Advanced DATA Step Techniques

Neil Howard, Parke-Davis/Warner-Lambert, Ann Arbor, MI

Abstract

Understanding the intricacies of the DATA step can make all the difference in your SAS programming. There are additional SUGI 25 tutorials on the following DATA step topics:

- arrays,
- SAS date and time functions,
- debugging,
- functions and formats,
- efficiency,
- INPUT statement.

This tutorial focuses on the more advanced techniques that capitalize on the power of the DATA step and working with (and around) the default actions. Topics include:

- compile versus execution time activities;
- organizing your data to maximize execution;
- data defaults, data conversions;
- missing values, formatting values;
- ordering variables;
- functions for:
  - editing data,
  - assigning values,
  - shortening expressions
  - performing table lookup;
- data management;
- effectively creating SAS data sets;
- the logic of the MERGE;
- efficiency techniques.

'Real world' examples are presented to illustrate each topic.

Introduction

SAS procedures are powerful and easy to use, but the DATA step offers the programmer a tool with almost unlimited potential. In the real world, we're lucky if systems are integrated, data is clean and system interfaces are seamless. The DATA step can help you, your programmers, your program, and your users perform better in the real world – especially when you take advantage of the available advanced features. Given that any of the topics/examples covered in this presentation have more than enough details, idiosyncrasies, and caveats to warrant its own tutorial, we will address selected essential processing tips and a range of "real world" situations that illustrate:

- DATA step compile and execute
- coding efficiencies
- maximizing execution
- data: type conversions and missing values
- other data issues

DATA Step Compile vs. Execute

There is a distinct compile action and execution for each DATA and PROC step in a SAS program. Each step is compiled, then executed, independently and sequentially. Understanding the defaults of each activity in DATA step processing is critical to achieving accurate results. During the compilation of a DATA step, the following actions (among others) occur:

- syntax scan
- SAS source code translation to machine language
- definition of input and output files
- creates:
  - input buffer (if reading any non-SAS data),
  - Program Data Vector (PDV),
  - and data set descriptor information
- set variable attributes for output SAS data set
- capture variables to be initialized to missing

The variables output to the SAS data set are determined at compile time; the automatic variables are never written, unless they have been assigned to SAS data set variables set up in the PDV (_N_, _ERROR_, end=, in=, point=, first., last., and implicit array indices); the variables written are specified by user written DROP and/or KEEP statements or data set options; the default being all non-automatic variables in the PDV. The output routines are also determined at compile time. The following statements are compile-time only statements. They provide information to the PDV, and cannot by default (except in the macro language) be conditionally executed. Placement of the last four statements (shown below) is critical because the attributes of variables are determined by the first reference to the compiler:

- drop, keep, rename
- label
- retain
- length
- format, informat
- attrib
- array

Once compilation has completed, the DATA step is executed: the I/O engine supervisor optimizes the executable image by controlling looping, handling the initialize-to-missing instruction, and identifying the observations to be read. Variables in the PDV are initialized, the DATA step program is called, the user-controlled DATA step machine code statements are executed, and the default output of observations is handled.
By understanding the default activities of the DATA step, the SAS programmer can make informed and intelligent coding decisions. Code will be more flexible and efficient, debugging will be straightforward and make more sense, and program results can be interpreted readily.

**Coding Efficiencies & Maximizing Execution**

The SAS system affords the programmer a multitude of choices in coding the DATA step. The key to optimizing your code lies in recognizing the options and understanding the implications. This may not feel like advanced information, but the application of these practices has far-reaching effects.

Permanently store data in SAS data sets. The SET statement is dramatically more efficient for reading data in the DATA step than any form of the INPUT statement (list, column, formatted). SAS data sets offer additional advantages, most notably the self-documenting aspects and the ability to maintain them with procedures such as DATASETS. And they can be passed directly to other program steps.

A “shell” DATA step can be useful. Code declarative, compile-only statements (LENGTH, RETAIN, ARRAY) grouped, preceding the executable statements. Block-code other non-executables like DROP, KEEP, RENAME, ATTRIB, LABEL statements following the executable statements. Use of this structure will serve as a check list for the housekeeping chores and consistent location of important information. Use consistent case, spaces, indentation, and blank lines liberally for readability and to isolate units of code or to delineate DO-END constructions.

Use meaningful names for data sets and variables, and use labels to enhance the output. Comment as you code; titles and footnotes enhance an audit trail. Based on your understanding of the data, code IF-THEN-ELSE or SELECT statements in order of probability of execution. Execute only the statements you need, in the order that you need them. Read and write data (variables and observations) selectively, reading selection fields first, using DROP/KEEP, creating indexes. Prevent unnecessary processing. Avoid GOTOs. Simplify logical expressions and complex calculations, using parentheses to highlight precedence and for clarification. Use DATA step functions for their simplicity and arrays for their ability to compact code and data references.

