
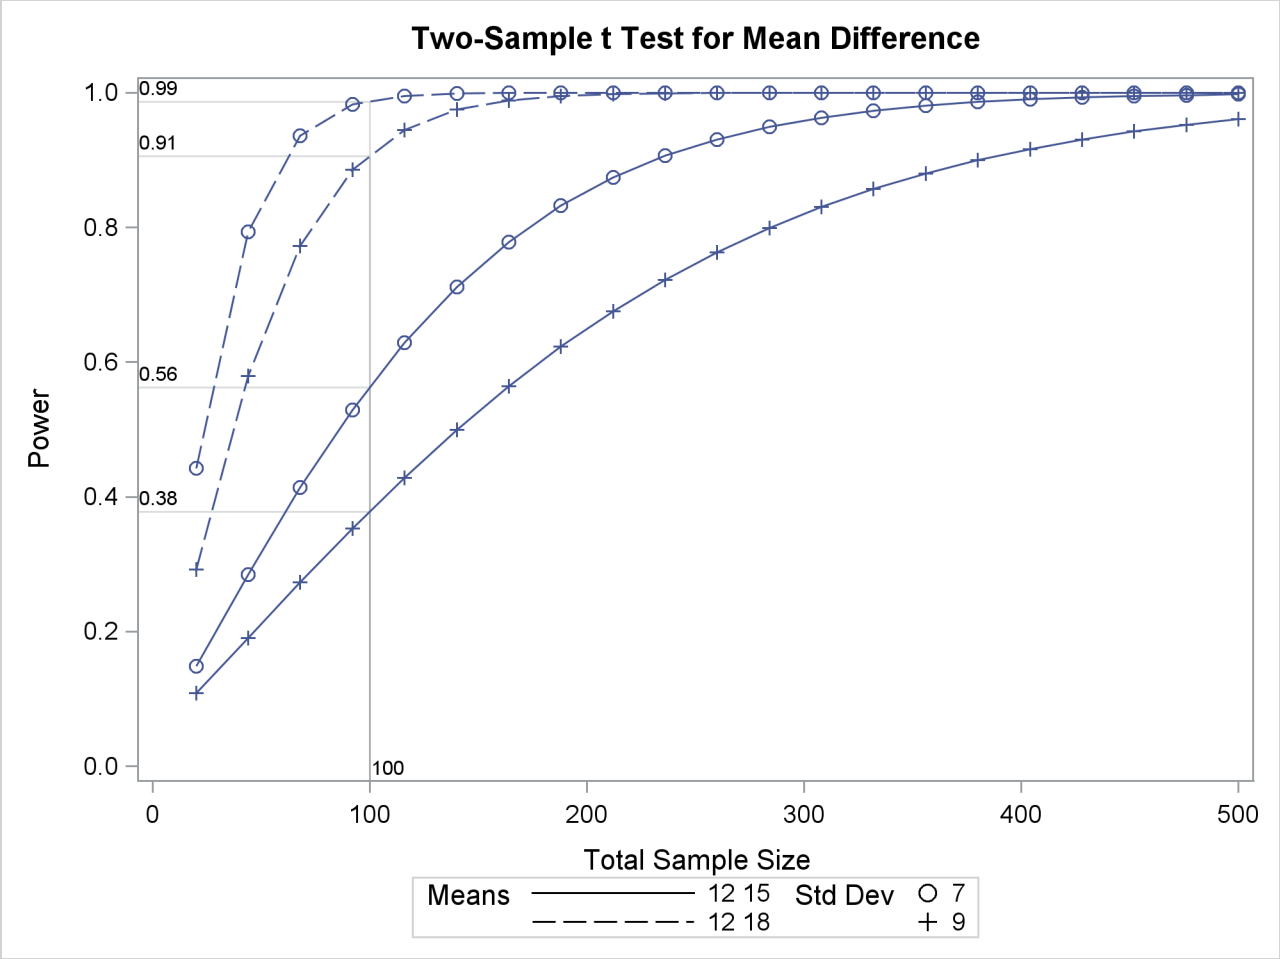
You can also add reference lines for the X axis by using the XOPTS= option instead of the YOPTS= option. For example, the following PLOT statement produces Output 70.8.13, which has crossing reference lines highlighting the sample size of 100:

```
plot x=n min=20 max=500
   xopts=(ref=100 crossref=yes);
```

Note that the values that label the reference lines at the X axis in Output 70.8.12 and at the Y axis in Output 70.8.13 are linearly interpolated from two neighboring points on the curves. Thus they might not exactly match corresponding values that are computed directly from the methods in the section "Computational Methods and Formulas" on page 5841—that is, computed by PROC POWER in the absence of a PLOT statement. The two ways of computing these values generally differ by a negligible amount.

Output 70.8.13 Plot with CROSSREF=YES Style Reference Lines from X Axis



Linking Plot Features to Analysis Parameters

You can use the VARY option in the PLOT statement to specify which of the following features you want to associate with analysis parameters.

- line style
- plotting symbol
- color
- panel

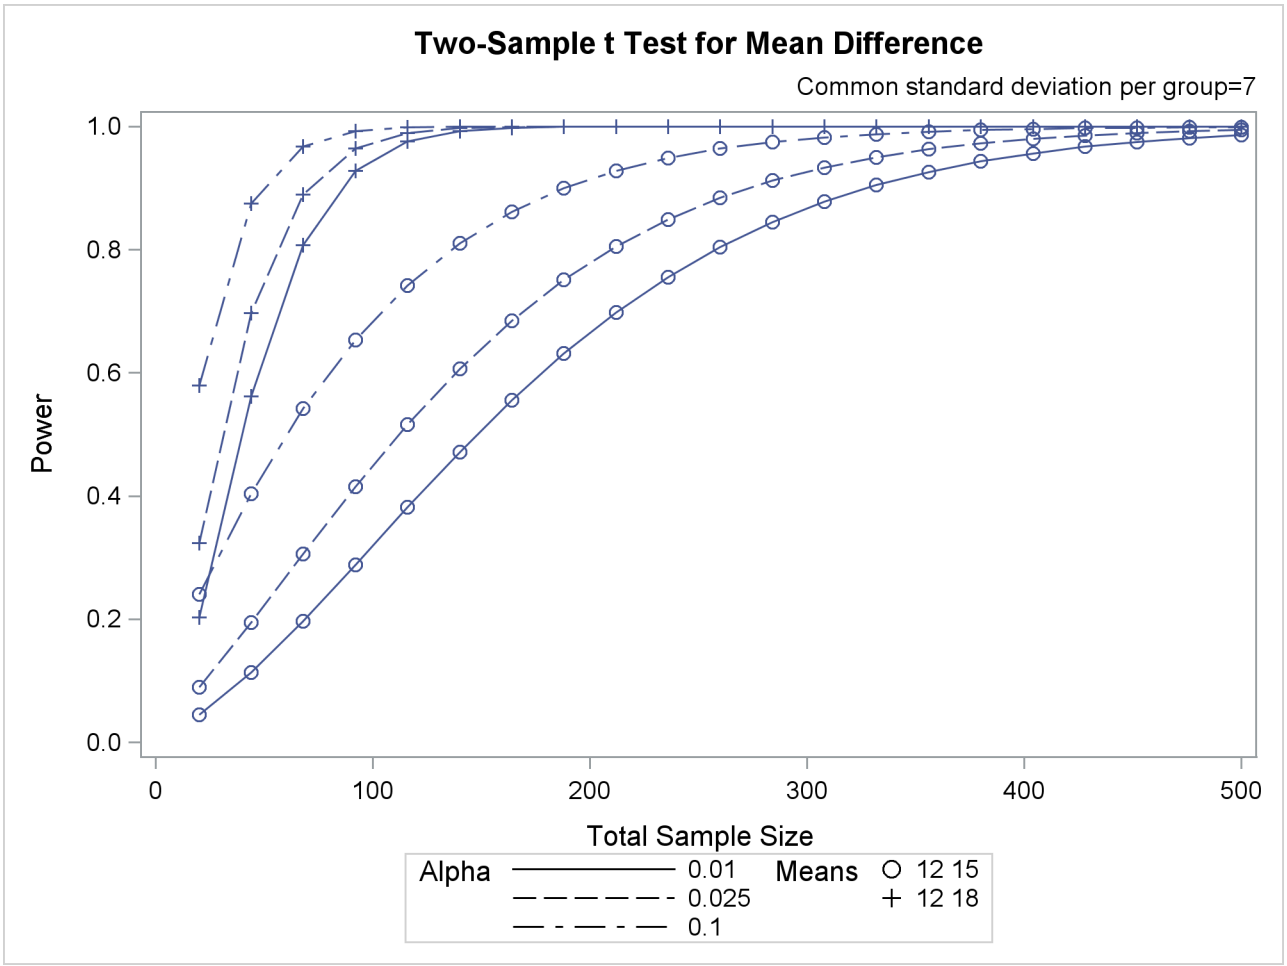
You can specify mappings between each of these features and one or more analysis parameters, or you can simply choose a subset of these features to use (and rely on default settings to associate these features with multiple-valued analysis parameters).

Suppose you supplement the sample size analysis in Output 70.8.5 to include three values of alpha, by using the following statements:

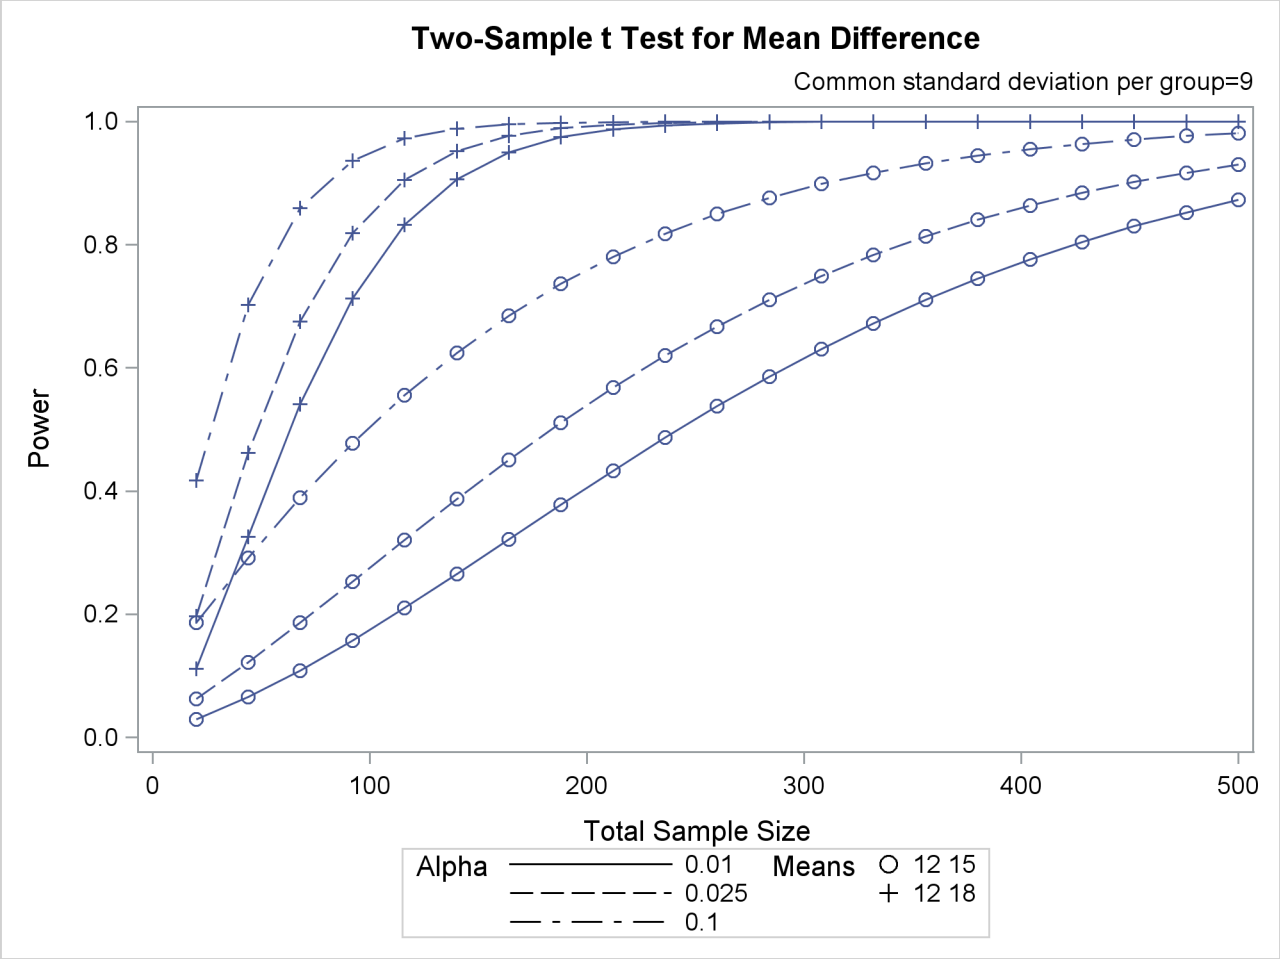
```
proc power plotonly;
   twosamplemeans test=diff
      groupmeans   = 12 | 15 18
      stddev       = 7 9
      alpha        = 0.01 0.025 0.1
      power        = .
      ntotal       = 100;
   plot x=n min=20 max=500;
run;
```

The defaults for the VARY option in the PLOT statement specify line style varying by the ALPHA= parameter, plotting symbol varying by the GROUPMEANS= parameter, panel varying by the STDDEV= parameter, and color remaining constant. The resulting plot, consisting of two panels, is shown in Output 70.8.14.

Output 70.8.14 Plot with Default VARY Settings



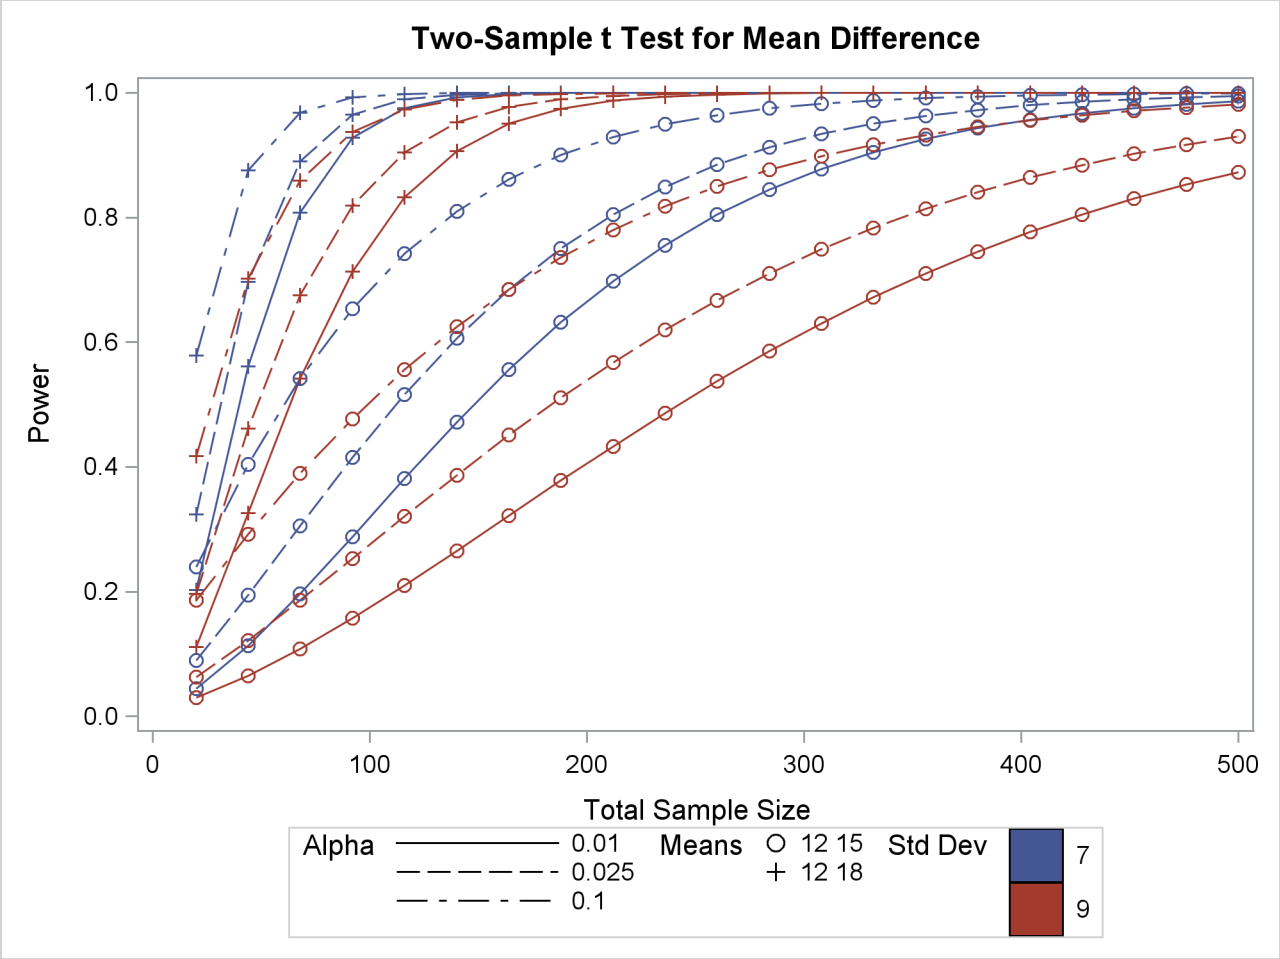
Output 70.8.14 *continued*



Suppose you want to produce a plot with only one panel that varies color in addition to line style and plotting symbol. Include the LINESTYLE, SYMBOL, and COLOR keywords in the VARY option in the PLOT statement, as follows, to produce the plot in Output 70.8.15:

```
plot x=n min=20 max=500
   vary (linestyle, symbol, color);
```

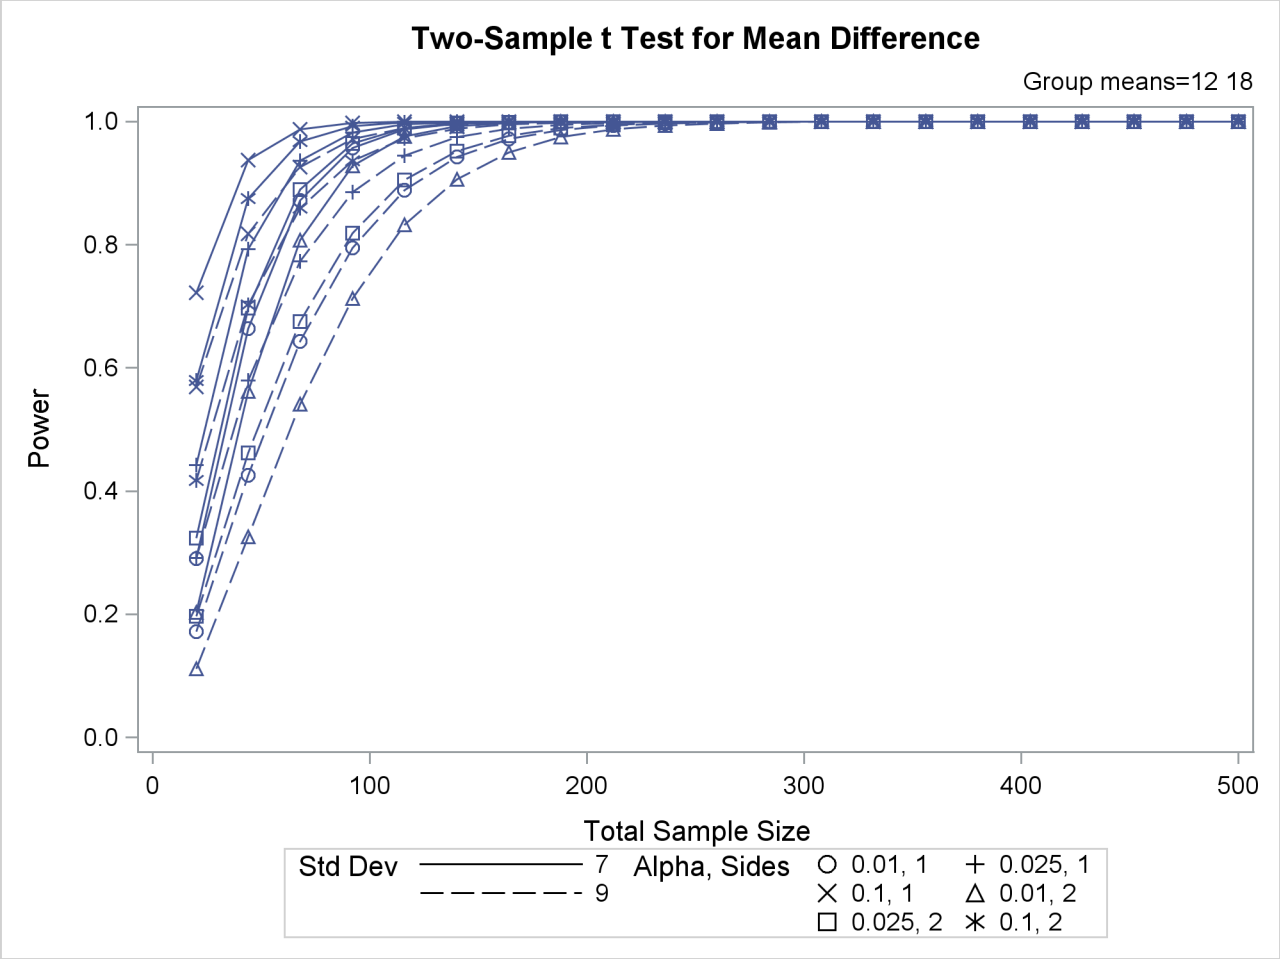
Output 70.8.15 Plot with Varying Color Instead of Panel



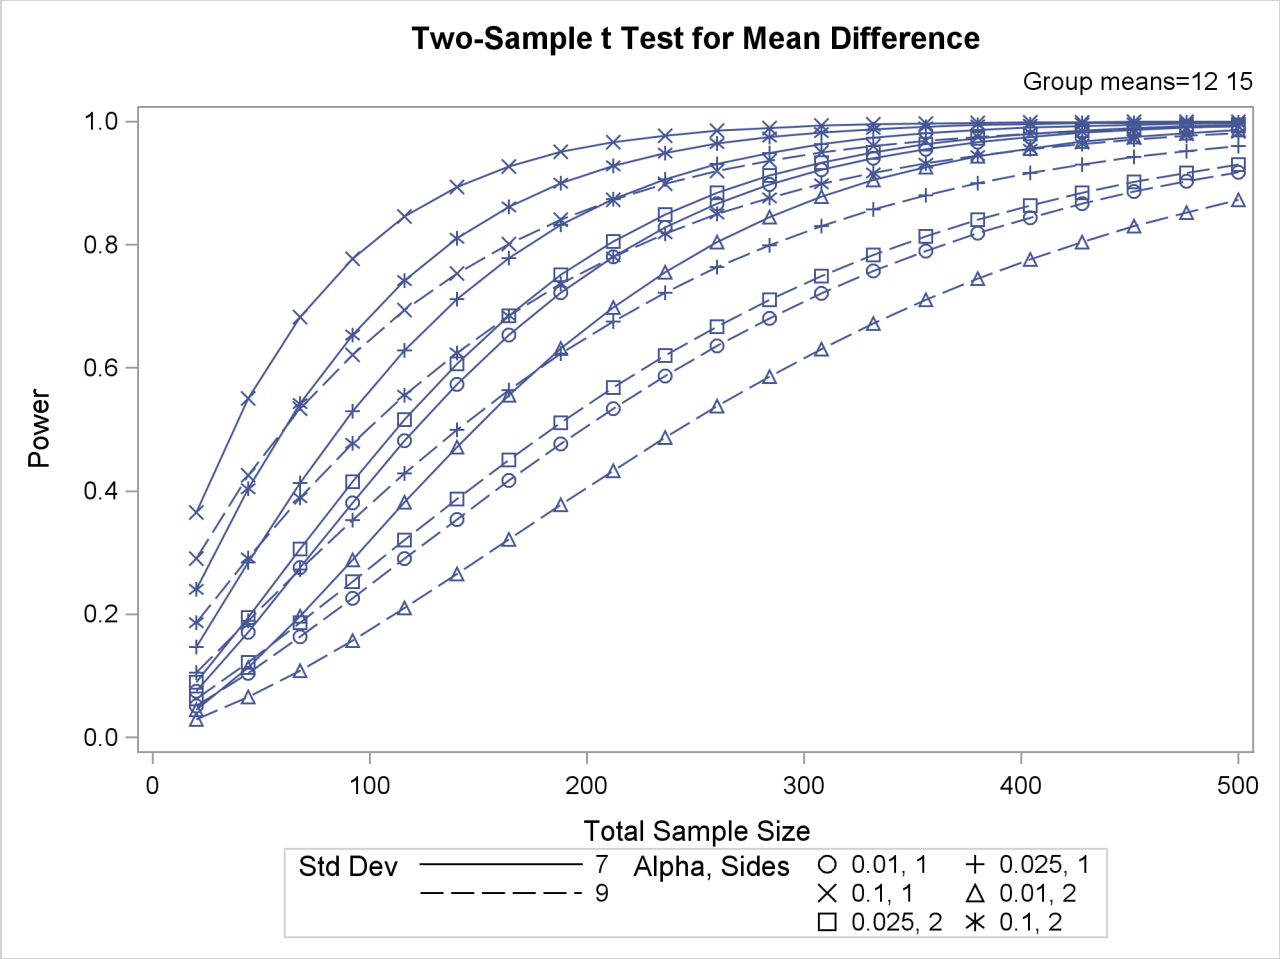
Finally, suppose you want to specify which features are used *and* which analysis parameters they are linked to. The following PLOT statement produces a two-panel plot (shown in Output 70.8.16) in which line style varies by standard deviation, plotting symbol varies by both alpha and sides, and panel varies by means:

```
plot x=n min=20 max=500
   vary (linestyle by stddev,
         symbol by alpha sides,
         panel by groupmeans);
```

Output 70.8.16 Plot with Features Explicitly Linked to Parameters



Output 70.8.16 *continued*



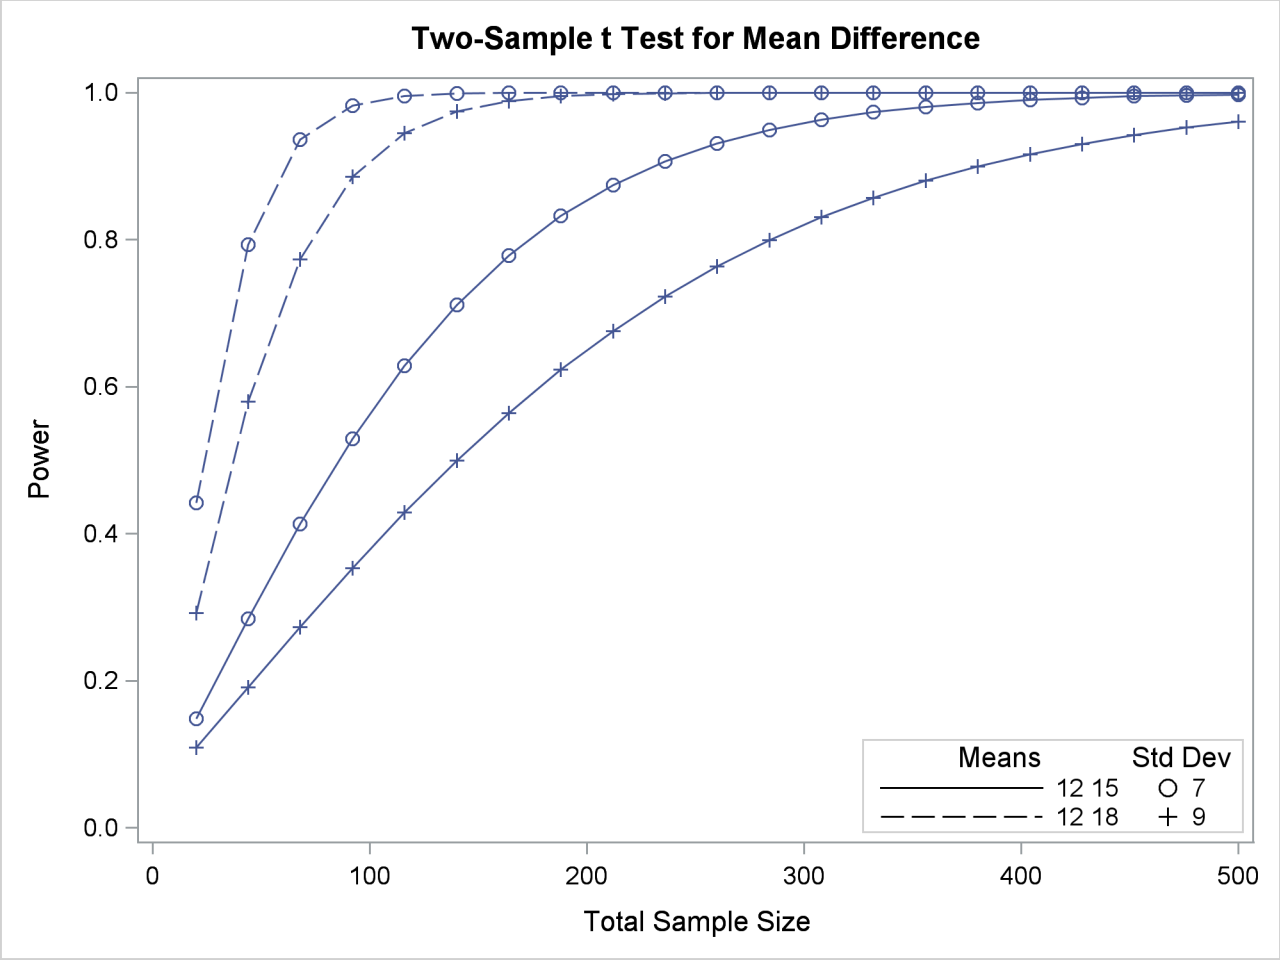
Choosing Key (Legend) Styles

The default style for the key (or "legend") is one that displays the association between levels of features and levels of analysis parameters, located below the X axis. For example, Output 70.8.5 demonstrates this style of key.

You can reproduce Output 70.8.5 with the same key but a different location, inside the plotting region, by using the POS=INSET option within the KEY=BYFEATURE option in the PLOT statement. The following statements product the plot in Output 70.8.17:

```
proc power plotonly;
   twosamplemeans test=diff
      groupmeans   = 12 | 15 18
      stddev       = 7 9
      power        = .
      ntotal       = 200;
   plot x=n min=20 max=500
      key = byfeature(pos=inset);
run;
```

Output 70.8.17 Plot with a By-Feature Key inside the Plotting Region

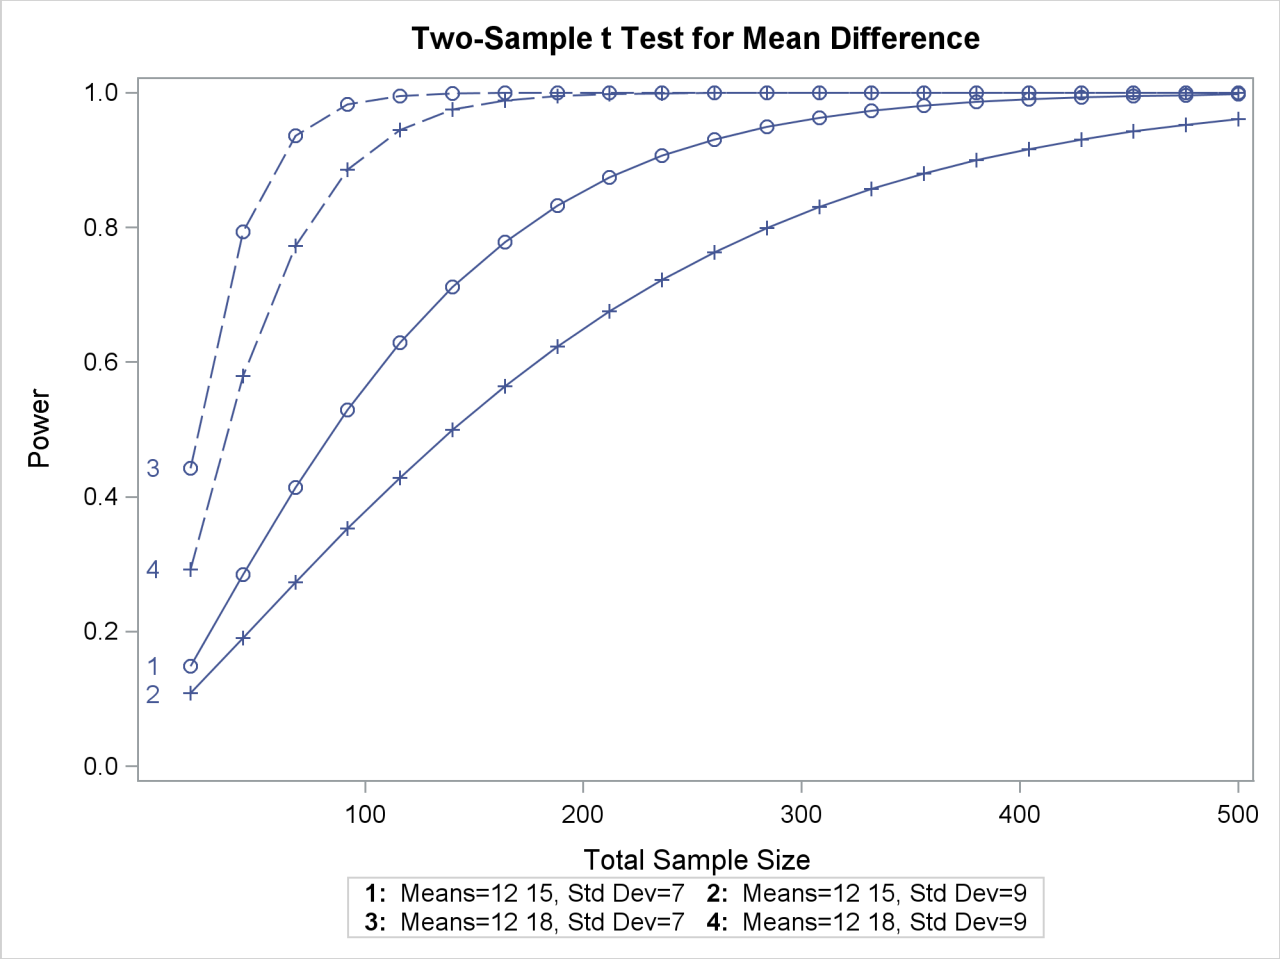


Alternatively, you can specify a key that identifies each individual curve separately by number by using the KEY=BYCURVE option in the PLOT statement:

```
plot x=n min=20 max=500
   key = bycurve;
```

The resulting plot is shown in Output 70.8.18.

Output 70.8.18 Plot with a Numbered By-Curve Key

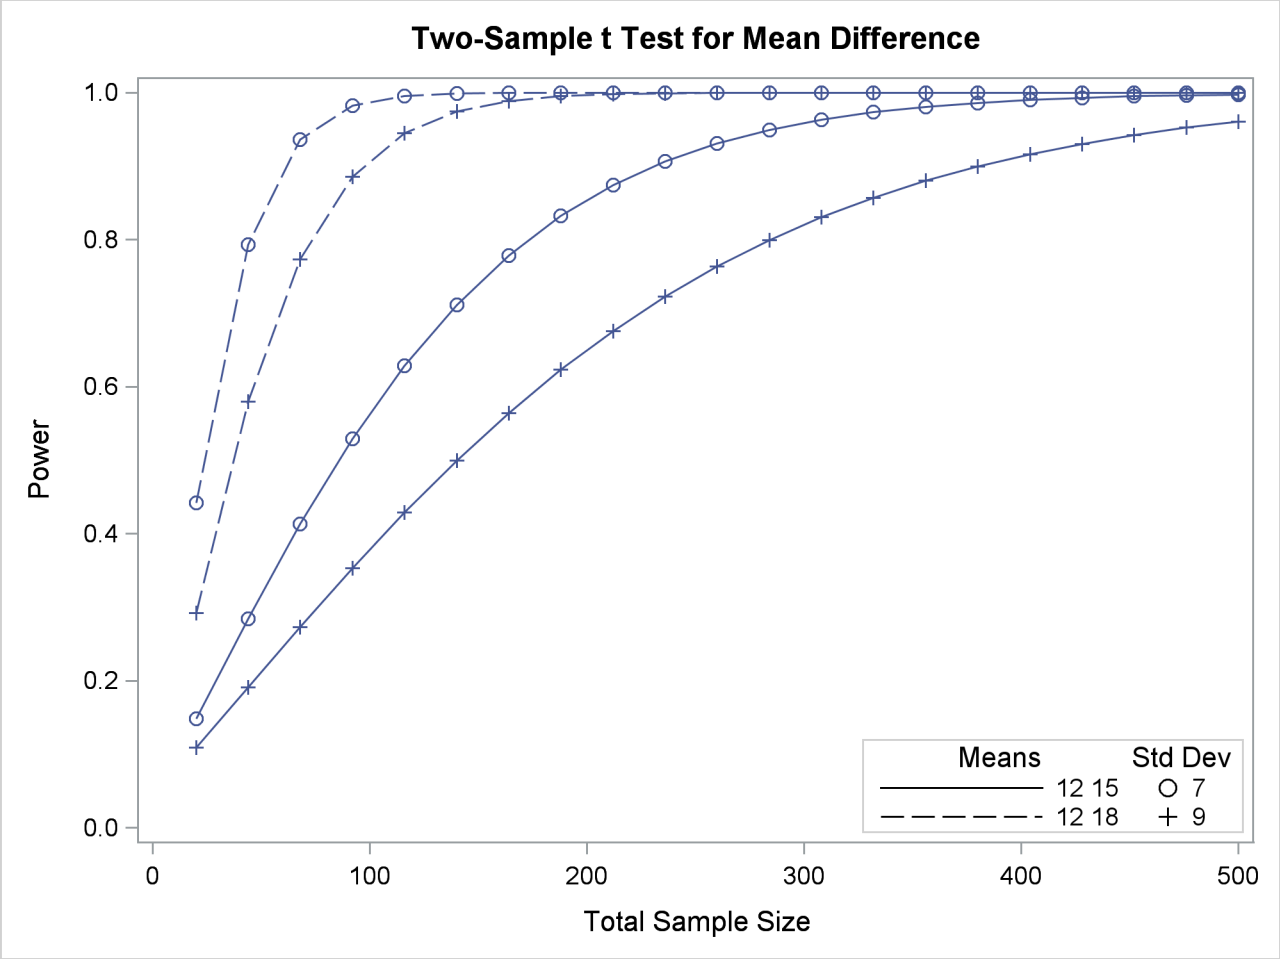


Use the NUMBERS=OFF option within the KEY=BYCURVE option to specify a nonnumbered key that identifies curves with samples of line styles, symbols, and colors:

```
plot x=n min=20 max=500
   key = bycurve(numbers=off pos=inset);
```

The POS=INSET suboption places the key within the plotting region. The resulting plot is shown in Output 70.8.19.

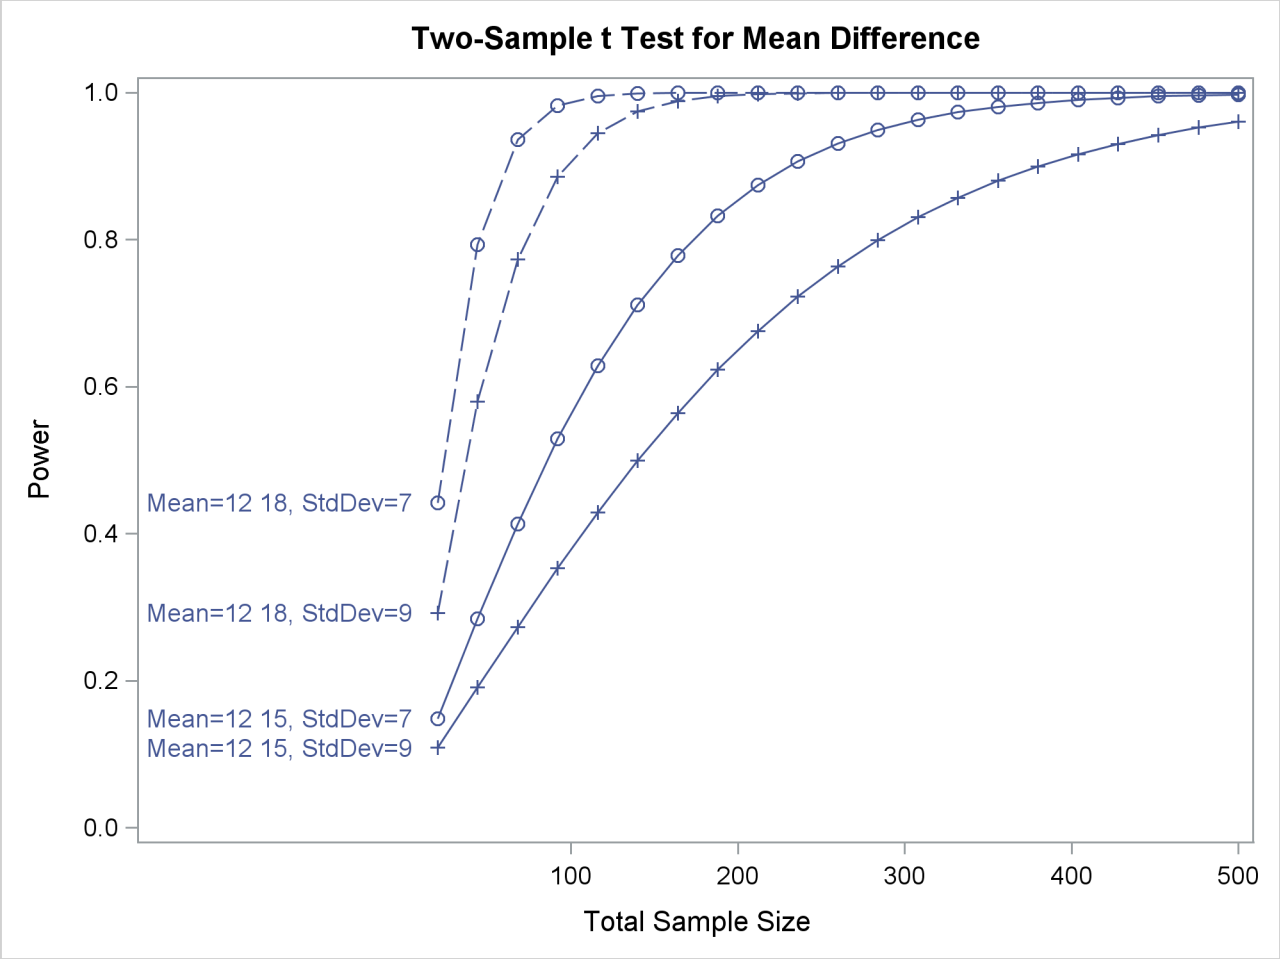
Output 70.8.19 Plot with a Nonnumbered By-Curve Key



Finally, you can attach labels directly to curves with the KEY=ONCURVES option. The following PLOT statement produces Output 70.8.20:

```
plot x=n min=20 max=500
   key = oncurves;
```

Output 70.8.20 Plot with Directly Labeled Curves



Modifying Symbol Locations

The default locations for plotting symbols are the points computed directly from the power and sample size algorithms. For example, Output 70.8.5 shows plotting symbols corresponding to computed points. The curves connecting these points are interpolated (as indicated by the INTERPOL= option in the PLOT statement).

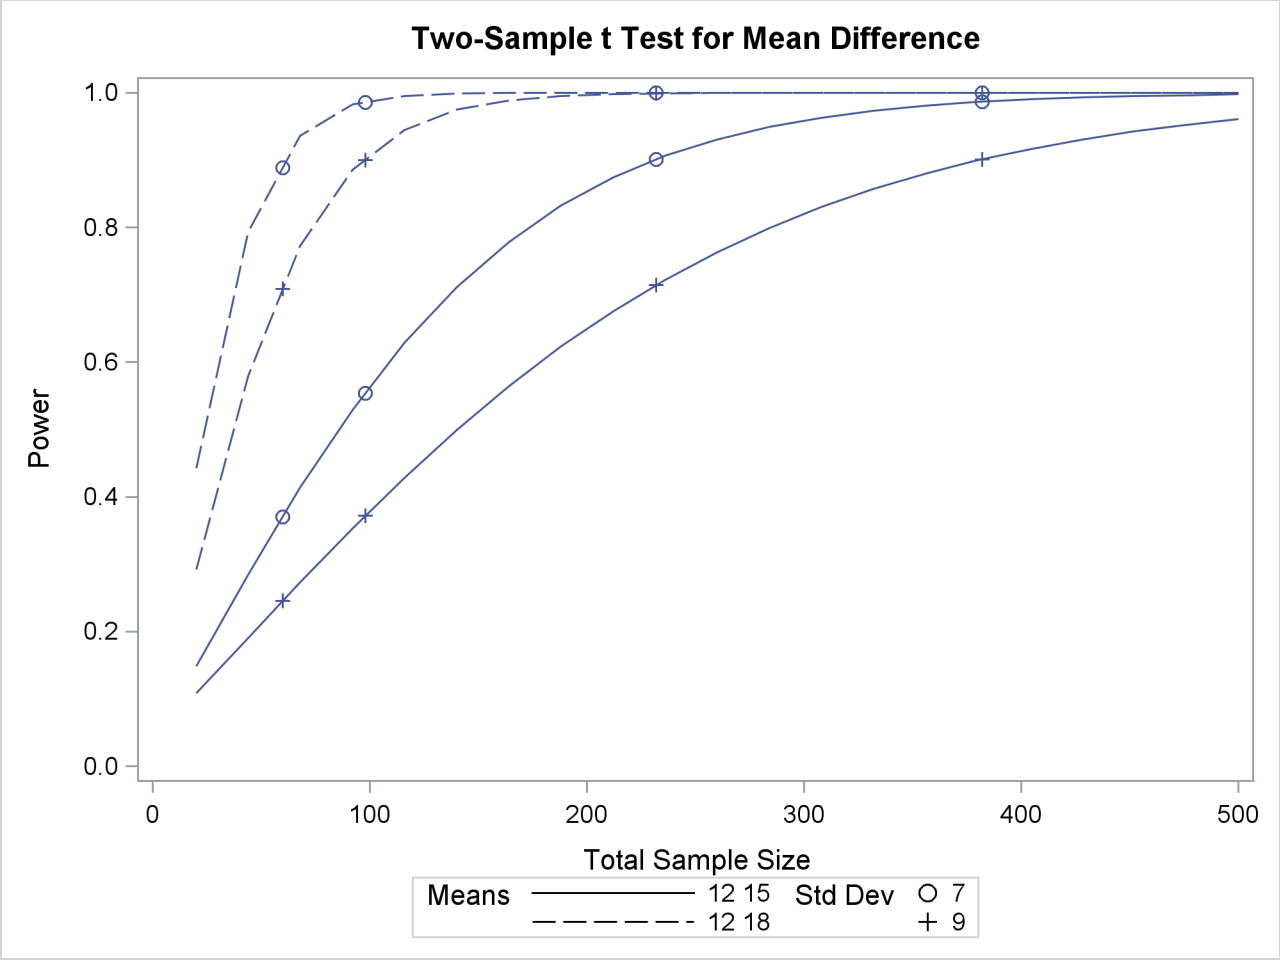
You can modify the locations of plotting symbols by using the MARKERS= option in the PLOT statement. The MARKERS=ANALYSIS option places plotting symbols at locations corresponding to the input specified in the analysis statement preceding the PLOT statement. You might prefer this as an alternative to using reference lines to highlight specific points. For example, you can reproduce Output 70.8.5, but with the plotting symbols located at the sample sizes shown in Output 70.8.1, by using the following statements:

```
proc power plotonly;
   twosamplemeans test=diff
      groupmeans   = 12 | 15 18
      stddev       = 7 9
      power        = .
      ntotal       = 232 382 60 98;
```

```
   plot x=n min=20 max=500
      markers=analysis;
run;
```

The analysis statement here is the TWOSAMPLEMEANS statement. The MARKERS=ANALYSIS option in the PLOT statement causes the plotting symbols to occur at sample sizes specified by the NTOTAL= option in the TWOSAMPLEMEANS statement: 232, 382, 60, and 98. The resulting plot is shown in Output 70.8.21.

Output 70.8.21 Plot with MARKERS=ANALYSIS

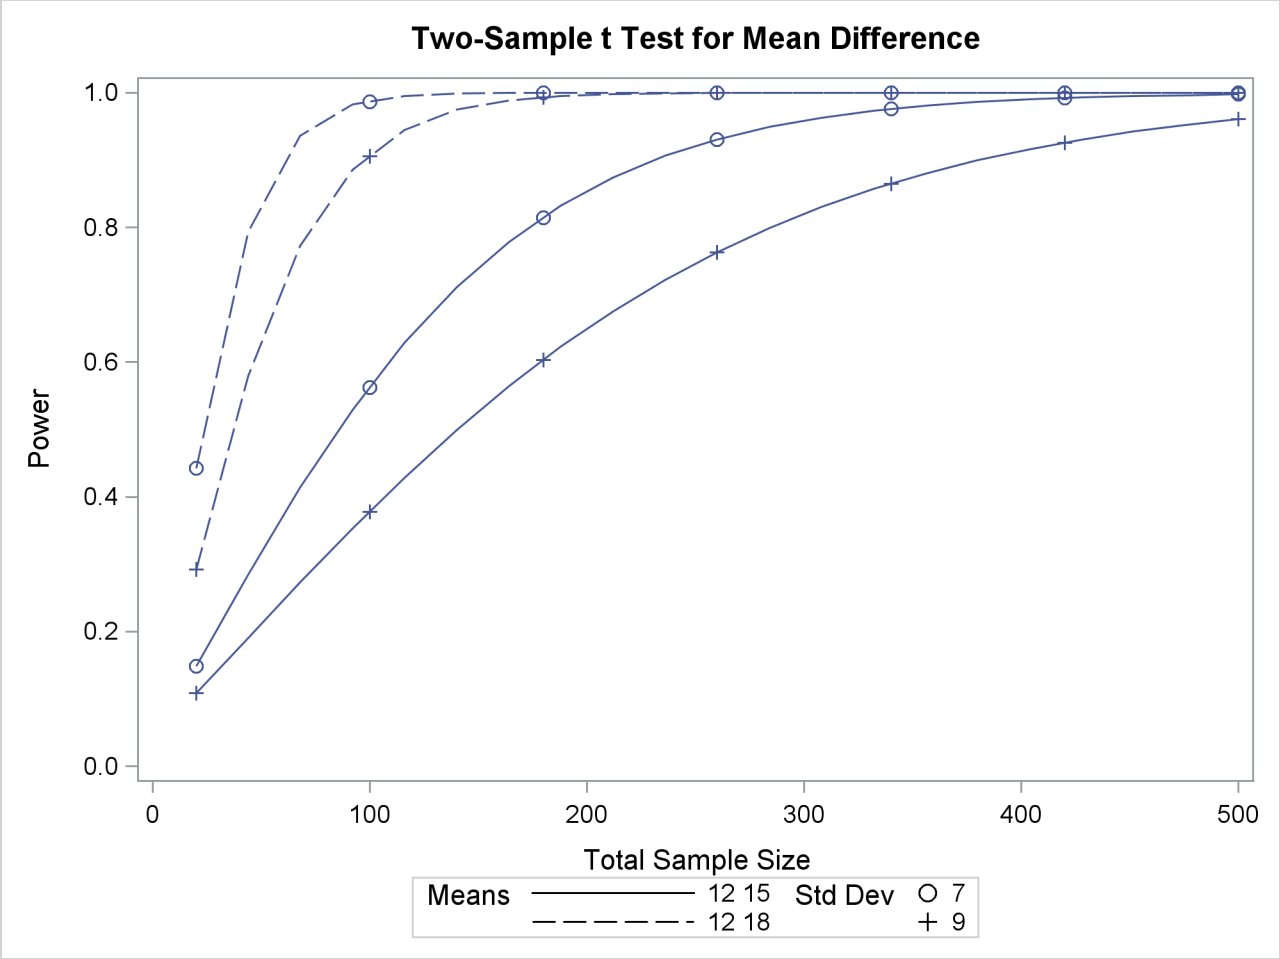


You can also use the MARKERS=NICE option to align symbols with the tick marks on one of the axes (the X axis when the X= option is used, or the Y axis when the Y= option is used):

```
   plot x=n min=20 max=500
      markers=nice;
```

The plot created by this PLOT statement is shown in Output 70.8.22.

Output 70.8.22 Plot with MARKERS=NICE



Note that the plotting symbols are aligned with the tick marks on the X axis because the X= option is specified.

Example 70.9: Binary Logistic Regression with Independent Predictors

Suppose you are planning an industrial experiment similar to the analysis in "Getting Started: LOGISTIC Procedure" on page 4038 of Chapter 53, "The LOGISTIC Procedure," but for a different type of ingot. The primary test of interest is the likelihood ratio chi-square test of the effect of heating time on the readiness of the ingots for rolling. Ingots will be randomized independently into one of four different heating times (5, 10, 15, and 20 minutes) with allocation ratios 2:3:3:2 and three different soaking times (2, 4, and 6 minutes) with allocation ratios 2:2:1. The mass of each ingot will be measured as a covariate.

You want to know how many ingots you must sample to have a 90% chance of detecting an odds ratio as small as 1.2 for a five-minute heating time increase. The odds ratio is defined here as the odds of the ingot not being ready given a heating time of h minutes divided by the odds given a heating time of $h-5$ minutes,

for any time h. You will use a significance level of $\alpha = 0.1$ to balance Type I and Type II errors since you consider their importance to be roughly equal.

The distributions of heating time and soaking time are determined by the design, but you must conjecture the distribution of ingot mass. Suppose you expect its distribution to be approximately normal with mean 4 kg and standard deviation between 1 kg and 2 kg.

You are powering the study for an odds ratio of 1.2 for the heating time, but you must also conjecture odds ratios for soaking time and mass. You suspect that the odds ratio for a unit increase in soaking time is about 1.4, and the odds ratio for a unit increase in mass is between 1 and 1.3.

Finally, you must provide a guess for the average probability of an ingot not being ready for rolling, averaged across all possible design profiles. Existing data suggest that this probability lies between 0.15 and 0.25.

You decide to evaluate sample size at the two extremes of each parameter for which you conjectured a range. Use the following statements to perform the sample size determination:

```
proc power;
   logistic
      vardist("Heat") = ordinal((5 10 15 20) : (0.2 0.3 0.3 0.2))
      vardist("Soak") = ordinal((2 4 6) : (0.4 0.4 0.2))
      vardist("Mass1") = normal(4, 1)
      vardist("Mass2") = normal(4, 2)
      testpredictor = "Heat"
      covariates = "Soak" | "Mass1" "Mass2"
      responseprob = 0.15 0.25
      testoddsratio = 1.2
      units= ("Heat" = 5)
      covoddsratios = 1.4 | 1 1.3
      alpha = 0.1
      power = 0.9
      ntotal = .;
run;
```

The VARDIST= option is used to define the distributions of the predictor variables. The distributions of heating and soaking times are defined by the experimental design, with ordinal probabilities derived from the allocation ratios. The two conjectured standard deviations for the ingot mass are represented in the Mass1 and Mass2 distributions. The TESTPREDICTOR= option identifies the predictor being tested, and the COVARIATES= option specifies the scenarios for the remaining predictors in the model (soaking time and mass). The RESPONSEPROB= option specifies the overall response probability, and the TESTODDSRATIO= and UNITS= options indicate the odds ratio and increment for heating time. The COVODDSRATIOS= option specifies the scenarios for the odds ratios of soaking time and mass. The default DEFAULTUNIT=1 option specifies a unit change for both of these odds ratios. The ALPHA= option sets the significance level, and the POWER= option defines the target power. Finally, the NTOTAL= option with a missing value (.) identifies the parameter to solve for.

Output 70.9.1 shows the results.

Output 70.9.1 Sample Sizes for Test of Heating Time in Logistic Regression

The POWER Procedure
Likelihood Ratio Chi-Square Test for One Predictor

Fixed Scenario Elements

Method	Shieh-O'Brien approximation
Alpha	0.1
Test Predictor	Heat
Odds Ratio for Test Predictor	1.2
Unit for Test Pred Odds Ratio	5
Nominal Power	0.9

Computed N Total

Index	Response Prob	-Covariates-		--Cov ORs-		-Cov Units-		Total N Bins	Actual Power	N Total
1	0.15	Soak	Mass1	1.4	1.0	1	1	120	0.900	1878
2	0.15	Soak	Mass1	1.4	1.3	1	1	120	0.900	1872
3	0.15	Soak	Mass2	1.4	1.0	1	1	120	0.900	1878
4	0.15	Soak	Mass2	1.4	1.3	1	1	120	0.900	1857
5	0.25	Soak	Mass1	1.4	1.0	1	1	120	0.900	1342
6	0.25	Soak	Mass1	1.4	1.3	1	1	120	0.900	1348
7	0.25	Soak	Mass2	1.4	1.0	1	1	120	0.900	1342
8	0.25	Soak	Mass2	1.4	1.3	1	1	120	0.900	1369

The required sample size ranges from 1342 to 1878, depending on the unknown true values of the overall response probability, mass standard deviation, and soaking time odds ratio. The overall response probability clearly has the largest influence among these parameters, with a sample size increase of almost 40% going from 0.25 to 0.15.

Example 70.10: Wilcoxon-Mann-Whitney Test

Consider a hypothetical clinical trial to treat interstitial cystitis (IC), a painful, chronic inflammatory condition of the bladder with no known cause that most commonly affects women. Two treatments will be compared: lidocaine alone ("lidocaine") versus lidocaine plus a fictitious experimental drug called Mironel ("Mir+lido"). The design is balanced, randomized, double-blind, and female-only. The primary outcome is a measure of overall improvement at week 4 of the study, measured on a seven-point Likert scale as shown in Table 70.34.

Table 70.34 Self-Report Improvement Scale

"Compared to when I started this study, my condition is:"	
Much worse	–3
Worse	–2
Slightly worse	–1
The same	0
Slightly better	+1
Better	+2
Much better	+3

The planned data analysis is a one-sided Wilcoxon-Mann-Whitney test with $\alpha = 0.05$ where the alternative hypothesis represents greater improvement for "Mir+lido."

You are asked to graphically assess the power of the planned trial for sample sizes between 100 and 250, assuming that the conditional outcome probabilities given treatment are equal to the values in Table 70.35.

Table 70.35 Conjectured Conditional Probabilities

	Response						
Treatment	–3	–2	–1	0	+1	+2	+3
Lidocaine	0.01	0.04	0.20	0.50	0.20	0.04	0.01
Mir+lido	0.01	0.03	0.15	0.35	0.30	0.10	0.06

Use the following statements to compute the power at sample sizes of 100 and 250 and generate a power curve:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power;
   twosamplewilcoxon
      vardist("lidocaine") = ordinal ((-3 -2 -1 0 1 2 3) :
                                      (.01 .04 .20 .50 .20 .04 .01))
      vardist("Mir+lido") = ordinal ((-3 -2 -1 0 1 2 3) :
                                     (.01 .03 .15 .35 .30 .10 .06))
      variables = "lidocaine" | "Mir+lido"
      sides = u
      ntotal = 100 250
      power = .;
   plot step=10;
run;

ods graphics off;
```

The ODS LISTING STYLE=HTMLBLUECML statement specifies the HTMLBLUECML style, which is suitable for use with PROC POWER because it allows both marker symbols and line styles to vary. See the section "ODS Styles Suitable for Use with PROC POWER" on page 5897 for more information.

The VARDIST= option is used to define the distribution for each treatment, and the VARIABLES= option specifies the distributions to compare. The SIDES=U option corresponds to the alternative hypothesis that the second distribution ("Mir+lido") is more favorable. The NTOTAL= option specifies the total sample sizes of interest, and the POWER= option with a missing value (.) identifies the parameter to solve for. The default GROUPWEIGHTS= and ALPHA= options specify a balanced design and significance level $\alpha = 0.05$.

The STEP=10 option in the PLOT statement requests a point for each sample size increment of 10. The default values for the X=, MIN=, and MAX= plot options specify a sample size range of 100 to 250 (the same as in the analysis) for the X axis.

The tabular and graphical results are shown in Output 70.10.1 and Output 70.10.2, respectively.

Output 70.10.1 Power Values for Wilcoxon-Mann-Whitney Test

The POWER Procedure
Wilcoxon-Mann-Whitney Test

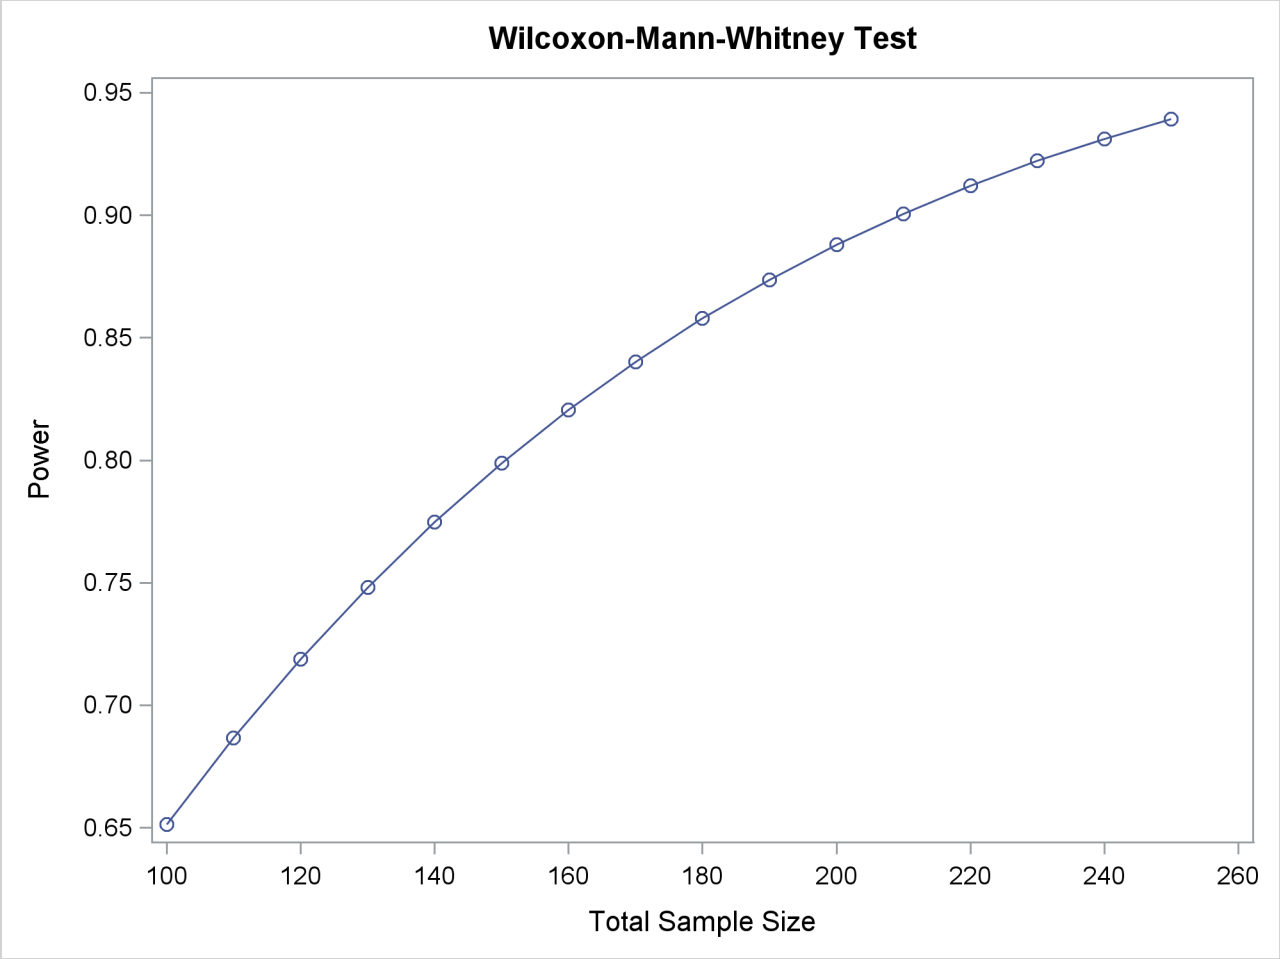
Fixed Scenario Elements

Method	O'Brien-Castelloe approximation
Number of Sides	U
Group 1 Variable	lidocaine
Group 2 Variable	Mir+lido
Pooled Number of Bins	7
Alpha	0.05
Group 1 Weight	1
Group 2 Weight	1
NBins Per Group	1000

Computed Power

Index	N Total	Power
1	100	0.651
2	250	0.939

Output 70.10.2 Plot of Power versus Sample Size for Wilcoxon Power Analysis



The achieved power ranges from 0.651 to 0.939, increasing with sample size.

Chapter 71

The Power and Sample Size Application

Contents

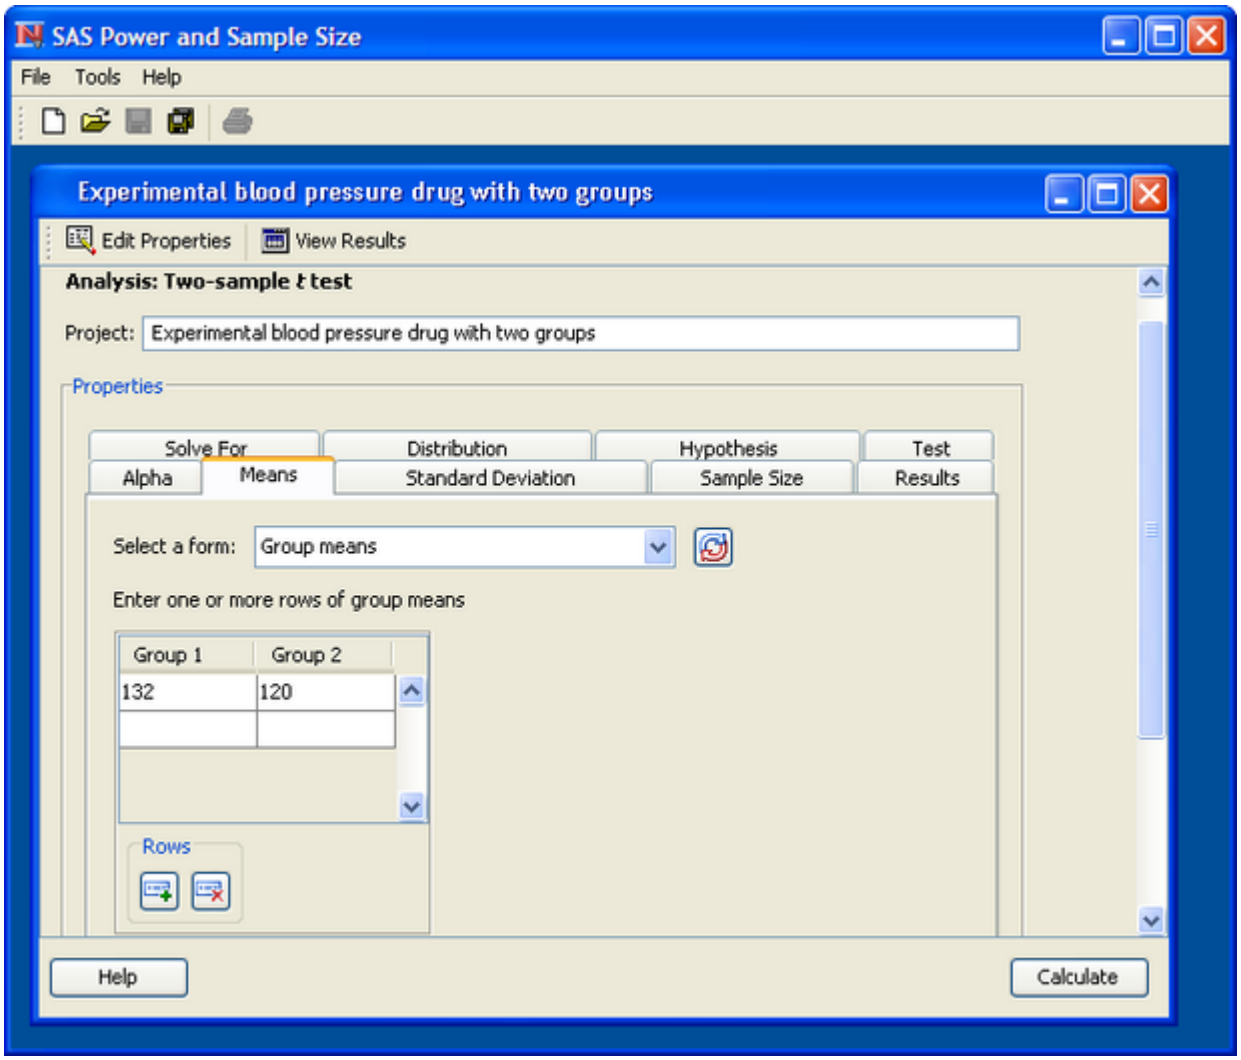
Overview: PSS Application

SAS Power and Sample Size

The SAS Power and Sample Size application (PSS) is a desktop application that provides easy access to power analysis and sample size determination techniques. The application is intended for students and researchers as well as experienced SAS users and statisticians.

Figure 71.1 shows the graphical user interface. PSS relies on the SAS/STAT procedures POWER and GLMPOWER for its computations.

Figure 71.1 PSS Application



This section describes the statistical tasks that are available with the application as well as its principal features.

Analyses

PSS provides power and sample size computations for a variety of statistical analyses. Included are *t* tests for means; equivalence tests and confidence intervals for means and proportions; exact binomial, chi-square, Fisher's exact, and McNemar tests for proportions; correlation and regression (multiple and logistic); one-way analysis of variance; linear models; tests of distribution; and rank tests for comparing survival curves.

Table 71.1 lists the analyses that are available.

Table 71.1 Available Analyses

Category	Analysis
Means	One-sample *t* test
	Paired *t* test
	Two-sample *t* test
Confidence intervals	One proportion
	One-sample means
	Paired means
	Two-sample means
Equivalence tests	One proportion
	One-sample means
	Paired means
	Two-sample means
Proportions	One proportion
	Two correlated proportions
	Two independent proportions
Correlation and regression	Pearson correlation coefficient
	Logistic regression with a binary response
	Multiple regression
Analysis of variance and linear models	One-way ANOVA
	General linear univariate models
Survival analysis	Two-sample survival rank tests
Distribution tests	Wilcoxon Mann-Whitney test for two distributions

Features

PSS provides multiple input parameter options, stores the results in a project format, displays power curves, and produces narratives for the results. Narratives are descriptions of the input parameters and include a statement about the computed power or sample size. The SAS log and SAS code are also available.

All analyses offer computation of power or sample size. Some analyses offer computation of sample size per group as well as total sample size.

Where appropriate, several alternate ways of entering values for certain parameters are offered. For example, in the two-sample *t* test analysis, means can be entered for individual groups or as a difference. The null mean difference can be specified as a default of zero or can be explicitly entered.

Information about existing analyses is stored in a project format. You can access each project to review the results or to edit your input parameters and produce another analysis.

Getting Started: PSS Application

Overview

This section is intended to get you off to a quick start with PSS. More detailed information about using the application is found in "How to Use: PSS Application" on page 5984 and in the example sections.

To start the application on a PC using the Windows operating system, select **Start►Programs►SAS►SAS Power and Sample Size 3.1** (or the latest release).

When you first use the application for a release, you are asked some configuration questions. For more information see the section "Configuration" on page 6002.

As an inital step, you also must define a SAS connection. If you have Foundation SAS software installed on the PC that you are using for PSS, this step can be done for you automatically. To define a connection or to determine whether one has already been defined, see the section "SAS Connections" on page 5984.

The Basic Steps

Here are the basic steps that you follow to use PSS.

1. Start a new project by selecting **File►New** on the menu bar or clicking the **New** icon on the toolbar.
2. In the New window, select the desired analysis type and click **OK**.

   A project window for the analysis type appears with the Edit Properties page displayed. (The tabs on the Edit Properties page and their content vary according to the analysis type.)
3. Click each tab to enter the relevant data for the analysis. (For more information about the types of data to enter, see the example sections.)
4. After you have entered all the data, click the **Calculate** button.
5. After PSS calculates the results, the project window displays the View Results page with the Summary Table tab displayed by default.

6. To view other results or to review the SAS code or the SAS log, click any of the tabs on the left side of the View Results page.

7. To print any results page, select **File►Print** on the menu bar.

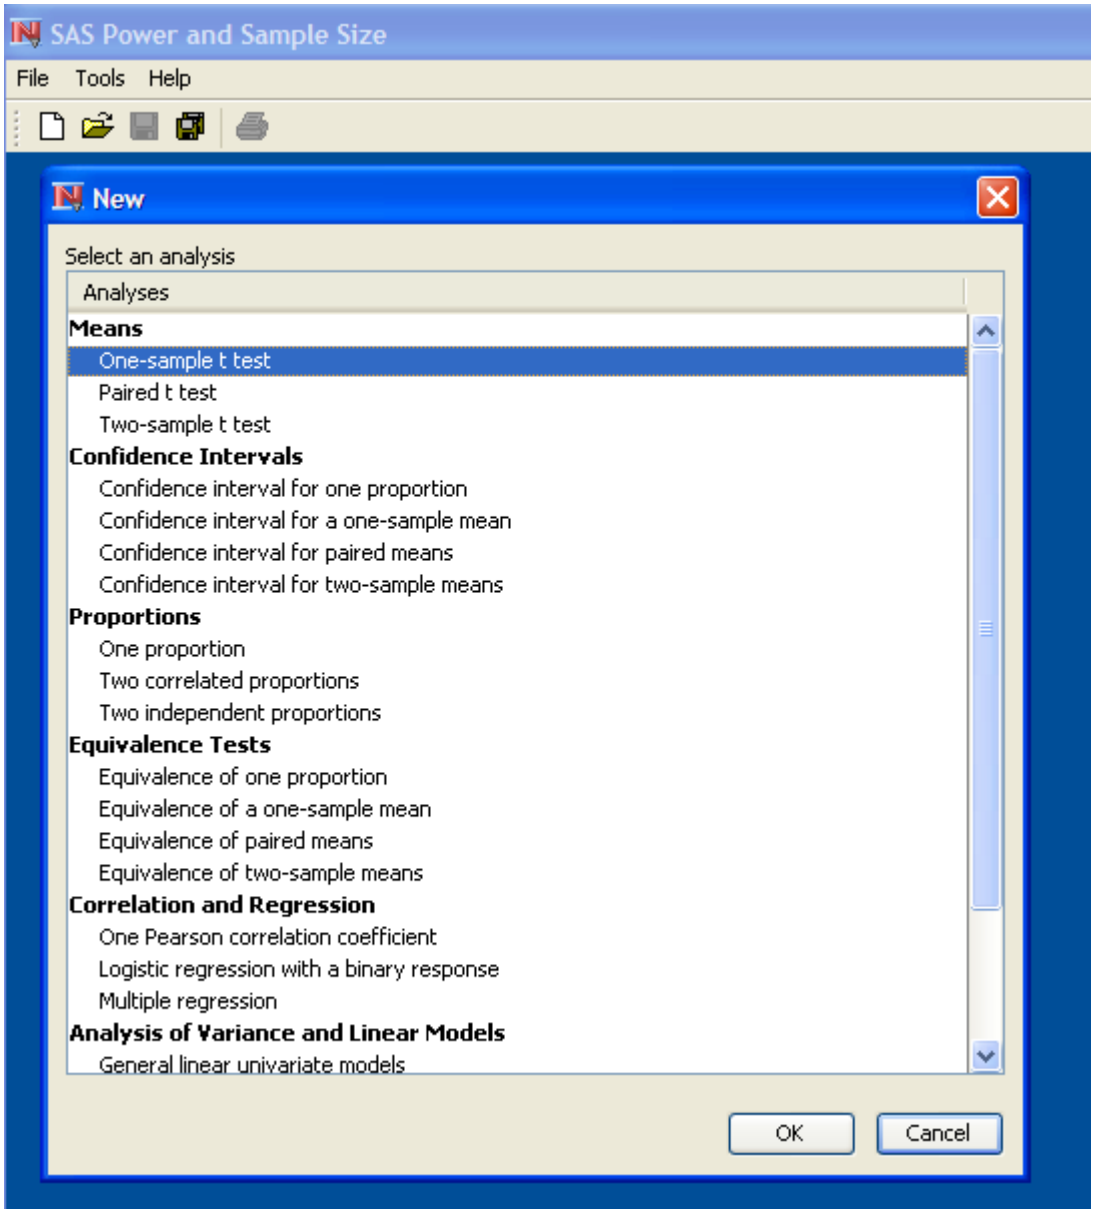
The remainder of this section takes you through a simple example.

A Simple Example

Suppose you want to determine the power for a new marketing study. You want to compare car sales in the southeastern region to the national average of 1.0 car per salesperson per day. You believe that the actual average for the region is 1.6 cars per salesperson per day. You want to test if the mean for a single group is larger than a specific value, so the one-sample *t* test is the appropriate analysis. The conjectured mean is 1.6 and the null mean is 1.0. You intend to use a significance level of 0.05 for the one-sided test. You want to calculate power for two standard deviations, 0.5 and 0.75, and two sample sizes, 10 and 20 dealerships.

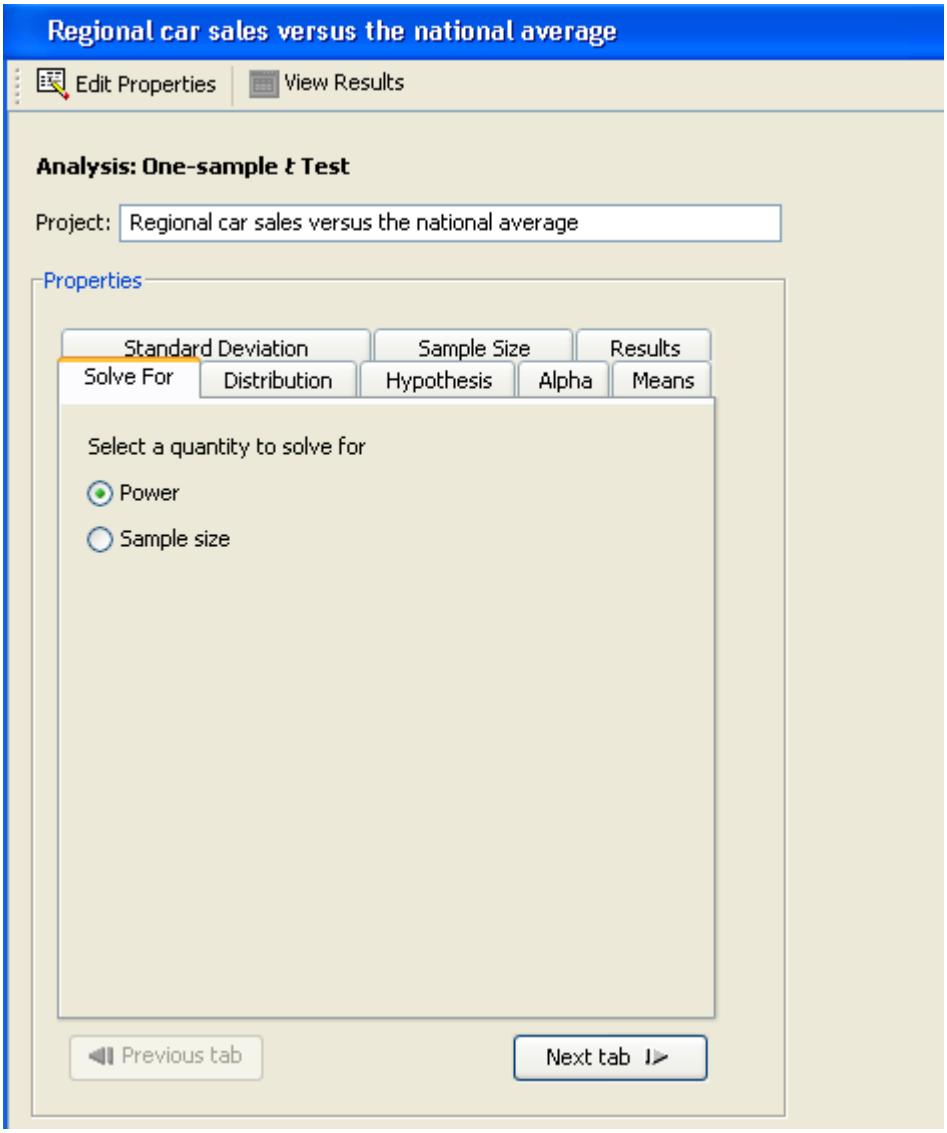
First, open a new project by selecting **File►New** on the menu bar or clicking the **New** icon on the toolbar. The New window appears. Then, select the appropriate analysis.

Figure 71.2 New Window



For this example, the selected analysis is the **One-sample t test** in the **Means** section, as shown at the top of Figure 71.2. Select the analysis from the list and click **OK**. The **One-sample t test** project window appears with the Edit Properties page displayed, as shown in Figure 71.3.

Figure 71.3 Edit Properties Page



Enter a descriptive label of the project in the **Project:** field. For the example, change the description to `Regional car sales versus the national average`. The description is used to identify the project when you reopen it from the Open window.

Select **File►Save** to save the description change. Note in Figure 71.3 that the title bar of the window contains your project description after you have saved the change.

Properties of the project are displayed on several tabs. You can change from tab to tab by clicking a tab or by clicking the **Next tab** or **Previous tab** buttons. To display help about the properties for a tab, click the **Help** button at the bottom of the Edit Properties page.

Entering Parameter Values

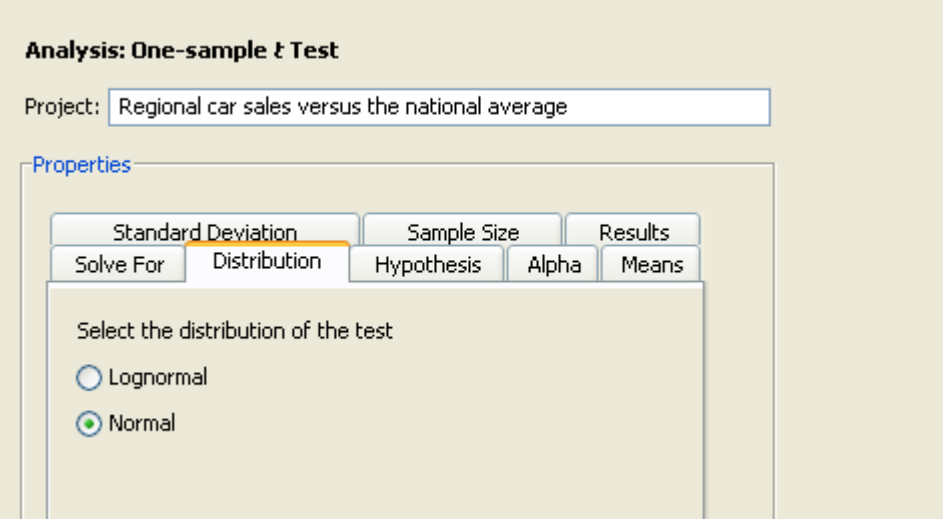
First, click the **Solve For** tab and choose to calculate power or sample size. For this example, select the **Power** option, as shown in Figure 71.3.

Next, you must provide values for two analysis options and four parameters. These parameters are set in separate tabs on the Edit Properties page and are labeled **Distribution**, **Hypothesis**, **Alpha**, **Mean**, **Standard Deviation**, and **Sample Size**.

Distribution

Click the **Distribution** tab to select a **Normal** or **Lognormal** distribution. For the example, you are using means rather than mean ratios, so select **Normal**, as shown in Figure 71.4.

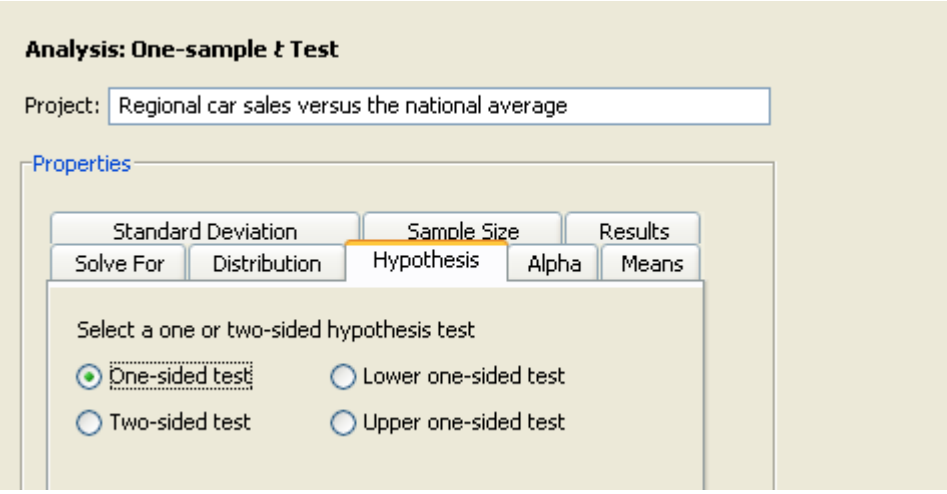
Figure 71.4 Distribution Tab



Hypothesis

Click the **Hypothesis** tab to select a one- or two-sided test. Because you are interested only in whether the southeastern region produces higher daily car sales than the national average, select **One-sided test**, as shown in Figure 71.5.

Figure 71.5 Hypothesis Tab

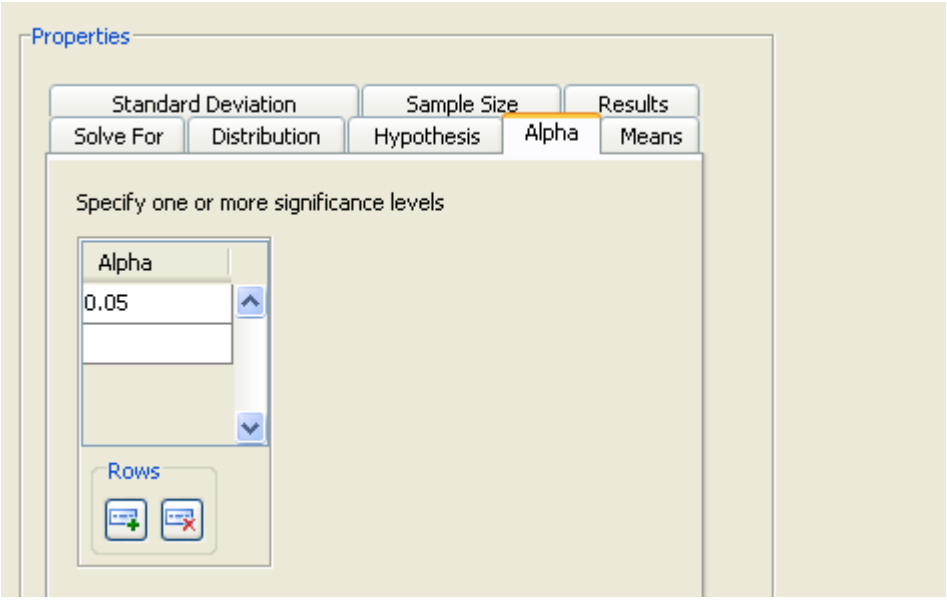


There are three one-sided test options: **One-sided test**, **Upper one-sided test**, and **Lower one-sided test**. The **Upper one-sided test** option would also be appropriate for this example.

Alpha

Click the **Alpha** tab to specify one or more significance levels. Enter `0.05`, as shown in Figure 71.6.

Figure 71.6 Alpha Tab

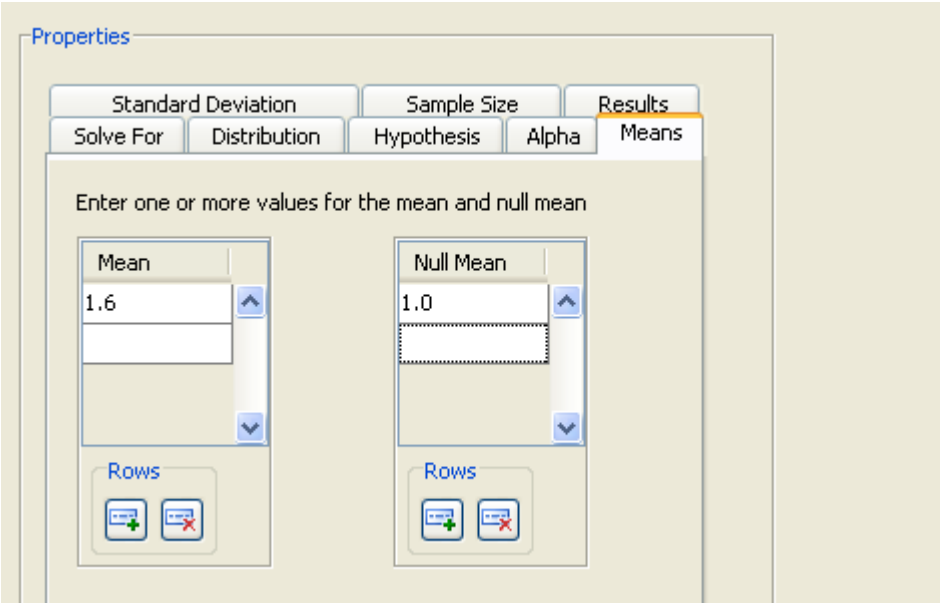


This value will be the default unless the default has been changed in the Preferences window. To set preferences, select **Tools►Preferences** on the menu bar. For more information about setting preferences, see the section "Setting Preferences" on page 5988.

Mean

Click the **Means** tab to enter one or more means and null means. For the example, enter `1.6` in the Mean table and `1.0` in the Null Mean table. Figure 71.7 shows the entered values.

Figure 71.7 Means Tab

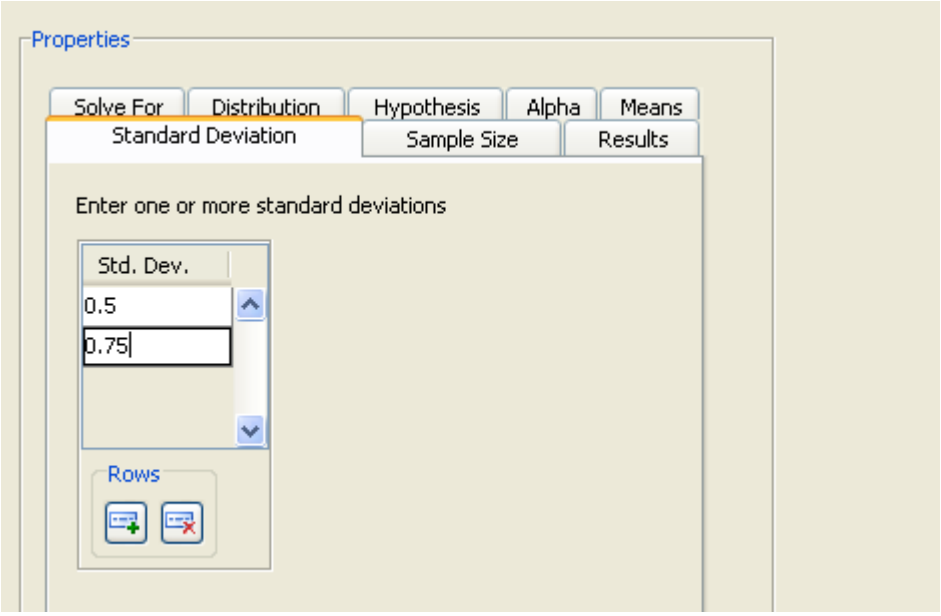


Note that additional input rows are available if you want to enter additional sets of parameters. You can also append and delete rows using the and buttons beneath the table. In addition, by selecting a row and right-clicking, you can choose to insert and delete rows in the body of the table from a pop-up menu.

Standard Deviation

Click the **Standard Deviation** tab to enter standard deviations. You are interested in two standard deviations, `0.5` and `0.75`. Enter them in the table, as shown in Figure 71.8.

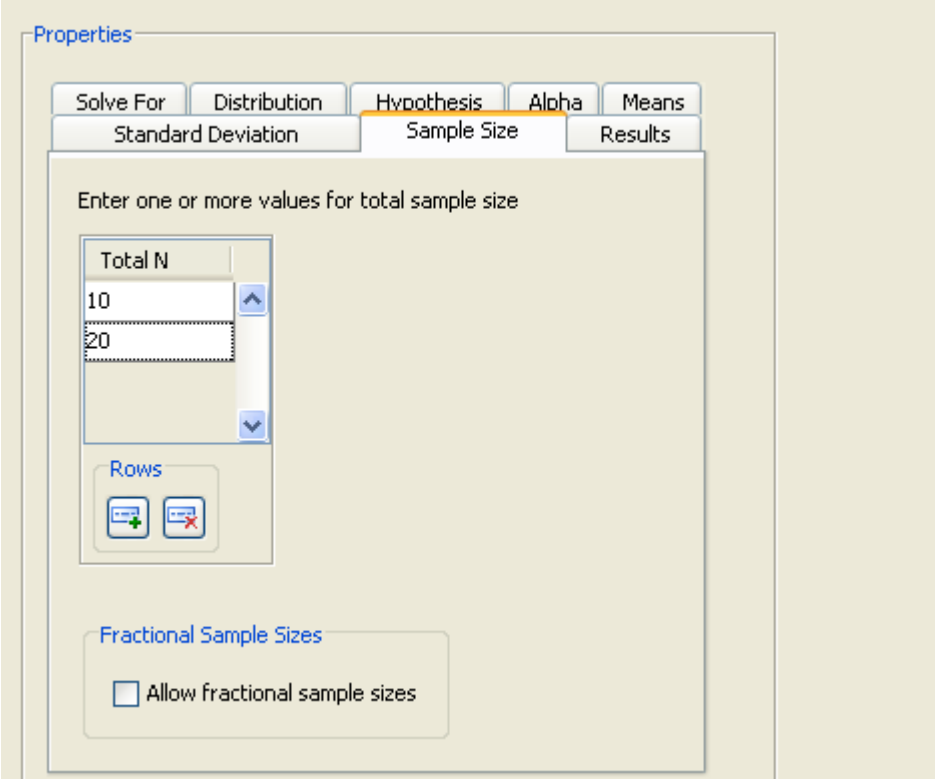
Figure 71.8 Standard Deviation Tab



Sample Size

You want to be able to sample between `10` and `20` dealerships. Click the **Sample Size** tab and enter these two values, as shown in Figure 71.9.

Figure 71.9 Sample Size Tab



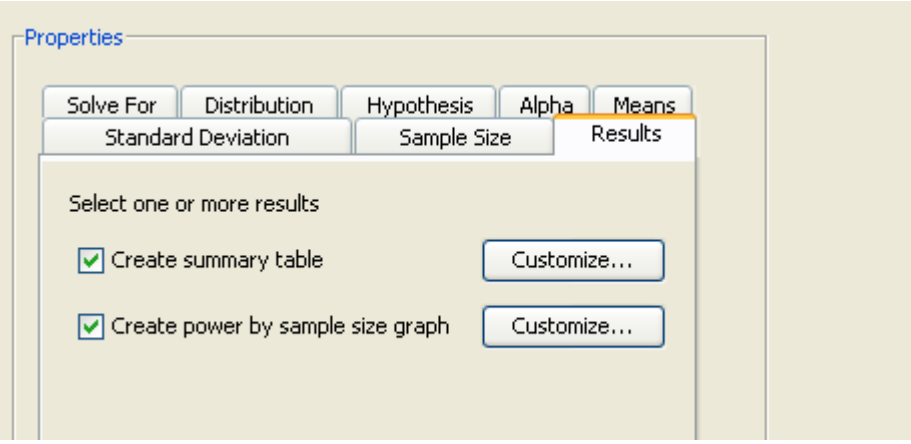
Scenarios

The input values are combined into one or more scenarios. In this case, each of the two standard deviations is combined with each of the two sample sizes for a total of four scenarios. Then power is computed for each scenario. In this example, only a single value or setting is present for the mean, null mean, and alpha level, so they are common to all scenarios.

Results Options

Click the **Results** tab to select results options including a Summary Table and a Power by Sample Size graph.

Figure 71.10 Results Tab

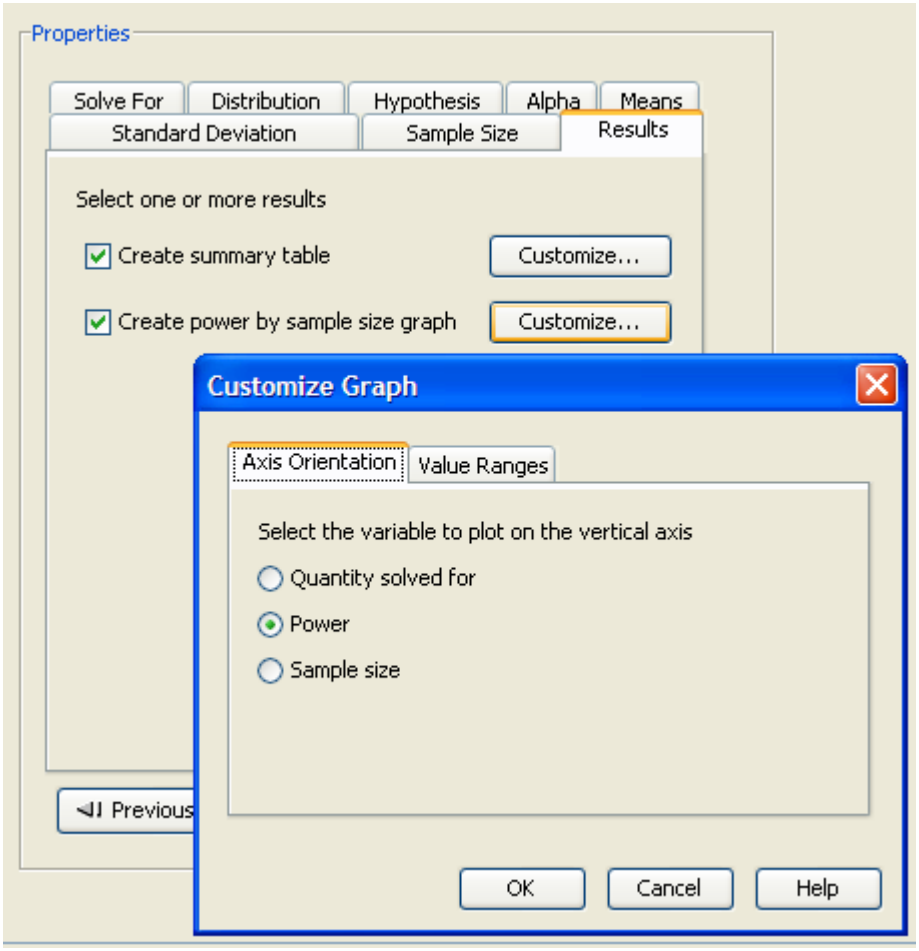


For this example, select both results check boxes: **Create summary table** and **Create power by sample size graph**, as shown in Figure 71.10. These selections can also be set as preferences; see the section "Setting Preferences" on page 5988.

Customizing the Power by Sample Size Graph

Click the **Customize** button beside the **Create power by sample size graph** check box to customize the graph. The Customize Graph window contains two tabs: **Axis Orientation** and **Value Ranges**, as shown in Figure 71.11.

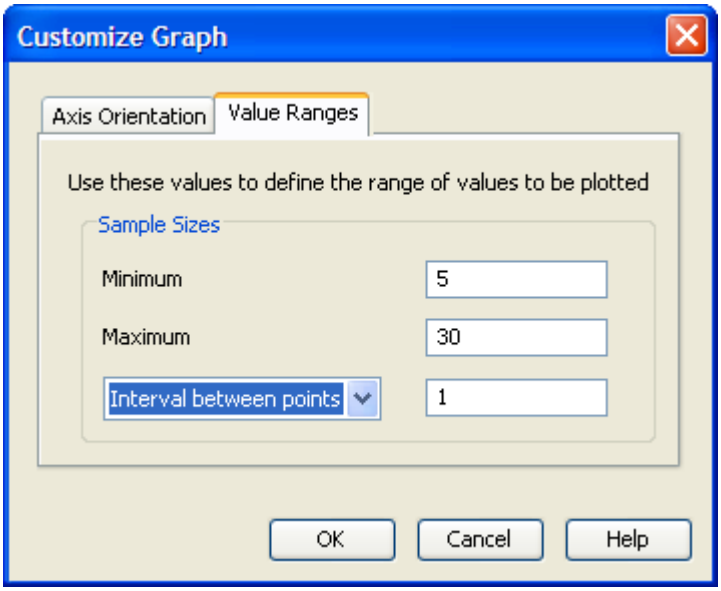
Figure 71.11 Customize Graph Window with Axis Orientation Tab



Click the **Axis Orientation** tab to select which quantity you would like to plot on the vertical axis. You can choose to display the quantity solved for (either power or sample size) on the vertical axis or you can choose to display power or sample size on the vertical axis with the other quantity appearing on the horizontal axis. The default is **Quantity solved for** (or power) on the vertical axis, which is appropriate for this graph.

The summary table is created using the two sample sizes specified in the Sample Size table, 10 and 20. If you want to create a graph that contains more than these two sample sizes, you can do so by customizing the value ranges for the graph. Click the **Value Ranges** tab to set the axis range for sample sizes, as shown in Figure 71.12.

Figure 71.12 Customize Graph Window with Value Ranges Tab



Enter `5` for the minimum and `30` for the maximum. Also, select **Interval between points** in the drop-down list and enter a value of `1`. These values set the sample size axis to range from 5 to 30 in increments of 1. The completed Value Ranges section of the window is shown in Figure 71.12.

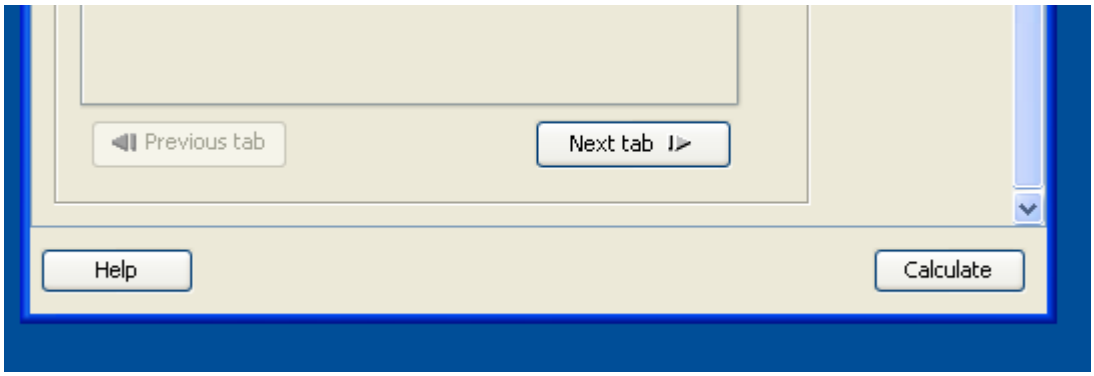
When you solve for power, you can set a range for sample size values, but not for the powers; and vice versa when you solve for sample size. That is, you cannot set the range of axis values for the quantity that you are solving for.

Click **OK** to save the values that you have entered and return to the Edit Properties page.

Performing the Analysis

You have now specified all of the necessary input values. Click **Calculate** to perform the analysis, as shown in Figure 71.13.

Figure 71.13 Calculate Button on the Edit Properties Page



Alternatively, you could choose to save the information that you have entered by selecting **File►Save** from the menu bar or clicking the **Save** toolbar icon, and perform the analysis at another time. No error checking is done when you save the project.

You can close the project by selecting **File►Close** on the menu bar or clicking the window close **X** in the upper right corner of the project window. You can reopen a project by selecting **File►Open** on the menu bar or clicking the **Open** toolbar icon.

For this example, click **Calculate**.

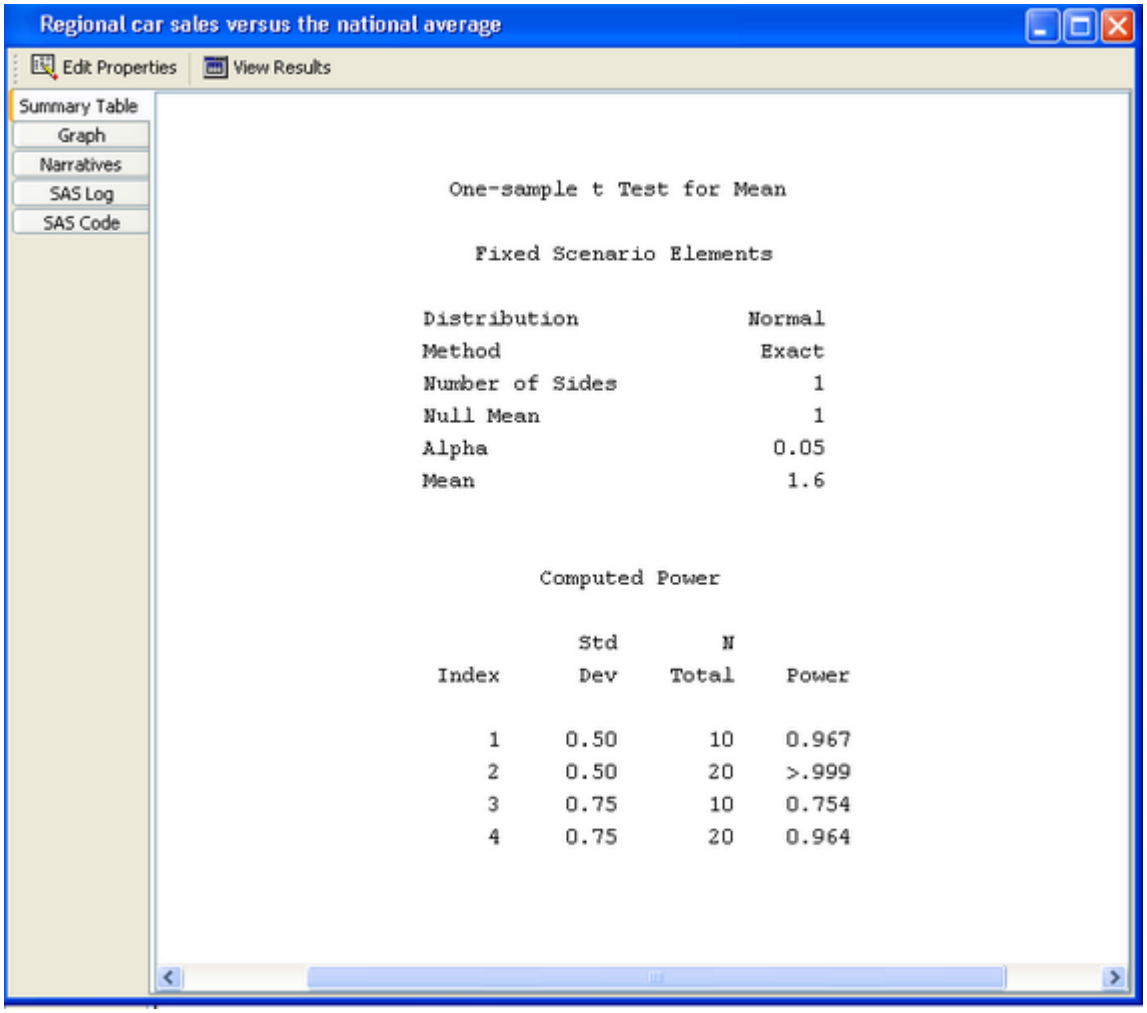
Viewing the Results

Results appear on the View Results page and are viewable in separate tabs. The tabs include **Summary Table**, **Graph**, **Narratives**, **SAS Log**, and **SAS Code** (located on the left side of the View Results page). The **Summary Table** and **Graph** tabs appear if you selected those options on the **Results** tab of the Edit Properties page. The other tabs always appear.

Summary Table

Click the **Summary Table** tab to view the summary table.

Figure 71.14 Summary Table Tab with Fixed Scenario Elements and Computed Power Tables



The Summary table consists of two subtables, as shown in Figure 71.14. The `Fixed Scenario Elements` table includes the parameters or options that have a single value for the analysis. The `Computed Power` table contains the input parameters that have been given more than one value, and it shows the computed quantity, power.

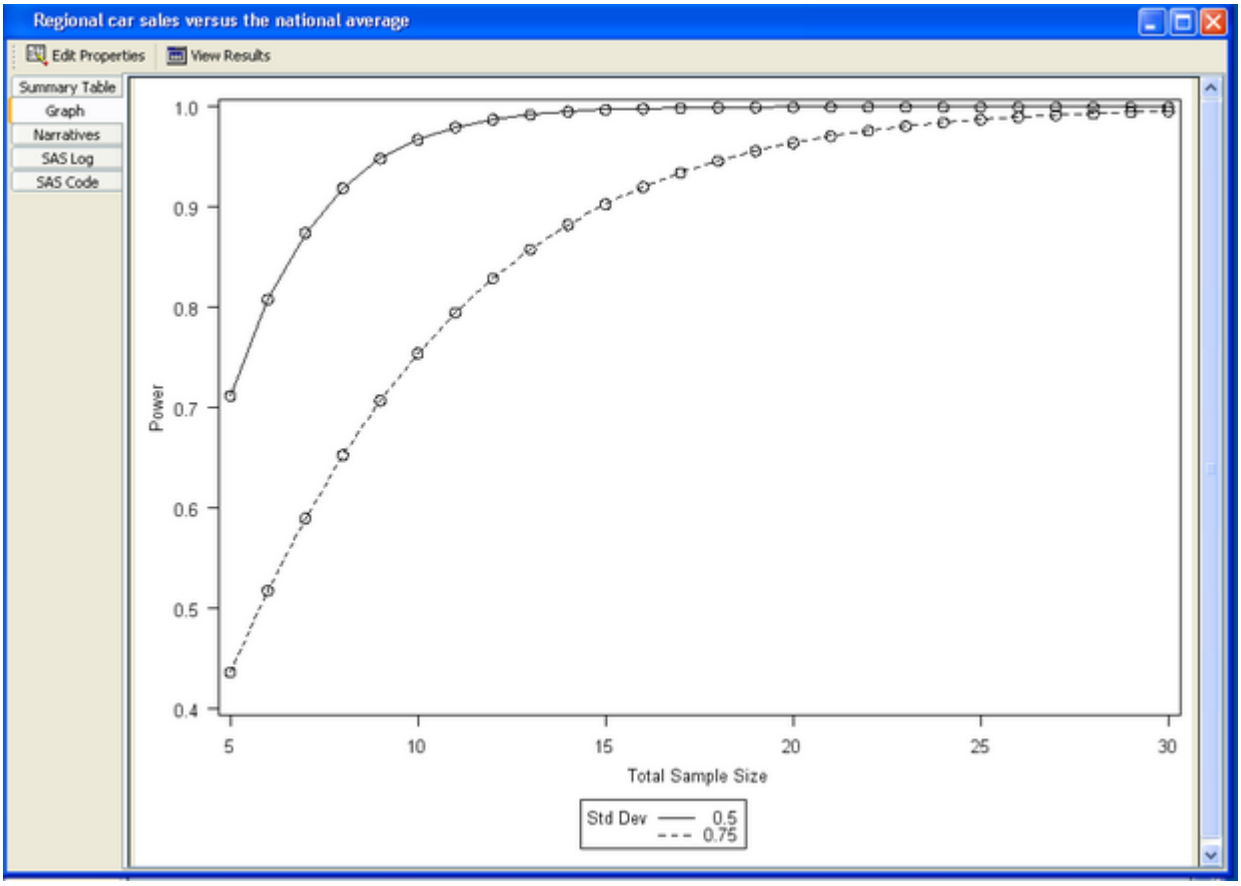
Thus, the `Computed Power` table contains four rows for the four combinations of standard deviation and sample size. From the table you can see that all four powers are high. The smallest value of power, 0.754, is associated with the largest standard deviation and the smallest sample size. In other words, the probability of rejecting the null hypothesis is greater than 75% in all four scenarios.

Power by Sample Size Graph

Click the **Graph** tab to view the power by sample size graph.

The power by sample size graph in Figure 71.15 contains one curve for each standard deviation. For a standard deviation of 0.5 (the upper curve), increasing sample size above 10 does not lead to much increase in power. If you are satisfied with a power of 0.75 or greater, 10 samples would be adequate for standard deviations between 0.5 and 0.75.

Figure 71.15 Graph Tab with Power by Sample Size Graph



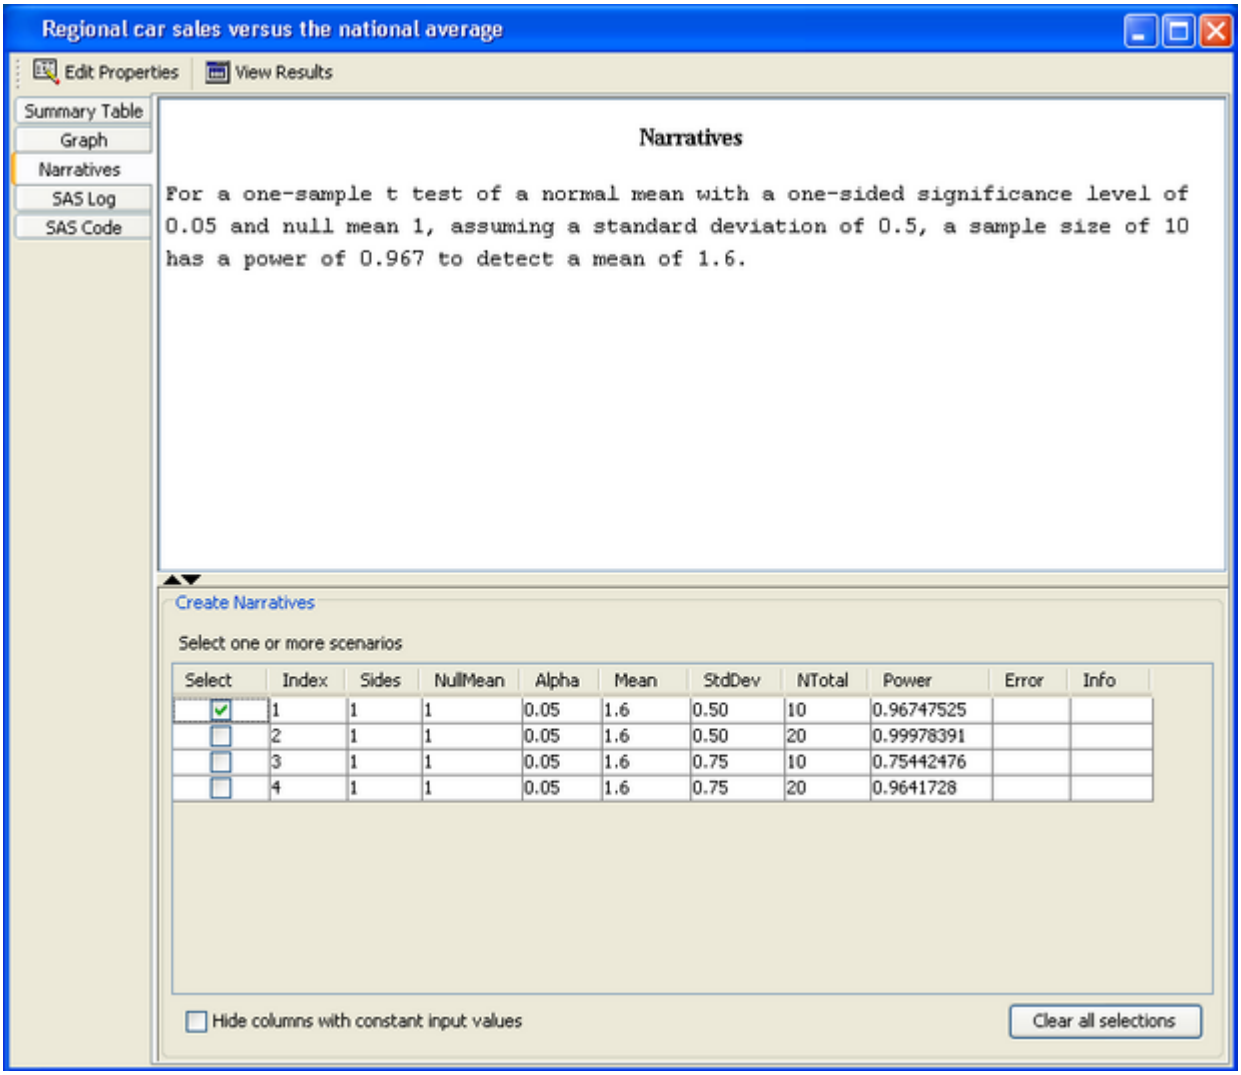
Narratives

Click the **Narratives** tab to display a facility for creating narratives.

Narratives are descriptions of the values that compose each scenario and include a statement about the computed power or sample size.

To create narratives, choose one or more scenarios in the table at the bottom of the tab. A narrative for each selected scenario is displayed in the top portion of the tab. See Figure 71.16.

Figure 71.16 Narrative Tab



For the example, select the first row in the table. The following narrative is displayed for the scenario with a standard deviation of 0.5 and a sample size of 10:

```
For a one-sample t test of a normal mean with a one-sided significance
level of 0.05 and null mean 1, assuming a standard deviation of 0.5, a
sample size of 10 has a power of 0.967 to detect a mean of 1.6.
```

You can select several rows in the table. As you select each one, a corresponding narrative is created and displayed in the top portion of the table. Selecting a second scenario (the third row) produces the following output, where the narrative for the first row is followed by the narrative for the third row:

```
For a one-sample t test of a normal mean with a one-sided significance
level of 0.05 and null mean 1, assuming a standard deviation of 0.5, a
sample size of 10 has a power of 0.967 to detect a mean of 1.6.

For a one-sample t test of a normal mean with a one-sided significance
level of 0.05 and null mean 1, assuming a standard deviation of 0.75, a
sample size of 10 has a power of 0.754 to detect a mean of 1.6.
```

Other Results

Other results include the SAS log and the SAS code.

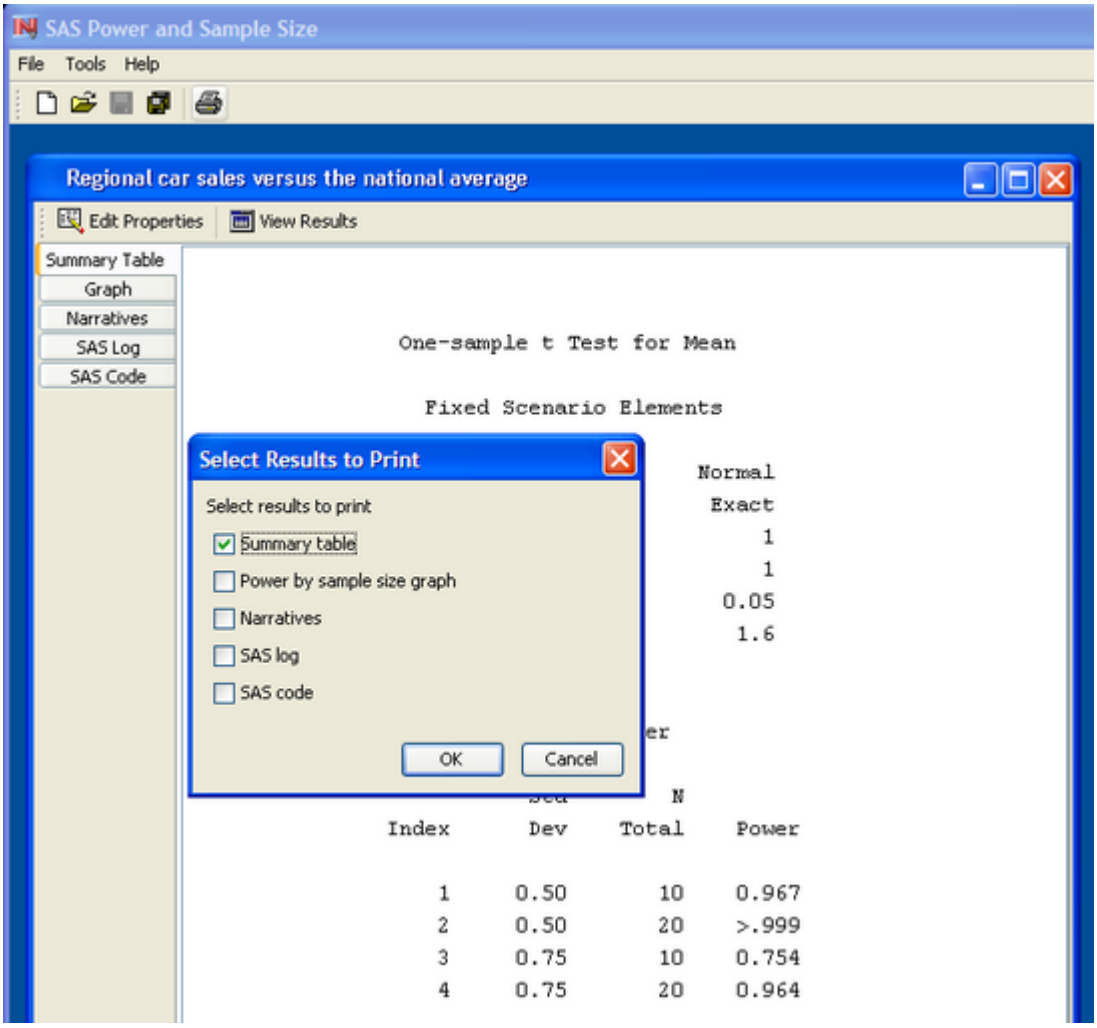
The SAS log that was produced when the **Calculate** button was last clicked appears on the **SAS Log** tab.

The SAS statements that produced the results appear on the **SAS Code** tab.

Printing Results

To print one or more results, select **File►Print** from the menu bar or click the **Print** toolbar icon. A window is displayed that lists all available results, as shown in Figure 71.17. Select the results that you want to print and click **OK**.

Figure 71.17 Print Selection Window



Changing Properties

If you want to change some values of the properties and rerun the analysis, change to the Edit Properties page and continue. The icons for selecting the Edit Properties and View Results pages are in the command bar just below the project window title.

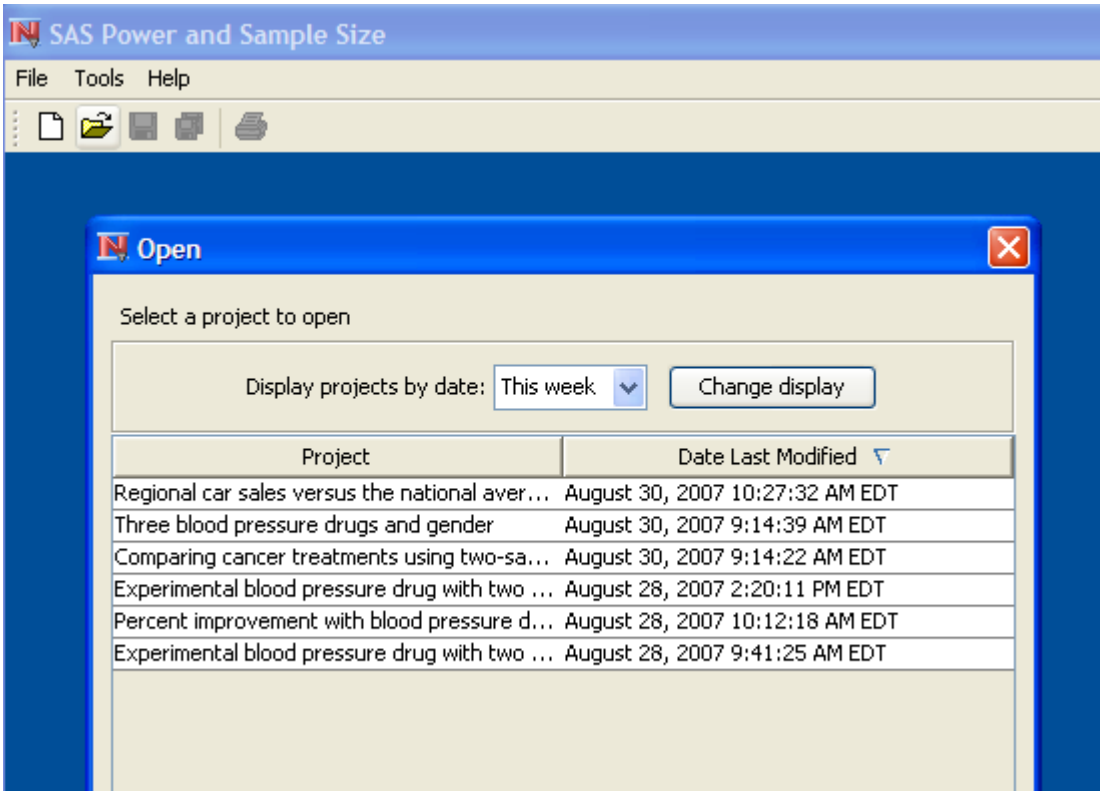
Closing the Project

When you are finished working with a project, close it by clicking the **X** in the upper right corner of the project window or selecting **File►Close** on the menu bar. If you have not saved the project, you will be asked if you want to save it before closing.

Opening a Project

You can reopen existing projects using the Open window. Select **File►Open** on the menu bar or click the **Open** toolbar icon.

Figure 71.18 Open Window Containing the Analysis Created in the Example



As shown in Figure 71.18, the analysis that you just completed is listed in the table. The label that you assigned to it, `Regional car sales versus the national average`, appears in the **Project** column of the table. The table also contains the date that the analysis was last modified. If you do not see the project that you are looking for, change the value of the **Display projects by date** box to `All` by selecting `All` from the drop-down list, and click the **Change display** button.

You can sort the projects in the table by clicking the header of the desired column. The sort direction is indicated by arrows displayed in the column header.

Select the project that you want to open and click **OK**. You can also double-click the project entry to open it.

Changing Values and Rerunning the Analysis

After viewing the graph, you might want to re-create the graph with a different range for sample sizes. On the **Results** tab of the Edit Properties page, click the **Customize** button for the power by sample size graph. The **Customize Graph** window is displayed.

On the **Value Ranges** tab of the window, change the Maximum value in the Sample Size table from `30` to `20`. Click **OK**.

Rerun the analysis by clicking **Calculate**. The View Results page is displayed again and the graph now has the new maximum value for the sample size axis.

How to Use: PSS Application

Overview

The PSS application is an application that resides on your desktop. It requires a connection to SAS software either on your desktop machine or a remote machine. You can set default values for several parameters and options as preferences. More detail on creating and editing projects is provided. Projects can be imported and exported.

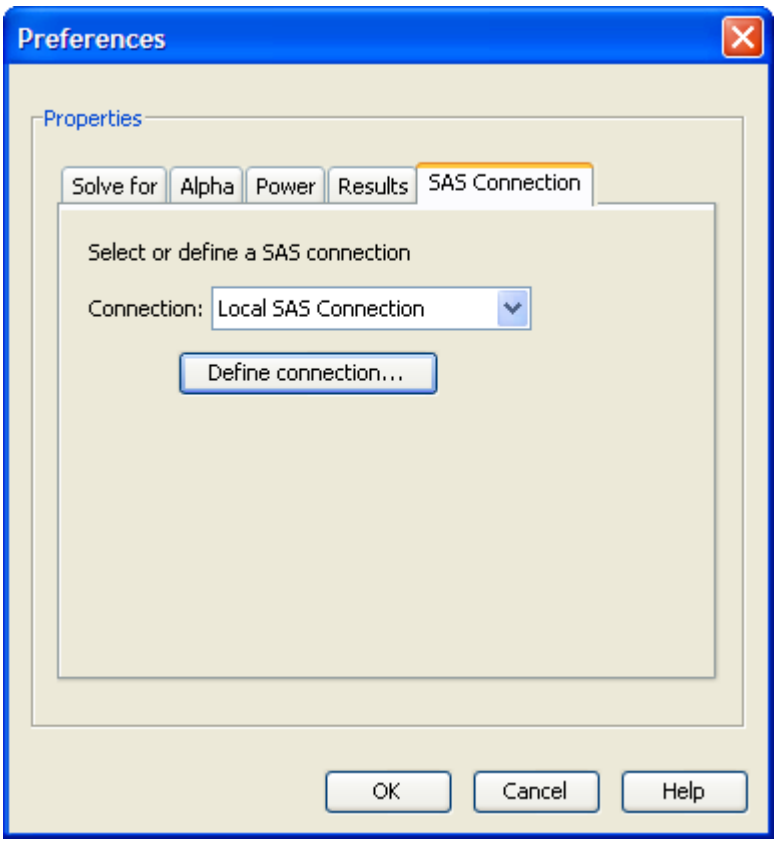
SAS Connections

Connections to SAS servers are defined in the Preferences window. To access the Preferences window, select **Tools►Preferences** on the menu bar.

Click the **SAS Connection** tab to select or define a connection to a SAS server. A connection to a SAS server is required in order to calculate results. The server can be on your local (desktop) machine or on a remote machine.

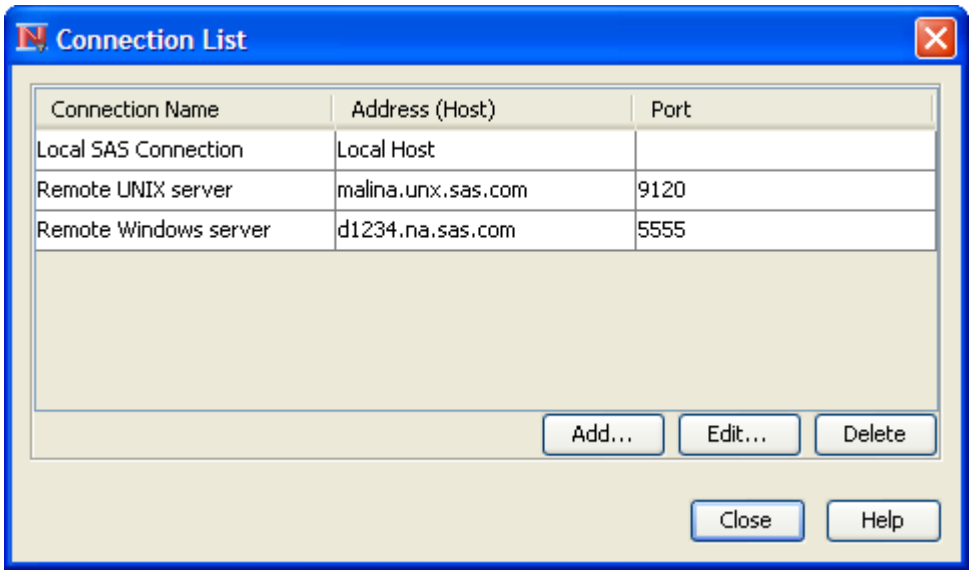
You can define several SAS connections and choose the one you want to use. To select a previously defined connection, choose it from the **Connection** list on the **SAS Connection** tab; see Figure 71.19.

Figure 71.19 SAS Connection Tab



To define a SAS connection, click the **Define connection** button. The Connection List window appears, as shown in Figure 71.20. To create a new connection, click **Add**. To edit an existing connection, select it in the Connection List and click **Edit**.

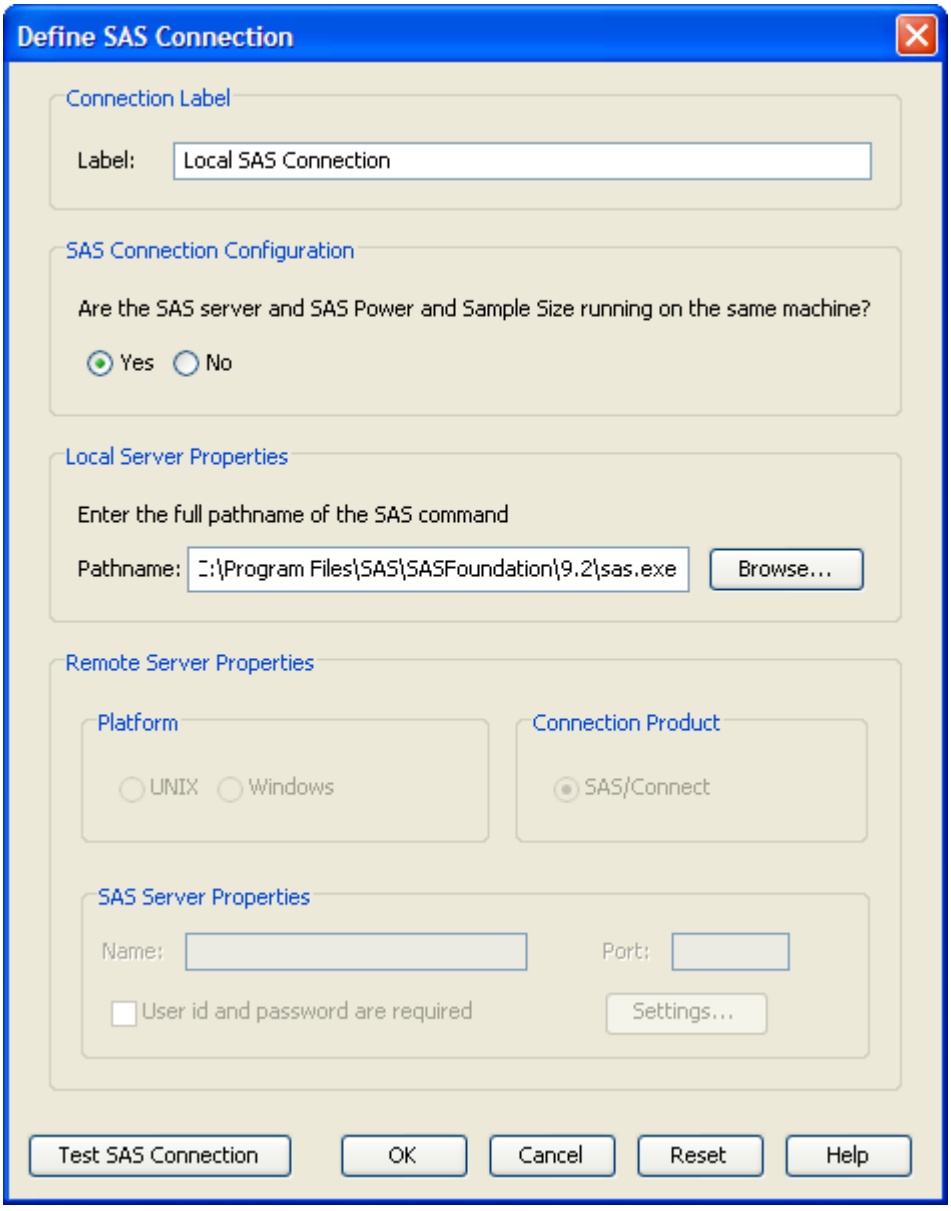
Figure 71.20 Connection List



Defining a SAS Connection

After you click the **Add** or **Edit** button, the Define SAS Connection window appears, as shown in Figure 71.21. If you clicked **Edit**, the previously defined information is available for editing.

Figure 71.21 Define Connection Window



Enter a descriptive label for the connection. The label is used to distinguish among the connections in the connections list.

Then, select **Yes** or **No** to specify whether the SAS connection is to the local machine (that is, the one on which PSS is running) or to a remote machine, respectively.

Defining a Local Connection

To define a connection to the local machine, enter the full path name of (or browse for) the SAS executable file (*sas.exe* on Microsoft Windows).

Test the SAS connection by clicking the **Test SAS Connection** button.

Defining a Remote Connection

To define a connection to a remote machine, select either the **UNIX** or **Windows** option to indicate that the remote SAS server is on a machine running the UNIX or Microsoft Windows operating systems, respectively. Then, specify the machine name and port number that the SAS/Connect spawner is using on the remote machine. Contact the SAS server administrator for this information.

If the remote machine is running Microsoft Windows, select the **User id and password are required** if authentication is required to access the SAS server (that is, if the SAS `-security` option is used). By default, authentication is required for SAS servers running on UNIX operating systems.

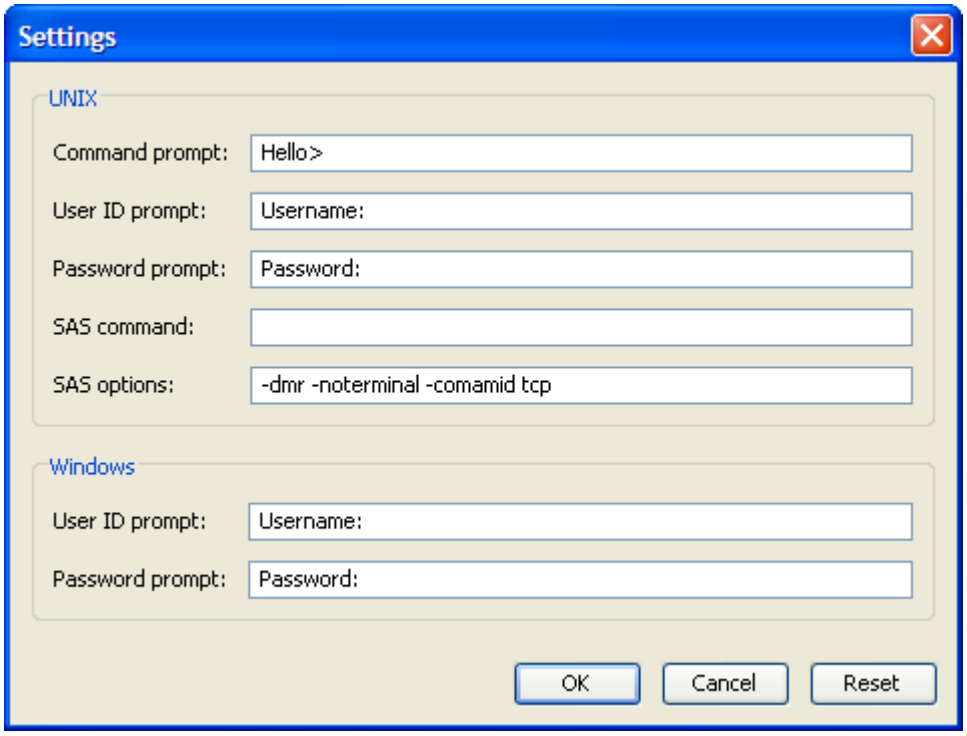
Test the SAS connection by clicking the **Test SAS Connection** button.

Additional Settings

Click the **Settings** button on the Define SAS Connection window to access some additional settings for a remote connection to a SAS server. For the most part these settings are prompts that PSS expects to receive from the SAS/CONNECT spawner on the remote machine, as shown in Figure 71.22.

If the remote SAS server is on a UNIX machine, you must specify the full pathname of the SAS command. Contact the SAS server administrator for this information.

Figure 71.22 Connection Settings Window

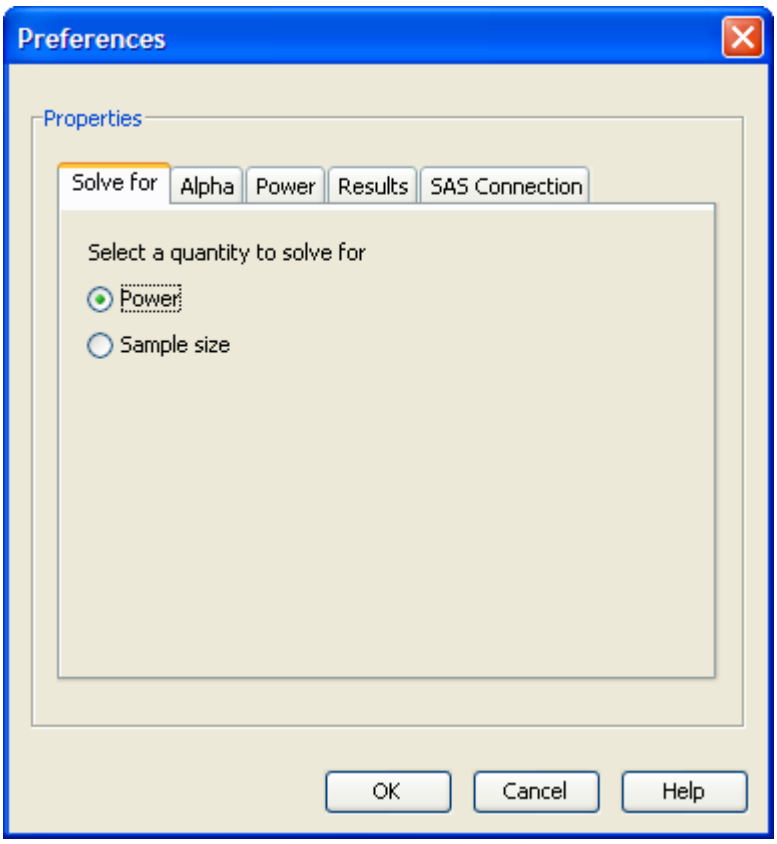


Setting Preferences

In the Preferences window you can set default values for options that are used by all analyses.

To access the Preferences window, select **Tools►Preferences** on the menu bar. Figure 71.23 shows the Preferences window.

Figure 71.23 Preferences Window



Preference values are used as the defaults for each newly opened project (that is, those that are opened from the New window). For a specific project, each of these default values can be overridden on the Edit Properties page.

Changes in preferences do not change the state of an existing analysis (that is, one that is accessed from the Open window).

Selecting the Quantity to Solve For

Click the **Solve For** tab to select **Power** or **Sample Size** as the default value to be solved for; see Figure 71.23. For confidence interval analyses, selecting **Power** is equivalent to selecting **Prob(Width)**.

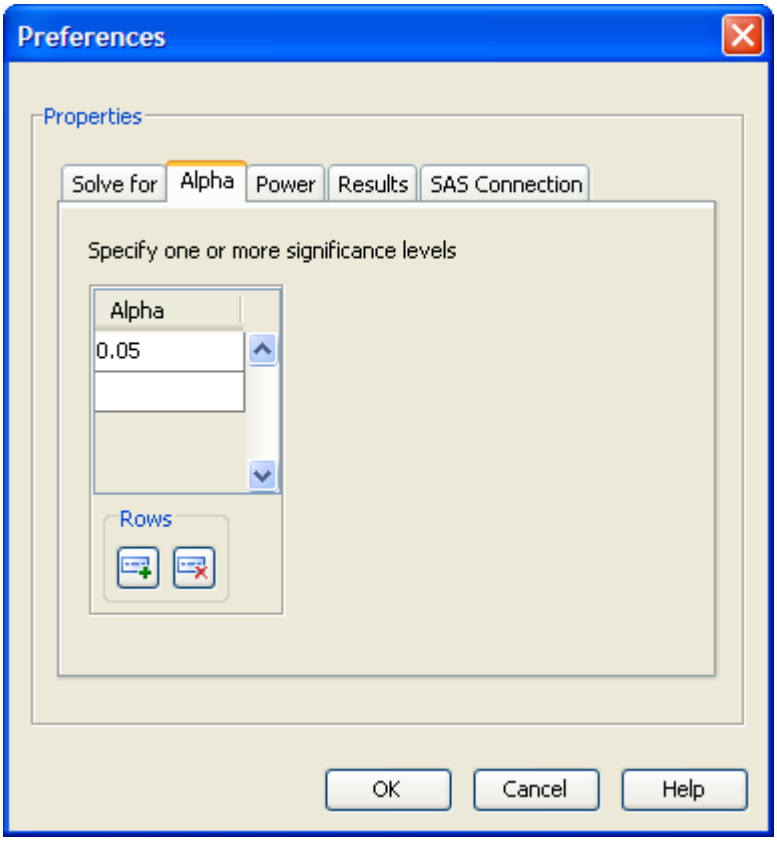
For analyses that offer both **Sample size per group** and **Total sample size**, the **Sample size** option on this page corresponds to total sample size.

Setting Alphas

Click the **Alpha** tab to enter one or more values for alpha. Alpha is the significance level (false positive probability). For confidence interval analyses, alpha values are transformed into confidence levels by $(1 - alpha)$. For example, an alpha of 0.05 would represent a confidence level of 0.95.

To set default values of alpha, enter one or more values in the **Alpha** data entry table. See Figure 71.24. It is not necessary to have any default values for alpha. Add more rows to the table as needed using the button at the bottom of the table.

Figure 71.24 Alpha Preference Tab

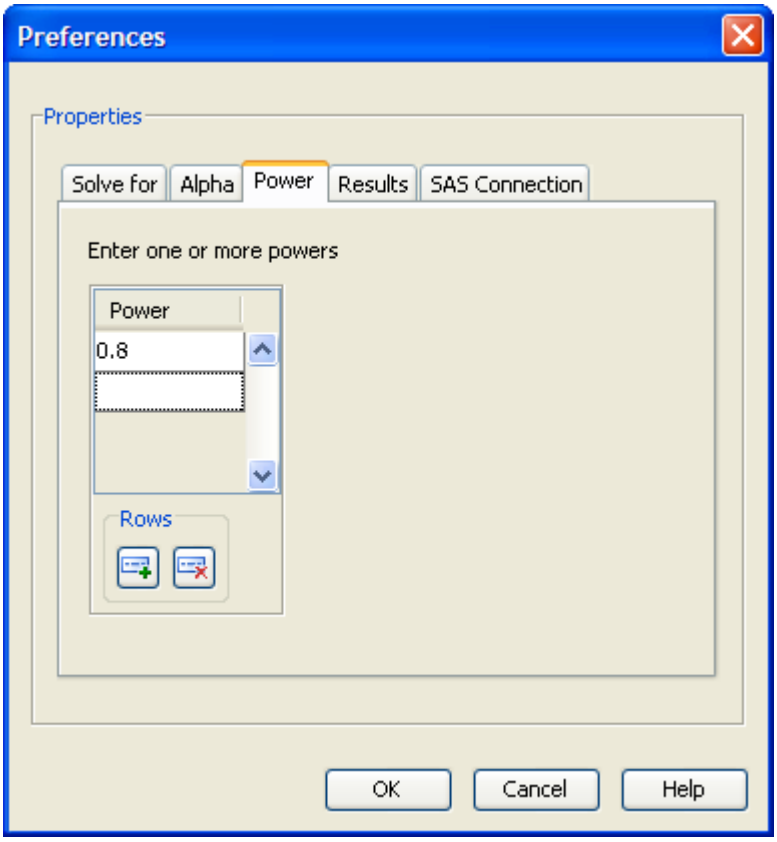


Setting Powers

Click the **Power** tab to enter one or more values for power. It is not necessary to have any default values for power. For confidence interval analyses, power values are treated as prob(width) values.

To set default values of power, enter one or more values in the **Power** data entry table; see Figure 71.25.

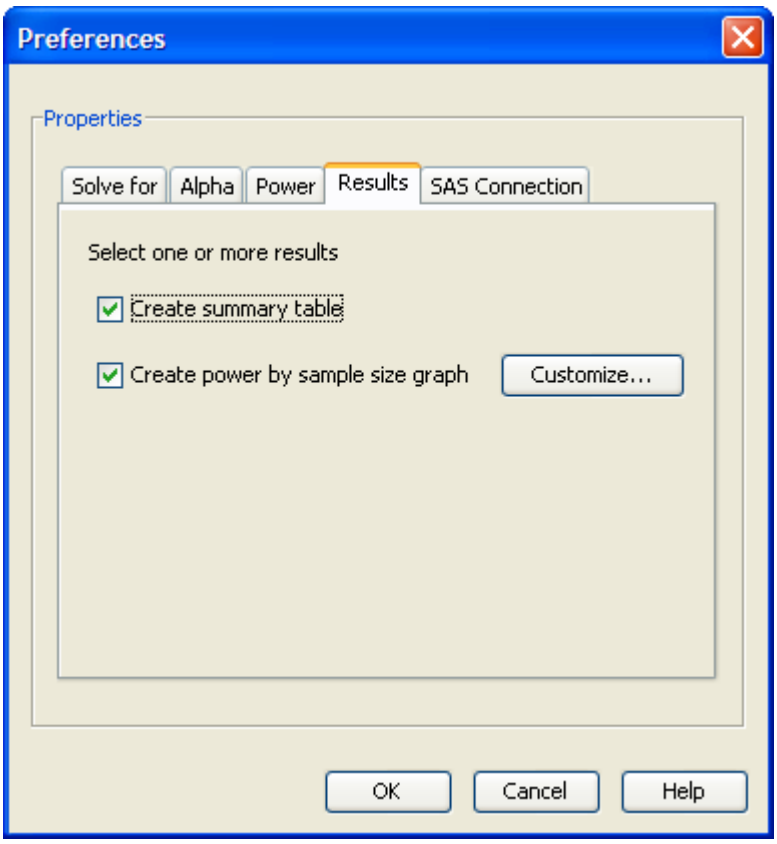
Figure 71.25 Power Preference Tab



Setting Results Options

Click the **Results** tab to make default selections for the summary table and the power by sample size graph options; see Figure 71.26.

Figure 71.26 Results Options Preferences Tab



The summary table consists of the input parameter values and the calculated quantity (power or sample size). Select the **Create summary table** check box to create the table by default.

To request that an analysis create a power by sample size graph by default, select the **Create power by sample size graph** check box.

Creating and Editing PSS Projects

A PSS project is an instance of an analysis. The first decision in using PSS is to choose the appropriate test or design. Select the **File►New** on the menu bar or click the **New** icon on the toolbar. The New window appears with a list of the available analyses. Select the type of analysis that you want from the list and click **OK**.

When the project is first opened, the Edit Properties page is displayed. It is described in the section "Editing Properties" on page 5993.

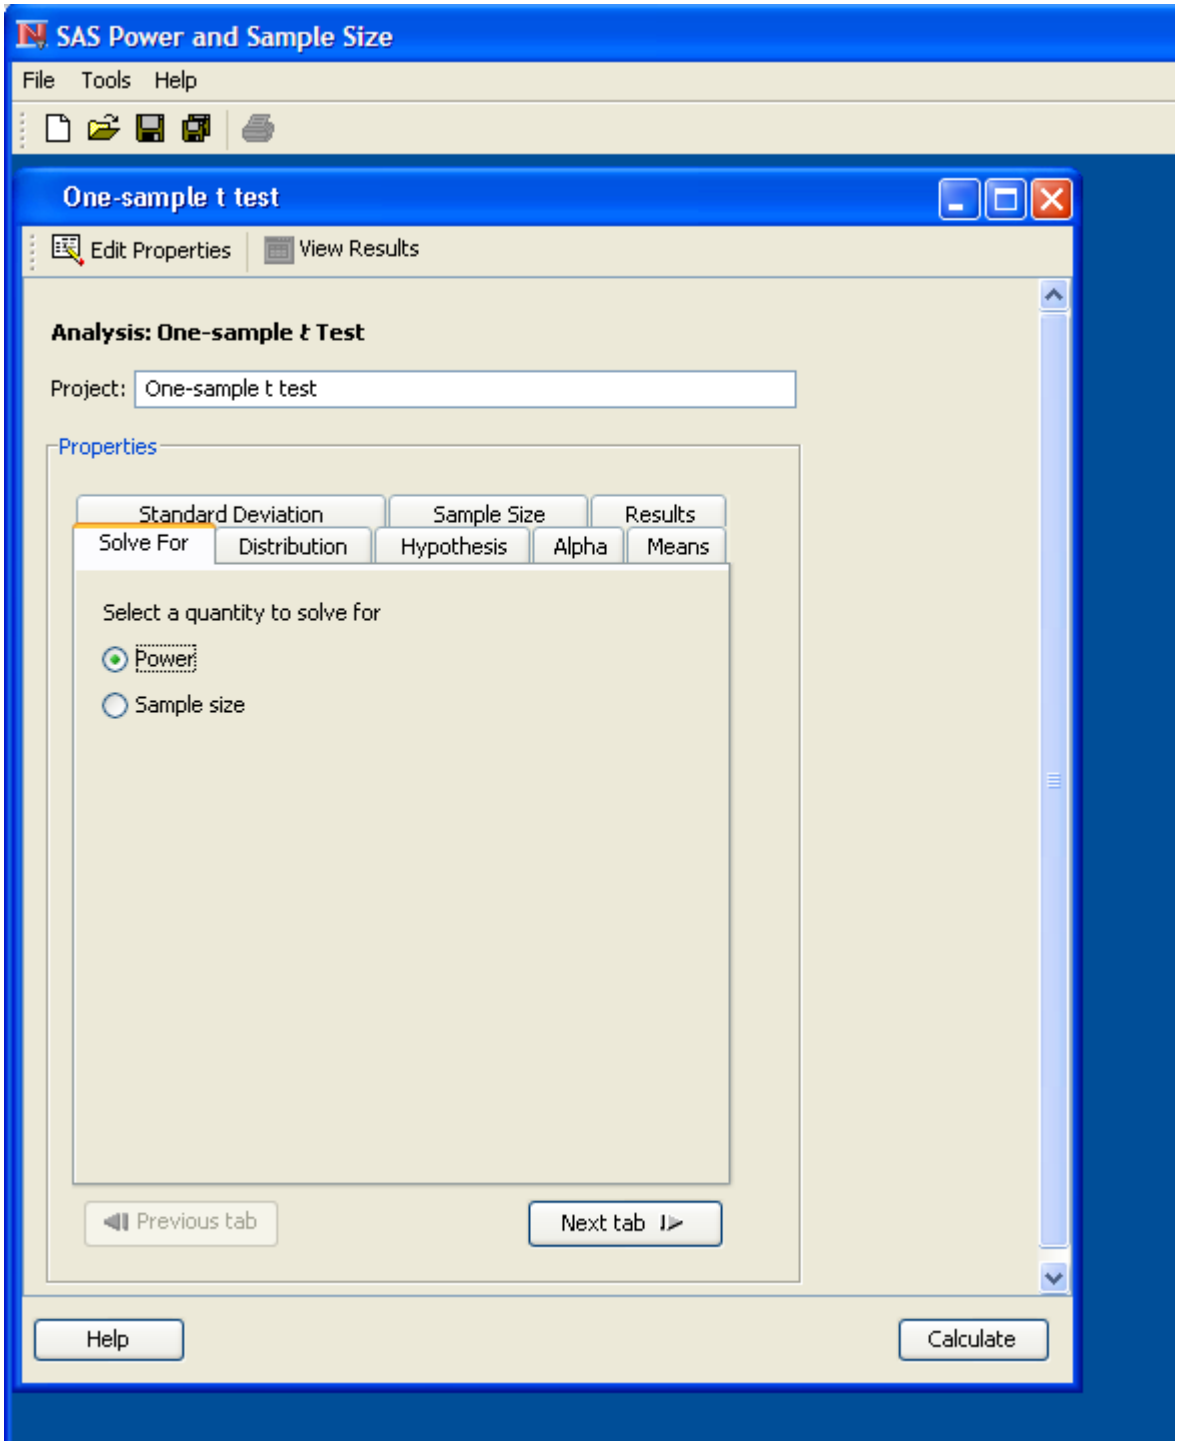
After the properties have been specified and the analysis is performed, the View Results page is displayed. See the section "Viewing the Results" on page 5997.

A project that has been saved and closed can be reopened from the Open window. Select **File►Open** on the menu bar or click the **Open** icon on the toolbar.

Editing Properties

The Edit Properties page consists of several analysis options and input parameters that are relevant to the particular analysis. These options and parameters are organized on several tabs, as shown in Figure 71.27.

Figure 71.27 Edit Properties Page

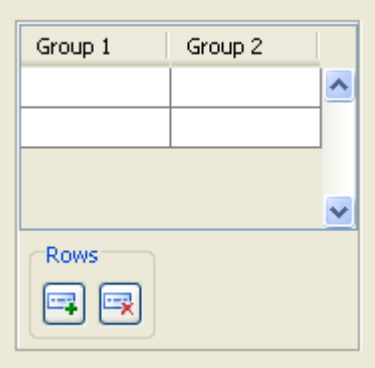


The Edit Properties page contains various controls by which you can enter values or select choices. In addition to the usual data entry controls such as text fields and check boxes, several specialized controls are present: data entry tables and the Alternate Forms control. More detailed descriptions follow.

Using Data Tables

Data entry tables are composed of data entry fields for one or more rows and columns. Figure 71.28 shows a two-row, two-column table.

Figure 71.28 Two-Column Data Entry Table with Controls



Type an appropriate value in each field. It is not necessary to type data in all rows or to delete empty rows. However, if a table has more than one column, the cells of a row must be completely filled or completely blank. Rows with values in some but not all cells are not allowed.

To append more rows, click the button beneath the table. To delete the last row of the table, click the button.

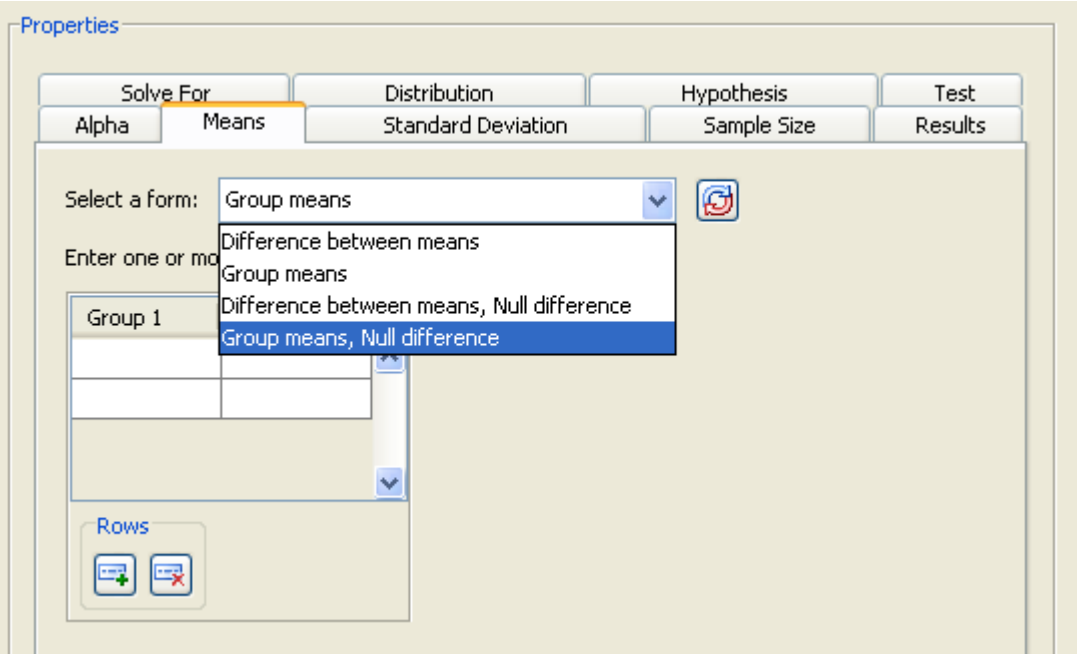
Also, you can display a pop-up menu to perform additional actions such as inserting and deleting rows. First, select the row to insert before or delete, then right-click to display the pop-menu and select the desired action.

Using Alternate Forms

For some input parameters, there are several ways in which data may be entered. For example, in the two-sample *t* test analysis, group means can be entered as either individual means or a difference between means.

The alternate forms are displayed in a drop-down list with an adjacent button, as shown in Figure 71.29. The button enables you to cycle through the alternatives, displaying each one in turn. To see what forms are available, you can open the drop-down list and select the one you want or you can click the button until the form that you want is displayed.

Figure 71.29 Select a form Drop-Down List and Button



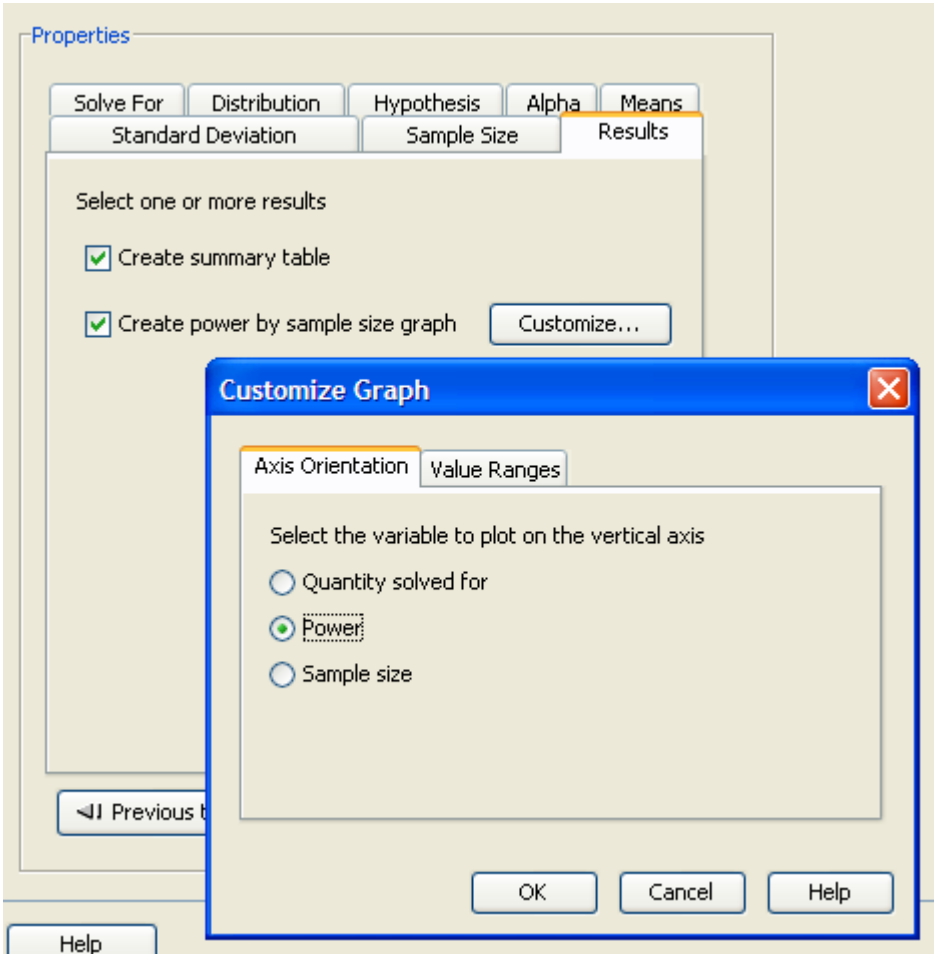
The alternate form last used for an analysis is saved and displayed as the default when a new instance of the analysis is opened.

Customizing Graphs

The Edit Properties page for all analyses contains a **Results** tab. You can choose to create a graph, and you can optionally choose to customize the graph by clicking the **Customize** button that is beside the **Create power and sample size graph** choice.

As shown in Figure 71.30, the Customize Graph window consists of an **Axis Orientation** tab and a **Value Ranges** tab. Use the **Axis Orientation** options to specify which axes you want used for power and for sample size. Use the **Value Ranges** settings to specify the axis range for the non-target quantity (that is, the power axis if you are solving for sample size or the sample size axis if you are solving for power).

Figure 71.30 Customize Graph Window



When specifying a value range, you can specify a minimum value and a maximum value. Also, you can select either the `Number of points` or the `Interval between points` choice for the axis and specify a value. All of these values are optional; specify only the ones you want.

Scenarios

A scenario is one instance of a complete set of values for an analysis. For example, if two alpha values and two total sample size values are specified with all other input parameters taking only a single value, there would be four scenarios—the four combinations of two alphas and two sample sizes.

Performing the Analysis

To perform the analysis, click **Calculate** at the lower right of the Edit Properties page. The input parameters are checked for validity, and the analysis is performed. The View Results page is then displayed.

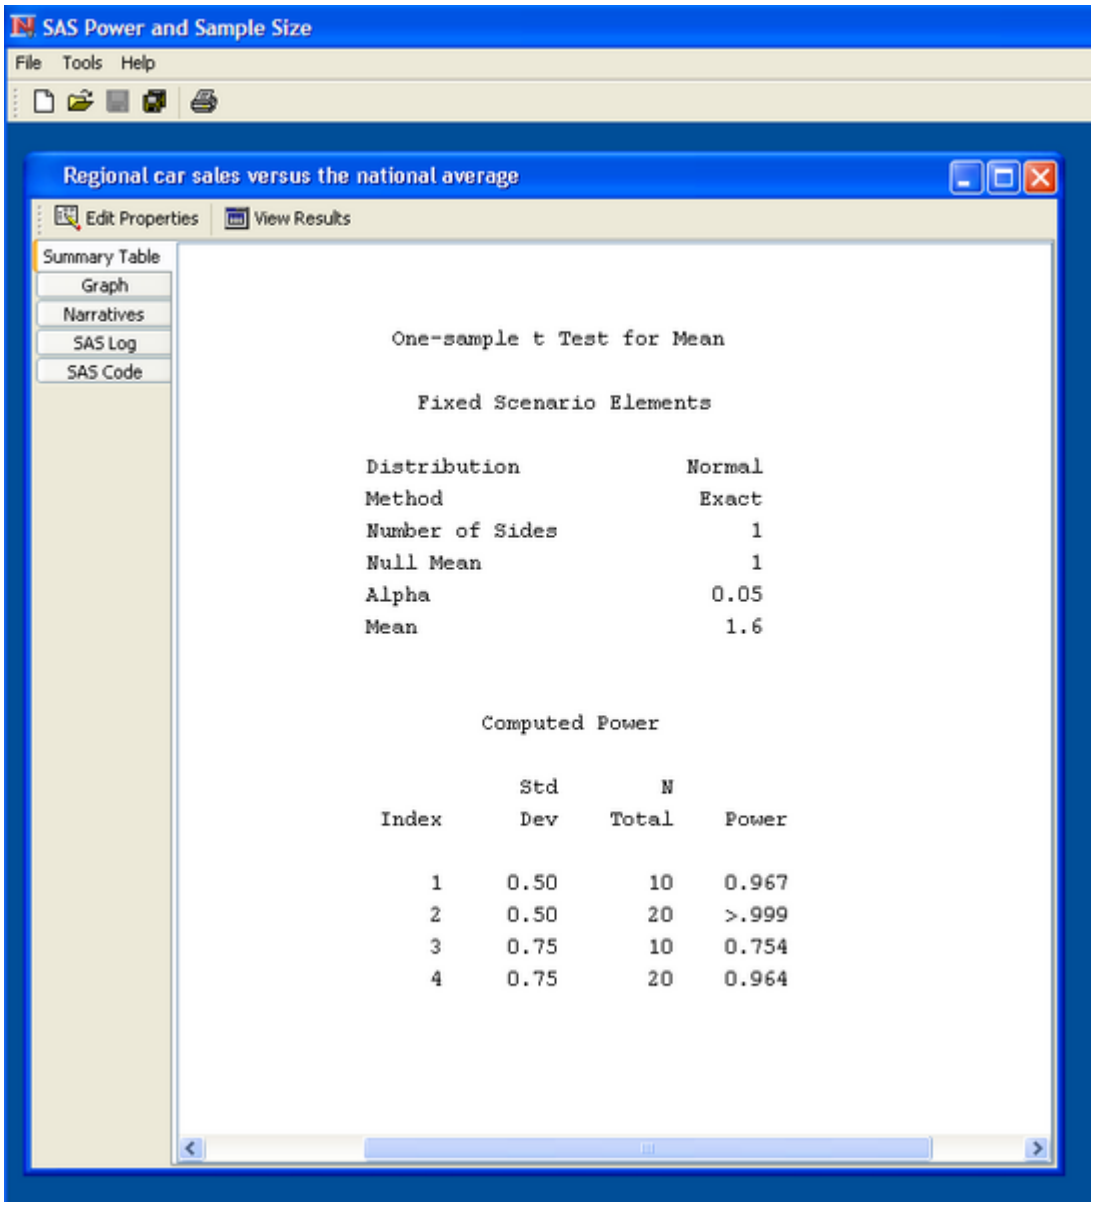
Viewing the Results

The results appear in separate tabs on the View Results Page. These tabs include **Summary Table**, **Graph**, **Narratives**, **SAS Log**, and **SAS Code**.

Viewing the Summary Table

Click the **Summary Table** tab to view the summary table. It consists of two subtables, as shown in Figure 71.31. The `Fixed Scenario Elements` table includes the options and parameter values that are constant for the analysis. The `Computed Power` table includes the calculated power or sample size values and the values for input parameters that have multiple values specified for the analysis.

Figure 71.31 View Results Page with Summary Table

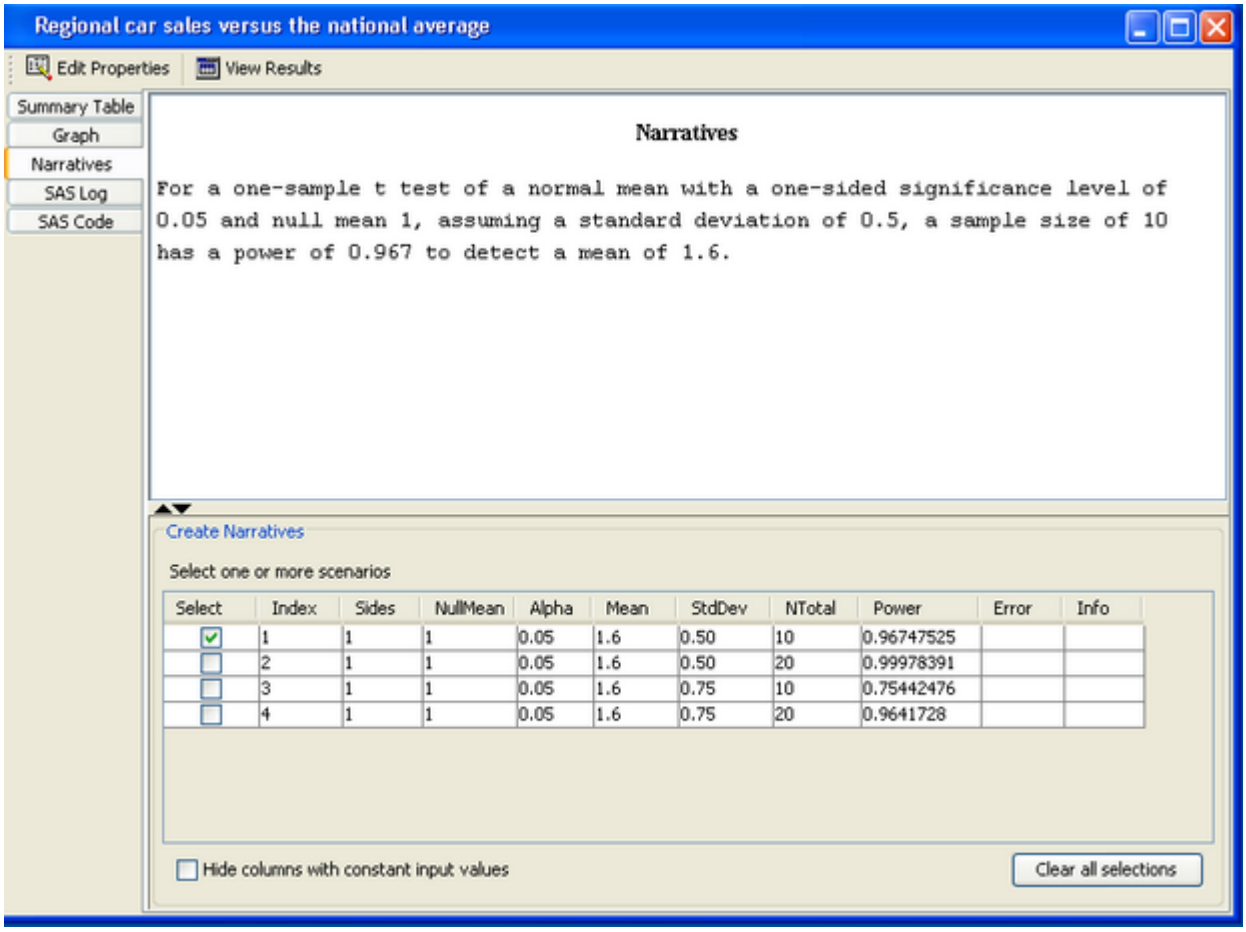


Creating Narratives

Click the **Narratives** tab to display a facility to create narratives. Narratives are descriptions of the input parameter values and calculated quantities in sentence or paragraph form. Each narrative corresponds to one calculated quantity value.

The **Narratives** tab is divided into a narrative selector panel and a narrative display panel. To create a narrative, select the row in the narrative selector panel that corresponds to it. You can select as many rows as you want. See Figure 71.32.

Figure 71.32 Narrative Selector and Display



The narrative selector table often contains columns whose values do not vary. For example, in Figure 71.32, the Sides, NullMean, Alpha, and Mean columns contain values that do not vary. You can hide these columns by selecting the **Hide columns with constant input values** check box.

Viewing the SAS Log and Code

Click the **SAS Code** tab to view the SAS statements that are used to generate the analysis results. Click the **SAS Log** tab to view the SAS log that corresponds to the analysis.

The SAS code differs slightly from the statements in the SAS log. Statements that are used to place the results in the location maintained by the application are not included. This is done to prevent you from overwriting the results stored by the application if you run the SAS code outside of the application.

Printing Results

To print one or more results, click the **Print** icon on the toolbar or select **File►Print** on the menu bar. The Select Results to Print window is displayed. You can choose to print one or more of the results by selecting the corresponding options here.

Saving the Project

To save a project, click the **Save** toolbar icon or select **File►Save** from the menu bar. Projects can be saved even if some of the information is invalid. Error checking is performed when the **Calculate** button is clicked.

Closing the Project

To close a project, click the **X** in the upper right corner of the project window or select **File►Close** from the menu bar.

Importing and Exporting Projects

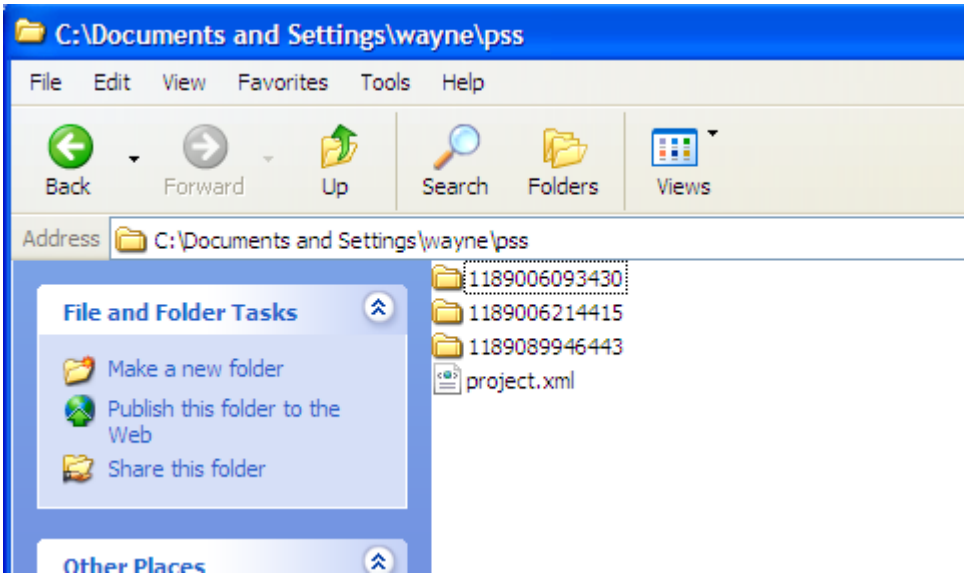
PSS projects can be imported from the same machine or a different machine. Also, the active project (the project that is open and on top of any other open projects) can be exported.

Importing Projects

A PSS project that was created on another machine or by another user can be imported and used. Also, importing projects is the recommended way of moving existing PSS projects that were created with PSS release 2.0 (a Web application) to PSS release 3.1 (a desktop application).

PSS files are stored in a folder entitled *pss*. The *pss* folder contains a *project.xml* file and individual folders for each project. See Figure 71.33.

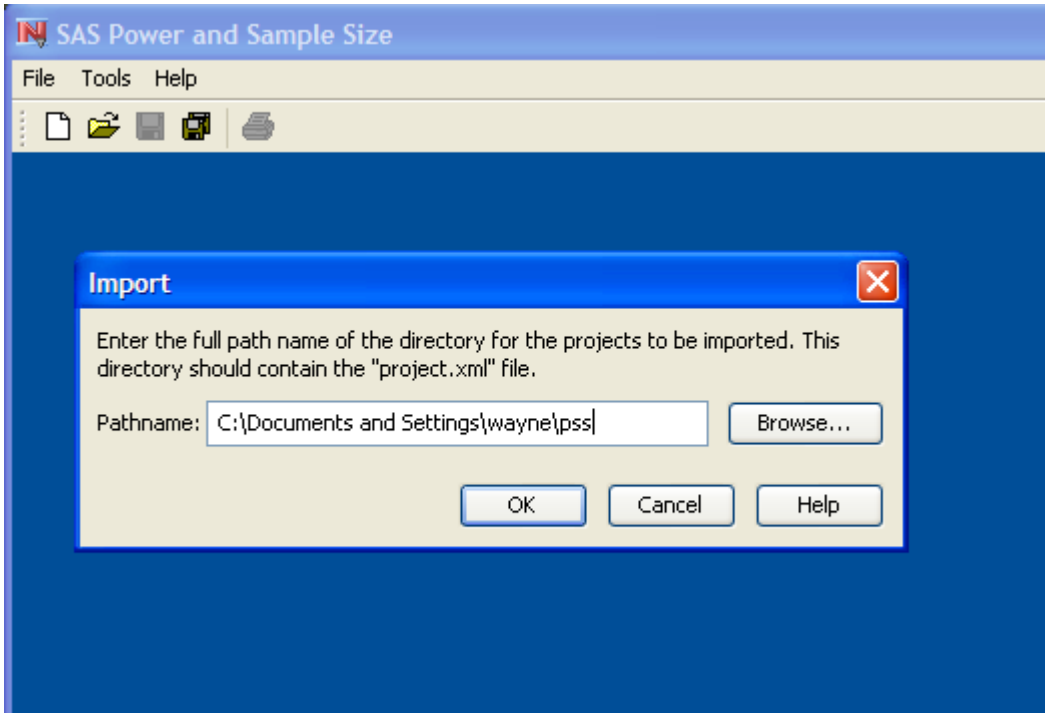
Figure 71.33 PSS Directory Structure



If PSS files are on another machine, they must first be copied to a temporary location on the desktop machine that is running PSS. The entire *pss* folder should be copied.

To import projects, select **File►Import** from the menu bar. Then, specify the full pathname of the *pss* folder.

Figure 71.34 Import Projects Window



To import PSS 2.0 files, you need to find the *pss* folder. The easiest way to do this is to search for the *project.xml* file. If you find several files with this name, you need to decide which one or more to import.

Exporting the Active Project

If you want to send a PSS project to someone, you can export the active project. The active project is the one that is open and that has focus (is displayed on top of any other open projects). Select **File►Export active project** and specify a temporary directory to hold the exported project.

The recipient must import the project using PSS.

Details: PSS Application

Software Requirements

PSS is available in SAS 9.2 for the following platforms: Microsoft Windows XP and Vista.

Two configurations are available for SAS connections: local and remote. With the local configuration, PSS and SAS 9.2 must reside on the same machine. With the remote configuration, PSS and SAS 9.2 can reside on different machines. SAS connections are defined and selected on the **SAS Connection** tab on the Preferences window. More information about SAS connections is found in the section "SAS Connections" on page 5984.

For both configurations, Base SAS and SAS/STAT software must be installed and SAS/GRAPH software is recommended.

For the remote configuration, SAS/CONNECT and SAS/IntrNet software must also be installed. For more information about configuring the remote SAS server, click **Help►Contents** on the menu bar and then click **Configuring a Remote SAS Server** under **Special Topics** in the table of contents.

Installation

SAS Power and Sample Size is installed separately from the SAS/STAT product. Contact your SAS site representative to have the application installed.

SAS Power and Sample Size is installed using the SAS Software Deployment Wizard. It is listed as an available product with, but separate from, Foundation SAS which contains the SAS/STAT and SAS/GRAPH products that are required for using the application.

Configuration

When you first run SAS Power and Sample Size 3.1 (PSS), you are asked to provide configuration information.

First, you are asked for the name of a directory to contain the your power and sample size projects. A folder named *pss* is created in the specified directory, and projects are stored in the *pss* folder. This directory cannot be the same as the one used by PSS 2.0. If it is, PSS requires that another folder name be provided.

Then, if the appropriate release of the SAS System is available on the desktop machine, you are asked whether a connection should be automatically created to it. If you respond No, then PSS informs you that a connection to the SAS server is necessary and asks if you want to select one now or later. A connection to a SAS server is not necessary to use the application until the **Calculate** button on the Edit Properties page of a project is clicked. More information about connections is available in the section "Setting Preferences" on page 5988.

Then, PSS displays a wizard to help you import existing PSS projects from either a previous release (PSS 2.0) or the current one (PSS 3.1). More information is available in the section "Importing Projects" on page 5999.

Example: Two-Sample *t* Test

Overview

The one-sample *t* test compares the mean of a sample to a given value. The two-sample *t* test compares the means of two samples. The paired *t* test compares the mean of the differences in the observations to a given number. PSS provides power and sample size computations for all of these types of *t* tests. For more information about power and sample size analysis for *t* tests, see Chapter 70, "The POWER Procedure."

The two-sample *t* test tests for differences or ratios between means for two groups. The groups are assumed to be independent. This example describes three examples using the two-sample *t* test: for equal variances, for unequal variances, and for mean ratios.

Test of Two Independent Means for Equal Variances

Suppose you are interested in testing whether an experimental drug produces a lower systolic blood pressure than a placebo does. Will 25 subjects per treatment group yield a satisfactory power for this test? From previous work, you expect that the blood pressure is 132 for the control group and 120 for the drug treatment group and that the standard deviation is 15 for both groups. You want to use a one-sided test with a signifi-

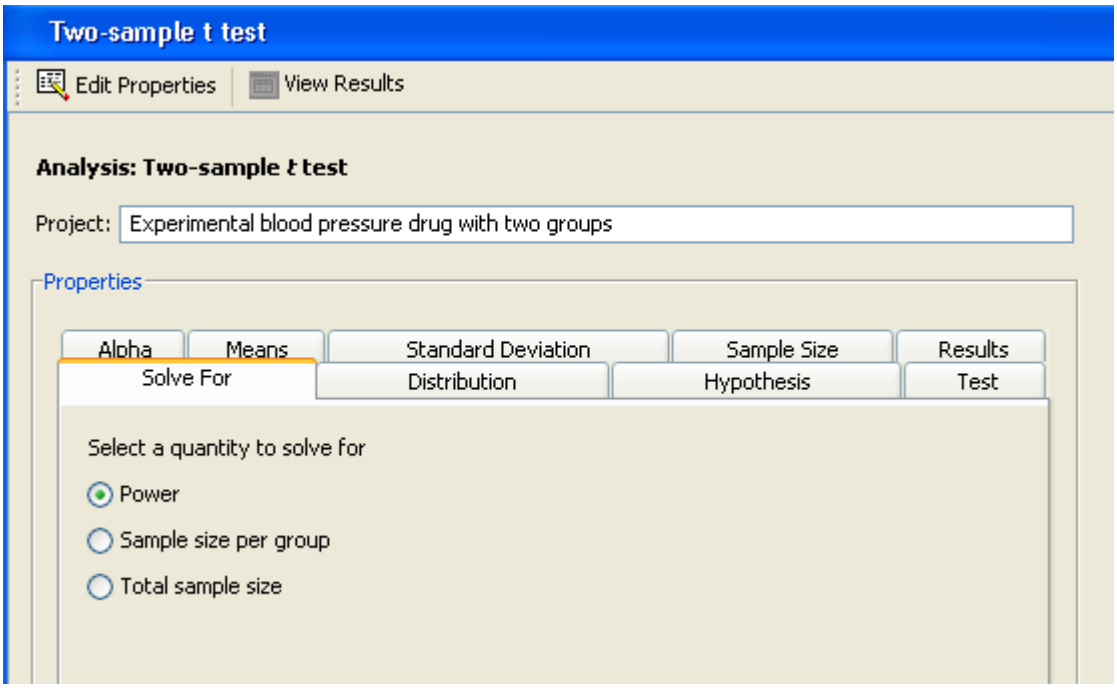
cance level of 0.05. Because there are two independent groups and you are assuming that blood pressure is normally distributed, the two-sample *t* test is an appropriate analysis.

Start by creating a new project. Select **File►New**. In the New window, select **Two-sample *t* test** from the list. The Two-Sample *t* test project window appears, with the Edit Properties page displayed.

Editing Properties

On this page enter a name to describe the project and enter project properties. Click each tab on the Edit Properties page to enter the desired properties. You can also change tabs by clicking the **Next tab** or **Previous tab** buttons. See Figure 71.3.

Figure 71.35 Two-Sample *t* Test



Project Description

The description is used to identify this particular project in the Open and Delete windows. Type a description for your project in the **Project:** text box.

For this example, change the description to `Experimental blood pressure drug with two groups`, as shown in Figure 71.35.

Solve For

For the two-sample *t* test analysis, you can choose to solve for power, sample size per group, or total sample size. Specify the desired quantity type on the **Solve For** tab.

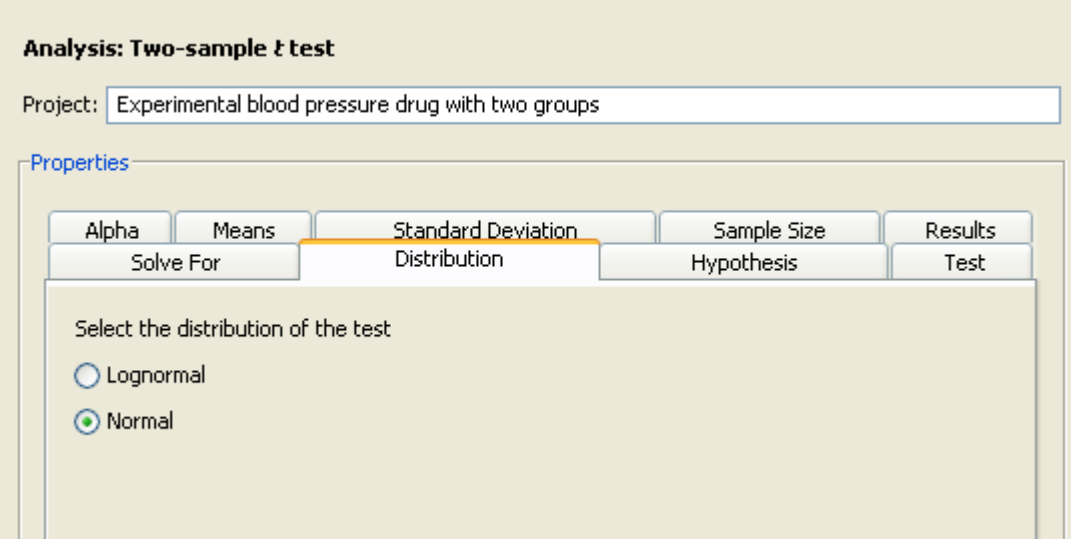
Click the **Solve For** tab and select the **Power** option as shown in Figure 71.35. For information about

solving for sample size, see the section "Solving for Sample Size" on page 6023.

Distribution

Click the **Distribution** tab to select a distribution option that specifies the underlying distribution for the test statistic, as shown in Figure 71.36.

Figure 71.36 Distribution Tab

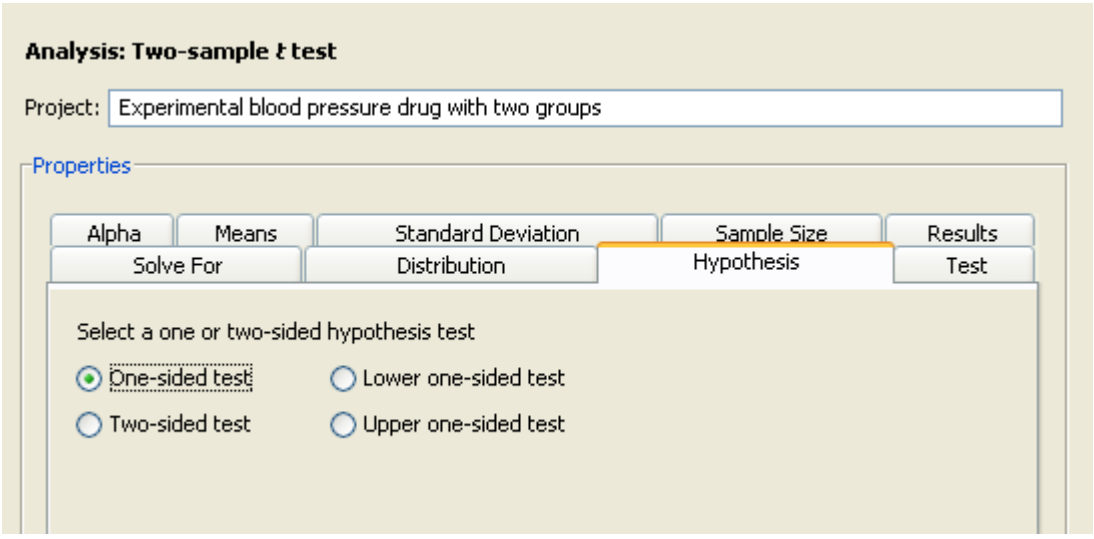


For this example, you are interested in means rather than mean ratios, so select the **Normal** option.

Hypothesis

Click the **Hypothesis** tab to select the type of test; see Figure 71.37.

Figure 71.37 Hypothesis Tab



You can choose either a one- or two-sided test. If you do not know the direction of the effect (that is, whether it is positive or negative), the two-sided test is appropriate. If you know the effect's direction, the one-sided test is appropriate. For the one-sided test, the alternative hypothesis is assumed to be in the same direction as the effect. If you specify a one-sided test and the effect is in the unexpected direction, the results of the analysis are invalid.

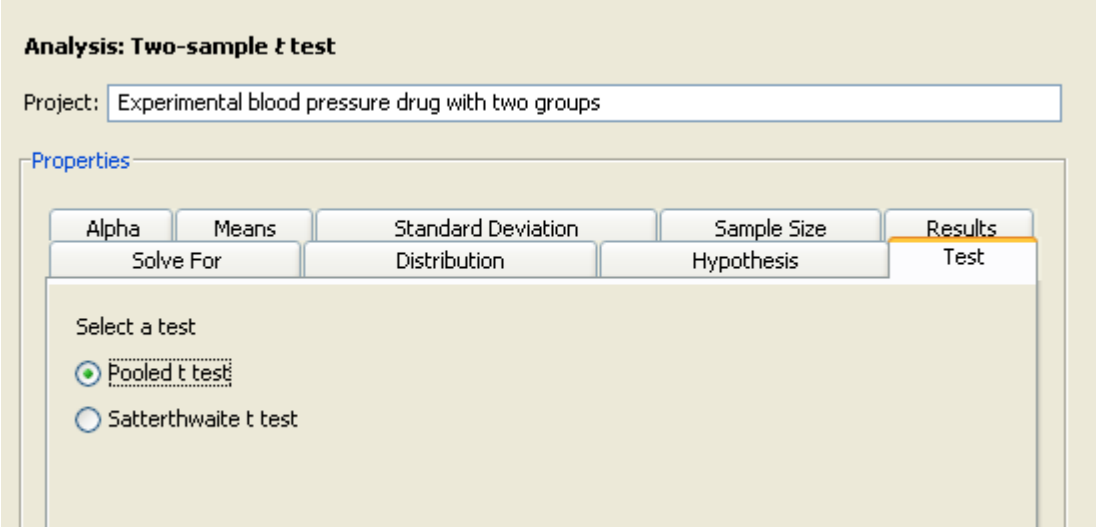
The **One-sided test** option assumes that you know the correct direction of the test. Select the **Lower one-sided test** and **Upper one-sided test** options to explicitly indicate the direction of the one-sided test.

Because you are interested only in whether the experimental drug lowers blood pressure, select the **One-sided test** option on the **Hypothesis** tab.

Test

Click the **Test** tab to select either the pooled *t* test or the Satterthwaite *t* test.

Figure 71.38 Test Tab

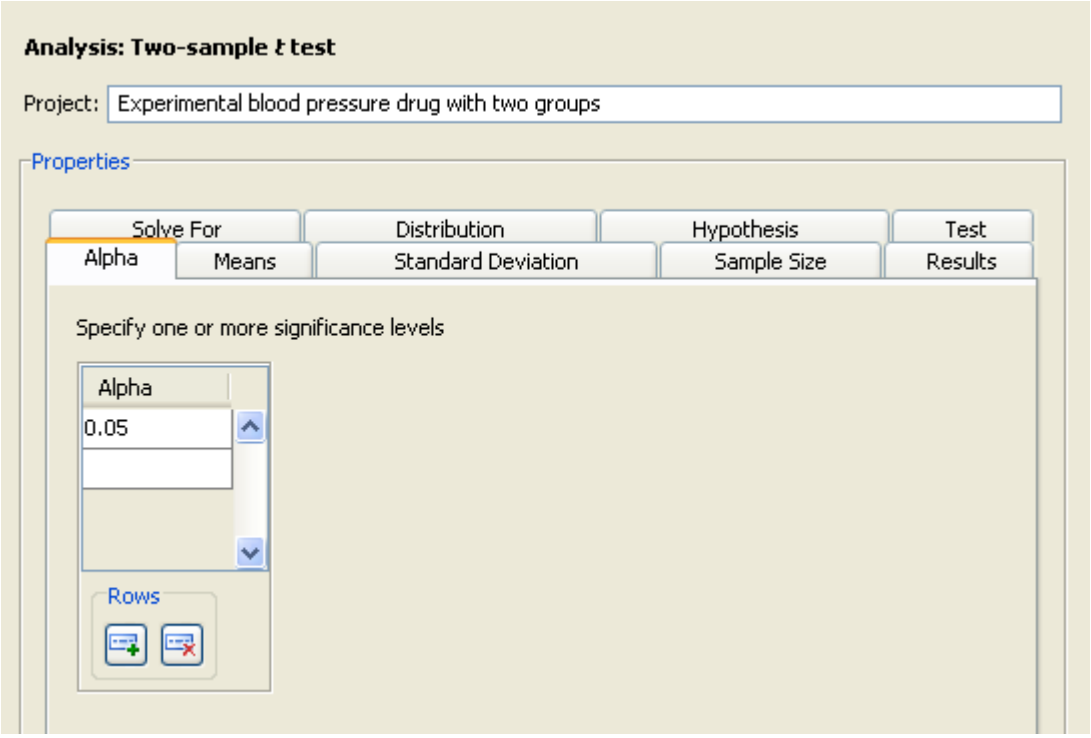


With the independent variances that the example uses, select **Pooled *t* test** option. The Satterthwaite *t* test is used with unequal variances; it is available only with the normal distribution.

Alpha

Click the **Alpha** tab to specify one or more significance levels, as shown in Figure 71.39.

Figure 71.39 Alpha Tab



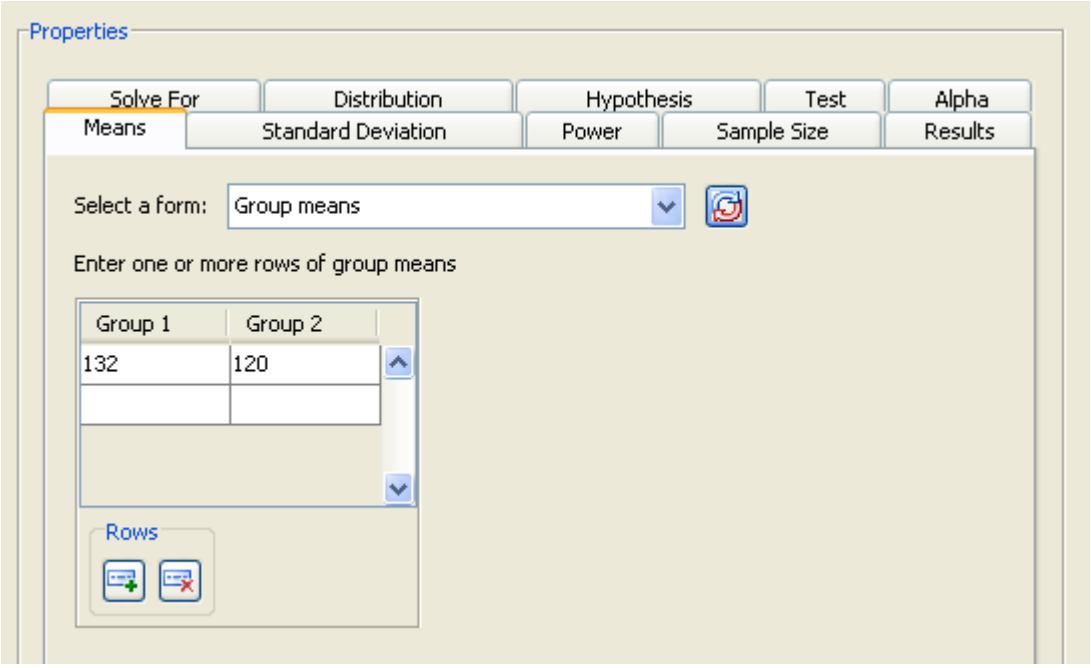
Alpha is the significance level (that is, the probability of falsely rejecting the null hypothesis). If you frequently use the same values for alpha, set them as defaults in the Preferences window. See the section "Setting Preferences" on page 5988 for more information about setting preferences.

Type the desired significance level of 0.05 in the first cell of the Alpha table (if it is not already the default value).

Means

Click the **Means** tab to select one of four possible ways to enter the means and the null mean difference, as shown in Figure 71.40.

Figure 71.40 Means Tab



Select one of the following forms from the **Select A Form** list. The four available forms are:

Difference between means
: Enter the difference between the group means. The null mean difference is assumed to be 0.

Group means
: Enter the means for each group. The null mean difference is assumed to be 0. The difference is formed by subtracting the mean for group 1 from the mean for group 2.

Difference between means, Null difference
: Enter the difference between the group means and a null mean difference.

Group means, Null difference
: Enter the means for each group and a null mean difference. The difference is formed by subtracting the mean for group 1 from the mean for group 2.

For this analysis, you can enter the means for the two groups either individually or as a difference. If your null mean difference is not zero, enter that value in the Null Mean table. (The Null Mean table is displayed only for the **Group means, Null Difference** and **Difference between means, Null difference** forms.)

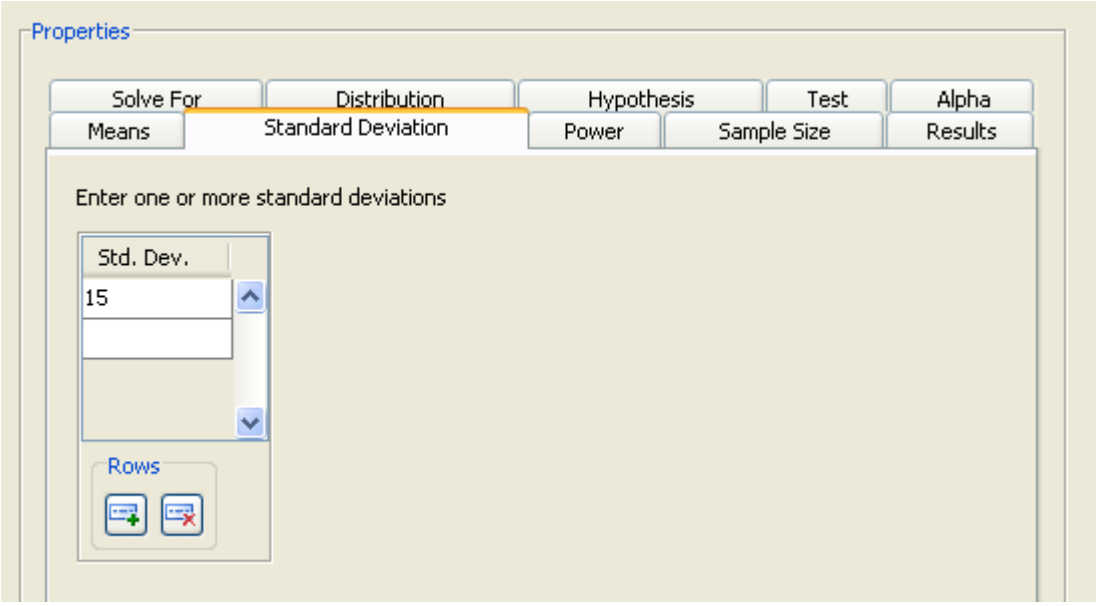
For this example, a null mean difference of 0 is reasonable, so select the **Group means** form from the list, as shown in Figure 71.40. Enter the control mean of `132` in the first row of the first column and the experimental mean of `120` in the first row of the second column.

Standard Deviation

Click the **Standard Deviation** tab to enter the standard deviation for the two groups. It is assumed to be equal for both groups.

For the example, enter a single value of 15, as shown in Figure 71.41.

Figure 71.41 Standard Deviation Tab



Sample Size

Click the **Sample Size** tab to select one of three possible ways to enter the sample sizes, as shown in Figure 71.40.

Select one of the following forms from the **Select A Form** list:

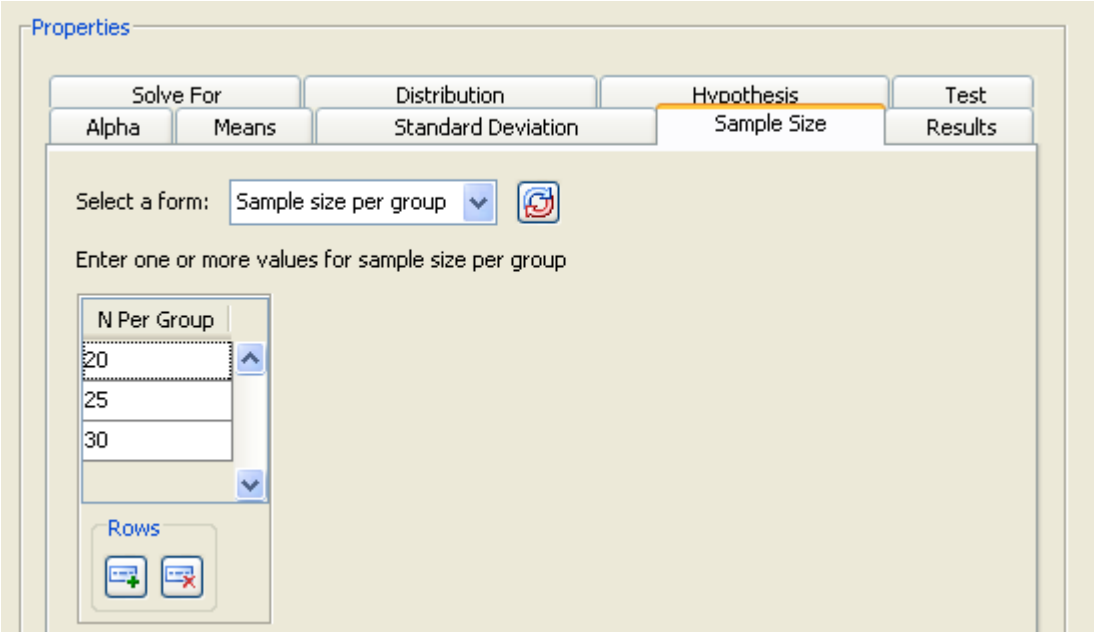
Sample size per group
: Enter the sample size for one of the two groups. The group sizes are assumed to be equal.

Group sample sizes
: Enter the sample size for each of the two groups. The group sizes can be equal or unequal.

Total N, Group weights
: Enter the total sample size for the two groups and the relative sample sizes for each group. For more information about using relative sample sizes, see the section "Using Unequal Group Sizes" on page 6024.

Examine the alternatives by clicking the **Select a form** down arrow. For this example, select the **Sample size per group** form. You want to examine a curve of powers in the power by sample size graph, so enter the values 20, 25, and 30 in the Sample Size table, as shown in Figure 71.42. If you need to add more rows to the table, add them by clicking the button beneath the table.

Figure 71.42 Sample Size Tab



Summary of Properties

Table 71.2 contains the values of the input parameters for the example.

Table 71.2 Summary of Input Properties

Parameter	Value
Solve for	Power
Distribution	Normal
Hypothesis	One-sided test
Test	Pooled t test
Alpha	0.05
Means form	Group means
Means	132, 120
Standard deviation	15
Sample size form	Sample size per group
Sample size	20, 25, 30

Results

Click the **Results** tab to request desired results. Summary table and power by sample size graph options are available.

For the example, select the **Create summary table** and **Create power by sample size graph** check boxes.

Click **Calculate** to perform the analysis. If there are no errors in the input values, the View Results page appears. If there are errors in the input parameter values, you are prompted to correct them.

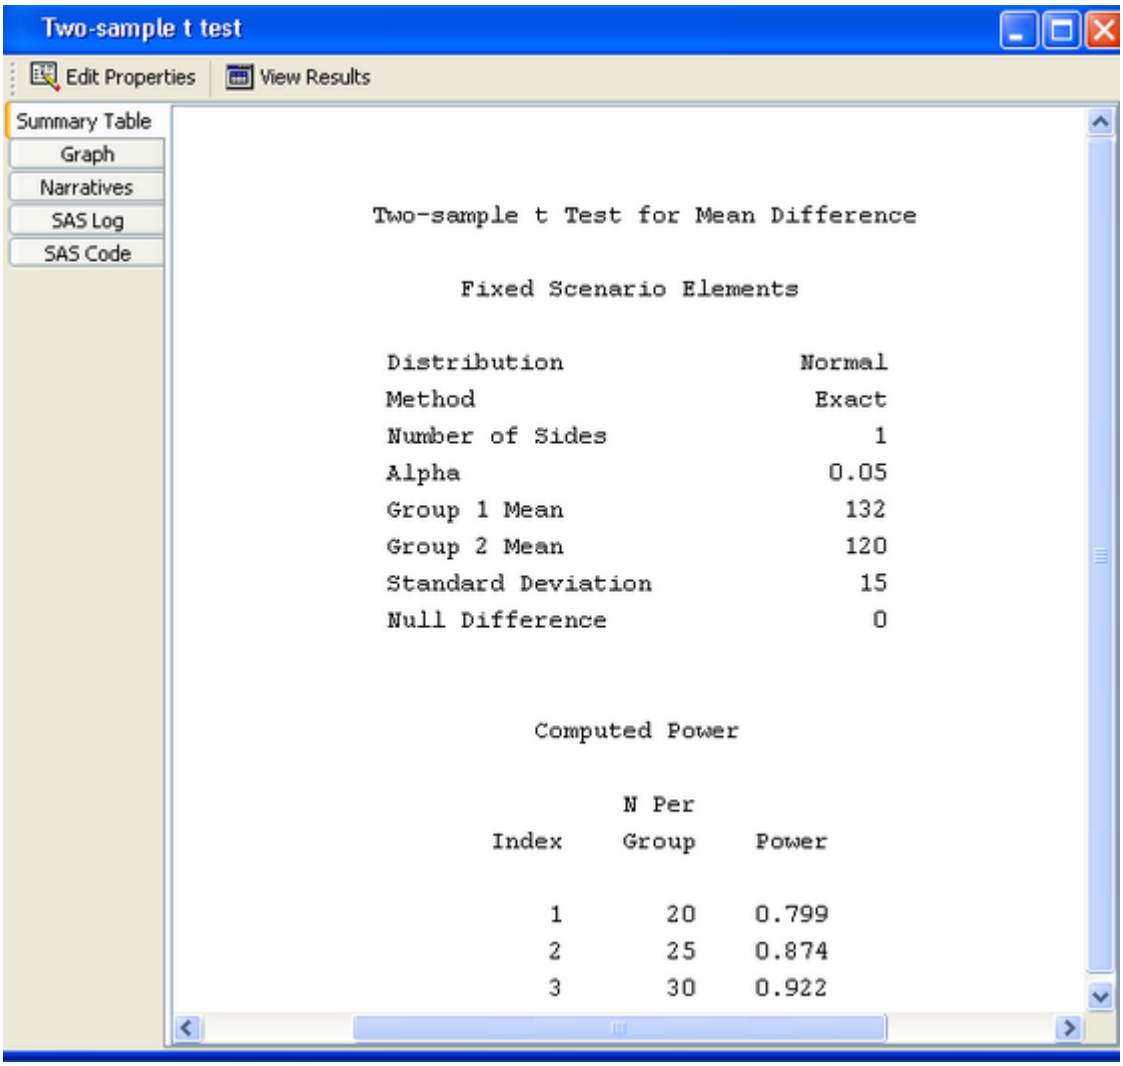
Viewing Results

The results are listed on separate tabs on the View Results page. Click the tab of each result that you want to view.

Summary Table

Click the **Summary Table** tab to view a table that includes the values of the input parameters and the computed quantity (in this example, power). See Figure 71.43.

Figure 71.43 Results Page with Summary Table



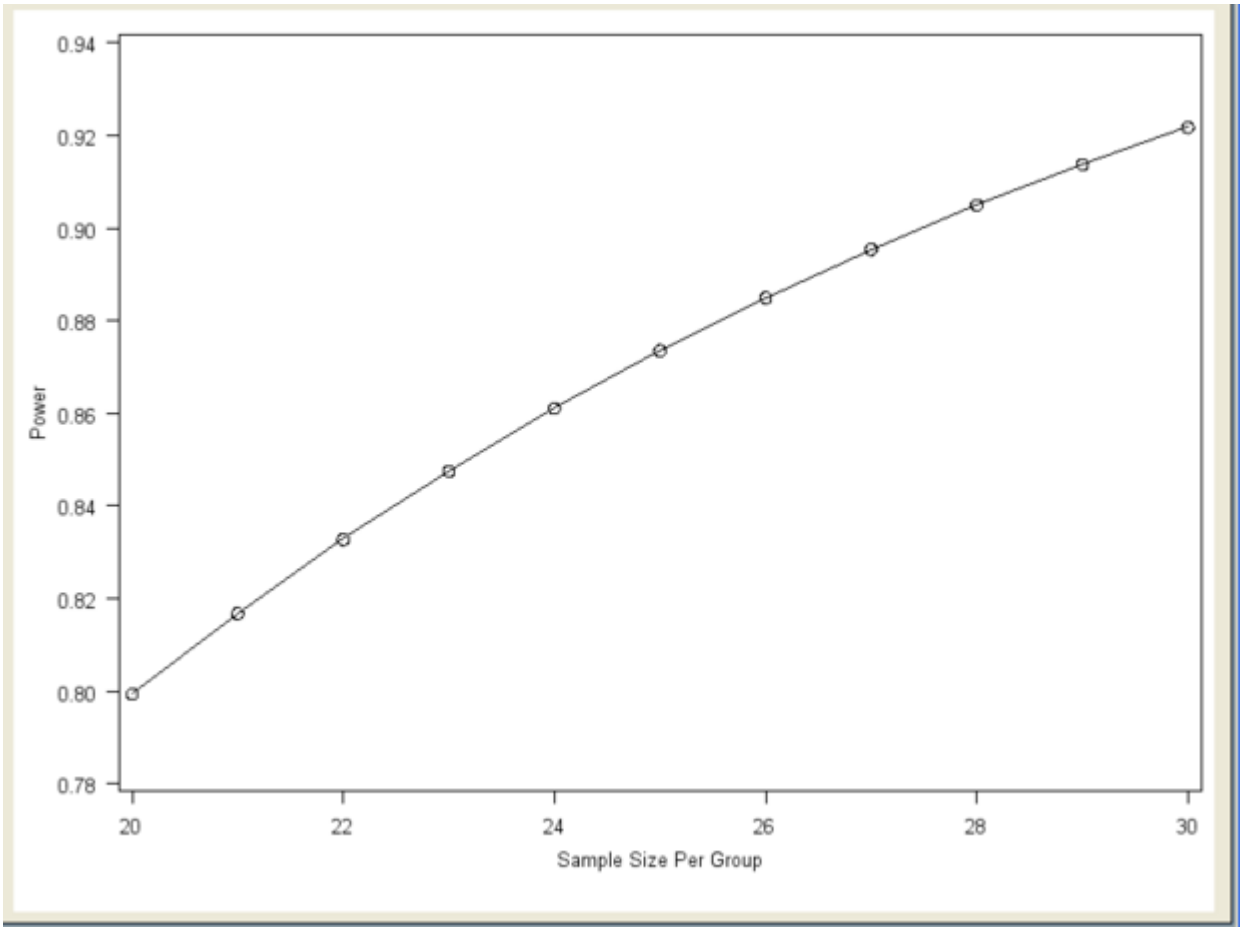
The table consists of two subtables: the `Fixed Scenario Elements` table that contains the input param-

eters that have only one value for the analysis, and the `Computed Power` table that contains the input parameters that have more than one value for the analysis and the corresponding power. Only the N per group parameter appears in the `Computed Power` table; all of the other input parameters have a single value. The computed power for a sample size per group of 25 is 0.874. Thus, you have a probability of 0.87 that the study will find the expected result if the assumptions and conjectured values are correct.

Power by Sample Size Graph

Click the **Graph** tab to view a power by sample size graph that displays power on the vertical axis and sample size per group on the horizontal axis. See Figure 71.44.

Figure 71.44 Power by Sample Size Graph

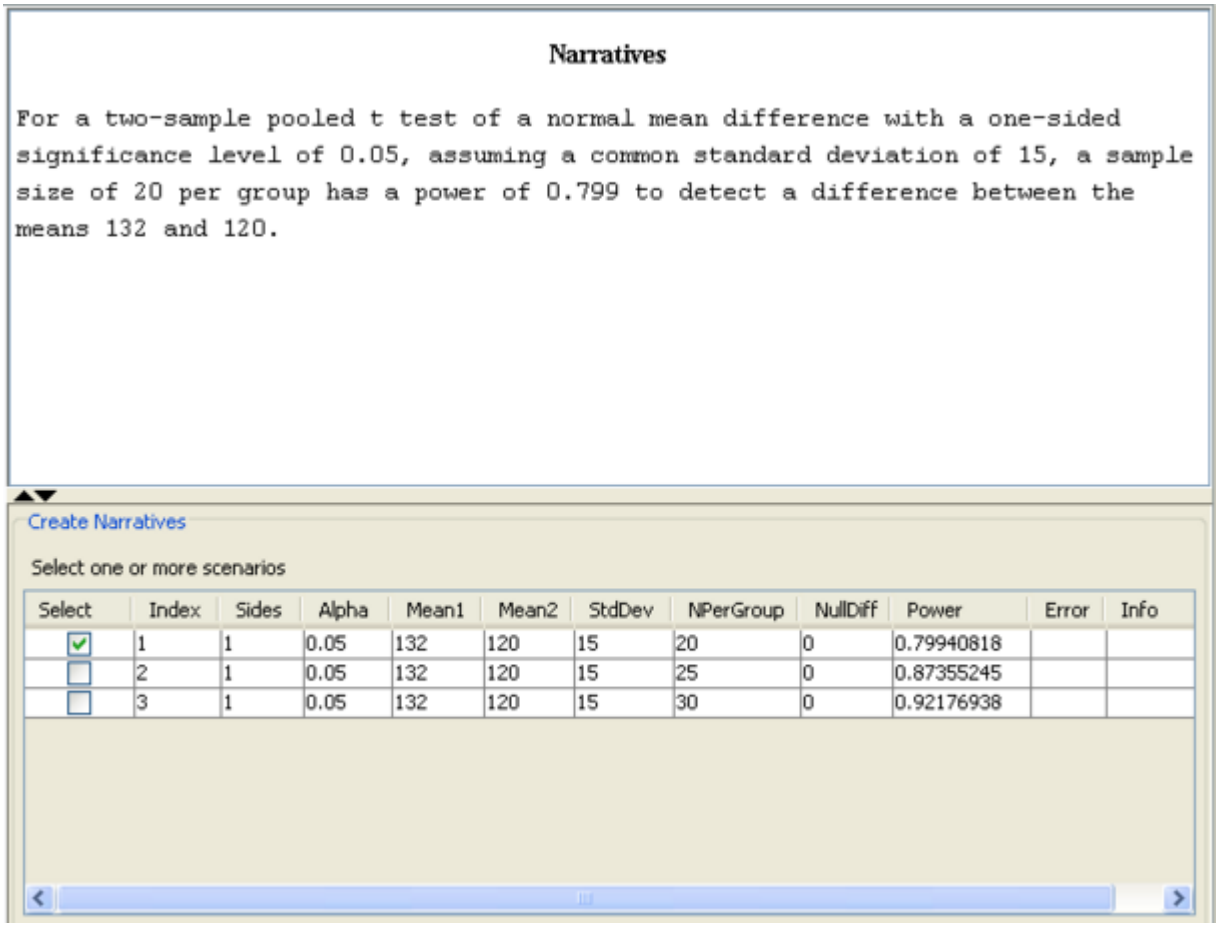


The range of values for the horizontal axis is 20 to 30, which were the smallest and largest values, respectively, that you entered on the **Sample Size** tab. You can customize the graph by specifying the values for the sample size axis (see the section "Customizing Graphs" on page 5995).

Narratives

Click the **Narratives** tab to create and display a sentence- or paragraph-length text summary of the input parameter values and the computed quantity for combinations of the input parameter values; see Figure 71.45.

Figure 71.45 Narrative Selector and Display



To create a narrative, selected the desired scenario (row) in the narrative selector table at the bottom of the **Narratives** tab.

In this example, select the narrative for the sample size per group of 20, which yields a power of 0.799. The following text summary is displayed:

```
For a two-sample pooled t test of a normal mean difference with a one-sided
significance level of 0.05, assuming a common standard deviation of
15, a sample size of 20 per group has a power of 0.799 to detect a
difference between the means 132 and 120.
```

To create other narratives, select the desired rows in the narrative selector table. If you also select the second row for the sample size of 25, another text summary is displayed below the first one:

```
For a two-sample pooled t test of a normal mean difference with a one-sided
significance level of 0.05, assuming a common standard deviation of
15, a sample size of 20 per group has a power of 0.799 to detect a
difference between the means 132 and 120.
```

```
For a two-sample pooled t test of a normal mean difference with a one-sided
significance level of 0.05, assuming a common standard deviation of
15, a sample size of 25 per group has a power of 0.874 to detect a
difference between the means 132 and 120.
```

To change some values of the analysis and rerun it, select the Edit Properties page, change the desired properties, and click the **Calculate** button again.

Test of Two Independent Means for Unequal Variances

In the preceding example, you assumed that the population standard deviations were equal. If you believe that the population standard deviations are not equal, use the same two-sample *t* test analysis as with the preceding example, but change the test option and enter group standard deviations.

You can use the previous example to demonstrate this test. If the project is not already open, open it by selecting **File►Open** on the menu bar, and then selecting the project that you have been using.

Make a copy of the project by selecting **File►Save As**. Enter a different project description, `Experimental blood pressure drug with two groups for unequal variances`. Click **OK**.

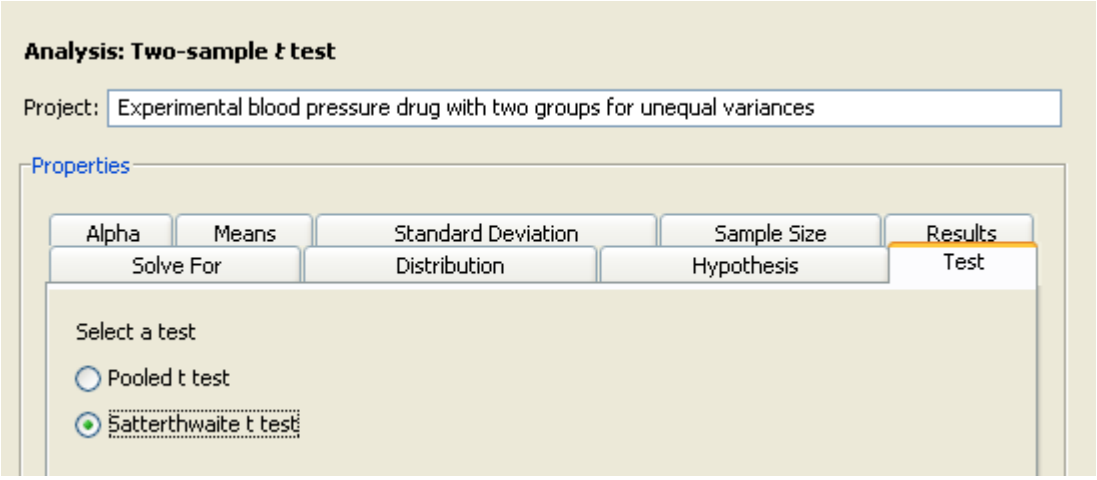
The copy of the project is opened, and the current project is closed.

Editing Properties

Test

On the **Test** tab of the copied project, change the test to **Satterthwaite t test**, as shown in Figure 71.46.

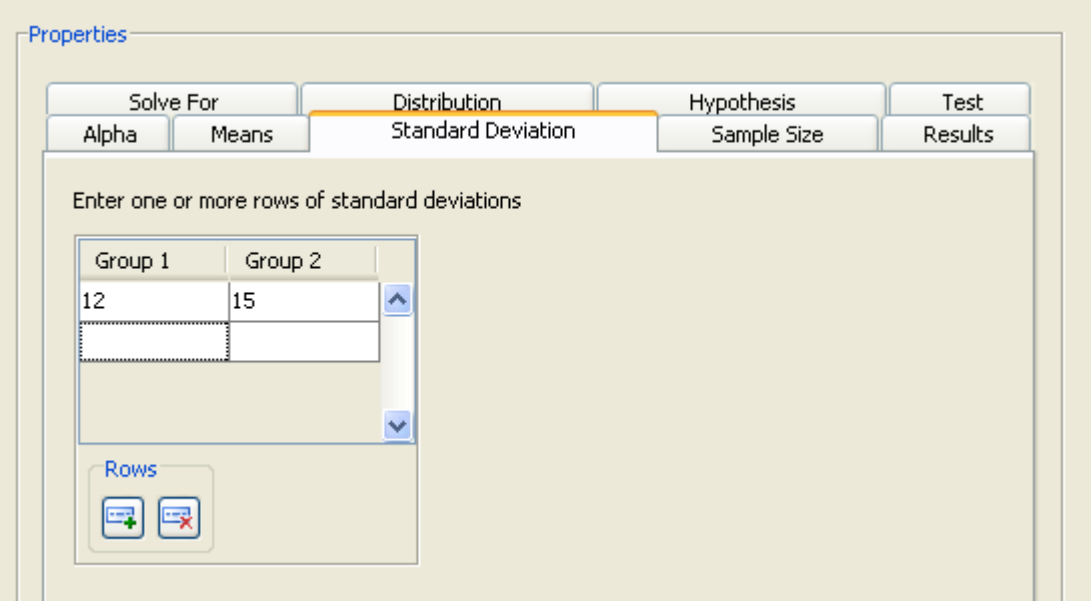
Figure 71.46 Satterthwaite *t* Test Option



Specifying Group Standard Deviations

Click the **Standard Deviation** tab and enter the group standard deviations of 12 and 15 on a single row, as shown in Figure 71.47.

Figure 71.47 Group Standard Deviations



Summary of Input Parameters

Table 71.3 contains the values of the input parameters for the example.

Table 71.3 Summary of Input Parameters

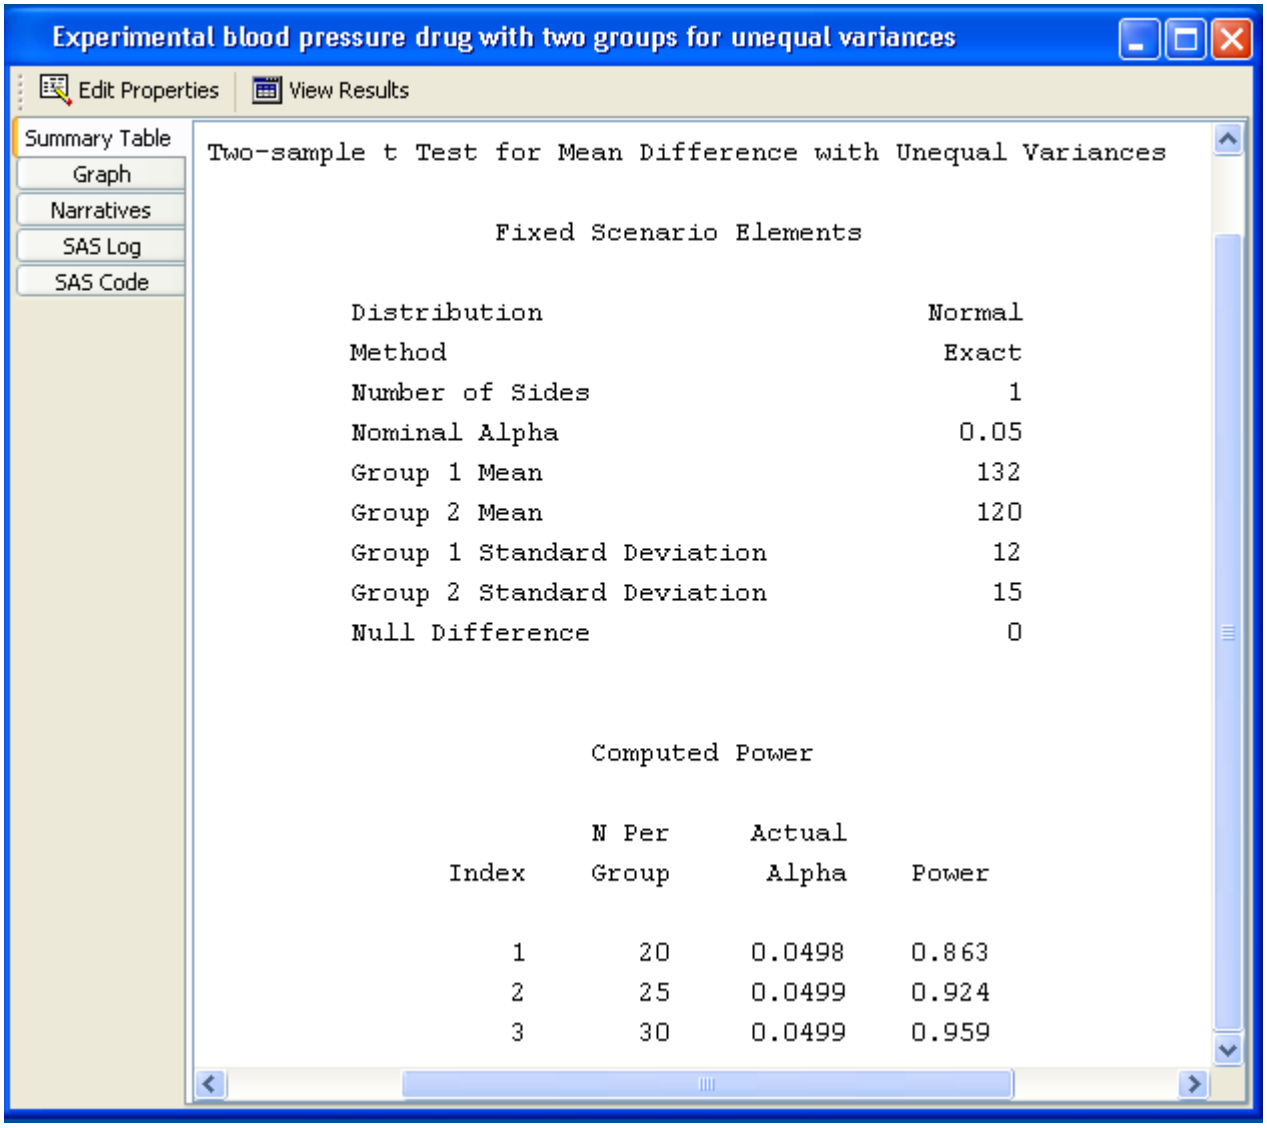
Parameter	Value
Distribution	Normal
Hypothesis	One-sided test
Test	Satterthwaite t test
Alpha	0.05
Means form	Group means
Means	132, 120
Standard deviation	12, 15
Sample size form	Sample size per group
Sample size	20, 25, 30

Click **Calculate** to run the analysis.

Viewing Results

The power for a sample size per group of 25 is 0.924, as shown in Figure 71.48. Notice that the actual alpha is 0.0499. This is because the Satterthwaite *t* test is (slightly) biased.

Figure 71.48 Satterthwaite Test Results



If you modified the previous example, when you select the **Narratives** tab, the following message is displayed:

```
Previously selected narratives have been cleared because one or more input
parameter values have changed.
```

In the previous analysis, you created narratives for two scenarios. Because this analysis uses group standard deviations, those selected narratives were cleared. The message would also have appeared if you had changed the number of scenarios.

Use the narrative selector table to create other narratives.

Test of Mean Ratios

Instead of comparing means for a control and drug treatment group, you might want to investigate whether the blood pressure of the treatment group is lowered by a given percentage of the control group, say 10 percent. That is, you expect the ratio of the treatment group to the control group to be 90% or less.

PSS provides a two-sample *t* test of a mean ratio when the data are lognormally distributed.

For mean ratios, the coefficient of variation (CV) is used instead of standard deviation. In this example, you can expect the CV to be between 0.5 and 0.6. You also want to compare an equally weighted sampling of groups with an overweighted sampling in which the control group contains twice as many subjects as the treatment group: 50 and 25, respectively.

Make a copy of the project by selecting **File►Save As**. Enter a different project description, `Percent improvement with blood pressure drug`.

The copy of the project is opened.

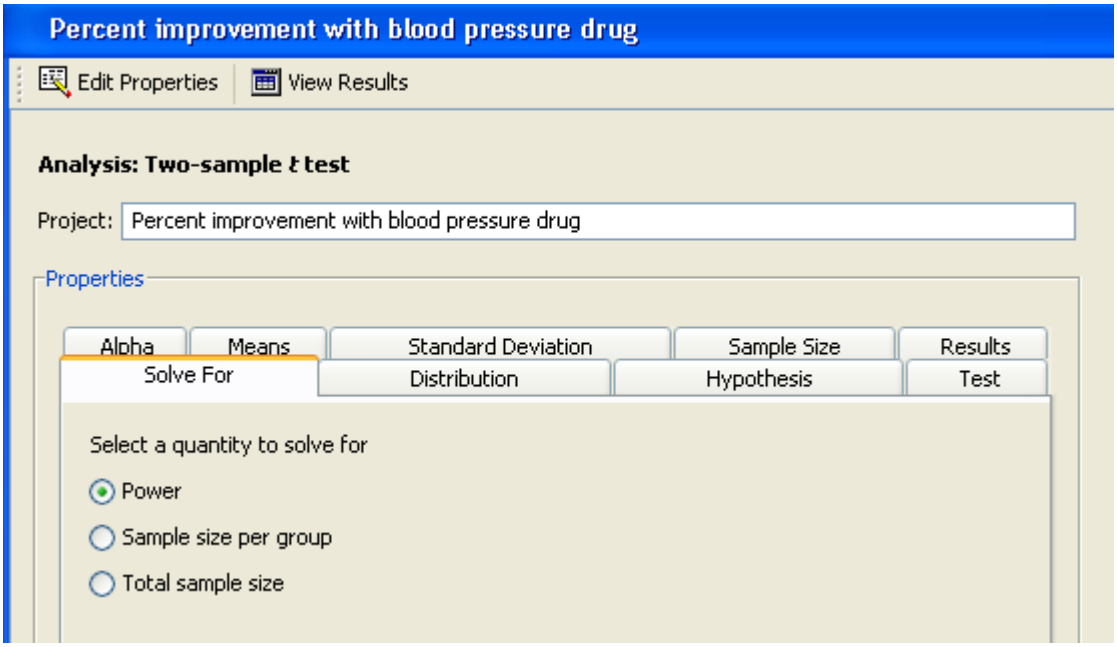
Editing Properties

Several of the input parameters for the test of mean ratios differ from the ones described in the section "Test of Two Independent Means for Equal Variances" on page 6002. Mean ratios and coefficients of variation are used instead of mean differences and standard deviations. These two parameters are discussed in detail in this section. For the input parameters and options that have been discussed previously in this example, only the values for this example are given.

Solve For Tab

Click the **Solve For** tab to select the **Power** option as the quantity to be solved for, as shown in Figure 71.49.

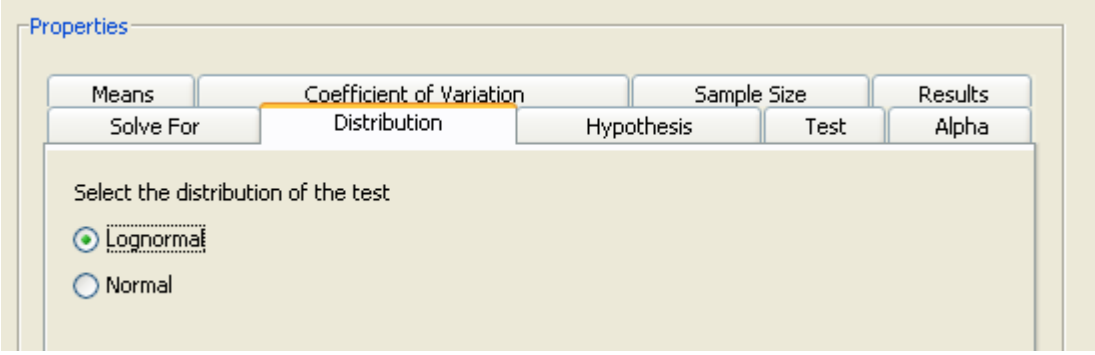
Figure 71.49 Project Description, Solve for Tab



Distribution

You are interested in mean ratios rather than means, so select the **Lognormal** option on the **Distribution** tab, as shown in Figure 71.50.

Figure 71.50 Distribution Tab with Lognormal Option



Hypothesis and Alpha

Click the **Hypothesis** tab and select the **One-sided test** option.

Click the **Alpha** tab and type 0.05 as the significance level in the first cell of the table, if it is not already there.

Means

Click the **Means** tab to select the input form for entering mean ratios. There are four alternate forms for entering means or mean ratios:

Mean ratio
: Enter the ratio of the two group means—that is, the treatment mean divided by the reference mean. The null ratio is assumed to be 1.

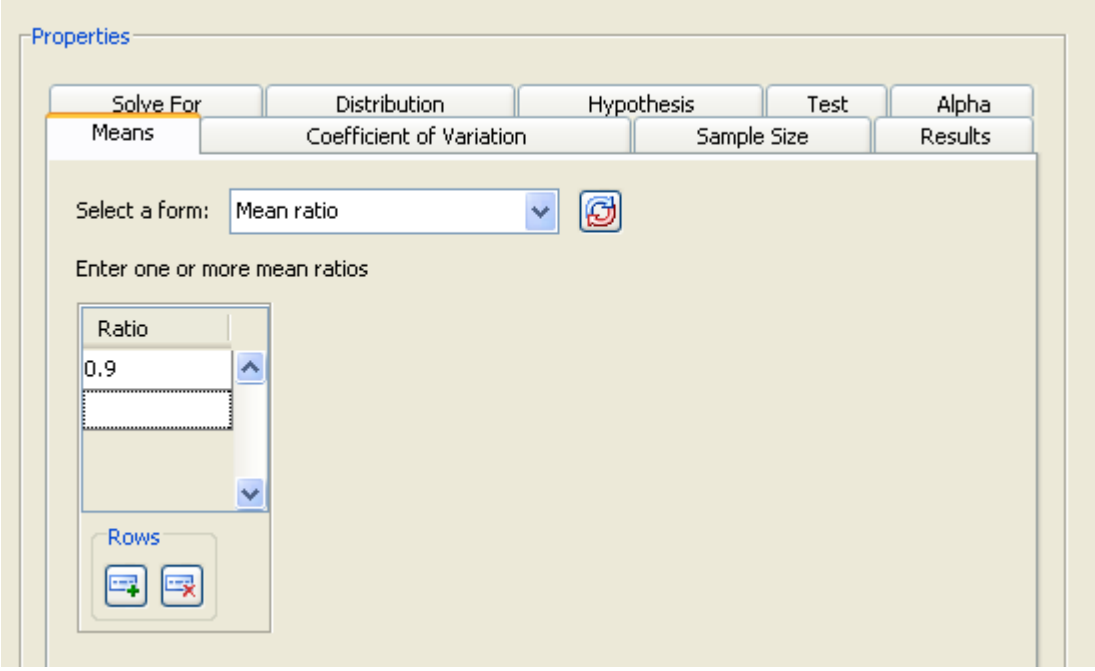
Group means
: Enter the means for each group. The ratio of the means is formed by dividing the mean for group 2 by the mean for group 1. The null ratio is assumed to be 1.

Mean ratio, Null ratio
: Enter the ratio of the two group means—that is, the treatment mean divided by the reference mean. Enter the null ratio.

Group means, Null ratio
: Enter the means for each group. The ratio of the means is formed by dividing the mean for group 2 by the mean for group 1. Enter the null ratio.

As shown in Figure 71.51, select the **Mean ratio** form which uses a default null ratio of 1. Enter a single mean ratio value of 0.9.

Figure 71.51 Means Tab with Mean Ration Form and Values

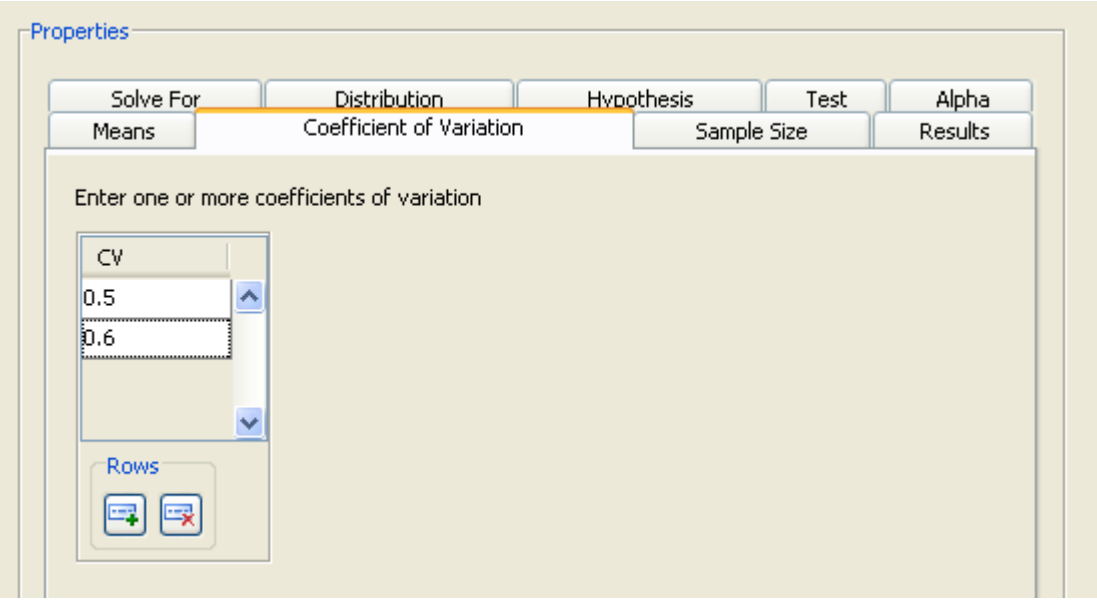


Coefficient of Variation

On the **Coefficient of Variation** tab, enter the coefficients of variation. They are assumed to be equal for the two groups.

For this example, enter 0.5 and 0.6, as shown in Figure 71.52.

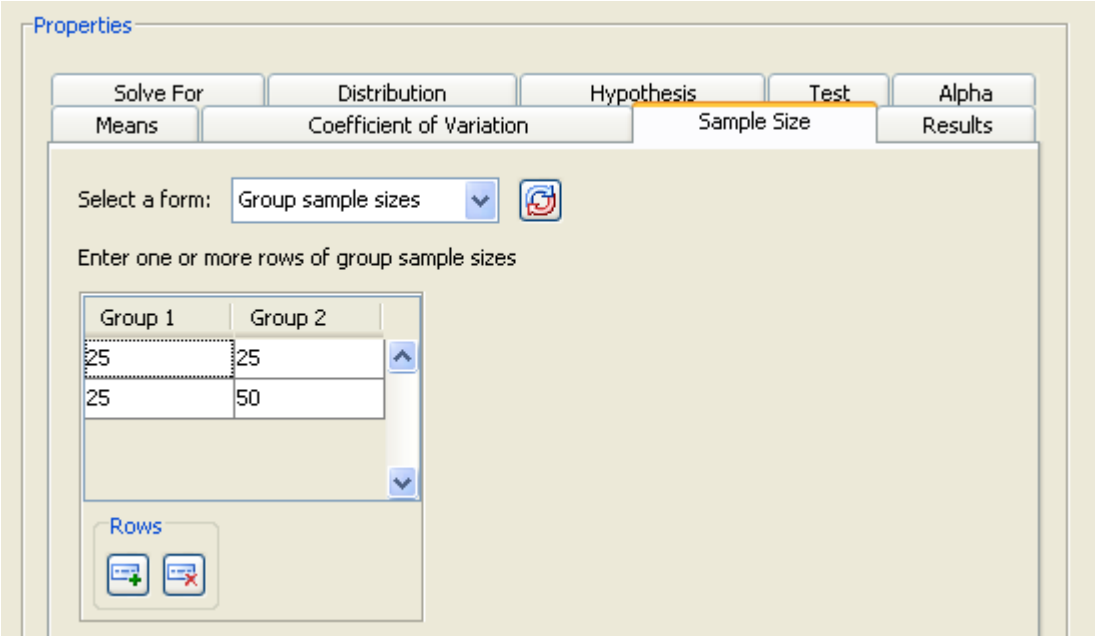
Figure 71.52 Coefficient of Variation Tab



Sample Size

On the **Sample Size** tab, select the **Group sample sizes** form and enter two sets of values: 25 and 25 in the first row and 25 and 50 in the second row, as shown in Figure 71.53.

Figure 71.53 Sample Sizes



Summary of Input Parameters

Table 71.4 contains the values of the input parameters for the example.

Table 71.4 Summary of Input Parameters

Parameter	Value
Hypothesis	One-sided test
Distribution	Lognormal
Alpha	0.05
Means form	Mean ratio
Mean ratio	0.9
Coefficients of variation	0.5, 0.6
Sample size form	Group sample sizes
Sample Size	(25, 25), (25, 50)

Results

On the **Results** tab, select the **Create summary table** and **Create power by sample size graph** check boxes.

Click **Calculate** to perform the analysis.

In this case, the following message is displayed:

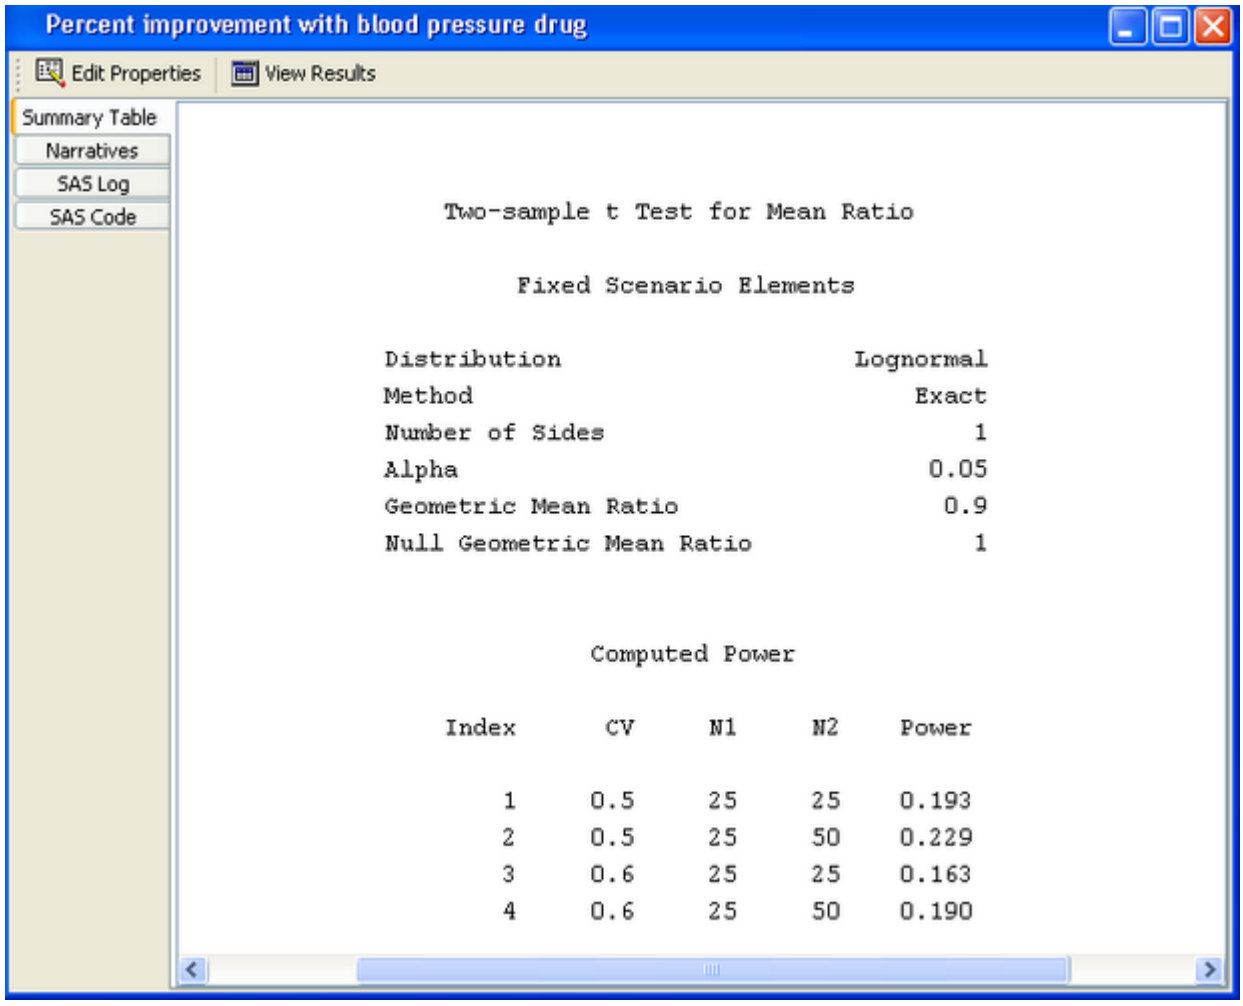
```
The power by sample size graph is not available when specifying sample
sizes for two groups.
```

If you want a power by sample size graph, you can choose to plot total sample size instead by using the `Total N, Group weights` sample size form on the **Sample Size** tab. For more information about using this input form, see the section "Using Unequal Group Sizes" on page 6024.

Viewing Results

The first thing that you notice from the summary table in Figure 71.54 is that the calculated powers are quite low—they range from 0.163 to 0.229. You have less than a 25% probability of detecting the difference that you are looking for. Clearly, this set of parameter values leads to insufficient power. To increase power, you might choose a larger sample size or a larger alpha.

Figure 71.54 Summary Table



You can also see that oversampling the control group improves power slightly, 0.229 versus 0.193 for the coefficient of variation of 0.5. However, this is a marginal increase that is probably not worth the added expense.

For the example, use larger sample sizes with equal cell sizes. Return to the Edit Properties page by clicking the **Edit Properties** icon near the top of the window.

Then, on the **Sample size** tab, change to the **Sample size per group** form. Specify sample sizes of 50, 100, 150, and 200, as shown in Figure 71.55.

Figure 71.55 Modified Sample Size Values

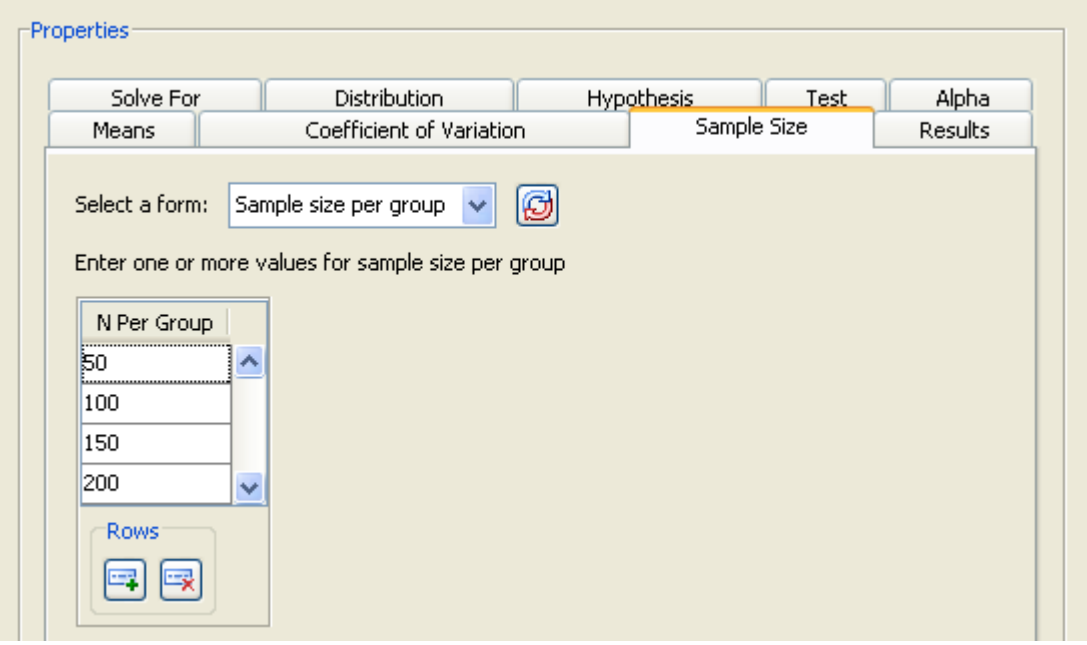


Table 71.5 contains the modified values of the input parameters for the example.

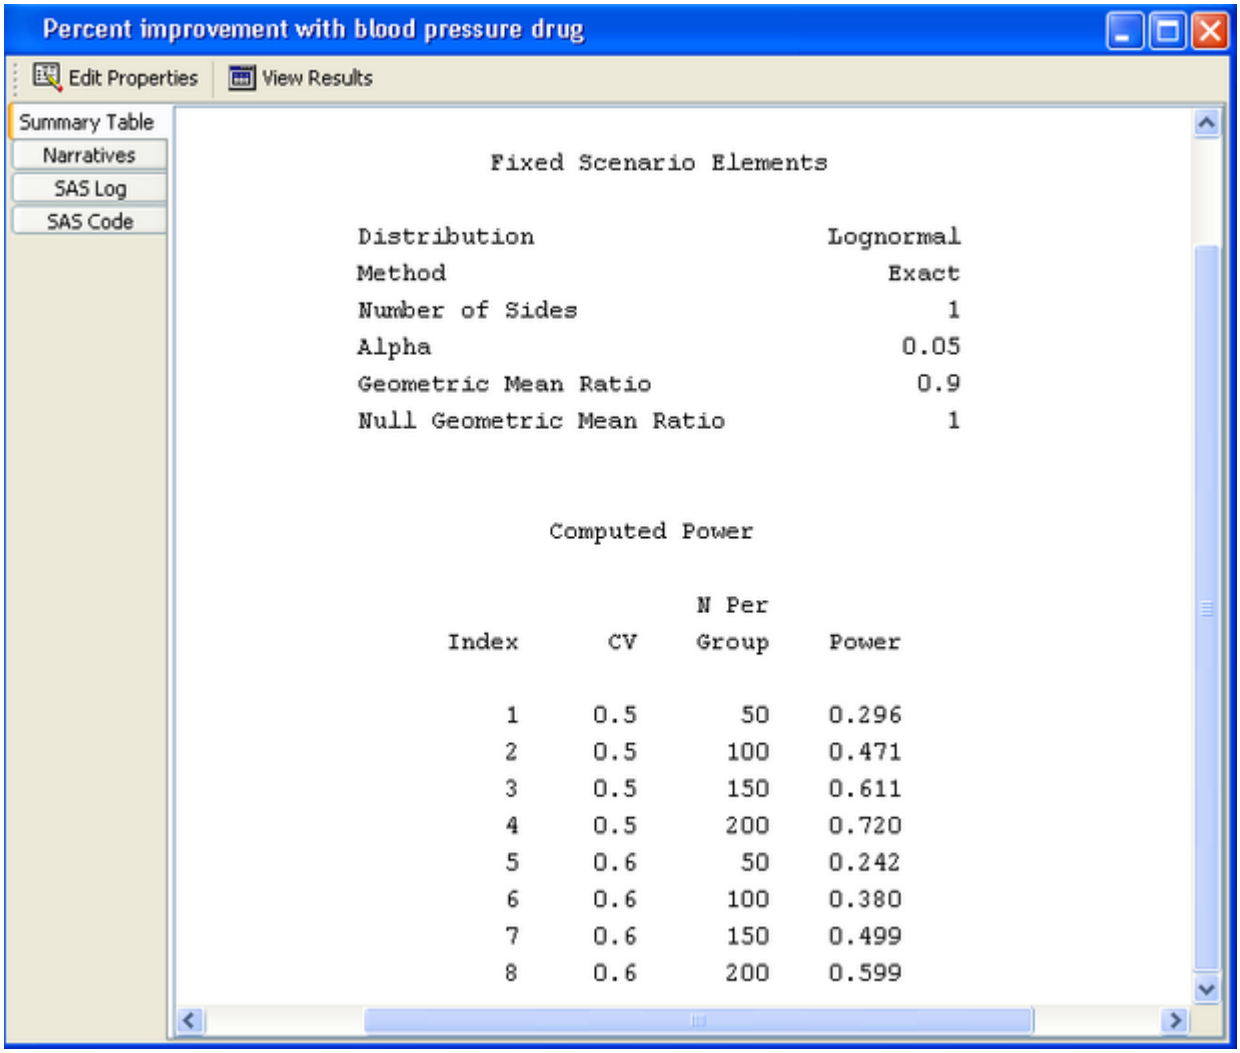
Table 71.5 Modified Summary of Input Parameters

Parameter	Value
Sample size form	Sample size per group
Sample size	50, 100, 150, 200

Rerun the analysis by clicking **Calculate**.

Figure 71.56 displays the summary table. The largest sample size of 200 (per group) yields a power of 0.72 for a coefficient of variation of 0.5, and 0.599 for one of 0.6. With a total of 400 subjects, you still have a 30% to 40% probability of not detecting the effect even if it exists.

Figure 71.56 Summary Table for Modified Sample Sizes

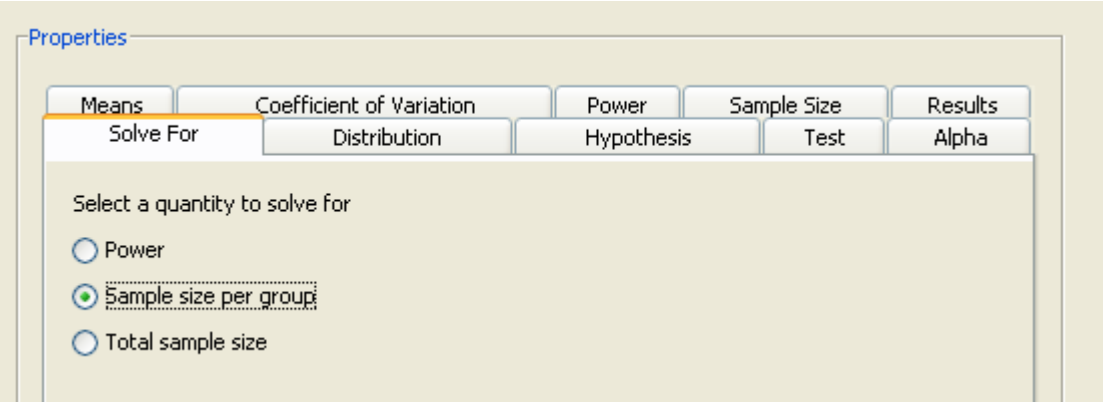


Additional Topics

Solving for Sample Size

Several types of analysis enable you to solve for either total sample size or sample size per group. The sample size per group choice assumes equal group sizes. When solving for total sample size, the group sizes can be equal or unequal. Select the desired quantity on the **Solve For** tab. An example of these options is shown in Figure 71.57.

Figure 71.57 Solve For Tab with Sample Size Selected



For either of the two sample size options, you must specify one or more values for power on the **Power** tab. If you frequently use the same values for power, set them as the default in the Preferences window, which is accessed by **Tools►Preferences**. Changing preferences affects only projects that you create after the change; existing projects are not affected.

If you select total sample size, you must specify whether the group sizes are equal or unequal. Select the appropriate option on the **Sample Size** tab. For unequal group sizes, you must specify the relative sample sizes for the two groups. For information about providing relative sample sizes, see the section "Using Unequal Group Sizes" on page 6024.

Using Unequal Group Sizes

When solving for either power or total sample size, you might have unequal group sizes. If so, you must provide relative sample sizes for the groups. Weights must be greater than 0 but do not have to sum to 1.

Select the **Total N, Group weights** form on the **Sample Size** tab. Enter total sample sizes of 30 and 60 in the **Total N** table. Select the **Unequal group sizes** option and click **Enter Relative Sample Sizes**, as seen in Figure 71.58.

Figure 71.58 Sample Size Tab with Group Weights Form

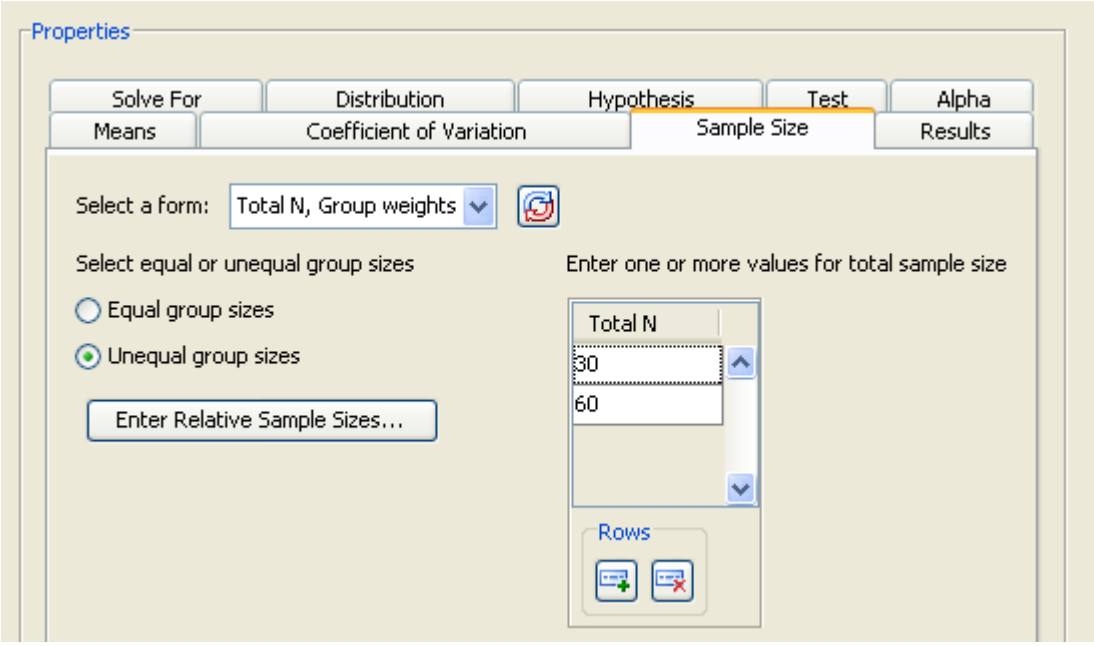


Figure 71.59 displays the window in which you can enter relative sample sizes. As an example, enter 2 for the first group and 1 for the second. In this case, you are sampling the drug treatment group twice as often as the control group.

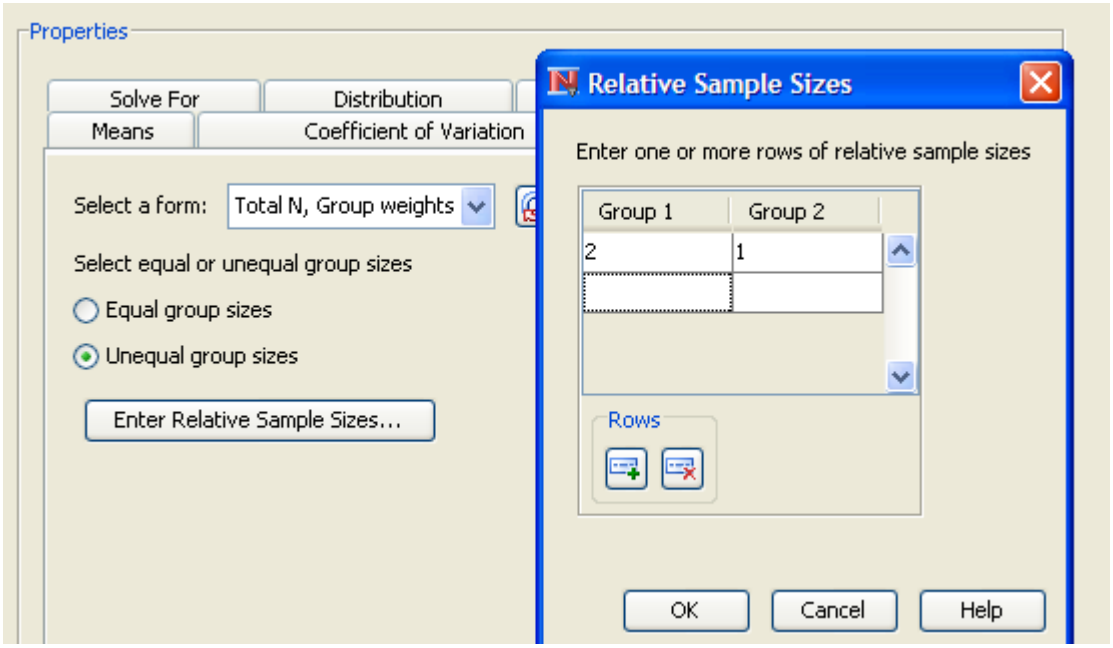
Figure 71.59 Relative Sample Sizes Window



The weights control how the total sample size is divided between the two groups. In the example, the sample size for groups 1 and 2 is 20 and 10, respectively, for a total sample size of 30.

Click **OK** to save the values and return to the Edit Properties page.

Example: Analysis of Variance

Overview

PSS offers power and sample size calculations for analysis of variance in two tasks: one-way ANOVA and general linear univariate models. Optional contrasts are available in both tasks.

In the one-way ANOVA task, you can solve for sample size per group as well as total sample size. The contrast facility for the one-way ANOVA task enables you to select orthogonal polynomials as well as to specify contrast coefficients. For more information about power and sample size analysis for one-way ANOVA, see Chapter 70, "The POWER Procedure."

In the general linear univariate models task, you specify linear models for a single dependent variable. Type III tests and contrasts of fixed effects are included, and the model can include covariates. For more information about power and sample size analysis for linear univariate models, see Chapter 43, "The GLMPOWER Procedure."

The Example

Suppose you are interested in testing how two experimental drugs affect systolic blood pressure relative to a standard drug. You want to include both men and women in the study. You have a two-factor design: a drug factor with three levels and a gender factor with two levels. You choose a main-effects-only model because you do not expect a drug by gender interaction. You want to calculate the sample size that will produce a power of 0.9 using a significance level of 0.05. You believe that the error standard deviation is between 5 and 7 mm pressure. This is a two-way analysis of variance, so the general linear univariate models task is the appropriate one.

Editing Properties

Start by opening the New window (**File►New**). In the **Analysis of Variance and Linear models** section of the New window, select **General linear univariate models**. The **General univariate linear models** project appears, with the Edit Properties page displayed.

Project Description

For the example, change the project description to `Three blood pressure drugs and gender`.

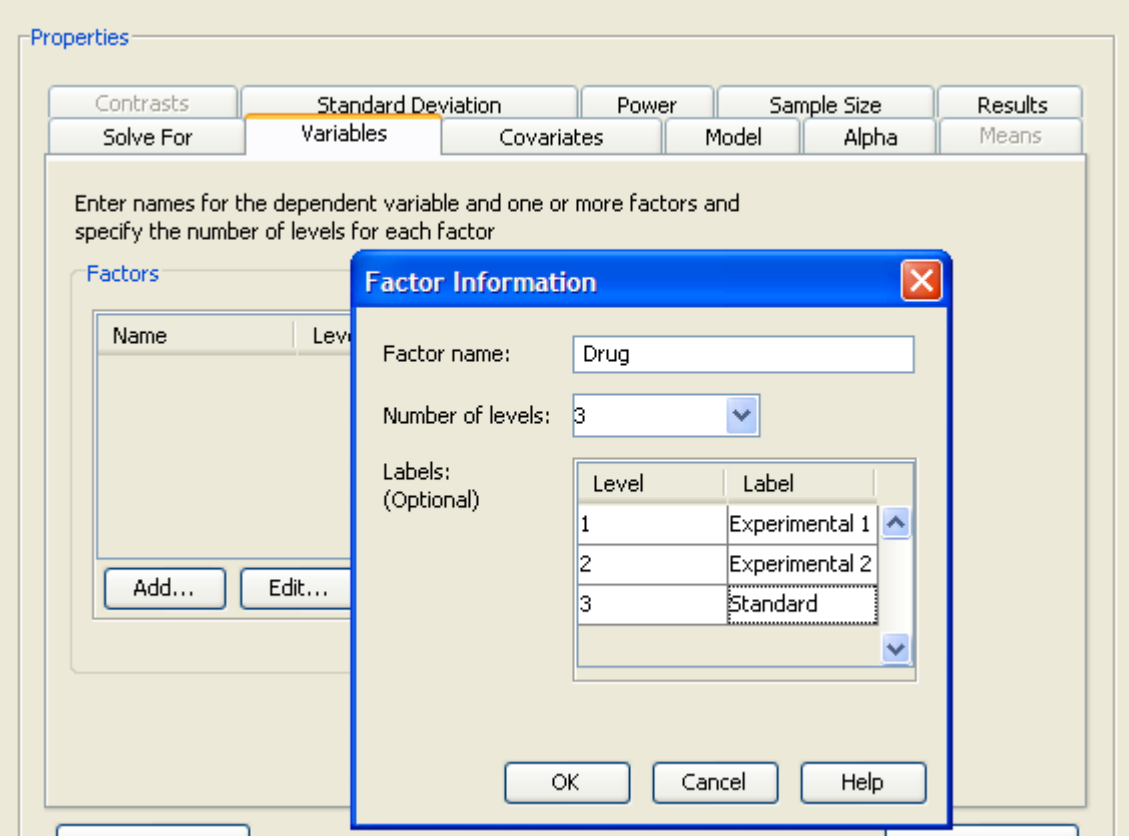
Solve For

Click the **Solve For** tab and select the **Sample size** option.

Variables

Click the **Variables** tab to enter the names of the factors in the design. Click the **Add** button. The Factor Definition window appears, as shown in Figure 71.60.

Figure 71.60 Factor Definition Window



Enter the name for the first factor, `Drug`, and enter the number of factor levels in the **Number of levels:** list box. There are three levels for this factor. Optionally, you can provide a label for each factor level. This label is used to identify factor levels on other tabs of the Edit Properties page. For this example enter the labels `Experimental 1`, `Experimental 2`, and `Standard` for the three levels of the `Drug` factor. Click **OK** when you are finished.

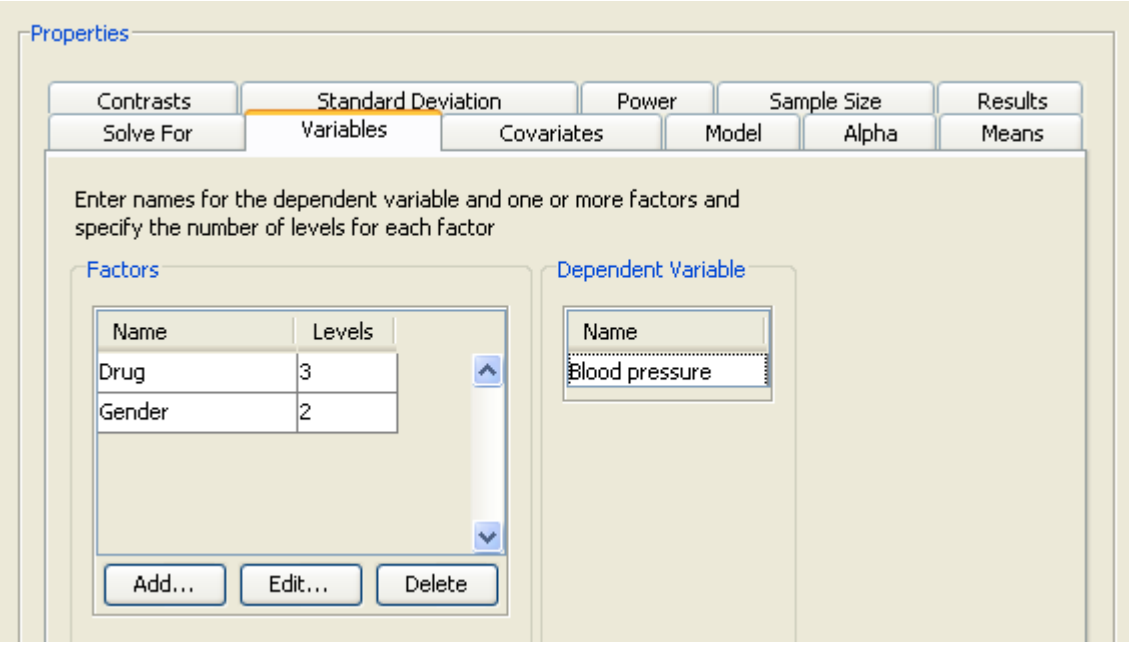
Click the **Add** button again and repeat the process for the second factor, `Gender` with two levels and labels `Female` and `Male`.

Factors can contain blanks and other special characters. Do not use an asterisk (*) because a factor name with an asterisk might be confused with an interaction effect. Factor names can be any length, but they must be distinct from one another in the first 32 characters.

On the **Variables** tab, you can also specify the name of the dependent variable; in this example, `Blood pressure` is used.

The completed **Variables** tab is shown in Figure 71.61.

Figure 71.61 Variables Tab with Factors and Number of Levels



Model

Click the **Model** tab, then choose from three model options:

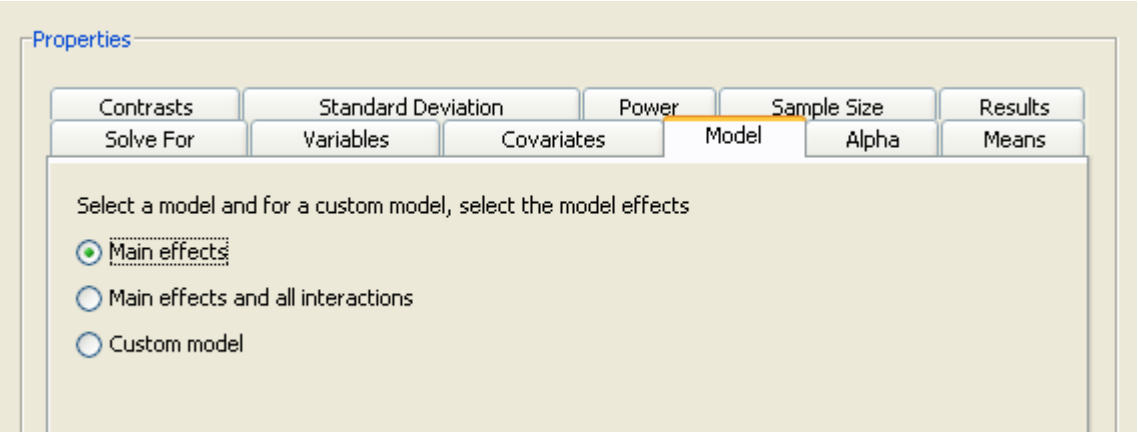
Main effects
: Only the main effects are included in the model.

Main effects and all interactions
: The main effects and all possible interactions are included in the model.

Custom model
: Selected effects are included in the model. The effects are selected in a model builder that is displayed when this model is selected. For more information about specifying a custom model, see the section "Specifying a Custom Model" on page 6039.

For this example, choose the default **Main effects** model, as shown in Figure 71.62.

Figure 71.62 Model Tab with Main Effects Selected



Alpha

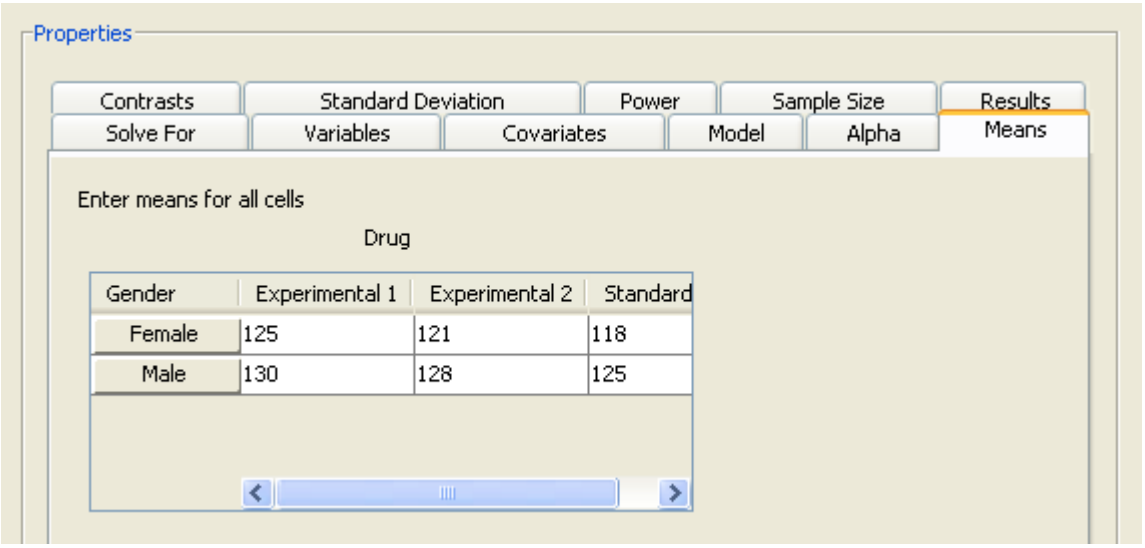
Click the **Alpha** tab to specify one or more significance levels. For the example, specify a single significance level of 0.05.

Alpha is the significance level (that is, the probability of falsely rejecting the null hypothesis). If you frequently use the same values for alpha, set them as the defaults in the Preferences window (**Tools►Preferences**).

Means

Click the **Means** tab to enter projected cell means for each cell of the design. The completed means for the example are shown in Figure 71.63.

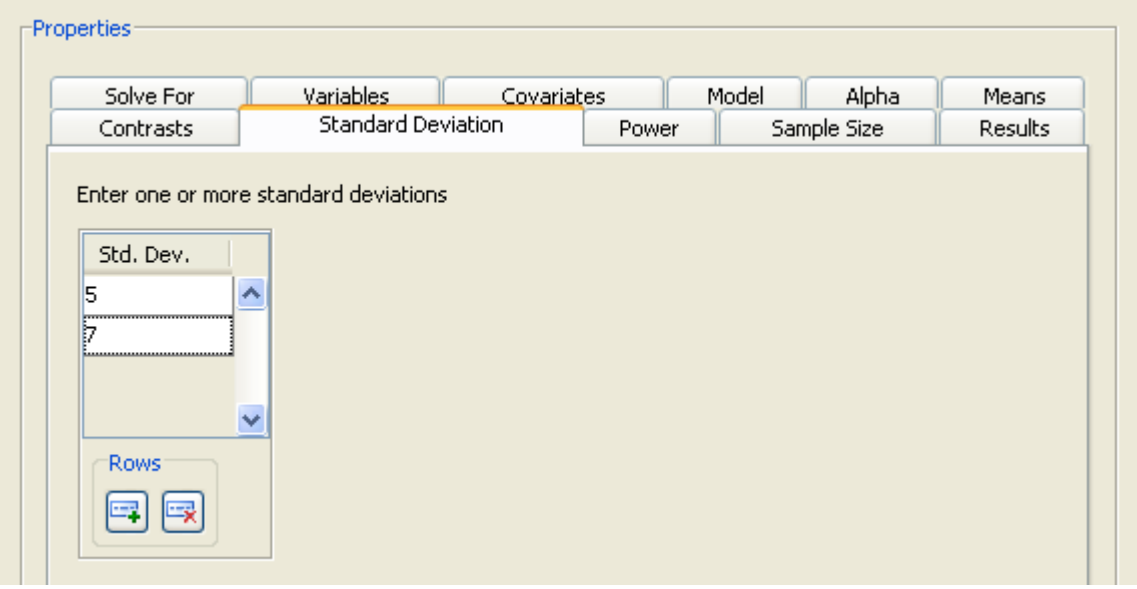
Figure 71.63 Means Tab with Cell Means



Standard Deviation

Click the **Standard Deviation** tab to specify one or more conjectured error standard deviations. The standard deviation is the same as the root mean squared error. For this example, enter two standard deviations, 5 and 7, as shown in Figure 71.64.

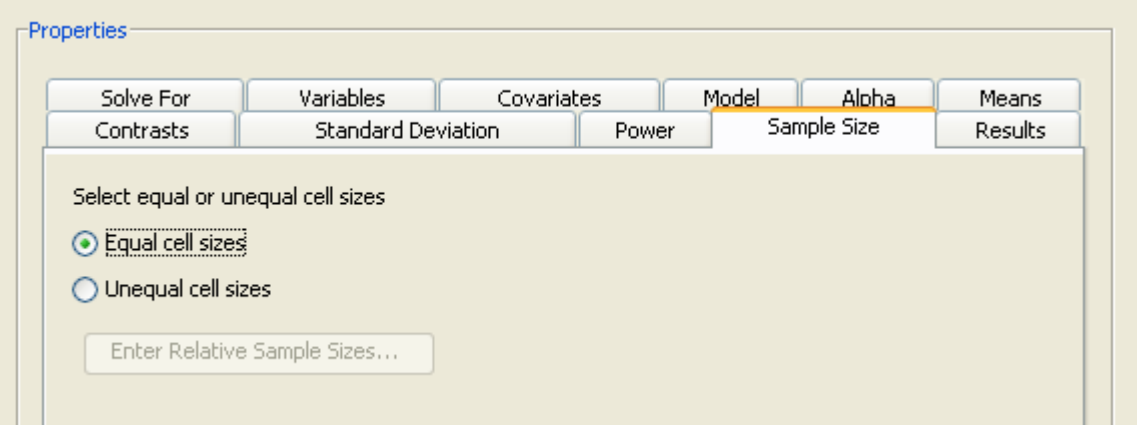
Figure 71.64 Standard Deviations Tab



Relative Sample Size

Click the **Sample Size** tab to select whether cell sample sizes are equal or unequal.

Figure 71.65 Sample Size Tab with Equal Cell Sample Sizes



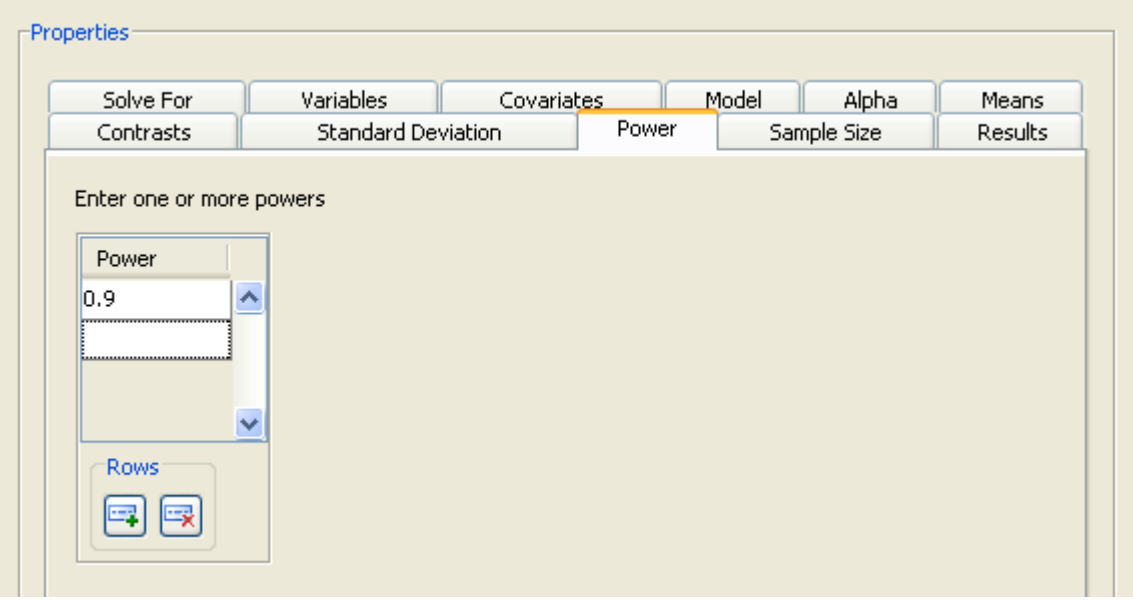
For the example, select the **Equal cell sizes** option, as shown in Figure 71.65.

When solving for sample size, it is necessary to specify whether the cell sample sizes are equal or unequal. If cell sizes are unequal, relative sample size weights must also be specified. For more information about providing sample size weights, see the section "Using Unequal Cell Sizes" on page 6036.

Power

Click the **Power** tab to specify one or more powers. For this example, enter a single power of 0.9, as shown in Figure 71.66.

Figure 71.66 Power Tab



Summary of Input Parameters

Table 71.6 contains the values of the input parameters for the example.

Table 71.6 Summary of Input Parameters

Parameter	Value
Model	Main effects
Alpha	0.05
Means	See Table 71.7
Standard deviation	5, 7
Relative sample sizes	Equal cell sizes
Power	0.9

Table 71.7 Cell Means

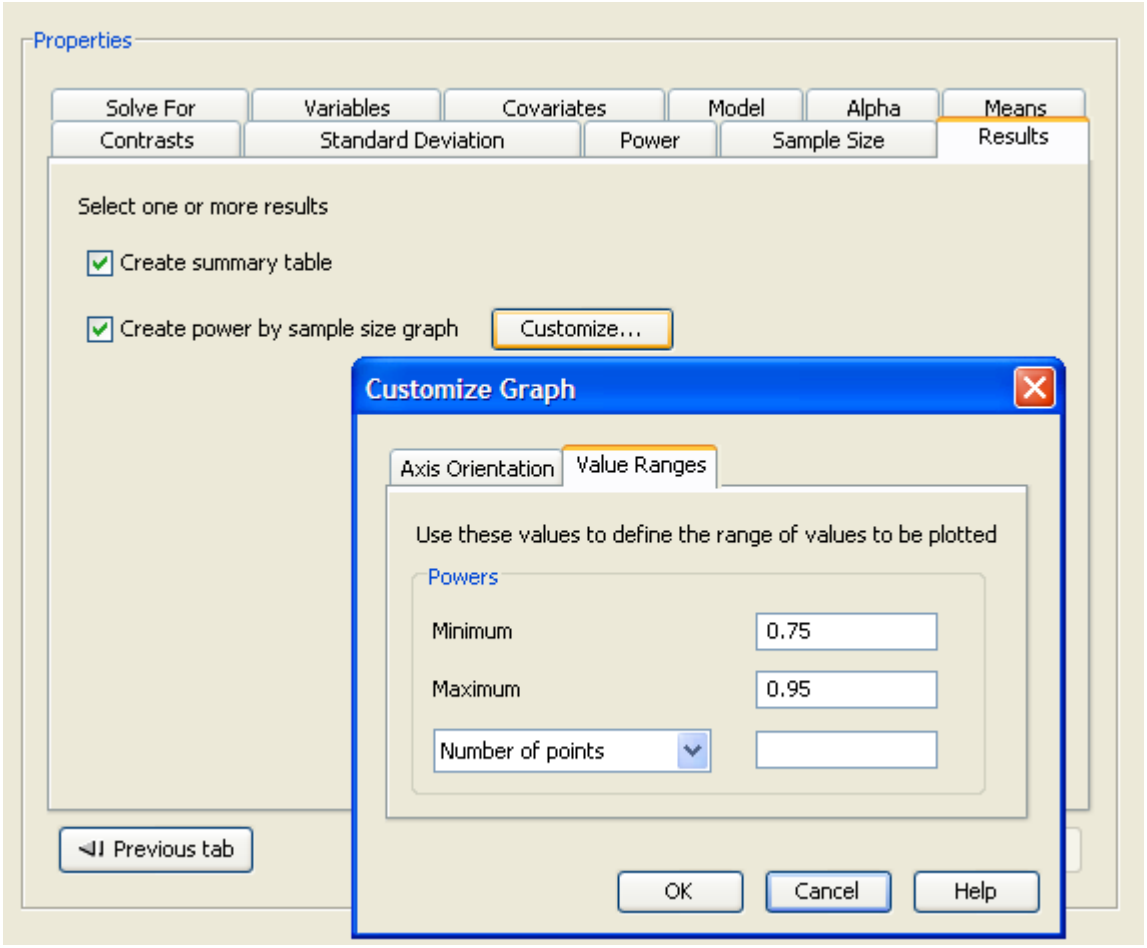
Gender	Drug		
	Experimental 1	Experimental 2	Standard
Female	125	121	118
Male	130	128	125

Results Options

Click the **Results** tab to select desired results. For the example, select both the **Create summary table** and **Create power by sample size graph** check boxes.

The graph consists of four points, one for each of the four scenarios that were created by combining the two factor main effects with the two standard deviations. This graph is not very informative, so specify a range of powers for the horizontal power axis. To change the power axis of the graph, click the **Customize** button beside the **Create power by sample size graph** check box to open the Customize Graph window.

Figure 71.67 Value Ranges on Customize Graph Window



Click the **Value Ranges** tab and enter a minimum power of 0.75 and a maximum power of 0.95, as shown in Figure 71.67. Click **OK** to close the window.

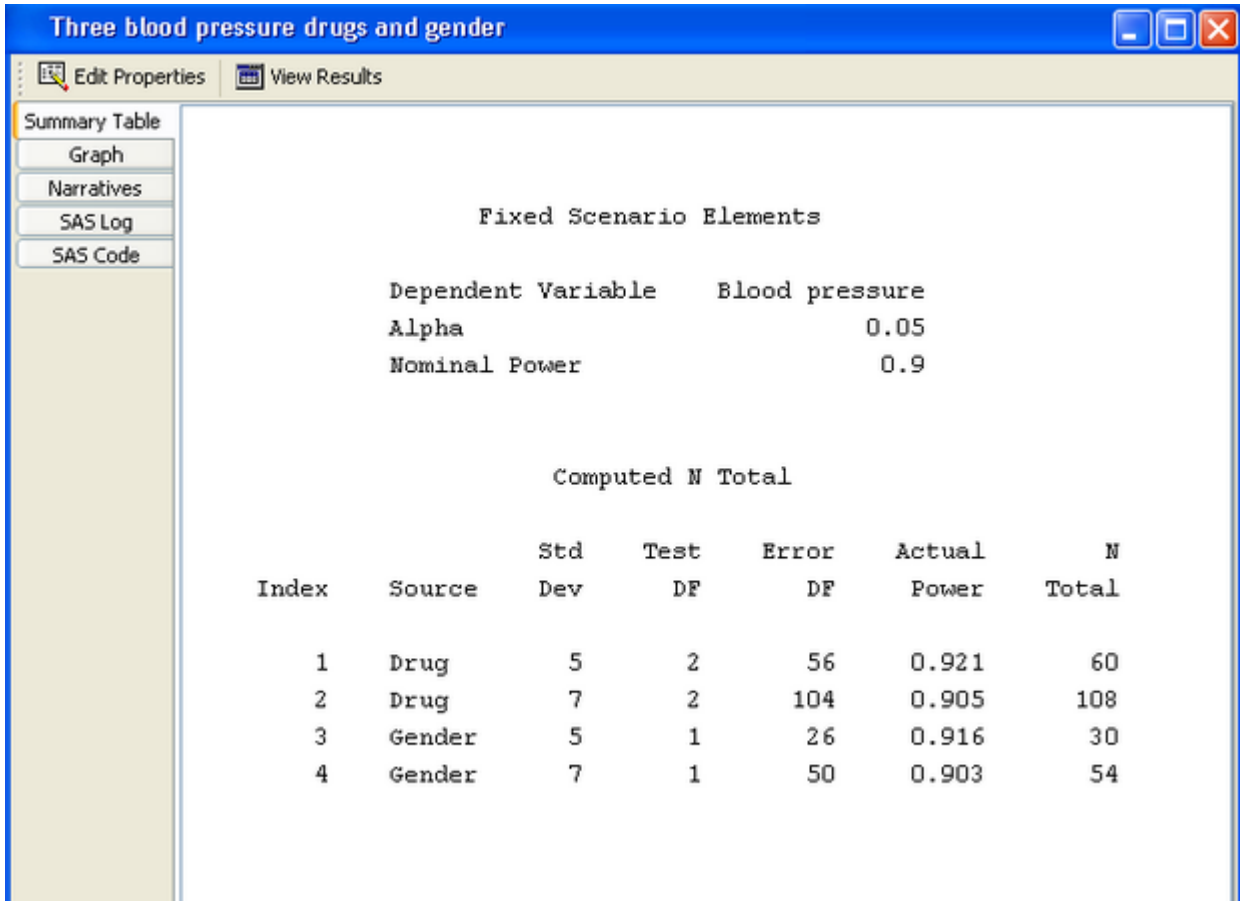
Now, click **Calculate** to perform the analysis.

Viewing Results

The results are displayed in separate tabs on the View Results page.

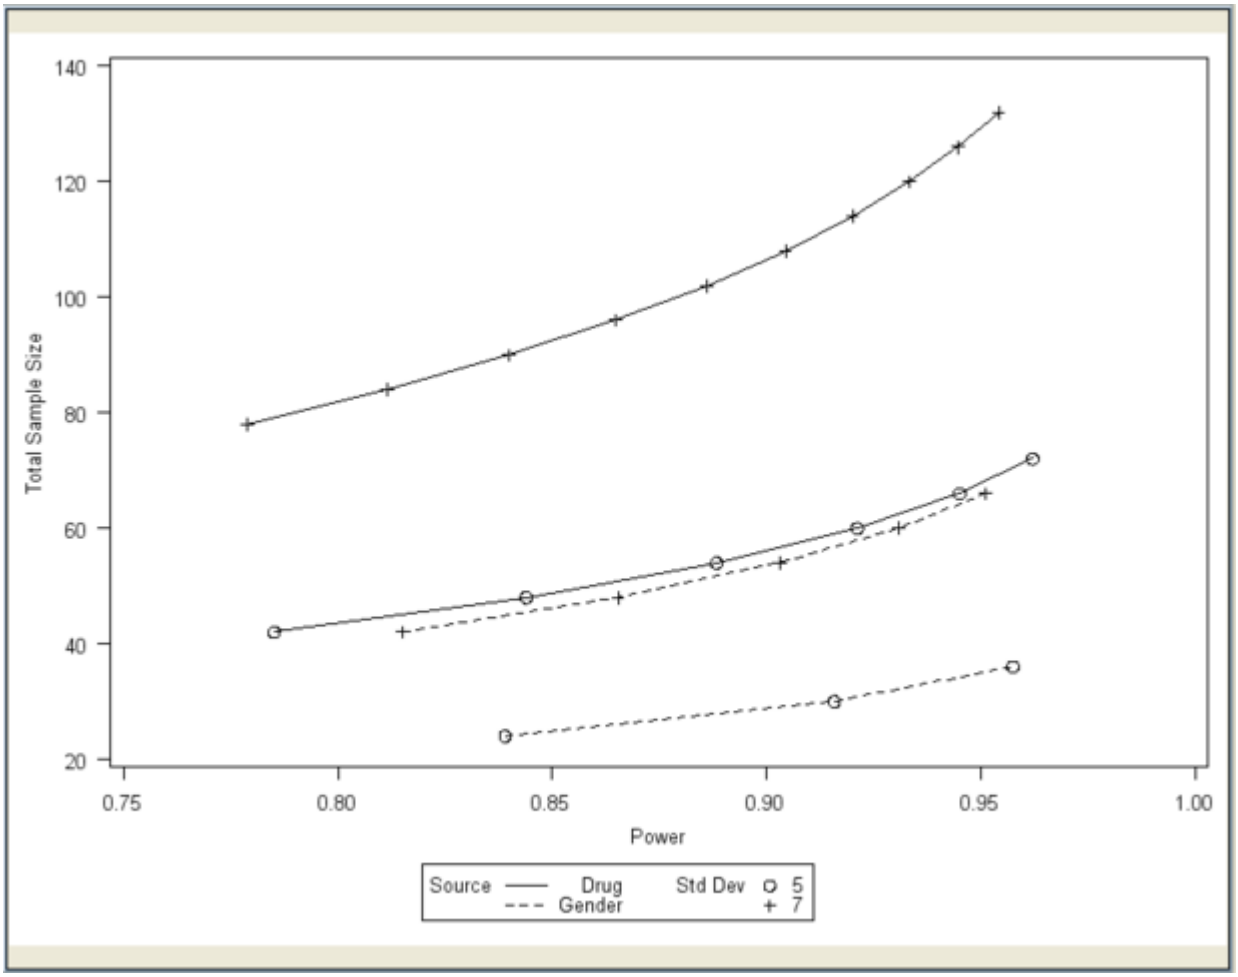
Click the **Summary Table** tab to view the summary table. In the `Computed N Total` table, sample sizes are listed for each combination of factor and standard deviation (Figure 71.68). You need a total sample size between 60 and 108 to yield a power of 0.9 for the `Drug` effect if the standard deviation is between 5 and 7. You need a sample size of half that for the `Gender` effect.

Figure 71.68 Summary Table



Click the **Graph** tab to view the power by sample size graph, as shown in Figure 71.69. One approximately linear curve is displayed for each standard deviation and factor combination.

Figure 71.69 Power by Sample Size Graph



Click the **Narratives** tab to create narratives of one or more scenarios. Select the first scenario, the Drug effect with the standard deviation of 5, in the narrative selector table. Note that the cell means are not included in the following narrative description:

