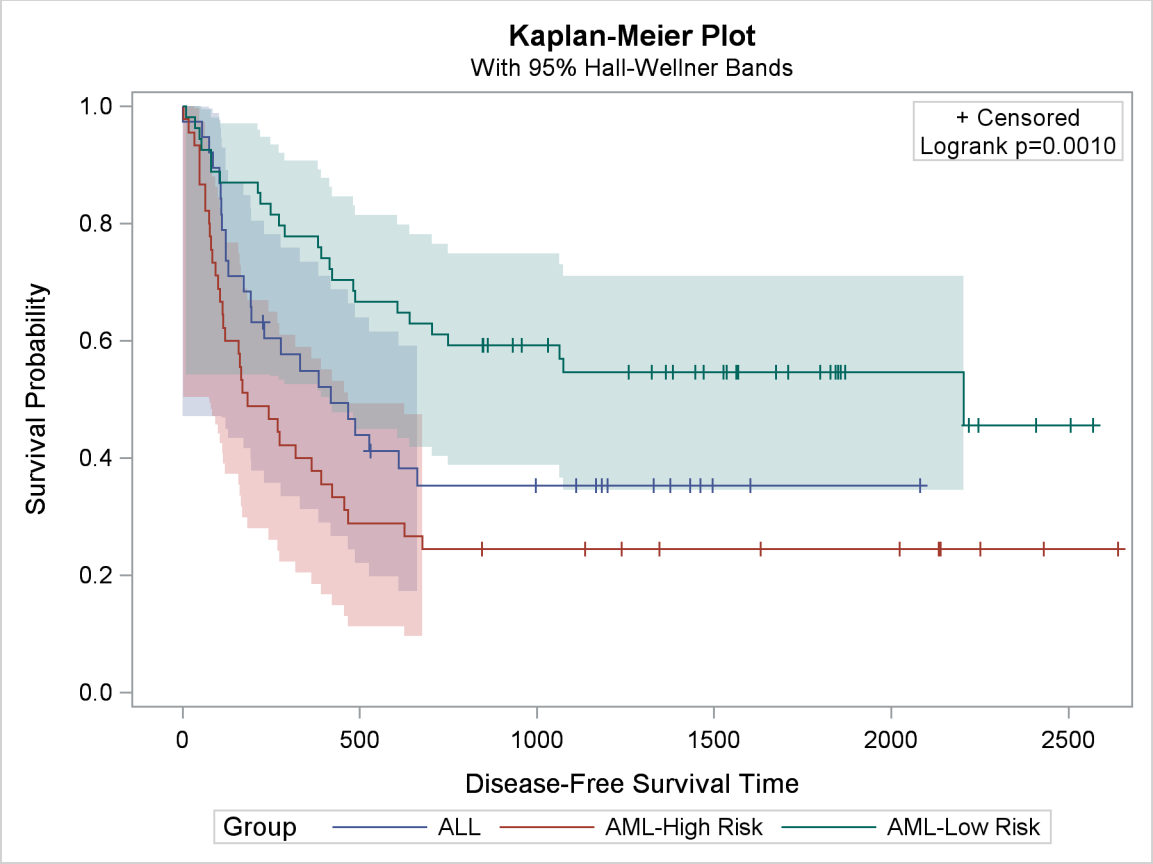
```
proc template;
   define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
      dynamic NStrata xName plotAtRisk plotCensored plotCL plotHW plotEP labelCL
         labelHW labelEP maxTime xtickVals xtickValFitPol method StratumID
         classAtRisk plotBand plotTest GroupName yMin Transparency SecondTitle
         TestName pValue;
      BeginGraph;
         if (NSTRATA=1)
            if (EXISTS(STRATUMID))
               entrytitle "Kaplan-Meier Plot for " STRATUMID;
            else
               entrytitle "Kaplan-Meier Plot";
            endif;
            if (PLOTATRISK)
               entrytitle "with Number of Subjects at Risk" / textattrs=
                  GRAPHVALUETEXT;
            endif;
            layout overlay / xaxisopts=(shortlabel=XNAME offsetmin=.05 linearopts=
               (viewmax=MAXTIME tickvaluelist=XTICKVALS tickvaluefitpolicy=
               XTICKVALFITPOL)) yaxisopts=(label="Survival Probability" shortlabel
               ="Survival" linearopts=(viewmin=0 viewmax=1 tickvaluelist=(0 .2 .4
               .6 .8 1.0)));
               .
               .
               .
            endlayout;
         else
            entrytitle "Kaplan-Meier Plot";
            if (EXISTS(SECONDTITLE))
               entrytitle SECONDTITLE / textattrs=GRAPHVALUETEXT;
            endif;
            layout overlay / xaxisopts=(shortlabel=XNAME offsetmin=.05 linearopts=
               (viewmax=MAXTIME tickvaluelist=XTICKVALS tickvaluefitpolicy=
               XTICKVALFITPOL)) yaxisopts=(label="Survival Probability" shortlabel
               ="Survival" linearopts=(viewmin=0 viewmax=1 tickvaluelist=(0 .2 .4
               .6 .8 1.0)));
               .
               .
               .
            endlayout;
         endif;
      EndGraph;
   end;
run;
```

Three ENTRYTITLE statements are changed. Notice that you must provide a PROC TEMPLATE statement and optionally a RUN statement in addition to making the title changes. Submit the PROC TEMPLATE step to SAS along with the following PROC LIFETEST step to create the modified graph:

```
proc lifetest data=sashelp.BMT plots=survival(cb=hw test);
   time T * Status(0);
   strata Group;
run;
```

The results are displayed in Output 22.3.2.

Output 22.3.2 Kaplan-Meier Plot



Modifying the Axes

The template option `linearopts=(viewmin=0 viewmax=1 tickvaluelist=(0 .2 .4 .6 .8 1.0))` controls the minimum value displayed, the maximum value displayed, and the ticks on the vertical axis. You can change the range of the vertical axis or the ticks in either version of the template by changing this option everywhere that it occurs. The following specification changes the ticks but not the range of values: `linearopts=(viewmin=0 viewmax=1 tickvaluelist=(0 .25 .5 .75 1.0))`.

When there is a single stratum, the LAYOUT OVERLAY statement (which controls the axes) is as follows:

```
layout overlay / xaxisopts=(shortlabel=XNAME offsetmin=.05
   linearopts=(viewmax=MAXTIME tickvaluelist=XTICKVALS
   tickvaluefitpolicy=XTICKVALFITPOL)) yaxisopts=(label=
   "Survival Probability" shortlabel="Survival" linearopts=(viewmin=
   0 viewmax=1 tickvaluelist=(0 .2 .4 .6 .8 1.0)));
```

The LAYOUT OVERLAY statement with more than one stratum is identical. With added comments, the statement is as follows:

```
layout overlay /                          /*-----------------------------*/
          xaxisopts=(                     /* X axis options              */
                                          /* label= is not specified, so */
                                          /* it comes from data object   */
                                          /* column label                */
             shortlabel=XNAME             /* alternative shorter label   */
                                          /* comes from dynamic          */
             offsetmin=.05                /* add 5% padding on minimum   */
                                          /* side of the x axis          */
             linearopts=(                 /* linear axis (not log axis)  */
                viewmax=MAXTIME           /* largest value to display,   */
                                          /* comes from dynamic          */
                tickvaluelist=XTICKVALS   /* tick value list comes from  */
                                          /* a dynamic                   */
                tickvaluefitpolicy=       /* fit policy comes from a     */
                   XTICKVALFITPOL))       /* dynamic - controls tick     */
                                          /* value collision avoidance   */
                                          /* strategies including        */
                                          /* rotation                    */
                                          /*-----------------------------*/
          yaxisopts=(                     /* Y axis options              */
             label="Survival Probability" /* axis label                  */
             shortlabel="Survival"        /* shorter label for short axes*/
             linearopts=(                 /* linear axis (not log axis)  */
                viewmin=0                 /* smallest value to display   */
                viewmax=1                 /* largest value to display    */
                tickvaluelist=            /* list of tick values to      */
                   (0 .2 .4 .6 .8 1.0))); /* display                     */
                                          /*-----------------------------*/
```

You can change any of these values in several ways:

- You can specify literal values or macro variables when previously a dynamic variable was used. Example: change VIEWMAX=MAXTIME to VIEWMAX=2000.
- You can change literal specifications. Example: change VIEWMAX=1 TICKVALUELIST= (0 .2 .4 .6 .8 1.0) to VIEWMAX=0.75 TICKVALUELIST=(0 .25 .5 .75) to restrict the range on the Y axis.
- You can add options. Example: specify LABEL="Time" in the XAXISOPTS= option. Example: specify LABELATTRS=(SIZE=12PX) in the XAXISOPTS= and YAXISOPTS= options to change the font size for the labels. Example: specify TICKVALUEATTRS=(SIZE=10PX) in the XAXISOPTS= and YAXISOPTS= options to change the font size for the ticks.
- You can delete options. Example: delete VIEWMIN=0 VIEWMAX=1 from the YAXISOPTS= option.

If you frequently find yourself changing the title or the axes, you can make it easier by creating a template where those options are controlled by macro variables. For example, this template is easier to modify than the default template:

```
%let TitleText0 = METHOD " Survival Estimate";
%let TitleText1 = &titletext0 " for " STRATUMID;
%let TitleText2 = &titletext0 "s";
%let yOptions   = label="Survival Probability"
                  shortlabel="Survival"
                  linearopts=(viewmin=0 viewmax=1
                              tickvaluelist=(0 .2 .4 .6 .8 1.0));
%let xOptions   = shortlabel=XNAME
                  offsetmin=.05
                  linearopts=(viewmax=MAXTIME tickvaluelist=XTICKVALS
                              tickvaluefitpolicy=XTICKVALFITPOL);
proc template;
   define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
      dynamic NStrata xName plotAtRisk plotCensored plotCL plotHW plotEP labelCL
         labelHW labelEP maxTime xtickVals xtickValFitPol method StratumID
         classAtRisk plotBand plotTest GroupName yMin Transparency SecondTitle
         TestName pValue;
      BeginGraph;
         if (NSTRATA=1)
            if (EXISTS(STRATUMID))
               entrytitle &titletext1;
            else
               entrytitle &titletext0;
            endif;
            if (PLOTATRISK)
               entrytitle "with Number of Subjects at Risk" / textattrs=
                  GRAPHVALUETEXT;
            endif;
            layout overlay / xaxisopts=(&xoptions) yaxisopts=(&yoptions);
               .
               .
               .
            endlayout;
         else
            entrytitle &titletext2;
            if (EXISTS(SECONDTITLE))
               entrytitle SECONDTITLE / textattrs=GRAPHVALUETEXT;
            endif;
            layout overlay / xaxisopts=(&xoptions) yaxisopts=(&yoptions);
               .
               .
               .
            endlayout;
         endif;
      EndGraph;
   end;
run;
```

Creating a Template That is Easy to Modify

This example shows how you can modularize the entire template. The goal is to modularize the template and use macros such that simple changes, such as title changes, are no more complicated than the following:

```
%SurvivalTemplateRestore

%let TitleText0 = "Kaplan-Meier Plot";
%let TitleText1 = &titletext0 " for " STRATUMID;
%let TitleText2 = &titletext0;

%SurvivalTemplate
```

You can modularize the entire template as follows:

```
%macro SurvivalTemplateRestore;

   %global TitleText0 TitleText1 TitleText2 yOptions xOptions tips
           groups bandopts gridopts blockopts censored censorstr;

   %let TitleText0 = METHOD " Survival Estimate";
   %let TitleText1 = &titletext0 " for " STRATUMID;
   %let TitleText2 = &titletext0 "s";         /* plural: Survival Estimates */

   %let yOptions   = label="Survival Probability"
                     shortlabel="Survival"
                     linearopts=(viewmin=0 viewmax=1
                                 tickvaluelist=(0 .2 .4 .6 .8 1.0));

   %let xOptions   = shortlabel=XNAME
                     offsetmin=.05
                     linearopts=(viewmax=MAXTIME tickvaluelist=XTICKVALS
                                 tickvaluefitpolicy=XTICKVALFITPOL);

   %let tips       = rolename=(_tip1=ATRISK _tip2=EVENT) tip=(y x Time _tip1 _tip2);

   %let groups     = group=STRATUM index=STRATUMNUM;

   %let bandopts   = &groups modelname="Survival";

   %let gridopts   = autoalign=(TOPRIGHT BOTTOMLEFT TOP BOTTOM)
                     border=true BackgroundColor=GraphWalls:Color Opaque=true;

   %let blockopts  = repeatedvalues=true valuehalign=start valuefitpolicy=truncate
                     labelposition=left labelattrs=GRAPHVALUETEXT
                     valueattrs=GRAPHDATATEXT(size=7pt) includemissingclass=false;

   %let censored   = markerattrs=(symbol=plus);
   %let censorstr  = "+ Censored";
```

```
%macro SurvivalTemplate;
   proc template;
      define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
      dynamic NStrata xName plotAtRisk plotCL plotHW plotEP labelCL
         %if %nrbquote(&censored) ne %then plotCensored;
         labelHW labelEP maxTime xtickVals xtickValFitPol method StratumID
         classAtRisk plotBand plotTest GroupName yMin Transparency SecondTitle
         TestName pValue;
         BeginGraph;

            if (NSTRATA=1)
               if (EXISTS(STRATUMID))
                  entrytitle &titletext1;
               else
                  entrytitle &titletext0;
               endif;
               if (PLOTATRISK)
                  entrytitle "with Number of Subjects at Risk" / textattrs=
                     GRAPHVALUETEXT;
               endif;

               layout overlay / xaxisopts=(&xoptions) yaxisopts=(&yoptions);
                  %singlestratum

%mend;
```

```
%SurvivalTemplate
%mend;
```

This modularized template is available in the SAS sample library. If you are using the SAS windowing environment, select **Help ► Getting Started with SAS Software**. Select the **Contents** tab. Expand **Learning to Use SAS**, expand **SAS Sample Programs**, and expand **SAS/STAT**. Select **Samples**. Search for and select **PROC LIFETEST Template**.

The following changes were made to the template:

- The outer macro, **%SurvivalTemplateRestore**, defines a set of macros and a set of global macro variables. This macro makes it easier to restore the default macros and macro variables. You should not use this outer macro to modify the templates. You should use it only to provide and restore all of the defaults.
- Many options, including most of the options that are specified in multiple places in the template, are extracted to macro variables.
- The main body of the template is in a macro, **%SurvivalTemplate**, so that it is easier to recompile the template after making changes.
- The table for *p*-values is stored in the macro, **%Entry_P**.
- The revised template for the single-stratum case is stored in the macro **%SingleStratum**.
- The revised template for the multiple-stratum case is stored in the macro **%MultipleStrata**.
- The template has been re-indented.

These changes make it easier to identify the relevant parts of the template, modify them, and recompile the template. All subsequent parts of this example modify this rewritten and more modular template.

Do not edit the template inside the **%SurvivalTemplateRestore** macro. Rather, copy the %LET statements and macro definitions and modify them outside the context of the **%SurvivalTemplateRestore** macro. If you work this way, then you can restore the defaults with a two step process:

1 You can restore the default macros and macro variables by running the following step:

```
%SurvivalTemplateRestore
```

2 You can restore the default template by running the following step:

```
proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

A simple, complete program, with set up, template modification, and clean up works as follows:

```
                                          /* Make the macros and macro      */
%SurvivalTemplateRestore                  /* variables available            */

%let TitleText0 = "Kaplan-Meier Plot";    /* Change the title.              */
%let TitleText1 = &titletext0 " for " STRATUMID;
%let TitleText2 = &titletext0;

%SurvivalTemplate                         /* Compile the template with      */
                                          /* the new title.                 */

proc lifetest data=sashelp.BMT            /* Perform the analysis and make  */
              plots=survival(cb=hw test); /* the graph.                     */
   time T * Status(0);
   strata Group;
run;

%SurvivalTemplateRestore                  /* Restore the default macros     */
                                          /* and macro variables.           */

proc template;                            /* Restore the default template.  */
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

The results of this step are not shown, but this same template modification is discussed in the next section. The **%SurvivalTemplateRestore** macro creates the macros and macro variables that you can modify to change the template. The **%SurvivalTemplate** macro compiles the template with the macro variable changes and macro changes (if any were performed). By default, the compiled template is stored in the Sasuser.Templat item store. PROC LIFETEST makes the graph. The **%SurvivalTemplateRestore** macro restores the default macros and macro variables. The **%SurvivalTemplateRestore** macro ends by calling the **%SurvivalTemplate** macro, so it also compiles and stores the default template in the Sasuser.Templat item store. The PROC TEMPLATE step deletes the compiled template from the Sasuser.Templat item store so that the original template from the Sashelp.Tmplmst item store is used in subsequent runs.

Deleting the compiled template from the Sasuser.Templat item store does not change the macros or macro variables. Hence, if you do not restore the macros and macro variables, but you delete the compiled template, change a different macro variable, and recompile the template in the same SAS session, you will see the effects of both changes. In practice, you do not need to restore the default macros and macro variables when you are done unless (as is the case in this example) you go on in the same SAS session to make other template changes and you do not want your previous template changes to affect subsequent graphs.

If you modify and manipulate this template frequently, you might find it more convenient to modify the **%SurvivalTemplateRestore** macro along the following lines:

```
%macro SurvivalTemplateRestore(action);
   .
   .
   .
   %if       &action = compile %then %SurvivalTemplate;
   %else %if &action = delete  %then %do;
      proc template;
         delete Stat.Lifetest.Graphics.ProductLimitSurvival;
      run;
   %end;
%mend;
```

This modification enables you to clean up with a single step.

Modifying the Plot Title in the Revised Template

This example changes the title of the survival plot in PROC LIFETEST from "Product-Limit Survival Estimates" to "Kaplan-Meier Plot" as follows, using the modularized template with macros:

```
%SurvivalTemplateRestore

%let TitleText0 = "Kaplan-Meier Plot";
%let TitleText1 = &titletext0 " for " STRATUMID;
%let TitleText2 = &titletext0;

%SurvivalTemplate
```

The **%SurvivalTemplateRestore** macro from the preceding section, "Creating a Template That is Easy to Modify" on page 768, provides the modularized template code. The three %LET statements modify the titles, and the **%SurvivalTemplate** macro compiles the modified template. The following step, along with the modified template, creates Output 22.3.3:

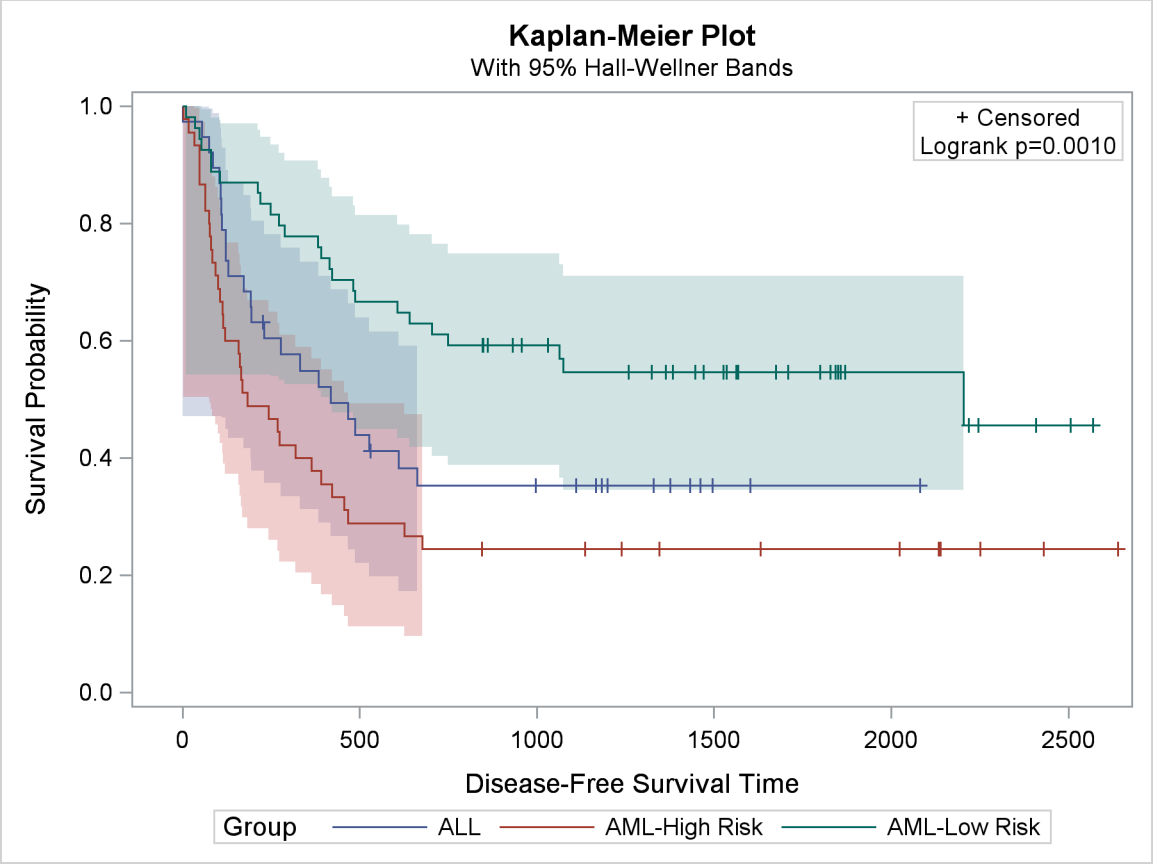
```
proc lifetest data=sashelp.BMT plots=survival(cb=hw test);
   time T * Status(0);
   strata Group;
run;
```

You can restore the default macros, macro variables, and template by running the following steps:

```
%SurvivalTemplateRestore

proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Output 22.3.3 Kaplan-Meier Plot Created with the Revised Template



Modifying the Legend and Inset Table

You can easily modify many other features of this template. For example, you can change the locations of the inset table and the legend, which are controlled by the following statements:

```
%let gridopts = autoalign=(TOPRIGHT BOTTOMLEFT TOP BOTTOM)
                border=true BackgroundColor=GraphWalls:Color Opaque=true;
layout gridded / rows=2 &gridopts;

DiscreteLegend "Survival" / title=GROUPNAME location=outside;
```

The LAYOUT GRIDDED statement produces the two-row inset table displayed in the top right corner. The AUTOALIGN= option provides the preferred locations inside the plot for this table, ordered from most preferred to least preferred. You can add new locations or rearrange the existing locations. The DISCRETELEGEND statement places the legend outside of the plot. You can move it inside and print only one legend entry across each row instead of three. This has the effect of changing the orientation of the legend from a row to a column. The modified statements are as follows:

```
%let gridopts = autoalign=(BottomRight TOPRIGHT BOTTOMLEFT TOP BOTTOM)
                border=true BackgroundColor=GraphWalls:Color Opaque=true;
layout gridded / rows=2 &gridopts;

DiscreteLegend "Survival" / title=GROUPNAME across=1 location=inside
   autoalign=(TopRight BottomLeft Top Bottom);
```

These changes are incorporated into the template as follows:

```
%SurvivalTemplateRestore

%let TitleText0 = "Kaplan-Meier Plot";
%let TitleText1 = &titletext0 " for " STRATUMID;
%let TitleText2 = &titletext0;

%let gridopts = autoalign=(BottomRight TOPRIGHT BOTTOMLEFT TOP BOTTOM)
                border=true BackgroundColor=GraphWalls:Color Opaque=true;

%macro multiplestrata;
  if (PLOTHW)
     bandplot LimitUpper=HW_UCL LimitLower=HW_LCL x=TIME / &bandopts
              datatransparency=Transparency;
   endif;
   if (PLOTEP)
      bandplot LimitUpper=EP_UCL LimitLower=EP_LCL x=TIME / &bandopts
               datatransparency=Transparency;
   endif;
   if (PLOTCL)
      if (PLOTBAND)
         bandplot LimitUpper=SDF_UCL LimitLower=SDF_LCL x=TIME / &bandopts
                  display=(outline);
      else
         bandplot LimitUpper=SDF_UCL LimitLower=SDF_LCL x=TIME / &bandopts
                  datatransparency=Transparency;
      endif;
   endif;

   stepplot y=SURVIVAL x=TIME / &groups name="Survival" &tips;

   if (PLOTCENSORED)
      scatterplot y=CENSORED x=TIME / &groups &censored;
   endif;

   if (PLOTATRISK)
      innermargin / align=bottom;
         blockplot x=TATRISK block=ATRISK / class=CLASSATRISK
            display=(label values) &blockopts;
      endinnermargin;
   endif;

   DiscreteLegend "Survival" / title=GROUPNAME across=1 location=inside
      autoalign=(TopRight BottomLeft Top Bottom);

   if (PLOTCENSORED)
      if (PLOTTEST)
         layout gridded / rows=2 &gridopts;
            entry &censorstr;
            %entry_p
         endlayout;
      else
```

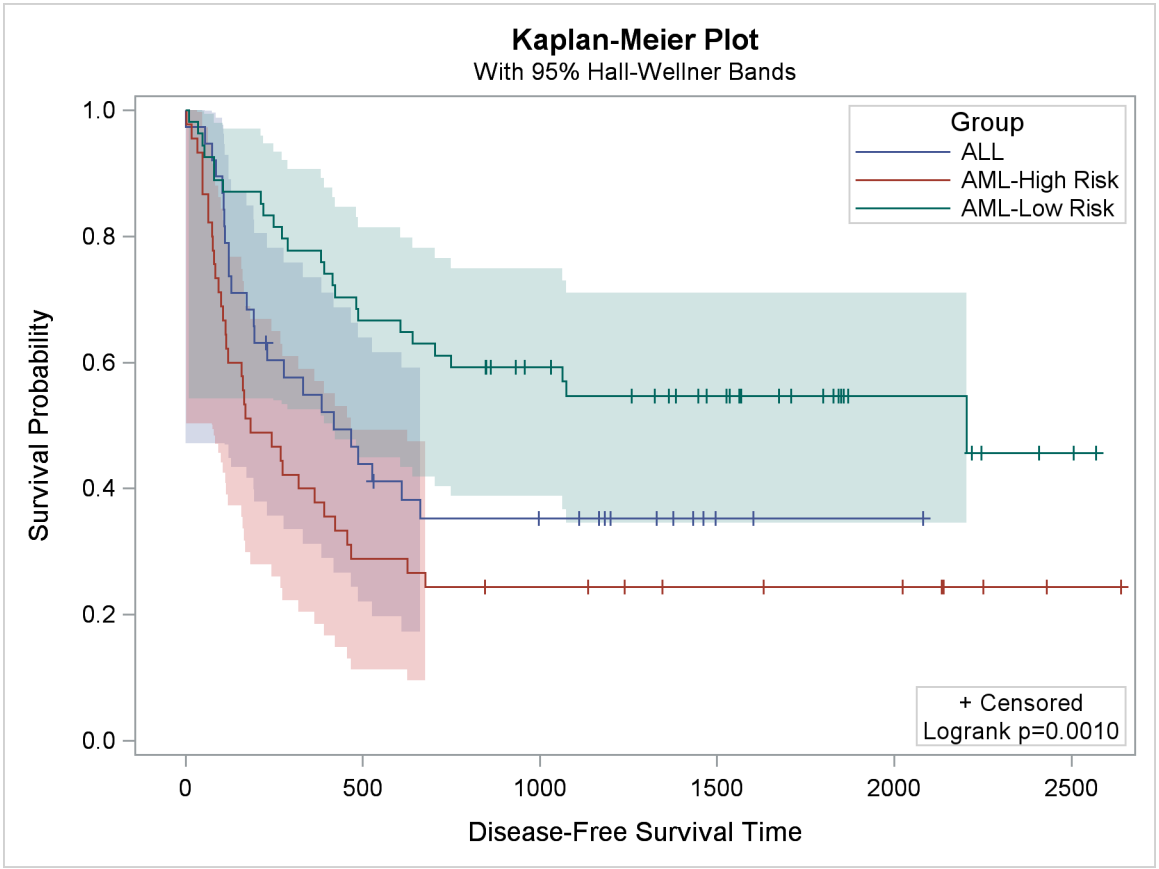
```
         layout gridded / rows=1 &gridopts;
            entry &censorstr;
         endlayout;
      endif;
   else
      if (PLOTTEST)
         layout gridded / rows=1 &gridopts;
            %entry_p
         endlayout;
      endif;
   endif;
%mend;

%SurvivalTemplate
```

The new template along with the following statements produce Output 22.3.4:

```
proc lifetest data=sashelp.BMT plots=survival(cb=hw test);
   time T * Status(0);
   strata Group;
run;
```

Output 22.3.4 Kaplan-Meier Plot with Legend Modifications



You can restore the default macros, macro variables, and template by running the following steps:

```
%SurvivalTemplateRestore

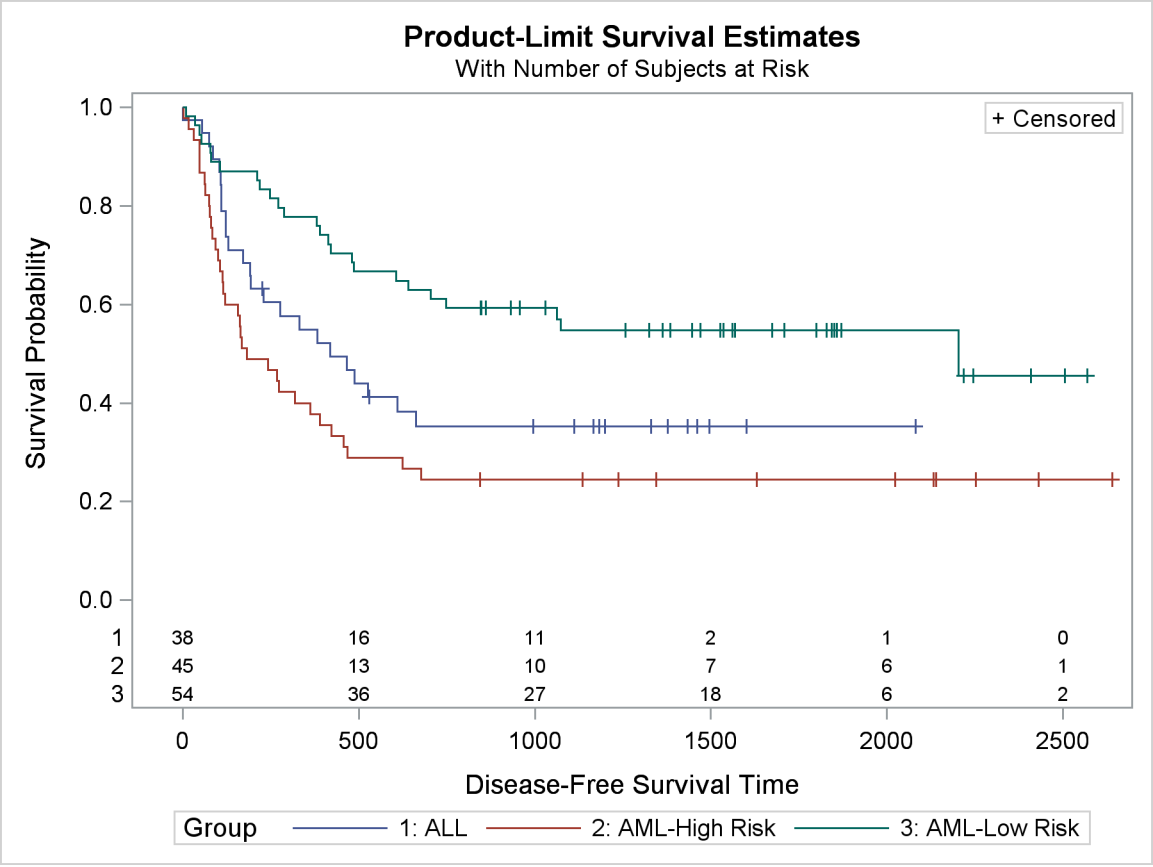
proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Modifying the Layout and Adding a New Inset Table

Example 51.2 of Chapter 51, "The LIFETEST Procedure," uses the following statements to make the plot shown in Output 22.3.5:

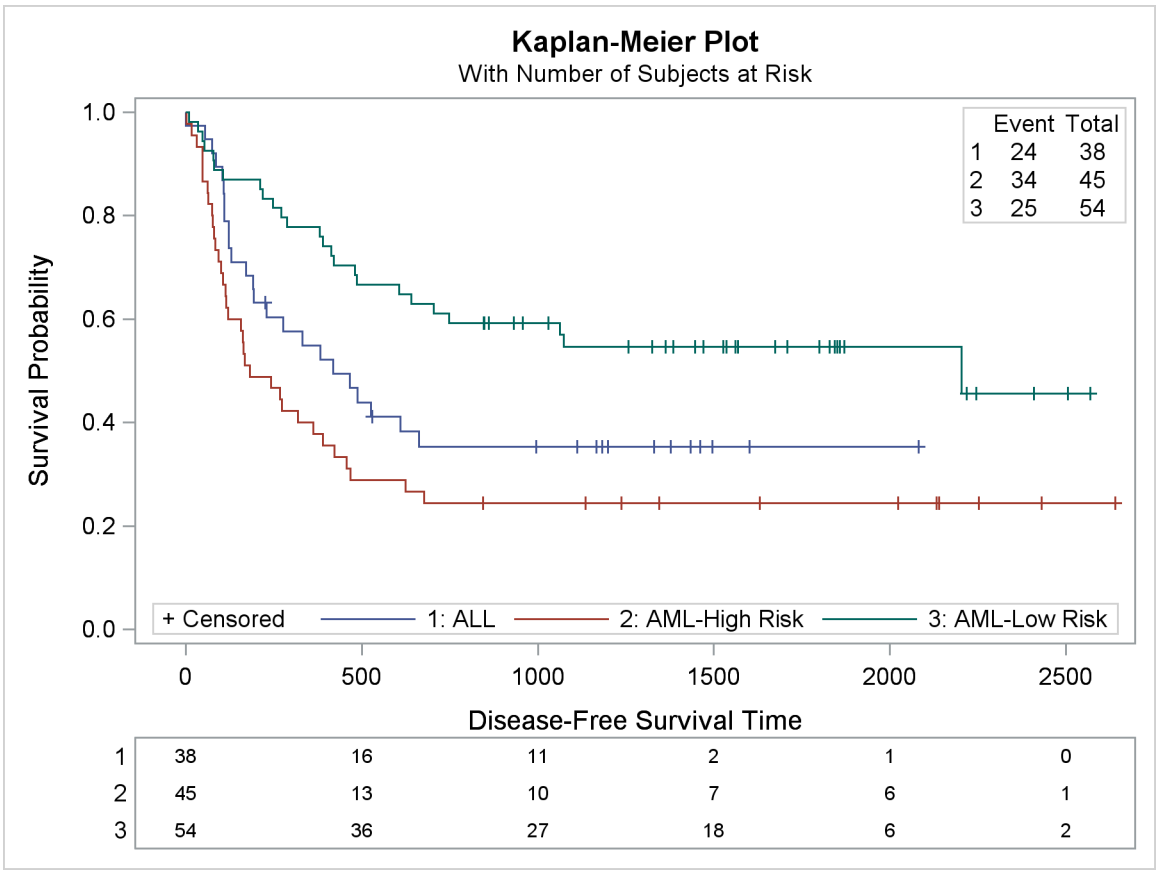
```
proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

Output 22.3.5 Survival Plot with Number of Subjects At Risk



Output 22.3.5 displays the estimated disease-free survival functions for the three leukemia groups with the number of subjects at risk at 0, 500, 1,000, 1,500, 2,000, and 2,500 days. The rest of this example shows you how to modify the template to produce the plot displayed in Output 22.3.6. This new plot differs from the old plot in several ways. It has a new inset table in the top right corner with the number of observations and the number of events in the each stratum. The legend has been moved inside the plot and combined with the old inset table that showed the marker for censored observations. The information about the subjects at risk has been moved into a table below the plot. Also, the title change from the first part of the example is retained. These changes are easy, if they are broken down and performed one step at a time.

Output 22.3.6 Kaplan-Meier Plot with a Different Layout



You can begin this step by submitting the original macro definitions from the section "Creating a Template That is Easy to Modify" on page 768:

```
%SurvivalTemplateRestore
```

Notice that the survival plot template has two major parts: a layout that is used when there is only one stratum and a layout that is used with more than one stratum. You can see the two major parts in the definition of the **%SurvivalTemplate** macro. Every section of this example has more than one stratum, so it is the changes to the second layout and the **%MultipleStrata** macro (or more precisely the ELSE portion of the template) that are affecting the results.

PROC LIFETEST makes available a series of dynamic variables that it does not display by default. See the section "Additional Dynamic Variables for Survival Plots Using ODS Graphics" on page 3936 in Chapter 51, "The LIFETEST Procedure," for information about these dynamic variables. You can use these dynamic variables to add the new inset table to the plot. The following statements show how to add a gridded layout to the graph:

```
dynamic NObs1 NObs2 NObs3 NEvent1 NEvent2 NEvent3;
layout gridded / columns=3 border=TRUE autoalign=(TopRight);
   entry "";      entry "Event";   entry "Total";
   entry "1";     entry NEvent1;   entry NObs1;
   entry "2";     entry NEvent2;   entry NObs2;
   entry "3";     entry NEvent3;   entry Nobs3;
endlayout;
```

These statements are added to the end of the **%MultipleStrata** macro.

The at-risk information in Output 22.3.5 is produced by the following BLOCKPLOT statement, which is displayed in the context of the IF and INNERMARGIN statements that go with it:

```
if (PLOTATRISK)
   innermargin / align=bottom;
      blockplot x=TATRISK block=ATRISK / class=CLASSATRISK
         display=(label values) &blockopts;
   endinnermargin;
endif;
```

In the next step, the at-risk block plot is moved out of the plot and into a table below the plot. The template has a new overall layout—a LAYOUT LATTICE that has two panels stacked vertically, one for the plot and one for the at-risk information. Using ROWWEIGHTS=(.85 .15), the plot on top occupies 85% of the display and the at-risk information in the second panel occupies 15%. The option COLUMNDATARANGE=UNIONALL creates a common axis across the two panels. In these next steps, you also move the legend inside (similar to a previous part of this example) and rearrange the three inset boxes.

The new template structure is as follows:

```
%let TitleText2 = "Kaplan-Meier Plot";

%macro SurvivalTemplate;
   proc template;
      define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
         dynamic NStrata xName plotAtRisk plotCL plotHW plotEP labelCL
            %if %nrbquote(&censored) ne %then plotCensored;
            labelHW labelEP maxTime xtickVals xtickValFitPol method StratumID
            classAtRisk plotBand plotTest GroupName yMin Transparency SecondTitle
            TestName pValue;
         BeginGraph;

            entrytitle &titletext2;
            if (EXISTS(SECONDTITLE))
               entrytitle SECONDTITLE / textattrs=GRAPHVALUETEXT;
            endif;

            layout lattice /  rows=2 columns=1 columndatarange=unionall
                              rowweights=(.85 .15);
               layout overlay / xaxisopts=(&xoptions) yaxisopts=(&yoptions);
                  %multiplestrata
               endlayout;

               layout overlay / xaxisopts=(display=none);
                  blockplot x=TATRISK block=ATRISK / class=CLASSATRISK
                  display=(label values) &blockopts;
               endlayout;
            endlayout;

         EndGraph;
      end;
   run;
%mend;

%macro multiplestrata;
  if (PLOTHW)
      bandplot LimitUpper=HW_UCL LimitLower=HW_LCL x=TIME / &bandopts
               datatransparency=Transparency;
   endif;
   if (PLOTEP)
      bandplot LimitUpper=EP_UCL LimitLower=EP_LCL x=TIME / &bandopts
               datatransparency=Transparency;
   endif;
   if (PLOTCL)
      if (PLOTBAND)
         bandplot LimitUpper=SDF_UCL LimitLower=SDF_LCL x=TIME / &bandopts
                  display=(outline);
      else
         bandplot LimitUpper=SDF_UCL LimitLower=SDF_LCL x=TIME / &bandopts
                  datatransparency=Transparency;
      endif;
   endif;
```

```
   stepplot y=SURVIVAL x=TIME / &groups name="Survival" &tips;

   if (PLOTCENSORED)
      scatterplot y=CENSORED x=TIME / &groups &censored;
   endif;

   DiscreteLegend "Survival" / title=GROUPNAME location=outside;

   if (PLOTCENSORED)
      if (PLOTTEST)
         layout gridded / rows=2 &gridopts;
            entry &censorstr;
            %entry_p
         endlayout;
      else
         layout gridded / rows=1 &gridopts;
            entry &censorstr;
         endlayout;
      endif;
   else
      if (PLOTTEST)
         layout gridded / rows=1 &gridopts;
            %entry_p
         endlayout;
      endif;
   endif;

   dynamic NObs1 NObs2 NObs3 NEvent1 NEvent2 NEvent3;
   layout gridded / columns=3 border=TRUE autoalign=(TopRight);
      entry "";      entry "Event";   entry "Total";
      entry "1";     entry NEvent1;   entry NObs1;
      entry "2";     entry NEvent2;   entry NObs2;
      entry "3";     entry NEvent3;   entry Nobs3;
   endlayout;
%mend;

%SurvivalTemplate
```

You can further simplify the plot by moving the legend inside, removing the title from the legend (which is currently the variable name Group), and instead adding "+ Censored" (the contents of the inset table) to the legend in place of the title, as in the following statement:

```
DiscreteLegend "Survival" / title="+ Censored"
   titleattrs=GraphValueText location=inside autoalign=(Bottom);
```

The option TITLEATTRS=GRAPHVALUETEXT is specified so that the "+ Censored" appears in the same font as the other entries in the legend and appears to be just another part of the legend. All of the statements for making the old inset table can now be removed from the template. The full template also plots bands, which are not used in this example, so they can also be removed. The resulting template is as follows:

```
%let TitleText2 = "Kaplan-Meier Plot";
```

```
%macro SurvivalTemplate;
   proc template;
      define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
         dynamic NStrata xName plotAtRisk plotCL plotHW plotEP labelCL
            %if %nrbquote(&censored) ne %then plotCensored;
            labelHW labelEP maxTime xtickVals xtickValFitPol method StratumID
            classAtRisk plotBand plotTest GroupName yMin Transparency SecondTitle
            TestName pValue;
         BeginGraph;

            entrytitle &titletext2;
            if (EXISTS(SECONDTITLE))
               entrytitle SECONDTITLE / textattrs=GRAPHVALUETEXT;
            endif;

            layout lattice /  rows=2 columns=1 columndatarange=unionall
                              rowweights=(.85 .15);
               layout overlay / xaxisopts=(&xoptions) yaxisopts=(&yoptions);
                  %multiplestrata
               endlayout;

               layout overlay / xaxisopts=(display=none);
                  blockplot x=TATRISK block=ATRISK / class=CLASSATRISK
                  display=(label values) &blockopts;
               endlayout;
            endlayout;

         EndGraph;
      end;
   run;
%mend;

%macro MultipleStrata;

   stepplot y=SURVIVAL x=TIME / &groups name="Survival" &tips;

   if (PLOTCENSORED)
      scatterplot y=CENSORED x=TIME / &groups &censored;
   endif;

   DiscreteLegend "Survival" / title="+ Censored"
      titleattrs=GraphValueText location=inside autoalign=(Bottom);

   dynamic NObs1 NObs2 NObs3 NEvent1 NEvent2 NEvent3;
   layout gridded / columns=3 border=TRUE autoalign=(TopRight);
      entry "";      entry "Event";   entry "Total";
      entry "1";     entry NEvent1;   entry NObs1;
      entry "2";     entry NEvent2;   entry NObs2;
      entry "3";     entry NEvent3;   entry Nobs3;
   endlayout;
%mend;

%SurvivalTemplate
```

The following step uses the new template to create the desired plot:

```
proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

The plot is displayed in Output 22.3.6 at the beginning of this section.

This example removed a great deal of functionality from the default template so that the final, modified template would be relatively simple and understandable, but this is not necessary. The template could have been modified without deleting the first LAYOUT OVERLAY and other statements. The strategy for template modification illustrated in this example can be applied to any complicated template: identify the overall structure, isolate the relevant pieces, and then make changes in stages. Since the modified template no longer works for all analyses, it is important that you delete it when you are done, as in the following example:

```
%SurvivalTemplateRestore

proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Changing Line Styles

The survival plot for multiple strata has a separate step function for each stratum. The information that goes into making each stratum appears as a separate group of observations in the data object that is displayed in the graph. The template options GROUP=STRATUM and INDEX=STRATUMNUM specify the data object columns that provide the information for identifying each stratum. The GROUP= column provides the stratum name, and the INDEX= column provides a numeric index that identifies each group. There are no options that explicitly control the colors or other aspects of the appearance of information about each stratum. The number of groups can be large, and it is not known at the time the template is written how many groups must be accommodated. Therefore, group information is controlled by ODS styles. The style elements **GraphData1**, **GraphData2**, **GraphData3**, and so on control the appearance of groups. See the section "Some Common Style Elements" on page 652 for more information.

You can use the HTMLBLUE style when you want groups to be distinguished only by color. Alternatively, you can easily modify any other style to be an all-color style like HTMLBLUE. For example:

```
proc template;
   define style styles.Statistical2;
      parent = Statistical;
      style Graph from Graph / attrpriority = "Color";
      end;
   run;
```

You can instead use the SAS autocall macro **%ModStyle**. See the section "Creating an All-Color Style" on page 678 in Chapter 21, "Statistical Graphics Using ODS," for more information. The easiest way to use the **%ModStyle** macro is as follows:

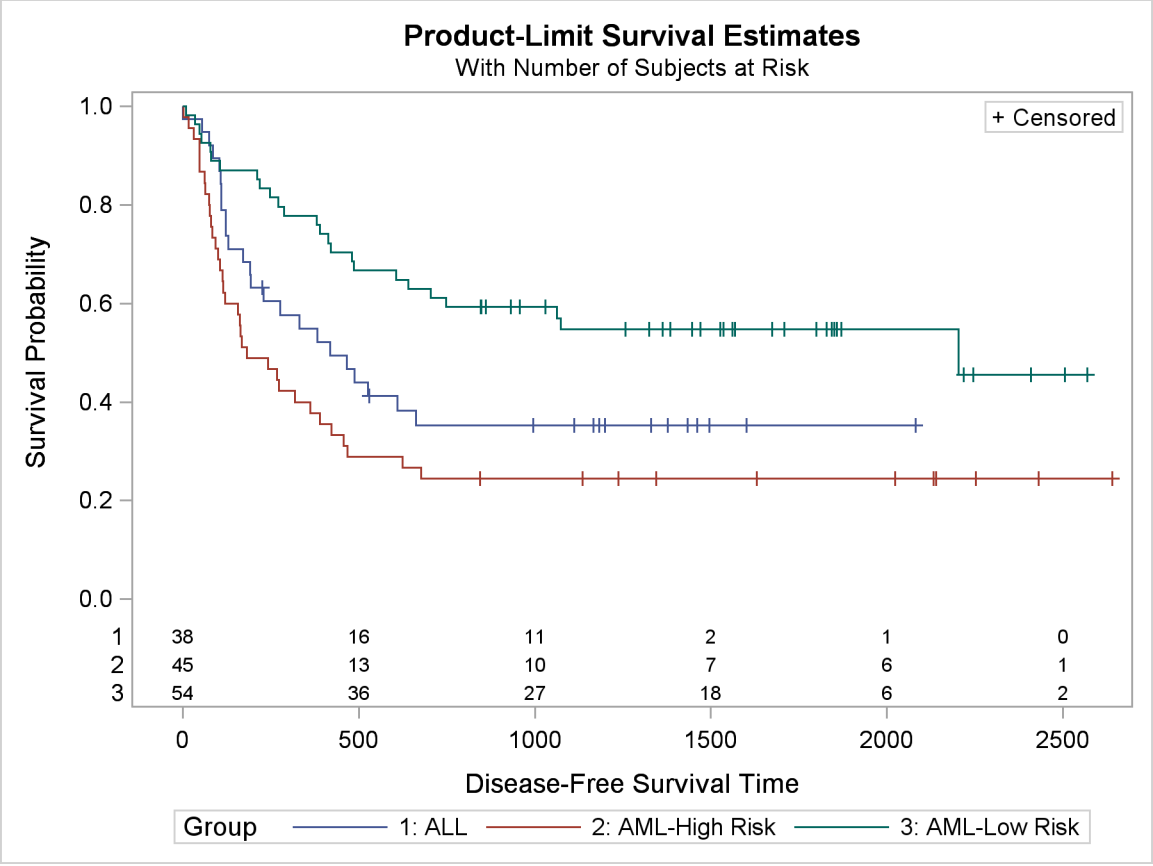
```
%modstyle(name=StatColor, parent=statistical)

ods listing style=StatColor;

proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

A new style called STATCOLOR is created that inherits from the STATISTICAL style. The result (since no other options were specified) is an all-color style. All lines have the same solid line style instead of the default, which uses different line styles. The results are displayed in Output 22.3.7.

Output 22.3.7 Survival Plot with an All-Color Style



There are many other changes you can make to styles, and many other ways to use the **%ModStyle** macro. The following steps illustrate three ways to change the colors. The first uses the **%ModStyle** macro and an explicit color list to create an all-color style for the first three groups. The second creates an all-color style by redefining **GraphData1** through **GraphData3**. The third creates a new style by redefining **GraphData1** through **GraphData3**, inheriting from the old style elements, but overriding the colors. Only the last style change is actually used in this example to make a graph. The following steps create the graph displayed in Output 22.3.8:

```
%modstyle(name=StatColor, parent=HTMLBlue, colors=purple orange silver)

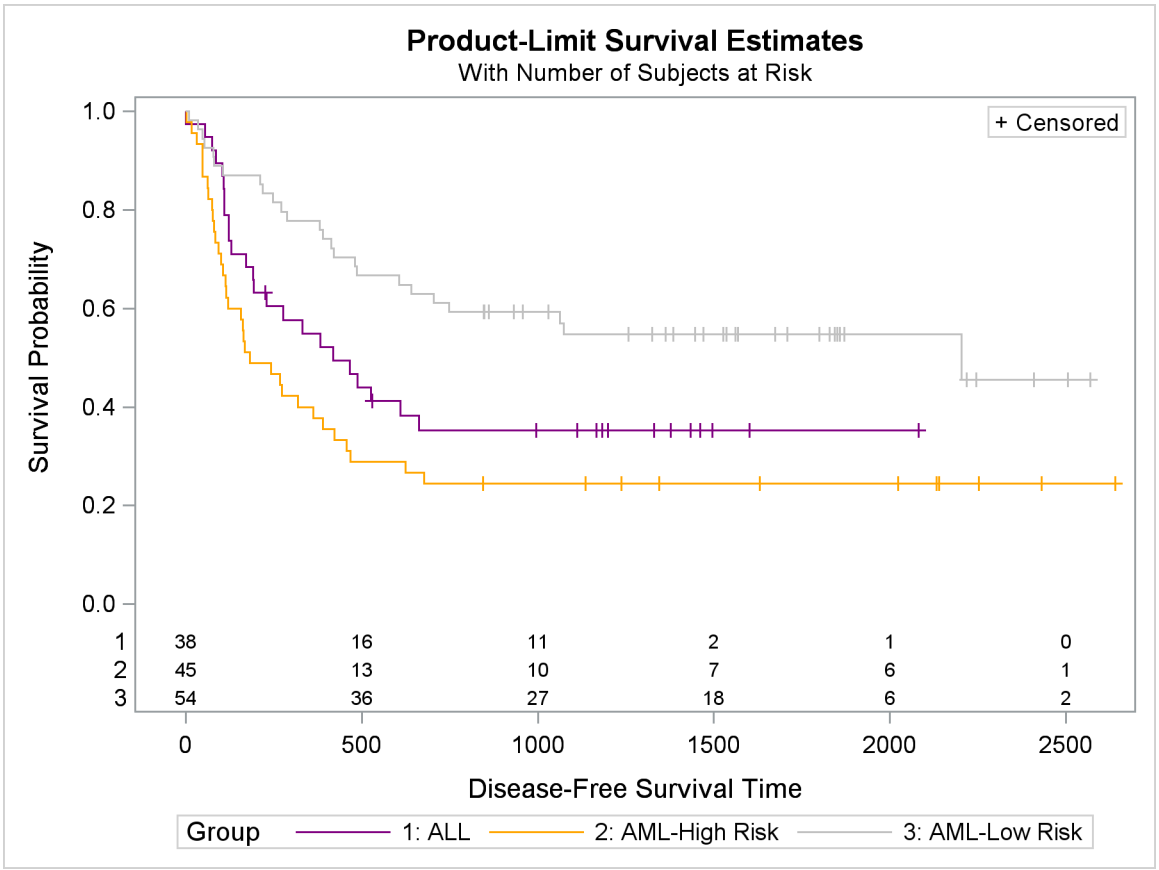
proc template;
   define style Styles.StatColor;
      parent = Styles.HTMLBlue;
      style GraphData1 / contrastcolor = purple;
      style GraphData2 / contrastcolor = orange;
      style GraphData3 / contrastcolor = silver;
   end;
run;

proc template;
   define style Styles.StatColor;
      parent = Styles.HTMLBlue;
      style GraphData1 from GraphData1 / contrastcolor = purple;
      style GraphData2 from GraphData2 / contrastcolor = orange;
      style GraphData3 from GraphData3 / contrastcolor = silver;
   end;
run;

ods listing style=StatColor;

proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

Output 22.3.8 Survival Plot with a Modified Style



Most other examples in this section change the graph template. This example creates a new style template. Since a new template is created instead of modifying an existing template, there is nothing that must be cleaned up in this example. However, you can delete the new style template as follows:

```
proc template;
   delete Styles.StatColor;
run;
```

Alternatively, there is no harm in leaving it around since it has no effect unless you explicitly specify it on a destination statement.

Changing Fonts

You can change the fonts for the axis labels by using the LABELATTRS= option for both the X and Y axes. You can change the fonts for the tick values by using the TICKVALUEATTRS= option for both the X and Y axes. The following steps illustrate:

```
%SurvivalTemplateRestore

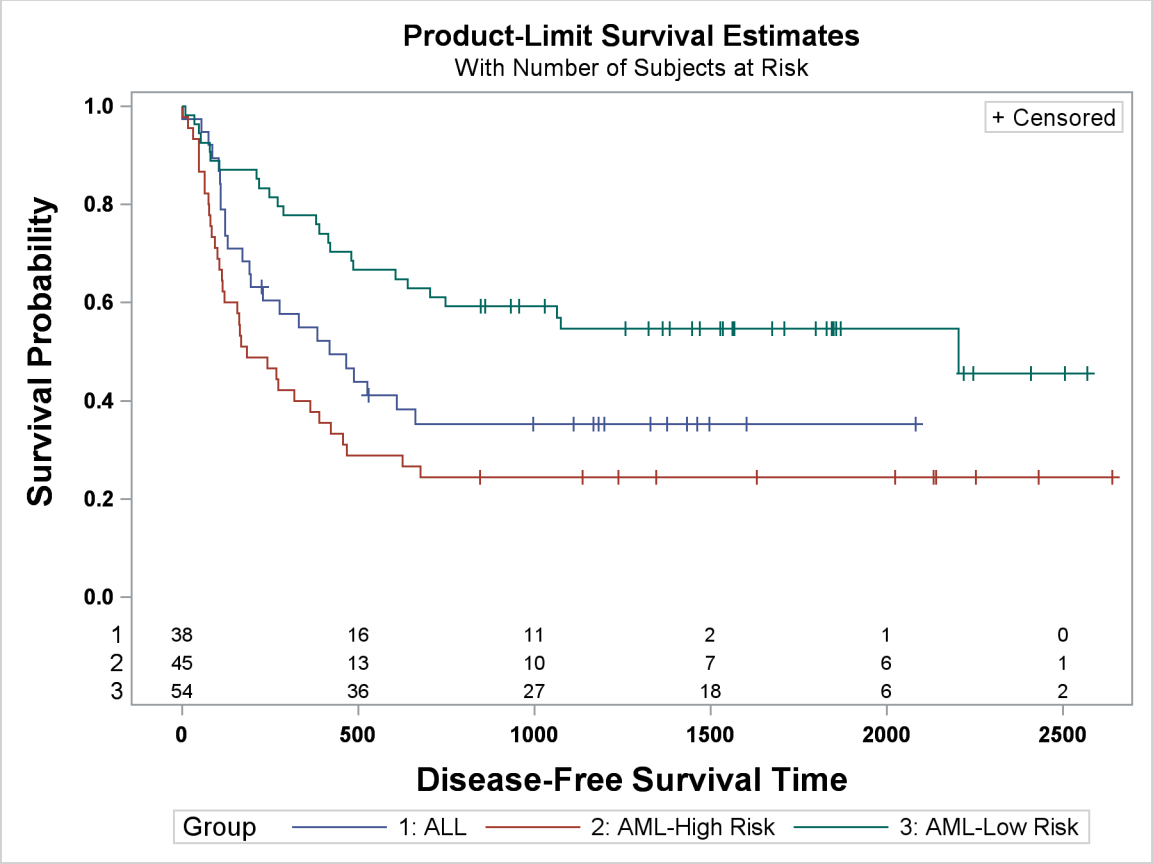
%let yOptions   = label="Survival Probability"
                  shortlabel="Survival"
                  labelattrs=(size=12pt weight=bold)
                  tickvalueattrs=(size=8pt weight=bold)
                  linearopts=(viewmin=0 viewmax=1
                              tickvaluelist=(0 .2 .4 .6 .8 1.0));

%let xOptions   = shortlabel=XNAME
                  offsetmin=.05
                  labelattrs=(size=12pt weight=bold)
                  tickvalueattrs=(size=8pt weight=bold)
                  linearopts=(viewmax=MAXTIME tickvaluelist=XTICKVALS
                              tickvaluefitpolicy=XTICKVALFITPOL);
%SurvivalTemplate

proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

These steps create axis label fonts that are greater than the default (12-point rather than 10-point) and are bold. The tick value fonts are smaller than the default (8-point rather than 9-point) and again are bold. The results are displayed in Output 22.3.9.

Output 22.3.9 Survival Plot with a Modified Axis Label Font



You can restore the default macros, macro variables, and template by running the following steps:

```
%SurvivalTemplateRestore

proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Instead of changing a graph template to change fonts, you can change the fonts by modifying the ODS style. The following steps write the HTMLBLUE style and its parent style STATISTICAL to a file and display only those lines that pertain to fonts:

```
filename temp1 'temp1.tpl' lrecl=100;
filename temp2 'temp2.tpl' lrecl=100;
filename temp  ('temp1.tpl' 'temp2.tpl') lrecl=100;

proc template;
   source styles.htmlblue    / file=temp1;
   source styles.statistical / file=temp2;
run;
```

```
data _null_;
   infile temp pad;
   input line $ 1-100;
   file print;
   if index(lowcase(line), 'font') then put line;
run;
```

The results are displayed in Output 22.3.10.

Output 22.3.10 The Part of the HTMLBLUE Style That Pertains to Fonts

```
style fonts /
'TitleFont2' = ("<sans-serif>, <MTsans-serif>, Helvetica, Helv",2,bold)
'TitleFont' = ("<sans-serif>, <MTsans-serif>, Helvetica, Helv",3,bold)
'StrongFont' = ("<sans-serif>, <MTsans-serif>, Helvetica, Helv",2,bold)
'EmphasisFont' = ("<sans-serif>, <MTsans-serif>, Helvetica, Helv",2,italic)
'FixedFont' = ("<monospace>, Courier",2)
'BatchFixedFont' = ("SAS Monospace, <monospace>, Courier, monospace",2)
'FixedHeadingFont' = ("<monospace>, Courier, monospace",2)
'FixedStrongFont' = ("<monospace>, Courier, monospace",2,bold)
'FixedEmphasisFont' = ("<monospace>, Courier, monospace",2,italic)
'headingEmphasisFont' = ("<sans-serif>, <MTsans-serif>, Helvetica, Helv",2,bold
italic)
'headingFont' = ("<sans-serif>, <MTsans-serif>, Helvetica, Helv",2,bold)
'docFont' = ("<sans-serif>, <MTsans-serif>, Helvetica, Helv",2);
style GraphFonts /
'GraphDataFont' = ("<sans-serif>, <MTsans-serif>",7pt)
'GraphUnicodeFont' = ("<MTsans-serif-unicode>",9pt)
'GraphValueFont' = ("<sans-serif>, <MTsans-serif>",9pt)
'GraphLabelFont' = ("<sans-serif>, <MTsans-serif>",10pt)
'GraphFootnoteFont' = ("<sans-serif>, <MTsans-serif>",10pt,italic)
'GraphTitleFont' = ("<sans-serif>, <MTsans-serif>",11pt,bold)
'GraphTitle1Font' = ("<sans-serif>, <MTsans-serif>",14pt,bold)
'GraphAnnoFont' = ("<sans-serif>, <MTsans-serif>",10pt);
font = fonts('HeadingFont')
font = fonts('DocFont')
font = Fonts('headingEmphasisFont');
font = Fonts('TitleFont2');
font = Fonts('docFont');
```

If neither of these styles contains the right information, you can also display the DEFAULT style, which is the parent of the STATISTICAL style, as follows:

```
filename temp1 'temp1.tpl' lrecl=100;
filename temp2 'temp2.tpl' lrecl=100;
filename temp3 'temp3.tpl' lrecl=100;
filename temp  ('temp1.tpl' 'temp2.tpl' 'temp3.tpl') lrecl=100;

proc template;
   source styles.htmlblue    / file=temp1;
   source styles.statistical / file=temp2;
   source styles.default     / file=temp3;
run;
```

```
data _null_;
   infile temp pad;
   input line $ 1-100;
   file print;
   if index(lowcase(line), 'font') then put line;
run;
```

The results of this step are not shown.

The following step creates a new style, STATBIGFONT, that redefines the **GraphLabelFont** style element from an ordinary 10-point font to a bold 12-point font and the **GraphValueFont** style element from an ordinary 9-point font to a bold 8-point font:

```
proc template;
   define style Styles.StatBigFont;
      parent = Styles.HTMLBlue;
      style graphfonts from graphfonts /
         'GraphLabelFont' = ("<sans-serif>, <MTsans-serif>",12pt,bold)
         'GraphValueFont' = ("<sans-serif>, <MTsans-serif>",8pt,bold);
   end;
run;
```

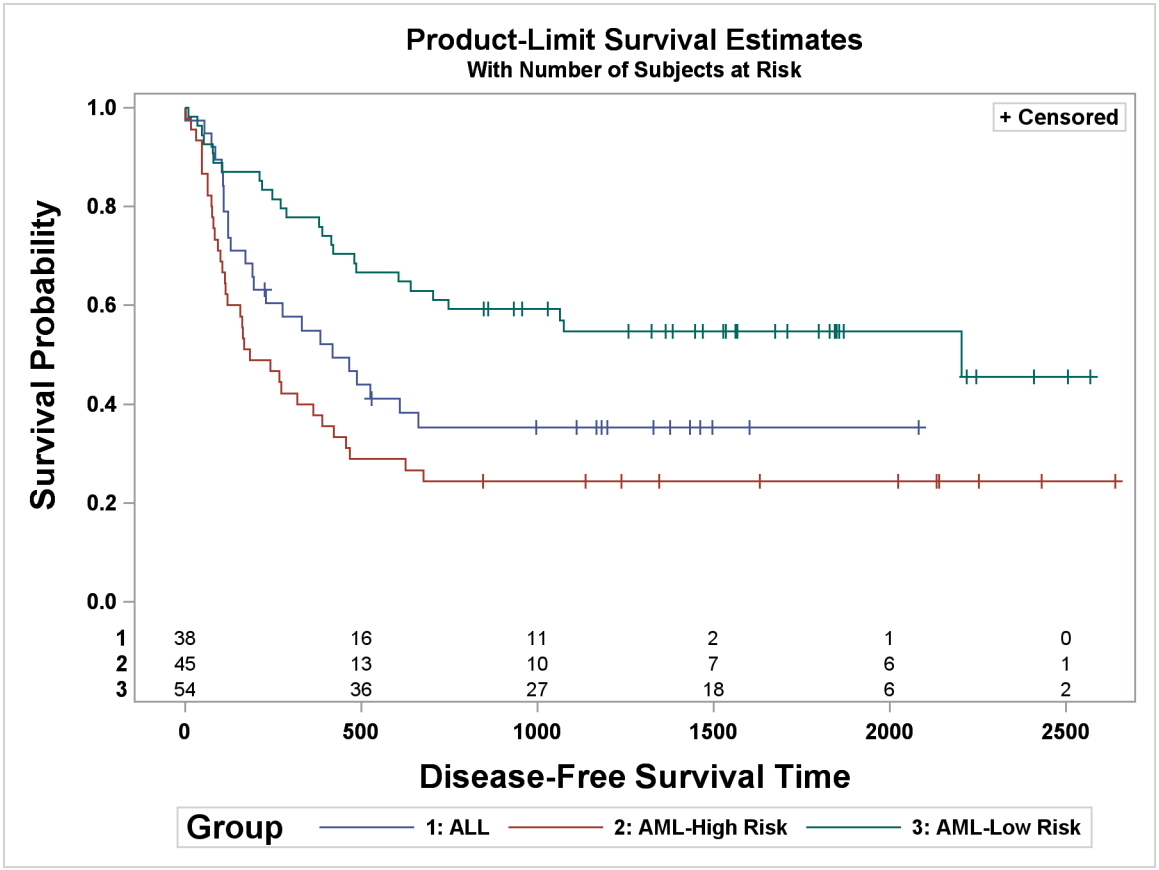
The following step creates the graph that is displayed in Output 22.3.11:

```
ods listing style=StatBigFont;

proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

The graph displayed in Output 22.3.11 is almost identical to the one displayed in Output 22.3.9. They differ since the **GraphLabelFont** style element also controls the title for the legend, and the **GraphValueFont** style element also controls the labels for the at-risk information table.