**Data Conversions**

Character to numeric, and numeric to character, conversions occur when:

- incorrect argument types passed to function
- comparisons of unlike type variables occur
- performing type-specific operations (arithmetic) or concatenation (character)

SAS will perform default conversions where necessary and possible, but the programmer should handle all conversions to insure accuracy. The following code illustrates:

- default conversion,
- numeric-to-character conversion using PUT function,
- character-to-numeric conversion with INPUT function:

```sas
data convert1;
  length x $ 2 y $ 1;
  set insas; *contains numeric variables flag and code;
  x = flag;
  y = code;
run;

data convert2;
  length x $ 2 y 8;
  set insas; *contains numeric variables flag and code;
  x = put(flag, 2.);
  y = input(put(code, 1.), 8.);
run;

data convert3;
  length z 2;
  set insas; *contains character variable status;
  z = input(status, 2.);
run;
```

**Missing Data**

The DATA step provides many opportunities for serious editing of data and handling unknown, unexpected, or missing values. When a programmer is anticipating these conditions, it is straightforward to detect and avoid missing data; treat missing data as acceptable within the scope of an application; and even capitalize on the presence of missing data. When a value is stored as “missing” in a SAS data set, its value is the equivalent of negative infinity, less than any other value that could be present. Numeric missings are represented by a “.” (a period); character by “” (blank). Remember this in range checking and recoding. Explicitly handle missing data in IF-THEN-ELSE constructions; in PROC FOMATS used for recoding; and in calculations. The first statement in the following example:

```sas
if age < 8 then agegroup = "child";
if agegroup = " " then delete;
```

will include any observations where age is missing in the agegroup “child”. This may or may not be appropriate for your application. A better statement might be:

```sas
if (. < age < 8) then agegroup = "child";
```

Depending on the user’s application, it may be appropriate to distinguish between different types of missing values encountered in the data. Take advantage of the twenty-eight special missing values:

- .
- .
- .
- .

```sas
if comment = "unknown" then age = .;
else if comment = "refused to answer" then age = .A;
else if comment = "don’t remember" then age = .B;
```
All these missing values test the same. Once a missing value has resulted or been assigned, it stays with the data, unless otherwise changed during some stage of processing. It is possible to test for the presence of missing data with the N and NMISS functions:

```sas
y = nmiss(age, height, weight, name);
** y contains the number of nonmissing arguments;

z = n(a,b,c,d);
** z contains the number of missings in the list;
```

Within the DATA step, the programmer can encounter missing data in arithmetic operations. Remember that in simple assignment statements, missing values propagate from the right side of the equal sign to the left; if any argument in the expression on right is missing, the result on the left will be missing. Watch for the “missing values generated” messages in the SAS log. Although DATA step functions assist in handling missing values, it is important to understand their defaults as well. Both the SUM and MEAN functions ignore missing values in calculations: SUM will add all the non-missing arguments and MEANS will add the nonmissings and divide by the number of nonmissings. If all the arguments to SUM or MEANS are missing, the result of the calculations will be missing. This works for MEAN, but not for SUM, particularly if the intention is to use the result in a later calculation:

```sas
x = a + b + c; * if any argument is missing, x = . ;
x = SUM(a,b,c); *with missing argument, x is sum of nonmissings;
x = SUM(a,b,c,0); * if a,b,c are missing, result will be zero;
y = (d + e + f + g) / 4; *number of nonmissings is divided by 4;
y = MEAN(d,e,f,g); * if all arguments are missing, y = . ;
```

Since there are 90+ DATA step functions, the moral of the function story is to research how each handles missing values. New variables created in the DATA step are by default initialized to missing at the beginning of each iteration. Declare a RETAIN statement to override the default:

```sas
retain total 0;
total = total + add_it;
* this will work as long as add_it is never missing;
```

The SUM statement combines all the best features of the RETAIN statement and the SUM function:

```sas
total + add_it;
*total is automatically RETAINed;
* add_it is added as if using the SUM function;
* missings will not wipe out the accumulating total;
```

Missing values in the right-most data set coded on a MERGE or UPDATE statement have different effects on the left-most data set. When there are common variables in the MERGE data sets, missings coming from the right will overwrite. However, UPDATE protects the variables in the master file (left-most) from missings coming from the transaction file. (See Real World 7 example.)

** Re-Ordering Variables

SAS-L users periodically carry on the discussion of re-ordering variables as they appear in a SAS data set. Remember that as the compiler is creating the PDV, variables are added in the order they are encountered in the DATA step by the compiler. This becomes their default position order in the PDV and data set descriptor. The best way to force a specific order is with a RETAIN statement, with attention to placement. Make sure it is the first reference to the variable and the attributes are correct. It is possible to use a LENGTH statement to accomplish this, but a variable attribute could be inadvertently altered.

```sas
data new:
  retain c a v;
  * first reference to a b c;
set indata;
  * incoming position order is a b c;
x = a || b || c;
run;
```

** Handling Character Data

Character-handling DATA step functions can simplify string manipulation. Understand the defaults and how each function handles missing data for optimal use.

** Length of target variables

Target refers to the variable on the left of the equal sign in an assignment statement where a function is used on the right to produce a result. The default length for a numeric target is 8; however, for some character functions the default is 200, or the length of the source argument. The SCAN function operates unexpectedly:

```sas
data null;
x= 'abcdefghijklmnopqrstuvwxyz';
y = scan(x,1,'k');
put y=;
run;
y=abcdefghij;
* y has length of 200;
```

The results from SUBSTR are different:

```sas
data old;
a='abcdefghijklmnopqrstuvwxyz';
b=2; c=9;
run;
data new;
set old;
x=substr(a,23,4);
y=substr(a,b,3);
z=substr(a,b,c);
put a= b= c= x= y= z=;
```

Other Data Issues
SUBSTR as pseudo-variable

Another SAS-L discussion involved the use of SUBSTR as a pseudo-variable. Note that when the function appears to the left of the equal sign in the assignment statement, text replacement occurs in the source argument:

```
data fixit;
  source = 'abcdefghijklmnopqrstuvwxyz';
  substr(source, 12, 10) = '##########';
  put source=;
run;
```

```
source=abcdefghijk##########vwxyz
```

Numeric substring

A similar function to SUBSTR if often desired for numerics. One cumbersome solution involves: 1) performing numeric to character conversion, 2) using SUBSTR to parse the string, and 3) converting the found string back to numeric. SAS would also do such conversions for you if you reference a numeric as an argument to a character function or include a character variable in a numeric calculation. See section on data conversions.