```
For the usual F test of the Drug effect in the general linear univariate
model with fixed class effects [Blood pressure = Drug Gender] using a
significance level of 0.05, assuming the specified cell means and an
error standard deviation of 5, a total sample size of 60 assuming a
balanced design is required to obtain a power of at least 0.9.  The
actual power is 0.921.
```

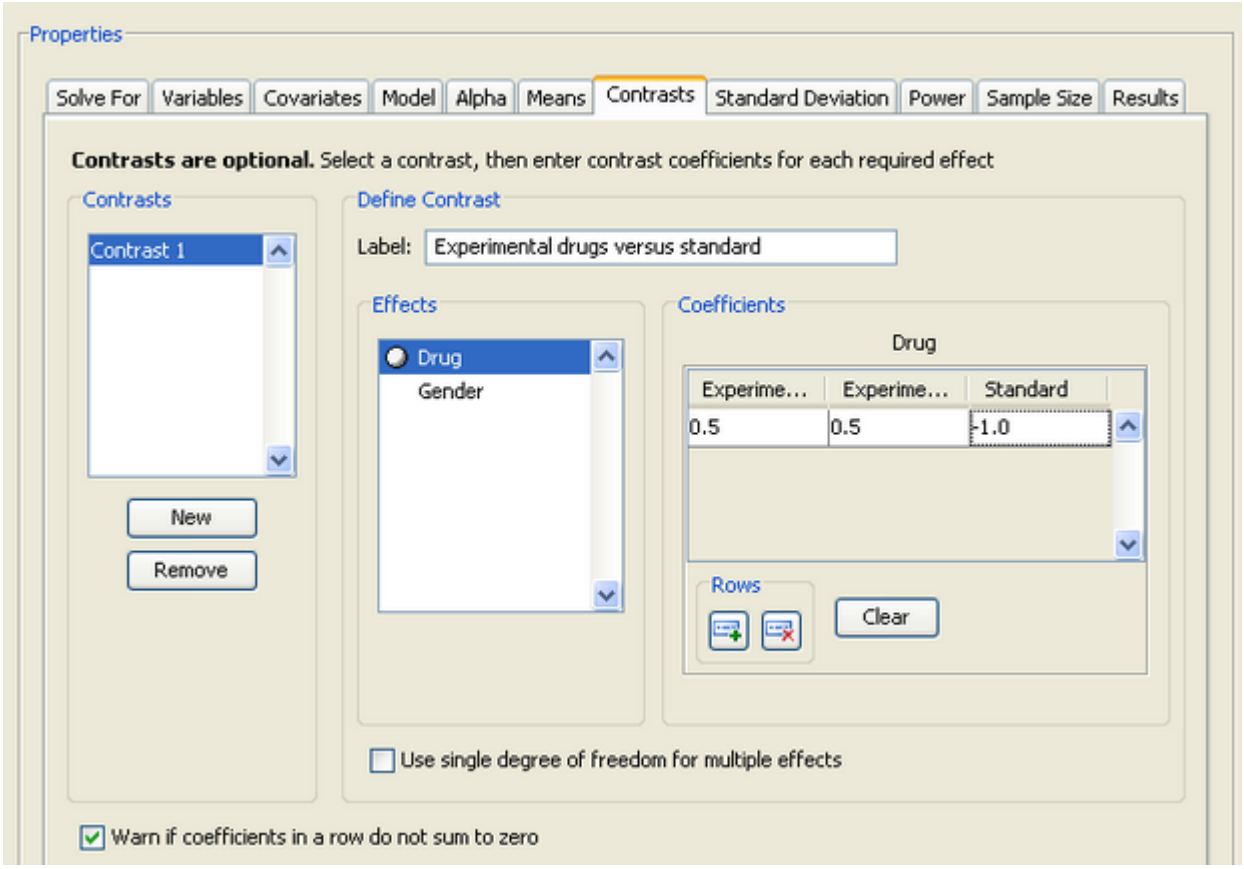
For more information about using the narrative facility, see the section "Creating Narratives" on page 5998.

Additional Topics

Adding Contrasts

Click the **Contrasts** tab to define one or more contrasts. Contrasts are optional. PSS allows contrasts to be added when using either a main effects model or a main effects and interactions model. At least two factors must have been specified in order to be able to enter contrasts. The contrast tab appears in Figure 71.70.

Figure 71.70 Contrast Tab with Coefficients



To create a contrast, click the **New** button. Then, select the newly created contrast (`Contrast 1`) from the list.

Specify a label for the contrast in the **Label** field. The label should be different from all of the factor names and all interactions in the model, as well as other contrast labels.

Then, for each term you want to include in the contrast, select the term in the **Effects** list and enter at least two coefficients per term. It is not necessary to enter zeros; blanks are considered to be zeros.

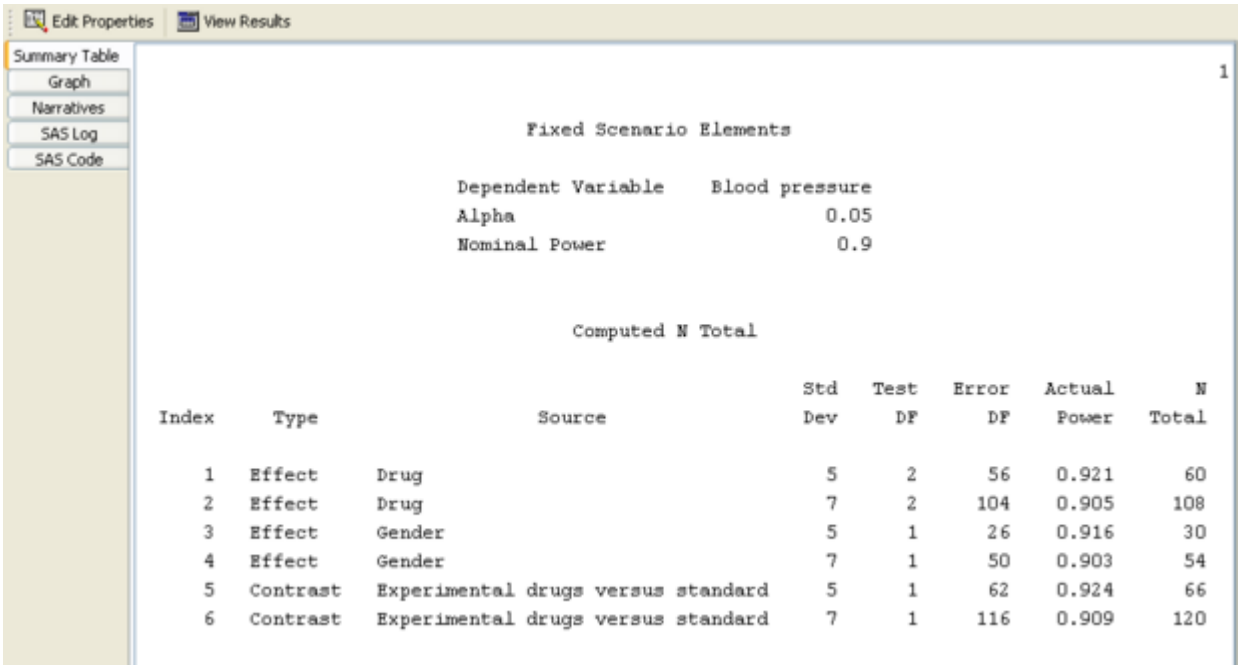
To clear all of the contrast coefficients for a term, click the **Clear** button. To remove a previously defined contrast, select it from the **Contrasts** list and click the **Remove** button.

In this example, you are interested in comparing the two experimental drugs to the standard drug. As shown

in Figure 71.70, the contrast coefficients are 0.5, 0.5, and −1 for the three levels of the Drug effect.

Figure 71.71 shows the two scenarios for the contrast at the bottom of the `Computed N Total` table. The two scenarios also appear in the graph but the graph is not shown here.

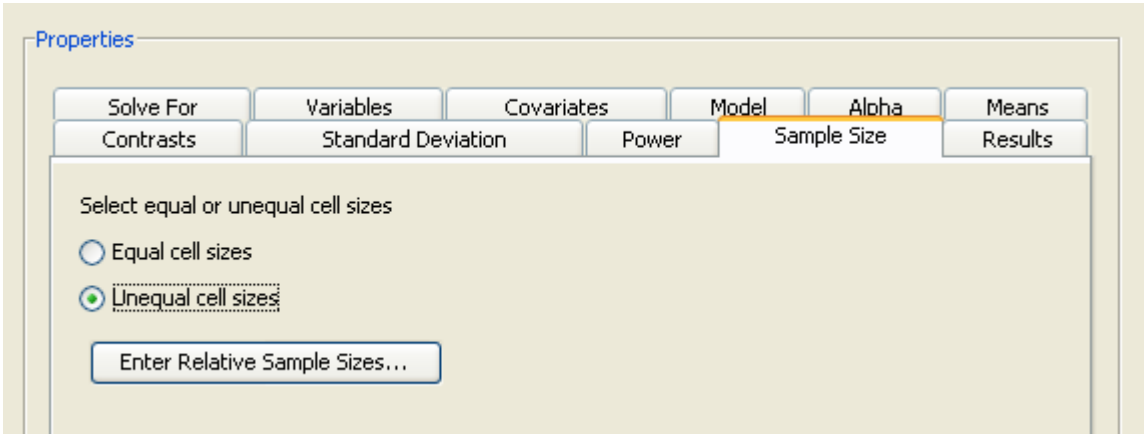
Figure 71.71 Computed N Total Table for the Contrast



Using Unequal Cell Sizes

Click the **Sample Size** tab to select the equal or unequal cell sizes option.

Figure 71.72 Sample Size Tab



For the example, select the **Unequal cell sizes** option, as seen in Figure 71.72, and then click the **Enter Relative Sample Sizes** button.

Figure 71.73 shows the window in which you can enter relative sample sizes. As an example, enter the sample size weights from Table 71.8.

Table 71.8 Sample Size Weights

	Drug		
Gender	**Experimental 1**	**Experimental 2**	**Standard**
Males	1	1	2
Females	1	1	2

If you have unequal cell sizes, you must enter relative sample size weights for the cells. Weights do not have to sum to 1 across the cells. Some weights can be zero, but enough weights must be greater than zero so that the effects and contrasts are estimable.

In this case, you want the sample size of the standard group to be twice that of each of the two experimental groups. Click **OK** to save the values and return to the Edit Properties page.

Figure 71.73 Relative Sample Sizes Window

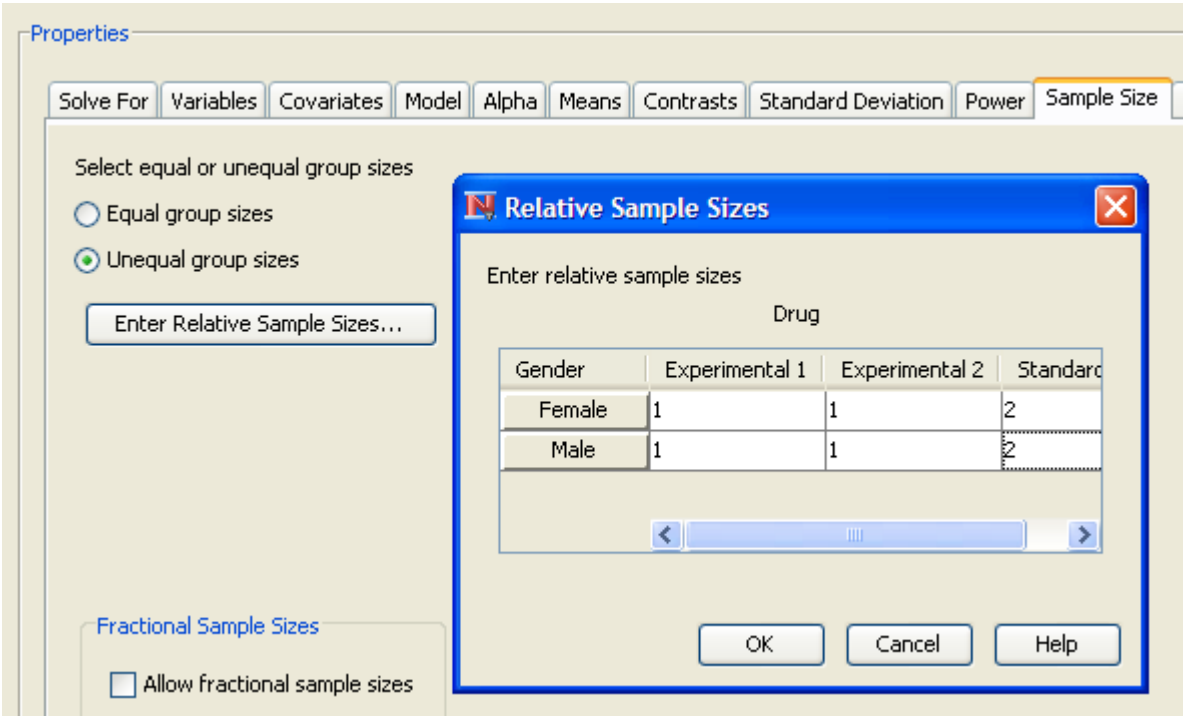


Figure 71.74 shows the summary table for the Drug by Gender example.

Figure 71.74 Summary Table for Unbalanced Design Example

1

Fixed Scenario Elements

Dependent Variable	Blood pressure
Weight Variable	_Weight_
Alpha	0.05
Nominal Power	0.9

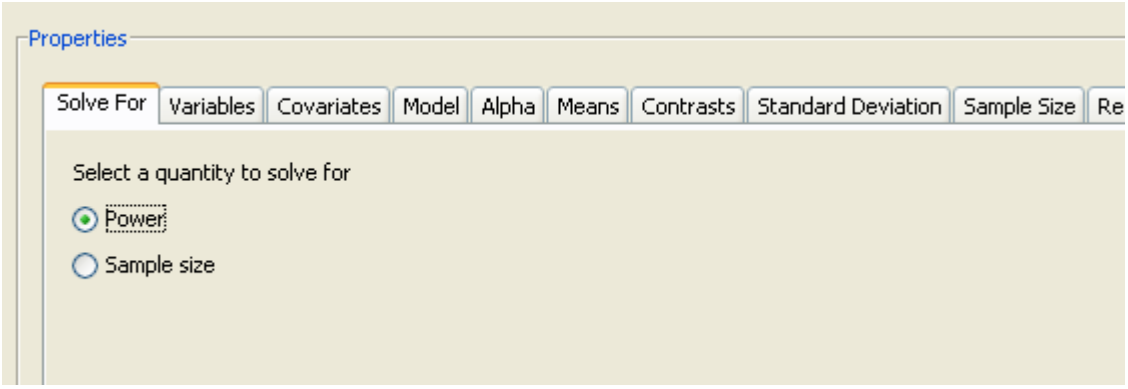
Computed N Total

Index	Type	Source	Std Dev	Test DF	Error DF	Actual Power	N Total
1	Effect	Drug	5	2	52	0.910	56
2	Effect	Drug	7	2	100	0.902	104
3	Effect	Gender	5	1	28	0.944	32
4	Effect	Gender	7	1	52	0.926	56
5	Contrast	Experimental drugs versus standard	5	1	52	0.911	56
6	Contrast	Experimental drugs versus standard	7	1	100	0.901	104

Solving for Power

In addition to solving for sample size, you can also solve for power. Figure 71.75 shows the two options. Click the **Solve For** tab to select the **Power** option.

Figure 71.75 Solve For Tab with Power Option Selected



When solving for power, you must provide sample size information. For the general linear univariate model analysis, you provide this information by using one of two alternate forms. To choose the desired alternate form, select the desired form from the **Select a form** list box on the **Sample Size** tab. The alternate forms are:

Sample size per cell
: Enter the sample size for a cell. Cell sizes are assumed to be equal. Sample size is reported in the summary table as total sample size.

Total N, Cell weights
: Enter the total sample size and specify whether cell sizes are to be equal or unequal. Select the **Equal cell sizes** or **Unequal cell sizes** option. For unequal cell sizes, you also enter cell weights. Click the **Enter Relative Sample Sizes** button to display a window that is used to enter the data. For more information about using unequal cell sizes, see the section "Using Unequal Cell Sizes" on page 6036.

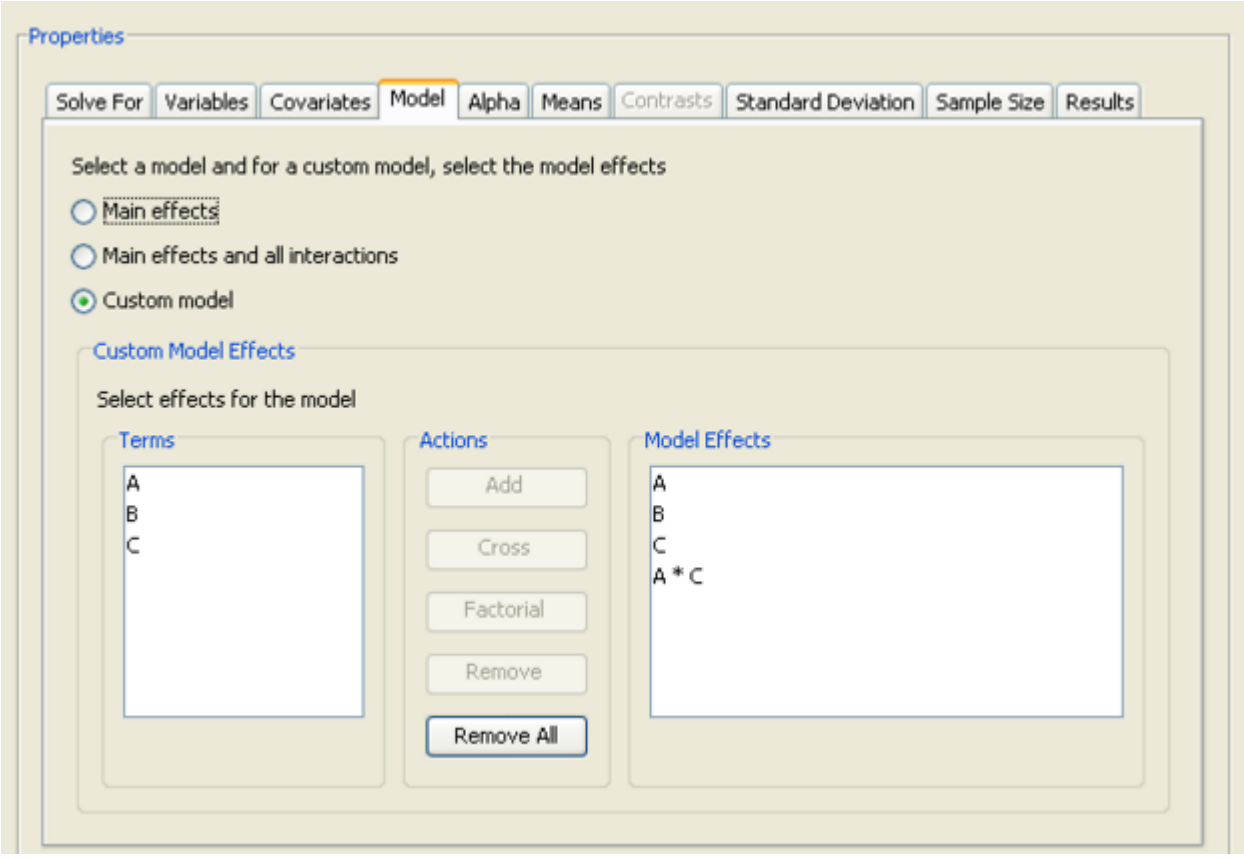
Specifying a Custom Model

Click the **Model** tab to select from three types of models: a **Main effects** model, a **Main effects and all interactions** model, and a **Custom model**.

To specify a custom model, select the **Custom model** option; then a model building facility is displayed.

The facility displays a list of the factors on the left. Construct the desired model using the **Add**, **Cross**, and **Factorial** buttons. The example shown in Figure 71.76 has the three main effects and one of the four possible interactions.

Figure 71.76 Model Tab with Custom Model Builder Displayed



Add the three main effects (`A`, `B`, `C`) by selecting them in the **Terms** list and clicking the **Add** button. Add the `A*B` interaction by selecting the `A` and `B` factors in the **Terms** list and clicking the **Cross** button.

To create the complete factorial design of several factors, select the factors in the **Terms** list, then click the **Factorial** button. All possible main effects and interactions are added to the **Model Effects** list.

To remove effects, select them in the **Model Effects** list and click the **Remove** button. Clicking the **Remove All** button removes all effects in the model.

Including Covariates

Click the **Covariates** tab to enter covariate information.

Figure 71.77 Covariates Tab with Proportional Reduction in Variance Form

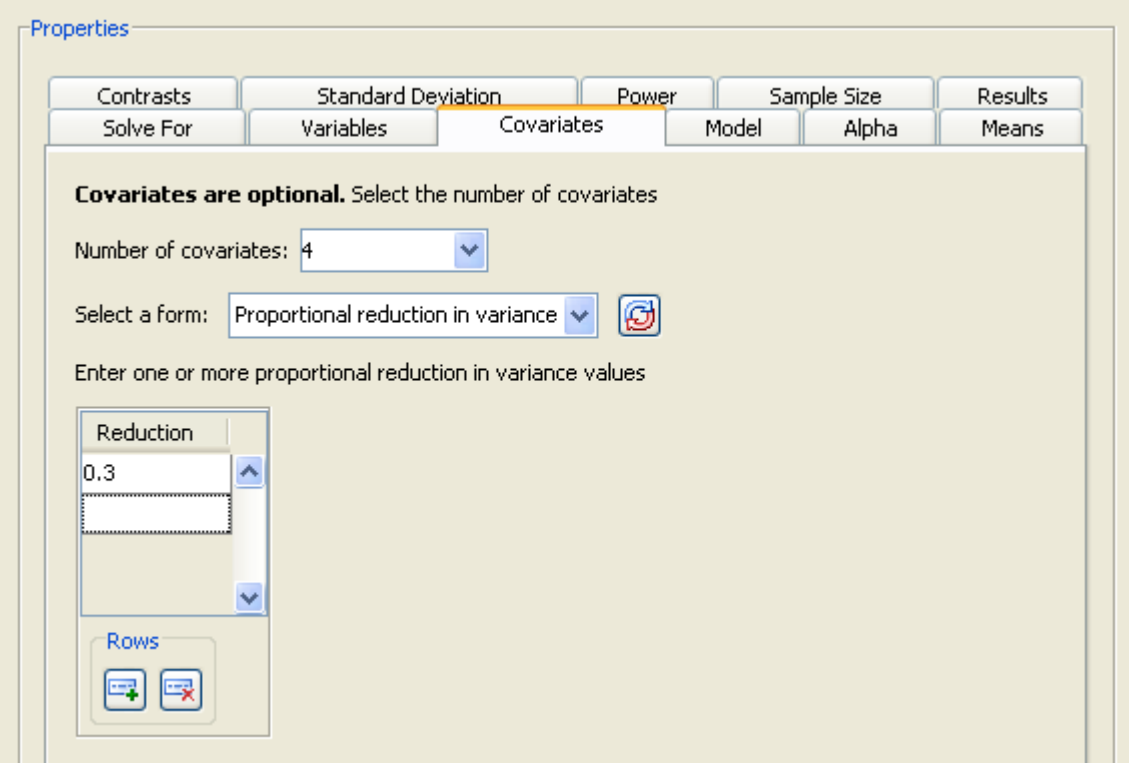


Figure 71.77 illustrates four covariates and a proportional reduction in variation of 0.3. The results for the analysis are not shown.

Covariates are optional. If you have covariates, include the total number of degrees of freedom for all covariates. To do this, add the number of continuous covariates and the sum of the degrees of freedom of the classification covariates, and enter this total in the **Number of Covariates** list box. For example, with two continuous covariates and a single classification covariate factor with three levels, the total would be $2 + (3 - 1) = 4$.

Also, you must enter the correlation between the dependent variable and the set of covariates. Two alternate forms are available: **Multiple correlation** and **Proportional reduction in variance**. Select the desired form and enter one or more values.

The multiple correlation is between the set of covariates and the dependent variable. Proportional reduction in variation is how much the variance of the dependent variable is reduced by the inclusion of the covariates, expressed as a proportion between 0 and 1.

Example: Two-Sample Survival Rank Tests

Overview

Survival analysis often involves the comparison of survival curves. PSS provides sample size and power calculations for two-sample survival rank analyses. Several rank tests are available: Gehan, log-rank, and Tarone-Ware. There are also several ways to specify the survival functions. For more information about power and sample size analysis for survival rank tests, see Chapter 70, "The POWER Procedure."

The Example

Suppose you want to compare survival rates for an existing cancer treatment and a new treatment. You intend to use a log-rank test to compare the overall survival curves for the two treatments. You want to determine a sample size to achieve a power of 0.8 for a two-sided test using a balanced design, with a significance level of 0.05.

The survival curve of patients for the existing treatment is known to be approximately exponential with a median survival time of five years. You think that the proposed treatment will yield a survival curve described by the times and probabilities listed in Table 71.9. Patients are to be accrued uniformly over two years and followed for three years.

Table 71.9 Survival Probabilities for Proposed Treatment

Time	Probability
1	0.95
2	0.90
3	0.75
4	0.70
5	0.60

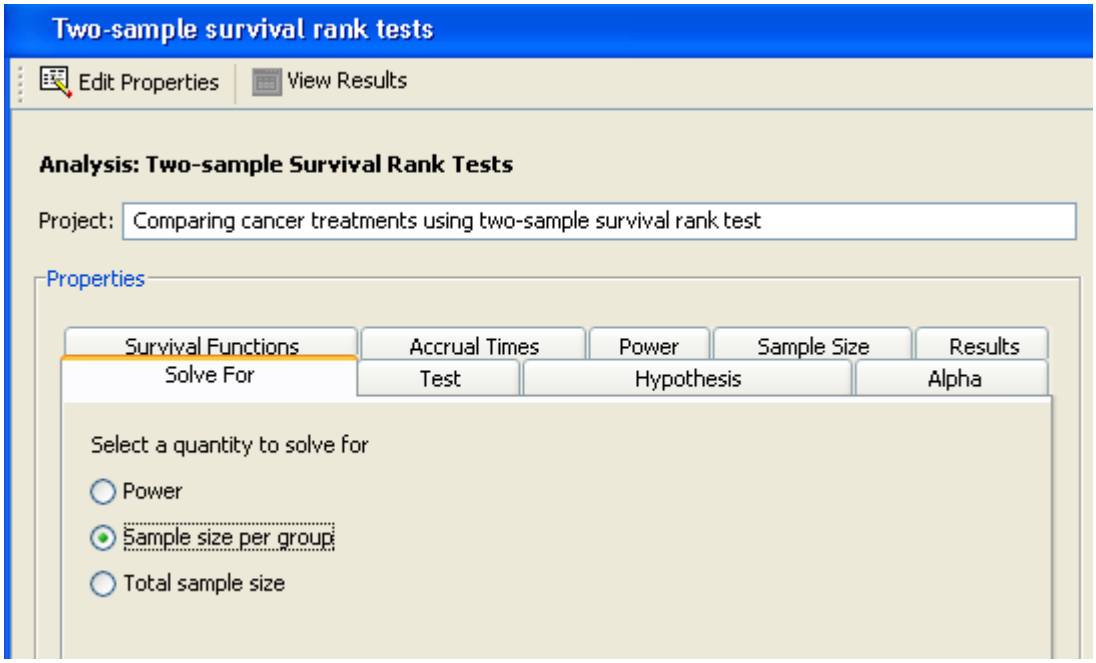
To create a new survival analysis project, select **File►New**, Then, under the **Survival Analysis** section, select **Two-sample survival rank tests** and click **OK**. The **Two-sample survival rank tests** project appears with the Edit Properties page displayed.

Editing Properties

Project Description

For the example, change the project description to `Comparing cancer treatments using two-sample survival rank test`.

Figure 71.78 Project Description and Solve For Tab



Solve For

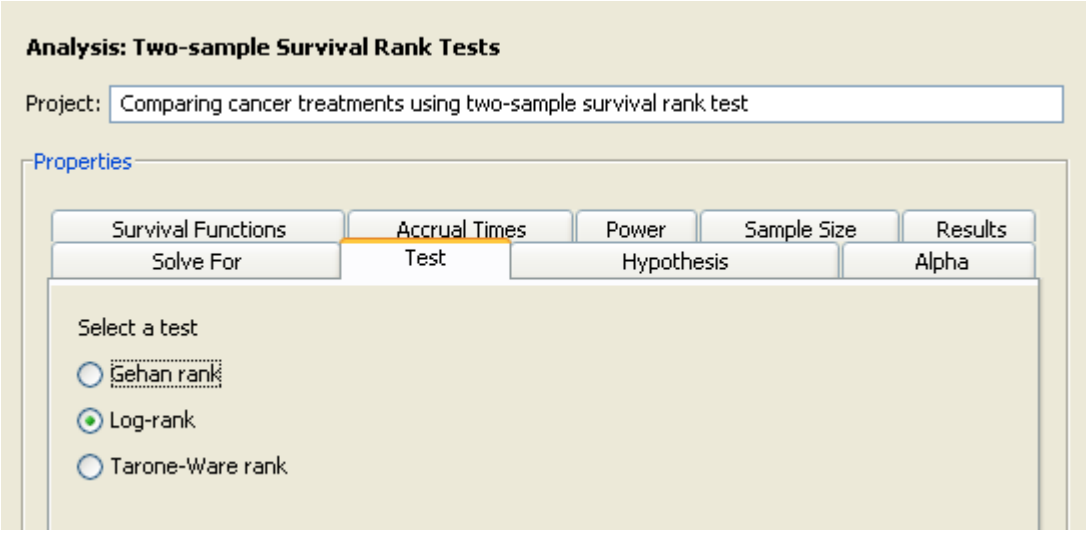
Click the **Solve For** tab to select the quantity to solve for. For this example, select the **Sample size per group** option, as shown in Figure 71.78. For information about calculating total sample size, see the section "Solving for Sample Size" on page 6023.

In this analysis you can solve for power, sample size per group, or total sample size.

Test

Click the **Test** tab to select a rank test. For this example, select the **Log-rank** option, as shown in Figure 71.79.

Figure 71.79 Test Tab

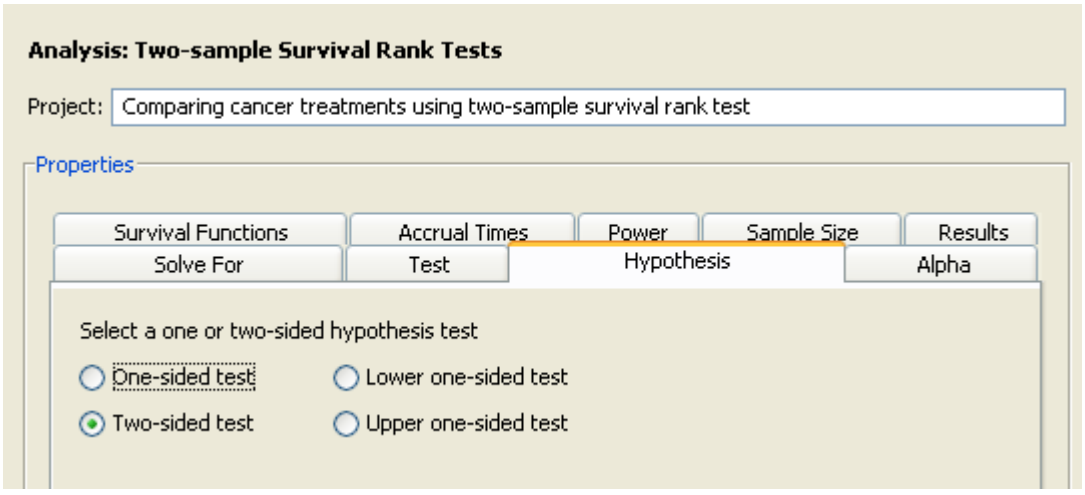


Several rank tests are available: Gehan, log-rank, and Tarone-Ware. The Gehan test is most sensitive to survival differences near the beginning of the study period, the log-rank test is uniformly sensitive throughout the study period, and the Tarone-Ware test is somewhere in between.

Hypothesis

Click the **Hypothesis** tab to select a one- or two-sided test. For the example, select the **Two-sided test** option, as shown in Figure 71.80.

Figure 71.80 Hypothesis Tab

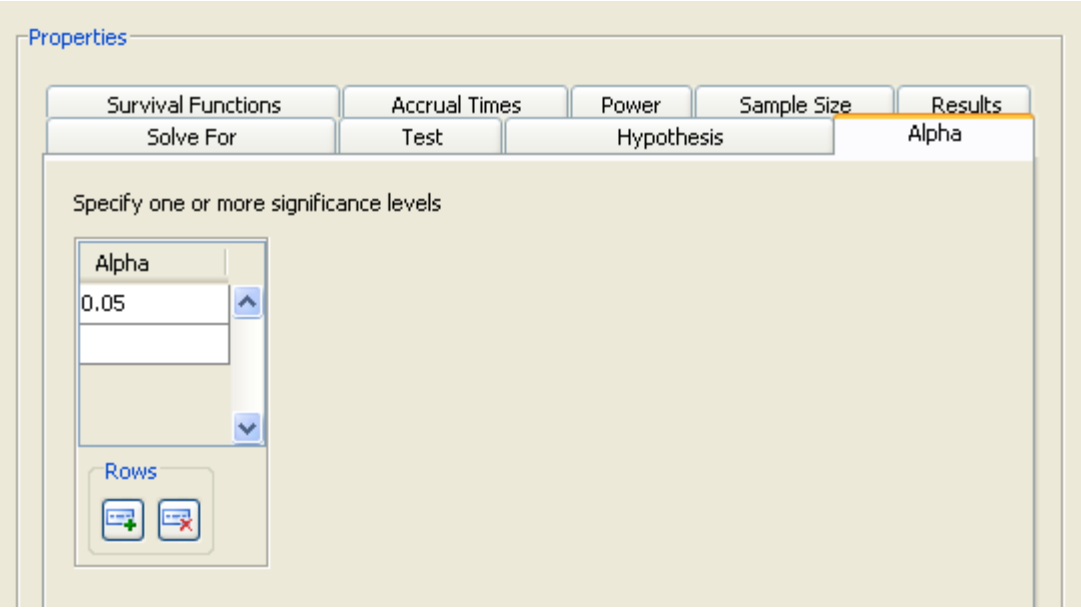


You can choose either a one- or two-sided test. For the one-sided test, the alternative hypothesis is assumed to be in the same direction as the effect. If you do not know the direction of the effect (that is, whether it is positive or negative), the two-sided test is appropriate. If you know the effect's direction, the one-sided test is appropriate. If you specify a one-sided test and the effect is in the unexpected direction, the results of the analysis are invalid.

Alpha

Click the **Alpha** tab to enter one or more values for the significance level. For the example, enter the desired significance level of 0.05 in the first cell of the Alpha table, as shown in Figure 71.81, if it is not already the default value.

Figure 71.81 Alpha Tab

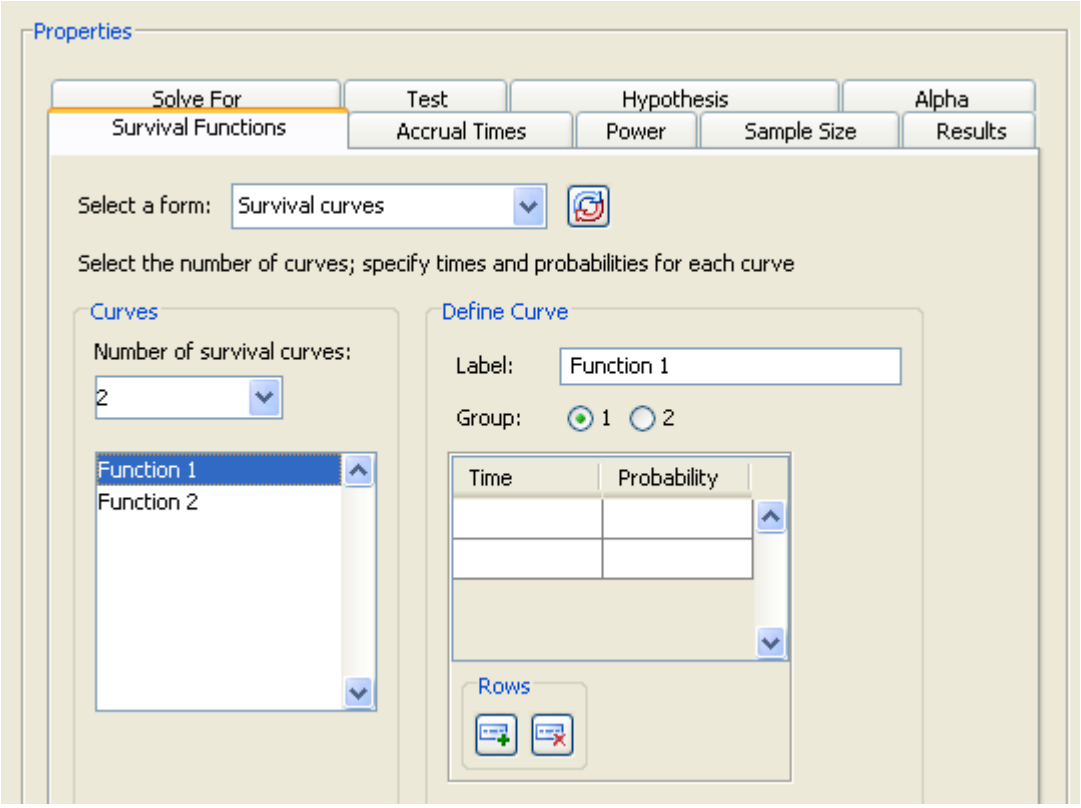


The significance level is the probability of falsely rejecting the null hypothesis. If you frequently use the same values for alpha, set them as the defaults in the Preferences window.

Survival Functions

Click the **Survival Functions** tab to select the input form for the survival functions.

Figure 71.82 Survival Functions Tab with Number of Curves



Examine the input alternatives available in the **Select a form** list. There are four alternate forms for entering survival functions. The first three apply only to exponential curves; the fourth applies to both piecewise linear and exponential curves.

Group median survival times
: Enter median survival times for the two groups.

Group hazards
: Enter hazards for the two groups.

Hazards, Hazard ratios
: Enter hazards for the reference group and hazard ratios.

Survival curves
: Enter survival probabilities and their associated times for each of several curves. Select or enter the number of curves from the drop-down list; at least two curves are required. Then, for each curve, select it in the left-hand list, select the Group 1 or Group 2 option, and then define the survival curve by entering pairs of times and probabilities. Enter a time and probability pair only if the probability is less than that of the previous pair.

For information about using the other forms, see the section "Using the Other Survival Curve Forms" on page 6055.

For each survival curve, select the curve in the left-hand list. Then, enter a descriptive label and select which group it is for. The labels should be unique. Finally, enter pairs of survival times and probabilities.

When you enter probabilities, enter a time and probability pair only when the probability for a survival curve changes. For example, if the probability for curve 1 at time 1 and 2 is 0.9 and at time 3 is 0.8, enter 0.9 for time 1 and 0.8 for time 3.

To specify an exponential survival curve, enter a single time and probability pair. In the example, the exponential curve for the existing treatment is defined by a probability of 0.5 at time 5.

The units of time for the survival curves must correspond to the units for the accrual, follow-up, and total times, which are described in the section "Accrual Times" on page 6048.

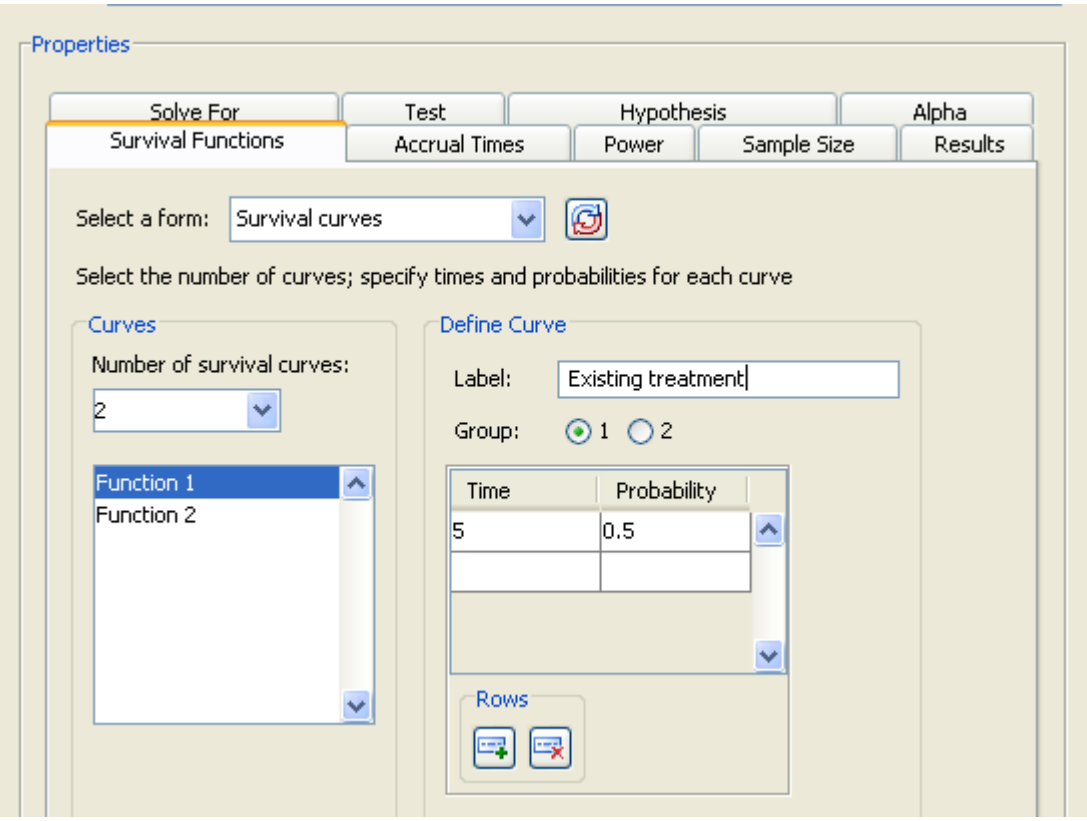
You can also compare several survival curves. For example, if you have two scenarios, A and B, for group 1's curve and two scenarios, C and D, for group 2's curve, then specify probabilities for the four curves and assign A and B to group 1 and C and D to group 2.

For the example, select the **Survival curves** form, as shown in Figure 71.82. Enter the value, 2, in the **Number of survival curves** list box.

For the example enter the following values:

- For the first survival curve, enter a label of `Existing treatment` and select the **Group 1** option. For the first curve, enter a time of 5 and a probability of 0.5. Figure 71.83 shows the resulting values.

Figure 71.83 Survival Times and Probabilities for Curve 1

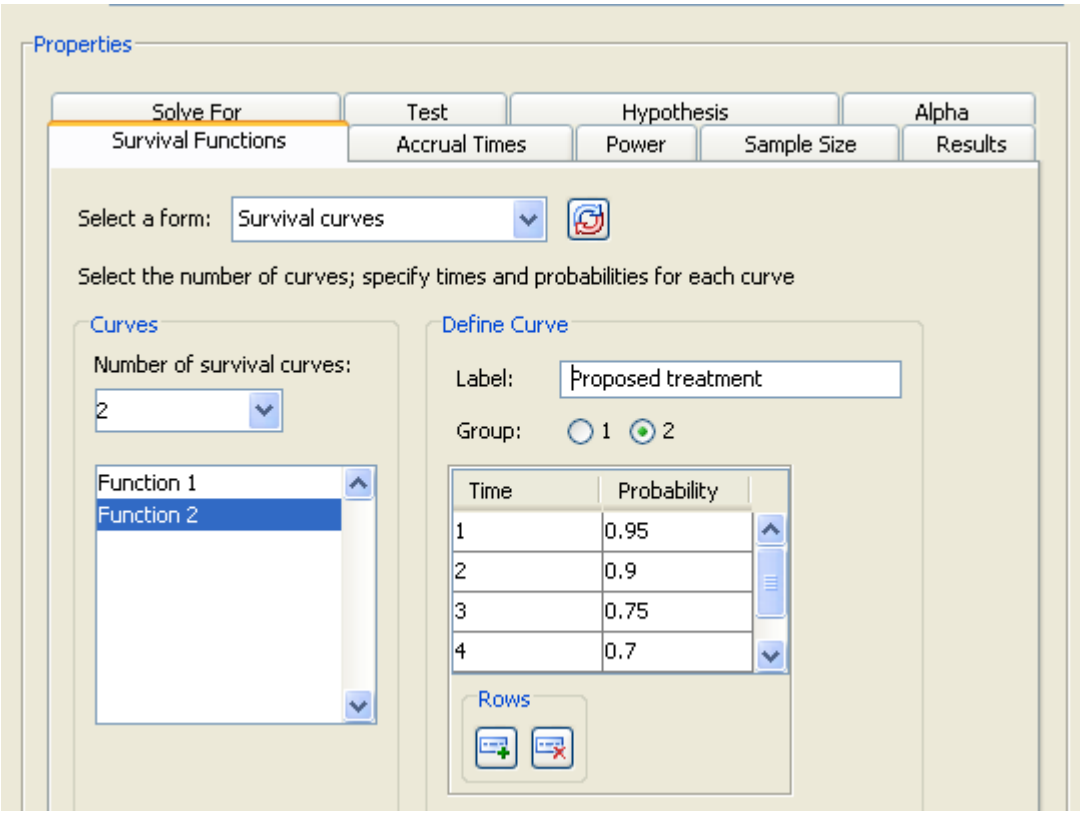


- For the second curve select `Function 2` in the selection list on the left side of the tab. Enter a label of `Proposed treatment` and select the **Group 2** option. Then, enter time values of 1 through 5 and

the corresponding probabilities of 0.95, 0.9, 0.75, 0.7, and 0.6. To add rows to the table, click the button beneath the table.

Figure 71.84 shows these values; the last row of the time and probability table is not displayed.

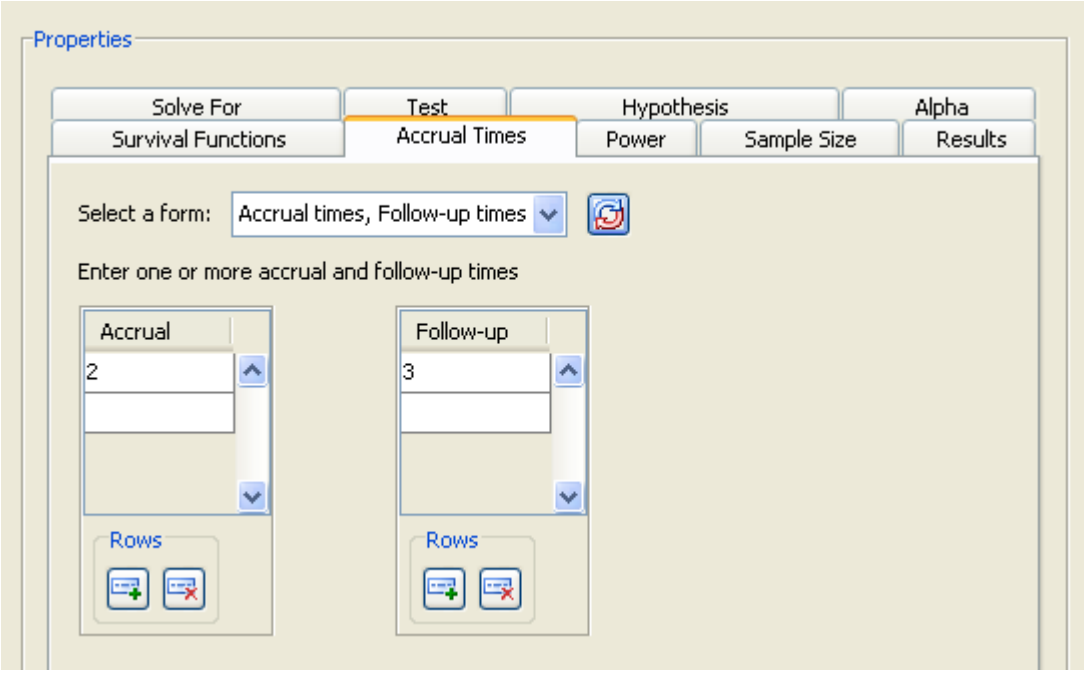
Figure 71.84 Survival Times and Probabilities for Curve 2



Accrual Times

Click the **Accrual times** tab to select an input form for accrual times and to enter the times.

Figure 71.85 Accrual Times Tab



Examine the alternatives available in the **Select a form** list.

Accrual time is the period during which subjects are brought into the study. Follow-up time is the period during which subjects are observed after all subjects have been included in the study. Total time is the sum of accrual and follow-up time. The units of time for the accrual, follow-up, and total times must correspond to the units you used specified for the survival curves.

When you enter survival curves, the sum of the accrual and follow-up times must be less than the largest time for each survival curve. This does not apply to survival curves represented by a single time, which represent exponential curves.

On the **Accrual Times** tab, there are three alternate forms for entering accrual and follow-up times:

Accrual times, Follow-up times
: Enter accrual and follow-up times.

Accrual times, Total times
: Enter accrual and total times.

Follow-up times, Total times
: Enter follow-up and total times.

For the example, select the **Accrual times, Follow-up times** form. Then enter a single value of `2` in the Accrual table and a value of `3` in the Follow-up table, as shown in Figure 71.85.

Power

Click the **Power** tab to enter one or more power values. For the example, enter a single value of `0.8`.

When you calculate sample size, it is necessary to specify one or more powers.

Summary of Input Parameters

Table 71.10 contains the values of the input parameters for the example.

Table 71.10 Summary of Input Parameters

Parameter	Value
Solve for	Sample size per group
Test	Log-rank
Hypothesis	Two-sided test
Alpha	0.05
Survival function form	Survival curves
Survival curves	See Table 71.11 and Table 71.12
Accrual and follow-up times form	Accrual time, Follow-up times
Accrual times	2
Follow-up times	3
Power	0.8

Table 71.11 and Table 71.12 contain times and probabilities for the two survival curves, respectively.

Table 71.11 Survival Times and Probabilities for Existing Treatment (Survival Curve 1)

Time	Probability
5	0.5

Table 71.12 Survival Times and Probabilities for Proposed Treatment (Survival Curve 2)

Time	Probability
1	0.95
2	0.90
3	0.75
4	0.70
5	0.60

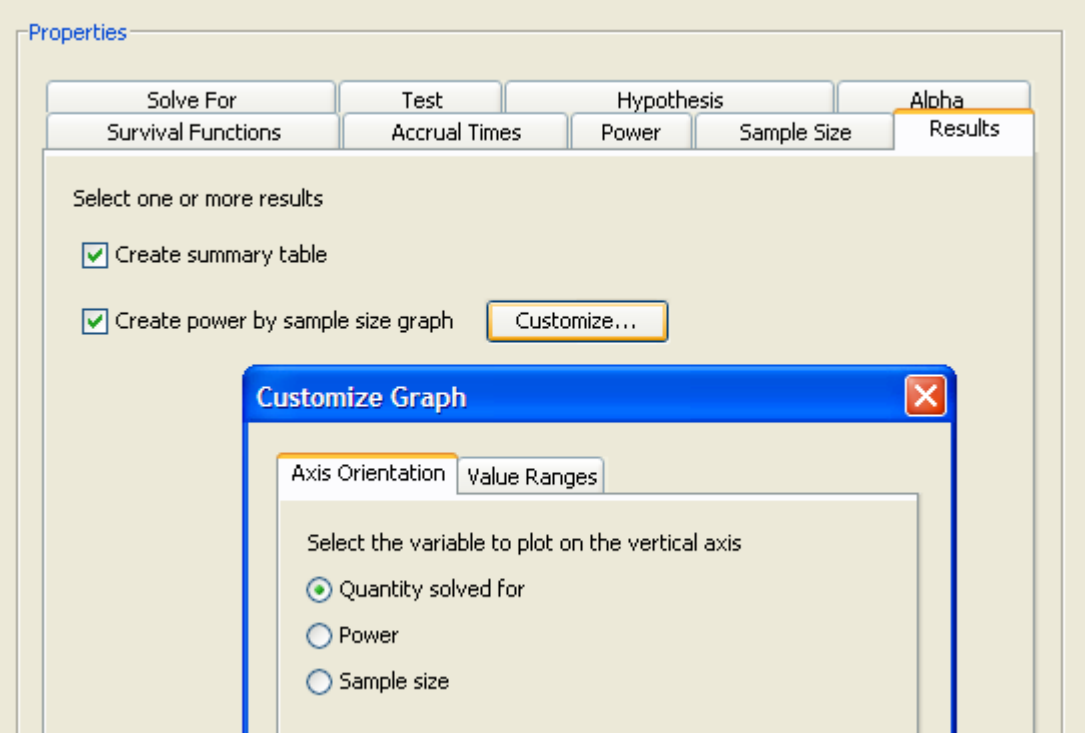
Result Options

Click the **Results** tab to specify the desired result options. For the example, request both results by selecting both the **Create summary table** and **Create power by sample size graph** check boxes.

Specifying only one power (as in this example) produces a graph with a single point. You might be interested in a plot of sample sizes for a range of powers—say, between 0.75 and 0.85. You can customize the graph by specifying the values for the power axis. Also, you might want to change the appearance of the graph to have sample size (per group) on the vertical axis and power on the horizontal axis.

Click the **Customize** button beside the **Create power by sample size graph** check box to customize the graph. The Customize Graph window is displayed, as shown in Figure 71.86.

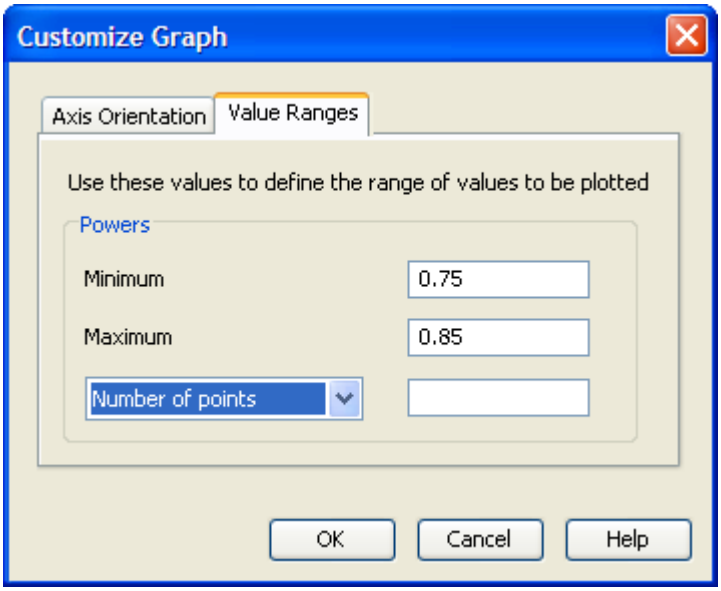
Figure 71.86 Customize Graph Window with Axis Orientation Tab



Click the **Axis Orientation** tab to select which variable to plot on the vertical axis. For the example, select the **Quantity solved for** option, as shown in Figure 71.86. This option plots sample size on the vertical axis and power on the horizontal axis. You could also have chosen the **Sample size** option.

Click the **Value Ranges** tab to enter minimum and maximum values for a plot axis. For the example, enter a minimum of `0.75` and a maximum of `0.85` in the Powers text boxes. This sets the range of values on the axis for powers. The completed Value Ranges tab of the window is displayed in Figure 71.87. You can set the axis values only for the quantity that is not being solved for.

Figure 71.87 Customize Graph Window with Value Ranges Tab



Click **OK** to save the values that you have entered and return to the Edit Properties page.

Then, click **Calculate** to perform the analysis. If there are no errors in the input parameter values, the View Results page appears. If there are errors in the input parameter values, you are prompted to correct them.

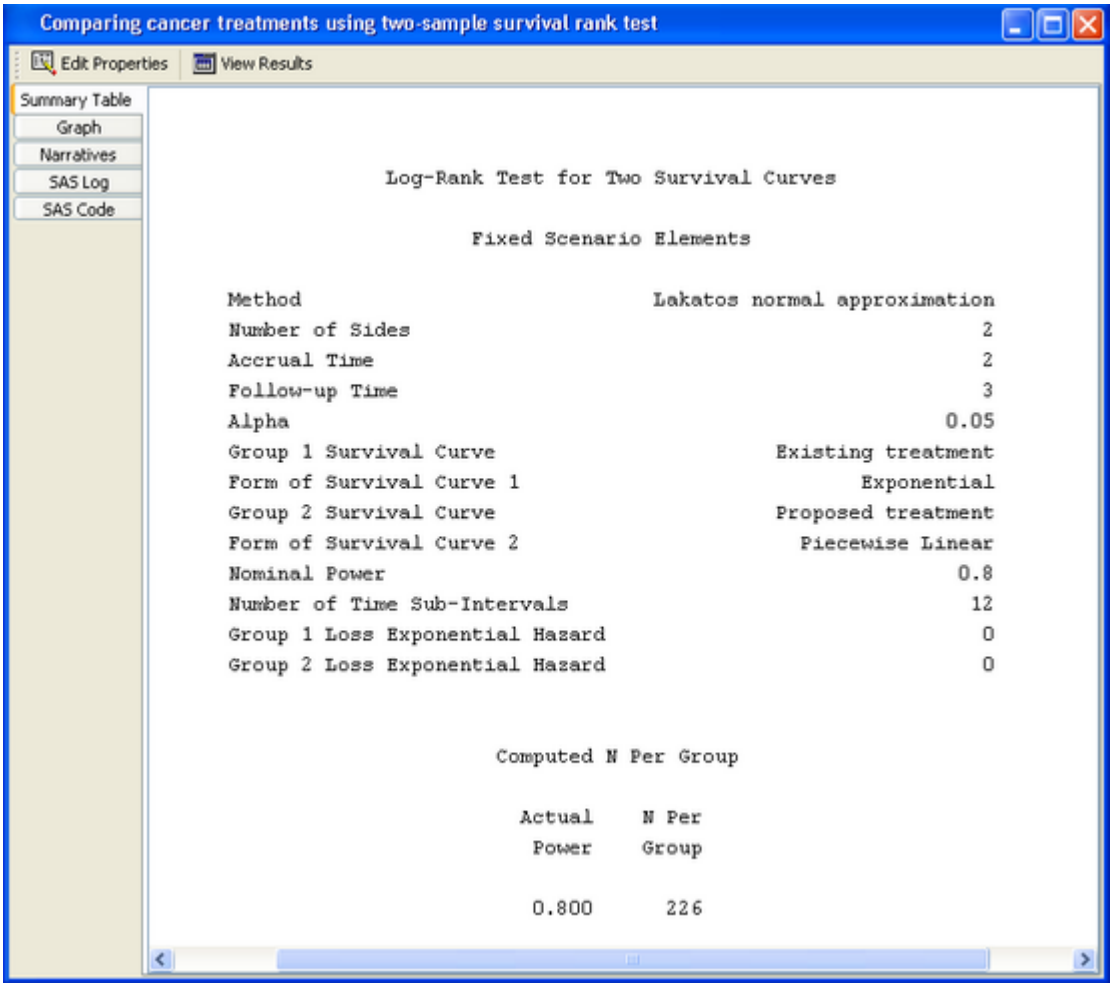
Viewing Results

The results appear in separate tabs on the View Results page of the project. Select the tab of each result that you want to view.

Summary Table

Click the **Summary Table** tab to view the summary table. It is composed of two subtables. As shown in Figure 71.88, the `Fixed Scenario Elements` and `Computed N Per Group` tables include the values of the input parameters and the computed quantity (in this case, sample size per group, `N per group`). The sample size per group for the single requested scenario is 226.

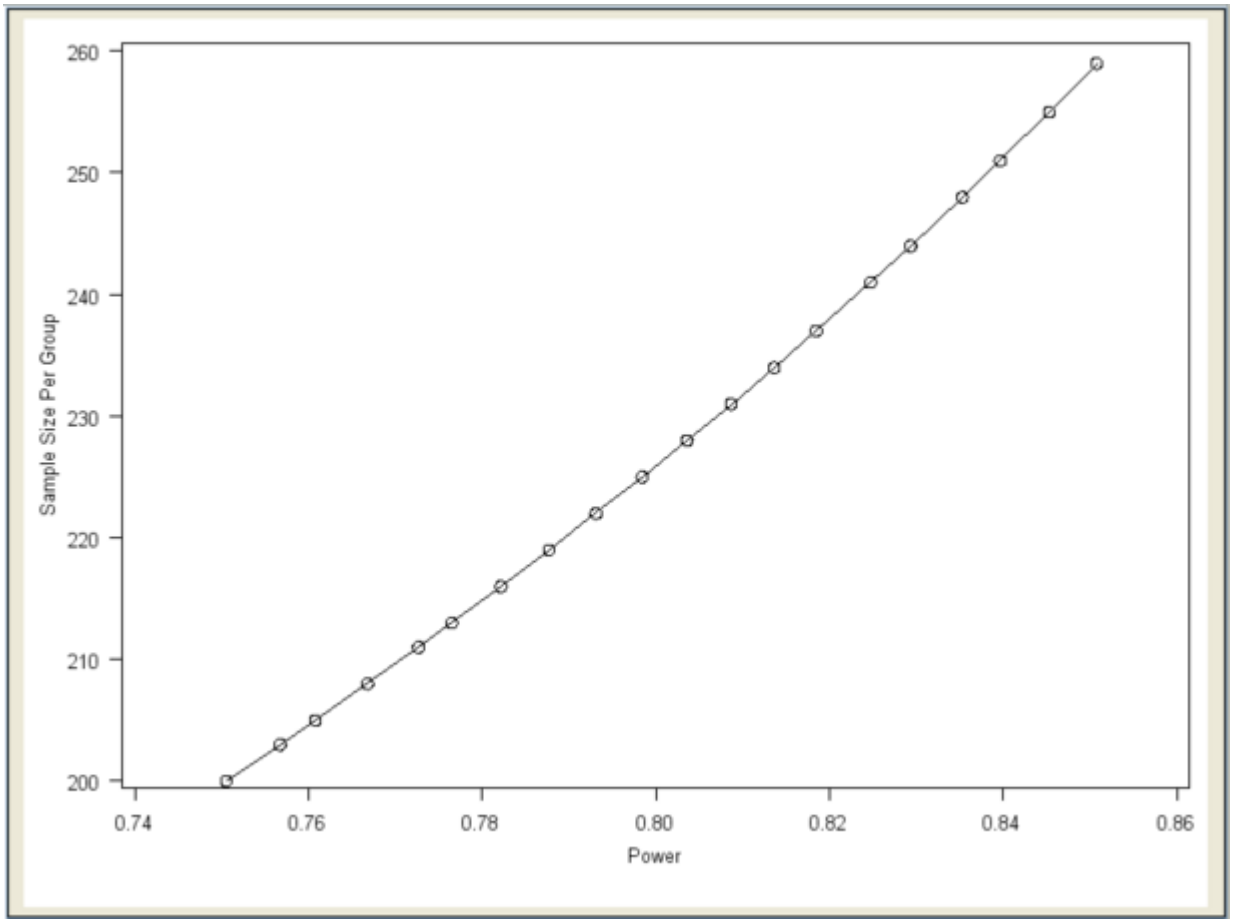
Figure 71.88 Summary Table



Power by Sample Size Graph

Click the **Graph** tab to view the power by sample size graph.

Figure 71.89 Power by Sample Size Graph



As you can see in Figure 71.89, the graph is curved slightly upward with larger powers associated with larger sample sizes. Sample size is plotted on the vertical axis as requested in the Customize Graph window.

Narratives

Click the **Narratives** tab to create one or more narratives. To generate a narrative, select the single scenario in the narrative selector table at the bottom of the tab. The narrative for this task does not include the survival times and probabilities for the survival curves:

```
For a log-rank test comparing two survival curves with a two-sided
significance level of 0.05, assuming uniform accrual with an accrual
time of 2 and a follow-up time of 3, a sample size of 226 per group is
required to obtain a power of at least 0.8 for the exponential curve,
"Existing treatment," and the piecewise linear curve, "Proposed treatment."
The actual power is 0.800.
```

For information about selecting additional narratives when multiple scenarios are present, see the section "Creating Narratives" on page 5998.

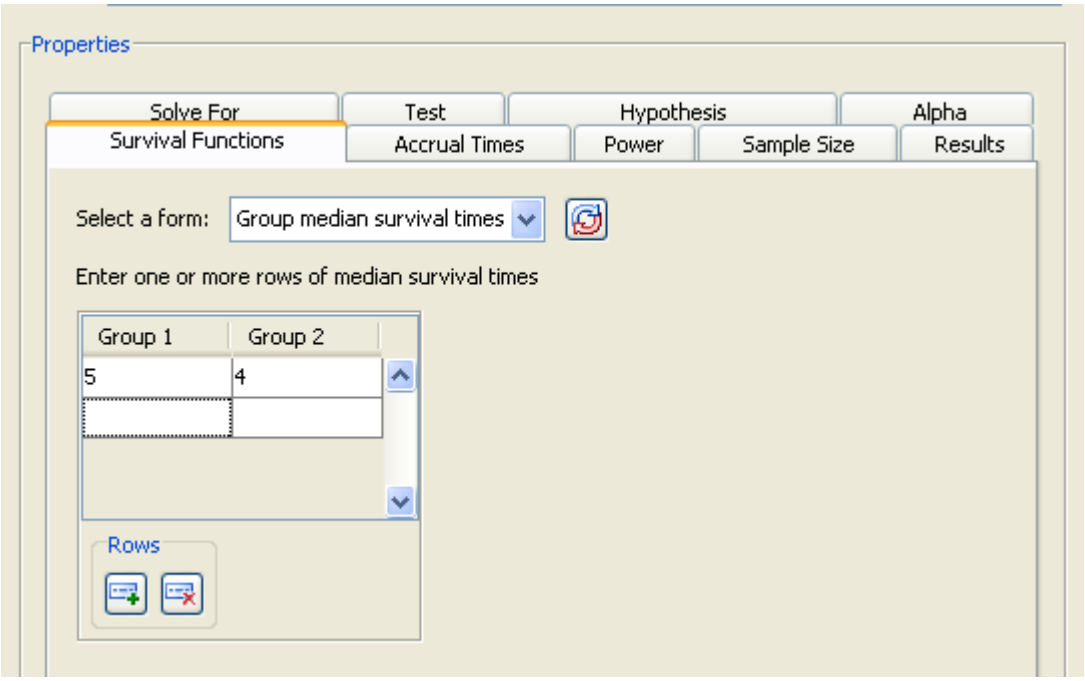
Additional Topics

Using the Other Survival Curve Forms

Survival functions can be specified as median survival times, hazards, or a combination of hazards for one group and hazard ratios. These all assume exponential curves.

Suppose you are interested in comparing the proposed and existing treatments using their median survival times. The survival times are five years and four years for the two groups, respectively.

Figure 71.90 Median Survival Times and List of Alternate Forms



Click the **Survival Functions** tab and examine the list of alternate forms available in the **Select a form:** list. For this example, select the **Group median survival times** option.

For the example, enter `5` and `4` in the first row of the table. The completed table is shown in Figure 71.90.

You can enter one or more sets of two median survival times. The results of the analysis are not shown.

Chapter 72

The PRINCOMP Procedure

Contents

Overview: PRINCOMP Procedure

The PRINCOMP procedure performs principal component analysis. As input you can use raw data, a correlation matrix, a covariance matrix, or a sum-of-squares-and-crossproducts (SSCP) matrix. You can create output data sets containing eigenvalues, eigenvectors, and standardized or unstandardized principal component scores.

Principal component analysis is a multivariate technique for examining relationships among several quantitative variables. The choice between using factor analysis and using principal component analysis depends

in part on your research objectives. You should use the PRINCOMP procedure if you are interested in summarizing data and detecting linear relationships. You can use principal components to reduce the number of variables in regression, clustering, and so on. See Chapter 9, "Introduction to Multivariate Procedures," for a detailed comparison of the PRINCOMP and FACTOR procedures.

You can use ODS Graphics to display the scree plot, component pattern plot, component pattern profile plot, matrix plot of component scores, and component score plots. These plots are especially valuable tools in exploratory data analysis.

Principal component analysis was originated by Pearson (1901) and later developed by Hotelling (1933). The application of principal components is discussed by Rao (1964), Cooley and Lohnes (1971), and Gnanadesikan (1977). Excellent statistical treatments of principal components are found in Kshirsagar (1972), Morrison (1976), and Mardia, Kent, and Bibby (1979).

Given a data set with p numeric variables, you can compute p principal components. Each principal component is a linear combination of the original variables, with coefficients equal to the eigenvectors of the correlation or covariance matrix. The eigenvectors are customarily taken with unit length. The principal components are sorted by descending order of the eigenvalues, which are equal to the variances of the components.

Principal components have a variety of useful properties (Rao 1964; Kshirsagar 1972):

- The eigenvectors are orthogonal, so the principal components represent jointly perpendicular directions through the space of the original variables.
- The principal component scores are jointly uncorrelated. Note that this property is quite distinct from the previous one.
- The first principal component has the largest variance of any unit-length linear combination of the observed variables. The jth principal component has the largest variance of any unit-length linear combination orthogonal to the first $j-1$ principal components. The last principal component has the smallest variance of any linear combination of the original variables.
- The scores on the first j principal components have the highest possible generalized variance of any set of unit-length linear combinations of the original variables.
- The first j principal components provide a least squares solution to the model

  $$\mathbf{Y} = \mathbf{XB} + \mathbf{E}$$

  where $\mathbf{Y}$ is an $n \times p$ matrix of the centered observed variables; $\mathbf{X}$ is the $n \times j$ matrix of scores on the first j principal components; $\mathbf{B}$ is the $j \times p$ matrix of eigenvectors; $\mathbf{E}$ is an $n \times p$ matrix of residuals; and you want to minimize trace($\mathbf{E}'\mathbf{E}$), the sum of all the squared elements in $\mathbf{E}$. In other words, the first j principal components are the best linear predictors of the original variables among all possible sets of j variables, although any nonsingular linear transformation of the first j principal components would provide equally good prediction. The same result is obtained if you want to minimize the determinant or the Euclidean (Schur, Frobenious) norm of $\mathbf{E}'\mathbf{E}$ rather than the trace.
- In geometric terms, the j-dimensional linear subspace spanned by the first j principal components provides the best possible fit to the data points as measured by the sum of squared perpendicular distances from each data point to the subspace. This is in contrast to the geometric interpretation

of least squares regression, which minimizes the sum of squared vertical distances. For example, suppose you have two variables. Then, the first principal component minimizes the sum of squared perpendicular distances from the points to the first principal axis. This is in contrast to least squares, which would minimize the sum of squared vertical distances from the points to the fitted line.

Principal component analysis can also be used for exploring polynomial relationships and for multivariate outlier detection (Gnanadesikan 1977), and it is related to factor analysis, correspondence analysis, allometry, and biased regression techniques (Mardia, Kent, and Bibby 1979).

Getting Started: PRINCOMP Procedure

The following data provide crime rates per 100,000 people in seven categories for each of the 50 states in 1977. Since there are seven numeric variables, it is impossible to plot all the variables simultaneously. Principal components can be used to summarize the data in two or three dimensions, and they help to visualize the data. The following statements produce Figure 72.1 through Figure 72.5.

```

proc princomp out=Crime_Components plots= score(ellipse ncomp=3);
   id State;
run;
```

Figure 72.1 displays the PROC PRINCOMP output, beginning with simple statistics followed by the correlation matrix. The PROC PRINCOMP statement requests by default principal components computed from the correlation matrix, so the total variance is equal to the number of variables, 7.

Figure 72.1 Number of Observations and Simple Statistics from the PRINCOMP Procedure

Variables              7
```

Figure 72.1 *continued*

Simple Statistics

	Murder	Rape	Robbery	Assault
Mean	7.444000000	25.73400000	124.0920000	211.3000000
StD	3.866768941	10.75962995	88.3485672	100.2530492

Simple Statistics

	Burglary	Larceny	Auto_Theft
Mean	1291.904000	2671.288000	377.5260000
StD	432.455711	725.908707	193.3944175

Correlation Matrix

	Murder	Rape	Robbery	Assault	Burglary	Larceny	Auto_Theft
Murder	1.0000	0.6012	0.4837	0.6486	0.3858	0.1019	0.0688
Rape	0.6012	1.0000	0.5919	0.7403	0.7121	0.6140	0.3489
Robbery	0.4837	0.5919	1.0000	0.5571	0.6372	0.4467	0.5907
Assault	0.6486	0.7403	0.5571	1.0000	0.6229	0.4044	0.2758
Burglary	0.3858	0.7121	0.6372	0.6229	1.0000	0.7921	0.5580
Larceny	0.1019	0.6140	0.4467	0.4044	0.7921	1.0000	0.4442
Auto_Theft	0.0688	0.3489	0.5907	0.2758	0.5580	0.4442	1.0000

Figure 72.2 displays the eigenvalues. The first principal component explains about 58.8% of the total variance, the second principal component explains about 17.7%, and the third principal component explains about 10.4%. Note that the eigenvalues sum to the total variance.

The eigenvalues indicate that two or three components provide a good summary of the data, two components accounting for 76% of the total variance and three components explaining 87%. Subsequent components contribute less than 5% each.

Figure 72.2 Results of Principal Component Analysis: PROC PRINCOMP

Eigenvalues of the Correlation Matrix

	Eigenvalue	Difference	Proportion	Cumulative
1	4.11495951	2.87623768	0.5879	0.5879
2	1.23872183	0.51290521	0.1770	0.7648
3	0.72581663	0.40938458	0.1037	0.8685
4	0.31643205	0.05845759	0.0452	0.9137
5	0.25797446	0.03593499	0.0369	0.9506
6	0.22203947	0.09798342	0.0317	0.9823
7	0.12405606		0.0177	1.0000

Figure 72.3 displays the eigenvectors. From the eigenvectors matrix, you can represent the first principal component Prin1 as a linear combination of the original variables:

$$\begin{aligned}\text{Prin1} &= 0.300279 \times (\text{Murder}) \\ &\quad + 0.431759 \times (\text{Rape}) \\ &\quad + 0.396875 \times (\text{Robbery}) \\ &\quad . \\ &\quad . \\ &\quad . \\ &\quad + 0.295177 \times (\text{Auto\_Theft})\end{aligned}$$

Similarly, the second principal component Prin2 is

$$\begin{aligned}\text{Prin2} &= -0.629174 \times (\text{Murder}) \\ &\quad - 0.169435 \times (\text{Rape}) \\ &\quad + 0.042247 \times (\text{Robbery}) \\ &\quad . \\ &\quad . \\ &\quad . \\ &\quad - 0.502421 \times (\text{Auto\_Theft})\end{aligned}$$

where the variables are standardized.

Figure 72.3 Results of Principal Component Analysis: PROC PRINCOMP

Eigenvectors

	Prin1	Prin2	Prin3	Prin4	Prin5	Prin6	Prin7
Murder	0.300279	-.629174	0.178245	-.232114	0.538123	0.259117	0.267593
Rape	0.431759	-.169435	-.244198	0.062216	0.188471	-.773271	-.296485
Robbery	0.396875	0.042247	0.495861	-.557989	-.519977	-.114385	-.003903
Assault	0.396652	-.343528	-.069510	0.629804	-.506651	0.172363	0.191745
Burglary	0.440157	0.203341	-.209895	-.057555	0.101033	0.535987	-.648117
Larceny	0.357360	0.402319	-.539231	-.234890	0.030099	0.039406	0.601690
Auto_Theft	0.295177	0.502421	0.568384	0.419238	0.369753	-.057298	0.147046

The first component is a measure of the overall crime rate since the first eigenvector shows approximately equal loadings on all variables. The second eigenvector has high positive loadings on variables Auto_Theft and Larceny and high negative loadings on variables Murder and Assault. There is also a small positive loading on Burglary and a small negative loading on Rape. This component seems to measure the preponderance of property crime over violent crime. The interpretation of the third component is not obvious.

The ODS GRAPHICS statement enables the PRINCOMP procedure to produce statistical graphs by using ODS Graphics. See Chapter 21, "Statistical Graphics Using ODS," for more information. PLOTS=SCORE(ELLIPSE NCOMP=3) in the PROC PRINCOMP statement requests the pairwise component score plots for the first three components with a 95% prediction ellipse overlaid on each of the scatter plot. Figure 72.4 shows the plot of the first two components. It is possible to identify regional trends on the plot of the first two components. Nevada and California are at the extreme right, with high overall crime rates but an average ratio of property crime to violent crime. North and South Dakota are at the extreme left, with low overall crime rates. Southeastern states tend to be at the bottom of the plot, with a higher-than-average ratio of violent crime to property crime. New England states tend to be in the upper part of the plot, with a higher-than-average ratio of property crime to violent crime. Assuming the first two components are from a bivariate normal distribution, the ellipse identifies Nevada as a possible outlier.

Figure 72.4 Plot of the First Two Component Scores

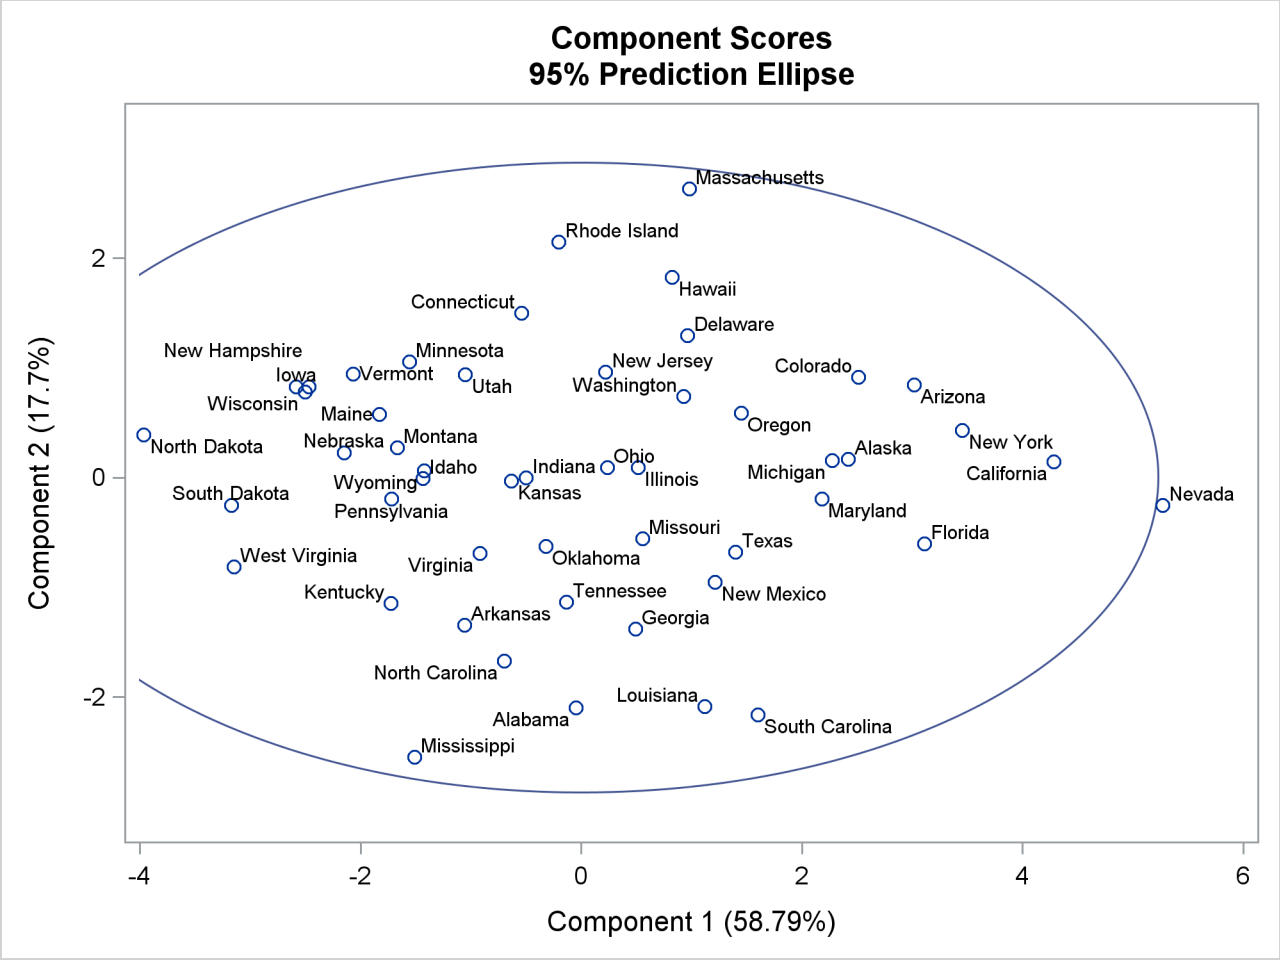

Figure 72.5 shows the plot of the first and third components. Assuming the first and the third components are from a bivariate normal distribution, the ellipse identifies Nevada, Massachusetts, and New York as possible outliers.

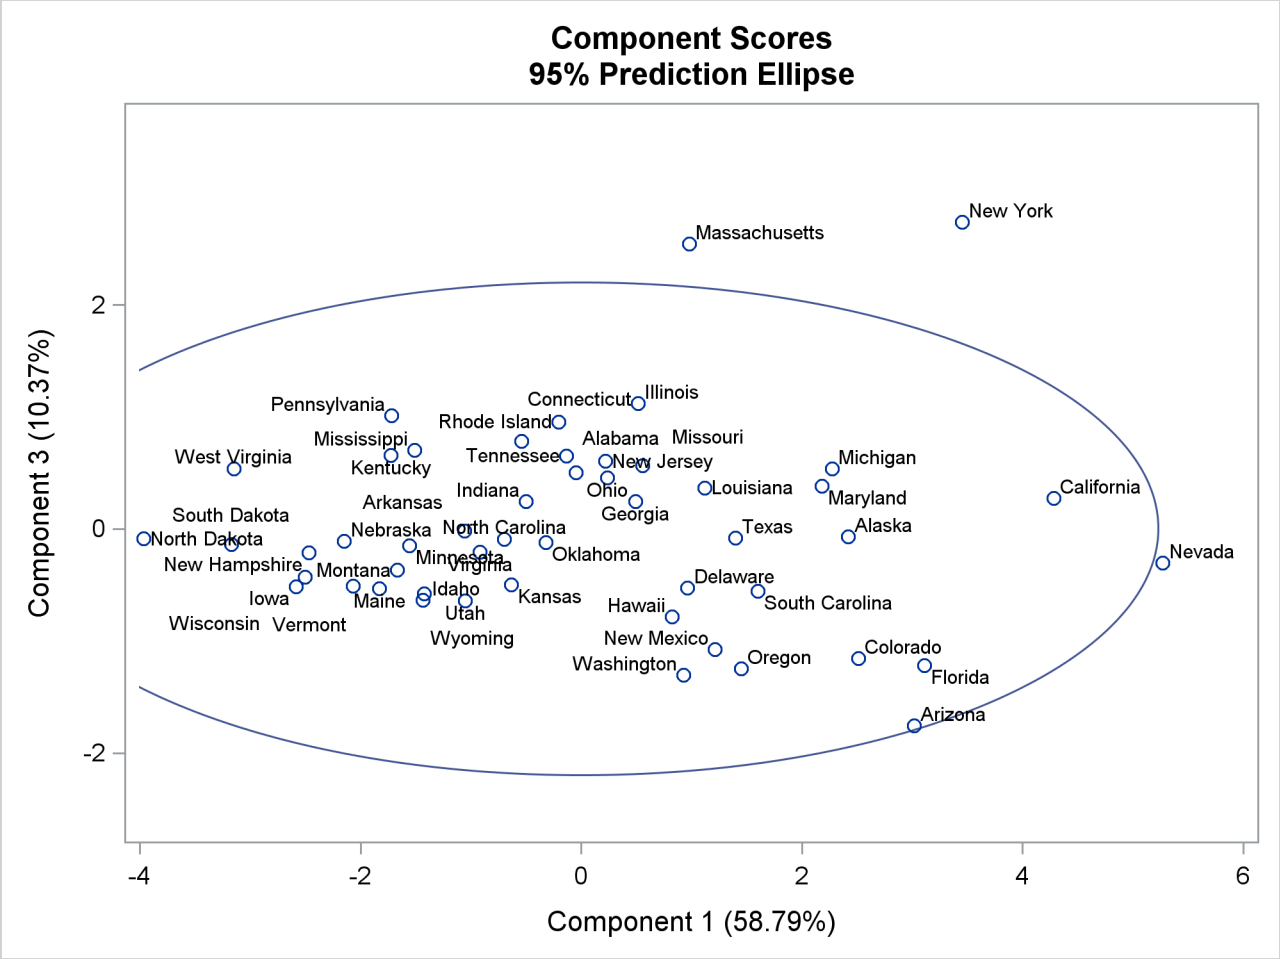
Figure 72.5 Plot of the First and Third Component Scores



The most striking feature of the plot of the first and third principal components is that Massachusetts and New York are outliers on the third component.

Syntax: PRINCOMP Procedure

The following statements are available in PROC PRINCOMP:

PROC PRINCOMP < *options* > **;**
BY *variables* **;**
FREQ *variable* **;**
ID *variables* **;**
PARTIAL *variables* **;**
VAR *variables* **;**
WEIGHT *variable* **;**

Usually only the VAR statement is used in addition to the PROC PRINCOMP statement. The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC PRINCOMP statement. The remaining statements are described in alphabetical order.

PROC PRINCOMP Statement

PROC PRINCOMP < *options* > **;**

The PROC PRINCOMP statement starts the PRINCOMP procedure and optionally identifies input and output data sets, specifies the analyses performed, and controls displayed output. Table 72.1 summarizes the options.

Table 72.1 Summary of PROC PRINCOMP Statement Options

Option	Description
Specify data sets	
DATA=	Specifies input data set name
OUT=	Specifies output data set name
OUTSTAT=	Specifies output data set name containing various statistics
Specify details of analysis	
COV	Computes the principal components from the covariance matrix
N=	Specifies the number of principal components to be computed
NOINT	Omits the intercept from the model
PREFIX=	Specifies a prefix for naming the principal components
PARPREFIX=	Specifies a prefix for naming the residual variables
SINGULAR=	Specifies the singularity criterion
STD	Standardizes the principal component scores
VARDEF=	Specifies the divisor used in calculating variances and standard deviations
Suppress the display of output	
NOPRINT	Suppresses the display of all output
Specify ODS Graphics details	
PLOTS=	Specifies options that control the details of the plots

The following list provides details about these options.

COVARIANCE

COV

computes the principal components from the covariance matrix. If you omit the COV option, the correlation matrix is analyzed. Use of the COV option causes variables with large variances to be more strongly associated with components with large eigenvalues and causes variables with small variances to be more strongly associated with components with small eigenvalues. You should not specify the COV option unless the units in which the variables are measured are comparable or the variables are standardized in some way.

DATA=*SAS-data-set*

specifies the SAS data set to be analyzed. The data set can be an ordinary SAS data set or a TYPE=ACE, TYPE=CORR, TYPE=COV, TYPE=FACTOR, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV data set (see Appendix A, "Special SAS Data Sets"). Also, the PRINCOMP procedure can read the _TYPE_='COVB' matrix from a TYPE=EST data set. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

N=*number*

specifies the number of principal components to be computed. The default is the number of variables. The value of the N= option must be an integer greater than or equal to zero.

NOINT

omits the intercept from the model. In other words, the NOINT option requests that the covariance or correlation matrix not be corrected for the mean. When you use the PRINCOMP procedure with the NOINT option, the covariance matrix and, hence, the standard deviations are not corrected for the mean. If you are interested in the standard deviations corrected for the mean, you can get them by using a procedure such as the MEANS procedure.

If you use a TYPE=SSCP data set as input to the PRINCOMP procedure and list the variable Intercept in the VAR statement, the procedure acts as if you had also specified the NOINT option. If you use NOINT and also create an OUTSTAT= data set, the data set is TYPE=UCORR or TYPE=UCOV rather than TYPE=CORR or TYPE=COV.

NOPRINT

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, "Using the Output Delivery System."

OUT=*SAS-data-set*

creates an output SAS data set that contains all the original data as well as the principal component scores.

If you want to create a permanent SAS data set, you must specify a two-level name. For details about OUT= data sets, see the section "Output Data Sets" on page 6072. See *SAS Language Reference: Concepts* for more information about permanent SAS data sets.

OUTSTAT=*SAS-data-set*

creates an output SAS data set that contains means, standard deviations, number of observations, correlations or covariances, eigenvalues, and eigenvectors. If you specify the COV option, the data set is TYPE=COV or TYPE=UCOV, depending on the NOINT option, and it contains covariances; otherwise, the data set is TYPE=CORR or TYPE=UCORR, depending on the NOINT option, and it contains correlations. If you specify the PARTIAL statement, the OUTSTAT= data set contains R squares as well.

If you want to create a permanent SAS data set, you must specify a two-level name. For details about OUTSTAT= data sets, see the section "Output Data Sets" on page 6072. See *SAS Language Reference: Concepts* for more information about permanent SAS data sets.

PLOTS < **(***global-plot-options***)** > < **=** *plot-request* < *(options)* > >

PLOTS < **(***global-plot-options***)** > < **= (***plot-request* < *(options)* > < **...** *plot-request* < *(options)* > **>) >**

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=(scatter pattern)
plots(unpack)=scree
plots(ncomp=3 flip)=(pattern(circles=0.5 1.0) score)
```

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;
proc princomp plots=all;
   var x1--x10;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

If ODS Graphics is enabled, but do not specify the PLOTS= option, PROC PRINCOMP produces the scree plot by default.

The global plot options include the following:

FLIP

flips or interchanges the X-axis and Y-axis dimension for the component score plots and the component pattern plots. For example, if there are three components, the default plots (y * x) are Component 2 * Component 1, Component 3 * Component 1, and Component 3 * Component 2. When you specify PLOTS(FLIP), the plots are Component 1 * Component 2, Component 1 * Component 3, and Component 2 * Component 3.

NCOMP=*n*

specifies the number of components $n(\geq 2)$ to be plotted for the component pattern plots and the component score plots. If the NCOMP= option is again specified in an individual plot, such as PLOTS=SCORE(NCOMP= m), the value m will determine the number of components to be plotted in the component score plots. Be aware that the number of plots ($\frac{n\times(n-1)}{2}$) produced grows quadratically when n increases. The default is 5 or the total number of components $m(\geq 2)$, whichever is smaller. If $n > m$, NCOMP= m will be used.

ONLY

suppresses the default plots. Only plots specifically requested are displayed.

UNPACKPANEL

UNPACK

suppresses paneling in the scree plot. By default, multiple plots can appear in an output panel. Specify UNPACKPANEL to get each plot in a separate panel. You can specify PLOTS(UNPACKPANEL) to unpack the default plots. You can also specify UNPACKPANEL as a suboption with SCREE (such as PLOTS=SCREE(UNPACKPANEL)).

The plot requests include the following:

ALL
produces all appropriate plots. You can specify other options with ALL; for example, to request all plots and unpack only the scree plot, specify PLOTS=(ALL SCREE(UNPACKPANEL)).

EIGEN | EIGENVALUE | SCREE < (UNPACKPANEL) >
produces the scree plot of eigenvalues and proportion variance explained. By default, both plots are output in a panel. Specify PLOTS= SCREE(UNPACKPANEL) to get each plot in a separate panel.

MATRIX
produces the matrix plot of principal component scores.

NONE
suppresses the display of all graphics output.

PATTERN < (*pattern-options*) >
produces the pairwise component pattern plots. Each variable is plotted as an observation whose coordinates are correlations between the variable and the two corresponding components on the plot. Use the NCOMP= option (for instance, PLOTS=PATTERN(NCOMP=3)) described in the following to control the number of plots to be displayed.

The available *pattern-options* are as follows:

CIRCLES < = *number list* >
plots the variance percentage circles. Each number in the list must be greater than 0. If the number is greater than or equal to 1, it is interpreted as a percentage and divided by 100; CIRCLES=0.05 and CIRCLES=5 are equivalent. For each number (c) specified, a ($c \times 100\%$) variance circle is created.

By default, there is no circle for the scatter pattern plot (PLOTS=PATTERN) and a unit circle with a 100% variance circle is plotted for the vector pattern plot (PLOTS=PATTERN (VECTOR)). You can display multiple circles by specifying PLOTS=PATTERN(CIRCLES=). For example, specifying PLOTS=PATTERN(CIRCLES= .3 .6 1.0) will display the 30%, 60%, and 100% variance circles in the pattern plots.

FLIP
flips or interchanges the X-axis and Y-axis dimensions for the component pattern plots. Specify PLOTS=PATTERN(FLIP) to flip the X-axis and Y-axis dimensions.

NCOMP=*n*
specifies the number of components $n(\geq 2)$ to be plotted. The default is 5 or the total number of components $m(\geq 2)$, whichever is smaller. If $n > m$, NCOMP= m will be used. Be aware that the number of plots ($\frac{n \times (n-1)}{2}$) produced grows quadratically when n increases.

VECTOR
plots pattern in a vector form.

PATTERNPROFILE | PROFILE

produces the pattern profile plot. There is a profile for each component. The Y-axis value represents the correlation between the variable (corresponding to the X-axis value) and the profiled principal component.

SCORE < (*score-options*) >

produces the pairwise component score plots. Use the NCOMP= option (for instance, PLOTS=SCORE(NCOMP=3)) described in the following to control the number of plots to be displayed.

The available *score-options* are as follows:

ALPHA=*number list*

specifies a list of numbers for the prediction ellipses to be displayed in the score plots. Each value (α) in the list must be greater than 0. If α is greater than or equal to 1, it is interpreted as a percentage and divided by 100; ALPHA=0.05 and ALPHA=5 are equivalent.

ELLIPSE

requests prediction ellipses for the principal component scores of a new observation to be created in the principal component score plots. See the section "Confidence and Prediction Ellipses" in "The CORR Procedure" (*Base SAS Procedures Guide: Statistical Procedures*), for details about the computation of a prediction ellipse.

FLIP

flips or interchanges the X-axis and Y-axis dimensions for the component score plots. Specify PLOTS=SCORE(FLIP) to flip the X-axis and Y-axis dimensions.

NCOMP=*n*

specifies the number of components $n(\geq 2)$ to be plotted. The default is 5 or the total number of components $m(\geq 2)$, whichever is smaller. If $n > m$, NCOMP= m will be used. Be aware that the number of plots ($\frac{n\times(n-1)}{2}$) produced grows quadratically when n increases.

PREFIX=*name*

specifies a prefix for naming the principal components. By default, the names are Prin1, Prin2, ..., Prin*n*. If you specify PREFIX=ABC, the components are named ABC1, ABC2, ABC3, and so on. The number of characters in the prefix plus the number of digits required to designate the variables should not exceed the current name length defined by the VALIDVARNAME= system option.

PARPREFIX=*name*

PPREFIX=*name*

RPREFIX=*name*

specifies a prefix for naming the residual variables in the OUT= data set and the OUTSTAT= data set. By default, the prefix is R_. The number of characters in the prefix plus the maximum length of the variable names should not exceed the current name length defined by the VALIDVARNAME= system option.

SINGULAR=*p*

SING=*p*

specifies the singularity criterion, where $0 < p < 1$. If a variable in a PARTIAL statement has an R square as large as $1 - p$ when predicted from the variables listed before it in the statement, the variable is assigned a standardized coefficient of 0. By default, SINGULAR=1E−8.

STANDARD

STD

standardizes the principal component scores in the OUT= data set to unit variance. If you omit the STANDARD option, the scores have variance equal to the corresponding eigenvalue. Note that STANDARD has no effect on the eigenvalues themselves.

VARDEF=DF | N | WDF | WEIGHT | WGT

specifies the divisor used in calculating variances and standard deviations. By default, VARDEF=DF. The following table displays the values and associated divisors.

Value	Divisor		Formula
DF	error degrees of freedom	$n - i$	(before partialing)
		$n - p - i$	(after partialing)
N	number of observations	n	
WEIGHT | WGT	sum of weights	$\sum_{j=1}^{n} w_j$	
WDF	sum of weights minus one	$\left(\sum_{j=1}^{n} w_j\right) - i$	(before partialing)
		$\left(\sum_{j=1}^{n} w_j\right) - p - i$	(after partialing)

In the formulas for VARDEF=DF and VARDEF=WDF, p is the number of degrees of freedom of the variables in the PARTIAL statement, and i is 0 if the NOINT option is specified and 1 otherwise.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC PRINCOMP to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the PRINCOMP procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* **;**

The FREQ statement specifies a variable that provides frequencies for each observation in the DATA= data set. Specifically, if *n* is the value of the FREQ variable for a given observation, then that observation is used *n* times.

The analysis produced using a FREQ statement reflects the expanded number of observations. The total number of observations is considered equal to the sum of the FREQ variable. You could produce the same analysis (without the FREQ statement) by first creating a new data set that contains the expanded number of observations. For example, if the value of the FREQ variable is 5 for the first observation, the first 5 observations in the new data set would be identical. Each observation in the old data set would be replicated n_j times in the new data set, where n_j is the value of the FREQ variable for that observation.

If the value of the FREQ variable is missing or is less than one, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

ID Statement

ID *variables* **;**

The ID statement labels observations with values from the first ID variable in the principal component score plot. If one or more ID variables are specified, their values are displayed in tooltips of the component score plot and the matrix plot of component scores.

PARTIAL Statement

PARTIAL *variables* **;**

If you want to analyze a partial correlation or covariance matrix, specify the names of the numeric variables to be partialed out in the PARTIAL statement. The PRINCOMP procedure computes the principal components of the residuals from the prediction of the VAR variables by the PARTIAL variables. If you request an OUT= or OUTSTAT= data set, the residual variables are named by prefixing the characters R_ by default or the string specified in the PARPREFIX= option to the VAR variables.

VAR Statement

VAR *variables* **;**

The VAR statement lists the numeric variables to be analyzed. If you omit the VAR statement, all numeric variables not specified in other statements are analyzed. If, however, the DATA= data set is TYPE=SSCP, the default set of variables used as VAR variables does not include Intercept so that the correlation or covariance matrix is constructed correctly. If you want to analyze Intercept as a separate variable, you should specify it in the VAR statement.

WEIGHT Statement

WEIGHT *variable* **;**

If you want to use relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances.

The observation is used in the analysis only if the value of the WEIGHT statement variable is nonmissing and is greater than zero.

Details: PRINCOMP Procedure

Missing Values

Observations with missing values for any variable in the VAR, PARTIAL, FREQ, or WEIGHT statement are omitted from the analysis and are given missing values for principal component scores in the OUT= data set. If a correlation, covariance, or SSCP matrix is read, it can contain missing values as long as every pair of variables has at least one nonmissing entry.

Output Data Sets

OUT= Data Set

The OUT= data set contains all the variables in the original data set plus new variables containing the principal component scores. The N= option determines the number of new variables. The names of the

new variables are formed by concatenating the value given by the PREFIX= option (or Prin if PREFIX= is omitted) and the numbers 1, 2, 3, and so on. The new variables have mean 0 and variance equal to the corresponding eigenvalue, unless you specify the STANDARD option to standardize the scores to unit variance. Also, if you specify the COV option, the procedure computes the principal component scores from the corrected or the uncorrected (if the NOINT option is specified) variables rather than the standardized variables.

If you use a PARTIAL statement, the OUT= data set also contains the residuals from predicting the VAR variables from the PARTIAL variables.

An OUT= data set cannot be created if the DATA= data set is TYPE=ACE, TYPE=CORR, TYPE=COV, TYPE=EST, TYPE=FACTOR, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV.

OUTSTAT= Data Set

The OUTSTAT= data set is similar to the TYPE=CORR data set produced by the CORR procedure. The following table relates the TYPE= value for the OUTSTAT= data set to the options specified in the PROC PRINCOMP statement.

Options	**TYPE=**
(default)	CORR
COV	COV
NOINT	UCORR
COV NOINT	UCOV

Note that the default (neither the COV nor NOINT option) produces a TYPE=CORR data set.

The new data set contains the following variables:

- the BY variables, if any
- two new variables, _TYPE_ and _NAME_, both character variables
- the variables analyzed (that is, those in the VAR statement); or, if there is no VAR statement, all numeric variables not listed in any other statement; or, if there is a PARTIAL statement, the residual variables as described under the OUT= data set

Each observation in the new data set contains some type of statistic as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are as follows:

MEAN — mean of each variable. If you specify the PARTIAL statement, this observation is omitted.

STD — standard deviations. If you specify the COV option, this observation is omitted, so the SCORE procedure does not standardize the variables before computing scores. If you use the PARTIAL statement, the standard deviation of a variable is computed as its root mean squared error as predicted from the PARTIAL variables.

USTD	uncorrected standard deviations. When you specify the NOINT option in the PROC PRINCOMP statement, the OUTSTAT= data set contains standard deviations not corrected for the mean. However, if you also specify the COV option in the PROC PRINCOMP statement, this observation is omitted.
N	number of observations on which the analysis is based. This value is the same for each variable. If you specify the PARTIAL statement and the value of the VARDEF= option is DF or unspecified, then the number of observations is decremented by the degrees of freedom for the PARTIAL variables.
SUMWGT	the sum of the weights of the observations. This value is the same for each variable. If you specify the PARTIAL statement and VARDEF=WDF, then the sum of the weights is decremented by the degrees of freedom for the PARTIAL variables. This observation is output only if the value is different from that in the observation with _TYPE_='N'.
CORR	correlations between each variable and the variable specified by the _NAME_ variable. The number of observations with _TYPE_='CORR' is equal to the number of variables being analyzed. If you specify the COV option, no _TYPE_='CORR' observations are produced. If you use the PARTIAL statement, the partial correlations, not the raw correlations, are output.
UCORR	uncorrected correlation matrix. When you specify the NOINT option without the COV option in the PROC PRINCOMP statement, the OUTSTAT= data set contains a matrix of correlations not corrected for the means. However, if you also specify the COV option in the PROC PRINCOMP statement, this observation is omitted.
COV	covariances between each variable and the variable specified by the _NAME_ variable. _TYPE_='COV' observations are produced only if you specify the COV option. If you use the PARTIAL statement, the partial covariances, not the raw covariances, are output.
UCOV	uncorrected covariance matrix. When you specify the NOINT and COV options in the PROC PRINCOMP statement, the OUTSTAT= data set contains a matrix of covariances not corrected for the means.
EIGENVAL	eigenvalues. If the N= option requested fewer than the maximum number of principal components, only the specified number of eigenvalues are produced, with missing values filling out the observation.
SCORE	eigenvectors. The _NAME_ variable contains the name of the corresponding principal component as constructed from the PREFIX= option. The number of observations with _TYPE_='SCORE' equals the number of principal components computed. The eigenvectors have unit length unless you specify the STD option, in which case the unit-length eigenvectors are divided by the square roots of the eigenvalues to produce scores with unit standard deviations. To obtain the principal component scores, if the COV option is not specified, these coefficients should be multiplied by the standardized data. With the COV option, these coefficients should be multiplied by the centered data. Means obtained from the observation with _TYPE_='MEAN' and standard deviations obtained from the observation with _TYPE_='STD' should be used for centering and standardizing the data.
USCORE	scoring coefficients to be applied without subtracting the mean from the raw variables. _TYPE_='USCORE' observations are produced when you specify the NOINT option in the PROC PRINCOMP statement.

	To obtain the principal component scores, these coefficients should be multiplied by the data that are standardized by the uncorrected standard deviations obtained from the observation with _TYPE_='USTD'.
RSQUARED	R squares for each VAR variable as predicted by the PARTIAL variables
B	regression coefficients for each VAR variable as predicted by the PARTIAL variables. This observation is produced only if you specify the COV option.
STB	standardized regression coefficients for each VAR variable as predicted by the PARTIAL variables. If you specify the COV option, this observation is omitted.

The data set can be used with the SCORE procedure to compute principal component scores, or it can be used as input to the FACTOR procedure specifying METHOD=SCORE to rotate the components. If you use the PARTIAL statement, the scoring coefficients should be applied to the residuals, not the original variables.

Computational Resources

Let

$$
\begin{aligned}
n &= \text{number of observations} \\
v &= \text{number of VAR variables} \\
p &= \text{number of PARTIAL variables} \\
c &= \text{number of components}
\end{aligned}
$$

- The minimum allocated memory required (in bytes) is

$$232v + 120p + 48c + \max(8cv, 8vp + 4(v + p)(v + p + 1))$$

- The time required to compute the correlation matrix is roughly proportional to

$$n(v + p)^2 + \frac{p}{2}(v + p)(v + p + 1)$$

- The time required to compute eigenvalues is roughly proportional to v^3.
- The time required to compute eigenvectors is roughly proportional to cv^2.

Displayed Output

The PRINCOMP procedure displays the following items if the DATA= data set is not TYPE=CORR, TYPE=COV, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV:

- simple statistics, including the mean and std (standard deviation) for each variable. If you specify the NOINT option, the uncorrected standard deviation (ustd) is displayed.
- the correlation or, if you specify the COV option, the covariance matrix

The PRINCOMP procedure displays the following items if you use the PARTIAL statement:

- regression statistics, giving the R square and RMSE (root mean squared error) for each VAR variable as predicted by the PARTIAL variables (not shown)
- standardized regression coefficients or, if you specify the COV option, regression coefficients for predicting the VAR variables from the PARTIAL variables (not shown)
- the partial correlation matrix or, if you specify the COV option, the partial covariance matrix (not shown)

The PRINCOMP procedure displays the following item if you specify the COV option:

- the total variance

The PRINCOMP procedure displays the following items unless you specify the NOPRINT option:

- eigenvalues of the correlation or covariance matrix, as well as the difference between successive eigenvalues, the proportion of variance explained by each eigenvalue, and the cumulative proportion of variance explained
- the eigenvectors

ODS Table Names

PROC PRINCOMP assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 72.2. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

All of the tables are created with the specification of the PROC PRINCOMP statement; a few tables need an additional PARTIAL statement.

Table 72.2 ODS Tables Produced by PROC PRINCOMP

ODS Table Name	Description	Statement / Option
Corr	Correlation matrix	default
Cov	Covariance matrix	COV
Eigenvalues	Eigenvalues	default
Eigenvectors	Eigenvectors	default
NObsNVar	Number of observations, variables, and partial variables	default
ParCorr	Partial correlation matrix	PARTIAL statement
ParCov	Uncorrected partial covariance matrix	PARTIAL statement and COV
RegCoef	Regression coefficients	PARTIAL statement and COV
RSquareRMSE	Regression statistics: R squares and RMSEs	PARTIAL statement
SimpleStatistics	Simple statistics	default
StdRegCoef	Standardized regression coefficients	PARTIAL statement
TotalVariance	Total variance	COV

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

Some graphs are produced by default; other graphs are produced by using statements and options. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC PRINCOMP generates are listed in Table 72.3, along with the required statements and options.

Table 72.3 Graphs Produced by PROC PRINCOMP

ODS Graph Name	Plot Description	Statement and Option
PaintedScorePlot	Score plot of component 3 versus component 2, painted by component 1	PLOTS=SCORE when number of variables ≥ 3
PatternPlot	Component pattern plot	PLOTS=PATTERN
PatternProfilePlot	Component pattern profile plot	PLOTS=PATTERNPROFILE
ScoreMatrixPlot	Matrix plot of component scores	PLOTS=MATRIX
ScorePlot	Component score plot	PLOTS=SCORE
ScreePlot	Scree and variance plots	default and PLOTS=SCREE
VariancePlot	Variance proportion explained plot	PLOTS=SCREE(UNPACKPANEL)

Examples: PRINCOMP Procedure

Example 72.1: Temperatures

This example analyzes mean daily temperatures in selected cities in January and July. Both the raw data and the principal components are plotted to illustrate how principal components are orthogonal rotations of the original variables.

The following statements create the Temperature data set.

```
data Temperature;
   length Cityid $ 2;
   title 'Mean Temperature in January and July for Selected Cities ';
   input City $1-15 January July;
   Cityid = substr(City,1,2);
   datalines;
Mobile          51.2 81.6
Phoenix         51.2 91.2
Little Rock     39.5 81.4
Sacramento      45.1 75.2

   ... more lines ...

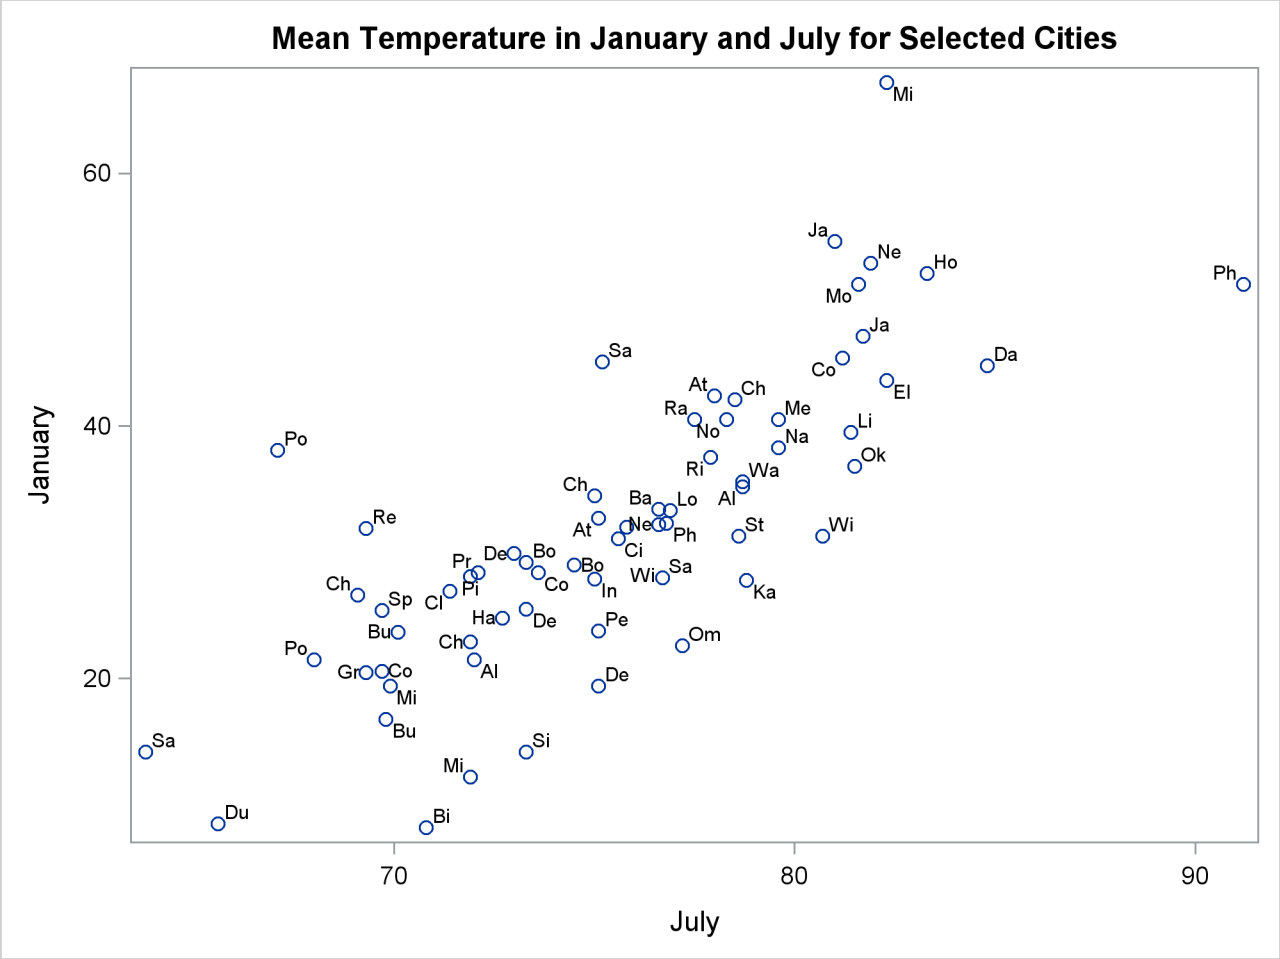
Cheyenne        26.6 69.1
;
```

The following statements plot the temperature data set. The Cityid variable instead of City is used as a data label in the scatter plot for possible label clashing.

```
title 'Mean Temperature in January and July for Selected Cities';
proc sgplot data=Temperature;
   scatter x=July y=January / datalabel=Cityid;
run;
```

The results are displayed in Output 72.1.1, which shows a scatter diagram of the 64 pairs of data points with July temperatures plotted against January temperatures.

Output 72.1.1 Plot of Raw Data



The following step requests a principal component analysis on the Temperature data set:

```
ods graphics on;

title 'Mean Temperature in January and July for Selected Cities';
proc princomp data=Temperature cov plots=score(ellipse);
   var July January;
   id Cityid;
run;
```

Output 72.1.2 displays the PROC PRINCOMP output. The standard deviation of January (11.712) is higher than the standard deviation of July (5.128). The COV option in the PROC PRINCOMP statement requests the principal components to be computed from the covariance matrix. The total variance is 163.474. The first principal component explains about 94% of the total variance, and the second principal component explains only about 6%. The eigenvalues sum to the total variance.

Note that January receives a higher loading on Prin1 because it has a higher standard deviation than July, and the PRINCOMP procedure calculates the scores by using the centered variables rather than the standardized variables.

Output 72.1.2 Results of Principal Component Analysis

Mean Temperature in January and July for Selected Cities

The PRINCOMP Procedure

Observations	64
Variables	2

Simple Statistics

	July	January
Mean	75.60781250	32.09531250
StD	5.12761910	11.71243309

Covariance Matrix

	July	January
July	26.2924777	46.8282912
January	46.8282912	137.1810888

Total Variance 163.47356647

Eigenvalues of the Covariance Matrix

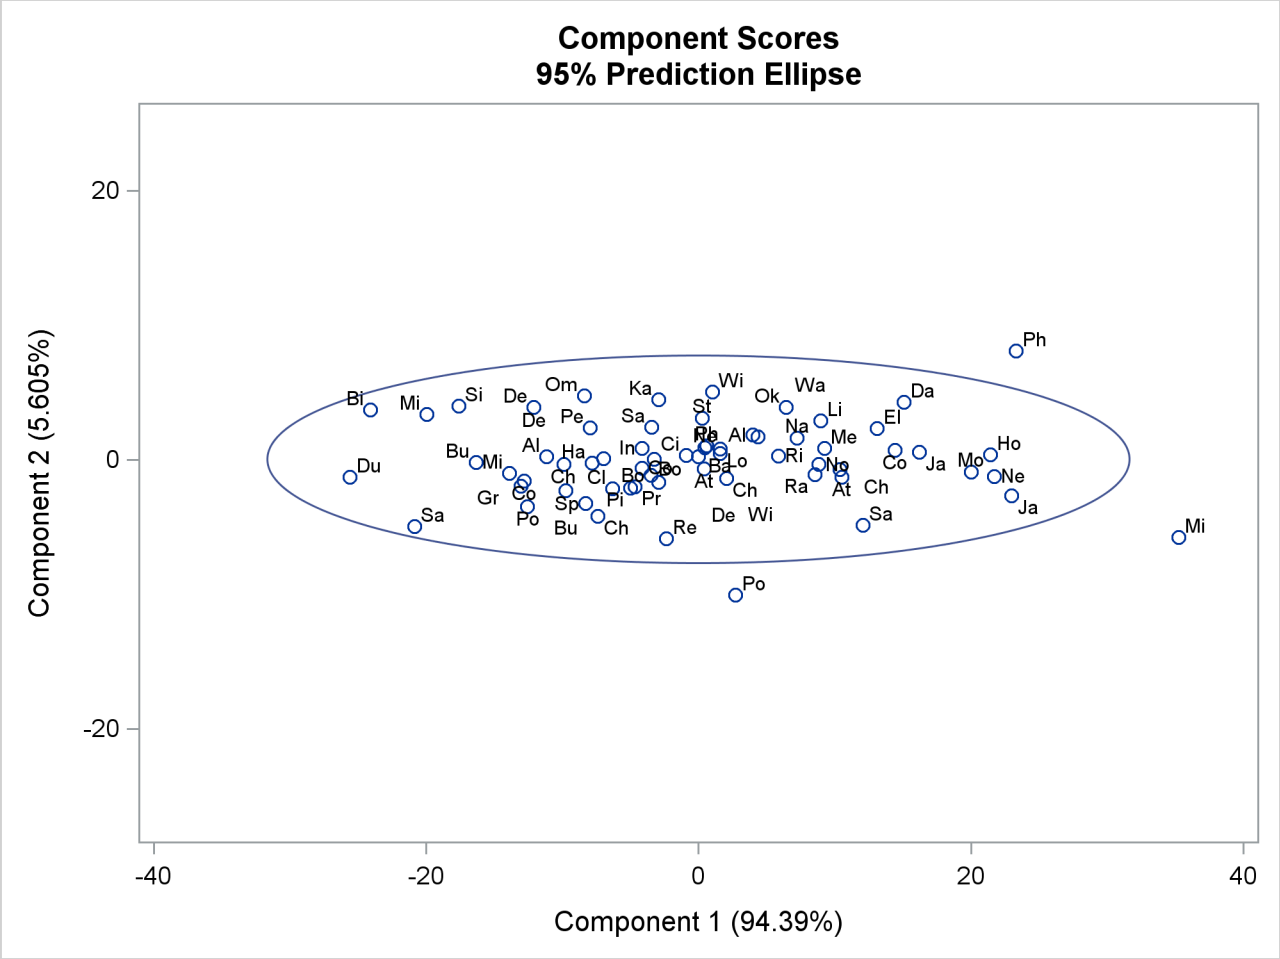
	Eigenvalue	Difference	Proportion	Cumulative
1	154.310607	145.147647	0.9439	0.9439
2	9.162960		0.0561	1.0000

Eigenvectors

	Prin1	Prin2
July	0.343532	0.939141
January	0.939141	-.343532

PLOTS=SCORE in the PROC PRINCOMP statement requests a plot of the second principal component against the first principal component as shown in Output 72.1.3. It is clear from this plot that the principal components are orthogonal rotations of the original variables and that the first principal component has a larger variance than the second principal component. In fact, the first component has a larger variance than either of the original variables July and January. The ellipse indicates that Miami, Phoenix, and Portland are possible outliers.

Output 72.1.3 Plot of Component 2 by Component 1



Example 72.2: Basketball Data

The data in this example are rankings of 35 college basketball teams. The rankings were made before the start of the 1985–86 season by 10 news services.

The purpose of the principal component analysis is to compute a single variable that best summarizes all 10 of the preseason rankings.

Note that the various news services rank different numbers of teams, varying from 20 through 30 (there is a missing rank in one of the variables, WashPost). And, of course, not all services rank the same teams, so there are missing values in these data. Each of the 35 teams is ranked by at least one news service.

The PRINCOMP procedure omits observations with missing values. To obtain principal component scores for all of the teams, it is necessary to replace the missing values. Since it is the best teams that are ranked, it is not appropriate to replace missing values with the mean of the nonmissing values. Instead, an ad hoc method is used that replaces missing values with the mean of the unassigned ranks. For example, if 20 teams are ranked by a news service, then ranks 21 through 35 are unassigned. The mean of ranks 21 through 35 is

28, so missing values for that variable are replaced by the value 28. To prevent the method of missing-value replacement from having an undue effect on the analysis, each observation is weighted according to the number of nonmissing values it has. See Example 73.2 in Chapter 73, "The PRINQUAL Procedure," for an alternative analysis of these data.

Since the first principal component accounts for 78% of the variance, there is substantial agreement among the rankings. The eigenvector shows that all the news services are about equally weighted; this is also suggested by the nearly horizontal line of the pattern profile plot in Output 72.2.3. So a simple average would work almost as well as the first principal component. The following statements produce Output 72.2.1.

```
/*-------------------------------------------------------------*/
/*                                                             */
/* Pre-season 1985 College Basketball Rankings                 */
/* (rankings of 35 teams by 10 news services)                  */
/*                                                             */
/* Note: (a) news services rank varying numbers of teams;      */
/*       (b) not all teams are ranked by all news services;    */
/*       (c) each team is ranked by at least one service;      */

Example 72.3: Job Ratings

This example uses the PRINCOMP procedure to analyze job performance. Police officers were rated by their supervisors in 14 categories as part of standard police departmental administrative procedure.

The following statements create the Jobratings data set:

```
options validvarname=any;
data Jobratings;
   input ('Communication Skills'n
          'Problem Solving'n
          'Learning Ability'n
          'Judgment Under Pressure'n
          'Observational Skills'n
          'Willingness to Confront Problems'n
          'Interest in People'n
          'Interpersonal Sensitivity'n
          'Desire for Self-Improvement'n
          'Appearance'n
          'Dependability'n
          'Physical Ability'n
          'Integrity'n
          'Overall Rating'n) (1.);
   datalines;
26838853879867
74758876857667
56757863775875

   ... more lines ...

76656399567486
;
```

The data set Jobratings contains 14 variables. Each variable contains the job ratings, using a scale measurement from 1 to 10 (1=fail to comply, 10=exceptional). The last variable Overall Rating contains a score as an overall index on how each officer performs.

The following statements request a principal component analysis on the Jobratings data set, output the scores to the Scores data set (OUT= Scores), and produce default plots. Note that variable Overall Rating is excluded from the analysis.

```
ods graphics on;

proc princomp data=Jobratings(drop='Overall Rating'n);
run;
```

Figure 72.3.1 and Figure 72.3.2 display the PROC PRINCOMP output, beginning with simple statistics followed by the correlation matrix. By default, the PROC PRINCOMP statement requests principal components computed from the correlation matrix, so the total variance is equal to the number of variables, 13. In this example, it would also be reasonable to use the COV option, which would cause variables with a high variance (such as Dependability) to have more influence on the results than variables with a low variance

(such as Learning Ability). If you used the COV option, scores would be computed from centered rather than standardized variables.

Figure 72.3.2 displays the eigenvalues. The first principal component explains about 50% of the total variance, the second principal component explains about 13.6%, and the third principal component explains about 7.7%. Note that the eigenvalues sum to the total variance. The eigenvalues indicate that three to five components provide a good summary of the data, with three components accounting for about 71.7% of the total variance and five components explaining about 82.7%. Subsequent components contribute less than 5% each.

Output 72.3.2 Eigenvalues and Eigenvectors from the PRINCOMP Procedure

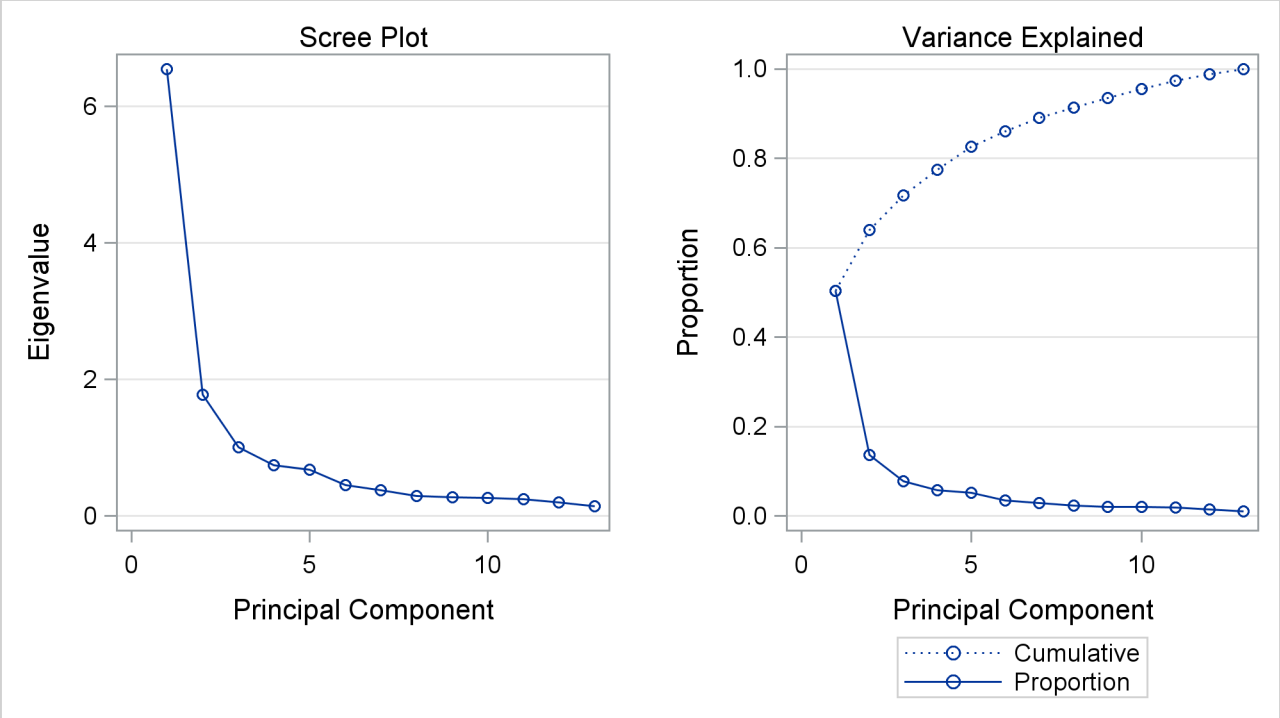
PROC PRINCOMP produces the scree plot as shown in Figure 72.3.3 by default when ODS Graphics is enabled. You can obtain more plots by specifying the PLOTS= option in the PROC PRINCOMP statement.

The "Scree Plot" on the left shows that the eigenvalue of the first component is approximately 6.5 and the eigenvalue of the second component is largely decreased to under 2.0. The "Variance Explained" plot on the right shows that you can explain a near 80% of total variance with the first four principal components.

Output 72.3.3 Scree Plot from the PRINCOMP Procedure



The first component reflects overall performance since the first eigenvector shows approximately equal loadings on all variables. The second eigenvector has high positive loadings on the variables Observational Skills and Willingness to Confront Problems but even higher negative loadings on the variables Interest in People and Interpersonal Sensitivity. This component seems to reflect the ability to take action, but it also reflects a lack of interpersonal skills. The third eigenvector has a very high positive loading on the variable Physical Ability and high negative loadings on the variables Problem Solving and Learning Ability. This component seems to reflect physical strength, but also shows poor learning and problem-solving skills.

In short, the three components represent the following:

First Component:	overall performance
Second Component:	smart, tough, and introverted
Third Component:	superior strength and average intellect

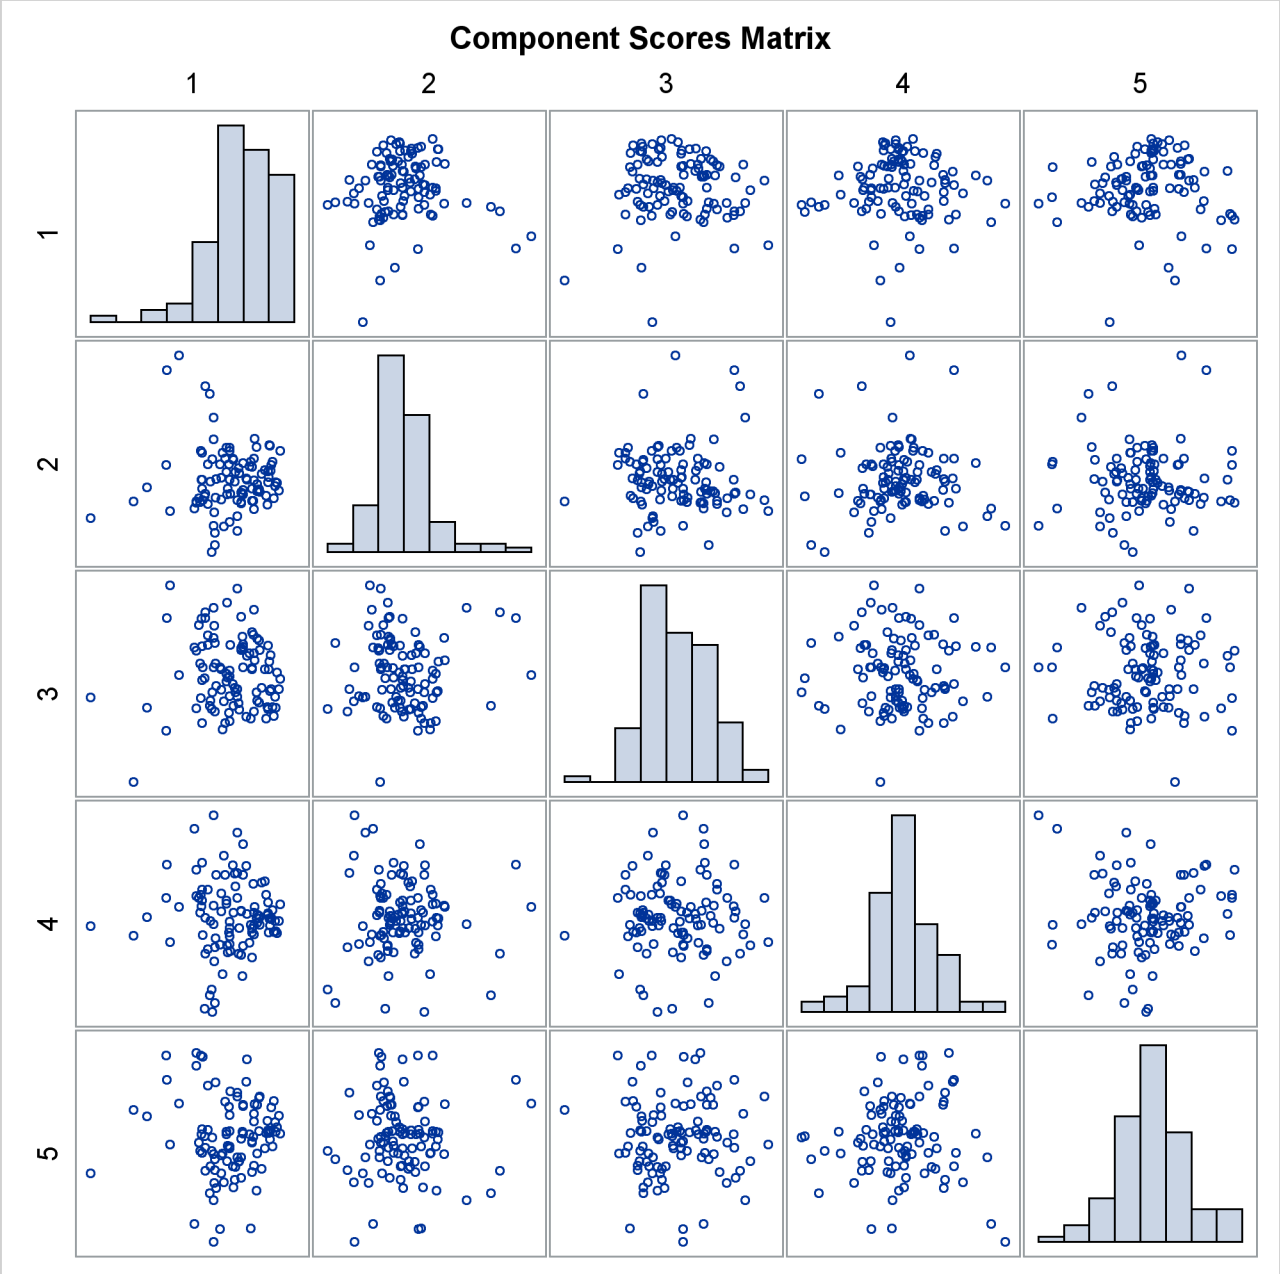
PROC PRINCOMP also produces other plots besides the scree plot, which are helpful while interpreting the results. The following statements request plots from the PRINCOMP procedure:

```
proc princomp data=Jobratings(drop='Overall Rating'n)
              plots(ncomp=3)=all n=5;
run;
```

PLOTS=ALL(NCOMP=3) in the PROC PRINCOMP statement requests all plots to be produced but limits the number of components to be plotted in the component pattern plots and the component score plots to three. The N=5 option sets the number of principal components to be computed to five. Besides a scree plot similar to the one shown before, the rest of plots are displayed in the following context.

Output 72.3.4 shows a matrix plot of component scores between the first five principal components. The histogram of each component is displayed in the diagonal element of the matrix. The histograms indicate that the first principal component is skewed to the left and the second principal component is slightly skewed to the right.

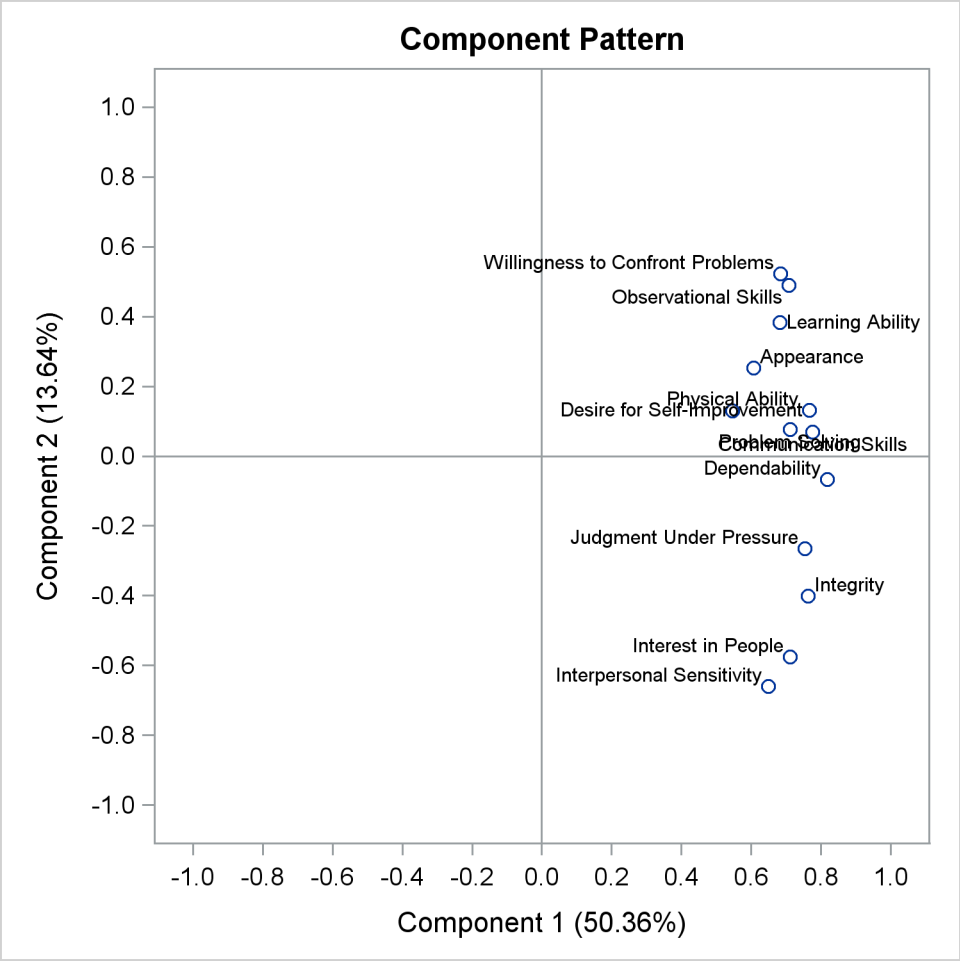
Output 72.3.4 Matrix Plot of Component Scores



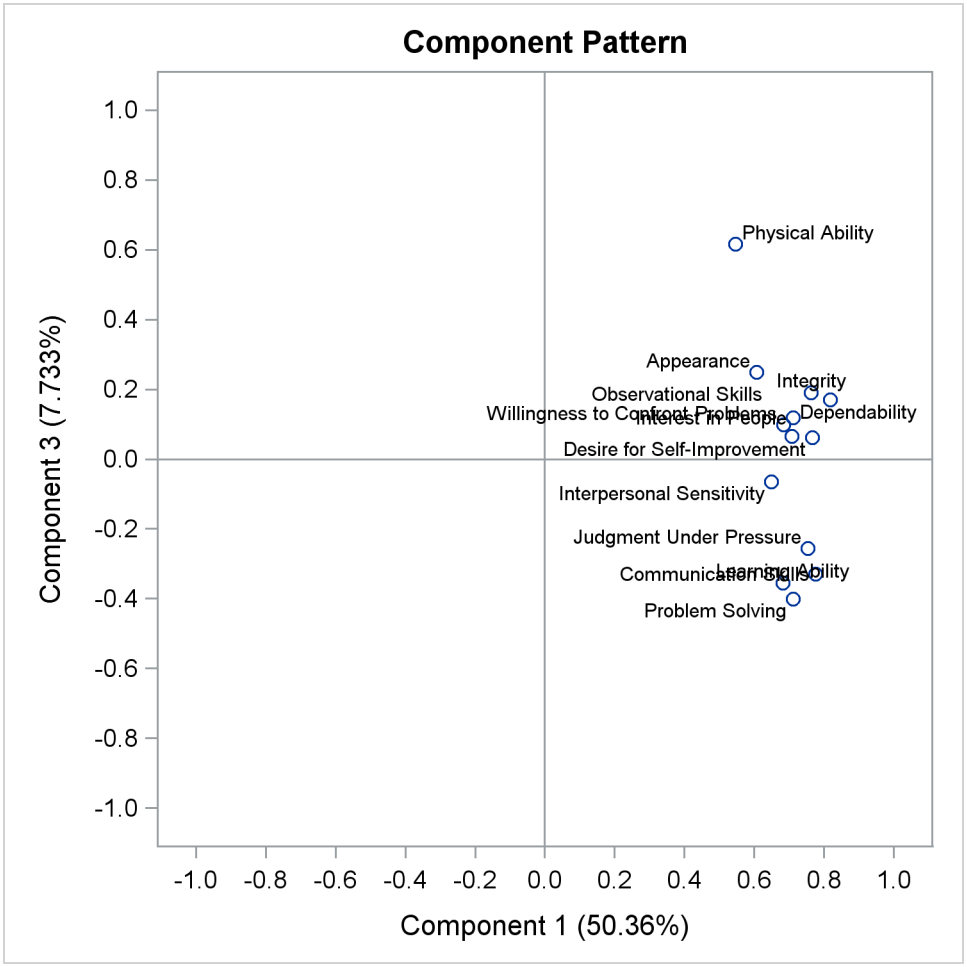
The pairwise component pattern plots are shown in Output 72.3.5 to Output 72.3.7. The pattern plots show the following:

- All variables positively and evenly correlate with the first principal component (Output 72.3.5 and Output 72.3.6).
- The variables Observational Skills and Willingness to Confront Problems correlate highly with the second component, and the variables Interest in People and Interpersonal Sensitivity correlate highly but negatively with the second component (Output 72.3.5).
- The variable Physical Ability correlates highly with the third component, and the variables Problem Solving and Learning Ability correlate highly but negatively with the third component (Output 72.3.6).
- The variable Observational Skills, Willingness to Confront Problems, Interest in People, and Interpersonal Sensitivity correlate highly (either positively or negatively) with the second component, but all have very low correlations with the third component; the variables Physical Ability and Problem Solving correlate highly (either positively or negatively) with the third component, but both have very low correlations with the second component (Output 72.3.7).

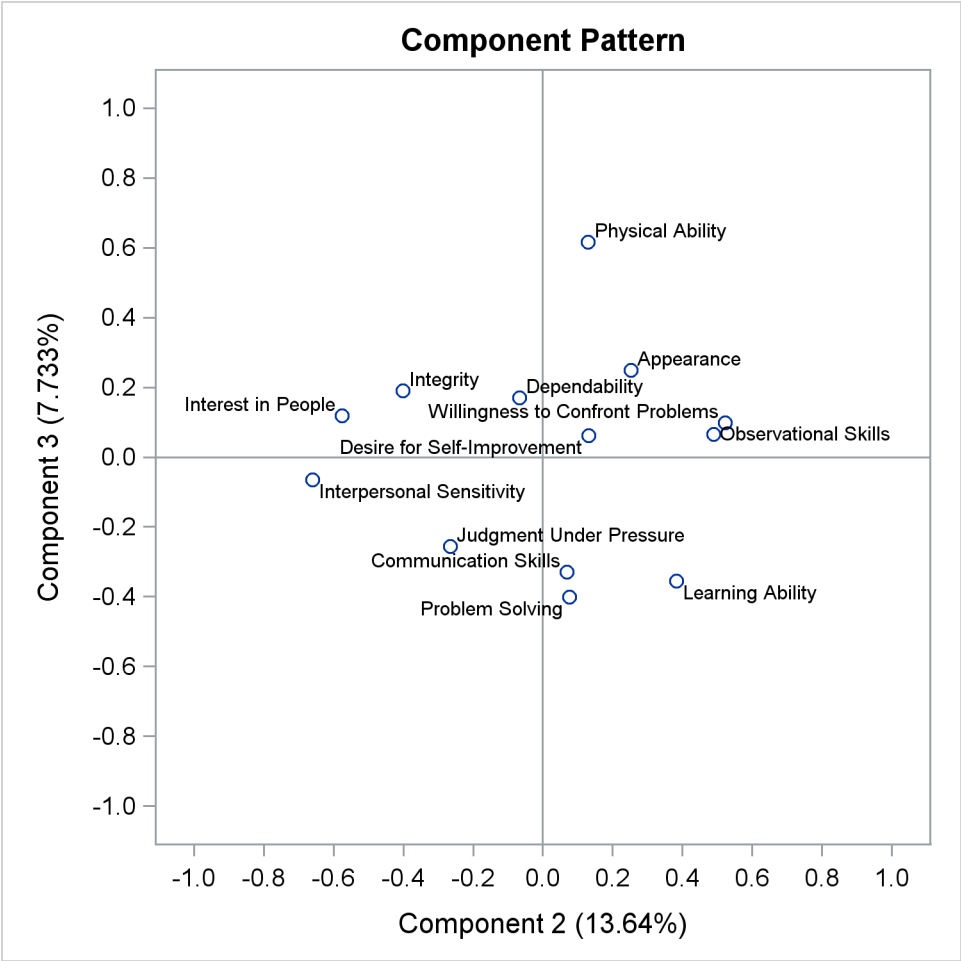
Output 72.3.5 Pattern Plot of Component 2 by Component 1



Output 72.3.6 Pattern Plot of Component 3 by Component 1

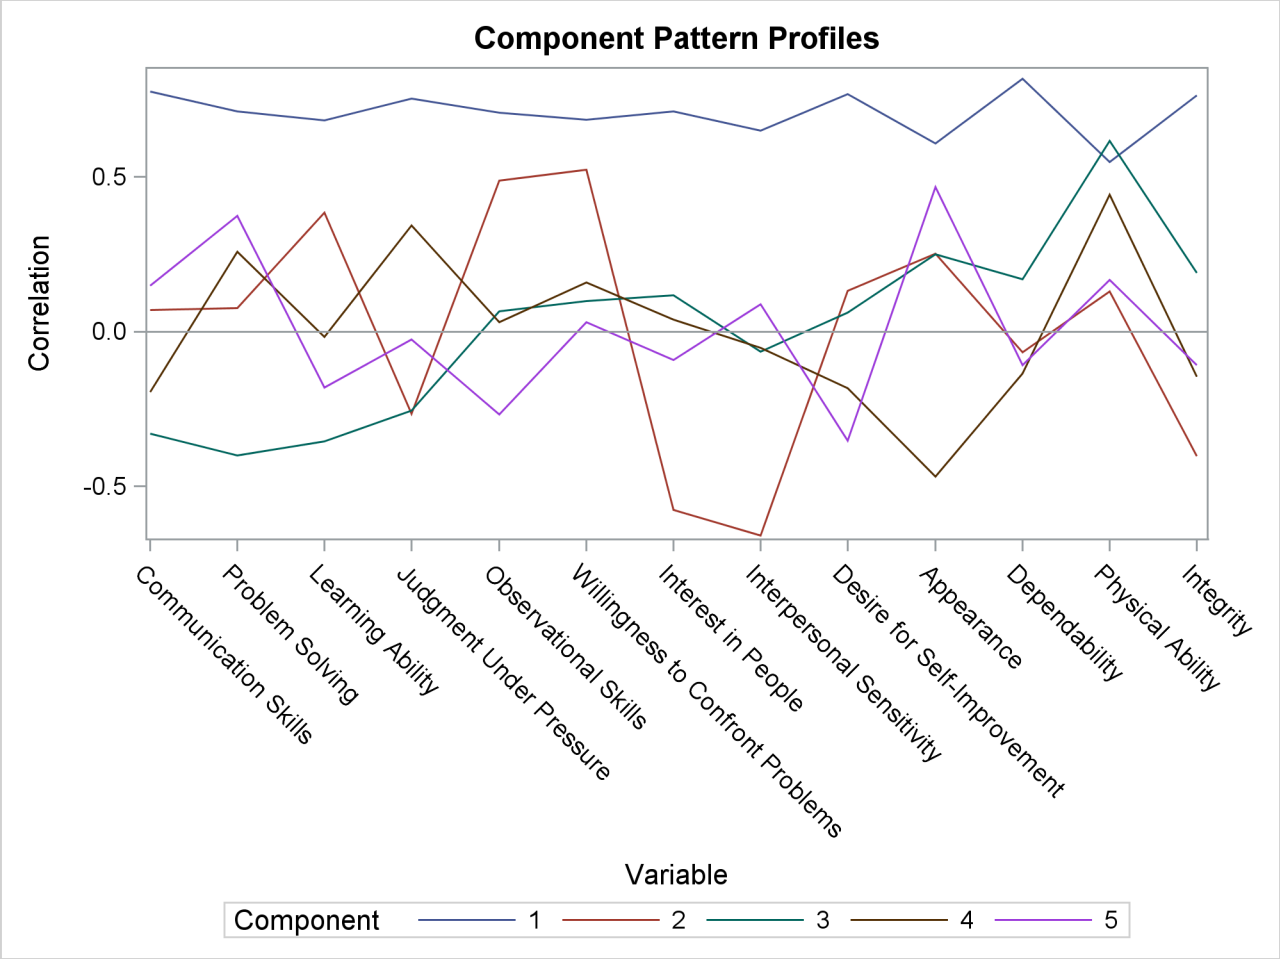


Output 72.3.7 Pattern Plot of Component 3 by Component 2



Output 72.3.8 shows a component pattern profile. As it was shown in the pattern plots, the nearly horizontal profile from the first component indicates that the first component is mostly correlated evenly across all variables.

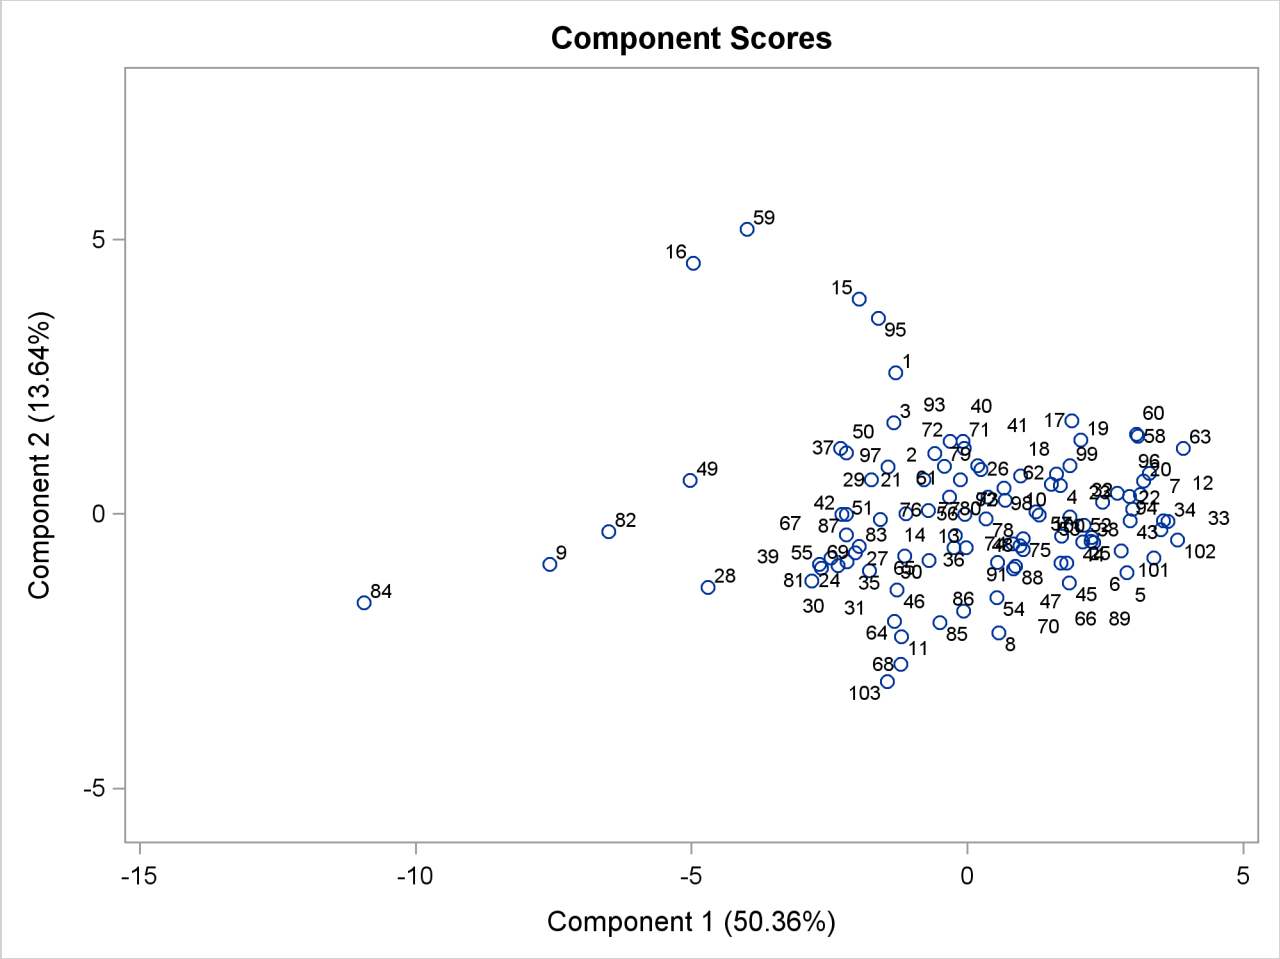
Output 72.3.8 Component Pattern Profile Plot from the PRINCOMP Procedure



Output 72.3.9 through Output 72.3.11 display the pairwise component score plots. Observation numbers are used as the plotting symbol.

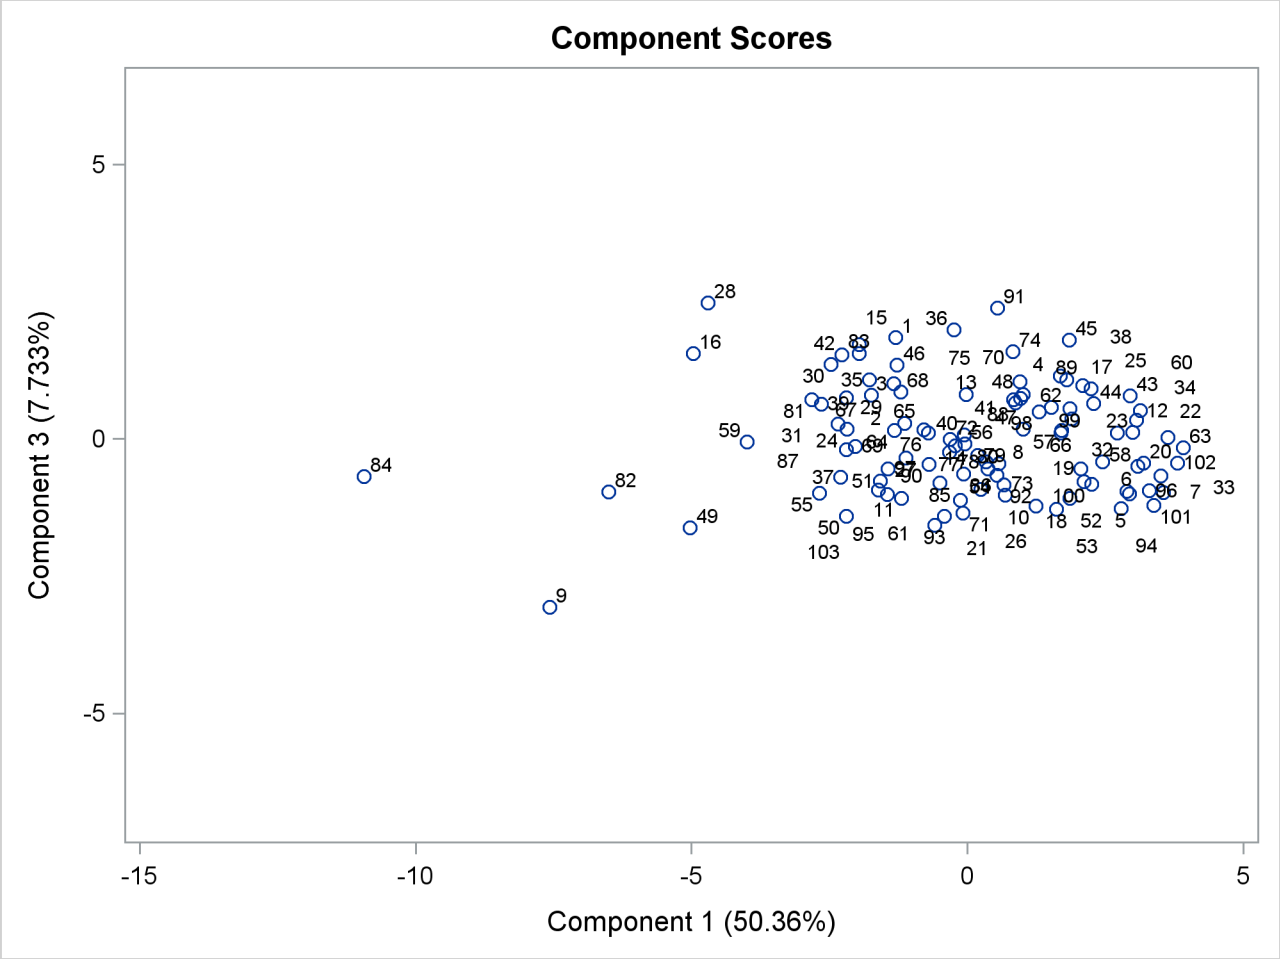
Output 72.3.9 shows a scatter plot of the first and third components. Observations 82, 9, and 84 seem like outliers on the first component; Observations 16 and 59 can be potential outliers on the second component.

Output 72.3.9 Component 2 versus Component 1



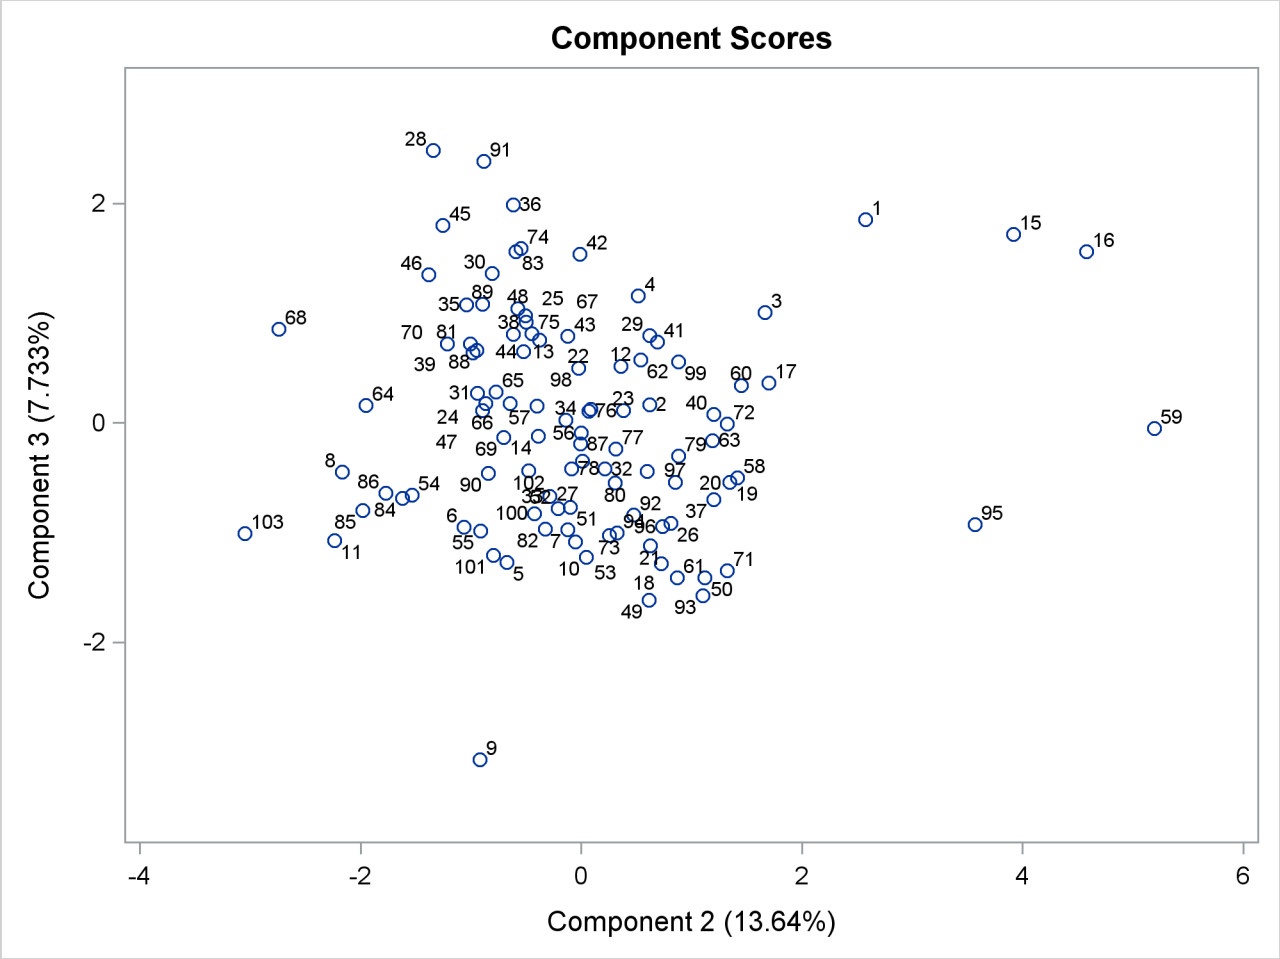
Output 72.3.10 shows a scatter plot of the first and third components. Observations 82, 9, and 84 seem like outliers on the first component.

Output 72.3.10 Component 3 versus Component 1



Output 72.3.11 shows a scatter plot of the second and third components. Observations 95, 15, 16, and 59 can be potential outliers on the second component.

Output 72.3.11 Component 3 versus Component 2



Output 72.3.12 shows a scatter plot of the second and third components, displaying density with color. Color interpolation is based on the first component, such as in the statistical style, going from blue (minimum density) to tan (median density) and to red (maximum density).

Output 72.3.12 Component 3 versus Component 2, Painted by Component 1

Chapter 73

The PRINQUAL Procedure

Contents

Overview: PRINQUAL Procedure

The PRINQUAL procedure performs principal component analysis (PCA) of qualitative, quantitative, or mixed data. PROC PRINQUAL is based on the work of Kruskal and Shepard (1974); Young, Takane, and de Leeuw (1978); Young (1981); and Winsberg and Ramsay (1983). PROC PRINQUAL finds linear and nonlinear transformations of variables, using the method of alternating least squares, that optimize properties of the transformed variables' correlation or covariance matrix. Nonoptimal transformations such as logarithm and rank are also available. You can use ODS Graphics to display the results. You can use PROC PRINQUAL to do the following:

- fit metric and nonmetric principal component analyses
- perform metric and nonmetric multidimensional preference (MDPREF) analyses (Carroll 1972)
- transform data prior to their use in other analyses
- reduce the number of variables for subsequent use in regression analyses, cluster analyses, and other analyses
- detect nonlinear relationships

PROC PRINQUAL provides three methods, each of which seeks to optimize a different property of the transformed variables' covariance or correlation matrix. These methods are as follows:

- maximum total variance, or MTV
- minimum generalized variance, or MGV
- maximum average correlation, or MAC

The MTV method is based on a PCA model, and it is the most commonly used method. All three methods attempt to find transformations that decrease the rank of the covariance matrix computed from the transformed variables. Transforming the variables to maximize the total variance accounted for by a few linear combinations locates the observations in a space with a dimensionality that approximates the stated number of linear combinations as much as possible, given the transformation constraints. Transforming the variables to minimize their generalized variance or maximize the average correlations also reduces the dimensionality, but without a stated target for the final dimensionality. See the section "The Three Methods of Variable Transformation" on page 6132 for more information about all three methods.

The data can contain variables measured on nominal, ordinal, interval, and ratio scales of measurement (Siegel 1956). Any mix is allowed with all methods. PROC PRINQUAL can do the following:

- transform nominal variables by optimally scoring the categories (Fisher 1938)
- transform ordinal variables monotonically by scoring the ordered categories so that order is weakly preserved (adjacent categories can be merged) and the covariance matrix is optimized. You can undo ties optimally or leave them tied (Kruskal 1964). You can also transform ordinal variables to ranks.
- transform interval and ratio scale of measurement variables linearly, or transform them nonlinearly with spline transformations (de Boor 1978; van Rijckevorsel 1982) or monotone spline transformations (Winsberg and Ramsay 1983). In addition, nonoptimal transformations for logarithm, rank, exponential, power, logit, and inverse trigonometric sine are available.
- estimate missing data without constraint, with category constraints (missing values within the same group get the same value), and with order constraints (missing value estimates in adjacent groups can be tied to preserve a specified ordering). See Gifi (1990) and Young (1981).

The transformed qualitative (nominal and ordinal) variables can be thought of as being quantified by the analysis, with the quantification done in the context set by the algorithm. The data are quantified so that the proportion of variance accounted for by a stated number of principal components is locally maximized, the generalized variance of the variables is locally minimized, or the average of the correlations is locally maximized.

The PROC PRINQUAL iterations produce a set of transformed variables. Each variable's new scoring satisfies a set of constraints based on the original scoring of the variable and the specified transformation type. First, all variables are required to satisfy standardization constraints; that is, all variables have a fixed mean and variance. The other constraints include linear constraints, weak order constraints, category constraints, and smoothness constraints. The new set of scores is selected from the sets of possible scorings that do not violate the constraints so that the method criterion is locally optimized.

Getting Started: PRINQUAL Procedure

PROC PRINQUAL can be used to fit a principal component model with nonlinear transformations of the variables and graphically display the results. This example finds monotonic transformations of ratings of automobiles.

```
title 'Ratings for Automobiles Manufactured in 1980';

data cars;
   input Origin $ 1-8 Make $ 10-19 Model $ 21-36
         (MPG Reliability Acceleration Braking Handling Ride
          Visibility Comfort Quiet Cargo) (1.);
   datalines;
GMC      Buick      Century         3334444544
GMC      Buick      Electra         2434453555
GMC      Buick      Lesabre         2354353545

   ... more lines ...

GMC      Pontiac    Sunbird         3134533234
;

ods graphics on;

proc prinqual data=cars plots=all maxiter=100;
   transform monotone(mpg -- cargo);
   id model;
run;
```

The PROC PRINQUAL statement names the input data set Cars. The ODS GRAPHICS statement, along with the PLOTS=ALL option, requests all graphical displays. The MDPREF option requests the PCA plot with the scores (automobiles) represented as points and the structure (variables) represented as vectors. By default, the vector lengths are increased by a factor of 2.5 to produce a better graphical display. If instead you were to specify MDPREF=1, you would get the actual vectors, and they would all be short and would end near the origin where there are a lot of points. It is often the case that increasing the vector lengths by a factor of 2 or 3 makes a better graphical display, so by default the vector lengths are increased by a factor of 2.5. Up to 100 iterations are requested with the MAXITER= option. All of the numeric variable are specified with a MONOTONE transformation, so their original values, 1 to 5, are optimally rescored to maximize fit to a two-component model while preserving the original order. The Model variable provides the labels for the row points in the plot.

The iteration history table is shown in Figure 73.1. The monotonic transformations allow the PCA to account for 5% more variance in two principal components than the ordinary PCA model applied to the untransformed data.

Figure 73.1 Automobile Ratings Iteration History

Ratings for Automobiles Manufactured in 1980

The PRINQUAL Procedure

PRINQUAL MTV Algorithm Iteration History

Iteration Number	Average Change	Maximum Change	Proportion of Variance	Criterion Change	Note
1	0.18087	1.24219	0.53742

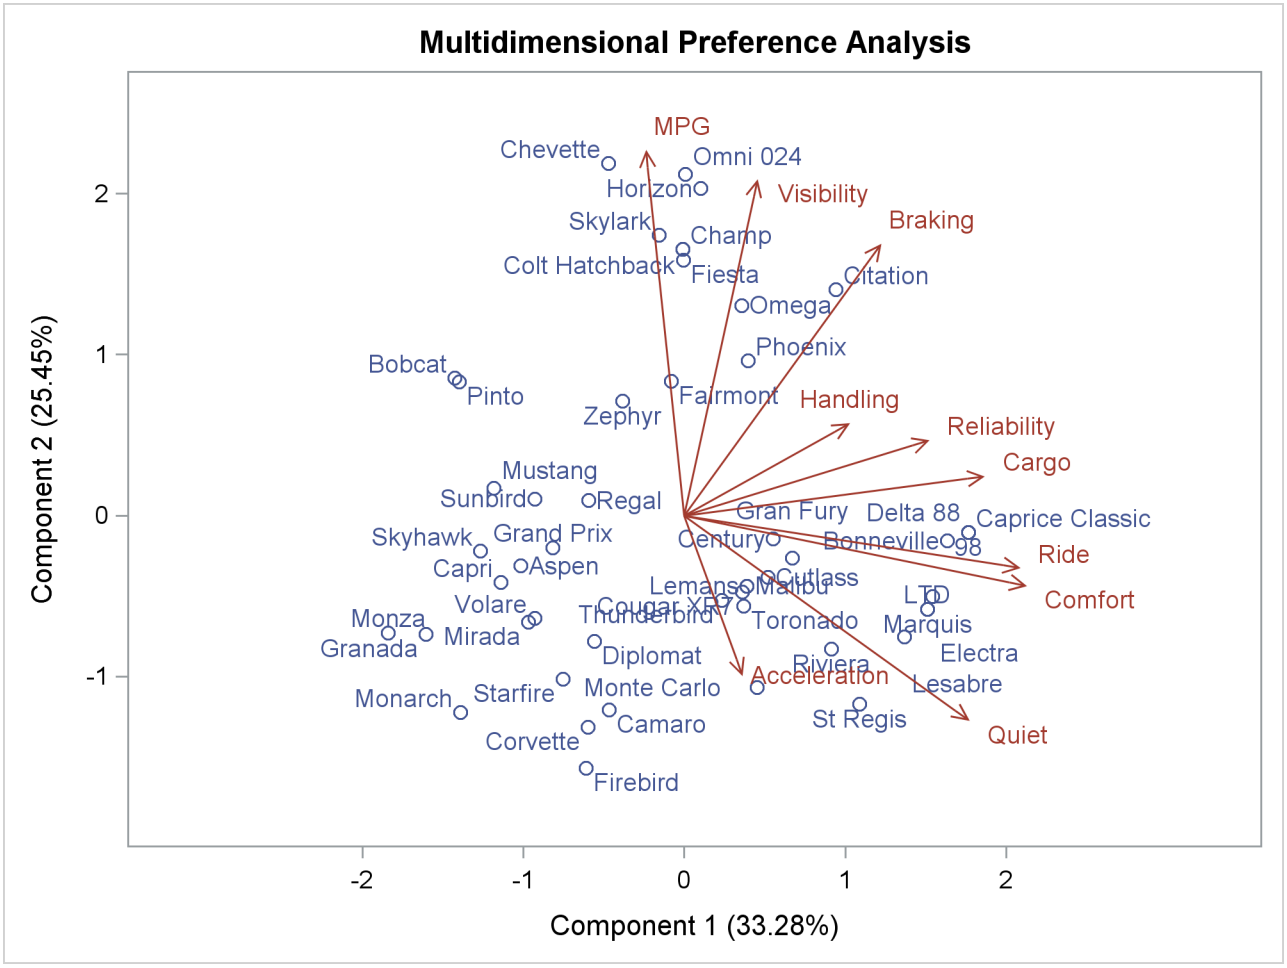
Algorithm converged.

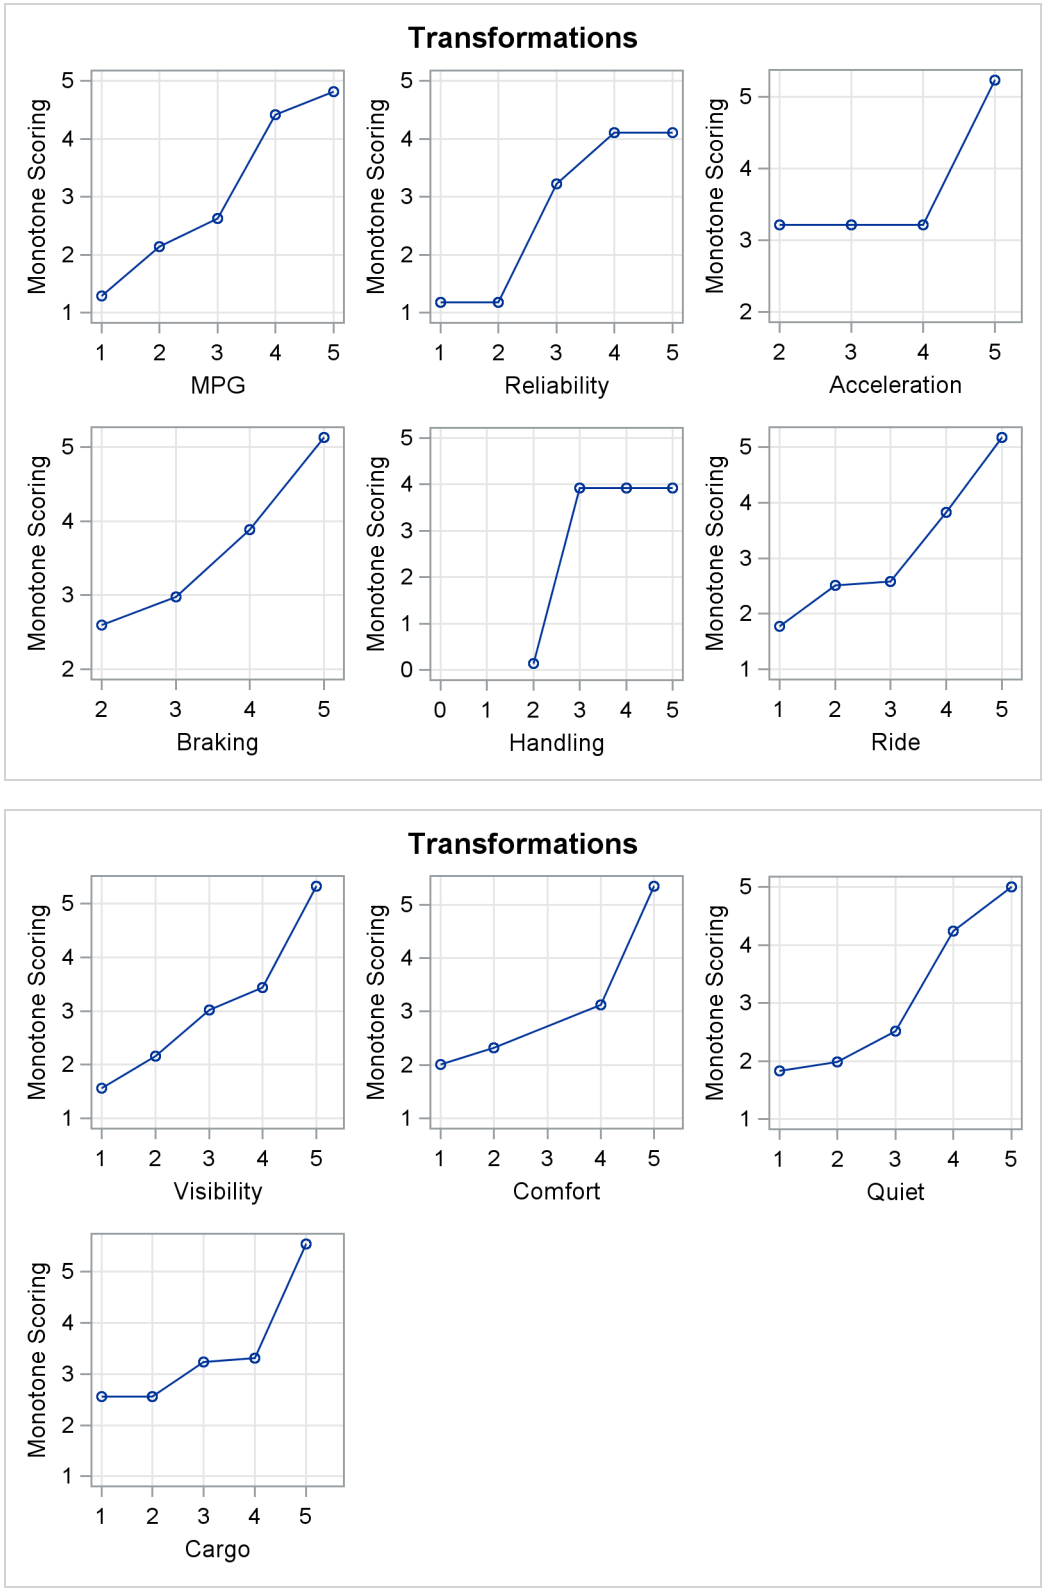
The PCA biplot in Figure 73.2 shows the transformed automobile ratings projected into the two-dimensional plane of the analysis. The automobiles on the left tend to be smaller than the autos on the right, and the autos at the top tend to be cheaper than the autos at the bottom. The vectors can help you interpret the plot of the scores. Longer vectors show the variables that better fit the two-dimensional model. A larger component of them is in the plane of the plot. In contrast, shorter vectors show the variables that do not fit the two-dimensional model as well. They tend to be located less in the plot and more away from the plot; hence their projection into the plot is shorter. To envision this, lay a pencil on your desk directly under a light, and slowly rotate it up to form a 90-degree angle with your desk. As you do so, the shadow or projection of the pencil onto your desk will get progressively shorter. The results show, for example, that the Chevette would be expected to do well on gas mileage but not well on quiet and acceleration. In contrast, the Corvette and the Firebird have the opposite pattern.

Figure 73.2 Automobile Ratings PCA Biplot



There are many patterns shown in the transformations in Figure 73.3. The transformation of Braking, for example, is not very different from the original scoring. The optimal scoring for other variables, such as Acceleration and Handling, is binary. Automobiles are differentiated by high versus everything else or low versus everything else.

Figure 73.3 Automobile Ratings Transformations



Syntax: PRINQUAL Procedure

The following statements are available in PROC PRINQUAL.

PROC PRINQUAL < *options* > **;**
TRANSFORM *transform(variables* < */ t-options* >*)*
< *transform(variables* < */ t-options* >*) . . .* > **;**
ID *variables* **;**
FREQ *variable* **;**
WEIGHT *variable* **;**
BY *variables* **;**

To use PROC PRINQUAL, you need the PROC PRINQUAL and TRANSFORM statements. You can abbreviate all *options* and *t-options* to their first three letters. This is a special feature of PROC PRINQUAL and is not generally true of other SAS/STAT procedures.

The rest of this section provides detailed syntax information about each of the preceding statements, beginning with the PROC PRINQUAL statement. The remaining statements are described in alphabetical order.

PROC PRINQUAL Statement

PROC PRINQUAL < *options* > **;**

The PROC PRINQUAL statement invokes the PRINQUAL procedure. Optionally, this statement identifies an input data set, creates an output data set, specifies the algorithm and other computational details, and controls displayed output. The options listed in Table 73.1 are available in the PROC PRINQUAL statement.

Table 73.1 Summary of PROC PRINQUAL Statement Options

Option	Description
Input Data Set Options	
DATA=	Specifies input SAS data set
Output Data Set Details	
APPROXIMATIONS	Outputs approximations to transformed variables
APREFIX=	Specifies prefix for approximation variables
CORRELATIONS	Outputs correlations and component structure matrix
MDPREF=	Specifies a multidimensional preference analysis
OUT=	Specifies output data set
PREFIX=	Specifies prefix for principal component scores
REPLACE	Replaces raw data with transformed data
SCORES	Outputs principal component scores
STANDARD	Standardizes principal component scores
TPREFIX=	Specifies prefix for transformed variables

Table 73.1 *continued*

Option	Description
TSTANDARD=	Specifies transformation standardization
Method and Iterations	
CCONVERGE=	Specifies minimum criterion change
CHANGE=	Specifies number of first iteration to be displayed
CONVERGE=	Specifies minimum data change
COVARIANCE	Analyzes covariances
DUMMY	Initializes using dummy variables
INITITER=	Specifies number of MAC initialization iterations
MAXITER=	Specifies maximum number of iterations
METHOD=	Specifies iterative algorithm
NOCHECK	Suppresses numerical error checking
N	Specifies number of principal components
REFRESH=	Specifies number of MGV models before refreshing
REITERATE	Restarts iterations
SINGULAR=	Specifies singularity criterion
TYPE=	Specifies input observation type
Missing Data Handling	
MONOTONE=	Includes monotone special missing values
NOMISS	Excludes observations with missing values
UNTIE=	Unties special missing values
Control Displayed Output	
NOPRINT	Suppresses displayed output
PLOTS=	Specifies ODS Graphics details

The following list describes these options in alphabetical order.

APREFIX=*name*

APR=*name*

specifies a prefix for naming the approximation variables. By default, APREFIX=A. Specifying the APREFIX= option also implies the APPROXIMATIONS option.

APPROXIMATIONS

APPROX

APP

includes principal component approximations to the transformed variables (Eckart and Young 1936) in the output data set. Variable names are constructed from the value of the APREFIX= option and the input variable names. If you specify the APREFIX= option, then approximations are automatically included. If you specify the APPROXIMATIONS option and not the APREFIX= option, then the APPROXIMATIONS option uses the default, APREFIX=A, to construct the variable names.

CCONVERGE=*n*

CCO=*n*

specifies the minimum change in the criterion being optimized that is required to continue iterating. By default, CCONVERGE=0.0. The CCONVERGE= option is ignored for METHOD=MAC. For the MGV method, specify CCONVERGE=–2 to ensure data convergence.

CHANGE=*n*

CHA=*n*

specifies the number of the first iteration to be displayed in the iteration history table. The default is CHANGE=1. When you specify a larger value for n, the first $n - 1$ iterations are not displayed, thus speeding up the analysis. The CHANGE= option is most useful with the MGV method, which is much slower than the other methods.

CONVERGE=*n*

CON=*n*

specifies the minimum average absolute change in standardized variable scores that is required to continue iterating. By default, CONVERGE=0.00001. Average change is computed over only those variables that can be transformed by the iterations—that is, all LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE variables and nonoptimal transformation variables with missing values. For more information, see the section "Optimal Transformations" on page 6126.

COVARIANCE

COV

computes the principal components from the covariance matrix. The variables are always centered to mean zero. If you do not specify the COVARIANCE option, the variables are also standardized to variance one, which means the analysis is based on the correlation matrix.

CORRELATIONS

COR

includes correlations and the component structure matrix in the output data set. By default, this information is not included.

DATA=*SAS-data-set*

specifies the SAS data set to be analyzed. The data set must be an ordinary SAS data set; it cannot be a TYPE=CORR or TYPE=COV data set. If you omit the DATA= option, PROC PRINQUAL uses the most recently created SAS data set.

DUMMY

DUM

expands variables specified for OPSCORE optimal transformations to dummy variables for the initialization (Tenenhaus and Vachette 1977). By default, the initial values of OPSCORE variables are the actual data values. The dummy variable nominal initialization requires considerable time and memory, so it might not be possible to use the DUMMY option with large data sets. No separate report of the initialization is produced. Initialization results are incorporated into the first iteration displayed in the iteration history table. For details, see the section "Optimal Transformations" on page 6126.

INITITER=*n*

INI=*n*

specifies the number of MAC iterations required to initialize the data before starting MTV or MGV iterations. By default, INITITER=0. The INITITER= option is ignored if METHOD=MAC.

MAXITER=*n*

MAX=*n*

specifies the maximum number of iterations. By default, MAXITER=30.

MDPREF<=*n***>**

MDP<=*n***>**

specifies a multidimensional preference analysis by implying the STANDARD, SCORES, and CORRELATIONS options. This option also suppresses warnings when there are more variables than observations.

When ODS Graphics is enabled, an MDPREF plot is produced with points for each row and vectors for each column. Often, the vectors are short, and a better graphical display is produced when the vectors are stretched. The absolute lengths of each vector can optionally be changed by specifying MDPREF=*n*. Then the vector coordinates are all multiplied by *n*. Usually, *n* will be a value such as 2, 2.5, or 3. The default is 2.5. Specify MDPREF=1 to see the vectors without any stretching. The relative lengths of the different vectors is important and interpretable, and these are preserved by the stretching.

METHOD=MAC | MGV | MTV

MET=MAC | MGV | MTV

specifies the optimization method. By default, METHOD=MTV. Values of the METHOD= option are MTV, for maximum total variance; MGV, for minimum generalized variance; and MAC, for maximum average correlation. You can use the MAC method when all variables are positively correlated or when no monotonicity constraints are placed on any transformations. See the section "The Three Methods of Variable Transformation" on page 6132 for more information.

MONOTONE=*two-letters*

MON=*two-letters*

specifies the first and last special missing value in the list of those special missing values to be estimated using within-variable order and category constraints. By default, there are no order constraints on missing value estimates. The *two-letters* value must consist of two letters in alphabetical order. For example, MONOTONE=DF means that the estimate of .D must be less than or equal to the estimate of .E, which must be less than or equal to the estimate of .F; no order constraints are placed on estimates of ._, .A through .C, and .G through .Z. For details, see the sections "Missing Values" on page 6138 and "Optimal Scaling" on page 7910 in Chapter 93, "The TRANSREG Procedure."

N=*n*

specifies the number of principal components to be computed. By default, N=2.

NOCHECK

NOC

turns off computationally intensive numerical error checking for the MGV method. If you do not specify the NOCHECK option, the procedure computes R square from the squared length of the predicted values vector and compares this value to the R square computed from the error sum of squares that is a byproduct of the sweep algorithm (Goodnight 1978). If the two values of R square differ by more than the square root of the value of the SINGULAR= option, a warning is displayed, the value of the REFRESH= option is halved, and the model is refit after refreshing. Specifying the NOCHECK option slightly speeds up the algorithm. Note that other less computationally intensive error checking is always performed.

NOMISS

NOM

excludes all observations with missing values from the analysis, but does not exclude them from the OUT= data set. If you omit the NOMISS option, PROC PRINQUAL simultaneously computes the optimal transformations of the nonmissing values and estimates the missing values that minimize squared error.

Casewise deletion of observations with missing values occurs when you specify the NOMISS option, when there are missing values in IDENTITY variables, when there are weights less than or equal to 0, or when there are frequencies less than 1. Excluded observations are output with a blank value for the _TYPE_ variable, and they have a weight of 0. They do not contribute to the analysis but are scored and transformed as *supplementary* or passive observations. See the sections "Passive Observations" on page 6145 and "Missing Values" on page 6138 for more information about excluded observations and missing data.

NOPRINT

NOP

suppresses the display of all output. This option disables the Output Delivery System (ODS), including ODS Graphics, for the duration of the procedure. For more information, see Chapter 20, "Using the Output Delivery System."

OUT=*SAS-data-set*

specifies an output SAS data set that contains results of the analysis. If you omit the OUT= option, PROC PRINQUAL still creates an output data set and names it by using the DATA*n* convention. If you want to create a permanent SAS data set, you must specify a two-level name. (See the discussion in *SAS Language Reference: Concepts*.) You can use the REPLACE, APPROXIMATIONS, SCORES, and CORRELATIONS options to control what information is included in the output data set. For details, see the section "Output Data Set" on page 6140.

PLOTS < **(***global-plot-options***)** > < **=** *plot-request* < *(options)* > >

PLOTS < **(***global-plot-options***)** > < **= (***plot-request* < *(options)* > < **...** *plot-request* < *(options)* > **>) >**

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses from around the plot request. Here are some examples:

```
plots=none
plots=transformation
plots(unpack)=transformation
```

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;

proc prinqual plots=all;
   transformation spline(x1-x10);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

If ODS Graphics is enabled, but do not specify the PLOTS= option, then PROC PRINQUAL produces an MDPREF plot when the MDPREF option is specified.

The global plot options include the following:

FLIP

FLI

flips or interchanges the X-axis and Y-axis dimensions for MDPREF plots. The FLIP option can be specified either as a global plot option (for example, PLOTS(FLIP)) or with the MDPREF option (for example, PLOTS=MDPREF(FLIP)).

INTERPOLATE

INT

uses observations that are excluded from the analysis for interpolation in the fit and transformation plots. By default, observations with zero weight are excluded from all plots. These include observations with a zero, negative, or missing weight or frequency and observations excluded due to missing and invalid values. You can specify PLOTS(INTERPOLATE)=(*plot-requests*) to include some of these observations in the plots. You can use this option, for example, with sparse data sets to show smoother functions over the range of the data (see the section "The PLOTS(INTERPOLATE) Option" on page 7953 in Chapter 93, "The TRANSREG Procedure").

ONLY

ONL

suppresses the default plots. Only plots specifically requested are displayed.

UNPACKPANEL

UNPACK

UNP

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACKPANEL to get each plot in a separate panel.

The plot requests include the following:

ALL

produces all appropriate plots.

TRANSFORMATION

TRA

TRANSFORMATION(UNPACK)

TRA(UNP)

plots the variable transformations. By default, multiple plots can appear in some output panels. Specify UNPACKPANEL to display each plot in a separate panel.

MDPREF

MDP

plots multidimensional preference analysis results. The MDPREF plot can also be requested by specifying the MDPREF option in the PROC statement outside the PLOTS= option.

NONE

suppresses all plots.

PREFIX=*name*

PRE=*name*

specifies a prefix for naming the principal components. By default, PREFIX=Prin. As a result, the principal component default names are Prin1, Prin2,..., Prin*n*.

REFRESH=*n*

REF=*n*

specifies the number of variables to scale in the MGV method before computing a new inverse. By default, REFRESH=5. PROC PRINQUAL uses the REFRESH= option in the sweep algorithm of the MGV method. Large values for the REFRESH= option make the method run faster but with more numerical error. Small values make the method run more slowly but with more numerical accuracy.

REITERATE

REI

enables PROC PRINQUAL to use previous transformations as starting points. The REITERATE option affects only variables that are iteratively transformed (specified as LINEAR, SPLINE, MSPLINE, SSPLINE, UNTIE, OPSCORE, and MONOTONE). For iterative transformations, the REITERATE option requests a search in the input data set for a variable that consists of the value of the TPREFIX= option followed by the original variable name. If such a variable is found, it is used to provide the initial values for the first iteration. The final transformation is a member of the transformation family defined by the original variable, not the transformation family defined by the initialization variable. See the section "REITERATE Option Usage" on page 6144.

REPLACE

REP

replaces the original data with the transformed data in the output data set. The names of the transformed variables in the output data set correspond to the names of the original variables in the input data set. If you do not specify the REPLACE option, both original variables and transformed variables (with names constructed from the TPREFIX= option and the original variable names) are included in the output data set.

SCORES

SCO

includes principal component scores in the output data set. By default, scores are not included.

SINGULAR=*n*

SIN=*n*

specifies the largest value within rounding error of zero. By default, SINGULAR=1E–8. PROC PRINQUAL uses the value of the SINGULAR= option for checking $(1 - R^2)$ when constructing full-rank matrices of predictor variables, checking denominators before dividing, and so on.

STANDARD

STD

standardizes the principal component scores in the output data set to mean zero and variance one instead of the default mean zero and variance equal to the corresponding eigenvalue. See the SCORES option.

TPREFIX=*name*

TPR=*name*

specifies a prefix for naming the transformed variables. By default, TPREFIX=T. The TPREFIX= option is ignored if you specify the REPLACE option.

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z

TST=CEN | NOM | ORI | Z

specifies the standardization of the transformed variables in the OUT= data set. By default, TSTANDARD=ORIGINAL. When you specify the TSTANDARD= option in the PROC statement, it the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization just for selected variables.

CENTER centers the output variables to mean zero, but the variances are the same as the variances of the input variables.

NOMISS sets the means and variances of the transformed variables in the OUT= data set, computed over all output values that correspond to nonmissing values in the input data set, to the means and variances computed from the nonmissing observations of the original variables. The TSTANDARD=NOMISS specification is useful with missing data. When a variable is linearly transformed, the final variable contains the original nonmissing values and the missing value estimates. In other words, the nonmissing values are unchanged. If your data have no missing values, TSTANDARD=NOMISS and TSTANDARD=ORIGINAL produce the same results.

ORIGINAL sets the means and variances of the transformed variables to the means and variances of the original variables. This is the default.

Z standardizes the variables to mean zero, variance one.

For nonoptimal variable transformations, the means and variances of the original variables are actually the means and variances of the nonlinearly transformed variables, unless you specify the ORIGINAL nonoptimal *t-option* in the TRANSFORM statement. For example, if a variable X with no missing values is specified as LOG, then, by default, the final transformation of X is simply LOG(X), not LOG(X) standardized to the mean of X and variance of X.

TYPE='*text* '|*name*

TYP='*text* '|*name*

specifies the valid value for the _TYPE_ variable in the input data set. If PROC PRINQUAL finds an input _TYPE_ variable, it uses only observations with a _TYPE_ value that matches the TYPE= value. This enables a PROC PRINQUAL OUT= data set containing correlations to be used as input to PROC PRINQUAL without requiring a WHERE statement to exclude the correlations. If a _TYPE_ variable is not in the data set, all observations are used. The default is TYPE='SCORE', so if you do not specify the TYPE= option, only observations with _TYPE_ = 'SCORE' are used.

PROC PRINQUAL displays a note when it reads observations with blank values of _TYPE_, but it does not automatically exclude those observations. Data sets created by the TRANSREG and PRINQUAL procedures have blank _TYPE_ values for those observations that were excluded from the analysis due to nonpositive weights, nonpositive frequencies, or missing data. When these observations are read again, they are excluded for the same reason that they were excluded from their original analysis, not because their _TYPE_ value is blank.

UNTIE=*two-letters*

UNT=*two-letters*

specifies the first and last special missing values in the list of those special missing values that are to be estimated with within-variable order constraints but no category constraints. The *two-letters* value must consist of two letters in alphabetical order. By default, there are category constraints but no order constraints on special missing value estimates. For details, see the section "Missing Values" on page 6138. Also, see the section "Optimal Scaling" on page 7910 in Chapter 93, "The TRANSREG Procedure."

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC PRINQUAL to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the PRINQUAL procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* **;**

If one variable in the input data set represents the frequency of occurrence for other values in the observation, list the variable's name in a FREQ statement. PROC PRINQUAL then treats the data set as if each observation appeared *n* times, where *n* is the value of the FREQ variable for the observation. Noninteger values of the FREQ variable are truncated to the largest integer less than the FREQ value. The observation is used in the analysis only if the value of the FREQ statement variable is greater than or equal to 1.

ID Statement

ID *variables* **;**

The ID statement includes additional character or numeric variables in the output data set. The variables must be contained in the input data set.

TRANSFORM Statement

TRANSFORM *transform(variables < / t-options >) < transform(variables < / t-options >) . . . >* **;**

The TRANSFORM statement lists the variables to be analyzed (*variables*) and specifies the transformation (*transform*) to apply to each variable listed. You must specify a transformation for each variable list in the TRANSFORM statement. The variables are variables in the data set. The *t-options* are transformation options that provide details for the transformation; these depend on the *transform* chosen. The *t-options* are listed after a slash in the parentheses that enclose the variables.

For example, the following statements find a quadratic polynomial transformation of all variables in the data set:

```
proc prinqual;
   transform spline(_all_ / degree=2);
run;
```

Or, if N1 through N10 are nominal variables and M1 through M10 are ordinal variables, you can use the following statements:

```
proc prinqual;
   transform opscore(N1-N10) monotone(M1-M10);
run;
```

The following sections describe the transformations available (specified with *transform*) and the options available for some of the transformations (specified with *t-options*).

Families of Transformations

There are three types of transformation families: nonoptimal, optimal, and other. The families are described as follows:

Nonoptimal transformations	preprocess the specified variables, replacing each one with a single new nonoptimal, nonlinear transformation.
Optimal transformations	replace the specified variables with new, iteratively derived optimal transformation variables that fit the specified model better than the original variable (except in contrived cases where the transformation fits the model exactly as well as the original variable).
Other transformations	are the IDENTITY and SSPLINE transformations. These do not fit into either of the preceding categories.

Table 73.2 summarizes the transformations in each family.

Table 73.2 Transformation Families

Transformation	Description
Nonoptimal Transformations	
ARSIN	Inverse trigonometric sine
EXP	Exponential
LOG	Logarithm
LOGIT	Logit
POWER	Raises variables to specified power
RANK	Transforms to ranks
Optimal Transformations	
LINEAR	Linear
MONOTONE	Monotonic, ties preserved
MSPLINE	Monotonic B-spline
OPSCORE	Optimal scoring

Table 73.2 *continued*

Transformation	Description
SPLINE	B-spline
UNTIE	Monotonic, ties not preserved
Other Transformations	
IDENTITY	Identity, no transformation
SSPLINE	Iterative smoothing spline

The *transform* is followed by a variable (or list of variables) enclosed in parentheses. Optionally, depending on the *transform*, the parentheses can also contain *t-options*, which follow the variables and a slash. For example, the following statement computes the LOG transformation of X and Y:

```
transform log(X Y);
```

A more complex example follows:

```
transform spline(Y / nknots=2) log(X1 X2 X3);
```

The preceding statement uses the SPLINE transformation of the variable Y and the LOG transformation of the variables X1, X2, and X3. In addition, it uses the NKNOTS= option with the SPLINE transformation and specifies two knots.

The rest of this section provides syntax details for members of the three families of transformations. The *t-options* are discussed in the section "Transformation Options (t-options)" on page 6128.

Nonoptimal Transformations

Nonoptimal transformations are computed before the iterative algorithm begins. Nonoptimal transformations create a single new transformed variable that replaces the original variable. The new variable is not transformed by the subsequent iterative algorithms (except for a possible linear transformation and missing value estimation).

The following list provides syntax and details for nonoptimal variable transformations.

ARSIN

ARS

finds an inverse trigonometric sine transformation. Variables specified in the ARSIN *transform* must be numeric and in the interval ($-1.0 \leq x \leq 1.0$), and they are typically continuous.

EXP

exponentiates variables (x is transformed to a^x). To specify the value of a, use the PARAMETER= *t-option*. By default, a is the mathematical constant $e = 2.718\ldots$. Variables specified with the EXP *transform* must be numeric, and they are typically continuous.

LOG

transforms variables to logarithms (x is transformed to $\log_a(x)$). To specify the base of the logarithm, use the PARAMETER= *t-option*. The default is a natural logarithm with base $e = 2.718\ldots$. Variables specified with the LOG *transform* must be numeric and positive, and they are typically continuous.

LOGIT

finds a logit transformation on the variables. The logit of x is $\log(x/(1-x))$. Unlike other transformations, LOGIT does not have a three-letter abbreviation. Variables specified with the LOGIT *transform* must be numeric and in the interval $(0.0 < x < 1.0)$, and they are typically continuous.

POWER

POW

raises variables to a specified power (x is transformed to x^a). You must specify the power parameter a by specifying the PARAMETER= *t-option* following the variables.

```
power(variable / parameter=number)
```

You can use POWER for squaring variables (PARAMETER=2), reciprocal transformations (PARAMETER=–1), square roots (PARAMETER=0.5), and so on. Variables specified with the POWER *transform* must be numeric, and they are typically continuous.

RANK

RAN

transforms variables to ranks. Ranks are averaged within ties. The smallest input value is assigned the smallest rank. Variables specified with the RANK *transform* must be numeric.

Optimal Transformations

Optimal transformations are iteratively derived. Missing values for these types of variables can be optimally estimated (see the section "Missing Values" on page 6138). See the sections "OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations" on page 7911 and "SPLINE and MSPLINE Transformations" on page 7912 in Chapter 93, "The TRANSREG Procedure," for more information about the optimal transformations.

The following list provides syntax and details for optimal transformations.

LINEAR

LIN

finds an optimal linear transformation of each variable. For variables with no missing values, the transformed variable is the same as the original variable. For variables with missing values, the transformed nonmissing values have a different scale and origin than the original values. Variables specified with the LINEAR *transform* must be numeric.

MONOTONE

MON

finds a monotonic transformation of each variable, with the restriction that ties are preserved. The Kruskal (1964) secondary least squares monotonic transformation is used. This transformation weakly preserves order and category membership (ties). Variables specified with the MONOTONE *transform* must be numeric, and they are typically discrete.

MSPLINE

MSP

finds a monotonically increasing B-spline transformation with monotonic coefficients (de Boor 1978; de Leeuw 1986) of each variable. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY= *t-options* with MSPLINE. By default, PROC PRINQUAL uses a quadratic spline. Variables specified with the MSPLINE *transform* must be numeric, and they are typically continuous.

OPSCORE

OPS

finds an optimal scoring of each variable. The OPSCORE transformation assigns scores to each class (level) of the variable. The Fisher (1938) optimal scoring method is used. Variables specified with the OPSCORE *transform* can be either character or numeric; numeric variables should be discrete.

SPLINE

SPL

finds a B-spline transformation (de Boor 1978) of each variable. By default, PROC PRINQUAL uses a cubic polynomial transformation. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY *t-options* with SPLINE. Variables specified with the SPLINE *transform* must be numeric, and they are typically continuous.

UNTIE

UNT

finds a monotonic transformation of each variable without the restriction that ties are preserved. PROC PRINQUAL uses the Kruskal (1964) primary least squares monotonic transformation method. This transformation weakly preserves order but not category membership (it might untie some previously tied values). Variables specified with the UNTIE *transform* must be numeric, and they are typically discrete.

Other Transformations

IDENTITY

IDE

specifies variables that are not changed by the iterations. The IDENTITY transformation is used for variables when no transformation and no missing data estimation are desired. However, the REFLECT, ADDITIVE, TSTANDARD=Z, and TSTANDARD=CENTER options can linearly transform all variables, including IDENTITY variables, after the iterations. Observations with missing values in IDENTITY variables are excluded from the analysis, and no optimal scores are computed for missing values in IDENTITY variables. Variables specified with the IDENTITY *transform* must be numeric.

SSPLINE

SSP

finds an iterative smoothing spline transformation of each variable. The SSPLINE transformation does not generally minimize squared error. You can specify the smoothing parameter with either the SM= *t-option* or the PARAMETER= *t-option*. The default smoothing parameter is SM=0. Variables specified with the SSPLINE *transform* must be numeric, and they are typically continuous.

Transformation Options (t-options)

If you use a nonoptimal, optimal, or other transformation, you can use *t-options*, which specify additional details of the transformation. The *t-options* are specified within the parentheses that enclose variables and are listed after a slash. For example:

```
proc prinqual;
   transform spline(X Y / nknots=3);
run;
```

The preceding statements find an optimal variable transformation (SPLINE) of the variables X and Y and use a *t-option* to specify the number of knots (NKNOTS=). The following is a more complex example:

```
proc prinqual;
   transform spline(Y / nknots=3) spline(X1 X2 / nknots=6);
run;
```

These statements use the SPLINE transformation for all three variables and use *t-options* as well; the NKNOTS= option specifies the number of knots for the spline.

The following sections discuss the *t-options* available for nonoptimal, optimal, and other transformations.

Table 73.3 summarizes the *t-options*.

Table 73.3 Transformation Options

Option	Description
Nonoptimal Transformation	
ORIGINAL	Uses original mean and variance
Parameter Specification	
PARAMETER=	Specifies miscellaneous parameters
SM	Specifies smoothing parameter
Spline	
DEGREE=	Specifies the degree of the spline
EVENLY	Spaces the knots evenly
KNOTS=	Specifies the interior knots or break points
NKNOTS=	Creates *n* knots
Other t-options	
NAME=	Renames variables
REFLECT	Reflects the variable around the mean
TSTANDARD=	Specifies transformation standardization

Nonoptimal Transformation t-options

ORIGINAL

ORI

matches the variable's final mean and variance to the mean and variance of the original variable. By default, the mean and variance are based on the transformed values. The ORIGINAL *t-option* is available for all of the nonoptimal transformations.

Parameter t-options

PARAMETER=*number*

PAR=*number*

specifies the transformation parameter. The PARAMETER= *t-option* is available for the EXP, LOG, POWER, SMOOTH, and SSPLINE transformations. For EXP, the parameter is the value to be exponentiated; for LOG, the parameter is the base value; and for POWER, the parameter is the power. For SMOOTH and SSPLINE, the parameter is the raw smoothing parameter. (See the SM= option for an alternative way to specify the smoothing parameter.) The default for the PARAMETER= *t-option* for the LOG and EXP transformations is $e = 2.718\ldots$. The default parameter for SSPLINE is computed from SM=0. For the POWER transformation, you must specify the PARAMETER= *t-option*; there is no default.

SM=*n*

specifies a smoothing parameter in the range 0 to 100, just like PROC GPLOT uses. For example, SM=50 in PROC PRINQUAL is equivalent to I=SM50 on the SYMBOL statement with PROC GPLOT. You can specify the SM= *t-option* only with the SSPLINE transformation. The smoothness of the function increases as the value of the smoothing parameter increases. By default, SM=0.

Spline t-options

The following *t-options* are available with the SPLINE and MSPLINE optimal transformations.

DEGREE=*n*

DEG=*n*

specifies the degree of the B-spline transformation. The degree must be a nonnegative integer. The defaults are DEGREE=3 for SPLINE variables and DEGREE=2 for MSPLINE variables.

The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

EVENLY<=*n***>**

EVE<=*n***>**

is used with the NKNOTS= *t-option* to space the knots evenly. The differences between adjacent knots are constant. If you specify NKNOTS=*k*, *k* knots are created at

$$\text{minimum} + i((\text{maximum} - \text{minimum})/(k+1))$$

for $i = 1, \ldots, k$. For example, if you specify

```
spline(X / knots=2 evenly)
```

and the variable X has a minimum of 4 and a maximum of 10, then the two interior knots are 6 and 8. Without the EVENLY *t-option*, the NKNOTS= *t-option* places knots at percentiles, so the knots are not evenly spaced.

By default for the SPLINE and MSPLINE transformations, the smaller exterior knots are all the same and just a little smaller than the minimum. Similarly, by default, the larger exterior knots are all the same and just a little larger than the maximum. However, if you specify EVENLY=*n*, then the *n* exterior knots are evenly spaced as well. The number of exterior knots must be greater than or equal to the degree. You can specify values larger than the degree when you want to interpolate slightly beyond the range or your data. The exterior knots must be less than the minimum or greater than the maximum, and hence the knots across all sets are not precisely equally spaced. For example, with data ranging from 0 to 10, and with EVENLY=3 and NKNOTS=4, the first exterior knots are –4.000000000001, –2.000000000001, and –0.000000000001, the interior knots are 2, 4, 6, and 8, and the second exterior knots are 10.000000000001, 12.000000000001, and 14.000000000001.

KNOTS=*number-list* | *n* **TO** *m* **BY** *p*

KNO=*number-list* | *n* **TO** *m* **BY** *p*

specifies the interior knots or break points. By default, there are no knots. The first time you specify a value in the knot list, it indicates a discontinuity in the *n*th (from DEGREE=*n*) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the $(n-1)$th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times to decrease the smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the KNOTS= *t-option* with the NKNOTS= *t-option*. You should keep the number of knots small. (See the section "Specifying the Number of Knots" on page 7913 in Chapter 93, "The TRANSREG Procedure.")

NKNOTS=*n*

NKN=*n*

creates *n* knots, the first at the $100/(n+1)$ percentile, the second at the $200/(n+1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the 25th percentile, the median, and the 75th percentile. By default, NKNOTS=0. The NKNOTS= *t-option* must be ≥ 0.

You cannot use the NKNOTS= *t-option* with the KNOTS= *t-option*. You should keep the number of knots small. (See the section "Specifying the Number of Knots" on page 7913 in Chapter 93, "The TRANSREG Procedure.")

Other t-options

The following *t-options* are available for all transformations.

NAME=*(variable-list)*

NAM=*(variable-list)*

renames variables as they are used in the TRANSFORM statement. This option allows a variable to be used more than once. For example, if the variable X is a character variable, then the following step stores both the original character variable X and a numeric variable XC that contains category numbers in the output data set.

```
proc prinqual data=A n=1 out=B;
   transform linear(Y) opscore(X / name=(XC));
   id X;
run;
```

REFLECT

REF

reflects the transformation

$$y = -(y - \bar{y}) + \bar{y}$$

after the iterations are completed and before the final standardization and results calculations.

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z

TST=CEN | NOM | ORI | Z

specifies the standardization of the transformed variables in the OUT= data set. By default, TSTANDARD=ORIGINAL. When the TSTANDARD= option is specified in the PROC PRINQUAL statement, it specifies the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization only for selected variables.

WEIGHT Statement

WEIGHT *variable* **;**

When you use a WEIGHT statement, a weighted residual sum of squares is minimized. The WEIGHT statement has no effect on degrees of freedom or number of observations, but the weights affect most other calculations. The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than 0.

Details: PRINQUAL Procedure

The Three Methods of Variable Transformation

The three methods of variable transformation provided by PROC PRINQUAL are discussed in the following sections.

The Maximum Total Variance (MTV) Method

The MTV method (Young, Takane, and de Leeuw 1978) is based on the principal component model, and it attempts to maximize the sum of the first r eigenvalues of the covariance matrix. This method transforms variables to be (in a least squares sense) as similar to linear combinations of r principal component score variables as possible, where r can be much smaller than the number of variables. This maximizes the total variance of the first r components (the trace of the covariance matrix of the first r principal components). See *SAS Technical Report R-108*.

On each iteration, the MTV algorithm alternates classical principal component analysis (Hotelling 1933) with optimal scaling (Young 1981). When all variables are ordinal preference ratings, this corresponds to MDPREF analysis (Carroll 1972). You can request the dummy variable initialization method suggested by Tenenhaus and Vachette (1977), who independently propose the same iterative algorithm for nominal and interval scale-of-measurement variables.

The Minimum Generalized Variance (MGV) Method

The MGV method (Sarle 1984) uses an iterated multiple regression algorithm in an attempt to minimize the determinant of the covariance matrix of the transformed variables. This method transforms each variable to be (in a least squares sense) as similar to linear combinations of the remaining variables as possible. This locally minimizes the generalized variance of the transformed variables, the determinant of the covariance matrix, the volume of the parallelepiped defined by the transformed variables, and the sphericity (the extent to which a quadratic form in the optimized covariance matrix defines a sphere). See *SAS Technical Report R-108*.

On each iteration for each variable, the MGV algorithm alternates multiple regression with optimal scaling. The multiple regression involves predicting the selected variable from all other variables. You can request a dummy variable initialization by using a modification of the Tenenhaus and Vachette (1977) method that is appropriate with a regression algorithm. This method can be viewed as a way of investigating the nature of the linear and nonlinear dependencies in, and the rank of, a data matrix containing variables that can be nonlinearly transformed. This method tries to create a less-than-full-rank data matrix. The matrix contains the transformation of each variable that is most similar to what the other transformed variables predict.

The Maximum Average Correlation (MAC) Method

The MAC method (de Leeuw 1985) uses an iterated constrained multiple regression algorithm in an attempt to maximize the average of the elements of the correlation matrix. This method transforms each variable to be (in a least squares sense) as similar to the average of the remaining variables as possible.

On each iteration for each variable, the MAC algorithm alternates computing an equally weighted average of the other variables with optimal scaling. The MAC method is similar to the MGV method in that each variable is scaled to be as similar to a linear combination of the other variables as possible, given the constraints on the transformation. However, optimal weights are not computed. You can use the MAC method when all variables are positively correlated or when no monotonicity constraints are placed on any transformations. Do not use this method with negatively correlated variables when some optimal transformations are constrained to be increasing because the signs of the correlations are not taken into account. The MAC method is useful as an initialization method for the MTV and MGV methods.

Understanding How PROC PRINQUAL Works

In the following example, PROC PRINQUAL uses the MTV method to linearize a curved scatter plot. Let

$$\begin{aligned} X_1 &= -1 \text{ to } 1 \text{ by } 0.02 \\ X_2 &= X_1^3 + \epsilon \\ X_3 &= X_2^5 + \epsilon \end{aligned}$$

where ϵ is normal error.

These three variables define a curved swarm of points in three-dimensional space. First, the SGSCATTER procedure is used to display two-dimensional views of these data. Next, PROC PRINQUAL is used to straighten the scatter plot, making it more one-dimensional by finding a smooth transformation of each variable. The N=1 option in the PROC PRINQUAL statement requests one principal component. The TRANSFORM statement requests a cubic spline transformation with nine knots. *Splines* are curves, which are usually required to be continuous and smooth. See the section "Splines" on page 6137 for more information about splines. See Smith (1979) for an excellent introduction to splines.

PROC PRINQUAL transforms each variable to be as much as possible like the first principal component (or more generally, to be close to the space defined by the first N= principal components). One component accounts for 92 percent of the variance of the untransformed data and over 99 percent of the variance of the transformed data (see Figure 73.5). Note that the results did not converge in the default 50 iterations, so more iterations were requested using the MAXITER= option. The transformations are requested by specifying PLOTS=TRANSFORMATION and are displayed in Figure 73.6.

PROC PRINQUAL creates an output data set that contains both the original and transformed variables. The original variables are named X1, X2, and X3, and the transformed variables are named TX1, TX2, and TX3. The transformed variables are displayed using the SGSCATTER procedure in Figure 73.7.

The following statements produce Figure 73.4 through Figure 73.7:

```
ods graphics on;

* Generate Three-Dimensional Data;
data X;
   do X1 = -1 to 1 by 0.02;
      X2 = X1 ** 3 + 0.05 * normal(7);
      X3 = X1 ** 5 + 0.05 * normal(7);
      output;
   end;
run;

proc sgscatter data=x;
   plot x1*x2 x1*x3 x3*x2;
   run;

* Try to Straighten the Scatter Plot;
proc prinqual data=X n=1 maxiter=2000 plots=transformation out=results;
   title 'Linearize the Scatter Plot';
   transform spline(X1-X3 / nknots=9);
run;

* Plot the Linearized Scatter Plot;
proc sgscatter data=results;
   plot tx1*tx2 tx1*tx3 tx3*tx2;
   run;
```

The three-dimensional data in Figure 73.4 and Figure 73.7 are displayed in three two-dimensional plots, arrayed as if they were three faces of a cube that was flattened as you might flatten a box.

Figure 73.6 Transformations

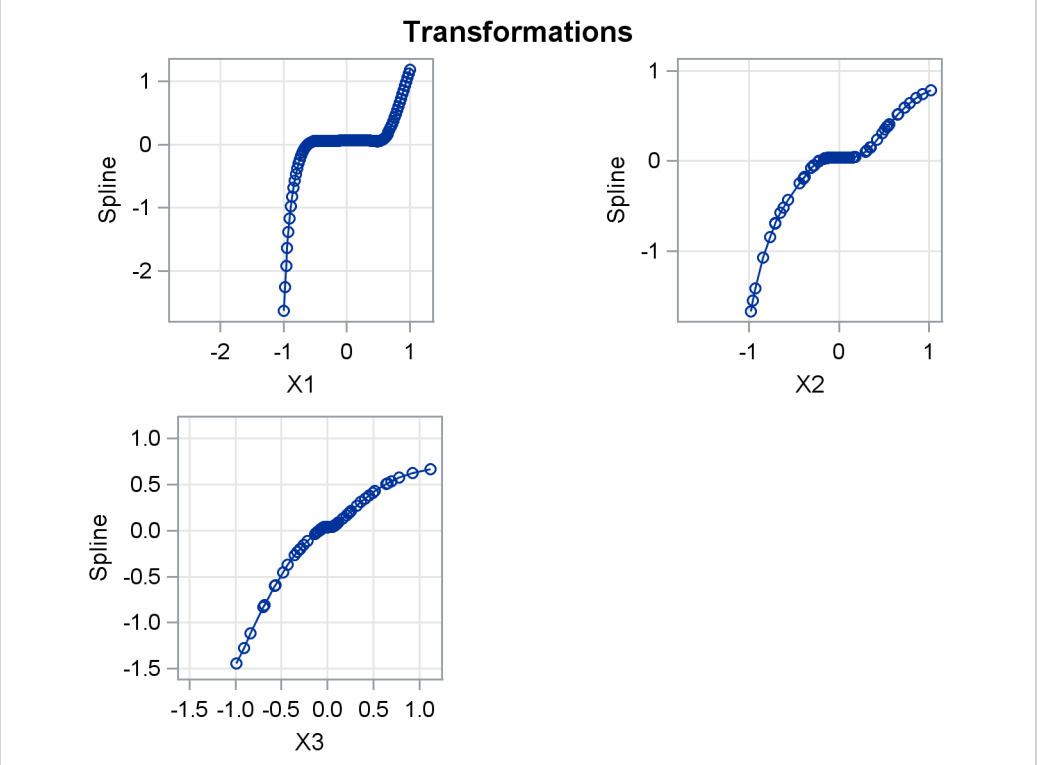

Figure 73.7 Linearized Scatter Plot

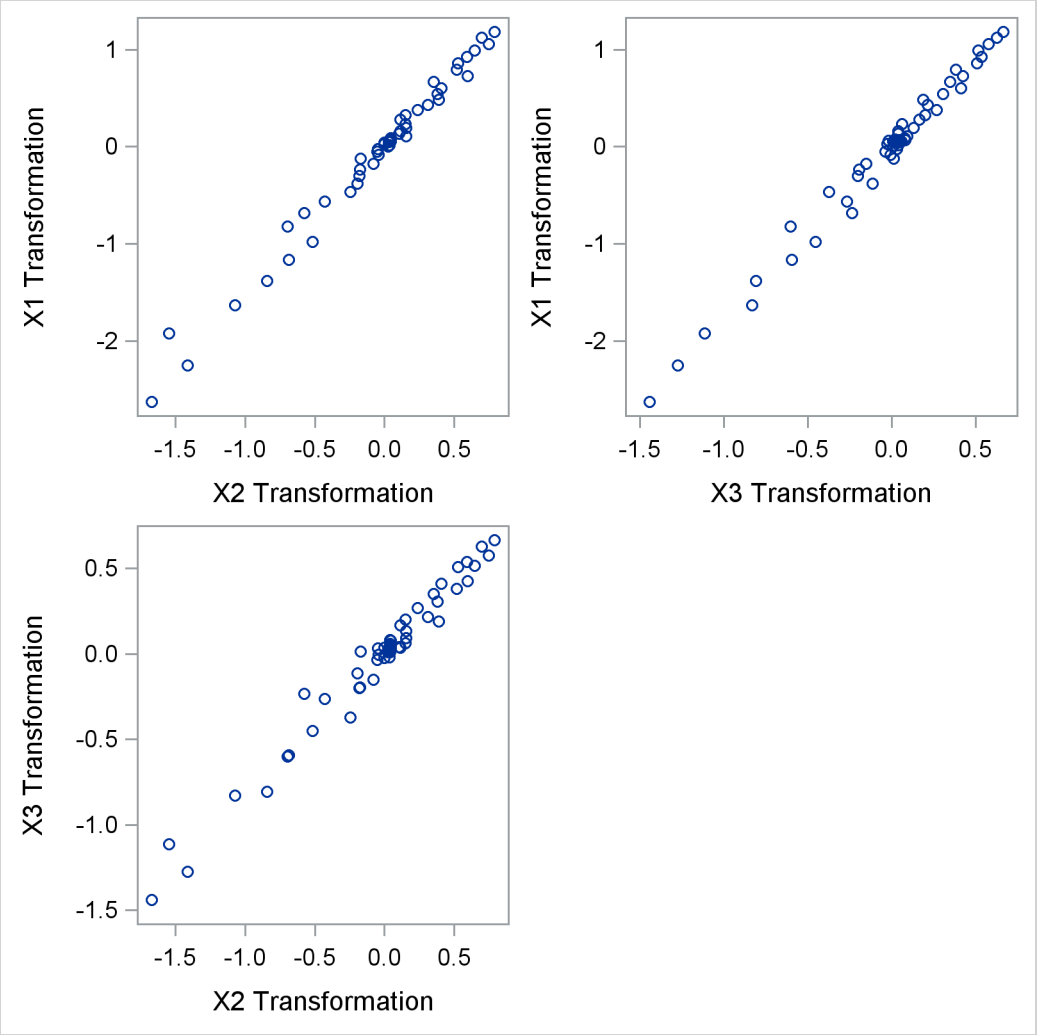

Splines

Splines are curves, and they are usually required to be continuous and smooth. Splines are usually defined as piecewise polynomials of degree n with function values and first $n-1$ derivatives that agree at the points where they join. The abscissa values of the join points are called *knots*. The term "spline" is also used for polynomials (splines with no knots) and piecewise polynomials with more than one discontinuous derivative. Splines with no knots are generally smoother than splines with knots, which are generally smoother than splines with multiple discontinuous derivatives. Splines with few knots are generally smoother than splines with many knots; however, increasing the number of knots usually increases the fit of the spline function to the data. Knots give the curve freedom to bend to follow the data more closely. See Smith (1979) for an excellent introduction to splines. There are many examples and detailed discussions of splines in Chapter 93, "The TRANSREG Procedure." See the sections "Linear and Nonlinear Regression Functions" on page 7862, "Smoothing Splines" on page 7875, "SPLINE and MSPLINE Transformations" on page 7912, "Specifying the Number of Knots" on page 7913, "SPLINE, BSPLINE, and PSPLINE Compar-

isons" on page 7915, "Linear and Nonlinear Regression Functions" on page 7862, "Simultaneously Fitting Two Regression Functions" on page 7866, and examples Example 93.18 and Example 93.1.

Missing Values

PROC PRINQUAL can estimate missing values, subject to optional constraints, so that the covariance matrix is optimized. The procedure provides several approaches for handling missing data. When you specify the NOMISS option in the PROC PRINQUAL statement, observations with missing values are excluded from the analysis. Otherwise, missing data are estimated, using variable means as initial estimates. Missing values for OPSCORE character variables are treated the same as any other category during the initialization. See the section "Missing Values" on page 7901 in Chapter 93, "The TRANSREG Procedure," for more information about missing data estimation.

Controlling the Number of Iterations

Several options in the PROC PRINQUAL statement control the number of iterations performed. Iteration terminates when any one of the following conditions is satisfied:

- The number of iterations equals the value of the MAXITER= option.
- The average absolute change in variable scores from one iteration to the next is less than the value of the CONVERGE= option.
- The criterion change is less than the value of the CCONVERGE= option.

With the MTV method, the change in the proportion of variance criterion can become negative when the data have converged so that it is numerically impossible, within machine precision, to increase the criterion. Because the MTV algorithm is convergent, a negative criterion change is the result of very small amounts of rounding error. The MGV method displays the average squared multiple correlation (which is not the criterion being optimized), so the criterion change can become negative well before convergence. The MAC method criterion (average correlation) is never computed, so the CCONVERGE= option is ignored for METHOD=MAC. You can specify a negative value for either convergence option if you want to define convergence only in terms of the other convergence option.

With the MGV method, iterations minimize the generalized variance (determinant), but the generalized variance is not reported for two reasons. First, in most data sets, the generalized variance is almost always near zero (or will be after one or two iterations), which is its minimum. This does not mean that iteration is complete; it simply means that at least one multiple correlation is at or near one. The algorithm continues minimizing the determinant in $(m-1), (m-2)$ dimensions, and so on. Because the generalized variance is almost always near zero, it does not provide a good indication of how the iterations are progressing. The mean R square provides a better indication of convergence. The second reason for not reporting the generalized variance is that almost no additional time is required to compute R square values for each step. This is because the error sum of squares is a byproduct of the algorithm at each step. Computing the

determinant at the end of each iteration adds more computations to an already computationally intensive algorithm.

You can increase the number of iterations to ensure convergence by increasing the value of the MAXITER= option and decreasing the value of the CONVERGE= option. Because the average absolute change in standardized variable scores seldom decreases below 1E–11, you typically do not specify a value for the CONVERGE= option less than 1E–8 or 1E–10. Most of the data changes occur during the first few iterations, but the data can still change after 50 or even 100 iterations. You can try different combinations of values for the CONVERGE= and MAXITER= options to ensure convergence without extreme overiteration. If the data do not converge with the default specifications, specify the REITERATE option, or try CONVERGE=1E–8 and MAXITER=50, or CONVERGE=1E–10 and MAXITER=200.

Performing a Principal Component Analysis of Transformed Data

PROC PRINQUAL produces an iteration history table that displays (for each iteration) the iteration number, the maximum and average absolute change in standardized variable scores computed over the iteratively transformed variables, the criterion being optimized, and the criterion change. In order to examine the results of the analysis in more detail, you can analyze the information in the output data set by using other SAS procedures.

Specifically, use the PRINCOMP procedure to perform a principal components analysis on the transformed data. PROC PRINCOMP accepts the raw data from PROC PRINQUAL but issues a warning, because the PROC PRINQUAL output data set has _NAME_ and _TYPE_ variables but is not a TYPE=CORR data set. You can ignore this warning.

If the output data set contains both scores and correlations, you must subset it for analysis with PROC PRINCOMP. Otherwise, the correlation observations are treated as ordinary observations and the PROC PRINCOMP results are incorrect. For example, consider the following statements:

```
proc prinqual data=a out=b correlations replace;
   transform spline(var1-var50 / nknots=3);
run;

proc princomp data=b;
   where _TYPE_='SCORE';
run;
```

Also note that the proportion of variance accounted for, as reported by PROC PRINCOMP, can exceed the proportion of variance accounted for in the last PROC PRINQUAL iteration. This is because PROC PRINQUAL reports the variance accounted for by the components analysis that generated the current scaling of the data, not a components analysis of the current scaling of the data.

Using the MAC Method

You can use the MAC algorithm alone by specifying METHOD=MAC, or you can use it as an initialization algorithm for METHOD=MTV and METHOD=MGV analyses by specifying the iteration option INITITER=. If any variables are negatively correlated, do not use the MAC algorithm with monotonic transformations (MONOTONE, UNTIE, and MSPLINE) because the signs of the correlations among the variables are not used when computing variable approximations. If an approximation is negatively correlated with the original variable, monotone constraints would make the optimally scaled variable a constant, which is not allowed (see the section "Avoiding Constant Transformations" on page 6143). When used with other transformations, the MAC algorithm can reverse the scoring of the variables. So, for example, if variable X is designated LOG(X) with METHOD=MAC and TSTANDARD=ORIGINAL, the final transformation (for example, TX) might not be LOG(X). If TX is not LOG(X), it has the same mean as LOG(X) and the same variance as LOG(X), and it is perfectly negatively correlated with LOG(X). PROC PRINQUAL displays a note for every variable that is reversed in this manner.

You can use the METHOD=MAC algorithm to reverse the scorings of some rating variables before a factor analysis. The correlations among bipolar ratings such as 'like - dislike', 'hot - cold', and 'fragile - monumental' are typically both positive and negative. If some items are reversed to say 'dislike - like', 'cold - hot', and 'monumental - fragile', some of the negative signs can be eliminated, and the factor pattern matrix would be cleaner. You can use PROC PRINQUAL with METHOD=MAC and LINEAR transformations to reverse some items, maximizing the average of the intercorrelations.

Output Data Set

PROC PRINQUAL produces an output data set by default. By specifying the OUT=, APPROXIMATIONS, SCORES, REPLACE, and CORRELATIONS options in the PROC PRINQUAL statement, you can name this data set and control its contents.

By default, the procedure creates an output data set that contains variables with _TYPE_='SCORE'. These observations contain original variables, transformed variables, components, or data approximations. If you specify the CORRELATIONS option in the PROC PRINQUAL statement, the data set also contains observations with _TYPE_='CORR'; these observations contain correlations or component structure information.

Structure and Content

The output data set can have 16 different forms, depending on the specified combinations of the REPLACE, SCORES, APPROXIMATIONS, and CORRELATIONS options. You can specify any combination of these options. To illustrate, assume that the data matrix consists of N observations and m variables, and n components are computed. Then define the following:

D the $N \times m$ matrix of original data with variable names that correspond to the names of the variables in the input data set. However, when you use the OPSCORE transformation on character variables, those variables are replaced by numeric variables that contain category numbers.

T the $N \times m$ matrix of transformed data with variable names constructed from the value of the TPREFIX= option (if you do not specify the REPLACE option) and the names of the variables in the input data set

S the $N \times n$ matrix of component scores with variable names constructed from the value of the PREFIX= option and integers

A the $N \times m$ matrix of data approximations with variable names constructed from the value of the APREFIX= option and the names of the variables in the input data set

$\mathbf{R_{TD}}$ the $m \times m$ matrix of correlations between the transformed variables and the original variables with variable names that correspond to the names of the variables in the input data set. When missing values exist, casewise deletion is used to compute the correlations.

$\mathbf{R_{TT}}$ the $m \times m$ matrix of correlations among the transformed variables with the variable names constructed from the value of the TPREFIX= option (if you do not specify the REPLACE option) and the names of the variables in the input data set

$\mathbf{R_{TS}}$ the $m \times n$ matrix of correlations between the transformed variables and the principal component scores (component structure matrix) with variable names constructed from the value of the PREFIX= option and integers

$\mathbf{R_{TA}}$ the $m \times m$ matrix of correlations between the transformed variables and the variable approximations with variable names constructed from the value of the APREFIX= option and the names of the variables in the input data set

To create a data set Work.A that contains all information, specify the following options in the PROC PRINQUAL statement:

```
proc prinqual scores approximations correlations out=a;
```

Also use a TRANSFORM statement appropriate for your data. Then the Work.A data set contains the following:

D	T	S	A
$\mathbf{R_{TD}}$	$\mathbf{R_{TT}}$	$\mathbf{R_{TS}}$	$\mathbf{R_{TA}}$

To eliminate the bottom partitions that contain the correlations and component structure, do not specify the CORRELATIONS option. For example, use the following PROC PRINQUAL statement with an appropriate TRANSFORM statement:

```
proc prinqual scores approximations out=a;
```

Then the Work.A data set contains the following:

D	T	S	A

Suppose you use the following PROC PRINQUAL statement (with an appropriate TRANSFORM statement):

```
proc prinqual out=a;
```

This creates a data set Work.A of the following form:

```
D T
```

To output transformed data and component scores only, specify the following options in the PROC PRINQUAL statement:

```
proc prinqual replace scores out=a;
```

Then the Work.A data set contains the following:

```
T S
```

TYPE and _NAME_ Variables

In addition to the preceding information, the output data set contains two character variables, the variable _TYPE_ (length 8) and the variable _NAME_ (length 32).

The _TYPE_ variable has the value 'SCORE' if the observation contains variables, transformed variables, components, or data approximations; the _TYPE_ variable has the value 'CORR' if the observation contains correlations or component structure.

By default, the _NAME_ variable has values 'ROW1', 'ROW2', and so on, for the observations with _TYPE_='SCORE'. If you use an ID statement, the variable _NAME_ contains the formatted ID variable for SCORES observations. The values of the variable _NAME_ for observations with _TYPE_='CORR' are the names of the transformed variables.

Certain procedures, such as PROC PRINCOMP, which can use the PROC PRINQUAL output data set, issue a warning that the PROC PRINQUAL data set contains _NAME_ and _TYPE_ variables but is not a TYPE=CORR data set. You can ignore this warning.

Variable Names

The TPREFIX=, APREFIX=, and PREFIX= options specify prefixes for the transformed and approximation variable names and for principal component score variables, respectively. PROC PRINQUAL constructs transformed and approximation variable names from a prefix and the first characters of the original variable name. The number of characters in the prefix plus the number of characters in the original variable name (including the final digits, if any) required to uniquely designate the new variables should not exceed 32. For example, if the APREFIX= parameter that you specify is one character, PROC PRINQUAL adds the first 31 characters of the original variable name; if your prefix is four characters, only the first 28 characters of the original variable name are added.

Effect of the TSTANDARD= and COVARIANCE Options

The values in the output data set are affected by the TSTANDARD= and COVARIANCE options. If you specify TSTANDARD=NOMISS, the NOMISS standardization is performed on the transformed data after the iterations have been completed, but before the output data set is created. The new means and variances are used in creating the output data set. Then, if you do not specify the COVARIANCE option, the data are transformed to mean zero and variance one. The principal component scores and data approximations are computed from the resulting matrix. The data are then linearly transformed to have the mean and variance specified by the TSTANDARD= option. The data approximations are transformed so that the means within each pair of a transformed variable and its approximation are the same. The ratio of the variance of a variable approximation to the variance of the corresponding transformed variable equals the proportion of the variance of the variable that is accounted for by the components model.

If you specify the COVARIANCE option and do not specify TSTANDARD=Z, you can input the transformed data to PROC PRINCOMP, again specifying the COVARIANCE option, to perform a components analysis of the results of PROC PRINQUAL. Similarly, if you do not specify the COVARIANCE option with PROC PRINQUAL and you input the transformed data to PROC PRINCOMP without the COVARIANCE option, you receive the same report. However, some combinations of PROC PRINQUAL options, such as COVARIANCE and TSTANDARD=Z, while valid, produce approximations and scores that cannot be reproduced by PROC PRINCOMP.

The component scores in the output data set are computed from the correlations among the transformed variables, or from the covariances if you specified the COVARIANCE option. The component scores are computed after the TSTANDARD=NOMISS transformation, if specified. The means of the component scores in the output data set are always zero. The variances equal the corresponding eigenvalues, unless you specify the STANDARD option; then the variances are set to one.

Avoiding Constant Transformations

There are times when the optimal scaling produces a constant transformed variable. This can happen with the MONOTONE, UNTIE, and MSPLINE transformations when the target is negatively correlated with the original input variable. It can happen with all transformations when the target is uncorrelated with the original input variable. When this happens, the procedure modifies the target to avoid a constant transformation. This strategy avoids certain nonoptimal solutions.

If the transformation is monotonic and a constant transformed variable results, the procedure multiplies the target by –1 and tries the optimal scaling again. If the transformation is not monotonic or if the multiplication by –1 did not help, the procedure tries using a random target. If the transformation is still constant, the previous nonconstant transformation is retained. When a constant transformation is avoided by any strategy, this message is displayed: “A constant transformation was avoided for *name*.”

Constant Variables

Constant and almost constant variables are zeroed and ignored.

Character OPSCORE Variables

Character OPSCORE variables are replaced by a numeric variable containing category numbers before the iterations, and the character values are discarded. Only the first eight characters are considered in determining category membership. If you want the original character variable in the output data set, give it a different name in the OPSCORE specification (OPSCORE(x / name=(x2)) and name the original variable in the ID statement (ID x;).

REITERATE Option Usage

You can use the REITERATE option to perform additional iterations when PROC PRINQUAL stops before the data have adequately converged. For example, suppose you execute the following code:

```
proc prinqual data=A cor out=B;
   transform mspline(X1-X5);
run;
```

If the transformations do not converge in the default 30 iterations, you can perform more iterations without repeating the first 30 iterations, as follows:

```
proc prinqual data=B reiterate cor out=B;
   transform mspline(X1-X5);
run;
```

Note that a WHERE statement is not necessary to exclude the correlation observations. They are automatically excluded because their _TYPE_ variable value is not 'SCORE'.

You can also use the REITERATE option to specify starting values other than the original values for the transformations. Providing alternate starting points might avoid local optima. Here are two examples.

```
proc prinqual data=A out=B;
   transform rank(X1-X5);
run;

proc prinqual data=B reiterate out=C;
   /* Use ranks as the starting point. */
   transform monotone(X1-X5);
run;

data B;
   set A;
   array TXS[5] TX1-TX5;
   do j = 1 to 5;
      TXS[j] = normal(0);
   end;
run;
```

```
proc prinqual data=B reiterate out=C;
   /* Use a random starting point. */
   transform monotone(X1-X5);
run;
```

Note that divergence with the REITERATE option, particularly in the second iteration, is not an error since the initial transformation is not required to be a valid member of the transformation family. When you specify the REITERATE option, the iteration does not terminate when the criterion change is negative during the first 10 iterations.

Passive Observations

Observations can be excluded from the analysis for several reasons, including zero weight, zero frequency, missing values in variables designated as IDENTITY, or missing values with the NOMISS option specified. These observations are passive in that they do not contribute to determining transformations, R square, total variance, and so on. However, some information can be computed for them, such as approximations, principal component scores, and transformed values. Passive observations in the output data set have a blank value for the variable _TYPE_.

Missing value estimates for passive observations might converge slowly with METHOD=MTV. In the following example, the missing value estimates should be 2, 5, and 8. Since the nonpassive observations do not change, the procedure converges in one iteration but the missing value estimates do not converge. The extra iterations produced by specifying CONVERGE=–1 and CCONVERGE=–1, as shown in the second PROC PRINQUAL step that follows, generate the expected results.

```

proc prinqual nomiss data=A nomiss n=1 out=B method=mtv converge=-1 cconverge=-1;
   transform lin(X Y);
run;
```

```
proc print;
run;
```

Computational Resources

This section provides information about the computational resources required to run PROC PRINQUAL.

Let

N = number of observations
m = number of variables
n = number of principal components
k = maximum spline degree
p = maximum number of knots

- For the MTV algorithm, more than

$$56m + 8Nm + 8\,(6N + (p + k + 2)(p + k + 11))$$

  bytes of array space are required.

- For the MGV and MAC algorithms, more than $56m$ plus the maximum of the data matrix size and the optimal scaling work space bytes of array space are required. The data matrix size is $8Nm$ bytes. The optimal scaling work space requires less than $8\,(6N + (p + k + 2)(p + k + 11))$ bytes.

- For the MTV and MGV algorithms, more than $56m + 4m(m + 1)$ bytes of array space are required.

- PROC PRINQUAL tries to store the original and transformed data in memory. If there is not enough memory, a utility data set is used, potentially resulting in a large increase in execution time. The amount of memory for the preceding data formulas is an underestimate of the amount of memory needed to handle most problems. These formulas give an absolute minimum amount of memory required. If a utility data set is used, and if memory could be used with perfect efficiency, then roughly the amount of memory stated previously would be needed. In reality, most problems require at least two or three times the minimum.

- PROC PRINQUAL sorts the data once. The sort time is roughly proportional to $mN^{3/2}$.

- For the MTV algorithm, the time required to compute the variable approximations is roughly proportional to $2Nm^2 + 5m^3 + nm^2$.

- For the MGV algorithm, one regression analysis per iteration is required to compute model parameter estimates. The time required to accumulate the crossproduct matrix is roughly proportional to Nm^2. The time required to compute the regression coefficients is roughly proportional to m^3. For each variable for each iteration, the swept crossproduct matrix is updated with time roughly proportional to m(N+m). The swept crossproduct matrix is updated for each variable with time roughly proportional to m^2, until computations are refreshed, requiring all sweeps to be performed again.

- The only computationally intensive part of the MAC algorithm is the optimal scaling, since variable approximations are simple averages.
- Each optimal scaling is a multiple regression problem, although some transformations are handled with faster special-case algorithms. The number of regressors for the optimal scaling problems depends on the original values of the variable and the type of transformation. For each monotone spline transformation, an unknown number of multiple regressions is required to find a set of coefficients that satisfies the constraints. The B-spline basis is generated twice for each SPLINE and MSPLINE transformation for each iteration. The time required to generate the B-spline basis is roughly proportional to Nk^2.

Displayed Output

The main output from PROC PRINQUAL is the output data set. However, the procedure does produce displayed output in the form of an iteration history table that includes the following:

- iteration number
- the criterion being optimized
- criterion change
- maximum and average absolute change in standardized variable scores computed over variables that can be iteratively transformed
- notes
- final convergence status

ODS Table Names

PROC PRINQUAL assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 73.4 along with the PROC statement options needed to produce the table. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 73.4 ODS Tables Produced by PROC PRINQUAL

ODS Table Name	Description	Option
ConvergenceStatus	Convergence Status	default
Footnotes	Iteration History Footnotes	default
MAC	MAC Iteration History	METHOD=MAC
MGV	MGV Iteration History	METHOD=MGV
MTV	MTV Iteration History	METHOD=MTV
PctVar	Percentage of Variance	nonprinting

The nonprinting "PctVar" table is not displayed and does not appear in the ODS trace output unless you specify it in an ODS OUTPUT statement, as in the following example:

```
ods output pctvar=pvardataset;
```

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

The plots are produced only when you specify the options shown in the table. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC PRINQUAL generates are listed in Table 73.5, along with the required statements and options.

Table 73.5 Graphs Produced by PROC PRINQUAL

ODS Graph Name	Plot Description	Option
MDPrefPlot	Multidimensional preference analysis	MDPREF
TransformationPlot	Variable transformation	PLOTS=TRANSFORMATION

Examples: PRINQUAL Procedure

Example 73.1: Multidimensional Preference Analysis of Automobile Data

This example uses PROC PRINQUAL to perform a nonmetric multidimensional preference (MDPREF) analysis (Carroll 1972). MDPREF analysis is a principal component analysis of a data matrix with columns that correspond to people and rows that correspond to objects. The data are ratings or rankings of each person's preference for each object. The data are the transpose of the usual multivariate data matrix. (In other words, the columns are people; in the more typical matrix the rows represent people.) The final result of an MDPREF analysis is a biplot (Gabriel 1981) of the resulting preference space. A biplot displays the judges and objects in a single plot by projecting them onto the plane in the transformed variable space that accounts for the most variance.

In 1980, 25 judges gave their preferences for each of 17 new automobiles. The ratings were made on a 0 to 9 scale, with 0 meaning very weak preference and 9 meaning very strong preference for the automobile. The following statements create a SAS data set with the manufacturer and model of each automobile along with the ratings:

```
title 'Preference Ratings for Automobiles Manufactured in 1980';

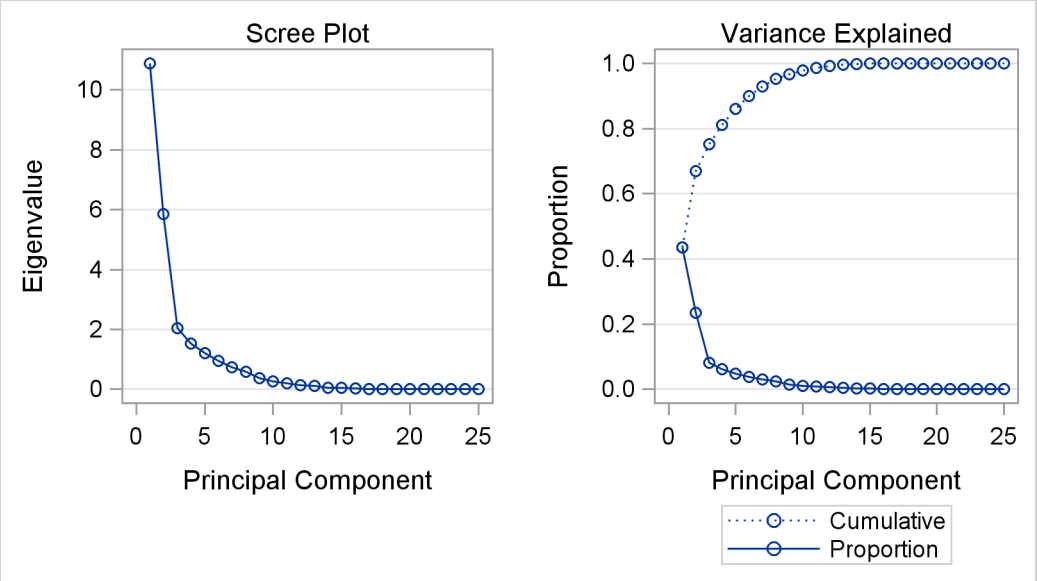
;
```

The following statements run PROC PRINCOMP and create a scree plot. The results of this step are shown in Output 73.1.1.

```
ods graphics on;
* Principal Component Analysis of the Original Data;
proc princomp data=CarPref;
   ods select ScreePlot;
   var '1'n-'25'n;
run;
```

Output 73.1.1 Eigenvalue Plot



The scree or eigenvalue plot in Output 73.1.1 shows that two principal components should be retained. There is a clear separation between the first two components and the remaining components. There are eight eigenvalues that are precisely zero because there are eight fewer observations than variables in the data matrix. One additional eigenvalue is zero, for a total of nine zero eigenvalues, since the correlation matrix is based on centered data. The following statements create the data set and perform a principal component analysis of the original data.

PROC PRINQUAL fits the nonmetric MDPREF model. PROC PRINQUAL monotonically transforms the raw judgments to maximize the proportion of variance accounted for by the first two principal components. The MONOTONE option is specified in the TRANSFORM statement to request a nonmetric MDPREF analysis; alternatively, you can instead specify the IDENTITY option for a metric analysis. Several options are used in the PROC PRINQUAL statement. The option DATA=CarPref specifies the input data set, OUT=Results creates an output data set, and N=2 and the default METHOD=MTV transform the data to better fit a two-component model. The REPLACE option replaces the original data with the monotonically transformed data in the OUT= data set. The MDPREF option standardizes the component scores to variance one so that the geometry of the biplot is correct, and it creates two variables in the OUT= data set named Prin1 and Prin2. These variables contain the standardized principal component scores and structure matrix, which are used to make the biplot. If the variables in data matrix $\mathbf{X}$ are standardized to mean zero and variance one, and n is the number of rows in $\mathbf{X}$, then $\mathbf{X} = \mathbf{V}\mathbf{\Lambda}^{1/2}\mathbf{W}'$ is the principal component model, where $\mathbf{X}'\mathbf{X}/(n-1) = \mathbf{W}\mathbf{\Lambda}\mathbf{W}'$. The $\mathbf{W}$ and $\mathbf{\Lambda}$ contain the eigenvectors and eigenvalues of the correlation matrix of $\mathbf{X}$. The first two columns of $\mathbf{V}$, the standardized component scores, and $\mathbf{W}\mathbf{\Lambda}^{1/2}$, which is the structure matrix, are output. The advantage of creating a biplot based on principal components is that coordinates do not depend on the sample size. The following statements transform the data and produce Output 73.1.2.

```
* Transform the Data to Better Fit a Two Component Model;
proc prinqual data=CarPref out=Results n=2 replace mdpref;
   title2 'Multidimensional Preference (MDPREF) Analysis';
   title3 'Optimal Monotonic Transformation of Preference Data';
   id model;
   transform monotone('1'n-'25'n);
run;
```

30	0.00027	0.00454	0.82995	0.00000	Not Converged

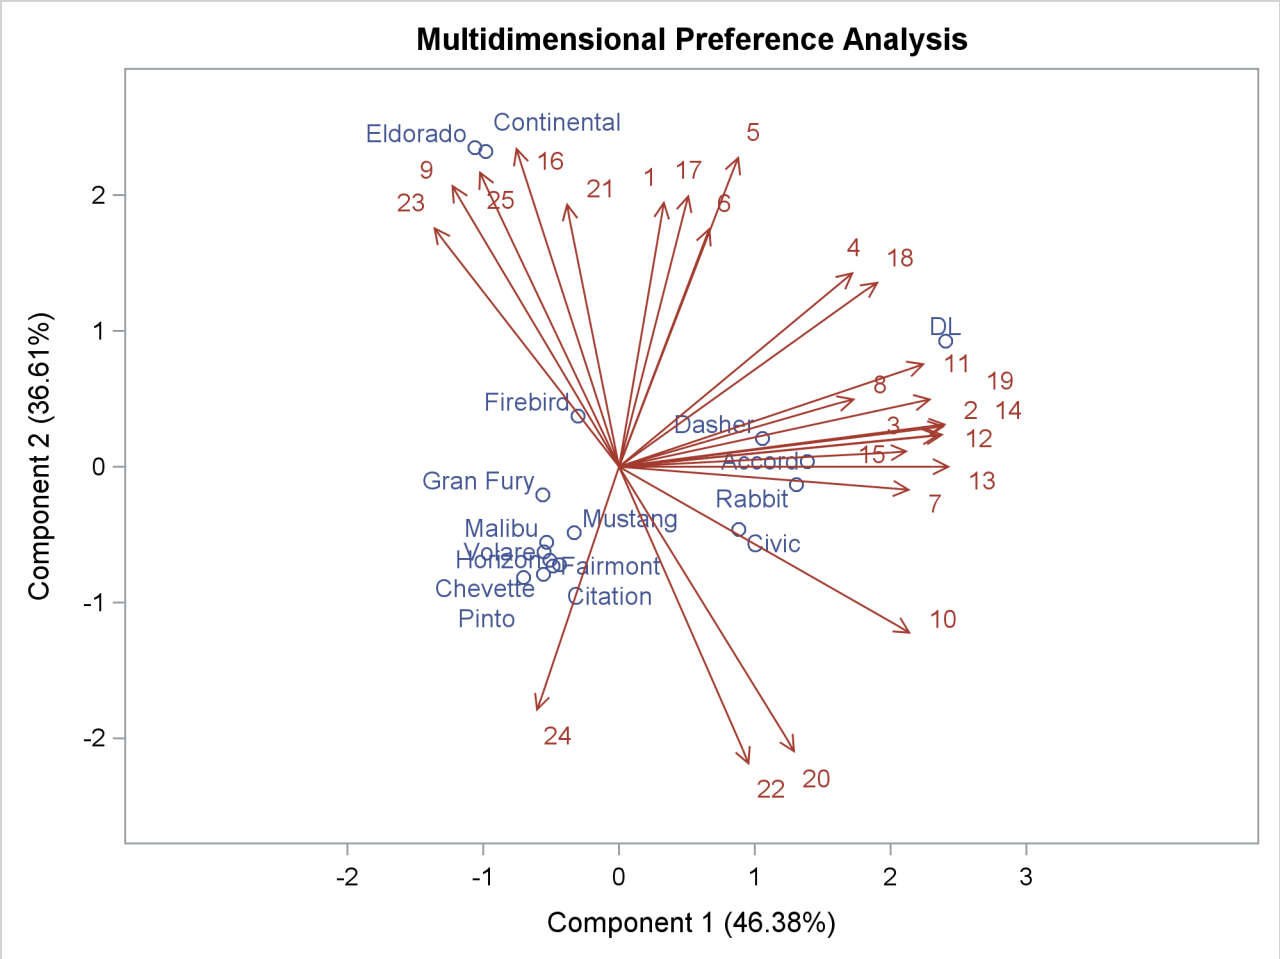
WARNING: Failed to converge, however criterion change is less than 0.0001.

The iteration history displayed by PROC PRINQUAL indicates that the proportion of variance is increased from an initial 0.66946 to 0.82995. The proportion of variance accounted for by PROC PRINQUAL on the first iteration equals the cumulative proportion of variance shown by PROC PRINCOMP for the first two principal components. PROC PRINQUAL's initial iteration performs a standard principal component analysis of the raw data. The columns labeled Average Change, Maximum Change, and Criterion Change contain values that always decrease, indicating that PROC PRINQUAL is improving the transformations at a monotonically decreasing rate over the iterations. This does not always happen, and when it does not, it suggests that the analysis might be converging to a degenerate solution. See Example 73.2 for a discussion

of a degenerate solution. The algorithm does not converge in 30 iterations. However, the criterion change is small, indicating that more iterations are unlikely to have much effect on the results.

The biplot, shown in Output 73.1.3, is automatically displayed by PROC PRINQUAL when ODS Graphics is enabled and the MDPREF option is specified.

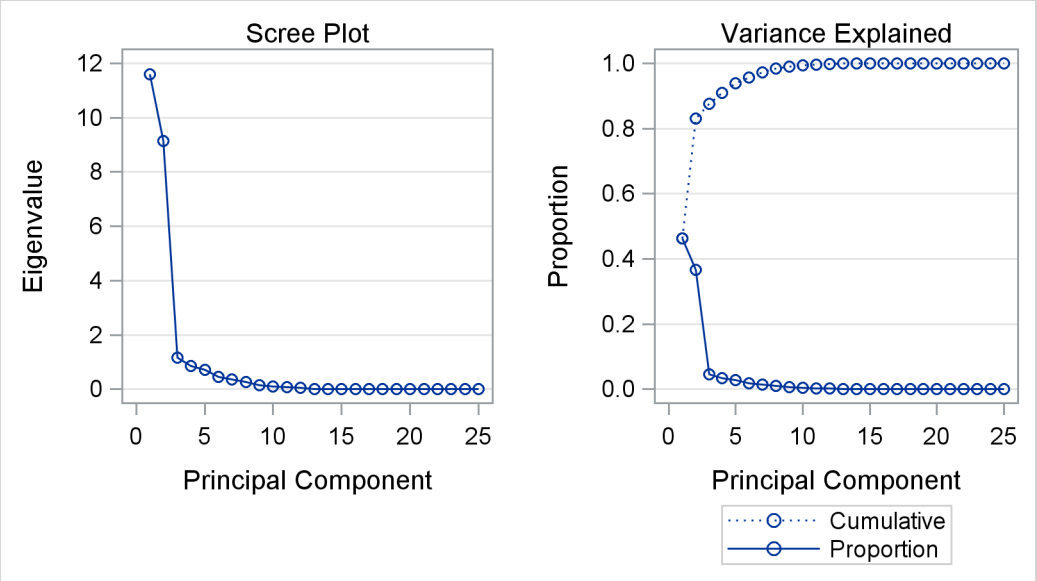
Output 73.1.3 Biplot Made with PRINQUAL



The second PROC PRINCOMP analysis is performed on the transformed data. The WHERE statement is used to retain only the monotonically transformed judgments. The scree plot shows that the first two eigenvalues are now much larger than the remaining smaller eigenvalues. The second eigenvalue has increased markedly at the expense of the next several eigenvalues. Two principal components seem to be necessary and sufficient to adequately describe these judges' preferences for these automobiles. The cumulative proportion of variance displayed by PROC PRINCOMP for the first two principal components is 0.83. The following statements perform the analysis and produce Output 73.1.4:

```
* Final Principal Component Analysis;
proc princomp data=Results;
   ods select ScreePlot;
   var '1'n-'25'n;
   where _TYPE_='SCORE';
run;
```

Output 73.1.4 Transformed Data Eigenvalue Plot



The remainder of the example discusses the MDPREF biplot. A biplot is a plot that displays the relation between the row points and the columns of a data matrix. The rows of $\mathbf{V}$, the standardized component scores, and $\mathbf{W}\mathbf{\Lambda}^{1/2}$, the structure matrix, contain enough information to reproduce $\mathbf{X}$. The (i, j) element of $\mathbf{X}$ is the product of row i of $\mathbf{V}$ and row j of $\mathbf{W}\mathbf{\Lambda}^{1/2}$. If all but the first two columns of $\mathbf{V}$ and $\mathbf{W}\mathbf{\Lambda}^{1/2}$ are discarded, the (i, j) element of $\mathbf{X}$ is approximated by the product of row i of $\mathbf{V}$ and row j of $\mathbf{W}\mathbf{\Lambda}^{1/2}$.

Since the MDPREF analysis is based on a principal component model, the dimensions of the MDPREF biplot are the first two principal components. The first principal component is the longest dimension through the MDPREF biplot. The first principal component is overall preference, which is the most salient dimension in the preference judgments. One end points in the direction that is on the average preferred most by the judges, and the other end points in the least preferred direction. The second principal component is orthogonal to the first principal component, and it is the orthogonal direction that is the second most salient. The interpretation of the second dimension varies from example to example.

With an MDPREF biplot, it is geometrically appropriate to represent each automobile (object) by a point and each judge by a vector. The automobile points have coordinates that are the scores of the automobile on the first two principal components. The judge vectors emanate from the origin of the space and go through a point whose coordinates are the coefficients of the judge (variable) on the first two principal components.

The absolute length of a vector is arbitrary. However, the relative lengths of the vectors indicate fit, with the squared lengths being proportional to the communalities that you can get in PROC FACTOR output. The direction of the vector indicates the direction that is most preferred by the individual judge, with preference increasing as the vector moves from the origin. Let $\mathbf{v}'$ be row i of $\mathbf{V}$, $\mathbf{u}'$ be row j of $\mathbf{U} = \mathbf{W}\mathbf{\Lambda}^{1/2}$, $\|\mathbf{v}\|$ be the length of $\mathbf{v}$, $\|\mathbf{u}\|$ be the length of $\mathbf{u}$, and θ be the angle between $\mathbf{v}$ and $\mathbf{u}$. The predicted degree of preference that an individual judge has for an automobile is $\mathbf{u}'\mathbf{v} = \|\mathbf{u}\|\,\|\mathbf{v}\|\cos\theta$. Each automobile point can be orthogonally projected onto the vector. The projection of automobile i on vector j is $\mathbf{u}((\mathbf{u}'\mathbf{v})/(\mathbf{u}'\mathbf{u}))$, and the length of this projection is $\|\mathbf{v}\|\cos\theta$. The automobile that projects farthest along a vector in the direction it points is that judge's most preferred automobile, since the length of this projection, $\|\mathbf{v}\|\cos\theta$, differs from the predicted preference, $\|\mathbf{u}\|\,\|\mathbf{v}\|\cos\theta$, only by $\|\mathbf{u}\|$, which is constant for each judge.

To interpret the biplot, look for directions through the plot that show a continuous change in some attribute of the automobiles, or look for regions in the plot that contain clusters of automobile points and determine what attributes the automobiles have in common. Points that are tightly clustered in a region of the plot represent automobiles that have the same preference patterns across the judges. Vectors that point in roughly the same direction represent judges who have similar preference patterns.

In the biplot, American automobiles are located at the left of the space, while European and Japanese automobiles are located at the right. At the top of the space are expensive American automobiles (Cadillac Eldorado, Lincoln Continental), while at the bottom are inexpensive ones (Ford Pinto, Chevrolet Chevette). The first principal component differentiates American from imported automobiles, and the second arranges automobiles by price and other associated characteristics.

The two expensive American automobiles form a cluster, the sporty automobile (Pontiac Firebird) is by itself, the Volvo DL is by itself, and the remaining imported autos form a cluster, as do the remaining American autos. It seems there are 5 prototypical automobiles in this set of 17, in terms of preference patterns among the 25 judges.

Most of the judges prefer the imported automobiles, especially the Volvo. There is also a fairly large minority that prefer the expensive autos, whether or not they are American (those with vectors that point toward one o'clock), or simply prefer expensive American automobiles (vectors that point toward eleven o'clock). There are two judges who prefer anything except expensive American autos (five o'clock vectors), and one who prefers inexpensive American autos (seven o'clock vector).

Several vectors point toward the upper-right corner of the plot, toward a region with no automobiles. This is the region between the European and Japanese autos at the right and the luxury autos at the top. This suggests that there is a market for luxury Japanese and European automobiles.

Example 73.2: Principal Components of Basketball Rankings

The data in this example are 1985–1986 preseason rankings of 35 U.S. college basketball teams by 10 different news services. The services do not all rank the same teams or the same number of teams, so there are missing values in these data. Each of the 35 teams in the data set is ranked by at least one news service. One way of summarizing these data is with a principal component analysis, since the rankings should all be related to a single underlying variable, the first principal component.

You can use PROC PRINQUAL to estimate the missing ranks and compute scores for all observations. You can formulate a PROC PRINQUAL analysis that assumes that the observed ranks are ordinal variables and replaces the ranks with new numbers that are monotonic with the ranks and better fit the one principal component model. The missing rank estimates need to be constrained since a news service would have positioned the unranked teams below the teams it ranked. PROC PRINQUAL should impose order constraints within the nonmissing values and between the missing and nonmissing values, but not within the missing values. PROC PRINQUAL has sophisticated missing data handling facilities; however, these facilities cannot directly handle this problem. The solution requires reformulating the problem.

By performing some preliminary data manipulations, specifying the N=1 option in the PROC PRINQUAL statement, and specifying the UNTIE transformation in the TRANSFORM statement, you can make the missing value estimates conform to the requirements. The PROC MEANS step finds the largest rank for each variable. The next DATA step replaces missing values with a value that is one larger than the largest observed rank. The PROC PRINQUAL N=1 option specifies that the variables should be transformed to make them as one-dimensional as possible. The UNTIE transformation in the TRANSFORM statement monotonically transforms the ranks, untying any ties in an optimal way. Because the only ties are for the values that replace the missing values, and because these values are larger than the observed values, the rescoring of the data satisfies the preceding requirements.

The following statements create the data set and perform the transformations discussed previously. These statements produce Output 73.2.1 and Output 73.2.2.

```
*  Preseason 1985 College Basketball Rankings
*  (rankings of 35 teams by 10 news services)
*
*  Note:(a) Various news services rank varying numbers of teams.
*       (b) Not all 35 teams are ranked by all news services.
*       (c) Each team is ranked by at least one service.
*       (d) Rank 20 is missing for UPI.;

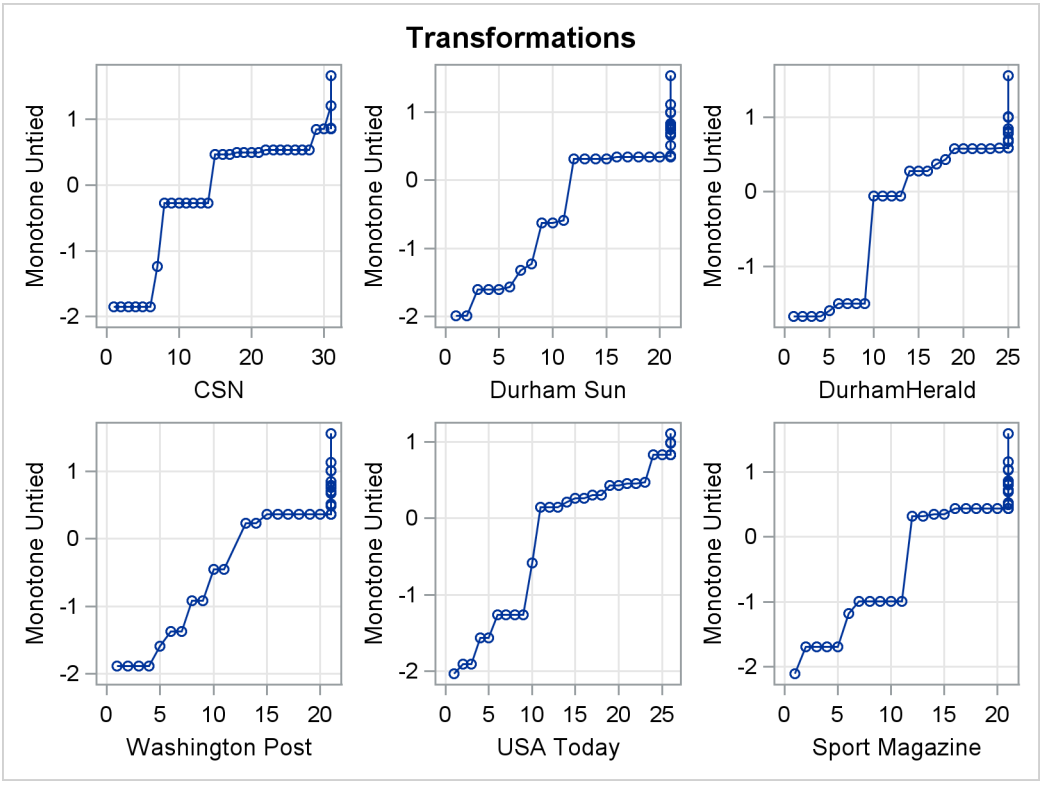
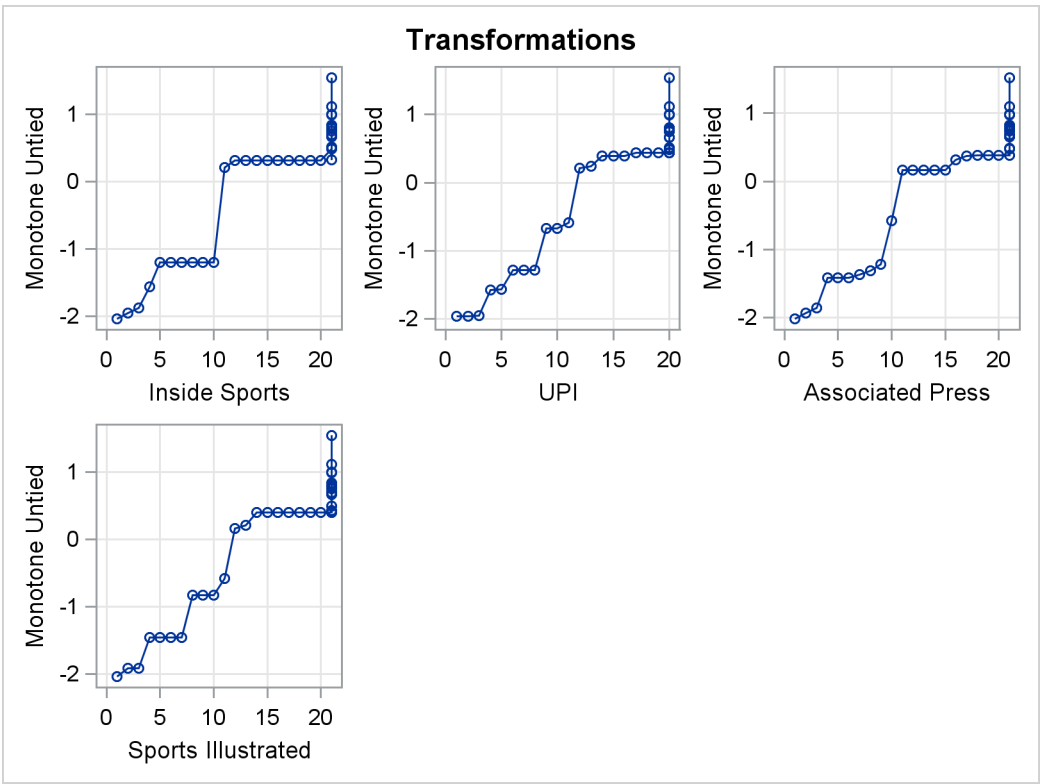
Output 73.2.2 Transformations





An alternative approach is to use the pairwise deletion option of the CORR procedure to compute the correlation matrix and then use PROC PRINCOMP or PROC FACTOR to perform the principal component analysis. This approach has several disadvantages. The correlation matrix might not be positive semidefinite (psd), an assumption required for principal component analysis. PROC PRINQUAL always produces a psd correlation matrix. Even with pairwise deletion, PROC CORR removes the six observations that have only a single nonmissing value from this data set. Finally, it is still not possible to calculate scores on the principal components for those teams that have missing values.

You can compute the composite ranking by using PROC PRINCOMP and some preliminary data manipulations, similar to those discussed previously.

Chapter 72, "The PRINCOMP Procedure," contains an example where the average of the unused ranks in each poll is substituted for the missing values, and each observation is weighted by the number of nonmissing values. This method has much to recommend it. It is much faster and simpler than using PROC PRINQUAL. It is also much less prone to degeneracies and capitalization on chance. However, PROC PRINCOMP does not allow the nonmissing ranks to be monotonically transformed and the missing values untied to optimize fit.

PROC PRINQUAL monotonically transforms the observed ranks and estimates the missing ranks (within the constraints given previously) to account for almost 95 percent of the variance of the transformed data by just one dimension. PROC FACTOR is then used to report details of the principal component analysis of the transformed data. As shown by the Factor Pattern values in Output 73.2.3, nine of the ten news services have a correlation of 0.95 or larger with the scores on the first principal component after the data are optimally transformed. The scores are sorted and the composite ranking is displayed following the PROC FACTOR output. More confidence can be placed in the stability of the scores for teams that are ranked by the majority of the news services than in scores for teams that are seldom ranked.

The monotonic transformations are plotted for each of the ten news services. See Output 73.2.2. These plots show the values of the raw ranks (with the missing ranks replaced by the maximum rank plus one) versus the rescored (transformed) ranks. The transformations are the step functions that maximize the fit of the data to the principal component model. Smoother transformations could be found by using MSPLINE transformations, but MSPLINE transformations would not correctly handle the missing data problem.

The following statements perform the final analysis and produce Output 73.2.3:

```

31	UCLA	2.52481
32	Pittsburgh	3.00907
33	Old Dominion	3.03324
34	St. Joseph's	3.39259
35	Houston	4.69614

The ordinary PROC PRINQUAL missing data handling facilities do not work for these data because they do not constrain the missing data estimates properly. If you code the missing ranks as missing and specify linear transformations, then you can compute least squares estimates of the missing values without transforming the observed values. The first principal component then accounts for 92 percent of the variance after 20 iterations. However, Virginia Tech is ranked number 11 by its score even though it appeared in only one poll (Inside Sports ranked it number 13, anchoring it firmly in the middle). Specifying monotone transformations is also inappropriate since they too allow unranked teams to move in between ranked teams.

With these data, the combination of monotone transformations and the freedom to score the missing ranks without constraint leads to degenerate transformations. PROC PRINQUAL tries to merge the 35 points into two points, producing a perfect fit in one dimension. There is evidence for this after 20 iterations when the Average Change, Maximum Change, and Criterion Change values are all increasing, instead of the more stable decreasing change rate seen in the analysis shown. The change rates all stop increasing after 41 iterations, and it is clear by 70 or 80 iterations that one component will account for 100 percent of the transformed variables variance after sufficient iteration. While this might seem desirable (after all, it is a perfect fit), you should, in fact, be on guard when this happens. Whenever convergence is slow, the rates of change increase, or the final data perfectly fit the model, the solution is probably degenerating because of too few constraints on the scorings.

PROC PRINQUAL can account for 100 percent of the variance by scoring Montana and UCLA with one positive value on all variables and scoring all the other teams with one negative value on all variables. This inappropriate analysis suggests that all ranked teams are equally good except for two teams that are less good. Both of these two teams are ranked by only one news service, and their only nonmissing rank is last in the poll. This accounts for the degeneracy.

Chapter 74

The PROBIT Procedure

Contents

Overview: PROBIT Procedure

The PROBIT procedure calculates maximum likelihood estimates of regression parameters and the natural (or threshold) response rate for quantal response data from biological assays or other discrete event data. This includes probit, logit, ordinal logistic, and extreme value (or gompit) regression models.

Probit analysis developed from the need to analyze qualitative (dichotomous or polytomous) dependent variables within the regression framework. Many response variables are binary by nature (yes/no), while others are measured ordinally rather than continuously (degree of severity). Collett (2003) and Agresti (2002), for example, have shown ordinary least squares (OLS) regression to be inadequate when the dependent variable is discrete. Probit or logit analyses are more appropriate in this case.

The PROBIT procedure computes maximum likelihood estimates of the parameters β and C of the probit equation by using a modified Newton-Raphson algorithm. When the response Y is binary, with values 0 and 1, the probit equation is

$$p = \Pr(Y = 0) = C + (1 - C)F(\mathbf{x}'\beta)$$

where

β is a vector of parameter estimates

F is a cumulative distribution function (normal, logistic, or extreme value)

$\mathbf{x}$ is a vector of explanatory variables

p is the probability of a response

C is the natural (threshold) response rate

Notice that PROC PROBIT, by default, models the probability of the *lower* response levels. The choice of the distribution function F (normal for the probit model, logistic for the logit model, and extreme value or Gompertz for the gompit model) determines the type of analysis. For most problems, there is relatively little difference between the normal and logistic specifications of the model. Both distributions are symmetric about the value zero. The extreme value (or Gompertz) distribution, however, is not symmetric, approaching 0 on the left more slowly than it approaches 1 on the right. You can use the extreme value distribution where such asymmetry is appropriate.

For ordinal response models, the response, Y, of an individual or an experimental unit can be restricted to one of a (usually small) number, $k+1 (k \geq 1)$, of ordinal values, denoted for convenience by $1, \ldots, k, k+1$. For example, the severity of coronary disease can be classified into three response categories as 1=no disease, 2=angina pectoris, and 3=myocardial infraction. The PROBIT procedure fits a common slopes cumulative

model, which is a parallel-lines regression model based on the cumulative probabilities of the response categories rather than on their individual probabilities. The cumulative model has the form

$$\Pr(Y \leq 1 \mid \mathbf{x}) = F(\mathbf{x}'\beta)$$

$$\Pr(Y \leq i \mid \mathbf{x}) = F(\alpha_i + \mathbf{x}'\beta), \quad 2 \leq i \leq k$$

where $\alpha_2, \ldots, \alpha_k$ are $k - 1$ intercept parameters. By default, the covariate vector $\mathbf{x}$ contains an overall intercept term.

You can set or estimate the natural (threshold) response rate C. Estimation of C can begin either from an initial value that you specify or from the rate observed in a control group. By default, the natural response rate is fixed at zero.

An observation in the data set analyzed by the PROBIT procedure might contain the response and explanatory values for one subject. Alternatively, it might provide the number of observed events from a number of subjects at a particular setting of the explanatory variables. In this case, PROC PROBIT models the probability of an event.

The PROBIT procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." For specific information about the graphics available in the PROBIT procedure, see the section "ODS Graphics" on page 6228.

Getting Started: PROBIT Procedure

The following example illustrates how you can use the PROBIT procedure to compute the threshold response rate and regression parameter estimates for quantal response data.

Estimating the Natural Response Threshold Parameter

Suppose you want to test the effect of a drug at 12 dosage levels. You randomly divide 180 subjects into 12 groups of 15—one group for each dosage level. You then conduct the experiment and, for each subject, record the presence or absence of a positive response to the drug. You summarize the data by counting the number of subjects responding positively in each dose group. Your data set is as follows:

```
data study;
   input Dose Respond @@;
   Number = 15;
   datalines;
0     3   1.1   4   1.3   4   2.0   3   2.2   5   2.8   4
3.7   5   3.9   9   4.4   8   4.8  11   5.9  12   6.8  13
;
```

The variable dose represents the amount of drug administered. The first group, receiving a dose level of 0, is the control group. The variable number represents the number of subjects in each group. All groups

are equal in size; hence, number has the value 15 for all observations. The variable respond represents the number of subjects responding to the associated drug dosage.

You can model the probability of positive response as a function of dosage by using the following statements:

```
ods graphics on;

proc probit data=study log10 optc plots=(predpplot ippplot);
   model respond/number=dose;
   output out=new p=p_hat;
run;

ods graphics off;
```

The DATA= option specifies that PROC PROBIT analyze the SAS data set study. The LOG10 option replaces the first continuous independent variable (dose) with its common logarithm. The OPTC option estimates the natural response rate. When you use the LOG10 option with the OPTC option, any observations with a dose value less than or equal to zero are used in the estimation as a control group.

The PLOTS= option in the PROC PROBIT statement, together with the ODS GRAPHICS statement, requests two plots for the estimated probability values and dosage levels. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." For specific information about the graphics available in the PROBIT procedure, see the section "ODS Graphics" on page 6228.

The MODEL statement specifies a proportional response by using the variables respond and number in *events/trials* syntax. The variable dose is the stimulus or explanatory variable.

The OUTPUT statement creates a new data set, new, that contains all the variables in the original data set, and a new variable, p_hat, that represents the predicted probabilities.

The results from this analysis are displayed in the following figures.

Figure 74.1 displays background information about the model fit. Included are the name of the input data set, the response variables used, and the number of observations, events, and trials. The last line in Figure 74.1 shows the final value of the log-likelihood function.

Figure 74.2 displays the table of parameter estimates for the model. The parameter C, which is the natural response threshold or the proportion of individuals responding at zero dose, is estimated to be 0.2409. Since both the intercept and the slope coefficient have significant p-values (0.0020, 0.0010), you can write the model for

$$\Pr(\text{response}) = C + (1 - C)F(\mathbf{x}'\beta)$$

as

$$\Pr(\text{response}) = 0.2409 + 0.7591(\Phi(-4.1439 + 6.2308 \times \log_{10}(\text{dose})))$$

where Φ is the normal cumulative distribution function.

Finally, PROC PROBIT specifies the resulting tolerance distribution by providing the mean MU and scale parameter SIGMA as well as the covariance matrix of the distribution parameters in Figure 74.3.

Figure 74.1 Model Fitting Information for the PROBIT Procedure

The Probit Procedure

Model Information

Data Set	WORK.STUDY
Events Variable	Respond
Trials Variable	Number
Number of Observations	12
Number of Events	81
Number of Trials	180
Number of Events In Control Group	3
Number of Trials In Control Group	15
Name of Distribution	Normal
Log Likelihood	-104.3945783

Figure 74.2 Model Parameter Estimates for the PROBIT Procedure

Analysis of Maximum Likelihood Parameter Estimates

Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	-4.1438	1.3415	-6.7731	-1.5146	9.54	0.0020
Log10(Dose)	1	6.2308	1.8996	2.5076	9.9539	10.76	0.0010
_C_	1	0.2409	0.0523	0.1385	0.3433		

Figure 74.3 Tolerance Distribution Estimates for the PROBIT Procedure

Estimated Covariance Matrix for Tolerance Parameters

	MU	SIGMA	_C_
MU	0.001158	-0.000493	0.000954
SIGMA	-0.000493	0.002394	-0.000999
_C_	0.000954	-0.000999	0.002731

The PLOT=PREDPPLOT option creates the plot in Figure 74.4, showing the relationship between dosage level, observed response proportions, and estimated probability values. The dashed lines represent pointwise confidence bands for the fitted probabilities, and a reference line is plotted at the estimated threshold value of 0.24.

The PLOT=IPPPLOT option creates the plot in Figure 74.5, showing the inverse relationship between dosage level and observed response proportions/estimated probability values. The dashed lines represent pointwise fiducial limits for the predicted values of the dose variable, and a reference line is also plotted at the estimated threshold value of 0.24.

The two plot options can be put together with the PLOTS= option, as shown in the PROC PROBIT statement.

Figure 74.4 Plot of Observed and Fitted Probabilities versus Dose Level

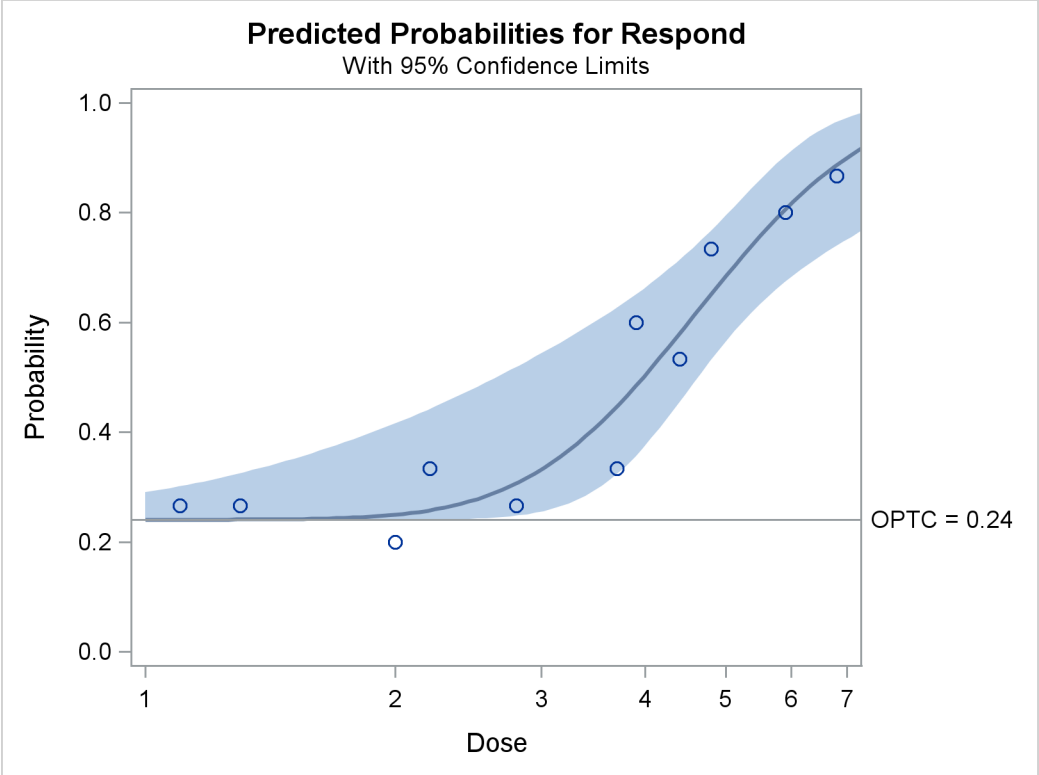

Figure 74.5 Inverse Predicted Probability Plot with Fiducial Limits

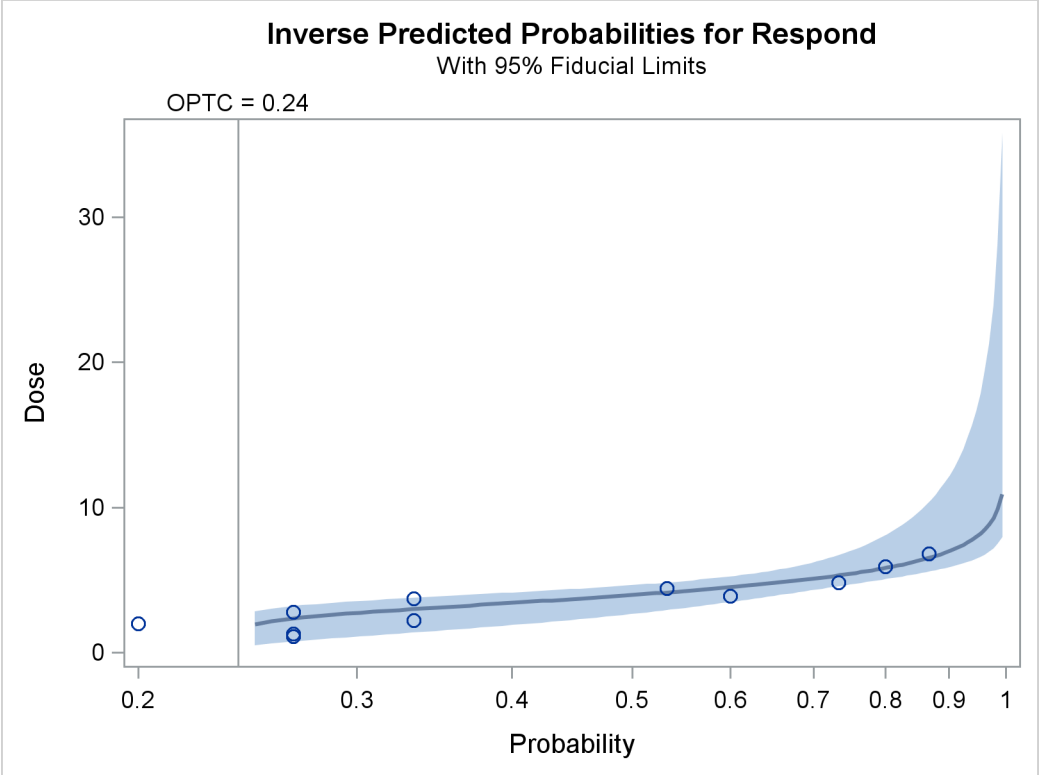

Syntax: PROBIT Procedure

The following statements are available in PROC PROBIT:

PROC PROBIT < *options* > **;**
MODEL *response=independents* < */ options* > **;**

BY *variables* **;**
CLASS *variables* **;**
OUTPUT < **OUT=***SAS-data-set* > < *options* > **;**
WEIGHT *variable* **;**

CDFPLOT < **VAR=** *variable* > < *options* > **;**
INSET < *keyword-list* > < */ options* > **;**
IPPPLOT < **VAR=** *variable* > < *options* > **;**
LPREDPLOT < **VAR=** *variable* > < *options* > **;**
PREDPPLOT < **VAR=** *variable* > < *options* > **;**

A MODEL statement is required. Only a single MODEL statement can be used with one invocation of the PROBIT procedure. If multiple MODEL statements are present, only the last one is used. Main effects and higher-order terms can be specified in the MODEL statement, as in the GLM procedure. If a CLASS statement is used, it must precede the MODEL statement.

The CDFPLOT, INSET, IPPPLOT, LPREDPLOT, and PREDPPLOT statements are used to produce graphical output. You can use any appropriate combination of the graphical statements after the MODEL statement.

PROC PROBIT Statement

PROC PROBIT < *options* > **;**

The PROC PROBIT statement starts the procedure. You can specify the following *options* in the PROC PROBIT statement.

COVOUT
writes the parameter estimate covariance matrix to the OUTEST= data set.

C=*rate*

OPTC
controls how the natural response is handled. Specify the OPTC option to request that the natural response rate C be estimated. Specify the C=*rate* option to set the natural response rate or to provide the initial estimate of the natural response rate. The natural response rate value must be a number between 0 and 1.

- If you specify neither the OPTC nor the C= option, a natural response rate of zero is assumed.

- If you specify both the OPTC and the C= option, the C= option should be a reasonable initial estimate of the natural response rate. For example, you could use the ratio of the number of responses to the number of subjects in a control group.
- If you specify the C= option but not the OPTC option, the natural response rate is set to the specified value and not estimated.
- If you specify the OPTC option but not the C= option, PROC PROBIT's action depends on the response variable, as follows:
  - If you specify either the LN or LOG10 option and some subjects have the first independent variable (dose) values less than or equal to zero, these subjects are treated as a control group. The initial estimate of C is then the ratio of the number of responses to the number of subjects in this group.
  - If you do not specify the LN or LOG10 option or if there is no control group, then one of the following occurs:
    - If all responses are greater than zero, the initial estimate of the natural response rate is the minimal response rate (the ratio of the number of responses to the number of subjects in a dose group) across all dose levels.
    - If one or more of the responses is zero (making the response rate zero in that dose group), the initial estimate of the natural rate is the reciprocal of twice the largest number of subjects in any dose group in the experiment.

DATA=*SAS-data-set*

specifies the SAS data set to be used by PROC PROBIT. By default, the procedure uses the most recently created SAS data set.

GOUT=*graphics-catalog*

specifies a graphics catalog in which to save graphics output.

HPROB=*p*

specifies a minimum probability level for the Pearson's chi-square to indicate a good fit. The default value is 0.10. The LACKFIT option must also be specified for this option to have any effect. For Pearson's goodness-of-fit chi-square values with probability greater than the HPROB= value, the fiducial limits, if requested with the INVERSECL option, are computed by using a critical value of 1.96. For chi-square values with probability less than the value of the HPROB= option, the critical value is a 0.95 two-sided quantile value taken from the t distribution with degrees of freedom equal to $(k-1) \times m - q$, where k is the number of levels for the response variable, m is the number of different sets of independent variable values, and q is the number of parameters fit in the model. Note that the HPROB= option can also appear in the MODEL statement.

INEST=*SAS-data-set*

specifies an input SAS data set that contains initial estimates for all the parameters in the model. See the section "INEST= *SAS-data-set*" on page 6219 for a detailed description of the contents of the INEST= data set.

INVERSECL< (PROB=*rates***) >**

computes confidence limits for the values of the first continuous independent variable (such as dose) that yield selected response rates. You can optionally specify a list of response rates as *rates*. The response rates must be between zero and one, and can be a list separated by blanks, commas, or in the form of a DO list.

For example,

```
PROB = .1 TO .9 by .1
PROB = .1 .2 .3 .4
PROB = .01, .25, .75, .9
```

are valid lists of response rates.

If the algorithm fails to converge (this can happen when C is nonzero), missing values are reported for the confidence limits. See the section "Inverse Confidence Limits" on page 6223 for details. Note that the INVERSECL option can also appear in the MODEL statement.

LACKFIT

performs two goodness-of-fit tests (a Pearson's chi-square test and a log-likelihood ratio chi-square test) for the fitted model.

To compute the test statistics, proper grouping of the observations into subpopulations is needed. You can use the AGGREGATE or AGGREGATE= option for this end. See the entry for the AGGREGATE and AGGREGATE= options under the MODEL statement. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the *events/trials* syntax.

NOTE: This test is not appropriate if the data are very sparse, with only a few values at each set of the independent variable values.

If the Pearson's chi-square test statistic is significant, then the covariance estimates and standard error estimates are adjusted. See the section "Lack-of-Fit Tests" on page 6221 for a description of the tests. Note that the LACKFIT option can also appear in the MODEL statement.

LOG

LN

analyzes the data by replacing the first continuous independent variable with its natural logarithm. This variable is usually the level of some treatment such as dosage. In addition to the usual output given by the INVERSECL option, the estimated dose values and 95% fiducial limits for dose are also displayed. If you specify the OPTC option, any observations with a dose value less than or equal to zero are used in the estimation as a control group. If you do not specify the OPTC option with the LOG or LN option, then any observations with the first continuous independent variable values less than or equal to zero are ignored.

LOG10

specifies an analysis like that of the LN or LOG option, except that the common logarithm (log to the base 10) of the dose value is used rather than the natural logarithm.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

NOPRINT

suppresses the display of all output including graphics. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, "Using the Output Delivery System."

OPTC

controls how the natural response is handled. See the description of the C= option on page 6171 for details.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the order in which to sort the levels of the classification variables (which are specified in the CLASS statement). This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent.

This order also applies to the levels of the response variable. Response level ordering is important because PROC PROBIT always models the probability of response levels at the beginning of the ordering. See the section "Response Level Ordering" on page 6217 for further details.

For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

OUTEST=*SAS-data-set*

specifies a SAS data set to contain the parameter estimates and, if the COVOUT option is specified, their estimated covariances. If you omit this option, the output data set is not created. The contents of the data set are described in the section "OUTEST= *SAS-data-set*" on page 6224.

PLOT | PLOTS < =*plot-request* **>**

PLOT | PLOTS < =(*plot-request* **< . . .** *plot-request* **>) >**

specifies options that control details of the plots created by ODS Graphics. These plots are related to a dose variable, which is identified as the first single continuous independent variable in the MODEL statement. If there are interaction terms with this variable in the model, the PROBIT procedure will not produce any plot.

You can specify more than one plot request within the parentheses after PLOTS=. For a single plot request, you can omit the parentheses.

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;

proc probit plots=predplot;
   model r/n = dose;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The following plot requests are available.

ALL
creates all appropriate plots.

CDFPLOT<(LEVEL=(*character-list*))>
requests the plot of predicted cumulative distribution function (CDF) of the multinomial response variable as a function of a single continuous independent variable (dose variable). This single continuous independent variable must be the first single continuous independent variable listed in the MODEL statement. You can request this plot only with a multinomial model.

The LEVEL= suboption specifies the levels of the multinomial response variable for which the CDF curves are requested. There are $k-1$ curves for a k-level multinomial response variable (for the highest level, it is the constant line 1). You can specify any of them to be plotted by the LEVEL= suboption.

IPPPLOT
requests the inverse plot of the predicted probability against the first single continuous variable (dose variable) in the MODEL statement for the binomial model. You can request this plot only with a binomial model. The confidence limits for the predicted values of the dose variable are the computed fiducial limits, not the inverse of the confidence limits of the predicted probabilities. Refer to the section "Inverse Confidence Limits" on page 6223 for more details.

LPREDPLOT<(LEVEL=(*character-list*))>
requests the plot of the linear predictor $\mathbf{x}'\mathbf{b}$ against the first single continuous variable (dose variable) in the MODEL statement for either the binomial model or the multinomial model. The confidence limits for the predicted values are available only for the binomial model.

For the multinomial model, you can use the LEVEL= suboption to specify the levels for which the linear predictor lines are plotted.

NONE
suppresses all plots.

PREDPPLOT<(LEVEL=(*character-list*))>
requests the plot of the predicted probability against the first single continuous variable (dose variable) in the MODEL statement for both the binomial model and the multinomial model. Confidence limits are available only for the binomial model.

For the multinomial model, you can use the LEVEL= suboption to specify the levels for which the linear predictor lines are plotted.

XDATA=*SAS-data-set*
specifies an input SAS data set that contains values for all the independent variables in the MODEL statement and variables in the CLASS statement. If there are covariates specified in a MODEL statement, you specify fixed values for the effects in the MODEL statement by the XDATA= data set when predicted values and/or fiducial limits for a single continuous variable (dose variable) are required. These specified values for the effects in the MODEL statement are also used for generating plots. See the section "XDATA= *SAS-data-set*" on page 6224 for a detailed description of the contents of the XDATA= data set.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC PROBIT to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the PROBIT procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CDFPLOT Statement

CDFPLOT < **VAR=** *variable* > < *options* > **;**

The CDFPLOT statement plots the predicted cumulative distribution function (CDF) of the multinomial response variable as a function of a single continuous independent variable (dose variable). You can use this statement only after a multinomial model statement.

VAR=*variable*
specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= *variable* is not specified, the first single continuous variable in the independent

variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

The predicted cumulative distribution function is defined as

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}})$$

where $j = 1, \ldots, k$ are the indexes of the k levels of the multinomial response variable, F is the CDF of the distribution used to model the cumulative probabilities, $\hat{\mathbf{b}}$ is the vector of estimated parameters, $\mathbf{x}$ is the covariate vector, $\hat{a}_j$ are estimated ordinal intercepts with $\hat{a}_1 = 0$, and C is the threshold parameter, either known or estimated from the model. Let x_1 be the covariate corresponding to the dose variable and $\mathbf{x}_{-1}$ be the vector of the rest of the covariates. Let the corresponding estimated parameters be $\hat{b}_1$ and $\hat{\mathbf{b}}_{-1}$. Then

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + x_1\hat{b}_1 + \mathbf{x}'_{-1}\hat{\mathbf{b}}_{-1})$$

To plot $\hat{F}_j$ as a function of x_1, $\mathbf{x}_{-1}$ must be specified. You can use the XDATA= option to provide the values of $\mathbf{x}_{-1}$ (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

specify the levels of the multinomial response variable for which the CDF curves are requested, and add features to the plot. There are $k - 1$ curves for a k-level multinomial response variable (for the highest level, it is the constant line 1). You can specify any of them to be plotted by the LEVEL= option in the CDFPLOT statement. See the LEVEL= option for how to specify the levels.

An attached box on the right side of the plot is used to label these curves with the names of their levels. You can specify the color of this box by using the CLABBOX= option.

You can use options in the CDFPLOT statement to do the following:

- superimpose specification limits
- specify the levels for which the CDF curves are requested
- specify graphical enhancements (such as color or text height)

Summary of Options

Table 74.1 through Table 74.7 list all *options* by function. The "Dictionary of Options" on page 6180 describes each option in detail.

CDF Options

Table 74.1 Options for CDFPLOT

LEVEL=(*character-list*)	Specifies the names of the levels for which the CDF curves are requested
NOTHRESH	Suppresses the threshold line
THRESHLABPOS=*value*	Specifies the position for the label of the threshold line

General Options

Table 74.2 Color Options

CAXIS=*color*	Specifies color for axis
CFIT=*color*	Specifies color for fitted curves
CFRAME=*color*	Specifies color for frame
CGRID=*color*	Specifies color for grid lines
CHREF=*color*	Specifies color for HREF= lines
CLABBOX=*color*	Specifies color for label box
CTEXT=*color*	Specifies color for text
CVREF=*color*	Specifies color for VREF= lines

Table 74.3 Options to Enhance Plots Produced on Graphics Devices

ANNOTATE=*SAS-data-set*	Specifies an Annotate data set
INBORDER	Requests a border around plot
LFIT=*linetype*	Specifies line style for fitted curves
LGRID=*linetype*	Specifies line style for grid lines
NOFRAME	Suppresses the frame around plotting areas
NOGRID	Suppresses grid lines
NOFIT	Suppresses CDF curves
NOHLABEL	Suppresses horizontal labels
NOHTICK	Suppresses horizontal ticks
NOVTICK	Suppresses vertical ticks
TURNVLABELS	Vertically strings out characters in vertical labels
WFIT=*n*	Specifies thickness for fitted curves
WGRID=*n*	Specifies thickness for grids
WREFL=*n*	Specifies thickness for reference lines

Table 74.4 Axis Options

HAXIS=*value1 to value2 <by value3>*	Specifies tick mark values for horizontal axis
HOFFSET=*value*	Specifies offset for horizontal axis
HLOWER=*value*	Specifies lower limit on horizontal axis scale
HUPPER=*value*	Specifies upper limit on horizontal axis scale
NHTICK=*n*	Specifies number of ticks for horizontal axis
NVTICK=*n*	Specifies number of ticks for vertical axis
VAXIS=*value1 to value2 <by value3>*	Specifies tick mark values for vertical axis
VAXISLABEL=*'label'*	Specifies label for vertical axis
VOFFSET=*value*	Specifies offset for vertical axis
VLOWER=*value*	Specifies lower limit on vertical axis scale
VUPPER=*value*	Specifies upper limit on vertical axis scale
WAXIS=*n*	Specifies thickness for axis

Table 74.5 Graphics Catalog Options

DESCRIPTION=*'string'*	Specifies description for graphics catalog member
NAME=*'string'*	Specifies name for plot in graphics catalog

Table 74.6 Options for Text Enhancement

FONT=*font*	Specifies software font for text
HEIGHT=*value*	Specifies height of text outside framed areas
INFONT=*font*	Specifies software font for text inside framed areas
INHEIGHT=*value*	Specifies height of text inside framed areas

Table 74.7 Options for Reference Lines

HREF< (INTERSECT)> =value-list	Requests horizontal reference line
HREFLABELS= ('label1',. . . ,'labeln')	Specifies labels for HREF= lines
HREFLABPOS=*n*	Specifies vertical position of labels for HREF= lines
LHREF=*linetype*	Specifies line style for HREF= lines
LVREF=*linetype*	Specifies line style for VREF= lines
VREF<(INTERSECT)> =value-list	Requests vertical reference line
VREFLABELS= *('label1',. . . ,'labeln')*	Specifies labels for VREF= lines
VREFLABPOS=*n*	Specifies horizontal position of labels for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the CDFPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an Annotate data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the CDF plot. The ANNOTATE= data set you specify in the CDFPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted CDF curves. The default is the first color in the device color list.

CFRAME=*color*

CFR=*color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CLABBOX=*color*

specifies the color for the area enclosed by the label box for CDF curves. This area is not shaded by default.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*

CV=*color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION="*string*"

DES="*string*"

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2* **<** *by value3* **>**

specifies tick mark values for the horizontal axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists follow:

```
haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10
```

HEIGHT=*value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies offset for horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF <(INTERSECT)> =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=*'label1',...,'labeln'*

HREFLABEL=*'label1',...,'labeln'*

HREFLAB=*'label1',...,'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Top
2	Staggered from top
3	Bottom
4	Staggered from bottom
5	Alternating from top
6	Alternating from bottom

INBORDER

requests a border around CDF plots.