Output 22.3.11 Survival Plot with a Modified `GraphLabelFont` Style Element



You can delete the new style template as follows:

```
proc template;
   delete Styles.StatBigFont;
run;
```

Changing How Censored Data Are Displayed

By default, PROC LIFETEST displays a plus to indicate censoring. This example illustrates how to change that symbol to a small filled circle both on the step plots and in the inset box. The following steps change the template and create Output 22.3.12:

```
%SurvivalTemplateRestore

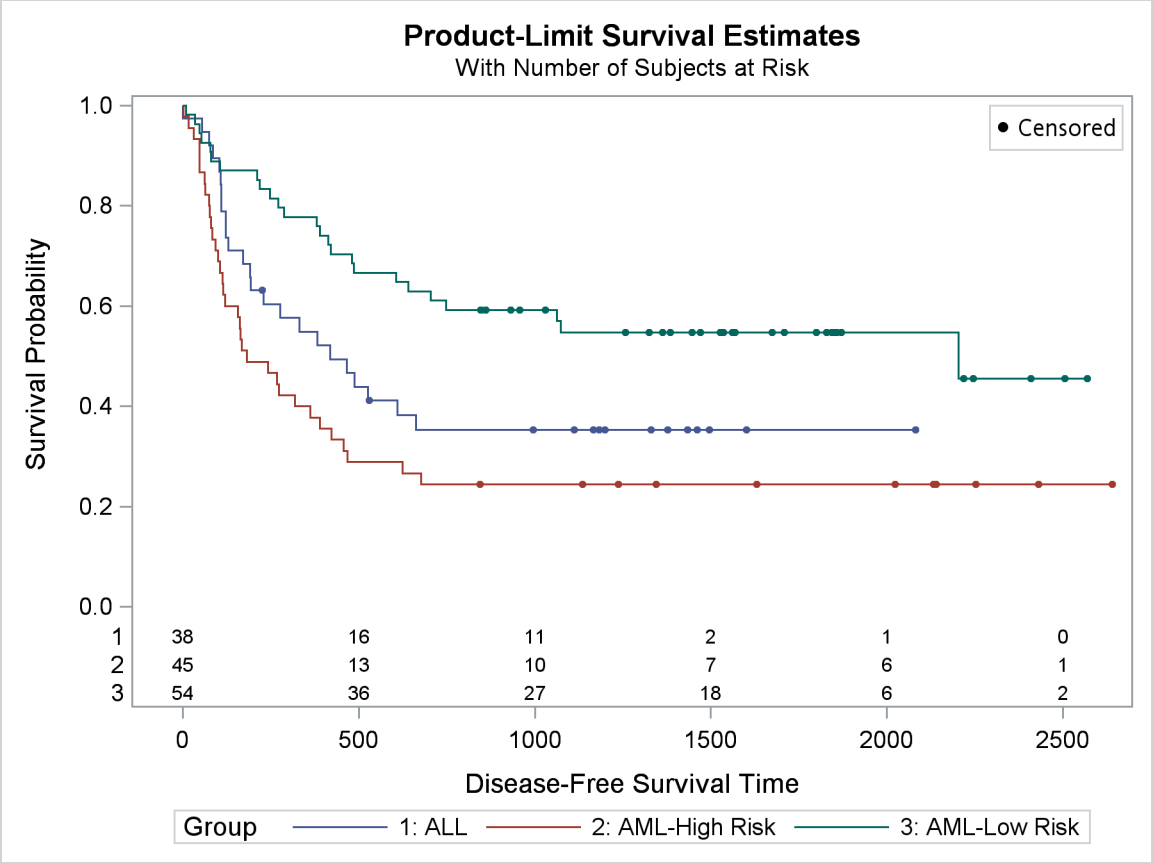
%let censored  = markerattrs=(symbol=circlefilled size=3px);
%let censorstr = "(*ESC*){Unicode '25cf'x} Censored"
                 / textattrs=GraphValueText (family=GraphUnicodeText:FontFamily);

%SurvivalTemplate

proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

The Unicode Consortium http://unicode.org/ provides a list of character codes at http://www.unicode.org/charts/charindex.html.

Output 22.3.12 Survival Plot with a Modified Display of Censoring



The following step suppresses the censoring information by using the NOCENSOR option in the survival plot request:

```
proc lifetest data=sashelp.BMT plots=survival(nocensor atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

Alternatively, you could make a template change to have the same effect and create Output 22.3.13 as follows:

```
%let censored = ;

%SurvivalTemplate;

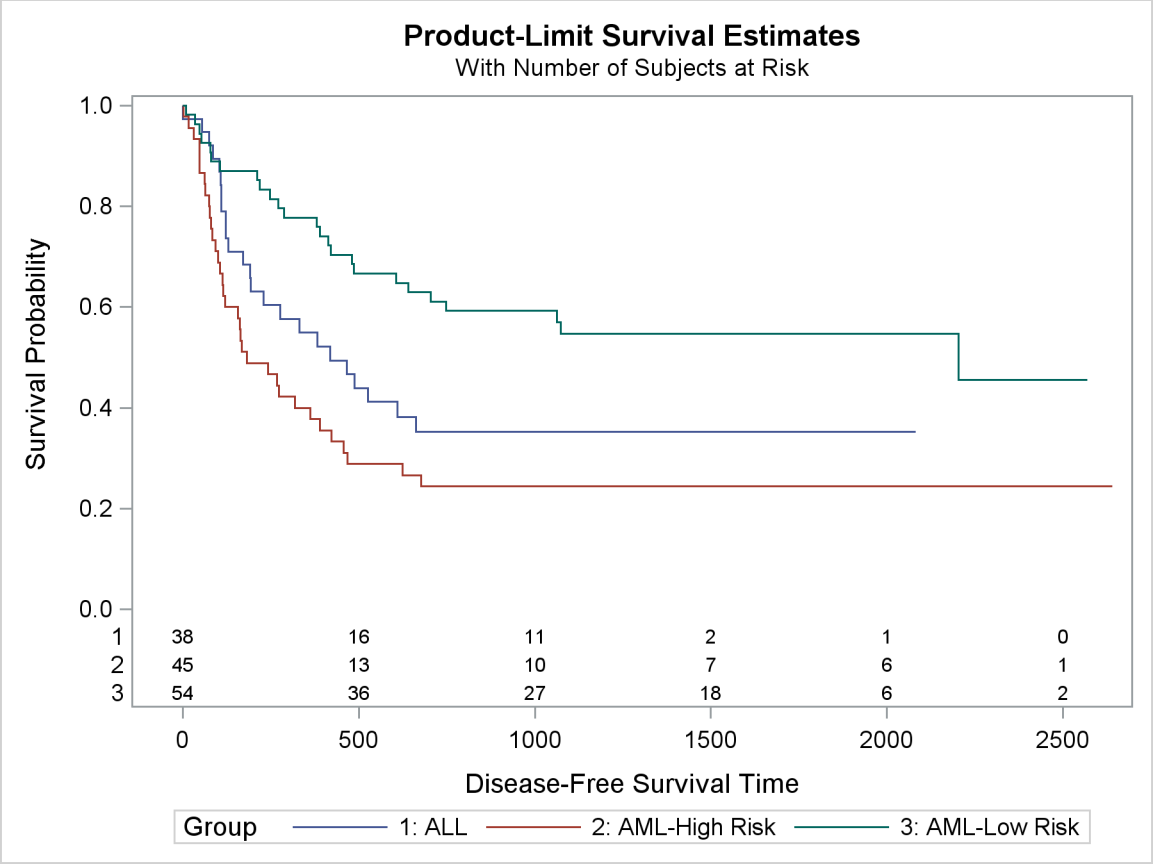
proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

This step works because the modularized template was written to include the following DYNAMIC statement:

```
dynamic NStrata xName plotAtRisk plotCL plotHW plotEP labelCL
   %if %nrbquote(&censored) ne %then plotCensored;
   labelHW labelEP maxTime xtickVals xtickValFitPol method StratumID
   classAtRisk plotBand plotTest GroupName yMin Transparency SecondTitle
   TestName pValue;
```

The DYNAMIC statement names the variables that are set by the procedure and control aspects of the graph. The plotCensored dynamic variable controls whether the censoring information is plotted. It is omitted from the list of dynamic variables when the macro variable Censored is null, so all aspects of the graph that are conditionally displayed based on the value of the dynamic variable plotCensored are suppressed.

Output 22.3.13 Survival Plot with No Display of Censoring



You can restore the default macros, macro variables, and template by running the following steps:

```
%SurvivalTemplateRestore

proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Displaying Survival Summary Statistics

PROC LIFETEST passes a number of summary statistics as dynamic variables to the survival plot template. See the section "Additional Dynamic Variables for Survival Plots Using ODS Graphics" on page 3936 in Chapter 51, "The LIFETEST Procedure," for information about these dynamic variables. In this example, the graph template is modified to display survival summary statistics.

The following steps create Output 22.3.14:

```
%SurvivalTemplateRestore

%let fmt = bestd6.;

%macro header;
   entry halign=right "Subjects";
   entry halign=right "Event";
   entry halign=right "Censored";
   entry halign=right "Median Survival";
   entry halign=right PctMedianConfid;
   entry halign=left  "CL";
%mend;

%macro table1;
   columnheaders;
      layout overlay / pad=(top=5);
         layout gridded / columns=6 border=TRUE;
            dynamic PctMedianConfid NObs NEvent Median
                    MedianLower MedianUpper;
            %header
            entry halign=right NObs;
            entry halign=right NEvent;
            entry halign=right eval(NObs-NEvent);
            entry halign=right eval(put(Median,&fmt));
            entry halign=right eval(put(MedianLower,&fmt));
            entry halign=right eval(put(MedianUpper,&fmt));
         endlayout;
      endlayout;
   endcolumnheaders;
%mend;
```

Output 22.3.14 Survival Plot with Survival Summary Statistics

	Subjects	Event	Censored	Median Survival	95% CL	
ALL	38	24	14	418	192	.
AML-High Risk	45	34	11	183	113	390
AML-Low Risk	54	25	29	2204	641	.

```
%macro table2;
   columnheaders;
      layout overlay / pad=(top=5);
         layout gridded / columns=7 border=TRUE;
            dynamic PctMedianConfid;
            entry " ";
            %header
            %do i = 1 %to 6;
               dynamic StrVal&i NObs&i NEvent&i Median&i
                       LowerMedian&i UpperMedian&i;
               if (&i <= nstrata)
                  entry halign=left StrVal&i;
                  entry halign=right NObs&i;
                  entry halign=right NEvent&i;
                  entry halign=right eval(NObs&i-NEvent&i);
```

```
                  entry halign=right eval(put(Median&i,&fmt));
                  entry halign=right eval(put(LowerMedian&i,&fmt));
                  entry halign=right eval(put(UpperMedian&i,&fmt));
               endif;
            %end;
         endlayout;
      endlayout;
   endcolumnheaders;
%mend;

%macro SurvivalTemplate;
   proc template;
      define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
         dynamic NStrata xName plotAtRisk plotCL plotHW plotEP labelCL
            %if %nrbquote(&censored) ne %then plotCensored;
            labelHW labelEP maxTime xtickVals xtickValFitPol method StratumID
            classAtRisk plotBand plotTest GroupName yMin Transparency SecondTitle
            TestName pValue;
         BeginGraph / designheight=defaultdesignwidth;

            if (NSTRATA=1)
               if (EXISTS(STRATUMID))
                  entrytitle &titletext1;
               else
                  entrytitle &titletext0;
               endif;
               if (PLOTATRISK)
                  entrytitle "with Number of Subjects at Risk" / textattrs=
                     GRAPHVALUETEXT;
               endif;

               layout lattice / rows=1 columns=1;
                  layout overlay / xaxisopts=(&xoptions) yaxisopts=(&yoptions);
                     %singlestratum
                  endlayout;
                  %table1
               endlayout;

            else
               entrytitle &titletext2;
               if (EXISTS(SECONDTITLE))
                  entrytitle SECONDTITLE / textattrs=GRAPHVALUETEXT;
               endif;

               layout lattice / rows=1 columns=1;
                  layout overlay / xaxisopts=(&xoptions) yaxisopts=(&yoptions);
                     %multiplestrata
                  endlayout;
                  %table2
               endlayout;
            endif;
         EndGraph;
      end;
   run;
```

```
%mend;

%SurvivalTemplate

proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group;
run;
```

This example adds new macros that provide the portions of the template that produce the survival summary statistics table. This template allows for the display of tables with up to six strata. The template could be modified to handle more strata, particularly if the height of the graphical display area is increased, but the graph starts getting busy with too many strata.

The **%Header** macro provides a header for the table of summary statistics. In the single-stratum case, it provides all of the column headers. In the multiple-strata case, a blank header for the first column must be provided in addition to the column headers in the **%Header** macro.

The **%Table1** macro provides the summary statistics table for the single-stratum case. A LAYOUT OVERLAY statement adds padding to the top of the table so that it is separated from the legend. A LAYOUT GRIDDED statement creates a table with six columns. The six ENTRY statements in the **%Header** macro provide the column headers, and the six ENTRY statements in the **%Table1** macro provide the one-line body of the table.

The **%Table2** macro provides the summary statistics table for the multiple-strata case. A LAYOUT OVERLAY statement adds padding to the top of the table so that it is separated from the legend. A LAYOUT GRIDDED statement creates a table with seven columns. The blank ENTRY statement along with the eight ENTRY statements in the **%Header** macro provide the column headers, and the seven ENTRY statements in the **%Table2** macro provide the multi-line body of the table. These ENTRY statements are in a macro DO loop and are repeated six times for up to six strata. This macro also has a DYNAMIC statement that declares the dynamic variables whose values appear in the table.

The **%SurvivalTemplate** macro is modified to accommodate the table. For both the single-stratum and multiple-strata cases, a LAYOUT LATTICE statement is added so that a COLUMNHEADERS block can be added with the survival summary statistics table. The **%Table1** and **%Table2** macros are then added. The new statements could have been directly added to the **%SurvivalTemplate** macro instead of creating two additional macros. The additional macros were created solely to provide a more modular and readable template.

You can restore the default macros, macro variables, and template by running the following steps:

```
%SurvivalTemplateRestore

proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Example 22.4: Customizing Panels

This example illustrates how to modify the regression fit diagnostics panel shown in Figure 21.1 in Chapter 21, "Statistical Graphics Using ODS," so that it displays a subset of the component plots. The original panel consists of eight plots and a summary statistics box. The ODS trace output from PROC REG shown previously shows that the template for the diagnostics panel is **Stat.REG.Graphics.DiagnosticsPanel**. The following statements display the template:

```
proc template;
   source Stat.REG.Graphics.DiagnosticsPanel;
run;
```

An abridged version of the results is shown next:

```
define statgraph Stat.Reg.Graphics.DiagnosticsPanel;
   notes "Diagnostics Panel";
   dynamic . . .;
   BeginGraph / designheight=defaultDesignWidth;
      entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL
         halign=center textattrs=GRAPHTITLETEXT "Fit Diagnostics"
         " for " _DEPNAME;
      layout lattice / columns=3 rowgutter=10 columngutter=10
         shrinkfonts=true rows=3;
         layout overlay / xaxisopts=(shortlabel='Predicted');
            . . .
         endlayout;
         layout overlay / xaxisopts=(shortlabel='Predicted');
            . . .
         endlayout;
         layout overlay / xaxisopts=(label='Leverage' offsetmax=0.05)
            . . .
         endlayout;
         layout overlay / yaxisopts=(label="Residual" shortlabel=
            "Resid") xaxisopts=(label="Quantile");
            . . .
         endlayout;
         layout overlayequated / xaxisopts=(shortlabel='Predicted')
            . . .
         endlayout;
         layout overlay / xaxisopts=(linearopts=(integer=true) label=
            "Observation" shortlabel="Obs" offsetmax=0.05) yaxisopts=(
            offsetmin=0.05 offsetmax=0.05);
            . . .
         endlayout;
         layout overlay / xaxisopts=(label="Residual") yaxisopts=(label
            ="Percent");
            . . .
         endlayout;
         layout lattice / columns=2 rows=1 rowdatarange=unionall
            columngutter=0;
            . . .
         endlayout;
```

```
         if (_SHOWSTATS =1)
            layout overlay;
            . . .
         endLayout;
         endif;
         if (_SHOWSTATS = 2)
            layout overlay / yaxisopts=(gridDisplay=auto_off label=
            "Residual");
            . . .
         endlayout;
         endif;
      endlayout;
   EndGraph;
end;
```

The outermost components of the template are a BEGINGRAPH/ENDGRAPH block with a lattice layout with ROWS=3 and COLUMNS=3 that defines the 3×3 panel of plots. Inside that are nine layouts, one for each cell, the last of which is conditionally defined. The LAYOUT statements define the components of the panel from left to right and top to bottom. You can eliminate some of the panels and produce a 2×2 panel as follows:

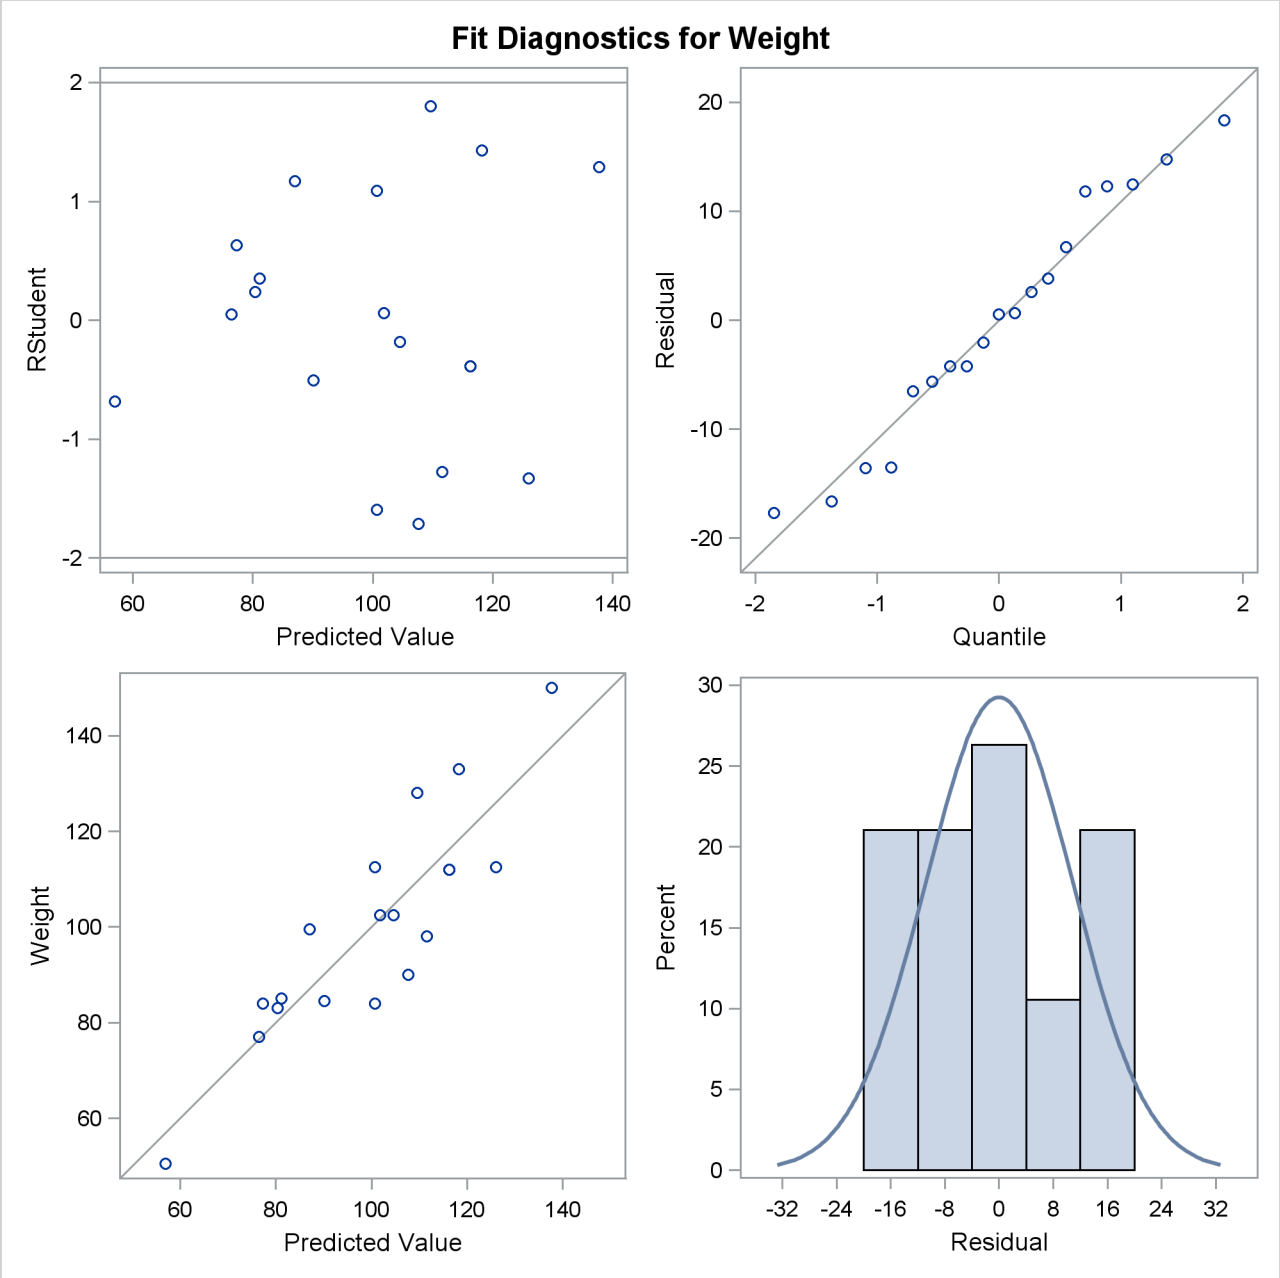
```
proc template;
   define statgraph Stat.Reg.Graphics.DiagnosticsPanel;
      notes "Diagnostics Panel";
      dynamic _DEPLABEL _DEPNAME _MODELLABEL _OUTLEVLABEL _TOTFREQ _NPARM
         _NOBS _OUTCOOKSDLABEL _SHOWSTATS _NSTATSCOLS _DATALABEL _SHOWNObs
         _SHOWTOTFREQ _SHOWNParm _SHOWEDF _SHOWMSE _SHOWRSquare
         _SHOWAdjRSq _SHOWSSE _SHOWDepMean _SHOWCV _SHOWAIC _SHOWBIC
         _SHOWCP _SHOWGMSEP _SHOWJP _SHOWPC _SHOWSBC _SHOWSP _EDF _MSE
         _RSquare _AdjRSq _SSE _DepMean _CV _AIC _BIC _CP _GMSEP _JP _PC
         _SBC _SP;
      BeginGraph / designheight=defaultDesignWidth;
         entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL
            halign=center textattrs=GRAPHTITLETEXT "Fit Diagnostics"
            " for " _DEPNAME;
         layout lattice / columns=2 rowgutter=10 columngutter=10
            shrinkfonts=true rows=2;
            layout overlay / xaxisopts=(shortlabel='Predicted');
               referenceline y=-2;
               referenceline y=2;
               scatterplot y=RSTUDENT x=PREDICTEDVALUE / primary=true
                  datalabel=_OUTLEVLABEL rolename=(_tip1=OBSERVATION _id1=
                  ID1 _id2=ID2 _id3=ID3 _id4=ID4 _id5=ID5) tip=(y x _tip1
                  _id1 _id2 _id3 _id4 _id5);
            endlayout;
            layout overlay / yaxisopts=(label="Residual" shortlabel=
               "Resid") xaxisopts=(label="Quantile");
               lineparm slope=eval (STDDEV(RESIDUAL)) y=eval (
                  MEAN(RESIDUAL)) x=0 / extend=true lineattrs=
                  GRAPHREFERENCE;
               scatterplot y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval (
                  PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/
                  (0.25 + N(RESIDUAL)))) / markerattrs=GRAPHDATADEFAULT
```

```
                primary=true
                rolename=(s=eval (SORT(DROPMISSING(RESIDUAL))) nq=eval (
                PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)
                /(0.25 + N(RESIDUAL))))) tiplabel=(nq="Quantile"
                s="Residual")
                tip=(nq s);
            endlayout;
            layout overlayequated / xaxisopts=(shortlabel='Predicted')
               yaxisopts=(label=_DEPLABEL shortlabel="Observed")
               equatetype=square;
               lineparm slope=1 x=0 y=0 / extend=true lineattrs=
                  GRAPHREFERENCE;
               scatterplot y=DEPVAR x=PREDICTEDVALUE / primary=true
                  datalabel=_OUTLEVLABEL rolename=(_tip1=OBSERVATION _id1=
                  ID1 _id2=ID2 _id3=ID3 _id4=ID4 _id5=ID5) tip=(y x _tip1
                  _id1 _id2 _id3 _id4 _id5);
            endlayout;
            layout overlay / xaxisopts=(label="Residual") yaxisopts=(label
               ="Percent");
               histogram RESIDUAL / primary=true;
               densityplot RESIDUAL / name="Normal" legendlabel="Normal"
                  lineattrs=GRAPHFIT;
            endlayout;
         endlayout;
      EndGraph;
   end;
run;

proc reg data=sashelp.class;
   model Weight = Height;
run; quit;
```

This template plots the residuals by predicted values, the Q-Q plot, the actual by predicted plot, and the residual histogram. The results are shown in Output 22.4.1.

Output 22.4.1 Diagnostics Panel with Four Plots



This new template is a straightforward modification of the original template. The COLUMNS=2 and ROWS=2 options in the LAYOUT LATTICE statement request a 2×2 lattice. The LAYOUT statement blocks for components 1, 3, 6, 8, and 9 are deleted. **NOTE:** You do not need to understand every aspect of a template to modify it if you can recognize the overall structure and a few key options.

You can restore the original template as follows:

```
proc template;
   delete Stat.REG.Graphics.DiagnosticsPanel;
run;
```

Example 22.5: Customizing Axes and Reference Lines

This example illustrates several ways that you can change the plot axes in a scatter plot. The example uses PROC CORRESP to perform a correspondence analysis. It is taken from the section "Getting Started: CORRESP Procedure" on page 1910 in Chapter 31, "The CORRESP Procedure." It uses the following data:

```
title "Number of Ph.D.'s Awarded from 1973 to 1978";

data PhD;
   input Science $ 1-19 y1973-y1978;
   label y1973 = '1973'
         y1974 = '1974'
         y1975 = '1975'
         y1976 = '1976'
         y1977 = '1977'
         y1978 = '1978';
   datalines;
Life Sciences       4489 4303 4402 4350 4266 4361
Physical Sciences   4101 3800 3749 3572 3410 3234
Social Sciences     3354 3286 3344 3278 3137 3008
Behavioral Sciences 2444 2587 2749 2878 2960 3049
Engineering         3338 3144 2959 2791 2641 2432
Mathematics         1222 1196 1149 1003  959  959
;
```

The following steps perform the correspondence analysis and create Output 22.5.1:

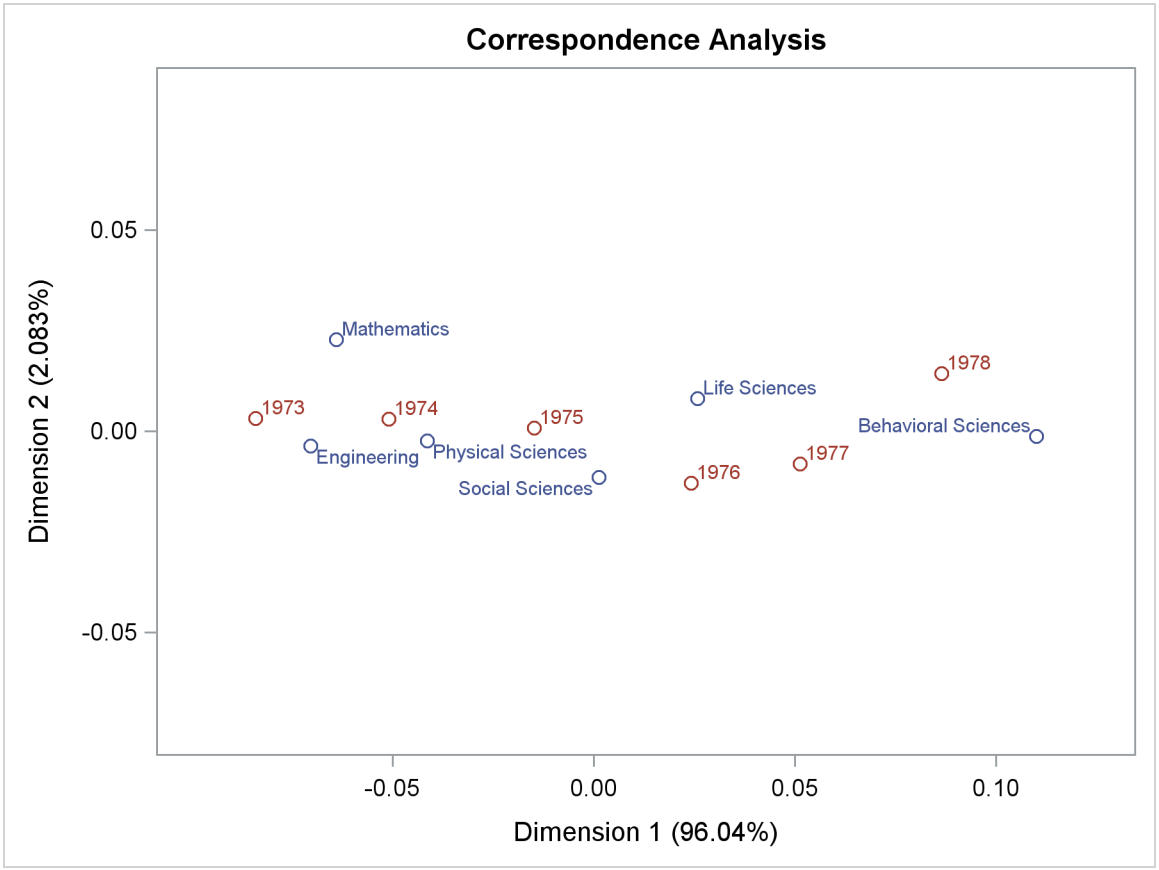
```
ods graphics on;
ods trace on;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

The trace output for this step (not shown) shows that the template for this plot is **Stat.Corresp.Graphics.Configuration**. The following step displays this template:

```
proc template;
   source Stat.Corresp.Graphics.Configuration;
run;
```

Output 22.5.1 Default Scatter Plot



The results are as follows:

```
define statgraph Stat.Corresp.Graphics.Configuration;
   dynamic xVar yVar head legend;
   begingraph;
      entrytitle HEAD;
      layout overlayequated / equatetype=fit xaxisopts=(offsetmin=0.1
         offsetmax=0.1) yaxisopts=(offsetmin=0.1 offsetmax=0.1);
         scatterplot y=YVAR x=XVAR / group=GROUP index=INDEX
            datalabel=LABEL datalabelattrs=GRAPHVALUETEXT
            name="Type" tip=(y x datalabel group)
            tiplabel=(group="Point");
         if (LEGEND)
            discretelegend "Type";
         endif;
      endlayout;
   endgraph;
end;
```

You can add reference lines to the scatter plot at specified X and Y values by using the REFERENCELINE statement, as in the following example:

```
proc template;
   define statgraph Stat.Corresp.Graphics.Configuration;
      dynamic xVar yVar head legend;
      begingraph;
         entrytitle HEAD;
         layout overlayequated / equatetype=fit xaxisopts=(offsetmin=0.1
            offsetmax=0.1) yaxisopts=(offsetmin=0.1 offsetmax=0.1);

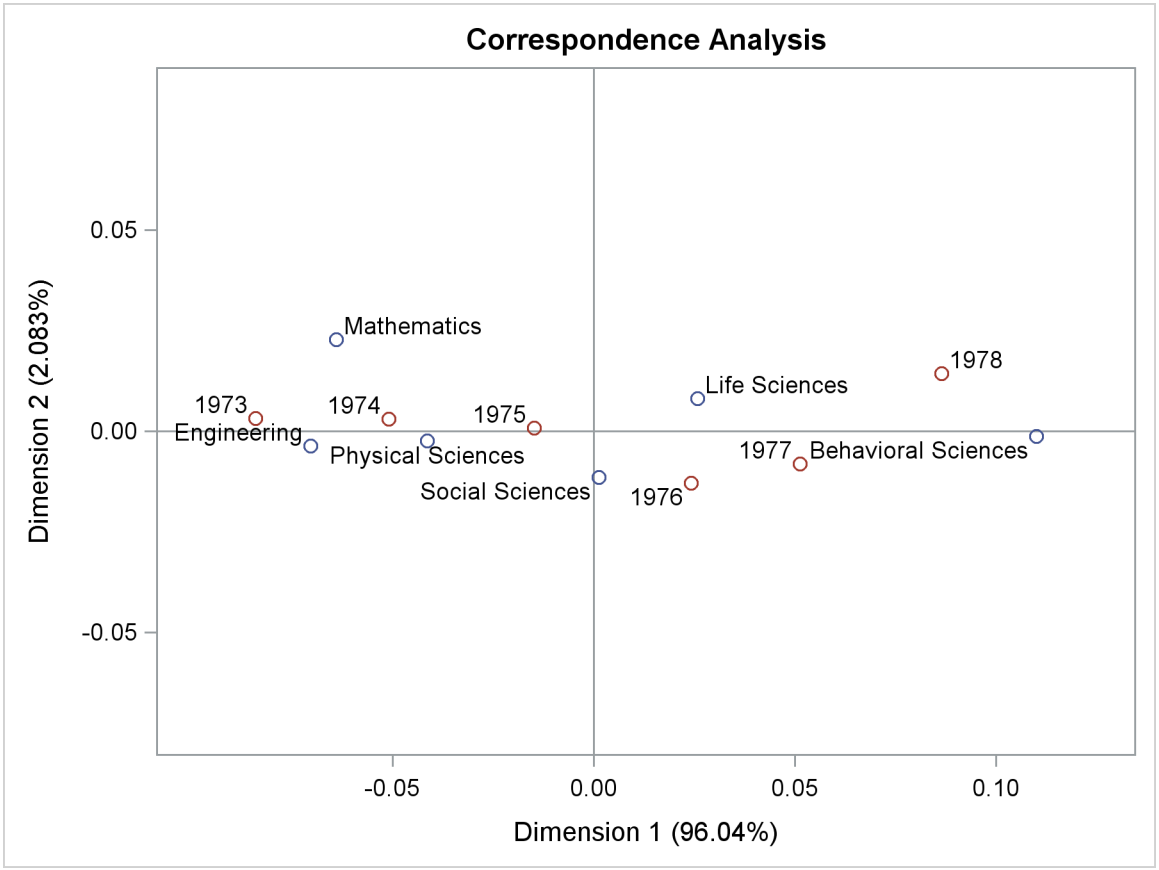
            referenceline x=0;
            referenceline y=0;

            scatterplot y=YVAR x=XVAR / group=GROUP index=INDEX
               datalabel=LABEL datalabelattrs=GRAPHVALUETEXT
               name="Type" tip=(y x datalabel group)
               tiplabel=(group="Point");
            if (LEGEND)
               discretelegend "Type";
            endif;
         endlayout;
      endgraph;
   end;
run;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

When you modify templates, it is important to note that the order of the statements within the LAYOUT OVERLAYEQUATED (or more typically, the LAYOUT OVERLAY) is significant. Here, the reference lines are added before the scatter plot so that the reference lines are drawn before the scatter plot. Consequently, labels and markers that coincide with the reference lines are drawn over the reference lines. The results, with reference lines, are displayed in Output 22.5.2.

Output 22.5.2 Scatter Plot with Reference Lines Added



You can restore the default graph template as follows:

```
proc template;
   delete Stat.Corresp.Graphics.Configuration;
run;
```

The next steps show how you can change the style so that a frame is not shown:

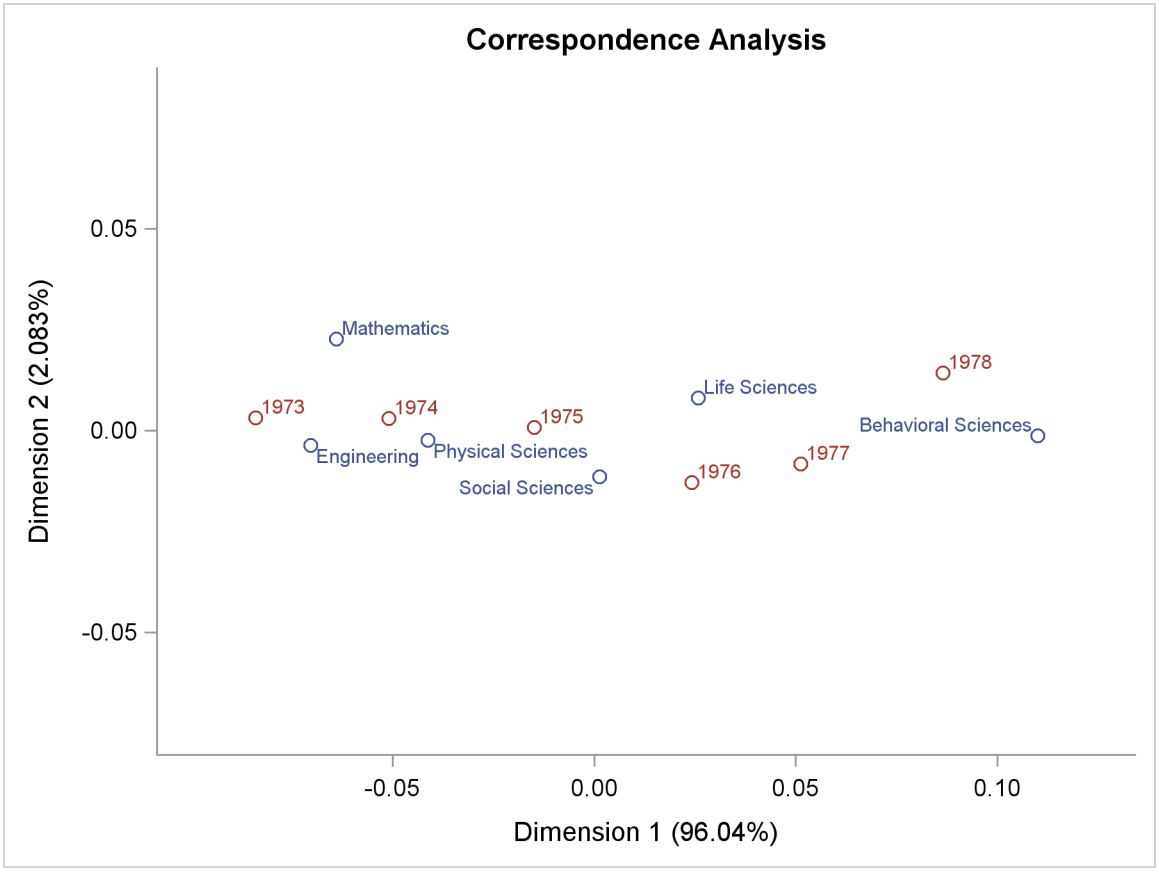
```
proc template;
   define style noframe;
      parent=styles.htmlblue;
      style graphwalls from graphwalls / frameborder=off;
   end;
run;

ods listing style=noframe;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

The results, shown in Output 22.5.3, display an X-axis and a Y-axis without a frame. Unlike the previous change, which affects only the **`ConfigPlot`** display, this change affects all plots created with the NOFRAME style.

Output 22.5.3 Scatter Plot with No Axis Frame



Alternatively, you can also add reference lines and delete the entire axis frame using the WALLDISPLAY=NONE and the DISPLAY= option in the graph template, as in the following example:

```
proc template;
   define statgraph Stat.Corresp.Graphics.Configuration;
      dynamic xVar yVar head legend;
      begingraph;
         entrytitle HEAD;

         layout overlayequated / equatetype=fit walldisplay=none
            xaxisopts=(display=(tickvalues) offsetmin=0.1 offsetmax=0.1)
            yaxisopts=(display=(tickvalues) offsetmin=0.1 offsetmax=0.1);

            referenceline x=0;
            referenceline y=0;

            scatterplot y=YVAR x=XVAR / group=GROUP index=INDEX
               datalabel=LABEL datalabelattrs=GRAPHVALUETEXT
               name="Type" tip=(y x datalabel group)
```

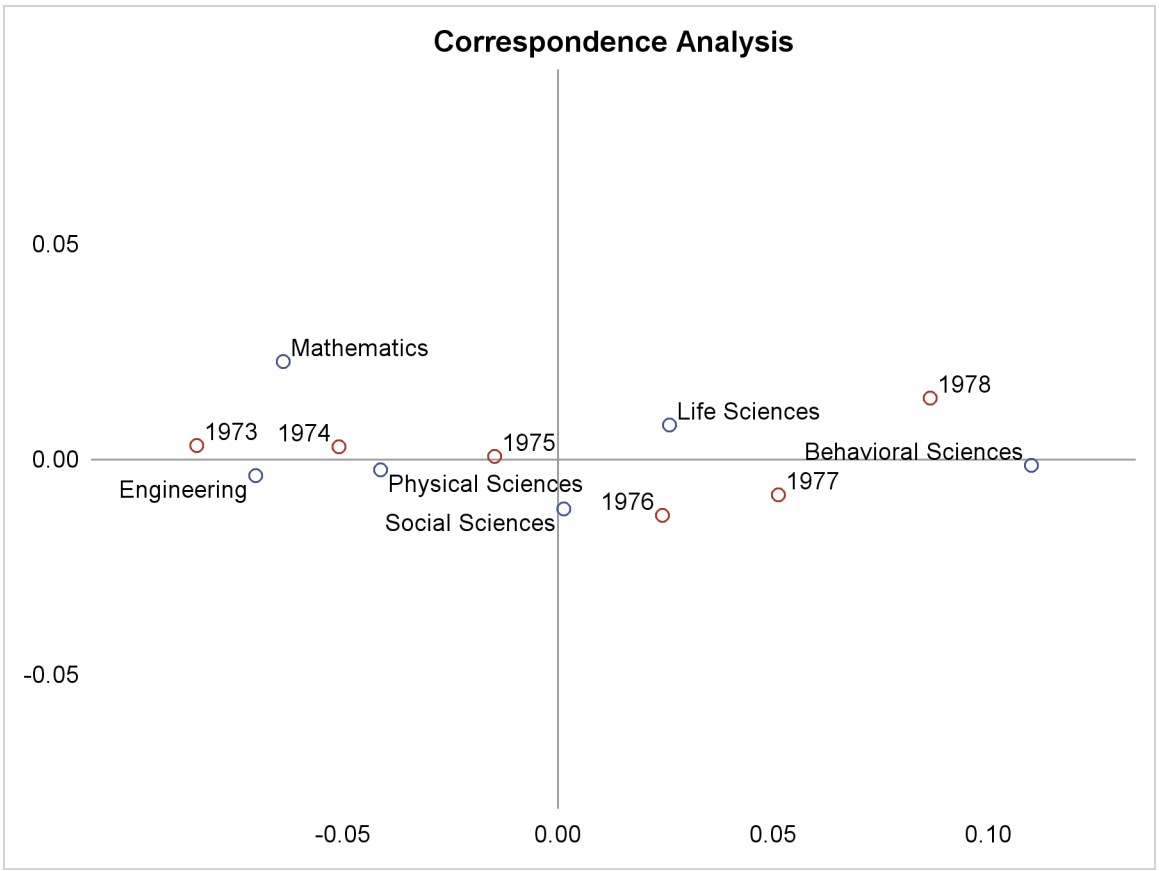
```
            tiplabel=(group="Point");
         if (LEGEND)
            discretelegend "Type";
         endif;
      endlayout;
   endgraph;
end;
run;

ods listing style=htmlblue;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

The results are shown in Output 22.5.4.

Output 22.5.4 Scatter Plot with Internal Axes



Instead of DISPLAY=(TICKVALUES), you can use DISPLAY=NONE (not shown) to remove the tick values from the display as well. You can change the tick values, as in the following example:

```
proc template;
   define statgraph Stat.Corresp.Graphics.Configuration;
      dynamic xVar yVar head legend;
      begingraph;
         entrytitle HEAD;

         layout overlayequated / equatetype=fit
            commonaxisopts=(tickvaluelist=(0))
            xaxisopts=(offsetmin=0.1 offsetmax=0.1)
            yaxisopts=(offsetmin=0.1 offsetmax=0.1);

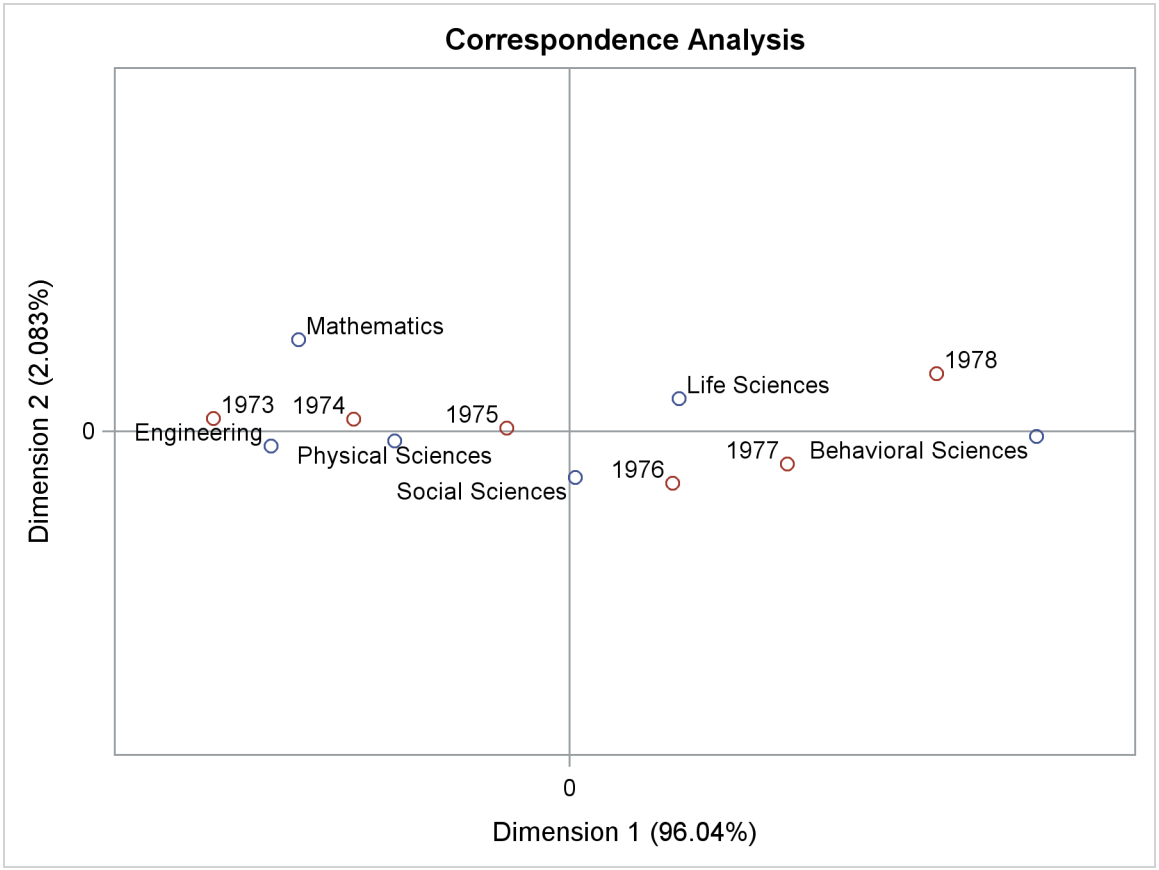
            referenceline x=0;
            referenceline y=0;

            scatterplot y=YVAR x=XVAR / group=GROUP index=INDEX
               datalabel=LABEL datalabelattrs=GRAPHVALUETEXT
               name="Type" tip=(y x datalabel group)
               tiplabel=(group="Point");
            if (LEGEND)
               discretelegend "Type";
            endif;
         endlayout;
      endgraph;
   end;
run;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

Since the axes in this plot are equated, the ticks are specified using the option **commonaxisopts = (tickvaluelist = (*tick-value-list*))**. This example only shows ticks at zero, but you can specify lists of values instead. The results are shown in Output 22.5.5.

Output 22.5.5 Scatter Plot with Tick Marks Specified



If the axes are not equated, then the tick value list is specified with the LINEAROPTS= option, as in the following statement:

```
layout overlay / xaxisopts=(linearopts=(viewmin=-0.1 viewmax=0.1
                                        tickvaluelist=(-0.1 0 0.1))
                            offsetmin=0.1 offsetmax=0.1)
                 yaxisopts=(linearopts=(viewmin=-0.1 viewmax=0.1
                                        tickvaluelist=(-0.1 0 0.1))
                            offsetmin=0.1 offsetmax=0.1);
```

The preceding statement uses the VIEWMIN= and VIEWMAX= options to specify the beginning and end of the data range that is shown. Specifying a tick value list does not extend or restrict the range of data shown in the plot. When axes share common options, it might be more convenient to use a macro to specify the options. The following two statements are equivalent to the preceding statement:

```
%let opts = linearopts=(viewmin=-0.1 viewmax=0.1
            tickvaluelist=(-0.1 0 0.1)) offsetmin=0.1 offsetmax=0.1;
layout overlay / xaxisopts=(&opts) yaxisopts=(&opts);
```

You can restore the default graph template as follows:

```
proc template;
   delete Stat.Corresp.Graphics.Configuration;
run;
```

Example 22.6: Adding Text to Every Graph

This example shows how to add text to one or more graphs. For example, you can create a macro variable, with project and date information, as follows:

```
%let date = Project 17.104, &sysdate;
```

In order to add this information to a set of graphs, you need to first know the names of their templates. You can list the names of every graph template for SAS/STAT procedures or for a particular procedure as follows:

```
proc template;
   list stat     / where=(type='Statgraph');
   list stat.reg / where=(type='Statgraph');
run;
```

The results for PROC REG are shown in Output 22.6.1.

Output 22.6.1 PROC REG Templates

```

23     Stat.Reg.Graphics.StepSelectionCriterionPanel           Statgraph
24     Stat.Reg.Graphics.StepSelectionCriterionPlot            Statgraph
25     Stat.Reg.Graphics.VIFPlot                               Statgraph
26     Stat.Reg.Graphics.rstudentByLeverage                    Statgraph
```

You can show the source for the graph templates for SAS/STAT procedures or for a particular procedure as follows:

```
options ls=96;
proc template;
   source stat     / where=(type='Statgraph');
   source stat.reg / where=(type='Statgraph');
options ls=80;
```

The results of this step are not shown. However, Example 22.4 shows a portion of the template for the PROC REG diagnostics panel. Here, the OPTIONS statement is used to set a line size of 96, which sometimes works better than the smaller default line size when showing the source for large and complicated templates.

An abridged version of the first few lines of the diagnostics panel template is displayed next:

```
define statgraph Stat.Reg.Graphics.DiagnosticsPanel;
   notes "Diagnostics Panel";
   dynamic . . .;
   BeginGraph / designheight=defaultDesignWidth;
      entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL
         halign=center textattrs=GRAPHTITLETEXT "Fit Diagnostics"
         " for " _DEPNAME;
      . . .
```

Adding a Date and Project Stamp to a Few Graphs

You can add the project and date to the bottom of all graphs produced with PROC REG by putting a PROC TEMPLATE statement in front of the template source code, and adding an MVAR and ENTRYFOOTNOTE statement after every BEGINGRAPH statement, as in the following example:

```
proc template;
   define statgraph Stat.Reg.Graphics.DiagnosticsPanel;
      notes "Diagnostics Panel";
      dynamic . . .;
      BeginGraph / designheight=defaultDesignWidth;

         mvar date;
         entryfootnote halign=left textattrs=GraphValueText date;

         entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL
            halign=center textattrs=GRAPHTITLETEXT "Fit Diagnostics"
            " for " _DEPNAME;
         . . .
```

The MVAR statement enables you to dynamically customize the template and graph at procedure run time, just as the DYNAMIC statement enables the procedure to dynamically customize the template and graph. With the MVAR statement, you can modify the template once and reuse that modification as the macro changes over time: Alternatively, you can modify the templates as follows:

```
entryfootnote halign=left textattrs=GRAPHVALUETEXT "&date";
```

However, you would then have to resubmit your templates every time the macro variable changed. The substitution for the macro variable date occurs at different times in the two preceding cases. In the former

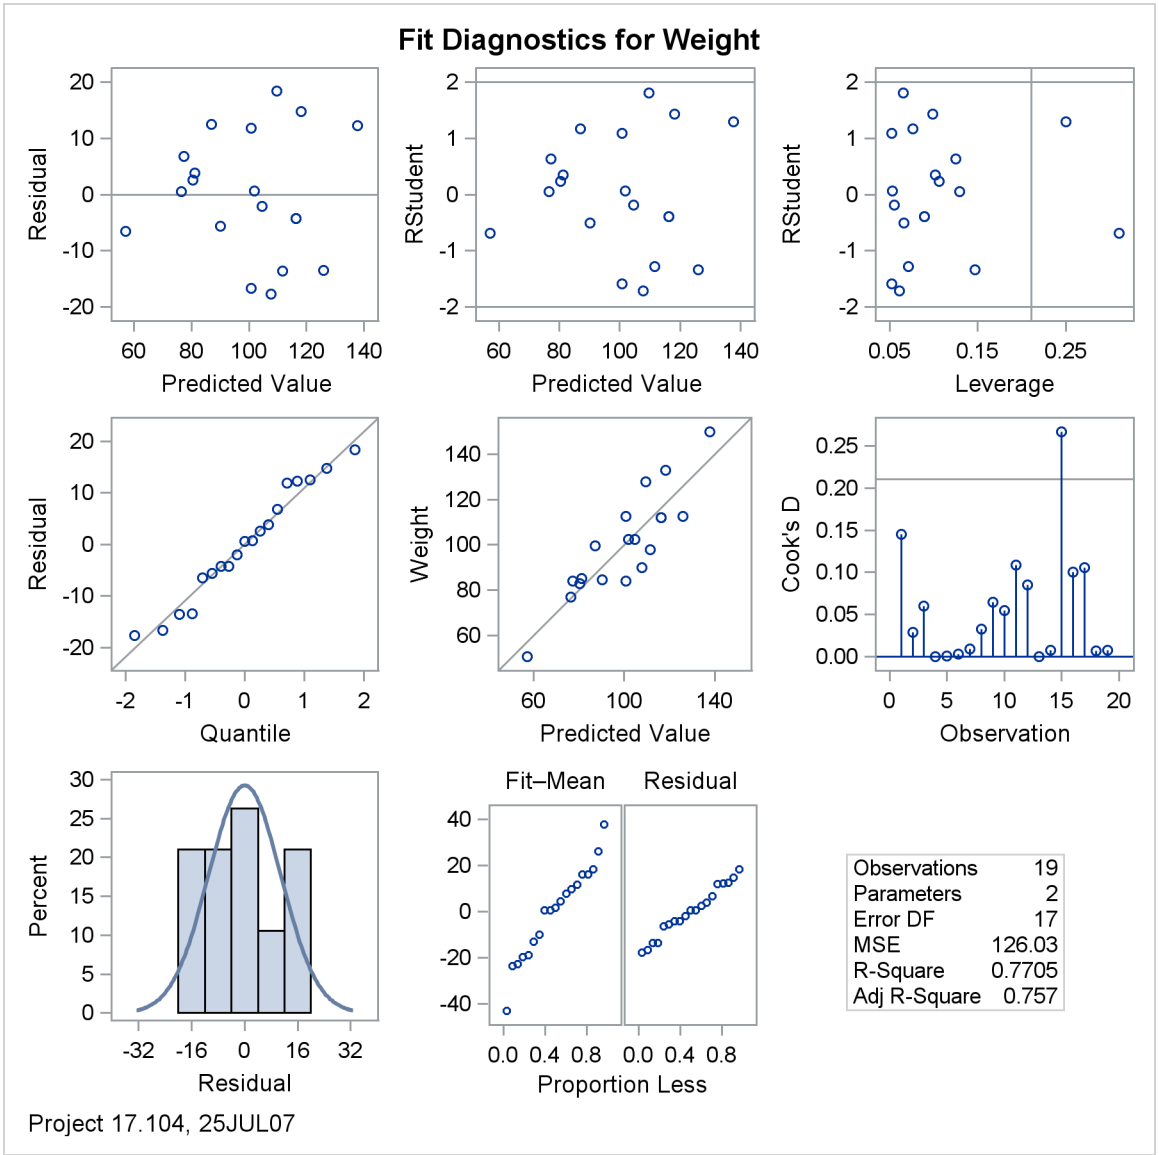
case, ODS looks for the value of the macro variable date at the time the template is used, and then the current date variable is used to set the text in the ENTRYFOOTNOTE statement, every time the template is used. In the latter case, SAS substitutes the value of the macro variable once, at the time that the PROC TEMPLATE step is executed.

The following steps use the Class data set and produce Output 22.6.2:

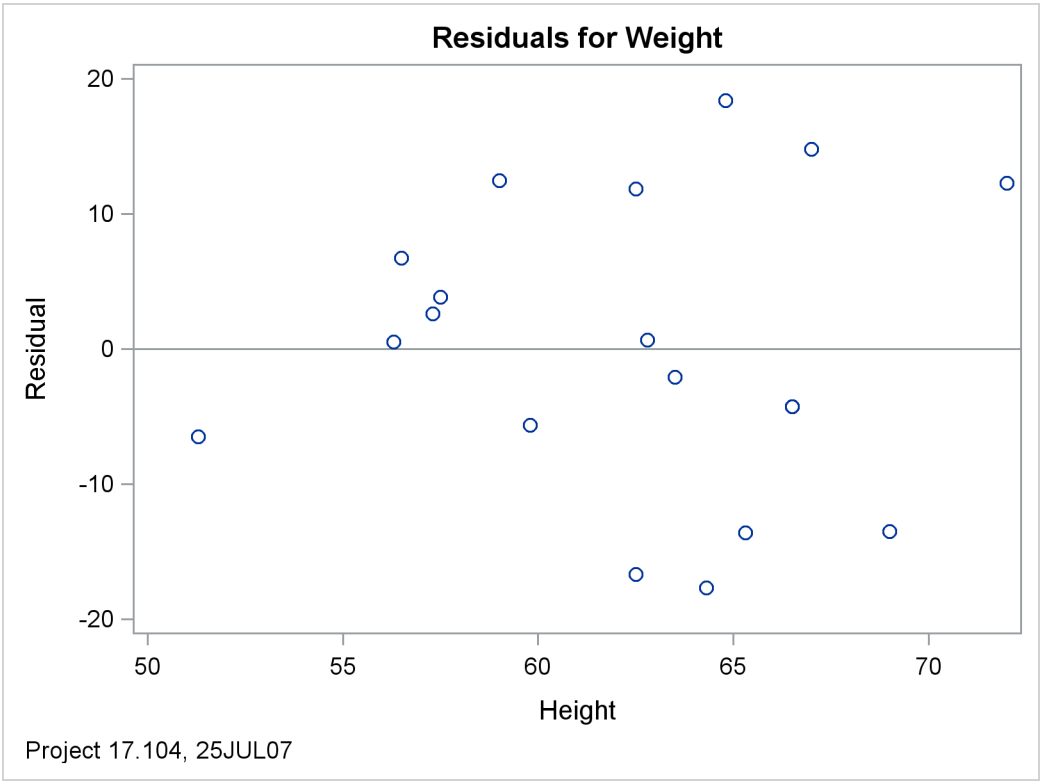
```
ods graphics on;

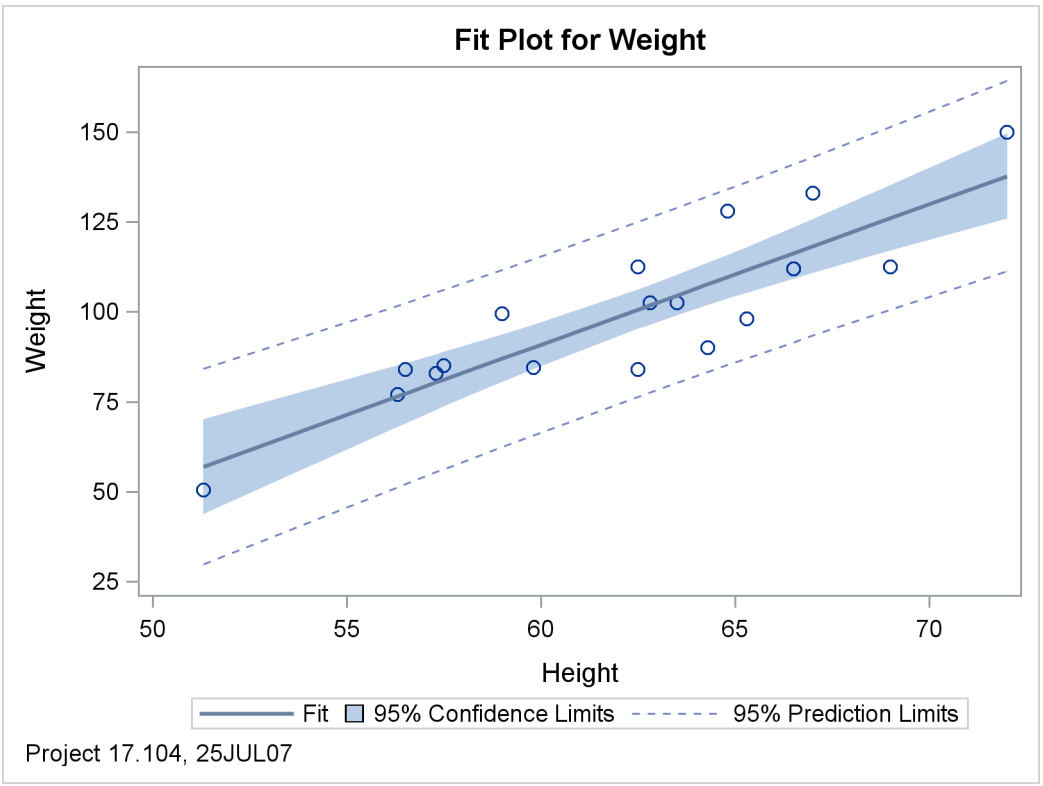
proc reg data=sashelp.class plots=fit(stats=none);
   model weight = height;
run; quit;
```

Output 22.6.2 PROC REG Plots with Project and Date Stamp



Output 22.6.2 *continued*





You can restore all of the default templates for PROC REG by running the following step:

```
proc template;
   delete stat.reg;
run;
```

Alternatively, you can specify **delete stat** to restore all SAS/STAT templates to their default definitions.

