Paper 4809-2020

Exploring Online Drug Reviews using Text Analytics, Sentiment Analysis and Data Mining Models

Thu Dinh, Oklahoma State University
Goutam Chakraborty, Oklahoma State University
Miriam McGaugh, Oklahoma State University

ABSTRACT

Drug reviews play a very significant role in providing crucial medical care information for both healthcare professionals and consumers. Customers are utilizing online review sites to voice opinions and express sentiments about experienced drugs. However, a potential buyer typically finds it very hard to go through all comments before making a purchase decision. Another big challenge is the unstructured and textual nature of the reviews, which makes it difficult for readers to classify comments into meaningful insights. For these reasons, this paper primarily aims to classify the side effect level and effectiveness level of prescribed drugs by using text analytics and predictive models within SAS® Enterprise Miner™. Additionally, the paper explores specific effectiveness and potential side effects of each prescription drug through sentiment analysis and text mining within SAS® Visual Text Analytics. The study's results show that the best performing model for side effect level classification is the rule-based model with a validation misclassification rate at 27.1%. Regarding effectiveness level classification, the text rule builder model also works best with a 22.4% validation misclassification rate. These models are further validated by using a transfer learning algorithm to evaluate performance and generalization. The results can be used to develop practical guidelines and useful references to facilitate prospective patients in making better informed purchase decisions.

INTRODUCTION

With the rapid growth in the number of available online reviews sites and discussion boards, today's consumers are increasingly relying on online resources to aid in purchase decisions. Review sites provide existing customers the opportunity to share objective feedback about products and services they have personal experience with, which in turn facilitates prospective consumers purchase decisions. According to recent customer behavior surveys, nearly 95% of shoppers read online reviews before making a purchase (Spiegel Research Center, 2017) and 97% of buyers consider online reviews as a major useful source of information when making a purchase decision (Fan and Fuel, 2016). Typically, online drug reviews consist of two parts - ratings and textual comments. While ratings indicate the overall evaluation of customer using a numeric scale, textual comments can often provide more useful insights into the effectiveness and side effects of the drug, which overall ratings cannot. However, with the increasing number of textual comments from users, it has become more and more challenging for potential users to go through all reviews before making decisions. Therefore, an efficient structured algorithm is needed to explore the reviews and classify them into meaningful features which can serve as helpful recommendation to potential buyers. In view of that, the primary goal of this study is to construct a data-mining model to classify the side effect level and effectiveness level of prescription drugs. Additionally, the study also attempts to detect the potential side effects and explore specific effectiveness of each prescribed drug to facilitate prospective patients in selecting the best drug for treatment. The training data are collected from *druglib.com* to build predictive models which are then validated using additional data gathered from *drugs.com* using transfer learning. The results of the study are expected to help develop

some useful references and practical guidelines for prospective drug users in making informed purchase decisions.

DATA PREPARATION

DATA SOURCE

The data for this research paper are retrieved from two independent websites, *Druglib.com* and *Drugs.com*, which are among the largest and most widely visited pharmaceutical information resources for both consumers and healthcare professionals. These datasets are stored in '.tsv' (tab separated values) files and originally compiled by Felix Gräßer *et al.,* 2018. The data are available for download within the UC Irvine Machine Learning Repository (UC-Irvine, 2018). The downloaded datasets are converted to excel format and then imported to SAS® Enterprise Miner and SAS® Visual Text Analytics for further analysis.

DATA DICTIONARY

The first dataset from *Druglib.com* consists of patient reviews on 541 drugs along with 1,808 related conditions. Reviews are provided on three aspects including benefits, side effects and overall comment. Similarly, ratings are also available for three aspects: 5-level side effect rating, 5-level effectiveness rating, and 10-star overall satisfaction rating. There are a total of 4,143 observations with nine attributes as shown in Table 1 below:

Variable	Description	Datatype
ID	Index of review entry	Numerical
UrlDrugName	Name of drug	Categorical
Condition	Patient condition (reason for using drug)	Text
BenefitsReview	Patient review on benefits	Text
Effectiveness	*5-level effectiveness rating* (Ineffective, Marginally Effective, Moderately Effective, Considerably Effective, Highly Effective)	Categorical
SideEffectsReview	Patient review on side effects	Text
SideEffects	*5-level side effect rating* (No Side Effects, Mild Side Effects, Moderate Side Effects, Severe Side Effects, Extremely Severe Side Effects)	Categorical
CommentsReview	Patient overall comment	Text
Rating	10-star overall satisfaction rating	Numerical

Figure 1 - Partial data from the Druglib.com dataset

The second dataset from *Drugs.com* provides patient reviews on 3,654 drugs along with 836 related conditions and a 10-star patient rating which reflects overall patient satisfaction.