LEVEL=(*character-list***)**

ORDINAL=(*character-list***)**

specifies the names of the levels for which CDF curves are requested. Names should be quoted and separated by space. If there is no correct name provided, no CDF curve is plotted.

LFIT=*linetype*

specifies a line style for fitted curves. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1).

LGRID=*linetype*

specifies a line style for all grid lines. *linetype* is between 1 and 46. The default is 35.

LHREF=*linetype*

LH=*linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype*

LV=*linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME=*'string'*
specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NOFIT
suppresses the fitted CDF curves.

NOFRAME
suppresses the frame around plotting areas.

NOGRID
suppresses grid lines.

NOHLABEL
suppresses horizontal labels.

NOHTICK
suppresses horizontal tick marks.

NOTHRESH
suppresses the threshold line.

NOVLABEL
suppresses vertical labels.

NOVTICK
suppresses vertical tick marks.

THRESHLABPOS=*n*
specifies the horizontal position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Left
2	Right

VAXIS=*value1 to value2 < by value3 >*
specifies tick mark values for the vertical axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists follow:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL=*'string'*
specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=*'label1',. . . ,'labeln'*

VREFLABEL=*'label1',. . . ,'labeln'*

VREFLAB=*'label1',. . . ,'labeln'*

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Left
2	Right

VUPPER=*value*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *value* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*

specifies line thickness for fitted curves. The default value is 1.

WGRID=*n*

specifies line thickness for grids. The default value is 1.

WREFL=*n*

specifies line thickness for reference lines. The default value is 1.

CLASS Statement

CLASS *variables* < / **TRUNCATE** > **;**

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC PROBIT statement. You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE
specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

INSET Statement

INSET < *keyword-list* > < / *options* > **;**

The box or table of summary information produced on plots made with the CDFPLOT, IPPPLOT, LPREDPLOT, or PREDPPLOT statement is called an *inset*. You can use the INSET statement to customize both the information that is printed in the inset box and the appearance of the inset box. To supply the information that is displayed in the inset box, you specify *keywords* corresponding to the information you want shown. For example, the following statements produce a predicted probability plot with the number of trials, the number of events, the name of the distribution, and the estimated optimum natural threshold in the inset.

```
proc probit data=epidemic;
   model r/n = dose;
   predpplot ;
   inset nobs ntrials nevents dist optc;
run;
```

By default, inset entries are identified with appropriate labels. However, you can provide a customized label by specifying the *keyword* for that entry followed by the equal sign (=) and the label in quotes.

For example, the following INSET statement produces an inset containing the number of observations and the name of the distribution, labeled “Sample Size” and “Distribution” in the inset.

```
inset nobs='Sample Size' dist='Distribution';
```

If you specify a keyword that does not apply to the plot you are creating, then the keyword is ignored.

The *options* control the appearance of the box.

If you specify more than one INSET statement, only the first one is used.

Keywords Used in the INSET Statement

Table 74.8 and Table 74.9 list keywords available in the INSET statement to display summary statistics, distribution parameters, and distribution fitting information.

Table 74.8 Summary Statistics

NOBS	Number of observations
NTRIALS	Number of trials
NEVENTS	Number of events
C	User-input threshold
OPTC	Estimated natural threshold
NRESPLEV	Number of levels of the response variable

Table 74.9 General Information

CONFIDENCE	Confidence coefficient for all confidence intervals
DIST	Name of the distribution

Options Used in the INSET Statement

Table 74.10 and Table 74.11 list the options available in the INSET statement.

Table 74.10 Color and Pattern Options

CFILL=*color*	Specifies color for filling box
CFILLH=*color*	Specifies color for filling box header
CFRAME=*color*	Specifies color for frame
CHEADER=*color*	Specifies color for text in header
CTEXT=*color*	Specifies color for text

Table 74.11 General Appearance Options

FONT=*font*	Specifies software font for text
HEIGHT=*value*	Specifies height of text
HEADER=*'quoted string'*	Specifies text for header or box title
NOFRAME	Omits frame around box
POS= *value* <DATA | PERCENT>	Determines the position of the inset. The *value* can be a compass point (N, NE, E, SE, S, SW, W, NW) or a pair of coordinates (x, y) enclosed in parentheses. The coordinates can be specified in axis percentage units or axis data units.
REFPOINT= *name*	Specifies the reference point for an inset that is positioned by a pair of coordinates with the POS= option. You use the REFPOINT= option in conjunction with the POS= coordinates. The REFPOINT= option specifies which corner of the inset frame you have specified with coordinates (x, y), and it can take the value of BR (bottom right), BL (bottom left), TR (top right), or TL (top left). The default is REFPOINT=BL. If the inset position is specified as a compass point, then the REFPOINT= option is ignored.

IPPPLOT Statement

IPPPLOT < *variable* > < *options* > **;**

The IPPPLOT statement plots the inverse of the predicted probability (IPP) against a single continuous variable (dose variable) in the MODEL statement for the binomial model. You can only use this statement after a binomial model statement. The confidence limits for the predicted values of the dose variable are the computed fiducial limits, not the inverse of the confidence limits of the predicted probabilities. Refer to the section "Inverse Confidence Limits" on page 6223 for more details.

VAR= *variable*

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

For the binomial model, the response variable is a probability. An estimate of the dose level $\hat{x}_1$ needed for a response of p is given by

$$\hat{x}_1 = (F^{-1}(p) - \mathbf{x}'_{-1}\hat{\mathbf{b}}_{-1})/\hat{b}_1$$

where F is the cumulative distribution function used to model the probability, $\mathbf{x}_{-1}$ is the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ is the vector of the estimated parameters corresponding to $\mathbf{x}_{-1}$, and $\hat{b}_1$ is the estimated parameter for the dose variable of interest.

To plot $\hat{x}_1$ as a function of p, $\mathbf{x}_{-1}$ must be specified. You can use the XDATA= option to provide the values of $\mathbf{x}_{-1}$ (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

add features to the plot.

You can use options in the IPPPLOT statement to do the following:

- superimpose specification limits
- suppress or add the observed data points on the plot
- suppress or add the fiducial limits on the plot
- specify graphical enhancements (such as color or text height)

Summary of Options

Table 74.12 through Table 74.18 list all *options* by function. The "Dictionary of Options" on page 6190 describes each option in detail.

IPP Options

Table 74.12 Plot Layout Options for IPPPLOT

NOCONF	Suppresses fiducial limits
NODATA	Suppresses observed data points on the plot
NOTHRESH	Suppresses the threshold line
THRESHLABPOS=*value*	Specifies the position for the label of the threshold line

General Options

Table 74.13 Color Options

CAXIS=*color*	Specifies color for axis
CFIT=*color*	Specifies color for fitted curves
CFRAME=*color*	Specifies color for frame
CGRID=*color*	Specifies color for grid lines
CHREF=*color*	Specifies color for HREF= lines
CTEXT=*color*	Specifies color for text
CVREF=*color*	Specifies color for VREF= lines

Table 74.14 Options to Enhance Plots Produced on Graphics Devices

ANNOTATE=*SAS-data-set*	Specifies an Annotate data set
INBORDER	Requests a border around plot
LFIT=*linetype*	Specifies line style for fitted curves and confidence limits
LGRID=*linetype*	Specifies line style for grid lines
NOFRAME	Suppresses the frame around plotting areas
NOGRID	Suppresses grid lines
NOFIT	Suppresses fitted curves
NOHLABEL	Suppresses horizontal labels
NOHTICK	Suppresses horizontal ticks
NOVTICK	Suppresses vertical ticks
TURNVLABELS	Vertically strings out characters in vertical labels

INFONT=*font*	Specifies software font for text inside framed areas
INHEIGHT=*value*	Specifies height of text inside framed areas

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the IPPPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an Annotate data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the IPP plot. The ANNOTATE= data set you specify in the IPPPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted IPP curves. The default is the first color in the device color list.

CFRAME=*color*

CFR=*color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*

CV=*color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION=*'string'*

DES=*'string'*

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2* **<** *by value3* **>**

specifies tick mark values for the horizontal axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists follow:

```
haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10
```

HEIGHT=*value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies offset for horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF <(INTERSECT)> =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=*'label1'***,...,***'labeln'*

HREFLABEL=*'label1'***,...,***'labeln'*

HREFLAB=*'label1'***,...,***'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Top
2	Staggered from top
3	Bottom
4	Staggered from bottom
5	Alternating from top
6	Alternating from bottom

INBORDER

requests a border around IPP plots.

LFIT=*linetype*

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1) and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

LGRID=*linetype*

specifies a line style for all grid lines. The value for *linetype* must be between 1 and 46. The default is 35.

LHREF=*linetype*

LH=*linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype*

LV=*linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME=*'string'*

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NOCONF

suppresses fiducial limits from the plot.

NODATA

suppresses observed data points from the plot.

NOFIT

suppresses the fitted IPP curves.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESHLABPOS=*n*

specifies the vertical position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Top
2	Bottom

VAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the vertical axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists follow:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL=*'string'*

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=*'label1',. . . ,'labeln'*

VREFLABEL=*'label1',. . . ,'labeln'*

VREFLAB=*'label1',. . . ,'labeln'*

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Left
2	Right

VUPPER=*value*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *value* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*
specifies line thickness for fitted curves. The default value is 1.

WGRID=*n*
specifies line thickness for grids. The default value is 1.

WREFL=*n*
specifies line thickness for reference lines. The default value is 1.

LPREDPLOT Statement

LPREDPLOT < **VAR=** *variable* > < *options* > **;**

The LPREDPLOT statement plots the linear predictor (LPRED) $\mathbf{x}'\mathbf{b}$ against a single continuous variable (dose variable) in the MODEL statement for either the binomial model or the multinomial model. The confidence limits for the predicted values are available only for the binomial model.

VAR= *variable*
specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement for which the linear predictor plot is plotted. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

Let x_1 be the covariate of the dose variable, $\mathbf{x}_{-1}$ be the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ be the vector of estimated parameters corresponding to $\mathbf{x}_{-1}$, and $\hat{b}_1$ be the estimated parameter for the dose variable of interest.

To plot $\hat{\mathbf{x}}'\mathbf{b}$ as a function of x_1, $\mathbf{x}_{-1}$ must be specified. You can use the XDATA= option to provide the values of $\mathbf{x}_{-1}$ (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options
add features to the plot.

For the multinomial model, you can use the LEVEL= option to specify the levels for which the linear predictor lines are plotted. The lines are labeled by the names of their levels in the middle.

You can use options in the LPREDPLOT statement to do the following:

- superimpose specification limits
- suppress or add the observed data points on the plot for the binomial model
- suppress or add the confidence limits for the binomial model
- specify the levels for which the linear predictor lines are requested for the multinomial model
- specify graphical enhancements (such as color or text height)

Summary of Options

Table 74.19 through Table 74.25 list all *options* by function. The "Dictionary of Options" on page 6198 describes each option in detail.

LPRED Options

Table 74.19 Plot Layout Options for LPREDPLOT

LEVEL=(*character-list*)	Specifies the names of the levels for which the linear predictor lines are requested (only for the multinomial model)
NOCONF	Suppresses fiducial limits (only for the binomial model)
NODATA	Suppresses observed data points on the plot (only for the binomial model)
NOTHRESH	Suppresses the threshold line
THRESHLABPOS=*value*	Specifies the position for the label of the threshold line

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the LPREDPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an Annotate data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the LPRED plot. The ANNOTATE= data set you specify in the LPREDPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted LPRED lines. The default is the first color in the device color list.

CFRAME=*color*

CFR=*color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*

CV=*color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION=*'string'*

DES=*'string'*

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the horizontal axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists follow:

```
haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10
```

HEIGHT=*value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies offset for horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=*'label1',...,'labeln'*

HREFLABEL=*'label1',...,'labeln'*

HREFLAB=*'label1',...,'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Top
2	Staggered from top
3	Bottom
4	Staggered from bottom
5	Alternating from top
6	Alternating from bottom

INBORDER

requests a border around LPRED plots.

LEVEL=(*character-list***)**

ORDINAL=(*character-list***)**

specifies the names of the levels for which linear predictor lines are requested. Names should be quoted and separated by space. If there is no correct name provided, no LPRED line is plotted.

LFIT=*linetype*

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1) and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

LGRID=*linetype*

specifies a line style for all grid lines. The value for *linetype* is between 1 and 46. The default is 35.

LHREF=*linetype*

LH=*linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype*

LV=*linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME=*'string'*

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NOCONF

suppresses confidence limits from the plot. This works only for the binomial model. Confidence limits are not plotted for the multinomial model.

NODATA

suppresses observed data points from the plot. This works only for the binomial model. Data points are not plotted for the multinomial model.

NOFIT

suppresses the fitted LPRED lines.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESHLABPOS=*n*

specifies the horizontal position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Left
2	Right

VAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the vertical axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists follow:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL=*'string'*

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=*'label1',...,'labeln'*

VREFLABEL=*'label1',...,'labeln'*

VREFLAB=*'label1',...,'labeln'*

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Left
2	Right

VUPPER=*number*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *number* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*
specifies line thickness for fitted lines. The default value is 1.

WGRID=*n*
specifies line thickness for grids. The default value is 1.

WREFL=*n*
specifies line thickness for reference lines. The default value is 1.

MODEL Statement

< *label:* > **MODEL** *response=effects* < / *options* > **;**

< *label:* > **MODEL** *events/trials=effects* < / *options* > **;**

The MODEL statement names the variables used as the response and the independent variables. Additionally, you can specify the distribution used to model the response, as well as other options. Only a single MODEL statement can be used with one invocation of the PROBIT procedure. If multiple MODEL statements are present, only the last is used. Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure.

The optional *label*, which must be a valid SAS name, is used to label output from the matching MODEL statement.

The *response* can be a single variable with a value that is used to indicate the level of the observed response. For example, the response might be a variable called Symptoms that takes on the values 'None,' 'Mild,' or 'Severe.' Note that, for dichotomous response variables, the probability of the lower sorted value is modeled by default (see the section "Details: PROBIT Procedure" on page 6216). Because the model fit by the PROBIT procedure requires ordered response levels, you might need to use either the ORDER=DATA option in the PROC PROBIT statement or a numeric coding of the response to get the desired ordering of levels.

Alternatively, the response can be specified as a pair of variable names separated by a slash (/). The value of the first variable, *events*, is the number of positive responses (or events). The value of the second variable, *trials*, is the number of trials. Both variables must be numeric and nonnegative, and the ratio of the first variable value to the second variable value must be between 0 and 1, inclusive. For example, the variables might be hits, a variable containing the number of hits for a baseball player, and AtBats, a variable containing the number of times at bat. A model for hitting proportion (batting average) as a function of age could be specified as

```
model hits/AtBats=age;
```

The *effects* following the equal sign are the covariates in the model. Higher-order effects, such as interactions and nested terms, are allowed in the list, as in the GLM procedure. Variable names and combinations of variable names representing higher-order terms are allowed to appear in this list. Classification variables can be used as effects, and indicator variables are generated for the class levels. If you do not specify any covariates following the equal sign, an intercept-only model is fit.

The following options are available in the MODEL statement.

AGGREGATE

AGGREGATE=*variable-list*

specifies the subpopulations on which the Pearson's chi-square test statistic and the log-likelihood ratio chi-square test statistic (deviance) are calculated if the LACKFIT option is specified. See the section "Rescaling the Covariance Matrix" on page 6222 for details of Pearson's chi-square and deviance calculations.

Observations with common values in the given list of variables are regarded as coming from the same subpopulation. Variables in the list can be any variables in the input data set. Specifying the AGGREGATE option is equivalent to specifying the AGGREGATE= option with a variable list that includes all independent variables in the MODEL statement. The PROBIT procedure sorts the input data set according to the variables specified in this list. Information for the sorted data set is reported in the "Response-Covariate Profile" table.

The deviance and Pearson's goodness-of-fit statistics are calculated if the LACKFIT option is specified in the MODEL statement. The calculated results are reported in the "Goodness-of-Fit" table. If the Pearson's chi-square test is significant with the test level specified by the HPROB= option, the fiducial limits, if required with the INVERSECL option in the MODEL statement, are modified (see the section "Inverse Confidence Limits" on page 6223 for details). Also, the covariance matrix is rescaled by the dispersion parameter when the SCALE= option is specified.

ALPHA=*value*

sets the significance level for the confidence intervals for regression parameters, fiducial limits for the predicted values, and confidence intervals for the predicted probabilities. The value must be between 0 and 1. The default value is ALPHA=0.05.

CONVERGE=*value*

specifies the convergence criterion. Convergence is declared when the maximum change in the parameter estimates between Newton-Raphson steps is less than the value specified. The change is a relative change if the parameter is greater than 0.01 in absolute value; otherwise, it is an absolute change.

By default, CONVERGE=1.0E−8.

CORRB

displays the estimated correlation matrix of the parameter estimates.

COVB

displays the estimated covariance matrix of the parameter estimates.

DISTRIBUTION=*distribution-type*

DIST=*distribution-type*

D=*distribution-type*

specifies the cumulative distribution function used to model the response probabilities. The distributions are described in the section "Details: PROBIT Procedure" on page 6216. Valid values for *distribution-type* are as follows:

NORMAL	the normal distribution for the probit model
LOGISTIC	the logistic distribution for the logit model

EXTREMEVALUE | EXTREME | GOMPERTZ the extreme value, or Gompertz distribution for the gompit model

By default, DISTRIBUTION=NORMAL.

HPROB=*p*

specifies a minimum probability level for the Pearson's chi-square to indicate a good fit. The default value is 0.10. The LACKFIT option must also be specified for this option to have any effect. For Pearson's goodness-of-fit chi-square values with probability greater than the HPROB= value, the fiducial limits, if requested with the INVERSECL option, are computed by using a critical value of 1.96. For chi-square values with probability less than the value of the HPROB= option, the critical value is a 0.95 two-sided quantile value taken from the t distribution with degrees of freedom equal to $(k-1) \times m - q$, where k is the number of levels for the response variable, m is the number of different sets of independent variable values, and q is the number of parameters fit in the model. If you specify the HPROB= option in both the PROC PROBIT and MODEL statements, the MODEL statement option takes precedence.

INITIAL=*values*

sets initial values for the parameters in the model other than the intercept. The values must be given in the order in which the variables are listed in the MODEL statement. If some of the independent variables listed in the MODEL statement are classification variables, then there must be as many values given for that variable as there are classification levels minus 1. The INITIAL option can be specified as follows.

Type of List	Specification
List separated by blanks	`initial=3 4 5`
List separated by commas	`initial=3,4,5`

By default, all parameters have initial estimates of zero.

NOTE: The INITIAL= option is overwritten by the INEST= option in the PROC PROBIT statement.

INTERCEPT=*value*

initializes the intercept parameter to *value*. By default, INTERCEPT=0.

INVERSECL< (PROB=*rates***) >**

computes confidence limits for the values of the first continuous independent variable (such as dose) that yield selected response rates. You can optionally specify a list of response rates as *rates*. The response rates must be between zero and one; they can be a list separated by blanks, commas, or in the form of a DO list. For example, the following expressions are all valid lists of response rates:

```
PROB = .1 TO .9 by .1
PROB = .1 .2 .3 .4
PROB = .01, .25, .75, .9
```

If the algorithm fails to converge (this can happen when C is nonzero), missing values are reported for the confidence limits. See the section "Inverse Confidence Limits" on page 6223 for details.

ITPRINT

displays the iteration history, the final evaluation of the gradient, and the second derivative matrix (Hessian).

LACKFIT

performs two goodness-of-fit tests (a Pearson's chi-square test and a log-likelihood ratio chi-square test) for the fitted model.

To compute the test statistics, proper grouping of the observations into subpopulations is needed. You can use the AGGREGATE or AGGREGATE= option for this purpose. See the entry for the AGGREGATE and AGGREGATE= options under the MODEL statement. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the *events/trials* syntax.

NOTE: This test is not appropriate if the data are very sparse, with only a few values at each set of the independent variable values.

If the Pearson's chi-square test statistic is significant, then the covariance estimates and standard error estimates are adjusted. See the section "Lack-of-Fit Tests" on page 6221 for a description of the tests. Note that the LACKFIT option can also appear in the PROC PROBIT statement. See the section "PROC PROBIT Statement" on page 6171 for details.

MAXITER=*value*

MAXIT=*value*

specifies the maximum number of iterations to be performed in estimating the parameters. By default, MAXITER=50.

NOINT

fits a model with no intercept parameter. If the INTERCEPT= option is also specified, the intercept is fixed at the specified value; otherwise, it is set to zero. This is most useful when the response is binary. When the response has k levels, then $k - 1$ intercept parameters are fit. The NOINT option sets the intercept parameter corresponding to the lowest response level equal to zero. A Lagrange multiplier, or score, test for the restricted model is computed when the NOINT option is specified.

SCALE=*scale*

enables you to specify the method for estimating the dispersion parameter. To correct for overdispersion or underdispersion, the covariance matrix is multiplied by the estimate of the dispersion parameter. Valid values for *scale* are as follows:

D | DEVIANCE — specifies that the dispersion parameter be estimated by the deviance divided by its degrees of freedom.

P | PEARSON — specifies that the dispersion parameter be estimated by the Pearson's chi-square statistic divided by its degrees of freedom. This is set as the default method for estimating the dispersion parameter.

You can use the AGGREGATE= option to define the subpopulations for calculating the Pearson's chi-square statistic and the deviance.

The "Goodness-of-Fit " table includes the Pearson's chi-square statistic, the deviance, their degrees of freedom, the ratio of each statistic divided by its degrees of freedom, and the corresponding p-value.

SINGULAR=*value*

specifies the singularity criterion for determining linear dependencies in the set of independent variables. The sum of squares and crossproducts matrix of the independent variables is formed and swept. If the relative size of a pivot becomes less than the value specified, then the variable corresponding to the pivot is considered to be linearly dependent on the previous set of variables considered. By default, *value*=1E−12.

OUTPUT Statement

OUTPUT < **OUT=***SAS-data-set keyword=name . . . keyword=name* > **;**

The OUTPUT statement creates a new SAS data set containing all variables in the input data set and, optionally, the fitted probabilities, the estimate of $\mathbf{x}'\beta$, and the estimate of its standard error. Estimates of the probabilities, $\mathbf{x}'\beta$, and the standard errors are computed for observations with missing response values as long as the values of all the explanatory variables are nonmissing. This enables you to compute these statistics for additional settings of the explanatory variables that are of interest but for which responses are not observed.

You can specify multiple OUTPUT statements. Each OUTPUT statement creates a new data set and applies only to the preceding MODEL statement. If you want to create a permanent SAS data set, you must specify a two-level name (refer to *SAS Language Reference: Concepts* for more information about permanent SAS data sets).

Details on the specifications in the OUTPUT statement are as follows:

keyword=name specifies the statistics to include in the output data set and assigns names to the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

PROB | P cumulative probability estimates

$$p = C + (1 - C)F(a_j + \mathbf{x}'\beta)$$

STD standard error estimates of $a_j + \mathbf{x}'\mathbf{b}$

XBETA estimates of $a_j + \mathbf{x}'\beta$

OUT=*SAS-data-set* names the output data set. By default, the new data set is named by using the DATA*n* convention.

When the *single variable response* syntax is used, the _LEVEL_ variable is added to the output data set, and there are $k - 1$ output observations for each input observation, where k is the number of response levels. There is no observation output corresponding to the highest response level. For each of the $k - 1$ observations, the PROB variable contains the fitted probability of obtaining a response level up to the level indicated by the _LEVEL_ variable, the XBETA variable contains $a_j + \mathbf{x}'\mathbf{b}$, where j references the levels ($a_1 = 0$), and the STD variable contains the standard error estimate of the XBETA variable. See the section "Details: PROBIT Procedure" on page 6216 for the formulas for the parameterizations.

PREDPPLOT Statement

PREDPPLOT < **VAR=** *variable* > < *options* > **;**

The PREDPPLOT statement plots the predicted probability against a single continuous variable (dose variable) in the MODEL statement for both the binomial model and the multinomial model. Confidence limits are available only for the binomial model. An attached box on the right side of the plot is used to label predicted probability curves with the names of their levels for the multinomial model. You can specify the color of this box by using the CLABBOX= option.

VAR=*variable*

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

The predicted probability is

$$\hat{p} = C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}})$$

for the binomial model and

$$\begin{aligned} \hat{p}_1 &= C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}}) \\ \hat{p}_j &= (1 - C)(F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}}) - F(\hat{a}_{j-1} + \mathbf{x}'\hat{\mathbf{b}})) \quad j = 2, \ldots, k-1 \\ \hat{p}_k &= (1 - C)(1 - F(\hat{a}_{k-1} + \mathbf{x}'\hat{\mathbf{b}})) \end{aligned}$$

for the multinomial model with k response levels, where F is the cumulative distribution function used to model the probability, $\mathbf{x}'$ is the vector of the covariates, $\hat{a}_j$ are the estimated ordinal intercepts with $\hat{a}_1 = 0$, C is the threshold parameter, either known or estimated from the model, and $\hat{\mathbf{b}}'$ is the vector of estimated parameters.

To plot $\hat{p}$ (or $\hat{p}_j$) as a function of a continuous variable x_1, the remaining covariates $\mathbf{x}_{-1}$ must be specified. You can use the XDATA= option to provide the values of $\mathbf{x}_{-1}$ (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

enable you to plot the observed data and add features to the plot.

You can use options in the PREDPPLOT statement to do the following:

- superimpose specification limits
- suppress or add observed data points for the binomial model
- suppress or add confidence limits for the binomial model

- specify the levels for which predicted probability curves are requested for the multinomial model
- specify graphical enhancements (such as color or text height)

Summary of Options

Table 74.26 through Table 74.32 list all *options* by function. The "Dictionary of Options" on page 6211 describes each option in detail.

PREDPPLOT Options

Table 74.26 Plot Layout Options for PREDPPLOT

LEVEL=(*character-list*)	Specifies the names of the levels for which the predicted probability curves are requested (only for the multinomial model)
NOCONF	Suppresses confidence limits
NODATA	Suppresses observed data points on the plot
NOTHRESH	Suppresses the threshold line
THRESHLABPOS=*value*	Specifies the position for the label of the threshold line

General Options

Table 74.27 Color Options

CAXIS=*color*	Specifies color for the axes
CFIT=*color*	Specifies color for fitted curves
CFRAME=*color*	Specifies color for frame
CGRID=*color*	Specifies color for grid lines
CHREF=*color*	Specifies color for HREF= lines
CLABBOX=*color*	Specifies color for label box
CTEXT=*color*	Specifies color for text
CVREF=*color*	Specifies color for VREF= lines

Table 74.28 Options to Enhance Plots Produced on Graphics Devices

ANNOTATE=*SAS-data-set*	Specifies an Annotate data set
INBORDER	Requests a border around plot
LFIT=*linetype*	Specifies line style for fitted curves and confidence limits
LGRID=*linetype*	Specifies line style for grid lines
NOFRAME	Suppresses the frame around plotting areas
NOGRID	Suppresses grid lines
NOFIT	Suppresses fitted curves
NOHLABEL	Suppresses horizontal labels
NOHTICK	Suppresses horizontal ticks
NOVTICK	Suppresses vertical ticks
TURNVLABELS	Vertically strings out characters in vertical labels
WFIT=*n*	Specifies thickness for fitted curves
WGRID=*n*	Specifies thickness for grids
WREFL=*n*	Specifies thickness for reference lines

Table 74.29 Axis Options

HAXIS=*value1 to value2 <by value3>*	Specifies tick mark values for horizontal axis
HOFFSET=*value*	Specifies offset for horizontal axis
HLOWER=*value*	Specifies lower limit on horizontal axis scale
HUPPER=*value*	Specifies upper limit on horizontal axis scale
NHTICK=*n*	Specifies number of ticks for horizontal axis
NVTICK=*n*	Specifies number of ticks for vertical axis
VAXIS=*value1 to value2 <by value3>*	Specifies tick mark values for vertical axis
VAXISLABEL=*'label'*	Specifies label for vertical axis
VOFFSET=*value*	Specifies offset for vertical axis
VLOWER=*value*	Specifies lower limit on vertical axis scale
VUPPER=*value*	Specifies upper limit on vertical axis scale
WAXIS=*n*	Specifies thickness for axis

Table 74.30 Graphics Catalog Options

DESCRIPTION=*'string'*	Specifies description for graphics catalog member
NAME=*'string'*	Specifies name for plot in graphics catalog

Table 74.31 Options for Text Enhancement

FONT=*font*	Specifies software font for text
HEIGHT=*value*	Specifies height of text used outside framed areas
INFONT=*font*	Specifies software font for text inside framed areas
INHEIGHT=*value*	Specifies height of text inside framed areas

Table 74.32 Options for Reference Lines

HREF<(INTERSECT)> =*value-list*	Requests horizontal reference line
HREFLABELS= ('label1',...,'labeln')	Specifies labels for HREF= lines
HREFLABPOS=*n*	Specifies vertical position of labels for HREF= lines
LHREF=*linetype*	Specifies line style for HREF= lines
LVREF=*linetype*	Specifies line style for VREF= lines
VREF<(INTERSECT)> =*value-list*	Requests vertical reference line
VREFLABELS= ('label1',...,'labeln')	Specifies labels for VREF= lines
VREFLABPOS=*n*	Specifies horizontal position of labels for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the PREDPPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an Annotate data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the predicted probability plot. The ANNOTATE= data set you specify in the PREDPPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted predicted probability curves. The default is the first color in the device color list.

CFRAME=*color*

CFR=*color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*

CV=*color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION=*'string'*

DES=*'string'*

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the horizontal axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists follow:

```
haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10
```

HEIGHT=*value*

specifies the height of text used outside framed areas.

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies the offset for the horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=*'label1'***,. . . ,***'labeln'*

HREFLABEL=*'label1'***,. . . ,***'labeln'*

HREFLAB=*'label1'***,. . . ,***'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

n	**label placement**
1	Top
2	Staggered from top
3	Bottom
4	Staggered from bottom
5	Alternating from top
6	Alternating from bottom

INBORDER

requests a border around predicted probability plots.

LEVEL=(*character-list***)**

ORDINAL= (*character-list***)**

specifies the names of the levels for which predicted probability curves are requested. Names should be quoted and separated by space. If there is no correct name provided, no fitted probability curve is plotted.

LFIT=*linetype*

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1) and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

LGRID=*linetype*

specifies a line style for all grid lines. The value for *linetype* is between 1 and 46. The default is 35.

LHREF=*linetype*

LH=*linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype*

LV=*linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME=*'string'*

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NOCONF

suppresses confidence limits from the plot. This works only for the binomial model. Confidence limits are not plotted for the multinomial model.

NODATA

suppresses observed data points from the plot. This works only for the binomial model. The data points are not plotted for the multinomial model.

NOFIT

suppresses the fitted predicted probability curves.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESHLABPOS=*n*

specifies the horizontal position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

n	label placement
1	Left
2	Right

VAXIS=*value1 to value2 < by value3 >*

specifies tick mark values for the vertical axis; *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists follow:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL=*'string'*

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=*'label1',...,'labeln'*

VREFLABEL=*'label1',...,'labeln'*

VREFLAB=*'label1',...,'labeln'*

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

n	label placement
1	Left
2	Right

VUPPER=*value*
specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *value* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*
specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*
specifies line thickness for fitted curves. The default value is 1.

WGRID=*n*
specifies line thickness for grids. The default value is 1.

WREFL=*n*
specifies line thickness for reference lines. The default value is 1.

WEIGHT Statement

WEIGHT *variable* **;**

A WEIGHT statement can be used with PROC PROBIT to weight each observation by the value of the variable specified. The contribution of each observation to the likelihood function is multiplied by the value of the weight variable. Observations with zero, negative, or missing weights are not used in model estimation.

Details: PROBIT Procedure

Missing Values

PROC PROBIT does not use any observations having missing values for any of the independent variables, the response variables, or the weight variable. If only the response variables are missing, statistics requested in the OUTPUT statement are computed.

Response Level Ordering

For binary response data, PROC PROBIT fits the following model by default:

$$\Phi^{-1}\left(\frac{p-C}{1-C}\right) = \mathbf{x}'\beta$$

where p is the probability of the response level identified as the first level in the "Weighted Frequency Counts for the Ordered Response Categories" table in the output and Φ is the normal cumulative distribution function. By default, the covariate vector $\mathbf{x}$ contains an intercept term. This is sometimes called Abbot's formula.

Because of the symmetry of the normal (and logistic) distribution, the effect of reversing the order of the two response values is to change the signs of β in the preceding equation.

By default, response levels appear in ascending, sorted order (that is, the lowest level appears first, and then the next lowest, and so on). There are a number of ways that you can control the sort order of the response categories and, therefore, which level is assigned the first ordered level. One of the most common sets of response levels is {0,1}, with 1 representing the event with the probability that is to be modeled.

Consider the example where Y takes the values 1 and 0 for event and nonevent, respectively, and EXPOSURE is the explanatory variable. By default, PROC PROBIT assigns the first ordered level to response level 0, causing the probability of the nonevent to be modeled. There are several ways to change this.

Besides recoding the variable Y, you can do the following:

- assign a format to Y such that the first formatted value (when the formatted values are put in sorted order) corresponds to the event. For the following example, Y=0 could be assigned formatted value 'nonevent' and Y=1 could be assigned formatted value 'event.' Since ORDER=FORMATTED by default, Y=1 becomes the first ordered level. See Example 74.3 for an illustration of this method.

```
proc format;
   value disease 1='event' 0='nonevent';
run;
proc probit;
   model y=exposure;
   format y disease.;
run;
```

- arrange the input data set so that Y=1 appears first and use the ORDER=DATA option in the PROC PROBIT statement. Since ORDER=DATA sorts levels in order of their appearance in the data set, Y=1 becomes the first ordered level. Note that this option causes classification variables to be sorted by their order of appearance in the data set, also.

Computational Method

The log-likelihood function is maximized by means of a ridge-stabilized Newton-Raphson algorithm. Initial regression parameter estimates are set to zero. The INITIAL= and INTERCEPT= options in the MODEL statement can be used to give nonzero initial estimates.

The log-likelihood function, L, is computed as

$$L = \sum_i w_i \ln(p_i)$$

where the sum is over the observations in the data set, w_i is the weight for the ith observation, and p_i is the modeled probability of the observed response. In the case of the events/trials syntax in the MODEL statement, each observation contributes two terms corresponding to the probability of the event and the probability of its complement:

$$L = \sum_i w_i [r_i \ln(p_i) + (n_i - r_i) \ln(1 - p_i)]$$

where r_i is the number of events and n_i is the number of trials for observation i. This log-likelihood function differs from the log-likelihood function for a binomial or multinomial distribution by additive terms consisting of the log of binomial or multinomial coefficients. These terms are parameter-independent and do not affect the model estimation or the standard errors and tests.

The estimated covariance matrix, $\mathbf{V}$, of the parameter estimates is computed as the negative inverse of the information matrix of second derivatives of L with respect to the parameters evaluated at the final parameter estimates. Thus, the estimated covariance matrix is derived from the observed information matrix rather than the expected information matrix (these are generally not the same). The standard error estimates for the parameter estimates are taken as the square roots of the corresponding diagonal elements of $\mathbf{V}$.

If convergence of the maximum likelihood estimates is attained, a Type III chi-square test statistic is computed for each effect, testing whether there is any contribution from any of the levels of the effect. This statistic is computed as a quadratic form in the appropriate parameter estimates by using the corresponding submatrix of the asymptotic covariance matrix estimate. Refer to Chapter 41, "The GLM Procedure," and Chapter 15, "The Four Types of Estimable Functions," for more information about Type III estimable functions.

The asymptotic covariance matrix is computed as the inverse of the observed information matrix. Note that if the NOINT option is specified and classification variables are used, the first classification variable contains a contribution from an intercept term. The results are displayed in an ODS table named "Type3Analysis".

Chi-square tests for individual parameters are Wald tests based on the observed information matrix and the parameter estimates. If an effect has a single degree of freedom in the parameter estimates table, the chi-square test for this parameter is equivalent to the Type III test for this effect.

Prior to SAS 8.2, a multiple-degrees-of-freedom statistic was computed for each effect to test for contribution from any level of the effect. In general, the Type III test statistic in a main-effect-only model (no interaction terms) will be equal to the previously computed effect statistic, unless there are collinearities among the effects. If there are collinearities, the Type III statistic will adjust for them, and the value of the Type III statistic and the number of degrees of freedom might not be equal to those of the previous effect statistic.

The theory behind these tests assumes large samples. If the samples are not large, it might be better to base the tests on log-likelihood ratios. These changes in log likelihood can be obtained by fitting the model twice, once with all the parameters of interest and once leaving out the parameters to be tested. Refer to Cox and Oakes (1984) for a discussion of the merits of some possible test methods.

If some of the independent variables are perfectly correlated with the response pattern, then the theoretical parameter estimates can be infinite. Although fitted probabilities of 0 and 1 are not especially pathological, infinite parameter estimates are required to yield these probabilities. Due to the finite precision of computer arithmetic, the actual parameter estimates are not infinite. Indeed, since the tails of the distributions allowed in the PROBIT procedure become small rapidly, an argument to the cumulative distribution function of around 20 becomes effectively infinite. In the case of such parameter estimates, the standard error estimates and the corresponding chi-square tests are not trustworthy.

Distributions

The distributions, $F(x)$, allowed in the PROBIT procedure are specified with the DISTRIBUTION= option in the MODEL statement. The cumulative distribution functions for the available distributions are

Cumulative Distribution Function	Distribution
$\int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{z^2}{2}\right)\, dz$	Normal
$\frac{1}{1+e^{-x}}$	Logistic
$1 - e^{-e^{x}}$	Extreme value or Gompertz

The variances of these three distributions are not all equal to 1, and their means are not all equal to zero. Their means and variances are shown in the following table, where γ is the Euler constant.

Distribution	Mean	Variance
Normal	0	1
Logistic	0	$\pi^2/3$
Extreme value or Gompertz	$-\gamma$	$\pi^2/6$

When comparing parameter estimates by using different distributions, you need to take into account the different scalings and, for the extreme value (or Gompertz) distribution, a possible shift in location. For example, if the fitted probabilities are in the neighborhood of 0.1 to 0.9, then the parameter estimates from the logistic model should be about $\pi/\sqrt{3}$ larger than the estimates from the probit model.

INEST= *SAS-data-set*

The INEST= data set names a SAS data set that specifies initial estimates for all the parameters in the model.

The INEST= data set must contain the intercept variables (named Intercept for binary response model and Intercept, Intercept2, Intercept3, and so forth, for multinomial response models) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in a BY group, the first one read is used for that BY group.

If the INEST= data set also contains the _TYPE_ variable, only observations with the _TYPE_ value "PARMS" are used as starting values. Combining the INEST= data set and the option MAXIT= in the MODEL statement, partial scoring can be done, such as predicting on a validation data set by using the model built from a training data set.

You can specify starting values for the iterative algorithm in the INEST= data set. This data set overwrites the INITIAL= option in the MODEL statement, which is a little difficult to use for models with multilevel interaction effects. The INEST= data set has the same structure as the "OUTEST= *SAS-data-set*" on page 6224, but it is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization.

Model Specification

For a two-level response, the probability that the lesser response occurs is modeled by the probit equation as

$$p = C + (1 - C)F(\mathbf{x}'\mathbf{b})$$

The probability of the other (complementary) event is $1 - p$.

For a multilevel response with outcomes labeled l_i for $i = 1, 2, \ldots, k$, the probability, p_j, of observing level l_j is as follows:

$$\begin{aligned}
p_1 &= C + (1 - C)F(\mathbf{x}'\mathbf{b}) \\
p_2 &= (1 - C)\left(F(a_2 + \mathbf{x}'\mathbf{b}) - F(\mathbf{x}'\mathbf{b})\right) \\
&\vdots \\
p_j &= (1 - C)\left(F(a_j + \mathbf{x}'\mathbf{b}) - F(a_{j-1} + \mathbf{x}'\mathbf{b})\right) \\
&\vdots \\
p_k &= (1 - C)(1 - F(a_{k-1} + \mathbf{x}'\mathbf{b}))
\end{aligned}$$

Thus, for a k-level response, there are $k - 2$ additional parameters, $a_2, a_3, \ldots, a_{k-1}$, estimated. These parameters are denoted by Intercept$j$, $j = 2, 3, \ldots, k - 1$, in the output.

An intercept parameter is always added to the set of independent variables as the first term in the model unless the NOINT option is specified in the MODEL statement. If a classification variable taking on k levels is used as one of the independent variables, a set of k indicator variables is generated to model the effect of this variable. Because of the presence of the intercept term, there are at most $k - 1$ degrees of freedom for this effect in the model.

Lack-of-Fit Tests

Two goodness-of-fit tests can be requested from the PROBIT procedure: a Pearson's chi-square test and a log-likelihood ratio chi-square test.

To compute the test statistics, you can use the AGGREGATE or AGGREGATE= option grouping the observations into subpopulations. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes that each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the *events/trials* syntax.

If the Pearson's goodness-of-fit chi-square test is requested and the p-value for the test is too small, variances and covariances are adjusted by a heterogeneity factor (the goodness-of-fit chi-square divided by its degrees of freedom) and a critical value from the t distribution is used to compute the fiducial limits. The Pearson's chi-square test statistic is computed as

$$\chi^2_P = \sum_{i=1}^{m} \sum_{j=1}^{k} \frac{(r_{ij} - n_i \hat{p}_{ij})^2}{n_i \hat{p}_{ij}}$$

where the sum on i is over grouping, the sum on j is over levels of response, r_{ij} is the frequency of response level j for the ith grouping, n_i is the total frequency for the ith grouping, and $\hat{p}_{ij}$ is the fitted probability for the jth level at the ith grouping.

The likelihood ratio chi-square test statistic is computed as

$$\chi^2_D = 2 \sum_{i=1}^{m} \sum_{j=1}^{k} r_{ij} \ln\left(\frac{r_{ij}}{n_i \hat{p}_{ij}}\right)$$

This quantity is sometimes called the deviance. If the modeled probabilities fit the data, these statistics should be approximately distributed as chi-square with degrees of freedom equal to $(k-1) \times m - q$, where k is the number of levels of the multinomial or binomial response, m is the number of sets of independent variable values (covariate patterns), and q is the number of parameters fit in the model.

In order for the Pearson's statistic and the deviance to be distributed as chi-square, there must be sufficient replication within the groupings. When this is not true, the data are sparse, and the p-values for these statistics are not valid and should be ignored. Similarly, these statistics, divided by their degrees of freedom, cannot serve as indicators of overdispersion. A large difference between the Pearson's statistic and the deviance provides some evidence that the data are too sparse to use either statistic.

Rescaling the Covariance Matrix

One way of correcting overdispersion is to multiply the covariance matrix by a dispersion parameter. You can supply the value of the dispersion parameter directly, or you can estimate the dispersion parameter based on either the Pearson's chi-square statistic or the deviance for the fitted model.

The Pearson's chi-square statistic χ^2_P and the deviance χ^2_D are defined in the section "Lack-of-Fit Tests" on page 6221. If the SCALE= option is specified in the MODEL statement, the dispersion parameter is estimated by

$$\widehat{\sigma}^2 = \begin{cases} \chi^2_P/(m(k-1)-q) & \text{SCALE=PEARSON} \\ \chi^2_D/(m(k-1)-q) & \text{SCALE=DEVIANCE} \\ (\textit{constant})^2 & \text{SCALE=}\textit{constant} \end{cases}$$

In order for the Pearson's statistic and the deviance to be distributed as chi-square, there must be sufficient replication within the subpopulations. When this is not true, the data are sparse, and the p-values for these statistics are not valid and should be ignored. Similarly, these statistics, divided by their degrees of freedom, cannot serve as indicators of overdispersion. A large difference between the Pearson's statistic and the deviance provides some evidence that the data are too sparse to use either statistic.

You can use the AGGREGATE (or AGGREGATE=) option to define the subpopulation profiles. If you do not specify this option, each observation is regarded as coming from a separate subpopulation. For *events/trials* syntax, each observation represents n Bernoulli trials, where n is the value of the *trials* variable; for *single-trial* syntax, each observation represents a single trial. Without the AGGREGATE (or AGGREGATE=) option, the Pearson's chi-square statistic and the deviance are calculated only for *events/trials* syntax.

Note that the parameter estimates are not changed by this method. However, their standard errors are adjusted for overdispersion, affecting their significance tests.

Tolerance Distribution

For a single independent variable, such as a dosage level, the models for the probabilities can be justified on the basis of a population with mean μ and scale parameter σ of tolerances for the subjects. Then, given a dose x, the probability, P, of observing a response in a particular subject is the probability that the subject's tolerance is less than the dose or

$$P = F\left(\frac{x-\mu}{\sigma}\right)$$

Thus, in this case, the intercept parameter, b_0, and the regression parameter, b_1, are related to μ and σ by

$$b_0 = -\frac{\mu}{\sigma},\ b_1 = \frac{1}{\sigma}$$

NOTE: The parameter σ is not equal to the standard deviation of the population of tolerances for the logistic and extreme value distributions.

Inverse Confidence Limits

In bioassay problems, estimates of the values of the independent variables that yield a desired response are often needed. For instance, the value yielding a 50% response rate (called the ED50 or LD50) is often used. The INVERSECL option requests that confidence limits be computed for the value of the independent variable that yields a specified response. These limits are computed only for the first continuous variable effect in the model. The other variables are set either at their mean values if they are continuous or at the reference (last) level if they are discrete variables. For a discussion of inverse confidence limits, see Hubert, Bohidar, and Peace (1988).

For the PROBIT procedure, the response variable is a probability. An estimate of the first continuous variable value needed to achieve a response of p is given by

$$\hat{x}_1 = \frac{1}{b_1}\left(F^{-1}(p) - \mathbf{x}^{*\prime}\mathbf{b}^*\right)$$

where F is the cumulative distribution function used to model the probability, $\mathbf{x}^*$ is the vector of independent variables excluding the first one, which can be specified by the XDATA= option described in the section "XDATA= *SAS-data-set*" on page 6224, $\mathbf{b}^*$ is the vector of parameter estimates excluding the first one, and b_1 is the estimated regression coefficient for the independent variable of interest. This estimate assumes that there is no natural response rate ($C = 0$). When C is nonzero, the quantiles and confidence limits for the independent variable correspond to the adjusted probability $C + (1 - C)p$, rather than to p. As a result, an estimate of the value yielding response rate p is associated with the $(p-C)/(1-C)$ quantile. For example, if $C = 0.1$ then an estimate of the LD50 is found corresponding to the 0.44 quantile. This value can be thought of as yielding 50% of the variable's effect, but a 44% response rate. For both binary and ordinal models, the INVERSECL option provides estimates of the value of x_1, which yields Pr(first response level) $= p$, for various values of p.

This estimator is given as a ratio of random variables, such as $r = a/b$. Confidence limits for this ratio can be computed by using Fieller's theorem. A brief description of this theorem follows. See Finney (1971) for a more complete description of Fieller's theorem.

If the random variables a and b are thought to be distributed as jointly normal, then for any fixed value r the following probability statement holds if z is an $\alpha/2$ quantile from the standard normal distribution and $\mathbf{V}$ is the variance-covariance matrix of a and b:

$$\Pr\left((a - rb)^2 > z^2(V_{aa} - 2rV_{ab} + r^2V_{bb})\right) = \alpha$$

Usually the inequality can be solved for r to yield a confidence interval. The PROBIT procedure uses a value of 1.96 for z, corresponding to an α value of 0.05, unless the goodness-of-fit p-value is less than the specified value of the HPROB= option. When this happens, the covariance matrix is scaled by the heterogeneity factor, and a t distribution quantile is used for z.

It is possible for the roots of the equation for r to be imaginary or for the confidence interval to be all points outside of an interval. In these cases, the limits are set to missing by the PROBIT procedure.

Although the normal and logistic distribution give comparable fitted values of p if the empirically observed proportions are not too extreme, they can give appreciably different values when extrapolated into the tails. Correspondingly, the estimates of the confidence limits and dose values can be different for the two distri-

butions even when they agree quite well in the body of the data. Extrapolation outside of the range of the actual data is often sensitive to model assumptions, and caution is advised if extrapolation is necessary.

OUTEST= *SAS-data-set*

The OUTEST= data set contains parameter estimates and the log likelihood for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different models used by the PROBIT procedure. If you specify the COVOUT option, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates.

The OUTEST= data set contains each variable used as a dependent or independent variable in any MODEL statement. One observation consists of parameter values for the model with the dependent variable having the value -1. If you specify the COVOUT option, there are additional observations containing the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

MODEL	a character variable containing the label of the MODEL statement, if present, or blank otherwise
NAME	a character variable containing the name of the dependent variable for the parameter estimates observations or the name of the row for the covariance matrix estimates
TYPE	a character variable containing the type of the observation, either PARMS for parameter estimates or COV for covariance estimates
DIST	a character variable containing the name of the distribution modeled
LNLIKE	a numeric variable containing the last computed value of the log likelihood
_C_	a numeric variable containing the estimated threshold parameter
INTERCEPT	a numeric variable containing the intercept parameter estimates and covariances

Any BY variables specified are also added to the OUTEST= data set.

XDATA= *SAS-data-set*

The XDATA= data set is used for specifying values for the effects in the MODEL statement when predicted values and/or fiducial limits for a single continuous variable (dose variable) are required. It is also used for plots specified by the CDFPLOT, IPPPLOT, LPREDPLOT, and PREDPPLOT statement.

The XDATA= data names a SAS data set that contains user input values for all the independent variables in the MODEL statement and the variables in the CLASS statement. The XDATA= data set has the same structure as the DATA= data set but is not required to have all the variables or observations that appear in the DATA= data set.

The XDATA= data set must contain all the independent variables in the MODEL statement and variables in the CLASS statement. Even though variables in the CLASS statement are not used in the MODEL

statement, valid values are required for these variables in the XDATA= data set. Missing values are not allowed. For independent variables in the MODEL statement, although the dose variable's value is not used in the computing of predicted values and/or fiducial limits for the dose variable, missing values are not allowed in the XDATA= data set for any of the independent variables. Missing values are allowed for the dependent variables and other variables if they are included in the XDATA= data set and not listed in the CLASS statement.

If BY processing is used, the XDATA= data set should also include the BY variables, and there must be at least one valid observation for each BY group. If there is more than one valid observation in one BY group, the last one read is used for that BY group.

If there is no XDATA= data set in the PROC PROBIT statement, by default, the PROBIT procedure will use overall mean for effects containing continuous variable (or variables) and the highest level of a single classification variable as reference level. The rules are summarized as follows:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

Traditional High-Resolution Graphics

This section provides examples of using syntax available with the traditional high-resolution plots. A more modern alternative is to use ODS Graphics. See the section "ODS Graphics" on page 6228 for details.

There are four plot statements that you can use to request traditional high-resolution plots: CDFPLOT, IPPPLOT, LPREDPLOT, and PREDPPLOT. Some of these statements apply only to either the binomial model or the multinomial model. Table 74.33 shows the availability of these statements for different models.

Table 74.33 Plot Statement Availability

Statement	Binomial	Multinomial
CDFPLOT	No	Yes
IPPPLOT	Yes	No
LPREDPLOT	Yes	Yes
PREDPPLOT	Yes	Yes

The following example uses the data set study in the section "Estimating the Natural Response Threshold Parameter" on page 6167 to illustrate how to create high-resolution plots for the binomial model:

```
proc probit data=study log10 optc;
   model respond/number=dose;
   predpplot var=dose cfit=blue; inset;
   lpredplot var=dose cfit=blue; inset;
   ippplot   var=dose cfit=blue; inset/pos=se;
run;
```

All plot statements must follow the MODEL statement. The VAR= option specifies a continuous independent variable (dose variable) against which the predicted probability or the linear predictor is plotted. The INSET statement requests the inset box with summary information. See the section "INSET Statement" on page 6185 for more details.

The PREDPPLOT statement creates a plot that shows the relationship between dosage level, observed response proportions, and estimated probability values. See the section "PREDPPLOT Statement" on page 6208 for more details. The IPPPLOT statement creates a similar plot. See the section "IPPPLOT Statement" on page 6187 for details about this plot. The LPREDPLOT statement creates a linear predictor plot, which is described in the section "LPREDPLOT Statement" on page 6195.

The following example uses the data set multi from Example 74.2 to illustrate how to create high-resolution plots for the multinomial model:

```
proc probit data=multi order=data;
   class prep symptoms;
   model symptoms=prep ldose;
   cdfplot var=ldose  level=("None" "Mild" "Severe")
             cfit=blue cframe=ligr noconf;
   lpredplot var=ldose  level=("None" "Mild" "Severe")
             cfit=blue cframe=ligr;
   predpplot var=ldose  level=("None" "Mild" "Severe")
             cfit=blue cframe=ligr;
   weight n;
run;
```

The CDFPLOT statement creates a plot that shows the relationship between the cumulative response probabilities and the dose levels. The multinomial model plots are similar to those with the binomial model.

Displayed Output

If you request the iteration history (ITPRINT), PROC PROBIT displays the following:

- the current value of the log likelihood
- the ridging parameter for the modified Newton-Raphson optimization process
- the current estimate of the parameters
- the current estimate of the parameter C for a natural (threshold) model
- the values of the gradient and the Hessian on the last iteration

If you include classification variables, PROC PROBIT displays the following:

- the numbers of levels for each classification variable
- the (ordered) values of the levels

- the number of observations used

After the model is fit, PROC PROBIT displays the following:

- the name of the input data set
- the name of the dependent variables
- the number of observations used
- the number of events and the number of trials
- the final value of the log-likelihood function
- the parameter estimates
- the standard error estimates of the parameter estimates
- approximate chi-square test statistics for the test

If you specify the COVB or CORRB options, PROC PROBIT displays the following:

- the estimated covariance matrix for the parameter estimates
- the estimated correlation matrix for the parameter estimates

If you specify the LACKFIT option, PROC PROBIT displays the following:

- a count of the number of levels of the response and the number of distinct sets of independent variables
- a goodness-of-fit test based on the Pearson's chi-square
- a goodness-of-fit test based on the likelihood-ratio chi-square

If you specify only one independent variable, the normal distribution is used to model the probabilities, and the response is binary, then PROC PROBIT displays the following:

- the mean MU of the stimulus tolerance
- the scale parameter SIGMA of the stimulus tolerance
- the covariance matrix for MU, SIGMA, and the natural response parameter *C*

If you specify the INVERSECL options, PROC PROBIT also displays the following:

- the estimated dose along with the 95% fiducial limits for probability levels 0.01 to 0.10, 0.15 to 0.85 by 0.05, and 0.90 to 0.99

ODS Table Names

PROC PROBIT assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 74.34 ODS Tables Produced by PROC PROBIT

ODS Table Name	Description	Statement	Option
ClassLevels	Classification variable levels	CLASS	Default
ConvergenceStatus	Convergence status	MODEL	Default
CorrB	Parameter estimate correlation matrix	MODEL	CORRB
CovB	Parameter estimate covariance matrix	MODEL	COVB
CovTolerance	Covariance matrix for location and scale	MODEL	Default
GoodnessOfFit	Goodness-of-fit tests	MODEL	LACKFIT
Heterogeneity	Heterogeneity correction	MODEL	LACKFIT
IterHistory	Iteration history	MODEL	ITPRINT
LagrangeStatistics	Lagrange statistics	MODEL	NOINT
LastGrad	Last evaluation of the gradient	MODEL	ITPRINT
LastHess	Last evaluation of the Hessian	MODEL	ITPRINT
LogProbitAnalysis	Probit analysis for log dose	MODEL	INVERSECL
ModelInfo	Model information	MODEL	Default
MuSigma	Location and scale	MODEL	Default
NObs	Observations summary	PROC	Default
ParameterEstimates	Parameter estimates	MODEL	Default
ParmInfo	Parameter indices	MODEL	Default
ProbitAnalysis	Probit analysis for linear dose	MODEL	INVERSECL
ResponseLevels	Response-covariate profile	MODEL	LACKFIT
ResponseProfiles	Counts for ordinal data	MODEL	Default
Type3Analysis	Type III tests	MODEL	Default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

These ODS graphs are controlled by the PLOTS= option in the PROC statement. You can specify more than one graph request with the PLOTS= option. Table 74.35 summarizes these requests.

Table 74.35 Options for Plots

Option	Plot
ALL	All appropriate plots
CDFPLOT	Estimated cumulative probability
IPPPLOT	Inverse predicted probability
LPREDPLOT	Linear predictor
NONE	No plot
PREDPPLOT	Predicted probability

The following subsections provide information about these graphs.

ODS Graph Names

PROC PROBIT assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 74.36.

Table 74.36 Graphs Produced by PROC PROBIT

ODS Graph Name	Plot Description	Statement	PLOTS= Option
CDFPlot	Estimated cumulative probability	PROC	CDFPLOT
IPPPlot	Inverse predicted probability	PROC	IPPPLOT
LPredPlot	Linear predictor	PROC	LPREDPLOT
PredPPlot	Predicted probability	PROC	PREDPPLOT

CDF Plot

For a multinomial model, the predicted cumulative distribution function is defined as

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}})$$

where $j = 1, \ldots, k$ are the indexes of the k levels of the multinomial response variable, F is the CDF of the distribution used to model the cumulative probabilities, $\hat{\mathbf{b}}$ is the vector of estimated parameters, $\mathbf{x}$ is the covariate vector, $\hat{a}_j$ are estimated ordinal intercepts with $\hat{a}_1 = 0$, and C is the threshold parameter, either known or estimated from the model. Let x_1 be the covariate corresponding to the dose variable and $\mathbf{x}_{-1}$ be the vector of the rest of the covariates. Let the corresponding estimated parameters be $\hat{b}_1$ and $\hat{\mathbf{b}}_{-1}$. Then

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + x_1\hat{b}_1 + \mathbf{x}'_{-1}\hat{\mathbf{b}}_{-1})$$

To plot $\hat{F}_j$ as a function of x_1, $\mathbf{x}_{-1}$ must be specified. You can use the XDATA= option to provide the values of $\mathbf{x}_{-1}$ (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

The LEVEL= suboption specify the levels of the multinomial response variable for which the CDF curves are requested. There are $k-1$ curves for a k-level multinomial response variable (for the highest level, it is the constant line 1). You can specify any of them to be plotted by the LEVEL= suboption. See the plot in Output 74.2.6 for an example.

Inverse Predicted Probability Plot

For the binomial model, the response variable is a probability. An estimate of the dose level $\hat{x}_1$ needed for a response of p is given by

$$\hat{x}_1 = (F^{-1}(p) - \mathbf{x}'_{-1}\hat{\mathbf{b}}_{-1})/\hat{b}_1$$

where F is the cumulative distribution function used to model the probability, $\mathbf{x}_{-1}$ is the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ is the vector of the estimated parameters corresponding to $\mathbf{x}_{-1}$, and $\hat{b}_1$ is the estimated parameter for the dose variable of interest.

To plot $\hat{x}_1$ as a function of p, $\mathbf{x}_{-1}$ must be specified. You can use the XDATA= option to provide the values of $\mathbf{x}_{-1}$ (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

Output 74.4.12 in Example 74.4 shows an inverse predicted probability plot.

Linear Predictor Plot

For both binomial models and multinomial models, the linear predictor $\mathbf{x}'\mathbf{b}$ can be plotted against the first single continuous variable (dose variable) in the MODEL statement.

Let x_1 be the covariate of the dose variable, $\mathbf{x}_{-1}$ be the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ be the vector of estimated parameters corresponding to $\mathbf{x}_{-1}$, and $\hat{b}_1$ be the estimated parameter for the dose variable of interest.

To plot $\hat{\mathbf{x}}'\mathbf{b}$ as a function of x_1, $\mathbf{x}_{-1}$ must be specified. You can use the XDATA= option to provide the values of $\mathbf{x}_{-1}$ (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

For the multinomial model, you can use the LEVEL= suboption to specify the levels for which the linear predictor lines are plotted.

The confidence limits for the predicted values are only available for the binomial model. Output 74.4.13 in Example 74.4 shows a linear predictor plot for a binomial model.

Predicted Probability Plot

The predicted probability is

$$\hat{p} = C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}})$$

for the binomial model and

$$\begin{aligned}
\hat{p}_1 &= C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}}) \\
\hat{p}_j &= (1 - C)(F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}}) - F(\hat{a}_{j-1} + \mathbf{x}'\hat{\mathbf{b}})), \quad j = 2, \ldots, k-1 \\
\hat{p}_k &= (1 - C)(1 - F(\hat{a}_{k-1} + \mathbf{x}'\hat{\mathbf{b}}))
\end{aligned}$$

for the multinomial model with k response levels, where F is the cumulative distribution function used to model the probability, $\mathbf{x}'$ is the vector of the covariates, $\hat{a}_j$ are the estimated ordinal intercepts with $\hat{a}_1 = 0$, C is the threshold parameter, either known or estimated from the model, and $\hat{\mathbf{b}}'$ is the vector of estimated parameters.

To plot $\hat{p}$ (or $\hat{p}_j$) as a function of a continuous variable x_1, the remaining covariates $\mathbf{x}_{-1}$ must be specified. You can use the XDATA= option to provide the values of $\mathbf{x}_{-1}$ (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow these rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

For the multinomial model, you can use the LEVEL= suboption to specify the levels for which the linear predictor lines are plotted.

Confidence limits are plotted only for the binomial model. Output 74.1.7 in Example 74.1 shows a predicted probability plot for a binomial model; and Output 74.2.3 in Example 74.2 shows a predicted probability plot for a multinomial model.

Examples: PROBIT Procedure

Example 74.1: Dosage Levels

In this example, Dose is a variable representing the level of a stimulus, N represents the number of subjects tested at each level of the stimulus, and Response is the number of subjects responding to that level of the stimulus. Both probit and logit response models are fit to the data. The LOG10 option in the PROC PROBIT statement requests that the log base 10 of Dose is used as the independent variable. Specifically, for a given level of Dose, the probability p of a positive response is modeled as

$$p = \Pr(\text{Response}) = F\left(b_0 + b_1 \times \log_{10}(\text{Dose})\right)$$

The probabilities are estimated first by using the normal distribution function (the default) and then by using the logistic distribution function. Note that, in this model specification, the natural rate is assumed to be zero.

The LACKFIT option specifies lack-of-fit tests and the INVERSECL option specifies inverse confidence limits.

In the DATA step that reads the data, a number of observations are generated that have a missing value for the response. Although the PROBIT procedure does not use the observations with the missing values to fit the model, it does give predicted values for all nonmissing sets of independent variables. These data points fill in the plot of fitted and observed values in the logistic model displayed in Output 74.1.7. The plot, requested with the PLOT=PREDPPLOT option, displays the estimated logistic cumulative distribution function and the observed response rates.

The following statements produce Output 74.1.1:

```
data a;
   infile cards eof=eof;
   input Dose N Response @@;
   Observed= Response/N;
   output;
   return;
eof: do Dose=0.5 to 7.5 by 0.25;
        output;
     end;
   datalines;

	MU	SIGMA
MU	0.002418	-0.000409
SIGMA	-0.000409	0.004072

The p-values in the goodness-of-fit table of 0.6009 for the Pearson's chi-square and 0.4616 for the likelihood ratio chi-square indicate an adequate fit for the model fit with the normal distribution.

Tolerance distribution parameter estimates for the normal distribution indicate a mean tolerance for the population of 0.5303.

Output 74.1.2 displays probit analysis with the logarithm of dose levels. The LD50 (ED50 for log dose) is 0.5303, the dose corresponding to a probability of 0.5. This is the same as the mean tolerance for the normal distribution.

Output 74.1.2 Probit Analysis with Normal Distribution

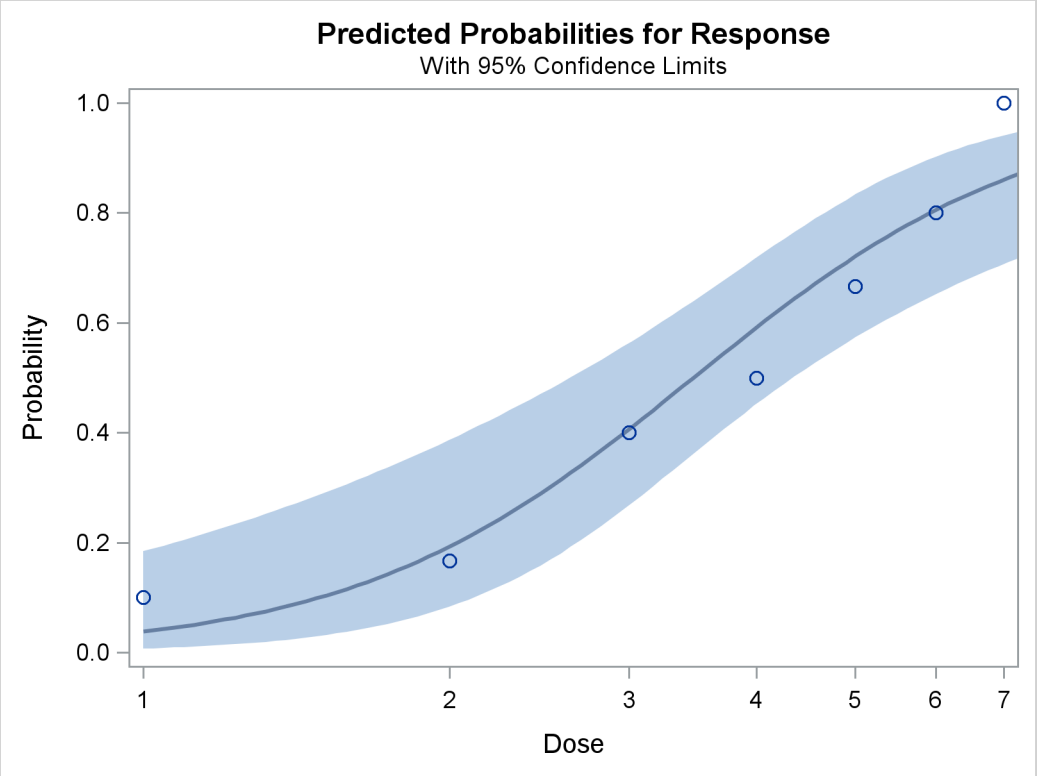
The PLOT=PREDPPLOT option together with the ODS GRAPHICS statement creates the plot of observed and fitted probabilities in Output 74.1.7. The dashed line represent pointwise confidence bands for the probabilities.

Output 74.1.7 Plot of Observed and Fitted Probabilities



Example 74.2: Multilevel Response

In this example, two preparations, a standard preparation and a test preparation, are each given at several dose levels to groups of insects. The symptoms are recorded for each insect within each group, and two multilevel probit models are fit. Because the natural sort order of the three levels is not the same as the response order, the ORDER=DATA option is specified in the PROC PROBIT statement to get the desired order. The following statements fit two models:

```
data multi;
   input Prep $ Dose Symptoms $ N;
   LDose=log10(Dose);
   if Prep='test' then PrepDose=LDose;
   else PrepDose=0;
   datalines;
stand     10      None       33
stand     10      Mild        7
stand     10      Severe     10
stand     20      None       17
stand     20      Mild       13
```

```
stand     20      Severe     17
stand     30      None       14
stand     30      Mild        3
stand     30      Severe     28
stand     40      None        9
stand     40      Mild        8
stand     40      Severe     32
test      10      None       44
test      10      Mild        6
test      10      Severe      0
test      20      None       32
test      20      Mild       10
test      20      Severe     12
test      30      None       23
test      30      Mild        7
test      30      Severe     21
test      40      None       16
test      40      Mild        6
test      40      Severe     19
;

proc probit order=data data=multi;
   class Prep Symptoms;
   nonpara: model Symptoms=Prep LDose PrepDose / lackfit;
   weight N;
run;

proc probit order=data data=multi ;
   class Prep Symptoms;
   parallel: model Symptoms=Prep LDose / lackfit;
   weight N;
run;
```

Results of these two models are shown in Output 74.2.1 and Output 74.2.2. The first model allows for nonparallelism between the dose response curves for the two preparations by inclusion of an interaction between Prep and LDose. The interaction term is labeled PrepDose in the "Analysis of Parameter Estimates" table. The results of this first model indicate that the parameter for the interaction term is not significant, having a Wald chi-square of 0.73. Also, since the first model is a generalization of the second, a likelihood ratio test statistic for this same parameter can be obtained by multiplying the difference in log likelihoods between the two models by 2. The value obtained, $2 \times (-345.94 - (-346.31))$, is 0.73. This is in close agreement with the Wald chi-square from the first model. The lack-of-fit test statistics for the two models do not indicate a problem with either fit.

Output 74.2.1 Multilevel Response: Nonparallel Analysis

Symptoms	3	None Mild Severe

Output 74.2.2 *continued*

Analysis of Maximum Likelihood Parameter Estimates

Parameter		DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept		1	3.4148	0.4126	2.6061	4.2235	68.50	<.0001
Intercept2		1	0.4678	0.0558	0.3584	0.5772	70.19	<.0001
Prep	stand	1	−0.5675	0.1259	−0.8142	−0.3208	20.33	<.0001
Prep	test	0	0.0000	.	.	.	.	.
LDose		1	−2.3721	0.2949	−2.9502	−1.7940	64.68	<.0001

The negative coefficient associated with LDose indicates that the probability of having no symptoms (Symptoms='None') or no or mild symptoms (Symptoms='None' or Symptoms='Mild') decreases as LDose increases; that is, the probability of a severe symptom increases with LDose. This association is apparent for both treatment groups.

The negative coefficient associated with the standard treatment group (Prep = stand) indicates that the standard treatment is associated with more severe symptoms across all Ldose values.

The following statements use the PLOTS= option to create the plot shown in Output 74.2.3 and Output 74.2.4. Output 74.2.3 is the plot of the probabilities of the response taking on individual levels as a function of LDose. Since there are two covariates, LDose and Prep, the value of the classification variable Prep is fixed at the highest level, test. Instead of individual response level probabilities, the CDFPLOT option creates the plot of the cumulative response probabilities with confidence limits shown in Output 74.2.4.

```
ods graphics on;

proc probit data=multi order=data
            plots=(predpplot(level=("None" "Mild" "Severe"))

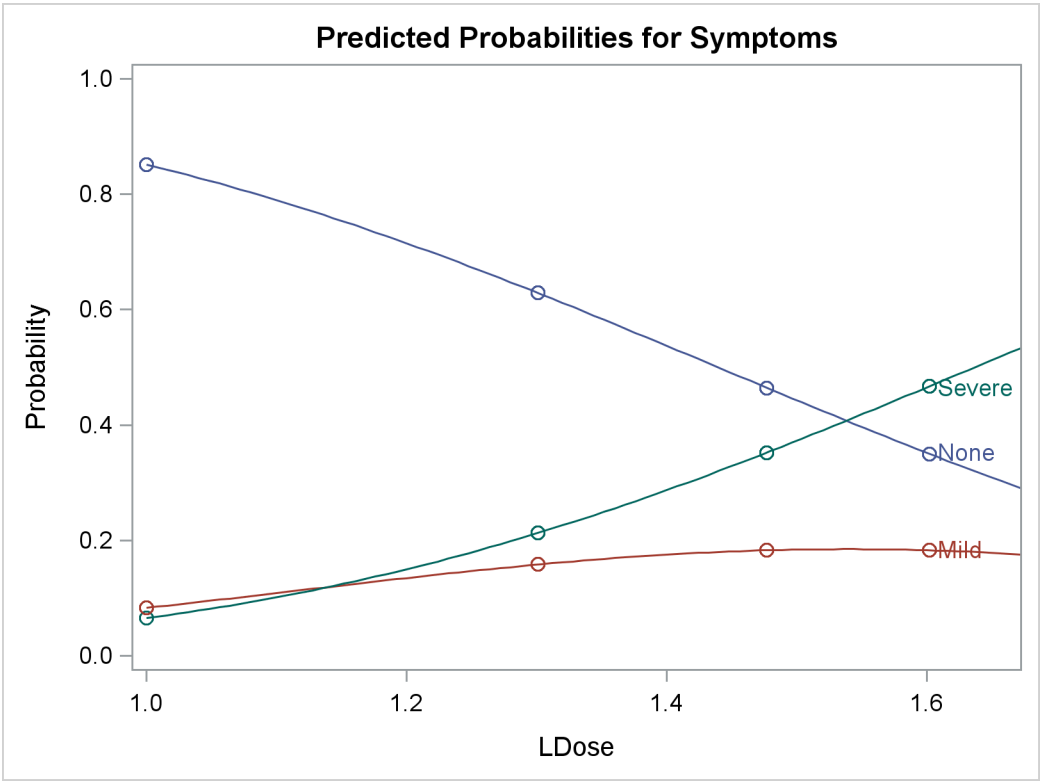
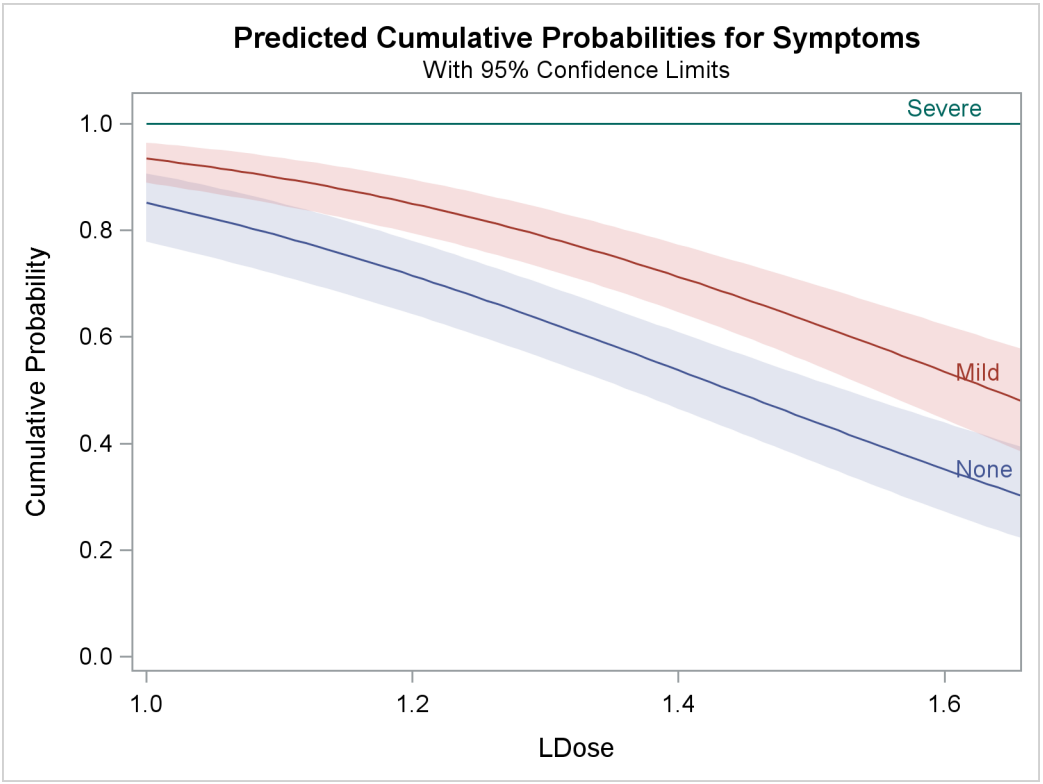
   weight N;
run;

ods graphics off;
```

Output 74.2.3 Plot of Predicted Probabilities for the Test Preparation Group



Output 74.2.4 Plot of Predicted Cumulative Probabilities for the Test Preparation Group



The following statements use the XDATA= data set to create plots of predicted probabilities and cumulative probabilities with Prep set to the stand level. The resulting plots are shown in Output 74.2.5 and Output 74.2.6.

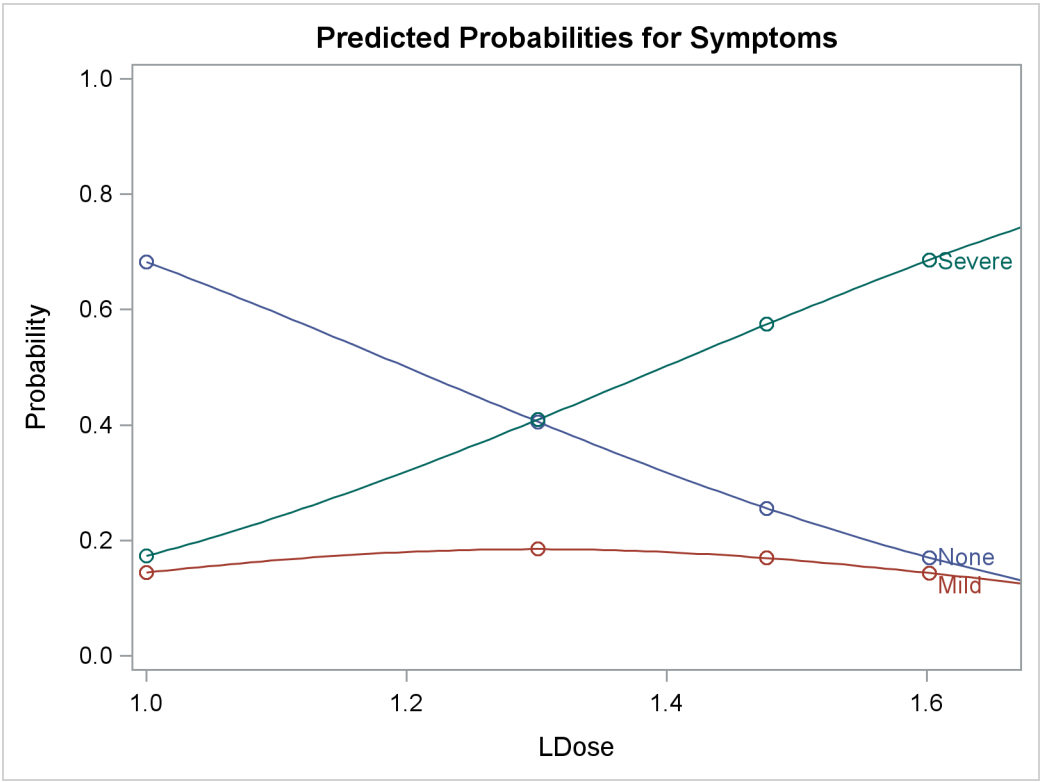
```
data xrow;
   input Prep $ Dose Symptoms $ N;
   LDose=log10(Dose);
   datalines;
stand     40      Severe     32
run;

ods graphics on;

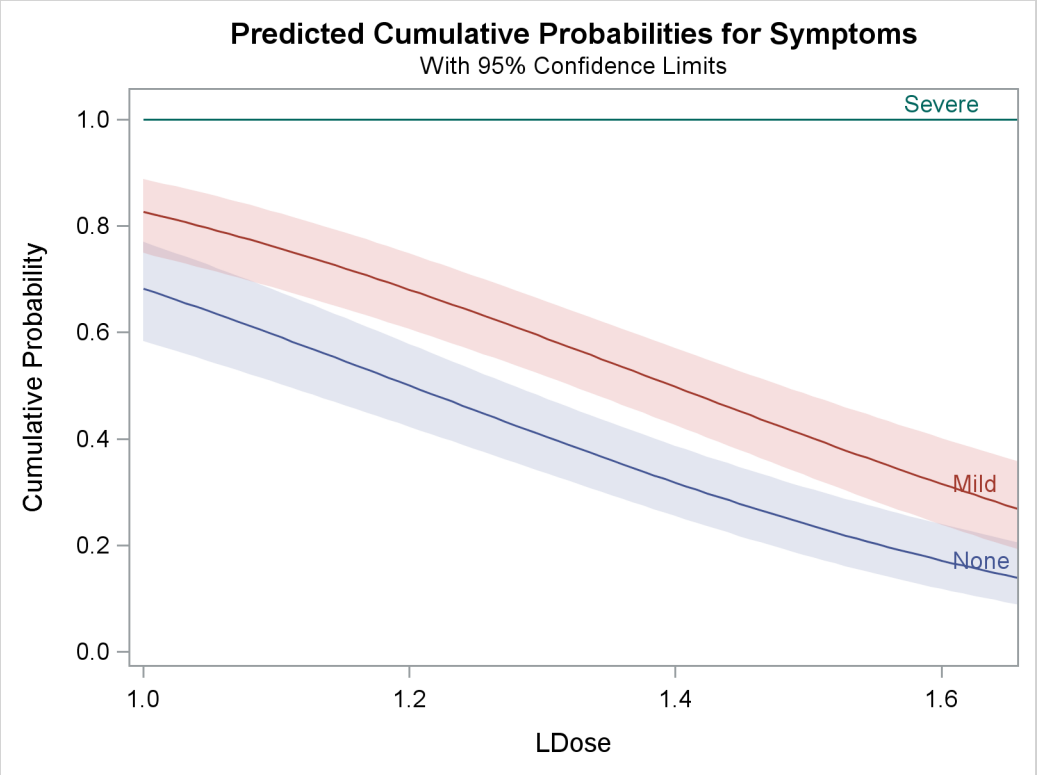
proc probit data=multi order=data xdata=xrow
            plots=(predpplot(level=("None" "Mild" "Severe"))
                   cdfplot(level=("None" "Mild" "Severe")));
   class Prep Symptoms;
   parallel: model Symptoms=Prep LDose / lackfit;
   weight N;
run;

ods graphics off;
```

Output 74.2.5 Plot of Predicted Probabilities for the Standard Preparation Group



Output 74.2.6 Plot of Predicted Cumulative Probabilities for the Standard Preparation Group



Example 74.3: Logistic Regression

In this example, a series of people are asked whether or not they would subscribe to a new newspaper. For each person, the variables sex (Female, Male), age, and subs (1=yes,0=no) are recorded. The PROBIT procedure is used to fit a logistic regression model to the probability of a positive response (subscribing) as a function of the variables sex and age. Specifically, the probability of subscribing is modeled as

$$p = \Pr(\text{subs} = 1) = F\left(b_0 + b_1 \times \text{sex} + b_2 \times \text{age}\right)$$

where F is the cumulative logistic distribution function.

By default, the PROBIT procedure models the probability of the lower response level for binary data. One way to model Pr(subs $=$ 1) is to format the response variable so that the formatted value corresponding to subs=1 is the lower level. The following statements format the values of subs as 1 = 'accept' and 0 = 'reject', so that PROBIT models Pr(accept) $=$ Pr(subs $=$ 1). They produce Output 74.3.1.

```
data news;
   input sex $ age subs @@;
   datalines;
Female     35    0   Male       44    0
Male       45    1   Female     47    1
Female     51    0   Female     47    0
Male       54    1   Male       47    1
Female     35    0   Female     34    0
```

```
Female     48    0   Female     56    1
Male       46    1   Female     59    1
Female     46    1   Male       59    1
Male       38    1   Female     39    0

age	292.04051848	216.20829515	13487.329973

Analysis of Maximum Likelihood Parameter Estimates

Parameter		DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept		1	-5.7620	2.7635	-11.1783	-0.3458	4.35	0.0371
sex	Female	1	-2.4224	0.9559	-4.2959	-0.5489	6.42	0.0113
sex	Male	0	0.0000	.	.	.	.	.
age		1	0.1649	0.0652	0.0371	0.2927	6.40	0.0114

Output 74.3.1 shows that there appears to be an effect due to both the variables sex and age. The positive coefficient for age indicates that older people are more likely to subscribe than younger people. The negative coefficient for sex indicates that females are less likely to subscribe than males.

Example 74.4: An Epidemiology Study

The data in this example, which are from an epidemiology study, consist of five variables: the number, r, of individuals surviving after an epidemic, out of n treated, for combinations of medicine dosage (dose), treatment (treat = A, B), and sex (sex = 0(Female), 1(Male)).

To see whether the two treatments have different effects on male and female individual survival rates, the interaction term between the two variables treat and sex is included in the model.

The following invocation of PROC PROBIT fits the binary probit model to the grouped data:

```
data epidemic;
   input treat$ dose n r sex @@;
   label dose = Dose;
   datalines;
A  2.17 142 142  0   A   .57 132  47  1
A  1.68 128 105  1   A  1.08 126 100  0
A  1.79 125 118  0   B  1.66 117 115  1
B  1.49 127 114  0   B  1.17  51  44  1
B  2.00 127 126  0   B   .80 129 100  1
;

data xval;
   input treat $ dose sex ;
   datalines;
B  2.  1
;

ods graphics on;

proc probit optc lackfit covout data=epidemic
            outest = out1 xdata = xval
            Plots=(predpplot ippplot lpredplot);
   class treat sex;
   model r/n = dose treat sex sex*treat/corrb covb inversecl;
   output out = out2 p =p;
run;

ods graphics off;
```

The results of this analysis are shown in the outputs that follow.

Output 74.4.1 displays the table of level information for *all* classification variables in the CLASS statement.

Output 74.4.1 Class Level Information

The Probit Procedure

Class Level Information

Name	Levels	Values
treat	2	A B
sex	2	0 1

Output 74.4.2 displays the table of parameter information for the effects in the MODEL statement.

Output 74.4.2 Parameter Information

Output 74.4.3 displays background information about the model fit. Included are the name of the input data set, the response variables used, the numbers of observations, events, and trials, the type of distribution, and the final value of the log-likelihood function.

Output 74.4.3 Model Information

The Probit Procedure

Model Information

Data Set	WORK.EPIDEMIC
Events Variable	r
Trials Variable	n
Number of Observations	10
Number of Events	1011
Number of Trials	1204
Name of Distribution	Normal
Log Likelihood	-387.2467391

Output 74.4.4 displays the table of goodness-of-fit tests requested with the LACKFIT option in the PROC PROBIT statement. Two goodness-of-fit statistics, the Pearson's chi-square statistic and the likelihood ratio chi-square statistic, are computed. The grouping method for computing these statistics can be specified by the AGGREGATE= option. The details can be found in the AGGREGATE= option, and an example can be found in the second part of this example. By default, the PROBIT procedure uses the covariates in the MODEL statement to do grouping. Observations with the same values of the covariates in the MODEL statement are grouped into cells and the two statistics are computed according to these cells. The total number of cells and the number of levels for the response variable are reported next in the "Response-Covariate Profile."

In this example, neither the Pearson's chi-square nor the log-likelihood ratio chi-square tests are significant at the 0.1 level, which is the default test level used by the PROBIT procedure. That means that the model, which includes the interaction of treat and sex, is suitable for this epidemiology data set. (Further investigation shows that models without the interaction of treat and sex are not acceptable by either test.)

Output 74.4.4 Goodness-of-Fit Tests and Response-Covariate Profile

Goodness-of-Fit Tests

Statistic	Value	DF	Value/DF	Pr > ChiSq
Pearson Chi-Square	4.9317	4	1.2329	0.2944

Response-Covariate Profile

Response Levels	2
Number of Covariate Values	10

Output 74.4.5 displays the Type III test results for all effects specified in the MODEL statement, which include the degrees of freedom for the effect, the Wald Chi-Square test statistic, and the p-value.

Output 74.4.5 Type III Tests

Type III Analysis of Effects

Effect	DF	Wald Chi-Square	Pr > ChiSq
dose	1	42.1691	<.0001
treat	1	16.1421	<.0001
sex	1	1.7710	0.1833
treat*sex	1	13.9343	0.0002

Output 74.4.6 displays the table of parameter estimates for the model. The PROBIT procedure displays information for all the parameters of an effect. Degenerate parameters are indicated by 0 degree of freedom. Confidence intervals are computed for all parameters with nonzero degrees of freedom, including the natural threshold C if the OPTC option is specified in the PROC PROBIT statement. The confidence level can be specified by the ALPHA= option in the MODEL statement. The default confidence level is 95%.

Output 74.4.6 Analysis of Parameter Estimates

Analysis of Maximum Likelihood Parameter Estimates

Parameter		DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept		1	−0.8871	0.3632	−1.5991	−0.1752	5.96	0.0146

From Table 74.4.6, you can see the following results:

- The variable dose has a significant positive effect on the survival rate.
- Individuals under treatment A have a lower survival rate.
- Male individuals have a higher survival rate.
- Female individuals under treatment A have a higher survival rate.

Output 74.4.7 and Output 74.4.8 display tables of estimated covariance matrix and estimated correlation matrix for estimated parameters with a nonzero degree of freedom, respectively. They are computed by the inverse of the Hessian matrix of the estimated parameters.

Output 74.4.9 displays the computed values and fiducial limits for the first single continuous variable dose in the MODEL statement, given the probability levels, without the effect of the natural threshold, and when the option INSERSECL in the MODEL statement is specified. If there is no single continuous variable in the MODEL specification but the INVERSECL option is specified, an error is reported.

Output 74.4.9 Probit Analysis on Dose

The Probit Procedure

If the XDATA= option is used to input a data set for the independent variables in the MODEL statement, the PROBIT procedure uses these values for the independent variables other than the single continuous variable. Missing values are not permitted in the XDATA= data set for the independent variables, although the value for the single continuous variable is not used in the computing of the fiducial limits. A suitable valid value should be given. In the data set xval created by the SAS statements on page 6249, dose = 2. Only one observation from the XDATA= data set is used to produce a probit analysis table for a combination of classification variable levels. If more than one observation is present in the XDATA= data set, only the last observation is used.

See the section "XDATA= *SAS-data-set*" on page 6224 for the default values for those effects other than the single continuous variable, for which the fiducial limits are computed.

In this example, there are two classification variables, treat and sex. Fiducial limits for the dose variable are computed for the highest level of the classification variables, treat = B and sex = 1, which is the default specification. Since these are the default values, you would get the same values and fiducial limits if you did not specify the XDATA= option in this example. The confidence level for the fiducial limits can be specified by the ALPHA= option in the MODEL statement. The default level is 95%.

If a LOG10 or LOG option is used in the PROC PROBIT statement, the values and the fiducial limits are computed for both the single continuous variable and its logarithm.

Output 74.4.10 displays the OUTEST= data set. All parameters for an effect are included. The name of a parameter is generated by combining the variable names and levels in the effect. The maximum length of a parameter name is 32.

Output 74.4.10 Outest Data Set for Epidemiology Study

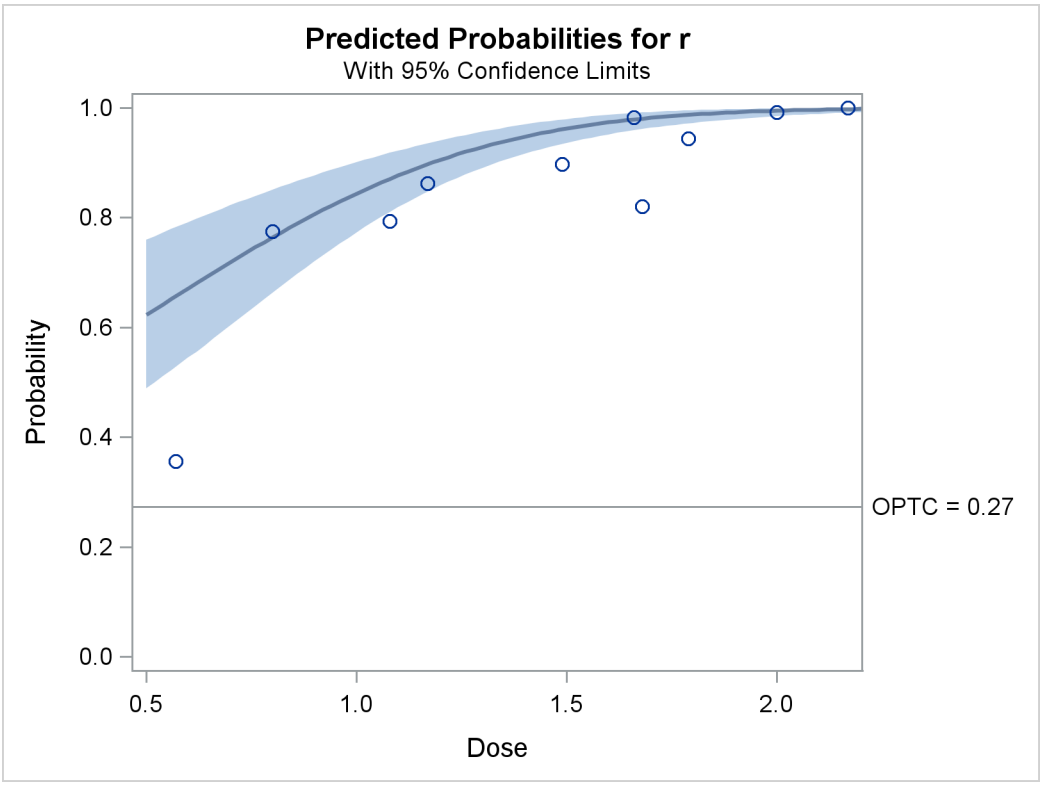
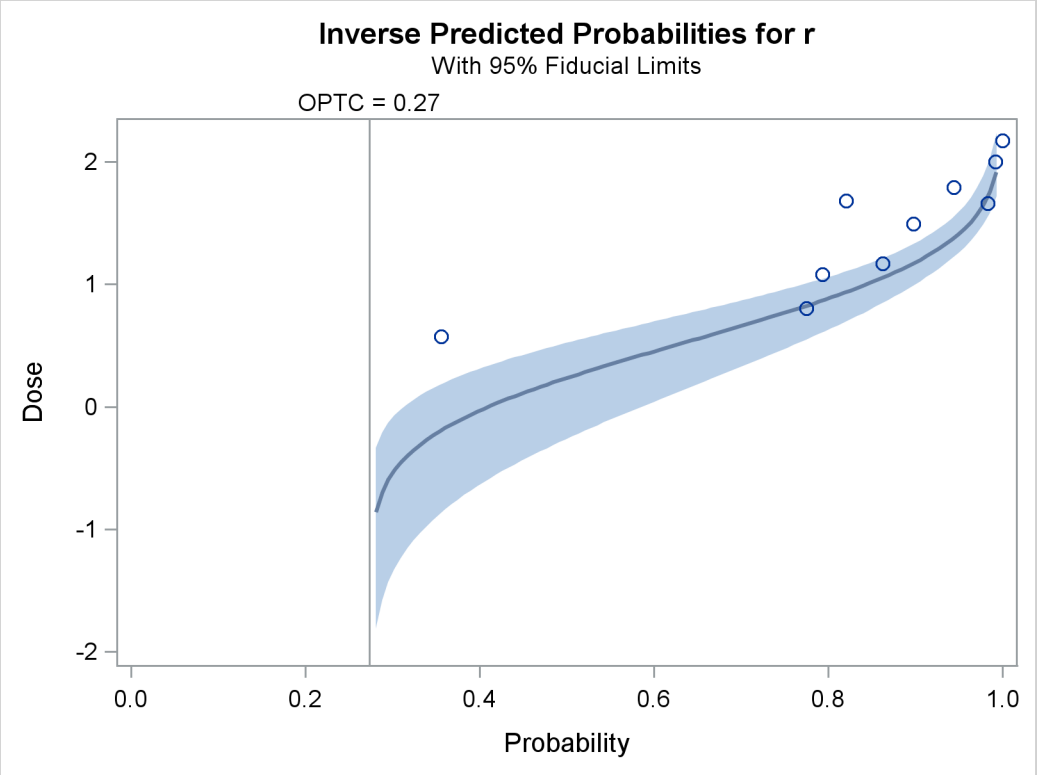
The plots in the following three outputs, Output 74.4.11, Output 74.4.12, and Output 74.4.13, are generated by the PLOTS= option. The first plot, specified with the PREDPPLOT option, is the plot of the predicted probability against the first single continuous variable dose in the MODEL statement. You can specify values of other independent variables in the MODEL statement by using an XDATA= data set or by using the default values.

The second plot, specified with the IPPPLOT option, is the inverse of the predicted probability plot with the fiducial limits. It should be pointed out that the fiducial limits are *not* just the inverse of the confidence limits in the predicted probability plot; see the section "Inverse Confidence Limits" on page 6223 for the computation of these limits. The third plot, specified with the LPREDPLOT option, is the plot of the linear predictor $\mathbf{x}'_{\_}$ against the first single continuous variable with the Wald confidence intervals.

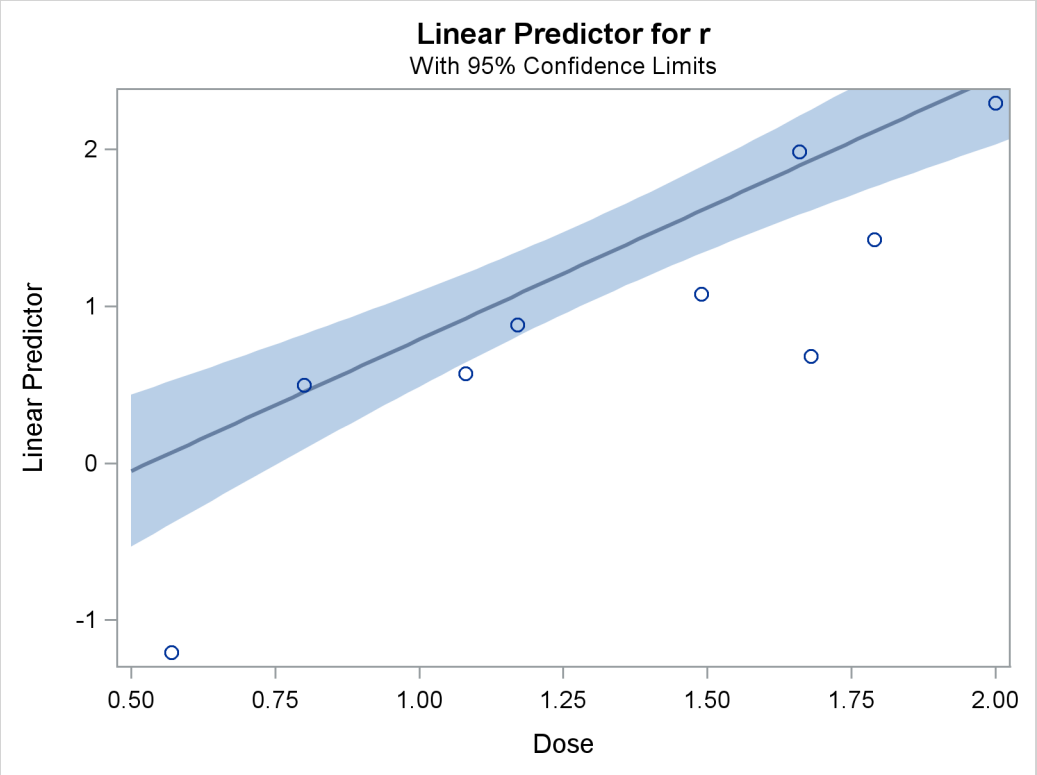
Output 74.4.11 Predicted Probability Plot



Output 74.4.12 Inverse Predicted Probability Plot



Output 74.4.13 Linear Predictor Plot



When you combine the INEST= data set and the MAXIT= option in the MODEL statement, the PROBIT procedure can do prediction, if the parameterizations for the models used for the training data and the validation data are exactly the same. The following SAS statements show an example:

```
data validate;
   input treat $ dose  sex  n r group @@;
   datalines;
B  2.0  0  44 43  1   B  2.0  1  54 52  2

A  2.0  0  66 65  5   A  2.0  1  89 88  6
A  1.5  1  45 38  7   A  1.5  0  66 59  8
;

proc probit optc data=validate inest=out1;
   class treat sex;
   model r/n = dose treat sex sex*treat  / maxit = 0 ;
   output out = out3 p =p;
run ;

proc probit optc lackfit data=validate inest=out1;
   class treat sex;
   model r/n = dose treat sex sex*treat / aggregate = group ;
   output out = out4 p =p;
run ;
```

After the first invocation of PROC PROBIT, you have the estimated parameters and their covariance matrix in the data set OUTEST = Out1, and the fitted probabilities for the training data set epidemic in the data set OUTPUT = Out2. See Output 74.4.10 for the data set Out1 and Output 74.4.14 for the data set Out2.

The validation data are collected in data set validate. The second invocation of PROC PROBIT simply passes the estimated parameters from the training data set epidemic to the validation data set validate for prediction. The predicted probabilities are stored in the data set OUTPUT = Out3 (see Output 74.4.15). The third invocation of PROC PROBIT passes the estimated parameters as initial values for a new fit of the validation data set with the same model. Predicted probabilities are stored in the data set OUTPUT = Out4 (see Output 74.4.16). Goodness-of-fit tests are computed based on the cells grouped by the AGGREGATE= group variable. Results are shown in Output 74.4.17.

Chapter 75

The QUANTREG Procedure

Contents

Overview: QUANTREG Procedure

The QUANTREG procedure models the effects of covariates on the conditional quantiles of a response variable by means of quantile regression.

Ordinary least squares (OLS) regression models the relationship between one or more covariates X and the *conditional mean* of the response variable Y given $X = x$. Quantile regression, which was introduced by Koenker and Bassett (1978), extends the regression model to *conditional quantiles* of the response variable, such as the median or the 90th percentile. Quantile regression is particularly useful when the rate of change in the conditional quantile, expressed by the regression coefficients, depends on the quantile.

Figure 75.1 Trout Density in Streams

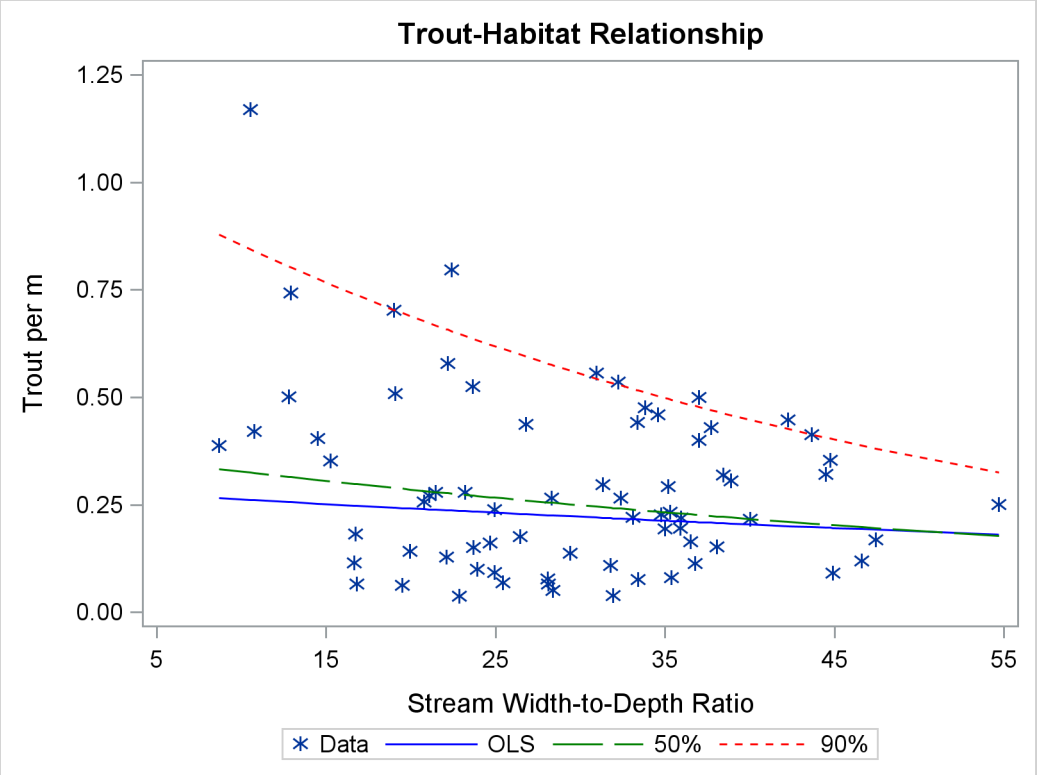

Figure 75.1 illustrates an ecological study in which it is revealing to model upper conditional quantiles. The points represent measurements of trout density and stream width-to-depth ratio taken at 13 streams over seven years.

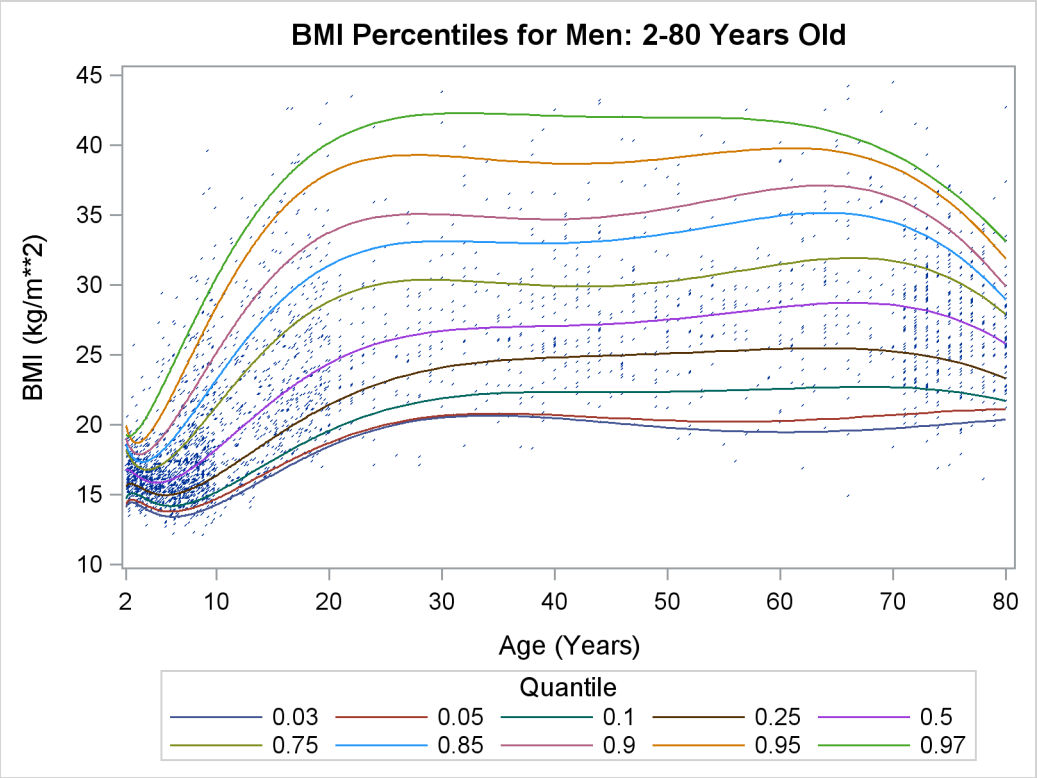
As analyzed by Dunham, Cade, and Terrell (2002), in addition to the ratio, trout density depends on a number of unmeasured limiting factors related to the integrity of stream habitat. The interaction of these

factors results in unequal variances for the conditional distributions of density given the ratio. When the ratio is the "active" limiting effect, changes in the upper conditional percentiles of density provide a better estimate of this effect than changes in the conditional mean.

The two dashed curves represent the conditional 90th and 50th percentiles of density as determined with the QUANTREG procedure. The analysis was done by using a simple linear regression model for the logarithm of density. (The curves in Figure 75.1 were obtained by transforming the fitted lines back to the original scale. For more details, see the section "Analysis of Fish-Habitat Relationships" on page 6267.) The slope parameter for the 90th percentile has an estimated value of −0.0215 and is significant with a p-value less than 0.01. On the other hand, the slope parameter for the 50th percentile is not significantly different from zero. Similarly, the slope parameter for the mean, obtained with OLS regression, is not significantly different from zero.

Figure 75.2 Quantiles for Body Mass Index



Quantile regression is especially useful with data that are heterogeneous in the sense that the tails and the central location of the conditional distributions vary differently with the covariates. An even more pronounced example of heterogeneity is shown in Figure 75.2, which plots the body mass index of 8,250 men versus their age.

Here, both upper (overweight) and lower (underweight) conditional quantiles are important because they provide the basis for developing growth charts and establishing health standards. The curves in Figure 75.2 were determined with the QUANTREG procedure by using polynomial quantile regression; details are provided in the section "Growth Charts for Body Mass Index" on page 6272. Clearly, the rate of change with age (as expressed by the regression coefficients), particularly for ages less than 20, is different for each conditional quantile.

Heterogeneous data occur in many fields, including biomedicine, econometrics, survival analysis, and ecology. Quantile regression, which includes median regression as a special case, provides a complete picture of the covariate effect when a set of percentiles is modeled, and so it offers the capability to capture important features of the data that might be missed by models that average over the conditional distribution.

Because it makes no distributional assumption about the error term in the model, quantile regression offers considerable model robustness. The assumption of normality, which is often made with OLS regression in order to compute conditional quantiles as offsets from the mean, forces a common set of regression coefficients for all the quantiles. Obviously, quantiles with common slopes would be inappropriate in the preceding examples.

Quantile regression is also flexible in the sense that it does not involve a link function that relates the variance and the mean of the response variable. Generalized linear models, which you can fit with the GENMOD procedure, require both a link function and a distributional assumption such as the normal or Poisson distribution. The goal of generalized linear models is inference about the regression parameters in the linear predictor for the mean of the population. In contrast, the goal of quantile regression is inference on regression coefficients for the conditional quantiles of a response variable that is usually assumed to be continuous.

Quantile regression also offers a degree of data robustness. Unlike OLS regression, it is robust to extreme points in the response direction (outliers). However, it is not robust to extreme points in the covariate space (leverage points). When both types of robustness are of concern, you should consider using the ROBUSTREG procedure (Chapter 77, "The ROBUSTREG Procedure.")

Also, unlike OLS regression, quantile regression is equivariant to monotone transformations of the response variable. For instance, as illustrated in the trout example, the logarithm of the 90th conditional percentile of trout density is the 90th conditional percentile of the logarithm of density.

Note that quantile regression cannot be carried out simply by segmenting the unconditional distribution of the response variable and then obtaining least squares fits for the subsets. This approach leads to disastrous results when, for example, the data include outliers. In contrast, quantile regression uses *all* of the data for fitting quantiles, even the extreme quantiles.

Features

The main features of the QUANTREG procedure are as follows:

- offers simplex, interior point, and smoothing algorithms for estimation
- provides sparsity, rank, and resampling methods for confidence intervals
- provides asymptotic and bootstrap methods for covariance and correlation matrices of the estimated parameters
- provides the Wald, likelihood ratio, and rank tests for the regression parameter estimates and the Wald test for heteroscedasticity
- provides outlier and leverage-point diagnostics

- enables parallel computing when multiple processors are available
- provides row-wise or column-wise output data sets with multiple quantiles
- provides regression quantile spline fits
- produces fit plots, diagnostic plots, and quantile process plots by using ODS Graphics

The next section provides notation and a formal definition for quantile regression.

Quantile Regression

Quantile regression generalizes the concept of a univariate quantile to a conditional quantile given one or more covariates. Recall that a student's score on a test is at the τth quantile if his or her score is better than that of $100\tau\%$ of the students who took the test. The score is also said to be at the 100τth percentile.

For a random variable Y with probability distribution function

$$F(y) = \text{Prob}\,(Y \leq y)$$

the τth quantile of Y is defined as the inverse function

$$Q(\tau) = \inf\{y : F(y) \geq \tau\}$$

where $0 < \tau < 1$. In particular, the median is $Q(1/2)$.

For a random sample $\{y_1, \ldots, y_n\}$ of Y, it is well known that the sample median minimizes the sum of absolute deviations

$$\text{median} = \arg\min_{\xi \in \mathbf{R}} \sum_{i=1}^{n} |y_i - \xi|$$

Likewise, the general τth sample quantile $\xi(\tau)$, which is the analog of $Q(\tau)$, is formulated as the minimizer

$$\xi(\tau) = \arg\min_{\xi \in \mathbf{R}} \sum_{i=1}^{n} \rho_\tau(y_i - \xi)$$

where $\rho_\tau(z) = z(\tau - I(z < 0))$, $0 < \tau < 1$, and where $I(\cdot)$ denotes the indicator function. The loss function ρ_τ assigns a weight of τ to positive residuals $y_i - \xi$ and a weight of $1 - \tau$ to negative residuals.

Using this loss function, the linear conditional quantile function extends the τth sample quantile $\xi(\tau)$ to the regression setting in the same way that the linear conditional mean function extends the sample mean. Recall that OLS regression estimates the linear conditional mean function $E(Y|X = x) = x'\beta$ by solving for

$$\hat{\beta} = \arg\min_{\beta \in \mathbf{R}^p} \sum_{i=1}^{n} (y_i - x_i'\beta)^2$$

The estimated parameter $\hat{\beta}$ minimizes the sum of squared residuals in the same way that the sample mean $\hat{\mu}$ minimizes the sum of squares:

$$\hat{\mu} = \arg\min_{\mu \in \mathbf{R}} \sum_{i=1}^{n} (y_i - \mu)^2$$

Likewise, quantile regression estimates the linear conditional quantile function, $Q(\tau|X = x) = x'\beta(\tau)$, by solving

$$\hat{\beta}(\tau) = \arg\min_{\beta \in \mathbf{R}^p} \sum_{i=1}^{n} \rho_\tau(y_i - x_i'\beta)$$

for $\tau \in (0, 1)$. The quantity $\hat{\beta}(\tau)$ is called the τth *regression quantile*. The case $\tau = 0.5$, which minimizes the sum of absolute residuals, corresponds to median regression, which is also known as L_1 regression.

The set of regression quantiles

$$\{\beta(\tau) : \tau \in (0, 1)\}$$

is referred to as the *quantile process*.

The QUANTREG procedure computes the quantile function $Q(\tau|X = x)$ and conducts statistical inference on the estimated parameters $\hat{\beta}(\tau)$.

Getting Started: QUANTREG Procedure

The following examples demonstrate how you can use the QUANTREG procedure to fit linear models for selected quantiles or for the entire quantile process. The first example explains the use of the procedure in the fish-habitat example, and the second example explains the use of the procedure to construct growth charts for body mass index.

Analysis of Fish-Habitat Relationships

Quantile regression is used extensively in ecological studies (Cade and Noon 2003). Recently, Dunham, Cade, and Terrell (2002) applied quantile regression to analyze fish-habitat relationships for Lahontan cutthroat trout in 13 streams of the eastern Lahontan basin, which covers most of northern Nevada and parts of southern Oregon. The density of trout (number of trout per meter) was measured by sampling stream sites from 1993 to 1999. The width-to-depth ratio of the stream site was determined as a measure of stream habitat.

The goal of this study was to explore the relationship between the conditional quantiles of trout density and the width-to-depth ratio. The scatter plot of the data in Figure 75.1 indicates a nonlinear relationship, and so it is reasonable to fit regression models for the conditional quantiles of the log of density. Since regression quantiles are equivariant under any monotonic (linear or nonlinear) transformation (Koenker and Hallock 2001), the exponential transformation converts the conditional quantiles to the original density scale.

The data set trout, which follows, includes the average numbers of Lahontan cutthroat trout per meter of stream (Density), the logarithm of Density (LnDensity), and the width-to-depth ratios (WDRatio) for 71 samples.

The following statements use the QUANTREG procedure to fit a simple linear model for the 50th and 90th percentiles of LnDensity:

```
ods graphics on;

proc quantreg data=trout alpha=0.1 ci=resampling;
   model LnDensity = WDRatio / quantile=0.5 0.9
                               CovB seed=1268;
   test WDRatio / wald lr;
run;
```

The MODEL statement specifies a simple linear regression model with LnDensity as the response variable Y and WDRatio as the covariate X. The QUANTILE= option requests that the regression quantile function $Q(\tau|X = x) = x'\beta(\tau)$ be estimated by solving

$$\hat{\beta}(\tau) = \arg\min_{\beta \in \mathbf{R}^2} \sum_{i=1}^{n} \rho_\tau(y_i - x_i'\beta)$$

where $\tau = (0.5, 0.9)$.

By default, the regression coefficients $\hat{\beta}(\tau)$ are estimated with the simplex algorithm, which is explained in the section "Simplex Algorithm" on page 6290. The ALPHA= option requests 90% confidence limits for the regression parameters, and the option CI=RESAMPLING specifies that the intervals are to be computed with the MCMB resampling method of He and Hu (2002). By specifying the CI=RESAMPLING option, the QUANTREG procedure also computes standard errors, t values, and p-values of regression parameters with the MCMB resampling method. The SEED= option specifies a seed for the resampling method. The COVB option requests covariance matrices for the estimated regression coefficients, and the TEST statement requests tests for the hypothesis that the slope parameter (the coefficient of WDRatio) is zero.

Figure 75.3 displays model information and summary statistics for the variables in the model. The summary statistics include the median and the standardized median absolute deviation (MAD), which are robust measures of univariate location and scale, respectively. See Huber (1981, p. 108) for more details about the standardized MAD.

Figure 75.3 Model Fitting Information and Summary Statistics

The QUANTREG Procedure

LnDensity	-2.0511	-1.3813	-0.8669	-1.4973	0.7682	0.8214

Figure 75.4 and Figure 75.5 display the parameter estimates, standard errors, 95% confidence limits, t values, and p-values that are computed by the resampling method.

Figure 75.4 Parameter Estimates at QUANTILE=0.5

Parameter Estimates

Parameter	DF	Estimate	Standard Error	90% Confidence Limits		t Value	Pr > |t|
Intercept	1	−0.9811	0.3952	−1.6400	−0.3222	−2.48	0.0155
WDRatio	1	−0.0136	0.0123	−0.0341	0.0068	−1.11	0.2705

Figure 75.5 Parameter Estimates at QUANTILE=0.9

Parameter Estimates

Parameter	DF	Estimate	Standard Error	90% Confidence Limits		t Value	Pr > |t|
Intercept	1	0.0576	0.2606	−0.3769	0.4921	0.22	0.8257
WDRatio	1	−0.0215	0.0075	−0.0340	−0.0091	−2.88	0.0053

The 90th percentile of trout density can be predicted from the width-to-depth ratio as follows:

$$y_{90} = \exp(0.0576 - 0.0215x)$$

This is the upper dashed curve plotted in Figure 75.1. The lower dashed curve for the median can be obtained in a similar fashion.

The covariance matrices for the estimated parameters are shown in Figure 75.6. The resampling method used for the confidence intervals is used to compute these matrices.

Figure 75.6 Covariance Matrices of the Estimated Parameters

Estimated Covariance Matrix for Quantile = 0.5

	Intercept	WDRatio
Intercept	0.156191	−.004653
WDRatio	−.004653	0.000151

Estimated Covariance Matrix for Quantile = 0.9

	Intercept	WDRatio
Intercept	0.067914	−.001877
WDRatio	−.001877	0.000056

The tests requested with the TEST statement are shown in Figure 75.7. Both the Wald test and the likelihood

ratio test indicate that the coefficient of width-to-depth ratio is significantly different from zero at the 90th percentile, but the deference is not significant at the median.

Figure 75.7 Tests of Significance

Test Results

Quantile	Test	Test Statistic	DF	Chi-Square	Pr > ChiSq
0.5	Wald	1.2339	1	1.23	0.2666

0.9	Likelihood Ratio	9.0529	1	9.05	0.0026

In many quantile regression problems it is useful to examine how the estimated regression parameters for each covariate change as a function of τ in the interval $(0, 1)$. The following statements use the QUANTREG procedure to request the estimated quantile processes $\hat{\beta}(\tau)$ for the slope and intercept parameters:

```
proc quantreg data=trout alpha=0.1 ci=resampling;
   model LnDensity = WDRatio / quantile=process seed=1268
                               plot=quantplot;
run;
```

The QUANTILE=PROCESS option requests an estimate of the quantile process for each regression parameter. The options ALPHA=0.1 and CI=RESAMPLING specify that 90% confidence bands for the quantile processes are to be computed with the resampling method.

Figure 75.8 displays a portion of the objective function table for the entire quantile process. The objective function is evaluated at 77 values of τ in the interval $(0, 1)$. The table also provides predicted values of the conditional quantile function $Q(\tau)$ at the mean for WDRatio, which can be used to estimate the conditional density function.

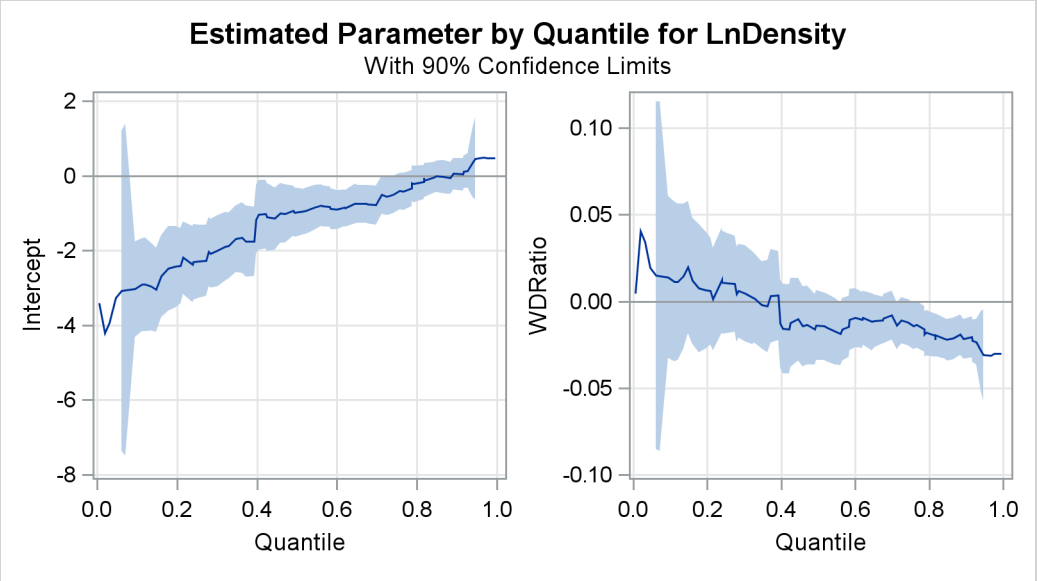
The PLOT=QUANTPLOT option in the MODEL statement, together with ODS Graphics, requests a plot of the estimated quantile processes. The left side of Figure 75.10 displays the process for the intercept, and the right side displays the process for the coefficient of WDRatio.

The process plot for WDRatio shows that the slope parameter changes from positive to negative as the quantile increases, and it changes sign with a sharp drop at the 40th percentile. The 90% confidence bands show that the relationship between LnDensity and WDRatio (expressed by the slope) is not significant below the 78th percentile. This situation can also be seen in Figure 75.9, which shows that 0 falls between the lower and upper confidence limits of the slope parameter for quantiles below 0.78. Since the confidence intervals for the extreme quantiles are not stable due to insufficient data, the confidence band is not displayed outside the interval (0.05, 0.95).

Figure 75.10 Quantile Processes for Intercept and Slope



Growth Charts for Body Mass Index

Body mass index (BMI) is defined as the ratio of weight (kg) to squared height (m^2) and is a widely used measure for categorizing individuals as overweight or underweight. The percentiles of BMI for specified ages are of particular interest. As age increases, these percentiles provide growth patterns of BMI not only for the majority of the population, but also for underweight or overweight extremes of the population. In addition, the percentiles of BMI for a specified age provide a reference for individuals at that age with respect to the population.

Smooth quantile curves have been widely used for reference charts in medical diagnosis to identify unusual subjects, whose measurements lie in the tails of the reference distribution. This example explains how to use the QUANTREG procedure to create growth charts for BMI.

A SAS data set named bmimen was created by merging and cleaning the 1999–2000 and 2001–2002 survey results for men published by the National Center for Health Statistics. This data set contains the variables Weight (kg), Height (m), BMI (kg/m^2), Age (year), and SeQN (respondent sequence number) for 8,250 men. More details can be found in Chen (2005).

The data set used in this example is a subset of the original data set of Chen (2005). It contains the two variables BMI and Age with 3264 observations.

```
data bmimen;
   input BMI Age @@;
   SqrtAge = sqrt(Age);
   InveAge = 1/Age;
   LogBMI  = log(BMI);
datalines;
18.6  2.0 17.1  2.0 19.0  2.0 16.8  2.0 19.0  2.1  15.5   2.1
16.7  2.1 16.1  2.1 18.0  2.1 17.8  2.1 18.3  2.1  16.9   2.1
```

```
   ... more lines ...

29.0 80.0 24.1 80.0 26.6 80.0 24.2 80.0 22.7 80.0  28.4  80.0
26.3 80.0 25.6 80.0 24.8 80.0 28.6 80.0 25.7 80.0  25.8  80.0
22.5 80.0 25.1 80.0 27.0 80.0 27.9 80.0 28.5 80.0  21.7  80.0
33.5 80.0 26.1 80.0 28.4 80.0 22.7 80.0 28.0 80.0  42.7  80.0
;
```

The logarithm of BMI is used as the response (although this does not improve the quantile regression fit, it helps with statistical inference.) A preliminary median regression is fitted with a parametric model, which involves six powers of Age.

The following statements invoke the QUANTREG procedure:

```
proc quantreg data=bmimen algorithm=interior(tolerance=1e-5) ci=resampling;
   model logbmi = inveage sqrtage age sqrtage*age
                  age*age age*age*age
                  / diagnostics cutoff=4.5 quantile=.5 seed=1268;
   id age bmi;
   test_age_cubic: test age*age*age / wald lr rankscore(tau);
run;
```

The MODEL statement provides the model, and the option QUANTILE=0.5 requests median regression, which computes $\hat{\beta}(\frac{1}{2})$ by using the interior point algorithm as requested with the ALGORITHM= option. See the section "Interior Point Algorithm" on page 6291 for details about this algorithm.

Figure 75.11 displays the estimated parameters, standard errors, 95% confidence intervals, t values, and p-values that are computed by the resampling method as requested by the CI= option. All of the parameters are considered significant since the p-values are smaller than 0.001.

Figure 75.11 Parameter Estimates with Median Regression: Men

The QUANTREG Procedure

Parameter Estimates

Parameter	DF	Estimate	Standard Error	95% Confidence Limits		t Value	Pr > |t|
Intercept	1	7.8909	0.8168	6.2895	9.4924	9.66	<.0001
InveAge	1	-1.8354	0.4350	-2.6884	-0.9824	-4.22	<.0001
SqrtAge	1	-5.1247	0.7135	-6.5237	-3.7257	-7.18	<.0001
Age	1	1.9759	0.2537	1.4785	2.4733	7.79	<.0001
SqrtAge*Age	1	-0.3347	0.0424	-0.4179	-0.2515	-7.89	<.0001
Age*Age	1	0.0227	0.0029	0.0170	0.0284	7.77	<.0001
Age*Age*Age	1	-0.0000	0.0000	-0.0001	-0.0000	-7.40	<.0001

The TEST statement requests Wald, likelihood ratio, and rank tests for the significance of the cubic term in Age. The test results, shown in Figure 75.12, indicate that this term is significant. Higher-order terms are not significant.

Figure 75.12 Test of Significance for Cubic Term

Test test_age_cubic Results

Test	Test Statistic	DF	Chi-Square	Pr > ChiSq
Wald	54.7417	1	54.74	<.0001
Likelihood Ratio	56.9473	1	56.95	<.0001
Rank_Tau	42.5731	1	42.57	<.0001

Median regression and, more generally, quantile regression are robust to extremes of the response variable. The DIAGNOSTICS option in the MODEL statement requests a diagnostic table of outliers, shown in Figure 75.13, which uses a cutoff value specified with the CUTOFF= option. The variables specified in the ID statement are included in the table.

With CUTOFF=4.5, 14 men are identified as outliers. All of these men have large positive standardized residuals, which indicates that they are overweight for their age. The cutoff value 4.5 is ad hoc; it corresponds to a probability less than 0.5E−5 if normality is assumed, but the standardized residuals for median regression usually do not meet this assumption.

In order to construct the chart shown in Figure 75.2, the same model used for median regression is used for other quantiles. Note that the QUANTREG procedure can compute fitted values for multiple quantiles.

Figure 75.13 Diagnostics with Median Regression

Diagnostics

Obs	Age	BMI	Standardized Residual	Outlier
1337	8.900000	36.500000	5.3575	*
1376	9.200000	39.600000	5.8723	*
1428	9.400000	36.900000	5.3036	*
1505	9.900000	35.500000	4.8862	*
1764	14.900000	46.800000	5.6403	*
1838	16.200000	50.400000	5.9138	*
1845	16.300000	42.600000	4.6683	*
1870	16.700000	42.600000	4.5930	*
1957	18.100000	49.900000	5.5053	*
2002	18.700000	52.700000	5.8106	*
2016	18.900000	48.400000	5.1603	*
2264	32.000000	55.600000	5.3085	*
2291	35.000000	60.900000	5.9406	*
2732	66.000000	14.900000	-4.7849	*

The following statements request fitted values for 10 quantile levels ranging from 0.03 to 0.97:

```
proc quantreg data=bmimen algorithm=interior(tolerance=1e-5) ci=none;
   model logbmi = inveage sqrtage age sqrtage*age
                  age*age age*age*age
                  / quantile=0.03,0.05,0.1,0.25,0.5,0.75,
```

```
                                0.85,0.90,0.95,0.97;
   output out=outp pred=p/columnwise;
run;

data outbmi;
   set outp;
   pbmi = exp(p);
run;

proc sgplot data=outbmi;
   title 'BMI Percentiles for Men: 2-80 Years Old';
   yaxis label='BMI (kg/m**2)' min=10 max=45 values=(10 15 20 25 30 35 40 45);
   xaxis label='Age (Years)' min=2 max=80 values=(2 10 20 30 40 50 60 70 80);

   scatter x=age y=bmi /markerattrs=(size=1);
   series  x=age y=pbmi/group=QUANTILE;
run;
```

The fitted values are stored in the OUTPUT data set outp. The COLUMNWISE option arranges these fitted values for all quantiles in the single variable p by groups of the quantiles. After the exponential transformation, the fitted BMI values together with the original BMI values are plotted against age to create the display shown in Figure 75.2.

The fitted quantile curves reveal important information. During the quick growth period (ages 2 to 20), the dispersion of BMI increases dramatically; it becomes stable during middle age, and then it contracts after age 60. This pattern suggests that effective population weight control should start in childhood.

Compared to the 97th percentile in reference growth charts published by CDC in 2000 (Kuczmarski et al. 2002), the 97th percentile for 10-year-old boys in Figure 75.2 is 6.4 BMI units higher (an increase of 27%). This can be interpreted as a warning of overweight or obesity. See Chen (2005) for a detailed analysis.

Syntax: QUANTREG Procedure

PROC QUANTREG < *options* > ;
BY *variables* ;
CLASS *variables* ;
EFFECT *name* = *effect-type* (*variables* < / *options* >) ;
ID *variables* ;
MODEL *response* = *independents* < / *options* > ;
OUTPUT < *OUT= SAS-data-set* > < *options* > ;
PERFORMANCE < *options* > ;
TEST *effects* < / *options* > ;
WEIGHT *variable* ;

The PROC QUANTREG statement invokes the procedure. The CLASS statement specifies which explanatory variables are treated as categorical. The ID statement names variables to identify observations in the outlier diagnostics tables. The MODEL statement is required and specifies the variables used in the regression. Main effects and interaction terms can be specified in the MODEL statement, as in the GLM

procedure (Chapter 41, "The GLM Procedure.") The OUTPUT statement creates an output data set containing predicted values, residuals, and estimated standard errors. The PERFORMANCE statement tunes the performance of PROC QUANTREG by using single or multiple processors available in the hardware. The TEST statement requests linear tests for the model parameters. The WEIGHT statement identifies a variable in the input data set whose values are used to weight the observations. In one invocation of PROC QUANTREG, multiple OUTPUT and TEST statements are allowed.

PROC QUANTREG Statement

PROC QUANTREG < *options* > **;**

The PROC QUANTREG statement invokes the procedure. You can specify the following options in the PROC QUANTREG statement.

ALGORITHM=*algorithm* **< (** *suboptions* **) >**
specifies an algorthm to estimate the regression parameters. Three algorithms are available: simplex (SIMPLEX), interior point (INTERIOR), and smoothing (SMOOTH).

The default algorithm depends on the number of the observations (n) and the number of the covariates (p) in the model estimation. See Table 75.1 for the relevant defaults.

Table 75.1 The Default Estimation Algorithm

	$p \leq 100$	$p > 100$
$n \leq 5000$	Simplex	Smoothing
$n > 5000$	Interior point	Smoothing

Table 75.2 summarizes the options available for each of these methods.

Table 75.2 Options for Estimation Algorithms

ALGORITHM= Value	Algorithm	Suboptions
SIMPLEX	Simplex	MAXSTATIONARY=
INTERIOR	Interior point	KAPPA= MAXIT= TOLERANCE=
SMOOTH	Smoothing	RRATIO=

With ALGORITHM=SIMPLEX you can specify the following *suboption*:

- MAXSTATIONARY=*m* specifies that if the objective funtion has not improved for *m* consecutive iterations, the algorithm termintates. By default, *m*=1000.

With ALGORITHM=INTERIOR you can specify the following *suboptions*:

- KAPPA=*value* specifies the step length parameter for the interior point algorithm. This parameter should be between 0 and 1. The larger the parameter, the faster the algorithm. However,

numeric instability can occur as the parameter approaches 1. By default, KAPPA=0.99995. See the section "Interior Point Algorithm" on page 6291 for details.

- MAXIT=*m* sets the maximum number of iterations for the interior point algorithm. By default, *m*=1000.
- TOLERANCE=*value* specifies the tolerance for the convergence criterion of the interior point algorithm. The default *value* is 1E−8. The QUANTREG procedure uses the duality gap as the convergence criterion. See the section "Interior Point Algorithm" on page 6291 for details.

With the interior point algorithm, you can use the PERFORMANCE statement to enable parallel computing when multiple processors are available in the hardware.

With ALGORITHM=SMOOTH you can specify the following *suboption*:

- RRATIO=*value* specifies the reduction ratio for the smoothing algorithm. This ratio is used for reducing the threshold of the smoothing algorithm. The *value* should be between 0 and 1. In theory, the smaller the reduction ration, the faster the smoothing algorithm. However, the optimal ratio is quite data dependent in practice. See the section "Smoothing Algorithm" on page 6294 for details.

ALPHA=*value*

sets the confidence level for the confidence intervals for regression parameters. The *value* must be between 0 and 1. The default is ALPHA=0.05, corresponding to a 0.95 confidence interval.

CI=NONE | RANK | SPARSITY<(BF | HS)></IID> | RESAMPLING<(NREP=*n*)>

specifies a method to compute confidence intervals for regression parameters. When you specify CI=SPARSITY or CI=RESAMPLING, the QUANTREG procedure also computes standard errors, *t* values, and *p*-values for regression parameters.

The following table summarizes these methods.

Table 75.3 Options for Confidence Intervals

Value of CI=	Method	Additional Options
NONE	No confidence intervals computed	
RANK	By inverting rank-score tests	
SPARSITY	By estimating sparsity function	HS BF IID
RESAMPLING	By resampling	NREP

By default, when there are fewer than 5,000 observations, fewer than 20 variables in the data set, and the algorithm is simplex, the QUANTREG procedure computes confidence intervals by using the inverting rank-score test method; otherwise, the resampling method is used.

By default, confidence intervals are not computed for the quantile process, which is estimated when you specify the QUANTILE=PROCESS option in the MODEL statement. Confidence intervals for the quantile process are computed with the sparsity or resampling methods when you specify CI=SPARSITY or CI=RESAMPLING, respectively. The rank method for confidence intervals is not available with quantile processes because it is computationally prohibitive.

With the SPARSITY option, there are two suboptions for estimating the sparsity function. If you specify the IID suboption, the sparsity function is estimated by assuming that the errors in the linear model are independent and identically distributed (iid). By default, the sparsity function is estimated by assuming that the conditional quantile function is locally linear. See the section "Sparsity" on page 6297 for details. With both methods two bandwidth selection methods are available. You can specify the Bofinger method with the BF suboption or the Hall-Sheather method with the HS suboption. By default, the Hall-Sheather method is used.

With the RESAMPLING option, you can specify the number of repeats with the NREP=*n* suboption. By default, NREP=200. The value of *n* must be greater than 50.

DATA=*SAS-data-set*

specifies the input SAS data set used by the QUANTREG procedure. By default, the most recently created SAS data set is used.

INEST=*SAS-data-set*

specifies an input SAS data set that contains initial estimates for all the parameters in the model. The interior point algorithm and the smoothing algorithm use these estimates as a start. See the section "INEST= Data Set" on page 6303 for a detailed description of the contents of the INEST= data set.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the order in which to sort the levels of the classification variables (which are specified in the CLASS statement). This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

OUTEST=*SAS-data-set*

specifies an output SAS data set containing the parameter estimates for all quantiles. See the section "OUTEST= Data Set" on page 6303 for a detailed description of the contents of the OUTEST= data set.

PLOT | PLOTS<(*global-plot-options***)> <=***plot-request***>**

PLOT | PLOTS<(*global-plot-options***)> <=(***plot-request* **<...** *plot-request* **>)>**

specifies options that control details of the plots. These plots fall into two categories, diagnostic plots and fit plots. If you do not specify the PLOTS= option, PROC QUANTREG produces the quantile fit plot by default when a single continuous variable is specified in the model. You can use the PLOTS= option in the PROC statement to request various diagnostic plots. In addition to these two categories of plots, you can use the PLOT= option in the MODEL statement to request the quantile process plot for any effects specified in the model.

When you specify one *plot-request*, you can omit the parentheses around the plot request. Here are some examples:

```
plots=ddplot
plots=(ddplot rdplot)
```

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;

proc quantreg plots=fitplot;
  model y=x1;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The *global-plot-options* apply to all plots generated by the QUANTREG procedure. The following global plot option is available:

MAXPOINTS=NONE | *number*

specifies that plots with elements that require processing more than *number* points be suppressed. The default is MAXPOINTS=5000. This cutoff is ignored if you specify MAXPOINTS=NONE.

ONLY

suppresses the default quantile fit plot. Only plots specifically requested are displayed.

You can specify more than one plot request within the parentheses after PLOTS=. For a single plot request, you can omit the parentheses. The following plot requests are available.

ALL

creates all appropriate plots.

DDPLOT<(LABEL=ALL | LEVERAGE | NONE | OUTLIER)>

creates a plot of robust distance against Mahalanobis distance. See the section "Leverage Point and Outlier Detection" on page 6302 for details about robust distance. The LABEL= option specifies how the points on this plot are to be labeled, as summarized by the following table.

Table 75.4 Options for Label

Value of LABEL=	Label Method
ALL	Label all points
LEVERAGE	Label leverage points
NONE	No labels
OUTLIERS	Label outliers

By default, the QUANTREG procedure labels both outliers and leverage points.

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

FITPLOT<(NOLIMITS | SHOWLIMITS | NODATA)>

creates a plot of fitted conditional quantiles against the single continuous variable that is specified in the model. This plot is produced only when the response is modeled as a function of a single continuous variable. Multiple lines or curves are drawn on this plot if you specify several quantiles with the QUANTILE= option in the MODEL statement. By default, confidence limits are added to the plot when a single quantile is requested, and the confidence limits are not shown on the plot when multiple quantiles are requested. The NOLIMITS option suppresses these limits. The SHOWLIMITS option adds these limits when multiple quantiles are requested. The NODATA option suppresses the observed data, which are superimposed on the plot by default.

HISTOGRAM

creates a histogram for the standardized residuals based on the quantile regression estimates. The histogram is superimposed with a normal density curve and a kernel density curve.

NONE

suppresses all plots.

QQPLOT

creates the normal quantile-quantile plot for the standardized residuals based on the quantile regression estimates.

RDPLOT<(LABEL=ALL | LEVERAGE | NONE | OUTLIER)>

creates the plot of standardized residual against robust distance. See the section "Leverage Point and Outlier Detection" on page 6302 for details about robust distance. The LABEL= option specifies a label method for points on this plot. These label methods are described in Table 75.4.

By default, the QUANTREG procedure labels both outliers and leverage points.

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

PP

requests preprocessing to speed up the interior point algorithm or the smoothing algorithm. The preprocessing uses a subsampling algorithm to reduce the original problem to a smaller one iteratively. It assumes that the data set is evenly distributed. Preprocessing should be used only for very large data sets, such as data sets with more than 100,000 observations. See Portnoy and Koenker (1997) for details.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC QUANTREG to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the QUANTREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / **TRUNCATE** > **;**

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC QUANTREG statement. You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE
specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

EFFECT Statement

EFFECT *name = spline(variables < / options >)* **;**

The EFFECT statement names a constructed effect that you can use to specify terms in the MODEL statement. Each constructed effect corresponds to a collection of columns that are referred to using the name you supply. You can specify multiple EFFECT statements, and all EFFECT statements must precede the MODEL statement.

After the keyword EFFECT, the name of the effect is specified. This name must appear in only one EFFECT statement and must not be the name of a variable in the input data set. After an equal sign, the *effect-type* is specified followed by the list of variables used in defining the effect within parentheses. In SAS 9.2, the QUANTREG procedure supports only spline effects. You can also specify options pertaining to the effect definition after a slash following the variable list. The SPLIT option is always turned on for the QUANTREG procedure. For more details about the syntax with spline effects, see the section "EFFECT Statement" on page 406 of Chapter 19, "Shared Concepts and Topics."

The QUANTREG procedure supports the regression spline effect. A spline effect expands variables into spline bases whose form depends on the options that you specify. Design matrix columns are generated separately for each of the numeric variables specified, and these columns are collectively referred to by the name that you specify. By default the spline basis generated for each variable is a cubic B-spline basis with three equally spaced knots positioned between the minimum and maximum values of that variable. You can find more details about regression splines and spline bases in the section "EFFECT Statement" on page 406 of Chapter 19, "Shared Concepts and Topics."

ID Statement

ID *variables* **;**

When the diagnostics table is requested with the DIAGNOSTICS option in the MODEL statement, the variables listed in the ID statement are displayed in addition to the observation number. These values are useful for identifying observations. If the ID statement is omitted, only the observation number is displayed.

MODEL Statement

< label: > MODEL *response* = < *effects* > < / *options* > **;**

Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure (Chapter 41, "The GLM Procedure.") Classification variables in the MODEL statement must be specified in the CLASS statement.

The optional *label*, which must be a valid SAS name, is used to label output from the matching MODEL statement.

Options

You can specify the following options for the model fit.

CORRB
produces the estimated correlation matrix of the parameter estimates. When the resampling method is used to compute the confidence intervals, the QUANTREG procedure computes the bootstrap correlation. When the sparsity method is used to compute the confidence intervals, the procedure computes the asymptotic correlation based on an estimator of the sparsity function. The rank method for confidence intervals does not provide a correlation estimate.

COVB
produces the estimated covariance matrix of the parameter estimates. When the resampling method is used to compute the confidence intervals, the QUANTREG procedure computes the bootstrap covariance. When the sparsity method is used to compute the confidence intervals, the procedure computes the asymptotic covariance based on an estimator of the sparsity function. The rank method for confidence intervals does not provide a covariance estimate.

CUTOFF=*value*
specifies the multiplier of the cutoff value for outlier detection. The default *value* is 3.

DIAGNOSTICS< (ALL) >
requests the outlier diagnostics. By default, only observations identified as outliers or leverage points are displayed. To request that all observations be displayed, specify the ALL option.

ITPRINT
displays the iteration history of the interior point algorithm or the smoothing algorithm.

LEVERAGE< (CUTOFF=*value* | **CUTOFFALPHA=***value* | **H=***n***) >**
requests an analysis of leverage points for the continuous covariates. The results are added to the diagnostics table, which you can request with the DIAGNOSTICS option in the MODEL statement. You can specify the cutoff value for leverage-point detection with the CUTOFF= option. The default cutoff value is $\sqrt{\chi^2_{p;1-\alpha}}$, where α can be specified with the CUTOFFALPHA= option. By default, $\alpha = 0.025$. You can use the H= option to specify the number of points to be minimized for the MCD algorithm used for the leverage-point analysis. By default, H=$[(3n+p+1)/4]$, where n is the number of observations and p is the number of independent variables. The LEVERAGE option is ignored if the model includes classification variables as covariates.

NODIAG
suppresses the computation for outlier diagnostics. If you specify the NODIAG option, the diagnostics summary table will not be provided.

NOINT
specifies no intercept regression.

NOSUMMARY
suppresses the computation for summary statistics. If you specify the NOSUMMARY option, the summary statistics table will not be provided.

PLOT=*plot-option*

PLOTS=(*plot-options***)**
You can use the PLOTS= option in the MODEL statement together with ODS Graphics to request the quantile process plot in addition to all plots available with the PLOT= option in the PROC statement. The plot options in the PROC statement overwrite the plot options in the MODEL statement if you specify the same options in both statements.

You can specify the following plot option only in the MODEL statement:

QUANTPLOT<(EFFECTS) </ <NOLIMITS> <EXTENDCI> <UNPACK> <OLS> > >
plots the regression quantile process. The estimated coefficient of each specified covariate effect is plotted as a function of the quantile. If you do not specify a covariate effect, quantile processes are plotted for all covariate effects in the MODEL statement. You can use the NOLIMITS option to suppress confidence bands for the quantile processes. By default, confidence bands are plotted, and process plots are displayed in panels, each of which can hold up to four plots. By default, the confidence limits are plotted for quantiles in the range between 0.05 and 0.95. You can use the EXTENDCI option to plot the confidence limits even for quantiles outside this range. You can use the UNPACK option to create individual process plots. For an individual process plot, you can superimpose the ordinary least squares estimate and its confidence limits by specifying the OLS option. The confidence level of the ordinary least squares estimate is specified with the ALPHA= option in the PROC statement.

Again, ODS Graphics must be enabled before requesting plots.

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

QUANTILE=*number-list* | **PROCESS**
specifies the quantile levels for the quantile regression. You can specify any number of quantile levels in (0, 1). You can also compute the entire quantile process by specifying the PROCESS option. Only the simplex algorithm is available for computing the quantile process.

If you do not specify the QUANTILE= option, the QUANTREG procedure fits a median regression, which corresponds to QUANTILE=0.5.

SCALE=*number*
specifies the scale value used to compute the standardized residuals. By default, the scale is computed as the corrected median of absolute residuals. See the section "Leverage Point and Outlier Detection" on page 6302 for details.

SEED=*number*

specifies the seed for the random number generator used to compute the MCMB confidence intervals. This seed is also used to randomly select the subgroups for preprocessing when you specify the PP option in the PROC statement. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock.

By default or if you specify zero, the QUANTREG procedure generates a seed between one and one billion.

SINGULAR=*value*

sets the tolerance for testing singularity of the information matrix and the crossproducts matrix for the initial least squares estimates. Roughly, the test requires that a pivot be at least this value times the original diagonal value. By default, SINGULAR=1E−12.

OUTPUT Statement

OUTPUT < *OUT=SAS-data-set* > *keyword=name* < *. . . keyword=name* > < */ COLUMNWISE* > **;**

The OUTPUT statement creates a SAS data set containing statistics calculated after fitting models for all specified quantiles with the QUANTILE= option in the MODEL statement. At least one specification of the form *keyword=name* is required.

All variables in the original data set are included in the new data set, along with the variables created as options to the OUTPUT statement. These new variables contain fitted values and estimated quantiles. If you want to create a permanent SAS data set, you must specify a two-level name (refer to *SAS Language Reference: Concepts* for more information about permanent SAS data sets).

If you specify multiple quantiles in the MODEL statement, the COLUMNWISE option arranges the created OUTPUT data set in column-wise form. This arrangement repeats the input data for each quantile. By default, the OUTPUT data set is created in row-wise form. For each appropriate keyword specified in the OUTPUT statement, one variable for each specified quantile is generated. These variables appear in the sorted order of the specified quantiles.

The following specifications can appear in the OUTPUT statement:

OUT=*SAS-data-set* specifies the new data set. By default, the procedure uses the DATA*n* convention to name the new data set.

keyword=name specifies the statistics to include in the output data set and gives names to the new variables. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

LEVERAGE specifies a variable to indicate leverage points. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the MODEL statement. See the section "Leverage Point and Outlier Detection" on page 6302 for how to define LEVERAGE.

MAHADIST | MD specifies a variable to contain the Mahalanobis distance. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the MODEL statement.

OUTLIER specifies a variable to indicate outliers. See the section "Leverage Point and Outlier Detection" on page 6302 for how to define OUTLIER.

PREDICTED | P specifies a variable to contain the estimated response.

QUANTILE | Q specifies a variable to contain the quantile for which the quantile regression is fitted. If you specify the COLUMNWISE option, this variable is created by default. If multiple quantiles are specified in the MODEL statement and the COLUMNWISE option is not specified, this variable is not created.

RESIDUAL | RES specifies a variable to contain the residuals (unstandardized)

$$y_i - \mathbf{x}_i^T \hat{\beta}$$

ROBDIST | RD specifies a variable to contain the robust MCD distance. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the MODEL statement.

SPLINE | SP specifies a variable to contain the estimated spline effect, which includes all spline effects in the model and their interactions.

SRESIDUAL | SR specifies a variable to contain the standardized residuals

$$\frac{y_i - \mathbf{x}_i^T \hat{\beta}}{\hat{\sigma}}$$

See the section "Leverage Point and Outlier Detection" on page 6302 for how to compute σ.

STDP specifies a variable to contain the estimates of the standard errors of the estimated response.

PERFORMANCE Statement

The PERFORMANCE statement is used to change default options that affect the performance of PROC QUANTREG and to request tables that show the performance options in effect and timing details.

PERFORMANCE < *options* > **;**

The following options are available:

CPUCOUNT= *1-1024*

CPUCOUNT=*ACTUAL*

specifies the number of processors to use in the computation of the interior point algorithm. CPUCOUNT=ACTUAL sets CPUCOUNT to be the number of physical processors available. Note that this can be less than the physical number of CPUs if the SAS process has been restricted by system administration tools. Setting CPUCOUNT= to a number greater than the actual number of available

CPUs might result in reduced performance. This option overrides the SAS system option CPUCOUNT=. If CPUCOUNT=1, then NOTHREADS is in effect, and PROC QUANTREG uses singly threaded code.

DETAILS
requests the "PerfSettings" table that shows the performance settings in effect and the "Timing" table that provides a broad timing breakdown of the PROC QUANTREG step.

THREADS
enables multithreaded computation for the interior point algorithm. This option overrides the SAS system option THREADS | NOTHREADS. If you do not specify the ALGORITHM=INTERIOR option, then PROC QUANTREG ignores this option and uses singly threaded code.

NOTHREADS
disables multithreaded computation for the interior point algorithm. This option overrides the SAS system option THREADS | NOTHREADS.

TEST Statement

< *label:* **>** **TEST** *effects* **<** */ options* **>** **;**

In quantile regression analysis, you might be interested in testing whether a covariate effect is statistically signficant for a given quantile. In other situations, you might be interested in testing whether the coeficients of a covariate are the same across a set of quantiles. You can use the TEST Statement to perform these tests.

Testing Effects of Covariates

You can use TEST statement to obtain a test for the canonical linear hypothesis concerning the parameters of the tested effects

$$\beta_j = 0, \quad j = i_1, \ldots, i_q$$

where q is the total number of parameters of the tested effects. The tested *effects* can be any set of effects in the MODEL statement. Three types of tests (Wald, likelihood ratio, and rank methods) are available for testing effects of covariates by the following *options* in the TEST statement after a slash (/):.

WALD
requests Wald tests.

LR
requests likelihood ratio tests.

RANKSCORE < (NORMAL | WILCOXON | SIGN | TAU) >
requests rank tests. The NORMAL, WILCOXON, and SIGN functions are implemented and suitable for iid error models, and the TAU score function is implemented and appropriate for non-iid error models. By default, the TAU score function is used. See Koenker (2005) for more information about the score functions.

Testing for Heteroscedasticity

You can test whether there is any difference among the estimated coefficients across quantiles if several quantiles are specified in the MODEL statement. The test for such heteroscedasticity can be requested by the option QINTERACT after a slash (/) in the TEST statement. See Example 75.5.

You can submit multiple TEST statements, provided that they appear after the MODEL statement. The optional *label*, which must be a valid SAS name, is used to identify output from the corresponding TEST statement. See the section "Linear Test" on page 6300 for details about these tests.

WEIGHT Statement

WEIGHT *variable* **;**

The WEIGHT statement specifies a weight variable in the input data set.

To request weighted quantile regression, place the weights in a variable and specify the name in the WEIGHT statement. The values of the WEIGHT variable can be nonintegral and are not truncated. Observations with nonpositive or missing values for the weight variable do not contribute to the fit of the model. See the section "Details: QUANTREG Procedure" on page 6288 for more information about weighted quantile regression.

Details: QUANTREG Procedure

Quantile Regression as an Optimization Problem

The model for linear quantile regression is

$$y = A'\beta + \epsilon$$

where $y = (y_1, \ldots, y_n)'$ is the $(n \times 1)$ vector of responses, $A' = (x_1, \ldots, x_n)'$ is the $(n \times p)$ regressor matrix, $\beta = (\beta_1, \ldots, \beta_p)'$ is the $(p \times 1)$ vector of unknown parameters, and $\epsilon = (\epsilon_1, \ldots, \epsilon_n)'$ is the $(n \times 1)$ vector of unknown errors.

L_1 regression, also known as median regression, is a natural extension of the sample median when the response is conditioned on the covariates. In L_1 regression, the least absolute residuals estimate $\hat{\beta}_{LAR}$, referred to as the L_1*-norm estimate*, is obtained as the solution of the minimization problem

$$\min_{\beta \in \mathbf{R}^p} \sum_{i=1}^{n} |y_i - x_i'\beta|$$

More generally, for quantile regression Koenker and Bassett (1978) defined the τth *regression quantile*, $0 < \tau < 1$, as any solution to the minimization problem

$$\min_{\beta \in \mathbf{R}^p} [\sum_{i \in \{i: y_i \geq x_i' \beta\}} \tau |y_i - x_i' \beta| + \sum_{i \in \{i: y_i < x_i' \beta\}} (1-\tau) |y_i - x_i' \beta|]$$

The solution is denoted as $\hat{\beta}(\tau)$, and the L_1-norm estimate corresponds to $\hat{\beta}(1/2)$. The τth regression quantile is an extension of the τth sample quantile $\hat{\xi}(\tau)$, which can be formulated as the solution of

$$\min_{\xi \in \mathbf{R}} \left[\sum_{i \in \{i: y_i \geq \xi\}} \tau |y_i - \xi| + \sum_{i \in \{i: y_i < \xi\}} (1-\tau) |y_i - \xi| \right]$$

If you specify weights $w_i, i = 1, \ldots, n$, with the WEIGHT statement, weighted quantile regression is carried out by solving

$$\min_{\beta_w \in \mathbf{R}^p} [\sum_{i \in \{i: y_i \geq x_i' \beta_w\}} w_i \tau |y_i - x_i' \beta_w| + \sum_{i \in \{i: y_i < x_i' \beta_w\}} w_i (1-\tau) |y_i - x_i' \beta_w|]$$

Weighted regression quantiles β_w can be used for L-estimation; refer to Koenker and Zhao (1994).

Optimization Algorithms

The optimization problem for median regression has been formulated and solved as a linear programming (LP) problem since the 1950s. Variations of the simplex algorithm, especially the method of Barrodale and Roberts (1973), have been widely used to solve this problem. The simplex algorithm is computationally demanding in large statistical applications, and in theory the number of iterations can increase exponentially with the sample size. This algorithm is often useful with data containing no more than tens of thousands of observations.

Several alternatives have been developed to handle L_1 regression for larger data sets. The interior point approach of Karmarkar (1984) solves a sequence of quadratic problems in which the relevant interior of the constraint set is approximated by an ellipsoid. The worst-case performance of the interior point algorithm has been proved to be better than that of the simplex algorithm. More important, experience has shown that the interior point algorithm is advantageous for larger problems.

Like L_1 regression, general quantile regression fits nicely into the standard primal-dual formulations of linear programming.

In addition to the interior point method, various heuristic approaches are available for computing L_1-type solutions. Among these, the finite smoothing algorithm of Madsen and Nielsen (1993) is the most useful. It approximates the L_1-type objective function with a smoothing function, so that the Newton-Raphson algorithm can be used iteratively to obtain a solution after a finite number of iterations. The smoothing algorithm extends naturally to general quantile regression.

The QUANTREG procedure implements the simplex, interior point, and smoothing algorithms. The remainder of this section describes these algorithms in more detail.

Simplex Algorithm

Let $\mu = [y - A'\beta]_+$, $\nu = [A'\beta - y]_+$, $\phi = [\beta]_+$, and $\varphi = [-\beta]_+$, where $[z]_+$ is the nonnegative part of z.

Let $D_{LAR}(\beta) = \sum_{i=1}^{n} |y_i - x_i'\beta|$. For the L_1 problem, the simplex approach solves $\min_\beta D_{LAR}(\beta)$ by reformulating it as the constrained minimization problem

$$\min_{\beta}\{e'\mu + e'\nu | y = A'\beta + \mu - \nu, \{\mu, \nu\} \in \mathbf{R}_+^n\}$$

where e denotes an $(n \times 1)$ vector of ones.

Let $B = [A' \ -A' \ I \ -I]$, $\theta = (\phi' \ \varphi' \ \mu' \ \nu')'$, and $d = (\mathbf{0}' \ \mathbf{0}' \ e' \ e')'$, where $\mathbf{0}' = (0\,0 \ \ldots \ 0)_p$. The reformulation presents a standard LP problem:

$$\begin{array}{ll} (P) & \min_{\theta} d'\theta \\ \text{subject to} & B\theta = y \\ & \theta \geq 0 \end{array}$$

This problem has the dual formulation

$$\begin{array}{ll} (D) & \max_{z} y'z \\ \text{subject to} & B'z \leq d \end{array}$$

which can be simplified as

$$\max_{z} y'z; \ \text{ subject to } Az = 0, z \in [-1, 1]^n$$

By setting $\eta = \frac{1}{2}z + \frac{1}{2}e, b = \frac{1}{2}Ae$, the problem becomes

$$\max_{\eta} y'\eta; \ \text{ subject to } A\eta = b, \eta \in [0, 1]^n$$

For quantile regression, the minimization problem is $\min_\beta \sum \rho_\tau(y_i - x_i'\beta)$, and a similar set of steps leads to the dual formulation

$$\max_{z} y'z; \ \text{ subject to } Az = (1 - \tau)Ae, z \in [0, 1]^n$$

The QUANTREG procedure solves this LP problem by using the simplex algorithm of Barrodale and Roberts (1973). This algorithm solves the primary LP problem (P) by two stages, which exploit the special structure of the coefficient matrix B. The first stage picks the columns in A' or $-A'$ as pivotal columns. The second stage interchanges the columns in I or $-I$ as basis or nonbasis columns, respectively. The algorithm obtains an optimal solution by executing these two stages interactively. Moreover, because of the special structure of B, only the main data matrix A is stored in the current memory.

Although this special version of the simplex algorithm was introduced for median regression, it extends naturally to quantile regression for any given quantile and even to the entire quantile process (Koenker and d'Orey 1994). It greatly reduces the computing time required by the general simplex algorithm, and it is suitable for data sets with fewer than 5,000 observations and 50 variables.

Interior Point Algorithm

There are many variations of interior point algorithms. The QUANTREG procedure uses the primal-dual predictor-corrector algorithm implemented by Lustig, Marsden, and Shanno (1992). The text by Roos, Terlaky, and Vial (1997) provides more information about this particular algorithm. The following brief introduction of this algorithm uses the notation in the first reference.

To be consistent with the conventional LP setting, let $c = -y$, $b = (1-\tau)Ae$, and let u be the general upper bound. The linear program to be solved is

$$\begin{aligned} & min\{c'z\} \\ \text{subject to} \quad & Az = b \\ & 0 \le z \le u \end{aligned}$$

To simplify the computation, this is treated as the *primal* problem. The problem has n variables. The index i denotes a variable number, and k denotes an iteration number. If k is used as a subscript or superscript, it denotes "of iteration k."

Let v be the primal slack so that $z + v = u$. Associate dual variables w with these constraints. The interior point algorithm solves the system of equations to satisfy the Karush-Kuhn-Tucker (KKT) conditions for optimality:

$$\begin{aligned} & Az = b \\ & z + v = u \\ & A't + s - w = c \\ & ZSe = 0 \\ & VWe = 0 \\ & z, s, v, w \ge 0 \\ \text{where} \quad & W = diag(w) \text{ (that is, } W_{i,j} = w_i \text{ if } i = j,\ W_{i,j} = 0 \text{ otherwise)} \\ & V = diag(v), Z = diag(z), S = diag(s) \end{aligned}$$

These are the conditions for feasibility, with the addition of *complementarity* conditions $ZSe = 0$ and $VWe = 0$. $c'z = b't - u'w$ must occur at the optimum. Complementarity forces the optimal objectives of the primal and dual to be equal, $c'z_{opt} = b't_{opt} - u'w_{opt}$, as

$$0 = v'_{opt}w_{opt} = (u - z_{opt})'w_{opt} = u'w_{opt} - z'_{opt}w_{opt}$$

$$\begin{aligned} 0 = z'_{opt}s_{opt} = s'_{opt}z_{opt} = (c - A't_{opt} + w_{opt})'z_{opt} = \\ c'z_{opt} - t'_{opt}(Az_{opt}) + w'_{opt}z_{opt} = c'z_{opt} - b't_{opt} + u'w_{opt} \end{aligned}$$

Therefore

$$0 = c'z_{opt} - b't_{opt} + u'w_{opt}$$

The *duality gap*, $c'z - b't + u'w$, is used to measure the convergence of the algorithm. You can specify a tolerance for this convergence criterion with the TOLERANCE= option in the PROC statement.

Before the optimum is reached, it is possible for a solution (z, t, s, v, w) to violate the KKT conditions in one of several ways:

- Primal bound constraints can be broken, $\delta_b = u - z - v \neq 0$.
- Primal constraints can be broken, $\delta_c = b - Az \neq 0$.
- Dual constraints can be broken, $\delta_d = c - A't - s + w \neq 0$.
- Complementarity conditions are unsatisfied, $z's \neq 0$ and $v'w \neq 0$.

The interior point algorithm works by using Newton's method to find a direction $(\Delta z^k, \Delta t^k, \Delta s^k, \Delta v^k, \Delta w^k)$ to move from the current solution $(z^k, t^k, s^k, v^k, w^k)$ toward a better solution:

$$(z^{k+1}, t^{k+1}, s^{k+1}, v^{k+1}, w^{k+1}) = (z^k, t^k, s^k, v^k, w^k) + \kappa(\Delta z^k, \Delta t^k, \Delta s^k, \Delta v^k, \Delta w^k)$$

κ is the *step length* and is assigned a value as large as possible, but not so large that a z_i^{k+1} or s_i^{k+1} is "too close" to zero. You can control the step length with the KAPPA= option in the PROC statement.

The QUANTREG procedure implements a predictor-corrector variant of the primal-dual interior point algorithm. First, Newton's method is used to find a direction $(\Delta z^k_{aff}, \Delta t^k_{aff}, \Delta s^k_{aff}, \Delta v^k_{aff}, \Delta w^k_{aff})$ in which to move. This is known as the *affine* step.

In iteration k, the *affine* step system that must be solved is

$$\begin{aligned}
&\Delta z_{aff} + \Delta v_{aff} = \delta_b \\
&A\Delta z_{aff} = \delta_c \\
&A'\Delta t_{aff} + \Delta s_{aff} - \Delta w_{aff} = \delta_d \\
&S\Delta z_{aff} + Z\Delta s_{aff} = -ZSe \\
&V\Delta w_{aff} + W\Delta z_{aff} = -VWe
\end{aligned}$$

Therefore, the computations involved in solving the affine step are

$$\begin{aligned}
&\Theta = SZ^{-1} + WV^{-1} \\
&\rho = \Theta^{-1}(\delta_d + (S - W)e - V^{-1}W\delta_b) \\
&\Delta t_{aff} = (A\Theta^{-1}A')^{-1}(\delta_c + A\rho) \\
&\Delta z_{aff} = \Theta^{-1}A'\Delta t_{aff} - \rho \\
&\Delta v_{aff} = \delta_b - \Delta z_{aff} \\
&\Delta w_{aff} = -We - V^{-1}W\Delta z_{aff} \\
&\Delta s_{aff} = -Se - Z^{-1}S\Delta z_{aff}
\end{aligned}$$

$$\begin{aligned}
&(z_{aff}, t_{aff}, s_{aff}, v_{aff}, w_{aff}) = (z, t, s, v, w) + \\
&\kappa(\Delta z_{aff}, \Delta t_{aff}, \Delta s_{aff}, \Delta v_{aff}, \Delta w_{aff})
\end{aligned}$$

where κ is the *step length* as before.

The success of the affine step is gauged by calculating the complementarity of $z's$ and $v'w$ at $(z^k_{aff}, t^k_{aff}, s^k_{aff}, v^k_{aff}, w^k_{aff})$ and comparing it with the complementarity at the starting point $(z^k, t^k, s^k, v^k, w^k)$. If the affine step was successful in reducing the complementarity by a substantial amount, the need for centering is not great, and a value close to zero is assigned to σ in a second linear system (see following), which is used to determine a centering vector. If, however, the affine step was unsuccessful, then centering is deemed beneficial, and a value close to 1.0 is assigned to σ. In other words, the value of σ is adaptively altered depending on progress made toward the optimum.

The following linear system is solved to determine a centering vector $(\Delta z_c, \Delta t_c, \Delta s_c, \Delta v_c, \Delta w_c)$ from $(z_{aff}, t_{aff}, s_{aff}, v_{aff}, w_{aff})$:

$$\begin{aligned}
&\Delta z_c + \Delta v_c = 0\\
&A\Delta z_c = 0\\
&A'\Delta t_c + \Delta s_c - \Delta w_c = 0\\
&S\Delta z_c + Z\Delta s_c = -Z_{aff}S_{aff}e + \sigma\mu e\\
&V\Delta w_c + W\Delta v_c = -V_{aff}W_{aff}e + \sigma\mu e
\end{aligned}$$

where

$$\begin{aligned}
&\zeta_{start} = z's + v'w, \text{ complementarity at the start of the iteration}\\
&\zeta_{aff} = z'_{aff}s_{aff} + v'_{aff}w_{aff}, \text{ the affine complementarity}\\
&\mu = \zeta_{aff}/2n, \text{ the average complementarity}\\
&\sigma = (\zeta_{aff}/\zeta_{start})^3
\end{aligned}$$

Therefore, the computations involved in solving the centering step are

$$\begin{aligned}
&\rho = \Theta^{-1}(\sigma\mu(Z^{-1} - V^{-1})e - Z^{-1}Z_{aff}S_{aff}e + V^{-1}V_{aff}W_{aff}e)\\
&\Delta t_c = (A\Theta^{-1}A')^{-1}A\rho\\
&\Delta z_c = \Theta^{-1}A'\Delta t_c - \rho\\
&\Delta v_c = -\Delta z_c\\
&\Delta w_c = \sigma\mu V^{-1}e - V^{-1}V_{aff}W_{aff}e - V^{-1}W_{aff}\Delta v_c\\
&\Delta s_c = \sigma\mu Z^{-1}e - Z^{-1}Z_{aff}S_{aff}e - Z^{-1}S_{aff}\Delta z_c
\end{aligned}$$

Then

$$\begin{aligned}
&(\Delta z, \Delta t, \Delta s, \Delta v, \Delta w) =\\
&(\Delta z_{aff}, \Delta t_{aff}, \Delta s_{aff}, \Delta v_{aff}, \Delta w_{aff}) +\\
&(\Delta z_c, \Delta t_c, \Delta s_c, \Delta v_c, \Delta w_c)
\end{aligned}$$

$$\begin{aligned}
&(z^{k+1}, t^{k+1}, s^{k+1}, v^{k+1}, w^{k+1}) =\\
&(z^k, t^k, s^k, v^k, w^k) +\\
&\kappa(\Delta z, \Delta t, \Delta s, \Delta v, \Delta w)
\end{aligned}$$

where, as before, κ is the *step length* assigned a value as large as possible, but not so large that a z_i^{k+1}, s_i^{k+1}, v_i^{k+1}, or w_i^{k+1} is "too close" to zero.

Although the predictor-corrector variant entails solving two linear systems instead of one, fewer iterations are usually required to reach the optimum. The additional overhead of the second linear system is small because the matrix $(A\Theta^{-1}A')$ has already been factorized in order to solve the first linear system.

You can specify the starting point with the INEST= option in the PROC statement. By default, the starting point is set to be the least squares estimate.

Smoothing Algorithm

To minimize the sum of the absolute residuals $D_{LAR}(\beta)$, the smoothing algorithm approximates the non-differentiable function D_{LAR} by the following smooth function, which is referred to as the Huber function:

$$D_\gamma(\beta) = \sum_{i=1}^{n} H_\gamma(r_i(\beta))$$

where

$$H_\gamma(t) = \begin{cases} t^2/(2\gamma) & \text{if } |t| \le \gamma \\ |t| - \gamma/2 & \text{if } |t| > \gamma \end{cases}$$

Here $r_i(\beta) = y_i - x_i'\beta$, and the *threshold* γ is a positive real number. The function D_γ is continuously differentiable and a minimizer β_γ of D_γ is close to a minimizer $\hat{\beta}_{LAR}$ of $D_{LAR}(\beta)$ when γ is close to zero.

The advantage of the smoothing algorithm as described in Madsen and Nielsen (1993) is that the L_1 solution $\hat{\beta}_{LAR}$ can be detected when $\gamma > 0$ is small. In other words, it is not necessary to let γ converge to zero in order to find a minimizer of $D_{LAR}(\beta)$. The algorithm terminates before going through the entire sequence of values of γ that are generated by the algorithm. Convergence is indicated by no change of the status of residuals $r_i(\beta)$ as γ goes through this sequence.

The smoothing algorithm extends naturally from L_1 regression to general quantile regression; refer to Chen (2007). The function

$$D_{\rho_\tau}(\beta) = \sum_{i=1}^{n} \rho_\tau(y_i - x_i'\beta)$$

can be approximated by the smooth function

$$D_{\gamma,\tau}(\beta) = \sum_{i=1}^{n} H_{\gamma,\tau}(r_i(\beta))$$

where

$$H_{\gamma,\tau}(t) = \begin{cases} t(\tau-1) - \frac{1}{2}(\tau-1)^2\gamma & \text{if } t \le (\tau-1)\gamma \\ \frac{t^2}{2\gamma} & \text{if } (\tau-1)\gamma \le t \le \tau\gamma \\ t\tau - \frac{1}{2}\tau^2\gamma & \text{if } t \ge \tau\gamma \end{cases}$$

The function $H_{\gamma,\tau}$ is determined by whether $r_i(\beta) \leq (\tau-1)\gamma$, $r_i(\beta) \geq \tau\gamma$, or $(\tau-1)\gamma \leq r_i(\beta) \leq \tau\gamma$. These inequalities divide $\mathbf{R}^p$ into subregions separated by the parallel hyperplanes $r_i(\beta) = (\tau-1)\gamma$ and $r_i(\beta) = \tau\gamma$. The set of all such hyperplanes is denoted by $B_{\gamma,\tau}$:

$$B_{\gamma,\tau} = \{\beta \in \mathbf{R}^p | \exists i : r_i(\beta) = (\tau-1)\gamma \text{ or } r_i(\beta) = \tau\gamma\}$$

Define the sign vector $s_\gamma(\beta) = (s_1(\beta), \ldots, s_n(\beta))'$ as

$$s_i = s_i(\beta) = \begin{cases} -1 & \text{if } r_i(\beta) \leq (\tau-1)\gamma \\ 0 & \text{if } (\tau-1)\gamma \leq r_i(\beta) \leq \tau\gamma \\ 1 & \text{if } r_i(\beta) \geq \tau\gamma \end{cases}$$

and introduce

$$w_i = w_i(\beta) = 1 - s_i^2(\beta)$$

Therefore,

$$H_{\gamma,\tau}(r_i(\beta)) = \frac{1}{2\gamma} w_i r_i^2(\beta)$$
$$+ s_i[\frac{1}{2} r_i(\beta) + \frac{1}{4}(1-2\tau)\gamma + s_i(r_i(\beta)(\tau - \frac{1}{2}) - \frac{1}{4}(1-2\tau+2\tau^2)\gamma)]$$

yielding

$$D_{\gamma,\tau}(\beta) = \frac{1}{2\gamma} r' W_{\gamma,\tau} r + v'(s) r + c(s)$$

where $W_{\gamma,\tau}$ is the diagonal $n \times n$ matrix with diagonal elements $w_i(\beta)$, $v'(s) = (s_1((2\tau-1)s_1 + 1)/2, \ldots, s_n((2\tau-1)s_n+1)/2)$, $c(s) = \sum[\frac{1}{4}(1-2\tau)\gamma s_i - \frac{1}{4}s_i^2(1-2\tau+2\tau^2)\gamma]$, and $r(\beta) = (r_1(\beta), \ldots, r_n(\beta))'$.

The gradient of $D_{\gamma,\tau}$ is given by

$$D^{(1)}_{\gamma,\tau}(\beta) = -A[\frac{1}{\gamma} W_{\gamma,\tau}(\beta) r(\beta) + v(s)]$$

and for $\beta \in \mathbf{R}^p \backslash B_{\gamma,\tau}$ the Hessian exists and is given by

$$D^{(2)}_{\gamma,\tau}(\beta) = \frac{1}{\gamma} A W_{\gamma,\tau}(\beta) A'$$

The gradient is a continuous function in $\mathbf{R}^p$, whereas the Hessian is piecewise constant.

Following Madsen and Nielsen (1993), the vector s is referred to as a *γ-feasible sign vector* if there exists $\beta \in \mathbf{R}^p \backslash B_{\gamma,\tau}$ with $s_\gamma(\beta) = s$. If s is *γ-feasible*, then Q_s is defined as the quadratic function $Q_s(\alpha)$ that is derived from $D_{\gamma,\tau}(\beta)$ by substituting s for s_γ. Thus, for any β with $s_\gamma = s$,

$$Q_s(\alpha) = \frac{1}{2}(\alpha-\beta)' D^{(2)}_{\gamma,\tau}(\beta)(\alpha-\beta) + D^{(1)}_{\gamma,\tau}(\beta)(\alpha-\beta) + D_{\gamma,\tau}(\beta)$$

In the domain $C_s = \{\alpha | s_\gamma(\alpha) = s\}$

$$D_{\gamma,\tau}(\alpha) = Q_s(\alpha)$$

For each $\gamma > 0$ and $\theta \in \mathbf{R}^p$, there can be one or several corresponding quadratics Q_s. If $\theta \notin B_{\gamma,\tau}$ then Q_s is characterized by θ and γ, but for $\theta \in B_{\gamma,\tau}$ the quadratic is not unique. Therefore, a *reference*

$$(\gamma, \theta, s)$$

determines the quadratic.

Again following Madsen and Nielsen (1993), let

(γ, θ, s) be a *feasible reference* if s is a γ*-feasible sign vector* with $\theta \in C_s$, and

(γ, θ, s) be a *solution reference* if it is feasible and θ minimizes $D_{\gamma,\tau}$.

The smoothing algorithm for minimizing D_{ρ_τ} is based on minimizing $D_{\gamma,\tau}$ for a set of decreasing γ. For each new value of γ, information from the previous solution is used. Finally, when γ is small enough, a solution can be found by the modified Newton-Raphson algorithm as stated by Madsen and Nielsen (1993):

find an initial solution reference $(\gamma, \beta_\gamma, s)$

repeat

decrease γ

find a solution reference $(\gamma, \beta_\gamma, s)$

until $\gamma = 0$

β_0 is the solution.

By default, the initial solution reference is found by letting β_γ be the least squares solution. Alternatively, you can specify the initial solution reference with the INEST= option in the PROC statement. Then γ and s are chosen according to these initial values.

There are several approaches for determining a decreasing sequence of values of γ. The QUANTREG procedure uses a strategy by Madsen and Nielsen (1993). The computation involved is not significant comparing with the Newton-Raphson step. You can control the ratio of consecutive decreasing values of γ with the RRATIO= suboption of the ALGORITHM= option in the PROC statement. By default,

$$\text{RRATIO} = \begin{cases} 0.1 & \text{if } n \geq 10000 \text{ and } p \leq 20 \\ 0.9 & \text{if } \frac{p}{n} \geq 0.1 \text{ or } \{n \leq 5000 \text{ and } p \geq 300\} \\ 0.5 & \text{otherwise} \end{cases}$$

For the L_1 and quantile regression, it turns out that the smoothing algorithm is very efficient and competitive, especially for a *fat* data set—namely, when $\frac{p}{n} > 0.05$ and AA' is dense. Refer to Chen (2007) for a complete smoothing algorithm and details.

Confidence Interval

The QUANTREG procedure provides three methods to compute confidence intervals for the regression quantile parameter $\beta(\tau)$: sparsity, rank, and resampling. The sparsity method is the most direct and the

fastest, but it involves estimation of the sparsity function, which is not robust for data that are not independently and identically distributed. To deal with this problem, the QUANTREG procedure computes a Huber sandwich estimate by using a local estimate of the sparsity function. The rank method, which computes confidence intervals by inverting the rank score test, does not suffer from this problem, but it uses the simplex algorithm and is computationally expensive with large data sets. The resampling method, which uses the bootstrap approach, addresses these problems, but at a computation cost.

Based on these properties, the QUANTREG uses a combination of the resampling and rank methods as the default. For data sets with more than either 5,000 observations or 20 variables, the QUANTREG procedure uses the MCMB resampling method; otherwise it uses the rank method. You can request a particular method by using the CI= option in the PROC statement.

Sparsity

Consider the linear model

$$y_i = x_i'\beta + \epsilon_i$$

and assume that $\{\epsilon_i\}$, $i = 1, \ldots, n$, are iid with a distribution F and a density $f = F'$, where $f(F^{-1}(\tau)) > 0$ in a neighborhood of τ. Under some mild conditions

$$\sqrt{n}(\hat{\beta}(\tau) - \beta(\tau)) \rightarrow N(0, \omega^2(\tau, F)\Omega^{-1})$$

where $\omega^2(\tau, F) = \tau(1-\tau)/f^2(F^{-1}(\tau))$ and $\Omega = \lim_{n\rightarrow\infty} n^{-1}\sum x_i x_i'$. Refer to Koenker and Bassett (1982).

This asymptotic distribution for the regression quantile $\hat{\beta}(\tau)$ can be used to construct confidence intervals. However, the reciprocal of the density function

$$s(\tau) = [f(F^{-1}(\tau))]^{-1}$$

which is called the *sparsity function*, must first be estimated.

Since

$$s(t) = \frac{d}{dt}F^{-1}(t)$$

$s(t)$ can be estimated by the difference quotient of the empirical quantile function—that is,

$$\hat{s}_n(t) = [\hat{F}_n^{-1}(t + h_n) - \hat{F}_n^{-1}(t - h_n)]/2h_n$$

where $\hat{F}_n$ is an estimate of F^{-1} and h_n is a bandwidth that tends to zero as $n \rightarrow \infty$.

The QUANTREG procedure provides two bandwidth methods. The Bofinger bandwidth

$$h_n = n^{-1/5}\left(\frac{4.5s^2(t)}{(s^{(2)}(t))^2}\right)^{1/5}$$

is an optimizer of mean squared error for standard density estimation, and the Hall-Sheather bandwidth

$$h_n = n^{-1/3}z_\alpha^{2/3}\left(\frac{1.5s(t)}{s^{(2)}(t)}\right)^{1/3}$$

is based on Edgeworth expansions for studentized quantiles, where $s^{(2)}(t)$ is the second derivative of $s(t)$ and z_α satisfies $\Phi(z_\alpha) = 1 - \alpha/2$ for the construction of $1 - \alpha$ confidence intervals. The quantity

$$\frac{s(t)}{s^{(2)}(t)} = \frac{f^2}{2(f^{(1)}/f)^2 + [(f^{(1)}/f)^2 - f^{(2)}/f]}$$

is not sensitive to f and can be estimated by assuming f is Gaussian.

$\hat{F}^{-1}$ can be estimated by the empirical quantile function of the residuals from the quantile regression fit,

$$\hat{F}^{-1}(t) = r_{(i)}, \quad \text{for } t \in [(i-1)/n, i/n),$$

or the empirical quantile function of regression proposed by Bassett and Koenker (1982),

$$\hat{F}^{-1}(t) = \overline{x}'\hat{\beta}(t)$$

The QUANTREG procedure interpolates the first empirical quantile function and gets the piecewise linear version

$$\hat{F}^{-1}(t) = \begin{cases} r_{(1)} & \text{if } t \in [0, 1/2n) \\ \lambda r_{(i+1)} + (1-\lambda) r_{(i)} & \text{if } t \in [(2j-1)/2n, (2i+1)/2n) \\ r_{(n)} & \text{if } t \in [(2n-1), 1] \end{cases}$$

$\hat{F}^{-1}$ is set to a constant if $t \pm h_n$ falls outside $[0, 1]$.

This estimator of the sparsity function is sensitive to the iid assumption. Alternately, Koenker and Machado (1999) considered the non-iid case. By assuming local linearity of the conditional quantile function $Q(\tau|x)$ in x, they proposed a local estimator of the density function by using the difference quotient. A Huber sandwich estimate of the covariance and standard error is computed and used to construct the confidence intervals. One difficulty with this method is the selection of the bandwidth when using the difference quotient. With a small sample size, either the Bofinger or the Hall-Sheather bandwidth tends to be too large to assure local linearity of the conditional quantile function. The QUANTREG procedure uses a heuristic bandwidth selection in these cases.

By default, the QUANTREG procedure computes non-iid confidence intervals. You can request iid confidence intervals with the IID option in the PROC statement.

Inversion of Rank Tests

The classical theory of rank tests can be extended to test the hypothesis H_0: $\beta_2 = \eta$ in the linear regression model $y = X_1\beta_1 + X_2\beta_2 + \epsilon$. Here $(X_1, X_2) = A'$. See Gutenbrunner and Jureckova (1992) for more details. By inverting this test, confidence intervals can be computed for the regression quantiles that correspond to β_2.

The rank score function $\hat{a}_n(t) = (\hat{a}_{n1}(t), \ldots, \hat{a}_{nn}(t))$ can be obtained by solving the dual problem

$$\max_a \{(y - X_2\eta)'a | X_1'a = (1-t)X_1'e,\ a \in [0,1]^n\}$$

For a fixed quantile τ, integrating $\hat{a}_{ni}(t)$ with respect to the τ-quantile score function

$$\varphi_\tau(t) = \tau - I(t < \tau)$$

yields the τ-quantile scores

$$\hat{b}_{ni} = -\int_0^1 \varphi_\tau(t)\, d\hat{a}_{ni}(t) = \hat{a}_{ni}(\tau) - (1-\tau)$$

Under the null hypothesis H_0: $\beta_2 = \eta$

$$S_n(\eta) = n^{-1/2} X_2' \hat{b}_n(\eta) \to N(0, \tau(1-\tau)\Omega_n)$$

for large n, where $\Omega_n = n^{-1} X_2'(I - X_1(X_1'X_1)^{-1}X_1')X_2$.

Let

$$T_n(\eta) = \frac{1}{\sqrt{\tau(1-\tau)}} S_n(\eta)\Omega_n^{-1/2}$$

Then $T_n(\hat{\beta}_2(\tau)) = 0$ from the constraint $A\hat{a} = (1-\tau)Ae$ in the full model. In order to obtain confidence intervals for β_2, a critical value can be specified for T_n. The dual vector $\hat{a}_n(\eta)$ is a piecewise constant in η, and η can be altered without compromising the optimality of $\hat{a}_n(\eta)$ as long as the signs of the residuals in the primal quantile regression problem do not change. When η gets to such a boundary, the solution does change, but can be restored by taking one simplex pivot. The process can continue in this way until $T_n(\eta)$ exceeds the specified critical value. Since $T_n(\eta)$ is piecewise constant, interpolation can be used to obtain the desired level of confidence interval; see Koenker and d'Orey (1994).

Resampling

The bootstrap can be implemented to compute confidence intervals for regression quantile estimates. As in other regression applications, both the residual bootstrap and the xy-pair bootstrap can be used. The former assumes iid random errors and resamples from the residuals, while the later resamples xy pairs and accommodates some forms of heteroscedasticity. Koenker (1994) considered a more interesting resampling mechanism, resampling directly from the full regression quantile process, which he called the Heqf bootstrap.

In contrast with these bootstrap methods, Parzen, Wei, and Ying (1994) observed that

$$S(\beta) = n^{-1/2} \sum_{i=1}^{n} x_i(\tau - I(y_i \le x_i'\beta))$$

which is the estimating equation for the τth regression quantile, is a pivotal quantity for the τth quantile regression parameter β_τ. In other words, the distribution of $S(\beta)$ can be generated exactly by a random vector U, which is a weighted sum of independent, re-centered Bernoulli variables. They further showed that for large n, the distribution of $\hat{\beta}(\tau) - \beta_\tau$ can be approximated by the conditional distribution of $\hat{\beta}_U - \hat{\beta}_n(\tau)$, where $\hat{\beta}_U$ solves an augmented quantile regression problem with $n+1$ observations with $x_{n+1} = -n^{-1/2}u/\tau$ and y_{n+1} sufficiently large for a given realization of u. By exploiting the asymptotically pivot role of the quantile regression "gradient condition," this approach also achieves some robustness to certain heteroscedasticity.

Although the bootstrap method by Parzen, Wei, and Ying (1994) is much simpler, it is too time-consuming for relatively large data sets, especially for high-dimensional data sets. The QUANTREG procedure implements a new, general resampling method developed by He and Hu (2002), which is referred to as the

Markov chain marginal bootstrap (MCMB). For quantile regression, the MCMB method has the advantage that it solves p one-dimensional equations instead of p-dimensional equations, as do the previous bootstrap methods. This greatly improves the feasibility of the resampling method in computing confidence intervals for regression quantiles.

Covariance-Correlation

You can specify the COVB and CORRB options in the MODEL statement to request covariance and correlation matrices for the estimated parameters.

The QUANTREG procedure provides two methods for computing the covariance and correlation matrices of the estimated parameters: an asymptotic method and a bootstrap method. Bootstrap covariance and correlation matrices are computed when resampling confidence intervals are computed. Asymptotic covariance and correlation matrices are computed when asymptotic confidence intervals are computed. The rank method for confidence intervals does not provide a covariance-correlation estimate.

Asymptotic Covariance-Correlation

This method corresponds to the sparsity method for the confidence intervals. For the sparsity function in the computation of the asymptotic covariance and correlation, the QUANTREG procedure provides both iid and non-iid estimates. By default, the QUANTREG procedure computes non-iid estimates.

Bootstrap Covariance-Correlation

This method corresponds to the resampling method for the confidence intervals. The Markov chain marginal bootstrap (MCMB) method is used.

Linear Test

Consider the linear model

$$y_i = x'_{1i}\beta_1 + x'_{2i}\beta_2 + \epsilon_i$$

where β_1 and β_2 are $p-$ and $q-$dimensional unknown parameters, and $\{\epsilon_i\}$, $i = 1, \ldots, n$, are errors with unknown density function f_i. Let $x'_i = (x'_{1i}, x'_{2i})$; $\hat{\beta}_1(\tau)$ and $\hat{\beta}_2(\tau)$ be the parameter estimates for β_1 and β_2 respecitively at the τth quantile. The covariance matrix Ω for the parameter estimates is partitioned correspondingly as Ω_{ij} with $i = 1, 2$; $j = 1, 2$; and $\Omega^{22} = (\Omega_{22} - \Omega_{21}\Omega_{11}^{-1}\Omega_{12})^{-1}$.

Testing Effects of Covariates

Three tests are available in the QUANTREG procedure for the linear null hypothesis $H_0 : \beta_2 = 0$ at the τth quantile.

The Wald test statistic, which is based on the estimated coefficients for the unrestricted model, is given by

$$T_W(\tau) = \hat{\beta}_2'(\tau)\hat{\Sigma}(\tau)^{-1}\hat{\beta}_2(\tau)$$

where $\hat{\Sigma}(\tau)$ is an estimator of the covariance of $\hat{\beta}_2(\tau)$. The QUANTREG procedure provides two estimators for the covariance, as described in the previous section. The estimator based on the asymptotic covariance is

$$\hat{\Sigma}(\tau) = \frac{1}{n}\hat{\omega}(\tau)^2\Omega^{22}$$

where $\hat{\omega}(\tau) = \sqrt{\tau(1-\tau)}\hat{s}(\tau)$ and $\hat{s}(\tau)$ is the estimated sparsity function. The estimator based on the bootstrap covariance is the empirical covariance of the MCMB samples.

The likelihood ratio test is based on the difference between the objective function values in the restricted and unrestricted models. Let $D_0(\tau) = \sum \rho_\tau(y_i - x_i\hat{\beta}(\tau))$ and $D_1(\tau) = \sum \rho_\tau(y_i - x_{1i}\hat{\beta}_1(\tau))$, and set

$$T_{LR}(\tau) = 2(\tau(1-\tau)\hat{s}(\tau))^{-1}(D_1(\tau) - D_0(\tau))$$

where $\hat{s}(\tau)$ is the estimated sparsity function.

The rank test statistic is given by

$$T_R(\tau) = S_n' M_n^{-1} S_n / A^2(\varphi)$$

where

$$S_n = n^{-1/2}(X_2 - \hat{X_2})'\hat{b_n}$$

$$\Psi = diag(f_i(Q_{y_i}(\tau|x_{1i}, x_{2i})))$$

$$\hat{X_2} = X_1(X_1'\Psi X_1)^{-1}X_1'X_2$$

$$M_n = (X_2 - \hat{X_2})(X_2 - \hat{X_2})'/n$$

$$\hat{b}_{ni} = \int_0^1 \hat{a}_{ni}(t)d\varphi(t)$$

$$\hat{a}(t) = \max_a\{y'a | X_1'a = (1-t)X_1'e,\ a \in [0,1]^n\}$$

$$A^2(\varphi) = \int_0^1 (\varphi(t) - \bar{\varphi}(t))^2 dt$$

$$\bar{\varphi}(t) = \int_0^1 \varphi(t)dt$$

and $\varphi(t)$ is a score function.

The following score functions are available in the QUANTREG procedure:

Wilcoxon scores: $\phi(t) = t - 1/2$

Normal scores: $\phi(t) = \Phi^{-1}(t)$, where Φ is the normal distribution function

Sign scores: $\phi(t) = 1/2 \text{ sign}(t - 1/2)$

Tau scores: $\phi_\tau(t) = \tau - I(t < \tau)$.

The rank test statistic $T_R(\tau)$, unlike Wald tests or likelihood ratio tests, requires no estimation of the nuisance parameter f_i under iid error models (Gutenbrunner et al. 1993).

Koenker and Machado (1999) prove that the three test statistics ($T_W(\tau)$, $T_{LR}(\tau)$, and $T_R(\tau)$) are asymptotically equivalent and that their distributions converge to χ^2_q under the null hypothesis, where q is the dimension of β_2.

Testing for Heteroscedasticity

After you obtain the parameter estimates for several quantiles specified in the MODEL statement, you can test whether there are significant difference for the estimates for the same covariates across the quantiles. For example, if you want to test whether the parameters β_2 are the same across quantiles, the null hypothesis H_0 can be written as: $\beta_2(\tau_1) = ... = \beta_2(\tau_k)$, where $\tau_j, j = 1, ..., k$, are the quantiles specified in the MODEL statement. See Koenker and Bassett (1982) for details.

Leverage Point and Outlier Detection

The QUANTREG procedure uses robust multivariate location and scale estimates for leverage-point detection.

Mahalanobis distance is defined as

$$MD(x_i) = [(x_i - \bar{x})' \bar{C}(A)^{-1} (x_i - \bar{x})]^{1/2}$$

where $\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i$ and $\bar{C}(A) = \frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})'(x_i - \bar{x})$ are the empirical multivariate location and scale. Here, $x_i = (x_{i1}, \ldots, x_{i(p-1)})'$ does not include the intercept variable. The relationship between the Mahalanobis distance $MD(x_i)$ and the matrix $H = (h_{ij}) = A'(AA')^{-1}A$ is

$$h_{ii} = \frac{1}{n-1} MD_i^2 + \frac{1}{n}$$

Robust distance is defined as

$$RD(x_i) = [(x_i - T(A))' C(A)^{-1} (x_i - T(A))]^{1/2}$$

where $T(A)$ and $C(A)$ are robust multivariate location and scale estimates computed with the minimum covariance determinant (MCD) method of Rousseeuw and Van Driessen (1999).

These distances are used to detect leverage points. You can use the DIAGNOSTICS and LEVERAGE options in the MODEL statement to request leverage-point and outlier diagnostics. Two new variables, Leverage and Outlier, are created and saved in an output data set specified in the OUTPUT statement.

Let $C(p) = \sqrt{\chi^2_{p;1-\alpha}}$ be the cutoff value. The variable LEVERAGE is defined as

$$\text{LEVERAGE} = \begin{cases} 0 & \text{if } RD(x_i) \leq C(p) \\ 1 & \text{otherwise} \end{cases}$$

You can specify a cutoff value with the LEVERAGE option in the MODEL statement.

Residuals $r_i, i = 1, \ldots, n$, based on quantile regression estimates are used to detect vertical outliers. The variable OUTLIER is defined as

$$\text{OUTLIER} = \begin{cases} 0 & \text{if } |r_i| \leq k\sigma \\ 1 & \text{otherwise} \end{cases}$$

You can specify the multiplier k of the cutoff value with the CUTOFF= option in the MODEL statement. You can specify the scale σ with the SCALE= option in the MODEL statement. By default, $k = 3$ and the scale σ is computed as the corrected median of the absolute residuals $\sigma = \text{median}\{|r_i|/\beta_0, i = 1, \ldots, n\}$, where $\beta_0 = \Phi^{-1}(0.75)$ is an adjustment constant for consistency with the normal distribution.

An ODS table called DIAGNOSTICS contains these two variables.

INEST= Data Set

The INEST= data set specifies initial estimates for all the parameters in the model. The INEST= data set must contain the intercept variable (named Intercept) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in one BY group, the first one read is used for that BY group.

If the INEST= data set also contains the _TYPE_ variable, only observations with the _TYPE_ value 'PARMS' are used as starting values.

You can specify starting values for the interior point algorithm or the smoothing algorithm in the INEST= data set. The INEST= data set has the same structure as the OUTEST= data set but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization. If you specify more than one quantile in the MODEL statement, the same initial values are used for all quantiles.

OUTEST= Data Set

The OUTEST= data set contains parameter estimates for the specified model with all quantiles. A set of observations is created for each quantile specified. You can also specify a label in the MODEL statement to distinguish between the estimates for different models used by the QUANTREG procedure.

Note that, if the QUANTREG procedure does not produce valid solutions, the parameter estimates are set to missing in the OUTEST data set.

If created, this data set contains all variables specified in the MODEL statement and the BY statement. Each observation consists of parameter values for a specified quantile with the dependent variable having the value -1.

The following variables are also added to the data set:

MODEL	a character variable of length 8 containing the label of the MODEL statement, if present. Otherwise, the variable's value is blank.
ALGORITHM	a character variable of length 8 containing the name of the algorithm used for computing the parameter estimates, either SIMPLEX, INTERIOR, or SMOOTH
TYPE	a character variable of length 8 containing the type of the observation. it is fixed as PARMS to indicate that the observation includes parameter estimates.
STATUS	a character variable of length 12 containing the status of model fitting, either NORMAL, NOUNIQUE, or NOVALID
Intercept	a numeric variable containing the intercept parameter estimates
QUANTILE	a numeric variable containing the specified quantile levels

Any BY variables specified are also added to the OUTEST= data set.

Computational Resources

The various algorithms need different amounts of memory for working space. Let p be the number of parameters estimated and n be the number of observations used in the model estimation.

For the simplex algorithm, the minimum working space (in bytes) needed is

$$2np + 6n + 10p$$

for the interior point algorithm,

$$np + p^2 + 13n + 4p$$

and for the smoothing algorithm,

$$np + p^2 + 6n + 4p$$

For the last two algorithms, if you want to use preprocessing, an extra amount

$$np + 6n + 2p$$

is needed.

If sufficient space is available, the input data set is kept in memory; otherwise, the input data set is reread as necessary, and the execution time of the procedure increases substantially.

ODS Table Names

The QUANTREG procedure assigns a name to each table it creates. You can specify these names when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 75.5 ODS Tables Produced in PROC QUANTREG

ODS Table Name	Description	Statement	Option
ClassLevels	Classification variable levels	CLASS	default
CorrB	Parameter estimate correlation matrix	MODEL	CORRB
CovB	Parameter estimate covariance matrix	MODEL	COVB
Diagnostics	Outlier diagnostics	MODEL	DIAGNOSTICS
DiagSummary	Summary of the outlier diagnostics	MODEL	DIAGNOSTICS
IPIterHistory	Iteration history (Interior Point)	MODEL	ITPRINT
ModelInfo	Model information	MODEL	default
NObs	Number of observations	PROC	default

SMIterHistory	Iteration history (Smoothing)	MODEL	ITPRINT
SummaryStatistics	Summary statistics for model variables	MODEL	default
Tests	Results for tests	TEST	default
ScalableTiming	Timing details	PERFORMANCE	DETAILS

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

For a single quantile, two plots are particularly useful in revealing outliers and leverage points. The first is a scatter plot of the standardized residuals for the specified quantile against the robust distances. The second is a scatter plot of the robust distances against the classical Mahalanobis distances. You can request these two plots by using the PLOT=RDPLOT and PLOT=DDPLOT options.

You can also request a normal quantile-quantile plot and a histogram of the standardized residuals for the specified quantile with the PLOT=QQPLOT and PLOT=HISTOGRAM options, respectively.

You can request a plot of fitted conditional quantiles by the single continuous variable specified in the model with the PLOT=FITPLOT option.

All these plots can be requested by specifying corresponding plot options in either the PROC statement or the MODEL statement. If you specify same plot options in both statements, options in the PROC statement override options in the MODEL statement.

You can specify the PLOT=QUANTPLOT option in only the MODEL statement to request a quantile process plot with confidence bands.

The plot options in the PROC statement and the MODEL statement are summarized in Table 75.6. See the PLOT= option in the PROC statement and the PLOT= option in the MODEL statement for details.

Table 75.6 Options for Plots

Keyword	Plot
ALL	All appropriate plots
DDPLOT	Robust distance vs. Mahalanobis distance
FITPLOT	Conditional quantile fit vs. independent variable
HISTOGRAM	Histogram of standardized robust residuals
NONE	No plot
QUANTPLOT	Scatter plot of regression quantile
QQPLOT	Q-Q plot of standardized robust residuals
RDPLOT	Standardized robust residual vs. robust distance

The following subsections provide information about these graphs.

ODS Graph Names

The QUANTREG procedure assigns a name to each graph it creates. You can use these names to reference the graphs when using ODS. The names along with the required statements and options are listed in Table 75.7.

Table 75.7 Graphs Produced by PROC QUANTREG

ODS Graph Name	Plot Description	Statement	Option
DDPlot	Robust distance versus Mahalanobis distance	PROC MODEL	DDPLOT
FitPlot	Quantile fit versus independent variable	PROC MODEL	FITPLOT
Histogram	Histogram of standardized robust residuals	PROC MODEL	HISTOGRAM
QQPlot	Q-Q plot of standardized robust residuals	PROC MODEL	QQPLOT
QuantPanel	Panel of quantile plots with confidence limits	MODEL	QUANTPLOT
QuantPlot	Scatter plot for regression quantiles with confidence limits	MODEL	QUANTPLOT UNPACK
RDPlot	Standardized robust residual versus robust distance	PROC MODEL	RDPLOT

Fit Plot

When the model has a single independent continuous variable (with or without the intercept), the QUANTREG procedure automatically creates a plot of fitted conditional quantiles against this independent variable for one or more quantiles specified in the MODEL statement.

The following example reuses the trout data set in the section "Analysis of Fish-Habitat Relationships" on page 6267 to show the fit plot for one or several quantiles.

```
ods graphics on;

proc quantreg data=trout ci=resampling;
   model LnDensity = WDRatio / quantile=0.9 seed=1268;
run;

proc quantreg data=trout ci=resampling;
   model LnDensity = WDRatio / quantile=0.5 0.75 0.9 seed=1268;
run;
```

For a single quantile, the confidence limits for the fitted conditional quantiles are also plotted if you specify the CI=RESAMPLING or CI=SPARSITY option. (See Figure 75.14.) For multiple quantiles, confidence limits are not plotted by default. (See Figure 75.15.) You can add the confidence limits on the plot by specifying the option PLOT=FITPLOT(SHOWLIMITS).

The QUANTREG procedure also provides fit plots for quantile regression splines and polynomials if they are based on a single continuous variable. Refer to Example 75.4 and Example 75.5 for some examples.

Figure 75.14 Fit Plot with Confidence Limits

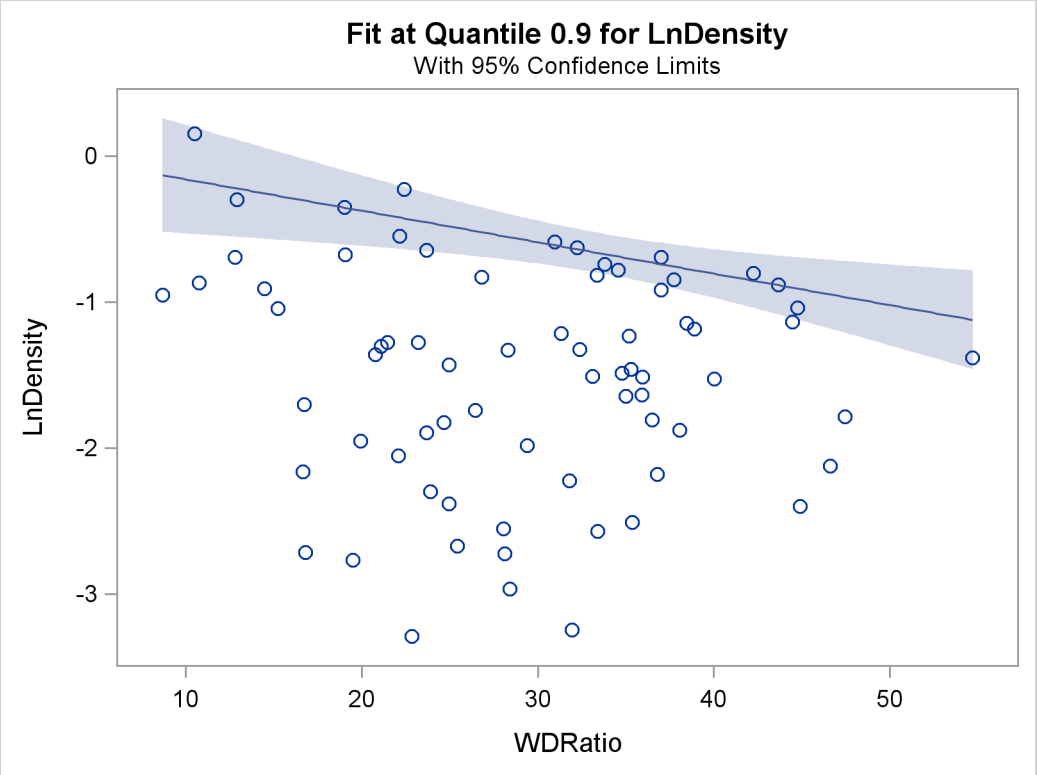

Figure 75.15 Fit Plot for Multiple Quantiles

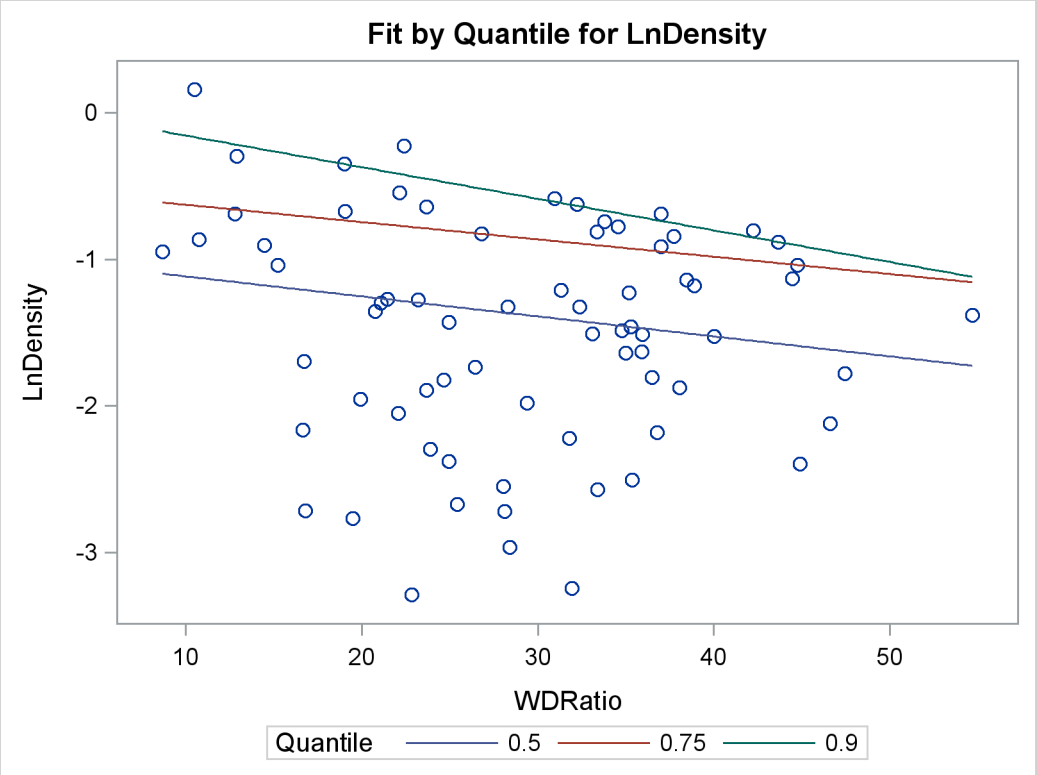

Quantile Process Plot

A quantile process plot is a scatter plot of an estimated regression parameter against quantile. You can request this plot with the PLOT=QUANTPLOT option in the MODEL statement when multiple regression quantiles or the entire quantile process is computed. Quantile process plots are often used to check model variations at different quantiles, which is usually called model heterogeneity.

By default, panels are used to hold multiple process plots (up to four in each panel). You can use the UNPACK option to request individual process plots. Figure 75.10 in the section "Analysis of Fish-Habitat Relationships" on page 6267 shows a panel with two quantile process plots. Output 75.2.9 in Example 75.2 shows a single quantile process plot. Example 75.3 demonstrates more quantile process plots and their usage.

Distance-Distance Plot

The distance-distance plot (DDPLOT) is mainly used for leverage-point diagnostics. It is a scatter plot of the robust distances against the classical Mahalanobis distances for the continuous independent variables. See the section "Leverage Point and Outlier Detection" on page 6302 for details about the robust distance. If there is a classification variable specified in the model, this plot is not created.

You can use the PLOT=DDPLOT option to request this plot. The following statements use the growth data set in Example 75.2 to create a single plot, shown in Output 75.2.4 in Example 75.2:

```
ods graphics on;

proc quantreg data=growth ci=resampling plot=ddplot;
   model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2
               lintr2 gedy2 Iy2 gcony2 lblakp2 pol2 ttrad2
               / quantile=.5 diagnostics leverage(cutoff=8) seed=1268;
   id Country;
run;
```

The reference lines represent the cutoff values. The diagonal line is also drawn to show the distribution of the distances. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the LABEL= option as described in Table 75.4.

Residual-Distance Plot

The residual-distance plot (RDPLOT) is used for both outlier and leverage-point diagnostics. It is a scatter plot of the standardized residuals against the robust distances. See the section "Leverage Point and Outlier Detection" on page 6302 for details about the robust distance. If a classification variable is specified in the model, this plot is not created.

You can use the PLOT=RDPLOT option to request this plot. The following statements use the growth data set in Example 75.2 to create a single plot, shown in Output 75.2.3 in Example 75.2:

```
ods graphics on;

proc quantreg data=growth ci=resampling plot=rdplot;
```

```
   model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2
               lintr2 gedy2 Iy2 gcony2 lblakp2 pol2 ttrad2
               / quantile=.5 diagnostics leverage(cutoff=8) seed=1268;
   id Country;
run;
```

The reference lines represent the cutoff values. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the LABEL= option as described in Table 75.4.

If you specify ID variables in the ID statement, instead of observation numbers, the values of the first ID variable are used as labels.

Histogram and Q-Q Plot

PROC QUANTREG produces a histogram and a Q-Q plot for the standardized residuals. The histogram is superimposed with a normal density curve and a kernel density curve. Using the growth data set in Example 75.2, the following statements create the plot shown in Output 75.2.5 in Example 75.2:

```
ods graphics on;

proc quantreg data=growth ci=resampling plot=histogram;
   model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2
               lintr2 gedy2 Iy2 gcony2 lblakp2 pol2 ttrad2
               / quantile=.5 diagnostics leverage(cutoff=8) seed=1268;
   id Country;
run;
```

Examples: QUANTREG Procedure

Example 75.1: Comparison of Algorithms

This example illustrates and compares the three algorithms for regression estimation available in the QUANTREG procedure. The simplex algorithm is the default because of its stability. Although this algorithm is slower than the interior point and smoothing algorithms for large data sets, the difference is not as significant for data sets with fewer than 5,000 observations and 50 variables. The simplex algorithm can also compute the entire quantile process, which is shown in Example 75.2.

The following statements generate 1,000 random observations. The first 950 observations are from a linear model, and the last 50 observations are significantly biased in the y-direction. In other words, 5% of the observations are contaminated with outliers.

```
data a (drop=i);
   do i=1 to 1000;
      x1=rannor(1234);
      x2=rannor(1234);
```

```
      e=rannor(1234);
      if i > 950 then y=100 + 10*e;
      else y=10 + 5*x1 + 3*x2 + 0.5 * e;
      output;
   end;
run;
```

The following statements invoke the QUANTREG procedure to fit a median regression model with the default simplex algorithm. They produce the results in Output 75.1.1 through Output 75.1.3.

```
proc quantreg data=a;
   model y = x1 x2;
run;
```

Output 75.1.1 displays model information and summary statistics for variables in the model. It indicates that the simplex algorithm is used to compute the optimal solution and the rank method is used to compute confidence intervals of the parameters.

By default, the QUANTREG procedure fits a median regression model. This is indicated by the quantile value 0.5 in Output 75.1.2, which also displays the objective function value and the predicted value of the response at the means of the covariates.

Output 75.1.3 displays parameter estimates and confidence limits. These estimates are reasonable, which indicates that median regression is robust to the 50 outliers.

Output 75.1.1 Model Fit Information and Summary Statistics with Simplex Algorithm

BMI Percentiles for Men: 2–80 Years Old

The QUANTREG Procedure

Model Information

Output 75.1.3 Parameter Estimates with Simplex Algorithm

Parameter Estimates

Parameter	DF	Estimate	95% Confidence Limits	
Intercept	1	10.0364	9.9959	10.0756
x1	1	5.0106	4.9602	5.0388
x2	1	3.0294	2.9944	3.0630

The following statements refit the model by using the interior point algorithm:

```
proc quantreg algorithm=interior(tolerance=1e-6)
              ci=none data=a;
   model y = x1 x2 / itprint nosummary;
run;
```

The TOLERANCE= option specifies the stopping criterion for convergence of the interior point algorithm, which is controlled by the duality gap. Although the default criterion is 1E−8, the value 1E−6 is often sufficient. The ITPRINT option requests the iteration history for the algorithm. The option CI=NONE suppresses the computation of confidence limits, and the option NOSUMMARY suppresses the table of summary statistics.

Output 75.1.4 displays model fit information.

Output 75.1.4 Model Fit Information with Interior Point Algorithm

Output 75.1.9 displays the parameter estimates obtained with the smoothing algorithm, which are identical to those obtained with the simplex and interior point algorithms. All three algorithms should have the same parameter estimates unless the problem does not have a unique solution.

Output 75.1.9 Parameter Estimates with Smoothing Algorithm

Parameter Estimates		
Parameter	**DF**	**Estimate**
Intercept	1	10.0364
x1	1	5.0106
x2	1	3.0294

The interior point algorithm and the smoothing algorithm offer better performance than the simplex algorithm for large data sets. Refer to Chen (2004) for more details on choosing an appropriate algorithm on the basis of data set size. All three algorithms should have the same parameter estimates, unless the optimization problem has multiple solutions.

Example 75.2: Quantile Regression for Econometric Growth Data

This example uses a SAS data set named Growth, which contains economic growth rates for countries during two time periods, 1965–1975 and 1975–1985. The data come from a study by Barro and Lee (1994) and have also been analyzed by Koenker and Machado (1999).

There are 161 observations and 15 variables in the data set. The variables, which are listed in the following table, include the national growth rates (GDP) for the two periods, 13 covariates, and a name variable (Country) for identifying the countries in one of the two periods.

Variable	Description
Country	Country's name and period
GDP	Annual change per capita GDP
lgdp2	Initial per capita GDP
mse2	Male secondary education
fse2	Female secondary education
fhe2	Female higher education
mhe2	Male higher education
lexp2	Life expectancy
lintr2	Human capital
gedy2	Education/GDP
ly2	Investment/GDP
gcony2	Public consumption/GDP
lblakp2	Black market premium
pol2	Political instability
ttrad2	Growth rate terms trade

The goal is to study the effect of the covariates on GDP. The following statements request median regression for a preliminary exploration. They produce the results in Output 75.2.1 through Output 75.2.6.

```

The QUANTREG procedure employs the default simplex algorithm to estimate the parameters. The MCMB resampling method is used to compute confidence limits.

Output 75.2.1 displays model information and summary statistics for the variables in the model. Six summary statistics are computed, including the median and the median absolute deviation (MAD), which are robust measures of univariate location and scale, respectively. For the variable lintr2 (Human Capital), both the mean and standard deviation are much larger than the corresponding robust measures, median and MAD. This indicates that this variable might have outliers.

Output 75.2.1 Model Information and Summary Statistics

BMI Percentiles for Men: 2–80 Years Old

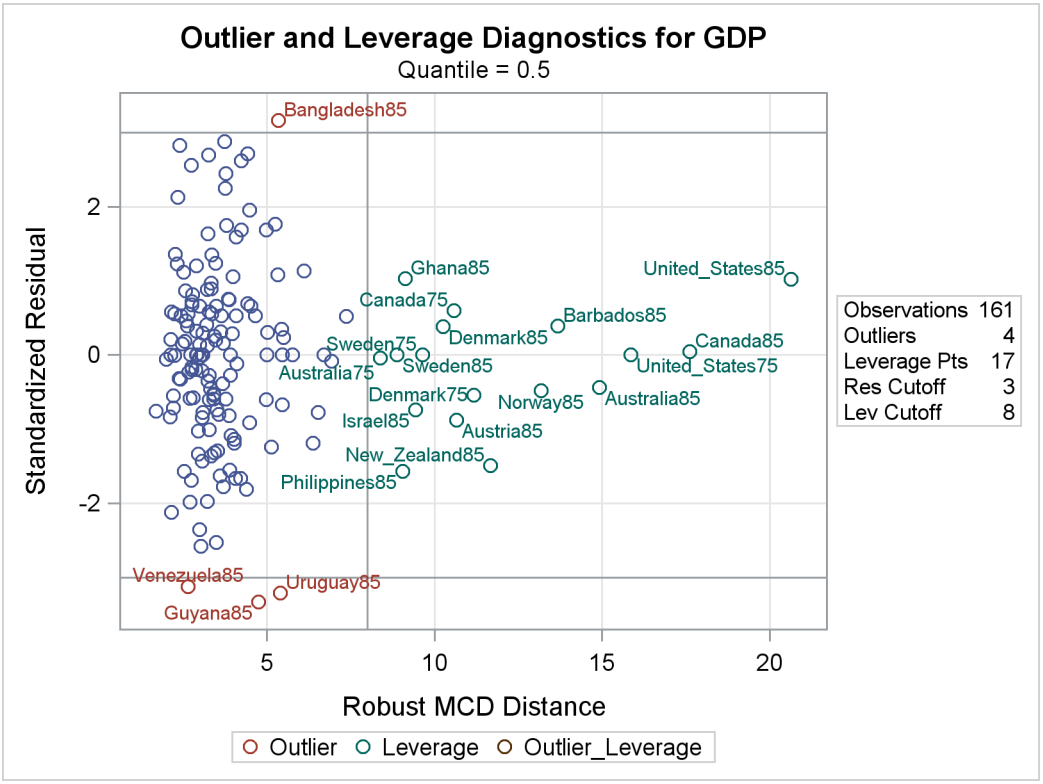
Diagnostics for the median regression fit are displayed in Output 75.2.3 and Output 75.2.4, which are requested with the PLOTS= option. Output 75.2.3 plots the standardized residuals from median regression against the robust MCD distance. This display is used to diagnose both vertical outliers and horizontal leverage points. Output 75.2.4 plots the robust MCD distance against the Mahalanobis distance. This display is used to diagnose leverage points.

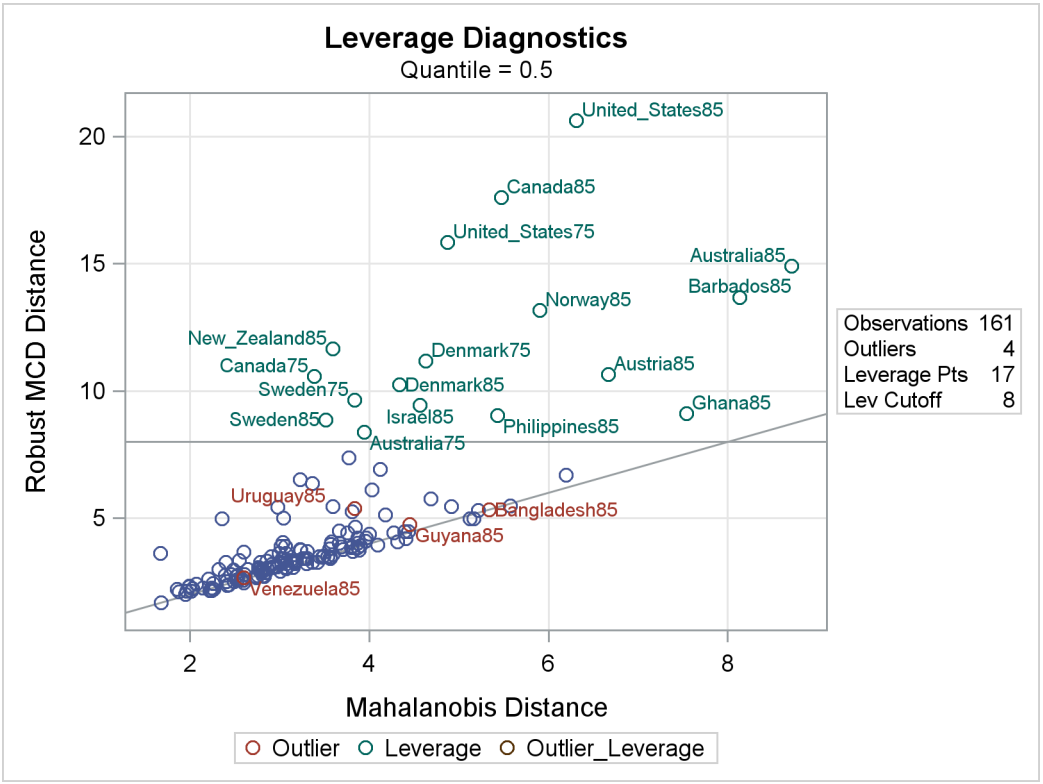
The cutoff value 8 specified with the LEVERAGE option is close to the maximum of the Mahalanobis distance. Eighteen points are diagnosed as high leverage points, and almost all are countries with high human capital, which is the major contributor to the high leverage as observed from the summary statistics. Four points are diagnosed as outliers by using the default cutoff value of 3. However, these are not extreme outliers.

A histogram of the standardized residuals and two fitted density curves are displayed in Output 75.2.5. This shows that median regression fits the data well.

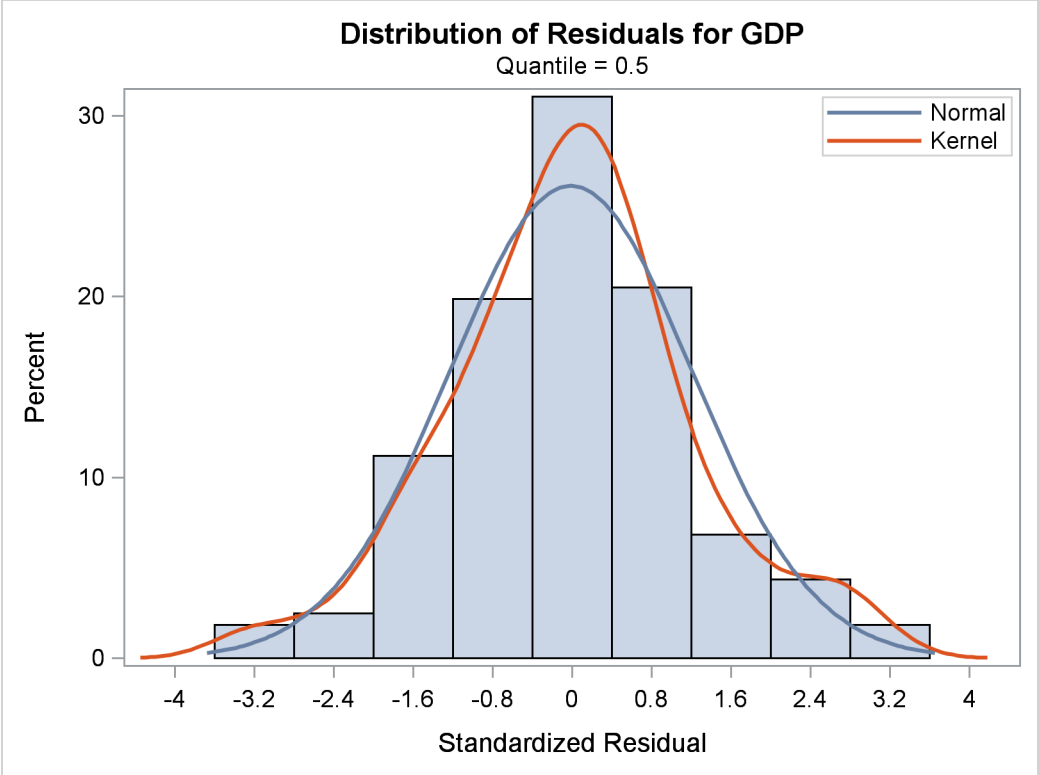
Output 75.2.3 Residual-Robust Distance Plot



Output 75.2.4 Robust Distance-Mahalanobis Distance Plot



Output 75.2.5 Histogram for Residuals



Tests of significance for the initial per-capita GDP (LGDP2) are shown in Output 75.2.6.

Output 75.2.6 Tests for Regression Coefficient

Test test_lgdp2 Results

Test	Test Statistic	DF	Chi-Square	Pr > ChiSq
Wald	43.2684	1	43.27	<.0001
Likelihood Ratio	36.3047	1	36.30	<.0001

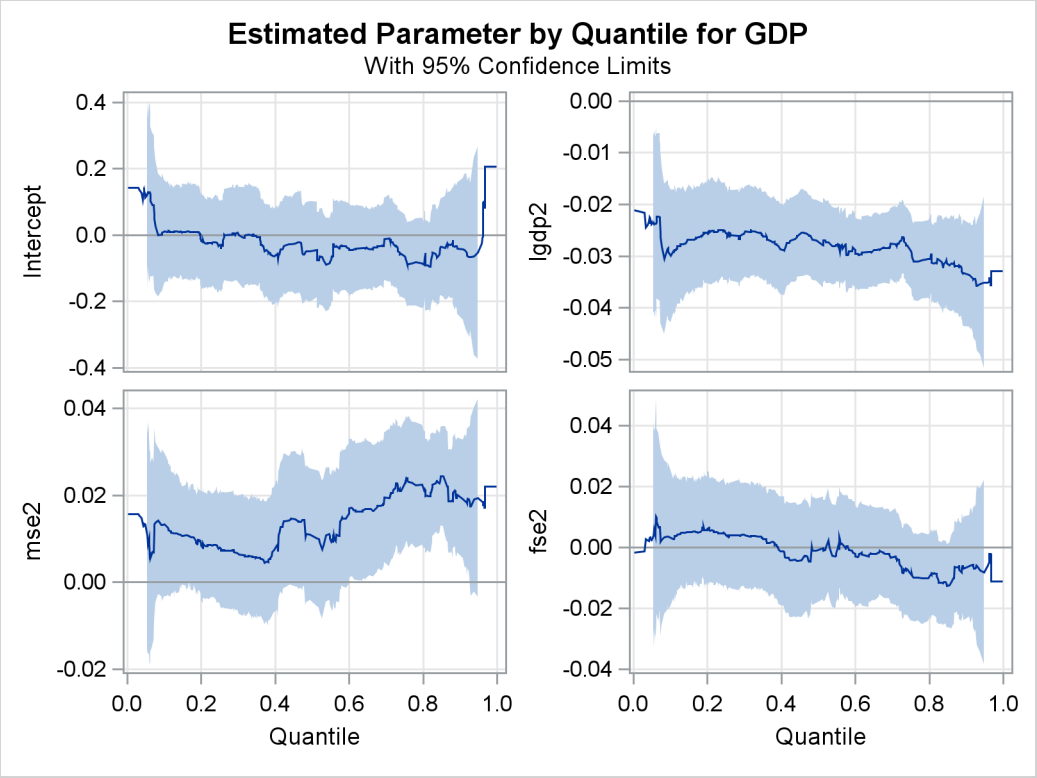
The QUANTREG procedure computes entire quantile processes for covariates when you specify QUANTILE=PROCESS in the MODEL statement, as follows:

```
proc quantreg data=growth ci=resampling;
   model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2 lintr2
               gedy2 Iy2 gcony2 lblakp2 pol2 ttrad2
               / quantile=process plot=quantplot seed=1268;
run;
```

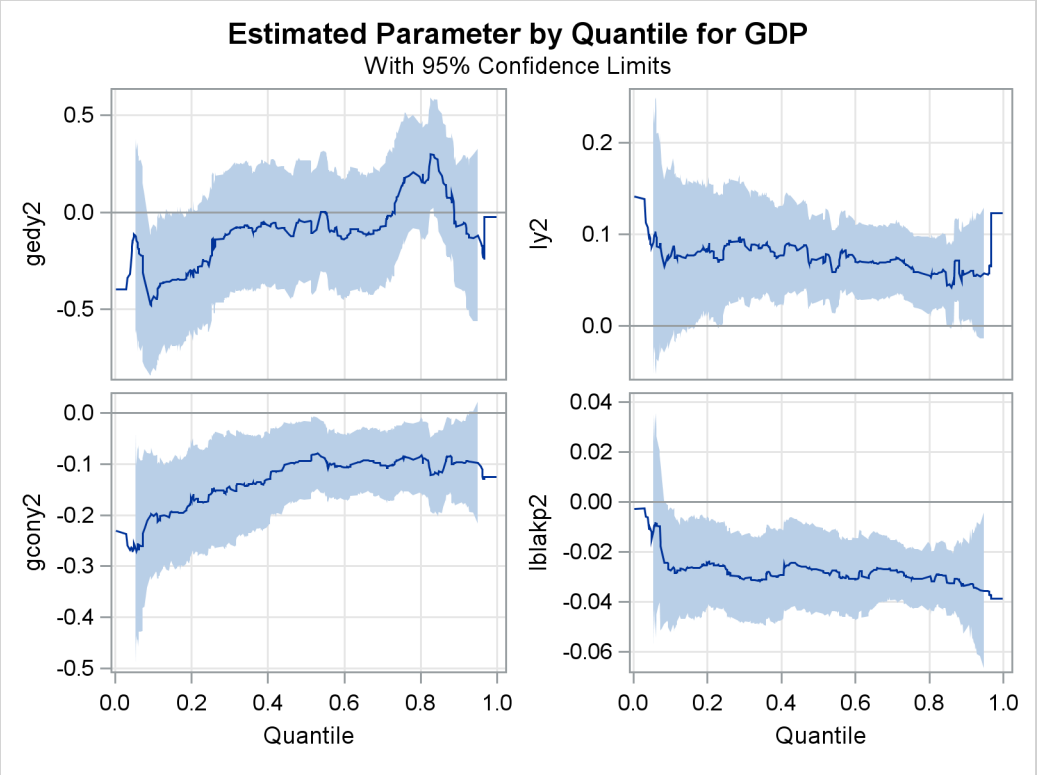
Confidence limits for quantile processes can be computed with the sparsity or resampling methods, but not the rank method, because the computation would be prohibitively expensive.

A total of 14 quantile process plots are produced. Output 75.2.7 and Output 75.2.8 display two panels of eight selected process plots. The 95% confidence bands are shaded.

Output 75.2.7 Quantile Processes with 95% Confidence Bands



Output 75.2.8 Quantile Processes with 95% Confidence Bands

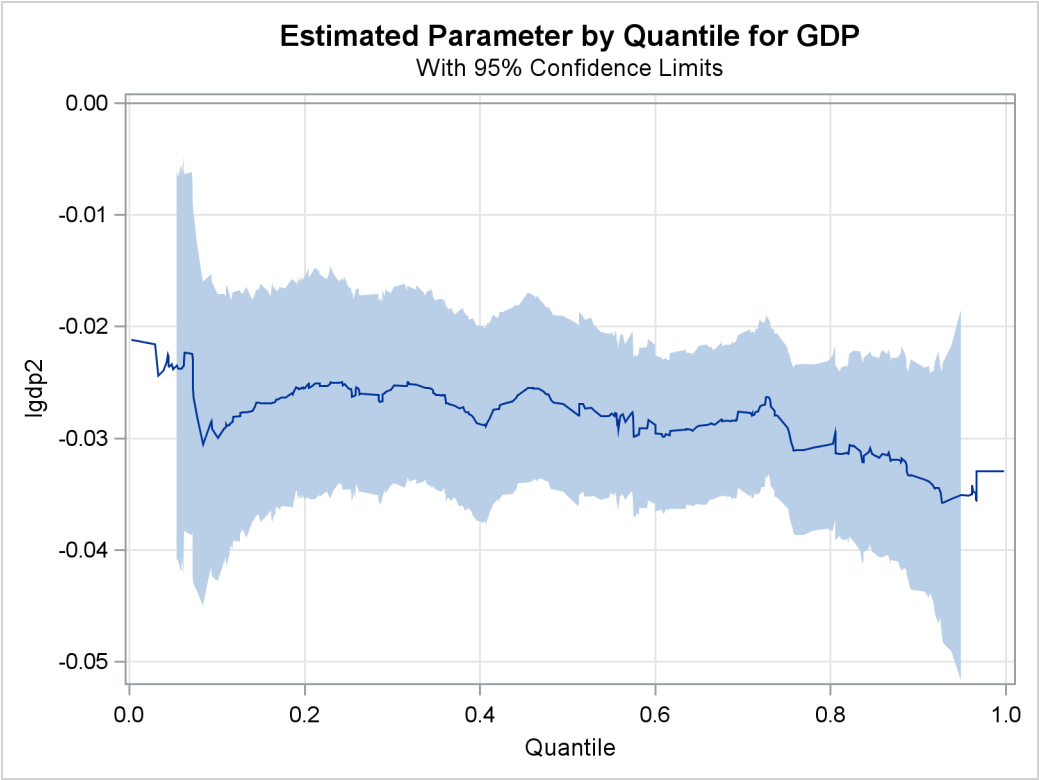


As pointed out by Koenker and Machado (1999), previous studies of the Barro growth data have focused on the effect of the initial per-capita GDP on the growth of this variable (annual change per-capita GDP). A single process plot for this effect can be requested with the following statements:

```
proc quantreg data=growth ci=resampling;
   model GDP = lgdp2 mse2 fse2 fhe2 mhe2 lexp2 lintr2
               gedy2 Iy2 gcony2 lblakp2 pol2 ttrad2
               / quantile=process plot=quantplot(lgdp2) seed=1268;
run;
```

The plot is shown in Output 75.2.9.

Output 75.2.9 Quantile Process Plot for LGDP2



The confidence bands here are computed with the MCMB resampling method, unlike in Koenker and Machado (1999), where the rank method was used to compute confidence limits for a few selected points. Output 75.2.9 suggests that the effect of the initial level of GDP is relatively constant over the entire distribution, with a slightly stronger effect in the upper tail.

The effects of other covariates are quite varied. An interesting covariate is public consumption/GDP (gcony2) (first plot in second panel), which has a constant effect over the upper half of the distribution and a larger effect in the lower tail. For an analysis of the effects of the other covariates, refer to Koenker and Machado (1999).

Example 75.3: Quantile Regression Analysis of Birth-Weight Data

This example is patterned after a quantile regression analysis of covariates associated with birth weight that was carried out by Koenker and Hallock (2001). Their study used a subset of the June 1997 Detailed Natality Data published by the National Center for Health Statistics and demonstrated that conditional quantile functions provide more complete information about the covariate effects than ordinary least squares regression.

As in Koenker and Hallock (2001) and Abreveya (2001), this example uses data for live, singleton births to mothers in the United States who were recorded as black or white, and who were between the ages of 18

and 45. For convenience, this example uses 50,000 observations, which were randomly selected from the qualified observations. Observations with missing data for any of the variables were deleted.

The following table describes the variables in the data.

Variable	Description
Weight	Infant's birth weight
Black	Indicator of black mother
Married	Indicator of married mother
Boy	Indicator of boy
Visit	Prenatal visit: 0 = no visit, 1 = visit in second trimester, 2 = visit in last trimester, 3 = visit in first trimester
Ed	Mother's education level: 0 = high school, 1 = some college, 2 = college, 3 = less than high school
Smoke	Indicator of smoking mother
CigsPer	Number of cigarettes smoked per day
Mom_Age	Mother's age
M_WtGain	Mother's weight gain during pregnancy

There are four levels of education of the mother. By default, the QUANTREG procedure treats the highest level (3 - less than high school) as a reference level. The regression coefficients of other levels measure the effect relative to this level. Likewise, there are four levels of prenatal medical care of the mother, and a first visit in the first trimester serves as the reference level. These two variables are treated as classification variables in the model.

The following statements fit a regression model for 19 quantiles of birth weight, which are evenly spaced in the interval $(0, 1)$. The model includes linear and quadratic effects for the age of the mother and for weight gain during pregnancy.

```
ods graphics on;

proc quantreg ci=sparsity/iid algorithm=interior(tolerance=5.e-4)
              data=sashelp.bweight;
   class visit ed;
   model weight = black married boy visit ed smoke
                  cigsper mom_age mom_age*mom_age
                  m_wtgain m_wtgain*m_wtgain /
                  quantile= 0.05 to 0.95 by 0.05
                  plot=quantplot;
run;
```

weight	3062.0	3402.0	3720.0	3370.8	566.4	504.1

Output 75.3.1 displays the model information and summary statistics for the variables in the model.

Among the 11 independent variables, Black, Married, Boy, and Smoke are binary variables. For these variables, the mean represents the proportion in the category. The two continuous variables, Mom_Age and M_WtGain, are centered at their medians, which are 27 and 30, respectively.

The quantile plots for the intercept and the other 15 factors with nonzero degree of freedom are shown in the following four panels. In each plot, the regression coefficient at a given quantile indicates the effect on birth weight of a unit change in that factor, assuming that the other factors are fixed. The bands represent 95% confidence intervals.

Although the data set used here is a subset of the Natality data set, the results are quite similar to those of Koenker and Hallock (2001) for the full data set.

In Output 75.3.2, the first plot is for the intercept. As explained by Koenker and Hallock (2001), the intercept "may be interpreted as the estimated conditional quantile function of the birth-weight distribution of a girl born to an unmarried, white mother with less than a high school education, who is 27 years old and had a weight gain of 30 pounds, didn't smoke, and had her first prenatal visit in the first trimester of the pregnancy."

The second plot shows that infants born to black mothers weigh less than infants born to white mothers, especially in the lower tail of the birth-weight distribution. The third plot shows that marital status has a large positive effect on birth weight, especially in the lower tail. The fourth plot shows that boys weigh more than girls for any chosen quantile; this difference is smaller in the lower quantiles of the distribution.

In Output 75.3.3, the first three plots deal with prenatal care. Compared with babies born to mothers who had a prenatal visit in the first trimester, babies born to mothers who received no prenatal care weigh less, especially in the lower quantiles of the birth-weight distributions. As noted by Koenker and Hallock (2001), "babies born to mothers who delayed prenatal visits until the second or third trimester have substantially *higher* birthweights in the lower tail than mothers who had a prenatal visit in the first trimester. This might be interpreted as the self-selection effect of mothers confident about favorable outcomes."

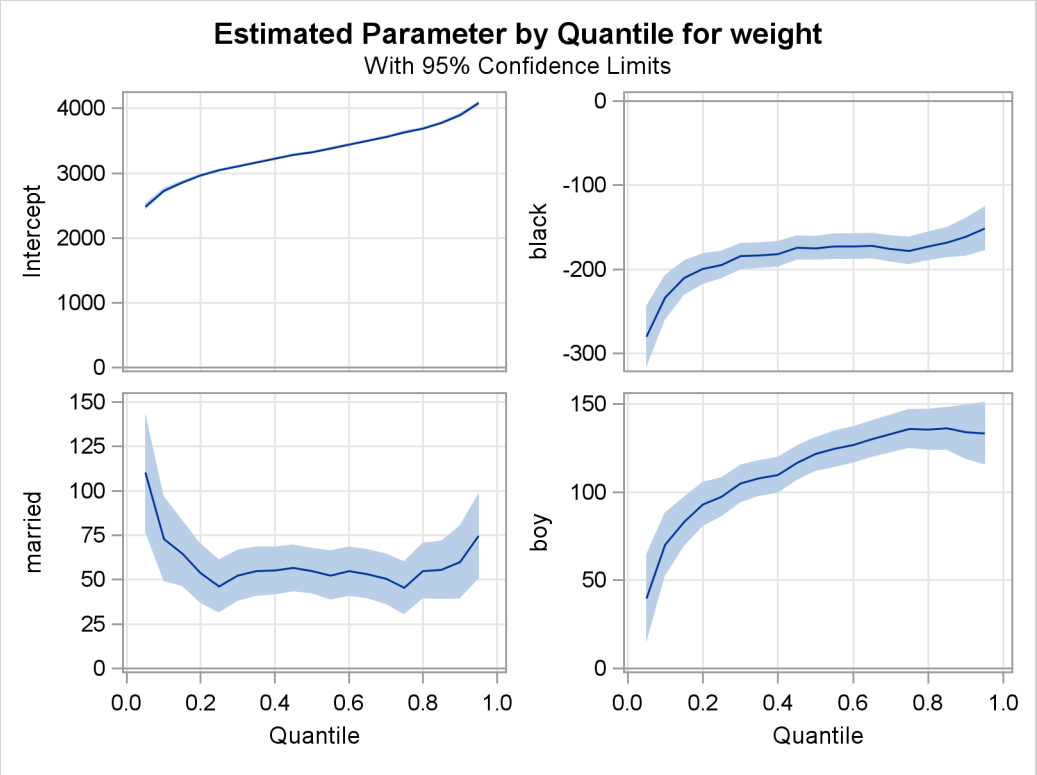
The fourth plot in Output 75.3.3 and the first two plots in Output 75.3.4 are for variables related to education. Education beyond high school is associated with a positive effect on birth weight. The effect of high school education is uniformly around 15 grams across the entire birth-weight distribution (this is a pure location shift effect), while the effect of some college and college education is more positive in the lower quantiles than the upper quantiles.

The remaining two plots in Output 75.3.4 show that smoking is associated with a large negative effect on birth weight.

The linear and quadratic effects for the two continuous variables are shown in Output 75.3.5. Both of these variables are centered at their median. At the lower quantiles, the quadratic effect of the mother's age is more concave. The optimal age at the first quantile is about 33, and the optimal age at the third quantile is about 38. The effect of the mother's weight gain is clearly positive, as indicated by the narrow confidence bands for both linear and quadratic coefficients.

Refer to Koenker and Hallock (2001) for more details about the covariate effects discovered with quantile regression.

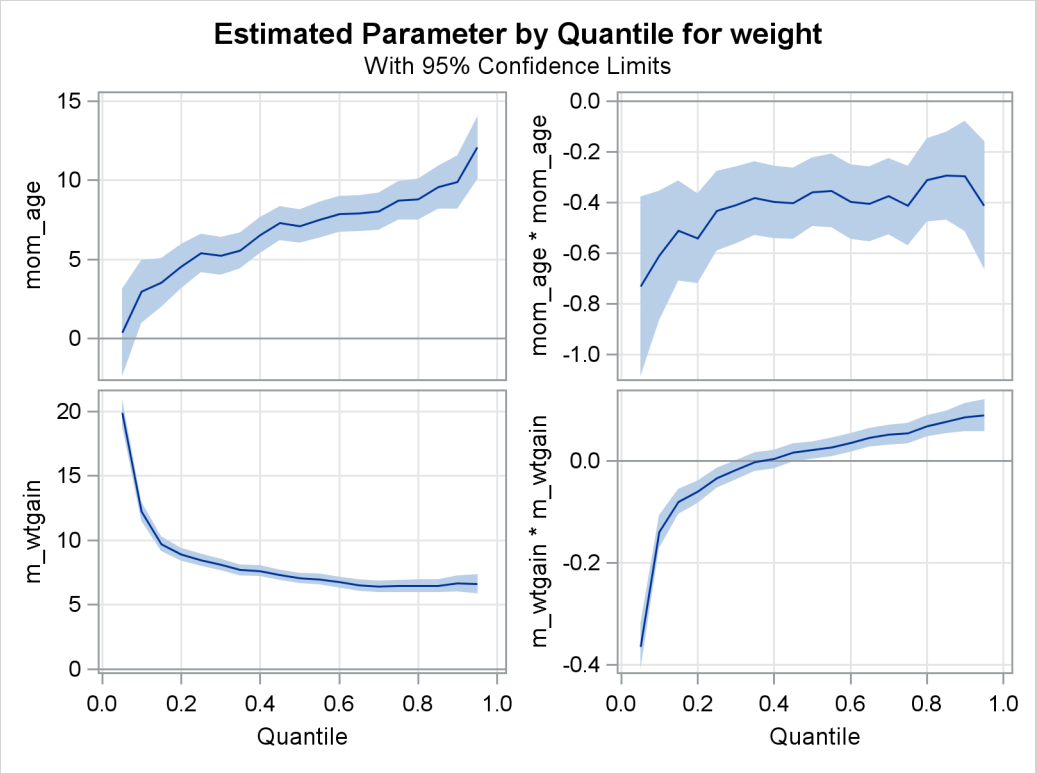
Output 75.3.2 Quantile Processes with 95% Confidence Bands



Output 75.3.3 Quantile Processes with 95% Confidence Bands

Output 75.3.4 Quantile Processes with 95% Confidence Bands

Output 75.3.5 Quantile Processes with 95% Confidence Bands



Example 75.4: Nonparametric Quantile Regression for Ozone Levels

Tracing seasonal trends in the level of tropospheric ozone is essential for predicting high-level periods, observing long-term trends, and discovering potential changes in pollution. Traditional methods for modeling seasonal effects are based on the conditional mean of ozone concentration; however, the upper conditional quantiles are more critical from a public health perspective. In this example, the QUANTREG procedure fits conditional quantile curves for seasonal effects by using nonparametric quantile regression with cubic B-splines.

The data used here are from Chock, Winkler, and Chen (2000), who studied the association between daily mortality and ambient air pollutant concentrations in Pittsburgh, Pennsylvania. The data set ozone contains the following two variables: Ozone (daily-maximum one-hour ozone concentration (ppm)) and Days (index of 1,095 days (3 years)).

```
data ozone;
  days = _n_;
  input ozone @@;
datalines;
0.0060 0.0060 0.0320 0.0320 0.0320 0.0150 0.0150 0.0150 0.0200 0.0200
0.0160 0.0070 0.0270 0.0160 0.0150 0.0240 0.0220 0.0220 0.0220 0.0185
0.0150 0.0150 0.0110 0.0070 0.0070 0.0240 0.0380 0.0240 0.0265 0.0290

   ... more lines ...

0.0220 0.0210 0.0210 0.0130 0.0130 0.0130 0.0330 0.0330 0.0330 0.0325
0.0320 0.0320 0.0320 0.0120 0.0200 0.0200 0.0200 0.0320 0.0320 0.0250
0.0180 0.0180 0.0270 0.0270 0.0290
;
```

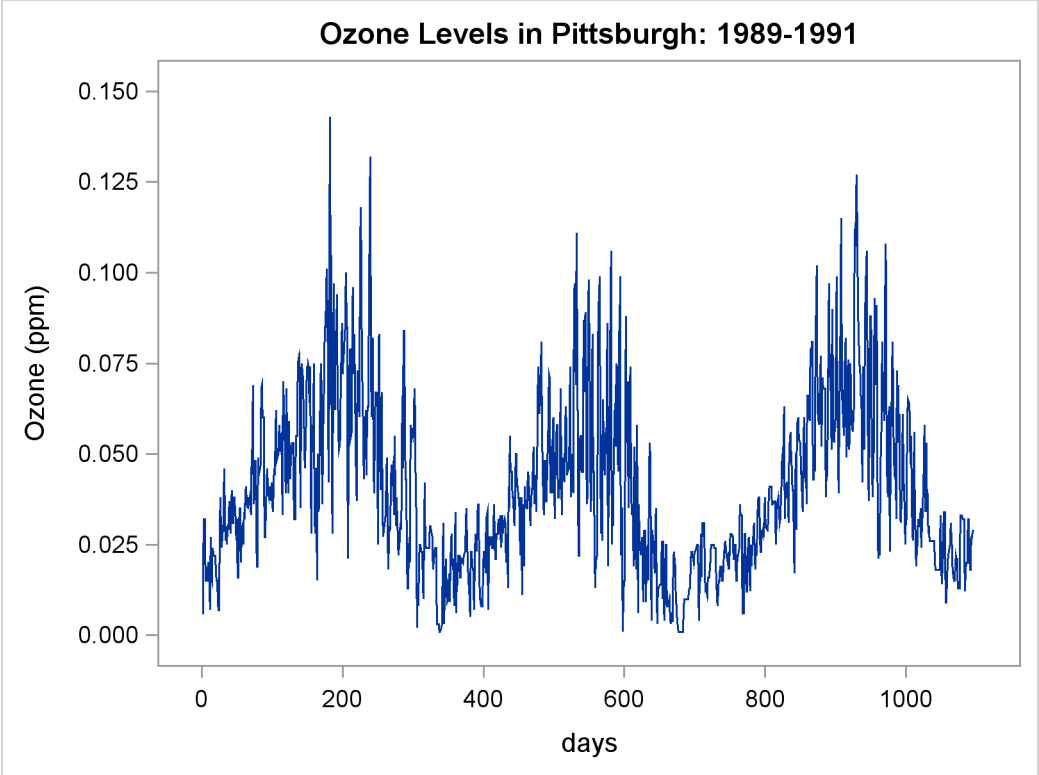
Output 75.4.1, which displays the time series plot of ozone concentration for the three years, shows a clear seasonal pattern.

In this example, cubic B-splines are used to fit the seasonal effect. These splines are generated with 11 knots, which split the 3 years into 12 seasons. The following statements create the spline basis and fit multiple quantile regression spline curves:

```
ods graphics on;

proc quantreg data=ozone algorithm=smooth ci=none plot=fitplot(nodata);
   effect sp = spline( days / knotmethod = list
          (90 182 272 365 455 547 637 730 820 912 1002) );
   model ozone = sp / quantile = 0.5 0.75 0.90 0.95 seed=1268;
run;
```

Output 75.4.1 Time Series of Ozone Levels in Pittsburgh, Pennsylvania

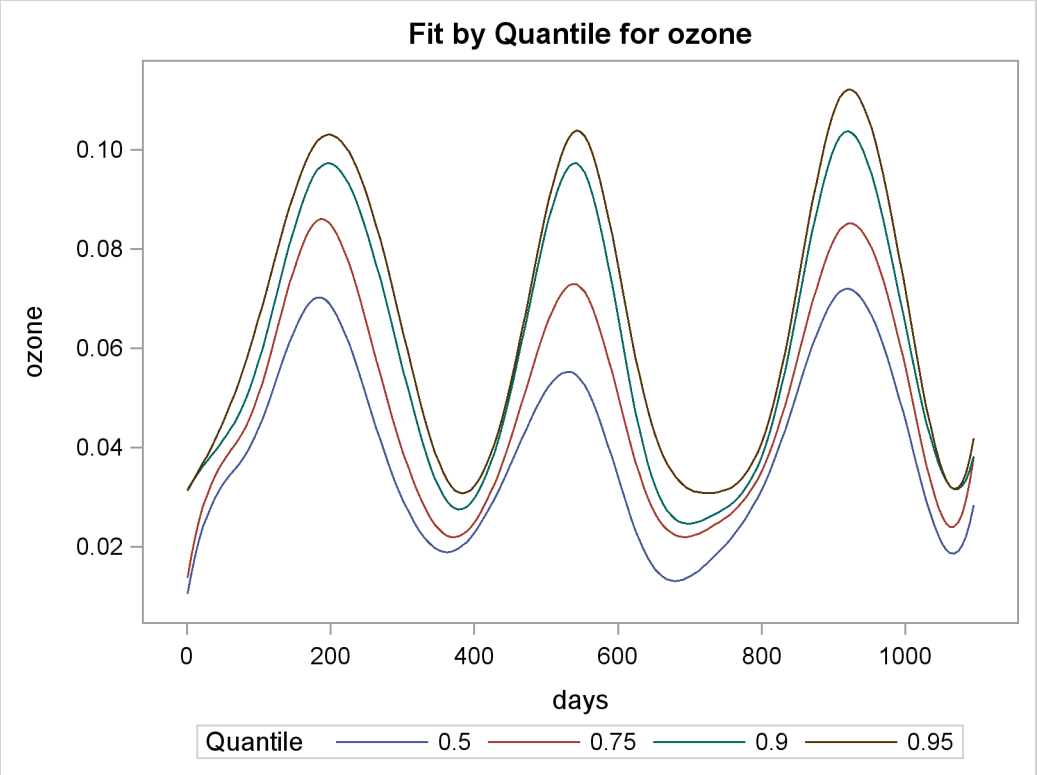


The EFFECT statement creates spline bases for the variable Days. The KNOTMETHOD=LIST option provides all internal knots for these bases. Cubic spline bases are generated by default. These bases are treated as components of the spline effect *sp*, which is used in the MODEL statement. Spline fits for four quantiles are requested with the QUANTILE= option.

When ODS Graphics is enabled, the QUANTREG procedure automatically generates a fit plot, which includes all fitted curves.

Output 75.4.2 displays these curves obtained with the QUANTREG procedure. The curves show that peak ozone levels occur in the summer. For the three years (1989–1991), the median curve (labeled 50%) does not cross the 0.08 ppm line, which is the 1997 EPA 8-hour standard. The median curve and the 75% curve show a drop for the ozone concentration levels in 1990. However, with the 90% and 95% curves, peak ozone levels tend to increase. This indicates that there might have been more days with low ozone concentration in 1990, but the top 10% and 5% tend to have higher ozone concentration levels.

Output 75.4.2 Quantiles of Ozone Levels in Pittsburgh, Pennsylvania



The quantile curves also show that high ozone concentration in 1989 had a longer duration than in 1990 and 1991. This is indicated by the wider spread of the quantile curves in 1989.

Example 75.5: Quantile Polynomial Regression for Salary Data

This example uses the data set from a university union survey of salaries of professors in 1991. The survey covered departments in U.S. colleges and universities that list programs in statistics. The goal here is to examine the relationship between faculty salaries and years of service.

The data include salaries and years of service for 459 professors. The scatter plot in Output 75.5.1 shows that the relationship is not linear, and a quadratic or cubic regression curve is appropriate. Output 75.5.1 shows a cubic curve.

The curve in Output 75.5.1 does not adequately describe the conditional salary distributions and how they change with length of service. Output 75.5.2 shows the 25th, 50th, and 75th percentiles for each number of years, which gives a better picture of the conditional distributions.

```
data salary;
  input Salaries Years @@;
  label Salaries='Salaries (1000s of dollars)';
datalines;
54.94   2  58.24   2  58.11   2  52.23   2  52.98    2  57.62    2
```

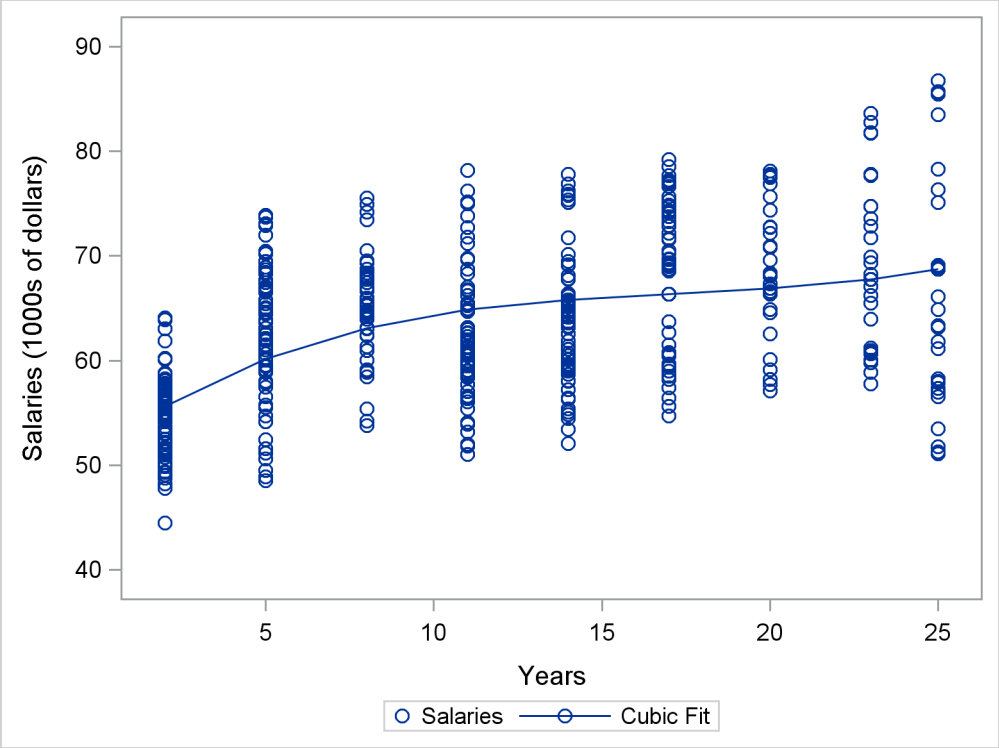
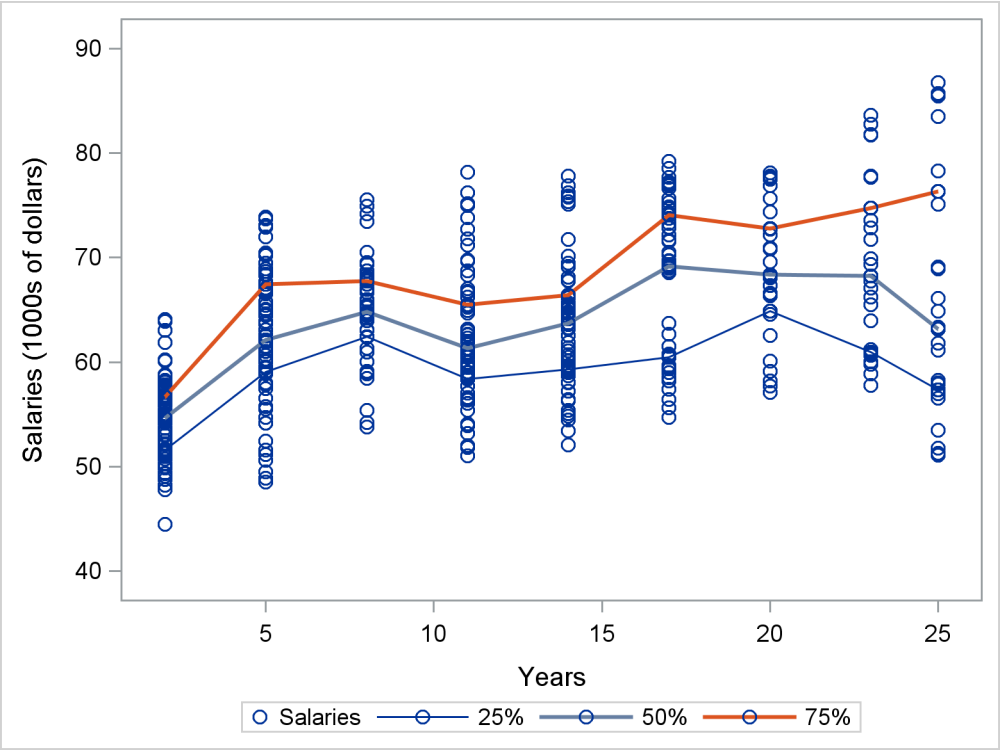
69.13  25  63.15  25  66.13  25
;
```

Output 75.5.1 Salary with Years as Professor: Cubit Fit



Output 75.5.2 Salary with Years as Professor: Sample Quantiles



These descriptive percentiles do not clearly show trends with length of service. The following statements use the QUANTREG procedure to obtain a smooth version by using polynomial quantile regression. The results are shown in Output 75.5.3 and Output 75.5.5.

```
ods graphics on;

proc quantreg data=salary ci=sparsity;
   model salaries = years years*years years*years*years
                    /quantile=0.25 0.5 0.75
                    plot=fitplot(showlimits);

test  years/QINTERACT;

run;
```

Output 75.5.3 displays the regression coefficients for the three quantiles, from which you can see that there is a difference among the estimated parameters of the variable *years* across the three quantiles. To test whether the difference is significant, you can specify the option QINTERACT in the TEST statement. Output 75.5.4 indicates that the difference is not significant with the p-value greater than 0.05.

Output 75.5.3 Regression Coefficients

3.4026	2	0.1825

The three fitted quantile curves with 95% confidence limits in the Output 75.5.5 clearly show that salary dispersion increases gradually with length of service. After 15 years, a salary over $70,000 is relatively high, while a salary less than $60,000 is relatively low. Percentile curves of this type are useful in medical science as reference curves; see Yu, Lu, and Stabder (2003).

Output 75.5.5 Salary with Years as Professor: Regression Quantiles

Chapter 76

The REG Procedure

Contents

Overview: REG Procedure

The REG procedure is one of many regression procedures in the SAS System. It is a general-purpose procedure for regression, while other SAS regression procedures provide more specialized applications.

Other SAS/STAT procedures that perform at least one type of regression analysis are the CATMOD, GENMOD, GLM, LOGISTIC, MIXED, NLIN, ORTHOREG, PROBIT, RSREG, and TRANSREG procedures. SAS/ETS procedures are specialized for applications in time series or simultaneous systems. These other SAS/STAT regression procedures are summarized in Chapter 4, "Introduction to Regression Procedures," which also contains an overview of regression techniques and defines many of the statistics computed by PROC REG and other regression procedures.

PROC REG provides the following capabilities:

- multiple MODEL statements
- nine model-selection methods
- interactive changes both in the model and the data used to fit the model
- linear equality restrictions on parameters
- tests of linear hypotheses and multivariate hypotheses
- collinearity diagnostics
- predicted values, residuals, studentized residuals, confidence limits, and influence statistics
- correlation or crossproduct input
- requested statistics available for output through output data sets
- ODS Graphics. For more information, see the section "ODS Graphics" on page 6472.

Nine model-selection methods are available in PROC REG. In the simplest method, PROC REG fits the complete model that you specify. The other eight methods involve various ways of including or excluding variables from the model. You specify these methods with the SELECTION= option in the MODEL statement.

The methods are identified in the following list and are explained in detail in the section "Model-Selection Methods" on page 6427.

NONE	no model selection. This is the default. The complete model specified in the MODEL statement is fit to the data.
FORWARD	forward selection. This method starts with no variables in the model and adds variables.
BACKWARD	backward elimination. This method starts with all variables in the model and deletes variables.
STEPWISE	stepwise regression. This is similar to the FORWARD method except that variables already in the model do not necessarily stay there.
MAXR	forward selection to fit the best one-variable model, the best two-variable model, and so on. Variables are switched so that R^2 is maximized.
MINR	similar to the MAXR method, except that variables are switched so that the increase in R^2 from adding a variable to the model is minimized.
RSQUARE	finds a specified number of models with the highest R^2 in a range of model sizes.
ADJRSQ	finds a specified number of models with the highest adjusted R^2 in a range of model sizes.
CP	finds a specified number of models with the lowest C_p in a range of model sizes.

Getting Started: REG Procedure

Simple Linear Regression

Suppose that a response variable Y can be predicted by a linear function of a regressor variable X. You can estimate β_0, the intercept, and β_1, the slope, in

$$Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$$

for the observations $i = 1, 2, \ldots, n$. Fitting this model with the REG procedure requires only the following MODEL statement, where y is the outcome variable and x is the regressor variable.

```
proc reg;
   model y=x;
run;
```

For example, you might use regression analysis to find out how well you can predict a child's weight if you know that child's height. The following data are from a study of nineteen children. Height and weight are measured for each child.

```
title 'Simple Linear Regression';
data Class;
   input Name $ Height Weight Age @@;
   datalines;
Alfred  69.0 112.5 14  Alice  56.5  84.0 13  Barbara 65.3  98.0 13

William 66.5 112.0 15
;
```

The equation of interest is

$$\text{Weight} = \beta_0 + \beta_1 \text{Height} + \epsilon$$

The variable Weight is the response or dependent variable in this equation, and β_0 and β_1 are the unknown parameters to be estimated. The variable Height is the regressor or independent variable, and ϵ is the unknown error. The following commands invoke the REG procedure and fit this model to the data.

```
ods graphics on;

proc reg;
   model Weight = Height;
run;

ods graphics off;
```

Figure 76.1 includes some information concerning model fit.

The F statistic for the overall model is highly significant (F=57.076, p<0.0001), indicating that the model explains a significant portion of the variation in the data.

The degrees of freedom can be used in checking accuracy of the data and model. The model degrees of freedom are one less than the number of parameters to be estimated. This model estimates two parameters, β_0 and β_1; thus, the degrees of freedom should be $2 - 1 = 1$. The corrected total degrees of freedom are always one less than the total number of observations in the data set, in this case $19 - 1 = 18$.

Several simple statistics follow the ANOVA table. The Root MSE is an estimate of the standard deviation of the error term. The coefficient of variation, or Coeff Var, is a unitless expression of the variation in the data. The R-square and Adj R-square are two statistics used in assessing the fit of the model; values close to 1 indicate a better fit. The R-square of 0.77 indicates that Height accounts for 77% of the variation in Weight.

Figure 76.1 ANOVA Table

Simple Linear Regression

The REG Procedure
Model: MODEL1
Dependent Variable: Weight

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	7193.24912	7193.24912	57.08	<.0001
Error	17	2142.48772	126.02869		
Corrected Total	18	9335.73684			

Root MSE	11.22625	R-Square	0.7705
Dependent Mean	100.02632	Adj R-Sq	0.7570
Coeff Var	11.22330		

The "Parameter Estimates" table in Figure 76.2 contains the estimates of β_0 and β_1. The table also contains the t statistics and the corresponding p-values for testing whether each parameter is significantly different from zero. The p-values ($t = -4.43$, $p = 0.0004$ and $t = 7.55$, $p < 0.0001$) indicate that the intercept and Height parameter estimates, respectively, are highly significant.

From the parameter estimates, the fitted model is

$$\text{Weight} = -143.0 + 3.9 \times \text{Height}$$

Figure 76.2 Parameter Estimates

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-143.02692	32.27459	-4.43	0.0004
Height	1	3.89903	0.51609	7.55	<.0001

If ODS Graphics is enabled, then PROC REG produces a variety of plots. Figure 76.3 shows a plot of the residuals versus the regressor and Figure 76.4 shows a panel of diagnostic plots.

Figure 76.3 Residuals vs. Regressor

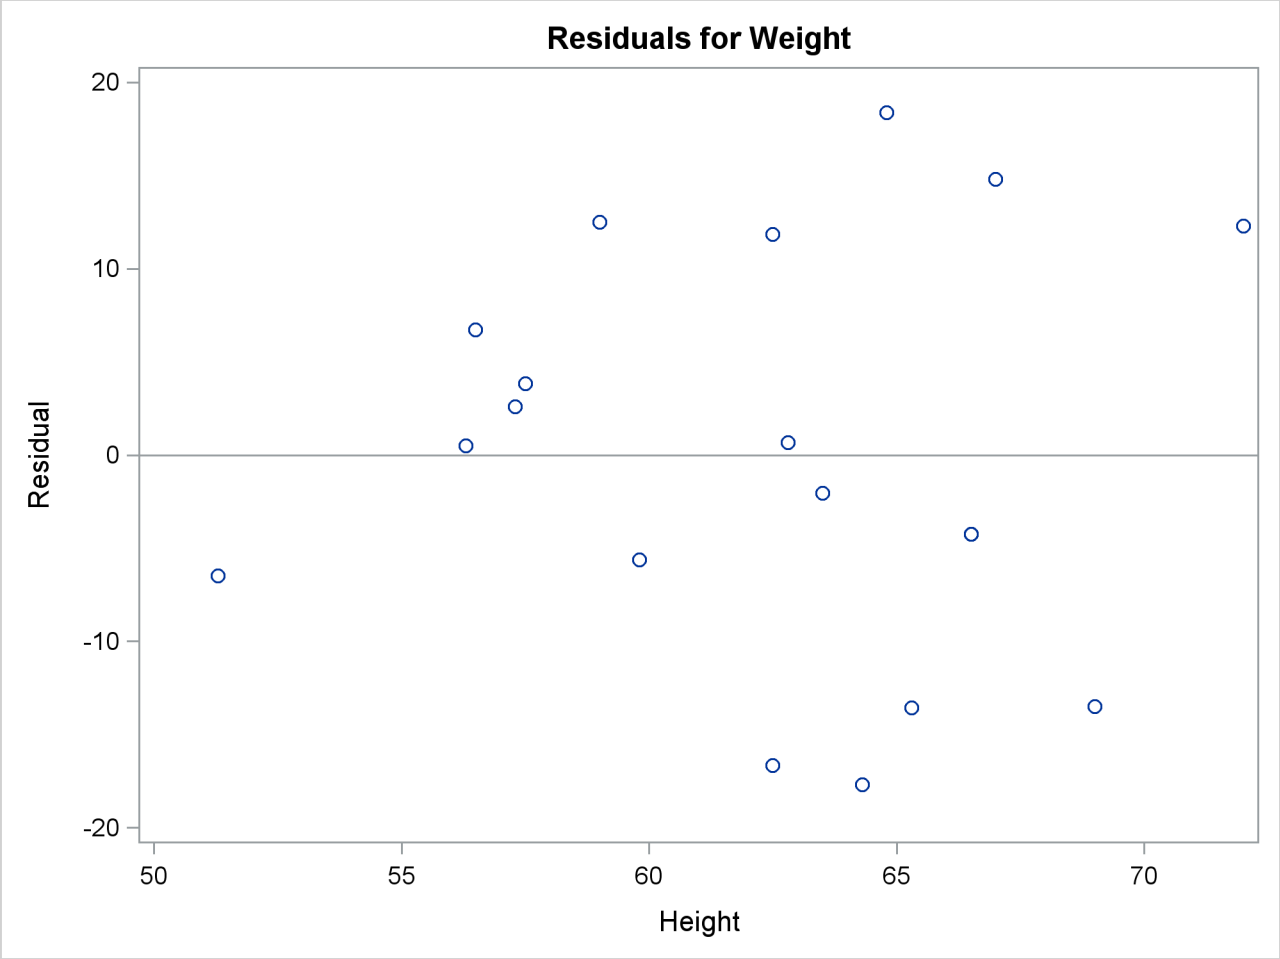

Figure 76.4 Fit Diagnostics

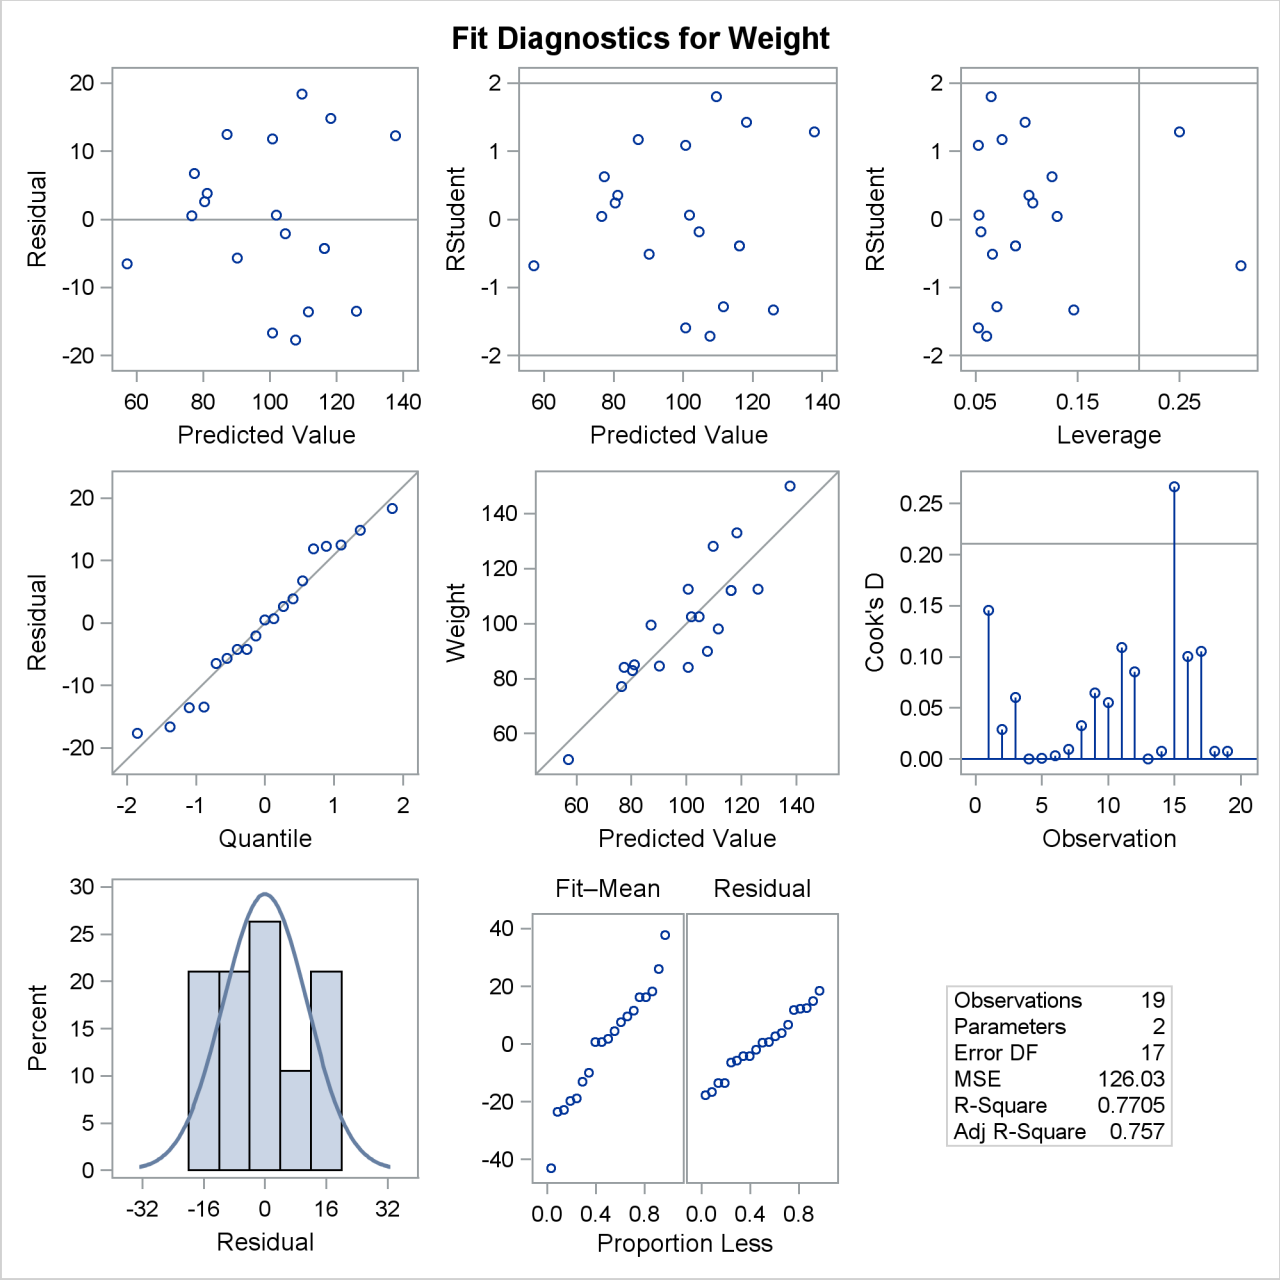

A trend in the residuals would indicate nonconstant variance in the data. The plot of residuals by predicted values in the upper-left corner of the diagnostics panel in Figure 76.4 might indicate a slight trend in the residuals; they appear to increase slightly as the predicted values increase. A fan-shaped trend might indicate the need for a variance-stabilizing transformation. A curved trend (such as a semicircle) might indicate the need for a quadratic term in the model. Since these residuals have no apparent trend, the analysis is considered to be acceptable.

Polynomial Regression

Consider a response variable Y that can be predicted by a polynomial function of a regressor variable X. You can estimate β_0, the intercept; β_1, the slope due to X; and β_2, the slope due to X^2, in

$$Y_i = \beta_0 + \beta_1 X_i + \beta_2 X_i^2 + \epsilon_i$$

for the observations $i = 1, 2, \ldots, n$.

Consider the following example on population growth trends. The population of the United States from 1790 to 2000 is fit to linear and quadratic functions of time. Note that the quadratic term, YearSq, is created in the DATA step; this is done since polynomial effects such as Year*Year cannot be specified in the MODEL statement in PROC REG. The data are as follows:

```
data USPopulation;
   input Population @@;
   retain Year 1780;
   Year       = Year+10;
   YearSq     = Year*Year;
   Population = Population/1000;
datalines;
3929 5308 7239 9638 12866 17069 23191 31443 39818 50155
62947 75994 91972 105710 122775 131669 151325 179323 203211
226542 248710 281422
;

ods graphics on;

proc reg data=USPopulation plots=ResidualByPredicted;
   var YearSq;
   model Population=Year / r clm cli;
run;
```

The DATA option ensures that the procedure uses the intended data set. Any variable that you might add to the model but that is not included in the first MODEL statement must appear in the VAR statement.

The "Analysis of Variance" and "Parameter Estimates" tables are displayed in Figure 76.5.

Figure 76.5 ANOVA Table and Parameter Estimates

The REG Procedure
Model: MODEL1
Dependent Variable: Population

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	146869	146869	228.92	<.0001
Error	20	12832	641.58160		
Corrected Total	21	159700			

Root MSE	25.32946	R-Square	0.9197
Dependent Mean	94.64800	Adj R-Sq	0.9156
Coeff Var	26.76175		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-2345.85498	161.39279	-14.54	<.0001
Year	1	1.28786	0.08512	15.13	<.0001

The Model F statistic is significant (F=228.92, p<0.0001), indicating that the model accounts for a significant portion of variation in the data. The R-square indicates that the model accounts for 92% of the variation in population growth. The fitted equation for this model is

$$\text{Population} = -2345.85 + 1.29 \times \text{Year}$$

In the MODEL statement, three options are specified: R requests a residual analysis to be performed, CLI requests 95% confidence limits for an individual value, and CLM requests these limits for the expected value of the dependent variable. You can request specific $100(1-\alpha)\%$ limits with the ALPHA= option in the PROC REG or MODEL statement.

Figure 76.6 shows the "Output Statistics" table. The residual, its standard error, and the studentized residuals are displayed for each observation. The studentized residual is the residual divided by its standard error. The magnitude of each studentized residual is shown in a print plot. Studentized residuals follow a t distribution and can be used to identify outlying or extreme observations. Asterisks (*) extending beyond the dashed lines indicate that the residual is more than three standard errors from zero. Many observations having absolute studentized residuals greater than two might indicate an inadequate model. Cook's D is a measure of the change in the predicted values upon deletion of that observation from the data set; hence, it measures the influence of the observation on the estimated regression coefficients.

20	23.666	0.948	|*	0.065
21	23.389	1.356	|**	0.159
22	23.077	2.234	|****	0.511

Figure 76.7 shows the residual statistics table. A fairly close agreement between the PRESS statistic (see Table 76.8) and the Sum of Squared Residuals indicates that the MSE is a reasonable measure of the predictive accuracy of the fitted model (Neter, Wasserman, and Kutner 1990).

Figure 76.7 Residual Statistics

Sum of Residuals	0
Sum of Squared Residuals	12832
Predicted Residual SS (PRESS)	16662

Graphical representations are very helpful in interporting the information in the "Output Statistics" table. When ODS Graphics is enabled, the REG procedure produces a default set of diagnostic plots that are appropriate for the requested analysis.

Figure 76.8 displays a panel of diagnostics plots. These diagnostics indicate an inadequate model:

- The plots of residual and studentized residual versus predicted value show a clear quadratic pattern.
- The plot of studentized residual versus leverage seems to indicate that there are two outlying data points. However, the plot of Cook's D distance versus observation number reveals that these two points are just the data points for the endpoint years 1790 and 2000. These points show up as apparent outliers because the departure of the linear model from the underlying quadratic behavior in the data shows up most strongly at these endpoints.
- The normal quantile plot of the residuals and the residual histogram are not consistent with the assumption of Gaussian errors. This occurs as the residuals themselves still contain the quadratic behavior that is not captured by the linear model.
- The plot of the dependent variable versus the predicted value exhibits a quadratic form around the 45-degree line that represents a perfect fit.
- The "Residual-Fit" (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals shows that the spread in the residuals is no greater than the spread in the centered fit. For inappropriate models, the spread of the residuals in such a plot is often greater than the spread of the centered fit. In this case, the RF plot shows that the linear model does indeed capture the increasing trend in the data, and hence accounts for much of the variation in the response.

Figure 76.8 Diagnostics Panel

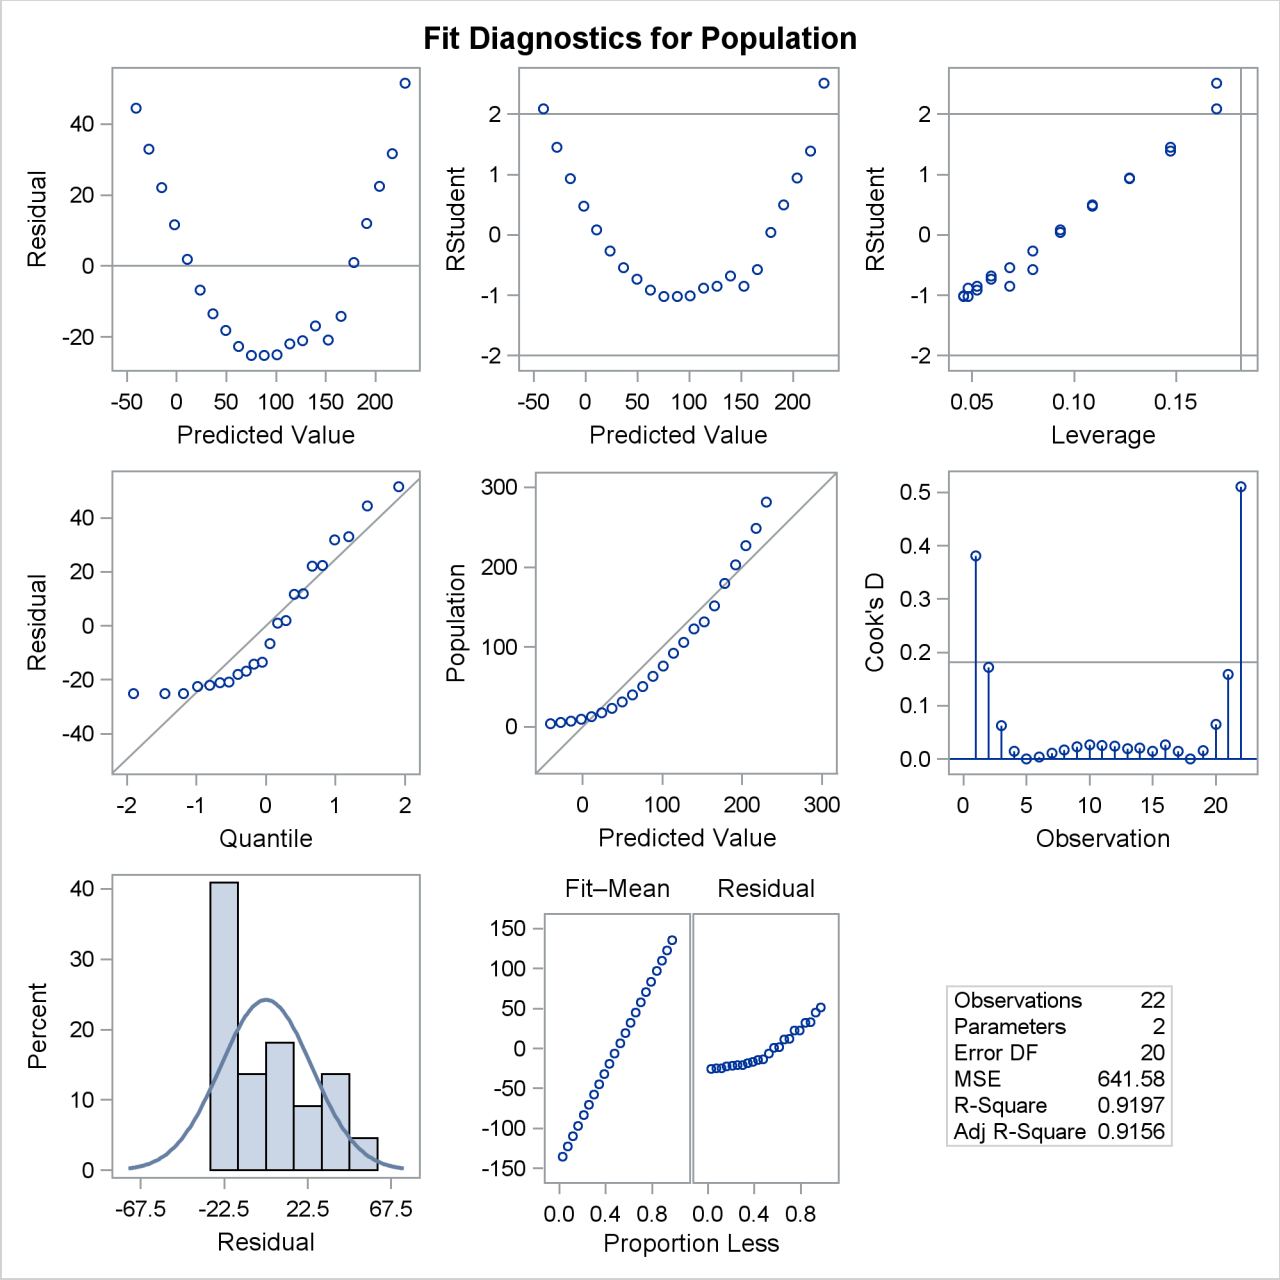

Figure 76.9 shows a plot of residuals versus Year. Again you can see the quadratic pattern that strongly indicates that a quadratic term should be added to the model.

Figure 76.9 Residual Plot

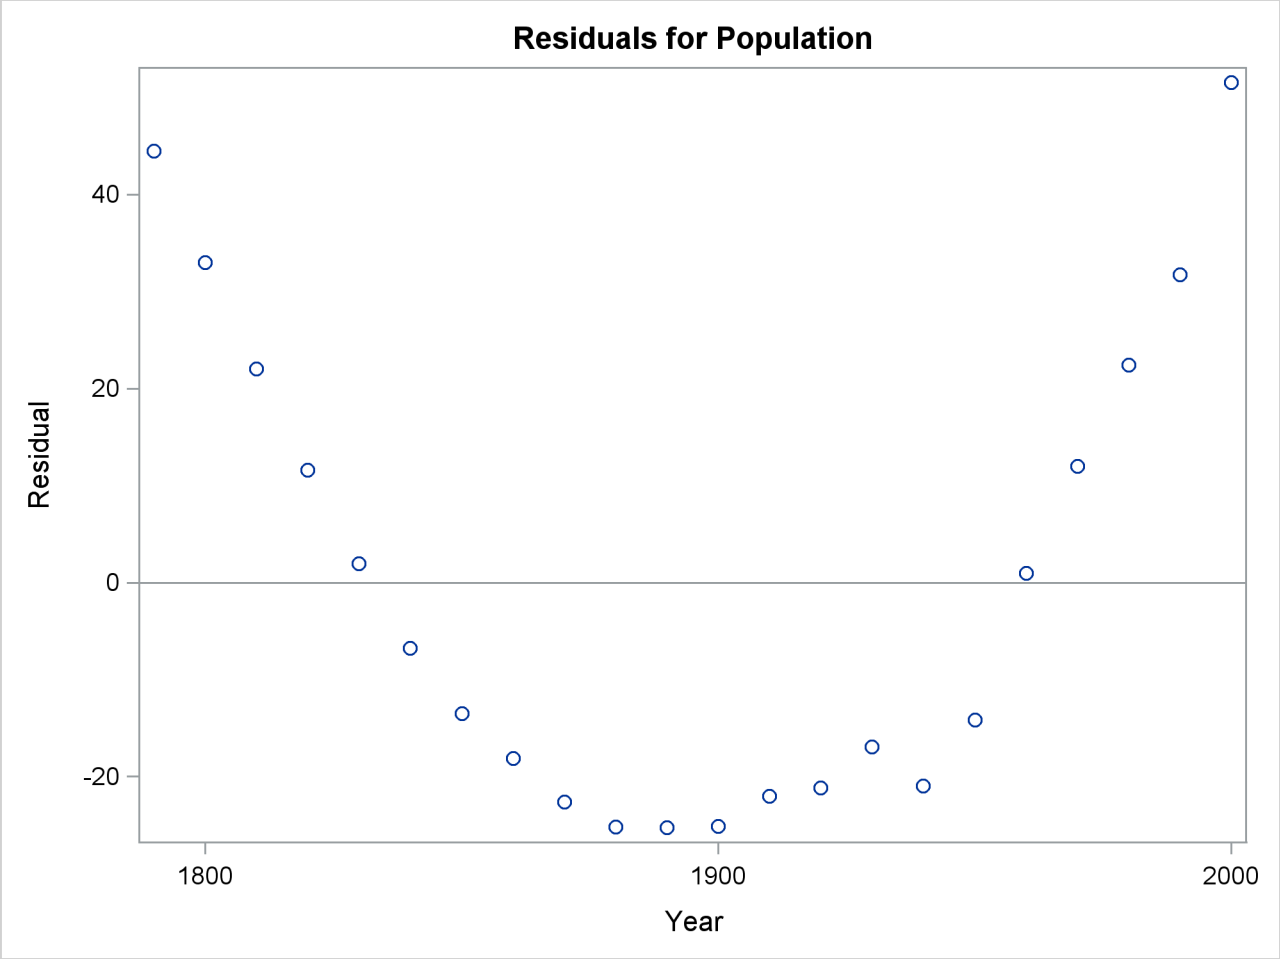

Figure 76.10 shows the "FitPlot" consisting of a scatter plot of the data overlaid with the regression line, and 95% confidence and prediction limits. Note that this plot also indicates that the model fails to capture the quadratic nature of the data. This plot is produced for models containing a single regressor. You can use the ALPHA= option in the model statement to change the significance level of the confidence band and prediction limits.

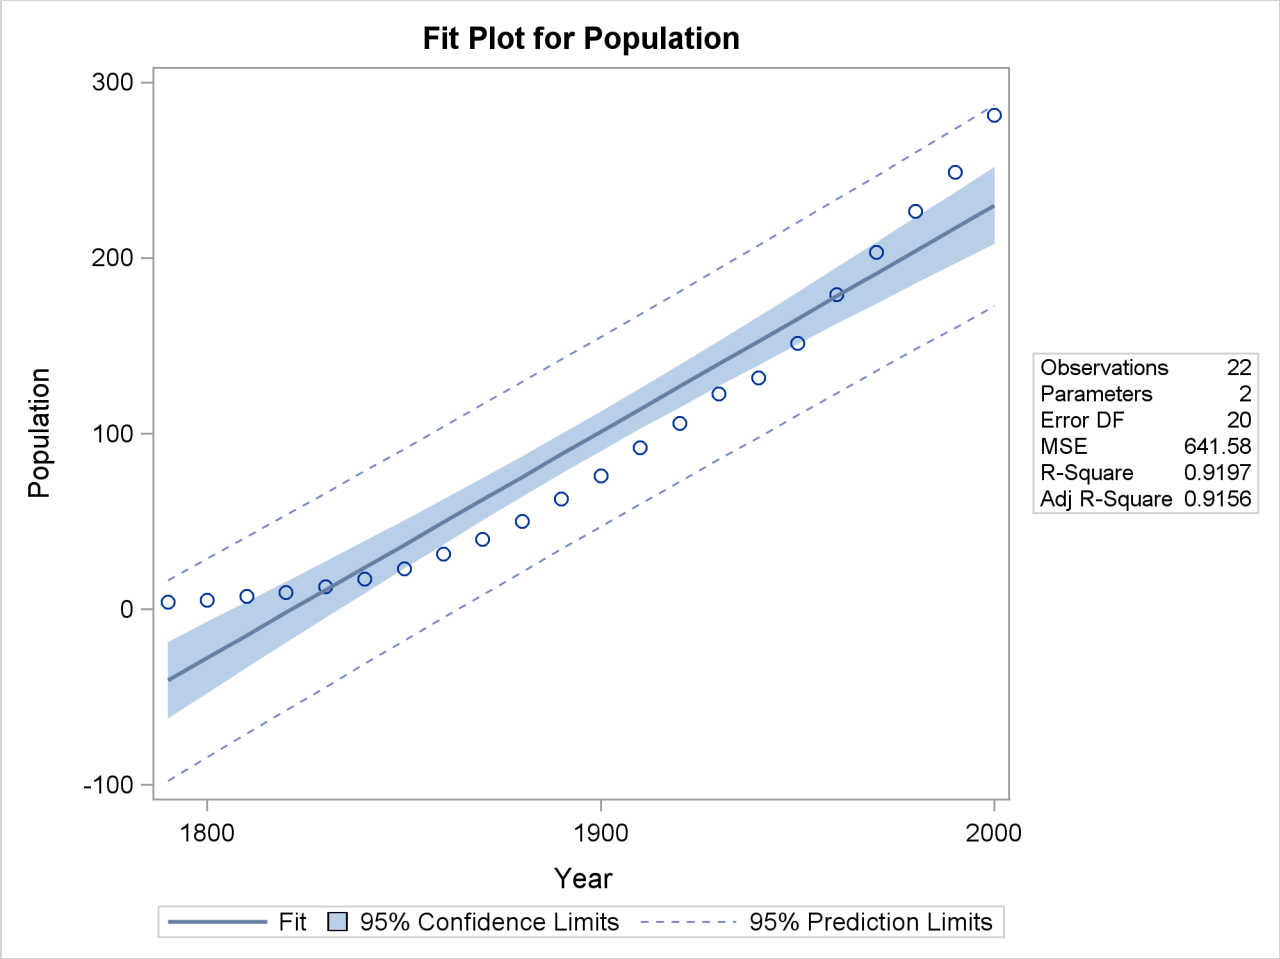
Figure 76.10 Fit Plot



These default plots provide strong evidence that the Yearsq needs to be added to the model. You can use the interactive feature of PROC REG to do this by specifying the following statements:

```
add YearSq;
print;
run;
```

The ADD statement requests that YearSq be added to the model, and the PRINT command causes the model to be refit and displays the ANOVA and parameter estimates for the new model. The print statement also produces updated ODS graphical displays.

Figure 76.11 displays the ANOVA table and parameter estimates for the new model.

Figure 76.11 ANOVA Table and Parameter Estimates

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	159529	79765	8864.19	<.0001
Error	19	170.97193	8.99852		
Corrected Total	21	159700			

Root MSE	2.99975	R-Square	0.9989
Dependent Mean	94.64800	Adj R-Sq	0.9988
Coeff Var	3.16938		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	21631	639.50181	33.82	<.0001
Year	1	-24.04581	0.67547	-35.60	<.0001
YearSq	1	0.00668	0.00017820	37.51	<.0001

The overall F statistic is still significant (F=8864.19, p<0.0001). The R-square has increased from 0.9197 to 0.9989, indicating that the model now accounts for 99.9% of the variation in Population. All effects are significant with p<0.0001 for each effect in the model.