You can add text to the top or the bottom of a graph by using the ENTRYTITLE or the ENTRYFOOTNOTE statement, respectively. With both statements, you can put the text in the HALIGN=RIGHT, HALIGN=LEFT, or HALIGN=CENTER positions. You can add text to titles even if they already have a centered title. For example, the ENTRYTITLE statement in the diagnostic panel has text on the left (which is conditionally displayed) and a centered title:

```
entrytitle halign=left textattrs=GraphValueText _MODELLABEL
   halign=center textattrs=GraphTitleText "Fit Diagnostics"
   " for " _DEPNAME;
```

The current title can be followed by HALIGN=RIGHT and more text.

Adding Data Set Information to a Graph

You might, for example, want to add text to a set of graphs that indicates the most recently created data set. The following example shows you how you can do this with the syslast macro variable:

```
%let data = &syslast;

. . .

mvar data;
entrytitle halign=left textattrs=GraphValueText "Data: " data
   halign=center textattrs=GraphTitleText "Fit Diagnostics"
   " for " _DEPNAME;

. . .
```

Of course, this only makes sense when you are analyzing the last data set created. Alternatively, you can incorporate the name of the data set in the title, as in the following example:

```
%let data = &syslast;

. . .

mvar data;
entrytitle halign=center textattrs=GraphTitleText
           "Fit Diagnostics for Data Set " data;

. . .
```

Adding a Date and Project Stamp to All Graphs

Sometimes, you can automate the process of template modification. For example, you can automatically add an MVAR and ENTRYFOOTNOTE statement to every graph template, as in the following example:

```
ods path sashelp.tmplmst(read);
proc datasets library=sasuser nolist; delete templat(memtype=itemstor); run;
ods path sasuser.templat(update) sashelp.tmplmst(read);

options ls=256;

proc template;
   source / where=(type='Statgraph') file="tpls.sas";
run;

options ls=80;

data _null_;
   infile 'tpls.sas' lrecl=256 pad;
   input line $ 1-256;
   file 'newtpls.sas';
   put line;
   line = left(lowcase(line));
   if line =: 'begingraph' then
      put 'mvar __date;' /
          'entryfootnote halign=left textattrs=GraphValueText __date;';

   file log;
   if index(line, '__date') then
      put 'ERROR: Name __date already used.' / line;
   if index(line, 'entryfootnote') then put line;
run;

proc template;
   %include 'newtpls.sas' / nosource;
run;
```

These statements write all ODS graph templates to a file, read that file, and write out a new file with an MVAR and ENTRYFOOTNOTE statement added after every BEGINGRAPH statement. Then these new templates are compiled with PROC TEMPLATE. These steps assume that no BEGINGRAPH statement is longer than 256 characters. Most graphs do not have footnotes. Those that do will now have multiple footnotes. You might want to manually combine them or write a more complicated program to handle them. These steps also assume that the name __date is not used anywhere. However, the program does check this and also lists all ENTRYFOOTNOTE statements. Be careful to check the SAS log to ensure that all templates compile without error. Also, before using templates that are automatically modified, make sure your modifications are reasonable.

You can delete Sasuser.Templat and hence all modified templates (assuming the default template search path) as follows:

```
ods path sashelp.tmplmst(read);
proc datasets library=sasuser nolist;
   delete templat(memtype=itemstor);
run;
ods path sasuser.templat(update) sashelp.tmplmst(read);
```

Example 22.7: PROC TEMPLATE Statement Order and Primary Plots

This example uses artificial data to illustrate two basic principles of template writing: that statement order matters and that one of the plotting statements is the primary statement. The data are a sample from a bivariate normal distribution. A custom graph template and PROC SGRENDER are used to plot the data along with vectors and ellipses. The plot consists of four components: a scatterplot of the data; vectors whose end points come from other variables in the data set; ellipses whose parameters are specified in the template; and reference lines whose locations are specified in the template. Initially, thick lines are used to show what happens at the places where the lines and points intersect.

The following steps create the input SAS data set:

```
data x;
   input x y;
   label x = 'Normal(0, 4)' y = 'Normal(0, 1)';
   datalines;
-4  0
 4  0
 0 -2
 0  2
;

data y(drop=i);
   do i = 1 to 2500;
      r1 = normal( 104 );
      r2 = normal( 104 ) * 2;
      output;
   end;
run;

data all;
   merge x y;
run;
```

The data set All contains four variables. The variables r1 and r2 contain the random data. These variables contain 2500 nonmissing observations. The data set also contains the variables x and y, which contain the end points for the vectors. These variables contain four nonmissing observations and 2496 observations that are all missing. A data set like this is not unusual when creating overlaid plots. Different overlays often require input data with very different sizes. First, the data are plotted by using a template that is deliberately constructed to demonstrate a number of problems that can occur with statement order.

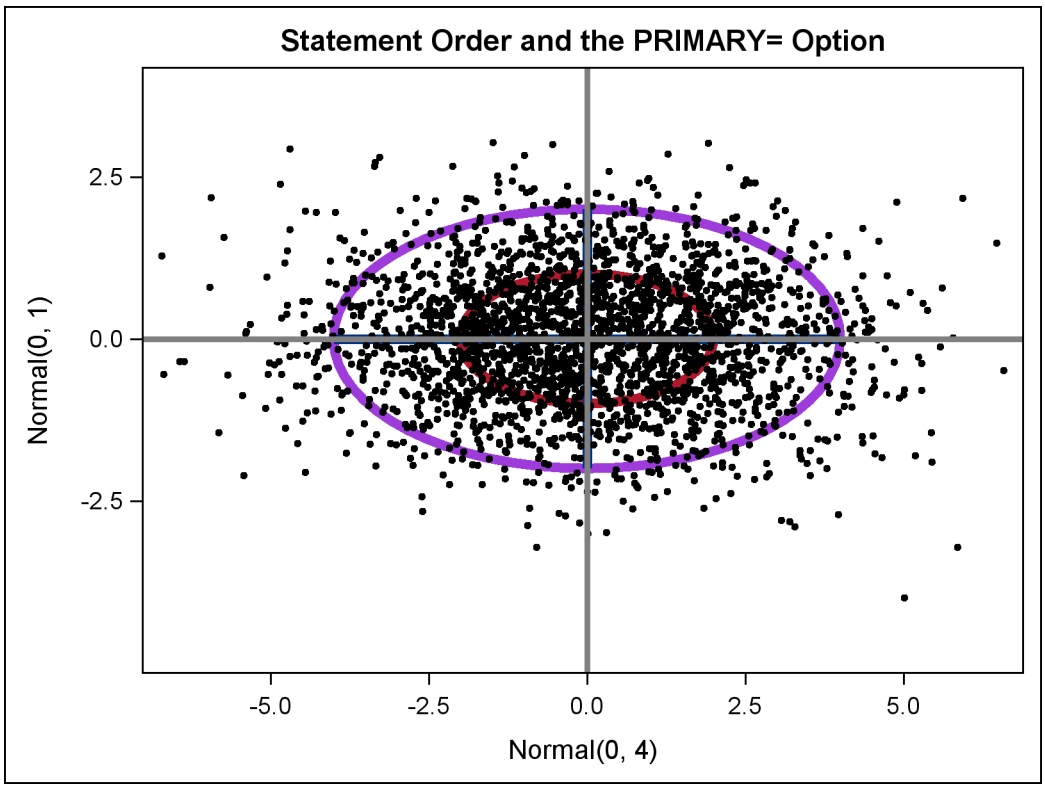
The following steps create Output 22.7.1:

```
proc template;
   define statgraph Plot;
      begingraph;
         entrytitle 'Statement Order and the PRIMARY= Option';
         layout overlayequated / equatetype=fit;
            ellipseparm semimajor=eval(sqrt(4)) semiminor=1
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData2(pattern=solid thickness=5);
            ellipseparm semimajor=eval(2 * sqrt(4)) semiminor=2
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData5(pattern=solid thickness=5);
            vectorplot  y=y x=x xorigin=0 yorigin=0 /
                        arrowheads=false lineattrs=GraphFit(thickness=5);
            scatterplot y=r1 x=r2 /
                        markerattrs=(symbol=circlefilled size=3);
            referenceline x=0 / lineattrs=(thickness=3);
            referenceline y=0 / lineattrs=(thickness=3);
         endlayout;
      endgraph;
   end;
run;

ods listing style=listing;

proc sgrender data=all template=plot;
run;
```

Output 22.7.1 Statements Specified in a Nonoptimal Order



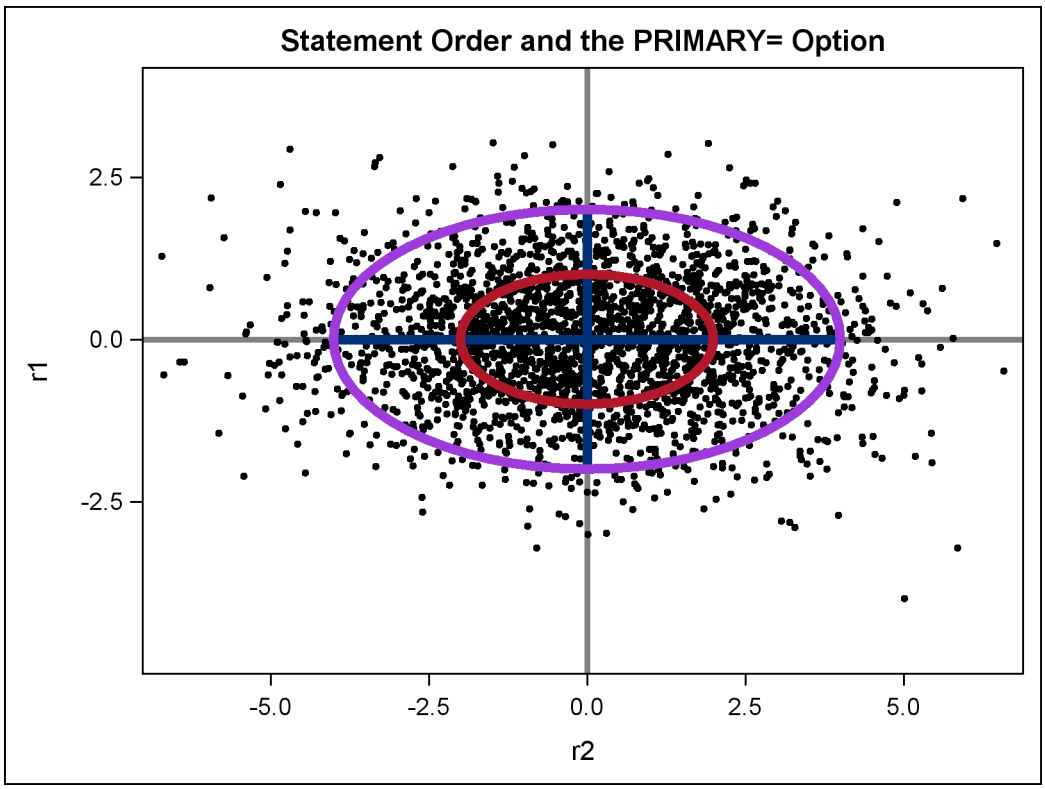
There are a number of problems with the plot in Output 22.7.1. The reference lines obliterate the vectors, and the data are on top of everything but the reference lines. It might be more reasonable to plot the reference lines first, the data next, the vectors next, and the ellipses last. The following steps do this and produce Output 22.7.2:

```
proc template;
   define statgraph Plot;
      begingraph;
         entrytitle 'Statement Order and the PRIMARY= Option';
         layout overlayequated / equatetype=fit;
            referenceline x=0 / lineattrs=(thickness=3);
            referenceline y=0 / lineattrs=(thickness=3);
            scatterplot y=r1 x=r2 /
                        markerattrs=(symbol=circlefilled size=3);
            vectorplot  y=y x=x xorigin=0 yorigin=0 /
                        arrowheads=false lineattrs=GraphFit(thickness=5);
            ellipseparm semimajor=eval(sqrt(4)) semiminor=1
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData2(pattern=solid thickness=5);
            ellipseparm semimajor=eval(2 * sqrt(4)) semiminor=2
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData5(pattern=solid thickness=5);
         endlayout;
      endgraph;
   end;
run;
```

```
ods listing style=listing;

proc sgrender data=all template=plot;
run;
```

Output 22.7.2 Statement Order Fixed



Output 22.7.2 looks better than Output 22.7.1, but the labels for the axes have changed. Output 22.7.1 has the labels of the variables x and y as axis labels, whereas Output 22.7.2 uses the names of the variables r1 and r2. This is because in the Output 22.7.1, the first plot is the vector plot of x and y (which have labels), and in Output 22.7.2, the first plot is the scatter plot of r1 and r2 (which do not have labels). By default, the first plot is the *primary plot*, and the primary plot is used to determine the axis type and labels. You can designate the vector plot as the primary plot with the PRIMARY=TRUE option.

The following statements make the final plot, this time with default line thicknesses, and produce Output 22.7.3:

```
proc template;
   define statgraph Plot;
      begingraph;
         entrytitle 'Statement Order and the PRIMARY= Option';
         layout overlayequated / equatetype=fit;
            referenceline x=0;
            referenceline y=0;
            scatterplot y=r1 x=r2 / markerattrs=(symbol=circlefilled size=3);

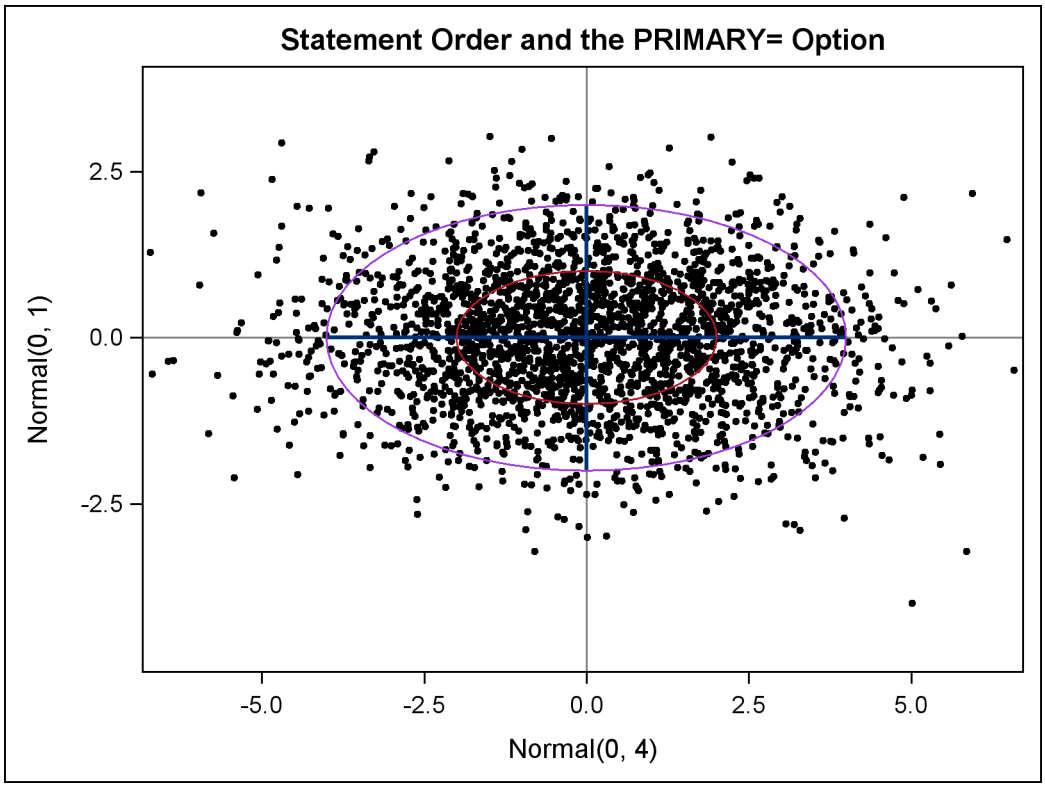
            vectorplot  y=y x=x xorigin=0 yorigin=0 / primary=true
                        arrowheads=false lineattrs=GraphFit;

            ellipseparm semimajor=eval(sqrt(4)) semiminor=1
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData2(pattern=solid);
            ellipseparm semimajor=eval(2 * sqrt(4)) semiminor=2
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData5(pattern=solid);
         endlayout;
      endgraph;
   end;
run;

ods listing style=listing;

proc sgrender data=all template=plot;
run;
```

Output 22.7.3 Statement Order Fixed and Primary Plot Specified



The axis labels in Output 22.7.3 and the overprinting of plot elements look better than in the previous plots. You can further adjust the line thicknesses if you want to emphasize or deemphasize components of this plot. The following list discusses the syntax of the GTL statements used in this example.

- The template has an ENTRYTITLE statement that specifies the title.
- The template has an equated overlay. This means that a centimeter on one axis represents the same data range as a centimeter on the other axis. This is done instead of the more common LAYOUT OVERLAY since with these data, the shape and geometry of the data have meaning even though the ranges of the two axis variables are different. The option EQUATETYPE=SQUARE is used to make a square plot, but since the X-axis variable has a larger range than the Y-axis variable, and since the default plot size is wider than high, EQUATETYPE=FIT is specified. The axes are equated but use the available space.
- A vertical reference line is drawn at X=0, and a horizontal reference line is drawn at Y=0.
- The scatter plot is based on the Y-axis variable r2 and the X-axis variable r1. The markers are filled circles with a size of three pixels. This is smaller than the default size and works well with a plot that displays many points.
- The vector plot is based on the Y-axis variable y and the X-axis variable x. The vectors are solid lines with no heads emanating from the origin (X=0 and Y=0). The color and other line attributes such as thickness come from the attributes of the **GraphFit** style element. This is the primary plot, so the default axis labels are the variable labels for the X= and Y= variables if they exist or the variable names if the variables do not have labels.
- The plot also displays two ellipses with X=0 and Y=0 at their center. Their widths are expressions, and their heights are constant. The expressions are not needed in this example; they are used to illustrate the syntax. The SEMIMAJOR= option specifies half the length of the major axis for the ellipse, and the SEMIMINOR= option specifies half the length of the minor axis for the ellipse. The SLOPE= option specifies the slope of the major axis for the ellipse. The colors of the ellipses and other line properties are based on the **GraphData2** and **GraphData5** style elements, but the line pattern attribute from the style is overridden.

Chapter 23

The ACECLUS Procedure

Contents

Overview: ACECLUS Procedure

The ACECLUS (approximate covariance estimation for clustering) procedure obtains approximate estimates of the pooled within-cluster covariance matrix when the clusters are assumed to be multivariate normal with equal covariance matrices. Neither cluster membership nor the number of clusters needs to be known. PROC ACECLUS is useful for preprocessing data to be subsequently clustered by the CLUSTER or FASTCLUS procedure.

Many clustering methods perform well with spherical clusters but poorly with elongated elliptical clusters (Everitt 1980, pp. 77–97). If the elliptical clusters have roughly the same orientation and eccentricity, you can apply a linear transformation to the data to yield a spherical within-cluster covariance matrix—that is, a covariance matrix proportional to the identity. Equivalently, the distance between observations can be measured in the metric of the inverse of the pooled within-cluster covariance matrix. The remedy is difficult

to apply, however, because you need to know what the clusters are in order to compute the sample within-cluster covariance matrix. One approach is to estimate iteratively both cluster membership and within-cluster covariance (Wolfe 1970; Hartigan 1975). Another approach is provided by Art, Gnanadesikan, and Kettenring (1982). They have devised an ingenious method for estimating the within-cluster covariance matrix without knowledge of the clusters. The method can be applied before any of the usual clustering techniques, including hierarchical clustering methods.

First, Art, Gnanadesikan, and Kettenring (1982) obtain a decomposition of the total-sample sum-of-squares-and-crossproducts (SSCP) matrix into within-cluster and between-cluster SSCP matrices computed from pairwise differences between observations, rather than differences between observations and means. Then, they show how the within-cluster SSCP matrix based on pairwise differences can be approximated without knowing the number or the membership of the clusters. The approximate within-cluster SSCP matrix can be used to compute distances for cluster analysis, or it can be used in a canonical analysis similar to canonical discriminant analysis. For more information, see Chapter 28, "The CANDISC Procedure."

Art, Gnanadesikan, and Kettenring demonstrate by Monte Carlo calculations that their method can produce better clusters than the Euclidean metric even when the approximation to the within-cluster SSCP matrix is poor or the within-cluster covariances are moderately heterogeneous. The algorithm used by the ACECLUS procedure differs slightly from the algorithm used by Art, Gnanadesikan, and Kettenring. In the following sections, the PROC ACECLUS algorithm is described first; then, differences between PROC ACECLUS and the method used by Art, Gnanadesikan, and Kettenring are summarized.

Background

It is well known from the literature on nonparametric statistics that variances and, hence, covariances can be computed from pairwise differences instead of deviations from means. (For example, Puri and Sen (1971, pp. 51–52) show that the variance is a U statistic of degree 2.) Let $\mathbf{X} = (x_{ij})$ be the data matrix with n observations (rows) and v variables (columns), and let $\bar{x}_j$ be the mean of the jth variable. The sample covariance matrix $\mathbf{S} = (s_{jk})$ is usually defined as

$$s_{jk} = \frac{1}{n-1} \sum_{i=1}^{n} (x_{ij} - \bar{x}_j)(x_{ik} - \bar{x}_k)$$

The matrix $\mathbf{S}$ can also be computed as

$$s_{jk} = \frac{1}{n(n-1)} \sum_{i=2}^{n} \sum_{h=1}^{i-1} (x_{ij} - x_{hj})(x_{ik} - x_{hk})$$

Let $\mathbf{W} = (w_{jk})$ be the pooled within-cluster covariance matrix, q be the number of clusters, n_c be the number of observations in the cth cluster, and

$$d''_{ic} = \begin{cases} 1 & \text{if observation } i \text{ is in cluster } c \\ 0 & \text{otherwise} \end{cases}$$

The matrix $\mathbf{W}$ is normally defined as

$$w_{jk} = \frac{1}{n-q} \sum_{c=1}^{q} \sum_{i=1}^{n} d''_{ic} (x_{ij} - \bar{x}_{cj})(x_{ik} - \bar{x}_{ck})$$

where $\bar{x}_{cj}$ is the mean of the jth variable in cluster c. Let

$$d'_{ih} = \begin{cases} \frac{1}{n_c} & \text{if observations } i \text{ and } h \text{ are in cluster } c \\ 0 & \text{otherwise} \end{cases}$$

The matrix $\mathbf{W}$ can also be computed as

$$w_{jk} = \frac{1}{n-q} \sum_{i=2}^{n} \sum_{h=1}^{i-1} d'_{ih}(x_{ij} - x_{hj})(x_{ik} - x_{hk})$$

If the clusters are not known, d'_{ih} cannot be determined. However, an approximation to $\mathbf{W}$ can be obtained by using instead

$$d_{ih} = \begin{cases} 1 & \text{if } \sum_{j=1}^{v} \sum_{k=1}^{v} m_{jk}(x_{ij} - x_{hj})(x_{ik} - x_{hk}) \le u^2 \\ 0 & \text{otherwise} \end{cases}$$

where u is an appropriately chosen value and $\mathbf{M} = (m_{jk})$ is an appropriate metric. Let $\mathbf{A} = (a_{jk})$ be defined as

$$a_{jk} = \frac{\sum_{i=2}^{n} \sum_{h=1}^{i-1} d_{ih}(x_{ij} - x_{hj})(x_{ik} - x_{hk})}{2 \sum_{i=2}^{n} \sum_{h=1}^{i-1} d_{ih}}$$

If all of the following conditions hold, $\mathbf{A}$ equals $\mathbf{W}$:

- All within-cluster distances in the metric $\mathbf{M}$ are less than or equal to u.
- All between-cluster distances in the metric $\mathbf{M}$ are greater than u.
- All clusters have the same number of members n_c.

If the clusters are of unequal size, $\mathbf{A}$ gives more weight to large clusters than $\mathbf{W}$ does, but this discrepancy should be of little importance if the population within-cluster covariance matrices are equal. There might be large differences between $\mathbf{A}$ and $\mathbf{W}$ if the cutoff u does not discriminate between pairs in the same cluster and pairs in different clusters. Lack of discrimination might occur for one of the following reasons:

- The clusters are not well separated.
- The metric $\mathbf{M}$ or the cutoff u is not chosen appropriately.

In the former case, little can be done to remedy the problem. The remaining question concerns how to choose $\mathbf{M}$ and u. Consider $\mathbf{M}$ first. The best choice for $\mathbf{M}$ is $\mathbf{W}^{-1}$, but $\mathbf{W}$ is not known. The solution is to use an iterative algorithm:

1. Obtain an initial estimate of $\mathbf{A}$, such as the identity or the total-sample covariance matrix. See the INITIAL= option in the PROC ACECLUS statement for more information.
2. Let $\mathbf{M}$ equal $\mathbf{A}^{-1}$.
3. Recompute $\mathbf{A}$ by using the preceding formula.

4. Repeat steps 2 and 3 until the estimate stabilizes.

Convergence is assessed by comparing values of $\mathbf{A}$ on successive iterations. Let $\mathbf{A}_i$ be the value of $\mathbf{A}$ on the ith iteration and $\mathbf{A}_0$ be the initial estimate of $\mathbf{A}$. Let $\mathbf{Z}$ be a user-specified $v \times v$ matrix. See the METRIC= option in the PROC ACECLUS statement for more information. The convergence measure is

$$e_i = \frac{1}{v} \parallel \mathbf{Z}'(\mathbf{A}_i - \mathbf{A}_{i-1})\mathbf{Z} \parallel$$

where $\parallel \cdots \parallel$ indicates the Euclidean norm—that is, the square root of the sum of the squares of the elements of the matrix. In PROC ACECLUS, $\mathbf{Z}$ can be the identity or an inverse factor of $\mathbf{S}$ or diag($\mathbf{S}$). Iteration stops when e_i falls below a user-specified value. See the CONVERGE= option or the MAXITER= option in the PROC ACECLUS statement for more information.

The remaining question of how to choose u has no simple answer. In practice, you must try several different values. PROC ACECLUS provides four different ways of specifying u:

- You can specify a constant value for u. This method is useful if the initial estimate of $\mathbf{A}$ is quite good. See the ABSOLUTE option and the THRESHOLD= option in the PROC ACECLUS statement for more information.
- You can specify a threshold value $t > 0$ that is multiplied by the root mean square distance between observations in the current metric on each iteration to give u. Thus, the value of u changes from iteration to iteration. This method is appropriate if the initial estimate of $\mathbf{A}$ is poor. See the THRESHOLD= option in the PROC ACECLUS statement for more information.
- You can specify a value p, $0 < p < 1$, to be transformed into a distance u such that approximately a proportion p of the pairwise Mahalanobis distances between observations in a random sample from a multivariate normal distribution will be less than u in repeated sampling. The transformation can be computed only if the number of observations exceeds the number of variables, preferably by at least 10 percent. This method also requires a good initial estimate of $\mathbf{A}$. See the PROPORTION= option and the ABSOLUTE option in the PROC ACECLUS statement for more information.
- You can specify a value p, $0 < p < 1$, to be transformed into a value t that is then multiplied by $1/\sqrt{2v}$ times the root mean square distance between observations in the current metric on each iteration to yield u. The value of u changes from iteration to iteration. This method can be used with a poor initial estimate of $\mathbf{A}$. See the PROPORTION= option in the PROC ACECLUS statement for more information.

In most cases, the analysis should begin with the last method, using values of p between 0.5 and 0.01 and using the full covariance matrix as the initial estimate of $\mathbf{A}$.

Proportions p are transformed to distances t by using the formula

$$t^2 = 2v \left\{ \left[F^{-1}_{v,n-v}(p) \right]^{\frac{n-v}{n-1}} \right\}$$

where $F^{-1}_{v,n-v}$ is the quantile (inverse cumulative distribution) function of an F random variable with v and $n-v$ degrees of freedom. The squared Mahalanobis distance between a single pair of observations sampled from a multivariate normal distribution is distributed as $2v$ times an F random variable with v and $n - v$

degrees of freedom. The distances between two pairs of observations are correlated if the pairs have an observation in common. The quantile function is raised to the power given in the preceding formula to compensate approximately for the correlations among distances between pairs of observations that share a member. Monte Carlo studies indicate that the approximation is acceptable if the number of observations exceeds the number of variables by at least 10 percent.

If $\mathbf{A}$ becomes singular, step 2 in the iterative algorithm cannot be performed because $\mathbf{A}$ cannot be inverted. In this case, let $\mathbf{Z}$ be the matrix as defined in discussing the convergence measure, and let $\mathbf{Z}'\mathbf{A}\mathbf{Z} = \mathbf{R}'\mathbf{\Lambda}\mathbf{R}$, where $\mathbf{R}'\mathbf{R} = \mathbf{R}\mathbf{R}' = \mathbf{I}$ and $\mathbf{\Lambda} = (\lambda_{jk})$ is diagonal. Let $\mathbf{\Lambda}^* = (\lambda^*_{jk})$ be a diagonal matrix, where $\lambda^*_{jj} = \max(\lambda_{jj}, g \text{ trace}(\mathbf{\Lambda}))$, and $0 < g < 1$ is a user-specified singularity criterion (see the SINGULAR= option in the PROC ACECLUS statement for more information). Then $\mathbf{M}$ is computed as $\mathbf{Z}\mathbf{R}'(\mathbf{\Lambda}^*)^{-1}\mathbf{R}\mathbf{Z}'$.

The ACECLUS procedure differs from the method used by Art, Gnanadesikan, and Kettenring (1982) in several respects:

- The Art, Gnanadesikan, and Kettenring method uses the identity matrix as the initial estimate, whereas the ACECLUS procedure enables you to specify any symmetric matrix as the initial estimate and defaults to the total-sample covariance matrix. The default initial estimate in PROC ACECLUS is chosen to yield invariance under nonsingular linear transformations of the data but might sometimes obscure clusters that become apparent if the identity matrix is used.
- The Art, Gnanadesikan, and Kettenring method carries out all computations with SSCP matrices, whereas the ACECLUS procedure uses estimated covariance matrices because covariances are easier to interpret than crossproducts.
- The Art, Gnanadesikan, and Kettenring method uses the m pairs with the smallest distances to form the new estimate at each iteration, where m is specified by the user, whereas the ACECLUS procedure uses all pairs closer than a given cutoff value. Kettenring (1984) says that the m-closest-pairs method seems to give the user more direct control. PROC ACECLUS uses a distance cutoff because it yields a slight decrease in computer time and because in some cases, such as widely separated spherical clusters, the results are less sensitive to the choice of distance cutoff than to the choice of m. Much research remains to be done on this issue.
- The Art, Gnanadesikan, and Kettenring method uses a different convergence measure. Let $\mathbf{A}_i$ be computed on each iteration by using the m-closest-pairs method, and let $\mathbf{B}_i = \mathbf{A}_{i-1}^{-1}\mathbf{A}_i - \mathbf{I}$, where $\mathbf{I}$ is the identity matrix. The convergence measure is equivalent to trace($\mathbf{B}_i^2$).

Analyses of the Fisher (1936) iris data, consisting of measurements of petal and sepal length and width for 50 specimens from each of three iris species, are summarized in Table 23.1. The number of misclassified observations out of 150 is given for four clustering methods:

- k-means as implemented in PROC FASTCLUS with MAXC=3, MAXITER=99, and CONV=0
- Ward's minimum variance method as implemented in PROC CLUSTER
- average linkage on Euclidean distances as implemented in PROC CLUSTER
- the centroid method as implemented in PROC CLUSTER

Each hierarchical analysis is followed by the TREE procedure with NCL=3 to determine cluster assignments at the three-cluster level. Clusters with 20 or fewer observations are discarded by using the DOCK=20 option. The observations in a discarded cluster are considered unclassified.

Each method is applied to the following data:

- the raw data
- the data standardized to unit variance by the STANDARD procedure
- two standardized principal components accounting for 95 percent of the standardized variance and having an identity total-sample covariance matrix, computed by the PRINCOMP procedure with the STD option
- four standardized principal components having an identity total-sample covariance matrix, computed by PROC PRINCOMP with the STD option
- the data transformed by PROC ACECLUS, using seven different settings of the PROPORTION= (P=) option
- four canonical variables having an identity pooled within-species covariance matrix, computed using the CANDISC procedure

Theoretically, the best results should be obtained by using the canonical variables from PROC CANDISC. PROC ACECLUS yields results comparable to those from PROC CANDISC for values of the PROPORTION= option ranging from 0.005 to 0.02. At PROPORTION=0.04, average linkage and the centroid method show some deterioration, but *k*-means and Ward's method continue to produce excellent classifications. At larger values of the PROPORTION= option, all methods perform poorly, although no worse than with four standardized principal components.

Table 23.1 Number of Misclassified and Unclassified Observations Using Fisher's (1936) Iris Data

	Clustering Method			
Data	***k*-means**	**Ward's**	**Average Linkage**	**Centroid**
raw data	16*	16*	25 + 12**	14*
standardized data	25	26	33+4	33+4
two standardized principal components	29	31	30+9	27+32
four standardized principal components	39	27	32+7	45+11
transformed by ACECLUS P=0.32	39	10+9	7+25	
transformed by ACECLUS P=0.16	39	18+9	7+19	7+26
transformed by ACECLUS P=0.08	19	9	3+13	5+16
transformed by ACECLUS P=0.04	4	5	1+19	3+12
transformed by ACECLUS P=0.02	4	3	3	3
transformed by ACECLUS P=0.01	4	4	3	4
transformed by ACECLUS P=0.005	4	4	4	4
canonical variables	3	5	4	4+1

* A single number represents misclassified observations with no unclassified observations.

** Where two numbers are separated by a plus sign, the first is the number of misclassified observations; the second is the number of unclassified observations.

This example demonstrates the following:

- PROC ACECLUS can produce results as good as those from the optimal transformation.
- PROC ACECLUS can be useful even when the within-cluster covariance matrices are moderately heterogeneous.
- The choice of the distance cutoff as specified by the PROPORTION= or the THRESHOLD= option is important, and several values should be tried.
- Commonly used transformations such as standardization and principal components can produce poor classifications.

Although experience with the Art, Gnanadesikan, and Kettenring and PROC ACECLUS methods is limited, the results so far suggest that these methods help considerably more often than they hinder the subsequent cluster analysis, especially with normal-mixture techniques such as *k*-means and Ward's minimum variance method.

Getting Started: ACECLUS Procedure

The following example demonstrates how you can use the ACECLUS procedure to obtain approximate estimates of the pooled within-cluster covariance matrix and to compute canonical variables for subsequent analysis. You use PROC ACECLUS to preprocess data before you cluster it by using the FASTCLUS or CLUSTER procedure.

Suppose you want to determine whether national figures for birth rates, death rates, and infant death rates can be used to determine certain types or categories of countries. You want to perform a cluster analysis to determine whether the observations can be formed into groups suggested by the data. Previous studies indicate that the clusters computed from this type of data can be elongated and elliptical. Thus, you need to perform a linear transformation on the raw data before the cluster analysis.

The following data[1] from Rouncefield (1995) are the birth rates, death rates, and infant death rates for 97 countries. The following statements create the SAS data set Poverty:

```
data poverty;
   input Birth Death InfantDeath Country &$20. @@;
   datalines;
24.7  5.7  30.8 Albania             12.5 11.9  14.4 Bulgaria

   ... more lines ...

41.7 10.3    66 Zimbabwe
;
```

[1] These data have been compiled from the United Nations *Demographic Yearbook* 1990 (United Nations publications, Sales No. E/F.91.XII.1, copyright 1991, United Nations, New York) and are reproduced with the permission of the United Nations.

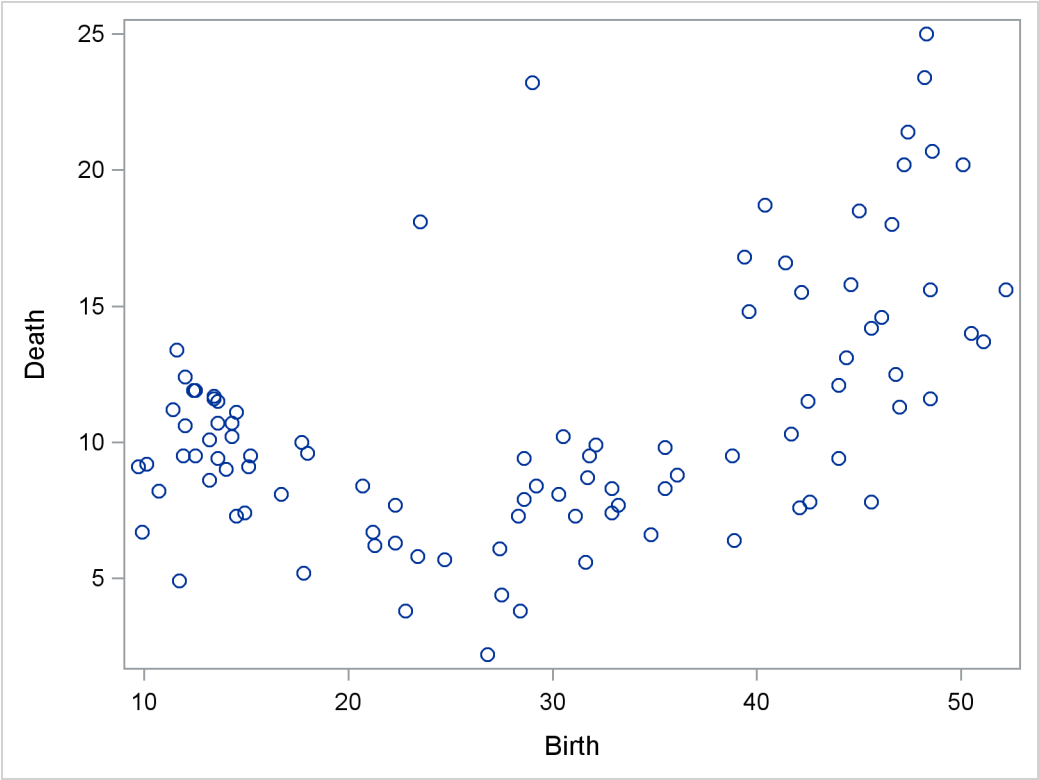
The data set Poverty contains the character variable Country and the numeric variables Birth, Death, and InfantDeath, which represent the birth rate per thousand, death rate per thousand, and infant death rate per thousand, respectively. The $20. format in the INPUT statement specifies that the variable Country is a character variable with a length of 20. The preceding & enables the reading of blanks in the middle of the country names. The double trailing at sign (@@) in the INPUT statement specifies that observations are input from each line until all values have been read.

It is often useful when beginning a cluster analysis to look at the data graphically. The following statements use the SGPLOT procedure to make a scatter plot of the variables Birth and Death.

```
proc sgplot data=poverty;
   scatter y=Death x=Birth;
run;
```

The plot, displayed in Figure 23.1, indicates the difficulty of dividing the points into clusters. Plots of the other variable pairs (not shown) display similar characteristics. The clusters that comprise these data might be poorly separated and elongated. Data with poorly separated or elongated clusters must be transformed.

Figure 23.1 Scatter Plot of Original Poverty Data: Birth Rate versus Death Rate



If you know the within-cluster covariances, you can transform the data to make the clusters spherical. However, since you do not know what the clusters are, you cannot calculate exactly the within-cluster covariance matrix. The ACECLUS procedure estimates the within-cluster covariance matrix to transform the data, even when you have no knowledge of cluster membership or the number of clusters.

The following statements perform the ACECLUS procedure transformation by using the SAS data set Poverty:

```
proc aceclus data=poverty out=ace proportion=.03;
   var Birth Death InfantDeath;
run;
```

The OUT= option creates an output data set called Ace to contain the canonical variable scores. The PROPORTION= option specifies that approximately 3 percent of the pairs are included in the estimation of the within-cluster covariance matrix. The VAR statement specifies that the variables Birth, Death, and InfantDeath are used in computing the canonical variables.

The results of this analysis are displayed in Figure 23.2 through Figure 23.5.

Figure 23.2 displays the number of observations, the number of variables, and the settings for the PROPORTION and CONVERGE options. The PROPORTION option is set at 0.03, as specified in the previous statements. The CONVERGE parameter is set at its default value of 0.001. Figure 23.2 next displays the means, standard deviations, and sample covariance matrix of the analytical variables.

Figure 23.2 Means, Standard Deviations, and Covariance Matrix from the ACECLUS Procedure

The ACECLUS Procedure

Approximate Covariance Estimation for Cluster Analysis

Observations	97	Proportion	0.0300
Variables	3	Converge	0.00100

Means and Standard Deviations

Variable	Mean	Standard Deviation
Birth	29.2299	13.5467
Death	10.8361	4.6475
InfantDeath	54.9010	45.9926

COV: Total Sample Covariances

	Birth	Death	InfantDeath
Birth	183.512951	30.610056	534.794969
Death	30.610056	21.599205	139.925900
InfantDeath	534.794969	139.925900	2115.317811

The type of matrix used for the initial within-cluster covariance estimate is displayed in Figure 23.3. In this example, that initial estimate is the full covariance matrix. The threshold value that corresponds to the PROPORTION=0.03 setting is given as 0.292815.

Figure 23.3 Table of Iteration History from the ACECLUS Procedure

Initial Within-Cluster Covariance Estimate = Full Covariance Matrix

Threshold = 0.292815

Figure 23.3 *continued*

Iteration History

Iteration	RMS Distance	Distance Cutoff	Pairs Within Cutoff	Convergence Measure
1	2.449	0.717	385.0	0.552025
2	12.534	3.670	446.0	0.008406
3	12.851	3.763	521.0	0.009655
4	12.882	3.772	591.0	0.011193
5	12.716	3.723	628.0	0.008784
6	12.821	3.754	658.0	0.005553
7	12.774	3.740	680.0	0.003010
8	12.631	3.699	683.0	0.000676

Algorithm converged.

Figure 23.3 displays the iteration history. For each iteration, PROC ACECLUS displays the following measures:

- root mean square distance between all pairs of observations
- distance cutoff for including pairs of observations in the estimate of within-cluster covariances (equal to RMS*Threshold)
- number of pairs within the cutoff
- convergence measure

Figure 23.4 displays the approximate within-cluster covariance matrix and the table of eigenvalues from the canonical analysis. The first column of the eigenvalues table contains numbers for the eigenvectors. The next column of the table lists the eigenvalues of Inv(ACE)*(COV-ACE).

Figure 23.4 Approximate Within-Cluster Covariance Estimates

ACE: Approximate Covariance Estimate Within Clusters

	Birth	Death	InfantDeath
Birth	5.94644949	-0.63235725	6.28151537
Death	-0.63235725	2.33464129	1.59005857
InfantDeath	6.28151537	1.59005857	35.10327233

Eigenvalues of Inv(ACE)*(COV-ACE)

	Eigenvalue	Difference	Proportion	Cumulative
1	63.5500	54.7313	0.8277	0.8277
2	8.8187	4.4038	0.1149	0.9425
3	4.4149		0.0575	1.0000

The next three columns of the eigenvalue table (Figure 23.4) display measures of the relative size and importance of the eigenvalues. The first column lists the difference between each eigenvalue and its successor. The last two columns display the individual and cumulative proportions that each eigenvalue contributes to the total sum of eigenvalues.

The raw and standardized canonical coefficients are displayed in Figure 23.5. The coefficients are standardized by multiplying the raw coefficients with the standard deviation of the associated variable. The ACECLUS procedure uses these standardized canonical coefficients to create the transformed canonical variables, which are the linear transformations of the original input variables, Birth, Death, and InfantDeath.

Figure 23.5 Raw and Standardized Canonical Coefficients from the ACECLUS Procedure

Eigenvectors (Raw Canonical Coefficients)

	Can1	Can2	Can3
Birth	0.125610	0.457037	0.003875
Death	0.108402	0.163792	0.663538
InfantDeath	0.134704	-.133620	-.046266

Standardized Canonical Coefficients

	Can1	Can2	Can3
Birth	1.70160	6.19134	0.05249
Death	0.50380	0.76122	3.08379
InfantDeath	6.19540	-6.14553	-2.12790

The following statements invoke the CLUSTER procedure, using the SAS data set Ace created in the previous ACECLUS procedure:

```
proc cluster data=ace outtree=tree noprint method=ward;
   var can1 can2 can3 ;
   copy Birth--Country;
run;
```

The OUTTREE= option creates the output SAS data set Tree that is used in a subsequent step to display cluster membership. The NOPRINT option suppresses the display of the output. The METHOD= option specifies Ward's minimum-variance clustering method.

The VAR statement specifies that the canonical variables computed in the ACECLUS procedure are used in the cluster analysis. The COPY statement specifies that all the variables from the SAS data set Poverty (Birth—Country) are added to the output data set Tree.

The following statements use PROC TREE to create an output SAS data set called New. The NCLUSTERS= option specifies the number of clusters desired in the SAS data set New. The NOPRINT option suppresses the display of the output.

```
proc tree data=tree out=new nclusters=3 noprint;
   copy Birth Death InfantDeath can1 can2 ;
   id Country;
run;
```

The COPY statement copies the canonical variables Can1 and Can2 (computed in the preceding ACECLUS procedure) and the original analytical variables Birth, Death, and InfantDeath into the output SAS data set New.

The following statements invoke the SGPLOT procedure, using the SAS data set created by PROC TREE:

```
proc sgplot data=new;
   scatter y=Death x=Birth / group=cluster;
   keylegend / title="Cluster Membership";
run;

proc sgplot data=new;
   scatter y=can2 x=can1 / group=cluster;
   keylegend / title="Cluster Membership";
run;
```

The first PROC SGPLOT statement requests a scatter plot of the two variables Birth and Death, using the variable CLUSTER as the identification variable.

The second PROC SGPLOT statement requests a plot of the two canonical variables, using the value of the variable CLUSTER as the identification variable.

Figure 23.6 and Figure 23.7 display the separation of the clusters when three clusters are calculated.

Figure 23.6 Scatter Plot of Poverty Data, Identified by Cluster

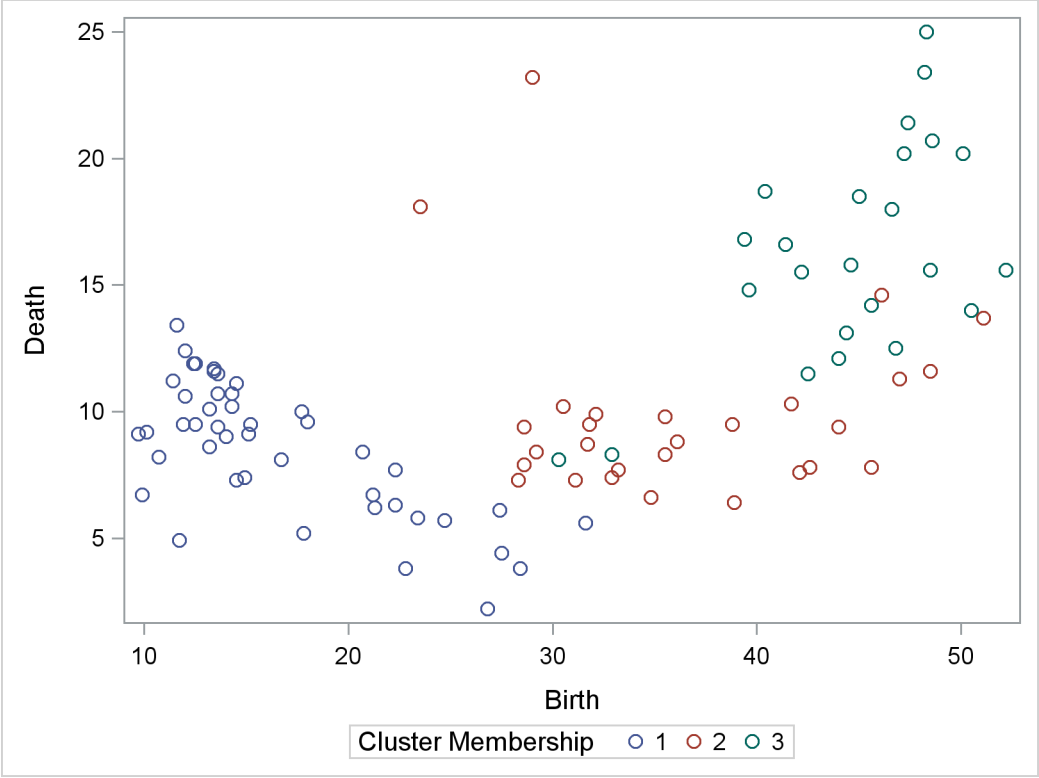


Figure 23.7 Scatter Plot of Canonical Variables

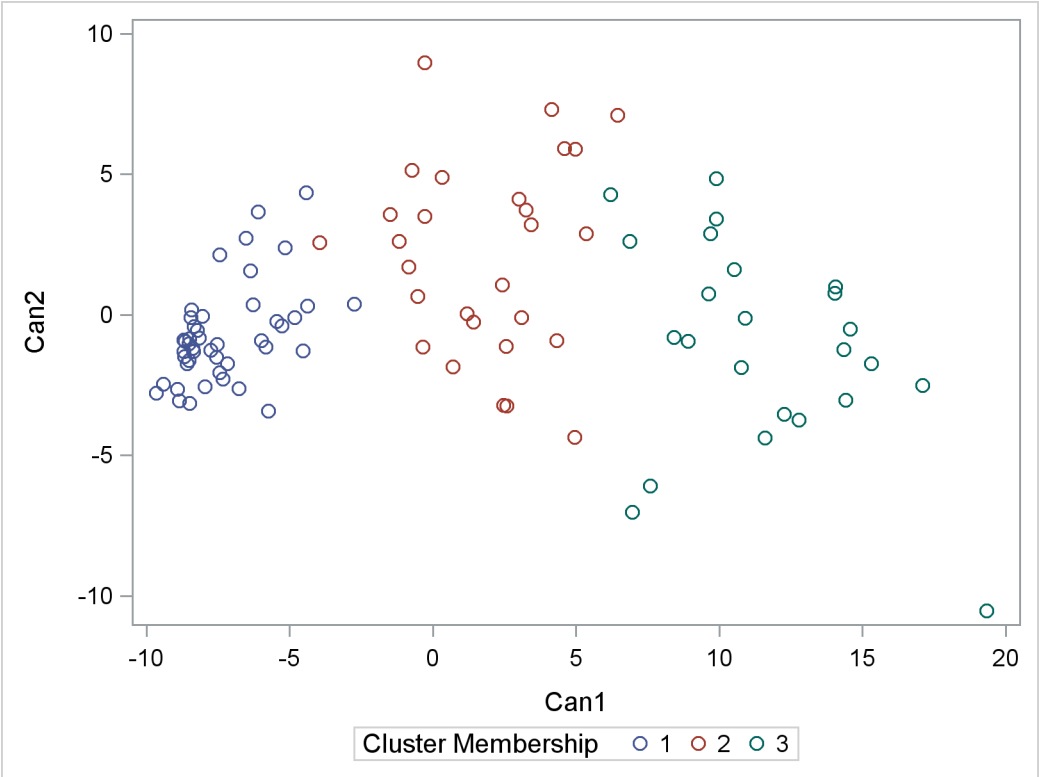

Syntax: ACECLUS Procedure

The following statements are available in the ACECLUS procedure:

PROC ACECLUS PROPORTION=*p* | **THRESHOLD=***t* < *options*> **;**
BY *variables* **;**
FREQ *variable* **;**
VAR *variables* **;**
WEIGHT *variable* **;**

Usually you need only the VAR statement in addition to the required PROC ACECLUS statement. The optional BY, FREQ, VAR, and WEIGHT statements are described in alphabetical order after the PROC ACECLUS statement.

PROC ACECLUS Statement

PROC ACECLUS PROPORTION=*p* | **THRESHOLD=***t* < *options* > **;**

The PROC ACECLUS statement starts the ACECLUS procedure. The options available with the PROC ACECLUS statement are summarized in Table 23.2 and discussed in the following sections. Note that, if you specify the METHOD=COUNT option, you must specify either the PROPORTION= or the MPAIRS= option. Otherwise, you must specify either the PROPORTION= or THRESHOLD= option.

Table 23.2 Summary of PROC ACECLUS Statement Options

Options	Description
Specify clustering options	
METHOD=	Specifies the clustering method
MPAIRS=	Specifies number of pairs for estimating within-cluster covariance (when you specify the option METHOD=COUNT)
PROPORTION=	Specifies proportion of pairs for estimating within-cluster covariance
THRESHOLD=	Specifies the threshold for including pairs in the estimation of the within-cluster covariance
Specify input and output data sets	
DATA=	Specifies input data set name
OUT=	Specifies output data set name
OUTSTAT=	Specifies output data set name containing various statistics
Specify iteration options	
ABSOLUTE	Uses absolute instead of relative threshold
CONVERGE=	Specifies convergence criterion
INITIAL=	Specifies initial estimate of within-cluster covariance matrix
MAXITER=	Specifies maximum number of iterations
METRIC=	Specifies metric in which computations are performed
SINGULAR=	Specifies singularity criterion
Specify canonical analysis options	
N=	Specifies number of canonical variables
PREFIX=	Specifies prefix for naming canonical variables
Control displayed output	
NOPRINT	Suppresses the display of the output
PP	Produces PP-plot of distances between pairs from last iteration
QQ	Produces QQ-plot of power transformation of distances between pairs from last iteration
SHORT	Omits all output except for iteration history and eigenvalue table

The following list provides details about the options.

ABSOLUTE
causes the THRESHOLD= value or the threshold computed from the PROPORTION= option to be treated absolutely rather than relative to the root mean square distance between observations. Use the ABSOLUTE option only when you are confident that the initial estimate of the within-cluster covariance matrix is close to the final estimate, such as when the INITIAL= option specifies a data set created by a previous execution of PROC ACECLUS by using the OUTSTAT= option.

CONVERGE=*c*
specifies the convergence criterion. By default, CONVERGE= 0.001. Iteration stops when the convergence measure falls below the value specified by the CONVERGE= option or when the iteration limit as specified by the MAXITER= option is exceeded, whichever happens first.

DATA=*SAS-data-set*
specifies the SAS data set to be analyzed. By default, PROC ACECLUS uses the most recently created SAS data set.

INITIAL=*name*
specifies the matrix for the initial estimate of the within-cluster covariance matrix. Valid values for *name* are as follows:

DIAGONAL | D
uses the diagonal matrix of sample variances as the initial estimate of the within-cluster covariance matrix.

FULL | F
uses the total-sample covariance matrix as the initial estimate of the within-cluster covariance matrix.

IDENTITY | I
uses the identity matrix as the initial estimate of the within-cluster covariance matrix.

INPUT=*SAS-data-set*
specifies a SAS data set from which to obtain the initial estimate of the within-cluster covariance matrix. The data set can be TYPE=CORR, COV, UCORR, UCOV, SSCP, or ACE, or it can be an ordinary SAS data set. See Appendix A, "Special SAS Data Sets," for descriptions of CORR, COV, UCORR, UCOV, and SSCP data sets. See the section "Output Data Sets" on page 841 for a description of ACE data sets.

If you do not specify the INITIAL= option, the default is the matrix specified by the METRIC= option. If neither the INITIAL= nor the METRIC= option is specified, INITIAL=FULL is used if there are enough observations to obtain a nonsingular total-sample covariance matrix; otherwise, INITIAL=DIAGONAL is used.

MAXITER=*n*
specifies the maximum number of iterations. By default, MAXITER=10.

METHOD=COUNT | C | THRESHOLD | T
specifies the clustering method. The METHOD=THRESHOLD option requests a method (also the default) that uses all pairs closer than a given cutoff value to form the estimate at each iteration. The METHOD=COUNT option requests a method that uses a number of pairs, m, with the smallest distances to form the estimate at each iteration.

METRIC=*name*

specifies the metric in which the computations are performed, implies the default value for the INITIAL= option, and specifies the matrix $\mathbf{Z}$ used in the formula for the convergence measure e_i and for checking singularity of the $\mathbf{A}$ matrix. Valid values for *name* are as follows:

DIAGONAL | D	uses the diagonal matrix of sample variances diag($\mathbf{S}$) and sets $\mathbf{Z} = \text{diag}(\mathbf{S})^{-\frac{1}{2}}$, where the superscript $-\frac{1}{2}$ indicates an inverse factor.
FULL | F	uses the total-sample covariance matrix $\mathbf{S}$ and sets $\mathbf{Z} = \mathbf{S}^{-\frac{1}{2}}$.
IDENTITY | I	uses the identity matrix $\mathbf{I}$ and sets $\mathbf{Z} = \mathbf{I}$.

If you do not specify the METRIC= option, METRIC=FULL is used if there are enough observations to obtain a nonsingular total-sample covariance matrix; otherwise, METRIC=DIAGONAL is used.

The option METRIC= is rather technical. It affects the computations in a variety of ways, but for well-conditioned data the effects are subtle. For most data sets, the METRIC= option is not needed.

MPAIRS=*m*

specifies the number of pairs to be included in the estimation of the within-cluster covariance matrix when METHOD=COUNT is requested. The values of *m* must be greater than 0 but less than or equal to $(totfq \times (totfq-1))/2$, where *totfq* is the sum of nonmissing frequencies specified in the FREQ statement. If there is no FREQ statement, *totfq* equals the number of total nonmissing observations.

N=*n*

specifies the number of canonical variables to be computed. The default is the number of variables analyzed. N=0 suppresses the canonical analysis.

NOPRINT

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, "Using the Output Delivery System."

OUT=*SAS-data-set*

creates an output SAS data set that contains all the original data as well as the canonical variables having an estimated within-cluster covariance matrix equal to the identity matrix. If you want to create a permanent SAS data set, you must specify a two-level name. See *SAS Language Reference: Concepts* for more information about permanent SAS data sets.

OUTSTAT=*SAS-data-set*

specifies a TYPE=ACE output SAS data set that contains means, standard deviations, number of observations, covariances, estimated within-cluster covariances, eigenvalues, and canonical coefficients. If you want to create a permanent SAS data set, you must specify a two-level name. See *SAS Language Reference: Concepts* for more information about permanent SAS data sets.

PROPORTION=*p*

PERCENT=*p*

P=*p*

specifies the percentage of pairs to be included in the estimation of the within-cluster covariance matrix. The value of *p* must be greater than 0. If *p* is greater than or equal to 1, it is interpreted as a percentage and divided by 100; PROPORTION=0.02 and PROPORTION=2 are equivalent. When

you specify METHOD=THRESHOLD, a threshold value is computed from the PROPORTION= option under the assumption that the observations are sampled from a multivariate normal distribution.

When you specify METHOD=COUNT, the number of pairs, m, is computed from PROPORTION=p as

$$m = \text{floor}\left(\frac{p}{2} \times totfq \times (totfq - 1)\right)$$

where *totfq* is the number of total nonmissing observations.

PP

produces a PP probability plot of distances between pairs of observations computed in the last iteration.

PREFIX=*name*

specifies a prefix for naming the canonical variables. By default the names are Can1, Can2, ..., CAN*n*. If you specify PREFIX=ABC, the variables are named ABC1, ABC2, ABC3, and so on. The number of characters in the prefix plus the number of digits required to designate the variables should not exceed the name length defined by the VALIDVARNAME= system option. For more information about the VALIDVARNAME= system option, see *SAS System Options: Reference*.

QQ

produces a QQ probability plot of a power transformation of the distances between pairs of observations computed in the last iteration. **CAUTION:** The QQ plot can require an enormous amount of computer time.

SHORT

omits all items from the standard output except for the iteration history and the eigenvalue table.

SINGULAR=*g*

SING=*g*

specifies a singularity criterion $0 < g < 1$ for the total-sample covariance matrix **S** and the approximate within-cluster covariance estimate **A**. The default is SINGULAR=1E−4.

THRESHOLD=*t*

T=*t*

specifies the threshold for including pairs of observations in the estimation of the within-cluster covariance matrix. A pair of observations is included if the Euclidean distance between them is less than or equal to t times the root mean square distance computed over all pairs of observations.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC ACECLUS to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the ACECLUS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

If you specify the INITIAL=INPUT= option and the INITIAL=INPUT= data set does not contain any of the BY variables, the entire INITIAL=INPUT= data set provides the initial value for the matrix **A** for each BY group in the DATA= data set.

If the INITIAL=INPUT= data set contains some but not all of the BY variables, or if some BY variables do not have the same type or length in the INITIAL=INPUT= data set as in the DATA= data set, then PROC ACECLUS displays an error message and stops.

If all the BY variables appear in the INITIAL=INPUT= data set with the same type and length as in the DATA= data set, then each BY group in the INITIAL=INPUT= data set provides the initial value for **A** for the corresponding BY group in the DATA= data set. All BY groups in the DATA= data set must also appear in the INITIAL= INPUT= data set. The BY groups in the INITIAL=INPUT= data set must be in the same order as in the DATA= data set. If you specify NOTSORTED in the BY statement, identical BY groups must occur in the same order in both data sets. If you do not specify NOTSORTED, some BY groups can appear in the INITIAL= INPUT= data set, but not in the DATA= data set; such BY groups are not used in the analysis.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* **;**

If a variable in your data set represents the frequency of occurrence for the observation, include the name of that variable in the FREQ statement. The procedure then treats the data set as if each observation appears *n* times, where *n* is the value of the FREQ variable for the observation. If a value of the FREQ variable is not integral, it is truncated to the largest integer not exceeding the given value. Observations with FREQ values less than one are not included in the analysis. The total number of observations is considered equal to the sum of the FREQ variable.

VAR Statement

VAR *variables* **;**

The VAR statement specifies the numeric variables to be analyzed. If the VAR statement is omitted, all numeric variables not specified in other statements are analyzed.

WEIGHT Statement

WEIGHT *variable* **;**

If you want to specify relative weights for each observation in the input data set, place the weights in a variable in the data set and specify that variable name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances. The values of the WEIGHT variable can be nonintegral and are not truncated. An observation is used in the analysis only if the value of the WEIGHT variable is greater than zero.

The WEIGHT and FREQ statements have a similar effect, except in calculating the divisor of the **A** matrix.