There are a total of 215,063 observations in the dataset with seven attributes as presented in Table 2 below:

Variable	Description	Datatype
ID	Index of review entry	Numerical
DrugName	Name of drug	Categorical
Condition	Patient condition (reason for using drug)	Categorical
Review	Patient review	Text

METHODOLOGY

APPROACH

Figure 3 – Analysis approach

TARGET VARIABLES

The severity of side effects and the level of effectiveness in the *Druglib.com* dataset are rated by reviewers using the 5-point Likert scale, while those in the *Drugs.com* are not rated. We randomly pick a subsample from the *Drugs.com* dataset and manually annotate labels of side effect levels and effectiveness levels. In order to reduce the workload and the confusion of labeling, we create new target variables for the *Druglib.com* dataset as following:

Target Variables	Values	Level	Frequency count (%)
SideEffectLevel	No Side Effects	0	131 (20.00%)
	Mild / Moderate Side Effects	1	420 (64.12%)
	Severe / Extremely Severe Side Effects	2	104 (15.88%)
EffectivenessLevel	Ineffective	0	61 (9.31 %)
	Marginally / Moderately Effective	1	128 (19.54%)
	Considerably / Highly Effective	2	466 (71.15%)

Table 3 – Model target variables

SIDE EFFECT CLASSIFICATION

To classify the side effect levels of drugs from users' reviews, the following text mining and predictive modeling process is implemented.

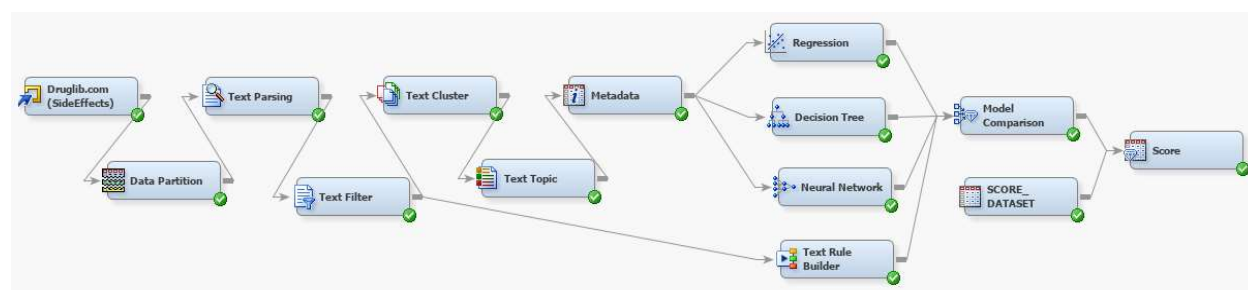

Figure 4 - Modeling diagram for side effect classification

The process flow and certain settings for individual nodes are customized based on best recommended practices in text analytics (Chakraborty, Pagolu, & Garla, 2014).

In this process flow, the "SideEffectLevel" variable is set as the categorical target variable and the "SideEffectsReview" variable is set as the text input variable to build predictive models for side effect level classification. These models are implemented by employing text mining for features identification and machine learning techniques for building classification models.

DATA PARTITION

The *druglib*.com dataset is imported to SAS® Enterprise Miner™ 14.3 via the Import File node and then partitioned in to 70% training data and 30% validation data via the Data Partition node.

Figure 9 - Text Cluster descriptive terms for reviews on side effects

Text Cluster node generates eight well-separated clusters as shown in Figure 8 and Figure 9. Cluster 7 has the highest frequency (22%) with such descriptive terms as "week", "start", "feel", "first", "morning", "hour", "feeling", etc., which often occur together. This implies that some side effects from the above cluster could be related to bad feeling, not feeling like to eat in the morning, or hard to sleep at night which often happen on the first few days/ weeks using the drugs.

Figure 10 - Text Topic results for reviews on side effects

Figure 10 shows 15 different topics with corresponding number of terms in each topic and number of documents that contain the topic terms. For example, topic 2 indicates that drug users may experience some side effects like severe nausea or diarrhea, whereas topic 5 addresses other side effects related to pains in muscle, chest, join, or abdominal pains. Topic 7 mentions dry mouth or dry skin as possible side effects while from topic 12, other major concerns that reviewers express are regarding the extreme horrible mood or anxiety. Meanwhile, topic 11 indicates that some reviewers experience no side effect at all.