A simpler and less error-prone solution (trick) is the use of the numeric MOD and INT functions:

```
data new;
  a=123456;
  x = int(a/1000);
  y = mod(a,1000);
  z = mod(int(a/100),100);
  put a= x= y= z=;
run;
```

```
a=123456
x=123
y=456
z=34
```

Handling imbedded blanks

The TRIM and TRIMN functions are used to removed embedded blanks. Notice the different results:

```
data _null_
string1='trimmed ';
string2=?
string3=!
string4=.
  w=string1||string2;
data ifexp iferr;
set expenses;
```

Table Lookup

Recoding is a common programming challenge, and can be accomplished in several ways:

- hard-coded IF statements
- MERGE
- PROC FORMAT with the PUT function
- data driven FORMATs.

Hard-Coded IF Statements

For this example, we know the DEPTINFO (descriptive information for each DEPTNAME) for each sort code (SORTCD):

- 1001 Operations
- 1002 Hardware
- 1003 Software (IBM)
- 1004 Software (MAC)
- 1005 LAN/WAN
- 1006 Technical Support
- 1007 Help Desk 1008 Administrative Support
- 1009 Documentation Library
- 1010 Incentive Program
- 1011 Unassigned
- 1012 Unassigned
- 1013 Unassigned
- 1014 Unassigned
- 1015 Unassigned

```
data ifexp iferr;
set expenses;
```

The users want a listing and separate SAS data set with valid expense data (an “unassigned” sortcode with expenses is considered an error). The deliverables will be an error report and an error file to facilitate corrections.

```
EXAMPLE 1: Table Lookup with IF statements:
```

```
data ifexp iferr;
set expenses;
```

length deptname $25;
if 1001 le sortcd le 1010 then
do;
  if sortcd = 1001 then deptname = 'Operations';
  else if sortcd = 1002 then deptname = 'Hardware';
  else if sortcd = 1003 then deptname = 'Software (IBM)';
  else if sortcd = 1004 then deptname = 'Software (MAC)';
  ... output ifexp;
end;
else output iferr;
run;

This method uses the IF/ELSE statements efficiently and accomplishes the objective. But having a separate data set for users to track the sort codes they can still assign would be more useful and easily maintainable.

### Table Lookup using MERGE

**EXAMPLE 2:** Table Lookup with MERGE (assuming a data set with department descriptions (DEPTINFO) for each SORTCD has been created:

```sas
proc sort data=expenses;
  by sortcd;
run;

proc sort data=deptinfo;
  by sortcd;
run;

data expens2 errdept missmnth;
  merge expenses(in=inexp) deptinfo(in=indpt);
  by sortcd;
  if inexp and indpt then
do;
    if index(upcase(deptname),'UNASSIGNED') > 0 then
      output errdept;
    else output expens2;
  end;
  else if inexp and not indpt then output errdept;
  else if (indpt and not inexp) and
         index(upcase(deptname),'UNASSIGNED') = 0
  then output missmnth;
run;
```

The MERGE provides the users with a “bonus” file by coding multiple data set names on the DATA statement and using the IN= option on the MERGE statement. Data set EXPENS2 contains the valid expense data; ERRDEPT holds the incorrect expense data; and MISSMNTH (optional) shows which sortcodes have no expense data for the month.

### PROC FORMAT with the PUT function

**EXAMPLE 3:** PROC FORMAT with PUT function:

```
proc format;
  value regfmt 100-200 = "NE"
  201-300 = "NW"
  301-400 = "SE"
  401-500 = "SW";
run;
```

Accomplishing data recoding using PROC FORMAT with the PUT function provides several benefits to the users and programmer: it is readable; easy to maintain -- the list of values need only be changed in one location; the formats can be permanently stored in a format library; the DATA step code itself is shorter and easier to follow.

### Data Driven PROC FORMAT Generation

**EXAMPLE 4:** Table Lookup using a SAS data set to generate the PROC FORMAT:

```
data fdnm(keep=start end label fmtname);
  set deptinfo end=eofdept;
  length label $32;
  start = sortcd;
  end = sortcd;
  label = deptname;
  fmtname = 'convdept';
  output fdnm;
  if eofdept then
do;
    start = .;
    end = .;
    label = 'ERROR';
    fmtname = 'convdept';
    output fdnm;
  end;
run;
```

```
proc format cntlin=work.fdnm;
run;
```