Details: ACECLUS Procedure

Missing Values

Observations with missing values are omitted from the analysis and are given missing values for canonical variable scores in the OUT= data set.

Output Data Sets

OUT= Data Set

The OUT= data set contains all the variables in the original data set plus new variables containing the canonical variable scores. The N= option determines the number of new variables. The OUT= data set is not created if N=0. The names of the new variables are formed by concatenating the value given by the PREFIX= option (or the prefix CAN if the PREFIX= option is not specified) and the numbers 1, 2, 3, and so on. The OUT= data set can be used as input to PROC CLUSTER or PROC FASTCLUS. The cluster analysis should be performed on the canonical variables, not on the original variables.

OUTSTAT= Data Set

The OUTSTAT= data set is a TYPE=ACE data set containing the following variables:

- the BY variables, if any
- the two new character variables, _TYPE_ and _NAME_
- the variables analyzed—that is, those in the VAR statement, or, if there is no VAR statement, all numeric variables not listed in any other statement

Each observation in the new data set contains some type of statistic as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are as follows:

MEAN	mean of each variable
STD	standard deviation of each variable
N	number of observations on which the analysis is based. This value is the same for each variable.
SUMWGT	sum of the weights if a WEIGHT statement is used. This value is the same for each variable.
COV	covariances between each variable and the variable named by the _NAME_ variable. The number of observations with _TYPE_=COV is equal to the number of variables being analyzed.
ACE	estimated within-cluster covariances between each variable and the variable named by the _NAME_ variable. The number of observations with _TYPE_=ACE is equal to the number of variables being analyzed.
EIGENVAL	eigenvalues of INV(ACE)*(COV−ACE). If the N= option requests fewer than the maximum number of canonical variables, only the specified number of eigenvalues are produced, with missing values filling out the observation.
RAWSCORE	raw canonical coefficients. To obtain the canonical variable scores, these coefficients should be multiplied by the raw data centered by means obtained from the observation with _TYPE_='MEAN'.
SCORE	standardized canonical coefficients. The _NAME_ variable contains the name of the corresponding canonical variable as constructed from the PREFIX= option. The number of observations with _TYPE_=SCORE equals the number of canonical variables computed. To obtain the canonical variable scores, these coefficients should be multiplied by the standardized data, using means obtained from the observation with _TYPE_='MEAN' and standard deviations obtained from the observation with _TYPE_='STD'.

The OUTSTAT= data set can be used in the following conditions:

- to initialize another execution of PROC ACECLUS
- to compute canonical variable scores with the SCORE procedure
- as input to the FACTOR procedure, specifying METHOD=SCORE, to rotate the canonical variables

Computational Resources

Let

$$\begin{aligned} n &= \text{number of observations} \\ v &= \text{number of variables} \\ i &= \text{number of iterations} \end{aligned}$$

Memory

The memory in bytes required by PROC ACECLUS is approximately

$$8(2n(v+1)+21v+5v^2)$$

bytes. If you request the PP or QQ option, an additional $4n(n-1)$ bytes are needed.

Time

The time required by PROC ACECLUS is roughly proportional to

$$2nv^2+10v^3+i\left(\frac{n^2v}{2}+nv^2+5v^3\right)$$

Displayed Output

Unless the SHORT option is specified, the ACECLUS procedure displays the following items:

- Means and Standard Deviations of the input variables
- the **S** matrix, labeled COV: Total Sample Covariances
- the name or value of the matrix used for the Initial Within-Cluster Covariance Estimate
- the Threshold value if the PROPORTION= option is specified

For each iteration, PROC ACECLUS displays the following items:

- the Iteration number
- RMS Distance, the root mean square distance between all pairs of observations
- the Distance Cutoff (u) for including pairs of observations in the estimate of the within-cluster covariances, which equals the RMS distance times the threshold
- the number of Pairs Within Cutoff
- the Convergence Measure (e_i) as specified by the METRIC= option

If the SHORT option is not specified, PROC ACECLUS also displays the **A** matrix, labeled ACE: Approximate Covariance Estimate Within Clusters.

The ACECLUS procedure displays a table of eigenvalues from the canonical analysis containing the following items:

- Eigenvalues of Inv(ACE)*(COV−ACE)
- the Difference between successive eigenvalues
- the Proportion of variance explained by each eigenvalue
- the Cumulative proportion of variance explained

If the SHORT option is not specified, PROC ACECLUS displays the following items:

- the Eigenvectors or raw canonical coefficients
- the standardized eigenvectors or standard canonical coefficients

ODS Table Names

PROC ACECLUS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 23.3 ODS Tables Produced by PROC ACECLUS

ODS Table Name	Description	Statement	Option
ConvergenceStatus	Convergence status	PROC	default
DataOptionInfo	Data and option information	PROC	default
Eigenvalues	Eigenvalues of Inv(ACE)*(COV–ACE)	PROC	default
Eigenvectors	Eigenvectors (raw canonical coefficients)	PROC	default
InitWithin	Initial within-cluster covariance estimate	PROC	INITIAL=INPUT
IterHistory	Iteration history	PROC	default
SimpleStatistics	Simple statistics	PROC	default
StdCanCoef	Standardized canonical coefficients	PROC	default
Threshold	Threshold value	PROC	PROPORTION=
TotSampleCov	Total sample covariances	PROC	default
Within	Approximate covariance estimate within clusters	PROC	default

Example: ACECLUS Procedure

Example 23.1: Transformation and Cluster Analysis of Fisher Iris Data

The iris data published by Fisher (1936) have been widely used for examples in discriminant analysis and cluster analysis. The sepal length, sepal width, petal length, and petal width are measured in millimeters on 50 iris specimens from each of three species, *Iris setosa, I. versicolor,* and *I. virginica*. Mezzich and Solomon (1980) discuss a variety of cluster analyses of the iris data.

In this example PROC ACECLUS is used to transform the iris data, which is available from the Sashelp library, and the clustering is performed by PROC FASTCLUS. Compare this with the example in Chapter 35, "The FASTCLUS Procedure." The results from the FREQ procedure display fewer misclassifications when PROC ACECLUS is used.

The following statements produce Output 23.1.1 through Output 23.1.5:

```
title 'Fisher (1936) Iris Data';

proc aceclus data=sashelp.iris out=ace p=.02 outstat=score;
   var SepalLength SepalWidth PetalLength PetalWidth ;
run;

proc sgplot data=ace;
   scatter y=can2 x=can1 / group=Species;
   keylegend / title="Species";
run;

proc fastclus data=ace maxc=3 maxiter=10 conv=0 out=clus;
   var can:;
run;

proc freq;
   tables cluster*Species;
run;
```

Chapter 24

The ANOVA Procedure

Contents

Overview: ANOVA Procedure

The ANOVA procedure performs *analysis of variance* (ANOVA) for balanced data from a wide variety of experimental designs. In analysis of variance, a continuous response variable, known as a *dependent variable*, is measured under experimental conditions identified by classification variables, known as *independent variables*. The variation in the response is assumed to be due to effects in the classification, with random error accounting for the remaining variation.

The ANOVA procedure is one of several procedures available in SAS/STAT software for analysis of variance. The ANOVA procedure is designed to handle balanced data (that is, data with equal numbers of observations for every combination of the classification factors), whereas the GLM procedure can analyze both balanced and unbalanced data. Because PROC ANOVA takes into account the special structure of a balanced design, it is faster and uses less storage than PROC GLM for balanced data.

Use PROC ANOVA for the analysis of balanced data only, with the following exceptions: one-way analysis of variance, Latin square designs, certain partially balanced incomplete block designs, completely nested (hierarchical) designs, and designs with cell frequencies that are proportional to each other and are also proportional to the background population. These exceptions have designs in which the factors are all orthogonal to each other.

For further discussion, see Searle (1971, p. 138). PROC ANOVA works for designs with block diagonal $\mathbf{X}'\mathbf{X}$ matrices where the elements of each block all have the same value. The procedure partially tests this requirement by checking for equal cell means. However, this test is imperfect: some designs that cannot be analyzed correctly might pass the test, and designs that can be analyzed correctly might not pass. If your design does not pass the test, PROC ANOVA produces a warning message to tell you that the design is unbalanced and that the ANOVA analyses might not be valid; if your design is not one of the special cases described here, then you should use PROC GLM instead. Complete validation of designs is not performed in PROC ANOVA since this would require the whole $\mathbf{X}'\mathbf{X}$ matrix; if you're unsure about the validity of PROC ANOVA for your design, you should use PROC GLM.

CAUTION: If you use PROC ANOVA for analysis of unbalanced data, you must assume responsibility for the validity of the results.

The ANOVA procedure automatically produces graphics as part of its ODS output. For general information about ODS graphics, see the section "ODS Graphics" on page 890 and Chapter 21, "Statistical Graphics Using ODS."

Getting Started: ANOVA Procedure

The following examples demonstrate how you can use the ANOVA procedure to perform analyses of variance for a one-way layout and a randomized complete block design.

One-Way Layout with Means Comparisons

A one-way analysis of variance considers one treatment factor with two or more treatment levels. The goal of the analysis is to test for differences among the means of the levels and to quantify these differences. If there are two treatment levels, this analysis is equivalent to a t test comparing two group means.

The assumptions of analysis of variance (Steel and Torrie 1980) are that treatment effects are additive and experimental errors are independently random with a normal distribution that has mean zero and constant variance.

The following example studies the effect of bacteria on the nitrogen content of red clover plants. The treatment factor is bacteria strain, and it has six levels. Five of the six levels consist of five different *Rhizobium trifolii* bacteria cultures combined with a composite of five *Rhizobium meliloti* strains. The sixth level is a composite of the five *Rhizobium trifolii* strains with the composite of the *Rhizobium meliloti*. Red clover plants are inoculated with the treatments, and nitrogen content is later measured in milligrams. The data are derived from an experiment by Erdman (1946) and are analyzed in Chapters 7 and 8 of Steel and Torrie (1980). The following DATA step creates the SAS data set Clover:

```
title1 'Nitrogen Content of Red Clover Plants';
data Clover;
   input Strain $ Nitrogen @@;
   datalines;
3DOK1  19.4 3DOK1  32.6 3DOK1  27.0 3DOK1  32.1 3DOK1  33.0
3DOK5  17.7 3DOK5  24.8 3DOK5  27.9 3DOK5  25.2 3DOK5  24.3
3DOK4  17.0 3DOK4  19.4 3DOK4   9.1 3DOK4  11.9 3DOK4  15.8
3DOK7  20.7 3DOK7  21.0 3DOK7  20.5 3DOK7  18.8 3DOK7  18.6
3DOK13 14.3 3DOK13 14.4 3DOK13 11.8 3DOK13 11.6 3DOK13 14.2
COMPOS 17.3 COMPOS 19.4 COMPOS 19.1 COMPOS 16.9 COMPOS 20.8
;
```

The variable Strain contains the treatment levels, and the variable Nitrogen contains the response. The following statements produce the analysis.

```
proc anova data = Clover;
   class strain;
   model Nitrogen = Strain;
run;
```

The classification variable is specified in the CLASS statement. Note that, unlike the GLM procedure, PROC ANOVA does not allow continuous variables on the right-hand side of the model. Figure 24.1 and Figure 24.2 display the output produced by these statements.

Figure 24.1 Class Level Information

Nitrogen Content of Red Clover Plants

The ANOVA Procedure

Class Level Information

Class	Levels	Values
Strain	6	3DOK1 3DOK13 3DOK4 3DOK5 3DOK7 COMPOS

Number of Observations Read	30
Number of Observations Used	30

The "Class Level Information" table shown in Figure 24.1 lists the variables that appear in the CLASS statement, their levels, and the number of observations in the data set.

Figure 24.2 displays the ANOVA table, followed by some simple statistics and tests of effects.

Figure 24.2 ANOVA Table

Nitrogen Content of Red Clover Plants

The ANOVA Procedure

Dependent Variable: Nitrogen

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	5	847.046667	169.409333	14.37	<.0001
Error	24	282.928000	11.788667		
Corrected Total	29	1129.974667			

R-Square	Coeff Var	Root MSE	Nitrogen Mean
0.749616	17.26515	3.433463	19.88667

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Strain	5	847.0466667	169.4093333	14.37	<.0001

The degrees of freedom (DF) column should be used to check the analysis results. The model degrees of freedom for a one-way analysis of variance are the number of levels minus 1; in this case, $6 - 1 = 5$. The Corrected Total degrees of freedom are always the total number of observations minus one; in this case $30 - 1 = 29$. The sum of Model and Error degrees of freedom equal the Corrected Total.

The overall F test is significant ($F = 14.37$, $p < 0.0001$), indicating that the model as a whole accounts for a significant portion of the variability in the dependent variable. The F test for Strain is significant,

indicating that some contrast between the means for the different strains is different from zero. Notice that the Model and Strain F tests are identical, since Strain is the only term in the model.

The F test for Strain ($F = 14.37$, $p < 0.0001$) suggests that there are differences among the bacterial strains, but it does not reveal any information about the nature of the differences. Mean comparison methods can be used to gather further information. The interactivity of PROC ANOVA enables you to do this without re-running the entire analysis. After you specify a model with a MODEL statement and execute the ANOVA procedure with a RUN statement, you can execute a variety of statements (such as MEANS, MANOVA, TEST, and REPEATED) without PROC ANOVA recalculating the model sum of squares.

The following command requests means of the Strain levels with Tukey's studentized range procedure.

```
means strain / tukey;
```

Results of Tukey's procedure are shown in Figure 24.3.

Figure 24.3 Tukey's Multiple Comparisons Procedure

```
                Nitrogen Content of Red Clover Plants

                        The ANOVA Procedure

          Tukey's Studentized Range (HSD) Test for Nitrogen

             Alpha                                      0.05
             Error Degrees of Freedom                     24
             Error Mean Square                       11.78867
             Critical Value of Studentized Range      4.37265
             Minimum Significant Difference            6.7142

        Means with the same letter are not significantly different.

           Tukey Grouping          Mean      N    Strain

                        A        28.820      5    3DOK1
                        A
                   B    A        23.980      5    3DOK5
                   B
                   B    C        19.920      5    3DOK7
                   B    C
                   B    C        18.700      5    COMPOS
                        C
                        C        14.640      5    3DOK4
                        C
                        C        13.260      5    3DOK13
```

Examples of implications of the multiple comparisons results are as follows:

- Strain 3DOK1 fixes significantly more nitrogen than all but 3DOK5.
- While 3DOK5 is not significantly different from 3DOK1, it is also not significantly better than all the rest, though it is better than the bottom two groups.

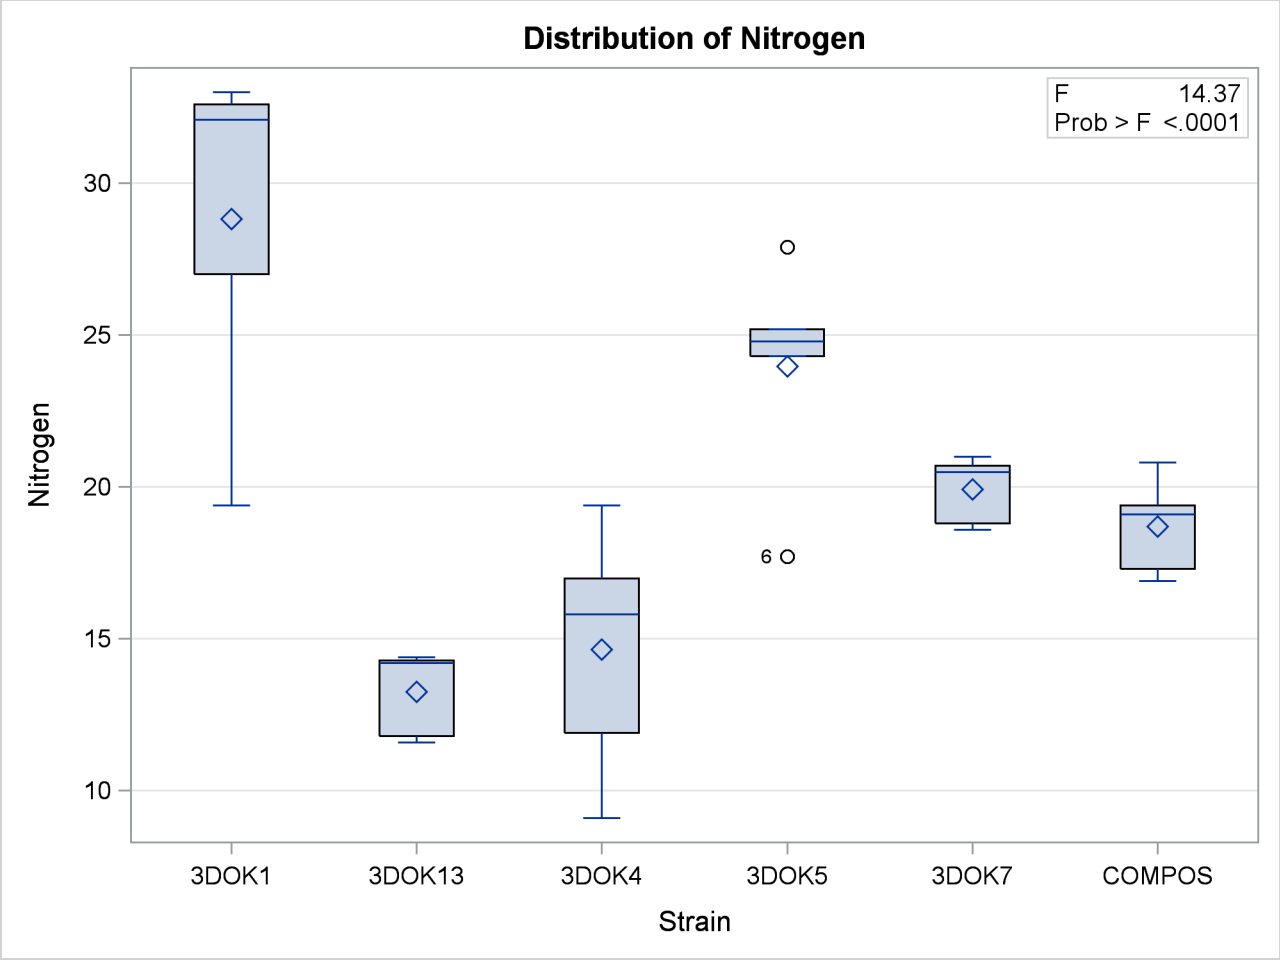
Although the experiment has succeeded in separating the best strains from the worst, more experimentation is required in order to clearly distinguish the very best strain.

If ODS Graphics is enabled, ANOVA also displays by default a plot that enables you to visualize the distribution of nitrogen content for each treatment. The following statements, which are the same as the previous analysis but with ODS graphics enabled, additionally produce Figure 24.4.

```
ods graphics on;
proc anova data = Clover;
   class strain;
   model Nitrogen = Strain;
run;
ods graphics off;
```

When ODS Graphics is enabled and you fit a one-way analysis of variance model, the ANOVA procedure output includes a box plot of the dependent variable values within each classification level of the independent variable. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." For specific information about the graphics available in the ANOVA procedure, see the section "ODS Graphics" on page 890.

Figure 24.4 Box Plot of Nitrogen Content for each Treatment



Randomized Complete Block with One Factor

This example illustrates the use of PROC ANOVA in analyzing a randomized complete block design. Researchers are interested in whether three treatments have different effects on the yield and worth of a particular crop. They believe that the experimental units are not homogeneous. So, a blocking factor is introduced that allows the experimental units to be homogeneous within each block. The three treatments are then randomly assigned within each block.

The data from this study are input into the SAS data set RCB:

```
title1 'Randomized Complete Block';
data RCB;
   input Block Treatment $ Yield Worth @@;
   datalines;
1 A 32.6 112   1 B 36.4 130   1 C 29.5 106
2 A 42.7 139   2 B 47.1 143   2 C 32.9 112
3 A 35.3 124   3 B 40.1 134   3 C 33.6 116
;
```

The variables Yield and Worth are continuous response variables, and the variables Block and Treatment are the classification variables. Because the data for the analysis are balanced, you can use PROC ANOVA to run the analysis.

The statements for the analysis are

```
proc anova data=RCB;
   class Block Treatment;
   model Yield Worth=Block Treatment;
run;
```

The Block and Treatment effects appear in the CLASS statement. The MODEL statement requests an analysis for each of the two dependent variables, Yield and Worth.

Figure 24.5 shows the "Class Level Information" table.

Figure 24.5 Class Level Information

```
                          Randomized Complete Block

                             The ANOVA Procedure

                           Class Level Information

                     Class          Levels    Values

                     Block               3    1 2 3

                     Treatment           3    A B C

                  Number of Observations Read           9
                  Number of Observations Used           9
```

The "Class Level Information" table lists the number of levels and their values for all effects specified in the CLASS statement. The number of observations in the data set are also displayed. Use this information to make sure that the data have been read correctly.

The overall ANOVA table for Yield in Figure 24.6 appears first in the output because it is the first response variable listed on the left side in the MODEL statement.

Figure 24.6 Overall ANOVA Table for Yield

Randomized Complete Block

The ANOVA Procedure

Dependent Variable: Yield

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	225.2777778	56.3194444	8.94	0.0283
Error	4	25.1911111	6.2977778		
Corrected Total	8	250.4688889			

R-Square	Coeff Var	Root MSE	Yield Mean
0.899424	6.840047	2.509537	36.68889

The overall F statistic is significant ($F = 8.94$, $p = 0.0283$), indicating that the model as a whole accounts for a significant portion of the variation in Yield and that you can proceed to evaluate the tests of effects.

The degrees of freedom (DF) are used to ensure correctness of the data and model. The Corrected Total degrees of freedom are one less than the total number of observations in the data set; in this case, $9-1 = 8$. The Model degrees of freedom for a randomized complete block are $(b-1)+(t-1)$, where b =number of block levels and t =number of treatment levels. In this case, this formula leads to $(3-1)+(3-1) = 4$ model degrees of freedom.

Several simple statistics follow the ANOVA table. The R-Square indicates that the model accounts for nearly 90% of the variation in the variable Yield. The coefficient of variation (C.V.) is listed along with the Root MSE and the mean of the dependent variable. The Root MSE is an estimate of the standard deviation of the dependent variable. The C.V. is a unitless measure of variability.

The tests of the effects shown in Figure 24.7 are displayed after the simple statistics.

Figure 24.7 Tests of Effects for Yield

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Block	2	98.1755556	49.0877778	7.79	0.0417
Treatment	2	127.1022222	63.5511111	10.09	0.0274

For Yield, both the Block and Treatment effects are significant ($F = 7.79$, $p = 0.0417$ and $F = 10.09$, $p = 0.0274$, respectively) at the 95% level. From this you can conclude that blocking is useful for this variable and that some contrast between the treatment means is significantly different from zero.

Figure 24.8 shows the ANOVA table, simple statistics, and tests of effects for the variable Worth.

Figure 24.8 ANOVA Table for Worth

```
                          Randomized Complete Block

                            The ANOVA Procedure

Dependent Variable: Worth

                                      Sum of
Source                        DF        Squares    Mean Square   F Value   Pr > F

Model                          4    1247.333333     311.833333      8.28   0.0323

Error                          4     150.666667      37.666667

Corrected Total                8    1398.000000

               R-Square     Coeff Var      Root MSE    Worth Mean

               0.892227      4.949450      6.137318      124.0000

Source                        DF       Anova SS    Mean Square   F Value   Pr > F

Block                          2    354.6666667    177.3333333      4.71   0.0889
Treatment                      2    892.6666667    446.3333333     11.85   0.0209
```

The overall F test is significant ($F = 8.28$, $p = 0.0323$) at the 95% level for the variable Worth. The Block effect is not significant at the 0.05 level but is significant at the 0.10 confidence level ($F = 4.71$, $p = 0.0889$). Generally, the usefulness of blocking should be determined before the analysis. However, since there are two dependent variables of interest, and Block is significant for one of them (Yield), blocking appears to be generally useful. For Worth, as with Yield, the effect of Treatment is significant ($F = 11.85$, $p = 0.0209$).

Issuing the following command produces the Treatment means.

```
    means Treatment;
run;
```

Figure 24.9 displays the treatment means and their standard deviations for both dependent variables.

Figure 24.9 Means of Yield and Worth

Randomized Complete Block

The ANOVA Procedure

Level of Treatment	N	Yield Mean	Yield Std Dev	Worth Mean	Worth Std Dev
A	3	36.8666667	5.22908532	125.000000	13.5277493
B	3	41.2000000	5.43415127	135.666667	6.6583281
C	3	32.0000000	2.19317122	111.333333	5.0332230

Syntax: ANOVA Procedure

The following statements are available in PROC ANOVA.

PROC ANOVA < *options* > ;
CLASS *variables* < / *option* > ;
MODEL *dependents=effects* < / *options* > ;
ABSORB *variables* ;
BY *variables* ;
FREQ *variable* ;
MANOVA < *test-options* >< / *detail-options* > ;
MEANS *effects* < / *options* > ;
REPEATED *factor-specification* < / *options* > ;
TEST < **H=***effects* > **E=***effect* ;

The PROC ANOVA, CLASS, and MODEL statements are required, and they must precede the first RUN statement. The CLASS statement must precede the MODEL statement. If you use the ABSORB, FREQ, or BY statement, it must precede the first RUN statement. The MANOVA, MEANS, REPEATED, and TEST statements must follow the MODEL statement, and they can be specified in any order. These four statements can also appear after the first RUN statement.

Table 24.1 summarizes the function of each statement (other than the PROC statement) in the ANOVA procedure:

Table 24.1 Statements in the ANOVA Procedure

Statement	Description
ABSORB	absorbs classification effects in a model
BY	specifies variables to define subgroups for the analysis
CLASS	declares classification variables
FREQ	specifies a frequency variable
MANOVA	performs a multivariate analysis of variance
MEANS	computes and compares means
MODEL	defines the model to be fit

Table 24.1 *continued*

Statement	Description
REPEATED	performs multivariate and univariate repeated measures analysis of variance
TEST	constructs tests that use the sums of squares for effects and the error term you specify

PROC ANOVA Statement

PROC ANOVA < *options* > **;**

The PROC ANOVA statement starts the ANOVA procedure.

You can specify the following options in the PROC ANOVA statement:

DATA=*SAS-data-set*
names the SAS data set used by the ANOVA procedure. By default, PROC ANOVA uses the most recently created SAS data set.

MANOVA
requests the multivariate mode of eliminating observations with missing values. If any of the dependent variables have missing values, the procedure eliminates that observation from the analysis. The MANOVA option is useful if you use PROC ANOVA in interactive mode and plan to perform a multivariate analysis.

MULTIPASS
requests that PROC ANOVA reread the input data set, when necessary, instead of writing the values of dependent variables to a utility file. This option decreases disk space usage at the expense of increased execution times and is useful only in rare situations where disk space is at an absolute premium.

NAMELEN=*n*
specifies the length of effect names to be n characters long, where n is a value between 20 and 200 characters. The default length is 20 characters.

NOPRINT
suppresses the normal display of results. The NOPRINT option is useful when you want to create only the output data set with the procedure. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, "Using the Output Delivery System," for more information.

ORDER=DATA | FORMATTED | FREQ | INTERNAL
specifies the order in which to sort the levels of the classification variables (which are specified in the CLASS statement). This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent.

OUTSTAT=*SAS-data-set*

names an output data set that contains sums of squares, degrees of freedom, F statistics, and probability levels for each effect in the model. If you use the CANONICAL option in the MANOVA statement and do not use an M= specification in the MANOVA statement, the data set also contains results of the canonical analysis. See the section "Output Data Set" on page 885 for more information.

PLOTS < (MAXPOINTS=NONE | *number*) > < =NONE >

PLOTS=NONE

controls the plots produced through ODS Graphics. When ODS Graphics is enabled, the ANOVA procedure can display a grouped box plot of the input data with groups defined by an effect in the model. Such a plot is produced by default if you have a one-way model, with only a single classification variable, or if you use a MEANS statement. Specify the PLOTS=NONE option to prevent these plots from being produced when ODS Graphics is enabled.

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;
proc anova data = Clover;
   class strain;
   model Nitrogen = Strain;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The following option can be specified in parentheses after PLOTS.

MAXPOINTS=NONE | *number*

specifies that plots with elements that require processing of more than *number* points be suppressed. The default is MAXPOINTS=5000. This limit is ignored if you specify MAXPOINTS=NONE.

ABSORB Statement

ABSORB *variables* **;**

Absorption is a computational technique that provides a large reduction in time and memory requirements for certain types of models. The *variables* are one or more variables in the input data set.

For a main effect variable that does not participate in interactions, you can absorb the effect by naming it in an ABSORB statement. This means that the effect can be adjusted out before the construction and solution of the rest of the model. This is particularly useful when the effect has a large number of levels.

Several variables can be specified, in which case each one is assumed to be nested in the preceding variable in the ABSORB statement.

NOTE: When you use the ABSORB statement, the data set (or each BY group, if a BY statement appears) must be sorted by the variables in the ABSORB statement. Including an absorbed variable in the CLASS list or in the MODEL statement might produce erroneous sums of squares. If the ABSORB statement is used, it must appear before the first RUN statement or it is ignored.

When you use an ABSORB statement and also use the INT option in the MODEL statement, the procedure ignores the option but produces the uncorrected total sum of squares (SS) instead of the corrected total SS.

See the section "Absorption" on page 3228 in Chapter 41, "The GLM Procedure," for more information.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC ANOVA to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the ANOVA procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Since sorting the data changes the order in which PROC ANOVA reads observations, the sorting order for the levels of the classification variables might be affected if you have also specified the ORDER=DATA option in the PROC ANOVA statement.

If the BY statement is used, it must appear before the first RUN statement, or it is ignored. When you use a BY statement, the interactive features of PROC ANOVA are disabled.

When both a BY and an ABSORB statement are used, observations must be sorted first by the variables in the BY statement, and then by the variables in the ABSORB statement.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / **TRUNCATE** > **;**

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC ANOVA statement. You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE
specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

FREQ Statement

FREQ *variable* **;**

The FREQ statement names a variable that provides frequencies for each observation in the DATA= data set. Specifically, if *n* is the value of the FREQ variable for a given observation, then that observation is used *n* times.

The analysis produced by using a FREQ statement reflects the expanded number of observations. For example, means and total degrees of freedom reflect the expanded number of observations. You can produce

the same analysis (without the FREQ statement) by first creating a new data set that contains the expanded number of observations. For example, if the value of the FREQ variable is 5 for the first observation, the first 5 observations in the new data set would be identical. Each observation in the old data set would be replicated n_i times in the new data set, where n_i is the value of the FREQ variable for that observation.

If the value of the FREQ variable is missing or is less than 1, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

If the FREQ statement is used, it must appear before the first RUN statement or it is ignored.

MANOVA Statement

MANOVA < *test-options* > < *detail-options* > **;**

If the MODEL statement includes more than one dependent variable, you can perform multivariate analysis of variance with the MANOVA statement. The *test-options* define which effects to test, while the *detail-options* specify how to execute the tests and what results to display.

When a MANOVA statement appears before the first RUN statement, PROC ANOVA enters a multivariate mode with respect to the handling of missing values; in addition to observations with missing independent variables, observations with *any* missing dependent variables are excluded from the analysis. If you want to use this mode of handling missing values but do not need any multivariate analyses, specify the MANOVA option in the PROC ANOVA statement.

Test Options

You can specify the following options in the MANOVA statement as *test-options* in order to define which multivariate tests to perform.

H=*effects* **| INTERCEPT | _ALL_**

specifies effects in the preceding model to use as hypothesis matrices. For each SSCP matrix $\mathbf{H}$ associated with an effect, the H= specification computes an analysis based on the characteristic roots of $\mathbf{E}^{-1}\mathbf{H}$, where $\mathbf{E}$ is the matrix associated with the error effect. The characteristic roots and vectors are displayed, along with the Hotelling-Lawley trace, Pillai's trace, Wilks' lambda, and Roy's greatest root. By default, these statistics are tested with approximations based on the F distribution. To test them with exact (but computationally intensive) calculations, use the MSTAT=EXACT option.

Use the keyword INTERCEPT to produce tests for the intercept. To produce tests for all effects listed in the MODEL statement, use the keyword _ALL_ in place of a list of effects.

For background and further details, see the section "Multivariate Analysis of Variance" on page 3252 in Chapter 41, "The GLM Procedure."

E=*effect*

specifies the error effect. If you omit the E= specification, the ANOVA procedure uses the error SSCP (residual) matrix from the analysis.

M=*equation,. . . ,equation* | **(***row-of-matrix,. . . ,row-of-matrix***)**

specifies a transformation matrix for the dependent variables listed in the MODEL statement. The equations in the M= specification are of the form

$$\begin{aligned} c_1 \times \textit{dependent-variable} \quad &\pm \quad c_2 \times \textit{dependent-variable} \\ \cdots \quad &\pm \quad c_n \times \textit{dependent-variable} \end{aligned}$$

where the c_i values are coefficients for the various *dependent-variables*. If the value of a given c_i is 1, it can be omitted; in other words $1 \times Y$ is the same as Y. Equations should involve two or more dependent variables. For sample syntax, see the section "Examples" on page 870.

Alternatively, you can input the transformation matrix directly by entering the elements of the matrix with commas separating the rows, and parentheses surrounding the matrix. When this alternate form of input is used, the number of elements in each row must equal the number of dependent variables. Although these combinations actually represent the columns of the **M** matrix, they are displayed by rows.

When you include an M= specification, the analysis requested in the MANOVA statement is carried out for the variables defined by the equations in the specification, not the original dependent variables. If you omit the M= option, the analysis is performed for the original dependent variables in the MODEL statement.

If an M= specification is included without either the MNAMES= or the PREFIX= option, the variables are labeled MVAR1, MVAR2, and so forth by default.

For further information, see the section "Multivariate Analysis of Variance" on page 3252 in Chapter 41, "The GLM Procedure."

MNAMES=*names*

provides names for the variables defined by the equations in the M= specification. Names in the list correspond to the M= equations or the rows of the **M** matrix (as it is entered).

PREFIX=*name*

is an alternative means of identifying the transformed variables defined by the M= specification. For example, if you specify PREFIX=DIFF, the transformed variables are labeled DIFF1, DIFF2, and so forth.

Detail Options

You can specify the following options in the MANOVA statement after a slash as *detail-options*:

CANONICAL

produces a canonical analysis of the **H** and **E** matrices (transformed by the **M** matrix, if specified) instead of the default display of characteristic roots and vectors.

MSTAT=FAPPROX

MSTAT=EXACT

specifies the method of evaluating the multivariate test statistics. The default is MSTAT=FAPPROX, which specifies that the multivariate tests are evaluated by using the usual approximations based on the F distribution, as discussed in the "Multivariate Tests" section in Chapter 4, "Introduction to Regression Procedures." Alternatively, you can specify MSTAT=EXACT to compute exact p-values for three of the four tests (Wilks' lambda, the Hotelling-Lawley trace, and Roy's greatest root) and an improved F-approximation for the fourth (Pillai's trace). While MSTAT=EXACT provides better control of the significance probability for the tests, especially for Roy's Greatest Root, computations for the exact p-values can be appreciably more demanding, and are in fact infeasible for large problems (many dependent variables). Thus, although MSTAT=EXACT is more accurate for most data, it is not the default method. For more information about the results of MSTAT=EXACT, see the section "Multivariate Analysis of Variance" on page 3252 in Chapter 41, "The GLM Procedure."

ORTH

requests that the transformation matrix in the M= specification of the MANOVA statement be orthonormalized by rows before the analysis.

PRINTE

displays the error SSCP matrix **E**. If the **E** matrix is the error SSCP (residual) matrix from the analysis, the partial correlations of the dependent variables given the independent variables are also produced.

For example, the statement

```
manova / printe;
```

displays the error SSCP matrix and the partial correlation matrix computed from the error SSCP matrix.

PRINTH

displays the hypothesis SSCP matrix **H** associated with each effect specified by the H= specification.

SUMMARY

produces analysis-of-variance tables for each dependent variable. When no **M** matrix is specified, a table is produced for each original dependent variable from the MODEL statement; with an **M** matrix other than the identity, a table is produced for each transformed variable defined by the **M** matrix.

Examples

The following statements give several examples of using a MANOVA statement.

```
proc anova;
   class A B;
   model Y1-Y5=A B(A);
   manova h=A e=B(A) / printh printe;
   manova h=B(A) / printe;
   manova h=A e=B(A) m=Y1-Y2,Y2-Y3,Y3-Y4,Y4-Y5
          prefix=diff;

   manova h=A e=B(A) m=(1 -1  0  0  0,
                        0  1 -1  0  0,
                        0  0  1 -1  0,
                        0  0  0  1 -1) prefix=diff;
run;
```

The first MANOVA statement specifies A as the hypothesis effect and B(A) as the error effect. As a result of the PRINTH option, the procedure displays the hypothesis SSCP matrix associated with the A effect; and, as a result of the PRINTE option, the procedure displays the error SSCP matrix associated with the B(A) effect.

The second MANOVA statement specifies B(A) as the hypothesis effect. Since no error effect is specified, PROC ANOVA uses the error SSCP matrix from the analysis as the **E** matrix. The PRINTE option displays this **E** matrix. Since the **E** matrix is the error SSCP matrix from the analysis, the partial correlation matrix computed from this matrix is also produced.

The third MANOVA statement requests the same analysis as the first MANOVA statement, but the analysis is carried out for variables transformed to be successive differences between the original dependent variables. The PREFIX=DIFF specification labels the transformed variables as DIFF1, DIFF2, DIFF3, and DIFF4.

Finally, the fourth MANOVA statement has the identical effect as the third, but it uses an alternative form of the M= specification. Instead of specifying a set of equations, the fourth MANOVA statement specifies rows of a matrix of coefficients for the five dependent variables.

As a second example of the use of the M= specification, consider the following:

```
proc anova;
   class group;
   model dose1-dose4=group / nouni;
   manova h = group
          m = -3*dose1 -   dose2 +   dose3 + 3*dose4,
                 dose1 -   dose2 -   dose3 +   dose4,
                -dose1 + 3*dose2 - 3*dose3 +   dose4
          mnames = Linear Quadratic Cubic
          / printe;
run;
```

The M= specification gives a transformation of the dependent variables dose1 through dose4 into orthogonal polynomial components, and the MNAMES= option labels the transformed variables as LINEAR, QUADRATIC, and CUBIC, respectively. Since the PRINTE option is specified and the default residual matrix is used as an error term, the partial correlation matrix of the orthogonal polynomial components is also produced.

For further information, see the section "Multivariate Analysis of Variance" on page 3252 in Chapter 41, "The GLM Procedure."

MEANS Statement

MEANS *effects* < / *options* > **;**

PROC ANOVA can compute means of the dependent variables for any effect that appears on the right-hand side in the MODEL statement.

You can use any number of MEANS statements, provided that they appear after the MODEL statement. For example, suppose A and B each have two levels. Then, if you use the following statements

```
proc anova;
   class A B;
   model Y=A B A*B;
   means A B / tukey;
   means A*B;
run;
```

means, standard deviations, and Tukey's multiple comparison tests are produced for each level of the main effects A and B, and just the means and standard deviations for each of the four combinations of levels for A*B. Since multiple comparisons options apply only to main effects, the single MEANS statement

```
means A B A*B / tukey;
```

produces the same results.

Options are provided to perform multiple comparison tests for only main effects in the model. PROC ANOVA does not perform multiple comparison tests for interaction terms in the model; for multiple comparisons of interaction terms, see the LSMEANS statement in Chapter 41, "The GLM Procedure."

Table 24.2 summarizes categories of options available in the MEANS statement.

Table 24.2 Options Available in the MEANS Statement

Task	Available options
Perform multiple comparison tests	BON
	DUNCAN
	DUNNETT
	DUNNETTL
	DUNNETTU
	GABRIEL
	GT2
	LSD
	REGWQ
	SCHEFFE
	SIDAK
	SMM

Table 24.2 *continued*

Task	Available options
Perform multiple comparison tests	SNK T TUKEY WALLER
Specify additional details for multiple comparison tests	ALPHA= CLDIFF CLM E= KRATIO= LINES NOSORT
Test for homogeneity of variances	HOVTEST
Compensate for heterogeneous variances	WELCH

Descriptions of these options follow. For a further discussion of these options, see the section "Multiple Comparisons" on page 3234 in Chapter 41, "The GLM Procedure."

ALPHA=*p*

specifies the level of significance for comparisons among the means. By default, ALPHA=0.05. You can specify any value greater than 0 and less than 1.

BON

performs Bonferroni *t* tests of differences between means for all main effect means in the MEANS statement. See the CLDIFF and LINES options, which follow, for a discussion of how the procedure displays results.

CLDIFF

presents results of the BON, GABRIEL, SCHEFFE, SIDAK, SMM, GT2, T, LSD, and TUKEY options as confidence intervals for all pairwise differences between means, and the results of the DUNNETT, DUNNETTU, and DUNNETTL options as confidence intervals for differences with the control. The CLDIFF option is the default for unequal cell sizes unless the DUNCAN, REGWQ, SNK, or WALLER option is specified.

CLM

presents results of the BON, GABRIEL, SCHEFFE, SIDAK,SMM, T, and LSD options as intervals for the mean of each level of the variables specified in the MEANS statement. For all options except GABRIEL, the intervals are confidence intervals for the true means. For the GABRIEL option, they are *comparison intervals* for comparing means pairwise: in this case, if the intervals corresponding to two means overlap, the difference between them is insignificant according to Gabriel's method.

DUNCAN

performs Duncan's multiple range test on all main effect means given in the MEANS statement. See the LINES option for a discussion of how the procedure displays results.

DUNNETT <(*formatted-control-values*)>
performs Dunnett's two-tailed *t* test, testing if any treatments are significantly different from a single control for all main effects means in the MEANS statement.

To specify which level of the effect is the control, enclose the formatted value in quotes in parentheses after the keyword. If more than one effect is specified in the MEANS statement, you can use a list of control values within the parentheses. By default, the first level of the effect is used as the control. For example,

```
means a / dunnett('CONTROL');
```

where CONTROL is the formatted control value of A. As another example,

```
means a b c / dunnett('CNTLA' 'CNTLB' 'CNTLC');
```

where CNTLA, CNTLB, and CNTLC are the formatted control values for A, B, and C, respectively.

DUNNETTL <(*formatted-control-value*)>
performs Dunnett's one-tailed *t* test, testing if any treatment is significantly less than the control. Control level information is specified as described previously for the DUNNETT option.

DUNNETTU <(*formatted-control-value*)>
performs Dunnett's one-tailed *t* test, testing if any treatment is significantly greater than the control. Control level information is specified as described previously for the DUNNETT option.

E=*effect*
specifies the error mean square used in the multiple comparisons. By default, PROC ANOVA uses the residual Mean Square (MS). The effect specified with the E= option must be a term in the model; otherwise, the procedure uses the residual MS.

GABRIEL
performs Gabriel's multiple-comparison procedure on all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

GT2
see the SMM option.

HOVTEST

HOVTEST=BARTLETT

HOVTEST=BF

HOVTEST=LEVENE <(TYPE=ABS | SQUARE)>

HOVTEST=OBRIEN <(W=*number*)>
requests a homogeneity of variance test for the groups defined by the MEANS effect. You can optionally specify a particular test; if you do not specify a test, Levene's test (Levene 1960) with TYPE=SQUARE is computed. Note that this option is ignored unless your MODEL statement specifies a simple one-way model.

The HOVTEST=BARTLETT option specifies Bartlett's test (Bartlett 1937), a modification of the normal-theory likelihood ratio test.

The HOVTEST=BF option specifies Brown and Forsythe's variation of Levene's test (Brown and Forsythe 1974).

The HOVTEST=LEVENE option specifies Levene's test (Levene 1960), which is widely considered to be the standard homogeneity of variance test. You can use the TYPE= option in parentheses to specify whether to use the absolute residuals (TYPE=ABS) or the squared residuals (TYPE=SQUARE) in Levene's test. The default is TYPE=SQUARE.

The HOVTEST=OBRIEN option specifies O'Brien's test (O'Brien 1979), which is basically a modification of HOVTEST=LEVENE(TYPE=SQUARE). You can use the W= option in parentheses to tune the variable to match the suspected kurtosis of the underlying distribution. By default, W=0.5, as suggested by O'Brien (1979, 1981).

See the section "Homogeneity of Variance in One-Way Models" on page 3247 in Chapter 41, "The GLM Procedure," for more details on these methods. Example 41.10 in the same chapter illustrates the use of the HOVTEST and WELCH options in the MEANS statement in testing for equal group variances.

KRATIO=*value*

specifies the Type 1/Type 2 error seriousness ratio for the Waller-Duncan test. Reasonable values for KRATIO are 50, 100, and 500, which roughly correspond for the two-level case to ALPHA levels of 0.1, 0.05, and 0.01. By default, the procedure uses the default value of 100.

LINES

presents results of the BON, DUNCAN, GABRIEL, REGWQ, SCHEFFE, SIDAK,SMM, GT2, SNK, T, LSD TUKEY, and WALLER options by listing the means in descending order and indicating nonsignificant subsets by line segments beside the corresponding means. The LINES option is appropriate for equal cell sizes, for which it is the default. The LINES option is also the default if the DUNCAN, REGWQ, SNK, or WALLER option is specified, or if there are only two cells of unequal size. If the cell sizes are unequal, the harmonic mean of the cell sizes is used, which might lead to somewhat liberal tests if the cell sizes are highly disparate. The LINES option cannot be used in combination with the DUNNETT, DUNNETTL, or DUNNETTU option. In addition, the procedure has a restriction that no more than 24 overlapping groups of means can exist. If a mean belongs to more than 24 groups, the procedure issues an error message. You can either reduce the number of levels of the variable or use a multiple comparison test that allows the CLDIFF option rather than the LINES option.

LSD

see the T option.

NOSORT

prevents the means from being sorted into descending order when the CLDIFF or CLM option is specified.

REGWQ

performs the Ryan-Einot-Gabriel-Welsch multiple range test on all main effect means in the MEANS statement. See the LINES option for a discussion of how the procedure displays results.

SCHEFFE

performs Scheffé's multiple-comparison procedure on all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

SIDAK

performs pairwise t tests on differences between means with levels adjusted according to Sidak's inequality for all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

SMM

GT2

performs pairwise comparisons based on the studentized maximum modulus and Sidak's uncorrelated-t inequality, yielding Hochberg's GT2 method when sample sizes are unequal, for all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

SNK

performs the Student-Newman-Keuls multiple range test on all main effect means in the MEANS statement. See the LINES option for a discussion of how the procedure displays results.

T

LSD

performs pairwise t tests, equivalent to Fisher's least-significant-difference test in the case of equal cell sizes, for all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

TUKEY

performs Tukey's studentized range test (HSD) on all main effect means in the MEANS statement. (When the group sizes are different, this is the Tukey-Kramer test.) See the CLDIFF and LINES options for discussions of how the procedure displays results.

WALLER

performs the Waller-Duncan k-ratio t test on all main effect means in the MEANS statement. See the KRATIO= option for information about controlling details of the test, and see the LINES option for a discussion of how the procedure displays results.

WELCH

requests Welch's (1951) variance-weighted one-way ANOVA. This alternative to the usual analysis of variance for a one-way model is robust to the assumption of equal within-group variances. This option is ignored unless your MODEL statement specifies a simple one-way model.

Note that using the WELCH option merely produces one additional table consisting of Welch's ANOVA. It does not affect all of the other tests displayed by the ANOVA procedure, which still require the assumption of equal variance for exact validity.

See the section "Homogeneity of Variance in One-Way Models" on page 3247 in Chapter 41, "The GLM Procedure," for more details on Welch's ANOVA. Example 41.10 in the same chapter illustrates the use of the HOVTEST and WELCH options in the MEANS statement in testing for equal group variances.

MODEL Statement

MODEL *dependents=effects* < / *options* > **;**

The MODEL statement names the dependent variables and independent effects. The syntax of effects is described in the section "Specification of Effects" on page 881. For any model effect involving classification variables (interactions as well as main effects), the number of levels cannot exceed 32,767. If no independent effects are specified, only an intercept term is fit. This tests the hypothesis that the mean of the dependent variable is zero. All variables in effects that you specify in the MODEL statement must appear in the CLASS statement because PROC ANOVA does not allow for continuous effects.

You can specify the following options in the MODEL statement; they must be separated from the list of independent effects by a slash.

INTERCEPT

INT

displays the hypothesis tests associated with the intercept as an effect in the model. By default, the procedure includes the intercept in the model but does not display associated tests of hypotheses. Except for producing the uncorrected total SS instead of the corrected total SS, the INT option is ignored when you use an ABSORB statement.

NOUNI

suppresses the display of univariate statistics. You typically use the NOUNI option with a multivariate or repeated measures analysis of variance when you do not need the standard univariate output. The NOUNI option in a MODEL statement does not affect the univariate output produced by the REPEATED statement.

REPEATED Statement

REPEATED *factor-specification* < / *options* > **;**

When values of the dependent variables in the MODEL statement represent repeated measurements on the same experimental unit, the REPEATED statement enables you to test hypotheses about the measurement factors (often called *within-subject factors*), as well as the interactions of within-subject factors with independent variables in the MODEL statement (often called *between-subject factors*). The REPEATED statement provides multivariate and univariate tests as well as hypothesis tests for a variety of single-degree-of-freedom contrasts. There is no limit to the number of within-subject factors that can be specified. For more details, see the section "Repeated Measures Analysis of Variance" on page 3253 in Chapter 41, "The GLM Procedure."

The REPEATED statement is typically used for handling repeated measures designs with one repeated response variable. Usually, the variables on the left-hand side of the equation in the MODEL statement represent one repeated response variable.

This does not mean that only one factor can be listed in the REPEATED statement. For example, one repeated response variable (hemoglobin count) might be measured 12 times (implying variables Y1 to Y12

on the left-hand side of the equal sign in the MODEL statement), with the associated within-subject factors treatment and time (implying two factors listed in the REPEATED statement). See the section "Examples" on page 880 for an example of how PROC ANOVA handles this case.

Designs with two or more repeated response variables can, however, be handled with the IDENTITY transformation; see Example 41.9 in Chapter 41, "The GLM Procedure," for an example of analyzing a doubly-multivariate repeated measures design.

When a REPEATED statement appears, the ANOVA procedure enters a multivariate mode of handling missing values. If any values for variables corresponding to each combination of the within-subject factors are missing, the observation is excluded from the analysis.

The simplest form of the REPEATED statement requires only a *factor-name*. With two repeated factors, you must specify the *factor-name* and number of levels (*levels*) for each factor. Optionally, you can specify the actual values for the levels (*level-values*), a *transformation* that defines single-degree-of freedom contrasts, and *options* for additional analyses and output. When more than one within-subject factor is specified, *factor-names* (and associated level and transformation information) must be separated by a comma in the REPEATED statement. These terms are described in the following section, "Syntax Details."

Syntax Details

You can specify the following terms in the REPEATED statement.

factor-specification

The *factor-specification* for the REPEATED statement can include any number of individual factor specifications, separated by commas, of the following form:

factor-name levels < (level-values) > < transformation >

where

factor-name names a factor to be associated with the dependent variables. The name should not be the same as any variable name that already exists in the data set being analyzed and should conform to the usual conventions of SAS variable names.

When specifying more than one factor, list the dependent variables in the MODEL statement so that the within-subject factors defined in the REPEATED statement are nested; that is, the first factor defined in the REPEATED statement should be the one with values that change least frequently.

levels specifies the number of levels associated with the factor being defined. When there is only one within-subject factor, the number of levels is equal to the number of dependent variables. In this case, *levels* is optional. When more than one within-subject factor is defined, however, *levels* is required, and the product of the number of levels of all the factors must equal the number of dependent variables in the MODEL statement.

(level-values) specifies values that correspond to levels of a repeated-measures factor. These values are used to label output; they are also used as spacings for constructing

orthogonal polynomial contrasts if you specify a POLYNOMIAL transformation. The number of level values specified must correspond to the number of levels for that factor in the REPEATED statement. Enclose the *level-values* in parentheses.

The following *transformation* keywords define single-degree-of-freedom contrasts for factors specified in the REPEATED statement. Since the number of contrasts generated is always one less than the number of levels of the factor, you have some control over which contrast is omitted from the analysis by which transformation you select. The only exception is the IDENTITY transformation; this transformation is not composed of contrasts, and it has the same degrees of freedom as the factor has levels. By default, the procedure uses the CONTRAST transformation.

CONTRAST<(*ordinal-reference-level*)>
generates contrasts between levels of the factor and a reference level. By default, the procedure uses the last level; you can optionally specify a reference level in parentheses after the keyword CONTRAST. The reference level corresponds to the ordinal value of the level rather than the level value specified. For example, to generate contrasts between the first level of a factor and the other levels, use

```
contrast(1)
```

HELMERT generates contrasts between each level of the factor and the mean of subsequent levels.

IDENTITY generates an identity transformation corresponding to the associated factor. This transformation is *not* composed of contrasts; it has n degrees of freedom for an n-level factor, instead of $n - 1$. This can be used for doubly-multivariate repeated measures.

MEAN<(*ordinal-reference-level*)>
generates contrasts between levels of the factor and the mean of all other levels of the factor. Specifying a reference level eliminates the contrast between that level and the mean. Without a reference level, the contrast involving the last level is omitted. See the CONTRAST transformation for an example.

POLYNOMIAL generates orthogonal polynomial contrasts. Level values, if provided, are used as spacings in the construction of the polynomials; otherwise, equal spacing is assumed.

PROFILE generates contrasts between adjacent levels of the factor.

For examples of the transformation matrices generated by these contrast transformations, see the section "Repeated Measures Analysis of Variance" on page 3253 in Chapter 41, "The GLM Procedure."

You can specify the following options in the REPEATED statement after a slash:

CANONICAL
performs a canonical analysis of the **H** and **E** matrices corresponding to the transformed variables specified in the REPEATED statement.

MSTAT=FAPPROX

MSTAT=EXACT

specifies the method of evaluating the multivariate test statistics. The default is MSTAT=FAPPROX, which specifies that the multivariate tests are evaluated by using the usual approximations based on the F distribution, as discussed in the "Multivariate Tests" section in Chapter 4, "Introduction to Regression Procedures." Alternatively, you can specify MSTAT=EXACT to compute exact p-values for three of the four tests (Wilks' lambda, the Hotelling-Lawley trace, and Roy's greatest root) and an improved F-approximation for the fourth (Pillai's trace). While MSTAT=EXACT provides better control of the significance probability for the tests, especially for Roy's Greatest Root, computations for the exact p-values can be appreciably more demanding, and are in fact infeasible for large problems (many dependent variables). Thus, although MSTAT=EXACT is more accurate for most data, it is not the default method. For more information about the results of MSTAT=EXACT, see the section "Multivariate Analysis of Variance" on page 3252 in Chapter 41, "The GLM Procedure."

NOM

displays only the results of the univariate analyses.

NOU

displays only the results of the multivariate analyses.

PRINTE

displays the **E** matrix for each combination of within-subject factors, as well as partial correlation matrices for both the original dependent variables and the variables defined by the transformations specified in the REPEATED statement. In addition, the PRINTE option provides sphericity tests for each set of transformed variables. If the requested transformations are not orthogonal, the PRINTE option also provides a sphericity test for a set of orthogonal contrasts.

PRINTH

displays the **H** (SSCP) matrix associated with each multivariate test.

PRINTM

displays the transformation matrices that define the contrasts in the analysis. PROC ANOVA always displays the **M** matrix so that the transformed variables are defined by the rows, not the columns, of the displayed **M** matrix. In other words, PROC ANOVA actually displays $\mathbf{M}'$.

PRINTRV

produces the characteristic roots and vectors for each multivariate test.

SUMMARY

produces analysis-of-variance tables for each contrast defined by the within-subjects factors. Along with tests for the effects of the independent variables specified in the MODEL statement, a term labeled MEAN tests the hypothesis that the overall mean of the contrast is zero.

UEPSDEF=*unbiased-epsilon-definition*

specifies the type of adjustment for the univariate F test that is displayed in addition to the Greenhouse-Geisser adjustment. The default is UEPSDEF=HFL, corresponding to the corrected form of the Huynh-Feldt adjustment (Huynh and Feldt 1976; Lecoutre 1991). Other alternatives are UEPSDEF=HF, the uncorrected Huynh-Feldt adjustment (the only available method in previous releases of

SAS/STAT software), and UEPSDEF=CM, the adjustment of Chi and Muller (2009). See the section "Hypothesis Testing in Repeated Measures Analysis" on page 3255 in Chapter 41, "The GLM Procedure," for details about these adjustments.

Examples

When specifying more than one factor, list the dependent variables in the MODEL statement so that the within-subject factors defined in the REPEATED statement are nested; that is, the first factor defined in the REPEATED statement should be the one with values that change least frequently. For example, assume that three treatments are administered at each of four times, for a total of twelve dependent variables on each experimental unit. If the variables are listed in the MODEL statement as Y1 through Y12, then the following REPEATED statement

```
repeated trt 3, time 4;
```

implies the following structure:

	Dependent Variables											
	Y1	Y2	Y3	Y4	Y5	Y6	Y7	Y8	Y9	Y10	Y11	Y12
Value of trt	1	1	1	1	2	2	2	2	3	3	3	3
Value of time	1	2	3	4	1	2	3	4	1	2	3	4

The REPEATED statement always produces a table like the preceding one.

For more information about repeated measures analysis and about using the REPEATED statement, see the section "Repeated Measures Analysis of Variance" on page 3253 in Chapter 41, "The GLM Procedure."

TEST Statement

TEST < **H=** *effects* > **E=** *effect* **;**

Although an F value is computed for all SS in the analysis by using the residual MS as an error term, you can request additional F tests that use other effects as error terms. You need a TEST statement when a nonstandard error structure (as in a split plot) exists.

CAUTION: The ANOVA procedure does not check any of the assumptions underlying the F statistic. When you specify a TEST statement, you assume sole responsibility for the validity of the F statistic produced. To help validate a test, you might want to use the GLM procedure with the RANDOM statement and inspect the expected mean squares. In the GLM procedure, you can also use the TEST option in the RANDOM statement.

You can use as many TEST statements as you want, provided that they appear after the MODEL statement.

You can specify the following terms in the TEST statement.

H=*effects* specifies which effects in the preceding model are to be used as hypothesis (numerator) effects.

E=*effect* specifies one, and only one, effect to use as the error (denominator) term. The **E=** specification is required.

The following example uses two TEST statements and is appropriate for analyzing a split-plot design.

```
proc anova;
   class a b c;
   model y=a|b(a)|c;
   test h=a e=b(a);
   test h=c a*c e=b*c(a);
run;
```

Details: ANOVA Procedure

Specification of Effects

In SAS analysis-of-variance procedures, the variables that identify levels of the classifications are called *classification variables*, and they are declared in the CLASS statement. Classification variables are also called *categorical*, *qualitative*, *discrete*, or *nominal variables*. The values of a classification variable are called *levels*. Classification variables can be either numeric or character. This is in contrast to the *response* (or *dependent*) *variables*, which are continuous. Response variables must be numeric.

The analysis-of-variance model specifies *effects*, which are combinations of classification variables used to explain the variability of the dependent variables in the following manner:

- Main effects are specified by writing the variables by themselves in the CLASS statement: A B C. Main effects used as independent variables test the hypothesis that the mean of the dependent variable is the same for each level of the factor in question, ignoring the other independent variables in the model.
- Crossed effects (interactions) are specified by joining the CLASS variables with asterisks in the MODEL statement: A*B A*C A*B*C. Interaction terms in a model test the hypothesis that the effect of a factor does not depend on the levels of the other factors in the interaction.
- Nested effects are specified by following a main effect or crossed effect with a CLASS variable or list of CLASS variables enclosed in parentheses in the MODEL statement. The main effect or crossed effect is nested within the effects listed in parentheses: B(A) C*D(A B). Nested effects test hypotheses similar to interactions, but the levels of the nested variables are not the same for every combination within which they are nested.

The general form of an effect can be illustrated by using the CLASS variables A, B, C, D, E, and F:

A ∗ B ∗ C(D E F)

The crossed list should come first, followed by the nested list in parentheses. Note that no asterisks appear within the nested list or immediately before the left parenthesis.

Main Effects Models

For a three-factor main effects model with A, B, and C as the factors and Y as the dependent variable, the necessary statements are

```
proc anova;
   class A B C;
   model Y=A B C;
run;
```

Models with Crossed Factors

To specify interactions in a factorial model, join effects with asterisks as described previously. For example, these statements specify a complete factorial model, which includes all the interactions:

```
proc anova;
   class A B C;
   model Y=A B C A*B A*C B*C A*B*C;
run;
```

Bar Notation

You can shorten the specifications of a full factorial model by using bar notation. For example, the preceding statements can also be written

```
proc anova;
   class A B C;
   model Y=A|B|C;
run;
```

When the bar (|) is used, the expression on the right side of the equal sign is expanded from left to right by using the equivalents of rules 2–4 given in Searle (1971, p. 390). The variables on the right- and left-hand sides of the bar become effects, and the cross of them becomes an effect. Multiple bars are permitted. For instance, A | B | C is evaluated as follows:

$$
\begin{aligned}
\text{A | B | C} &\rightarrow \{\text{ A | B }\}\text{ | C} \\
&\rightarrow \{\text{ A B A*B }\}\text{ | C} \\
&\rightarrow \text{A B A*B C A*C B*C A*B*C}
\end{aligned}
$$

You can also specify the maximum number of variables involved in any effect that results from bar evaluation by specifying that maximum number, preceded by an @ sign, at the end of the bar effect. For example, the specification A | B | C@2 results in only those effects that contain two or fewer variables; in this case, A B A*B C A*C and B*C.

The following table gives more examples of using the bar and at operators.

A | C(B)	is equivalent to	A C(B) A*C(B)
A(B) | C(B)	is equivalent to	A(B) C(B) A*C(B)
A(B) | B(D E)	is equivalent to	A(B) B(D E)
A | B(A) | C	is equivalent to	A B(A) C A*C B*C(A)
A | B(A) | C@2	is equivalent to	A B(A) C A*C
A | B | C | D@2	is equivalent to	A B A*B C A*C B*C D A*D B*D C*D

Consult the section "Specification of Effects" on page 3209 in Chapter 41, "The GLM Procedure," for further details on bar notation.

Nested Models

Write the effect that is nested within another effect first, followed by the other effect in parentheses. For example, if A and B are main effects and C is nested within A and B (that is, the levels of C that are observed are not the same for each combination of A and B), the statements for PROC ANOVA are

```
proc anova;
   class A B C;
   model y=A B C(A B);
run;
```

The identity of a level is viewed within the context of the level of the containing effects. For example, if City is nested within State, then the identity of City is viewed within the context of State.

The distinguishing feature of a nested specification is that nested effects never appear as main effects. Another way of viewing nested effects is that they are effects that pool the main effect with the interaction of the nesting variable.

See the "Automatic Pooling" section, which follows.

Models Involving Nested, Crossed, and Main Effects

Asterisks and parentheses can be combined in the MODEL statement for models involving nested and crossed effects:

```
proc anova;
   class A B C;
   model Y=A B(A) C(A) B*C(A);
run;
```

Automatic Pooling

In line with the general philosophy of the GLM procedure, there is no difference between the statements

```
model Y=A B(A);
```

and

```
model Y=A A*B;
```

The effect B becomes a nested effect by virtue of the fact that it does not occur as a main effect. If B is not written as a main effect in addition to participating in A*B, then the sum of squares that is associated with B is pooled into A*B.

This feature allows the automatic pooling of sums of squares. If an effect is omitted from the model, it is automatically pooled with all the higher-level effects containing the CLASS variables in the omitted effect (or within-error). This feature is most useful in split-plot designs.