TEXT RULE BUILDER

The Text Rule Builder node is a Boolean rule-based categorizer that automatically generates an ordered set of rules that are useful in describing and predicting the target variable (SideEffectLevel).

The Text Rule Builder node is designed with five different settings (*Very High/ High/ Medium/ Low/ Very Low*) for Generalization Error, Purity of Rules and Exhaustiveness.

- ***Generalization Error*** determines the predicted probability for rules that use an untrained dataset. Higher values do a better job of preventing overtraining at a cost of not finding potentially useful rules.

- ***Purity of Rules*** determines how selective each rule is by controlling the maximum p-value necessary to add a term to a rule. Highest value results in the fewest, purest rules while lowest value results in the most rules that handle the most terms.

- ***Exhaustiveness*** determines the exhaustiveness of the rule search process, or how many potential rules are considered at each step. As Exhaustiveness increases, the amount of time that the Text Rule Builder node requires and the probability of overtraining the model are also increased.

Given the above setting properties, after trial and error, the customized setting with *very high* Generalization Error, *very low* Purity of Rules and *medium* Exhaustiveness produces the best results with lowest validation Misclassification Rate and Average Square Error in classifying side effect levels.

The Text Rule Builder node also has one special feature – the ***Change Target Values*** window that allows active learning so that a user can interact with the algorithm to iteratively build a better predictive model. Specifically, the Change Target Values window enables the flexibility to view and reassign target values, then rerun the Text Rule Builder node and iteratively refine the model.

Figure 11 – The Change Target Values Window from Text Rule Builder node

Figure 11 shows some observations when a rule predicted a target value that is different from the assigned target value. For example, the first row mentions about mild tiredness, mild joint aches, and slight difficult sleeping, all of which suggest that the level of side effect should be 1 (Mild/ Moderate Side Effect). Hence, the assigned Target value should be changed from 0 to 1 which matches the predicted target value. Similarly, for the fourth observations, the comment addresses about two possible side effects of the drug, whereas the original target value is 0 (No Side Effect). Therefore, the assigned target should be changed from 0 to 1. For the last observation in Figure 11, given the severe side effects described in the comment, the assigned target value should be changed from 1 to 2 to accurately reflect the true level/ degree of the side effects. Overall, by utilizing the adaptive learning feature of the Text Rule Builder node, we can improve the resulting text categorization accuracy.

Some of the final rules generated by the Text Rule Builder model node are provided as below.

Target Value	Rule #	Rule	Valid Precision ▾	Precision	Valid Recall	Recall	Valid F1 score	F1 score	Valid True Positive/Total	True Positive/Total

Figure 12 - Text Rule Builder results for classifying reviews on side effects

The above Rules Obtained table displays some rules for predicting the target variable. For example, Rule 52 says that for a document to satisfy this rule, it must contain the term "no side effect" so the target variable is assigned value "0". Similarly, Rule 10, 7, 8, and 1 mention that if the comment contains any one of those terms "occasional", "a bit", "slightly", or "mild", then it is classified as level 1 side effect (target value =1). Meanwhile, based on rules 42 and 43, if a document has such terms as "horrible", "severe", "extreme", the target variable should be assigned value "2".

The order of the rules for each category in the table is important. The rule in the first row for each category is discovered by considering all documents and is the first rule that is added into the rule set. The rule in the second row of the table for each category is learned by analyzing all documents that were not covered by the first rule, and so on. The remaining columns in the table indicate the accuracy of the rules. Take rule 43 for example, this rule has a valid precision of 94.19% which implies that the precision (True Positive/ Total Category) in validation data for all rules up to this point in the table for the target value in matching documents that are actually assigned to that target value is 94.19%. The number of correctly matching documents in the validation data for this rule is 43 out of total 48 documents that match this rule, as indicated by the Valid True Positive/ Total column.

The Text Rule Builder model is then compared with other data mining models including Regression, Decision Tree, and Neural Network to find out the optimal model in classifying side effects reviews into three respective levels of rating. As previously mentioned in Figure 4, in all these models, the categorical variable "SideEffectLevel" is set as the target variable and the text variable "SideEffectsReview" is set as the input variable. Other key settings are specified as below.