The overhead associated with this solution comes from reading the DEPTINFO dataset and using it to make a CNTLIN dataset for PROC FORMAT (see SAS log). The temporary dataset, WORK.FDNM, is passed to PROC FORMAT with the CNTLIN= options to create the SAS format CONVDEPT:

```
FORMAT NAME: CONVDEPT LENGTH: 22 NUMBER OF VALUES: 18
MIN LENGTH: 1 MAX LENGTH: 40 DEFAULT LENGTH 22 FUZZ: STD
START   END   LABEL (VER. 6.11)
.       .       ERROR
0       1000   ERROR
1001     1001   Operations
1002     1002   Hardware
1003     1003   Software (IBM)
1004     1004   Software (MAC)
1005     1005   LAN/WAN
1006     1006   Technical Support
1007     1007   Help Desk
1008     1008   Administrative Support
1009     1009   Documentation Library
```

Advanced Tutorials
Once the format (or informat) has been created, it can be used to read the expense data with an informat statement, print the expense data using the format in a PROC PRINT, or apply the format to the SORTCD variable in the expense program giving the users the monthly expense and error reports required:

```sas
data fmtexp fmterr;
  set expenses;
  length deptname $25;
  deptname = put(sortcd,convdept.);
  if deptname = 'ERROR' or
     index(upcase(deptname), 'UNASSIGNED') gt 0)
    output fmterr;
  else output fmtexp;
run;
```

Using format from CNTLIN with PROC PRINT:

```sas
Using format from CNTLIN with PROC PRINT:
```

Table Lookup Conclusions

For small lists and table lookups against small lists on relatively static data, the MERGE example is preferable to IF/ELSE. Where data are volatile, or the lookup list is very large, it will prove more efficient to use the PROC FORMAT with the PUT function and/or create the formats from data that drives the list. The formats are easily maintained, excellent documentation, and provide a mechanism for making changes in only one location in the program.

Notice from the example that other applications of PROC FORMAT with the PUT function become apparent. The table lookup can re-code variables, assign values, range-check values, and shorten expressions.

Data Set Management

Here’s where the rubber meets the road -- the odd challenges encountered in user applications, like ‘em or not. And this is where the power of the DATA step can be the most effective -- in handling “real world” situations:

- referencing a data set at compile time
- oddly located “bad” records
- writing for word processing packages
- variable-length raw data records
- deleting observations based on last in a series
- optimizing first. processing
- manipulating sort order
- choosing MERGE or UPDATE

Real Word 1: Referencing a Data Set at Compile Time

It is often necessary to capture the number of observations in a data set at compile time:

```sas
data _null_;
  call SYMPUT('n_obs', put(n_obs, 5.));
  stop;
set indata nobs = n_obs;
run;
```

The SYMPUT function in the example above will capture the number of observations from the data set descriptor at compile time, without processing any data. The value of the macro variable &n_obs becomes available to reference from another program step.

Real World 2: Other People’s Data

Other people’s data entry programs can cause unexpected problems. Suppose there’s a bug in the CICS/COBOL program that collects sales data. The first record for each city and each hour is known to be “bad” data. The COBOL programmers get rid of the record when they pass the data to the General Ledger system. However, other departments can only read the raw data for ad hoc reports. This input data shows which lines should be deleted (note: you can’t delete the first observation and every third observation because there aren’t always three people working in an hour):

```sas
BOSTON 7 BILL 107000 --
delete this
BOSTON 7 DAVE 345998
BOSTON 7 JEAN 356754
BOSTON 8 DAVE         40 --
delete this
BOSTON 8 BILL         98
BOSTON 8 JEAN         64
```

A simple way to solve this problem uses the features of PROC SORT. After you read the raw data, sort the data by city and hour (not by name, so SAS will retain the names in the order they appeared in original data set). This sort assures there will never be HOUR 7 for LONDON occurring immediately after HOUR 7 for BOSTON. Use the first.hour automatic SAS variable to delete bad data.

```sas
proc sort data=citysale;
  by city hour;
run;
```

This input data shows which lines should be deleted (note: you can’t delete the first observation and every third observation because there aren’t always three people working in an hour):

```sas
proc sort data=citysale;
  by city hour;
run;
```

Data dropit keepit;
set citysale;

```
```

Table Lookup Conclusions

For small lists and table lookups against small lists on relatively static data, the MERGE example is preferable to IF/ELSE. Where data are volatile, or the lookup list is very large, it will prove more efficient to use the PROC FORMAT with the PUT function and/or create the formats from data that drives the list. The formats are easily maintained, excellent documentation, and provide a mechanism for making changes in only one location in the program.

Notice from the example that other applications of PROC FORMAT with the PUT function become apparent. The table lookup can re-code variables, assign values, range-check values, and shorten expressions.

Data Set Management

Here’s where the rubber meets the road -- the odd challenges encountered in user applications, like ‘em or not. And this is where the power of the DATA step can be the most effective -- in handling “real world” situations:
by city hour;
  if first.hour then
    do;
      output dropit;
      delete;
    end;
    output keepit;
  run;

Using first.hour would drop these:

<table>
<thead>
<tr>
<th>CITY</th>
<th>NAME</th>
<th>HOUR</th>
<th>DOLLARS</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>BILL</td>
<td>7</td>
<td>107000</td>
</tr>
<tr>
<td>BOSTON</td>
<td>DAVE</td>
<td>8</td>
<td>40</td>
</tr>
<tr>
<td>BOSTON</td>
<td>JEAN</td>
<td>9</td>
<td>98</td>
</tr>
<tr>
<td>LONDON</td>
<td>MONTY</td>
<td>15</td>
<td>567838</td>
</tr>
<tr>
<td>LONDON</td>
<td>JEAN</td>
<td>16</td>
<td>56</td>
</tr>
<tr>
<td>LONDON</td>
<td>HELEN</td>
<td>17</td>
<td>773</td>
</tr>
<tr>
<td>PARIS</td>
<td>SERGEI</td>
<td>3</td>
<td>7698</td>
</tr>
</tbody>
</table>