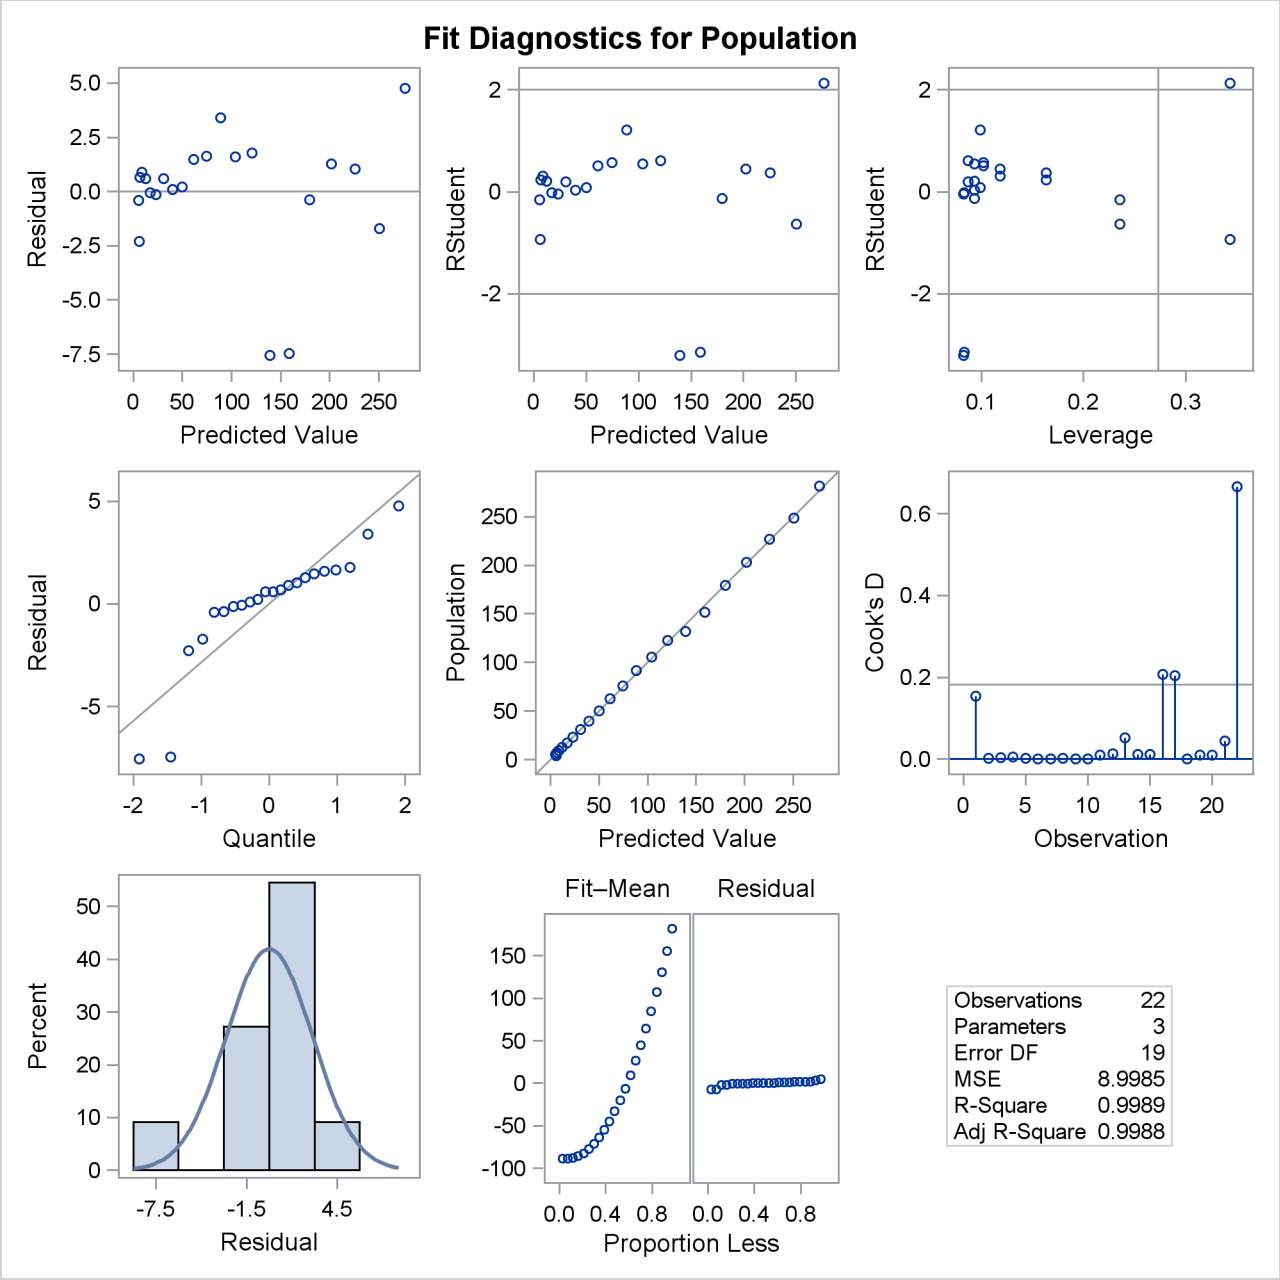
The fitted equation is now

$$\text{Population} = 21631 - 24.046 \times \text{Year} + 0.0067 \times \text{Yearsq}$$

Figure 76.12 show the panel of diagnostics for this quadratic polynomial model. These diagnostics indicate that this model is considerably more successful than the corresponding linear model:

- The plots of residuals and studentized residuals versus predicted values exhibit no obvious patterns.
- The points on the plot of the dependent variable versus the predicted values lie along a 45-degree line, indicating that the model successfully predicts the behavior of the dependent variable.
- The plot of studentized residual versus leverage shows that the years 1790 and 2000 are leverage points with 2000 showing up as an outlier. This is confirmed by the plot of Cook's D distance versus observation number. This suggests that while the quadratic model fits the current data well, the model might not be quite so successful over a wider range of data. You might want to investigate whether the population trend over the last couple of decades is growing slightly faster than quadratically.

Figure 76.12 Diagnostics Panel



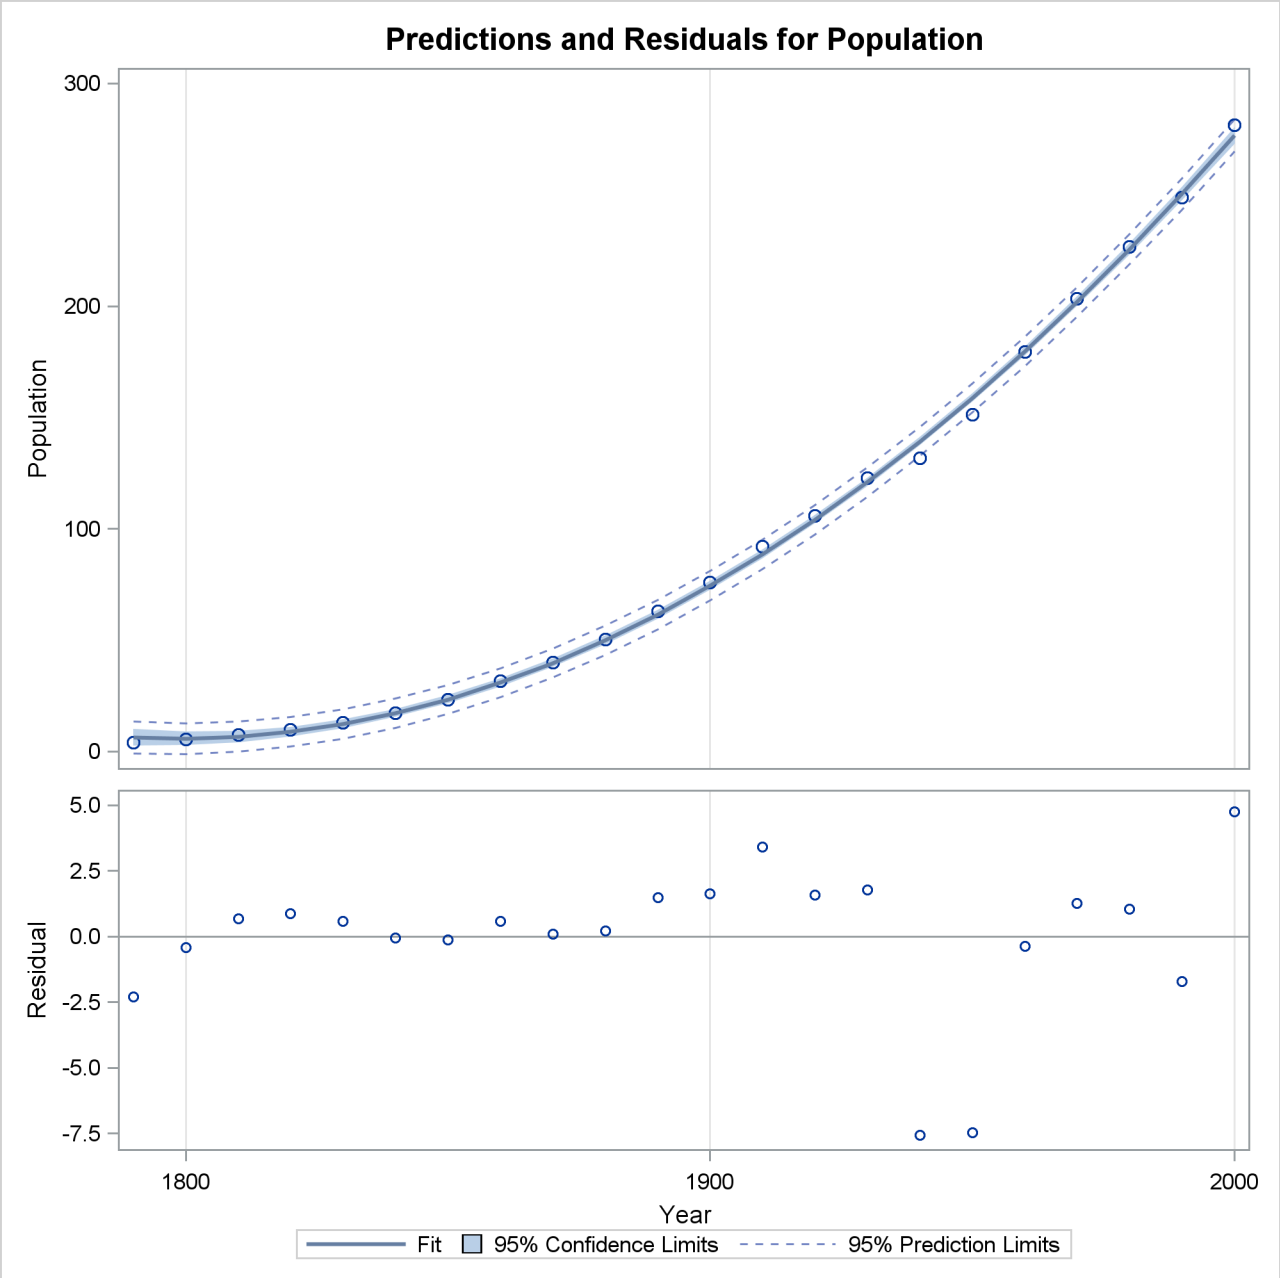
When a model contains more than one regressor, PROC REG does not produce a fit plot. However, when all the regressors in the model are functions of a single variable, it is appropriate to plot predictions and residuals as a function of that variable. You request such plots by using the PLOTS=PREDICTIONS option in the PROC REG statement, as the following code illustrates:

```
proc reg data=USPopulation plots=predictions(X=Year);
   model Population=Year Yearsq;
quit;
```

```
ods graphics off;
```

Figure 76.13 shows the data, predictions, and residuals by Year. These plots confirm that the quadratic polynomial model successfully model the growth in U.S. population between the years 1780 and 2000.

Figure 76.13 Predictions and Residuals by Year



To complete an analysis of these data, you might want to examine influence statistics and, since the data are essentially time series data, examine the Durbin-Watson statistic.

Using PROC REG Interactively

The REG procedure can be used interactively. After you specify a model with a MODEL statement and run PROC REG with a RUN statement, a variety of statements can be executed without reinvoking PROC REG.

The section "Interactive Analysis" on page 6423 describes which statements can be used interactively. These interactive statements can be executed singly or in groups by following the single statement or group of statements with a RUN statement. Note that the MODEL statement can be repeated. This is an important difference from the GLM procedure, which supports only one MODEL statement.

If you use PROC REG interactively, you can end the REG procedure with a DATA step, another PROC step, an ENDSAS statement, or a QUIT statement. The syntax of the QUIT statement is

```
quit;
```

When you are using PROC REG interactively, additional RUN statements do not end PROC REG but tell the procedure to execute additional statements.

When a BY statement is used with PROC REG, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure.

When you use PROC REG interactively, you can fit a model, perform diagnostics, and then refit the model and perform diagnostics on the refitted model. Most of the interactive statements implicitly refit the model; for example, if you use the ADD statement to add a variable to the model, the regression equation is automatically recomputed. The two exceptions to this automatic recomputing are the PAINT and REWEIGHT statements. These two statements do not cause the model to be refitted. To refit the model, you can follow these statements either with a REFIT statement, which causes the model to be explicitly recomputed, or with another interactive statement that causes the model to be implicitly recomputed.

Syntax: REG Procedure

The following statements are available in PROC REG:

PROC REG < *options* > ;
< **label:** >**MODEL** *dependents*=< *regressors* > < / *options* > ;
BY *variables* ;
FREQ *variable* ;
ID *variables* ;
VAR *variables* ;
WEIGHT *variable* ;
ADD *variables* ;
DELETE *variables* ;
< **label:** >**MTEST** < *equation, . . . ,equation* > < / *options* > ;
OUTPUT < **OUT=***SAS-data-set* >< *keyword=names* > < . . . *keyword=names* > ;
PAINT < *condition* | **ALLOBS** > < / *options* > | < **STATUS** | **UNDO** > ;
RESTRICT *equation, . . . ,equation* ;
REWEIGHT < *condition* | **ALLOBS** > < / *options* > | < **STATUS** | **UNDO** > ;
PLOT < *yvariable*xvariable* > < *=symbol* > < . . . *yvariable*xvariable* > < *=symbol* > < / *options* > ;
PRINT < *options* > < **ANOVA** > < **MODELDATA** > ;
REFIT ;
RESTRICT *equation, . . . ,equation* ;
REWEIGHT < *condition* | **ALLOBS** > < / *options* > | < **STATUS** | **UNDO** > ;
< **label:** >**TEST** *equation,*< *,. . . ,equation* > < / *option* > ;

Although there are numerous statements and options available in PROC REG, many analyses use only a few of them. Often you can find the features you need by looking at an example or by scanning this section.

In the preceding list, brackets denote optional specifications, and vertical bars denote a choice of one of the specifications separated by the vertical bars. In all cases, *label* is optional.

The PROC REG statement is required. To fit a model to the data, you must specify the MODEL statement. If you want to use only the options available in the PROC REG statement, you do not need a MODEL statement, but you must use a VAR statement. (See the example in the section "OUTSSCP= Data Sets" on page 6422.) Several MODEL statements can be used. In addition, several MTEST, OUTPUT, PAINT, PLOT, PRINT, RESTRICT, and TEST statements can follow each MODEL statement.

The ADD, DELETE, and REWEIGHT statements are used interactively to change the regression model and the data used in fitting the model. The ADD, DELETE, MTEST, OUTPUT, PLOT, PRINT, RESTRICT, and TEST statements implicitly refit the model; changes made to the model are reflected in the results from these statements. The REFIT statement is used to refit the model explicitly and is most helpful when it follows PAINT and REWEIGHT statements, which do not refit the model.

The BY, FREQ, ID, VAR, and WEIGHT statements are optionally specified once for the entire PROC step, and they must appear before the first RUN statement.

When a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as an input data set to PROC REG, statements and options that require the original data are not available. Specifically, the OUTPUT, PAINT, PLOT, and REWEIGHT statements and the MODEL and PRINT statement options P, R, CLM, CLI, DW, DWPROB, INFLUENCE, PARTIAL, and PARTIALDATA are disabled.

You can specify the following statements with the REG procedure in addition to the PROC REG statement:

ADD	adds independent variables to the regression model.
BY	specifies variables to define subgroups for the analysis.
DELETE	deletes independent variables from the regression model.
FREQ	specifies a frequency variable.
ID	names a variable to identify observations in the tables.
MODEL	specifies the dependent and independent variables in the regression model, requests a model selection method, displays predicted values, and provides details on the estimates (according to which options are selected).
MTEST	performs multivariate tests across multiple dependent variables.
OUTPUT	creates an output data set and names the variables to contain predicted values, residuals, and other diagnostic statistics.
PAINT	paints points in scatter plots.
PLOT	generates scatter plots.
PRINT	displays information about the model and can reset options.
REFIT	refits the model.
RESTRICT	places linear equality restrictions on the parameter estimates.
REWEIGHT	excludes specific observations from analysis or changes the weights of observations used.
TEST	performs an F test on linear functions of the parameters.
VAR	lists variables for which crossproducts are to be computed, variables that can be interactively added to the model, or variables to be used in scatter plots.
WEIGHT	declares a variable to weight observations.

PROC REG Statement

PROC REG < *options* > **;**

The PROC REG statement is required. If you want to fit a model to the data, you must also use a MODEL statement. If you want to use only the PROC REG options, you do not need a MODEL statement, but you must use a VAR statement. If you do not use a MODEL statement, then the COVOUT and OUTEST= options are not available.

Table 76.1 lists the options you can use with the PROC REG statement. Note that any option specified in the PROC REG statement applies to all MODEL statements.

Table 76.1 PROC REG Statement Options

Option	Description
Data Set Options	
DATA=	names a data set to use for the regression
OUTEST=	outputs a data set that contains parameter estimates and other model fit summary statistics
OUTSSCP=	outputs a data set that contains sums of squares and crossproducts
COVOUT	outputs the covariance matrix for parameter estimates to the OUTEST= data set
EDF	outputs the number of regressors, the error degrees of freedom, and the model R^2 to the OUTEST= data set
OUTSEB	outputs standard errors of the parameter estimates to the OUTEST= data set
OUTSTB	outputs standardized parameter estimates to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
OUTVIF	outputs the variance inflation factors to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
PCOMIT=	performs incomplete principal component analysis and outputs estimates to the OUTEST= data set
PRESS	outputs the PRESS statistic to the OUTEST= data set
RIDGE=	performs ridge regression analysis and outputs estimates to the OUTEST= data set
RSQUARE	same effect as the EDF option
TABLEOUT	outputs standard errors, confidence limits, and associated test statistics of the parameter estimates to the OUTEST= data set
ODS Graphics Options	
PLOTS=	produces ODS graphical displays
Traditional Graphics Options	
ANNOTATE=	specifies an annotation data set
GOUT=	specifies the graphics catalog in which graphics output is saved
Display Options	
CORR	displays correlation matrix for variables listed in MODEL and VAR statements

Table 76.1 *continued*

Option	Description
SIMPLE	displays simple statistics for each variable listed in MODEL and VAR statements
USSCP	displays uncorrected sums of squares and crossproducts matrix
ALL	displays all statistics (CORR, SIMPLE, and USSCP)
NOPRINT	suppresses output
LINEPRINTER	creates printer plots
Other Options	
ALPHA=	sets significance value for confidence and prediction intervals and tests
SINGULAR=	sets criterion for checking for singularity

Following are explanations of the options that you can specify in the PROC REG statement (in alphabetical order).

Note that any option specified in the PROC REG statement applies to all MODEL statements.

ALL

requests the display of many tables. Using the ALL option in the PROC REG statement is equivalent to specifying ALL in every MODEL statement. The ALL option also implies the CORR, SIMPLE, and USSCP options.

ALPHA=*number*

sets the significance level used for the construction of confidence intervals. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the PROC REG option TABLEOUT; the MODEL options CLB, CLI, and CLM; the OUTPUT statement keywords LCL, LCLM, UCL, and UCLM; the PLOT statement keywords LCL., LCLM., UCL., and UCLM.; and the PLOT statement options CONF and PRED.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an input data set containing annotate variables, as described in *SAS/GRAPH: Reference*. You can use this data set to add features to the traditional graphics that you request with the PLOT statement. Features provided in this data set are applied to all plots produced in the current run of PROC REG. To add features to individual plots, use the ANNOTATE= option in the PLOT statement. This option cannot be used if the LINEPRINTER option is specified.

CORR

displays the correlation matrix for all variables listed in the MODEL or VAR statement.

COVOUT

outputs the covariance matrices for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is also specified. See the section "OUTEST= Data Set" on page 6416.

DATA=*SAS-data-set*

names the SAS data set to be used by PROC REG. The data set can be an ordinary SAS data set or

a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set. If one of these special TYPE= data sets is used, the OUTPUT, PAINT, PLOT, and REWEIGHT statements, ODS Graphics, and some options in the MODEL and PRINT statements are not available. See Appendix A, "Special SAS Data Sets," for more information about TYPE= data sets. If the DATA= option is not specified, PROC REG uses the most recently created SAS data set.

EDF

outputs the number of regressors in the model excluding and including the intercept, the error degrees of freedom, and the model R^2 to the OUTEST= data set.

GOUT=*graphics-catalog*

specifies the graphics catalog in which traditional graphics output is saved. The default *graphics-catalog* is WORK.GSEG. The GOUT= option cannot be used if the LINEPRINTER option is specified.

LINEPRINTER | LP

creates printer plots. If you do not specify this option, requested plots are created on a high-resolution graphics device. See the PLOTS= option for information about using ODS graphics to create modern statistical graphics.

NOPRINT

suppresses the normal display of results. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, "Using the Output Delivery System," for more information.

OUTEST=*SAS-data-set*

requests that parameter estimates and optional model fit summary statistics be output to this data set. See the section "OUTEST= Data Set" on page 6416 for details. If you want to create a permanent SAS data set, you must specify a two-level name (refer to the section "SAS Files" in *SAS Language Reference: Concepts* for more information about permanent SAS data sets).

OUTSEB

outputs the standard errors of the parameter estimates to the OUTEST= data set. The value SEB for the variable _TYPE_ identifies the standard errors. If the RIDGE= or PCOMIT= option is specified, additional observations are included and identified by the values RIDGESEB and IPCSEB, respectively, for the variable _TYPE_. The standard errors for ridge regression estimates and IPC estimates are limited in their usefulness because these estimates are biased. This option is available for all model selection methods except RSQUARE, ADJRSQ, and CP.

OUTSSCP=*SAS-data-set*

requests that the sums of squares and crossproducts matrix be output to this TYPE=SSCP data set. See the section "OUTSSCP= Data Sets" on page 6422 for details. If you want to create a permanent SAS data set, you must specify a two-level name (refer to the section "SAS Files" in *SAS Language Reference: Concepts* for more information about permanent SAS data sets).

OUTSTB

outputs the standardized parameter estimates as well as the usual estimates to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The values RIDGESTB and IPCSTB for the variable _TYPE_ identify ridge regression estimates and IPC estimates, respectively.

OUTVIF

outputs the variance inflation factors (VIF) to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The factors are the diagonal elements of the inverse of the correlation matrix of regressors as adjusted by ridge regression or IPC analysis. These observations are identified in the output data set by the values RIDGEVIF and IPCVIF for the variable _TYPE_.

PCOMIT=*list*

requests an incomplete principal component (IPC) analysis for each value *m* in the list. The procedure computes parameter estimates by using all but the last *m* principal components. Each value of *m* produces a set of IPC estimates, which are output to the OUTEST= data set. The values of *m* are saved by the variable _PCOMIT_, and the value of the variable _TYPE_ is set to IPC to identify the estimates. Only nonnegative integers can be specified with the PCOMIT= option.

If you specify the PCOMIT= option, RESTRICT statements are ignored.

PLOTS <(*global-plot-options***)> <= *plot-request* <(***options***)>>**

PLOTS <(*global-plot-options***)> <= (***plot-request* <(***options***)>** **<... *plot-request* <(***options***)>>)>**

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots        = none
plots        = diagnostics(unpack)
plots        = (all fit(stats)=none)
plots(label) = (rstudentbyleverage cooksd)
plots(only)  = (diagnostics(stats=all) fit(nocli stats=(aic sbc)
```

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;

proc reg;
   model y = x1-x10;
run;

proc reg plots=diagnostics(stats=(default aic sbc));
   model y = x1-x10;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC REG produces a default set of plots. Table 76.2 lists the default set of plots produced.

Table 76.2 Default Graphs Produced

Plot	Conditional On
DiagnosticsPanel	Unconditional
ResidualPlot	Unconditional
FitPlot	Model with one regressor (excluding intercept)
PartialPlot	PARTIAL option specified in MODEL statement
RidgePanel	RIDGE= option specified in PROC REG or MODEL statement

For models with multiple dependent variables, separate plots are produced for each dependent variable. For jobs with more than one MODEL statement, plots are produced for each model statement.

The *global-options* apply to all plots generated by the REG procedure, unless it is altered by a *specific-plot-option*. The following global plot options are available:

LABEL
specifies that the LABEL option be applied to each plot that supports a LABEL option. See the descriptions of the specific plots for details.

MAXPOINTS=NONE | *number*
specifies that plots with elements that require processing more than *number* points be suppressed. The default is MAXPOINTS=5000. This cutoff is ignored if you specify MAXPOINTS=NONE.

MODELLABEL
requests that the model label be displayed in the upper-left corner of all plots. This option is useful when you use more than one MODEL statement.

ONLY
suppress the default plots. Only plots specifically requested are displayed.

STATS=ALL | **DEFAULT** | **NONE** | (*plot-statistics*)
requests statistics that are included on the fit plot and diagnostics panel. Table 76.3 lists the statistics that you can request. STATS=ALL requests all these statistics; STATS=NONE suppresses them.

Table 76.3 Statistics Available on Plots

Keyword	Default	Description
ADJRSQ	x	adjusted R-square
AIC		Akaike's information criterion
BIC		Sawa's Bayesian information criterion
CP		Mallows' C_p statistic
COEFFVAR		coefficient of variation
DEPMEAN		mean of dependent
DEFAULT		all default statistics

Table 76.3 *continued*

Keyword	Default	Description
EDF	x	error degrees of freedom
GMSEP		estimated MSE of prediction, assuming multivariate normality
JP		final prediction error
MSE	x	mean squared error
NOBS	x	number of observations used
NPARM	x	number of parameters in the model (including the intercept)
PC		Amemiya's prediction criterion
RSQUARE	x	R-square
SBC		SBC statistic
SP		SP statistic
SSE		error sum of squares

You request statistics in addition to the default set by including the keyword DEFAULT in the *plot-statistics* list.

UNPACK
suppresses paneling.

USEALL
specifies that predicted values at data points with missing dependent variable(s) be included on appropriate plots. By default, only points used in constructing the SSCP matrix appear on plots.

The following specific plots are available:

ADJRSQ < (*adjrsq-options*) >
displays the adjusted R-square values for the models examined when you request variable selection with the SELECTION= option in the MODEL statement.

The following *adjrsq-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL
requests that the model number corresponding to the one displayed in the "Subset Selection Summary" table be used to label the model with the largest adjusted R-square statistic at each value of the number of parameters.

LABELVARS
requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the largest adjusted R-square statistic at each value of the number of parameters.

AIC < (*aic-options*) >
displays Akaike's information criterion (AIC) for the models examined when you request variable selection with the SELECTION= option in the MODEL statement.

The following *aic-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL
requests that the model number corresponding to the one displayed in the "Subset Selection Summary" table be used to label the model with the smallest AIC statistic at each value of the number of parameters.

LABELVARS
requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the smallest AIC statistic at each value of the number of parameters.

ALL
produces all appropriate plots.

BIC <(*bic-options*)>
displays Sawa's Bayesian information criterion (BIC) for the models examined when you request variable selection with the SELECTION= option in the MODEL statement.

The following *bic-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL
requests that the model number corresponding to the one displayed in the "Subset Selection Summary" table be used to label the model with the smallest BIC statistic at each value of the number of parameters.

LABELVARS
requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the smallest BIC statistic at each value of the number of parameters.

COOKSD <(LABEL)>
plots Cook's D statistic by observation number. Observations whose Cook's D statistic lies above the horizontal reference line at value $4/n$, where n is the number of observations used, are deemed to be influential (Rawlings 1998). If you specify the LABEL option, then points deemed as influential are labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables in one or more ID statements, then the first ID variable you specify is used for the labeling.

CP <(*cp-options*)>
displays Mallow's C_p statistic for the models examined when you request variable selection with the SELECTION= option in the MODEL statement. For models where you request the RSQUARE, ADJRSQ, or CP selection, reference lines corresponding to the equations $C_p = p$ and $C_p = 2p - p_{full}$, where p_{full} is the number of parameters in the full model (excluding the intercept) and p is the number of parameters in the subset model (including the intercept), are displayed on the plot of C_p versus p. For the purpose of parameter estimation, Hocking (1976) suggests selecting a model where $C_p \leq 2p - p_{full}$. For the purpose of prediction,

Hocking suggests the criterion $C_p \leq p$. Mallows (1973) suggests that all subset models with C_p small and near p be considered for further study.

The following *cp-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL
requests that the model number corresponding to the one displayed in the "Subset Selection Summary" table be used to label the model with the smallest C_p statistic at each value of the number of parameters.

LABELVARS
requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the smallest C_p statistic at each value of the number of parameters.

CRITERIA | CRITERIONPANEL < (*criteria-options*) >
produces a panel of fit criteria for the models examined when you request variable selection with the SELECTION= option in the MODEL statement. The fit criteria displayed are R-square, adjusted R-square, Mallow's C_p, Akaike's information criterion (AIC), Sawa's Bayesian information criterion (BIC), and Schwarz's Bayesian information criterion (SBC). For SELECTION=RSQUARE, SELECTION=ADJRSQ, or SELECTION=CP, scatter plots of these statistics versus the number of parameters (including the intercept) are displayed. For other selection methods, line plots of these statistics as function of the selection step number are displayed.

The following *criteria-options* are available:

LABEL
requests that the model number corresponding to the one displayed in the "Subset Selection Summary" table be used to label the best model at each value of the number of parameters. This option applies only to the RSQUARE, ADJRSQ, and CP selection methods.

LABELVARS
requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the best model at each value of the number of parameters. Since these labels are typically long, LABELVARS is supported only when the panel is unpacked. This option applies only to the RSQUARE, ADJRSQ, and CP selection methods.

UNPACK
suppresses paneling. Separate plots are produced for each of the six fit statistics. For models where you request the RSQUARE, ADJRSQ, or CP selection, two reference lines corresponding to the equations $C_p = p$ and $C_p = 2p - p_{full}$, where p_{full} is the number of parameters in the full model (excluding the intercept) and p is the number of parameters in the subset model (including the intercept), are displayed on the plot of C_p versus p. For the purpose of parameter estimation, Hocking (1976) suggests selecting a model where $C_p \leq 2p - p_{full}$. For the purpose of prediction, Hocking suggests the criterion $C_p \leq p$. Mallows (1973) suggests that all subset models with C_p small and near p be considered for further study.

DFBETAS < (*DFBETAS-options*) >

produces panels of DFBETAS by observation number for the regressors in the model. Note that each panel contains at most six plots, and multiple panels are used in the case where there are more than six regressors (including the intercept) in the model. Observations whose DFBETAS' statistics for a regressor are greater in magnitude than $2/\sqrt{n}$, where n is the number of observations used, are deemed to be influential for that regressor (Rawlings 1998).

The following *DFBETAS-options* are available:

COMMONAXES

specifies that the same DFBETAS axis be used in all panels when multiple panels are needed. By default, the DFBETAS axis is chosen independently for each panel. If you also specify the *UNPACK* option, then the same DFBETAS axis is used for each regressor.

LABEL

specifies that observations whose magnitude are greater than $2/\sqrt{n}$ be labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables on one or more ID statements, then the first ID variable you specify is used for the labeling.

UNPACK

suppresses paneling. The DFBETAS statistics for each regressor are displayed on separate plots.

DFFITS < (LABEL) >

plots the DFFITS statistic by observation number. Observations whose DFFITS' statistic is greater in magnitude than $2\sqrt{p/n}$, where n is the number of observations used and p is the number of regressors, are deemed to be influential (Rawlings 1998). If you specify the LABEL option, then these influential observations are labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables in one or more ID statements, then the first ID variable you specify is used for the labeling.

DIAGNOSTICS < (*diagnostics-options*) >

produces a summary panel of fit diagnostics:

- residuals versus the predicted values
- studentized residuals versus the predicted values
- studentized residuals versus the leverage
- normal quantile plot of the residuals
- dependent variable values versus the predicted values
- Cook's D versus observation number
- histogram of the residuals
- "Residual-Fit" (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals
- box plot of the residuals if you specify the STATS=NONE suboption

You can specify the following *diagnostics-options*:

STATS=*stats-options*
determines which model fit statistics are included in the panel. See the global STATS= suboption for details. The PLOTS= suboption of the DIAGNOSTICSPANEL option overrides the global PLOTS= suboption.

UNPACK
produces the eight plots in the panel as individual plots. Note that you can also request individual plots in the panel by name without having to unpack the panel.

FITPLOT | FIT < (*fit-options***) >**
produces a scatter plot of the data overlaid with the regression line, confidence band, and prediction band for models that depend on at most one regressor excluding the intercept.

You can specify the following *fit-options*:

NOCLI
suppresses the prediction limits.

NOCLM
suppresses the confidence limits.

NOLIMITS
suppresses the confidence and prediction limits.

STATS=*stats-options*
determines which model fit statistics are included in the panel. See the global STATS= suboption for details. The PLOTS= suboption of the FITPLOT option overrides the global PLOTS= suboption.

OBSERVEDBYPREDICTED < (LABEL) >
plots dependent variable values by the predicted values. If you specify the LABEL option, then points deemed as outliers or influential (see the RSTUDENTBYLEVERAGE option for details) are labeled.

NONE
suppresses all plots.

PARTIAL < (UNPACK) >
produces panels of partial regression plots for each regressor with at most six regressors per panel. If you specify the UNPACK option, then all partial plot panels are unpacked.

PREDICTIONS (X=*numeric-variable* **<** *prediction-options* **>)**
produces a panel of two plots whose horizontal axis is the variable you specify in the required X= suboption. The upper plot in the panel is a scatter plot of the residuals. The lower plot shows the data overlaid with the regression line, confidence band, and prediction band. This plot is appropriate for models where all regressors are known to be functions of the single variable that you specify in the X= suboption.

You can specify the following *prediction-options*:

NOCLI
suppresses the prediction limits.

NOCLM
suppresses the confidence limits

NOLIMITS
suppresses the confidence and prediction limits

SMOOTH
requests a nonparametric smooth of the residuals as a function of the variable you specify in the X= suboption. This nonparametric fit is a loess fit that uses local linear polynomials, linear interpolation, and a smoothing parameter selected that yields a local minimum of the corrected Akaike information criterion (AICC). See Chapter 52, "The LOESS Procedure," for details. The SMOOTH option is not supported when a FREQ statement is used.

UNPACK
suppresses paneling.

QQPLOT | QQ
produces a normal quantile plot of the residuals.

RESIDUALBOXPLOT | BOXPLOT < (LABEL) >
produces a box plot consisting of the residuals. If you specify label option, points deemed far-outliers are labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables in one or more ID statements, then the first ID variable you specify is used for the labeling.

RESIDUALBYPREDICTED < (LABEL) >
plots residuals by predicted values. If you specify the LABEL option, then points deemed as outliers or influential (see the RSTUDENTBYLEVERAGE option for details) are labeled.

RESIDUALS < *residual-options*) >
produces panels of the residuals versus the regressors in the model. Note that each panel contains at most six plots, and multiple panels are used in the case where there are more than six regressors (including the intercept) in the model.

The following *residual-options* are available:

SMOOTH
requests a nonparametric smooth of the residuals for each regressor. Each nonparametric fit is a loess fit that uses local linear polynomials, linear interpolation, and a smoothing parameter selected that yields a local minimum of the corrected Akaike information criterion (AICC). See Chapter 52, "The LOESS Procedure," for details. The SMOOTH option is not supported when a FREQ statement is used.

UNPACK
suppresses paneling.

RESIDUALHISTOGRAM
produces a histogram of the residuals.

RFPLOT | RF
produces a "Residual-Fit" (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals. This plot "shows how much variation in the data is explained by the fit and how much remains in the residuals" (Cleveland 1993).

RIDGE | RIDGEPANEL | RIDGEPLOT <(*ridge-options*)>
creates panels of VIF values and standardized ridge estimates by ridge values for each coefficient. The VIF values for each coefficient are connected by lines and are displayed in the upper plot in each panel. The points corresponding to the standardized estimates of each coefficient are connected by lines and are displayed in the lower plot in each panel. By default, at most 10 coefficients are represented in a panel and multiple panels are produced for models with more than 10 regressors. For ridge estimates to be computed and plotted, the OUTEST= option must be specified in the PROC REG statement, and the RIDGE= list must be specified in either the PROC REG or the MODEL statement. (See Example 76.5.)

The following *ridge-options* are available:

COMMONAXES
specifies that the same VIF axis and the same standardized estimate axis are used in all panels when multiple panels are needed. By default, these axes are chosen independently for the regressors shown in each panel.

RIDGEAXIS=LINEAR | LOG
specifies the axis type used to display the ridge parameters. The default is RIDGEAXIS=LINEAR. Note that the point with the ridge parameter equal to zero is not displayed if you specify RIDGEAXIS=LOG.

UNPACK
suppresses paneling. The traces of the VIF statistics and standardized estimates are shown in separate plots.

VARSPERPLOT=ALL

VARSPERPLOT=*number*
specifies the maximum number of regressors displayed in each panel or in each plot if you additionally specify the *UNPACK* option. If you specify VARSPERPLOT=ALL, then the VIF values and ridge traces for all regressors are displayed in a single panel.

VIFAXIS=LINEAR | LOG
specifies the axis type used to display the VIF statistics. The default is VIFAXIS=LINEAR.

RSQUARE <(*rsquare-options*)>
displays the R-square values for the models examined when you request variable selection with the SELECTION= option in the MODEL statement.

The following *rsquare-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL

requests that the model number corresponding to the one displayed in the "Subset Selection Summary" table be used to label the model with the largest R-square statistic at each value of the number of parameters.

LABELVARS

requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the largest R-square statistic at each value of the number of parameters.

RSTUDENTBYLEVERAGE < (LABEL) >

plots studentized residuals by leverage. Observations whose studentized residuals lie outside the band between the reference lines RSTUDENT $= \pm 2$ are deemed outliers. Observations whose leverage values are greater than the vertical reference LEVERAGE $= 2p/n$, where p is the number of parameters including the intercept and n is the number of observations used, are deemed influential (Rawlings 1998). If you specify the LABEL option, then points deemed as outliers or influential are labeled. If you do not specify an ID variable, the observation number within the current BY group is used as the label. If you specify one or more ID variables in one or more ID statements, then the first ID variable you specify is used for the labeling.

RSTUDENTBYPREDICTED < (LABEL) >

plots studentized residuals by predicted values. If you specify the LABEL option, then points deemed as outliers or influential (see the RSTUDENTBYLEVERAGE option for details) are labeled.

SBC < (*sbc-options*) >

displays Schwarz's Bayesian information criterion (SBC) for the models examined when you request variable selection with the SELECTION= option in the MODEL statement.

The following *sbc-options* are available for models where you request the RSQUARE, ADJRSQ, or CP selection method:

LABEL

requests that the model number corresponding to the one displayed in the "Subset Selection Summary" table be used to label the model with the smallest SBC statistic at each value of the number of parameters.

LABELVARS

requests that the list (excluding the intercept) of the regressors in the relevant model be used to label the model with the smallest SBC statistic at each value of the number of parameters.

PRESS

outputs the PRESS statistic to the OUTEST= data set. The values of this statistic are saved in the variable _PRESS_. This option is available for all model selection methods except RSQUARE, ADJRSQ, and CP.

RIDGE=*list*

requests a ridge regression analysis and specifies the values of the ridge constant k (see the section

"Computations for Ridge Regression and IPC Analysis" on page 6466). Each value of k produces a set of ridge regression estimates that are placed in the OUTEST= data set. The values of k are saved by the variable _RIDGE_, and the value of the variable _TYPE_ is set to RIDGE to identify the estimates.

Only nonnegative numbers can be specified with the RIDGE= option. Example 76.5 illustrates this option.

If ODS Graphics is enabled (see the section "ODS Graphics" on page 6472), then ridge regression plots are automatically produced. These plots consist of panels containing ridge traces for the regressors, with at most eight ridge traces per panel.

If you specify the RIDGE= option, RESTRICT statements are ignored.

RSQUARE
has the same effect as the EDF option.

SIMPLE
displays the sum, mean, variance, standard deviation, and uncorrected sum of squares for each variable used in PROC REG.

SINGULAR=*n*
tunes the mechanism used to check for singularities. The default value is machine dependent but is approximately 1E−7 on most machines. This option is rarely needed.

Singularity checking is described in the section "Computational Methods" on page 6467.

TABLEOUT
outputs the standard errors and $100(1-\alpha)\%$ confidence limits for the parameter estimates, the t statistics for testing if the estimates are zero, and the associated p-values to the OUTEST= data set. The _TYPE_ variable values STDERR, LnB, UnB, T, and PVALUE, where $n = 100(1-\alpha)$, identify these rows in the OUTEST= data set. The α level can be set with the ALPHA= option in the PROC REG or MODEL statement. The OUTEST= option must be specified in the PROC REG statement for this option to take effect.

USSCP
displays the uncorrected sums-of-squares and crossproducts matrix for all variables used in the procedure.

ADD Statement

ADD *variables* **;**

The ADD statement adds independent variables to the regression model. Only variables used in the VAR statement or used in MODEL statements before the first RUN statement can be added to the model. You can use the ADD statement interactively to add variables to the model or to include a variable that was previously deleted with a DELETE statement. Each use of the ADD statement modifies the MODEL label.

See the section "Interactive Analysis" on page 6423 for an example.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC REG to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the REG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

When a BY statement is used with PROC REG, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure. A BY statement that appears after the first RUN statement is ignored.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

DELETE Statement

DELETE *variables* **;**

The DELETE statement deletes independent variables from the regression model. The DELETE statement performs the opposite function of the ADD statement and is used in a similar manner. Each use of the DELETE statement modifies the MODEL label.

For an example of how the ADD statement is used (and how the DELETE statement can be used), see the section "Interactive Analysis" on page 6423.

FREQ Statement

FREQ *variable* **;**

When a FREQ statement appears, each observation in the input data set is assumed to represent *n* observations, where *n* is the value of the FREQ variable. The analysis produced when you use a FREQ statement is the same as an analysis produced by using a data set that contains *n* observations in place of each observation in the input data set. When the procedure determines degrees of freedom for significance tests, the total number of observations is considered to be equal to the sum of the values of the FREQ variable.

If the value of the FREQ variable is missing or is less than 1, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

The FREQ statement must appear before the first RUN statement, or it is ignored.

ID Statement

ID *variables* **;**

When one of the MODEL statement options CLI, CLM, P, R, and INFLUENCE is requested, the variables listed in the ID statement are displayed beside each observation. These variables can be used to identify each observation. If the ID statement is omitted, the observation number is used to identify the observations.

Although there are no restrictions on the length of ID variables, PROC REG might truncate ID values to 16 characters for display purposes.

MODEL Statement

< *label:* **>** **MODEL** *dependents=< regressors > < / options >* **;**

After the keyword MODEL, the dependent (response) variables are specified, followed by an equal sign and the regressor variables. Variables specified in the MODEL statement must be numeric variables in the data set being analyzed. For example, if you want to specify a quadratic term for variable *X1* in the model, you cannot use X1*X1 in the MODEL statement but must create a new variable (for example, X1SQUARE=X1*X1) in a DATA step and use this new variable in the MODEL statement. The label in the MODEL statement is optional.

Table 76.4 lists the options available in the MODEL statement. Equations for the statistics available are given in the section "Model Fit and Diagnostic Statistics" on page 6441.

Table 76.4 MODEL Statement Options

Option	Description
Model Selection and Details of Selection	
SELECTION=	specifies model selection method
BEST=	specifies maximum number of subset models displayed or output to the OUTEST= data set
DETAILS	produces summary statistics at each step
DETAILS=	specifies the display details for FORWARD, BACKWARD, and STEPWISE methods

Table 76.4 *continued*

Option	Description
GROUPNAMES=	provides names for groups of variables
INCLUDE=	includes first n variables in the model
MAXSTEP=	specifies maximum number of steps that might be performed
NOINT	fits a model without the intercept term
PCOMIT=	performs incomplete principal component analysis and outputs estimates to the OUTEST= data set
RIDGE=	performs ridge regression analysis and outputs estimates to the OUTEST= data set
SLE=	sets criterion for entry into model
SLS=	sets criterion for staying in model
START=	specifies number of variables in model to begin the comparing and switching process
STOP=	stops selection criterion
Statistics	
ADJRSQ	computes adjusted R^2
AIC	computes Akaike's information criterion
B	computes parameter estimates for each model
BIC	computes Sawa's Bayesian information criterion
CP	computes Mallows' C_p statistic
GMSEP	computes estimated MSE of prediction assuming multivariate normality
JP	computes J_p, the final prediction error
MSE	computes MSE for each model
PC	computes Amemiya's prediction criterion
RMSE	displays root MSE for each model
SBC	computes the SBC statistic
SP	computes S_p statistic for each model
SSE	computes error sum of squares for each model
Data Set Options	
EDF	outputs the number of regressors, the error degrees of freedom, and the model R^2 to the OUTEST= data set
OUTSEB	outputs standard errors of the parameter estimates to the OUTEST= data set
OUTSTB	outputs standardized parameter estimates to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
OUTVIF	outputs the variance inflation factors to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
PRESS	outputs the PRESS statistic to the OUTEST= data set
RSQUARE	has same effect as the EDF option
Regression Calculations	
I	displays inverse of sums of squares and crossproducts
XPX	displays sums-of-squares and crossproducts matrix

Table 76.4 *continued*

Option	Description
Details on Estimates	
ACOV	displays heteroscedasticity- consistent covariance matrix of estimates and heteroscedasticity-consistent standard errors
ACOVMETHOD=	specifies method for computing the asymptotic heteroscedasticity-consistent covariance matrix
COLLIN	produces collinearity analysis
COLLINOINT	produces collinearity analysis with intercept adjusted out
CORRB	displays correlation matrix of estimates
COVB	displays covariance matrix of estimates
HCC	displays heteroscedasticity-consistent standard errors
HCCMETHOD=	specifies method for computing the asymptotic heteroscedasticity-consistent covariance matrix
LACKFIT	performs lack-of-fit test
PARTIALR2	displays squared semipartial correlation coefficients computed using Type I sums of squares
PCORR1	displays squared partial correlation coefficients computed using Type I sums of squares
PCORR2	displays squared partial correlation coefficients computed using Type II sums of squares
SCORR1	displays squared semipartial correlation coefficients computed using Type I sums of squares
SCORR2	displays squared semipartial correlation coefficients computed using Type II sums of squares
SEQB	displays a sequence of parameter estimates during selection process
SPEC	tests that first and second moments of model are correctly specified
SS1	displays the sequential sums of squares
SS2	displays the partial sums of squares
STB	displays standardized parameter estimates
TOL	displays tolerance values for parameter estimates
WHITE	displays heteroscedasticity-consistent standard errors
VIF	computes variance-inflation factors
Predicted and Residual Values	
CLB	computes $100(1-\alpha)\%$ confidence limits for the parameter estimates
CLI	computes $100(1-\alpha)\%$ confidence limits for an individual predicted value
CLM	computes $100(1-\alpha)\%$ confidence limits for the expected value of the dependent variable
DW	computes a Durbin-Watson statistic
DWPROB	computes a Durbin-Watson statistic and p-value
INFLUENCE	computes influence statistics
P	computes predicted values

Table 76.4 *continued*

Option	Description
PARTIAL	displays partial regression plots for each regressor
PARTIALDATA	displays partial regression data
R	produces analysis of residuals
Display Options and Other Options	
ALL	requests the following options: ACOV, CLB, CLI, CLM, CORRB, COVB, HCC, I, P, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, XPX
ALPHA=	sets significance value for confidence and prediction intervals and tests
NOPRINT	suppresses display of results
SIGMA=	specifies the true standard deviation of error term for computing CP and BIC
SINGULAR=	sets criterion for checking for singularity

You can specify the following options in the MODEL statement after a slash (/).

ACOV

displays the estimated asymptotic covariance matrix of the estimates under the hypothesis of heteroscedasticity and heteroscedasticity-consistent standard errors of parameter estimates. See the HCCMETHOD= option and the HCC option and the section "Testing for Heteroscedasticity" on page 6459 for more information.

ACOVMETHOD=0,1,2, or 3

See the HCCMETHOD= option.

ADJRSQ

computes R^2 adjusted for degrees of freedom for each model selected (Darlington 1968; Judge et al. 1980).

AIC

outputs Akaike's information criterion for each model selected (Akaike 1969; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the AIC statistic is also added to the SubsetSelSummary table.

ALL

requests all these options: ACOV, CLB, CLI, CLM, CORRB, COVB, HCC, I, P, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, and XPX.

ALPHA=*number*

sets the significance level used for the construction of confidence intervals for the current MODEL statement. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the MODEL options CLB, CLI, and CLM; the OUTPUT statement keywords LCL, LCLM, UCL, and UCLM; the PLOT statement keywords LCL., LCLM., UCL., and UCLM.; and the

PLOT statement options CONF and PRED. If you specify this option in the MODEL statement, it takes precedence over the ALPHA= option in the PROC REG statement.

B

is used with the RSQUARE, ADJRSQ, and CP model-selection methods to compute estimated regression coefficients for each model selected.

BEST=*n*

is used with the RSQUARE, ADJRSQ, and CP model-selection methods. If SELECTION=CP or SELECTION=ADJRSQ is specified, the BEST= option specifies the maximum number of subset models to be displayed or output to the OUTEST= data set. For SELECTION=RSQUARE, the BEST= option requests the maximum number of subset models for each size.

If the BEST= option is used without the B option (displaying estimated regression coefficients), the variables in each MODEL are listed in order of inclusion instead of the order in which they appear in the MODEL statement.

If the BEST= option is omitted and the number of regressors is less than 11, all possible subsets are evaluated. If the BEST= option is omitted and the number of regressors is greater than 10, the number of subsets selected is, at most, equal to the number of regressors. A small value of the BEST= option greatly reduces the CPU time required for large problems.

BIC

outputs Sawa's Bayesian information criterion for each model selected (Sawa 1978; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the BIC statistic is also added to the SubsetSelSummary table.

CLB

requests the $100(1-\alpha)\%$ upper and lower confidence limits for the parameter estimates. By default, the 95% limits are computed; the ALPHA= option in the PROC REG or MODEL statement can be used to change the α level. If any of the MODEL statement options ACOV, HCC, or WHITE are in effect, then the CLB option also produces heteroscedasticity-consistent $100(1-\alpha)\%$ upper and lower confidence limits for the parameter estimates.

CLI

requests the $100(1-\alpha)\%$ upper and lower confidence limits for an individual predicted value. By default, the 95% limits are computed; the ALPHA= option in the PROC REG or MODEL statement can be used to change the α level. The confidence limits reflect variation in the error, as well as variation in the parameter estimates. See the section "Predicted and Residual Values" on page 6434 and Chapter 4, "Introduction to Regression Procedures," for more information.

CLM

displays the $100(1-\alpha)\%$ upper and lower confidence limits for the expected value of the dependent variable (mean) for each observation. By default, the 95% limits are computed; the ALPHA= in the PROC REG or MODEL statement can be used to change the α level. This is not a prediction interval (see the CLI option) because it takes into account only the variation in the parameter estimates, not the variation in the error term. See the section "Predicted and Residual Values" on page 6434 and Chapter 4, "Introduction to Regression Procedures," for more information.

COLLIN

requests a detailed analysis of collinearity among the regressors. This includes eigenvalues, condition indices, and decomposition of the variances of the estimates with respect to each eigenvalue. See the section "Collinearity Diagnostics" on page 6439.

COLLINOINT

requests the same analysis as the COLLIN option with the intercept variable adjusted out rather than included in the diagnostics. See the section "Collinearity Diagnostics" on page 6439.

CORRB

displays the correlation matrix of the estimates. This is the $(\mathbf{X}'\mathbf{X})^{-1}$ matrix scaled to unit diagonals.

COVB

displays the estimated covariance matrix of the estimates. This matrix is $(\mathbf{X}'\mathbf{X})^{-1}s^2$, where s^2 is the estimated mean squared error.

CP

outputs Mallows' C_p statistic for each model selected (Mallows 1973; Hocking 1976) to the OUTEST= data set. See the section "Criteria Used in Model-Selection Methods" on page 6430 for a discussion of the use of C_p. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the C_p statistic is also added to the SubsetSelSummary table.

DETAILS

DETAILS=*name*

specifies the level of detail produced when the BACKWARD, FORWARD, or STEPWISE method is used, where *name* can be ALL, STEPS, or SUMMARY. The DETAILS or DETAILS=ALL option produces entry and removal statistics for each variable in the model building process, ANOVA and parameter estimates at each step, and a selection summary table. The option DETAILS=STEPS provides the step information and summary table. The option DETAILS=SUMMARY produces only the summary table. The default if the DETAILS option is omitted is DETAILS=STEPS.

DW

calculates a Durbin-Watson statistic to test whether or not the errors have first-order autocorrelation. (This test is appropriate only for time series data.) Note that your data should be sorted by the date/time ID variable before you use this option. The sample autocorrelation of the residuals is also produced. See the section "Autocorrelation in Time Series Data" on page 6465.

DWPROB

calculates a Durbin-Watson statistic and a p-value to test whether or not the errors have first-order autocorrelation. Note that it is not necessary to specify the DW option if the DWPROB option is specified. (This test is appropriate only for time series data.) Note that your data should be sorted by the date/time ID variable before you use this option. The sample autocorrelation of the residuals is also produced. See the section "Autocorrelation in Time Series Data" on page 6465.

EDF

outputs the number of regressors in the model excluding and including the intercept, the error degrees of freedom, and the model R^2 to the OUTEST= data set.

GMSEP

outputs the estimated mean square error of prediction assuming that both independent and dependent

variables are multivariate normal (Stein 1960; Darlington 1968) to the OUTEST= data set. (Note that Hocking's formula (1976, eq. 4.20) contains a misprint: "$n - 1$" should read "$n - 2$.") If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the GMSEP statistic is also added to the SubsetSelSummary table.

GROUPNAMES=*'name1' 'name2' ...*

provides names for variable groups. This option is available only in the BACKWARD, FORWARD, and STEPWISE methods. The group name can be up to 32 characters. Subsets of independent variables listed in the MODEL statement can be designated as variable groups. This is done by enclosing the appropriate variables in braces. Variables in the same group are entered into or removed from the regression model at the same time. However, if the tolerance of any variable (see the TOL option on page 6385) in a group is less than the setting of the SINGULAR= option, then the variable is not entered into the model with the rest of its group. If the GROUPNAMES= option is not used, then the names GROUP1, GROUP2, ..., GROUP*n* are assigned to groups encountered in the MODEL statement. Variables not enclosed by braces are used as groups of a single variable.

For example:

```
model y={x1 x2} x3 / selection=stepwise
  groupnames='x1 x2' 'x3';
```

Another example:

```
model y={ht wgt age} bodyfat / selection=forward
  groupnames='htwgtage' 'bodyfat';
```

HCC

requests heteroscedasticity-consistent standard errors of the parameter estimates. You can use the HCCMETHOD= option to specify the method used to compute the heteroscedasticity-consistent covariance matrix.

HCCMETHOD=0,1,2, or 3

specifies the method used to obtain a heteroscedasticity-consistent covariance matrix for use with the ACOV, HCC, or WHITE option in the MODEL statement and for heteroscedasticity-consistent tests with the TEST statement. The default is HCCMETHOD=0. See the section "Testing for Heteroscedasticity" on page 6459 for details.

I

displays the $(\mathbf{X}'\mathbf{X})^{-1}$ matrix. The inverse of the crossproducts matrix is bordered by the parameter estimates and SSE matrices.

INCLUDE=*n*

forces the first n independent variables listed in the MODEL statement to be included in all models. The selection methods are performed on the other variables in the MODEL statement. The INCLUDE= option is not available with SELECTION=NONE.

INFLUENCE

requests a detailed analysis of the influence of each observation on the estimates and the predicted values. See the section "Influence Statistics" on page 6443 for details.

JP

outputs J_p, the estimated mean square error of prediction for each model selected assuming that the values of the regressors are fixed and that the model is correct to the OUTEST= data set. The J_p statistic is also called the final prediction error (FPE) by Akaike (Nicholson 1948; Lord 1950; Mallows 1967; Darlington 1968; Rothman 1968; Akaike 1969; Hocking 1976; Judge et al. 1980). If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the J_p statistic is also added to the SubsetSelSummary table.

LACKFIT

performs a lack-of-fit test. See the section "Testing for Lack of Fit" on page 6460 for more information. Refer to Draper and Smith (1981) for a discussion of lack-of-fit tests.

MSE

computes the mean square error for each model selected (Darlington 1968).

MAXSTEP=*n*

specifies the maximum number of steps that are done when SELECTION=FORWARD, SELECTION=BACKWARD, or SELECTION=STEPWISE is used. The default value is the number of independent variables in the model for the FORWARD and BACKWARD methods and three times this number for the stepwise method.

NOINT

suppresses the intercept term that is otherwise included in the model.

NOPRINT

suppresses the normal display of regression results. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, "Using the Output Delivery System," for more information.

OUTSEB

outputs the standard errors of the parameter estimates to the OUTEST= data set. The value SEB for the variable _TYPE_ identifies the standard errors. If the RIDGE= or PCOMIT= option is specified, additional observations are included and identified by the values RIDGESEB and IPCSEB, respectively, for the variable _TYPE_. The standard errors for ridge regression estimates and incomplete principal components (IPC) estimates are limited in their usefulness because these estimates are biased. This option is available for all model-selection methods except RSQUARE, ADJRSQ, and CP.

OUTSTB

outputs the standardized parameter estimates as well as the usual estimates to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The values RIDGESTB and IPCSTB for the variable _TYPE_ identify ridge regression estimates and IPC estimates, respectively.

OUTVIF

outputs the variance inflation factors (VIF) to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The factors are the diagonal elements of the inverse of the correlation matrix of regressors as adjusted by ridge regression or IPC analysis. These observations are identified in the output data set by the values RIDGEVIF and IPCVIF for the variable _TYPE_.

P

calculates predicted values from the input data and the estimated model. The display includes the

observation number, the ID variable (if one is specified), the actual and predicted values, and the residual. If the CLI, CLM, or R option is specified, the P option is unnecessary. See the section "Predicted and Residual Values" on page 6434 for more information.

PARTIAL

requests partial regression leverage plots for each regressor. You can use the PARTIALDATA option to obtain a tabular display of the partial regression leverage data. If ODS Graphics is enabled (see the section "ODS Graphics" on page 6472), then these partial plots are produced in panels with up to six plots per panel. See the section "Influence Statistics" on page 6443 for more information.

PARTIALDATA

requests partial regression leverage data for each regressor. You can request partial regression leverage plots of these data with the PARTIAL option. See the section "Influence Statistics" on page 6443 for more information.

PARTIALR2 < (< TESTS > < SEQTESTS >) >

See the SCORR1 option.

PC

outputs Amemiya's prediction criterion for each model selected (Amemiya 1976; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the PC statistic is also added to the SubsetSelSummary table.

PCOMIT=*list*

requests an IPC analysis for each value *m* in the list. The procedure computes parameter estimates by using all but the last *m* principal components. Each value of *m* produces a set of IPC estimates, which is output to the OUTEST= data set. The values of *m* are saved by the variable _PCOMIT_, and the value of the variable _TYPE_ is set to IPC to identify the estimates. Only nonnegative integers can be specified with the PCOMIT= option.

If you specify the PCOMIT= option, RESTRICT statements are ignored. The PCOMIT= option is ignored if you use the SELECTION= option in the MODEL statement.

PCORR1

displays the squared partial correlation coefficients computed using Type I sum of squares (SS). This is calculated as SS/(SS+SSE), where SSE is the error sum of squares.

PCORR2

displays the squared partial correlation coefficients computed using Type II sums of squares. These are calculated the same way as with the PCORR1 option, except that Type II SS are used instead of Type I SS.

PRESS

outputs the PRESS statistic to the OUTEST= data set. The values of this statistic are saved in the variable _PRESS_. This option is available for all model-selection methods except RSQUARE, ADJRSQ, and CP.

R

requests an analysis of the residuals. The results include everything requested by the P option plus the standard errors of the mean predicted and residual values, the studentized residual, and Cook's

D statistic to measure the influence of each observation on the parameter estimates. See the section "Predicted and Residual Values" on page 6434 for more information.

RIDGE=*list*

requests a ridge regression analysis and specifies the values of the ridge constant k (see the section "Computations for Ridge Regression and IPC Analysis" on page 6466). Each value of k produces a set of ridge regression estimates that are placed in the OUTEST= data set. The values of k are saved by the variable _RIDGE_, and the value of the variable _TYPE_ is set to RIDGE to identify the estimates.

Only nonnegative numbers can be specified with the RIDGE= option. Example 76.5 illustrates this option.

If you specify the RIDGE= option, RESTRICT statements are ignored. The RIDGE= option is ignored if you use the SELECTION= option in the MODEL statement.

RMSE

displays the root mean square error for each model selected.

RSQUARE

has the same effect as the EDF option.

SBC

outputs the SBC statistic for each model selected (Schwarz 1978; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the SBC statistic is also added to the SubsetSelSummary table.

SCORR1 < (< TESTS > < SEQTESTS >) >

displays the squared semipartial correlation coefficients computed using Type I sums of squares. This is calculated as SS/SST, where SST is the corrected total SS. If the NOINT option is used, the uncorrected total SS is used in the denominator. The optional arguments TESTS and SEQTESTS request are sequentially added to a model. The F-test values are computed as the Type I sum of squares for the variable in question divided by a mean square error. If you specify the TESTS option, the denominator MSE is the residual mean square for the full model specified in the MODEL statement. If you specify the SEQTESTS option, the denominator MSE is the residual mean square for the model containing all the independent variables that have been added to the model up to and including the variable in question. The TESTS and SEQTESTS options are not supported if you specify model selection methods or the RIDGE or PCOMIT options. Note that the PARTIALR2 option is a synonym for the SCORR1 option.

SCORR2 < (TESTS) >

displays the squared semipartial correlation coefficients computed using Type II sums of squares. These are calculated the same way as with the SCORR1 option, except that Type II SS are used instead of Type I SS. The optional TEST argument requests F tests and p-values as variables are sequentially added to a model. The F-test values are computed as the Type II sum of squares for the variable in question divided by the residual mean square for the full model specified in the MODEL statement. The TESTS option is not supported if you specify model selection methods or the RIDGE or PCOMIT options.

SELECTION=*name*

specifies the method used to select the model, where *name* can be FORWARD (or F), BACKWARD (or B), STEPWISE, MAXR, MINR, RSQUARE, ADJRSQ, CP, or NONE (use the full model). The default method is NONE. See the section "Model-Selection Methods" on page 6427 for a description of each method.

SEQB

produces a sequence of parameter estimates as each variable is entered into the model. This is displayed as a matrix where each row is a set of parameter estimates.

SIGMA=*n*

specifies the true standard deviation of the error term to be used in computing the CP and BIC statistics. If the SIGMA= option is not specified, an estimate from the full model is used. This option is available in the RSQUARE, ADJRSQ, and CP model-selection methods only.

SINGULAR=*n*

tunes the mechanism used to check for singularities. If you specify this option in the MODEL statement, it takes precedence over the SINGULAR= option in the PROC REG statement. The default value is machine dependent but is approximately 1E−7 on most machines. This option is rarely needed. Singularity checking is described in the section "Computational Methods" on page 6467.

SLENTRY=*value*

SLE=*value*

specifies the significance level for entry into the model used in the FORWARD and STEPWISE methods. The defaults are 0.50 for FORWARD and 0.15 for STEPWISE.

SLSTAY=*value*

SLS=*value*

specifies the significance level for staying in the model for the BACKWARD and STEPWISE methods. The defaults are 0.10 for BACKWARD and 0.15 for STEPWISE.

SP

outputs the S_p statistic for each model selected (Hocking 1976) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the SP statistic is also added to the SubsetSelSummary table.

SPEC

performs a test that the first and second moments of the model are correctly specified. See the section "Testing for Heteroscedasticity" on page 6459 for more information.

SS1

displays the sequential sums of squares (Type I SS) along with the parameter estimates for each term in the model. See Chapter 15, "The Four Types of Estimable Functions," for more information about the different types of sums of squares.

SS2

displays the partial sums of squares (Type II SS) along with the parameter estimates for each term in the model. See the SS1 option also.

SSE

computes the error sum of squares for each model selected.

START=*s*

is used to begin the comparing-and-switching process in the MAXR, MINR, and STEPWISE methods for a model containing the first *s* independent variables in the MODEL statement, where *s* is the START value. For these methods, the default is START=0.

For the RSQUARE, ADJRSQ, and CP methods, START=*s* specifies the smallest number of regressors to be reported in a subset model. For these methods, the default is START=1.

The START= option cannot be used with model-selection methods other than the six described here.

STB

produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor.

STOP=*s*

causes PROC REG to stop when it has found the "best" *s*-variable model, where *s* is the STOP value. For the RSQUARE, ADJRSQ, and CP methods, STOP=*s* specifies the largest number of regressors to be reported in a subset model. For the MAXR and MINR methods, STOP=*s* specifies the largest number of regressors to be included in the model.

The default setting for the STOP= option is the number of variables in the MODEL statement. This option can be used only with the MAXR, MINR, RSQUARE, ADJRSQ, and CP methods.

TOL

produces tolerance values for the estimates. Tolerance for a variable is defined as $1 - R^2$, where R^2 is obtained from the regression of the variable on all other regressors in the model. See the section "Collinearity Diagnostics" on page 6439 for more details.

VIF

produces variance inflation factors with the parameter estimates. Variance inflation is the reciprocal of tolerance. See the section "Collinearity Diagnostics" on page 6439 for more detail.

WHITE

See the HCC option.

XPX

displays the $\mathbf{X}'\mathbf{X}$ crossproducts matrix for the model. The crossproducts matrix is bordered by the $\mathbf{X}'\mathbf{Y}$ and $\mathbf{Y}'\mathbf{Y}$ matrices.

MTEST Statement

< *label:* **>** **MTEST** < *equation* < , . . . , *equation* > > < / *options* > **;**

where each *equation* is a linear function composed of coefficients and variable names. The *label* is optional.

The MTEST statement is used to test hypotheses in multivariate regression models where there are several dependent variables fit to the same regressors. If no equations or options are specified, the MTEST statement tests the hypothesis that all estimated parameters except the intercept are zero.

The hypotheses that can be tested with the MTEST statement are of the form

$$(\mathbf{L}\boldsymbol{\beta} - \mathbf{cj})\mathbf{M} = 0$$

where $\mathbf{L}$ is a linear function on the regressor side, $\boldsymbol{\beta}$ is a matrix of parameters, $\mathbf{c}$ is a column vector of constants, $\mathbf{j}$ is a row vector of ones, and $\mathbf{M}$ is a linear function on the dependent side. The special case where the constants are zero is

$$\mathbf{L}\boldsymbol{\beta}\mathbf{M} = \mathbf{0}$$

See the section "Multivariate Tests" on page 6461 for more details.

Each linear function extends across either the regressor variables or the dependent variables. If the equation is across the dependent variables, then the constant term, if specified, must be zero. The equations for the regressor variables form the $\mathbf{L}$ matrix and $\mathbf{c}$ vector in the preceding formula; the equations for dependent variables form the $\mathbf{M}$ matrix. If no equations for the dependent variables are given, PROC REG uses an identity matrix for $\mathbf{M}$, testing the same hypothesis across all dependent variables. If no equations for the regressor variables are given, PROC REG forms a linear function corresponding to a test that all the nonintercept parameters are zero.

As an example, consider the following statements:

```
model y1 y2 y3=x1 x2 x3;
mtest x1,x2;
mtest y1-y2, y2 -y3, x1;
mtest y1-y2;
```

The first MTEST statement tests the hypothesis that the $X1$ and $X2$ parameters are zero for $Y1$, $Y2$, and $Y3$. In addition, the second MTEST statement tests the hypothesis that the $X1$ parameter is the same for all three dependent variables. For the same model, the third MTEST statement tests the hypothesis that all parameters except the intercept are the same for dependent variables $Y1$ and $Y2$.

You can specify the following options in the MTEST statement:

CANPRINT
displays the canonical correlations for the hypothesis combinations and the dependent variable combinations. If you specify

```
mtest / canprint;
```

the canonical correlations between the regressors and the dependent variables are displayed.

DETAILS
displays the $\mathbf{M}$ matrix and various intermediate calculations.

MSTAT=FAPPROX

MSTAT=EXACT

specifies the method of evaluating the multivariate test statistics. The default is MSTAT=FAPPROX, which specifies that the multivariate tests are evaluated by using the usual approximations based on the F distribution, as discussed in the "Multivariate Tests" section in Chapter 4, "Introduction to Regression Procedures." Alternatively, you can specify MSTAT=EXACT to compute exact p-values for three of the four tests (Wilks' lambda, the Hotelling-Lawley trace, and Roy's greatest root) and an improved F approximation for the fourth (Pillai's trace). While MSTAT=EXACT provides better control of the significance probability for the tests, especially for Roy's greatest root, computations for the exact p-values can be appreciably more demanding, and are in fact infeasible for large problems (many dependent variables). Thus, although MSTAT=EXACT is more accurate for most data, it is not the default method.

PRINT

displays the **H** and **E** matrices.

OUTPUT Statement

OUTPUT < **OUT=***SAS-data-set*>< *keyword=names*> < . . . *keyword=names*> ;

The OUTPUT statement creates a new SAS data set that saves diagnostic measures calculated after fitting the model. The OUTPUT statement refers to the most recent MODEL statement. At least one *keyword=names* specification is required.

All the variables in the original data set are included in the new data set, along with variables created in the OUTPUT statement. These new variables contain the values of a variety of statistics and diagnostic measures that are calculated for each observation in the data set. If you want to create a permanent SAS data set, you must specify a two-level name (for example, *libref.data-set-name*).

For more information about permanent SAS data sets, refer to the section "SAS Files" in *SAS Language Reference: Concepts*.

The OUTPUT statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set for PROC REG. See the section "Input Data Sets" on page 6412 for more details.

The statistics created in the OUTPUT statement are described in this section. More details are given in the section "Predicted and Residual Values" on page 6434 and the section "Influence Statistics" on page 6443. Also see Chapter 4, "Introduction to Regression Procedures," for definitions of the statistics available from the REG procedure.

You can specify the following options in the OUTPUT statement:

OUT=*SAS data set*

gives the name of the new data set. By default, the procedure uses the DATA*n* convention to name the new data set.

keyword=names

specifies the statistics to include in the output data set and names the new variables that contain the

statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable or variables to contain the statistic.

In the output data set, the first variable listed after a keyword in the OUTPUT statement contains that statistic for the first dependent variable listed in the MODEL statement; the second variable contains the statistic for the second dependent variable in the MODEL statement, and so on. The list of variables following the equal sign can be shorter than the list of dependent variables in the MODEL statement. In this case, the procedure creates the new names in order of the dependent variables in the MODEL statement.

For example, the following SAS statements create an output data set named b:

```
proc reg data=a;
   model y z=x1 x2;
   output out=b
      p=yhat zhat
      r=yresid zresid;
run;
```

In addition to the variables in the input data set, b contains the following variables:

- yhat, with values that are predicted values of the dependent variable y
- zhat, with values that are predicted values of the dependent variable z
- yresid, with values that are the residual values of y
- zresid, with values that are the residual values of z

You can specify the following keywords in the OUTPUT statement. See the section "Model Fit and Diagnostic Statistics" on page 6441 for computational formulas.

Table 76.5 Keywords for OUTPUT Statement

Keyword	Description
COOKD=*names*	Cook's D influence statistic
COVRATIO=*names*	standard influence of observation on covariance of betas, as discussed in the section "Influence Statistics" on page 6443
DFFITS=*names*	standard influence of observation on predicted value
H=*names*	leverage, $x_i(\mathbf{X}'\mathbf{X})^{-1}x_i'$
LCL=*names*	lower bound of a $100(1-\alpha)\%$ confidence interval for an individual prediction. This includes the variance of the error, as well as the variance of the parameter estimates.
LCLM=*names*	lower bound of a $100(1-\alpha)\%$ confidence interval for the expected value (mean) of the dependent variable
PREDICTED | P=*names*	predicted values
PRESS=*names*	ith residual divided by $(1-h)$, where h is the leverage, and where the model has been refit without the ith observation
RESIDUAL | R=*names*	residuals, calculated as ACTUAL minus PREDICTED
RSTUDENT=*names*	a studentized residual with the current observation deleted

Table 76.5 *continued*

Keyword	Description
STDI=*names*	standard error of the individual predicted value
STDP=*names*	standard error of the mean predicted value
STDR=*names*	standard error of the residual
STUDENT=*names*	studentized residuals, which are the residuals divided by their standard errors
UCL=*names*	upper bound of a $100(1-\alpha)\%$ confidence interval for an individual prediction
UCLM=*names*	upper bound of a $100(1-\alpha)\%$ confidence interval for the expected value (mean) of the dependent variable

PAINT Statement

PAINT < *condition* | **ALLOBS** > < / *options* > **;**

PAINT < *STATUS* | *UNDO* > **;**

The PAINT statement is used with line printer plots. See the PLOTS= option for information about using ODS graphics to create modern statistical graphics.

The PAINT statement selects observations to be *painted* or highlighted in a scatter plot on line printer output; the PAINT statement is ignored if the LINEPRINTER option is not specified in the PROC REG statement.

All observations that satisfy *condition* are painted using some specific symbol. The PAINT statement does not generate a scatter plot and must be followed by a PLOT statement, which does generate a scatter plot. Several PAINT statements can be used before a PLOT statement, and all prior PAINT statement requests are applied to all later PLOT statements.

The PAINT statement lists the observation numbers of the observations selected, the total number of observations selected, and the plotting symbol used to paint the points.

On a plot, paint symbols take precedence over all other symbols. If any position contains more than one painted point, the paint symbol for the observation plotted last is used.

The PAINT statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set for PROC REG. Also, the PAINT statement cannot be used for models with more than one dependent variable. Note that the syntax for the PAINT statement is the same as the syntax for the REWEIGHT statement.

Specifying Condition

Condition is used to select observations to be painted. The syntax of *condition* is

variable compare value

or

variable compare value *logical* *variable compare value*

where

variable is one of the following:

- a variable name in the input data set
- OBS**.**, which is the observation number
- *keyword***.**, where *keyword* is a keyword for a statistic requested in the OUTPUT statement

compare is an operator that compares *variable* to *value*. *Compare* can be any one of the following: <, <=, >, >=, =, ^ =. The operators LT, LE, GT, GE, EQ, and NE, respectively, can be used instead of the preceding symbols. Refer to the "Expressions" section in *SAS Language Reference: Concepts* for more information about comparison operators.

value gives an unformatted value of *variable*. Observations are selected to be painted if they satisfy the condition created by *variable compare value*. *Value* can be a number or a character string. If *value* is a character string, it must be eight characters or less and must be enclosed in quotes. In addition, *value* is case-sensitive. In other words, the statements

```
paint name='henry';
```

and

```
paint name='Henry';
```

are not the same.

logical is one of two logical operators. Either AND or OR can be used. To specify AND, use AND or the symbol &. To specify OR, use OR or the symbol |.

Here are some examples of the *variable compare value* form:

```
paint name='Henry';
paint residual.>=20;
paint obs.=99;
```

Here are some examples of the *variable compare value* *logical* *variable compare value* form:

```
paint name='Henry'|name='Mary';
paint residual.>=20 or residual.<=10;
paint obs.>=11 and residual.<=20;
```

Using ALLOBS

Instead of specifying *condition*, the ALLOBS option can be used to select all observations. This is most useful when you want to unpaint all observations. For example,

```
paint allobs / reset;
```

resets the symbols for all observations.

Options in the PAINT Statement

The following options can be used when either a condition is specified, the ALLOBS option is specified, or nothing is specified before the slash. If only an option is listed, the option applies to the observations selected in the previous PAINT statement, *not* to the observations selected by reapplying the condition from the previous PAINT statement. For example, in the statements

```
paint r.>0 / symbol='a';
reweight r.>0;
refit;
paint / symbol='b';
```

the second PAINT statement paints only those observations selected in the first PAINT statement. No additional observations are painted even if, after refitting the model, there are new observations that meet the condition in the first PAINT statement.

NOTE: Options are not available when either the UNDO or STATUS option is used.

You can specify the following options after a slash (/).

NOLIST
suppresses the display of the selected observation numbers. If the NOLIST option is not specified, a list of observations selected is written to the log. The list includes the observation numbers and painting symbol used to paint the points. The total number of observations selected to be painted is also shown.

RESET
changes the painting symbol to the current default symbol, effectively unpainting the observations selected. If you set the default symbol by using the SYMBOL= option in the PLOT statement, the RESET option in the PAINT statement changes the painting symbol to the symbol you specified. Otherwise, the default symbol of '1' is used.

SYMBOL='character'
specifies a painting symbol. If the SYMBOL= option is omitted, the painting symbol is either the one used in the most recent PAINT statement or, if there are no previous PAINT statements, the symbol '@'. For example,

```
paint / symbol='#';
```

changes the painting symbol for the observations selected by the most recent PAINT statement to '#'. As another example,

```
paint temp lt 22 / symbol='c';
```

changes the painting symbol to 'c' for all observations with TEMP<22. In general, the numbers 1, 2, ..., 9 and the asterisk are not recommended as painting symbols. These symbols are used as default symbols in the PLOT statement, where they represent the number of replicates at a point. If SYMBOL=" is used, no painting is done in the current plot. If SYMBOL=' ' is used, observations are painted with a blank and are no longer seen on the plot.

STATUS and UNDO

Instead of specifying *condition* or the ALLOBS option, you can use the STATUS or UNDO option as follows:

STATUS
lists (in the log) the observation number and plotting symbol of all currently painted observations.

UNDO
undoes changes made by the most recent PAINT statement. Observations might be, but are not necessarily, unpainted. For example:

```
paint obs. <=10 / symbol='a';
\Codecomment{...other interactive statements}
paint obs.=1 / symbol='b';
\Codecomment{...other interactive statements}
paint undo;
```

The last PAINT statement changes the plotting symbol used for observation 1 back to 'a'. If the statement

```
paint / reset;
```

is used instead, observation 1 is unpainted.

PLOT Statement

PLOT < *yvariable*xvariable* > < *=symbol* > < . . . *yvariable*xvariable* > < *=symbol* > < */ options* > **;**

The PLOT statement is used with line printer and traditional graphics. See the PLOTS= option for information about using ODS graphics to create modern statistical graphics.

The PLOT statement in PROC REG displays scatter plots with *yvariable* on the vertical axis and *xvariable* on the horizontal axis. Line printer plots are generated if the LINEPRINTER option is specified in the PROC REG statement; otherwise, the traditional graphics are created. Points in line printer plots can be marked with *symbols*, while global graphics statements such as GOPTIONS and SYMBOL are used to enhance the

traditional graphics. Note that the plots you request by using the PLOT statement are independent of the ODS graphical displays (see the section "ODS Graphics" on page 6472) that are available in PROC REG.

As with most other interactive statements, the PLOT statement implicitly refits the model. For example, if a PLOT statement is preceded by a REWEIGHT statement, the model is recomputed, and the plot reflects the new model.

If there are multiple MODEL statements preceding a PLOT statement, then the PLOT statement refers to the latest MODEL statement.

The PLOT statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as input to PROC REG.

You can specify several PLOT statements for each MODEL statement, and you can specify more than one plot in each PLOT statement.

Specifying Yvariables, Xvariables, and Symbol

More than one *yvariable*∗*xvariable* pair can be specified to request multiple plots. The *yvariables* and *xvariables* can be as follows:

- any variables specified in the VAR or MODEL statement before the first RUN statement
- *keyword*., where *keyword* is a regression diagnostic statistic available in the OUTPUT statement (see Table 76.6). For example,

  ```
  plot predicted.*residual.;
  ```

  generates one plot of the predicted values by the residuals for each dependent variable in the MODEL statement. These statistics can also be plotted against any of the variables in the VAR or MODEL statements.
- the keyword OBS. (the observation number), which can be plotted against any of the preceding variables
- the keyword NPP. or NQQ., which can be used with any of the preceding variables to construct normal P-P or Q-Q plots, respectively (see the section "Construction of Q-Q and P-P Plots" on page 6466 for more information)
- keywords for model fit summary statistics available in the OUTEST= data set with _TYPE_= PARMS (see Table 76.6). A SELECTION= method (other than NONE) must be requested in the MODEL statement for these variables to be plotted. If one member of a *yvariable*∗*xvariable* pair is from the OUTEST= data set, the other member must also be from the OUTEST= data set.

The OUTPUT statement and the OUTEST= option are not required when their keywords are specified in the PLOT statement.

The *yvariable* and *xvariable* specifications can be replaced by a set of variables and statistics enclosed in parentheses. When this occurs, all possible combinations of *yvariable* and *xvariable* are generated. For example, the following two statements are equivalent:

```
plot (y1 y2)*(x1 x2);
plot y1*x1 y1*x2 y2*x1 y2*x2;
```

The statement

```
plot;
```

is equivalent to respecifying the most recent PLOT statement without any options. However, the line printer options COLLECT, HPLOTS=, SYMBOL=, and VPLOTS=, described in the section "Line Printer Plots" on page 6402, apply across PLOT statements and remain in effect if they have been previously specified.

Options used for the traditional graphics are described in the following section; see "Line Printer Plots" on page 6402 for more information.

Traditional Graphics

The display of traditional graphics is described in the following paragraphs, the options are summarized in Table 76.6 and described in the section "Dictionary of PLOT Statement Options" on page 6397.

Several line printer statements and options are not supported for the traditional graphics. In particular the PAINT statement is disabled, as are the PLOT statement options CLEAR, COLLECT, HPLOTS=, NOCOLLECT, SYMBOL=, and VPLOTS=. To display more than one plot per page or to collect plots from multiple PLOT statements, use the PROC GREPLAY statement (see *SAS/GRAPH: Reference*). Also note that traditional graphics options are not recognized for line printer plots.

The fitted model equation and a label are displayed in the top margin of the plot; this display can be suppressed with the NOMODEL option. If the label is requested but cannot fit on one line, it is not displayed. The equation and label are displayed on one line when possible; if more lines are required, the label is displayed in the first line with the model equation in successive lines. If displaying the entire equation causes the plot to be unacceptably small, the equation is truncated. Table 76.7 lists options to control the display of the equation.

Four statistics are displayed by default in the right margin: the number of observations, R^2, the adjusted R^2, and the root mean square error. The display of these statistics can be suppressed with the NOSTAT option. You can specify other options to request the display of various statistics in the right margin; see Table 76.7.

A default reference line at zero is displayed if residuals are plotted. If the dependent variable is plotted against the independent variable in a simple linear regression model, the fitted regression line is displayed by default. Default reference lines can be suppressed with the NOLINE option; the lines are not displayed if the OVERLAY option is specified.

Specialized plots are requested with special options. For each coefficient, the RIDGEPLOT option plots the ridge estimates against the ridge values k; see the description of the RIDGEPLOT option in the section "Dictionary of PLOT Statement Options" on page 6397 for more details. The CONF option plots $100(1-\alpha)\%$ confidence intervals for the mean while the PRED option plots $100(1-\alpha)\%$ prediction intervals; see the description of these options in the section "Dictionary of PLOT Statement Options" on page 6397 for more details.

If a SELECTION= method is requested, the fitted model equation and the statistics displayed in the margin correspond to the selected model. For the ADJRSQ and CP methods, the selected model is treated as a submodel of the full model. If a CP.*NP. plot is requested, the CHOCKING= and CMALLOWS= options

display model selection reference lines; see the descriptions of these options in the section "Dictionary of PLOT Statement Options" on page 6397 for more details.

PLOT Statement variable Keywords

The following table lists the keywords available as PLOT statement *xvariables* and *yvariables*. All keywords have a trailing dot; for example, "*COOKD.*" requests Cook's D statistic. Neither the OUTPUT statement nor the OUTEST= option needs to be specified.

Table 76.6 Keywords for PLOT Statement *xvariables*

Keyword	Description
Diagnostic Statistics	
COOKD.	Cook's D influence statistics
COVRATIO.	standard influence of observation on covariance of betas
DFFITS.	standard influence of observation on predicted value
H.	leverage
LCL.	lower bound of $100(1-\alpha)\%$ confidence interval for individual prediction
LCLM.	lower bound of $100(1-\alpha)\%$ confidence interval for the mean of the dependent variable
PREDICTED. | PRED. | P.	predicted values
PRESS.	residuals from refitting the model with current observation deleted
RESIDUAL. | R.	residuals
RSTUDENT.	studentized residuals with the current observation deleted
STDI.	standard error of the individual predicted value
STDP.	standard error of the mean predicted value
STDR.	standard error of the residual
STUDENT.	residuals divided by their standard errors
UCL.	upper bound of $100(1-\alpha)\%$ confidence interval for individual prediction
UCLM.	upper bound of $100(1-\alpha)\%$ confidence interval for the mean of the dependent variables
Other Keywords Used with Diagnostic Statistics	
NPP.	normal probability-probability plot
NQQ.	normal quantile-quantile plot
OBS.	observation number (cannot plot against OUTEST= statistics)
Model Fit Summary Statistics	
ADJRSQ.	adjusted R-square
AIC.	Akaike's information criterion
BIC.	Sawa's Bayesian information criterion
CP.	Mallows' C_p statistic
EDF.	error degrees of freedom
GMSEP.	estimated MSE of prediction, assuming multivariate normality
IN.	number of regressors in the model not including the intercept
JP.	final prediction error

Table 76.6 *continued*

Keyword	Description
MSE.	mean squared error
NP.	number of parameters in the model (including the intercept)
PC.	Amemiya's prediction criterion
RMSE.	root MSE
RSQ.	R-square
SBC.	SBC statistic
SP.	SP statistic
SSE.	error sum of squares

Summary of PLOT Statement Graphics Options

The following table lists the PLOT statement *options* by function. These *options* are available unless the LINEPRINTER option is specified in the PROC REG statement. For complete descriptions, see the section "Dictionary of PLOT Statement Options" on page 6397.

Table 76.7 Traditional Graphics Options

Option	Description
General Graphics Options	
ANNOTATE=*SAS-data-set*	specifies the annotate data set
CHOCKING=*color*	requests a reference line for C_p model selection criteria
CMALLOWS=*color*	requests a reference line for the C_p model selection criterion
CONF	requests plots of $100(1-\alpha)\%$ confidence intervals for the mean
DESCRIPTION='*string*'	specifies a description for graphics catalog member
NAME='*string*'	names the plot in the graphics catalog
OVERLAY	overlays plots from the same model
PRED	requests plots of $100(1-\alpha)\%$ prediction intervals for individual responses
RIDGEPLOT	requests the ridge trace for ridge regression
Axis and Legend Options	
LEGEND=*LEGENDn*	specifies LEGEND statement to be used
NOLEGEND	suppresses display of the legend
HAXIS=*values*	specifies tick mark values for horizontal axis
VAXIS=*values*	specifies tick mark values for vertical axis
Reference Line Options	
HREF=*values*	specifies reference lines perpendicular to horizontal axis
LHREF=*linetype*	specifies line style for HREF= lines
LLINE=*linetype*	specifies line style for lines displayed by default
LVREF=*linetype*	specifies line style for VREF= lines
NOLINE	suppresses display of any default reference line
VREF=*values*	specifies reference lines perpendicular to vertical axis
Color Options	

Table 76.7 *continued*

Option	Description
CAXIS=*color*	specifies color for axis line and tick marks
CFRAME=*color*	specifies color for frame
CHREF=*color*	specifies color for HREF= lines
CLINE=*color*	specifies color for lines displayed by default
CTEXT=*color*	specifies color for text
CVREF=*color*	specifies color for VREF= lines
Options for Displaying the Fitted Model Equation	
MODELFONT=*font*	specifies font of model equation and model label
MODELHT=*value*	specifies text height of model equation and model label
MODELLAB='*label*'	specifies model label
NOMODEL	suppresses display of the fitted model and the label
Options for Displaying Statistics in the Plot Margin	
AIC	displays Akaike's information criterion
BIC	displays Sawa's Bayesian information criterion
CP	displays Mallows' C_p statistic
EDF	displays the error degrees of freedom
GMSEP	displays the estimated MSE of prediction assuming multivariate normality
IN	displays the number of regressors in the model not including the intercept
JP	displays the J_p statistic
MSE	displays the mean squared error
NOSTAT	suppresses display of the default statistics: the number of observations, R-square, adjusted R-square, and root mean square error
NP	displays the number of parameters in the model including the intercept, if any
PC	displays the PC statistic
SBC	displays the SBC statistic
SP	displays the S_p statistic
SSE	displays the error sum of squares
STATFONT=*font*	specifies font of text displayed in the margin
STATHT=*value*	specifies height of text displayed in the margin

Dictionary of PLOT Statement Options

The following entries describe the PLOT statement *options* in detail. Note that these *options* are available unless you specify the LINEPRINTER option in the PROC REG statement.

AIC

displays Akaike's information criterion in the plot margin.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an input data set that contains appropriate variables for annotation. This applies only to displays created with the current PLOT statement. See *SAS/GRAPH: Reference* for more information.

BIC

displays Sawa's Bayesian information criterion in the plot margin.

CAXIS=*color*

CAXES=*color*

CA=*color*

specifies the color for the axes, frame, and tick marks.

CFRAME=*color*

CFR=*color*

specifies the color for filling the area enclosed by the axes and the frame.

CHOCKING=*color*

requests reference lines corresponding to the equations $C_p = p$ and $C_p = 2p - p_{full}$, where p_{full} is the number of parameters in the full model (excluding the intercept) and p is the number of parameters in the subset model (including the intercept). The *color* must be specified; the $C_p = p$ line is solid and the $C_p = 2p - p_{full}$ line is dashed. Only PLOT statements of the form PLOT CP.*NP. produce these lines.

For the purpose of parameter estimation, Hocking (1976) suggests selecting a model where $C_p \leq 2p - p_{full}$. For the purpose of prediction, Hocking suggests the criterion $C_p \leq p$. You can request the single reference line $C_p = p$ with the CMALLOWS= option. If, for example, you specify both CHOCKING=RED and CMALLOWS=BLUE, then the $C_p = 2p - p_{full}$ line is red and the $C_p = p$ line is blue.

CHREF=*color*

CH=*color*

specifies the color for lines requested with the HREF= option.

CLINE=*color*

CL=*color*

specifies the color for lines displayed by default. See the NOLINE option for details.

CMALLOWS=*color*

requests a $C_p = p$ reference line, where p is the number of parameters (including the intercept) in the subset model. The *color* must be specified; the line is solid. Only PLOT statements of the form PLOT CP.*NP. produce this line.

Mallows (1973) suggests that all subset models with C_p small and near p be considered for further study. See the CHOCKING= option for related model-selection criteria.

CONF

is a keyword used as a shorthand option to request plots that include $(100-\alpha)\%$ confidence intervals for the mean response. The ALPHA= option in the PROC REG or MODEL statement selects the

significance level α, which is 0.05 by default. The CONF option is valid for simple regression models only, and is ignored for plots where confidence intervals are inappropriate. The CONF option replaces the CONF95 option; however, the CONF95 option is still supported when the ALPHA= option is not specified. The OVERLAY option is ignored when the CONF option is specified.

CP

displays Mallows' C_p statistic in the plot margin.

CTEXT=*color*

CT=*color*

specifies the color for text including tick mark labels, axis labels, the fitted model label and equation, the statistics displayed in the margin, and legends.

CVREF=*color*

CV=*color*

specifies the color for lines requested with the VREF= option.

DESCRIPTION='*string* **'**

DESC='*string* **'**

specifies a descriptive string, up to 40 characters, that appears in the description field of the PROC GREPLAY master menu.

EDF

displays the error degrees of freedom in the plot margin.

GMSEP

displays the estimated mean square error of prediction in the plot margin. Note that the estimate is calculated under the assumption that both independent and dependent variables have a multivariate normal distribution.

HAXIS=*values*

HA=*values*

specifies tick mark values for the horizontal axis.

HREF=*values*

specifies where reference lines perpendicular to the horizontal axis are to appear.

IN

displays the number of regressors in the model (not including the intercept) in the plot margin.

JP

displays the J_p statistic in the plot margin.

LEGEND=LEGEND*n*

specifies the LEGEND*n* statement to be used. The LEGEND*n* statement is a global graphics statement; see *SAS/GRAPH: Reference* for more information.

LHREF=*linetype*

LH=*linetype*

specifies the line style for lines requested with the HREF= option. The default *linetype* is 2. Note that LHREF=1 requests a solid line. See *SAS/GRAPH: Reference* for a table of available line types.

LLINE=*linetype*

LL=*linetype*

specifies the line style for reference lines displayed by default; see the NOLINE option for details. The default *linetype* is 2. Note that LLINE=1 requests a solid line.

LVREF=*linetype*

LV=*linetype*

specifies the line style for lines requested with the VREF= option. The default *linetype* is 2. Note that LVREF=1 requests a solid line.

MODELFONT=*font*

specifies the font used for displaying the fitted model label and the fitted model equation. See *SAS/GRAPH: Reference* for tables of software fonts.

MODELHT=*height*

specifies the text height for the fitted model label and the fitted model equation.

MODELLAB='*label* '

specifies the label to be displayed with the fitted model equation. By default, no label is displayed. If the label does not fit on one line, it is not displayed. See the section "Traditional Graphics" on page 6394 for more information.

MSE

displays the mean squared error in the plot margin.

NAME='*string* '

specifies a descriptive string, up to eight characters, that appears in the name field of the PROC GREPLAY master menu. The default *string* is REG.

NOLEGEND

suppresses the display of the legend.

NOLINE

suppresses the display of default reference lines. A default reference line at zero is displayed if residuals are plotted. If the dependent variable is plotted against the independent variable in a simple regression model, then the fitted regression line is displayed by default. Default reference lines are not displayed if the OVERLAY option is specified.

NOMODEL

suppresses the display of the fitted model equation.

NOSTAT

suppresses the display of statistics in the plot margin. By default, the number of observations, R-square, adjusted R-square, and root MSE are displayed.

NP

displays the number of regressors in the model including the intercept, if any, in the plot margin.

OVERLAY

overlays all plots specified in the PLOT statement from the same model on one set of axes. The variables for the first plot label the axes. The procedure automatically scales the axes to fit all of the variables unless the HAXIS= or VAXIS= option is used. Default reference lines are not displayed. A default legend is produced; the LEGEND= option can be used to customize the legend.

PC

displays the PC statistic in the plot margin.

PRED

is a keyword used as a shorthand option to request plots that include $(100-\alpha)\%$ prediction intervals for individual responses. The ALPHA= option in the PROC REG or MODEL statement selects the significance level α, which is 0.05 by default. The PRED option is valid for simple regression models only, and is ignored for plots where prediction intervals are inappropriate. The PRED option replaces the PRED95 option; however, the PRED95 option is still supported when the ALPHA= option is not specified. The OVERLAY option is ignored when the PRED option is specified.

RIDGEPLOT

creates overlaid plots of ridge estimates against ridge values for each coefficient. The points corresponding to the estimates of each coefficient in the plot are connected by lines. For ridge estimates to be computed and plotted, the OUTEST= option must be specified in the PROC REG statement, and the RIDGE=list must be specified in either the PROC REG or MODEL statement.

SBC

displays the SBC statistic in the plot margin.

SP

displays the S_p statistic in the plot margin.

SSE

displays the error sum of squares in the plot margin.

STATFONT=*font*

specifies the font used for displaying the statistics that appear in the plot margin. See *SAS/GRAPH: Reference* for tables of software fonts.

STATHT=*height*

specifies the text height of the statistics that appear in the plot margin.

USEALL

specifies that predicted values at data points with missing dependent variable(s) be included on appropriate plots. By default, only points used in constructing the SSCP matrix appear on plots.

VAXIS=*values*

VA=*values*

specifies tick mark values for the vertical axis.

VREF=*values*

specifies where reference lines perpendicular to the vertical axis are to appear.

Line Printer Plots

Line printer plots are requested with the LINEPRINTER option in the PROC REG statement. Points in line printer plots can be marked with *symbols*, which can be specified as a single character enclosed in quotes or the name of any variable in the input data set.

If a character variable is used for the symbol, the first (leftmost) nonblank character in the formatted value of the variable is used as the plotting symbol. If a character in quotes is specified, that character becomes the plotting symbol. If a character is used as the plotting symbol, and if there are different plotting symbols needed at the same point, the symbol '?' is used at that point.

If an unformatted numeric variable is used for the symbol, the symbols '1', '2', . . . , '9' are used for variable values 1, 2, . . . , 9. For noninteger values, only the integer portion is used as the plotting symbol. For values of 10 or greater, the symbol '*' is used. For negative values, a '?' is used. If a numeric variable is used, and if there is more than one plotting symbol needed at the same point, the sum of the variable values is used at that point. If the sum exceeds 9, the symbol '*' is used.

If a symbol is not specified, the number of replicates at the point is displayed. The symbol '*' is used if there are 10 or more replicates.

If the LINEPRINTER option is used, you can specify the following options in the PLOT statement after a slash (/):

CLEAR

clears any collected scatter plots before plotting begins but does not turn off the COLLECT option. Use this option when you want to begin a new collection with the plots in the current PLOT statement. For more information about collecting plots, see the COLLECT and NOCOLLECT options in this section.

COLLECT

specifies that plots begin to be collected from one PLOT statement to the next and that subsequent plots show an overlay of all collected plots. This option enables you to overlay plots before and after changes to the model or to the data used to fit the model. Plots collected before changes are unaffected by the changes and can be overlaid on later plots. You can request more than one plot with this option, and you do not need to request the same number of plots in subsequent PLOT statements. If you specify an unequal number of plots, plots in corresponding positions are overlaid. For example, the statements

```
plot residual.*predicted. y*x / collect;
run;
```

produce two plots. If these statements are then followed by

```
plot residual.*x;
run;
```

two plots are again produced. The first plot shows residual against X values overlaid on residual against predicted values. The second plot is the same as that produced by the first PLOT statement.

Axes are scaled for the first plot or plots collected. The axes are not rescaled as more plots are collected.

Once specified, the COLLECT option remains in effect until the NOCOLLECT option is specified.

HPLOTS=*number*

sets the number of scatter plots that can be displayed across the page. The procedure begins with one plot per page. The value of the HPLOTS= option remains in effect until you change it in a later PLOT statement. See the VPLOTS= option for an example.

NOCOLLECT

specifies that the collection of scatter plots ends after adding the plots in the current PLOT statement. PROC REG starts with the NOCOLLECT option in effect. After you specify the NOCOLLECT option, any following PLOT statement produces a new plot that contains only the plots requested by that PLOT statement.

For more information, see the COLLECT option.

OVERLAY

enables requested scatter plots to be superimposed. The axes are scaled so that points on all plots are shown. If the HPLOTS= or VPLOTS= option is set to more than one, the overlaid plot occupies the first position on the page. The OVERLAY option is similar to the COLLECT option in that both options produce superimposed plots. However, OVERLAY superimposes only the plots in the associated PLOT statement; COLLECT superimposes plots across PLOT statements. The OVERLAY option can be used when the COLLECT option is in effect.

SYMBOL='*character***'**

changes the default plotting symbol used for all scatter plots produced in the current and in subsequent PLOT statements. Both SYMBOL=" and SYMBOL=' ' are allowed.

If the SYMBOL= option has not been specified, the default symbol is '1' for positions with one observation, '2' for positions with two observations, and so on. For positions with more than 9 observations, '*' is used. The SYMBOL= option (or a plotting symbol) is needed to avoid any confusion caused by this default convention. Specifying a particular symbol is especially important when either the OVERLAY or COLLECT option is being used.

If you specify the SYMBOL= option and use a number for *character*, that number is used for all points in the plot. For example, the statement

```
plot y*x / symbol='1';
```

produces a plot with the symbol '1' used for all points.

If you specify a plotting symbol and the SYMBOL= option, the plotting symbol overrides the SYMBOL= option. For example, in the statements

```
plot y*x y*v='.' / symbol='*';
```

the symbol used for the plot of Y against X is '*', and a '.' is used for the plot of Y against V.

If a paint symbol is defined with a PAINT statement, the paint symbol takes precedence over both the SYMBOL= option and the default plotting symbol for the PLOT statement.

VPLOTS=*number*

sets the number of scatter plots that can be displayed down the page. The procedure begins with one plot per page. The value of the VPLOTS= option remains in effect until you change it in a later PLOT statement.

For example, to specify a total of six plots per page, with two rows of three plots, use the HPLOTS= and VPLOTS= options as follows:

```
plot y1*x1 y1*x2 y1*x3 y2*x1 y2*x2 y2*x3 /
     hplots=3 vplots=2;
run;
```

PRINT Statement

PRINT < *options* > < *ANOVA* > < *MODELDATA* > **;**

The PRINT statement enables you to interactively display the results of MODEL statement options, produce an ANOVA table, display the data for variables used in the current model, or redisplay the options specified in a MODEL or a previous PRINT statement. In addition, like most other interactive statements in PROC REG, the PRINT statement implicitly refits the model; thus, effects of REWEIGHT statements are seen in the resulting tables. If ODS Graphics is enabled (see the section "ODS Graphics" on page 6472), the PRINT statement also requests the use of the ODS graphical displays associated with the current model.

The following specifications can appear in the PRINT statement:

options

interactively displays the results of MODEL statement options, where *options* is one or more of the following: ACOV, ALL, CLI, CLM, COLLIN, COLLINOINT, CORRB, COVB, DW, I, INFLUENCE, P, PARTIAL, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, or XPX. See the section "MODEL Statement" on page 6374 for a description of these options.

ANOVA

produces the ANOVA table associated with the current model. This is either the model specified in the last MODEL statement or the model that incorporates changes made by ADD, DELETE, or REWEIGHT statements after the last MODEL statement.

MODELDATA

displays the data for variables used in the current model.

Use the statement

```
print;
```

to reprint options in the most recently specified PRINT or MODEL statement.

Options that require original data values, such as R or INFLUENCE, cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set to PROC REG. See the section "Input Data Sets" on page 6412 for more detail.

REFIT Statement

REFIT ;

The REFIT statement causes the current model and corresponding statistics to be recomputed immediately. No output is generated by this statement. The REFIT statement is needed after one or more REWEIGHT statements to cause them to take effect before subsequent PAINT or REWEIGHT statements. This is sometimes necessary when you are using statistical conditions in REWEIGHT statements. For example, consider the following statements:

```
paint student.>2;
plot student.*p.;
reweight student.>2;
refit;
paint student.>2;
plot student.*p.;
```

The second PAINT statement paints any additional observations that meet the condition after deleting observations and refitting the model. The REFIT statement is used because the REWEIGHT statement does not cause the model to be recomputed. In this particular example, the same effect could be achieved by replacing the REFIT statement with a PLOT statement.

Most interactive statements can be used to implicitly refit the model; any plots or statistics produced by these statements reflect changes made to the model and changes made to the data used to compute the model. The two exceptions are the PAINT and REWEIGHT statements, which do not cause the model to be recomputed.

RESTRICT Statement

RESTRICT *equation* < *, . . . , equation* > **;**

A RESTRICT statement is used to place restrictions on the parameter estimates in the MODEL preceding it. More than one RESTRICT statement can follow each MODEL statement. Each RESTRICT statement replaces any previous RESTRICT statement. To lift all restrictions on a model, submit a new MODEL statement. If there are several restrictions, separate them with commas. The statement

```
restrict equation1=equation2=equation3;
```

is equivalent to imposing the two restrictions

```
restrict equation1=equation2;
restrict equation2=equation3;
```

Each restriction is written as a linear equation and can be written as

equation

or

equation = equation

The form of each *equation* is

$$c_1 \times variable_1 \pm c_2 \times variable_2 \pm \cdots \pm c_n \times variable_n$$

where the c_j's are constants and the $variable_j$'s are any regressor variables.

When no equal sign appears, the linear combination is set equal to zero. Each variable name mentioned must be a variable in the MODEL statement to which the RESTRICT statement refers. The keyword INTERCEPT can also be used as a variable name, and it refers to the intercept parameter in the regression model.

Note that the parameters associated with the variables are restricted, not the variables themselves. Restrictions should be consistent and not redundant.

Examples of valid RESTRICT statements include the following:

```
restrict x1;
restrict a+b=1;
restrict a=b=c;
restrict a=b, b=c;
restrict 2*f=g+h, intercept+f=0;
restrict f=g=h=intercept;
```

The third and fourth statements in this list produce identical restrictions. You cannot specify

```
restrict f-g=0,
         f-intercept=0,
         g-intercept=1;
```

because the three restrictions are not consistent. If these restrictions are included in a RESTRICT statement, one of the restrict parameters is set to zero and has zero degrees of freedom, indicating that PROC REG is unable to apply a restriction.

The restrictions usually operate even if the model is not of full rank. Check to ensure that DF$= -1$ for each restriction. In addition, the model DF should decrease by 1 for each restriction.

The parameter estimates are those that minimize the quadratic criterion (SSE) subject to the restrictions. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as zero.

The method used for restricting the parameter estimates is to introduce a Lagrangian parameter for each restriction (Pringle and Rayner 1971). The estimates of these parameters are displayed with test statistics. Note that the t statistic reported for the Lagrangian parameters does not follow a Student's t distribution, but its square follows a beta distribution (LaMotte 1994). The p-value for these parameters is computed using the beta distribution.

The Lagrangian parameter γ measures the sensitivity of the SSE to the restriction constant. If the restriction constant is changed by a small amount ϵ, the SSE is changed by $2\gamma\epsilon$. The t ratio tests the significance of the restrictions. If γ is zero, the restricted estimates are the same as the unrestricted estimates, and a change in the restriction constant in either direction increases the SSE.

RESTRICT statements are ignored if the PCOMIT= or RIDGE= option is specified in the PROC REG statement.

REWEIGHT Statement

REWEIGHT < *condition* | *ALLOBS* > < / *options* > **;**

REWEIGHT < *STATUS* | *UNDO* > **;**

The REWEIGHT statement interactively changes the weights of observations that are used in computing the regression equation. The REWEIGHT statement can change observation weights, or set them to zero, which causes selected observations to be excluded from the analysis. When a REWEIGHT statement sets observation weights to zero, the observations are not deleted from the data set. More than one REWEIGHT statement can be used. The requests from all REWEIGHT statements are applied to the subsequent statements. Each use of the REWEIGHT statement modifies the MODEL label.

The model and corresponding statistics are not recomputed after a REWEIGHT statement. For example, consider the following statements:

```
reweight r.>0;
reweight r.>0;
```

The second REWEIGHT statement does not exclude any additional observations since the model is not recomputed after the first REWEIGHT statement. Either use a REFIT statement to explicitly refit the model, or implicitly refit the model by following the REWEIGHT statement with any other interactive statement except a PAINT statement or another REWEIGHT statement.

The REWEIGHT statement cannot be used if a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as an input data set to PROC REG. Note that the syntax used in the REWEIGHT statement is the same as the syntax in the PAINT statement.

The syntax of the REWEIGHT statement is described in the following sections.

For detailed examples of using this statement, see the section "Reweighting Observations in an Analysis" on page 6453.

Specifying Condition

Condition is used to find observations to be reweighted. The syntax of *condition* is

variable compare value

or

variable compare value logical variable compare value

where

variable is one of the following:

- a variable name in the input data set
- OBS**.**, which is the observation number
- *keyword***.**, where *keyword* is a keyword for a statistic requested in the OUTPUT statement. The keyword specification is applied to all dependent variables in the model.

compare is an operator that compares *variable* to *value*. *Compare* can be any one of the following: <, <=, >, >=, =, ^ =. The operators LT, LE, GT, GE, EQ, and NE, respectively, can be used instead of the preceding symbols. Refer to the "Expressions" chapter in *SAS Language Reference: Concepts* for more information about comparison operators.

value gives an unformatted value of *variable*. Observations are selected to be reweighted if they satisfy the condition created by *variable compare value*. *Value* can be a number or a character string. If *value* is a character string, it must be eight characters or less and must be enclosed in quotes. In addition, *value* is case-sensitive. In other words, the following two statements are not the same:

```
reweight name='steve';

reweight name='Steve';
```

logical is one of two logical operators. Either AND or OR can be used. To specify AND, use AND or the symbol &. To specify OR, use OR or the symbol |.

Here are some examples of the *variable compare value* form:

```
reweight obs. le 10;
reweight temp=55;
reweight type='new';
```

Here are some example of the *variable compare value logical variable compare value* form:

```
reweight obs.<=10 and residual.<2;
reweight student.<-2 or student.>2;
reweight name='Mary' | name='Susan';
```

Using ALLOBS

Instead of specifying *condition*, you can use the ALLOBS option to select all observations. This is most useful when you want to restore the original weights of all observations. For example,

```
reweight allobs / reset;
```

resets weights for all observations and uses all observations in the subsequent analysis. Note that

```
reweight allobs;
```

specifies that all observations be excluded from analysis. Consequently, using ALLOBS is useful only if you also use one of the options discussed in the following section.

Options in the REWEIGHT Statement

The following options can be used when either a condition, ALLOBS, or nothing is specified before the slash. If only an option is listed, the option applies to the observations selected in the previous REWEIGHT statement, not to the observations selected by reapplying the condition from the previous REWEIGHT statement. For example, consider the following statements:

```
reweight r.>0 / weight=0.1;
refit;
reweight;
```

The second REWEIGHT statement excludes from the analysis only those observations selected in the first REWEIGHT statement. No additional observations are excluded even if there are new observations that meet the condition in the first REWEIGHT statement.

NOTE: Options are not available when either the UNDO or STATUS option is used.

NOLIST

suppresses the display of the selected observation numbers. If you omit the NOLIST option, a list of observations selected is written to the log.

RESET

resets the observation weights to their original values as defined by the WEIGHT statement or to WEIGHT=1 if no WEIGHT statement is specified. For example,

```
reweight / reset;
```

resets observation weights to the original weights in the data set. If previous REWEIGHT statements have been submitted, this REWEIGHT statement applies only to the observations selected by the previous REWEIGHT statement. Note that, although the RESET option does reset observation weights to their original values, it does not cause the model and corresponding statistics to be recomputed.

WEIGHT=*value*

changes observation weights to the specified nonnegative real number. If you omit the WEIGHT= option, the observation weights are set to zero, and observations are excluded from the analysis. For example:

```
reweight name='Alan';
\Codecomment{...other interactive statements}
reweight / weight=0.5;
```

The first REWEIGHT statement changes weights to zero for all observations with name='Alan', effectively deleting these observations. The subsequent analysis does not include these observations. The second REWEIGHT statement applies only to those observations selected by the previous REWEIGHT statement, and it changes the weights to 0.5 for all the observations with NAME='Alan'. Thus, the next analysis includes all original observations; however, those observations with NAME='Alan' have their weights set to 0.5.

STATUS and UNDO

If you omit *condition* and the ALLOBS options, you can specify one of the following options.

STATUS
writes to the log the observation's number and the weight of all reweighted observations. If an observation's weight has been set to zero, it is reported as deleted. However, the observation is not deleted from the data set, only from the analysis.

UNDO
undoes the changes made by the most recent REWEIGHT statement. Weights might be, but are not necessarily, reset. For example, consider the following statements:

```
reweight student.>2 / weight=0.1;
reweight;
reweight undo;
```

The first REWEIGHT statement sets the weights of observations that satisfy the condition to 0.1. The second REWEIGHT statement sets the weights of the same observations to zero. The third REWEIGHT statement undoes the second, changing the weights back to 0.1.

TEST Statement

<label:> TEST *equation,<,...,equation><option>* **;**

The TEST statement tests hypotheses about the parameters estimated in the preceding MODEL statement. It has the same syntax as the RESTRICT statement except that it supports an option. Each equation specifies a linear hypothesis to be tested. The rows of the hypothesis are separated by commas.

Variable names must correspond to regressors, and each variable name represents the coefficient of the corresponding variable in the model. An optional label is useful to identify each test with a name. The keyword INTERCEPT can be used instead of a variable name to refer to the model's intercept.

The REG procedure performs an F test for the joint hypotheses specified in a single TEST statement. More than one TEST statement can accompany a MODEL statement. The numerator is the usual quadratic form of the estimates; the denominator is the mean squared error. If hypotheses can be represented by

$$\mathbf{L}\boldsymbol{\beta} = \mathbf{c}$$

then the numerator of the F test is

$$\mathbf{Q} = (\mathbf{Lb} - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-1}(\mathbf{Lb} - \mathbf{c})$$

divided by degrees of freedom, where $\mathbf{b}$ is the estimate of $\boldsymbol{\beta}$. For example:

```
model y=a1 a2 b1 b2;
aplus: test a1+a2=1;
b1:    test b1=0, b2=0;
b2:    test b1, b2;
```

The last two statements are equivalent; since no constant is specified, zero is assumed.

Note that, when the ACOV, HCC, or WHITE option is specified in the MODEL statement, tests are recomputed using the heteroscedasticity-consistent covariance matrix specified with the HCCMETHOD= option in the MODEL statement (see the section "Testing for Heteroscedasticity" on page 6459).

One option can be specified in the TEST statement after a slash (/):

PRINT

displays intermediate calculations. This includes $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'$ bordered by $\mathbf{Lb}-\mathbf{c}$, and $(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-1}$ bordered by $(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-1}(\mathbf{Lb}-\mathbf{c})$.

VAR Statement

VAR *variables* **;**

The VAR statement is used to include numeric variables in the crossproducts matrix that are not specified in the first MODEL statement.

Variables not listed in MODEL statements before the first RUN statement must be listed in the VAR statement if you want the ability to add them interactively to the model with an ADD statement, to include them in a new MODEL statement, or to plot them in a scatter plot with the PLOT statement.

In addition, if you want to use options in the PROC REG statement and do not want to fit a model to the data (with a MODEL statement), you must use a VAR statement.

WEIGHT Statement

WEIGHT *variable* **;**

A WEIGHT statement names a variable in the input data set with values that are relative weights for a weighted least squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, then the weighted estimates are the best linear unbiased estimates (BLUE).

Values of the weight variable must be nonnegative. If an observation's weight is zero, the observation is deleted from the analysis. If a weight is negative or missing, it is set to zero, and the observation is excluded from the analysis. A more complete description of the WEIGHT statement can be found in Chapter 41, "The GLM Procedure."

Observation weights can be changed interactively with the REWEIGHT statement.

Details: REG Procedure

Missing Values

PROC REG constructs only one crossproducts matrix for the variables in all regressions. If any variable needed for any regression is missing, the observation is excluded from all estimates. If you include variables with missing values in the VAR statement, the corresponding observations are excluded from all analyses, even if you never include the variables in a model. PROC REG assumes that you might want to include these variables after the first RUN statement and deletes observations with missing values.

Input Data Sets

PROC REG does not compute new regressors. For example, if you want a quadratic term in your model, you should create a new variable when you prepare the input data. For example, the statement

```
model y=x1 x1*x1;
```

is not valid. Note that this MODEL statement is valid in the GLM procedure.

The input data set for most applications of PROC REG contains standard rectangular data, but special TYPE=CORR, TYPE=COV, and TYPE=SSCP data sets can also be used. TYPE=CORR and TYPE=COV data sets created by the CORR procedure contain means and standard deviations. In addition, TYPE=CORR data sets contain correlations and TYPE=COV data sets contain covariances. TYPE=SSCP data sets created in previous runs of PROC REG that used the OUTSSCP= option contain the sums of squares and crossproducts of the variables.

See Appendix A, "Special SAS Data Sets," and the "SAS Files" section in *SAS Language Reference: Concepts* for more information about special SAS data sets.

These summary files save CPU time. It takes nk^2 operations (where n=number of observations and k=number of variables) to calculate crossproducts; the regressions are of the order k^3. When n is in the thousands and k is less than 10, you can save 99% of the CPU time by reusing the SSCP matrix rather than recomputing it.

When you want to use a special SAS data set as input, PROC REG must determine the TYPE for the data set. PROC CORR and PROC REG automatically set the type for their output data sets. However, if you create the data set by some other means (such as a DATA step), you must specify its type with the TYPE= data set option. If the TYPE for the data set is not specified when the data set is created, you can specify TYPE= as a data set option in the DATA= option in the PROC REG statement. For example:

```
proc reg data=a(type=corr);
```

When a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used with PROC REG, statements and options that require the original data values have no effect. The OUTPUT, PAINT, PLOT, and REWEIGHT

statements and the MODEL and PRINT statement options P, R, CLM, CLI, DW, INFLUENCE, and PARTIAL are disabled since the original observations needed to calculate predicted and residual values are not present.

Example Using TYPE=CORR Data Set

The following statements use PROC CORR to produce an input data set for PROC REG. The fitness data for this analysis can be found in Example 76.2.

```
proc corr data=fitness outp=r noprint;
   var Oxygen RunTime Age Weight RunPulse MaxPulse RestPulse;
proc print data=r;
proc reg data=r;
   model Oxygen=RunTime Age Weight;
run;
```

Since the OUTP= data set from PROC CORR is automatically set to TYPE=CORR, the TYPE= data set option is not required in this example. The data set containing the correlation matrix is displayed by the PRINT procedure as shown in Figure 76.14. Figure 76.15 shows results from the regression that uses the TYPE=CORR data as an input data set.

Age	1	−0.17388	0.09955	−1.75	0.0921
Weight	1	−0.05444	0.06181	−0.88	0.3862

The following example uses the saved crossproducts matrix:

```
proc reg data=fitness outsscp=sscp noprint;
   model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse;
proc print data=sscp;
proc reg data=sscp;
   model Oxygen=RunTime Age Weight;
run;
```

First, all variables are used to fit the data and create the SSCP data set. Figure 76.16 shows the PROC PRINT display of the SSCP data set. The SSCP data set is then used as the input data set for PROC REG, and a reduced model is fit to the data.

Figure 76.16 TYPE=SSCP Data Set Created by PROC REG

Coeff Var	5.67416		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	93.12615	7.55916	12.32	<.0001
RunTime	1	-3.14039	0.36738	-8.55	<.0001
Age	1	-0.17388	0.09955	-1.75	0.0921
Weight	1	-0.05444	0.06181	-0.88	0.3862

In the preceding example, the TYPE= data set option is not required since PROC REG sets the OUTSSCP= data set to TYPE=SSCP.

Output Data Sets

OUTEST= Data Set

The OUTEST= specification produces a TYPE=EST output SAS data set containing estimates and optional statistics from the regression models. For each BY group on each dependent variable occurring in each MODEL statement, PROC REG outputs an observation to the OUTEST= data set. The variables output to the data set are as follows:

- the BY variables, if any
- _MODEL_, a character variable containing the label of the corresponding MODEL statement, or MODEL*n* if no label is specified, where *n* is 1 for the first MODEL statement, 2 for the second model statement, and so on
- _TYPE_, a character variable with the value 'PARMS' for every observation

- _DEPVAR_, the name of the dependent variable
- _RMSE_, the root mean squared error or the estimate of the standard deviation of the error term
- Intercept, the estimated intercept, unless the NOINT option is specified
- all the variables listed in any MODEL or VAR statement. Values of these variables are the estimated regression coefficients for the model. A variable that does not appear in the model corresponding to a given observation has a missing value in that observation. The dependent variable in each model is given a value of -1.

If you specify the COVOUT option, the covariance matrix of the estimates is output after the estimates; the _TYPE_ variable is set to the value 'COV' and the names of the rows are identified by the character variable, _NAME_.

If you specify the TABLEOUT option, the following statistics listed by _TYPE_ are added after the estimates:

- STDERR, the standard error of the estimate
- T, the t statistic for testing if the estimate is zero
- PVALUE, the associated p-value
- LnB, the $100(1-\alpha)$ lower confidence limit for the estimate, where n is the nearest integer to $100(1-\alpha)$ and α defaults to 0.05 or is set by using the ALPHA= option in the PROC REG or MODEL statement
- UnB, the $100(1-\alpha)$ upper confidence limit for the estimate

Specifying the option ADJRSQ, AIC, BIC, CP, EDF, GMSEP, JP, MSE, PC, RSQUARE, SBC, SP, or SSE in the PROC REG or MODEL statement automatically outputs these statistics and the model R^2 for each model selected, regardless of the model selection method. Additional variables, in order of occurrence, are as follows:

- _IN_, the number of regressors in the model not including the intercept
- _P_, the number of parameters in the model including the intercept, if any
- _EDF_, the error degrees of freedom
- _SSE_, the error sum of squares, if the SSE option is specified
- _MSE_, the mean squared error, if the MSE option is specified
- _RSQ_, the R^2 statistic
- _ADJRSQ_, the adjusted R^2, if the ADJRSQ option is specified
- _CP_, the C_p statistic, if the CP option is specified
- _SP_, the S_p statistic, if the SP option is specified

- _JP_, the J_p statistic, if the JP option is specified
- _PC_, the PC statistic, if the PC option is specified
- _GMSEP_, the GMSEP statistic, if the GMSEP option is specified
- _AIC_, the AIC statistic, if the AIC option is specified
- _BIC_, the BIC statistic, if the BIC option is specified
- _SBC_, the SBC statistic, if the SBC option is specified

The following statements produce and display the OUTEST= data set. This example uses the population data given in the section "Polynomial Regression" on page 6346. Figure 76.18 through Figure 76.20 show the regression equations and the resulting OUTEST= data set.

```
proc reg data=USPopulation outest=est;
   m1: model Population=Year;
   m2: model Population=Year YearSq;
proc print data=est;
run;
```

Figure 76.18 Regression Output for Model M1

Figure 76.19 Regression Output for Model M2

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	159529	79765	8864.19	<.0001
Error	19	170.97193	8.99852		
Corrected Total	21	159700			

Root MSE	2.99975	R-Square	0.9989
Dependent Mean	94.64800	Adj R-Sq	0.9988
Coeff Var	3.16938		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	21631	639.50181	33.82	<.0001
Year	1	-24.04581	0.67547	-35.60	<.0001
YearSq	1	0.00668	0.00017820	37.51	<.0001

Figure 76.20 OUTEST= Data Set

Obs	_MODEL_	_TYPE_	_DEPVAR_	_RMSE_	Intercept	Year	Population	YearSq
1	m1	PARMS	Population	25.3295	-2345.85	1.2879	-1	.
2	m2	PARMS	Population	2.9998	21630.89	-24.0458	-1	.006684346

The following modification of the previous example uses the TABLEOUT and ALPHA= options to obtain additional information in the OUTEST= data set:

```
proc reg data=USPopulation outest=est tableout alpha=0.1;
   m1: model Population=Year/noprint;
   m2: model Population=Year YearSq/noprint;
proc print data=est;
run;
```

Notice that the TABLEOUT option causes standard errors, t statistics, p-values, and confidence limits for the estimates to be added to the OUTEST= data set. Also note that the ALPHA= option is used to set the confidence level at 90%. The OUTEST= data set is shown in Figure 76.21.

Figure 76.21 The OUTEST= Data Set When TABLEOUT Is Specified

Obs	_MODEL_	_TYPE_	_DEPVAR_	_RMSE_	Intercept	Year	Population	YearSq

11	m2	L90B	Population	2.9998	20525.11	-25.2138	.	0.0064
12	m2	U90B	Population	2.9998	22736.68	-22.8778	.	0.0070

A slightly different OUTEST= data set is created when you use the RSQUARE selection method. The following statements request only the "best" model for each subset size but ask for a variety of model selection statistics, as well as the estimated regression coefficients. An OUTEST= data set is created and displayed. See Figure 76.22 and Figure 76.23 for the results.

```
proc reg data=fitness outest=est;
   model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
         / selection=rsquare mse jp gmsep cp aic bic sbc b best=1;
proc print data=est;
run;
```

OUTSSCP= Data Sets

The OUTSSCP= option produces a TYPE=SSCP output SAS data set containing sums of squares and crossproducts. A special row (observation) and column (variable) of the matrix called Intercept contain the number of observations and sums. Observations are identified by the character variable _NAME_. The data set contains all variables used in MODEL statements. You can specify additional variables that you want included in the crossproducts matrix with a VAR statement.

The SSCP data set is used when a large number of observations are explored in many different runs. The SSCP data set can be saved and used for subsequent runs, which are much less expensive since PROC REG never reads the original data again. If you run PROC REG once to create only a SSCP data set, you should list all the variables that you might need in a VAR statement or include all the variables that you might need in a MODEL statement.

The following statements use the fitness data from Example 76.2 to produce an output data set with the OUTSSCP= option. The resulting output is shown in Figure 76.24.

```
proc reg data=fitness outsscp=sscp;
   var Oxygen RunTime Age Weight RestPulse RunPulse MaxPulse;
proc print data=sscp;
run;
```

Since a model is not fit to the data and since the only request is to create the SSCP data set, a MODEL statement is not required in this example. However, since the MODEL statement is not used, the VAR statement is required.

Figure 76.24 SSCP Data Set Created with OUTSSCP= Option: REG Procedure

Obs	_TYPE_	_NAME_	Intercept	Oxygen	RunTime	Age

Interactive Analysis

PROC REG enables you to change interactively both the model and the data used to compute the model, and to produce and highlight scatter plots. See the section "Using PROC REG Interactively" on page 6356 for an overview of interactive analysis that uses PROC REG. The following statements can be used interactively (without reinvoking PROC REG): ADD, DELETE, MODEL, MTEST, OUTPUT, PAINT, PLOT, PRINT, REFIT, RESTRICT, REWEIGHT, and TEST. All interactive features are disabled if there is a BY statement.

The ADD, DELETE, and REWEIGHT statements can be used to modify the current MODEL. Every use of an ADD, DELETE, or REWEIGHT statement causes the model label to be modified by attaching an additional number to it. This number is the cumulative total of the number of ADD, DELETE, or REWEIGHT statements following the current MODEL statement.

A more detailed explanation of changing the data used to compute the model is given in the section "Reweighting Observations in an Analysis" on page 6453.

The following statements illustrate the usefulness of the interactive features. First, the full regression model is fit to the Class data (see the section "Getting Started: REG Procedure" on page 6342), and Figure 76.25 is produced.

```
ods graphics on;

proc reg data=Class plots(modelLabel only)=ResidualByPredicted;
   model Weight=Age Height;
run;
```

Figure 76.25 Interactive Analysis: Full Model

The REG Procedure
Model: MODEL1
Dependent Variable: Weight

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	7215.63710	3607.81855	27.23	<.0001
Error	16	2120.09974	132.50623		
Corrected Total	18	9335.73684			

Root MSE	11.51114	R-Square	0.7729
Dependent Mean	100.02632	Adj R-Sq	0.7445
Coeff Var	11.50811		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-141.22376	33.38309	-4.23	0.0006
Age	1	1.27839	3.11010	0.41	0.6865
Height	1	3.59703	0.90546	3.97	0.0011

Next, the regression model is reduced by the following statements, and Figure 76.26 is produced.

```
delete age;
print;
run;
```

Figure 76.26 Interactive Analysis: Reduced Model

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	7193.24912	7193.24912	57.08	<.0001
Error	17	2142.48772	126.02869		
Corrected Total	18	9335.73684			

Root MSE	11.22625	R-Square	0.7705
Dependent Mean	100.02632	Adj R-Sq	0.7570
Coeff Var	11.22330		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-143.02692	32.27459	-4.43	0.0004
Height	1	3.89903	0.51609	7.55	<.0001

Note that the MODEL label has been changed from MODEL1 to MODEL1.1, since the original MODEL has been changed by the delete statement.

When ODS Graphics is enabled, updated plots are produced whenever a PRINT statement is used. The option

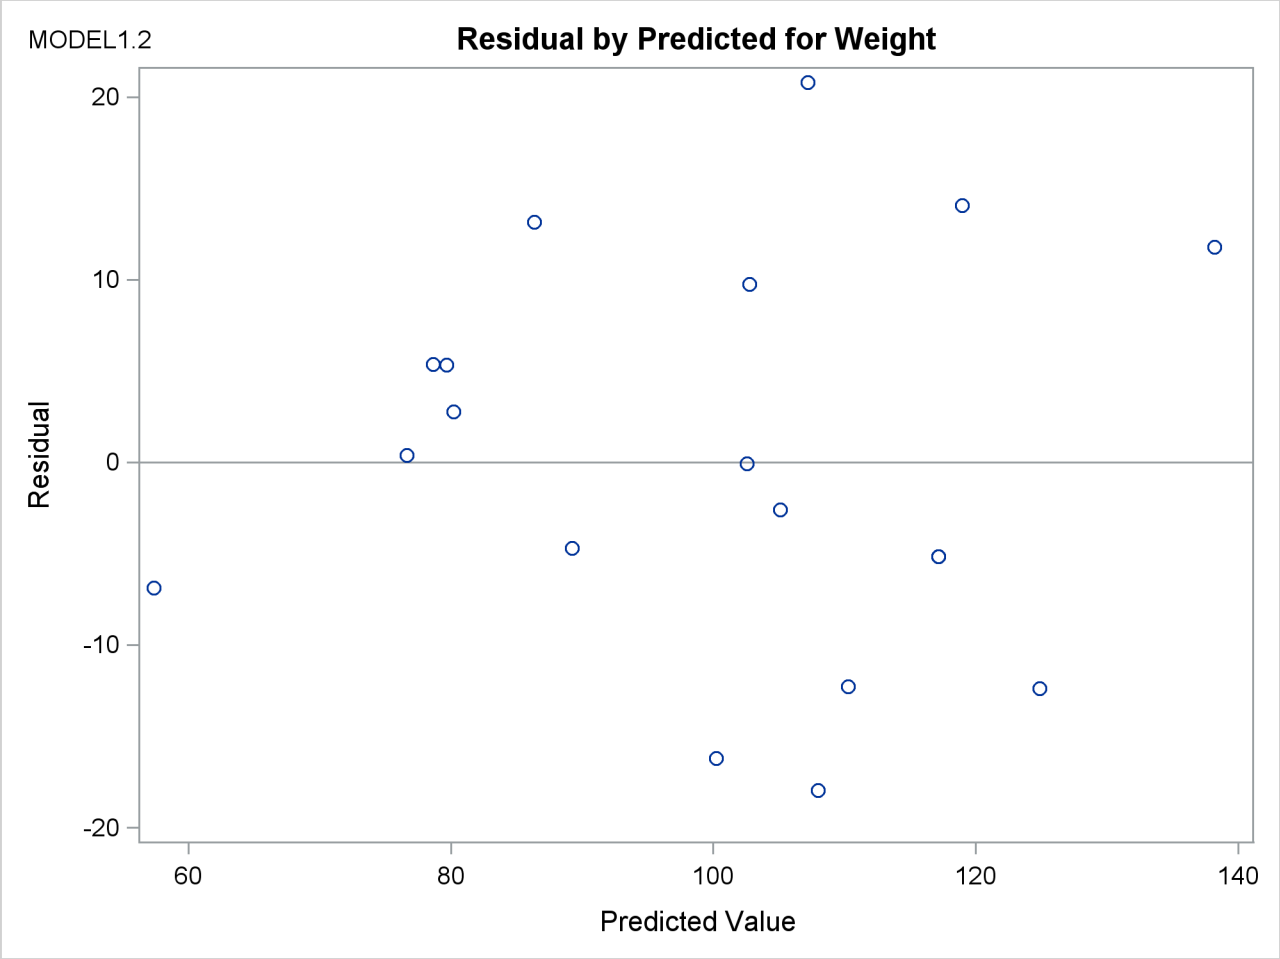
```
plots(modelLabel only)=ResidualByPredicted
```

in the PROC REG statement specifies that the only plot produced is a scatter plot of residuals by predicted values. The MODELLABEL option specifies that the current model label is added to the plot.

The following statements generate a scatter plot of the residuals against the predicted values from the full model. Figure 76.27 is produced, and the scatter plot shows a possible outlier.

```
add age;
print;
run;
```

Figure 76.27 Interactive Analysis: Scatter Plot

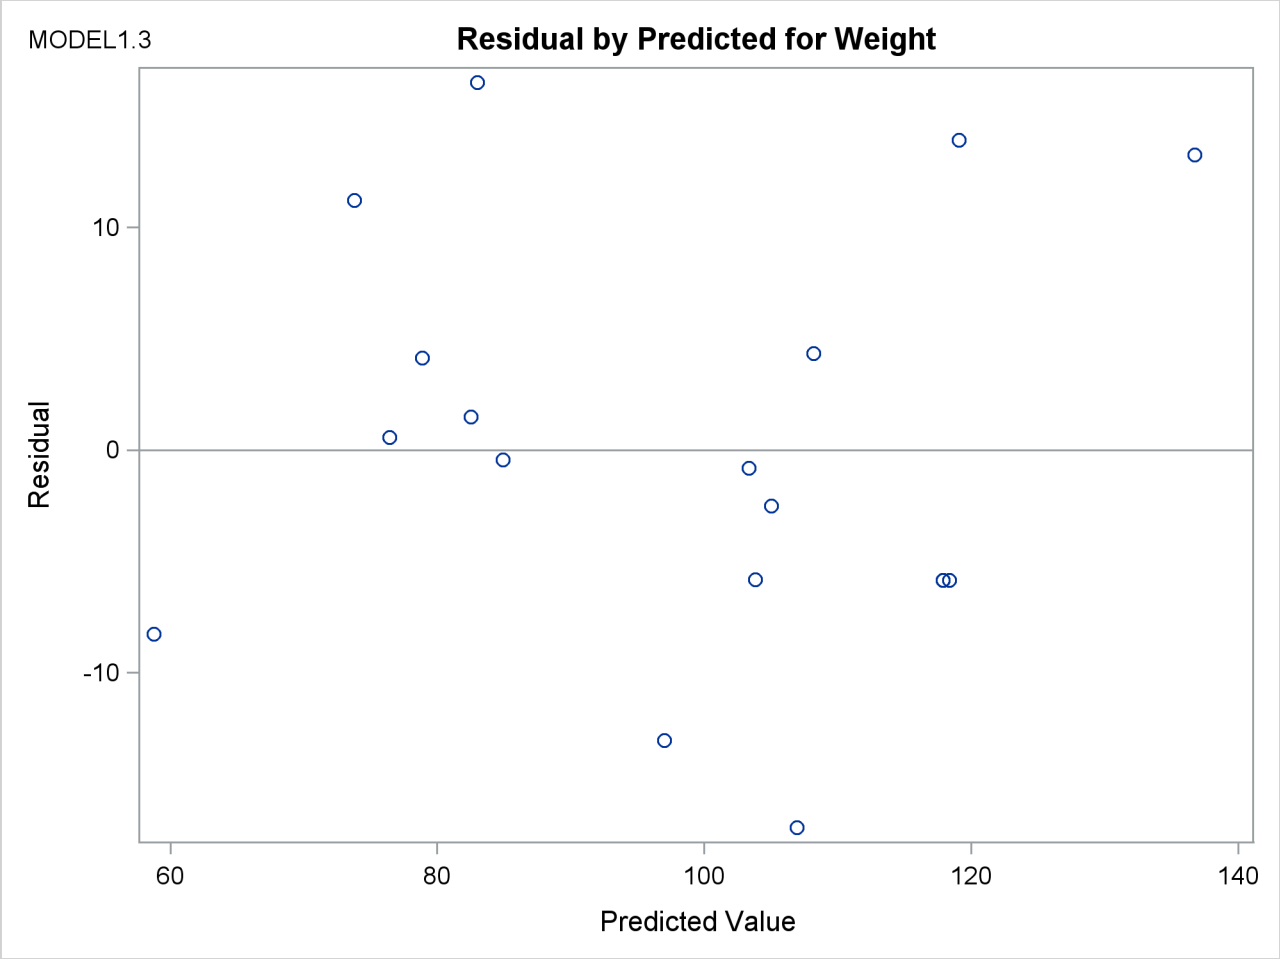


The following statements delete the observation with the largest residual, refit the regression model, and produce a scatter plot of residuals against predicted values for the refitted model. Figure 76.28 shows the new scatter plot.

```
reweight r.>20;
print;
run;

ods graphics off;
```

Figure 76.28 Interactive Analysis: Scatter Plot



Model-Selection Methods

The nine methods of model selection implemented in PROC REG are specified with the SELECTION= option in the MODEL statement. Each method is discussed in this section.

Full Model Fitted (NONE)

This method is the default and provides no model selection capability. The complete model specified in the MODEL statement is used to fit the model. For many regression analyses, this might be the only method you need.

Forward Selection (FORWARD)

The forward-selection technique begins with no variables in the model. For each of the independent variables, the FORWARD method calculates F statistics that reflect the variable's contribution to the model if it

is included. The p-values for these F statistics are compared to the SLENTRY= value that is specified in the MODEL statement (or to 0.50 if the SLENTRY= option is omitted). If no F statistic has a significance level greater than the SLENTRY= value, the FORWARD selection stops. Otherwise, the FORWARD method adds the variable that has the largest F statistic to the model. The FORWARD method then calculates F statistics again for the variables still remaining outside the model, and the evaluation process is repeated. Thus, variables are added one by one to the model until no remaining variable produces a significant F statistic. Once a variable is in the model, it stays.

Backward Elimination (BACKWARD)

The backward elimination technique begins by calculating F statistics for a model which includes all of the independent variables. Then the variables are deleted from the model one by one until all the variables remaining in the model produce F statistics significant at the SLSTAY= level specified in the MODEL statement (or at the 0.10 level if the SLSTAY= option is omitted). At each step, the variable showing the smallest contribution to the model is deleted.

Stepwise (STEPWISE)

The stepwise method is a modification of the forward-selection technique and differs in that variables already in the model do not necessarily stay there. As in the forward-selection method, variables are added one by one to the model, and the F statistic for a variable to be added must be significant at the SLENTRY= level. After a variable is added, however, the stepwise method looks at all the variables already included in the model and deletes any variable that does not produce an F statistic significant at the SLSTAY= level. Only after this check is made and the necessary deletions are accomplished can another variable be added to the model. The stepwise process ends when none of the variables outside the model has an F statistic significant at the SLENTRY= level and every variable in the model is significant at the SLSTAY= level, or when the variable to be added to the model is the one just deleted from it.

Maximum R^2 Improvement (MAXR)

The maximum R^2 improvement technique does not settle on a single model. Instead, it tries to find the "best" one-variable model, the "best" two-variable model, and so forth, although it is not guaranteed to find the model with the largest R^2 for each size.

The MAXR method begins by finding the one-variable model producing the highest R^2. Then another variable, the one that yields the greatest increase in R^2, is added. Once the two-variable model is obtained, each of the variables in the model is compared to each variable not in the model. For each comparison, the MAXR method determines if removing one variable and replacing it with the other variable increases R^2. After comparing all possible switches, the MAXR method makes the switch that produces the largest increase in R^2. Comparisons begin again, and the process continues until the MAXR method finds that no switch could increase R^2. Thus, the two-variable model achieved is considered the "best" two-variable model the technique can find. Another variable is then added to the model, and the comparing-and-switching process is repeated to find the "best" three-variable model, and so forth.

The difference between the STEPWISE method and the MAXR method is that all switches are evaluated before any switch is made in the MAXR method. In the STEPWISE method, the "worst" variable might

be removed without considering what adding the "best" remaining variable might accomplish. The MAXR method might require much more computer time than the STEPWISE method.

Minimum R^2 (MINR) Improvement

The MINR method closely resembles the MAXR method, but the switch chosen is the one that produces the smallest increase in R^2. For a given number of variables in the model, the MAXR and MINR methods usually produce the same "best" model, but the MINR method considers more models of each size.

R^2 Selection (RSQUARE)

The RSQUARE method finds subsets of independent variables that best predict a dependent variable by linear regression in the given sample. You can specify the largest and smallest number of independent variables to appear in a subset and the number of subsets of each size to be selected. The RSQUARE method can efficiently perform all possible subset regressions and display the models in decreasing order of R^2 magnitude within each subset size. Other statistics are available for comparing subsets of different sizes. These statistics, as well as estimated regression coefficients, can be displayed or output to a SAS data set.

The subset models selected by the RSQUARE method are optimal in terms of R^2 for the given sample, but they are not necessarily optimal for the population from which the sample is drawn or for any other sample for which you might want to make predictions. If a subset model is selected on the basis of a large R^2 value or any other criterion commonly used for model selection, then all regression statistics computed for that model under the assumption that the model is given a priori, including all statistics computed by PROC REG, are biased.

While the RSQUARE method is a useful tool for exploratory model building, no statistical method can be relied on to identify the "true" model. Effective model building requires substantive theory to suggest relevant predictors and plausible functional forms for the model.

The RSQUARE method differs from the other selection methods in that RSQUARE always identifies the model with the largest R^2 for each number of variables considered. The other selection methods are not guaranteed to find the model with the largest R^2. The RSQUARE method requires much more computer time than the other selection methods, so a different selection method such as the STEPWISE method is a good choice when there are many independent variables to consider.

Adjusted R^2 Selection (ADJRSQ)

This method is similar to the RSQUARE method, except that the adjusted R^2 statistic is used as the criterion for selecting models, and the method finds the models with the highest adjusted R^2 within the range of sizes.

Mallows' C_p Selection (CP)

This method is similar to the ADJRSQ method, except that Mallows' C_p statistic is used as the criterion for model selection. Models are listed in ascending order of C_p.

Additional Information about Model-Selection Methods

If the RSQUARE or STEPWISE procedure (as documented in *SAS User's Guide: Statistics, Version 5 Edition*) is requested, PROC REG with the appropriate model-selection method is actually used.

Reviews of model-selection methods by Hocking (1976) and Judge et al. (1980) describe these and other variable-selection methods.

Criteria Used in Model-Selection Methods

When many significance tests are performed, each at a level of, for example, 5%, the overall probability of rejecting at least one true null hypothesis is much larger than 5%. If you want to guard against including any variables that do not contribute to the predictive power of the model in the population, you should specify a very small SLE= significance level for the FORWARD and STEPWISE methods and a very small SLS= significance level for the BACKWARD and STEPWISE methods.

In most applications, many of the variables considered have some predictive power, however small. If you want to choose the model that provides the best prediction computed using the sample estimates, you need only to guard against estimating more parameters than can be reliably estimated with the given sample size, so you should use a moderate significance level, perhaps in the range of 10% to 25%.

In addition to R^2, the C_p statistic is displayed for each model generated in the model-selection methods. The C_p statistic is proposed by Mallows (1973) as a criterion for selecting a model. It is a measure of total squared error defined as

$$C_p = \frac{SSE_p}{s^2} - (N - 2p)$$

where s^2 is the MSE for the full model, and SSE_p is the sum-of-squares error for a model with p parameters including the intercept, if any. If C_p is plotted against p, Mallows recommends the model where C_p first approaches p. When the right model is chosen, the parameter estimates are unbiased, and this is reflected in C_p near p. For further discussion, refer to Daniel and Wood (1980).

The adjusted R^2 statistic is an alternative to R^2 that is adjusted for the number of parameters in the model. The adjusted R^2 statistic is calculated as

$$\text{ADJRSQ} = 1 - \frac{(n - i)(1 - R^2)}{n - p}$$

where n is the number of observations used in fitting the model, and i is an indicator variable that is 1 if the model includes an intercept, and 0 otherwise.

Limitations in Model-Selection Methods

The use of model-selection methods can be time-consuming in some cases because there is no built-in limit on the number of independent variables, and the calculations for a large number of independent variables can be lengthy. The recommended limit on the number of independent variables for the MINR method is $20 + i$, where i is the value of the INCLUDE= option.

For the RSQUARE, ADJRSQ, or CP method, with a large value of the BEST= option, adding one more variable to the list from which regressors are selected might significantly increase the CPU time. Also, the time required for the analysis is highly dependent on the data and on the values of the BEST=, START=, and STOP= options.

Parameter Estimates and Associated Statistics

The following example uses the fitness data from Example 76.2. Figure 76.30 shows the parameter estimates and the tables from the SS1, SS2, STB, CLB, COVB, and CORRB options:

```
proc reg data=fitness;
   model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse
         / ss1 ss2 stb clb covb corrb;
run;
```

The procedure first displays an analysis of variance table (Figure 76.29). The F statistic for the overall model is significant, indicating that the model explains a significant portion of the variation in the data.

Figure 76.29 ANOVA Table

The REG Procedure
Model: MODEL1
Dependent Variable: Oxygen

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	6	722.54361	120.42393	22.43	<.0001
Error	24	128.83794	5.36825		
Corrected Total	30	851.38154			

Root MSE	2.31695	R-Square	0.8487
Dependent Mean	47.37581	Adj R-Sq	0.8108
Coeff Var	4.89057		

The procedure next displays parameter estimates and some associated statistics (Figure 76.30). First, the estimates are shown, followed by their standard errors. The next two columns of the table contain the t

statistics and the corresponding probabilities for testing the null hypothesis that the parameter is not significantly different from zero. These probabilities are usually referred to as p-values. For example, the Intercept term in the model is estimated to be 102.9 and is significantly different from zero. The next two columns of the table are the result of requesting the SS1 and SS2 options, and they show sequential and partial sums of squares (SS) associated with each variable. The standardized estimates (produced by the STB option) are the parameter estimates that result when all variables are standardized to a mean of 0 and a variance of 1. These estimates are computed by multiplying the original estimates by the standard deviation of the regressor (independent) variable and then dividing by the standard deviation of the dependent variable. The CLB option adds the upper and lower 95% confidence limits for the parameter estimates; the α level can be changed by specifying the ALPHA= option in the PROC REG or MODEL statement.

Figure 76.30 SS1, SS2, STB, CLB, COVB, and CORRB Options: Parameter Estimates

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|	Type I SS

For further discussion of the parameters and statistics, see the section "Displayed Output" on page 6467, and Chapter 4, "Introduction to Regression Procedures."

Predicted and Residual Values

The display of the predicted values and residuals is controlled by the P, R, CLM, and CLI options in the MODEL statement. The P option causes PROC REG to display the observation number, the ID value (if an ID statement is used), the actual value, the predicted value, and the residual. The R, CLI, and CLM options also produce the items under the P option. Thus, P is unnecessary if you use one of the other options.

The R option requests more detail, especially about the residuals. The standard errors of the mean predicted value and the residual are displayed. The studentized residual, which is the residual divided by its standard error, is both displayed and plotted. A measure of influence, Cook's D, is displayed. Cook's D measures the change to the estimates that results from deleting each observation (Cook 1977, 1979). This statistic is very similar to DFFITS.

The CLM option requests that PROC REG display the $100(1-\alpha)\%$ lower and upper confidence limits for the mean predicted values. This accounts for the variation due to estimating the parameters only. If you want a $100(1-\alpha)\%$ confidence interval for observed values, then you can use the CLI option, which adds in the variability of the error term. The α level can be specified with the ALPHA= option in the PROC REG or MODEL statement.

You can use these statistics in PLOT and PAINT statements. This is useful in performing a variety of regression diagnostics. For definitions of the statistics produced by these options, see Chapter 4, "Introduction to Regression Procedures."

The following statements use the U.S. population data found in the section "Polynomial Regression" on page 6346. The results are shown in Figure 76.32 and Figure 76.33.

```
data USPop2;
   input Year @@;
   YearSq=Year*Year;

After producing the usual analysis of variance and parameter estimates tables (Figure 76.32), the procedure displays the results of requesting the options for predicted and residual values (Figure 76.33). For each observation, the requested information is shown. Note that the ID variable is used to identify each observation. Also note that, for observations with missing dependent variables, the predicted value, standard error of the predicted value, and confidence intervals for the predicted value are still available.

The columnar print plot of studentized residuals and Cook's D statistics are displayed as a result of requesting the R option. In the plot of studentized residuals, the large number of observations with absolute values greater than two indicates an inadequate model. You can use ODS Graphics to obtain plots of studentized residuals by predicted values or leverage; see Example 76.1 for a similar example.

Models of Less Than Full Rank

If the model is not full rank, there are an infinite number of least squares solutions for the estimates. PROC REG chooses a nonzero solution for all variables that are linearly independent of previous variables and a zero solution for other variables. This solution corresponds to using a generalized inverse in the normal equations, and the expected values of the estimates are the Hermite normal form of $\mathbf{X}$ multiplied by the true parameters:

$$E(\mathbf{b}) = (\mathbf{X}'\mathbf{X})^{-}(\mathbf{X}'\mathbf{X})\boldsymbol{\beta}$$

Degrees of freedom for the zeroed estimates are reported as zero. The hypotheses that are not testable have t tests reported as missing. The message that the model is not full rank includes a display of the relations that exist in the matrix.

The following statements use the fitness data from Example 76.2. The variable Dif=RunPulse−RestPulse is created. When this variable is included in the model along with RunPulse and RestPulse, there is a linear dependency (or exact collinearity) between the independent variables. Figure 76.34 shows how this problem is diagnosed.

```
data fit2;
   set fitness; Dif=RunPulse-RestPulse;
proc reg data=fit2;
   model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse Dif;
run;
```

Dif	0	0	.	.	.

PROC REG produces a message informing you that the model is less than full rank. Parameters with DF=0 are not estimated, and parameters with DF=B are biased. In addition, the form of the linear dependency among the regressors is displayed.

Collinearity Diagnostics

When a regressor is nearly a linear combination of other regressors in the model, the affected estimates are unstable and have high standard errors. This problem is called *collinearity* or *multicollinearity*. It is a good idea to find out which variables are nearly collinear with which other variables. The approach in PROC REG follows that of Belsley, Kuh, and Welsch (1980). PROC REG provides several methods for detecting collinearity with the COLLIN, COLLINOINT, TOL, and VIF options.

The COLLIN option in the MODEL statement requests that a collinearity analysis be performed. First, $\mathbf{X}'\mathbf{X}$ is scaled to have 1s on the diagonal. If you specify the COLLINOINT option, the intercept variable is adjusted out first. Then the eigenvalues and eigenvectors are extracted. The analysis in PROC REG is reported with eigenvalues of $\mathbf{X}'\mathbf{X}$ rather than singular values of $\mathbf{X}$. The eigenvalues of $\mathbf{X}'\mathbf{X}$ are the squares of the singular values of $\mathbf{X}$.

The condition indices are the square roots of the ratio of the largest eigenvalue to each individual eigenvalue. The largest condition index is the condition number of the scaled $\mathbf{X}$ matrix. Belsey, Kuh, and Welsch (1980) suggest that, when this number is around 10, weak dependencies might be starting to affect the regression estimates. When this number is larger than 100, the estimates might have a fair amount of numerical error (although the statistical standard error almost always is much greater than the numerical error).

For each variable, PROC REG produces the proportion of the variance of the estimate accounted for by each principal component. A collinearity problem occurs when a component associated with a high condition index contributes strongly (variance proportion greater than about 0.5) to the variance of two or more variables.

The VIF option in the MODEL statement provides the variance inflation factors (VIF). These factors measure the inflation in the variances of the parameter estimates due to collinearities that exist among the regressor (independent) variables. There are no formal criteria for deciding if a VIF is large enough to affect the predicted values.

The TOL option requests the tolerance values for the parameter estimates. The tolerance is defined as $1/VIF$.

For a complete discussion of the preceding methods, refer to Belsley, Kuh, and Welsch (1980). For a more detailed explanation of using the methods with PROC REG, refer to Freund and Littell (1986).

This example uses the COLLIN option on the fitness data found in Example 76.2. The following statements produce Figure 76.35.

```
proc reg data=fitness;
   model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse
         / tol vif collin;
run;
```

Model Fit and Diagnostic Statistics

This section gathers the formulas for the statistics available in the MODEL, PLOT, and OUTPUT statements. The model to be fit is $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$, and the parameter estimate is denoted by $\mathbf{b} = (\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{Y}$. The subscript i denotes values for the ith observation, the parenthetical subscript (i) means that the statistic is computed by using all observations except the ith observation, and the subscript jj indicates the jth diagonal matrix entry. The ALPHA= option in the PROC REG or MODEL statement is used to set the α value for the t statistics.

Table 76.8 contains the summary statistics for assessing the fit of the model.

Table 76.8 Formulas and Definitions for Model Fit Summary Statistics

MODEL Option or Statistic	Definition or Formula
n	the number of observations
p	the number of parameters including the intercept
i	1 if there is an intercept, 0 otherwise
$\hat{\sigma}^2$	the estimate of pure error variance from the SIGMA= option or from fitting the full model
SST_0	the uncorrected total sum of squares for the dependent variable

Table 76.8 *continued*

MODEL Option or Statistic	Definition or Formula
SST_1	the total sum of squares corrected for the mean for the dependent variable
SSE	the error sum of squares
MSE	$\frac{SSE}{n-p}$
R^2	$1-\frac{SSE}{SST_i}$
ADJRSQ	$1-\frac{(n-i)(1-R^2)}{n-p}$
AIC	$n\ln\left(\frac{SSE}{n}\right)+2p$
BIC	$n\ln\left(\frac{SSE}{n}\right)+2(p+2)q-2q^2$ where $q=\frac{n\hat{\sigma}^2}{SSE}$
CP (C_p)	$\frac{SSE}{\hat{\sigma}^2}+2p-n$
GMSEP	$\frac{MSE(n+1)(n-2)}{n(n-p-1)}=\frac{1}{n}S_p(n+1)(n-2)$
JP (J_p)	$\frac{n+p}{n}MSE$
PC	$\frac{n+p}{n-p}(1-R^2)=J_p\left(\frac{n}{SST_i}\right)$
PRESS	the sum of squares of $predr_i$ (see Table 76.9)
RMSE	$\sqrt{MSE}$
SBC	$n\ln\left(\frac{SSE}{n}\right)+p\ln(n)$
SP (S_p)	$\frac{MSE}{n-p-1}$

Table 76.9 contains the diagnostic statistics and their formulas; these formulas and further information can be found in Chapter 4, "Introduction to Regression Procedures," and in the section "Influence Statistics" on page 6443. Each statistic is computed for each observation.

Table 76.9 Formulas and Definitions for Diagnostic Statistics

MODEL Option or Statistic	Formula
PRED ($\widehat{\mathbf{Y}}_i$)	$\mathbf{X}_i\mathbf{b}$

PRESS(predr$_i$)	$\frac{r_i}{1-h_i}$

Influence Statistics

This section discusses the INFLUENCE option, which produces several influence statistics, and the PARTIAL option, which produces partial regression leverage plots.

The INFLUENCE Option

The INFLUENCE option (in the MODEL statement) requests the statistics proposed by Belsley, Kuh, and Welsch (1980) to measure the influence of each observation on the estimates. Influential observations are those that, according to various criteria, appear to have a large influence on the parameter estimates.

Let $\mathbf{b}(i)$ be the parameter estimates after deleting the ith observation; let $s(i)^2$ be the variance estimate after deleting the ith observation; let $\mathbf{X}(i)$ be the $\mathbf{X}$ matrix without the ith observation; let $\hat{y}(i)$ be the ith value predicted without using the ith observation; let $r_i = y_i - \hat{y}_i$ be the ith residual; and let h_i be the ith diagonal of the projection matrix for the predictor space, also called the *hat matrix*:

$$h_i = \mathbf{x}_i(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_i'$$

Belsley, Kuh, and Welsch (1980) propose a cutoff of $2p/n$, where n is the number of observations used to fit the model and p is the number of parameters in the model. Observations with h_i values above this cutoff should be investigated.

For each observation, PROC REG first displays the residual, the studentized residual (RSTUDENT), and the h_i. The studentized residual RSTUDENT differs slightly from STUDENT since the error variance is estimated by $s^2_{(i)}$ without the ith observation, not by s^2. For example,

$$\text{RSTUDENT} = \frac{r_i}{s_{(i)}\sqrt{(1-h_i)}}$$

Observations with RSTUDENT larger than 2 in absolute value might need some attention.

The COVRATIO statistic measures the change in the determinant of the covariance matrix of the estimates by deleting the ith observation:

$$\text{COVRATIO} = \frac{\det\left(s^2(i)(\mathbf{X}'_{(i)}\mathbf{X}_{(i)})^{-1}\right)}{\det\left(s^2(\mathbf{X}'\mathbf{X})^{-1}\right)}$$

Belsley, Kuh, and Welsch (1980) suggest that observations with

$$|\text{COVRATIO} - 1| \geq \frac{3p}{n}$$

where p is the number of parameters in the model and n is the number of observations used to fit the model, are worth investigation.

The DFFITS statistic is a scaled measure of the change in the predicted value for the ith observation and is calculated by deleting the ith observation. A large value indicates that the observation is very influential in its neighborhood of the $\mathbf{X}$ space.

$$\text{DFFITS} = \frac{\hat{y}_i - \hat{y}_{(i)}}{s_{(i)}\sqrt{h_{(i)}}}$$

Large values of DFFITS indicate influential observations. A general cutoff to consider is 2; a size-adjusted cutoff recommended by Belsley, Kuh, and Welsch (1980) is $2\sqrt{p/n}$, where n and p are as defined previously.

The DFFITS statistic is very similar to Cook's D, defined in the section "Predicted and Residual Values" on page 6434.

The DFBETAS statistics are the scaled measures of the change in each parameter estimate and are calculated by deleting the ith observation:

$$\text{DFBETAS}_j = \frac{b_j - b_{(i)j}}{s_{(i)}\sqrt{(\mathbf{X}'\mathbf{X})_{jj}}}$$

where $(\mathbf{X}'\mathbf{X})_{jj}$ is the (j, j)th element of $(\mathbf{X}'\mathbf{X})^{-1}$.

In general, large values of DFBETAS indicate observations that are influential in estimating a given parameter. Belsley, Kuh, and Welsch (1980) recommend 2 as a general cutoff value to indicate influential observations and $2/\sqrt{n}$ as a size-adjusted cutoff.

The following statements use the population example in the section "Polynomial Regression" on page 6346. See Figure 76.32 for the fitted regression equation. The INFLUENCE option produces the tables shown in Figure 76.36 and Figure 76.37.

```
proc reg data=USPopulation;
   model Population=Year YearSq / influence;
run;
```

Sum of Residuals	-4.7569E-11
Sum of Squared Residuals	170.97193
Predicted Residual SS (PRESS)	237.71229

In Figure 76.36, observations 16, 17, and 19 exceed the cutoff value of 2 for RSTUDENT. None of the observations exceeds the general cutoff of 2 for DFFITS or the DFBETAS, but observations 16, 17, and 19 exceed at least one of the size-adjusted cutoffs for these statistics. Observations 1 and 19 exceed the cutoff for the hat diagonals, and observations 1, 2, 16, 17, and 18 exceed the cutoffs for COVRATIO. Taken together, these statistics indicate that you should look first at observations 16, 17, and 19 and then perhaps investigate the other observations that exceeded a cutoff.

When ODS Graphics is enabled, you can request influence diagnostic plots by using the PLOTS= option in the PROC REG statement as shown in the following statements:

```
ods graphics on;

proc reg data=USPopulation
      plots(label)=(CooksD RStudentByLeverage DFFITS DFBETAS);
   id Year;
   model Population=Year YearSq;
run;

ods graphics off;
```

The LABEL suboption specified in the PLOTS(LABEL)= option requests that observations that exceed the relevant cutoffs for the statistics being plotted are labeled. Since Year has been named in an ID statement, the value of Year is used for the labels. The requested plots are shown in Figure 76.38.

Figure 76.38 Influence Diagnostics

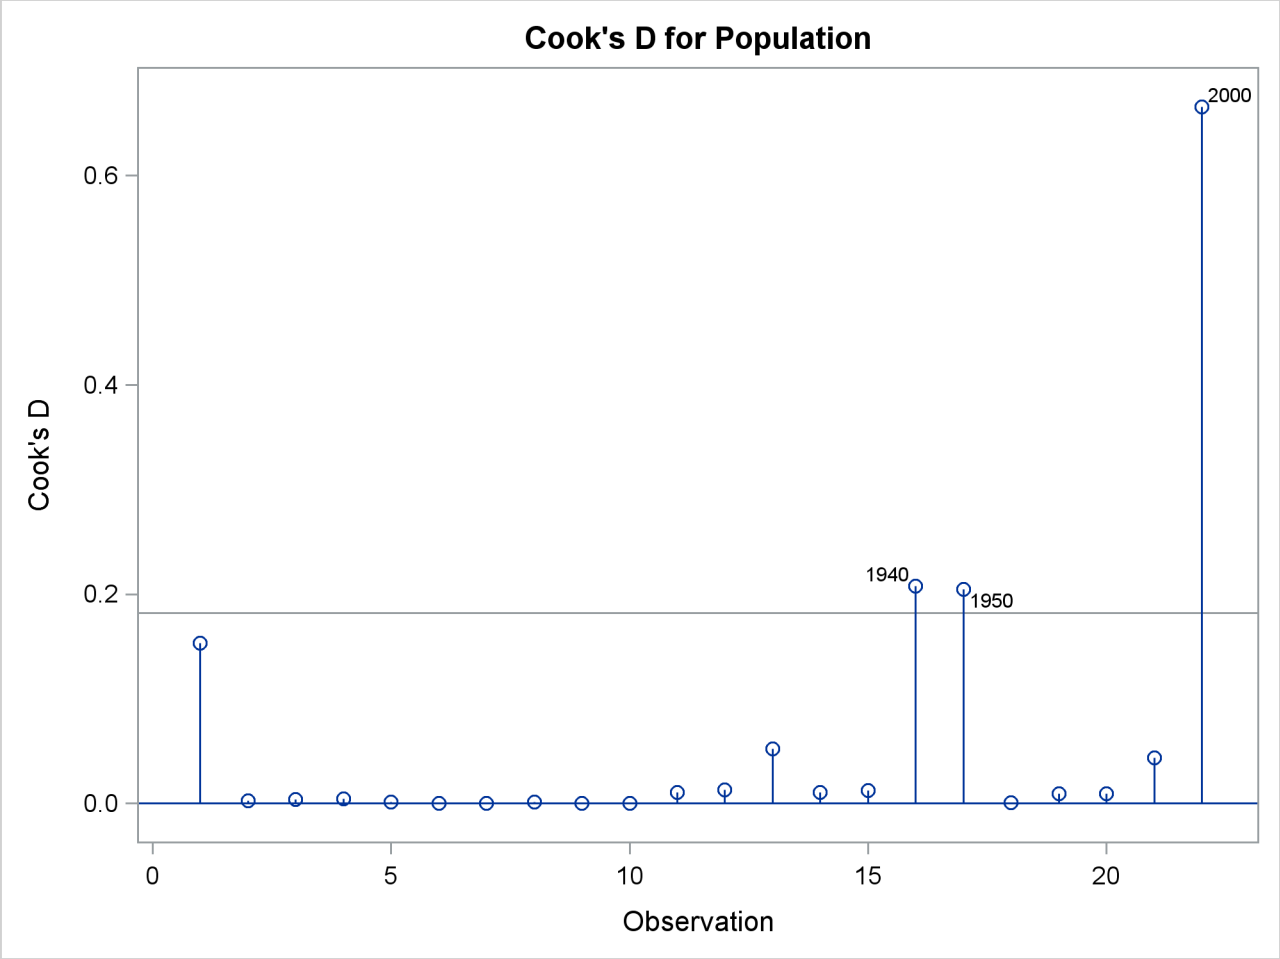

Figure 76.38 *continued*

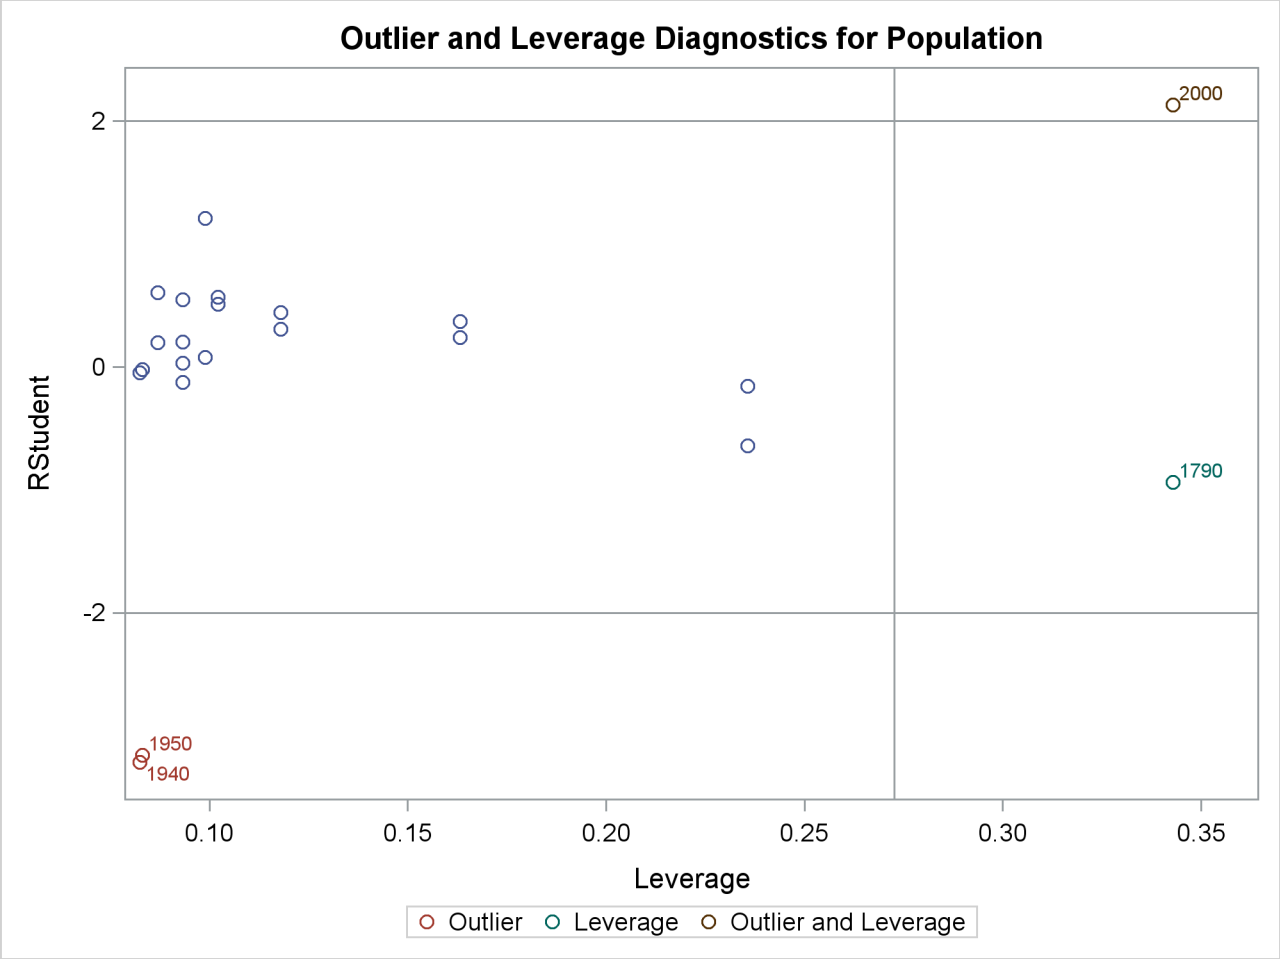

Figure 76.38 *continued*

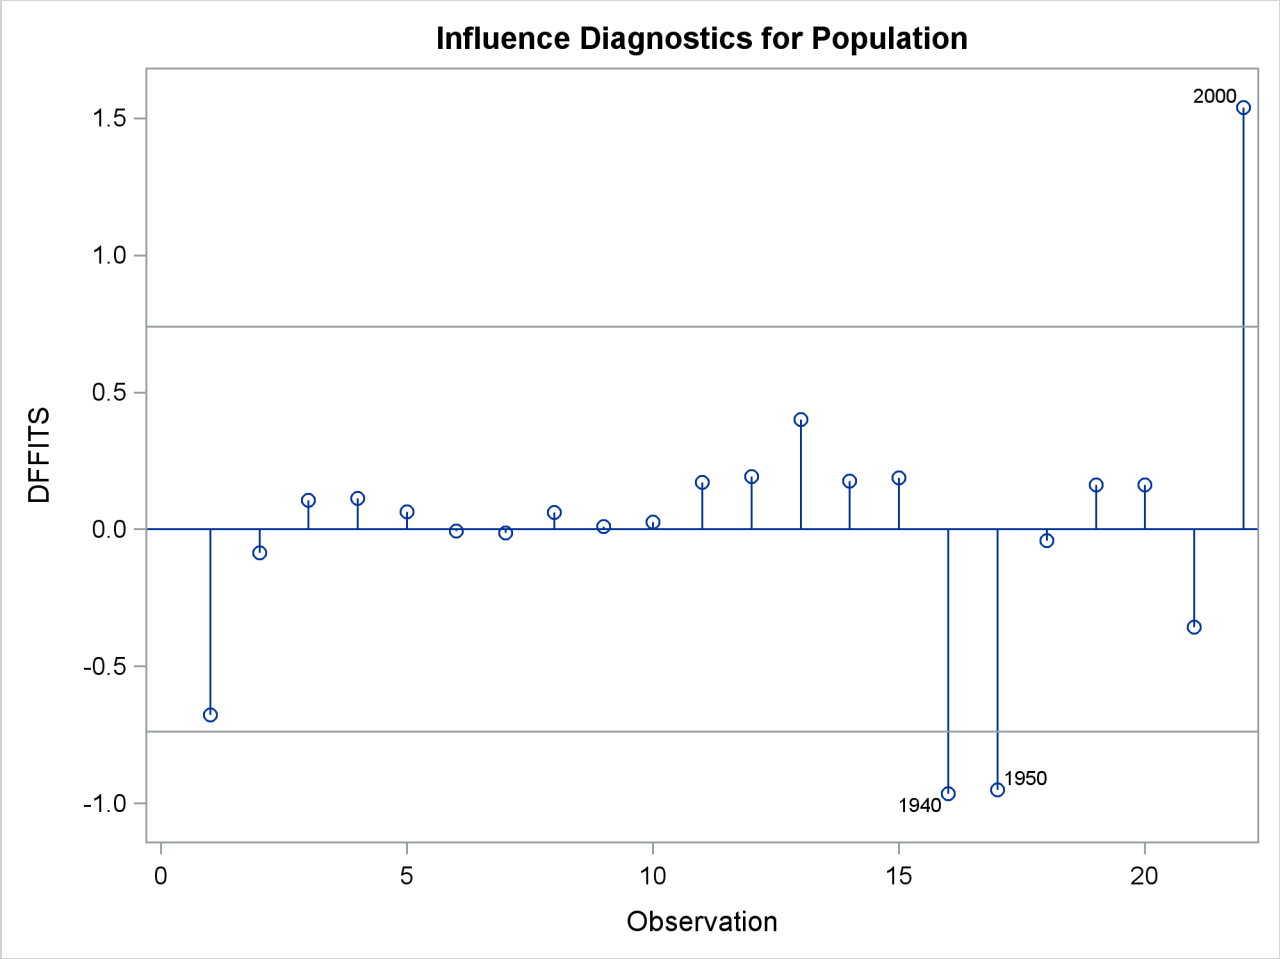

Figure 76.38 *continued*

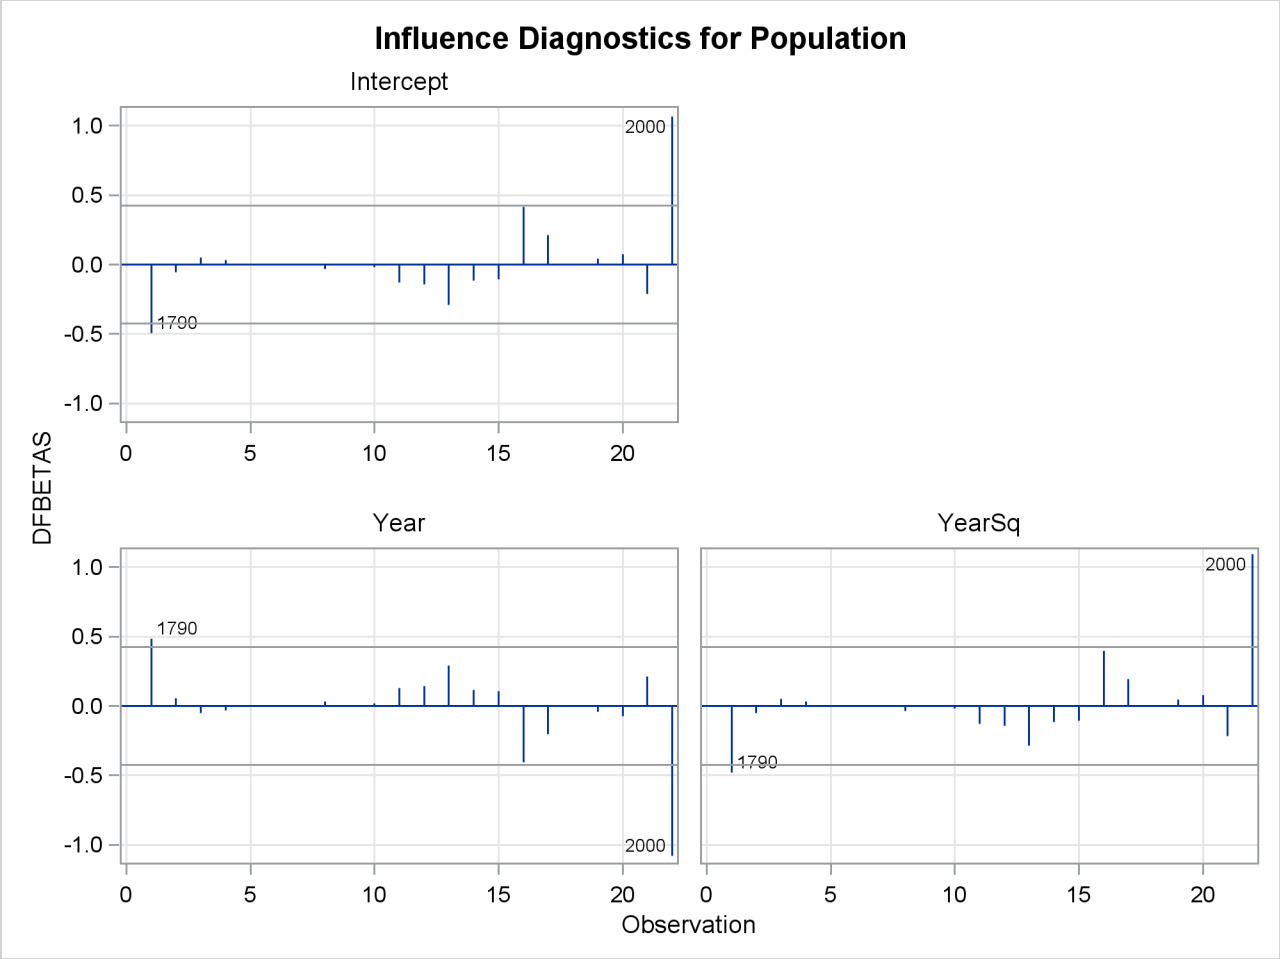


The PARTIAL and PARTIALDATA Options

The PARTIAL option in the MODEL statement produces partial regression leverage plots. If ODS Graphics is not enabled, this option requires the use of the LINEPRINTER option in the PROC REG statement. One plot is created for each regressor in the current full model. For example, plots are produced for regressors included by using ADD statements; plots are not produced for interim models in the various model-selection methods but only for the full model. If you use a model-selection method and the final model contains only a subset of the original regressors, the PARTIAL option still produces plots for all regressors in the full model. If ODS Graphics is enabled, these plots are produced as high-resolution graphics, in panels with a maximum of six partial regression leverage plots per panel. Multiple panels are displayed for models with more than six regressors.

For a given regressor, the partial regression leverage plot is the plot of the dependent variable and the regressor after they have been made orthogonal to the other regressors in the model. These can be obtained by plotting the residuals for the dependent variable against the residuals for the selected regressor, where the residuals for the dependent variable are calculated with the selected regressor omitted, and the residuals for the selected regressor are calculated from a model where the selected regressor is regressed on the remaining regressors. A line fit to the points has a slope equal to the parameter estimate in the full model.

When ODS Graphics is not enabled, points in the plot are marked by the number of replicates appearing at one position. The symbol '*' is used if there are 10 or more replicates. If an ID statement is specified, the leftmost nonblank character in the value of the ID variable is used as the plotting symbol.

The PARTIALDATA option in the MODEL statement produces a table that contains the partial regression data that are displayed in the partial regression leverage plots. You can request partial regression data even if you do not requests plots with the PARTIAL option.

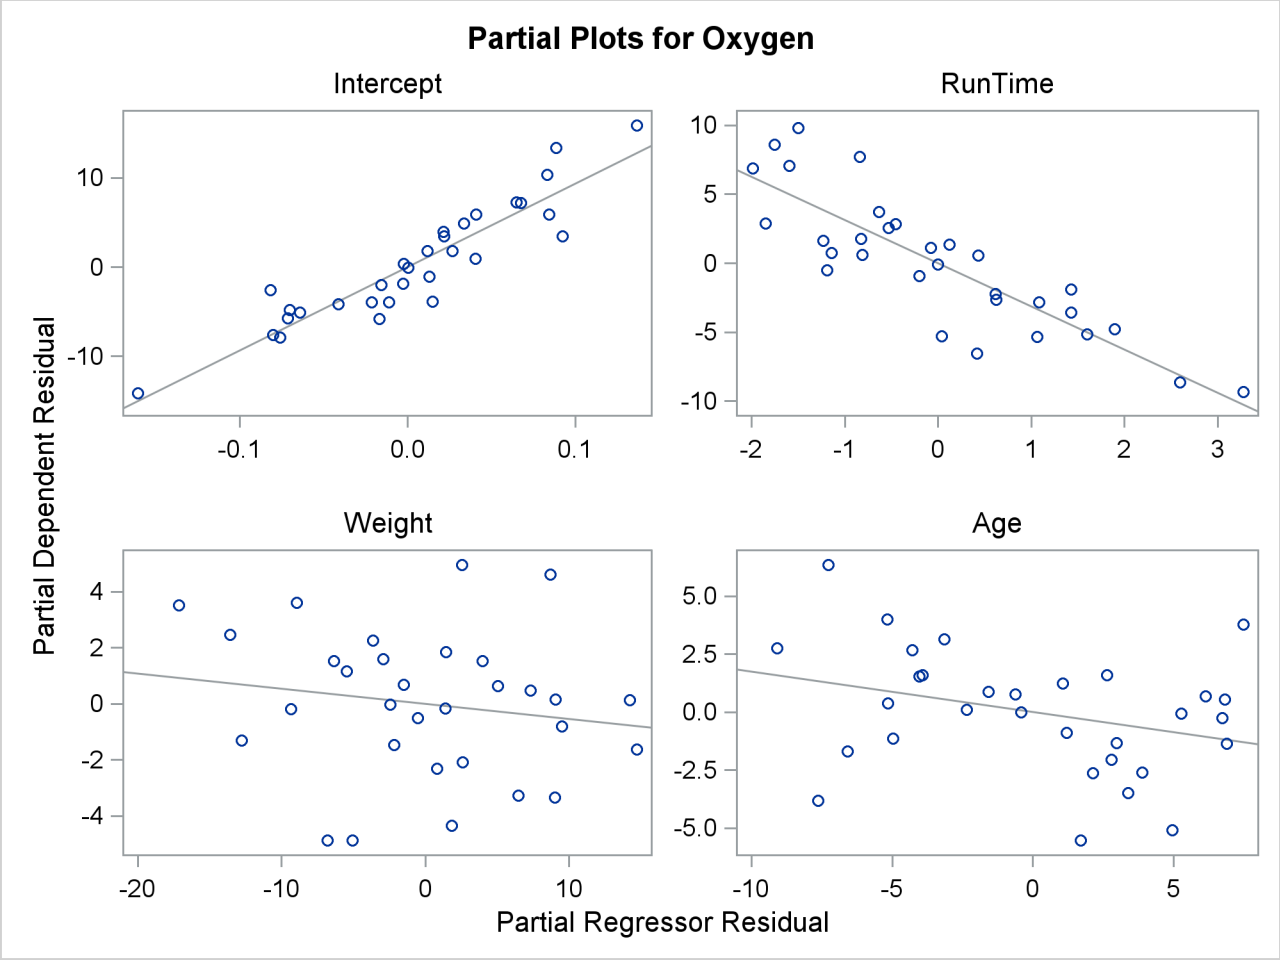
The following statements use the fitness data in Example 76.2 with the PARTIAL option and ODS Graphics to produce the partial regression leverage plots. The plots are shown in Figure 76.39.

```
ods graphics on;

proc reg data=fitness;
   model Oxygen=RunTime Weight Age / partial;
run;

ods graphics off;
```

Figure 76.39 Partial Regression Leverage Plots



Reweighting Observations in an Analysis

Reweighting observations is an interactive feature of PROC REG that enables you to change the weights of observations used in computing the regression equation. Observations can also be deleted from the analysis (not from the data set) by changing their weights to zero. In the following statements, the Class data (in the section "Getting Started: REG Procedure" on page 6342) are used to illustrate some of the features of the REWEIGHT statement. First, the full model is fit, and the residuals are displayed in Figure 76.40.

```
proc reg data=Class;
   model Weight=Age Height / p;
   id Name;
run;
```

Predicted Residual SS (PRESS)	3272.72186

Upon examining the data and residuals, you realize that observation 17 (Ronald) was mistakenly included in the analysis. Also, you would like to examine the effect of reweighting to 0.5 those observations with residuals that have absolute values greater than or equal to 17. The following statements show how you

request this reweighting:

```
reweight obs.=17;
reweight r. le -17 or r. ge 17 / weight=0.5;
print p;
run;
```

At this point, a message appears (in the log) that tells you which observations have been reweighted and what the new weights are. Figure 76.41 is produced.

Predicted Residual SS (PRESS)	2287.57621

The first REWEIGHT statement excludes observation 17, and the second REWEIGHT statement reweights observations 12 and 16 to 0.5. An important feature to note from this example is that the model is not refit until after the PRINT statement. REWEIGHT statements do not cause the model to be refit. This is so that multiple REWEIGHT statements can be applied to a subsequent model.

In this example, since the intent is to reweight observations with large residuals, the observation that was mistakenly included in the analysis should be deleted; then the model should be fit for those remaining observations, and the observations with large residuals should be reweighted. To accomplish this, use the

REFIT statement. Note that the model label has been changed from MODEL1 to MODEL1.2 since two REWEIGHT statements have been used. The following statements produce Figure 76.42:

```
reweight allobs / weight=1.0;
reweight obs.=17;
refit;
reweight r. le -17 or r. ge 17 / weight=.5;
print;
run;
```

Predicted Residual SS (PRESS)	2473.87984

Notice that this results in a slightly different model than the previous set of statements: only observation 16 is reweighted to 0.5. Also note that the model label is now MODEL1.5 since five REWEIGHT statements have been used for this model.

Another important feature of the REWEIGHT statement is the ability to nullify the effect of a previous or all REWEIGHT statements. First, assume that you have several REWEIGHT statements in effect and you want to restore the original weights of all the observations. The following REWEIGHT statement accomplishes this and produces Figure 76.43:

```
reweight allobs / reset;
print;
run;
```

Figure 76.43 Restoring Weights of All Observations

Sum of Residuals	0
Sum of Squared Residuals	1694.87114
Predicted Residual SS (PRESS)	2547.22751

The resulting model reflects changes made only by the first REWEIGHT statement since the third REWEIGHT statement negates the effect of the second REWEIGHT statement. Observations 1, 3, 9, 10, 12, 16, and 17 have their weights changed to 0.75. Note that the label MODEL1.9 reflects the use of nine REWEIGHT statements for the current model.

Now suppose you want to reset the observations selected by the most recent REWEIGHT statement to their original weights. Use the REWEIGHT statement with the RESET option to do this. The following statements produce Figure 76.45:

```
reweight r. le -12 or r. ge 12 / weight=.75;
reweight r. le -17 or r. ge 17 / weight=.5;
reweight / reset;
```

```
print;
run;
```

Sum of Residuals	0
Sum of Squared Residuals	1879.08980
Predicted Residual SS (PRESS)	2959.57279

Note that observations that meet the condition of the second REWEIGHT statement (residuals with an absolute value greater than or equal to 17) now have weights reset to their original value of 1. Observations 1, 3, 9, 10, and 17 have weights of 0.75, but observations 12 and 16 (which meet the condition of the second REWEIGHT statement) have their weights reset to 1.

Notice how the last three examples show three ways to change weights back to a previous value. In the first example, ALLOBS and the RESET option are used to change weights for all observations back to their original values. In the second example, the UNDO option is used to negate the effect of a previous REWEIGHT statement, thus changing weights for observations selected in the previous REWEIGHT statement to the weights specified in still another REWEIGHT statement. In the third example, the RESET option is used to change weights for observations selected in a previous REWEIGHT statement back to their original values. Finally, note that the label MODEL1.12 indicates that 12 REWEIGHT statements have been applied to the original model.

Testing for Heteroscedasticity

The regression model is specified as $y_i = \mathbf{x}_i\boldsymbol{\beta} + \epsilon_i$, where the ϵ_i's are identically and independently distributed: $E(\boldsymbol{\epsilon}) = 0$ and $E(\boldsymbol{\epsilon}'\boldsymbol{\epsilon}) = \sigma^2\mathbf{I}$. If the ϵ_i's are not independent or their variances are not constant, the parameter estimates are unbiased, but the estimate of the covariance matrix is inconsistent.

In the case of heteroscedasticity, if the regression data are from a simple random sample, then White (1980), showed that matrix

$$\mathrm{HC}_0 = (\mathbf{X}'\mathbf{X})^{-1}(\mathbf{X}'\mathrm{diag}(e_i^2)\mathbf{X})(\mathbf{X}'\mathbf{X})^{-1}$$

where

$$e_i = y_i - \mathbf{x}_i\mathbf{b}$$

is an asymptotically consistent estimate of the covariance matrix. MacKinnon and White (1985) introduced three alternative heteroscedasticity-consistent covariance matrix estimators that are all asymptotically equivalent to the estimator HC_0 but that typically have better small sample behavior. These estimators labeled HC_1, HC_2, and HC_3 are defined as follows:

$$\mathrm{HC}_1 = \frac{n}{n-p}\mathrm{HC}_0$$

where n is the number of observations and p is the number of regressors including the intercept.

$$\mathrm{HC}_2 = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathrm{diag}(\frac{e_i^2}{1-h_{ii}})\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}$$

where

$$h_{ii} = \mathbf{x}_i(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_\mathbf{i}'$$

is the leverage of the ith observation.

$$\mathrm{HC}_3 = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathrm{diag}(\frac{e_i^2}{(1-h_{ii})^2})\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}$$

Long and Ervin (2000) studied the performance of these estimators and recommend using the HC_3 estimator if the sample size is less than 250.

You can use the HCCMETHOD=0,1,2, or 3 in the MODEL statement to select a heteroscedasticity-consistent covariance matrix estimator, with HC_0 being the default. The ACOV option in the MODEL

statement displays the heteroscedasticity-consistent covariance matrix estimator in effect and adds heteroscedasticity-consistent standard errors, also known as White standard errors, to the parameter estimates table. If you specify the HCC or WHITE option in the MODEL statement, but do not also specify the ACOV option, then the heteroscedasticity-consistent standard errors are added to the parameter estimates table but the heteroscedasticity- consistent covariance matrix is not displayed.

The SPEC option performs a model specification test. The null hypothesis for this test maintains that the errors are homoscedastic and independent of the regressors and that several technical assumptions about the model specification are valid. For details, see theorem 2 and assumptions 1–7 of White (1980). When the model is correctly specified and the errors are independent of the regressors, the rejection of this null hypothesis is evidence of heteroscedasticity. In implementing this test, an estimator of the average covariance matrix (White 1980, p. 822) is constructed and inverted. The nonsingularity of this matrix is one of the assumptions in the null hypothesis about the model specification. When PROC REG determines this matrix to be numerically singular, a generalized inverse is used and a note to this effect is written to the log. In such cases, care should be taken in interpreting the results of this test.

When you specify the SPEC, ACOV, HCC, or WHITE option in the MODEL statement, tests listed in the TEST statement are performed with both the usual covariance matrix and the heteroscedasticity-consistent covariance matrix requested with the HCCMETHOD= option. Tests performed with the consistent covariance matrix are asymptotic. For more information, refer to White (1980).

Both the ACOV and SPEC options can be specified in a MODEL or PRINT statement.

Testing for Lack of Fit

The test for lack of fit compares the variation around the model with "pure" variation within replicated observations. This measures the adequacy of the specified model. In particular, if there are n_i replicated observations $Y_{i1}, \ldots, Y_{in_i}$ of the response all at the same values $\mathbf{x}_i$ of the regressors, then you can predict the true response at $\mathbf{x}_i$ either by using the predicted value $\hat{Y}_i$ based on the model or by using the mean $\bar{Y}_i$ of the replicated values. The test for lack of fit decomposes the residual error into a component due to the variation of the replications around their mean value (the "pure" error) and a component due to the variation of the mean values around the model prediction (the "bias" error):

$$\sum_i \sum_{j=1}^{n_i} \left(Y_{ij} - \hat{Y}_i\right)^2 = \sum_i \sum_{j=1}^{n_i} \left(Y_{ij} - \bar{Y}_i\right)^2 + \sum_i n_i \left(\bar{Y}_i - \hat{Y}_i\right)^2$$

If the model is adequate, then both components estimate the nominal level of error; however, if the bias component of error is much larger than the pure error, then this constitutes evidence that there is significant lack of fit.

If some observations in your design are replicated, you can test for lack of fit by specifying the LACKFIT option in the MODEL statement (see Example 76.6). Note that, since all other tests use total error rather than pure error, you might want to hand-calculate the tests with respect to pure error if the lack of fit is significant. On the other hand, significant lack of fit indicates that the specified model is inadequate, so if this is a problem you can also try to refine the model.

Multivariate Tests

The MTEST statement described in the section "MTEST Statement" on page 6385 can test hypotheses involving several dependent variables in the form

$$(\mathbf{L}\boldsymbol{\beta} - \mathbf{cj})\mathbf{M} = 0$$

where $\mathbf{L}$ is a linear function on the regressor side, $\boldsymbol{\beta}$ is a matrix of parameters, $\mathbf{c}$ is a column vector of constants, $\mathbf{j}$ is a row vector of ones, and $\mathbf{M}$ is a linear function on the dependent side. The special case where the constants are zero is

$$\mathbf{L}\boldsymbol{\beta}\mathbf{M} = 0$$

To test this hypothesis, PROC REG constructs two matrices called $\mathbf{H}$ and $\mathbf{E}$ that correspond to the numerator and denominator of a univariate F test:

$$\begin{aligned}\mathbf{H} &= \mathbf{M}'(\mathbf{LB} - \mathbf{cj})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-1}(\mathbf{LB} - \mathbf{cj})\mathbf{M} \\ \mathbf{E} &= \mathbf{M}'(\mathbf{Y}'\mathbf{Y} - \mathbf{B}'(\mathbf{X}'\mathbf{X})\mathbf{B})\mathbf{M}\end{aligned}$$

These matrices are displayed for each MTEST statement if the PRINT option is specified.

Four test statistics based on the eigenvalues of $\mathbf{E}^{-1}\mathbf{H}$ or $(\mathbf{E}+\mathbf{H})^{-1}\mathbf{H}$ are formed. These are Wilks' lambda, Pillai's trace, the Hotelling-Lawley trace, and Roy's greatest root. These test statistics are discussed in Chapter 4, "Introduction to Regression Procedures."

The following code creates MANOVA data from Morrison (1976):

```
* Manova Data from Morrison (1976, 190);
data a;
input sex $ drug $ @;
do rep=1 to 4;
   input y1 y2 @;
   sexcode=(sex='m')-(sex='f');
   drug1=(drug='a')-(drug='c');
   drug2=(drug='b')-(drug='c');
   sexdrug1=sexcode*drug1;
   sexdrug2=sexcode*drug2;
   output;
end;
datalines;
m a  5  6  5  4  9  9  7  6
```

```
m b  7  6  7  7  9 12  6  8
m c 21 15 14 11 17 12 12 10
f a  7 10  6  6  9  7  8 10
f b 10 13  8  7  7  6  6  9
f c 16 12 14  9 14  8 10  5
;
```

The following statements perform a multivariate analysis of variance and produce Figure 76.46 through Figure 76.49:

```
proc reg;
   model y1 y2=sexcode drug1 drug2 sexdrug1 sexdrug2;
   y1y2drug: mtest y1=y2, drug1,drug2;
   drugshow: mtest drug1, drug2 / print canprint;
run;
```

Test of H0: The canonical correlations in the current row and all that follow are zero

	Likelihood Ratio	Approximate F Value	Num DF	Den DF	Pr > F
1	0.16862952	12.20	4	34	<.0001
2	0.94028273	1.14	1	18	0.2991

Multivariate Statistics and F Approximations

S=2 M=-0.5 N=7.5

Statistic	Value	F Value	Num DF	Den DF	Pr > F
Wilks' Lambda	0.16862952	12.20	4	34	<.0001
Pillai's Trace	0.88037810	7.08	4	36	0.0003
Hotelling-Lawley Trace	4.63953666	19.40	4	19.407	<.0001
Roy's Greatest Root	4.57602675	41.18	2	18	<.0001

NOTE: F Statistic for Roy's Greatest Root is an upper bound.
NOTE: F Statistic for Wilks' Lambda is exact.

The four multivariate test statistics are all highly significant, giving strong evidence that the coefficients of drug1 and drug2 are not zero for both dependent variables.

Autocorrelation in Time Series Data

When regression is performed on time series data, the errors might not be independent. Often errors are autocorrelated; that is, each error is correlated with the error immediately before it. Autocorrelation is also a symptom of systematic lack of fit. The DW option provides the Durbin-Watson d statistic to test that the autocorrelation is zero:

$$d = \frac{\sum_{i=2}^{n}(e_i - e_{i-1})^2}{\sum_{i=1}^{n} e_i^2}$$

The value of d is close to 2 if the errors are uncorrelated. The distribution of d is reported by Durbin and Watson (1951). Tables of the distribution are found in most econometrics textbooks, such as Johnston (1972) and Pindyck and Rubinfeld (1981).

The sample autocorrelation estimate is displayed after the Durbin-Watson statistic. The sample is computed as

$$r = \frac{\sum_{i=2}^{n} e_i e_{i-1}}{\sum_{i=1}^{n} e_i^2}$$

This autocorrelation of the residuals might not be a very good estimate of the autocorrelation of the true errors, especially if there are few observations and the independent variables have certain patterns. If there are missing observations in the regression, these measures are computed as though the missing observations did not exist.

Positive autocorrelation of the errors generally tends to make the estimate of the error variance too small, so confidence intervals are too narrow and true null hypotheses are rejected with a higher probability than the stated significance level. Negative autocorrelation of the errors generally tends to make the estimate of the error variance too large, so confidence intervals are too wide and the power of significance tests is reduced. With either positive or negative autocorrelation, least squares parameter estimates are usually not as efficient as generalized least squares parameter estimates. For more details, refer to Judge et al. (1985, Chapter 8) and the *SAS/ETS User's Guide*.

The following SAS statements request the DWPROB option for the U.S. population data (see Figure 76.50). If you use the DW option instead of the DWPROB option, then p-values are not produced.

```
proc reg data=USPopulation;
   model Population=Year YearSq / dwProb;
run;
```

Computations for Ridge Regression and IPC Analysis

In ridge regression analysis, the crossproduct matrix for the independent variables is centered (the NOINT option is ignored if it is specified) and scaled to one on the diagonal elements. The ridge constant k (specified with the RIDGE= option) is then added to each diagonal element of the crossproduct matrix. The ridge regression estimates are the least squares estimates obtained by using the new crossproduct matrix.

Let $\mathbf{X}$ be an $n \times p$ matrix of the independent variables after centering the data, and let $\mathbf{Y}$ be an $n \times 1$ vector corresponding to the dependent variable. Let $\mathbf{D}$ be a $p \times p$ diagonal matrix with diagonal elements as in $\mathbf{X}'\mathbf{X}$. The ridge regression estimate corresponding to the ridge constant k can be computed as

$$\mathbf{D}^{-\frac{1}{2}}(\mathbf{Z}'\mathbf{Z} + k\mathbf{I}_p)^{-1}\mathbf{Z}'\mathbf{Y}$$

where $\mathbf{Z} = \mathbf{X}\mathbf{D}^{-\frac{1}{2}}$ and $\mathbf{I}_p$ is a $p \times p$ identity matrix.

For IPC analysis, the smallest m eigenvalues of $\mathbf{Z}'\mathbf{Z}$ (where m is specified with the PCOMIT= option) are omitted to form the estimates.

For information about ridge regression and IPC standardized parameter estimates, parameter estimate standard errors, and variance inflation factors, refer to Rawlings (1988), Neter, Wasserman, and Kutner (1990), and Marquardt and Snee (1975). Unlike Rawlings (1988), the REG procedure uses the mean squared errors of the submodels instead of the full model MSE to compute the standard errors of the parameter estimates.

Construction of Q-Q and P-P Plots

If a normal probability-probability or quantile-quantile plot for the variable x is requested, the n nonmissing values of x are first ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

If a Q-Q plot is requested (with a PLOT statement of the form PLOT *yvariable*∗NQQ.), the ith-ordered value $x_{(i)}$ is represented by a point with y-coordinate $x_{(i)}$ and x-coordinate $\Phi^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $\Phi(\cdot)$ is the standard normal distribution.

If a P-P plot is requested (with a PLOT statement of the form PLOT *yvariable*∗NPP.), the ith-ordered value $x_{(i)}$ is represented by a point with y-coordinate $\frac{i}{n}$ and x-coordinate $\Phi\left(\frac{x_{(i)}-\mu}{\sigma}\right)$, where μ is the mean of the nonmissing x-values and σ is the standard deviation. If an x-value has multiplicity k (that is, $x_{(i)} = \cdots = x_{(i+k-1)}$), then only the point $\left(\Phi\left(\frac{x_{(i)}-\mu}{\sigma}\right), \frac{i+k-1}{n}\right)$ is displayed.

Computational Methods

The REG procedure first composes a crossproducts matrix. The matrix can be calculated from input data, reformed from an input correlation matrix, or read in from an SSCP data set. For each model, the procedure selects the appropriate crossproducts from the main matrix. The normal equations formed from the crossproducts are solved by using a sweep algorithm (Goodnight 1979). The method is accurate for data that are reasonably scaled and not too collinear.

The mechanism that PROC REG uses to check for singularity involves the diagonal (pivot) elements of $\mathbf{X}'\mathbf{X}$ as it is being swept. If a pivot is less than SINGULAR*CSS, then a singularity is declared and the pivot is not swept (where CSS is the corrected sum of squares for the regressor and SINGULAR is machine dependent but is approximately 1E−7 on most machines or reset in the PROC REG statement).

The sweep algorithm is also used in many places in the model-selection methods. The RSQUARE method uses the leaps-and-bounds algorithm by Furnival and Wilson (1974).

Computer Resources in Regression Analysis

The REG procedure is efficient for ordinary regression; however, requests for optional features can greatly increase the amount of time required.

The major computational expense in the regression analysis is the collection of the crossproducts matrix. For p variables and n observations, the time required is proportional to np^2. For each model run, PROC REG needs time roughly proportional to k^3, where k is the number of regressors in the model. Include an additional nk^2 for the R, CLM, or CLI option and another nk^2 for the INFLUENCE option.

Most of the memory that PROC REG needs to solve large problems is used for crossproducts matrices. PROC REG requires $4p^2$ bytes for the main crossproducts matrix plus $4k^2$ bytes for the largest model. If several output data sets are requested, memory is also needed for buffers.

See the section "Input Data Sets" on page 6412 for information about how to use TYPE=SSCP data sets to reduce computing time.

Displayed Output

Many of the more specialized tables are described in detail in previous sections. Most of the formulas for the statistics are in Chapter 4, "Introduction to Regression Procedures," while other formulas can be found

in the section "Model Fit and Diagnostic Statistics" on page 6441 and the section "Influence Statistics" on page 6443.

The analysis-of-variance table includes the following:

- the Source of the variation, Model for the fitted regression, Error for the residual error, and C Total for the total variation after correcting for the mean. The Uncorrected Total Variation is produced when the NOINT option is used.
- the degrees of freedom (DF) associated with the source
- the Sum of Squares for the term
- the Mean Square, the sum of squares divided by the degrees of freedom
- the F Value for testing the hypothesis that all parameters are zero except for the intercept. This is formed by dividing the mean square for Model by the mean square for Error.
- the Prob>F, the probability of getting a greater F statistic than that observed if the hypothesis is true. This is the significance probability.

Other statistics displayed include the following:

- Root MSE is an estimate of the standard deviation of the error term. It is calculated as the square root of the mean square error.
- Dep Mean is the sample mean of the dependent variable.
- C.V. is the coefficient of variation, computed as 100 times Root MSE divided by Dep Mean. This expresses the variation in unitless values.
- R-square is a measure between 0 and 1 that indicates the portion of the (corrected) total variation that is attributed to the fit rather than left to residual error. It is calculated as SS(Model) divided by SS(Total). It is also called the *coefficient of determination*. It is the square of the multiple correlation—in other words, the square of the correlation between the dependent variable and the predicted values.
- Adj R-square, the adjusted R^2, is a version of R^2 that has been adjusted for degrees of freedom. It is calculated as

$$\bar{R}^2 = 1 - \frac{(n-i)(1-R^2)}{n-p}$$

  where i is equal to 1 if there is an intercept and 0 otherwise, n is the number of observations used to fit the model, and p is the number of parameters in the model.

The parameter estimates and associated statistics are then displayed, and they include the following:

- the Variable used as the regressor, including the name Intercept to represent the estimate of the intercept parameter

- the degrees of freedom (DF) for the variable. There is one degree of freedom unless the model is not full rank.
- the Parameter Estimate
- the Standard Error, the estimate of the standard deviation of the parameter estimate
- T for H0: Parameter=0, the t test that the parameter is zero. This is computed as the Parameter Estimate divided by the Standard Error.
- the Prob > |T|, the probability that a t statistic would obtain a greater absolute value than that observed given that the true parameter is zero. This is the two-tailed significance probability.

If model-selection methods other than NONE, RSQUARE, ADJRSQ, and CP are used, the analysis-of-variance table and the parameter estimates with associated statistics are produced at each step. Also displayed are the following:

- C(p), which is Mallows' C_p statistic
- bounds on the condition number of the correlation matrix for the variables in the model (Berk 1977)

After statistics for the final model are produced, the following is displayed when the method chosen is FORWARD, BACKWARD, or STEPWISE:

- a Summary table listing Step number, Variable Entered or Removed, Partial and Model R-square, and C(p) and F statistics

The RSQUARE method displays its results beginning with the model containing the fewest independent variables and producing the largest R^2. Results for other models with the same number of variables are then shown in order of decreasing R^2, and so on, for models with larger numbers of variables. The ADJRSQ and CP methods group models of all sizes together and display results beginning with the model having the optimal value of adjusted $R^2$and C_p, respectively.

For each model considered, the RSQUARE, ADJRSQ, and CP methods display the following:

- Number in Model or IN, the number of independent variables used in each model
- R-square or RSQ, the squared multiple correlation coefficient

If the B option is specified, the RSQUARE, ADJRSQ, and CP methods produce the following:

- Parameter Estimates, the estimated regression coefficients

If the B option is not specified, the RSQUARE, ADJRSQ, and CP methods display the following:

- Variables in Model, the names of the independent variables included in the model

ODS Table Names

PROC REG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 76.10 ODS Tables Produced by PROC REG

ODS Table Name	Description	Statement	Option
ACovEst	Consistent covariance of estimates matrix	MODEL	ALL, ACOV

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

The following sections describe the ODS graphical displays produced by PROC REG.

Diagnostics Panel

The "Diagnostics Panel" provides a display that you can use to get an overall assessment of your model. See Figure 76.8 for an example.

The panel contains the following plots:

- residuals versus the predicted values
- externally studentized residuals (RSTUDENT) versus the predicted values
- externally studentized residuals versus the leverage
- normal quantile-quantile plot (Q-Q plot) of the residuals
- dependent variable values versus the predicted values
- Cook's D versus observation number
- histogram of the residuals
- "Residual-Fit" (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals
- box plot of the residuals if you specify the STATS=NONE suboption

Patterns in the plots of residuals or studentized residuals versus the predicted values, or spread of the residuals being greater than the spread of the centered fit in the RF plot, are indications of an inadequate model. Patterns in the spread about the 45-degree reference line in the plot of the dependent variable values versus the predicted values are also indications of an inadequate model.

The Q-Q plot, residual histogram, and box plot of the residuals are useful for diagnosing violations of the normality and homoscedasticity assumptions. If the data in a Q-Q plot come from a normal distribution, the points will cluster tightly around the reference line. A normal density is overlaid on the residual histogram to help in detecting departures form normality.

Following Rawlings (1998), reference lines are shown on the relevant plots to identify observations deemed outliers or influential. Observations whose externally studentized residual magnitudes exceed 2 are deemed outliers. Observations whose leverage value exceeds $2p/n$ or whose Cook's D value exceeds $4/n$ are deemed influential (p is the number of regressors including the intercept, and n is the number of observations used in the analysis). If you specify the LABEL suboption of the PLOTS=DIAGNOSTICS option, then the points deemed outliers or influential are labeled on the appropriate plots.

Fit statistics are shown in the lower right of the plot and can be customized or suppressed by using the STATS= suboption of the PLOTS=DIAGNOSTICS option.

Residuals by Regressor Plots

Panels of plots of the residuals versus each of the regressors in the model are produced by default. Patterns in these plots are indications of an inadequate model. To help in detecting patterns, you can use the SMOOTH= suboption of the PLOTS=RESIDUALS option to add loess fits to these residual plots. See Figure 76.1.6 for an example.

Fit and Prediction Plots

A fit plot consisting of a scatter plot of the data overlaid with the regression line, as well as confidence and prediction limits, is produced for models depending on a single regressor. Fit statistics are shown to the right of the plot and can be customized or suppressed by using the STATS= suboption of the PLOTS=FIT option.

When a model contains more than one regressor, a fit plot is not appropriate. However, if all the regressors in the model are transformations of a single variable in the input data set, then you can request a scatter plot of the dependent variable overlaid with a fit line and confidence and prediction limits versus this variable. You can also plot residuals versus this variable. You request these plots, shown in a panel, with the PLOTS=PREDICTION option. See Figure 76.13 for an example.

Influence Plots

In addition to the "Cook's D Plot" and the "RStudent By Leverage Plot," you can request plots of the DFBETAS and DFFITS statistics versus observation number by using the PLOTS=DFBETAS and PLOTS=DFFITS options. You can also obtain partial regression leverage plots by using the PLOTS=PARTIAL option. See the section "Influence Statistics" on page 6443 for examples of these plots and details about their interpretation.

Ridge and VIF Plots

When you use ridge regression, you can request plots of the variance inflation factor (VIF) values and standardized ridge estimates by ridge values for each coefficient with the PLOTS=RIDGE option. See Example 76.5 for examples.

Variable Selection Plots

When you request variable selection by using the SELECTION= option in the MODEL statement, you can request plots of fit criteria for the models examined by using the PLOTS=CRITERIA option. The fit criteria are displayed versus the step number for the FORWARD, BACKWARD, and STEPWISE selection methods and the step at which the optimal value of each criterion is obtained is indicated using a "Star" marker. For the all-subset-based selection methods (SELECTION=RSQUARE|ADJRSQ|CP), the fit criteria are displayed versus the number of observations in the model.

The criteria are shown in a panel, but you can use the UNPACK suboption of the PLOTS=CRITERIA option to obtain separate plots for each criterion. You can also use the LABEL suboption of the PLOTS=CRITERIA option to request that optimal models be labeled on the plots. Example 76.2 provides several examples.

ODS Graph Names

PROC REG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 76.11.

Table 76.11 ODS Graphical Displays Produced by PROC REG

ODS Graph Name	Plot Description	PLOTS Option
AdjrsqPlot	Adjusted R-square statistic for models examined doing variable selection	ADJRSQ
AICPlot	AIC statistic for models examined doing variable selection	AIC
BICPlot	BIC statistic for models examined doing variable selection	BIC
CooksDPlot	Cook's D statistic versus observation number	COOKSD
CPPlot	C_p statistic for models examined doing variable selection	CP
DFFITSPlot	DFFITS statistics versus observation number	DFFITS
DFBETASPanel	Panel of DFBETAS statistics versus observation number	DFBETAS
DFBETASPlot	DFBETAS statistics versus observation number	DFBETAS(UNPACK)
DiagnosticsPanel	Panel of fit diagnostics	DIAGNOSTICS
FitPlot	Regression line, confidence limits, and prediction limits overlaid on scatter plot of data	FIT
ObservedByPredicted	Dependent variable versus predicted values	OBSERVEDBYPREDICTED
PartialPlot	Partial regression plot	PARTIAL
PredictionPanel	Panel of residuals and fit versus specified variable	PREDICTIONS

Table 76.11 *continued*

ODS Graph Name	Plot Description	PLOTS Option
PredictionPlot	Regression line, confidence limits, and prediction limits versus specified variable	PREDICTIONS(UNPACK)
PredictionResidualPlot	Residuals versus specified variable	PREDICTIONS(UNPACK)
QQPlot	Normal quantile plot of residuals	QQ
ResidualBoxPlot	Box plot of residuals	BOXPLOT
ResidualByPredicted	Residuals versus predicted values	RESIDUALBYPREDICTED
ResidualHistogram	Histogram of fit residuals	RESIDUALHISTOGRAM
ResidualPlot	Plot of residuals versus regressor	RESIDUALS
RFPlot	Side-by-side plots of quantiles of centered fit and residuals	RF
RidgePanel	Plot of VIF and ridge traces	RIDGE
RidgePlot	Plot of ridge traces	RIDGE(UNPACK)
RSquarePlot	R-square statistic for models examined doing variable selection	RSQUARE
RStudentByLeverage	Studentized residuals versus leverage	RSTUDENTBYLEVERAGE
RStudentByPredicted	Studentized residuals versus predicted values	RSTUDENTBYPREDICTED
SBCPlot	SBC statistic for models examined doing variable selection	SBC
SelectionCriterionPanel	Panel of fit statistics for models examined doing variable selection	CRITERIA
VIFPlot	Plot of VIF traces	RIDGE(UNPACK)

Examples: REG Procedure

Example 76.1: Modeling Salaries of Major League Baseball Players

This example features the use of ODS Graphics in the process of building models by using the REG procedure and highlights the use of fit and influence diagnostics.

The following data set contains salary and performance information for Major League Baseball players who played at least one game in both the 1986 and 1987 seasons, excluding pitchers. The salaries (*Sports Illustrated,* April 20, 1987) are for the 1987 season and the performance measures are from 1986 (Collier Books, *The 1987 Baseball Encyclopedia Update*).

```
data baseball;
  length name $ 18;
  length team $ 12;
  input name $ 1-18 no_atbat no_hits no_home no_runs no_rbi no_bb yr_major
        cr_atbat cr_hits cr_home cr_runs cr_rbi cr_bb league $
        division $ team $ position $ no_outs no_assts no_error salary;
  logSalary = log10(salary);
  label name="Player's Name"
     no_hits="Hits in 1986"
     no_runs="Runs in 1986"
     no_rbi="RBIs in 1986"
     no_bb="Walks in 1986"
     yr_major="Years in MLB"
     cr_hits="Career Hits"
     salary="1987 Salary in $ Thousands"
     logSalary = "log10(Salary)";
  datalines;

;
```

Suppose you want to investigate whether you can model the players' salaries for the 1987 season based on batting statistics for the previous season and lifetime batting performance. Since the variation in salaries is much greater for higher salaries, it is appropriate to apply a log transformation for this analysis. The following statements begin the analysis:

```
ods graphics on;

proc reg data=baseball;
   id name team league;
   model logSalary = no_hits no_runs no_rbi no_bb yr_major cr_hits;
run;
```

Output 76.1.1 shows the default output produced by PROC REG. The number of observations table shows that 59 observations are excluded because they have missing values for at least one of the variables used in the analysis. The analysis of variance and parameter estimates tables provide details about the fitted model.

Output 76.1.1 Default Output from PROC REG

The REG Procedure
Model: MODEL1
Dependent Variable: logSalary log10(Salary)

Number of Observations Read	322
Number of Observations Used	263
Number of Observations with Missing Values	59

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	6	22.92208	3.82035	60.56	<.0001
Error	256	16.14954	0.06308		
Corrected Total	262	39.07162			

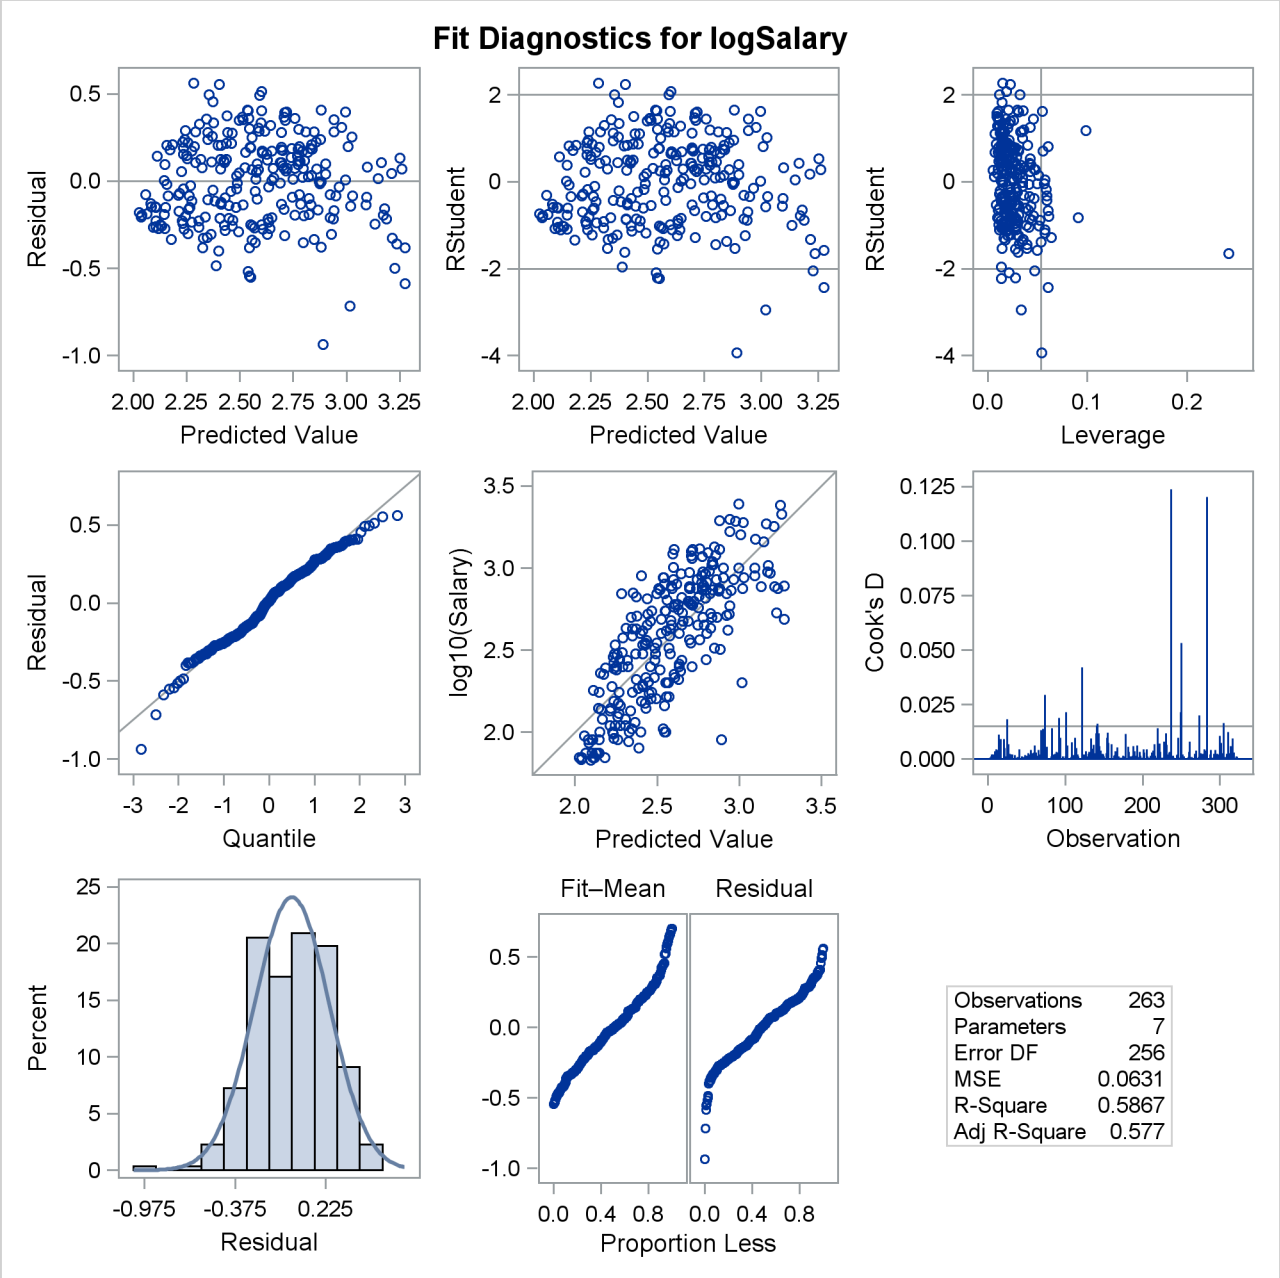
Root MSE	0.25117	R-Square	0.5867
Dependent Mean	2.57416	Adj R-Sq	0.5770
Coeff Var	9.75719		

Parameter Estimates

Variable	Label	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	Intercept	1	1.80065	0.05912	30.46	<.0001
no_hits	Hits in 1986	1	0.00288	0.00091244	3.15	0.0018
no_runs	Runs in 1986	1	0.00008638	0.00173	0.05	0.9602
no_rbi	RBIs in 1986	1	0.00054382	0.00102	0.53	0.5947
no_bb	Walks in 1986	1	0.00292	0.00104	2.81	0.0054
yr_major	Years in MLB	1	0.03087	0.00836	3.69	0.0003
cr_hits	Career Hits	1	0.00010384	0.00006328	1.64	0.1020

Before you accept a regression model, it is important to examine influence and fit diagnostics to see whether the model might be unduly influenced by a few observations and whether the data support the assumptions that underlie the linear regression. To facilitate such investigations, you can obtain diagnostic plots by enabling ODS Graphics.

Output 76.1.2 Fit Diagnostics

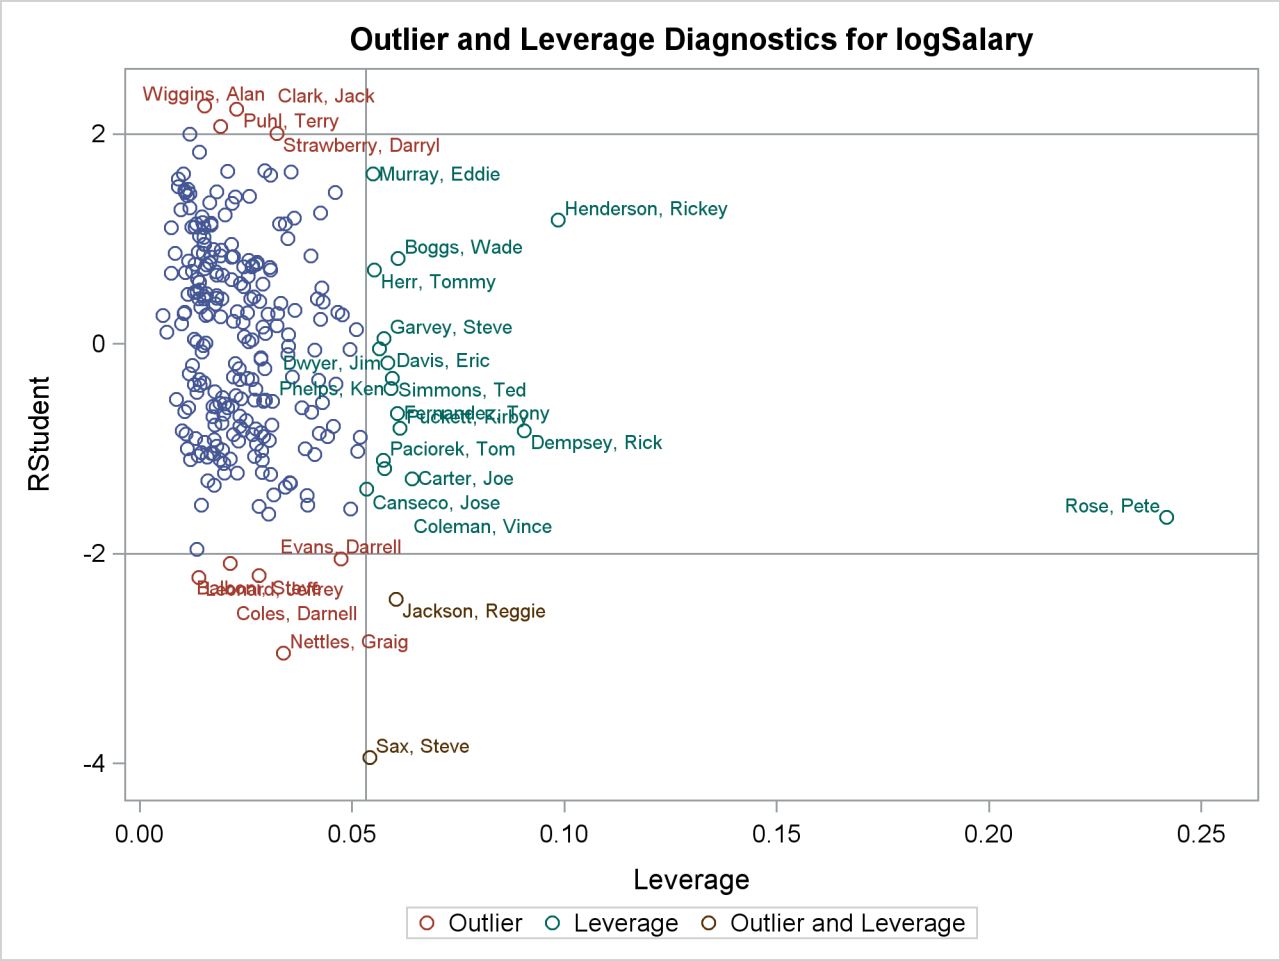


Output 76.1.2 shows a panel of diagnostic plots. The plot of externally studentized residuals (RStudent) by leverage values reveals that there is one observation with very high leverage that might be overly influencing the fit produced. The plot of Cook's *D* by observation also indicates two highly influential observations. To investigate further, you can use the PLOTS= option in the PROC REG statement as follows to produce labeled versions of these plots:

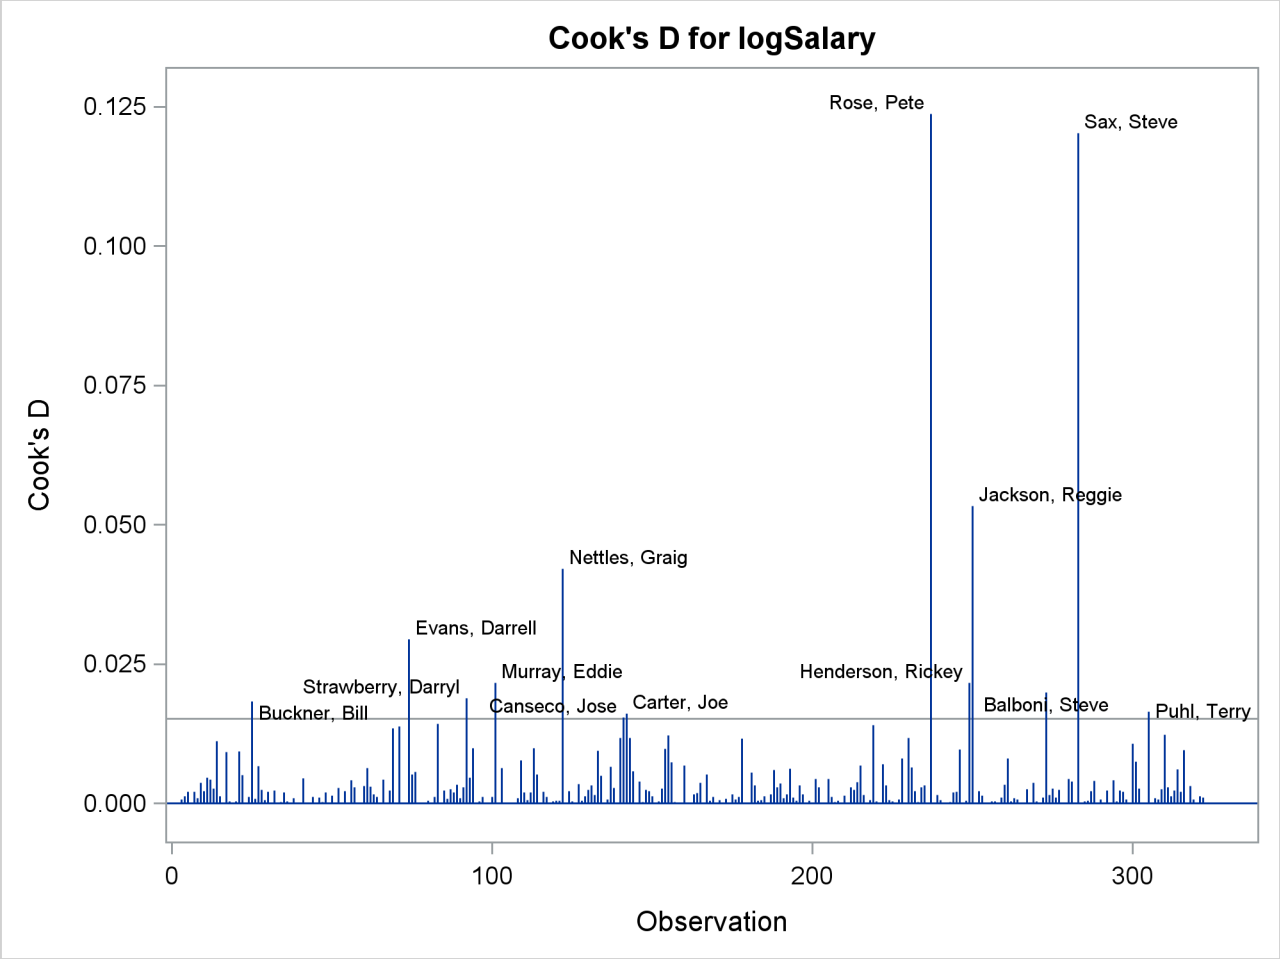
```
proc reg data=baseball
         plots(only label)=(RStudentByLeverage CooksD);
   id name team league;
   model logSalary = no_hits no_runs no_rbi no_bb yr_major cr_hits;
run;
```

Output 76.1.3 and Output 76.1.4 reveal that Pete Rose is the highly influential observation. You might obtain a better fit to the remaining data if you omit his statistics when building the model.

Output 76.1.3 Outlier and Leverage Diagnostics



Output 76.1.4 Cook's D

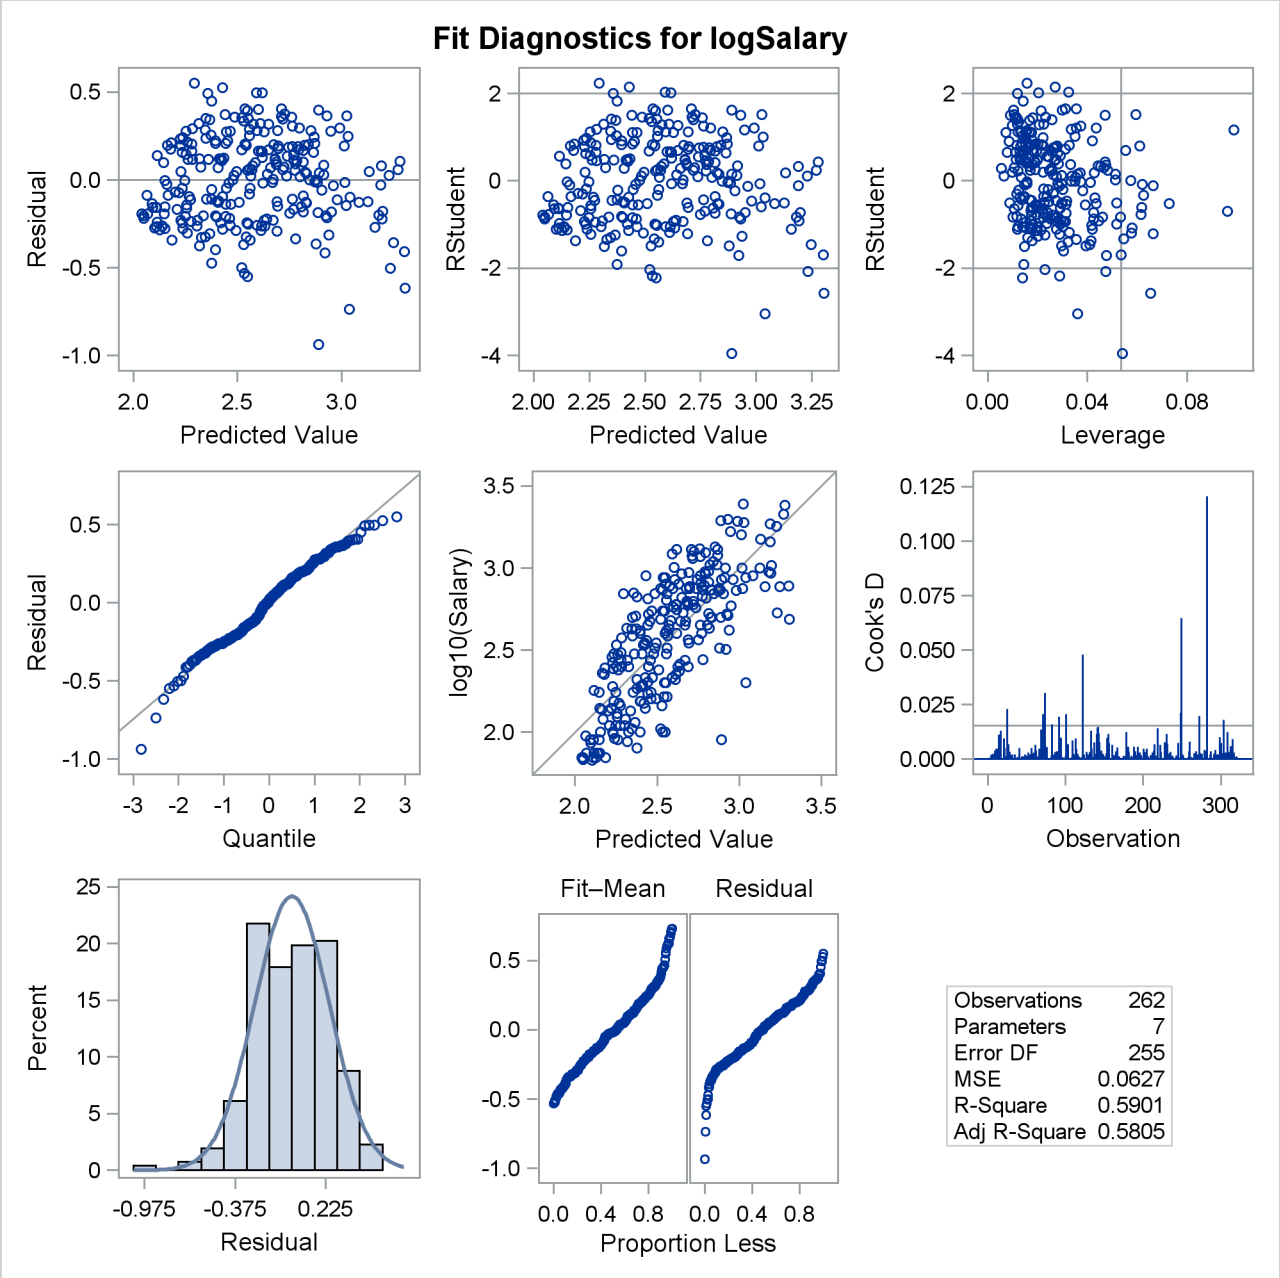


The following statements use a WHERE statement to omit Pete Rose's statistics when building the model. An alternative way to do this within PROC REG is to use a REWEIGHT statement. See "Reweighting Observations in an Analysis" on page 6453 for details about reweighting.

```
proc reg data=baseball
         plots=(RStudentByLeverage(label) residuals(smooth));
   where name^="Rose, Pete";
   id name team league;
   model logSalary = no_hits no_runs no_rbi no_bb yr_major cr_hits;
run;
```

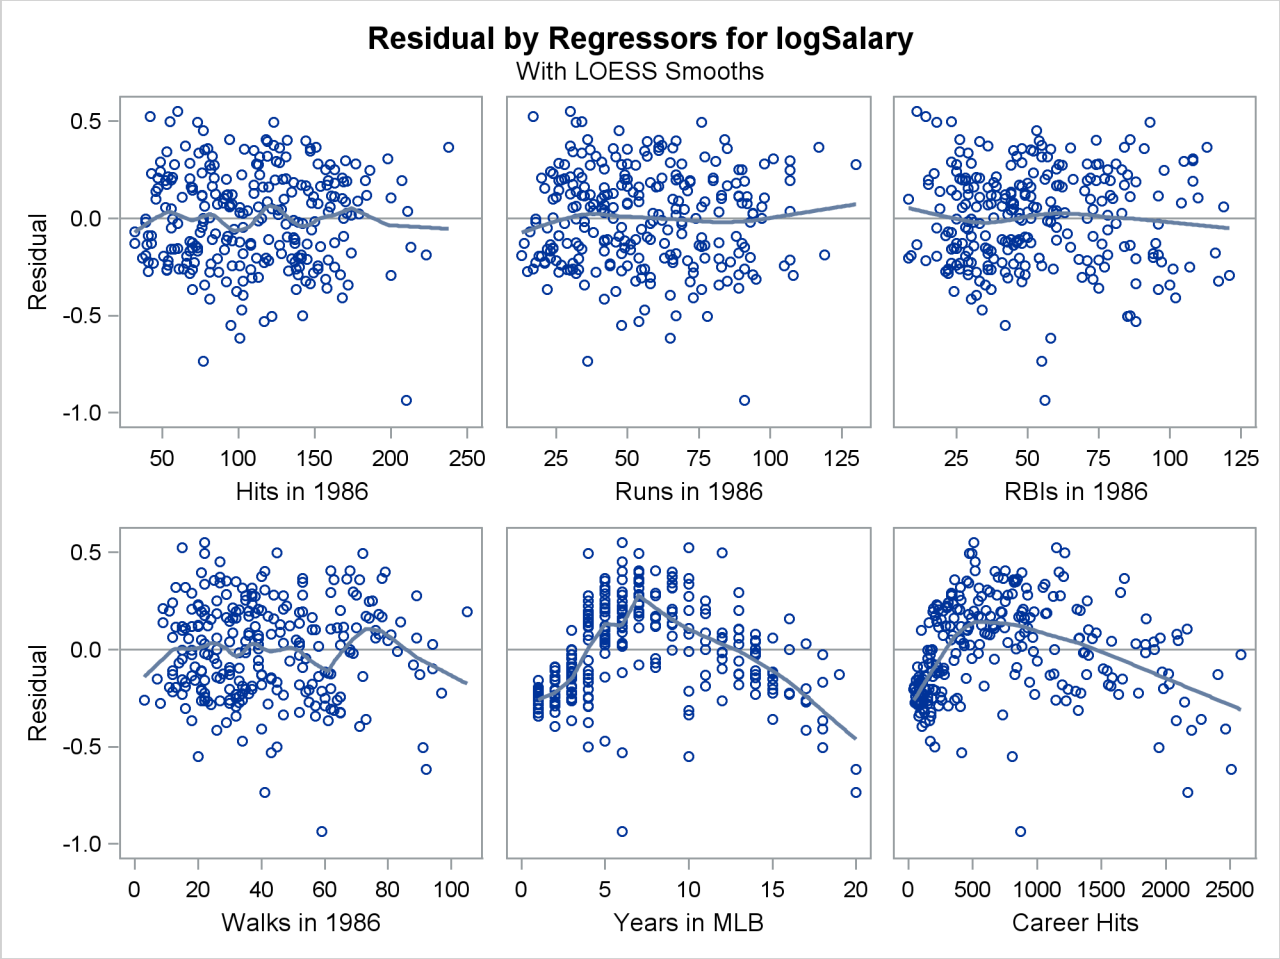
Output 76.1.5 shows the new fit diagnostics panel. You can see that there are still several influential and outlying observations. One possible reason for observing outliers is that the linear model specified is not appropriate to capture the variation in this data. You can often see evidence of an inappropriate model by observing patterns in plots of residuals.

Output 76.1.5 Fit Diagnostics



Output 76.1.6 shows plots of the residuals by the regressors in the model. When you specify the RESIDUALS(SMOOTH) suboption of the PLOTS option in the PROC REG statement, a loess fit is overlaid on each of these plots. You can see the same clear pattern in the residual plots for yr_major and cr_hits. Players near the start of their careers and players near the end of their careers get paid less than the model predicts.

Output 76.1.6 Residuals by Regressors



You can address this lack of fit by using polynomials of degree 2 for these two variables as shown in the following statements:

```
data baseball;
   set baseball(where=(name^="Rose, Pete")) ;
   yr_major2 = yr_major*yr_major;
   cr_hits2  = cr_hits*cr_hits;
run;

proc reg data=baseball
      plots=(diagnostics(stats=none) RStudentByLeverage(label)
             CooksD(label) Residuals(smooth)
             DFFITS(label) DFBETAS ObservedByPredicted(label));
   id name team league;
   model logSalary = no_hits no_runs no_rbi no_bb yr_major cr_hits
                     yr_major2 cr_hits2;
run;
ods graphics off;
```

Output 76.1.7 shows the analysis of variance and parameter estimates for this model. Note that the R-square value of 0.787 for this model is considerably larger than the R-square value of 0.587 for the initial model shown in Output 76.1.1.

Output 76.1.7 Output from PROC REG

The REG Procedure
Model: MODEL1
Dependent Variable: logSalary log10(Salary)

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	8	30.69367	3.83671	117.13	<.0001
Error	253	8.28706	0.03276		
Corrected Total	261	38.98073			

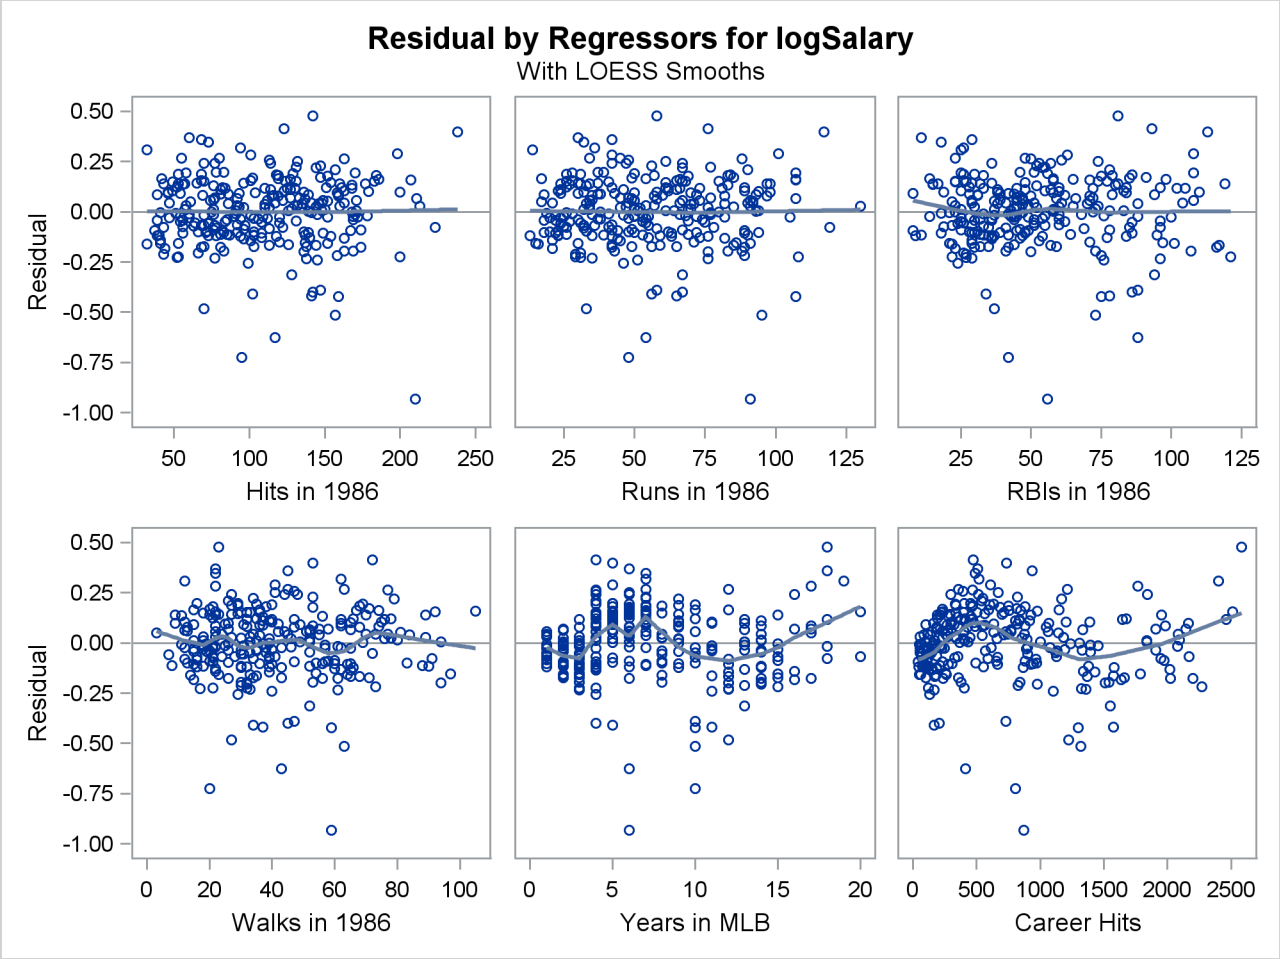
Root MSE	0.18098	R-Square	0.7874
Dependent Mean	2.57301	Adj R-Sq	0.7807
Coeff Var	7.03393		

Parameter Estimates

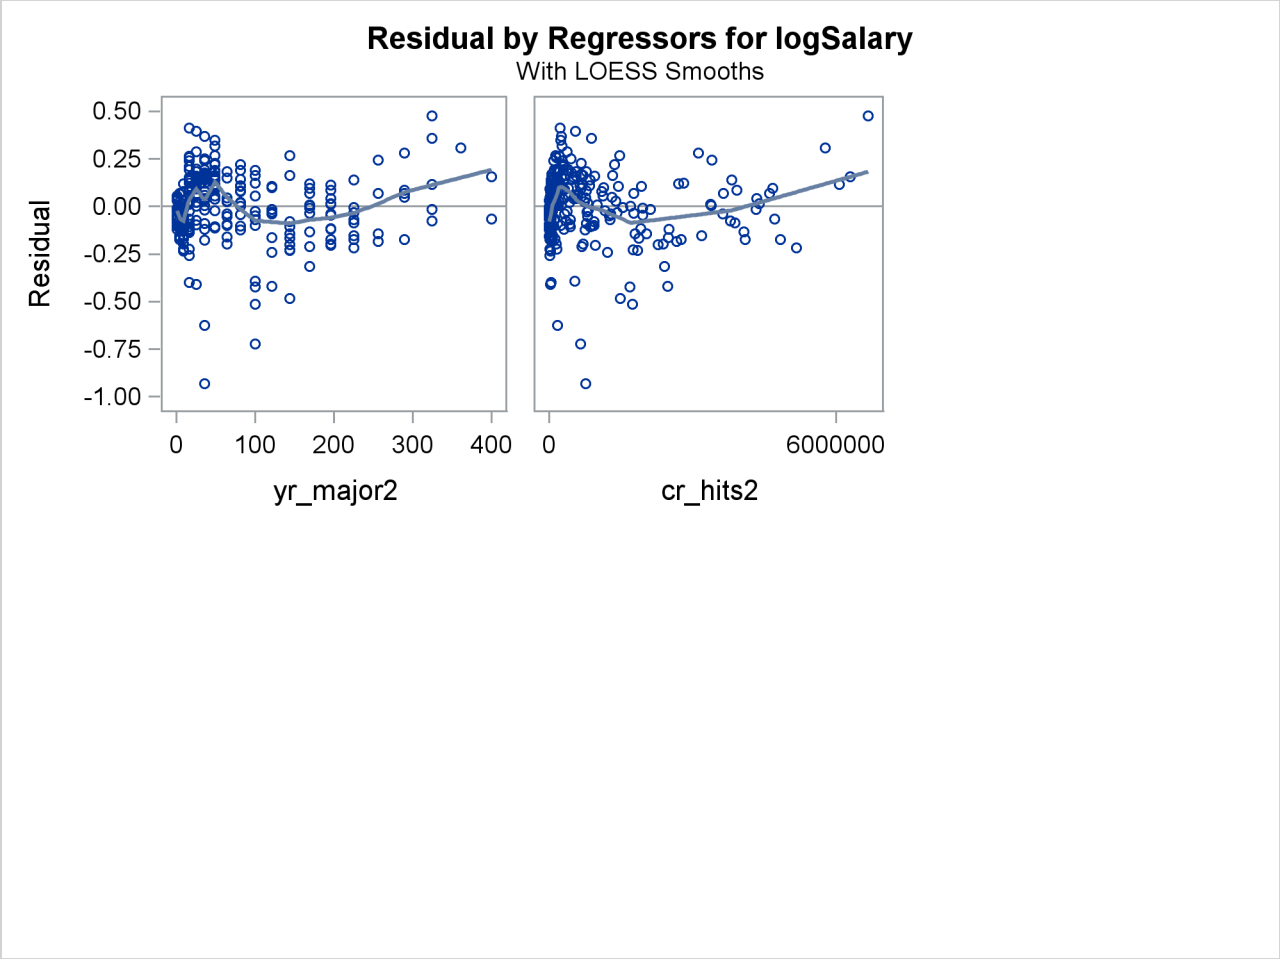
Variable	Label	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	Intercept	1	1.64564	0.05030	32.72	<.0001
no_hits	Hits in 1986	1	-0.00005539	0.00069200	-0.08	0.9363
no_runs	Runs in 1986	1	0.00093586	0.00125	0.75	0.4549
no_rbi	RBIs in 1986	1	0.00187	0.00074649	2.51	0.0127
no_bb	Walks in 1986	1	0.00218	0.00075057	2.90	0.0040
yr_major	Years in MLB	1	0.10383	0.01495	6.94	<.0001
cr_hits	Career Hits	1	0.00073955	0.00011970	6.18	<.0001
yr_major2		1	-0.00625	0.00071687	-8.73	<.0001
cr_hits2		1	-1.44072E-7	4.348471E-8	-3.31	0.0011

The plots of residuals by regressors in Output 76.1.8 and Output 76.1.9 show that the strong pattern in the plots for cr_majors and cr_hits has been reduced, although there is still some indication of a pattern remaining in these residuals. This suggests that a quadratic function might be insufficient to capture dependence of salary on these regressors.

Output 76.1.8 Residuals by Regressors

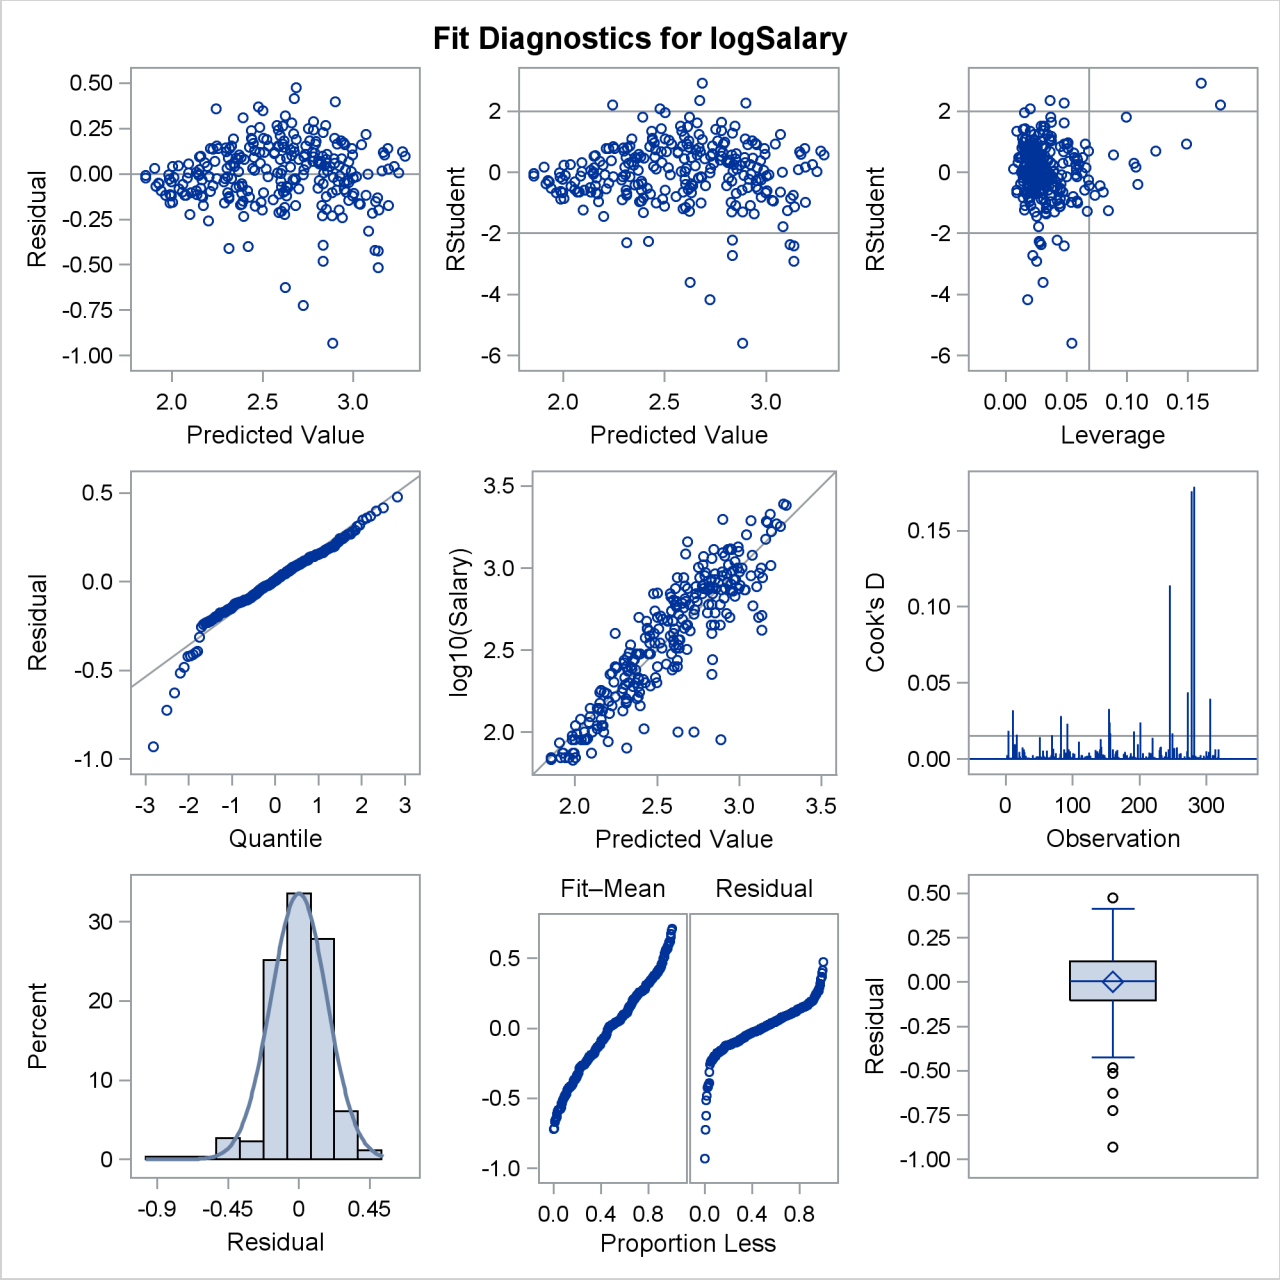


Output 76.1.9 Residuals by Regressors

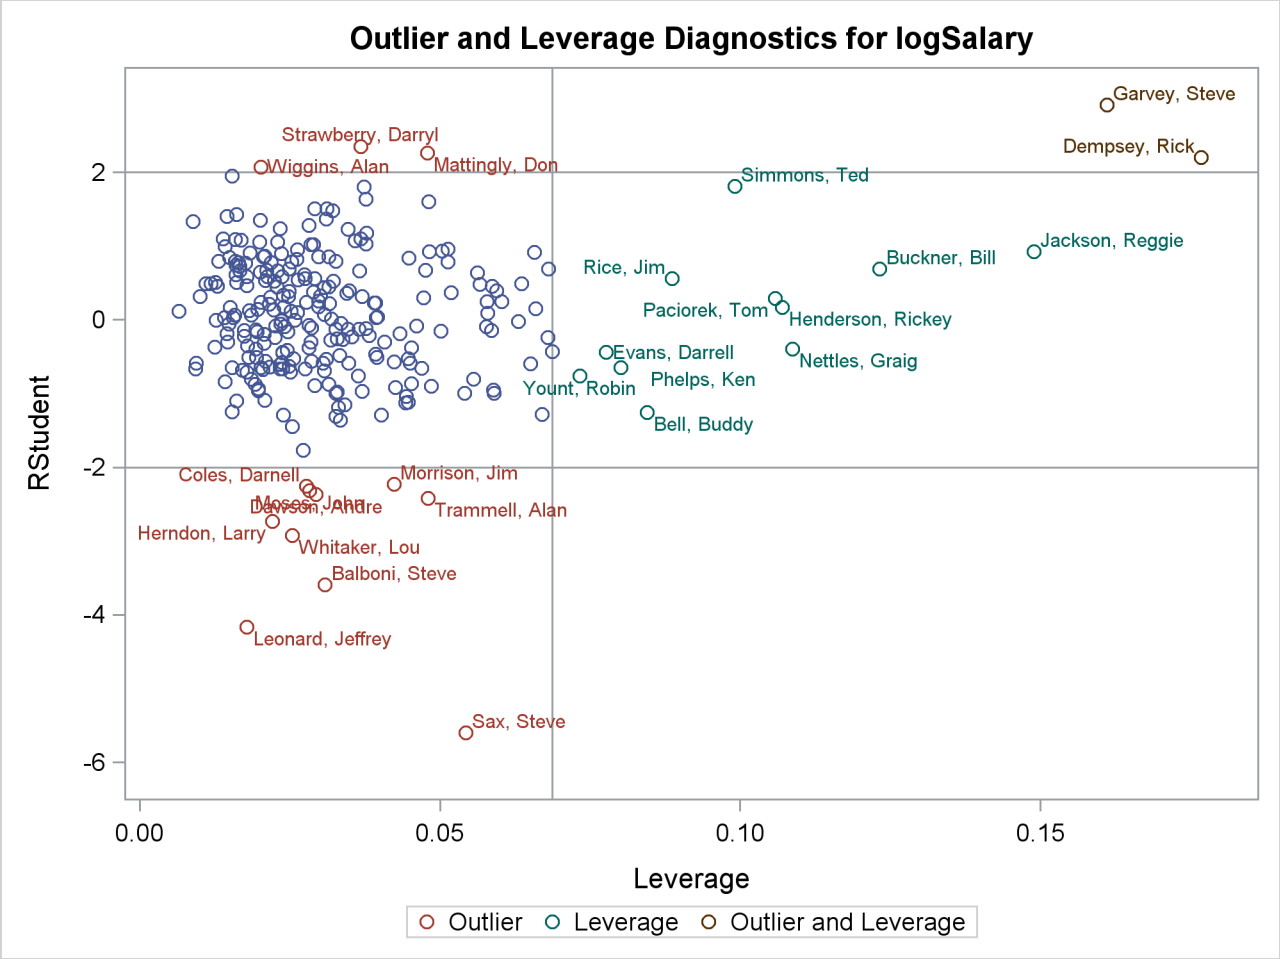


Output 76.1.10 show the diagnostics plots; three of the plots, with points of interest labeled, are shown individually in Output 76.1.11, Output 76.1.12, and Output 76.1.13. The STATS=NONE suboption specified in the PLOTS=DIAGNOSTICS option replaces the inset of statistics with a box plot of the residuals in the fit diagnostics panel. The observed by predicted value plot reveals a reasonably successful model for explaining the variation in salary for most of the players. However, the model tends to overpredict the salaries of several players near the lower end of the salary range. This bias can also be seen in the distribution of the residuals that you can see in the histogram, Q-Q plot, and box plot in Output 76.1.10.

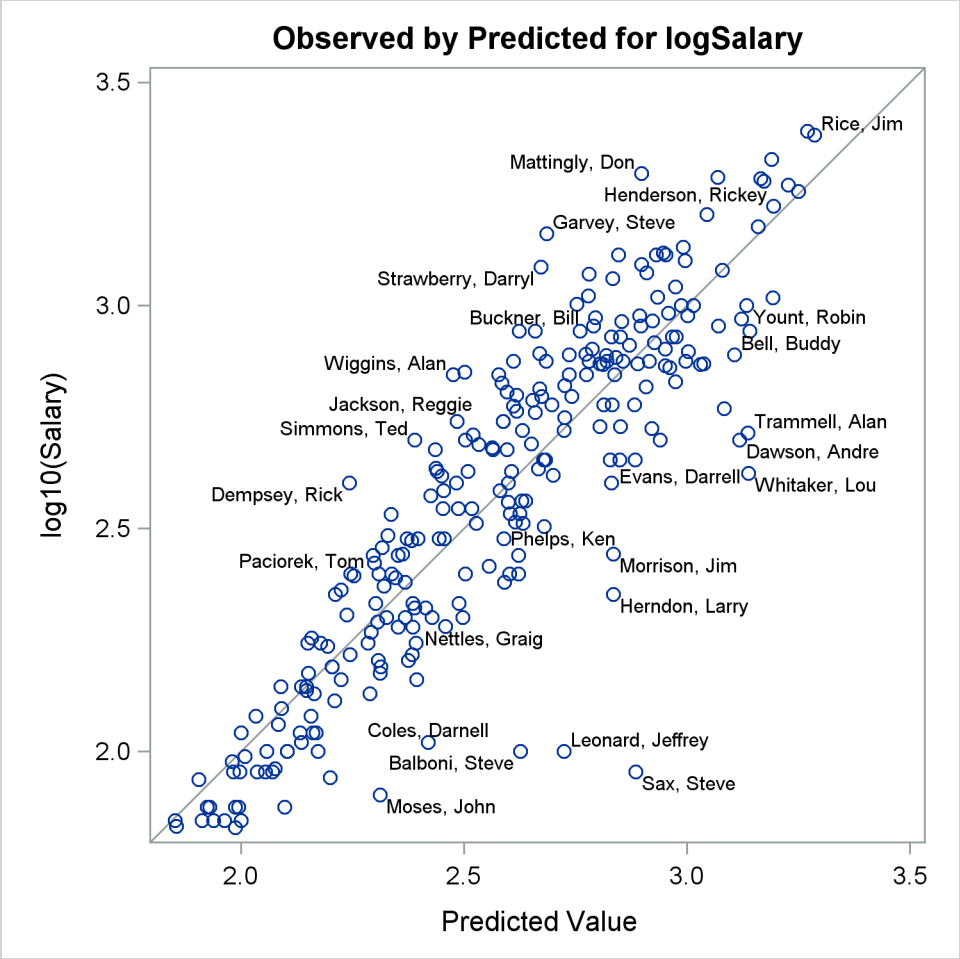
Output 76.1.10 Fit Diagnostics



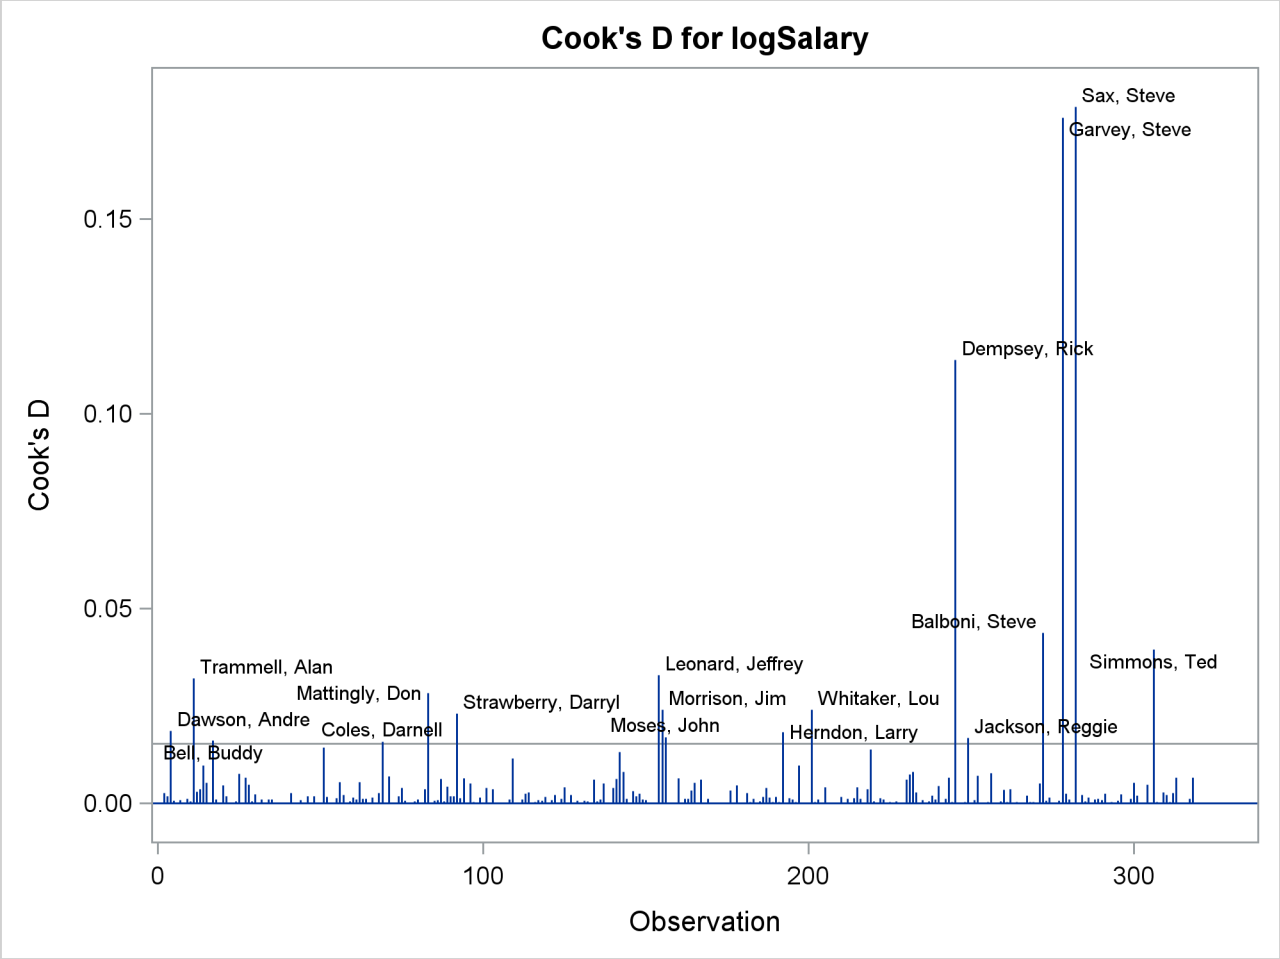
Output 76.1.11 Outlier and Leverage Diagnostics



Output 76.1.12 Observed by Predicted Values

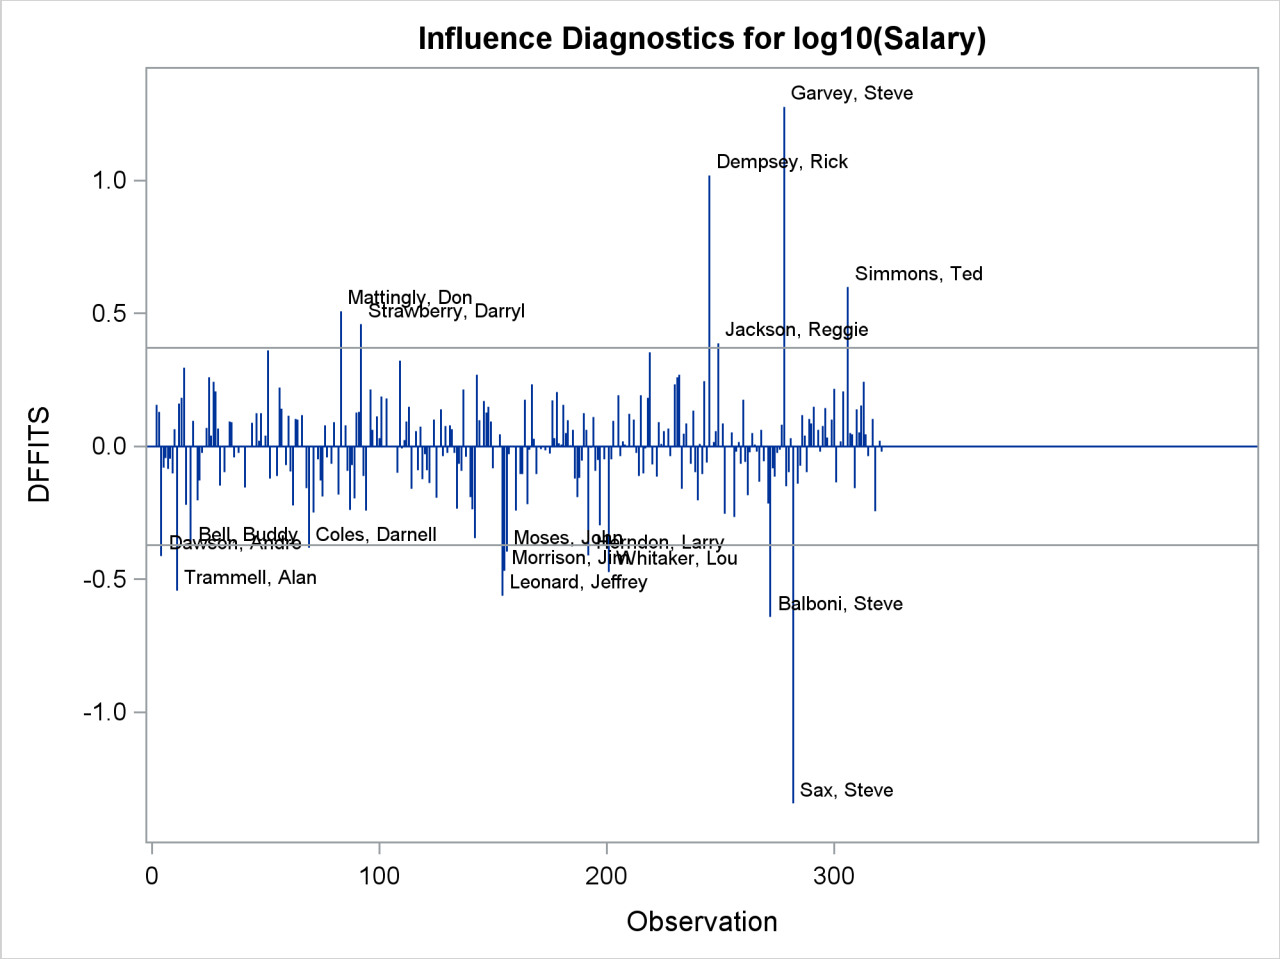


Output 76.1.13 Cook's D

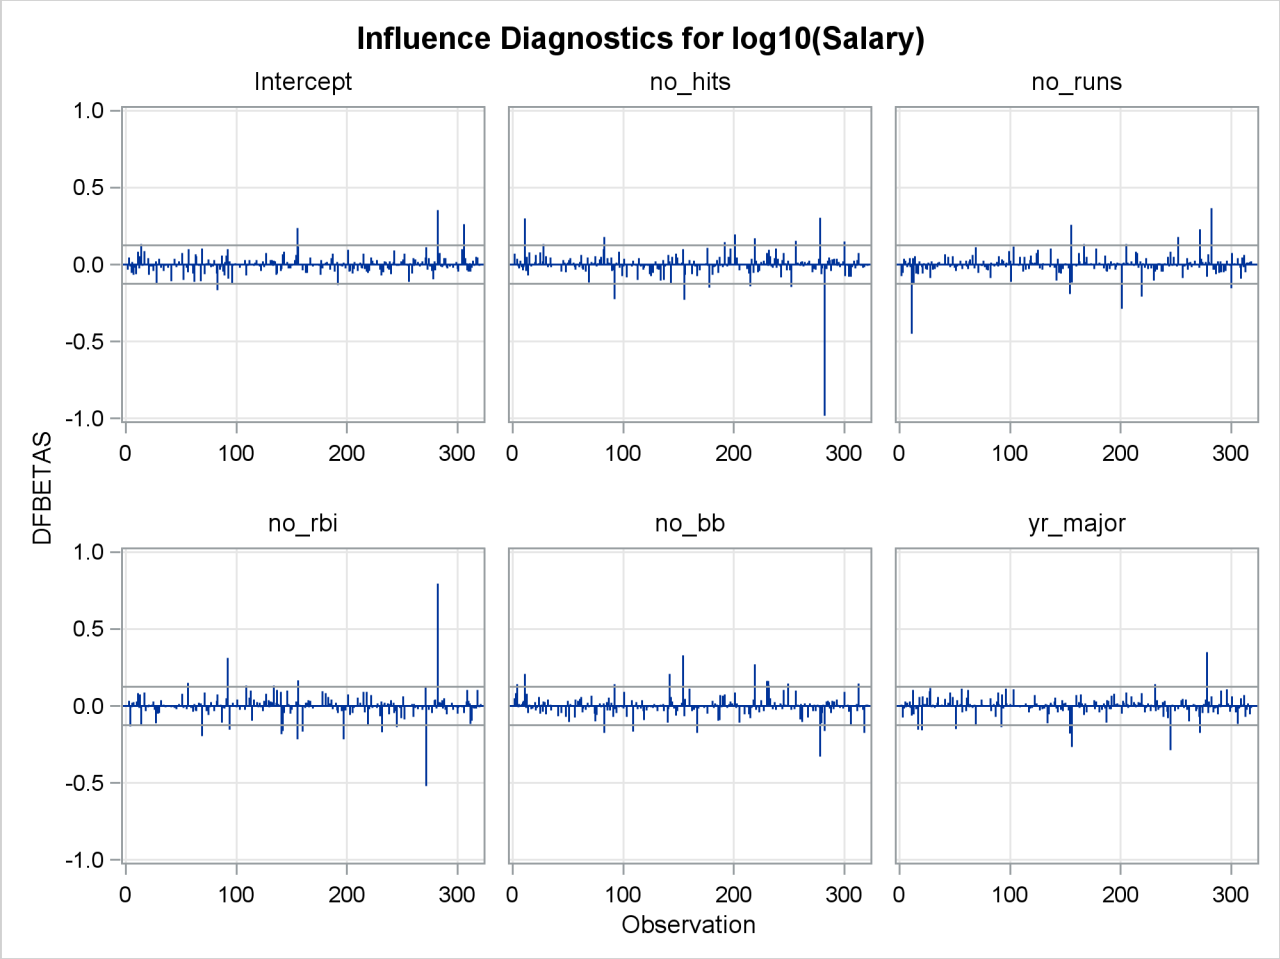


The RStudent by leverage plot in Output 76.1.11 and the Cook's *D* plot in Output 76.1.13 show that there are still a number of influential observations. By specifying the DFFITS and DFBETAS suboptions of the PLOTS= option, you obtain additional influence diagnostics plots shown in Output 76.1.14 and Output 76.1.15. See "Influence Statistics" on page 6443 for details about the interpretation DFFITS and DFBETAS statistics.

Output 76.1.14 DFFITS



Output 76.1.15 DFBETAS



You can continue this analysis by investigating how the influential observations identified in the various influence plots affect the fit. You can also use PROC ROBUSTREG to obtain a fit that is resistant to the presence of high leverage points and outliers.

Example 76.2: Aerobic Fitness Prediction

Aerobic fitness (measured by the ability to consume oxygen) is fit to some simple exercise tests. The goal is to develop an equation to predict fitness based on the exercise tests rather than on expensive and cumbersome oxygen consumption measurements. Three model-selection methods are used: forward selection, backward selection, and MAXR selection. Here are the data:

```
*-------------------Data on Physical Fitness-------------------*
| These measurements were made on men involved in a physical   |
| fitness course at N.C.State Univ. The variables are Age      |
| (years), Weight (kg), Oxygen intake rate (ml per kg body     |
| weight per minute), time to run 1.5 miles (minutes), heart   |
| rate while resting, heart rate while running (same time      |
| Oxygen rate measured), and maximum heart rate recorded while |
| running.                                                     |

;
```

The following statements demonstrate the FORWARD, BACKWARD, and MAXR model selection methods:

```
proc reg data=fitness;
   model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
         / selection=forward;
   model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
         / selection=backward;
   model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
         / selection=maxr;
run;
```

Output 76.2.1 shows the sequence of models produced by the FORWARD model-selection method.

Output 76.2.1 Forward Selection Method: PROC REG

The REG Procedure
Model: MODEL1
Dependent Variable: Oxygen

Forward Selection: Step 1

Variable RunTime Entered: R-Square = 0.7434 and C(p) = 13.6988

Bounds on condition number: 8.7312, 104.83

The final variable available to add to the model, RestPulse, is not added since it does not meet the 50% (the default value of the SLE option is 0.5 for FORWARD selection) significance-level criterion for entry into the model.

The BACKWARD model-selection method begins with the full model. Output 76.2.2 shows the steps of the BACKWARD method. RestPulse is the first variable deleted, followed by Weight. No other variables are deleted from the model since the variables remaining (Age, RunTime, RunPulse, and MaxPulse) are all significant at the 10% (the default value of the SLS option is 0.1 for the BACKWARD elimination method) significance level.

Output 76.2.2 Backward Selection Method: PROC REG

Bounds on condition number: 8.7438, 137.13

Note that for all three of these methods, RestPulse contributes least to the model. In the case of forward selection, it is not added to the model. In the case of backward selection, it is the first variable to be removed from the model. In the case of MAXR selection, RestPulse is included only for the full model.

For the STEPWISE, BACKWARD, and FORWARD selection methods, you can control the amount of detail displayed by using the DETAILS option, and you can use ODS Graphics to produce plots that show how selection criteria progress as the selection proceeds. For example, the following statements display only the selection summary table for the FORWARD selection method (Output 76.2.4) and produce the plots shown in Output 76.2.5 and Output 76.2.6.

```
ods graphics on;

proc reg data=fitness plots=(criteria sbc);
   model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
         / selection=forward details=summary;
run;
```

Output 76.2.4 Forward Selection Summary

The REG Procedure
Model: MODEL1
Dependent Variable: Oxygen

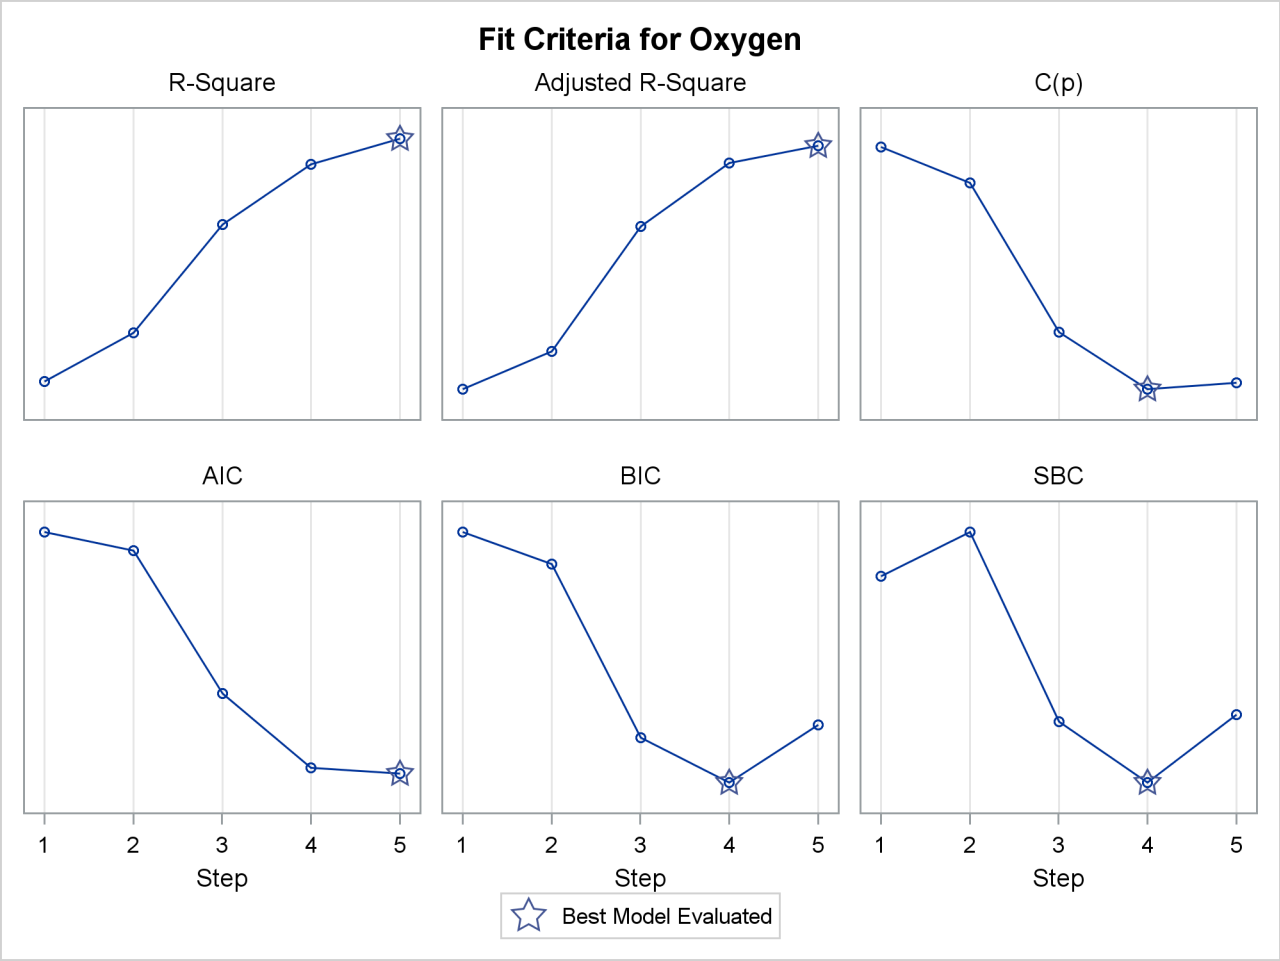
Summary of Forward Selection

Step	Variable Entered	Number Vars In	Partial R-Square	Model R-Square	C(p)	F Value	Pr > F
1	RunTime	1	0.7434	0.7434	13.6988	84.01	<.0001
2	Age	2	0.0209	0.7642	12.3894	2.48	0.1267
3	RunPulse	3	0.0468	0.8111	6.9596	6.70	0.0154
4	MaxPulse	4	0.0257	0.8368	4.8800	4.10	0.0533
5	Weight	5	0.0112	0.8480	5.1063	1.84	0.1871

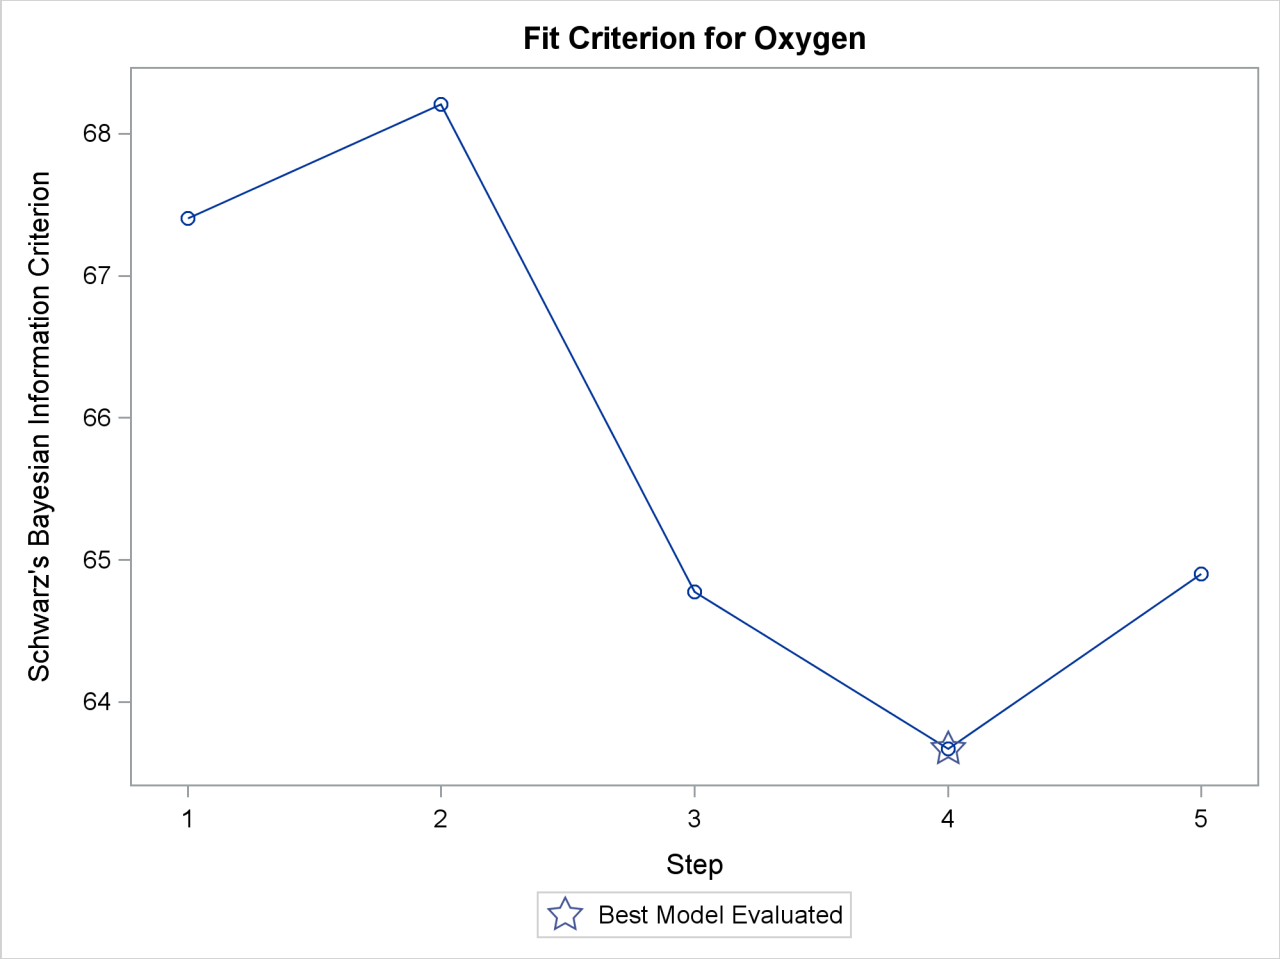
Output 76.2.5 show how six fit criteria progress as the forward selection proceeds. The step at which each criterion achieves its best value is indicated. For example, the BIC criterion achieves its minimum value for

the model at step 4. Note that this does not mean that the model at step 4 achieves the smallest BIC criterion among all possible models that use a subset of the regressors; the model at step 4 yields the smallest BIC statistic among the models at each step of the forward selection. Output 76.2.6 show the progression of the SBC statistic in its own plot. If you want to see six of the selection criteria in individual plots, you can specify the UNPACK suboption of the PLOTS=CRITERIA option in the PROC REG statement.

Output 76.2.5 Fit Criteria



Output 76.2.6 SBC Criterion



Next, the RSQUARE model-selection method is used to request R^2 and C_p statistics for all possible combinations of the six independent variables. The following statements produce Output 76.2.7:

```
proc reg data=fitness plots=(criteria(label) cp);
   model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
         / selection=rsquare cp;
   title 'Physical fitness data: all models';
run;
```

Output 76.2.7 All Models by the RSQUARE Method: PROC REG

Physical fitness data: all models

The REG Procedure
Model: MODEL1
Dependent Variable: Oxygen

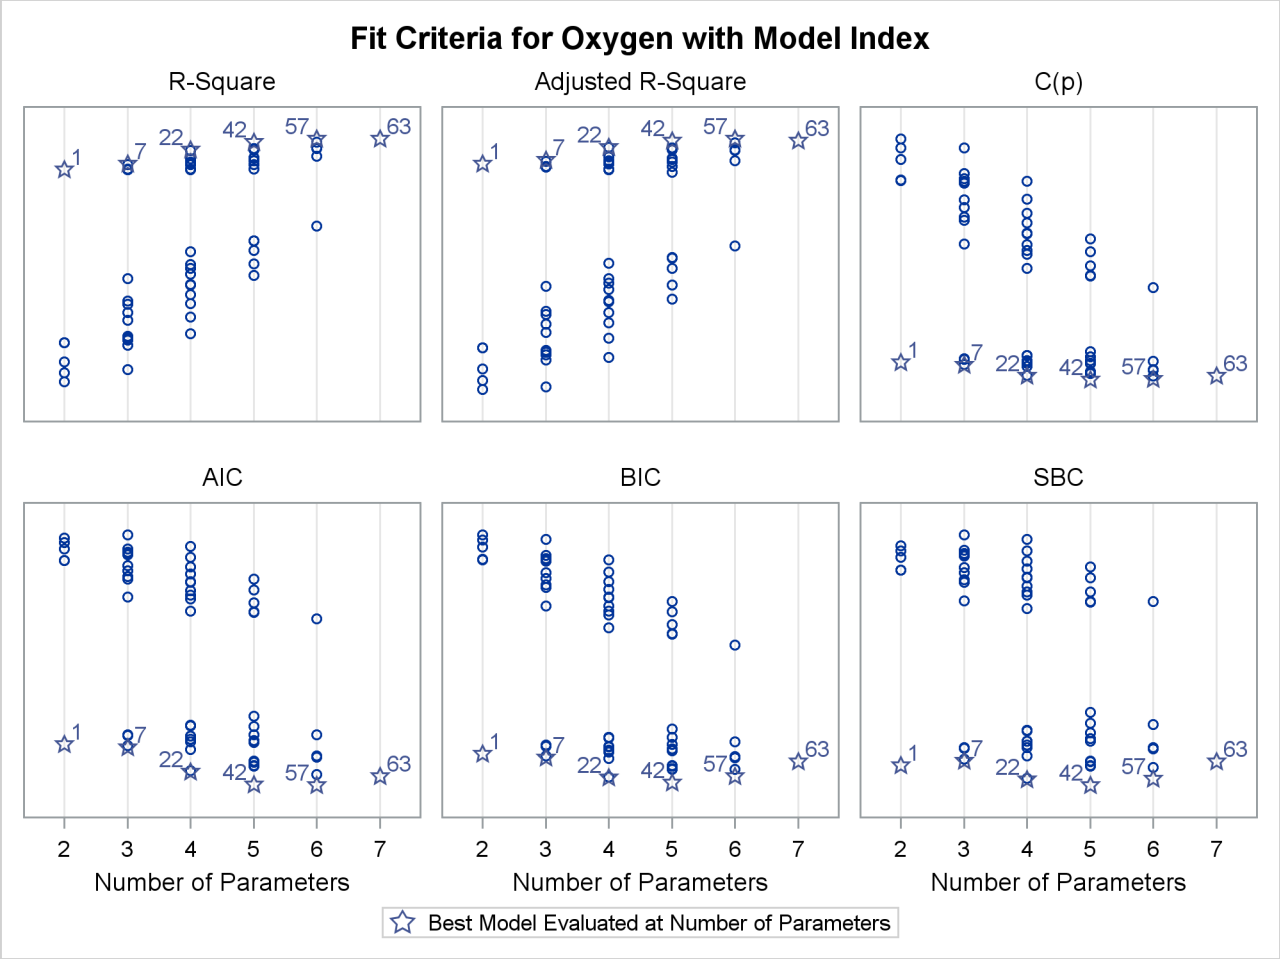
The models in Output 76.2.7 are arranged first by the number of variables in the model and then by the magnitude of R^2 for the model.

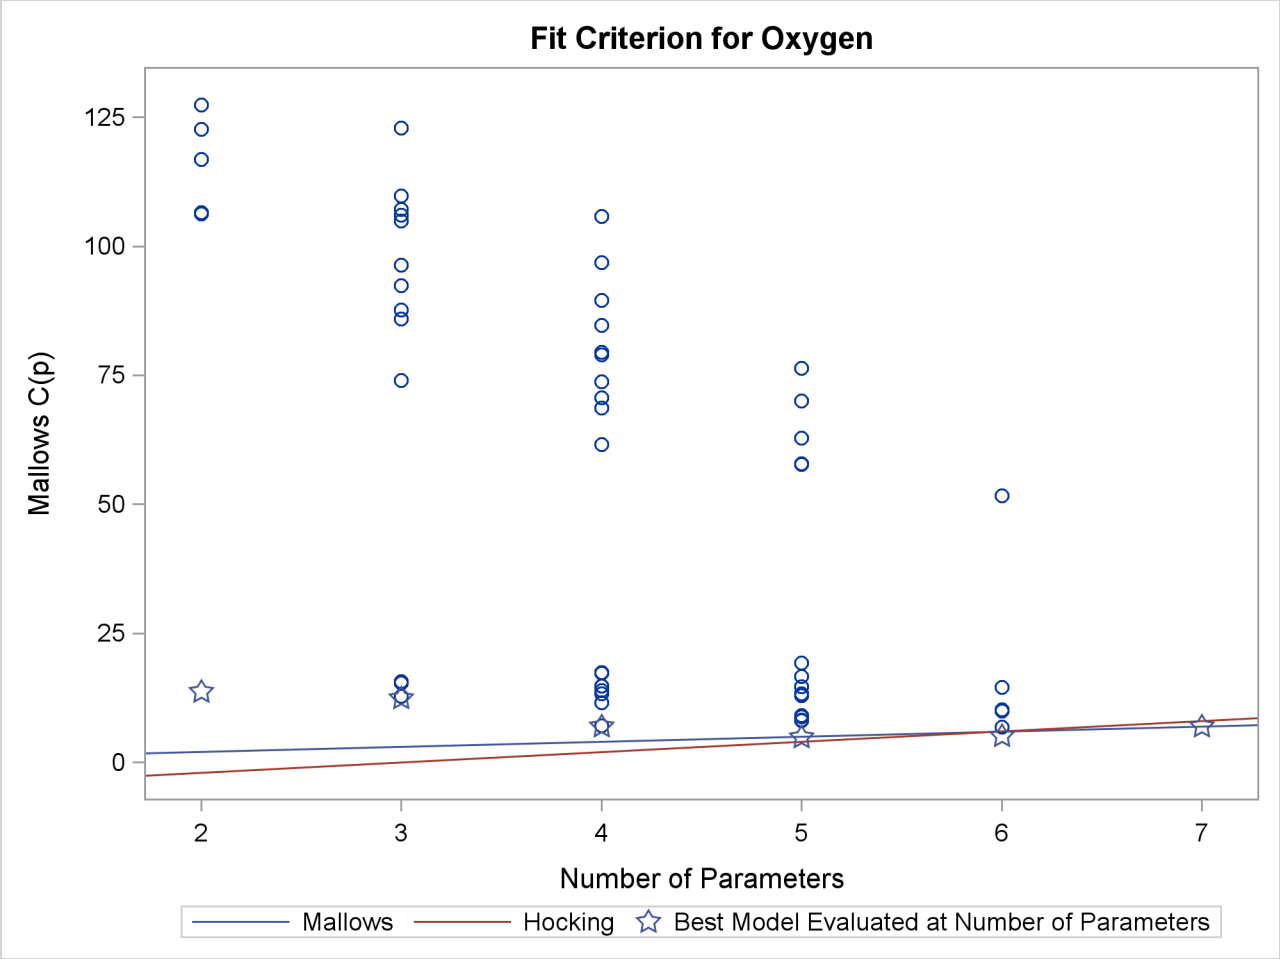
Output 76.2.8 shows the panel of fit criteria for the RSQUARE selection method. The best models (based on the R-square statistic) for each subset size are indicated on the plots. The LABEL suboption specifies that these models are labeled by the model number that appears in the summary table shown in Output 76.2.7.

Output 76.2.8 Fit Criteria



Output 76.2.9 shows the plot of the C_p criterion by number of regressors in the model. Useful reference lines suggested by Mallows (1973) and Hocking (1976) are included on the plot. However, because all possible subset models are included on this plot, the better models are all compressed near the bottom of the plot.

Output 76.2.9 C_p Criterion



The following statements use the BEST=20 option in the model statement and SELECTION=CP to restrict attention to the models that yield the 20 smallest values of the C_p statistic:

```
proc reg data=fitness plots(only)=cp(label);
   model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
         / selection=cp best=20;
run;

ods graphics off;
```

Output 76.2.10 shows the summary table listing the regressors in the 20 models that yield the smallest C_p values, and Output 76.2.11 presents the results graphically. Reference lines $C_p = 2p - p_{full}$ and $C_p = p$ are shown on this plot. See the PLOTS=CP option on page 6365 for interpretations of these lines. For the Fitness data, these lines indicate that a six-variable model is a reasonable choice for doing parameter estimation, while a five-variable model might be suitable for doing prediction.