8

REGRESSION

The Regression node is set up with below settings:

- Model selection method is set to *Stepwise*
- Model selection criterion is set to *Validation Misclassification*

DECISION TREE

The Decision Tree node is set up with below settings:

- Subtree selection method is set to *Assessment* (i.e., the smallest subtree with the best assessment value is chosen)
- Subtree assessment measure is set to *Misclassification*

NEURAL NETWORK

After trial and error, the Neural Network node is set up with below setting:

- Network architecture: *Normalized Radial Basis Function with equal width and height*
- Number of hidden units: *3*
- Target Layer Combination Function: *Linear*
- Target Layer Activation Function: *Softmax*
- Target Layer Error Function: *MBernoulli (Multiple Bernoulli)*
- Model selection criterion is set to *Misclassification*

MODEL COMPARISON

The Model Comparison node is connected to all four predictive model nodes including Text Rule Builder, Regression, Decision Tree, and Neural Network to find out the optimal model in classifying side effects reviews into three respective levels of rating. The settings for the Model Comparison node are set up as following:

- Model selection statistic: *Misclassification Rate*
- Model selection table: *Validation*

The Model Comparison results are provided in the below table.

Fit Statistics							
Selected Model	Model Description	Target Variable	Selection Criterion: Valid: Misclassification Rate ▲	Valid: Average Squared Error	Valid: Kolmogorov-Smirnov Statistic	Valid: Roc Index	Valid: Gini Coefficient
Y	Text Rule Builder	DrugSideEffectLevel	0.270635	0.057946	0.615	0.847	0.693
	Regression	DrugSideEffectLevel	0.278715	0.137069	0.493	0.822	0.643
	Neural Network	DrugSideEffectLevel	0.281124	0.138462	0.484	0.819	0.637
	Decision Tree	DrugSideEffectLevel	0.301205	0.14676	0.417	0.778	0.556

Figure 13 – Fit statistics comparison between models for side effect level classification.

Given the study's decision prediction goal, the most relevant selection criteria to rate model performance should be based on the Validation Misclassification Rate. Figure 13 indicates that among the four competing models, the Text Rule Builder appears to be the best performing model in classifying side effect reviews into the three respective levels (No Side Effects – Mild/ Moderate Side Effects - Severe / Extremely Severe Side Effects) since it has the lowest Validation Misclassification Rate at 27.06% as compared to the other three

models. Additionally, this rule-based model also performed better than three remaining models in terms of lowest Validation Average Square Error and highest values for all other three metrics (Kolmogorov-Smirnov Statistics, Roc Index, and Gini Coefficient).

EFFECTIVENESS LEVEL CLASSIFICATION

To classify the effectiveness level of drugs from patients' benefits comments, the following text mining and predictive modeling process is implemented.

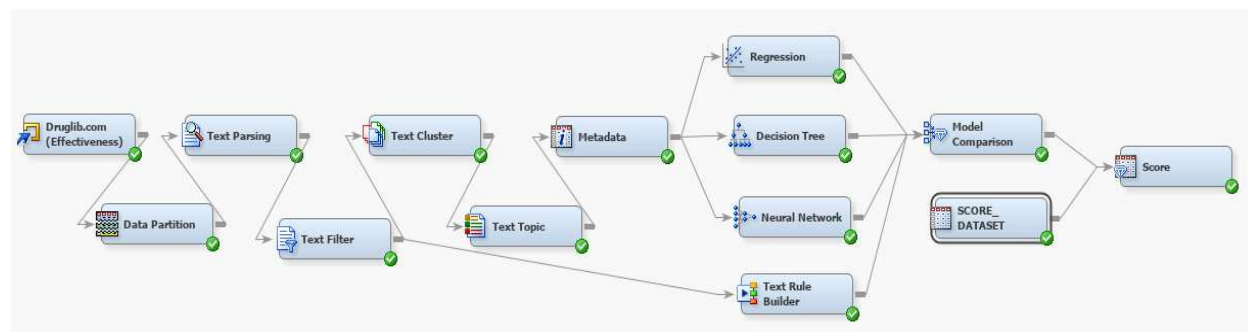

Figure 14 – Modeling diagram for effectiveness classification

The process flow is basically similar to that of side effect level classification, apart from the difference that the categorical target variable is now set to be "EffectivenessLevel" and the text input variable is "benefitsReview".