Using first.hour would keep these:

<table>
<thead>
<tr>
<th>CITY</th>
<th>NAME</th>
<th>HOUR</th>
<th>DOLLARS</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>DAVE</td>
<td>7</td>
<td>345998</td>
</tr>
<tr>
<td>BOSTON</td>
<td>JEAN</td>
<td>7</td>
<td>356754</td>
</tr>
<tr>
<td>BOSTON</td>
<td>JEAN</td>
<td>8</td>
<td>98</td>
</tr>
<tr>
<td>BOSTON</td>
<td>DAVE</td>
<td>9</td>
<td>63</td>
</tr>
<tr>
<td>BOSTON</td>
<td>BILL</td>
<td>9</td>
<td>25</td>
</tr>
<tr>
<td>LONDON</td>
<td>MONTY</td>
<td>15</td>
<td>245810</td>
</tr>
<tr>
<td>LONDON</td>
<td>JEAN</td>
<td>15</td>
<td>45625</td>
</tr>
<tr>
<td>LONDON</td>
<td>MONTY</td>
<td>15</td>
<td>32</td>
</tr>
<tr>
<td>LONDON</td>
<td>MONTY</td>
<td>17</td>
<td>546</td>
</tr>
<tr>
<td>PARIS</td>
<td>PIERRE</td>
<td>3</td>
<td>7936</td>
</tr>
<tr>
<td>PARIS</td>
<td>AIMEE</td>
<td>3</td>
<td>12948</td>
</tr>
</tbody>
</table>

**Real World 3: VP’s Admin likes WORD**

The user wants mailing labels from their SAS data set in WORD format. The text strings ‘NAME’ and ‘LOCATION’ must appear on the first line of the file; on the subsequent data lines, each field must be separated by the WORD tab character (hex value =09). After the OUTLABEL file (ASCII) is written, it is “pulled” into WORD and merged with the WORD label document:

```
libname newlabl 'c:saspaper';
filename outlabel 'c:saspaper\barbnew.txt';
*** the note-1 field to stuff the envelopes with the right document;***  
    note-1 appears on the checklist but not the labels;
proc sort data=newlabl.barb;
    by note1 lastname name1;
run;
proc print data=newlabl.barb;
    title 'SAS dataset: newlabl.barb -- do labels with WORD';
    title2 'Envelope checklist';
    id name1;
    var lastname deptloc note1 note2;
run;
```

```
data _null_;    
    set newlabl.barb;
    length hextab $1;
    retain hextab '09'x;
    file outlabel;
    if _n_ = 1 then put @1 hextab 'NAME' hextab 'LOCATION';
    put hextab : $1. name1 : $15.-l lastname : $15.-l hextab : $1. deptloc : $8.-l ;
run;
```

The resulting ASCII file is ready to bring into WORD (tab characters do not display):

<table>
<thead>
<tr>
<th>NAME</th>
<th>LOCATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>LORD GEOFFREY VANDERSNEER</td>
<td>1111/111</td>
</tr>
<tr>
<td>BOBBIT ALITTLE</td>
<td>3195/717</td>
</tr>
<tr>
<td>LEOPOLD BLOOM</td>
<td>6969/069</td>
</tr>
<tr>
<td>HERMAN MELVILLE</td>
<td>8592/533</td>
</tr>
<tr>
<td>GEORGIA ONMYMIND</td>
<td>4854/217</td>
</tr>
<tr>
<td>ISHMAEL SAILOR</td>
<td>3299/007</td>
</tr>
<tr>
<td>MAX ANDERSON</td>
<td>4423/129</td>
</tr>
<tr>
<td>BILBO BAGGINS</td>
<td>9366/941</td>
</tr>
<tr>
<td>WRASSE BALDARCHER</td>
<td>5467/149</td>
</tr>
<tr>
<td>R. T. EFMANUAL</td>
<td>1929/507</td>
</tr>
<tr>
<td>SEAMUS JOYCE</td>
<td>6969/069</td>
</tr>
<tr>
<td>DONNA REED</td>
<td>7907/626</td>
</tr>
<tr>
<td>THOMAS T. RHYMER</td>
<td>8832/777</td>
</tr>
<tr>
<td>PUDDIN TAME</td>
<td>8633/321</td>
</tr>
<tr>
<td>KERMIT PHROG</td>
<td>9923/555</td>
</tr>
</tbody>
</table>

**Real World 4: Hinky Data**

Transferring ASCII files between various software packages and platforms can also cause problems. When an ASCII file was transferred between a MACINTOSH mail program to a PC, the text lines were written as variable length records (vs. fixed on the MAC), and many apostrophes became represented by hex code 12 (shows as a '.' in the SAS LOG). In addition, the MAC tab character became ‘>’ in the translated file.

If a 40 page story is late for a publishing deadline: you can:
- beg secretary to make changes in WP package;
- make changes in the word processor yourself; or
- write program using character manipulation functions.