Output 76.2.10 C_p Selection Summary: PROC REG

The REG Procedure

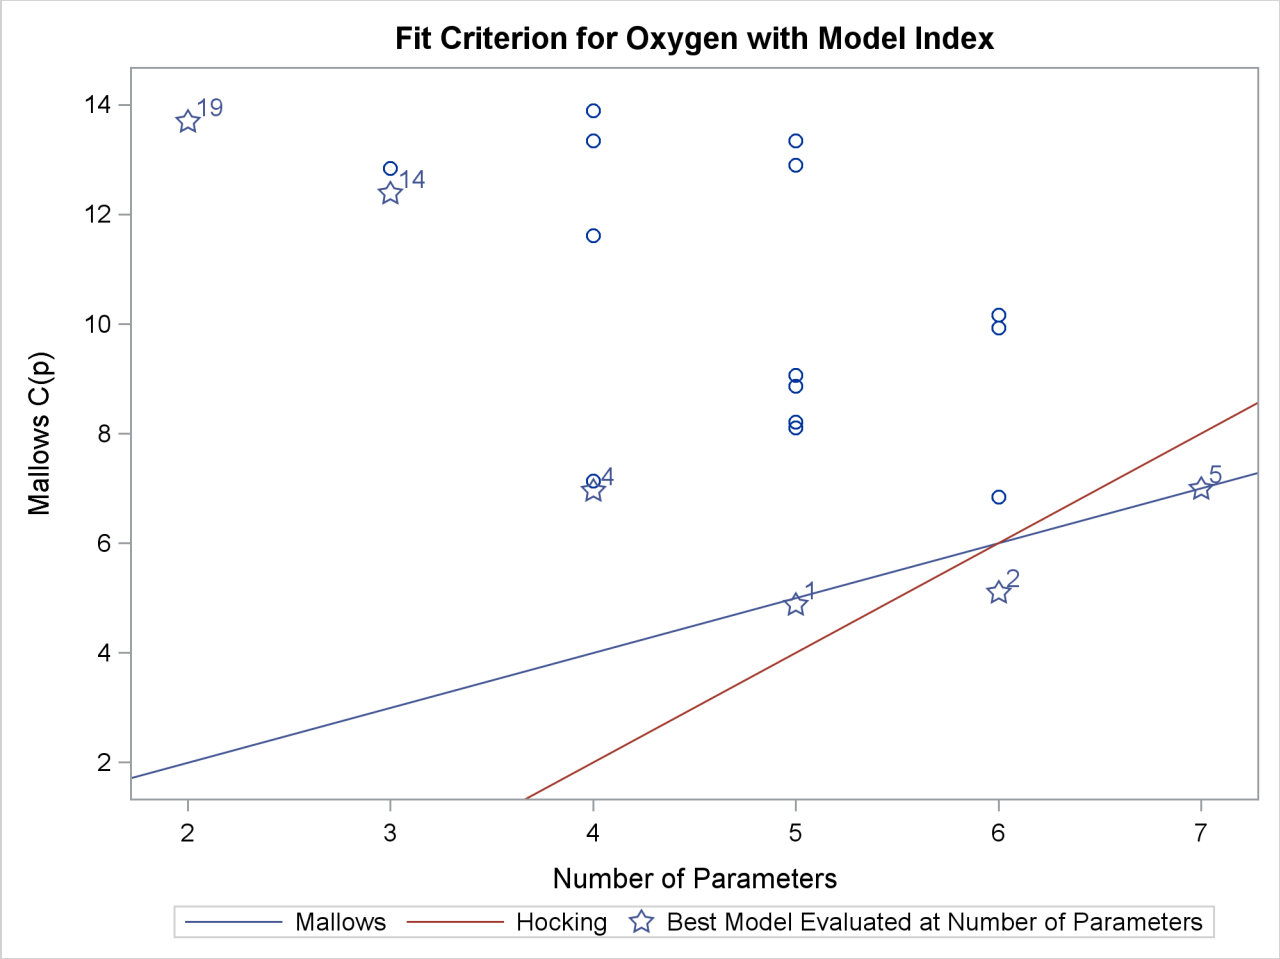
20	3	13.8974	0.7673	Age RunTime RestPulse

Output 76.2.11 C_p Criterion



Before making a final decision about which model to use, you would want to perform collinearity diagnostics. Note that, since many different models have been fit and the choice of a final model is based on R^2, the statistics are biased and the p-values for the parameter estimates are not valid.

Example 76.3: Predicting Weight by Height and Age

In this example, the weights of schoolchildren are modeled as a function of their heights and ages. The example shows the use of a BY statement with PROC REG, multiple MODEL statements, and the OUTEST= and OUTSSCP= options, which create data sets. Here are the data:

```
*------------Data on Age, Weight, and Height of Children-------*
| Age (months), height (inches), and weight (pounds) were      |
| recorded for a group of school children.                     |
| From Lewis and Taylor (1967).                                |
*--------------------------------------------------------------*;
```

```
data htwt;
   input sex $ age :3.1 height weight @@;
   datalines;
f 143 56.3  85.0 f 155 62.3 105.0 f 153 63.3 108.0 f 161 59.0  92.0
f 191 62.5 112.5 f 171 62.5 112.0 f 185 59.0 104.0 f 142 56.5  69.0

m 151 59.3  87.0
;
```

Modeling is performed separately for boys and girls. Since the BY statement is used, interactive processing is not possible in this example; no statements can appear after the first RUN statement.

The following statements produce Output 76.3.1 through Output 76.3.4:

```
proc reg outest=est1 outsscp=sscp1 rsquare;
   by sex;
   eq1: model  weight=height;
   eq2: model  weight=height age;

proc print data=sscp1;
   title2 'SSCP type data set';

proc print data=est1;
   title2 'EST type data set';
run;
```

Output 76.3.1 Height and Weight Data: Submodel for Female Children

```

For both female and male children, the overall F statistics for both models are significant, indicating that the model explains a significant portion of the variation in the data. For females, the full model is

$$\text{weight} = -150.57 + 3.60 \times \text{height} + 1.91 \times \text{age}$$

and for males, the full model is

$$\text{weight} = -113.71 + 2.68 \times \text{height} + 3.08 \times \text{age}$$

The OUTSSCP= data set is shown in Output 76.3.5. Note how the BY groups are separated. Observations with _TYPE_='N' contain the number of observations in the associated BY group. Observations with _TYPE_='SSCP' contain the rows of the uncorrected sums of squares and crossproducts matrix. The observations with _NAME_='Intercept' contain crossproducts for the intercept.

Output 76.3.5 SSCP Matrix

SSCP type data set

10	m	N		126.0	126.00	126.00	126.00

The OUTEST= data set is displayed in Output 76.3.6; again, the BY groups are separated. The _MODEL_ column contains the labels for models from the MODEL statements. If no labels are specified, the defaults MODEL1 and MODEL2 would appear as values for _MODEL_. Note that _TYPE_='PARMS' for all observations, indicating that all observations contain parameter estimates. The _DEPVAR_ column displays the dependent variable, and the _RMSE_ column gives the root mean square error for the associated model. The Intercept column gives the estimate for the intercept for the associated model, and variables with the same name as variables in the original data set (height, age) give parameter estimates for those variables. The dependent variable, weight, is shown with a value of -1. The _IN_ column contains the number of regressors in the model not including the intercept; _P_ contains the number of parameters in the model; _EDF_ contains the error degrees of freedom; and _RSQ_ contains the R^2 statistic. Finally, note that the _IN_, _P_, _EDF_, and _RSQ_ columns appear in the OUTEST= data set since the RSQUARE option is specified in the PROC REG statement.

Output 76.3.6 OUTEST Data Set

Example 76.4: Regression with Quantitative and Qualitative Variables

At times it is desirable to have independent variables in the model that are qualitative rather than quantitative. This is easily handled in a regression framework. Regression uses qualitative variables to distinguish between populations. There are two main advantages of fitting both populations in one model. You gain the ability to test for different slopes or intercepts in the populations, and more degrees of freedom are available for the analysis.

Regression with qualitative variables is different from analysis of variance and analysis of covariance. Analysis of variance uses qualitative independent variables only. Analysis of covariance uses quantitative variables in addition to the qualitative variables in order to account for correlation in the data and reduce MSE; however, the quantitative variables are not of primary interest and merely improve the precision of the analysis.

Consider the case where Y_i is the dependent variable, $\mathbf{X1}_i$ is a quantitative variable, $\mathbf{X2}_i$ is a qualitative variable taking on values 0 or 1, and $\mathbf{X1}_i\mathbf{X2}_i$ is the interaction. The variable $\mathbf{X2}_i$ is called a dummy, binary, or indicator variable. With values 0 or 1, it distinguishes between two populations. The model is of the form

$$\mathbf{Y}_i = \beta_0 + \beta_1\mathbf{X1}_i + \beta_2\mathbf{X2}_i + \beta_3\mathbf{X1}_i\mathbf{X2}_i + \boldsymbol{\epsilon}_i$$

for the observations $i = 1, 2, \ldots, n$. The parameters to be estimated are β_0, β_1, β_2, and β_3. The number of dummy variables used is one less than the number of qualitative levels. This yields a nonsingular $\mathbf{X}'\mathbf{X}$ matrix. See Chapter 10 of Neter, Wasserman, and Kutner (1990) for more details.

An example from Neter, Wasserman, and Kutner (1990) follows. An economist is investigating the relationship between the size of an insurance firm and the speed at which it implements new insurance innovations. He believes that the type of firm might affect this relationship and suspects that there might be some interaction between the size and type of firm. The dummy variable in the model enables the two firms to have different intercepts. The interaction term enables the firms to have different slopes as well.

In this study, $\mathbf{Y}_i$ is the number of months from the time the first firm implemented the innovation to the time it was implemented by the ith firm. The variable $\mathbf{X1}_i$ is the size of the firm, measured in total assets of the firm. The variable $\mathbf{X2}_i$ denotes the firm type; it is 0 if the firm is a mutual fund company and 1 if the firm is a stock company. The dummy variable enables each firm type to have a different intercept and slope.

The previous model can be broken down into a model for each firm type by plugging in the values for $\mathbf{X2}_i$. If $\mathbf{X2}_i = 0$, the model is

$$\mathbf{Y}_i = \beta_0 + \beta_1\mathbf{X1}_i + \boldsymbol{\epsilon}_i$$

This is the model for a mutual company. If $\mathbf{X2}_i = 1$, the model for a stock firm is

$$\mathbf{Y}_i = (\beta_0 + \beta_2) + (\beta_1 + \beta_3)\mathbf{X1}_i + \boldsymbol{\epsilon}_i$$

This model has intercept $\beta_0 + \beta_2$ and slope $\beta_1 + \beta_3$.

The data[1] follow. Note that the interaction term is created in the DATA step since polynomial effects such as size*type are not allowed in the MODEL statement in the REG procedure.

```
title 'Regression With Quantitative and Qualitative Variables';
data insurance;

;
run;
```

The following statements begin the analysis:

```
proc reg data=insurance;
   model time = size type sizetype;
run;
```

The ANOVA table is displayed in Output 76.4.1.

Output 76.4.1 ANOVA Table and Parameter Estimates

Regression With Quantitative and Qualitative Variables

The REG Procedure
Model: MODEL1
Dependent Variable: time

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	3	1504.41904	501.47301	45.49	<.0001
Error	16	176.38096	11.02381		
Corrected Total	19	1680.80000			

Root MSE	3.32021	R-Square	0.8951
Dependent Mean	19.40000	Adj R-Sq	0.8754
Coeff Var	17.11450		

[1] From Neter, J., et al., *Applied Linear Statistical Models*, Third Edition, Copyright (c) 1990, Richard D. Irwin. Reprinted with permission of The McGraw-Hill Companies.

Output 76.4.1 *continued*

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	33.83837	2.44065	13.86	<.0001
size	1	-0.10153	0.01305	-7.78	<.0001
type	1	8.13125	3.65405	2.23	0.0408
sizetype	1	-0.00041714	0.01833	-0.02	0.9821

The overall F statistic is significant (F=45.490, p<0.0001). The interaction term is not significant (t=−0.023, p=0.9821). Hence, this term should be removed and the model refitted, as shown in the following statements:

```
   delete sizetype;
   print;
run;
```

The DELETE statement removes the interaction term (sizetype) from the model. The new ANOVA and parameter estimates tables are shown in Output 76.4.2.

Output 76.4.2 ANOVA Table and Parameter Estimates

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	1504.41333	752.20667	72.50	<.0001
Error	17	176.38667	10.37569		
Corrected Total	19	1680.80000			

Root MSE	3.22113	R-Square	0.8951
Dependent Mean	19.40000	Adj R-Sq	0.8827
Coeff Var	16.60377		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	33.87407	1.81386	18.68	<.0001
size	1	-0.10174	0.00889	-11.44	<.0001
type	1	8.05547	1.45911	5.52	<.0001

The overall F statistic is still significant (F=72.497, p<0.0001). The intercept and the coefficients associated with size and type are significantly different from zero (t=18.675, p<0.0001; t=−11.443, p<0.0001; t=5.521, p<0.0001, respectively). Notice that the R^2 did not change with the omission of the interaction term.

The fitted model is

$$\text{time} = 33.87 - 0.102 \times \text{size} + 8.055 \times \text{type}$$

The fitted model for a mutual fund company ($X2_i = 0$) is

$$\text{time} = 33.87 - 0.102 \times \text{size}$$

and the fitted model for a stock company ($X2_i = 1$) is

$$\text{time} = (33.87 + 8.055) - 0.102 \times \text{size}$$

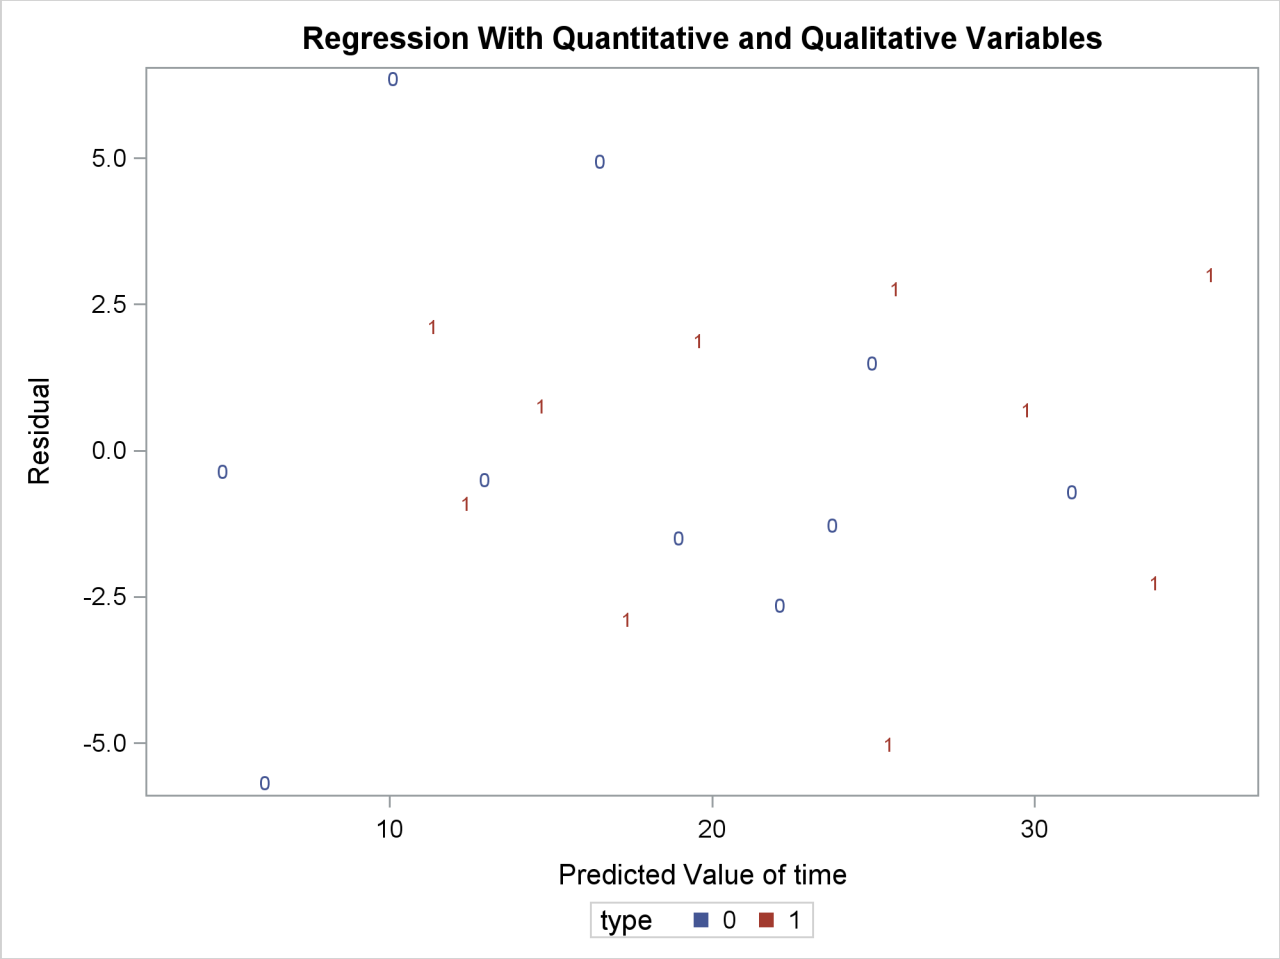
So the two models have different intercepts but the same slope.

The following statements first use an OUTPUT statement to save the residuals and predicted values from the new model in the OUT= data set. Next PROC SGPLOT is used to produce Output 76.4.3, which plots residuals versus predicted values. The firm type is used as the plot symbol; this can be useful in determining if the firm types have different residual patterns.

```
    output out=out r=r p=p;
run;

proc sgplot data=out;
  scatter x=p y=r / markerchar=type group=type;
run;
```

Output 76.4.3 Plot of Residual vs. Predicted Values

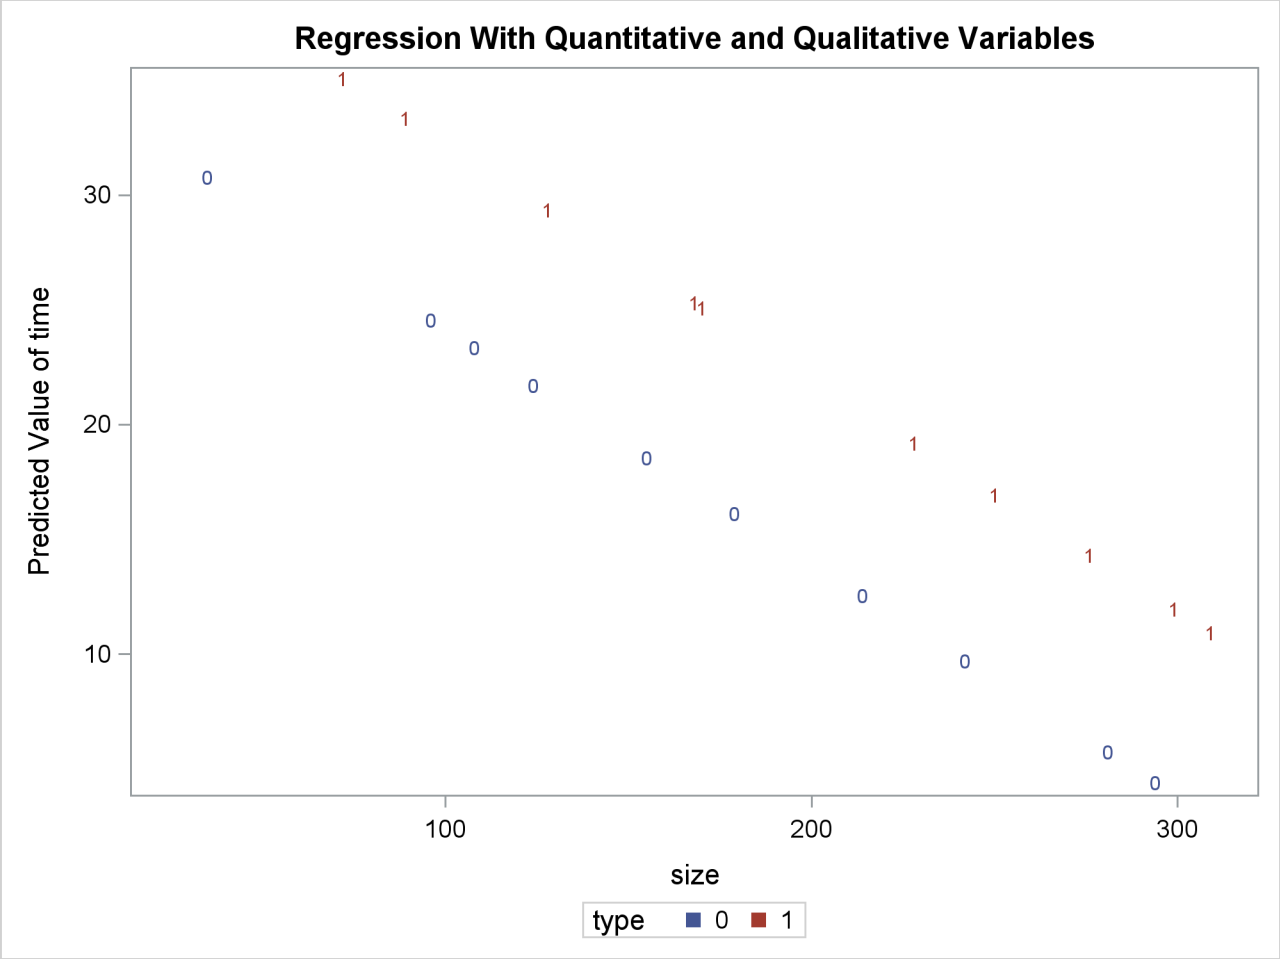


The residuals show no major trend. Neither firm type by itself shows a trend either. This indicates that the model is satisfactory.

The following statements produce the plot of the predicted values versus size that appears in Output 76.4.4, where the firm type is again used as the plotting symbol:

```
proc sgplot data=out;
  scatter x=size y=p / markerchar=type group=type;
run;
```

Output 76.4.4 Plot of Predicted vs. Size



The different intercepts are very evident in this plot.

Example 76.5: Ridge Regression for Acetylene Data

This example uses the acetylene data in Marquardt and Snee (1975) to illustrate the RIDGEPLOT and OUTVIF options. Here are the data:

```
data acetyl;
   input x1-x4 @@;
   x1x2 = x1 * x2;
   x1x1 = x1 * x1;
   label x1   = 'reactor temperature(celsius)'
         x2   = 'h2 to n-heptone ratio'
         x3   = 'contact time(sec)'
         x4   = 'conversion percentage'
         x1x2= 'temperature-ratio interaction'
         x1x1= 'squared temperature';
```

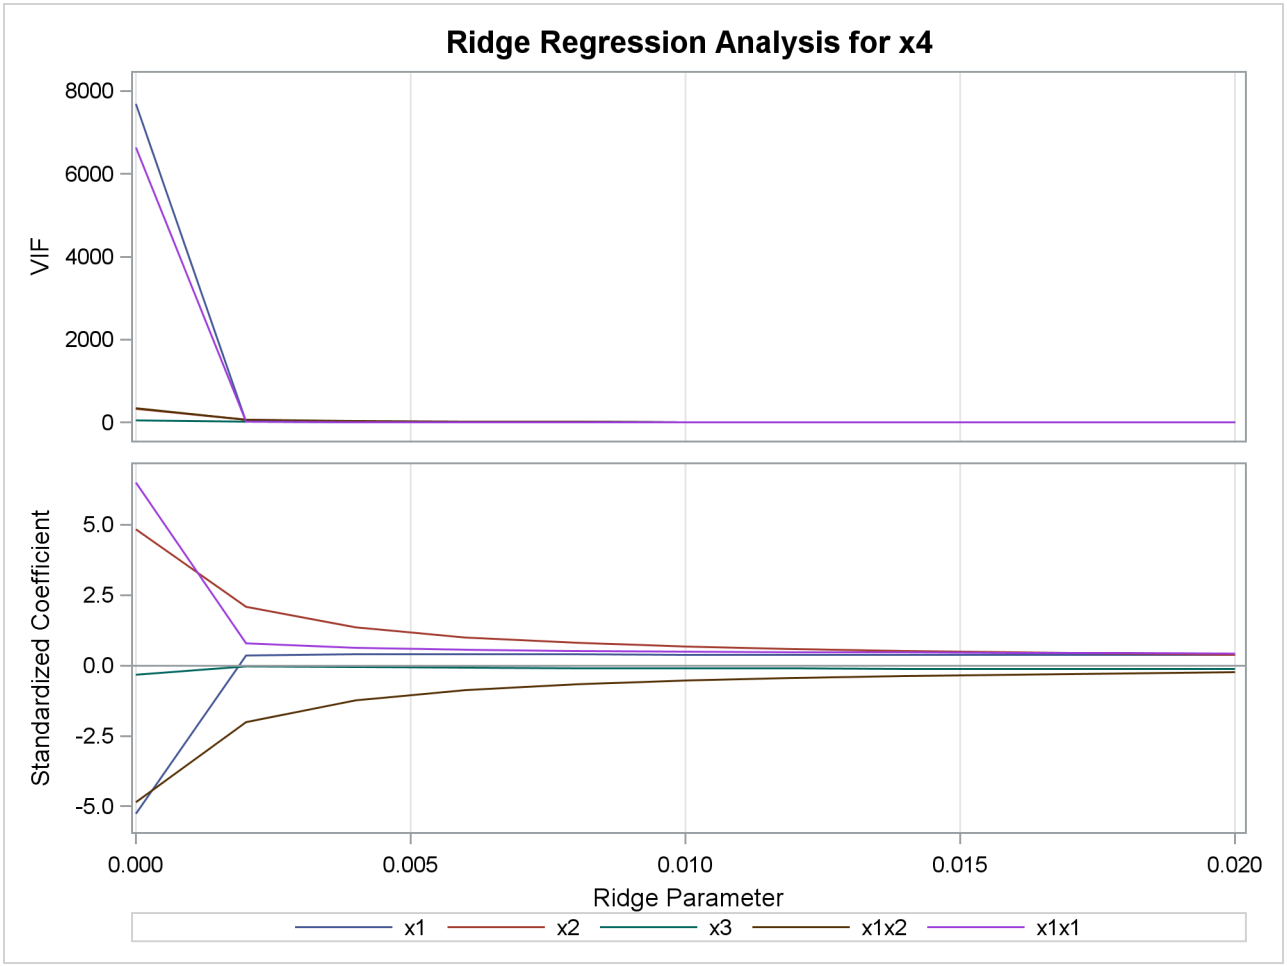
```
   datalines;
1300  7.5 .012 49   1300  9   .012  50.2 1300 11 .0115 50.5
1300 13.5 .013 48.5 1300 17   .0135 47.5 1300 23 .012  44.5
1200  5.3 .04  28   1200  7.5 .038  31.5 1200 11 .032  34.5
1200 13.5 .026 35   1200 17   .034  38   1200 23 .041  38.5
1100  5.3 .084 15   1100  7.5 .098  17   1100 11 .092  20.5
1100 17   .086 29.5
;

ods graphics on;

proc reg data=acetyl outvif
         outest=b ridge=0 to 0.02 by .002;
   model x4=x1 x2 x3 x1x2 x1x1;
run;
proc print data=b;
run;
```

When ODS Graphics is enabled and you request ridge regression by using the RIDGE= option in the PROC REG statement, PROC REG produces a panel showing variance inflation factors (VIF) in the upper plot in the panel and ridge traces in the lower plot. This panel is shown in Output 76.5.1.

Output 76.5.1 Ridge Regression and VIF Traces



The OUTVIF option outputs the variance inflation factors to the OUTEST= data set that is shown in Output 76.5.2.

Output 76.5.2 OUTEST Data Set Showing VIF Values

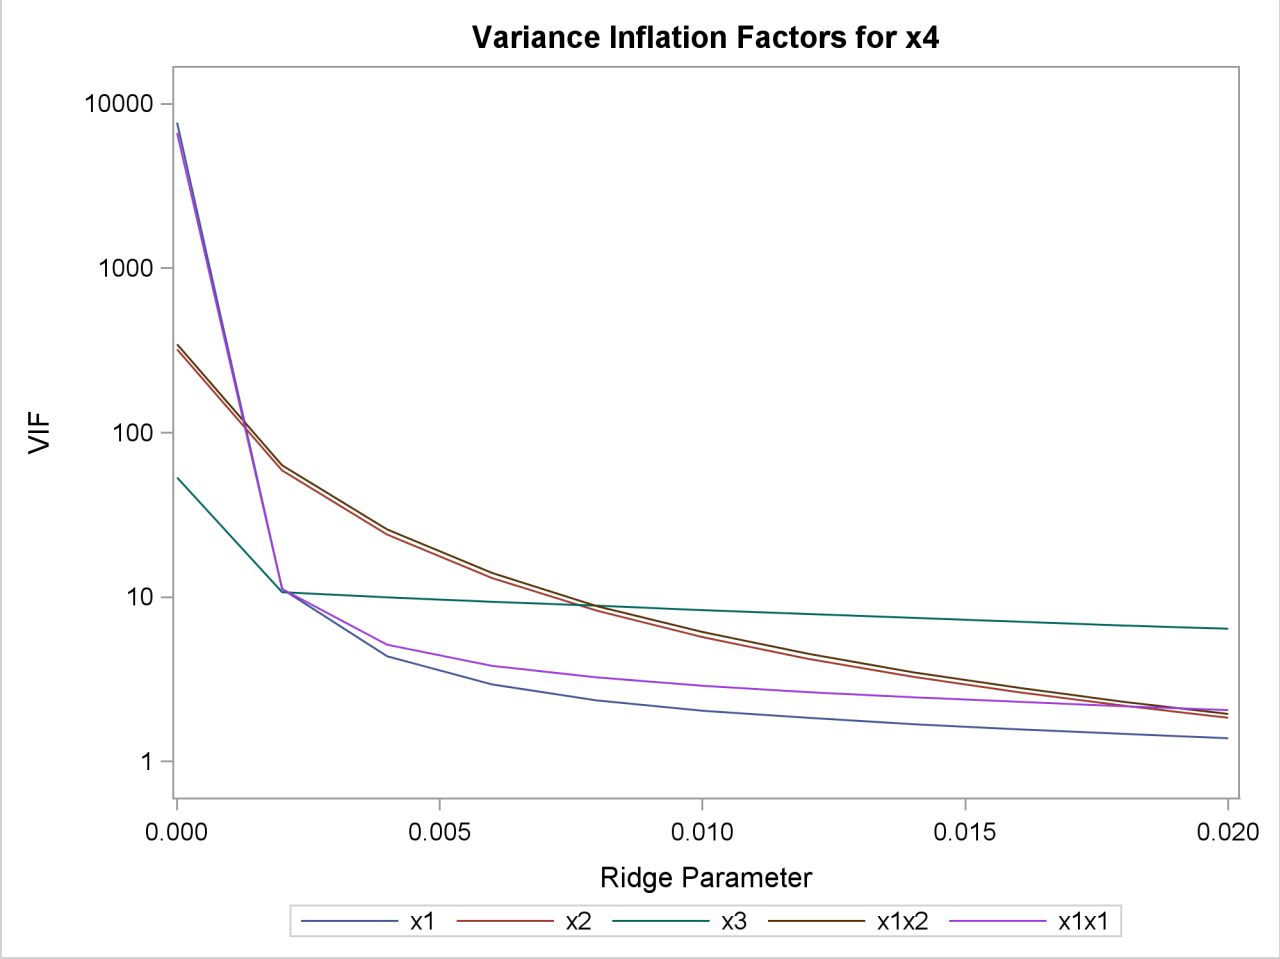
If you want to obtain separate plots containing the ridge traces and VIF traces, you can specify the UNPACK suboption in the PLOTS=RIDGE option. You can also request that one or both of the VIF axis and ridge parameter axis be displayed on a logarithmic scale. You can see in Output 76.5.1 that the VIF traces for several of the parameters are nearly indistinguishable when displayed on a linear scale. The following code illustrates how you obtain separate VIF and ridge traces with the VIF values displayed on a logarithmic scale. Note that you can obtain plots of VIF values even though you do not specify the OUTVIF option in the PROC REG statement.

```
proc reg data=acetyl plots(only)=ridge(unpack VIFaxis=log)
         outest=b ridge=0 to 0.02 by .002;
   model x4=x1 x2 x3 x1x2 x1x1;
run;

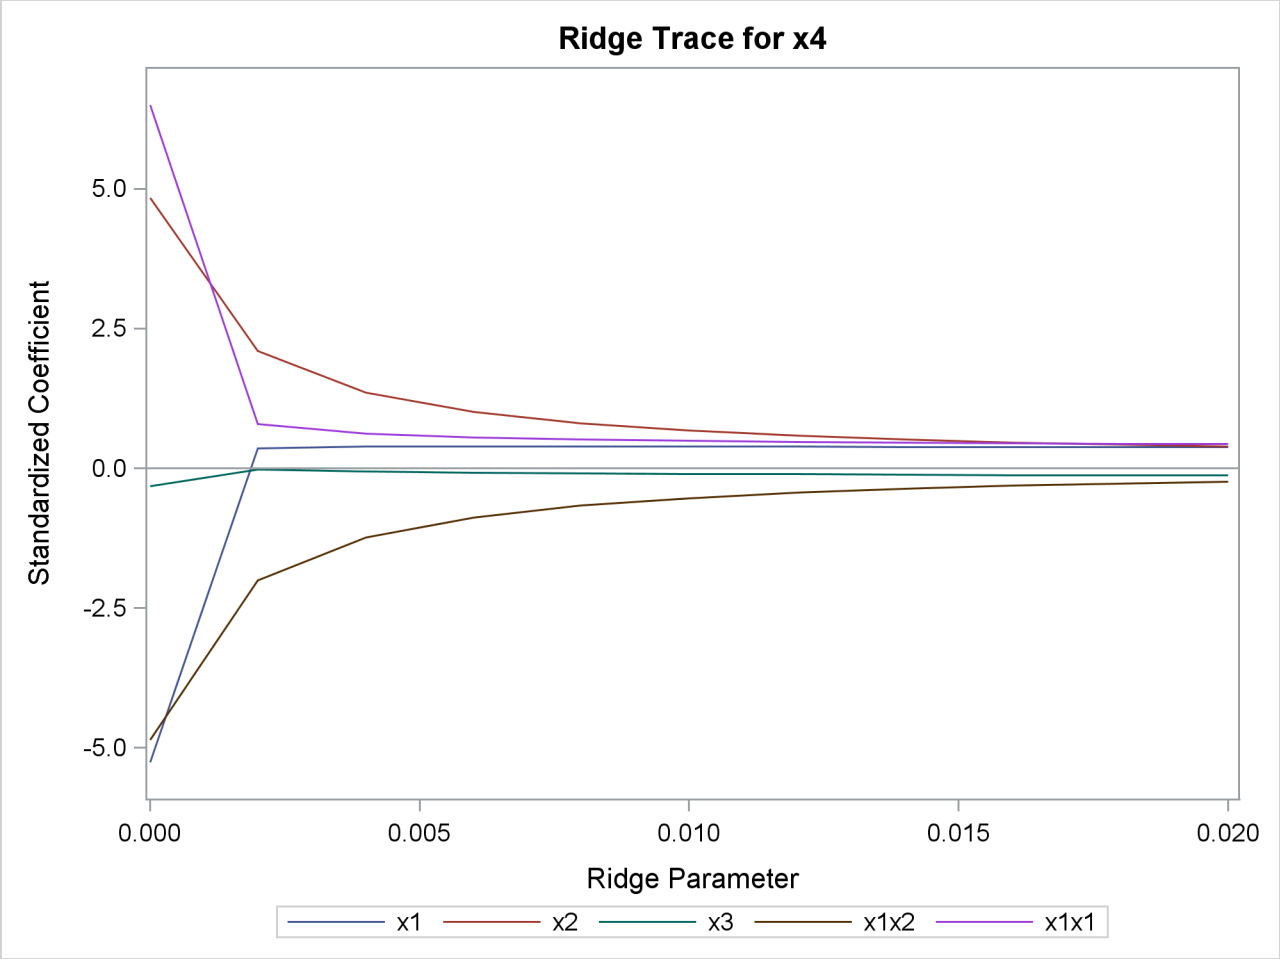
ods graphics off;
```

The requested plots are shown in Output 76.5.3 and Output 76.5.4.

Output 76.5.3 VIF Traces



Output 76.5.4 Ridge Traces



Example 76.6: Chemical Reaction Response

This example shows how you can use lack-of-fit tests with the REG procedure. See the section "Testing for Lack of Fit" on page 6460 for details about lack-of-fit tests.

In a study of the percentage of raw material that responds in a reaction, researchers identified the following five factors:

- the feed rate of the chemicals (FeedRate), ranging from 10 to 15 liters per minute
- the percentage of the catalyst (Catalyst), ranging from 1% to 2%
- the agitation rate of the reactor (AgitRate), ranging from 100 to 120 revolutions per minute
- the temperature (Temperature), ranging from 140 to 180 degrees Celsius
- the concentration (Concentration), ranging from 3% to 6%

The following data set contains the results of an experiment designed to estimate main effects for all factors:

```
data reaction;
  input FeedRate Catalyst AgitRate Temperature
        Concentration ReactionPercentage;
datalines;
10.0   1.0  100   140  6.0   37.5
10.0   1.0  120   180  3.0   28.5
10.0   2.0  100   180  3.0   40.4
10.0   2.0  120   140  6.0   48.2
15.0   1.0  100   180  6.0   50.7
15.0   1.0  120   140  3.0   28.9
15.0   2.0  100   140  3.0   43.5
15.0   2.0  120   180  6.0   64.5
12.5   1.5  110   160  4.5   39.0
12.5   1.5  110   160  4.5   40.3
12.5   1.5  110   160  4.5   38.7
12.5   1.5  110   160  4.5   39.7
;
```

The first eight runs of this experiment enable orthogonal estimation of the main effects for all factors. The last four comprise four replicates of the centerpoint.

The following statements fit a linear model. Because this experiment includes replications, you can test for lack of fit by using the LACKFIT option in the MODEL statement.

```
proc reg data=reaction;
   model  ReactionPercentage=FeedRate Catalyst AgitRate
                             Temperature Concentration / lackfit;
run;
```

Output 76.6.1 shows that the lack of fit for the linear model is significant, indicating that a more complex model is required. Models that include interactions should be investigated. In this case, this will require additional experimentation to obtain appropriate data for estimating the effects.

Output 76.6.1 Analysis of Variance

The REG Procedure
Model: MODEL1
Dependent Variable: ReactionPercentage

Chapter 77

The ROBUSTREG Procedure

Contents

Overview: ROBUSTREG Procedure

The main purpose of robust regression is to detect outliers and provide resistant (stable) results in the presence of outliers. In order to achieve this stability, robust regression limits the influence of outliers. Historically, three classes of problems have been addressed with robust regression techniques:

- problems with outliers in the *y*-direction (response direction)
- problems with multivariate outliers in the *x*-space (that is, outliers in the covariate space, which are also referred to as leverage points)
- problems with outliers in both the *y*-direction and the *x*-space

Many methods have been developed in response to these problems. However, in statistical applications of outlier detection and robust regression, the methods most commonly used today are Huber M estimation, high breakdown value estimation, and combinations of these two methods. The ROBUSTREG procedure provides four such methods: M estimation, LTS estimation, S estimation, and MM estimation.

- M estimation was introduced by Huber (1973), and it is the simplest approach both computationally and theoretically. Although it is not robust with respect to leverage points, it is still used extensively in data analysis when contamination can be assumed to be mainly in the response direction.
- Least trimmed squares (LTS) estimation is a high breakdown value method introduced by Rousseeuw (1984). The breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness. The performance of this method was improved by the FAST-LTS algorithm of Rousseeuw and Van Driessen (2000).
- S estimation is a high breakdown value method introduced by Rousseeuw and Yohai (1984). With the same breakdown value, it has a higher statistical efficiency than LTS estimation.
- MM estimation, introduced by Yohai (1987), combines high breakdown value estimation and M estimation. It has both the high breakdown property and a higher statistical efficiency than S estimation.

Features

The main features of the ROBUSTREG procedure are as follows:

- offers four estimation methods: M, LTS, S, and MM
- provides 10 weight functions for M estimation
- provides robust R-square and deviance for all estimates
- provides asymptotic covariance and confidence intervals for regression parameter with the M, S, and MM methods

- provides robust Wald and F tests for regression parameters with the M and MM methods
- provides Mahalanobis distance and robust Mahalanobis distance with generalized minimum covariance determinant (MCD) algorithm
- provides outlier and leverage-point diagnostics
- supports parallel computing for S and LTS estimates
- supports constructed effects including spline and multimember effects
- produces fit plots and diagnostic plots by using ODS Graphics

Getting Started: ROBUSTREG Procedure

The following examples demonstrate how you can use the ROBUSTREG procedure to fit a linear regression model and obtain outlier and leverage-point diagnostics.

M Estimation

This example shows how you can use the ROBUSTREG procedure to do M estimation, which is a commonly used method for outlier detection and robust regression when contamination is mainly in the response direction.

```
data stack;
   input  x1 x2 x3 y exp$ @@;

;
```

The data set stack is the well-known stack-loss data set presented by Brownlee (1965). The data describe the operation of a plant for the oxidation of ammonia to nitric acid and consist of 21 four-dimensional observations. The explanatory variables for the response stack-loss (y) are the rate of operation (x1), the cooling water inlet temperature (x2), and the acid concentration (x3).

The following ROBUSTREG statements analyze the data:

```
proc robustreg data=stack;
   model y = x1 x2 x3 / diagnostics leverage;
   id    exp;
   test  x3;
run;
```

By default, the procedure does M estimation with the bisquare weight function, and it uses the median method for estimating the scale parameter. The MODEL statement specifies the covariate effects. The DIAGNOSTICS option requests a table for outlier diagnostics, and the LEVERAGE option adds leverage-point diagnostic results to this table for continuous covariate effects. The ID statement specifies that the variable exp is used to identify each observation (experiment) in this table. If the ID statement is omitted, the observation number is used to identify the observations. The TEST statement requests a test of significance for the covariate effects specified. The results of this analysis are displayed in the following figures.

Figure 77.1 Model Fitting Information and Summary Statistics

The ROBUSTREG Procedure

Model Information

Data Set	WORK.STACK
Dependent Variable	y
Number of Independent Variables	3
Number of Observations	21
Method	M Estimation

Summary Statistics

Variable	Q1	Median	Q3	Mean	Standard Deviation	MAD
x1	53.0000	58.0000	62.0000	60.4286	9.1683	5.9304
x2	18.0000	20.0000	24.0000	21.0952	3.1608	2.9652
x3	82.0000	87.0000	89.5000	86.2857	5.3586	4.4478
y	10.0000	15.0000	19.5000	17.5238	10.1716	5.9304

Figure 77.1 displays the model fitting information and summary statistics for the response variable and the continuous covariates. The columns labeled Q1, Median, and Q3 provide the lower quantile, median, and upper quantile, respectively. The column labeled MAD provides a robust estimate of the univariate scale, which is computed as the standardized median absolute deviation (MAD). See Huber (1981, p. 108) for more details about the standardized MAD. The columns labeled Mean and Standard Deviation provide the usual mean and standard deviation. A large difference between the standard deviation and the MAD for a variable indicates some extreme values for this variable. In the stack-loss data, the stack-loss (response y) has the biggest difference between the standard deviation and the MAD.

Figure 77.2 Model Parameter Estimates

Parameter Estimates

Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	-42.2854	9.5045	-60.9138	-23.6569	19.79	<.0001
x1	1	0.9276	0.1077	0.7164	1.1387	74.11	<.0001
x2	1	0.6507	0.2940	0.0744	1.2270	4.90	0.0269
x3	1	-0.1123	0.1249	-0.3571	0.1324	0.81	0.3683
Scale	1	2.2819					

Figure 77.2 displays the table of robust parameter estimates, standard errors, and confidence limits. The row labeled Scale provides a point estimate of the scale parameter in the linear regression model, which is obtained by the median method. See the section "M Estimation" on page 6560 for more information about scale estimation methods. For the stack-loss data, M estimation yields the fitted linear model:

$$\hat{y} = -42.2845 + 0.9276\text{x1} + 0.6507\text{x2} - 0.1123\text{x3}$$

Figure 77.3 Diagnostics

Diagnostics

Obs	exp	Mahalanobis Distance	Robust MCD Distance	Leverage	Standardized Robust Residual	Outlier
1	e1	2.2536	5.5284	*	1.0995	
2	e2	2.3247	5.6374	*	-1.1409	
3	e3	1.5937	4.1972	*	1.5604	
4	e4	1.2719	1.5887		3.0381	*
21	e21	2.1768	3.6573	*	-4.5733	*

Figure 77.3 displays outlier and leverage-point diagnostics. Standardized robust residuals are computed based on the estimated parameters. Both the Mahalanobis distance and the robust MCD distance are displayed. Outliers and leverage points, identified with asterisks, are defined by the standardized robust residuals and robust MCD distances that exceed the corresponding cutoff values displayed in the diagnostics summary. Observations 4 and 21 are outliers because their standardized robust residuals exceed the cutoff value in absolute value. The procedure detects four observations with high leverage. Leverage points (points with high leverage) with smaller standardized robust residuals than the cutoff value in absolute value are called good leverage points; others are called bad leverage points. Observation 21 is a bad leverage point.

Two particularly useful plots for revealing outliers and leverage points are a scatter plot of the standardized robust residuals against the robust distances (RDPLOT) and a scatter plot of the robust distances against the classical Mahalanobis distances (DDPLOT).

For the stack-loss data, the following statements produce the RDPLOT in Figure 77.4 and the DDPLOT in Figure 77.5. The histogram and the normal quantile-quantile plots (shown in Figure 77.6 and Figure 77.7, respectively) for the standardized robust residuals are also created with the HISTOGRAM and QQPLOT suboptions of the PLOTS= option.

```
ods graphics on;

proc robustreg data=stack plots=(rdplot ddplot histogram qqplot);
   model y = x1 x2 x3;
run;

ods graphics off;
```

These plots are helpful in identifying outliers in addition to good and bad high leverage points.

These plots are requested when ODS Graphics is enabled by specifying the PLOTS= option in the PROC ROBUSTREG statement. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." For specific information about the graphics available in the ROBUSTREG procedure, see the section "ODS Graphics" on page 6587.

Figure 77.4 RDPLOT for Stackloss Data

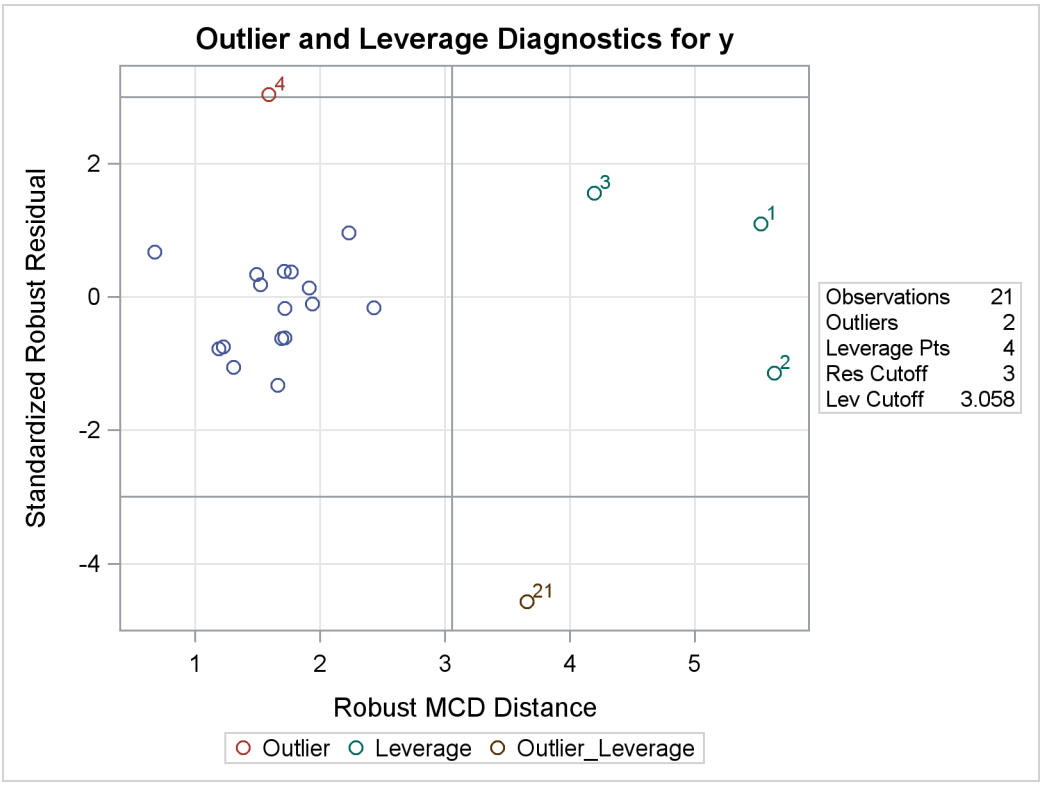

Figure 77.5 DDPLOT for Stackloss Data

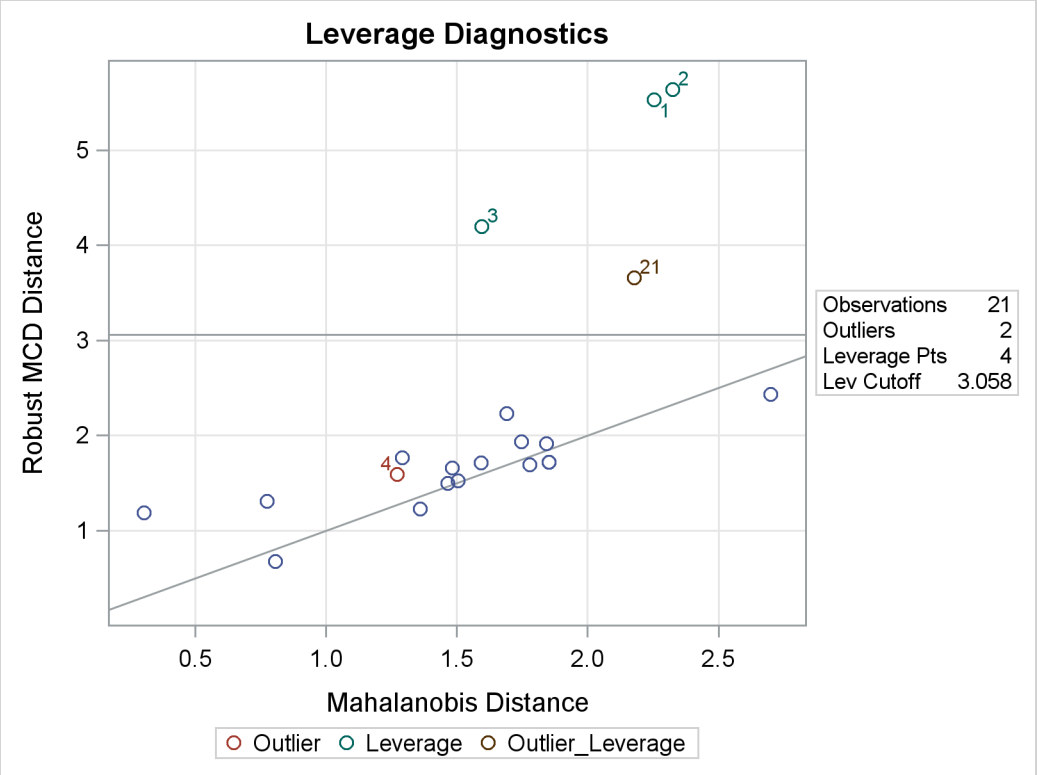

Figure 77.6 Histogram

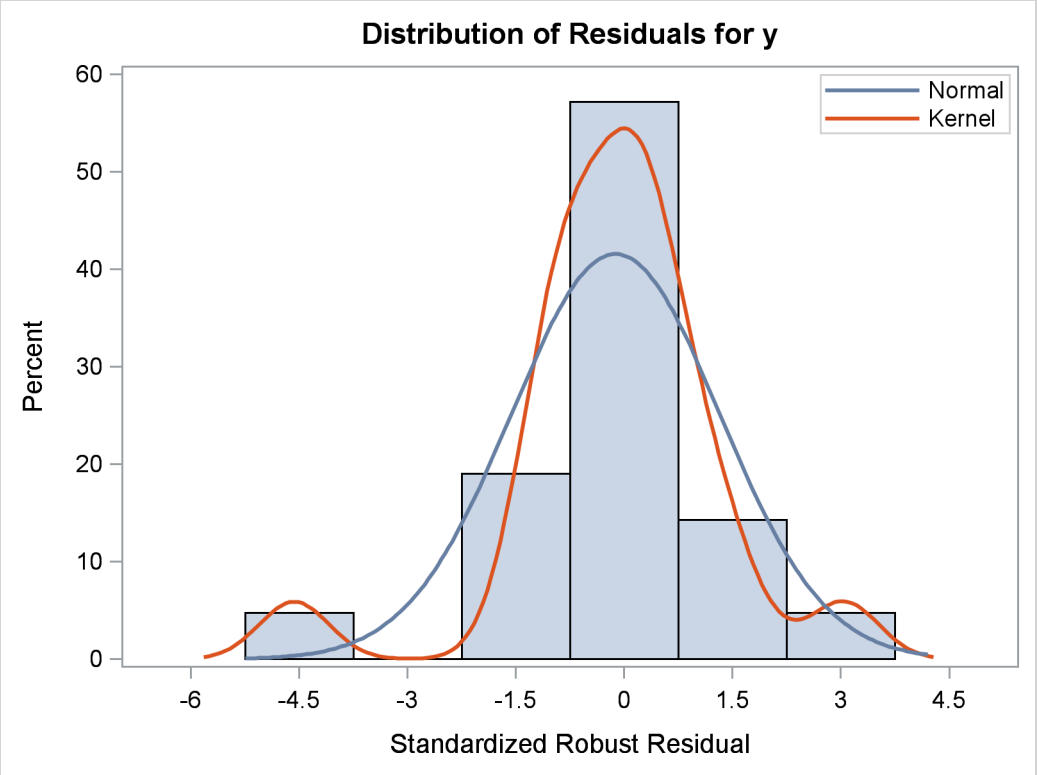

Figure 77.7 Q-Q Plot

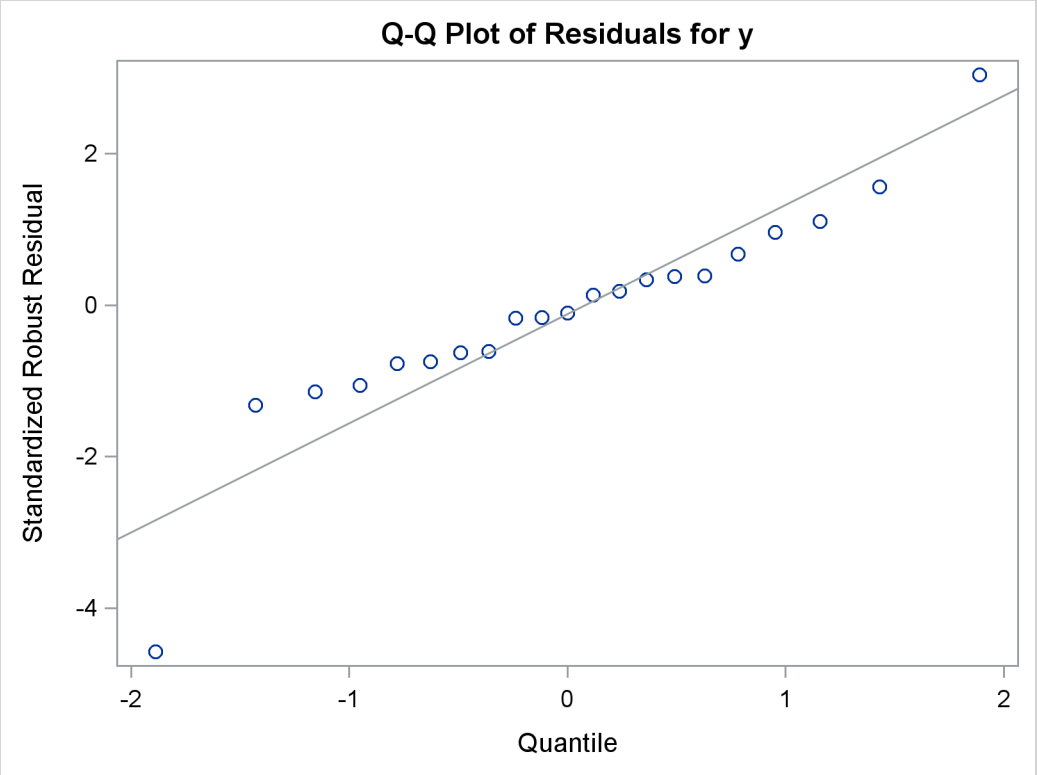

Figure 77.8 displays robust versions of goodness-of-fit statistics for the model. You can use the robust information criteria, AICR and BICR, for model selection and comparison. For both AICR and BICR, the lower the value, the more desirable the model.

Figure 77.8 Goodness-of-Fit Statistics

Goodness-of-Fit

Statistic	Value
R-Square	0.6659
AICR	29.5231
BICR	36.3361
Deviance	125.7905

Figure 77.9 displays the test results requested by the TEST statement. The ROBUSTREG procedure conducts two robust linear tests, the ρ test and the R_n^2 test. See the section "Linear Tests" on page 6565 for information about how the procedure computes test statistics and the correction factor lambda. Due to the large p-values for both tests, you can conclude that the effect x3 is not significant at the 5% level.

Figure 77.9 Test of Significance

Robust Linear Test

Test	Test Statistic	Lambda	DF	Chi-Square	Pr > ChiSq
Rho	0.9378	0.7977	1	1.18	0.2782
Rn2	0.8092		1	0.81	0.3683

For the bisquare weight function, the default tuning constant, $c = 4.685$, is chosen to yield a 95% asymptotic efficiency of the M estimates with the Gaussian distribution. See the section "M Estimation" on page 6560 for details. The smaller the constant c, the lower the asymptotic efficiency but the sharper the M estimate as an outlier detector. For the stack-loss data set, you could consider using a sharper outlier detector.

In the following invocation of the ROBUSTREG procedure, a smaller constant, $c = 3.5$, is used. This tuning constant corresponds to an efficiency close to 85%. See Chen and Yin (2002) for the relationship between the tuning constant and asymptotic efficiency of M estimates.

```
proc robustreg method=m(wf=bisquare(c=3.5)) data=stack;
   model y = x1 x2 x3 / diagnostics leverage;
   id    exp;
   test  x3;
run;
```

Figure 77.10 displays the table of robust parameter estimates, standard errors, and confidence limits with the constant $c = 3.5$.

The refitted linear model is

$$\hat{y} = -37.1076 + 0.8191x1 + 0.5173x2 - 0.0728x3$$

Figure 77.10 Model Parameter Estimates

The ROBUSTREG Procedure

Parameter Estimates

Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	-37.1076	5.4731	-47.8346	-26.3805	45.97	<.0001
x1	1	0.8191	0.0620	0.6975	0.9407	174.28	<.0001

LTS Estimation

If the data are contaminated in the x-space, M estimation does not do well. The following example shows how you can use LTS estimation to deal with this situation.

```
data hbk;

;
```

The data set hbk is an artificial data set generated by Hawkins, Bradu, and Kass (1984). Both ordinary least squares (OLS) estimation and M estimation (not shown here) suggest that observations 11 to 14 are outliers. However, these four observations were generated from the underlying model, whereas observations 1 to 10 were contaminated. The reason that OLS estimation and M estimation do not pick up the contaminated observations is that they cannot distinguish good leverage points (observations 11 to 14) from bad leverage points (observations 1 to 10). In such cases, the LTS method identifies the true outliers.

The following statements invoke the ROBUSTREG procedure with the LTS estimation method:

```
proc robustreg data=hbk fwls method=lts;
   model y = x1 x2 x3 / diagnostics leverage;
   id index;
run;
```

Figure 77.12 displays the model fitting information and summary statistics for the response variable and independent covariates.

Figure 77.12 Model Fitting Information and Summary Statistics

Figure 77.13 displays information about the LTS fit, which includes the breakdown value of the LTS estimate. The breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness. In this example the LTS estimate minimizes the sum of 57 smallest squares of residuals. It can still estimate the true underlying model if the remaining 18 observations are contaminated. This corresponds to the breakdown value around 0.25, which is set as the default.

Figure 77.13 LTS Profile

LTS Profile

Total Number of Observations	75
Number of Squares Minimized	57
Number of Coefficients	4
Highest Possible Breakdown Value	0.2533

Figure 77.14 displays parameter estimates for covariates and scale. Two robust estimates of the scale parameter are displayed. See the section "Final Weighted Scale Estimator" on page 6569 for how these estimates are computed. The weighted scale estimator (Wscale) is a more efficient estimator of the scale parameter.

Figure 77.14 LTS Parameter Estimates

LTS Parameter Estimates

Parameter	DF	Estimate
Intercept	1	−0.3431
x1	1	0.0901
x2	1	0.0703
x3	1	−0.0731
Scale (sLTS)	0	0.7451
Scale (Wscale)	0	0.5749

Figure 77.15 displays outlier and leverage-point diagnostics. The ID variable index is used to identify the observations. If you do not specify this ID variable, the observation number is used to identify the observations. However, the observation number depends on how the data are read. The first 10 observations are identified as outliers, and observations 11 to 14 are identified as good leverage points.

Syntax: ROBUSTREG Procedure

The following statements are available in PROC ROBUSTREG:

PROC ROBUSTREG < *options* > **;**
BY *variables* **;**
CLASS *variables* **;**
EFFECT *name=effect-type (variables* < */options* >*)* **;**
ID *variables* **;**
MODEL *response=* < *effects* > < */options* > **;**
OUTPUT < *OUT=SAS-data-set* > < *options* > **;**
PERFORMANCE < *options* > **;**
TEST *effects* **;**
WEIGHT *variable* **;**

The PROC ROBUSTREG statement invokes the procedure. The METHOD= option in the PROC ROBUSTREG statement selects one of the four estimation methods, M, LTS, S, and MM. By default, Huber M estimation is used. The MODEL statement is required and specifies the variables used in the regression. Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure (Chapter 41, "The GLM Procedure.") The CLASS statement specifies which explanatory variables are treated as categorical. The ID statement names variables to identify observations in the outlier diagnostics tables. The WEIGHT statement identifies a variable in the input data set whose values are used to weight the observations. The OUTPUT statement creates an output data set that contains final weights, predicted values, and residuals. The TEST statement requests robust linear tests for the model parameters. The PERFORMANCE statement tunes the performance of the procedure by using single or multiple processors available on the hardware. In one invocation of PROC ROBUSTREG, multiple OUTPUT and TEST statements are allowed.

PROC ROBUSTREG Statement

PROC ROBUSTREG < *options* > **;**

The PROC ROBUSTREG statement invokes the procedure. You can specify the following options in the PROC ROBUSTREG statement.

COVOUT
saves the estimated covariance matrix in the OUTEST= data set. This option is not supported for LTS estimation.

DATA=*SAS-data-set*
specifies the input SAS data set used by PROC ROBUSTREG. By default, the most recently created SAS data set is used.

FWLS

requests that final weighted least squares estimates be computed. These estimates are equivalent to the least squares estimates after the detected outliers are deleted.

INEST=*SAS-data-set*

specifies an input SAS data set that contains initial estimates for all the parameters in the model. See the section "INEST= Data Set" on page 6584 for a detailed description of the contents of the INEST= data set.

ITPRINT

displays the iteration history for the iteratively reweighted least squares algorithm used by M and MM estimation. You can also use this option in the MODEL statement.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the order in which to sort the levels of the classification variables (which are specified in the CLASS statement). This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

OUTEST=*SAS-data-set*

specifies an output SAS data set that contains the parameter estimates, and, if the COVOUT option is specified, the estimated covariance matrix. See the section "OUTEST= Data Set" on page 6585 for a detailed description of the contents of the OUTEST= data set.

PLOT | PLOTS <(*global-plot-options*)> <=*plot-request*>

PLOT | PLOTS<(*global-plot-options*)> <=(*plot-request* <...*plot-request*>)>

specifies options that control details of the plots. If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC ROBUSTREG produces the robust fit plot by default when the model includes a single continuous independent variable.

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;
proc robustreg data=stack plots=all;
   model y = x1 x2 x3;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The *global-plot-options* apply to all plots generated by the ROBUSTREG procedure. The following *global-plot-option* is available:

ONLY

suppresses the default robust fit plot. Only plots specifically requested are displayed.

You can specify more than one *plot-request* within the parentheses after PLOTS=. For a single plot request, you can omit the parentheses. The following *plot-requests* are available.

ALL

creates all appropriate plots.

DDPLOT<(LABEL=ALL | LEVERAGE | NONE | OUTLIER)>

creates a plot of robust distance against Mahalanobis distance. See the section "Leverage Point and Outlier Detection" on page 6582 for details about robust distance. The LABEL= option specifies how the points on this plot are to be labeled, as summarized by the following table.

Table 77.1 Options for Label

Value of LABEL=	Label Method
ALL	Label all points
LEVERAGE	Label leverage points
NONE	No labels
OUTLIERS	Label outliers

By default, the ROBUSTREG procedure labels both outliers and leverage points.

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

FITPLOT<(NOLIMITS)>

creates a plot of robust fit against the single independent continuous variable specified in the

model. You can request this plot when only a single independent continuous variable is specified in the model. Confidence limits are added on the plot by default. The NOLIMITS option suppresses these limits.

HISTOGRAM
creates a histogram for the standardized robust residuals. The histogram is superimposed with a normal density curve and a kernel density curve.

NONE
suppresses all plots.

QQPLOT
creates the normal quantile-quantile plot for the standardized robust residuals.

RDPLOT<(LABEL=ALL | LEVERAGE | NONE | OUTLIER)>
creates the plot of standardized robust residual against robust distance. See the section "Leverage Point and Outlier Detection" on page 6582 for details about robust distance. The LABEL= option specifies a label method for points on this plot. These label methods are described in Table 77.1.

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

SEED=*number*
specifies the seed for the random number generator used to randomly select the subgroups and subsets for LTS and S estimation. By default or if you specify zero, the ROBUSTREG procedure generates a random seed.

METHOD=*method type* **<(** *options* **)>**
specifies the estimation method and some additional *options* for the estimation method. PROC ROBUSTREG provides four estimation methods: M estimation, LTS estimation, S estimation, and MM estimation. The default method is M estimation.

NOTE: Since the LTS and S methods use subsampling algorithms, these methods are not suitable in an analysis with variables that have only a few unequal values or a few unequal values within one BY group. For example, indicator variables that correspond to a classification variable often fall into this type. The same issue also applies to the initial LTS and S estimates in the MM method. In case of a model that includes classification independent variables or continuous independent variables with a few unequal values, the M method is recommended.

Options with METHOD=M

With METHOD=M, you can specify the following additional *options*:

ASYMPCOV=H1 | H2 | H3
specifies the type of asymptotic covariance computed for the M estimate. The three types are described in the section "Asymptotic Covariance and Confidence Intervals" on page 6565. By default, ASYMPCOV= H1.

CONVERGENCE=*criterion* **<(EPS=***value***)>**
specifies a convergence criterion for the M estimate. The three criteria listed in the following table are available.

Table 77.2 Options to Specify Convergence Criteria

Type	Option
Coefficient	CONVERGENCE=COEF
Residual	CONVERGENCE=RESID
Weight	CONVERGENCE=WEIGHT

By default, CONVERGENCE = COEF. You can specify the precision of the convergence criterion with the EPS= option. By default, EPS=1.E−8.

MAXITER=*n*
sets the maximum number of iterations during the parameter estimation. By default, MAXITER=1,000.

SCALE=*scale type* | *value*
specifies the scale parameter or a method for estimating the scale parameter. These methods and options are summarized in the following table.

Table 77.3 Options to Specify Scale

Scale	Option	Default d
Fixed constant	SCALE=*value*	
Huber estimate	SCALE=HUBER<(D=d)>	2.5
Median estimate	SCALE=MED	
Tukey estimate	SCALE=TUKEY<(D=d)>	2.5

By default, SCALE = MED.

WF | WEIGHTFUNCTION=*function type*
specifies the weight function used for the M estimate. The ROBUSTREG procedure provides 10 weight functions, which are listed in the following table. You can specify the parameters in these functions with the A=, B=, and C= options. These functions are described in the section "M Estimation" on page 6560. The default weight function is bisquare.

Table 77.4 Options to Specify Weight Functions

Weight Function	Option	Default a, b, c
Andrews	WF=ANDREWS<(C=c)>	1.339
Bisquare	WF=BISQUARE<(C=c)>	4.685
Cauchy	WF=CAUCHY<(C=c)>	2.385
Fair	WF=FAIR<(C=c)>	1.4
Hampel	WF=HAMPEL<(<A=a> <B=b> <C=c>)>	2, 4, 8
Huber	WF=HUBER<(C=c)>	1.345
Logistic	WF=LOGISTIC<(C=c)>	1.205
Median	WF=MEDIAN<(C=c)>	0.01
Talworth	WF=TALWORTH<(C=c)>	2.795
Welsch	WF=WELSCH<(C=c)>	2.985

Options with METHOD=LTS

With METHOD=LTS, you can specify the following additional *options*:

CSTEP=*n*

specifies the number of concentration steps (C-steps) for the LTS estimate. See the section "LTS Estimate" on page 6567 for information about how the default value is determined.

H=*n*

specifies the quantile for the LTS estimate. See the section "LTS Estimate" on page 6567 for information about how the default value is determined.

IADJUST=ALL | NONE

requests (IADJUST=ALL) or suppresses (IADJUST=NONE) the intercept adjustment for all estimates in the LTS algorithm. By default, the intercept adjustment is used for data sets with fewer than 10,000 observations. See the section "Algorithm" on page 6567 for details.

NBEST=*n*

specifies the number of best solutions kept for each subgroup during the computation of the LTS estimate. The default number is 10, which is the maximum number allowed.

NREP=*n*

specifies the number of times to repeat least squares fit in subgroups during the computation of the LTS estimate. See the section "LTS Estimate" on page 6567 for information about how the default number is determined.

SUBANALYSIS

requests a display of the subgrouping information and parameter estimates within subgroups. This option generates the ODS tables shown in Table 77.5.

Table 77.5 ODS Tables Available with SUBANALYSIS Option

ODS Table Name	Description
BestEstimates	Best final estimates for LTS
BestSubEstimates	Best estimates for each subgroup
CStep	C-step information for LTS
Groups	Grouping information for LTS

SUBGROUPSIZE=*n*

specifies the data set size of the subgroups in the computation of the LTS estimate. The default number is 300.

Options with METHOD=S

With METHOD=S, you can specify the following additional *options*:

ASYMPCOV=H1 | H2 | H3 | H4

specifies the type of asymptotic covariance computed for the S estimate. The four types are described in the section "Asymptotic Covariance and Confidence Intervals" on page 6572. By default, ASYMPCOV= H4.

CHIF= TUKEY | YOHAI

specifies the χ function for the S estimate. PROC ROBUSTREG provides two χ functions, Tukey's bisquare function and Yohai's optimal function, which you can request with CHIF=TUKEY and CHIF=YOHAI, respectively. The default is Tukey's bisquare function.

EFF=*value*

specifies the efficiency (as a fraction) for the S estimate. The parameter k_0 in the χ function is determined by this efficiency. The default efficiency is determined such that the consistent S estimate has the breakdown value of 25%. This option is overwritten by the K0= option if both of them are used.

K0=*value*

specifies the $k0$ parameter in the χ function of the S estimate. For CHIF=TUKEY, the default is 1.548. For CHIF=YOHAI, the default is 0.66. These default values correspond to a 50% breakdown value of the consistent S estimate.

MAXITER=*n*

sets the maximum number of iterations for computing the scale parameter of the S estimate. By default, MAXITER=1000.

NREP=*n*

specifies the number of repeats of subsampling in the computation of the S estimate. See the section "Algorithm" on page 6570 for information about how the default number of repeats is determined.

NOREFINE
suppresses the refinement for the S estimate. See the section "Algorithm" on page 6570 for details.

SUBSETSIZE=*n*
specifies the size of the subset for the S estimate. See the section "Algorithm" on page 6570 for information about how the default value is determined.

TOLERANCE=*value*
specifies the tolerance for the S estimate of the scale. The default value is 0.001.

Options with METHOD=MM

With METHOD=MM, you can specify the following additional *options*:

ASYMPCOV=H1 | H2 | H3 | H4
specifies the type of asymptotic covariance computed for the MM estimate. The four types are described in the section "Details: ROBUSTREG Procedure" on page 6560. By default, ASYMPCOV= H4.

BIASTEST< (ALPHA=*number***) >**
requests the bias test for the final MM estimate. See the section "Bias Test" on page 6574 for details about this test.

CHIF= TUKEY | YOHAI
selects the χ function for the MM estimate. PROC ROBUSTREG provides two χ functions: Tukey's bisquare function and Yohai's optimal function, which you can request with CHIF=TUKEY and CHIF=YOHAI, respectively. The default is Tukey's bisquare function. This χ function is also used by the initial S estimate if you specify the INITEST=S option.

CONVERGENCE=*criterion***< (EPS=***number***) >**
specifies a convergence criterion for the MM estimate. The three criteria listed in Table 77.6 are available.

Table 77.6 Options to Specify Convergence Criteria

Type	Option
Coefficient	CONVERGENCE=COEF
Residual	CONVERGENCE=RESID
Weight	CONVERGENCE=WEIGHT

By default, CONVERGENCE = COEF. You can specify the precision of the convergence criterion with the EPS= option. By default, EPS=1.E−8.

EFF=*value*
specifies the efficiency (as a fraction) for the MM estimate. The parameter k_1 in the χ function is determined by this efficiency. The default efficiency is set to 0.85, which corresponds to $k_1 = 3.440$ for CHIF=TUKEY or $k_1 = 0.868$ for CHIF=YOHAI.

INITH=*h*
specifies the integer h for the initial LTS estimate used by the MM estimator. See the section "Algorithm" on page 6573 for how to specify h and how the default is determined.

INITEST=LTS | S
specifies the initial estimator for the MM estimator. By default, the LTS estimator with its default settings is used as the initial estimator for the MM estimator.

K0=*number*
specifies the parameter k_0 in the χ function for the MM estimate. For CHIF=TUKEY, the default is $k_0 = 2.9366$. For CHIF=YOHAI, the default is $k_0 = 0.7405$. These default values correspond to the 25% breakdown value of the MM estimator.

MAXITER=*n*
sets the maximum number of iterations during the parameter estimation. By default, MAXITER=1,000.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC ROBUSTREG to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the ROBUSTREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / **TRUNCATE** > **;**

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC ROBUSTREG statement. You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE
specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

EFFECT Statement

EFFECT *name = effect-type (variables* < */ options* > *)* **;**

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 397 of Chapter 19, "Shared Concepts and Topics."

The following *effect-types* are available:

COLLECTION	is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
LAG	is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period. **Note:** The LAG *effect-type* is experimental in this release.
MULTIMEMBER | MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.

POLYNOMIAL | POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 77.7 summarizes important options for each type of EFFECT statement.

Table 77.7 Important EFFECT Statement Options

Option	Description
Options for Collection Effects	
DETAILS	Displays the constituents of the collection effect
Options for Lag Effects	
DESIGNROLE=	Names a variable that controls to which lag design an observation is assigned
DETAILS	Displays the lag design of the lag effect
NLAG=	Specifies the number of periods in the lag
PERIOD=	Names the variable that defines the period
WITHIN=	Names the variable or variables that define the group within which each period is defined
Options for Multimember Effects	
NOEFFECT	Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns
WEIGHT=	Specifies the weight variable for the contributions of each of the classification effects
Options for Polynomial Effects	
DEGREE=	Specifies the degree of the polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Options for Spline Effects	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion
DEGREE=	Specifies the degree of the spline transformation
KNOTMETHOD=	Specifies how to construct the knots for spline effects

For further details about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section "EFFECT Statement" on page 406 of Chapter 19, "Shared Concepts and Topics."

ID Statement

ID *variables* **;**

When the diagnostics table is requested with the DIAGNOSTICS option in the MODEL statement, the variables listed in the ID statement are displayed in addition to the observation number. These variables can be used to identify each observation. If the ID statement is omitted, the observation number is used to identify the observations.

MODEL Statement

<label:> **MODEL** *response = < effects > < / options >* **;**

Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure (Chapter 41, "The GLM Procedure.")

The optional *label*, which must be a valid SAS name, is used to label the model in the OUTEST data set.

You can specify the following options for the model fit.

ALPHA=*value*
specifies the significance level for the confidence intervals for regression parameters. The value must be between 0 and 1. By default, ALPHA=0.05.

CORRB
produces the estimated correlation matrix of the parameter estimates.

COVB
produces the estimated covariance matrix of the parameter estimates.

CUTOFF=*value*
specifies the multiplier of the cutoff value for outlier detection. By default, CUTOFF=3.

DIAGNOSTICS< (ALL) >
requests the outlier diagnostics. By default, only observations identified as outliers or leverage points are displayed. To request that all observations be displayed, specify the ALL option.

FAILRATIO=*value*
specifies the threshold of failure ratio for the subsampling algorithm of an LTS or S estimate. It also applies to the initial LTS or S step in an MM estimate. The threshold must be between 0 and 1. Its default value is 0.99. See the section "LTS Estimate" on page 6567 or "S Estimate" on page 6569 for details.

ITPRINT
displays the iteration history for the iteratively reweighted least squares algorithm used by M and MM estimation. You can also use this option in the PROC statement.

LEVERAGE < (*leverage-options*) >

requests an analysis of leverage points for the covariates. The results are added to the diagnostics table, which you can request with the DIAGNOSTICS option in the MODEL statement.

The following *leverage-options* are available:

CUTOFF=*value*

specifies the leverage cutoff value for leverage-point detection. See the section "Leverage Point and Outlier Detection" on page 6582 for details. The cutoff value can also be specified with the leverage cutoff α value by using the CUTOFFALPHA= option.

CUTOFFALPHA=*value*

specifies the leverage cutoff α value for leverage-point detection. The respective leverage cutoff value equals $\sqrt{\chi^2_{p;1-\alpha}}$ (or $\sqrt{\chi^2_{q;1-\alpha}}$ if projection is applied in the generalized MCD algorithm). By default, $\alpha = 0.025$.

H | QUANTILE=*n*

specifies the quantile to be minimized for the MCD algorithm that is used for the leverage-point analysis. By default, H=$[(3n + p + 1)/4]$, where n is the number of observations and p is the number of independent variables excluding the intercept.

MCDALPHA=*value*

specifies the MCD cutoff α value for the final MCD reweighting step. The respective MCD cutoff value equals $\sqrt{\chi^2_{p;1-\alpha}}$ (or $\sqrt{\chi^2_{q;1-\alpha}}$ if projection is applied in the generalized MCD algorithm). By default, $\alpha = 0.025$.

MCDCUTOFF | MCDCUTOFF=*value*

specifies the MCD cutoff value for the final MCD reweighting step. See the section "Mahalanobis Distance versus Robust Distance" on page 6576 and Rousseeuw and Van Driessen (1999) for details. The cutoff value can also be specified with the MCD cutoff α value by using the MCDALPHA= option.

MCDINFO

requests that detailed information about the MCD covariance estimate be displayed, including the low-dimensional structure, the breakdown value, the MCD center, and the MCD covariance itself. The option outputs the ODS tables of the MCD profile, MCD center, MCD covariance, and MCD correlation.

OPC | OFFPLANECOEF

requests the ODS table of the coefficients for MCD-dropped components, when projection is applied in the generalized MCD algorithm. The OFFPLANECOEF option is ignored for the regular MCD algorithm.

PALPHA | PROJECTIONALPHA=*value*

specifies the projection cutoff α value to be used to judge whether an observation is on or off the low-dimensional hyperplane identified by the generalized MCD algorithm. The respective projection cutoff value equals $\sqrt{\chi^2_{1;1-\alpha}}$. By default, $\alpha = 0.001$.

PCUTOFF | PROJECTIONCUTOFF=*value*

specifies the projection cutoff value to be used to judge whether an observation is on or off the low-dimensional hyperplane identified by the projected MCD algorithm. See the section "Mahalanobis Distance versus Robust Distance" on page 6576 and Rousseeuw and Van Driessen (1999) for details. The projection cutoff value can also be specified with the projection cutoff α value by using the PALPHA= option.

PTOL | PROJECTIONTOLERANCE=*value*

specifies the projection tolerance value for the low-dimensional structure detection. See the section "Leverage Point and Outlier Detection" on page 6582 for details.

NOGOODFIT

suppresses the computation of goodness-of-fit statistics.

NOINT

specifies no-intercept regression.

SINGULAR=*value*

specifies the tolerance for testing singularity of the information matrix and the crossproducts matrix for the initial least squares estimates. Roughly, the test requires that a pivot be at least *value* times the original diagonal value. By default, SINGULAR=1.E−12.

OUTPUT Statement

OUTPUT < *OUT=SAS-data-set* > *keyword=name* < *. . . keyword=name* > **;**

The OUTPUT statement creates an output SAS data set that contains statistics calculated after fitting the model. At least one specification of the form *keyword=name* is required.

All variables in the original data set are included in the new data set, along with the variables that are created with *keyword* options in the OUTPUT statement. These new variables contain fitted values and estimated quantiles. If you want to create a permanent SAS data set, you must specify a two-level name (refer to *SAS Language Reference: Concepts* for more information about permanent SAS data sets).

The following specifications can appear in the OUTPUT statement:

OUT=*SAS-data-set* specifies the new data set. By default, the procedure uses the DATA*n* convention to name the new data set.

keyword=name specifies the statistics to include in the output data set and gives names to the new variables. Specify a keyword for each desired statistic (see the following list), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

LEVERAGE specifies a variable to indicate leverage points. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the PROC ROBUSTREG

statement. See the section "Leverage Point and Outlier Detection" on page 6582 for how to define LEVERAGE.

MD — specifies a variable to contain the Mahalanobis distances. See the section "Robust Distance" on page 6576 for the definition of Mahalanobis distance.

OUTLIER — specifies a variable to indicate outliers. See the section "Leverage Point and Outlier Detection" on page 6582 for information about how to define OUTLIER.

PMD — specifies a variable to contain the projected Mahalanobis distances. See the section "Robust Distance" on page 6576 for the definition of projected Mahalanobis distance.

POD — specifies a variable to contain the projected off-plane distances. See the section "Robust Distance" on page 6576 for the definition of off-plane distance.

PRD — specifies a variable to contain the projected robust MCD Mahalanobis distances. See the section "Robust Distance" on page 6576 for the definition of projected robust distance.

PREDICTED | P — specifies a variable to contain the estimated responses

$$\hat{y}_i = \mathbf{x}_i^T \hat{\theta}$$

RD — specifies a variable to contain the robust MCD Mahalanobis distances. See the section "Robust Distance" on page 6576 for the definition of robust distance.

RESIDUAL | R — specifies a variable to contain the unstandardized residuals

$$y_i - \hat{y}_i \text{ or } y_i - \mathbf{x}_i^T \hat{\theta}$$

SRESIDUAL | SR — specifies a variable to contain the standardized residuals

$$\frac{y_i - \hat{y}_i}{\hat{\sigma}} \text{ or } \frac{y_i - \mathbf{x}_i^T \hat{\theta}}{\hat{\sigma}}.$$

By default, the LTS method uses Wscale as $\hat{\sigma}$ for computing the standardized residuals.

STDP — specifies a variable to contain the estimates of the standard errors of the estimated mean responses

$$\mathbf{x}_i^T \Sigma \mathbf{x}_i$$

where Σ denotes the covariance matrix of the parameter estimates. You can request the ODS table of this covariance matrix by using the COVB option of the MODEL statement. The STDP= option is applied to M, S, and MM estimation, but not to LTS estimation.

WEIGHT — specifies a variable to contain the computed final weights.

PERFORMANCE Statement

The PERFORMANCE statement is used to change default options that affect the performance of PROC ROBUSTREG and to request tables that show the performance options in effect and timing details. See Chen (2002) for some empirical results.

PERFORMANCE < *options* > **;**

The following options are available:

CPUCOUNT=*n* | *ACTUAL*
specifies the number of processors to use for forming crossproduct matrices. You can specify any integer in the range 1-1024 for *n*. CPUCOUNT=ACTUAL sets CPUCOUNT to be the number of physical processors available. Note that this can be less than the physical number of CPUs if the SAS process has been restricted by system administration tools. Setting CPUCOUNT= to a number greater than the actual number of available CPUs might result in reduced performance. This option overrides the SAS system option CPUCOUNT=. If CPUCOUNT=1, then NOTHREADS is in effect, and PROC ROBUSTREG uses singly threaded code.

DETAILS
requests the "PerfSettings" table that shows the performance settings in effect and the "Timing" table that provides a broad timing breakdown of the PROC ROBUSTREG step.

THREADS
enables multithreaded computation. This option overrides the SAS system option THREADS | NOTHREADS.

NOTHREADS
disables multithreaded computation. This option overrides the SAS system option THREADS | NOTHREADS.

TEST Statement

<*label:*> **TEST** *effects* **;**

With M estimation and MM estimation, the TEST statement provides a means of obtaining a test for the canonical linear hypothesis concerning the parameters of the tested effects

$$\theta_j = 0, \quad j = i_1, \ldots, i_q$$

where q is the total number of parameters of the tested effects.

PROC ROBUSTREG provides two kinds of robust tests: the ρ test and the R_n^2 test. They are described in the section "Details: ROBUSTREG Procedure" on page 6560. No test is available for LTS and S estimation.

The optional *label*, which must be a valid SAS name, is used to label output from the corresponding TEST statement.

WEIGHT Statement

WEIGHT *variable* **;**

The WEIGHT statement specifies a weight variable in the input data set.

If you want to use fixed weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. The values of the WEIGHT variable can be nonintegral and are not truncated. Observations with nonpositive or missing values for the weight variable do not contribute to the fit of the model.

Details: ROBUSTREG Procedure

This section describes the statistical and computational aspects of the ROBUSTREG procedure. The following notation is used throughout this section.

Let $X = (x_{ij})$ denote an $n \times p$ matrix, $y = (y_1, \ldots, y_n)^T$ denote a given n-vector of responses, and $\theta = (\theta_1, \ldots, \theta_p)^T$ denote an unknown p-vector of parameters or coefficients whose components are to be estimated. The matrix X is called the design matrix. Consider the usual linear model

$$y = X\theta + e$$

where $e = (e_1, \ldots, e_n)^T$ is an n-vector of unknown errors. It is assumed that (for a given X) the components e_i of e are independent and identically distributed according to a distribution $L(\cdot/\sigma)$, where σ is a scale parameter (usually unknown). Often $L(\cdot) \approx \Phi(\cdot)$, the standard normal distribution function. The vector of residuals for a given value of $\hat{\theta}$ is denoted by $r = (r_1, \ldots, r_n)^T$ and the ith row of the matrix X is denoted by x_i^T.

M Estimation

M estimation in the context of regression was first introduced by Huber (1973) as a result of making the least squares approach robust. Although M estimators are not robust with respect to leverage points, they are popular in applications where leverage points are not an issue.

Instead of minimizing a sum of squares of the residuals, a Huber-type M estimator $\hat{\theta}_M$ of θ minimizes a sum of less rapidly increasing functions of the residuals:

$$Q(\theta) = \sum_{i=1}^{n} \rho(\frac{r_i}{\sigma})$$

where $r = y - X\theta$. For the ordinary least squares estimation, ρ is the square function, $\rho(z) = z^2$.

If σ is known, then by taking derivatives with respect to θ, $\hat{\theta}_M$ is also a solution of the system of p equations:

$$\sum_{i=1}^{n} \psi(\frac{r_i}{\sigma}) x_{ij} = 0, \ j = 1, \ldots, p$$

where $\psi = \frac{\partial \rho}{\partial z}$. If ρ is convex, $\hat{\theta}_M$ is the unique solution.

The ROBUSTREG procedure solves this system by using iteratively reweighted least squares (IRLS). The weight function $w(x)$ is defined as

$$w(z) = \frac{\psi(z)}{z}$$

The ROBUSTREG procedure provides 10 kinds of weight functions through the WEIGHTFUNCTION= option in the MODEL statement. Each weight function corresponds to a ρ function. See the section "Weight Functions" on page 6562 for a complete discussion. You can specify the scale parameter σ with the SCALE= option in the PROC statement.

If σ is unknown, both θ and σ are estimated by minimizing the function

$$Q(\theta, \sigma) = \sum_{i=1}^{n} [\rho(\frac{r_i}{\sigma}) + a]\sigma, \ a > 0$$

The algorithm proceeds by alternately improving $\hat{\theta}$ in a location step and $\hat{\sigma}$ in a scale step.

For the scale step, three methods are available to estimate σ, which you can select with the SCALE= option.

1. (SCALE=HUBER<(D=d)>) Compute $\hat{\sigma}$ by the iteration

$$(\hat{\sigma}^{(m+1)})^2 = \frac{1}{nh} \sum_{i=1}^{n} \chi_d(\frac{r_i}{\hat{\sigma}^{(m)}})(\hat{\sigma}^{(m)})^2$$

where

$$\chi_d(x) = \begin{cases} x^2/2 & \text{if } |x| < d \\ d^2/2 & \text{otherwise} \end{cases}$$

is the Huber function and $h = \frac{n-p}{n}(d^2 + (1-d^2)\Phi(d) - 0.5 - d\sqrt{2\pi}e^{-\frac{1}{2}d^2})$ is the Huber constant (Huber 1981, p. 179). You can specify d with the D= option. By default, $d = 2.5$.

2. (SCALE=TUKEY<(D=d)>) Compute $\hat{\sigma}$ by solving the supplementary equation

$$\frac{1}{n-p} \sum_{i=1}^{n} \chi_d(\frac{r_i}{\sigma}) = \beta$$

where

$$\chi_d(x) = \begin{cases} \frac{3x^2}{d^2} - \frac{3x^4}{d^4} + \frac{x^6}{d^6} & \text{if } |x| < d \\ 1 & \text{otherwise} \end{cases}$$

Here $\psi = \frac{1}{6}\chi_1'$ is Tukey's bisquare function, and $\beta = \int \chi_d(s)d\Phi(s)$ is the constant such that the solution $\hat{\sigma}$ is asymptotically consistent when $L(\cdot/\sigma) = \Phi(\cdot)$ (Hampel et al. 1986, p. 149). You can specify d with the D= option. By default, $d = 2.5$.

3. (SCALE=MED) Compute $\hat{\sigma}$ by the iteration

$$\hat{\sigma}^{(m+1)} = \text{median}\{|y_i - x_i^T \hat{\theta}^{(m)}|/\beta_0, i = 1, \ldots, n\}$$

where $\beta_0 = \Phi^{-1}(.75)$ is the constant such that the solution $\hat{\sigma}$ is asymptotically consistent when $L(\cdot/\sigma) = \Phi(\cdot)$ (Hampel et al. 1986, p. 312).

SCALE = MED is the default.

Algorithm

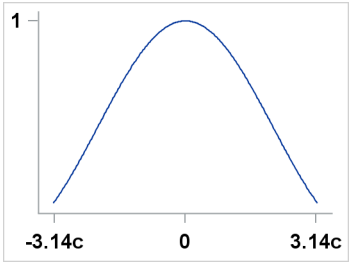
The basic algorithm for computing M estimates for regression is iteratively reweighted least squares (IRLS). As the name suggests, a weighted least squares fit is carried out inside an iteration loop. For each iteration, a set of weights for the observations is used in the least squares fit. The weights are constructed by applying a weight function to the current residuals. Initial weights are based on residuals from an initial fit. The ROBUSTREG procedure uses the unweighted least squares fit as a default initial fit. The iteration terminates when a convergence criterion is satisfied. The maximum number of iterations is set to 1,000. You can specify the weight function and the convergence criteria.

Weight Functions

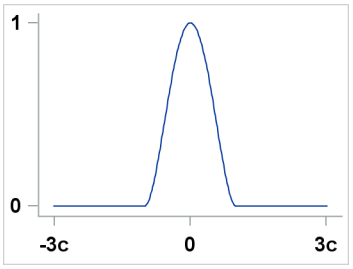
You can specify the weight function for M estimation with the WEIGHTFUNCTION= option. The ROBUSTREG procedure provides 10 weight functions. By default, the procedure uses the bisquare weight function. In most cases, M estimates are more sensitive to the parameters of these weight functions than to the type of the weight function. The median weight function is not stable and is seldom recommended in data analysis; it is included in the procedure for completeness. You can specify the parameters for these weight functions. Except for the Hampel and median weight functions, default values for these parameters are defined such that the corresponding M estimates have 95% asymptotic efficiency in the location model with the Gaussian distribution (Holland and Welsch 1977).

The following list shows the weight functions available. See Table 77.4 for the default values of the constants in these weight functions.

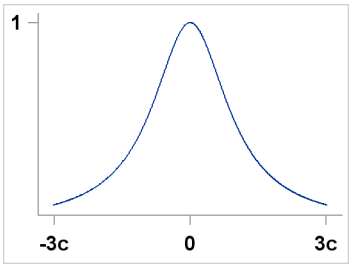
Andrews $$W(x,c) = \begin{cases} \frac{\sin(\frac{x}{c})}{\frac{x}{c}} & \text{if } |x| \le \pi c \\ 0 & \text{otherwise} \end{cases}$$



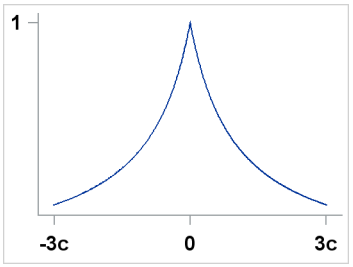
Bisquare $$W(x,c) = \begin{cases} (1-(\frac{x}{c})^2)^2 & \text{if } |x| < c \\ 0 & \text{otherwise} \end{cases}$$



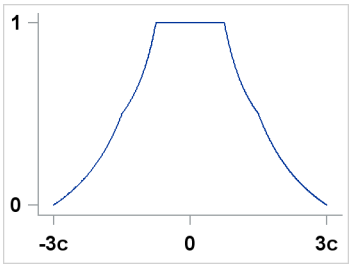
Cauchy $$W(x,c) = \frac{1}{1+(\frac{|x|}{c})^2}$$



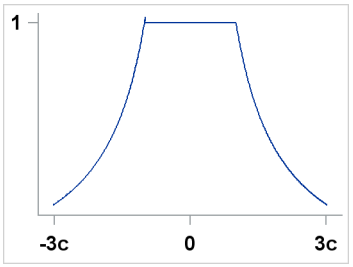
Fair $$W(x,c) = \frac{1}{(1+\frac{|x|}{c})}$$



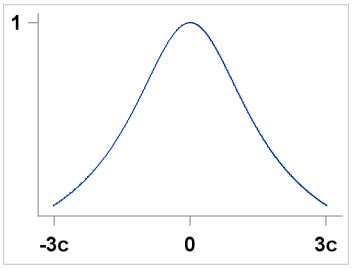
Hampel $$W(x,a,b,c) = \begin{cases} 1 & |x| < a \\ \frac{a}{|x|} & a < |x| \le b \\ \frac{a}{|x|}\frac{c-|x|}{c-b} & b < |x| \le c \\ 0 & \text{otherwise} \end{cases}$$



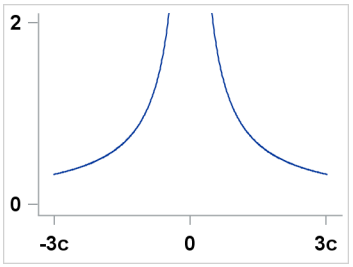
Huber $$W(x,c) = \begin{cases} 1 & \text{if } |x| < c \\ \frac{c}{|x|} & \text{otherwise} \end{cases}$$



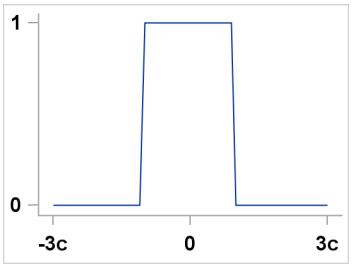
Logistic $W(x,c) = \frac{\tanh(\frac{x}{c})}{\frac{x}{c}}$



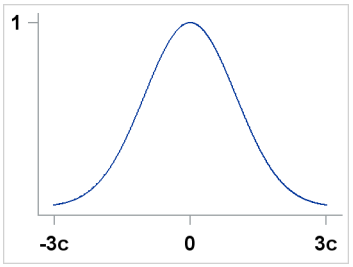
Median $W(x,c) = \begin{cases} \frac{1}{c} & \text{if } x = 0 \\ \frac{1}{|x|} & \text{otherwise} \end{cases}$



Talworth $W(x,c) = \begin{cases} 1 & \text{if } |x| < c \\ 0 & \text{otherwise} \end{cases}$



Welsch $W(x,c) = \exp(-\frac{1}{2}(\frac{x}{c})^2)$



Convergence Criteria

The following convergence criteria are available in PROC ROBUSTREG:

- relative change in the coefficients (CONVERGENCE= COEF)
- relative change in the scaled residuals (CONVERGENCE= RESID)
- relative change in weights (CONVERGENCE= WEIGHT)

You can specify the criteria with the CONVERGENCE= option in the PROC statement. The default is CONVERGENCE= COEF.

You can specify the precision of the convergence criterion with the EPS= suboption. The default is EPS=1.E−8.

In addition to these convergence criteria, a convergence criterion based on scale-independent measure of the gradient is always checked. See Coleman et al. (1980) for more details. A warning is issued if this criterion is not satisfied.

Asymptotic Covariance and Confidence Intervals

The following three estimators of the asymptotic covariance of the robust estimator are available in PROC ROBUSTREG:

$$\text{H1: } K^2 \frac{[1/(n-p)]\sum(\psi(r_i))^2}{[(1/n)\sum(\psi'(r_i))]^2}(X^TX)^{-1}$$

$$\text{H2: } K \frac{[1/(n-p)]\sum(\psi(r_i))^2}{[(1/n)\sum(\psi'(r_i))]}W^{-1}$$

$$\text{H3: } K^{-1}\frac{1}{(n-p)}\sum(\psi(r_i))^2 W^{-1}(X^TX)W^{-1}$$

where $K = 1 + \frac{p}{n}\frac{\text{Var}(\psi')}{(E\psi')^2}$ is a correction factor and $W_{jk} = \sum \psi'(r_i)x_{ij}x_{ik}$. Refer to Huber (1981, p. 173) for more details.

You can specify the asymptotic covariance estimate with the option ASYMPCOV= option. The ROBUSTREG procedure uses H1 as the default because of its simplicity and stability. Confidence intervals are computed from the diagonal elements of the estimated asymptotic covariance matrix.

R Square and Deviance

The robust version of R-square is defined as

$$R^2 = \frac{\sum \rho(\frac{y_i-\hat{\mu}}{\hat{s}}) - \sum \rho(\frac{y_i - x_i^T\hat{\theta}}{\hat{s}})}{\sum \rho(\frac{y_i-\hat{\mu}}{\hat{s}})}$$

and the robust deviance is defined as the optimal value of the objective function on the σ^2 scale

$$D = 2(\hat{s})^2 \sum \rho(\frac{y_i - x_i^T\hat{\theta}}{\hat{s}})$$

where $\rho' = \psi$, $\hat{\theta}$ is the M estimator of θ, $\hat{\mu}$ is the M estimator of location, and $\hat{s}$ is the M estimator of the scale parameter in the full model.

Linear Tests

Two tests are available in PROC ROBUSTREG for the canonical linear hypothesis

$$H_0: \quad \theta_j = 0, \quad j = i_1, \ldots, i_q$$

where q is the total number of parameters of the tested effects. The first test is a robust version of the F test, which is referred to as the ρ test. Denote the M estimators in the full and reduced models as $\hat{\theta}(0) \in \Omega_0$ and $\hat{\theta}(1) \in \Omega_1$, respectively. Let

$$\begin{aligned} Q_0 &= Q(\hat{\theta}(0)) = \min\{Q(\theta)|\theta \in \Omega_0\} \\ Q_1 &= Q(\hat{\theta}(1)) = \min\{Q(\theta)|\theta \in \Omega_1\} \end{aligned}$$

with

$$Q = \sum_{i=1}^{n} \rho(\frac{r_i}{\sigma})$$

The robust F test is based on the test statistic

$$S_n^2 = \frac{2}{q}[Q_1 - Q_0]$$

Asymptotically $S_n^2 \sim \lambda\chi_q^2$ under H_0, where the standardization factor is $\lambda = \int \psi^2(s)d\Phi(s)/\int \psi'(s)\, d\Phi(s)$ and Φ is the cumulative distribution function of the standard normal distribution. Large values of S_n^2 are significant. This test is a special case of the general τ test of Hampel et al. (1986, Section 7.2).

The second test is a robust version of the Wald test, which is referred to as R_n^2 test. The test uses a test statistic

$$R_n^2 = n(\hat{\theta}_{i_1}, \ldots, \hat{\theta}_{i_q})H_{22}^{-1}(\hat{\theta}_{i_1}, \ldots, \hat{\theta}_{i_q})^T$$

where $\frac{1}{n}H_{22}$ is the $q \times q$ block (corresponding to $\theta_{i_1}, \ldots, \theta_{i_q}$) of the asymptotic covariance matrix of the M estimate $\hat{\theta}_M$ of θ in a p-parameter linear model.

Under H_0, the statistic R_n^2 has an asymptotic χ^2 distribution with q degrees of freedom. Large values of R_n^2 are significant. Refer to Hampel et al. (1986, Chapter 7) for more details.

Model Selection

When M estimation is used, two criteria are available in PROC ROBUSTREG for model selection. The first criterion is a counterpart of the Akaike (1974) information criterion for robust regression (AICR); it is defined as

$$\text{AICR} = 2\sum_{i=1}^{n} \rho(r_{i:p}) + \alpha p$$

where $r_{i:p} = (y_i - x_i^T\hat{\theta})/\hat{\sigma}$, $\hat{\sigma}$ is a robust estimate of σ and $\hat{\theta}$ is the M estimator with p-dimensional design matrix.

As with AIC, α is the weight of the penalty for dimensions. The ROBUSTREG procedure uses $\alpha = 2E\psi^2/E\psi'$ (Ronchetti 1985) and estimates it by using the final robust residuals.

The second criterion is a robust version of the Schwarz information criteria (BICR); it is defined as

$$\text{BICR} = 2\sum_{i=1}^{n} \rho(r_{i:p}) + p\log(n)$$

High-Breakdown-Value Estimation

The *breakdown value* of an estimator is defined as the smallest fraction of contamination that can cause the estimator to take on values arbitrarily far from its value on the uncontamined data. The breakdown value of an estimator can be used as a measure of the robustness of the estimator. Rousseeuw and Leroy (1987) and others introduced the following high-breakdown-value estimators for linear regression.

LTS Estimate

The least trimmed squares (LTS) estimate proposed by Rousseeuw (1984) is defined as the p-vector

$$\hat{\theta}_{LTS} = \arg\min_{\theta} Q_{LTS}(\theta) \text{ with } Q_{LTS}(\theta) = \sum_{i=1}^{h} r^2_{(i)}$$

where $r^2_{(1)} \leq r^2_{(2)} \leq ... \leq r^2_{(n)}$ are the ordered squared residuals $r^2_i = (y_i - x_i^T\theta)^2$, $i = 1, \ldots, n$, and h is defined in the range $\frac{n}{2} + 1 \leq h \leq \frac{3n+p+1}{4}$.

You can specify the parameter h with the H= option in the PROC statement. By default, $h = [\frac{3n+p+1}{4}]$. The breakdown value is $\frac{n-h}{n}$ for the LTS estimate.

The ROBUSTREG procedure computes LTS estimates by using the FAST-LTS algorithm of Rousseeuw and Van Driessen (2000). The estimates are often used to detect outliers in the data, which are then down-weighted in the resulting weighted LS regression.

Algorithm

Least trimmed squares (LTS) regression is based on the subset of h observations (out of a total of n observations) whose least squares fit possesses the smallest sum of squared residuals. The coverage h can be set between $\frac{n}{2}$ and n. The LTS method was proposed by Rousseeuw (1984, p. 876) as a highly robust regression estimator with breakdown value $\frac{n-h}{n}$. The ROBUSTREG procedure uses the FAST-LTS algorithm given by Rousseeuw and Van Driessen (2000). The intercept adjustment technique is also used in this implementation. However, because this adjustment is expensive to compute, it is optional. You can use the IADJUST option in the PROC statement to request or suppress the intercept adjustment. By default, PROC ROBUSTREG does intercept adjustment for data sets with fewer than 10,000 observations. The steps of the algorithm are described briefly as follows. Refer to Rousseeuw and Van Driessen (2000) for details.

1. The default h is $[\frac{3n+p+1}{4}]$, where p is the number of independent variables. You can specify any integer h with $[\frac{n}{2}]+1 \leq h \leq [\frac{3n+p+1}{4}]$ with the H= option in the MODEL statement. The breakdown value for LTS, $\frac{n-h}{n}$, is reported. The default h is a good compromise between breakdown value and statistical efficiency.

2. If $p = 1$ (single regressor), the procedure uses the exact algorithm of Rousseeuw and Leroy (1987, p. 172).

3. If $p \geq 2$, the procedure uses the following algorithm. If $n < 2ssubs$, where *ssubs* is the size of the subgroups (you can specify *ssubs* by using the SUBGROUPSIZE= option in the PROC statement; by default, $ssubs = 300$), draw a random p-subset and compute the regression coefficients by using these p points (if the regression is degenerate, draw another p-subset). Compute the absolute residuals for all observations in the data set, and select the first h points with smallest absolute residuals. From this selected h-subset, carry out *nsteps* C-steps (concentration steps; see Rousseeuw and Van Driessen (2000) for details). You can specify *nsteps* with the CSTEP= option in the PROC statement; by default, $nsteps = 2$. Redraw p-subsets and repeat the preceding computing procedure *nrep* times, and then find the *nbsol* (at most) solutions with the lowest sums of h squared residuals. You can specify *nrep* with the NREP= option in the PROC statement. By default, NREP=min{500, $\binom{n}{p}$}. For small n and p, all $\binom{n}{p}$ subsets are used and the NREP= option is ignored (Rousseeuw and Hubert 1996). You can specify *nbsol* with the NBEST= option in the PROC statement. By default, NBEST=10. For each of these *nbsol* best solutions, take C-steps until convergence and find the best final solution.

4. If $n \geq 5ssubs$, construct five disjoint random subgroups with size *ssubs*. If $2ssubs < n < 5ssubs$, the data are split into at most four subgroups with *ssubs* or more observations in each subgroup, so that each observation belongs to a subgroup and the subgroups have roughly the same size. Let *nsubs* denote the number of subgroups. Inside each subgroup, repeat the procedure in step 3 $[\frac{nrep}{nsubs}]$ times and keep the *nbsol* best solutions. Pool the subgroups, yielding the merged set of size n_{merged}. In the merged set, for each of the $nsubs \times nbsol$ best solutions, carry out *nsteps* C-steps by using n_{merged} and $h_{merged} = [n_{merged}\frac{h}{n}]$ and keep the *nbsol* best solutions. In the full data set, for each of these *nbsol* best solutions, take C-steps by using n and h until convergence and find the best final solution.

NOTE: At step 3 in the algorithm, a randomly selected p-subset might be degenerate (that is, its design matrix might be singular). If the total number of p-subsets from any subgroup is more than 4,000 and the ratio of degenerate p-subsets is more than the threshold specified in FAILRATIO option, the algorithm is terminated with a error message.

R-Square

The robust version of R-square for the LTS estimate is defined as

$$R^2_{LTS} = 1 - \frac{s^2_{LTS}(X, y)}{s^2_{LTS}(\mathbf{1}, y)}$$

for models with the intercept term and as

$$R^2_{LTS} = 1 - \frac{s^2_{LTS}(X, y)}{s^2_{LTS}(\mathbf{0}, y)}$$

for models without the intercept term, where

$$s_{LTS}(X, y) = d_{h,n}\sqrt{\frac{1}{h}\sum_{i=1}^{h} r^2_{(i)}}$$

Note that s_{LTS} is a preliminary estimate of the parameter σ in the distribution function $L(\cdot/\sigma)$.

Here $d_{h,n}$ is chosen to make s_{LTS} consistent, assuming a Gaussian model. Specifically,

$$\begin{aligned} d_{h,n} &= 1/\sqrt{1 - \frac{2n}{hc_{h,n}}\phi(1/c_{h,n})} \\ c_{h,n} &= 1/\Phi^{-1}(\frac{h+n}{2n}) \end{aligned}$$

with Φ and ϕ being the distribution function and the density function of the standard normal distribution, respectively.

Final Weighted Scale Estimator

The ROBUSTREG procedure displays two scale estimators, s_{LTS} and Wscale. The estimator Wscale is a more efficient scale estimator based on the preliminary estimate s_{LTS}; it is defined as

$$\text{Wscale} = \sqrt{\frac{\sum_i w_i {r_i}^2}{\sum_i w_i - p}}$$

where

$$w_i = \begin{cases} 0 & \text{if } |r_i|/s_{LTS} > k \\ 1 & \text{otherwise} \end{cases}$$

You can specify k with the CUTOFF= option in the MODEL statement. By default, $k = 3$.

S Estimate

The S estimate proposed by Rousseeuw and Yohai (1984) is defined as the p-vector

$$\hat{\theta}_S = \arg\min_{\theta} S(\theta)$$

where the dispersion $S(\theta)$ is the solution of

$$\frac{1}{n-p}\sum_{i=1}^{n}\chi(\frac{y_i - x_i^T\theta}{S}) = \beta$$

Here β is set to $\int \chi(s)d\Phi(s)$ such that $\hat{\theta}_S$ and $S(\hat{\theta}_S)$ are asymptotically consistent estimates of θ and σ for the Gaussian regression model. The breakdown value of the S estimate is

$$\frac{\beta}{\max_s \chi(s)}$$

The ROBUSTREG procedure provides two choices for χ: Tukey's bisquare function and Yohai's optimal function.

Tukey's bisquare function, which you can specify with the option CHIF=TUKEY, is

$$\chi_{k_0}(s) = \begin{cases} 3(\frac{s}{k_0})^2 - 3(\frac{s}{k_0})^4 + (\frac{s}{k_0})^6, & \text{if } |s| \le k_0 \\ 1 & \text{otherwise} \end{cases}$$

The constant k_0 controls the breakdown value and efficiency of the S estimate. If you specify the efficiency by using the EFF= option, you can determine the corresponding k_0. The default k_0 is 2.9366 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 75.9%.

The Yohai function, which you can specify with the option CHIF=YOHAI, is

$$\chi_{k_0}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \le 2k_0 \\ k_0^2[b_0 + b_1(\frac{s}{k_0})^2 + b_2(\frac{s}{k_0})^4 & \\ \quad +b_3(\frac{s}{k_0})^6 + b_4(\frac{s}{k_0})^8] & \text{if } 2k_0 < |s| \le 3k_0 \\ 3.25k_0^2 & \text{if } |s| > 3k_0 \end{cases}$$

where $b_0 = 1.792$, $b_1 = -0.972$, $b_2 = 0.432$, $b_3 = -0.052$, and $b_4 = 0.002$. If you specify the efficiency by using the EFF= option, you can determine the corresponding k_0. By default, k_0 is set to 0.7405 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 72.7%.

Algorithm

The ROBUSTREG procedure implements the algorithm by Marazzi (1993) for the S estimate, which is a refined version of the algorithm proposed by Ruppert (1992). The refined algorithm is briefly described as follows.

Initialize iter = 1.

1. Draw a random q-subset of the total n observations and compute the regression coefficients by using these q observations (if the regression is degenerate, draw another q-subset), where $q \ge p$ can be specified with the SUBSIZE= option. By default, $q = p$.

2. Compute the residuals: $r_i = y_i - \sum_{j=1}^{p} x_{ij}\theta_j$ for $i = 1, \ldots, n$. If iter $= 1$, set $s^* = 2\text{median}\{|r_i|, i = 1, \ldots, n\}$; if $s^* = 0$, set $s^* = \min\{|r_i|, i = 1, \ldots, n\}$;
   else while $\sum_{i=1}^{n} \chi(r_i/s^*) > (n-p)\beta$, set $s^* = 1.5s^*$; go to step 3.
   If iter > 1 and $\sum_{i=1}^{n} \chi(r_i/s^*) <= (n-p)\beta$, go to step 3; otherwise, go to step 5.

3. Solve for s the equation

$$\frac{1}{n-p}\sum_{i=1}^{n} \chi(r_i/s) = \beta$$

   using an iterative algorithm.

4. If iter > 1 and $s > s^*$, go to step 5. Otherwise, set $s^* = s$ and $\theta^* = \theta$. If $s^* <$ TOLS, return s^* and θ^*; otherwise, go to step 5.

5. If iter $<$ NREP, set iter = iter $+ 1$ and return to step 1; otherwise, return s^* and θ^*.

The ROBUSTREG procedure does the following refinement step by default. You can request that this refinement not be done by using the NOREFINE option in the PROC statement.

6. Let $\psi = \chi'$. Using the values s^* and θ^* from the previous steps, compute M estimates θ_M and σ_M of θ and σ with the setup for M estimation that is described in the section "M Estimation" on page 6560. If $\sigma_M > s^*$, give a warning and return s^* and θ^*; otherwise, return σ_M and θ_M.

You can specify TOLS with the TOLERANCE= option; by default, TOLERANCE=0.001. Alternately, you can specify NREP with the NREP= option. You can also use the options NREP=NREP0 or NREP=NREP1 to determine NREP according to the following table. NREP=NREP0 is set as the default.

Table 77.9 Default NREP

P	NREP0	NREP1
1	150	500
2	300	1000
3	400	1500
4	500	2000
5	600	2500
6	700	3000
7	850	3000
8	1250	3000
9	1500	3000
>9	1500	3000

NOTE: At step 1 in the algorithm, a randomly selected q-subset might be degenerate. If the total number of q-subsets from any subgroup is more than 4,000 and the ratio of degenerate q-subsets is more than the threshold specified in FAILRATIO option, the algorithm is terminated with a error message.

R-Square and Deviance

The robust version of R-square for the S estimate is defined as

$$R_S^2 = 1 - \frac{(n-p)S_p^2}{(n-1)S_\mu^2}$$

for the model with the intercept term and

$$R_S^2 = 1 - \frac{(n-p)S_p^2}{nS_0^2}$$

for the model without the intercept term, where S_p is the S estimate of the scale in the full model, S_μ is the S estimate of the scale in the regression model with only the intercept term, and S_0 is the S estimate of the scale without any regressor. The deviance D is defined as the optimal value of the objective function on the σ^2 scale:

$$D = S_p^2$$

Asymptotic Covariance and Confidence Intervals

Since the S estimate satisfies the first-order necessary conditions as the M estimate, it has the same asymptotic covariance as that of the M estimate. All three estimators of the asymptotic covariance for the M estimate in the section "Asymptotic Covariance and Confidence Intervals" on page 6565 can be used for the S estimate. Besides, the weighted covariance estimator H4 described in the section "Asymptotic Covariance and Confidence Intervals" on page 6575 is also available and is set as the default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.

MM Estimation

MM estimation is a combination of high-breakdown-value estimation and efficient estimation, which was introduced by Yohai (1987). It has the following three steps:

1. Compute an initial (consistent) high-breakdown-value estimate $\hat{\theta}'$. The ROBUSTREG procedure provides two kinds of estimates as the initial estimate: the LTS estimate and the S estimate. By default, the LTS estimate is used because of its speed and high breakdown value. The breakdown value of the final MM estimate is decided by the breakdown value of the initial LTS estimate and the constant k_0 in the χ function. To use the S estimate as the initial estimate, you specify the INITEST=S option in the PROC statement. In this case, the breakdown value of the final MM estimate is decided only by the constant k_0. Instead of computing the LTS estimate or the S estimate as the initial estimate, you can also specify the initial estimate explicitly by using the INEST= option in the PROC statement. See the section "INEST= Data Set" on page 6584 for details.

2. Find $\hat{\sigma}'$ such that

$$\frac{1}{n-p}\sum_{i=1}^{n}\chi\left(\frac{y_i - x_i^T\hat{\theta}'}{\hat{\sigma}'}\right) = \beta$$

where $\beta = \int \chi(s)d\Phi(s)$.

The ROBUSTREG procedure provides two choices for χ: Tukey's bisquare function and Yohai's optimal function.

Tukey's bisquare function, which you can specify with the option CHIF=TUKEY, is

$$\chi_{k_0}(s) = \begin{cases} 3(\frac{s}{k_0})^2 - 3(\frac{s}{k_0})^4 + (\frac{s}{k_0})^6 & \text{if } |s| \le k_0 \\ 1 & \text{otherwise} \end{cases}$$

where k_0 can be specified with the K0= option. The default k_0 is 2.9366 such that the asymptotically consistent scale estimate $\hat{\sigma}'$ has the breakdown value of 25%.

Yohai's optimal function, which you can specify with the option CHIF=YOHAI, is

$$\chi_{k_0}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \le 2k_0 \\ k_0^2[b_0 + b_1(\frac{s}{k_0})^2 + b_2(\frac{s}{k_0})^4 & \\ \quad +b_3(\frac{s}{k_0})^6 + b_4(\frac{s}{k_0})^8] & \text{if } 2k_0 < |s| \le 3k_0 \\ 3.25k_0^2 & \text{if } |s| > 3k_0 \end{cases}$$

where $b_0 = 1.792$, $b_1 = -0.972$, $b_2 = 0.432$, $b_3 = -0.052$, and $b_4 = 0.002$. You can specify k_0 with the K0= option. The default k_0 is 0.7405 such that the asymptotically consistent scale estimate $\hat{\sigma}'$ has the breakdown value of 25%.

3. Find a local minimum $\hat{\theta}_{MM}$ of

$$Q_{MM} = \sum_{i=1}^{n} \rho(\frac{y_i - x_i^T \theta}{\hat{\sigma}'})$$

such that $Q_{MM}(\hat{\theta}_{MM}) \leq Q_{MM}(\hat{\theta}')$. The algorithm for M estimation is used here.

The ROBUSTREG procedure provides two choices for ρ: Tukey's bisquare function and Yohai's optimal function.

Tukey's bisquare function, which you can specify with the option CHIF=TUKEY, is

$$\rho(s) = \chi_{k_1}(s) = \begin{cases} 3(\frac{s}{k_1})^2 - 3(\frac{s}{k_1})^4 + (\frac{s}{k_1})^6 & \text{if } |s| \leq k_1 \\ 1 & \text{otherwise} \end{cases}$$

where k_1 can be specified with the K1= option. The default k_1 is 3.440 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

Yohai's optimal function, which you can specify with the option CHIF=YOHAI, is

$$\rho(s) = \chi_{k_1}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_1 \\ k_1^2[b_0 + b_1(\frac{s}{k_1})^2 + b_2(\frac{s}{k_1})^4 & \\ \quad + b_3(\frac{s}{k_1})^6 + b_4(\frac{s}{k_1})^8] & \text{if } 2k_1 < |s| \leq 3k_1 \\ 3.25k_1^2 & \text{if } |s| > 3k_1 \end{cases}$$

where k_1 can be specified with the K1= option. The default k_1 is 0.868 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

Algorithm

The initial LTS estimate is computed using the algorithm described in the section "LTS Estimate" on page 6567. You can control the quantile of the LTS estimate with the option INITH=h, where h is an integer between $[\frac{n}{2}] + 1$ and $[\frac{3n+p+1}{4}]$. By default, $h = [\frac{3n+p+1}{4}]$, which corresponds to a breakdown value of around 25%.

The initial S estimate is computed using the algorithm described in the section "S Estimate" on page 6569. You can control the breakdown value and efficiency of this initial S estimate by the constant k_0, which can be specified with the K0 option.

The scale parameter σ is solved by an iterative algorithm

$$(\sigma^{(m+1)})^2 = \frac{1}{(n-p)\beta} \sum_{i=1}^{n} \chi_{k_0}(\frac{r_i}{\sigma^{(m)}})(\sigma^{(m)})^2$$

where $\beta = \int \chi_{k_0}(s) d\Phi(s)$.

Once the scale parameter is computed, the iteratively reweighted least squares (IRLS) algorithm with fixed scale parameter is used to compute the final MM estimate.

Convergence Criteria

In the iterative algorithm for the scale parameter, the relative change of the scale parameter controls the convergence.

In the iteratively reweighted least squares algorithm, the same convergence criteria for the M estimate used before are used here.

Bias Test

Although the final MM estimate inherits the high-breakdown-value property, its bias due to the distortion of the outliers can be high. Yohai, Stahel, and Zamar (1991) introduced a bias test. The ROBUSTREG procedure implements this test when you specify the BIASTEST option in the PROC statement. This test is based on the initial scale estimate $\hat{\sigma}'$ and the final scale estimate $\hat{\sigma}'_1$, which is the solution of

$$\frac{1}{n-p}\sum_{i=1}^{n}\chi\left(\frac{y_i - x_i^T\hat{\theta}_{MM}}{\hat{\sigma}'_1}\right) = \beta$$

Let $\psi_{k_0}(z) = \frac{\partial\chi_{k_0}(z)}{\partial z}$ and $\psi_{k_1}(z) = \frac{\partial\chi_{k_1}(z)}{\partial z}$. Compute

$$\begin{aligned}
\tilde{r}_i &= (y_i - x_i^T\hat{\theta}')/\hat{\sigma}' \quad \text{for } i = 1,\ldots,n \\
v_0 &= \frac{(1/n)\sum\psi'_{k_0}(\tilde{r}_i)}{(\hat{\sigma}'_1/n)\sum\psi_{k_0}(\tilde{r}_i)\tilde{r}_i}
\end{aligned}$$

$$\begin{aligned}
p_i^{(0)} &= \frac{\psi_{k_0}(\tilde{r}_i)}{(1/n)\sum\psi'_{k_0}(\tilde{r}_i)} \quad \text{for } i = 1,\ldots,n \\
p_i^{(1)} &= \frac{\psi_{k_1}(\tilde{r}_i)}{(1/n)\sum\psi'_{k_1}(\tilde{r}_i)} \quad \text{for } i = 1,\ldots,n \\
d^2 &= \frac{1}{n}\sum(p_i^{(1)} - p_i^{(0)})^2
\end{aligned}$$

Let

$$T = \frac{2n(\hat{\sigma}'_1 - \hat{\sigma}')}{v_0 d^2(\hat{\sigma}')^2}$$

Standard asymptotic theory shows that T approximately follows a χ^2 distribution with p degrees of freedom. If T exceeds the α quantile χ^2_α of the χ^2 distribution with p degrees of freedom, then the ROBUSTREG procedure gives a warning and recommends that you use other methods. Otherwise, the final MM estimate and the initial scale estimate are reported. You can specify α with the ALPHA= option following the BIASTEST option. By default, ALPHA=0.99.

Asymptotic Covariance and Confidence Intervals

Since the MM estimate is computed as a M estimate with a known scale in the last step, the asymptotic covariance for the M estimate can be used here for the asymptotic covariance of the MM estimate. Besides the three estimators H1, H2, and H3 as described in the section "Asymptotic Covariance and Confidence Intervals" on page 6565, a weighted covariance estimator H4 is available. H4 is calculated as

$$K^2 \frac{[1/(n-p)]\sum(\psi(r_i))^2}{[(1/n)\sum(\psi'(r_i))]^2} W^{-1}$$

where $K = 1 + \frac{p}{n}\frac{\mathrm{Var}(\psi')}{(E\psi')^2}$ is the correction factor and $W_{jk} = \frac{1}{\bar{w}}\sum w_i x_{ij} x_{ik}$, $\bar{w} = \frac{1}{n}\sum w_i$.

You can specify these estimators with the option ASYMPCOV= [H1 | H2 | H3 | H4]. The ROBUSTREG procedure uses H4 as the default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.

R Square and Deviance

The robust version of R-square for the MM estimate is defined as

$$R^2 = \frac{\sum \rho(\frac{y_i - \hat{\mu}}{\hat{s}}) - \sum \rho(\frac{y_i - x_i^T\hat{\theta}}{\hat{s}})}{\sum \rho(\frac{y_i - \hat{\mu}}{\hat{s}})}$$

and the robust deviance is defined as the optimal value of the objective function on the σ^2 scale,

$$D = 2(\hat{s})^2 \sum \rho(\frac{y_i - x_i^T\hat{\theta}}{\hat{s}})$$

where $\rho' = \psi$, $\hat{\theta}$ is the MM estimator of θ, $\hat{\mu}$ is the MM estimator of location, and $\hat{s}$ is the MM estimator of the scale parameter in the full model.

Linear Tests

For MM estimation, the same ρ test and R_n^2 test used for M estimation can be used. See the section "Linear Tests" on page 6565 for details.

Model Selection

For MM estimation, the same two model selection methods used for M estimation can be used. See the section "Model Selection" on page 6566 for details.

Robust Distance

The ROBUSTREG procedure uses the robust multivariate location and scatter estimates for leverage-point detection. The procedure computes a robust version of the Mahalanobis distance by using a generalized minimum covariance determinant (MCD) method. The original MCD method was proposed by Rousseeuw (1984).

Algorithm

PROC ROBUSTREG implements a generalized MCD algorithm based on the fast-MCD algorithm formulated by Rousseeuw and Van Driessen (1999), which is similar to the algorithm for least trimmed squares (LTS).

Mahalanobis Distance versus Robust Distance

The canonical Mahalanobis distance is defined as

$$MD(x_i) = [(x_i - \bar{x})^T \bar{C}(X)^{-1}(x_i - \bar{x})]^{1/2}$$

where $\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i$ and $\bar{C}(X) = \frac{1}{n-1}\sum_{i=1}^{n}(x_i - \bar{x})^T(x_i - \bar{x})$ are the empirical multivariate location and scatter, respectively. Here $x_i = (x_{i1}, \ldots, x_{ip})^T$ excludes the intercept. The relation between the Mahalanobis distance $MD(x_i)$ and the hat matrix $H = (h_{ij}) = X(X^TX)^{-1}X^T$ is

$$h_{ii} = \frac{1}{n-1}MD_i^2 + \frac{1}{n}$$

The canonical robust distance is defined as

$$RD(x_i) = [(x_i - T(X))^T C(X)^{-1}(x_i - T(X))]^{1/2}$$

where $T(X)$ and $C(X)$ are the robust multivariate location and scatter, respectively, obtained by MCD.

To achieve robustness, the MCD algorithm estimates the covariance of a multivariate data set mainly through an MCD h-point subset of the data set. This subset has the smallest sample-covariance determinant among all the possible h-subsets. Accordingly, the breakdown value for the MCD algorithm equals $\frac{(n-h)}{n}$. This means the MCD estimate is reliable, even if up to $\frac{100(n-h)}{n}\%$ observations in the data set are contaminated.

Low-Dimensional Structure

It is possible that the original data is in p dimensional space, but the h-point subset that yields the minimum covariance determinant lies in a lower-dimensional hyperplane. Applying the canonical MCD algorithm to such a data set would result in a singular covariance problem (called exact fit in Rousseeuw and Van Driessen (1999)), so that the relevant robust distances cannot be computed. To deal with the singularity problem and provide further leverage point analysis, PROC ROBUSTREG implements a generalized MCD

algorithm. See the section "Generalized MCD Algorithm" on page 6579 for details. The algorithm distinguishes in-(hyper)plane points from off-(hyper)plane points, and performs MCD leverage point analysis in the dimension-reduced space by projecting all points onto the hyperplane.

Low-dimensional structure is often induced by classification covariates. Suppose, in a study with 25 female subjects and 5 male subjects, that *gender* is the only classification effect. If the breakdown setting is larger than $\frac{5}{(25+5)}$, the canonical MCD algorithm fails, and so does the relevant leverage point analysis. In this case, the MCD h-subset would contain only female observations and the constant *gender* in the h-subset would cause the relevant MCD estimate to be singular. The generalized MCD algorithm solves that problem by identifying all male observations as off-plane leverage points, and then carries out the leverage point analysis with all the other covariates being centered separately for female and male groups against their group means.

In general, low-dimensional structure is not necessarily due to classification covariates. Imagine that 80 children are supposed to play on a straight trail (denoted by $y = x$), but some adventurous children go off the trail. The following statements generate the children data and the relevant scatter plot.

```
data children;
  do i=1 to 80;
     off_trail=ranuni(321)>.9;
     x=rannor(111)*ranuni(321);
     trail_x=(i-40)/80*3;
     trail_y=trail_x;
     if off_trail=1 then y=x-1+rannor(321);
     else y=x;
     output;
  end;
run;

proc sgplot data=children;
   series   x=trail_x y=trail_y/lineattrs=(color="red" pattern=4);
   scatter  x=x y=y/group=off_trail;
   ellipse  x=x y=y/alpha=.05 lineattrs=(color="green" pattern=34);
run;
```

Figure 77.17 shows the positions of all the 80 children, the trail (as a red dashed line), and a contour curve of regular Mahalanobis distance centered at the mean position (as a green dotted ellipse). In terms of regular Mahalanobis distance, the associated covariance estimate is not singular, but its relevant leverage point analysis completely ignores the trail (which is the entity of the low-dimensional structure). The children outside of the ellipse are defined as leverage points, but the children off the trail would not be viewed as leverage points unless they have large Mahalanobis distances. As mentioned in Rousseeuw and Van Driessen (1999), the canonical MCD method can find the low-dimensional structure, but it does not provide further robust covariance estimation because the MCD covariance estimate is singular. As an improved version of the canonical MCD method, the generalized MCD method can find the trail, identify the children off the trail as off-plane leverage points, and further execute in-plane leverage analysis. The following statements apply the generalized MCD algorithm on the children data set.

```
ods graphics on;
proc robustreg data=children plots=ddplot(label=none);
   model i = x y/leverage(mcdinfo opc);
run;
ods graphics off;
```

Figure 77.17 Scatter Plot for Children Data

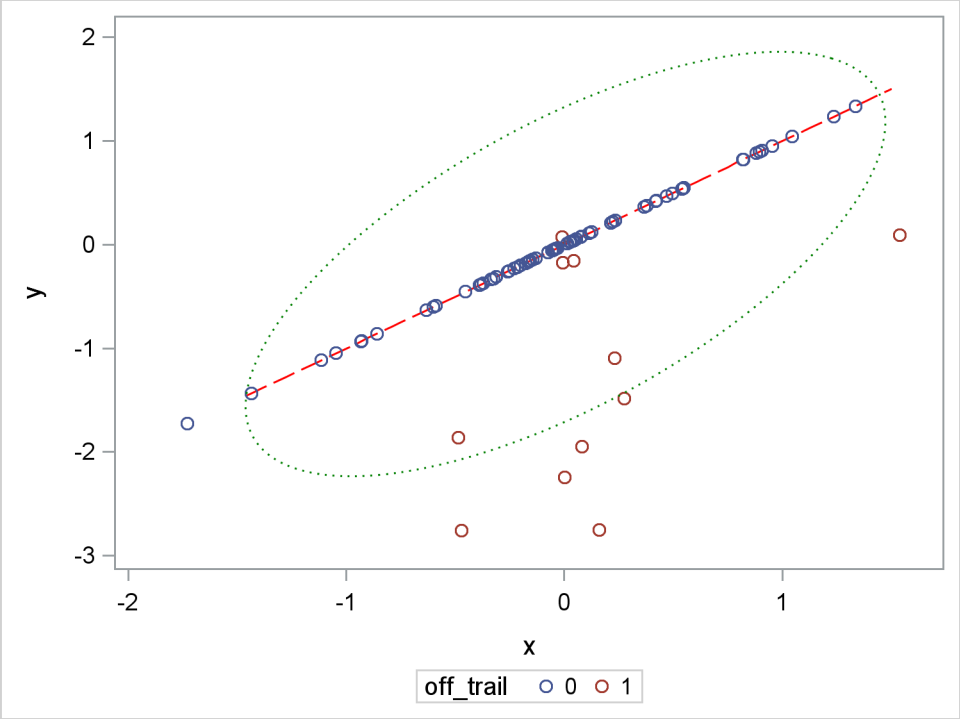


Figure 77.18 exactly identifies the equation underlying the trail. The analysis projects off-plane points onto the trail and computes their projected robust distances and projected Mahalanobis distances the same way as is done for the in-plane points.

Figure 77.18 Robust Dependence Equations

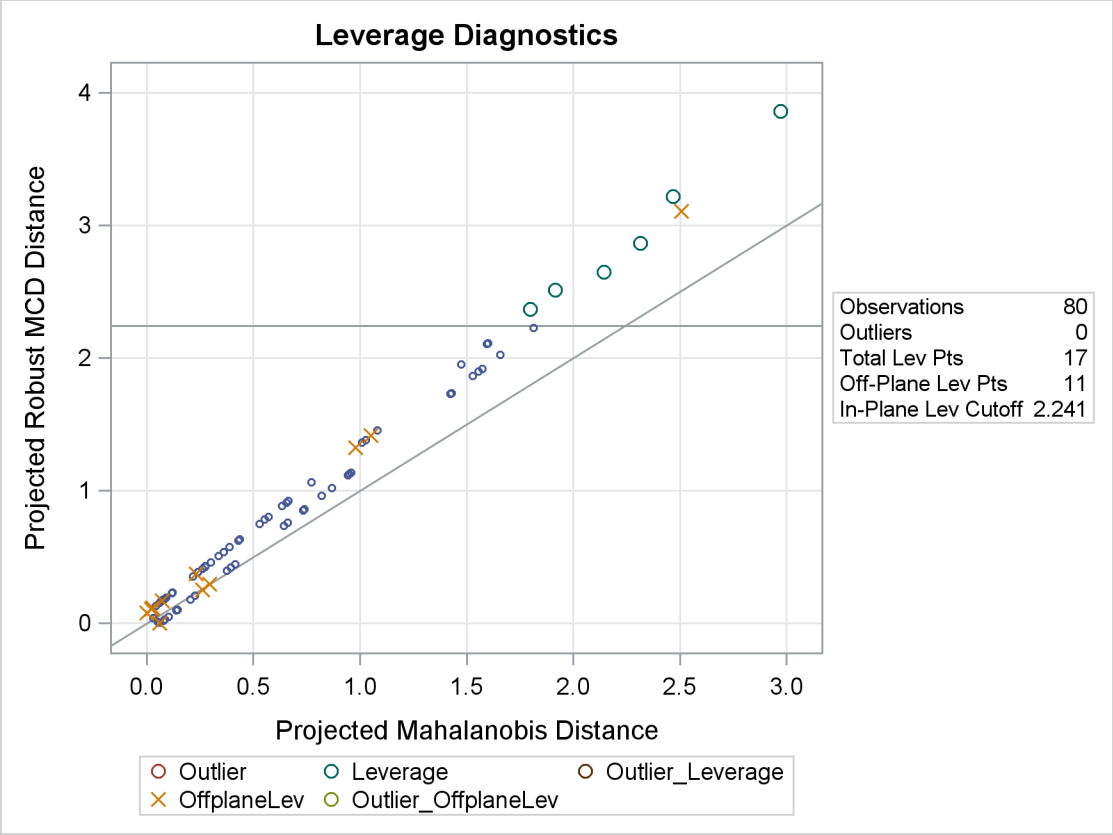
```
                    The ROBUSTREG Procedure

NOTE:  The following robust dependence equations simultaneously hold for 86.25%
       of the observations in the data set. The breakdown setting for the MCD
       algorithm is 25.00%.

                                  y =  x
```

Figure 77.19 shows the relevant distance-distance plot. Robust distance is typically larger than Mahalanobis distance because the sample covariance can be strongly influenced by unusual points that cause the sample covariance to be larger than the MCD covariance.

Figure 77.19 DDPlot for Children Data



NOTE: The PROC ROBUSTREG step in this example is used to obtain the leverage diagnostics; the response is not relevant for this analysis.

Through the off-plane and in-plane symbols and the horizontal cutoff line in Figure 77.19, you can separate all the children into four groups:

- on-trail and close to the MCD center
- on-trail but far away from the MCD center
- off-trail but close to the MCD center
- off-trail and far away from the MCD center

The children in the latter three groups are defined as leverage points in PROC ROBUSTREG.

Generalized MCD Algorithm

The generalized MCD algorithm follows the same resampling strategy as the canonical MCD algorithm by Rousseeuw and Van Driessen (1999) but with modifications in the following aspects.

1. Data are orthonormalized before further processing. The orthonormalized covariates, x_i^*, are defined by $x_i^* = (x_i - \bar{x})P\Lambda^{-1/2}$, where P and Λ are the eigenvector and eigenvalue matrices of $\bar{C}(X)$ (that is, $\bar{C}(X) = P\Lambda P^T$).

2. Let

$$S_h(X^*) = \frac{1}{h-1}\sum_{j=1}^{h}(x_{i_j}^* - \bar{x}^*)^T(x_{i_j}^* - \bar{x}^*) = \sum_{j=1}^{p-1}\lambda_j p_j {p_j}^T$$

denote the covariance and eigendecomposition for a low-dimensional h-subset $\{x_{i_1}^*, \cdots, x_{i_h}^*\}$, where $\bar{x}^* = \frac{1}{h}\sum_{j=1}^{h} x_{i_j}^*$ and the eigenvalues satisfy

$$\lambda_1 \geq \cdots \geq \lambda_q > 0 = \lambda_{q+1} = \cdots = \lambda_p$$

Then, the rank of $S_h(X^*)$ equals q, and the pseudo-determinant of $S_h(X^*)$ is defined as $\prod_{j=1}^{q}\lambda_j$. In finite precision arithmetic, q is defined as the number of λ's with $\frac{\lambda_i}{\lambda_1}$ being larger than a certain tolerance value. You can specify this tolerance with the PTOL suboption of the LEVERAGE option.

3. Given $S_h(X^*)$ and $\bar{x}^*$ as the covariance and center estimates, the projected Mahalanobis distance for x_i is defined as

$$\left[\sum_{j=1}^{q}\frac{\left((x_i^* - \bar{x}^*)p_j\right)^2}{\lambda_j}\right]^{1/2}$$

The generalized algorithm also computes off-plane distance for each x_i as

$$\left[\sum_{j=q+1}^{p}\left((x_i^* - \bar{x}^*)p_j\right)^2\right]^{1/2}$$

In finite precision arithmetic, $\left((x_i^* - \bar{x}^*)p_j\right)^2$ in the previous off-plane formula are truncated to zero if they satisfy

$$\frac{\left((x_i^* - \bar{x}^*)p_j\right)^2}{\lambda_j} \leq \text{cutoff}$$

You can tune this cutoff by using either the PCUTOFF or the PALPHA suboption of the LEVERAGE option. The points with zero off-plane distances are called in-plane points; otherwise, they are called off-plane points. Analogous to ordering all points in terms of their canonical Mahalanobis distances, with the generalized MCD algorithm the points are first sorted by their off-plane distances, and the points with the same off-plane distance values are further sorted by their projected Mahalanobis distances.

4. Instead of comparing the determinants of h-subset covariance matrices, the generalized algorithm compares both the ranks and pseudo-determinants of the h-subset covariance matrices. If the ranks of two matrices are different, the matrix with smaller rank is treated as if its determinant were smaller. If two matrices are of the same rank, they are compared in terms of their pseudo-determinants.

5. Suppose that the $S_h(X^*)$ of the minimum determinant is singular. Then the relevant low-dimensional structure or hyperplane can be identified by using the eigendecomposition of $S_h(X^*)$. The eigenvectors that correspond to the nonzero eigenvalues form a basis for the low-dimensional hyperplane. The projected off-plane distance (POD) for x_i is defined as the off-plane distance associated with the $S_h(X^*)$. To provide further leverage analysis on the low-dimensional hyperplane, every x_i^* is transformed into $(x_i^* p_1, \cdots, x_i^* p_q)$, where p_j are the eigenvectors of the $S_h(X^*)$. The projected robust distance (PRD) is then computed as the reweighted Mahalanobis distance on all the transformed in-plane points. The off-plane points are assigned zero weights at the reweighting stage, because they are leverage points by definition. The in-plane points are classified into two groups, the normal group and the in-plane leverage group. This classification is made by comparing their projected robust distances with a leverage cutoff value. See the section "Leverage Point and Outlier Detection" on page 6582 for details. This reweighting process mirrors the one proposed by Rousseeuw and Van Driessen (1999). However, the degrees of freedom p for the reweighting critical χ^2 value is replaced by q. You can control the χ^2 critical value with the MCDCUTOFF or the MCDALPHA option.

If the data set under investigation has a low-dimensional structure, you can use two ODS objects, "DependenceEquations" and "MCDDependenceEquations," to identify the regressors that are linear combinations of other regressors plus certain constants. The equations in "DependenceEquations" hold for the entire data set, while the equations in "MCDDependenceEquations" apply only to the majority of the observations.

By using the OPC suboption of the LEVERAGE option, you can request an ODS table called "DroppedComponents." Figure 77.20 shows the "DroppedComponents" table for the children data example. This table contains a set of coefficient vectors for regressors, which form a basis of the complementary space for the relevant low-dimensional structure.

Figure 77.20 MCD Dropped Components

Coefficients for MCD-Dropped Components

Parameter	Robust Drop1
x	-1.000
y	1.0000

By using the MCDINFO suboption of the LEVERAGE option, you can request that detailed information about the MCD covariance estimate be displayed in four ODS tables: "MCDProfile," "MCDCenter," "MCDCov," and "MCDCorr." Figure 77.21 shows an example of the MCD information tables for the children data. The number of dimensions in the table "MCDProfile" equals the number of nonintercept regressors minus the number of design dropped components. The specified value of H is the same as h for the h-subset that you can specify with the QUANTILE= suboption of the LEVERAGE option in the MODEL statement, and the reweighted H is the number of observations that are actually used to compute the MCD center and MCD covariance after the reweighting step of the MCD algorithm.

Figure 77.21 MCD Information

MCD Profile

Number of Dimensions	2

Leverage Point and Outlier Detection

The regular variable LEVERAGE is defined as

$$\text{LEVERAGE} = \begin{cases} 0 & \text{if } RD(x_i) \le C(p) \\ 1 & \text{otherwise} \end{cases}$$

where $C(p) = \sqrt{\chi^2_{p;1-\alpha}}$ is the cutoff value. $C(p)$ can be set with the leverage CUTOFF option, and α can be set with the leverage CUTOFFALPHA option.

If projected robust distances are computed for a data set that has a low-dimensional structure, the default cutoff value is $C(q) = \sqrt{\chi^2_{q;1-\alpha}}$ where q is the dimensionality of the low-dimensional space. The LEVER-

AGE is then defined as

$$\text{LEVERAGE} = \begin{cases} 0 & \text{if POD}(x_i) = 0 \text{ and PRD}(x_i) \le C(q) \\ 1 & \text{if POD}(x_i) = 0 \text{ and PRD}(x_i) > C(q) \text{ (called in-plane leverage)} \\ 1 & \text{if POD}(x_i) > 0 \text{ (called off-plane leverage)} \end{cases}$$

where POD is the projected off-plane distance and PRD denotes the projected robust distance. You can specify a cutoff value with the CUTOFF or the CUTOFFALPHA suboptions of the LEVERAGE option in the MODEL statement.

Residuals $r_i, i = 1, \ldots, n$, based on robust regression estimates are used to detect vertical outliers. The variable OUTLIER is defined as

$$\text{OUTLIER} = \begin{cases} 0 & \text{if } |r_i| \le k\hat{\sigma} \\ 1 & \text{otherwise} \end{cases}$$

where $\hat{\sigma}$ is the estimated scale in the model and the multiplier k of the cutoff value is specified by the CUTOFF= option in the MODEL statement. By default, $k = 3$.

An ODS table called "Diagnostics" contains the LEVERAGE and OUTLIER variables.

Implementation of the WEIGHT Statement

You can use the WEIGHT statement to specify a weight variable in the input data set. See the section "WEIGHT Statement" on page 6559 for more information. This section describes how PROC ROBUSTREG implements the WEIGHT statement for each of the estimation methods and for leverage detection.

M Estimation

If you use M estimation with a known scale, instead of minimizing $Q(\theta) = \sum_{i=1}^{n} \rho(\frac{r_i}{\sigma})$, the weighted M estimation minimizes the weighted Huber-type objective function

$$Q(\theta) = \sum_{i=1}^{n} v_i \rho(\frac{r_i}{\sigma}),$$

where v is the weight variable specified by the WEIGHT statement. If you use M estimation with an unknown scale, the weight variable is used in the location steps but not in the scale steps. See the section "M Estimation" on page 6560 and the SCALE= option for more details. For estimating the covariance of the weighted M estimation, $\psi(r_i)$ and $\psi'(r_i)$ are obtained from the final iteration of the weighted M estimation, and $X^T X$ and W are respectively replaced by $X^T V X$ and $W_{jk} = \sum v_i \psi'(r_i) x_{ij} x_{ik}$, where V is a diagonal matrix with its diagonal elements being v_i's. See the section "Asymptotic Covariance and Confidence Intervals" on page 6565 for more information. The weight variable does not affect the model degrees of freedom p and the error degrees of freedom $n - p$.

LTS Estimation

LTS estimation ignores the weight variable.

S Estimation

S estimation applies the weight variable only in its M-refinement step. Except for the initial estimates, the M-refinement step of S estimation is the same as the weighted M estimation with unknown scale. If you use the NOREFINE suboption, S estimation ignores the weight variable along with the M-refinement step.

MM Estimation

By default, the initial step of MM estimation is the initial LTS estimation. Unlike the regular LTS estimation, the initial LTS estimation is applied on the weighted data $(y_i{}^*, x_i{}^*)$'s, where $y_i{}^* = \sqrt{v_i}\, y_i$ and $x_i{}^* = \sqrt{v_i}\, x_i$. After the initial LTS estimation, the weight variable is ignored for the subsequent scale adjustment.

You can use INITEST=S to specify the initial S estimation as the initial step of the MM estimation. Similarly to the regular S estimation, the weight variable is used only in the M-refinement step of the initial S estimation. There is no subsequent scale adjustment step if the initial S estimation is applied.

Except for the initial estimates, the final M estimation of the MM estimation is the same as the weighted M estimation with known scale.

Final Weighted Least Squares Estimation

Final weighted least squares estimation is always applied on the weighted data $(y_i{}^*, x_i{}^*)$ no matter how the weight variable is applied in the preceding estimation. For example, if the option METHOD=LTS is specified along with the option FWLS, although the outliers identified by LTS estimation do not depend on the weight variable, final weighted least squares estimation applies the weight variable on all the points that are not outliers.

Robust Distances and Leverage Detection

Robust distance computation ignores the weight variable. Because leverage detection depends on robust distance, it also ignores the weight variable.

INEST= Data Set

When you use M or MM estimation, you can use the INEST= data set to specify initial estimates for all the parameters in the model. The INEST= option is ignored if you specify LTS or S estimation by using the METHOD=LTS or METHOD=S option or if you specify the INITEST= option after the METHOD=MM option in the PROC statement. The INEST= data set must contain the intercept variable (named Intercept) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in a BY group, the first one read is used for that BY group.

If the INEST= data set also contains the _TYPE_ variable, only observations with _TYPE_ value "PARMS" are used as starting values.

You can specify starting values for the iteratively reweighted least squares algorithm in the INEST= data set. The INEST= data set has the same structure as the OUTEST= data set but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization.

OUTEST= Data Set

The OUTEST= data set contains parameter estimates for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different models used by the ROBUSTREG procedure. If the COVOUT option is specified, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates. If the ROBUSTREG procedure does not converge, the parameter estimates are set to missing in the OUTEST data set.

The OUTEST= data set contains all variables specified in the MODEL statement and the BY statement. One observation consists of parameter values for the model with the dependent variable having the value -1. If the COVOUT option is specified, there are additional observations that contain the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

MODEL	is a character variable that contains the label of the MODEL statement, if present. Otherwise, the variable's value is blank.
NAME	is a character variable that contains the name of the dependent variable for the parameter estimates or the name of the row for the covariance matrix estimates.
TYPE	is a character variable that contains the type of the observation, either PARMS for parameter estimates or COV for covariance estimates.
METHOD	is a character variable that contains the type of estimation method: either M estimation, LTS estimation, S estimation, or MM estimation.
STATUS	is a character variable that contains the status of model fitting: either Converged, Warning, or Failed.
INTERCEPT	is a numeric variable that contains the intercept parameter estimates and covariances.
SCALE	is a numeric variable that contains the scale parameter estimates.

Any BY variables specified are also added to the OUTEST= data set.

Computational Resources

The algorithms for the various estimation methods need a different amount of memory for working space. Let p be the number of parameters estimated and n be the number of observations used in the model estimation.

For M estimation, the minimum working space (in bytes) needed is

$$3n + 2p^2 + 30p$$

If sufficient space is available, the input data set is also kept in memory; otherwise, the input data set is read again for computing the iteratively reweighted least squares estimates and the execution time of the procedure increases substantially. For each reweighted least squares, $O(np^2 + p^3)$ multiplications and additions are required for computing the crossproduct matrix and its inverse. The $O(v)$ notation means that, for large values of the argument, v, $O(v)$ is approximately a constant times v.

Since the iteratively reweighted least squares algorithm converges very quickly (normally within fewer than 20 iterations), the computation of M estimates is fast.

LTS estimation is more expensive in computation. The minimum working space (in bytes) needed is

$$np + 12n + 4p^2 + 60p$$

The memory is mainly used to store the current data used by LTS for modeling. The LTS algorithm uses subsampling and spends much of its computing time on resampling and computing estimates for subsamples. Since it resamples if singularity is detected, it might take more time if the data set has serious singularities.

The MCD algorithm for leverage-point diagnostics is similar to the LTS algorithm.

ODS Table Names

The ROBUSTREG procedure assigns a name to each table it creates. You can specify these names when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 77.10 ODS Tables Produced by PROC ROBUSTREG

ODS Table Name	Description	Statement	Option
BestEstimates	Best final estimates for LTS	PROC	SUBANALYSIS
BestSubEstimates	Best estimates for each subgroup	PROC	SUBANALYSIS
BiasTest	Bias test for MM estimation	PROC	BIASTEST
ClassLevels	Classification variable levels	CLASS	Default
CorrB	Parameter estimate correlation matrix	MODEL	CORRB
CovB	Parameter estimate covariance matrix	MODEL	COVB
CStep	C-step for LTS fitting	PROC	SUBANALYSIS

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

If the model includes a single continuous independent variable, a plot of robust fit against this variable (FITPLOT) is provided by default. Two plots are particularly useful in revealing outliers and leverage

points. The first is a scatter plot of the standardized robust residuals against the robust distances (RDPLOT). The second is a scatter plot of the robust distances against the classical Mahalanobis distances (DDPLOT). In addition to these two plots, a histogram and a quantile-quantile plot of the standardized robust residuals are also helpful.

PROC ROBUSTREG assigns a name to each graph it creates using ODS. You can use these names to refer to the graphs when using ODS. The names and PLOTS= options are listed in Table 77.11.

Table 77.11 Graphs Produced by PROC ROBUSTREG

ODS Graph Name	Plot Description	Statement	PLOTS= Option
DDPlot	Robust distance versus Mahalanobis distance (or projected robust distance versus Projected Mahalanobis distance)	PROC	DDPLOT
FitPlot	Robust fit versus independent variable	PROC	FITPLOT
Histogram	Histogram of standardized robust residuals	PROC	HISTOGRAM
QQPlot	Q-Q plot of standardized robust residuals	PROC	QQPLOT
RDPlot	Standardized robust residual versus robust distance (or projected robust distance)	PROC	RDPLOT

Fit Plot

When the model has a single independent continuous variable (with or without the intercept), the ROBUSTREG procedure automatically creates a plot of robust fit against this independent variable.

The following simple example shows the fit plot. The data, from Rousseeuw and Leroy (1987, Table 3), include the logarithm of surface temperature and the logarithm of light intensity for 47 stars in the direction of the constellation Cygnus.

```
data star;
   input index x y @@;
   label x = 'Log Temperature'
         y = 'Log Light Intensity';
   datalines;
1   4.37  5.23     25  4.38  5.02
2   4.56  5.74     26  4.42  4.66
3   4.26  4.93     27  4.29  4.66
4   4.56  5.74     28  4.38  4.90
5   4.30  5.19     29  4.22  4.39
6   4.46  5.46     30  3.48  6.05
7   3.84  4.65     31  4.38  4.42
8   4.57  5.27     32  4.56  5.10
9   4.26  5.57     33  4.45  5.22
10  4.37  5.12     34  3.49  6.29
11  3.49  5.73     35  4.23  4.34
12  4.43  5.45     36  4.62  5.62
13  4.48  5.42     37  4.53  5.10
14  4.01  4.05     38  4.45  5.22
15  4.29  4.26     39  4.53  5.18
16  4.42  4.58     40  4.43  5.57
17  4.23  3.94     41  4.38  4.62
```

```
18  4.42  4.18     42  4.45  5.06
19  4.23  4.18     43  4.50  5.34
20  3.49  5.89     44  4.45  5.34
21  4.29  4.38     45  4.55  5.54
22  4.29  4.22     46  4.45  4.98
23  4.42  4.42     47  4.42  4.50
24  4.49  4.85
;
```

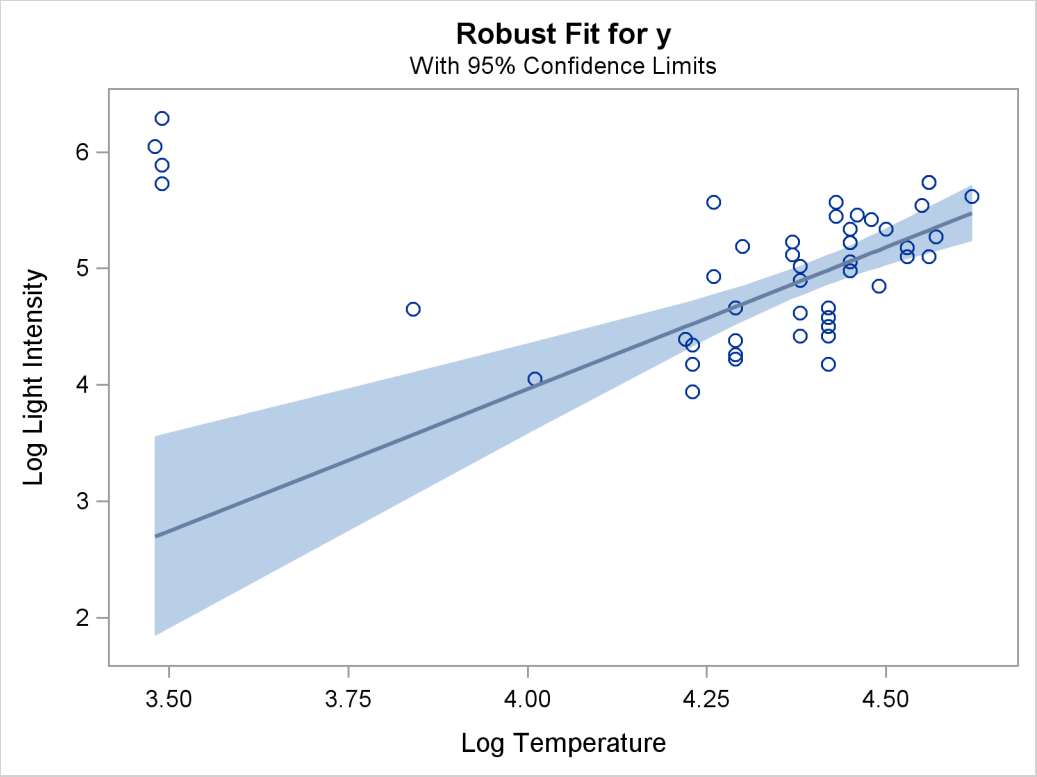
The following statements plot the robust fit of the logarithm of light intensity with the MM method against the logarithm of the surface temperature.

```
ods graphics on;

proc robustreg data=star method=mm ;
    model y = x;
run;
```

Figure 77.22 shows the fit plot. Confidence limits are added on the plot by default.

Figure 77.22 Robust Fit



You can suppress the confidence limits with the NOLIMITS option, as shown in the following statements:

```
proc robustreg data=star method=mm plot=fitplot(nolimits);
    model y = x;
run;
```

Distance-Distance Plot

The distance-distance plot (DDPLOT) is mainly used for leverage-point diagnostics. It is a scatter plot of the robust distances (or projected robust distances) against the classical Mahalanobis distances (or projected classical Mahalanobis distances) for the independent variables. See the section "Leverage Point and Outlier Detection" on page 6582 for details about the robust distance.

You can use the PLOT=DDPLOT option to request this plot. The following statements use the stack data set in the section "M Estimation" on page 6533 to create the single plot shown in Figure 77.5.

```
proc robustreg data=stack plot=ddplot;
   model y = x1 x2 x3;
run;
```

The reference lines represent the cutoff values. The diagonal line is also drawn to show the distribution of the distances. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the LABEL= option as described in Table 77.1.

If you specify ID variables in the ID statement, the values of the first ID variable instead of observation numbers are used as labels.

Residual-Distance Plot

The residual-distance plot (RDPLOT) is used for both outlier and leverage-point diagnostics. It is a scatter plot of the standardized robust residuals against the robust distances. See the section "Leverage Point and Outlier Detection" on page 6582 for details about the robust distance.

You can use the PLOT=RDPLOT option to request this plot. The following statements use the stack data set in the section "M Estimation" on page 6533 to create the plot shown in Figure 77.4.

```
proc robustreg data=stack plot=rdplot;
   model y = x1 x2 x3;
run;
```

The reference lines represent the cutoff values. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the LABEL= option as described in Table 77.1.

If you specify ID variables in the ID statement, the values of the first ID variable instead of observation numbers are used as labels.

Histogram and Q-Q Plot

PROC ROBUSTREG produces a histogram and a Q-Q plot for the standardized robust residuals. The histogram is superimposed with a normal density curve and a kernel density curve. Using the stack data set in the section "M Estimation" on page 6533, the following statements create the plots in Figure 77.6 and Figure 77.7.

```
proc robustreg data=stack plots=(histogram qqplot);
   model y = x1 x2 x3;
run;
```

Examples: ROBUSTREG Procedure

Example 77.1: Comparison of Robust Estimates

This example contrasts several of the robust methods available in the ROBUSTREG procedure.

The following statements generate 1,000 random observations. The first 900 observations are from a linear model, and the last 100 observations are significantly biased in the *y*-direction. In other words, 10% of the observations are contaminated with outliers.

```
data a (drop=i);
   do i=1 to 1000;
      x1=rannor(1234);
      x2=rannor(1234);
      e=rannor(1234);
      if i > 900 then y=100 + e;
      else y=10 + 5*x1 + 3*x2 + .5 * e;
      output;
   end;
run;
```

The following statements invoke PROC REG and PROC ROBUSTREG with the data set a.

```
proc reg data=a;
   model y = x1 x2;
run;

proc robustreg data=a method=m ;
   model y = x1 x2;
run;

proc robustreg data=a method=mm seed=100;
   model y = x1 x2;
run;

proc robustreg data=a method=s seed=100;
   model y = x1 x2;
run;

proc robustreg data=a method=lts seed=100;
   model y = x1 x2;
run;
```

The tables of parameter estimates generated by using M estimation, MM estimation, S estimation, and LTS estimation in the ROBUSTREG procedure are shown in Output 77.1.2, Output 77.1.3, Output 77.1.4, and Output 77.1.5, respectively. For comparison, the ordinary least squares (OLS) estimates produced by the REG procedure (Chapter 76, "The REG Procedure") are shown in Output 77.1.1. The four robust methods, M, MM, S, and LTS, correctly estimate the regression coefficients for the underlying model (10, 5, and 3), but the OLS estimate does not.

Output 77.1.1 OLS Estimates for Data with 10% Contamination

The next statements demonstrate that if the percentage of contamination is increased to 40%, the M method and the MM method with default options fail to estimate the underlying model. Output 77.1.6 and Output 77.1.7 display these estimates. However, by tuning the constant c for the M method and the constants INITH and K0 for the MM method, you can increase the breakdown values of the estimates and capture the right model. Output 77.1.8 and Output 77.1.9 display these estimates. Similarly, you can tune the constant EFF for the S method and the constant H for the LTS method and correctly estimate the underlying model with these methods. Results are not presented.

When there are bad leverage points, the M method fails to estimate the underlying model no matter what constant c you use. In this case, other methods (LTS, S, and MM) in PROC ROBUSTREG, which are robust to bad leverage points, correctly estimate the underlying model.

The following statements generate 1,000 observations with 1% bad high leverage points.

```
data c (drop=i);
   do i=1 to 1000;
      x1=rannor(1234);
      x2=rannor(1234);
      e=rannor(1234);
      if i > 600 then y=100 + e;
      else y=10 + 5*x1 + 3*x2 + .5 * e;
      if i < 11 then x1=200 * rannor(1234);
      if i < 11 then x2=200 * rannor(1234);
      if i < 11 then y= 100*e;
      output;
   end;
run;

proc robustreg data=c method=mm(inith=502 k0=1.8) seed=100;
   model y = x1 x2;
run;

proc robustreg data=c method=s(k0=1.8) seed=100;
   model y = x1 x2;
run;

proc robustreg data=c method=lts(h=502) seed=100;
   model y = x1 x2;
run;
```

Output 77.1.10 displays the MM estimates with initial LTS estimates, Output 77.1.11 displays the S estimates, and Output 77.1.12 displays the LTS estimates.

Output 77.1.10 MM Estimates for Data with 1% Leverage Points

Example 77.2: Robust ANOVA

The classical analysis of variance (ANOVA) technique based on least squares assumes that the underlying experimental errors are normally distributed. However, data often contain outliers due to recording or other errors. In other cases, extreme responses occur when control variables in the experiments are set to extremes. It is important to distinguish these extreme points and determine whether they are outliers or important extreme cases. You can use the ROBUSTREG procedure for robust analysis of variance based on M estimation. Typically, there are no high leverage points in a well-designed experiment, so M estimation is appropriate.

The following example shows how to use the ROBUSTREG procedure for robust ANOVA.

An experiment was carried out to study the effects of two successive treatments (T1, T2) on the recovery time of mice with certain diseases. Sixteen mice were randomly assigned into four groups for the four different combinations of the treatments. The recovery times (time) were recorded (in hours) as shown in the following data set recover.

```
data recover;
   input  T1 $ T2 $ time @@;
   datalines;
0 0 20.2  0 0 23.9  0 0 21.9  0 0 42.4
1 0 27.2  1 0 34.0  1 0 27.4  1 0 28.5
0 1 25.9  0 1 34.5  0 1 25.1  0 1 34.2
1 1 35.0  1 1 33.9  1 1 38.3  1 1 39.9
;
```

The following statements invoke the GLM procedure (Chapter 41, "The GLM Procedure") for a standard ANOVA:

```
proc glm data=recover;
    class T1 T2;
    model time = T1 T2 T1*T2;
run;
```

Output 77.2.1 Overall ANOVA

The GLM Procedure

Dependent Variable: time

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	3	209.9118750	69.9706250	1.86	0.1905

Example 77.3: Growth Study of De Long and Summers

Robust regression and outlier detection techniques have considerable applications to econometrics. The following example from Zaman, Rousseeuw, and Orhan (2001) shows how these techniques substantially improve the ordinary least squares (OLS) results for the growth study of De Long and Summers.

De Long and Summers (1991) studied the national growth of 61 countries from 1960 to 1985 by using OLS with the following data set growth.

```
data growth;
   input country$ GDP LFG EQP NEQ GAP @@;
   datalines;
Argentin  0.0089 0.0118 0.0214 0.2286 0.6079
Austria   0.0332 0.0014 0.0991 0.1349 0.5809
Belgium   0.0256 0.0061 0.0684 0.1653 0.4109
Bolivia   0.0124 0.0209 0.0167 0.1133 0.8634

   ... more lines ...

Venezuel  0.0120 0.0378 0.0340 0.0760 0.4974
Zambia   -0.0110 0.0275 0.0702 0.2012 0.8695
Zimbabwe  0.0110 0.0309 0.0843 0.1257 0.8875
;
```

The regression equation they used is

$$\mathrm{GDP} = \beta_0 + \beta_1 \mathrm{LFG} + \beta_2 \mathrm{GAP} + \beta_3 \mathrm{EQP} + \beta_4 \mathrm{NEQ} + \epsilon$$

where the response variable is the growth in gross domestic product per worker (GDP) and the regressors are labor force growth (LFG), relative GDP gap (GAP), equipment investment (EQP), and nonequipment investment (NEQ).

The following statements invoke the REG procedure (Chapter 76, "The REG Procedure") for the OLS analysis:

```
proc reg data=growth;
   model GDP  = LFG GAP EQP NEQ ;
run;
```

The OLS analysis shown in Output 77.3.1 indicates that GAP and EQP have a significant influence on GDP at the 5% level.

Output 77.3.1 OLS Estimates

NEQ	1	0.0849	0.0314	0.0233	0.1465	7.30	0.0069
Scale	0	0.0116					

Output 77.3.12 displays the final weighted least squares estimates, which are identical to those reported in Zaman, Rousseeuw, and Orhan (2001).

Example 77.4: Constructed Effects

The algorithms of PROC ROBUSTREG assume that a response variable is linearly dependent on the regressors. However, in practice, a response often depends on some factors in a nonlinear manner. This example demonstrates how a nonlinear response-factor relationship can be modeled by using constructed effects. (See the section "EFFECT Statement" on page 406 of Chapter 19, "Shared Concepts and Topics," for details.)

The following data set contains 526 female observations and 474 male observations sampled from 2003 National Health and Nutrition Examination Survey (NHANES). Each observation is composed of three values: *bmi* (body mass index), *age*, and *gender*, measured for subjects whose ages are between 20 and 60.

```
data one;
   input bmi age gender$ @@;
   datalines;
46.16 30.33 F 20.67 31.83 F 30.98 51.33 F 30.71 31.42 F

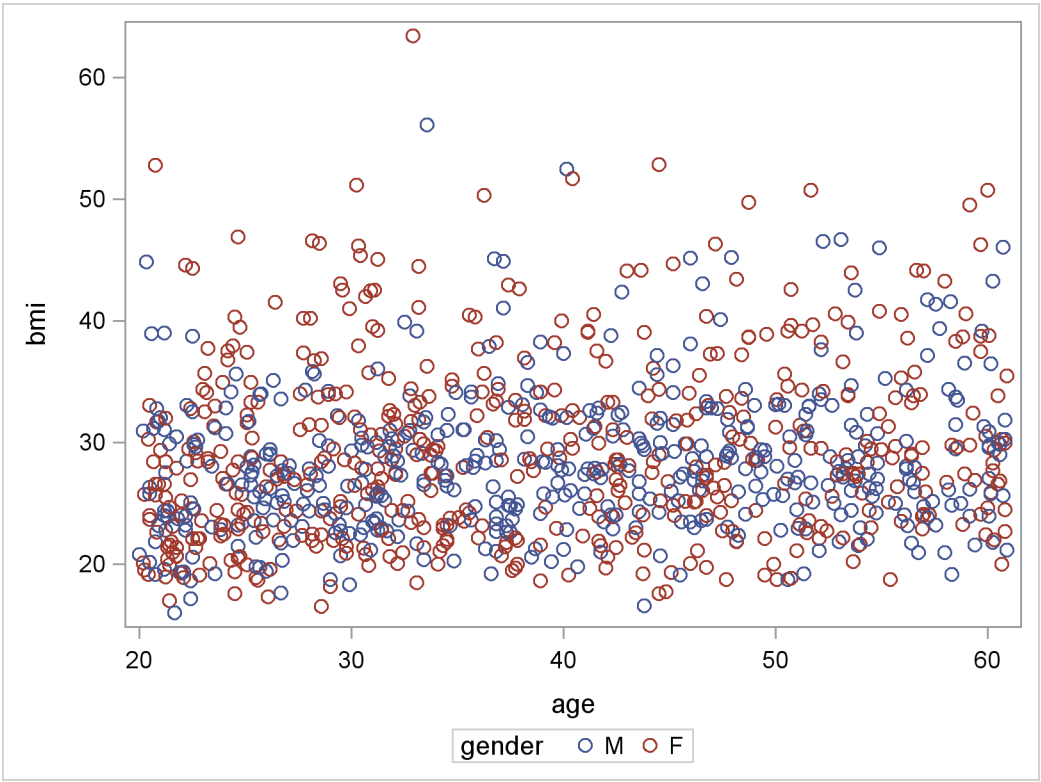
26.53 24.83 M 33.33 42.08 F 30.52 32.50 F 31.89 38.17 F
32.20 35.92 F 21.73 26.67 M 32.10 39.33 M 25.13 51.75 M
;
```

The goal of this analysis is to evaluate whether the *bmi-age* curves are different between women and men at a 5% significance level. In order to provide sufficient flexibility to model the effect of *age* on *bmi*, you can use regression splines that you define with an EFFECT statement. In this example, a regression spline of degree 2 with three knots is used for variable *age*. The knots are placed at the 25, 50, and 75 percentiles of *age*. This analysis assume that there is no interaction between *gender* and *age*, so that the *bmi-age* curves for women and men are the same up to a constant. The following statements produce the *bmi-age* scatter plot shown in Output 77.4.1:

```
proc sort data=one;
   by age;
run;

ods graphics on;
proc sgplot data=one;
   scatter x=age y=bmi/group=gender;
run;
```

Output 77.4.1 Scatter Plot for BMI Data



The observations with large *bmi* values (for example, *bmi* > 40) are outliers that can substantially influence an ordinary least squares (OLS) analysis. Output 77.4.1 shows that the distributions of *bmi* conditional on *age* are skewed toward the side of large *bmi*, and there are more observations with large *bmi* values (outliers) in the female group. Hence you can expect a significant *gender* difference in the *bmi-age* OLS regression analysis. This expectation is confirmed by the OLS *gender* *p*-value = 0.0059 in Output 77.4.2, which is produced by the following statements:

```
proc glmselect data=one;
   class gender;
   effect age_sp=spl(age/degree=2 knotmethod=percentiles(3));
   model bmi= gender age_sp /selection=none showpvalues;
   output out=out_ols P=pred R=res;
run;
```

Output 77.4.2 OLS Estimates

The GLMSELECT Procedure
Least Squares Model (No Selection)

Parameter Estimates

Parameter		DF	Estimate	Standard Error	t Value	Pr > |t|
Intercept		1	29.890089	1.022825	29.22	<.0001
gender	F	1	1.167332	0.422565	2.76	0.0058
gender	M	0	0	.	.	.
age_sp	1	1	-4.404487	1.473761	-2.99	0.0029
age_sp	2	1	-3.329537	1.374096	-2.42	0.0156
age_sp	3	1	-0.966875	1.314964	-0.74	0.4623
age_sp	4	1	-1.611621	1.123854	-1.43	0.1519
age_sp	5	1	-0.484787	1.701281	-0.28	0.7757
age_sp	6	0	0	.	.	.

A robust regression method can reduce the outlier influence by automatically assigning smaller or even zero weights to outliers. For the *bmi* data, a robust regression method is likely to set less weight on observations with large *bmi*, so more female observations would receive smaller weights than male observations. The following statements invoke PROC ROBUSTREG with the *bmi* data set:

```
proc robustreg data=one method=s seed=100;
   class gender;
   effect age_sp=spl(age/degree=2 knotmethod=percentiles(3));
   model bmi = gender age_sp;
   output out=out_s P=pred R=res;
run;
```

Output 77.4.3 shows the parameter estimates and the diagnostics summary produced by PROC ROBUSTREG with the S method. In contrast to OLS, the robust *p*-value= 0.5573 of the *gender* coefficient indicates that the *gender* effect is not significant. The outlier diagnostics based on the S estimates find 19 outliers that are assigned lower weights by the S method than by the OLS method.

Output 77.4.3 S Estimates and S Diagnostics Summary

Diagnostics Summary

Observation Type	Proportion	Cutoff
Outlier	0.0190	3.0000

To further compare the OLS and S outputs, the following statements plot the *bmi* predictions in variable *age* for both methods in the same graph, which is shown in Output 77.4.4:

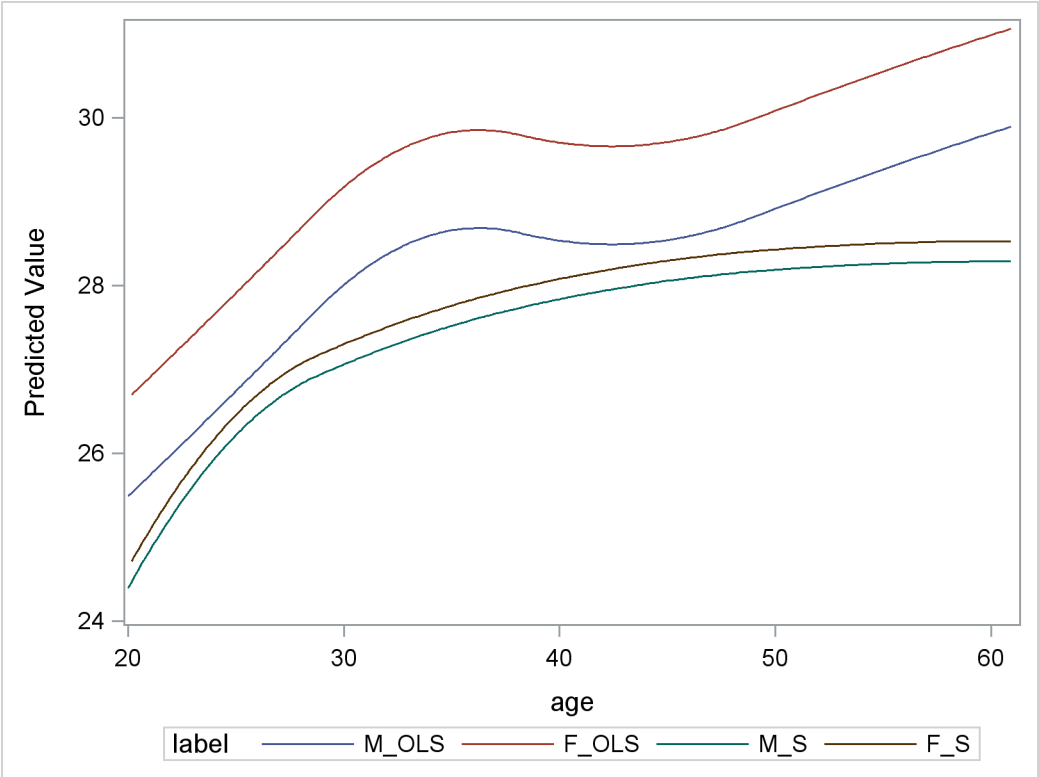
```
data out2_s;
   set out_s;
   if gender="F" then label="F_S  ";
   if gender="M" then label="M_S  ";
run;

data out2_ols;
   merge one out_ols;
   if gender='F' then label='F_OLS';
   if gender='M' then label='M_OLS';
   keep pred bmi gender age label;
run;

data out2;
   set out2_ols out2_s;
run;

proc sgplot data=out2;
   series x=age y=pred/group=label;
run;
```

Output 77.4.4 OLS and S Predictions



You can observe the following differences between the OLS and S predictions:

- The OLS prediction is larger
- The OLS curves have a local maximum near $age = 35$

Then, a question remains: is the significance of the *gender* effect for the OLS regression due solely to the outlying observations? To tentatively answer this question, the following statements drop the observations with the top 10% of *bmi* values from the original data set and reapply OLS and S methods on the reduced data set:

```
data three;
   set one;
   where bmi<38.315;
run;

proc robustreg data=three method=s seed=100;
   class gender;
   effect age_sp=spl(age/degree=2 knotmethod=percentiles(3));
   model bmi = gender age_sp;
   output out=out_s P=pred R=res;
run;

data out2_s;
   set out_s;
```

```
   if gender="F" then label="F_S  ";
   if gender="M" then label="M_S  ";
run;

proc glmselect data=three outdesign=four;
   class gender;
   effect age_sp=spl(age/degree=2 knotmethod=percentiles(3));
   model bmi= gender age_sp /selection=none showpvalues;
   output out=out_ols P=pred R=res;
run;

data out2_ols;
   merge three out_ols;
   if gender='F' then label='F_OLS';
   if gender='M' then label='M_OLS';
   keep pred bmi gender age label;
run;

data out2;
   set out2_ols out2_s;
run;

proc sgplot data=out2;
   series x=age y=pred/group=label;
run;
ods graphics off;
```

Output 77.4.5 S Estimates

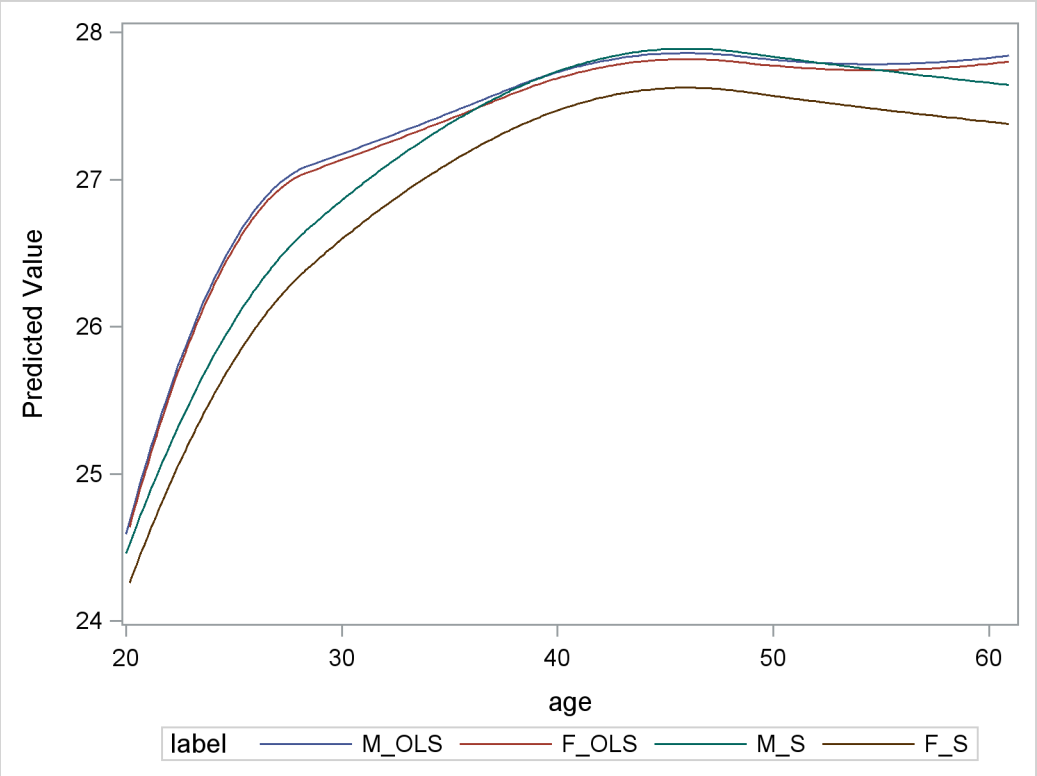
Output 77.4.7 OLS and S Predictions on the Reduced Data Set



In the reduced data set, 71 female observations and 29 male observations are dropped. Output 77.4.5 and Output 77.4.6 respectively show the refitted S and OLS parameter estimates, and Output 77.4.7 displays the fitted curves on the reduced data set. You can see that *gender* is no longer significant for the OLS model, and the OLS turning pattern has also disappeared, but the new S curves do not change much from the previous ones. The OLS *bmi-age* curves in Output 77.4.7 are closer to the S curves than to the OLS curves in Output 77.4.4. This suggests that indeed the difference between the OLS and S estimate results are due solely to the influence of the outlying observations.

Example 77.5: Robust Diagnostics

This example models the selling price of a house as a function of several covariates. One of these covariates is a classification variable that indicates whether a house is located on a corner lot (called a corner house in this example). Because corner houses are relatively rare, the inclusion of this classification effect in the model introduces a low-dimensional structure (that is, the majority of the observations are located in a lower dimensional hyperplane defined by being non-corner houses) into the design matrix. As discussed in "Robust Distance" on page 6576, the presence of this low dimensional structure causes difficulties in the traditional computation of robust distances. This example illustrates how you can use the projected robust distance to address those difficulties and to obtain meaningful leverage diagnostics. It also shows how you can use the RDPLOT and DDPLOT options to illustrate the outlier-leverage relationship.

The following house price data set contains 66 home resale records on seven variables from February 15 to April 30, 1993 (The Data and Story Library, 2005). The records are randomly selected from the database maintained by the Albuquerque Board of Realtors.

```
data house;
   input price sqft age feats ne cor tax @@;
   label price = "Selling price"
         sqft  = "Square feet of living space"
         age   = "Age of home in year"
         feats = "Number out of 11 features (dishwasher, refrigerator,
                  microwave, disposer, washer, intercom, skylight(s),
                  compactor, dryer, handicap fit, cable TV access)"
         ne    = "Located in northeast sector of city (1) or not (0)"
         cor   = "Corner location (1) or not (0)"
         tax   = "Annual taxes";
   sum = sqft+age+feats+ne+cor+tax;
   id  = _N_;
   datalines;
2050 2650 13 7 1 0 1639
2150 2664  6 5 1 0 1193

1999 2580  4 4 1 0 1732

   ... more lines ...

 870 1273  4 4 0 0  638
 869 1165  7 4 0 0  694
 766 1200  7 4 0 1  634
 739  970  4 4 0 1  541
;
```

To illustrate the dependence detection ability of the generalized MCD algorithm, an extra variable sum is created such that all the observations satisfy

$$\text{sum} = \text{sqft} + \text{age} + \text{feats} + \text{ne} + \text{cor} + \text{tax}$$

Adding sum does not change the rank of the original design matrix, so that sum is expected to be ignored in the model and also in the diagnostics. The next statements apply the MM method and the generalized MCD algorithm to the house price data.

```
ods graphics on;
proc robustreg data=house method=MM plots=all;
   model price= sqft age feats ne cor tax sum/leverage(opc mcdinfo) diagnostics;
run;
```

As shown in Output 77.5.1 and Output 77.5.2, PROC ROBUSTREG finds the design dependence equation and forces the parameter estimate of variable sum to be zero.

Output 77.5.1 MM Estimates

The ROBUSTREG Procedure

Parameter Estimates

Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	46.4062	79.1714	-108.767	201.5792	0.34	0.5578
sqft	1	0.3809	0.0756	0.2327	0.5291	25.37	<.0001
age	1	-2.6067	1.7610	-6.0582	0.8449	2.19	0.1388
feats	1	8.3627	14.7107	-20.4697	37.1951	0.32	0.5697
ne	1	65.0081	40.1329	-13.6508	143.6671	2.62	0.1053
cor	1	-19.2997	38.1907	-94.1520	55.5526	0.26	0.6133
tax	1	0.4699	0.1260	0.2229	0.7170	13.90	0.0002
sum	0	0.0000	.	.	.	.	.
Scale	0	157.5593					

Output 77.5.2 Design Dependence Equations

```
NOTE: The following variables have been ignored in the MCD computation because
      of linear dependence.

                  sum =  sqft + age + feats + ne + cor + tax
```

Moreover, PROC ROBUSTREG also identifies a robust dependence equation on cor in Output 77.5.3, which holds for 77.27% of the observations but not for the entire data set.

Output 77.5.3 Robust Dependence Equations

```
NOTE:  The following robust dependence equations simultaneously hold for 77.27%
      of the observations in the data set. The breakdown setting for the MCD
      algorithm is 22.73%.

                                  cor =  0
```

Another way to represent the low-dimensional structure is to specify the coefficients of the MCD-dropped components on the data (see Output 77.5.4), which form a basis of the complementary space to the relevant low-dimensional hyperplane.

Output 77.5.4 Coefficients for MCD-Dropped Components

Coefficients for MCD-Dropped Components

Parameter	Design Drop0	Robust Drop1
sqft	0	0
age	0	0
feats	0	0
ne	0	0
cor	0	1.0000
tax	0	0
sum	1.0000	0

By definitions of projected robust distance and leverage point, an observation is called an off-plane leverage point if at least one of the robust or design dependence equations does not apply to the observation. In this example, the observations with cor $= 1$ are all off-plane leverage points. Output 77.5.5 lists the leverage points and outliers along with the relevant distance measurements and standardized residuals.

Output 77.5.5 Diagnostics

Diagnostics

Obs	Projected Distance: Mahalanobis	Projected Distance: Robust	Projected Distance: Off-Plane	Leverage	Standardized Robust Residual	Outlier
1	3.5567	4.0211	0.0000	*	0.8522	
13	4.0034	5.2310	0.0000	*	0.1411	
15	1.3221	1.5219	2.3681	*	0.0226	
16	1.0839	1.0905	2.3681	*	0.4148	
18	1.9452	2.4655	2.3681	*	-0.2789	
20	3.6006	4.0771	2.3681	*	-0.0150

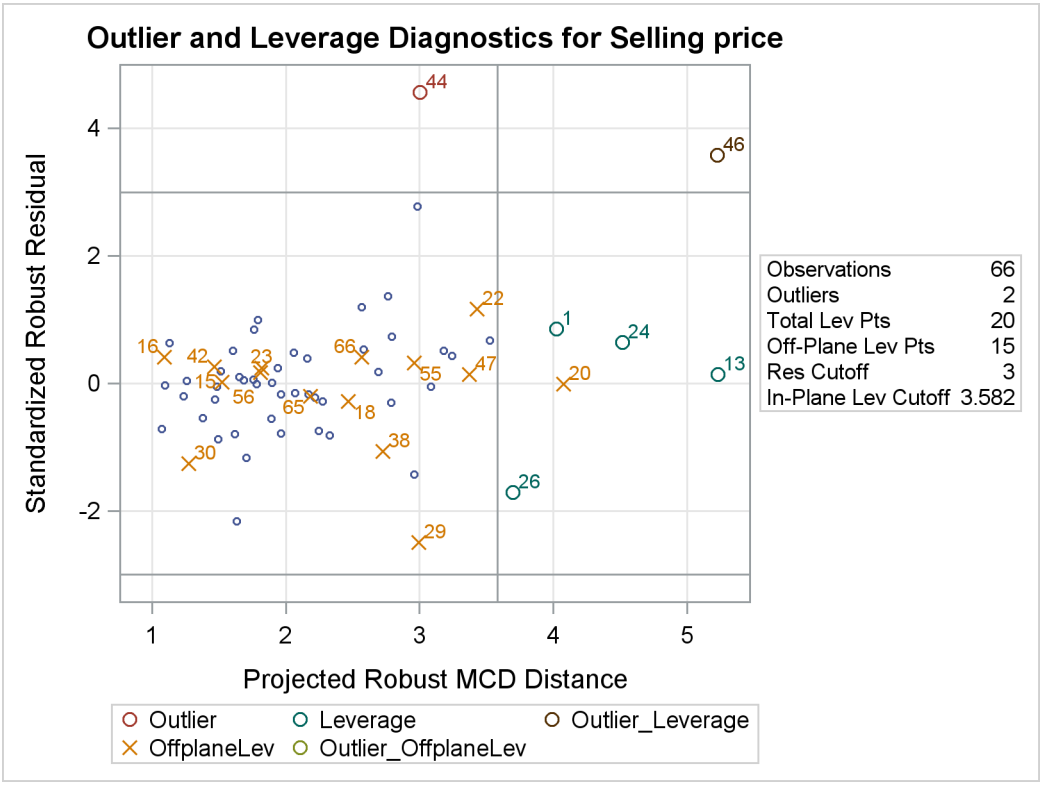
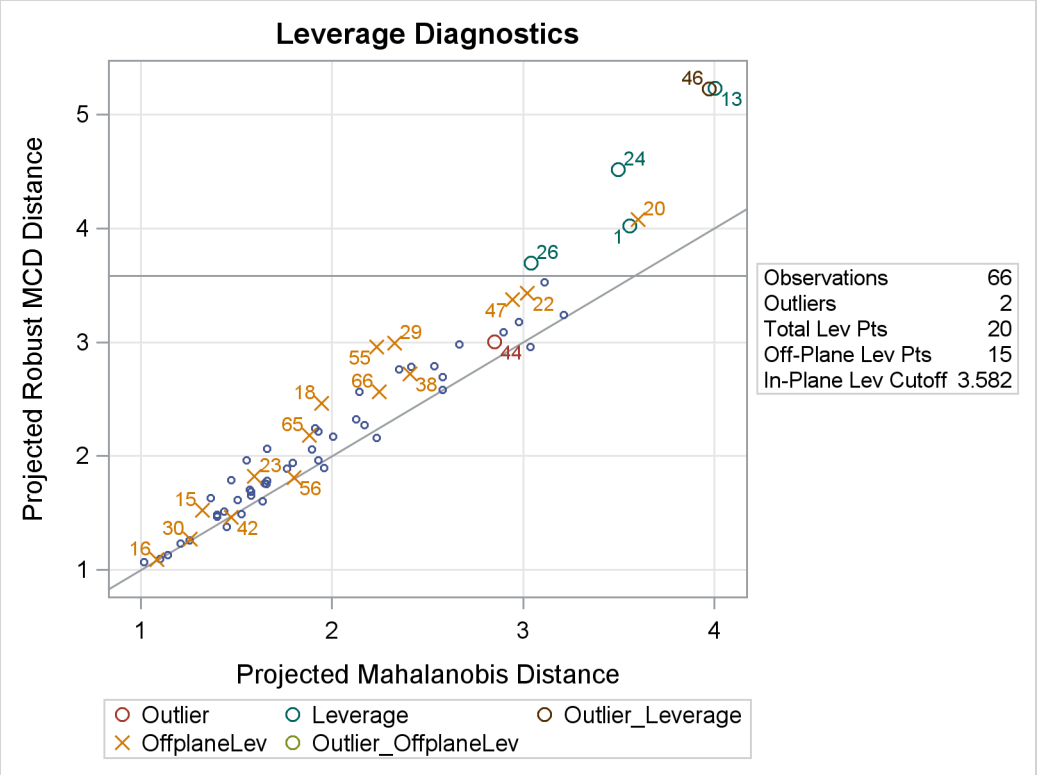
30	1.2587	1.2714	2.3681	*	-1.2558	
38	2.4064	2.7249	2.3681	*	-1.0620	
42	1.4722	1.4645	2.3681	*	0.2584	
44	2.8491	3.0019	0.0000		4.5665	*
46	3.9725	5.2271	0.0000	*	3.5835	*
47	2.9431	3.3728	2.3681	*	0.1365	
55	2.2325	2.9590	2.3681	*	0.3217	
56	1.7999	1.8119	2.3681	*	0.1715	
65	1.8831	2.1822	2.3681	*	-0.1990	
66	2.2483	2.5673	2.3681	*	0.4134	

From Output 77.5.6 and Output 77.5.7, you can see that there is no apparent corner-related difference for the houses in terms of standardized robust residual and projected MD versus projected RD, although all the corner houses are defined as off-plane leverage points.

Output 77.5.6 Projected RDPLOT



Output 77.5.7 Projected DDPLOT



Output 77.5.8 shows more details of the robust diagnostics. The number of dimensions indicates that six regressors are used in the MCD analysis. Since sum is excluded in model fitting, it is ignored in the MCD analysis. The number of robust dropped components equals 1 due to cor. The number of off-plane points implies the 15 corner-house observations. The reweighted value of H is the number of observations that are finally used to estimate the MCD covariance.

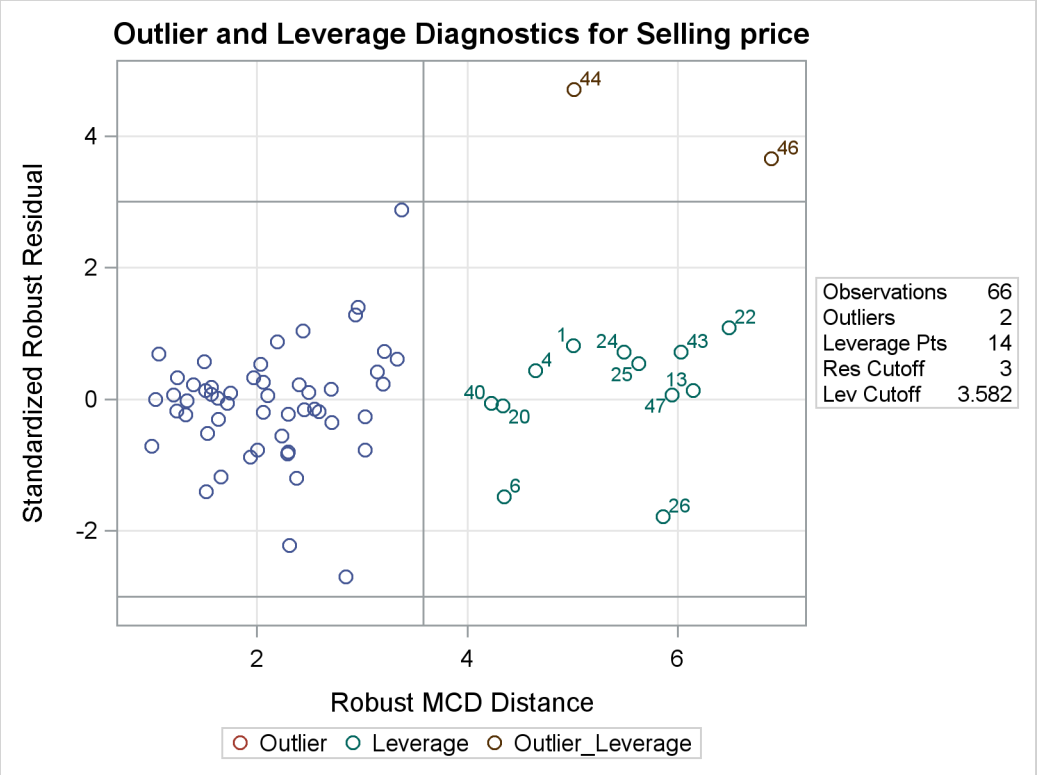
sum	0.986126	−0.21829	0.448759	0.339204	0	0.968747	1

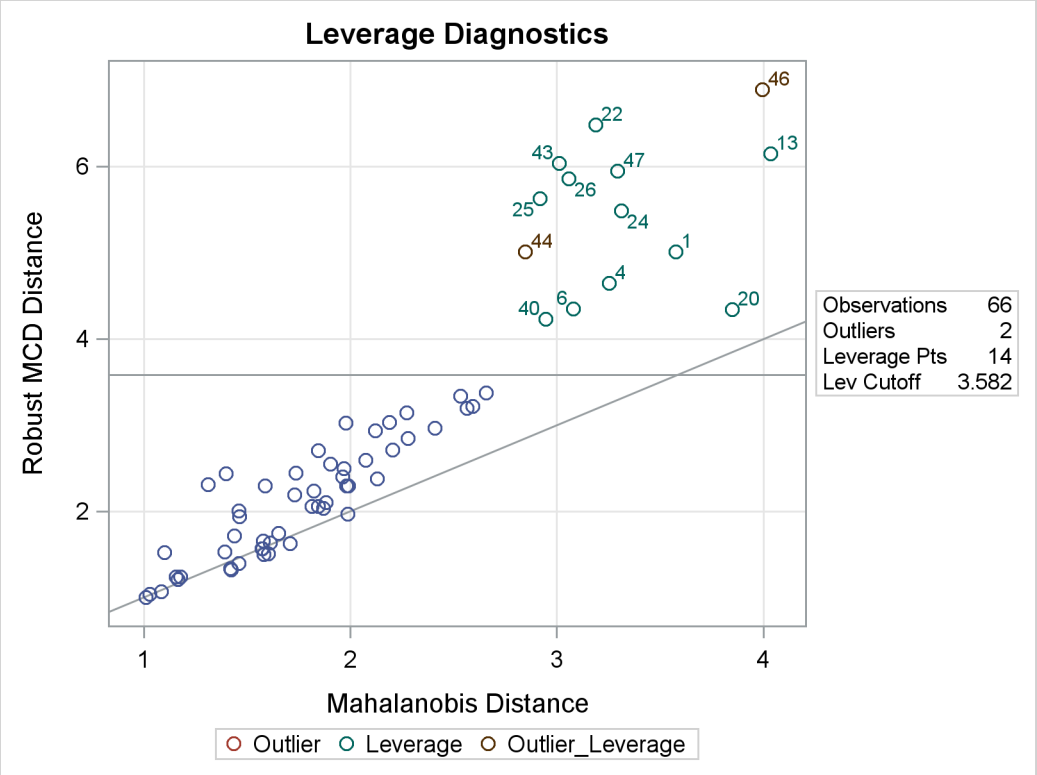
You might speculate that the projected MD and projected RD are equal to the regular MD and RD on the same data set without the variable cor. In fact, this is not true. (See Output 77.5.9 and Output 77.5.10 for the RDPLOT and DDPLOT on the data set without cor.) When included in the MODEL, cor is dropped in the distance calculation, but it is still used for the initial orthonormalization step and the h-subset searching. In this example, inclusion of cor causes all the other covariates to be centered separately for corner houses and non-corner houses. However, without cor, the centering process does not distinguish corner houses from non-corner houses, so that the MCD algorithm can still be influenced by cor through the correlation between cor and other covariates. The following statements drop the variable cor and produce the RDPLOT and DDPLOT for the reduced model, which are shown in Output 77.5.9 and Output 77.5.10:

```
proc robustreg data=house method=MM plots=all;
  model price= sqft age feats ne tax/leverage(mcdinfo) diagnostics;
run;
ods graphics off;
```

Output 77.5.9 RDPLOT for the Reduced Model



Output 77.5.10 DDPLOT for the Reduced Model



Compared with Output 77.5.8, Output 77.5.11 shows the changes of the MCD information by removing cor from the model. You can see that the corner houses are no longer identified as off-plane points and the reweighted value of H is increased from 47 to 52. The breakdown value is intact because it depends only on the specified value of H and the total number of observations.

Output 77.5.11 MCD Information for the Reduced Model

Chapter 78

The RSREG Procedure

Contents

Overview: RSREG Procedure

The RSREG procedure uses the method of least squares to fit quadratic response surface regression models. Response surface models are a kind of general linear model in which attention focuses on characteristics of the fit response function and in particular, where optimum estimated response values occur.

In addition to fitting a quadratic function, you can use the RSREG procedure to do the following:

- test for lack of fit
- test for the significance of individual factors
- analyze the canonical structure of the estimated response surface
- compute the ridge of optimum response
- predict new values of the response

The RSREG procedure uses ODS Graphics to display the response surfaces, residuals, fit diagnostics, and ridges of optimum response. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS."

Comparison to Other SAS Software

Other SAS/STAT procedures can be used to fit the response surface, but the RSREG procedure is more specialized. PROC RSREG uses a much more compact model syntax than other procedures; for example, the following statements model a three-factor response surface in the REG, GLM, and RSREG procedures:

```
proc reg;
   model y=x1 x1*x1
           x2 x1*x2 x2*x2
           x3 x1*x3 x2*x3 x3*x3;
run;

proc glm;
   model y=x1|x2|x3@2;
run;

proc rsreg;
   model y=x1 x2 x3;
run;
```

Additionally, PROC RSREG includes specialized methodology for analyzing the fitted response surface, such as canonical analysis and optimum response ridges.

Note that the ADX Interface in SAS/QC software provides an *interactive* environment for constructing and analyzing many different kinds of experiments, including response surface experiments. The ADX Interface is the preferred interactive SAS System tool for analyzing experiments, since it includes facilities for checking underlying assumptions and graphically optimizing the response surface; see *Getting Started with the SAS ADX Interface for Design of Experiments* for more information. The RSREG procedure is appropriate for analyzing experiments in a batch environment.

Terminology

Variables are referred to according to the following conventions:

factor variables	independent variables used to construct the quadratic response surface. To estimate the necessary parameters, each variable must have at least three distinct values in the data. Independent variables must be numeric.
response variables	the dependent variables to which the quadratic response surfaces are fit. Dependent variables must be numeric.
covariates	additional independent variables for use in the regression but not in the formation of the quadratic response surface. Covariates must be numeric.
WEIGHT variable	a variable for weighting the observations in the regression. The WEIGHT variable must be numeric.
ID variables	variables not previously described that are transferred to an output data set containing statistics for each observation in the input data set. This data set is created by using the OUT= option in the PROC RSREG statement. ID variables can be either character or numeric.
BY variables	variables for grouping observations. Separate analyses are obtained for each BY group. BY variables can be either character or numeric.

Getting Started: RSREG Procedure

A Response Surface with a Simple Optimum

This example uses the three-factor quadratic model discussed in John (1971). Settings of the temperature, gas–liquid ratio, and packing height are controlled factors in the production of a certain chemical; Schneider and Stockett (1963) performed an experiment in order to determine the values of these three factors that minimize the unpleasant odor of the chemical. The following statements input the SAS data set smell; the variable Odor is the response, while the variables T, R, and H are the independent factors.

```
title 'Response Surface with a Simple Optimum';
data smell;
   input Odor T R H @@;
   label
      T = "Temperature"
      R = "Gas-Liquid Ratio"
      H = "Packing Height";
   datalines;
 66 40 .3 4     39 120 .3 4     43 40 .7 4     49 120 .7  4
 58 40 .5 2     17 120 .5 2     -5 40 .5 6    -40 120 .5  6
 65 80 .3 2      7  80 .7 2     43 80 .3 6    -22  80 .7  6
-31 80 .5 4    -35  80 .5 4    -26 80 .5 4
;
```

The following statements invoke PROC RSREG on the data set smell. Figure 78.1 through Figure 78.3 display the results of the analysis, including a lack-of-fit test requested with the LACKFIT option.

```
proc rsreg data=smell;
   model Odor = T R H / lackfit;
run;
```

Figure 78.1 displays the coding coefficients for the transformation of the independent variables to lie between −1 and 1, simple statistics for the response variable, hypothesis tests for linear, quadratic, and crossproduct terms, and the lack-of-fit test. The hypothesis tests can be used to gain a rough idea of importance of the effects; here the crossproduct terms are not significant. However, the lack of fit for the model is significant, so more complicated modeling or further experimentation with additional variables should be performed before firm conclusions are made concerning the underlying process.

Figure 78.1 Summary Statistics and Analysis of Variance

Response Surface with a Simple Optimum

The RSREG Procedure

Coding Coefficients for the Independent Variables

Factor	Subtracted off	Divided by
T	80.000000	40.000000
R	0.500000	0.200000
H	4.000000	2.000000

Response Surface for Variable Odor

Response Mean	15.200000
Root MSE	22.478508
R-Square	0.8820
Coefficient of Variation	147.8849

Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Linear	3	7143.250000	0.3337	4.71	0.0641
Quadratic	3	11445	0.5346	7.55	0.0264
Crossproduct	3	293.500000	0.0137	0.19	0.8965
Total Model	9	18882	0.8820	4.15	0.0657

Residual	DF	Sum of Squares	Mean Square	F Value	Pr > F
Lack of Fit	3	2485.750000	828.583333	40.75	0.0240
Pure Error	2	40.666667	20.333333		
Total Error	5	2526.416667	505.283333		

Parameter estimates and the factor ANOVA are shown in Figure 78.2. Looking at the parameter estimates, you can see that the crossproduct terms are not significantly different from zero, as noted previously. The Estimate column contains estimates based on the raw data, and the Parameter Estimate from Coded Data column contains estimates based on the coded data. The factor ANOVA table displays tests for all four parameters corresponding to each factor—the parameters corresponding to the linear effect, the quadratic effect, and the effects of the crossproducts with each of the other two factors. The only factor with a significant overall effect is R, indicating that the level of noise left unexplained by the model is still too high to estimate the effects of T and H accurately. This might be due to the lack of fit.

Figure 78.2 Parameter Estimates and Hypothesis Tests

Parameter	DF	Estimate	Standard Error	t Value	Pr > |t|	Parameter Estimate from Coded Data
Intercept	1	568.958333	134.609816	4.23	0.0083	-30.666667
T	1	-4.102083	1.489024	-2.75	0.0401	-12.125000
R	1	-1345.833333	335.220685	-4.01	0.0102	-17.000000
H	1	-22.166667	29.780489	-0.74	0.4902	-21.375000
T*T	1	0.020052	0.007311	2.74	0.0407	32.083333
R*T	1	1.031250	1.404907	0.73	0.4959	8.250000
R*R	1	1195.833333	292.454665	4.09	0.0095	47.833333
H*T	1	0.018750	0.140491	0.13	0.8990	1.500000
H*R	1	-4.375000	28.098135	-0.16	0.8824	-1.750000
H*H	1	1.520833	2.924547	0.52	0.6252	6.083333

Factor	DF	Sum of Squares	Mean Square	F Value	Pr > F	Label
T	4	5258.016026	1314.504006	2.60	0.1613	Temperature
R	4	11045	2761.150641	5.46	0.0454	Gas-Liquid Ratio
H	4	3813.016026	953.254006	1.89	0.2510	Packing Height

Figure 78.3 displays the canonical analysis and eigenvectors. The canonical analysis indicates that the directions of principal orientation for the predicted response surface are along the axes associated with the three factors, confirming the small interaction effect in the regression ANOVA (Figure 78.1). The largest eigenvalue (48.8588) corresponds to the eigenvector $\{0.238091,\ 0.971116,\ -0.015690\}$, the largest component of which (0.971116) is associated with R; similarly, the second-largest eigenvalue (31.1035) is associated with T. The third eigenvalue (6.0377), associated with H, is quite a bit smaller than the other two, indicating that the response surface is relatively insensitive to changes in this factor. The coded form of the canonical analysis indicates that the estimated response surface is at a minimum when T and R are both near the middle of their respective ranges (that is, the coded critical values for T and R are both near 0) and H is relatively high; in uncoded terms, the model predicts that the unpleasant odor is minimized when $T = 84.876502$, $R = 0.539915$, and $H = 7.541050$.

Figure 78.3 Canonical Analysis and Eigenvectors

Factor	Critical Value Coded	Uncoded	Label
T	0.121913	84.876502	Temperature
R	0.199575	0.539915	Gas-Liquid Ratio
H	1.770525	7.541050	Packing Height

Predicted value at stationary point: -52.024631

Eigenvalues	Eigenvectors T	R	H
48.858807	0.238091	0.971116	-0.015690
31.103461	0.970696	-0.237384	0.037399
6.037732	-0.032594	0.024135	0.999177

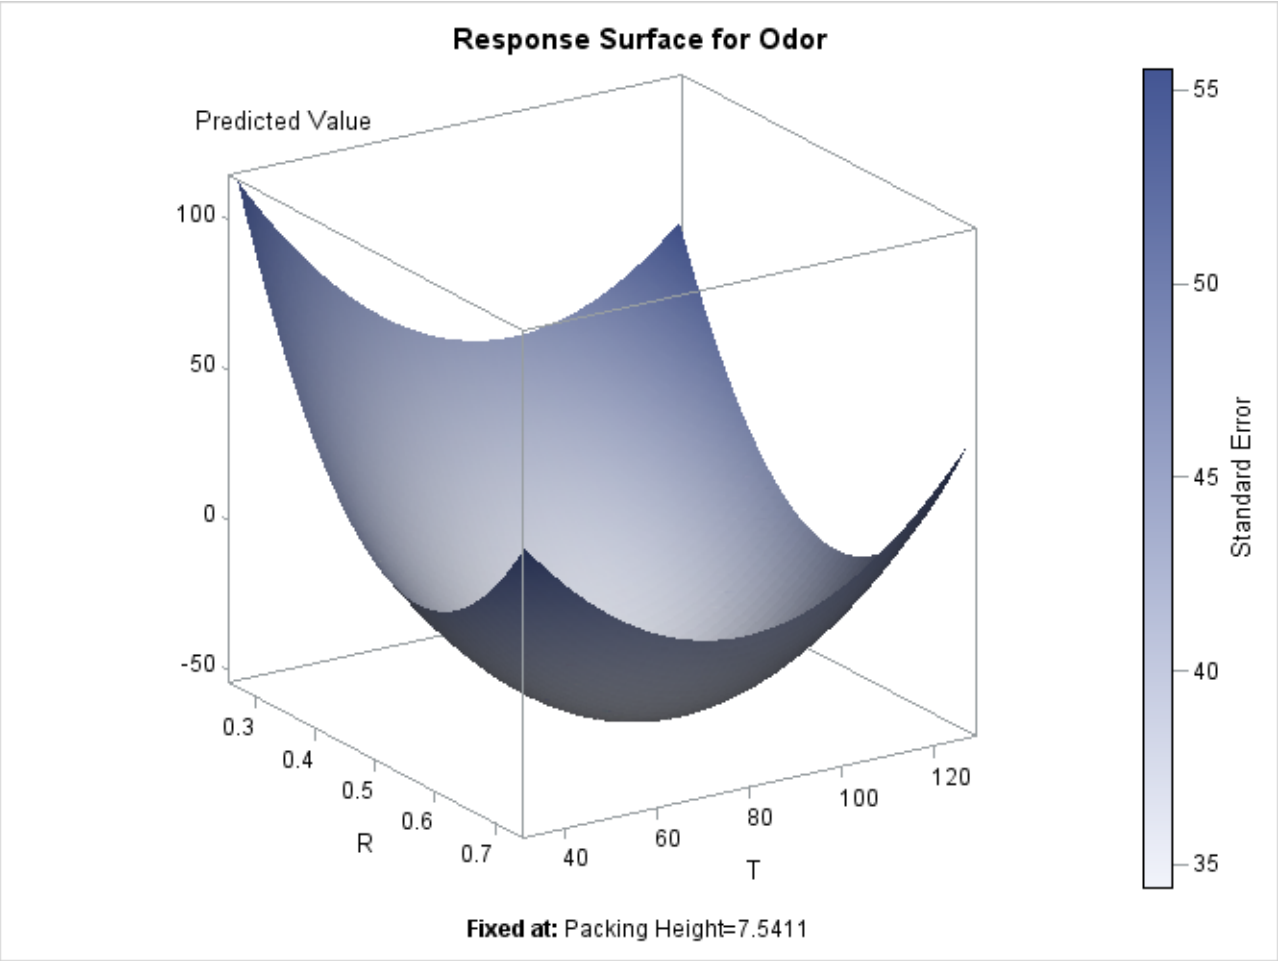
Stationary point is a minimum.

To plot the response surface with respect to two of the factor variables, fix H, the least significant factor variable, at its estimated optimum value. The following statements use ODS Graphics to display the surface:

```
ods graphics on;
proc rsreg data=smell
           plots(unpack)=surface(3d at(H=7.541050));
   model Odor = T R H;
   ods select 'T * R = Pred';
run;
ods graphics off;
```

Note that the ODS SELECT statement is specified to select the plot of interest.

Figure 78.4 The Response Surface at the Optimum H



Alternatively, the following statements produce an output data set containing the surface information, which you can then use for plotting surfaces or searching for optima. The first DATA step fixes H, the least significant factor variable, at its estimated optimum value (7.541), and generates a grid of points for T and R. To ensure that the grid data do not affect parameter estimates, the response variable (Odor) is set to missing. (See the section "Missing Values" on page 6646.) The second DATA step concatenates these grid points to the original data. Then PROC RSREG computes predictions for the combined data. The last DATA step subsets the predicted values over just the grid points, which excludes the predictions at the original data.

```
data grid;
   do;
      Odor =  .  ;
      H    = 7.541;
      do T = 20 to 140 by 5;
         do R = .1 to .9 by .05;
            output;
         end;
      end;
   end;
data grid;
   set smell grid;
run;
```

```
proc rsreg data=grid out=predict noprint;
   model Odor = T R H / predict;
run;

data grid;
   set predict;
   if H = 7.541;
run;
```

Syntax: RSREG Procedure

The following statements are available in PROC RSREG.

PROC RSREG < *options* > **;**
MODEL *responses= independents* < */ options* > **;**
RIDGE < *options* > **;**
WEIGHT *variable* **;**
ID *variables* **;**
BY *variables* **;**

The PROC RSREG and MODEL statements are required.

The BY, ID, MODEL, RIDGE, and WEIGHT statements are described after the PROC RSREG statement, and they can appear in any order.

PROC RSREG Statement

PROC RSREG < *options* > **;**

The PROC RSREG statement invokes the procedure. You can specify the following options in the PROC RSREG statement.

DATA=*SAS-data-set*
specifies the input SAS data set that contains the data to be analyzed. By default, PROC RSREG uses the most recently created SAS data set.

NOPRINT
suppresses the normal display of results when only the output data set is required.

For more information, see the description of the NOPRINT option in the MODEL and RIDGE statements.

Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, "Using the Output Delivery System," for more information.

OUT=*SAS-data-set*

creates an output SAS data set that contains statistics for each observation in the input data set. In particular, this data set contains the BY variables, the ID variables, the WEIGHT variable, the variables in the MODEL statement, and the output options requested in the MODEL statement. You must specify output statistic options in the MODEL statement; otherwise, the output data set is created but contains no observations. To create a permanent SAS data set, you must specify a two-level name (see *SAS Language Reference: Concepts* for more information about permanent SAS data sets). For more details, see the section "OUT=SAS-data-set" on page 6651.

PLOTS <(*global-plot-option***) >=***plot-request< (options)* **>**

PLOTS <(*global-plot-option***) >=(***plot-request< (options)* **>< . . .** *plot-request< (options)* **> >)**

controls the plots produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses from around the *plot-request*. For example:

```
plots = all
plots = (diagnostics ridge surface(unpack))
plots(unpack) = surface(overlaypairs)
```

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;
proc rsreg plots=all;
   model y=x;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

By default, no graphs are created; you must specify the PLOTS= option to make graphs. See Figure 78.4, Output 78.1.5, Output 78.1.6, Output 78.2.3, and Output 78.2.4 for examples of the ODS graphical displays.

The following *global-plot-option* is available.

UNPACKPANELS | UNPACK

suppresses paneling. By default, multiple plots can appear in some output *panels*. Specify the UNPACK option to display each plot separately.

The following *plot-requests* are available.

ALL

produces all appropriate plots. You can specify other options with ALL; for example, to display all plots and unpack the SURFACE contours you can specify **`plots=(all surface(unpack))`**.

DIAGNOSTICS <(LABEL | UNPACK)>

displays a panel of summary fit diagnostic plots. The plots produced and their usage are discussed in Table 78.1.

Table 78.1 Diagnostic Plots

Diagnostic Plot	Usage
Cook's *D* statistic versus observation number	Evaluate influence of an observation on the entire parameter estimate vector
Dependent variable values versus predicted values	Evaluate adequacy of fit and detect influential observations
Externally studentized residuals (RStudent) versus leverage	Detect outliers and influential (high-leverage) observations
Externally studentized residuals versus predicted values	Evaluate adequacy of fit and detect outliers
Histogram of residuals	Confirm normality of error terms
Normal quantile plot of residuals	Confirm normality and homogeneity of error terms, and detect outliers
Residuals versus predicted values	Evaluate adequacy of fit and detect outliers
Residual-fit (RF) spread plot	side-by-side quantile plots of the centered fit and the residuals show "how much variation in the data is explained by the fit and how much remains in the residuals" (Cleveland 1993)

Observations satisfying RStudent > 2 or RStudent < –2 are called *outliers*, and observations with leverage > $2p/n$ are called *influential*, where n is the number of observations used in fitting the model and p is the number of parameters used in the model (Rawlings, Pantula, and Dickey 1998). Specifying the LABEL option labels the influential and outlying observations—the label is the first ID variable if the ID statement is specified; otherwise, it is the observation number. Note in the Cook's *D* plot that only observations with *D* exceeding $4/n$ are labeled; these are also called influential observations. The UNPACK option displays each diagnostic plot separately. See Output 78.2.3 for an example of the diagnostics panel.

FIT <(GRIDSIZE=*number*)>

plots the predicted values against a single predictor when you have only one factor or only one covariate in the model. The GRIDSIZE= option specifies the number of points at which the fitted values are computed; by default, GRIDSIZE=200.

NONE

suppresses all plots.

RESIDUALS <(UNPACK | SMOOTH)>

displays plots of residuals against each factor and covariate. The UNPACK option displays each residual plot separately. The SMOOTH option overlays a loess smooth on each residual plot; see Chapter 52, "The LOESS Procedure," for more information. See Output 78.1.5 for an example of this plot.

RIDGE <(UNPACK)>

displays the maximum and/or minimum ridge plots. This option is available only when a MAXIMUM or MINIMUM option is specified in the RIDGE statement. The UNPACK option displays the estimated response and factor level ridge plots separately. See Output 78.1.5 for an example of this plot.

SURFACE <(*surface-options*)>
displays the response surface for each response variable and each pair of factors with all other factors and covariates fixed at their means. By default a panel of contour plots is produced; see Output 78.1.6 for an example of this plot. The following *surface-options* can be specified:

3D displays three-dimensional surface plots instead of contour plots. See Figure 78.4 for an example of this plot.

AT <*keyword*><(*variable=value-list* | *keyword* <...*variable=value-list* | *keyword*>)>
specifies fixed values for factors and covariates. You can specify one or more numbers in the *value-list* or one of the following *keywords*:

MIN	sets the variable to its minimum value.
MEAN	sets the variable to its mean value.
MIDRANGE	sets the variable to the middle value: $\frac{\max + \min}{2}$.
MAX	sets the variable to its maximum value.

Specifying a keyword immediately after AT sets the default value of all variables; for example, **`AT MIN`** sets all variables not displayed on an axis to their minimum values. By default, continuous variables are set to their means (**`AT MEAN`**) when they are not used on an axis. For example, if your model contains variables X1, X2, and X3, then specifying **`AT(X1=7 9)`** produces a contour plot of X2 versus X3 fixing X1 = 7 and then another contour plot with X1 = 9, along with contour plots of X1 versus X2 fixing X3 at its mean, and X1 versus X3 fixing X2 at its mean.

EXTEND=*value* extends the surface *value*-times the range of each factor in each direction, which enables you to see more of the fitted surface. For example, if factor A has range $[0, 10]$, then specifying **`EXTEND=0.1`** will compute and display the surface for A in $[-1, 11]$. You can specify $value \geq 0$; by default, $value = 0.1$.

FILL=PRED | SE | NONE produces a filled contour plot for either the predicted values or the standard errors. FILL=SE is the default. If the 3D option is also specified, then the contour plot is projected onto the surface.

GRIDSIZE=*n* creates an $n \times n$ grid of points at which the estimated values for the surface and standard errors are computed, for $n \geq 1$. By default, $n = 50$.

LINE<=PRED | SE | NONE> produces a contour line plot for either the predicted values or the standard errors. LINE=PRED is the default. If the 3D option is also specified, then specifying LINE displays a grid on the surface, and the other LINE= specifications are ignored.

NODESIGN suppresses the display of the design points on the contour surface plots and the overlaid contour-line plots.

OVERLAYPAIRS produces overlaid contour line plots for all pairs of response variables in addition to the contour surface plots. See Figure 78.6 for an example of this plot.

ROTATE=*angle* rotates the 3-D surface plots *angle* degrees, $-180 < angle < 180$. By default, $angle = 57$.

TILT=*angle* tilts the 3-D surface plots *angle* degrees, $-180 < angle < 180$. By default, $angle = 20$.

UNPACKPANELS | UNPACK suppresses paneling, and displays each surface plot separately.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC RSREG to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the RSREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

ID Statement

ID *variables* **;**

The ID statement names variables that are to be transferred to the data set created by the OUT= option in the PROC RSREG statement.

MODEL Statement

MODEL *responses=independents* < / *options* > **;**

In the MODEL statement, you specify the response (dependent) variables followed by an equal sign and then the independent variables, some of which can be covariates.

Table 78.2 summarizes the *options* available in the MODEL statement. The *statistic options* specify which statistics are output to the OUT= data set. If none of the *statistic options* are selected, the data set is created but contains no observations. The *statistic option* keywords become values of the special variable _TYPE_ in the output data set.

Table 78.2 MODEL Statement Options

Task	Options
Analyze original data	NOCODE
Fit model to first BY group only	BYOUT
Declare covariates	COVAR=
Request additional statistics	PRESS
Request additional tests	LACKFIT
Suppress displayed output	NOANOVA
	NOOPTIMAL
	NOPRINT
Task	**Statistic Options**
Output statistics	ACTUAL
	PREDICT
	RESIDUAL
	L95
	U95
	L95M
	U95M
	D

The following list describes these options in alphabetical order.

ACTUAL
specifies that the observed response values from the input data set be written to the output data set.

BYOUT
uses only the first BY group to estimate the model. Subsequent BY groups have scoring statistics computed in the output data set only. The BYOUT option is used only when a BY statement is specified.

COVAR=*n*
declares that the first *n* variables on the right side of the model are simple linear regressors (covariates) and not factors in the quadratic response surface. By default, PROC RSREG forms quadratic and crossproduct effects for all regressor variables in the MODEL statement.

See the section "Handling Covariates" on page 6649 for more details and Example 78.2 for an example that uses covariates.

D
specifies that Cook's D influence statistic be written to the output data set.

See Chapter 4, "Introduction to Regression Procedures," for details and formulas.

LACKFIT
performs a lack-of-fit test.

See Draper and Smith (1981) for a discussion of lack-of-fit tests.

L95

specifies that the lower bound of a 95% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates.

See Chapter 4, "Introduction to Regression Procedures," for details and formulas.

L95M

specifies that the lower bound of a 95% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates.

See Chapter 4, "Introduction to Regression Procedures," for details and formulas.

NOANOVA

NOAOV

suppresses the display of the analysis of variance and parameter estimates from the model fit.

NOCODE

performs the canonical and ridge analyses with the parameter estimates derived from fitting the response to the original values of the factor variables, rather than their coded values (see the section "Coding the Factor Variables" on page 6646 for more details). Use this option if the data are already stored in a coded form.

NOOPTIMAL

NOOPT

suppresses the display of the canonical analysis for the quadratic response surface.

NOPRINT

suppresses the display of both the analysis of variance and the canonical analysis.

PREDICT

specifies that the values predicted by the model be written to the output data set.

PRESS

computes and displays the predicted residual sum of squares (PRESS) statistic for each dependent variable in the model. The PRESS statistic is added to the summary information at the beginning of the analysis of variance, so if the NOANOVA or NOPRINT option is specified, then the PRESS option has no effect.

See Chapter 4, "Introduction to Regression Procedures," for details and formulas.

RESIDUAL

specifies that the residuals, calculated as ACTUAL − PREDICTED, be written to the output data set.

U95

specifies that the upper bound of a 95% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates.

See Chapter 4, "Introduction to Regression Procedures," for details and formulas.

U95M

specifies that the upper bound of a 95% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates.

See Chapter 4, "Introduction to Regression Procedures," for details and formulas.

RIDGE Statement

RIDGE < *options* > **;**

A RIDGE statement computes the ridge of optimum response. The ridge starts at a given point $\mathbf{x_0}$, and the point on the ridge at radius r from $\mathbf{x_0}$ is the collection of factor settings that optimizes the predicted response at this radius. You can think of the ridge as climbing or falling as fast as possible on the surface of predicted response. Thus, the ridge analysis can be used as a tool to help interpret an existing response surface or to indicate the direction in which further experimentation should be performed.

The default starting point, $\mathbf{x_0}$, has each coordinate equal to the point midway between the highest and lowest values of the factor in the design. The default radii at which the ridge is computed are 0, 0.1, . . ., 0.9, 1. If the ridge analysis is based on the response surface fit to coded values for the factor variables (see the section "Coding the Factor Variables" on page 6646 for details), then this results in a ridge that starts at the point with a coded zero value for each coordinate and extends toward, but not beyond, the edge of the range of experimentation. Alternatively, both the center point of the ridge and the radii at which it is to be computed can be specified.

You can specify the following options in the RIDGE statement:

CENTER=*uncoded-factor-values*

gives the coordinates of the point $\mathbf{x_0}$ from which to begin the ridge. The coordinates should be given in the original (uncoded) factor variable values and should be separated by commas. There must be as many coordinates specified as there are factors in the model, and the order of the coordinates must be the same as that used in the MODEL statement. This starting point should be well inside the range of experimentation. The default sets each coordinate equal to the value midway between the highest and lowest values for the associated factor.

MAXIMUM

MAX

computes the ridge of maximum response. Both the MIN and MAX options can be specified; at least one must be specified.

MINIMUM

MIN

computes the ridge of minimum response. Both the MIN and MAX options can be specified; at least one must be specified.

NOPRINT

suppresses the display of the ridge analysis when only an output data set is required.

OUTR=*SAS-data-set*

creates an output SAS data set containing the computed optimum ridge.

For details, see the section "OUTR=SAS-data-set" on page 6652.

RADIUS=*coded-radii*

gives the distances from the ridge starting point at which to compute the optima. The values in the list represent distances between coded points. The list can take any of the following forms or can be composed of mixtures of them:

$m_1, m_2, \ldots, m_n$	specifies several values.
m TO n	specifies a sequence where m equals the starting value, n equals the ending value, and the increment equals 1.
m TO n BY i	specifies a sequence where m equals the starting value, n equals the ending value, and i equals the increment.

Mixtures of the preceding forms should be separated by commas. The default list runs from 0 to 1 by increments of 0.1. The following are examples of valid lists.

```
radius=0 to 5 by .5;
radius=0, .2, .25, .3, .5 to 1.0 by .1;
```

WEIGHT Statement

WEIGHT *variable* **;**

When a WEIGHT statement is specified, a weighted residual sum of squares

$$\sum_i w_i (y_i - \hat{y}_i)^2$$

is minimized, where w_i is the value of the variable specified in the WEIGHT statement, y_i is the observed value of the response variable, and $\hat{y}_i$ is the predicted value of the response variable.

The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than zero. The WEIGHT statement has no effect on degrees of freedom or number of observations. If the weights for the observations are proportional to the reciprocals of the error variances, then the weighted least squares estimates are best linear unbiased estimators (BLUE).

Details: RSREG Procedure

Introduction to Response Surface Experiments

Many industrial experiments are conducted to discover which values of given factor variables optimize a response. If each factor is measured at three or more values, a quadratic response surface can be estimated by least squares regression. The predicted optimal value can be found from the estimated surface if the surface is shaped like a simple hill or valley. If the estimated surface is more complicated, or if the predicted optimum is far from the region of experimentation, then the shape of the surface can be analyzed to indicate the directions in which new experiments should be performed.

Suppose that a response variable y is measured at combinations of values of two factor variables, x_1 and x_2. The quadratic response surface model for this variable is written as

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_1^2 + \beta_4 x_2^2 + \beta_5 x_1 x_2 + \epsilon$$

The steps in the analysis for such data are as follows:

1. model fitting and analysis of variance, including lack-of-fit testing, to estimate parameters
2. canonical analysis to investigate the shape of the predicted response surface
3. ridge analysis to search for the region of optimum response

Model Fitting and Analysis of Variance

The first task in analyzing the response surface is to estimate the parameters of the model by least squares regression and to obtain information about the fit in the form of an analysis of variance. The estimated surface is typically curved: a *hill* with the peak occurring at the unique estimated point of maximum response, a *valley,* or a *saddle surface* with no unique minimum or maximum. Use the results of this phase of the analysis to answer the following questions:

- What is the contribution of each type of effect—linear, quadratic, and crossproduct—to the statistical fit? The ANOVA table with sources labeled "Regression" addresses this question.
- What part of the residual error is due to lack of fit? Does the quadratic response model adequately represent the true response surface? If you specify the LACKFIT option in the MODEL statement, then the ANOVA table with sources labeled "Residual" addresses this question. See the section "Lack-of-Fit Test" on page 6645 for details.
- What is the contribution of each factor variable to the statistical fit? Can the response be predicted accurately if the variable is removed? The ANOVA table with sources labeled "Factor" addresses this question.
- What are the predicted responses for a grid of factor values? (See the section "Plotting the Surface" on page 6647 and the section "Searching for Multiple Response Conditions" on page 6647.)

Lack-of-Fit Test

The lack-of-fit test compares the variation around the model with *pure* variation within replicated observations. This measures the adequacy of the quadratic response surface model. In particular, if there are n_i replicated observations $Y_{i1}, \ldots, Y_{in_i}$ of the response all at the same values $\mathbf{x}_i$ of the factors, then you can predict the true response at $\mathbf{x}_i$ either by using the predicted value $\hat{Y}_i$ based on the model or by using the mean $\bar{Y}_i$ of the replicated values. The lack-of-fit test decomposes the residual error into a component due to the variation of the replications around their mean value (the *pure* error) and a component due to the variation of the mean values around the model prediction (the *bias* error):

$$\sum_i \sum_{j=1}^{n_i} \left(Y_{ij} - \hat{Y}_i\right)^2 = \sum_i \sum_{j=1}^{n_i} \left(Y_{ij} - \bar{Y}_i\right)^2 + \sum_i n_i \left(\bar{Y}_i - \hat{Y}_i\right)^2$$

If the model is adequate, then both components estimate the nominal level of error; however, if the bias component of error is much larger than the pure error, then this constitutes evidence that there is significant lack of fit.

If some observations in your design are replicated, you can test for lack of fit by specifying the LACKFIT option in the MODEL statement. Note that, since all other tests use total error rather than pure error, you might want to hand-calculate the tests with respect to pure error if the lack of fit is significant. On the other hand, significant lack of fit indicates that the quadratic model is inadequate, so if this is a problem you can also try to refine the model, possibly by using PROC GLM for general polynomial modeling; see Chapter 41, "The GLM Procedure," for more information. Example 78.1 illustrates the use of the LACKFIT option.

Canonical Analysis

The second task in analyzing the response surface is to examine the overall shape of the curve and determine whether the estimated stationary point is a maximum, a minimum, or a saddle point. The canonical analysis can be used to answer the following questions:

- Is the surface shaped like a hill, a valley, or a saddle, or is it flat?
- If there is a unique optimum combination of factor values, where is it?
- To which factor or factors are the predicted responses most sensitive?

The eigenvalues and eigenvectors in the matrix of second-order parameters characterize the shape of the response surface. The eigenvectors point in the directions of principal orientation for the surface, and the signs and magnitudes of the associated eigenvalues give the shape of the surface in these directions. Positive eigenvalues indicate directions of upward curvature, and negative eigenvalues indicate directions of downward curvature. The larger an eigenvalue is in absolute value, the more pronounced is the curvature of the response surface in the associated direction. Often, all the coefficients of an eigenvector except for one are relatively small, indicating that the vector points roughly along the axis associated with the factor corresponding to the single large coefficient. In this case, the canonical analysis can be used to determine the relative sensitivity of the predicted response surface to variations in that factor. (See the section "Getting Started: RSREG Procedure" on page 6630 for an example.)

Ridge Analysis

If the estimated surface is found to have a simple optimum well within the range of experimentation, the analysis performed by the preceding two steps might be sufficient. In more complicated situations, further search for the region of optimum response is required. The method of ridge analysis computes the estimated ridge of optimum response for increasing radii from the center of the original design. The ridge analysis answers the following question:

- If there is not a unique optimum of the response surface within the range of experimentation, in which direction should further searching be done in order to locate the optimum?

You can use the RIDGE statement to compute the ridge of maximum or minimum response.

Coding the Factor Variables

For the results of the canonical and ridge analyses to be interpretable, the values of different factor variables should be comparable. This is because the canonical and ridge analyses of the response surface are not invariant with respect to differences in scale and location of the factor variables. The analysis of variance is not affected by these changes. Although the actual predicted surface does not change, its parameterization does. The usual solution to this problem is to code each factor variable so that its minimum in the experiment is -1 and its maximum is 1 and to carry through the analysis with the coded values instead of the original ones. This practice has the added benefit of making 1 a reasonable boundary radius for the ridge analysis since 1 represents approximately the edge of the experimental region. By default, PROC RSREG computes the linear transformation to perform this coding as the data are initially read in, and the canonical and ridge analyses are performed on the model fit to the coded data. The actual form of the coding operation for each value of a variable is

$$coded\ value = (original\ value - M)/S$$

where M is the average of the highest and lowest values for the variable in the design and S is half their difference.

Missing Values

If an observation has missing data for any of the variables used by the procedure, then that observation is not used in the estimation process. If one or more response variables are missing, but no factor or covariate variables are missing, then predicted values and confidence limits are computed for the output data set, but the residual and Cook's D statistic are missing.

Plotting the Surface

Specifying the PLOTS=SURFACE option in the PROC RSREG statement displays contour plots for all pairs of factors in the model (see Example 78.1), while specifying the PLOTS=SURFACE(3D) option displays a three-dimensional surface as shown in Figure 78.4.

You can also generate predicted values for a grid of points with the PREDICT option (see the section "Getting Started: RSREG Procedure" on page 6630 for an example) and then use these values to create a contour plot or a three-dimensional plot of the response surface over a two-dimensional grid. Any two factor variables can be chosen to form the grid for the plot. Several plots can be generated by using different pairs of factor variables.

Searching for Multiple Response Conditions

Suppose you have the following data with two factors and three responses, and you want to find the factor setting that produces responses in a certain region:

```
data a;
   input x1 x2 y1 y2 y3;
   datalines;
-1      -1          1.8 1.940  3.6398
-1       1          2.6 1.843  4.9123
 1      -1          5.4 1.063  6.0128
 1       1          0.7 1.639  2.3629
 0       0          8.5 0.134  9.0910
 0       0          3.0 0.545  3.7349
 0       0          9.8 0.453 10.4412
 0       0          4.1 1.117  5.0042
 0       0          4.8 1.690  6.6245
 0       0          5.9 1.165  6.9420
 0       0          7.3 1.013  8.7442
 0       0          9.3 1.179 10.2762
 1.4142  0          3.9 0.945  5.0245
-1.4142  0          1.7 0.333  2.4041
 0       1.4142     3.0 1.869  5.2695
 0      -1.4142     5.7 0.099  5.4346
;
```

You want to find the values of x1 and x2 that maximize y1 subject to y2<2 and y3<y2+y1. The exact answer is not easy to obtain analytically, but you can obtain a practically feasible solution by checking conditions across a grid of values in the range of interest. First, append a grid of factor values to the observed data, with missing values for the responses:

```
data b;
   set a end=eof;
   output;
   if eof then do;
      y1=.;
      y2=.;
      y3=.;
      do x1=-2 to 2 by .1;
         do x2=-2 to 2 by .1;
            output;
         end;
      end;
   end;
run;
```

Next, use PROC RSREG to fit a response surface model to the data and to compute predicted values for both the observed data and the grid, putting the predicted values in a data set c:

```
proc rsreg data=b out=c;
   model y1 y2 y3=x1 x2 / predict;
run;
```

Finally, find the subset of predicted values that satisfy the constraints, sort by the unconstrained variable, and display the top five predictions:

```
data d;
   set c;
   if y2<2;
   if y3<y2+y1;

proc sort data=d;
   by descending y1;
run;

data d; set d;
   if (_n_ <= 5);
proc print;
run;
```

The results are displayed in Figure 78.5. They indicate that optimal values of the factors are around 0.3 for x1 and around –0.5 for x2.

Figure 78.5 Top Five Predictions

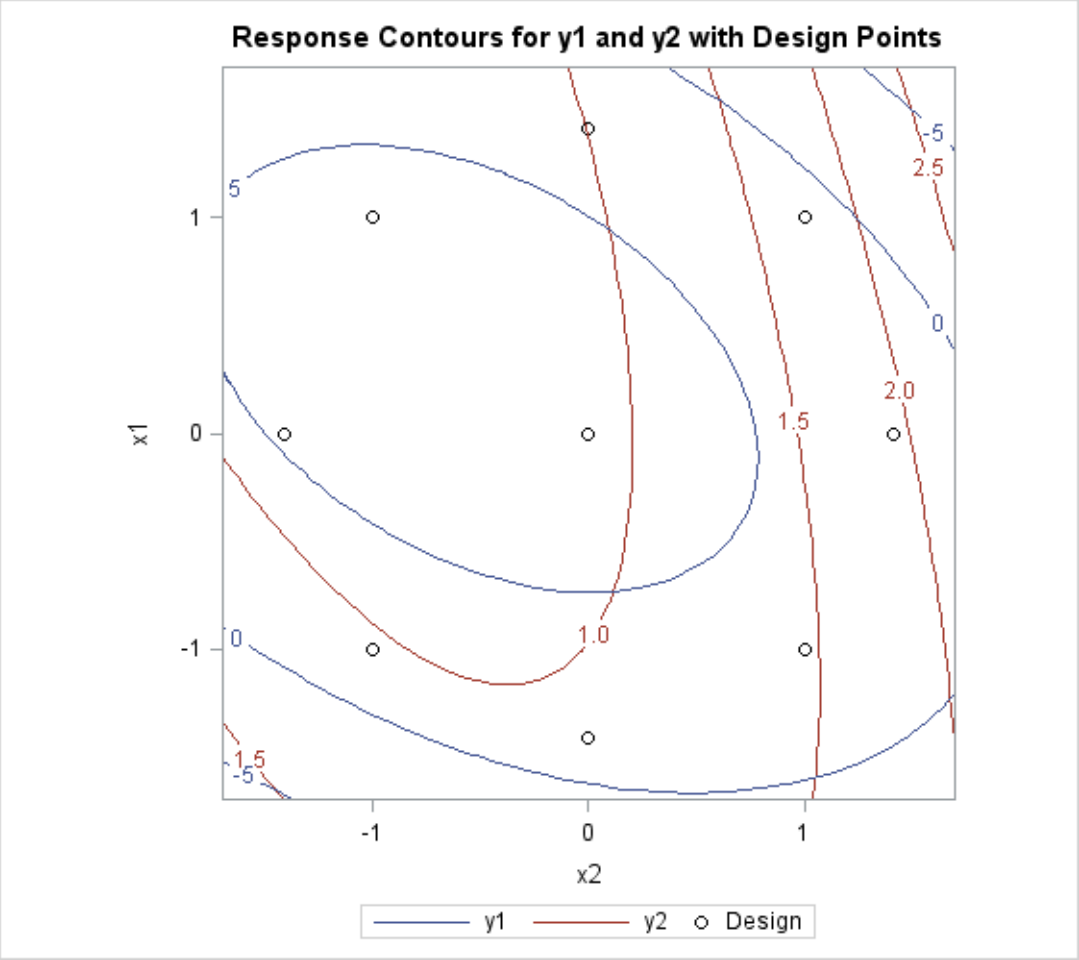
Obs	x1	x2	_TYPE_	y1	y2	y3
1	0.3	-0.5	PREDICT	6.92570	0.75784	7.60471
2	0.3	-0.6	PREDICT	6.91424	0.74174	7.54194
3	0.3	-0.4	PREDICT	6.91003	0.77870	7.64341
4	0.4	-0.6	PREDICT	6.90769	0.73357	7.51836
5	0.4	-0.5	PREDICT	6.90540	0.75135	7.56883

If you are also interested in simultaneously optimizing y1 and y2, you can specify the following statements to make a visual comparison of the two response surfaces by overlaying their contour plots:

```
ods graphics on;
proc rsreg data=a plots=surface(overlaypairs);
   model y1 y2=x1 x2;
run;
ods graphics off;
```

Figure 78.6 shows that you have to make some compromises in any attempt to maximize both y1 and y2; however, you might be able to maximize y1 while minimizing y2.

Figure 78.6 Overlaid Line Contours of Predicted Responses



Handling Covariates

Covariate regressors are added to a response surface model because they are believed to account for a sizable yet relatively uninteresting portion of the variation in the data. What the experimenter is really interested in is the response corrected for the effect of the covariates. A common example is the block effect in a block design. In the canonical and ridge analyses of a response surface, which estimate responses at hypothetical

levels of the factor variables, the actual value of the predicted response is computed by using the average values of the covariates. The estimated response values do optimize the estimated surface of the response corrected for covariates, but true prediction of the response requires actual values for the covariates. You can use the COVAR= option in the MODEL statement to include covariates in the response surface model. Example 78.2 illustrates the use of this option.

Computational Method

Canonical Analysis

For each response variable, the model can be written in the form

$$y_i = \mathbf{x}_i' \mathbf{A} \mathbf{x}_i + \mathbf{b}' \mathbf{x}_i + \mathbf{c}' \mathbf{z}_i + \epsilon_i$$

where

y_i is the ith observation of the response variable.

$\mathbf{x}_i$ $= (x_{i1}, x_{i2}, \ldots, x_{ik})'$ are the k factor variables for the ith observation.

$\mathbf{z}_i$ $= (z_{i1}, z_{i2}, \ldots, z_{iL})'$ are the L covariates, including the intercept term.

$\mathbf{A}$ is the $k \times k$ symmetrized matrix of quadratic parameters, with diagonal elements equal to the coefficients of the pure quadratic terms in the model and off-diagonal elements equal to half the coefficient of the corresponding crossproduct.

$\mathbf{b}$ is the $k \times 1$ vector of linear parameters.

$\mathbf{c}$ is the $L \times 1$ vector of covariate parameters, one of which is the intercept.

ϵ_i is the error associated with the ith observation. Tests performed by PROC RSREG assume that errors are independently and normally distributed with mean zero and variance σ^2.

The parameters in $\mathbf{A}$, $\mathbf{b}$, and $\mathbf{c}$ are estimated by least squares. To optimize $\mathbf{y}$ with respect to $\mathbf{x}$, take partial derivatives, set them to zero, and solve:

$$\frac{\partial y}{\partial \mathbf{x}} = 2\mathbf{x}'\mathbf{A} + \mathbf{b}' = \mathbf{0} \quad \Longrightarrow \quad \mathbf{x} = -\frac{1}{2}\mathbf{A}^{-1}\mathbf{b}$$

You can determine if the solution is a maximum or minimum by looking at the eigenvalues of $\mathbf{A}$:

If the eigenvalues...	then the solution is...
are all negative	a maximum
are all positive	a minimum
have mixed signs	a saddle point
contain zeros	in a flat area

Ridge Analysis

If the largest eigenvalue is positive, its eigenvector gives the direction of steepest ascent from the stationary point; if the largest eigenvalue is negative, its eigenvector gives the direction of steepest descent. The eigenvectors corresponding to small or zero eigenvalues point in directions of relative flatness.

The point on the optimum response ridge at a given radius R from the ridge origin is found by optimizing

$$(\mathbf{x}_0 + \mathbf{d})'\mathbf{A}(\mathbf{x}_0 + \mathbf{d}) + \mathbf{b}'(\mathbf{x}_0 + \mathbf{d})$$

over $\mathbf{d}$ satisfying $\mathbf{d}'\mathbf{d} = R^2$, where $\mathbf{x}_0$ is the $k \times 1$ vector containing the ridge origin and $\mathbf{A}$ and $\mathbf{b}$ are as previously discussed. By the method of Lagrange multipliers, the optimal $\mathbf{d}$ has the form

$$\mathbf{d} = -(\mathbf{A} - \mu\mathbf{I})^{-1}(\mathbf{A}\mathbf{x}_0 + 0.5\mathbf{b})$$

where $\mathbf{I}$ is the $k \times k$ identity matrix and μ is chosen so that $\mathbf{d}'\mathbf{d} = R^2$. There can be several values of μ that satisfy this constraint; the correct one depends on which sort of response ridge is of interest. If you are searching for the ridge of maximum response, then the appropriate μ is the unique one that satisfies the constraint and is greater than all the eigenvalues of $\mathbf{A}$. Similarly, the appropriate μ for the ridge of minimum response satisfies the constraint and is less than all the eigenvalues of $\mathbf{A}$. (See Myers and Montgomery (1995) for details.)

Output Data Sets

OUT=SAS-data-set

An output data set containing statistics requested with options in the MODEL statement for each observation in the input data set is created whenever the OUT= option is specified in the PROC RSREG statement. The data set contains the following variables:

- the BY variables
- the ID variables
- the WEIGHT variable
- the independent variables in the MODEL statement
- the variable _TYPE_, which identifies the observation type in the output data set. _TYPE_ is a character variable with a length of eight, and it takes on the values 'ACTUAL', 'PREDICT', 'RESIDUAL', 'U95M', 'L95M', 'U95', 'L95', and 'D', corresponding to the options specified.
- the response variables containing special output values identified by the _TYPE_ variable

All confidence limits use the two-tailed Student's t value.

OUTR=SAS-data-set

An output data set containing the optimum response ridge is created when the OUTR= option is specified in the RIDGE statement. The data set contains the following variables:

- the current values of the BY variables
- a character variable _DEPVAR_ containing the name of the dependent variable
- a character variable _TYPE_ identifying the type of ridge being computed, MINIMUM or MAXIMUM. If both MAXIMUM and MINIMUM are specified, the data set contains observations for the minimum ridge followed by observations for the maximum ridge.
- a numeric variable _RADIUS_ giving the distance from the ridge starting point
- the values of the model factors at the estimated optimum point at distance _RADIUS_ from the ridge starting point
- a numeric variable _PRED_, which is the estimated expected value of the dependent variable at the optimum
- a numeric variable _STDERR_, which is the standard error of the estimated expected value

Displayed Output

All estimates and hypothesis tests assume that the model is correctly specified and the errors are distributed according to classical statistical assumptions.

The output displayed by PROC RSREG includes the following.

Estimation and Analysis of Variance

- The actual form of the coding operation for each value of a variable is

$$coded\ value = \frac{1}{S}(original\ value - M)$$

  where M is the average of the highest and lowest values for the variable in the design and S is half their difference. The Subtracted off column contains the M values for this formula for each factor variable, and S is found in the Divided by column.

- The summary table for the response variable contains the following information.
  - "Response Mean" is the mean of the response variable in the sample. When a WEIGHT statement is specified, the mean $\bar{y}$ is calculated by

$$\bar{y} = \frac{\sum_i w_i y_i}{\sum_i w_i}$$

  - "Root MSE" estimates the standard deviation of the response variable and is calculated as the square root of the "Total Error" mean square.
  - The "R-Square" value is R^2, or the coefficient of determination. R^2 measures the proportion of the variation in the response that is attributed to the model rather than to random error.
  - The "Coefficient of Variation" is 100 times the ratio of the "Root MSE" to the "Response Mean."

- A table analyzing the significance of the terms of the regression is displayed. Terms are brought into the regression in four steps: (1) the "Intercept" and any covariates in the model, (2) "Linear" terms like X1 and X2, (3) pure "Quadratic" terms like X1*X1 or X2*X2, and (4) "Crossproduct" terms like X1*X2. The table displays the following information:
  - the degrees of freedom in the DF column, which should be the same as the number of corresponding parameters unless one or more of the parameters are not estimable
  - Type I Sum of Squares, also called the sequential sums of squares, which measures the reduction in the error sum of squares as sets of terms (Linear, Quadratic, and so forth) are added to the model
  - R-Square, which measures the portion of total R^2 contributed as each set of terms (Linear, Quadratic, and so forth) is added to the model
  - F Value, which tests the null hypothesis that all parameters in the term are zero by using the Total Error mean square as the denominator. This is a test of a Type I hypothesis, containing the usual F test numerator, conditional on the effects of subsequent variables not being in the model.
  - Pr > F, which is the significance value or probability of obtaining at least as great an F ratio given that the null hypothesis is true.

- The Sum of Squares column partitions the "Total Error" into "Lack of Fit" and "Pure Error." When "Lack of Fit" is significant, there is variation around the model other than random error (such as cubic effects of the factor variables).
  - The "Total Error" Mean Square estimates σ^2, the variance.
  - F Value tests the null hypothesis that the variation is adequately described by random error.

- A table containing the parameter estimates from the model is displayed.
  - The Estimate column contains the parameter estimates based on the *uncoded* values of the factor variables. If an effect is a linear combination of previous effects, the parameter for the effect is not estimable. When this happens, the degrees of freedom are zero, the parameter estimate is set to zero, and estimates and tests on other parameters are conditional on this parameter being zero.
  - The Standard Error column contains the estimated standard deviations of the parameter estimates based on *uncoded* data.
  - The t Value column contains t values of a test of the null hypothesis that the true parameter is zero when the *uncoded* values of the factor variables are used.
  - The Pr > |T| column gives the significance value or probability of a greater absolute t ratio given that the true parameter is zero.

  - The Parameter Estimate from Coded Data column contains the parameter estimates based on the *coded* values of the factor variables. These are the estimates used in the subsequent canonical and ridge analyses.

- The sum of squares are partitioned by the factors in the model, and an analysis table is displayed. The test on a factor is a joint test on all the parameters involving that factor. For example, the test for the factor X1 tests the null hypothesis that the true parameters for X1, X1*X1, and X1*X2 are all zero.

Canonical Analysis

- The Critical Value columns contain the values of the factor variables that correspond to the stationary point of the fitted response surface. The critical values can be at a minimum, maximum, or saddle point.

- The eigenvalues and eigenvectors are from the matrix of quadratic parameter estimates based on the coded data. They characterize the shape of the response surface.

Ridge Analysis

- The Coded Radius column contains the distance from the coded version of the associated point to the coded version of the origin of the ridge. The origin is given by the point at radius zero.

- The Estimated Response column contains the estimated value of the response variable at the associated point. The standard error of this estimate is also given. This quantity is useful for assessing the relative credibility of the prediction at a given radius. Typically, this standard error increases rapidly as the ridge moves up to and beyond the design perimeter, reflecting the inherent difficulty of making predictions beyond the range of experimentation.

- The Uncoded Factor Values columns contain the values of the uncoded factor variables that give the optimum response at this radius from the ridge origin.

ODS Table Names

PROC RSREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 78.3. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 78.3 ODS Tables Produced by PROC RSREG

ODS Table Name	Description	Statement
Coding	Coding coefficients for the independent variables	default
ErrorANOVA	Error analysis of variance	default
FactorANOVA	Factor analysis of variance	default
FitStatistics	Overall statistics for fit	default
ModelANOVA	Model analysis of variance	default
ParameterEstimates	Estimated linear parameters	default
Ridge	Ridge analysis for optimum response	RIDGE
Spectral	Spectral analysis	default
StationaryPoint	Stationary point of response surface	default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

PROC RSREG assigns a name to each graph it creates using ODS. The names are listed in Table 78.4. You can use these names to reference the graphs when using ODS. You must also specify the PLOTS= option and any other options indicated in Table 78.4.

Table 78.4 Graphs Produced by PROC RSREG

ODS Graph Name	Plot Description	PLOTS= Option
FitPlot	Fit plot for 1 predictor	FIT
DiagnosticsPanel	Panel of fit diagnostics	DIAGNOSTICS
CooksDPlot	Cook's *D* plot	DIAGNOSTICS(UNPACK)
ObservedByPredicted	Observed by predicted	DIAGNOSTICS(UNPACK)
QQPlot	Residual Q-Q plot	DIAGNOSTICS(UNPACK)
ResidualByPredicted	Residual by predicted values	DIAGNOSTICS(UNPACK)
ResidualHistogram	Residual histogram	DIAGNOSTICS(UNPACK)
RFPlot	RF plot	DIAGNOSTICS(UNPACK)
RStudentByPredicted	Studentized residuals by predicted	DIAGNOSTICS(UNPACK)
RStudentByLeverage	RStudent by hat diagonals	DIAGNOSTICS(UNPACK)
ResidualPlots	Panel of residuals by predictors	RESIDUALS
	Residuals by predictors	RESIDUALS(UNPACK)
RidgePlots	Panel of ridge plot and factors	RIDGE (with RIDGE MAX or MIN)
	Ridge plot	RIDGE(UNPACK) (with RIDGE MAX or MIN)
	Ridge factors	RIDGE(UNPACK) (with RIDGE MAX or MIN)

	3-D surface plots	SURFACE(3D UNPACK)
ContourOverlay	Panel of overlaid line-contour plots	SURFACE(OVERLAYPAIRS)
	Overlaid line-contour plots	SURFACE(OVERLAYPAIRS UNPACK)

Examples: RSREG Procedure

Example 78.1: A Saddle Surface Response Using Ridge Analysis

Myers (1976) analyzes an experiment reported by Frankel (1961) aimed at maximizing the yield of mercaptobenzothiazole (MBT) by varying processing time and temperature. Myers (1976) uses a two-factor model in which the estimated surface does not have a unique optimum. A ridge analysis is used to determine the region in which the optimum lies. The objective is to find the settings of time and temperature in the processing of a chemical that maximize the yield. The following statements produce Output 78.1.1 through Output 78.1.6:

```
data d;
   input Time Temp MBT;

Output 78.1.1 displays the coding coefficients for the transformation of the independent variables to lie between -1 and 1 and some simple statistics for the response variable.

Output 78.1.1 Coding and Response Variable Information

The RSREG Procedure

Coding Coefficients for the Independent Variables

Factor	Subtracted off	Divided by
Time	12.000000	8.000000
Temp	250.000000	30.000000

Response Surface for Variable MBT: Percent Yield Mercaptobenzothiazole

Response Mean	79.916667
Root MSE	4.615964
R-Square	0.8003
Coefficient of Variation	5.7760

Output 78.1.2 shows that the lack of fit for the model is highly significant. Since the quadratic model does not fit the data very well, firm statements about the underlying process should not be based only on the current analysis. Note from the analysis of variance for the model that the test for the time factor is not significant. If further experimentation is undertaken, it might be best to fix Time at a moderate to high value and to concentrate on the effect of temperature. In the actual experiment discussed here, extra runs were made that confirmed the results of the following analysis.

Output 78.1.2 Analyses of Variance

Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Linear	2	313.585803	0.4899	7.36	0.0243
Quadratic	2	146.768144	0.2293	3.44	0.1009
Crossproduct	1	51.840000	0.0810	2.43	0.1698
Total Model	5	512.193947	0.8003	4.81	0.0410

Residual	DF	Sum of Squares	Mean Square	F Value	Pr > F
Lack of Fit	3	124.696053	41.565351	39.63	0.0065
Pure Error	3	3.146667	1.048889		
Total Error	6	127.842720	21.307120		

Parameter	DF	Estimate	Standard Error	t Value	Pr > |t|	Parameter Estimate from Coded Data
Intercept	1	-545.867976	277.145373	-1.97	0.0964	82.173110
Time	1	6.872863	5.004928	1.37	0.2188	-1.014287
Temp	1	4.989743	2.165839	2.30	0.0608	-8.676768
Time*Time	1	0.021631	0.056784	0.38	0.7164	1.384394
Temp*Time	1	-0.030075	0.019281	-1.56	0.1698	-7.218045
Temp*Temp	1	-0.009836	0.004304	-2.29	0.0623	-8.852519

Output 78.1.2 *continued*

Factor	DF	Sum of Squares	Mean Square	F Value	Pr > F
Time	3	61.290957	20.430319	0.96	0.4704
Temp	3	461.250925	153.750308	7.22	0.0205

Factor	Label
Time	Reaction Time (Hours)
Temp	Temperature (Degrees Centigrade)

The canonical analysis (Output 78.1.3) indicates that the predicted response surface is shaped like a saddle. The eigenvalue of 2.5 shows that the valley orientation of the saddle is less curved than the hill orientation, with an eigenvalue of −9.99. The coefficients of the associated eigenvectors show that the valley is more aligned with Time and the hill with Temp. Because the canonical analysis resulted in a saddle point, the estimated surface does not have a unique optimum.

Output 78.1.3 Canonical Analysis

Factor	Critical Value Coded	Uncoded	Label
Time	−0.441758	8.465935	Reaction Time (Hours)
Temp	−0.309976	240.700718	Temperature (Degrees Centigrade)

Predicted value at stationary point: 83.741940

Eigenvalues	Eigenvectors Time	Temp
2.528816	0.953223	−0.302267
−9.996940	0.302267	0.953223

Stationary point is a saddle point.

However, the ridge analysis in Output 78.1.4 and the ridge plot in Output 78.1.5 indicate that maximum yields result from relatively high reaction times and low temperatures. A contour plot of the predicted response surface, shown in Output 78.1.6, confirms this conclusion.

Output 78.1.4 Ridge Analysis

Estimated Ridge of Maximum Response for Variable
MBT: Percent Yield Mercaptobenzothiazole

Coded Radius	Estimated Response	Standard Error	Uncoded Factor Values Time	Temp
0.0	82.173110	2.665023	12.000000	250.000000

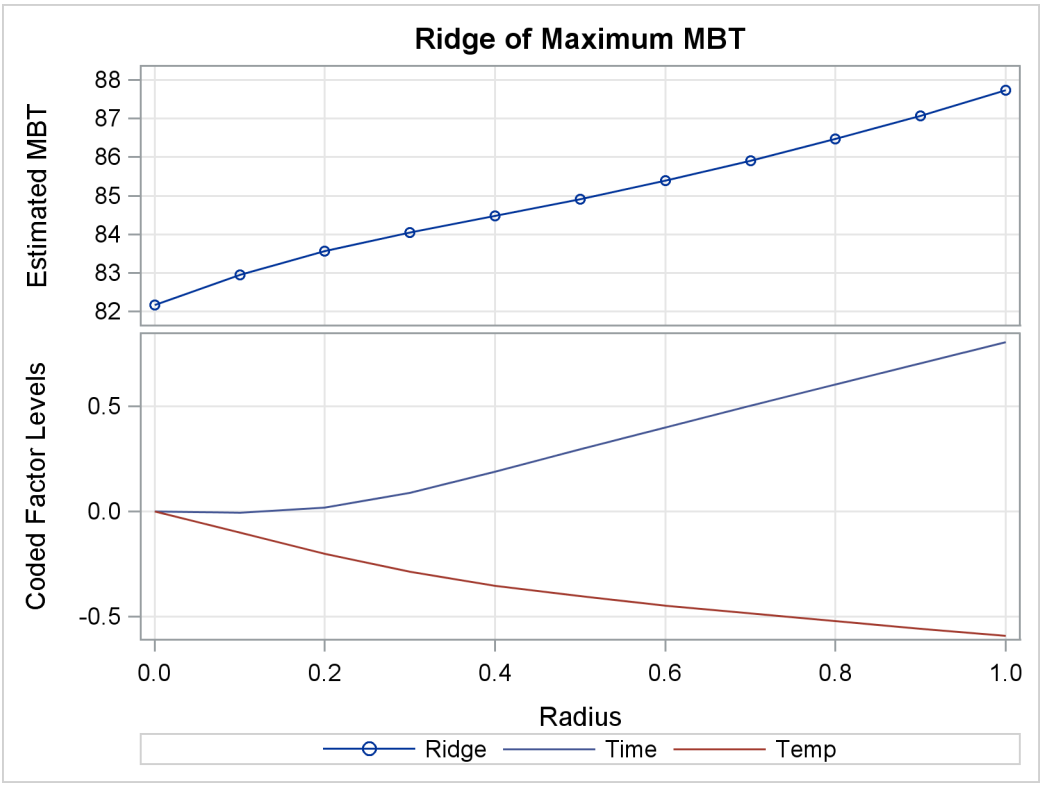
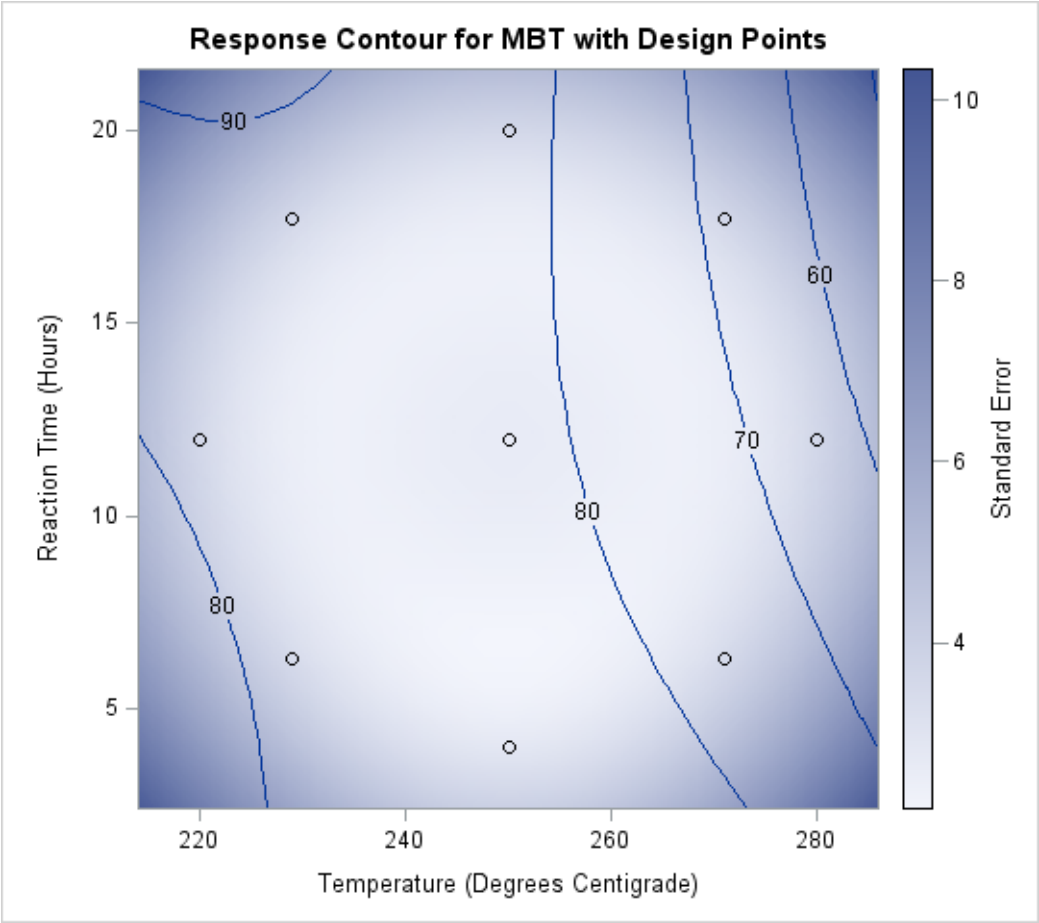
Output 78.1.5 Ridge Plot of Predicted Response Surface



Output 78.1.6 Contour Plot of Predicted Response Surface



Example 78.2: Response Surface Analysis with Covariates

One way of viewing covariates is as extra sources of variation in the dependent variable that can mask the variation due to primary factors. This example demonstrates the use of the COVAR= option in PROC RSREG to fit a response surface model to the dependent variables corrected for the covariates.

You have a chemical process with a yield that you hypothesize to be dependent on three factors: reaction time, reaction temperature, and reaction pressure. You perform an experiment to measure this dependence. You are willing to include up to 20 runs in your experiment, but you can perform no more than 8 runs on the same day, so the design for the experiment is composed of three blocks. Additionally, you know that the grade of raw material for the reaction has a significant impact on the yield. You have no control over this, but you keep track of it. The following statements create a SAS data set containing the results of the experiment:

```
data Experiment;
   input Day Grade Time Temp Pressure Yield;
   datalines;
1 67      -1     -1     -1         32.98
1 68      -1      1      1         47.04
1 70       1     -1      1         67.11
1 66       1      1     -1         26.94
1 74       0      0      0        103.22
1 68       0      0      0         42.94
2 75      -1     -1      1        122.93
2 69      -1      1     -1         62.97
2 70       1     -1     -1         72.96
2 71       1      1      1         94.93
2 72       0      0      0         93.11
2 74       0      0      0        112.97
3 69       1.633  0      0         78.88
3 67      -1.633  0      0         52.53
3 68       0      1.633  0         68.96
3 71       0     -1.633  0         92.56
3 70       0      0      1.633     88.99
3 72       0      0     -1.633    102.50
3 70       0      0      0         82.84
3 72       0      0      0        103.12
;
```

Your first analysis neglects to take the covariates into account. The following statements use PROC RSREG to fit a response surface to the observed yield, but note that Day and Grade are omitted:

```
proc rsreg data=Experiment;
   model Yield = Time Temp Pressure;
run;
```

The ANOVA results shown in Output 78.2.1 indicate that *no* process variable effects are significantly larger than the background noise.

Output 78.2.1 Analysis of Variance Ignoring Covariates

The RSREG Procedure

Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Linear	3	1880.842426	0.1353	0.67	0.5915
Quadratic	3	2370.438681	0.1706	0.84	0.5023
Crossproduct	3	241.873250	0.0174	0.09	0.9663
Total Model	9	4493.154356	0.3233	0.53	0.8226

Residual	DF	Sum of Squares	Mean Square
Total Error	10	9405.129724	940.512972

However, when the yields are adjusted for covariate effects of day and grade of raw material, very strong process variable effects are revealed. The following statements produce the ANOVA results in Output 78.2.2. Note that in order to include the effects of the classification factor Day as covariates, you need to create dummy variables indicating each day separately.

```
data Experiment;
   set Experiment;
   d1 = (Day = 1);
   d2 = (Day = 2);
   d3 = (Day = 3);

ods graphics on;
proc rsreg data=Experiment plots=all;
   model Yield = d1-d3 Grade Time Temp Pressure / covar=4;
run;
ods graphics off;
```

The results show very strong effects due to both the covariates and the process variables.

Output 78.2.2 Analysis of Variance Including Covariates

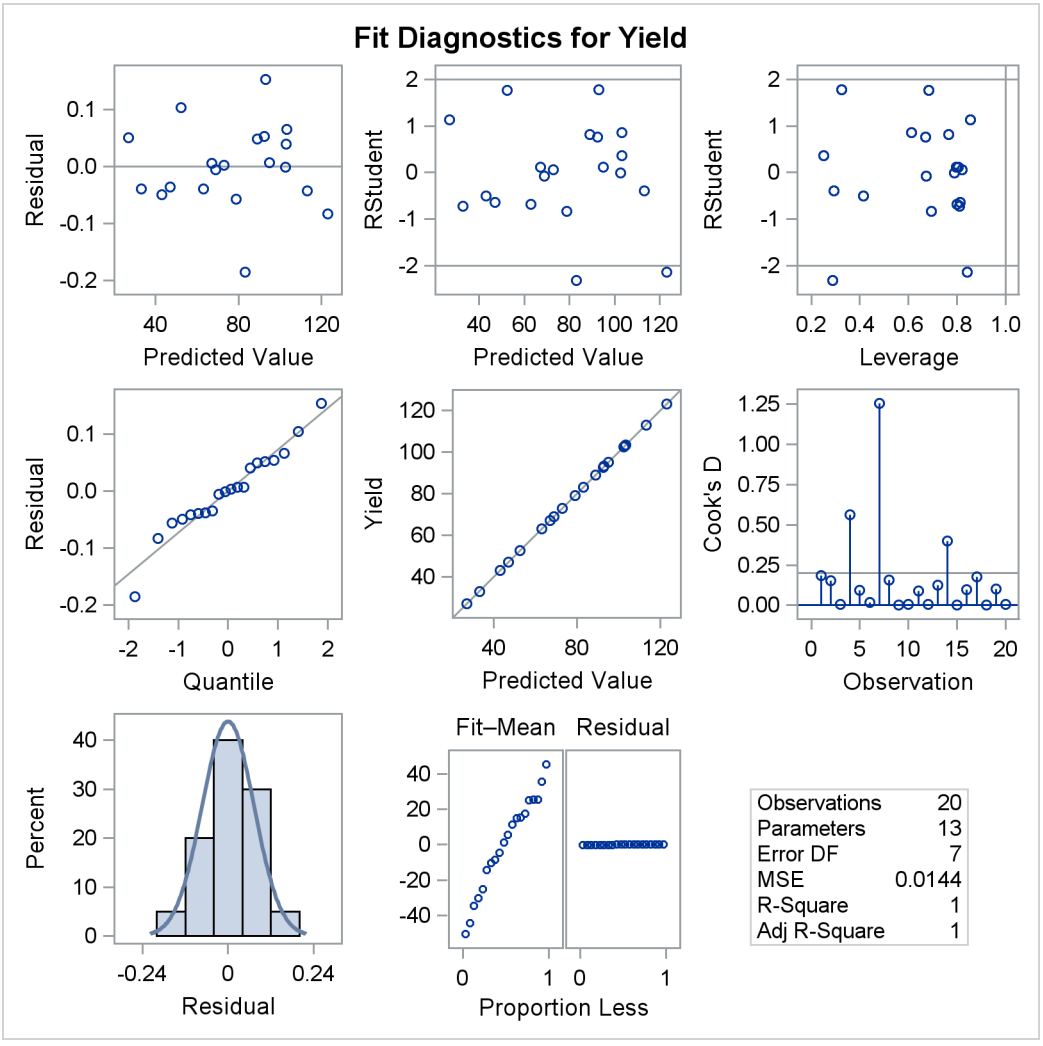
The RSREG Procedure

Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Covariates	3	13695	0.9854	316957	<.0001
Linear	3	156.524497	0.0113	3622.53	<.0001
Quadratic	3	22.989775	0.0017	532.06	<.0001
Crossproduct	3	23.403614	0.0017	541.64	<.0001
Total Model	12	13898	1.0000	80413.2	<.0001

Residual	DF	Sum of Squares	Mean Square
Total Error	7	0.100820	0.014403

The number of observations in the data set might be too small for the diagnostic plots in Output 78.2.3 to dependably identify problems; however, some outliers are indicated. The residual plots in Output 78.2.4 do not display any obvious structure.

Output 78.2.3 Fit Diagnostics



Output 78.2.4 Residual Plots

Chapter 79

The SCORE Procedure

Contents

Overview: SCORE Procedure

The SCORE procedure multiplies values from two SAS data sets, one containing coefficients (for example, factor-scoring coefficients or regression coefficients) and the other containing raw data to be scored using the coefficients from the first data set. The result of this multiplication is a SAS data set containing linear combinations of the coefficients and the raw data values.

Many statistical procedures output coefficients that PROC SCORE can apply to raw data to produce scores. The new score variable is formed as a linear combination of raw data and scoring coefficients. For each observation in the raw data set, PROC SCORE multiplies the value of a variable in the raw data set by the matching scoring coefficient from the data set of scoring coefficients. This multiplication process is repeated

for each variable in the VAR statement. The resulting products are then summed to produce the value of the new score variable. This entire process is repeated for each observation in the raw data set. In other words, PROC SCORE cross multiplies part of one data set with another.

Raw Data Set

The raw data set can contain the original data used to calculate the scoring coefficients, or it can contain an entirely different data set. The raw data set must contain all the variables needed to produce scores. In addition, the scoring coefficients and the variables in the raw data set that are used in scoring must have the same names. See the section "Getting Started: SCORE Procedure" on page 6672 for more information.

Scoring Coefficients Data Set

The data set containing scoring coefficients must contain two special variables: the _TYPE_ variable and the _NAME_ or _MODEL_ variable.

- The _TYPE_ variable identifies the observations that contain scoring coefficients.
- The _NAME_ or _MODEL_ variable provides a SAS name for the new score variable.

PROC SCORE first looks for a _NAME_ variable in the SCORE= input data set. If there is such a variable, the variable's value is what SCORE uses to name the new score variable. If the SCORE= data set does not have a _NAME_ variable, then PROC SCORE looks for a _MODEL_ variable.

For example, PROC FACTOR produces an output data set that contains factor-scoring coefficients. In this output data set, the scoring coefficients are identified by _TYPE_='SCORE'. For _TYPE_='SCORE', the _NAME_ variable has values of 'Factor1', 'Factor2', and so forth. PROC SCORE gives the new score variables the names Factor1, Factor2, and so forth.

As another example, the REG procedure produces an output data set that contains parameter estimates. In this output data set, the parameter estimates are identified by _TYPE_='PARMS'. The _MODEL_ variable contains the label used in the MODEL statement in PROC REG, or it uses MODEL*n* if no label is specified. This label is the name PROC SCORE gives to the new score variable.

Standardization of Raw Data

PROC SCORE automatically standardizes or centers the DATA= variables for you, based on information from the original variables and analysis from the SCORE= data set.

If the SCORE= scoring coefficients data set contains observations with _TYPE_='MEAN' and _TYPE_='STD', then PROC SCORE standardizes the raw data before scoring. For example, this type of SCORE= data set can come from PROC PRINCOMP without the COV option.

If the SCORE= scoring coefficients data set contains observations with _TYPE_='MEAN' but _TYPE_='STD' is absent, then PROC SCORE centers the raw data (the means are subtracted) before scoring. For example, this type of SCORE= data set can come from PROC PRINCOMP with the COV option.

If the SCORE= scoring coefficients data set does not contain observations with _TYPE_='MEAN' and _TYPE_='STD', or if you use the NOSTD option, then PROC SCORE does not center or standardize the raw data.

If the SCORE= scoring coefficients are obtained from observations with _TYPE_='USCORE', then PROC SCORE "standardizes" the raw data by using the uncorrected standard deviations identified by _TYPE_='USTD', and the means are not subtracted from the raw data. For example, this type of SCORE= data set can come from PROC PRINCOMP with the NOINT option. For more information about _TYPE_='USCORE' scoring coefficients in TYPE=UCORR or TYPE=UCOV output data sets, see Appendix A, "Special SAS Data Sets."

You can use PROC SCORE to score the data that were also used to generate the scoring coefficients, although more typically, scoring results are directly obtained from the OUT= data set in a procedure that computes scoring coefficients. When scoring new data, it is important to realize that PROC SCORE assumes that the new data have approximately the same scales as the original data. For example, if you specify the COV option with PROC PRINCOMP for the original analysis, the scoring coefficients in the PROC PRINCOMP OUTSTAT= data set are not appropriate for standardized data. With the COV option, PROC PRINCOMP will not output _TYPE_='STD' observations to the OUTSTAT= data set, and PROC SCORE will only subtract the means of the original (not new) variables from the new variables before multiplying. Without the COV option in PROC PRINCOMP, both the original variable means and standard deviations will be in the OUTSTAT= data set, and PROC SCORE will subtract the original variable means from the new variables and divide them by the original variable standard deviations before multiplying.

In general, procedures that output scoring coefficients in their OUTSTAT= data sets provide the necessary information for PROC SCORE to determine the appropriate standardization. However, if you use PROC SCORE with a scoring coefficients data set that you constructed without _TYPE_='MEAN' and _TYPE_='STD' observations, you might have to do the relevant centering or standardization of the new data first. If you do this, you must use the means and standard deviations of the original variables—that is, the variables that were used to generate the coefficients—not the means and standard deviations of the variables to be scored.

See the section "Getting Started: SCORE Procedure" on page 6672 for further illustration.

Getting Started: SCORE Procedure

The SCORE procedure multiplies the values from two SAS data sets and creates a new data set to contain the results of the multiplication. The variables in the new data set are linear combinations of the variables in the two input data sets. Typically, one of these data sets contains raw data that you want to score, and the other data set contains scoring coefficients.

The following example demonstrates how to use the SCORE procedure to multiply values from two SAS data sets, one containing factor-scoring coefficients and the other containing raw data to be scored using the scoring coefficients.

Suppose you are interested in the performance of three different types of schools: private schools, state-run urban schools, and state-run rural schools. You want to compare the schools' performances as measured by student grades on standard tests in English, mathematics, and biology. You administer these tests and record the scores for each of the three types of schools.

The following DATA step creates the SAS data set Schools. The data are provided by Chaseling (1996).

```
data Schools;
   input Type $ English Math Biology @@;
   datalines;
p  52  55  45  p  42  49  40  p  63  64  54
p  47  50  51  p  64  69  47  p  63  67  54
p  59  63  42  p  56  61  41  p  41  44  72

   ... more lines ...

r  50  47  49  r  55  48  46  r  38  36  51
;
```

The data set Schools contains the character variable Type, which represents the type of school. Valid values are p (private schools), r (state-run rural schools), and u (state-run urban schools).

The three numeric variables in the data set are English, Math, and Biology, which represent the student scores for English, mathematics, and biology, respectively. The double trailing at sign (@@) in the INPUT statement specifies that observations are input from each line until all values are read.

The following statements invoke the FACTOR procedure to compute the data set of factor scoring coefficients. The statements perform a principal components factor analysis that uses all three numeric variables in the SAS data set Schools. The OUTSTAT= option requests that PROC FACTOR output the factor scores to the data set Scores. The NOPRINT option suppresses display of the output.

```
proc factor data=Schools score outstat=Scores noprint;
   var english math biology;
run;

proc score data=schools score=Scores out=New;
   var english math biology;
   id type;
run;
```

The SCORE procedure is then invoked using Schools as the raw data set to be scored and Scores as the scoring data set. The OUT= option creates the SAS data set New to contain the linear combinations.

The VAR statement specifies that the variables English, Math, and Biology are used in computing scores. The ID statement copies the variable Type from the Schools data set to the output data set New.

The following statements print the SAS output data set Scores, the first two observations from the original data set Schools, and the first two observations of the resulting data set New.

```
title 'OUTSTAT= Data Set from PROC FACTOR';
proc print data=Scores;
run;

title 'First Two Observations of the DATA= Data Set from PROC SCORE';
proc print data=Schools(obs=2);
run;

title 'First Two Observations of the OUT= Data Set from PROC SCORE';
proc print data=New(obs=2);
run;
```

Figure 79.1 displays the output data set Scores produced by the FACTOR procedure. The last observation (number 11) contains the scoring coefficients (_TYPE_='SCORE'). Only one factor has been retained.

2	p	42	49	40

Figure 79.3 lists the first two observations of the output data set New created by PROC SCORE.

Figure 79.3 Listing of the New Data Set

First Two Observations of the OUT= Data Set from PROC SCORE

Obs	Type	Factor1
1	p	-0.17604
2	p	-0.80294

The score variable Factor1 in the New data set is named according to the value of the _NAME_ variable in the Scores data set. The values of the variable Factor1 are computed as follows: the DATA= data set variables are standardized using the same means and standard deviations that PROC FACTOR used when extracting the factors because the Scores data set contains observations with _TYPE_='MEAN' and _TYPE_='STD'.

Note that in order to correctly use standardized scoring coefficients created by other procedures such as PROC FACTOR in this example, the data to be scored must be standardized in the same way that the data were standardized when the scoring coefficients were computed. Otherwise, the resulting scores might be incorrect. PROC SCORE does this automatically if the SCORE= data set is the original OUTSTAT= data set output from the procedure creating the scoring coefficients.

These standardized variables are then multiplied by their respective standardized scoring coefficients from the data set Scores. These products are summed over all three variables, and the sum is the value of the new variable Factor1. The first two values of the scored variable Factor1 are obtained as follows:

$$\left(\frac{(52-55.525)}{12.949}\times 0.390\right)+\left(\frac{(55-52.325)}{12.356}\times 0.378\right)+\left(\frac{(45-50.350)}{12.239}\times 0.347\right)=-0.17604$$

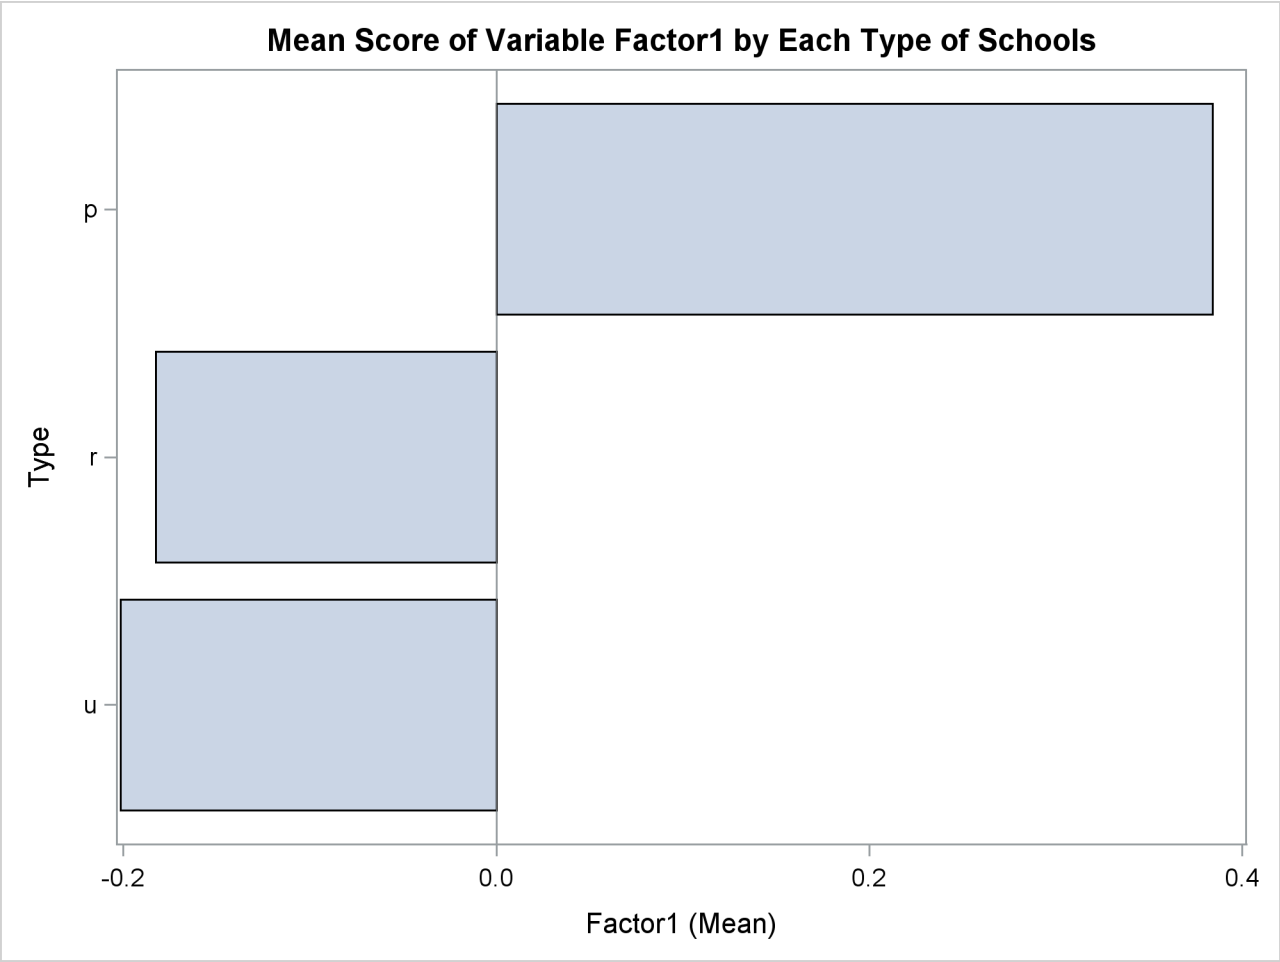
$$\left(\frac{(42-55.525)}{12.949}\times 0.390\right)+\left(\frac{(49-52.325)}{12.356}\times 0.378\right)+\left(\frac{(40-50.350)}{12.239}\times 0.347\right)=-0.80294$$

The following statements request that the SGPLOT procedure produce a horizontal bar chart of the variable Type. The length of each bar represents the mean of the variable Factor1.

```
title 'Mean Score of Variable Factor1 by Each Type of Schools';
proc sgplot data=New;
   hbar type / stat = mean response=Factor1;
run;
```

Figure 79.4 displays the mean score of the variable Factor1 for each of the three school types. For private schools (Type=p), the average value of the variable Factor1 is 0.384, while for state-run schools the average values are much lower. The state-run urban schools (Type=u) have the lowest mean value of –0.202, and the state-run rural schools (Type=r) have a mean value of –0.183.

Figure 79.4 Bar Chart of School Type



Syntax: SCORE Procedure

The following statements are available in the SCORE procedure:

PROC SCORE DATA=SAS-data-set< *options* > **;**
BY *variables* **;**
ID *variables* **;**
VAR *variables* **;**

The only required statement is the PROC SCORE statement. The BY, ID, and VAR statements are described following the PROC SCORE statement.

PROC SCORE Statement

PROC SCORE DATA= *SAS-data-set* < *options* > **;**

You can specify the following options in the PROC SCORE statement.

DATA=*SAS-data-set*
names the input SAS data set containing the raw data to score. This option is required.

NOSTD
suppresses centering and scaling of the raw data. Ordinarily, if PROC SCORE finds _TYPE_='MEAN', _TYPE_= 'USCORE', _TYPE_='USTD', or _TYPE_='STD' observations in the SCORE= data set, the procedure uses these to standardize the raw data before scoring.

OUT=*SAS-data-set*
specifies the name of the SAS data set created by PROC SCORE. If you want to create a permanent SAS data set, you must specify a two-level name. See *SAS Language Reference: Concepts* for more information about permanent SAS data sets. If the OUT= option is omitted, PROC SCORE still creates an output data set and automatically names it according to the DATA*n* convention, as if you omitted a data set name in a DATA statement.

PREDICT
specifies that PROC SCORE should treat coefficients of −1 in the SCORE= data set as 0. In regression applications, the dependent variable is coded with a coefficient of −1. Applied directly to regression results, PROC SCORE produces negative residuals (see the description of the RESIDUAL option, which follows); the PREDICT option produces predicted values instead.

RESIDUAL
reverses the sign of each score. Applied directly to regression results, PROC SCORE produces negative residuals (PREDICT−ACTUAL); the RESIDUAL option produces positive residuals (ACTUAL−PREDICT) instead.

SCORE=*SAS-data-set*
names the data set containing the scoring coefficients. If you omit the SCORE= option, the most

recently created SAS data set is used. This data set must have two special variables: _TYPE_ and either _NAME_ or _MODEL_.

TYPE=*name* **or** *'string'*

specifies the observations in the SCORE= data set that contain scoring coefficients. The TYPE= procedure option is unrelated to the data set option that has the same name. PROC SCORE examines the values of the special variable _TYPE_ in the SCORE= data set. When the value of _TYPE_ matches TYPE=*name*, the observation in the SCORE= data set is used to score the raw data in the DATA= data set.

If you omit the TYPE= option, scoring coefficients are read from observations with either _TYPE_='SCORE' or _TYPE_='USCORE'. Because the default for PROC SCORE is TYPE=SCORE, you need not specify the TYPE= option for factor scoring or for computing scores from OUTSTAT= data sets from the CANCORR, CANDISC, PRINCOMP, or VARCLUS procedure. When you use regression coefficients from PROC REG, specify TYPE=PARMS.

The maximum length of the argument specified in the TYPE= option depends on the length defined by the VALIDVARNAME= SAS system option. For additional information, see *SAS Language Reference: Dictionary*.

Note that the TYPE= option setting is not case sensitive. For example, the two option settings TYPE='MyScore' and TYPE='myscore' are equivalent.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC SCORE to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SCORE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

You can specify a BY statement to apply separate groups of scoring coefficients to the entire DATA= data set.

If the DATA= data set does not contain any of the BY variables, the entire DATA= data set is scored by each BY group of scoring coefficients in the SCORE= data set.

If the DATA= data set contains some but not all of the BY variables, or if some BY variables do not have the same type or length in the DATA= data set as in the SCORE= data set, then PROC SCORE prints an error message and stops.

If all the BY variables appear in the DATA= data set with the same type and length as in the SCORE= data set, then each BY group in the DATA= data set is scored using scoring coefficients from the corresponding BY group in the SCORE= data set. The BY groups in the DATA= data set must be in the same order as in the SCORE= data set. All BY groups in the DATA= data set must also appear in the SCORE= data set. If you do not specify the NOTSORTED option, some BY groups can appear in the SCORE= data set but not in the DATA= data set; such BY groups are not used in computing scores.

ID Statement

ID *variables* **;**

The ID statement identifies variables from the DATA= data set to be included in the OUT= data set. If there is no ID statement, all variables from the DATA= data set are included in the OUT= data set. The ID variables can be character or numeric.

VAR Statement

VAR *variables* **;**

The VAR statement specifies the variables to be used in computing scores. These variables must be in both the DATA= and SCORE= input data sets and must be numeric. If you do not specify a VAR statement, the procedure uses all numeric variables in the SCORE= data set. You should almost always specify a VAR statement with PROC SCORE because you would rarely use all the numeric variables in your data set to compute scores.

Details: SCORE Procedure

Missing Values

If one of the scoring variables in the DATA= data set has a missing value for an observation, all the scores have missing values for that observation. The exception to this criterion is that if the PREDICT option is specified, the variable with a coefficient of −1 can tolerate a missing value and still produce a prediction score. Also, a variable with a coefficient of 0 can tolerate a missing value.

If a scoring coefficient in the SCORE= data set has a missing value for an observation, the coefficient is not used in creating the new score variable for the observation. In other words, missing values of scoring coefficients are treated as zeros. This treatment affects only the observation in which the missing value occurs.

Regression Parameter Estimates from PROC REG

If the SCORE= data set is an OUTEST= data set produced by PROC REG and if you specify TYPE=PARMS, the interpretation of the new score variables depends on the PROC SCORE options chosen and the variables listed in the VAR statement. If the VAR statement contains only the independent variables used in a model in PROC REG, the new score variables give the predicted values. If the VAR statement contains the dependent variables and the independent variables used in a model in PROC REG, the interpretation of the new score variables depends on the PROC SCORE options chosen. If you omit both the PREDICT and the RESIDUAL options, the new score variables give negative residuals (PREDICT−ACTUAL). If you specify the RESIDUAL option, the new score variables give positive residuals (ACTUAL−PREDICT). If you specify the PREDICT option, the new score variables give predicted values.

Unless you specify the NOINT option for PROC REG, the OUTEST= data set contains the variable Intercept. The SCORE procedure uses the intercept value in computing the scores.

Output Data Set

PROC SCORE produces an output data set but displays no output. The output OUT= data set contains the following variables:

- the ID variables, if any
- all variables from the DATA= data set, if no ID variables are specified
- the BY variables, if any
- the new score variables, named from the _NAME_ or _MODEL_ values in the SCORE= data set

Computational Resources

Let

v = number of variables used in computing scores
s = number of new score variables
b = maximum number of new score variables in a BY group
n = original input value

Memory

The array storage required is approximately $8(4v+(3+v)b+s)$ bytes. When you do not use BY processing, the array storage required is approximately $8(4v + (4 + v)s)$ bytes.

Time

The time required to construct the scoring matrix is roughly proportional to vs, and the time needed to compute the scores is roughly proportional to nvs.

Examples: SCORE Procedure

The following three examples use a subset of the Fitness data set. The complete data set is given in Chapter 76, "The REG Procedure."

Example 79.1: Factor Scoring Coefficients

This example shows how to use PROC SCORE with factor scoring coefficients. First, the FACTOR procedure produces an output data set containing scoring coefficients in observations identified by _TYPE_='SCORE'. These data, together with the original data set Fitness, are supplied to PROC SCORE, resulting in a data set containing scores Factor1 and Factor2. The following statements produce Output 79.1.1 through Output 79.1.3:

```
   /* This data set contains only the first 12 observations   */
   /* from the full data set used in the chapter on PROC REG. */
data Fitness;
   input Age Weight Oxygen RunTime RestPulse RunPulse @@;
   datalines;

Since the PROC SCORE statement does not contain the NOSTD option, the data in the Fitness data set are standardized before scoring. For each variable specified in the VAR statement, the mean and standard deviation are obtained from the FactOut data set. For each observation in the Fitness data set, the variables are then standardized. For example, for observation 1 in the Fitness data set, the variable Age is standardized to $0.5569 = [(44 - 42.4167)/2.8431]$.

After the data in the Fitness data set are standardized, the standardized values of the variables in the VAR statement are multiplied by the matching coefficients in the FactOut data set, and the resulting products are summed. This sum is output as a value of the new score variable.

Output 79.1.3 displays the FScore data set produced by PROC SCORE. This data set contains the variables Age, Weight, Oxygen, RunTime, RestPulse, and RunPulse from the Fitness data set. It also contains Factor1 and Factor2, the two new score variables.

Output 79.1.3 OUT= Data Set from PROC SCORE Reproduced with PROC PRINT

Example 79.2: Regression Parameter Estimates

In this example, PROC REG computes regression parameter estimates for the Fitness data. (See Example 79.1 to for more information about how to create the Fitness data set.) The parameter estimates are output to a data set and used as scoring coefficients. For the first part of this example, PROC SCORE is used to score the Fitness data, which are the same data used in the regression.

In the second part of this example, PROC SCORE is used to score a new data set, Fitness2. For PROC SCORE, the TYPE= specification is PARMS, and the names of the score variables are found in the variable _MODEL_, which gets its values from the model label. The following code produces Output 79.2.1 through Output 79.2.3:

```
proc reg data=Fitness outest=RegOut;
   OxyHat: model Oxygen=Age Weight RunTime RunPulse RestPulse;
   title 'Regression Scoring Example';
run;
proc print data=RegOut;
   title2 'OUTEST= Data Set from PROC REG';
run;

proc score data=Fitness score=RegOut out=RScoreP type=parms;
   var Age Weight RunTime RunPulse RestPulse;
run;
```

```
proc print data=RScoreP;
   title2 'Predicted Scores for Regression';
run;

proc score data=Fitness score=RegOut out=RScoreR type=parms;
   var Oxygen Age Weight RunTime RunPulse RestPulse;
run;
proc print data=RScoreR;
   title2 'Negative Residual Scores for Regression';
run;
```

Output 79.2.1 shows the PROC REG output. The column labeled "Parameter Estimates" lists the parameter estimates. These estimates are output to the RegOut data set.

Output 79.2.1 Creating an OUTEST= Data Set with PROC REG

Age	1	-0.63045	0.42503	-1.48	0.1885
Weight	1	-0.10586	0.11869	-0.89	0.4068
RunTime	1	-1.75698	0.93844	-1.87	0.1103
RunPulse	1	-0.22891	0.12169	-1.88	0.1090
RestPulse	1	-0.17910	0.13005	-1.38	0.2176

Output 79.2.2 lists the RegOut data set. Note that _TYPE_='PARMS' and _MODEL_='OXYHAT', which are from the label in the MODEL statement in PROC REG.

Output 79.2.2 OUTEST= Data Set from PROC REG Reproduced with PROC PRINT

Regression Scoring Example
OUTEST= Data Set from PROC REG

Obs	_MODEL_	_TYPE_	_DEPVAR_	_RMSE_	Intercept	Age
1	OxyHat	PARMS	Oxygen	2.53970	151.916	−0.63045

Obs	Weight	RunTime	RunPulse	Rest Pulse	Oxygen
1	−0.10586	−1.75698	−0.22891	−0.17910	−1

Output 79.2.3 lists the data sets created by PROC SCORE. Since the SCORE= data set does not contain observations with _TYPE_='MEAN' or _TYPE_='STD', the data in the Fitness data set are not standardized before scoring. The SCORE= data set contains the variable Intercept, so this intercept value is used in computing the score. To produce the RScoreP data set, the VAR statement in PROC SCORE includes only the independent variables from the model in PROC REG. As a result, the OxyHat variable contains predicted values. To produce the RScoreR data set, the VAR statement in PROC SCORE includes both the dependent variables and the independent variables from the model in PROC REG. As a result, the OxyHat variable contains negative residuals (PREDICT−ACTUAL) as shown in Output 79.2.4. If the RESIDUAL option is specified, the variable OxyHat contains positive residuals (ACTUAL−PREDICT). If the PREDICT option is specified, the OxyHat variable contains predicted values.

Output 79.2.3 Predicted Scores from the OUT= Data Set Created by PROC SCORE

Regression Scoring Example
Predicted Scores for Regression

;
proc print data=Fitness2;
   title 'Regression Scoring Example';
   title2 'New Raw Data Set to be Scored';
run;

proc score data=Fitness2 score=RegOut out=NewPred type=parms
           nostd predict;
   var Oxygen Age Weight RunTime RunPulse RestPulse;
run;

proc print data=NewPred;
   title2 'Predicted Scores for Regression';
   title3 'for Additional Data from FITNESS2';
run;
```

Output 79.2.5 lists the Fitness2 data set.