DATA PARTITION

The *druglib*.com dataset is imported to SAS® Enterprise Miner™ 14.3 via the Import File node and then partitioned into 70% training data and 30% validation data via the Data Partition node.

Figure 15 - Text Parsing results for reviews on effectiveness

Some of the most commonly used words by reviewers in the comments are "benefit", "effective", "better", "improve", etc., which is expected as these words generally relate to some benefits of prescription drugs.

Figure 19 - Text Cluster descriptive terms for reviews on effectiveness

The Text Cluster node generates eight well-separated clusters as shown in Figure 18 and Figure 19. Cluster 7 has the highest frequency (58%) with such descriptive terms as "help", "skin", "able", "clear", "improve", "look", "reduce", "feel", "better", etc., which often occur together. This indicates that some effectiveness from the above cluster could be regarding better sleep, acne cleared, improved skin/ look, reduced anxiety, and better feeling.

Figure 20 - Text Topic results for reviews on effectiveness

Figure 20 shows 15 different topics with corresponding number of terms in each topic and number of documents that contain the topic terms. Topic 1 shows that there are some drugs which benefits outweigh side effects. Topic 7 identifies some improvement in skin treatment like reducing lines and wrinkles, whereas, topic 11 addresses lower blood pressure. Topic 15 indicates that some medicines only show slightly effectiveness.

TEXT RULE BUILDER

The Text Rule Builder node generates an ordered set of rules that together are useful in describing and predicting the target variable (EffectivenessLevel). After trial and error, the customized setting with *very low* Generalization Error, *very low* Purity of Rules and *low* Exhaustiveness produce the best results with lowest Validation Misclassification Rate and Average Squared Error.

Target Value	Rule # ▲	Rule	Precision	Valid Precision	Recall	Valid Recall	F1 score	Valid F1 score	True Positive/ Total	Valid True Positive/ Total

Figure 21 - Text Rule Builder results for reviews on effectiveness

These rules are presented as the conjunction of terms and their negations. For example, Rule 5 "greatly & ~brown spot" says that for a document to satisfy this rule, it must contain the term "greatly" and should not contain the term "brown spot".

MODEL COMPARISON

The Model Comparison node is connected to all four predictive model nodes including Text Rule Builder, Regression, Decision Tree, and Neural Network to find out the optimal model in classifying benefits reviews into three respective levels of rating. As previously mentioned in Figure 14, in all these models, the categorical variable "EffectivenessLevel" is set as the target variable and the text variable "benefitsReview" is set as the input variable. The Model selection statistic is set to be the Validation Misclassification Rate.

The Model Comparison results are provided as below.

Fit Statistics

Selected Model	Model Description	Target Variable	Selection Criterion: Valid: Misclassification Rate	Valid: Average Squared Error	Valid: Kolmogorov-Smirnov Statistic	Valid: Roc Index	Valid: Gini Coefficient
Y	Text Rule Builder	DrugEffectivenessLevel	0.224441	0.044305	0.412	0.771	0.5427
	Regression	DrugEffectivenessLevel	0.26506	0.135422	0.226	0.636	0.2731
	Decision Tree	DrugEffectivenessLevel	0.265863	0.138375	0.166	0.592	0.1847
	Neural Network	DrugEffectivenessLevel	0.266667	0.136348	0.213	0.641	0.283

Figure 22 – Fit statistics comparison between models for effectiveness level classification

Figure 22 indicates that Text Rule Builder is still the best performing model in classifying benefits reviews into three effectiveness levels (Ineffective – Marginally / Moderately Effective - Considerably / Highly Effective) since it has the lowest Validation Misclassification

rate at 22.44% as compared to the other three models. This rule-based model also performs better than three remaining models in terms of lowest Validation Average Square Error and highest values for all other three metrics (Kolmogorov-Smirnov Statistics, Roc Index, and Gini Coefficient).

GENERALIZATION

The best performing model in side effect levels classification is scored on a new independent score dataset to evaluate model validation and generalization. The score dataset is created by randomly picking a sample of 500 observations from the second original dataset retrieved from *Drugs.com* with manually annotated labels. The results from scoring are provided as below.