The “damaged” file (note periods instead of apostrophes and > ):

```
>l1 never see another loss like that. No more soldiers, no more blood. She hadn't ever tried to talk to the ghosts; it was hard to tell which one was >The travel clerk didn't have to remind her not to approach the time tourists, said to the uncaring sky. "What's the good of all these dead custers, anyway?"
```

(undamaged text deleted)
end; else put @1 textline; run;

I'll never see another loss like that. No more soldiers, no more blood. She hadn't ever tried to talk to the ghosts; it was hard to tell which one was The travel clerk didn't have to remind her not to approach the time tourists, uncaring sky. "What's the good of all these dead custers, anyway?"

Real World 6: Need to delete last in a series

A health care worker has a data set with unequal lines of data per person for different years with the same variables per line. The objectives:

- keep all lines for person if last yr is 1991 or less
- delete all lines if year on last record is GE 1992:

```
data yrinfo;
length id 3 yr 3 info $10;
input id yr info;
cards;
1 80 asthma
1 82 bronchitis
1 83 asthma
1 86 pneumonia
1 91 pleurisy <--- keep all for id 1
2 90 bronchitis
2 91 bronchitis
2 92 sinusitis <--- delete all for id 2
3 80 bronchitis
; run;
```

The simplest solution is a sort of the input data by ID and descending YR. This order allows the first.yr automatic variable to be the last year in the patient's data. When first.yr is greater than or equal to 92, then a delete flag (DELFLAG) will be set. The code creates two data sets: KEEPIT and DELEITEIT; however, in a production environment, it might only be necessary to use a subsetting IF (if delflag=0;) to output only the desired observations:

```
data yrinfo;
length id 3 yr 3 info $10;
input id yr info;
cards;
1 80 asthma
1 82 bronchitis
1 83 asthma
1 86 pneumonia
1 91 pleurisy <--- keep all for id 1
2 90 bronchitis
2 91 bronchitis
2 92 sinusitis <--- delete all for id 2
3 80 bronchitis
; run;
```

```
proc sort data=yrinfo;
    by id descending yr ;
run;
```

```
data keepit deleiteit;
    set yrinfo;
    by id descending yr ;
    length delflag 3;
    retain delflag ;
    if first.id then delflag = 0;
    if first.id and first.yr and yr ge 92 then delflag = 1;
    if delflag = 1 then do;
        output deleiteit;
        delete;
    end;
    if delflag = 0 then output keepit;
run;
```

Real World 6: They Want WHAT??!!!

The creation of a "super-sort" variable can allow you to minimize the number of first. variables used to successfully process a data set. In this example, trouble tickets (TICKET) can be assigned to multiple directors (DIRECTOR) and multiple reporting areas (AREA) for investigation of system outages (DURATION). The system outages (OUTAGES) can affect multiple lines of business (LINEBUSN):

<table>
<thead>
<tr>
<th>TICKET</th>
<th>LINEBUSN</th>
<th>DIRECTOR</th>
<th>AREA</th>
<th>DURATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>321</td>
<td>NET</td>
<td>TURNER OPERATIONS</td>
<td>35</td>
<td></td>
</tr>
<tr>
<td>565</td>
<td>CRP</td>
<td>MILLER SOFTWARE</td>
<td>12</td>
<td></td>
</tr>
<tr>
<td>565</td>
<td>CRP</td>
<td>MILLER LAN/WAN</td>
<td>12</td>
<td></td>
</tr>
<tr>
<td>565</td>
<td>NET</td>
<td>MILLER SOFTWARE</td>
<td>15</td>
<td></td>
</tr>
<tr>
<td>565</td>
<td>NET</td>
<td>MILLER LAN/WAN</td>
<td>30</td>
<td></td>
</tr>
<tr>
<td>565</td>
<td>BUS</td>
<td>MILLER SOFTWARE</td>
<td>30</td>
<td></td>
</tr>
<tr>
<td>565</td>
<td>BUS</td>
<td>MILLER LAN/WAN</td>
<td>30</td>
<td></td>
</tr>
<tr>
<td>436</td>
<td>CRP</td>
<td>JONES HARDWARE</td>
<td>80</td>
<td></td>
</tr>
<tr>
<td>436</td>
<td>CRP</td>
<td>MILLER SOFTWARE</td>
<td>25</td>
<td></td>
</tr>
<tr>
<td>436</td>
<td>NET</td>
<td>JONES HARDWARE</td>
<td>75</td>
<td></td>
</tr>
<tr>
<td>436</td>
<td>NET</td>
<td>MILLER SOFTWARE</td>
<td>25</td>
<td></td>
</tr>
<tr>
<td>436</td>
<td>BUS</td>
<td>MILLER SOFTWARE</td>
<td>75</td>
<td></td>
</tr>
<tr>
<td>436</td>
<td>BUS</td>
<td>JONES HARDWARE</td>
<td>25</td>
<td></td>
</tr>
</tbody>
</table>

To complete the tracking process, users want two reports:
1) a summary by line of business and director showing the total number of minutes for each ticket and the number of areas affected; 2) a list indicating line of business at the top of each page for every unique line of business/director/ticket combination. A "super-sort" variable can be created (using character concatenation) to simplify processing, replacing the more tedious first. processing for all the combinations of LINEBUSN, DIRECTOR and TICKET (though NOT AREA):

```
data sortexmp;
    set outages;
    length suprsort $11;
    suprsort =linebusn||substr(director,1,5)||put(ticket,3.0);
run;
```