Output 79.2.5 Listing of the Fitness2 Data Set

Regression Scoring Example
New Raw Data Set to be Scored

Obs	Age	Weight	Oxygen	Run Time	Rest Pulse	Run Pulse
1	45	66.45	44.754	11.12	51	176
2	47	79.15	47.273	10.60	47	162
3	54	83.12	51.855	10.33	50	166
4	49	81.42	49.156	8.95	44	180

PROC SCORE scores the Fitness2 data set by using the parameter estimates in the RegOut data set. These parameter estimates result from fitting a regression equation to the Fitness data set. The NOSTD option is specified, so the raw data are not standardized before scoring. (However, the NOSTD option is not necessary here. The SCORE= data set does not contain observations with _TYPE_='MEAN' or _TYPE_='STD', so standardization is not performed.) The VAR statement contains the dependent variables and the independent variables used in PROC REG. In addition, the PREDICT option is specified. This combination gives predicted values for the new score variable. The name of the new score variable is OxyHat, from the value of the _MODEL_ variable in the SCORE= data set. Output 79.2.6 shows the data set produced by PROC SCORE.

Output 79.2.6 Predicted Scores from the OUT= Data Set Created by PROC SCORE and Reproduced Using PROC PRINT

Regression Scoring Example
Predicted Scores for Regression
for Additional Data from FITNESS2

3	54	83.12	51.855	10.33	50	166	43.9682
4	49	81.42	49.156	8.95	44	180	47.5949

Example 79.3: Custom Scoring Coefficients

This example uses a specially created custom scoring data set and produces Output 79.3.1 and Output 79.3.2. The first scoring coefficient creates a variable that is Age−Weight; the second scoring coefficient evaluates the variable RunPulse−RstPulse; and the third scoring coefficient totals all six variables. Since the scoring coefficients data set (data set A) does not contain any observations with _TYPE_='MEAN' or _TYPE_='STD', the data in the Fitness data set (see Example 79.1) are not standardized before scoring.

The following statements produce Output 79.3.1 and Output 79.3.2:

```
data A;
   input _type_ $ _name_ $
         Age Weight RunTime RunPulse RestPulse;
   datalines;
SCORE  AGE_WGT  1 -1  0  0  0
SCORE  RUN_RST  0  0  0  1 -1
SCORE  TOTAL    1  1  1  1  1
;
proc print data=A;
   title 'Constructed Scoring Example';
   title2 'Scoring Coefficients';
run;

proc score data=Fitness score=A out=B;
   var Age Weight RunTime RunPulse RestPulse;
run;
proc print data=B;
   title2 'Scored Data';
run;
```

Output 79.3.1 Custom Scoring Data Set and Scored Fitness Data: PROC PRINT

Chapter 80

The SEQDESIGN Procedure

Contents

Overview: SEQDESIGN Procedure

The purpose of the SEQDESIGN procedure is to design interim analyses for clinical trials. Clinical trials are experiments on human subjects to demonstrate the efficacy and safety of new drugs or treatments. A simple example is a trial to test the effectiveness of a new drug in humans by comparing the outcomes in a group of patients who receive the new drug with the outcomes in a comparable group of patients who receive a placebo.

A clinical trial is conducted according to a plan called a *protocol*. A protocol details the objectives of the trial, the data collection process, and the analysis. The protocol specifies the null hypothesis and an alternative hypothesis, a test statistic, the probability α of a Type I error, the probability β of a Type II error, the sample size needed to attain a specified power of $1 - \beta$ at an alternative reference, and critical values that are associated with the test statistic.

In a fixed-sample trial, data about all individuals are first collected and then examined at the end of the study. Most major trials have committees that periodically monitor safety and efficacy data during the trial and recommend that a trial be stopped for safety concerns such as an unacceptable toxicity level. In certain situations, the committee might recommend that a trial be stopped for efficacy. In contrast to a fixed-sample trial, a group sequential trial provides for interim analyses before the completion of the trial while maintaining the specified overall Type I and Type II error probabilities.

A group sequential trial is most useful in situations where it is important to monitor the trial to prevent unnecessary exposure of patients to an unsafe new drug, or alternatively to a placebo treatment if the new drug shows significant improvement. In most cases, if a group sequential trial stops early for safety concerns,

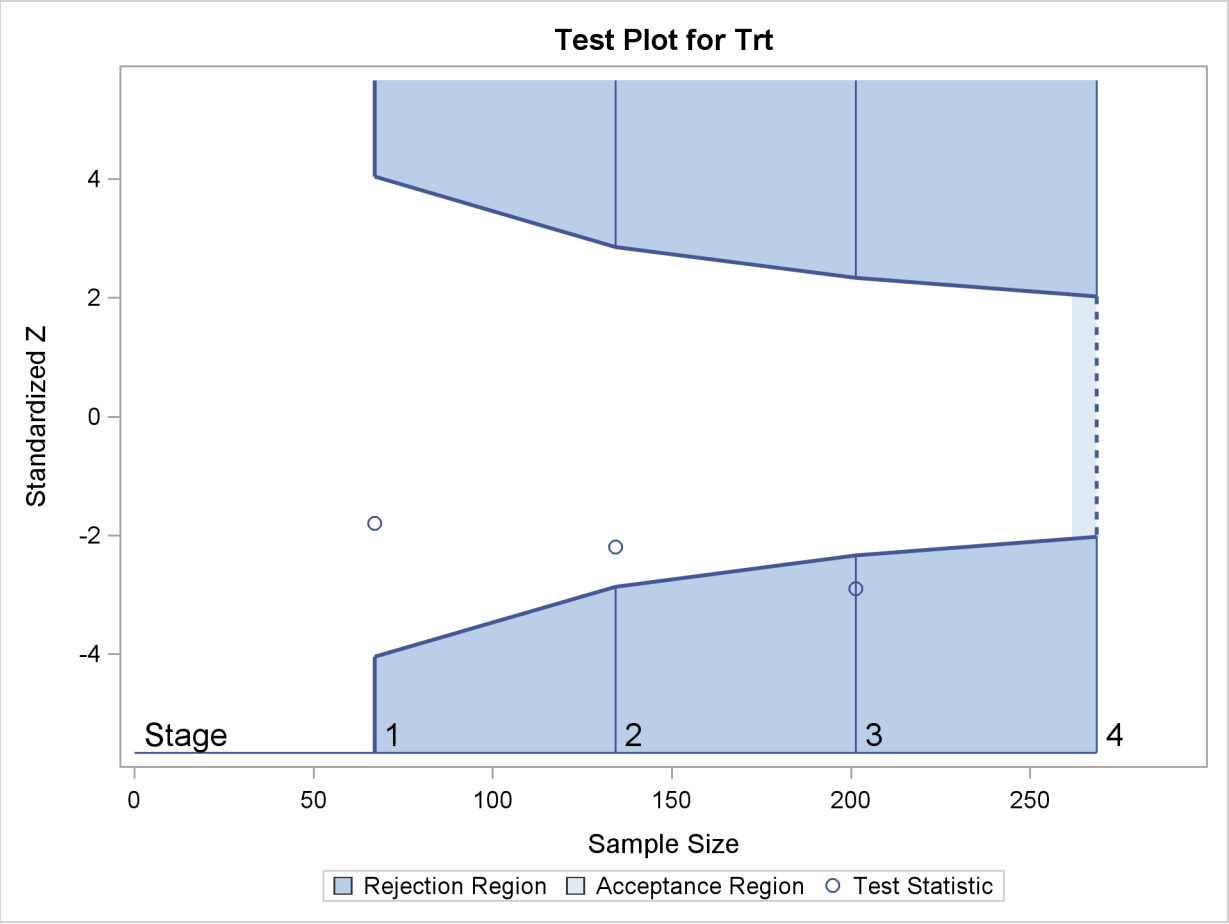
fewer patients are exposed to the new treatment than in the fixed-sample trial. If a trial stops early for efficacy reasons, the new treatment is available sooner than it would be in a fixed-sample trial. Early stopping can also save time and resources.

A group sequential design provides detailed specifications for a group sequential trial. In addition to the usual specification for a fixed-sample design, it provides the total number of stages (the number of interim stages plus a final stage) and a stopping criterion to reject, to accept, or to either reject or accept the null hypothesis at each interim stage. It also provides critical values and the sample size at each stage for the trial.

At each interim stage, the data collected at the current stage in addition to the data collected at previous stages are analyzed, and statistics such as a maximum likelihood test statistic and its associated standard error are computed. The test statistic is then compared with critical values that are generated from the sequential design, and the trial is stopped or continued. If a trial continues to the final stage, the null hypothesis is either rejected or accepted. The critical values for each stage are chosen in such a way that the overall α and β are maintained at the specified levels.

Figure 80.1 shows a two-sided symmetric group sequential trial that stops early to reject the null hypothesis that the parameter Trt is zero.

Figure 80.1 Sequential Plot for Two-Sided Test



The trial has four stages, which are indicated by the vertical lines labeled 1, 2, 3, and 4. With early stopping to reject the null hypothesis, the lower rejection boundary is constructed by connecting the lower critical values for the stages. Similarly, the upper rejection boundary is constructed by connecting the upper critical values for the stages. The horizontal axis indicates the sample size for the group sequential trial, and the vertical axis indicates the values of the test statistic on the standardized Z scale.

At each interim stage, if the test statistic falls into a rejection region (the darker shaded areas in Figure 80.1), the trial stops and the null hypothesis is rejected. Otherwise, the trial continues to the next stage. At the final stage (stage 4), the null hypothesis is rejected if Z falls into a rejection region. Otherwise, the null hypothesis is not rejected. In Figure 80.1, the test statistic does not fall into the rejection regions for stages 1 and 2, and so the trial continues to stage 3. At stage 3, the test statistic falls into the rejection region, and the null hypothesis is rejected.

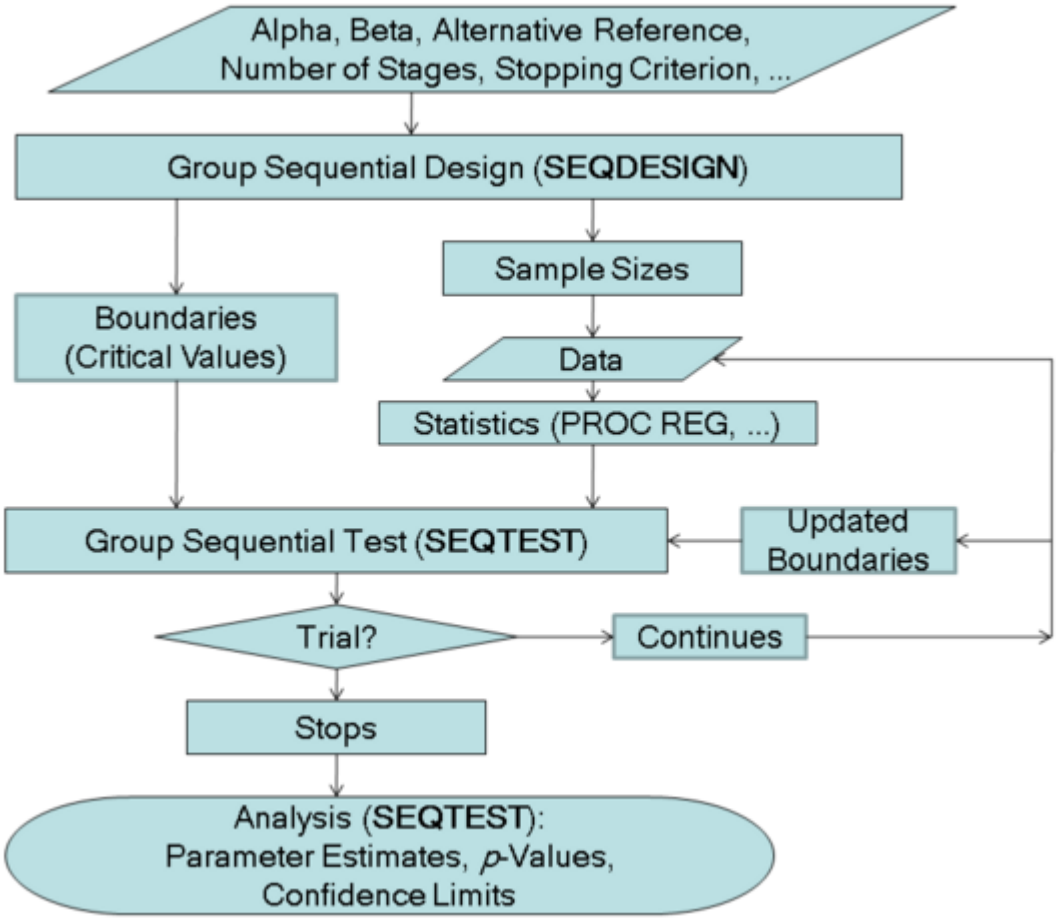
A group sequential trial usually involves six steps:

1. You specify the statistical details of the design, including the null and alternative hypotheses, a test statistic for the hypothesis test, the Type I and II error probabilities, a stopping criterion, the total number of stages, and the relative information level at each stage.
2. You compute the boundary values for the trial based on the specifications in Step 1. You also compute the sample size required at each stage for the specified hypothesis test.
3. At each stage, you collect additional data with the required sample sizes. The data available at each stage include the data collected at previous stages in addition to the data collected at the current stage.
4. At each stage, you analyze the available data with a procedure such as the REG procedure, and you compute the test statistic.
5. At each stage, you compare the test statistic with the corresponding boundary values. You stop the trial to reject or accept the hypothesis, or you continue the trial to the next stage. If you continue the trial to the final stage, you either accept or reject the hypothesis.
6. After the trial stops, you compute parameter estimates, confidence limits for the parameter, and a p-value for the hypothesis test.

You use the SEQDESIGN procedure at Step 2 to compute the initial boundary values and required sample sizes for the trial. You use the companion SEQTEST procedure at Step 5 to compare the test statistic with its boundary values. At stage 1, the boundary values are derived by using the boundary information tables created by the SEQDESIGN procedure. These boundary information tables are structured for input to the SEQTEST procedure. At each subsequent stage, the boundary values are derived by using the test information tables are created by the SEQTEST procedure at the previous stage. These test information tables are also structured for input to the SEQTEST procedure. You also use the SEQTEST procedure at Step 6 to compute parameter estimates, confidence limits, and p-values after the trial stops.

The flowchart in Figure 80.2 summarizes the steps in a typical group sequential trial and the relevant SAS procedures.

Figure 80.2 Group Sequential Trial



Features of the SEQDESIGN Procedure

The SEQDESIGN procedure assumes that the standardized Z test statistics for the null hypothesis $H_0 : \theta = 0$ at the stages have the joint canonical distribution with the information levels at the stages for the parameter θ. This implies that these test statistics are normally distributed. If the test statistic is not normally distributed, then it is assumed that the test statistic is computed from a large sample such that the statistic has an approximately normal distribution. See the section "Statistical Assumptions for Group Sequential Designs" on page 6739 for a detailed description of the joint canonical distribution.

You can use the SEQDESIGN procedure to compute required sample sizes for commonly used hypothesis tests. Note that for a fixed-sample design, you should use the POWER and GLMPOWER procedures to compute sample sizes.

The applicable tests include tests for binomial proportions and the log-rank test for two survival distributions. See the section "Applicable One-Sample Tests and Sample Size Computation" on page 6770, the section "Applicable Two-Sample Tests and Sample Size Computation" on page 6772, and the section "Applicable Regression Parameter Tests and Sample Size Computation" on page 6781 for examples of applicable tests in group sequential trials.

At each stage, the data are analyzed with a statistical procedure such as the REG procedure, and a test statistic and its associated information level are computed. The information level is the amount of information available about the unknown parameter. For a maximum likelihood statistic, the information level is the inverse of its variance.

At each stage, you use the SEQTEST procedure to derive the boundary values that correspond to the information level associated with the test statistic. You then use the SEQTEST procedure to compare the test statistic with these boundary values. When a trial is stopped at an interim stage or at the final stage, the SEQTEST procedure also derives parameter estimates, confidence limits for the parameter, and a p-value for hypothesis testing.

Output from the SEQDESIGN Procedure

In addition to computing the boundary values for a group sequential design, the SEQDESIGN procedure computes the following quantities:

- maximum sample size (as a percentage of the corresponding fixed-sample size) if the trial does not stop at an interim stage
- average sample numbers (as percentages of the corresponding fixed-sample sizes for nonsurvival data or fixed-sample numbers of events for survival data) under various hypothetical references, including the null and alternative references
- stopping probabilities at each stage under various hypothetical references to indicate how likely it is that the trial will stop at that stage
- sample sizes required at each stage for the specified hypothesis test
- numbers of events required at each stage for the specified hypothesis test with survival data

You can create more than one design with multiple DESIGN statements in the SEQDESIGN procedure and then choose the design with the most desirable features. The next two subsections introduce some basic aspects of group sequential designs that are useful for getting started with the SEQDESIGN procedure.

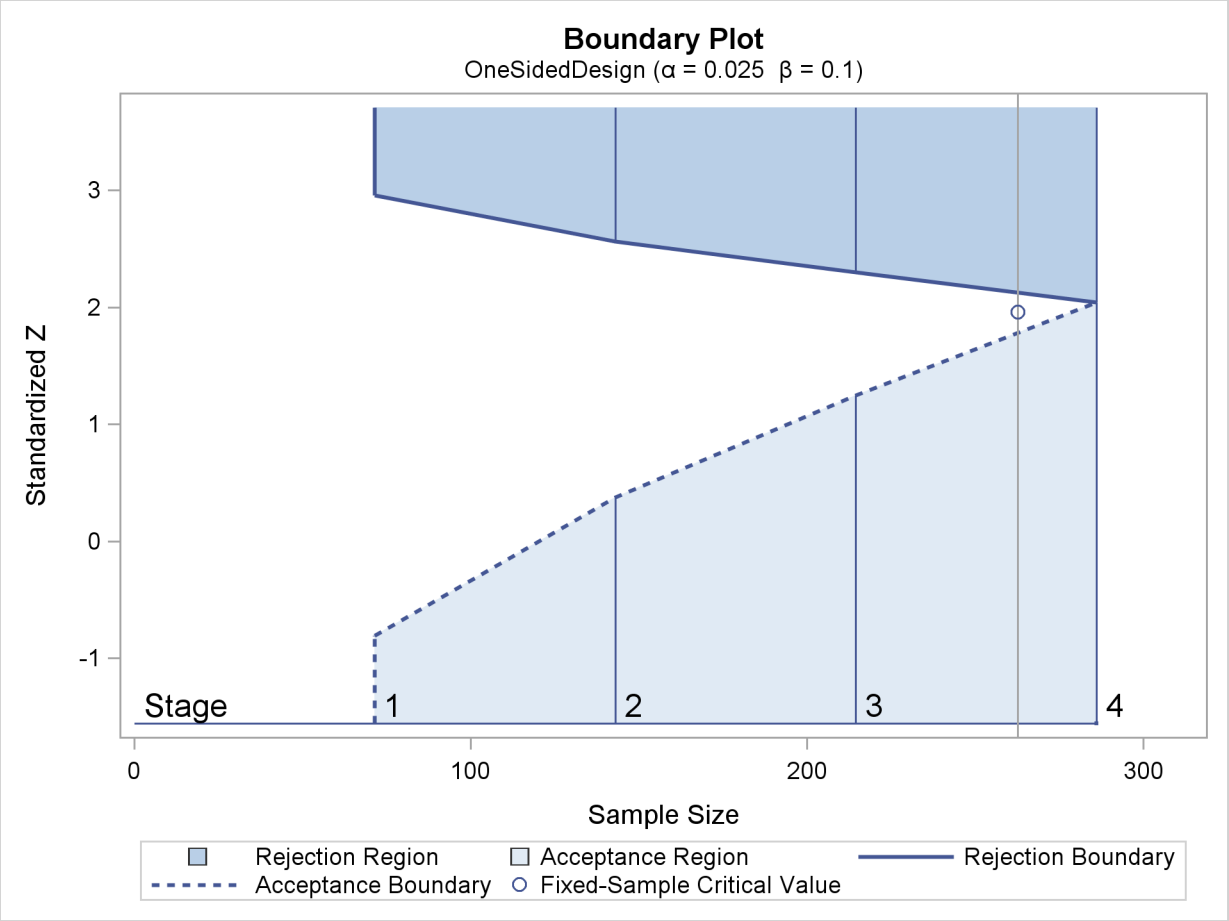
Boundaries for Group Sequential Designs

A one-sided test is a test of a hypothesis with either a lower alternative ($H_1 : \theta < 0$) or an upper alternative ($H_1 : \theta > 0$), and a two-sided test is a test with a two-sided alternative ($H_1 : \theta \neq 0$). The number of critical values for a test depends on whether the alternative is one-sided or two-sided, and it also depends on whether the trial is conducted with a fixed-sample design or a group sequential design.

For a fixed-sample trial, a one-sided test has one critical value and a two-sided test has two critical values. These critical values are computed with the specified Type I error probability α. In contrast, at each interim stage of a group sequential trial, a one-sided test has up to two critical values and a two-sided group sequential test has up to four critical values. Thus, there are two or four possible boundaries for a group sequential design, and each boundary is a set of critical values, one from each stage.

Figure 80.3 illustrates the boundaries for a one-sided test with an upper alternative that allows for early stopping to either reject or accept the null hypothesis.

Figure 80.3 Boundary Plot for One-Sided Design



With an upper alternative, as in this example, the design has the following two boundaries: an upper α (rejection) boundary for the rejection region that consists of upper rejection critical values and an upper β (acceptance) boundary for the acceptance region that consists of upper acceptance critical values. The stages are indicated by vertical lines with accompanying stage numbers. In Figure 80.3, the horizontal axis indicates the cumulative sample size for the group sequential trial. The vertical axis indicates the critical values at each stage on the standardized Z scale. Other scales can be used for the vertical axis, including the MLE scale, score statistic scale, and p-value scale.

At each interim stage, if the test statistic is in the rejection region (darker shaded area in Figure 80.3), the trial stops and the null hypothesis is rejected. If the test statistic is in the acceptance region (lightly shaded area in Figure 80.3), the trial stops and the hypothesis is accepted. Otherwise, the trial continues to the next stage. If the trial proceeds to the final stage (stage 4), the upper α and upper β critical values are identical, and the trial stops to either reject or accept the null hypothesis.

Group Sequential Methods

For a group sequential design, there are two possible boundaries for a one-sided test and four possible boundaries for a two-sided test. Each boundary consists of one boundary value (critical value) for each stage. The SEQDESIGN procedure provides various methods for computing the boundary values.

The boundary value for a fixed-sample test cannot be applied to each stage of sequential design because, as shown by Armitage, McPherson, and Rowe (1969), repeated significance tests at a fixed level on accumulating data increase the probability of a Type I error. For example, with a fixed-sample two-sided test, the critical values ± 1.96 for a standardized Z statistic produce a Type I error probability level $\alpha = 0.05$. But for a two-sided group sequential test with two equally spaced stages, if the same critical values ± 1.96 are used to reject the null hypothesis at these two stages, the Type I error probability level is $\alpha = 0.083$, larger than the fixed-sample α.

Numerous methods are available for deriving the critical values for each boundary in a sequential design. Pocock (1977) applies repeated significance tests to group sequential trials with equal-size groups and derives a constant critical value on the standardized normal Z scale across all stages that maintains the specified Type I error probability level. O'Brien and Fleming (1979) propose a sequential procedure that has boundary values (in absolute value) decrease over the stages on the standardized normal Z scale.

The SEQDESIGN procedure provides the following three types of methods:

- fixed boundary shape methods, which derive boundaries with specified boundary shapes
- Whitehead methods, which adjust boundaries derived for continuous monitoring so that they apply to discrete monitoring
- error spending methods

Each type of methods uses a distinct approach to derive the boundary values for a group sequential trial. Whitehead methods require much less computation with resulting Type I error probability and power that are close but differ slightly from the specified values due to the approximations used in deriving the tests (Jennison and Turnbull 2000, p. 106). Fixed boundary shape methods derive boundary values by estimating a fixed number of parameters and require more computation. Error spending methods derive boundary values at each stage sequentially and require much more computation than other types of methods for group sequential trials with a large number of stages.

Within each type of methods, you can choose methods that creating boundary values range from conservative stopping boundary values at early stages to liberal stopping boundary values at very early stages.

You can use the SEQDESIGN procedure to specify methods from the same type for each design. A different method can be specified for each boundary separately, but all methods in a design must be of the same type.

Fixed Boundary Shape Methods

The fixed boundary shape methods include the unified family methods and the Haybittle-Peto method. The unified family methods (Kittelson and Emerson 1999) derive boundaries from specified boundary shapes.

These methods include Pocock's method (Pocock 1977) and the O'Brien-Fleming method (O'Brien and Fleming 1979) as special cases.

The Haybittle-Peto method (Haybittle 1971; Peto et al. 1976) uses a value of 3 for the critical values in interim stages, so the critical value at the final stage is close to the critical value for the fixed-sample design. In the SEQDESIGN procedure, the Haybittle-Peto method has been generalized to allow for different boundary values at interim stages.

Whitehead Methods

Whitehead and Stratton (1983) and Whitehead (1997, 2001) develop triangular and straight-line boundaries by adapting tests constructed for continuous monitoring to discrete monitoring of group sequential tests. With continuous monitoring, the values for each boundary fall in a straight line when plotted on the score statistic scale. The discrete boundary is derived by subtracting the expected overshoot from the continuous boundary to obtain the desired Type I and Type II error probabilities. For a design with early stopping to either reject or accept the null hypothesis, the boundaries form a triangle when plotted on the score statistic scale. See the section "Score Statistic" on page 6729 for a detailed description of the score statistic.

Error Spending Methods

For every sequential design, the α and β errors at each stage can be computed from the boundary values. On the other hand, you can derive the boundary values from specified α and β errors for each stage. The error spending function approach (Lan and DeMets 1983) uses an error spending function to specify the errors at each stage for each boundary and then derives the boundary values.

Getting Started: SEQDESIGN Procedure

This section illustrates a clinical study design that uses a two-sided O'Brien-Fleming design (O'Brien and Fleming 1979) to stop the trial early for ethical concerns about possible harm or for unexpectedly strong efficacy of the new drug.

Suppose that a pharmaceutical company is conducting a clinical trial to test the efficacy of a new cholesterol-lowering drug. The primary focus is low-density lipoprotein (LDL), the so-called bad cholesterol, which is a risk factor for coronary heart disease. LDL is measured in mg/dL, milligrams per deciliter of blood.

The trial consists of two groups of equally allocated patients with elevated LDL levels: an experimental group given the new drug and a placebo control group. Suppose the changes in LDL level after the treatment for individuals in the experimental and control groups are normally distributed with means μ_e and μ_c, respectively, and have a common variance σ^2. Then the null hypothesis of no effect for the new drug is $H_0 : \theta = 0$, where $\theta = \mu_e - \mu_c$.

For a fixed-sample design with a total sample size N, the MLE for θ is computed as $\hat{\theta} = \hat{\mu}_e - \hat{\mu}_c$, where $\hat{\mu}_e$ and $\hat{\mu}_c$ are the sample means of the decreases in LDL level in the experimental and control groups, respectively.

Following the derivation in the section "Test for the Difference between Two Normal Means" on page 6773, the statistic $\hat{\theta}$ has a normal distribution

$$\hat{\theta} \sim N\left(\theta, \frac{4\sigma^2}{N}\right)$$

Thus, under the null hypothesis $H_0 : \theta = 0$, the standardized statistic

$$Z = \frac{\hat{\theta}}{\sqrt{\frac{4\sigma^2}{N}}} \sim N(0, 1)$$

The Z statistic can be used to test the null hypothesis H_0. If the variance σ^2 is unknown, the sample variance can be used to compute the test statistic if it is assumed that the sample variance is computed from a large sample such that the Z statistic has an approximately standard normal distribution.

With a Type I error probability $\alpha = 0.05$, the critical values for the Z statistic are given by $\Phi^{-1}(\alpha/2) = -1.96$ and $\Phi^{-1}(1-\alpha/2) = 1.96$, where Φ is the cumulative standard normal distribution function. At the end of study, if $Z \geq 1.96$, the null hypothesis is rejected for harmful drug effect, and if $Z \leq -1.96$, the null hypothesis is rejected for efficacy of the new drug. Otherwise, the null hypothesis is not rejected and the drug effect is not significant.

Also suppose that for the trial, the alternative reference $\theta = -10$ is the clinically meaningful difference that the trial should detect with a high probability (power). Further suppose that a good estimate of the standard deviation for the changes in LDL level is $\hat{\sigma} = 20$. The following statements invoke the SEQDESIGN procedure and request a four-stage O'Brien-Fleming design for standardized normal test statistics:

```
ods graphics on;
proc seqdesign altref=-10
               plots=boundary(hscale=samplesize)
               ;
   TwoSidedOBrienFleming: design nstages=4
                          method=obf
                          ;
   samplesize model=twosamplemean(stddev=20);
ods output Boundary=Bnd_LDL;
run;
ods graphics off;
```

The ALTREF= option specifies the alternative reference, and the actual maximum information is derived in the SEQDESIGN procedure. With ODS Graphics enabled, the PLOTS=BOUNDARY option displays a boundary plot with the rejection and acceptance regions.

In the DESIGN statement, the label `TwoSidedOBrienFleming` identifies the design in the output tables. By default (or equivalently if you specify ALT=TWOSIDED and STOP=REJECT in the DESIGN statement), the design has a two-sided alternative hypothesis in which early stopping in the interim stages occurs to reject the null hypothesis. That is, at each interim stage, the trial either is stopped to reject the null hypothesis or continues to the next stage.

The NSTAGES=4 option in the DESIGN statement specifies the total number of stages in the group sequential trial, including three interim stages and a final stage. In the SEQDESIGN procedure, the null hypothesis for the design is $H_0 : \theta = 0$. By default (or equivalently if you specify ALPHA=0.05 and BETA=0.10 in

the DESIGN statement), the design has a Type I error probability $\alpha = 0.05$, and a Type II error probability $\beta = 0.10$; the latter corresponds to a power of $1 - \beta = 0.90$ at the alternative reference $H_1 : \theta = -10$.

For a two-sided design with early stopping to reject the null hypothesis, there are two boundaries for the design: an upper α boundary that consists of upper rejection critical values and a lower α boundary that consists of lower rejection critical values. Each boundary is a set of critical values, one from each stage. With the METHOD=OBF option in the DESIGN statement, the O'Brien-Fleming method is used for the two boundaries for the design; see Figure 80.7.

A property of the boundaries constructed with the O'Brien-Fleming design is that the null hypothesis is more difficult to reject in the early stages than in the later stages. That is, the trial is rejected in the early stages only with overwhelming evidence, because in these stages there might not be a sufficient number of responses for a reliable estimate of the treatment effect.

The SAMPLESIZE statement with the MODEL=TWOSAMPLEMEAN option uses the derived maximum information to compute required sample sizes for a two-sample test for mean difference. The ODS OUTPUT statement with the BOUNDARY=BND_LDL option creates an output data set named BND_LDL which contains the resulting boundary information.

In a clinical trial, the amount of information about an unknown parameter available from the data can be measured by the Fisher information. For a maximum likelihood statistic, the information level is the inverse of its variance. See the section "Maximum Likelihood Estimator" on page 6728 for a detailed description of Fisher information. At each stage of the trial, data are collected and analyzed with a statistical procedure, and a test statistic and its corresponding information level are computed.

In this example, you can use the REG procedure to compute the maximum likelihood estimate $\hat{\theta}$ for the drug effect and the corresponding standard error for $\hat{\theta}$. At stage 1, you can use the SEQTEST procedure to compare the test statistic with adjusted boundaries derived from the boundary information stored in the BOUND_LDL data set. At each subsequent stage, you can use the SEQTEST procedure to compare the test statistic with adjusted boundaries derived from the boundary information stored in the test information table created by the SEQTEST procedure at the previous stage. The test information tables are structured for input to the SEQTEST procedure.

At each interim stage, the trial will either be stopped to reject the null hypothesis or continue to the next stage. At the final stage, the null hypothesis is either rejected or accepted.

By default (or equivalently if you specify INFO=EQUAL in the DESIGN statement), the SEQDESIGN procedure derives boundary values with equally spaced information levels for all stages—that is, the same information increment between successive stages. The "Design Information," "Method Information," and "Boundary Information" tables are displayed by default, as shown in Figure 80.4, Figure 80.5, and Figure 80.6, respectively.

The "Design Information" table in Figure 80.4 displays design specifications and four derived statistics: the actual maximum information, the maximum information, the average sample number under the null hypothesis (Null Ref ASN), and the average sample number under the alternative hypothesis (Alt Ref ASN). Except for the actual maximum information, each statistic is expressed as a percentage of the identical statistic for the corresponding fixed-sample information. The average sample number is the expected sample size (for nonsurvival data) or expected number of events (for survival data). Note that for a symmetric two-sided design, the ALTREF=−10 option implies a lower alternative reference of −10 and an upper alternative reference of 10.

Figure 80.4 O'Brien-Fleming Design Information

The SEQDESIGN Procedure
Design: TwoSidedOBrienFleming

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Reject Null
Method	O'Brien-Fleming
Boundary Key	Both
Alternative Reference	-10
Number of Stages	4
Alpha	0.05
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	102.2163
Max Information	0.107403
Null Ref ASN (Percent of Fixed Sample)	101.5728
Alt Ref ASN (Percent of Fixed Sample)	76.7397

The maximum information is the information level at the final stage of the group sequential trial. The Max Information (Percent Fixed-Sample) is the maximum information for the sequential design expressed as a percentage of the information for the corresponding fixed-sample design. In Figure 80.4, the Max Information (Percent Fixed-Sample) is 102.22%, which means that the information needed for the group sequential trial is 2.22% more than that of the corresponding fixed-sample design if the trial does not stop at any interim stage.

The Null Ref ASN (Percent Fixed-Sample) is the average sample number (expected sample size) required under the null hypothesis for the group sequential design expressed as a percentage of the sample size for the corresponding fixed-sample design. In Figure 80.4, the Null Ref ASN is 101.57%, which means that the expected sample size for the group sequential trial is 1.57% greater than the corresponding fixed-sample size.

Similarly, the Alt Ref ASN (Percent Fixed-Sample) is the average sample number (expected sample size) required under the alternative hypothesis for the group sequential design expressed as a percentage of the sample size for the corresponding fixed-sample design. In Figure 80.4, the Alt Ref ASN is 76.74%, which means that the expected sample size for the group sequential trial is 76.74% of the corresponding fixed-sample size. That is, if the alternative hypothesis is true, then on average, only 76.74% of the fixed-sample size is needed for the group sequential trial.

In this example, the O'Brien-Fleming design requires only a slight increase in sample size if the trial proceeds to the final stage. On the other hand, if the alternative hypothesis is correct, this design provides a substantial saving in sample size on average.

The "Method Information" table in Figure 80.5 displays the computed Type I and Type II error probabilities α and β, and the derived drift parameter for the design. For a two-sided test with early stopping to reject the null hypothesis, both lower and upper α boundaries are created. With the specified ALTREF= option, the alternative references are also included.

With the zero null reference, the drift parameter is the standardized alternative reference at the final stage $\theta_1\sqrt{I_X}$, where θ_1 is the alternative reference and I_X is the maximum information. See the section "Specified and Derived Parameters" on page 6764 for a detailed description of the drift parameter. The drift parameters for the design are derived in the SEQDESIGN procedure even if the alternative reference is not specified or derived in the procedure.

Figure 80.5 Method Information

Method Information

				Unified Family		
Boundary	Method	Alpha	Beta	Rho	Tau	C
Upper Alpha	O'Brien-Fleming	0.02500	0.10000	0.5	0	2.02429
Lower Alpha	O'Brien-Fleming	0.02500	0.10000	0.5	0	2.02429

Method Information

Boundary	Alternative Reference	Drift
Upper Alpha	10	3.277238
Lower Alpha	-10	-3.27724

The O'Brien-Fleming method belongs to the unified family of designs, which is parameterized by two parameters, ρ and τ, as implemented in the SEQDESIGN procedure. See Table 80.3 for parameter values of commonly used methods in the unified family. The "Method Information" table in Figure 80.5 displays the values of $\rho = 0.5$ and $\tau = 0$, which are the parameters for the O'Brien-Fleming method. The table also displays the derived parameter $C_\alpha = 2.0243$, which is used in the construction of symmetric lower and upper α boundaries; see the section "Unified Family Methods" on page 6749.

The "Boundary Information" table in Figure 80.6 displays the information level, including the proportion, actual level, and corresponding sample size (N) at each stage. The table also displays the lower and upper alternative references, and the lower and upper boundary values at each stage.

Figure 80.6 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

	Information Level			Alternative Reference	
Stage	Proportion	Actual	N	Lower	Upper
1	0.2500	0.026851	42.96116	-1.63862	1.63862
2	0.5000	0.053701	85.92233	-2.31736	2.31736
3	0.7500	0.080552	128.8835	-2.83817	2.83817
4	1.0000	0.107403	171.8447	-3.27724	3.27724

Boundary Information (Standardized Z Scale)
Null Reference = 0

	Boundary Values	
	Lower	Upper
Stage	Alpha	Alpha
1	-4.04859	4.04859
2	-2.86278	2.86278
3	-2.33745	2.33745
4	-2.02429	2.02429

The information proportion is the proportion of maximum information available at each stage and N is the corresponding sample size. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the procedure displays boundary values with the standardized Z scale in the boundary information table and the boundary plot. The alternative reference on the standardized Z scale at stage k is given by $\theta_1\sqrt{I_k}$, where θ_1 is the alternative reference and I_k is the information available at stage k, $k = 1, 2, 3, 4$. These standardized alternative references for the design are derived in the SEQDESIGN procedure even if the alternative reference is not specified or derived in the procedure.

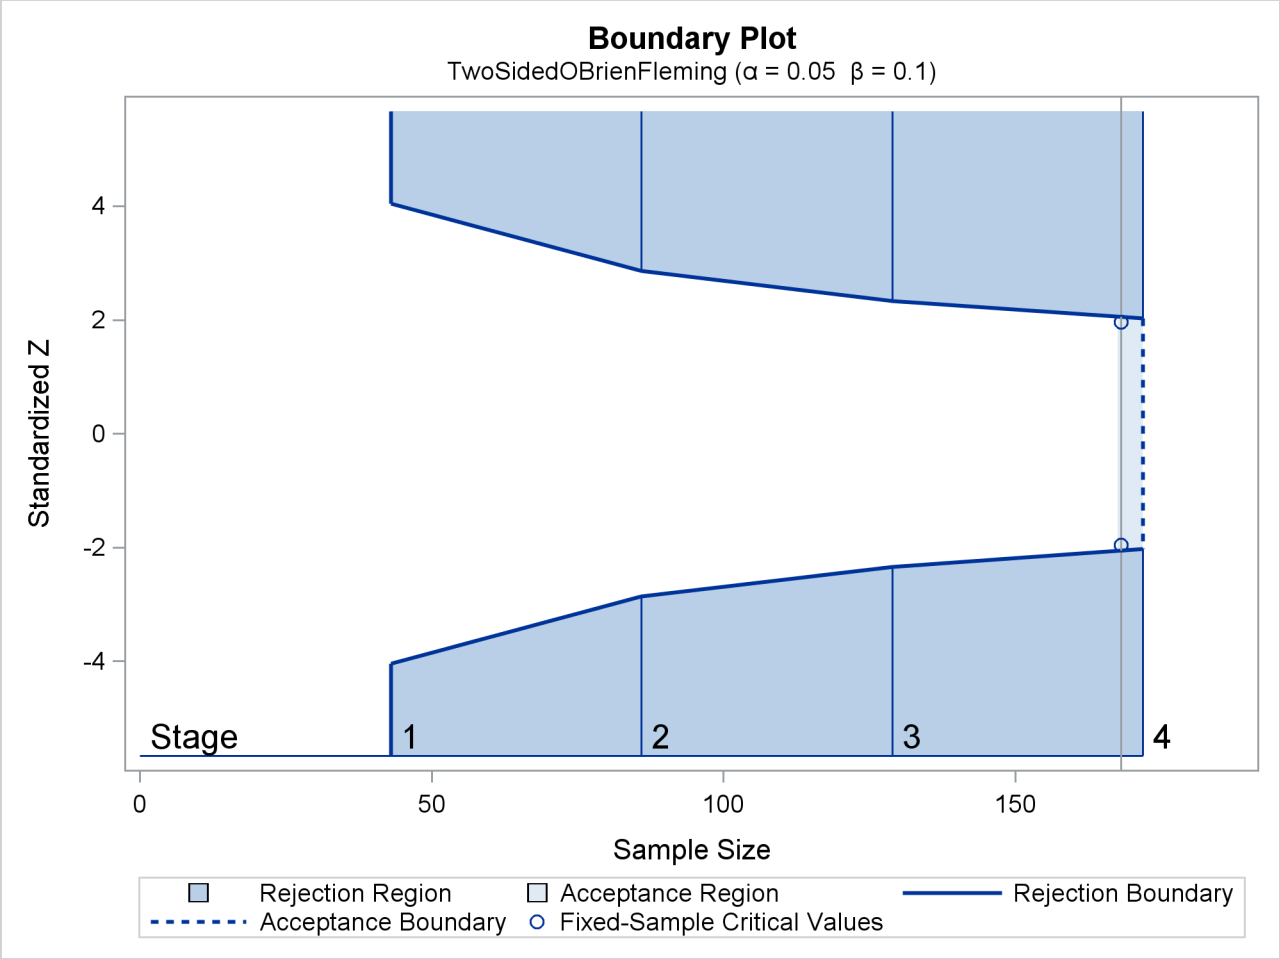
In this example, a standardized Z statistic is computed by standardizing the parameter estimate of the effect in LDL level. A lower Z test statistic indicates a beneficial effect. Consequently, at each interim stage, if the standardized Z test statistic is less than or equal to the corresponding lower α boundary value, the hypothesis $H_0 : \theta = 0$ is rejected for efficacy. If the test statistic is greater than or equal to the corresponding upper α boundary value, the hypothesis H_0 is rejected for harmful effect. Otherwise, the process continues to the next stage. At the final stage (stage 4), the hypothesis H_0 is rejected for efficacy if the Z statistic is less than or equal to the corresponding lower α boundary value -2.0243, and the hypothesis H_0 is rejected for harmful effect if the Z statistic is greater than or equal to the corresponding upper α boundary value 2.0243. Otherwise, the hypothesis of no significant difference is accepted.

Note that in a typical trial, the actual information levels do not match the information levels specified in the design. The SEQTEST procedure modifies the boundary values stored in the BOUND_LDL data set to adjust for these new information levels.

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Figure 80.7. This plot displays the boundary values in the "Boundary Information" table in Figure 80.6. The stages are indicated by vertical lines with accompanying stage numbers. The horizontal axis indicates the sample sizes for the stages. Note that comparing with a fixed-sample design, only a small increase in sample size is needed for the O'Brien-Fleming design, as shown in Figure 80.7.

If a test statistic at an interim stage is in the rejection region (shaded area), the trial stops and the null hypothesis is rejected. If the statistic is not in any rejection region, the trial continues to the next stage.

Figure 80.7 Boundary Plot



The boundary plot also displays critical values for the corresponding fixed-sample design. The symbol "○" identifies the fixed-sample critical values of -1.96 and 1.96, and the accompanying vertical line indicates the required sample size for the fixed-sample design at the horizontal axis. Note that the boundary values ± 2.0243 at the final stage are close to the fixed-sample critical values ± 1.96.

When you specify the SAMPLESIZE statement, the maximum information (either explicitly specified or derived in the SEQDESIGN procedure) is used to compute the required sample sizes for the study. The MODEL=TWOSAMPLEMEAN(STDDEV=20) option specifies the test for the difference between two normal means. See the section "Test for the Difference between Two Normal Means" on page 6773 for a detailed derivation of these required sample sizes.

The "Sample Size Summary" table in Figure 80.8 displays the parameters for the sample size computation and the resulting maximum and expected sample sizes.

Figure 80.8 Sample Size Summary

Sample Size Summary

Test	Two-Sample Means
Mean Difference	-10
Standard Deviation	20
Max Sample Size	171.8447
Expected Sample Size (Null Ref)	170.7627
Expected Sample Size (Alt Ref)	129.0137

The "Sample Sizes (N)" table in Figure 80.9 displays the required sample sizes at each stage for the trial, in both fractional and integer numbers. The derived fractional sample sizes are displayed under the heading "Fractional N." These sample sizes are rounded up to integers under the heading "Ceiling N." By default (or equivalently if you specify WEIGHT=1 in the MODEL=TWOSAMPLEMEAN option), the sample sizes for the two groups are equal for the two-sample test.

Figure 80.9 Derived Sample Sizes

Sample Sizes (N)
Two-Sample Z Test for Mean Difference

	Fractional N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	42.96	21.48	21.48	0.0269
2	85.92	42.96	42.96	0.0537
3	128.88	64.44	64.44	0.0806
4	171.84	85.92	85.92	0.1074

Sample Sizes (N)
Two-Sample Z Test for Mean Difference

	Ceiling N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	44	22	22	0.0275
2	86	43	43	0.0538
3	130	65	65	0.0812
4	172	86	86	0.1075

In practice, integer sample sizes are used in the trial, and the resulting information levels increase slightly. Thus, 22, 43, 65, and 86 individuals are needed in each of the two groups for the four stages, respectively.

Syntax: SEQDESIGN Procedure

The following statements are available in PROC SEQDESIGN:

PROC SEQDESIGN < *options* > **;**
  < *label:* > **DESIGN** *options* **;**
  SAMPLESIZE < *MODEL= option* > **;**

The PROC SEQDESIGN statement and the DESIGN statement are required for the SEQDESIGN procedure. Each DESIGN statement requests a new group sequential design, and multiple DESIGN statements can be used to create more than one design for comparison of features. The label, which must be a valid SAS name, is used to identify the design in the output tables and graphics. The SAMPLESIZE statement computes the required sample sizes for the design specified in each DESIGN statement. With a selected design, the SAMPLESIZE statement computes the required sample sizes for the trial.

PROC SEQDESIGN Statement

PROC SEQDESIGN < *options* > **;**

Table 80.1 summarizes the options in the PROC SEQDESIGN statement.

Table 80.1 Summary of PROC SEQDESIGN Options

Option	Description
Design Parameters	
ALTREF=	Specifies the alternative reference
BOUNDARYSCALE=	Specifies the statistic scale for the boundary
MAXINFO=	Specifies the maximum information level
Table Output	
ERRSPEND	Displays the cumulative error spending at each stage
PSS	Displays powers and expected sample sizes
STOPPROB	Displays expected cumulative stopping probabilities
Graphics Output	
PLOTS=ASN	Displays the expected sample numbers plot
PLOTS=BOUNDARY	Displays the detailed boundary plot
PLOTS=COMBINEDBOUNDARY	Displays the combined boundary plot
PLOTS=ERRSPEND	Displays the error spending plot
PLOTS=POWER	Displays the powers plot

By default, the SEQDESIGN procedure displays tables of design information, method information, and boundary information for each specified design. If ODS Graphics is enabled, it also displays a detailed boundary plot.

In addition, you can use output options to display output tables such as expected cumulative stopping probability at each stage under various hypothetical references. If ODS Graphics is enabled, you can also use output options to display plots such as powers and expected sample sizes under various hypothetical references.

The following options can be used in the PROC SEQDESIGN statement to derive boundary values for all sequential designs in the procedure. They are listed in alphabetical order.

ALTREF=θ_1 **< (< LOWER=**θ_{1l} **> < UPPER=**θ_{1u} **>) >**

specifies the alternative reference—that is, the hypothetical reference under the alternative hypothesis at which the power is computed. The LOWER= and UPPER= options are applicable only for a two-sided design with different lower and upper alternative references.

For a one-sided design, $\theta_{1l} = -|\theta_1|$ is the lower alternative reference and $\theta_{1u} = |\theta_1|$ is the upper alternative reference. For a two-sided design, the specified θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. If the LOWER= option is not specified, $\theta_{1l} = -|\theta_1|$, and if the UPPER= option is not specified, $\theta_{1u} = |\theta_1|$.

The specification of the ALTREF= option depends on the hypothesis used in the clinical trial. For example, suppose the null hypothesis $H_0 : \theta = 0$ with an alternative hypothesis $H_1 : \theta = \theta_1$ is used to compare two binomial populations, $p_a = p_b$. Then θ_1 is the proportion difference under H_1 if $\theta = p_a - p_b$, and θ_1 is the log odds ratio under H_1 if $\theta = \log\left(\frac{p_a(1-p_b)}{p_b(1-p_a)}\right)$.

If the ALTREF= option is not specified, the alternative reference θ_1 can also be specified or derived in the SAMPLESIZE statement. If θ_1 is specified or derived in the SAMPLESIZE statement, $\theta_{1l} = -|\theta_1|$ and $\theta_{1u} = |\theta_1|$ are the lower and upper alternative references, respectively.

Note that if the SAMPLESIZE statement is specified with a two-sided design, the sample sizes derived by using the lower and upper alternatives might be different. If θ_1 is specified or derived in the SAMPLESIZE statement, it is used to compute the sample sizes. Otherwise, the θ_1 specified in the ALTREF= option is used.

BOUNDARYSCALE=MLE | SCORE | STDZ | PVALUE

BSCALE=MLE | SCORE | STDZ | PVALUE

specifies the scale for the statistic that is displayed in the boundary table and boundary plots. The keywords MLE, SCORE, STDZ, and PVALUE correspond to the boundary with the maximum likelihood estimate scale, the score statistic scale, the standardized normal Z scale, and the p-value scale, respectively. The default is BOUNDARYSCALE=STDZ.

With the BOUNDARYSCALE=MLE or BOUNDARYSCALE=SCORE option, the maximum information must be either explicitly specified with the MAXINFO= option or derived in the SEQDESIGN procedure to provide the necessary information level at each stage to compute the boundary values. See the section "Boundary Scales" on page 6741 for a detailed description of the statistic scale for the boundary values.

Note that for a two-sided design, the p-value scale displays the one-sided fixed-sample p-value under the null hypothesis with a lower alternative hypothesis.

MAXINFO=*number*

specifies the maximum information level for the design. If the MAXINFO=option is specified and the alternative reference is either specified explicitly with the ALTREF= option or derived from the SAMPLESIZE statement, then the Type I and Type II error probability levels cannot be met simultaneously. In this case, the ALPHA= option in the DESIGN statement is applicable only with the BOUNDARYKEY=ALPHA option (which is the default) in the DESIGN statement, and the Type II error probability β is derived. The BETA= option in the DESIGN statement is applicable only with the BOUNDARYKEY=BETA option in the DESIGN statement, and the Type I error probability α is derived.

Table Output Options

The following options can be used in the PROC SEQDESIGN statement to display addition table output. They are listed in alphabetical order.

ERRSPEND

displays the error spending at each stage for each boundary in the design.

PSS < (CREF= *numbers* **) >**

displays powers and expected sample sizes under various hypothetical references, where the numbers $c_i \geq 0$.

For a one-sided design, the power and expected sample sizes under hypotheses $\theta = c_i\,\theta_1$ are displayed, where θ_1 is the alternative reference and c_i are the values specified in the CREF= option.

For a two-sided design, the power and expected sample sizes under hypotheses $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. The default is CREF= 0 0.5 1.0 1.5.

Note that for a symmetric two-sided design, only the power and expected sample sizes under hypotheses $\theta = c_i\,\theta_{1u}$ are derived. See the section "Type I and Type II Errors" on page 6746 for a detailed description of the power computation. See the section "Powers and Expected Sample Sizes" on page 6790 for a detailed description of the expected sample size computation.

STOPPROB < (CREF= *numbers* **) >**

displays expected cumulative stopping probabilities under various hypothetical references, where the numbers $c_i \geq 0$.

For a one-sided design, expected cumulative stopping probabilities at each stage under hypotheses $\theta = c_i\,\theta_1$ are displayed, where θ_1 is the alternative reference and c_i are the values specified in the CREF= option.

For a two-sided design, expected cumulative stopping probabilities at each stage under hypotheses $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only expected cumulative stopping probabilities under hypotheses $\theta = c_i\,\theta_{1u}$ are derived. The default is CREF= 0 0.5 1.0 1.5.

Graphics Output Options

This section describes the options for using ODS Graphics with the SEQDESIGN procedure to create plots.

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;
proc seqdesign altref=-10 plots=boundary(hscale=samplesize);
   TwoSidedOBrienFleming: design nstages=4 method=obf;
   samplesize model=twosamplemean(stddev=20);
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The following options can be used in the PROC SEQDESIGN statement to display graphs with ODS Graphics. They are listed in alphabetical order.

PLOTS < (ONLY) > < = *plot-request* >

PLOTS < (ONLY) > < = (*plot-request* < ... *plot-request* >) >

specifies options that control the details of the plots. The default is PLOTS=BOUNDARY. The global plot option ONLY suppresses the default plots and displays only plots specifically requested.

The plot request options are as follows.

ALL

produces all appropriate plots.

ASN < (CREF= *numbers*) >

displays a plot of the average sample numbers (expected sample sizes for nonsurvival data or expected numbers of events for survival data) under various hypothetical references, where the numbers $c_i \geq 0$. These average sample numbers are displayed as percentages of the average sample numbers for the corresponding fixed-sample design.

For a one-sided design, expected sample numbers under hypotheses $\theta = c_i\,\theta_1$ are displayed, where θ_1 is the alternative reference and c_i are the values specified in the CREF= option.

For a two-sided design, expected sample numbers under hypotheses $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only the average sample numbers under hypotheses $\theta = c_i\,\theta_{1u}$ are derived. The default is CREF= 0 to 1.5 by 0.01.

BOUNDARY < (HSCALE=INFO | SAMPLESIZE) >

displays a plot of the resulting sequential boundaries with the acceptance and rejection regions for each design. Either the information level (HSCALE=INFO) or the sample size (HSCALE=SAMPLESIZE) is displayed on the horizontal axis. If the maximum information is not available for the design, the information in percentage of its corresponding fixed-sample design are used in the plot. The stage number for each stage is displayed inside the plot. The default is HSCALE=INFO.

If the HSCALE=SAMPLESIZE option is specified. the SAMPLESIZE statement must also be specified. The options MODEL=INPUTNEVENTS, MODEL=TWOSAMPLESURVIVAL, and MODEL=PHREG in the SAMPLESIZE statement indicate survival data. For a sample that does not contain survival data, the sample size at each stage is displayed on the horizontal axis. For survival data, the number of events is displayed on the horizontal axis at each stage. The critical values for the corresponding fixed-sample design are also displayed in the plot.

COMBINEDBOUNDARY < (HSCALE=INFO | SAMPLESIZE | STAGE) >

displays a plot of the resulting sequential boundaries for all designs simultaneously. You can display the information level (HSCALE=INFO), the sample size (HSCALE=SAMPLESIZE), or the stage number (HSCALE=STAGE) on the horizontal axis. The default is HSCALE=INFO. With HSCALE=INFO, if the maximum information is not available for the design, then the information in percentage of its corresponding fixed-sample design is used in the plot.

If the HSCALE=SAMPLESIZE option is specified, the SAMPLESIZE statement must also be specified. The options MODEL=INPUTNEVENTS, MODEL=TWOSAMPLESURVIVAL, and MODEL=PHREG in the SAMPLESIZE statement indicate survival data. For a sample that does not contain survival data, the sample size at each stage is displayed on the horizontal axis. For survival data, the number of events is displayed on the horizontal axis at each stage.

ERRSPEND < (HSCALE=INFO | STAGE) >

displays a plot of the error spending for all sequential boundaries in the designs simultaneously. You can display the information level (HSCALE=INFO) or the stage number (HSCALE=STAGE) on the horizontal axis. With HSCALE=INFO, the information fractions are used in the plot. The default is HSCALE=STAGE.

NONE

suppresses all plots.

POWER < (CREF= *numbers* **) >**

displays a plot of the power curves under various hypothetical references, where the numbers $c_i \geq 0$.

For a one-sided design, powers under hypotheses $\theta = c_i\,\theta_1$ are displayed, where θ_1 is the alternative reference and c_i are the values specified in the CREF= option.

For a two-sided design, powers under hypotheses $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only powers under hypotheses $\theta = c_i\,\theta_{1u}$ are derived. The default is CREF= 0 to 1.5 by 0.01.

DESIGN Statement

< label: > **DESIGN** *< options >* **;**

The DESIGN statement requests a new group sequential design. You can use multiple DESIGN statements, and each DESIGN statement corresponds to a separate group sequential design.

Table 80.2 lists the options available in the DESIGN statement.

Table 80.2 Design Statement Options

Option	Description
Design Parameters	
ALPHA=	Specifies the Type I error probability level α
ALT=	Specifies the type of alternative hypothesis
BETA=	Specifies the Type II error probability level β
BETAOVERLAP=	Checks for overlapping of the lower and upper β boundaries in a two-sided design with error spending methods
BOUNDARYKEY=	Specifies the type of error probability to maintain
INFO=	Specifies the information levels
NSTAGES=	Specifies the number of stages
STOP=	Specifies the condition for early stopping
Boundary Methods	
METHOD=	Specifies methods for boundary values

The required NSTAGES= option specifies the number of stages. The METHOD= option is required if the number of stages specified in the NSTAGES= option is greater than one. The following options can be used in the DESIGN statement. They are listed in alphabetical order.

ALPHA=α **< (< LOWER=**α_l **> < UPPER=**α_u **>) >**

specifies the Type I error probability α. The default is $\alpha = 0.05$. The LOWER= and UPPER= options are applicable only for the two-sided design. The LOWER= option specifies the lower Type I error probability α_l, and the upper Type I error probability is computed as $\alpha_u = \alpha - \alpha_l$. The UPPER= option specifies the upper Type I error probability α_u, and the lower Type I error probability is computed as $\alpha_l = \alpha - \alpha_u$. If both LOWER= and UPPER= options are not specified, $\alpha_l = \alpha_u = \alpha/2$.

If both the MAXINFO= and ALTREF= options are specified, then the Type I and Type II error probability levels cannot be met simultaneously. In this case, the ALPHA= option is applicable only with the BOUNDARYKEY=ALPHA option (which is the default), and the Type II error probability β is derived.

ALT=LOWER | UPPER | TWOSIDED

specifies the type of alternative hypothesis in the design. For a test of $H_0 : \theta = 0$, the keywords LOWER, UPPER, and TWOSIDED correspond to the alternatives of $\theta < 0$, $\theta > 0$, and $\theta \neq 0$, respectively. The default is ALT=TWOSIDED.

BETA=β **< (< LOWER=**β_l **> < UPPER=**β_u **>) >**

specifies the Type II error probability level β. The default is $\beta = 0.10$. The LOWER= and UPPER= options are applicable only for the two-sided design. The LOWER= option specifies the lower Type II error probability level β_l, and the UPPER= option specifies the upper Type II error probability level β_u. If the LOWER= or UPPER= option is not specified, β is used.

If both the MAXINFO= and ALTREF= options are specified, then the Type I and Type II error probability levels cannot be met simultaneously. In this case, the BETA= option is applicable only with the BOUNDARYKEY=BETA option, and the Type I error probability α is derived.

BETAOVERLAP=ADJUST | NOADJUST

OVERLAP=ADJUST | NOADJUST

specifies whether to check for overlapping of the lower and upper β boundaries for the two corresponding one-sided tests. This option applies to two-sided designs with STOP=ACCEPT or STOP=BOTH that are constructed with error spending methods, and this type of overlapping might result from a small β spending at an interim stage. When you specify BETAOVERLAP=ADJUST, the procedure checks for this type of overlapping. If such overlapping is found, the β boundaries for the two-sided design at that stage are set to missing, and the β spending values at subsequent stages are adjusted, as described in the section "Boundary Adjustments for Overlapping Lower and Upper β Boundaries" on page 6763".

You can specify BETAOVERLAP=NOADJUST to request that no adjustment be made. The default is BETAOVERLAP=ADJUST.

BOUNDARYKEY=ALPHA | BETA | BOTH | NONE

specifies types of errors to be maintained in the resulting boundary. The default is BOUNDARYKEY=ALPHA if both ALTREF= and MAXINFO= options are specified. Otherwise, the default is BOUNDARYKEY=NONE for Whitehead methods with the STOP=BOTH option, and it is BOUNDARYKEY=BOTH for others.

See the section "Applicable Boundary Keys" on page 6765 for a detailed description of applicable boundary keys.

INFO=EQUAL

INFO=CUM(*numbers* **)**

specifies relative information levels for all stages in the design. The INFO=EQUAL option specifies equally spaced information levels, and the INFO=CUM option specifies cumulative relative information levels. The default is INFO=EQUAL.

If the number of information levels specified in the INFO=CUM option is less than the number of stages specified in the NSTAGES= option, the last available information increment is used as the information increment for each subsequent stage.

METHOD=WHITEHEAD < (TAU=τ < (<LOWER=τ_l > <UPPER=τ_u >) >) >

METHOD=*method*

METHOD(*boundary***) = *method***

specifies the methods for the boundaries in the design, where $0 \leq \tau < 0.5$.

For a one-sided design, an α boundary is created with the STOP=REJECT or STOP=BOTH option, and a β boundary is created with the STOP=ACCEPT or STOP=BOTH option. For a two-sided design, lower and upper α boundaries are created with the STOP=REJECT or STOP=BOTH option, and lower and upper β boundaries are created with the STOP=ACCEPT or STOP=BOTH option.

There are three types of methods available in the SEQDESIGN procedure. The unified family methods and Haybittle-Peto methods derive boundary values with fixed boundary shape; the Whitehead

methods derive boundary values by adjusting the boundary values generated from continuous monitoring; and the error spending methods derive the boundary values from the specified errors used at each stage. You can specify different methods for the same design, but all methods must be from the same group.

For a design with early stopping to reject or accept the null hypothesis, the METHOD=WHITEHEAD option uses Whitehead's triangular design and double-triangular design for a one-sided design and two-sided design, respectively (Whitehead and Stratton 1983; Whitehead 1997, 2001). For a design with early stopping only to reject the null hypothesis or only to accept the null hypothesis, you can specify the slope of the boundary line in the score statistic scale with the TAU= τ option. The default is TAU=0.25. See the section "Whitehead Methods" on page 6754 for a detailed description of the Whitehead methods.

The following options specify available error spending methods for the boundary. Each of these methods can be specified with the METHOD= option for all boundaries, or with the METHOD(*boundary*) = option for an individual boundary. See the section "Error Spending Methods" on page 6758 for a detailed description of these error spending methods.

ERRFUNCGAMMA < (GAMMA= γ **) >**
specifies a gamma cumulative error spending function for the boundary (Hwang, Shih, and DeCani 1990). The GAMMA= option specifies the gamma parameter γ in the function, where $\gamma \leq 3$. The boundaries created with $\gamma = 1$ are similar to the boundaries from the Pocock method, and the boundaries created with $\gamma = -4$ or $\gamma = -5$ are similar to the boundaries from the O'Brien-Fleming method. The default is GAMMA=-2, which is the average of $\gamma = 1$ and $\gamma = -5$.

ERRFUNCOBF
specifies the O'Brien-Fleming-type cumulative error spending function for the boundary (Lan and DeMets 1983).

ERRFUNCPOC
specifies the Pocock-type cumulative error spending function for the boundary (Lan and DeMets 1983).

ERRFUNCPOW < (RHO=ρ **) >**
specifies a power cumulative error spending function for the boundary (Jennison and Turnbull 2000, p. 148). The RHO= option specifies the power parameter ρ in the function, where $\rho \geq 0.25$. The boundaries created with $\rho = 1$ are similar to the boundaries from the Pocock method, and the boundaries created with $\rho = 3$ are similar to the boundaries from the O'Brien-Fleming method. The default is RHO=2, which is the average of $\rho = 1$ and $\rho = 3$.

ERRSPEND (*numbers* **)**
specifies the relative cumulative error spending at each stage.

With a fixed boundary shape, you can use the following available Haybittle-Peto methods and unified family methods to derive the boundary. You can specify each of these methods in the METHOD= option for all boundaries, or in the METHOD(*boundary*) = option for an individual boundary. See the section "Haybittle-Peto Method" on page 6754 for a detailed description of the Haybittle-Peto methods, and see the section "Unified Family Methods" on page 6749 for a detailed description of unified family methods.

HP | HAYBITTLE | PETO < (Z= *numbers* **| PVALUE=** *numbers* **) >**
specifies the Haybittle-Peto method (Haybittle 1971; Peto et al. 1976). The values specified are used to create the boundary values. The boundary value at the final stage can be derived in the procedure to maintain the Type I and Type II error probability levels. The default is Z=3.

OBF | OBRIENFLEMING
specifies the O'Brien-Fleming method (O'Brien and Fleming 1979). The O'Brien-Fleming method is equivalent to a power family method with RHO=0.5.

POC | POCOCK
specifies the Pocock method (Pocock 1977). The Pocock method is equivalent to a power family method with RHO=0.

POW | POWER < (RHO=ρ) >
specifies a power family method (Wang and Tsiatis 1987; Emerson and Fleming 1989; Pampallona and Tsiatis 1994). The RHO= option specifies the power parameter ρ in the power family method, where $\rho \geq -0.25$. The power family method with $\rho = 0$ corresponds to the Pocock method, and the power family method with $\rho = 0.5$ corresponds to the O'Brien-Fleming method. The default is RHO=0.25, a value halfway between the Pocock and O'Brien-Fleming methods. A power family method is equivalent to a unified family method with RHO=ρ and TAU=0.

TRI | TRIANGULAR < (TAU=τ) >
specifies a unified family triangular method (Kittelson and Emerson 1999), where $0 \leq \tau \leq 1$. The default is TAU=1.0. The triangular method is identical to the unified family method with RHO=0.5 and TAU=τ. Note that this unified family triangular method is different from Whitehead's triangular method.

UNI | UNIFIED < (< TAU=τ > < RHO=ρ >) >
specifies a unified family method (Kittelson and Emerson 1999). The TAU= and RHO= options specify the τ and ρ parameters in a unified family method, respectively, where $\rho \geq 0$ and $0 \leq \tau \leq 2\rho$. The defaults are TAU=0 and RHO=0.25. See the section "Unified Family Methods" on page 6749 for a detailed description of the unified family methods.

The O'Brien-Fleming, Pocock, power family, and triangular methods are all special cases of the unified family methods. Table 80.3 summarizes the corresponding parameters in the unified family for these methods.

Table 80.3 Parameters in the Unified Family for Various Methods

Method	Option	Unified Family	
		Rho	Tau
Pocock	POC	0	0
O'Brien-Fleming	OBF	0.5	0
Power family	POW (RHO=ρ)	ρ	0
Triangular	TRI (TAU=τ)	0.5	τ

Note that the power parameter $\rho = 1/2 - \Delta = \rho^* - 1/2$, where Δ is the power parameter used in Jennison and Turnbull (2000) and Wang and Tsiatis (1987) and ρ^* is the power parameter used in Kittelson and Emerson (1999).

If a method with specified parameters is used for all boundaries in the design, you can use the METHOD= option to specify the method. Otherwise, you can use the following METHOD(*boundary*)= options to specify different methods from the same group for the boundaries.

METHOD(ALPHA)=*method*

METHOD(REJECT)=*method*

specifies the method for the α boundary of a one-sided design or the lower and upper α boundaries for a two-sided design.

METHOD(LOWERALPHA)=*method*

METHOD(LOWERREJECT)=*method*

specifies the method for the lower α boundary of a two-sided design.

METHOD(UPPERALPHA)=*method*

METHOD(UPPERREJECT)=*method*

specifies the method for the upper α boundary of a two-sided design.

METHOD(BETA)=*method*

METHOD(ACCEPT)=*method*

specifies the method for the β boundary of a one-sided design or the lower and upper β boundaries for a two-sided design.

METHOD(LOWERBETA)=*method*

METHOD(LOWERACCEPT)=*method*

specifies the method for the lower β boundary of a two-sided design.

METHOD(UPPERBETA)=*method*

METHOD(UPPERACCEPT)=*method*

specifies the method for the upper β boundary of a two-sided design.

NSTAGES=*number*

specifies the number of stages for the design. This option is required in the DESIGN statement, and the maximum allowed number of stages is 25.

STOP=ACCEPT | REJECT | BOTH

specifies the condition of early stopping for the design. The keywords ACCEPT, REJECT, and BOTH correspond to early stopping only to accept, only to reject, and either to accept or reject the null hypothesis H_0, respectively. The default is STOP=REJECT.

SAMPLESIZE Statement

SAMPLESIZE < *MODEL= option* > **;**

If each observation in the data set provides one unit of information in a hypothesis testing such as a one-sample test for the mean, the SAMPLESIZE statement computes the required sample sizes for the sequential design specified in each DESIGN statement. However, for a survival analysis, an individual in the survival time data might provide only partial information because of censoring. For this hypothesis, the SAMPLESIZE statement computes the required numbers of events. With additional accrual information in a survival analysis, the sample sizes can also be computed.

Only one SAMPLESIZE statement can be specified. For each specified group sequential design, the SAMPLESIZE statement computes the required sample sizes or numbers of events. The SAMPLESIZE statement is not required if the SEQDESIGN procedure is used only to compare features among different designs. Table 80.4 lists the options available in the SAMPLESIZE statement.

Table 80.4 SAMPLESIZE Statement Options

Option	Description
Fixed-Sample Models	
INPUTNOBS	Specifies the sample size for fixed-sample design
INPUTNEVENTS	Specifies the number of events for fixed-sample design
One-Sample Models	
ONESAMPLEMEAN	Specifies the one-sample Z test for mean
ONESAMPLEFREQ	Specifies the one-sample test for binomial proportion
Two-Sample Models	
TWOSAMPLEMEAN	Specifies the two-sample Z test for mean difference
TWOSAMPLEFREQ	Specifies the two-sample test for binomial proportions
TWOSAMPLESURVIVAL	specifies the log-rank test for two survival distributions
Regression Models	
REG	Specifies the test for a regression parameter
LOGISTIC	Specifies the test for a logistic regression parameter
PHREG	Specifies the test for a proportional hazards regression parameter

The MODEL= option specifies the input sample size or number of events from a fixed-sample study, or it specifies a statistical model to compute the required sample size. The MODEL=INPUTNOBS option specifies the input sample size from a fixed-sample study of nonsurvival data, and the MODEL=INPUTNEVENTS option specifies the number of events from a fixed-sample study of survival data. The remaining MODEL= options specify the statistical models used to compute the required sample size. The default is MODEL=TWOSAMPLEMEAN, the two-sample Z test for the mean difference.

With the MODEL=INPUTNOBS or MODEL=INPUTNEVENTS option, the required sample size or number of events for the group sequential trial is computed by multiplying the input sample size or number of events by the ratio between the design information level and its corresponding fixed-sample information level. This ratio can be obtained by dividing the Max Information (Percent Fixed-Sample) in the "Design Information" table by 100. See the section "Design Information" on page 6789 for a description of the "Design Information" table.

Fixed-Sample Models

The following two options compute the required sample size or number of events for a group sequential trial by using the sample size or number of events for the fixed-sample design.

MODEL=INPUTNOBS < (*options*) >
specifies the sample size information for a fixed-sample design. The available options are as follows:

- N= n
- SAMPLE= ONE | TWO
- WEIGHT= w_a < w_b >
- MATCHNOBS= YES | NO

The required N=n option specifies the sample size n for the fixed-sample design. The SAMPLE=ONE option specifies a one-sample test, and the SAMPLE=TWO option specifies a two-sample test. The default is SAMPLE=ONE.

With a two-sample test, the WEIGHT= option specifies the sample size allocation weights for the two groups. If w_b is not specified, $w_b = 1$ is used. The default is WEIGHT=1, equal allocation for the two groups. The derived fractional sample sizes are rounded up to integers, and the MATCHNOBS=YES option requests these integer sample sizes to match the sample size allocation.

See the section "Input Sample Size for Fixed-Sample Design" on page 6768 for a detailed description of the input sample size for the fixed-sample design in sample size computation.

MODEL=INPUTNEVENTS < (*options*) >
specifies the number of events D for a fixed-sample survival test. The available options are as follows:

- D= d
- SAMPLE= ONE | TWO

The required D=d option specifies the fixed-sample number of events d. The SAMPLE=ONE option specifies a one-sample test, and the SAMPLE=TWO option specifies a two-sample test. The default is SAMPLE=ONE.

In order to derive the sample size, addition options are needed. The available options for the sample size computation are as follows:

- HAZARD= h_a < h_b >
- MEDSURVTIME= t_a < t_b >
- WEIGHT= w_a < w_b >
- ACCRATE= r_a
- ACCTIME= T_a
- FOLTIME= T_f
- TOTALTIME= T

The hazard rates are needed for the sample size computation. For a one-sample test, the HAZARD= h_a option specifies the hazard rate h_a explicitly, and the MEDSURVTIME=t_a option specifies the hazard rate implicitly through the median survival time t_a. Similarly, for a two-sample test, the HAZARD= h_a h_b option specifies the hazard rates h_a and h_b for groups A and B explicitly, and the MEDSURVTIME=t_a t_b option specifies hazard rates for groups A and B implicitly through the median survival times t_a and t_b. Also, for a two-sample test, $h_b = h_a$ if h_b is not specified and $t_b = t_a$ if t_b is not specified.

With a two-sample test, the WEIGHT= option specifies the sample size allocation weights for the two groups. If w_b is not specified, $w_b = 1$ is used. The default is WEIGHT=1.

Assuming that the hazard rates are constant and the individual accrual is uniform in the accrual time T_a with a constant accrual rate r_a, the sample size and study time can be derived.

The ACCRATE= option specifies the constant accrual rate r_a, and the ACCTIME= and FOLTIME= options specify the accrual time T_a and follow-up time T_f, respectively. The TOTALTIME= option specifies the total study time, $T = T_a + T_f$.

If the ACCRATE= option is specified, then one of the ACCTIME=, FOLTIME, and TOTALTIME options is required for the sample size computation. Otherwise, two of the ACCTIME=, FOLTIME, and TOTALTIME options are required to compute the accrual rate and sample size.

See the section "Input Number of Events for Fixed-Sample Design" on page 6768 for a detailed description of the input number of events for the fixed-sample design in sample size computation.

One-Sample Models

The following two options compute the required sample size for a one-sample group sequential test.

MODEL=ONESAMPLEMEAN < (*options*) >
specifies the one-sample Z test for mean. The available options are as follows:

- MEAN= μ_1
- STDDEV= σ

The MEAN= option specifies the alternative reference μ_1 and is required if the alternative reference is not specified or derived in the procedure. If the MEAN=option is not specified, the specified or derived alternative reference is used.

The STDDEV= option specifies the standard deviation σ. The default is STDDEV=1. See the section "Test for a Normal Mean" on page 6770 for a detailed description of the one-sample Z test for mean.

Note that the one-sample Z test for mean also includes the paired difference in two-treatment comparison (Jennison and Turnbull 2000, pp. 51–52), where μ_1 is the mean of differences within pairs under the alternative hypothesis and σ is the standard deviation for the mean of differences within pairs.

MODEL=ONESAMPLEFREQ < (*options*) >

specifies the one-sample test for binomial proportion with the null hypothesis $H_0 : \theta = 0$ and the alternative hypothesis $H_1 : \theta = \theta_1$, where $\theta = p - p_0$ and $\theta_1 = p_1 - p_0$. The available options are as follows:

- NULLPROP= p_0
- PROP= p_1
- REF= NULLPROP | PROP

The NULLPROP= and PROP= options specify the proportions under the null and alternative hypotheses, respectively. The default for the null reference is NULLPROP=0.5. The PROP= option is required if the alternative reference is not specified or derived in the procedure. If the PROP= option is not specified, the specified or derived alternative reference θ_1 is used to compute the alternative reference $p_1 = p_0 + \theta_1$.

The REF= option specifies the hypothesis under which the proportion is used in the sample size computation. The REF=NULLPROP option uses the null hypothesis, and the REF=PROP option uses the alternative hypothesis to compute the sample size. The default is REF=PROP. See the section "Test for a Binomial Proportion" on page 6771 for a detailed description of the one-sample tests for proportion.

Two-Sample Models

The following three options compute the required sample size or number of events for a two-sample group sequential trial.

MODEL=TWOSAMPLEMEAN < (*options*) >

specifies the two-sample Z test for mean difference. The available options are as follows:

- MEANDIFF= θ_1
- STDDEV= σ_a $< \sigma_b >$
- WEIGHT= w_a $< w_b >$
- MATCHNOBS= YES | NO

The MEANDIFF= option specifies the alternative reference θ_1 and is required if the alternative reference is not specified or derived in the procedure. If the MEANDIFF= option is not specified, the specified or derived alternative reference is used.

The STDDEV= option specifies the standard deviations σ_a and σ_b. If σ_b is not specified, $\sigma_b = \sigma_a$. The default is STDDEV=1.

The WEIGHT= option specifies the sample size allocation weights for the two groups. If w_b is not specified, $w_b = 1$ is used. The default is WEIGHT=1, equal sample size for the two groups. The derived fractional sample sizes are rounded up to integers, and the MATCHNOBS=YES option requests these integer sample sizes to match the sample size allocation. The default is MATCHNOBS=NO.

See the section "Test for the Difference between Two Normal Means" on page 6773 for a detailed description of the two-sample Z test for mean difference.

MODEL=TWOSAMPLEFREQ < (*options*) >
specifies the two-sample test for binomial proportions. The available options are as follows:

- NULLPROP= $p_{0a} < p_{0b} >$
- PROP= p_{1a}
- TEST= PROP | LOGOR | LOGRR
- REF= NULLPROP | PROP | AVGNULLPROP | AVGPROP
- WEIGHT= $w_a < w_b >$
- MATCHNOBS= YES | NO

The NULLPROP= option specifies proportions $p_a = p_{0a}$ and $p_b = p_{0b}$ in groups A and B, respectively, under the null hypothesis. If p_{0b} is not specified, $p_{0b} = p_{0a}$. The default is NULLPROP=0.5.

The PROP= option specifies proportion $p_a = p_{1a}$ in group A under the alternative hypothesis. The proportion p_{1b} in group B under the alternative hypothesis is given by $p_{1b} = p_{0b}$. The PROP= option is required if the alternative reference is not specified or derived in the procedure. If the PROP= option is not specified, the specified or derived alternative reference is used to compute p_{1a}, the proportion in group A under the alternative hypothesis.

The TEST= option specified the null hypothesis $H_0 : \theta = 0$ in the test. The TEST=PROP option uses the difference in proportions $\theta = (p_a - p_b) - (p_{0a} - p_{0b})$, the TEST=LOGOR option uses the log odds-ratio test $\theta = \delta - \delta_0$, where

$$\delta = \log\left(\frac{p_a(1-p_b)}{p_b(1-p_a)}\right) \qquad \delta_0 = \log\left(\frac{p_{0a}(1-p_{0b})}{p_{0b}(1-p_{0a})}\right)$$

and the TEST=LOGRR option uses the log relative risk test with $\theta = \delta - \delta_0$, where

$$\delta = \log\left(\frac{p_a}{p_b}\right) \qquad \delta_0 = \log\left(\frac{p_{0a}}{p_{0b}}\right)$$

The default is TEST=LOGOR.

The REF= option specifies the hypothesis under which the proportions are used in the sample size computation. The REF=NULLPROP option uses the null proportions p_{0a} and p_{0b}, the REF=PROP option uses the alternative proportions p_{1a} and p_{1b}, the REF=AVGNULLPROP option uses the average null proportion, and the REF=AVGPROP option uses the average alternative proportion. The default is REF=PROP.

The WEIGHT= option specifies the sample size allocation weights for the two groups. If w_b is not specified, $w_b = 1$ is used. The default is WEIGHT=1, equal sample size for the two groups. The derived fractional sample sizes are also rounded up to integers, and the MATCHNOBS=YES option requests that these integer sample sizes match the sample size allocation.

See the section "Test for the Difference between Two Binomial Proportions" on page 6774, the section "Test for Two Binomial Proportions with a Log Odds Ratio Statistic" on page 6776, and the section "Test for Two Binomial Proportions with a Log Relative Risk Statistic" on page 6777 for a detailed description of the two-sample tests for proportions.

MODEL=TWOSAMPLESURVIVAL < (*options*) >

MODEL=TWOSAMPLESURV < (*options*) >

specifies the log-rank test for two survival distributions with the null hypothesis $H_0 : \theta = \delta - \delta_0 = 0$, where the parameter $\delta = -\log(h_a/h_b)$, δ_0 is the value of δ under the null hypothesis and the values h_a and h_b are the hazard rates for groups A and B, respectively.

The available options for the number of events are as follows:

- NULLHAZARD= $h_{0a} < h_{0b} >$
- NULLMEDSURVTIME= $t_{0a} < t_{0b} >$
- HAZARD= h_{1a}
- MEDSURVTIME= t_{1a}
- HAZARDRATIO= λ_1

The NULLHAZARD= option specifies hazard rates $h_a = h_{0a}$ and $h_b = h_{0b}$ for groups A and B, respectively, under the null hypothesis. If h_{0b} is not specified, $h_{0b} = h_{0a}$. The NULLMEDSURVTIME= option specifies the median survival times $t_a = t_{0a}$ and $t_b = t_{0b}$ under the null hypothesis. If t_{0b} is not specified, $t_{0b} = t_{0a}$. If both NULLHAZARD= and NULLMEDSURVTIME= option are not specified, NULLHAZARD=0.06931, which corresponds to NULLMEDSURVTIME=10, is used.

The hazard rate for group B under the alternative hypothesis $h_{1b} = h_{0b}$, as the hazard rate under the null hypothesis. The HAZARD=, MEDSURVTIME=, and HAZARDRATIO= options specify the group A hazard rate h_{1a}, the group A median survival time t_{1a}, and the hazard ratio $\lambda_1 = h_{1a}/h_{1b}$, respectively, under the alternative hypothesis. The HAZARD=, MEDSURVTIME=, or HAZARDRATIO= option is required if the alternative reference is not specified or derived in the procedure. If these three options are not specified, the specified or derived alternative reference θ_1 is used to compute h_{1a} from the equation:

$$\theta_1 = -\log(\frac{h_{1a}}{h_{1b}}) - (-\log(\frac{h_{0a}}{h_{0b}})) = -\log(\frac{h_{1a}}{h_{0a}})$$

In order to derive the sample size, additional options are needed. The available options for the sample size computation are as follows:

- REF= NULLHAZARD | HAZARD
- WEIGHT= $w_a < w_b >$
- ACCRATE= r_a
- ACCTIME= T_a
- FOLTIME= T_f
- TOTALTIME= T

The REF= option specifies the hypothesis under which the hazard is used in the sample size computation. The REF=NULLHAZARD option uses the null hypothesis, and the REF=HAZARD option uses the alternative hypothesis. The default is REF=HAZARD.

The WEIGHT= option specifies the sample size allocation weights for the two groups. If w_b is not specified, $w_b = 1$ is used. The default is WEIGHT=1, equal sample size for the two groups.

With the available maximum information, the number of events can be derived for the specified hypothesis. Assuming that the hazard rates are constant and the individual accrual is uniform in the accrual time T_a with a constant accrual rate r_a, the sample size and study time can be derived.

The ACCRATE= option specifies the constant accrual rate r_a, and the ACCTIME= and FOLTIME= options specify the accrual time T_a and follow-up time T_f, respectively. The TOTALTIME= option specifies the total study time, $T = T_a + T_f$.

If the ACCRATE= option is specified, then one of the ACCTIME=, FOLTIME=, and TOTALTIME= options is required for the sample size computation. Otherwise, two of the ACCTIME=, FOLTIME=, and TOTALTIME= options are required to compute the accrual rate and sample size.

See the section "Test for Two Survival Distributions with a Log-Rank Test" on page 6779 for a detailed description of the two-sample log-rank test for survival data.

Regression Models

The following three options compute the required sample size or number of events for group sequential tests on a regression parameter.

MODEL=REG < (*options*) >

specifies the Z test for a normal regression parameter. The available options are as follows:

- BETA= β_1
- VARIANCE= σ_y^2
- XVARIANCE= σ_x^2
- XRSQUARE= r_x^2

The BETA= option specifies the alternative reference β_1 and is required if the alternative reference is not specified or derived in the procedure. If the BETA= option is not specified, $\beta_1 = \theta_1$, the specified or derived alternative reference.

The VARIANCE= and XVARIANCE= options specify the variances for the response variable Y and covariate X, respectively. The defaults are VARIANCE=1 and XVARIANCE=1. For a model with more than one covariate, the XRSQUARE= option can be used to derive the variance of X after adjusting for other covariates. The default is XRSQUARE=0.

See the section "Test for a Parameter in the Regression Model" on page 6781 for a detailed description of the Z test for the regression parameter.

MODEL=LOGISTIC < (*options*) >

specifies the Z test for a logistic regression parameter. The available options are as follows:

- BETA= β_1
- PROP= p
- XVARIANCE= σ_x^2
- XRSQUARE= r_x^2

The BETA= option specifies the alternative reference β_1 and is required if the alternative reference is not specified or derived in the procedure. If the BETA= option is not specified, $\beta_1 = \theta_1$, the specified or derived alternative reference.

The PROP= option specifies the proportion of the binary response variable Y. The default is PROP=0.5. The XVARIANCE= option specifies the variance of the covariate X. The default is XVARIANCE=1. For a model with more than one covariate, the XRSQUARE= option can be used to derive the variance of X after adjusting for other covariates. The default is XRSQUARE=0.

See the section "Test for a Parameter in the Logistic Regression Model" on page 6782 for a detailed description of the Z test for the logistic regression parameter.

MODEL=PHREG < (*options*) >

specifies the Z test for a proportional hazards regression parameter. The available options for the number of events are as follows:

- BETA= β_1
- XVARIANCE= σ_x^2
- XRSQUARE= r_x^2

The BETA= option specifies the alternative reference β_1 and is required if the alternative reference is not specified or derived in the procedure. If the BETA= option is not specified, $\beta_1 = \theta_1$, the specified or derived alternative reference.

The XVARIANCE= option specifies the variance of the covariate X. The default is XVARIANCE=1. For a model with more than one covariate, the XRSQUARE= option can be used to derive the variance of X after adjusting for other covariates. The default is XRSQUARE=0.

In order to derive the sample size, additional options are needed. The available options for the sample size computation are as follows:

- HAZARD= h_a
- MEDSURVTIME= t_a
- ACCRATE= r_a
- ACCTIME= T_a
- FOLTIME= T_f
- TOTALTIME= T

The hazard rate is required for the sample size computation. The HAZARD= h_a option specifies the hazard rate h_a explicitly, and the MEDSURVTIME=t_a option specifies the hazard rate implicitly through the median survival time t_a.

Assuming that the hazard rates are constant and the individual accrual is uniform in the accrual time T_a with a constant accrual rate r_a, the sample size and study time can be derived.

The ACCRATE= option specifies the constant accrual rate r_a, the ACCTIME= option specifies the accrual time T_a, and the FOLTIME= option specifies the follow-up time T_f. The TOTALTIME= option specifies the total study time, $T = T_a + T_f$.

If the ACCRATE= option is specified, then one of the ACCTIME=, FOLTIME=, and TOTALTIME= options is required for the sample size computation. Otherwise, two of the ACCTIME=, FOLTIME=, and TOTALTIME= options are required to compute the accrual rate and sample size.

See the section "Test for a Parameter in the Proportional Hazards Regression Model" on page 6783 for a detailed description of the Z test for the proportional hazards regression parameter.

Details: SEQDESIGN Procedure

Fixed-Sample Clinical Trials

A clinical trial is a research study in consenting human beings to answer specific health questions. One type of trial is a treatment trial, which tests the effectiveness of an experimental treatment. An example is a planned experiment designed to assess the efficacy of a treatment in humans by comparing the outcomes in a group of patients who receive the test treatment with the outcomes in a comparable group of patients who receive a placebo control treatment, where patients in both groups are enrolled, treated, and followed over the same time period.

A clinical trial is conducted according to a plan called a protocol. The protocol provides detailed description of the study. For a fixed-sample trial, the study protocol contains detailed information such as the null hypothesis, the one-sided or two-sided test, and the Type I and II error probability levels. It also includes the test statistic and its associated critical values in the hypothesis testing.

Generally, the efficacy of a new treatment is demonstrated by testing a hypothesis $H_0 : \theta = 0$ in a clinical trial, where θ is the parameter of interest. For example, to test whether a population mean μ is greater than a specified value μ_0, $\theta = \mu - \mu_0$ can be used with an alternative $\theta > 0$.

A one-sided test is a test of the hypothesis with either an upper (greater) or a lower (lesser) alternative, and a two-sided test is a test of the hypothesis with a two-sided alternative. The drug industry often prefers to use a one-sided test to demonstrate clinical superiority based on the argument that a study should not be run if the test drug would be worse (Chow, Shao, and Wang 2003, p. 28). But in practice, two-sided tests are commonly performed in drug development (Senn 1997, p. 161). For a fixed Type I error probability α, the sample sizes required by one-sided and two-sided tests are different. Refer to Senn (1997, pp. 161–167) for a detailed description of issues involving one-sided and two-sided tests.

For independent and identically distributed observations $y_1, y_2, \ldots, y_n$ of a random variable, the likelihood function for θ is

$$L(\theta) = \prod_{j=1}^{n} L_i(\theta)$$

where θ is the population parameter and $L_i(\theta)$ is the probability or probability density of y_i. Using the likelihood function, two statistics can be derived that are useful for inference: the maximum likelihood estimator and the score statistic.

Maximum Likelihood Estimator

The maximum likelihood estimate (MLE) of θ is the value $\hat{\theta}$ that maximizes the likelihood function for θ. Under mild regularity conditions, $\hat{\theta}$ is an asymptotically unbiased estimate of θ with variance $1/E_\theta(I(\theta))$, where $I(\theta)$ is the Fisher information

$$I(\theta) = -\frac{\partial^2 \log(L(\theta))}{\partial \theta^2}$$

and $E_\theta(I(\theta))$ is the expected Fisher information (Diggle et al. 2002, p. 340)

$$E_\theta(I(\theta)) = -E_\theta\left(\frac{\partial^2 \log(L(\theta))}{\partial \theta^2}\right)$$

The score function for θ is defined as

$$S(\theta) = \frac{\partial \log(L(\theta))}{\partial \theta}$$

and usually, the MLE can be derived by solving the likelihood equation $S(\theta) = 0$. Asymptotically, the MLE is normally distributed (Lindgren 1976, p. 272):

$$\hat{\theta} \sim N\left(\theta, \frac{1}{E_\theta(I(\theta))}\right)$$

If the Fisher information $I(\theta)$ does not depend on θ, then $I(\theta)$ is known. Otherwise, either the expected information evaluated at the MLE $\hat{\theta}$ ($E_{\theta=\hat{\theta}}(I(\theta))$) or the observed information $I(\hat{\theta})$ can be used for the Fisher information (Cox and Hinkley 1974, p. 302; Efron and Hinkley 1978, p. 458), where the observed Fisher information

$$I(\hat{\theta}) = -\left(\frac{\partial^2 \log(L(\theta))}{\partial \theta^2} \mid \theta = \hat{\theta}\right)$$

If the Fisher information $I(\theta)$ does depend on θ, the observed Fisher information is recommended for the variance of the maximum likelihood estimator (Efron and Hinkley 1978, p. 457).

Thus, asymptotically, for large n,

$$\hat{\theta} \sim N\left(\theta, \frac{1}{I}\right)$$

where I is the information, either the expected Fisher information $E_{\theta=0}(I(\theta))$ or the observed Fisher information $I\hat{\theta}$).

So to test $H_0 : \theta = 0$ versus $H_1 : \theta \neq 0$, you can use the standardized Z test statistic

$$Z = \frac{\hat{\theta}}{\sqrt{\text{Var}(\hat{\theta})}} = \hat{\theta}\sqrt{I} \sim N(0, 1)$$

and the two-sided p-value is given by

$$\text{Prob}(|Z| > |z_0|) = 1 - 2\Phi(|z_0|)$$

where Φ is the cumulative standard normal distribution function and z_0 is the observed Z statistic.

If the BOUNDARYSCALE=SCORE is specified in the SEQDESIGN procedure, the boundary values for the test statistic are displayed in the score statistic scale. With the standardized Z statistic, the score statistic $S = Z\sqrt{I} = \hat{\theta} I$ and

$$S \sim N\,(0,\ I)$$

Score Statistic

The score statistic is based on the score function for θ,

$$S(\theta) = \frac{\partial \log(L(\theta))}{\partial \theta}$$

Under the null hypothesis $H_0 : \theta = 0$, the score statistic $S(0)$ is the first derivative of the log likelihood evaluated at the null reference 0:

$$S(0) = \frac{\partial \log(L(\theta))}{\partial \theta} \,|\, \theta = 0$$

Under regularity conditions, $S(0)$ is asymptotically normally distributed with mean zero and variance $E_{\theta=0}(I(\theta))$, the expected Fisher information evaluated at the null hypothesis $\theta = 0$ (Kalbfleisch and Prentice 1980, p. 45), where $I(\theta)$ is the Fisher information

$$I(\theta) = -E\left(\frac{\partial^2 \log(L(\theta))}{\partial \theta^2}\right)$$

That is, for large n,

$$S(0) \sim N\,(0,\ E_{\theta=0}(I(\theta)))$$

Asymptotically, the variance of the score statistic $S(0)$, $E_{\theta=0}(I(\theta))$, can also be replaced by the expected Fisher information evaluated at the MLE $\theta = \hat{\theta}$ $(E_{\theta=\hat{\theta}}(I(\theta)))$, the observed Fisher information evaluated at the null hypothesis $\theta = 0$ $(I(0))$, or the observed Fisher information evaluated at the MLE $\theta = \hat{\theta}$ $(I(\hat{\theta}))$ (Kalbfleisch and Prentice 1980, p. 46), where

$$I(0) = -\left(\frac{\partial^2 \log(L(\theta))}{\partial \theta^2} \,|\, \theta = 0\right)$$

$$I(\hat{\theta}) = -\left(\frac{\partial^2 \log(L(\theta))}{\partial \theta^2} \,|\, \theta = \hat{\theta}\right)$$

Thus, asymptotically, for large n,

$$S(0) \sim N\,(0,\ I)$$

where I is the information, either an expected Fisher information ($E_{\theta=0}(I(\theta))$ or $E_{\theta=\hat{\theta}}(I(\theta))$) or a observed Fisher information ($I(0)$ or $I(\hat{\theta})$).

So to test $H_0 : \theta = 0$ versus $H_1 : \theta \neq 0$, you can use the standardized Z test statistic

$$Z = \frac{S(0)}{\sqrt{I}}$$

If the BOUNDARYSCALE=MLE is specified in the SEQDESIGN procedure, the boundary values for the test statistic are displayed in the MLE scale. With the standardized Z statistic, the MLE statistic $\hat{\theta} = Z/\sqrt{I} = U(0)/I$ and

$$\hat{\theta} \sim N\left(0,\ \frac{1}{I}\right)$$

One-Sample Test for Mean

The following one-sample test for mean is used to demonstrate fixed-sample clinical trials in the section "One-Sided Fixed-Sample Tests in Clinical Trials" on page 6731 and the section "Two-Sided Fixed-Sample Tests in Clinical Trials" on page 6733.

Suppose $y_1, y_2, \ldots, y_n$ are n observations of a response variable Y from a normal distribution

$$y_i \sim N\left(\theta,\ \sigma^2\right)$$

where θ is the unknown mean and σ^2 is the known variance.

Then the log likelihood function for θ is

$$\log(L(\theta)) = \sum_{j=1}^{n} -\frac{1}{2}\frac{(y_j - \theta)^2}{\sigma^2} + c$$

where c is a constant. The first derivative is

$$\frac{\partial \log(L(\theta))}{\partial \theta} = \frac{1}{\sigma^2}\sum_{j=1}^{n}(y_j - \theta) = \frac{n}{\sigma^2}(\overline{y} - \theta)$$

where $\overline{y}$ is the sample mean.

Setting the first derivative to zero, the MLE of θ is $\hat{\theta} = \overline{y}$, the sample mean. The variance for $\hat{\theta}$ can be derived from the Fisher information

$$I(\theta) = -\frac{\partial^2 \log(L(\theta))}{\partial \theta^2} = \frac{n}{\sigma^2}$$

Since the Fisher information $I_0 = I(\theta)$ does not depend on θ in this case, $1/I_0$ is used as the variance for $\hat{\theta}$. Thus the sample mean $\overline{y}$ has a normal distribution with mean θ and variance σ^2/n:

$$\hat{\theta} = \overline{y} \sim N\left(\theta,\ \frac{1}{I_0}\right) = N\left(\theta,\ \frac{\sigma^2}{n}\right)$$

Under the null hypothesis $H_0 : \theta = 0$, the score statistic

$$S(0) = \frac{\partial \log(L(\theta))}{\partial \theta} | \theta = 0 = \frac{n}{\sigma^2} \overline{y}$$

has a mean zero and variance

$$I(\theta) = -\frac{\partial^2 \log(L(\theta))}{\partial \theta^2} = \frac{n}{\sigma^2}$$

With the MLE $\hat{\theta}$, the corresponding standardized statistic is computed as $Z = \hat{\theta}\sqrt{I_0} = \overline{y}/(\sigma/\sqrt{n})$, which has a normal distribution with variance 1:

$$Z \sim N\left(\theta\sqrt{I_0},\, 1\right) = N\left(\frac{\theta}{\sigma/\sqrt{n}},\, 1\right)$$

Also, the corresponding score statistic is computed as $S = \hat{\theta} I_0 = n\overline{y}/\sigma^2$ and

$$S \sim N\left(\theta I_0,\, I_0\right) = N\left(\frac{n\theta}{\sigma^2},\, \frac{n}{\sigma^2}\right)$$

which is identical to $S(0)$ computed under the null hypothesis $H_0 : \theta = 0$.

Note that if the variable Y does not have a normal distribution, then it is assumed that the sample size n is large such that the sample mean has an approximately normal distribution.

One-Sided Fixed-Sample Tests in Clinical Trials

A one-sided test has either an upper (greater) or a lower (lesser) alternative. This section describes one-sided tests with upper alternatives only. Corresponding results for one-sided tests with lower alternatives can be derived similarly.

For a one-sided test of $H_0 : \delta \leq \delta_0$ with an upper alternative $H_1 : \delta > \delta_0$, an equivalent null hypothesis is $H_0 : \theta \leq 0$ with an upper alternative $H_1 : \theta > 0$, where $\theta = \delta - \delta_0$. A fixed-sample test rejects H_0 if the standardized test statistic $Z_0 = \hat{\theta}\sqrt{I_0} \geq C_\alpha$, where $\hat{\theta}$ is the sample estimate of θ and $C_\alpha = \Phi^{-1}(1-\alpha)$ is the critical value.

The p-value of the test is given by $1 - \Phi(Z_0)$, and the hypothesis H_0 is rejected if the p-value is less than α. An upper $(1-\alpha)$ confidence interval has the lower limit

$$\theta_l = \hat{\theta} - \frac{\Phi^{-1}(1-\alpha)}{\sqrt{I_0}} = \frac{Z_0 - \Phi^{-1}(1-\alpha)}{\sqrt{I_0}}$$

The hypothesis H_0 is rejected if the confidence interval for the parameter θ does not contain zero—that is, if the lower limit θ_l is greater than 0.

With an alternative reference $\theta = \theta_1$, $\theta_1 > 0$, a Type II error probability is defined as

$$\beta = P_{\theta=\theta_1}(Z_0 < C_\alpha)$$

which is equivalent to

$$\beta = P_{\theta=\theta_1}\left(Z_0 - \theta_1\sqrt{I_0} \;<\; C_\alpha - \theta_1\sqrt{I_0}\right) = \Phi\left(C_\alpha - \theta_1\sqrt{I_0}\right)$$

Thus, $\Phi^{-1}(\beta) = C_\alpha - \theta_1\sqrt{I_0}$. Then, with $C_\alpha = \Phi^{-1}(1-\alpha)$,

$$\theta_1\sqrt{I_0} = \Phi^{-1}(1-\alpha) + \Phi^{-1}(1-\beta)$$

The drift parameter $\theta_1\sqrt{I_0}$ can be computed for specified α and β and the maximum information is given by

$$I_0 = \left(\frac{\Phi^{-1}(1-\alpha) + \Phi^{-1}(1-\beta)}{\theta_1}\right)^2$$

If the maximum information is available, then the required sample size can be derived. For example, in a one-sample test for the mean with a specific standard deviation σ, the sample size n required for the test is

$$n = \sigma^2 I_0 = \sigma^2\left(\frac{\Phi^{-1}(1-\alpha) + \Phi^{-1}(1-\beta)}{\theta_1}\right)^2$$

On the other hand, if the alternative reference θ_1, standard deviation σ, and sample size n are all specified, then α can be derived for a given β and, similarly, β can be derived for a given α.

With an alternative reference $\theta = \theta_1$, $\theta_1 > 0$, the power $1-\beta$ is the probability of correctly rejecting the null hypothesis H_0 at θ_1:

$$1 - \beta = 1 - P_{\theta=\theta_1}(Z_0 < C_\alpha) = \Phi\left(\theta_1\sqrt{I_0} - C_\alpha\right)$$

Superiority Trials

A superiority trial that tests the response to a new drug is clinically superior to a comparative placebo control or active control therapy. If a positive value indicates a beneficial effect, a test for superiority has

$$H_0 : \theta \le 0 \qquad H_1 : \theta > 0$$

where H_0 is the hypothesis of nonsuperiority and H_1 is the alternative hypothesis of superiority.

The superiority test rejects the hypothesis H_0 and declares superiority if the standardized statistic $Z_0 = \hat{\theta}\sqrt{I_0} \ge C_\alpha$, where the critical value $C_\alpha = \Phi^{-1}(1-\alpha)$.

For example, if θ is the response difference between the treatment and placebo control groups, then a superiority trial can be

$$H_0 : \theta \le 0 \qquad H_1 : \theta = 6$$

with a Type I error probability level $\alpha = 0.025$ and a power $1-\beta = 0.90$ at $\theta_1 = 6$.

Noninferiority Trials

A noninferiority trial does not compare the response to a new treatment with the response to a placebo. Instead, it demonstrates the effectiveness of a new treatment compared with that of a nonexisting placebo by showing that the response of a new treatment is not clinically inferior to the response of a standard therapy with an established effect. That is, this type of trial attempts to demonstrate that the new treatment effect is not worse than the standard therapy effect by an acceptable margin. These trials are often performed when there is an existing effective therapy for a serious disease, and therefore a placebo control group cannot be ethically included.

It can be difficult to specify an appropriate noninferiority margin. One practice is to choose with reference to the effect of the active control in historical placebo-controlled trials (Snapinn 2000, p. 20). With this practice, there is some basis to imply that the new treatment is better than the placebo for a positive noninferiority trial.

If a positive value indicates a beneficial effect, a test for noninferiority has a null hypothesis $\delta \leq -\delta_0$ and an alternative hypothesis $\delta = \delta_1 > -\delta_0$, where $\delta_0 > 0$ is the specified noninferiority margin.

An equivalent test has

$$H_0 : \theta \leq 0 \qquad H_1 : \theta = \theta_1 > 0$$

where the parameter $\theta = \delta + \delta_0$, H_0 is the null hypothesis of inferiority, and H_1 is the alternative hypothesis of noninferiority,

The noninferiority test rejects the hypothesis H_0 and declares noninferiority if the standardized statistic $Z_0 = \hat{\theta}\sqrt{I_0} = (\hat{\delta} + \delta_0)\sqrt{I_0} \geq C_\alpha$, where the critical value $C_\alpha = \Phi^{-1}(1-\alpha)$.

For example, if δ is the response difference between the treatment and active control groups and $\delta_0 = 2$ is the noninferiority margin, then a noninferiority trial with a power $1 - \beta = 0.90$ at $\delta_1 = 1$ might be

$$H_0 : \theta \leq 0 \qquad H_1 : \theta = 3$$

where $\theta = \delta + \delta_0 = \delta + 2$.

Two-Sided Fixed-Sample Tests in Clinical Trials

A two-sided test is a test of a hypothesis with a two-sided alternative. Two-sided tests include simple symmetric tests and more complicated asymmetric tests that might have distinct lower and upper alternative references.

Symmetric Two-Sided Tests for Equality

For a symmetric two-sided test with the null hypothesis $\delta = \delta_0$ against the alternative $\delta \neq \delta_0$, an equivalent null hypothesis is $H_0 : \theta = 0$ with a two-sided alternative $H_1 : \theta \neq 0$, where $\theta = \delta - \delta_0$. A fixed-sample test rejects H_0 if $|\hat{\theta}\sqrt{I_0}| \geq C_{\alpha/2}$, where $\hat{\theta}$ is a sample estimate of θ and $C_{\alpha/2} = \Phi^{-1}(1-\alpha/2)$ is the critical value.

A common two-sided test is the test for the response difference between a treatment group and a control group. The null and alternative hypotheses are $H_0 : \theta = 0$ and $H_1 : \theta \neq 0$, respectively, where θ is the response difference between the two groups. If a greater value indicates a beneficial effect, then there are three possible results:

- The test rejects the hypothesis H_0 of equality and indicates that the treatment is significantly better if the standardized statistic $Z_0 = \hat{\theta}\sqrt{I_0} \geq C_{\alpha/2}$.
- The test rejects the hypothesis H_0 and indicates the treatment is significantly worse if the standardized statistic $Z_0 = \hat{\theta}\sqrt{I_0} \leq -C_{\alpha/2}$.
- The test indicates no significant difference between the two responses if $-C_{\alpha/2} < \hat{\theta}\sqrt{I_0} < C_{\alpha/2}$.

The p-value of the test is $2(1 - \Phi(Z_0))$ if $Z_0 > 0$ and $2\Phi(Z_0)$ if $Z_0 \leq 0$. The hypothesis H_0 is rejected if the p-value of the test is less than α—that is, if $1 - \Phi(Z_0) < \alpha/2$ or $\Phi(Z_0) < \alpha/2$. A symmetric $(1 - \alpha)$ confidence interval for θ has lower and upper limits

$$\left(\hat{\theta} - \frac{C_{\alpha/2}}{\sqrt{I_0}}\,,\ \ \hat{\theta} + \frac{C_{\alpha/2}}{\sqrt{I_0}}\right)$$

which is

$$\left(\frac{1}{\sqrt{I_0}}\left(Z_0 - C_{\alpha/2}\right)\,,\ \ \frac{1}{\sqrt{I_0}}\left(Z_0 + C_{\alpha/2}\right)\right)$$

The hypothesis H_0 is rejected if the confidence interval for the parameter θ does not contain zero. That is, the lower limit is greater than zero or the upper limit is less than zero.

With an alternative reference $\theta = \theta_1 > 0$, a Type II error probability is defined as

$$\beta = P_{\theta=\theta_1}(-C_{\alpha/2} \ < \ Z_0 \ < \ C_{\alpha/2})$$

which is

$$\beta = P_{\theta=\theta_1}\left((-C_{\alpha/2} - \theta_1\sqrt{I_0}) \ < \ (Z_0 - \theta_1\sqrt{I_0}) \ < \ (C_{\alpha/2} - \theta_1\sqrt{I_0})\right)$$

Thus

$$\beta = \Phi\left(C_{\alpha/2} - \theta_1\sqrt{I_0}\right) - \Phi\left(-C_{\alpha/2} - \theta_1\sqrt{I_0}\right)$$

The resulting power $1 - \beta$ is the probability of correctly rejecting the null hypothesis, which includes the probability for the lower alternative and the probability for the upper alternative. The SEQDESIGN procedure uses only the probability of correctly rejecting the null hypothesis for the correct alternative in the power computation.

Thus, under the upper alternative hypothesis, the power in the SEQDESIGN procedure is computed as the probability of rejecting the null hypothesis for the upper alternative, $1. - \Phi\left(C_{\alpha/2} - \theta_1\sqrt{I_0}\right) = \Phi\left(\theta_1\sqrt{I_0} - C_{\alpha/2}\right)$, and a very small probability of rejecting the null hypothesis for the lower alternative, $\Phi\left(-C_{\alpha/2} - \theta_1\sqrt{I_0}\right)$, is ignored. This power computation is more rational than the power based on the probability of correctly rejecting the null hypothesis (Whitehead 1997, p. 75).

That is,

$$\beta = P_{\theta=\theta_1}\left((Z_0 - \theta_1\sqrt{I_0}) \;<\; (C_{\alpha/2} - \theta_1\sqrt{I_0})\right) = \Phi\left(C_{\alpha/2} - \theta_1\sqrt{I_0}\right)$$

Then with $\Phi^{-1}(\beta) = C_{\alpha/2} - \theta_1\sqrt{I_0}$,

$$\theta_1\sqrt{I_0} = C_{\alpha/2} - \Phi^{-1}(\beta) = \Phi^{-1}(1-\alpha/2) + \Phi^{-1}(1-\beta)$$

The drift parameter $\theta_1\sqrt{I_0}$ can be derived for specified α and β, and the maximum information is given by

$$I_0 = \left(\frac{\Phi^{-1}(1-\alpha/2) + \Phi^{-1}(1-\beta)}{\theta_1}\right)^2$$

If the maximum information is available, then the required sample size can be derived. For example, in a one-sample test for mean, if the standard deviation σ is known, the sample size n required for the test is

$$n = \sigma^2 I_0 = \sigma^2\left(\frac{\Phi^{-1}(1-\alpha/2) + \Phi^{-1}(1-\beta)}{\theta_1}\right)^2$$

On the other hand, if the alternative reference θ_1, standard deviation σ, and sample size n are all known, then α can be derived with a given β and, similarly, β can be derived with a given α.

Generalized Two-Sided Tests for Equality

For a generalized two-sided test with the null hypothesis $\delta = \delta_0$ against the alternative $\delta \neq \delta_0$, an equivalent null hypothesis is $H_0 : \theta \leq 0$ with a two-sided alternative $H_1 : \theta \neq 0$, where $\theta = \delta - \delta_0$. A fixed-sample test rejects H_0 if the standardized statistic $Z_0 = \hat{\theta}\sqrt{I_0} < -C_{\alpha_l}$ or $Z_0 = \hat{\theta}\sqrt{I_0} > C_{\alpha_u}$, where the critical values $C_{\alpha_l} = \Phi^{-1}(1-\alpha_l)$ and $C_{\alpha_u} = \Phi^{-1}(1-\alpha_u)$.

With the lower alternative reference $\theta_{1l} < 0$, a lower Type II error probability is defined as

$$\beta_l = P_{\theta=\theta_{1l}}\left(-C_{\alpha_l} \;\leq\; Z_{0l}\sqrt{I_0}\right) = P_{\theta=\theta_{1l}}\left(-C_{\alpha_l} - \theta_{1l}\sqrt{I_0} \;\leq\; Z_{0l}\sqrt{I_0} - \theta_{1l}\sqrt{I_0}\right)$$

This implies

$$\beta_l = 1 - \Phi(-C_{\alpha_l} - \theta_{1l}\sqrt{I_0})$$

and the power is the probability of correctly rejecting the null hypothesis for the lower alternative,

$$1 - \beta_l = \Phi(-C_{\alpha_l} - \theta_{1l}\sqrt{I_0})$$

The lower drift parameter is derived as

$$\theta_{1l}\sqrt{I_0} = -\left(\Phi^{-1}(1-\alpha_l) + \Phi^{-1}(1-\beta_l)\right)$$

Then, with specified α_l and β_l, if the maximum information is known, the lower alternative reference θ_{1l} can be derived. If the maximum information is unknown, then with the specified lower alternative reference θ_{1l}, the maximum information required is

$$I_{0l} = \left(\frac{\Phi^{-1}(1-\alpha_l) + \Phi^{-1}(1-\beta_l)}{-\theta_{1l}} \right)^2$$

Similarly, the upper drift parameter is derived as

$$\theta_{1u}\sqrt{I_0} = \Phi^{-1}(1-\alpha_u) + \Phi^{-1}(1-\beta_u)$$

For a given α_u, β_u, and the upper alternative reference θ_{1u}, the maximum information required is

$$I_{0u} = \left(\frac{\Phi^{-1}(1-\alpha_u) + \Phi^{-1}(1-\beta_u)}{\theta_{1u}} \right)^2$$

Thus, the maximum information required for the design is given by

$$I_0 = \max\left(I_{0l},\ I_{0u} \right)$$

Note that with the maximum information level I_0, if $I_{0l} < I_0$, then the derived power from the lower alternative is larger than the specified $1-\beta_l$. Similarly, if $I_{0u} < I_0$, then the derived power from the upper alternative is larger than the specified $1-\beta_u$.

If maximum information is available, the required sample size can be derived. For example, in a one-sample test for mean, if the standard deviation σ is known, the sample size n required for the test is $n = \sigma^2 I_0$.

On the other hand, if the alternative references, Type I error probabilities α_l and α_u, standard deviation σ, and sample size n are all specified, then the Type II error probabilities β_l and β_u and the corresponding powers can be derived.

Group Sequential Methods

A group sequential design provides interim analyses before the formal completion of a trial. The monitoring process provides possible early stopping for either positive or negative results and thus reduces the time to complete the trial. With a specified number of stages, the design creates critical values such that at each interim analysis, a hypothesis can be rejected, accepted, or continued to the next time point. At the final stage, a hypothesis is either rejected or accepted. Usually, the critical values are derived such that the specified overall Type I and Type II error probability levels are maintained in the design.

For example, to test a null hypothesis H_0 with an upper alternative in a fixed-sample design, a critical value c_α is created. The null hypothesis H_0 is rejected if the test statistic is greater than or equal to the critical value c_α. Otherwise, H_0 is accepted. But, for a group sequential design with early stopping to reject or accept the null hypothesis H_0, there are two critical values created at each interim analysis: an α critical value $c_{\alpha k}$ to reject the null hypothesis and a β critical value $c_{\beta k}$ to accept the null hypothesis. The null hypothesis H_0 is rejected if the test statistic is greater than or equal to the α critical value $c_{\alpha k}$, and H_0 is

accepted if the test statistic is less than the β critical value $c_{\beta k}$. If the test statistic is between these two critical values, the process continues to the next stage. At the final stage, the two critical values are equal, and the hypothesis is either rejected or accepted.

Armitage, McPherson, and Rowe (1969) showed that repeated significance tests at a fixed level on accumulating data increase the probability of obtaining a significant result under the null hypothesis. For example, with a significance level 0.05 in a two-sided fixed-sample test, the critical value is 1.96. If this value is used in a five-stage group sequential trial with early stopping to reject the null hypothesis, then the probability of rejecting the null hypothesis at or before the fifth stage is 0.14169, much larger than the nominal value 0.05 (Armitage, McPherson, and Rowe 1969, p. 239).

Pocock (1977) applied these repeated significance tests to group sequential trials with equally spaced information levels and derives a constant critical value on the standardized normal Z scale across all stages that maintains the Type I error probability level. For example, with a significance level 0.05 in a two-sided test, the derived critical value at each stage is 2.413 on the standardized normal Z scale, larger than the fixed-sample critical value 1.96. The corresponding nominal p-value is 0.0158, which is smaller than the fixed-sample p-value 0.025 (Pocock 1977, p. 193).

O'Brien and Fleming (1979) proposed a sequential procedure that has boundary values decrease over the stages on the standardized normal Z scale to make the early stop less likely. The procedure has conservative stopping boundary values at very early stages, and boundary values at the final stage are close to the fixed-sample design. For example, with a significance level 0.05 in a two-sided test, the derived critical values at these five stages on the standardized normal Z scale are 4.562, 3.226, 2.634, 2.281, and 2.040.

Wang and Tsiatis (1987), Emerson and Fleming (1989) and Pampallona and Tsiatis (1994) generalized the Pocock and O'Brien-Fleming methods to the power family, where a power parameter is used to allow a continuous set of designs between the Pocock and O'Brien-Fleming methods.

Kittelson and Emerson (1999) extended the methods in the power family even further to the unified family, which also includes the exact triangular method. The shape and location of each of the four boundaries can be independently specified in the unified family methods.

Whitehead and Stratton (1983) and Whitehead (1997, 2001) developed triangular methods by adapting tests for continuous monitoring to discrete monitoring. With early stopping to reject or accept the null hypothesis in a one-sided test, the derived continuation region has a triangular shape for the score-scaled boundaries. Only elementary calculations are needed to derive the boundary values for Whitehead's triangular methods.

For a sequential design, you can derive the α and β error probabilities at each stage from the boundaries. On the other hand, you can derive the boundaries from specified α and β error probabilities at each stage. The error spending function approach (Lan and DeMets 1983) uses the error spending function to specify the error probabilities at each stage and then uses these probabilities to derive the boundaries. You can specify α and β explicitly or implicitly with an error spending function for the cumulative probabilities.

Refer to Jennison and Turnbull (2000, pp. 5–11) for a more detailed history of group sequential methods.

The following three types of methods are available in the SEQDESIGN procedure to derive boundaries in a sequential design:

- fixed boundary shape methods, which derive boundaries with specified boundary shapes. These include the unified family method and Haybittle-Peto method.

- Whitehead methods, which adjust the boundaries from continuous monitoring for discrete monitoring
- error spending methods

You can use the SEQDESIGN procedure to specify methods from the same group for each design. A different method can be specified for each boundary separately, but all methods in a design must be from the same group.

Fixed Boundary Shape Methods

The fixed boundary shape methods include the unified family method (Kittelson and Emerson 1999) and the Haybittle-Peto method (Haybittle 1971; Peto et al. 1976). The unified family methods derive the boundary values with the specified boundary shape. The unified family methods include the Pocock method (Pocock 1977), the O'Brien-Fleming method (O'Brien and Fleming 1979), the power family method (Wang and Tsiatis 1987; Emerson and Fleming 1989; Pampallona and Tsiatis 1994), and the triangular method (Kittelson and Emerson 1999). See the section "Unified Family Methods" on page 6749 for a detailed description of the methods that use the unified family approach.

The Haybittle-Peto method uses a value of 3 for the critical values in interim stages, so that the critical value at the final stage is close to the original design without interim monitoring. In the SEQDESIGN procedure, the Haybittle-Peto method has been generalized to allow for different boundary values at different stages. See the section "Haybittle-Peto Method" on page 6754 for a detailed description of the Haybittle-Peto method.

Whitehead Methods

The Whitehead methods (Whitehead and Stratton 1983; Whitehead 1997, 2001) derive the boundary values by adapting the continuous monitoring tests to the discrete monitoring of group sequential tests. The Type I error probability and power corresponding to the resulting boundaries are extremely close but differ slightly from the specified values because of the approximations used in deriving the tests (Jennison and Turnbull 2000, p. 106). The SEQDESIGN procedure provides the BOUNDARYKEY= option to adjust the boundary value at the final stage for the exact Type I or Type II error probability level. See the section "Whitehead Methods" on page 6754 for a detailed description of Whitehead's methods.

Error Spending Methods

An error spending method (Lan and DeMets 1983) uses the error spending function to specify the error spending at each stage and then uses these error probabilities to derive the boundary values. You can specify these errors explicitly or with an error spending function for these cumulative errors. See the section "Error Spending Methods" on page 6758 for a detailed description of the error spending methods.

Error spending methods derive boundary values at each stage sequentially and require much more computation than other types of methods for group sequential trials with a large number of stages, especially for a two-sided asymmetric design with early stopping to accept H_0, or to reject or accept H_0.

The sample size requirement for some applicable tests can also be computed in the procedure. After the actual data from a clinical trial are collected, you can then use the boundary information created in the SEQDESIGN procedure to perform a group sequential test in the SEQTEST procedure.

Statistical Assumptions for Group Sequential Designs

The SEQDESIGN procedure assumes that with a total number of stages K, the sequence of the standardized test statistics $\{Z_1, Z_2, \ldots, Z_K\}$ has the canonical joint distribution with information levels $\{I_1, I_2, \ldots, I_K\}$ for the parameter θ (Jennison and Turnbull 2000, p. 49):

- $(Z_1, Z_2, \ldots, Z_K)$ is multivariate normal
- $Z_k \sim N\left(\theta\sqrt{I_k},\, 1\right),\ k = 1, 2, \ldots, K$
- $\mathrm{Cov}(Z_{k_1}, Z_{k_2}) = \sqrt{(I_{k_1}/I_{k_2})},\quad 1 \le k_1 \le k_2 \le K$

In terms of the maximum likelihood estimator, $\hat{\theta}_k = Z_k/\sqrt{I_k}, k = 1, 2, \ldots, K$, the canonical joint distribution can be expressed as follows:

- $(\hat{\theta}_1, \hat{\theta}_2, \ldots, \hat{\theta}_K)$ is multivariate normal
- $\hat{\theta}_k \sim N\left(\theta,\, 1/I_k\right),\ k = 1, 2, \ldots, K$
- $\mathrm{Cov}(\hat{\theta}_{k_1}, \hat{\theta}_{k_2}) = 1/I_{k_2},\quad 1 \le k_1 \le k_2 \le K$

Furthermore, in terms of the score statistics $S_k = Z_k\sqrt{I_k}, k = 1, 2, \ldots, K$, the canonical joint distribution can be expressed as follows:

- $(S_1, S_2, \ldots, S_K)$ is multivariate normal
- $S_k \sim N\left(\theta\, I_k,\, I_k\right),\ k = 1, 2, \ldots, K$
- $\mathrm{Cov}(S_{k_1}, S_{k_2}) = \mathrm{Var}(S_{k_1}) = I_{k_1},\quad 1 \le k_1 \le k_2 \le K$

That is, the increments S_1, $S_2 - S_1, \ldots,$ and $S_K - S_{(K-1)}$ are independently distributed.

If the test statistic is computed from the data that are not from a normal distribution, such as a binomial distribution, then it is assumed that the test statistic is computed from a large sample such that the statistic has an approximately normal distribution.

If the increments S_1, $S_2 - S_1, \ldots,$ and $S_K - S_{(K-1)}$ are not independently distributed, then it is inappropriate to use group sequential methods in the SEQDESIGN procedure. One such example is the Gehan statistic, which is a weighted log-rank statistic for censored data. Refer to Jennison and Turnbull (2000, pp. 232–233, 276–277) and Proschan, Lan, and Wittes (2006, pp. 150–151) for a description of statistics with nonindependent increments.

If a trial stops at an early interim stage with only a small number of responses observed, it can lead to a distrust of the statistical findings, which rely on the assumption that the sample is large (Whitehead 1997, p. 167). A group sequential design can be specified such that at the first interim analysis, there are a sufficient number of responses to ensure that the analysis to be conducted is both reliable and persuasive (Whitehead 1997, p. 167).

Alternatively, a method such as the O'Brien-Fleming method can be used to derive conservative stopping boundary values at very early stages to make the early stop less likely. That is, the trial is stopped in early stages only with overwhelming evidence.

A simple example of the group sequential tests is the test for a normal mean, $\mu = \mu_0$. Suppose $y_1, y_2, \ldots, y_n$ are n observations of a response variable Y in a data set from a normal distribution with an unknown mean μ and a known variance σ^2. Then the maximum likelihood estimate of μ is the sample mean

$$\overline{y} = \frac{1}{n} \sum_{j=1}^{n} y_j$$

The sample mean has a normal distribution with mean μ and variance σ^2/n:

$$\overline{y} \sim N\left(\mu, \frac{\sigma^2}{n}\right)$$

An equivalent hypothesis for $\mu = \mu_0$ is $H_0 : \theta = 0$, where $\theta = \mu - \mu_0$. The MLE statistic for θ,

$$\hat{\theta} = \overline{y} - \mu_0 \sim N\left(\theta, {I_0}^{-1}\right)$$

where the information $I_0 = n/\sigma^2$.

For a group sequential test with K stages, there are $N_1, N_2, \ldots, N_K$ observations available at these stages. At stage k, the sample mean is computed as

$$\overline{y}_k = \frac{1}{N_k} \sum_{j=1}^{N_k} y_{kj}$$

where y_{kj} is the value of the jth observation available at the kth stage and N_k is the cumulative sample size at stage k, which includes the N_{k-1} observations collected at previous stages and the $N_k - N_{k-1}$ observations collected at the current stage.

The maximum likelihood estimate

$$\hat{\theta}_k = \overline{y}_k - \mu_0 \sim N\left(\theta, {I_k}^{-1}\right)$$

where the information

$$I_k = \frac{1}{\mathrm{Var}(\overline{y}_k)} = \frac{N_k}{\sigma^2}$$

is the inverse of the variance.

Thus, the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} = (\overline{y}_k - \mu_0)\sqrt{I_k} \sim N\left(\theta\sqrt{I_k}, 1\right)$$

The covariance of Z_{k_1} and Z_{k_2}, $1 \le k_1 \le k_2 \le K$ can be expressed as

$$\mathrm{Cov}(Z_{k_1}, Z_{k_2}) = \frac{1}{\sqrt{(I_{k_1} I_{k_2})}} \mathrm{Cov}(S_{k_1}, S_{k_2})$$

where $S_{k_1} = Z_{k_1}\sqrt{I_{k_1}}$ and $S_{k_2} = Z_{k_2}\sqrt{I_{k_2}}$.

Since $S_{k_2} - S_{k_1}$ is independent of S_{k_1}, $\mathrm{Cov}(S_{k_1}, S_{k_2}) = \mathrm{Var}(S_{k_1}) = I_{k_1}$ and

$$\mathrm{Cov}(Z_{k_1}, Z_{k_2}) = \frac{1}{\sqrt{(I_{k_1} I_{k_2})}} I_{k_1} = \sqrt{I_{k_1}/I_{k_2}}$$

Thus the statistics $\{Z_1, Z_2, \ldots, Z_K\}$ has the canonical joint distribution with information levels $\{I_1, I_2, \ldots, I_K\}$ for the parameter μ. See the section "Applicable One-Sample Tests and Sample Size Computation" on page 6770, the section "Applicable Two-Sample Tests and Sample Size Computation" on page 6772, and the section "Applicable Regression Parameter Tests and Sample Size Computation" on page 6781 for more examples of applicable tests in group sequential trials.

Boundary Scales

The boundaries computed by the SEQDESIGN procedure are applied to test statistics computed during the analysis, and so generally, the scale you select for the boundaries is determined by the scale of the statistics that you will be using.

The following scales are available in the SEQDESIGN procedure:

- MLE, maximum likelihood estimate
- standardized Z
- score statistic S
- p-value

These scales are all equivalent for a given set of boundary values—that is, there exists a unique transformation between any two of these scales. If you know the boundary values in terms of statistics from one scale, you can uniquely derive the boundary values of statistics for other scales. You can specify the scale with the BOUNDARYSCALE= option; the default is BOUNDARYSCALE=STDZ, the standardized Z scale.

You can also select the boundary scale to better examine the features of an individual group sequential design or to compare features among multiple designs. For example, with the standardized Z scale, the boundary values for the Pocock design are identical across all stages, and the O'Brien-Fleming design has boundary values (in absolute value) that decrease over the stages.

The remaining section demonstrates the transformations from one scale to the other scales. If the maximum likelihood estimate $\hat{\theta}$ is computed by the analysis, then

$$\hat{\theta} \sim N\left(\theta,\ \frac{1}{I}\right)$$

where I is the Fisher information if it does not depend on θ. Otherwise, I is either the expected Fisher information evaluated at $\hat{\theta}$ or the observed Fisher information. See the section "Maximum Likelihood Estimator" on page 6728 for a detailed description of these statistics.

With the MLE statistic $\hat{\theta}$, the corresponding standardized Z statistic is computed as

$$Z = \hat{\theta}\sqrt{I} \sim N\left(\theta\sqrt{I},\ 1\right)$$

and the corresponding score statistic is computed as

$$S = \hat{\theta}\, I \sim N\left(\theta\, I,\ I\right)$$

Similarly, if a score statistic S is computed by the analysis, then with

$$S \sim N\left(\theta\, I,\ I\right)$$

where I is the information, either an expected Fisher information ($E_{\theta=0}(I(\theta))$ or $E_{\theta=\hat{\theta}}(I(\theta))$) or an observed Fisher information ($I(0)$ or $I(\hat{\theta})$).

The corresponding standardized Z statistic is computed as

$$Z = \frac{S}{\sqrt{I}} \sim N\left(\theta\sqrt{I},\ 1\right)$$

and the corresponding MLE-scaled statistic is computed as

$$\hat{\theta} = \frac{S}{I} \sim N\left(\theta,\ \frac{1}{I}\right)$$

With a standardized normal Z statistic, the corresponding fixed-sample nominal p-value depends on the type of alternative hypothesis. With an upper alternative, the nominal p-value is defined as the one-sided p-value under the null hypothesis $H_0 : \theta = 0$ with an upper alternative:

$$p_k = 1 - \Phi(Z)$$

With a lower alternative or a two-sided alternative, the nominal p-value is defined as the one-sided p-value under the null hypothesis $H_0 : \theta = 0$ with a lower alternative:

$$p_k = \Phi(Z)$$

which is an increasing function of the standardized Z statistic (Emerson, Kittelson, and Gillen 2005, p. 12).

The BOUNDARYSCALE= MLE, STDZ, SCORE, and PVALUE options display the boundary values in the MLE, standardize Z, score, and p-value scales, respectively. For example, suppose $y_{k1}, y_{k2}, \ldots, y_{kn_k}$

are n_k observations of a response variable Y in a data set from a normal distribution with an unknown mean μ and a known variance σ^2. Then

$$y_{kj} \sim N\left(\mu, \sigma^2\right)$$

for $k = 1, 2, \ldots, K$, where K is the number of groups and n_k is the number of observations at group k.

If N_k is the cumulative number of observations for the first k groups, then the sample mean from these N_k observations

$$\overline{y}_k = \frac{1}{N_k} \sum_{j=1}^{N_k} y_{kj}$$

has a normal distribution with mean θ and variance σ^2/N_k:

$$\overline{y}_k \sim N\left(\theta, \frac{\sigma^2}{N_k}\right)$$

To test the null hypothesis $\mu = \mu_0$, $H_0 : \theta = 0$, where $\theta = \mu - \mu_0$ can be used. The MLE of θ is $\hat{\theta}_k = \overline{y}_k - \mu_0$ and

$$\hat{\theta}_k \sim N\left(\theta, \frac{1}{I_k}\right)$$

where the information is the inverse of the variance of $\overline{y}_k$,

$$I_k = \frac{N_k}{\sigma^2}$$

The corresponding standardized Z statistic is

$$Z_k = \hat{\theta}_k \, I_k^{\frac{1}{2}} \sim N\left(\theta \, I_k^{\frac{1}{2}}, 1\right)$$

The score statistic in the SEQDESIGN procedure is then given by

$$S_k = \hat{\theta}_k \, I_k = Z_k \, I_k^{\frac{1}{2}} \sim N\left(\theta \, I_k, I_k\right)$$

For a null hypothesis $H_0 : \theta = 0$ with an upper alternative, the nominal p-value of the standardized Z statistic is $p_k = 1 - \Phi(Z_k)$. For a null hypothesis $H_0 : \theta = 0$ with a lower alternative or a two-sided alternative, the nominal p-value of the standardized Z statistic is $p_k = \Phi(Z_k)$.

Boundary Variables

The boundaries created in group sequential trials depend on the type of the alternative hypothesis and the early stopping criterion. Table 80.5 shows the boundaries created with various design specifications.

Table 80.5 Boundary Variables

Specifications		Boundary Variables			
Alternative		**Lower**		**Upper**	
Hypothesis	**Early Stopping**	**Alpha**	**Beta**	**Beta**	**Alpha**
Lower	Accept H_0		X		
	Reject H_0	X			
	Accept/Reject H_0	X	X		
Upper	Accept H_0			X	
	Reject H_0				X
	Accept/Reject H_0			X	X
Two-sided	Accept H_0		X	X	
	Reject H_0	X			X
	Accept/Reject H_0	X	X	X	X

Up to four boundaries can be generated in a group sequential design:

- the upper α boundary, to reject the null hypothesis for the upper alternative
- the upper β boundary, to accept the null hypothesis with an upper alternative
- the lower β boundary, to accept the null hypothesis with a lower alternative
- the lower α boundary, to reject the null hypothesis for the lower alternative

For a two-sided design, the null hypothesis is accepted only if both the hypothesis is accepted with an upper alternative and the hypothesis is accepted with a lower alternative.

For a one-sided design with a lower alternative, only the lower boundaries are created. Similarly, for a one-sided design with an upper alternative, only the upper boundaries are created. For example, Figure 80.10 shows the boundary plot for a one-sided test with an upper alternative.

Figure 80.10 Boundary Plot for One-Sided Test

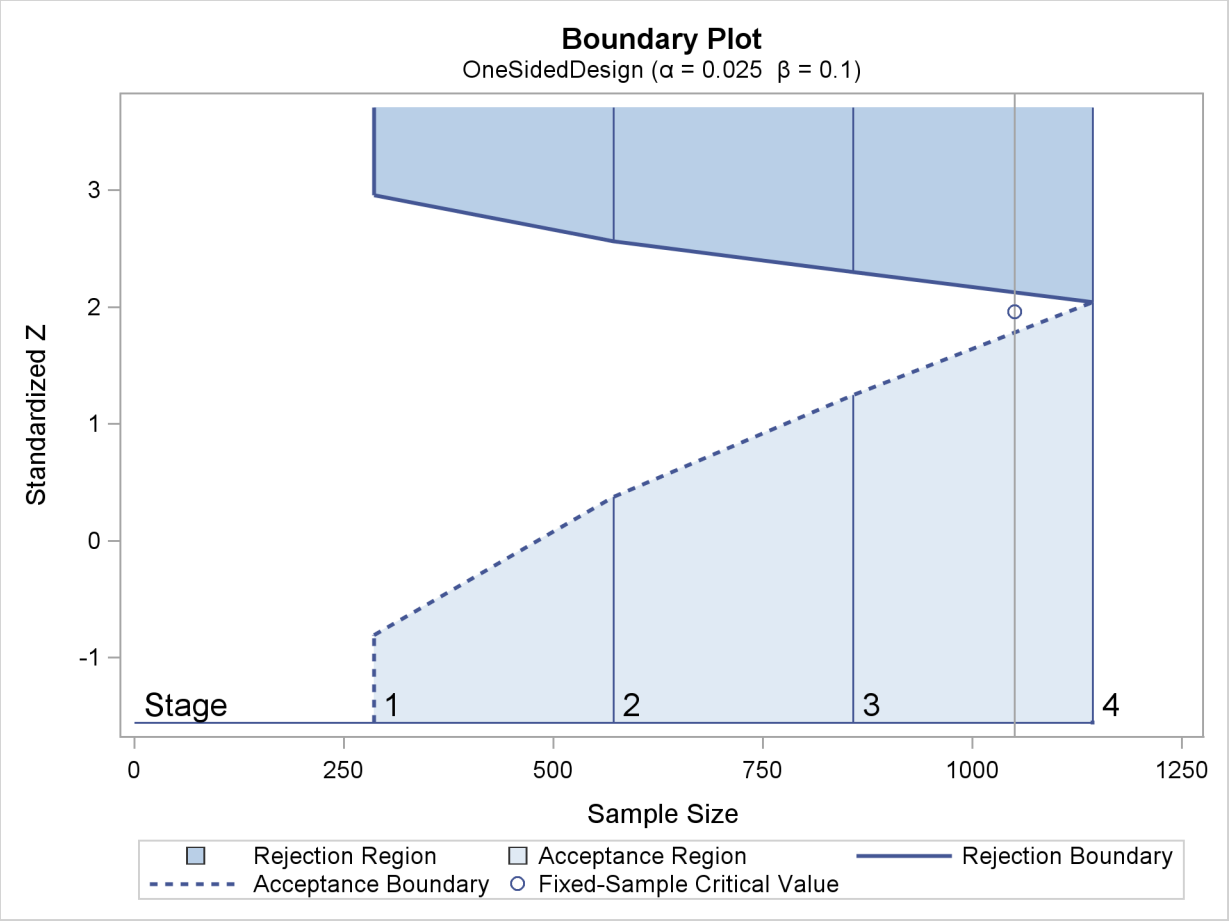


Figure 80.10 corresponds to a one-sided sequential design with early stopping to reject or accept the null hypothesis. For a sequential test with early stopping only to reject the null hypothesis, there are no acceptance boundary values at interim stages. The acceptance boundary value and its associated acceptance region are displayed only at the final stage. Similarly, for a sequential test with early stopping only to accept the null hypothesis, there are no rejection boundary values at interim stages. The rejection boundary value and its associated rejection region are displayed only at the final stage.

For a two-sided design, both the lower and upper boundaries are created. For a design with early stopping to reject the null hypothesis, α boundaries are created. Similarly, for a design with early stopping to accept the null hypothesis, β boundaries are created. For a design with early stopping to accept or reject the null hypothesis, both the α and β boundaries are created.

For example, Figure 80.11 shows the boundary plot for a two-sided test.

Figure 80.11 Boundary Plot for Two-Sided Test

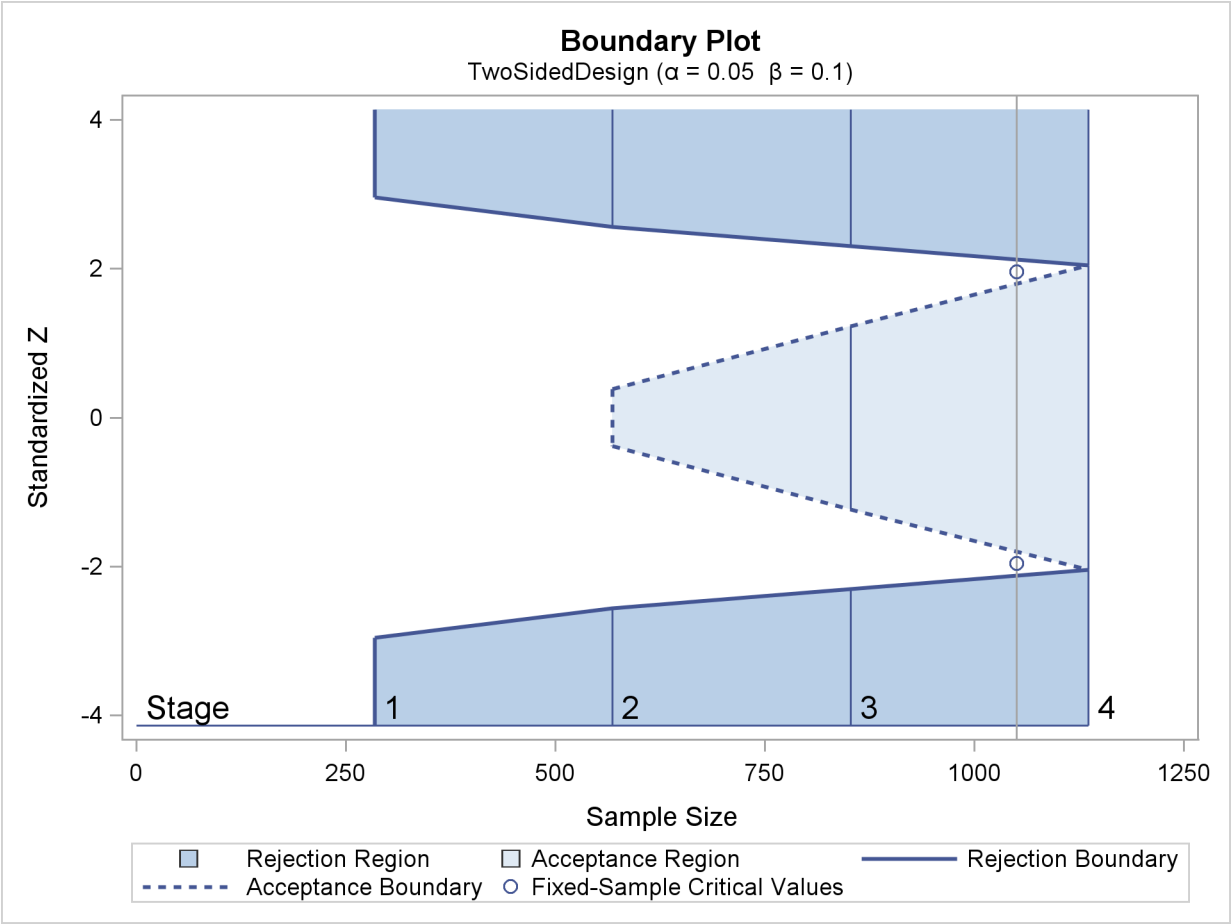

Figure 80.11 corresponds to a two-sided sequential design with early stopping to reject or accept the null hypothesis. For a sequential test with early stopping only to reject the null hypothesis, there are no acceptance boundary values at interim stages. The acceptance boundary value and its associated acceptance region are displayed only at the final stage. Similarly, for a sequential test with early stopping only to accept the null hypothesis, there are no rejection boundary values at interim stages. The rejection boundary value and its associated rejection region are displayed only at the final stage.

Type I and Type II Errors

The Type I error is the error of rejecting the null hypothesis when the null hypothesis is correct, and the Type II error is the error of not rejecting the null hypothesis when the null hypothesis is incorrect. The level of significance α is the probability of making a Type I error. The Type II error depends on the hypothetical reference of the alternative hypothesis, and the Type II error probability β is defined as the probability of not rejecting the null hypothesis when a specific alternative reference is true. The power $1 - \beta$ is then defined as the probability of rejecting the null hypothesis at the alternative reference.

In a sequential design, if the maximum information and alternative reference are not both specified, the critical values are created such that both the specified Type I and the specified Type II error probability levels are maintained in the design. Otherwise, the critical values are created such that either the specified Type I error probability or the specified Type II error probability is maintained.

One-Sided Tests

For a K-stage group sequential design with an upper alternative hypothesis $H_1 : \theta = \theta_1$ and early stopping to reject or accept the null hypothesis $H_0 : \theta = 0$, the boundaries contain the upper α critical values a_k and upper β critical values b_k, $k = 1, 2, \ldots, K$. At each interim stage, $b_k < a_k$, the null hypothesis H_0 is rejected if the observed statistic $z_k \geq a_k$, H_0 is accepted if $z_k < b_k$, or the process is continued to the next stage if $b_k \leq z_k < a_k$. At the final stage $b_K = a_K$, the hypothesis is either rejected or accepted.

The overall Type I error probability α is given by

$$\alpha = \sum_{k=1}^{K} \alpha_k$$

where α_k is the α spending at stage k. That is, at stage 1,

$$\alpha_1 = P_{\theta=0}(\, z_1 \geq a_1 \,)$$

At a subsequent stage k,

$$\alpha_k = P_{\theta=0}(\, b_j \leq z_j < a_j, j = 1, 2, \ldots, k-1,\, z_k \geq a_k)$$

Similarly, the Type II error probability

$$\beta = \sum_{k=1}^{K} \beta_k$$

where β_k is the β spending at stage k. That is, at stage 1,

$$\beta_1 = P_{\theta=\theta_1}(\, z_1 < b_1 \,)$$

At a subsequent stage k,

$$\beta_k = P_{\theta=\theta_1}(\, b_j \leq z_j < a_j, j = 1, 2, \ldots, k-1,\, z_k < b_k \,)$$

With an upper alternative hypothesis $H_1 : \theta = \theta_1 > 0$, the power $1 - \beta$ is the probability of rejecting the null hypothesis for the upper alternative.

$$1 - \beta = 1 - \sum_{k=1}^{K} \beta_k = \sum_{k=1}^{K} P_{\theta=\theta_1}(\, b_j \leq z_j < a_j, j = 1, 2, \ldots, k-1,\, z_k \geq a_k)$$

For a design with early stopping to reject H_0 only, the interim upper β critical values are set to $-\infty$, $b_k = -\infty, k = 1, 2, \ldots, K-1$, and $\beta = \beta_K$. For a design with early stopping to accept H_0 only, the interim upper α critical values are set to ∞, $a_k = \infty, k = 1, 2, \ldots, K-1$, and $\alpha = \alpha_K$.

Similarly, the Type I and Type II error probabilities for a K-stage design with a lower alternative hypothesis $H_0 : \theta = -\theta_1$ can also be derived.

Two-Sided Tests

For a K-stage group sequential design with two-sided alternative hypotheses $H_{1u} : \theta = \theta_{1u}$ and $H_{1l} : \theta = \theta_{1l}$, and early stopping to reject or accept the null hypothesis $H_0 : \theta = 0$, the boundaries contain the upper α critical values a_k, upper β critical values b_k, lower β critical values $\_b_k$, and lower α critical values $\_a_k$, $k = 1, 2, \ldots, K$. At each interim stage, $\_a_k < \_b_k \le b_k < a_k$, the null hypothesis H_0 is rejected if the observed statistic $z_k \ge a_k$ or $z_k \le \_a_k$, H_0 is accepted if $\_b_k < z_k < b_k$, or the process is continued to the next stage if $b_k \le z_k < a_k$ or $\_a_k < z_k \le \_b_k$. At the final stage $b_K = a_K$ and $\_b_K = \_a_K$, the hypothesis is either rejected or accepted.

The overall upper Type I error probability α_u is given by

$$\alpha_u = \sum_{k=1}^{K} \alpha_{uk}$$

where α_{uk} is the α spending at stage k for the upper alternative. That is, at stage 1,

$$\alpha_{u1} = P_{\theta=0}(z_1 \ge a_1)$$

At a subsequent stage k,

$$\alpha_{uk} = P_{\theta=0}(\_a_j < z_j \le \_b_j \text{ or } b_j \le z_j < a_j, j = 1, 2, \ldots, k-1, z_k \ge a_k)$$

Similarly, the overall lower Type I error probability α_l can also be derived, and the overall Type I error probability $\alpha = \alpha_l + \alpha_u$.

The overall upper Type II error probability β_u is given by

$$\beta_u = \sum_{k=1}^{K} \beta_{uk}$$

where β_{uk} is the upper β spending at stage k. That is, at stage 1,

$$\beta_{u1} = P_{\theta=\theta_{1u}}(z_1 < \_a_1 \text{ or } \_b_1 < z_1 < b_1)$$

At a subsequent stage k,

$$\beta_{uk} = P_{\theta=\theta_{1u}}(\_a_j < z_j \le \_b_j \text{ or } b_j \le z_j < a_j, \; j = 1, 2, \ldots, k-1, \; z_k < \_a_k \text{ or } \_b_k < z_k < b_k)$$

With an upper alternative hypothesis $H_1 : \theta = \theta_{1u} > 0$, the power $1 - \beta_u$ is the probability of rejecting the null hypothesis for the upper alternative:

$$1 - \beta_u = 1 - \sum_{k=1}^{K} \beta_{uk}$$

which is

$$P_{\theta=\theta_{1u}}(\_a_j < z_j \leq \_b_j \text{ or } b_j \leq z_j < a_j,\ j = 1, 2, \ldots, k-1,\ z_k \geq a_k)$$

The overall lower Type II error probability β_l and power $1 - \beta_l$ can be similarly derived.

For a design with early stopping only to reject H_0, both the interim lower and upper β critical values are set to missing, $k = 1, 2, \ldots, K-1$, and $\beta_{lK} = \beta_l$, $\beta_{uK} = \beta_u$. For a design with early stopping only to accept H_0, the interim upper α critical values are set to ∞, $a_{uk} = \infty$, and the interim lower α critical values are set to $-\infty$, $a_{lk} = -\infty$, $k = 1, 2, \ldots, K-1$, and $\alpha_{uK} = \alpha_u$, $\alpha_{lK} = \alpha_l$.

Unified Family Methods

Unified family methods (Kittelson and Emerson 1999) derive boundary values with a specified boundary shape. For example, Pocock's method (Pocock 1977) derives equal boundary values for all stages in the standardized Z scale. In addition to Pocock's method, the unified family methods include the O'Brien-Fleming, power family, and unified family triangular methods.

The boundary values at each stage depend on the information fractions

$$\Pi_k = \frac{I_k}{I_X}$$

where I_k is the information available at stage k and I_X is the maximum information, the information available at the end of the trial if the trial does not stop early.

Boundary Values in Standardized *Z* Scale

With the unified family method, the boundary values for the upper α boundary $Z_{\alpha u}$, upper β boundary $Z_{\beta u}$, lower β boundary $Z_{\beta l}$, and lower α boundary $Z_{\alpha l}$, using the standardized normal scale, are given by the following:

- $Z_{\alpha u}(\Pi_k) = f_{\alpha u}(\Pi_k)\, C_{\alpha u}$
- $Z_{\beta u}(\Pi_k) = \theta_{1u}\, I_k^{\frac{1}{2}} - f_{\beta u}(\Pi_k)\, C_{\beta u}$
- $Z_{\beta l}(\Pi_k) = \theta_{1l}\, I_k^{\frac{1}{2}} + f_{\beta l}(\Pi_k)\, C_{\beta l}$
- $Z_{\alpha l}(\Pi_k) = -f_{\alpha l}(\Pi_k)\, C_{\alpha l}$

where $\theta_{1l}(<0)$ and $\theta_{1u}(>0)$ are the lower and upper alternative references, $f_{\alpha l}(\Pi_k)$, $f_{\beta l}(\Pi_k)$, $f_{\beta u}(\Pi_k)$, and $f_{\alpha u}(\Pi_k)$ are the specified shape functions, and $C_{\alpha l}$, $C_{\beta l}$, $C_{\beta u}$, and $C_{\alpha u}$ are the critical values derived to achieve the specified α and β levels.

If a derived lower β boundary value $Z_{\beta l}(\Pi_k)$ is greater than its corresponding upper β boundary value $Z_{\beta u}(\Pi_k)$, then both values are set to missing.

Note that the drift parameters $d_l = \theta_{1l}\sqrt{I_X}$ and $d_u = \theta_{1u}\sqrt{I_X}$ are derived in the SEQDESIGN procedure. The boundary values in standardized Z scale can be derived without specifying the maximum information and alternative reference.

Shape Parameters

The shape function in the SEQDESIGN procedure is given by

$$f(\Pi_k) = f(\Pi_k;\tau,\rho) = \tau\,\Pi_k^{\frac{1}{2}} + \Pi_k^{-\rho} = \Pi_k^{\frac{1}{2}}\,(\tau + \Pi_k^{-(\rho+\frac{1}{2})})$$

where the parameters $\rho \geq 0$ and $0 \leq \tau \leq 2\rho$. can be specified for each boundary separately.

The parameters τ and ρ determine the shape of the boundaries. Special cases of the unified family methods also include power family methods and triangular methods. Table 80.6 summarizes the corresponding parameter values in the unified family for these methods.

Table 80.6 Parameters in the Unified Family for Various Methods

Method	Option	Unified Family	
		Rho	Tau
Pocock	POC	0	0
O'Brien-Fleming	OBF	0.5	0
Power family	POW (RHO=ρ)	ρ	0
Triangular	TRI (TAU=τ)	0.5	τ

Note that the power parameter $\rho = 1/2 - \Delta = \rho^* - 1/2$, where Δ is the power parameter used in Jennison and Turnbull (2000) and Wang and Tsiatis (1987) and ρ^* is the power parameter used in Kittelson and Emerson (1999).

Also note that instead of the three parameters used in the unified family methods by Kittelson and Emerson (1999), only two parameters are used in the SEQDESIGN procedure. The other parameter is fixed at zero.

Boundary Values in MLE Scale

If the maximum information is available, the boundary values derived from a unified family method can also be displayed in the MLE scale:

- $\theta_{\alpha u}(\Pi_k) = I_k^{-\frac{1}{2}}\, f_{\alpha u}(\Pi_k)\, C_{\alpha u}$

- $\theta_{\beta u}(\Pi_k) = \theta_{1u} - I_k^{-\frac{1}{2}} f_{\beta u}(\Pi_k) C_{\beta u}$
- $\theta_{\beta l}(\Pi_k) = \theta_{1l} + I_k^{-\frac{1}{2}} f_{\beta l}(\Pi_k) C_{\beta l}$
- $\theta_{\alpha l}(\Pi_k) = -I_k^{-\frac{1}{2}} f_{\alpha l}(\Pi_k) C_{\alpha l}$

These MLE scale boundary values are computed by multiplying $I_k^{-\frac{1}{2}}$ by the standardized Z scale boundary values at stage k.

Boundary Values in Score Scale

If the maximum information is available, the boundary values derived from a unified family method can also be displayed in the score scale:

- $S_{\alpha u}(\Pi_k) = I_k^{\frac{1}{2}} f_{\alpha u}(\Pi_k) C_{\alpha u}$
- $S_{\beta u}(\Pi_k) = \theta_{1u} I_k - I_k^{\frac{1}{2}} f_{\beta u}(\Pi_k) C_{\beta u}$
- $S_{\beta l}(\Pi_k) = \theta_{1l} I_k + I_k^{\frac{1}{2}} f_{\beta l}(\Pi_k) C_{\beta l}$
- $S_{\alpha l}(\Pi_k) = -I_k^{\frac{1}{2}} f_{\alpha l}(\Pi_k) C_{\alpha l}$

These MLE scale boundary values are computed by multiplying $I_k^{\frac{1}{2}}$ by the standardized Z scale boundary values at stage k.

Boundary Values in *p*-Value Scale

For a design with a lower alternative or a two-sided alternative, the p-value scale boundary values are the cumulative normal distribution function values of the standardized Z boundary values:

- $P_{\alpha u}(\Pi_k) = \Phi(Z_{\alpha u}(\Pi_k))$
- $P_{\beta u}(\Pi_k) = \Phi(Z_{\beta u}(\Pi_k))$
- $P_{\beta l}(\Pi_k) = \Phi(Z_{\beta l}(\Pi_k))$
- $P_{\alpha l}(\Pi_k) = \Phi(Z_{\alpha l}(\Pi_k))$

These nominal p-values are the one-sided fixed-sample p-values under the null hypothesis with a lower alternative.

For a one-sided design with an upper alternative, the p-value scale boundary values are the one-sided fixed-sample p-values under the null hypothesis with an upper alternative:

- $P_{\alpha u}(\Pi_k) = 1 - \Phi(Z_{\alpha u}(\Pi_k))$
- $P_{\beta u}(\Pi_k) = 1 - \Phi(Z_{\beta u}(\Pi_k))$

Pocock's Method

The shape function for Pocock's method (Pocock 1977) is given by

$$f(\Pi_k) = 1$$

The resulting boundary values for a two-sided design with an early stopping to reject the null hypothesis $H_0 : \theta = 0$ are as follows:

- $Z_{\alpha u}(\Pi_k) = C_{\alpha u}$
- $Z_{\alpha l}(\Pi_k) = -C_{\alpha l}$

That is, the rejection boundary values are constant over all stages of different information levels in the standardized Z scale.

Note that compared with other designs, Pocock's design tends to stop the trials early with a larger p-value. For a new treatment, Pocock's design to stop a trial early with a large p-value might not be persuasive enough to make a new treatment widely accepted (Pocock and White 1999). A Pocock design is illustrated in Example 80.3.

O'Brien-Fleming Method

The shape function for the O'Brien-Fleming method (O'Brien and Fleming 1979) is given by

$$f(\Pi_k) = \Pi_k^{-\frac{1}{2}}$$

The resulting boundary values for a two-sided design with early stopping to reject the null hypothesis $H_0 : \theta = 0$ are as follows:

- $Z_{\alpha u}(\Pi_k) = \Pi_k^{-\frac{1}{2}} C_{\alpha u}$
- $Z_{\alpha l}(\Pi_k) = -\Pi_k^{-\frac{1}{2}} C_{\alpha l}$

That is, the rejection boundaries are inversely proportional to the square root of the information levels in the standardized Z scale.

In the score scale, these boundaries can be displayed as follows:

- $S_{\alpha u}(\Pi_k) = C_{\alpha u}\, I_X^{\frac{1}{2}}$

- $S_{\alpha l}(\Pi_k) = -C_{\alpha l}\, I_X^{\frac{1}{2}}$

which are constants over all stages in the score scale. An O'Brien-Fleming design is illustrated in Example 80.2.

Power Family Method

The shape function for a power family method (Wang and Tsiatis 1987; Emerson and Fleming 1989; Pampallona and Tsiatis 1994) is given by

$$f(\Pi_k) = \Pi_k^{-\rho}$$

The resulting boundary values for a two-sided design with early stopping to reject the null hypothesis $H_0 : \theta = 0$ are as follows:

- $Z_{\alpha u}(\Pi_k) = \Pi_k^{-\rho}\, C_{\alpha u}$
- $Z_{\alpha l}(\Pi_k) = -\Pi_k^{-\rho}\, C_{\alpha l}$

The rejection boundaries depend on the power parameter ρ. The power family includes the Pocock and O'Brien-Fleming methods, and the power parameter is used to allow continuous movement between these two methods.

Triangular Method

The shape function for a triangular method (Kittelson and Emerson 1999) in the unified family is given by

$$f(\Pi_k) = \Pi_k^{-\frac{1}{2}} + \tau\, \Pi_k^{\frac{1}{2}}$$

The resulting boundary values for a two-sided design with early stopping to reject the null hypothesis $H_0 : \theta = 0$ are as follows:

- $Z_{\alpha u}(\Pi_k) = (\Pi_k^{-\frac{1}{2}} + \tau\, \Pi_k^{\frac{1}{2}})\, C_{\alpha u} = C_{\alpha u}\, \Pi_k^{-\frac{1}{2}}\, (1 + \tau\, \Pi_k)$
- $Z_{\alpha l}(\Pi_k) = -(\Pi_k^{-\frac{1}{2}} + \tau\, \Pi_k^{\frac{1}{2}})\, C_{\alpha l} = -C_{\alpha l}\, \Pi_k^{-\frac{1}{2}}\, (1 + \tau\, \Pi_k)$

In the score scale, these boundaries are as follows:

- $S_{\alpha u}(\Pi_k) = C_{\alpha u}\, I_X^{\frac{1}{2}}\, (1 + \tau\, \Pi_k) = C_{\alpha u}\, I_X^{\frac{1}{2}} + C_{\alpha u} \tau I_X^{-\frac{1}{2}}\, I_k$
- $S_{\alpha l}(\Pi_k) = -C_{\alpha l}\, I_X^{\frac{1}{2}}\, (1 + \tau\, \Pi_k) = -C_{\alpha l}\, I_X^{\frac{1}{2}} - C_{\alpha l} \tau I_X^{-\frac{1}{2}}\, I_k$

Thus, in the score scale, the boundary function is a linear function of the information I_k. With these straight-line boundaries, a triangular method for a one-sided trial with early stopping to reject or accept the null hypothesis produces a triangular continuation region. Similarly, for a two-sided design, the continuation region is a union of two separate triangular regions. A triangular method is illustrated in Example 80.6.

Haybittle-Peto Method

The Haybittle-Peto method (Haybittle 1971; Peto et al. 1976) uses a value of 3 for the critical values in interim stages, so that the critical value at the final stage is close to the original design without interim monitoring.

In the SEQDESIGN procedure, the Haybittle-Peto method has been generalized to allow for different boundary values at different stages. That is, with the standardized normal scale, the boundary values are given by the following:

- $Z_{\alpha u}(\Pi_k) = z_{\alpha uk}$
- $Z_{\beta u}(\Pi_k) = \theta_{1u}\, I_k^{\frac{1}{2}} - z_{\beta uk}$
- $Z_{\beta l}(\Pi_k) = \theta_{1l}\, I_k^{\frac{1}{2}} + z_{\beta lk}$
- $Z_{\alpha l}(\Pi_k) = -z_{\alpha lk}$

where θ_{1l} and θ_{1u} are the lower and upper alternative references and the boundary values $z_{\alpha uk}$, $z_{\beta uk}$, $z_{\beta lk}$, and $z_{\alpha lk}$ are specified either explicitly with the HP(Z= *numbers*) option or implicitly with the HP(PVALUE= *numbers*) option. The HP(PVALUE= *numbers*) option specifies the nominal p-values p_k for the corresponding boundary values z_k:

$$z_k = \Phi^{-1}(1 - p_k)$$

The Haybittle-Peto method is illustrated in Example 80.5.

Whitehead Methods

The Whitehead methods (Whitehead and Stratton 1983; Whitehead 1997, 2001) derive boundary values by adjusting the boundary values generated from continuous monitoring. With continuous monitoring, the boundary values are on a straight line in the score scale for each boundary. For a group sequential design, the boundary values at an interim stage k depend on the information fractions

$$\Pi_k = \frac{I_k}{I_X}$$

where I_k is the information available at stage k and I_X is the maximum information, the information available at the end of the trial if the trial does not stop early.

One-Sided Symmetric Designs

A one-sided symmetric design is a one-sided design with identical Type I and Type II error probabilities. For a one-sided symmetric design with an upper alternative, $\alpha_u = \beta_u$, the boundary values in the score scale from continuous monitoring are as follows:

- $S_{\alpha u}(\Pi_k) = C_u\theta_u^{-1} + \tau_u\theta_u I_k$
- $S_{\beta u}(\Pi_k) = \theta_u\, I_k - (C_u\theta_u^{-1} - \tau_u\theta_u I_k)$

where θ_u is the upper alternative reference, τ_u is a specified constant for the slope, $0 \le \tau_u < \frac{1}{2}$, and C_u is a constant, fixed for STOP=BOTH and derived for STOP=ACCEPT and STOP=REJECT.

The upper β boundary value can also be expressed as

- $S_{\beta u}(\Pi_k) = -C_u\theta_u^{-1} + (1-\tau_u)\theta_u I_k$

Thus, these straight-line boundaries form a triangle in the score statistic scale.

To adjust for the nature of discrete monitoring, the group sequential boundary values are given by the following:

- $S_{\alpha u}(\Pi_k) = C_u\theta_u^{-1} + \tau_u\theta_u I_k - g_k$
- $S_{\beta u}(\Pi_k) = -C_u\theta_u^{-1} + (1-\tau_u)\theta_u I_k + g_k$

where $g_1 = 0.583\sqrt{I_1}$ and $g_k = 0.583\sqrt{I_k - I_{(k-1)}}$, $k > 1$ are the adjustments.

Note that with the adjustment g_k, the resulting boundaries form a Christmas tree shape within the original triangle and are referred to as the Christmas tree boundaries (Whitehead 1997, p. 73).

One-Sided Asymmetric Designs

For a one-sided asymmetric design with an upper alternative, $\alpha_u \neq \beta_u$, the boundary values computed using the score scale, are given by the following:

- $S_{\alpha u}(\Pi_k) = C_u\tilde{\theta}_u^{-1} + \tau_u\tilde{\theta}_u I_k - g_k$
- $S_{\beta u}(\Pi_k) = -C_u\tilde{\theta}_u^{-1} + (1-\tau_u)\tilde{\theta}_u I_k + g_k$

where $\tilde{\theta_u}$ is the modified alternative reference

$$\tilde{\theta_u} = \frac{2\Phi^{-1}(1-\alpha_u)}{\Phi^{-1}(1-\alpha_u) + \Phi^{-1}(1-\beta_u)}\,\theta_u$$

The modified alternative reference $\tilde{\theta}_u = \theta_u$ if $\alpha_u = \beta_u$.

For a design with early stopping to reject or accept the null hypothesis, $S_{\alpha u}(1) = S_{\beta u}(1)$, the boundary values at the final stage are equal. The modified drift parameter $\tilde{d}_u$ is given by

$$\tilde{d}_u = \tilde{\theta}_u \sqrt{I_X} = \frac{1}{1-2\tau_u}\left(\sqrt{{h_K}^2 + 2C_u(1-2\tau_u)} - h_K\right)$$

where $h_K = g_K \, I_X^{-\frac{1}{2}} = 0.583\sqrt{1-\Pi_{(K-1)}}$.

A one-sided Whitehead design with early stopping to reject or accept the null hypothesis is illustrated in Example 80.7.

Two-Sided Designs

The boundary values for a two-sided design are generated by combining boundary values from two one-sided designs. With the STOP=BOTH option, this produces a double triangular design (Whitehead 1997, p. 98).

The boundary values for a two-sided design, using the score scale, are then given by the following:

- $S_{\alpha u}(\Pi_k) = C_u \tilde{\theta}_u^{-1} + \tau_u \tilde{\theta}_u I_k - g_k$
- $S_{\beta u}(\Pi_k) = -C_u \tilde{\theta}_u^{-1} + (1-\tau_u)\tilde{\theta}_u I_k + g_k$
- $S_{\beta l}(\Pi_k) = -C_l \tilde{\theta}_l^{-1} + (1-\tau_l)\tilde{\theta}_l I_k - g_k$
- $S_{\alpha l}(\Pi_k) = C_l \tilde{\theta}_l^{-1} + \tau_l \tilde{\theta}_l I_k + g_k$

where the modified alternative references are

$$\tilde{\theta}_u = \frac{2\Phi^{-1}(1-\alpha_u)}{\Phi^{-1}(1-\alpha_u) + \Phi^{-1}(1-\beta_u)}\,\theta_u$$

$$\tilde{\theta}_l = \frac{2\Phi^{-1}(1-\alpha_l)}{\Phi^{-1}(1-\alpha_l) + \Phi^{-1}(1-\beta_l)}\,\theta_l$$

The modified alternative reference $\tilde{\theta}_u = \theta_u$ if $\alpha_u = \beta_u$ and $\tilde{\theta}_l = \theta_l$ if $\alpha_l = \beta_l$.

For a design with early stopping to reject or accept the null hypothesis, the two upper boundary values at the final stage are identical and the two lower boundary values at the final stage are identical. That is, $S_{\alpha l}(1) = S_{\beta l}(1)$ and $S_{\alpha u}(1) = S_{\beta u}(1)$. These modified drift parameters are then given by

$$\tilde{d}_l = \tilde{\theta}_l \sqrt{I_X} = \frac{1}{1-2\tau_l}\left(\sqrt{{h_K}^2 + 2C_l(1-2\tau_l)} - h_K\right)$$

$$\tilde{d}_u = \tilde{\theta}_u \sqrt{I_X} = \frac{1}{1-2\tau_u}\left(\sqrt{{h_K}^2 + 2C_u(1-2\tau_u)} - h_K\right)$$

where $h_K = g_K I_X^{-\frac{1}{2}} = 0.583\sqrt{1-\Pi_{(K-1)}}$.

For a design with early stopping to reject the null hypothesis, or a design with early stopping to accept the null hypothesis, you can specify the slope parameters τ_u and τ_l in the TAU= option, and then the intercept parameters C_u and C_l, and the resulting boundary values are derived. If both the maximum information and alternative references are specified, the procedure derives C_u and C_l by maintaining either the overall α levels (BOUNDARYKEY=ALPHA) or the overall β levels (BOUNDARYKEY=BETA). If the maximum information and alternative reference are not both specified, the procedure derives the boundary values C_u and C_l by maintaining both the overall α and overall β levels.

For a design with early stopping to reject or accept the null hypothesis (STOP=BOTH), Whitehead's triangular test uses $\tau_u = \tau_l = 0.25$ and compute $C_u = -2\log(2\alpha_u)$ and $C_l = -2\log(2\alpha_l)$ for the boundary values. If the maximum information and alternative reference are both specified, the BOUNDARYKEY=ALPHA option uses the specified α values to compute the β values and boundary values. The final-stage boundary values are modified to maintain the overall α levels if they exist. Similarly, the BOUNDARYKEY=BETA option uses the specified β values to compute the α values and boundary values. The final-stage boundary values are modified to maintain the overall β levels if they exist.

If the maximum information and alternative reference are not both specified, the specified α and β values are used to derive boundary values. The BOUNDARYKEY=NONE option uses these boundary values without adjustment. The BOUNDARYKEY=ALPHA option modifies the final-stage boundary values to maintain the overall α levels if they exist. Similarly, the BOUNDARYKEY=BETA option modifies the final-stage boundary values to maintain the overall β levels if they exist.

Applicable Boundary Keys

Table 80.7 lists applicable boundary keys for a design that uses Whitehead methods.

Table 80.7 Applicable Boundary Keys for Whitehead Methods

	Specified Parameters		Boundary Keys			
Early Stopping	**(Alt Ref – Max Info)**	**Tau**	**Alpha**	**Beta**	**None**	**Both**
Reject H_0	X	X	X	X		
Accept H_0	X	X	X	X		
Reject/Accept H_0	X	0.25	X	X		
Reject H_0		X				X
Accept H_0		X				X
Reject/Accept H_0		0.25	X	X	X	

Note that the symbol "X" under "(Alt Ref – Max Info)" indicates that both alternative reference and maximum information are specified.

For a design with early stopping to reject the null hypothesis, or a design with early stopping to accept the null hypothesis, you can specify the slope parameter τ_u in the TAU= option, and then the intercept parameter C_u and the resulting boundary values are derived. If both the maximum information and alternative reference are specified, the procedure derives C_u by maintaining either the overall α levels (BOUNDARYKEY=ALPHA) or the overall β levels (BOUNDARYKEY=BETA). If the maximum information and alternative reference are not both specified, the procedure derives the boundary values and C_u by maintaining both the overall α and overall β levels.

For a design with early stopping to reject or accept the null hypothesis (STOP=BOTH), Whitehead's triangular test uses $\tau_u = 0.25$ and solves $C_u = 2\log(\frac{1}{2\alpha_u})$ for the boundary values. If the maximum information and alternative reference are both specified, the BOUNDARYKEY=ALPHA option uses the specified α value to compute the β value and boundary values. The final-stage boundary value is modified to maintain the overall α level if it exists. Similarly, the BOUNDARYKEY=BETA option uses the specified β value to compute the α value and boundary values. The final-stage boundary value is modified to maintain the overall β level if it exists.

If the maximum information and alternative reference are not both specified, the specified α and β values are used to derive boundary values. The BOUNDARYKEY=NONE option uses these boundary values without adjustment. The BOUNDARYKEY=ALPHA option modifies the final-stage boundary value to maintain the overall α level if it exists. Similarly, the BOUNDARYKEY=BETA option modifies the final-stage boundary value to maintain the overall β level if it exists.

Error Spending Methods

For each sequential design, the α and β errors spent at each stage can be computed from the boundary values. For example, for a K-stage design with an upper alternative hypothesis $H_1 : \theta = \theta_1$ and early stopping to reject the null hypothesis $H_0 : \theta = 0$, the boundary values in a standardized Z scale are the upper α critical values $a_k, k = 1, 2, \ldots, K$. At each interim stage, the null hypothesis H_0 is rejected if the observed standardized Z statistic $z_k \geq a_k$. Otherwise, the process continues to the next stage. At the final stage, the hypothesis is rejected if $z_K \geq a_K$. Otherwise, the null hypothesis is accepted.

The boundary values a_k are derived such that the overall Type I error probability

$$\alpha = \sum_{k=1}^{K} \alpha_k$$

where α_k is the α spending at stage k. That is, at stage 1,

$$\alpha_1 = P_{\theta=0}\,(\,z_1 \geq a_1\,)$$

At a subsequent stage k,

$$\alpha_k = P_{\theta=0}\,(\,z_j < a_j, j = 1, 2, \ldots, k-1,\ z_k \geq a_k\,)$$

Since each design can be uniquely identified by the α and β errors spent at each stage, a design can then be derived by specifying the α and β errors to be used at each stage. The error spending method (Lan and DeMets 1983) distributes the error to be used at each stage and then derives the boundary values. Numerous forms of the error spending function are available. Kim and DeMets (1987) examine the functions $f(t) = t$, $f(t) = t^{\frac{3}{2}}$, and $f(t) = t^2$, where t is the information fraction. Jennison and Turnbull (2000, p. 148) generalize these functions to the power functions $f(t;\rho) = t^\rho, \rho > 0$.

The ERRFUNCPOC option uses the cumulative error spending function (Lan and DeMets 1983)

$$E(t) = \begin{cases} 1 & \text{if } t \geq 1 \\ \log(\,1 + (e-1)t) & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

With a specified error of α or β, the cumulative error spending at stage k is $\alpha\, E(\Pi_k)$ or $\beta\, E(\Pi_k)$, where $\Pi_k = I_k/I_X$ is the information fraction at stage k. The method produces boundaries similar to those produced with Pocock's method.

The ERRFUNCOBF option uses the cumulative error spending function (Lan and DeMets 1983)

$$E(t;a) = \begin{cases} 1 & \text{if } t \geq 1 \\ \frac{1}{a}\, 2\,(1 - \Phi(\frac{z_{(1-a/2)}}{\sqrt{t}})) & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

where a is either α for the α spending function or β for the β spending function. That is, with a specified error of α or β, the cumulative error spending at stage k is $\alpha\, E(\Pi_k;\alpha)$ or $\beta\, E(\Pi_k;\beta)$. The method produces boundaries similar to those produced with the O'Brien-Fleming method.

The ERRFUNCGAMMA option uses the gamma cumulative error spending function (Hwang, Shih, and DeCani 1990)

$$E(t;\gamma) = \begin{cases} 1 & \text{if } t \geq 1 \\ \frac{1-e^{-\gamma t}}{1-e^{-\gamma}} & \text{if } 0 < t < 1, \gamma \neq 0 \\ t & \text{if } 0 < t < 1, \gamma = 0 \\ 0 & \text{otherwise} \end{cases}$$

where γ is the parameter γ specified in the GAMMA= option. That is, with a specified error of α or β, the cumulative error spending at stage k is $\alpha\, E(\Pi_k;\gamma)$ or $\beta\, E(\Pi_k;\gamma)$.

The ERRFUNCPOW option uses the cumulative error spending function (Jennison and Turnbull 2000, p. 148)

$$E(t;\rho) = \begin{cases} 1 & \text{if } t \geq 1 \\ t^{\rho} & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

where ρ is the power parameter specified in the RHO= option. That is, with a specified error of α or β, the cumulative error spending at stage k is $\alpha\, E(\Pi_k;\rho)$ or $\beta\, E(\Pi_k;\rho)$.

Error spending methods derive boundary values at each stage sequentially and require much more computation than other types of methods for group sequential trials with a large number of stages, especially for a two-sided asymmetric design with early stopping to accept H_0, or to reject or accept H_0.

Note that for a two-sided design with the STOP=BOTH or STOP=ACCEPT option, at each interim stage, the SEQDESIGN procedure first produces the lower and upper β boundary values based on the one-sided β spending. If the lower β boundary value is greater than or equal to its corresponding upper β boundary value, there is no early stopping to accept the null hypothesis at this stage, and the corresponding β spending is distributed proportionally to the remaining stages.

For the error spending functions not available in the SEQDESIGN procedure, you can first compute the corresponding error spending at each stage explicitly, then use the SEQDESIGN procedure with the ERRSPEND= option to specify these errors directly.

For example, if the information levels are equally spaced in a five-stage design, the option ERRFUNCPOW (RHO=2) produces relative cumulative errors of $(1/5)^2$, $(2/5)^2$, $(3/5)^2$, $(4/5)^2$, and 1. This is equivalent to using the option ERRSPEND (1 4 9 16 25).

A one-sided error spending design is illustrated in Example 80.8 and a two-sided asymmetric error spending design is illustrated in Example 80.11.

Acceptance (β) Boundary

In a group sequential trial, the rejection boundary is derived under the null hypothesis H_0 and is used to stop the trial early to reject H_0. Similarly, the acceptance boundary is derived under the alternative hypothesis and is used to stop the trial early to accept H_0. But, for a trial with early stopping either to reject or to accept the null hypothesis, dependency exists between these two boundaries. This section describes the effects of the acceptance boundary on the derivation of the rejection boundary in a group sequential trial.

The following statements create a one-sided four-stage group sequential design with early stopping either to reject or to accept H_0:

```
ods graphics on;
proc seqdesign altref=10;
   ErrSpendPower_2: design nstages=4
                    method=errfuncpow(rho=2)
                    alt=upper   stop=both
                    alpha=0.025 beta=0.10;
run;
ods graphics off;
```

The ALTREF=10 option specifies the alternative reference 10. The METHOD=ERRFUNCPOW(RHO=2) option uses a $\rho = 2$ power family error spending method to generate the rejection boundary. The ALPHA=0.025 and BETA=0.10 options specify the Type I error level 0.025 and Type II error level 0.10, respectively.

The power parameter $\rho = 2$ used in the design lies between $\rho = 1$ and $\rho = 3$, where the boundaries created with the $\rho = 1$ power family error spending method are similar to the boundaries created from the Pocock method, and the boundaries created with $\rho = 3$ are similar to the boundaries created from the O'Brien-Fleming method.

The "Boundary Information" table in Figure 80.12 shows the rejection and acceptance boundary values at the stages. With an error spending function method, the boundary values are derived sequentially. In particular, the rejection boundary value at a stage is derived conditionally on both rejection and acceptance boundary values at the previous stage. See the section "Error Spending Methods" on page 6758 for a detailed description of the error spending methods.

Figure 80.12 Boundary Information

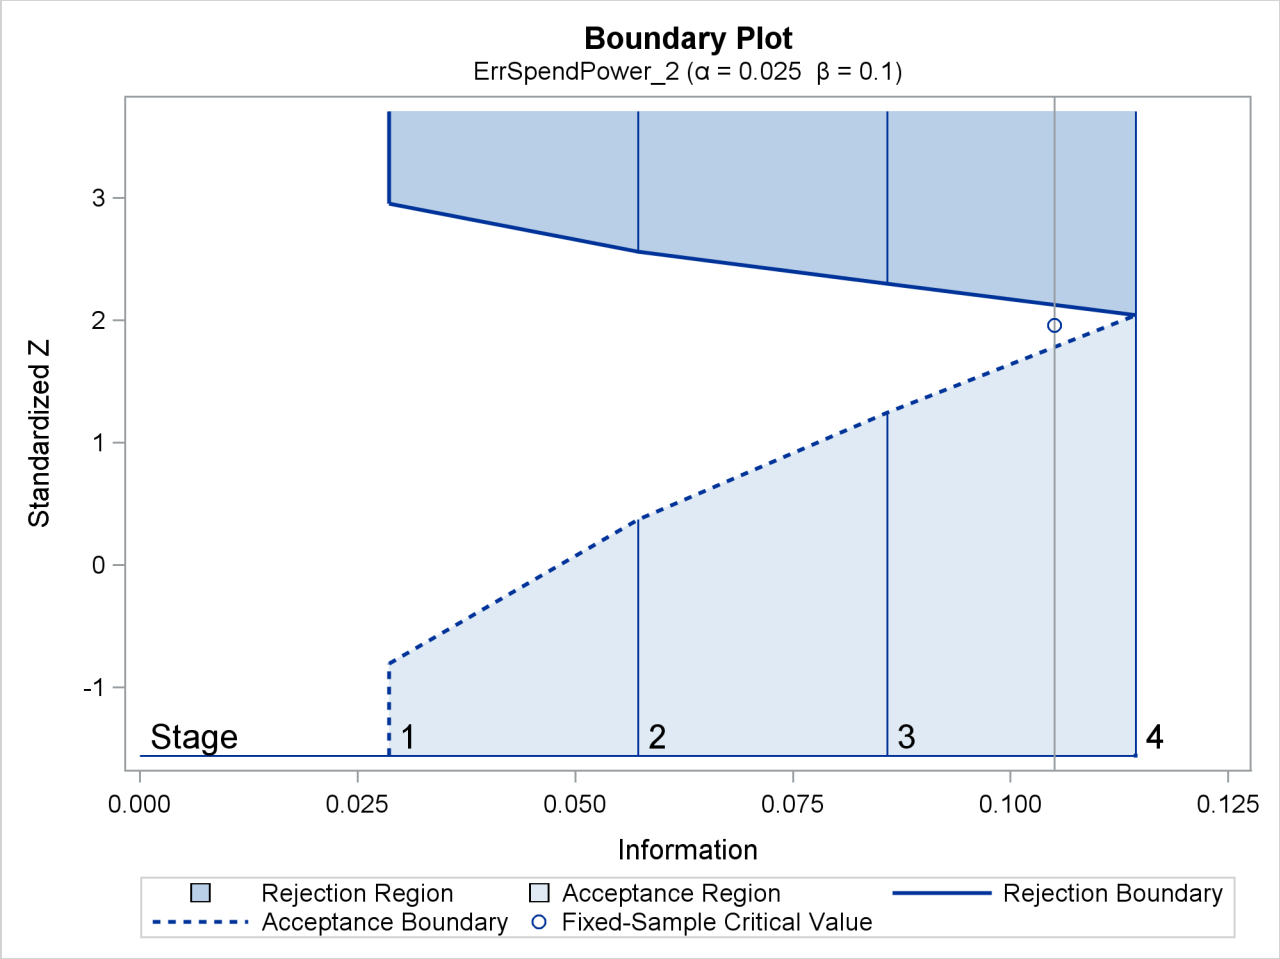
The SEQDESIGN Procedure
Design: ErrSpendPower_2

Boundary Information (Standardized Z Scale)
Null Reference = 0

	---Information Level--		-Alternative- --Reference--	-----Boundary Values---- ----------Upper---------	
Stage	Proportion	Actual	Upper	Beta	Alpha
1	0.2500	0.028605	1.69130	-0.80640	2.95517
2	0.5000	0.05721	2.39186	0.37356	2.55934
3	0.7500	0.085815	2.92942	1.24940	2.29904
4	1.0000	0.11442	3.38261	2.04182	2.04182

With ODS Graphics enabled, the "Boundary Plot" is displayed by default, as shown in Figure 80.13. The continuation region is affected by the acceptance boundary, and the rejection boundary is thus adjusted for this acceptance boundary to maintain the Type I error level.

Figure 80.13 Boundary Plot



For a design with early stopping either to accept or to reject H_0, the shapes of boundaries affect the critical value at the final stage. For the acceptance boundary, a liberal method at early stages, such as a $\rho = 1$ power family error spending method, lowers the critical value at the final stage. For the rejection boundary, a conservative method at early stages, such as a $\rho = 3$ power family error spending method, also lowers the critical value at the final stage. In addition, a larger Type II error level also lowers the critical value at the final stage. The resulting critical value at the final stage might even be less than the critical value for the corresponding fixed-sample design.

To illustrates how this can occur, the following statements use a $\rho = 1$ power family error spending method for the acceptance boundary and a $\rho = 3$ power family error spending method for the rejection boundary to create a group sequential design:

```
proc seqdesign altref=10;
   ErrSpendPower_3_1: design nstages=4
                      method(alpha)=errfuncpow(rho=3)
                      method(beta)= errfuncpow(rho=1)
                      alt=upper   stop=both
                      alpha=0.025 beta=0.10;
run;
```

The resulting "Boundary Information" table in Figure 80.14 shows that the boundary value at the final stage 1.9267 is less than 1.96, the critical value of the corresponding fixed-sample design.

Figure 80.14 Boundary Information

The SEQDESIGN Procedure
Design: ErrSpendPower_3_1

Boundary Information (Standardized Z Scale)
Null Reference = 0

			-Alternative-	-----Boundary Values----	
	---Information Level--		--Reference--	----------Upper---------	
Stage	Proportion	Actual	Upper	Beta	Alpha
1	0.2500	0.029725	1.72410	-0.23587	3.35935
2	0.5000	0.05945	2.43824	0.63117	2.76024
3	0.7500	0.089175	2.98622	1.31554	2.35119
4	1.0000	0.1189	3.44819	1.92672	1.92672

That is, H_0 can be rejected even if the test statistic at the final stage is less than the critical value for the corresponding fixed-sample design, which is not desirable. Therefore, for a design with an acceptance boundary, the design should be used with care.

Another reason why the rejection boundary should not be affected by the acceptance boundary is that a Data and Safety Monitoring Board (DSMB) might not strictly adhere to this acceptance boundary, and thus the Type I error level might not be maintained. Therefore, it might not be desirable for the rejection boundary to be affected by the acceptance boundary (Lan and DeMets 2009, p. 103).

To avoid this problem, you can create a design with only a rejection boundary, and then provide a strategy for early stopping to accept H_0 without affecting the rejection boundary. The available strategies include:

- creating a separate design with early stopping only to accept H_0, and then using this acceptance boundary as a guideline
- using the conditional power approach

For a group sequential design with early stopping only to reject H_0, the conditional power at an interim stage k is the probability that H_0 will be rejected at the final stage under a specified hypothetical reference, given the observed statistic at stage k. A small conditional power indicates a small probability of success (rejecting H_0) given the current data, and the trial can be stopped early to accept H_0 (Lan, Simon, and Halperin 1982; Lan and DeMets 2009, p. 101). For a detailed description of conditional power, see the section "Stochastic Curtailment" in "The SEQTEST Procedure."

Boundary Adjustments for Overlapping Lower and Upper β Boundaries

For the fixed boundary shape methods and Whitehead methods, the boundary values for all stages are derived simultaneously for each boundary. For a two-sided design with STOP=ACCEPT or STOP=BOTH, simultaneous derivation might result in overlapping of the lower and upper β boundaries. That is, at an interim stage k, the lower β boundary value might be greater than its corresponding upper β boundary value. In this case, these two β boundary values are set to missing and the design does not stop at stage k to accept the null hypothesis (Jennison and Turnbull 2000, p. 113).

For the error spending methods, the boundary values are derived sequentially for the stages. For a two-sided design with STOP=ACCEPT or STOP=BOTH, a small β spending at an interim stage might result in overlapping of the lower and upper β boundaries for the two corresponding one-sided tests. Specifically, this form of overlapping occurs at an interim stage k if the upper β boundary value derived from the one-sided test for the upper alternative is less than the lower β boundary value derived from the one-sided test for the lower alternative (Kittelson and Emerson 1999, pp. 881–882; Rudser and Emerson 2007, p. 6). You can use the BETAOVERLAP= option to specify how this type of overlapping is to be handled.

If BETAOVERLAP=ADJUST (which is the default) is specified, the procedure derives the boundary values for the two-sided design and then checks for overlapping of the two one-sided β boundaries at interim stages. If overlapping occurs at a particular stage, the β boundary values for the two-sided design are set to missing (so the trial does not stop to accept the null hypothesis at this stage), and the β spending values at subsequent stages are adjusted proportionally as follows.

If the β boundary values are set to missing at stage k in a K-stage trial, the adjusted β spending value at stage k, e'_k, is updated for these missing β boundary values, and then the β spending values at subsequent stages are adjusted proportionally by

$$e'_j = e'_k + \frac{e_j - e_k}{e_K - e_k}\,(e_K - e'_k)$$

for $j = k+1, \ldots, K$, where e_j and e'_j are the cumulative β spending values st stage j before and after the adjustment, respectively.

After all these adjusted β spending values are computed, the boundary values are then further modified for these adjusted β spending values.

If you specify BETAOVERLAP=NOADJUST, no adjustment is made when overlapping of one-sided β boundaries occurs. The BETAOVERLAP= option is illustrated in Example 80.10.

Specified and Derived Parameters

In the SEQDESIGN procedure, the type of alternative hypothesis (ALT= option) and the condition for early stopping (STOP= option) must be specified for each sequential design. The drift parameters are derived for each design specified. Other parameters, such as Type I error probability α, Type II error probability β, the alternative reference θ_1, and maximum information are either specified or derived in the SEQDESIGN procedure.

Table 80.8 summarizes the available combinations for the specified and derived parameters in the SEQDESIGN procedure.

Table 80.8 Specified and Derived Parameters in the SEQDESIGN Procedure

Specified Parameters				Derived Parameters				
Alt Ref	**Max Info**	**Alpha**	**Beta**	**Alt Ref**	**Max Info**	**Alpha**	**Beta**	**Drift**
Z	X	X					X	X
Z	X		X			X		X
Z	X					X	X	X
Z		X	X		X			X
	X	X	X	X				X
		X	X					X

The symbol "X" indicates that the parameter is either specified or derived in the design and the symbol "Z" indicates that the alternative reference is either specified explicitly with the ALTREF= option or derived from the SAMPLESIZE statement. The drift parameter is always derived in the SEQDESIGN procedure.

For example, if the ALTREF= option is specified without the MAXINFO= option being specified, then the maximum information is derived in the SEQDESIGN procedure with the specified α and β, as illustrated in Example 80.5.

The drift parameter is the standardized reference difference at the final stage. For a design, the drift parameter is

$$d_l = \theta_{1l}\sqrt{I_X}$$

if it has a lower alternative, and

$$d_u = \theta_{1u}\sqrt{I_X}$$

if it has an upper alternative, where I_X is the maximum information and θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively.

If the alternative reference and the maximum information are not both specified, then the specified α and β are used to derive the drift parameter. Then if either the alternative reference or the maximum information is specified, the other is derived from the drift parameter.

If both the alternative reference and the maximum information are specified, then either the α error or the β error is derived in the procedure. However, for a Haybittle-Peto method with the BOUNDARYKEY=NONE option, both α and β errors are derived from the completely specified boundary values.

For a nonsymmetric two-sided design with different lower and upper specifications (such as different lower and upper α errors, β errors, or alternative references in absolute values), the derived lower and upper boundaries are not symmetric. If the alternative references θ_{1l} and θ_{1u} are not both specified, then the SEQDESIGN procedure assumes symmetric alternative references, $\theta_1 = \theta_{1u} = -\theta_{1l}$, for the computation of the boundary values.

Applicable Boundary Keys

In the SEQDESIGN procedure, the BOUNDARYKEY= option in the DESIGN statement specifies the types of errors to be maintained for the design. Table 80.9 lists applicable boundary keys for designs that use unified family and Haybittle-Peto methods, designs that use error spending methods, and designs that use the Haybittle-Peto method only.

Table 80.9 Applicable Boundary Keys for Designs without Whitehead Methods

Method	Specified Parameters (Alt Ref – Max Info)	Boundary Keys			
		Alpha	Beta	None	Both
Unified	X	X	X		
Unified/Haybittle-Peto	X	X	X		
Error spending	X	X	X		
Haybittle-Peto	X	X	X	X	
Unified/Haybittle-Peto					X
Error spending					X
Haybittle-Peto					X

Note that the symbol "X" under "(Alt Ref – Max Info)" indicates that both the alternative reference and maximum information are specified, and the method "Unified/Haybittle-Peto" indicates that both the unified method and the Haybittle-Peto method are used in the same design.

If the ALTREF= and MAXINFO= options are both specified, then Type I and Type II error probability levels cannot be met simultaneously if both error probabilities are specified. The BOUNDARYKEY=ALPHA option maintains the Type I error probability level α and derives Type II error probability β. The BOUNDARYKEY=BETA option maintains the Type II error probability level β and derives Type I error probability α.

If the Haybittle-Peto method is used for all boundaries, the BOUNDARYKEY=NONE option uses the specified α boundary value (STOP=REJECT or STOP=BOTH) and the specified β boundary value (STOP=ACCEPT) at the final stage for the design.

If the ALTREF= and MAXINFO= options are not both specified, the BOUNDARYKEY=BOTH option derives boundary values that maintain both Type I and Type II error probability levels.

Table 80.10 lists applicable boundary keys for a design that uses Whitehead methods.

Table 80.10 Applicable Boundary Keys for Whitehead Methods

	Specified Parameters		Boundary Keys			
Early Stopping	**(Alt Ref – Max Info)**	**Tau**	**Alpha**	**Beta**	**None**	**Both**
Reject H_0	X	X	X	X		
Accept H_0	X	X	X	X		
Reject/Accept H_0	X	0.25	X	X		
Reject H_0		X				X
Accept H_0		X				X
Reject/Accept H_0		0.25	X	X	X	

Note that the symbol "X" under "(Alt Ref – Max Info)" indicates that both alternative reference and maximum information are specified.

If the ALTREF= and MAXINFO= options are both specified, then Type I and Type II error probability levels cannot be achieved simultaneously if both are specified. the BOUNDARYKEY=ALPHA option maintains the Type I error probability level α and derives Type II error probability β. The BOUNDARYKEY=BETA option maintains the Type II error probability level β and derives the Type I error probability α.

If the ALTREF= and MAXINFO= options are not both specified, then for a design with the STOP=REJECT or STOP=ACCEPT option, the BOUNDARYKEY=BOTH option derives boundary values that maintain both Type I and Type II error probability levels. If the STOP=BOTH option is specified, Whitehead's triangular method produces boundaries with approximate Type I and Type II error probabilities. The BOUNDARYKEY=NONE option specifies no adjustment to these boundaries. The BOUNDARYKEY=ALPHA and BOUNDARYKEY=BETA options maintain the Type I error probability level α and Type II error probability level β, respectively, by adjusting boundary values at the final stage.

Sample Size Computation

The SEQDESIGN procedure assumes that the data are from a multivariate normal distribution and the sequence of the standardized test statistics $\{Z_1, Z_2, \ldots, Z_K\}$ has the following canonical joint distribution:

- $(Z_1, Z_2, \ldots, Z_K)$ is multivariate normal
- $Z_k \sim N\left(\theta\sqrt{I_k}, 1\right)$
- $\mathrm{Cov}(Z_{k_1}, Z_{k_2}) = \sqrt{I_{k_1}/I_{k_2}} \quad , \quad 1 \le k_1 \le k_2 \le K$

where K is the total number of stages and I_k is the information available at stage k.

If the test statistic is computed from the data that are not from a normal distribution, such as a binomial distribution, then it is assumed that the test statistic is computed from a large sample such that the statistic has an approximately normal distribution.

In a typical clinical trial, the sample size required depends on the Type I error probability level α, alternative reference θ_1, power $1-\beta$, and variance of the response variable. Given a one-sided null hypothesis $H_0 : \theta = 0$ with an upper alternative hypothesis $H_1 : \theta = \theta_1$, the information required for a fixed-sample test is given by

$$I_0 = \frac{(\Phi^{-1}(1-\alpha) + \Phi^{-1}(1-\beta))^2}{\theta_1^2}$$

The parameter θ and the subsequent alternative reference θ_1 depend on the test specified in the clinical trial. For example, suppose you are comparing two binomial populations $p_a = p_b$; then $\theta = p_a - p_b$ is the difference between two proportions if the proportion difference statistic is used, and $\theta = \log\left(\frac{p_a(1-p_b)}{p_b(1-p_a)}\right)$, the log odds ratio for the two proportions if the log odds ratio statistic is used.

If the maximum likelihood estimate $\hat{\theta}$ from the likelihood function can be derived, then the asymptotic variance for $\hat{\theta}$ is $\mathrm{Var}(\hat{\theta}) = 1/I$, where I is Fisher information for θ. The resulting statistic $\hat{\theta}$ corresponds to the MLE statistic scale as specified in the BOUNDARYSCALE=MLE option in the PROC SEQDESIGN statement, $\hat{\theta}\sqrt{I}$ corresponds to the standardized Z scale (BOUNDARYSCALE=STDZ), and $\hat{\theta}\, I$ corresponds to the score statistic scale (BOUNDARYSCALE=SCORE).

Alternatively, if the score statistic S is derived in a statistical procedure, it can be used as the test statistic and its asymptotic variance is given by Fisher information, I. In this case, $S/\sqrt{I}$ corresponds to the standardized Z scale and S/I corresponds to the MLE statistic scale.

For a group sequential trial, the maximum information I_X is derived in the SEQDESIGN procedure with the specified α, β, and θ_1. With the maximum information

$$I_X = \frac{1}{\mathrm{Var}(\hat{\theta})}$$

the sample size required for a specified test statistic in the trial can be evaluated or estimated from the known or estimated variance of the response variable. Note that different designs might produce different maximum information levels for the same hypothesis, and this in turn might require a different number of observations for the trial.

If each observation in the data set provides one unit of information in a hypothesis testing, such as a one-sample test for the mean, the required sample size for the sequential design can be derived from the maximum information. However, for a survival analysis, an individual in the survival time data might provide only partial information because of censoring. In this case, the required number of events can be derived from the maximum information. With addition accrual information, the sample size can also be computed.

The SEQDESIGN procedure provides sample size computation for some one-sample and two-sample tests in the SAMPLESIZE statement. It also provides sample size computation for tests of a parameter in regression models such as normal regression, logistic regression, and proportional hazards regression. In addition, the procedure can also compute the required sample size or number of events from the corresponding number in the fixed-sample design.

Table 80.11 lists the options available in the SAMPLESIZE statement.

Table 80.11 SAMPLESIZE Statement Options

Option	Description
Fixed-Sample Models	
INPUTNOBS	specifies sample size for fixed-sample design
INPUTNEVENTS	specifies number of events for fixed-sample design
One-Sample Models	
ONESAMPLEMEAN	specifies one-sample Z test for mean
ONESAMPLEFREQ	specifies one-sample test for binomial proportion
Two-Sample Models	
TWOSAMPLEMEAN	specifies two-sample Z test for mean difference
TWOSAMPLEFREQ	specifies two-sample test for binomial proportions
TWOSAMPLESURVIVAL	specifies log-rank test for two survival distributions
Regression Models	
REG	specifies test for a regression parameter
LOGISTIC	specifies test for a logistic regression parameter
PHREG	specifies test for a proportional hazards regression parameter

The MODEL=INPUTNOBS and MODEL=INPUTNEVENTS options are described next, and the remaining options are described in the next three sections.

Input Sample Size for Fixed-Sample Design

The MODEL=INPUTNOBS option derives the sample size required for a group sequential trial from the sample size n_0 for the corresponding fixed-sample design. With the N= n_0 option specifying the sample size n_0 for a fixed-sample design, the sample size required for a group sequential trial is then computed as

$$N_X = \frac{I_X}{I_0}\, n_0$$

where I_X is the maximum information for the group sequential design and I_0 is the information for the corresponding fixed-sample design. The information ratio between I_X and I_0 is derived in the SEQDESIGN procedure.

The SAMPLE=ONE option specifies a one-sample test, and the SAMPLE=TWO option specifies a two-sample test. For a two-sample test, the WEIGHT= option specifies the sample size allocation weights for the two groups.

Input Number of Events for Fixed-Sample Design

The MODEL=INPUTNOBS option derives the number of events required for a group sequential trial from the number of events d_0 for the corresponding fixed-sample design. With the D= d_0 option specifies the

number of events d_0 for a fixed-sample survival analysis, the number of events required for a group sequential trial is then computed as

$$d_X = \frac{I_X}{I_0}\ d_0$$

where I_X is the maximum information for the group sequential design and I_0 is the information for the corresponding fixed-sample design. The information ratio between I_X and I_0 is derived in the SEQDESIGN procedure.

The SAMPLE=ONE option specifies a one-sample test, and the SAMPLE=TWO option specifies a two-sample test. For a two-sample test, the WEIGHT= option specifies the sample size allocation weights for the two groups.

With the computed number of events d_X for a group sequential survival design, the required total sample size and sample size at each stage can be derived with specifications of hazard rates, accrual rate, and accrual time.

For a study group, if the hazard rate h is constant, corresponding to an exponential survival distribution, and the individual accrual is uniform in the accrual time T_a with a constant accrual rate r_a, Kim and Tsiatis (1990, pp. 83–84) show that the expected number of events by time t is given by

$$D_h(t) = \begin{cases} r_a\left(t - \frac{1-e^{-ht}}{h}\right) & \text{if } t \le T_a \\ r_a\left(T_a - \frac{e^{-ht}}{h}(e^{hT_a} - 1)\right) & \text{if } t > T_a \end{cases}$$

For a one-sample design, such as a proportional hazards regression, the expected number of events by time t is $E(t) = D_h(t)$, where h is the hazard rate for the group. For a two-sample design, such as a log-rank test for two survival distributions, the expected number of events by time t is

$$E(t) = \frac{R}{R+1} D_{h_a}(t) + \frac{1}{R+1} D_{h_b}(t)$$

where h_a and h_b are hazard rates in groups A and B, respectively, and R is the ratio of the sample size allocation weights w_a/w_b.

If the accrual rate r_a is specified without the accrual time T_a, follow-up time T_f, and total study time $T = T_a + T_f$, the SEQDESIGN procedure computes the minimum and maximum accrual times from the following equation, as described in Kim and Tsiatis (1990, p. 85):

$$\frac{d_X}{r_a} \le T_a \le E^{-1}(d_X)$$

If the accrual rate r_a is specified with one of the three time parameters—the accrual time, follow-up time, and total study time—then the other two time parameters are computed in the SEQDESIGN procedure. Similarly, if the accrual rate r_a is not specified, but two of the three time parameters are specified, then the accrual rate is derived in the SEQDESIGN procedure.

With the accrual rate r_a and the accrual time T_a, the total sample size is

$$N_X = r_a\ T_a$$

At each stage k, the number of events is given by

$$d_k = \frac{I_k}{I_X}\ d_X$$

The corresponding time T_k can be derived from the equation for the expected number of events, $E(t) = d_k$, and the resulting sample size is computed as

$$N_k = r_a\ T_k$$

The following three sections describe examples of test statistics with their resulting information levels, which can then be used to derive the required sample size. The maximum likelihood estimators are used for all tests except to compare two survival distributions with a log-rank test, where a score statistic is used.

Applicable One-Sample Tests and Sample Size Computation

The SEQDESIGN procedure provides sample size computation for two one-sample tests: normal mean and binomial proportion. The required sample size depends on the variance of the response variable—that is, the sample proportion for a binomial proportion test.

In a typical clinical trial, a hypothesis is designed to reject, not accept, the null hypothesis to show the evidence for the alternative hypothesis. Thus, in most cases, the proportion under the alternative hypothesis is used to derive the required sample size. For a test of the binomial proportion, the REF=NULLPROP and REF=PROP options use proportions under the null and alternative hypotheses, respectively.

Test for a Normal Mean

The MODEL=ONESAMPLEMEAN option in the SAMPLESIZE statement derives the sample size required to test a normal mean by using the sample mean statistic for the null hypothesis $\mu = \mu_0$. At stage k, the sample mean is computed as

$$\overline{y}_k = \frac{1}{N_k}\sum_{j=1}^{N_k} y_{kj}$$

where y_{kj} is the value of the jth observation available in the kth stage and N_k is the cumulative sample size at stage k.

An equivalent hypothesis is $H_0 : \theta = 0$, where $\theta = \mu - \mu_0$.

The MLE statistic for θ,

$$\hat{\theta}_k = \overline{y}_k - \mu_0 \sim N\left(\theta,\ {I_k}^{-1}\right)$$

where the information

$$I_k = \frac{1}{\mathrm{Var}(\hat{\theta})} = \frac{1}{\mathrm{Var}(\overline{y}_k)} = \frac{N_k}{\sigma^2}$$

is the inverse of the variance.

That is, the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} = (\overline{y}_k - \mu_0)\sqrt{I_k} \sim N\left(\theta\sqrt{I_k}, 1\right)$$

Thus, to test the hypothesis $H_0 : \theta = 0$ against a two-sided alternative $H_1 : \theta = \theta_1$, H_0 is rejected at stage k if the statistic Z_k is less than or equal to the lower α boundary value or if Z_k is greater than or equal to the upper α boundary value at stage k.

If the variance σ^2 is unknown, the sample variance can be used if it is assumed that the sample variance is computed from a large sample such that the test statistic has an approximately normal distribution.

The maximum information is needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the MEAN=θ_1 option in the SAMPLESIZE statement is used to specify the alternative reference and thus to derive the maximum information.

In the SEQDESIGN procedure, the computed total sample size

$$N_K = \sigma^2 \; I_X$$

where I_X is the maximum information and σ is the specified standard deviation. With an available maximum information, you can specify the MODEL=ONESAMPLEMEAN(STDDEV= σ) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC MEANS can be used to derive a one-sample Z test for a normal mean.

Test for a Binomial Proportion

The MODEL=ONESAMPLEFREQ option in the SAMPLESIZE statement derives the sample size required to test a binomial proportion by using the null hypothesis $p = p_0$, where p is the proportion of a binomial population. At stage k, the MLE for p is computed as

$$\hat{p}_k = \frac{1}{N_k} \sum_{j=1}^{N_k} y_{kj}$$

where y_{kj} is the value of the jth observation available in the kth stage and N_k is the cumulative sample size at stage k.

An equivalent hypothesis is $H_0 : \theta = 0$, where $\theta = p - p_0$. If p_0 is not close to 0 or 1, then for a large sample, $\hat{\theta}_k = \hat{p}_k - p_0$ has an approximately normal distribution

$$\hat{\theta}_k \sim N\left(\theta, \; I_k^{-1}\right)$$

where the information $I_k = (p\,(1-p)\,/\,N_k)^{-1}$ is the inverse of the variance $\mathrm{Var}(\hat{\theta})$.

Then the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} \sim N\left(\theta\sqrt{I_k}, 1\right)$$

In practice, the estimated sample proportion $\hat{p}$ at stage k can be used to derive the information I_k and test statistic Z_k. Thus, to test the hypothesis H_0 against an upper alternative $H_1 : \theta = \theta_1 > 0$, H_0 is rejected at stage k if the statistic Z_k is greater than or equal to the upper α boundary at stage k.

The maximum information I_X is needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the PROP= option in the SAMPLESIZE statement is used to specify the alternative reference and to derive the maximum information for the sample size calculation.

It is assumed that the sample size is sufficiently large such that the test statistic has an approximately normal distribution. With the hypotheses $H_0 : p = p_0$ and $H_1 : p = p_1$, the SEQDESIGN procedure derives the total sample size

$$N_X = p^* (1 - p^*) I_X$$

where $p^* = p_0$ if REF=NULLPROP is specified. Otherwise, $p^* = p_1$.

If the PROP= option in the SAMPLESIZE statement is not specified, then the alternative reference θ_1 derived in the SEQDESIGN procedure is used to compute $p_1 = p_0 + \theta_1$.

The ALTREF= option in the PROC statement can be used to specify θ_1. Otherwise, the PROP= option in the SAMPLESIZE statement must be specified.

For example, with $H_0 : p = 0.5$, $H_1 : p = 0.6$, and REF=PROP (which is the default),

$$N_K = p^*(1 - p^*) I_X = (0.6 \times 0.4) I_X = 0.24 I_X$$

You can specify the MODEL=ONESAMPLEFREQ option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC GENMOD with the default DIST=NORMAL option in the MODEL statement can be used to derive the Z test for a binomial proportion.

Applicable Two-Sample Tests and Sample Size Computation

The SEQDESIGN procedure provides sample size computation for two-sample tests: the test for the difference between two normal means, tests for binomial proportions, and the log-rank test for two survival distributions. These tests for binomial proportions include the test for the difference between two binomial proportions, the log odds ratio test for binomial proportions, and the log relative risk test for binomial proportions,

For a test of difference between two sample means, the required sample size depends on the assumed sample variances. Similarly, for a test of two-sample proportions, the required sample size depends on the assumed sample proportions. For a log-rank test of two survival distributions, the required sample size depends on the assumed sample hazard rates, accrual rate, and accrual time.

If the REF=NULLPROP or REF=NULLHAZARD option is specified, the proportions or hazard rates under the null hypothesis are used to derive the required sample size or number of events. Otherwise, the REF=PROP option (which is the default in the MODEL=TWOSAMPLEFREQ option) or the

REF=HAZARD option (which is the default in the MODEL=TWOSAMPLESURVIVAL option) uses proportions or hazard rates under the alternative hypothesis to derive the required sample size or number of events.

Test for the Difference between Two Normal Means

The MODEL=TWOSAMPLEMEAN option in the SAMPLESIZE statement derives the sample size required to test the difference between the means of two normal populations μ_a and μ_b by using the null hypothesis $H_0 : \theta = 0$, where $\theta = \mu_a - \mu_b$.

At stage k, the MLE for θ is computed as

$$\hat{\theta}_k = \overline{y}_{ak} - \overline{y}_{bk} = \frac{1}{N_{ak}} \sum_{j=1}^{N_{ak}} y_{akj} - \frac{1}{N_{bk}} \sum_{j=1}^{N_{bk}} y_{bkj}$$

where y_{akj} and y_{bkj} are the values of the jth observation available in the kth stage groups A and B, respectively, and N_{ak} and N_{bk} are the cumulative sample sizes at stage k for these two groups.

The statistic $\hat{\theta}_k$ has a normal distribution

$$\hat{\theta}_k \sim N\left(\theta,\ {I_k}^{-1}\right)$$

where the information I_k is the inverse of the variance $\mathrm{Var}(\hat{\theta}_k) = \sigma_a^2/N_{ak} + \sigma_b^2/N_{bk}$.

Then the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} \sim N\left(\theta\sqrt{I_k},\ 1\right)$$

Thus, to test the hypothesis $H_0 : \theta = 0$ against an upper alternative $H_1 : \theta = \theta_1, \theta_1 > 0$, H_0 is rejected at stage k if the statistic $Z_k \geq a_k$, the upper α boundary for the standardized Z statistic at stage k.

If the variances σ_a^2 and σ_b^2 are unknown, the sample variances can be used to derive the information I_k if it is assumed that each sample variance is computed from a large sample such that the test statistic has an approximately normal distribution.

The maximum information is needed to derive the required sample size. If the maximum information is not specified or derived in the procedure, the alternative reference θ_1^* specified in the MEANDIFF option is used to derive the maximum information.

Note that in order to derive the sample sizes N_{ak} and N_{bk} uniquely from the information, $N_{ak} = R\, N_{bk}$ is assumed for $k = 1, 2, \ldots, K$, where $R = w_a/w_b$ is the constant allocation ratio computed from the WEIGHT=w_a w_b option in the SAMPLESIZE statement.

In PROC SEQDESIGN, the computed total sample sizes for the two groups are

$$N_{aK} = (\sigma_a^2 + R\,\sigma_b^2)\,I_X = R\,(\frac{\sigma_a^2}{R} + \sigma_b^2)\,I_X$$

$$N_{bK} = (\frac{\sigma_a^2}{R} + \sigma_b^2)\,I_X$$

where I_X is the maximum information derived in the SEQDESIGN procedure, R is the constant allocation ratio, and σ_a and σ_b are the specified standard deviations.

For $R = 1$, the two sample sizes are equal, then

$$N_{aK} = N_{bK} = \frac{N_K}{2} = (\sigma_a^2 + \sigma_b^2)\,I_X$$

If the variances from the two groups are equal, $\sigma_a^2 = \sigma_b^2 = \sigma^2$, then the total sample sizes for the two groups are

$$N_{aK} = (1 + R)\,\sigma^2\,I_X$$

$$N_{bK} = (1 + \frac{1}{R})\,\sigma^2\,I_X$$

and the total sample size is

$$N_X = N_{aK} + N_{bK} = \frac{(R+1)^2}{R}\,\sigma^2\,I_X$$

Furthermore, for $R = 1$, the two sample sizes are equal, then

$$N_{aK} = N_{bK} = \frac{N_X}{2} = 2\,\sigma^2\,I_X$$

With an available maximum information, you can specify the MODEL=TWOSAMPLEMEAN(WEIGHT= R STDDEV= σ_a σ_b) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC GLM can be used to derive the two-sample Z test for the mean difference.

Test for the Difference between Two Binomial Proportions

The MODEL=TWOSAMPLEFREQ(TEST=PROP) option in the SAMPLESIZE statement derives the sample size required to test the difference between two binomial populations with $H_0 : \theta = 0$, where $\theta = p_a - p_b$. At stage k, the MLE for θ is

$$\hat{\theta}_k = \hat{p}_{ak} - \hat{p}_{bk} = \frac{1}{N_{ak}} \sum_{j=1}^{N_{ak}} y_{akj} - \frac{1}{N_{bk}} \sum_{j=1}^{N_{bk}} y_{bkj}$$

where y_{akj} and y_{bkj} are the values of the jth observation available in the kth stage for groups A and B, respectively, and N_{ak} and N_{bk} are the cumulative sample sizes at stage k for these two groups.

For sufficiently large sample sizes N_{ak} and N_{bk}, the statistic $\hat{\theta}_k$ has an approximate normal distribution

$$\hat{\theta}_k \sim N\left(\theta,\ {I_k}^{-1}\right)$$

where the information is the inverse of the variance

$$\mathrm{Var}(\hat{\theta}_k) = \frac{p_a\,(1-p_a)}{N_{ak}} + \frac{p_b\,(1-p_b)}{N_{bk}}$$

Thus, the standardized statistic

$$Z_k = \hat{\theta}_k\sqrt{I_k} \sim N\left(\theta\sqrt{I_k},\ 1\right)$$

In practice, $p_a = \hat{p}_a$ and $p_b = \hat{p}_b$, the estimated sample proportions for groups A and B, respectively, at stage k, can be used to derive the information I_k and the test statistic Z_k. Thus, to test the hypothesis H_0 against an upper alternative $H_1 : \theta > 0$, H_0 is rejected at stage k if the statistic $Z_k \geq a_k$, the upper α boundary for the standardized Z statistic at stage k.

The maximum information I_X is needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the PROP= option in the SAMPLESIZE statement is used to provide proportions under the alternative hypothesis for the alternative reference and then to derive the maximum information.

The proportions in the two groups are needed to derive the sample size. Also, in order to derive the sample sizes N_{ak} and N_{bk} uniquely from the information, $N_{ak} = R\,N_{bk}$ is assumed for $k = 1, 2, \ldots, K$, where $R = w_a/w_b$ is the constant allocation ratio computed from the WEIGHT=w_a w_b option in the SAMPLESIZE statement. Then

$$I_X = \left(\frac{p_a\,(1-p_a)}{N_{aK}} + \frac{p_b\,(1-p_b)}{N_{bK}}\right)^{-1} = \frac{N_{aK}}{p_a(1-p_a) + R\,p_b(1-p_b)}$$

In PROC SEQDESIGN, the total sample sizes in the two groups are computed as

$$N_{aK} = \left(p_a^*\,(1-p_a^*) + R\,p_b^*\,(1-p_b^*)\right)\,I_X$$

$$N_{bK} = \frac{1}{R}\,N_{aK}$$

where $R = w_a/w_b$ is the constant allocation ratio, and p_a^* and p_b^* are proportions specified with the REF= option:

- REF=NULLPROP uses proportions under H_0: $p_a^* = p_{0a}$, $p_b^* = p_{0b}$
- REF=AVGNULLPROP uses the average proportion under H_0: $p_a^* = p_b^* = (Rp_{0a} + p_{0b})/(R+1)$
- REF=PROP uses proportions under H_1: $p_a^* = p_{1a}$, $p_b^* = p_{1b}$
- REF=AVGPROP uses the average proportion under H_1 : $p_a^* = p_b^* = (Rp_{1a} + p_{1b})/(R+1)$

The total sample size is given by

$$N_X = N_{aK} + N_{bK} = (R+1)\left(\frac{1}{R}\,p_a^*(1-p_a^*) + p_b^*(1-p_b^*)\right) I_X$$

For $R = 1$, the two sample sizes are equal,

$$N_{aK} = N_{bK} = \frac{N_X}{2} = \left(\,p_a^*(1-p_a^*) + p_b^*(1-p_b^*)\right) I_X$$

You can specify the MODEL=TWOSAMPLEFREQ(TEST=PROP WEIGHT=R) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC GENMOD with the default DIST=NORMAL option in the MODEL statement can be used to derive the two-sample Z test for proportion difference.

Test for Two Binomial Proportions with a Log Odds Ratio Statistic

The MODEL=TWOSAMPLEFREQ(TEST=LOGOR) option in the SAMPLESIZE statement derives the sample size required to test two binomial proportions by using a log odds ratio statistic. The odds ratio is the ratio of the odds in one group to the odds in the other group, and the log odds ratio is the logarithm of the odds ratio

$$\theta = \log\left(\frac{p_a/(1-p_a)}{p_b/(1-p_b)}\right) = \log\left(\frac{p_a(1-p_b)}{p_b(1-p_a)}\right)$$

The hypothesis of no difference between two proportions, $p_a = p_b$, can be tested through the null hypothesis $H_0 : \theta = 0$, where θ is the log odds ratio. For example, with $H_0 : p_a = p_b = 0.6$ and $H_1 : p_a = 0.8$, $p_b = 0.6$, it corresponds to the equivalent hypothesis $H_0 : \theta = 0$ and $H_1 : \theta = \log\left(\frac{0.8(1-0.6)}{0.6(1-0.8)}\right) = \log(8/3) = 0.98083$.

The maximum likelihood estimate of θ is given by

$$\hat{\theta} = \log\left(\frac{\hat{p}_a(1-\hat{p}_b)}{\hat{p}_b(1-\hat{p}_a)}\right)$$

with an asymptotic variance

$$\mathrm{Var}(\hat{\theta}) = I^{-1} = \frac{1}{N_a\,p_a(1-p_a)} + \frac{1}{N_b\,p_b(1-p_b)}$$

where I is the information (Diggle et al. 2002, pp. 341–342). That is, the standardized statistic

$$Z_k = \hat{\theta}_k\sqrt{I_k} \sim N\left(\theta\sqrt{I_k},\, 1\right)$$

In practice, $p_a = \hat{p}_a$ and $p_b = \hat{p}_b$, the estimated sample proportions for groups A and B, respectively, at stage k, can be used to derive the information I_k and the test statistic $Z_k = \hat{\theta}_k\sqrt{I_k}$ if the two sample sizes N_a and N_b are sufficiently large such that the test statistic has an approximately normal distribution.

The maximum information I_X is needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the PROP= option in the SAMPLESIZE statement is used to provide proportions under the alternative hypothesis for the alternative reference and then to derive the maximum information.

In order to derive the sample sizes N_{ak} and N_{bk} uniquely from the information, $N_{ak} = R\, N_{bk}$ is assumed for $k = 1, 2, \ldots, K$, where $R = w_a/w_b$ is the constant allocation ratio computed from the WEIGHT=w_a w_b option in the SAMPLESIZE statement. Then with

$$I_X = N_{bK}\left(\frac{1}{R\, p_a(1-p_a)} + \frac{1}{p_b(1-p_b)}\right)^{-1}$$

the sample size can be computed.

In PROC SEQDESIGN, the total sample sizes in the two groups are computed as

$$N_{bK} = I_X\left(\frac{1}{R\, p_a^*(1-p_a^*)} + \frac{1}{p_b^*(1-p_b^*)}\right)$$

$$N_{aK} = R\, N_{bK}$$

where $R = w_a/w_b$ is the constant allocation ratio, and p_a^* and p_b^* are proportions specified with the REF= option:

- REF=NULLPROP uses proportions under H_0: $p_a^* = p_{0a}$, $p_b^* = p_{0b}$
- REF=AVGNULLPROP uses the average proportion under H_0: $p_a^* = p_b^* = (Rp_{0a} + p_{0b})/(R+1)$
- REF=PROP uses proportions under H_1: $p_a^* = p_{1a}$, $p_b^* = p_{1b}$
- REF=AVGPROP uses the average proportion under H_1 : $p_a^* = p_b^* = (Rp_{1a} + p_{1b})/(R+1)$

You can specify the MODEL=TWOSAMPLEFREQ(TEST=LOGOR WEIGHT=R) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC LOGISTIC can be used to derive the log odds ratio statistic.

Test for Two Binomial Proportions with a Log Relative Risk Statistic

The MODEL=TWOSAMPLEFREQ(TEST=LOGRR) option in the SAMPLESIZE statement derives the sample size required to test two binomial proportions by using a log relative risk statistic. The relative risk is the ratio of the proportion in one group to the proportion in the other group. The log relative risk statistic is the logarithm of the relative risk

$$\theta = \log\left(\frac{p_a}{p_b}\right)$$

The hypothesis of no difference between two proportions, $p_a = p_b$, can be tested through the null hypothesis $H_0 : \theta = 0$. For example, with $H_0 : p_a = p_b = 0.6$ and $H_1 : p_a = 0.8,\ p_b = 0.6$, it corresponds to the equivalent hypothesis $H_0 : \theta = 0$ and $H_1 : \theta = \log\left(\frac{0.8}{0.6}\right) = \log(4/3) = 0.28768$.

The maximum likelihood estimate of θ is given by

$$\hat{\theta} = \log\left(\frac{\hat{p}_a}{\hat{p}_b}\right)$$

with an asymptotic variance

$$I^{-1} = \frac{1 - p_a}{N_a\, p_a} + \frac{1 - p_b}{N_b\, p_b}$$

where I is the information (Chow and Liu 1998, p. 329).

In practice, $p_a = \hat{p}_a$ and $p_b = \hat{p}_b$, the estimated sample proportions for groups A and B, respectively, at stage k, are used to derive the information I_k and the test statistic $Z_k = \hat{\theta}_k \sqrt{I_k}$.

The maximum information I_X and proportions p_a and p_b are needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the PROP= option in the SAMPLESIZE statement is used to provide proportions under the alternative hypothesis for the alternative reference and then to derive the maximum information.

Note that in order to derive the sample sizes N_{ak} and N_{bk} uniquely from the information, $N_{ak} = R\, N_{bk}$ is assumed for $k = 1, 2, \ldots, K$, where $R = w_a/w_b$ is the constant allocation ratio computed from the WEIGHT=w_a w_b option in the SAMPLESIZE statement. Then the sample size can be computed from

$$I_X = N_{bK}\left(\frac{1 - p_a}{R\, p_a} + \frac{1 - p_b}{p_b}\right)^{-1}$$

In PROC SEQDESIGN, the computed sample sizes in the two groups are

$$N_{bK} = I_X\left(\frac{1 - p_a^*}{R\, p_a^*} + \frac{1 - p_b^*}{p_b^*}\right)$$

$$N_{aK} = R\, N_{bK}$$

where $R = w_a/w_b$ is the constant allocation ratio, and p_a^* and p_b^* are proportions specified with the REF= option:

- REF=NULLPROP uses proportions under H_0: $p_a^* = p_{0a}$, $p_b^* = p_{0b}$
- REF=AVGNULLPROP uses the average proportion under H_0: $p_a^* = p_b^* = (Rp_{0a} + p_{0b})/(R + 1)$
- REF=PROP uses proportions under H_1: $p_a^* = p_{1a}$, $p_b^* = p_{1b}$
- REF=AVGPROP uses the average proportion under H_1 : $p_a^* = p_b^* = (Rp_{1a} + p_{1b})/(R + 1)$

You can specify the MODEL=TWOSAMPLEFREQ(TEST=LOGRR WEIGHT=R) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC LOGISTIC can be used to derive the log relative risk statistic.

Test for Two Survival Distributions with a Log-Rank Test

The MODEL=TWOSAMPLESURV option in the SAMPLESIZE statement derives the number of events required for a log-rank test of two survival distributions. The analysis of survival data involves the survival times for both censored and uncensored data. A noncensored survival time is the time from treatment to an event such as remission or relapse for an individual. A censored survival time is the time from treatment to the time of analysis for an individual surviving at that time, and the status is unknown beyond that time.

Let T be the random variable of the survival time. Then the survival function

$$S(t) = \Pr(T > t)$$

is the probability that an individual from the population has a survival time that exceeds t. And the hazard function is given by

$$h(t) = \frac{f(t)}{S(t)}$$

where $f(t)$ is the density function of T.

The hazard functions can be used to test the equality of two survival distributions $S_a(t) = S_b(t)$ with the null hypothesis $H_0 : h_a(t) = h_b(t), t > 0$, where $S_a(t)$ and $S_b(t)$ are survival functions for groups A and B, respectively, and $h_a(t)$ and $h_b(t)$ are the corresponding hazard functions.

If the two hazards are proportional, $h_a(t) = \lambda\, h_b(t)$, where λ is a constant, then an equivalent null hypothesis is

$$H_0 : \lambda = \frac{h_a(t)}{h_b(t)} = 1$$

Alternatively, another equivalent null hypothesis is given by

$$H_0 : \theta = -\log(\lambda) = 0$$

Suppose that the hazard rate h is a constant. Then with a specified median survival time T_m, the hazard rate can be derived from the equation

$$e^{-h\,T_m} = \frac{1}{2}$$

Denote the distinct event times at stage k as $\tau_{kj}, j = 1, 2, \ldots, t_k$, where t_k is the total number of distinct event times. Then the score statistic is the log-rank statistic (Jennison and Turnbull 2000, pp. 259–261; Whitehead 1997, pp. 36–39)

$$S_k = \sum_{j=1}^{t_k} (d_{akj} - e_{akj})$$

where d_{akj} is the number of events from group A and e_{akj} is the number of expected events from A. The number of expected events from A is computed as

$$e_{akj} = d_{kj} \frac{r_{akj}}{r_{kj}}$$

where d_{kj} is the number of events from both groups, r_{akj} is the number of individuals from the treatment group who survived up to time τ_{kj}, and r_{kj} is the number of individuals from both groups who survived up to time τ_{kj}.

If the number of events d_{kj} is small relative to r_{kj}, the number of individuals survived up to time τ_{kj}, then with a sufficiently large sample size, S_k has an approximately normal distribution

$$S_k \sim N(\theta\, I_k,\ I_k)$$

where the variance of S_k is the estimated information

$$I_k = \sum_{j=1}^{t_k} \frac{r_{akj}\, r_{bkj}\, d_{kj}}{r_{kj}^2}$$

In order to derive the number of events from the information I_k, $N_{ak} = R\, N_{bk}$ is assumed for $k = 1, 2, \ldots, K$, where $R = w_a/w_b$ is the constant allocation ratio computed from the WEIGHT=w_a w_b option in the SAMPLESIZE statement.

The maximum information I_X is needed to derive the required sample size. If the maximum information is specified or derived with the ALTREF= option in the procedure, the HAZARD=, MEDSURVTIME=, and HAZARDRATIO= options are not applicable. Otherwise, the HAZARD=, MEDSURVTIME=, or HAZARDRATIO= option is used to compute the alternative reference and then to derive the maximum information for the sample size calculation.

With $N_{aK} = R\, N_{bK}$, if the number of events is few relative to the number of individuals who survived, then $r_{aKj} \approx R\, r_{bKj}$, and

$$I_X \approx \sum_{j=1}^{t_K} \frac{R}{(R+1)^2} d_{Kj} = \frac{R}{(R+1)^2}\, D_X$$

where D_X is the total number of events.

Thus, the required total number of events

$$D_X = \frac{(R+1)^2}{R}\, I_X$$

For a study group, if the hazard rate is constant, corresponding to an exponential survival distribution, and the individual accrual is uniform in the accrual time T_a with a constant accrual rate r_a, then the required total sample size and sample size at each stage can be derived. See the section "Input Number of Events for Fixed-Sample Design" on page 6768 for a detailed description of the sample size computation that uses hazard rates, accrual rate, and accrual time.

You can specify the MODEL=TWOSAMPLESURVIVAL option in the SAMPLESIZE statement to compute the required total number of events and individual number of events at each stage. With the specifications of hazard rates, accrual rate, and accrual time, the required total sample size and individual sample size at each stage can also be derived. If the REF=NULLHAZARD option is specified, the hazard rates under the null hypothesis, h_{0a} and h_{0b}, are used in the sample size computation. Otherwise, the hazard rates under the alternative hypothesis, h_{1a} and h_{1b}, are used. A procedure such as PROC LIFETEST can be used to derive the log-rank statistic.

Applicable Regression Parameter Tests and Sample Size Computation

The SEQDESIGN procedure provides sample size computation for tests of a regression parameter in three regression models: normal regression, logistic regression, and proportional hazards regression.

To test a parameter β_1 in a regression model, the variance of the parameter estimate $\hat{\beta}_1$ is needed for the sample size computation. In a simple regression model with one covariate X1, the variance of $\hat{\beta}_1$ is inversely related to the variance of X1, σ_x^2. That is,

$$\text{Var}(\hat{\beta}_1) \propto \frac{1}{N\,\sigma_x^2}$$

for the normal regression and logistic regression models, where N is the sample size, and

$$\text{Var}(\hat{\beta}_1) \propto \frac{1}{D\,\sigma_x^2}$$

for the proportional hazards regression model, where D is the number of events.

For a regression model with more than one covariate, the variance of $\hat{\beta}_1$ for the normal regression and logistic regression models is inversely related to the variance of X1 after adjusting for other covariates. That is,

$$\text{Var}(\hat{\beta}_1) \propto \frac{1}{N\,(1-r_x^2)\,\sigma_x^2}$$

where $\hat{\beta}_1$ is the estimate of the parameter β_1 in the model and r_x^2 is the R square from the regression of X1 on other covariates—that is, the proportion of the variance σ_x^2 explained by these covariates.

Similarly, for a proportional hazards regression model,

$$\text{Var}(\hat{\beta}_1) \propto \frac{1}{D\,(1-r_x^2)\,\sigma_x^2}$$

Thus, with the derived maximum information, the required sample size or number of events can also be computed for the testing of a parameter in a regression model with covariates.

Test for a Parameter in the Regression Model

The MODEL=REG option in the SAMPLESIZE statement derives the sample size required for a Z test of a normal regression. For a normal linear regression model, the response variable is normally distributed with the mean equal to a linear function of the explanatory variables and the constant variance σ^2.

The normal linear model is

$$\mathbf{y} \sim N\left(\mathbf{X}\boldsymbol{\beta},\, \sigma_y^2\,\mathbf{I}_{(N)}\right)$$

where $\mathbf{Y}_{(N\times 1)}$ is the vector of the N observed responses, $\mathbf{X}_{(N\times p)}$ is the design matrix for these N observations, $\boldsymbol{\beta}_{(p\times 1)}$ is the parameter vector, and $\mathbf{I}_{(N)}$ is the $(N \times N)$ identity matrix.

The least squares estimate is

$$\hat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{Y}$$

and is normally distributed with mean $\boldsymbol{\beta}$ and variance

$$\text{Var}(\hat{\boldsymbol{\beta}}) = \sigma_y^2(\mathbf{X}'\mathbf{X})^{-1}$$

For a model with only one covariate X1,

$$\hat{\beta}_1 \sim N\left(\beta_1,\ \text{Var}(\hat{\beta}_1)\right)$$

where the variance

$$\text{Var}(\hat{\beta}_1) = I_{\beta_1}^{-1} = \sigma_y^2\ \frac{1}{N\,\sigma_x^2}$$

Thus, with the derived maximum information $I_X = I_{\beta_1}$, the required sample size is given by

$$N = I_X\ \frac{\sigma_y^2}{\sigma_x^2}$$

For a normal linear model with more than one covariate, the variance of a single parameter β_1 is

$$\text{Var}(\hat{\beta}_1) = \sigma_y^2\ (\mathbf{X}'\mathbf{X})^{-1}_{(11)} = \sigma_y^2\ \frac{1}{N\,\sigma_x^2\,(1-r_x^2)}$$

where $(\mathbf{X}'\mathbf{X})^{-1}_{(11)}$ is the diagonal element of the $(\mathbf{X}'\mathbf{X})^{-1}$ matrix corresponding to the parameter β_1, σ_x^2 is the variance of the variable X1, and r_x^2 is the proportion of variance of X1 explained by other covariates. The value $\sigma_x^2\,(1-r_x^2)$ represents the variance of X1 after adjusting for all other covariates.

Thus, with the derived maximum information I_X, the required sample size is

$$N = I_X\ \frac{\sigma_y^2}{(1-r_x^2)\,\sigma_x^2}$$

In the SEQDESIGN procedure, you can specify the MODEL=REG(VARIANCE=σ_y^2 XVARIANCE=σ_x^2 XRSQUARE=r_x^2) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A SAS procedure such as PROC REG can be used to compute the parameter estimate and its standard error at each stage.

Test for a Parameter in the Logistic Regression Model

The MODEL=LOGISTIC option in the SAMPLESIZE statement derives the sample size required for a Z test of a logistic regression parameter. The linear logistic model has the form

$$\text{logit}(p) = \log\left(\frac{p}{1-p}\right) = \mathbf{x}\boldsymbol{\beta}$$

where p is the response probability to be modeled and $\boldsymbol{\beta}$ is a vector of parameters.

Following the derivation in the section "Test for a Parameter in the Regression Model" on page 6781, the required sample size for testing a parameter in $\boldsymbol{\beta}$ is given by

$$N = I_X \frac{\sigma_y^2}{(1 - r_x^2)\,\sigma_x^2}$$

With the variance of the logit response, $\sigma_y^2 = 1/(p(1-p))$,

$$N = I_X \frac{1}{p(1-p)} \frac{1}{(1 - r_x^2)\,\sigma_x^2}$$

where σ_x^2 is the variance of X and r_x^2 is the proportion of variance explained by other covariates.

In the SEQDESIGN procedure, you can specify the MODEL=LOGISTIC(PROP=p XVARIANCE=σ_x^2 XRSQUARE=r_x^2) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage.

A SAS procedure such as PROC LOGISTIC can be used to compute the parameter estimate and its standard error at each stage.

Test for a Parameter in the Proportional Hazards Regression Model

The MODEL=PHREG option in the SAMPLESIZE statement derives the number of events required for a Z test of a proportional hazards regression parameter. For analyses of survival data, Cox's semiparametric model is often used to examine the effect of explanatory variables on hazard rates. The survival time of each observation in the population is assumed to follow its own hazard function, $h_i(t)$, expressed as

$$h_i(t) = h(t; \mathbf{X}_i) = h_0(t) \exp(\mathbf{X}_i' \boldsymbol{\beta})$$

where $h_0(t)$ is an arbitrary and unspecified baseline hazard function, $\mathbf{x}_i$ is the vector of explanatory variables for the ith individual, and $\boldsymbol{\beta}$ is the vector of regression parameters associated with the explanatory variables.

Hsieh and Lavori (2000, p. 553) show that the required number of events for testing a parameter in $\boldsymbol{\beta}$, β_1, associated with the variable X1 is given by

$$D_X = I_X \frac{1}{(1 - r_x^2)\;\sigma_x^2}$$

where σ_x^2 is the variance of X1 and r_x^2 is the proportion of variance of X1 explained by other covariates.

In the SEQDESIGN procedure, you can specify the MODEL=PHREG(XVARIANCE=σ_x^2 XRSQUARE=r_x^2) option in the SAMPLESIZE statement to compute the required number of events and individual number of events at each stage.

A SAS procedure such as PROC PHREG can be used to compute the parameter estimate and its standard error at each stage.

Note that for a two-sample test, X1 is an indicator variable and is the only covariate in the model. Thus, if the two sample sizes are equal, then the variance $\sigma_x^2 = 1/4$ and the required number of events for testing the parameter β_1 is given by

$$D_X = I_X \frac{1}{\sigma_x^2} = 4\, I_X$$

See the section "Input Number of Events for Fixed-Sample Design" on page 6768 for a detailed description of the sample size computation that uses hazard rates, accrual rate, and accrual time.

Aspects of Group Sequential Designs

This section summarizes various aspects of group sequential designs that are encountered in applications of the SEQDESIGN procedure. Features are illustrated through two-sided designs with $\alpha = 0.05$ and $\beta = 0.10$. The null hypothesis $H_0 : \theta = 0$ and an alternative reference $\theta_1 = \pm 0.25$ are used for the designs with early stopping only to reject the null hypothesis.

Canonical Joint Distribution

The SEQDESIGN procedure assumes that with a total number of stages K, the sequence of the standardized test statistics $\{Z_1, Z_2, \ldots, Z_K\}$ has the canonical joint distribution with information levels $\{I_1, I_2, \ldots, I_K\}$ for the parameter θ (Jennison and Turnbull 2000, p. 49):

- $(Z_1, Z_2, \ldots, Z_K)$ is multivariate normal
- $Z_k \sim N\left(\theta\sqrt{I_k}, 1\right),\ k = 1, 2, \ldots, K$
- $\mathrm{Cov}(Z_{k_1}, Z_{k_2}) = \sqrt{(I_{k_1}/I_{k_2})},\quad 1 \le k_1 \le k_2 \le K$

Normality Assumption

The SEQDESIGN procedure derives the boundary values by assuming that the sequence of the standardized test statistics $\{Z_1, Z_2, \ldots, Z_K\}$ has the canonical joint distribution with information levels $\{I_1, I_2, \ldots, I_K\}$ for the parameter θ. If the test statistic Z_k does not have a normal distribution, it is assumed that the test statistic is computed from a large sample, so that the resulting statistic has an approximately normal distribution.

Number of Stages

For group sequential trials with fixed significance level α, power $1 - \beta$, and alternative reference, if the number of stages is increased, the required maximum information is also increased, but the average sample number under the alternative hypothesis is likely to decrease.

For example, for two-sided designs with early stopping only to reject the null hypothesis $H_0 : \theta = 0$, $\alpha = 0.05$, and $\beta = 0.10$ at the alternative reference $\theta_1 = \pm 0.25$, the O'Brien-Fleming method increases the maximum information from 168.12 for a fixed-sample design to 169.32 for a two-stage design, 172.57 for a five-stage design, and then 174.42 for a ten-stage design. In the mean time, the average sample number (as a percentage of fixed-sample) under the alternative hypothesis decreases from 100 for a fixed-sample design to 85.11 for a two-stage design, 75.03 for a five-stage design, and then 71.80 for a ten-stage design. The reduction in average sample number decreases as the number of stages increases. Thus there seems to be little to gain from choosing a design with more than five stages (Pocock 1982, p. 155).

Alternative Reference

The alternative reference θ_1 is the hypothetical reference under the alternative hypothesis at which the power is computed. It is a treatment value that the investigators would hope to detect with high probability (Jennison and Turnbull 2000, p. 21).

For a group sequential design with specified parameters such as α and β errors, the drift parameter $\theta_1\sqrt{I_X}$ is always derived in the SEQDESIGN procedure. Thus, with a smaller alternative reference θ_1, a larger maximum information level I_X is needed. That is, in order to detect a smaller difference with the same high power, a larger sample size is required.

Maximum Information

In a clinical trial, the amount of information about an unknown parameter available from the data can be measured by the Fisher information, the variance of the score statistic. The maximum information is the information level needed at the final stage of the group sequential trial if the trial does not stop at an interim stage. For a group sequential design, the maximum information can be derived with the specified alternative reference.

The maximum information is proportional to the sample size or number of events required for the design. Thus, it can also be used to compare different designs. Generally, a design with a larger probability to stop the trial early tends to have a larger maximum information. For example, for two-sided four-stage designs with early stopping only to reject H_0, $\alpha = 0.05$, and $\beta = 0.10$ at the alternative reference $\theta_1 = \pm 0.25$, the Pocock method has a maximum information of 198.91 and the O'Brien-Fleming method has a maximum information of 171.84, indicating a much larger information level required for the Pocock method.

Drift Parameter

The drift parameter $\theta_1\sqrt{I_X}$ is derived for each design in the SEQDESIGN procedure, where θ_1 is the alternative reference. It is proportional to the square root of maximum information required for the design and can be used to compare maximum information for different designs with the same alternative reference. For example, for two-sided four-stage designs with early stopping only to reject H_0, $\alpha = 0.05$, and $\beta = 0.10$, the Pocock method has a drift parameter 3.526 and the O'Brien-Fleming method has a drift parameter 3.277, indicating that a larger maximum information level is required for the Pocock method than for the O'Brien-Fleming method.

Average Sample Number

The average sample number is the expected sample size (for nonsurvival data) or expected number of events (for survival data) of the design under a specific hypothetical reference. The percent average sample numbers with respect to the corresponding fixed-sample design are displayed in the SEQDESIGN procedure.

The design that requires a larger maximum information level tends to have a smaller average sample number under the alternative hypothesis. For example, for two-sided four-stage designs with early stopping only to reject H_0, $\alpha = 0.05$, and $\beta = 0.10$ at the alternative reference $\theta_1 = \pm 0.25$, the Pocock design has a maximum information of 198.91 and an average sample number (in percentage of fixed-sample design) of 69.75 under the alternative hypothesis, and the O'Brien-Fleming design has a maximum information of 171.84 and an average sample number of 76.74.

Sample Size

The maximum information for the sequential design expressed as a percentage of its corresponding fixed-sample information is derived in the SEQDESIGN procedure. The sample size or number of events needed for a group sequential trial is computed by multiplying the sample size or number of events for the corresponding fixed-sample design by the derived percentage.

If the sample size or number of events for the fixed-sample design is available, you can use the MODEL=INPUTNOBS or MODEL=INPUTNEVENTS option in the SAMPLESIZE statement to derive the sample size or number of events needed at each stage. Otherwise, with the specified or derived maximum information, you can use the MODEL= option in the SAMPLESIZE statement to specify a hypothesis test and then to derive the sample size or number of events needed at each stage. See the section "Sample Size Computation" on page 6766 for the sample size computation for commonly used tests.

Summary of Methods in Group Sequential Designs

There are three different types of methods available in the SEQDESIGN procedure: fixed boundary shape methods for specified boundary shape, Whitehead methods for boundaries from continuous monitoring, and error spending methods for specified error spending at each stage.

The fixed boundary shape methods include unified family methods and Haybittle-Peto methods. The unified family methods include Pocock, O'Brien-Fleming, power family, and triangular methods.

Pocock Method

Pocock derives the constant boundary on the standardized Z scale to demonstrate the sequential design while maintaining the overall α and β levels (Pocock 1977). The resulting boundary tends to stop the trials early with a larger p-value. This boundary is commonly called a Pocock boundary, but Pocock himself does not advocate these boundary values for stopping a trial early to reject the null hypothesis, because large p-values might not be persuasive enough (Pocock and White 1999). Also, the nominal p-value at the final stage is much smaller than the overall p-value of the design. That is, the trial might stop at the final stage with a small nominal p-value, but the test is not rejected, which might not be easy to justify.

O'Brien-Fleming Method

O'Brien-Fleming boundary values are inversely proportional to the square root of information levels on the standardized Z scale (O'Brien and Fleming 1979). The O'Brien-Fleming boundary is conservative in the early stages and tends to stop the trials early only with a small p-value. But the nominal value at the final stage is close to the overall p-value of the design.

Power Family Method

The power family method (Wang and Tsiatis 1987; Emerson and Fleming 1989; Pampallona and Tsiatis 1994) generalizes the Pocock and O'Brien-Fleming methods with a power parameter to allow continuous movement between the Pocock and O'Brien-Fleming methods. The power parameter is $\rho = 0$ for the Pocock method and $\rho = 0.5$ for the O'Brien-Fleming method.

Triangular Method

The unified family triangular method (Kittelson and Emerson 1999) contains straight-line boundaries on the score scale. For a one-sided trial with early stopping either to reject and to accept the null hypothesis, the method produces a triangular continuation region. The boundary shape is specified with the slope parameter τ.

Unified Family Method

The unified family method (Kittelson and Emerson 1999) extends power family methods to incorporate the triangular method, which contains straight-line boundaries on the score scale.

Haybittle-Peto Method

The Haybittle-Peto method (Haybittle 1971; Peto et al. 1976) uses a Z value of 3 for the critical values in interim stages and derives the critical value at the final stage. With this method, the final-stage critical value is close to the original design without interim monitoring. The SEQDESIGN procedure extends this method further to allow for different Z or nominal p-values for the boundaries.

Whitehead Method

Whitehead methods (Whitehead and Stratton 1983; Whitehead 1997, 2001) derive the boundary values by adapting the continuous monitoring tests to the discrete monitoring of group sequential tests. With early stopping to reject or accept the null hypothesis in a one-sided test, the derived continuation region has a triangular shape on the score-scaled boundaries. Only elementary calculations are needed to derive the boundary values in Whitehead's triangular methods. The resulting Type I error probability and power are extremely close but differ slightly from the specified values due to the approximations used in deriving the tests (Jennison and Turnbull 2000, p. 106). The SEQDESIGN procedure provides the BOUNDARYKEY= option to adjust the boundary value at the final stage for the exact Type I or Type II error probability levels.

Error Spending Method

The error spending method uses the specified α and β errors to be used at each stage of the design to derive the boundary values.

Error Spending Function Method

The error spending function method uses the error spending function to compute the α and β errors to be used at each stage of the design and then to derive the boundary values for these errors. The following four error spending functions are available in the SEQDESIGN procedure:

- The Pocock-type error spending function (Lan and DeMets 1983) produces boundaries similar to those produced with Pocock's method.
- The O'Brien-Fleming-type error spending function (Lan and DeMets 1983) produces boundaries similar to those produced with the O'Brien-Fleming method.
- The gamma error spending function (Hwang, Shih, and DeCani 1990) specifies a gamma cumulative error spending function indexed by the gamma parameter γ. The boundaries created with $\gamma = 1$ are similar to the boundaries from the Pocock method, and the boundaries created with $\gamma = -4$ or $\gamma = -5$ are similar to the boundaries from the O'Brien-Fleming method.
- The power error spending function (Jennison and Turnbull 2000, p. 148) specifies a power cumulative error spending function indexed by the power parameter ρ. The boundaries created with $\rho = 1$ are similar to the boundaries from the Pocock method, and the boundaries created with $\rho = 3$ are similar to the boundaries from the O'Brien-Fleming method.

Table Output

For each design, the SEQDESIGN procedure displays the "Design Information," "Method Information," and "Boundary Information" tables by default.

Boundary Information

The "Boundary Information" table displays the following information at each stage:

- proportion of information
- actual information level, if the maximum information is either specified or derived
- alternative references with the specified statistic scale. If a p-value scale is specified, the standardized Z scale is used.
- boundary values with the specified statistic scale to reject or accept the null hypothesis

Note that implicitly, the boundary information table also contains variables for the boundary scale, stopping criterion, and type of alternative hypothesis. That is, if an ODS statement is used to save the table, the data set also contains the variables _Scale_ for the boundary scale, _Stop_ for the stopping criterion, and _ALT_ for the type of alternative hypothesis.

Design Information

The "Design Information" table displays the design specifications and derived statistics. The derived Max Information (Percent Fixed-Sample) is the maximum information for the sequential design in percentage of the corresponding fixed-sample information.

The Null Ref ASN (Percent Fixed-Sample) is the average sample number (expected sample size for nonsurvival data or expected number of events for survival data) required under the null hypothesis for the group sequential design in percentage of the corresponding fixed-sample design. Similarly, the Alt Ref ASN (Percent Fixed-Sample) is the average sample number required under the alternative reference for the group sequential design in percentage of the corresponding fixed-sample design.

If both the maximum information (MAXINFO= option) and the alternative reference θ_1 (ALTREF= option) are specified, then either the ALPHA= option is used to derive the Type II error probability β (BOUNDARYKEY=ALPHA) or the BETA= option is used to derive the Type I error probability α (BOUNDARYKEY=BETA).

Error Spending Information

The "Error Spending Information" table displays the following information at each stage:

- proportion of information
- actual information level, if the maximum information is either specified or derived
- cumulative error spending for each boundary

Method Information

The "Method Information" table displays detailed method information for the design. For each boundary, it displays the following:

- the group sequential method used
- the α or β errors
- the specified parameter ρ, if an error spending function is used
- the specified parameters ρ and τ with the derived critical value C, if a unified family method is used
- the alternative reference θ_1, if either the ALTREF= or the MAXINFO= option is specified

- the derived drift parameter, $\theta_1 \sqrt{I_X}$, where I_X is the maximum information and θ_1 is the alternative reference

Note that the alternative references are displayed with the MLE scale in the "Method Information" table. In contrast, the alternative references in the "Boundary Information" table are displayed with the specified statistic scale (if the p-value scale is not specified) or the standardized Z scale (if the p-value scale is specified).

Powers and Expected Sample Sizes

The "Powers and Expected Sample Sizes" table displays the following information under each of the specified hypothetical references $\theta = c_i \theta_1$, where θ_1 is the alternative reference and c_i are values specified in the CREF= option.

- coefficient c_i for the hypothetical references. The value $c_i = 0$ corresponds to the null hypothesis and $c_i = 1$ corresponds to the alternative hypothesis
- power
- expected sample size, as percentage of fixed-sample size

For a one-sided design, the power and expected sample sizes under the hypothetical references $\theta = c_i \theta_1$ are displayed.

For a two-sided symmetric design, the power and expected sample sizes under each of the hypothetical references $\theta = c_i \theta_{1u}$ are displayed, where θ_{1u} is the upper alternative reference.

For a two-sided asymmetric design, the power and expected sample sizes under each of the hypothetical references $\theta = c_i \theta_{1l}$ and $\theta = c_i \theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively.

For a two-sided design, the power is the probability of correctly rejecting the null hypothesis for the correct alternative. Thus, under the null hypothesis, the displayed power corresponds to a one-sided Type I error probability level—that is, the lower α level or the upper α level.

The expected sample size as a percentage of the corresponding fixed-sample design is

$$100 \times \frac{\sum_{k=1}^{K} p_k \, I_k}{I_0}$$

where p_k is the stopping probability at stage k, $\sum_{k=1}^{K} p_k \, I_k$ is the expected information level, and I_0 is the information level for the fixed-sample design.

Sample Size Summary

When you use the SAMPLESIZE statement with the SEQDESIGN procedure, the "Sample Size Summary" table displays parameters for the sample size computation. It also displays the expected sample sizes or numbers of events for the model under both the null and alternative hypotheses.

The expected sample size is the average sample size

$$\frac{\sum_{k=1}^{K} p_k I_k}{I_0} N_0$$

where p_k is the stopping probability at stage k, $\sum_{k=1}^{K} p_k I_k$ is the expected information level, I_0 is the information level for the fixed-sample design, and N_0 is the sample size for the fixed-sample design.

The expected number of events is the average number of events

$$\frac{\sum_{k=1}^{K} p_k I_k}{I_0} D_0$$

where D_0 is the fixed-sample number of events for the model.

Sample Size Information

The "Sample Sizes (N)" table displays the required sample sizes and information levels at each stage, in both fractional and integer numbers. The derived fractional sample sizes are under the heading "Fractional N." These sample sizes are rounded up to integers under the heading "Ceiling N." The matched integer sample sizes are also displayed for two-sample tests.

The "Required Number of Events (D)" table displays the required number of events required and information level at each stage.

The "Number of Events (D) and Sample Sizes (N)" table displays the number of events and sample size required at each stage with the study time. The derived times under the heading "Fractional Time" are not integers. These times are rounded up to integers under the heading "Ceiling Time."

Stopping Probabilities

The "Expected Cumulative Stopping Probabilities" table displays the following information under each of the specified hypothetical references $\theta = c_i\theta_1$, where c_i are values specified in the CREF= option, and θ_1 is the alternative reference:

- coefficient c_i for the hypothetical references. The value $c_i = 0$ corresponds to the null hypothesis, and $c_i = 1$ corresponds to the alternative hypothesis
- expected stopping stage
- source of the stopping probability: reject H_0 (with STOP=REJECT or STOP=BOTH), accept H_0 (with STOP=ACCEPT or STOP=BOTH), or either reject or accept H_0 (with STOP=BOTH)
- expected cumulative stopping probabilities at each stage

For a one-sided design, the expected cumulative stopping probabilities under the hypothetical references $\theta = c_i\theta_1$ are displayed.

For a two-sided design, the expected cumulative stopping probabilities under each of the hypothetical references $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively.

Note that for a symmetric two-sided design, only the expected cumulative stopping probabilities under the hypothetical references $\theta = c_i\theta_{1u}$ are derived.

The expected stopping stage is given by $k_0 + d$, where the integer k_0 and the fraction d $(0 \leq d < 1)$ are derived from the expected information level equation

$$\sum_{k=1}^{K} p_k\, I_k = I_{k_0} + d\,(I_{(k_0+1)} - I_{k_0})$$

where p_k is the stopping probability at stage k.

For equally spaced information levels, the expected stopping stage is reduced to the weighted average

$$\sum_{k=1}^{K} p_k\, k$$

ODS Table Names

PROC SEQDESIGN assigns a name to each table it creates. You must use these names to reference tables when using the Output Delivery System (ODS). These names are listed in Table 80.12. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 80.12 ODS Tables Produced by PROC SEQDESIGN

ODS Table Name	Description	Statement	Option
Boundary	Boundary values		
Design	Design information		
ErrSpend	Error spending		ERRSPEND
Method	Method information		
PowerSampleSize	Power and expected sample size		PSS
SampleSize	Derived sample sizes	SAMPLESIZE	
SampleSizeSummary	Sample size summary	SAMPLESIZE	
StopProb	Stopping probabilities		STOPPROB

Graphics Output

This section describes the use of ODS for creating graphics with the SEQDESIGN procedure. To request these graphs, ODS Graphics must be enabled and you must specify the associated graphics options in the PROC SEQDESIGN statement. Except for the PLOTS=BOUNDARY option, where a detailed boundary plot is generated for each design separately, each option produces a plot for all designs together. For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS."

Sequential ASN Plot

The PLOTS=ASN option displays the average sample numbers (expected sample sizes for nonsurvival data or expected numbers of events for survival data) under various hypothetical references. The average sample numbers are connected for each design, and these connected curves for all designs are displayed in the "Sequential ASN Plot" graph.

For a one-sided design, average sample numbers under the hypothetical references $\theta = c_i\theta_1$ are displayed, where c_i are the values specified in the CREF= option and θ_1 is the alternative reference. The horizontal axis displays the c_i values of these hypothetical references.

For a two-sided design, average sample numbers under each of the hypothetical references $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. The horizontal axis displays $-c_i$ values for lower hypothetical references $\theta = c_i\theta_{1l}$ and c_i values for upper hypothetical references $\theta = c_i\theta_{1u}$.

Note that for a symmetric two-sided design, only average sample numbers under the hypothetical references $\theta = c_i\theta_{1u}$ are derived.

Sequential Boundary Plot

The PLOTS=BOUNDARY option displays boundary values and the acceptance and rejection regions at each stage for each design separately in the "Detailed Boundary Information" graph. The BOUNDARYSCALE= option is used to specify the scale of the boundaries on the vertical axis. The keywords MLE, SCORE, STDZ, and PVALUE in the BOUNDARYSCALE= option correspond to the boundary with the MLE scale, score statistic scale, standardized normal Z scale, and p-value scale, respectively.

The stage numbers are displayed on the horizontal axis. In addition, the HSCALE= option in the PLOTS=BOUNDARY option can be used to specify the scale on the horizontal axis. The keywords INFO and SAMPLESIZE in the HSCALE= option correspond to the information levels and sample sizes, respectively.

Combined Sequential Boundary Plot

The PLOTS=COMBINEDBOUNDARY option displays boundary values. The boundary values are connected for each boundary in each design, and these connected curves for all designs are displayed in the "Sequential Boundary Information" graph. The BOUNDARYSCALE= option is used to specify the scale of the boundaries on the vertical axis. The keywords MLE, SCORE, STDZ, and PVALUE in the BOUND-

ARYSCALE= option correspond to the boundary with the MLE scale, score statistic scale, standardized normal Z scale, and p-value scale, respectively.

The HSCALE= option in the PLOTS=COMBINEDBOUNDARY option can be used to specify the scale on the horizontal axis. The keywords INFO, SAMPLESIZE, and STAGE in the HSCALE= option correspond to the information levels, sample sizes, and stage numbers, respectively.

Sequential Error Spending Plot

The PLOTS=ERRSPEND option displays the cumulative error spending at each stage on each boundary in the "Sequential Error Spending Plot" graph. A legend table uses the design labels to identify the curves for the corresponding design in the plot. Another legend table uses symbols to identify boundaries in the plot.

Sequential Power Plot

The PLOTS=POWER option displays the powers under various hypothetical references. The powers are connected for each design, and these connected curves for all designs are displayed in the "Sequential Power Plot" graph.

For a one-sided design, powers under hypothetical references $\theta = c_i\theta_1$ are displayed, where c_i are the values specified in the CREF= option and θ_1 is the alternative reference. The horizontal axis displays the c_i values of these hypothetical references.

For a two-sided design, powers under hypothetical references $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. The horizontal axis displays $-c_i$ values for lower hypothetical references $\theta = c_i\theta_{1l}$ and c_i values for upper hypothetical references $\theta = c_i\theta_{1u}$.

Note that for a symmetric two-sided design, only powers under hypothetical references $\theta = c_i\theta_{1u}$ are derived.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

PROC SEQDESIGN assigns a name to each graph it creates. You can use these names to reference the graphs when using ODS. To request these graphs, ODS Graphics must be enabled and you must specify the options indicated in Table 80.13.

Table 80.13 Graphs Produced by PROC SEQDESIGN

ODS Graph Name	Plot Description	Option
ASNPlot	Average sample numbers	PLOTS=ASN
BoundaryPlot	Detailed boundary values	PLOTS=BOUNDARY
CombinedBoundaryPlot	Boundary values	PLOTS=COMBINEDBOUNDARY
ErrSpendPlot	Error spending	PLOTS=ERRSPEND
PowerPlot	Power curves	PLOTS=POWER

Acknowledgments

In addition to being shaped by the research literature listed in the section "References" on page 6892, the development of the SEQDESIGN and SEQTEST procedures has benefited significantly from the advice and expertise of the following researchers:

- Lu Cui, Eisai Medical Research
- Alex Dmitrienko, Eli Lilly
- Scott Emerson, University of Washington
- Gordon Lan, Johnson & Johnson
- Steve Snapinn, Amgen
- John Whitehead, University of Reading

The time and effort that these researchers have contributed is gratefully acknowledged.

Examples: SEQDESIGN Procedure

The following examples demonstrate the usage of group sequential methods. Example 80.1 uses the NSTAGES=1 option to derive boundaries of critical values for a fixed-sample design. The remaining examples use different methods to create boundaries for various group sequential designs.

Example 80.1: Creating Fixed-Sample Designs

This example demonstrates a one-sided fixed-sample design and a two-sided fixed-sample design. The following statements request a fixed-sample design with an upper alternative:

```
ods graphics on;
proc seqdesign pss
               ;
   OneSidedFixedSample: design nstages=1
                               alt=upper
                               alpha=0.025 beta=0.10
                               ;
   samplesize model=onesamplemean(mean=0.25);
run;
ods graphics off;
```

In the DESIGN statement, the label `OneSidedFixedSample` identifies the design in the output tables. The NSTAGES=1 option specifies that the design has only one stage; this corresponds to a fixed-sample design. In the SEQDESIGN procedure, the null hypothesis for the design is $H_0 : \theta = 0$ and the ALT=UPPER option specifies an upper alternative hypothesis $H_1 : \theta = \theta_1 > 0$. The MEAN=0.25 option in the SAMPLESIZE statement specifies the upper alternative reference $\theta_1 = 0.25$.

The options ALPHA=0.025 and BETA=0.10 specify the Type I error probability level $\alpha = 0.025$ and the Type II error probability level $\beta = 0.10$. That is, the design has a power $1 - \beta = 0.90$ at $\theta_1 = 0.25$.

The "Design Information" table in Output 80.1.1 displays design specifications and the derived statistics such as power. As expected, the derived statistics such as maximum information and average sample number (in percentage of its corresponding fixed-sample information) are 100 for the fixed-sample design (NSTAGES=1). Also, for a fixed-sample design, the STOP= and METHOD= options in the DESIGN statement are not applicable.

Output 80.1.1 One-Sided Fixed-Sample Design Information

The SEQDESIGN Procedure
Design: OneSidedFixedSample

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Upper
Alternative Reference	0.25
Number of Stages	1
Alpha	0.025
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	100
Max Information	168.1188
Null Ref ASN (Percent of Fixed Sample)	100
Alt Ref ASN (Percent of Fixed Sample)	100

The "Method Information" table in Output 80.1.2 displays the α and β error levels. It also displays the derived drift parameter, which is the standardized reference improvement, $\theta_1\sqrt{I_0}$, where θ_1 is the alternative reference and I_0 is the maximum information for the design. If either θ_1 or I_0 is specified, the other statistic is derived in the SEQDESIGN procedure. For a fixed-sample design,

$$\theta_1\sqrt{I_0} = \Phi^{-1}(1-\alpha) + \Phi^{-1}(1-\beta) = \Phi^{-1}(0.975) + \Phi^{-1}(0.90) = 3.2415$$

Output 80.1.2 Method Information

Method Information

Boundary	Alpha	Beta	Alternative Reference	Drift
Upper Alpha	0.02500	0.10000	0.25	3.241516

The "Boundary Information" table in Output 80.1.3 displays information level, alternative reference, and boundary value at each stage. The information proportion indicates the proportion of maximum information available at the stage. With only one stage for a fixed-sample design, the proportion is 1. With the SAMPLESIZE statement, the required sample size N is also displayed under the heading "Information Level."

Output 80.1.3 Boundary Information

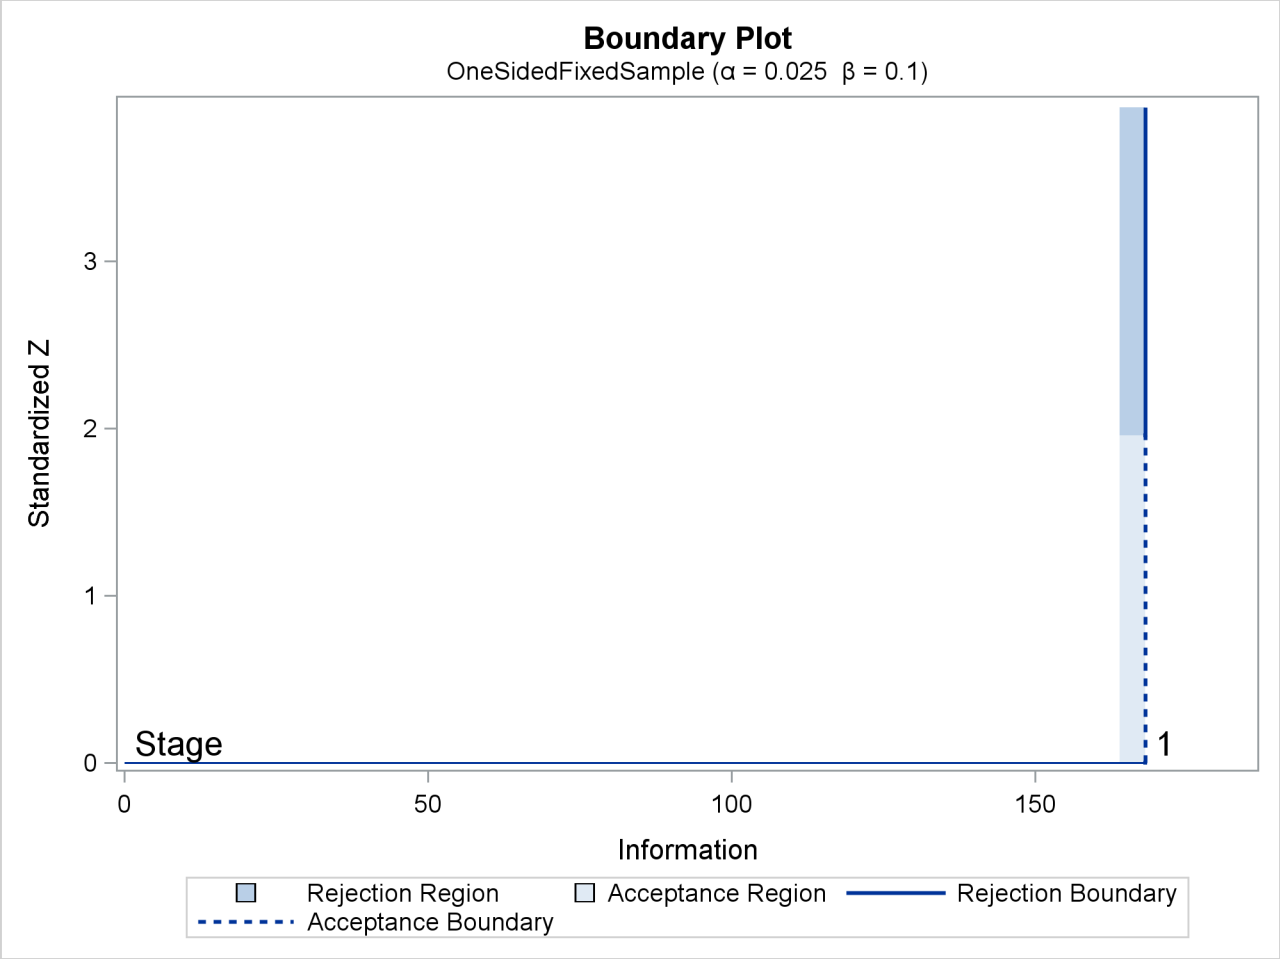
Boundary Information (Standardized Z Scale)
Null Reference = 0

	Information Level			Alternative Reference	Boundary Values
Stage	Proportion	Actual	N	Upper	Upper Alpha
1	1.0000	168.1188	168.1188	3.24152	1.95996

By default (or equivalently if you specify BOUNDARYSCALE=STDZ), output alternative references and boundaries are displayed with the standardized normal Z scale. The alternative reference on the standardized Z scale at stage 1 is given by $\theta_1\sqrt{I_1}$, where I_1 is the information level at stage 1. With a boundary value 1.96, the hypothesis of $\theta = 0$ is rejected if the standardized normal statistic $Z \geq 1.96$.

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.1.4. The boundary values in the "Boundary Information" table in Figure 80.1.3 are displayed in the plot.

Output 80.1.4 Boundary Plot



The "Sample Size Summary" table in Output 80.1.5 displays parameters for the sample size computation of the test for a normal mean.

Output 80.1.5 Sample Size Summary

Sample Size Summary

Test	One-Sample Mean
Mean	0.25
Standard Deviation	1
Max Sample Size	168.1188
Expected Sample Size (Null Ref)	168.1188
Expected Sample Size (Alt Ref)	168.1188

The "Sample Sizes (N)" table in Output 80.1.6 displays the derived sample sizes, in both fractional and integer numbers. With the resulting integer sample sizes, the corresponding information level is slightly larger than the level from the design. This can increase the power slightly if the integer sample size is used in the trial.

Output 80.1.6 Derived Sample Sizes

Sample Sizes (N)
One-Sample Z Test for Mean

Stage	Fractional N N	Fractional N Information	Ceiling N N	Ceiling N Information
1	168.12	168.1	169	169.0

The following statements request a two-sided fixed-sample design with a specified alternative reference:

```
ods graphics on;
proc seqdesign altref=1.2
               pss
               ;
   TwoSidedFixedSample: design nstages=1
                               alt=twosided
                               alpha=0.05 beta=0.10
                               ;
   samplesize model=twosamplemean(stddev=2 weight=2);
run;
ods graphics off;
```

In the SEQDESIGN procedure, the null hypothesis for the design is $H_0 : \theta = 0$. The ALT=TWOSIDED option specifies a two-sided alternative hypothesis $H_1 : \theta = \theta_1 \neq 0$. The ALTREF=1.2 option in the PROC SEQDESIGN statement specifies the alternative reference $\theta_1 = \pm 1.2$.

The ALPHA=0.05 option (which is the default) specifies the two-sided Type I error probability level $\alpha = 0.05$. That is, the lower and upper Type I error probabilities $\alpha_l = \alpha_u = 0.025$. The BETA=0.10 option (which is the default) specifies the Type II error probability level $\beta = 0.10$, and the design has a power $1 - \beta = 0.90$ at the alternative reference $\theta_1 = \pm 1.2$.

The "Design Information" table in Output 80.1.7 displays design specifications and the derived power. With a specified alternative reference, the maximum information is derived.

Output 80.1.7 Two-Sided Fixed-Sample Design Information

The SEQDESIGN Procedure
Design: TwoSidedFixedSample

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Alternative Reference	1.2
Number of Stages	1
Alpha	0.05
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	100
Max Information	7.296822
Null Ref ASN (Percent of Fixed Sample)	100
Alt Ref ASN (Percent of Fixed Sample)	100

The "Method Information" table in Output 80.1.8 displays the α and β errors, alternative references, and drift parameter. For a fixed-sample design, the derived drift parameter

$$\theta_1\sqrt{I_0} = \Phi^{-1}(1-\frac{\alpha}{2}) + \Phi^{-1}(1-\beta) = \Phi^{-1}(0.975) + \Phi^{-1}(0.90) = 3.2415$$

Output 80.1.8 Method Information

Method Information

Boundary	Alpha	Beta	Alternative Reference	Drift
Upper Alpha	0.02500	0.10000	1.2	3.241516
Lower Alpha	0.02500	0.10000	-1.2	-3.24152

With a specified alternative reference $\theta_1 = 1.2$, the maximum information

$$I_0 = \left(\frac{3.2415}{1.2}\right)^2 = 7.2968$$

The default "Boundary Information" table in Output 80.1.9 displays information level, alternative reference, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative reference and boundary values are displayed with the standardized normal Z scale. Thus, the standardized alternative references $\pm\theta_1\sqrt{I_0}$ are displayed.

Output 80.1.9 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

Stage	Information Level Proportion	Information Level Actual	Information Level N	Alternative Reference Lower	Alternative Reference Upper
1	1.0000	7.296822	131.3428	-3.24152	3.24152

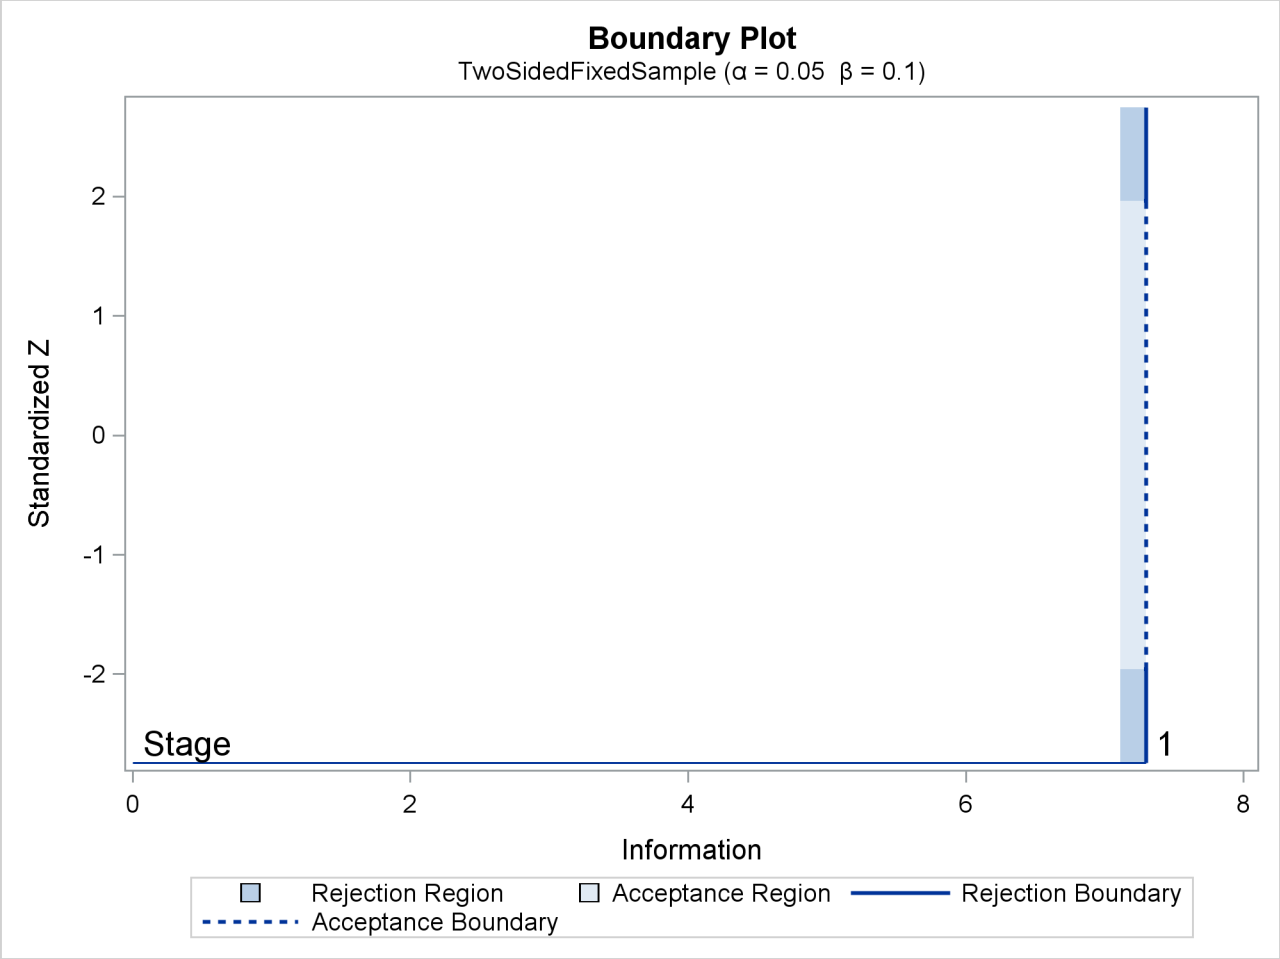
Boundary Information (Standardized Z Scale)
Null Reference = 0

Stage	Boundary Values Lower Alpha	Boundary Values Upper Alpha
1	-1.95996	1.95996

With boundary values of -1.96 and 1.96, the hypothesis of $\theta = 0$ is rejected if the standardized normal statistic $Z \geq 1.96$ or $Z \leq -1.96$.

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.1.10 . The boundary values in the "Boundary Information" table in Figure 80.1.9 are displayed in the plot.

Output 80.1.10 Boundary Plot



The "Sample Size Summary" table in Output 80.1.11 displays parameters for the sample size computation of the test for a normal mean.

Output 80.1.11 Sample Size Summary

Sample Size Summary

Test	Two-Sample Means
Mean Difference	1.2
Standard Deviation	2
Max Sample Size	131.3428
Expected Sample Size (Null Ref)	131.3428
Expected Sample Size (Alt Ref)	131.3428
Weight (Group A)	2
Weight (Group B)	1

The "Sample Sizes (N)" table in Output 80.1.12 displays the derived sample sizes, in both fractional and integer numbers. With the WEIGHT=2 option, the allocation ratio is 2 for the first group and 1 for the second group. With the resulting integer sample sizes, the corresponding information level is slightly larger

than the level from the design. This can increase the power slightly if the integer sample size is used in the trial.

Output 80.1.12 Derived Sample Sizes

Sample Sizes (N)
Two-Sample Z Test for Mean Difference

	Fractional N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	131.34	87.56	43.78	7.2968

Sample Sizes (N)

Example 80.2: Creating a One-Sided O'Brien-Fleming Design

This example demonstrates a group sequential design for a clinical study. A clinic is conducting a study on the effect of vitamin C supplements in treating flu symptoms. The study groups consist of patients in the clinic with their first sign of flu symptoms within the last 24 hours. These individuals are randomly assigned to either the control group, which receives the placebo pills, or the treatment group, which receives large doses of vitamin C supplements. At the end of a five-day period, the flu symptoms of each individual are recorded.

Suppose that from past experience, 60% of individuals experiencing flu symptoms have the symptoms disappeared within five days. The clinic wants to detect a 75% symptoms disappearance with a high probability in the trial. A test that compares the proportions directly is to specify a null hypothesis $H_0 : \theta = p_a - p_b = 0$ with a Type I error probability level $\alpha = 0.025$, where p_a and p_b are the proportions of symptoms' disappearance in the treatment group and control group, respectively. A one-sided alternative $H_1 : \theta > 0$ is also specified with a power of $1 - \beta = 0.90$ at $H_1 : \theta = 0.15$.

For a one-sided fixed-sample design, the critical value for the standardized Z test statistic is given by $C_\alpha = \Phi^{-1}(1-\alpha) = 1.96$. That is, at the end of study, if the test statistic $z \geq C_\alpha$, then the null hypothesis is rejected and the efficacy of vitamin C supplements is declared. Otherwise, the null hypothesis is not rejected and the effect of vitamin C supplements is not significant.

To achieve a $1 - \beta = 0.90$ power at $H_1 : \theta = 0.15$ for a fixed-sample design, the information required is given by

$$I_0 = \frac{(\Phi^{-1}(1-\alpha) + \Phi^{-1}(1-\beta))^2}{0.15^2} = \frac{(1.96 + 1.28155)^2}{0.0225} = 466.99$$

With an equal sample size on the treatment and control groups, $N_a = N_b$, the sample size required for each group under H_1 is computed from the information I_0:

$$N_a = N_b = \left(p_{1a}\left(1 - p_{1a}\right) + p_{1b}\left(1 - p_{1b}\right)\right) I_0$$

where $p_{1a} = 0.75$ and $p_{1b} = 0.60$ are proportions in the treatment and control groups under H_1. That is,

$$N_a = N_b = (0.75 \times 0.25 + 0.6 \times 0.4) \times 466.99 = 199.64$$

Thus, 200 individuals are required for each group in the fixed-sample study. See the section "Test for the Difference between Two Binomial Proportions" on page 6774 for a detailed derivation of these required sample sizes.

Instead of a fixed-sample design for the trial, a group sequential design is used to stop the trial early for ethical concerns of possible harm or an unexpected strong efficacy outcome of the new drug. It can also save time and resources in the process. The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design that uses an O'Brien-Fleming method for normally distributed statistics. The design uses a one-sided alternative hypothesis H_1 with early stopping to reject or accept H_0.

```
ods graphics on;
proc seqdesign altref=0.15
               ;
   OneSidedOBrienFleming: design nstages=4
                          method=obf
                          alt=upper   stop=both
                          alpha=0.025 beta=0.10
                          ;
   samplesize model=twosamplefreq(nullprop=0.6 test=prop);
ods output Boundary=Bnd_Prop;
run;
ods graphics off;
```

In a sequential design, a hypothesis can be rejected, accepted, or continued to the next time point at each interim stage. The STOP=BOTH option specifies early stopping to reject or accept the null hypothesis. The "Design Information," "Method Information," and "Boundary Information" tables are displayed by default.

The "Design Information" table in Output 80.2.1 displays design specifications and derived statistics such as power and maximum information. With a specified alternative reference, ALTREF=0.15, the maximum information I_X is derived.

Output 80.2.1 Design Information

The SEQDESIGN Procedure
Design: OneSidedOBrienFleming

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Upper
Early Stop	Accept/Reject Null
Method	O'Brien-Fleming
Boundary Key	Both
Alternative Reference	0.15
Number of Stages	4
Alpha	0.025
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	107.6741
Max Information	502.8343
Null Ref ASN (Percent of Fixed Sample)	61.12891
Alt Ref ASN (Percent of Fixed Sample)	75.89782

The Max Information (Percent Fixed-Sample) is the ratio in percentage between the maximum information for the group sequential design and the information required for a corresponding fixed-sample design:

$$100 \times \frac{I_X}{I_0} = 100 \times \frac{502.83}{466.99} = 107.67$$

That is, if the group sequential trial does not stop at any interim stages, the information needed is 7.67% more than is needed for the corresponding fixed-sample design. For a two-sample test for binomial proportions, the information is proportional to the sample size. Thus, 7.67% more observations are needed for the group sequential trial.

The Null Ref ASN (Percent Fixed-Sample) is the ratio in percentage between the expected sample size required under the null hypothesis for the group sequential design and the sample size required for the corresponding fixed-sample design. With a ratio of 61.1%, the expected sample size for the group sequential trial under the null hypothesis is 61.1% of the sample size in the corresponding fixed-sample design.

Similarly, the Alt Ref ASN (Percent Fixed-Sample) is the ratio in percentage between the expected sample size required under the alternative hypothesis for the group sequential design and the sample size required for the corresponding fixed-sample design. With a ratio of 75.9%, the expected sample size for the group sequential trial under the alternative hypothesis is 75.9% of the sample size in the corresponding fixed-sample design.

For a one-sided design with an upper alternative and early stopping to reject or accept the null hypothesis, upper α and β boundaries are created. The "Method Information" table in Output 80.2.2 displays the Type I error probability α, the Type II error probability β, and the derived drift parameter. The drift parameter is the standardized reference improvement between the alternative and null hypotheses at the final stage. It is also the standardized alternative reference at the final stage if the null reference is zero.

Output 80.2.2 Method Information

Method Information

Boundary	Method	Alpha	Beta	Unified Family Rho	Unified Family Tau	Unified Family C
Upper Alpha	O'Brien-Fleming	0.02500	.	0.5	0	1.9784
Upper Beta	O'Brien-Fleming	.	0.10000	0.5	0	1.3852

Method Information

Boundary	Alternative Reference	Drift
Upper Alpha	0.15	3.363595
Upper Beta	0.15	3.363595

With the METHOD=OBF option, the O'Brien-Fleming method is used for each boundary. The O'Brien-Fleming method is one of the unified family methods, and the "Method Information" table displays the corresponding parameter ρ in the unified family method. The table also displays the critical values $C_\alpha = 1.9784$ for the α boundary and $C_\beta = 1.3852$ for the β boundary. These critical values are used to create the boundary values.

The "Boundary Information" table in Output 80.2.3 displays information level, alternative reference, and boundary values at each stage. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative references and boundary values are displayed with the standardized Z statistic scale. The resulting standardized alternative reference at stage k is given by $\theta_1\sqrt{I_k}$, where θ_1 is the alternative reference and I_k is the information level at stage k, $k = 1, 2, 3, 4$.

Output 80.2.3 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

Stage	Information Level Proportion	Information Level Actual	Information Level N	Alternative Reference Upper	Boundary Values Upper Beta	Boundary Values Upper Alpha
1	0.2500	125.7086	107.4808	1.68180	-1.08860	3.95679
2	0.5000	251.4171	214.9617	2.37842	0.41946	2.79788
3	0.7500	377.1257	322.4425	2.91296	1.31347	2.28446
4	1.0000	502.8343	429.9233	3.36360	1.97840	1.97840

By default (or equivalently if you specify INFO=EQUAL), equally spaced information levels are used. An information proportion is the proportion of maximum information available at each stage. With the derived maximum information, the actual information level at each stage is also displayed. With the SAMPLESIZE statement, the required sample size N is also displayed under the heading "Information Level."

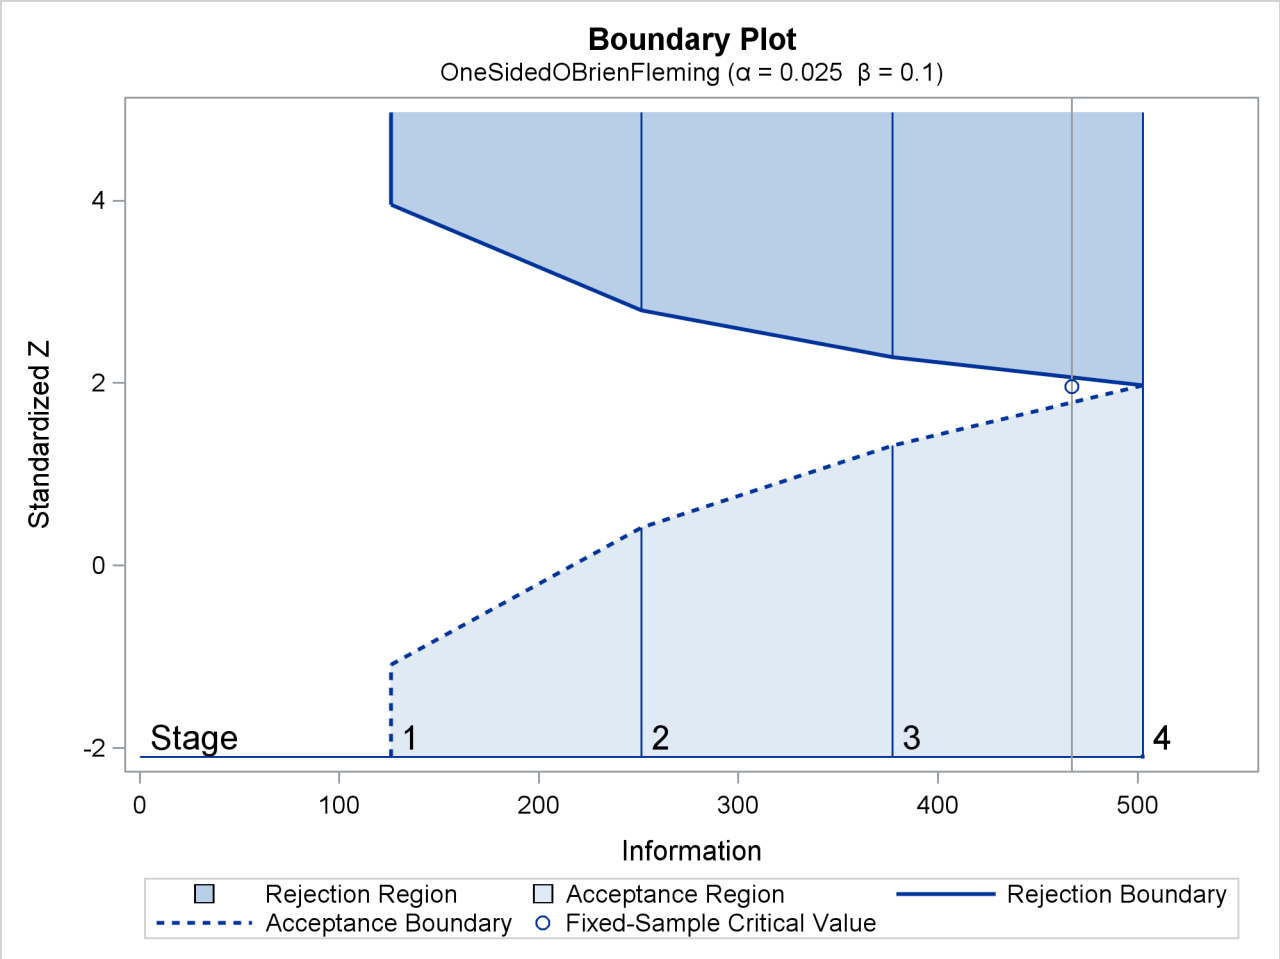
At each interim stage, if the standardized Z test statistic is larger than or equal to the corresponding upper α boundary, then the hypothesis $H_0 : \theta = 0$ is rejected. If the test statistic is less than the corresponding upper

β boundary, then the trial is stopped and the hypothesis H_0 is accepted. Otherwise, the process continues to the next stage. At the final stage, stage 4, the trial stops and the hypothesis H_0 is rejected if the standardized Z statistic $Z_4 \geq 1.9784$. Otherwise, the trial is accepted.

The ODS OUTPUT statement with the BOUNDARY=BND_PROP option creates an output data set that contains the resulting boundary information. After the actual data from the clinical trial are collected and analyzed at each stage with a procedure such as PROC GENMOD, the SEQTEST procedure is used to test the resulting statistics at stage 1 with the boundary information stored in the BOUND_PROP data set.

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.2.4.

Output 80.2.4 Boundary Plot



The horizontal axis indicates the information levels for the design. The stages are indicated by vertical lines with accompanying stage numbers. If at any stage a test statistic is in a rejection region, the trial stops and the hypothesis is rejected. If a test statistic is in an acceptance region, then the trial also stops and the hypothesis is accepted. If the statistic is not in a rejection region or an acceptance region, the trial continues to the next stage. The boundary plot also displays the information level and critical value for the corresponding fixed-sample design.

The SEQDESIGN procedure derives the drift parameter $\theta_1\sqrt{I_X}$, where θ_1 is the alternative reference and I_X is the maximum information. If either θ_1 or I_X is specified, the other can be derived. With the SAMPLESIZE statement, the maximum information is used to compute the required sample size for the study.

The "Sample Size Summary" table in Output 80.2.5 displays parameters for the sample size computation. With the MODEL=TWOSAMPLEFREQ(NULLPROP=0.6 TEST=PROP) option in the SAMPLESIZE statement, the total sample size in each group for testing the difference between two proportions is computed. By default (or equivalently if you specify REF=PROP in the MODEL=TWOSAMPLEFREQ option), the required sample sizes are computed under the alternative hypothesis. That is,

$$N_a = N_b = \left(p_{1a}\left(1 - p_{1a}\right) + p_{1b}\left(1 - p_{1b}\right)\right) I_X$$

where $p_{1b} = 0.60$ and $p_{1a} = p_{1b} + \theta_1 = 0.75$ are the proportions in the control and treatment groups, respectively, under the alternative hypothesis H_1. See the section "Test for the Difference between Two Binomial Proportions" on page 6774 for a detailed description of these parameters.

Output 80.2.5 Sample Size Summary

Sample Size Summary

Test	Two-Sample Proportions
Null Proportion	0.6
Proportion (Group A)	0.75
Test Statistic	Z for Proportion
Reference Proportions	Alt Ref
Max Sample Size	429.9233
Expected Sample Size (Null Ref)	244.0768
Expected Sample Size (Alt Ref)	303.0464

The "Sample Sizes (N)" table in Output 80.2.6 displays the required sample sizes at each stage, in both fractional and integer numbers. The derived fractional sample sizes are under the heading "Fractional N." These sample sizes are rounded up to integers under the heading "Ceiling N." In practice, integer sample sizes are used, and the resulting information levels increase slightly. Thus, 54, 108, 162, and 215 individuals are needed in each group for the four stages, respectively.

Output 80.2.6 Derived Sample Sizes

Sample Sizes (N)
Two-Sample Z Test for Proportion Difference

	Fractional N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	107.48	53.74	53.74	125.7
2	214.96	107.48	107.48	251.4
3	322.44	161.22	161.22	377.1
4	429.92	214.96	214.96	502.8

Sample Sizes (N)
Two-Sample Z Test for Proportion Difference

	Ceiling N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	108	54	54	126.3
2	216	108	108	252.6
3	324	162	162	378.9
4	430	215	215	502.9

Example 80.3: Creating Two-Sided Pocock and O'Brien-Fleming Designs

This example requests two 4-stage group sequential designs for normally distributed statistics with equally spaced information levels at all stages. One design uses Pocock's method and the other uses the O'Brien-Fleming method. The following statements invoke the SEQDESIGN procedure and request these two designs:

```
proc seqdesign altref=0.4
               pss
               stopprob
               errspend
               ;
   TwoSidedPocock:        design nstages=4 method=poc;
   TwoSidedOBrienFleming: design nstages=4 method=obf;
   samplesize model=twosamplemean(stddev=0.8 weight=2);
run;
```

By default (or equivalently if you specify ALT=TWOSIDED and STOP=REJECT in the DESIGN statement), each design has a null hypothesis H_0 with a two-sided alternative with early stopping to reject H_0.

The "Design Information" table in Output 80.3.1 displays design specifications and derived statistics for the Pocock's design. With the specified ALTREF= option, the maximum information $I_X = 77.6984$ is also derived.

Output 80.3.1 Pocock Design Information

The SEQDESIGN Procedure
Design: TwoSidedPocock

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Reject Null
Method	Pocock
Boundary Key	Both
Alternative Reference	0.4
Number of Stages	4
Alpha	0.05
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	118.3143
Max Information	77.69844
Null Ref ASN (Percent of Fixed Sample)	115.6074
Alt Ref ASN (Percent of Fixed Sample)	69.74805

With the corresponding fixed-sample information

$$I_0 = \frac{(\Phi^{-1}(1-\alpha/2) + \Phi^{-1}(1-\beta))^2}{0.4^2} = \frac{(1.96 + 1.28155)^2}{0.16} = 65.6728$$

the fixed-sample information ratio is $77.6984/65.6728 = 1.1831$.

For a two-sided design with early stopping to reject the null hypothesis, lower and upper α boundaries are created. The "Method Information" table in Output 80.3.2 displays the α and β errors, alternative references, and derived drift parameters, which are the standardized alternative references at the final stage.

Output 80.3.2 Method Information

Method Information

Boundary	Method	Alpha	Beta	Unified Family Rho	Unified Family Tau	Unified Family C
Upper Alpha	Pocock	0.02500	0.10000	0	0	2.36129
Lower Alpha	Pocock	0.02500	0.10000	0	0	2.36129

Method Information

Boundary	Alternative Reference	Drift
Upper Alpha	0.4	3.525869
Lower Alpha	-0.4	-3.52587

With the METHOD=POC option, the Pocock method is used for each boundary. The Pocock method is one of the unified family methods, and the table also displays its corresponding parameters $\rho = 0$ as a unified family method and the derived parameters $C = 2.3613$ for the boundary values.

With the PSS option, the "Power and Expected Sample Sizes" table in Output 80.3.3 displays powers and expected sample sizes under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and c_i are values specified in the CREF= option. By default, $c_i = 0, 0.5, 1.0, 1.5$.

Output 80.3.3 Power and Expected Sample Size Information

Powers and Expected Sample Sizes
Reference = CRef * (Alt Reference)

CRef	Power	-Sample Size- Percent Fixed-Sample
0.0000	0.02500	115.6074
0.5000	0.34252	104.0615
1.0000	0.90000	69.7480
1.5000	0.99869	43.6600

Note that at $c_i = 0$, the null reference $\theta = 0$, and the power 0.025 corresponds to the one-sided Type I error probability 0.025. At $c_i = 1$, $\theta = \theta_1$, the power 0.9 is the power of the design. The expected sample sizes are displayed in a percentage scale to its corresponding fixed-sample size design. With the specified SAMPLESIZE statement, the expected sample sizes for the specified model in the SAMPLESIZE statement are also displayed.

With the STOPPROB option, the "Expected Cumulative Stopping Probabilities" table in Output 80.3.4 displays the expected cumulative stopping stage and cumulative stopping probability to reject the null hypothesis H_0 at each stage under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and c_i are values specified in the CREF= option. By default, $c_i = 0, 0.5, 1.0, 1.5$.

Output 80.3.4 Stopping Probabilities

Expected Cumulative Stopping Probabilities
Reference = CRef * (Alt Reference)

CRef	Expected Stopping Stage	Source	--------Stopping Probabilities------- Stage_1	Stage_2	Stage_3	Stage_4
0.0000	3.908	Reject Null	0.01821	0.03155	0.04176	0.05000
0.5000	3.518	Reject Null	0.07005	0.15939	0.25242	0.34327
1.0000	2.358	Reject Null	0.27482	0.58074	0.78638	0.90002
1.5000	1.476	Reject Null	0.61145	0.92348	0.98900	0.99869

Note that at $c_i = 0$, the cumulative stopping probability to reject H_0 at the final stage is the overall Type I error probability 0.05. At $c_i = 1$, the alternative hypothesis $H_1 : \theta = \theta_1$, the cumulative stopping probability to reject H_0 includes both the probability in the lower rejection region and the probability in the upper rejection region. This stopping probability to reject H_0 at the final stage, 0.90002, is slightly

greater than the power $1-\beta = 0.90$, which corresponds to the cumulative stopping probability in the upper rejection region only. See the section "Type I and Type II Errors" on page 6746 for a detailed description of the Type II error probability β.

The "Boundary Information" table in Output 80.3.5 displays the information level, alternative references, and boundary values at each stage. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the standardized Z scale is used to display the alternative references and boundary values. The resulting standardized alternative reference at stage k is given by $\theta_1\sqrt{I_k}$, where θ_1 is the alternative reference and I_k is the information level at stage k, $k = 1, 2, 3, 4$.

Output 80.3.5 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

	Information Level			Alternative Reference	
Stage	Proportion	Actual	N	Lower	Upper
1	0.2500	19.42461	55.94288	-1.76293	1.76293
2	0.5000	38.84922	111.8858	-2.49317	2.49317
3	0.7500	58.27383	167.8286	-3.05349	3.05349
4	1.0000	77.69844	223.7715	-3.52587	3.52587

Boundary Information (Standardized Z Scale)
Null Reference = 0

	Boundary Values	
Stage	Lower Alpha	Upper Alpha
1	-2.36129	2.36129
2	-2.36129	2.36129
3	-2.36129	2.36129
4	-2.36129	2.36129

By default (or equivalently if you specify INFO=EQUAL in the DESIGN statement), equally spaced information levels are used. With the SAMPLESIZE statement, the required sample size N is also displayed under the heading "Information Level." With the Pocock method, the standardized Z boundary values are identical at all stages for each α boundary.