### SCORING RESULTS FOR SIDE EFFECT LEVEL CLASSIFICATION
Figure 23 - Comparison of probability distribution of side effect level classification across train, validate, and score datasets

Figure 23 illustrates the probability distribution of each side effect level's categorization across train, validate, and score datasets. For example, the three vertical histograms on the far left depict the probability distribution of classifying users' comments into level 2 rating (Severe / Extremely Severe Side Effects) across three independent datasets. These three histograms have similar patterns (gradually decreasing) either in the train dataset (first row), in the validate dataset (second row), or in the score dataset (third row). The same rules can be observed in the distribution of the probability of categorizing drug users'

comments into level 1 rating - Mild / Moderate Side Effects (evidenced by the three vertical histograms in the middle) or into level 0 rating - No Side Effects (shown by the three vertical histograms on the far right). Also, looking from a horizontal dimension, the histograms depict different patterns across three levels, thus the model seems to work well in classification among three respective levels.

Overall, the histograms show consistent patterns for each rating level across various datasets, and different patterns across three levels. This implies that the selected text rule builder model is stable and robust, therefore can be used for further generalization in classifying drug side effect levels.

SCORING RESULTS FOR EFFECTIVENESS LEVEL CLASSIFICATION

Figure 24 - Comparison of probability distribution of effectiveness level classification across train, validate, and score datasets

Figure 24 illustrates the probability distribution of categorizing each effectiveness level across train, validate, and score datasets. Similar to the scoring results of side effect classification, the histograms for effectiveness classification have consistent patterns for each rating level across train, validate and score datasets. This implies that the selected text rule builder model is working well in classifying the reviews in the score dataset into three respective levels of drug benefits rating.

To sum up, the scoring results for both side effect classification and effectiveness classification indicate that the probability distribution of classifying users' comments into

three respective levels of either side effects or effectiveness in the score dataset looks considerably similar to those in the training and validation datasets. This essentially implies that the selected Text Rule Builder models are validated and likely to work well for the score data, hence, they can be further improved for generalization in drug reviews classification.

DRUG EFFECTIVENESS EVALUATION

SENTIMENT ANALYSIS BY SAS VISUAL TEXT ANALYTICS

In order to detect or evaluate the specific effectiveness of a given drug, users' overall reviews for anti-depression drugs from *Drugs.com* have been subset to a new dataset (approximately 14,425 reviews). This subset is then imported to SAS Visual Text Analytics for Natural Language Processing (using Concepts and Text Parsing), Sentiment Analysis, Feature Extraction (via Text Topic), and Text Modeling (i.e., Document Categorization).
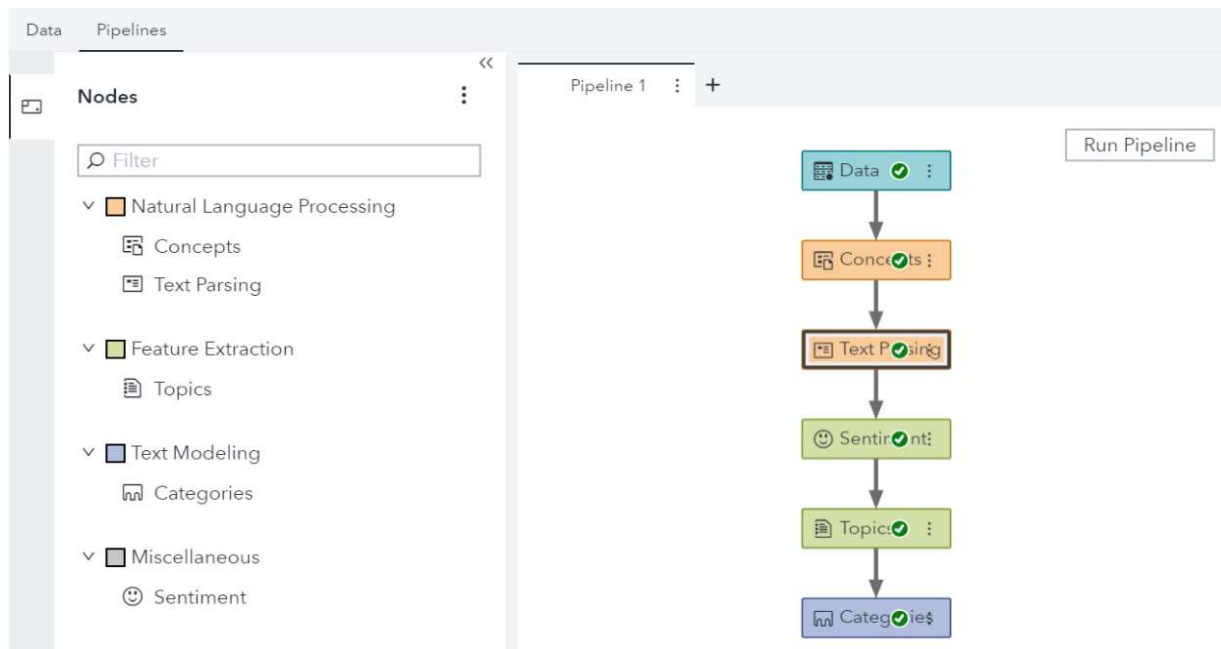