Using PROC ANOVA Interactively

PROC ANOVA can be used interactively. After you specify a model in a MODEL statement and run PROC ANOVA with a RUN statement, a variety of statements (such as MEANS, MANOVA, TEST, and REPEATED) can be executed without PROC ANOVA recalculating the model sum of squares.

the section "Syntax: ANOVA Procedure" on page 862 describes which statements can be used interactively. You can execute these interactive statements individually or in groups by following the single statement or group of statements with a RUN statement. Note that the MODEL statement cannot be repeated; the ANOVA procedure allows only one MODEL statement.

If you use PROC ANOVA interactively, you can end the procedure with a DATA step, another PROC step, an ENDSAS statement, or a QUIT statement. The syntax of the QUIT statement is

```
quit;
```

When you use PROC ANOVA interactively, additional RUN statements do not end the procedure but tell PROC ANOVA to execute additional statements.

When a WHERE statement is used with PROC ANOVA, it should appear before the first RUN statement. The WHERE statement enables you to select only certain observations for analysis without using a subsetting DATA step. For example, the statement `where group ne 5` omits observations with GROUP=5 from the analysis. See *SAS Language Reference: Dictionary* for details about this statement.

When a BY statement is used with PROC ANOVA, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure.

Interactivity is also disabled when there are different patterns of missing values among the dependent variables. For details, see the section "Missing Values," which follows.

Missing Values

For an analysis involving one dependent variable, PROC ANOVA uses an observation if values are nonmissing for that dependent variable and for all the variables used in independent effects.

For an analysis involving multiple dependent variables without the MANOVA or REPEATED statement, or without the MANOVA option in the PROC ANOVA statement, a missing value in one dependent variable does not eliminate the observation from the analysis of other nonmissing dependent variables. For an analysis with the MANOVA or REPEATED statement, or with the MANOVA option in the PROC ANOVA statement, the ANOVA procedure requires values for all dependent variables to be nonmissing for an observation before the observation can be used in the analysis.

During processing, PROC ANOVA groups the dependent variables by their pattern of missing values across observations so that sums and cross products can be collected in the most efficient manner.

If your data have different patterns of missing values among the dependent variables, interactivity is disabled. This could occur when some of the variables in your data set have missing values and either of the following conditions obtain:

- You do not use the MANOVA option in the PROC ANOVA statement.
- You do not use a MANOVA or REPEATED statement before the first RUN statement.

Output Data Set

The OUTSTAT= option in the PROC ANOVA statement produces an output data set that contains the following:

- the BY variables, if any
- _TYPE_, a new character variable. This variable has the value 'ANOVA' for observations corresponding to sums of squares; it has the value 'CANCORR', 'STRUCTUR', or 'SCORE' if a canonical analysis is performed through the MANOVA statement and no M= matrix is specified.
- _SOURCE_, a new character variable. For each observation in the data set, _SOURCE_ contains the name of the model effect from which the corresponding statistics are generated.
- _NAME_, a new character variable. The variable _NAME_ contains the name of one of the dependent variables in the model or, in the case of canonical statistics, the name of one of the canonical variables (CAN1, CAN2, and so on).
- four new numeric variables, SS, DF, F, and PROB, containing sums of squares, degrees of freedom, F values, and probabilities, respectively, for each model or contrast sum of squares generated in the analysis. For observations resulting from canonical analyses, these variables have missing values.
- if there is more than one dependent variable, then variables with the same names as the dependent variables represent

- for _TYPE_='ANOVA', the crossproducts of the hypothesis matrices
- for _TYPE_='CANCORR', canonical correlations for each variable
- for _TYPE_='STRUCTUR', coefficients of the total structure matrix
- for _TYPE_='SCORE', raw canonical score coefficients

The output data set can be used to perform special hypothesis tests (for example, with the IML procedure in SAS/IML software), to reformat output, to produce canonical variates (through the SCORE procedure), or to rotate structure matrices (through the FACTOR procedure).

Computational Method

Let $\mathbf{X}$ represent the $n \times p$ design matrix. The columns of $\mathbf{X}$ contain only 0s and 1s. Let $\mathbf{Y}$ represent the $n \times 1$ vector of dependent variables.

In the GLM procedure, $\mathbf{X}'\mathbf{X}$, $\mathbf{X}'\mathbf{Y}$, and $\mathbf{Y}'\mathbf{Y}$ are formed in main storage. However, in the ANOVA procedure, only the diagonals of $\mathbf{X}'\mathbf{X}$ are computed, along with $\mathbf{X}'\mathbf{Y}$ and $\mathbf{Y}'\mathbf{Y}$. Thus, PROC ANOVA saves a considerable amount of storage as well as time. The memory requirements for PROC ANOVA are asymptotically linear functions of n^2 and nr, where n is the number of dependent variables and r the number of independent parameters.

The elements of $\mathbf{X}'\mathbf{Y}$ are cell totals, and the diagonal elements of $\mathbf{X}'\mathbf{X}$ are cell frequencies. Since PROC ANOVA automatically pools omitted effects into the next higher-level effect containing the names of the omitted effect (or within-error), a slight modification to the rules given by Searle (1971, p. 389) is used.

1. PROC ANOVA computes the sum of squares for each effect as if it is a main effect. In other words, for each effect, PROC ANOVA squares each cell total and divides by its cell frequency. The procedure then adds these quantities together and subtracts the correction factor for the mean (total squared over N).
2. For each effect involving two CLASS variable names, PROC ANOVA subtracts the SS for any main effect with a name that is contained in the two-factor effect.
3. For each effect involving three CLASS variable names, PROC ANOVA subtracts the SS for all main effects and two-factor effects with names that are contained in the three-factor effect. If effects involving four or more CLASS variable names are present, the procedure continues this process.

Displayed Output

PROC ANOVA first displays a table that includes the following:

- the name of each variable in the CLASS statement
- the number of different values or Levels of the CLASS variables

- the Values of the CLASS variables
- the Number of observations in the data set and the number of observations excluded from the analysis because of missing values, if any

PROC ANOVA then displays an analysis-of-variance table for each dependent variable in the MODEL statement. This table breaks down the Total Sum of Squares for the dependent variable into the portion attributed to the Model and the portion attributed to Error. It also breaks down the Mean Square term, which is the Sum of Squares divided by the degrees of freedom (DF). The analysis-of-variance table also lists the following:

- the Mean Square for Error (MSE), which is an estimate of σ^2, the variance of the true errors
- the F Value, which is the ratio produced by dividing the Mean Square for the Model by the Mean Square for Error. It tests how well the model as a whole (adjusted for the mean) accounts for the dependent variable's behavior. This F test is a test of the null hypothesis that all parameters except the intercept are zero.
- the significance probability associated with the F statistic, labeled "Pr > F"
- R-Square, R^2, which measures how much variation in the dependent variable can be accounted for by the model. The R^2 statistic, which can range from 0 to 1, is the ratio of the sum of squares for the model divided by the sum of squares for the corrected total. In general, the larger the R^2 value, the better the model fits the data.
- C.V., the coefficient of variation, which is often used to describe the amount of variation in the population. The C.V. is 100 times the standard deviation of the dependent variable divided by the Mean. The coefficient of variation is often a preferred measure because it is unitless.
- Root MSE, which estimates the standard deviation of the dependent variable. Root MSE is computed as the square root of Mean Square for Error, the mean square of the error term.
- the Mean of the dependent variable

For each effect (or source of variation) in the model, PROC ANOVA then displays the following:

- DF, degrees of freedom
- Anova SS, the sum of squares, and the associated Mean Square
- the F Value for testing the hypothesis that the group means for that effect are equal
- Pr > F, the significance probability value associated with the F Value

When you specify a TEST statement, PROC ANOVA displays the results of the requested tests. When you specify a MANOVA statement and the model includes more than one dependent variable, PROC ANOVA produces these additional statistics:

- the characteristic roots and vectors of $\mathbf{E}^{-1}\mathbf{H}$ for each $\mathbf{H}$ matrix

- the Hotelling-Lawley trace
- Pillai's trace
- Wilks' lambda
- Roy's greatest root

See Example 41.6 in Chapter 41, "The GLM Procedure," for an example of the MANOVA results. These MANOVA tests are discussed in Chapter 4, "Introduction to Regression Procedures."

ODS Table Names

PROC ANOVA assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 24.3. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 24.3 ODS Tables Produced by PROC ANOVA

ODS Table Name	Description	Statement / Option
AltErrTests	Anova tests with error other than MSE	TEST E=
Bartlett	Bartlett's homogeneity of variance test	MEANS / HOVTEST=BARTLETT
CLDiffs	Multiple comparisons of pairwise differences	MEANS / CLDIFF or DUNNETT or (Unequal cells and not LINES)
CLDiffsInfo	Information for multiple comparisons of pairwise differences	MEANS / CLDIFF or DUNNETT or (Unequal cells and not LINES)
CLMeans	Multiple comparisons of means with confidence/comparison interval	MEANS / CLM with (BON or GABRIEL or SCHEFFE or SIDAK or SMM or T or LSD)
CLMeansInfo	Information for multiple comparisons of means with confidence/comparison interval	MEANS / CLM
CanAnalysis	Canonical analysis	(MANOVA or REPEATED) / CANONICAL
CanCoef	Canonical coefficients	(MANOVA or REPEATED) / CANONICAL
CanStructure	Canonical structure	(MANOVA or REPEATED) / CANONICAL
CharStruct	Characteristic roots and vectors	(MANOVA / not CANONICAL) or (REPEATED / PRINTRV)
ClassLevels	Classification variable levels	CLASS statement
DependentInfo	Simultaneously analyzed dependent variables	default when there are multiple dependent variables with different patterns of missing values

Table 24.3 *continued*

ODS Table Name	Description	Statement / Option
Epsilons	Greenhouse-Geisser and Huynh-Feldt epsilons	REPEATED statement
ErrorSSCP	Error SSCP matrix	(MANOVA or REPEATED) / PRINTE
FitStatistics	R-Square, C.V., Root MSE, and dependent mean	default
HOVFTest	Homogeneity of variance ANOVA	MEANS / HOVTEST
HypothesisSSCP	Hypothesis SSCP matrix	(MANOVA or REPEATED) / PRINTE
MANOVATransform	Multivariate transformation matrix	MANOVA / M=
MCLines	Multiple comparisons LINES output	MEANS / LINES or ((DUNCAN or WALLER or SNK or REGWQ) and not (CLDIFF or CLM)) or (Equal cells and not CLDIFF)
MCLinesInfo	Information for multiple comparison LINES output	MEANS / LINES or ((DUNCAN or WALLER or SNK or REGWQ) and not (CLDIFF or CLM)) or (Equal cells and not CLDIFF)

Sphericity	Sphericity tests	REPEATED / PRINTE
Tests	Summary ANOVA for specified MANOVA H= effects	MANOVA / H= SUMMARY
Welch	Welch's ANOVA	MEANS / WELCH

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

When ODS Graphics is enabled, if you specify a one-way analysis of variance model, with just one independent classification variable, or if you use a MEANS statement, then the ANOVA procedure will produce a grouped box plot of the response values versus the classification levels. For an example of the box plot, see the section "One-Way Layout with Means Comparisons" on page 855.

ODS Graph Names

PROC ANOVA produces a single graph, the name of which you can use for referencing it in ODS. The name is listed in Table 24.4.

Table 24.4 ODS Graphic Produced by PROC ANOVA

ODS Graph Name	Plot Description
BoxPlot	Box plot of observed response values by classification levels

Examples: ANOVA Procedure

Example 24.1: Randomized Complete Block With Factorial Treatment Structure

This example uses statements for the analysis of a randomized block with two treatment factors occurring in a factorial structure. The data, from Neter, Wasserman, and Kutner (1990, p. 941), are from an experiment examining the effects of codeine and acupuncture on post-operative dental pain in male subjects. Both treatment factors have two levels. The codeine levels are a codeine capsule or a sugar capsule. The acupuncture levels are two inactive acupuncture points or two active acupuncture points. There are four distinct treatment combinations due to the factorial treatment structure. The 32 subjects are assigned to eight blocks of four subjects each based on an assessment of pain tolerance.

The data for the analysis are balanced, so PROC ANOVA is used. The data are as follows:

```
title1 'Randomized Complete Block With Two Factors';
data PainRelief;
   input PainLevel Codeine Acupuncture Relief @@;
   datalines;
1 1 1 0.0  1 2 1 0.5  1 1 2 0.6  1 2 2 1.2
2 1 1 0.3  2 2 1 0.6  2 1 2 0.7  2 2 2 1.3
3 1 1 0.4  3 2 1 0.8  3 1 2 0.8  3 2 2 1.6
4 1 1 0.4  4 2 1 0.7  4 1 2 0.9  4 2 2 1.5
5 1 1 0.6  5 2 1 1.0  5 1 2 1.5  5 2 2 1.9
6 1 1 0.9  6 2 1 1.4  6 1 2 1.6  6 2 2 2.3
7 1 1 1.0  7 2 1 1.8  7 1 2 1.7  7 2 2 2.1
8 1 1 1.2  8 2 1 1.7  8 1 2 1.6  8 2 2 2.4
;
```

The variable PainLevel is the blocking variable, and Codeine and Acupuncture represent the levels of the two treatment factors. The variable Relief is the pain relief score (the higher the score, the more relief the patient has).

The following statements invokes PROC ANOVA. The blocking variable and treatment factors appear in the CLASS statement. The bar between the treatment factors Codeine and Acupuncture adds their main effects as well as their interaction Codeine*Acupuncture to the model.

```
proc anova data=PainRelief;
   class PainLevel Codeine Acupuncture;
   model Relief = PainLevel Codeine|Acupuncture;
run;
```

The results from the analysis are shown in Output 24.1.1, Output 24.1.2, and Output 24.1.3.

Output 24.1.1 Class Level Information

```
                Randomized Complete Block With Two Factors

                          The ANOVA Procedure

```

Output 24.1.2 ANOVA Table

Randomized Complete Block With Two Factors

The ANOVA Procedure

Dependent Variable: Relief

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	10	11.33500000	1.13350000	78.37	<.0001
Error	21	0.30375000	0.01446429		
Corrected Total	31	11.63875000			

R-Square	Coeff Var	Root MSE	Relief Mean
0.973902	10.40152	0.120268	1.156250

The Class Level Information and ANOVA table are shown in Output 24.1.1 and Output 24.1.2. The classification level information summarizes the structure of the design. It is good to check these consistently in search of errors in the DATA step. The overall F test is significant, indicating that the model accounts for a significant amount of variation in the dependent variable.

Output 24.1.3 Tests of Effects

Source	DF	Anova SS	Mean Square	F Value	Pr > F
PainLevel	7	5.59875000	0.79982143	55.30	<.0001
Codeine	1	2.31125000	2.31125000	159.79	<.0001
Acupuncture	1	3.38000000	3.38000000	233.68	<.0001
Codeine*Acupuncture	1	0.04500000	0.04500000	3.11	0.0923

Output 24.1.3 shows tests of the effects. The blocking effect is significant; hence, it is useful. The interaction between codeine and acupuncture is significant at the 90% level but not at the 95% level. The significance level of this test should be determined before the analysis. The main effects of both treatment factors are highly significant.

Example 24.2: Alternative Multiple Comparison Procedures

The following is a continuation of the first example in the section "One-Way Layout with Means Comparisons" on page 855. You are studying the effect of bacteria on the nitrogen content of red clover plants, and the analysis of variance shows a highly significant effect. The following statements create the data set and compute the analysis of variance as well as Tukey's multiple comparisons test for pairwise differences between bacteria strains; the results are shown in Figure 24.1, Figure 24.2, and Figure 24.3

```
title1 'Nitrogen Content of Red Clover Plants';
data Clover;
   input Strain $ Nitrogen @@;
   datalines;
3DOK1  19.4 3DOK1  32.6 3DOK1  27.0 3DOK1  32.1 3DOK1  33.0
3DOK5  17.7 3DOK5  24.8 3DOK5  27.9 3DOK5  25.2 3DOK5  24.3
3DOK4  17.0 3DOK4  19.4 3DOK4   9.1 3DOK4  11.9 3DOK4  15.8
3DOK7  20.7 3DOK7  21.0 3DOK7  20.5 3DOK7  18.8 3DOK7  18.6
3DOK13 14.3 3DOK13 14.4 3DOK13 11.8 3DOK13 11.6 3DOK13 14.2
COMPOS 17.3 COMPOS 19.4 COMPOS 19.1 COMPOS 16.9 COMPOS 20.8
;

proc anova data=Clover;
   class Strain;
   model Nitrogen = Strain;
   means Strain / tukey;
run;
```

The interactivity of PROC ANOVA enables you to submit further MEANS statements without re-running the entire analysis. For example, the following command requests means of the Strain levels with Duncan's multiple range test and the Waller-Duncan k-ratio t test.

```
   means Strain / duncan waller;
run;
```

Results of the Waller-Duncan k-ratio t test are shown in Output 24.2.1.

Output 24.2.1 Waller-Duncan K-ratio t Test

```
                    Nitrogen Content of Red Clover Plants

                              The ANOVA Procedure

                  Waller-Duncan K-ratio t Test for Nitrogen

                   Kratio                              100

                   F Value                           14.37
                   Critical Value of t             1.91873
                   Minimum Significant Difference   4.1665
```

Output 24.2.1 *continued*

Means with the same letter are not significantly different.

Waller Grouping	Mean	N	Strain
A	28.820	5	3DOK1
B	23.980	5	3DOK5
B C			
C B	19.920	5	3DOK7
C			
C D	18.700	5	COMPOS
D			
E D	14.640	5	3DOK4
E			
E	13.260	5	3DOK13

The Waller-Duncan k-ratio t test is a multiple range test. Unlike Tukey's test, this test does not operate on the principle of controlling Type I error. Instead, it compares the Type I and Type II error rates based on Bayesian principles (Steel and Torrie 1980).

The Waller Grouping column in Output 24.2.1 shows which means are significantly different. From this test, you can conclude the following:

- The mean nitrogen content for strain 3DOK1 is higher than the means for all other strains.
- The mean nitrogen content for strain 3DOK5 is higher than the means for COMPOS, 3DOK4, and 3DOK13.
- The mean nitrogen content for strain 3DOK7 is higher than the means for 3DOK4 and 3DOK13.
- The mean nitrogen content for strain COMPOS is higher than the mean for 3DOK13.
- Differences between all other means are not significant based on this sample size.

Output 24.2.2 shows the results of Duncan's multiple range test. Duncan's test is a result-guided test that compares the treatment means while controlling the comparison-wise error rate. You should use this test for planned comparisons only (Steel and Torrie 1980). The results and conclusions for this example are the same as for the Waller-Duncan k-ratio t test. This is not always the case.

Output 24.2.2 Duncan's Multiple Range Test

If you only perform the LSD tests when the overall model F test is significant, then this is called Fisher's protected LSD test. Note that the LSD tests should be used for planned comparisons.

The TUKEY tests shown in Output 24.2.4 find fewer significant differences than the other three tests. This is not unexpected, as the TUKEY test controls the Type I experimentwise error rate. For a complete discussion of multiple comparison methods, see the section "Multiple Comparisons" on page 3234 in Chapter 41, "The GLM Procedure."

Example 24.3: Split Plot

In some experiments, treatments can be applied only to groups of experimental observations rather than separately to each observation. When there are two nested groupings of the observations on the basis of treatment application, this is known as a *split plot design*. For example, in integrated circuit fabrication it is of interest to see how different manufacturing methods affect the characteristics of individual chips. However, much of the manufacturing process is applied to a relatively large wafer of material, from which many chips are made. Additionally, a chip's position within a wafer might also affect chip performance. These two groupings of chips—by wafer and by position-within-wafer—might form the *whole plots* and the *subplots*, respectively, of a split plot design for integrated circuits.

The following statements produce an analysis for a split-plot design. The CLASS statement includes the variables Block, A, and B, where B defines subplots within BLOCK*A whole plots. The MODEL statement includes the independent effects Block, A, Block*A, B, and A*B. The TEST statement asks for an F test of the A effect that uses the Block*A effect as the error term. The following statements produce Output 24.3.1 and Output 24.3.2:

```

Output 24.3.1 *continued*

Split Plot Design

The ANOVA Procedure

Dependent Variable: Response

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	11	182.0200000	16.5472727	7.85	0.0306
Error	4	8.4300000	2.1075000		
Corrected Total	15	190.4500000			

R-Square	Coeff Var	Root MSE	Response Mean
0.955736	3.609007	1.451723	40.22500

First, notice that the overall F test for the model is significant.

Output 24.3.2 Tests of Effects

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Block	1	131.1025000	131.1025000	62.21	0.0014
A	3	40.1900000	13.3966667	6.36	0.0530
Block*A	3	6.9275000	2.3091667	1.10	0.4476
B	1	2.2500000	2.2500000	1.07	0.3599
A*B	3	1.5500000	0.5166667	0.25	0.8612

Tests of Hypotheses Using the Anova MS for Block*A as an Error Term

Source	DF	Anova SS	Mean Square	F Value	Pr > F
A	3	40.19000000	13.39666667	5.80	0.0914

The effect of Block is significant. The effect of A is not significant: look at the F test produced by the TEST statement, not at the F test produced by default. Neither the B nor A*B effects are significant. The test for Block*A is irrelevant, as this is simply the main-plot error.

Example 24.4: Latin Square Split Plot

The data for this example is taken from Smith (1951). A Latin square design is used to evaluate six different sugar beet varieties arranged in a six-row (Rep) by six-column (Column) square. The data are collected over two harvests. The variable Harvest then becomes a split plot on the original Latin square design for whole plots. The following statements produce Output 24.4.1, Output 24.4.2, and Output 24.4.3:

```
title1 'Sugar Beet Varieties';
title3 'Latin Square Split-Plot Design';
data Beets;
   do Harvest=1 to 2;
      do Rep=1 to 6;
         do Column=1 to 6;
            input Variety Y @;
            output;
            end;
         end;
      end;

Tests of Hypotheses Using the Anova MS for Column*Rep*Variety as an Error Term

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Rep	5	4.32069444	0.86413889	5.31	0.0029
Column	5	1.57402778	0.31480556	1.93	0.1333
Variety	5	20.61902778	4.12380556	25.34	<.0001

Output 24.4.3 *continued*

Tests of Hypotheses Using the Anova MS for Rep*Harvest as an Error Term

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Harvest	1	60.68347222	60.68347222	39.32	0.0015

Output 24.4.3 shows that the effects for Rep and Harvest are significant, while the Column effect is not. The average Ys for the six different Varietys are significantly different. For these four tests, look at the output produced by the two TEST statements, not at the usual ANOVA procedure output. The Variety*Harvest interaction is not significant. All other effects in the default output should either be tested by using the results from the TEST statements or are irrelevant as they are only error terms for portions of the model.

Example 24.5: Strip-Split Plot

In this example, four different fertilizer treatments are laid out in vertical strips, which are then split into subplots with different levels of calcium. Soil type is stripped across the split-plot experiment, and the entire experiment is then replicated three times. The dependent variable is the yield of winter barley. The data come from the notes of G. Cox and A. Rotti.

The input data are the 96 values of Y, arranged so that the calcium value (Calcium) changes most rapidly, then the fertilizer value (Fertilizer), then the Soil value, and, finally, the Rep value. Values are shown for Calcium (0 and 1); Fertilizer (0, 1, 2, 3); Soil (1, 2, 3); and Rep (1, 2, 3, 4). The following example produces Output 24.5.1, Output 24.5.2, Output 24.5.3, and Output 24.5.4.

```

Output 24.5.1 Class Level Information

Strip-split Plot

The ANOVA Procedure

Class Level Information

Class	Levels	Values
Rep	4	1 2 3 4
Soil	3	1 2 3
Calcium	2	0 1
Fertilizer	4	0 1 2 3

Number of Observations Read	96
Number of Observations Used	96

Output 24.5.2 ANOVA Table

Strip-split Plot

The ANOVA Procedure

Dependent Variable: Yield

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	95	31.89149583	0.33569996	.	.
Error	0	0.00000000	.		
Corrected Total	95	31.89149583			

R-Square	Coeff Var	Root MSE	Yield Mean
1.000000	.	.	5.427292

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Rep	3	6.27974583	2.09324861	.	.
Fertilizer	3	7.22127083	2.40709028	.	.
Rep*Fertilizer	9	6.08211250	0.67579028	.	.
Calcium	1	0.27735000	0.27735000	.	.
Calcium*Fertilizer	3	1.96395833	0.65465278	.	.
Rep*Calcium(Fertili)	12	1.76705833	0.14725486	.	.
Soil	2	1.92658958	0.96329479	.	.
Rep*Soil	6	1.66761042	0.27793507	.	.
Soil*Fertilizer	6	0.68828542	0.11471424	.	.
Rep*Soil*Fertilizer	18	1.58698125	0.08816563	.	.
Soil*Calcium	2	0.04493125	0.02246562	.	.
Soil*Calcium*Fertili	6	0.18936042	0.03156007	.	.
Rep*Soil*Calc(Ferti)	24	2.19624167	0.09151007	.	.

Notice in Output 24.5.2 that the default tests against the residual error rate are all unavailable. This is because the Soil*Calcium*Rep(Fertilizer) term in the model takes up all the degrees of freedom, leaving none for estimating the residual error rate. This is appropriate in this case since the TEST statements give the specific error terms appropriate for testing each effect. Output 24.5.3 displays the output produced by the various TEST statements. The only significant effect is the Calcium*Fertilizer interaction.

Output 24.5.3 Tests of Effects

Tests of Hypotheses Using the Anova MS for Rep*Fertilizer as an Error Term

Level of Calcium	N	Yield Mean	Yield Std Dev
0	48	5.48104167	0.54186141
1	48	5.37354167	0.61565219

Level of Soil	N	Yield Mean	Yield Std Dev
1	32	5.54312500	0.55806369
2	32	5.51093750	0.62176315
3	32	5.22781250	0.51825224

Output 24.5.4 *continued*

Level of Calcium	Level of Fertilizer	N	Yield Mean	Yield Std Dev
0	0	12	5.34666667	0.45029956
0	1	12	5.08833333	0.44986530
0	2	12	5.62666667	0.44707806
0	3	12	5.86250000	0.52886027
1	0	12	5.02166667	0.47615569
1	1	12	5.17000000	0.31826233
1	2	12	5.88250000	0.59856077
1	3	12	5.42000000	0.68409197

Output 24.5.4 shows the results of the MEANS statement, displaying for various effects and combinations of effects, as requested. You can examine the Calcium*Fertilizer means to understand the interaction better.

In this example, you could reduce memory requirements by omitting the Soil*Calcium*Rep(Fertilizer) effect from the model in the MODEL statement. This effect then becomes the ERROR effect, and you can omit the last TEST statement in the statements shown earlier. The test for the Soil*Calcium effect is then given in the Analysis of Variance table in the top portion of output. However, for all other tests, you should look at the results from the TEST statement. In large models, this method might lead to significant reductions in memory requirements.

Chapter 25

The BOXPLOT Procedure

Contents

Overview: BOXPLOT Procedure

The BOXPLOT procedure creates side-by-side box-and-whiskers plots of measurements organized in groups. A box-and-whiskers plot displays the mean, quartiles, and minimum and maximum observations for a group. Throughout this chapter, this type of plot, which can contain one or more box-and-whiskers plots, is referred to as a *box plot*.

The PLOT statement of the BOXPLOT procedure produces a box plot. You can specify more than one PLOT statement to produce multiple box plots. You can use options in the PLOT statement to do the following:

- control the style of the box-and-whiskers plots
- specify one of several methods for calculating quantile statistics (percentiles)
- add block legends and symbol markers to reveal stratification in data
- display vertical and horizontal reference lines
- control axis values and labels
- overlay the box plot with plots of additional variables
- control the layout and appearance of the plot

The INSET and INSETGROUP statements produce boxes or tables (referred to as *insets*) of summary statistics or other data on a box plot. An INSET statement produces an inset of statistics pertaining to the entire box plot. An INSETGROUP statement produces an inset containing statistics calculated separately for each group. An INSET or INSETGROUP statement by itself does not produce a display; it must be used with a PLOT statement.

You can use options in an INSET or INSETGROUP statement to control insets in these ways:

- specify the position of the inset
- specify a header for the inset
- specify graphical enhancements, such as background colors, text colors, text height, text font, and drop shadows

The BOXPLOT procedure can produce two kinds of graphical output:

- traditional graphics
- ODS Statistical Graphics output

Traditional graphics are saved in graphics catalogs with entry type GRSEG. Their appearance is controlled by global statements such as the GOPTIONS, AXIS, and SYMBOL statements (as described in *SAS/GRAPH: Reference*) and numerous specialized PLOT statement options. You must have a SAS/GRAPH® license to produce traditional graphics.

ODS Statistical Graphics (or ODS Graphics for short) is an extension to the Output Delivery System (ODS). Graphs are produced in standard image file formats (such as PNG) instead of graphics catalogs, and the details of their appearance and layout are controlled by ODS styles and templates rather than by global statements and procedure options.

When ODS Graphics is enabled (for example, with the ODS GRAPHICS ON statement) PROC BOXPLOT produces ODS Graphics output. Otherwise, it produces traditional graphics. See Chapter 21, "Statistical Graphics Using ODS," for a thorough discussion of ODS Graphics.

See the section "Getting Started: BOXPLOT Procedure" on page 911 for examples producing box plots via the traditional graphics system and ODS Graphics.

NOTE: Prior to SAS 9.2, traditional graphics produced by PROC BOXPLOT were extremely basic by default. Producing attractive graphical output required the careful selection of colors, fonts, and other elements, which were specified via SAS/GRAPH statements and PLOT statement options. Beginning with SAS 9.2, the default appearance of traditional box plots is governed by the prevailing ODS style, which automatically produces attractive, consistent output. You can specify the NOGSTYLE system option to prevent the ODS style from affecting the appearance of traditional graphs.

Getting Started: BOXPLOT Procedure

This section introduces the BOXPLOT procedure with simple examples demonstrating commonly used options. Complete syntax for the BOXPLOT procedure is presented in the section "Syntax: BOXPLOT Procedure" on page 919, and advanced examples are presented in the section "Examples: BOXPLOT Procedure" on page 969.

Creating Box Plots from Raw Data

A petroleum company uses a turbine to heat water into steam that is pumped into the ground to make oil less viscous and easier to extract. This process occurs 20 times daily, and the amount of power (in kilowatts) used to heat the water to the desired temperature is recorded. The following statements create a SAS data set called Turbine that contains the power output measurements for 10 nonconsecutive days:

```
data Turbine;
   informat Day date7.;
   format Day date5.;
   label KWatts='Average Power Output';
   input Day @;
   do i=1 to 10;
```

```
      input KWatts @;
      output;
      end;
   drop i;
   datalines;

;
```

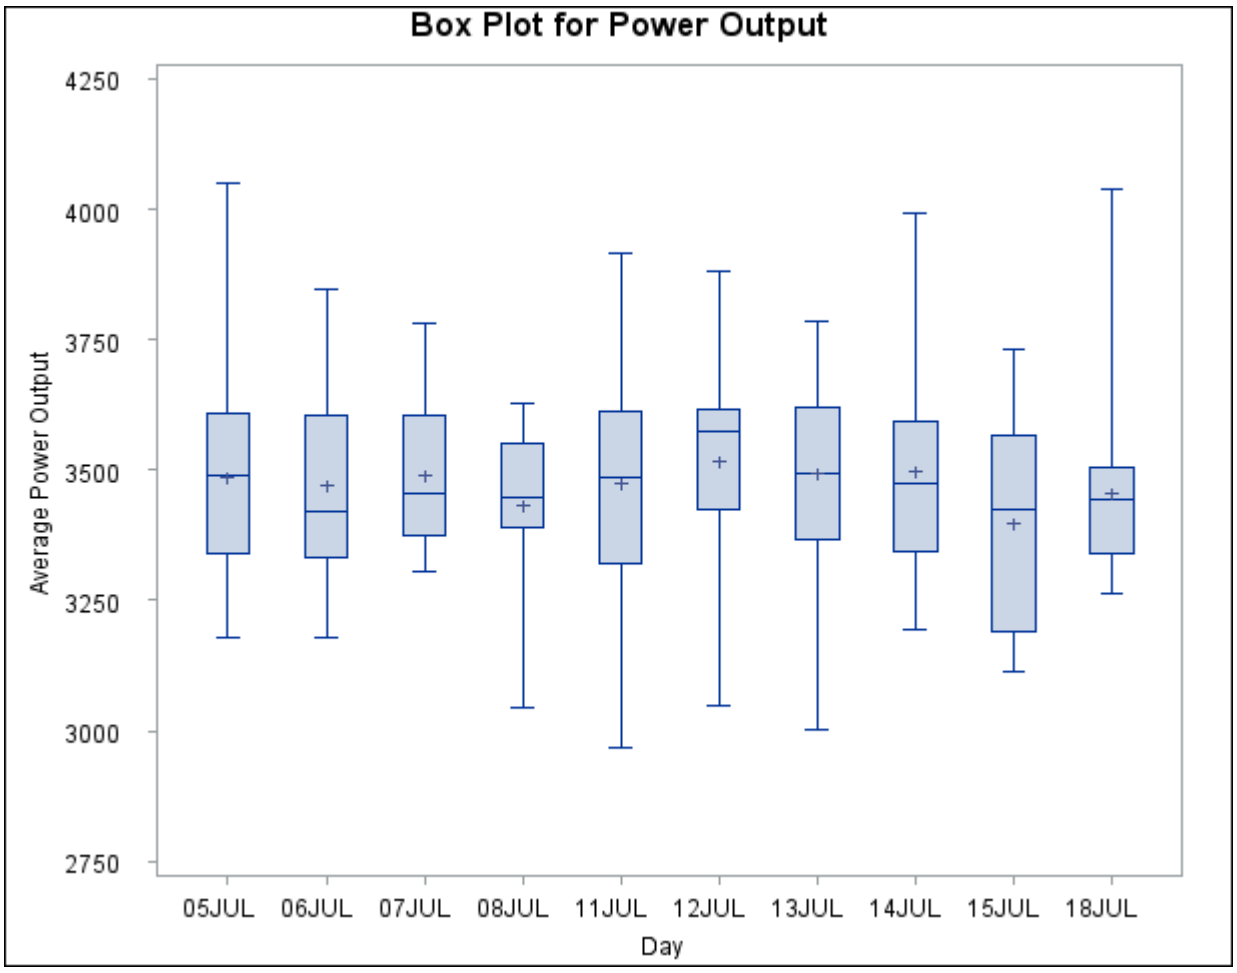
In the data set Turbine, each observation contains the date and the power output for a single heating. The first 20 observations contain the outputs for the first day, the second 20 observations contain the outputs for the second day, and so on. Because the variable Day classifies the observations into groups, it is referred to as the *group variable*. The variable KWatts contains the output measurements and is referred to as the *analysis variable*.

The following statements create a box plot showing the distribution of power output for each day:

```
ods graphics off;
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
run;
```

The input data set Turbine is specified with the DATA= option in the PROC BOXPLOT statement. The PLOT statement requests a box-and-whiskers plot for each group of data. After the keyword PLOT, you specify the analysis variable (in this case, KWatts), followed by an asterisk and the group variable (Day). The ODS GRAPHICS OFF statement specified before the PROC BOXPLOT statement disables ODS Graphics, so the box plot is produced using traditional graphics. The box plot is shown in Figure 25.1.

Figure 25.1 Box Plot for Power Output Data



The box plot displayed in Figure 25.1 represents summary statistics for the analysis variable KWatts. Each of the 10 box-and-whiskers plots describes the variable KWatts for a particular day. The plot elements and the statistics they represent are as follows:

- The length of the box represents the interquartile range (the distance between the 25th and 75th percentiles).
- The symbol in the box interior represents the group mean.
- The horizontal line in the box interior represents the group median.
- The vertical lines (called *whiskers*) issuing from the box extend to the group minimum and maximum values.

Creating Box Plots from Summary Data

The previous example illustrates how you can create box plots from raw data. However, in some applications the data are provided as summary statistics. This example illustrates how you can use the BOXPLOT procedure with data of this type.

The following statements create the data set Oilsum, which provides the data from the preceding example in summarized form:

```
data Oilsum;
   input Day KWattsL KWatts1 KWattsX KWattsM
             KWatts3 KWattsH KWattsS KWattsN;
   informat Day date7. ;
   format Day date5. ;
   label Day    ='Date of Measurement'
         KWattsL='Minimum Power Output'
         KWatts1='25th Percentile'
         KWattsX='Average Power Output'
         KWattsM='Median Power Output'
         KWatts3='75th Percentile'
         KWattsH='Maximum Power Output'
         KWattsS='Standard Deviation of Power Output'
         KWattsN='Group Sample Size';
   datalines;

18JUL94 3263 3340.0 3456.05 3444.0 3505.5 4040 173.5 20
;
```

Oilsum contains exactly one observation for each group. Note that, as in the previous example, the groups are indexed by the variable Day. A listing of Oilsum is shown in Figure 25.2.

Figure 25.2 The Summary Data Set Oilsum

Box Plot for Power Output

Day	KWatts L	KWatts1	KWattsX	KWatts M	KWatts3	KWatts H	KWatts S	KWatts N
05JUL	3180	3340.0	3487.40	3490.0	3610.0	4050	220.3	20
06JUL	3179	3333.5	3471.65	3419.5	3605.0	3849	210.4	20
07JUL	3304	3376.0	3488.30	3456.5	3604.5	3781	147.0	20
08JUL	3045	3390.5	3434.20	3447.0	3550.0	3629	157.6	20
11JUL	2968	3321.0	3475.80	3487.0	3611.5	3916	258.9	20
12JUL	3047	3425.5	3518.10	3576.0	3615.0	3881	211.6	20
13JUL	3002	3368.5	3492.65	3495.5	3621.5	3787	193.8	20
14JUL	3196	3346.0	3496.40	3473.5	3592.5	3994	212.0	20
15JUL	3115	3188.5	3398.50	3426.0	3568.5	3731	199.2	20
18JUL	3263	3340.0	3456.05	3444.0	3505.5	4040	173.5	20

There are eight summary variables in Oilsum:

- KWattsL contains the group minima (low values).
- KWatts1 contains the 25th percentile (first quartile) for each group.
- KWattsX contains the group means.
- KWattsM contains the group medians.
- KWatts3 contains the 75th percentile (third quartile) for each group.
- KWattsH contains the group maxima (high values).
- KWattsS contains the group standard deviations.
- KWattsN contains the group sizes.

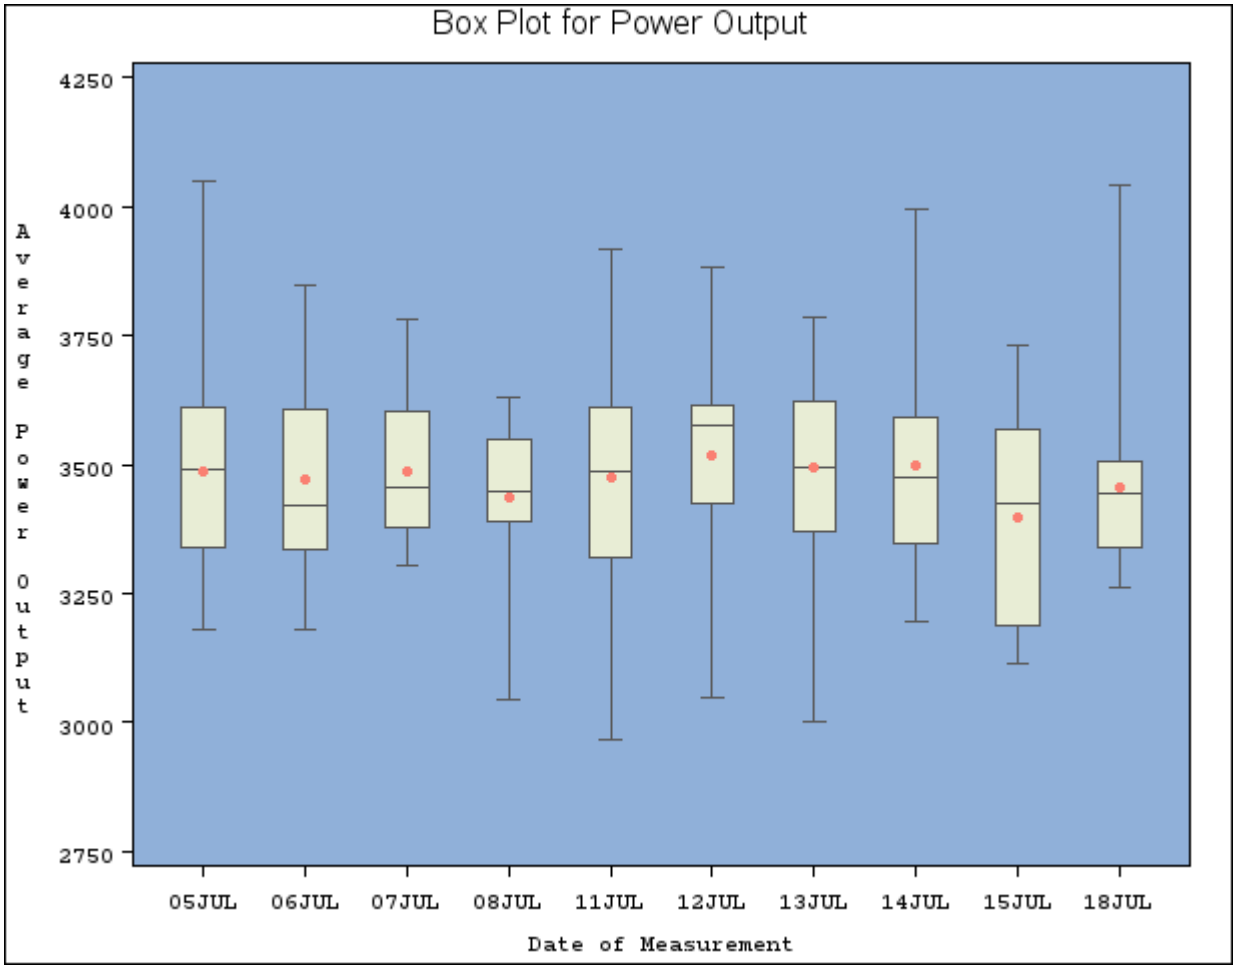
You can use this data set as input to the BOXPLOT procedure by specifying it with the HISTORY= option in the PROC BOXPLOT statement. Detailed requirements for HISTORY= data sets are presented in the section "HISTORY= Data Set" on page 953.

The following statements produce a box plot of the summary data from the Oilsum data set:

```
options nogstyle;
title 'Box Plot for Power Output';
symbol value=dot color=salmon;
proc boxplot history=Oilsum;
   plot KWatts*Day / cframe   = vligb
                     cboxes   = dagr
                     cboxfill = ywh;
run;
options gstyle;
goptions reset=symbol;
```

The NOGSTYLE system option causes PROC BOXPLOT to ignore ODS styles when producing the box plot. Instead, the SYMBOL statement and options specified after the slash (/) in the PLOT statement control its appearance. The GSTYLE system option restores the use of ODS styles for subsequent high-resolution graphics output. For more information about SYMBOL statements, see *SAS/GRAPH: Reference*. The resulting box plot is shown in Figure 25.3.

Figure 25.3 High-Resolution Box Plot with NOGSTYLE



Saving Summary Data with Outliers

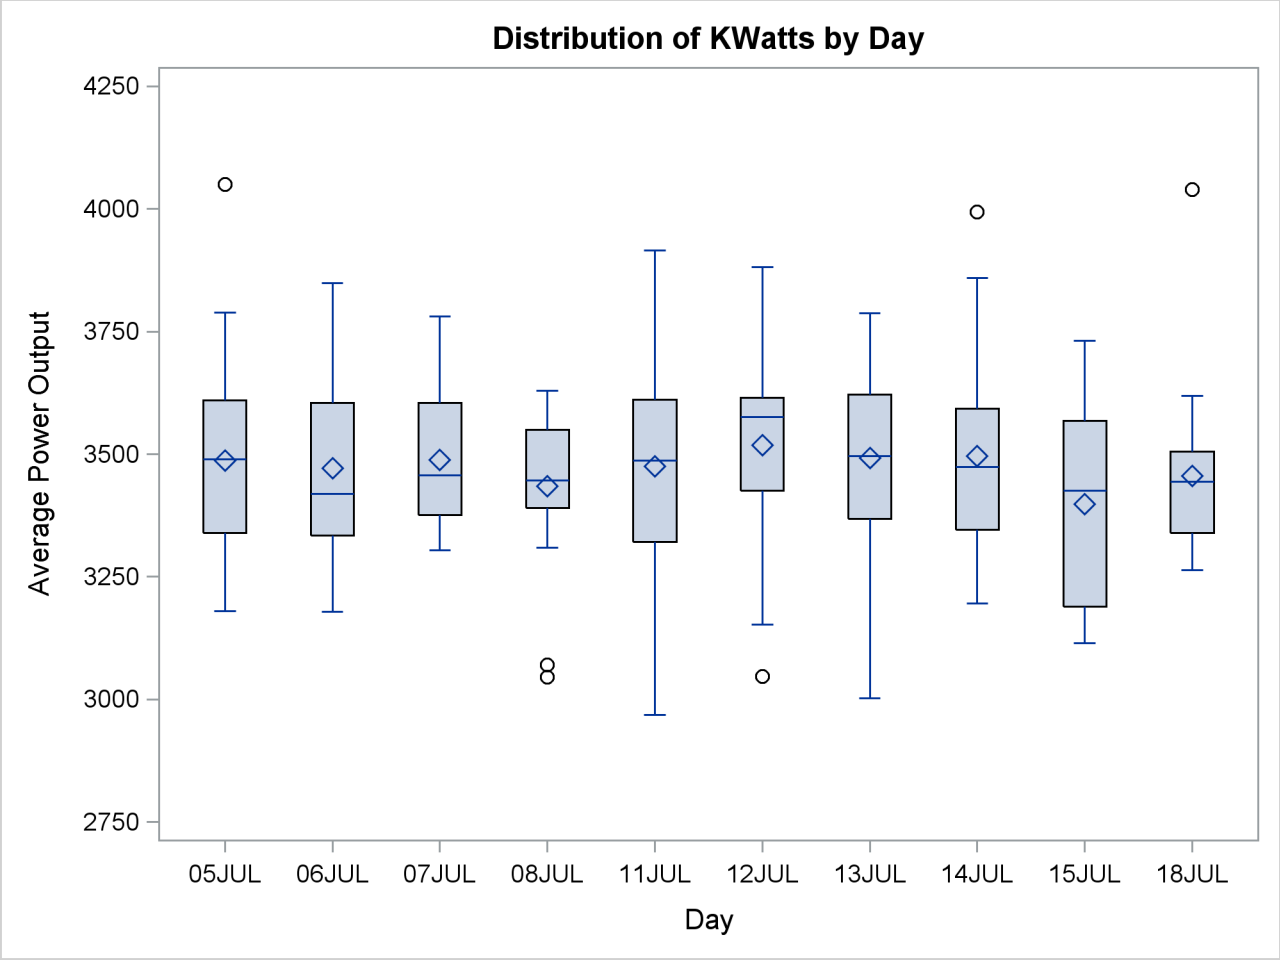
In a *schematic* box plot, outlier values within a group are plotted as separate points beyond the whiskers of the box-and-whiskers plot. See the section "Styles of Box Plots" on page 954 and the description of the BOXSTYLE= option for a complete description of schematic box plots.

The following statements use the BOXSTYLE= option to produce a schematic box plot of the data from the Turbine data set. The OUTBOX= option creates a summary data set named OilSchematic. The ODS GRAPHICS ON statement specified before the PROC BOXPLOT statement enables ODS Graphics, so the box plot is created using ODS Graphics instead of traditional graphics.

```
title 'Schematic Box Plot for Power Output';
ods graphics on;
proc boxplot data=Turbine;
   plot KWatts*Day / boxstyle = schematic
                     outbox   = OilSchematic;
run;
```

The schematic box plot is shown in Figure 25.4. Note the outliers plotted for several of the groups.

Figure 25.4 Schematic Box Plot of Power Output



Whereas the Oilsum data set from the section "Creating Box Plots from Summary Data" on page 914 contains a *variable* for each summary statistic and one observation per group, the OUTBOX= data set OilSchematic contains one *observation* for each summary statistic in each group. The _TYPE_ variable identifies the statistic and the _VALUE_ variable contains its value. In addition, the OilSchematic data set contains an observation recording each outlier value for each group. Figure 25.5 shows a partial listing of the OilSchematic data set.

Figure 25.5 The Summary Data Set OilSchematic

Schematic Box Plot for Power Output

Day	_VAR_	_TYPE_	_VALUE_
05JUL	KWatts	N	20.00
05JUL	KWatts	MIN	3180.00
05JUL	KWatts	Q1	3340.00
05JUL	KWatts	MEAN	3487.40
05JUL	KWatts	MEDIAN	3490.00
05JUL	KWatts	Q3	3610.00
05JUL	KWatts	MAX	4050.00
05JUL	KWatts	STDDEV	220.26
05JUL	KWatts	HIWHISKR	3789.00
05JUL	KWatts	HIGH	4050.00
06JUL	KWatts	N	20.00
06JUL	KWatts	MIN	3179.00
06JUL	KWatts	Q1	3333.50
06JUL	KWatts	MEAN	3471.65
06JUL	KWatts	MEDIAN	3419.50
06JUL	KWatts	Q3	3605.00
06JUL	KWatts	MAX	3849.00
06JUL	KWatts	STDDEV	210.43
07JUL	KWatts	N	20.00
07JUL	KWatts	MIN	3304.00
07JUL	KWatts	Q1	3376.00
07JUL	KWatts	MEAN	3488.30
07JUL	KWatts	MEDIAN	3456.50
07JUL	KWatts	Q3	3604.50
07JUL	KWatts	MAX	3781.00
07JUL	KWatts	STDDEV	147.02
08JUL	KWatts	N	20.00
08JUL	KWatts	MIN	3045.00
08JUL	KWatts	Q1	3390.50
08JUL	KWatts	MEAN	3434.20
08JUL	KWatts	MEDIAN	3447.00
08JUL	KWatts	Q3	3550.00
08JUL	KWatts	MAX	3629.00
08JUL	KWatts	STDDEV	157.64
08JUL	KWatts	LOWHISKR	3309.00
08JUL	KWatts	LOW	3070.00
08JUL	KWatts	LOW	3045.00
11JUL	KWatts	N	20.00
11JUL	KWatts	MIN	2968.00
11JUL	KWatts	Q1	3321.00

Observations with the _TYPE_ variable values “HIGH” and “LOW” contain outlier values. If you want to use a summary data set to re-create a schematic box plot, you *must* create an OUTBOX= data set in order to save the outlier data.

Syntax: BOXPLOT Procedure

The syntax for the BOXPLOT procedure is as follows:

PROC BOXPLOT *options* ;
BY *variables* ;
ID *variables* ;
INSET *keywords* < */options* > ;
INSETGROUP *keywords* < */ options* > ;
PLOT *analysis-variable*group-variable* < *(block-variables)* > < *=symbol-variable* > < */ options* > ;

Both the PROC BOXPLOT and PLOT statements are required. You can specify any number of PLOT statements within a single PROC BOXPLOT invocation.

PROC BOXPLOT Statement

PROC BOXPLOT *options* ;

The PROC BOXPLOT statement starts the BOXPLOT procedure. The following options can appear in the PROC BOXPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an ANNOTATE= type data set, as described in *SAS/GRAPH: Reference*, which enhances traditional graphics box plots requested in subsequent PLOT statements. **NOTE:** The ANNOTATE= option is ignored when ODS Graphics is enabled.

BOX=*SAS-data-set*

names an input data set containing group summary statistics and outlier values. Typically, this data set is created as an OUTBOX= data set in a previous run of PROC BOXPLOT. Each group summary statistic or outlier value is recorded in a separate observation in a BOX= data set, so there are multiple observations per group. You cannot use a BOX= data set together with a DATA= or HISTORY= data set. If you do not specify one of these input data sets, the procedure uses the most recently created SAS data set as a DATA= data set.

DATA=*SAS-data-set*

names an input data set containing raw data to be analyzed. You cannot use a DATA= data set together with a BOX= or HISTORY= data set. If you do not specify one of these input data sets, the procedure uses the most recently created SAS data set as a DATA= data set.

GOUT=< *libref.* >*output catalog*

specifies the SAS catalog in which to save traditional graphics output that is produced by the BOXPLOT procedure. If you omit the libref, PROC BOXPLOT looks for the catalog in the temporary library called WORK and creates the catalog if it does not exist. **NOTE:** The GOUT= option is ignored when ODS Graphics is enabled.

HISTORY=*SAS-data-set*
HIST=*SAS-data-set*

names an input data set containing group summary statistics. Typically, this data set is created as an OUTHISTORY= data set in a previous run of PROC BOXPLOT, but it can also be created using a SAS summarization procedure such as the MEANS procedure. The HISTORY= data set can contain only one observation for each value of the group variable. You cannot use a HISTORY= data set with a DATA= or BOX= data set. If you do not specify one of these three input data sets, PROC BOXPLOT uses the most recently created data set as a DATA= data set.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC BOXPLOT to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the BOXPLOT procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

ID Statement

ID *variables* **;**

The ID statement specifies variables used to identify observations. The ID variables must be variables in the input data set.

If you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option, the value of an ID variable is used to label each extreme observation. When you specify a BOX= data set, the label values come from the variable _ID_, if it is present in the data set. When you specify a DATA= or HISTORY= input data set, or a BOX= data set that does not contain the variable _ID_, the labels come from the first variable listed in the ID statement. If ID statement is specified, the outliers are not labeled.

INSET Statement

INSET *keywords* < / options > **;**

A PLOT statement in the BOXPLOT procedure can be followed by a series of INSET and INSETGROUP statements. Each INSET statement in that series produces one inset in the box plot produced by the preceding PLOT statement. If the box plot occupies multiple panels, the inset appears on each panel.

The data requested using the *keywords* are displayed in the order in which they are specified. Summary statistics requested with an INSET statement are calculated using the observations in all groups.

keywords identify summary statistics or other data to be displayed in the inset. By default, inset statistics are identified with appropriate labels, and numeric values are printed using appropriate formats. However, you can provide customized labels and formats. You provide the customized label by specifying the *keyword* for that statistic followed by an equal sign (=) and the label in quotes. Labels can have up to 24 characters. You provide the numeric format in parentheses after the *keyword*. Note that if you specify both a label and a format for a statistic, the label must appear before the format.

The available keywords are listed in Table 25.1.

options control the appearance of the inset. Most of these options apply only to traditional graphics and are ignored when ODS Graphics is enabled. Table 25.2 lists all the INSET statement options and identifies those that are valid when ODS Graphics is enabled. Complete descriptions for each option follow.

Table 25.1 INSET Statement Keywords

Keyword	Description
DATA=	(label, value) pairs from *SAS-data-set*
MEAN	mean of all observations
MIN	minimum observed value
MAX	maximum observed value
NMIN	minimum group size
NMAX	maximum group size
NOBS	number of observations in box plot
STDDEV	pooled standard deviation

The DATA= keyword specifies a SAS data set containing (label, value) pairs to be displayed in an inset. The data set must contain the variables _LABEL_ and _VALUE_. _LABEL_ is a character variable of up to 24 characters whose values provide labels for inset entries. _VALUE_ can be character or numeric, and provides values displayed in the inset. The label and value from each observation in the DATA= data set occupy one line in the inset.

The *pooled standard deviation* requested with the STDDEV keyword is defined as

$$s_p = \sqrt{\frac{\sum_{i=1}^{N} s_i^2 (n_i - 1)}{\sum_{i=1}^{N} (n_i - 1)}}$$

where N is the number of groups, n_i is the size of the ith group, and s_i^2 is the variance of the ith group.

Table 25.2 INSET Statement Options

Option	Description	ODS Graphics
CFILL=	specifies color of inset background	
CFILLH=	specifies color of inset header background	
CFRAME=	specifies color of inset frame	
CHEADER=	specifies color of inset header text	
CSHADOW=	specifies color of inset drop shadow	
CTEXT=	specifies color of inset text	
DATA	specifies data units for POSITION=(x, y) coordinates	
FONT=	specifies font of inset text	
FORMAT=	specifies format of values in inset	✓
HEADER=	specifies inset header text	✓
HEIGHT=	specifies height of inset and header text	
NOFRAME	suppresses frame around inset	✓
POSITION=	specifies position of inset	✓
REFPOINT=	specifies reference point of inset positioned with POSITION=(x, y) coordinates	

Following are descriptions of the options that you can specify in the INSET statement after a slash (/). Only those options marked with † are applicable when ODS Graphics is enabled.

CFILL=*color* | **BLANK**

specifies the color of the inset background (including the header background if you do not specify the CFILLH= option).

If you do not specify the CFILL= option, then by default the background is empty. This means that items that overlap the inset (such as box-and-whiskers plots or reference lines) show through the inset. If you specify any value for the CFILL= option, then overlapping items no longer show through the inset. Specify CFILL=BLANK to leave the background uncolored and also to prevent items from showing through the inset.

CFILLH=*color*

specifies the color of the header background. By default, if you do not specify a CFILLH= color, the CFILL= color is used.

CFRAME=*color*

specifies the color of the frame around the inset. By default, the frame is the same color as the axis of the plot.

CHEADER=*color*

specifies the color of the header text. By default, if you do not specify a CHEADER= color, the INSET statement CTEXT= color is used.

CSHADOW=*color*

CS=*color*

specifies the color of the drop shadow. If you do not specify the CSHADOW= option, a drop shadow is not displayed.

CTEXT=*color*

CT=*color*

specifies the color of the text in the inset. By default, the inset text color is the same as the other text in the box plot.

DATA

specifies that data coordinates be used in positioning the inset with the POSITION= option. The DATA option is available only when you specify POSITION= (x, y), and it must be placed immediately after the coordinates (x, y). See the entry for the POSITION= option.

FONT=*font*

specifies the font of the text.

† FORMAT=*format*

specifies a format for all the values displayed in an inset. If you specify a format for a particular statistic, then this format overrides the format you specified with the FORMAT= option.

† HEADER='*string***'**

specifies the header text. The *string* can be up to 40 characters. If you do not specify the HEADER= option, no header line appears in the inset.

HEIGHT=*value*

specifies the height of the inset and header text.

† NOFRAME

suppresses the frame drawn around the inset.

† POSITION=*position*

† POS=*position*

determines the position of the inset. The *position* can be a compass point keyword, a margin keyword, or (for traditional graphics) a pair of coordinates (x, y). You can specify coordinates in axis percent units or axis data units. For more information, see the section "Positioning Insets" on page 958. By default, POSITION=NW, which positions the inset in the upper-left (northwest) corner of the plot.

REFPOINT=BR | BL | TR | TL

RP=BR | BL | TR | TL

specifies the reference point for an inset that is positioned by a pair of coordinates with the POSITION= option. Use the REFPOINT= option with POSITION= coordinates. The REFPOINT= option specifies which corner of the inset frame you want positioned at coordinates (x, y). The keywords

BL, BR, TL, and TR represent bottom left, bottom right, top left, and top right, respectively. The default is REFPOINT=BL.

If you specify the position of the inset as a compass point or margin keyword, the REFPOINT= option is ignored.

INSETGROUP Statement

INSETGROUP *keywords* < / options > **;**

A PLOT statement in the BOXPLOT procedure can be followed by a series of INSET and INSETGROUP statements. Each INSETGROUP statement in that series displays statistics associated with individual groups in the box plot produced by the preceding PLOT statement. No more than two INSETGROUP statements can be associated with a given PLOT statement: one that displays group statistics above the box plot and one that displays group statistics below it. The data requested using the *keywords* are displayed in the order in which they are specified.

keywords identify summary statistics to be displayed in the insets. By default, inset statistics are identified with appropriate labels, and numeric values are printed using appropriate formats. However, you can provide customized labels and formats. You provide the customized label by specifying the *keyword* for that statistic followed by an equal sign (=) and the label in quotes. Labels can have up to 24 characters. You provide the numeric format in parentheses after the *keyword*. Note that if you specify both a label and a format for a statistic, the label must appear before the format. The keywords are listed in Table 25.3.

options control the appearance of the insets. Table 25.4 lists all the options in the INSETGROUP statement. Complete descriptions for each option follow.

Table 25.3 INSETGROUP Statement Keywords

Keyword	Description
MEAN	group mean
MIN	group minimum value
MAX	group maximum value
N	number of observations in group
NHIGH	number of outliers above upper fence
NLOW	number of outliers below lower fence
NOUT	total number of outliers in group
Q1	first quartile of group values
Q2	second quartile of group values
Q3	third quartile of group values
RANGE	range of group values
STDDEV	group standard deviation

Table 25.4 lists the options available in the INSETGROUP statement. All of these options apply to traditional graphics only. They are ignored when ODS Graphics is enabled.

Table 25.4 INSETGROUP Statement Options

Option	Description
CFILL=	specifies color of inset background
CFILLH=	specifies color of inset header background
CFRAME=	specifies color of inset frame
CHEADER=	specifies color of inset header text
CTEXT=	specifies color of inset text
FONT=	specifies font of inset text
FORMAT=	specifies format of values in inset
HEADER=	specifies inset header text
HEIGHT=	specifies height of inset and header text
NOFRAME	suppresses frame around inset
POSITION=	specifies position of inset

Following are descriptions of the options that you can specify in the INSETGROUP statement after a slash (/).

CFILL=*color*

specifies the color of the inset background (including the header background if you do not specify the CFILLH= option). If you do not specify the CFILL= option, then by default the background is empty.

CFILLH=*color*

specifies the color of the header background. By default, if you do not specify a CFILLH= color, the CFILL= color is used.

CFRAME=*color*

specifies the color of the frame around the inset. By default, the frame is the same color as the axis of the plot.

CHEADER=*color*

specifies the color of the header text. By default, if you do not specify a CHEADER= color, the CTEXT= color is used.

CTEXT=*color*

CT=*color*

specifies the color of the inset text. By default, the inset text color is the same as the other text in the plot.

FONT=*font*

specifies the font of the inset text. By default, the font is SIMPLEX.

FORMAT=*format*

specifies a format for all the values displayed in an inset. If you specify a format for a particular statistic, then this format overrides the format you specified with the FORMAT= option.

HEADER='*string*'
specifies the header text. The *string* can be up to 40 characters. If you do not specify the HEADER= option, no header line appears in the inset.

HEIGHT=*value*
specifies the height of the inset and header text.

NOFRAME
suppresses the frame drawn around the inset.

POSITION=*position*

POS=*position*
determines the position of the inset. Valid positions are TOP, TOPOFF, AXIS, and BOTTOM. By default, POSITION=TOP.

Position Keyword	Description
TOP	top of plot, immediately above axis frame
TOPOFF	top of plot, offset from axis frame
AXIS	bottom of plot, immediately above horizontal axis
BOTTOM	bottom of plot, below horizontal axis label

PLOT Statement

PLOT *(analysis-variables)*group-variable < (block-variables)> < =symbol-variable> < / options >*
;

You can specify multiple PLOT statements after the PROC BOXPLOT statement. The components of the PLOT statement are as follows:

analysis-variables identify one or more variables to be analyzed. An analysis variable is required. If you specify more than one analysis variable, enclose the list in parentheses. For example, the following statements request distinct box plots for the variables Weight, Length, and Width:

```
proc boxplot data=Summary;
   plot (Weight Length Width)*Day;
run;
```

group-variable specifies the variable that identifies groups in the data. The group variable is required. In the preceding PLOT statement, Day is the group variable.

block-variables specify optional variables that group the data into blocks of consecutive groups. These blocks are labeled in a legend, and each block variable provides one level of labels in the legend.

symbol-variable specifies an optional variable whose levels (unique values) determine the symbol marker used to plot the means. Distinct symbol markers are displayed for points corresponding to the various levels of the symbol variable. You can specify the symbol markers with SYMBOL*n* statements (refer to *SAS/GRAPH: Reference* for complete details).

options enhance the appearance of the box plot, request additional analyses, save results in data sets, and so on. Complete descriptions of each option follow.

Many PLOT statement options apply only to traditional graphics and are ignored when ODS Graphics is enabled. Table 25.5 lists all the PLOT statement options by function and indicates which are applicable with ODS Graphics.

PLOT Statement Options

Table 25.5 PLOT Statement Options

Option	Description	ODS Graphics
Options for Controlling Box Appearance		
BOXCONNECT=	connects features of adjacent box-and-whiskers plots with line segments	✓
BOXSTYLE=	specifies style of box-and-whiskers plots	✓
BOXWIDTH=	specifies width of box-and-whiskers plots	
BOXWIDTHSCALE=	specifies that widths of box-and-whiskers plots vary proportionately to group size	✓
CBOXES=	specifies color for outlines of box-and-whiskers plots	
CBOXFILL=	specifies fill color for interior of box-and-whiskers plots	
IDCOLOR=	specifies outlier symbol color in schematic box-and-whiskers plots	
IDCTEXT=	specifies outlier label color in schematic box-and-whiskers plots	
IDFONT=	specifies outlier label font in schematic box-and-whiskers plots	
IDHEIGHT=	specifies outlier label height in schematic box-and-whiskers plots	
IDSYMBOL=	specifies outlier symbol in schematic box-and-whiskers plots	
LBOXES=	specifies line types for outlines of box-and-whiskers plots	
NOSERIFS	eliminates serifs from whiskers of box-and-whiskers plots	✓
NOTCHES	specifies that box-and-whiskers plots be notched	✓
PCTLDEF=	specifies percentile definition used for box-and-whiskers plots	✓
Options for Plotting and Labeling Points		
ALLLABEL=	labels means of box-and-whiskers plots	
CLABEL=	specifies color for labels requested with ALLLABEL= option	
CCONNECT=	specifies color for line segments requested with BOXCONNECT= option	
LABELANGLE=	specifies angle for labels requested with ALLLABEL= option	
SYMBOLLEGEND=	specifies LEGEND statement for levels of symbol variable	
SYMBOLORDER=	specifies order in which symbols are assigned for levels of symbol variable	

Table 25.5 *continued*

Option	Description	ODS Graphics
Reference Line Options		
CHREF=	specifies color for lines requested by HREF= option	
CVREF=	specifies color for lines requested by VREF= option	
FRONTREF	draws reference lines in front of boxes	
HREF=	requests reference lines perpendicular to horizontal axis	✓
HREFLABELS=	specifies labels for HREF= lines	✓
HREFLABPOS=	specifies position of HREFLABELS= labels	
LHREF=	specifies line type for HREF= lines	
LVREF=	specifies line type for VREF= lines	
NOBYREF	specifies that reference line information in a data set be applied uniformly to plots created for all BY groups	✓
VREF=	requests reference lines perpendicular to vertical axis	✓
VREFLABELS=	specifies labels for VREF= lines	✓
VREFLABPOS=	specifies position of VREFLABELS= labels	
Block Variable Legend Options		
BLOCKLABELPOS=	specifies position of label for block variable legend	
BLOCKLABTYPE=	specifies text size of block variable legend	
BLOCKPOS=	specifies vertical position of block variable legend	✓
BLOCKREP	repeats identical consecutive labels in block variable legend	✓
CBLOCKLAB=	specifies colors for filling frames enclosing block variable labels	
CBLOCKVAR=	specifies colors for filling background of block variable legend	
Axis and Axis Label Options		
CAXIS=	specifies color for axis lines and tick marks	
CFRAME=	specifies fill color for frame for plot area	
CONTINUOUS	produces horizontal axis for continuous group variable values (traditional graphics only)	
CTEXT=	specifies color for tick mark values and axis labels	
HAXIS=	specifies major tick mark values for horizontal axis	
HEIGHT=	specifies height of axis label and axis legend text	
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis	
HOFFSET=	specifies length of offset at both ends of horizontal axis	
NOHLABEL	suppresses horizontal axis label	✓
NOTICKREP	specifies that only first occurrence of repeated, adjacent character group values be labeled on horizontal axis	
NOVANGLE	requests vertical axis labels that are strung out vertically	
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis	
TURNHLABELS	requests horizontal tick labels that are strung out vertically	
VAXIS=	specifies major tick mark values for vertical axis	✓
VFORMAT=	specifies format for vertical axis tick marks	✓

Table 25.5 *continued*

Option	Description	ODS Graphics
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis	
VOFFSET=	specifies length of offset at both ends of vertical axis	
VZERO	forces origin to be included in vertical axis	
WAXIS=	specifies width of axis lines	
Input Data Set Options		
MISSBREAK	specifies that a missing value between identical character group values signify the start of a new group	✓
Output Data Set Options		
OUTBOX=	produces an output data set containing group summary statistics and outlier values	✓
OUTHISTORY=	produces an output data set containing group summary statistics	✓
Graphical Enhancement Options		
ANNOTATE=	specifies annotate data set that adds features to box plot	
BWSLEGEND	displays a legend identifying the function of group size specified with BOXWIDTHSCALE= option	
DESCRIPTION=	specifies string that appears in description field of PROC GREPLAY master menu for high-resolution graphics box plot	
FONT=	specifies font for labels and legends on plots	
HORIZONTAL	requests a horizontal box plot with ODS Graphics	✓
HTML=	specifies URLs to be associated with box-and-whiskers plots	
NAME=	specifies name that appears in name field of PROC GREPLAY master menu for high-resolution graphics box plot	
NLEGEND	requests legend displaying group sizes	
OUTHIGHHTML=	specifies URLs to be associated with high outliers on box-and-whiskers plots	
OUTLOWHTML=	specifies URLs to be associated with low outliers on box-and-whiskers plots	
PAGENUM=	specifies form of label used in pagination	
PAGENUMPOS=	specifies position of page number requested with PAGENUM= option	
Grid Options		
CGRID=	specifies color for grid requested with ENDGRID or GRID option	
ENDGRID	adds grid after last box-and-whiskers plot	
GRID	adds grid to box plot	✓
LENDGRID=	specifies line type for grid requested with ENDGRID option	
LGRID=	specifies line type for grid requested with GRID option	
WGRID=	specifies width of grid lines	

Table 25.5 *continued*

Option	Description	ODS Graphics
Plot Layout Options		
INTERVAL=	specifies natural time interval between consecutive group positions when time, date, or datetime format is associated with numeric group variable	
INTSTART=	specifies first major tick mark value on horizontal axis when date, time, or datetime format is associated with numeric group variable	
MAXPANELS=	specifies maximum number of panels used for box plot	✓
NOCHART	suppresses creation of box plot	✓
NOFRAME	suppresses frame for plot area	
NPANELPOS=	specifies number of group positions per panel	✓
REPEAT	repeats last group position on panel as first group position of next panel	✓
TOTPANELS=	specifies number of panels to be used to display box plot	✓
Overlay Options		
CCOVERLAY=	specifies colors for line segments connecting points on overlays	
COVERLAY=	specifies colors for points on overlays	
LOVERLAY=	specifies line types for line segments connecting points on overlays	
NOOVERLAYLEGEND	suppresses overlay legend	✓
OVERLAY=	specifies variables to be plotted on overlays	✓
OVERLAYHTML=	specifies URLs to be associated with overlay plot points	
OVERLAYID=	specifies labels for overlay plot points	
OVERLAYLEGLAB=	specifies label for overlay legend	✓
OVERLAYSYM=	specifies symbols used for overlays	
OVERLAYSYMHT=	specifies heights for overlay symbols	
WOVERLAY=	specifies widths for line segments connecting points on overlays	
Clipping Options		
CCLIP=	specifies color for plot symbol for clipped points	
CLIPFACTOR=	determines extent to which extreme values are clipped	
CLIPLEGEND=	specifies text for clipping legend	
CLIPLEGPOS=	specifies position of clipping legend	
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text	
CLIPSYMBOL=	specifies plot symbol for clipped points	
CLIPSYMBOLHT=	specifies symbol marker height for clipped points	
COVERLAYCLIP=	specifies color for clipped points on overlays	
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays	
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays	

Table 25.5 *continued*

Option	Description	ODS Graphics
Options for Box Plots Produced Using Styles		
BLOCKVAR=	groups block legends whose backgrounds are filled with colors from style	✓
BOXES=	groups boxes whose outlines are drawn with colors from style	
BOXFILL=	groups boxes that are filled with colors from style	

Following are explanations of the options you can specify in the PLOT statement after a slash (/). Only those options marked with † are applicable when ODS Graphics is enabled.

ALLLABEL=VALUE | (*variable*)
labels the point plotted for the mean of each box-and-whiskers plot with its VALUE or with the value of a *variable* in the input data set.

ANNOTATE=*SAS-data-set*
specifies an ANNOTATE= type data set, as described in *SAS/GRAPH: Reference*.

BLOCKLABELPOS=ABOVE | LEFT
specifies the position of a block variable label in the block legend. The keyword ABOVE places the label immediately above the legend, and LEFT places the label to the left of the legend. Use the keyword LEFT with labels that are short enough to fit in the margin of the plot; otherwise, they are truncated. The default keyword is ABOVE.

BLOCKLABTYPE=SCALED | TRUNCATED
BLOCKLABTYPE=*height*
specifies how lengthy block variable values are treated when there is insufficient space to display them in the block legend. If you specify BLOCKLABTYPE=SCALED, the values are uniformly reduced in height so that they fit. If you specify BLOCKLABTYPE=TRUNCATED, lengthy values are truncated on the right until they fit. You can also specify a text height in vertical percent screen units for the values. By default, lengthy values are not displayed. For more information, see the section "Displaying Blocks of Data" on page 963.

† BLOCKPOS=*n*
specifies the vertical position of the legend for the values of the block variables. Values of *n* and the corresponding positions are as follows. By default, BLOCKPOS=1.

n	Legend Position
1	top of plot, offset from axis frame
2	top of plot, immediately above axis frame
3	bottom of plot, immediately above horizontal axis
4	bottom of plot, below horizontal axis label

† BLOCKREP
specifies that block variable values for all groups be displayed. By default, only the first block variable value in any block is displayed, and repeated block variable values are not displayed.

† BLOCKVAR=*variable* **|** **(***variable-list***)**

specifies variables whose values are used to assign colors for filling the background of the legend associated with block variables. A list of BLOCKVAR= variables must be enclosed in parentheses. BLOCKVAR= variables are matched with block variables by their order in the respective variable lists. While the values of a CBLOCKVAR= variable are color names, values of a BLOCKVAR= variable are used to group block legends for assigning fill colors from the ODS style. Block legends with the same BLOCKVAR= variable value are filled with the same color.

† BOXCONNECT=MEAN | MEDIAN | MAX | MIN | Q1 | Q3

† BOXCONNECT

specifies that the points in adjacent box-and-whiskers plots representing group means, medians, maximum values, minimum values, first quartiles, or third quartiles be connected with line segments. If the BOXCONNECT option is specified without a keyword identifying the points to be connected, group means are connected. By default, no points are connected.

BOXES=(*variable***)**

specifies a variable whose values are used to assign colors for the outlines of box-and-whiskers plots. While the values of a CBOXES= variable are color names, values of the BOXES= variable are used to group box-and-whiskers plots for assigning outline colors from the ODS style. The outlines of box-and-whiskers plots of groups with the same BOXES= variable value are drawn using the same color.

BOXFILL=(*variable***)**

specifies a variable whose values are used to assign fill colors for box-and-whiskers plots. While the values of a CBOXFILL= variable are color names, values of the BOXFILL= variable are used to group box-and-whiskers plots for assigning fill colors from the ODS style. Box-and-whiskers plots of groups with the same BOXFILL= variable value are filled with the same color.

† BOXSTYLE=*keyword*

specifies the style of the box-and-whiskers plots displayed. If you specify BOXSTYLE=SKELETAL, the whiskers are drawn from the edges of the box to the extreme values of the group. This plot is sometimes referred to as a skeletal box-and-whiskers plot. By default, the whiskers are drawn with serifs. You can specify the NOSERIFS option to draw the whiskers without serifs.

In the following descriptions, the terms *fence* and *far fence* refer to the distance from the first and third quartiles (25th and 75th percentiles, respectively), expressed in terms of the interquartile range (IQR). For example, the lower fence is located at $1.5 \times$ IQR below the 25th percentile; the upper fence is located at $1.5 \times$ IQR above the 75th percentile. Similarly, the lower far fence is located at $3 \times$ IQR below the 25th percentile; the upper far fence is located at $3 \times$ IQR above the 75th percentile.

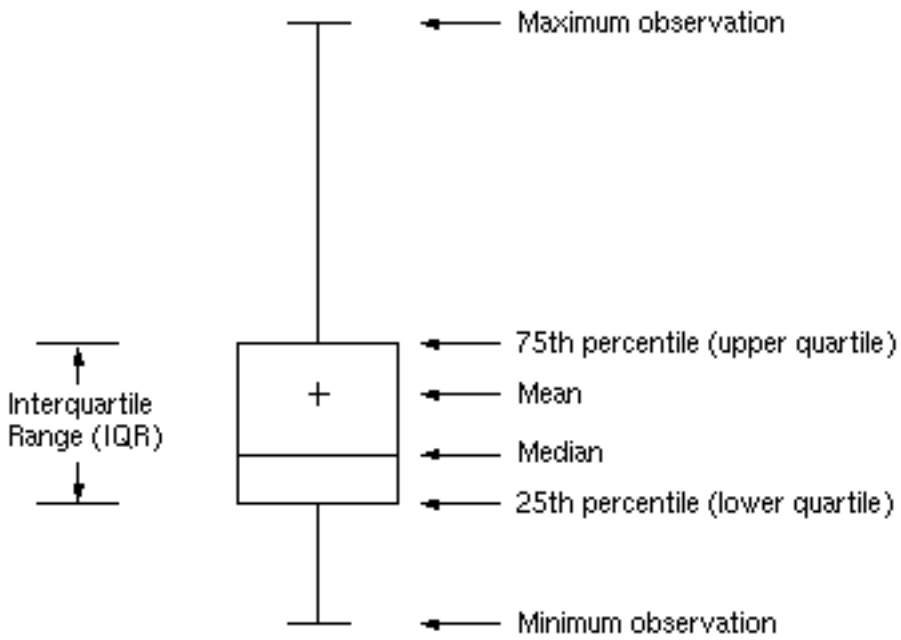
If you specify BOXSTYLE=SCHEMATIC, a whisker is drawn from the upper edge of the box to the largest observed value within the upper fence, and another is drawn from the lower edge of the box to the smallest observed value within the lower fence. Serifs are added to the whiskers by default. Observations outside the fences are identified with a special symbol. For traditional graphics you can specify the shape and color for this symbol with the IDSYMBOL= and IDCOLOR= options. The default symbol is a square. This type of plot corresponds to the schematic box-and-whiskers plot described in Chapter 2 of Tukey (1977). See Figure 25.8 and the discussion in the section "Styles of Box Plots" on page 954 for more information.

If you specify BOXSTYLE=SCHEMATICID, a schematic box-and-whiskers plot is displayed in which an ID variable value is used to label the symbol marking each observation outside the upper and lower fences. A BOX= data set can contain a variable named _ID_ that is used as the ID variable. Otherwise, the first variable listed in the ID statement provides the labels.

If you specify BOXSTYLE=SCHEMATICIDFAR, a schematic box-and-whiskers plot is displayed in which the value of the ID variable is used to label the symbol marking each observation outside the lower and upper far fences. Observations between the fences and the far fences are identified with a symbol but are not labeled with the ID variable.

Figure 25.6 illustrates the elements of a skeletal box-and-whiskers plot.

Figure 25.6 Skeletal Box-and-Whiskers Plot



The skeletal style of the box-and-whiskers plot shown in Figure 25.6 is the default.

BOXWIDTH=*value*

specifies the width (in horizontal percent screen units) of the box-and-whiskers plots.

† BOXWIDTHSCALE=*value*

specifies that the box-and-whiskers plot width is to vary proportionately to a particular function of the group size n. The function is determined by the *value*.

If you specify a positive value, the widths are proportional to n^{value}. In particular, if you specify BOXWIDTHSCALE=1, the widths are proportional to the group size. If you specify BOXWIDTHSCALE=0.5, the widths are proportional to $\sqrt{n}$, as described by McGill, Tukey, and Larsen (1978). If you specify BOXWIDTHSCALE=0, the widths are proportional to $\log(n)$. See Example 25.4 for an illustration of the BOXWIDTHSCALE= option.

You can specify the BWSLEGEND option to display a legend identifying the function of n used to determine the box-and-whiskers plot widths.

By default, the box widths are constant.

BWSLEGEND
displays a legend identifying the function of group size n specified with the BOXWIDTHSCALE= option. No legend is displayed if all group sizes are equal. The BWSLEGEND option is not applicable unless you also specify the BOXWIDTHSCALE= option.

CAXIS=*color*

CAXES=*color*

CA=*color*
specifies the color for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement.

CBLOCKLAB=*color* | **(***color-list***)**
specifies fill colors for the frames that enclose the block variable labels in a block legend. By default, these areas are not filled. Colors in the CBLOCKLAB= list are matched with block variables in the order in which they appear in the PLOT statement.

CBLOCKVAR=*variable* | **(***variable-list***)**
specifies variables whose values are colors for filling the background of the legend associated with block variables. CBLOCKVAR= variables are matched with block variables by their order in the respective variable lists. Each CBLOCKVAR= variable must be a character variable of no more than eight characters in the input data set, and its values must be valid SAS/GRAPH color names (refer to *SAS/GRAPH: Reference* for complete details). A list of CBLOCKVAR= variables must be enclosed in parentheses.

The procedure matches the CBLOCKVAR= variables with block variables in the order specified. That is, each block legend is filled with the color value of the CBLOCKVAR= variable of the first observation in each block. In general, values of the ith CBLOCKVAR= variable are used to fill the block of the legend corresponding to the ith block variable.

By default, fill colors are not used for the block variable legend. The CBLOCKVAR= option is available only when block variables are used in the PLOT statement.

CBOXES=*color* | **(***variable***)**
specifies the colors for the outlines of the box-and-whiskers plots created with the PLOT statement. You can use one of the following approaches:

- You can specify CBOXES=*color* to provide a single outline color for all the box-and-whiskers plots.
- You can specify CBOXES=*(variable)* to provide a distinct outline color for each box-and-whiskers plot as the value of the variable. The variable must be a character variable of up to eight characters in the input data set, and its values must be valid SAS/GRAPH color names (refer to *SAS/GRAPH: Reference* for complete details). The outline color of the plot displayed for a particular group is the value of the variable in the observations corresponding to this group. Note that if there are multiple observations per group in the input data set, the values of the variable should be identical for all the observations in a given group.

CBOXFILL=*color* | **(***variable***)**
specifies the interior fill colors for the box-and-whiskers plots. You can use one of the following approaches:

- You can specify CBOXFILL=*color* to provide a single color for all of the box-and-whiskers plots.
- You can specify CBOXFILL=*(variable)* to provide a distinct color for each box-and-whiskers plot as the value of the variable. The variable must be a character variable of up to eight characters in the input data set, and its values must be valid SAS/GRAPH color names (or the value EMPTY, which you can use to suppress color filling). Refer to *SAS/GRAPH: Reference* for complete details. The interior color of the box displayed for a particular group is the value of the variable in the observations corresponding to this group. Note that if there are multiple observations per group in the input data set, the values of the variable should be identical for all the observations in a given group.

By default, the interiors are not filled.

CCLIP=*color*
specifies a color for the plotting symbol that is specified with the CLIPSYMBOL= option to mark clipped values. The default color is the color specified in the COLOR= option in the SYMBOL1 statement.

CCONNECT=*color*
specifies the color for line segments connecting points on the plot. The default color is the color specified in the COLOR= option in the SYMBOL1 statement. This option is not applicable unless you also specify the BOXCONNECT= option.

CCOVERLAY=(*color-list***)**
specifies the colors for line segments connecting points on overlay plots. Colors in the CCOVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list. By default, points are connected by line segments of the same color as the plotted points. You can specify the value NONE to suppress the line segments connecting points of an overlay plot.

CFRAME=*color*
specifies the color for filling the rectangle enclosed by the axes and the frame. By default, this area is not filled. The CFRAME= option cannot be used in conjunction with the NOFRAME option.

CGRID=*color*
specifies the color for the grid requested by the ENDGRID or GRID option. By default, the grid is the same color as the axes.

CHREF=*color*
specifies the color for the lines requested by the HREF= option.

CLABEL=*color*
specifies the color for labels produced by the ALLLABEL= option. The default color is the CTEXT= color.

CLIPFACTOR=*factor*

requests clipping of extreme values on the box plot. The *factor* that you specify determines the extent to which these values are clipped, and it must be greater than 1.

For examples of the CLIPFACTOR= option, see Figure 25.17 and Figure 25.18. Related clipping options are CCLIP=, CLIPLEGEND=, CLIPLEGPOS=, CLIPSUBCHAR=, and CLIPSYMBOL=.

CLIPLEGEND='*label***'**

specifies the *label* for the legend that indicates the number of clipped boxes when the CLIPFACTOR= option is used. The *label* must be no more than 16 characters and must be enclosed in quotes. For an example, see Figure 25.18.

CLIPLEGPOS= TOP | BOTTOM

specifies the position for the legend that indicates the number of clipped boxes when the CLIPFACTOR= option is used. The keyword TOP or BOTTOM positions the legend at the top or bottom of the chart, respectively. Do not specify CLIPLEGPOS=TOP together with the BLOCKPOS=1 or BLOCKPOS=2 option. By default, CLIPLEGPOS=BOTTOM.

CLIPSUBCHAR='*character***'**

specifies a substitution character (such as '#') for the label provided with the CLIPLEGEND= option. The substitution character is replaced with the number of boxes that are clipped. For example, suppose that the following statements produce a chart in which three boxes are clipped:

```
proc boxplot data=Pistons;
   plot Diameter*Hour /
      clipfactor  = 1.5
      cliplegend  = 'Boxes clipped=#'
      clipsubchar = '#' ;
run;
```

Then the clipping legend displayed on the chart will be "Boxes clipped=3".

CLIPSYMBOL=*symbol*

specifies a plot symbol used to identify clipped points on the chart and in the legend when the CLIPFACTOR= option is used. You should use this option in conjunction with the CLIPFACTOR= option. The default *symbol* is CLIPSYMBOL=SQUARE.

CLIPSYMBOLHT=*value*

specifies the height for the symbol marker used to identify clipped points on the chart when the CLIPFACTOR= option is used. The default is the height specified with the H= option in the SYMBOL statement.

For general information about clipping options, refer to the section "Clipping Extreme Values" on page 965.

CONTINUOUS

specifies that numeric group variable values be treated as continuous values. By default, the values of a numeric group variable are considered discrete values unless the HAXIS= option is specified. **NOTE:** The CONTINUOUS option is not supported for ODS Graphics output. For more information, see the discussion in the section "Continuous Group Variables" on page 956.

COVERLAY=(*color-list*)
specifies the colors used to plot overlay variables. Colors in the COVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list.

COVERLAYCLIP=*color*
specifies the color used to plot clipped values on overlay plots when the CLIPFACTOR= option is used.

CTEXT=*color*
specifies the color for tick mark values and axis labels. The default color is the color specified in the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*
specifies the color for the lines requested by the VREF= option.

DESCRIPTION=‘*string*’
DES=‘*string*’
specifies a description of a box plot produced with high-resolution graphics. The description appears in the PROC GREPLAY master menu and can be no longer than 256 characters. The default description is the analysis variable name.

ENDGRID
adds a grid to the rightmost portion of the plot, beginning with the first labeled major tick mark position that follows the last box-and-whiskers plot. You can use the HAXIS= option to force space to be added to the horizontal axis.

FONT=*font*
specifies a font for labels and legends. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the GOPTIONS statement. Refer to *SAS/GRAPH: Reference* for more information about the GOPTIONS statement.

FRONTREF
draws reference lines specified with the HREF= and VREF= options in front of box-and-whiskers plots. By default, reference lines are drawn behind the box-and-whiskers plots and can be obscured by filled boxes.

† GRID
adds a grid to the box plot. Grid lines are horizontal lines positioned at labeled major tick marks, and they cover the length and height of the plotting area.

HAXIS=*value-list*
HAXIS=AXIS*n*
specifies tick mark values for the horizontal (group) axis. If the group variable is numeric, the values must be numeric and equally spaced. If the group variable is character, values must be quoted strings of up to 16 characters. Optionally, you can specify an axis name defined in a previous AXIS statement. Refer to *SAS/GRAPH: Reference* for more information about the AXIS statement.

If you are producing traditional graphics, specifying the HAXIS= option with a numeric group variable causes the group variable values to be treated as continuous values. For more information, see the description of the CONTINUOUS option and the discussion in the section “Continuous Group

Variables" on page 956. Numeric values can be given in an explicit or implicit list. If a date, time, or datetime format is associated with a numeric group variable, SAS datetime literals can be used. Examples of HAXIS= lists follow:

- haxis=0 2 4 6 8 10
- haxis=0 to 10 by 2
- haxis='LT12A' 'LT12B' 'LT12C' 'LT15A' 'LT15B' 'LT15C'
- haxis='20MAY88'D to '20AUG88'D by 7
- haxis='01JAN88'D to '31DEC88'D by 30

If the group variable is numeric, the HAXIS= list must span the group variable values. If the group variable is character, the HAXIS= list must include all of the group variable values. You can add group positions to the box plot by specifying HAXIS= values that are not group variable values.

If you specify a large number of HAXIS= values, some of these can be thinned to avoid collisions between tick mark labels. To avoid thinning, use one of the following methods.

- Shorten values of the group variable by eliminating redundant characters. For example, if your group variable has values LOT1, LOT2, LOT3, and so on, you can use the SUBSTR function in a DATA step to eliminate LOT from each value, and you can modify the horizontal axis label to indicate that the values refer to lots.
- Use the TURNHLABELS option to turn the labels vertically.
- Use the NPANELPOS= option to force fewer group positions per panel.

HEIGHT=*value*

specifies the height (in vertical screen percent units) of the text for axis labels and legends. This value takes precedence over the HTEXT= value specified in the GOPTIONS statement. This option is recommended for use with fonts specified with the FONT= option or with the FTEXT= option in the GOPTIONS statement. Refer to *SAS/GRAPH: Reference* for complete information about the GOPTIONS statement.

HMINOR=*n*

HM=*n*

specifies the number of minor tick marks between major tick marks on the horizontal axis. Minor tick marks are not labeled. The default is HMINOR=0.

HOFFSET=*value*

specifies the length (in percent screen units) of the offset at both ends of the horizontal axis. You can eliminate the offset by specifying HOFFSET=0.

† HORIZONTAL

produces a horizontal box plot, with group variable values on the vertical axis and analysis variable values on the horizontal axis. The HORIZONTAL option is supported only with ODS Graphics.

† HREF=*value-list*

HREF=*SAS-data-set*

draws reference lines perpendicular to the horizontal (group) axis on the box plot. You can use this option in the following ways:

- You can specify the values for the lines with an HREF= list. If the group variable is numeric, the values must be numeric. If the group variable is character, the values must be quoted strings of up to 16 characters. If the group variable is formatted, the values must be given as internal values. Examples of HREF= values follow:

```
href=5
href=5 10 15 20 25 30
href='Shift 1' 'Shift 2' 'Shift 3'
```

- You can specify reference line values as the values of a variable named _REF_ in an HREF= data set. The type and length of _REF_ must match those of the group variable specified in the PLOT statement. Optionally, you can provide labels for the lines as values of a variable named _REFLAB_, which must be a character variable of up to 16 characters. If you want distinct reference lines to be displayed in plots for different analysis variables specified in the PLOT statement, you must include a character variable named _VAR_, whose values are the analysis variable names. If you do not include the variable _VAR_, all of the lines are displayed in all of the plots. Each observation in an HREF= data set corresponds to a reference line. If BY variables are used in the input data set, the same BY variable structure must be used in the reference line data set unless you specify the NOBYREF option.

Unless the CONTINUOUS or HAXIS= option is specified, numeric group variable values are treated as discrete values, and only HREF= values matching these discrete values are valid. Other values are ignored.

† HREFLABELS='*label1*' **...** '*labeln*'

† HREFLABEL='*label1*' **...** '*labeln*'

† HREFLAB='*label1*' **...** '*labeln*'

specifies labels for the reference lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of the HREFLABELS= label, as described in the following table. By default, n=2.

HREFLABPOS=	Label Position
1	along top of plot area
2	staggered from top to bottom of plot area
3	along bottom of plot area
4	staggered from bottom to top of plot area

HTML=*variable*

specifies uniform resource locators (URLs) as values of the specified character variable (or formatted values of a numeric variable). These URLs are associated with box-and-whiskers plots when graphics output is directed into HTML. The value of the HTML= variable should be the same for each observation with a given value of the group variable.

IDCOLOR=*color*

specifies the color of the symbol marker used to identify outliers in schematic box-and-whiskers plots

(that is, when you specify the keyword SCHEMATIC, SCHEMATICID, or SCHEMATICIDFAR with the BOXSTYLE= option). The default color is the color specified with the CBOXES= option.

IDCTEXT=*color*
specifies the color for the text used to label outliers when you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option. The default value is the color specified with the CTEXT= option.

IDFONT=*font*
specifies the font for the text used to label outliers when you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option. The default font is SIMPLEX.

IDHEIGHT=*value*
specifies the height for the text used to label outliers when you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option. The default value is the height specified with the HTEXT= option in the GOPTIONS statement. Refer to *SAS/GRAPH: Reference* for complete information about the GOPTIONS statement.

IDSYMBOL=*symbol*
specifies the symbol marker used to identify outliers in schematic box plots. The default symbol is SQUARE.

INTERVAL=DAY | DTDAY | HOUR | MINUTE | MONTH | QTR | SECOND
specifies the natural time interval between consecutive group positions when a time, date, or datetime format is associated with a numeric group variable. By default, the INTERVAL= option uses the number of group positions per panel (screen or page) that you specify with the NPANELPOS= option. The default time interval keywords for various time formats are shown in the following table.

Format	Default Keyword	Format	Default Keyword
DATE	DAY	MONYY	MONTH
DATETIME	DTDAY	TIME	SECOND
DDMMYY	DAY	TOD	SECOND
HHMM	HOUR	WEEKDATE	DAY
HOUR	HOUR	WORDDATE	DAY
MMDDYY	DAY	YYMMDD	DAY
MMSS	MINUTE	YYQ	QTR

You can use the INTERVAL= option to modify the effect of the NPANELPOS= option, which specifies the number of group positions per panel. The INTERVAL= option enables you to match the scale of the horizontal axis to the scale of the group variable without having to associate a different format with the group variable.

For example, suppose that your formatted group values span an overall time interval of 100 days and a DATETIME format is associated with the group variable. Since the default interval for the DATETIME format is DTDAY and since NPANELPOS=25 by default, the plot is displayed with four panels.

Now, suppose that your data span an overall time interval of 100 hours and a DATETIME format is associated with the group variable. The plot for these data is created in a single panel, but the data

occupy only a small fraction of the plot since the scale of the data (hours) does not match that of the horizontal axis (days). If you specify INTERVAL=HOUR, the horizontal axis is scaled for 25 hours, matching the scale of the data, and the plot is displayed with four panels.

You should use the INTERVAL= option only in conjunction with the CONTINUOUS or HAXIS= option, which produces a horizontal axis of continuous group variable values. For more information, see the descriptions of the CONTINUOUS and HAXIS= options, and the discussion in the section "Continuous Group Variables" on page 956.

INTSTART=*value*

specifies the starting value for a numeric horizontal axis when a date, time, or datetime format is associated with the group variable. If the value specified is greater than the first group variable value, this option has no effect.

LABELANGLE=*angle*

specifies the angle at which labels requested with the ALLLABEL= option are drawn. A positive angle rotates the labels counterclockwise; a negative angle rotates them clockwise. By default, labels are oriented horizontally.

LBOXES=*linetype*

LBOXES=(*variable***)**

specifies the line types for the outlines of the box-and-whiskers plots. You can use one of the following approaches:

- You can specify LBOXES=*linetype* to provide a single linetype for all of the box-and-whiskers plots.
- You can specify LBOXES=*(variable)* to provide a distinct line type for each box-and-whiskers plot. The variable must be a numeric variable in the input data set, and its values must be valid SAS/GRAPH linetype values (numbers ranging from 1 to 46). The line type for the plot displayed for a particular group is the value of the variable in the observations corresponding to this group. Note that if there are multiple observations per group in the input data set, the values of the variable should be identical for all of the observations in a given group.

The default value is 1, which produces solid lines. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

LENDGRID=*linetype*

specifies the line type for the grid requested with the ENDGRID option. The default value is 1, which produces a solid line. If you use the LENDGRID= option, you do not need to specify the ENDGRID option. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

LGRID=*linetype*

specifies the line type for the grid requested with the GRID option. The default value is 1, which produces a solid line. If you use the LGRID= option, you do not need to specify the GRID option. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

LHREF=*linetype*

LH=*linetype*

specifies the line type for reference lines requested with the HREF= option. The default value is 2, which produces a dashed line. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

LOVERLAY=(*linetypes***)**

specifies line types for the line segments connecting points on overlay plots. Line types in the LOVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list.

LVREF=*linetype*

LV=*linetype*

specifies the line type for reference lines requested by the VREF= option. The default value is 2, which produces a dashed line. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

† MAXPANELS=*n*

specifies the maximum number of panels used to display a box plot. By default, $n = 20$.

† MISSBREAK

determines how groups are formed when observations are read from a DATA= data set and a character group variable is provided. When you specify the MISSBREAK option, observations with missing values of the group variable are not processed. Furthermore, the next observation with a nonmissing value of the group variable is treated as the beginning observation of a new group even if this value is identical to the most recent nonmissing group value. In other words, by specifying the option MISSBREAK and by inserting an observation with a missing group variable value into a group of consecutive observations with the same group variable value, you can split the group into two distinct groups of observations.

By default (that is, when you omit the MISSBREAK option), observations with missing values of the group variable are not processed, and all remaining observations with the same consecutive value of the group variable are treated as a single group.

NAME='*string*'

specifies a name for the box plot, not more than eight characters, that appears in the PROC GREPLAY master menu.

NLEGEND

requests a legend displaying group sizes. If the size is the same for each group, that number is displayed. Otherwise, the minimum and maximum group sizes are displayed.

† NOBYREF

specifies that the reference line information in an HREF= or VREF= data set be applied uniformly to box plots created for all the BY groups in the input data set. If you specify the NOBYREF option, you do not need to provide BY variables in the reference line data set. By default, you must provide BY variables.

† NOCHART

suppresses the creation of the box plot. You typically specify the NOCHART option when you are using the procedure to compute group summary statistics and save them in an output data set.

NOFRAME

suppresses the default frame drawn around the plot.

† NOHLABEL

suppresses the label for the horizontal (group) axis. Use the NOHLABEL option when the meaning of the axis is evident from the tick mark labels, such as when a date format is associated with the group variable.

† NOOVERLAYLEGEND

suppresses the legend for overlay plots that is displayed by default when the OVERLAY= option is specified.

† NOSERIFS

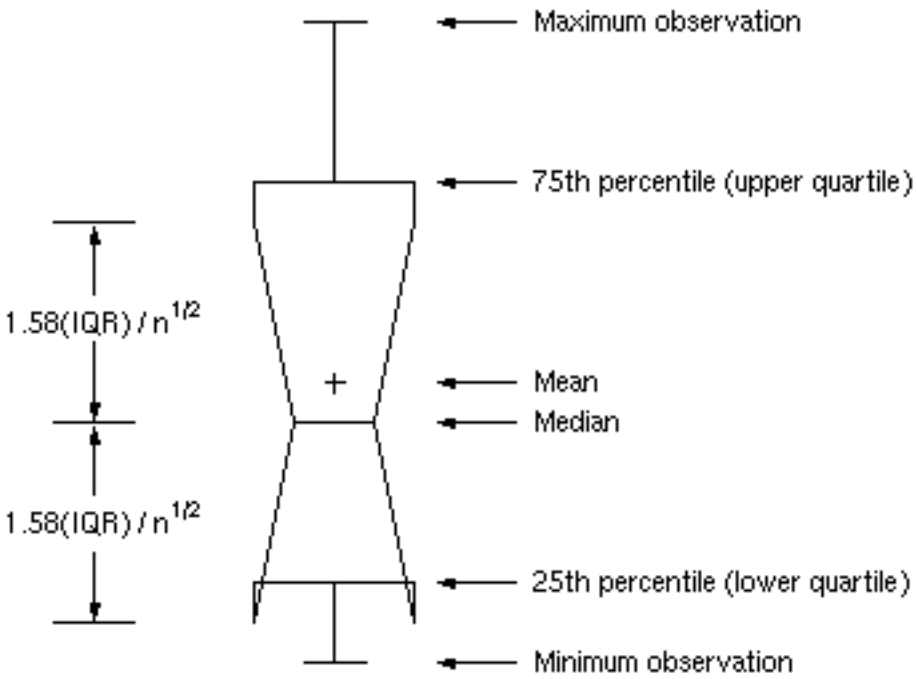
eliminates serifs from the whiskers of box-and-whiskers plots.

† NOTCHES

specifies that box-and-whiskers plots be notched. The endpoints of the notches are located at the median plus and minus $1.58(\mathrm{IQR}/\sqrt{n})$, where IQR is the interquartile range and n is the group size. The medians (central lines) of two box-and-whiskers plots are significantly different at approximately the 0.95 confidence level if the corresponding notches do not overlap.

Refer to McGill, Tukey, and Larsen (1978) for more information. Figure 25.7 illustrates the NOTCHES option. Notice the folding effect at the bottom, which happens when the endpoint of a notch is beyond its corresponding quartile. This situation typically occurs when the group size is small.

Figure 25.7 Box Plot: The NOTCHES Option



NOTICKREP
applies to character-valued group variables and specifies that only the first occurrence of repeated, adjacent group values be labeled on the horizontal axis.

NOVANGLE
requests that the vertical axis label be strung out vertically.

† NPANELPOS=*n*

NPANEL=*n*
specifies the number of group positions per panel. You typically specify the NPANELPOS= option to display more box-and-whiskers plots on a panel than the default number, which is $n = 25$.

You can specify a positive or negative number for n. The absolute value of n must be at least 5. If n is positive, the number of positions is adjusted so that it is approximately equal to n and so that all panels display approximately the same number of group positions. If n is negative, no balancing is done, and each panel (except possibly the last) displays approximately $|n|$ positions. In this case, the approximation is due only to axis scaling.

You can use the INTERVAL= option to change the effect of the NPANELPOS= option when a date or time format is associated with the group variable. The INTERVAL= option enables you to match the scale of the horizontal axis to the scale of the group variable without having to associate a different format with the group variable.

† OUTBOX=*SAS-data-set*
creates an output data set that contains group summary statistics and outlier values for a box plot. You can use an OUTBOX= data set as a BOX= input data set in a subsequent run of the procedure. See the section "OUTBOX= Data Set" on page 949 for details.

OUTHIGHHTML=*variable*
specifies a variable whose values are URLs to be associated with outlier points above the upper fence on a schematic box plot when graphics output is directed into HTML.

† OUTHISTORY=*SAS-data-set*
creates an output data set that contains the group summary statistics. You can use an OUTHISTORY= data set as a HISTORY= input data set in a subsequent run of the procedure. See the section "OUTHISTORY= Data Set" on page 950 for details.

OUTLOWHTML=*variable*
specifies a variable whose values are URLs to be associated with outlier points below the lower fence on a schematic box plot when graphics output is directed into HTML.

† OVERLAY=(*variable-list***)**
specifies variables to be plotted as overlays on the box plot. One value for each overlay variable is plotted at each group position. If there are multiple observations with the same group variable value in the input data set, the overlay variable values from the first observation in each group are plotted. By default, the points in an overlay plot are connected with line segments.

OVERLAYCLIPSYM=*symbol*
specifies the symbol used to plot clipped values on overlay plots when the CLIPFACTOR= option is used.

OVERLAYCLIPSYMHT=*value*

specifies the height for the symbol used to plot clipped values on overlay plots when the CLIPFACTOR= option is used.

OVERLAYHTML=(*variable-list***)**

specifies variables whose values are URLs to be associated with points on overlay plots when graphics output is directed into HTML. Variables in the OVERLAYHTML= list are matched with variables in the corresponding positions in the OVERLAY= list.

OVERLAYID=(*variable-list***)**

specifies variables whose formatted values are used to label points on overlays. Variables in the OVERLAYID= list are matched with variables in the corresponding positions in the OVERLAY= list. The value of the OVERLAYID= variable should be the same for each observation with a given value of the group variable.

† OVERLAYLEGLAB='*label***'**

specifies the label displayed to the left of the overlay legend produced by the OVERLAY= option. The label can be up to 16 characters and must be enclosed in quotes. The default label is "Overlays:".

OVERLAYSYM=(*symbol-list***)**

specifies symbols used to plot overlay variables. Symbols in the OVERLAYSYM= list are matched with variables in the corresponding positions in the OVERLAY= list.

OVERLAYSYMHT=(*value-list***)**

specifies the heights of symbols used to plot overlay variables. Symbol heights in the OVERLAYSYMHT= list are matched with variables in the corresponding positions in the OVERLAY= list.

PAGENUM='*string***'**

specifies the form of the label used for pagination. The string can be up to 16 characters, and it must include one or two occurrences of the substitution character '#'. The first '#' is replaced with the page number, and the optional second '#' is replaced with the total number of pages.

The PAGENUM= option is useful when you are working with a large number of groups, resulting in multiple pages of output. For example, suppose that each of the following PLOT statements produces multiple pages:

```
proc boxplot data=Pistons;
   plot Diameter*Hour / pagenum='Page #';
   plot Diameter*Hour / pagenum='Page # of #';
   plot Diameter*Hour / pagenum='#/#';
run;
```

The third page produced by the first statement would be labeled "Page 3". The third page produced by the second statement would be labeled "Page 3 of 5". The third page produced by the third statement would be labeled "3/5".

By default, no page number is displayed.

PAGENUMPOS=TL | TR | BL | BR | TL100 | TR100 | BL0 | BR0

specifies where to position the page number requested with the PAGENUM= option. The keywords TL, TR, BL, and BR correspond to the positions top left, top right, bottom left, and bottom right, respectively. You can use the TL100 and TR100 keywords to ensure that the page number appears at the very top of a page when a title is displayed. The BL0 and BR0 keywords ensure that the page number appears at the very bottom of a page when footnotes are displayed.

The default value is BR.

† PCTLDEF=*index*

specifies one of five definitions used to calculate percentiles in the construction of box-and-whiskers plots. The index can be 1, 2, 3, 4, or 5. The five corresponding percentile definitions are discussed in the section "Percentile Definitions" on page 955. The default index is 5.

† REPEAT

† REP

specifies that the horizontal axis of a plot that spans multiple panels be arranged so that the last group position on a panel is repeated as the first group position on the next panel. The REPEAT option facilitates cutting and pasting panels together. When a SAS DATETIME format is associated with the group variable, the REPEAT option is the default.

SKIPHLABELS=*n*

SKIPHLABEL=*n*

specifies the number *n* of consecutive tick mark labels, beginning with the second tick mark label, that are thinned (not displayed) on the horizontal (group) axis. For example, specifying SKIPHLABEL=1 causes every other label to be skipped. Specifying SKIPHLABEL=2 causes the second and third labels to be skipped, the fifth and sixth labels to be skipped, and so forth.

The default value of the SKIPHLABELS= option is the smallest value *n* for which tick mark labels do not collide. A specified *n* will be overridden to avoid collision. To reduce thinning, you can use the TURNHLABELS option.

SYMBOLLEGEND=LEGEND*n*

SYMBOLLEGEND=NONE

controls the legend for the levels of a symbol variable (see Example 25.1). You can specify SYMBOLLEGEND=LEGEND*n*, where *n* is the number of a LEGEND statement defined previously. You can specify SYMBOLLEGEND=NONE to suppress the default legend. Refer to *SAS/GRAPH: Reference* for more information about the LEGEND statement.

SYMBOLORDER=DATA | INTERNAL | FORMATTED

SYMORD=DATA | INTERNAL | FORMATTED

specifies the order in which symbols are assigned for levels of the symbol variable. The DATA keyword assigns symbols to values in the order in which values appear in the input data set. The INTERNAL keyword assigns symbols based on sorted order of internal values of the symbol variable, and the FORMATTED keyword assigns them based on sorted formatted values. The default value is FORMATTED.

† TOTPANELS=*n*

specifies the total number of panels to be used to display the plot. This option overrides the NPANELPOS= option.

TURNHLABELS

TURNHLABEL

turns the major tick mark labels for the horizontal (group) axis so that they are arranged vertically. By default, labels are arranged horizontally.

Note that arranging the labels vertically might leave insufficient vertical space on the panel for a plot.

† VAXIS=*value-list*

† VAXIS=AXIS*n*

specifies major tick mark values for the vertical axis of a box plot. The values must be listed in increasing order, must be evenly spaced, and must span the range of values displayed in the plot. You can specify the values with an explicit list or with an implicit list, as shown in the following example:

```
proc boxplot;
   plot Width*Hour / vaxis=0 2 4 6 8;
   plot Width*Hour / vaxis=0 to 8 by 2;
run;
```

You can also specify a previously defined AXIS statement with the VAXIS= option.

† VFORMAT=*format*

specifies a format to be used for displaying tick mark labels on the vertical axis of the box plot.

VMINOR=*n*

VM=*n*

specifies the number of minor tick marks between major tick marks on the vertical axis. Minor tick marks are not labeled. By default, VMINOR=0.

VOFFSET=*value*

specifies the length in percent screen units of the offset at the ends of the vertical axis.

† VREF=*value-list*

† VREF=*SAS-data-set*

draws reference lines perpendicular to the vertical axis. You can use this option in the following ways:

- Specify the values for the lines with a VREF= list:

  ```
  vref=20
  vref=20 40 80
  ```

- Specify the values for the lines as the values of a numeric variable named _REF_ in a VREF= data set. Optionally, you can provide labels for the lines as values of a variable named _REFLAB_, which must be a character variable of up to 16 characters. If you want distinct reference lines to be displayed in plots for different analysis variables specified in the PLOT statement, you must include a character variable named _VAR_, whose values are the names of the analysis variables. If you do not include the variable _VAR_, all of the lines are displayed in all of the plots. Each observation in the VREF= data set corresponds to a reference line. If BY variables are used in the input data set, the same BY-variable structure must be used in the VREF= data set unless you specify the NOBYREF option.

† VREFLABELS='*label1*' **...** '*labeln*'

† VREFLABEL='*label1*' **...** '*labeln*'

† VREFLAB='*label1*' **...** '*labeln*'

specifies labels for the reference lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of the VREFLABELS= label, as described in the following table. By default, *n=1*.

n	Label Position
1	left-justified in plot area
2	right-justified in plot area
3	left-justified in right margin

VZERO

forces the origin to be included in the vertical axis for a box plot.

WAXIS=*n*

specifies the width in pixels for the axis and frame lines. By default, *n=1*.

WGRID=*n*

specifies the width in pixels for grid lines requested with the ENDGRID and GRID options. By default, *n=1*.

WOVERLAY=(*value-list***)**

specifies the widths in pixels for the line segments connecting points on overlay plots. Widths in the WOVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list. By default, all overlay widths are 1.

Details: BOXPLOT Procedure

Summary Statistics Represented by Box Plots

Table 25.6 lists the summary statistics represented in each box-and-whiskers plot.

Table 25.6 Summary Statistics Represented by Box Plots

Group Summary Statistic	Feature of Box-and-Whiskers Plot
maximum	endpoint of upper whisker
third quartile (75th percentile)	upper edge of box
median (50th percentile)	line inside box
mean	symbol marker
first quartile (25th percentile)	lower edge of box
minimum	endpoint of lower whisker

Note that you can request different box plot styles, as discussed in the section "Styles of Box Plots" on page 954, and as illustrated in Example 25.2.

Output Data Sets

OUTBOX= Data Set

The OUTBOX= data set saves group summary statistics and outlier values. The following variables can be saved:

- the group variable
- the variable _VAR_, containing the analysis variable name
- the variable _TYPE_, identifying features of box-and-whiskers plots
- the variable _VALUE_, containing values of box-and-whiskers plot features
- the variable _ID_, containing labels for outliers
- the variable _HTML_, containing URLs associated with plot features

_ID_ is included in the OUTBOX= data set only if the keyword SCHEMATICID or SCHEMATICIDFAR is specified with the BOXSTYLE= option. _HTML_ is present only if one or more of the HTML=, OUTHIGHHTML=, and OUTLOWHTML= options are specified.

Each observation in an OUTBOX= data set records the value of a single feature of one group's box-and-whiskers plot, such as its mean. The _TYPE_ variable identifies the feature whose value is recorded in _VALUE_. Table 25.7 lists valid _TYPE_ variable values.

Table 25.7 Valid _TYPE_ Values in an OUTBOX= Data Set

TYPE	Description
N	group size
MIN	minimum group value
Q1	group first quartile
MEDIAN	group median
MEAN	group mean
Q3	group third quartile
MAX	group maximum value
STDDEV	group standard deviation
LOW	low outlier value
HIGH	high outlier value
LOWHISKR	low whisker value, if different from MIN
HIWHISKR	high whisker value, if different from MAX
FARLOW	low far outlier value
FARHIGH	high far outlier value

Additionally, the following variables, if specified, are included:

- block variables
- symbol variable
- BY variables
- ID variables

OUTHISTORY= Data Set

The OUTHISTORY= data set saves group summary statistics. The following variables are saved:

- the group variable
- group minimum variables named by *analysis-variable* suffixed with *L*
- group first-quartile variables named by *analysis-variable* suffixed with *1*
- group mean variables named by *analysis-variable* suffixed with *X*
- group median variables named by *analysis-variable* suffixed with *M*
- group third-quartile variables named by *analysis-variable* suffixed with *3*

- group maximum variables named by *analysis-variable* suffixed with *H*
- group standard deviation variables named by *analysis-variable* suffixed with *S*
- group size variables named by *analysis-variable* suffixed with *N*

If an analysis variable name has the maximum length of 32 characters, PROC BOXPLOT forms summary statistic names from its first 16 characters, its last 15 characters, and the appropriate suffix.

Subgroup summary variables are created for each analysis variable specified in the PLOT statement. For example, consider the following statements:

```
proc boxplot data=Steel;
   plot (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set Summary contains variables named Lot, WidthL, Width1, WidthM, WidthX, Width3, WidthH, WidthS, WidthN, DiameterL, Diameter1, DiameterM, DiameterX, Diameter3, DiameterH, DiameterS, and DiameterN.

Additionally, the following variables, if specified, are included:

- BY variables
- block variables
- symbol variable
- ID variables

Note that an OUTHISTORY= data set does not contain outlier values, and therefore cannot be used, in general, to save a schematic box plot. You can use an OUTBOX= data set to save a schematic box plot summary.

Input Data Sets

DATA= Data Set

You can read analysis variable measurements from a data set specified with the DATA= option in the PROC BOXPLOT statement. Each analysis variable specified in the PLOT statement must be a SAS variable in the data set. This variable provides measurements that are organized into groups indexed by the group variable. The group variable, specified in the PLOT statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each analysis variable and a value for the group variable. If the ith group contains n_i measurements, there should be n_i consecutive observations for which the value of the group variable is the index of the ith group. For example, if each group contains 20 items and there are 30 groups, the DATA= data set should contain 600 observations. Other variables that can be read from a DATA= data set include the following:

- block variables

- symbol variable
- BY variables
- ID variables

BOX= Data Set

You can read group summary statistics and outlier information from a BOX= data set specified in the PROC BOXPLOT statement. This enables you to reuse OUTBOX= data sets that have been created in previous runs of the BOXPLOT procedure to reproduce schematic box plots.

A BOX= data set must contain the following variables:

- the group variable
- _VAR_, containing the analysis variable name
- _TYPE_, identifying features of box-and-whiskers plots
- _VALUE_, containing values of those features

Each observation in a BOX= data set records the value of a single feature of one group's box-and-whiskers plot, such as its mean. Consequently, a BOX= data set contains multiple observations per group. These must appear consecutively in the BOX= data set.

The _TYPE_ variable identifies the feature whose value is recorded in a given observation. The following table lists valid _TYPE_ variable values.

Table 25.8 Valid _TYPE_ Values in a BOX= Data Set

TYPE	Description
N	group size
MIN	group minimum value
Q1	group first quartile
MEDIAN	group median
MEAN	group mean
Q3	group third quartile
MAX	group maximum value
STDDEV	group standard deviation
LOW	low outlier value
HIGH	high outlier value
LOWHISKR	low whisker value, if different from MIN
HIWHISKR	high whisker value, if different from MAX
FARLOW	low far outlier value
FARHIGH	high far outlier value

The features identified by _TYPE_ values N, MIN, Q1, MEDIAN, MEAN, Q3, and MAX are required for each group.

Other variables that can be read from a BOX= data set include the following:

- the variable _ID_, containing labels for outliers
- the variable _HTML_, containing URLs to be associated with features on box plots
- block variables
- symbol variable
- BY variables
- ID variables

When you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option, values of _ID_ are used as outlier labels. If _ID_ does not exist in the BOX= data set, the values of the first variable listed in the ID statement are used.

HISTORY= Data Set

You can read group summary statistics from a HISTORY= data set specified in the PROC BOXPLOT statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the BOXPLOT procedure or to read output data sets created with SAS summarization procedures, such as PROC UNIVARIATE.

Note that a HISTORY= data set does *not* contain outlier information. Therefore, in general you cannot reproduce a schematic box plot from summary statistics saved in an OUTHISTORY= data set. To save and reproduce schematic box plots, use OUTBOX= and BOX= data sets.

A HISTORY= data set must contain the following:

- the group variable
- a group minimum variable for each analysis variable
- a group first-quartile variable for each analysis variable
- a group median variable for each analysis variable
- a group mean variable for each analysis variable
- a group third-quartile variable for each analysis variable
- a group maximum variable for each analysis variable
- a group standard deviation variable for each analysis variable
- a group size variable for each analysis variable

The names of the group summary statistics variables must be the analysis variable name concatenated with the following special suffix characters.

Group Summary Statistic	Suffix Character
group minimum	L
group first quartile	1
group median	M
group mean	X
group third quartile	3
group maximum	H
group standard deviation	S
group size	N

For example, consider the following statements:

```
proc boxplot history=Summary;
   plot (Weight Yieldstrength) * Batch;
run;
```

The data set Summary must include the variables Batch, WeightL, Weight1, WeightM, WeightX, Weight3, WeightH, WeightS, WeightN, YieldstrengthL, Yieldstrength1, YieldstrengthM, YieldstrengthX, Yieldstrength3, YieldstrengthH, YieldstrengthS, and YieldstrengthN.

Note that if you specify an analysis variable whose name contains the maximum of 32 characters, the summary variable names must be formed from the first 16 characters and the last 15 characters of the analysis variable name, suffixed with the appropriate character.

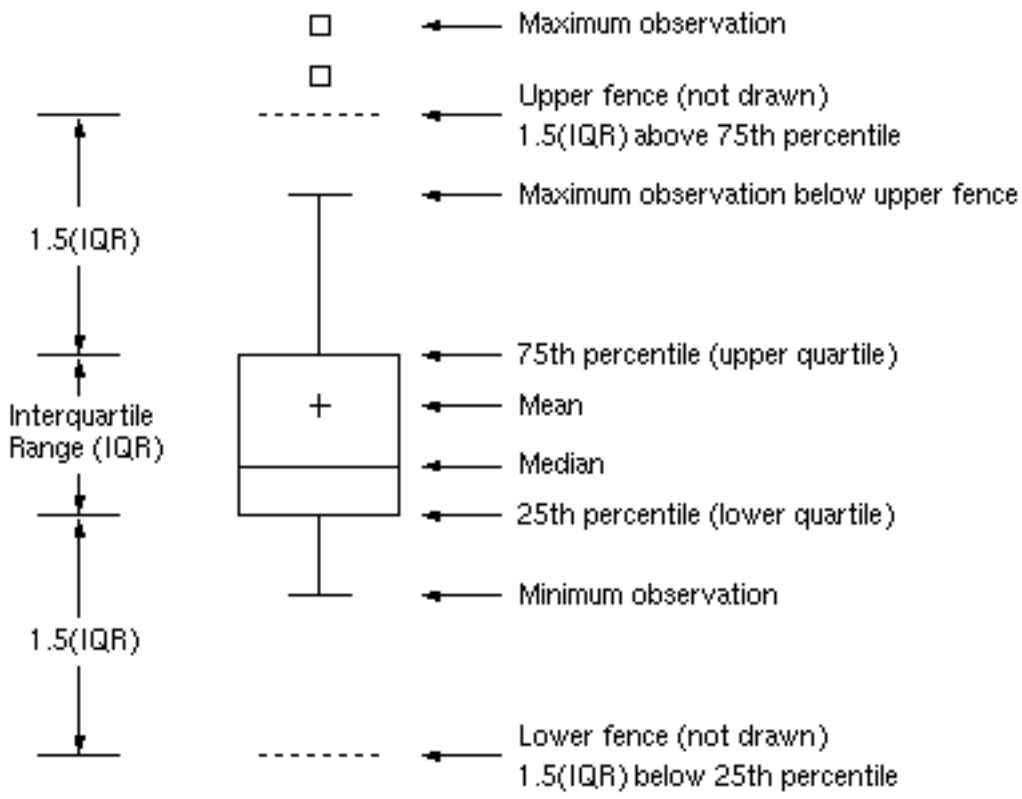
These other variables can be read from a HISTORY= data set:

- block variables
- symbol variable
- BY variables
- ID variables

Styles of Box Plots

A box-and-whiskers plot is displayed for the measurements in each group on the box plot. The *skeletal* style of the box-and-whiskers plot shown in Figure 25.6 is the default. You can produce a *schematic* box plot by specifying the BOXSTYLE=SCHEMATIC option in the PLOT statement. Figure 25.8 illustrates a typical schematic box plot and the locations of the fences (which are not displayed in actual output). See the description of the BOXSTYLE= option for complete details.

Figure 25.8 Schematic Box-and-Whiskers Plot



You can draw connecting lines between adjacent box-and-whiskers plots by using the BOXCONNECT=*keyword* option. For example, BOXCONNECT=MEAN connects the points representing the means of adjacent groups. Other available keywords are MIN, Q1, MEDIAN, Q3, and MAX. Specifying BOXCONNECT without a keyword is equivalent to specifying BOXCONNECT=MEAN. You can specify the color for the connecting lines with the CCONNECT= option.

Percentile Definitions

You can use the PCTLDEF= option to specify one of five definitions for computing quantile statistics (percentiles). Suppose that n is the number of nonmissing values for a variable and that $x_1, x_2, \ldots, x_n$ represent the ordered values of the analysis variable. For the tth percentile, set $p = t/100$.

For the following definitions numbered 1, 2, 3, and 5, express np as

$$np = j + g$$

where j is the integer part of np, and g is the fractional part of np. For definition 4, let

$$(n+1)p = j + g$$

The tth percentile (call it y) can be defined as follows:

PCTLDEF=1 weighted average at x_{np}

$$y = (1-g)x_j + gx_{j+1}$$

where x_0 is taken to be x_1.

PCTLDEF=2 observation numbered closest to np

$$y = x_i$$

where i is the integer part of $np + 1/2$ if $g \neq 1/2$. If $g = 1/2$, then $y = x_j$ if j is even, or $y = x_{j+1}$ if j is odd.

PCTLDEF=3 empirical distribution function

$$y = x_j \text{ if } g = 0$$

$$y = x_{j+1} \text{ if } g > 0$$

PCTLDEF=4 weighted average aimed at $x_{p(n+1)}$

$$y = (1-g)x_j + gx_{j+1}$$

where x_{n+1} is taken to be x_n.

PCTLDEF=5 empirical distribution function with averaging

$$y = (x_j + x_{j+1})/2 \text{ if } g = 0$$

$$y = x_{j+1} \text{ if } g > 0$$

Missing Values

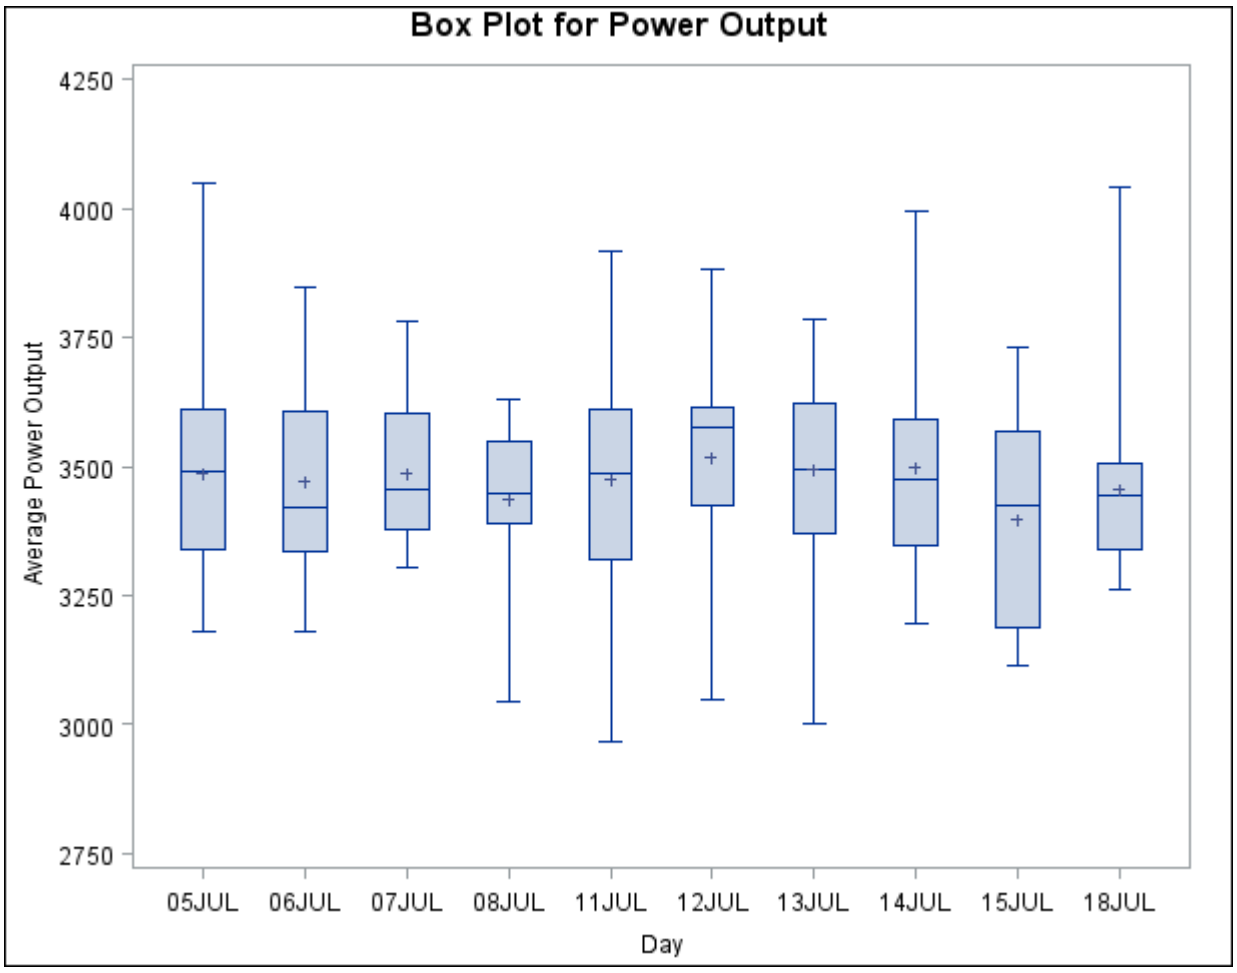
An observation read from an input data set is not analyzed if the value of the group variable is missing. For a particular analysis variable, an observation read from a DATA= data set is not analyzed if the value of the analysis variable is missing.