At each interim stage, the hypothesis of $H_0 : \theta = 0$ is rejected if the standardized normal test statistic $z \le -2.36129$, the lower α boundary, or $z \ge 2.36129$, the upper α boundary. Otherwise, the trial continues to the next stage. At the final stage, stage 4, the trial stops and the hypothesis is rejected if the test statistic $|z_4| \ge 2.36129$. Otherwise, the hypothesis is accepted.

The "Error Spending Information" in Output 80.3.6 displays cumulative error spending at each stage for each boundary. It shows that more α errors are used in early stages than in later stages.

Output 80.3.6 Error Spending Information

Error Spending Information

	-Information Level-	--------Cumulative Error Spending-------			
		-------Lower------		-------Upper------	
Stage	Proportion	Alpha	Beta	Beta	Alpha
1	0.2500	0.00911	0.00002	0.00002	0.00911
2	0.5000	0.01577	0.00002	0.00002	0.01577
3	0.7500	0.02088	0.00002	0.00002	0.02088
4	1.0000	0.02500	0.10000	0.10000	0.02500

The "Sample Size Summary" table in Output 80.3.7 displays the specified parameters for the sample size computation of the two-sample test for mean difference.

Output 80.3.7 Sample Size Summary

Sample Size Summary

Test	Two-Sample Means
Mean Difference	0.4
Standard Deviation	0.8
Max Sample Size	223.7715
Expected Sample Size (Null Ref)	218.652
Expected Sample Size (Alt Ref)	131.9167
Weight (Group A)	2
Weight (Group B)	1

The "Sample Sizes (N)" table in Output 80.3.8 displays the derived sample sizes at each stage, in both fractional and integer numbers. With the WEIGHT=2 option, the allocation ratio is 2 for the first group and 1 for the second group. See the section "Test for the Difference between Two Normal Means" on page 6773 for the derivation of these sample sizes. With the fixed-sample information ratio 1.1831, the derived sample sizes in fractional numbers are derived by multiplying 1.1831 by the corresponding sample sizes in the fixed-sample design.

Output 80.3.8 Sample Sizes

Sample Sizes (N)
Two-Sample Z Test for Mean Difference

	Fractional N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	55.94	37.30	18.65	19.4246
2	111.89	74.59	37.30	38.8492
3	167.83	111.89	55.94	58.2738
4	223.77	149.18	74.59	77.6984

Sample Sizes (N)
Two-Sample Z Test for Mean Difference

	Ceiling N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	57	38	19	19.7917
2	113	75	38	39.4082
3	168	112	56	58.3333
4	225	150	75	78.1250

These fractional sample sizes are rounded up to integers under the heading "Ceiling N." When the resulting integer sample sizes are used, the corresponding information levels are slightly larger than the levels from the design. This can increase the power slightly if a trial uses these integer sample sizes.

Note that compared with other designs, a Pocock design can stop the trial early with a larger p-value. However, this might not be persuasive enough to make a new treatment widely accepted (Pocock and White, 1999).

The "Design Information" table in Output 80.3.9 displays design specifications and the derived statistics for the O'Brien-Fleming design. With the specified ALTREF= option, the maximum information $I_X = 67.1268$ is derived.

Output 80.3.9 O'Brien-Fleming Design Information

The SEQDESIGN Procedure
Design: TwoSidedOBrienFleming

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Reject Null
Method	O'Brien-Fleming
Boundary Key	Both
Alternative Reference	0.4
Number of Stages	4
Alpha	0.05
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	102.2163
Max Information	67.12682
Null Ref ASN (Percent of Fixed Sample)	101.5728
Alt Ref ASN (Percent of Fixed Sample)	76.7397

With the corresponding fixed-sample information

$$I_0 = \frac{(\Phi^{-1}(1-\alpha/2) + \Phi^{-1}(1-\beta))^2}{0.4^2} = \frac{(1.96 + 1.28155)^2}{0.16} = 65.6728$$

the fixed-sample information ratio is $67.1268/65.6728 = 1.022$. That is, the maximum information for the O'Brien-Fleming design is only 2.2% more than for the corresponding fixed-sample design.

The "Method Information" table in Output 80.3.10 displays the Type I α level and Type II β level. It also displays the derived drift parameter $\theta_1\sqrt{I_X}$, which is the standardized alternative reference at the final stage.

Output 80.3.10 Method Information

Method Information

				Unified Family		
Boundary	Method	Alpha	Beta	Rho	Tau	C
Upper Alpha	O'Brien-Fleming	0.02500	0.10000	0.5	0	2.02429
Lower Alpha	O'Brien-Fleming	0.02500	0.10000	0.5	0	2.02429

Method Information

Boundary	Alternative Reference	Drift
Upper Alpha	0.4	3.277238
Lower Alpha	-0.4	-3.27724

With the METHOD=OBF option, the O'Brien-Fleming method is used for each boundary. The O'Brien-Fleming method is one of the unified family methods, and the table also displays its corresponding parameters $\rho = 0.5$ as a unified family method and the derived parameter $C = 2.0243$ for the boundary values.

With the PSS option, the "Power and Expected Sample Sizes" table in Output 80.3.11 displays powers and expected sample sizes under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and c_i are values specified in the CREF= option.

Output 80.3.11 Power and Expected Sample Size Information

Powers and Expected Sample Sizes
Reference = CRef * (Alt Reference)

CRef	Power	-Sample Size- Percent Fixed-Sample
0.0000	0.02500	101.5728
0.5000	0.36495	96.3684
1.0000	0.90000	76.7397
1.5000	0.99821	57.2590

Compared with the corresponding Pocock design, the O'Brien-Fleming design has a smaller maximum sample size, and smaller expected sample sizes under hypothetical references $\theta = 0$ and $\theta = 0.5\theta_1$, but larger expected sample sizes under hypothetical references $\theta = \theta_1$ and $\theta = 1.5\theta_1$.

With the STOPPROB option, the "Expected Cumulative Stopping Probabilities" table in Output 80.3.12 displays the expected stopping stage and cumulative stopping probability to reject the null hypothesis at each stage under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and c_i are values specified in the CREF= option.

Output 80.3.12 Stopping Probabilities

Expected Cumulative Stopping Probabilities
Reference = CRef * (Alt Reference)

CRef	Expected Stopping Stage	Source	--------Stopping Probabilities------- Stage_1	Stage_2	Stage_3	Stage_4
0.0000	3.975	Reject Null	0.00005	0.00422	0.02091	0.05000
0.5000	3.771	Reject Null	0.00062	0.04430	0.18392	0.36515
1.0000	3.003	Reject Null	0.00798	0.29296	0.69603	0.90000
1.5000	2.241	Reject Null	0.05584	0.73031	0.97315	0.99821

Compared with the corresponding Pocock design, the O'Brien-Fleming design has smaller stopping probabilities in early stages under each hypothetical reference.

The "Boundary Information" table in Output 80.3.13 displays the boundary values for the design that uses the O'Brien-Fleming method. Compared with the Pocock method, the standardized statistics α boundary values derived from the O'Brien-Fleming method in absolute values are larger in early stages and smaller in

later stages. This makes the O'Brien-Fleming design less likely to reject the null hypothesis in early stages than the Pocock design. With the derived parameter $C = 2.0243$ for the α boundary, the α boundaries at stage j are computed as $C\sqrt{4/j}$, $j = 1, \ldots, 4$.

Output 80.3.13 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

	Information Level			Alternative Reference	
Stage	Proportion	Actual	N	Lower	Upper
1	0.2500	16.7817	48.33131	-1.63862	1.63862
2	0.5000	33.56341	96.66262	-2.31736	2.31736
3	0.7500	50.34511	144.9939	-2.83817	2.83817
4	1.0000	67.12682	193.3252	-3.27724	3.27724

Boundary Information (Standardized Z Scale)
Null Reference = 0

	Boundary Values	
	Lower	Upper
Stage	Alpha	Alpha
1	-4.04859	4.04859
2	-2.86278	2.86278
3	-2.33745	2.33745
4	-2.02429	2.02429

The "Error Spending Information" in Output 80.3.14 displays cumulative error spending at each stage for each boundary. With smaller α spending in early stages for the O'Brien-Fleming method, it also indicates that the O'Brien-Fleming design is less likely to reject the null hypothesis in early stages than the Pocock design.

Output 80.3.14 Error Spending Information

Error Spending Information

	Information Level	Cumulative Error Spending			
		Lower		Upper	
Stage	Proportion	Alpha	Beta	Beta	Alpha
1	0.2500	0.00003	0.00000	0.00000	0.00003
2	0.5000	0.00211	0.00000	0.00000	0.00211
3	0.7500	0.01046	0.00000	0.00000	0.01046
4	1.0000	0.02500	0.10000	0.10000	0.02500

The "Sample Size Summary" table in Output 80.3.15 displays the specified parameters for the sample size computation of the two-sample test for mean difference.

Output 80.3.15 Sample Size Summary

Sample Size Summary

Test	Two-Sample Means
Mean Difference	0.4
Standard Deviation	0.8
Max Sample Size	193.3252
Expected Sample Size (Null Ref)	192.1081
Expected Sample Size (Alt Ref)	145.1404
Weight (Group A)	2
Weight (Group B)	1

The "Sample Sizes (N)" table in Output 80.3.16 displays the derived sample sizes at each stage, in both fractional and integer numbers. With the fixed-sample information ratio 1.0222, the required sample sizes in fractional numbers are derived by multiplying 1.0222 by the corresponding sample sizes in the fixed-sample design.

Output 80.3.16 Derived Sample Sizes

Sample Sizes (N)
Two-Sample Z Test for Mean Difference

	Fractional N			
Stage	N	N(Grp 1)	N(Grp 2)	Information

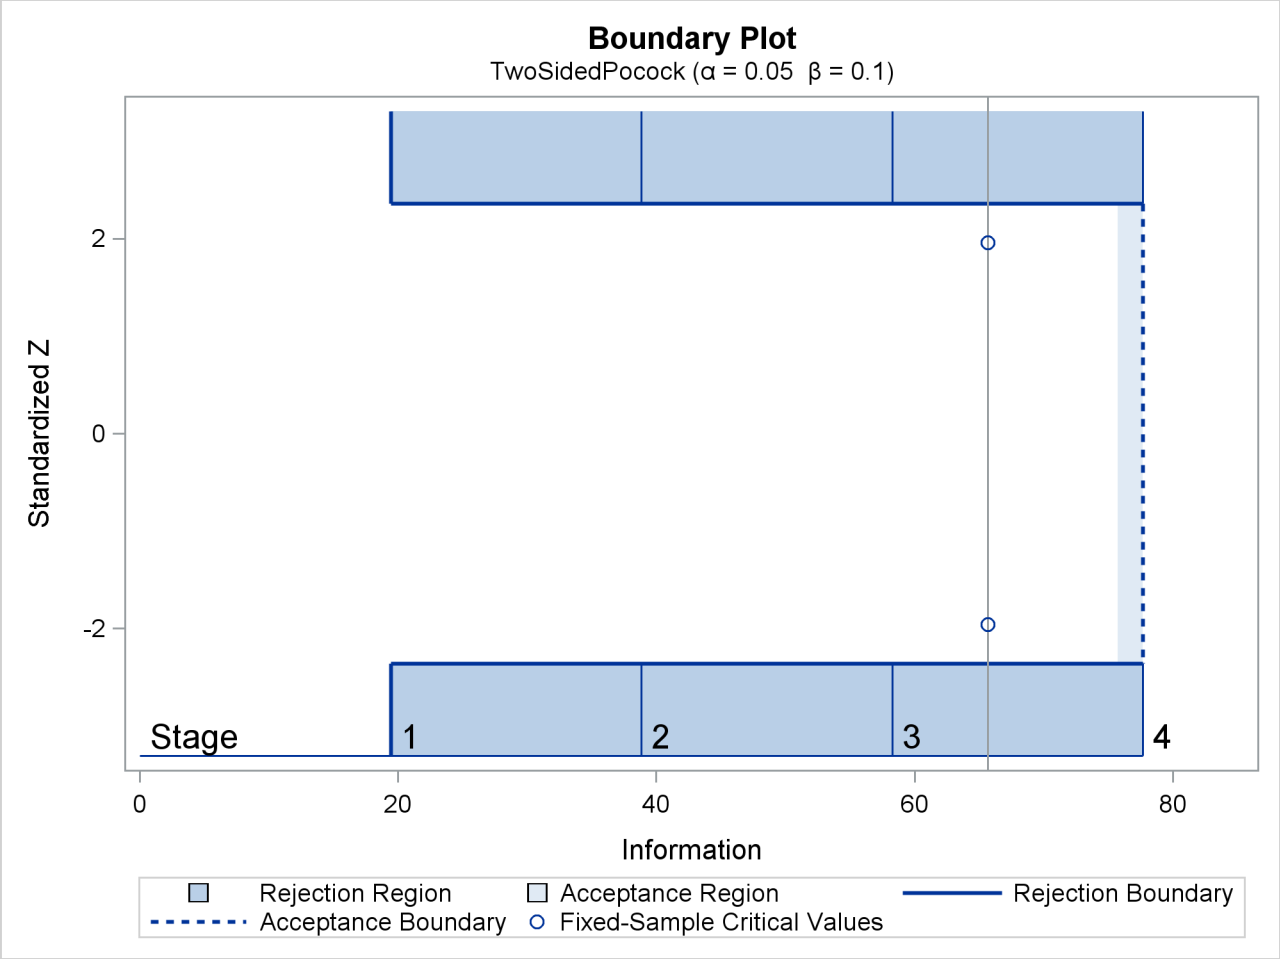
Example 80.4: Generating Graphics Display for Sequential Designs

This example creates the same group sequential design as in Example 80.3 and creates graphics by using ODS Graphics. The following statements request all available graphs in the SEQDESIGN procedure:

```
ods graphics on;
proc seqdesign altref=0.4
               plots=all
               ;
   TwoSidedPocock:        design nstages=4 method=poc;
   TwoSidedOBrienFleming: design nstages=4 method=obf;
run;
ods graphics off;
```

With the PLOTS=ALL option, a detailed boundary plot with the rejection region and acceptance region is displayed for the Pocock design, as shown in Output 80.4.1. By default (or equivalently if you specify STOP=REJECT), the rejection boundaries are also generated at interim stages.

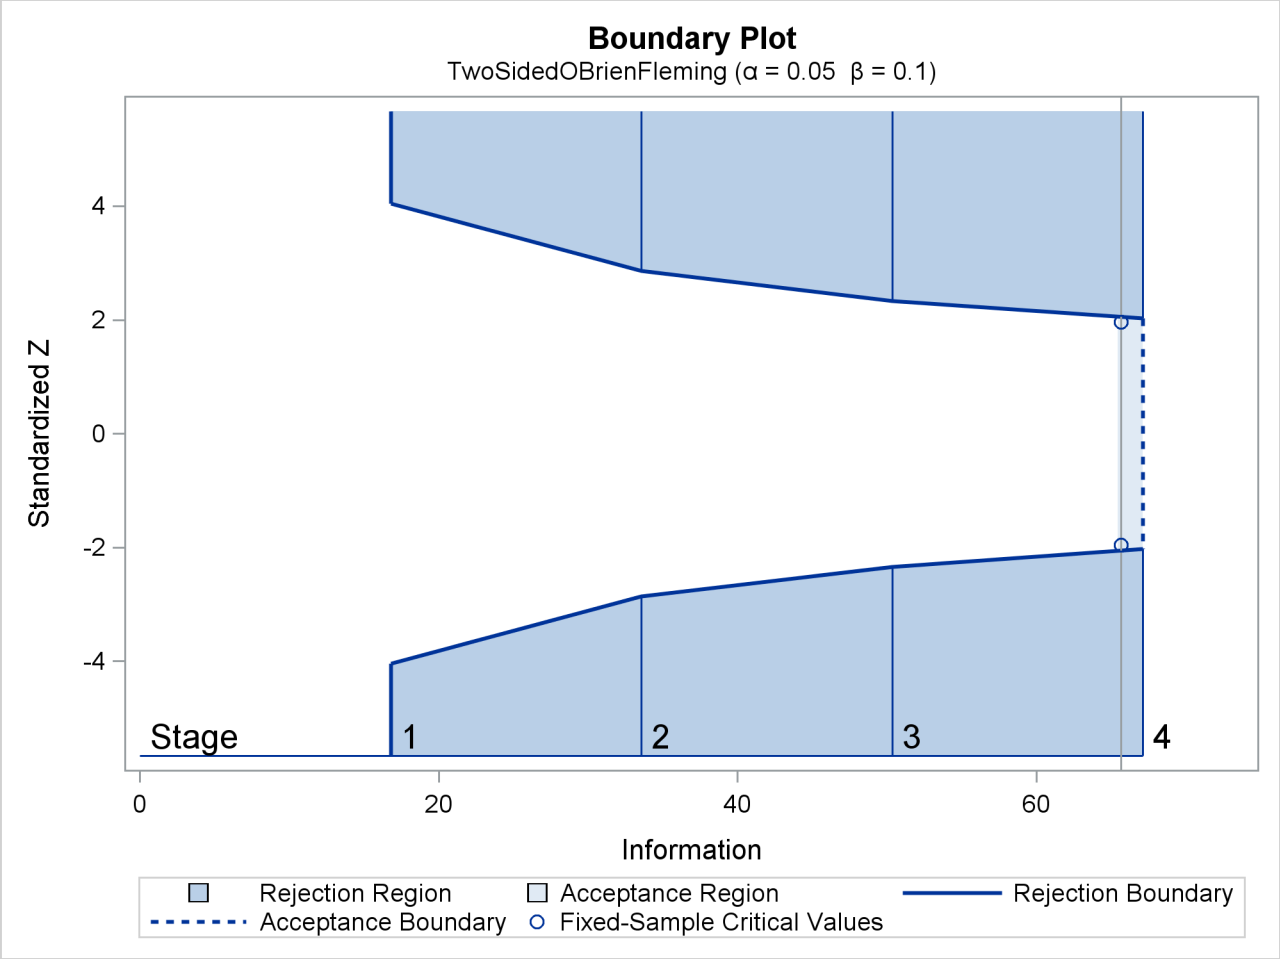
Output 80.4.1 Pocock Boundary Plot



The plot shows identical boundary values in each boundary in the standardized Z scale for the Pocock design. The information level and critical value for the corresponding fixed-sample design are also displayed.

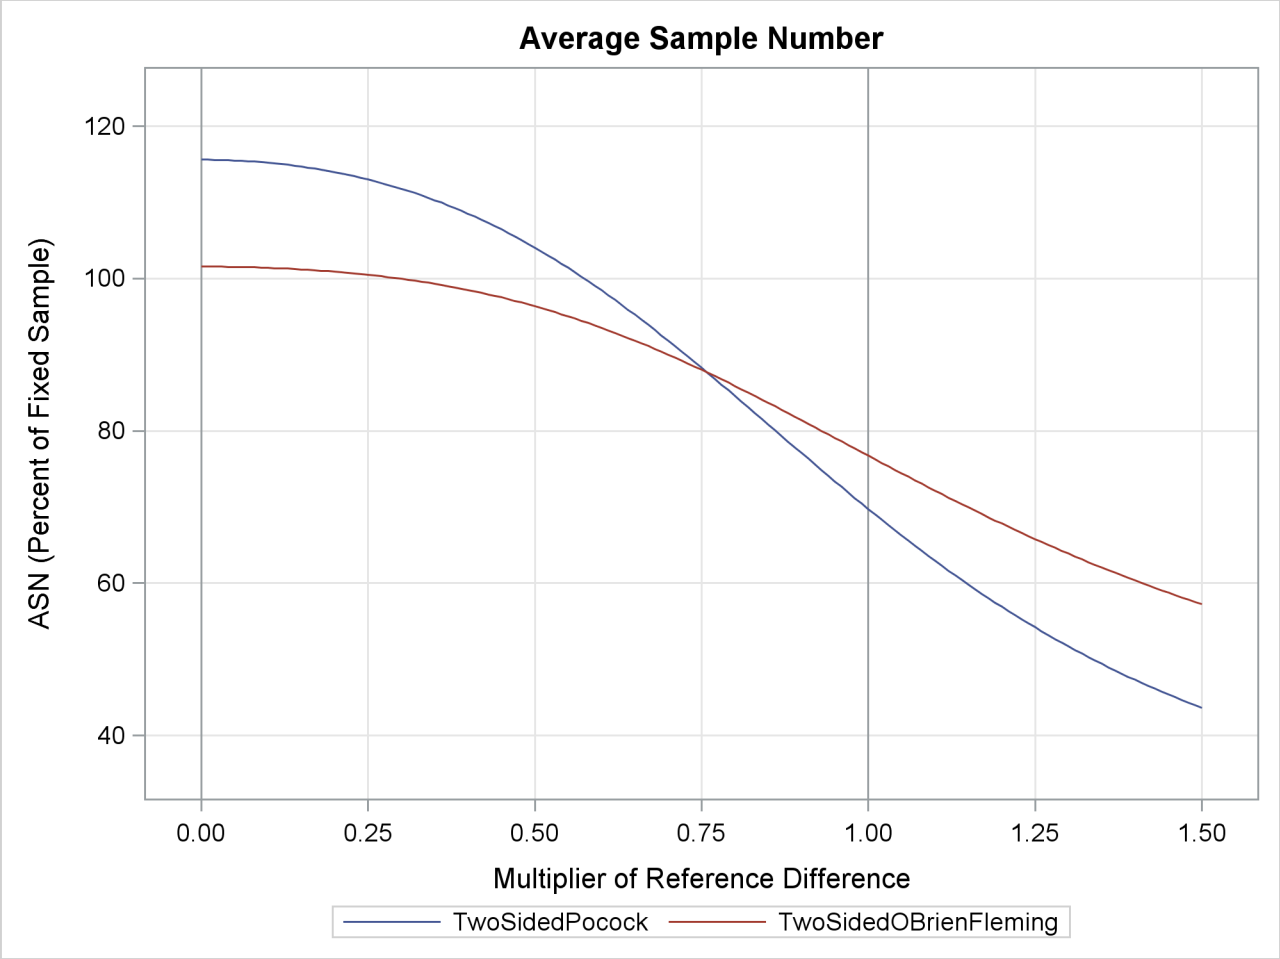
With the PLOTS=ALL option, a detailed boundary plot with the rejection region and acceptance region is also displayed for the O'Brien-Fleming design, as shown in Output 80.4.2. The plot shows that the rejection boundary values are decreasing as the trial advances in the standardized Z scale.

Output 80.4.2 O'Brien-Fleming Boundary Plot



With the PLOTS=ALL option, the procedure displays a plot of average sample numbers (expected sample sizes for nonsurvival data or expected numbers of events for survival data) under various hypothetical references for all designs simultaneously, as shown in Output 80.4.3. By default, the option CREF= $0, 0.01, 0.02, \ldots, 1.50$ and expected sample sizes under the hypothetical references $\theta = c_i\ \theta_1$ are displayed, where c_i are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

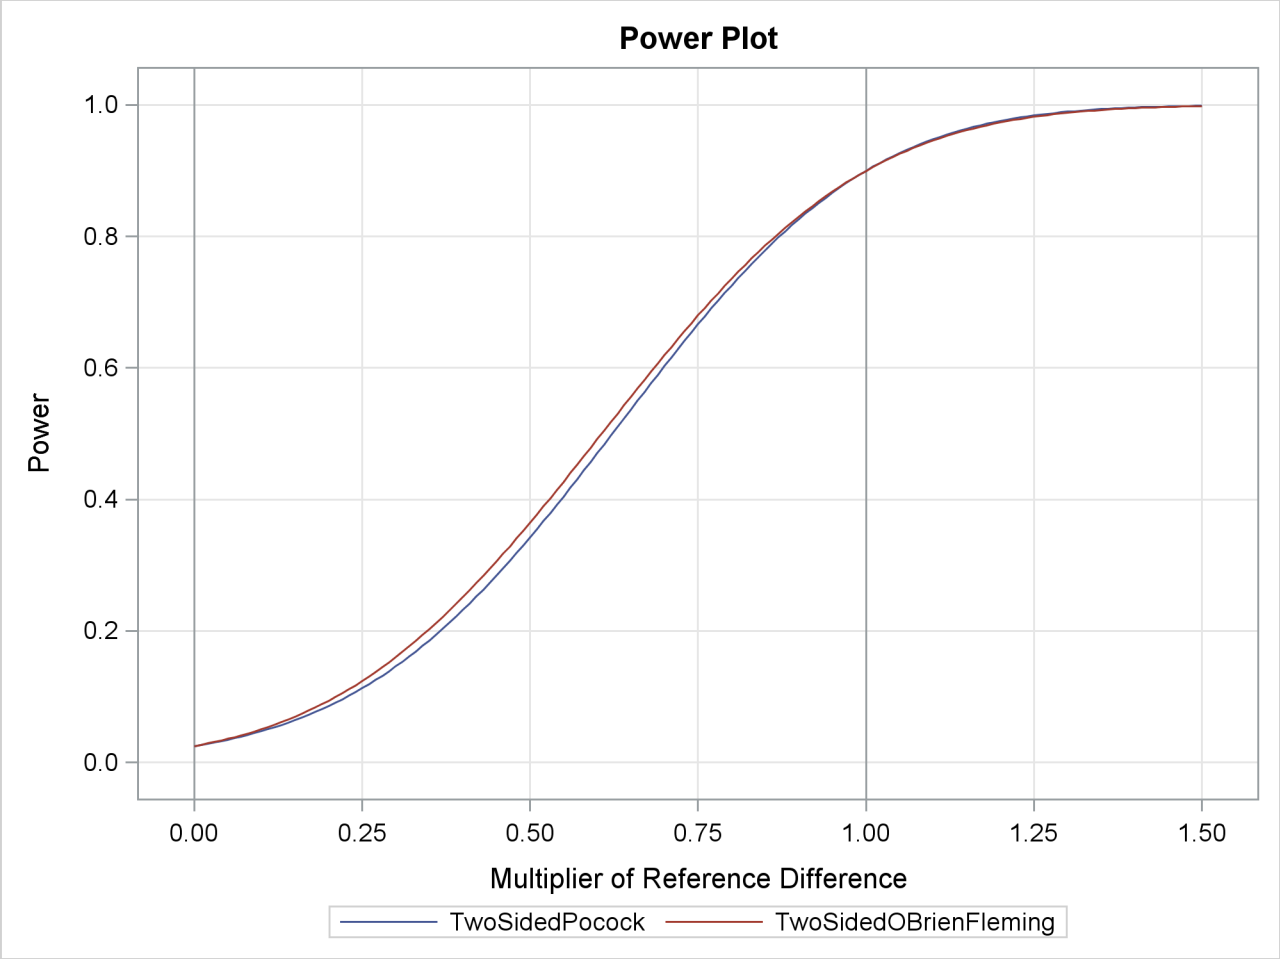
Output 80.4.3 ASN Plot



The plot shows that the Pocock design has a larger expected sample size than the O'Brien-Fleming design under the null hypothesis ($c_i = 0$) and has a smaller expected sample size under the alternative hypothesis ($c_i = 1$).

With the PLOTS=ALL option, the procedure displays a plot of the power curves under various hypothetical references for all designs simultaneously, as shown in Output 80.4.4. By default, the option CREF= $0, 0.01, 0.02, \ldots, 1.50$ and powers under hypothetical references $\theta = c_i\,\theta_1$ are displayed, where c_i are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

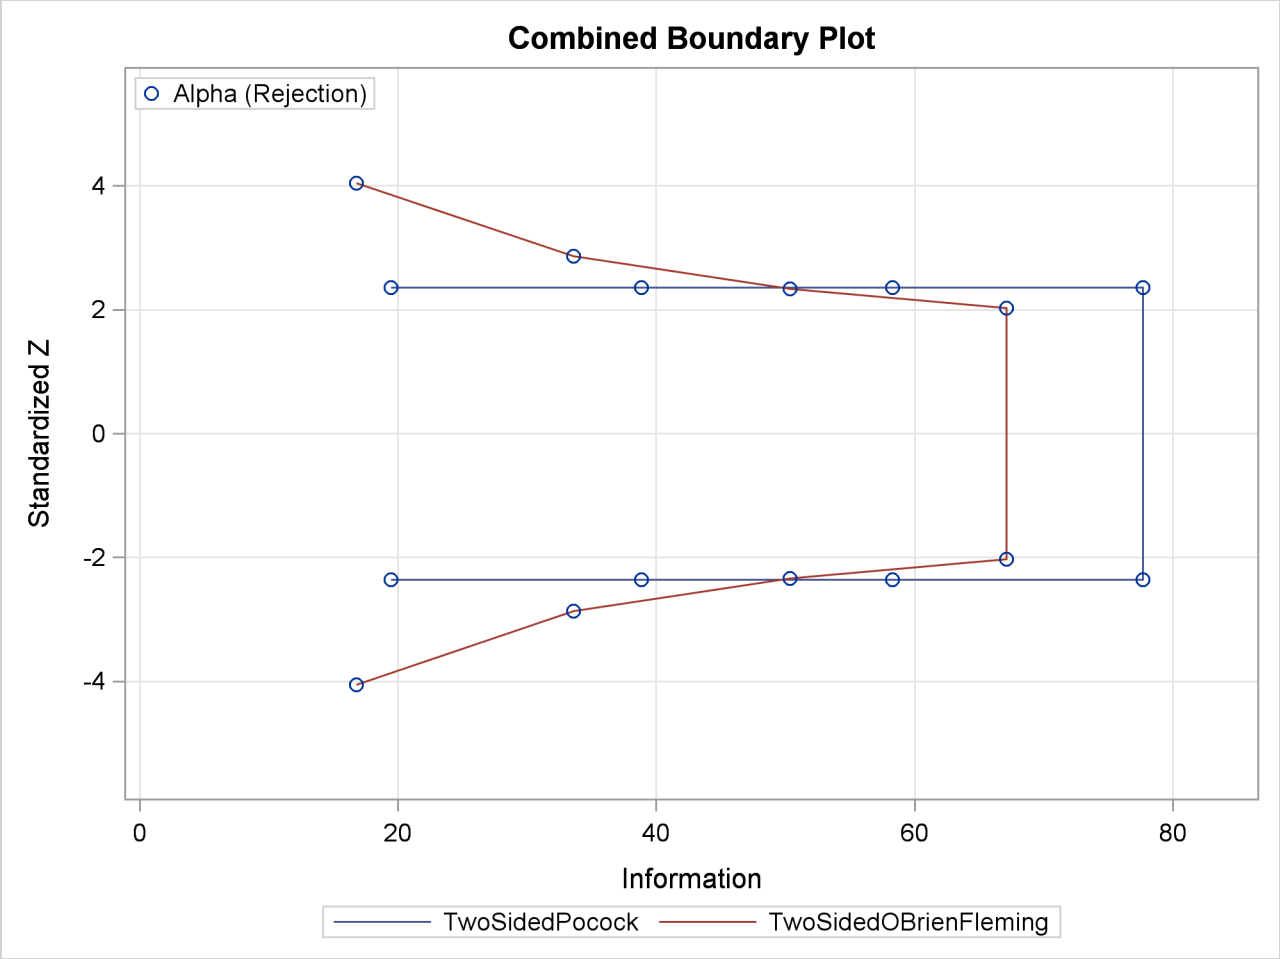
Output 80.4.4 Power Plot



Under the null hypothesis, $c_i = 0$, the power is 0.025, the upper Type I error probability. Under the alternative hypothesis, $c_i = 1$, the power is 0.9, one minus the Type II error probability. The plot shows only minor difference between the two designs.

With the PLOTS=ALL option, the procedure displays a plot of sequential boundaries for all designs simultaneously, as shown in Output 80.4.5. By default (or equivalently if you specify HSCALE=INFO in the COMBINEDBOUNDARY option), the information levels are used on the horizontal axis.

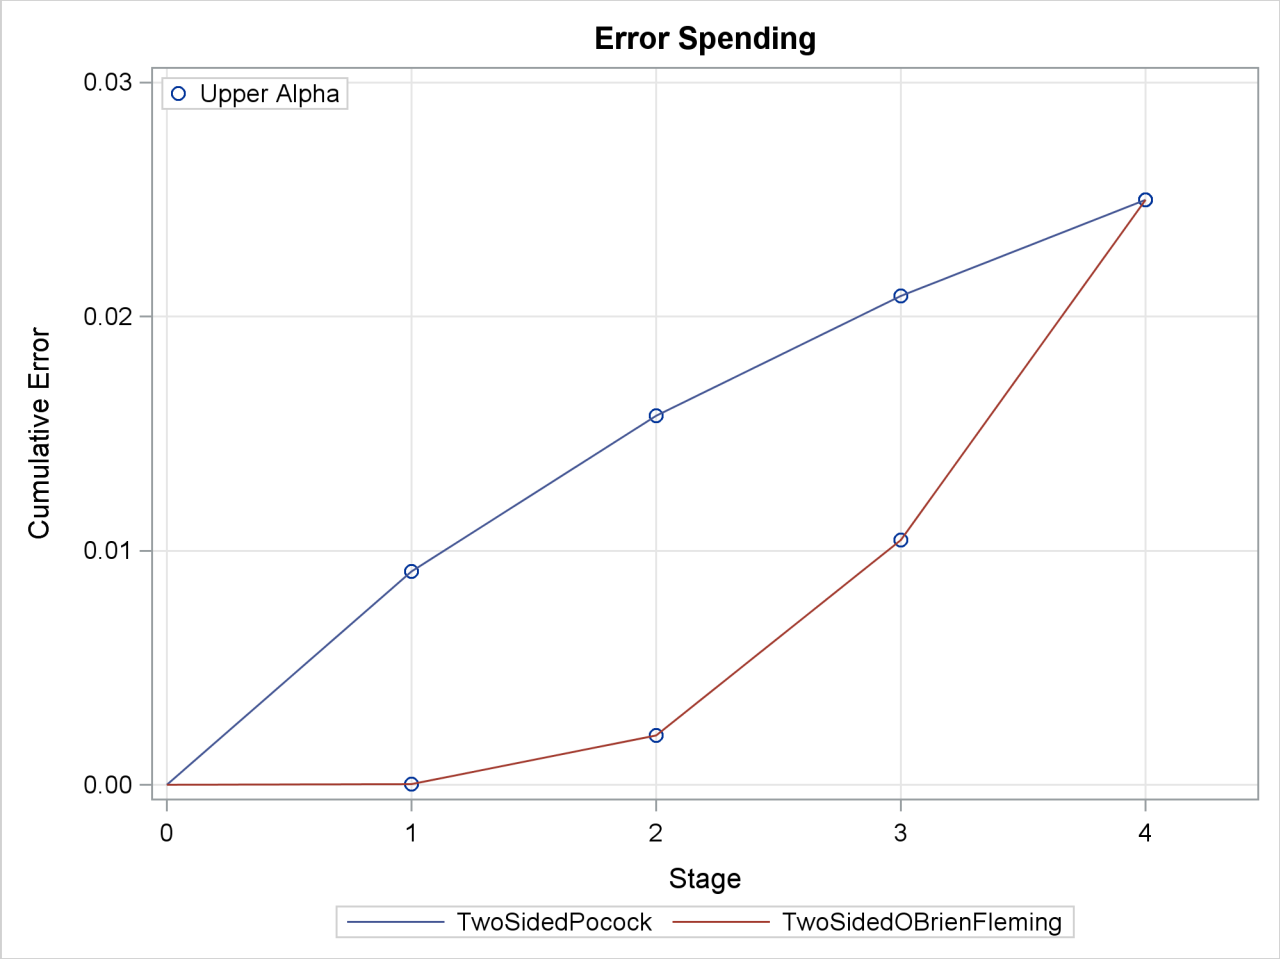
Output 80.4.5 Combined Boundary Plot



The plot shows that the α boundary values (in absolute value) created from the O'Brien-Fleming method are greater in early stages and smaller in later stages than the boundary values from the Pocock method. The plot also shows that the information level in the Pocock design is larger than the corresponding level in the O'Brien-Fleming design at each stage.

With the PLOTS=ALL option, the procedure displays a plot of cumulative error spends for all boundaries in the designs simultaneously, as shown in Output 80.4.6. With a symmetric two-sided design, cumulative error spending is displayed only for the upper α boundary. The plot shows that for the upper α boundary, the O'Brien-Fleming method spends fewer errors in early stages and more errors in later stages than the corresponding Pocock method.

Output 80.4.6 Error Spending Plot



Example 80.5: Creating Designs Using Haybittle-Peto Methods

This example requests two 3-stage group sequential designs for normally distributed statistics. Each design uses a Haybittle-Peto method with a two-sided alternative and early stopping to reject the hypothesis. One design uses the specified interim boundary Z values and derives the final-stage boundary value for the specified α and β errors. The other design uses the specified boundary Z values and derives the overall α and β errors.

The following statements specify the interim boundary Z values and derive the final-stage boundary value for the specified $\alpha = 0.05$ and $\beta = 0.10$:

```
ods graphics on;
proc seqdesign altref=0.25
               errspend
               stopprob
               plots=errspend
               ;
   OneSidedPeto: design nstages=3
```

```
                  method=peto( z=3)
                  alt=upper   stop=reject
                  alpha=0.05  beta=0.10;
run;
ods graphics off;
```

The "Design Information" table in Output 80.5.1 displays design specifications and maximum information in percentage of its corresponding fixed-sample design.

Output 80.5.1 Haybittle-Peto Design Information

The SEQDESIGN Procedure
Design: OneSidedPeto

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Upper
Early Stop	Reject Null
Method	Haybittle-Peto
Boundary Key	Both
Alternative Reference	0.25
Number of Stages	3
Alpha	0.05
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	100.2466
Max Information	137.3592
Null Ref ASN (Percent of Fixed Sample)	100.1192
Alt Ref ASN (Percent of Fixed Sample)	87.35

The "Method Information" table in Output 80.5.2 displays the α and β errors and the derived drift parameter, which is the standardized alternative reference at the final stage.

Output 80.5.2 Method Information

Method Information

Boundary	Method	Alpha	Beta	Alternative Reference	Drift
Upper Alpha	Haybittle-Peto	0.05000	0.10000	0.25	2.930009

With the STOPPROB option, the "Expected Cumulative Stopping Probabilities" table in Output 80.5.3 displays the expected stopping stage and cumulative stopping probability to reject the null hypothesis at each stage under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and $c_i = 0, 0.5, 1, 1.5$ are the default values in the CREF= option.

Output 80.5.3 Stopping Probabilities

Expected Cumulative Stopping Probabilities
Reference = CRef * (Alt Reference)

CRef	Expected Stopping Stage	Source	----Stopping Probabilities--- Stage_1	Stage_2	Stage_3
0.0000	2.996	Reject Null	0.00135	0.00246	0.05000
0.5000	2.941	Reject Null	0.01561	0.04372	0.42762
1.0000	2.614	Reject Null	0.09538	0.29057	0.90000
1.5000	1.944	Reject Null	0.32185	0.73442	0.99698

The "Boundary Information" table in Output 80.5.4 displays information level, alternative references, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the standardized Z scale is used to display the alternative references and boundary values. The resulting standardized alternative reference at stage k is given by $\theta_1\sqrt{I_k}$, where θ_1 is the alternative reference and I_k is the information level at stage k, $k = 1, 2, 3$.

Output 80.5.4 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

Stage	---Information Level-- Proportion	Actual	-Alternative- --Reference-- Upper	-Boundary Values- ------Upper------ Alpha
1	0.3333	45.7864	1.69164	3.00000
2	0.6667	91.57281	2.39234	3.00000
3	1.0000	137.3592	2.93001	1.65042

At each interim stage, if the standardized statistic $z \geq 3$, the trial is stopped and the null hypothesis is rejected. If the statistic $z < 3$, the trial continues to the next stage. At the final stage, the null hypothesis is rejected if the statistic $z_3 > 1.65$. Otherwise, the hypothesis is accepted. Note that the boundary values at the final stage, 1.65, are close to the critical values 1.645 in the corresponding fixed-sample design.

The "Error Spending Information" in Output 80.5.5 displays cumulative error spending at each stage for each boundary. The stage 1 α spending 0.00135 corresponds to the one-sided p-value for a standardized Z statistic, $Z > 3$.

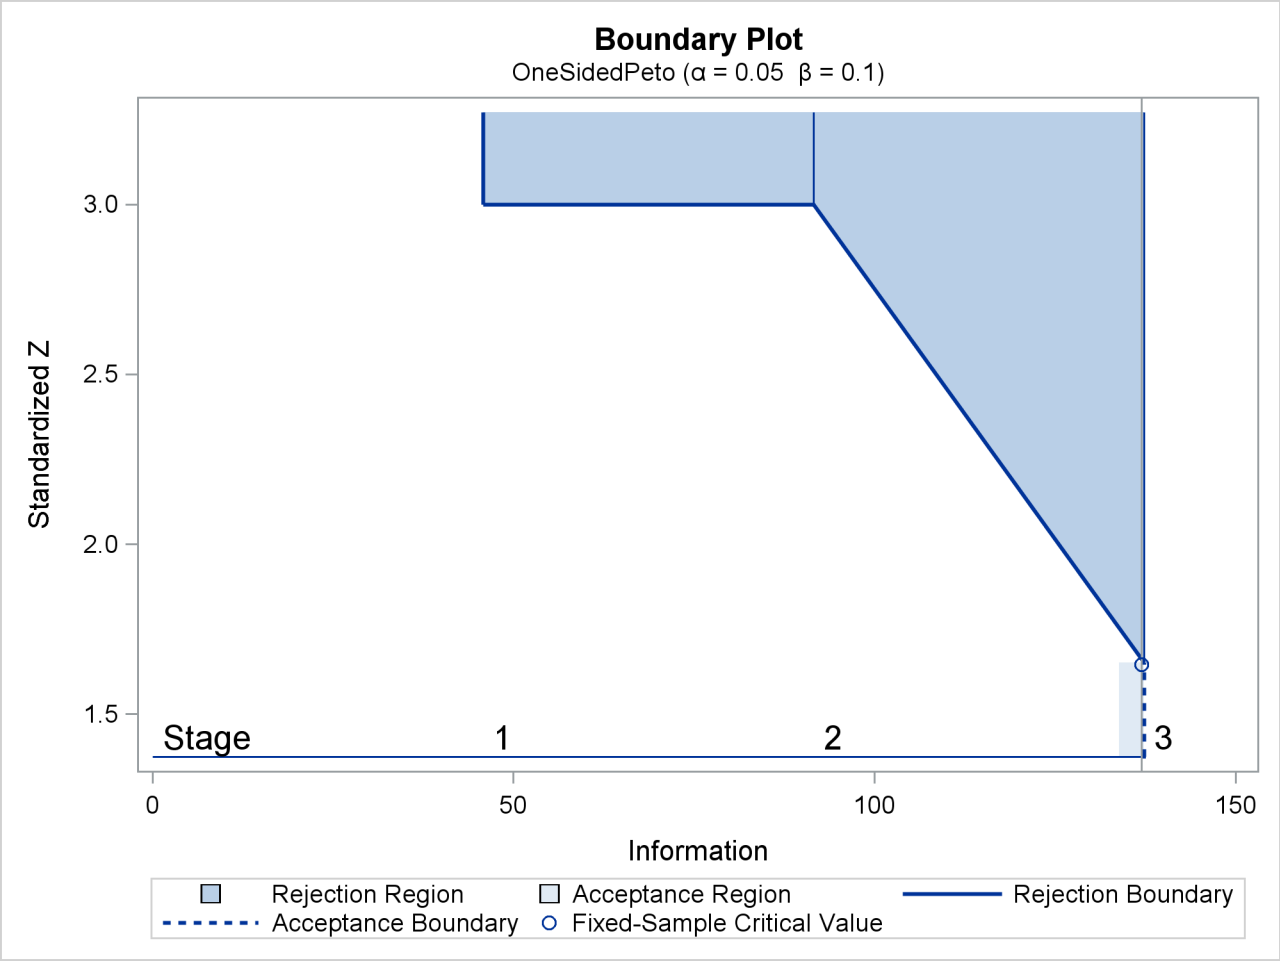
Output 80.5.5 Error Spending Information

Error Spending Information

Stage	-Information Level- Proportion	-Cumulative Error Spending- ----------Upper---------- Beta	Alpha
1	0.3333	0.00000	0.00135
2	0.6667	0.00000	0.00246
3	1.0000	0.10000	0.05000

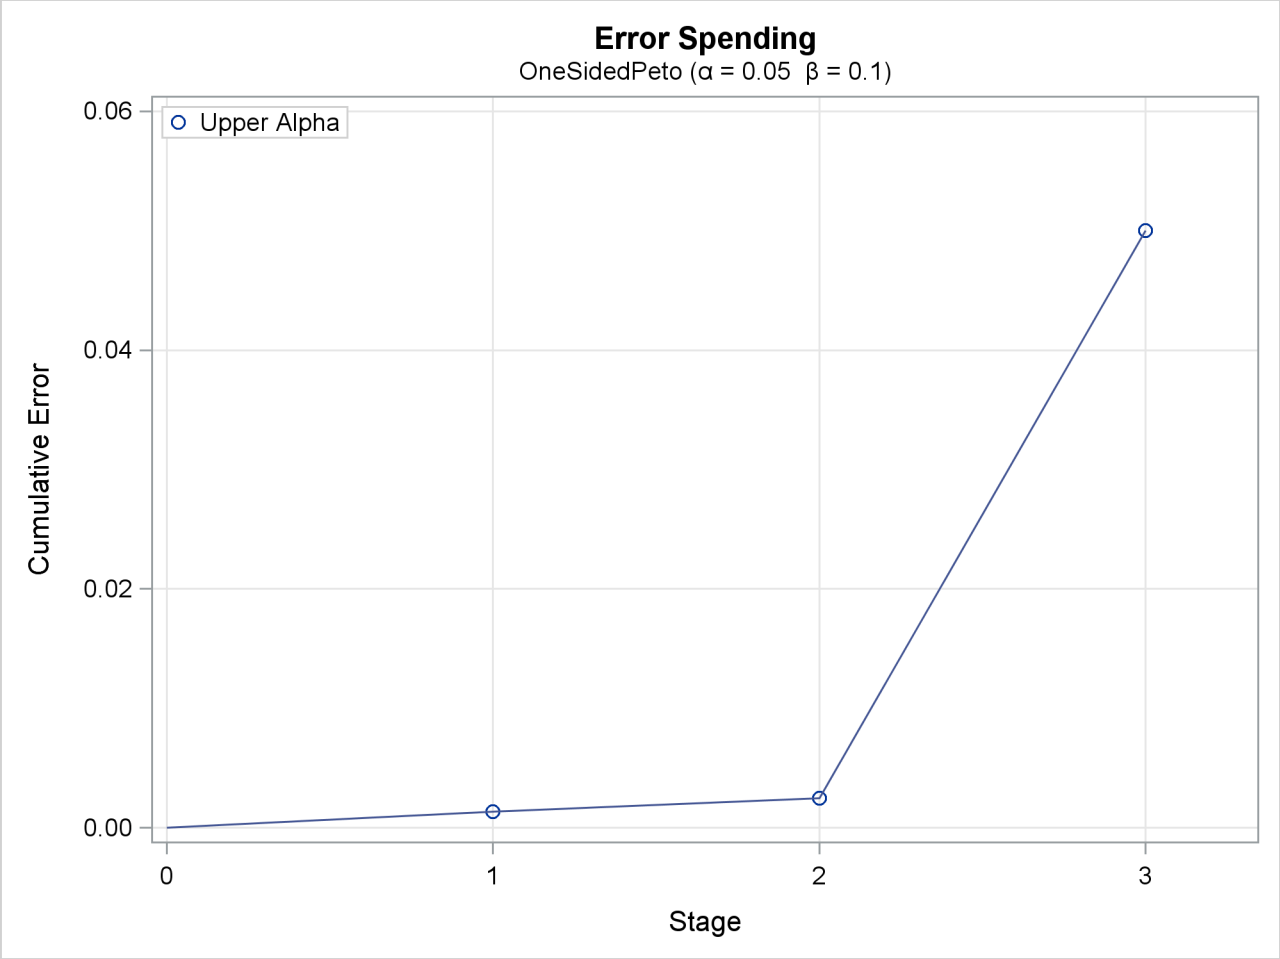
With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.5.6. With the STOP=REJECT option, the interim rejection boundaries are displayed.

Output 80.5.6 Boundary Plot



With the PLOTS=ERRSPEND option, the procedure displays a plot of error spending for each boundary, as shown in Output 80.5.7. The error spending values in the "Error Spending Information" in Output 80.5.4 are displayed in the plot. As expected, the error spending at each of the first two stages is small, with the standardized Z boundary value 3.

Output 80.5.7 Error Spending Plot



The following statements specify the boundary Z values and derive the α and β errors from these completely specified boundary values:

```
ods graphics on;
proc seqdesign altref=0.25
               maxinfo=200
               errspend
               stopprob
               plots=errspend
               ;
   OneSidedPeto: design nstages=3
                 method=peto(z=3 2.5 2)
                 alt=upper  stop=reject
                 boundarykey=none
                 ;
run;
ods graphics off;
```

The "Design Information" table in Output 80.5.8 displays design specifications and derived α and β error levels.

Output 80.5.8 Design Information

The SEQDESIGN Procedure
Design: OneSidedPeto

3	1.0000	200	3.53553	2.00000

The "Error Spending Information" in Output 80.5.12 displays cumulative error spending at each stage for each boundary. The first-stage α spending 0.00135 corresponds to the one-sided p-value for a standardized Z statistic, $Z > 3$.

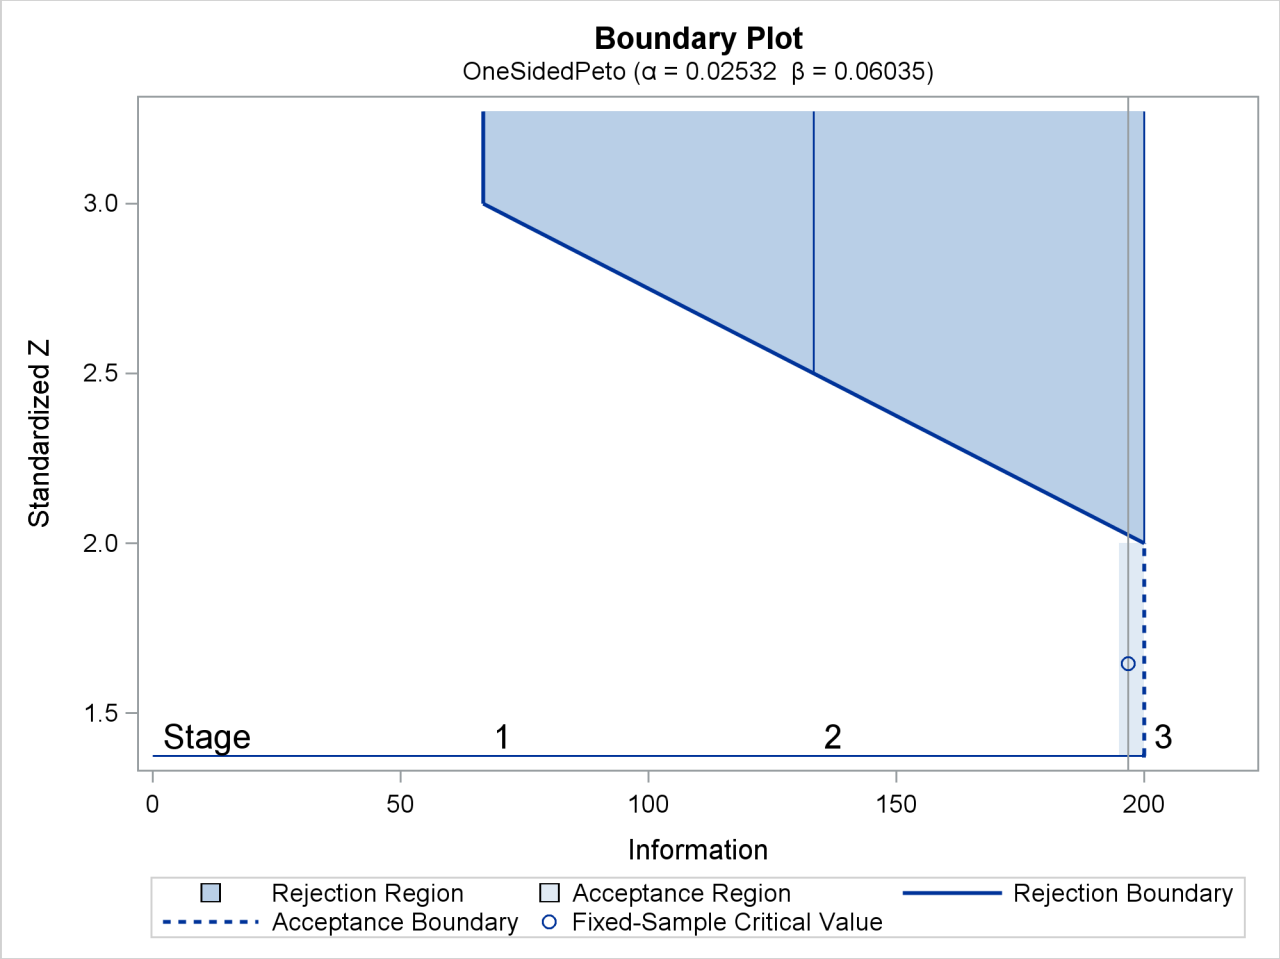
Output 80.5.12 Error Spending Information

Error Spending Information

Stage	Information Level Proportion	Cumulative Error Spending Upper Beta	Cumulative Error Spending Upper Alpha
1	0.3333	0.00000	0.00135
2	0.6667	0.00000	0.00702
3	1.0000	0.06035	0.02532

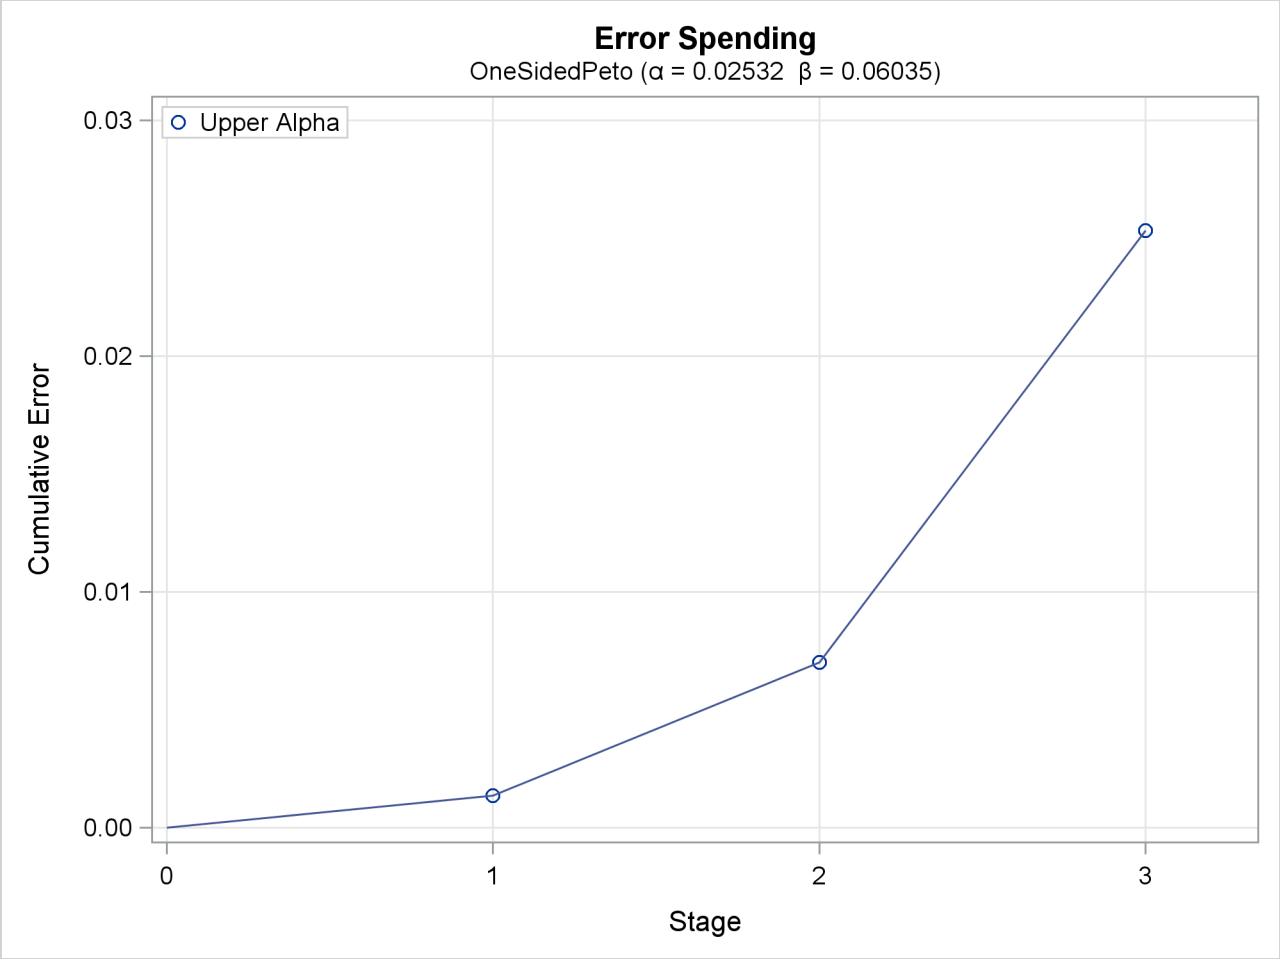
With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.5.13. With the STOP=REJECT option, the interim rejection boundaries are displayed.

Output 80.5.13 Boundary Plot



With the PLOTS=ERRSPEND option, the procedure displays a plot of error spending for each boundary, as shown in Output 80.5.14. The error spending values in the "Error Spending Information" table in Output 80.5.10 are displayed in the plot.

Output 80.5.14 Error Spending Plot



Example 80.6: Creating Designs with Various Stopping Criteria

This example requests three 5-stage group sequential designs for normally distributed statistics. Each design uses a triangular method with the specified one-sided upper alternative reference $\theta_1 = 0.2$. The resulting boundary values are displayed with the score scale. Note that these unified family triangular designs are different from Whitehead's triangular designs.

The following statements request three designs with different stopping criterion:

```
ods graphics on;
proc seqdesign altref=0.2
               bscale=score
               errspend
               plots=(combinedboundary errspend(hscale=info))
               ;
   StopToRejectAccept: design nstages=5 method=tri alt=upper stop=both;
   StopToReject:       design nstages=5 method=tri alt=upper stop=reject;
   StopToAccept:       design nstages=5 method=tri alt=upper stop=accept;
run;
ods graphics off;
```

The first design has early stopping to reject or accept the null hypothesis H_0.

The "Design Information" table in Output 80.6.1 displays design specifications and derived statistics. With the specified alternative reference, the maximum information is derived.

Output 80.6.1 Triangular Design Information

The SEQDESIGN Procedure
Design: StopToRejectAccept

Design Information

Statistic Distribution	Normal
Boundary Scale	Score
Alternative Hypothesis	Upper
Early Stop	Accept/Reject Null
Method	Triangular
Boundary Key	Both
Alternative Reference	0.2

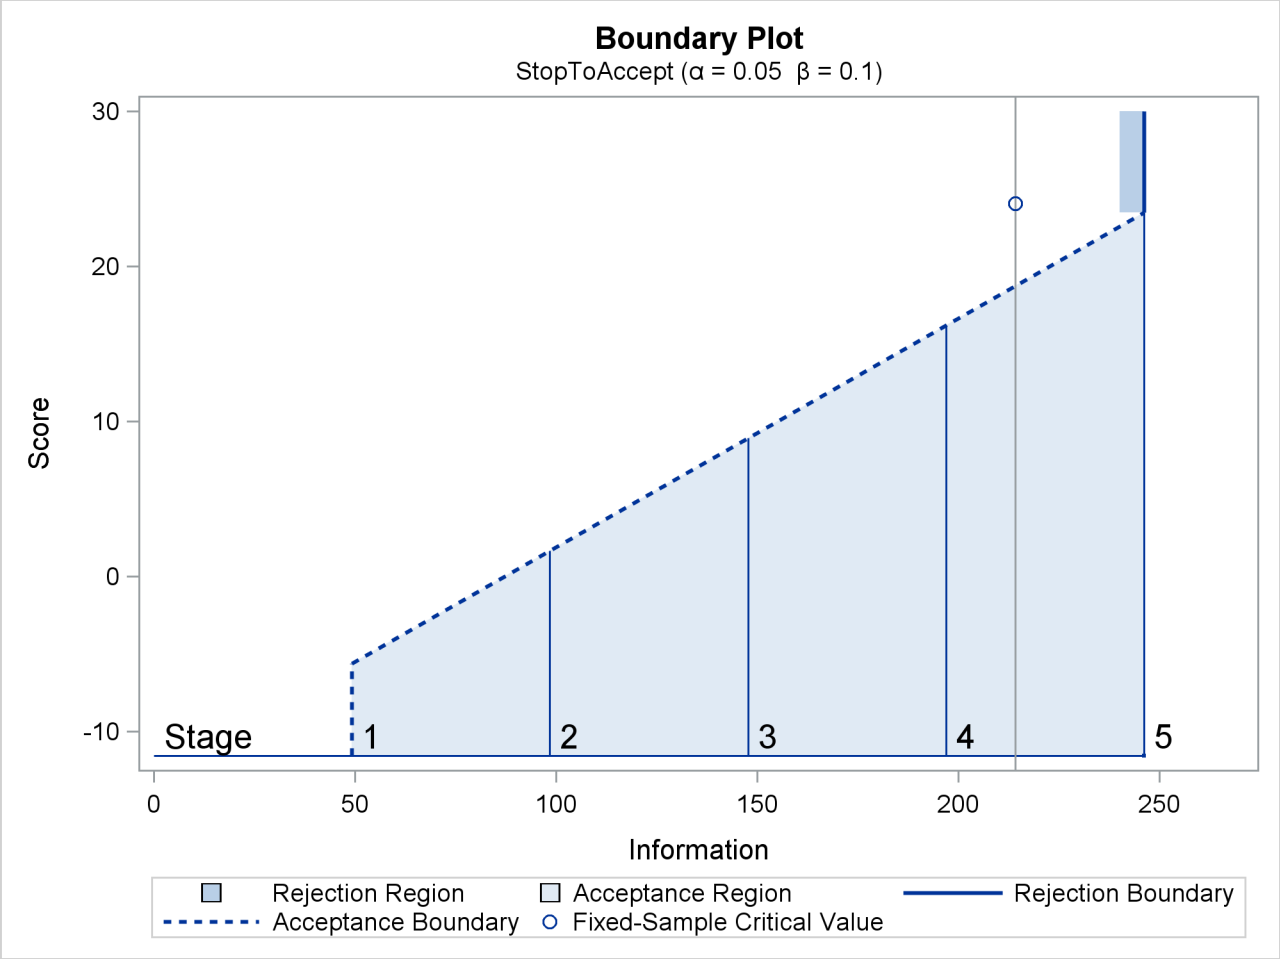
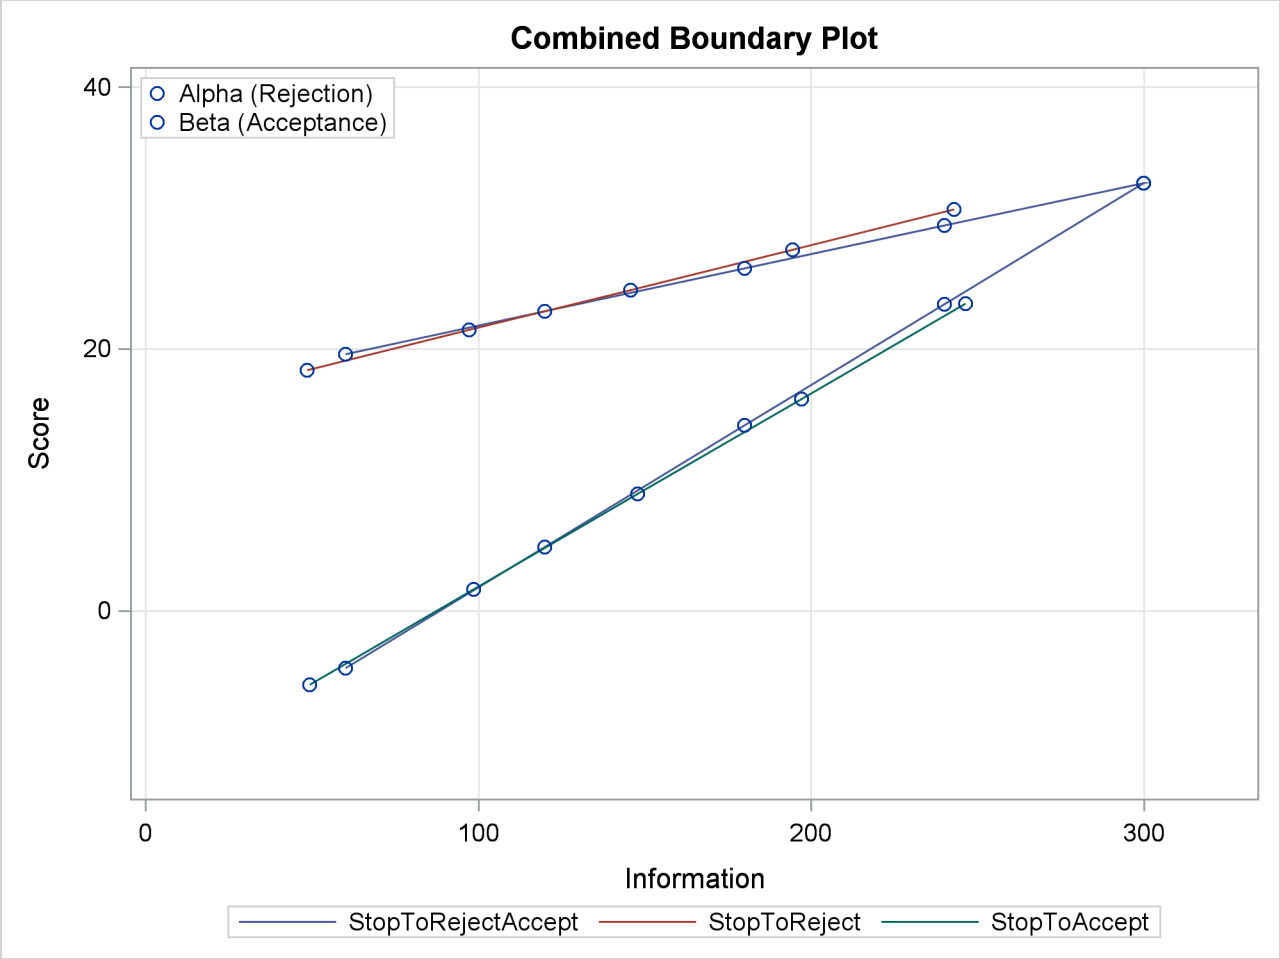
With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.6.15. For a triangular design, these rejection boundaries form a straight line with the score scale.

Output 80.6.15 Boundary Plot with Score Scale



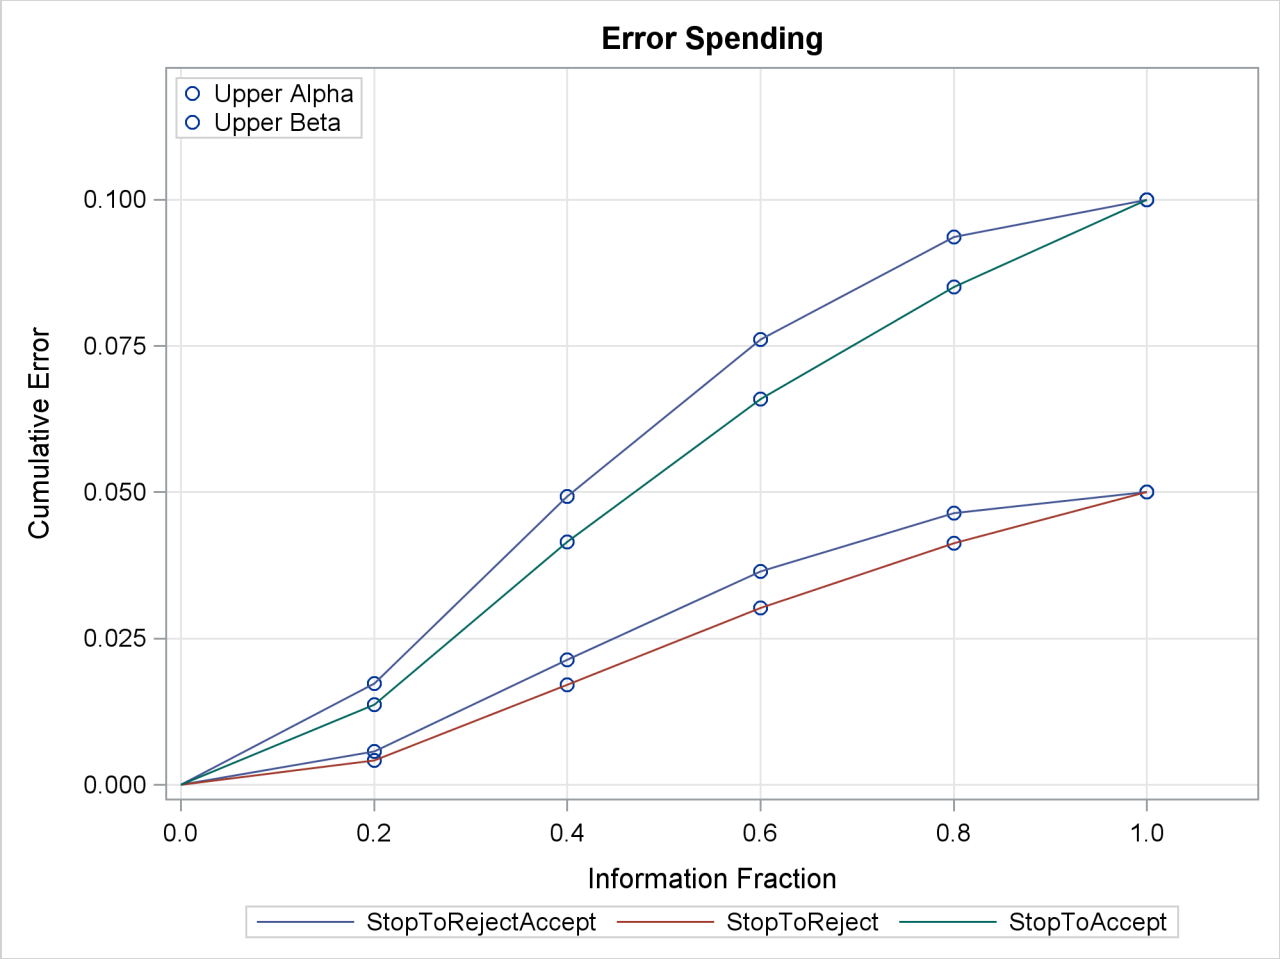
With the PLOTS=COMBINEDBOUNDARY option, a plot of the resulting sequential boundaries for all designs is displayed, as shown in Output 80.6.16. The plot shows that the design with early stopping to reject and to accept H_0 has larger maximum information than the other two designs.

Output 80.6.16 Combined Boundary Plot with Score Scale



With the PLOTS=ERRSPEND(HSCALE=INFO) option, the error spending plot is displayed with the information level on the horizontal axis, as shown in Output 80.6.17. The design with early stopping to reject or accept the null hypothesis H_0 has larger α spending and larger β spending in early stages than the other two designs.

Output 80.6.17 Error Spending Plot



Example 80.7: Creating Whitehead's Triangular Designs

This example requests three 4-stage Whitehead's triangular designs for normally distributed statistics. Each design has a one-sided alternative hypothesis with early stopping to reject or accept the null hypothesis H_0. Note that Whitehead's triangular designs are different from unified family triangular designs.

Suppose that a clinic is conducting a study of the effect of a new cancer treatment. The study consists of exposing mice to a carcinogen and randomly assigning them to either the control group or the treatment group. The event of interest is death from cancer induced by the carcinogen, and the response is the time from randomization to death.

Following the derivations in the section "Test for Two Survival Distributions with a Log-Rank Test" on page 6779, the hypothesis $H_0 : \theta = -\log(\lambda) = 0$ with an alternative hypothesis $H_1 : \theta = \theta_1 > 0$ is used, where λ is the hazard ratio between the treatment group and the control group.

Also suppose that from past experience, the median survival time for the control group is $t_0 = 20$ days, and the study wants to detect a $t_1 = 40$ days' median survival time with a 80% power in the trial. Assuming exponential survival functions for the two groups, the hazard rates can be computed from

$$S_j(t_j) = e^{-h_j t_j} = \frac{1}{2}$$

where $j = 0, 1$.

Thus, with $h_0 = 0.0346574$ and $h_1 = 0.0173287$, the hazard ratio $\lambda_1 = h_1/h_0 = 1/2$, and the alternative reference is

$$\theta_1 = -\log(\lambda_1) = -\log(\frac{1}{2}) = 0.693147$$

The following statements invoke the SEQDESIGN procedure and specify three Whitehead's triangular designs:

```
ods graphics on;
proc seqdesign altref=0.693147
               bscale=score
               plots=combinedboundary
               ;
   BoundaryKeyNone:  design nstages=4
                            method=whitehead
                            boundarykey=none
                            alt=upper   stop=both
                            alpha=0.05  beta=0.20
                            ;
   BoundaryKeyAlpha: design nstages=4
                            method=whitehead
                            boundarykey=alpha
                            alt=upper   stop=both
                            alpha=0.05  beta=0.20
                            ;
   BoundaryKeyBeta:  design nstages=4
                            method=whitehead
                            boundarykey=beta
                            alt=upper   stop=both
                            alpha=0.05  beta=0.20
                            ;
run;
ods graphics off;
```

Whitehead methods with early stopping to reject or accept the null hypothesis create boundaries that approximately satisfy the Type I and Type II error probability specification. The BOUNDARYKEY=NONE option specifies no adjustment to the boundary value at the final stage to maintain either a Type I or a Type II error probability level.

The "Design Information" table in Output 80.7.1 displays design specifications and maximum information. Note that with the BOUNDARYKEY=NONE option, the derived errors $\alpha = 0.05071$ and $\beta = 0.19771$ are not the same as the specified errors $\alpha = 0.05$ and $\beta = 0.20$.

Output 80.7.1 Whitehead Design Information

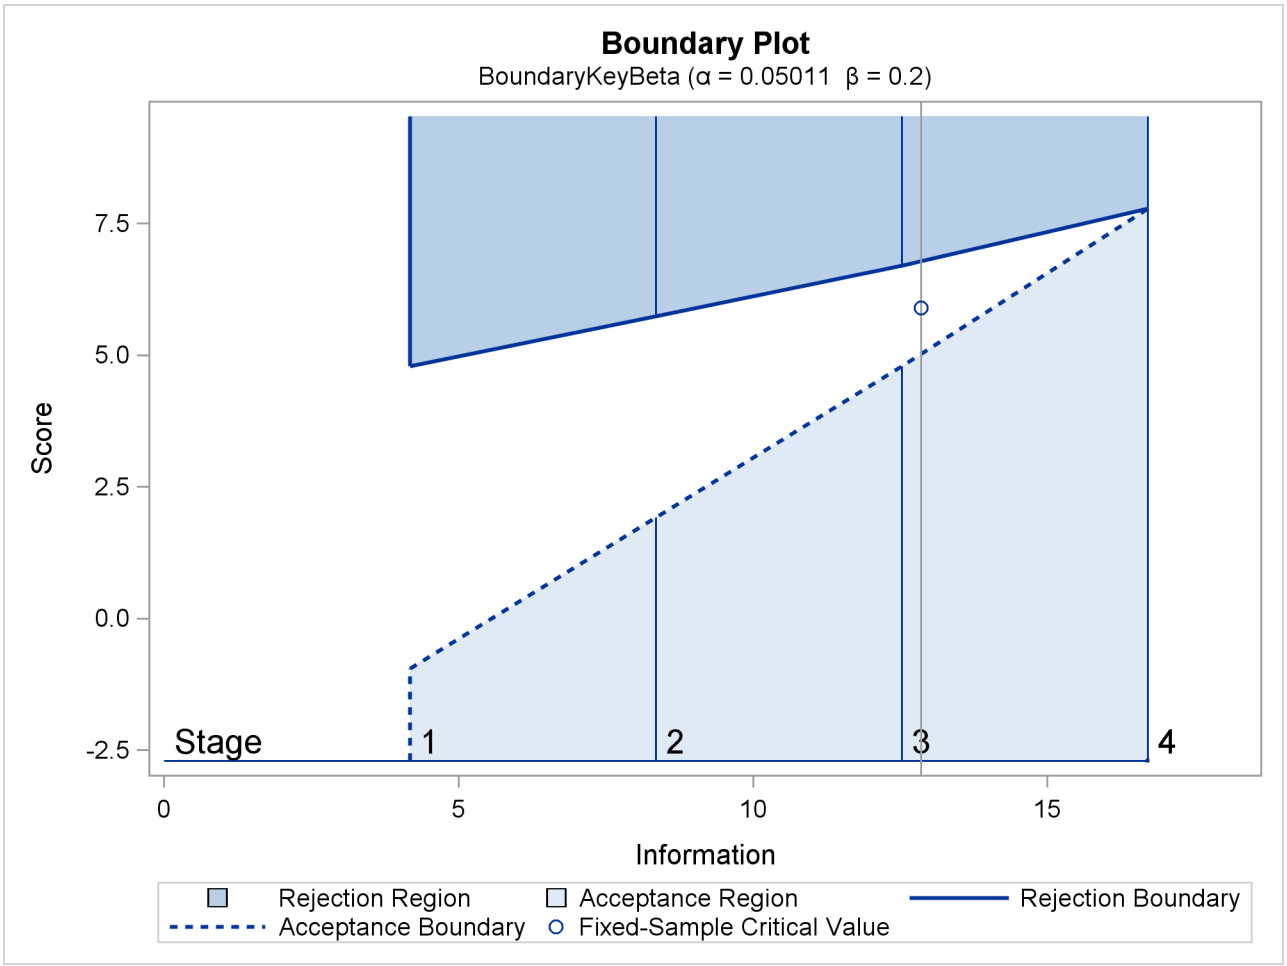
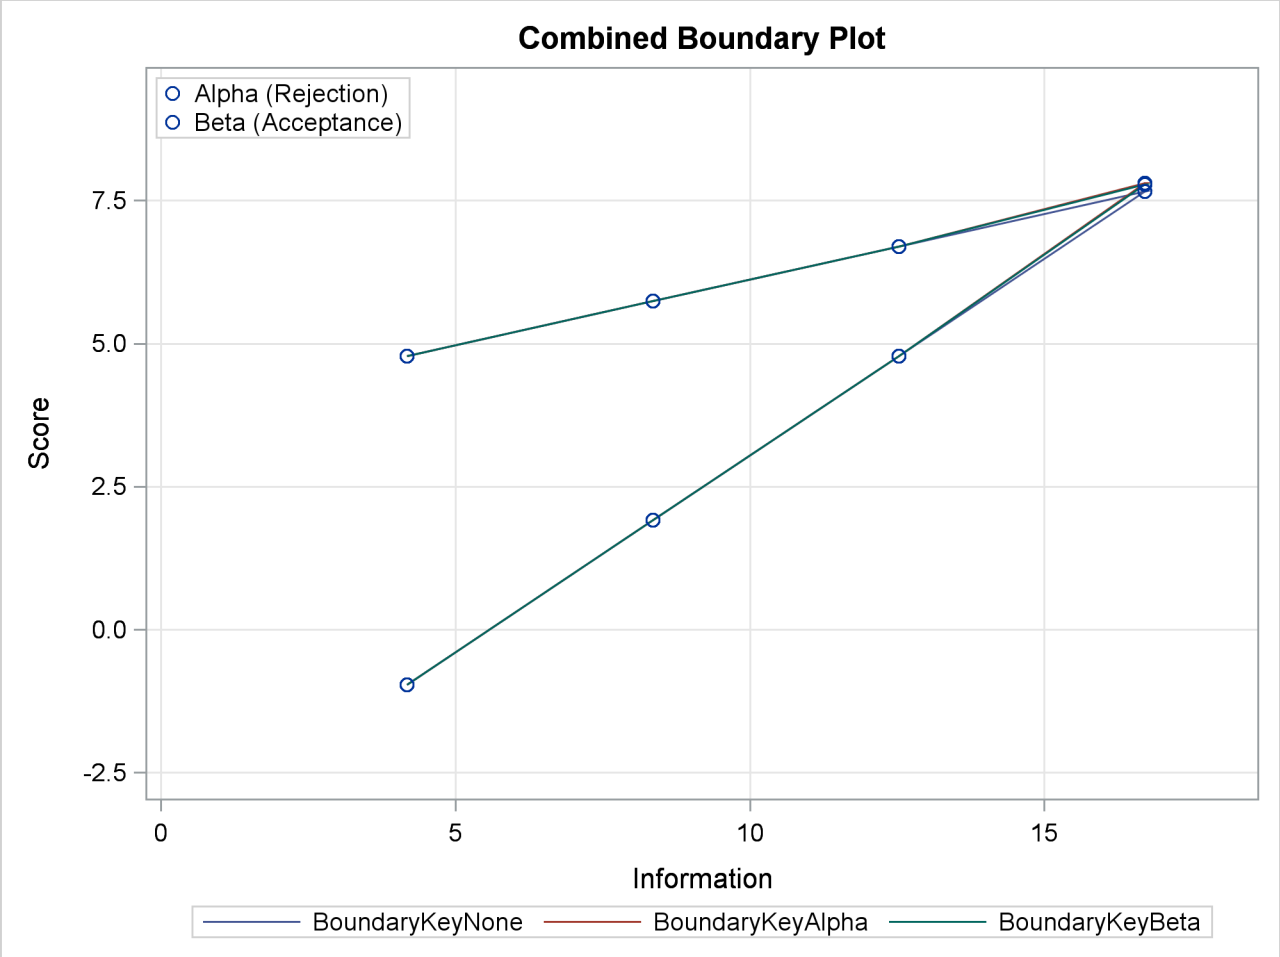
With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.7.12.

Output 80.7.12 Boundary Plot



With the PLOTS=COMBINEDBOUNDARY option, a combined plot of group sequential boundaries for all designs is displayed, as shown in Output 80.7.13. It shows that three designs are similar, with a slightly smaller boundary value at the final stage for the design with the BOUNDARYKEY=NONE option.

Output 80.7.13 Combined Boundary Plot



The following statements invoke the SEQDESIGN procedure and specify the SAMPLESIZE statement to derive required sample sizes for a log-rank test comparing two survival distributions for the treatment effect (Jennison and Turnbull 2000 pp. 77–79; Whitehead 1997, pp. 36–39):

```
proc seqdesign altref=0.693147
               bscale=score
               ;
   BoundaryKeyAlpha: design nstages=4
                            method=whitehead
                            boundarykey=alpha
                            alt=upper   stop=both
                            alpha=0.05  beta=0.20
                            ;
   samplesize model=twosamplesurvival
                   ( nullhazard=0.03466 accrate=10);
run;
```

The design is identical to the previous design with the BOUNDARYKEY=ALPHA option except with the addition of the sample size computation.

The "Sample Size Summary" table in Output 80.7.14 displays parameters for the sample size computation. Since the ACCTIME= option is not specified for the accrual time, the minimum and maximum accrual times are derived for the specified accrual rate.

Output 80.7.14 Sample Size Summary

The SEQDESIGN Procedure
Design: BoundaryKeyAlpha

Sample Size Summary

Test	Two-Sample Survival
Null Hazard Rate	0.03466
Hazard Rate (Group A)	0.01733
Hazard Rate (Group B)	0.03466
Hazard Ratio	0.5
log(Hazard Ratio)	-0.69315

Example 80.8: Creating a One-Sided Error Spending Design

This example requests a five-stage, one-sided group sequential design for normally distributed statistics. The design uses an O'Brien-Fleming-type error spending function for the α boundary and a Pocock-type error spending function for the β boundary. The following statements request a one-sided design by using different α and β spending functions:

```
ods graphics on;
proc seqdesign altref=0.2  errspend
               pss(cref=0 0.5 1)
               stopprob(cref=0 0.5 1)
               plots=(asn power errspend)
               ;
   OneSidedErrorSpending: design nstages=5
                          method(alpha)=errfuncobf
                          method(beta)=errfuncpoc
                          alt=upper  stop=both
                          alpha=0.025
                          ;
run;
ods graphics off;
```

The "Design Information" table in Output 80.8.1 displays design specifications and the derived statistics. With the specified alternative reference, the maximum information is derived.

Output 80.8.1 Error Spending Method Design Information

The SEQDESIGN Procedure

With the PSS option, the "Power and Expected Sample Sizes" table in Output 80.8.4 displays powers and expected sample sizes under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and $c_i = 0, 0.5, 1, 1.5$ are the default values in the CREF= option.

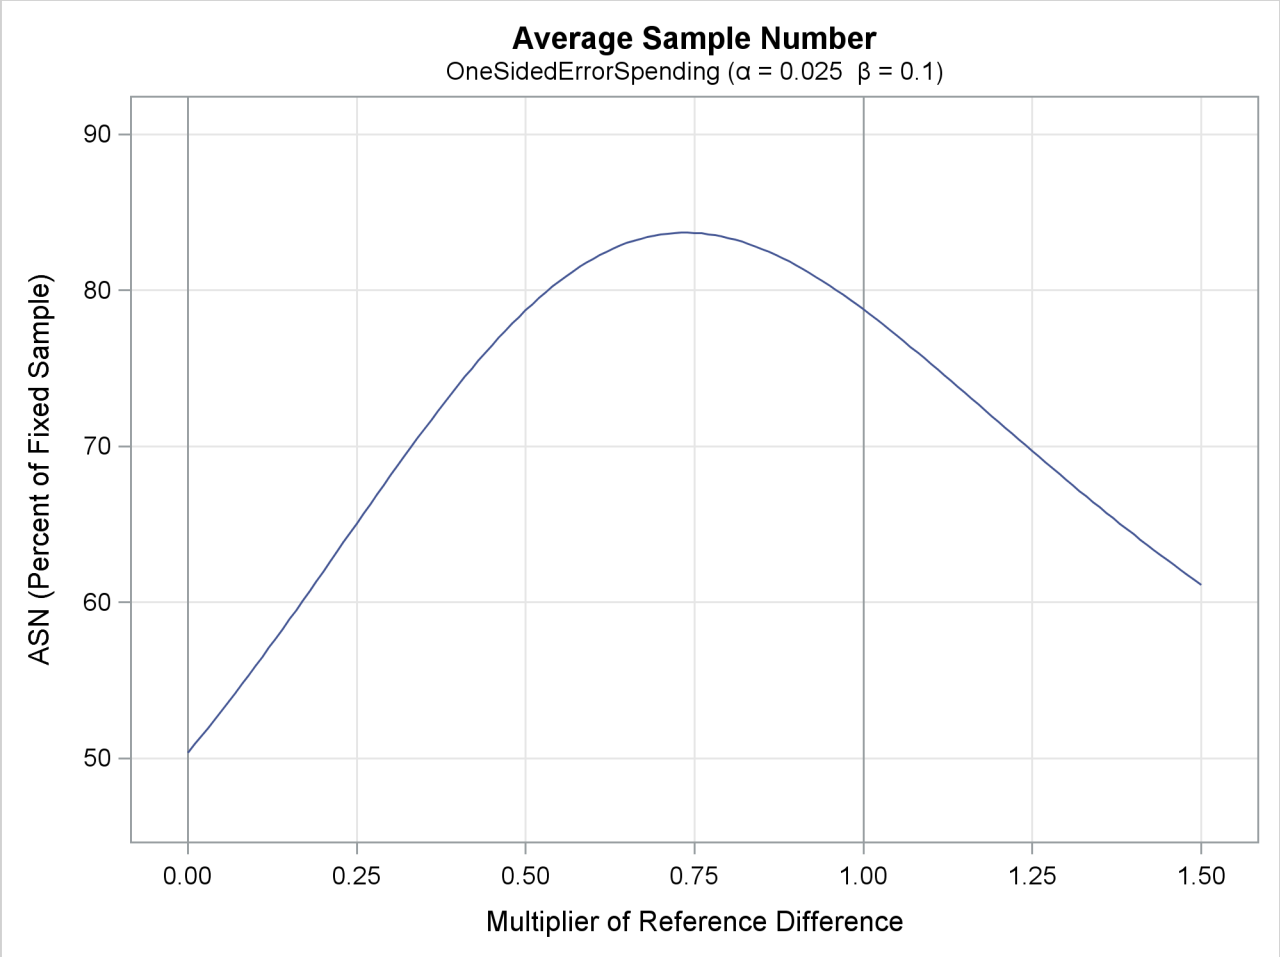
Output 80.8.4 Power and Expected Sample Size Information

Powers and Expected Sample Sizes
Reference = CRef * (Alt Reference)

CRef	Power	-Sample Size- Percent Fixed-Sample
0.0000	0.02500	50.3541
0.5000	0.38724	78.7219
1.0000	0.90000	78.7722

With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in Output 80.8.5. By default, expected sample sizes under the hypotheses $\theta = c_i\,\theta_1$, $c_i = 0, 0.01, 0.02, \ldots, 1.50$, are displayed, where θ_1 is the alternative reference.

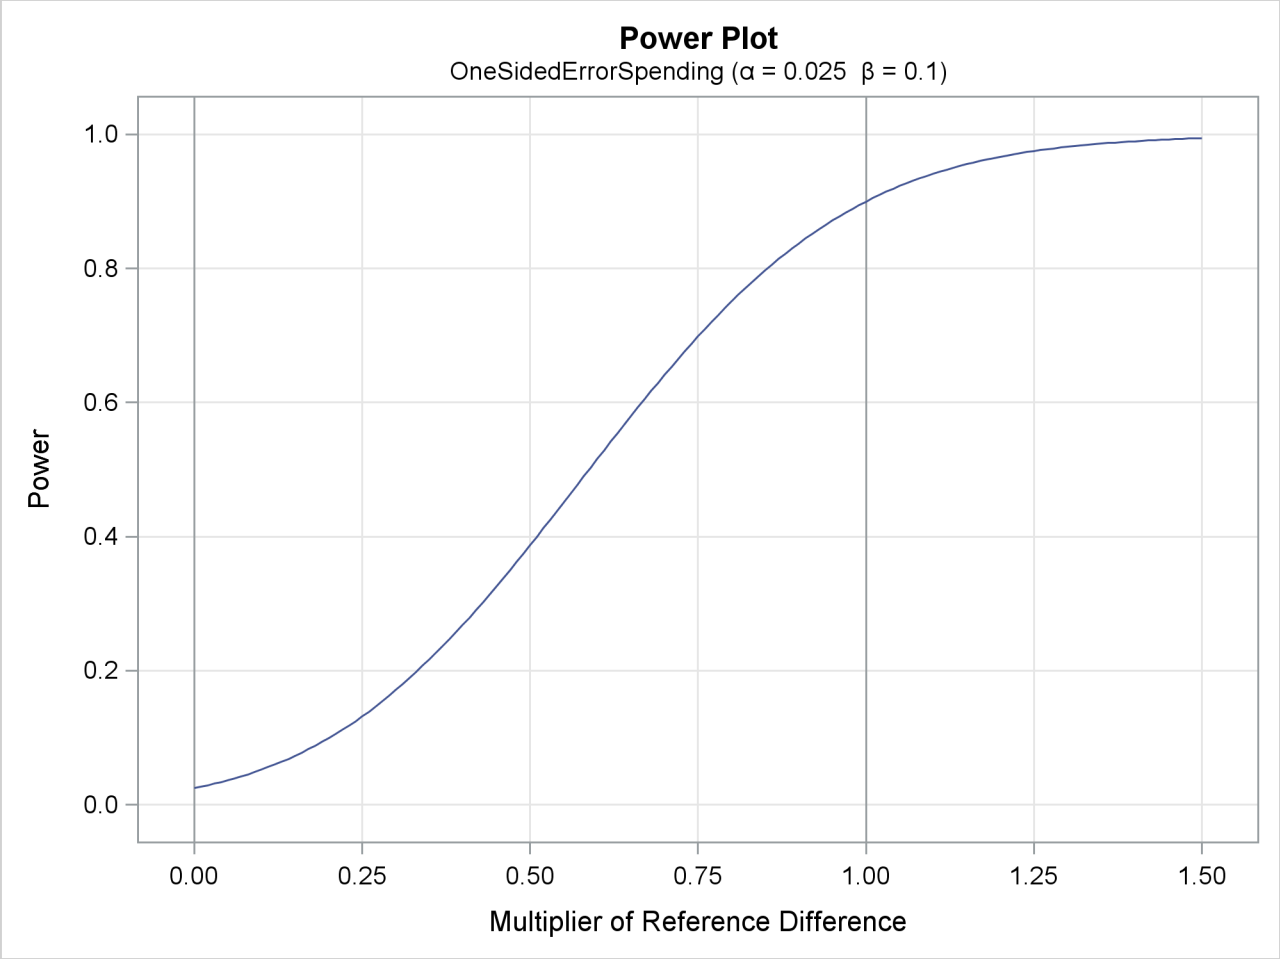
Output 80.8.5 ASN Plot



With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references for all designs simultaneously, as shown in Output 80.8.6. By default, the option CREF= $0, 0.01, 0.02, \ldots, 1.50$ and powers under hypothetical references $\theta = c_i\,\theta_1$ are displayed, where c_i are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

Under the null hypothesis, $c_i = 0$, the power is 0.025, the upper Type I error probability. Under the alternative hypothesis, $c_i = 1$, the power is 0.9, one minus the Type II error probability. The plot shows only minor difference between the two designs.

Output 80.8.6 Power Plot



The "Boundary Information" table in Output 80.8.7 displays information level, alternative reference, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative reference and boundary values are displayed with the standardized Z scale. That is, the resulting standardized alternative reference at stage k is given by $\theta_1\sqrt{I_k}$, where θ_1 is the specified alternative reference and I_k is the information level at stage k, $k = 1, 2, \ldots, 5$.

Output 80.8.7 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

	---Information Level--		-Alternative- --Reference--	-----Boundary Values---- ----------Upper---------	
Stage	Proportion	Actual	Upper	Beta	Alpha

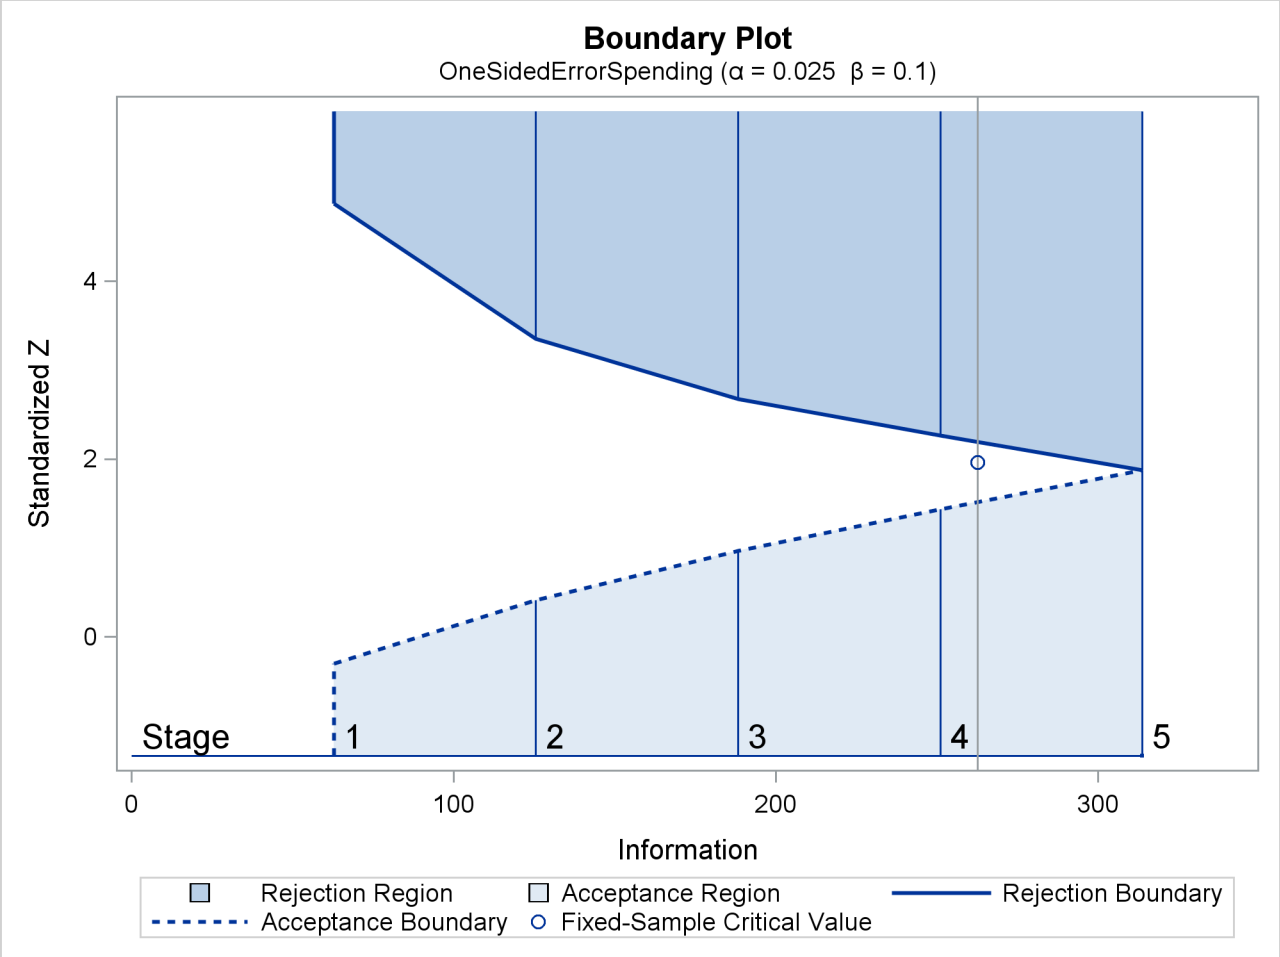
5	1.0000	313.7196	3.54243	1.87522	1.87522

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.8.8. This plot displays the boundary values in the "Boundary Information" table in Output 80.8.7.

Output 80.8.8 Boundary Plot



The "Error Spending Information" table in Output 80.8.9 displays cumulative error spending at each stage for each boundary.

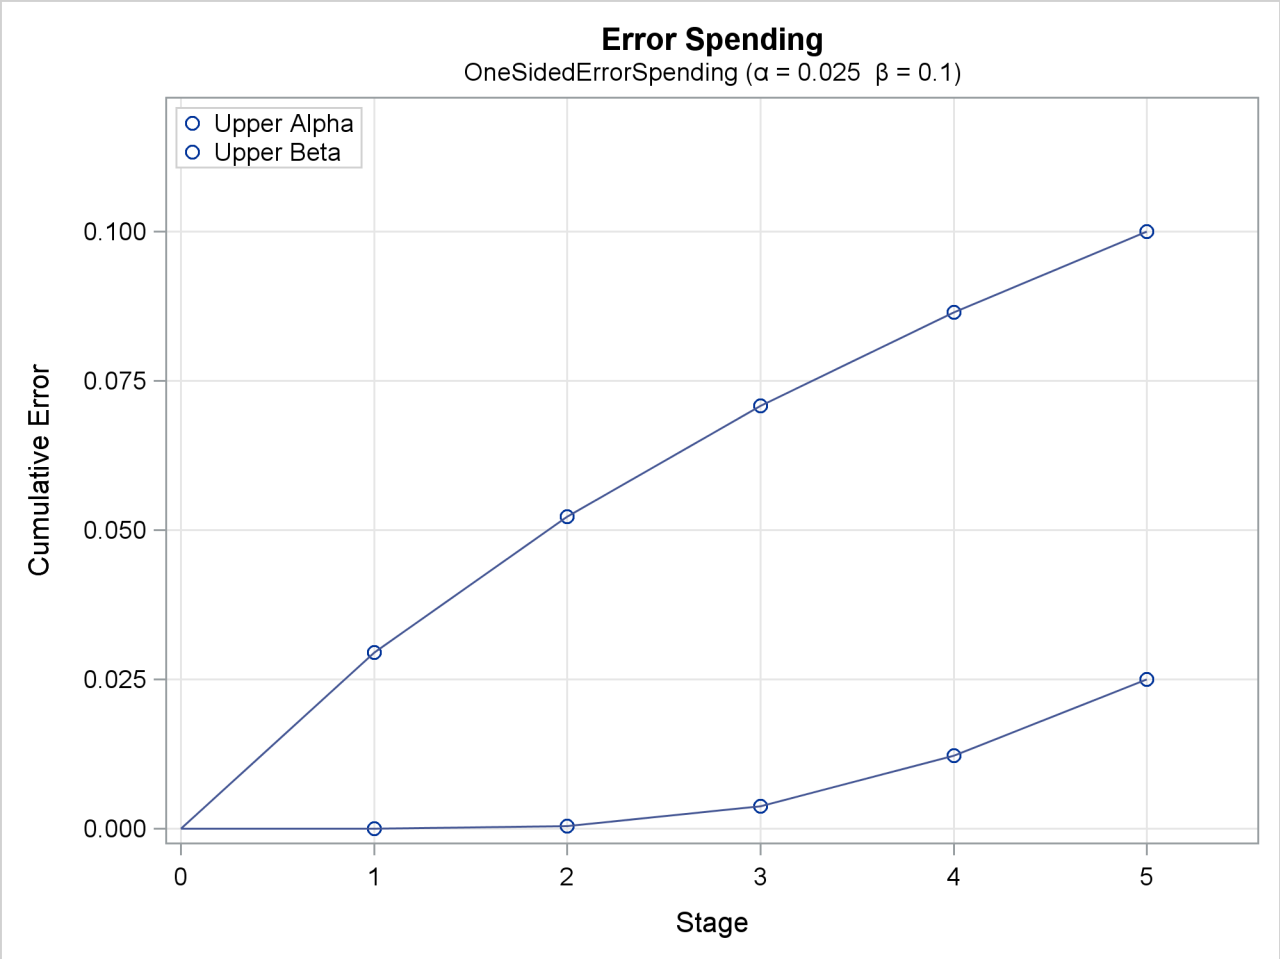
Output 80.8.9 Error Spending Information

Error Spending Information

	-Information Level-	-Cumulative Error Spending-	
		----------Upper----------	
Stage	Proportion	Beta	Alpha
1	0.2000	0.02954	0.00000
2	0.4000	0.05231	0.00039
3	0.6000	0.07085	0.00381
4	0.8000	0.08648	0.01221
5	1.0000	0.10000	0.02500

With the PLOTS=ERRSPEND option, the procedure displays a plot of error spending for each boundary, as shown in Output 80.8.10. This plot displays the cumulative error spending at each stage in the "Error Spending Information" table in Output 80.8.9. The O'Brien-Fleming-type α spending function is conservative in early stages because it uses much less at early stages than in the later stages. In contrast, the Pocock-type β spending function uses more at early stages than in the later stages.

Output 80.8.10 Error Spending Plot



Example 80.9: Creating Designs with Various Number of Stages

This example requests three group sequential designs for normally distributed statistics. Each design uses the power family error spending function with the default power parameter $\rho = 2$. The specified error spending method is between the approximated Pocock method ($\rho = 1$) and the approximated O'Brien-Fleming method ($\rho = 3$) (Jennison and Turnbull 1999, p. 148). The three designs are identical except for the specified number of stages. The following statements request these three group sequential designs:

```
ods graphics on;
proc seqdesign plots=( asn
                       power
                       combinedboundary
                       errspend(hscale=info)
                       )
                ;
   TwoStageDesign:  design nstages=2
                    method=errfuncpow
                    alt=upper  stop=reject
                    ;
   FiveStageDesign: design nstages=5
                    method=errfuncpow
                    alt=upper  stop=reject
                    ;
   TenStageDesign:  design nstages=10
                    method=errfuncpow
                    alt=upper  stop=reject
                    ;
run;
ods graphics off;
```

The "Design Information" table in Output 80.9.1 displays design information for the two-stage design.

Output 80.9.1 Design Information

The SEQDESIGN Procedure
Design: TwoStageDesign

Design Information

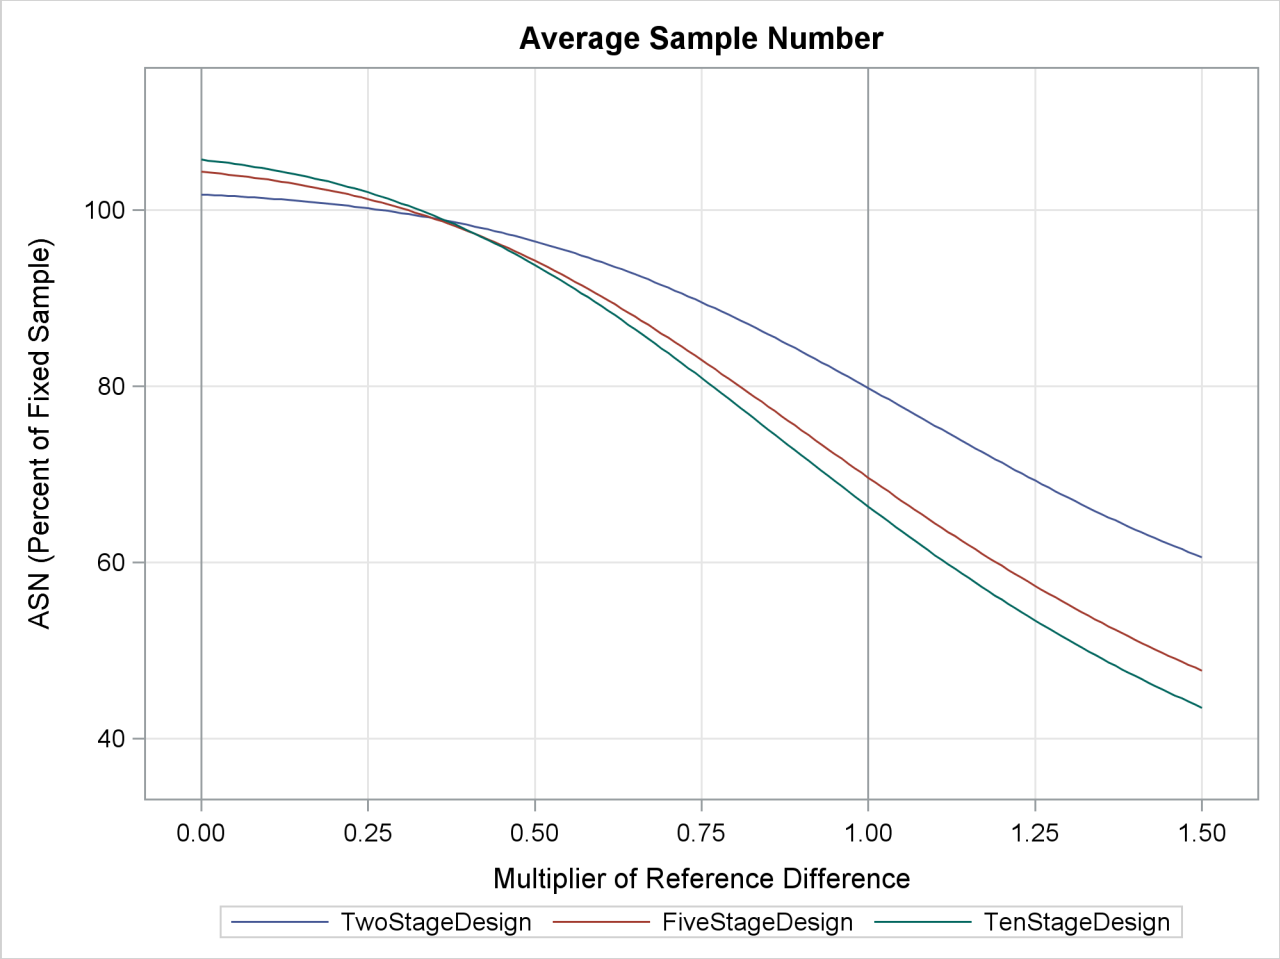
8	0.8000	2.71076	2.04503
9	0.9000	2.87519	1.94355
10	1.0000	3.03072	1.84765

With the PLOTS=ASN option, the procedure displays a plot of average sample numbers under various hypothetical references for all designs simultaneously, as shown in Output 80.9.7. By default, the option CREF= $0, 0.01, 0.02, \ldots, 1.50$ and expected sample sizes under the hypothetical references $\theta = c_i\,\theta_1$ are displayed, where c_i are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

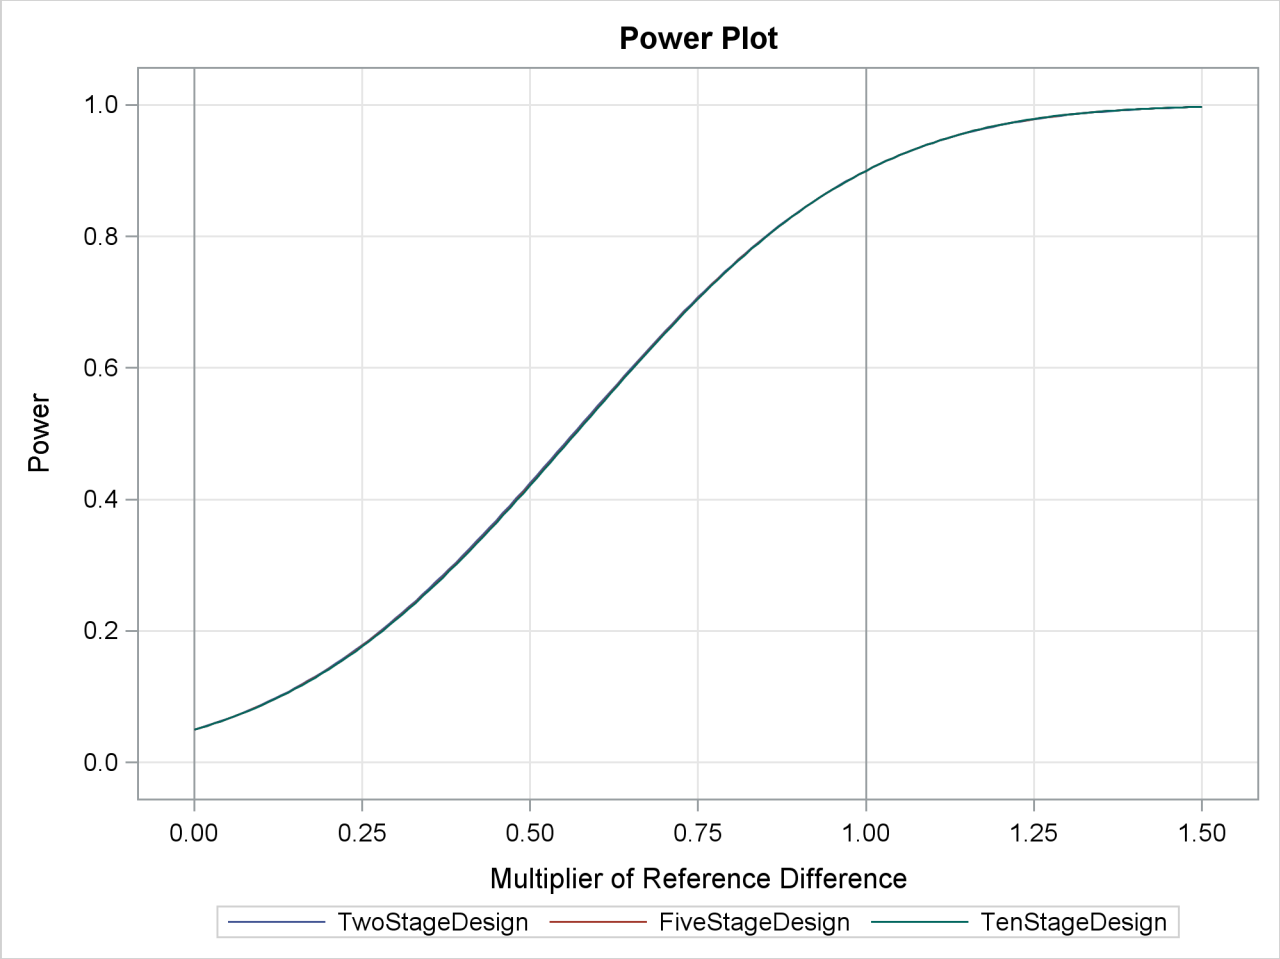
Output 80.9.7 ASN Plot



The plot shows that as the number of stages increases, the average sample number as a percentage of the fixed-sample design increases under the null hypothesis ($c_i = 0$) but decreases under the alternative hypothesis ($c_i = 1$).

With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references for all designs simultaneously, as shown in Output 80.9.8. By default, the option CREF= $0, 0.01, 0.02, \ldots, 1.50$ and powers under hypothetical references $\theta = c_i\,\theta_1$ are displayed, where c_i are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

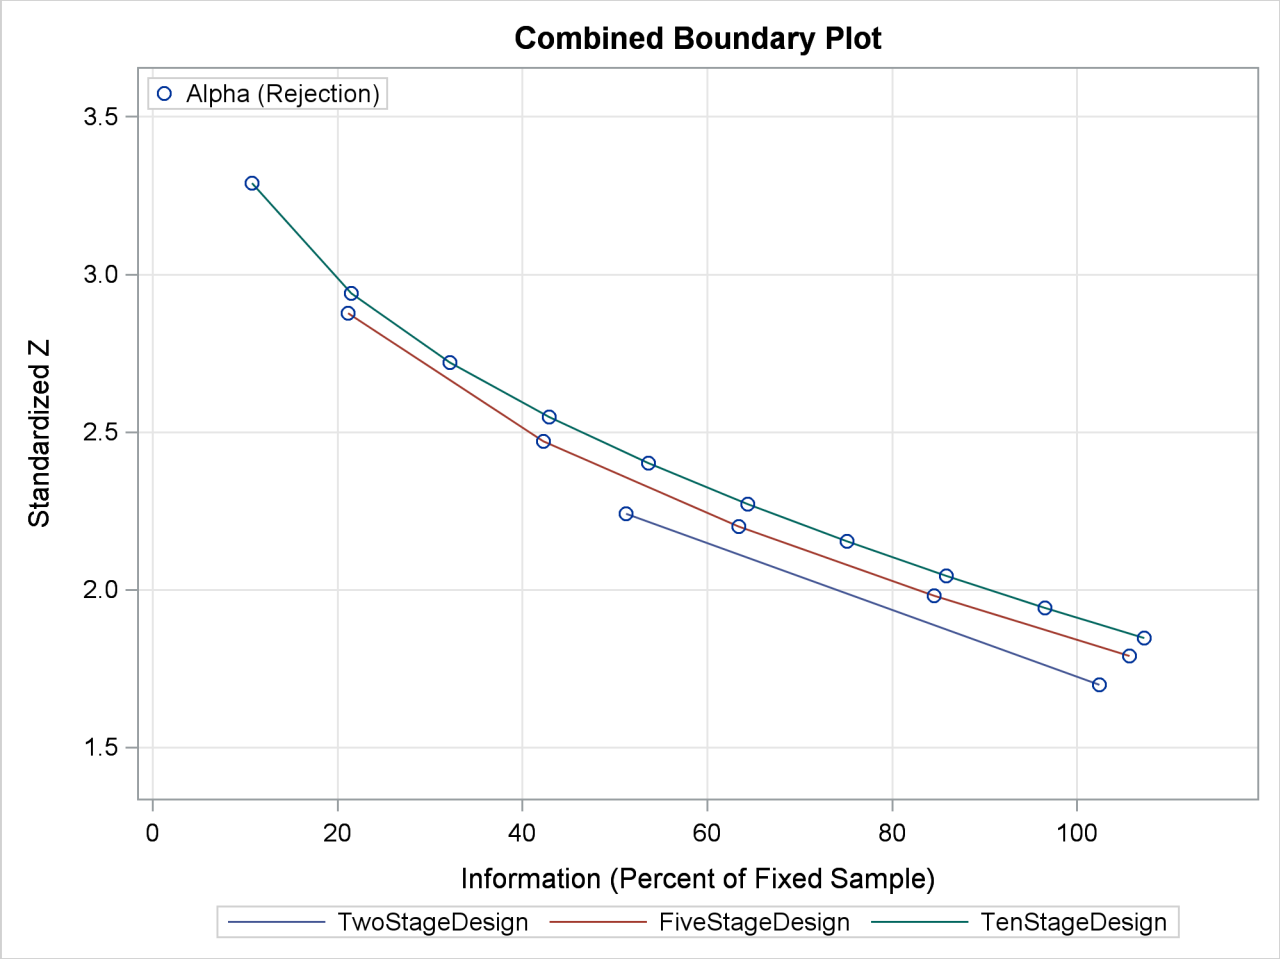
Output 80.9.8 Power Plot



Under the null hypothesis, $c_i = 0$, the power is 0.05, the upper Type I error probability. Under the alternative hypothesis, $c_i = 1$, the power is 0.9, one minus the Type II error probability. The plot shows only minor difference among the three designs.

With the PLOTS=COMBINEDBOUNDARY option, the procedure displays a plot of sequential boundaries for all designs simultaneously, as shown in Output 80.9.9. By default (or equivalently if you specify COMBINEDBOUNDARY(HSCALE=INFO)), the information levels are used on the horizontal axis. Since the maximum information is not available for the design, the percent information ratios with respect to the corresponding fixed-sample design are displayed in the plot.

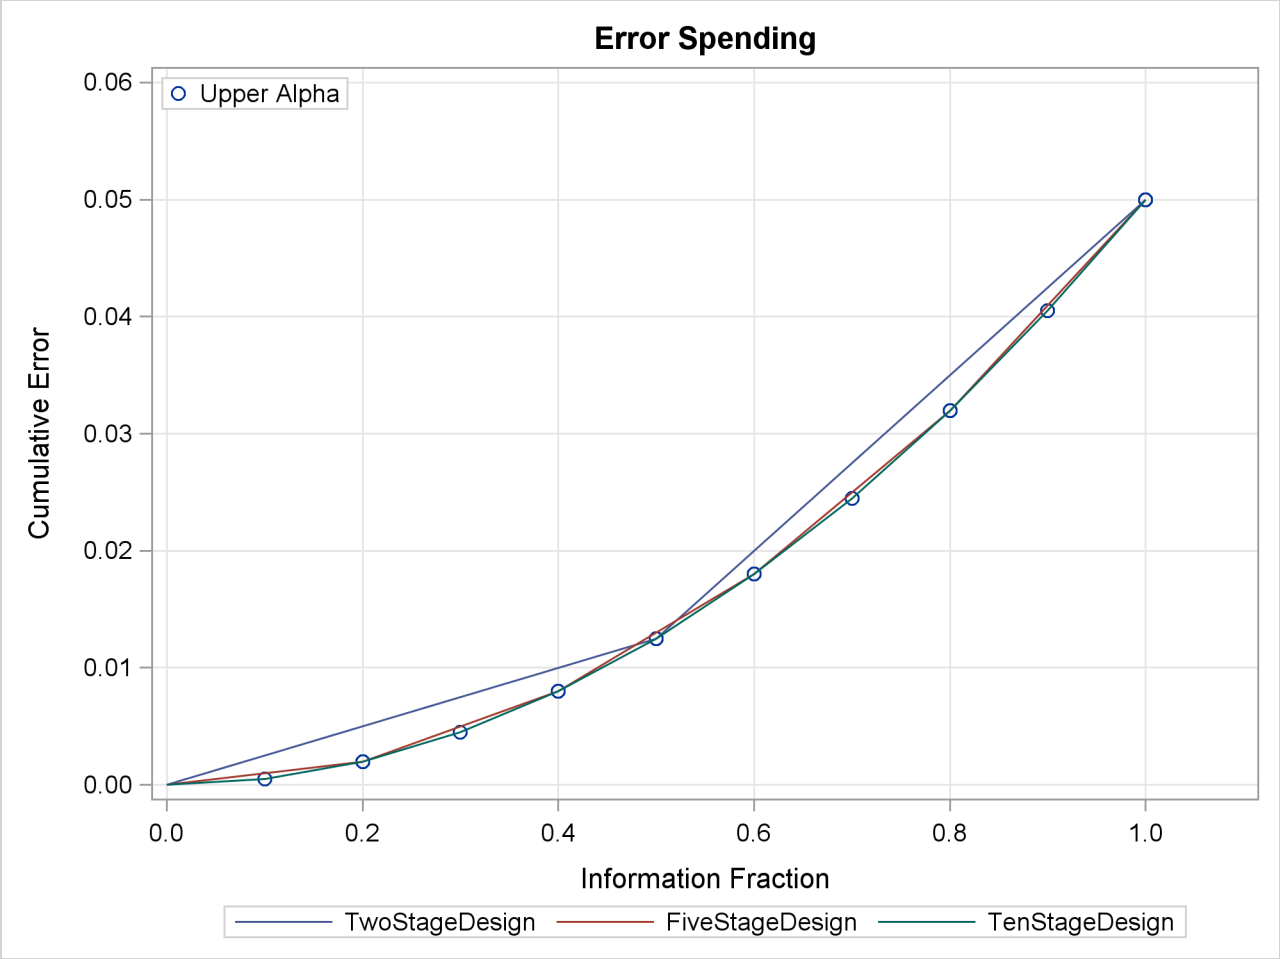
Output 80.9.9 Combined Boundary Plot



The plot shows that as the number of stages increases, the maximum information increases and the α boundary values also increase.

With the PLOTS=ERRSPEND(HSCALE=INFO) option, the procedure displays a plot of cumulative error spends for all boundaries in the designs simultaneously, as shown in Output 80.9.10.

Output 80.9.10 Error Spending Plot



The plot shows similar error spending for these three designs since all three designs are generated from the same power family error spending function.

Example 80.10: Creating Two-Sided Error Spending Designs with and without Overlapping Lower and Upper β Boundaries

This example requests two three-stage group sequential designs for normally distributed statistics. Each design uses a power family error spending function with a specified two-sided alternative hypothesis H_1 : $\theta_1 = \pm 0.2$ and early stopping only to accept the null hypothesis H_0.

The first design uses the BETAOVERLAP=NOADJUST option to derive acceptance boundary values without adjusting for the possible overlapping of the lower and upper β boundaries computed from the two corresponding one-sided tests. The second design uses the BETAOVERLAP=ADJUST option to test the overlapping of the β boundaries at each interim stage based on the two corresponding one-sided tests and then to set the β boundary values at the stage to missing if overlapping occurs at that stage.

The following statements request a two-sided design with the BETAOVERLAP=NOADJUST option:

```
ods graphics on;
proc seqdesign altref=0.2 errspend;
   design nstages=3
          method=errfuncpow
          alt=twosided  stop=accept
          betaoverlap=noadjust
          beta=0.09
          ;
run;
ods graphics off;
```

The "Design Information" table in Output 80.10.1 displays design specifications and the derived statistics for the first design. With the specified alternative reference $\theta_1 = 0.2$, the maximum information is derived.

Output 80.10.1 Design Information

The SEQDESIGN Procedure
Design: Design_1

Design Information

Statistic Distribution	Normal

Alt Ref ASN (Percent of Fixed Sample)	102.1476

The "Boundary Information" table in Output 80.10.2 displays the information level, alternative reference, and boundary values. With a specified alternative reference θ_1, the maximum information is derived from the procedure, and the actual information level at each stage is displayed in the table. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative reference and boundary values are displayed with the standardized Z scale. The alternative reference at stage k is given by $\theta_1\sqrt{I_k}$, where θ_1 is the specified alternative reference and I_k is the information level at stage k, $k = 1, 2, 3$.

Output 80.10.2 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

	--Information Level-		------Alternative----- ------Reference------		----Boundary Values--- ---Lower--	---Upper--
Stage	Proportion	Actual	Lower	Upper	Beta	Beta
1	0.3333	94.31094	-1.94228	1.94228	-0.08239	0.08239
2	0.6667	188.6219	-2.74679	2.74679	-0.90351	0.90351
3	1.0000	282.9328	-3.36412	3.36412	-1.92519	1.92519

The "Error Spending Information" table in Output 80.10.3 displays the cumulative error spending at each stage for each boundary.

Output 80.10.3 Error Spending Information

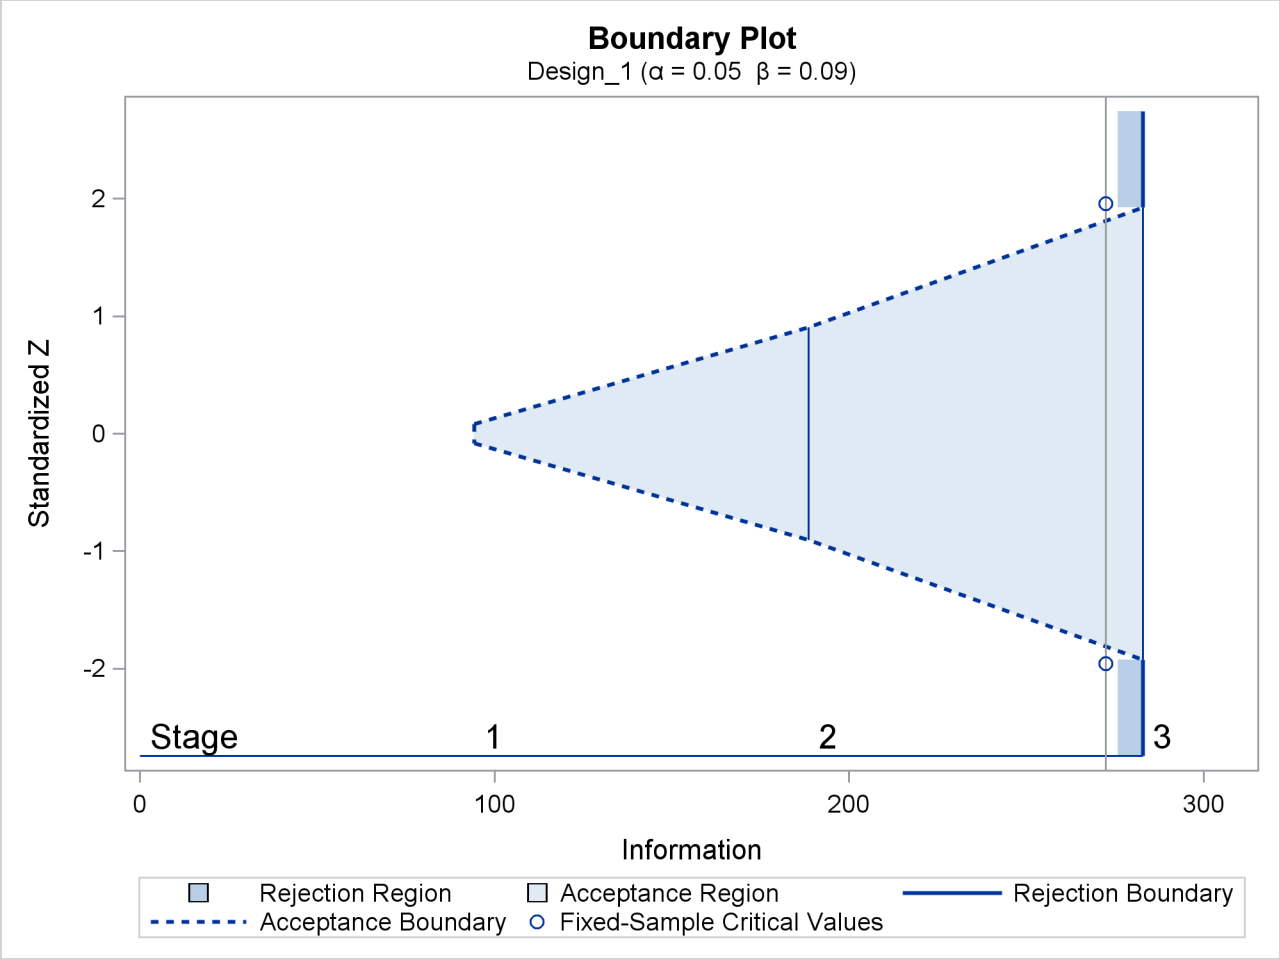
Error Spending Information

	-Information Level-	--------Cumulative Error Spending------- -------Lower------		-------Upper------	
Stage	Proportion	Alpha	Beta	Beta	Alpha
1	0.3333	0.00000	0.01000	0.01000	0.00000
2	0.6667	0.00000	0.04000	0.04000	0.00000
3	1.0000	0.02500	0.09000	0.09000	0.02500

With the STOP=ACCEPT option, the design does not stop at interim stages to reject H_0, and the α spending at each interim stage is zero. For the power family error spending function with the default parameter $\rho = 2$, the beta spending at stage 1 is $(1/3)^\rho \beta = (1/3)^2 0.09 = 0.01$, and the cumulative beta spending at stage 2 is $(2/3)^\rho \beta = (2/3)^2 0.09 = 0.04$.

With ODS Graphics enabled, a detailed boundary plot with the acceptance and rejection regions is displayed, as shown in Output 80.10.4.

Output 80.10.4 Boundary Plot



The following statements request a two-sided design with the BETAOVERLAP=ADJUST option, which is the default:

```
ods graphics on;
proc seqdesign altref=0.2 errspend;
   design nstages=3
          method=errfuncpow
          alt=twosided
          stop=accept
          betaoverlap=adjust
          beta=0.09
          ;
run;
ods graphics off;
```

With the BETAOVERLAP=ADJUST option, the procedure first derives the usual β boundary values for the two-sided design and then checks for overlapping of the β boundaries for the two corresponding one-sided tests at each stage. If this type of overlapping occurs at a particular stage, the β boundary values for that stage are set to missing, the β spending values at that stage are reset to zero, and the β spending values at subsequent stages are adjusted proportionally.

The boundary values without adjusting for the possible overlapping of the two one-sided β boundaries are identical to the boundary values derived in the first design (with the BETAOVERLAP=NOADJUST option, as shown in Output 80.10.2). At stage 1, the upper β boundary value for the corresponding one-sided test is

$$\theta_1\sqrt{I_1} - \Phi^{-1}(1-\beta_1) = 0.2\sqrt{94.31094} - \Phi^{-1}(0.99) = 1.94228 - 2.32635 = -0.38407$$

where $\theta_1 = 0.2$ is the upper alternative reference, $I_1 = 94.31094$ is the information level at stage 1, and $\beta_1 = 0.01$ is the β spending at stage 1 (as shown in Output 80.10.3).

Similarly, the lower β boundary value for the corresponding one-sided test is computed as 0.38407. Since the upper β boundary value is less than the lower β boundary at stage 1, overlapping occurs, and so the β boundary values for the two-sided design are set to missing at stage 1.

With the β boundary values set to missing at stage 1 and the β spending $\beta'_1 = 0$ the β spending values at subsequent interim stages are adjusted proportionally. In this example, the adjusted β spending at stage 2 is computed as

$$\beta'_2 = \beta'_1 + \frac{\beta_2 - \beta_1}{\beta_3 - \beta_1}(\beta_3 - \beta'_1) = 0 + \frac{0.04 - 0.01}{0.09 - 0.01}0.09 = 0.03375$$

where β_k is the cumulative β spending at stage k before the adjustment, $k = 1, 2, 3$.

The "Design Information" table in Output 80.10.5 displays design specifications and derived statistics for the design.

Output 80.10.5 Design Information

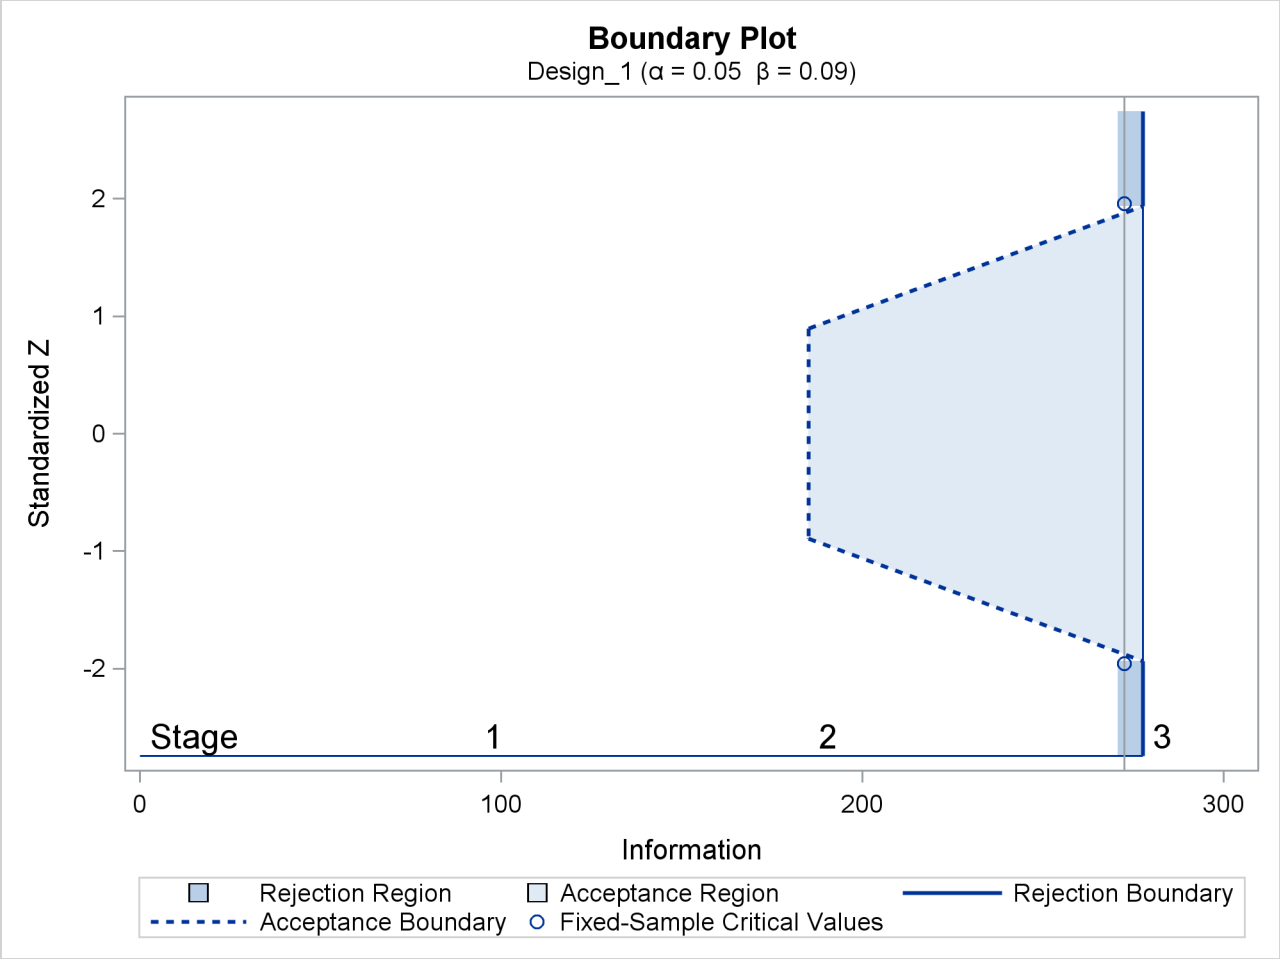
Output 80.10.8 Boundary Plot



Example 80.11: Creating a Two-Sided Asymmetric Error Spending Design with Early Stopping to Reject H_0

This example requests a three-stage two-sided asymmetric group sequential design for normally distributed statistics.

The O'Brien-Fleming boundary can be approximated using a power family error spending function with parameter $\rho = 3$, and the Pocock boundary can be approximated using a power family error spending function with parameter $\rho = 1$ (Jennison and Turnbull 2000, p. 148). The following statements use the power family error spending function to creates a two-sided asymmetric design with early stopping to reject the null hypothesis H_0:

```
ods graphics on;
proc seqdesign altref=1.0
               pss(cref=0 0.5 1)
               stopprob(cref=0 0.5 1)
               errspend
               plots=(asn power errspend)
               ;
```

```
   TwoSidedErrorSpending: design nstages=3
                          method(upperalpha)=errfuncpow(rho=3)
                          method(loweralpha)=errfuncpow(rho=1)
                          info=cum(2 3 4)
                          alt=twosided
                          stop=reject
                          alpha=0.075(upper=0.025)
                          ;
run;
ods graphics off;
```

The design uses power family error spending functions with $\rho = 1$ for the lower α boundary and $\rho = 3$ for the upper α boundary. Thus, the design is conservative in the early stages and tends to stop the trials early only with a small p-value for the upper α boundary. The upper α level 0.025 is specified explicitly, and the lower α level is computed as $0.075 - 0.025 = 0.05$.

The "Design Information" table in Output 80.11.1 displays design specifications and the derived maximum information. Note that in order to attain the same information level for the asymmetric lower and upper boundaries, the derived power at the lower alternative 0.92963 is larger than the default 0.90.

Output 80.11.1 Design Information

The SEQDESIGN Procedure
Design: TwoSidedErrorSpending

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Reject Null
Method	Error Spending
Boundary Key	Both
Alternative Reference	1
Number of Stages	3
Alpha	0.075
Alpha (Lower)	0.05
Alpha (Upper)	0.025
Beta (Lower)	0.07037
Beta (Upper)	0.1
Power (Lower)	0.92963
Power (Upper)	0.9
Max Information (Percent of Fixed Sample)	102.4384
Max Information	10.76365
Null Ref ASN (Percent of Fixed Sample)	100.4877
Lower Alt Ref ASN (Percent of Fixed Sample)	64.8288
Upper Alt Ref ASN (Percent of Fixed Sample)	75.98778

The "Method Information" table in Output 80.11.2 displays the specified α and β error levels and the derived drift parameter. With the same information level used for the asymmetric lower and upper boundaries, only one of the β levels is maintained, and the other is derived to have the level less than or equal to the default level.

Output 80.11.2 Method Information

Method Information

Boundary	Method	Alpha	Beta	----Error Spending---- Function
Upper Alpha	Error Spending	0.02500	0.10000	Power (Rho=3)
Lower Alpha	Error Spending	0.05000	0.07037	Power (Rho=1)

Method Information

Boundary	Alternative Reference	Drift
Upper Alpha	1	3.280801
Lower Alpha	-1	-3.2808

With the STOPPROB(CREF=0 0.5 1) option, the "Expected Cumulative Stopping Probabilities" table in Output 80.11.3 displays the expected stopping stage and cumulative stopping probability to reject the null hypothesis H_0 at each stage under hypothetical references $\theta = 0$ (null hypothesis H_0), $\theta = 0.5\,\theta_1$, and $\theta = \theta_1$ (alternative hypothesis H_1), where θ_1 is the alternative reference.

Output 80.11.3 Stopping Probabilities

Expected Cumulative Stopping Probabilities
Reference = CRef * (Alt Reference)

CRef	Ref	Expected Stopping Stage	Source
0.0000	Lower Alt	2.924	Rej Null (Lower Alt)

1.0000	Upper Alt	0.33927	0.69357	0.90001

"Rej Null (Lower Alt)" and "Rej Null (Upper Alt)" under the heading "Source" indicate the probabilities of rejecting the null hypothesis for the lower alternative and for the upper alternative, respectively. "Reject Null" indicates the probability of rejecting the null hypothesis for either the lower or upper alternative.

Note that with the STOP=REJECT option, the cumulative stopping probability of accepting the null hypothesis H_0 at each interim stage is zero and is not displayed.

With the PSS(CREF=0 0.5 1.0) option, the "Power and Expected Sample Sizes" table in Output 80.11.4 displays powers and expected sample sizes under hypothetical references $\theta = 0$ (null hypothesis H_0), $\theta = 0.5\,\theta_1$, and $\theta = \theta_1$ (alternative hypothesis H_1), where θ_1 is the alternative reference. The expected sample sizes are displayed in a percentage scale relative to the corresponding fixed-sample size design.

Output 80.11.4 Power and Expected Sample Size Information

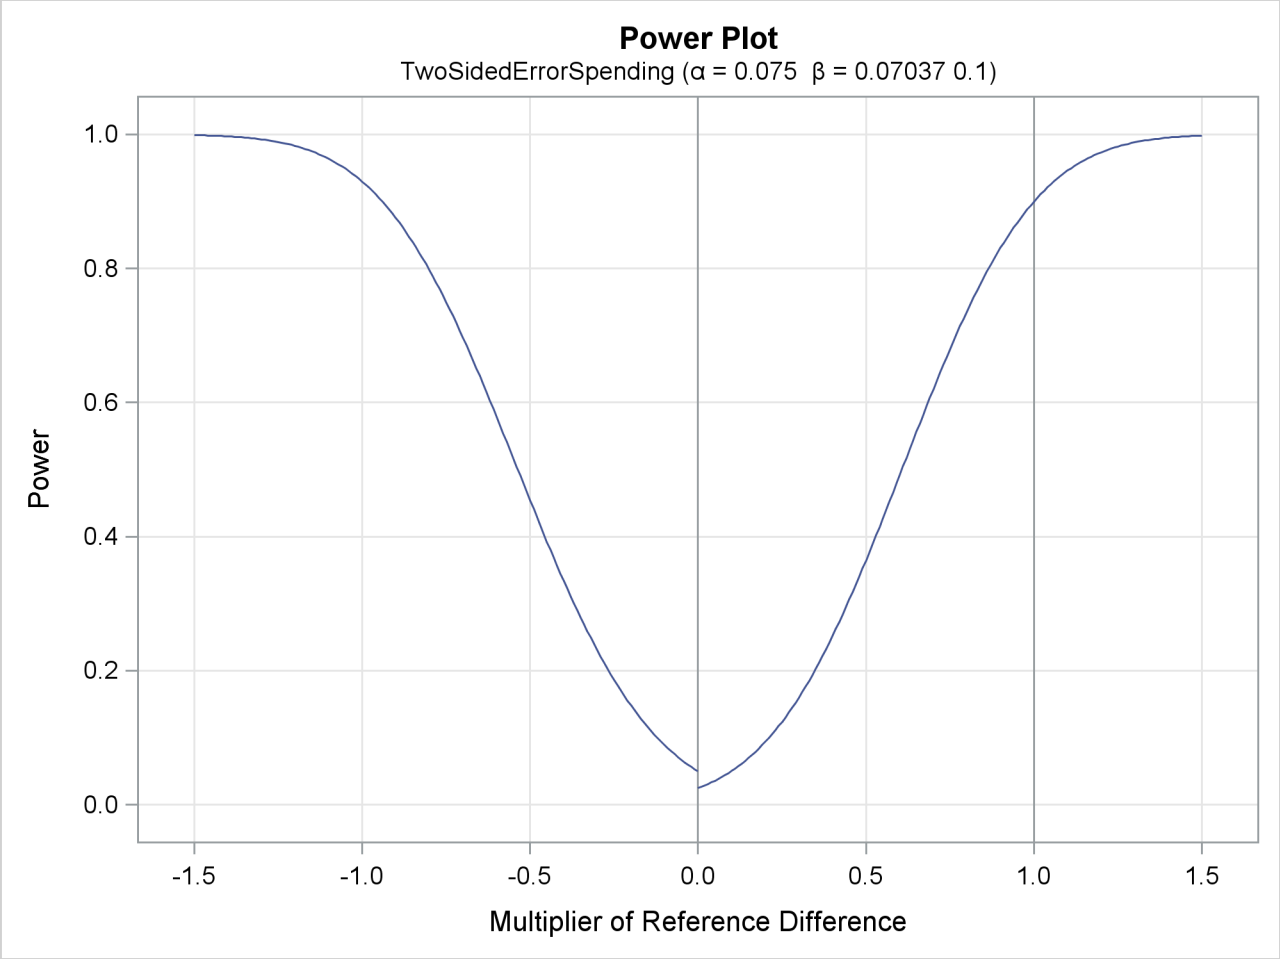
Powers and Expected Sample Sizes
Reference = CRef * (Alt Reference)

CRef	Ref	Power	-Sample Size- Percent Fixed-Sample
0.0000	Lower Alt	0.05000	100.4877
0.5000	Lower Alt	0.45370	88.5090
1.0000	Lower Alt	0.92963	64.8288
0.0000	Upper Alt	0.02500	100.4877
0.5000	Upper Alt	0.36458	96.2309
1.0000	Upper Alt	0.90000	75.9878

Note that at $c_i = 0$, the null reference $\theta = 0$, the power with the lower alternative is the lower α error 0.05, and the power with the upper alternative is the upper α error 0.025. At $c_i = 1$, the alternative reference $\theta = \theta_1$, the power with the upper alternative is the specified power 0.90, and the power with the lower alternative 0.92963 is greater than the specified power 0.90 because the same information level is used for these two asymmetric boundaries.

With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references, as shown in Output 80.11.5. By default, powers under the lower hypotheses $\theta = c_i\,\theta_{1l}$ and under the upper hypotheses $\theta = c_i\,\theta_{1u}$ are displayed for a two-sided asymmetric design, where $c_i = 0, 0.01, 0.02, \ldots, 1.50$ and $\theta_{1l} = -1$ and $\theta_{1u} = 1$ are the lower and upper alternative references, respectively.

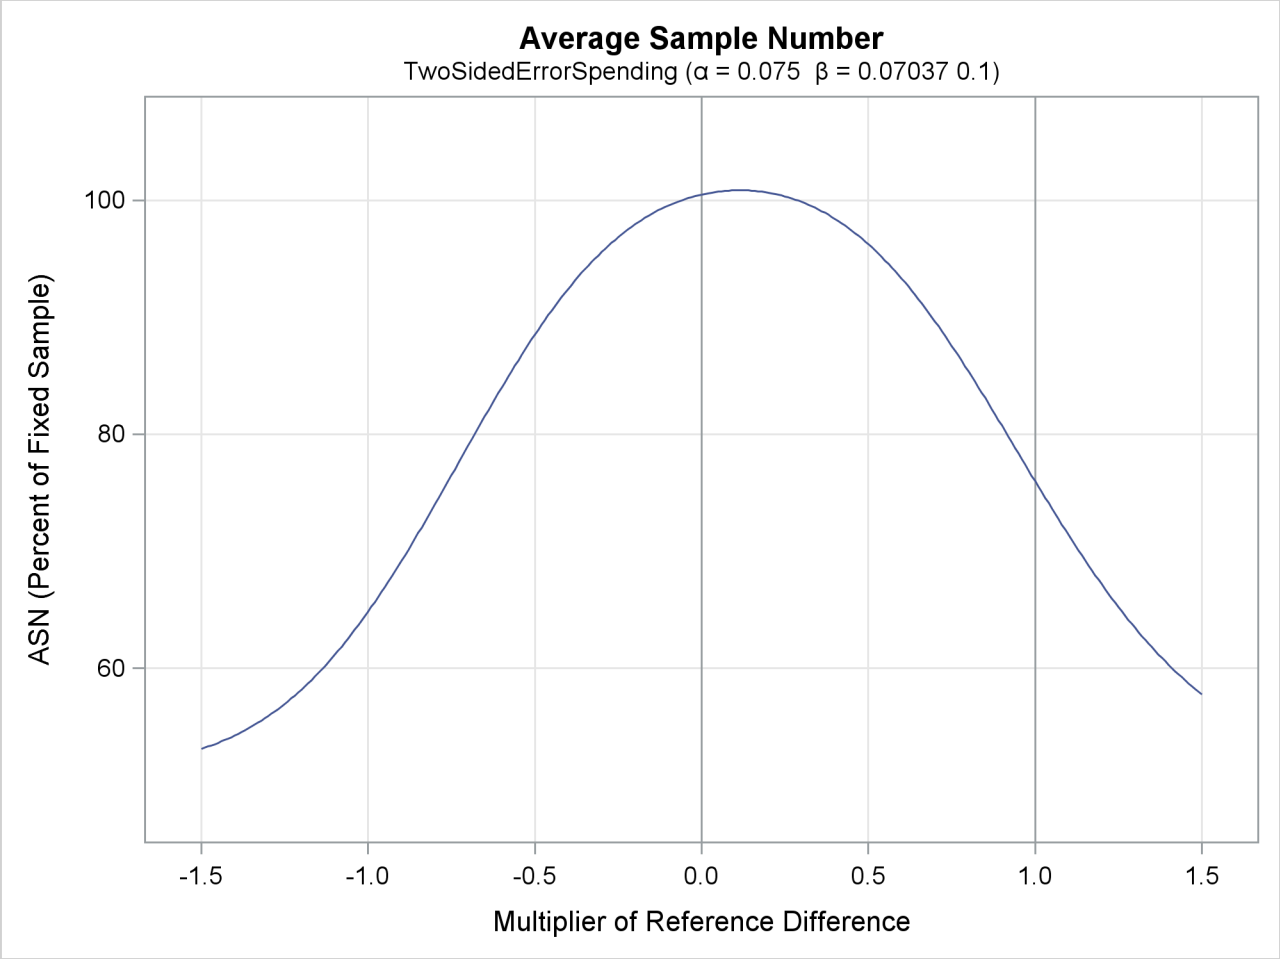
Output 80.11.5 Power Plot



The horizontal axis displays the multiplier of the reference difference. A positive multiplier corresponds to c_i for the upper alternative hypothesis, and a negative multiplier corresponds to $-c_i$ for the lower alternative hypothesis. For lower reference hypotheses, the power is the lower α error 0.05 under the null hypothesis ($c_i = 0$) and is 0.92963 under the alternative hypothesis ($c_i = 1$). For upper reference hypotheses, the power is the upper α error 0.025 under the null hypothesis ($c_i = 0$) and is 0.90 under the alternative hypothesis ($c_i = 1$).

With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in Output 80.11.6. By default, expected sample sizes under the lower hypotheses $\theta = c_i\,\theta_{1l}$ and under the upper hypotheses $\theta = c_i\,\theta_{1u}$, $c_i = 0, 0.01, 0.02, \ldots, 1.50$, are displayed for a two-sided asymmetric design, where $\theta_{1l} = -1$ and $\theta_{1u} = 1$ are the lower and upper alternative references, respectively.

Output 80.11.6 ASN Plot



The horizontal axis displays the multiplier of the reference difference. A positive multiplier corresponds to c_i for the upper alternative hypothesis and a negative multiplier corresponds to $-c_i$ for the lower alternative hypothesis.

The "Boundary Information" table in Output 80.11.7 displays the information levels, alternative references, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the standardized Z scale is used to display the alternative references and boundary values. The resulting standardized alternative references at stage k are given by $\pm\theta_1\sqrt{I_k}$, where θ_1 is the specified alternative reference and I_k is the information level at stage k, $k = 1, 2, 3$.

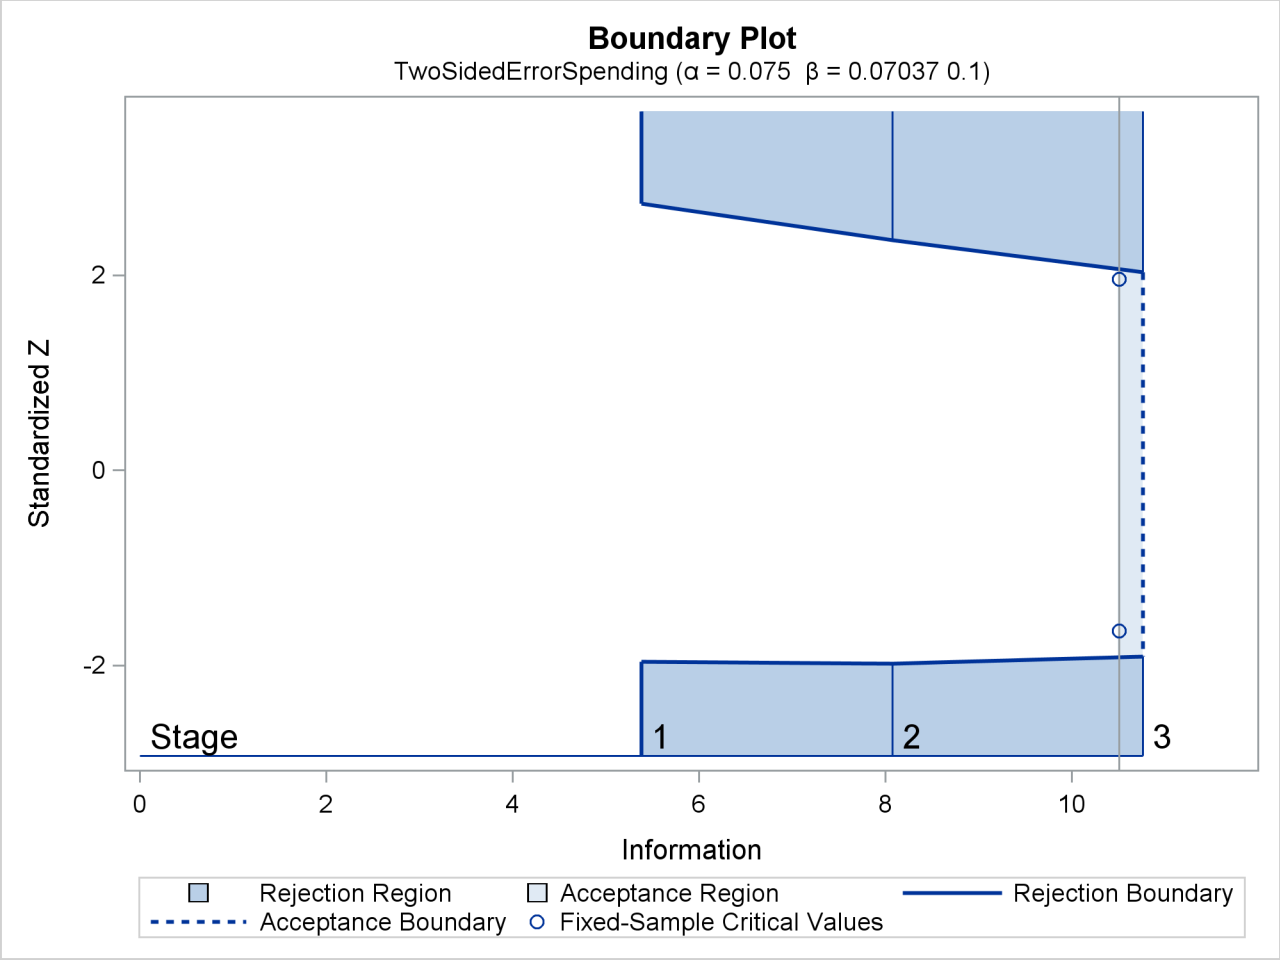
Output 80.11.7 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

Stage	--Information Level- Proportion	Actual	------Alternative----- -------Reference------ Lower	Upper	----Boundary Values--- ---Lower-- Alpha	---Upper-- Alpha
1	0.5000	5.381827	-2.31988	2.31988	-1.95996	2.73437
2	0.7500	8.07274	-2.84126	2.84126	-1.98394	2.35681
3	1.0000	10.76365	-3.28080	3.28080	-1.90855	2.02853

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.11.8.

Output 80.11.8 Boundary Plot



The "Error Spending Information" table in Output 80.11.9 displays the cumulative error spending at each stage for each boundary.

Output 80.11.9 Error Spending Information

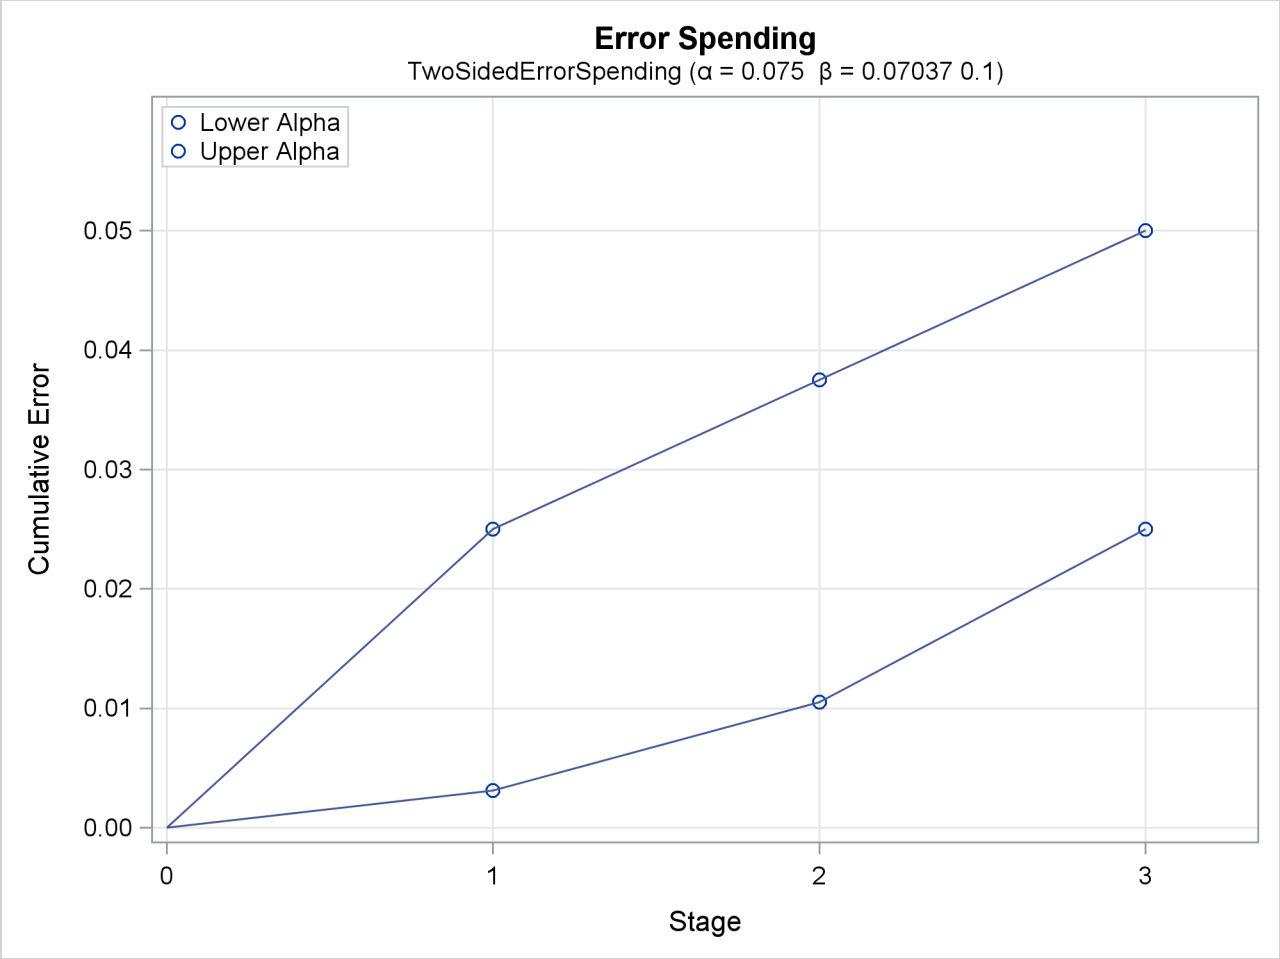
Error Spending Information

Stage	-Information Level- Proportion	--------Cumulative Error Spending------- -------Lower------ Alpha	Beta	-------Upper------ Beta	Alpha
1	0.5000	0.02500	0.00000	0.00001	0.00313
2	0.7500	0.03750	0.00000	0.00001	0.01055
3	1.0000	0.05000	0.07037	0.10000	0.02500

With the STOP=REJECT option, there is no early stopping to accept H_0, and the corresponding β spending at an interim stage is computed from the rejection region. For example, the upper β spending at stage 1 (0.00001) is the probability of rejecting H_0 for the lower alternative under the upper alternative reference.

With the PLOTS=ERRSPEND option, the procedure displays a plot of the cumulative error spending on each boundary at each stage, as shown in Output 80.11.10.

Output 80.11.10 Error Spending Plot



Example 80.12: Creating a Two-Sided Asymmetric Error Spending Design with Early Stopping to Reject or Accept H_0

This example requests a four-stage two-sided asymmetric group sequential design for normally distributed statistics. The O'Brien-Fleming boundary can be approximated by a gamma family error spending function with parameter $\gamma = -4$ or -5, and the Pocock boundary can be approximated with parameter $\gamma = 1$ (Hwang, Shih, and DeCani 1990, p. 1440). The following statements use the gamma error spending function with early stopping to reject or accept the null hypothesis H_0:

```
ods graphics on;
proc seqdesign altref=2
               pss(cref=0 0.5 1)
               stopprob(cref=0 1)
               errspend
               plots=(asn power errspend)
               ;
```

```
TwoSidedAsymmetric: design nstages=4
                    method=errfuncgamma(gamma=1)
                    method(beta)=errfuncgamma(gamma=-2)
                    method(upperalpha)=errfuncgamma(gamma=-5)
                    alt=twosided
                    stop=both
                    beta=0.1
                    ;
run;
ods graphics off;
```

The design uses gamma family error spending functions with $\gamma = -5$ for the upper α boundary, $\gamma = 1$ for the lower α boundary, and $\gamma = -2$ for the lower and upper β boundaries.

The "Design Information" table in Output 80.12.1 displays design specifications and the derived maximum information. Note that in order to attain the same information level for the asymmetric lower and upper boundaries, the derived power at the upper alternative 0.93655 is larger than the specified $1 - \beta = 0.90$.

Output 80.12.1 Design Information

The SEQDESIGN Procedure
Design: TwoSidedAsymmetric

"Rej Null (Lower Alt)" and "Rej Null (Upper Alt)" under the heading "Source" indicate the probabilities of rejecting the null hypothesis for the lower alternative and for the upper alternative, respectively. "Reject Null" indicates the probability of rejecting the null hypothesis for either the lower or upper alternative, "Accept Null" indicates the probability of accepting the null hypothesis, and "Total" indicates the total probability of stopping the trial.

With the PSS(CREF=0 0.5 1.0) option, the "Power and Expected Sample Sizes" table in Output 80.12.4 displays powers and expected sample sizes under hypothetical references $\theta = 0$ (null hypothesis H_0), $\theta = 0.5\,\theta_1$, and $\theta = \theta_1$ (alternative hypothesis H_1), where θ_1 is the alternative reference. The expected sample sizes are displayed in a scale that indicates a percentage of its corresponding fixed-sample size design.

Output 80.12.4 Power and Expected Sample Size Information

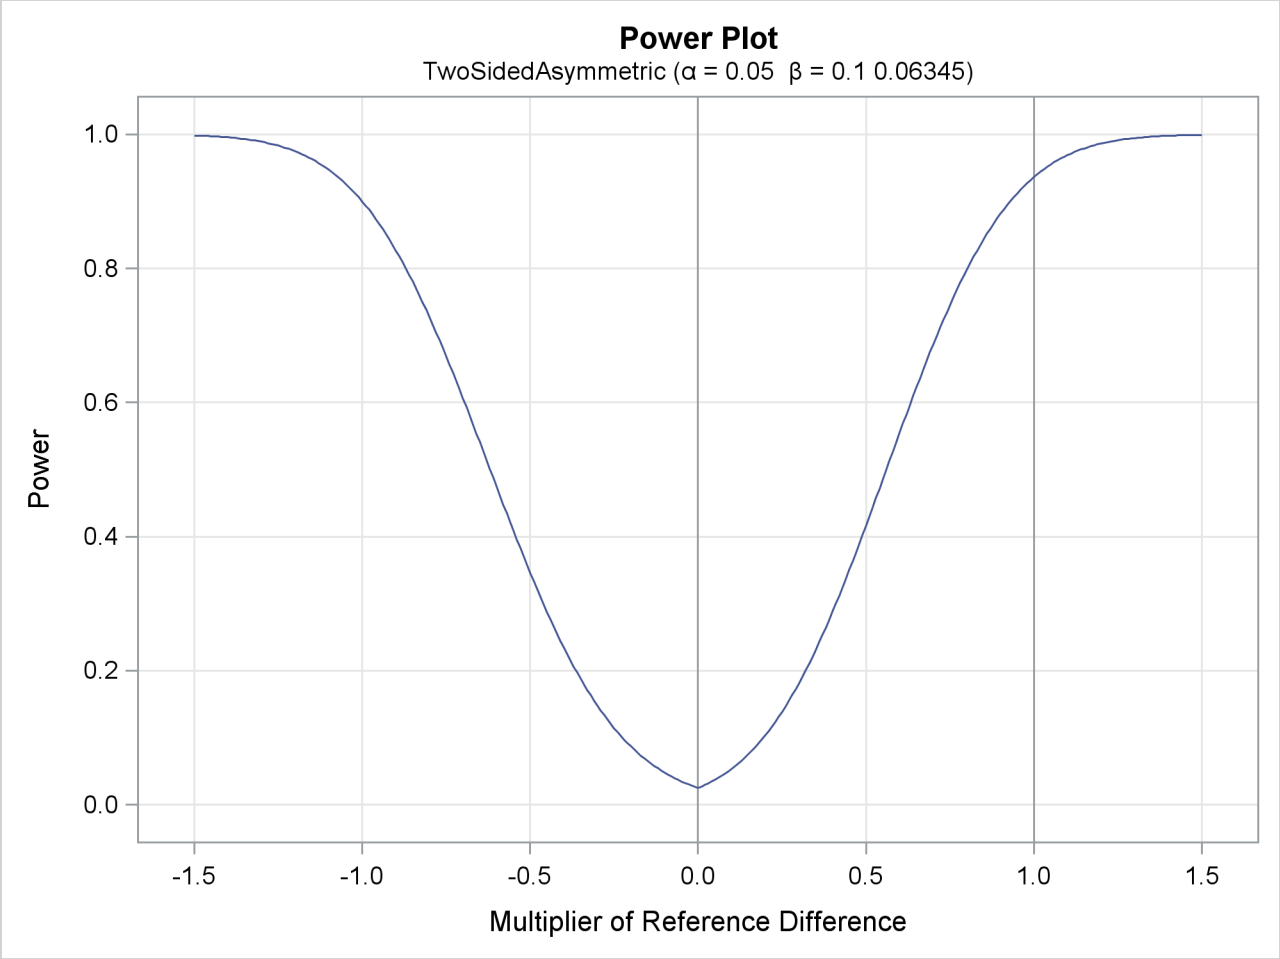
Powers and Expected Sample Sizes
Reference = CRef * (Alt Reference)

CRef	Ref	Power	-Sample Size- Percent Fixed-Sample
0.0000	Lower Alt	0.02500	74.1665
0.5000	Lower Alt	0.34601	75.8425
1.0000	Lower Alt	0.90000	59.1027
0.0000	Upper Alt	0.02500	74.1665
0.5000	Upper Alt	0.41647	85.3976
1.0000	Upper Alt	0.93655	73.7880

Note that at $c_i = 0$, the null reference $\theta = 0$, the power with the lower alternative is the lower α error 0.025, and the power with the upper alternative is the upper α error 0.025. At $c_i = 1$, the alternative reference $\theta = \theta_1$, the power with the lower alternative is the specified power 0.90, and the power with the upper alternative 0.93655 is greater than the specified power 0.90 because the same information level is used for these two asymmetric boundaries.

With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references, as shown in Output 80.12.5. By default, powers under the lower hypotheses $\theta = c_i\,\theta_{1l}$ and under the upper hypotheses $\theta = c_i\,\theta_{1u}$, are displayed for a two-sided asymmetric design, where $c_i = 0, 0.01, 0.02, \ldots, 1.50$ and $\theta_{1l} = -1$ and $\theta_{1u} = 1$ are the lower and upper alternative references, respectively.

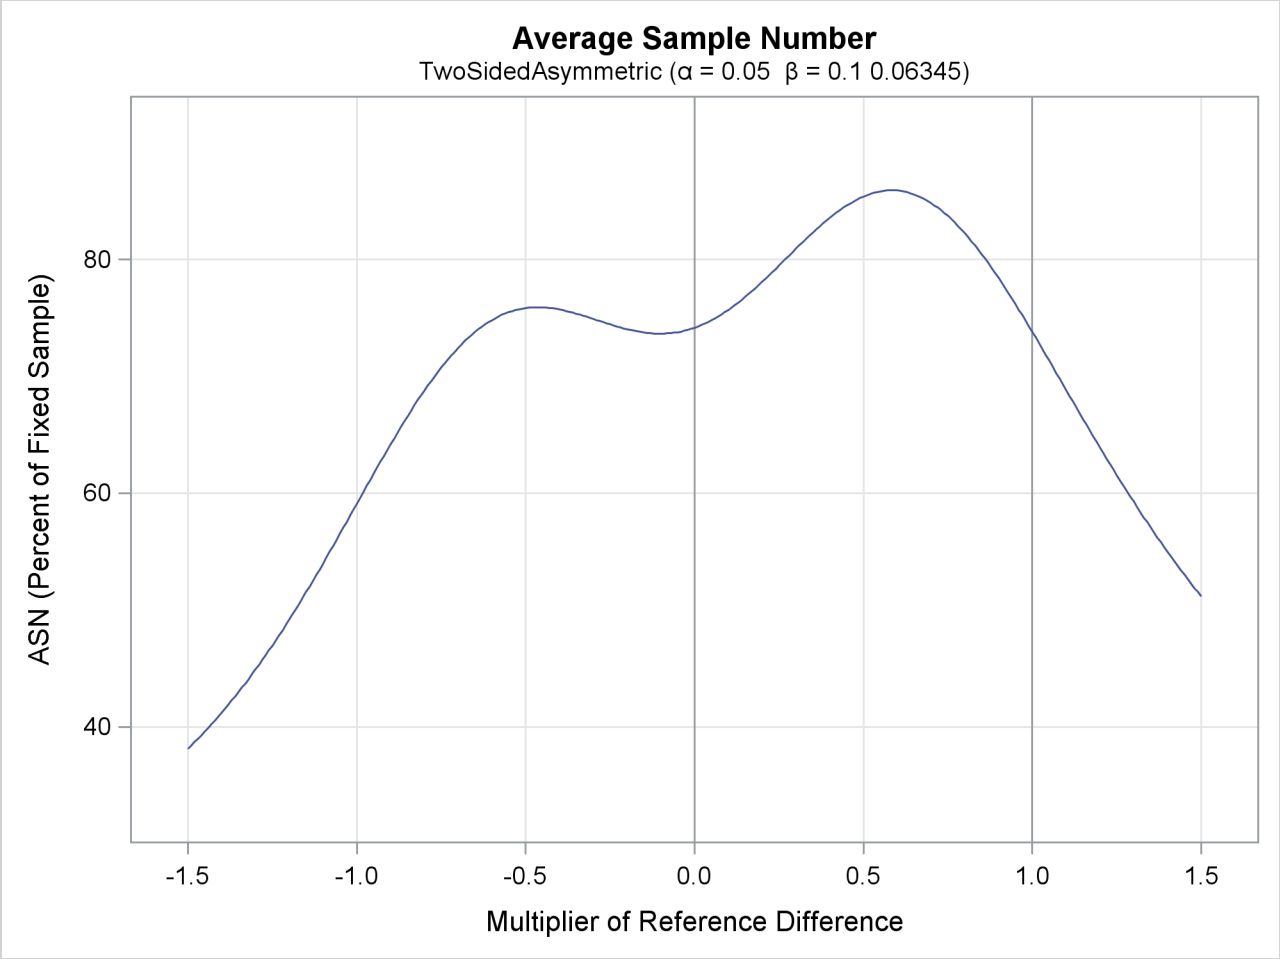
Output 80.12.5 Power Plot



The horizontal axis displays the multiplier of the reference difference. A positive multiplier corresponds to c_i for the upper alternative hypothesis, and a negative multiplier corresponds to $-c_i$ for the lower alternative hypothesis. For lower reference hypotheses, the power is the lower α error 0.025 under the null hypothesis ($c_i = 0$) and is 0.90 under the alternative hypothesis ($c_i = 1$). For upper reference hypotheses, the power is the upper α error 0.025 under the null hypothesis ($c_i = 0$) and is 0.93655 under the alternative hypothesis ($c_i = 1$).

With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in Output 80.12.6. By default, expected sample sizes under the lower hypotheses $\theta = c_i\,\theta_{1l}$ and under the upper hypotheses $\theta = c_i\,\theta_{1u}$ are displayed for a two-sided asymmetric design, where $c_i = 0, 0.01, 0.02, \ldots, 1.50$ and $\theta_{1l} = -1$ and $\theta_{1u} = 1$ are the lower and upper alternative references, respectively.

Output 80.12.6 ASN Plot



The horizontal axis displays the multiplier of the reference difference. A positive multiplier corresponds to c_i for the upper alternative hypothesis, and a negative multiplier corresponds to $-c_i$ for the lower alternative hypothesis.

By default (or equivalently if you specify BETAOVERLAP=ADJUST), the SEQDESIGN procedure first derives boundary values without adjusting for the possible overlapping of the two one-sided β boundaries based on two corresponding one-sided tests. Then the procedure checks for overlapping of the β boundaries at the interim stages. Since the two β boundaries overlap at stage 1, the β boundary values for stage 1 are set to missing, the β spending values at stage 1 are set to zero, and the β spending values at subsequent stages are adjusted proportionally.

The "Boundary Information" table in Output 80.12.7 displays the information levels, alternative references, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the standardized Z scale is used to display the alternative references and boundary values. The resulting standardized alternative references at stage k is given by $\pm\theta_1\sqrt{I_k}$, where θ_1 is the specified alternative reference and I_k is the information level at stage k, $k = 1, 2, 3, 4$.

Output 80.12.7 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

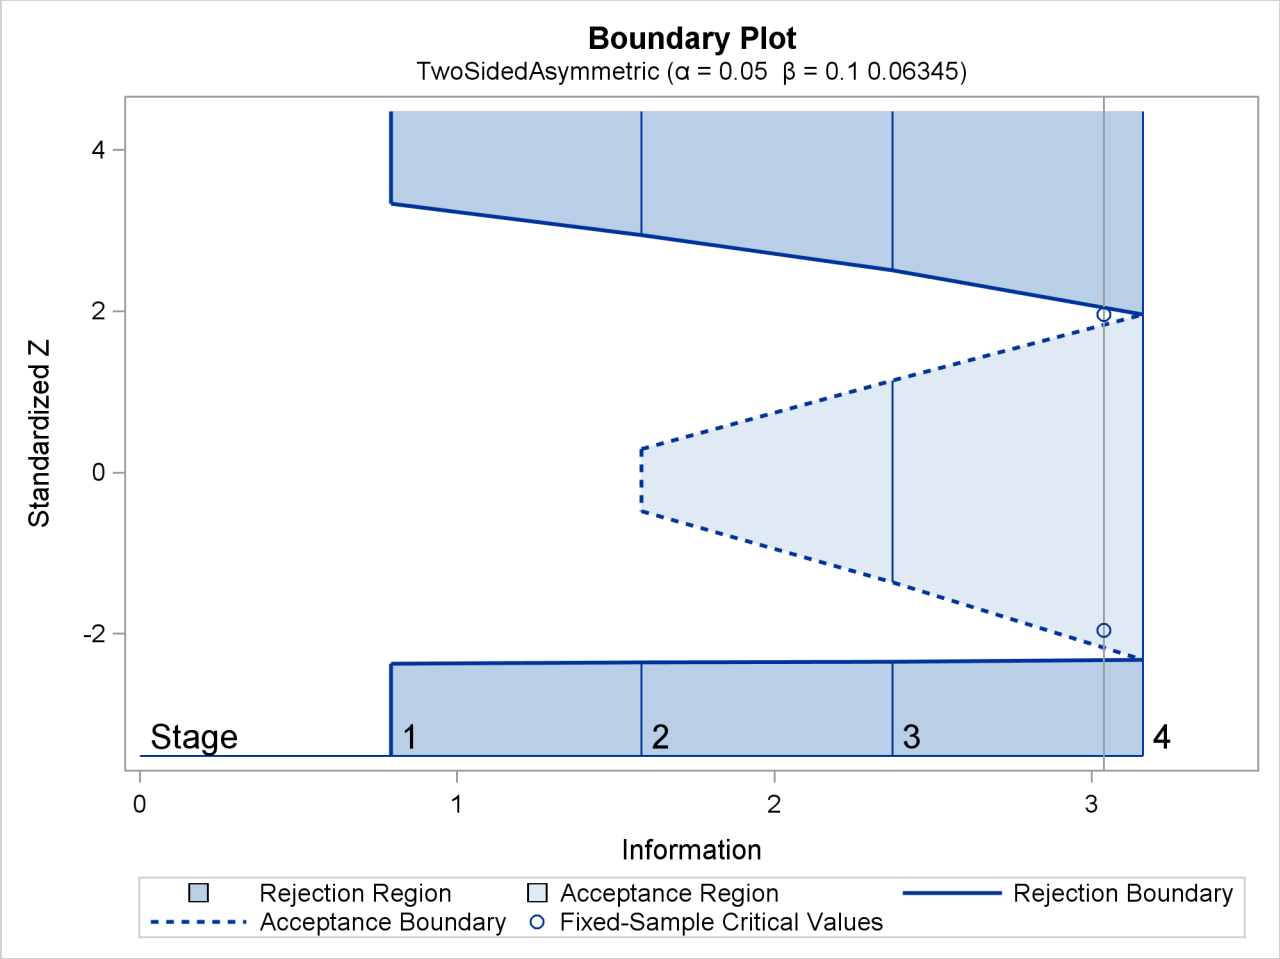
2	-2.35714	-0.48408	0.29400	2.94871
3	-2.34861	-1.36183	1.13898	2.50473
4	-2.32105	-2.32105	1.95675	1.95675

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 80.12.8.

Output 80.12.8 Boundary Plot



The "Error Spending Information" in Output 80.12.9 displays the cumulative error spending at each stage for each boundary.

Output 80.12.9 Error Spending Information

Error Spending Information

	-Information Level-	--------Cumulative Error Spending-------			
		-------Lower------		-------Upper------	
Stage	Proportion	Alpha	Beta	Beta	Alpha
1	0.2500	0.00875	0.00000	0.00002	0.00042
2	0.5000	0.01556	0.01863	0.01184	0.00190
3	0.7500	0.02087	0.04935	0.03132	0.00704
4	1.0000	0.02500	0.10000	0.06345	0.02500

With the β boundary values missing at stage 1, there is no early stopping to accept H_0 at stage 1, and the corresponding β spending at stage 1 is computed from the rejection region. For example, the upper β spending at stage 1 (0.00002) is the probability of rejecting H_0 for the lower alternative under the upper alternative reference.

With the PLOTS=ERRSPEND option, the procedure displays a plot of the cumulative error spending on each boundary at each stage, as shown in Output 80.12.10.

Output 80.12.10 Error Spending Plot

Chapter 81

The SEQTEST Procedure

Contents

Overview: SEQTEST Procedure

The purpose of the SEQTEST procedure is to perform interim analyses for clinical trials. Clinical trials are experiments on human beings to demonstrate the efficacy and safety of new drugs or treatments. A simple example is a trial to test the effectiveness of a new drug in humans by comparing the outcomes in a group of patients who receive the new drug with the outcomes in a comparable group of patients who receive a placebo.

A clinical trial is conducted according to a plan called a *protocol*. A protocol details the objectives of the trial, the data collection process, and the analyses of the data. The protocol contains information such as a null hypothesis and an alternative hypothesis, a test statistic, the probability α of a Type I error (incorrectly rejecting the null hypothesis), the probability β of a Type II error (incorrectly accepting the null hypothesis), the sample size needed to attain a specified power (probability of correctly rejecting the null hypothesis) of $1 - \beta$ at an alternative reference, and critical values that are associated with the test statistic for hypothesis testing.

In a fixed-sample trial, data about all individuals are first collected and then examined at the end of the study. Most major trials have data safety monitoring boards or data monitoring committees that periodically monitor safety and efficacy data during the trial and recommend that a trial be stopped for safety concerns such as an unacceptable toxicity level. In certain rare situations, the board or committee might even recommend that a trial be stopped for efficacy. In contrast to a fixed-sample trial, a group sequential trial provides for interim analyses before the formal completion of the trial while maintaining the specified overall Type I and Type II error probability levels.

A group sequential trial is most useful in situations where it is important to monitor the trial to prevent unnecessary exposure of patients to an unsafe new drug, or alternatively to a placebo treatment if the new drug shows significant improvement. If a group sequential trial stops early, then it usually requires fewer participants than a corresponding fixed-sample trial.

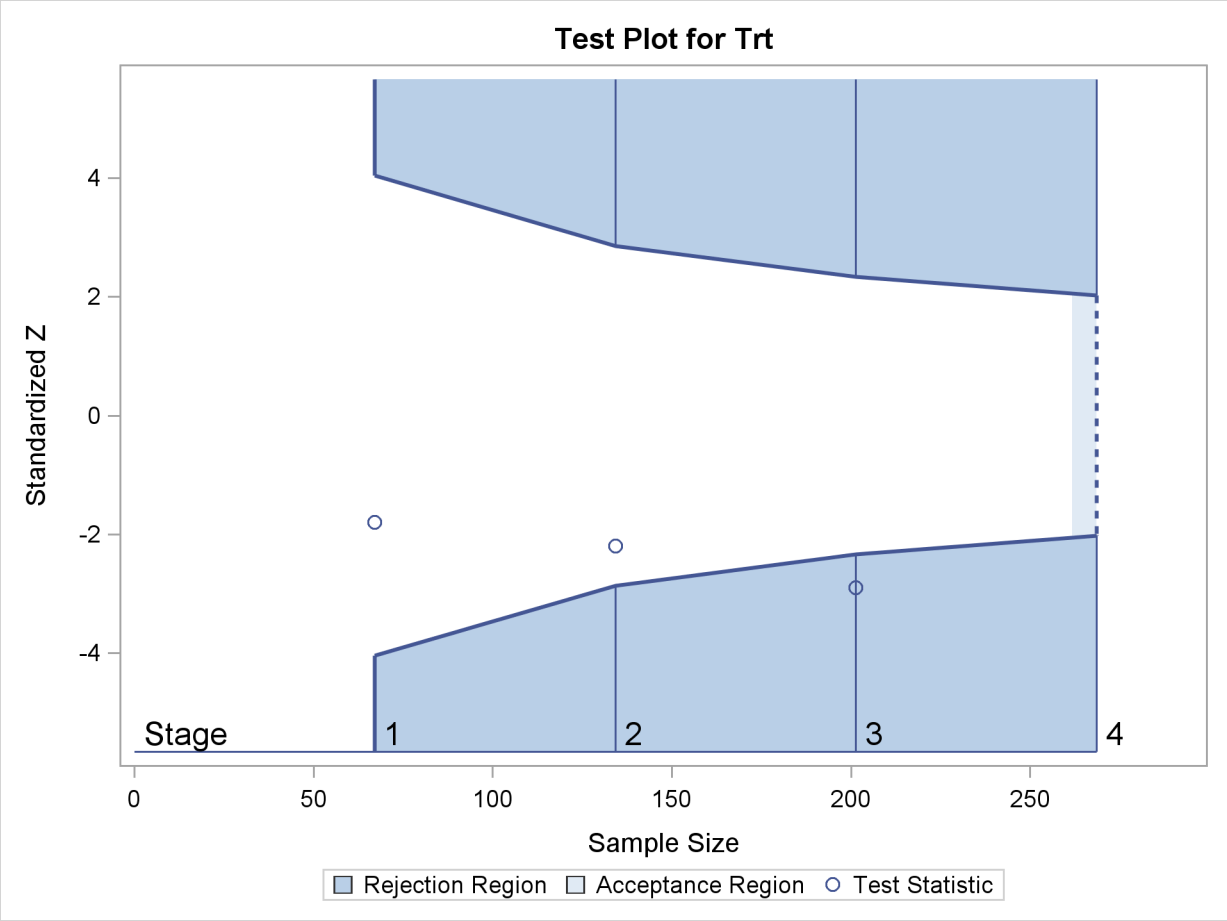
Thus, in most cases, if a group sequential trial stops early for safety of the new treatment, fewer patients will be exposed to the new treatment than in the fixed-sample trial. Also, if a trial stops early for efficacy of the new treatment, the new treatment will be available sooner than it would be in a fixed-sample trial. Furthermore, if a trial stops early, this can also save time and resources.

A group sequential design provides detailed specifications for a group sequential trial. In addition to the usual specification for a fixed-sample design, it provides the total number of stages (the number of interim stages plus a final stage) and a stopping criterion to reject, to accept, or to either reject or accept the null hypothesis at each interim stage. It also provides critical values and the sample size at each stage for the trial.

At each interim stage, the data collected at the current stage in addition to the data collected at previous stages are analyzed, and statistics such as a maximum likelihood test statistic and its associated standard error are computed. The test statistic is then compared with its corresponding critical values at the stage, and the trial is stopped or continued. If a trial continues to the final stage, the null hypothesis is either rejected or accepted. The critical values for each stage are chosen in such a way to maintain the overall α level, the overall β level, or both the overall α and β levels.

Figure 81.1 shows a two-sided symmetric group sequential trial that stops early to reject the null hypothesis that the parameter Trt is zero.

Figure 81.1 Sequential Plot for Two-Sided Test



The trial has four stages, which are indicated by vertical lines with accompanying stage numbers. With early stopping to reject the null hypothesis, the lower rejection boundary is constructed by connecting the lower critical values (boundary values) for the stages. Similarly, the upper rejection boundary is constructed by connecting the upper critical values for the stages. The horizontal axis indicates the sample size for the group sequential trial, and the vertical axis indicates the boundary values and test statistics on the standardized Z scale.

At each interim stage, if the standardized Z test statistic falls into a rejection region (the darker shaded areas in Figure 81.1), the trial stops and the null hypothesis is rejected. Otherwise, the trial continues to the next stage. At the final stage (stage 4), the trial is rejected if Z falls into a rejection region. Otherwise, the trial is accepted. In Figure 81.1, the test statistic does not fall into the rejection regions for stages 1 and 2, and so the trial continues to stage 3. At stage 3, the test statistic falls into the rejection region, and the null hypothesis is rejected.

A group sequential trial usually involves six steps:

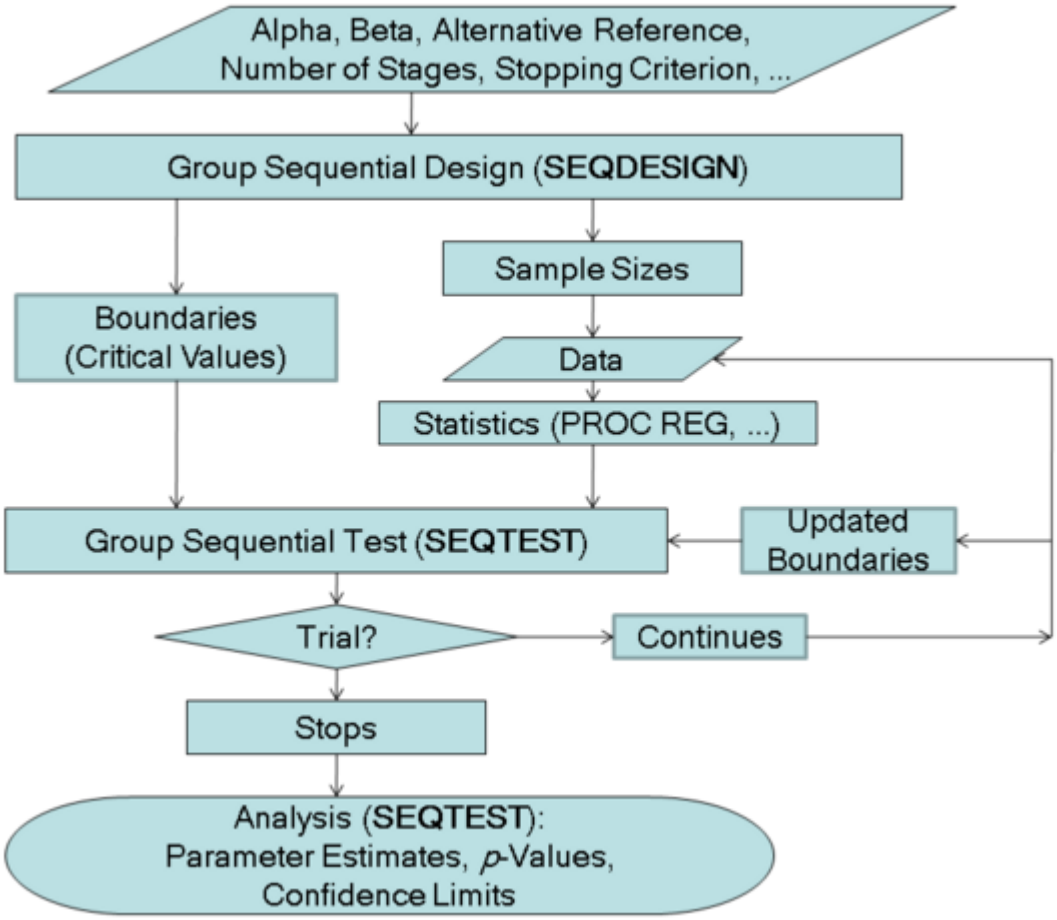
1. You specify the statistical details of the design, including the null and alternative hypotheses, a test statistic for the hypothesis test, the Type I and II error probabilities, a stopping criterion, the total number of stages, and the relative information level at each stage.
2. You compute the boundary values for the trial based on the specifications in Step 1. You also compute the sample size required at each stage for the specified hypothesis test.
3. At each stage, you collect additional data with the required sample sizes. The data available at each stage include the data collected at previous stages in addition to the data collected at the current stage.
4. At each stage, you analyze the available data with a procedure such as the REG procedure, and you compute the test statistic.
5. At each stage, you compare the test statistic with the corresponding boundary values. You stop the trial to reject or accept the hypothesis, or you continue the trial to the next stage. If you continue the trial to the final stage, you either accept or reject the hypothesis.
6. After the trial stops, you compute parameter estimates, confidence limits for the parameter, and a p-value for the hypothesis test.

You use the companion SEQDESIGN procedure at Step 2 to compute the boundary values and required sample sizes for the trial. You use the SEQTEST procedure at Step 5 to compare the test statistic with its boundary values. At stage 1, the boundary values are derived by using the boundary information tables created by the SEQDESIGN procedure. These boundary information tables are structured for input to the SEQTEST procedure. At each subsequent stage, the boundary values are derived by using the test information tables created by the SEQTEST procedure at the previous stage. These test information tables are also structured for input to the SEQTEST procedure. You also use the SEQTEST procedure at Step 6 to compute parameter estimates, confidence limits, and p-values after the trial stops.

Note that for some clinical trials, the information levels are derived from statistics based on individuals specified in the design plan and might not reach the target maximum information level. For example, if an estimate of the variance is used to compute the required sample size for a group sequential trial, the computed variance at each stage might not be the same as the estimated variance. Thus, instead of specifying the number of individuals in the protocol, the information level can be specified. You can then adjust the sample sizes with the updated variance estimates at interim stages to achieve the target maximum information level for the trial (Jennison and Turnbull 2000, p. 295).

The flowchart in Figure 81.2 summarizes the steps in a typical group sequential trial and the relevant SAS procedures.

Figure 81.2 Group Sequential Trial



Features of the SEQTEST Procedure

At each stage, the data are analyzed with a statistical procedure such as the REG procedure, and a test statistic and its associated information level are computed. The information level is the amount of information available about the unknown parameter. For a maximum likelihood statistic, the information level is the inverse of its variance.

At each stage, you use the SEQTEST procedure to compare the test statistic with its boundary values. At stage 1, the boundary values are derived by using the boundary information tables created by the SEQDESIGN procedure. At each subsequent stage, the boundary values are derived by using the test information tables created by the SEQTEST procedure at the previous stage.

If the observed information level does not match the corresponding information level in the BOUNDARY= data set, the SEQTEST procedure modifies the boundary values to adjust for new information levels at the current and subsequent stages. See the section "Boundary Adjustments for Information Levels" on page 6933 for a detailed description of these boundary adjustments.

Either you can specify the test statistic and its information level in the DATA= input data set, or you can specify the test statistic and its associated standard error in the PARMS= input data set. With the PARMS=

input data set, the information level for the test statistic is computed from its standard error. See the section "Input Data Sets" on page 6927 for a detailed description of these input data sets.

At the end of a trial, the parameter estimate is computed. The median unbiased estimate, confidence limits, and p-value depend on the specified sample space ordering. A sample space ordering specifies the ordering for test statistics that result in the stopping of a trial. That is, for all the statistics in the rejection region and in acceptance region, the SEQTEST procedure provides three different sample space orderings: the stagewise ordering uses counterclockwise ordering around the continuation region, the LR ordering uses the distance between the observed Z statistic z and its hypothetical value, and the MLE ordering uses the observed maximum likelihood estimate. See the section "Available Sample Space Orderings in a Sequential Test" on page 6940 for a detailed description of these orderings.

Output from the SEQTEST Procedure

In addition to the adjusted boundary values and test results for the group sequential trial, the SEQTEST procedure also computes the following quantities:

- average sample numbers (as percentages of the corresponding fixed-sample sizes for nonsurvival data or fixed-sample numbers of events for survival data) under various hypothetical references, including the null and alternative references
- stopping probabilities at each stage under various hypothetical references to indicate how likely it is that the trial will stop at that stage
- conditional power given the most recently observed statistic under specified hypothetical references
- predictive power given the most recently observed statistic
- repeated confidence intervals for the parameter from the observed statistic at each stage
- parameter estimate, p-value for hypothesis testing, and median and confidence limits for the parameter at the conclusion of a sequential trial

Getting Started: SEQTEST Procedure

The following example illustrates a clinical study that uses a two-sided O'Brien-Fleming design (O'Brien and Fleming 1979) to stop the trial early for ethical concerns about possible harm or for unexpectedly strong efficacy of the new drug.

Suppose that a pharmaceutical company is conducting a clinical trial to test the efficacy of a new cholesterol-lowering drug. The primary focus is low-density lipoprotein (LDL), the so-called bad cholesterol, which is a risk factor for coronary heart disease. LDL is measured in mg/dL, milligrams per deciliter of blood.

The trial consists of two groups of equally allocated patients with elevated LDL level: an experimental group given the new drug and a placebo control group. Suppose the changes in LDL level after the treatment for patients in the experimental and control groups are normally distributed with means μ_e and μ_c, respectively,

and have a common variance σ^2. Then the null hypothesis of no effect for the new drug is $H_0 : \theta = \mu_e - \mu_c = 0$. Also suppose that the alternative reference $\theta = -10$ is the clinically meaningful difference that the trial should detect with a high probability (power), and that a good estimate of the standard deviation for the changes in LDL level is $\hat{\sigma} = 20$.

The following statements invoke the SEQDESIGN procedure and request a four-stage O'Brien-Fleming design for standardized normal test statistics:

```
ods graphics on;
proc seqdesign altref=-10.0;
  TwoSidedOBrienFleming: design nstages=4
                         method=obf
                         ;
  samplesize model=twosamplemean(stddev=20);
  ods output Boundary=Bnd_LDL;
run;
ods graphics off;
```

The ALTREF= option specifies the alternative reference, and the actual maximum information is derived in the SEQDESIGN procedure.

In the DESIGN statement, the label `TwoSidedOBrienFleming` identifies the design in the output tables. By default (or equivalently if you specify ALT=TWOSIDED and STOP=REJECT), the design has a two-sided alternative hypothesis with early stopping in the interim stages only to reject the null hypothesis. That is, at each interim stage, the trial will either be stopped to reject the null hypothesis or continue to the next stage.

The NSTAGES=4 option in the DESIGN statement specifies the total number of stages in the group sequential trial, including three interim stages and a final stage. In the SEQDESIGN procedure, the null hypothesis for the design is $H_0 : \theta = 0$. By default (or equivalently if you specify ALPHA=0.05 and BETA=0.10), the design has a Type I error probability $\alpha = 0.05$, and a Type II error probability $\beta = 0.10$, which corresponds to a power of $1 - \beta = 0.90$ at the alternative reference $H_1 : \theta = -10$.

For a two-sided design with early stopping to reject the null hypothesis, there are two boundaries for the design: an upper α (rejection) boundary that consists of upper rejection critical values and a lower α boundary that consists of lower rejection critical values. Each boundary is a set of critical values, one from each stage. With the METHOD=OBF option in the DESIGN statement, the O'Brien-Fleming method is used for the two boundaries for the design; see Figure 81.5.

The SAMPLESIZE statement with the MODEL=TWOSAMPLEMEAN option uses the derived maximum information to compute required sample sizes for a two-sample test for mean difference.

The ODS OUTPUT statement with the BOUNDARY=BND_LDL option creates an output data set named BND_LDL which contains the resulting boundary information. At each stage of the trial, data are collected and analyzed with a statistical procedure, and a test statistic and its corresponding information level are computed.

In this example, you can use the REG procedure to compute the maximum likelihood estimate $\hat{\theta}$ for the drug effect and the corresponding standard error for $\hat{\theta}$. At stage 1, you can use the SEQTEST procedure to compare the test statistic with adjusted boundaries that are derived from the boundary information stored in the BOUND_LDL data set. At each subsequent stage, you can use the SEQTEST procedure to compare the test statistic with adjusted boundaries that are derived from the boundary information stored in the test information table that was created by the SEQTEST procedure at the previous stage. The test information tables are structured for input to the SEQTEST procedure.

At each interim stage, the trial will either be stopped to reject the null hypothesis or continue to the next stage. At the final stage, the null hypothesis is either rejected or accepted.

By default (or equivalently if you specify INFO=EQUAL), the SEQDESIGN procedure derives boundary values with equally spaced information levels for all stages—that is, the same information increment between successive stages.

The "Design Information" table in Figure 81.3 displays design specifications and three derived statistics: the maximum information, the average sample number under the null hypothesis (Null Ref ASN), and the average sample number under the alternative hypothesis (Alt Ref ASN). Each statistic is expressed as a percentage of the identical statistic for the corresponding fixed-sample information. The average sample number is the expected sample size (for nonsurvival data) or expected number of events (for survival data). When you specify an alternative reference (in this case, ALTREF=−10), the actual maximum information 0.1074 is also computed. Note that for a symmetric two-sided design, the ALTREF=−10 option implies a lower alternative reference of −10 and an upper alternative reference of 10.

Figure 81.3 O'Brien-Fleming Design Information

The SEQDESIGN Procedure
Design: TwoSidedOBrienFleming

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Reject Null
Method	O'Brien-Fleming
Boundary Key	Both
Alternative Reference	-10
Number of Stages	4
Alpha	0.05
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	102.2163
Max Information	0.107403
Null Ref ASN (Percent of Fixed Sample)	101.5728
Alt Ref ASN (Percent of Fixed Sample)	76.7397

The "Boundary Information" table in Figure 81.4 displays the information level, the lower and upper alternative references, and the lower and upper boundary values at each stage. By default (or equivalently if you specify INFO=EQUAL), the SEQDESIGN procedure uses equally spaced information levels for all stages.

Figure 81.4 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

Stage	Information Level Proportion	Information Level Actual	Information Level N	Alternative Reference Lower	Alternative Reference Upper
1	0.2500	0.026851	42.96116	-1.63862	1.63862
2	0.5000	0.053701	85.92233	-2.31736	2.31736
3	0.7500	0.080552	128.8835	-2.83817	2.83817
4	1.0000	0.107403	171.8447	-3.27724	3.27724

Boundary Information (Standardized Z Scale)
Null Reference = 0

Stage	Boundary Values Lower Alpha	Boundary Values Upper Alpha
1	-4.04859	4.04859
2	-2.86278	2.86278
3	-2.33745	2.33745
4	-2.02429	2.02429

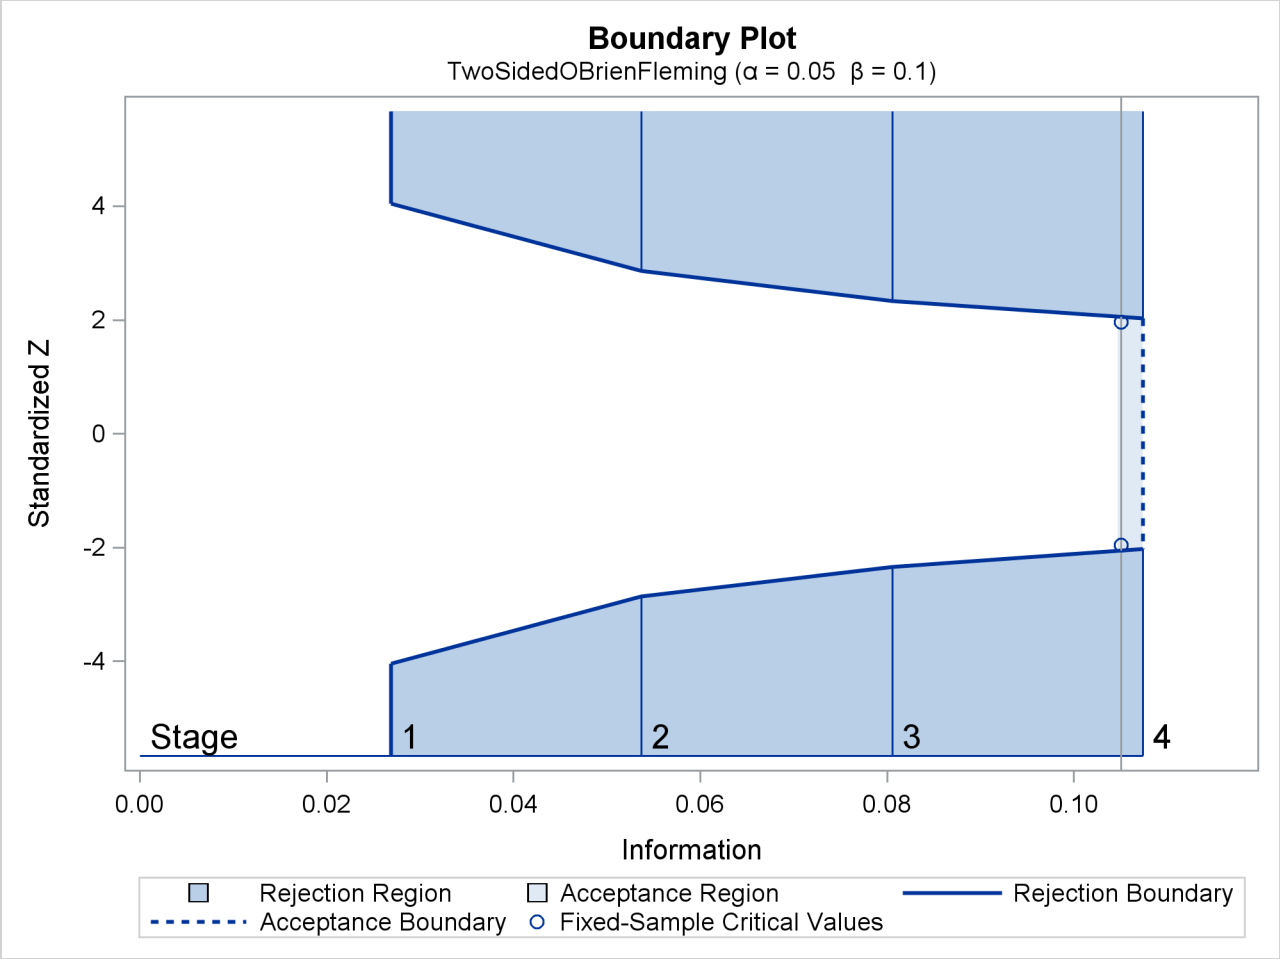
The information proportion is the proportion of maximum information available at each stage. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative references and boundary values are displayed with the standardized Z statistic scale. The alternative reference in the standardized Z scale at stage k is given by $\theta_1\sqrt{I_k}$, where θ_1 is the alternative reference and I_k is the information available at stage k, $k = 1, 2, 3, 4$.

In this example, a standardized Z statistic is computed by standardizing the parameter estimate of the effect in LDL level. A lower Z test statistic indicates a beneficial effect. Consequently, at each interim stage, if the standardized Z test statistic is less than or equal to the corresponding lower α boundary value, the hypothesis $H_0 : \theta = 0$ is rejected for efficacy. If the test statistic is greater than or equal to the corresponding upper α boundary value, the hypothesis H_0 is rejected for harmful effect. Otherwise, the process continues to the next stage. At the final stage (stage 4), the hypothesis H_0 is rejected for efficacy if the Z statistic is less than or equal to the corresponding lower α boundary value -2.0243, and the hypothesis H_0 is rejected for harmful effect if the Z statistic is greater than or equal to the corresponding upper α boundary value 2.0243. Otherwise, the hypothesis of no significant difference is accepted.

Note that in a typical trial, the actual information levels do not match the information levels specified in the design. Consequently, the SEQTEST procedure modifies the boundary values stored in the BND_LDL data set to adjust for these new information levels.

If ODS Graphics is enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Figure 81.5.

Figure 81.5 O'Brien-Fleming Boundary Plot



This boundary plot displays the boundary values in the "Boundary Information" table in Figure 81.4. The stages are indicated by vertical lines with accompanying stage numbers. The horizontal axis indicates the information levels for the stages. If a test statistic at an interim stage is in the rejection region (shaded area), the trial stops and the null hypothesis is rejected. If the statistic is not in any rejection region, the trial continues to the next stage. The plot also displays critical values for the corresponding fixed-sample design. The symbol "○" identifies the fixed-sample critical values of −1.96 and 1.96.

When you specify the SAMPLESIZE statement, the maximum information (either explicitly specified or derived in the SEQDESIGN procedure) is used to compute the required sample sizes for the study. The MODEL=TWOSAMPLEMEAN(STDDEV=20) option specifies the test for the difference between two normal means. See the section "Test for the Difference between Two Normal Means" in the chapter "The SEQDESIGN Procedure" for a detailed description of how these required sample sizes are calculated.

The "Sample Size Summary" table in Figure 81.6 displays the parameters for the sample size computation and the resulting maximum and expected sample sizes.

Figure 81.6 Required Sample Size Summary

Sample Size Summary

Test	Two-Sample Means
Mean Difference	-10
Standard Deviation	20
Max Sample Size	171.8447
Expected Sample Size (Null Ref)	170.7627
Expected Sample Size (Alt Ref)	129.0137

With the derived maximum information 0.1074 and the specified MODEL=TWOSAMPLEMEAN (STDDEV=20) option in the SAMPLESIZE statement, the total sample size in each group is

$$N_a = N_b = 2\sigma^2 I_X = 2 \times 20^2 \times 0.1074 = 85.92$$

The "Sample Sizes (N)" table in Figure 81.7 displays the required sample sizes at each stage for the trial, in both fractional and integer numbers. The derived fractional sample sizes are displayed under the heading "Fractional N." These sample sizes are rounded up to integers under the heading "Ceiling N." By default (or equivalently if you specify WEIGHT=1 in the MODEL=TWOSAMPLEMEAN option), the sample sizes for the two groups are equal for the two-sample test.

Figure 81.7 Required Sample Sizes

Sample Sizes (N)
Two-Sample Z Test for Mean Difference

	Fractional N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	42.96	21.48	21.48	0.0269
2	85.92	42.96	42.96	0.0537
3	128.88	64.44	64.44	0.0806
4	171.84	85.92	85.92	0.1074

Sample Sizes (N)
Two-Sample Z Test for Mean Difference

	Ceiling N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	44	22	22	0.0275
2	86	43	43	0.0538
3	130	65	65	0.0812
4	172	86	86	0.1075

In practice, integer sample sizes are used in the trial, and the resulting information levels increase slightly. Thus, each of the two groups needs 22, 43, 65, and 86 patients for the four stages, respectively.

Suppose that 22 patients are available in each group at stage 1 and that their measurements for LDL are saved in the data set LDL_1. Figure 81.8 lists the first 10 observations in the data set LDL_1.

Figure 81.8 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	Trt	Ldl
1	0	33.33
2	1	-14.89
3	0	15.30
4	1	4.71
5	0	26.89
6	1	-48.74
7	0	-39.35
8	1	-8.13
9	0	-8.22
10	1	12.35

The variable Trt is an indicator variable with value 1 for patients in the treatment group and value 0 for patients in the placebo control group. The variable Ldl is the LDL level of these patients.

The following statements use the REG procedure to estimate the mean treatment difference and its associated standard error at stage 1:

```
proc reg data=LDL_1;
   model Ldl=Trt;
ods output ParameterEstimates=Parms_LDL1;
run;
```

The following statements create the data set for the mean treatment difference and its associated standard error as a PARMS= data set, which will subsequently serve as an input data set for PROC SEQTEST. Note that all of the variables are required for a PARMS= data set, as described in the section "PARMS < (TESTVAR= *variable*) > = SAS Data Set" on page 6929.

```
data Parms_LDL1;
   set Parms_LDL1;
   if Variable='Trt';
   _Scale_='MLE';
   _Stage_= 1;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_LDL1;
   title 'Statistics Computed at Stage 1';
run;
```

Figure 81.9 displays the statistics computed at stage 1.

Figure 81.9 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	Trt	-2.52591	5.68572	MLE	1

Since the sample sizes derived are based on the estimated variance at the designing phase, the information level that corresponds to the test statistic at stage 1 is estimated by

$$I_1 = \frac{1}{s_1^2} = \frac{1}{5.686^2} = 0.0309$$

where s_1 is the standard error of the treatment estimate.

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_LDL
             Parms(Testvar=Trt)=Parms_LDL1
             infoadj=prop
             ;
ods output Test=Test_LDL1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS_LDL1 option specifies the input data set PARMS_LDL1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRT option identifies the test variable TRT in the data set.

By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the maximum information and the Type I error level are maintained. Furthermore, with the INFOADJ=PROP option (which is the default), the information levels at future interim stages (2 and 3) are adjusted proportionally from the levels provided in the BOUNDARY= data set.

The ODS OUTPUT statement with the TEST=TEST_LDL1 option creates an output data set named TEST_LDL1 which contains the updated boundary information for the test at stage 1, and the boundary information that is needed for the group sequential test at the next stage. See the section "Boundary Adjustments for Information Levels" on page 6933 for details.

The "Design Information" table in Figure 81.10 displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are adjusted for the updated information levels to maintain the Type I α level, and the maximum information remains the same as in the BOUNDARY= data set. But the derived Type II error probability β and power $1 - \beta$ are slightly different with new information levels. With the updated power $1 - \beta$, the corresponding fixed-sample design is also updated.

Figure 81.10 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.BND_LDL

Alt Ref ASN (Percent of Fixed Sample)	75.4928

The "Test Information" table in Figure 81.11 displays the boundary values for the test statistic. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), these statistics are displayed with the standardized Z scale. With the INFOADJ=PROP option (which is the default), information levels at future interim stages are derived proportionally from the corresponding levels provided in the BOUNDARY= data set.

Null Reference = 0

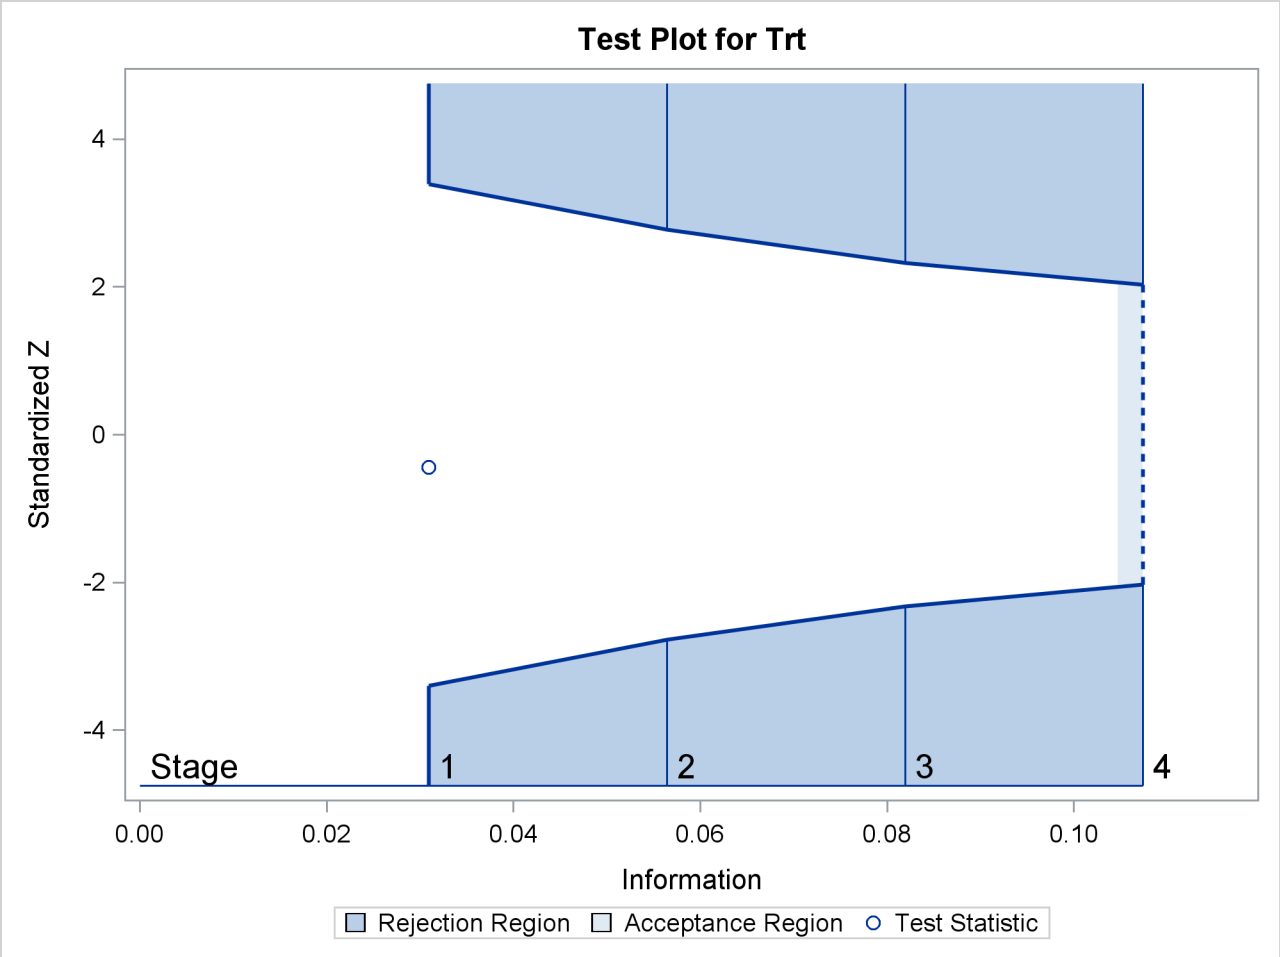
	Test	
	Trt	
Stage	Estimate	Action
1	-0.44426	Continue
2	.	
3	.	
4	.	

At stage 1, the standardized Z statistic -0.44426 is between the lower and upper α boundary values, and so the trial continues to the next stage. With the observed information level at stage 1, $I_1 = 0.0309$ (which is not substantially different from the target information level at stage 1), the trial continues to the next stage without adjustment of the sample size according to the study plan.

If an observed information level is different from its target level at an interim stage, the sample sizes at future stages can be adjusted to achieve the target maximum information level according to the study plan. That is, a study plan might modify the final sample size to achieve the target maximum information level if the observed information level is different from its target level by a specified amount at the interim stage. For example, if the variance estimate is used to compute the required sample size of a two-sample Z test for mean difference, the study plan might use the current variance estimate to update the required sample size for the trial (Jennison and Turnbull 2000, p. 295). See the section "Applicable Two-Sample Tests and Sample Size Computation" in "The SEQDESIGN Procedure" for a description of how to compute the sample size from the variance estimate.

If ODS Graphics is enabled, a detailed test plot with the rejection and acceptance regions is displayed, as shown in Figure 81.12. This plot displays the boundary values in the "Test Information" table in Figure 81.11. The stages are indicated by vertical lines with accompanying stage numbers. The horizontal axis indicates the information levels for the stages. As expected, the test statistic is in the continuation region between the lower and upper α boundaries.

Figure 81.12 Sequential Test Plot



The following statements use the REG procedure with the data available at the first two stages to estimate the mean treatment difference and its associated standard error at stage 2:

```
proc reg data=LDL_2;
   model Ldl=Trt;
ods output ParameterEstimates=Parms_LDL2;
run;
```

The following statements create and display (in Figure 81.13) the data set for the mean treatment difference and its associated standard error:

```
data Parms_LDL2;
   set Parms_LDL2;
   if Variable='Trt';
   _Scale_='MLE';
   _Stage_= 2;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_LDL2;
   title 'Statistics Computed at Stage 2';
run;
```

Figure 81.13 Statistics Computed at Stage 2

Statistics Computed at Stage 2

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	Trt	-8.37628	4.24405	MLE	2

Using the standard error for the treatment estimate available at stage 2, the information level that corresponds to the test statistic at stage 2 is estimated by

$$I_2 = \frac{1}{s_2^2} = \frac{1}{4.244^2} = 0.0555$$

where s_2 is the standard error of the treatment estimate at stage 2.

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
proc seqtest Boundary=Test_LDL1
             Parms(Testvar=Trt)=Parms_LDL2
             infoadj=prop
             ;
ods output Test=Test_LDL2;
run;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST_LDL2 option creates an output data set named TEST_LDL2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Test Information" table in Figure 81.14 displays the boundary values for the test statistic with the default standardized Z scale

Figure 81.14 Sequential Tests

The SEQTEST Procedure

Null Reference = 0

Stage	----------Test---------- ----------Trt---------- Estimate	Action
1	-0.44426	Continue
2	-1.97365	Continue
3	.	
4	.	

At stage 2, the standardized test statistic, $z = -8.37628/4.24405 = -1.97365$, is between its corresponding lower and upper α boundary values. Therefore, the trial continues to the next stage.

The following statements use the REG procedure with the data available at the first three stages to estimate the mean treatment difference and its associated standard error at stage 3:

```
proc reg data=LDL_3;
   model Ldl=Trt;
ods output ParameterEstimates=Parms_LDL3;
run;
```

The following statements create and display (in Figure 81.15) the data set for the mean treatment difference and its associated standard error:

```
data Parms_LDL3;
   set Parms_LDL3;
   if Variable='Trt';
   _Scale_='MLE';
   _Stage_= 3;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_LDL3;
   title 'Statistics Computed at Stage 3';
run;
```

Figure 81.15 Statistics Computed at Stage 3

Statistics Computed at Stage 3

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	Trt	-9.21369	3.42149	MLE	3

The following statements invoke the SEQTEST procedure to test for early stopping at stage 3:

```
ods graphics on;
proc seqtest Boundary=Test_LDL2
             Parms(Testvar=Trt)=Parms_LDL3
             infoadj=prop
             ;
ods output Test=Test_LDL3;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 3, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 3, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST_LDL3 option creates an output data set named TEST_LDL3 which contains the updated boundary information for the test at stage 3. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Test Information" table in Figure 81.16 displays the boundary values for the test statistic with the default standardized Z scale.

Figure 81.16 Sequential Tests

The SEQTEST Procedure

Test Information (Standardized Z Scale)
Null Reference = 0

Stage	--Information Level- Proportion	Actual	------Alternative----- -------Reference------ Lower	Upper	----Boundary Values--- ---Lower-- Alpha	---Upper-- Alpha
1	0.2880	0.030934	-1.75879	1.75879	-3.39532	3.39532
2	0.5169	0.055519	-2.35624	2.35624	-2.78456	2.78456
3	0.7953	0.085422	-2.92271	2.92271	-2.25480	2.25480
4	1.0000	0.107403	-3.27724	3.27724	-2.04573	2.04573

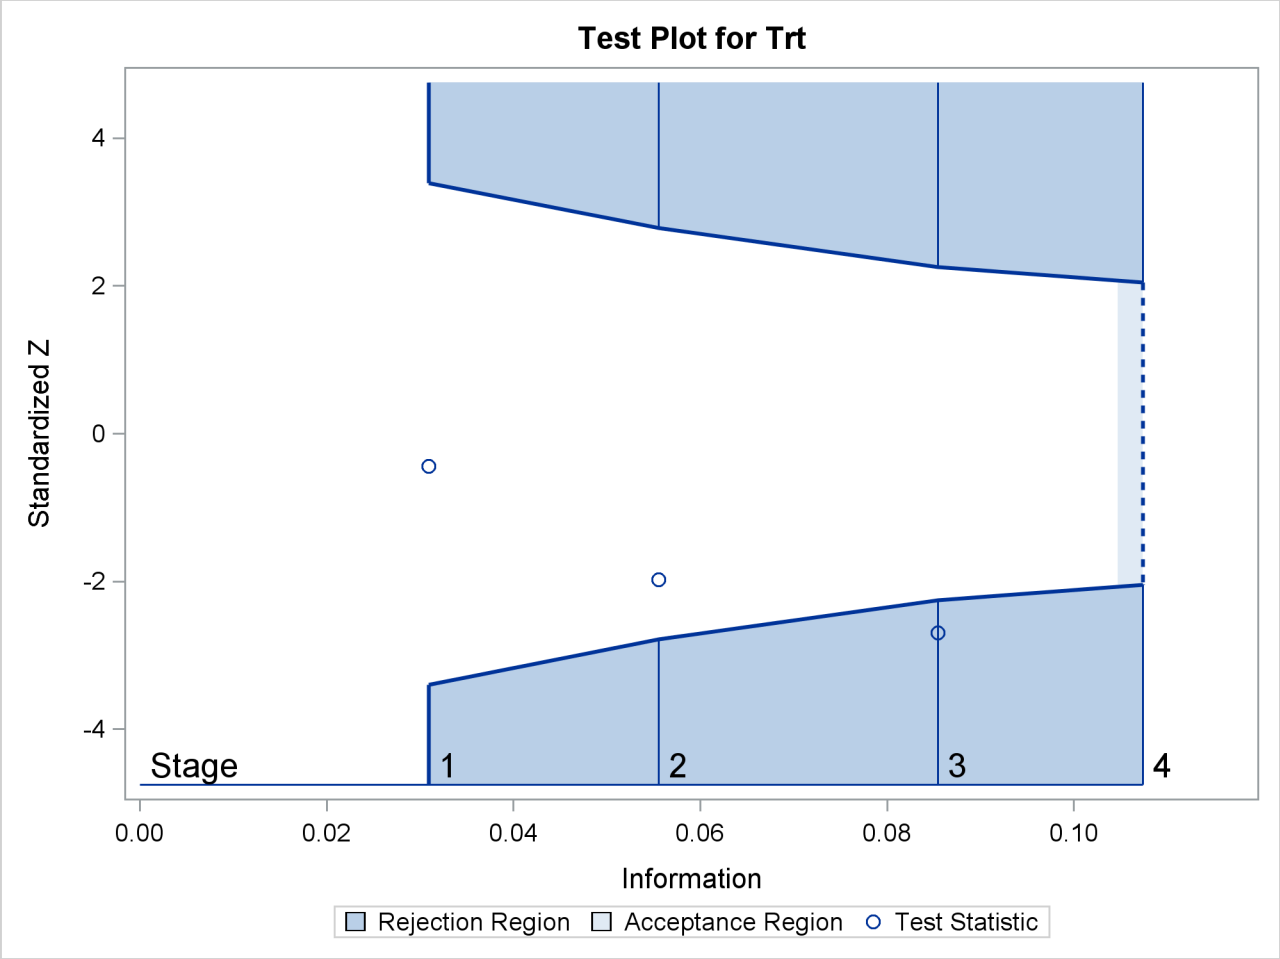
Test Information (Standardized Z Scale)
Null Reference = 0

Stage	----------Test---------- ----------Trt---------- Estimate	Action
1	-0.44426	Continue
2	-1.97365	Continue
3	-2.69289	Reject Null
4	.	

The sequential test stops at stage 3 to reject the null hypothesis for the lower alternative because the test statistic -2.69289 is less than the corresponding upper α boundary -2.25480. That is, the test demonstrates significant beneficial effect for the new drug.

The "Test Plot" displays boundary values for the design and the test statistic at the first three stages, as shown in Figure 81.17. It shows that the test statistic is in the "Rejection Region" below the lower α boundary at stage 3.

Figure 81.17 Sequential Test Plot



When a trial stops, the "Parameter Estimates" table in Figure 81.18 displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and p-value under the null hypothesis $H_0 : \theta = 0$. As expected, the p-value 0.0108 is significant at the two-sided α level, $\alpha = 0.05$, and the confidence interval does not contain the value zero. The p-value, unbiased median estimate, and confidence limits depend on the ordering of the sample space (k, z), where k is the stage number and z is the standardized Z statistic. See the section "Analysis after a Sequential Test" on page 6939 for a detailed description of these statistics.

Syntax: SEQTEST Procedure

The following PROC SEQTEST statement is required for the SEQTEST procedure:

PROC SEQTEST < *options* > **;**

PROC SEQTEST Statement

Table 81.1 summarizes the options in the PROC SEQTEST statement.

Table 81.1 Summary of PROC SEQTEST Options

Option	Description
Input Data Sets	
BOUNDARY=	Specifies the data set for boundary information
DATA=	Specifies the data set for parameter estimates and information levels
PARMS=	Specifies the data set for parameter estimates and standard errors
Boundaries	
BETAOVERLAP=	Checks for overlapping of the lower and upper β boundaries at the current and subsequent interim stages in a two-sided design
BOUNDARYKEY=	Specifies the boundary key to maintain Type I and II error probability levels
BOUNDARYSCALE=	Specifies the boundary scale
ERRSPENDADJ=	Specifies error spending methods for boundary adjustments
ERRSPENDMIN=	Specifies minimum error spending values for the boundaries
INFOADJ=	Specifies whether information levels at future interim stages should be adjusted

Table 81.1 *continued*

Option	Description
NSTAGES=	Specifies the number of stages
Test Statistics	
DATA(TESTVAR=)	Specifies the test variable in the DATA= data set
PARMS(TESTVAR=)	Specifies the test variable in the PARMS= data set
***p*-Values and Confidence Intervals**	
CIALPHA=	Specifies the significance levels for the confidence interval
CITYPE=	Specifies the types of confidence interval
ORDER=	Specifies the ordering of the sample space used to derive the *p*-values and confidence limits
Table Output	
CONDPOWER	Displays conditional powers
ERRSPEND	Displays the cumulative error spending at each stage
PREDPOWER	Displays the predictive powers
PSS	Displays the powers and expected sample sizes
RCI	Displays the repeated confidence intervals
STOPPROB	Displays the expected cumulative stopping probabilities
Graphics Output	
PLOTS=ASN	Displays the expected sample numbers plot
PLOTS=CONDPOWER	Displays the conditional powers plot
PLOTS=ERRSPEND	Displays the error spending plot
PLOTS=POWER	Displays the powers plot
PLOTS=RCI	Displays the repeated confidence intervals plot
PLOTS=TEST	Displays the boundary plot with test statistics

The BOUNDARY= option provides the information for the design and is required in the PROC SEQTEST statement. By default, the SEQTEST procedure displays tables of design information and test information. If ODS Graphics is enabled, the procedure also displays a sequential test plot.

The following options can be used in the PROC SEQTEST statement. They are listed in alphabetical order.

BETAOVERLAP=ADJUST | NOADJUST

OVERLAP=ADJUST | NOADJUST

specifies whether to check for overlapping of the lower and upper β boundaries for the two corresponding one-sided tests at the current and subsequent interim stages. This option applies to two-sided designs with early stopping to accept H_0, or to either accept or reject H_0. This type of overlapping might result from a small β spending at an interim stage. When you specify BETAOVERLAP=ADJUST, the procedure checks for this type of overlapping at the current and subsequent interim stages. If such overlapping is found, the β boundaries for the two-sided design at that stage are set to missing, and the β spending values at subsequent stages are adjusted, as described in the section "Boundary Adjustments for Overlapping Lower and Upper β Boundaries" on page 6936.

You can specify BETAOVERLAP=NOADJUST to request that no adjustment be made. The default is BETAOVERLAP=ADJUST.

BOUNDARY=*SAS-data-set*

names the required SAS data set that contains the design boundary information. At stage 1, the data set is usually created from the "Boundary Information" table created by the SEQDESIGN procedure. At each subsequent stage, the data set is usually created from the "Test Information" table created by the SEQTEST procedure at the previous stage. The data set includes the variables _Scale_ for the boundary scale, _Stop_ for the stopping criterion, and _ALT_ for the type of alternative hypothesis. It also includes _Stage_ for the stage number, Info_Prop for the information proportion, and a set of the boundary variables from Bound_LA, Bound_LB, Bound_UB, and Bound_UA for boundary values at each stage.

The data set might also include _Info_ for the actual information level, NObs for the number of observation, and Events for the number of events required at each stage.

BOUNDARYKEY=ALPHA | BETA | BOTH

specifies the boundary key to be maintained in the boundary adjustments. The BOUNDARYKEY=ALPHA option maintains the Type I α level and derives the Type II error probability, and the BOUNDARYKEY=BETA option maintains the Type II β level and derives the Type I error probability. The BOUNDARYKEY=BOTH option maintains both α and β levels simultaneously by deriving a new maximum information. The default is BOUNDARYKEY=ALPHA.

BOUNDARYSCALE=MLE | SCORE | STDZ | PVALUE

BSCALE=MLE | SCORE | STDZ | PVALUE

specifies the boundary scale to be displayed in the output boundary table and plot. The BOUNDARYSCALE=MLE, BOUNDARYSCALE=SCORE, BOUNDARYSCALE=STDZ, and BOUNDARYSCALE=PVALUE options correspond to the boundary with the maximum likelihood estimator scale, score statistic scale, standardized normal Z scale, and p-value scale, respectively. The default is BOUNDARYSCALE=STDZ.

With the BOUNDARYSCALE=MLE or BOUNDARYSCALE=SCORE option, either the MAXINFO= option must be specified or the _Info_ variable must be in the BOUNDARY= data set to provide the necessary information level at each stage to derive the boundary values. Usually, these values are obtained from analysis output in SAS procedures.

Note that for a two-sided design, the p-value scale displays the one-sided fixed-sample p-value under the null hypothesis with a lower alternative hypothesis.

CIALPHA=α < (< LOWER=α_l > < UPPER=α_u >) >

specifies the significance levels for the confidence interval, where $0 < \alpha < 1$, $0 < \alpha_l < 0.5$, and $0 < \alpha_u < 0.5$. The default is CIALPHA= 0.05.

For a lower confidence interval (CITYPE=LOWER), the CIALPHA=α option produces a $(1 - \alpha)$ lower confidence interval. For an upper confidence interval (CITYPE=UPPER), the CIALPHA=α option produces a $(1 - \alpha)$ upper confidence interval. The LOWER= and UPPER= suboptions are applicable only for a two-sided confidence interval (CITYPE=TWOSIDED). The LOWER= suboption specifies the lower significance level α_l and the upper significance level $\alpha_u = 1 - \alpha_l$. The UPPER= suboption specifies the upper significance level α_u and the lower significance level $\alpha_l = 1 - \alpha_u$. If both LOWER= and UPPER= suboptions are not specified, $\alpha_l = \alpha_u = \alpha/2$. The significance levels α_l and α_u are then used for the $(1 - \alpha_l)$ lower confidence limit and $(1 - \alpha_u)$ upper confidence limit, respectively.

CITYPE=LOWER | UPPER | TWOSIDED

specifies the type of confidence interval. The CITYPE=LOWER, CITYPE=UPPER, and CITYPE=TWOSIDED options correspond to the lower confidence interval, upper confidence interval, and two-sided confidence interval, respectively. The default is CITYPE=LOWER for the design with an upper alternative, CITYPE=UPPER for the design with a lower alternative, and CITYPE=TWOSIDED for the design with a two-sided alternative.

DATA < (TESTVAR=*variable***) >=***SAS-data-set*

names the SAS data set that contains the test statistic and its associated information level for the stage. The data set includes the stage variable _Stage_ and a variable to identify or derive the information level: _Info_ for the information level, NObs for the number of observation, or Events for the number of events. If the information level that corresponds to the test statistic is not available, the information level derived in the BOUNDARY= data set is used.

If the TESTVAR= option is specified, the data set also includes the test variable specified in the TESTVAR= option and the scale variable _Scale_ for the test statistic. Usually, these test variable values are obtained from analysis output in SAS procedures.

ERRSPENDADJ=*method*

ERRSPENDADJ(*boundary***)=***method*

BOUNDARYADJ=*method*

BOUNDARYADJ(*boundary***)=***method*

specifies methods to compute the error spending values at the current and future interim stages for the boundaries. This option is applicable only if the observed information level at the current stage does not match the value provided in the BOUNDARY= data set. These error spending values are then used to derive the updated boundary values. The default is ERRSPENDADJ=ERRLINE. Note that the information levels at future interim stages are determined by the INFOADJ= option.

The following options specify available error spending methods for boundary adjustment:

NONE

specifies that the cumulative error spending at each interim stage not be changed, even if the corresponding information level has been changed.

ERRLINE

specifies the linear interpolation method for the adjustment.

ERRFUNCGAMMA < (GAMMA= γ **) >**

specifies the gamma function method for the adjustment. The GAMMA= suboption specifies the γ parameter in the function, where $\gamma \leq 3$. The default is GAMMA=-2.

ERRFUNCOBF

specifies the approximate O'Brien-Fleming cumulative error spending function for the adjustment.

ERRFUNCPOC

specifies the approximate Pocock cumulative error spending function for the adjustment.

ERRFUNCPOW < (RHO= ρ **) >**

specifies the power function method for the adjustment. The RHO= suboption specifies the power parameter ρ in the function, where $\rho \geq 0.25$. The default is RHO=2.

See the section "Boundary Adjustments for Information Levels" on page 6933 for a detailed description of the available error spending methods for boundary adjustment in the SEQTEST procedure.

If an error spending method for boundary adjustments is used for all boundaries in a group sequential test, you can use the ERRSPENDADJ=*method* option to specify the method. Otherwise, you can use the following ERRSPENDADJ(*boundary*)=*method* options to specify different methods for the boundaries.

ERRSPENDADJ(ALPHA)=*method*

ERRSPENDADJ(REJECT)=*method*

BOUNDARYADJ(ALPHA)=*method*

BOUNDARYADJ(REJECT)=*method*

specifies the adjustment method for the α (rejection) boundary of a one-sided design or the lower and upper α boundaries of a two-sided design.

ERRSPENDADJ(LOWERALPHA)=*method*

ERRSPENDADJ(LOWERREJECT)=*method*

BOUNDARYADJ(LOWERALPHA)=*method*

BOUNDARYADJ(LOWERREJECT)=*method*

specifies the adjustment method for the lower α boundary of a two-sided design.

ERRSPENDADJ(UPPERALPHA)=*method*

ERRSPENDADJ(UPPERREJECT)=*method*

BOUNDARYADJ(UPPERALPHA)=*method*

BOUNDARYADJ(UPPERREJECT)=*method*

specifies the adjustment method for the upper α boundary of a two-sided design.

ERRSPENDADJ(BETA)=*method*

ERRSPENDADJ(ACCEPT)=*method*

BOUNDARYADJ(BETA)=*method*

BOUNDARYADJ(ACCEPT)=*method*

specifies the adjustment method for the β (acceptance) boundary of a one-sided design or the lower and upper β boundaries of a two-sided design.

ERRSPENDADJ(LOWERBETA)=*method*

ERRSPENDADJ(LOWERACCEPT)=*method*

BOUNDARYADJ(LOWERBETA)=*method*

BOUNDARYADJ(LOWERACCEPT)=*method*

specifies the adjustment method for the lower β boundary of a two-sided design.

ERRSPENDADJ(UPPERBETA)=*method*

ERRSPENDADJ(UPPERACCEPT)=*method*

BOUNDARYADJ(UPPERBETA)=*method*

BOUNDARYADJ(UPPERACCEPT)=*method*

specifies the adjustment method for the upper β boundary of a two-sided design.

ERRSPENDMIN=*numbers*

ERRSPENDMIN(*boundary***)=***numbers*

specifies the minimum error spending values at the current observed and future interim stages for the boundaries specified in the BOUNDARYKEY= option. The default is ERRSPENDMIN=0.

If a set of numbers is used for each boundary in the design, you can use the ERRSPENDMIN=*numbers* option. Otherwise, you can use the following ERRSPENDMIN(*boundary*)=*numbers* options to specify different sets of minimum error spending values for the boundaries. For a boundary, the error spending value at stage 1 is identical to its nominal p-value.

ERRSPENDMIN(ALPHA)=*numbers*

ERRSPENDMIN(REJECT)=*numbers*

specifies the minimum error spending values for the α boundary of a one-sided design or the lower and upper α boundaries of a two-sided design.

ERRSPENDMIN(LOWERALPHA)=*numbers*

ERRSPENDMIN(LOWERREJECT)=*numbers*

specifies the minimum error spending values for the lower α boundary of a two-sided design.

ERRSPENDMIN(UPPERALPHA)=*numbers*

ERRSPENDMIN(UPPERREJECT)=*numbers*

specifies the minimum error spending values for the upper α boundary of a two-sided design.

ERRSPENDMIN(BETA)=*numbers*

ERRSPENDMIN(ACCEPT)=*numbers*

specifies the minimum error spending values for the β boundary of a one-sided design or the lower and upper β boundaries of a two-sided design.

ERRSPENDMIN(LOWERBETA)=*numbers*

ERRSPENDMIN(LOWERACCEPT)=*numbers*

specifies the minimum error spending values for the lower β boundary of a two-sided design.

ERRSPENDMIN(UPPERBETA)=*numbers*

ERRSPENDMIN(UPPERACCEPT)=*numbers*

specifies the minimum error spending values for the upper β boundary of a two-sided design.

INFOADJ=NONE | PROP

specifies whether information levels at future interim stages are to be adjusted. If you specify INFOADJ=NONE, no adjustment is made, and the information levels are preserved at the levels provided in the BOUNDARY= data set. If you specify INFOADJ=PROP (which is the default), the information levels are adjusted proportionally from the levels provided in the BOUNDARY= data set. The section "Information Level Adjustments at Future Stages" on page 6933 describes how the adjustments are computed.

Note that if you specify BOUNDARYKEY=BOTH, the INFOADJ=NONE option is not applicable, and the INFOADJ=PROP option is used to adjusted the information levels at future stages proportionally from the levels provided in the BOUNDARY= data set to maintain both α and β levels.

NSTAGES=*number*

specifies the number of stages for the clinical trial. The default is the number derived from the BOUNDARY= data set.

The specified NSTAGES= number might or might not be the same as the number derived in the BOUNDARY= data set. You can use the NSTAGES= option to set the next stage as the final stage to compute the conditional power, as described in the section "Conditional Power Approach" on page 6937.

ORDER=LR | MLE | STAGEWISE

specifies the ordering of the sample space (k, z), where k is the stage number and z is the observed standardized Z statistic. The ordering is used to derive the p-values for the observed (k, z) statistic and to create unbiased median estimate and confidence limits from the statistic. The ORDER=LR option specifies the LR ordering that compares the distances between observed standardized Z statistics and their corresponding hypothetical values, the ORDER=MLE option specifies the MLE ordering that compares values in the MLE scale, and the ORDER=STAGEWISE specifies the stagewise ordering that uses counterclockwise ordering around the continuation region. The default is ORDER=STAGEWISE. See the section "Available Sample Space Orderings in a Sequential Test" on page 6940 for a detailed description of these sample space orderings.

PARMS < (TESTVAR=*variable***) > =***SAS-data-set*

names the SAS data set that contains the parameter estimate and its associated standard error for the stage. The data set includes the stage variable _Stage_, the test statistic Estimate, the standard error of the estimate StdErr, and the test statistic scale variable _Scale_. The standard error is are used to derive the information level. If the standard error is not available, the information level derived in the BOUNDARY= data set is used.

The data set also includes the variable Parameter, Effect, Variable, or Parm that contains the test variable specified in the TESTVAR= option. Usually, these test variable values are obtained from analysis output in SAS procedures.

Table Output Options

The following options can be used in the PROC SEQTEST statement to display additional table output. They are listed in alphabetical order.

CONDPOWER < (CREF=*numbers*) >**

displays conditional powers given the most recently observed statistic under specified hypothetical references, where the numbers $c_i \geq 0$. In the SEQTEST procedure, the conditional power is the probability that the test statistic at the final stage would exceed the rejection critical value given the observed statistic.

If interim stages exist between the current stage and the final stage, the conditional power is not the conditional probability to reject the null hypothesis H_0. In this case, you can set the next stage as the final stage, and the conditional power is the conditional probability to reject H_0.

For a one-sided test, the powers are derived under the hypothetical references $\theta = \hat{\theta}$ and $\theta = c_i\theta_1$, where $\hat{\theta}$ is the observed statistic, θ_1 is the alternative reference, and c_i are the values specified in the CREF= option. For a two-sided test, the powers are derived under hypothetical references $\theta = \hat{\theta}$,

$\theta = c_i\theta_{1l}$, and $\theta = c_i\theta_{1u}$, where θ_{1l} is the lower alternative reference and θ_{1u} is the upper alternative reference. The default is CREF= 0 0.5 1.0 1.5.

ERRSPEND

displays the error spending at each stage for each sequential boundary.

PREDPOWER

displays predictive powers given the most recently observed statistic. The predictive power is the posterior probability that the test statistic at the final stage would exceed the rejection critical value given the observed statistic and a prior distribution of the hypothetical reference. A noninformative prior is used in the procedure.

PSS < (CREF=*numbers* **) >**

displays powers and expected sample sizes under various hypothetical references, where the numbers $c_i \geq 0$.

For a one-sided design with the null reference $\theta_0 = 0$, the power and expected sample sizes under hypotheses $\theta = c_i\ \theta_1$ are displayed, where θ_1 is the alternative reference and c_i are the values specified in the CREF= option.

For a two-sided design, the power and expected sample sizes under hypotheses $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. The default is CREF= 0 0.5 1.0 1.5.

Note that for a symmetric two-sided design, only the power and expected sample sizes under hypotheses $\theta = c_i\ \theta_{1u}$ are derived.

RCI

displays repeated confidence intervals for the parameter from the observed statistic at each stage. Repeated confidence intervals include both rejection and acceptance confidence intervals.

With the STOP=REJECT or STOP=BOTH option, rejection confidence limits can be derived, and the null hypothesis $H_0 : \theta = 0$ is rejected if the lower rejection confidence limit is greater than 0 or the upper rejection confidence limit is less than 0.

With the STOP=ACCEPT or STOP=BOTH option, acceptance confidence limits can be derived, and the null hypothesis is accepted with alternative hypotheses $H_{1l} : \theta = \theta_{1l}$ and $H_{1u} : \theta = \theta_{1u}$ if the upper acceptance confidence limit is less than θ_{1u} and the lower acceptance confidence limit is greater than θ_{1l}.

STOPPROB < (CREF=*numbers* **) >**

displays expected cumulative stopping probabilities under various hypothetical references, where the numbers $c_i \geq 0$.

For a one-sided design, expected cumulative stopping probabilities at each stage under hypotheses $\theta = c_i\ \theta_1$ are displayed, where θ_1 is the alternative reference and c_i are the values specified in the CREF= option.

For a two-sided design, expected cumulative stopping probabilities at each stage under hypotheses $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only expected cumulative stopping probabilities under hypotheses $\theta = c_i\ \theta_{1u}$ are derived. The default is CREF= 0 0.5 1.0 1.5.

Graphics Output Options

The following options can be used in the PROC SEQTEST statement to display plots with ODS Graphics. They are listed in alphabetical order.

PLOTS < (ONLY) > < = *plot-request* >

PLOTS < (ONLY) > < = (*plot-request* < . . . *plot-request* >) >

specifies options that control the details of the plots. The default is PLOTS=TEST. The global plot option ONLY suppresses the default plots and displays only plots specifically requested.

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;
proc seqtest Boundary=Bnd_LDL
             Parms(Testvar=Trt)=Parms_LDL1
             Plots=(test errspend);
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The plot request options include the following.

ALL

produces all appropriate plots.

ASN < (CREF=*numbers*) >

displays a plot of the average sample numbers (expected sample sizes for nonsurvival data or expected number of events for survival data) under various hypothetical references, where the numbers $c_i \geq 0$.

For a one-sided design, expected sample numbers under hypotheses $\theta = c_i\,\theta_1$ are displayed, where θ_1 is the alternative reference and c_i are the values specified in the CREF= option.

For a two-sided design, expected sample numbers under hypotheses $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only the average sample numbers under hypotheses $\theta = c_i\,\theta_{1u}$ are derived. The default is CREF= 0 to 1.5 by 0.01.

CONDPOWER < (CREF=*numbers*) >

displays a plot of conditional powers given the most recently observed statistic under specified hypothetical references, where the numbers $c_i \geq 0$. In the SEQTEST procedure, the conditional power is the probability that the test statistic at the final stage would exceed the rejection critical value given the observed statistic.

For a one-sided test, the powers are derived under hypothetical references $\theta = \hat{\theta}$ and $\theta = c_i\theta_1$, where $\hat{\theta}$ is the observed statistic, θ_1 is the alternative reference, and c_i are the values specified in the CREF= option. For a two-sided test, the powers are derived under hypothetical references $\theta = \hat{\theta}$, $\theta = c_i\theta_{1l}$, and $\theta = c_i\theta_{1u}$, where θ_{1l} is the lower alternative reference and θ_{1u} is the upper alternative reference. The default is CREF= 0 to 1.5 by 0.01.

ERRSPEND < (HSCALE=INFO | STAGE) >

displays a plot of the error spending for all sequential boundaries in the designs simultaneously. You can display the information level (HSCALE=INFO) or the stage number (HSCALE=STAGE) on the horizontal axis. With HSCALE=INFO, the information fractions are used in the plot. The default is HSCALE=STAGE.

NONE

suppresses all plots.

POWER < (CREF=*numbers*) >

displays a plot of the power curves under various hypothetical references, where the numbers $c_i \geq 0$.

For a one-sided design, powers under hypotheses $\theta = c_i\,\theta_1$ are displayed, where θ_1 is the alternative reference and c_i are the values specified in the CREF= option.

For a two-sided design, powers under hypotheses $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only powers under hypotheses $\theta = c_i\,\theta_{1u}$ are derived. The default is CREF= 0 to 1.5 by 0.01.

RCI

displays a plot of repeated confidence intervals. Repeated confidence intervals include both rejection and acceptance confidence intervals.

With the STOP=REJECT or STOP=BOTH option, rejection confidence limits can be derived and the null hypothesis $H_0 : \theta = 0$ is rejected if the lower rejection confidence limit is greater than 0 or the upper rejection confidence limit is less than 0.

With the STOP=ACCEPT or STOP=BOTH option, acceptance confidence limits can be derived and the null hypothesis is accepted with alternative hypotheses $H_{1l} : \theta = \theta_{1l}$ and $H_{1u} : \theta = \theta_{1u}$ if the upper acceptance confidence limit is less than θ_{1u} and the lower acceptance confidence limit is greater than θ_{1l}.

TEST < (HSCALE=INFO | SAMPLESIZE) >

displays a plot of the sequential boundaries and test variables. Either the information level (HSCALE=INFO) or the sample size (HSCALE=SAMPLESIZE) is displayed on the horizontal axis. The HSCALE=SAMPLESIZE option is applicable only if the sample size information is available in both the input BOUNDARY= data set and input DATA= data set. The stage number for each stage is displayed inside the plot. The default is HSCALE=INFO.

Details: SEQTEST Procedure

Input Data Sets

The BOUNDARY= data set option is required, and if neither the DATA= nor the PARMS= data set option is specified, the procedure derives statistics such as Type I and Type II error probabilities from the BOUNDARY= data set. The resulting boundaries are displayed with the scale specified in the BOUNDARYSCALE= option.

BOUNDARY= SAS Data Set

The BOUNDARY= data set provides the boundary information for the sequential test. At stage 1, the data set is usually created with an ODS OUTPUT statement from the "Boundary Information" table created by the SEQDESIGN procedure. At each subsequent stage, the data set is usually created with an ODS OUTPUT statement from the "Test Information" table that was created by the SEQTEST procedure at the previous stage. See the section "Getting Started: SEQTEST Procedure" on page 6902 for an illustration of the BOUNDARY= data set option.

The BOUNDARY= data set contains the following variables:

- _Scale_, the boundary scale, with the value MLE for the maximum likelihood estimate, STDZ for the standardized Z, SCORE for the score statistic, or PVALUE for the nominal p-value. Note that for a two-sided design, the nominal p-value is the one-sided fixed-sample p-value under the null hypothesis with a lower alternative hypothesis.
- _Stop_, the stopping criterion, with the value REJECT for rejecting the null hypothesis H_0, ACCEPT for accepting H_0, or BOTH for both rejecting and accepting H_0
- _ALT_, the type of alternative hypothesis, with the value UPPER for an upper alternative, LOWER for a lower alternative, or TWOSIDED for a two-sided alternative
- _Stage_, the stage number
- the boundary variables, a subset of Bound_LA for lower α boundary, Bound_LB for lower β boundary, Bound_UB for upper β boundary, and Bound_UA for upper α boundary
- AltRef_L, the lower alternative reference, if ALT=LOWER or ALT=TWOSIDED
- AltRef_U, the upper alternative reference, if ALT=UPPER or ALT=TWOSIDED
- _InfoProp_, the information proportion at each stage

Optionally, the BOUNDARY= data set also contains the following variables:

- _Info_, the information level at each stage
- NObs, the required number of observations for nonsurvival data at each stage
- Events, the required number of events for survival data at each stage
- Parameter, the variable specified in the DATA(TESTVAR=) or PARMS(TESTVAR=) option
- Estimate, the parameter estimate

If the BOUNDARY= data set contains the variable Parameter for the test variable that is specified in the TESTVAR= option, and the variable Estimate for the test statistics, then these test statistics are also displayed in the output test information table and output test plot.

DATA < (TESTVAR= *variable*) > = SAS Data Set

The DATA= data set provides the test variable information for the current stage of the trial. Such data sets are usually created with an ODS OUTPUT statement by using a procedure such as PROC MEANS. See "Example 81.4: Testing a Binomial Proportion" on page 6995 for an illustration of the DATA= data set option.

The DATA= data set includes the following variables:

- _Stage_, the stage number
- _Scale_, the scale for the test statistic, with the value MLE for the maximum likelihood estimate, STDZ for the standardized Z, SCORE for the score statistic, or PVALUE for the nominal p-value
- _Info_, the information level
- NObs, the number of observations for nonsurvival data at each stage
- Events, the number of events for survival data at each stage
- test variable, specified in the TESTVAR= option, contains the test variable value in the scale specified in the _Scale_ variable

With the specified DATA= data set, the procedure derives boundary values from the information levels in the _Info_ variable. If the data set does not include the _Info_ variable, then the information levels are derived from the NObs or Events variable in the DATA= data set if the variable is also in the input BOUNDARY= data set. That is, the information level at stage k is computed as $I_k^* = I_k \times (n_k^*/n_k)$, where I_k and n_k are the information level and sample size at stage k in the BOUNDARY= data set and n_k^* is the sample size at stage k in the DATA= data set. Otherwise, the information levels from the BOUNDARY= data set are used.

If the TESTVAR= option is specified, the DATA= data set must also include the test variable for the test statistic and _Scale_ variable for the corresponding scale. Note that for a two-sided design, the nominal p-value is the one-sided fixed-sample p-value under the null hypothesis with a lower alternative hypothesis.

PARMS < (TESTVAR= *variable*) > = SAS Data Set

The PARMS= data set provides a parameter estimate and associated standard error for the current stage of the trial. Such data sets are usually created with an ODS OUTPUT statement by using procedures such as the GENMOD, GLM, LOGISTIC, and REG procedures. See the section "Getting Started: SEQTEST Procedure" on page 6902 for an illustration of the PARMS= data set option.

The PARMS= data set includes the following variables:

- _Stage_, the stage number
- _Scale_, the scale for the test statistic, with the value MLE for the maximum likelihood estimate, STDZ for the standardized Z, SCORE for the score statistic, or PVALUE for the nominal p-value
- Parameter, Effect, Variable, or Parm, which contains the variable specified in the TESTVAR= option
- Estimate, the parameter estimate
- StdErr, standard error of the parameter estimate

With the specified PARMS= data set, the information level is derived from the StdErr variable. For a score statistic, the information level I_k is the variance of the statistic, $\hat{s}_k^2$, where $\hat{s}_k$ is the standard error in the StdErr variable. Otherwise, the information level is the inverse of the variance of the statistic, $\hat{s}_k^{-2}$. If the data set does not include the StdErr variable, the information levels derived from the BOUNDARY= data set are used.

If the TESTVAR= option is specified, the PARMS= data set also includes the variable Parameter, Effect, Variable, or Parm for the test variable, Estimate for the test statistic, and _Scale_ variable for the corresponding scale. Note that for a two-sided design, the nominal p-value is the one-sided fixed-sample p-value under the null hypothesis with a lower alternative hypothesis.

Boundary Variables

The boundaries created in group sequential trials depend on the type of the alternative hypothesis and the early stopping criterion. Table 81.2 shows the boundaries created with various design specifications.

Table 81.2 Boundary Variables

Specifications		Boundary Variables			
Alternative		**Lower**		**Upper**	
Hypothesis	**Early Stopping**	**Alpha**	**Beta**	**Beta**	**Alpha**
Lower	Accept H_0		X		
	Reject H_0	X			
	Accept/Reject H_0	X	X		
Upper	Accept H_0			X	
	Reject H_0				X
	Accept/Reject H_0			X	X
Two-sided	Accept H_0		X	X	
	Reject H_0	X			X
	Accept/Reject H_0	X	X	X	X

Up to four different boundaries can be generated in a group sequential design:

- the upper α boundary, used to reject the null hypothesis in favor of an upper alternative hypothesis
- the upper β boundary, used to accept the null hypothesis with an upper alternative hypothesis
- the lower β boundary, used to accept the null hypothesis with a lower alternative hypothesis
- the lower α boundary, used to reject the null hypothesis in favor of a lower alternative hypothesis

For a two-sided design, the null hypothesis is accepted only if both the null hypothesis is accepted with an upper alternative hypothesis and the null hypothesis is accepted with a lower alternative hypothesis.

For a one-sided design with a lower alternative, only the lower boundaries are created. Similarly, for a one-sided design with an upper alternative, only the upper boundaries are created. For example, Figure 81.19 shows the boundary plot for a one-sided test with an upper alternative.

Figure 81.19 Boundary Plot for One-Sided Test

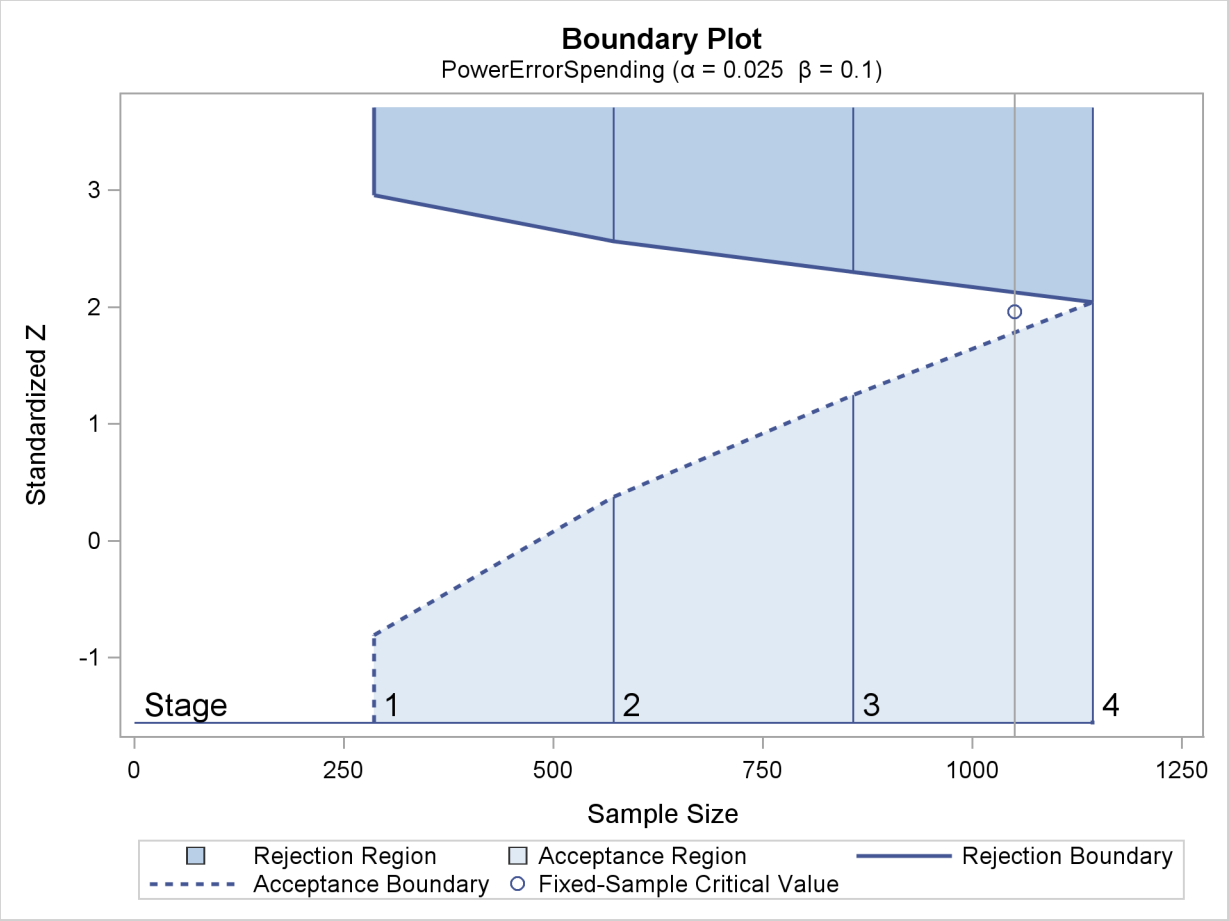

Figure 81.19 corresponds to a one-sided sequential design with early stopping to reject or accept the null hypothesis. For a sequential test with early stopping only to reject the null hypothesis, there are no acceptance boundary values at interim stages. The acceptance boundary value and its associated acceptance region are displayed only at the final stage. Similarly, for a sequential test with early stopping only to accept the null hypothesis, there are no rejection boundary values at interim stages. The rejection boundary value and its associated rejection region are displayed only at the final stage.

For a two-sided design, both the lower and upper boundaries are created. For a design with early stopping to reject the null hypothesis, α boundaries are created. Similarly, for a design with early stopping to accept the null hypothesis, β boundaries are created. For a design with early stopping to accept or reject the null hypothesis, both the α and β boundaries are created.

For example, Figure 81.20 shows the boundary plot for a two-sided test.

Figure 81.20 Boundary Plot for Two-Sided Test

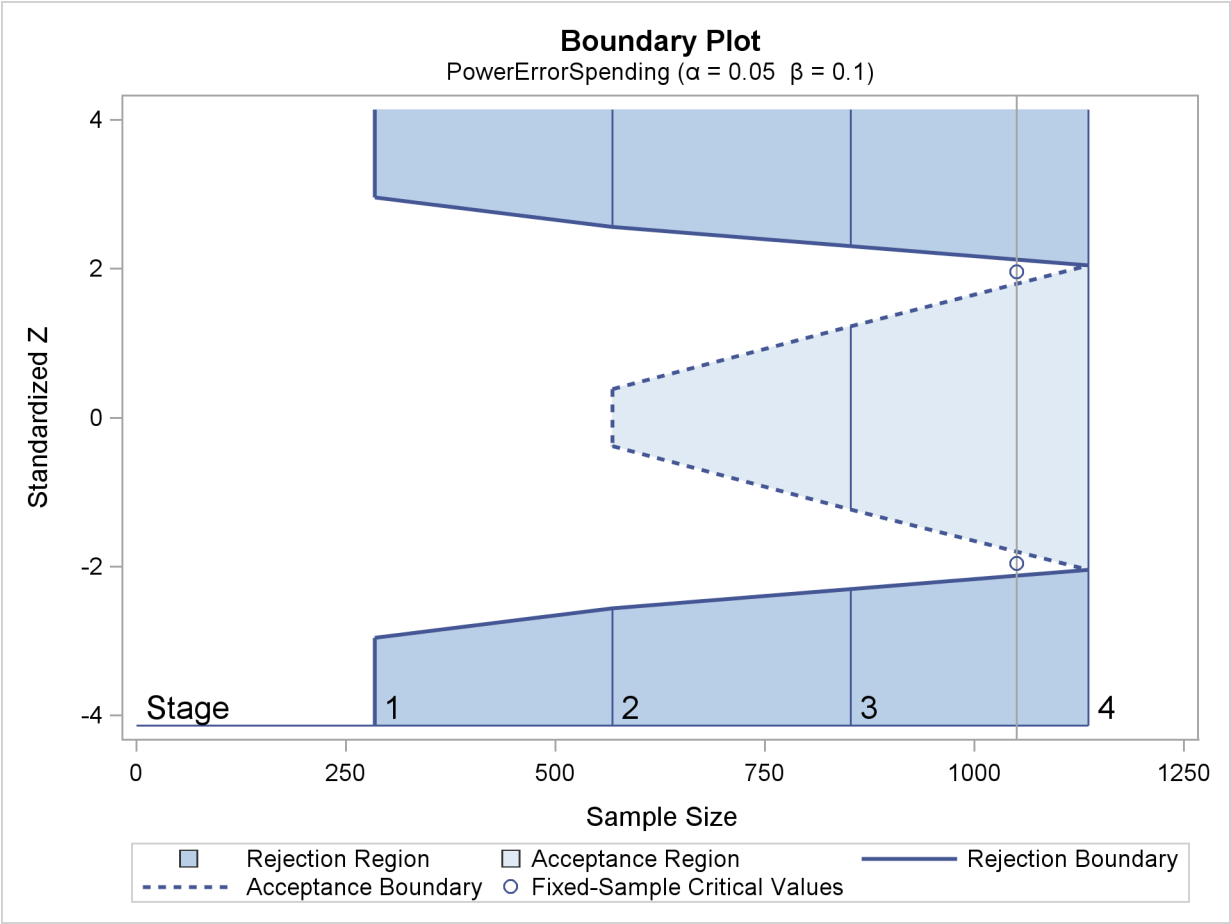

Figure 81.20 corresponds to a two-sided sequential design with early stopping to reject or accept the null hypothesis. For a sequential test with early stopping only to reject the null hypothesis, there are no acceptance boundary values at interim stages. The acceptance boundary value and its associated acceptance region are displayed only at the final stage. Similarly, for a sequential test with early stopping only to accept the null hypothesis, there are no rejection boundary values at interim stages. The rejection boundary value and its associated rejection region are displayed only at the final stage.

Information Level Adjustments at Future Stages

In a group sequential clinical trial, the information level for the observed test statistic at the current stage generally does not match the corresponding information level in the BOUNDARY= data set. By default (or equivalently if you specify INFOADJ=PROP), the SEQTEST procedure accommodates the observed information level by adjusting the information levels at future interim stages. The adjustment of information levels depends on the boundary key to be maintained in the boundary adjustments, which in turn is determined by the BOUNDARYKEY= option.

If you specify BOUNDARYKEY=ALPHA (which is the default) or BOUNDARYKEY=BETA, the maximum information level (the information level at the final stage) provided in the BOUNDARY= data set is maintained. In this case, if an observed information level at the current stage is different from the level provided in the BOUNDARY= data set, you can use the INFOADJ= option to determine whether the information levels at subsequent interim stages are to be adjusted. Specifying INFOADJ=NONE preserves the levels provided in the BOUNDARY= data set without adjustment. Specifying INFOADJ=PROP proportionally adjusts the levels provided in the BOUNDARY= data set as follows.

Denote the information level at stage k for the K-stage design that is stored in the BOUNDARY= data set by I_k, $k = 1, 2, \ldots, K$. Also denote the information level that corresponds to the test statistic at an interim stage k_0 by I'_{k_0}, $1 \leq k_0 \leq (K-1)$. Then for the updated design, the information level at stage k, $k = k_0 + 1, \ldots, (K-1)$, is computed as

$$I'_k = I'_{k_0} + (I_K - I'_{k_0}) \frac{I_k - I_{k_0}}{I_K - I_{k_0}}$$

Note that if $I'_{k_0} \geq I_K$, the information level at stage k_0 reaches the maximum information level in the design, the trial stops at stage k_0, and no future information levels are derived.

If you specify BOUNDARYKEY=BOTH, the maximum information level for the trial is not necessarily the same as the maximum information level saved in the BOUNDARY= data set. In this case, the INFOADJ=NONE option is not applicable, and the INFOADJ=PROP option is used to proportionally adjust the information levels at future interim stages with the updated maximum information I'_K. That is, with an updated I'_K, the information level at a future interim stage k is computed as

$$I'_k = I'_{k_0} + (I'_K - I'_{k_0}) \frac{I_k - I_{k_0}}{I'_K - I_{k_0}}$$

Boundary Adjustments for Information Levels

In a group sequential clinical trial, if the information level for the observed test statistic does not match the corresponding information level in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) can be used to modify information levels at future stages to accommodate this observed information level. With the adjusted information levels, the ERRSPENDADJ= option provides various methods to compute error spending values at the current and future interim stages. These error spending values are then used to derive boundary values in the SEQTEST procedure. See the section "Error Spending Methods" in the chapter "The SEQDESIGN Procedure" for a detailed description of how to use these error spending values to derive boundary values.

The ERRSPENDADJ=NONE option keeps the error spending the same at each stage. The ERRSPENDADJ=ERRLINE option uses a linear interpolation on the cumulative error spending in the design stored in the BOUNDARY= data set to derive the error spending for each unmatched information level (Kittelson and Emerson 1999, p. 882). That is, the cumulative error spending for an information level I is computed as

$$e(I) = \begin{cases} e_1 \left(\frac{I}{I_1}\right) & \text{if } I < I_1 \\ e_j + (\alpha_{j+1} - \alpha_j) \left(\frac{I - I_j}{I_{j+1} - I_j}\right) & \text{if } I_j \le I < I_{j+1} \\ e_K & \text{if } I \ge I_K \end{cases}$$

where $e_1, e_2, \ldots, e_K$ are the cumulative errors at the K stages of the design that is stored in the BOUNDARY= data set.

The ERRSPENDADJ=ERRFUNCPOC option uses Pocock-type cumulative error spending function (Lan and DeMets 1983):

$$E(t) = \begin{cases} 1 & \text{if } t \ge 1 \\ \log(1 + (e-1)t) & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

With an error level of α or β, the cumulative error spending for an information level I is $e(I) = \alpha\, E(I/I_K)$ or $e(I) = \beta\, E(I/I_K)$.

The ERRSPENDADJ=ERRFUNCOBF option uses O'Brien-Fleming-type cumulative error spending function (Lan and DeMets 1983):

$$E(t; a) = \begin{cases} 1 & \text{if } t \ge 1 \\ \frac{1}{a}\, 2\,(1 - \Phi(\frac{z_{(1-a/2)}}{\sqrt{t}})) & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

where a is either α for the α spending function or β for the β spending function, and Φ is the cumulative distribution function of the standardized Z statistic. That is, with an error level of α or β, the cumulative error spending for an information level I is $e(I) = \alpha\, E(I/I_K; \alpha)$ or $e(I) = \beta\, E(I/I_K; \beta)$.

The ERRSPENDADJ=ERRFUNCGAMMA option uses gamma cumulative error spending function (Hwang, Shih, and DeCani 1990):

$$E(t; \gamma) = \begin{cases} 1 & \text{if } t \ge 1 \\ \frac{1 - e^{-\gamma t}}{1 - e^{-\gamma}} & \text{if } 0 < t < 1, \gamma \ne 0 \\ t & \text{if } 0 < t < 1, \gamma = 0 \\ 0 & \text{otherwise} \end{cases}$$

where γ is the parameter γ specified in the GAMMA= option. That is, with an error level of α or β, the cumulative error spending for an information level I is $e(I) = \alpha\, E(I/I_K; \gamma)$ or $e(I) = \beta\, E(I/I_K; \gamma)$.

The ERRSPENDADJ=ERRFUNCPOW option uses power cumulative error spending function (Jennison and Turnbull 2000, p. 148):

$$E(t; \rho) = \begin{cases} 1 & \text{if } t \ge 1 \\ t^{\rho} & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

where ρ is the power parameter specified in the RHO= suboption. With an error level of α or β, the cumulative error spending for an information level I is $e(I) = \alpha\, E(I/I_K; \rho)$ or $e(I) = \beta\, E(I/I_K; \rho)$.

If the BOUNDARYKEY=BOTH option is specified, the maximum information required for the trial might not be the same as the maximum information level stored in the BOUNDARY= data set. In this case, the information levels at future stages are adjusted proportionally, and the same error spending values that were computed based on the maximum information level stored in the BOUNDARY= data set are used to derive boundary values for the trial.

If an error spending function is used to create boundaries for the design in the SEQDESIGN procedure, then in order to better maintain the design features throughout the group sequential trial, the same error spending function to create boundaries for the design in the SEQDESIGN procedure should be used to modify boundaries in the SEQTEST procedure at each subsequent stage.

Boundary Adjustments for Minimum Error Spending

In a group sequential clinical trial, boundary values created from a design such as an O'Brien-Fleming design might be too conservative in early stages. Thus the trial is unlikely to stop in early stages. Lan and Demets (1983, p. 662) suggest truncating boundary values to a number such as 3.5 for the trial to have a reasonable probability of stopping at early stages. Instead of truncating boundary values by a specified number, the ERRSPENDMIN= option provides individual minimum error spending at each interim stage to stop the trial early.

For a K-stage trial, denote the derived cumulative error spending at stage k after adjusting for information levels by $e_k, k = 1, 2, \ldots, K$. Also denote the specified minimum error spending at interim stage k by $\epsilon_k, k = 1, 2, \ldots, K-1$. Then the cumulative error spending at stage 1 is $e'_1 = \max(e_1,\ \epsilon_1)$. If $e_1 < e'_1$, the error spending values at subsequent interim stages are adjusted proportionally by

$$e'_j = e'_1 + \frac{e_j - e_1}{e_K - e_1}\,(e_K - e'_1)$$

for $j = 2, \ldots, K-1$.

The process is repeated at each subsequent interim stage. That is, at stage $k, k = 2, \ldots, K-1$, denote the updated cumulative β spending at stage j by e_j, $j = k, k+1, \ldots, K$. Then the cumulative error spending at stage k is $e'_k = \max(e_k,\ e'_{k-1} + \epsilon_k)$. If $e_k < e'_k$, the error spending values at subsequent interim stages are adjusted proportionally by

$$e'_j = e'_k + \frac{e_j - e_k}{e_K - e_k}\,(e_K - e'_k)$$

for $j = k+1, \ldots, K-1$.

Note that the ERRSPENDMIN= option is applicable only to the boundaries specified in the BOUNDARYKEY= option. That is, the ERRSPENDMIN= option is applicable to the α boundaries with BOUNDARYKEY=ALPHA or BOUNDARYKEY=BOTH, and it is applicable to the β boundaries with BOUNDARYKEY=BETA or BOUNDARYKEY=BOTH.

Boundary Adjustments for Overlapping Lower and Upper β Boundaries

In the SEQTEST procedure, the α and β spending values at the stages are used to derive the boundary values for the trial. For a two-sided design with early stopping to accept H_0, or to either reject or accept H_0, a zero β spending at an interim stage sets the β boundary values to missing. A small β spending at the current or subsequent interim stage might result in overlapping of the lower and upper β boundaries for the two corresponding one-sided tests. Specifically, this form of overlapping occurs at an interim stage k if the upper β boundary value that is derived from the one-sided test for the upper alternative is less than the lower β boundary value that is derived from the one-sided test for the lower alternative (Kittelson and Emerson 1999, pp. 881–882; Rudser and Emerson 2007, p. 6). You can use the BETAOVERLAP= option to specify how this type of overlapping is to be handled.

If BETAOVERLAP=ADJUST (which is the default) is specified, the procedure derives the boundary values for the two-sided design and then checks for overlapping of the two one-sided β boundaries at the current and subsequent interim stages. If overlapping occurs at a particular stage, the β boundary values for the two-sided design are set to missing (so the trial does not stop to accept the null hypothesis at this stage), and the β spending values at subsequent stages are adjusted proportionally as follows.

If the β boundary values are set to missing at stage k in a K-stage trial, the adjusted β spending value at stage k, e'_k, is updated for these missing β boundary values, and then the β spending values at subsequent stages are adjusted proportionally by

$$e'_j = e'_k + \frac{e_j - e_k}{e_K - e_k}\,(e_K - e'_k)$$

for $j = k+1, \ldots, K$, where e_j and e'_j are cumulative β spending values at stage j before and after the adjustment, respectively.

After all these adjusted β spending values are computed, the boundary values are then further modified for these adjusted β spending values.

If you specify BETAOVERLAP=NOADJUST, no adjustment is made when overlapping of one-sided β boundaries occurs.

Stochastic Curtailment

Lan, Simon, and Halperin (1982) introduce stochastic curtailment to stop a trial if, given current data, it is likely to predict the outcome of the trial with high probability. That is, a trial can be stopped to reject the null hypothesis H_0 if, given current data in the analyses, the conditional probability of rejecting H_0 under H_0 at the end of the trial is greater than γ, where the constant γ should be between 0.5 and 1 and values of 0.8 or 0.9 are recommended (Jennison and Turnbull 2000, p. 206). Similarly, a trial can be stopped to accept the null hypothesis H_0 if, given current data in the analyses, the conditional probability of rejecting H_0 under the alternative hypothesis H_1 at the end of the trial is less than γ.

The following two approaches for stochastic curtailment are available in the SEQTEST procedures: conditional power approach and predictive power approach. For each approach, the derived group sequential test is used as the reference test for rejection.

Conditional Power Approach

In the SEQTEST procedure, the conditional power at an interim stage k is the probability that the test statistic at the final stage (stage K) would exceed the rejection critical value (Cui, Hung, and Wang 1999, p. 854; Emerson, Kittelson, and Gillen 2005, p. 13). If there exist interim stages between the kth stage and the final stage, $k < K - 1$, the conditional power is not the conditional probability to reject the null hypothesis H_0. In this case, you can set the next stage as the final stage, and the conditional power is the conditional probability to reject H_0.

The conditional distribution of Z_K given the observed statistic z_k at the kth stage and the hypothetical reference θ is

$$Z_K \,|\, (z_k, \theta) \;\sim\; N\left(z_k \;\Pi_k^{\frac{1}{2}} + \theta \; I_X^{\frac{1}{2}} \left(1 - \Pi_k\right),\; 1 - \Pi_k \right)$$

where $\Pi_k = I_k / I_X$ is the fraction of information at the kth stage.

The power for the upper alternative, prob($Z_K > a_K \,|\, z_k, \theta$), is then given by

$$p_{ku}(\theta) = \Phi\left((1 - \Pi_k)^{-\frac{1}{2}} \left(z_k \;\Pi_k^{\frac{1}{2}} - a_K\right) \;+\; \theta \; I_X^{\frac{1}{2}} \left(1 - \Pi_k\right)^{\frac{1}{2}} \right)$$

where Φ is the cumulative distribution function of the standardized Z statistic and a_K is the upper critical value at the final stage.

Similarly, the power for the lower alternative, prob($Z_K < a_{\_K} \,|\, z_k, \theta$), is

$$p_{kl}(\theta) = 1 - \Phi\left((1 - \Pi_k)^{-\frac{1}{2}} \left(z_k \;\Pi_k^{\frac{1}{2}} - a_{\_K}\right) \;+\; \theta \; I_X^{\frac{1}{2}} \left(1 - \Pi_k\right)^{\frac{1}{2}} \right)$$

where $a_{\_K}$ is the lower critical value at the final stage.

A special case of the conditional power is the futility index (Ware, Muller, and Braunwald, 1985). It is one minus the conditional power under $H_1 : \theta = \theta_1$:

$$1 - p_{ku}(\theta_1) \;\text{ or }\; 1 - p_{kl}(\theta_1)$$

That is, it is the probability of accepting the null hypothesis under the alternative hypothesis given current data. A high futility index indicates a small probability of success (rejecting H_0) given the current data.

If $\theta = \hat{\theta}_k = z_k I_k^{-\frac{1}{2}}$, the maximum likelihood estimate at stage k, the powers for the upper and lower alternatives can be simplified:

$$p_{ku}(\theta) = \Phi\left((1 - \Pi_k)^{-\frac{1}{2}} \left(z_k \;\Pi_k^{-\frac{1}{2}} - a_K\right) \right)$$

$$p_{kl}(\theta) = 1 - \Phi\left((1 - \Pi_k)^{-\frac{1}{2}} \left(z_k \;\Pi_k^{-\frac{1}{2}} - a_{\_K}\right) \right)$$

Predictive Power Approach

The conditional power depends on the specified reference θ, which might be supported by the current data (Jennison and Turnbull 2000, p. 210). An alternative is to use the predictive power (Herson 1979), which is

a weighted average of the conditional power over values of θ. Without prior knowledge about θ, then with $\hat{\theta} = z_k/\sqrt{I_k}$, the maximum likelihood estimate at stage k, the posterior distribution for θ (Jennison and Turnbull 2000, p. 211) is

$$\theta \mid Z_K \sim N\left(\frac{z_k}{\sqrt{I_k}},\ \frac{1}{I_k}\right)$$

Thus, the predictive power at stage k for the upper and lower alternatives can be derived as

$$p_{ku} = 1 - \Phi\left((1-\Pi_k)^{-\frac{1}{2}}\ (a_K\ \Pi_k^{\frac{1}{2}} - z_k)\right)$$

$$p_{kl} = \Phi\left((1-\Pi_k)^{-\frac{1}{2}}\ (a_{\_K}\ \Pi_k^{\frac{1}{2}} - z_k)\right)$$

where a_K and $a_{\_K}$ are the upper and lower critical values at the final stage.

Repeated Confidence Intervals

In a group sequential test, repeated confidence intervals for a parameter θ are defined as a sequence of intervals $(\hat{\theta}_{kl}, \hat{\theta}_{ku}), k = 1, 2, \ldots, K$, for which a simultaneous coverage probability is maintained (Jennison and Turnbull 2000, p. 189). That is, a $(1-\alpha)$ sequence of repeated confidence intervals has

$$\text{Prob}(\hat{\theta}_{kl} \le \theta \le \hat{\theta}_{ku}) = 1 - \alpha$$

These confidence limits $\hat{\theta}_{kl}$ and $\hat{\theta}_{ku}$ can be created from observed statistic and boundary values at each stage.

Two-Sided Repeated Confidence Intervals

Two sequences of repeated confidence intervals can be derived for a two-sided test. One is a $(1-\alpha_l-\alpha_u)$ rejection repeated confidence intervals $(\hat{\theta}_{kl}(\alpha), \hat{\theta}_{ku}(\alpha)), k = 1, 2, \ldots, K$, and the other is a $(1-\beta_l-\beta_u)$ acceptance repeated confidence intervals $(\hat{\theta}_{kl}(\beta), \hat{\theta}_{ku}(\beta)), k = 1, 2, \ldots, K$, where α_l and α_u are the lower and upper Type I error probabilities for the test and β_l and β_u are the lower and upper Type II error probabilities for the test (Jennison and Turnbull 2000, p. 196).

The rejection lower and upper repeated confidence limits at stage k are

$$\hat{\theta}_{kl}(\alpha) = \hat{\theta}_k - \frac{a_k}{\sqrt{I_k}} \qquad \hat{\theta}_{ku}(\alpha) = \hat{\theta}_k - \frac{a_{\_k}}{\sqrt{I_k}}$$

The hypothesis is rejected for upper alternative if the lower limit $\hat{\theta}_{kl}(\alpha) > \theta_{0u}$ and is rejected for lower alternative if the upper limit $\hat{\theta}_{ku}(\alpha) < \theta_{0l}$. That is, the hypothesis is rejected if both θ_{0l} and θ_{0u} are not in a rejection repeated confidence interval $(\hat{\theta}_{kl}(\alpha), \hat{\theta}_{ku}(\alpha))$.

The acceptance lower and upper repeated confidence limits at stage k are

$$\hat{\theta}_{kl}(\beta) = \hat{\theta}_k + \left(\theta_{1l} - \frac{b_{\_k}}{\sqrt{I_k}}\right) \qquad \hat{\theta}_{ku}(\beta) = \hat{\theta}_k + \left(\theta_{1u} - \frac{b_k}{\sqrt{I_k}}\right)$$

The hypothesis is accepted if the lower limit $\hat{\theta}_{kl}(\beta) > \theta_{1l}$ and the upper limit $\hat{\theta}_{ku}(\beta) < \theta_{1u}$. That is, a repeated confidence interval is contained in the interval $(\theta_{1l}, \theta_{1u})$.

One-Sided Repeated Confidence Intervals

Like the two-sided repeated confidence intervals, two sequences of repeated confidence intervals can be derived for a one-sided test. Suppose the one-sided test has an upper alternative θ_{1u}. Then one sequence of repeated confidence intervals is a $(1-\alpha_u)$ rejection repeated confidence intervals $(\hat{\theta}_{kl}(\alpha), \infty)$, $k = 1, 2, \ldots, K$, and the other is a $(1-\beta_u)$ acceptance repeated confidence intervals $(-\infty, \hat{\theta}_{ku}(\beta))$, $k = 1, 2, \ldots, K$, where α_u and β_u are the upper Type I and Type II error probabilities for the test. Thus, a sequence of repeated confidence intervals with confidence level greater than or equal to $(1-\alpha_u-\beta_u)$ is given by $(\hat{\theta}_{kl}(\alpha), \hat{\theta}_{ku}(\beta))$.

The rejection lower repeated confidence limit and the acceptance upper repeated confidence limit at stage k are

$$\hat{\theta}_{kl}(\alpha) = \hat{\theta}_k - \left(\frac{a_k}{\sqrt{I_k}} - \theta_{0u}\right) \qquad \hat{\theta}_{ku}(\beta) = \hat{\theta}_k + \left(\theta_{1u} - \frac{b_k}{\sqrt{I_k}}\right)$$

The hypothesis is rejected if the lower limit $\hat{\theta}_{kl}(\alpha) > \theta_{0u}$. and it is accepted if the upper limit $\hat{\theta}_{ku}(\beta) < \theta_{1u}$.

Analysis after a Sequential Test

At the end of a trial, the hypothesis is either rejected or accepted. But the p-value, median, and confidence limits depend on the ordering the sample space (k, z), where k is the stage number and z is the standardized Z statistic.

Following the notations used in Jennison and Turnbull (2000, pp. 179–180), $(k', z') \succ (k, z)$ if (k', z') has a higher order or more extreme than (k, z). Then for a given ordering, the p-value, median, and confidence limits associated with the observed statistics (k, z) can be derived.

p-value

With the observed pair of statistics (k_0, z_0) when the trial is stopped, a one-sided upper p-value is computed as

$$\text{Prob}\{\,(k, z) \succeq (k_0, z_0)\,\}$$

A one-sided lower p-value is computed as

$$\text{Prob}\{\,(k, z) \preceq (k_0, z_0)\,\}$$

A two-sided p-value is twice the smaller of the lower and upper p-values.

Median Unbiased Estimate

With the observed pair (k_0, z_0), a median unbiased estimate θ_m is computed from

$$\text{Prob}\{\,(k,z) \succeq (k_0,z_0)\,|\,\theta_m\,\} = 0.50$$

Confidence Limits

With the observed pair (k_0, z_0), a lower $(1-\alpha_l)$ confidence limit for θ, θ_l, is computed from

$$\text{Prob}\{\,(k,z) \succeq (k_0,z_0)\,|\,\theta_l\,\} = \alpha_l$$

Similarly, an upper $(1-\alpha_u)$ confidence limit for θ, θ_u, is computed from

$$\text{Prob}\{\,(k,z) \preceq (k_0,z_0)\,|\,\theta_u\,\} = \alpha_u$$

Available Sample Space Orderings in a Sequential Test

At the end of a trial, the hypothesis is either rejected or accepted. Denote the stage number and the statistic at the end of a trial by a pair of statistics (k, z), where k is the stage number and z is the standardized Z statistic. Then an ordering on the sample space (k, z) is needed to derive the p-value, median, and confidence limits associated with the observed statistics (k^*, z^*).

The SEQTEST procedure provides the stagewise, LR, and MLE orderings. Refer to Jennison and Turnbull (2000 pp. 179–187) for a detailed description and comparison of these orderings.

Stagewise Ordering

If the continuation regions of a design are intervals, the stagewise ordering (Fairbanks and Madsen 1982; Tsiatis, Rosner, and Mehta 1984; Jennison and Turnbull 2000, pp. 179–180) uses counter-clockwise ordering around the continuation region to compute the p-value, unbiased median estimate, and confidence limits. This ordering depends on the stopping region, stopping stage, and standardized statistic at the stopping stage. But it does not depend on information levels beyond the observed stage. For a one-sided design with an upper alternative, $(k', z') \succ (k, z)$ if one of the following criteria holds:

- $k' = k$ and $z' > z$
- $k' < k$ and $z' \geq a_{k'}$, the upper α boundary at stage k'
- $k' > k$ and $z < b_k$, the upper β boundary at stage k

Similar criteria can be derived for a one-sided design with a lower alternative.

For a two-sided design with early stopping to reject the null hypothesis, $(k', z') \succ (k, z)$ if one of the following criteria holds:

- $k' = k$ and $z' > z$
- $k' < k$ and $z' \geq a_{k'}$, the upper α boundary at stage k'
- $k' > k$ and $z \leq \_a_k$, the lower α boundary at stage k

Note that the stagewise ordering is not applicable for two-sided designs with early stopping to accept H_0 or to either accept or reject H_0, which might have two disjoint continuous intervals at each interim stage.

For a two-sided design with early stopping either to reject or to accept the null hypothesis, $(k', z') \succ (k, z)$ if one of the following criteria holds:

- $z' \geq a_{k'}$ and $z < b_k$
- $z' > \_b_{k'}$ and $z \leq \_a_k$

That is, each value in the continuation region is less extreme than each value in the upper rejection region and more extreme than each value in the lower rejection region. Then, combining with the ordering defined for a two-sided design with early stopping to reject the null hypothesis, the p-value, median, and confidence limits can be derived for the observed statistics in the lower or upper rejection region.

Thus, if the stagewise ordering is specified in the SEQTEST procedure for a two-sided design with early stopping to either reject or accept the null hypothesis, the stagewise ordering is used to derive these statistics only if the observed statistics is in the lower or upper rejection region. Otherwise, the LR ordering is used.

LR Ordering

The LR ordering (Chang 1989) depends on the observed standardized Z statistic z, information levels, and a specified hypothetical reference. For the LR ordering under a given hypothesis $H : \theta = \theta_g$, $(k', z') \succ (k, z)$ if

$$(z' - \theta_g \sqrt{I_{k'}}) > (z - \theta_g \sqrt{I_k})$$

Under the null hypothesis $H_0 : \theta = 0$, it reduces to

$$z' > z$$

and can be used to derive statistics under H_0, such as p-values.

The LR ordering is applicable to all designs if all information levels are available. But depending on the boundary shape, some observed statistics (k, z) in the rejection region might be less extreme than the statistics in the acceptance region. That is, the p-value for observed statistics in the rejection region might be greater than the significance level.

MLE Ordering

The MLE ordering (Emerson and Fleming 1990) depends only on the observed maximum likelihood estimate. $(k', z') \succ (k, z)$ if

$$\frac{z'}{\sqrt{I_{k'}}} > \frac{z}{\sqrt{I_k}}$$

The MLE ordering is applicable to all designs if all information levels are available.

Applicable Tests and Sample Size Computation

The SEQDESIGN procedure assumes that the data are from a multivariate normal distribution and the sequence of the standardized test statistics $\{Z_1, Z_2, \ldots, Z_K\}$ have the following canonical joint distribution:

- $Z_k \sim N\left(\theta\sqrt{I_k}, 1\right)$
- $\mathrm{Cov}(Z_{k_1}, Z_{k_2}) = \sqrt{I_{k_1}/I_{k_2}} \quad , \quad 1 \le k_1 \le k_2 \le K$

where K is the total number of stages and I_k is the information available at stage k.

If the data are not from a normal distribution such as binomial distribution, then it is assumed that the test statistic is computed from a large sample such that the statistic has an approximately normal distribution.

In a clinical trial, the sample size required depends on the Type I error probability α, reference improvement θ_1, power $1-\beta$, and variance of the response variable. Given a null hypothesis $H_0 : \theta = 0$ with an upper alternative hypothesis $H_1 : \theta = \theta_1$, the information required for a fixed-sample test is given by

$$I_0 = \frac{(\Phi^{-1}(1-\alpha) + \Phi^{-1}(1-\beta))^2}{\theta_1^2}$$

where the parameter θ depends on the test specified in the clinical trial. For example, if you are comparing two binomial populations $H_0 : \theta = 0$, then $\theta = p_t - p_c$ is the difference between two proportions if the proportion difference statistic is used, and $\theta = \log\left(\frac{p_t(1-p_c)}{p_c(1-p_t)}\right)$, the log odds ratio for the two proportions if the log odds ratio statistic is used.

If the maximum likelihood estimate $\hat{\theta}$ from the likelihood function can be derived, then the asymptotic variance for $\hat{\theta}$ is $\mathrm{Var}(\hat{\theta}) = 1/I$, where I is Fisher's information for θ.

The resulting statistic $\hat{\theta}$ corresponds to the MLE scale as specified in the BOUNDARYSCALE=MLE option in the PROC SEQDESIGN statement, $\hat{\theta}\sqrt{I}$ corresponds to the standardized Z scale (BOUNDARYSCALE=STDZ), and $\hat{\theta}I$ corresponds to the score scale (BOUNDARYSCALE=SCORE).

Alternatively, if the score statistic is derived, it can also be used as the test statistic and its asymptotic variance is given by Fisher's information.

For a group sequential trial, the maximum information I_X is derived in the SEQDESIGN procedure by using the specified α, β, and θ_1. With the maximum information

$$I_X = \frac{1}{\text{Var}(\hat{\theta})}$$

the sample size required for a specified test statistic in the trial can be evaluated or estimated from the known or estimated variance of the response variable. Note that different designs might produce different maximum information levels for the same hypothesis, and this in turn might require a different number of observations for the trial.

With a specified test statistic, the required sample sizes at the stages can be computed. These tests include commonly used tests for normal means, binomial proportions, and survival distributions. See the section "Sample Size Computation" in "The SEQDESIGN Procedure" for a description of these tests.

Table Output

The SEQTEST procedure displays the "Design Information" and "Test Information" tables by default.

Conditional Power

The "Conditional Power Information" table displays the following information under a hypothetical reference:

- stopping stage
- MLE, observed maximum likelihood estimate
- conditional power under the hypothetical reference

For a one-sided test, the power are derived under hypothetical references $\theta = \hat{\theta}$ and $\theta = c_i\theta_1$, where $\hat{\theta}$ is the observed statistic, θ_1 is the alternative reference, and c_i are the values specified in the CREF= option. For a two-sided test, the power are derived under the hypothetical references $\theta = \hat{\theta}$, $\theta = c_i\theta_{1l}$, and $\theta = c_i\theta_{1u}$, where θ_{1l} is the lower alternative reference and θ_{1u} is the upper alternative reference. The default is CREF= 0 0.5 1.0 1.5.

Design Information

The "Design Information" table displays the design specifications and derived statistics. The derived Max Information (Percent Fixed-Sample) is the maximum information for the sequential design in percentage of the corresponding fixed-sample information.

The Null Ref ASN (Percent Fixed-Sample) is the average sample size required under the null hypothesis for the group sequential design in percentage of the corresponding fixed-sample design. Similarly, the Alt Ref ASN (Percent Fixed-Sample) is the average sample size required under the alternative reference for the group sequential design in percentage of the corresponding fixed-sample design.

Error Spending Information

The "Error Spending Information" table displays the following information at each stage:

- proportion of information
- actual information level, if the maximum information is either specified or derived
- cumulative error spending for each boundary

Parameter Estimates

The "Parameter Estimates" table displays the following information at the conclusion of a sequential trial:

- stopping stage
- parameter estimate
- median and confidence limits based on the specified ordering
- p-value for the hypothesis H_0 based on the specified ordering

Powers and Expected Sample Sizes

The "Powers and Expected Sample Sizes" table displays the following information under each of the specified hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and c_i are values specified in the CREF= option.

- coefficient c_i for the hypothetical references. The value $c_i = 0$ corresponds to the null hypothesis and $c_i = 1$ corresponds to the alternative hypothesis
- power
- expected sample size, as percentage of fixed-sample size

For a one-sided design, the power and expected sample sizes under the hypothetical references $\theta = c_i\theta_1$ are displayed.

For a two-sided symmetric design, the power and expected sample sizes under each of the hypothetical references $\theta = c_i\theta_{1u}$ are displayed, where θ_{1u} is the upper alternative reference.

For a two-sided asymmetric design, the power and expected sample sizes under each of the hypothetical references $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively.

For a two-sided design, the power is the probability of correctly rejecting the null hypothesis for the correct alternative. Thus, under the null hypothesis, the displayed power corresponds to a one-sided Type I error probability level—that is, the lower α level or the upper α level.

The expected sample size as a percentage of the corresponding fixed-sample design is

$$100 \times \frac{\sum_{k=1}^{K} p_k \, I_k}{I_0}$$

where p_k is the stopping probability at stage k, $\sum_{k=1}^{K} p_k \, I_k$ is the expected information level, and I_0 is the information level for the fixed-sample design.

Predictive Power

The "Predictive Power Information" table displays the following information:

- stopping stage
- MLE, observed maximum likelihood estimate
- predictive power

Repeated Confidence Intervals

The "Repeated Confidence Intervals" table displays the following information for the observed statistic at each stage:

- information level
- parameter estimate
- rejection confidence limits. The null hypothesis is rejected for the upper alternative if the lower rejection confidence limit is greater than the null parameter value. Similarly, the null hypothesis is rejected for the lower alternative if the upper rejection confidence limit is less than the null parameter value.
- acceptance confidence limits. The upper alternative hypothesis is rejected if the upper acceptance confidence limit is less than the upper alternative value. Similarly, the lower alternative hypothesis is rejected if the lower acceptance confidence limit is greater than the upper alternative value. For a two-sided design, if both upper and lower alternative hypothesis are rejected, the null hypothesis is accepted.

Stopping Probabilities

The "Expected Cumulative Stopping Probabilities" table displays the following information under each of the specified hypothetical references $\theta = c_i \theta_1$, where c_i are values specified in the CREF= option, and θ_1 is the alternative reference:

- coefficient c_i for the hypothetical references. The value $c_i = 0$ corresponds to the null hypothesis, and $c_i = 1$ corresponds to the alternative hypothesis

- expected stopping stage
- source of the stopping probability: reject H_0 (with STOP=REJECT or STOP=BOTH), accept H_0 (with STOP=ACCEPT or STOP=BOTH), or either reject or accept H_0 (with STOP=BOTH)
- expected cumulative stopping probabilities at each stage

For a one-sided design, the expected cumulative stopping probabilities under the hypothetical references $\theta = c_i\theta_1$ are displayed.

For a two-sided design, the expected cumulative stopping probabilities under each of the hypothetical references $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively.

Note that for a symmetric two-sided design, only the expected cumulative stopping probabilities under the hypothetical references $\theta = c_i\theta_{1u}$ are derived.

The expected stopping stage is given by $k_0 + d$ and is derived from the expected information level

$$\sum_{k=1}^{K} p_k\, I_k = I_{k_0} + d\,(I_{(k_0+1)} - I_{k_0})$$

where p_k is the stopping probability at stage k and $0 \leq d < 1$.

For equally spaced information levels, the expected stopping stage is reduced to the weighted average

$$\sum_{k=1}^{K} p_k\, k$$

Test Information

The "Test Information" table displays the following information at each stage:

- proportion of information
- actual information level, if the maximum information is available from the input BOUNDARY= data set
- alternative references with the specified statistic scale. If a p-value scale is specified, the standardized Z scale is used.
- boundary values with the specified statistic scale to reject or accept the null hypothesis

Note that implicitly, the test information table also contains variables for the boundary scale, stopping criterion, and type of alternative hypothesis. That is, if an ODS statement is used to save the table, the data set also contains the variables _Scale_ for the boundary scale, _Stop_ for the stopping criterion, and _ALT_ for the type of alternative hypothesis.

If the test variable is specified, the table also displays the following:

- test statistic
- resulting action of test statistic: continue to the next stage, accept the null hypothesis H_0, or reject H_0

ODS Table Names

PROC SEQTEST assigns a name to each table it creates. You must use these names to reference tables when using the Output Delivery System (ODS). These names are listed in Table 81.3. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 81.3 ODS Tables Produced by PROC SEQTEST

ODS Table Name	Description	Option
CondPower	Conditional power	CONDPOWER
Design	Design information	
ErrSpend	Error spending	ERRSPEND
ParameterEstimates	Parameter estimates	DATA(TESTVAR=) or PARMS(TESTVAR=)
PowerSampleSize	Power and expected sample sizes	PSS
PredPower	Predictive power	PREDPOWER
RepeatedCI	Repeated confidence intervals	RCI
StopProb	Stopping probabilities	STOPPROB
Test	Test statistics and boundary values	

Graphics Output

This section describes the use of ODS for creating graphics with the SEQTEST procedure. To request these graphs, ODS Graphics must be enabled and you must specify the associated graphics options in the PROC SEQTEST statement. For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS."

Sequential ASN Plot

The PLOTS=ASN option displays the average sample numbers (expected sample sizes for nonsurvival data or expected numbers of events for survival data) under various hypothetical references. The average sample numbers are connected for each design, and these connected curves for all designs are displayed in the "Sequential ASN Plot" graph.

For a one-sided design, average sample numbers under the hypothetical references $\theta = c_i\theta_1$ are displayed, where c_i are the values specified in the CREF= option and θ_1 is the alternative reference. The horizontal axis displays the c_i values of these hypothetical references.

For a two-sided design, average sample numbers under each of the hypothetical references $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. The horizontal axis displays $-c_i$ values for lower hypothetical references $\theta = c_i\theta_{1l}$ and c_i values for upper hypothetical references $\theta = c_i\theta_{1u}$. Note that for a symmetric two-sided design, only average sample numbers under the hypothetical references $\theta = c_i\theta_{1u}$ are derived.

If the trial stops after the sequential test, the hypothetical reference corresponding to the test statistic is also indicated in the plot.

Conditional Power Plot

The PLOTS=CONDPOWER option displays the conditional powers given the observed statistic under various hypothetical references. These powers are connected and are displayed in the "Conditional Power Plot" graph.

For a one-sided test, the power are derived under the hypothetical references $\theta = \hat{\theta}$ and $\theta = c_i\theta_1$, where $\hat{\theta}$ is the observed statistic, θ_1 is the alternative reference, and c_i are the values specified in the CREF= option. The horizontal axis displays these c_i values for hypothetical references.

For a two-sided test, the power are derived under hypothetical references $\theta = \hat{\theta}$, $\theta = c_i\theta_{1l}$, and $\theta = c_i\theta_{1u}$, where θ_{1l} is the lower alternative reference and θ_{1u} is the upper alternative reference. The horizontal axis displays $-c_i$ values for hypothetical references $\theta = c_i\theta_{1l}$ and c_i values for hypothetical references $\theta = c_i\theta_{1u}$.

If the trial stops after the sequential test, the hypothetical reference corresponding to the test statistic is also indicated in the plot.

Sequential Error Spending Plot

The PLOTS=ERRSPEND option displays the cumulative error spending at each stage on each boundary in the "Sequential Error Spending Plot" graph. A legend table uses the design labels to identify the curves for the corresponding design in the plot.

Sequential Power Plot

The PLOTS=POWER option displays the powers under various hypothetical references. The powers are connected for each design, and these connected curves for all designs are displayed in the "Sequential Power Plot" graph.

For a one-sided design, powers under hypothetical references $\theta = c_i\theta_1$ are displayed, where c_i are the values specified in the CREF= option and θ_1 is the alternative reference. The horizontal axis displays the c_i values of these hypothetical references.

For a two-sided design, powers under hypothetical references $\theta = c_i\theta_{1l}$ and $\theta = c_i\theta_{1u}$ are displayed, where θ_{1l} and θ_{1u} are the lower and upper alternative references, respectively. The horizontal axis displays $-c_i$ values for lower hypothetical references $\theta = c_i\theta_{1l}$ and c_i values for upper hypothetical references $\theta = c_i\theta_{1u}$. Note that for a symmetric two-sided design, only powers under hypothetical references $\theta = c_i\theta_{1u}$ are derived.

If the trial stops after the sequential test, the hypothetical reference corresponding to the test statistic is also indicated in the plot.

Repeated Confidence Intervals Plot

The PLOTS=RCI option displays repeated confidence intervals at each stage given the observed statistic at that stage. These repeated confidence intervals are displayed in the "Repeated Confidence Intervals Plot" graph.

Sequential Test Plot

The PLOTS=TEST option displays boundary values and test statistics in the "Test Plot" graph. The boundary values are connected for each boundary, and both the stage number and the information level at each stage are displayed. The legend table identifies the acceptance and rejection regions in the plot.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, "Statistical Graphics Using ODS."

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" on page 611 in Chapter 21, "Statistical Graphics Using ODS."

PROC SEQTEST assigns a name to each graph it creates. You can use these names to reference the graphs when using ODS. To request these graphs, ODS Graphics must be enabled and you must specify the options indicated in Table 81.4.

Table 81.4 Graphs Produced by PROC SEQTEST

ODS Graph Name	Plot Description	Option
AsnPlot	Average sample numbers	PLOTS=ASN
CondPowerPlot	Conditional power curves	PLOTS=CONDPOWER
ErrSpendPlot	Error spending	PLOTS=ERRSPEND
PowerPlot	Power curves	PLOTS=POWER
RepeatedCIPlot	Repeated confidence intervals	PLOTS=RCI
TestPlot	Boundary values and test statistics	PLOTS=TEST

Acknowledgments

In addition to being shaped by the research literature listed in the section "References" on page 7066, the development of the SEQDESIGN and SEQTEST procedures has benefited significantly from the advice and expertise of the following researchers:

- Lu Cui, Eisai Medical Research
- Alex Dmitrienko, Eli Lilly
- Scott Emerson, University of Washington
- Gordon Lan, Johnson & Johnson
- Steve Snapinn, Amgen
- John Whitehead, University of Reading

The time and effort that these researchers have contributed is gratefully acknowledged.

Examples: SEQTEST Procedure

The following examples perform group sequential tests with various designs and test statistics.

Four statistic scales are available for the input boundary values, the input test statistic, and the displayed test information in the SEQTEST procedure. These are the maximum likelihood estimator scale, score statistic scale, standardized normal Z scale, and p-value scale. There is a unique one-to-one transformation between any two of the scales, and you can use different scales for the input boundary values and input test statistic. These boundary values and test statistic are displayed with the scale specified in the BOUNDARYSCALE= option in the SEQTEST procedure.

Example 81.1: Testing the Difference between Two Proportions

This example demonstrates group sequential tests that use an O'Brien-Fleming group sequential design. A clinic is studying the effect of vitamin C supplements in treating flu symptoms. The study consists of patients in the clinic who have exhibited the first sign of flu symptoms within the last 24 hours. These patients are randomly assigned to either the control group (which receives placebo pills) or the treatment group (which receives large doses of vitamin C supplements). At the end of a five-day period, the flu symptoms of each patient are recorded.

Suppose that you know from past experience that flu symptoms disappear in five days for 60% of patients who experience flu symptoms. The clinic would like to detect a 75% symptom disappearance with a high

probability. A test that compares the proportions directly specifies the null hypothesis $H_0 : \theta = p_t - p_c = 0$ with a one-sided alternative $H_1 : \theta > 0$ and a power of 0.90 at $H_1 : \theta = 0.15$, where p_t and p_c are the proportions of symptom disappearance in the treatment group and control group, respectively.

The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design by using an O'Brien-Fleming method for normally distributed data. The design uses a one-sided alternative hypothesis with early stopping either to accept or reject the null hypothesis H_0. The BOUNDARYSCALE=MLE option uses the MLE scale to display statistics in the boundary table and boundary plots.