(Note numeric variable ticket converted to character for the substring);

```
data sortexmp;
    set outages;
    length suprsort $11;
    suprsort =linebusn||substr(director,1,5)||put(ticket,3.0);
run;
```

Subsequent processing uses the SUPRSORT variable to produce the detail report and summary report file in one data step:

```
data dirtotl(keep=linebusn director ticket numarea dirtot);
    set sortexmp;
    by suprsort;
    retain dirtot numarea;
    file detail print;
    if first.suprsort then do;
        dirtot=0;
        numarea = 0;
        put _page_ ;
        title 'detail listing by line of business';
        put @5 'line of business: ' linebusn;
        end;
        dirtot + duration;
        numarea + 1;
        put @1 linebusn director area ticket duration;
        if last.suprsort then output dirtotl;
    run;
```

```
data sortexmp;
    set outages;
    length suprsort $11;
    suprsort =linebusn||substr(director,1,5)||put(ticket,3.0);
run;
```

*(Note numeric variable ticket converted to character for the substring)*

```
data sortexmp;
    set outages;
    length suprsort $11;
    suprsort =linebusn||substr(director,1,5)||put(ticket,3.0);
run;
```

Subsequent processing uses the SUPRSORT variable to produce the detail report and summary report file in one data step:

```
data dirtotl(keep=linebusn director ticket numarea dirtot);
    set sortexmp;
    by suprsort;
    retain dirtot numarea;
    file detail print;
    if first.suprsort then do;
        dirtot=0;
        numarea = 0;
        put _page_ ;
        title 'detail listing by line of business';
        put @5 'line of business: ' linebusn;
        end;
        dirtot + duration;
        numarea + 1;
        put @1 linebusn director area ticket duration;
        if last.suprsort then output dirtotl;
    run;
```
by linebusn director;
run;
proc print data=dirtotl;
  by linebusn;
  sum dirtot;
run;

The SUPRSORT variable can also be used in SAS procedures, like PROC MEANS or PROC FREQ, to minimize the unnecessary _TYPE_s (PROC MEANS) or TABLEs (PROC FREQ) produced by using multiple BY statements. The summary report from data set DIRTOTL:

```
LINEBUSN=BUS
OBS DIRECTOR TICKET DIRTOT NUMAREA
1 JONES 436 25 1
2 MILLER 436 75 1
3 MILLER 565 60 2
------
LINEBUSN 160
```

And the detail report looks like:

```
-(new page) -detail listing by line of business
LINE OF BUSINESS: BUS
BUS JONES HARDWARE 436 25
-(new page) -detail listing by line of business
LINE OF BUSINESS: BUS
BUS MILLER SOFTWARE 436 75
-(new page) -detail listing by line of business
LINE OF BUSINESS: BUS
BUS MILLER LAN/WAN 565 30
```

Real World 7: Manipulating Sort Order

When a Performance Tracking system was coded, three-character codes were used for line of business. However, the users rejected the report because the lines of business printed in alphabetical order, not in the order that the customers expected. The first report generated appeared as follows:

```
Listing by Line of Business in Alpha Order
Line of Business=ACT
App Calc Performance
Name Used Objective
ACCOUNTS RECEIVABLE VIP 0.9756
CONTROLLER NONVIP 0.9900
GENERAL LEDGER NONVIP 0.9800
PAYROLL VIP 0.9787
Line of Business=CRP
App Calc Performance
Name Used Objective
BENEFITS NONVIP 0.9800
GROUNDS NONVIP 0.9800
HUMAN RESOURCES NONVIP 0.9500
MEDICAL NONVIP 0.9900
PURCHASING NONVIP 0.9800
RECEIVING NONVIP 0.9800
```

Real World 8: MERGE vs. UPDATE

If a file only needs a few changes, why recreate the entire file just to make those changes? This scenario demonstrates the benefit of the UPDATE statement over the MERGE for some applications. The master file (MASTER) contains names, birthdays, gift ideas and other information:

```
NAME  BDATE  SIZE  COLOR  INTEREST    WHAT
LIMIT
jody  08-23-84 g14  purple  Nancy Drew  niece       20
john  10-14-93 j4   red     Lion King  nephew   20
meghan 12-02-83 j5   green  music      godchild  50
morgan 12-02-83 j5   teal    theater  godchild  50
sal    04-11-45 mxl none    hang gliding college 5
mary ann 10-17-95 b18 pink   rattles  daughter 100
```

```
TRAVEL  NONVIP  0.9700
Line of Business=NET
App Calc Performance
Name Used Objective
LOCAL AREA NETWORK NONVIP 0.9900
ROLMI EQUIPMENT VIP 0.9900
SITE LICENSE NONVIP 0.9900
SYSTEM SOFTWARE VIP 0.9787
TECHNICAL SUPPORT VIP 0.9700
WIDE AREA NETWORK NONVIP 0.9900
```

Using PROC FORMAT, the system designer can code the line of business and force the specific expected order on the report:

```
proc format;
  value $lobord 'NET' = 1
     'CRP' = 2
     'OPR' = 3
     'ACT' = 4;
  value nicename 1 = 'NETWORK'
               2 = 'CORPORATE'
               3 = 'OPERATIONS'
               4 = 'ACCOUNTING';
run;

data neword;
  set applinfo;
  length ordlob 3.;
  ordlob = put(linebusn,$lobord.);
run;

proc sort data=neword;
  by ordlob appname;
run;
```