Continuous Group Variables

By default, the PLOT statement treats numerical group variable values as *discrete* values and spaces the boxes evenly on the plot. The following statements produce the box plot in Figure 25.9:

```
ods graphics off;
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
run;
```

Figure 25.9 Box Plot with Discrete Group Variable



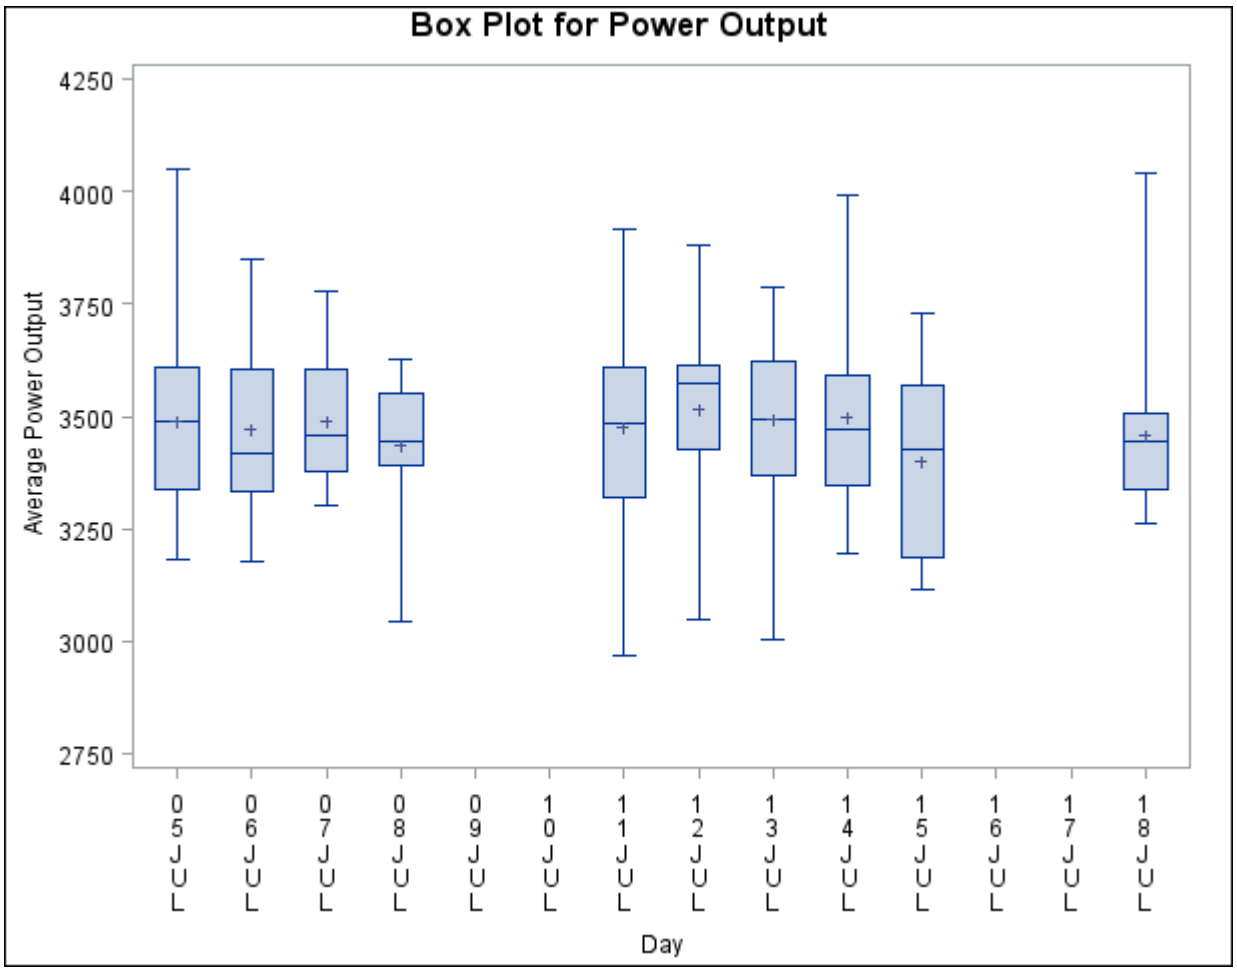
The labels on the horizontal axis in Figure 25.9 do not represent 10 consecutive days, but the box-and-whiskers plots are evenly spaced.

In order to treat the group variable as *continuous*, you can specify the CONTINUOUS or HAXIS= option when producing traditional graphics. Either option produces a box plot with a horizontal axis scaled for continuous group variable values. (ODS Graphics does not support a continuous group axis.)

The following statements produce the plot shown in Figure 25.10. The TURNHLABELS option orients the horizontal axis labels vertically so there is room to display them all.

```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day / turnhlabels
                     continuous;
run;
```

Figure 25.10 Box Plot with Continuous Group Variable



Note that the tick values on the horizontal axis represent consecutive days and that no box-and-whiskers plots are displayed for days when no turbine data were collected.

Positioning Insets

This section provides details on three different methods of positioning INSET boxes by using the POSITION= option. With the POSITION= option, you can specify the following:

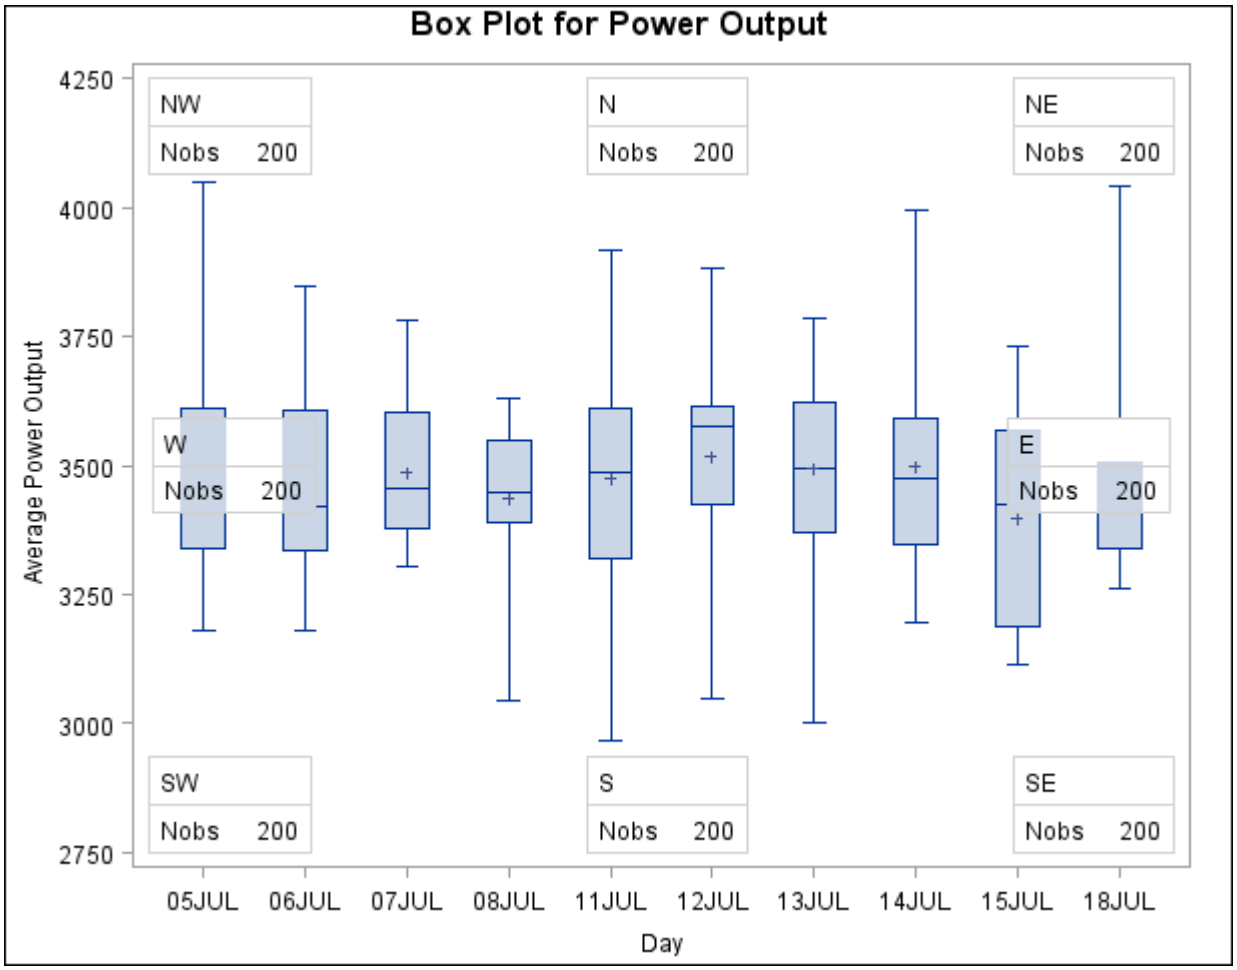
- compass points
- keywords for margin positions
- coordinates in data units or percent axis units

Positioning the Inset Using Compass Points

You can specify the eight compass points (N, NE, E, SE, S, SW, W, and NW) as keywords for the POSITION= option. The default inset position is NW. The following statements create the display in Figure 25.11, which illustrates all eight compass positions:

```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
   inset nobs / height=2.5 cfill=blank header='NW' pos=nw;
   inset nobs / height=2.5 cfill=blank header='N ' pos=n ;
   inset nobs / height=2.5 cfill=blank header='NE' pos=ne;
   inset nobs / height=2.5 cfill=blank header='E ' pos=e ;
   inset nobs / height=2.5 cfill=blank header='SE' pos=se;
   inset nobs / height=2.5 cfill=blank header='S ' pos=s ;
   inset nobs / height=2.5 cfill=blank header='SW' pos=sw;
   inset nobs / height=2.5 cfill=blank header='W ' pos=w ;
run;
```

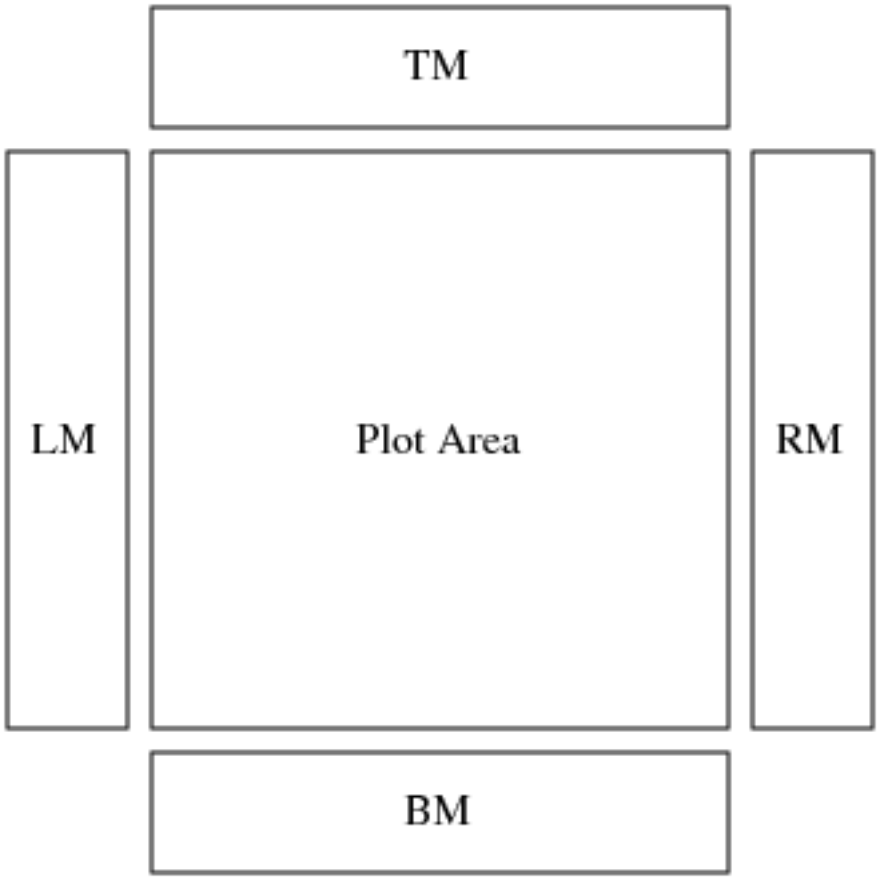
Figure 25.11 Insets Positioned Using Compass Points



Positioning the Inset in the Margins

You can also use the INSET statement to position an inset in one of the four margins surrounding the plot area by using the margin keyword LM, RM, TM, or BM, as illustrated in Figure 25.12.

Figure 25.12 Positioning Insets in the Margins



For an example of an inset placed in the top margin, see Output 25.1.1. Margin positions are recommended for insets containing a large number of statistics. If you attempt to display a lengthy inset in the interior of the plot, it is likely that the inset will collide with the data display.

Positioning the Inset Using Coordinates

You can also specify the position of an inset with coordinates by using the POSITION= (x, y) option. You can specify coordinates in axis percent units (the default) or in axis data units.

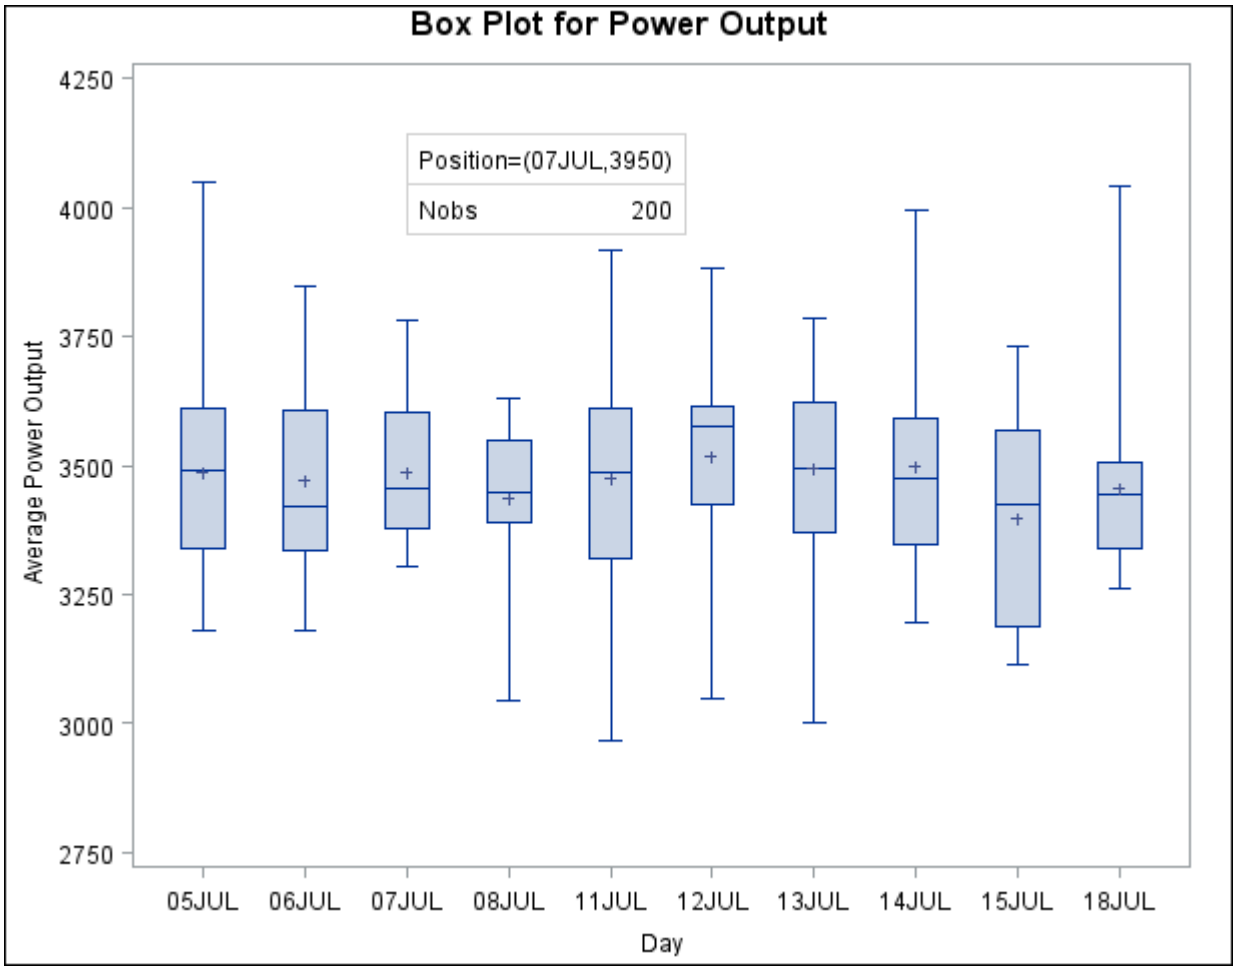
Data Unit Coordinates

If you specify the DATA option immediately following the coordinates, the inset is positioned using axis data units. For example, the following statements place the bottom-left corner of the inset at 07JUL on the horizontal axis and 3950 on the vertical axis:

```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
   inset nobs /
      header   = 'Position=(07JUL,3950)'
      position = ('07JUL94'd, 3950) data;
run;
```

The box plot is displayed in Figure 25.13. By default, the specified coordinates determine the position of the bottom-left corner of the inset. You can change this reference point with the REFPOINT= option, as in the next example.

Figure 25.13 Inset Positioned Using Data Unit Coordinates



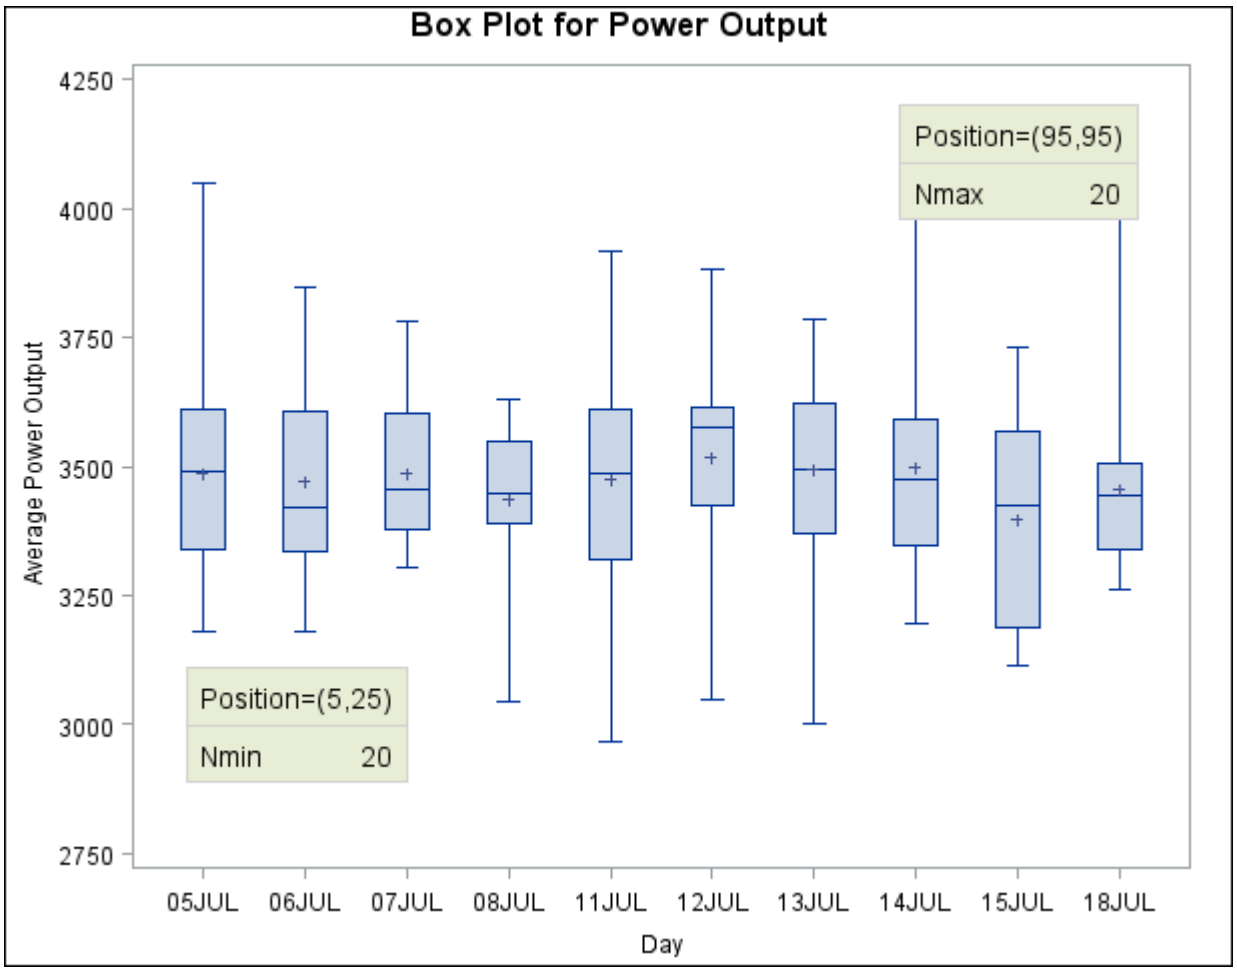
Axis Percent Unit Coordinates

If you do not use the DATA option, the inset is positioned using axis percent units. The coordinates of the bottom-left corner of the display are (0, 0), while the coordinates of the top-right corner are (100, 100). For example, the following statements create a box plot with two insets, both positioned using coordinates in axis percent units:

```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
   inset nmin / position = (5,25)
                header   = 'Position=(5,25)'
                height   = 3
                cfill    = ywh
                refpoint = tl;
   inset nmax / position = (95,95)
                header   = 'Position=(95,95)'
                height   = 3
                cfill    = ywh
                refpoint = tr;
run;
```

The display is shown in Figure 25.14. Notice that the REFPOINT= option is used to determine which corner of the inset is placed at the coordinates specified with the POSITION= option. The first inset has REFPOINT=TL, so the top-left corner of the inset is positioned 5% of the way across the horizontal axis and 25% of the way up the vertical axis. The second inset has REFPOINT=TR, so the top-right corner of the inset is positioned 95% of the way across the horizontal axis and 95% of the way up the vertical axis. Note also that coordinates in axis percent units must be *between* 0 and 100.

Figure 25.14 Inset Positioned Using Axis Percent Unit Coordinates



Displaying Blocks of Data

To display data organized in blocks of consecutive observations, specify one or more *block variables* in parentheses after the group variable in the PLOT statement. The block variables must be variables in the input data set. The BOXPLOT procedure displays a legend identifying blocks of consecutive observations with identical values of the block variables. The legend displays one track of values for each block variable containing formatted values of the block variable.

The values of a block variable must be the same for all observations with the same value of the group variable. In other words, groups must be nested within blocks determined by block variables.

The following statements create a SAS data set containing diameter measurements for a part produced on three different machines:

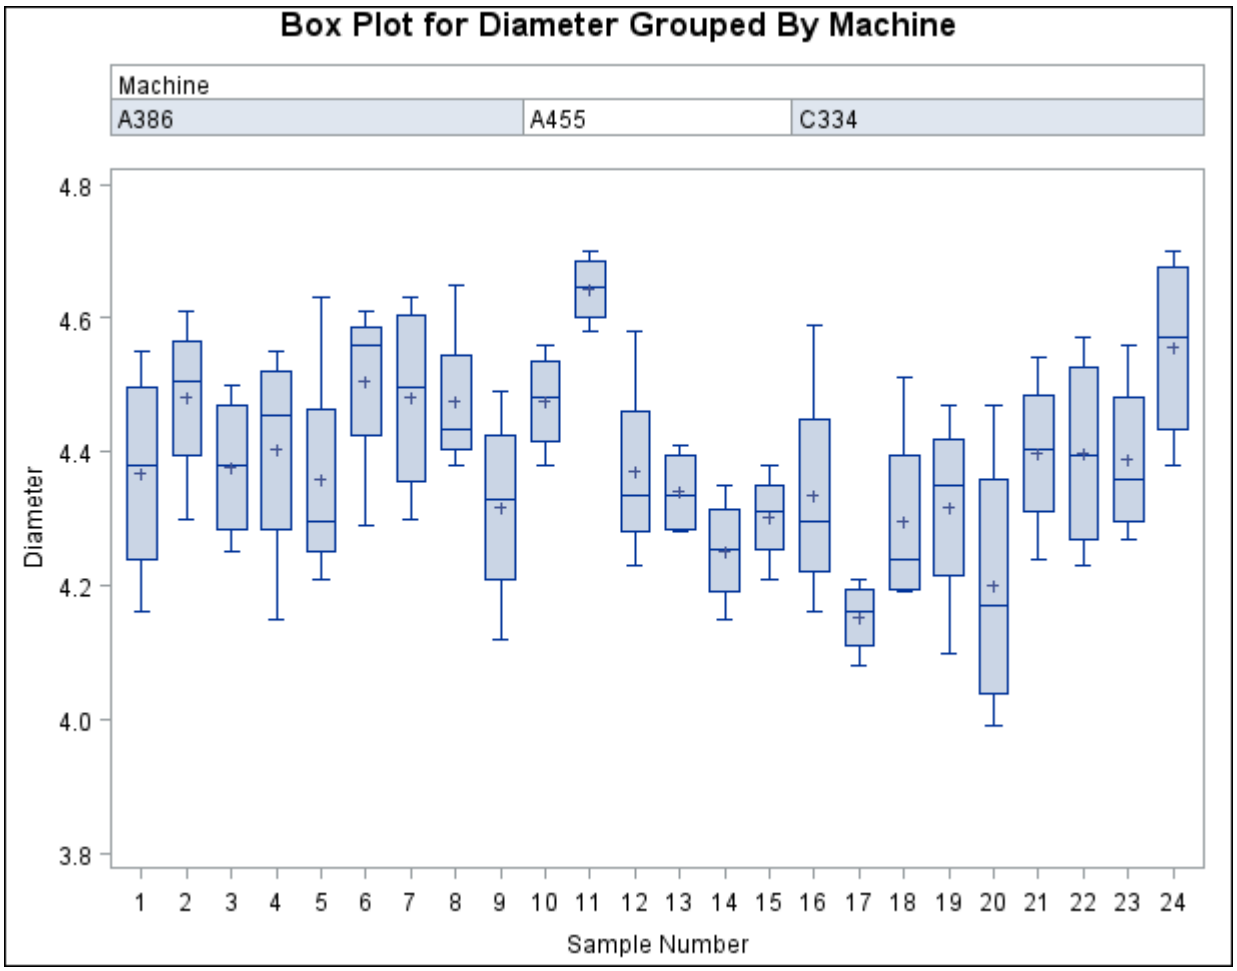
```
data Parts;
   length Machine $ 4;
   input Sample Machine $ @;
   do i= 1 to 4;
      input Diam @;
      output;
   end;
   drop i;
 datalines;
 1  A386  4.32 4.55 4.16 4.44
 2  A386  4.49 4.30 4.52 4.61
 3  A386  4.44 4.32 4.25 4.50
 4  A386  4.55 4.15 4.42 4.49
 5  A386  4.21 4.30 4.29 4.63
 6  A386  4.56 4.61 4.29 4.56
 7  A386  4.63 4.30 4.41 4.58
 8  A386  4.38 4.65 4.43 4.44
 9  A386  4.12 4.49 4.30 4.36
10  A455  4.45 4.56 4.38 4.51
11  A455  4.62 4.67 4.70 4.58
12  A455  4.33 4.23 4.34 4.58
13  A455  4.29 4.38 4.28 4.41
14  A455  4.15 4.35 4.28 4.23
15  A455  4.21 4.30 4.32 4.38
16  C334  4.16 4.28 4.31 4.59
17  C334  4.14 4.18 4.08 4.21
18  C334  4.51 4.20 4.28 4.19
19  C334  4.10 4.33 4.37 4.47
20  C334  3.99 4.09 4.47 4.25
21  C334  4.24 4.54 4.43 4.38
22  C334  4.23 4.48 4.31 4.57
23  C334  4.27 4.40 4.32 4.56
24  C334  4.70 4.65 4.49 4.38
;
```

The following statements create a box plot for the measurements in the Parts data set grouped into blocks by the block variable Machine:

```
ods graphics off;
title 'Box Plot for Diameter Grouped By Machine';
proc boxplot data=Parts;
   plot Diam*Sample (Machine);
   label Sample  = 'Sample Number'
         Machine = 'Machine'
         Diam    = 'Diameter';
run;
```

Note the LABEL statement used to provide labels for the axes and for the block legend. The plot is shown in Figure 25.15.

Figure 25.15 Box Plot Using a Block Variable



The unique consecutive values of Machine (A386, A455, and C334) are displayed in a legend above the plot. That is the default location of the block legend. You can control the position of the block legend with the BLOCKPOS= option. See the BLOCKPOS= option for details.

By default, block variable values that are too long to fit into the available space in a block legend are not displayed. You can specify the BLOCKLABTYPE= option to display lengthy labels. Specify BLOCKLABTYPE=SCALED to scale down the text size of the values so they all fit. Use BLOCKLAB-

TYPE=TRUNCATED to truncate lengthy values. You can also use BLOCKLABTYPE=*height* to specify a text height in vertical percent screen units for the values.

You can control the position of legend labels with the BLOCKLABELPOS= option. Valid BLOCKLABELPOS= values are ABOVE (the default, as shown in Figure 25.15) and LEFT.

Clipping Extreme Values

By default a box plot's vertical axis is scaled to accommodate all the values in all groups. If the variation between groups is large with respect to the variation within groups, or if some groups contain extreme outlier values, the vertical axis scale can become so large that the box-and-whiskers plots are compressed. In such cases, you can clip the extreme values to produce a more readable plot, as illustrated in the following example.

A company produces copper tubing. The diameter measurements (in millimeters) for 15 batches of five tubes each are provided in the data set Newtubes:

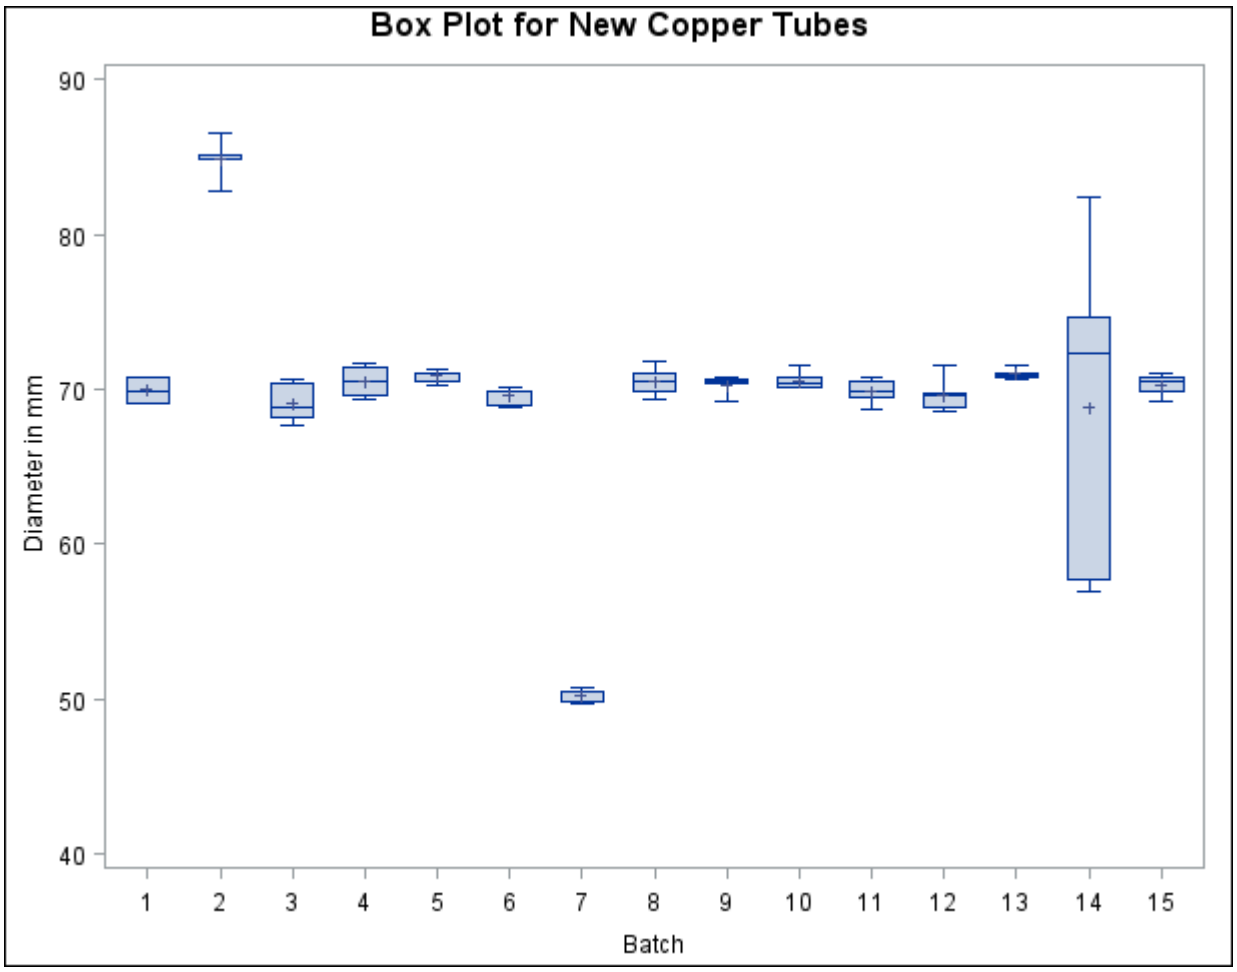
```
data Newtubes;
   label Diameter='Diameter in mm';
   do Batch = 1 to 15;
      do  i = 1 to 5;
         input Diameter @@;
         output;
      end;
   end;
datalines;
69.13  69.83  70.76  69.13  70.81
85.06  82.82  84.79  84.89  86.53
67.67  70.37  68.80  70.65  68.20
71.71  70.46  71.43  69.53  69.28
71.04  71.04  70.29  70.51  71.29
69.01  68.87  69.87  70.05  69.85
50.72  50.49  49.78  50.49  49.69
69.28  71.80  69.80  70.99  70.50
70.76  69.19  70.51  70.59  70.40
70.16  70.07  71.52  70.72  70.31
68.67  70.54  69.50  69.79  70.76
68.78  68.55  69.72  69.62  71.53
70.61  70.75  70.90  71.01  71.53
74.62  56.95  72.29  82.41  57.64
70.54  69.82  70.71  71.05  69.24
;
```

The following statements create a box plot of the tube diameters:

```
ods graphics off;
title 'Box Plot for New Copper Tubes' ;
proc boxplot data=Newtubes;
   plot Diameter*Batch;
run;
```

The box plot is shown in Figure 25.16.

Figure 25.16 Compressed Box Plots



Note that the diameters in batch 2 are significantly larger, and those in batch 7 significantly smaller, than those in most of the other batches. The default vertical axis scaling causes the box-and-whiskers plots to be compressed.

You can produce a more useful box plot by specifying the CLIPFACTOR=*factor* option, where *factor* is a value greater than one. Clipping is applied as follows:

1. The mean of the first quartile values ($\overline{Q1}$) and the mean of the third quartile values ($\overline{Q3}$) are computed across all groups.
2. The following values define the clipping range:

   $$y_{\max} = \overline{Q1} + (\overline{Q3} - \overline{Q1}) \times factor$$

   and

   $$y_{\min} = \overline{Q3} - (\overline{Q3} - \overline{Q1}) \times factor$$

   Any statistic greater than $y_{\max}$ or less than $y_{\min}$ is ignored during vertical axis scaling.

NOTE:

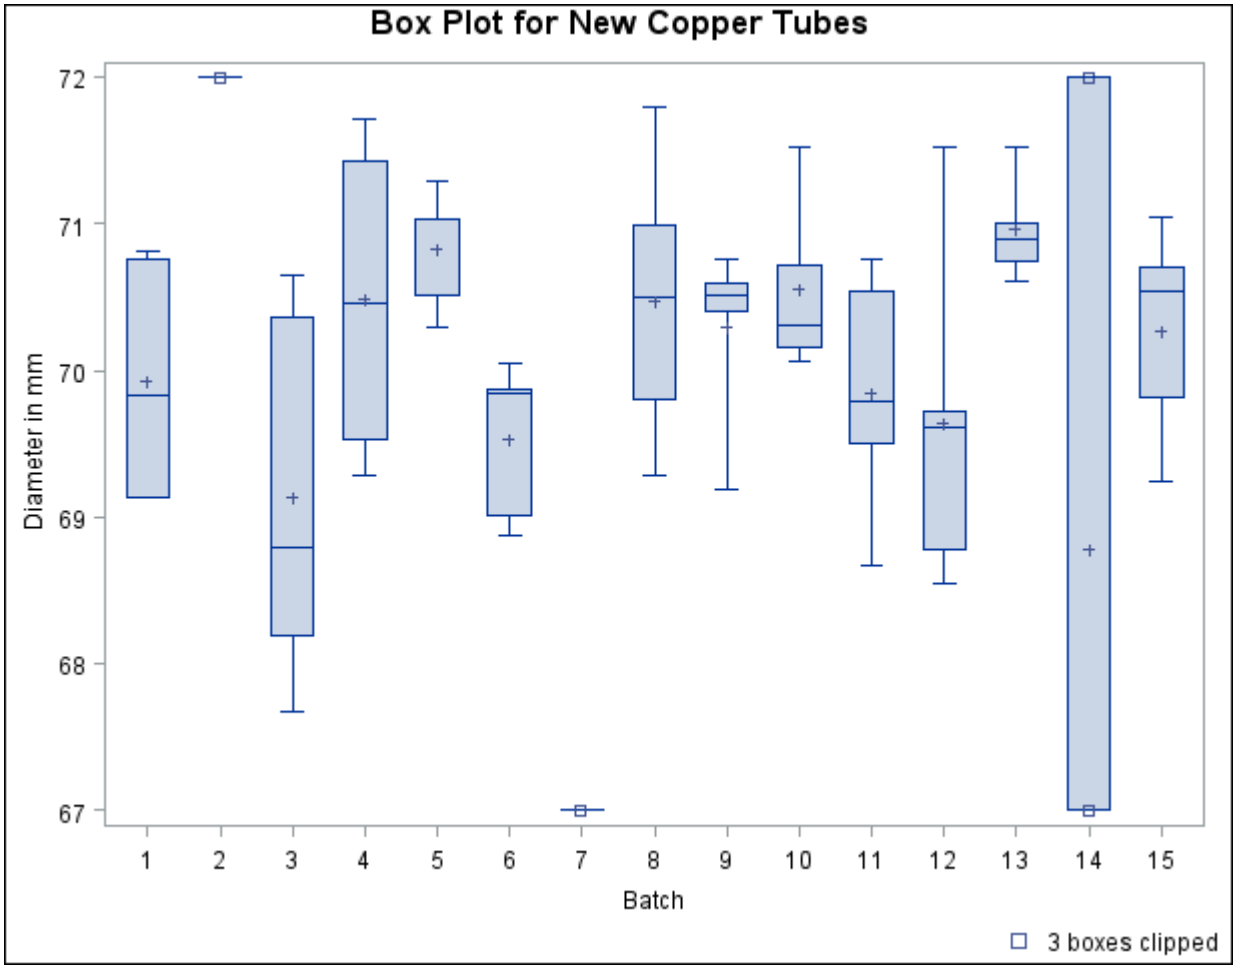
- Clipping is applied only to the plotted statistics and not to the statistics saved in an output data set.
- A special symbol is used for clipped points (the default symbol is a square), and a legend is added to the chart indicating the number of boxes that were clipped.

The following statements use a clipping factor of 1.5 to create a box plot of the same data plotted in Figure 25.16:

```
title 'Box Plot for New Copper Tubes' ;
proc boxplot data=Newtubes;
   plot Diameter*Batch /
      clipfactor = 1.5;
run;
```

The clipped box plot is shown in Figure 25.17.

Figure 25.17 Box Plot with Clip Factor of 1.5



In Figure 25.17 the extreme values are clipped, making the box plot more readable. The box-and-whiskers plots for batches 2 and 7 are clipped completely, while the plot for batch 14 is clipped at both the top and bottom. Clipped points are marked with a square, and a clipping legend is added at the lower right of the display.

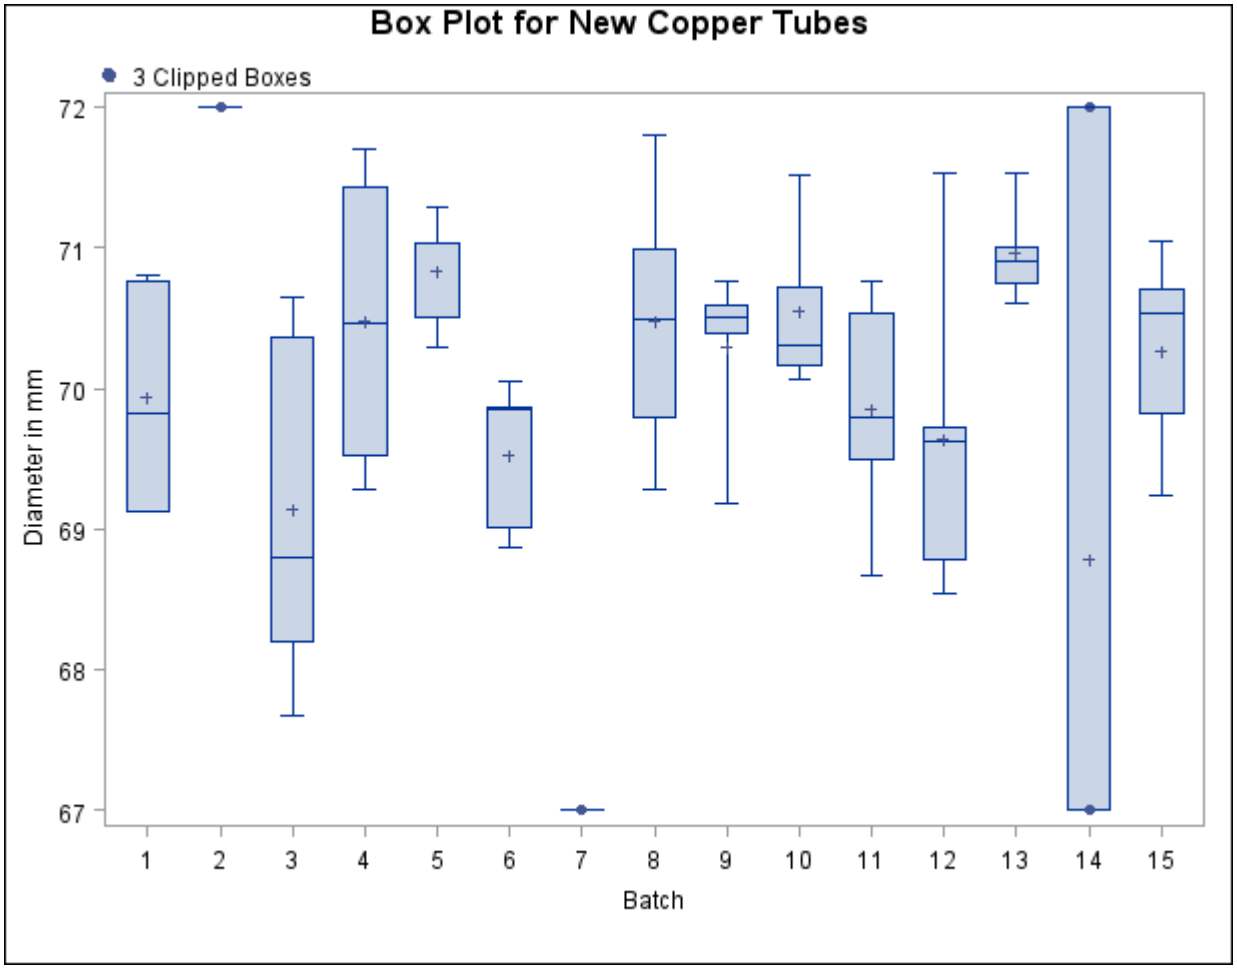
Other clipping options are available, as illustrated by the following statements:

```
title 'Box Plot for New Copper Tubes' ;
proc boxplot data=Newtubes;
   plot Diameter*Batch /
      clipfactor  = 1.5
      clipsymbol  = dot
      cliplegpos  = top
      cliplegend  = '# Clipped Boxes'
      clipsubchar = '#';
run;
```

Specifying CLIPSYMBOL=DOT marks the clipped points with a dot instead of the default square. Specifying CLIPLEGPOS=TOP positions the clipping legend at the top of the chart. The options CLIPLEGEND='# Clipped Boxes' and CLIPSUBCHAR='#' request the clipping legend "3 Clipped Boxes".

Figure 25.18 shows the modified box plot.

Figure 25.18 Box Plot Using Clipping Options



For more information about clipping options, see the appropriate entries in the section "PLOT Statement Options" on page 927.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

The appearance of a box plot produced using ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. PLOT statement options used to control the appearance of traditional high-resolution graphs are ignored for ODS Graphics output.

When producing ODS graphical displays, the PLOT statement assigns a name to each graph it creates. You can use this name to reference the graph when using ODS. The name is listed in Table 25.9.

Table 25.9 Graphs Produced by PROC BOXPLOT

ODS Graph Name	Plot Description
Boxplot	box-and-whiskers plots for groups

Examples: BOXPLOT Procedure

This section provides advanced examples of the PLOT statement.

Example 25.1: Displaying Summary Statistics in a Box Plot

This example demonstrates how you can use the INSET and INSETGROUP statements to include tables of summary statistics in your box plots. The following statements produce a box plot of the Turbine data set from the section "Getting Started: BOXPLOT Procedure" on page 911, augmented with insets containing summary statistics:

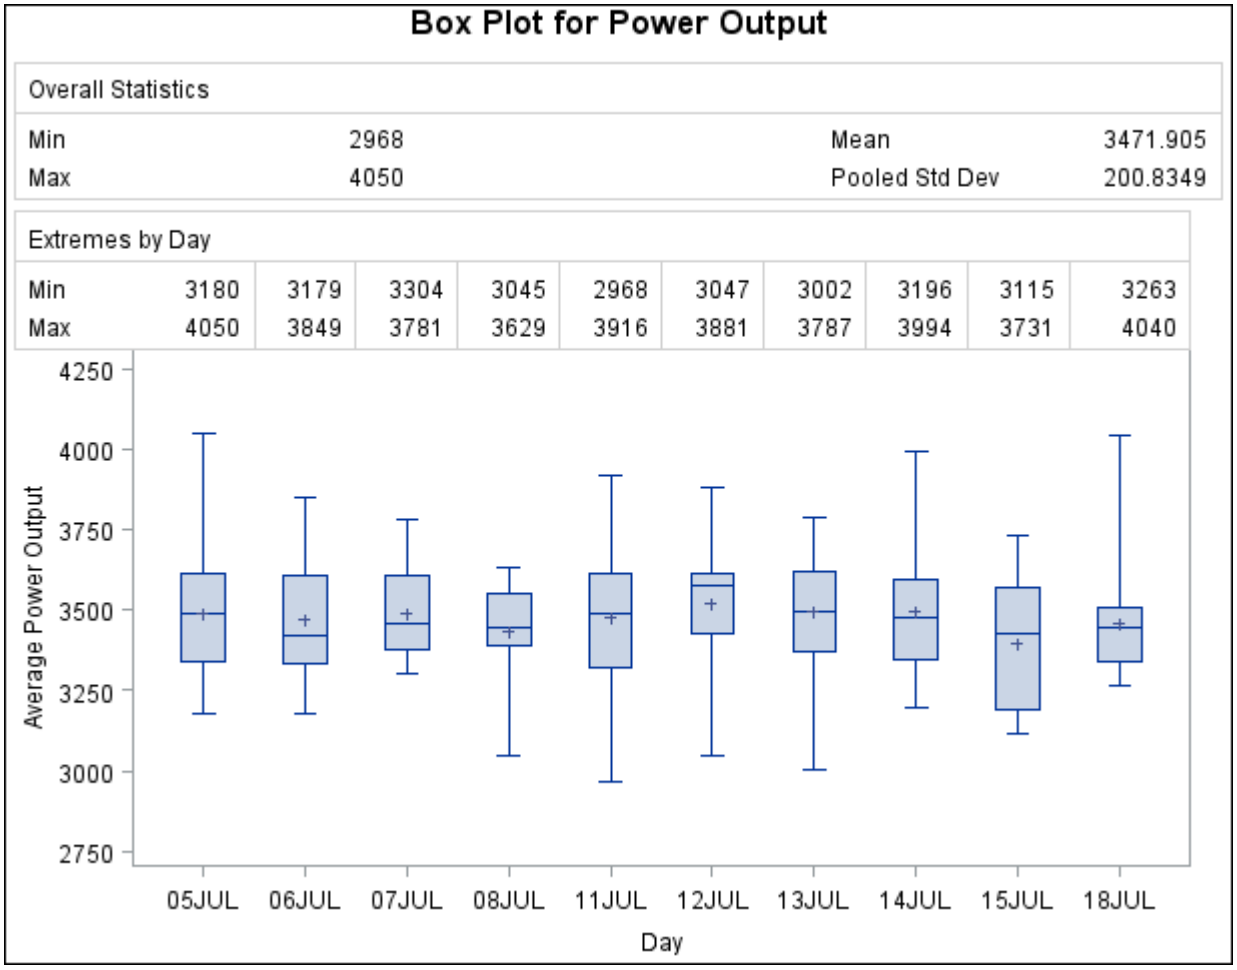
```
ods graphics off;
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
   inset min mean max stddev /
      header = 'Overall Statistics'
      pos    = tm;
   insetgroup min max /
      header = 'Extremes by Day';
run;
```

The INSET statement produces an inset of overall summary statistics. The keywords listed before the slash (/) request the minimum, mean, maximum, and standard deviation computed over all days. The POS=TM option places the inset in the top margin of the plot.

The INSETGROUP statement produces an inset containing statistics calculated for each group separately. The MIN and MAX keywords request the minimum and maximum observations from each day, respectively.

The resulting plot is shown in Output 25.1.1.

Output 25.1.1 Box Plot with Insets



Example 25.2: Using Box Plots to Compare Groups

In this example a box plot is used to compare the delay times of airline flights during the Christmas holidays with the delay times prior to the holiday period. The following statements create a data set named Times with the delay times in minutes for 25 flights each day. When a flight is canceled, the delay is recorded as a missing value.

```
data Times;
   informat Day date7. ;
   format   Day date7. ;
   input Day @ ;
   do Flight=1 to 25;
      input Delay @ ;
      output;
      end;
datalines;
16DEC88   4  12   2   2  18   5   6  21   0   0
          0  14   3   .   2   3   5   0   6  19
          7   4   9   5  10
17DEC88   1  10   3   3   0   1   5   0   .   .
          1   5   7   1   7   2   2  16   2   1
          3   1  31   5   0
18DEC88   7   8   4   2   3   2   7   6  11   3
          2   7   0   1  10   2   3  12   8   6
          2   7   2   4   5
19DEC88  15   6   9   0  15   7   1   1   0   2
          5   6   5  14   7  20   8   1  14   3
         10   0   1  11   7
20DEC88   2   1   0   4   4   6   2   2   1   4
          1  11   .   1   0   6   5   5   4   2
          2   6   6   4   0
21DEC88   2   6   6   2   7   7   5   2   5   0
          9   2   4   2   5   1   4   7   5   6
          5   0   4  36  28
22DEC88   3   7  22   1  11  11  39  46   7  33
         19  21   1   3  43  23   9   0  17  35
         50   0   2   1   0
23DEC88   6  11   8  35  36  19  21   .   .   4
          6  63  35   3  12  34   9   0  46   0
          0  36   3   0  14
24DEC88  13   2  10   4   5  22  21  44  66  13
          8   3   4  27   2  12  17  22  19  36
          9  72   2   4   4
25DEC88   4  33  35   0  11  11  10  28  34   3
         24   6  17   0   8   5   7  19   9   7
         21  17  17   2   6
26DEC88   3   8   8   2   7   7   8   2   5   9
          2   8   2  10  16   9   5  14  15   1
         12   2   2  14  18
;
```

In the following statements, the MEANS procedure is used to count the number of canceled flights for each day. This information is then added to the data set Times.

```
proc means data=Times noprint;
   var Delay;
   by Day;
   output out=Cancel nmiss=ncancel;

data Times;
   merge Times Cancel;
   by Day;
run;
```

The following statements create a data set named Weather containing information about possible causes for delays, and then merge this data set with the data set Times:

```
data Weather;
   informat Day date7. ;
   format   Day date7. ;
   length Reason $ 16 ;
input Day Flight Reason & ;
datalines;
16DEC88  8   Fog
17DEC88  18  Snow Storm
17DEC88  23  Sleet
21DEC88  24  Rain
21DEC88  25  Rain
22DEC88  7   Mechanical
22DEC88  15  Late Arrival
24DEC88  9   Late Arrival
24DEC88  22  Late Arrival
;

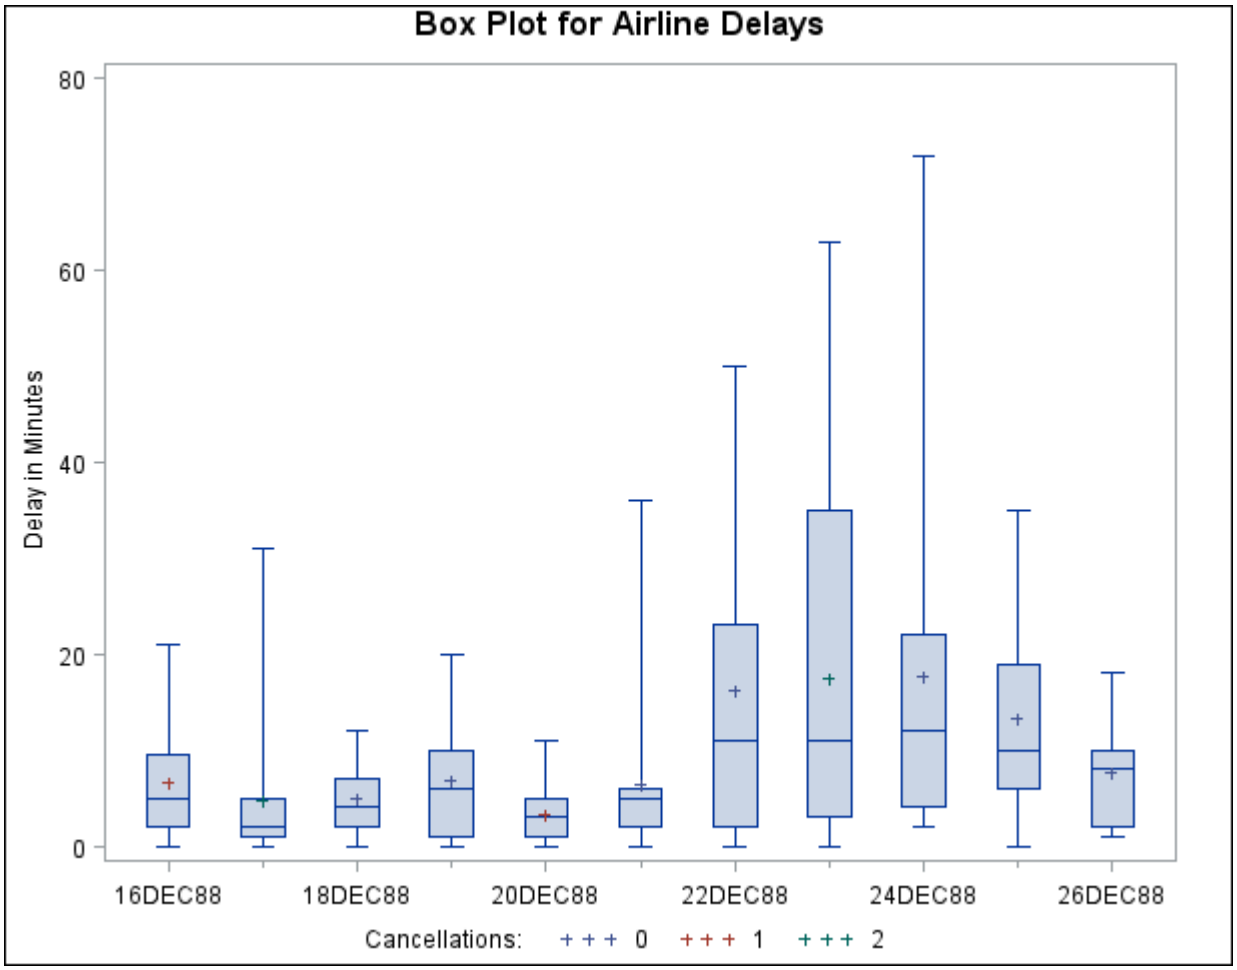
data Times;
   merge Times Weather;
   by Day Flight;
run;
```

The following statements create a box plot for the complete set of data:

```
ods graphics off;
symbol1 v=plus;
symbol2 v=square;
symbol3 v=triangle;
title 'Box Plot for Airline Delays';
proc boxplot data=Times;
   plot Delay*Day = ncancel /
       nohlabel
       symbollegend = legend1;
   legend1 label = ('Cancellations:');
   label Delay = 'Delay in Minutes';
run;
goptions reset=symbol;
```

The level of the *symbol variable* ncancel determines the symbol marker for each group mean, and the SYMBOLLEGEND= option controls the appearance of the legend for the symbols. The NOHLABEL option suppresses the horizontal axis label. The resulting box plot is shown in Output 25.2.1.

Output 25.2.1 Box Plot for Airline Data



The delay distributions from December 22 through December 25 are drastically different from the delay distributions during the pre-holiday period. Both the mean delay and the variability of the delays are much greater during the holiday period.

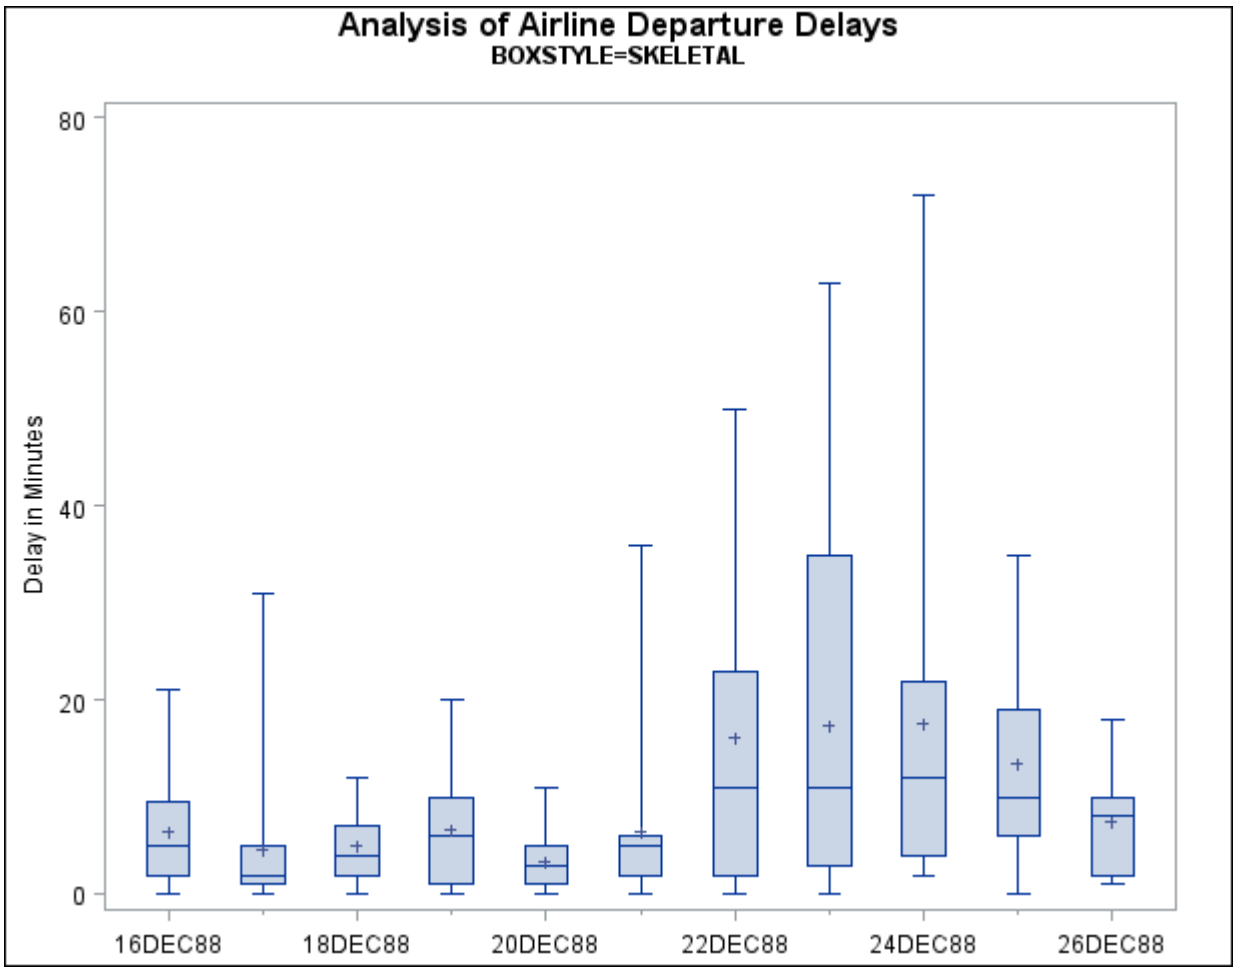
Example 25.3: Creating Various Styles of Box-and-Whiskers Plots

This example uses the flight delay data of the preceding example to illustrate how you can create box plots with various styles of box-and-whiskers plots. The following statements create a plot that displays skeletal box-and-whiskers plots:

```
title 'Analysis of Airline Departure Delays';
title2 'BOXSTYLE=SKELETAL';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = skeletal
      nohlabel;
   label Delay = 'Delay in Minutes';
run;
```

In a skeletal box-and-whiskers plot, the whiskers are drawn from the quartiles to the extreme values of the group. The skeletal box plot is the default style, so you can also produce a skeletal box plot by omitting the BOXSTYLE= option. Output 25.3.1 shows the skeletal box plot.