**Figure 25 – Sentiment analysis flow**

Concepts

Figure 26 – Number of documents per concept

16

As shown in Figure 26, predefined concepts such as nlpDate, nlpMeasure, nlpMoney, nlpOrganization, nlpPerson, and nlpPlace are built by the Concept node to extract useful facts that could be helpful for indexing and searching, as well as additional analysis (for example, automatic concept extraction in future narratives). Most of the documents fall into nlpNounGroup, nlpMeasure, and nlpDate concepts.

Text Parsing

The Text Parsing node automatically extracts terms and noun groups from text by associating different parts of speech and understanding the context. Figure 27 below displays the proportion of Kept versus Drop terms across different groups.

Figure 27 – Proportion of Kept versus Drop terms across different groups

Sentiment

The Sentiment node uses a domain-independent model that is included with SAS Visual Text Analytics. This rules-based analytic model computes sentiment relevancy for each post and classifies the emotion in unstructured text as *positive*, *negative*, or *neutral*. The results of Sentiment node are embedded in the Topic node's results as shown in Figure 28.
Text Topic

Figure 28 – Sentiment across different topics

17

Figure 28 demonstrates the sentiment classification across different topics. Overall, the documents that are categorized as negative sentiment accounts for large proportion in each topic. This implies that the overall reviews in the anti-depression data subset from drugs.com are mostly regarding side effects of the drugs. Some examples of observed common effects (both positive and negative) are provided in Figure 29 below.