Once the data is sorted by the coded variable and appname, the NICENAME format can be applied to substitute the long name for lines of business and manipulate the order of presentation on the users' reports:

```
List of Applications by Line of Business (in different order)
Line of Business=NETWORK
App Calc Performance
Name Used Objective
LOCAL AREA NETWORK NONVIP 0.9900
ROLMI EQUIPMENT VIP 0.9900
SITE LICENSE NONVIP 0.9900
SYSTEM SOFTWARE VIP 0.9787
TECHNICAL SUPPORT VIP 0.9700
WIDE AREA NETWORK NONVIP 0.9900
```

(Line of Business=CORPORATE, etc., follow.)
Using a MERGE to add a new person is fine. But the merge will produce unreliable results when changing values of any of the variables (Morgan’s favorite color to orange or Jody’s interest to Goose Bumps books). This application might suggest a file of change transactions (UPDTTRNS) and a merge by NAME and BDATE:

```
data newmstr2;
  merge master(in=inmast) updttrns(in=intran);
  by name bdate;
  if (inmast and intran) or (inmast and not intran)
    then output newmstr2;
  if intran and not inmast then output newmstr2;
run;
```

The resulting data set added Suzanne, but lost all of Jody’s information except INTEREST. Morgan’s color changed, but all of other information was lost:

<table>
<thead>
<tr>
<th>NAME</th>
<th>BDATE</th>
<th>SIZE</th>
<th>COLOR</th>
<th>INTEREST</th>
<th>WHAT</th>
</tr>
</thead>
<tbody>
<tr>
<td>jody</td>
<td>08/23/84</td>
<td>g14</td>
<td>None</td>
<td>Goose Bumps</td>
<td>niece</td>
</tr>
<tr>
<td>john</td>
<td>10/14/93</td>
<td>t4</td>
<td>red</td>
<td>Lion King</td>
<td>nephew</td>
</tr>
<tr>
<td>mary</td>
<td>10/17/95</td>
<td>b18</td>
<td>pink</td>
<td>rattles</td>
<td>daughter</td>
</tr>
<tr>
<td>meghan</td>
<td>12/02/83</td>
<td>j5</td>
<td>green</td>
<td>music</td>
<td>godchild</td>
</tr>
<tr>
<td>morgan</td>
<td>12/02/83</td>
<td>j5</td>
<td>orange</td>
<td>theater</td>
<td>godchild</td>
</tr>
<tr>
<td>sal</td>
<td>04/11/45</td>
<td>mxl</td>
<td>none</td>
<td>hang gliding</td>
<td>college</td>
</tr>
<tr>
<td>suzanne</td>
<td>11/15/50</td>
<td>na</td>
<td>na</td>
<td>mystery series</td>
<td>coworker</td>
</tr>
</tbody>
</table>

An UPDATE application is actually called for. Create an update transaction, using named input and the special missing option (_) to change only the variables requiring update. Use the same variables on the transaction file as on the master file. Variables in the transaction file with missing values will NOT overwrite the fields in the master file. (LIMIT for Morgan has been explicitly coded to ." to demonstrate this feature). Only those changes with the special missing character underscore (_) will update a master file field to missing (see Jody’s color):

```
data updttrns;
  length bdate 8 interest $15 limit 8;
  informat bdate mmddyy8.;
  input name= $& bdate= size= $ color= $ interest= $& what= $ limit=;
  missing _ ;
  cards;
  name=morgan bdate=12-02-83 color=orange limit=
  name=jody bdate=08-23-84 interest=Goose Bumps color=
  name=suzanne bdate=11-15-50 size=na color=na interest=mystery series limit=5
  what=coworker
  ;
run;
```

The UPDATE statement produces the desired result:

<table>
<thead>
<tr>
<th>NAME</th>
<th>BDATE</th>
<th>SIZE</th>
<th>COLOR</th>
<th>INTEREST</th>
<th>WHAT</th>
</tr>
</thead>
<tbody>
<tr>
<td>jody</td>
<td>08/23/84</td>
<td>g14</td>
<td>None</td>
<td>Goose Bumps</td>
<td>niece</td>
</tr>
<tr>
<td>john</td>
<td>10/14/93</td>
<td>t4</td>
<td>red</td>
<td>Lion King</td>
<td>nephew</td>
</tr>
<tr>
<td>mary</td>
<td>10/17/95</td>
<td>b18</td>
<td>pink</td>
<td>rattles</td>
<td>daughter</td>
</tr>
<tr>
<td>meghan</td>
<td>12/02/83</td>
<td>j5</td>
<td>green</td>
<td>music</td>
<td>godchild</td>
</tr>
<tr>
<td>morgan</td>
<td>12/02/83</td>
<td>j5</td>
<td>orange</td>
<td>theater</td>
<td>godchild</td>
</tr>
<tr>
<td>sal</td>
<td>04/11/45</td>
<td>mxl</td>
<td>none</td>
<td>hang gliding</td>
<td>college</td>
</tr>
<tr>
<td>suzanne</td>
<td>11/15/50</td>
<td>na</td>
<td>na</td>
<td>mystery series</td>
<td>coworker</td>
</tr>
</tbody>
</table>