Output 25.3.1 BOXSTYLE=SKELETAL

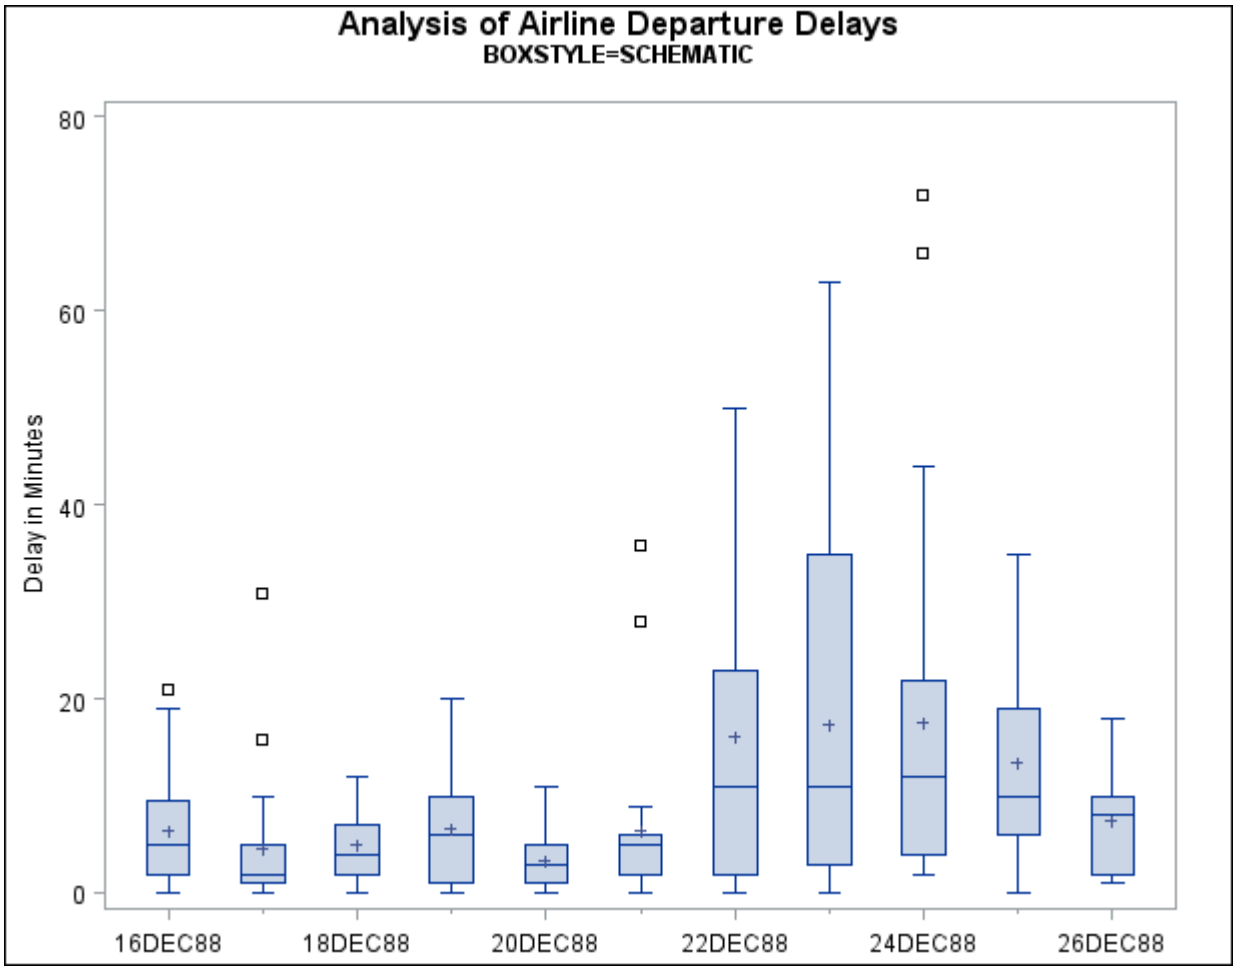


The following statements request a schematic box:

```
title 'Analysis of Airline Departure Delays';
title2 'BOXSTYLE=SCHEMATIC';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematic
      nohlabel;
   label Delay = 'Delay in Minutes';
run;
```

When you specify BOXSTYLE=SCHEMATIC, the whiskers are drawn to the most extreme points in the group that lie within the *fences*. The *upper fence* is defined as the third quartile (represented by the upper edge of the box) plus 1.5 times the interquartile range (IQR). The *lower fence* is defined as the first quartile (represented by the lower edge of the box) minus 1.5 times the interquartile range. Observations outside the fences are identified with a special symbol. The default symbol is a square, and you can specify the shape and color for this symbol with the IDSYMBOL= and IDCOLOR= options. Serifs are added to the whiskers by default. For further details, see the entry for the BOXSTYLE= option. The plot is shown in Output 25.3.2.

Output 25.3.2 BOXSTYLE=SCHEMATIC

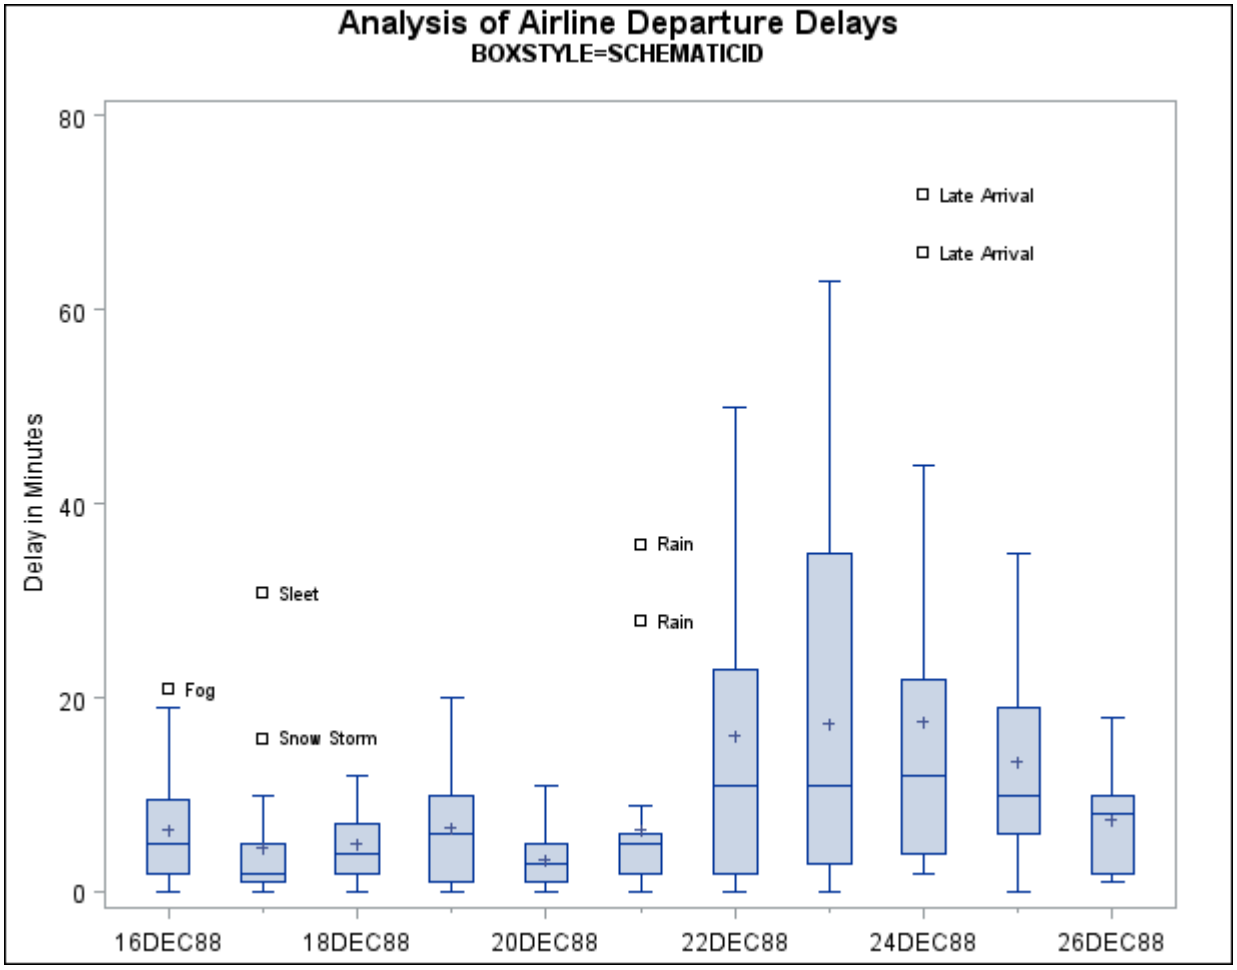


The following statements create a schematic box plot in which the observations outside the fences are labeled:

```
title 'Analysis of Airline Departure Delays';
title2 'BOXSTYLE=SCHEMATICID';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematicid
      nohlabel;
   id Reason;
   label Delay = 'Delay in Minutes';
run;
```

If you specify BOXSTYLE=SCHEMATICID, schematic box-and-whiskers plots are created and the value of the first ID variable (in this case, Reason) is used to label each observation outside the fences. The box plot is shown in Output 25.3.3.

Output 25.3.3 BOXSTYLE=SCHEMATICID

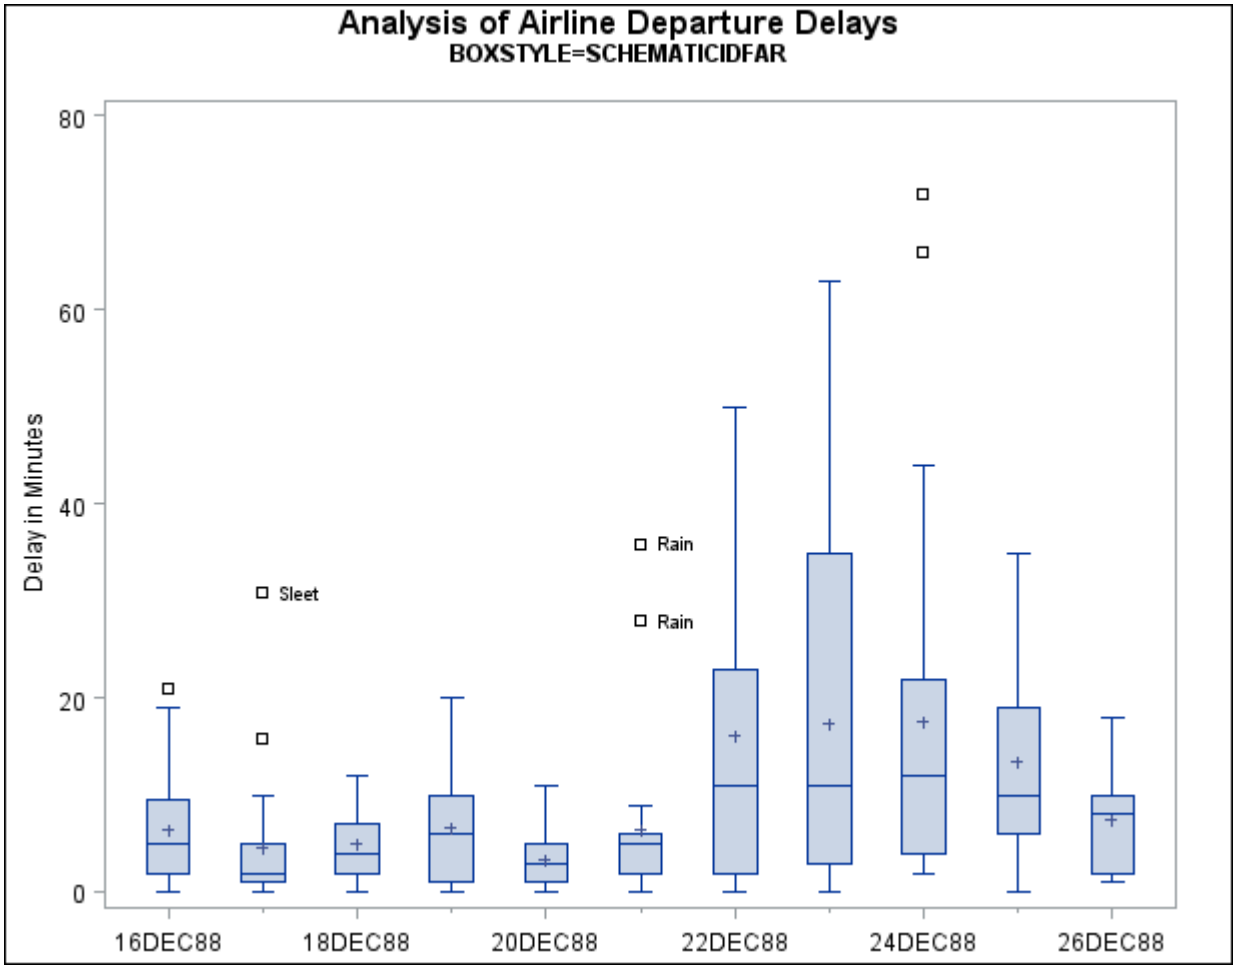


The following statements create a box plot with schematic box-and-whiskers plots in which only the extreme observations outside the fences are labeled:

```
title 'Analysis of Airline Departure Delays';
title2 'BOXSTYLE=SCHEMATICIDFAR';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematicidfar
      nohlabel;
   id Reason;
   label Delay = 'Delay in Minutes';
run;
```

If you specify BOXSTYLE=SCHEMATICIDFAR, the value of the first ID variable is used to label each observation outside the lower and upper *far fences*. The lower and upper far fences are located 3×IQR below the 25th percentile and 3×IQR above the 75th percentile, respectively. Observations between the fences and the far fences are identified with a symbol but are not labeled. The box plot is shown in Output 25.3.4.

Output 25.3.4 BOXSTYLE=SCHEMATICIDFAR



Other options for controlling the display of high-resolution graphics box plots include the BOXWIDTH=, BOXWIDTHSCALE=, CBOXES=, CBOXFILL=, and LBOXES= options.

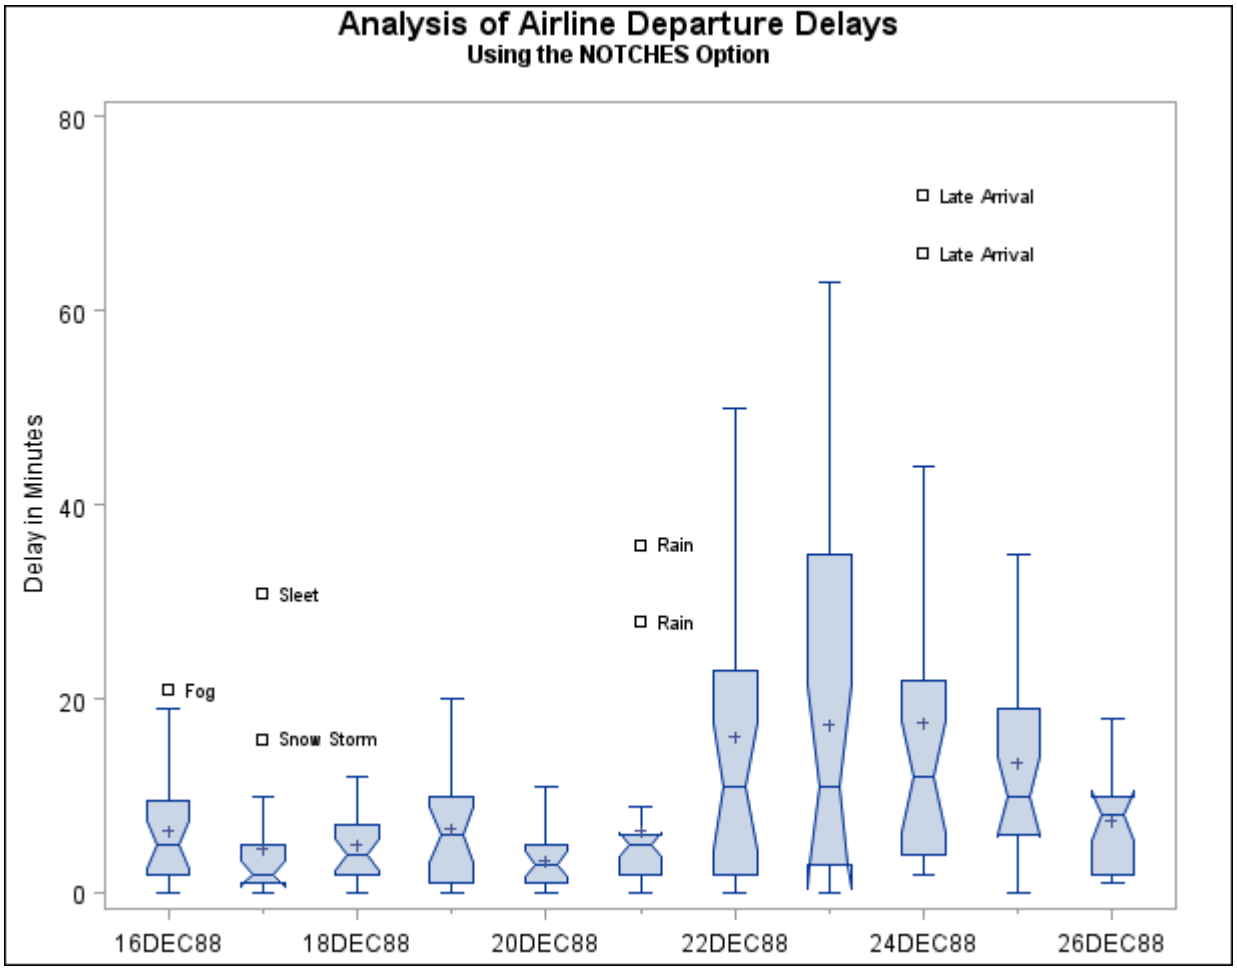
Example 25.4: Creating Notched Box-and-Whiskers Plots

The following statements use the flight delay data of Example 25.1 to create box-and-whiskers plots with notches:

```
title 'Analysis of Airline Departure Delays';
title2 'Using the NOTCHES Option';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematicid
      nohlabel
      notches;
   id Reason;
   label Delay = 'Delay in Minutes';
run;
```

The notches, requested with the NOTCHES option, measure the significance of the difference between two medians. The medians of two box plots are significantly different at approximately the 0.95 confidence level if the corresponding notches do not overlap. For example, in Output 25.4.1, the median for December 20 is significantly different from the median for December 24.

Output 25.4.1 Notched Side-by-Side Box-and-Whiskers Plots



Example 25.5: Creating Box-and-Whiskers Plots with Varying Widths

This example shows how to create a box plot with box-and-whiskers plots whose widths vary proportionately with the group size. The following statements create a SAS data set named Times2 that contains flight departure delays (in minutes) recorded daily for eight consecutive days:

```
data Times2;
     label Delay = 'Delay in Minutes';
     informat Day date7. ;
     format   Day date7. ;
     input Day @ ;
     do Flight=1 to 25;
        input Delay @ ;
        output;
        end;
datalines;
01MAR90   12  4   2   2  15   8   0  11   0   0
           0  12   3   .   2   3   5   0   6  25
           7   4   9   5  10
02MAR90   1   .   3   .   0   1   5   0   .   .
           1   5   7   .   7   2   2  16   2   1
           3   1  31   .   0
03MAR90   6   8   4   2   3   2   7   6  11   3
           2   7   0   1  10   2   5  12   8   6
           2   7   2   4   5
04MAR90  12   6   9   0  15   7   1   1   0   2
           5   6   5  14   7  21   8   1  14   3
          11   0   1  11   7
05MAR90   2   1   0   4   .   6   2   2   1   4
           1  11   .   1   0   .   5   5   .   2
           3   6   6   4   0
06MAR90   8   6   5   2   9   7   4   2   5   1
           2   2   4   2   5   1   3   9   7   8
           1   0   4  26  27
07MAR90   9   6   6   2   7   8   .   .  10   8
           0   2   4   3   .   .   .   7   .   6
           4   0   .   .   .
08MAR90   1   6   6   2   8   8   5   3   5   0
           8   2   4   2   5   1   6   4   5  10
           2   0   4   1   1
;
```

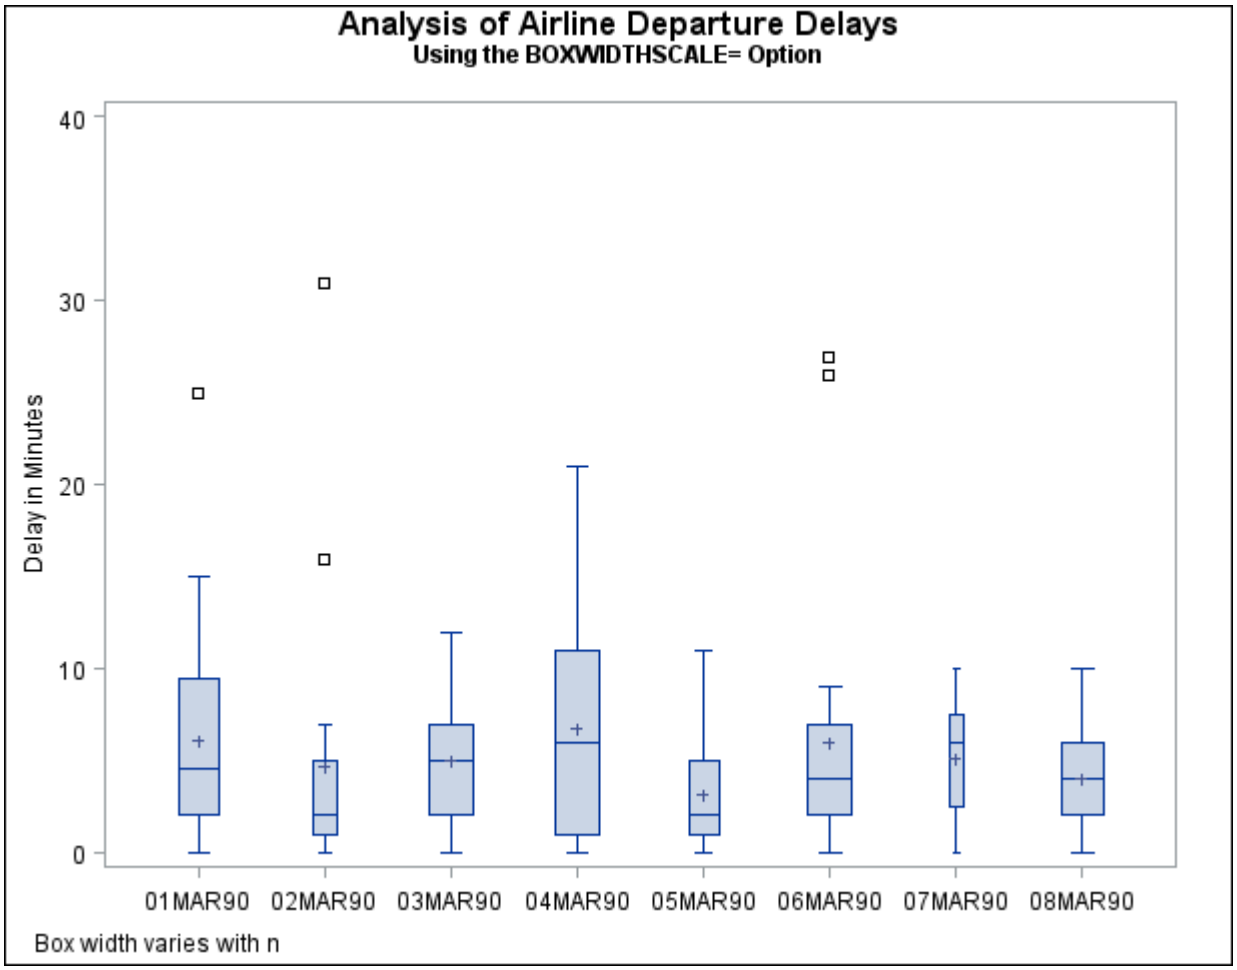
The following statements create a box plot with varying box widths:

```
title 'Analysis of Airline Departure Delays';
title2 'Using the BOXWIDTHSCALE= Option';
proc boxplot data=Times2;
   plot Delay*Day /
      nohlabel
      boxstyle      = schematic
      boxwidthscale = 1
      bwslegend;
run;
```

The BOXWIDTHSCALE=*value* option specifies that the widths of the box-and-whiskers plots vary in proportion to a particular function of the group size n. The function is determined by *value* and is identified on the box plot with a legend if the BWSLEGEND option is specified. The BOXWIDTHSCALE= option is useful in situations where the group sizes vary widely.

Output 25.5.1 shows the resulting box plot.

Output 25.5.1 Box Plot with Box-and-Whiskers Plots of Varying Widths



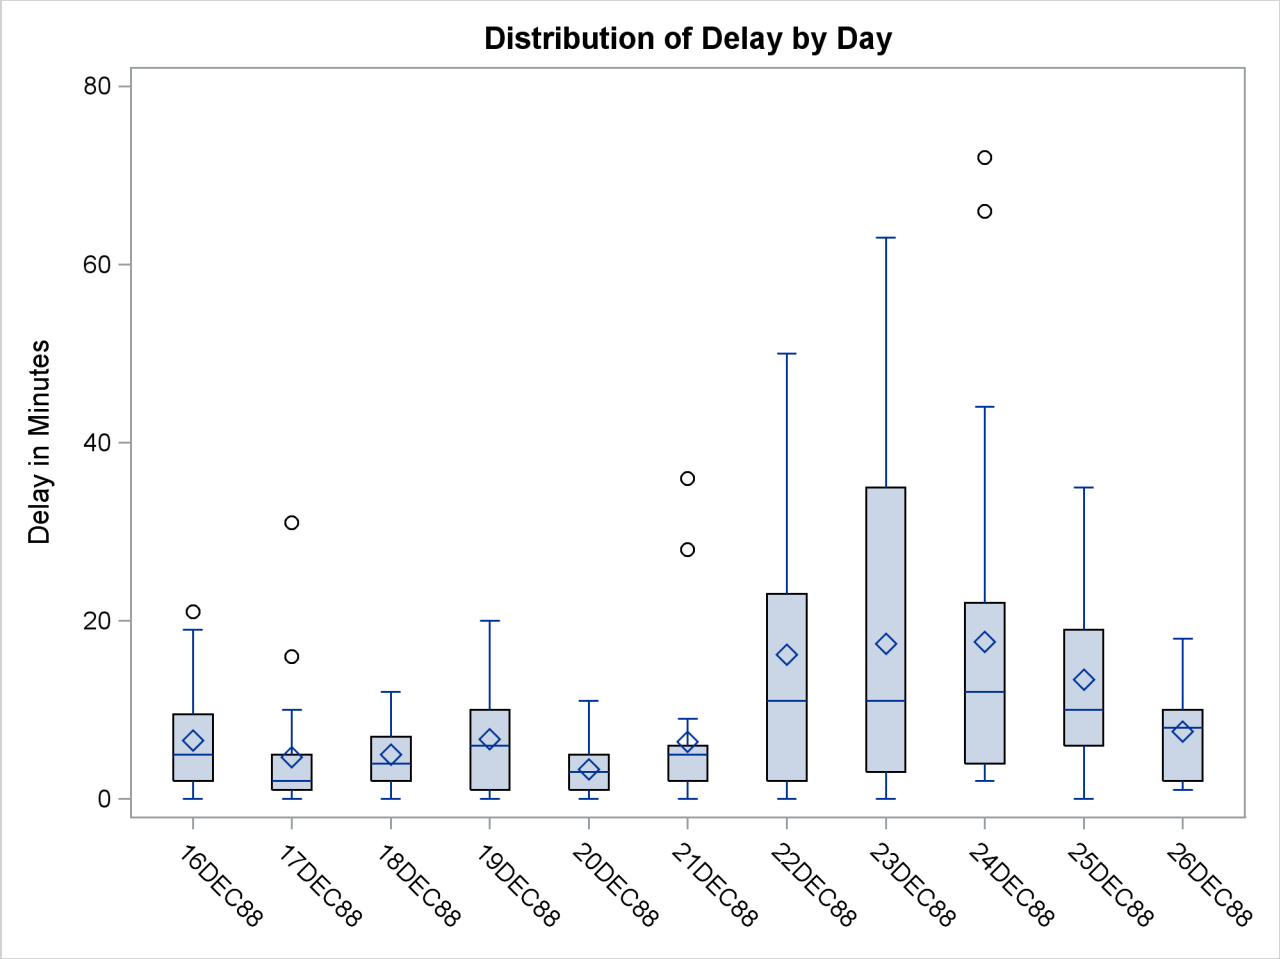
Example 25.6: Creating Box-and-Whiskers Plots Using ODS Graphics

The following statements use ODS Graphics to produce a box plot of the flight delay data from Example 25.2.

```
ods graphics on;
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematic
      nohlabel;
   label Delay = 'Delay in Minutes';
run;
```

The resulting box plot is shown in Output 25.6.1.

Output 25.6.1 Box Plot Produced Using ODS Graphics



ODS graphical displays, like traditional high-resolution graphs in SAS 9.2, are controlled by the ODS style currently in effect for the output destination where the box plots are produced. However, unlike high-resolution graphs, ODS graphs are unaffected by GOPTIONS and SYMBOL statements, and by PLOT statement options used to specify colors, fonts, and other features affecting box plot appearance. Options such as BOXSTYLE= and NOHLABEL *are* honored by the PLOT statement when producing ODS graphical output.

The following statements use the HORIZONTAL option, which is supported only by ODS Graphics, to produce a horizontal box plot:

```
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematic
      horizontal;
   label Delay = 'Delay in Minutes';
run;
```

The horizontal box plot is shown in Output 25.6.2.

Output 25.6.2 Horizontal Box Plot

Chapter 26

The CALIS Procedure

Contents

Overview: CALIS Procedure

Structural equation modeling is an important statistical tool in social and behavioral sciences. Structural equations express relationships among a system of variables that can be either observed variables (manifest variables) or unobserved hypothetical variables (latent variables). For an introduction to latent variable models, see Loehlin (2004), Bollen (1989b), Everitt (1984), or Long (1983); and for manifest variables with measurement errors, see Fuller (1987).

In structural models, as opposed to functional models, all variables are taken to be random rather than having fixed levels. For maximum likelihood (default) and generalized least squares estimation in PROC CALIS, the random variables are assumed to have an approximately multivariate normal distribution. Nonnormality, especially high kurtosis, can produce poor estimates and grossly incorrect standard errors and hypothesis tests, even in large samples. Consequently, the assumption of normality is much more important than in models with nonstochastic exogenous variables. You should remove outliers and consider transformations of nonnormal variables before using PROC CALIS with maximum likelihood (default) or generalized least squares estimation. If the number of observations is sufficiently large, Browne's asymptotically distribution-free (ADF) estimation method can be used. If your data sets contain random missing data, the full information maximum likelihood (FIML) method can be used.

You can use the CALIS procedure to estimate parameters and test hypotheses for constrained and unconstrained problems in various situations, including but not limited to the following:

- exploratory and confirmatory factor analysis of any order
- linear measurement-error models or regression with errors in variables
- multiple and multivariate linear regression
- multiple-group structural equation modeling with mean and covariance structures
- path analysis and causal modeling
- simultaneous equation models with reciprocal causation
- structured covariance and mean matrices in various forms

To specify models in PROC CALIS, you can use a variety of modeling languages:

- COSAN—a generalized version of the COSAN program (McDonald 1978, 1980), uses general mean and covariance structures to define models
- FACTOR—supports the input of latent factor and observed variable relations
- LINEQS—like the EQS program (Bentler 1995), uses equations to describe variable relationships
- LISMOD—utilizes LISREL (Jöreskog and Sörbom 1985) model matrices to define models
- MSTRUCT—supports direct parameterizations in the mean and covariance matrices

- PATH—provides an intuitive causal path specification interface
- RAM—utilizes the formulation of the reticular action model (McArdle and McDonald 1984) to define models
- REFMODEL—provides a quick way for model referencing and respecification

Various modeling languages are provided to suit a wide range of researchers' background and modeling philosophy. However, statistical situations might arise where one modeling language is more convenient than the others. This will be discussed in the section "Which Modeling Language?" on page 1012.

In addition to basic model specification, you can set various parameter constraints in PROC CALIS. Equality constraints on parameters can be achieved by simply giving the same parameter names in different parts of the model. Boundary, linear, and nonlinear constraints are supported as well. If parameters in the model are dependent on additional parameters, you can define the dependence by using the PARAMETERS and the SAS programming statements.

Before the data are analyzed, researchers might be interested in studying some statistical properties of the data. PROC CALIS can provide the following statistical summary of the data:

- covariance and mean matrices and their properties
- descriptive statistics like means, standard deviations, univariate skewness, and kurtosis measures
- multivariate measures of kurtosis
- coverage of covariances and means, missing patterns summary, and means of the missing patterns when the FIML estimation is used
- weight matrix and its descriptive properties

After a model is fitted and accepted by the researcher, PROC CALIS can provide the following supplementary statistical analysis:

- computing squared multiple correlations and determination coefficients
- direct and indirect effects partitioning with standard error estimates
- model modification tests such as Lagrange multiplier and Wald tests
- computing fit summary indices
- computing predicted moments of the model
- residual analysis
- factor rotations
- standardized solutions with standard errors
- testing parametric functions, individually or simultaneously

When fitting a model, you need to choose an estimation method. The following estimation methods are supported in the CALIS procedure:

- diagonally weighted least squares (DWLS, with optional weight matrix input)
- full information maximum likelihood (FIML, which can treat observations with random missing values)
- generalized least squares (GLS, with optional weight matrix input)
- maximum likelihood (ML, for multivariate normal data); this is the default method
- unweighted least squares (ULS)
- weighted least squares or asymptotically distribution-free method (WLS or ADF, with optional weight matrix input)

Estimation methods implemented in PROC CALIS do not exhaust all alternatives in the field. For example, the partial least squares (PLS) method is not implemented. See the section "Estimation Criteria" on page 1246 for details about estimation criteria used in PROC CALIS. Note that there is a SAS/STAT procedure called PROC PLS, which employs the partial least squares technique but for a different class of models than those of PROC CALIS. For general path analysis with latent variables, consider using PROC CALIS.

All estimation methods need some starting values for the parameter estimates. You can provide starting values for any parameters. If there is any estimate without a starting value provided, PROC CALIS determines the starting value by using one or any combination of the following methods:

- approximate factor analysis
- default initial values
- instrumental variable method
- matching observed moments of exogenous variables
- McDonald's method (McDonald and Hartmann 1992) method
- ordinary least squares estimation
- random number generation, if a seed is provided
- two-stage least squares estimation

Although no methods for initial estimates are completely foolproof, the initial estimation methods provided by PROC CALIS behave reasonably well in most common applications.

With initial estimates, PROC CALIS will iterate the solutions so as to achieve the optimum solution as defined by the estimation criterion. This is a process known as optimization. Because numerical problems can occur in any optimization process, the CALIS procedure offers several optimization algorithms so that you can choose alternative algorithms when the one being used fails. The following optimization algorithms are supported in PROC CALIS:

- Levenberg-Marquardt algorithm (Moré 1978)
- trust-region algorithm (Gay 1983)
- Newton-Raphson algorithm with line search
- ridge-stabilized Newton-Raphson algorithm
- various quasi-Newton and dual quasi-Newton algorithms: Broyden-Fletcher-Goldfarb-Shanno and Davidon-Fletcher-Powell, including a sequential quadratic programming algorithm for processing nonlinear equality and inequality constraints
- various conjugate gradient algorithms: automatic restart algorithm of Powell (1977), Fletcher-Reeves, Polak-Ribiere, and conjugate descent algorithm of Fletcher (1980)

In addition to the ability to save output tables as data sets by using the ODS OUTPUT statement, PROC CALIS supports the following types of output data sets so that you can save your analysis results for later use:

- OUTEST= data sets for storing parameter estimates and their covariance estimates
- OUTFIT= data sets for storing fit indices and some pertinent modeling information
- OUTMODEL= data sets for storing model specifications and final estimates
- OUTSTAT= data sets for storing descriptive statistics, residuals, predicted moments, and latent variable scores regression coefficients
- OUTWGT= data sets for storing the weight matrices used in the modeling

The OUTEST=, OUTMODEL=, and OUTWGT= data sets can be used as input data sets for subsequent analyses. That is, in addition to the input data provided by the DATA= option, PROC CALIS supports the following input data sets for various purposes in the analysis:

- INEST= data sets for providing initial parameter estimates. An INEST= data set could be an OUTEST= data set created from a previous analysis.
- INMODEL= data sets for providing model specifications and initial estimates. An INMODEL= data set could be an OUTMODEL= data set created from a previous analysis.
- INWGT= data sets for providing the weight matrices. An INWGT= data set could be an OUTWGT= data set created from a previous analysis.

The CALIS procedure uses ODS Graphics to create graphs as part of its output. High-quality residual histograms are available in PROC CALIS. See Chapter 21, "Statistical Graphics Using ODS," for general information about ODS Graphics. See the section "ODS Graphics" on page 1314 and the PLOTS= option on page 1047 for specific information about the statistical graphics available with the CALIS procedure.

Changes and Enhancements

The following sections describe the new features of this version of PROC CALIS.

Built-In Covariance and Mean Structures

PROC CALIS now supports the fitting of some standard covariance and mean patterns by using the COVPATTERN= and the MEANPATTERN= options. These standard covariance and mean patterns are built into PROC CALIS. You can call these built-in patterns by appropriate keywords without using explicit model specifications such as the MSTRUCT and MATRIX statements. For example, you can now test the compound symmetry pattern of a covariance matrix by simply specifying the COVPATTERN=COMPSYM option. PROC CALIS then generates the compound symmetry pattern internally for model fitting. To specify the same covariance pattern in the previous version of PROC CALIS, you would need to use the MSTRUCT statement and specify the parameters of the covariance pattern in the MATRIX statement. Another example is using the COVPATTERN=EQCOVMAT option to test the equality of covariance matrices among independent groups. See the COVPATTERN= and MEANPATTERN= options for details about the supported covariance and mean patterns.

Covariance and Mean Structure Analysis with the COSAN Model

PROC CALIS now supports covariance and mean structure analysis in the COSAN model. You can specify the central mean vector in each term of the mean structure formula. See the COSAN statement and the section "The COSAN Model" on page 1193 for details.

Extended PATH Modeling Language

You can specify variances, covariances, means, and intercepts as paths in the PATH statement. The syntax enables you to map all the parameters in the path diagram to the PATH statement specification. See the PATH statement for details. Even if you specify variances, covariances, means, or intercepts in the PVAR, PCOV, and MEAN statements (but not in the path statement), you can still display these parameter estimates as paths in the output table for the regular path effect (coefficient) estimates by using the EXTENDPATH option.

Full Information Maximum Likelihood Method

PROC CALIS implements the full information maximum likelihood method (FIML) for treating data with random missing values. The FIML method uses all the available information from the data set, including observations with missing values, so that it is statistically more efficient than the ML (maximum likelihood) method (as implemented in PROC CALIS). You can use METHOD=FIML to invoke the FIML method. In addition to the estimation, the FIML method also provides detailed analysis of the missing patterns such as the coverage statistics of the sample moments, frequencies and proportions of the missing patterns, and the descriptive statistics of the missing patterns. You can use new options MAXMISSPAT=, NOMISSPAT, and TMISSPAT= to control the output of missing patterns analysis.

Improved RAM Model Specification

You can now specify the variable list explicitly in the VAR= option of the RAM statement. This variable list is useful to make immediate references of the variables (manifest or latent) in the model. The mean structure specification of the RAM model is also supported. See the RAM statement and the section "The RAM Model" on page 1229 for details.

Unnamed Free Parameter Specification

You can specify free parameters in all models without using explicit parameter names (that is, unnamed free parameters). This makes your model specification more efficient. For example, in the PATH statement, you can specify only the paths without using the parameter names for the path effects (coefficients). PROC CALIS generates the parameter names automatically. However, you can also input the parameter names whenever it is necessary (for example, for setting parameter constraints). Unnamed free parameters specification is supported in all modeling languages. For details, see the syntax of the following statements: COV, FACTOR, LINEQS, MATRIX, MEAN, PATH, PCOV, PVAR, RAM, and VARIANCE.

Structural Equation Modeling Application

The Structural Equation Modeling Application is a graphical user interface to structural equation modeling techniques. You can specify models in graphical form to represent the hypothesized relationships among the variables. It is accessed from JMP software and uses the CALIS procedure for its computations.

The application enables you to define model variables in a path diagram by dragging data set variables to the diagram and to define the relationship between the model variables by using an arrow tool. You can move the variables to arrange the path diagram exactly the way you want. You can easily make a copy of a model, modify it, and analyze the new model, and you can compare several models with appropriate fit statistics. Finally, you can save the model specifications and the results for later use.

The Structural Equation Modeling Application provides access to a subset of the capabilities in the CALIS procedure. It supports mainly the PATH model specification through the path diagram interface. It does not support many other advanced features in PROC CALIS. For example, multiple-group analysis and full information maximum likelihood estimation are not available in the Structural Equation Modeling Application. For details, see *The Structural Equation Modeling Application*.

A Guide to the PROC CALIS Documentation

The CALIS procedure uses a variety of modeling languages to fit structural equation models. This chapter provides documentation for all of them. Additionally, some sections provide introductions to the model specification, the theory behind the software, and other technical details. While some introductory material and examples are provided, this chapter is not a textbook for structural equation modeling and related topics. For didactic treatment of structural equation models with latent variables, see Bollen (1989b) and Loehlin (2004).

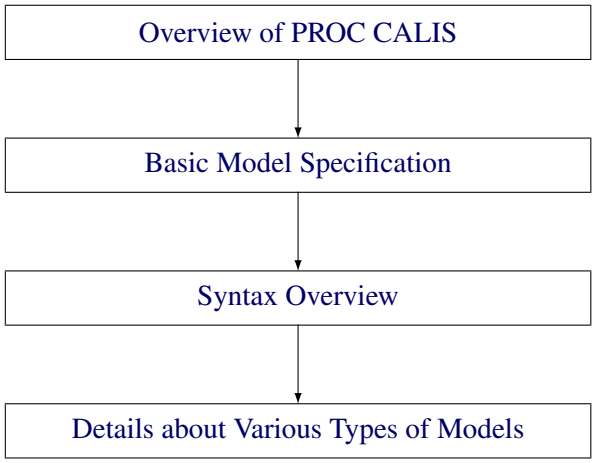
Reading this chapter sequentially is not a good strategy for learning about PROC CALIS. This section provides a guide or "road map" to the rest of the PROC CALIS chapter, starting with the basics and continuing through more advanced topics. Many sections assume that you already have a basic understanding of structural equation modeling.

The following table shows three different skill levels of using the CALIS procedure (basic, intermediate, and advanced) and their milestones.

Level	Milestone	Starting Section
Basic	You are able to specify simple models, but might make mistakes.	"Guide to the Basic Skill Level" on page 992
Intermediate	You are able to specify more sophisticated models with few syntactic and semantic mistakes.	"Guide to the Intermediate Skill Level" on page 997
Advanced	You are able to use the advanced options provided by PROC CALIS.	"Guide to the Advanced Skill Level" on page 999

In the next three sections, each skill level is discussed, followed by an introductory section of the reference topics that are not covered in any of the skill levels.

Guide to the Basic Skill Level



Overview of PROC CALIS

The section "Overview: CALIS Procedure" on page 986 gives you an overall picture of the CALIS procedure but without the details.

Basic Model Specification

The structural equation example in the section "Getting Started: CALIS Procedure" on page 1002 provides the starting point to learn the basic model specification. You learn how to represent your theory by using a

path diagram and then translate the diagram into the PATH model for PROC CALIS to analyze. Because the PATH modeling language is new, this example is useful whether or not you have previous experience with PROC CALIS. The PATH model is specified in the section "PATH Model" on page 1004. The corresponding results are shown and discussed in Example 26.16.

After you learn about the PATH modeling language and an example of its application, you can do either of the following:

- You can continue to learn more modeling languages in the section "Getting Started: CALIS Procedure" on page 1002.
- You can skip to the section "Syntax Overview" on page 996 for an overview of the PROC CALIS syntax and learn other modeling languages at a later time.

You do not need to learn all of the modeling languages in PROC CALIS. Any one of the modeling languages (LINEQS, LISMOD, PATH, or RAM) is sufficient for specifying a very wide class of structural equation models. PROC CALIS provides different kinds of modeling languages because different researchers might have previously learned different modeling languages or approaches. To get a general idea about different kinds of modeling languages, the following subsections in the "Getting Started: CALIS Procedure" section are useful:

- LINEQS: Section "LINEQS Model" on page 1006
- RAM: Section "RAM Model" on page 1005
- LISMOD: Section "LISMOD Model" on page 1008
- FACTOR: Section "A Factor Model Example" on page 1009
- MSTRUCT: Section "Direct Covariance Structures Analysis" on page 1011

After studying the examples in the "Getting Started: CALIS Procedure" section, you can strengthen your understanding of the various modeling languages by studying more examples such as those in section "Examples: CALIS Procedure" on page 1315. Unlike the examples in the "Getting Started: CALIS Procedure" section, the examples in the "Examples: CALIS Procedure" section include the analysis results in addition to the explanations of the model specifications.

You can start with the following two sets of basic examples:

- MSTRUCT model examples
  The basic MSTRUCT model examples demonstrate the testing of covariance structures directly on the covariance matrices. Although the MSTRUCT model is not the most common structural equation models in applications, these MSTRUCT examples can help you understand the basic form of covariance structures and the corresponding specifications in PROC CALIS.
- PATH model examples
  The basic PATH model examples demonstrate how you can represent your model by path diagrams and by the PATH modeling language. These examples show the most common applications of structural equation modeling.

The following is a summary of the basic MSTRUCT model examples:

- "Example 26.1: Estimating Covariances and Correlations" on page 1315 shows how you can estimate the covariances and correlations with standard error estimates for the variables in your model. The model you fit is a saturated covariance structure model.
- "Example 26.2: Estimating Covariances and Means Simultaneously" on page 1320 extends Example 26.1 to include the mean structures in the model. The model you fit is a saturated mean and covariance structure model.
- "Example 26.3: Testing Uncorrelatedness of Variables" on page 1322 shows a very basic covariance structure model, in which the covariance structures can be specified directly. The variables in this model are uncorrelated. You learn how to specify the covariance pattern directly.
- "Example 26.4: Testing Covariance Patterns" on page 1325 extends Example 26.3 to include other covariance structures that you can specify directly.
- "Example 26.5: Testing Some Standard Covariance Pattern Hypotheses" on page 1327 illustrates the use of built-in covariance patterns supported by PROC CALIS.

The following is a summary of the basic PATH model examples:

- "Example 26.6: Linear Regression Model" on page 1331 shows how you can fit a linear regression model with the PATH modeling language of PROC CALIS. This example also introduces the path diagram representation of "causal" models. You compare results obtained from PROC CALIS and from the REG procedure, which is designed specifically for regression analysis.
- "Example 26.7: Multivariate Regression Models" on page 1336 extends Example 26.6 in several different ways. You fit covariance structure models with more than one predictor, with direct and indirect effects. This example also discusses how you can choose the "best" model for your data.
- "Example 26.8: Measurement Error Models" on page 1354 explores the case where the predictor in simple linear regression is measured with error. The concept of latent true score variable is introduced. You use PROC CALIS to fit a simple measurement error model.
- "Example 26.9: Testing Specific Measurement Error Models" on page 1361 extends Example 26.8 to test special measurement error models with constraints. By using PROC CALIS, you can constrain your measurement error models in many different ways. For example, you can constrain the error variances or the intercepts to test specific hypotheses.
- "Example 26.10: Measurement Error Models with Multiple Predictors" on page 1367 extends Example 26.8 to include more predictors in the measurement error models. The measurement errors in the predictors can be correlated in the model.

More elaborate examples about the MSTRUCT and PATH models are listed as follows:

- "Example 26.16: Path Analysis: Stability of Alienation" on page 1415 shows you how to specify a simple PATH model and interpret the basic estimation results. The results are shown in considerable

detail. The output and analyses include: a model summary, an initial model specification, an initial estimation method, an optimization history and results, residual analyses, residual graphics, estimation results, squared multiple correlations, and standardized results.

- "Example 26.18: Fitting Direct Covariance Structures" on page 1437 shows you how to fit your covariance structures directly on the covariance matrix by using the MSTRUCT modeling language. You also learn how to use the FITINDEX statement to create a customized model fit summary and how to save the fit summary statistics into an external file.
- "Example 26.20: Testing Equality of Two Covariance Matrices Using a Multiple-Group Analysis" on page 1453 uses the MSTRUCT modeling language to illustrate a simple multiple-group analysis. You also learn how to use the ODS SELECT statement to customize your printed output.
- "Example 26.21: Testing Equality of Covariance and Mean Matrices between Independent Groups" on page 1458 uses the COVPATTERN= and MEANPATTERN= options to show some tests of equality of covariance and mean matrices between independent groups. It also illustrates how you can improve your model fit by the exploratory use of the Lagrange multiplier statistics for releasing equality constraints.
- "Example 26.23: Testing Competing Path Models for the Career Aspiration Data" on page 1492 illustrates how you can fit competing models by using the OUTMODEL= and INMODEL= data sets for transferring and modifying model information from one analysis to another. This example also demonstrates how you can choose the best model among several competing models for the same data.

After studying the PATH and MSTRUCT modeling languages, you are able to specify most commonly used structural equation models by using PROC CALIS. To broaden your scope of structural equation modeling, you can study some basic examples that use the FACTOR and LINEQS modeling languages. These basic examples are listed as follows:

- "Example 26.11: Measurement Error Models Specified As Linear Equations" on page 1372 explores another way to specify measurement error models in PROC CALIS. The LINEQS modeling language is introduced. You learn how to specify linear equations of the measurement error model by using the LINEQS statement. Unlike the PATH modeling language, in the LINEQS modeling language, you need to specify the error terms explicitly in the model specification.
- "Example 26.12: Confirmatory Factor Models" on page 1378 introduces a basic confirmatory factor model for test items. You use the FACTOR modeling language to specify the factor-variable relationships.
- "Example 26.13: Confirmatory Factor Models: Some Variations" on page 1389 extends Example 26.12 to include some variants of the confirmatory factor model. With the flexibility of the FACTOR modeling language, this example shows how you fit models with parallel items, tau-equivalent items, or partially parallel items.

More advanced examples that use the LINEQS and FACTOR modeling languages are listed as follows:

- "Example 26.14: The Full Information Maximum Likelihood Method" on page 1399 shows how you can use the full information maximum likelihood (FIML) method to estimate your model when your

data contain missing values. It illustrates the analysis of the data coverage of the sample variances, covariances, and means and the analysis of missing patterns and the mean profile. It also shows that the full information maximum likelihood method makes the maximum use of the available information from the data, as compared with the default ML (maximum likelihood) methods.

- "Example 26.15: Comparing the ML and FIML Estimation" on page 1409 discusses the similarities and differences between the ML and FIML estimation methods as implemented in PROC CALIS. It uses an empirical example to show how ML and FIML obtain the same estimation results when the data do not contain missing values.

- "Example 26.17: Simultaneous Equations with Mean Structures and Reciprocal Paths" on page 1430 is an econometric example that shows you how to specify models using the LINEQS modeling language. This example also illustrates the specification of reciprocal effects, the simultaneous analysis of the mean and covariance structures, the setting of bounds for parameters, and the definitions of metaparameters by using the PARAMETERS statement and SAS programming statements. You also learn how to shorten your output results by using some global display options such as the PSHORT and NOSTAND options in the PROC CALIS statement.

- "Example 26.19: Confirmatory Factor Analysis: Cognitive Abilities" on page 1441 uses the FACTOR modeling language to illustrate confirmatory factor analysis. In addition, you use the MODIFICATION option in the PROC CALIS statement to compute LM test indices for model modifications.

- "Example 26.24: Fitting a Latent Growth Curve Model" on page 1507 is an advanced example that illustrates the use of structural equation modeling techniques for fitting latent growth curve models. You learn how to specify random intercepts and random slopes by using the LINEQS modeling language. In addition to the modeling of the covariance structures, you also learn how to specify the mean structure parameters.

If you are familiar with the traditional Keesling-Wiley-Jöreskog measurement and structural models (Keesling 1972; Wiley 1973; Jöreskog 1973) or the RAM model (McArdle 1980), you can use the LISMOD or RAM modeling languages to specify structural equation models. The following example shows how to specify these types of models:

- "Example 26.22: Illustrating Various General Modeling Languages" on page 1483 extends Example 26.16, which uses the PATH modeling language, and shows how to use the other general modeling languages: RAM, LINEQS, and LISMOD. These modeling languages enable you to specify the same path model as in Example 26.16 and get equivalent results. This example shows the connections between the general modeling languages supported in PROC CALIS. A good understanding of Example 26.16 is a prerequisite for this example.

Once you are familiar with various modeling languages, you might wonder which modeling language should be used in a given situation. The section "Which Modeling Language?" on page 1012 provides some guidelines and suggestions.

Syntax Overview

The section "Syntax: CALIS Procedure" on page 1014 shows the syntactic structure of PROC CALIS. However, reading the "Syntax: CALIS Procedure" section sequentially might not be a good strategy. The

statements used in PROC CALIS are classified in the section "Classes of Statements in PROC CALIS" on page 1015. Understanding this section is a prerequisite for understanding single-group and multiple-group analyses in PROC CALIS. Syntax for single-group analyses is described in the section "Single-Group Analysis Syntax" on page 1018, and syntax for multiple-group analyses is described in the section "Multiple-Group Multiple-Model Analysis Syntax" on page 1019.

You might also want to get an overview of the options in the PROC CALIS statement. However, you can skip the detailed listing of the available options in the PROC CALIS statement. Most of these details serve as references, so you can consult them only when you need to. You can just read the summary tables for the available options in the PROC CALIS statement in the following subsections:

- "Data Set Options" on page 1020
- "Model and Estimation Options" on page 1021
- "Options for Fit Statistics" on page 1021
- "Options for Statistical Analysis" on page 1022
- "Global Display Options" on page 1022
- "Optimization Options" on page 1024

Details about Various Types of Models

Several subsections in the section "Details: CALIS Procedure" on page 1173 can help you gain a deeper understanding of the various types of modeling languages, as shown in the following table:

Language	Section
COSAN	"The COSAN Model" on page 1193
FACTOR	"The FACTOR Model" on page 1197
LINEQS	"The LINEQS Model" on page 1205
LISMOD	"The LISMOD Model and Submodels" on page 1212
MSTRUCT	"The MSTRUCT Model" on page 1220
PATH	"The PATH Model" on page 1223
RAM	"The RAM Model" on page 1229

The specification techniques you learn from the examples cover only parts of the modeling language. A more complete treatment of the modeling languages is covered in these subsections. In addition, you can also learn the mathematical models, model restrictions, and default parameterization of all supported modeling languages in these subsections.

Guide to the Intermediate Skill Level

At the intermediate level, you learn to minimize your mistakes in model specification and to establish more sophisticated modeling techniques. The following topics in the "Details: CALIS Procedure" section or elsewhere can help:

- The section "Naming Variables and Parameters" on page 1238 summarizes the naming rules and conventions for variable and parameter names in specifying models.
- The section "Setting Constraints on Parameters" on page 1239 covers various techniques of constraining parameters in model specifications.
- The section "Automatic Variable Selection" on page 1245 discusses how PROC CALIS treats variables in the models and variables in the data sets. It also discusses situations where the VAR statement specification is deemed necessary.
- The section "Computational Problems" on page 1291 discusses computational problems that occur quite commonly in structural equation modeling. It also discusses some possible remedies of the computational problem.
- The section "Missing Values and the Analysis of Missing Patterns" on page 1279 describes the default treatment of missing values.
- The statements REFMODEL on page 1158 and RENAMEPARM on page 1160 are useful when you need to make references to well-defined models when specifying a "new" model. See Example 26.27 for an application.

Revisit topics and examples covered at the basic level, as needed, to help you better understand the topics at the intermediate level.

You can also study the following more advanced examples:

- "Example 26.25: Higher-Order and Hierarchical Factor Models" on page 1513 is an advanced example for confirmatory factor analysis. It involves the specifications of higher-order and hierarchical factor models. Because higher-order factor models cannot be specified by the FACTOR modeling language, you need to use the LINEQS model specification instead. A second-order factor model and a bifactor model are fit. Linear constraints on parameters are illustrated by using the PARAMETERS statement and SAS programming statements. Relationships between the second-order factor model and the bifactor model are numerically illustrated.
- "Example 26.26: Linear Relations among Factor Loadings" on page 1529 is an advanced example of a first-order confirmatory factor analysis that uses the FACTOR modeling language. In this example, you learn how to use the PARAMETERS statement and SAS programming statements to set up dependent parameters in your model. You also learn how to specify the correlation structures for a specific confirmatory factor model.
- "Example 26.27: Multiple-Group Model for Purchasing Behavior" on page 1538 is a sophisticated example of analyzing a path model. The PATH modeling language is used. In this example, a two-group analysis of mean and covariance structures is conducted. You learn how to use the REFMODEL statement to reference properly defined models and the SIMTESTS statement to test a priori simultaneous hypotheses.
- "Example 26.28: Fitting the RAM and EQS Models by the COSAN Modeling Language" on page 1563 introduces the COSAN modeling language by connecting it with general RAM and EQS models. The model matrices of the RAM or EQS model are described. You specify these model matrices and the associated parameters in the COSAN modeling language.

- "Example 26.29: Second-Order Confirmatory Factor Analysis" on page 1596 constructs the covariance structure model of the second-order confirmatory factor model. You define the model matrices by using the COSAN modeling language.
- "Example 26.30: Linear Relations among Factor Loadings: COSAN Model Specification" on page 1604 shows how you can set linear constraints among model parameters under the COSAN model.
- "Example 26.31: Ordinal Relations among Factor Loadings" on page 1610 shows how you can set ordinal constraints among model parameters under the COSAN model.
- "Example 26.32: Longitudinal Factor Analysis" on page 1614 defines the covariance structures of a longitudinal factor model and shows how you can specify the covariance structure model with the COSAN modeling language.

Guide to the Advanced Skill Level

At the advanced level, you learn to use the advanced data analysis and output control tools supported by PROC CALIS.

Advanced Data Analysis Tools

The following advanced data analysis topics are discussed:

- Assessment of fit

  The section "Assessment of Fit" on page 1260 presents the fit indices used in PROC CALIS. However, the more important topics covered in this section are about how model fit indices are organized and used, how residuals can be used to gauge the fitting of individual parts of the model, and how the coefficients of determination are defined for equations.

  To customize your fit summary table, you can use the options on the FITINDEX statement.

- Effect partitioning

  The section "Total, Direct, and Indirect Effects" on page 1273 discusses the total, direct, and indirect effects and their computations. The stability coefficient of reciprocal causation is also defined.

  To customize the effect analysis, you can use the EFFPART statement.

- Counting and adjusting degrees of freedom

  The section "Counting the Degrees of Freedom" on page 1258 describes how PROC CALIS computes model fit degrees of freedom and how you can use some options on the PROC CALIS statement to make degrees-of-freedom adjustments.

  To adjust the model fit degrees of freedom, you can use the DFREDUCE= and NOADJDF options in the PROC CALIS statement.

- Standardized solutions

  Standardization schemes used in PROC CALIS are described and discussed in the section "Standardized Solutions" on page 1275.

Standardized solutions are displayed by default. You can turn them off by using the NOSTAND option of the PROC CALIS statement.

- Model modifications

  In the section "Modification Indices" on page 1277, modification indices such as Lagrange multiplier test indices and Wald statistics are defined and discussed. These indices can be used either to enhance your model fit or to make your model more precise.

  To limit the modification process only to those parameters of interest, you can use the LMTESTS statement to customize the sets of LM tests conducted on potential parameters.

- A Priori Parametric Function Testing

  You can use the TESTFUNC statement to test a priori hypotheses individually. You can use the SIMTESTS statement to test a priori hypotheses simultaneously.

Advanced Output Control Tools

To be more effective in presenting your analysis results, you need to be more sophisticated in controlling your output. Some customization tools have been discussed in the previous section "Advanced Data Analysis Tools" on page 999 and might have been mentioned in the examples included in the basic and the intermediate levels. In the following topics, these output control tools are presented in a more organized way so that you can have a systematic study scheme of these tools.

- Global output control tools in PROC CALIS

  You can control output displays in PROC CALIS either by the global display options or by the individual output printing options. Each global display option typically controls more than one output display, while each individual output display controls only one output display. The global display options can both enable and suppress output displays, and they can also alter the format of the output.

  See the ALL, PRINT, PSHORT, PSUMMARY, and NOPRINT options for ways to control the appearances of the output. See the section "Global Display Options" on page 1022 for details about the global display options and their relationships with the individual output display options. Also see the ORDERALL, ORDERGROUPS, ORDERMODELS, ORDERSPEC, PARMNAME, PRIMAT, NOORDERSPEC, NOPARMNAME, NOSTAND, and NOSE options which control the output formats.

- Customized analysis tools in PROC CALIS

  Many individual output displays in PROC CALIS can be customized via specific options or statements. If you do not use these customization tools, the default output will usually contain a large number of displays or displays with very large dimensions. These customized analysis tools are as follows:

  – The ON=, OFF=, ON(ONLY)= options in the FITINDEX statement enable you to select individual or groups of model fit indices or modeling information to display. You can still save the information of *all* fit indices in an external file by using the OUTFIT= option.
  – The EFFPART statement enables you to customize the effect analysis. You display only those effects of substantive interest.
  – The LMTESTS statement enables you to customize the sets of LM tests of interest. You test only those potential parameters that are theoretically and substantively possible.

- Output selection and destinations by the ODS system

  This kind of output control is used not only for PROC CALIS, but is used for all procedures that support the ODS system. The most common uses include output selection and output destinations assignment. You use the ODS SELECT statement together with the ODS table names or graph names to select particular output displays. See the section "ODS Table Names" on page 1298 for these names in PROC CALIS.

  The default output destination of PROC CALIS is the listing destination. You can add or change the destinations by using statements such as **`ods html`** (for html output), **`ods rtf`** (for rich text output), and so on. For details, see Chapter 20, "Using the Output Delivery System."

Reference Topics

Some topics in the "Details: CALIS Procedure" section are intended primarily for references—you consult them only when you encounter specific problems in the PROC CALIS modeling or when you need to know the very fine technical details in certain special situations. Many of these reference topics in the "Details: CALIS Procedure" section are not required for practical applications of structural equation modeling. The following technical topics are discussed:

- Measures of multivariate kurtosis and skewness

  This is covered in the section "Measures of Multivariate Kurtosis" on page 1279.

- Estimation criteria and the mathematical functions for estimation

  The section "Estimation Criteria" on page 1246 presents formulas for various estimation criteria. The relationships among these criteria are shown in the section "Relationships among Estimation Criteria" on page 1252. To optimize an estimation criterion, you usually need its gradient and Hessian functions. These functions are detailed in the section "Gradient, Hessian, Information Matrix, and Approximate Standard Errors" on page 1255, where you can also find information about the computation of the standard error estimates in PROC CALIS.

- Initial estimation

  Initial estimates are necessary for all kinds of iterative optimization techniques. They are described in section "Initial Estimates" on page 1282.

- Use of optimization techniques

  Optimization techniques are covered in section "Use of Optimization Techniques" on page 1283. See this section if you need to fine-tune the optimization.

- Output displays and control

  The output displays in PROC CALIS are listed in the section "Displayed Output" on page 1294. General requirements for the displays are also shown.

  With the ODS system, each table and graph has a name, which can be used on the ODS OUTPUT or ODS SELECT statement. See the section "ODS Table Names" on page 1298 for the ODS table and graph names.

- Input and output files

  PROC CALIS supports several input and output data files for data, model information, weight matrices, estimates, fit indices, and estimation and descriptive statistics. The uses and the structures of these input and output data files are described in the sections "Input Data Sets" on page 1173 and "Output Data Sets" on page 1176.