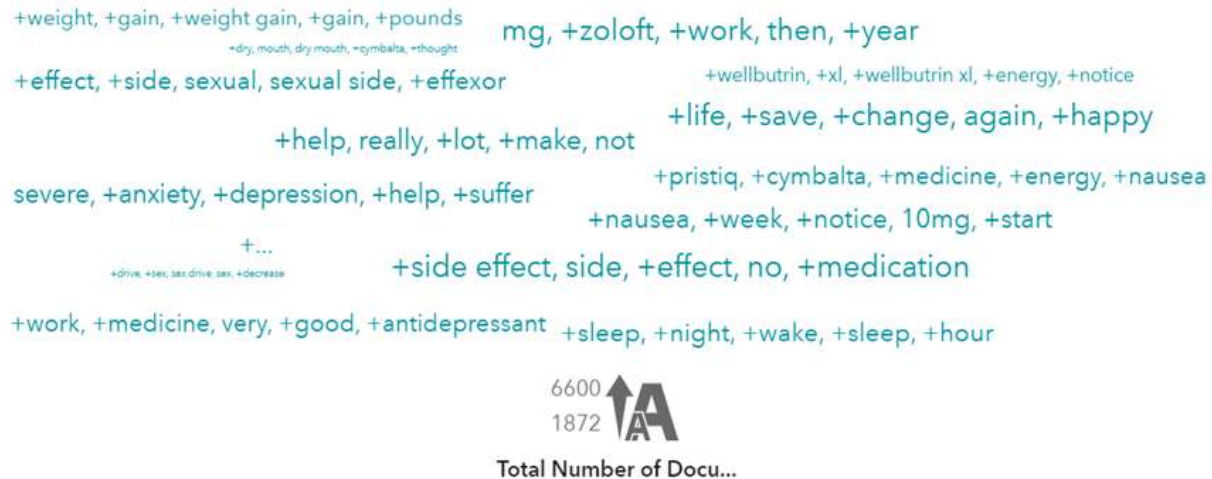

Figure 29 – Users' experienced effects from anti-depression drugs

TEXT ANALYTICS BY SAS ENTERPRISE MINER

Figure 30 - Unsupervised learning diagram for drug effectiveness evaluation

Figure 30 illustrates the process flow for unsupervised text analytics. For this part, only users' overall reviews for five common anti-depression drugs have been chosen for analysis. The SAS dataset for each of these drugs is created and imported into SAS® Enterprise Miner 14.3, which is then partitioned into two datasets using the Filter node, one for low and medium ratings (from 1 to 7) and the other for high ratings (from 8 to 10). Next, text analytics with unsupervised learning algorithm is applied on these datasets, in which the overall 'reviews' variable is treated as the only text variable with no target variable in order to evaluate the effectiveness of each drug. The node properties settings for *Text Parsing*, *Text Topic*, and *Text Cluster* are customized the same as those in the Side Effect Classification part. Only the settings for "Term Weight" option and "Minimum Number of Documents" option in the *Text Filter* node are switched to default settings. The final results from the *Text Cluster* nodes for each drug are provided as below.

Figure 38 - Text Cluster node output for Cymbalta rating 8-10 data

Figure 38 demonstrates 12 clusters that are generated for Cymbalta 8-10 rating data. Clusters 4, 5, 8, and 12 have highest frequency percentages, which show a blend of both benefits and side effects. Some reviewers compliment this drug as best, helpful, life saving anti-depressant treatment, whereas others claim a couple of negative effects including insomnia, nausea, headache, weight gain, loss of appetite, dizziness, and suicidal thought.

Effexor

Cluster ID	Descriptive Terms		Percentage ▼

Figure 40 - Text Cluster node output for Effexor rating 8-10 data

Figure 40 depicts six clusters generated for Effexor 8-10 rating data. Clusters 6 and 1 have highest frequency percentages, which implies that some effectiveness of Effexor are happy mood, well working antidepressant. Other experienced side effects are sweating, crying, and weight gain.

COMPARISON OF EFFECTIVENESS OF FIVE DRUGS

Drug	Low-rating effects	High-rating effects	Average rating
Wellbutrin XL	dry mouth, headache, loss of appetite	better feeling, happy mood, more energy	7.59
Lexapro	headache, weight gain, nausea, nightmare, insomnia	life-saving, able to help, finally work better	7.58
Prozac	severe anxiety, trouble sleeping, mostly in the morning	better feeling, happy mood	7.29
Cymbalta	nausea, back pain, sweating, weight gain, dizziness, anxiety	best, helpful, life-saving anti-depressant treatment	6.47
Effexor	trouble sleeping, horrible feelings, numbness, sweating, take long time to show effects	happy mood, well working antidepressant	5.82

Table 4 – Comparison of effectiveness of five anti-depressant drugs

Table 4 helps understand the specific benefits and side effects of each of the five selected prescribed anti-depression drugs, which can serve as practical guidelines to prospective clients in making informed decisions of choosing the best and suitable drug for anti-depressant treatment. For example, they may take into thorough consideration the possible side effects of a given drug and determine if the benefits can outweigh the side effects and then compare these features with those of other similar drugs. Hence, overall, sentiment analysis and text analytics with unsupervised learning algorithm as analyzed above can facilitate patients in exploring experienced users' reviews and provide them with helpful recommendations in selecting the best drug for their treatment.

CONCLUSION

Increasingly, customers are using social media and other Internet-based applications (e.g., online review sites, discussion forums) to express their sentiments on experienced drugs. These reviews contain a wealth of useful information regarding user preferences and experiences over multiple prescription drugs which can be further leveraged to provide valuable insights to both health care professionals and drug users. However, given the unstructured, qualitative, and textual nature of the comments, potential customers would find it overwhelmingly challenging to go through all online reviews before making purchase decisions. The present paper utilizes best practices of text mining and supervised learning algorithm within SAS® Enterprise Miner™ 14.3 to perform text analytics on online drugs reviews for feature engineering. Multiple predictive models are then optimized and trained on the extracted feature representations, among which the Text Rule Builder is found to be

the best performing model for drug side effects classification as well as for effectiveness classification. In addition, the paper also examines the transferability of the selected trained classification models to ensure for better validation and generalization across independent data sources. Further, unsupervised sentiment analysis and text mining using SAS® Visual Text Analytics from SAS® Viya are also employed to detect the specific side effects and effectiveness of several selected anti-depression drugs which can serve as practical guidelines for potential users. Overall, the study expects to provide valuable insights to assist prospective drug users in making informed purchase decisions and improve monitoring public health by revealing collective experience. A future challenge would be fully analyzing the reviews at deeper level by employing more sophisticated aspect-based sentiment analysis and more powerful advanced machine learning models for improved results.