```
ods graphics on;
proc seqdesign altref=0.15
               boundaryscale=mle
               ;
   OBrienFleming: design method=obf
                         nstages=4
                         alt=upper
                         stop=both
                         alpha=0.025
                         ;
   samplesize model=twosamplefreq(nullprop=0.6 test=prop);
ods output Boundary=Bnd_Count;
run;
ods graphics off;
```

The ODS OUTPUT statement with the BOUNDARY=BND_COUNT option creates an output data set named BND_COUNT which contains the resulting boundary information for the subsequent sequential tests.

The "Design Information" table in Output 81.1.1 displays design specifications. With the specified alternative hypothesis $H_1 : \theta = 0.15$, the maximum information is derived to achieve a power of 0.90 at H_1. The derived fixed-sample information ratio 1.0767 is the maximum information needed for a group sequential design relative to its corresponding fixed-sample design.

Output 81.1.1 O'Brien-Fleming Design Information

The SEQDESIGN Procedure
Design: OBrienFleming

Design Information

Statistic Distribution	Normal
Boundary Scale	MLE
Alternative Hypothesis	Upper
Early Stop	Accept/Reject Null
Method	O'Brien-Fleming
Boundary Key	Both
Alternative Reference	0.15
Number of Stages	4
Alpha	0.025
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	107.6741
Max Information	502.8343
Null Ref ASN (Percent of Fixed Sample)	61.12891
Alt Ref ASN (Percent of Fixed Sample)	75.89782

The "Boundary Information" table in Output 81.1.2 displays the information level, alternative reference, and boundary values at each stage. With the BOUNDARYSCALE=MLE option, the SEQDESIGN procedure displays the output boundaries with the maximum likelihood estimator scale.

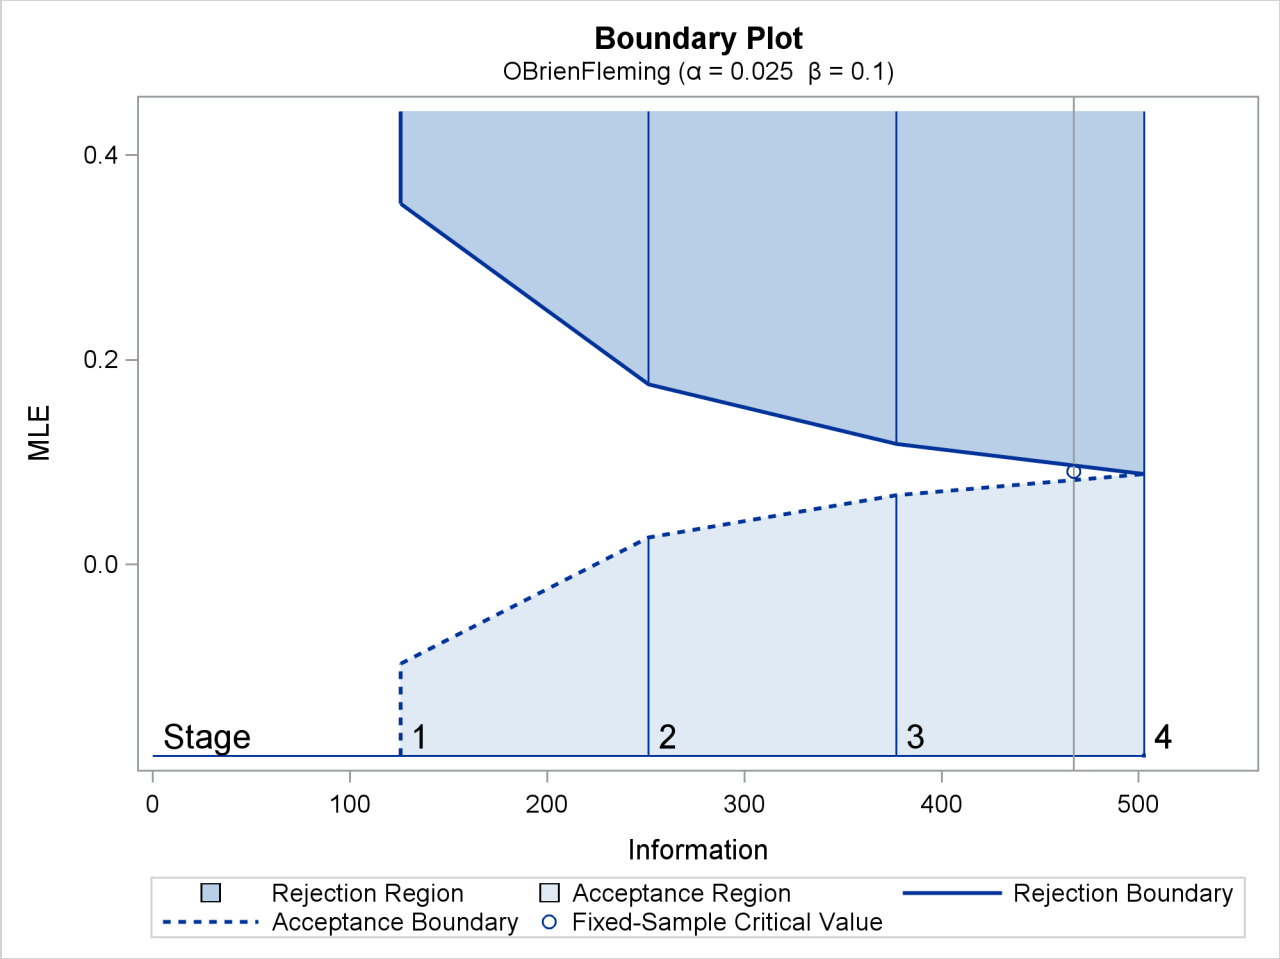
Output 81.1.2 O'Brien-Fleming Boundary Information

Boundary Information (MLE Scale)
Null Reference = 0

	Information Level			Alternative Reference	Boundary Values	
					Upper	
Stage	Proportion	Actual	N	Upper	Beta	Alpha
1	0.2500	125.7086	107.4808	0.15000	-0.09709	0.35291
2	0.5000	251.4171	214.9617	0.15000	0.02645	0.17645
3	0.7500	377.1257	322.4425	0.15000	0.06764	0.11764
4	1.0000	502.8343	429.9233	0.15000	0.08823	0.08823

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 81.1.3. The horizontal axis indicates the information levels for the design. The stages are indicated by vertical lines with accompanying stage numbers. If the test statistic at a stage is in a rejection region, the trial stops and the hypothesis is rejected. If the test statistic is in an acceptance region, then the trial also stops and the hypothesis is accepted. If the statistic is not in a rejection or an acceptance region, the trial continues to the next stage.

Output 81.1.3 O'Brien-Fleming Boundary Plot



The boundary plot also displays the information level and critical value for the corresponding fixed-sample design. The solid and dashed lines at the fixed-sample information level correspond to the rejection and acceptance lines, respectively.

With the SAMPLESIZE statement, the maximum information is used to derive the required sample size for the study. The "Sample Size Summary" table in Output 81.1.4 displays parameters for the sample size computation.

Output 81.1.4 Required Sample Size Summary

Sample Size Summary

Test	Two-Sample Proportions
Null Proportion	0.6
Proportion (Group A)	0.75
Test Statistic	Z for Proportion
Reference Proportions	Alt Ref
Max Sample Size	429.9233
Expected Sample Size (Null Ref)	244.0768
Expected Sample Size (Alt Ref)	303.0464

With the derived maximum information and the specified MODEL= option in the SAMPLESIZE statement, the total sample size in each group for testing the difference between two proportions under the alternative hypothesis is

$$N_1 = N_2 = \left(p_{1c}\left(1 - p_{1c}\right) + p_{1t}\left(1 - p_{1t}\right)\right) I_X$$

where $p_{1c} = 0.6$ and $p_{1t} = p_{1c} + \theta_1 = 0.75$. By default (or equivalently if you specify REF=PROP in the MODEL=TWOSAMPLEFREQ option), the required sample sizes are computed under the alternative hypothesis. See the section "Test for the Difference between Two Binomial Proportions" in the chapter "The SEQDESIGN Procedure" for a description of these parameters.

The "Sample Sizes (N)" table in Output 81.1.5 displays the required sample sizes at each stage, in both fractional and integer numbers. The derived sample sizes under the heading Fractional N which correspond to the design are not integers. These sample sizes are rounded up to integers under the heading Ceiling N. In practice, integer sample sizes are used, and the information levels increase slightly. Thus, 54, 108, 162, and 215 patients are needed in each group for the four stages, respectively.

Output 81.1.5 Required Sample Sizes

Sample Sizes (N)
Two-Sample Z Test for Proportion Difference

	Fractional N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	107.48	53.74	53.74	125.7
2	214.96	107.48	107.48	251.4
3	322.44	161.22	161.22	377.1
4	429.92	214.96	214.96	502.8

Sample Sizes (N)
Two-Sample Z Test for Proportion Difference

	Ceiling N			
Stage	N	N(Grp 1)	N(Grp 2)	Information
1	108	54	54	126.3
2	216	108	108	252.6
3	324	162	162	378.9
4	430	215	215	502.9

Suppose the trial follows the study plan, and 54 patients are available in each group at stage 1. The data set count_1 contains these 108 patients. Output 81.1.6 lists the first 10 observations of the data set.

Output 81.1.6 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	Trt	Resp
1	0	0
2	1	1
3	0	1
4	1	0
5	0	0
6	1	0
7	0	0
8	1	1
9	0	1
10	1	0

The Trt variable is a grouping variable with value 0 for a patient in the placebo control group and value 1 for a patient in the treatment group who is given vitamin C supplements. The Resp variable is an indicator variable with value 1 for a patient without flu symptoms after five days and value 0 for a patient with flu symptoms after five days.

The following statements use the GENMOD procedure to estimate the treatment effect at stage 1:

```
proc genmod data=count_1;
   model Resp= Trt;
ods output ParameterEstimates=Parms_Count1;
run;
```

Output 81.1.7 displays the treatment effect at stage 1.

Output 81.1.7 Stage 1 Treatment Difference

The GENMOD Procedure

Analysis Of Maximum Likelihood Parameter Estimates

Parameter	DF	Estimate	Standard Error	Wald 95% Confidence Limits		Wald Chi-Square	Pr > ChiSq
Intercept	1	0.6296	0.0627	0.5066	0.7526	100.68	<.0001
Trt	1	0.1111	0.0887	-0.0628	0.2850	1.57	0.2105
Scale	1	0.4611	0.0314	0.4035	0.5269		

NOTE: The scale parameter was estimated by maximum likelihood.

The test statistic is $\hat{\theta}_1 = \hat{p}_t - \hat{p}_c = 0.1111$, and its associated standard error is

$$\sqrt{\mathrm{Var}(\hat{\theta}_1)} = \sqrt{\frac{\hat{p}_c(1-\hat{p}_c)}{54} + \frac{\hat{p}_t(1-\hat{p}_t)}{54}} = 0.0887$$

The following statements create and display (in Output 81.1.8) the data set that contains the parameter estimate at stage 1, $\hat{\theta}_1 = 0.1111$, and its associated standard error $\sqrt{\text{Var}(\hat{\theta}_1)} = 0.0887$ which are used in the SEQTEST procedure:

```
data Parms_Count1;
   set Parms_Count1;
   if Parameter='Trt';
   _Scale_='MLE';
   _Stage_= 1;
   keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;

proc print data=Parms_Count1;
   title 'Statistics Computed at Stage 1';
run;
```

Output 81.1.8 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	Parameter	Estimate	StdErr	_Scale_	_Stage_
1	Trt	0.1111	0.0887	MLE	1

The initial required sample sizes are derived with the proportions $p_c = 0.6$ and $p_t = 0.75$. If the observed proportions are different from these assumed values, or if the number of available patients is different from the study plan in one of the stages, then the information level that corresponds to the test statistic is estimated from

$$I_k = \frac{1}{\text{Var}(\hat{\theta}_k)}$$

The following statements invoke the SEQTEST procedure and test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Count
             Parms(Testvar=Trt)=Parms_Count1
             infoadj=none
             errspendmin=0.001
             boundaryscale=mle
             errspend
             plots=errspend
             ;
ods output Test=Test_Count1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS_COUNT1 option specifies the input data set PARMS_COUNT1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRT option identifies the test variable TRT in the data set. The INFOADJ=NONE option maintains the information levels at future interim stages (2 and 3) as provided in the

BOUNDARY= data set. The BOUNDARYSCALE=MLE option displays the output boundaries in terms of the MLE scale.

The O'Brien-Fleming design is conservative in early stages and might not be desirable in a clinical trial. The ERRSPENDMIN=0.001 option specifies the minimum error spending at each stage to be 0.001, and it might increase the corresponding nominal p-value in early stages for the trial. The BOUNDARYSCALE=MLE option uses the MLE scale to display test statistics in the boundary table and boundary plots.

The ODS OUTPUT statement with the TEST=TEST_COUNT1 option creates an output data set named TEST_COUNT1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.1.9 displays design specifications. The derived statistics, such as the overall α and β levels, are derived from the specified maximum information and boundary values in the BOUNDARY= data set. Note that with a minor change in the information level at stage 1, the power also changes slightly from the design provided in the BOUNDARY= data set.

Output 81.1.9 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.BND_COUNT
Data Set	WORK.PARMS_COUNT1
Statistic Distribution	Normal
Boundary Scale	MLE
Alternative Hypothesis	Upper
Early Stop	Accept/Reject Null
Number of Stages	4
Alpha	0.025
Beta	0.10147
Power	0.89853
Max Information (Percent of Fixed Sample)	108.2301
Max Information	502.834283
Null Ref ASN (Percent of Fixed Sample)	61.09917
Alt Ref ASN (Percent of Fixed Sample)	73.9745

With the ERRSPEND option, the "Error Spending Information" table in Output 81.1.10 displays cumulative error spending at each stage for each boundary. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the Type I error level $\alpha = 0.025$ is maintained. Furthermore, with the ERRSPENDMIN=0.001 option, the α spending at each stage is greater than or equal to 0.001.

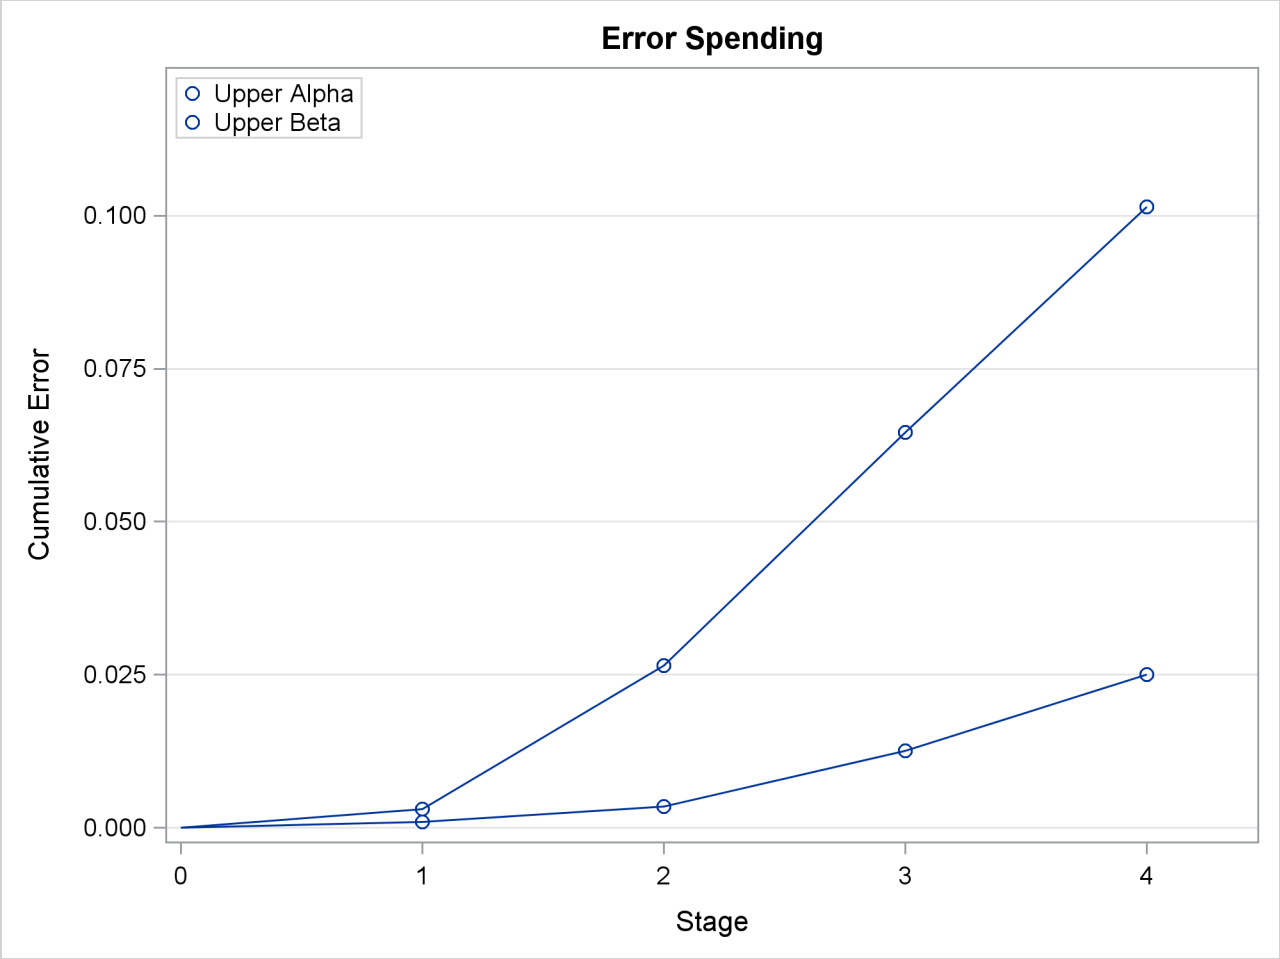
Output 81.1.10 Error Spending Information

Error Spending Information

Stage	---Information Level-- Proportion	Actual	-Cumulative Error Spending- ----------Upper---------- Beta	Alpha
1	0.2525	126.9871	0.00308	0.00100
2	0.5000	251.4171	0.02653	0.00343
3	0.7500	377.1257	0.06456	0.01254
4	1.0000	502.8343	0.10147	0.02500

With the PLOTS=ERRSPEND option, the procedure displays a plot of error spending for each boundary, as shown in Output 81.1.11. The error spending values in the "Error Spending Information" table in Output 81.1.10 are displayed in the plot.

Output 81.1.11 Error Spending Plot



The "Test Information" table in Output 81.1.12 displays the boundary values for the design, test statistic, and resulting action at each stage. With the BOUNDARYSCALE=MLE option, the maximum likelihood

estimator scale is used for the test statistic and boundary values. The table shows that the test statistic 0.1111 is between the upper α and β boundaries, so the trial continues to the next stage.

Output 81.1.12 Sequential Test

Test Information (MLE Scale)
Null Reference = 0

Stage	Information Level Proportion	Information Level Actual	Alternative Reference Upper	Boundary Values Upper Beta	Boundary Values Upper Alpha

Null Reference = 0

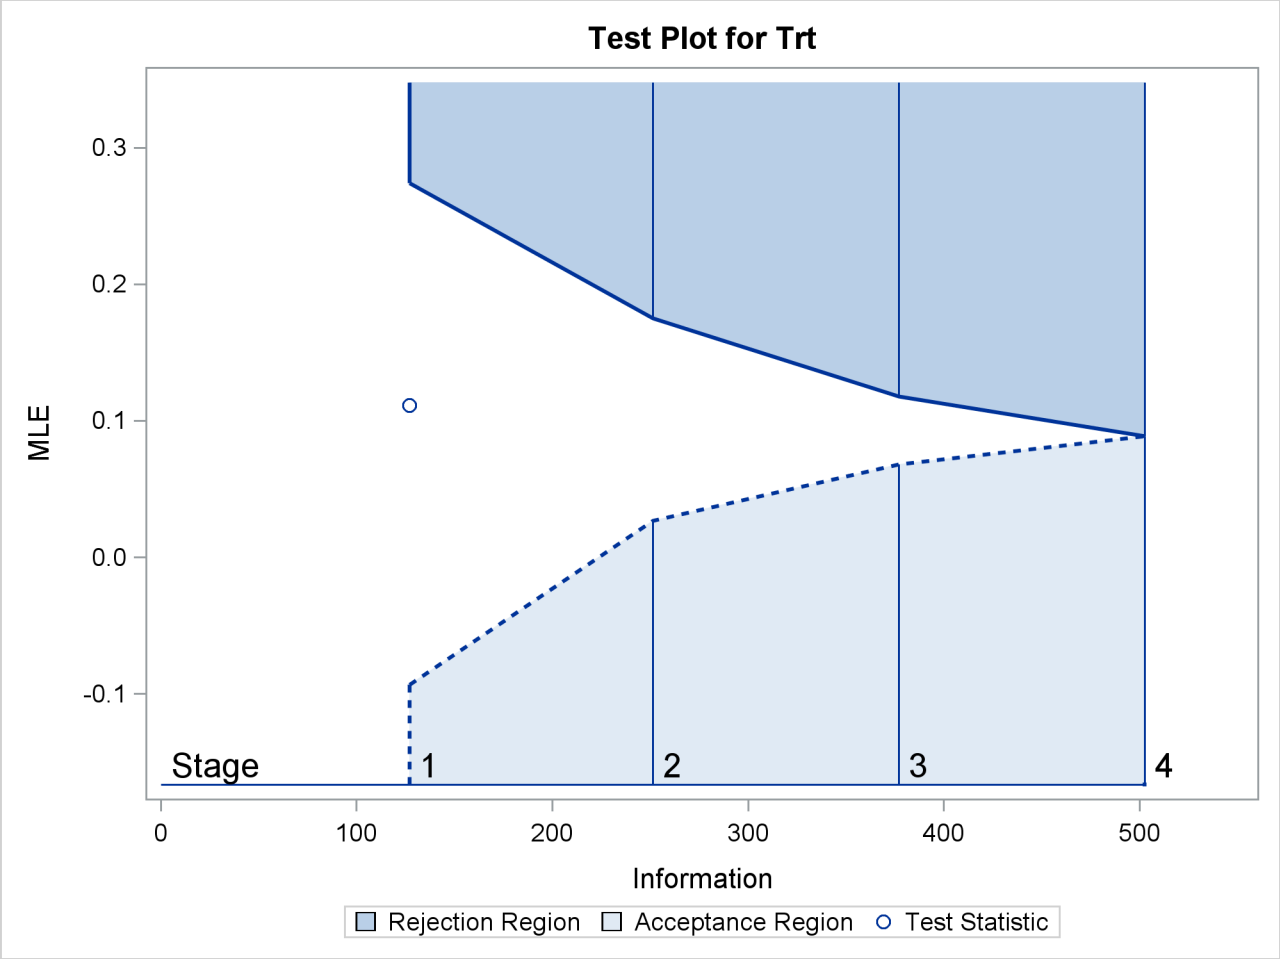
Stage	Test Trt Estimate	Test Trt Action
1	0.11111	Continue
2	.	
3	.	
4	.	

The information level at stage 1 is derived from the standard error,

$$I_1 = \frac{1}{\mathrm{Var}(\hat{\theta}_1)} = \frac{1}{(\mathrm{s.e.}(\hat{\theta}_1))^2} = 126.987$$

By default (or equivalently if you specify PLOTS=TEST), the "Test Plot" graph displays boundary values of the design and the test statistic at stage 1, as shown in Output 81.1.13. It also shows that the observed statistic is in the continuation region.

Output 81.1.13 Sequential Test Plot



The observed information level at stage 1, $I_1 = 126.987$, is slightly larger than the target information level at the design. If an observed information level in the study is substantially different from its target level in the design, then the sample sizes should be adjusted in the subsequent stages to achieve the target information levels.

Suppose the trial continues to the next stage, and 108 patients are available in each group at stage 2. The data set COUNT_2 contains these 216 patients.

The following statements use the GENMOD procedure to estimate the treatment effect at stage 2:

```
proc genmod data=Count_2;
   model Resp= Trt;
ods output ParameterEstimates=Parms_Count2;
run;
```

The following statements create the parameter estimate at stage 2, $\hat{\theta}_2 = \hat{p}_2 - \hat{p}_1 = 0.1759$, and its associated standard error $\sqrt{\text{Var}(\hat{\theta}_2)} = 0.0623$ into a test data set:

```
data Parms_Count2;
   set Parms_Count2;
   if Parameter='Trt';
   _Scale_='MLE';
   _Stage_= 2;
   keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;

proc print data=Parms_Count2;
   title 'Statistics Computed at Stage 2';
run;
```

Output 81.1.14 displays the test statistics at stage 2.

Output 81.1.14 Statistics Computed at Stage 2

Statistics Computed at Stage 2

Obs	Parameter	Estimate	StdErr	_Scale_	_Stage_
1	Trt	0.1759	0.0623	MLE	2

The following statements invoke the SEQTEST procedure and test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Count1
             Parms(Testvar=Trt)=Parms_Count2
             infoadj=none
             boundaryscale=mle
             ;
ods output Test=Test_Count2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST_COUNT2 option creates an output data set named TEST_COUNT2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Test Information" table in Output 81.1.15 displays the boundary values, test statistic, and resulting action at each stage. The table shows that the test statistic 0.17593 is larger than the corresponding upper alpha boundary value, so the trial stops to reject the hypothesis.

Output 81.1.15 Sequential Test

The SEQTEST Procedure

Test Information (MLE Scale)
Null Reference = 0

Stage	Information Level Proportion	Information Level Actual	Alternative Reference Upper	Boundary Values Upper Beta	Boundary Values Upper Alpha
1	0.2525	126.9871	0.15000	-0.09306	0.27423
2	0.5122	257.5571	0.15000	0.03019	0.17001
3	0.7500	377.1257	0.15000	0.06783	0.11826
4	1.0000	502.8343	0.15000	0.08878	0.08878

Test Information (MLE Scale)

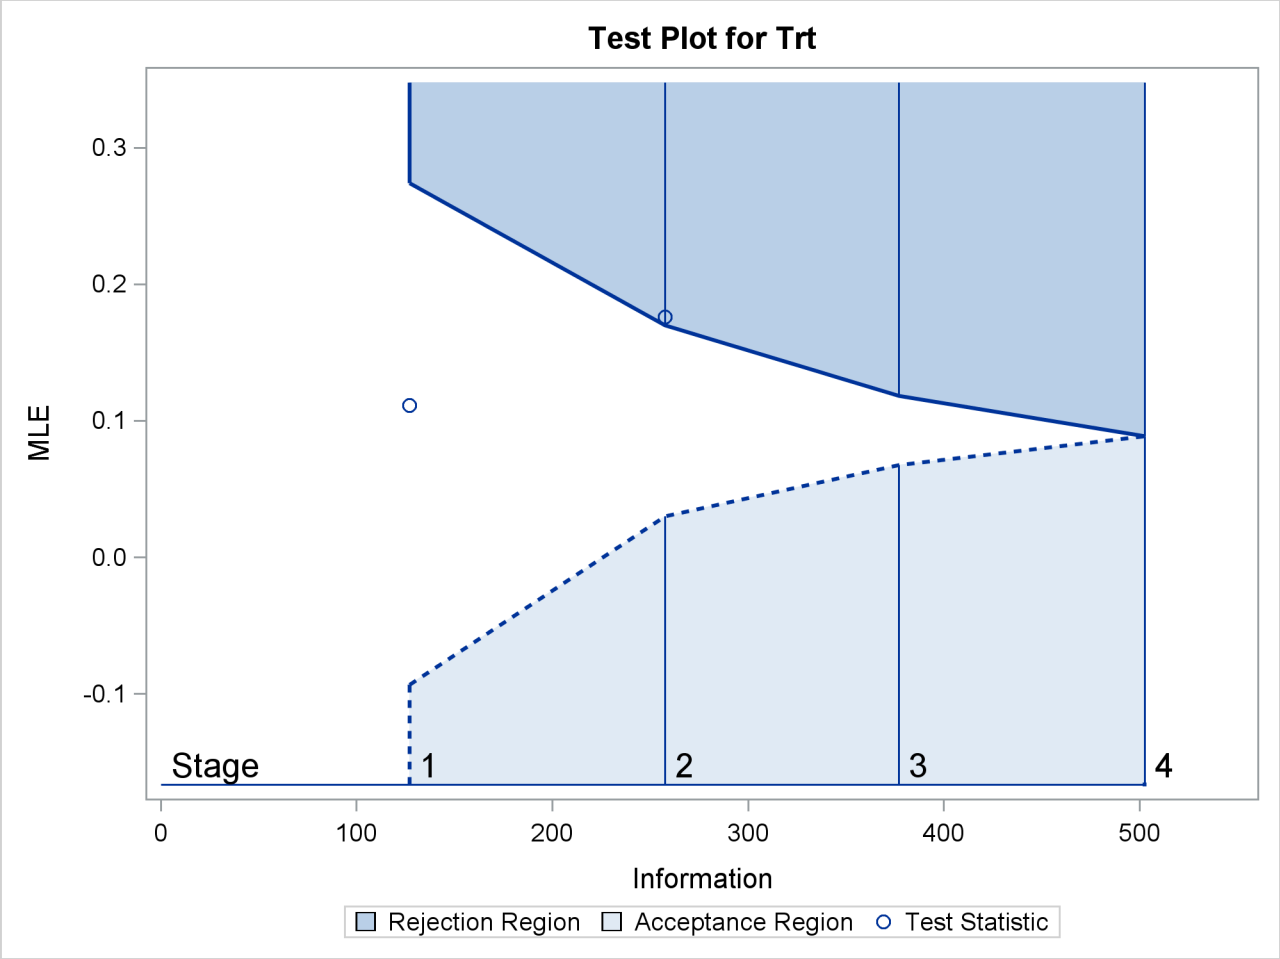
1	0.11111	Continue
2	0.17593	Reject Null
3	.	
4	.	

With ODS Graphics enabled, the "Test Plot" is displayed, as shown in Output 81.1.16. The plot displays boundary values of the design and the test statistics at the first two stages. As expected, the test statistic at stage 2 is in the "Upper Rejection Region" above the upper alpha boundary.

Output 81.1.16 Sequential Test Plot



After a trial is stopped, the "Parameter Estimates" table in Output 81.1.17 displays the stopping stage and the maximum likelihood estimate of the parameter. It also displays the p-value, median estimate, and confidence limits for the parameter that correspond to the observed statistic by using the specified sample space ordering.

Output 81.1.17 Parameter Estimates

Parameter Estimates
Stagewise Ordering

Parameter	Stopping Stage	MLE	p-Value for H0:Parm=0	Median Estimate	Lower 95% CL
Trt	2	0.175926	0.0031	0.174462	0.07059

The MLE statistic at the stopping stage is the maximum likelihood estimate of the parameter and is biased. The computation of p-value, unbiased median estimate, and confidence limits depends on the ordering of the sample space (k, z), where k is the stage number and z is the observed standardized Z statistic. By default

(or equivalently if you specify ORDER=STAGEWISE), the stagewise ordering that uses counterclockwise ordering around the continuation region is used to compute the p-value, unbiased median estimate, and confidence limits. As expected, the p-value is less than 0.025, and the confidence interval does not contain the null reference zero. With the stagewise ordering, the p-value is computed as

$$P_{\theta=0}\left(Z_1 > a_1\right) + P_{\theta=0}\left(Z_2 > z_2 \mid b_1 < Z_1 < a_1\right)$$

where z_2 is the observed standardized Z statistic at stage 2, Z_1 is the standardized normal variate at stage 1, Z_2 is the standardized normal variate at stage 2, and a_1 and b_1 are the stage 1 upper rejection and acceptance boundary values, respectively.

See the section "Available Sample Space Orderings in a Sequential Test" on page 6940 for a detailed description of the stagewise ordering.

Example 81.2: Testing an Effect in a Regression Model

This example demonstrates a two-sided group sequential test that uses an error spending design with early stopping to reject the null hypothesis. A study is conducted to examine the effects of Age (years), Weight (kg), RunTime (time in minutes to run 1.5 miles), RunPulse (heart rate while running), and MaxPulse (maximum heart rate recorded while running) on Oxygen (oxygen intake rate, ml per kg body weight per minute). The primary interest is whether oxygen intake rate is associated with weight.

The hypothesis is tested using the following linear model:

$$\text{Oxygen} = \text{Age} + \text{Weight} + \text{RunTime} + \text{RunPulse} + \text{MaxPulse}$$

The null hypothesis is $H_0 : \beta_w = 0$, where β_w is the regression parameter for the variable Weight. Suppose that $\beta_w = 0.10$ is the reference improvement that should be detected at a 0.90 level. Then the maximum information I_X can be derived in the SEQDESIGN procedure.

Following the derivations in the section "Test for a Parameter in the Regression Model" in the chapter "The SEQDESIGN Procedure," the required sample size can be derived from

$$N = I_X \, \frac{\sigma_y^2}{\left(1 - r_x^2\right)\sigma_x^2}$$

where σ_y^2 is the variance of the response variable in the regression model, r_x^2 is the proportion of variance of Weight explained by other covariates, and σ_x^2 is the variance of Weight.

Further suppose that from past experience, $\sigma_y^2 = 5$, $r_x^2 = 0.10$, and $\sigma_x^2 = 64$. Then the required sample size can be derived using the SAMPLESIZE statement in the SEQDESIGN procedure.

The following statements invoke the SEQDESIGN procedure and request a three-stage group sequential design for normally distributed data to test the null hypothesis of a regression parameter $H_0 : \beta_w = 0$ against the alternative $H_1 : \beta_w \neq 0$:

```
ods graphics on;
proc seqdesign altref=0.10;
   OBFErrorFunction: design method=errfuncobf
                           nstages=3
                           info=cum(2 3 4)
                           ;
   samplesize model=reg(variance=5 xvariance=64 xrsquare=0.10);
ods output Boundary=Bnd_Fit;
run;
ods graphics off;
```

By default (or equivalently if you specify ALPHA=0.05 and BETA=0.10), the procedure uses a Type I error probability 0.05 and a Type II error probability 0.10. The ALTREF=0.10 option specifies a power of $1 - \beta = 0.90$ at the alternative hypothesis $H_1 : \beta_w = \pm 0.10$. The INFO=CUM(2 3 4) option specifies that the study perform the first interim analysis with information proportion $2/4 = 0.5$—that is, after half of the total observations are collected.

The ODS OUTPUT statement with the BOUNDARY=BND_FIT option creates an output data set named BND_FIT which contains the resulting boundary information for the subsequent sequential tests.

The "Design Information" table in Output 81.2.1 displays design specifications and derived statistics. Since the alternative reference is specified, the maximum information is derived.

Output 81.2.1 Design Information

The SEQDESIGN Procedure
Design: OBFErrorFunction

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Reject Null
Method	Error Spending
Boundary Key	Both
Alternative Reference	0.1
Number of Stages	3
Alpha	0.05
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	101.8276
Max Information	1069.948
Null Ref ASN (Percent of Fixed Sample)	101.2587
Alt Ref ASN (Percent of Fixed Sample)	77.81586

The "Boundary Information" table in Output 81.2.2 displays information level, alternative reference, and boundary values at each stage.

Output 81.2.2 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

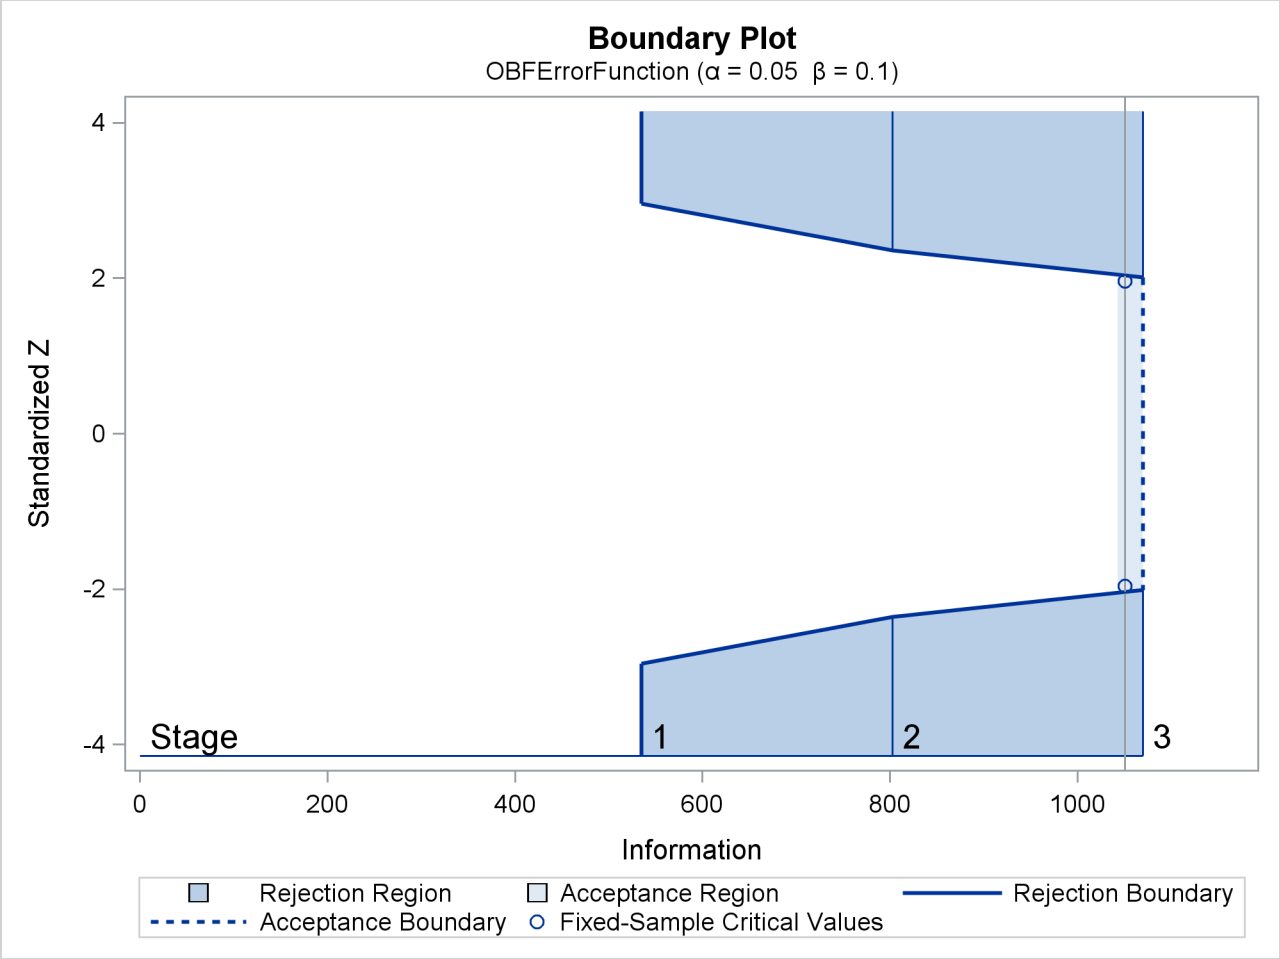
Stage	Information Level Proportion	Information Level Actual	Information Level N	Alternative Reference Lower	Alternative Reference Upper
1	0.5000	534.9738	46.43869	-2.31295	2.31295
2	0.7500	802.4606	69.65804	-2.83277	2.83277
3	1.0000	1069.948	92.87739	-3.27101	3.27101

Boundary Information (Standardized Z Scale)
Null Reference = 0

Stage	Boundary Values Lower Alpha	Boundary Values Upper Alpha
1	-2.96259	2.96259
2	-2.35902	2.35902
3	-2.01409	2.01409

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 81.2.3. The boundary plot also displays the information level and critical value for the corresponding fixed-sample design. This design has characteristics of an O'Brien-Fleming design; the probability for early stopping is low, and the maximum information and critical values at the final stage are similar to those of the corresponding fixed-sample design.

Output 81.2.3 Boundary Plot



With the MODEL=REG option in the SAMPLESIZE statement, the "Sample Size Summary" table in Output 81.2.4 displays the parameters for the sample size computation.

Output 81.2.4 Required Sample Size Summary

Sample Size Summary

Test	Reg Parameter
Parameter	0.1
Variance	5
X Variance	64
R Square (X)	0.1
Max Sample Size	92.87739
Expected Sample Size (Null Ref)	92.35845
Expected Sample Size (Alt Ref)	70.97617

The "Sample Sizes" table in Output 81.2.5 displays the required sample sizes for the group sequential clinical trial.

Output 81.2.5 Required Sample Sizes

Sample Sizes (N)
Z Test for Regression Parameter

	Fractional N		Ceiling N	
Stage	N	Information	N	Information
1	46.44	535.0	47	541.4
2	69.66	802.5	70	806.4
3	92.88	1069.9	93	1071.4

Thus, 47, 70, and 93 individuals are needed in stages 1, 2, and 3, respectively. Since the sample sizes are derived from estimated values of σ_y^2, r_x^2, and σ_x^2, the actual information levels might not achieve the target information levels. Thus, instead of specifying sample sizes in the protocol, you can specify the maximum information levels. Then if an actual information level is much less than the target level, you can increase the sample sizes for the remaining stages to achieve the desired information levels and power.

Suppose that 47 individuals are available at stage 1. Output 81.2.6 lists the first 10 observations of the trial data.

Output 81.2.6 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	Oxygen	Age	Weight	RunTime	Run Pulse	Max Pulse
1	54.5521	44	87.7676	11.6949	178.435	181.607
2	52.2821	40	75.4853	9.8872	184.433	183.667
3	62.1871	44	89.0638	8.7950	155.540	167.108
4	65.3269	42	67.7310	8.4577	162.926	173.877
5	59.9809	37	93.1902	9.3228	179.033	180.144
6	52.5588	47	75.9044	12.0385	177.753	175.033
7	51.7838	40	73.5422	11.6607	175.838	178.140
8	57.0024	43	81.2861	11.2219	160.963	171.770
9	48.0775	44	85.2290	13.1789	173.722	176.548
10	68.3357	38	80.2490	8.5066	171.824	184.011

The following statements use the REG procedure to estimate the slope β_w and its associated standard error at stage 1:

```
proc reg data=Fit_1;
   model Oxygen=Age Weight RunTime RunPulse MaxPulse;
   ods output ParameterEstimates=Parms_Fit1;
run;
```

The following statements create and display (in Output 81.2.7) the input data set that contains slope β_w and its associated standard error for the SEQTEST procedure:

```
data Parms_Fit1;
   set Parms_Fit1;
   if Variable='Weight';
   _Scale_='MLE';
   _Stage_= 1;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_Fit1;
   title 'Statistics Computed at Stage 1';
run;
```

Output 81.2.7 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	Weight	0.03772	0.04345	MLE	1

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Fit
             Parms(Testvar=Weight)=Parms_Fit1
             infoadj=prop
             errspendadj=errfuncobf
             order=lr
             stopprob
             ;
ods output Test=Test_Fit1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1 (this data set was generated in the SEQDESIGN procedure). Recall that these boundary values were derived for the information levels specified with the INFO=CUM(2 3 4) option in the SEQDESIGN procedure. The PARMS=PARMS_FIT1 option specifies the input data set PARMS_FIT1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=WEIGHT option identifies the test variable WEIGHT in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The ORDER=LR option uses the LR ordering to derive the p-value, the unbiased median estimate, and the confidence limits for the regression slope estimate. The ERRSPENDADJ=ERRFUNCOBF option adjusts the boundaries with the updated error spending values generated from an O'Brien-Fleming-type cumulative error spending function.

The ODS OUTPUT statement with the TEST=TEST_FIT1 option creates an output data set named TEST_FIT1 which contains the updated boundary information for the test at stage 1. The adjustment is needed because the observed information level is different from the information level in the BOUNDARY= data set. The data set TEST_FIT1 also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.2.8 displays the design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I α level. The maximum information remains the same as in the BOUNDARY= data set, but the derived Type II error probability β and power $1-\beta$ are different because of the new information level.

Output 81.2.8 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.BND_FIT
Data Set	WORK.PARMS_FIT1
Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Reject Null
Number of Stages	3
Alpha	0.05
Beta	0.09994
Power	0.90006
Max Information (Percent of Fixed Sample)	101.8057
Max Information	1069.94751
Null Ref ASN (Percent of Fixed Sample)	101.2416
Alt Ref ASN (Percent of Fixed Sample)	77.87607

With the STOPPROB option, the "Expected Cumulative Stopping Probabilities" table in Output 81.2.9 displays the expected stopping stage and cumulative stopping probability to reject the null hypothesis at each stage under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and $c_i = 0, 0.5, 1, 1.5$ by default. You can specify other values for c_i with the CREF= option.

Output 81.2.9 Stopping Probabilities

Expected Cumulative Stopping Probabilities
Reference = CRef * (Alt Reference)

CRef	Expected Stopping Stage	Source	----Stopping Probabilities--- Stage_1	Stage_2	Stage_3
0.0000	2.978	Reject Null	0.00289	0.01906	0.05000
0.5000	2.792	Reject Null	0.03373	0.17443	0.36566
1.0000	2.069	Reject Null	0.24884	0.68206	0.90006
1.5000	1.348	Reject Null	0.68172	0.97032	0.99820

The "Test Information" table in Output 81.2.10 displays the boundary values for the test statistic. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), these statistics are displayed with the standardized Z scale. The information level at stage 1 is derived from the standard error s_1 in the PARMS= data set,

$$I_1 = \frac{1}{s_1^2} = \frac{1}{0.043453^2} = 529.62$$

Output 81.2.10 Sequential Tests

Test Information (Standardized Z Scale)
Null Reference = 0

Stage	--Information Level- Proportion	Actual	------Alternative----- -------Reference------ Lower	Upper	----Boundary Values--- ---Lower-- Alpha	---Upper-- Alpha
1	0.4950	529.6232	-2.30135	2.30135	-2.97951	2.97951
2	0.7475	799.7853	-2.82805	2.82805	-2.36291	2.36291
3	1.0000	1069.948	-3.27101	3.27101	-2.01336	2.01336

Test Information (Standardized Z Scale)
Null Reference = 0

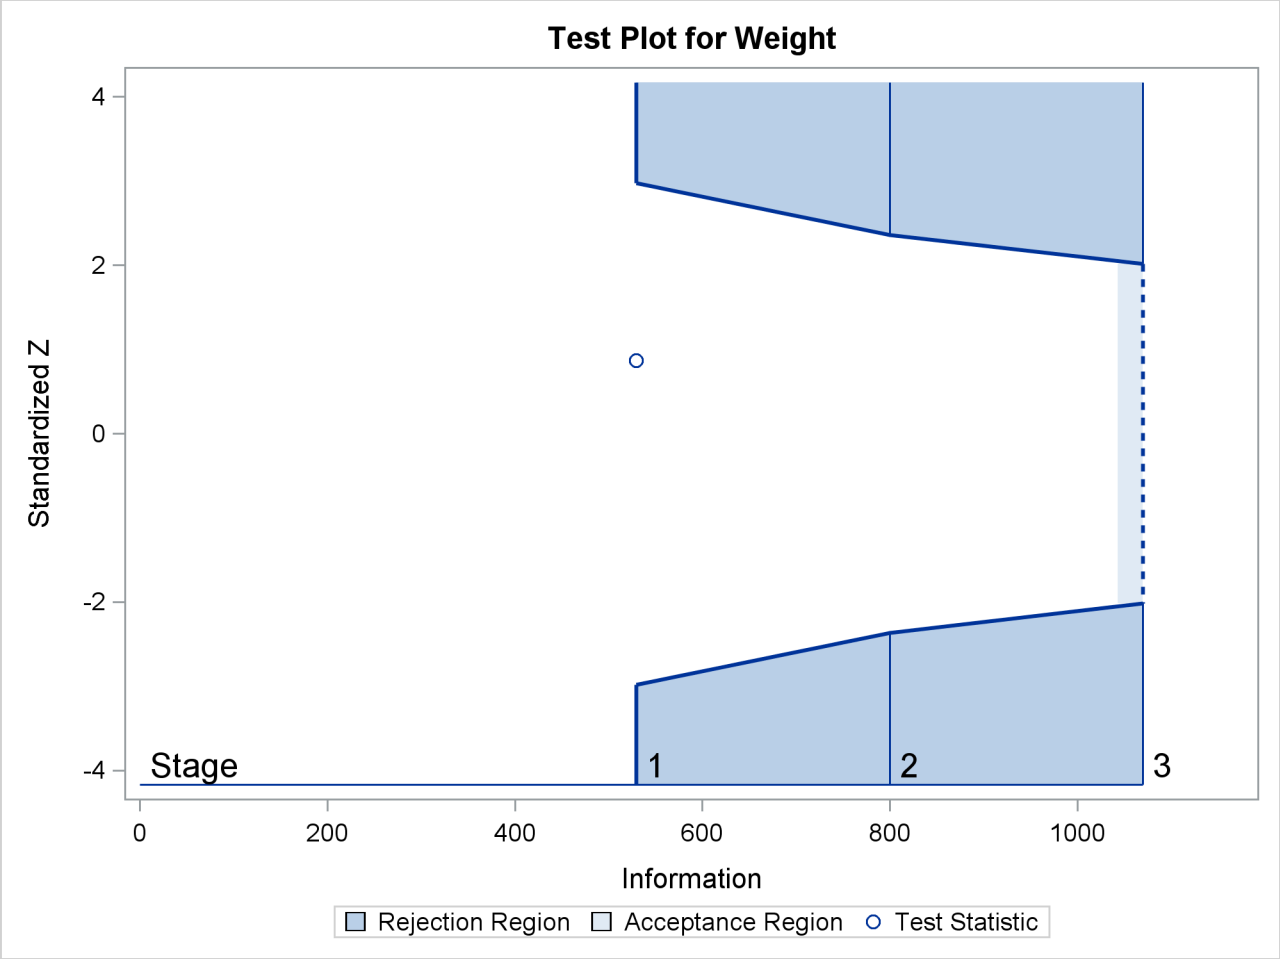
Stage	----------Test---------- ----------Weight--------- Estimate	Action
1	0.86798	Continue
2	.	
3	.	

With the INFOADJ=PROP option (which is the default), the information level at stage 2 is derived proportionally from the observed information at stage 1 and the information levels in the BOUNDARY= data set. See the section "Boundary Adjustments for Information Levels" on page 6933 for details about how the adjusted information levels are computed.

At stage 1, the standardized Z statistic 0.86798 is between the lower α boundary -2.97951 and the upper α boundary 2.97951, so the trial continues to the next stage.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in Output 81.2.11. As expected, the test statistic is in the continuation region between the lower and upper α boundaries.

Output 81.2.11 Sequential Test Plot



The following statements use the REG procedure to estimate the slope β_w and its associated standard error at stage 2:

```
proc reg data=Fit_2;
   model Oxygen=Age Weight RunTime RunPulse MaxPulse;
   ods output ParameterEstimates=Parms_Fit2;
run;
```

Note that the data set Fit_2 contains both the data from stage 1 and the data from stage 2.

The following statements create and display (in Output 81.2.12) the input data set that contains slope β_w and its associated standard error at stage 2 for the SEQTEST procedure:

```
data Parms_Fit2;
   set Parms_Fit2;
   if Variable='Weight';
   _Scale_='MLE';
   _Stage_= 2;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;
```

```
proc print data=Parms_Fit2;
   title 'Statistics Computed at Stage 2';
run;
```

Output 81.2.12 Statistics Computed at Stage 2

Statistics Computed at Stage 2

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	Weight	0.02932	0.03520	MLE	2

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
proc seqtest Boundary=Test_Fit1
             Parms(Testvar=Weight)=Parms_Fit2
             infoadj=prop
             errspendadj=errfuncobf
             order=lr
             ;
ods output Test=Test_Fit2;
run;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST_FIT2 option creates an output data set named TEST_FIT2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

Since the data set PARMS_FIT2 does not contain the test information at stage 1, the information level at stage 1 in the TEST_FIT1 data set is used to generate boundary values for the test at stage 2.

Following the process at stage 1, the slope estimate is also between its corresponding lower and upper α boundary values, so the trial continues to the next stage.

The following statements use the REG procedure to estimate the slope β_w and its associated standard error at the final stage:

```
proc reg data=Fit_3;
   model Oxygen=Age Weight RunTime RunPulse MaxPulse;
   ods output ParameterEstimates=Parms_Fit3;
run;
```

The following statements create the input data set that contains slope β_w and its associated standard error at stage 3 for the SEQTEST procedure:

```
data Parms_Fit3;
   set Parms_Fit3;
   if Variable='Weight';
   _Scale_='MLE';
   _Stage_= 3;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;
```

The following statements print (in Output 81.2.13) the test statistics at stage 3:

```
proc print data=Parms_Fit3;
   title 'Statistics Computed at Stage 3';
run;
```

Output 81.2.13 Statistics Computed at Stage 3

Statistics Computed at Stage 3

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	Weight	0.02189	0.03028	MLE	3

The following statements invoke the SEQTEST procedure to test the hypothesis:

```
ods graphics on;
proc seqtest Boundary=Test_Fit2
             Parms(testvar=Weight)=Parms_Fit3
             errspendadj=errfuncobf
             order=lr
             pss
             plots=(asn power)
             ;
ods output Test=Test_Fit3;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 3, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 3, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST_FIT3 option creates an output data set named TEST_FIT3 which contains the updated boundary information for the test at stage 3.

The "Design Information" table in Output 81.2.14 displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I α level.

Output 81.2.14 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.TEST_FIT2
Data Set	WORK.PARMS_FIT3
Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Reject Null
Number of Stages	3
Alpha	0.05
Beta	0.09514
Power	0.90486
Max Information (Percent of Fixed Sample)	102.0102
Max Information	1090.63724
Null Ref ASN (Percent of Fixed Sample)	101.4122
Alt Ref ASN (Percent of Fixed Sample)	77.22139

The maximum information is derived from the standard error associated with the slope estimate at the final stage and is larger than the target level. The derived Type II error probability β and power $1-\beta$ are different because of the new information levels.

With the PSS option, the "Power and Expected Sample Sizes" table in Output 81.2.15 displays powers and expected mean sample sizes under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and $c_i = 0, 0.5, 1, 1.5$ by default. You can specify the c_i values with the CREF= option.

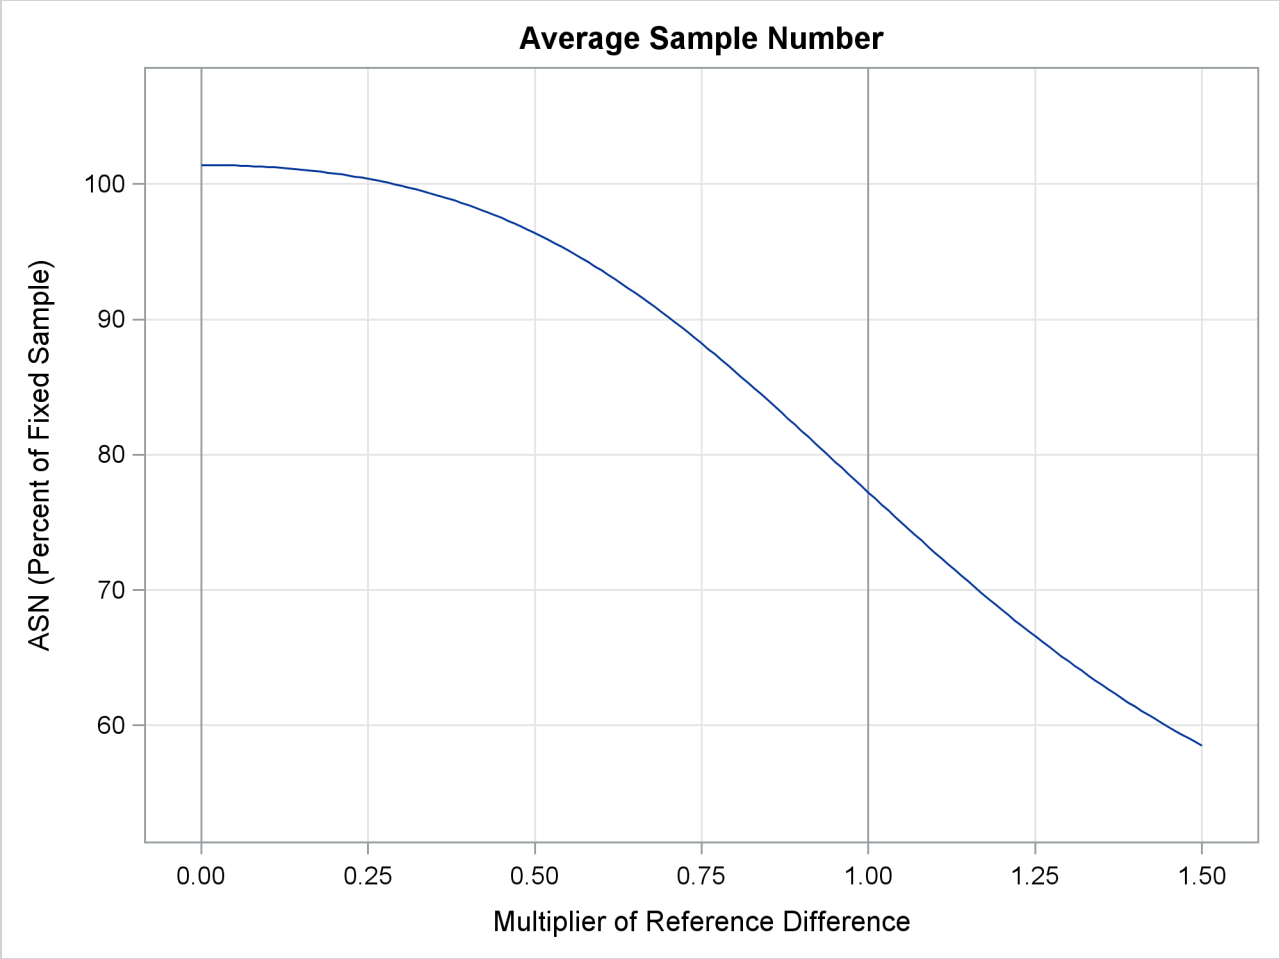
Output 81.2.15 Power and Expected Sample Size Information

Powers and Expected Sample Sizes
Reference = CRef * (Alt Reference)

CRef	Power	-Sample Size- Percent Fixed-Sample
0.0000	0.02500	101.4122
0.5000	0.37046	96.3754
1.0000	0.90486	77.2214
1.5000	0.99844	58.5301

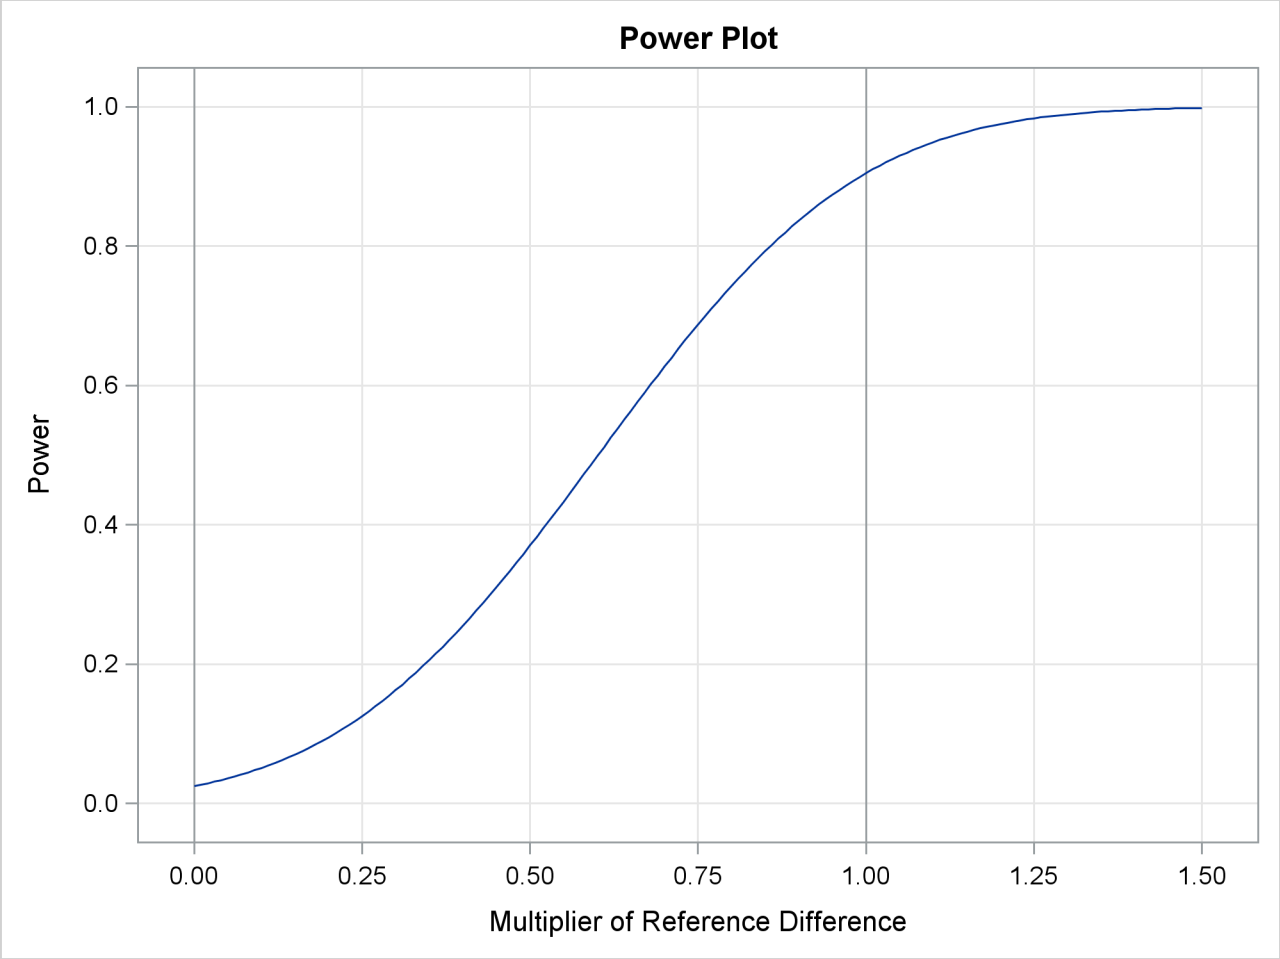
With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in Output 81.2.16. By default, expected sample sizes under the hypotheses $\theta = c_i\,\theta_1$, $c_i = 0, 0.01, 0.02, \ldots, 1.50$, are displayed, where θ_1 is the alternative reference.

Output 81.2.16 ASN Plot



With the PLOTS=POWER option, the procedure displays a plot of powers under various hypothetical references, as shown in Output 81.2.17. By default, powers under hypothetical references $\theta = c_i\,\theta_1$ are displayed, where $c_i = 0, 0.01, 0.02, \ldots, 1.50$ by default. You can specify c_i values with the CREF= option. The c_i values are displayed on the horizontal axis.

Output 81.2.17 Power Plot



Under the null hypothesis, $c_i = 0$, the power is 0.025, which is the upper Type I error probability. Under the alternative hypothesis, $c_i = 1$, the power is 0.90486, which is one minus the Type II error probability.

The "Test Information" table in Output 81.2.18 displays the boundary values for the test statistic with the default standardized Z scale. The information level at the current stage is derived from the standard error for the current stage in the PARMS= data set. At stage 3, the standardized slope estimate 0.72284 is still between the lower and upper α boundary values. Since it is the final stage, the trial stops to accept the null hypothesis that the variable Weight has no effect on the oxygen intake rate after adjusting for other covariates.

Output 81.2.18 Sequential Tests

Test Information (Standardized Z Scale)
Null Reference = 0

Stage	Information Level- Proportion	Actual	Alternative Reference Lower	Alternative Reference Upper	Boundary Values Lower Alpha	Boundary Values Upper Alpha
1	0.4856	529.6232	-2.30135	2.30135	-2.97951	2.97951
2	0.7401	807.1954	-2.84112	2.84112	-2.34945	2.34945
3	1.0000	1090.637	-3.30248	3.30248	-2.01885	2.01885

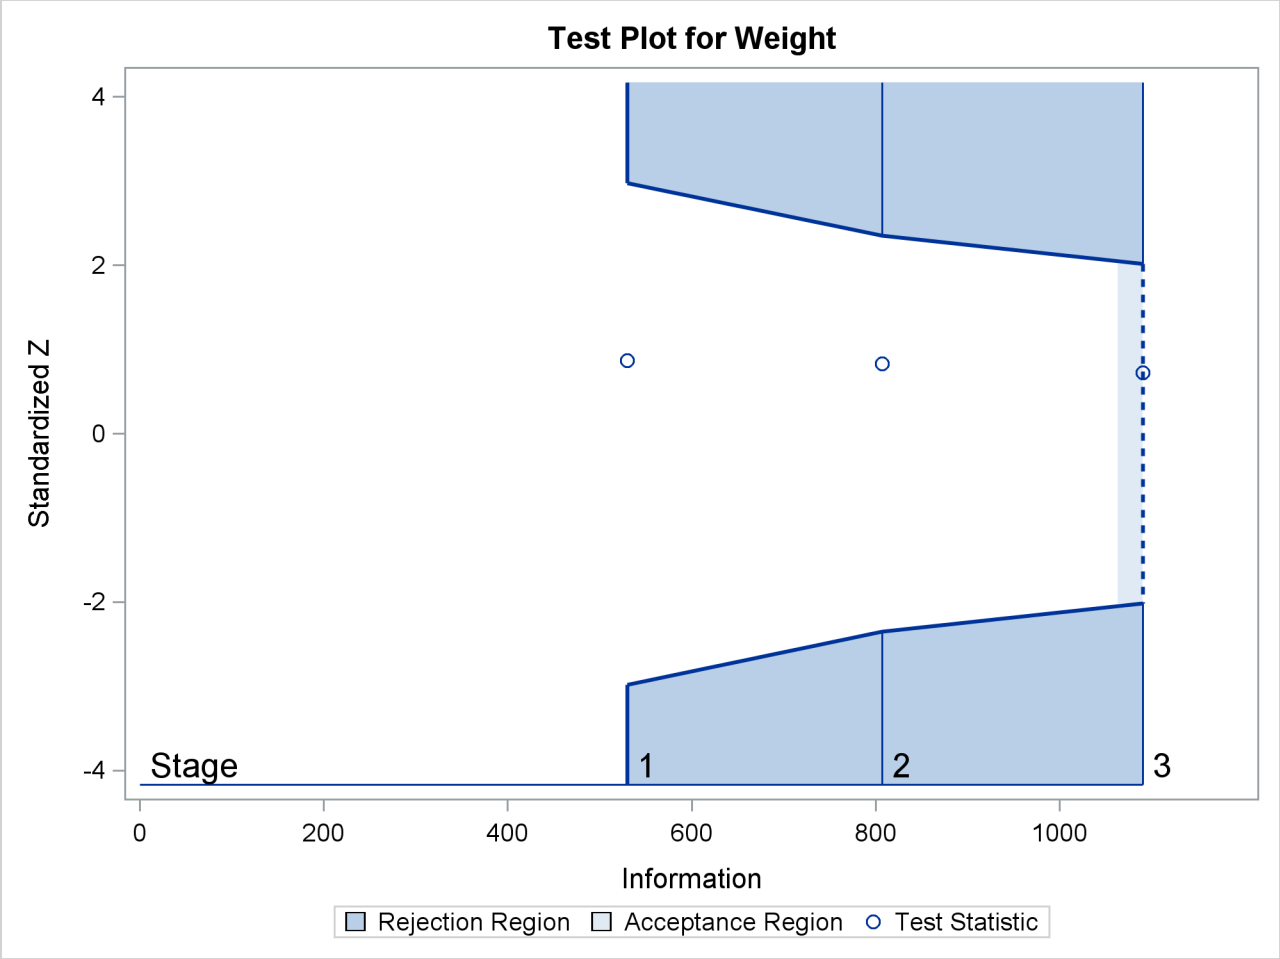
Test Information (Standardized Z Scale)
Null Reference = 0

Stage	Test Weight Estimate	Test Weight Action
1	0.86798	Continue
2	0.83305	Continue
3	0.72284	Accept Null

Since the data set FIT_3 contains the test information only at stage 3, the information levels at previous stages in the TEST_FIT2 data set are used to generate boundary values for the test.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in Output 81.2.19. As expected, the test statistic is in the acceptance region between the lower and upper α boundaries at the final stage.

Output 81.2.19 Sequential Test Plot



After a trial is stopped, the "Parameter Estimates" table in Output 81.2.20 displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and the p-value under the null hypothesis $H_0 : \beta_w = 0$.

Output 81.2.20 Parameter Estimates

Parameter Estimates
LR Ordering

Parameter	Stopping Stage	MLE	p-Value for H0:Parm=0	Median Estimate
Weight	3	0.021888	0.4699	0.021884

Parameter Estimates
LR Ordering

Parameter	95% Confidence Limits	
Weight	-0.03747	0.08123

As expected, the p-value 0.4699 is not significant at the $\alpha = 0.05$ level, and the confidence interval does contain the value zero. The p-value, unbiased median estimate, and confidence limits depend on the ordering of the sample space (k, z), where k is the stage number and z is the standardized Z statistic. With the specified LR ordering, the p-values are computed with the ordering $(k', z') \succ (k, z)$ if $z' > z$. See the section "Available Sample Space Orderings in a Sequential Test" on page 6940 for a detailed description of the LR ordering.

Example 81.3: Testing an Effect with Early Stopping to Accept H_0

This example demonstrates a two-sided group sequential test that uses an error spending design with early stopping to accept the null hypothesis H_0. The example is similar to Example 81.2 but with early stopping to accept H_0.

A study is conducted to examine the effects of Age (years), Weight (kg), RunTime (time in minutes to run 1.5 miles), RunPulse (heart rate while running), and MaxPulse (maximum heart rate recorded while running) on Oxygen (oxygen intake rate, ml per kg body weight per minute). The primary interest is whether oxygen intake rate is associated with weight.

The hypothesis is tested using the following linear model:

$$\text{Oxygen} = \text{Age} + \text{Weight} + \text{RunTime} + \text{RunPulse} + \text{MaxPulse}$$

The null hypothesis is $H_0 : \beta_w = 0$, where β_w is the regression parameter for the variable Weight. Suppose that $\beta_w = 0.10$ is the reference improvement that should be detected at a 0.90 level. Then the maximum information I_X can be derived in the SEQDESIGN procedure.

Following the derivations in the section "Test for a Parameter in the Regression Model" in the chapter "The SEQDESIGN Procedure," the required sample size can be derived from

$$N = I_X \frac{\sigma_y^2}{(1 - r_x^2)\,\sigma_x^2}$$

where σ_y^2 is the variance of the response variable in the regression model, r_x^2 is the proportion of variance of Weight explained by other covariates, and σ_x^2 is the variance of Weight.

Further suppose that from past experience, $\sigma_y^2 = 5$, $r_x^2 = 0.10$, and $\sigma_x^2 = 64$. Then the required sample size can be derived using the SAMPLESIZE statement in the SEQDESIGN procedure.

The following statements invoke the SEQDESIGN procedure and request a three-stage group sequential design for normally distributed data to test the null hypothesis of a regression parameter $H_0 : \beta_w = 0$ against the alternative $H_1 : \beta_w \neq 0$:

```
ods graphics on;
proc seqdesign altref=0.10;
   OBFErrorFunction: design method=errfuncgamma
                            stop=accept
                            nstages=3
                            info=cum(2 3 4);
```

```
   samplesize model=reg( variance=5 xvariance=64 xrsquare=0.10);
ods output Boundary=Bnd_Fit;
run;
ods graphics off;
```

By default (or equivalently if you specify ALPHA=0.05 and BETA=0.10), the procedure uses a Type I error probability 0.05 and a Type II error probability 0.10. The ALTREF=0.10 option specifies a power of $1-\beta = 0.90$ at the alternative hypothesis $H_1 : \beta_w = \pm 0.10$. The INFO=CUM(2 3 4) option specifies that the study perform the first interim analysis with information proportion $2/4 = 0.5$—that is, after half of the total observations are collected.

The ODS OUTPUT statement with the BOUNDARY=BND_FIT option creates an output data set named BND_FIT which contains the resulting boundary information for the subsequent sequential tests.

The "Design Information" table in Output 81.3.1 displays design specifications and derived statistics. Since the alternative reference is specified, the maximum information is derived.

Output 81.3.1 Error Spending Design Information

The SEQDESIGN Procedure
Design: OBFErrorFunction

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Accept Null

Alt Ref ASN (Percent of Fixed Sample)	101.8099

The "Boundary Information" table in Output 81.3.2 displays information level, alternative reference, and boundary values at each stage.

Output 81.3.2 Boundary Information

Boundary Information (Standardized Z Scale)
Null Reference = 0

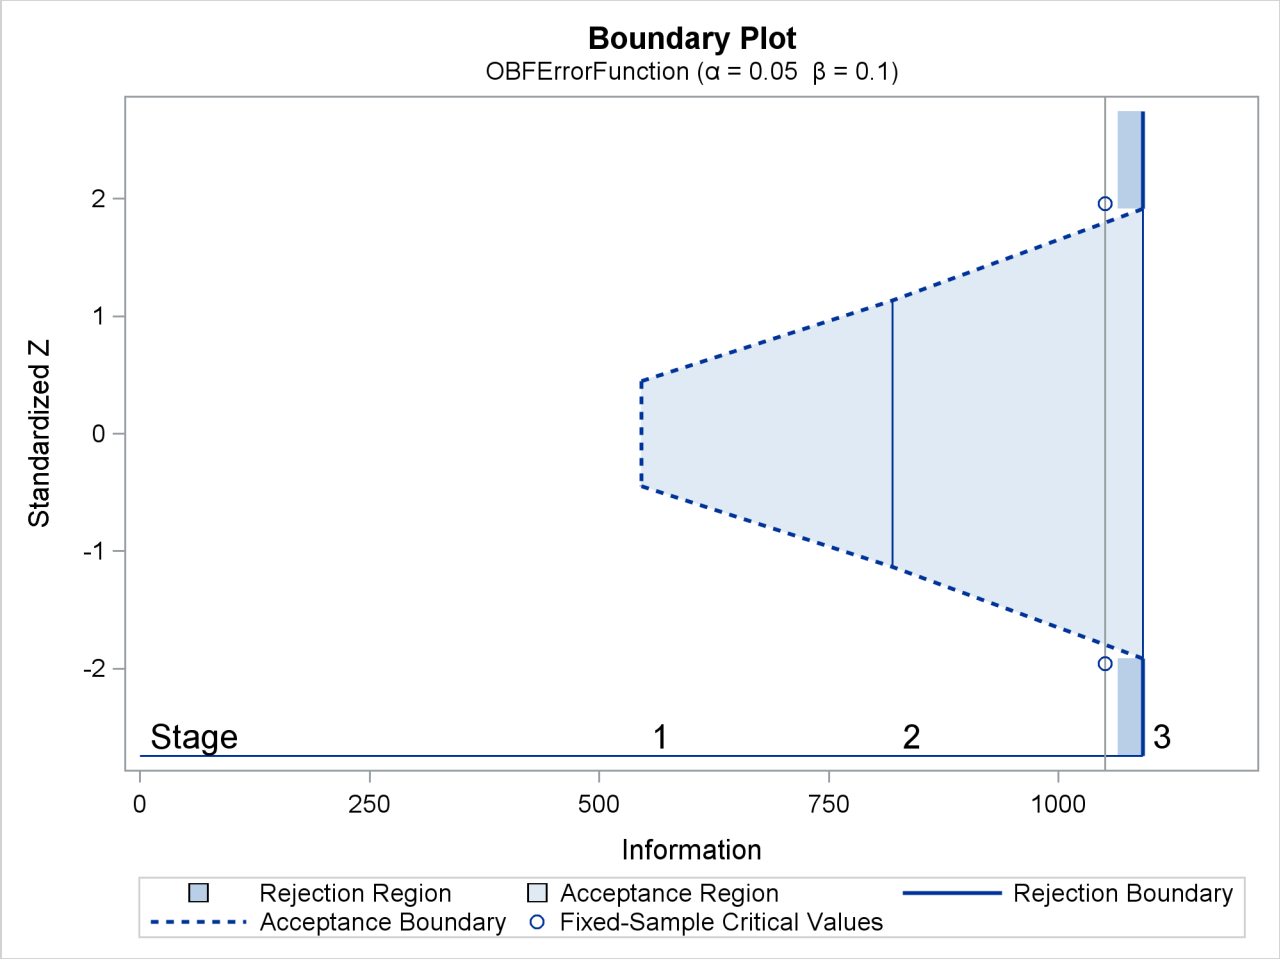
Stage	Information Level Proportion	Information Level Actual	Information Level N	Alternative Reference Lower	Alternative Reference Upper
1	0.5000	545.9862	47.39463	-2.33663	2.33663
2	0.7500	818.9792	71.09195	-2.86178	2.86178
3	1.0000	1091.972	94.78926	-3.30450	3.30450

Boundary Information (Standardized Z Scale)
Null Reference = 0

Stage	Boundary Values Lower Beta	Boundary Values Upper Beta
1	-0.44937	0.44937
2	-1.13583	1.13583
3	-1.91428	1.91428

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 81.3.3. The boundary plot also displays the information level and critical value for the corresponding fixed-sample design.

Output 81.3.3 Boundary Plot



With the MODEL=REG option in the SAMPLESIZE statement, the "Sample Size Summary" table in Output 81.3.4 displays the parameters for the sample size computation.

Output 81.3.4 Required Sample Size Summary

Sample Size Summary

Test	Reg Parameter
Parameter	0.1
Variance	5
X Variance	64
R Square (X)	0.1
Max Sample Size	94.78926
Expected Sample Size (Null Ref)	68.41207
Expected Sample Size (Alt Ref)	92.86057

The "Sample Sizes" table in Output 81.3.5 displays the required sample sizes for the group sequential clinical trial.

Output 81.3.5 Required Sample Sizes

Sample Sizes (N)
Z Test for Regression Parameter

	Fractional N		Ceiling N	
Stage	N	Information	N	Information
1	47.39	546.0	48	553.0
2	71.09	819.0	72	829.4
3	94.79	1092.0	95	1094.4

Thus, 48, 72, and 95 individuals are needed in stages 1, 2, and 3, respectively. Since the sample sizes are derived from estimated values of σ_y^2, r_x^2, and σ_x^2, the actual information levels might not achieve the target information levels. Thus, instead of specifying sample sizes in the protocol, you can specify the maximum information levels. Then if an actual information level is much less than the target level, you can increase the sample sizes for the remaining stages to achieve the desired information levels and power.

Suppose that 48 individuals are available at stage 1. Output 81.3.6 lists the first 10 observations of the trial data.

Output 81.3.6 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	Oxygen	Age	Weight	RunTime	Run Pulse	Max Pulse
1	54.5521	44	87.7676	11.6949	178.435	181.607
2	52.2821	40	75.4853	9.8872	184.433	183.667
3	62.1871	44	89.0638	8.7950	155.540	167.108
4	65.3269	42	67.7310	8.4577	162.926	173.877
5	59.9809	37	93.1902	9.3228	179.033	180.144
6	52.5588	47	75.9044	12.0385	177.753	175.033
7	51.7838	40	73.5422	11.6607	175.838	178.140
8	57.0024	43	81.2861	11.2219	160.963	171.770
9	48.0775	44	85.2290	13.1789	173.722	176.548
10	68.3357	38	80.2490	8.5066	171.824	184.011

The following statements use the REG procedure to estimate the slope β_w and its associated standard error at stage 1:

```
proc reg data=Fit_1;
   model Oxygen=Age Weight RunTime RunPulse MaxPulse;
   ods output ParameterEstimates=Parms_Fit1;
run;
```

The following statements create and display (in Output 81.3.7) the input data set that contains slope β_w and its associated standard error for the SEQTEST procedure:

```
data Parms_Fit1;
   set Parms_Fit1;
   if Variable='Weight';
   _Scale_='MLE';
   _Stage_= 1;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_Fit1;
   title 'Statistics Computed at Stage 1';
run;
```

Output 81.3.7 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	Weight	0.04660	0.04308	MLE	1

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Fit
             Parms(testvar=Weight)=Parms_Fit1
             infoadj=none
             errspendadj=errfuncgamma
             stopprob
             order=lr
             ;
ods output Test=Test_Fit1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS_FIT1 option specifies the input data set PARMS_FIT1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=WEIGHT option identifies the test variable WEIGHT in the data set. The INFOADJ=NONE option maintains the information level for stage 2 at the value provided in the BOUNDARY= data set.

The ORDER=LR option uses the LR ordering to derive the p-value, the unbiased median estimate, and the confidence limits for the regression slope estimate. The ERRSPENDADJ=ERRFUNCGAMMA option adjusts the boundaries with the updated error spending values generated from a gamma cumulative error spending function.

The ODS OUTPUT statement with the TEST=TEST_FIT1 option creates an output data set named TEST_FIT1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.3.8 displays the design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new informa-

tion levels to maintain the Type I α level. The maximum information remains the same as in the BOUNDARY= data set, but the derived Type II error probability β and power $1-\beta$ are different because of the new information level.

Output 81.3.8 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.BND_FIT
Data Set	WORK.PARMS_FIT1
Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Accept Null
Number of Stages	3
Alpha	0.05
Beta	0.10007
Power	0.89993
Max Information (Percent of Fixed Sample)	103.9498
Max Information	1091.97232
Null Ref ASN (Percent of Fixed Sample)	75.15846
Alt Ref ASN (Percent of Fixed Sample)	101.8296

With the STOPPROB option, the "Expected Cumulative Stopping Probabilities" table in Output 81.3.9 displays the expected stopping stage and the cumulative stopping probability of accepting the null hypothesis at each stage under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and $c_i = 0, 0.5, 1, 1.5$ by default. You can specify other values for c_i with the CREF= option.

Output 81.3.9 Stopping Probabilities

Expected Cumulative Stopping Probabilities
Reference = CRef * (Alt Reference)

CRef	Expected Stopping Stage	Source	----Stopping Probabilities--- Stage_1	Stage_2	Stage_3
0.0000	1.895	Accept Null	0.33304	0.76607	0.95000
0.5000	2.409	Accept Null	0.17680	0.40947	0.62828
1.0000	2.918	Accept Null	0.02636	0.05453	0.10007
1.5000	2.997	Accept Null	0.00109	0.00166	0.00242

The "Test Information" table in Output 81.3.10 displays the boundary values for the test statistic. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), these statistics are displayed with the standardized Z scale. The information level at stage 1 is derived from the standard error s_1 in the PARMS= data set,

$$I_1 = \frac{1}{s_1^2} = \frac{1}{0.04308^2} = 538.8$$

Output 81.3.10 Sequential Tests

Test Information (Standardized Z Scale)
Null Reference = 0

Stage	Information Level Proportion	Information Level Actual	Alternative Reference Lower	Alternative Reference Upper
1	0.4934	538.7887	-2.32118	2.32118
2	0.7500	818.9792	-2.86178	2.86178
3	1.0000	1091.972	-3.30450	3.30450

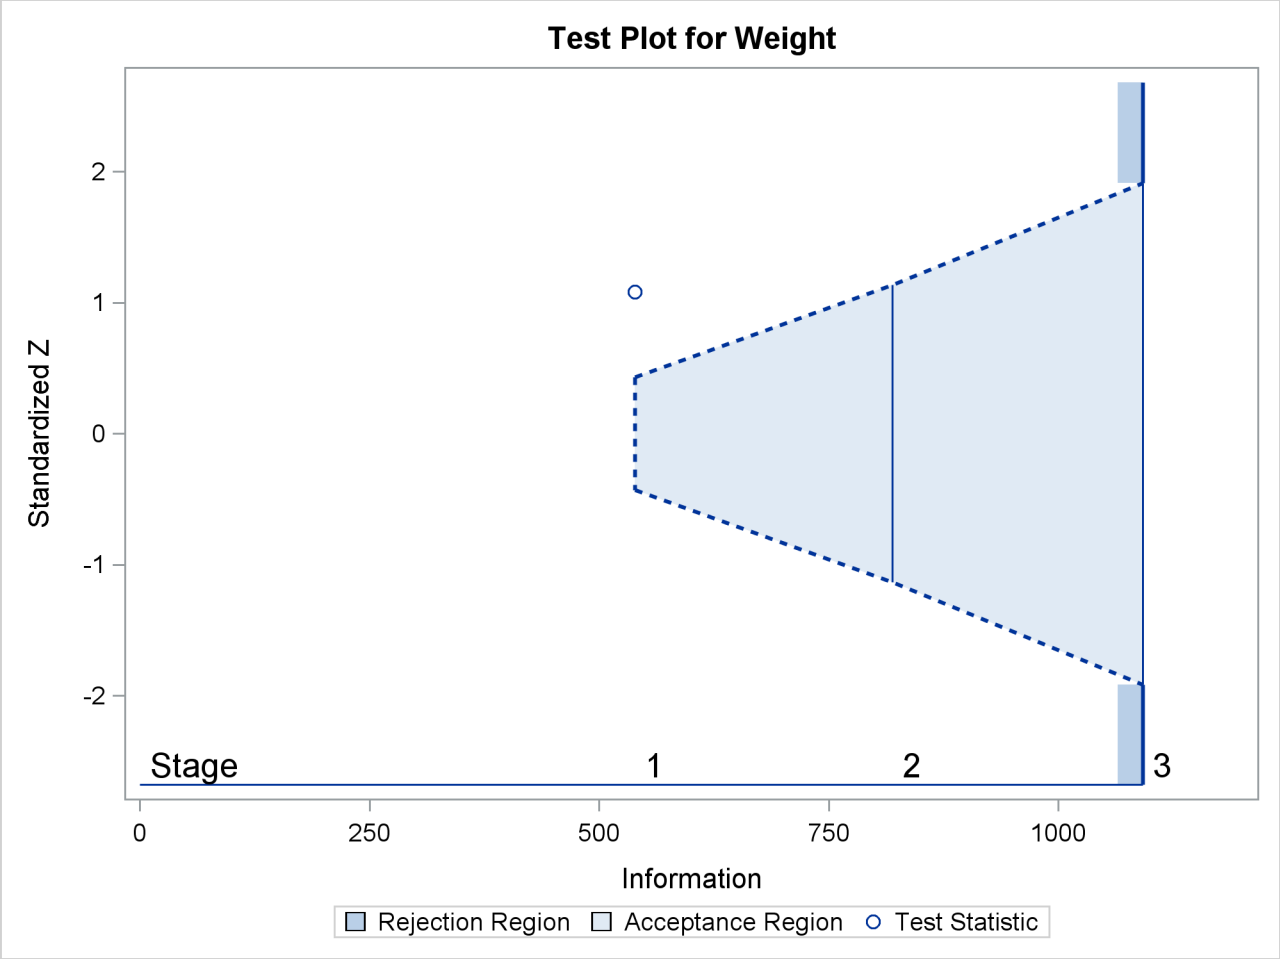
Test Information (Standardized Z Scale)
Null Reference = 0

Stage	Boundary Values Lower Beta	Boundary Values Upper Beta	Test Weight Estimate	Test Weight Action
1	-0.43033	0.43033	1.08174	Continue
2	-1.13623	1.13623	.	
3	-1.91431	1.91431	.	

At stage 1, the standardized Z statistic 1.08174 is greater than the upper β boundary 0.43033, so the trial continues to the next stage.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in Output 81.3.11. As expected, the test statistic is in the continuation region.

Output 81.3.11 Sequential Test Plot



The following statements use the REG procedure to estimate the slope β_w and its associated standard error at stage 2:

```
proc reg data=Fit_2;
   model Oxygen=Age Weight RunTime RunPulse MaxPulse;
   ods output ParameterEstimates=Parms_Fit2;
run;
```

Note that the data set Fit_2 contains both the data from stage 1 and the data from stage 2,

The following statements create and display (in Output 81.3.12) the input data set that contains slope β_w and its associated standard error at stage 2 for the SEQTEST procedure:

```
data Parms_Fit2;
   set Parms_Fit2;
   if Variable='Weight';
   _Scale_='MLE';
   _Stage_= 2;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;
```

```
proc print data=Parms_Fit2;
   title 'Statistics Computed at Stage 2';
run;
```

Output 81.3.12 Statistics Computed at Stage 2

Statistics Computed at Stage 2

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	Weight	0.02925	0.03490	MLE	2

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Fit1
             Parms(testvar=Weight)=Parms_Fit2
             errspendadj=errfuncgamma
             order=lr
             pss
             plots=(asn power)
             ;
ods output Test=Test_Fit2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

Since the data set PARMS_FIT2 does not contain the test information at stage 1, the information level at stage 1 in the TEST_FIT1 data set is used to generate boundary values for the test.

The ORDER=LR option uses the LR ordering to derive the p-value, unbiased median estimate, and confidence limits for the regression slope estimate.

The ODS OUTPUT statement with the TEST=TEST_FIT2 option creates an output data set named TEST_FIT2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.3.13 displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I α level.

Output 81.3.13 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.TEST_FIT1
Data Set	WORK.PARMS_FIT2
Statistic Distribution	Normal
Boundary Scale	Standardized Z
Alternative Hypothesis	Two-Sided
Early Stop	Accept Null
Number of Stages	3
Alpha	0.05
Beta	0.10009
Power	0.89991
Max Information (Percent of Fixed Sample)	103.9566
Max Information	1091.97232
Null Ref ASN (Percent of Fixed Sample)	75.18254
Alt Ref ASN (Percent of Fixed Sample)	101.8349

The derived Type II error probability β and power $1-\beta$ are different because of the new information levels.

With the PSS option, the "Power and Expected Sample Sizes" table in Output 81.3.14 displays powers and expected mean sample sizes under various hypothetical references $\theta = c_i\theta_1$, where θ_1 is the alternative reference and $c_i = 0, 0.5, 1, 1.5$ are the default values in the CREF= option.

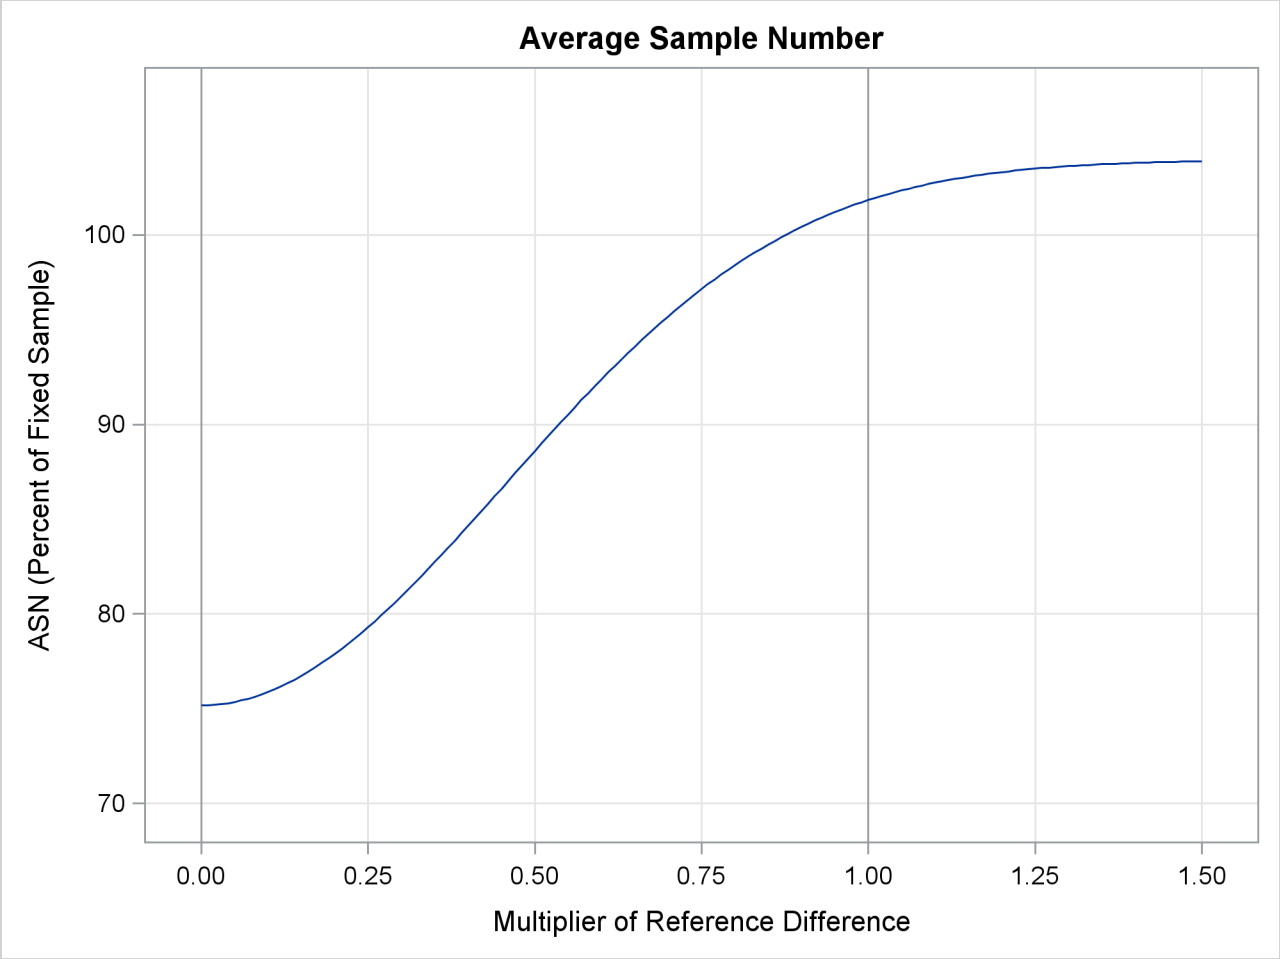
Output 81.3.14 Power and Expected Sample Size Information

Powers and Expected Sample Sizes
Reference = CRef * (Alt Reference)

CRef	Power	-Sample Size- Percent Fixed-Sample
0.0000	0.02500	75.1825
0.5000	0.37154	88.5975
1.0000	0.89991	101.8349
1.5000	0.99758	103.8843

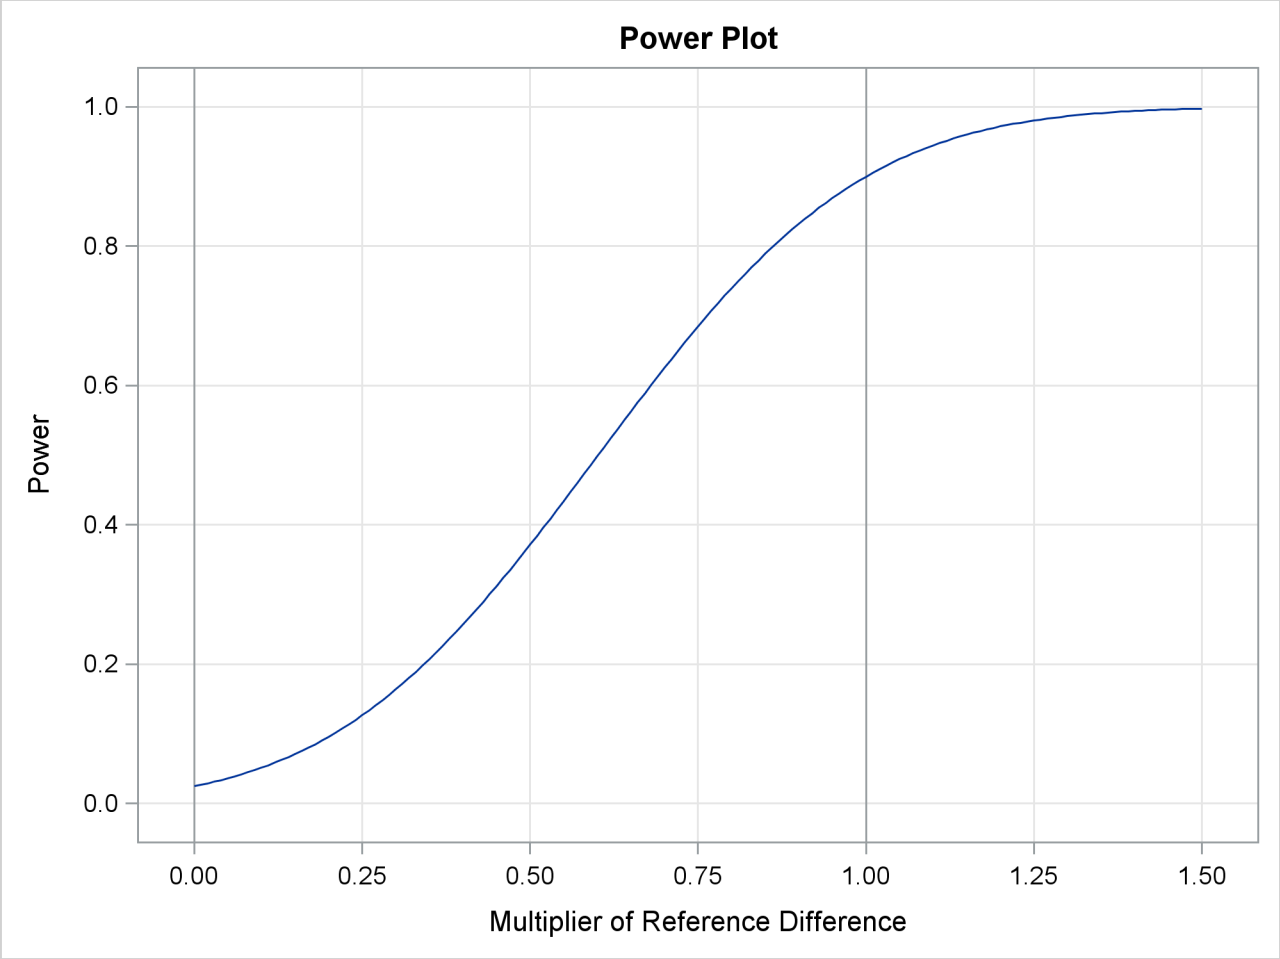
With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in Output 81.3.15. By default, expected sample sizes under the hypotheses $\theta = c_i\,\theta_1$, $c_i = 0, 0.01, 0.02, \ldots, 1.50$, are displayed, where θ_1 is the alternative reference.

Output 81.3.15 ASN Plot



With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references for all designs simultaneously, as shown in Output 81.3.16. By default, powers under hypothetical references $\theta = c_i\,\theta_1$ are displayed, where $c_i = 0, 0.01, 0.02, \ldots, 1.50$ by default. You can specify c_i values with the CREF= option. The c_i values are displayed on the horizontal axis.

Output 81.3.16 Power Plot



Under the null hypothesis, $c_i = 0$, the power is 0.025, which is the upper Type I error probability. Under the alternative hypothesis, $c_i = 1$, the power is 0.89991, which is one minus the Type II error probability, as displayed in the "Design Information" table in Output 81.3.13.

The "Test Information" table in Output 81.3.17 displays the boundary values for the test statistic with the default standardized Z scale. At stage 2, the standardized slope estimate 0.83805 is between the lower and upper β boundary values. The trial stops to accept the null hypothesis that the variable Weight has no effect on the oxygen intake rate after adjusting for other covariates.

Output 81.3.17 Sequential Tests

Test Information (Standardized Z Scale)
Null Reference = 0

Stage	Information Level Proportion	Information Level Actual	Alternative Reference Lower	Alternative Reference Upper
1	0.4934	538.7887	-2.32118	2.32118
2	0.7517	820.8509	-2.86505	2.86505
3	1.0000	1091.972	-3.30450	3.30450

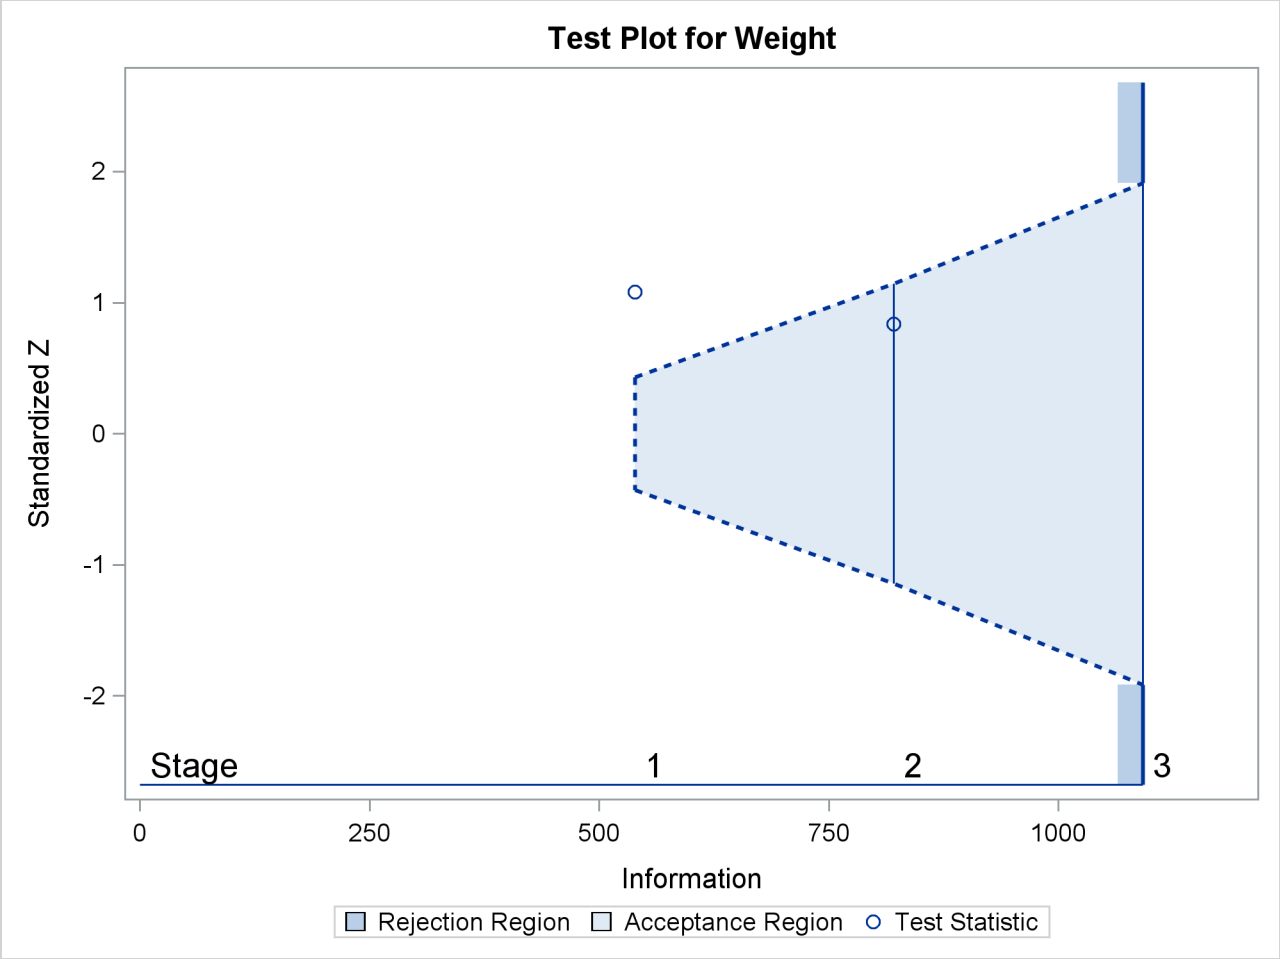
Test Information (Standardized Z Scale)
Null Reference = 0

Stage	Boundary Values Lower Beta	Boundary Values Upper Beta	Test Weight Estimate	Test Weight Action
1	-0.43033	0.43033	1.08174	Continue
2	-1.14239	1.14239	0.83805	Accept Null
3	-1.91408	1.91408	.	

Since the data set PARMS_FIT2 contains the test information only at stage 2, the information level at stage 1 in the TEST_FIT1 data set is used to generate boundary values for the test.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in Output 81.3.18. As expected, the test statistic is in the acceptance region between the lower and upper α boundaries at the final stage.

Output 81.3.18 Sequential Test Plot



After a trial is stopped, the "Parameter Estimates" table in Output 81.3.19 displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and the p-value under the null hypothesis $H_0 : \beta_w = 0$. As expected, the p-value 0.3056 is not significant at the $\alpha = 0.05$ level, and the confidence interval does contain the value zero. The p-value, unbiased median estimate, and confidence limits depend on the ordering of the sample space (k, z), where k is the stage number and z is the standardized Z statistic. With the specified LR ordering, the p-values are computed with the ordering $(k', z') \succ (k, z)$ if $z' > z$. See the section "Available Sample Space Orderings in a Sequential Test" on page 6940 for a detailed description of the LR ordering.

Output 81.3.19 Parameter Estimates

Parameter Estimates
LR Ordering

Parameter	Stopping Stage	MLE	p-Value for H0:Parm=0	Median Estimate
Weight	2	0.029251	0.3056	0.037080

Parameter Estimates

Parameter	95% Confidence Limits	
Weight	-0.03368	0.10532

Example 81.4: Testing a Binomial Proportion

This example tests a binomial proportion by using a four-stage group sequential design. Suppose a supermarket is developing a new store-brand coffee. From past studies, the positive response for the current store-brand coffee from customers is around 60%. The store is interested in whether the new brand has a better positive response than the current brand.

A power family method is used for the group sequential trial with the null hypothesis $H_0 : p = p_0 = 0.60$ and a one-sided upper alternative with a power of 0.80 at $H_1 : p = 0.70$. To accommodate the zero null reference that is assumed in the SEQDESIGN procedure, an equivalent hypothesis $H_0 : \theta = 0$ with $H_1 : \theta = 0.10$ is used, where $\theta = p - p_0$. The following statements request a power family method with early stopping to reject the null hypothesis:

```
ods graphics on;
proc seqdesign altref=0.10
               boundaryscale=mle
               ;
   PowerFamily: design method=pow
                       nstages=4
                       alt=upper
                       beta=0.20
                       ;
   samplesize model=onesamplefreq( nullprop=0.6);
ods output Boundary=Bnd_Prop;
run;
ods graphics off;
```

The NULLPROP= option in the SAMPLESIZE statement specifies $p_0 = 0.60$ for the sample size computation. The ODS OUTPUT statement with the BOUNDARY=BND_PROP option creates an output data set named BND_PROP which contains the resulting boundary information for the subsequent sequential tests.

With the BOUNDARYSCALE=MLE option, the procedure displays the output boundaries in terms of the maximum likelihood estimates. The "Design Information" table in Output 81.4.1 displays design specifica-

tions and derived statistics. With the specified alternative reference $\theta_1 = p_1 - p_0 = 0.7 - 0.6 = 0.1$, the maximum information 670.38 is also derived.

Output 81.4.1 Design Information

The SEQDESIGN Procedure
Design: PowerFamily

Design Information

Statistic Distribution	Normal
Boundary Scale	MLE
Alternative Hypothesis	Upper
Early Stop	Reject Null
Method	Power Family
Boundary Key	Both

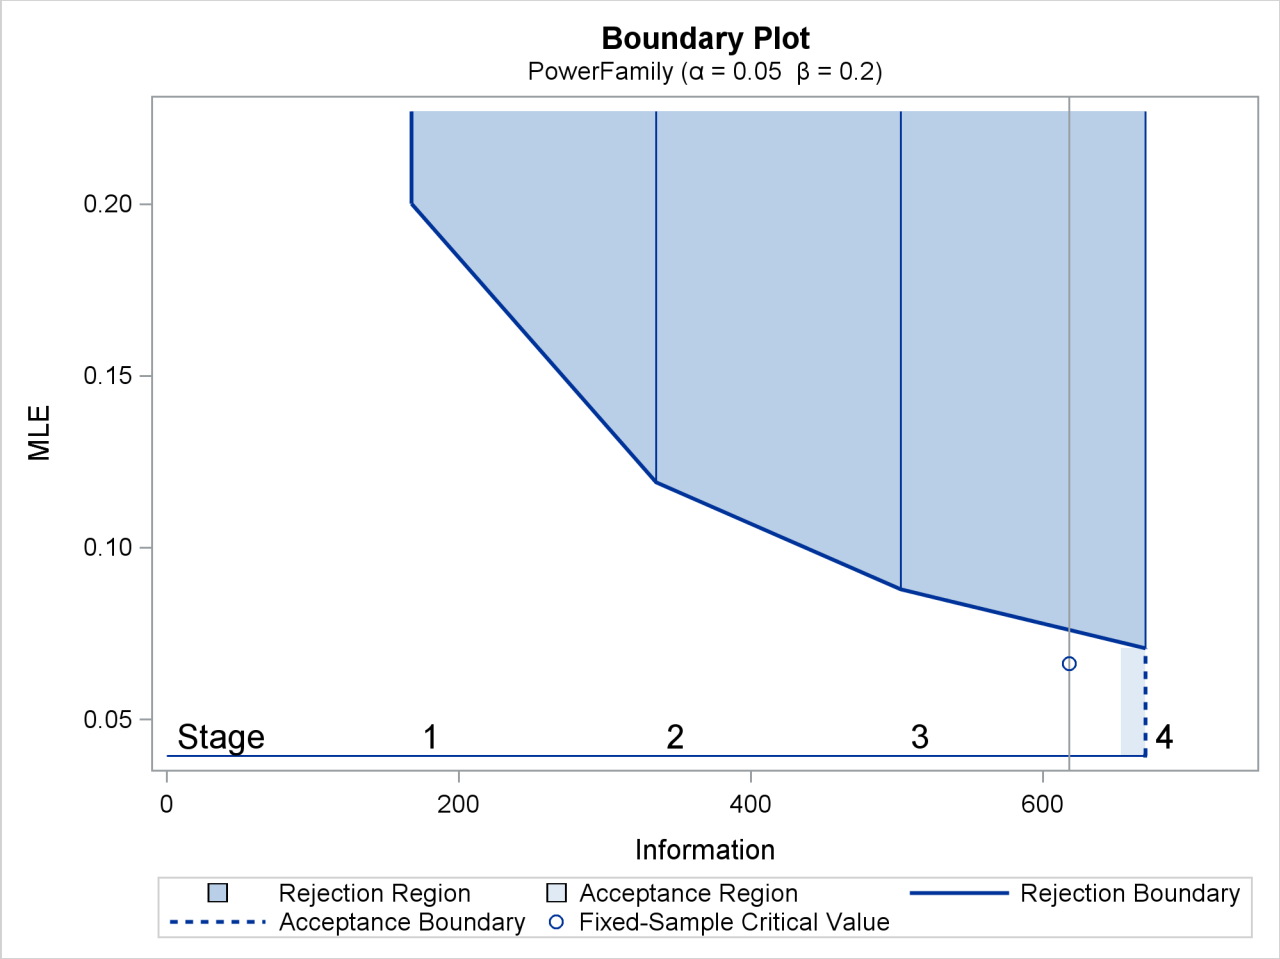
4	1.0000	670.3782	140.7794	0.10000	0.07077

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 81.4.3.

Output 81.4.3 Boundary Plot



With the MODEL=ONESAMPLEFREQ option in the SAMPLESIZE statement, the "Sample Size Summary" table in Output 81.4.4 displays the parameters for the sample size computation.

Output 81.4.4 Required Sample Size Summary

Sample Size Summary

Test	One-Sample Proportion
Null Proportion	0.6
Proportion	0.7
Test Statistic	Z for Proportion
Reference Proportion	Alt Ref
Max Sample Size	140.7794
Expected Sample Size (Null Ref)	138.828
Expected Sample Size (Alt Ref)	101.9333

The "Sample Sizes" table in Output 81.4.5 displays the required sample sizes for the group sequential clinical trial.

Output 81.4.5 Required Sample Sizes

Sample Sizes (N)
One-Sample Z Test for Proportion

	Fractional N		Ceiling N	
Stage	N	Information	N	Information
1	35.19	167.6	36	171.4
2	70.39	335.2	71	338.1
3	105.58	502.8	106	504.8
4	140.78	670.4	141	671.4

Thus, 36 customers are needed at stage 1, and 35 new customers are needed at each of the remaining stages. Suppose that 36 customers are available at stage 1. Output 81.4.6 lists the 10 observations in the data set count_1.

Output 81.4.6 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	Resp
1	1
2	1
3	0
4	0
5	1
6	1
7	0
8	1
9	1
10	1

The Resp variable is an indicator variable with a value of 1 for a customer with a positive response and a value of 0 for a customer without a positive response.

The following statements use the MEANS procedure to compute the mean response at stage 1:

```
proc means data=Prop_1;
   var Resp;
   ods output Summary=Data_Prop1;
run;
```

The following statements create and display (in Output 81.4.7) the data set for the centered mean positive response, $\hat{p} - p_0$:

```
data Data_Prop1;
   set Data_Prop1;
   _Scale_='MLE';
   _Stage_= 1;
   NObs= Resp_N;
   PDiff= Resp_Mean - 0.6;
   keep _Scale_ _Stage_ NObs PDiff;
run;
proc print data=Data_Prop1;
   title 'Statistics Computed at Stage 1';
run;
```

Output 81.4.7 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	_Scale_	_Stage_	NObs	PDiff
1	MLE	1	36	-0.016667

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Prop
             Data(Testvar=PDiff)=Data_Prop1
             infoadj=prop
             boundarykey=both
             boundaryscale=mle
             ;
ods output Test=Test_Prop1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The DATA=DATA_PROP1 option specifies the input data set DATA_PROP1 that contains the test statistic and its associated sample size at stage 1, and the TESTVAR=PDIFF option identifies the test variable PDIFF in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The BOUNDARYKEY=BOTH option maintains both the α and β levels. The BOUNDARYSCALE=MLE option displays the output boundaries in terms of the MLE scale.

The ODS OUTPUT statement with the TEST=TEST_PROP1 option creates an output data set named TEST_PROP1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.4.8 displays design specifications. With the specified BOUNDARYKEY=BOTH option, the information levels and boundary values at future stages are modified to maintain both the α and β levels.

Output 81.4.8 Design Information

The SEQTEST Procedure

Design Information

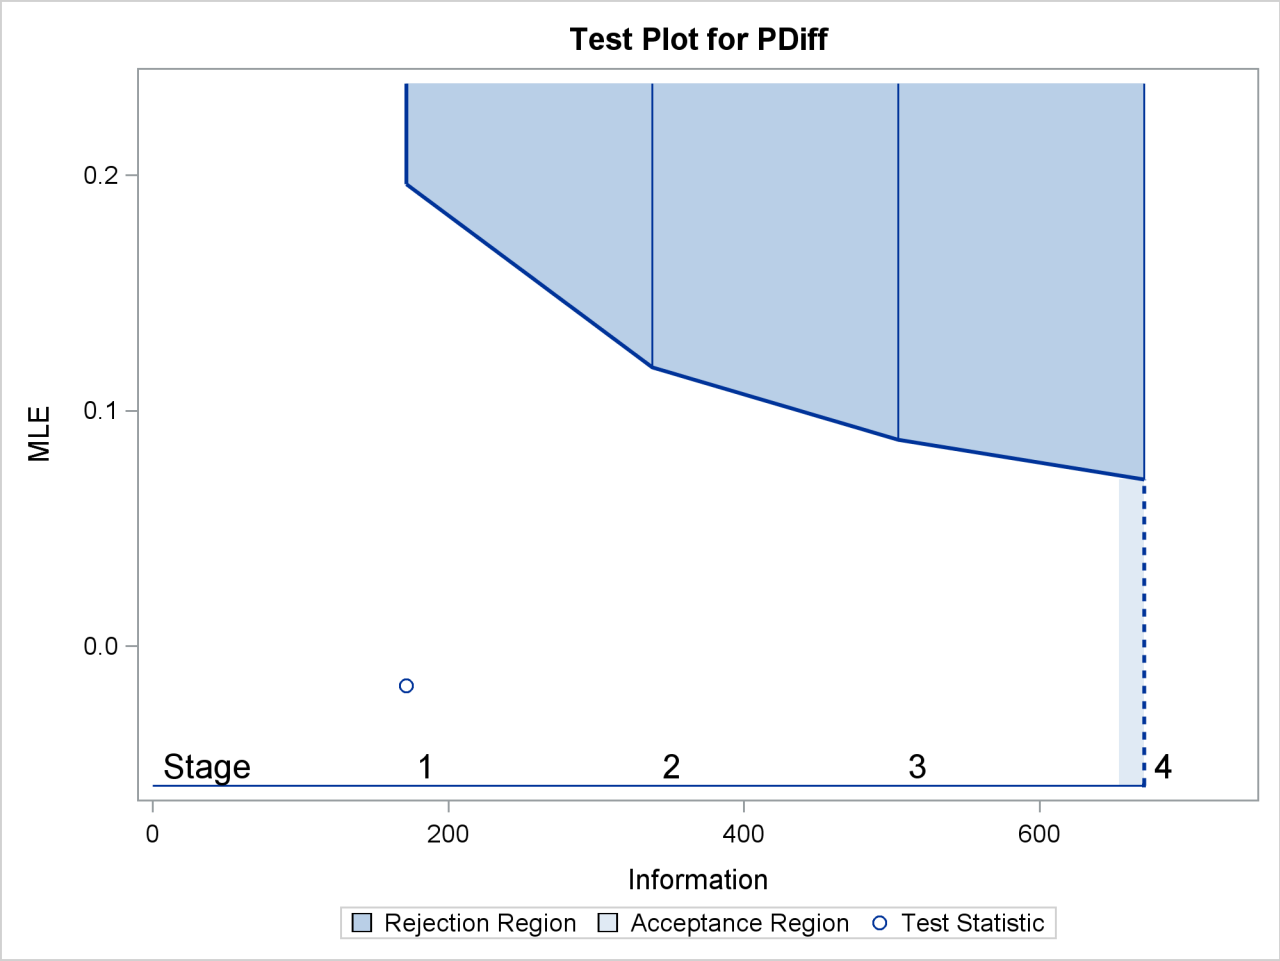
	Test PDiff	
Stage	Estimate	Action
1	-0.01667	Continue
2	.	
3	.	
4	.	

The information level at stage 1 is computed as $I_1^* = I_1 \times (n_1^*/n_1)$, where I_1 and n_1 are the information level and sample size at stage 1 in the BOUNDARY= data set, and $n_1^* = 36$ is the available sample size at stage 1.

With the INFOADJ=PROP option (which is the default), the information levels at interim stages 2 and 3 are derived proportionally from the information levels in the BOUNDARY= data set. At stage 1, the statistic $\hat{\theta} = \hat{p} - p_0 = 0.58333 - 0.6 = -0.01667$ is less than the upper α boundary value 0.19638, so the trial continues to the next stage.

With ODS Graphics enabled, a boundary plot with the rejection and acceptance regions is displayed, as shown in Output 81.4.10. As expected, the test statistic is in the continuation region.

Output 81.4.10 Sequential Test Plot



The following statements use the MEANS procedure to compute the mean response at stage 2:

```
proc means data=Prop_2;
   var Resp;
   ods output Summary=Data_Prop2;
run;
```

The following statements create and display (in Output 81.4.11) the data set for the centered mean positive response ($\hat{p} - p_0$) at stage 2:

```
data Data_Prop2;
   set Data_Prop2;
   _Scale_='MLE';
   _Stage_= 2;
   NObs= Resp_N;
   PDiff= Resp_Mean - 0.6;
   keep _Scale_ _Stage_ NObs PDiff;
run;

proc print data=Data_Prop2;
   title 'Statistics Computed at Stage 2';
run;
```

Output 81.4.11 Statistics Computed at Stage 2

Statistics Computed at Stage 2

Obs	_Scale_	_Stage_	NObs	PDiff
1	MLE	2	71	-0.064789

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Prop1
             Data(Testvar=PDiff)=Data_Prop2
             infoadj=prop
             boundarykey=both
             boundaryscale=mle
             condpower(cref=1)
             predpower
             plots=condpower
             ;
ods output test=Test_Prop2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The DATA= option specifies the input data set that contains the test statistic and its associated sample size at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST_PROP2 option creates an output data set named TEST_PROP2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The CONDPOWER(CREF=1) option requests the conditional power with the observed statistic under the alternative hypothesis, in addition to the conditional power under the hypothetical reference $\theta = \hat{\theta}$, the MLE estimate. The PREDPOWER option requests the noninformative predictive power with the observed statistic.

The "Test Information" table in Output 81.4.12 displays the boundary values for the test statistic with the specified MLE scale. The test statistic $\hat{\theta} = -0.06479$ is less than the corresponding upper α boundary 0.11831, so the sequential test does not stop at stage 2 to reject the null hypothesis.

Output 81.4.12 Sequential Tests

The SEQTEST Procedure

Test Information (MLE Scale)
Null Reference = 0

	Information Level			Alternative Reference	Boundary Values Upper

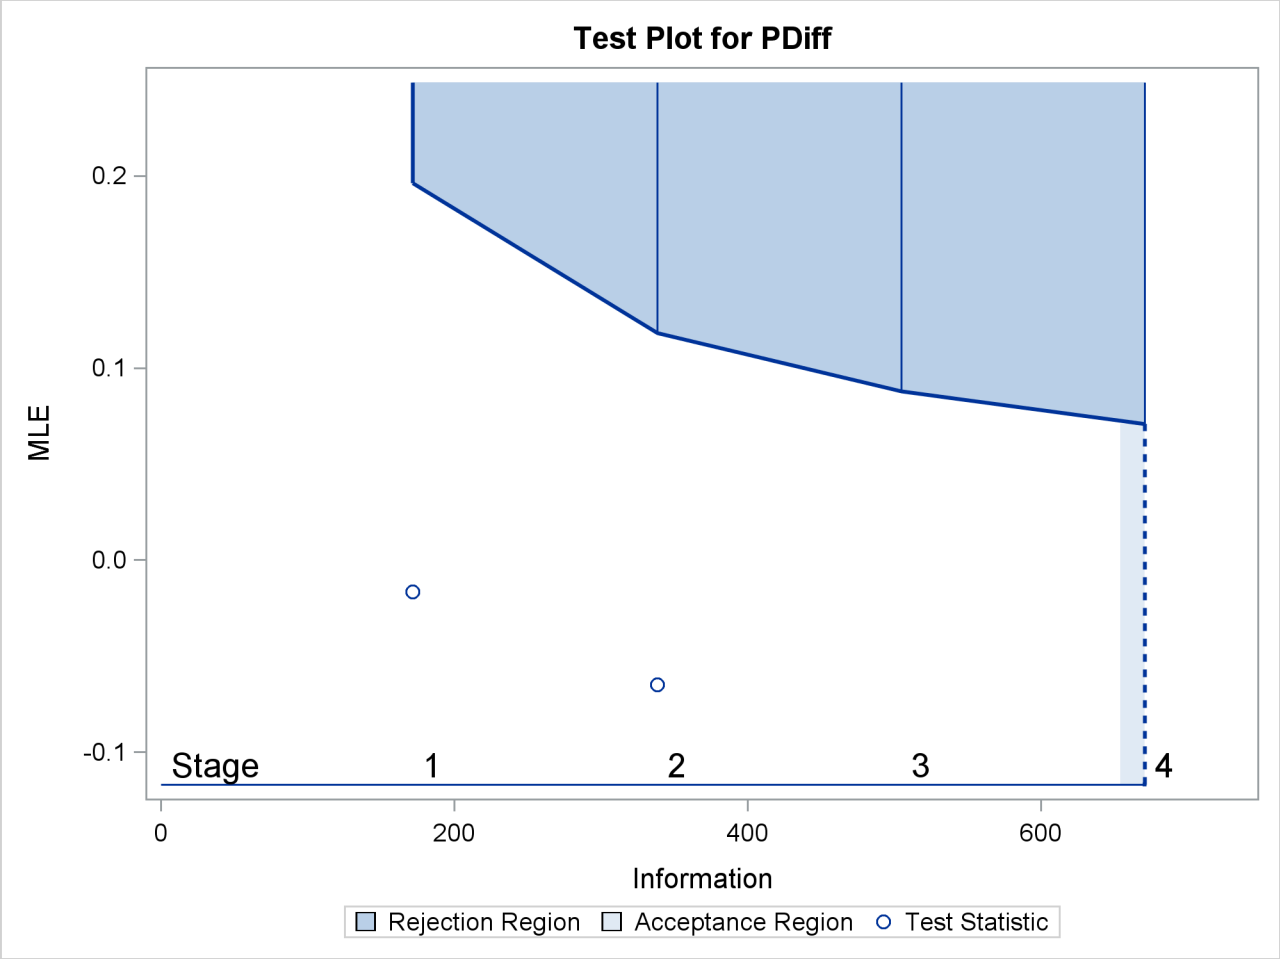
4	.	

With ODS Graphics enabled, the "Test Plot" displays boundary values of the design and the test statistic, as shown in Output 81.4.13. It also shows that the test statistic is in the "Continuation Region" below the upper α boundary value at stage 2.

Output 81.4.13 Sequential Test Plot



The predictive power is the probability to reject the null hypothesis under the posterior distribution with a noninformative prior given the observed statistic $\hat{\theta} = -0.06479$. The "Predictive Power Information" table in Output 81.4.14 indicates that the predictive power at $\hat{\theta} = -0.06479$ is 0.0002.

Output 81.4.14 Predictive Power

Predictive Power Information

Stopping Stage	MLE	Predictive Power
2	-0.06479	0.00020

The "Conditional Power Information" table in Output 81.4.15 displays conditional powers given the observed statistic under hypothetical references $\theta = \hat{\theta}$, the maximum likelihood estimate, and $\theta = \theta_1$. The constant c under CRef for the MLE is derived from $\hat{\theta} = c\theta_1$; that is, $c = \hat{\theta}/\theta_1 = -0.06479/0.1 = -0.6479$.

Output 81.4.15 Conditional Power

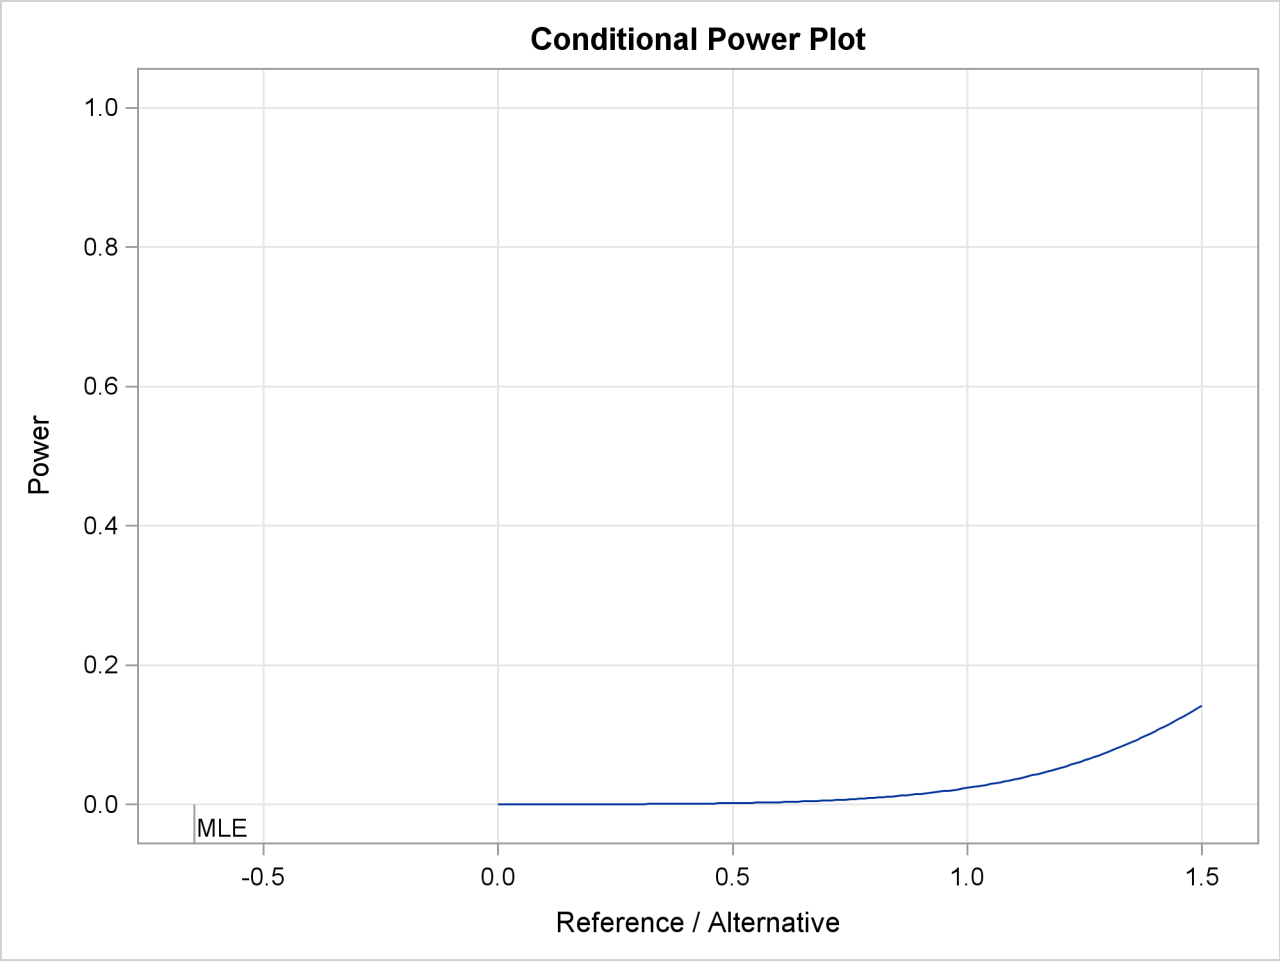
Conditional Power Information
Reference = CRef * (Alt Reference)

Stopping Stage	MLE	Reference Ref	Reference CRef	Conditional Power
2	−0.06479	MLE	−0.6479	0.00000
2	−0.06479	Alternative	1.0000	0.02368

The conditional power is the probability of rejecting the null hypothesis under these hypothetical references given the observed statistic $\hat{\theta} = -0.06479$. The table in Output 81.4.15 shows a weak conditional power of 0.02368 under the alternative hypothesis.

The "Conditional Power Plot" displays conditional powers given the observed statistic under various hypothetical references, as shown in Output 81.4.16. These references include $\theta = \hat{\theta}$, the maximum likelihood estimate, and $\theta = c_i\theta_1$, where θ_1 is the alternative reference and $c_i = 0, 0.01, \ldots, 1.50$ are constants that are specified in the CREF= option. Output 81.4.16 shows that the conditional power increases as c_i increases.

Output 81.4.16 Conditional Power Plot



With a predictive power 0.0002 and a conditional power of 0.02368 under H_1, the supermarket decides to stop the trial and accept the null hypothesis. That is, the positive response for the new store-brand coffee is not better than that for the current store-brand coffee.

Output 81.4.17 Predictive Power

Predictive Power Information

Stopping Stage	MLE	Predictive Power
2	-0.06479	0.00020

In the SEQTEST procedure, the conditional probability at an interim stage k is the probability that the test statistic at the final stage (stage 4) would exceed the rejection critical value. Since an interim stage exists between the current stage (stage 2) and the final stage, the conditional power is not the conditional probability to reject the null hypothesis H_0.

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2. The NSTAGES=3 option sets the next stage as the final stage (stage 3), and the BOUNDARYKEY=BOTH option derives the information level at stage 3 that maintain both Type I and Type II error probability levels. The CONDPOWER(CREF=1) option requests the conditional power with the observed statistic under the alternative hypothesis, in addition to the conditional power under the hypothetical reference $\theta = \hat{\theta}$, the MLE estimate.

```
proc seqtest Boundary=Test_Prop1
             Data(Testvar=PDiff)=Data_Prop2
             nstages=3
             boundarykey=both
             boundaryscale=mle
             condpower(cref=1)
             ;
run;
```

The "Test Information" table in Output 81.4.18 displays the boundary values for the test statistic with the specified MLE scale, assuming that the next stage is the final stage.

Output 81.4.18 Sequential Tests

The SEQTEST Procedure

Test Information (MLE Scale)
Null Reference = 0

3	.	

The "Conditional Power Information" table in Output 81.4.19 displays conditional powers given the observed statistic, assuming that the next stage is the final stage.

Output 81.4.19 Conditional Power

Conditional Power Information
Reference = CRef * (Alt Reference)

Stopping Stage	MLE	Reference Ref	Reference CRef	Conditional Power
2	-0.06479	MLE	-0.6479	0.00000
2	-0.06479	Alternative	1.0000	0.02278

The conditional power is the probability of rejecting the null hypothesis under these hypothetical references given the observed statistic $\hat{\theta} = -0.06479$. The table in Output 81.4.19 also shows a weak conditional power of 0.02278 under the alternative hypothesis.

Example 81.5: Comparing Two Proportions with a Log Odds Ratio Test

This example compares two binomial proportions by using a log odds ratio statistic in a five-stage group sequential test. A clinic is studying the effect of vitamin C supplements in treating flu symptoms. The study consists of patients in the clinic who exhibit the first sign of flu symptoms within the last 24 hours. These patients are randomly assigned to either the control group (which receives placebo pills) or the treatment group (which receives large doses of vitamin C supplements). At the end of a five-day period, the flu symptoms of each patient are recorded.

Suppose that you know from past experience that flu symptoms disappear in five days for 60% of patients who experience flu symptoms. The clinic would like to detect a 70% symptom disappearance with a high probability. A test that compares the proportions directly specifies the null hypothesis $H_0 : \theta = p_t - p_c = 0$ with a one-sided alternative $H_1 : \theta > 0$ and a power of 0.90 at $H_1 : \theta = 0.10$, where p_t and p_c are the proportions of symptom disappearance in the treatment group and control group, respectively. An alternative trial tests an equivalent hypothesis by using the log odds ratio statistics:

$$\theta = \log\left(\frac{(\frac{p_t}{1-p_t})}{(\frac{p_c}{1-p_c})}\right)$$

Then the null hypothesis is $H_0 : \theta = \theta_0 = 0$ and the alternative hypothesis is

$$H_1 : \theta = \theta_1 = \log\left(\frac{(\frac{0.70}{0.30})}{(\frac{0.6}{0.4})}\right) = 0.441833$$

The following statements invoke the SEQDESIGN procedure and request a five-stage group sequential design by using an error spending function method for normally distributed statistics. The design uses a two-sided alternative hypothesis with early stopping to reject the null hypothesis H_0.

```
ods graphics on;
proc seqdesign altref=0.441833
               boundaryscale=mle
               ;
   OneSidedErrorSpending: design method=errfuncpow
                                nstages=5
                                alt=upper
                                stop=accept
                                alpha=0.025;
   samplesize model=twosamplefreq( nullprop=0.6 test=logor);
ods output Boundary=Bnd_CSup;
run;
ods graphics off;
```

The ODS OUTPUT statement with the BOUNDARY=BND_CSUP option creates an output data set named BND_CSUP which contains the resulting boundary information for the subsequent sequential tests.

The "Design Information" table in Output 81.5.1 displays design specifications and derived statistics. With the specified alternative reference, the maximum information 56.30934 is derived.

Output 81.5.1 Design Information

The SEQDESIGN Procedure
Design: OneSidedErrorSpending

Design Information

3	604	302	302	33.8240
4	806	403	403	45.1360
5	1006	503	503	56.3360

Thus, 101 new patients are needed in each group at stages 1, 2, and 4, and 100 new patients are needed in each group at stages 3 and 5. Suppose that 101 patients are available in each group at stage 1. Output 81.5.6 lists the 10 observations in the data set count_1.

Output 81.5.6 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	TrtGrp	Resp
1	Control	1
2	C_Sup	0
3	Control	0
4	C_Sup	1
5	Control	1
6	C_Sup	1
7	Control	1
8	C_Sup	0
9	Control	0
10	C_Sup	1

The TrtGrp variable is a grouping variable with the value Control for a patient in the placebo control group and the value C_Sup for a patient in the treatment group who receives vitamin C supplements. The Resp variable is an indicator variable with the value 1 for a patient without flu symptoms after five days and the value 0 for a patient with flu symptoms after five days.

The following statements use the LOGISTIC procedure to compute the log odds ratio statistic and its associated standard error at stage 1:

```
proc logistic data=CSup_1 descending;
   class TrtGrp / param=ref;
   model Resp= TrtGrp;
   ods output ParameterEstimates=Parms_CSup1;
run;
```

The DESCENDING option is used to reverse the order for the response levels, so the LOGISTIC procedure is modeling the probability that Resp = 1.

The following statements create and display (in Output 81.5.7) the data set for the log odds ratio statistic and its associated standard error:

```
data Parms_CSup1;
   set Parms_CSup1;
   if Variable='TrtGrp' and ClassVal0='C_Sup';
   _Scale_='MLE';
   _Stage_= 1;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_CSup1;
   title 'Statistics Computed at Stage 1';
run;
```

Output 81.5.7 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	TrtGrp	0.3247	0.2856	MLE	1

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_CSup
             Parms(Testvar=TrtGrp)=Parms_CSup1
             infoadj=prop
             errspendadj=errfuncpow
             boundarykey=both
             boundaryscale=mle
             ;
ods output test=Test_CSup1; run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS_CSUP1 option specifies the input data set PARMS_CSUP1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRTGRP option identifies the test variable TRTGRP in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The ERRSPENDADJ=ERRFUNCPOW option adjusts the boundaries with the updated error spending values generated from the power error spending function. The BOUNDARYKEY=BOTH option maintains both the α and β levels. The BOUNDARYSCALE=MLE option displays the output boundaries in terms of the MLE scale.

The ODS OUTPUT statement with the TEST=TEST_CSUP1 option creates an output data set named TEST_CSUP1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.5.8 displays design specifications. With the specified BOUNDARYKEY=BOTH option, the information levels and boundary values at future stages are modified to maintain both the α and β levels.

Output 81.5.8 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.BND_CSUP
Data Set	WORK.PARMS_CSUP1
Statistic Distribution	Normal
Boundary Scale	MLE
Alternative Hypothesis	Upper
Early Stop	Accept Null
Number of Stages	5
Alpha	0.025
Beta	0.1
Power	0.9
Max Information (Percent of Fixed Sample)	104.6673
Max Information	56.3361718
Null Ref ASN (Percent of Fixed Sample)	57.02894
Alt Ref ASN (Percent of Fixed Sample)	102.1369

The "Test Information" table in Output 81.5.9 displays the boundary values for the test statistic with the specified MLE scale. With the INFOADJ=PROP option (which is the default), the information levels at future interim stages are derived proportionally from the observed information at stage 1 and the information levels in the BOUNDARY= data set.

Since the information level at stage 1 is derived from the PARMS= data set and other information levels are not specified, equal increments are used at remaining stages. At stage 1, the MLE statistic 0.32474 is greater than the corresponding upper β boundary value -0.29906, so the sequential test continues to the next stage.

Output 81.5.9 Sequential Tests

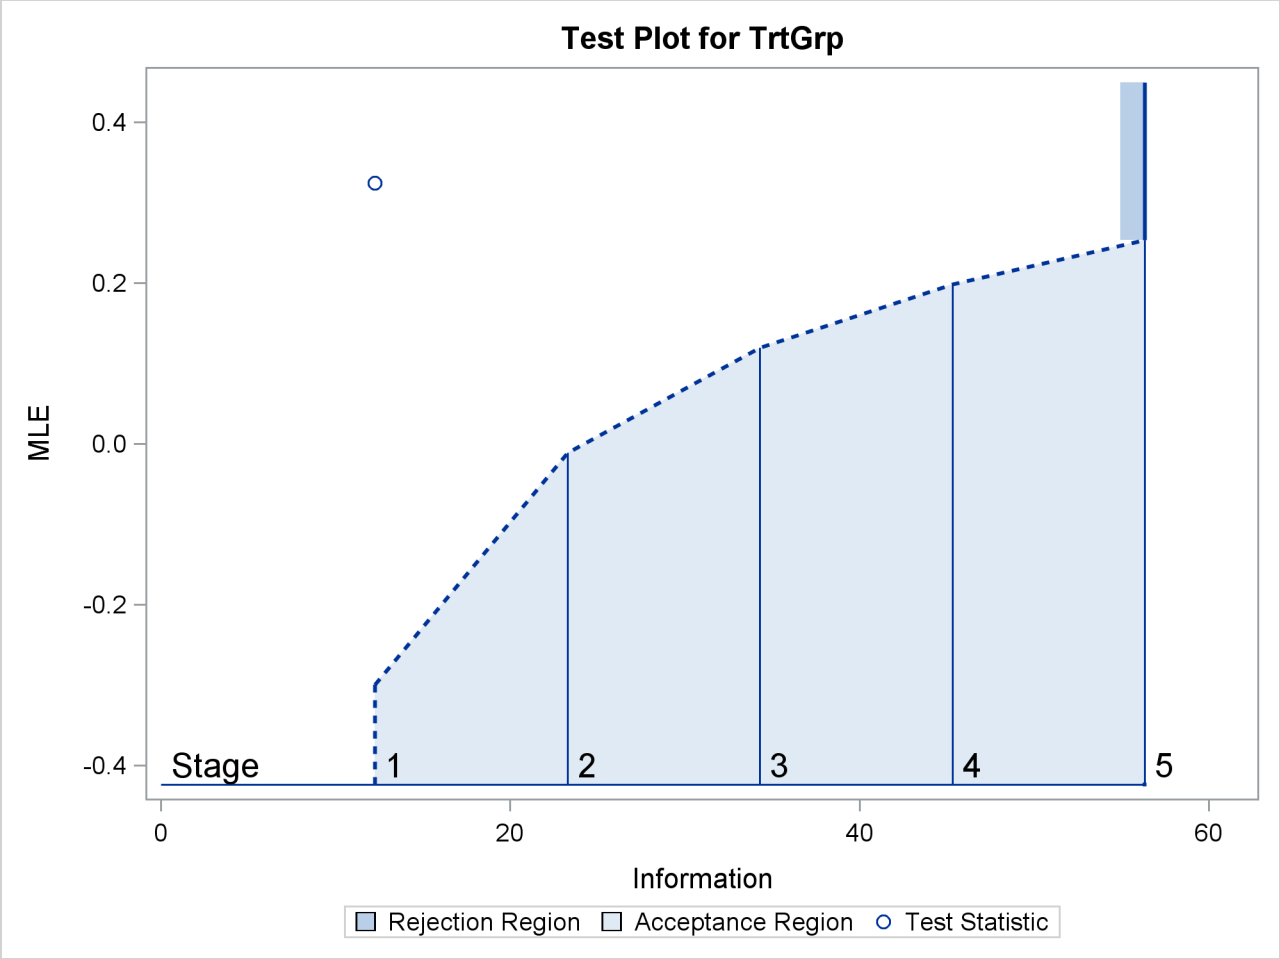
With ODS Graphics enabled, a boundary plot with the boundary values and test statistics is displayed, as shown in Output 81.5.10. As expected, the test statistic is in the continuation region.

Output 81.5.10 Sequential Test Plot



The following statements use the LOGISTIC procedure to compute the log odds ratio statistic and its associated standard error at stage 2:

```
proc logistic data=CSup_2 descending;
   class TrtGrp / param=ref;
   model Resp= TrtGrp;
   ods output ParameterEstimates=Parms_CSup2;
run;
```

The following statements create and display (in Output 81.5.11) the data set for the mean positive response and its associated standard error at stage 2:

```
data Parms_CSup2;
   set Parms_CSup2;
   if Variable='TrtGrp' and ClassVal0='C_Sup';
   _Scale_='MLE';
   _Stage_= 2;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;
proc print data=Parms_CSup2;
   title 'Statistics Computed at Stage 2';
run;
```

Output 81.5.11 Statistics Computed at Stage 2

Statistics Computed at Stage 2

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	TrtGrp	0.2356	0.2073	MLE	2

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
proc seqtest Boundary=Test_CSup1
             Parms( testvar=TrtGrp)=Parms_CSup2
             infoadj=prop
             errspendadj=errfuncpow
             boundarykey=both
             boundaryscale=mle
             ;
ods output Test=Test_CSup2;
run;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=CSUP_LDL2 option creates an output data set named CSUP_LDL2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Test Information" table in Output 81.5.12 displays the boundary values for the test statistic with the specified MLE scale. The test statistic 0.2356 is greater than the corresponding upper β boundary value -0.01068, so the sequential test continues to the next stage.

Output 81.5.12 Sequential Tests

Similar results are found at stages 3 and stage 4, so the trial continues to the final stage. The following statements use the LOGISTIC procedure to compute the log odds ratio statistic and its associated standard error at stage 5:

```
proc logistic data=CSup_5 descending;
   class TrtGrp / param=ref;
   model Resp= TrtGrp;
   ods output ParameterEstimates=Parms_CSup5;
run;
```

The following statements create and display (in Output 81.5.13) the data set for the log odds ratio statistic and its associated standard error at stage 5:

```
data Parms_CSup5;
   set Parms_CSup5;
   if Variable='TrtGrp' and ClassVal0='C_Sup';
   _Scale_='MLE';
   _Stage_= 5;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_CSup5;
   title 'Statistics Computed at Stage 5';
run;
```

Output 81.5.13 Statistics Computed at Stage 5

Statistics Computed at Stage 5

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	TrtGrp	0.2043	0.1334	MLE	5

The following statements invoke the SEQTEST procedure to test for the hypothesis at stage 5:

```
ods graphics on;
proc seqtest Boundary=Test_CSup4
             Parms( testvar=TrtGrp)=Parms_CSup5
             errspendadj=errfuncpow
             boundaryscale=mle
             cialpha=.025
             rci
             plots=rci
             ;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 5, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 5, and the TESTVAR= option identifies the test variable in the data set. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary value at stage 5 is derived to maintain the α level.

The "Test Information" table in Output 81.5.14 displays the boundary values for the test statistic with the specified MLE scale. The test statistic 0.2043 is less than the corresponding upper β boundary 0.25375, so the sequential test stops to accept the null hypothesis. That is, there is no reduction in duration of symptoms for the group receiving vitamin C supplements.

Output 81.5.14 Sequential Tests

The SEQTEST Procedure

Test Information (MLE Scale)
Null Reference = 0

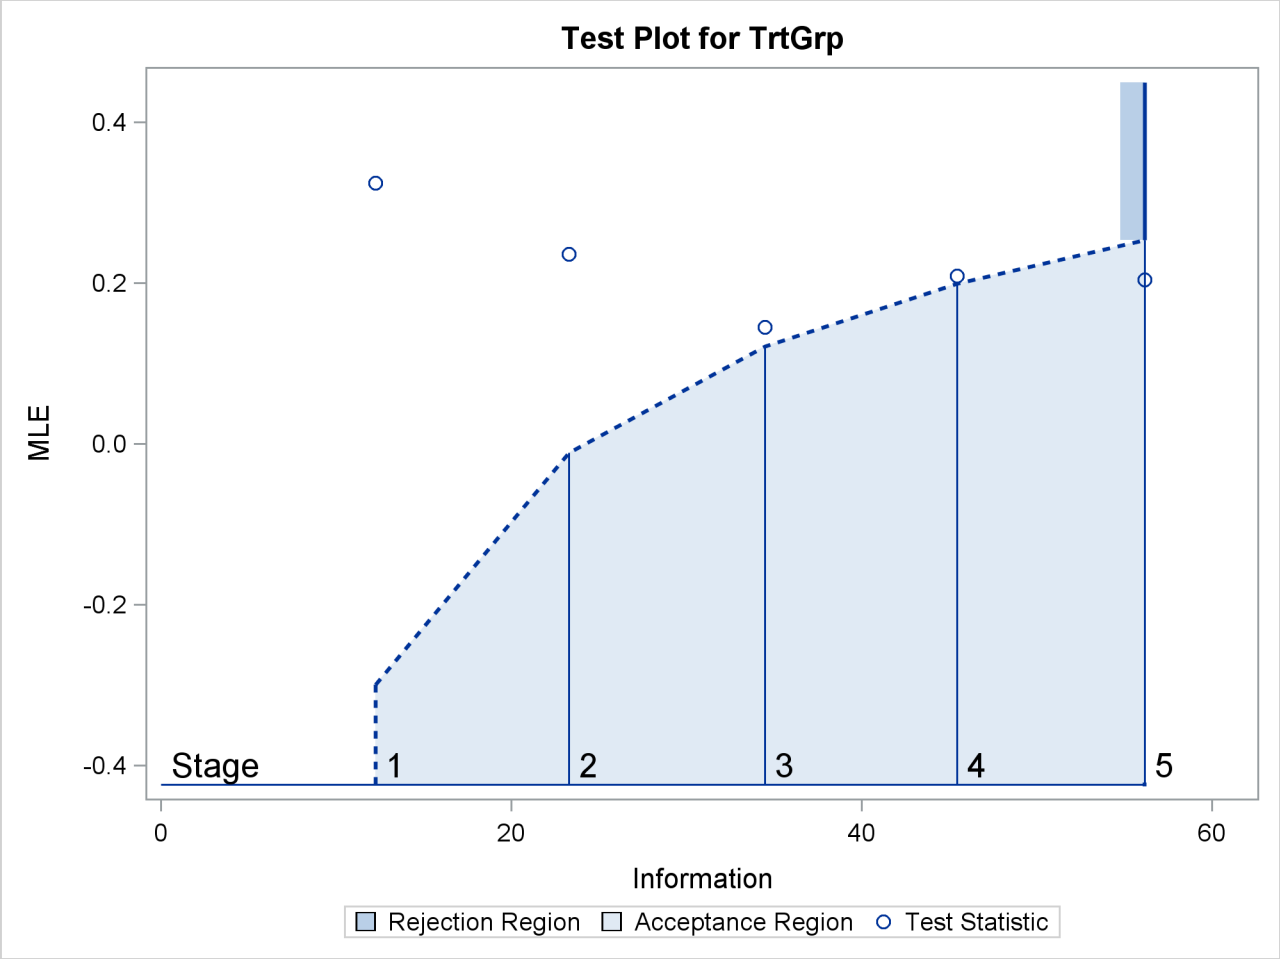
Stage	Information Level Proportion	Information Level Actual	Alternative Reference Upper
1	0.2183	12.26014	0.44183
2	0.4145	23.27916	0.44183
3	0.6141	34.48793	0.44183
4	0.8092	45.44685	0.44183
5	1.0000	56.16068	0.44183

Test Information (MLE Scale)
Null Reference = 0

Stage	Boundary Values Upper Beta	Test TrtGrp Estimate	Test TrtGrp Action
1	-0.29906	0.32474	Continue
2	-0.01068	0.23560	Continue
3	0.12134	0.14482	Continue
4	0.19899	0.20855	Continue
5	0.25375	0.20430	Accept Null

The "Test Plot" displays boundary values of the design and the test statistics, as shown in Output 81.5.15. It also shows that the test statistic is in the "Acceptance Region" at the final stage.

Output 81.5.15 Sequential Test Plot



After a trial is stopped, the "Parameter Estimates" table in Output 81.5.16 displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and the p-value under the null hypothesis $H_0 : \theta = 0$. As expected, the p-value 0.0456 is not significant at $\alpha = 0.025$ level and the lower 97.5% confidence limit is less than the value $\theta_0 = 0$. The p-value, unbiased median estimate, and confidence limits depend on the ordering of the sample space (k, z), where k is the stage number and z is the standardized Z statistic.

Output 81.5.16 Parameter Estimates

Parameter Estimates
Stagewise Ordering

Parameter	Stopping Stage	MLE	p-Value for H0:Parm=0	Median Estimate	Lower 97.5% CL
TrtGrp	5	0.204303	0.0456	0.234494	-0.03712

Since the test is accepted at stage 5, the p-value computed by using the default stagewise ordering can be expressed as

$$\alpha_u = P_{\theta=0}\left(z_5 < Z_5 \mid b_k < Z_k, k < 5\right)$$

where $z_5 = 1.53105$ is the test statistic at stage 5, Z_k is a standardized normal variate at stage k, and b_k is the upper β boundary value in the standardized Z scale at stage $k, k = 1, 2, \ldots, 5$.

With the RCI option, the "Repeated Confidence Intervals" table in Output 81.5.17 displays repeated confidence intervals for the parameter. For a one-sided test with an upper alternative hypothesis, since the upper acceptance repeated confidence limit 0.3924 at the final stage is less than the alternative reference 0.441833, the null hypothesis is accepted.

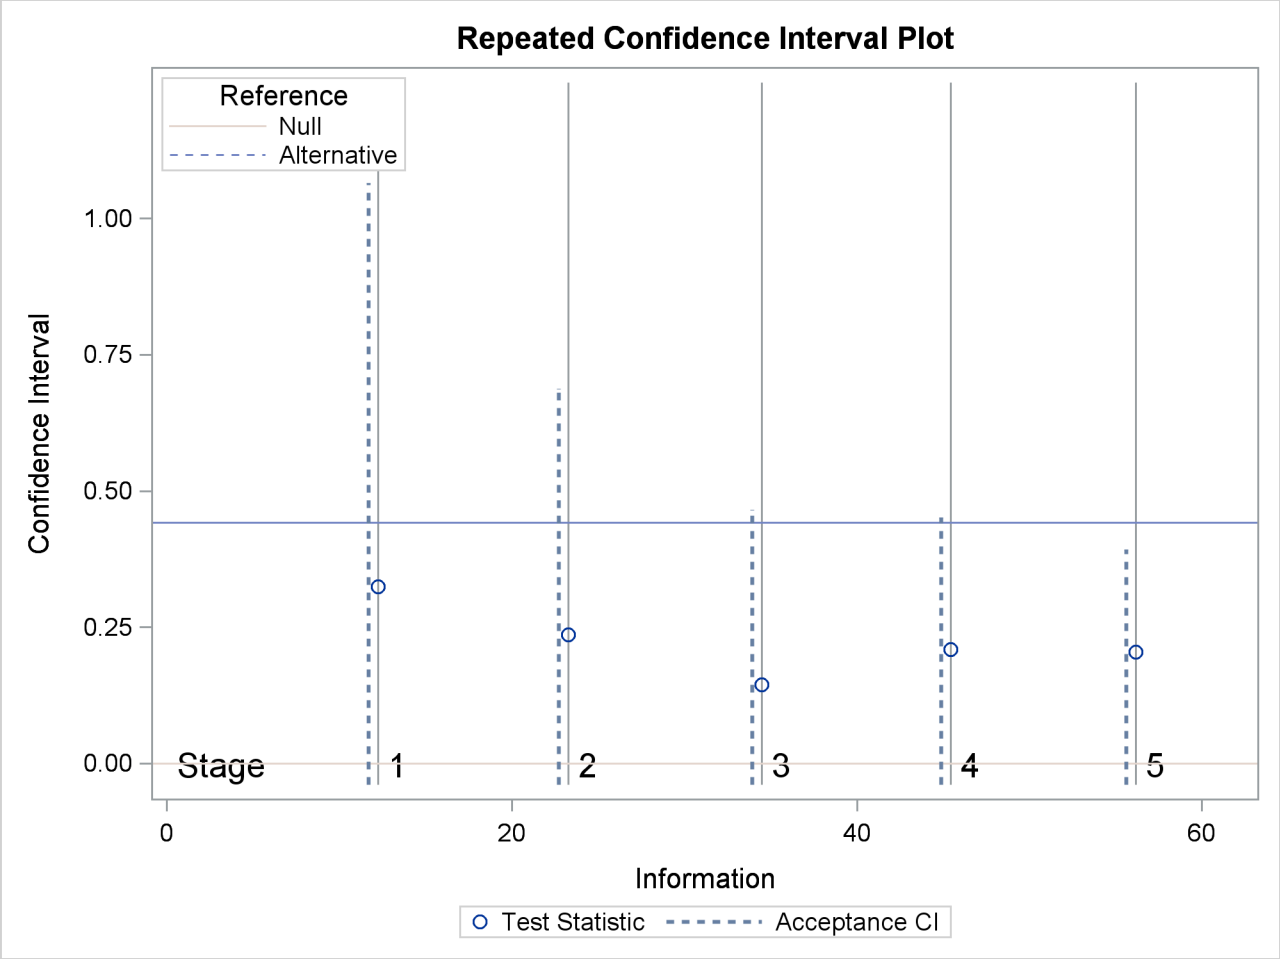
Output 81.5.17 Repeated Confidence Intervals

Repeated Confidence Intervals

Stage	Information Level	Parameter Estimate	-Acceptance Boundary- Upper 89.94% CL
1	12.2601	0.32474	1.0656
2	23.2792	0.23560	0.6881
3	34.4879	0.14482	0.4653
4	45.4468	0.20855	0.4514
5	56.1607	0.20430	0.3924

With the PLOTS=RCI option, the "Repeated Confidence Intervals Plot" displays repeated confidence intervals for the parameter, as shown in Output 81.5.18. It shows that the upper acceptance repeated confidence limit at the final stage is less than the alternative reference 0.441833. This implies that the study accepts the null hypothesis at the final stage.

Output 81.5.18 Repeated Confidence Intervals Plot



Example 81.6: Comparing Two Survival Distributions with a Log-Rank Test

This example requests a log-rank test that compares two survival distributions for the treatment effect (Jennison and Turnbull 2000, pp. 77–79; Whitehead 1997, pp. 36–39).

A clinic is studying the effect of a new cancer treatment. The study consists of mice exposed to a carcinogen and randomized to either the control group or the treatment group. The event of interest is the death from cancer induced by the carcinogen, and the response is the time from randomization to death.

Following the derivations in the section "Test for Two Survival Distributions with a Log-Rank Test" in the chapter "The SEQDESIGN Procedure," the hypothesis $H_0 : \theta = -\log(\lambda) = 0$ with an alternative hypothesis $H_1 : \theta = \theta_1 > 0$ can be used, where λ is the hazard ratio between the treatment group and control group.

Suppose that from past experience, the median survival time for the control group is $t_0 = 20$ weeks, and the study would like to detect a $t_1 = 40$ weeks median survival time with a 80% power in the trial. Assuming

exponential survival functions for the two groups, the hazard rates can be computed from

$$S_j(t_j) = e^{-h_j t_j} = \frac{1}{2}$$

where $j = 0, 1$.

Thus, with $h_0 = 0.03466$ and $h_1 = 0.01733$, the hazard ratio $\lambda_1 = h_1/h_0 = 1/2$ and the alternative hypothesis is

$$\theta_1 = -\log(\lambda_1) = -\log(\frac{1}{2}) = 0.69315$$

The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design for normally distributed data. The design uses a one-sided alternative hypothesis with early stopping to reject and to accept the null hypothesis H_0. Whitehead's triangular method is used to derive the boundaries.

```
ods graphics on;
proc seqdesign altref=0.69315
               boundaryscale=score
               ;
   OneSidedWhitehead: design method=whitehead
                             nstages=4
                             boundarykey=alpha
                             alt=upper  stop=both
                             beta=0.20;
   samplesize model=twosamplesurvival
                    ( nullhazard=0.03466
                      accrate=10);
run;
ods graphics off;
```

A Whitehead method creates boundaries that approximately satisfy the Type I and Type II error probability level specification. The BOUNDARYKEY=ALPHA option is used to adjust the boundary value at the last stage and to meet the specified Type I probability level.

The specified ACCRATE=10 option indicates that 10 mice will be accrued each week and the resulting minimum and maximum accrual times are displayed. With the BOUNDARYSCALE=SCORE option, the procedure displays the output boundaries with the score statistics.

The "Design Information" table in Output 81.6.1 displays design specifications and derived statistics.

Output 81.6.1 Design Information

The SEQDESIGN Procedure
Design: OneSidedWhitehead

Design Information

Statistic Distribution	Normal
Boundary Scale	Score
Alternative Hypothesis	Upper
Early Stop	Accept/Reject Null

Null Ref ASN (Percent of Fixed Sample)	62.6302
Alt Ref ASN (Percent of Fixed Sample)	74.00064

The "Boundary Information" table in Output 81.6.2 displays the information level, alternative reference, and boundary values at each stage.

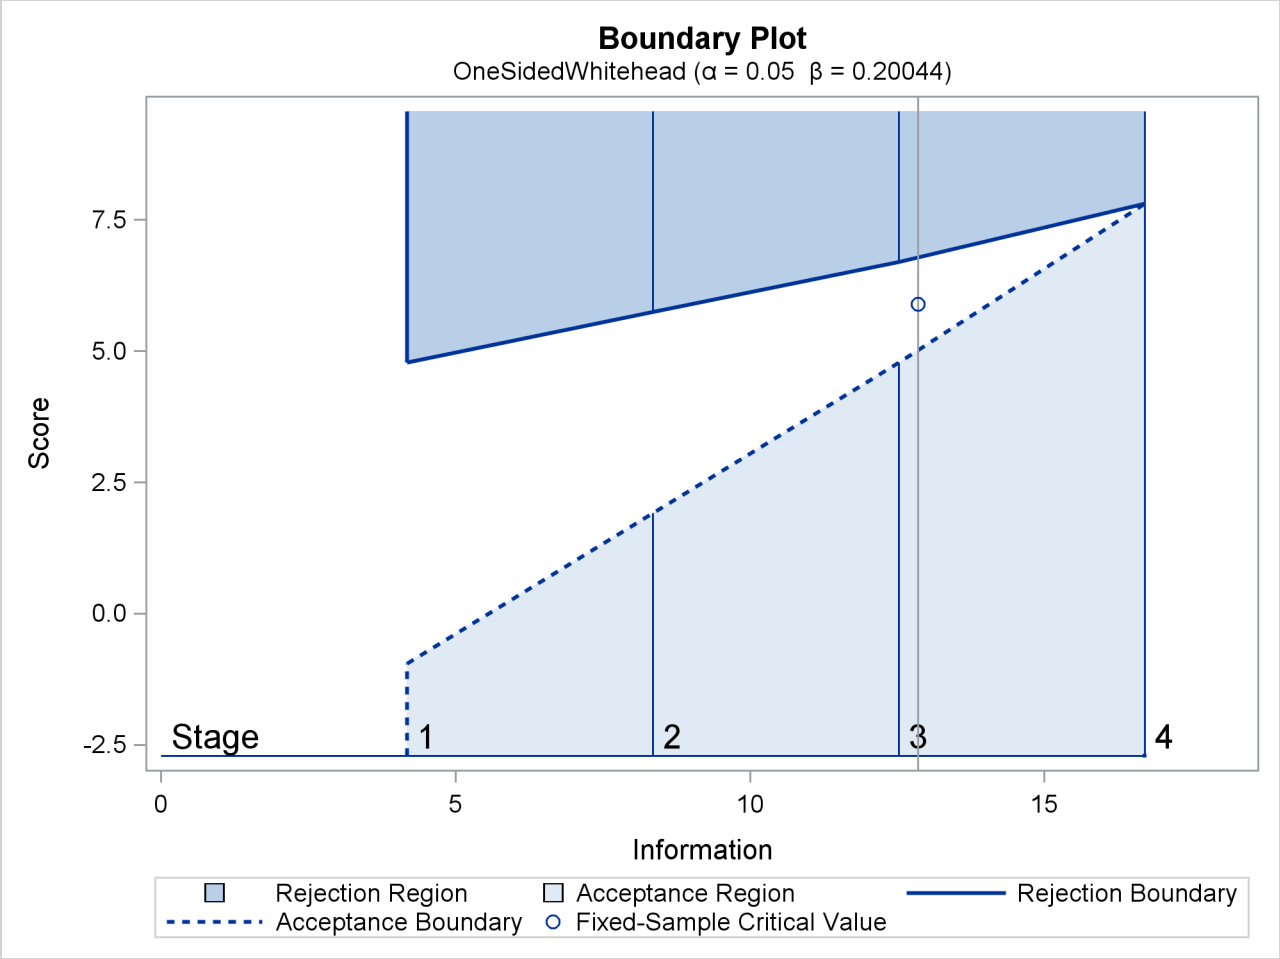
Output 81.6.2 Boundary Information

Boundary Information (Score Scale)
Null Reference = 0

	Information Level			Alternative Reference	Boundary Values	
					Upper	
Stage	Proportion	Actual	Events	Upper	Beta	Alpha
1	0.2500	4.176561	16.70624	2.89498	-0.95755	4.78773
2	0.5000	8.353122	33.41249	5.78997	1.91509	5.74527
3	0.7500	12.52968	50.11873	8.68495	4.78773	6.70282
4	1.0000	16.70624	66.82498	11.57993	7.81296	7.81296

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 81.6.3.

Output 81.6.3 Boundary Plot



With the MODEL=TWOSAMPLESURVIVAL option in the SAMPLESIZE statement, the "Sample Size Summary" table in Output 81.6.4 displays the parameters for the sample size computation.

Output 81.6.4 Required Sample Size Summary

Sample Size Summary

Test	Two-Sample Survival
Null Hazard Rate	0.03466
Hazard Rate (Group A)	0.01733
Hazard Rate (Group B)	0.03466
Hazard Ratio	0.499999
log(Hazard Ratio)	-0.69315
Reference Hazards	Alt Ref
Accrual Rate	10
Min Accrual Time	6.682498
Min Sample Size	66.82498
Max Accrual Time	25.401
Max Sample Size	254.01
Max Number of Events	66.82498

With a minimum accrual time of 6.6825 weeks and a maximum accrual time of 25.401 weeks, an accrual time of 20 weeks is used in the study.

The "Numbers of Events" table in Output 81.6.5 displays the required number of events for the group sequential clinical trial.

Output 81.6.5 Required Numbers of Events

Numbers of Events (D)
Two-Sample Log-Rank Test

Stage	D	Information
1	16.71	4.1766
2	33.41	8.3531
3	50.12	12.5297
4	66.82	16.7062

The following statements invoke the SEQDESIGN procedure and provide more detailed sample size information:

```
proc seqdesign altref=0.69315
               boundaryscale=score
               ;
   OneSidedWhitehead: design method=whitehead
                             nstages=4
                             boundarykey=alpha
                             alt=upper
                             stop=both
                             beta=0.20;
   samplesize model=twosamplesurvival
                     ( nullhazard=0.03466
                       accrate=10 acctime=20);
ods output Boundary=Bnd_Surv;
run;
```

The ODS OUTPUT statement with the BOUNDARY=BND_SURV option creates an output data set named BND_SURV which contains the resulting boundary information for the subsequent sequential tests.

With an accrual time of 20 weeks, the "Sample Size Summary" table in Output 81.6.6 displays the follow-up time for the trial.

Output 81.6.6 Required Sample Size Summary

The SEQDESIGN Procedure
Design: OneSidedWhitehead

Sample Size Summary

Test	Two-Sample Survival
Null Hazard Rate	0.03466
Hazard Rate (Group A)	0.01733

Two-Sample Log-Rank Test

	Ceiling Time	
Stage	N(Grp 2)	Information
1	60.00	4.1854
2	90.00	8.9322
3	100.00	12.7667
4	100.00	17.1377

Thus the study will perform three interim analyses after 12, 18, and 22 weeks and a final analysis after 27 weeks if the study does not stop at any of the interim analyses.

Note that the SEQDESIGN procedure does not compute numbers of events or sample sizes for all statistical models. If the number of events or sample size for a fixed-sample design is available, then the MODEL=INPUTNEVENTS or MODEL=INPUTNOBS option can be used to input fixed-sample information. For example, with a required fixed-sample number of events 51.4073, the following SAMPLESIZE statement can be used to produce the same sample size results:

```
samplesize model=inputnevents
                ( d=51.47 sample=two
                  hazard=0.03466 0.01733
                  accrate=10 acctime=20);
```

Suppose that 120 mice are available after week 12 for the first interim analysis. Output 81.6.8 lists the 10 observations in the data set weeks_1.

Output 81.6.8 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	Trt Gp	Event	Weeks
1	0	0	11
2	1	0	11
3	0	0	11
4	1	0	11
5	0	1	6
6	1	0	11
7	0	0	11
8	1	0	11
9	0	1	9
10	1	0	11

The TrtGp variable is a grouping variable with the value 0 for a mouse in the placebo control group and the value 1 for a mouse in the treatment group. The Weeks variable is the survival time variable measured in weeks and the Event variable is the censoring variable with the value 0 indicating censoring. That is, the values of Weeks are considered censored if the corresponding values of Event are 0; otherwise, they are considered as event times.

The following statements use the LIFETEST procedure to estimate the log-rank statistic at stage 1:

```
proc lifetest data=Surv_1;
   time Weeks*Event(0);
   test TrtGp;
ods output logunichisq=Parms_Surv1;
run;
```

The following statements create and display (in Output 81.6.9) the data set for the log-rank statistic and its associated standard error:

```
data Parms_Surv1;
   set Parms_Surv1(rename=(Statistic=Estimate));
   if Variable='TrtGp';
   _Scale_='Score';
   _Stage_= 1;
   keep Variable _Scale_ _Stage_ StdErr Estimate;
run;

proc print data=Parms_Surv1;
   title 'Statistics Computed at Stage 1';
run;
```

Output 81.6.9 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	TrtGp	3.2004	1.9979	Score	1

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Surv
             Parms(Testvar=TrtGp)=Parms_Surv1
             infoadj=none
             boundaryscale=score
             ;
ods output Test=Test_Surv1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS_SURV1 option specifies the input data set PARMS_SURV1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRTGP option identifies the test variable TRTGP in the data set. The INFOADJ=NONE option maintains the information levels for future interim stages (2 and 3) at the values provided in the BOUNDARY= data set.

The ODS OUTPUT statement with the TEST=TEST_SURV1 option creates an output data set named TEST_SURV1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.6.10 displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the maximum information and the Type I error level α are preserved. Since the computed information level at stage 1 is not the same as the value provided in the BOUNDARY= data set, the power has been modified.

Output 81.6.10 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.BND_SURV
Data Set	WORK.PARMS_SURV1
Statistic Distribution	Normal
Boundary Scale	Score

Early Stop	Accept/Reject Null
Number of Stages	4
Alpha	0.05
Beta	0.20055
Power	0.79945
Max Information (Percent of Fixed Sample)	130.0335
Max Information	16.7062448
Null Ref ASN (Percent of Fixed Sample)	62.80855
Alt Ref ASN (Percent of Fixed Sample)	74.19155

The "Test Information" table in Output 81.6.11 displays the boundary values for the test statistic with the SCORE statistic scale. Since only the information level at stage 1 is specified in the DATA= data set, the information levels at subsequent stages are derived proportionally from the corresponding information

levels provided in the BOUNDARY= data set. At stage 1, the score statistic 3.2004 is between the upper β boundary value -1.0386 and the upper α boundary value 4.7142, so the trial continues to the next stage.

Output 81.6.11 Sequential Tests

Test Information (Score Scale)

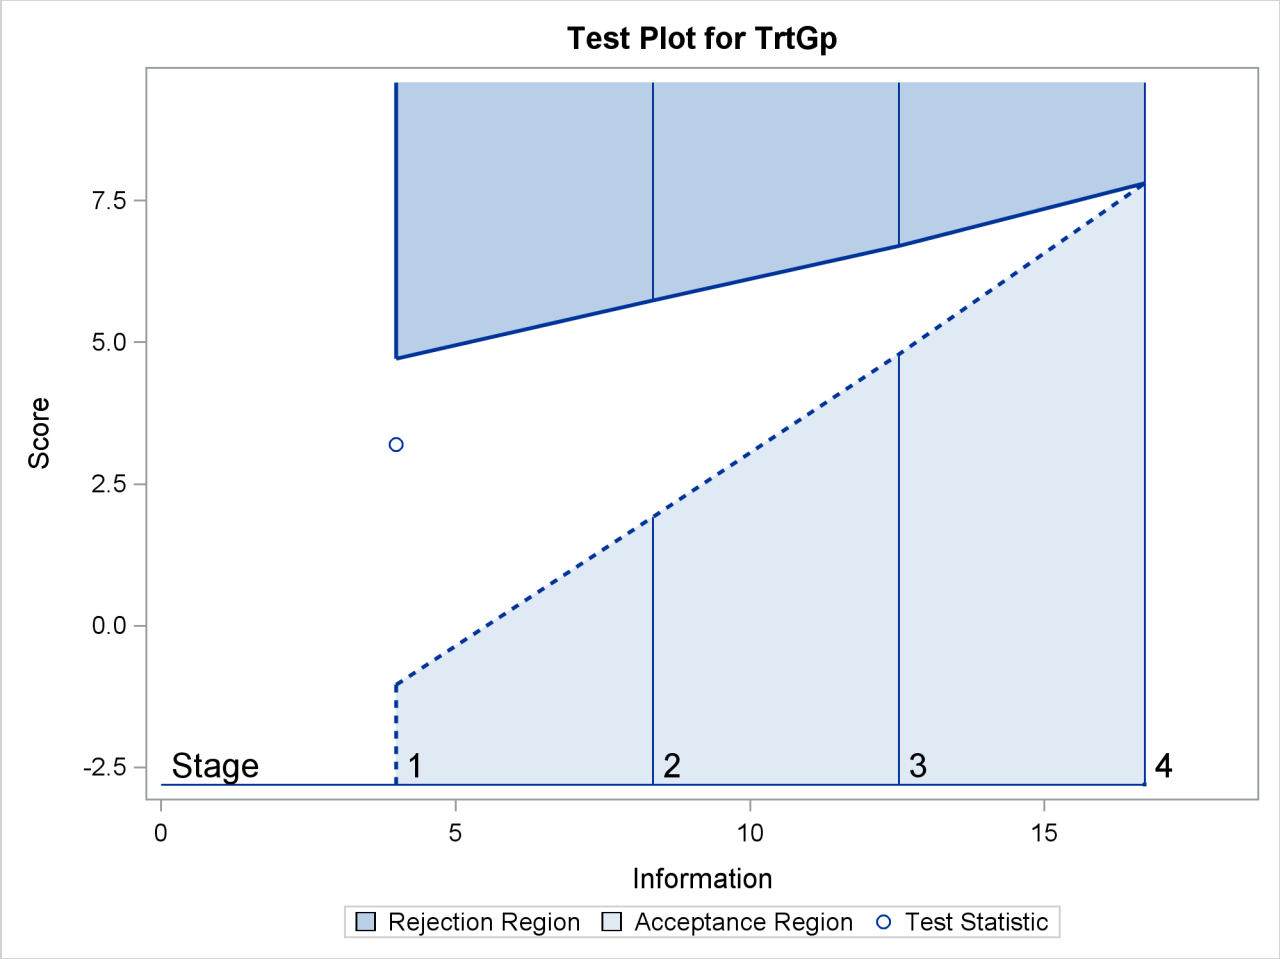
2	.	
3	.	
4	.	

Note that the observed information level 3.9917 corresponds to a proportion of 0.2389 in information level. If the observed information level is much smaller than the target proportion of 0.25, then you need to increase the accrual rate, accrual time, or follow-up time to achieve the target maximum information level for the trial. Scharfstein and Tsiatis (1998) use the simulation and bootstrap methods to modify the trial at interim stages to achieve the target maximum information level. These modifications should be specified in the study protocol or study plan before the study starts.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in Output 81.6.12. As expected, the test statistic is in the continuation region between the upper β and α boundary values.

Output 81.6.12 Sequential Test Plot



Note that the input DATA= option can also be used for the test statistics. For example, the following statements create and display (in Output 81.6.13) the data set for the log-rank statistic and its associated standard error after the LIFETEST procedure. Since the log-rank statistic is a score statistic, the corresponding information level is the variance of the statistic.

```
proc lifetest data=Surv_1;
   time Weeks*Event(0);
   test TrtGp;
ods output logunichisq=Parms_Surv1a;
run;

data Parms_Surv1a;
   set Parms_Surv1a(rename=(Statistic=TrtGp));
   keep _Scale_ _Stage_ _Info_ TrtGp;
   _Scale_='Score';
   _Stage_= 1;
   _Info_= StdErr * StdErr;
   if Variable='TrtGp';
run;
```

```
proc print data=Parms_Surv1a;
   title 'Statistics Computed at Stage 1';
run;
```

Output 81.6.13 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	TrtGp	_Scale_	_Stage_	_Info_
1	3.2004	Score	1	3.99170

The following statements can be used to invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Surv
             Data(Testvar=TrtGp)=Parms_Surv1a
             infoadj=none
             boundaryscale=score
             ;
ods output Test=Test_Surv1;
run;
ods graphics off;
```

The following statements use the LIFETEST procedure to compute the log-rank statistic and its associated standard error at stage 2:

```
proc lifetest data=Surv_2;
   time Weeks*Event(0);
   test TrtGp;
ods output logunichisq=Parms_Surv2;
run;
```

The following statements create and display (in Output 81.6.14) the data set for the log-rank statistic and its associated standard error for each of the first two stages:

```
data Parms_Surv2;
   set Parms_Surv2 (rename=(Statistic=Estimate));
   if Variable='TrtGp';
   _Scale_='Score';
   _Stage_= 2;
   keep Variable _Scale_ _Stage_ StdErr Estimate;
run;

proc print data=Parms_Surv2;
   title 'Statistics Computed at Stage 2';
run;
```

Output 81.6.14 Statistics Computed at Stage 2

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Surv1
             Parms(Testvar=TrtGp)=Parms_Surv2
             infoadj=none
             boundaryscale=score
             citype=lower
             ;
ods output Test=Test_Surv2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set. The INFOADJ=NONE option maintains the information level for stage 3 at the value provided in the BOUNDARY= data set.

The ODS OUTPUT statement with the TEST=TEST_SURV2 option creates an output data set named TEST_SURV2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage if the trial does not stop at the current stage.

The "Test Information" table in Output 81.6.15 displays the boundary values for the test statistic. The test statistic 7.31365 is larger than the corresponding upper α boundary 5.79886, so the study stops and rejects the null hypothesis. That is, there is evidence of reduction in hazard rate for the new treatment.

Output 81.6.15 Sequential Tests

The SEQTEST Procedure

Test Information (Score Scale)
Null Reference = 0

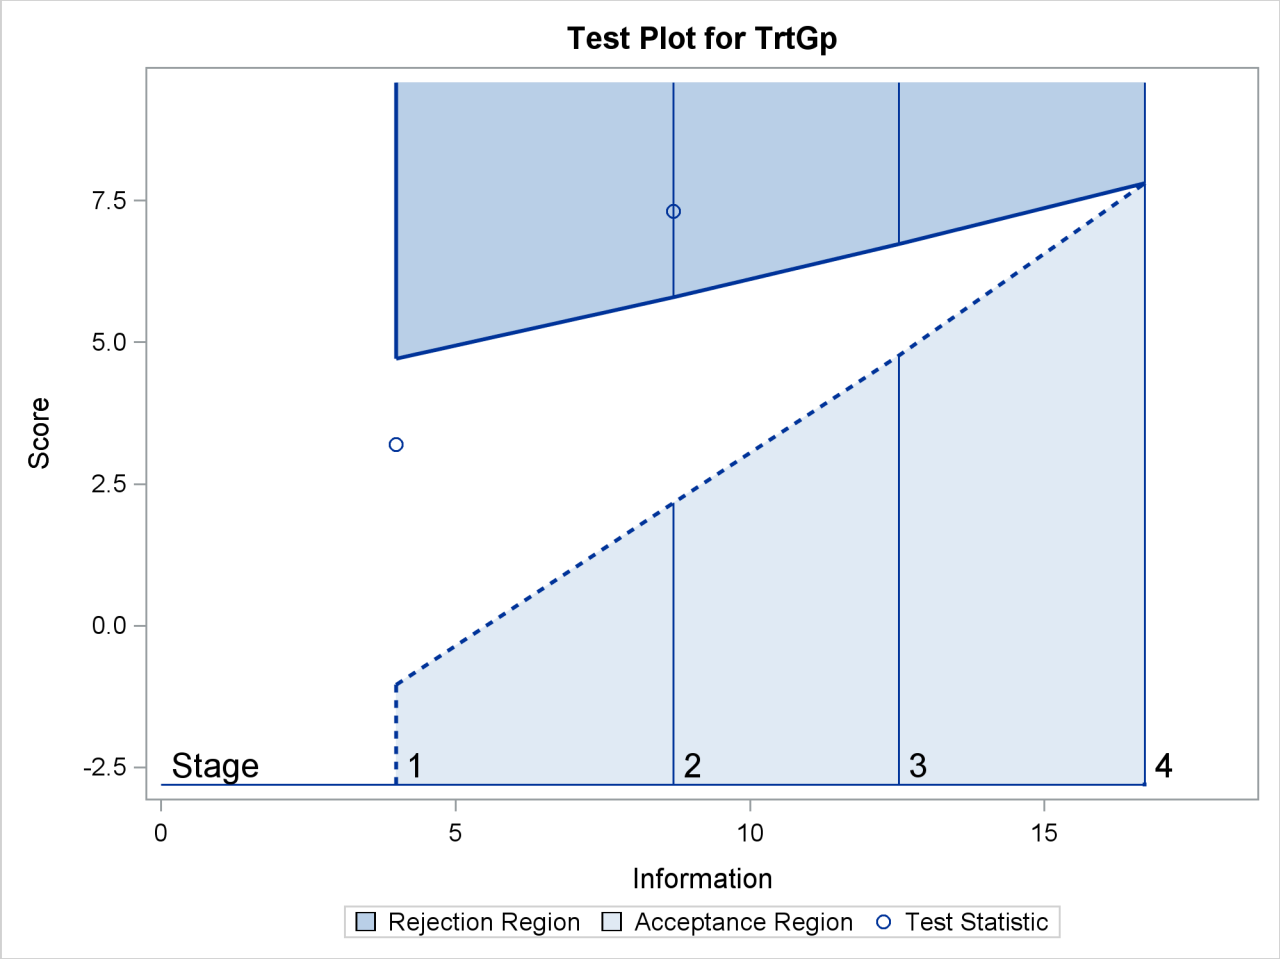
Stage	---Information Level-- Proportion	Actual	-Alternative- --Reference-- Upper	-----Boundary Values---- ----------Upper--------- Beta	Alpha
1	0.2389	3.991698	2.76685	-1.03860	4.71422
2	0.5205	8.696125	6.02772	2.17045	5.79332
3	0.7500	12.52968	8.68495	4.76306	6.72915
4	1.0000	16.70624	11.57993	7.81287	7.81287

Test Information (Score Scale)
Null Reference = 0

	----------Test---------- ----------TrtGp---------- _Stage_	Estimate	Action
	1	3.20040	Continue
	2	7.31365	Reject Null
	3	.	
	4	.	

With ODS Graphics enabled, the "Test Plot" displays boundary values of the design and the test statistic at the first two stages, as shown in Output 81.6.16. It also shows that the test statistic is in the "Rejection Region" above the upper α boundary value at stage 2.

Output 81.6.16 Sequential Test Plot



After the stopping of a trial, the "Parameter Estimates" table in Output 81.6.17 displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and p-value under the null hypothesis $H_0 : \theta = 0$.

Output 81.6.17 Parameter Estimates

Parameter Estimates
Stagewise Ordering

Parameter	Stopping Stage	MLE	p-Value for H0:Parm=0	Median Estimate	Lower 95% CL
TrtGp	2	0.841024	0.0139	0.810329	0.21615

As expected, the p-value 0.0139 is significant at the $\alpha = 0.05$ level and the lower 95% confidence limit is larger than $\theta_0 = 0$. The p-value, unbiased median estimate, and lower confidence limit depend on the ordering of the sample space (k, z), where k is the stage number and z is the standardized Z statistic. With

the specified stagewise ordering, the p-value is $p_1 + p_2$, where p_1 is the α spending at stage 1,

$$p_1 = P_{\theta=0}(Z_1\sqrt{I_1} \geq 4.71422) = 0.00915$$

$$p_2 = P_{\theta=0}(Z_2\sqrt{I_2} \geq 7.31365 \mid -1.04069 < Z_1\sqrt{I_1} < 4.71422)$$

where Z_k is a standardized normal variate and I_k is the information level at stage k for $k = 1, 2$.

Example 81.7: Testing an Effect in a Proportional Hazards Regression Model

This example compares two survival distributions for the treatment effect. The example uses a power family method to generate two-sided asymmetric boundaries and then uses a proportional hazards regression model to test the hypothesis with a covariate.

A clinic is conducting a clinical study for the effect of a new cancer treatment. The study consists of mice exposed to a carcinogen and randomized to either the control group or the treatment group. The event of interest is the death from cancer induced by the carcinogen, and the response is the time from randomization to death.

Consider the proportional hazards regression model

$$h(t;\ \text{TrtGp},\ \text{Wgt}) = h_0(t)\ \exp(\beta_g\ \text{TrtGp}\ +\ \beta_w \text{Wgt})$$

where $h_0(t)$ is an arbitrary and unspecified baseline hazard function, TrtGp is the grouping variable for the two groups, Wgt is the initial weight of the mice, and β_g and β_w are the regression parameters associated with the variables TrtGp and Wgt, respectively. The grouping variable has the value 0 for each mouse in the control group and the value 1 for each mouse in the treatment group.

The hypothesis $H_0 : \beta_g = 0$ with an alternative hypothesis $H_1 : \beta_g \neq 0$ is used for the study.

Suppose that from past experience, the median survival time for the control group is $t_0 = 20$ weeks. The study would like to detect a $t_1 = 40$ weeks median survival time with a 80% power in the trial. Assuming exponential survival functions for the two groups, the hazard rates can be computed from

$$S_j(t_j) = e^{-h_j t_j} = \frac{1}{2}$$

where $j = 0, 1$.

Thus, with the hazard rates $h_0 = 0.03466$ and $h_1 = 0.01733$, the hazard ratio $\exp(\beta_g) = h_1/h_0 = 1/2$ and the alternative hypothesis

$$\beta_{g1} = \log(\frac{1}{2}) = -0.69315$$

Following the derivations in the section "Test for a Parameter in the Proportional Hazards Regression Model" in the chapter "The SEQDESIGN Procedure," the required number of events for testing a parameter in $\boldsymbol{\beta}$ is given by

$$D_X = I_X \frac{1}{(1 - r_x^2)\ \sigma_x^2}$$

where σ_x^2 is the variance of TrtGp and r_x^2 is the proportion of variance of TrtGp explained by the variable Wgt.

If the two groups have the same number of mice in the study, then the MLE of the variance is $\hat{\sigma}_x^2 = 0.25$. Further, if $r_x^2 = 0.10$, then you can specify the MODEL=PHREG(XVARIANCE=0.25 XRSQUARE=0.10) option in the SAMPLESIZE statement in the SEQDESIGN procedure to compute the required number of events and the individual number of events at each stage.

The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design for normally distributed data. The design uses a two-sided alternative hypothesis with early stopping to reject the null hypothesis H_0. A power family method is used to derive the boundaries.

```
ods graphics on;
proc seqdesign altref=0.69315;
   TwoSidedPowerFamily: design method=pow
                               nstages=4
                               alpha=0.075(lower=0.025)
                               beta=0.20;
   samplesize model=phreg( xvariance=0.25 xrsquare=0.10
                           hazard=0.02451 accrate=10);
run;
ods graphics off;
```

The ALPHA=0.075(LOWER=0.025) option specifies a lower α level 0.025 for the lower rejection boundary and an upper α level $0.05 = 0.075 - 0.025$ for the upper rejection boundary. The geometric average hazard $\sqrt{h_0 \times h_1} = \sqrt{0.03466 \times 0.01733} = 0.02451$ is used in the HAZARD= option in the SAMPLESIZE statement to compute the required sample size. The specified ACCRATE=10 option indicates that 10 mice will be accrued each week and the resulting minimum and maximum accrual times will be displayed.

The "Design Information" table in Output 81.7.1 displays the design specifications and the derived statistics.

Output 81.7.1 Design Information

The SEQDESIGN Procedure
Design: TwoSidedPowerFamily

Design Information

Statistic Distribution	Normal
Boundary Scale	Standardized Z

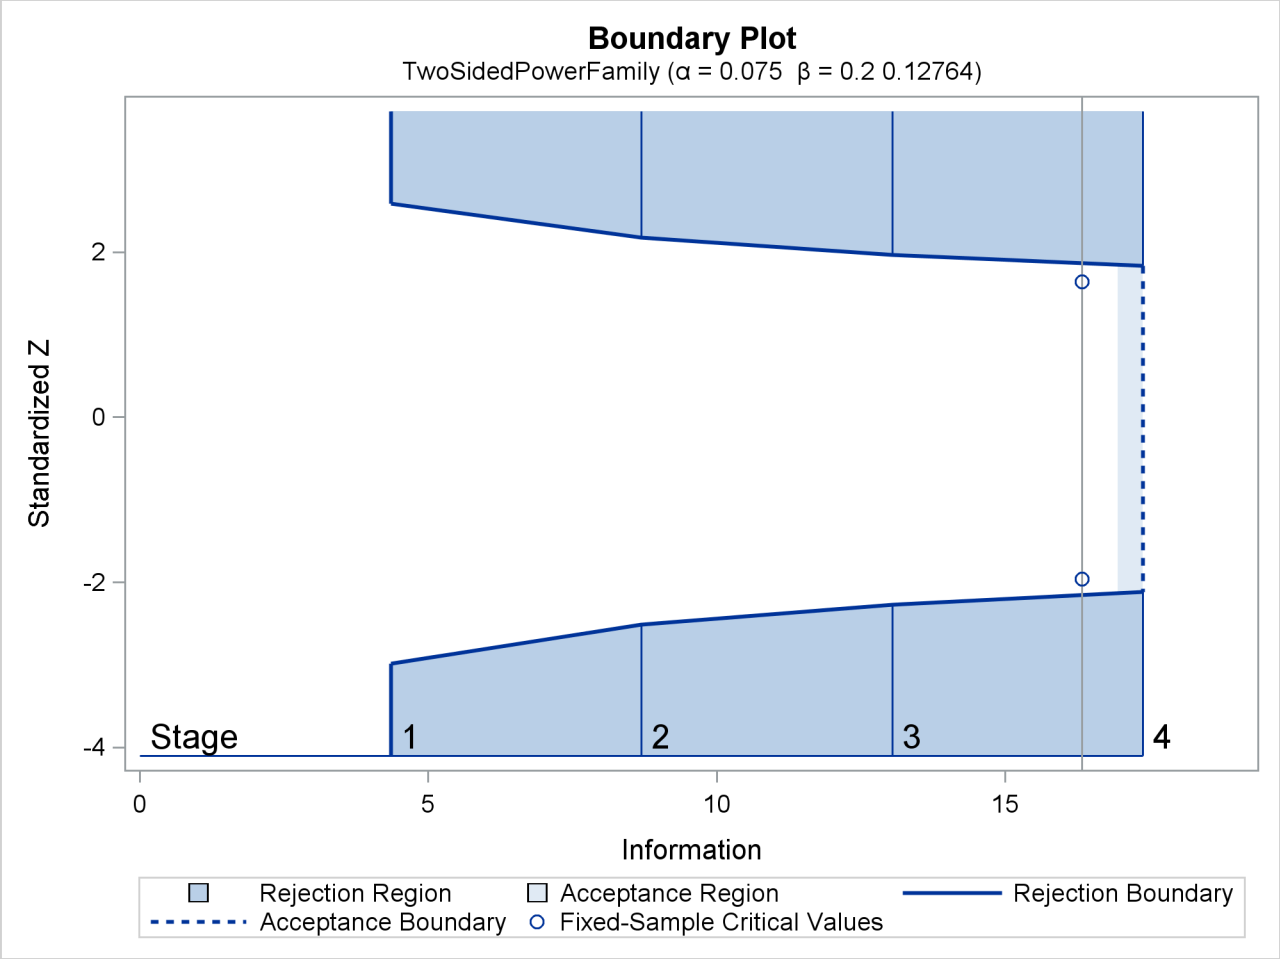
2	-2.51320	2.17917
3	-2.27093	1.96910
4	-2.11334	1.83246

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 81.7.3.

Output 81.7.3 Boundary Plot



With the MODEL=PHREG option in the SAMPLESIZE statement, the "Sample Size Summary" table in Output 81.7.4 displays the parameters used in the sample size computation for the proportional hazards regression model.

Output 81.7.4 Required Sample Size Summary

Sample Size Summary

Test	PH Reg Parameter
Parameter	0.69315
X Variance	0.25
R Square (X)	0.1
Hazard Rate	0.02451
Accrual Rate	10
Min Accrual Time	7.73017
Min Sample Size	77.3017
Max Accrual Time	27.97872
Max Sample Size	279.7872
Max Number of Events	77.3017

With a minimum accrual time of 7.73 weeks and maximum accrual time of 27.98 weeks, an accrual time of 20 weeks is used in the study. The "Numbers of Events" table in Output 81.7.5 displays the required numbers of events for the group sequential clinical trial.

Output 81.7.5 Required Sample Sizes

Numbers of Events (D)
Z Test for PH Regression Parameter

Stage	D	Information
1	19.33	4.3482
2	38.65	8.6964
3	57.98	13.0447
4	77.30	17.3929

The following statements invoke the SEQDESIGN procedure and provide more detailed sample size information with a 20-week accrual time:

```
proc seqdesign altref=0.69315;
   TwoSidedPowerFamily: design method=pow
                               nstages=4
                               alpha=0.075(lower=0.025)
                               beta=0.20;
   samplesize model=phreg( xvariance=0.25 xrsquare=0.10
                           hazard=0.02451
                           accrate=10 acctime=20);
ods output Boundary=Bnd_Time;
run;
```

The ODS OUTPUT statement with the BOUNDARY=BND_TIME option creates an output data set named BND_TIME which contains the resulting boundary information for the subsequent sequential tests.

With an accrual time of 20 weeks, the "Sample Size Summary" table in Output 81.7.6 displays the follow-up time for the trial.

Output 81.7.6 Sample Size Summary

The SEQDESIGN Procedure
Design: TwoSidedPowerFamily

Sample Size Summary

Test	PH Reg Parameter
Parameter	0.69315
X Variance	0.25
R Square (X)	0.1
Hazard Rate	0.02451
Accrual Rate	10
Accrual Time	20
Follow-up Time	10.34195
Total Time	30.34195
Max Number of Events	77.3017
Max Sample Size	200
Expected Sample Size (Null Ref)	199.4282
Expected Sample Size (Alt Ref)	188.6561

The "Numbers of Events and Sample Sizes" table in Output 81.7.7 displays the required sample sizes for the group sequential clinical trial.

Output 81.7.7 Numbers of Events and Sample Sizes

Numbers of Events (D) and Sample Sizes (N)
Z Test for PH Regression Parameter

2	41.90	20	200.00	9.4281
3	60.14	25	200.00	13.5309
4	79.26	31	200.00	17.8346

Thus, the study will perform three interim analyses after 14, 20, and 25 weeks and a final analysis after 31 weeks if the study does not stop at any of the interim analyses.

Suppose 140 mice are available for the first interim analysis after week 14. Output 81.7.8 lists the first 10 observations in the data set weeks_1.

Output 81.7.8 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	Trt Gp	Event	Wgt	Weeks
1	0	0	22.1659	12
2	1	0	28.4458	12
3	0	0	26.2857	12
4	1	0	25.0283	12
5	0	0	21.5114	12
6	1	0	23.2240	12
7	0	1	22.6845	6
8	1	0	27.9292	12
9	0	0	22.5514	12
10	1	1	27.3793	11

The TrtGp variable is a grouping variable with the value 0 for a mouse in the placebo control group and the value 1 for a mouse in the treatment group.

The Weeks variable is the survival time variable measured in weeks and the Event variable is the censoring variable with the value 0 indicating censoring. That is, the values of Weeks are considered censored if the corresponding values of Event are 0; otherwise, they are considered as event times.

The following statements use the PHREG procedure to estimate the treatment effect after adjusting for the Wgt variable at stage 1:

```
proc phreg data=Time_1;
   model Weeks*Event(0)= TrtGp Wgt;
ods output parameterestimates=Parms_Time1;
run;
```

The following statements create and display (in Output 81.7.9) the data set for the treatment effect MLE statistic and its associated standard error. Note that for a MLE statistic, the inverse of the variance of the statistic is the information.

```
data Parms_Time1;
   set Parms_Time1;
   if Parameter='TrtGp';
   _Scale_='MLE';
   _Stage_= 1;
   keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;

proc print data=Parms_Time1;
   title 'Statistics Computed at Stage 1';
run;
```

Output 81.7.9 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	Parameter	Estimate	StdErr	_Scale_	_Stage_
1	TrtGp	0.00836	0.46588	MLE	1

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Time
             Parms(Testvar=TrtGp)=Parms_Time1
             infoadj=prop
             order=lr
             ;
ods output Test=Test_Time1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS_TIME1 option specifies the input data set PARMS_TIME1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRTGP option identifies the test variable TRTGP in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The ORDER=LR option uses the LR ordering to derive the p-value, the unbiased median estimate, and the confidence limits for the regression slope estimate.

The ODS OUTPUT statement with the TEST=TEST_TIME1 option creates an output data set named TEST_TIME1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.7.10 displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I α level. The maximum information and the power have been modified for the new information levels.

Output 81.7.10 Design Information

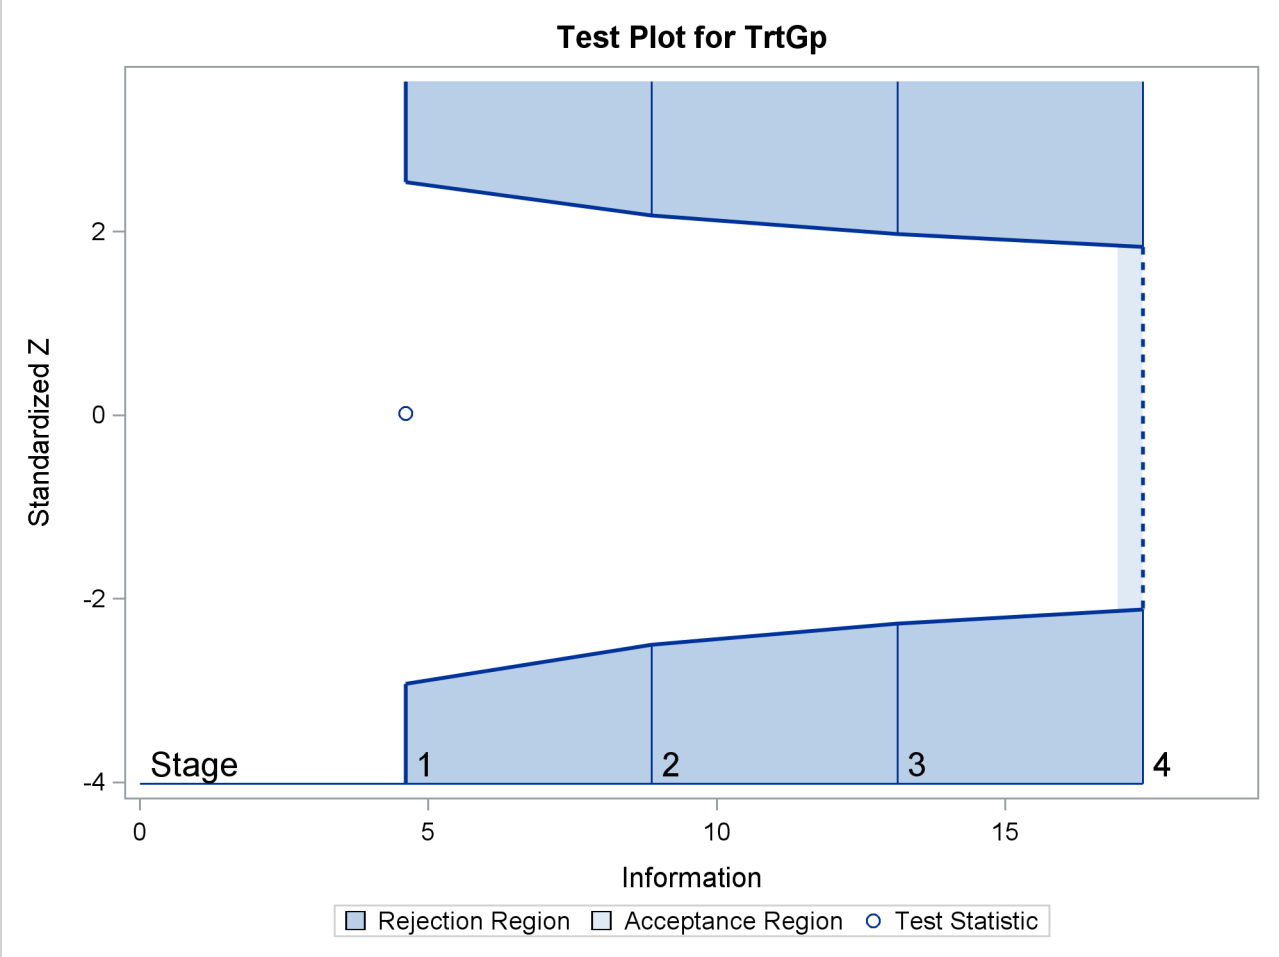
2	.	
3	.	
4	.	

With the INFOADJ=PROP option (which is the default), the information levels at interim stages 2 and 3 are derived proportionally from the information levels in the BOUNDARY= data set. At stage 1, the standardized Z statistic 0.01795 is between the lower and upper α boundary values of -2.92457 and 2.54086, so the trial continues to the next stage.

Note that the observed information level 4.6073 corresponds to a proportion of 0.2649 in the information level. If the observed information level is much larger than the target proportion of 0.25, then you can decrease the accrual rate, accrual time, or follow-up time to achieve target information levels for subsequent stages. These modifications should be specified in the study plan before the study begins.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in Output 81.7.12. As expected, the test statistic is in the continuation region between the lower and upper α boundary values.

Output 81.7.12 Sequential Test Plot



The following statements use the PHREG procedure to compute the MLE statistic and its associated standard error at stage 2:

```
proc phreg data=Time_2;
   model Weeks*Event(0)= TrtGp Wgt;
ods output parameterestimates= Parms_Time2;
run;
```

The following statements create the data set for the MLE statistic and its associated standard error at stage 2:

```
data Parms_Time2;
   set Parms_Time2;
   if Parameter='TrtGp';
   _Scale_='MLE';
   _Stage_= 2;
   keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;
```

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
proc seqtest Boundary=Test_Time1
             Parms(Testvar=TrtGp)=Parms_Time2
             infoadj=prop
             order=lr
             ;
ods output Test=Test_Time2;
run;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST_TIME2 option creates an output data set named TEST_TIME2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Test Information" table in Output 81.7.13 displays the boundary values for the test statistic with the MLE statistic scale. At stage 2, the standardized Z statistic -0.43552 is between the lower α and upper boundary values, -2.47689 and 2.14819, respectively, so the trial continues to the next stage.

Output 81.7.13 Sequential Tests

The SEQTEST Procedure

Test Information (Standardized Z Scale)

Since the data set PARMS_Time2 contains the test information only at stage 2, the information level at stage 1 in the TEST_Time1 data set is used to generate boundary values for the test.

Similarly, the test statistic at stage 3 is also between its corresponding lower and upper α boundary values. The trial continues to the next stage.

The following statements use the PHREG procedure to compute the MLE statistic and its associated standard error at the final stage:

```
proc phreg data=Time_4;
   model Weeks*Event(0)= TrtGp Wgt;
ods output parameterestimates= Parms_Time4;
run;
```

The following statements create and display (in Output 81.7.14) the data set for the MLE statistic and its associated standard error at each stage of the study:

```
data Parms_Time4;
   set Parms_Time4;
   if Parameter='TrtGp';
   _Scale_='MLE';
   _Stage_= 4;
   keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;
proc print data=Parms_Time4;
   title 'Statistics Computed at Stage 4';
run;
```

Output 81.7.14 Statistics Computed at Stage 4

Statistics Computed at Stage 4

Obs	Parameter	Estimate	StdErr	_Scale_	_Stage_
1	TrtGp	-0.04451	0.23971	MLE	4

The following statements invoke the SEQTEST procedure to test the hypothesis at stage 4:

```
ods graphics on;
proc seqtest Boundary=Test_Time3
             Parms(Testvar=TrtGp)=Parms_Time4
             order=lr
             ;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 4, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 4, and the TESTVAR= option identifies the test variable in the data set.

The "Test Information" table in Output 81.7.15 displays the boundary values for the test statistic. The standardized test statistic -0.1857 is between the lower and upper α boundary values of -2.10447 and 1.82112, respectively, so the study stops and accepts the null hypothesis. That is, there is no evidence of reduction in hazard rate for the new treatment.

Output 81.7.15 Sequential Tests

The SEQTEST Procedure

Test Information (Standardized Z Scale)
Null Reference = 0

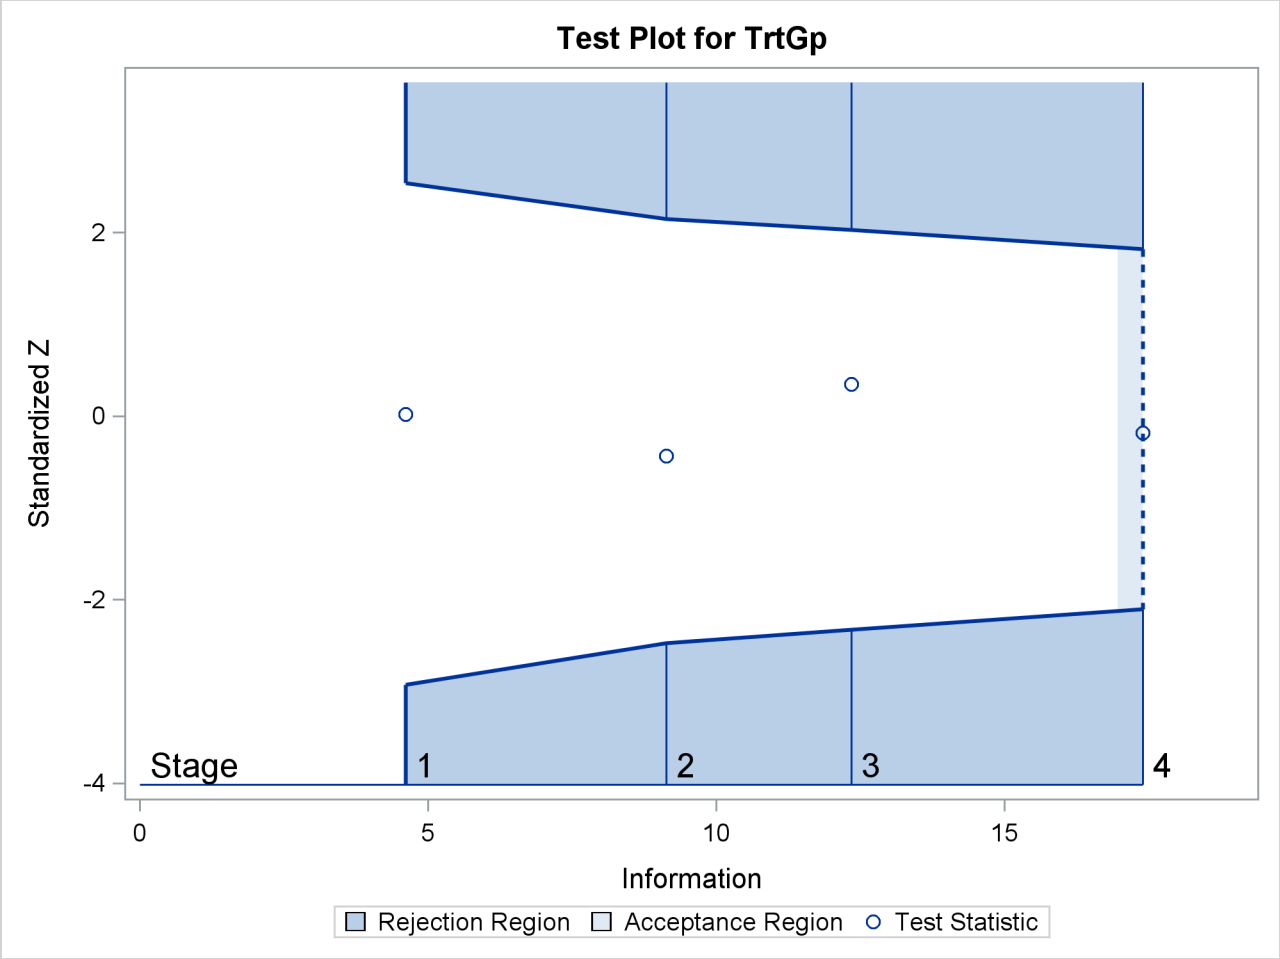
The "Test Plot" displays boundary values of the design and the test statistic at the first two stages, as shown in Output 81.7.16. It also shows that the test statistic is in the "Acceptance Region" between the lower and upper α boundary values at stage 4.

Output 81.7.16 Sequential Test Plot



After the stopping of a trial, the "Parameter Estimates" table in Output 81.7.17 displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and p-value under the null hypothesis $H_0 : \theta = 0$.

Output 81.7.17 Parameter Estimates

Parameter Estimates
LR Ordering

Parameter	Stopping Stage	MLE	p-Value for H0:Parm=0	Median Estimate
TrtGp	4	-0.044514	0.8525	-0.044577

Parameter Estimates
LR Ordering

Parameter	95% Confidence Limits	
TrtGp	-0.51461	0.42538

As expected, the two-sided p-value 0.8525 is not significant at the lower $\alpha = 0.025$ level and the upper $\alpha = 0.05$ level, and the two-sided 95% confidence interval contains the null value zero. The p-value, unbiased median estimate, and lower confidence limit depend on the ordering of the sample space (k, z), where k is the stage number and z is the standardized Z statistic. With the specified LR ordering, the two-sided p-value is derived from the one-sided p-value

$$p_u = \sum_{k=1}^{4} P_{\theta=0}\left(Z_k \geq z_4 \mid \_a_{k'} < Z_{k'} < a_{k'}, k' < k\right)$$

where $z_4 = -0.1857$ is the observed test statistic at stage 4, Z_k is a standardized normal variate at stage k, and $\_a_{k'}$ and $a_{k'}$ are the stage k lower and upper rejection boundary values, respectively.

Thus,

$$p_u = \alpha_u + P_{\theta=0}\left(z_4 \leq Z_4 < a_4 \mid \_a_{k'} < Z_{k'} < a_{k'}, k' < 4\right)$$

where $\alpha_u = 0.05$ is the upper α level and $a_4 = 1.82112$.

Since $P_{\theta=0}\left(z_4 \leq Z_4 \leq a_4 \mid \_a_{k'} < Z_{k'} < a_{k'}, k' < 4\right) = 0.52374$, $p_u = 0.05 + 0.52374 = 0.57374$, which is greater than 0.50. Thus, the two-sided p-value is given by $2 \times (1.0 - p_u) = 0.8525$.

Example 81.8: Testing an Effect in a Logistic Regression Model

This example requests a two-sided test for the dose effect in a dose-response model (Whitehead 1997, pp. 262–263). Consider the logistic regression model

$$\text{logit}(p) = \log\left(\frac{p}{1-p}\right) = \beta_0 + \beta_1 \,\text{LDose}$$

where $p = \text{Prob}(\text{Resp} = 1 \mid \text{LDose})$ is the response probability to be modeled for the binary response Resp and LDose = log(Dose +1) is the covariate. The dose levels are 0 for the control group, and they are 1, 3, and 6 for the three treatment groups.

Following the derivations in the section "Test for a Parameter in the Logistic Regression Model" in the chapter "The SEQDESIGN Procedure," the required sample size can be derived from

$$N = I_X \, \frac{\sigma_y^2}{(1 - r_x^2)\,\sigma_x^2}$$

where σ_y^2 is the variance of the response variable in the logistic regression model, r_x^2 is the proportion of variance of LDose explained by other covariates, and σ_x^2 is the variance of LDose.

Since LDose is the only covariate in the model, $r_x^2 = 0$. For a logistic model, the variance σ^2 can be estimated by

$$\sigma_y^2 = \frac{1}{\hat{p}(1-\hat{p})}$$

where $\hat{p}$ is the estimated probability of the response variable Resp. Thus, the sample size can be computed as

$$N = I_X \, \frac{1}{p(1-p)} \, \frac{1}{\sigma_x^2}$$

The null hypothesis $H_0 : \beta_1 = 0$ corresponds to no treatment effect. Suppose that the alternative hypothesis $H_1 : \beta_1 = 0.5$ is the reference improvement that should be detected at a 0.90 level.

Note that $\beta_1 = 0.5$ corresponds to an odds ratio of 2 between the treatment group with dose level 3 and the control group. The log odds ratio between the two groups is

$$\log\left(\frac{p_t(1-p_c)}{(1-p_t)p_0}\right) = \log\left(\frac{p_t}{1-p_t}\right) - \log\left(\frac{p_c}{1-p_c}\right)$$

which corresponds to

$$(\beta_0 + \beta_1 \log(3+1)) \; - \; (\beta_0 + \beta_1 \log(1)) = \beta_1 \log(4) = \log(2)$$

If the same number of patients are assigned in each of the four groups, then the MLE of the variance of LDose is $\hat{\sigma}_x^2 = 0.5345$. Further, if the response rate is 0.40, then the required sample size can be derived using the SAMPLESIZE statement in the SEQDESIGN procedure.

The following statements invoke the SEQDESIGN procedure and request a three-stage group sequential design for normally distributed data. The design has a null hypothesis of no treatment effect $H_0 : \beta_1 = 0$ with early stopping to reject the null hypothesis with a two-sided alternative hypothesis $H_1 : \beta_1 = \pm 0.5$.

```
ods graphics on;
proc seqdesign altref=0.5;
   TwoSidedErrorSpending: design method=errfuncpow
                                method(loweralpha)=errfuncpow(rho=1)
                                method(upperalpha)=errfuncpow(rho=3)
                                nstages=3
                                stop=both;
   samplesize model=logistic( prop=0.4 xvariance=0.5345);
ods output Boundary=Bnd_Dose;
run;
ods graphics off;
```

The ODS OUTPUT statement with the BOUNDARY=BND_DOSE option creates an output data set named BND_DOSE which contains the resulting boundary information for the subsequent sequential tests.

The "Design Information" table in Output 81.8.1 displays design specifications and derived statistics. Since the alternative reference is specified, the maximum information 47.22445 is derived.

Output 81.8.1 Error Spending Design Information

The SEQDESIGN Procedure
Design: TwoSidedErrorSpending

Design Information

Statistic Distribution	Normal

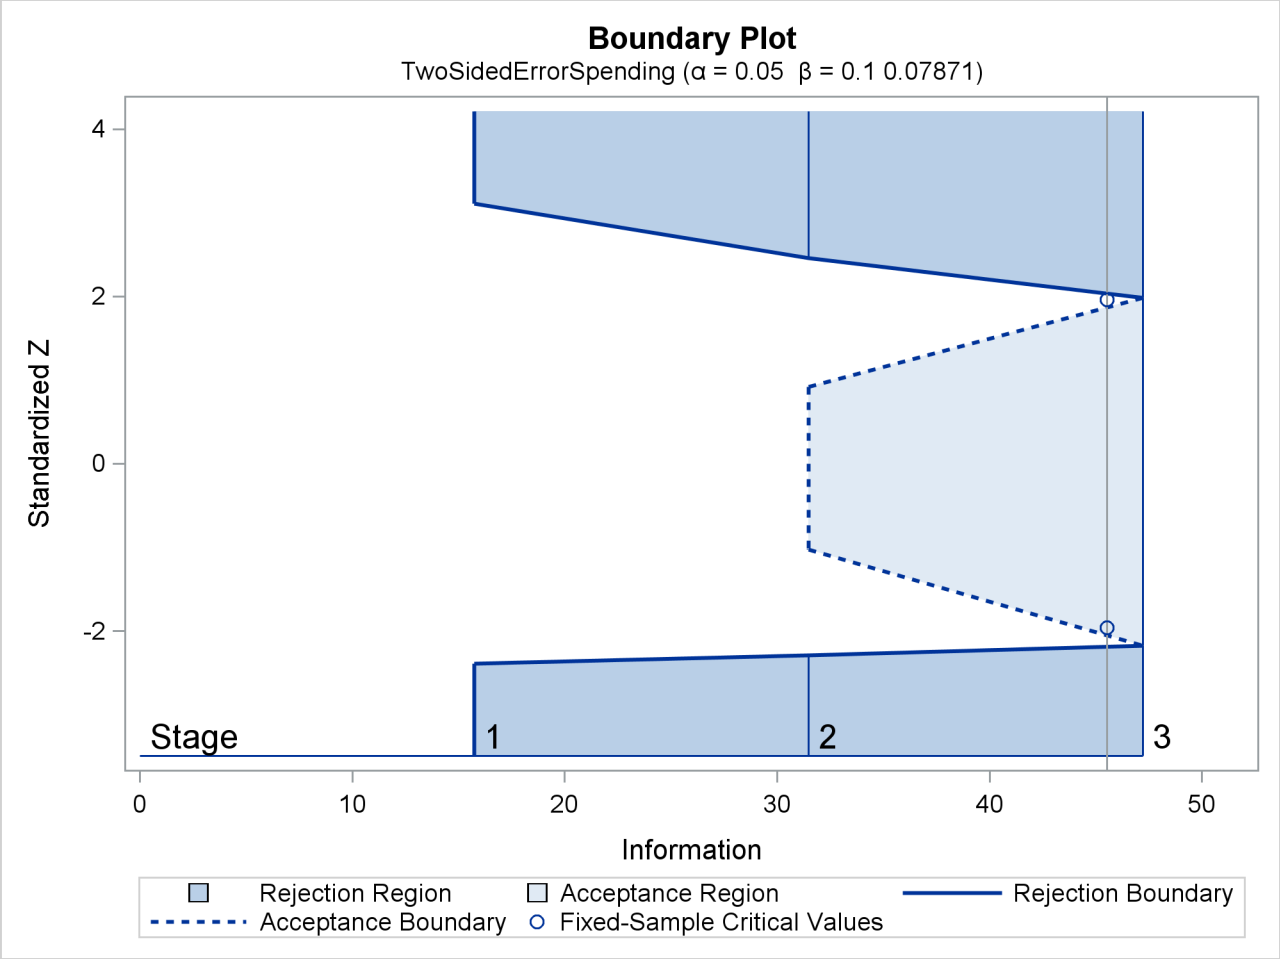
3	-2.17479	-2.17479	1.98311	1.98311

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 81.8.3.

Output 81.8.3 Boundary Plot



With the SAMPLESIZE statement, the "Sample Size Summary" table in Output 81.8.4 displays the parameters for the sample size computation.

Output 81.8.4 Required Sample Size Summary

Sample Size Summary

Test	Logistic Reg Parameter
Parameter	0.5
Proportion	0.4
X Variance	0.5345
R Square (X)	0
Max Sample Size	368.1357
Expected Sample Size (Null Ref)	282.0807
Expected Sample Size (Alt Ref)	270.4058

The "Sample Sizes" table in Output 81.8.5 displays the required sample sizes for the group sequential clinical trial.

Output 81.8.5 Required Sample Sizes

Sample Sizes (N)
Z Test for Logistic Regression Parameter

	Fractional N		Ceiling N	
Stage	N	Information	N	Information
1	122.71	15.7415	123	15.7784
2	245.42	31.4830	246	31.5569
3	368.14	47.2245	369	47.3353

That is, 123 new patients are needed in each stage and the number is rounded up to 124 for each stage to have a multiple of four for the four dose levels in the trial. Note that since the sample sizes are derived from an estimated response probability and are rounded up, the actual information levels might not match the corresponding target information levels.

Output 81.8.6 lists the first 10 observations of the trial data.

Output 81.8.6 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	Resp	Dose	LDose
1	0	0	0.00000
2	0	1	0.69315
3	1	3	1.38629
4	1	6	1.94591
5	1	0	0.00000
6	1	1	0.69315
7	1	3	1.38629
8	1	6	1.94591
9	0	0	0.00000
10	0	1	0.69315

The following statements use the LOGISTIC procedure to estimate the slope β_1 and its associated standard error at stage 1:

```
proc logistic data=Dose_1;
   model Resp(event='1')= LDose;
   ods output ParameterEstimates=Parms_Dose1;
run;
```

The following statements create and display (in Output 81.8.7) the input data set that contains slope β_1 and its associated standard error for the SEQTEST procedure:

```
data Parms_Dose1;
   set Parms_Dose1;
   if Variable='LDose';
   _Scale_='MLE';
   _Stage_= 1;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_Dose1;
   title 'Statistics Computed at Stage 1';
run;
```

Output 81.8.7 Statistics Computed at Stage 1

Statistics Computed at Stage 1

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	LDose	0.5741	0.2544	MLE	1

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Dose
             Parms(testvar=LDose)=Parms_Dose1
             infoadj=prop
             order=mle
             boundaryscale=mle
             ;
ods output Test=Test_Dose1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS_DOSE1 option specifies the input data set PARMS_DOSE1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=LDOSE option identifies the test variable LDOSE in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The ORDER=MLE option uses the MLE ordering to derive the p-value, the unbiased median estimate, and the confidence limits for the regression slope estimate.

The ODS OUTPUT statement with the TEST=TEST_DOSE1 option creates an output data set named TEST_DOSE1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.8.8 displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information

levels to maintain the Type I α level. The maximum information remains the same as the design stored in the BOUNDARY= data set, but the derived Type II error probability β and power $1-\beta$ are different because of the new information levels.

Output 81.8.8 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.BND_DOSE
Data Set	WORK.PARMS_DOSE1
Statistic Distribution	Normal
Boundary Scale	MLE
Alternative Hypothesis	Two-Sided
Early Stop	Accept/Reject Null
Number of Stages	3
Alpha	0.05
Beta (Lower)	0.09992
Beta (Upper)	0.07871
Power (Lower)	0.90008
Power (Upper)	0.92129
Max Information (Percent of Fixed Sample)	103.7231
Max Information	47.2244524
Null Ref ASN (Percent of Fixed Sample)	79.45049
Lower Alt Ref ASN (Percent of Fixed Sample)	66.05269
Upper Alt Ref ASN (Percent of Fixed Sample)	76.24189

The "Test Information" table in Output 81.8.9 displays the boundary values for the test statistic with the specified MLE scale.

Output 81.8.9 Sequential Tests

Test Information (MLE Scale)
Null Reference = 0

	Information Level		Alternative Reference	
Stage	Proportion	Actual	Lower	Upper
1	0.3272	15.45062	-0.50000	0.50000
2	0.6636	31.33753	-0.50000	0.50000
3	1.0000	47.22445	-0.50000	0.50000

Test Information (MLE Scale)
Null Reference = 0

	Boundary Values				Test	
	Lower		Upper		LDose	
Stage	Alpha	Beta	Beta	Alpha	Estimate	Action
1	-0.61078	.	.	0.79337	0.57409	Continue
2	-0.40974	-0.18169	0.16222	0.44033	.	
3	-0.31633	-0.31633	0.28860	0.28860	.	

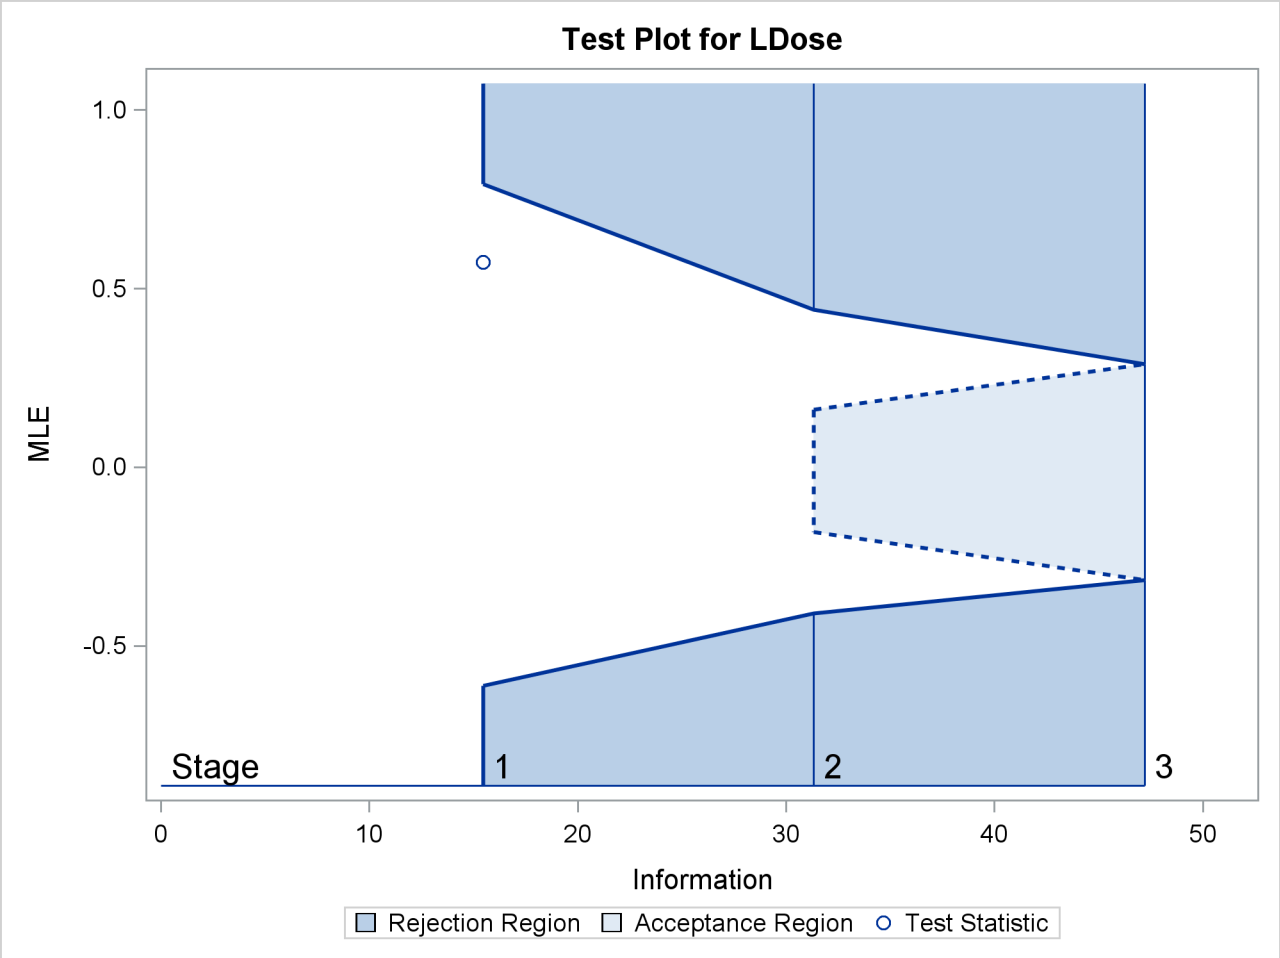
The information level at stage 1 is derived from the standard error s_1 in the PARMS= data set,

$$I_1 = \frac{1}{s_1^2} = \frac{1}{0.2544^2} = 15.45$$

With the INFOADJ=PROP option (which is the default), the information level at stage 2 is derived proportionally from the observed information at stage 1 and the information levels in the BOUNDARY= data set. At stage 1, the β boundary values are missing and there is no early stopping to accept H_0. The MLE statistic 0.57409 is between the lower and upper α boundaries, so the trial continues to the next stage.

With ODS Graphics enabled, a boundary plot with the boundary values and test statistics is displayed, as shown in Output 81.8.10. As expected, the test statistic is in the continuation region below the upper alpha boundary.

Output 81.8.10 Sequential Test Plot



The following statements use the LOGISTIC procedure to estimate the slope β_1 and its associated standard error at stage 2:

```
proc logistic data=dose_2;
   model Resp(event='1')=LDose;
   ods output ParameterEstimates=Parms_Dose2;
run;
```

The following statements create and display (in Output 81.8.11) the input data set that contains slope β_1 and its associated standard error at stage 2 for the SEQTEST procedure:

```
data Parms_Dose2;
   set Parms_Dose2;
   if Variable='LDose';
   _Scale_='MLE';
   _Stage_= 2;
   keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_Dose2;
   title 'Statistics Computed at Stage 2';
run;
```

Output 81.8.11 Statistics Computed at Stage 2

Statistics Computed at Stage 2

Obs	Variable	Estimate	StdErr	_Scale_	_Stage_
1	LDose	0.5213	0.1788	MLE	2

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Dose1
             Parms(Testvar=LDose)=Parms_Dose2
             infoadj=prop
             order=mle
             boundaryscale=mle
             rci
             plots=rci
             ;
ods output Test=Test_Dose2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ORDER=MLE option uses the MLE ordering to derive the p-value, unbiased median estimate, and confidence limits for the regression slope estimate.

The ODS OUTPUT statement with the TEST=TEST_DOSE2 option creates an output data set named TEST_DOSE2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in Output 81.8.12 displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I α level.

Output 81.8.12 Design Information

The SEQTEST Procedure

Design Information

BOUNDARY Data Set	WORK.TEST_DOSE1
Data Set	WORK.PARMS_DOSE2
Statistic Distribution	Normal
Boundary Scale	MLE
Alternative Hypothesis	Two-Sided
Early Stop	Accept/Reject Null
Number of Stages	3
Alpha	0.05
Beta (Lower)	0.0999
Beta (Upper)	0.07871
Power (Lower)	0.9001
Power (Upper)	0.92129
Max Information (Percent of Fixed Sample)	103.7227
Max Information	47.2244524
Null Ref ASN (Percent of Fixed Sample)	79.44086
Lower Alt Ref ASN (Percent of Fixed Sample)	66.04641
Upper Alt Ref ASN (Percent of Fixed Sample)	76.22739

The information is derived from the standard error associated with the slope estimate at the final stage and is larger than the target level. The derived Type II error probability β and power $1-\beta$ are different because of the new information levels.

The "Test Information" table in Output 81.8.13 displays the boundary values for the test statistic with the specified MLE scale. The information levels are derived from the standard errors in the PARMS= data set. At stage 2, the slope estimate 0.52128 is larger than 0.44091, the upper α boundary value, the trial stops to reject the null hypothesis of no treatment effect.

Output 81.8.13 Sequential Tests

Test Information (MLE Scale)
Null Reference = 0

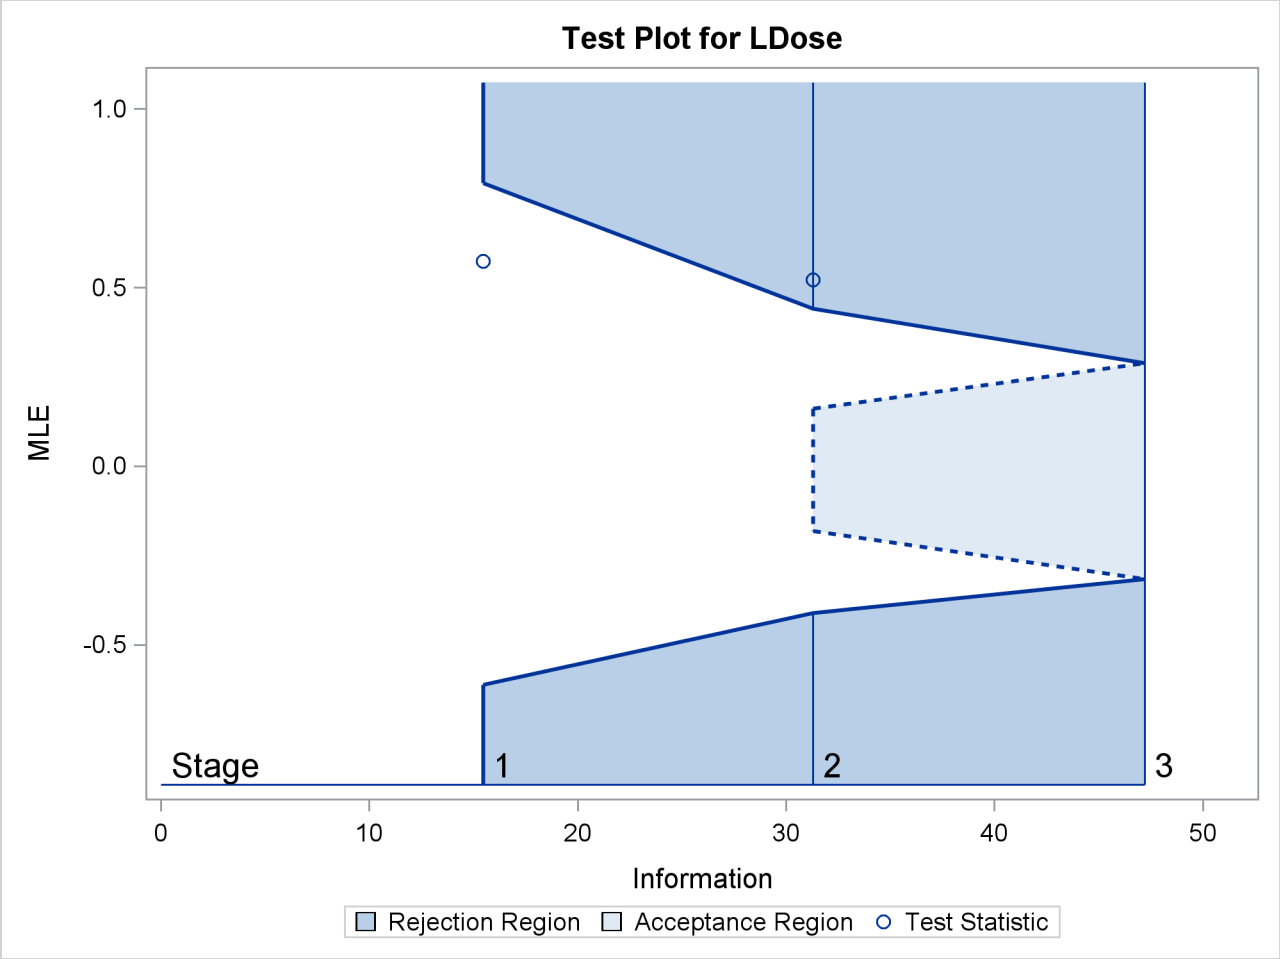
Stage	---Information Level-- Proportion	Actual	-------Alternative------ --------Reference------- Lower	Upper
1	0.3272	15.45062	−0.50000	0.50000
2	0.6624	31.28346	−0.50000	0.50000
3	1.0000	47.22445	−0.50000	0.50000

Test Information (MLE Scale)
Null Reference = 0

	----------Boundary Values---------- ---------Lower---------		---------Upper---------		----------Test--------- ---------LDose---------	
Stage	Alpha	Beta	Beta	Alpha	Estimate	Action
1	−0.61078	.	.	0.79337	0.57409	Continue
2	−0.41028	−0.18112	0.16166	0.44091	0.52128	Reject Null
3	−0.31628	−0.31628	0.28861	0.28861	.	

With ODS Graphics enabled, a boundary plot with the boundary values and test statistics is displayed, as shown in Output 81.8.14. As expected, the test statistic is above the upper α boundary in the upper rejection region at stage 2.

Output 81.8.14 Sequential Test Plot



After a trial is stopped, the "Parameter Estimates" table in Output 81.8.15 displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and the p-value under the null hypothesis $H_0 : \beta_1 = 0$.

Output 81.8.15 Parameter Estimates

Parameter Estimates
MLE Ordering

Parameter	Stopping Stage	MLE	p-Value for H0:Parm=0	Median Estimate
LDose	2	0.521275	0.0050	0.502647

Parameter Estimates
MLE Ordering

Parameter	95% Confidence Limits	
LDose	0.15745	0.85154

With the ORDER=MLE option, the MLE ordering is used to compute the p-value, unbiased median estimate, and confidence limits. As expected, the p-value 0.005 is significant at the $\alpha = 0.05$ level and the confidence interval does not contain the null reference zero.

With the RCI option, the "Repeated Confidence Intervals" table in Output 81.8.16 displays repeated confidence intervals for the parameter. For a two-sided test, since the rejection lower repeated confidence limit 0.0804 is greater than the null reference zero, the trial is stopped to reject the hypothesis.

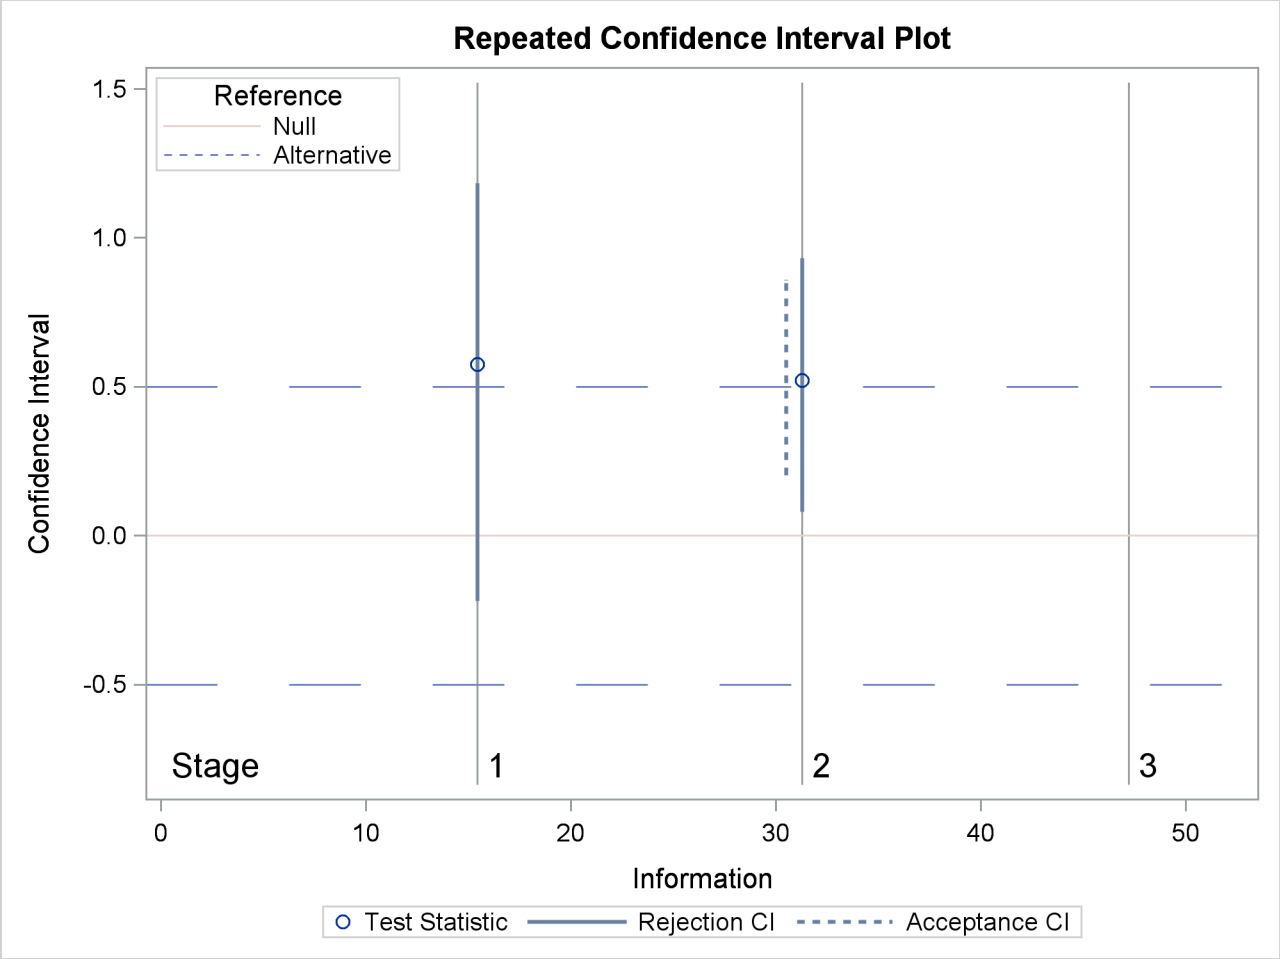
Output 81.8.16 Repeated Confidence Intervals

Repeated Confidence Intervals

Stage	Information Level	Parameter Estimate	-Rejection Boundary- Lower 97.5% Repeated CL	-Rejection Boundary- Upper 97.5% Repeated CL	-Acceptance Boundary- Lower 90.01% Repeated CL	-Acceptance Boundary- Upper 92.13% Repeated CL
1	15.4506	0.57409	-0.2193	1.1849	.	.
2	31.2835	0.52128	0.0804	0.9316	0.2024	0.8596

With the PLOTS=RCI option, the "Repeated Confidence Intervals Plot" displays repeated confidence intervals for the parameter, as shown in Output 81.8.17. It shows that the null reference zero is inside the rejection repeated confidence interval at stage 1 but outside the rejection repeated confidence interval at stage 2. This implies that the study stops at stage 2 to reject the hypothesis.

Output 81.8.17 Repeated Confidence Intervals Plot



Note that the hypothesis is accepted if at any stage, the acceptance repeated confidence interval falls within the interval $(-0.5, 0.5)$ of the alternative references.

Chapter 82

The SIM2D Procedure

Contents

Overview: SIM2D Procedure

The SIM2D procedure uses an LU decomposition technique to produce a spatial simulation for a Gaussian random field with a specified mean and covariance structure in two dimensions.

The simulation can be conditional or unconditional. If it is conditional, a set of coordinates and associated field values are read from a SAS data set. The resulting simulation honors these data values.

You can specify the mean structure as a quadratic function in the coordinates. Specify the semivariance by naming the form and supplying the associated parameters, or by using the contents of an item store file that was previously created by PROC VARIOGRAM.

PROC SIM2D can handle anisotropic and nested semivariogram models. Seven covariance models are supported: Gaussian, exponential, spherical, cubic, pentaspherical, sine hole effect, and Matérn. A single nugget effect is also supported.

You can specify the locations of simulation points in a GRID statement, or they can be read from a SAS data set. The grid specification is most suitable for a regular grid; the data set specification can handle any irregular pattern of points.

The SIM2D procedure writes the simulated values for each grid point to an output data set. The SIM2D procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." For more information about the graphics available in PROC SIM2D, see the section "ODS Graphics" on page 7108.

Introduction to Spatial Simulation

The purpose of spatial simulation is to produce a set of partial realizations of a spatial random field (SRF) $Z(\boldsymbol{s}), \boldsymbol{s} \in D \subset \mathcal{R}^2$ in a way that preserves a specified mean $\mu(\boldsymbol{s}) = E[Z(\boldsymbol{s})]$ and covariance structure $C_z(\boldsymbol{s}_1 - \boldsymbol{s}_2) = \text{Cov}(Z(\boldsymbol{s}_1), Z(\boldsymbol{s}_2))$. The realizations are partial in the sense that they occur only at a finite set of locations $(\boldsymbol{s}_1, \boldsymbol{s}_2, \cdots, \boldsymbol{s}_n)$. These locations are typically on a regular grid, but they can be arbitrary locations in the plane.

PROC SIM2D produces simulations for continuous processes in two dimensions by using the lower-upper (LU) decomposition method. In these simulations the possible values of the measured quantity $Z(\boldsymbol{s}_0)$ at location $\boldsymbol{s}_0 = (x_0, y_0)$ can vary continuously over a certain range. An additional assumption, needed for computational purposes, is that the spatial random field $Z(\boldsymbol{s})$ is Gaussian. The section "Details: SIM2D Procedure" on page 7102 provides more information about different types of spatial simulation and associated computational methods.

Spatial simulation is different from spatial prediction, where the emphasis is on predicting a point value at a given grid location. In this sense, spatial prediction is local. In contrast, spatial simulation is global; the emphasis is on the entire realization $(Z(\boldsymbol{s}_1), Z(\boldsymbol{s}_2), \cdots, Z(\boldsymbol{s}_n))$.

Given the correct mean $\mu(\boldsymbol{s})$ and covariance structure $C_z(\boldsymbol{s}_1 - \boldsymbol{s}_2)$, SRF quantities that are difficult or impossible to calculate in a spatial prediction context can easily be approximated by functions of multiple simulations.

Getting Started: SIM2D Procedure

Spatial simulation, just like spatial prediction, requires a model of spatial dependence, usually in terms of the covariance $C_z(\boldsymbol{h})$. For a given set of spatial data $Z(\boldsymbol{s}_i), i = 1, \cdots, n$, the covariance structure (both the form and parameter values) can be found by the VARIOGRAM procedure. This example uses the coal seam thickness data that are also used in the section "Getting Started: VARIOGRAM Procedure" on page 8174.

In this example, the data consist of coal seam thickness measurements (in feet) taken over an area of 100×100 (10^6 ft^2). The coordinates are offsets from a point in the southwest corner of the measurement area, with the north and east distances in units of thousands of feet.

Preliminary Spatial Data Analysis

A semivariance analysis of the coal seam thickness thick data set is performed in "Getting Started: VARIOGRAM Procedure" on page 8174 of the VARIOGRAM procedure. The analysis considers the spatial random field (SRF) $Z(\boldsymbol{s})$ of the Thick variable to be free of surface trends. The expected value $E[Z(\boldsymbol{s})]$ is then a constant $\mu(\boldsymbol{s}) = \mu$, which suggests that you can work with the original thickness data rather than residuals from a trend surface fit. In fact, a reasonable approximation of the spatial process generating the coal seam data is given by

$$Z(\boldsymbol{s}) = \mu + \varepsilon(\boldsymbol{s})$$

where $\varepsilon(\boldsymbol{s})$ is a Gaussian SRF with Gaussian covariance structure

$$C_z(\boldsymbol{h}) = c_0 \exp\left(-\frac{h^2}{a_0^2}\right)$$

Of note, the term "Gaussian" is used in two ways in this description. For a set of locations $\boldsymbol{s}_1, \boldsymbol{s}_2, \cdots, \boldsymbol{s}_n$, the random vector

$$\boldsymbol{Z}(\boldsymbol{s}) = \begin{bmatrix} Z(\boldsymbol{s}_1) \\ Z(\boldsymbol{s}_2) \\ \vdots \\ Z(\boldsymbol{s}_n) \end{bmatrix}$$

has a multivariate Gaussian or normal distribution $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$. The (i,j)th element of $\boldsymbol{\Sigma}$ is computed by $C_z(\boldsymbol{s}_i - \boldsymbol{s}_j)$, which happens to be a Gaussian functional form.

Any functional form for $C_z(\boldsymbol{h})$ that yields a valid covariance matrix $\boldsymbol{\Sigma}$ can be used. Both the functional form of $C_z(\boldsymbol{h})$ and the parameter values

$$\mu = 40.1173$$

$$c_0 = 7.4599$$

$$a_0 = 30.1111$$

are estimated by using PROC VARIOGRAM in section "Theoretical Semivariogram Model Fitting" on page 8183 in the VARIOGRAM procedure. Specifically, the expected value μ is reported in the VARIOGRAM procedure OUTV output data set, and the parameters c_0 and a_0 are estimates derived from a weighted least squares fit.

The choice of a Gaussian functional form for $C_z(\boldsymbol{h})$ is simply based on the data, and it is not at all crucial to the simulation. However, it *is* crucial to the simulation method used in PROC SIM2D that $Z(\boldsymbol{s})$ be a Gaussian SRF. For details, see the section "Computational and Theoretical Details of Spatial Simulation" on page 7102.

Investigating Variability by Simulation

The variability of $Z(\boldsymbol{s})$, as modeled by

$$Z(\boldsymbol{s}) = \mu + \varepsilon(\boldsymbol{s})$$

with the Gaussian covariance structure $C_z(\boldsymbol{h})$ found previously, is not obvious from the covariance model form and parameters. The variation around the mean of the surface is relatively small, making it difficult visually to pick up differences in surface plots of simulated realizations.

Instead, you can compute the mean for each location on a grid from a series of realizations in a simulation. Then, the standard deviation of all the simulated values at each grid location provides you with a measure of the variability of $Z(\boldsymbol{s})$ for the given covariance structure. You can also investigate variations at selected grid points in more detail, as shown in the "Example 82.2: Variability at Selected Locations" on page 7114.

The present example shows how to use ODS Graphics with PROC SIM2D to investigate the mean and standard deviation of simulated values. You use the thick data set which is available from the Sashelp library. In the data set, the Thick variable represents simulated observations of coal seam thickness. For your goal, you produce 5,000 realizations of a simulation with PROC SIM2D, where you specify the Gaussian model with the parameters found previously. You want the simulated data to pass through the simulated values, so first you define the data with the following data step:

```

```

Since this is a conditional simulation, you can specify the OBSERV option in the PLOTS option in PROC SIM2D to see the locations and values of the measured points in the area where you want to perform spatial simulations.

Furthermore, the SIM suboption in the PLOTS option specifies that you want to create a plot that shows the means of the simulated values across the region. The SIM suboption with no other arguments produces a plot that shows the contours of the simulated means in the foreground and the gradient of the simulated standard deviations in the background.

You obtain these PROC SIM2D results at the nodes of an output grid that you specify according to your application needs. In the present analysis, a convenient area that encompasses all the Thick data points is a square with a side length of 100,000 feet. You define a regular grid for your simulation in this area. Assume a distance of 2,500 feet between grid nodes in both directions for a smooth contour plot. Based on this choice, your square grid has 41 nodes on each side. This means that PROC SIM2D computes the simulated values at a total of 1,681 grid points. You use the GRID statement of the PROC SIM2D to specify this grid.

The SIMULATE statement specifies the parameters of your simulation across the output grid. In particular, the VAR= option specifies the conditional simulation variable. The number of realizations in the simulation is specified with the NUMREAL= option. The SEED= option specifies the seed for the simulation random number generator.

The spatial correlation model for the simulation is also specified in the SIMULATE statement. You specify the model type by using the FORM= option. The options SCALE= and RANGE= specify the covariance structure sill c_0 and range a_0 parameters, respectively, as discussed in the previous section.

Although it is not included in the original spatial structure, note that a minimal nugget effect is specified with the NUGGET= option to avoid singularity issues. Singularity can appear in the present example as a result of the combined use of the Gaussian covariance model and relatively short distances between nodes, data, or nodes and data in the simulation area.

These steps are implemented using the following DATA step and statements:

```
ods graphics on;

proc sim2d data=thick outsim=sim plot=(observ sim);
   coordinates xc=East yc=North;
   simulate var=Thick numreal=5000 seed=79931
      scale=7.4599 range=30.1111 nugget=1e-8 form=gauss;
   mean 40.1173;
   grid x=0 to 100 by 2.5 y=0 to 100 by 2.5;
run;
```

The table in Figure 82.1 shows the number of observations read and used in the conditional simulation. This table can provide you with useful information in case you have missing values in the input data.

Figure 82.1 Number of Observations for the thick Data Set

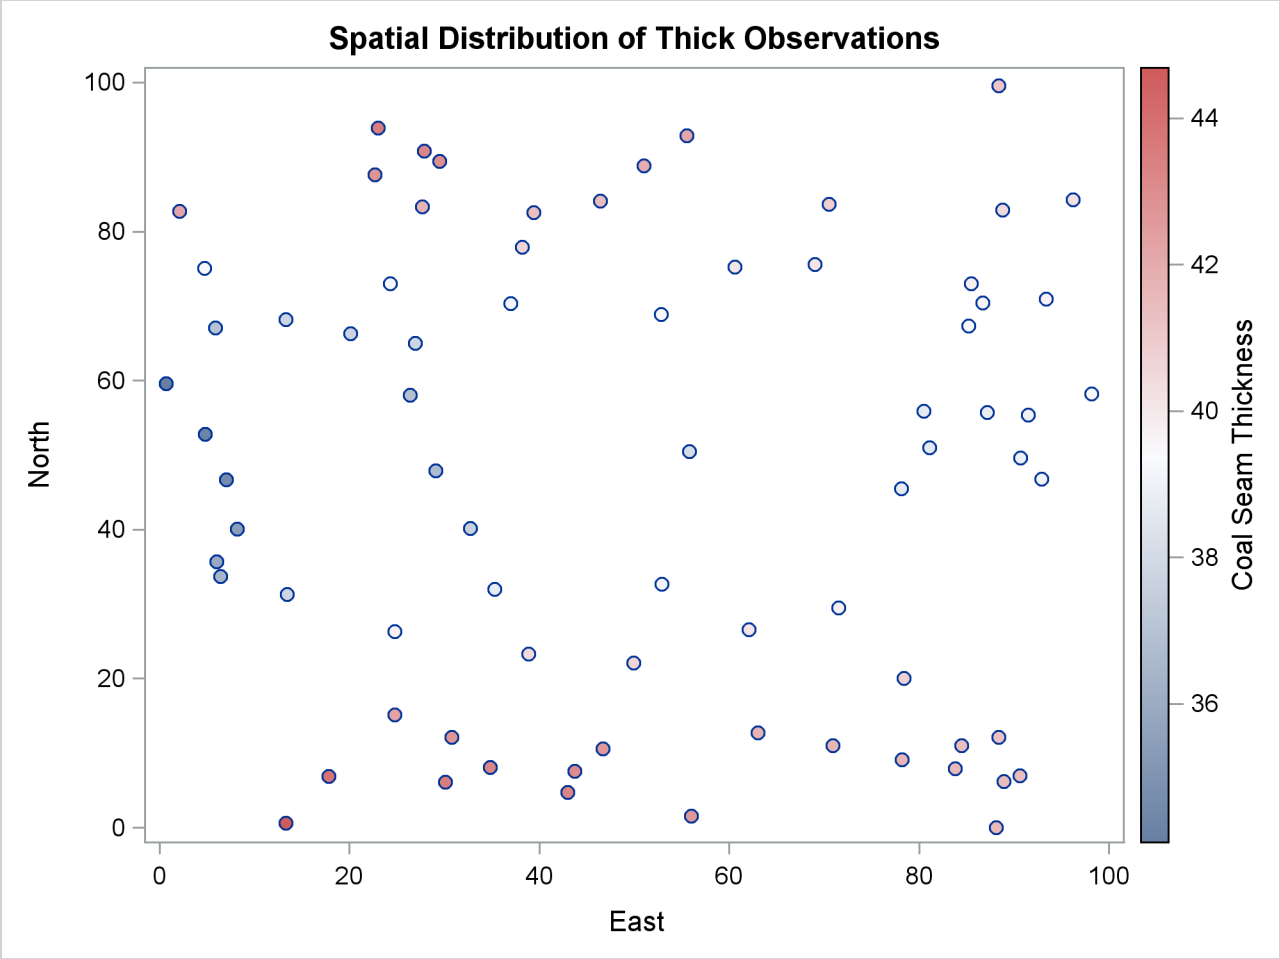
```
                Using PROC SIM2D for Spatial Simulation

                          The SIM2D Procedure
              Simulation: Sim1, Dependent Variable: Thick

                Number of Observations Read          75
                Number of Observations Used          75
```

The sample locations are then plotted in Figure 82.2. The figure clearly shows some small-scale variation that is typical of spatial data.

Figure 82.2 Scatter Plot of the Observations Spatial Distribution



PROC SIM2D also produces the table shown in Figure 82.3, which contains information about the type of simulation you run and the number of realizations requested.

Figure 82.3 Simulation Analysis Information

Simulation Information

Simulation Grid Points	1681
Type	Conditional
Number of Realizations	5000

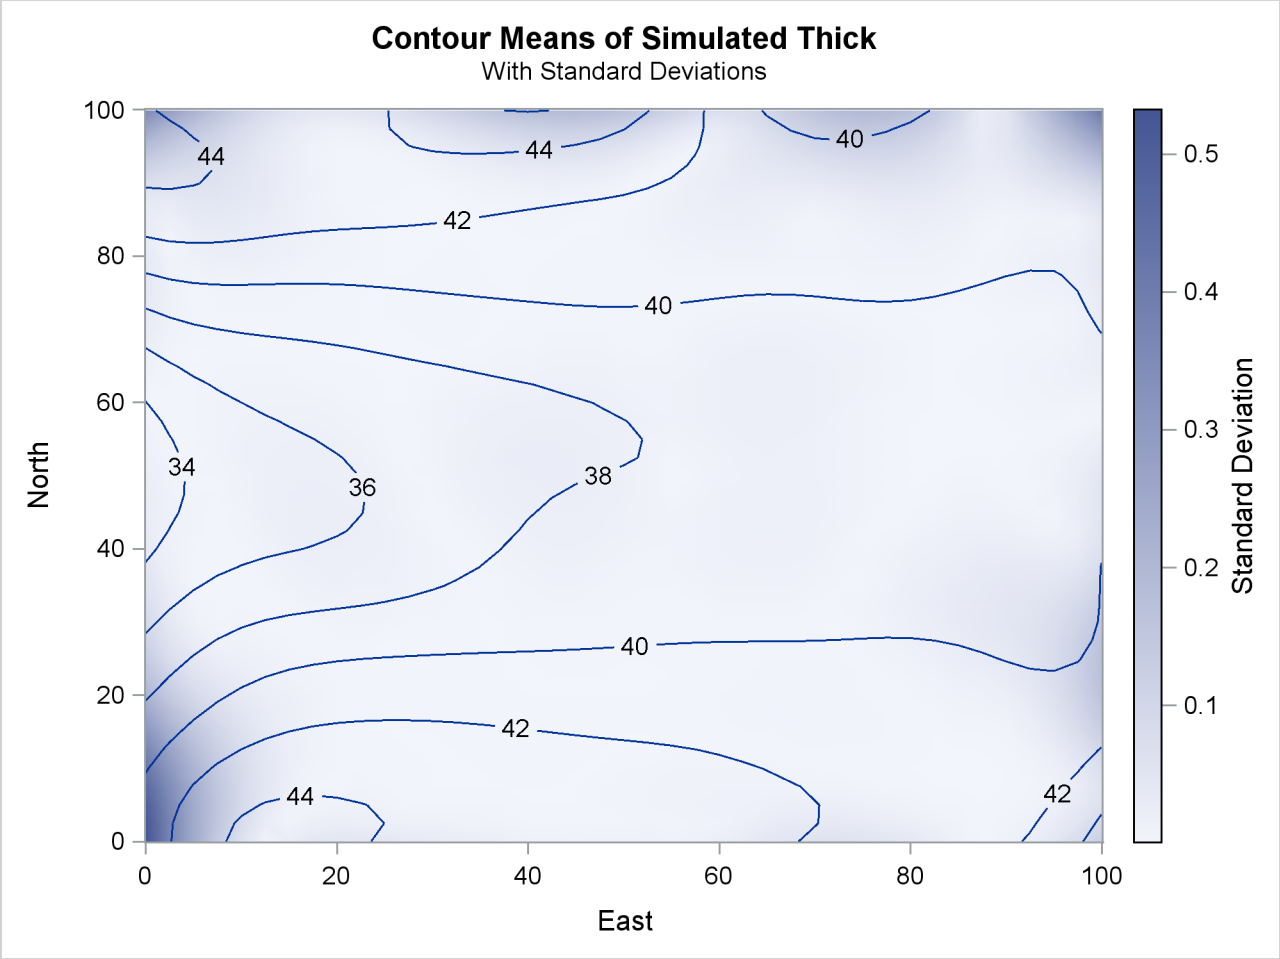
The table in Figure 82.4 displays the spatial correlation model information that is used by PROC SIM2D for the current simulation. If applicable, the table also provides the effective range. This is the distance r_ϵ at which the covariance is 5% of its value at zero. Here you specified the Gaussian model, for which the effective range r_ϵ is $\sqrt{3}a_0$.

Figure 82.4 Simulation Covariance Model Information

Covariance Model Information	
Type	Gaussian
Sill	7.4599
Range	30.1111
Effective Range	52.153955
Nugget Effect	1E-8

Eventually, the SIM2D procedure produces the requested simulation plot shown in Figure 82.5. The contours of the mean of the simulated values show the average of the simulated realizations at each grid node; the average is based on the given spatial structure characteristics. In this case, these means are also conditioned by the Thick observations across the region.

Figure 82.5 Contour Plot of Conditionally Simulated Coal Seam Thickness



Observe also the gradient that shows the standard deviation of the simulated values at each grid node. This gradient appears to be generally small throughout the region. A few exceptions are evident close to the region borders. In these areas the simulated realizations depend on a limited amount of neighboring data. The simulation at these locations relies mainly on the underlying spatial structure.

In addition to the simulation analysis, you can use the PROC SIM2D output to obtain statistical information about the simulated values at selected locations. Assume that you would like some basic statistics for the extreme southwest point at (East=0, North=0) and the point (East=75, North=75) toward the northeast corner of the region. You use the following DATA step to select the realizations for these points from the OUTSIM= output data set:

```
data selected;
   set sim(where=((gxc=0 and gyc=0) or (gxc=75 and gyc=75)));
   label gxc = "X-coord";
   label gyc = "Y-coord";
run;
```

Then, you use PROC SORT to sort the selected data set entries and PROC MEANS to produce the simulation statistics for the selected points. The following statements yield the mean, standard deviation, and maximum values of the 5,000 realizations of the Thick values at each one of the selected locations:

```
proc sort data=selected;
   by gxc gyc;
proc means data=selected Mean Std Max;
   class gxc gyc;
   ways 2;
   where (  ((gxc =  0) & (gyc =  0))
          | ((gxc = 75) & (gyc = 75)));
   var SValue;
run;

ods graphics off;
```

The requested statistics for the grid points (East=0, North=0) and (East=75,North=75) are shown in Figure 82.6.

Figure 82.6 Simulation Statistics at Grid Points (East=0, North=0) and (East=75, North=75)

Using PROC SIM2D for Spatial Simulation

The MEANS Procedure

Analysis Variable : SVALUE Simulated Value at Grid Point

X-coord	Y-coord	N Obs	Mean	Std Dev	Maximum
0	0	5000	40.6968472	0.5328597	42.6616357
75	75	5000	40.1090845	0.0024556	40.1197239

"Example 82.2: Variability at Selected Locations" on page 7114 shows you how to perform a simulation at a set of selected locations rather than on a domain-wide grid, and how to obtain more detailed statistics from the simulation.

Syntax: SIM2D Procedure

The following statements are available in PROC SIM2D:

PROC SIM2D *options* ;
  BY *variables* ;
  COORDINATES *coordinate-variables* ;
  GRID *grid-options* ;
  ID *variable* ;
  RESTORE *store-options* ;
  SIMULATE *simulate-options* ;
  MEAN *mean-options* ;

The SIMULATE and MEAN statements are hierarchical; you can specify any number of SIMULATE statements, but you must specify at least one. If you specify a MEAN statement, it refers to the preceding SIMULATE statement. If you omit the MEAN statement, a zero-mean model is simulated.

You must specify a single COORDINATES statement to identify the x and y coordinate variables in the input data set when you perform a conditional simulation. You must also specify a single GRID statement to specify the grid information.

Table 82.1 outlines the options available in PROC SIM2D classified by function.

Table 82.1 Options Available in the SIM2D Procedure

Task	Statement	Option
Data Set Options		
Specify an input data set	PROC SIM2D	DATA=
Specify a grid data set	GRID	GDATA=

Specify model and parameters from an item store	SIMULATE	STORESELECT

PROC SIM2D Statement

PROC SIM2D *options* **;**

You can specify the following options with the PROC SIM2D statement.

DATA=*SAS-data-set*
specifies a SAS data set that contains the x and y coordinate variables and the VAR= variables that are used in the SIMULATE statements. This data set is required if you specify the BY statement or the COORDINATES statement or if any of the SIMULATE statements are conditional—that is, if you specify the VAR= option in any of those. Otherwise, you do not need the DATA= option, and this option is ignored if you specify it.

IDGLOBAL
specifies that ascending observation numbers be used across BY groups for the observation labels in the appropriate output data sets and the OBSERVATIONS plot, instead of resetting the observation number in the beginning of each BY group. The IDGLOBAL option is ignored if no BY variables are specified. Also, if you specify the ID statement, then the IDGLOBAL option is ignored unless you also specify the IDNUM option in the PROC SIM2D statement.

IDNUM
specifies that the observation number be used for the observation labels in the appropriate output data sets and the OBSERVATIONS plot. The IDNUM option takes effect when you specify the ID statement; otherwise, it is ignored.

NARROW
restricts the variables included in the OUTSIM= data set. When you specify the NARROW option, only four variables are included. This option is useful when a large number of simulations are produced. Including only four variables reduces the memory required for the OUTSIM= data set. For details about the variables that are excluded with the NARROW option, see the section "Output Data Set" on page 7106.

NOPRINT
suppresses the normal display of results. The NOPRINT option is useful when you want only to create one or more output data sets with the procedure. **NOTE:** This option temporarily disables the Output Delivery System (ODS); see the section "ODS Graphics" on page 7108 for more information.

OUTSIM=*SAS-data-set*
specifies a SAS data set in which to store the simulation values, iteration number, simulate statement label, variable name, and grid location. For details, see the section "Output Data Set" on page 7106.

PLOTS <(*global-plot-option***)> <= ***plot-request* *< (options) >* **>**

PLOTS <(*global-plot-option***)> <= (***plot-request* *< (options) >* **<...** *plot-request* *< (options) >* **>) >**
controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=observ
plots=(observ(outl) sim)
plots=(sim(fill=mean line=sd obs=grad) sim(fill=sd))
```

ODS Graphics must be enabled before requesting plots. For example:

```
ods graphics on;

proc sim2d data=thick outsim=sim;
   coordinates xc=East yc=North;
   simulate var=Thick numreal=5000 seed=79931
      scale=7.4599 range=30.1111 form=gauss;
   mean 40.1173;
   grid x=0 to 100 by 2.5 y=0 to 100 by 2.5;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" on page 612 in Chapter 21, "Statistical Graphics Using ODS."

By default, no graphs are created; you must specify the PLOTS= option to make graphs.

The following *global-plot-option* is available:

ONLY
produces only plots that are specifically requested.

The following individual *plot-requests* and plot *options* are available:

ALL
produces all appropriate plots. You can specify other *options* with ALL. For example, to request all appropriate plots and an additional simulation plot, specify PLOTS=(ALL SIM).

EQUATE
specifies that all appropriate plots be produced in a way in which the axes coordinates have equal size units.

NONE
suppresses all plots.

OBSERVATIONS <(*observations-plot-options*)>

OBSERV <(*observations-plot-options*)>

OBS <(*observations-plot-options*)>
produces the observed data plot in conditional simulations. Only one observations plot is created if you specify the OBSERVATIONS option more than once within a PLOTS option.

The OBSERVATIONS option has the following suboptions:

GRADIENT
specifies that observations be displayed as circles colored by the observed measurement.

LABEL < (*label-option*) >
labels the observations. The label is the ID variable if the ID statement is specified; otherwise, it is the observation number. The *label-option* can be one of the following:

EQ=*number*
specifies that labels show for any observation whose value is equal to the specified *number*.

MAX=*number*
specifies that labels show for observations with values smaller than or equal to the specified *number*.

MIN=*number*
specifies that labels show for observations with values equal to or greater than the specified *number*.

If you specify multiple instances of the OBSERVATIONS option and you specify the LABEL suboption in any of those, then the resulting observations plot displays the observations labels. If more than one *label-option* is specified in multiple LABEL suboptions, then the prevailing *label-option* in the resulting OBSERVATIONS plot emerges by adhering to the choosing order: MIN, MAX, EQ.

OUTLINE
specifies that observations be displayed as circles with a border but with a completely transparent fill.

OUTLINEGRADIENT
is the same as OBSERVATIONS(GRADIENT) except that a border is shown around each observation.

SHOWMISSING
specifies that observations with missing values be displayed in addition to the observations with nonmissing values. By default, missing values locations are not shown on the plot. If you specify multiple instances of the OBSERVATIONS option and you specify the SHOWMISSING suboption in any of those, then the resulting observations plot displays the observations with missing values.

If you omit any of the GRADIENT, OUTLINE, and OUTLINEGRADIENT suboptions, the OUTLINEGRADIENT is the default suboption. If you specify multiple instances of the OBSERVATIONS option or multiple suboptions for OBSERVATIONS, then the resulting observations plot honors the last specified GRADIENT, OUTLINE, or OUTLINEGRADIENT suboption.

SIMULATION < (*sim-plot-options*) >

SIM < (*sim-plot-options*) >

specifies that simulation plots be produced. You can specify the SIM option multiple times in the same PLOTS option to request instances of plots with the following *sim-plot-options*:

ALPHA=*number*

specifies a parameter to obtain the confidence level for constructing confidence limits based on the simulation standard deviation. The value of *number* must be between 0 and 1, and the confidence level is $1-$*number*. The default is ALPHA=0.05; this corresponds to the confidence level of 95%. The ALPHA= suboption is used only for simulation plots in one dimension, and it is incompatible with the FILL and LINE suboptions.

CLONLY

specifies that only the confidence limits be shown in a simulation plot without the simulation mean. This suboption can be useful for identifying confidence limits when the simulation standard deviation is small at the simulation locations. CLONLY is used only for simulation band plots of simulations on a linear grid, and it is incompatible with the FILL and LINE suboptions.

CONNP

specifies that grid points that you provide as individual simulation locations be connected with a line on the area map. This suboption is ignored when you have a single grid point, a prediction grid in two dimensions, or when you also specify the NOMAP suboption. The CONNP suboption is incompatible with the FILL and LINE suboptions.

FILL=NONE | MEAN | SD

produces a surface plot for either the values of the means or the standard deviations. FILL=SD is the default. However, if you omit the FILL suboption the behavior depends on the LINE suboption as follows: If you specify LINE=NONE or entirely omit the LINE suboption, then the FILL suboption is set to its default value. If LINE=PRED or LINE=SE, then the FILL suboption is set to the same value as the LINE suboption.

LINE=NONE | MEAN | SD

produces a contour line plot for either the values of the means or the standard deviations. LINE=MEAN is the default. However, if you omit the LINE suboption the behavior depends on the FILL suboption as follows: If you specify FILL=NONE or entirely omit the FILL suboption, then the LINE suboption is set to its default value. If FILL=PRED or FILL=SE, then the LINE suboption is set to the same value as the FILL suboption.

NOMAP

specifies that the simulation plot be produced without a map of the domain where you have observations. The NOMAP suboption is used in the case of simulation in one dimension or at individual points. It is ignored in the case of unconditional simulation, and it is incompatible with the FILL and LINE suboptions.

OBS=*obs-options*

produces an overlaid scatter plot of the observations in addition to the specified contour plots. The following *obs-options* are available:

GRAD

specifies that observations be displayed as circles colored by the observed measurement. The same color gradient displays the means surface and the observations. The conditional simulation honors the observed values, so the means surface at the observation locations has the same color as the corresponding observations.

LINEGRAD

is the same as OBS=GRAD except that a border is shown around each observation. This option is useful for identifying the location of observations where the standard deviations are small, because at these points the color of the observations and the color of the surface are indistinguishable.

NONE

specifies that no observations be displayed.

OUTL

specifies that observations be displayed as circles with a border but with a completely transparent fill.

OBS=NONE is the default when you have a grid in two dimensions, and OBS=LINEGRAD is the default used in the area map when you specify a conditional simulation in one dimension.

SHOWD

specifies that the horizontal axis in scatter plots of linear simulation grids show the distance between grid points instead of the grid points' coordinates. When the area map is displayed, the simulation locations are also connected with a line. In all other grid configurations the SHOWD suboption is ignored, and it is incompatible with the FILL and LINE suboptions.

SHOWP

specifies that the grid points in band plots of linear simulation grids be shown as marks on the band plot. In all other grid configurations the SHOWP suboption is ignored, and it is incompatible with the FILL and LINE suboptions.

TYPE=BAND | BOX

requests a particular type of plot when you have a linear grid, regardless of the default SIM plot behavior in this case. The TYPE suboption is incompatible with the FILL and LINE suboptions.

If you specify multiple instances of the ALPHA, FILL, LINE, OBS, or TYPE suboptions in the same SIM option, then the resulting simulation plot honors the last value specified for any of the suboptions. Any combination where you specify FILL=NONE and LINE=NONE is not available. When the simulation grid is in two dimensions, only the FILL, LINE, and OBS suboptions apply. If you specify incompatible suboptions in the same SIM plot, then the plot instance is skipped.

The SIM option produces a surface or contour line plot for grids in two dimensions and a band plot or box plot for grids in one dimension or individual points. In two dimensions the plot illustrates the means and standard deviations of the simulation realizations at each grid point. By default, when you specify a linear grid with fewer than 10 points, PROC SIM2D produces a SIM box plot that depicts the simulation distribution at each point. For 10 or more points in a linear grid, the SIM plot is a band plot of the simulation means and the confidence limits at the 95% confidence level. You can override the default behavior in linear grids with the TYPE suboption. Simulation at individual locations always produces a SIM box plot.

In cases of conditional simulation in one dimension or at individual points an area map is produced that shows the observations and the grid points. Band plots of linear grids display the grid points as a line on the map. When you specify individual simulation locations, the grid points are indicated with marks on the area map. The area map appears on the side of conditional simulation band plots or box plots, unless you specify the NOMAP suboption. You can also label individual grid points or the ends of linear grid segments with the LABEL option of the GRID statement.

SEMIVARIOGRAM < (*semivar-plot-option*) >

SEMIVAR < (*semivar-plot-option*) >

specifies that the semivariogram used for the simulation be produced. You can use the following *semivar-plot-option*:

MAXD=*number*

specifies a positive value for the upper limit of the semivariogram horizontal axis of distance. The SEMIVARIOGRAM plot extends by default to a distance that depends on the correlation model range. You can use the MAXD= option to adjust the default maximum distance value for the plot.

The SEMIVARIOGRAM option produces a plot for each correlation model that you specify for your simulation tasks. In an anisotropic case, the plot is not produced if you assign different anisotropy angles for different model components. The only exception is when you specify zonal components at right angles with the nonzonal model components. Also, the SEMIVARIOGRAM option is ignored for models that consist of purely zonal components.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC SIM2D to obtain separate analyses on observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SIM2D procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

In PROC SIM2D it makes sense to use the BY statement only in conditional simulations where observations are involved. In particular, using the BY statement assumes that you have specified an input data set with the DATA= option in the PROC SIM2D statement. In PROC SIM2D if you omit the VAR= option in the SIMULATE statement, then this is a request for unconditional simulation even if you have specified the DATA= option in the PROC SIM2D statement. Therefore, it is possible to specify the BY statement and request mixed types of simulations by specifying multiple SIMULATE statements in the same PROC SIM2D step.

A special case occurs when you omit the DATA= option in the PROC SIM2D statement, your unconditional simulation correlation model input comes from an item store in the RESTORE statement, and this store has its own BY groups. The SIM2D procedure exhibits then a BY-like behavior, even though you specified no BY statement. This behavior enables you to distinguish the simulation tasks that depend on models in the different store BY groups.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

COORDINATES Statement

COORDINATES *coordinate-variables* **;**

The two options in the COORDINATES statement give the name of the variables in the DATA= data set that contains the values of the x and y coordinates of the conditioning data. You must specify the COORDINATES statement when you specify an input data set with the DATA= option in the PROC SIM2D statement.

Only one COORDINATES statement is allowed, and it is applied to all SIMULATE statements that have the VAR= specification. In other words, it is assumed that all the VAR= variables in all SIMULATE statements have the same x and y coordinates.

You can abbreviate the COORDINATES statement as COORD.

XCOORD=*(variable-name)*

XC=*(variable-name)*

gives the name of the variable that contains the x coordinate of the data in the DATA= data set.

YCOORD=*(variable-name)*

YC=*(variable-name)*

gives the name of the variable that contains the y coordinate of the data locations in the DATA= data set.

GRID Statement

GRID *grid-options* < / *option* > **;**

The GRID statement specifies the grid of spatial locations at which to perform the simulations. A single GRID statement is required and is applied to all SIMULATE statements. Specify the grid in one of the following three ways:

- Specify the x and y coordinates explicitly for a grid in two dimensions.
- Specify the NPTS= option in addition to the x and y coordinates to define a grid of individual points or in one dimension.
- Specify the coordinates by using a SAS data set for a grid of individual points or in one dimension.

The GRID statement has the following *grid-options*:

NPTS=*number*

NPTS=ALL

controls specification of a grid in one dimension or a grid of individual simulation locations.

When you specify the NPTS=*number* option and the coordinates of two points in the GRIDDATA= data set or in both the X= and Y= options, you request a linear simulation grid. Its direction is across the line defined by the specified points. The grid size is equal to the *number* of points that you specify in the NPTS= option, where $number \geq 2$.

When you specify the NPTS=ALL option and the coordinates for any number of points in the GRIDDATA= data set or in each of the X= and Y= options, the SIM2D procedure performs simulation only at the specified individual locations. Use the NPTS=ALL option to examine a set of individual points anywhere on the XY plane or to specify a custom grid in one dimension.

If the number of x coordinates and the number of y coordinates in the X= and Y= options, respectively, are different, then the NPTS= option is ignored; in that case, a two-dimensional grid is used according to the specified X= and Y= options.

If you specify a simulation grid with any number of points other than two in the GRIDDATA= data set, then the option NPTS=ALL has the same effect as omitting the NPTS= option.

X=*number*

X=$x_1, \ldots, x_m$

X=x_1 *to* x_m

X=x_1 *to* x_m *by* δx

specifies the x coordinate of the grid locations.

Y=*number*

Y=$y_1, \ldots, y_m$

Y=y_1 *to* y_m

Y=y_1 *to* y_m *by* δy

specifies the y coordinate of the grid locations.

Use the X= and Y= options of the GRID statement to specify a grid in one or two dimensions, or a grid of individual simulation locations.

For example, the following two GRID statements are equivalent:

```
GRID X=1,2,3,4,5  Y=0,2,4,6,8,10;
```

```
GRID X=1 TO 5 Y=0 to 10 by 2;
```

In the following example, the first GRID statement produces a grid in two dimensions. The second statement produces simulation output only for the four individual points at the locations (1,0), (2,5), (3,7), and (4,10) on the XY plane.

```
GRID X=1 TO 4 Y=0,5,7,10;
```

```
GRID X=1 TO 4 Y=0,5,7,10 NPTS=ALL;
```

In the next example, the first GRID statement specifies a 2-by-2 grid in two dimensions. The second GRID statement specifies a linear grid of eight points. The grid is in the direction of the line defined by the specified points (2,8) and (3,5) on the XY plane and it extends between these two points.

```
GRID X=2,3 Y=8,5;
```

```
GRID x=2,3 Y=8,5 NPTS=8;
```

The last example shows a GRID statement that specifies a linear grid made of seven points across the Y axis. In this case, the syntax is sufficient to fully define a linear grid without the NPTS= option.

```
GRID X=5 Y=3 TO 9;
```

To specify grid locations from a SAS data set, you must provide the name of the data set and the variables that contain the values of the x and y coordinates.

GRIDDATA=*SAS-data-set*

GDATA=*SAS-data-set*

specifies a SAS data set that contains the x and y grid coordinates. Use the GRIDDATA= option of the GRID statement to specify a grid in one dimension or a grid of individual simulation locations.

XCOORD=*(variable-name)*

XC=*(variable-name)*

gives the name of the variable that contains the x coordinate of the grid locations in the GRIDDATA= data set.

YCOORD=*(variable-name)*

YC=*(variable-name)*

gives the name of the variable that contains the y coordinate of the grid locations in the GRIDDATA= data set.

You can specify the following option in the GRID statement after a slash (/):

LABEL < (*suboption***) > =** *(character-list)*

specifies labels to tag grid points in simulation plots when you use grids in one dimension. You can specify one or more such labels as quoted strings in the *character-list*.

When the number of labels in the *character-list* exceeds the number of points in your grid, the labels in the list are used sequentially and any labels in excess are ignored. When the number of labels in the *character-list* is smaller than the number of points in your grid, the behavior is as follows:

- If an area map is included in the simulation plot, then blank labels are assigned to the remaining nonlabeled grid points on the map.
- For the simulation band and box plots, the coordinates of nonlabeled grid points are automatically assigned as their labels.

If the grid points are colinear and the horizontal axis displays distance, then two labels appear by default in the simulation plot. These are assigned to the first and the last points of the grid to help identify the ends of the linear grid segment on the plot map. This label pair is shown only when the plot includes an area map. Specifically, the two labels appear when you request simulation band plots, or simulation box plots for which you specify the SIM(SHOWD) suboption, if applicable. The two labels do not appear if you specify explicitly the NOMAP suboption in the PLOTS=SIM option.

The two labels have default values, unless you choose to specify your own labels with the LABEL= option. If you specify more than two labels in the *character-list* under these conditions, then only the first and last labels in the list are used; any additional labels in between are ignored.

The LABEL= option has the following *suboption*:

ALL

specifies that all individual points in the grid are assigned sequentially the labels you specify in the LABEL(ALL)= option when the SIM(SHOWD) suboption is applicable and specified in a simulation box plot. In all other cases, the ALL suboption is ignored.

The ALL suboption enables you to override the default behavior when the SIM(SHOWD) suboption is specified (the default behavior is to display labels only for the first and last grid points). As a result, you can use the ALL suboption to label grid grid points in both conditional and unconditional simulation tasks regardless of whether you specify the NOMAP suboption in the PLOTS=SIM option.

The LABEL= option is ignored when you produce simulation plots of grids in two dimensions.

ID Statement

ID *variable* **;**

The ID statement specifies which variable to include for identification of the observations in the labels and tool tips of the OBSERVATIONS plot and the tool tips of the SIM plot. The ID statement has an effect only when you perform conditional simulation.

In the SIM2D procedure you can specify only one ID variable in the ID statement. If no ID statement is given, then PROC SIM2D uses the observation number in the plots.

RESTORE Statement

RESTORE IN=*store-name* < / *option* > **;**

The RESTORE statement specifies an item store that provides spatial correlation model input for the PROC SIM2D simulation tasks. An item store is a binary file defined by the SAS System. You cannot modify the contents of an item store. The SIM2D procedure can use only item stores created by PROC VARIOGRAM.

Item stores enable you to use saved correlation models without having to repeat specification of these models in the SIMULATE statement. In principle, an item store contains the chosen model from a model fitting process in PROC VARIOGRAM. If more than one model form is fitted, then all successful fits are included in the item store. In this case, you can choose any of the available models to use for simulation with the STORESELECT(MODEL=) option in the SIMULATE statement. Successfully fitted models might include questionable fits, which are so flagged when you specify the INFO option to display model names.

The *store-name* is a usual one- or two-level SAS name, as for SAS data sets. If you specify a one-level name, then the item store resides in the WORK library and is deleted at the end of the SAS session. Since item stores are often used for postprocessing tasks, typical usage specifies a two-level name of the form *libname.membername*.

When you specify the RESTORE statement, the default output contains some general information about the input item store. This information includes the store name, label (if assigned), the data set that was used to create the store, BY group information, the procedure that created the store, and the creation date.

You can specify the following option in the RESTORE statement after a slash (/):

INFO < (*info-options*) >
specifies that additional information about the input item store be printed. This information is provided in two ODS tables. One table displays the variables in the item store, in addition to the mean and standard deviation for each of them. These statistics are based on the observations that were used to produce the store results. The second table shows the model on top of the list of all fitted models for each direction angle in the item store. The INFO option has the following *info-options*:

DETAILS

DET
specifies that more detailed information be displayed about the input item store. This option produces the full list of models for each direction angle in the item store, in addition to the model equivalence class. For more information about classes of equivalence, see the section "Classes of Equivalence" on page 8248 in the VARIOGRAM procedure. The DETAILS option is ignored if the input item store contains information about a single fitted model.

ONLY
specifies that only information about the input item store without any simulation tasks be displayed.

Each variable in an item store has a mean value that is passed to PROC SIM2D and used in simulations. If the mean in the item store is a missing value, then a zero mean is used by default. Specify the "MEAN Statement" on page 7101MEAN statement to override the mean information in the item store. For example, if you want to use only the correlation model in the item store and exclude the accompanying mean, then explicitly specify a zero mean in the "MEAN Statement" on page 7101MEAN statement.

When you specify an input item store with the RESTORE statement in PROC SIM2D, all the DATA= input data set variables must match input item store variables. If there are BY groups in the input DATA= set or in the input RESTORE variables, then PROC SIM2D handles the different cases as follows:

- If both PROC SIM2D has BY groups and the RESTORE statement has BY groups, then the analysis variables must match. This matching assumes implicitly that in each BY group of PROC SIM2D and the item store, the corresponding set of observations and correlation model comes from the same random field. This assumption is valid if you use the same data set, first in PROC VARIOGRAM to fit a model and save it in the item store, and then in PROC SIM2D to run simulations with the resulting correlation models.
- If PROC SIM2D has BY groups but the item store does not, then the item store is accepted only if the procedure and the item store analysis variables match. In this case, the same item store model choice iterates across the BY groups of the input data. You are advised to proceed with caution: each BY group in the input DATA= set corresponds to a different realization of a random field. Hence, by using the same correlation model for simulation purposes, you implicitly assume that all these different realizations are instances of the same random field.

- If PROC SIM2D has an input DATA= set and no BY groups but the item store has BY groups, then the item store is rejected
- If PROC SIM2D has no input DATA= set and the item store has BY groups, then PROC SIM2D runs unconditional simulations for the models in the store BY groups. See also the BY statement for more about the behavior in this case.

SIMULATE Statement

SIMULATE *simulate-options* **;**
